European Hematology Association (EHA)

EHA is a scientific society aiming to support research, education and clinical practice in hematology.
Its main objective is to be useful to scientific researchers, clinicians, medical students,
as well as all those working in other fields but who are interested in hematology.

The European Hematology Association was founded in June 1992.
Today, EHA – with over 2700 active members from 95 countries – is a consolidated organization
that pursues a large and growing number of projects and programs.

EHA aims to promote

- Exchange and dissemination of knowledge and scientific information in the field of hematology.
- Education and training in hematology.
- Medical practice in the area of hematology and the position of hematology as medical discipline.
- Scientific research in hematology.
- Exchange of information for all European doctors, scientists and other professionals interested in hematology.
- A unified European training program in hematology in collaboration with European National Societies of Hematology.

In order to achieve these goals, EHA

- Maintains regular contacts and organizes meetings with all European National Societies of Hematology.
- Holds an annual scientific and educational congress in a major European city; European Cooperative Groups and Networks are encouraged to take advantage of this major event to gather.
- Disseminates medical research, both basic and clinic, through the new journal Haematologica/The Hematology Journal.
- Has established a link with European National Societies of Hematology and other organizations such as the European Group for Bone Marrow Transplantation, European Association for Hematopathology, European Society of Medical Oncology, and American Society of Hematology.
- Provides postgraduate education through the annual congresses, seminars, courses, workshops and meetings organized in collaboration with the European School of Haematology.
- Has a Fellowship/Grants Program to promote research in hematology.
- Accredits scientific meetings and provides CME accounts in collaboration with the European National Societies for hematology.

If you recognize the need for a strong European Hematology Association
and would like to take advantage of the various activities of the Association,
you may wish to become a member of the EHA and contribute to its objectives.

Benefits of EHA Membership

- Subscription to Haematologica/ The Hematology Journal, including on-line access
- Reduced registration fee for EHA Annual Congresses
- Eligible to EHA Research Fellowships & Grants
- EHA Newsletter
- Access to EHA membership database
- Access to webcast sessions of the EHA Annual Congress – NEW!
- Entitled to apply for a scholarship to attend ESH-EHA scientific workshops

www.ehaweb.org

EUROPEAN HEMATOLOGY ASSOCIATION

EHA MEMBERSHIP

JOIN EHA NOW!

MAIN BENEFITS OF EHA MEMBERSHIP

- Subscription to Haematologica/ The Hematology Journal (impact factor 5.032)
- Reduction of € 180 on the individual registration fee for the EHA Annual Congress (junior members receive a reduction of € 105).
- Eligible to apply for EHA Research Fellowships & Grants
- Entitled to apply for a scholarship to attend EHA Scientific Workshops
- EHA Newsletter
- Access to the webcast of the EHA Annual Congress
- Access to the EHA membership database

ANNUAL MEMBERSHIP FEE

- € 125 per calendar year *(January to December)*
- € 85 per calendar year *(January to December)* for junior members*

* *hematologists within 15 years of graduation or with less than 10 years of post-doc experience*

EUROPEAN HEMATOLOGY ASSOCIATION

EHA Fellowship Program

One of EHA's goals is to promote the career development of young scientists involved in basic, clinical and experimental research in hematology. EHA funds research fellowships, including the long-established EHA – José Carreras Foundation Young Investigator Fellowship, for researchers in the field of malignant and non-malignant hematology. Each grant is for a two-year period. The next call for applications will be announced on the EHA website in October 2008. Awards will be made at the 14th Congress of EHA in Berlin and will be payable from January 2010.

EHA Partner Fellowship Program

A partner fellowship program has been established this year to support training in centres of excellence in Western Europe for the career development of young scientists involved in basic and clinical research in hematology in new accession and EU candidate countries. The goal of this program is to build up and create inter-institutional networks of collaboration between hematology institutes in Western Europe focusing on research and clinical hematology and similar institutes in new accession and EU candidate countries. The call for applications is announced on the EHA website and the deadline for the letter of interest is June 30, 2008. Deadline for full application is August 15, 2008 and notification of the award will be November 1, 2008.

EHA – ASH International Fellowship Award

The EHA-ASH International Fellowship Award was established in 2006. This award has been developed as a partnership between the European Hematology Association (EHA) and the American Society of Hematology (ASH) to provide hematologists in training or early in their careers the opportunity to conduct research in another country. The purpose of the program is to give both clinical and laboratory-based researchers an opportunity to establish new collaborations and experience research in a different environment. This program will benefit not only the individual participants, but also each host institution, as it will build stronger ties between the North American and European scientific community. The call for applications is announced on EHA and ASH websites and the deadline for the letter of intent is September 4, 2008. Deadline for full application is November 4, 2008. Awards will be made on July 1, 2009.

Submission: Detailed information on the EHA and EHA/ASH fellowship programs and submission is available in the Fellowships section at the EHA website: www.ehaweb.org or contact fellowships.grants@ehaweb.org

Would you like to gain research experience in another country? Do you need funding to do this?

The EHA-ASH®

International Fellowship Award

can make this possible.

The American Society of Hematology (ASH) and the European Hematology Association (EHA) have partnered to create the EHA-ASH International Fellowship Award to allow hematologists from the **United States and Europe** to conduct research in another country for up to two years. The program is open to ASH or EHA members who have a doctoral degree and are in a post-graduate hematology training program or actively engaged in laboratory or clinical research.

Each awardee will receive $75,000 to cover supplies, travel, housing, and a per diem. In addition, travel stipends to attend the ASH and EHA annual meetings will be offered during the award period.

For more information, visit ***www.hematology.org/education/awards/ifa.cfm.***

Don't miss this opportunity—submit your letter of intent by **September 4, 2008**. Please note: All letters of intent must be submitted in English.

Questions? If you have any questions or need additional information, please contact Courtney Krier, ASH Award Program Coordinator, at +1 202-776-0544 or *ckrier@hematology.org.*

13TH CONGRESS
JUNE 12 - 15, 2008
COPENHAGEN

Word of welcome

On behalf of the Scientific and Education Program Committee, we would like to welcome you to Copenhagen for the 13th Congress of the European Hematology Association. We have addressed the challenge of building a scientific program covering the various fields of haematology with a balance between the clinical and scientific topics. We now invite you to participate in the numerous sessions, including Education, Hematology-in-Focus, Science-in-Progress and Plenary sessions as well as the challenging Lunch Debates and Clinical Trial Updates. We also have a number of highly expert 'Meet-the-Expert' sessions and encourage you to register early to grasp the opportunity to exchange information in a very informal and friendly atmosphere. On Friday June 12th, and for the second year, the new Molecular Haematopoiesis Workshop will be take place, where cutting edge science will be presented in a new and exciting way and we hope to particularly attract scientists and young hematologists interested in a scientific career- please come along !

From the high number of abstracts submitted this year, we have also put together an interesting programme of simultaneous oral sessions and poster sessions. The 5 best abstracts have been selected for presentation during the Presidential Symposium on Saturday afternoon. Please take also time to visit the poster sessions when the authors will present their work to you in exchanges animated by expert moderators.

The complex issue of the “Relationship between academia and pharma” will be addressed during this year's joint EHA-ASH Symposium taking place on Saturday, June 14th, with the opportunity to exchange information and opinions from both sides of the Atlantic. The Joint Symposium of the European School of Hematology (ESH) and EHA will again take place on Friday, dedicated to “Communication with transplant patients, the complementary roles of doctors and nurses”. A number of meetings of EHA Scientific Working Groups will be held on Thursday evening, which we hope will help foster direct interactions between physicians and researcher in the various fields of haematology. In addition, 26 Satellite Symposia will run on Super Thursday, covering the State-of-the-Art in experimental and clinical haematology.

We would also like to welcome you to the Opening Ceremony which will take place on Friday, June 12th, directly followed by the presentation of the José Carreras Lecture by Professor John Goldman. In the same session, the winners of the EHA-José Carreras Young Investigator Fellowship and the additional EHA Fellowships and Grants will be presented. For the first time this year EHA has initiated a new award to honour outstanding physicians/scientists for their lifetime contribution to the advancement of hematology. The first EHA Jean Bernard Lifetime Achievement Award will be presented to Professor Dieter Hoelzer on Saturday afternoon.

The congress program is accredited for continuing medical education (CME) by the EHA-CME System, which is the new name for the European Council for Accreditation in Hematology (ECAH). EHA assures the continuity in collaboration with many of the original ECAH partners including the European School of Haematology (ESH). EHA and ESH are dedicated to establishing modern haematology in the European curriculum for medical postgraduate education. The scientific program of the 13th Congress of the EHA has also been reviewed and approved for accreditation by the American Medical Association (AMA).

Copenhagen is a very lively city, with a high tradition of hospitality, and is an excellent venue for the EHA Congress with its focus on exchange of ideas, discussion of results and networking, exchange of scientific principles all in the friendly and safe atmosphere of the city.

On behalf of the EHA Board and the Scientific and Education Committee of the 13th Congress: we are pleased to welcome you to this beautiful city and hope that this top hematology congress in Europe will provide you with fruitful and enjoyable interactions with your peers and induce new creative ideas for your work!

DASATINIB EFFICACY IN PATIENTS WITH IMATINIB-RESISTANT/-INTOLERANT PHILADELPHIA-CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA: 24-MONTH DATA FROM START-L

K. Porkka,[1] G. Martinelli,[2] O.G. Ottman,[3] H. Dombret,[4] F.T. Garzon,[5] C. Zhu,[5] R.A. Larson,[6] B. Simonsson[7]

[1]Helsinki University Central Hospital, HELSINKI, Finland; [2]S.Orsola-Malpighi Hospital, BOLOGNA, Italy; [3]Johann Wolfgang Goethe Universität, FRANKFURT, Germany; [4]Hôpital Saint-Louis, PARIS, France; [5]Bristol-Myers Squibb, WALLINGFORD, USA; [6]University of Chicago, CHICAGO, USA; [7]Uppsala University Hospital, UPPSALA, Sweden

Background. Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ALL) is characterized by rapid disease progression and transient responses to imatinib. Dasatinib is the most potent inhibitor of BCR-ABL and is 325-fold more potent than imatinib and 16-fold more potent that nilotinib *in vitro*. Dasatinib also inhibits SRC-family kinases, which may contribute to BCR-ABL-independent imatinib resistance in Ph+ALL. Initial findings from START-L demonstrated that dasatinib induces treatment responses in patients with Ph+ALL following imatinib failure. *Aims*. To investigate response durability with dasatinib 70 mg BID in patients with Ph+ALL, 24-month follow-up from the START-L trial has been analyzed. *Methods*. START-L is an open-label, international, multicenter study. Patients with imatinib-resistant or -intolerant Ph+ALL were recruited from January to July 2005. Dose escalation to 100 mg BID was allowed for inadequate response and reduction to 50 or 40 mg BID or interruption was allowed for toxicity. Trial objectives included the evaluation of hematologic and cytogenetic response rates and duration, progression-free survival (PFS) and overall survival duration, and safety/tolerability. *Results*. Among 46 recruited patients, median age was 48 years, median time from initial Ph+ALL diagnosis was 18 months (range 3-163), and 96% of patients were imatinib resistant. During imatinib therapy, 46% had received >600 mg/d, 52% had received imatinib for >12 months, and 50% had achieved a major cytogenetic response (MCyR). Prior to the trial, stem-cell transplantation (SCT) had been performed in 37% of patients and BCR-ABL mutations were present in 78%, including 20% with a T315I mutation. With a minimum follow-up of 24 months, a complete hematologic response (CHR) was achieved with dasatinib treatment in 35% of patients (42% excluding the subgroup with a baseline T315I mutation), a MCyR was achieved in 56% (68% excluding T315I) and a complete cytogenetic response (CCyR) was achieved in 54% (66% excluding T315I). MCyRs were achieved rapidly (median time to response 29 days) and were durable (median 6.3 months). Median PFS was 3.3 months (5.7 months excluding the T315I subgroup), and the 24-month overall survival rate was 31% (34% excluding T315I). In patients with or without baseline BCR-ABL mutations, similar rates of MCyR (55% *vs* 56%) and CCyR (52% *vs* 56%) were observed despite no patient with a T315I mutation achieving a response. Responses were more favorable in patients with prior SCT *vs* no prior SCT (MCyR 76% *vs* 45%; median PFS 7.2 *vs* 2.7 months). Grade 3/4 thrombocytopenia and neutropenia each occurred in 78% of patients. The most common grade 3/4 nonhematologic side-effects were gastrointestinal bleeding (11%), diarrhea (9%), asthenia (7%), and pleural effusion (7%). After 12 and 24 months, five (11%) and one (2%) patients remained on study, with 52% and 57% discontinuing after disease progression, respectively. Discontinuation following study drug toxicity occurred in 9%. *Summary and Conclusions.* In patients with Ph+ALL following imatinib failure, dasatinib 70 mg BID is associated with rapid and durable responses, and long-term survivors are evident. The notable efficacy and well-tolerated safety profile achieved with dasatinib in this very difficult-to-treat population supports the ongoing evaluation of dasatinib in the front-line Ph+ALL setting.

0002

HIGH DOSE METHOTREXATE IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: IMPACT OF THE PHARMACOGENETIC POLYMORPHISMS OF RFC1, MDR1 AND MRP2 ON PLASMA CONCENTRATIONS

M. Fakhoury, T. Adam de Beaumais, Y. Medard, D. Zhang, S. Azougagh, K. Yakouben, E. Jacqz-Aigrain

Robert Debre Hospital, PARIS, France

Background. Methotrexate (MTX) is an antifolate drug administered at high dose (5 g/m^3) (HD-MTX) in the treatment of childhood acute lymphoblastic leukemia (ALL). Its pharmacokinetics is characterized by a wide interindividual variability requiring drug monitoring. *Aims.* We assessed the individual and combined impact of transporters polymorphisms (RFC1, MDR1 and MRP2) on HD-MTX concentrations at H24, H48 and H72. *Methods.* A retrospective pharmacogenetics study was conducted in 86 children (58 boys; mean age: 6.3±4.0) with ALL including in EORTC 58951 protocol at Robert Debre Hospital. Informed consents were obtained. They received 3 or 4 courses of high dose methotrexate during the Interval therapy according to their risk group. For each course, MTX plasma concentrations at 24, 48 and 72 hours from the start of the infusion (H24, H48 and H72) were measured by EMIT®. Allelic variants of RFC1 (SLC19A1: G80A), P-glycoprotein (MDR1: C1236T, G2677T/A, C3435T) and MRP2 (ABCC2: C-24T, G1249A, T3563A, C3972T) were determined by real time polymerase *Results*. Dose-normalized MTX concentrations within each course presented a wide inter-individual variability at each sampling time but there was no inter-course difference. Therefore, MTX concentrations ([MTX]) collected during the first course and standardized by the administered dose, were used for analysis. Mutated RFC1 AA patients (n=31/85, 36.0%) had significantly higher [MTX]/dose at H24 (ratio of 5980 *vs* 3158; p=0.007) and H48 (ratio of 71 *vs* 47; p=0.012) compared to those with a wild-type genotype (WT). When comparing GA or AA patients to WT patients, this association remained significant (p=0.012 at H24 and p=0.023 at H48). The 3 MDR1 mutations were in strong linkage disequilibrium and influenced [MTX] at H48 (p<0.05): for MDR1 C3435T, mutated homozygous patients (n= 16/85, 18.6%) presented a median ratio of 89 for [MTX]/dose *vs* 55 for WT patients. The association remained significant (p=0.045) when comparing carriers of mutated variant to WT patients. Patients carrying a mutated variant for both genes (RFC1 G80A and MDR1 C3435T; n=42) presented higher [MTX] (median ratio [MTX]/dose: 75) than patients with mutated variant for only one gene (median ratio about 55; n=22 for patients RFC1 A80 variant/MDR1 WT and n=14 for RFC1 WT/MDR1 T3435 variant) and than WT patients for the both genes (median ratio: 37, n=4). Polymorphisms of MRP2 had no significant impact on [MTX] variability. *Conclusion*s. Our findings suggest that polymorphisms of RFC1 (G80A) and MDR1 (C1236T, G2677T/A, C3435T) contribute to the interindividual pharmacokinetic variability of high dose MTX. This first report of MDR1 C3435T polymorphism may be a useful tool to optimize MTX therapy. Further pharmacogenetic studies will include additional genes implicated in the metabolism and transport of MTX.

0003

IMPAIRED DEXAMETHASONE-RELATED INCREASE OF ANTICOAGULANTS IS ASSOCIATED WITH THE DEVELOPMENT OF OSTEONECROSIS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M.L. te Winkel, I.M. Appel, R. Pieters, M.M. van den Heuvel-Eibrink

ErasmusMC-Sophia Children's Hospital, ROTTERDAM, Netherlands

Background. Alterations of coagulation accompanied by impairment of microcirculation may be involved in the pathogenesis of osteonecrosis (ON) in childhood acute lymphoblastic leukemia (ALL). ALL induction treatment includes dexamethasone and asparaginase, which both influence coagulation. *Aims.* The main objective of this study is to investigate whether induction-therapy-related alterations in coagulation are associated with the development of ON in childhood ALL. *Methods*. Retrospectively, we evaluated coagulation parameters of 161 ALL patients: 24 who developed ON (ON-positive, median age: 13.8 (4.0-17.2) years) and 137

who did not (ON-negative, median age: 4.9 (1.0-16.7) years). We studied thrombin generation (prothrombin fragment 1+2, thrombin antithrombin complex), fibrinolysis (α2-antiplasmin, plasminogen, plasmin-α2AP complex, D-dimers), procoagulant factors (fibrinogen, factor II, V, VII, IX, X) and anticoagulant factors (antithrombin , protein C and protein S) at diagnosis and during induction treatment. *Results*. Coagulation parameters of ON-positive and ON-negative patients were similar at diagnosis. After 4 weeks induction treatment including dexamethasone, the anticoagulants antithrombin and protein S were significantly less increased in the ON-positive than in the ON-negative patients. Subsequently, after administration of 4 doses asparaginase and tapering dexamethasone, these coagulation parameters equally decreased in both ON-positive and ON-negative patients. As a result, the nadirs of antithrombin and protein S were significantly lower in ON-positive patients than in ON-negative patients, even reaching levels below lower normal limits in the ON-positive group. No dexamethasone-induced or asparaginase-induced differences of other coagulation parameters were found between both groups. *Conclusions*. We conclude that a reduced dexamethasone-related increase of antithrombin and protein S and subsequent decline of these anticoagulants below normal levels after introduction of asparaginase, may result in a hypercoagulable state. This therapy-induced hypercoagulable state may be a contributing factor to develop symptomatic ON in childhood ALL.

0004

REDUCED INTENSITY *VS* CONVENTIONAL MYELOABLATIVE CONDITIONING (RIC VS. MAC) ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) FOR PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): A SURVEY FROM THE ACUTE LEUKEMIA WORKING PARTY OF EBMT

M. Mohty,[1] M. Labopin,[2] T. Ruutu,[2] H. De Lavallade,[2] A. Gratwohl,[2] G. Socie,[2] J. Esteve,[2] R. Tabrizi,[2] A. Nagler,[2] V. Rocha[2]

[1]CHU de Nantes, NANTES; [2]ALWP of EBMT, PARIS, France

The exact role of RIC allo-SCT for adult patients with ALL is still under considerable debate. While the use of such so-called nonmyeloablative or RIC regimens has emerged as an attractive modality to decrease transplant-related mortality, toxicity might represent only one aspect of the problem, since ALL encompasses a group of chemosensitive diseases, raising concerns that significant reduction of the intensity of the preparative regimen may have a negative impact on long-term leukemic control. In this multicenter retrospective study, the outcomes of 601 adult (age at transplantation >45 y.) patients with ALL who underwent transplantation in complete remission (CR) with an HLA-identical sibling donor, were analyzed according to 2 types of conditioning: RIC in 97 patients, and standard MAC (or high-dose) in 504 patients. Both groups were comparable in terms of gender, CR status (CR1 and CR2), interval from diagnosis to allo-SCT, and recipient/donor CMV serostatus. Patients in the RIC groups were older (median 56 y. *vs* 50y in the MAC group; $p<0.0001$), Most of the patients in the MAC group received high dose TBI (80%), while the majority of the RIC regimens included either low-dose TBI or were ATG+chemotherapy-based regimens. The majority of patients (88%) from the RIC group received a PBSC graft. In the MAC group, the stem cell source consisted of bone marrow in 42% of patients. With a median follow-up of 13 months (range, 1-127), the incidences of grade II-IV and grade III-IV acute GVHD were: 35%, 14%, and 28%, 10% in the MAC and RIC groups respectively (p=NS). The cumulative incidence of non-relapse mortality at 2 years (NRM) was 32% (MAC) *vs* 22% (RIC) (p=0.04). The cumulative incidence of relapse at 2 years was 30% (MAC) *vs* 42% (RIC) (p=0.0007). However, the latter differences did not translate into any significant difference in term of leukemia-free survival (LFS) at 2 years: 38% (MAC) *vs* 37% (RIC) (p=0.42). In multivariate analysis for LFS, the status at transplant was the only factor associated with an improved LFS ($p<0.0001$, RR=0.55, 95%CI, 0.42-0.72). The results of this retrospective registry based study suggest that RIC regimens may reduce NRM rate after allo-SCT for adult ALL when compared to standard MAC regimens, but with a higher risk of disease relapse and no impact on LFS. The latter represent promising findings, since patients who received RIC are likely to have serious comorbidities, which led the transplantation center to choose RIC, and surely most of these patients would not have received a standard allo-SCT in most institutions. Therefore, RIC allo-SCT for adult ALL (>45 y.) may represent a valid therapeutic option when a conventional standard conditioning is not possible, warranting further prospective investigations.

0005

POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME: TWO CASES IN YOUNG ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

S. Reutenauer, J.F. Albucher, J. Pariente, H. Dumas, O. Milioto, M. Attal, C. Recher, F. Huguet

CHU Toulouse, TOULOUSE, France

The Posterior Reversible Encephalopathy Syndrome (PRES), primarily described by Hinchey *et al.* in 1996, occurs in cases of eclampsia, renal insufficiency, hypertension, or complicates immunosuppressive therapies or chemotherapies. In hematology, this syndrome has been described in pediatric acute leukemias, but not in adults. *Case 1*: A 19-year-old man, treated by GRAALL 2005 protocol for acute lymphoblastic leukemia (ALL), suddenly presents on day 28 of induction chemotherapy a unique tonic-clonic generalized seizure. This neurologic complication occurs in a context of hypertension and acute renal failure. MRI shows signal abnormalities predominating in posterior regions of the brain. With anticonvulsivant therapy, there is no recurrence of seizure. Follow-up MRI 15 days later is normalized, which allows further chemotherapy, without changes of drugs type or dose. *Case 2*: A 22-year-old woman, treated for ALL with the same protocol, suffers on day 23 of induction chemotherapy headaches, decreased alertness, followed by several tonic-clonic non generalized seizures, accompanied by homonymous left hemianopsia. She developed 7 days before an acute renal failure with severe hypertension. Encephalic MRI shows extensive signal abnormalities (Figure 1). With anticonvulsivant medication, and after quasi-normalization of MRI, consolidation course could be initiated 3 weeks later.

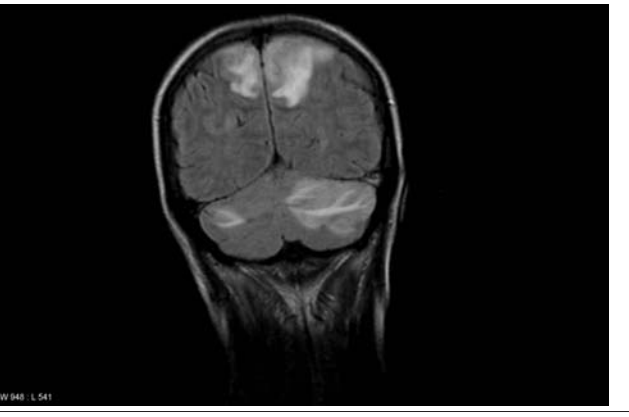

Figure 1.

MRI and clinical presentation of these 2 cases will be detailed. In these 2 cases, the only abnormalities found were neuroradiological, and permitted to diagnose PRES. It is a clinical and radiological entity defined by headaches, altered mental status, seizures and visual abnormalities, as well as characteristic MRI findings of vasogenic oedema in posterior regions of the brain. The main hypothesis for the pathophysiology of this oedema is impairment in cerebrovascular autoregulatory control, and especially in vertebrobasilar territory, due to its sparse sympathetic innervation. It classically occurs in a context of hypertension or hypervolemia, and can be caused by cytotoxic agents. This syndrome of posterior encephalopathy should be better-known by hematologists, because its prevention and its treatment are easily achieved by anticonvulsivant and antihypertensive agents, and can avoid irreversible evolution. Intensive ALL treatments, inspired by pediatric protocols should be added to the growing list of causes of PRES.

0006

EFFICACY AND TOLERABILITY OF INTRATHECAL LIPOSOMAL CYTARABINE FOR TREATMENT OF MENINGEAL RELAPSES IN ACUTE LYMPHOBLASTIC LEUKAEMIA: EXPERIENCE OF A SINGLE PEDIATRIC INSTITUTION

R. Parasole, G. Menna, N. Marra, A. Mangione, S. Buffardi, A. Misuraca, F. Petruzziello, V. Poggi

Santobono-Pausilipon Hospital, NAPOLI, Italy

Background. Treatment of Central Nervous System (CNS) recurrence in acute lymphoblastic leukemia (ALL) remains a problem for clinicians, often difficult to solve. A new liposomal formulation of cytarabine

(DepoCyte®), encapsulated into multivesicular lipid particles, has been used in leukemic meningitis. Liposomal cytarabine is slow released into the cerebrospinal fluid (CSF), resulting in prolonged drug exposure and presumable higher response rate. Recently neurological complications of DepoCyte have been reported in combination with high-dose systemic methotrexate and cytarabine. *Aims.* We studied the efficacy and tolerability of intrathecal administration of DepoCyte in 5 meningeal relapsed ALL children, treated in a single Paediatric Institution. Patients and *Results.* Between May 2005 and October 2007, five children (4 male and 1 female with Down Syndrome; age at diagnosis 2 to 16) with CNS relapsed ALL were treated with intrathecal DepoCyte at variable dose of 25-50 mg/dose. Concurrent dexamethasone therapy, at the dosage of 0,2 mg/kg/dose, twice a day for 5 days, was administered with each dose of i.t. drug. In all patients DepoCyte was associated with systemic chemotherapy and in 4 out of 5 patients to concurrent high dose of cytarabine (2 gr/m^2). Depocyte was started during the first cycle and continued every 15 days, independently from aplasia. Every patient received about 6-7 drug administrations. Liposomal cytarabine was well tolerated in all patients and all patients achieved complete liquoral clearance after the first three intrathecal drug administrations. Four out of them, treated concurrently with high-dose systemic cytarabine, had not showed any additional neurological side effects. Only one patient, a 16 year-old-boy, treated with adult dose (50 mg/dose) for age and weight, presented, after the third administration, grade II headache, rapidly reverted by increasing dexamethasone prophylaxis (0,5 mg/kg/dose). Characteristics of patients are resumed in Table 1. *Conclusions*. In this series, we demonstrate the feasibility and tolerability of intrathecal liposomal cytarabine administration in five children with CSN relapsed ALL. Hence, despite its potential neurotoxicity, DepoCyte remains an interesting formulation, especially in the paediatric setting, for its ability to reduce frequency and total number of intrathecal administrations due to its high detectable intrathecal levels up to 2 weeks. The properties of this formulation, associated with its efficacy, have a favourable impact on children compliance and quality of life; for this reason every effort are necessary to study the best application of DepoCyte in intensive treatment regimen.

THE PRESENCE OF CD56/CD16 IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA LEADS TO WORSE SURVIVAL AND CORRELATES WITH THE EXPRESSION OF CYTOTOXIC MOLECULES

L.F.F. Dalmazzo, R.H. Jacomo, R.L.G. Cunha, A.F. Marinato, L.L. Figueiredo-Pontes, A.B. Garcia, E.M. Rego, R.P. Falcão

University of Sao Paulo, RIBEIRÃO PRETO - SP, Brazil

Some cases of T-cell Acute Lymphoblastic Leukemia (T-cell ALL) express surface markers commonly found in natural-killer (NK) cells, such as CD56 and CD16. From january/2000 to december/2006, 84 cases of T-cell ALL were diagnosed at our institution. The presence of either CD56 and/or CD16 was identified in 24 of these patients (28.5%), which we designated as T/NK-ALL group. The aim of this study was to compare the clinical and laboratorial features, survival and expression of cytotoxic molecules, such as perforin, granzyme B and T-cell intracellular antigen-1 (TIA-1), in T/NK-ALL and T-ALL patients. Except for the TIA-1, which was analyzed by immunocytochemistry, all the others markers, including CD56, CD16, perforin and granzyme B, were studied by flow cytometry in blasts obtained from the bone marrow. Concerning the clinical characteristics, significant differences between T/NK-ALL and T-ALL groups were observed regarding age (24.9 *vs* 16.4 years, p=0.006) and platelets counts (177×10^9/L *vs* 75×10^9/L, p=0.03), respectively. The immunophenotypic features demonstrated different expression of some markers: CD34, CD45RA and CD33 were most expressed in the T/NK patients, while CD8 and TdT in the T-ALL patients (p<0.05). We also observed that T-cell ALL cases expressing CD56 and/or CD16 had worse prognosis. Kaplan-Meier method estimated that the mean duration of overall survival (863 *vs* 1869 days, p=0.02) and disease-free survival (855 *vs* 2095 days, p=0.002) was shorter in patients expressing CD56/CD16. In order to correlate the presence of CD56/CD16 with cytotoxic characteristics, blasts expression of perforin, granzyme B and TIA-1 was analyzed. These cytotoxic molecules were higher expressed in T/NK-ALL compared to T-ALL cases. Perforin, granzyme B and TIA-1 were detected in 12/17, 4/17 and 7/24 T/NK-ALL and in 1/20, 0/20 and 1/20 T-ALL patients, respectively (p<0.001, p=0.022 and p=0.038). Our results demonstrated that the presence of CD56 and/or CD16 predicts worse outcome and differentiates a specific subtype of T-cell ALL, with some clinical differences and high expression of cytotoxic molecules.

AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: STILL NOT OUT OF FASHION

F. Folber, M. Doubek, Y. Brychtova, M. Krejci, J. Kujickova, I. Palasek, B. Weinbergerova, D. Zackova, Z. Koristek, M. Navratil, Z. Racil, J. Kamelander, D. Dvorakova, J. Mayer

University Hospital Brno, BRNO, Czech Republic

Background. Postremission treatment in adult acute lymphoblastic leukemia (ALL) is still controversial, especially in the point of autologous peripheral blood stem cell transplantation (autoPBSCT). Aims. In this study we show results of autoPBSCT and maintenance therapy with oral 6-mercaptopurin and methotrexate compared to chemotherapy alone in the treatment of adult ALL. Methods. We retrospectively analysed data of 60 consecutive patients treated at our department according to our standard protocol in years 1997 to 2007. There were 35 males and 25 females, with a median age 35.2 years at the time of diagnosis (range: 17.3 to 70.7). Fifty-two (87%) patients had ALL, 7 (12%) lymphoblastic lymphoma (LBL), and 1 (2%) acute biphenotypic leukemia. Seventeen of 52 (28%) patients with ALL showed T lineage and 33 (55%) B lineage. Nine (17%) patients were found Ph positive. Seven (12%) patients were treated with chemotherapy and allogeneic stem cell transplantation (alloSCT). In the cases where there were no donors available, they were treated with chemotherapy alone (35 patients, 58%) or with chemotherapy followed by autoPBSCT and maintenance therapy (18 patients, 30%). Within a median follow-up of 14.7 months (range: 0.1 to 117.8) the data were analysed for achieving complete remission, disease progression, relapse, and causes of death. Results. Out of the total number of 60 patients, 49 (82%) achieved complete remission after the induction chemotherapy (CR1); 44 of 52 (85%) with ALL and 4 of 7 (57%) with LBL. The median PFS was 29.8 months in all patients and 58.1 months in patients in CR1. The median OS was 14.8 months in all patients and 39.6 months in patients in CR1. Patients treated with chemotherapy alone had shorter median PFS than patients who underwent autoPBSCT and maintenance therapy (8.4 *vs* 46.8 months in patients in CR1, p=0.017). Patients treated with chemotherapy alone had also shorter median OS than patients after autoPBSCT or alloSCT (13.0 *vs* 46.8 *vs* 44.3 months in patients in CR1, p=0.046). The differences remained statistically significant even after excluding Ph positive patients. There was no significant difference in PFS and OS in patients with B-ALL and T-ALL. Relapse of the disease was treated by chemotherapy with or without stem cell transplantation in 24 out of 26 cases, but only 7 patients achieved second complete remission. Most common causes of death were infection (41%), disease progression (24%) and bleeding (12%). *Summary and Conclusions*. According to our analysis, autoPBSCT coupled with maintenance chemotherapy is still an option in adult acute lymphoblastic leukemia and provides favourable OS and PFS rates, significantly better than those reached by chemotherapy alone.

0009

RESULTS OF TREATMENT WITH HYPER-CVAD / MTX-ARA-C, A DOSE-INTENSIVE REGIMEN, IN ADULT ACUTE LYMPHOCYTIC LEUKEMIA AND HIGHLY AGGRESSIVE LYMPHOMA IN A SINGLE CENTER IN CHINA

T. Niu, T. Liu, B.X. Xiang, Y-Q. Jia, H.-L. Zhu

West China Hospital,Sichuan University, CHENGDU,SICHUAN, China

Background. Although the safety and efficacy of the Hyper-CVAD/MTX-Ara-C regimen,a dose-intensive regimen, in hematologic malignancies has been well established by several clinical trials developed at the UT M. D. Anderson Cancer Center in the U.S.A, the results of this regimen in patients in China has not been well determined. *Aims*. The objective of this clinical study was to evaluate the efficacy and potential toxicity of this regimen in the adult patients with acute lymphocytic leukemia (ALL) and highly aggressive non-Hodgkin lymphoma (NHL) in our hospital in China. *Methods*. Between June 2004 and June 2007, fifty-six patients with ALL or highly aggressive lymphoma were treated with the Hyper-CVAD/MTX-Ara-C regimen in our institution. The median age of all patients was 26 years (range 13 to 60 years), and 35 patients (62.5%) were male. There were 32 previously untreated patients and 24 refractory/relapsed cases. Among the 41 patients with ALL, B-cell type was present in 82.93%, T-cell type in 17.07%, and Ph chromosome-positive ALL was present in 14.63%, refractory/relapsed disease in 43.90%. Among the 15 patients with highly aggressive NHL, lymphoblastic lymphoma was present in 46.67%, Burkitt's lymphoma was in 53.33% and refractory/relapsed disease in 40.00%. CNS involvement was present in 8% at diagnosis. Treatment consisted of four cycles of Hyper-CVAD alternating with four cycles of high-dose methotrexate (MTX) and cytarabine therapy, together with intrathecal CNS prophylaxis and aggressive supportive care with granulocyte colony-stimulating factor, transfusion and antibiotic prophylaxis therapy. Maintenance therapy based on the cytogenetics and immunophenotypes in most of patients contained 2-year treatment with mercaptopurine, MTX, vincristine, and prednisone (POMP). *Results*. The median follow-up duration was 7 months (range 1+ to 37+ months). Of the previously untreated 31 patients, twenty-nine patients (93.55%) achieved complete remission (CR) and no patients died during induction phase. Of the refractory /relapsed 24 patients, fourteen cases (58.33%) achieved CR. Interestingly, the CR rate of the patients with Burkitt's lymphoma was 75.00% (6/8). The median finished courses during the dose-intensive phase were 4 (range 1 to 8), and the median time to delivery of all eight courses was 10 months. The estimated 3-year overall survival for the untreated and refractory/relapsed patients with ALL was 46.80% and 28.60%, respectively. Meanwhile, the estimated 2-year overall survival for the aggressive NHL patients was 84.00%. Compared with the patients with ALL who did not receive CR and got less than four courses of this regimen, the patients who received CR and got more than four courses of this regimen showed much better overall survival ($p<0.05$). The incidence of CNS relapse was much lower (5%). Myelosuppression-associated complications including documented infections, fever of unknown origin, hemorrhage were the more frequent side effects. Other significant side effects included neurotoxicity, renal and hepatic toxicities, fatigue, mucositis, nausea, vomiting, diarrhea, skin rashes, and G-CSF therapy-associated bone aches. *Conclusions*. The study from our single center in China demonstrated that Hyper-CVAD/MTX-Ara-C, a dose-intensive regimen with much higher CR is superior to our previous regimens, even in highly aggressive lymphomas such as lymphoblastic and Burkitt's lymphoma, and refractory/relapsed ALL/lymphoma patients. Our data also showed that this regimen is less toxic and well tolerated in most of patients in China. Due to the aggressive supportive care, the expense with this regimen is more expensive than previous conventional chemotherapy. Long-term treatment benefits, such as disease-free survival rates and severe side effects need further investigation in a well-designed, multiple-center study in China with more eligible patients entering onto the study.

0010

KINETICS OF CEREBROSPINAL INFILTRATION IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA: A FLOW CYTOMETRY STUDY

M. Ramírez,[1] A. Gómez,[1] C. Martínez,[1] A. Lassaletta,[1] C. Moscardó,[2] I. Hernández,[3] J. Sánchez de Toledo,[4] T. Molins,[5] A. Muñoz,[6] M. Baragaño,[7] J.M. Couselo,[2] E. Cela,[8] L. Madero[1]

[1]Hospital Universitario Niño Jesús, MADRID, Spain; [2]Hospital General, ALICANTE; [3]Hospital Son Dureta, PALMA DE MALLORCA; [4]Hospital Vall de Hebron, BARCELONA; [5]Hospital Virgen del Camino, PAMPLONA, Spain; [6]Hospital Miguel Servet, ZARAGOZA; [7]Hospital San Rafael, MADRID, Spain; [8]Hospital Gregorio Marañón, MADRID, Spain

Background. Most children with acute lymphoblastic leukemia (ALL) have subclinical disease in the central nervous system (CNS) at diagnosis. Extramedullary organs such as the CNS may act as sanctuaries for lymphoblasts, preventing the exposure to adequate levels of chemotherapeutic drugs, and serving as a reservoir for protracted relapses. It is of interest to identify those children with ALL at high risk for CNS relapse, since additional or specific therapy could be imparted at earlier times. *Aims*. We are currently studying the role of flow cytometry for identifying ALL blasts in cerebrospinal fluid (CSF) samples of children with ALL, compared to standard cytological methods. In the present abstract we show our initial experience. *Methods*. We have prospectively evaluated 327 CSF samples corresponding to 66 children with ALL in 14 Spanish pediatric oncology units. Samples were obtained at the moment of lumbar puncture at diagnosis and at every day of intrathecal therapy. Leukemic blasts were defined as viable cells (dead cells were excluded by 7-Aminoactinomycin-D expression) that expressed the same cell surface markers than those of the original leukemia. A flow cytometry assay identifying up to 8 parameters in a single tube allowed us to study the kinetics of CSF leukemic blast infiltration during the induction, consolidation and maintenance phase of therapy. *Results*. As expected, we found a higher CFS infiltration at diagnosis among high-risk ALL compared to standard-risk ALL. Patients with high-risk ALL showed a faster clearance of CSF blasts than those with standard-risk ALL, probably due to the more intensive therapy. Flow cytometry was more sensible that cytological methods for detection of ALL. Cytological analyses were negative in all samples, except in a single case of high-risk ALL with extensive CNS infiltration. All patients are under treatment and there has been no relapse so far. *Conclusions*. This preliminary analysis of the ongoing study shows that flow cytometry is a sensible methodology that may help in the detection and follow up of CNS subclinical disease in children with ALL

0011

ALL-TRANS RETINOIC ACID PLAYS AN IMPORTANT ROLE IN EARLY RELAPSES PREVENTION IN INFANTS WITH MLL-REARRANGED LEUKEMIA

L. Fechina,[1] E. Shorikov,[1] L. Vakhonina,[2] G. Tsaur,[2] L. Saveliev,[3] A. Popov,[3] N. Myakova,[4] D. Litvinov,[4] K. Kondratchik,[4] S. Varfolomeeva,[4] T. Zagoskina,[5] O. Aleinikova,[6] A. Karachunsky,[4] A. Roumiantsev[4]

[1]Regional Children's Hospital, EKATERINBURG, Russian Federation; [2]Research Institute of Cells Technologies, EKATERINBURG, Russian Federation; [3]Ural State Medical Academy, EKATERINBURG, Russian Federation; [4]Research Center of Pediatric Hematology, MOSCOW, Russian Federation; [5]Research Institute of Hematology and Transfusion Medicine, KIROV, Russian Federation; [6]Center of Pediatric Oncology/Hematology, MINSK, Belarus, Republic of Belarus

Background. Out of all patients (pts) younger than 1 year suffering from acute lymphoblastic leukemia (ALL) outcome in infants with MLL-rearranged ALL remains most unfavorable. Despite of fast initial tumor burden and high CR rates achieved by current chemotherapy regimens further treatment often fails due to the MRD persistence on the molecular level leading to high proportion of early relapses. New treatment strategy must be developed to overcome the resistance of residual leukemic clone and prevent the relapses. The efficacy of ATRA in daily dose 25 mg/m^2 in combination with conventional chemotherapy in infants with ALL is under investigation. *Aims*. To determine the impact of ATRA consecutive courses included into MLL-Baby protocol in the prevention of early relapses comparing to ALL-MB 2002 - well established regimen in Russia and Belarus, applied in all children's age groups. *Methods*. From September 2003 till July 2007 45 pts with infants ALL were enrolled either on to MLL-Baby or ALL-MB 2002 protocols under the

decision of treating physician. Treatment has been approved by Local and Federal Ethics Committees. Parents' informed consent was obtained in all cases. Out of 22 and 23 pts allocated to MLL-Baby and ALL-MB 2002 respectively, MLL rearrangements were detected in 15 and 10 pts by cytogenetic and PCR methods correspondingly. Both groups were similarly distributed by median age 6 (1-10) and 6 (2-11) months (p=0.72); gender m/f : 7/9 and 2/7 (p=0.44); WBC: 114 (3-450) and 193 (21.5-360) per microliter (p=0.18); initial CNS disease: 4 and 1 pts. (p=0.81); immunophenotype: BI - 11 and 2 pts (p=0.18), BII - 0 and 2 pts (p=0.07), BIII - 4 and 2 pts (p=0.92), biphenotype-1 and 0 (p=0.45). MLL rearrangements in MLL-Baby and ALL-MB 2002 groups were as follows: t(4;11) -7 *vs* 7 pts (p=0.54); t(11;19) -4 *vs* 2 pts (p=0.83) respectively; t(10;11) -2 pts, t(1;11) -2 pts and del 11q23-1 pts have been detected only in MLL-Baby group. MLL-Baby and ALL-MB 2002 chemotherapy regimens are equally intensive and identical by risk-group distribution and design except CNS disease prophylaxis: in MLL-Baby cranial irradiation 12 Gy was performed only for high risk group (HRG) pts with initial CNS involvement and age older than 12 months, while pts allocated on to ALL-MB 2002 were irradiated despite of initial CNS status and risk-group. Cranial irradiation in MLL-Baby group is substituted by 5 additional intrathecal triplets. Pts with t(4;11) within both protocols have been stratified to the HRG arm. *Results*. We did not observe any significant difference in frequency of induction deaths: 1 *vs* 0; CR rates: 94% *vs* 96%; deaths in CR: 1 *vs* 0 but proportion of early relapses differed significantly: 2 *vs* 7 pts. on MLL-Baby and ALL-MB 2002 respectively (p=0.03). Probability of RFS was 0.85 SE 0.09 and 0.22 SE 0.13 (p=0.04) with median of follow-up 18 months (1-56). EFS, OS and DFS were higher on MLL-Baby although did not achieve statistical significance. *Conclusion.* Our preliminary results indicate that ATRA plays an important role in early relapses prevention in MLL-rearranged ALL in infants.

0012

OUTCOME OF 198 ADULTS AFTER RELAPSE OF ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) INCLUDED IN 4 CONSECUTIVE FIRST LINE PETHEMA TRIALS

S. Vives,[1] A. Oriol,[1] M. Tormo,[2] S. Brunet,[2] E. Del Potro,[2] J. Bueno,[2] J. Bergua,[2] J. Sarrá,[2] C. Grande,[2] C. Bethencourt,[2] J.M. Hernandez-Rivas,[2] C. Rivas,[2] J.M. Ribera[1]

[1]ICO Badalona-Hospital Germans Trias i Pujol, BADALONA; [2]PETHEMA Group. Spanish Society of Hematology, BARCELONA, Spain

Background and aims. Most adults with acute lymphoblastic leukemia (ALL) who achieve complete remission (CR) will relapse. We examined the outcome of 198 adults with recurring ALL, representing the 31% of 645 patients previously treated on PETHEMA first line trials (ALL89, ALL93HR and ALL03HR for high-risk ALL and ALL96IR for intermediate risk ALL). *Patients and methods*. All patients included in the prospective PETHEMA trials between January 1989 and January 2006 were eligible if they had experienced a first relapse. Rate of second CR achievement, disease-free survival (DFS) from CR2 to relapse, death from any cause or last follow-up and overall survival (OS) from relapse to death or last follow-up were assessed as outcome measures and the influence of patients baseline and relapse characteristics was analysed. *Results*. Baseline characteristics: 112 males (57%), median age 30 yr (range 15-69), 82 (41%) with WBC count >25×10^9/L, 45 (23%) with poor risk cytogenetics (i.e. t(9;22), t(4;11) or complex karyotype), 127 (64%) of precusor B-cell origin and 55 (28%) slow responders to initial treatment. First-line treatment included daunorubicin, prednisone, vincristine, asparaginase induction and early consolidations were followed by delayed consolidation and 2-yr maintenance (150 pts, 76%) or autologous (20 pts, 10%) or allogeneic (28 pts, 14%) SCT. Median time from CR1 to systemic relapse was 0.9 yr (range 0.1-9). Fifteen patients (8%) were unable to receive intensive treatment, 153 (77%) received standard ALL induction (equal or similar to first line treatment, N=58 or Hyper-CVAD, N=95), 13 (7%) received a fludarabine-idarubicin-based regimen and 17 (9%) underwent SCT without prior induction treatment. The induction death rate was 15% (29 pts), 83 pts (42%) achieved a second CR and 86 (43%) were resistant. Age <30 yr was associated with a higher probability of achieving CR (p=0.003). SCT was performed to 69 patients (35%) either during CR2 (59 pts: 13 auto, 28 allo, 18 unrelated) or active disease (4 auto, 6 allo). At last follow-up 27 patients (15%) remain alive of whom 7 (26%) have undergone an auto-SCT, 12 (44%) some modality of allo-SCT and 8 no SCT. However, 5-yr OS from relapse was 5% (95% CI 2-8) and 5-yr DFS from CR2 was 9% (95%CI 2-16). Young age (median OS 7 months in patients younger than 30 years *vs* 3 months in older patients; p=0.005) and time from CR1 to relapse (OS of 0% in those with a CR1 duration of less than 1 year, 11% for CR1 lasting more than 1 year; p=0.004) were associated to prolonged survival. Duration of CR1 was also associated with a longer CR2 (p=0.012). Young patients with late relapses (>1 year) had the best chance of remaining long-term survivors (5-yr OS 13%). *Conclusion*. Most adults with recurring ALL, whatever their prior treatment, cannot be rescued using currently available therapies. Young patients with late relapses are the only subgroup that may achieve long term survival.

METHYLENE TETRAHYDROFOLATE REDUCTASE (MTHFR) GENE POLYMORPHISM IN EGYPTIAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

A.A.G. Tantawy,[1] E.A. El-Bostany,[2] M. Abou El Asrar,[1] A.A.M Adly,[1] E.A. El-Ghouroury[2]

[1]Faculty of Medicine, Ain Shams University, CAIRO; [2]National Research Center, CAIRO, Egypt

Background. Genetic variations in the enzymes responsible for chemotherapy metabolism in cancer patients may play a role in determining relapse and toxicity risks.Methotrexate is a key drug in acute lymphoblastic leukemia (ALL) treatment,it inhibits DNA replication by blocking the conversion of 5,10 methylene tetrahydrofolate to 5- methylene tetrahydrofolate by methylene tetrahydrofolate reductase (MTHFR). MTHFR is central to folate metabolism and has two commom functional polymorphisms (C677T and A1298G). *Aim of study*. To assess the prevalence of MTHFR polymorphisms C677T and A1298G in Egyptian children with ALL and the relation to the frequency of drug induced complications and relapse rate. *Methods.* Forty ALL patients diagnosed and treated in the Pediatric Hematology/Oncology Unit,Children's Hospital,Ain Shams University, Cairo Egypt were included , all were treated according to the protocol of ALL-BFM 1990, and were followed up for 3.1-6.5 years (median 4.5 years). Data on age at diagnosis, sex,incidence as well as severity and duration of hepatic, mucosal and infectious complications during therapy were reported.MTHFR genotyping was done with a PCR-based RFLP assay. *Results*. Among the studied 40 ALL patients, the MTHFR C677T polymorphic allele frequency were 40%, 27.5%, and 32.5% for TT,CT,and CC genotypes respectively. The MTHFR A1298G polymorphic allele frequency were 40%, 35%, and 25% for AA,AC,and CC genotypes respectively. The TT genotype was significantly associated with increased toxicity during methotrexate therapy compared to other genotypes. Diarrhea and oral mucositis developed in 81.3%, 9%, and 7.7% in TT,CT, and CC genotypes respectively (p<0.0001). The oral mucositis index was higher in TT genotype compared to other MTHFR C677T alleles (21.6, 17.5, and 15.9 in TT,CT, and CC genotypes respectively; p<0.05). Elevated liver enzymes (ALT and AST) developed during therapy in 87.5%, 0%, and 7.7% in TT,CT, and CC genotypes respectively; p<0.0001. The TT genotype was significantly associated with relapse in 56.3% compared to 18.2% and 0% in CT and CC genotypes respectively (p=0.001). TT genotype was significantly associated with lower overall 5 years survival (39%,65%, and 92% in TT,CT, and CC genotypes respectively; p=0.02). There was no significant relation between MTHFR A1298G polymorphism and the risks of drug induced complications or relapse rate in the studied ALL patients. *Conclusions*. MTHFR TT genotype is significantly associated with increased mucosal and hepatic toxicity during methotrexate therapy as well as increased relapse rate in childhood ALL. Because of the relatively high prevalence of the TT genotype in Egyptian children with ALL, dosage modification of methotrexate in ALL protocols should be considered.

0014

LONG TERM COGNITIVE STATUS AND MAGNETIC RESONANCE IMAGING FINDINGS OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

S. Aytac Elmas,[1] S. Aytac,[2] I. Saatci,[3] F. Oktem,[4] M. Cetin,[2] S. Yetgin[2]

[1]Hacettepe University Faculty of Medicine, ANKARA; [2]Hacettepe University Faculty of Medicine Pediatric Hematology Department, ANKARA; [3]Hacettepe University Faculty of Medicine Radiology Department, ANKARA; [4]Hacettepe University Faculty of Medicine Pediatric Psychiatry Department, ANKARA, Turkey

Background. Despite improved survival in children with Acute Lymphoblastic Leukemia (ALL), long term complications still remain a big obstacle for those young people with a long life expectations. There were some new approaches to minimalize long term neurocognitive complications as some protocols discontinue giving prophylactic cranial radiotherapy. *Aims.* Our aim was to assess the long term neuropsychological

effect of treatment in children with ALL who were neurologically asemptomatic. *Method*. Between September 2003 and May 2007, ALL patients whose therapy was stopped at least 2 years ago and came to Hacettepe University Pediatric Hematology Department regularly for routine off-therapy control has been invited to this study and 52 of them were accept to be a part of this investigation. Cranial Magnetic Resonance Imaging(MRI) evaluations was done mean 64 months after cessation of therapy and 21 (40%) of them had no identifiable lesions however 22 (42%) had probable therapy associated lesions (cysts, unidentified bright object, cortical-cerebellar signal alterations) and 9(17%) had definitive lesions (atrophy, bleeding focus, gliosis). There were no statistically significant difference for gender, initial ages and treatment procols (Modified St. Jude Total XI and XIII) between those 3 groups of lesions in the MRI (p>0.05). Time interval between the cessation of theray and MRI evaluation show that children with definitive lesions was defined within a long time period (7,5±3 years) than children without any lesions (4,9±3,9 years). Prophlactic cranial radiotherapy was given 28 of 52 patients and there were no significant difference between patients with radiotherapy and without radiotherapy according to initial age and gender (p>0.05). 22 (78%) of 28 patient whose given radiotherapy showed that were probably and/or definitively therapy associated lesions in MRI. Moreover from those 5 patient who had an atrophy and 8 patient who had a bleeding focus in MRI bared that 4 and 7 of them has given radiotherapy in the past, respectively. Neurocognitive evaluation using WISC-R and WAISS show that there were no difference according to the verbal, performance and total IQ levels between patients with radiotherapy (87±19, 97±20 and 92±20) and without radiotherapy (94±20, 102±21 and 98±20), respectively (p>0.05). On the other hand, there were significant difference between patients without lesions, probable and derfinitive lesions according to the verbal IQ (94±18, 95±17 and 73±24, p=0,017), performance IQ (100±19, 105±17 and 85±27, p=0.038) and total IQ (96±18, 100±17 and 79±27, p=0.027), respectively. *Conclusions*. This study suggest that in the long term, most patients with ALL have MRI abnormalities that were significantly correlated with neurocognitive functions and previous radiotherapy. Patients with ALL must be followed up for these complications and detection of abnormalities in MRI tend to increase in a time period. Elimination of prophylactic cranial radiotherapy seems to be future consept in children with ALL therapy.

TREATMENT OF MULTIPLY RELAPSED LEUKEMIC MENINGITIS BY HIGH-DOSE INTRAARTERIAL CHEMOTHERAPY

A. Shuvaev,[1] V. Savello,[1] O. Sarjevsky[2]

[1]Military-Medical Academy, SAINT-PETERSBURG; [2]National Medico-surgical Center n.a. Pirogov, MOSCOW, Russian Federation

Background. With current treatment protocols there is a big part of patients with acute lymphoblastic leukemia (ALL) that will have long-term survival. The central nervous system (CNS) relapse may occur in 2-10% of them. In some part of patients, relapses may occur multiply and have resistance to systemic chemotherapy and CNS irradiation. There are no common standards for prophylaxis, and especially for treatment of neuroleukemia relapse. We have tried to implicate the superselective intraarterial chemotherapy that is used in primary CNS lymphoma to treatment of CNS relapse in adult ALL. *Material*. Patient (man, 26-years old) entered to the hematological department in 10/2005. In results of investigation the diagnosis of Acute lymphoblastic leukemia (CD19+cy CD79+CD10+CD34+cyTDT+HLA-DR+) was made. No CNS involvement was present by cytology. At the beginning, the induction chemotherapy with intrathecal chemoprophylactic was started in according to Hoeltzer protocol. A remission was reached after one course of induction. After late consolidation the patient had developed first isolated CNS relapse. The treatment was consisted of combination (methotrexate, cytarabine, and dexamethasone) intrathecal chemotherapy and whole-brain irradiation. In results of treatment the clearance of cerebrospinal fluid (CSF) was achieved. After the three months of maintenance therapy the second isolated CNS relapse had diagnosed in control lumbar puncture. The treatment by intrathecal chemotherapy and Hyper-CVAD protocol was started that had lead to third remission after one cycle of Hyper-CVAD. But after third cycle, the CNS isolated relapse had developed again. As the patient had received full-dose brain irradiation and CNS disease had resistance to common treatment tactics, we applied the method of intraarterial chemotherapy that used in treatment of primary CNS lymphoma. The treatment protocol consisted of one-month repeated 2-day chemotherapy: methotrexate (2500 mg each day, for a total dose of 5000 mg) administered intraarterially in arteria meningea media at both side, cyclophosphamide (500 mg/m^2 each day, for a total dose of 1000 mg/m^2) and etoposide (150 mg/m^2 each day, for a total dose of 300 mg/m^2) given intravenously; intrathecal administration of methotrexate 15 mg, cytarabine 30 mg and dexamethasone 4 mg in day 0 also used. Granulocyte-colony stimulating factor rescue was given on days 3-9 or until neutrophil recovery. The clearance of CSF was achieved during first course of treatment. There are no neurological toxicities during treatment. In control assessment after the 6 cycles of treatment there are no signs of leukemic lesions in CNS by contrast-enhanced magnetoresonance imaging, cytological or immunophenotyping evaluation of CSF, but there is a minimal residual disease of bone marrow with initial immunophenotype. After the 9th cycle of chemotherapy was completed, the patient had developed severe exacerbation of chronic hepatitis B and treatment was stopped. No signs of ALL relapse were present. *Conclusion*. Today the treatment of CNS relapses in adults ALL is difficult problem in oncohematology. The implication the treatments approaches of primary CNS lymphoma, as superselective intraarterial high-dose chemotherapy may serve as model for future clinical trials in treatment of CNS involvement in adult ALL.

0016

HYPER-CVAD IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: AN ANALYSIS OF THE DOSE-INTENSIVE (INDUCTION-CONSOLIDATION) PHASE

P. Silva-Coelho,[1] A. Carneiro,[2] I. Carvalho,[2] F. Principe,[2] J.E. Guimaraes[2]

[1]Hospital de Sao Joao, PORTO; [2]Hospital de Sao Joao, Department of Clinical Haematology, PORTO, Portugal

Background. Hyper-CVAD is a modified dose-intensive regimen for the treatment of adult ALL, developed by the group at M.D. Anderson (MDACC). *Aims*. To evaluate the efficacy and toxicity of the dose-intensive phase of Hyper-CVAD in adult acute lymphoblastic leukemia. *Methods*. Ten consecutive patients with relapsed ALL, diagnosed between January 1999 and July 2005, and 24 consecutive patients with ALL newly diagnosed between August 2005 and December 2007 were entered into this analysis. Patients with chronic myelogenous leukaemia, lymphoid blast phase were excluded. Immunophenotypic categories were set according to EGIL criteria. Treatment consisted of Hyper-CVAD, according to the schemata published by MDACC. Patients with Ph$^+$ or BCR-ABL$^+$ ALL were treated with Hyper-CVAD + imatinib, from January 2006 onwards. Evaluation of treatment results was restricted to the dose-intensive phase, due to poor maturation of data from maintenance phase. Responses and treatment outcomes were evaluated according to international standardized criteria defined for AML (2003). *Results*. Median age was 31 years (range, 18-76); 22% were at least 50 years old. Thirty-six percent were female. One patient had Down syndrome. Seventy percent had a performance score of 80 or greater (Karnofsky). Fifty-two percent were of B-cell phenotype, 41% of T-cell phenotype and 7% were biphenotypic (3.5% T/myeloid and 3.5% B/myeloid, all predominantly lymphoid according to EGIL score). Median haemoglobin level was 11.3 g/dL, median WBC was 8.8×10^9/L (WBC>30×10^9/L in 34%), and median platelet count was 67×10^9/L. Splenomegaly was present in 38%, hepatomegaly in 21%, lymphadenopathy in 40%, a mediastinal mass in 22% (all of T-cell phenotype in the latter). Forty-four percent of patients were at high-risk for CNS disease. CNS leukaemia was present in 15% of cases at diagnosis. Twelve-percent of cases were Ph-positive, all p190 (21% of B-cell cases), 9% displayed complex karyotypes, 9% were hyperdiploid, 21% were normal and 12% had insufficient metaphases. Of relapse cases included, all were in first relapse, 80% were systemic, 78% had been submitted to SCT (50% allogeneic, 50% autologous), and 3% had been submitted to previous radiotherapy. Ninety-two percent of patients achieved CR (48% after 1 course, median time to CR 40 days, 90.2% maintained CR and 9.8% relapsed during treatment, one each after 4, 5 and 6 cycles), 56% had less than 5% day 14 blasts, 3% had resistant disease, 6% died during induction (bacterial sepsis: 3% pneumonia, 3% peritonitis). Cerebellar toxicity occurred in 6%, mononeuropathy multiplex in 3%, subarachnoid haemorrhage in 3%, aspergillosis in 3%. Eighteen percent abandoned protocol - 3% each due to cerebellar toxicity, diagnosis of concomitant neoplasia and severe myocardial infarction, and 9% due to relapse of disease. Fifteen percent were referenced for allo-SCT. Febrile neutropenia rates ranged from 15% to 74%/cycle. Hospital stay duration medians varied between 17 and 25 days for odd cycles, and 18 and 24 days for even cycles. No significant effect of pretreatment characteristics in CR achievement/maintenance was observed. *Summary and Conclusions*. Hyper-CVAD is an efficacious and safe treatment regimen for remission induction and consolidation in ALL. Further follow-up time is needed to assess long-term results.

Acute myeloid leukemia - Biology I

SELECTIVE SILENCING OF THE NPM1 MUTANT PROTEIN AND APOPTOSIS INDUCTION UPON ATRA *IN VITRO* TREATMENT OF AML CELLS CARRYING NPM1 MUTATIONS

M.P. Martelli,[1] V. Pettirossi,[2] N. Manes,[2] F. Susta,[3] P.L. Orvietani,[3] A. Liso,[4] F. Mezzasoma,[2] F. Cecchetti,[2] M.F. De Marco,[2] B. Bigerna,[2] A. Pucciarini,[2] I. Nicoletti,[5] L. Binaglia,[3] C. Mecucci,[2] M.F. Martelli[2]

[1]Hematology Department, PERUGIA; [2]Hematology, University of Perugia, PERUGIA; [3]Biochemistry, University of Perugia, PERUGIA; [4]Hematology, University of Foggia, FOGGIA; [5]Internal Medicine and Oncology, University of Perugia, PERUGIA, Italy

We previously identified a new AML category carrying NPM1 mutations which lead to aberrant cytoplasmic expression of the nucleolar protein NPM1, hence the term NPMc+ AML [*Falini et al, NEJM 2005*]. This leukemia accounts for about one-third of adult AML and shows distinctive biological and clinical features [*Falini et al, Blood 2007, Review*]. Notably, AML carrying NPM1 mutations in the absence of FLT3-ITD are characterized by a favourable prognosis. However, still a proportion of NPMc+ AML cannot be cured by conventional treatments and new therapeutic strategies need to be explored. We previously identified OCI/AML3 as the only human AML cell line carrying cytoplasmic mutated NPM (type A) in the absence of FLT3-ITD [*Quentmeier et al, Leukemia 2005*]. Because of these features and the ability to engraft in NOD/SCID mice, the OCI-AML3 represents a remarkable tool for the study of NPMc$^+$ AML. Previous findings that ATRA exerts growth inhibitory effects on the OCI/AML3, prompt us to investigate the molecular mechanisms underlying the response to ATRA, with focus on the NPM mutant protein. Interestingly, clinical data recently presented by the group of Dohner at the last ASH meeting [Schlenk *et al.*, Abs # 297, ASH 2007] indicate ATRA might have a role in the therapy of NPMc+ AML patients, in particular when in the absence of FLT3 mutations. As cellular model for our studies, we also used primary leukemia cells originated from a patient with NPMc+ AML (mutation A) bearing FLT3-ITD mutation (MONT1) that have been propagated in NOD/SCID mice since 1999. Whilst NPM1mutation and cytoplasmic delocalization of the mutant protein appeared to be stable, unfortunately FLT3-ITD mutation was lost with time, thus we don't have at the moment a cellular system of NPM1 mutation in the presence of FLT3-ITD mutation. Early cell cycle arrest and pro-apoptotic effects of pharmacological doses of ATRA were confirmed in both cellular models *in vitro*. Morphological signs of differentiation were not evident. Western blot analysis using specific rabbit polyclonal antibodies showed marked downregulation of the leukemic NPM1 mutant protein upon ATRA treatment, preceding apoptosis activation (Figure 1).

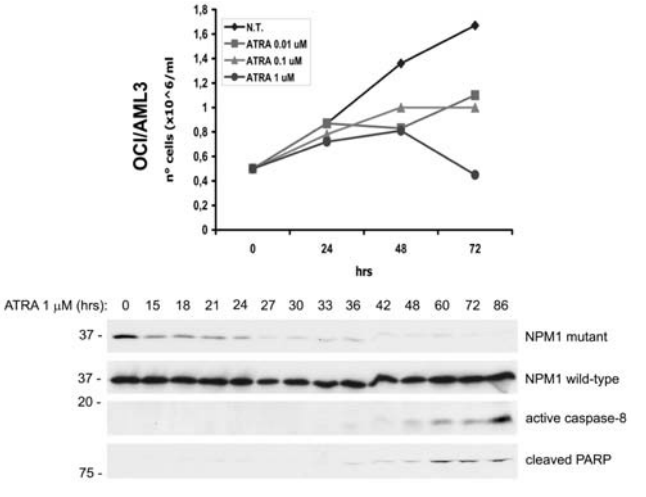

Figure 1.

On the other hand, wild-type *NPM1* protein levels remained unchanged, leading to a condition of *NPM1* haploinsufficiency. Semi-quantitative RT-PCR for NPM mutant A showed no change in mRNA expression following treatment, suggesting a regulation of the NPM mutant protein expression at post-transcriptional level. Indeed, this effect was partly reverted by concomitant treatment with proteasome-inhibitors. Downregulation of NPM mutant protein preceded activation of caspase-8, PARP-cleavage and Bax activation. No NF-kB activation was observed upon ATRA treatment. Importantly, these results were confirmed in the primary NPMc$^+$ AML cells from patient MONT1. Activation of caspase-8 suggests that the response to ATRA in NPMc$^+$ AML cells may be mediated through the death receptor pathway. Although protein levels of TRAIL, TRAIL receptors and TNF-α receptors seem to be unaffected, it might be possible that the *NPM1* mutant protein modulates the signalling through death cell receptors. Analysis of ATRA-induced transcriptome and proteome modifications in NPMc+ AML is ongoing and will be also presented, as well as further pre-clinical studies on patients' primary AML cells. In conclusion, our data suggest that NPM mutant protein might be involved in the *in vitro* response to ATRA in AML cells carrying *NPM1* mutations.

MIRNA EXPRESSION IN ACUTE MYELOID LEUKEMIA CELLS WITH DIFFERENT KARYOTYPES

S. Brundiers,[1] S. Brundiers,[2] K. Battmer,[2] M. Brugman,[1] M. Castoldi,[2] J. Krauter,[1] M. Muckenthaler,[2] A. Ganser,[1] M. Eder,[1] M. Scherr[1]

[1]Hannover Medical School, HANNOVER; [2]University of Heidelberg, HEIDELBERG, Germany

Background. Multiple cyto- and molecular genetic risk factors have been identified in acute myeloid leukemia (AML). microRNAs (miRNAs) are non-coding RNAs in the length of 21-25 nucleotides that are negative regulators of gene expression. For solid tumors and chronic lymphocytic leukemia, it has been shown that miRNA-expression may provide valuable diagnostic and prognostic parameters. *Aims.* Aim of this study was to determine whether miRNA-expression can discriminate (i) between normal progenitor and AML cells and (ii) between cytogenetically defined subgroups of AML and normal CD34$^+$ cells. *Methods*. Total RNA was isolated from purified CD34$^+$ cells from normal bone marrow (BM; CD34>90%, n=4) and peripheral blood (PB; CD34$^+$>95%, n=4), and from primary AML samples at initial diagnosis (CD34$^+$>50%) including samples with normal karyotype (n=5), inv(16) (n=4), -7 (n=4), t(8;21) (n=5), and complex karyotype (n=4), respectively. RNA quality was analyzed by Bioanalyzer, and miRNA-expression profiles were determined by using microarray analysis (miChip, 333 miRNAs) and miRNA-specific quantitative real-time reverse transcriptase-polymerase chain reaction (miR-qRT-PCR). Statistical analysis was performed using Bioconductor and a moderated t-test. Multiple testing corrections were done by calculating the false discovery rate (FDR) according to Benjamini & Hochberg. In addition, differences between miRNA-expression measured by miR-qRT-PCR were analyzed by using the 2-DDCT-method. *Results*. There was no significant difference in miRNA-expression between BM- and PB-derived CD34$^+$ cells. In contrast, we identified a set of thirty-eight out of 216 validated miRNAs differentially expressed between normal PB CD34$^+$ and AML samples based on statistically significant differences in expression levels determined by miChip (p<0.05). Expression levels of twelve miRNAs discriminate AML samples from PB derived CD34$^+$ cells with p<0.01 including miR-223 and miR-10a among others. When compared to miR-qRT-PCR, the expression of six miRNAs was statistically different between AML and PB-derived CD34$^+$ cells in both methods. Next, we analysed miRNA-expression profiles in cytogenetically defined subgroups of AML in comparison to PB derived CD34$^+$ cells. Our analysis identified a subset of nineteen miRNAs with differential expression between AML subgroups by both methods (p<0.05). For example, enhanced expression of miR-181a and reduced expression of miR-99b was found in inv(16) whereas reduced expression of miR-100 and miR-99b was found in t(8;21) as compared to PB derived CD34$^+$ cells. *Summary*. This study identifies a number of specific miRNAs with differential expression in AML and normal CD34$^+$ cells. Furthermore, miRNA expression is heterogeneous within cytogenetically defined subgroups of AML. Prospective studies and correlation to clinical outcome are warranted to confirm the value of miRNA-expression profiling in AML.

AML1/RUNX1 MUTATIONS ARE FREQUENT IN *DE NOVO* AML WITH CERTAIN CYTOGENETICS AND COOPERATING MOLECULAR MUTATIONS DIFFER DEPENDENT ON UNDERLYING CYTOGENETICS

S. Schnittger, F. Dicker, W. Kern, T. Haferlach, C. Haferlach

MLL Munich Leukemia Labortory, MUNICH, Germany

Background. Previous reports have shown that *AML1/RUNX1* mutations are associated with MDS and AML after MDS whereas *de novo* AML were poorly analyzed and cooperating mutations (coop mut) are not analyzed at all. *Aims.* We performed an analysis focused on *de novo* AML and on distinct cytogenetic subgroups. *Methods*. A selected group of 243 AML with normal karyotype (NK) or recurrent chromosomal imbalances were analyzed: NK (n=97); -7 (n=37), +8 (n=30), +13 (n=20), +21 (n=12), others (47). *Results.* In total 79 of 243 patients in these selected cytogenetic subgroups showed at least one RUNX1mut. 67/79 mutations were different. 19 patients (26%) had homozygous mutations and 5 (6.8%) had two different mutations. In NK 20% had *RUNX1mut*, 27% in -7, 33% in +8, 90% in +13, 58% in +21. These results for the first time show that *RUNX1mut* are frequent in *de novo* AML with certain cytogenetics. All cases were also analysed for FLT3-LM, *FLT3-TKD, MLL-PTD, NRAS, NPM1*, *JAK2* and *CEBPA*. NPM1mut and CEBPAmut were found to be mutually exclusive of *RUNX1mut*. The analysis for cooperating mutations (coop mut) was done for subgroups. NK subgroup: 29/79 carried coop mut, 18 x MLL-PTD, 15 x FLT3-LM and 3 x NRAS -7 subgroup: No coop mut was detected in the 10 RUNX1mut cases with -7. + 8 subgroup: In 2 RUNXmut cases 3/10 coop mut were detected. In contrast nearly all RUNXwt with +8 had an FLT3-LM, NPM1mut or NRASmut. +13 subgroup: only 3/20 had coop mut. Instead this specific cytogenetic subgroup shows a 4-fold-elevated FLT3 expression as an alternative cooperating event. Overall, MLL-PTD (62%) was found to be the most frequent coop mut for RUNX1 followed by FLT3-LM (52%) and NRAS (10%). *Summary and Conclusions.* 1) RUNX1mut are frequent in *de novo* AML with normal karyotype or single chromosomal imbalances. 2) Coop mut are frequent in some subgroups (NK and +21), rare (+13) or absent in others (-7, +8). 3) MLL-PTD plays a major role as coop mut in *RUNX1mut* AML.4) some subgroups may exhibit alternative cooperating mechanisms like overexpression of FLT3 in +13.

0020

HIGH INDO (INDOLEAMINE 2,3-DIOXYGENASE) MRNA LEVEL IN BLASTS OF ACUTE MYELOID LEUKEMIC PATIENTS PREDICTS POOR CLINICAL OUTCOME

M.E.D. Chamuleau,[1] A.A. van de Loosdrecht,[1] C.J. Hess,[1] A. Zevenbergen,[1] J.J.W.M. Janssen,[1] R. Delwel,[2] P.J.M. Valk,[2] B. Lowenberg,[1] G.J. Ossenkoppele[1]

[1]VU University Medical Center, AMSTERDAM; [2]Erasmus University Medical Center, ROTTERDAM, Netherlands

Background. Indoleamine 2,3-dioxygenase (IDO) degrades the amino acid tryptophan which is essential for T cells. Tryptophan depletion causes T cell cycle arrest and solid tumors that express high levels of IDO can create immune suppression. Recently, blasts of acute myeloid leukemic (AML) patients were shown to express the IDO protein. *Aims*. We now determined INDO (the encoding gene for IDO) mRNA expression in myeloid leukemic blasts of 285 AML patients by gene expression profiling. Results were validated by quantitative PCR (qPCR) analysis in blasts of an independent cohort of 71 patients. *Results*. Correlation of INDO expression to relevant known prognostic factors and survival identified high INDO expression as a strong negative independent predicting variable for overall and relapse free survival of AML patients. In a Cox regression model, INDO expression level >1.2 was the strongest predictor for survival (p<0.001 odds ratio (OR) 3.2), as compared to WBC (p=0.012, OR 1.006) and age (p=0.012, OR 1.024). As the groups of patients with good and poor cytogenetic risk profile were too small to use in a multiple regression model, the group with an intermediate cytogenetic risk profile was analyzed (n=40). Also in this group INDO expression was a strong predictor for survival (p=0.009, OR 1.146). Our results demonstrate that the INDO mRNA level is a strong independent predicting variable for the outcome of AML patients. As inhibition of IDO by orally available inhibitors like 1-methyl-tryptophan is effective in mice and synergistic with chemotherapy, we now provide more evidence for rapid exploration of the introduction of IDO inhibition in the treatment of AML patients.

0021

FARNESYLTRANSFERASE INHIBITOR SYNERGISTICALLY INCREASES RAPAMYCIN-INDUCED CELL GROWTH INHIBITION IN ACUTE MYELOID LEUKEMIA CELLS

J.-W. Cheong,[1] H.W. Lee,[1] J.I. Eom,[1] J.S. Kim,[1] Y.H. Min[2]

[1]Yonsei University College of Medicine, SEOUL, South-Korea; [2]BrainKorea21 Research Team of Nanobiomaterials for the Cell-Based Implants,YUMC, SEOUL, South-Korea

Proteins regulating the mammalian target of rapamycin (mTOR), as well as some of the targets of the mTOR kinase, are overexpressed or mutated in various human cancers. Accumulating evidences demonstrate that mTOR inhibitor rapamycin suppresses tumor cell growth *in vitro* and *in vivo*. However, it has been shown that acute myeloid leukemia (AML) cells showed substantial resistance to rapamycin-induced cell growth inhibition. Farnesyltransferase inhibitors suppress leukemia cell growth irrespective of Ras mutation. Here we evaluated the interaction between rapamycin and farnesyltransferase inhibitor FTI-277 in inhibiting cell growth in myeloid leukemia cells and analyzed its molecular mechanisms. Flow cytometric evaluation and Western blot analysis demonstrated that phospho(p)-mTOR and mTOR upstream Ras-like GTPase Rheb expression in primary leukemic blasts obtained from AML patients were significantly higher compared to normal bone marrow mononuclear cells (p<0.001 and p<0.001, respectively). We examined the inhibition extent of AML cell growth after treatment with rapamycin (100 μM) in the absence or presence of FTI-277 (10 μM). Cell proliferation was decreased to 87.3±5.3% and 78.7±4.4% of control group in the rapamycin- and FTI-277-treated cells, respectively. However, combined treatment of leukemia cell lines with rapamycin and FTI-277 (Rapa/FTI) led to a synergistic decrease to the level of 22.7±3.4% of control (p<0.001), which was associated with cell cycle arrest at the G2/M phase of cell (p<0.05). The synergistic inhibition of cell growth was associated with prominent downregulation of Rheb, p-mTOR, p-p70S6 kinase, and p-4E-BP1. Interestingly, levels of p-Akt/PKB and p-PTEN protein were markedly decreased in these leukemia cells after co-treatment with FTI-277 and rapamycin. These findings were also observed in the primary leukemia cells obtained from untreated patients with AML. Taken together, these findings indicate that coadministration of farnesyltransferase inhibitor and rapamycin might be a promising therapeutic strategy for AML.

0022

PIN1 IS UPREGULATED IN ACUTE MYELOID LEUKEMIA WITH C/EBPα MUTATIONS AND BLOCKS GRANULOCYTE DIFFERENTIATION VIA C-JUN

J.A. Pulikkan

LZG; AG BEHRE, HALLE, Germany

Transcription factor CCAAT enhancer binding protein alpha (C/EBPα) is one of the master regulators of granulopoiesis. Recent studies suggest that loss of function or expression of C/EBPalpha as one of the major causes for acute myeloid leukemia (AML). C/EBPα is mutated in around 9% of acute myeloid leukemia. The C/EBPα mutations reported are frame shift mutations at N-terminal domain and point mutations at basic region Leucine zipper. The mutant form of C/EBPα (C/EBPα-p30) shows dominant negative function over the wild type protein. Peptidyl-prolyl cis/trans isomerase, PIN1 binds to and isomerizes the peptidyl-prolyl bond in specific phosphorylated Ser/Thr-Pro motifs. *PIN1* has been shown to be overexpressed in many cancers and has significant role in tumorigenesis. We investigated the role of PIN1 in acute myeloid leukemia with C/EBPα mutation. We report C/EBPα-p30 could induce PIN1 transcription as analysed by quantitative Real-Time RT-PCR analysis. Affymetrix mRNA expression analysis show that PIN1 is upregulated in patients with different subtypes acute myeloid leukemia. Silencing of *PIN1* could overcome the dominant negative action of the C/EBPα-p30 over the C/EBPα-p42 transactivation capacity in promoter assay. Silencing PIN1 with inhibitor against PIN1 (PiB), leads to myeloid differentiation in AML blast cells with C/EBPα mutation and Kasumi-6 cells. Western blot analysis shows that PIN1 inhibition by PiB could upregulate wild type C/EBPα protein level. C/EBPα-p30 induces PIN1 promoter activity in association with E2F1 as assessed by luciferase promoter assay for the *PIN1* promoter. Interestingly, wild type C/EBPα interferes with the transactivation of the *PIN1* promoter and downregulates PIN1 mRNA expression. Next, we investigated the mechanism through which the C/EBPα-p30 blocks the wild type protein. c-Jun expression has been shown high in AML patients with C/EBPα muta-

tion and c-Jun could block C/EBPα function by protein-protein interaction. We show that *PIN1* regulate the protein stability of *c-Jun*. In summary, C/EBPα-p30 induces *PIN1* expression and increases the stability of c-Jun and c-Jun blocks the wild type C/EBPα. Our study demonstrates inhibition of PIN1 as a novel way of treating AML patients with C/EBPα mutation.

0023

GENOME-WIDE PROFILING OF DNA COPY NUMBER ABNORMALITIES IN ADULT ACUTE MYELOID LEUKEMIA (AML) USING HIGH DENSITY SINGLE NUCLEOTIDE POLYMORPHISM ARRAY

I. Iacobucci,[1] E. Ottaviani,[1] A. Astolfi,[2] F. Salmi,[1] N. Testoni,[1] S. Luatti,[1] C. Papayannidis,[1] P. Giannoulia,[1] F. De Rosa,[1] S. Paolini,[1] P.P. Piccaluga,[1] D. Cilloni,[3] A. Pession,[2] M. Baccarani,[1] G. Martinelli[1]

[1]Department of Hematology/Oncology Seràgnoli, BOLOGNA; [2]Pediatric Oncology and Hematology L. Seràgnoli, BOLOGNA; [3]Hematology, University of Turin at Orbassano, ORBASSANO, TURIN, Italy

Introduction. Acute myeloid leukemia (AML) is a heterogeneous disease with various chromosomal aberrations. The karyotype at diagnosis provides important prognostic information that influences therapy and outcome of this disease. However, using conventional chromosome banding techniques alone, karyotype abnormalities are detected in only half of all AML cases. Array-based analysis of single nucleotide polymorphism (SNP) takes the advantage to perform a high-throughput, genome wide screening of genomic imbalances. *Aims*. We sought to identify novel genomic regions of interest in normal karyotype AML and to identify novel candidate regions and disease-related genes in patients with complex karyotypes using genome-wide high resolution SNP-array. *Patients and Methods*. 28 AML patients were analyzed until now. Cases included FAB-M0, M1, M2, M4, M5, miscellaneous cytogenetic abnormalities and normal karyotype. 250 ng of genomic DNA were processed on 500K SNP array according to protocols provided by the manufacturer. Copy number state was calculated with respect to a set of 48 Hapmap normal individuals and a set of samples obtained from acute leukaemia cases in remission using Partek® Genomics Suite. *Results*. A wide spectrum of different genetic lesions (gains/losses) involving complete chromosome arms (del 16q, i(13q10), del 3p, del 7p, monosomy 9) or submicroscopic genomic intervals were identified in a substantial proportion of cases without differences in the frequency of losses or gains. Focal genetic alterations were detected at the breakpoints of previously cytogenetically identified chromosomal translocations, such as t(2;3)(p22-23)(q26-27) and t(1;11)(p32;q23). The most frequent genomic gains affected: 9p12 (*ZNF658B, FOXD4L2*), 22q11.1 (*PPYR1*), 5q31-q33 (*CDX1*) and 8p23.2 (*CSMD1*). The most frequent deletions were identified in *ACTBL1* (22q11), NF1 (17q11.2) and often in regions lacking annotated genes. Other recurring genetic lesions were uncommon. Some lesions affected regions with a single gene, such as: *ETAA1, FIGN, STK32B, PRAGMIN, PCM1, GLIS3, MRGPRX1, SESN3, BCL2L14*. Marked differences in the combination of copy number anomalies were identified across the different genetic subtypes of AML. Patients with normal karyotype showed no relevant genetic alterations. *Conclusion*. These data demonstrated that, in contrast to adult acute lymphoblastic leukaemia (ALL), AML is characterized by relatively few recurring copy number alterations, and that spectrum of genetic anomalies is significantly associated with AML disease subtype.

TREATMENT WITH PAN DEACETYLASE (DAC) INHIBITOR PANOBINOSTAT (LBH589) DEPLETES EZH2 AND DNMT1, DEREPRESSES JUNB AND SENSITIZES ACUTE MYELOID LEUKEMIA CELLS TO DECITABINE

W. Fiskus,[1] Y. Wang,[1] R. Rao,[1] P. Atadja,[2] K.N. Bhalla[1]

[1]Medical College of Georgia Cancer Center, AUGUSTA; [2]Novartis Institutes for Biomedical Research Inc., CAMBRIDGE, MA, USA

Background. The PRC (polycomb repressive complex) 2 is a multi-protein complex, which includes *EZH2*, *SUZ12* and *EED* proteins. The PRC2 complex possesses histone methyltransferase (HMTase) activity mediated by the SET domain of EZH2, which methylates histone H3 on lysine (K)-27. We recently reported that treatment with the pan-DAC inhibitor panobinostat (LBH589, Novartis Pharmaceutical Corp) acetylates and inhibits the ATP binding and chaperone function of heat shock protein (HSP) 90, as well as depletes the levels of EZH2, Suz12 and EED in cultured and primary AML cells (Mol Cancer Ther. 2006;5:3096). Recently, within the PRC2 complex, EZH2 was shown to interact with and modulate the DNA methyltransferases DNMT1 (the target of the MDS drug 5-azacytidine), DNMT3a and DNMT3b, which affects their binding to the EZH2-targeted gene promoters. *Aims*. In the present studies we determined the effects of panobinostat on the interaction between the PRC2 proteins EZH2 and EED, and DNMT1, in the cultured and primary acute leukemia cells. *Methods*. In CML blast crisis (CML-BC) K562 and LAMA-84 cells, treatment with ≥50 nM panobinostat disrupted the interaction of DNMT1 with Ezh2, as well as abrogated the chaperone association of DNMT1 and EZH2 with HSP90. *Results*. This resulted in proteasomal degradation of DNMT1 levels, which were restored by co-treatment with the proteasome inhibitor bortezomib. This was also seen following treatment with the HSP90 inhibitor 17-DMAG (250 nM). Additionally, panobinostat depleted the mRNA expression of DNMT1 in K562 cells. Panobinostat-mediated down regulation of DNMT1 levels was also associated with increase in the levels of JunB mRNA, which is known to be repressed by DNA hyper-methylation in CML-BC cells. Depletion of DNMT1 by shRNA or the DNA methyltransferase inhibitor decitabine treatment also increased JunB mRNA levels. Treatment with panobinostat and/or the decitabine induced JunB mRNA expression in CML cells. While treatment with panobinostat did not, decitabine treatment decreased the JunB, ERα and E-Cadherin promoter DNA methylation. However, utilizing chromatin immunoprecipitation (ChIP) analysis, panobinostat was shown to decrease the binding of DNMT1 to 183 bp region in the promoter upstream to the JunB ORF. Panobinostat also decreased Suv39H1 binding, as well as decreased 3Me K9 H3 and histone H3 acetylation levels in this region. Co-treatment with panobinostat and decitabine, *vs* treatment with either agent alone, caused greater depletion of *DNMT1* and induced more JunB mRNA. Co-treatment with panobinostat and decitabine also caused more loss of clonogenic survival of K562 cells, as well as induced more loss of viability of primary AML cells. *Summary*. In conclusion, treatment with pan-DAC inhibitor panobinostat not only depletes EZH2, but also attenuates DNMT1 levels, thereby targeting two epigenetic regulatory mechanisms. Panobinostat also derepresses JunB and sensitizes acute leukemia cells to decitabine.

DETECTION OF PROTEINASE 3 (PR3) GENE OVEREXPRESSION AND NUCLEAR DELOCALIZATION IN CBF ACUTE MYELOID LEUKEMIAS

D. Cilloni,[1] S. Carturan,[1] I. Defilippi,[1] R. Catalano,[1] E. Messa,[1] A. Rotolo,[1] P. Nicoli,[1] I. Iacobucci,[2] G. Martinelli,[2] E. Bracco,[1] A. Levis,[3] G. Saglio[1]

[1]University of Turin, TURIN; [2]University of Bologna, BOLOGNA; [3]Hematology Institute, ALESSANDRIA, Italy

Background. Proteinase 3 (PR3) gene codes for a serine protease with a broad spectrum of proteolytic activity. PR3 is involved in the control of proliferation of myeloid leukemia cells and it confers factor-independent growth to hematopoietic cells when abnormally expressed. The aim was to investigate the role of PR3 gene in leukemic haematopoiesis. *Methods.* We analyzed the expression levels of PR3 by RQ-PCR in 113 BM samples collected at diagnosis from AML patients. The FAB distribution was as follows: M0=5, M1=12, M2=38, M3=12, M4=37, M5=5, M6=4. 19 patients were characterized by t(8;21) and 16 by inv(16). Moreover we analyzed the expression levels in 57 BM and 42 PB samples from 88 MDS patients (44 RA, 32 RAEB and 12 secondary-AML) and in 15 BM and 40 PB samples from healthy volunteers. PR3 protein amount was analyzed by western blot (WB) and its localization by immunofluorescence assay. The transcriptional activity of CEBP/α, the nuclear factor that negatively regulates PR3 transcription, was investigated in parallel by RQ-PCR, WB and EMSA assay. Gain and loss of function experiments were performed by transfecting COS and 293T cell lines with a plasmid containing the full length PR3 sequence and HL60, Me-1, and Kasumi cell lines with specific shRNA. *Results*. We found that PR3 gene is significantly overexpressed in AML samples. The median value of 2-ΔΔCt is 740, (range 15-5043). Interestingly, patients affected by Core Binding Factor leukemias showed significantly higher PR3 values and lower CEPB/α levels compared to patients with normal karyotypes (NK) (p<0,0002 for t(8;21), p<0,001 for inv16). EMSA assay demonstrated the absence of CEBP/α DNA binding activity in CBF AML cells but not in NK AML. In addition, PR3 overexpression was detected in 60 % of the samples from RA patients (mean value: 10, range 3-268), and in all the cases of RAEB (mean value 201: range:128-803) and secondary AML (mean value 589, range 207-7131). WB demonstrated the correlation between the mRNA and protein amount. Interestingly, immunofluores-

cence demonstrated the de-localization of the protein within the nucleous in CBF AML but it is completely cytoplasmatic in leukemic cells with normal karyotype and in MDS. Transfection experiments with PR3 plasmid demonstrate that overexpression of PR3 results into a significant increasing of the proliferation rate and reduced apoptosis. By contrast transfection with shRNA triggers apoptosis and cell growth inhibition. Conclusion: PR3 gene expression and protein are significantly increased in AML and MDS, particularly in CBF leukemias in which the protein is completed delocalized within the nucleous. PR3 overepression is associated with CEBP/α downmodulation. Ectopic expression of PR3 induces increased proliferation and apoptosis arrest. The mechanism underlying the nuclear localization of PR3 in CBF leukemias and its pathogenetic role remains unexplored.

CXCR-4 POSITIVE ACUTE MYELOID LEUKEMIAS (AGE < 60 YEARS): IMMUNOPHENOTYPIC, CYTOMORPHOLOGIC, CYTOGENETIC, AND MOLECULAR CHARACTERISTICS

U. Oelschlaegel, B. Mohr, U. Schaekel, F. Kroschinsky, M. Schaich, G. Ehninger, C. Thiede

University Hospital Dresden, DRESDEN, Germany

Background. The interaction of the CXCR-4 receptor with its ligand SDF-1 plays a key role in the process of homing and mobilization of stem cells and might be involved in the trafficking of leukemic blasts, too. *Aims*. The aim of our study was to correlate the CXCR-4 expression with the main diagnostic features of AML. *Methods*. 682 AML patients (other than AML M3) under the age of 60 were included in our investigation. CXCR-4 expression was measured in whole bone marrow or peripheral blood performing multi-color flow cytometry (CD45 FITC/CXCR-4 PE/CD34 PerCP5.5). The cut-off was set at 20% CXCR-4 positive cells. Cytomorphologic, cytogenetic, and molecular analyses have been done in parallel. *Results*. Ninety percent of all patients express CXCR-4 (616/682 patients). These leukemias were significantly more assigned to a monocytic phenotype (33% *vs* 19%, p=0.0228). The percentage of CD34$^+$, HLA DR$^+$, aberrant CD19$^+$, or CD7$^+$ patients was clearly lower in the CXCR-4 positive *vs* negative group (51% *vs* 83%, p<0.0001; 91% *vs* 100%, p=0.0330; 4% *vs* 11%, p=0.0236; 9% *vs* 17%, p=0.0802). Furthermore, in CXCR-4 positive patients low risk cytogenetics was present less frequently (10% *vs* 27%, p=0.0002), whereas patients with high risk cytogenetics were equally distributed in both groups (22% *vs* 27%). There were significantly more NPM1 mutated or FLT3-ITD mutated cases in the CXCR-4 positive group (38% *vs* 8%, p<0.0001; 24% *vs* 6%, p=0.0005). In addition, the median expression level of CXCR-4 was higher on blasts of FLT3-ITD positive *vs* negative patients (81% *vs* 71%, p=0.0115). Interestingly, patients with NPM1 mutations expressed signifcantly more CXCR-4 compared to non mutated cases (87.9% *vs* 62.7%; p<0.0001), independent from the FLT3 status. *Conclusions*. CXCR-4 positive *vs* negative acute myeloid leukemias displayed distinct immunophenotypic and molecular characteristics. Especially the NPM1 mutation status seems to be correlated with CXCR-4 expression.

0027

FLT3 INTERNAL TANDEM DUPLICATION INVOLVING ITS UBIQUITIN DEPENDENT ENDOCYTOSIS MOTIF SUSPEND MODULATION BY HDM2 AND ARE ASSOCIATED WITH INFERIOR SURVIVAL IN AML

L. Wergeland,[1] E. Oveland,[2] S. Gry,[3] S.L. Bedringaas,[4] R. Hovland,[5] Bruserud,[4] B.T. Gjertsen[6]

[1]University of Bergen, BERGEN; [2]Department of Biomedicine, University of Bergen, BERGEN; [3]Bergen University College, BERGEN; [4]Institute of Medicine, University of Bergen, BERGEN; [5]Center for Medical Genetics, Haukeland University Hospital, BERGEN; [6]Department of Medicine, Haukeland University Hospital, BERGEN, Norway

Background. Internal tandem duplications in the juxtamembrane region of the receptor tyrosine kinase Flt3 (Flt3-ITD) and elevated expression of the oncogenic E3 ubiquitin ligase Hdm2 are frequent features of acute myeloid leukemia (AML). Hdm2 is a well known suppressor of p53, but is also associated with endocytosis of cell surface receptors. Recently we have shown that Hdm2 and Flt3 are reciprocally modulated upon DNA-damage therapy of AML cells *in vitro* and *in vivo*. *Aims*. To elucidate the mechanism behind the Flt3-Hdm2 modulation and the impact of various Flt3-ITDs. Furthermore, determine if the Flt3-Hdm2 modulation may have a clinical impact in AML. *Methods*. Primary AML cells and cell lines (NB4 and MV4-11) with wild type Flt3 (Flt3-wt) or mutated Flt3 (Flt3-ITD) were used with Flt3 ligand (FL), small molecular inhibitors and small interfering RNA (siRNA) to elucidate the relation between Flt3 and Hdm2 on protein level, mRNA expression and modulation of apoptosis. *Results*. Kinase inhibition of Flt3 increase Hdm2 in Flt3-wt cells, but not in Flt3-ITD cells. Modulation of FLt3 and Hdm2 by siRNA indicates that their protein levels are mutually dependent. Cell lines with Flt3-ITD have a more rapid cycling of receptors on the cell surface than cells with Flt3-wt. A sequence alignment of the juxtamembrane region of Flt3 and other related tyrosine kinase receptors lead to the identification of a putative Ubiquitin dependent endocytosis motif (UbE) in the juxtamembrane region of Flt3. Based on transfection studies of mutant Flt3 and Hdm2, internalisation of Flt3 is dependent on both Hdm2 E3 ligase activity and Flt3 UbE domain. A subset of AML patients with Flt3-ITD has a duplication of this domain (Flt3-2xUbE). These patients have a reduced level of surface Flt3 which significantly correlates to an elevated level of Hdm2, and survival data suggest a negative prognostic impact in the presence of Flt3xUbE. *Conclusions*. FLT3 receptor turnover involves Hdm2, and Flt3-ITD results in dysregulated receptor turnover attenuated for Hdm2-induced Flt3 down-regulation. A novel type of Flt3 mutations (Flt3-2xUbE) is associated with the Hdm2-Flt3-signalling pathway and may have prognostic impact within the group of Flt3-ITD positive AML patients.

MICRORNA PROFILING OF EVI1 DEREGULATED MYELOID LEUKEMIA

A. De Weer,[1] B. Poppe,[1] P. Mestdagh,[1] P. Van Vlierberghe,[1] N. Van Roy,[1] A. De Paepe,[1] B. Verhasselt,[2] J. Vandesompele,[2] F. Speleman[1]

[1]University Hospital, Centre for Medical Genetics, GHENT; [2]University Hospital, Dept of Chemistry, Microbiology and Immunology, GHENT, Belgium

Background. Chromosomal rearrangements involving the *EVI1* gene are a recurrent finding in malignant myeloid disorders. These translocations or inversions contribute to ectopic expression of the *EVI1* gene. *EVI1* transcriptional activation has also been reported in approximately 5 % of acute myeloid leukemia (AML) patients without chromosomal defects affecting the *EVI1* locus. Survival of patients with *EVI1* overexpressing leukemias is poor and new insights into the molecular pathology are needed as a basis for development of targeted therapies. Recently, microRNA deregulation was identified as a major contributor to cancer initiation and progression. Moreover, microRNA genes were shown to be directly regulated by activated proto-oncogenes. *Aims.* The aim of this study was to investigate which microRNA genes are implicated in the transcriptional pathways governed by the *EVI1* oncogene. *Methods*. SiRNA mediated *EVI1* knockdown was performed in *EVI1* overexpressing AML cell lines Kasumi-3 and UCSD-AML1 and validated by qRT-PCR and Western blotting. A total of 384 microRNAs were profiled through automated qRT-PCR using high-throughput quantitative stem-loop RT-PCR (Applied Biosystems). Integrated statistical analysis (SAM-analysis, delta Ct and confidence interval analysis) was performed to identify up- and downregulated microRNAs. *Results*. After siRNA treatment, a reduction of 90% on mRNA level and a reduction of 70% on protein level were observed for both EVI1 overexpressing cell lines Kasumi-3 and UCSD-AML1. Through integrated analysis several statistically significant up- (miR-184 and miR-182#) and downregulated (miR-155, miR-222 and miR-210) microRNAs were identified. *Conclusions*. We identified several *EVI1* regulated microRNAs after siRNA treatment of EVI1 overexpressing cell lines which are currently under further investigation in a large panel of AML patients. Furthermore, microRNA profiling of 3q26 rearranged *EVI1* overexpressing patient samples and non-rearranged *EVI1* overexpressing bone marrow samples is underway. Further studies will also include electroporation of antagomirs or microRNA mimics for *EVI1* regulated microRNAs to asses their contribution to the leukemic phenotype. The discovery of functionally relevant microRNAs may provide new targets for therapeutic intervention in AML.

CLASS II-ASSOCIATED INVARIANT CHAIN PEPTIDE (CLIP) EXPRESSION ON AML BLASTS NEGATIVELY AFFECTS ANTI-LEUKEMIC IMMUNITY BY INTERFERING WITH CD4+ T CELL RECOGNITION

M.M. van Luijn,[1] M.E. Chamuleau,[1] T.M. Westers,[1] J.A. Thompson,[2] S. Ostrand-Rosenberg,[2] A. Zevenbergen,[1] G.J. Ossenkoppele,[1] S.M. Van Ham,[3] A.A. Van de Loosdrecht[1]

[1]VU Medical Center, AMSTERDAM, Netherlands; [2]University of Maryland, BALTIMORE, USA; [3]Sanquin Research and Landsteiner Laboratory, AMSTERDAM, Netherlands

Background. The use of immunotherapeutic strategies during minimal residual disease (MRD) in AML patients emerges as an attractive modality to induce effective immune responses against residual leukemic blasts. As CD4+ T effector cells are indispensable in anti-leukemic immunity, the efficacy of HLA class II-restricted antigen presentation on AML blasts could be crucial. Previously, we showed that expression of the class II-associated invariant chain peptide (CLIP), a small remnant of the Invariant Chain (Ii) involved in the process of HLA class II antigen presentation, on AML blasts predicted a shortened disease-free survival (*Chamuleau et al; Canc Res 2004*). *Aims*. To investigate the contribution of CLIP/HLA-DR expression on AML blasts in anti-leukemic immune escape. *Methods*. Variable CLIP/HLA-DR amounts were created on various AML cell lines as a model to analyse the effect of CLIP on CD4+ T cell recognition. Selected cell lines were retrovirally transduced with specific Ii siRNAs. Differences in CLIP/HLA-DR were determined flow cytometrically by comparing CLIP to HLA-DR MFI ratios. Proliferation of healthy donor CD4+ T cells was measured by [3H]-thymidine incorporation after 5 days of culture. Furthermore, leukemic blasts from an AML patient were sorted for CLIP+ and CLIP- fractions by flow cytometry and co-cultured with PBMCs from the same patient. Cell growth and the TCR-Vβ repertoire of cultured CD4+ T cells were analysed for 28 days. *Results*. Kasumi-1 and THP-1 AML cell lines were selected for our model, as both expressed HLA-DR and CLIP. Both cell lines were silenced for Ii to down-modulate CLIP levels on the cell surface. Indeed, Ii-silenced cells not only showed a decrease of Ii, but also a marked down-modulation of CLIP amount per HLA-DR molecule (fold decline in CLIP/DR ratio of 1.4 for Kasumi-1 and 2.0 for THP-1). Non-modulated (DR+CLIP+) and modulated (DR+CLIP-) cells acted as stimulators for healthy donor CD4+ T cells in functionality assays using different stimulator to responder (S/R) ratios. Modulated DR+CLIP- Kasumi-1 and THP-1 cells induced strong S/R-dependent increases in CD4+ T cell proliferation compared to non-modulated DR+CLIP+ controls, as 2.6- and 3.3-fold increases were respectively found at the highest S/R ratio (means of two experiments performed in triplicate). Blocking of HLA-DR on stimulator cells using the L243 antibody abrogated CD4+ T cell proliferation, thereby confirming HLA-DR restriction of the proliferative response. These results were further supported by co-culture experiments with blasts and PBMCs from an AML patient. In the presence of CLIP- blasts, PBMCs remained viable during 28 days, while no PBMCs survived in co-culture with CLIP+ blasts, indicating an adverse role of CLIP in CD4+ T cell proliferation. Interestingly, TCR-Vβ analysis of CD4+ T cells in co-culture with CLIP- blasts showed a 10-fold increase of a Vβ8 CD4+ T cell clone (~70% of total CD4+ T cells) at day 28, as opposed to negative controls. *Summary and Conclusions*. These data support our hypothesis that CLIP expression on AML blasts abolishes the anti-leukemic CD4+ T cell response, both in an allogeneic and autologous setting. These findings may have important consequences for the design of cellular immunotherapy in AML.

0030

THE ROLE OF C-FLIP IN ACUTE MYELOID LEUKEMIA

D.P. McLornan,[1] M.F. McMullin,[2] K.I. Mills,[2] P.G. Johnston,[3] D.B. Longley[3]

[1]Queen'S University Belfast, BELFAST; [2]Department of Haematology, CCRCB, Queen's University, BELFAST; [3]Department of Oncology, CCRCB, Queen's University, BELFAST, Northern Ireland

Background. Acute myeloid leukemia (AML) is a heterogeneous disease and overall prognosis is poor. Defects in apoptosis certainly contribute to this aggressive clinical phenotype. The anti-apoptotic protein c-FLIP (cellular FLICE-Inhibitory Protein) is a key inhibitor of processing and activation of Caspase 8 at the Death Inducing Signalling Complexes (DISCs) formed by both the FAS and TRAIL (TNF-related apoptosis-inducing ligand) receptors. Differential splicing gives rise to both a long (c-FLIPL) and short (c-FLIPS) isoform. *Aims*. i) Investigate the role of c-FLIP in mediating drug resistance in AML. ii) Investigate if c-FLIP expression has prognostic significance in AML. *Methods*. Knock down of c-FLIP gene expression was carried out using a siRNA (FT siRNA) targeted against both isoforms in the U937 and K562 cell lines. Transient transfections were performed via standard nucleofection protocols (AMAXA™). The effects of c-FLIP gene silencing were studied alone and then in combination with standard induction agents and recombinant human TRAIL. Cell viability was assessed via Trypan Blue Exclusion Assay and apoptosis assessed via activation of Caspase 8, Caspase 3 and PARP cleavage in addition to the percentage of cells in the sub G0/G1 region as determined via standard Propidium Iodide Flow Cytometry protocols. The expression of FLIP and other antiapoptotic proteins have been assessed at both a protein and mRNA level from bone marrow aspirate samples (n=30) obtained following full ethical consent. The Microarray data was obtained from standard Affymetrix™ chips. *Results*. FT siRNA alone leads to apoptosis in the U937 cell line, but not the K562 cell line, as detected via immunoblotting for Caspase3 processing and PARP cleavage. Silencing c-FLIP also sensitises the U937 cell line, but not the K562 cell line, to the standard induction agents of Cytarabine and Etoposide but not to the topoisomerase II inhibitor Daunorubicin. In addition, FT siRNA sensitises both the U937 and K562 cell lines to recombinant human TRAIL with a dramatic increase in the percentage of apoptotic cells detected via Flow Cytometry and enhanced PARP and Caspase 8 activation. Microarray profiling of a large number of AML samples (n=318) demonstrated heterogeneity of c-FLIP m RNA expression and this appears to be independent of World Health Organisation (WHO) subclassification. Looking at each of the cytogenetic categories (Poor /Standard and Good risk) individually, when RNA expression is divided into < or > mean, then those with > mean FLIP expression persistently have poorer overall survival (Log Rank χ^2 58.284213, p value = 2.74818e-011). In the clinical samples there is wide intra-individual variation in c-FLIP, XIAP and Bcl-2 family member expression at both the protein and gene level and correlations with conventional risk factors and the endpoints of overall survival and recurrence free survival will be made. Further work will be performed to establish if there is correlation of gene expression with protein expression of c-FLIP isoforms. *Conclusions.* These results indicate that c-FLIP may be a key regulator of AML cell survival with potential prognostic significance. Targeting c- FLIP may be a therapeutic strategy for AML.

0031

IMMUNOGLOBULIN AND T CELL RECEPTOR REARRANGEMENTS IDENTIFICATION REVEALS POTENTIALLY NEW SUBGROUP WITHIN PEDIATRIC ACUTE BIPHENOTYPIC LEUKEMIAS

J. Volejnikova,[1] E. Mejstrikova,[2] E. Fronkova,[2] T. Valova,[2] L. Reznickova,[2] J. Zuna,[2] J. Stary,[2] O. Hrusak,[2] J. Trka[2]

[1]2nd Medical School, Charles University Prague, PRAGUE; [2]2nd Medical School, Charles University, PRAGUE, Czech Republic

Background. Acute biphenotypic leukemia (BAL) is an uncommon type of leukemia in which blasts markedly express antigens of more than one lineage. Whereas coexpression of antigens from different lineage is frequently observed in childhood leukemias, international EGIL classification based on immunophenotype was developed to distinguish cases with significant level of aberrant expression. EGIL provides a precise definition of BAL, although several weak points, eg. no regards to high heterogeneity of BAL, are discussed. Original lineages of cells undergoing malignant transformation and the mechanism of aberrant expression are different among BAL subgroups and are not yet entirely known. Immunoglobulin and T-cell receptor (Ig/TCR) gene rearrangements, arising during hematopoiesis, can indicate commitment to the lymphoid lineage and reflect the maturation stage of leukemic blasts. *Aims.* Our aim was to determine the lineage of BAL origin using Ig/TCR rearrangement analysis in a cohort of BAL cases diagnosed during 10-year period of national-wide childhood acute leukemia (AL) immunophenotyping. *Methods*. In all cases, complete morphological and immunophenotypic examination together with molecular genetic analysis of most frequent childhood AL genetic aberrations (TEL/AML1, BCR/ABL, MLL rearrangements) was performed. We analyzed complete and incomplete immunoglobulin heavy chain (IgH) rearrangements, light chain (IgL) rearrangements to the κ deleting element, complete rearrangements of TCRγ, TCRδ, TCRβ and incomplete rearrangements of TCRδ and TCRβ. *Results*. Between 09/1996 and 08/2006, 38 of 730 childhood AL patients fulfilled the EGIL criteria for BAL: 33 at diagnosis (29 ALL/My+, 4 AML/Ly+), 8 at relapse (6 ALL/My+, 2 AML/Ly+), 4 at both diagnosis and relapse. In cases with B-cell primary lineage, incidence and maturity of Ig/TCR rearrangements generally reflected immunophenotypic assign-

ment of leukemic blasts: In pro-B/My+ BAL, low total number of rearrangements was detected including mostly incomplete or complete IgH rearrangements, with no IgL rearrangements. On the contrary, pre-B/My+ BAL had 1-2 complete IgH rearrangements on one or both alleles and 1-2 IgL rearrangements, suggesting that leukemogenic hit occurred during the light chain recombination. Usage profiles of V and J gene segments and length of hypervariable CDR3 regions did not differ significantly from published non-BAL data, except for more frequent D3.9 segment use in BAL (p=0.004). In TEL/AML1+ leukemias, upregulation of recombinase activation genes caused by TEL/AML1 fusion protein was described. Similarly to non-BAL TEL/AML1+ leukemias, we found multiple Ig/TCR rearrangements in BAL TEL/AML1+ cases. Surprisingly, 4 of 6 pro/pre-T-ALLs with coexpression of myeloid markers had germline configuration of Ig/TCR genes; the same was observed in AMLs with coexpression of T-lymphoid markers (4 of 4 germline). *Summary*. Pattern of Ig/TCR rearrangements in BAL with primary B-cell lineage reflected lineage and developmental stage determined by flow cytometry. In TEL/AML1+ BAL cases, multiple Ig/TCR rearrangements were observed similarly to non-BAL TEL/AML1+ leukemias. We describe a specific subset of T/myeloid leukemias with germline configuration of Ig/TCR genes, resembling AML cases with T-lymphoid marker coexpression. These cases represent potentially a unique newly identified subgroup of childhood AL.

GENE TARGETS OF 11Q23 AMPLIFICATION AND CONCOMITANT 5Q DELETION IN AML/MDS CELLS

B. Schneider,[1] R. Geffers,[2] H. Quentmeier,[1] M. Kaufmann,[1] S. Nagel,[1] H.G. Drexler,[1] R.A.F. MacLeod[1]

[1]*German Collection of Microorganisms and Cell Cultures, BRAUNSCHWEIG;* [2]*Helmholtz Centre for Infection Research, BRAUNSCHWEIG, Germany*

Some patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) carry genomic amplification of the 11q23-24 region (amp11q), and which is considered a bad prognosis marker. While MLL remains a favored candidate, several reports highlight alternative candidates. Remarkably, amp-11q is invariably accompanied by deletions affecting the long arm of chromosome 5 (del5q) possibly marking disease progression. We addressed two main issues, namely concerning the identity of amp11q gene target(s) in AML/MDS, and whether the obligate partner 5q- gene target(s) match those unaccompanied by amp11q. Studies were performed on amp11q/del5q cell lines established from AML/MDS patients, using control cell lines with del5q alone. Cell lines were cytogenetically analysed by classical cytogenetics and FISH followed by array comparative genomic hybridization (aCGH) using Affymetrix 100K arrays to yield respective commonly deleted/amplified regions (CDR/CAR) on 5q/11q. Global gene expression was studied by transcriptional profiling using Affymetrix U133+2.0 arrays, reverse transcription (RT)-PCR, and realtime-PCR. Gene expression was also measured after treatment with lenalidomide which is believed to reactivate del5q target genes. aCGH analysis showed CAR at 11q22.3-25 at 106-135 Mbp, bimodally peaking at 118 Mbp and 129 Mbp in all del5q/amp11q cell lines. Three 5q CDR were present: at 104-134, 136-140, 162-3 Mbp. Expression analysis at 11q revealed that several peak-CAR genes were differentially overexpressed, showing upregulation, either *de novo* - *CHEK1, PAFAH1B2, KIAA0999, ATP5L*; or intensified - *MLL, NFRKB, H17/FOXRED1*, when compared to del5q alone. Known candidate del5q genes RPS14 and SPARC lay within a minor CDR (140-155 Mbp) present in 2/4 cell lines only. Commonly downregulated genes inside the 5q CDR in del5q/amp11q cells included CXXC5, HINT1, PCYOX1L, BRD8, PAIP; while KIAA04333, PJA2, TNFAIP8, RAPGEF6, HSPA4, SKP1A, were downregulated throughout. Proven MLL downstream targets, MEIS1, HOXA9 and HOXA7 were inconspicuously expressed in amp11q cells, however, where the top10 upregulated genes comprised *C6orf106, DLG1, PIP5KIA, ARFGEF1, EPS15L1, NMD3, NNT, CDK8, KIAA1008, IQCB1*; while *ZA20D3, C21orf56, ODAG, KCNN4, ADAR, P2RX1, GLG1, GMFG, ADD3, FLJ12770* were downregulated. Lenalidomide treatment reactivated the putative 5q target gene SPARC more intensively and progressively in AML cells with an MDS history than in *de novo* AML. Our data downplay the significance of MLL as an amp11q target, unless after upregulation its signalling properties in AML qualitatively differ from translocation cases. We have shortlisted alternative target genes upregulated in amp11q, and their potential downstream partners. Although a handful of 5q genes were differentially regulated in amp11q cells, patterns of 5q downregulation were broadly similar implying a common disease entity. Further work is in progress to determine which additional del5q genes are lenalidomide responsive to serve as potential functional targets. These data validate the first cell line model for amp11q AML with a history of MDS. Signalling pathway analysis of conspicuous target genes will be performed using both NCBI-DAVID and in-house software packages.

0033

PANOBINOSTAT (LBH589) + DOXORUBICIN: A PRECLINICALLY SYNERGISTIC COMBINATION AGAINST ACUTE MYELOID LEUKEMIA (AML) CELL LINES REPRESENTING A CLINICALLY PROMISING COMBINATION FOR PATIENTS WITH AML

P. Maiso,[1] E.M. Ocio,[1] E. Colado,[2] M. Garayoa,[1] P. Atadja,[3] A. Pandiella,[1] J.F. San Miguel[1]

[1]*Universidad de Salamanca, SALAMANCA, Spain;* [2]*Hospital Universitario de Salamanca, SALAMANCA, Spain;* [3]*Novartis Institutes for Biomedical Research, CAMBRIDGE, MA, USA*

Introduction. The combination of cytarabine with an anthracyclin has been the gold standard for the induction treatment of acute myeloid leukaemia (AML) patients for the last three decades. Nevertheless, 20-50% of patients fail to adequately respond to this scheme and among those that achieve complete response (CR) there is a relapse rate of around 50%. Therefore, novel strategies are needed in order to improve the outcome of these patients. *Methods*. The efficacy of the combination of panobinostat (LBH589; a potent pan-DAC inhibitor) with each one of four other agents (cytarabine, doxorubicin, fludarabine and bortezomib) was analyzed both *in vitro* (in four AML cell lines: HEL, HL-60, KG-1 and MV4.11, by means of MTT) and *ex vivo* (in freshly isolated cells from 6 AML patients by multiparametric flow cytometry). In addition the toxicity in normal hematopoietic cells was analyzed. Mechanistic studies (apoptosis, cell cycle profile, DioC6 staining, Western Blot and GEP analysis by microarrays) were performed in the HEL cell line. *Results*. Panobinostat potentiated the effects of cytarabine and fludarabine, and slightly improved that of bortezomib. The combination of panobinostat with doxorubicin (P+D) showed the highest synergistic effect. Therefore, remaining experiments focused on this combination. Forty-eight hours of culture with P+D showed a very important synergistic effect in the four AML cell lines (HEL, HL-60, KG-1 and MV4.11). This efficacy was confirmed in *ex vivo* experiments in blast cells isolated from six AML patients. In all six cases a potentiation was observed with P+D as compared to the efficacy of the single agents. In four cases this potentiation was in the synergistic range. Interestingly no potentiation was observed in terms of toxicity on non leukemic residual hematopoietic cells from the same patients' samples. Mechanistic experiments showed that P+D activated apoptosis (as assessed by Annexin V staining and PARP- and caspases-cleavage by Western Blot) in a time- and dose-dependent manner at concentrations that did not induce any cytotoxic effect when panobinostat and doxorubicin were used as single agents. P+D activated the intrinsic pathway of apoptosis with loss of mitochondrial membrane potential (by DioC6) and subsequent release of Cytochrome C to the cytoplasm. A decrease in MCL-1 and BCL-X cleavage was also observed with the combination while not with the single agents. P+D also induced cell cycle arrest. To evaluate the effect of these drugs and to determine overlaps between each effect, we compared the gene expression profile (GEP) of HEL cells exposed to each treatment. We identified a total of 841 probe sets significantly deregulated after 12 hours of treatment with P+D, 285 with the same dose of panobinostat for 24 hours and 43 for doxorubicin for 24 hours. Interestingly, 588 probe sets were exclusively deregulated after P+D treatment, indicating that panobinostat and doxorubicin affect different groups of genes and pathways. The classification of these genes revealed a clear effect on DNA damage and c-jun pathways. *Conclusion*. P+D show a marked synergistic activity against AML cells, with unique mechanism of action, and represent an attractive combination for clinical investigation.

0034

ABT-737 TARGETS THE COOPERATION OF BCL2 AND ONCOGENIC NRAS IN AN *IN VIVO* MULTI-STEP MODEL OF ACUTE MYELOID LEUKAEMIA

S. Beurlet,[1] N. Omidvar,[2] C. Le Pogam,[3] F. Herventin,[4] L. Sarda-Mantel,[4] P. Merlet,[4] A. Janin,[5] C. Leboeuf,[5] M.E. Noguera,[6] A. Soulie,[3] N. Setterblad,[7] M. Pla,[3] M. Konoplova,[8] M. Andreef,[8] C. Chomienne,[3] R.A. Padua[3]

[1]Inserm, PARIS, France; [2]University of Cardiff, School of Biosciences, CARDIFF, UK; [3]Inserm U718, PARIS, France; [4]Hôpital Bichat, PARIS, France; [5]Inserm U728 Hôpital Saint Louis, PARIS, France; [6]Hôpital Saint Louis, PARIS, France; [7]Institut universitaire hématologie Hôpital Saint Louis, PARIS, France; [8]MD Anderson Cancer Center, TEXAS, USA

Myelodysplastic syndromes (MDS) are clonal stem cell hematological disorders, which evolve to acute myeloid leukemia (AML) and thus model multi-step leukemogenesis. The prognosis of this disease is poor and until recently no therapeutic strategies were available. Activating RAS mutations and over-expression of BCL-2 are prognostic features of MDS/AML transformation. Using NRASD12 and BCL-2, we created two distinct models of MDS and AML; expression of hBCL-2 in a primitiv compartment by MMTV-TLR results in a disease resembling human MDS with bone marrow blasts of 15% and increased apoptosis assayed by TUNEL on liver sections, whilst the myeloid MRP8 promoter induces a disease with characteristics of human AML with marrow blasts of up to 90% and liver apoptosis patterns similar to wild type. Expanded leukemic stem cell [Lin-/Sca-1+/c-Kit+(LSK)] populations, increased myeloid colony growth and increased hBCL-2 expression in the RAS-GTP complex are observed in both MDS/AML diseases, which are transplantable. In the MDS mice the majority of the RAS and BCL-2 doubly stain localized to the plasma membrane, where active pro-apoptotic RAS is normally located, whereas in the AML disease RAS and BCL-2 co-localize in the mitochondria, where BCL-2 is normally found. This is concordant with the signaling profile where ERK is increased with decreased AKT in the RAS-mediated MDS mice and where both ERK and AKT are increased in the BCL-2-mediated AML disease. Thus we suggest that this complex can be a specific target for therapy. When hBCL-2 is switched off with doxycycline in the MDS mice, only partial reversal of the phenotype was observed as RAS recruits endogenous mouse (m)BCL-2 to remain active; thus demonstrating the role of the complex in the disease (Omidvar *et al.*, Cancer Research 67:11657, 2007). In order to target both human and mouse BCL2 the efficacy of *in vivo* treatment with the specific BH-3 mimetic inhibitor ABT-737 was determined. This small molecule links BCL2 and prevents the protein from inhibiting the pro-apoptotic complex BAX/BAK. We show that the treatment reduced efficiently the progression of the disease, increased the peripheral blood platelet counts, decreased the bone marrow blast and cleared the tissue invasion in the MDS mice or reduced tissue infiltration of the AML. *In vivo* imaging by SPECT using Tec-99m-labelled Annexin V shows that ABT-737 induces apoptosis of the blasts cells that infiltrate the liver and the spleen of the treated mice, which was confirmed by TUNEL on liver sections. ABT-737 can reduce the myeloid colony growth and the LSK expansion of these mice. This is concordant with the confocal study of these treated mice that show a decrease of co-localization in marrow cells of the AML-like mice and a reduction in RAS activity as both human and mouse BCL2 are targeted. In conclusion ABT 737 diminishes the formation of the RAS/BCL-2 and rescues many disease associated features. This represents the first *in vivo* progression model of MDS/AML dependent on the formation of a BCL-2:RAS-GTP complex.

Acute myeloid leukemia - Clinical I

A DOUBLE BLIND PLACEBO-CONTROLLED RANDOMIZED PHASE III STUDY OF HIGH DOSE CONTINUOUS INFUSION CYTOSINE ARABINOSIDE (ARAC) WITH OR WITHOUT VNP40101M (CLORETAZINE®) IN PATIENTS WITH FIRST RELAPSE OF ACUTE MYELOID LEUKEMIA (AML)

N. Norbert,[1] A. Pigneux,[2] D. Boscovic,[3] J. Kell,[4] T. Robak,[5] P. Staib,[6] B. Johnson,[7] S. O'Brien,[8] F. Giles[9]

[1]Institut Paoli-Calmettes, MARSEILLE, France; [2]Hôpital Haut Lévèque, BORDEUX, France; [3]Clinical Center of Serbia, BELGRADE, Serbia; [4]University Hospital of Wales, CARDIFF, UK; [5]Medical University of Lodz, LODZ, Poland; [6]Klinikum der Universitaet zu Koeln, COLOGNE, Germany; [7]Vion Pharmaceuticals, Inc., NEW HAVEN, USA; [8]MD Anderson Cancer Center, HOUSTON, USA; [9]CTRC University of Texas Health Science Center, SAN ANTONIO, USA

Background. VNP40101M is a novel alkylating agent which preferentially targets the O6 position of guanine resulting in DNA cross-links and has shown anti-leukemic activity in clinical trials. Aims. This abstract provides an update on a multi-center Phase III study that was conducted to compare overall response rate (ORR), defined as CR and CRp, and safety of VNP40101M + araC *vs* placebo + araC, in patients with AML in first relapse. Secondary endpoints were response duration, progression-free and overall survival (OS). Methods. Eligible patients were at least 18 years old, and in first relapse after CR1 of 3-24 months. Patients were randomized using a 2:1 schema to araC 1.5 g/m^2 (d1-3) + VNP40101M 600 mg/m^2 (treatment group), or araC 1.5 g/m^2 (d1-3) + placebo (control group). Patients with at least 20% blast reduction in the bone marrow could receive a second induction. Patients with CR or CRp could be consolidated according to original randomization, but at a lower dose of VNP40101M (400 mg/m^2) or placebo. The study design included a planned interim analysis of 50% patients enrolled (210 patients) for safety and efficacy by a data safety monitoring board (DSMB), which is detailed below. *Results*. Median age for 210 patients was 59 years; 63% patients had CR1 <12 months (median 290 days). ORR for treatment *vs* control group was 37% *vs* 19% (p=0.004); median OS for treatment *vs* control group was 128 *vs* 182 days (p=0.039). An independent safety review revealed on-study mortality (defined as death from any cause ≤30 days, or due to an adverse event ≤60 days from treatment) in 39% (55/140) of treatment group patients, and 8.6% (6/70) of control group patients. 67% (37/55) of treatment group deaths were due to infection, sepsis, or pneumonia. 18% (10/55) of treatment group deaths were due to pulmonary events (8/10 ARDS [4 with a history of prior BMT], 7/10 with intercurrent infection) occurring between days 9-96. Control group deaths were due to sepsis/pneumonia (2), AML (2), or multi-organ failure (2). Grade 3-4 neutropenia was reported in 95% of patients following first induction; however median time to neutrophil recovery was longer in the treatment *vs* control group (32 days *vs* 25 days). *Summary and Conclusions*. VNP40101M + araC is an active regimen in relapsed AML. In this study, higher ORR was achieved with VNP40101M + araC; however, any efficacy advantage could not translate to a survival benefit given the discrepancy in on-study mortality. Further study of VNP40101M in combination with araC in this population will include VNP40101M at a lower dose (400 mg/m^2) in combination with araC for induction, and standardized antimicrobial/antifungal and growth factor support.

A PHASE I STUDY WITH CP-4055 IN PATIENTS WITH HAEMATOLOGIC MALIGNANCIES

F.J. Giles,[1] S.M. O'Brien,[2] N. Vey,[3] D. Rizzieri,[4] J. Sarantopoulos,[1] T. Prebet,[3] F. Ravandi,[5] S. Faderl,[5] A. Charbonnier,[3] T.F. Jacobsen,[6] B.O. Nilsson,[6] K. Staudacher,[6] H.M. Kantarjian[5]

[1]CTRC at the University of Texas Health Science Center San Antonio, SAN ANTONIO, TEXAS, USA; [2]Univ.of Texas MDACC, HOUSTON, USA; [3]Institut Paoli-Calmettes, MARSEILLE, France; [4]Duke University Medical Center, DURHAM, USA; [5]University of Texas M. D. Anderson Cancer Center, HOUSTON, TX, USA; [6]Clavis Pharma ASA, OSLO, Norway

Background. CP-4055 (cytarabine 5'-elaidic acid ester) is a novel cytotoxic nucleoside analogue. Cytarabine is the backbone of therapy in leukaemia. CP-4055 has similar mechanism of action to cytarabine but, unlike cytarabine, it is independent of nucleoside transporters for cellu-

lar uptake. *Aims.* The aim is to determine the maximum tolerated dose (MTD) and the preferred infusion time in patients (pts) with haematologic malignancies. *Methods*. Following informed consent pts received IV CP-4055 over 2-4 hours (hrs) (Arm A) or 24 hrs (CIV, Arm B) in a day (d) 1-5 q3w schedule. The starting dose in Arm A was 300 mg/m^2/d and in Arm B 200 mg/m^2/d, with standard definitions of dose limiting toxicity (DLT) for haematologic malignancies. Dosing increments were by 50% or by 30% in case of grade 2 non-haematologic toxicities. *Results*. In the ongoing study, 77 pts [46 male, median age 60 yrs (range 21-92); ECOG PS 0-1: 59 pts, ECOG PS 2: 18 pts; AML 67 pts, ALL 3 pts, CMML-AML 2 pts, CML-BP 2 pts, BAL 1 pt, MDS 1 pt, CLL 1 pt; mean 3 lines prior chemotherapy (range 0-7)] have been treated at 3 US and 1 European centres. MTD has been determined at 2500 mg/m^2/d for both Arm A and B. Ten pts are ongoing at 2000 mg/m^2/d. *Safety*: nausea, diarrhea, fever, thrombocytopenia, elevation of liver function tests (LFTs), constipation and anemia were the most common possibly related AEs. All DLTs were reversible elevations of LFTs. Efficacy: 2 CR, 1 CRp and 2 PR were reported at doses 875-2500 mg/m^2/d (all AML, age 33-92 yrs). 23 pts with stable disease/mild myelosuppression received > 2 courses of CP-4055. *Summary and Conclusions.* Patients with haematologic malignancies tolerate CP-4055 well. The MTD was determined at 2500 mg/m^2/d for both 2-4 hrs IV and CIV. Clinical activity has been observed with manageable non-haematologic toxicity.

0037

REDUCED INTENSITY CONDITIONING (RIC) ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): LONG TERM RESULTS OF A *DONOR vs NO DONOR* COMPARISON

M. Mohty,[1] H. De Lavallade,[2] J. El-Cheikh,[2] P. Ladaique,[2] C. Faucher,[2] S. Fürst,[2] N. Vey,[2] D. Coso,[2] A.M. Stoppa,[2] J.A. Gastaut,[2] C. Chabannon,[2] D. Blaise[2]

[1]*CHU de Nantes, NANTES;* [2]*Institut Paoli-Calmettes, MARSEILLE, France*

Standard myeloablative allo-SCT is a well established therapy for adult patients with AML. However, because of the high incidence of procedure-related toxicity, this procedure is often limited to younger patients in good medical condition. RIC regimens have emerged as an attractive modality to decrease transplant-related toxicity. However, the issue of possible higher relapse rates after RIC allo-SCT is still under considerable debate, and no randomized studies between RIC-allo-SCT for AML and chemotherapy alone are yet available. This report describes the long term results of 95 consecutive AML patients, diagnosed between Nov. 1999 and Dec. 2003 in a single institution, and who were considered as potential candidates for RIC-allo-SCT. Using a genetic randomization through a *donor vs no donor* comparison, the aim of this analysis was to assess the real benefit of RIC-allo-SCT for adult AML and its impact on clinical outcome. In this series, 35 patients (37%; *donor* group) had an *identified* HLA-identical sibling donor, while the remaining 60 patients had no HLA-matched related donor (*no donor* group). As per institutional policy, HLA-matched unrelated donors were not considered during the study period. No significant differences in patients or AML features were found between the two groups. In the *donor* group, 25 patients (71%; median age, 51 (range, 26-60)) could actually proceed to the RIC-allo-SCT. The 10 remaining patients with an identified donor did not receive allo-SCT because of early relapse after CR (n=2), patient or donor refusal (n=6), and psychiatric disorders appearing before allo-SCT (n=2). The current median follow-up is 60 months. In an *intention-to-treat* analysis, the KM estimate of leukemia-free survival (LFS) was significantly higher in the *donor* group as compared to the *no donor* group (p=0.003; 60% *vs* 23% at 7 years). When restricting the analysis to patients who could actually receive the RIC-allo-SCT (median follow-up, 40 months from time of allo-SCT), the difference in LFS was also significant between this group of 25 patients (*transplant* group) and the remaining 70 patients (*no transplant* group) who did not receive allo-SCT (p=0.0002; 72% *vs* 24% at 7 years). In the *transplant* group, RIC-allo-SCT was performed at a median of 209 (range, 119-413) days after diagnosis. No major toxicities were encountered during RIC administration (fludarabine, busulfan and ATG), and only 3 patients died from transplant-related toxicity, for a cumulative incidence of TRM of 12% (95%CI, 3-32%) at last follow-up. This relatively low TRM translated towards a significantly higher overall survival (OS) in the *transplant* group as compared to the *no transplant* group (p=0.0003). In the *intention-to-treat* analysis, OS was still significantly higher in the *donor* group as compared to the *no donor* group (p=0.003; Figure 1). After controlling for all relevant factors, in the multivariate analysis, only actual performance of RIC-allo-SCT (p=0.0005; RR=4.1; 95%CI, 1.8-9.1), was significantly predictive of an improved LFS, further confirming the overall benefit of RIC-allo-SCT for adult AML patients. Based on these long term results, and given the low overall TRM rate observed in this high risk population, we conclude that if a matched related donor is identified, RIC-allo-SCT should be proposed since it represents a valid and potentially curative option for AML patients not eligible for standard myeloablative allo-SCT.

PHASE I STUDY OF F60008, A TRIPTOLIDE DERIVATIVE, IN PATIENTS WITH REFRACTORY OR RELAPSING ACUTE LEUKEMIAS

J.L. Harousseau,[1] H. Dombret,[2] A. Pigneux,[1] M. Michallet,[3] M. Brandely[4]

[1]*University Hospital, NANTES;* [2]*Hopital Saint Louis, PARIS;* [3]*Hopital Edouard Herriot, LYON;* [4]*Pirre Fabre Oncologie, BOULOGNE BILLANCOURT, France*

F60008 is a semi-synthetic derivative of triptolide. Triptolide was shown to induce apoptosis in a broad range of human tumor cell lines and in various leukemic cell lines as well as in primary acute myeloid leukemia (AML) blasts. Therefore, the first phase I study of F60008 was conducted in adult patients with refractory or relapsing acute leukemias. The primary objective was to establish the maximally tolerated dose (MTD) of F60008 given as one 30 minute infusion for 5 consecutive days every 15 days. Dose escalation was based initially on an accelerated titration design with 50% dose increment and one patient by dose level (DL). Twelve DLs from 0.15 to 13 mg/m^2/day were explored. After occurrence of a fatal acute respiratory distress syndrome concomitant with pulmonary leucostasis at 13 mg/m^2/day, lower DLs of 8.5, 5.7 and 7 mg/m^2/day were studied in cohorts of 3 to 6 patients. A total of 29 patients were treated: 26 AML and 3ALL. There were 18 males and 11 females with a median age of 57 years (range: 30-79). Ten of them (34.5%) had secondary AML. DLT was defined as any non-hematological grade > 3 toxicity or grade 4 pancytopenia >6 weeks. The MTD was the DL at which 2 out of 6 patients developed a DLT during the first cycle. At 8.5 mg/m^2/day, 6 patients were treated and 2 of them experienced grade 4 cerebellar toxicity. This DL met the criteria for MTD and the lower DL of 5.7 mg/m^2/day was given to a cohort of 6 patients without reporting of DLT. An intermediate DL of 7 mg/m^2 was thus tested in 7 patients (6 evaluable for MTD) and was also associated with the occurrence of grade 4 cerebellar toxicity in 2 patients. Overall, the most common drug-related adverse events were grade 1-2 nausea (17.2% of patients), grade 1-2 diarrhoea (13.8%), grade 3-4 neutropenia (10.3%) in addition to cerebellar toxicity (17.2%). The MTD was 7 mg/m^2/day and the recommended dose (RD) was 5.7 mg/m^2/day. One complete remission (CR) and one CR without full platelet recovery were reported at 8.5 mg/m^2/day; and one CR with pancytopenia was seen at 5.7 mg/m^2/day. All responses were in AML patients. In order to study a possible schedule-dependency of F60008 toxicity, the study protocol was amended to test the total daily dose given in 2 equal doses at 12 hours interval for 5 days. At 3 mg/m^2 bid (daily dose of 6 mg/m^2), no DLT was seen in 3 patients but at 4 mg/m^2 bid (daily dose of 8 mg/m^2), 1 of the 3 patients

developed grade 4 cerebellar toxicity which led to stop accrual. In conclusion, F60008 given once a day for 5 consecutive days has activity in refractory or relapsing AML patients at doses >5.7 mg/m^2/day which is the RD of this regimen. The DLT was cerebellar toxicity. Other regimens warrant further exploration.

0039

A NEW PROGNOSTIC MODEL FOR PATIENTS WITH SECONDARY ACUTE MYELOID LEUKEMIA: RESULTS OF THE DSIL AML96 TRIAL

M. Schaich,[1] W.E. Aulitzky,[2] H. Bodenstein,[3] M. Bornhäuser,[2] T. Illmer,[1] U. Schäkel,[1] N. Schmitz,[4] S. Soucek,[1] C. Thiede,[1] H. Wandt,[5] G. Ehninger[1]

[1]Universitätsklinikum C.G. Carus, DRESDEN; [2]Robert-Bosch-Krankenhaus, STUTTGART; [3]Klinikum Minden, MINDEN; [4]Krankenhaus St. Georg, HAMBURG; [5]Klinikum Nord, NÜRNBERG, Germany

Background and Aims. Secondary acute myeloid leukemia (AML) is regarded as an entity with a poor prognosis and patients were normally treated as high-risk AML. However, due to progress in elucidating the impact of cytogenetic and molecular markers for the prognosis and treatment outcome the entity of secondary AML may be as heterogeneous as the *de novo* disease. Thus, scoring systems are needed to subdivide this entity. *Patients and Methods*. Between February 1996 and November 2004 a total of 232 patients with secondary AML were treated within the AML96 trial of the German Study Initiative Leukemia (DSIL). Secondary AML was therapy-related in 80 patients (tAML) and following a myelodysplastic syndrome in 232 patients (mdsAML). All patients received double induction therapy. Consolidation therapy contained high-dose Ara-C and for patients ≤60 years the option of autologous or allogeneic hematopoietic stem cell transplantation (HSCT) according to cytogenetic risk. *Results*. Patients with mdsAML were older, had a higher percentage of CD34$^+$ blast cells, but in a lower extend aberrant karyotypes than patients with tAML. CR rate was 41%, 3-year overall survival (OS) 19% and 3-year relapse-free survival (RFS) 21% for all patients with secondary AML. In the multivariate analysis disease status (mdsAML *vs* tAML) was not an independent prognostic factor for treatment outcome. However, age proofed to be one of the strongest prognostic factors for treatment response and survival. Patients older than 60 years had a CR rate of 21%, a 3-year OS and RFS of 14% and 3% compared to 47%, 26% and 33% of their younger counterparts (p<0.0001, p=0.001 and p<0.0001), respectively. Looking at the group of patients ≤60 years thrombocyte count (p<0.0001) and NPM mutational status (p=0.04) at diagnosis were independent predictors for survival. Using these two at diagnosis parameters a prognostic model for survival was established for patients ≤60 years. The low-risk group had a 3-year overall survival of 71%, the intermediate risk group of 33% and the high-risk group of 5% (p<0.0001). *Conclusions*. The poor prognosis of patients with secondary AML is mostly conferred by an advanced age. For secondary AML patients ≤60 years we provide a new prognostic model for risk stratification using thrombocyte count and NPM mutational status at diagnosis.

0040

ACCURATE PREDICTION OF CYTOGENETIC SUBGROUPS IN PEDIATRIC ACUTE MYELOID LEUKEMIA WITH GENE EXPRESSION PROFILING; A CRITICAL VALIDATION STUDY

B.V. Balgobind,[1] M.M. van den Heuvel-Eibrink,[1] R.X. Menezes,[1] D. Reinhardt,[2] I.H.I.M. Hollink,[1] T.J.C.M. Arentsen-Peters,[1] E. van Wering,[3] G.J.L. Kaspers,[4] J. Cloos,[4] E. de Bont,[5] J. Cayuela,[6] A. Baruchel,[6] J. Trka,[7] J. Stary,[7] R. Pieters,[1] C.M. Zwaan,[1] M.L. den Boer[1]

[1]Erasmus MC - Sophia's Children Hospital, ROTTERDAM, Netherlands; [2]AML-BFM Study Group, HANNOVER, Germany; [3]DCOG, THE HAGUE, Netherlands; [4]VU Medical Center, AMSTERDAM, Netherlands; [5]UMCG-Beatrix Children Hospital, GRONINGEN, Netherlands; [6]St. Louis Hospital, PARIS, France; [7]2nd Medical School, Charles University, PRAGUE, Czech Republic

Background. Pediatric acute myeloid leukemia (AML) is a heterogeneous disease, in which early treatment response and cytogenetic abnormalities are the most important prognostic factors. AML is thought to arise from two different types of genetic aberrations, i.e. type-I (proliferation enhancing) mutations and type-II (differentiation impairing) mutations. Recent studies have focused on the potential to use gene expression profiling to classify AML. *Aims.* To determine whether gene expression signatures generated in a training cohort could correctly predict cytogenetic subgroups in a second and independent group of pediatric AML cases. *Methods*. We used Affymetrix Humane Genome U133 plus 2.0 oligonucleotide microarrays to generate gene expression profiles of 256 children with AML. Probe set intensities were normalized using the variance stabilization (VSN) procedure of R (version 2.2.0). This group was divided into a training cohort (n=170) and a validation cohort (n=86). The training cohort was further subdivided into a group of patients to identify predictive genes and to build a classifier and a 2nd group to test the accuracy of this classifier. Differentially expressed genes between AML subgroups were calculated using a linear model corrected for random effects, and corrected for multiple testing (Bioconductor package: Limma). *Results*. The classifier was built with the top 15 discriminating probe sets of every cytogenetic subgroup. Based on well-known cytogenetic subgroups [including MLL-gene rearrangements, t(8;21), inv(16), t(15;17) and t(7;12)] we identified a classifier that could reliably predict these subgroups. Moreover, when applied to the independent validation cohort of 86 patients, this classifier achieved a mean accuracy and sensitivity of more than 99% to correctly predict all cytogenetic subgroups in this independent validation cohort. *Conclusions*. In conclusion, gene expression profiling can correctly predict the majority of well-known cytogenetic subgroups in pediatric AML, with a high accuracy and high sensitivity, and can therefore be used as a diagnostic tool to assess the main cytogenetic subgroups.

0041

FLOW-CYTOMETRIC MINIMAL RESIDUAL DISEASE DETERMINATION IS A SURROGATE PROGNOSTICATOR IN ADULT AML PATIENTS WITH NORMAL KARYOTYPE

F. Buccisano,[1] L. Maurillo,[2] G. Del Poeta,[2] M.I. Del Principe,[1] D. Fraboni,[1] P. Panetta,[1] M. Irno Consalvo,[1] M. Rizzo,[1] L. Giannì,[1] S. Campagna,[1] S. Faccia,[1] D. Renzi,[1] M. Postorino,[1] M. Cantonetti,[1] F. Lo Coco,[1] S. Amadori,[1] A. Venditti[1]

[1]Tor Vergata University Hospital, ROMA; [2]S. Eugenio Hospital, ROMA, Italy

Background. In a remarkable proportion of adult AML patients (40-50%), no clonal abnormalities are found on standard cytogenetic analysis. In this group of patients, several gene mutations have been described, allowing to discriminate subgroups with distinct clinical outcome. Among these molecular signatures, FLT3, a receptor tyrosine kinase with important roles in hematopoietic stem/progenitor cell survival and proliferation, has been demonstrated to be mutated in about 1/3 of AML cases, identifying a subgroup of patients characterized by disappointing overall cure rates. Therefore, roughly 60% of patients with normal karyotype are not classifiable by this specific mutation. *Aims.* Given the prognostic role, in our experience, of MRD as determined by multiparametric flow-cytometry (MPFC), we investigated a group of patients with normal karyotype to compare the prognostic information coming from this parameter where no specific mutation of *FLT3* have been detected. *Methods*. We analyzed a group of 127 AML cases entered into the *EORTC/GIMEMA* protocols *AML10/AML12* (age<61yrs) or AML13/AML15/AML17 (age >61 yrs). By applying the maximally selected log-rank statistics, the threshold discriminating MRD negative from positive cases was set at 3.5×10^4 residual leukemic cells, a level that selected, at the post-consolidation time-point, two groups of patients with distinct prognosis.

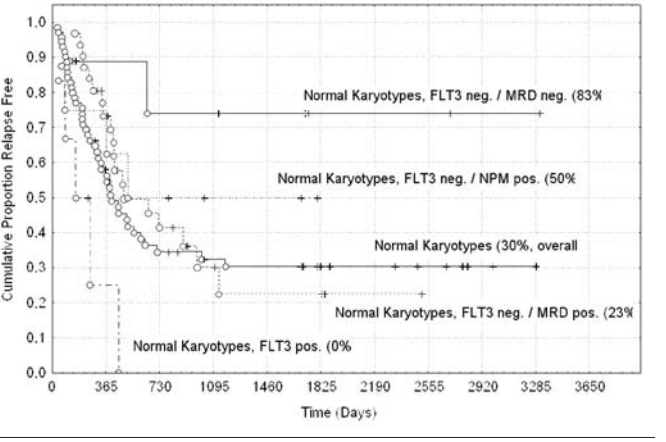

Figure 1.

Results. Seventy-two out of 127 (56%) had a normal karyotype. Among these 72, 53 were studied for FLT3 mutational status; in 13 (25%) a mutated variant of FLT3 was detected. Among the remaining 40 patients with normal karyotype and unmutated FLT3, 39 were evaluable for the MRD status at the post-consolidation time-point: 9 patients were MRD neg. and 30 MRD pos.. These two subsets showed a distinct outcome in terms of 5-years RFS, with FLT3 neg./MRD neg. showing a favorable prognosis as compared to FLT3 neg./MRD pos. (83 *vs* 23%, p=0.031). Interestingly, the latter group shared with those FLT3 positive a similar poor prognosis (Figure 1). When FLT3 status was combined with the mutated status of Nucleophosmin (NPM1) exon-12 gene, the favorable impact of NPM1 mutations on OS and EFS clearly emerged in the group of normal-karyotype AML without FLT3 mutations. In fact, in a subset of 44 patients where both the mutations were investigated, this combined analysis identified 8 out of 44 (18%) patients FLT3 unmutated/NPM1 mutated with a better outcome (5-years OS 50% and RFS 50%, respectively) which was however poorer than that of FLT3 unmutated/MRD neg. cases (Figure 1). *Conclusions*. MRD determination at the post-consolidation check point may help at improving the prognostic assessment of AML patients with normal karyotype, identifying a subgroup of patients with a better outcome as compared to those carrying specific molecular patterns.

0042

IMPACT OF DIFFERENT POSTREMISSION STRATEGIES ON QUALITY OF LIFE ACCORDING TO AGE AND AFFECTED LIFE CYCLE PHASE AT INITIAL DIAGNOSIS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

R.F. Schlenk,[1] K. Döhner,[1] M. Schlosser,[1] S. Groner,[1] D. Späth,[1] R. Hann,[1] D. Messerer,[2] J. Krauter,[3] I. Schäfer,[3] A. Ganser,[3] H. Döhner[1]

[1]University of Ulm, ULM; [2]University of Munich, MUNICH; [3]Hannover Medical School, HANNOVER, Germany

Background. Allogeneic stem cell transplantation (allo-SCT) in patients 16 to 60 of age with acute myeloid leukemia (AML) in first complete remission (CR) seems to have an negative short (Watson *et al.* Eur J Cancer 2004) and long term (Messerer *et al.* Haematologica 2008) impact on quality of life (QoL). In particluar, impaired leisure time activity, difficulties in role functioning, sexuality, and financial affaires as well as a reduced global health status have been reported after allo-SCT. However, the disease and treatment affect different phases of life such as the phase of professional education and family founding, the phase of the full nest with children in house followed by the empty nest phase where children leave home. *Aims.* To investigate the effects of postremission strategy in different age cohorts on QoL. *Methods*. Patients (age 16-60 years) from two multicenter treatment trials (AMLHD93, AMLHD98A) of the German-Austrian AML Study Group (AMLSG), treated between 1993 and 2004, completed a self-report questionnaire issued via the AMLSG Clinical Trials Office. Patients completed the EORTC Quality of Life-Core Questionnaire (QLQ-C30) supplemented by self-assessed concomitant diseases (18 organ complexes), late treatment effects and demographic details including percentage of disability. The QLQ-C30 incorporates 9 multi-item scales with five functional scales (physical, role, cognitive, emotional, social), three symptom scales (fatigue, pain, nausea/vomiting) and a global health and quality-of-life scale. Age groups based on age at diagnosis were defined as follows: i) age group-1: 16-34 years; ii) age group-2, 35-49 years; iii) age-group-3, 50-60 years. *Results*. A total of 1198 patients were registered for the two trials; of 491 patients alive at the time of QoL questionnaire, 394 were in first CR and 245 of these returned the questionnaire (62%). The median time from diagnosis to the QoL assessment was 4.8 years. The distribution of postremission therapy and of age group was n=77 allo-SCT (61 MRD, 16 MUD), n=50 autologous SCT, and n=118 conventional chemotherapy (CCT), as well as n=56 age group-1 (16-34 years), n=116 age group-2 (35-49 years) and n=73 age group-3 (50-60 years). Concomitant diseases were statistically less frequent (p=0.007) in age group-1 compared to age groups 2 and 3. The comparison of the percentage of employed/self-employed patients was restricted to age groups-1 and 2 due to natural retirement in age group-3. In age group-1 the percentage of employed/self-employed patients was 79% compared to 54% in age group-2 (p=0.002). Of note, there was no difference between the treatment strategies in age group-1 which was in contrast to the results in age group-2 where 63% of patients after CCT were employed/self-employed compared to 48% after SCT with no difference between allo-SCT and auto-SCT. Impairments in sexual life were more frequent in the age groups-2 (52%) and 3 (53%) compared to age group-1 (30%) (p=0.005) and, of note, these impairments were significantly more frequent in patients after SCT in age groups-2 and 3 (p=0.008). The general feeling/perception of a positive attitude in life was in trend more frequent in age group-1 (77%) compared to age group-2 (57%) and 3 (63%) (p=0.03) with no difference between postremission strategies. *Conclusions*. There seems to be a differential impact of postremission strategies on QoL according to different age groups with an unfavorable impact of SCT strategies especially in middle aged patients.

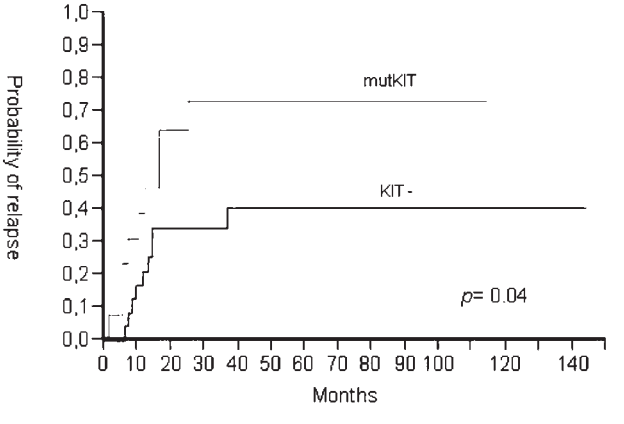
0043

IMPACT OF KIT MUTATIONS IN ACUTE MYELOID LEUKAEMIA WITH INV(16)

R.C. Cairoli,[1] A. Beghini,[2] C.B. Ripamonti,[3] G. Grillo,[3] G. Nadali,[4] E. Di Bona,[5] P. Colapietro,[2] G.B. Bertani,[3] E. Ravelli,[3] G. Nador,[3] C. Castagnola,[6] C Cattaneo,[7] E. Ottaviani,[8] P. Pioltelli,[9] A. Viola,[10] A. Cuneo,[5] F. Ferrara,[10] G. Martinelli,[8] M. Lazzarino,[6] G. Rossi,[7] G. Pizzolo,[4] E. Morra[3]

[1]Niguarda Hospital, MILANO; [2]Dept. of Biology and Genetics for Medical Sciences, MILANO; [3]Dept. of Haematology, Niguarda Hospital, MILANO; [4]Dept.of Clinical and Experimental Medicine, University of Verona, VERONA; [5]Dept. of Haematology, VICENZA; [6]Division of Haematology, University of Pavia, PAVIA; [7]Dept. of Haematology, University of Brescia, BRESCIA; [8]Dept. of Haematology, University of Bologna, BOLOGNA; [9]Division of Haematology, San Gerardo Hospital, MONZA; [10]Division of Haematology and Stem Cell Transplantation Unit, NAPOLI, Italy

Background. Several studies have recently pointed out the adverse impact of KIT mutations (mutKIT) on relapse incidence (RI) and overall survival (OS) in patients with t(8;21) AML. By contrast, the prognostic significance of mutKIT in patients with inv(16) remains unclear. *Aims*. Purpose of this study is to evaluate the prevalence and the effect on outcome of mutKIT in inv(16)(p13q22). *Patients and Methods*. 50 adults with inv(16) AML at diagnosis (median age 46.6 years, range: 17-88; M/F: 30 /20), were centrally analyzed for mutKIT in exon 2, 8, 10, 11 and 17. Mutations were detected using sequencing and other sensitive assays such as ARMS (amplification refractory mutation system) PCR for D816Y and D816H, enzymatic digestion with HINFI for D816V and with Tsp509I for N822K. *Results*. KIT mutations were documented in 17/50 patients (34%). Among the mutKIT cases, we detected mutations in exon 17 (n=12), exon 8 (n= 4) and exon 10 (n=1). We found no significant difference between the mutKIT *vs* the unmutated (KIT-) patients in WBC count at presentation (WBC 13.9x10^9/Liter, range 4.4 to 277.5 *vs* 19.4x10^9/Liter, range 2.5 to 130; Mann-Whitney U test: p=0.649). 42 patients (age <60 years) received intensive chemotherapy; of them, 13 resulted mutKIT upon mutational screening. CR was achieved in 13 of 13 mutKIT patients (100%) *vs* 27 of 29 KIT-patients (93%), (Fisher's exact test: p>0.999). With a median follow-up of 26 months (range: 2 to 147), the Kaplan-Meier plots showed a worse RI among the mutKIT *vs* the KIT- patients (log-rank test: p=0.04; Figure 1). We didn't observe any difference in OS between the two groups of patients (log-rank test: p=0.44).



Conclusions. KIT mutational status seems to influence the incidence of relapse, but not OS, in patients with inv(16) aged 60 years old or younger.

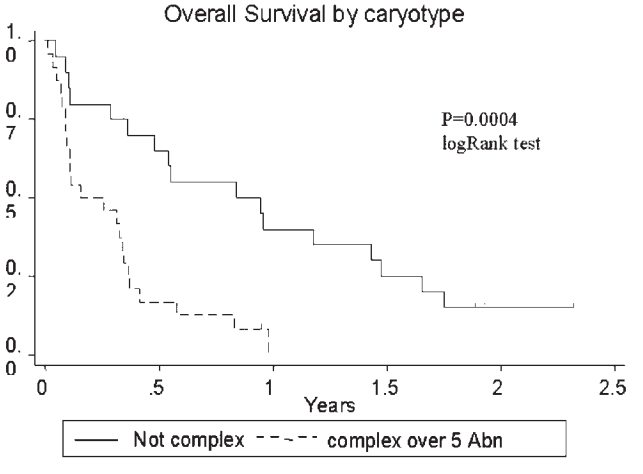
0044

GENTUZUMAB-OZOGAMICIN (GO) PLUS IDARUBICIN (I) AND CYTARABINE (C) AS INDUCTION TREATMENT FOR ELDERLY PATIENTS WITH POOR-RISK CYTOGENETICS ACUTE MYELOID LEUKEMIA (AML),RESULTS OF GOELAMS LAMR04 STUDY

J. Delaunay,[1] C. Recher,[2] N. Vey,[3] F. Witz,[2] B. Lioure,[2] O. Tournilhac,[1] C. Himberlin,[2] D. Bouscary,[2] N. Ifrah,[2] J.L. Harousseau[1]

[1]University Hospital of Nantes, NANTES; [2]University Hospital, TOULOUSE; [3]Institut Paoli Calmette, MARSEILLE, France

Introduction. The prognosis of AML in patients over 60 years of age remains very poor. As in younger patients karyotype is a major prognostic factor. Elderly patients with poor risk cytogenetics have a dismal outcome and complete remission (CR) rates with conventional chemotherapy are usually < 45% (and <25% if complex abnormalities). GO has been used in combination with chemotherapy in relapsed or newly diagnosed AML, but with reduced doses in order to decrease hepatic toxicity. Methods. In this multicentric open-label Phase II study we have evaluated the combination of I (8 mg/m/D x D1-5) + C (100 mg/m/D x D1-7) with GO (6 mg/m on D3) in AML patients aged 60-75 years with poor risk cytogenetics and fit enough to undergo cytotoxic chemotherapy. Other inclusion criteria were: CD33+ AML, PS 2, *de novo* or secondary AML (excluding M3 and Ph1 + AML), no cardiac, renal or hepatic dysfunction. Results. 44 pts aged 60-74 (median 68) were treated in 13 GOELAMS centers. Karyotype results were: complex (>5 abnormalities) in 24/44 (54%), chromosome 5 abnormalities in 24/44 with a significant association with complex Karyotype(p=0.02), chromosome 7 abnormalities in 29/44 and 3q21-21 abnormalities in 7/44. In 13 cases (30%) AML was secondary (chemoinduced 11, prior myeloproliferative or myelodysplastic syndrome 2). Median duration of hospitalisation was 31 D (4-51). In CR patients median duration of neutropenia was 19 D (14-28) and median duration of thrombocytopenia was 15D (5-29). Bacterial or fungal infections were documented in 71% of cases. 7 patients had severe bleeding including 3 deaths, (2 cerebral hemorrhage, 1 intestinal bleeding). Grade 2 hepatic dysfunction was seen in 30% of patients including 3 (7%) pts with veino-occlusive disease (one death). There were 17 (38%) CR (16 CR, 1 CRp), 6 (14%) toxic deaths and 21 (48%) failures. Prognosis factor impacted CR were PS (≥1) with 21% *vs* 66% p=0.003 and complex karyotype (≥5 Abn) 16% *vs* 65% p=0.001.Only 7/17 Pts in CR received a consolidation therapy. OS, EFS and cumulative incidence of relapse at 24 months were respectively 7.5%, 6.8% and 77%. In multivariate analysis, complex karyotype (≥5 abn) and LDH ≥1000 UI/L remain the most significant prognosis factors for OS. Also, Median OS was 3 *vs* 11 months for isolated cytogenetics abnormalities group *vs* complex karyotype group respectively. *Conclusion*. In this population of elderly but relatively fit patients with poor risk cytogenetics AML the addition of GO 6 mg/m^2 to conventional chemotherapy did not appear to increase the CR rate or OS in the whole population . However, CR rate and OS are significantly improved in the isolated cytogenetics abnormalities group indicating that alternative therapy must be defined for elderly patients with complex karyotype.



0045

PHASE II PILOT TRIAL OF GEMTUZUMAB OZOGAMICIN (MYLOTARG) IN COMBINATION WITH FLUDARABINE, CYTARABINE, IDARUBICIN (FLAI) AS INDUCTION THERAPY IN CD33-POSITIVE AML PATIENTS YOUNGER THAN 65 YEARS

A. Candoni,[1] G. Martinelli,[2] M. Tiribelli,[1] E. Simeone,[1] E. Toffoletti,[1] A. Michelutti,[1] A. Chiarvesio,[1] M. Malagola,[3] P.P. Piccaluga,[2] D. Russo,[3] R. Fanin[1]

[1]Division of Hematology, UDINE; [2]Institute of Hematology and Oncology Land A Seragnoli, BOLOGNA; [3]Chair of Hematology and BMT, BRESCIA, Italy

Introduction. The addition of gemtuzumab-ozogamicin (Mylotarg-GO) to an induction regimen including synergistic drugs, such as intermediate dose of cytarabine (Ara-C), idarubicin and fludarabine (FLAI), could reduce treatment failure in AML patients. Nevertheless, the role of this antibody target-therapy in first-line chemotherapy in patients younger than 65 years has not yet been defined. *Patients and Methods*. The primary goal of this prospective phase II pilot study was to evaluate the efficacy and the safety profile of FLAI plus GO as induction regimen. Thirty consecutive AML patients were classified, according to FAB, as follows: M0 (2 pts), M1-M2 (9 pts), and M4-M5 (16 pts). All patients were younger than 65 with a median age of 53 years (range 25-65). The M/F ratio was 16/14, and 21/30 (70%) of patients were poor-risk at diagnosis. CD33 expression exceeded 20% in all cases. The induction regimen (FLAI-GO) included fludarabine (30 mg/m^2) and Ara-C (2 g/m^2) on days 1-5, idarubicin (10 mg/m^2) on days 1, 3, and 5 and GO (3 mg/m^2) on day 6. Hematopoietic stem cell transplant (HSCT) was planned for all patients in first complete remission (CR) after consolidation with intermediate doses of Ara-C and idarubicin (IDAC-IDA). Cytogenetic, multidrug-resistance phenotype, FLT3 mutation, and WT1 expression analyses were performed at diagnosis in all patients. WT1 expression and cytogenetic (in positive cases) analyses were performed after induction to detect and follow MRD. *Results*. Patients were evaluated for response, treatment-related adverse events, overall survival and relapse free survival. After induction with FLAI-GO, CR rate was 90% (26 of 29 evaluable pts); one patient achieved partial remission and two were resistant. There was only one case of death during induction (DDI). After FLAI-GO, the mean value of WT1 dropped from 4200±2777 copies/104ABL to 192±399 copies/104ABL. The toxicity of FLAI-GO was comparable to FLAI alone; 57% of patients experienced transient and reversible GO infusion-related adverse events (especially fever and chills), but no cases of veno-occlusive disease occurred during CHT or after HSCT. After a median follow-up of 13 months (range 1-24), 25/30 (83%) patients are alive (25/25 in CR). The probability of 1-year OS and RFS was 90 and 80%, respectively. Allogeneic and autologus HSCT was performed in 16 (54%) and 4 (13%) patients, respectively. *Conclusions*. These preliminary results suggest that FLAI-GO is a feasible, effective and well tolerated induction regimen for AML patients younger than 65 years, with a high response rate. These results encourage the testing of this new regimen in a multicenter prospective trial. Compared to our previous published experience with FLAI alone, the addition of GO increases the antileukemic efficacy (74 *vs* 90% of CR). The majority of patients that received FLAI-GO obtained an optimal tumour debulking, with a favourable safety profile and low DDI (3%), which allowed a consolidation therapy with HSCT early and in a high proportion of cases (67%).

0046

FACTORS INFLUENCING CLINICAL DECISION MAKING IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML). REPORT ON 340 CONSECUTIVE PATIENTS JUDGED AS UNFIT TO RECEIVE INTENSIVE INDUCTION CHEMOTHERAPY

F. Ferrara,[1] S. Palmieri,[1] G. Gianfaldoni,[2] F. Leoni[2]

[1]Cardarelli Hospital, NAPOLI; [2]Department of Hematology, FIRENZE, Italy

Background. The incidence of AML increases progressively with age. Older patients more often have adverse biologic risk factors and present with clinically relevant comorbidities. As a consequence, a relevant selection is operated as to inclusion into clinical trials based on intensive induction chemotherapy (IC). However, a lack of validated guidelines results in a considerable heterogeneity in the therapeutic attitude between individual clinicians, clinics and geographical districts. *Aims*. In this report we analyzed a series of 340 consecutive patients with AML aged over 60 years, accounting for 48 % of the whole AML patient population observed throughout the period of the study, observed at two hematologic Institutions in Italy, who were considered as not eligible to receive IC. The aim was of defining most relevant reasons of exclusion taken into account in the daily practice. *Methods*. 340 patients with AML, with the exception of APL, aged over 60 years in the period from January 1995 to December 2007 were analyzed. All were judged as not eligible to receive IC aimed at complete remission achievement. *Results*. The median age was 75 years (range 61-94); 80 % of patients were aged over 70 years and 18 % over 80 years. 210 patients (62%) had *de novo* AML, while 130 (38%) had AML secondary to myelodysplatic syndrome. Median performance status (PS) was 3 (range 1-4). In particular, 35 patients (11%) had PS 1, 106 (32%) PS2, 135 (40%) PS 3 and 60 (18 %) PS 4. A concomitant disease (mainly cardiac, hepatic or chronic obstructive pulmonary disease) requiring appropriate treatment was present in 286 patients (82%) Less frequently (11%), severe neurologic disorders were found. 20 % of patients had other neoplasms (prostate cancer, lung cancer, colon cancer, others) and in 50 % of them malignancy was active. Documented infection at diagnosis was demonstrated in 15 % of patients. Of note, only 5 % of patients, judged as not eligible to IIC, were intensively treated after improvement of clinical status following supportive therapy. Specific reasons for exclusion from IC were: age over 80 (%), poor PS (75%), severe concomitant disease requiring specific treatment (60%), active infection (12%), concomitant malignancy (10%), distance from the hematologic institution (10%), lack of caregiver (5%) and patient's refusal (7%). Supportive care was given to all patients, while hydroxyurea was used in the case of leukocytosis (45 % of patients). Median survival was 3 months. Hospitalization was required in 75 % of patients because of infectious (70%) and hemorrhagic complications (34%). Of interest, the rate of inclusion into IC was no different by comparing two distinct decades, i.e. 1995-2000 and 2000-2005 (p=0.34), while age by itself had a major. *Conclusions*. Near half of older patients with AML are excluded from clinical trials aiming at CR achievement. In most cases, selection is operated according to clinical or logistic factors, while relevant biologic features such as cytogenetics at diagnosis are not taken into account. The adoption of well defined comorbidity scales could help for a standardization of elderly AML patient population.

0047

PEGFILGRASTIM IN PATIENTS WITH AML OLDER THAN 60 YEARS. AN ANALYSIS OF THE AML97#38 AND AML2004#69 STUDIES OF THE EAST GERMAN HAEMATOLOGY AND ONCOLOGY STUDY GROUP (OSHO)

H.K. Al-Ali

University of Leipzig, LEIPZIG, Germany

Limited data exist concerning the efficacy of pegfilgrastim in AML. Outcome of patients >60 years after induction-chemotherapy followed-by pegfilgrastim was analysed in the AML2004-study and compared to the outcome of patients who received filgrastim or no G-CSF following the same induction in the AML97-study. Pegfilgrastim serum concentrations and their correlation to WBC recovery are presented. *Methods.* Informed consent was obtained from all patients. 138 patients (77m/61f) received induction-chemotherapy (cytarabine 2 g/m^2 iv day 1,3,5,7 and mitoxantrone 10 mg/m^2 iv day 1,2) followed-by pegfilgrastim 6mg (sc) day 10 in the AML2004 study (group-A). 408 patients (212 m/196f) received the same induction-chemotherapy in the AML97-study followed-by filgrastim 5 µg/kg/day starting day 10 until ANC recovery (>0.5×10^9/L) (n=236,58%) (group-B) or no G-CSF (n=147,36%) (group-C). Patients who received G-CSF later than day 10 were excluded. *Results.* Gender, cytogenetics, and *de novo vs* secondary AML were similar in both studies. Median age in AML2004-, and AML97-study was 68 and 66 years respectively (p=0.001). TRM in the AML2004- and AML97-study was 17% and 13% respectively (p=0.3). Complete remission rate (CR) was 57% in both studies. CR in group-B and group-C were 60% and 51% respectively (p=0.04). There was no statistical difference in CR between group-A and group-B (p=0.6). In multivariate analysis, favourable cytogenetics (p=0.001) and filgrastim-treatment (p=0.04) were associated with higher CR. For group-A, ANC>0.5×10^9/L and WBC>1×10^9/L occurred at a median of 24 and 23 days respectively. In multivariate analysis, age <70 years, and CR were associated with earlier ANC and WBC recovery. Patients <70 years recovered at a median of 22 compared to 28 days for patients >70 years (p=0.002). Patients achieving CR, recovered at a median of 23 compared to 26 days for patients not in CR (p=0.0001). In the AML97-study, WBC>1×10^9/L occurred at a median of 23 days. In multivariate analysis, filgrastim-treatment, and occurrence of CR were associated with an earlier ANC and WBC recovery. Median duration of neutropenia grade 4 was 21 for group-B compared to 25 days for group-C (p<0.0001). For patients achieving CR, pegfilgrastim- and filgrastim-treatment were associated with an earlier ANC and WBC recovery compared to group-C patients in CR (p<0.0001). Median serum concentrations of pegfilgrastim at peak level and at WBC recovery were 87.6(range 8.4-445) and 2.7(range 0.2-40.2) ng/mL respectively. On day 21 of chemotherapy-cycle, median serum pegfilgrastim was 6.8 (range 1.9-64.7) ng/mL. There was no correlation between peak levels and WBC recovery. Therapeutic levels >2 ng/mL were measured for a median of 17(range 9-27) days after a single application. *Conclusions.* Pegfilgrastim had no negative impact on CR, TRM, or duration of neutropenia compared to filgrastim in patients with AML >60 years treated with the same induction-chemotherapy. An in-trial analysis, demonstrated not only the expected faster recovery from grade 4 neutropenia (particularly in patients achieving CR) but also an increase in CR rate with filgrastim-treatment compared to no G-CSF. Whether this is true for pegfilgrastim needs to be evaluated in studies. Some patients had sub-therapeutic pegfilgrastim levels on day 21 of chemotherapy-cycle. Measuring serum pegfilgrastim levels at regular intervals might identify patients who might require additional doses.

Anemia and bone marrow failure

0048

THE OUTCOME OF PATIENTS =60 YEARS WITH ACQUIRED APLASTIC ANEMIA TREATED WITH IMMUNOSUPPRESSIVE THERAPY (IST): NO DIFFERENCE IN RESPONSE RATE AND SURVIVAL BETWEEN STANDARD *vs* ATTENUATED IST

Y. Kao, W. Xu, J.M. Brandwein, J.H. Lipton, H.A. Messner, M.D. Minden, A.C. Schuh, A.D. Schimmer, K. Yee, V. Gupta

Princess Margaret Hospital, TORONTO, Canada

Background. Immunosuppressive therapy consisting of Antithymocyte-globulin (ATG) and cyclosporine (CSA) is the current standard of care for younger patients with acquired aplastic anemia (AA) who are not candidates for bone marrow transplantation. However, the optimal IST strategies for older patients are not well established due to concerns related to intolerability or toxicities associated with standard doses of IST used in younger patients. *Aims*. To evaluate the outcome of IST in an unselected population of older patients (≥60 years) with AA and to identify prognostic factors for survival. *Methods*. Retrospective chart review of all consecutive patients ≥60 years treated at Princess Margaret Hospital (PMH), Toronto, Canada for AA between 1993 and 2007. The diagnosis of AA was established according to the standard criteria (International Agranulocytosis and Aplastic Anemia Study, 1987). *Results*. The study includes 24 consecutive patients treated with IST at PMH. Median age was 70 years (range 61-78) and median follow up of survivors was 48 months (range 8-103). The severity of AA was: very severe (n=9), severe (n=13), and non-severe (n=2). Standard dose treatment was defined as ATGAM (160 mg/kg) or thymoglobuline (18.75 mg/kg) with or without CSA. Attenuated treatment was defined as ≤50% dose of ATGAM/thymoglobuline with CSA or CSA alone. Seven patients received standard dose treatment, and 17 patients received attenuated treatment. The decision regarding treatment intensity was made by the treating physician based on the physician's perception of tolerability of treatment in the individual patient. Six patients (25%) died early within 3 months of starting IST due to sepsis (n=4), bleeding (n=1), or cardiac complications (n=1). Out of 18 patients evaluable for response, 12 achieved CR/ PR according to criteria defined by Camitta (Acta Haematologica, 2000). The 2-year cumulative incidence of response was 42% (95% CI 26%-69%). Of the responders, three patients subsequently had relapse and received a second course of ATG with 2 out of 3 achieving a second response. The 10-year cumulative incidence of evolution to clonal disorders (MDS/AML/symptomatic PNH) was 19% (95% CI 6%-65%). The 3-year probability of overall survival and failure-free survival was 49% (95% CI 27%-68%) and 16% (95% CI 4%-35%), respectively. Moderate or severe co-morbidities (p=0.03) as determined by Charlson Co-morbidity Index and very severe AA (p=0.007) were associated with significantly inferior overall survival. There was no impact of standard *vs* attenuated treatment intensity on response rate (43% *vs* 53%, p=0.4) or 3-year survival (43% *vs* 51%, p=0.6). Early mortality appears higher in the standard treatment group although not statistically significant (43% *vs* 18%, p=0.4). *Summary and Conclusions*. Early mortality is a major problem in the treatment of older patients with AA. Future studies should focus on reducing the early mortality by investigating better supportive care strategies and less toxic IST regimens.

0049

DEVELOPMENT OF A DISEASE SEVERITY SCORING SYSTEM FOR TYPE 1 GAUCHER DISEASE

M.D. Cappellini,[1] T. Cox,[2] E.H. Giannini,[3] G.A. Grabowski,[3] W.L. Hwu,[4] H. Mankin,[5] A.M. Martins,[6] C. Sawyer,[7] S. Vom Dahl,[8] N. Weinreb,[9] M. Yeh,[7] A. Zimran[10]

[1]University of Milan, MILANO, Italy; [2]University of Cambridge, CAMBRIDGE, UK; [3]Cincinnati Children's Hospital Medical Center, CINCINNATI, USA; [4]National Taiwan University Hospital, TAIPEI, Taiwan; [5]Massachusetts General Hospital, BOSTON, USA; [6]Universidade Federal de Sao Paulo, SAO PAULO, Brazil; [7]Genzyme Corporation, CAMBRIDGE, USA; [8]St. Franziskus-Hospital, COLOGNE, Germany; [9]University Research Foundation for Lysosomal Storage Disorders, CORAL SPRINGS, USA; [10]Sha'are Zedek Medical Center, JERUSALEM, Israel

Background. A validated disease severity scoring system (DS3) for type 1 Gaucher disease (GD1) is needed to monitor progression and treatment response in individuals and to compare patient cohorts in clinical studies. *Aims.* To develop and test the reliability and validity of a DS3 to assess and monitor GD1 in routine clinical care and to stratify for disease severity in clinical studies. *Methods*. DS3 domains were established by an expert physician group using nominal group technique (NGT) consensus formation methodology. Items within domains were selected by Delphi survey of 32 international physician experts in GD1. The expert group analyzed survey data (including preliminary screening for reliability, feasibility, and face, content, discriminant, and predictive validity) to determine appropriate measurement techniques for each variable. Measurements were weighted considering how much morbidity and mortality each contributes to GD1. Severity scores for sample patient cases determined by NGT were compared to scores determined by the DS3 and the Zimran SSI, an existing severity scoring index for GD1. *Results*. The DS3 includes bone, hematological, visceral, and physician- and patient-reported domains. Clinical domains were populated with weighted measurements of GD1 signs and symptoms. Patient case scores assigned by the expert group were more highly correlated with DS3 scores (Pearson r=0.98) than those obtained with the existing SSI index (Pearson r=0.88). *Conclusions*. This provisional DS3 provides for accurate assessment of GD1 status. Testing of reliability and validity will continue for ultimate implementation of the DS3 in clinical practice and trials.

0050

DEFICIENCY OF RED CELL BOUND CD55 AND CD59 IN PATIENTS WITH RHEUMATOLOGICAL DISORDERS

A. Sarantopoulos,[1] E. Terpos,[2] S. Masouridi,[3] J. Stavropoulos,[2] G. Karagiannidis,[3] P. Konstantopoulou,[3] C. Antoniadis,[4] G. Vaiopoulos,[3] J. Meletis[3]

[1]Second Blood Transfusion Center, Laikon General Hospital, ATHENS,; [2]Department of Medical Research, 251 General Air Force Hospital, ATHENS; [3]First Dpt of Medicine, University of Athens School of Medicine, Laikon Hospital, ATHENS; [4]Department of Rheumatology, Asklepieion Hospital, ATHENS, Greece

Background. Inappropriate activation or blockage of the inhibition of complement system may be responsible for tissue damage in rheumatological disorders. CD55 and CD59 are complement regulatory proteins that are linked to the cell membrane via a glycosyl-phosphatidylinositol anchor. They are reduced mainly in paroxysmal nocturnal hemoglobinuria (PNH). The aim of this study was to evaluate the presence of CD55 and/or CD59 deficient erythrocytes in patients with rheumatological disorders and explore possible correlations with clinical parameters. *Patients and Methods*. CD55 and CD59 expression was evaluated in erythrocytes surface of 54 patients (10M/44F; median age 62.5 years) with different rheumatological diseases: 23 had rheumatoid arthritis (RA), 16 systemic lupus erythematosus (SEL), 11 Sjogren syndrome (SS), and 4 scleroderma. At the time of evaluation, all but 8 patients were under anti-inflammatory therapy. The detection of CD55- and CD59-deficient red cells was performed using the sephacryl-gel microtyping system (DiaMed-ID MicroTyping System PNH test, Cressier-sur-Morat, Switzerland). The presence of the deficient red cells was blindly scored by two independent observers and expressed semiquantitatively as 100%, 75%, 50%, 25% and 10%. In all samples with CD55- or CD59-negative populations Ham and sucrose lysis tests were also performed. Eight PNH patients and 121 healthy subjects were also studied as control groups. *Results*. Anemia was present in 29 patients (53%); none had positive direct Coombs test. Interestingly, all but one patient (with RA) had erythrocyte populations with CD55 and/or CD59 deficiency. More specifically, deficient red cells for both CD55/CD59 antigens were detected in 18 patients (33%): in 14 patients erythrocytes were deficient for both antigens at a proportion of 10%, while 4 patients had erythrocytes with 25% of CD55 deficiency and 10% of CD59 deficiency. Isolated CD55 negativity was observed in 33 patients (61%): 31 had red cells with 10% CD55 deficiency and only 2 had erythrocytes with 25% CD55 deficiency. Isolated CD59 deficiency was detected in only one SS and one scleroderma patient. There were no clinical or laboratory evidence of hemolysis in our patients. Among 121 normal subjects, two (1.6%) had red cells with double negativity for CD55/CD59, while 3 (2.4%) had erythrocytes with an isolated CD55 or CD59 deficiency; these red cells were counted for not more than 10% of the total. All patients with PNH had a simultaneous CD55/CD59 deficiency. Positive Ham and sucrose tests were found only in PNH patients. There was no correlation between the presence of these defective red cells and the type of rheumatological disease, type or length of anti-inflammatory therapy, presence of anemia, or titers of anti-nuclear or other detected

auto-antibodies. *Summary and Conclusions*. Our study provides evidence supporting the presence of erythrocytes with CD55 and/or CD59 deficiency in patients with rheumatological disorders. A reduction in CD55/CD59 synthesis, blockage or masking of these molecules by auto-antibodies, or proteolytic cleavage in relation to activation of complement on erythrocyte surfaces may be responsible for this acquired phenomenon. Further studies using molecular techniques will be required for clarifying the exact role of this deficiency to the increased susceptibility of these populations in complement lysis.

DETECTION OF CIRCULATING ANTI-ERYTHROPOIETIN ANTIBODIES IN PATIENTS WITH END STAGE RENAL DISEASE ON REGULAR HEMODIALYSIS

M. Attia, M. Eldin, M. Labib, A. Omer

Faculty of Medicine, Ismailia University, ISMAILIA, Egypt

Background. Recombinant human erythropoietin (rHuEPO) has been successfully and safely used to treat anemia in patients with end stage renal disease (ESRD). The safety profile of rHuEPO had been considered to be excellent with possible exception of hypertension and increased risk of dialysis access thrombosis. Recently, antibody-mediated pure red cell aplasia (PRCA) associated with administration of rHuEPO has been identified as a cause of major concern. The use of rHuEPO therapy can stimulate the development of neutralizing anti-EPO antibodies which probably cross react with the patient's endogenous EPO as well and lead to anemia that is more severe than even before the onset of rHuEPO therapy. *Aims*. It was to detect and evaluate the presence of anti-EPO antibodies in patients with ESRD on regular dialysis who are using rHuEPO. *Methods*. Serum anti-EPO antibodies were detected by quantitative ELISA technique in a total of 90 patients who are currently on regular hemodialysis and using rHuEPO alpha subcutaneously for more than 6 months. The dose and type of rHuEPO administrated in all studied patients was insignificantly different. All patients were subjected to full history taking and clinical examination. Complete blood count, reticulocytes count, serum creatinine, blood urea, serum albumin, serum ferritin, and hepatitis markers were done for all. Patients known to have hematological disease that cause bone marrow failure were excluded. *Results.* Our results showed that 35 patients (38.9%) had the anti-EPO antibodies in their blood, while 55 patients (61.1%) didn't have the circulating Abs. The mean hemoglobin (Hb) level was significantly lower in the antibody positive group (8.8 mg±1.35) than in the antibody negative group (9.42 mg±1.32) (p=0.000). The reticulocytes count was also significantly much lower in the patients who had anti-EPO antibodies with mean of 1.99 (±1.14) *vs* 3.15(±0.89) in the antibody negative (p=0.000). The dose of EPO administrated in both studied groups was insignificantly different. *Conclusions*. The incidence of anti-EPO Abs is high in ESRD patients on maintenance hemodialysis. Its presence is associated with increased incidence of anemia possibly due to immune-mediated inhibition of erythropoiesis as evidenced by reticulocytopenia.

0052

FLOW-CYTOMETRIC ANALYSIS OF BONE MARROW GRANULOCYTIC PROGENITOR/PRECURSOR CELLS IS A USEFUL TOOL FOR ESTABLISHING THE DIAGNOSIS OF CHRONIC IDIOPATHIC NEUTROPENIA

H. Koutala, M. Velegraki, M. Ximeri, G. Gvazava, M. Psyllaki, C. Kalpadakis, G. Eliopoulos, H. Papadaki

University of Crete School of Medicine, HERAKLION, CRETE, Greece

Background. Chronic idiopathic neutropenia (CIN) is defined as the persistent, unexplained reduction in the number of peripheral blood neutrophils. The diagnostic criteria of CIN are exclusion criteria: (a) neutropenia more than three months, (b) no evidence for any underlying disease associated with neutropenia, (c) no history of exposure to irradiation, use of chemical compounds or intake of drugs to which neutropenia might be ascribed, (d) normal bone marrow (BM) karyotype, (e) negative serum anti-neutrophil antibodies. *Aims.* To study the immunophenotypic quantitative and qualitative characteristics of BM granulocytic progenitor/precursor cells in patients with CIN compared to normal subjects and investigate the possible utility of flow-cytometry in establishing the diagnosis of CIN. *Methods*. Heparinized BM aspirates obtained from 16 patients with CIN and 28 healthy controls after informed consent, were stained within 12 hours of collection using a whole blood lysis technique and a panel of directly conjugated antibodies. Five-parameter, 3-color flow-cytometry was performed using CD45 *vs* side scatter (SSC) as the basic scattergram to define the granulocytic progenitor/precursor cell gate. The following populations were defined: the $CD34^+/CD33^+$ cells corresponding to the granulocytic progenitors; the DR^+ cells corresponding to myeloblasts; the $CD13^+/CD16^-$ cells comprising mainly to promyelocytes; the $CD11b^+/CD16^-$, $CD11b^+/CD16^{dim}$ and $CD11b^+/CD16^{bright}$ cells comprising mainly the myelocytes, metamyelocytes, and bands plus neutrophils, respectively. CD10 antigen, mainly expressed in bands and neutrophils among cells of the granulocytic lineage, was also studied. The myeloperoxidase (MPO) positive cells and SSC properties (mean SSC value) of total granulocytic cells were also evaluated to assess overall granularity. *Results*. The proportion of the $CD34^+/CD33^+$ granulocytic progenitor cells did not differ significantly between patients and controls. A significant increase was observed in the proportion of DR^+ myeloblasts in CIN patients (8.10±4.23%) compared to controls (4.59±1.24%; p=0.0033) suggesting a shift-to-the left of the granulocytic series. The proportion of $CD13^+/CD16^-$ cells (promyelocytes) did not differ significantly between patients and controls. However, a significant increase was obtained in the proportion of $CD11b^+/CD16^-$ cells (myelocytes) in patients (26.46±7.73%) compared to controls (17.99%±5.09%; p<0.0001) that was associated with a significant decrease in the proportion of $CD11b^+/CD16^{dim}$ (metamyelocytes) and $CD11b^+/CD16^{bright}$ (bands and neutrophils) cells in the patients (26.82±6.29% and 31.16±9.43%, respectively) compared to controls (21.76±5.44% and 49.02±11.88%, respectively; p=0.0056 and p<0.0001, respectively). In accordance with the low proportion of the mature cells of the granulocytic series was the low proportion of the $CD10^+$ cells in the CIN patients (13.48±14.93%) compared to controls (37.15±11.87%, p<0.0001). The proportion of MPO^+ cells and the mean SSC value did not differ significantly between patients and controls suggesting normal granularity of granulocytic precursor cells in CIN. *Conclusion*. Flow-cytometric analysis of BM granulocytic cells in CIN patients indicates a shift to-the-left with increased proportion of myeloblasts and myelocytes and decreased percentages of metamyelocytes, bands, and neutrophils compared to controls. The granular content of cells is normal suggesting the lack of dysplastic features of granulocytic series in CIN. Since diagnosis of CIN is mainly based on exclusion criteria, we suggest flow-cytometric immunophenotyping as an additional, useful tool for establishing diagnosis of CIN.

0053

PRESENCE OF THREE POINT MUTATIONS IN THE ELA2 GENE OF A PATIENT WITH SEVERE CONGENITAL NEUTROPENIA (SCN)

M. Lanciotti, G. Caridi, S. Pigullo, T. Lanza, C. Dufour

G. Gaslini Institute, GENOVA, Italy

Background. Severe congenital neutropenia (SCN) is an inborn disorder of granulopoiesis with a marked propensity to develop acute myeloid leukemia and myelodysplasia. Mutation of the ELA2 gene encoding neutrophil elastase are responsible for most cases of SCN and cyclic neutropenia (CN) a related but milder disorder of granulopoiesis. To date more than 50 distinct mutations of the ELA2 gene have been identified in patients with CN or SCN. With a few exceptions, specific ELA2 mutations are associated with SCN or CN, but not both, suggesting a genotype-phenotype correlation. *Aims*. Here we report the rare phenomenon of the presence of three point mutations in the ELA2 gene of a patient with SCN with a severe phenotype, characterised by long-lasting fungal pneumonia and myelodysplasia evolved to acute myeloid leukemia. The study of this case could give more information on the pathological mechanism of the congenital neutropenia. *Methods*. The ELA2 gene (GenBank Y00477) were amplified from genomic DNA extracted from peripheral blood of the patient and her parents and directly sequenced on ABI PRISM 3100. PCR fragments were also subcloned and individual clones were isolated and sequenced. Paternity and maternity were confirmed by specific microsatellite markers analysis. *Results*. Sequencing of ELA2 in genomic DNA of patient identified three different heterozygous single-base substitutions. One *de novo* mutation (2192G>A) generates a nonconservative amino acid missense substitution (V53M) within exon 3, it is described associated with CN phenotype. The second mutation is a previously undescribed single-base change (2240G>A) within exon 3 leading to amino acid missense substitution (V69M). This mutation was inherited from her unaffected mother. The third was a undescribed *de novo* intronic mutation (IVS3-22G>A). Both the undescribed mutations were neither detected in 80 healthy controls nor in 70 unrelated subjects who had neutropenia without ELA2 mutations, so that a polymorphic change could be excluded. The subcloning and sequencing of PCR amplified segment revealed that all three mutations always occurred together in cis on the maternal allele.

Summary and Conclusions. The presence of more than one mutation in ELA2 gene in a patient with SCN or CN is a very rare phenomena. So far only two cases (1 SCN and 1 CN) with a double mutation have been described. In both cases the presence of two mutations seems to have a positive effect on the diseases giving a clinical mild phenotype. On the contrary in our case the presence of the three mutations seems to have a sinergistic negative effect on the disease giving an extremely clinical severe phenotype. In fact the *de novo* V53M mutation has been reported in a case of CN which is a mild syndrome, with no increased propensity to develop acute myelogenous leukemia or mielodysplasia. The V69M mutation seems to be silent in the case of the unaffected mother, but it could have some synergistic effect on the structure of the patient protein giving rise to a particularly disrupting structure. The peculiarity of this case offers the opportunity to investigate molecular mechanism distinguishing SCN from CN.

0054

QUANTITATIVE EXPRESSION OF CD64 ON NEUTROPHIL GRANULOCYTES AS EARLY MARKER OF SEPSIS OR SEVERE INFECTION

G.B. Lobreglio, P. D'Aversa, L. Leo, S. Scolozzi, G. Fiore

A.O. Card G. Panico, TRICASE, Italy

Background. One of the most important aspects of infectious disease in recent decades has been the increase in cases of sepsis, endocarditis and bacteremia. Relevant studies have indicated that quantitative neutrophil (PMN) CD64 (high-affinity Fc receptor) expression is a worthwhile candidate for evaluation as a more sensitive and specific laboratory indicator of sepsis or the presence of a systemic acute inflammatory response. *Aims*. We prospectively evaluated performance of CD64 expression on PNMs as improved laboratory indicator of severe infection, sepsis/septic shock and compared it to serum procalcitonin (PCT), interleukin 6 (IL-6), other standard laboratory tests (ESR: erythrocyte sedimentation rate, CRP: C-reactive protein) and to the final results of blood cultures. *Methods*. 30 clinical samples, divided into two groups (Gr. 1, Gr. 2) were analysed. Gr. 1: 14 patients admitted in different Emergency Department of the hospital with clinical diagnosis of sepsis; Gr. 2: 16 samples as outpatients. In all samples the levels of leukocyte neutrophil CD64 were measured with Leuko64 kit (Trillium Diagnostics, Maine, USA) on haematology platform, CELL-DIN Sapphire (Abbott Laboratories, Abbott Park, USA); the other parameters mentioned were determined with different immunoassaies. Leuko64 test was considered positive for an index of expression of CD64 > 1,5. *Results*. Among 11 patients with positive blood cultures 10 had CD64 index >1,5; by contrast all the patients without infection had CD64 index <1,5: sensitivity 91,7%; specificity 100%. As shown in Table 1 there is a poor or fair correlation between CD64 index and other biochemical parameters. *Summary and Conclusions*. The rise of neutrophil CD64 index in patients with positive blood cultures suggests that it is an improved laboratory parameter in identifying patients with sepsis; moreover, the test is easy to perform on a routine hematology analyzer and thus may find a wider spread in clinical practice for studying early onset infection.

Table 1. Correlation indexes of the several markers pair and CD64 index against blood cultures result.

Correlation markers	Correlation index (r)
CD64 index - PCT	0,4740
CD64 index – IL- 6	0,4047
CD64 index - CRP	0,5921
CD64 index - ESR	-0,0495
Blood cultures + : 11	CD64 index >1,5: 10
Blood cultures - : 19	CD64 index <1,5: 20

0055

ALTERATIONS OF MESENCHYMAL STROMAL CELLS IN PATIENTS WITH APLASTIC ANEMIA

V. Petrova, N. Nifontova, A. Mikhaylova, J. Drize

National Hematology Research Centre, MOSCOW, Russian Federation

Background. Ineffective hematopoiesis in patients with aplastic anemia (AA) could be caused by hematopoietic stem cells (HSC) failure, disordered interactions between HSC and stromal cells and alterations in stromal microenvironment itself. Mesenchymal stromal cells (MSC) and their early progeny fibroblast colony forming units (CFU-F) are the progenitors of stromal microenvironment. *Aims*. The goal of the study was to investigate the main properties of CFU-F and MSC of AA patients. *Methods*. MSC were isolated by cultivating 2,5-3 ı 106 mononuclear cells from the bone marrow in the 25 cm^2-cultivation flasks in α-MEM with 10% of fetal calf serum. Cells were passaged on average once in 10 days. To induce osteogenic differentiation MSC were cultivated with dexametasone, ascorbate-2-phosphate and NaH2PO4. CFU-F frequency was calculated using standard assay. To characterize alterations in the expression of *FGF2* and *BMP4* in MSC and CFU-F semi-quantitative analysis of RT-PCR products was performed using PhosphoImager Cyclone, Packard Bell (USA) after Southern blot hybridization with appropriate sequences. The expression level of β-actin was used as a normalization factor. *Results*. The ability to establish MSC cultures was the same for donors and patients with AA. There were no CFU-F detected in the bone marrow of 3 out of 20 tested AA patients; 4 out of 20 contained regular-sized colonies, equal to the ones of the donors, and in 13 cases the formed colonies were much bigger than the donors' ones judging by size estimated using the electronic images by means of Scion Image software (28,7±1,3 px/mm^2 *vs* 9,1±0,5 px/mm^2 , p<0.001). The increase in CFU-F frequency and size of the colonies could be a consequence of alterations in the expression level of such genes as FGF2 and BMP4. The expression level of these genes in donor cultures was approximately the same in MSC and CFU-F (*for data see Table*). In MSC the FGF2 expression in donors and AA cultures did not differ, but in CFU-F the expression level of this gene increased gradually and reached maximum in patients with refractory anemia. The expression of BMP4 decreased in cultures from AA patients and increased up to donor's level in cultures from patients with severe AA. There was inverse negative relationship between the ability of AA MSC to perform osteogenic differentiation, estimated as +, 2+ and 3+, and expression of BMP4 (/3± 0.08, /2± 0.29,/± 1.00, /-/ - 1.06).

Table 1.

Group	CFU-F		MSC	Relative expression level			
	Number per 10^6 bm cells	% enlarged colonies	% of osteogenic differenciation	CFU-F		MSC	
				FGF2	BMP4	FGF2	BMP4
Donors	30.98 ± 10.4	0	100	0.54 ± 0.11	0.87 ± 0.32	0.65 ± 0.09	0.92 ± 0.27
AA	50.68 ± 19.91	57.14	80	0.77 ± 0.32	0.19 ± 0.07	0.83 ± 0.23	0.34 ± 0.12
Severe AA	50.47 ± 11.48	90	57.2	1.0 ± 0.15	1,24 ± 0.24	0.82 ± 0.26	1.28 ± 0.28
Ref. A	99.0 ± 53.6	25	25	1.5 ± 0.09	0.81 ± 0.26		

Conclusions. The data suggest that the ability of MSC to osteogenic differentiation reduced in AA patients accompanying the alterations in *BMP4* expression. The number and the size of CFU-F increased in patients correspondingly the deterioration of the disease. Simultaneously the expression level of FGF2 significantly increases in the CFU-F. It seems that alterations in the number of stromal precursor cells and changes of gene expression profile indicate the *attempts of the organism* to enlarge the hematopoietic territory for improvement of hematopoiesis.

0056

MULTIFOCAL LANGERHANS CELL HISTIOCYTOSIS IN ADULTS. SINGLE CENTER EXPERIENCE

D. Bogdanovic,[1] M. Cemerikic Martinovic,[1] D. Jovanovic Perunicic,[1] N. Bogunovic,[1] B. Milenkovic,[2] M. Pavlovic,[3] L. Medenica,[4] P. Kendereski,[5] R. Colovic,[6] P. Mandaric,[2] D. Colovic[1]

[1]Institute of Hematology CCS, BELGRADE; [2]Institut of lung diseases and TBC, BELGRADE; [3]Institute of infectious and tropic diseases, BELGRADE; [4]Clinics for dermatovenerology CCS, BELGRADE; [5]Institute of endocrinology CCS, BELGRADE; [6]Institute for digestive surgery CCS, BELGRADE, Serbia

Langerhans cell histiocytosis (LCH) is rare, clonal disease characterized by histocyte proliferation. Langerhans cells have specific immunophenotype and specific Bürbeck granule on electron microscopy. This disease is very rare in adults and most data are based on appearance of LCH in children. In adults, most of cases are single eosinohillic granuloma and multifocal disease is uncommon. Patients. In period of last 12 years, in a single center, we have evaluated and treated 6 patients with multifocal LCH. Patients were confirmed by specific immunohistochemistry profile, HLA-DR$^+$, S-100$^+$, CD1a$^+$, CD68$^+$ (Dako, Danmark) with also had positive Histiocyte X Ag$^+$ (Immunotech, France). We had predominance of male gender (5 males and one female), mean age of 54 years at presentation. The occurence of LCH was very different. Patients had the following types of the LCH 1) fever with bone marrow infiltration and infiltration of spleen; 2) multiple infiltrates in lungs with diabetes insipidus; 3) skin infiltration with erythrodermia, pulmonary lessions and cervical and axillar lymph node infiltrates; 4) multiple recidivant changes in lungs with affection of mediastinal lymph nodes; 5) multiple changes affecting spleen, liver, bone marrow and CNS; 6) multiple lymph node infiltration in neck. *Treatment*. From our 6 patients, in one we had noted spontaneous dissappearance of the disease after elective splenectomy, and we found previous intermittent course (fibrous scars in spleen and liver). In two patients lung surgery was necessary followed by short term corticoids. Two patients were treated with chemotherapy. Patient No 3 with eryhtrodermia was treated by LCH-1A protocol adjusted for adults, but patient No 5 was treated with LCH-2 protocol after limitted surgery and afterwards by other chemotherapy (*CHOP, MTX*) and by intratecal chemotherapy due to progression of the LCH in CNS. One patient was treated only by involved field radiotherapy. Besides the patient with CNS disease, who subsequently died due to progression, other five patients, all males, are in good condition, and all are in remission of the LCH lasting several years after treatment. *Conclusions*. Multifocal Langerhans cell histocytosis in adults is much rare disease than in childhood. It runs as chronic, intermittent disease, and do not need prompt chemotherapy except in cases with disease progression (scoring system of the International Histiocyte Society). Elective surgery is efficient in patients with lung affection and also radiotherapy has its place in selected cases. The establishment of specific LCH-A1 protocol will provide better treatment strategy in future therapy of adults with LCH.

0057

HIGH PROPORTION OF MIXED CHIMERISM WITH T-CELL DEPLETED PERIPHERAL STEM CELL TRANSPLANTS FOLLOWED BY T-CELL ADD-BACK IN PATIENTS WITH APLASTIC ANEMIA

F. Verholen, E. Levrat, E. Roosnek, M. Terrettaz, C. Helg, J.R. Passweg, C. Chalandon

Service d'hématologie, GENÈVE, Switzerland

Stable mixed chimerism has been described as being beneficial in patients with aplastic anemia after stem cell transplantation, as these patients were protected from severe graft *vs* host disease and from rejection, the major drivers of mortality in these patients. Patients with marrow failure syndrome do not need full donor chimerism as they do not benefit from a graft-versus-malignancy effect. Here we describe a protocol resulting in high rate of stable mixed chimerism in patients conditioned with cyclophosphamide + ATG and transplanted with peripheral stem cells depleted by Campath with add-back of T- lymphocytes post-transplant at different dose levels, according to donor-recipient relationship. We included 10 patients in this protocol, median age was 35,5 (15-58) years, 5 were male, donors were identical siblings in 7, mismatched related in 1 matched unrelated in 1 and mismatched unrelated in 1, respectively. Stem cell dose was 11.5 (5.4-40.2) CD34×10^6/kg. Time to neutrophil engraftment was 15 (8-17) days and to platelet engraftment 14 (8-24) days. Median follow-up of surviving patients is 627 days (13-2533). Acute grade II GvHD was observed in 1 patient (with the mismatched unrelated donor), this patient died subsequently, while all other patients remain alive. There is mild chronic GvHD in 1, none of the patients lost the graft. Chimerism analysis showed full donor chimerism in 2, transient mixed chimerism (defined as mixed chimerism developing into full donor chimerism) in 1, and stable mixed chimerism in 6, limited to mononuclear cells in 1 and observed in the granulocyte and mononuclear compartment in 5. Mixed chimerism remained stable for up to 4 years. A protocol of conditioning with cyclophosphamide and ATG and GvHD prophylaxis with T-cell depletion using Campath and T-cell addback may induce stable mixed chimerism in a large proportion of patients with aplastic anemia with low GvHD and graft failure risks.

0058

IDENTIFICATION OF NEW RPS19 DELETIONS IN DIAMOND-BLACKFAN ANEMIA USING THE MLPA TECHNIQUE

P. Quarello,[1] E. Garelli,[1] A. Carando,[1] M.F. Campagnoli,[1] A. Brusco,[2] P. Pappi,[2] M. Barberis,[2] I. Dianzani,[3] U. Ramenghi[1]

[1]Hematology Unit, Pediatric Department, University of Turin, TURIN, Italy; [2]Department of Genetics, Biology and Biochemistry, University of Turin, TURIN, Italy; [3]Department of Medical Sciences, University of Eastern Piedmont, NOVARA, Italy

Background. Diamond-Blackfan anemia (DBA, MIM105650) is a rare congenital pure red cell aplasia due to an intrinsic defect in erythropoietic progenitors. Defects in the RPS19 gene are the main known cause of DBA and account for 25% of patients. In literature four complete deletions of RPS19 gene found by FISH and microsatellite analysis were described (*Gustavsson et al 1997, Gustavsson et al 1998, Campagnoli et al 2004*). Other 4 partial gene deletions (exon 3, 4 and 5) were reported by a haplotype analysis approach (*Orfali et al, 2004*) or by sequencing (*Draptchinskaia et al 1999, Proust et al 2003*). The usual PCR-based methodology used for conventional mutation detection fails to detect heterozygous deletions. The aim of this study is to establish the actual contribution of unidentified deletions to the overall detection rate of RPS19 mutations. *Patients and Methods*. DBA Italian patients (pts) that did not carry RPS19 mutations but were apparently homozygous (55 pts) for the intragenic RPS19 SNPs (c.1-450T>C; c.71+80_71+81insC; c.71+89C>G; c.356+14A>G; c.357-90C>T; c.412-175C>T) were included in this study. The analysis was made using Multiplex ligation-dependent probe amplification technique (MLPA; MRC-Holland, Amsterdam). The MLPA kit is designed to detect deletions/duplications of one or more exons of the RPS19 gene. Deletions of probe recognition sequences were identified by a 35-50% reduced relative peak area of the amplification product. *Results*. We identified three heterozygous deletions that spanned the whole gene. Neither RPS19 intragenic deletions nor duplications were found. No deletions were discovered in 8p23.3-8p22, a region linked to DBA (*Gazda et al, 2001*). Conclusions. Our study shows that large deletions in the RPS19 gene are more frequent than expected, representing around 12% of all mutations detected in our cohort (*vs* an average of 6% reported in literature). RPS19 is involved in at least 27% of Italian DBA patients.

0059

ASYMPTOMATIC CEREBRAL MICROBLEEDS IN PATIENTS WITH APLASTIC ANEMIA

S. Sharma, P. Malhotra, V. Lal, P. Singh, N. Varma, S. Varma

Post Graduate Institute of Medical Education and Research, (PGIMER), CHANDIGARH, India

Background. Severe thrombocytopenia is an important risk factor for the development of intra cerebral hemorrhage (ICH). The present guidelines recommends prophylactic platelet transfusion in patients whose platelet count is below 10,000/μL. However, sometimes serious episodes of hemorrhage do occur at relatively high platelet counts emphasizing the importance of factors other than platelet count in the cause of bleed. Recent studies suggest that cerebral microbleeds (CMB) seen on T2* - weighted gradient echo magnetic resonance imaging (GE-MRI) sequences as rounded areas of signal loss, generally less than 1cm are an indicator of imminent ICH. *Aims.* The aim of the present study was to find out the prevalence of CMB in patients of Aplastic anemia (AA) who are neurologically asymptomatic and relate with future development of ICH in them. *Methods*. Twenty-six patients of AA (diagnosed by standard criterias) below 40 years of age underwent GE-MRI brain for evaluation of CMB. All patients underwent evaluation for AA in the form

of complete blood count, bone marrow aspiration and trephine biopsy, serum chemistries, infectious disease markers. Patients received different types of treatment (Allogeneic stem cell transplant, antithymocyte globulin and cyclosporine, danazol and supportive treatment) based on their financial affordability as they did not have health insurance. All patients were followed up for at least 6 months for development of overt ICH. *Results*. The median age of the patients was 20.5 years (range 12-40 years). The median values of complete blood counts were hemoglobin 5.7 gm/dL (range 2.5-9.2 gm/dL), white cell count 2320 (800-7000/μL), platelet count 11500 (700-45000) at the time of GE-MRI of brain. Three patients (11.5%) had CMB at baseline. Additionally two patients had asymptomatic cerebral macrobleeds (>1 cm). During follow-up period of 6 months, four patients developed spontaneous ICH (two documented on imaging and two presumed on the basis of symptoms). Out of these 4 patients, only one patient had documented CMB at diagnosis while other three patients did not have CMB at the time of diagnosis. *Conclusions*. Asymptomatic CMB were found in 11.5% of patients with AA below 40 years of age. The overall prevalence of asymptomatic ICH (CMB & macrobleeds) was 19.2%. The present study could not demonstrate association between presence of CMB at the time of diagnosis of AA and future development of spontaneous ICH.

0060

ENERCA2, THE EUROPEAN NETWORK AIMED AT IMPROVING THE DIAGNOSIS, EPIDEMIOLOGICAL KNOWLEDGE AND MEDICAL EDUCATION ON RARE AND CONGENITAL ANAEMIAS

P. Aguilar-Martinez,[1] on behalf of the ENERCA2[2]

[1]CHRU de Montpellier, MONTPELLIER, France; [2]Hospital Clinic Provincial, BARCELONA, Spain

Background and Aims. ENERCA is an European project co-financed by the EC Rare Disease Programme (DG SANCO) and co-ordinated from the Hospital Clínic i Provincial of Barcelona. Its primary goal is to contribute to the better knowledge, diagnosis, treatment and prevention of rare anaemias (RAs) in Europe. Here, we describe the achievements of the second phase of this project, *ENERCA2*, ran from September 2005 to August 2008. *Methods*. The *ENERCA2* Expert Group includes 12 members from several European countries and is organized into 9 working packages (WPs) with specific goals. Each *ENERCA2* WP has been working on a specific field dealing with rare anaemias. The main objectives of the current project are: 1) The provision of a fully revamped website, *ENERCA* website (*www.enerca.org*), launched in July 2006, providing two key information sources: a free-access section for patients, their families and the general public and an extranet section with restricted access for the professional community (WP1); 2) The intensive collection of epidemiological data concerning, i) neonatal screening on hemoglobinopathies in Europe (WP3), ii) membrane disorders, especially dealing with CDA (WP7) and on the indications of splenectomy for patients with hereditary spherocytosis (WP5), iii) red cell enzymopathies and their clinical and therapeutic aspects (WP7); 3) The construction of European databases on CDA (WP7) and thalassemia (WP9); 4) The organisation and the provision of a specialised European EQA dedicated to red cells diagnosis (HbA2 determination, specialized red cells cytology) (WP6); 5) The collection of data on experts European centres specialized in these disorders and the construction of lists of definitions of most of the uncommon anaemias, of support organizations listed by countries (WP1, WP4 and all the WPs). *Results*. The obtained information is available to the public in the free section of the website and to registered professionals, who have access to eight major ENERCA sections: 1) Expert Centres by countries, 2) Diagnosis flowcharts, which allow entering the patient's data and obtaining a basic orientation on the type of anaemia, 3) Professional on-line forum aimed at sharing data on difficult patient's records, 4) Database and registries section, which will allow to identify existing registries on RAs and to promote the development of new ones, 5) Guidelines and recommendations, prepared by several ENERCA WPs, 6) Medical Alert Card (MAC) that can be downloaded from the website, 7) Quality Assurance Programmes for laboratory diagnosis of RAs, 8) Newsletter (ENERCA News), published 3-4 times a year, which provides updated information on rare anaemias and on the ENERCA Expert Group activities. *Conclusions*. ENERCA is intended to promote cross-border cooperation among experts in Europe with the aim of implementing the creation and availability of easy-to-understand information for patients and updated knowledge on RAs in all its scientific, diagnostic, epidemiological and educational aspects for health professionals and services.

SEVERE IRON OVERLOAD IN TRANSFUSION DEPENDENT DIAMOND BLACKFAN ANEMIA PATIENTS

P. Quarello,[1] S. Roggero,[2] T. Vinciguerra,[3] F. Longo,[2] M. Borri,[2] A. Piga,[2] U. Ramenghi[4]

[1]University of Turin, TURIN; [2]San Luigi Gonzaga Hospital, TURIN; [3]Pediatric Department, TURIN; [4]Dept.of Pediatric Hematology, TURIN, Italy

Background. The mainstay of Diamond-Blackfan anemia (DBA) treatment is corticosteroids: approximately 80% of the patients (pts) initially respond. The remaining 20% who are unresponsive to corticosteroids, and others, who may become refractory despite an initial response or encounter unacceptable toxic side-effects, are placed on a chronic transfusion therapy. Iron overload represents a serious complication of potentially lifesaving blood transfusion. *Methods*. We report a retrospective analysis of iron overload and its related complications in a cohort of 29 transfusion dependent Italian DBA pts (16 females and 13 males). These pts performed at least an evaluation of liver iron concentration (LIC) measured by the non invasive technique of magnetic liver susceptometry using a Superconductive QUantum Interference Device (SQUID) between June 2000 and June 2007. All pts were treated with chelation therapy. This population was compared to a group of transfusion dependent pts affected by β-thalassemia major matched for sex and years of transfusion dependence in order to identify potential differences in the amount of iron overload, type and age at onset of iron related complications. *Results*. The median age at the first SQUID evaluation was 11 years (y), the median transfusion therapy duration was 8 y and the median chelation therapy (Deferoxamine s.c.) duration was 6 y. Deferoxamine was well tolerated in all pts. At first SQUID evaluation median ferritin level was 1700±1147 ng/mL, median LIC (Liver Iron Concentration) was 2045±1209 ±g/Fe/g liver w.w.. A severe iron overload (LIC> 2000) was observed in 15 pts (52%), 10 pts (34%) showed a moderate (LIC 1000-2000) and 3 (10%) a mild (LIC 400-1000) iron overload. Iron overload was absent in 1 pt only. We found that DBA pts, compared with the group of β-thalassemic pts, showed a statistically higher LIC (Welch Two Sample t-test; $p<0,01$). At the first SQUID evaluation 9 pts showed at least one complication related to iron overload. The total number of complications was 14: 4 pts had hypothyroidism, 4 hypogonadism, 3 osteoporosis, 2 diabetes mellitus, one strumental cardiopathy and one hypoparathyroidism . The median time of first complication was 14 years from diagnosis, 12,8 years from the beginning of regular transfusions therapy. *Conclusions*. Secondary hemochromatosis is a major medical problem in transfusion-dependent pts. We found a very severe iron overload in transfusion dependent DBA pts, significantly higher if compared with β-thalassemic pts. This difference might be explained by a non optimal chelation therapy (late onset, type, dose, prescription and compliance) in addition to an unknown biological mechanism that lead to an early severe iron overload. Therefore, we suggest that every patient receiving transfusions must have an accurate record of iron intake and a regular monitoring of iron overload and to test the efficacy/compliance of chelation treatment. Physicians taking care of transfusion dependent DBA pts must be concerned about the frequent and early complications such as cardiac toxicity, hypothyroidism and osteoporosis.

PULSED DEXAMETHASONE FOR THE TREATMENT OF PATIENTS WITH AUTOIMMUNE HEMOLYTIC ANEMIA

F.R. Mauro, I. Del Giudice, S. Coluzzi, D. Armiento, M.S. De Propris, M.C. De Nicolò, M.C. Arista, L. Quattrocchi, M.G. Mazzucconi, G. Girelli, R. Foà

University La Sapienza, ROMA, Italy

Background. Continuous steroid administration, as recommended by Damashek *et al*. more than 50 years ago, is still the gold-standard first-line therapy for autoimmune hemolytic anemia (AHA). While the activity of high dose dexamethasone has been largely investigated in immune thrombocytopenic purpura, little is known in AHA. *Aims*. The aim of this study was to evaluate the therapeutic activity and toxicity of dexamethasone pulse therapy in AHA patients. *Methods*. Twenty-five patients with a newly diagnosed AHA (17 cases) or a first relapse of AHA (8 cases) were treated. The median age of patients was 64 years (range: 20-76), 15 patients were females and 10 males. The immunohematologic study revealed an anti-erythrocyte antibody (AeAb) in all cases (IgG: 16; IgM: 4; IgG + IgM: 2; IgA: 1;IgG +IgA: 2). An idiopathic AHA was diagnosed in 17 cases (68%), while in 8 (32%) a concurrent disease was identified. (tumor: 2; autoimmune disease: 5, lymphoproliferative disease: 1

case).Treatment consisted of at least 6 courses of dexamethasone 20 mg, total dose, administered iv or im for 5 consecutive days, every 3 weeks. Between each dexamethasone course, patients received prednisone orally at the initial dose of 0.5 mg/kg/day. During the subsequent courses, prednisone was slowly tapered by 5 mg every 1- 2 weeks to a minimum dose of 10 mg 3 times a week in patients who reached a Hb value ≥12g/dL. After 6 courses of dexamethasone, response was assessed according to the Hb value combined with the evaluation of the direct antiglobulin test (DAT). Patients with no detectable AeAb and persistent Hb values ≥12 g/dL were considered as complete responders (CR) and steroid treatment withdrawn. Patients with persistent AeAb, but with a Hb increase of at least 3 g/dL, were considered as partial responders (PR). Three further dexamethasone courses were given to PR patients with Hb values <12 g/dL, while patients with a persistent Hb value ≥12 g/dL underwent a maintenance dose of 10 mg three times a week. All patients received folic acid supplementation, trimethoprim-cotrimoxazole as Pneumocystis carinii prophylaxis and proton pump inhibitors as prophylaxis of related gastritis. Bisphosphonates were given as prophylaxis of osteoporosis. Red cells were infused in the presence of severe and symptomatic anemia. *Results*. Response was assessed in 20 cases. The OR was 85% (CR: 10%; PR: 75%) and was similar in previously treated and untreated patients, while it was higher, though not significantly, in IgG cases compared to IgM±IgG cases (87% *vs* 75%; p=0.04). To date, an hemolytic relapse was observed in 1 case. The median duration of response of patients with PR and maintained with low doses of prednisone was 25 months (range: 3-64), and 9 and 41 months, respectively, in the 2 patients with idiopathic AHA who achieved a CR. No significant side effects were recorded. *Conclusions*. Pulsed dexamethasone therapy is effective and well tolerated in AHA patients. However, CR are rare. Additional studies need to be designed to explore new dexamethasone schedules and the association with other treatment approaches such as rituximab.

IMPROVEMENT OF HEMOGLOBIN LEVEL AND REDUCTION OF TRANSFUSION REQUIREMENT IN FOUR PATIENTS AFFECTED BY MYELODYSPLASTIC SYNDROMES AND PRIMARY MYELOFIBROSIS RECEIVING DEFERASIROX TREATMENT

E. Messa,[1] R. Catalano,[1] F. Messa,[1] F. Arruga,[1] I. Defilippi,[1] S. Carturan,[1] A. Rotolo,[1] D. Gioia,[2] A. Roetto,[1] E. Bracco,[1] A. Levis,[2] C. Camaschella,[3] D. Cilloni,[1] G. Saglio[1]

[1]University of Turin, TURIN; [2]Hematology Institute, ALESSANDRIA; [3]Vita Salute S.Raffaele, UNIVERSITY AND IRCC OF MILAN, Italy

Background. Transfusional iron overload is a frequent problem that clinicians have to face during treatment of patients affected by both myelodysplastic syndromes (MDS) and primary myelofibrosis (PMF). As a matter of fact, patients affected by low risk MDS or PMF have a relatively long term survival and develop, during the progression of disease, a transfusion requirement . That is why an iron overload and secondary hemosiderosis leading to a multi-organ failure frequently occurs. In order to avoid this complication, patients are now quite routinary treated with iron chelation (ICT), mainly due to the availabilty of oral chelators like Deferasirox. It has been recently reported that chelation therapy can reduced transfusion requirement and improve haemoglobin (Hb) levels in patients affected by MDS and PMF. *Aims.* Aims of our study were to evaluate the effects of ICT with the oral iron chelator Deferasirox on Hb level improvement and transfusion reduction in a population of MDS and PMF patients with transfusional iron overload. *Methods*. We retrospectively analized a population of 10 patients affected (7 MDS and 3 PMF) presenting with transfusional iron overload. Iron parameters and hemocromocytometric values were evaluated before chelation therapy and after one, three, six, and when available nine and twelve months of ICT. Statistical analysis was performed using the Mann-Whitney U test to compare continuous variables. A p<0,05 was considered significant. *Results*. Three MDS and one PMF patients out of 10 receiving ICT with Deferasirox showed an increase in haemoglobin level after few months of treatment. The median haemoglobin improvement calculated at the time of the best response was 2 g/dL (±0,5 g/dL). Two MDS patients reached within three and nine months a complete transfusional independence. The mean ferritin level was 4754 mg/L ±1633 (median 4786) before starting chelation therapy. The response was not correlated with ferritin reduction as in only one case serum ferritin was significantly reduced after three months. In the other cases, stable levels were maintained by low dosage of the drug .There were no statistically significant differences between the responders and non responders groups in terms of age, mean ferritin and Hb level before starting ICT, ferritin reduction during treatment and deferasirox daily dosage. None of the patients receiving chelation therapy for transfusional iron overload affected by thalassemia major or intermedia shows a comparable response in terms of hemoglobin level improvement. *Summary and Conclusions.* Here we describe four cases (three patients affected by MDS and one by PMF) in which iron chelation therapy with Deferasirox results into a significant improvement of the Hb levels and, in two cases, also into a complete transfusion independence. This almost unexpected effect of iron chelation treatment can be observed within few months and even with a very low drug dosage. Our observations confirm what already described sporadically and requires further investigations in order to better understand this peculiar Deferasirox's activity not observed during treatment with other iron chelators.

Chronic lymphocytic leukemia - Biology and Clinical prognosis

P53 MUTATIONS IN A LARGE COHORT OF CLL PATIENTS WITH 17P DELETION: DETAILED ANALYSIS OF MUTATION PROFILE, ALTERNATIVE MECHANISMS OF INACTIVATION, CLONE SIZE AND CLONAL EVOLUTION

T. Zenz,[1] T. Denzel,[1] S. Häbe,[1] J. Mohr,[1] D. Winkler,[1] A. Bühler,[1] N. Patten,[2] S. Truong,[2] H. Döhner,[1] S. Stilgenbauer[1]

[1]University of Ulm, ULM, Germany; [2]Roche Molecular Systems, PLEASANTON, USA

Background. The prognosis of CLL with 17p deletion is very poor. While it is generally accepted that inactivation of p53 (by mutation) underlies refractoriness of CLL with 17p deletion, no study has analysed a large cohort of CLL patients with 17p deletion with respect to TP53 mutations and investigated other mechanisms of p53 inactivation. *Methods.* In order to assess the incidence of TP53 mutations in CLL with 17p deletion we studied TP53 mutations in a large cohort (n=94 patients) of these patients. We used DHPLC to screen for TP53 mutations (Exons 2-11). Aberrant DHPLC profiles lead to sequencing of the respective exons. A sub-group of cases were also studied with an array based p53 mutation platform to confirm the absence of mutations. In addition, detailed genetic studies (VH-mutation status, ZAP70, FISH) were available for the patients. *Results*. We found mutations in the protein coding region of p53 in 71 of 94 CLL patients (76%) with 17p deletion. In the vast majority of the cases the clone size (mutated) correlated very closely with the FISH results. Only few cases had more than one mutation (2/73). The majority of mutations were located in the DNA binding domain of p53. While we found no mutations in exons 2, 3, 10 and 11, 88% of the mutations were located in exon 5 to 8. As further evidence that mutations may also be observed in cases with 17p deletion in a sub-clone, we also observed mutations in cases with less than 20% of cells carrying the 17p deletion. The analysis of follow-up samples in a number of these cases with low grade 17p-deletion showed definite evidence for the selection of the p53 deficient clone (mutation and deletion). Importantly, the mutation occurred prior to exposure to chemotherapy. In spite of this clear evidence for a classical tumor suppressor mechanism underlying the resistance to chemotherapy in cases with 17p deletion, there remain cases where no mutation in the exons of TP53 can be detected by DHPLC, direct sequencing and an array based p53 mutation analysis, suggesting that in these cases alternative mechanisms lead to inactivation of p53. These mechanisms (e.g. alternative splicing, downregulation, functional defect) are currently under investigation (p21/p53 FACS, mRNA analysis). *Conclusions*. The current study supports the role of p53 inactivation (by mutation) underlying the chemo-resistance of CLL with 17p deletion. The extend of mutations of the remaining allele and the demonstration of coexisting mutations even in cases with deletions in only the minority of cells suggests that p53 is the main biological target of 17p deletion and its clinical consequence.

GENOME-WIDE DNA ANALYSIS IDENTIFIES RECURRENT IMBALANCES PREDICTING OUTCOME IN CHRONIC LYMPHOCYTIC LEUKEMIA WITH 17P DELETION

F. Forconi,[1] A. Rinaldi,[2] I. Kwee,[2] E. Sozzi,[1] D. Raspadori,[1] P. Rancoita,[2] D. Rossi,[3] C. Deambrogi,[3] D. Capello,[3] E. Zucca,[2] D. Marconi,[4] R. Bomben,[4] V. Gattei,[4] F. Lauria,[1] G. Gaidano,[3] F. Bertoni[2]

[1]University of Siena, SIENA, Italy; [2]IOSI, BELLINZONA, Switzerland; [3]Ematologia, Università del Piemonte Orientale, NOVARA, Italy; [4]CRO, IRCCS, AVIANO, Italy

Background. Deletion of 17p(p53) identifies a rare subset of chronic lymphocytic leukemia (17p- CLL) with aggressive behavior. However, not all 17p- CLL behave poorly, and intrinsic mechanisms of dismal prognosis cannot simply be recapitulated by the genes deleted at the 17p locus. At present, chromosomal imbalances within the most aggressive 17p- CLL subset have not yet been defined. Genome-wide DNA analysis of copy number (CN) changes and loss of heterozygosity (LOH) is a new tool that can profile common recurrent chromosomal changes of pathogenetic significance in cancer. *Aims*. We aimed at identifying the recurrent genotype regulating tumor behavior of 17p- CLL by using very high-density SNP arrays. *Methods* Genome-wide DNA-profiling was performed in 18 patients with 17p- CLL (17p13.1 deletion in more than 60% nuclei) by means of the Human Mapping 250K-NspI arrays (Affymetrix, Santa Clara, CA, USA). Diagnosis and patients' management was performed according to 1996-NCI guidelines. Samples were collected at diagnosis and investigated for CD38 and ZAP-70 expression, mutational status of IGHV- and TP53-genes, and 13q-, 12+, 11q- and 17p- aberrations. Time from diagnosis to first treatment (TTT) and overall survival (OS) were chosen as indicators of clinical behavior. *Results.* All cases had multiple DNA imbalances with a median of 7 gains (range 2-11) and 10 losses (range 2-21) larger than 1Mb. Imbalances appeared more frequent in 17p- CLL than in unselected CLL. Concordance rate between FISH and SNP-arrays was >98%. Deletions of 13q14.3 locus occurred in 9/18 (50%) cases. The remaining most common deletions affected several loci on 8p (8p12, 8p21.1-p23.1, 8p23.1-p23.3), and the 9q21.33-q22.2 region. The most frequent gains targeted chromosome arms 2p (2p14-p16.1, 2p22.3-pter), 3q (3q24-q29), 8q (8q23.3-qter, 8q24.13-q24.1, 8q24.3), and 17q (17q21.2-q21.32, 17q21.32-q22). Losses at the 8p or 17p13 loci were associated with concomitant gains of 8q or 17q arms in 4/5 8p- or 4/18 17p- CLL, respectively, suggesting the presence of i(8q) or i(17q) isochromosomes. Among all alterations identified in 17p- CLL, 8p-loss (containing TRAIL-R1/2 genes) and 2p16.1-p14 gain (containing REL and BCL11a genes) appeared most interesting. In fact, 8p loss and 2p16.1-p14 gain also predicted significant shorter time from diagnosis to treatment (8p-loss) and overall survival (8p loss and 2p16.1-p14 gain, $p<0.05$). SNP analysis also detected a high frequency of LOH. Six patients displayed one or more copy-neutral LOH regions longer than 5 Mb, suggesting uniparental disomy. Three of these regions (3p12.2-p12.1, 4q25-q8.1, 6q23.3-q25.1) had been previously reported in CLL. *Summary and Conclusions.* The frequency of CN changes points to a highly unstable genome in 17p- CLL. The remarkable significant association of 8p loss and 2p14 gain with prognosis even in this small cohort claims for the role of specific genes other than TP53 in controlling tumor behavior and activity within the 17p- CLL category.

0066

HIGH-RESOLUTION SNP-ARRAY PROFILING OF CHRONIC LYMPHOCYTIC LEUKEMIA

J. Edelmann,[1] C. Schwänen,[1] K. Holzmann,[2] S. Stilgenbauer,[1] H. Döhner[1]

[1]Universitätsklinikum Ulm, ULM; [2]Microarray Core Facility, Universität Ulm, ULM, Germany

Background. Genomic aberrations are important prognostic factors in chronic lymphocytic leukemia (CLL) (*Döhner et al., NEJM, Dec. 2000*). With the development of SNP arrays a new screening method for genomic aberrations is available. Compared to matrix-comparative-genomic-hybridization (matrix-CGH) and chromosome banding, not only a higher resolution but also a detection of uniparental disomies (UPD) as copy number neutral losses of heterozygocity can be achieved. *Material and Methods*. The Affymetrix® 500k SNP array-set was used on samples of 30 CLL patients. Mononuclear cells were separated for CD19 by immunomagnetic beads. The CD19 negative fraction was used as intraindividual reference. DNA was hybridized to the Affymetrix® 500k Array Set and data analysed by the Copy Number Analyser for Gene Chip® (CNAG). FISH analysis (11q, 12, 13q, 14q,17p) was performed on all patients. Matrix - CGH using a 2.8k array was performed on 28 patients. *Results*. SNP array analysis showed genomic aberrations in 80% of all patients. Patients belonging to a good prognostic group defined by normal karyotype or del(13q) single had additional aberrations only at a rare frequency (4 in 18 patients). However patients with a del(17p) showed large genomic complexity with 14 additional aberrations in 4 patients. With respect to common recurrent aberrations, del(13q) was seen in 56.7%, biallelic deletion of the critical region 13q14.2-q14.3 in 13.3%, del(11q) in 16.7%, trisomy 12 as well as del(17p) in 13.3% and del(6q) was seen in 3.3% of all patients enrolled. All results from FISH analysis could be confirmed in SNP arrays. This also applied to the detection of small subclones down to a clone size of 20% aberrant cells. As compared to FISH, 19 additional copy number polymorphisms were detected in 10 patients. In comparison to matrix-CGH, SNP arrays revealed 5 additional copy number changes in 5 out of 28 patients. Altogether 14 UPDs could be detected in 6 patients but failed to be tumor specific except of one copy number neutral loss of heterozygocity (LOH) on chromosome 12. *Discussion*. SNP array analysis is a reliable diagnostic tool to detect genomic aberration in CLL since all aberrations displayed in FISH and matrix-CGH were also detectable by SNP arrays. With respect to FISH analysis, additional aberrations were detected in

33.3% and with respect to matrix-CGH in 17.9% of all patients. The high resolution of SNP arrays not only allows to better define breakpoints but also to detect smaller affected regions. New analysis softwares, validation experiments and larger numbers of patients are necessary to search for new recurrent aberrant regions. Intraindividual reference samples are necessary to rule out germline copy number polymorphisms and germline UPDs.

0067

COMMON HERPESVIRUSES AND CHRONIC LYMPHOCYTIC LEUKEMIA: MOLECULAR EVIDENCE FOR A POTENTIAL LINK WITH A SUBSET OF PATIENTS EXPRESSING STEREOTYPED IGHV4-34 B CELL RECEPTORS

E. Kostareli,[1] A. Hadzidimitriou,[1] N. Stavroyianni,[1] N. Darzentas,[2] A. Athanasiadou,[1] M. Gounari,[1] V. Bikos,[1] A. Agathaggelidis,[1] T. Touloumenidou,[1] I. Zorbas,[1] A. Kouvatsi,[3] N. Laoutaris,[4] A. Fassas,[1] A. Anagnostopoulos,[1] C. Belessi,[4] K. Stamatopoulos[1]

[1]G. Papanicolaou Hospital, THESSALONIKI; [2]INA, CERTH, THESSALONIKI; [3]School of Biology, Aristotle University of Thessaloniki, THESSALONIKI; [4]Nikea General Hospital, PIRAEUS, Greece

The CLL immunoglobulin repertoire is biased and uniquely characterized by the existence of subsets of cases expressing stereotyped B cell receptors (BCRs), suggesting recognition of a putative common - though still unknown- antigen. A major BCR stereotype in CLL is shared by IgG-switched cases utilizing the IGHV4-34 gene. The IGHV4-34 gene is inherently autoreactive and yet very frequent in normal B cells; however, IGHV4-34 antibody secretion is minimal in healthy individuals, suggesting an anergic status of IGHV4-34 cells. All syndromes with increased IGHV4-34 Abs appear to be associated with B cell proliferation and B cell lymphotropic viruses, particularly EBV and CMV. Along these lines, in the present study we explored possible links between persistent activation by EBV and CMV and development of CLL cases expressing the *IGHV4-34* gene. The study group included 80 CLL cases which utilized 24 different IGHV genes, with an intentional bias for the IGHV4-34 gene (23/80 cases). Following the 98% identity cut-off value, 61/80 cases (76.25%) were defined as *mutated*, whereas the remainder (19/80 sequences, 23.75%) had *unmutated* IGHV genes. A median of 3 (2-9) peripheral blood samples per case (overall 280 samples) were tested overtime by Real-Time PCR for the presence of CMV/EBV DNA. The threshold value was based on estimations for viral load corresponding to active (as opposed to latent) infection. Cases were considered as CMV/EBV positive only if two or more samples from different timepoints exceeded the real-time PCR threshold. Based on Real-Time PCR results, CLL cases were assigned to three distinct subgroups: i) group A: 50/80 double negative cases; ii) group B: 21/80 single positive cases (EBV-positive or CMV-positive); iii) group C: 9/80 double positive cases (EBV/CMV-positive). Striking differences with regard to IGHV repertoire were observed between the three subgroups. In particular, the double negative group was characterized by diverse IGHV gene usage (21 different IGHV genes) and a low frequency of the IGHV4-34 gene (5/50 cases; 10%). In contrast, the single positive group utilized 12 different IGHV genes, with a bias for IGHV4-34 (9/21 cases; 42.8%). Finally, all nine double positive cases utilized the IGHV4-34 gene. Remarkably, 7/9 double positive IGHV4-34 cases expressed the major BCR stereotype as described above. Double (EBV/CMV) positive cases with stereotyped IGHV4-34 BCRs also shared unique molecular and clinical features in that they were uniformly negative for CD38 and ZAP-70, had a young age at diagnosis and followed a strikingly indolent disease, indicating diminished responsiveness towards a selecting antigenic element. Based on these findings, we hypothesize that persistence of common herpesviruses could activate CLL progenitors expressing distinctive IGHV4-34 BCRs, promoting survival, expansion and, eventually, malignant transformation.

0068

THE RECEPTOR FOR HYALURONIC ACID MEDIATED MOTILITY (RHAMM): CHARACTERIZATION OF AN IMMUNOTHERAPEUTICAL TARGET WHICH IS ASSOCIATED WITH PROLIFERATION AND SHOWS PROGNOSTIC VALUE IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (B-CLL) PATIENTS

K. Giannopoulos,[1] K. Giannopoulos,[1] A. Buehler,[2] D. Mertens,[2] T. Barth,[2] I. Idler,[2] A. Kroeber,[2] J. Greiner,[2] A. Dmoszynska,[1] J. Rolinski,[1] H. Doehner,[2] S. Stilgenbauer,[2] M. Schmitt[2]

[1]Medical University of Lublin, LUBLIN, Poland; [2]University of Ulm, ULM, Germany

Background. Differential expression of molecules in chronic lymphocytic leukemia (CLL) patients might define prognostic markers and suitable targets for immunotherapy. Elevated levels of CD44, which is another hyaluronic acid receptor, was characterized in B-CLL as negative prognostic marker and correlated with the proliferative potential of CLL. *Aims.* We characterized RHAMM expression in CLL patients. Since the expression of immunogenic TAA might influence the clinical outcome by eliciting an immune response, we further characterized the expression of RHAMM-specific T cells in B-CLL patients. *Patients and methods*. Expression of the tumor-associated antigen (TAA) RHAMM as well as RHAMM-exon4 splice variant was assessed in series of 64 CLL patients. Immunohistochemisty-staining was performed for RHAMM, Ki-67 and CD40L in lymph nodes of CLL patients. Functional studies included CD40L stimulation, mixed lymphocyte cell culture with peptide, Cr release and ELISPOT assays. T regulatory cells were identified as $CD4^+CD25^{hi}FOXP3^+$ (Treg) by flow cytometry. *Results*. Increased RHAMM/TBP ratio was noted in advanced stages of the disease (0.006 in stage A, 0.03 in B and 0.05 in stage C according to Binet classification). qRT-PCR revealed higher RHAMM/TBP ratio in patients with unmutated IgVH status compared with mutated CLL cases (0.03 *vs* 0.005, p=0.003). High expression of RHAMM was observed in a patient with del(17p) (RHAMM/TBP ratio=0.077) when compared to a median RHAMM/TBP ratio of 0.0037 in patients with a normal karyotype. CLL cases with a higher RHAMM expression showed a significantly shorter median treatment-free survival (TFS) (14 *vs* 48.6 months, p=0.0028). In a bivariate analysis, patients with mutated IgV(H) and low RHAMM expression showed a longer TFS compared to IgV(H) unmutated cases with a high RHAMM expression (57.3 *vs* 8.9 months, p<0.0001). Immunohistochemisty-staining revealed that regions with a high RHAMM expression also stain positive for Ki-67 and CD40L. Correspondingly, in a functional in-vitro assay, enhanced expression of RHAMM was observed in CLL cells after stimulation with CD40L. These results suggest that RHAMM might be and indicator of proliferation capacity of CLL cells, which are induced to proliferate by CD40L in lymph nodes. The cytotoxic potential of RHAMM-specific T cells was shown to lyse both cells loaded with a RHAMM-derived epitope and CLL cells expressing RHAMM. We further speculated whether the RHAMM expression is associated with naturally occurring RHAMM-reactive T cells. Unexpectedly, the frequency of these T cells did correlate neither with the RHAMM expression nor with the mutational status nor with the stage of disease. However, patients with higher numbers of RHAMM-specific T cells tended to a have longer TFS when compared to those with limited numbers of RHAMM-specific T cells (24 *vs* 8 months, p=0.3). Therefore, it is possible that T cells specific for the CLL-specific TAA RHAMM have a protective effect. The protective immune effect of RHAMM-specific T cells might be hindered by an excess of Treg in patients with B-CLL when compared to healthy volunteers (HV) (n=18 *vs* n=10). Median Treg % among $CD4^+$ T cells was 11.17% in CLL *vs* 1.87% in HV (p<0.0001). The inverse correlation of R3 specific CD8+ T cells and Treg was noted (r2=-0.59, p=0.3). *Conclusions*. RHAMM expression appears to be of prognostic value and might reflect the proliferate capacity of CLL cells. Our results suggest that RHAMM represents an interesting target for immunotherapy since RHAMM specific T-cell responses have a protective effect resulting in longer TFS and RHAMM-specific T cells might directly lyse CLL cells. In CLL, RHAMM-specific T-cell response might be abrogated by an excess of Tregs.

Eugenio, Università di Tor Vergata, ROMA; [6]Università degli Studi di Torino, TORINO; [7]Università degli Studi del Piemonte Orientale Amedeo Avogadro, NOVARA, Italy

Background. CD38 is a powerful negative prognostic marker for patients with chronic lymphocytic leukemia (CLL), and has been reported to mediate interactions between CLL cells and the microenvironment, providing proliferation and survival signals for the neoplastic component. *Aims*. Moving from gene expression profiling studies (GEP) comparing CLL cases with different CD38 expression levels, we focused on genes allegedly involved in mechanisms regulating interactions between CLL cells and tumor microenvironment. *Methods*. For GEP studies, we selected purified cells from 12 CD38pos (CD38>30%) and 32 CD38neg (CD38<10%) CLLs. Functional and validation experiments were performed by utilizing flow cytometry, real-time quantitative PCR (RTQ-PCR), ELISA and immunohistochemistry (IHC). *Results*. (i) GEP allowed the identification of 132 differentially expressed genes (44 down-regulated and 88 up-regulated in CD38pos cases). Genes up-regulated in CD38pos cases included the C-C chemokines CCL3 (median-log difference, MLD=1.46) and CCL4 (MLD=1.36), whose over-expression was confirmed by RTQ-PCR in selected CLL (12 cases), and the integrin CD49d (MLD=1.14), that is known to correlate with CD38 protein expression in CLL (*Zucchetto et al. Leukemia, 2006*). ii) In order to evaluate whether CD38 triggering affects the production of CCL3 and CCL4 by CLL, leukemic cells from selected cases of CD38pos CLL (10 cases) were cultured for 14 and 24 hours (t14 and t24) in the presence of either the agonist anti-CD38 monoclonal antibody (mAb) IB4 or the non-agonistic anti-CD38 mAb IB6 as control. RTQ-PCR experiments clearly demonstrated higher levels for both CCL3 and CCL4 transcripts after 14 hours of CD38 engagement as compared to the control condition (t14 mean CCL3 fold increase=18, p=0.041; t14 mean CCL4 fold increase=13.8, p=0.005). Similarly, ELISA experiments performed on supernatants, showed a significant CCL3 and CCL4 enrichment after 24 hours of CD38 engagement (t24 mean CCL3 protein levels=0.9 ng/mL, mean fold increase=14, p=0.003; t24 mean CCL4 protein levels=1.7 ng/mL, mean fold increase=49, p=0.01). Consistently, CCL3 was detected by IHC in neoplastic cells from bone marrow biopsies (BMBs) of CD38pos but not CD38neg CLL. iii) immunophenotypic analysis of peripheral blood samples from CLL cases showed detectable levels of CCL3 and CCL4 receptors (CCR1 and CCR5) in monocytes as well as in cultured macrophages, which may therefore act as target cells for CCL3 and CCL4 released by CD38pos CLL cells. Consistently, high number of infiltrating CD68pos macrophages were found in BMBs of CD38pos but not of CD38neg CLLs. In parallel experiments, conditioned media (CM) from CCL3-stimulated macrophage cultures were collected; these CM were able to induce expression of the CD49d-ligand VCAM in human umbilical vein endothelial cells (HUVEC). According to preliminary ELISA experiments, TNFalpha was shown to be among the cytokines involved in VCAM up-regulation in HUVEC. Again, IHC analysis of CLL BMBs showed a meshwork of VCAM-1-positive cells in the context of lymphoid infiltrates of CD38pos but not of CD38neg cases. *Conclusion*. Altogether, these results identify molecules involved in a functional cross-talk between CD38/CD49d-expressing CLL and cells of the tumor microenvironment. This interplay may eventually affect survival and recirculation of tumor cells via the CD49d/VCAM pair.

Buzzati-Traverso, ROMA, Italy

Background. Subsets of B-cell chronic lymphocytic leukemia (CLL) carrying a stereotyped B-cell receptor (BCR) have been reported among cases expressing mutated (M) and unmutated (UM) IGHV genes. *Aims.* To correlate the presence/absence of stereotyped BCR, or the expression of particular IGH genes with disease progression or the presence of known prognosticators. *Methods*. A HCDR3-driven clustering was performed by sequence alignment using the ClustalX(1.83) program. HCDR3 amino acid sequences (n=1426; Kabat criteria) were obtained from 1398 unselected CLL patients. Clusters with homologous HCDR3 were selected for having a mean alignment score of at least 60/100. Time to treatment intervals (TTT) were available for 653 cases. Other availlable clinical parameters were Rai staging (n=654), CD38 (n=661), ZAP-70 (n=518), CD49d (n=501), and karyotype abnormalities evaluated by FISH (n=428). *Results*. We identified 71 clusters with homologous HCDR3, utilizing either identical or different IGHV genes. The 32/71 clusters with at least 3 cases/cluster (*confirmed*clusters) comprised 247 CLL (17.3%, UM/M=166/81). Seventeen/32 clusters were *UM clusters* (UM/M=153/3), 14/32 clusters were *M clusters*(UM/M=3/56) and a single cluster (expressing IGHV3-21 gene) was considered a mixed one (UM/M=10/22). Sixteen/32 clusters were common to other CLL datasets whereas 16 were novel clusters. *UM clusters* were significantly more represented in common (UM/M clusters=16/3) than in novel (UM/M clusters=5/11) clusters (p=0.018). By comparing molecular features with clinical parameters, the following findings emerged: i) Patients belonging to the IGHV3-21 cluster, expressing homologous HCDR3 always associated with IGLV3-21 gene, had TTT similar to UM cases and shorter than M CLL (p<0.001). Conversely, *IGHV3-21* CLL with heterologous HCDR3, rarely expressing *IGLV3-21* gene, had TTT closely dependent on their UM/M IGHV mutational status, as in the whole CLL series (p=0.036). Consistently, in M cases belonging to the IGHV3-21 cluster, TTT intervals were shorter than in IGHV3-21 M cases expressing heterologous HCDR3 (p=0.048). In agreement with these observations, IGHV3-21 CLL with homologous HCDR3 more frequently expressed unfavourable prognosticators than IGHV3-21 CLL with heterologous HCDR3 (p=0.002). ii) An UM cluster expressing genes from the IGHV1 family other than IGHV1-69 comprised 30 cases (UM/M=29/1), all but one expressing the IGKV1-39 gene. The prognosis of these patients was poor either if compared to all UM/M remaining cases (p<0.001), or to all the UM/M cases expressing the same IGHV genes but not included in clusters (p=0.009). The presence of unfavourable prognosticators was significantly higher in CLL from this cluster than in their heterologous counterparts (p=0.009). (iii) CLL expressing the IGHV3-23 gene (UM/M=25/109) virtually never belonged to clusters (4/134 cases in clusters); TTT in IGHV3-23 M CLL was significantly shorter than in all remaining M CLL (p=0.019), or in the M CLL subset expressing other IGHV3 family genes (p=0.021). Multivariate Cox proportional hazard analyses on 174 cases (109 cases if circumscribed to the IGHV3 family), selected Rai staging (p=0.0025), FISH (p=0.0025) and IGHV3-23 (p=0.013) as independent biologic prognosticators for M CLL. Conclusion: Novel molecular and clinical features were provided for CLL subsets expressing or not stereotyped BCR.

0071

HOW DOES MBL RELATE TO CLL PATHOGENESIS? A PERSPECTIVE FROM THE IMMUNOGLOBULIN GENE REPERTOIRE ANALYSIS

P.G. Ghia,[1] A. Dagklis,[1] C. Fazi,[1] V. Cantarelli,[1] D. Toniolo,[2] R. Massacane,[3] K. Stamatopoulos,[4] F. Caligaris-Cappio[1]

[1]Università Vita-Salute San Raffaele, MILANO, Italy; [2]Istituto Scientifico San Raffaele, MILANO, Italy; [3]ASL 22, P.O. Novi Ligure, NOVI LIGURE (AL), Italy; [4]G. Papanicolaou Hospital, THESSALONIKI, Greece

Background. The presence of Monoclonal B Lymphocytes circulating in the blood of otherwise healthy individuals is named Monoclonal B Lymphocytosis (MBL). In the majority of cases, MBL cells show a phenotype ($CD5^+$, $CD20^{low}$, IgM^{low}) that is virtually identical to that of chronic lymphocytic leukemia (CLL) cells. This resemblance suggests the idea of MBL as a precursor state of CLL, resembling the relationship between MGUS and Multiple Myeloma. On the one hand, this hypothesis appears to be well grounded as MBL is constantly monoclonal, is more frequent among relatives of CLL patients and affects mainly the elderly male individuals, as it occurs in CLL. On the other hand, this speculation seems rather simplistic since MBL is at least 100 times more frequent than CLL and the progressive restriction of the immune repertoire, including the appearance of monoclonality, is known to be part of the physiological senescence process of the normal immune system. *Aims*. We aimed at defining at molecular level whether an association between CLL and MBL existed, that might support the idea of MBL as precursor of CLL. *Methods*. The blood of 1725 healthy individuals >18 years of age was studied, after informed consent, by flow-cytometric analysis for the presence of MBL. In the positive cases, we amplified by PCR and direct sequenced the Immunoglobulin (IG)HV-D-J rearrangements expressed by 47 MBL cases which were then analyzed on the IMGT database and aligned to a comprehensive panel of IG sequences from CLL cases. *Results*. Eighty-nine MBL cases (5.2% of the total population) showed a CLL-like phenotype and were subjected to IG gene rearrangement analysis. Sequence analysis of the rearrangements showed a predominance of IGHV3 genes usage, followed by IGHV4 subgroup genes, resembling the normal repertoire. Around 80% of MBL cases expressed mutated IGHV genes and frequently used the IGHV4-59/61 gene which is rare in CLL, while the most common CLL-related IGHV genes (IGHV1-69 and IGHV4-34) were absent in MBL repertoire. Less than 7% MBL expressed HCDR3 sequences similar to those identified in CLL (*stereotyped receptors*), that are present in >25% of the cases. *Conclusions*. Our results show that the Immunoglobulin repertoire in MBL is overall different, in terms of IGHV gene usage and gene family preference, from that of CLL. Some MBL cases may express CLL-related *stereotyped* HCDR3 sequences, though at a frequency definitely lower than the one expected in CLL (>25%). Taken together, our results strongly suggest that MBL cells do not represent a pre-leukemic condition in all cases. That notwithstanding, the presence of 2 of these CLL-biased receptors does suggest that the potential to become a CLL is present within MBL cells, though at a low frequency, and this is not determined by the simple fact of showing a typical phenotype or being monoclonal, but is rather linked to the specific BCR expressed by each MBL case, which likely provides a different capacity to respond to distinct (antigenic) signals. A detailed molecular analysis of individual MBL may help to identify those few cases that necessitate a continuous clinical monitoring to anticipate disease progression.

0072

HS1 PROTEIN REVEALS ITS ROLE IN NORMAL AND LEUKEMIC B CELLS MIGRATION

C. Scielzo,[1] M.T.S. Bertilaccio,[2] M. Muzio,[2] M. Frenquelli,[2] B. Apollonio,[2] A. Dagklis,[2] G. Simonetti,[1] C. Fazi,[2] P. Ghia,[1] F. Caligaris-Cappio[1]

[1]Università Vita-Salute, MILANO, Italy; [2]San Raffaele Scientific Institute, MILAN, Italy

Background. In Chronic Lymphocytic Leukemia (CLL) the relationships between cell proliferation and accumulation within lymphoid organs are unclear, as are the rules that control CLL cell migration and re-circulation between peripheral blood and the lymphoid tissues. Given the role played by the cytoskeleton in controlling cell shape and motility, it becomes central to investigate the cytoskeleton organization of CLL cells. The organization of actin-containing microfilaments and vimentin-containing intermediate filaments in CLL reveals that adhesion structures are present and that the *in vitro* adhesion capacity is marked. Previous studies from our group demonstrated that Hematopoietic cell specific Lyn substrate 1 (HS1), a molecule pivotal in the signal transduction triggered by the stimulation through antigen receptor, is a putative prognostic marker in CLL. HS1 function in normal and leukemic B cells was unknown though , based on the sequence of the molecule, an actin-binding activity could be hypothesized, as well as a potential role in cytoskeleton organization. *Aims*. Based on these evidences, we aimed at determining the currently unknown specific role of HS1 in normal and leukemic B cells focusing on a potential role in controlling and regulating cytoskeleton structure, cell shape and movements. *Methods*. By immunoprecipitation experiments, confocal microscopy and mass spectrometry analysis of the co-immunoprecipitated bands, we have investigated HS1 interactions in CLL and normal B cells. To study its function, we silenced HS1 expression in a CLL cell line (MEC1) using an RNA Interference approach, and we utilized B lymphocytes from HS1 Knock-Out mice. Both cell types were then studied for their migration capacity in *in vitro* and *in vivo* assays. *Results*. We demonstrate that HS1 interacts with distinct cytoskeleton adapters, namely HIP-55 and, unexpectedly, Cortactin, which was not known to be present in lymphoid cells, being considered an epithelial-specific molecule. Further we show that HIP-55 interacts also with ZAP70, a protein kinase with a prognostic significance in CLL. Finally we provide evidence that both leukemic and normal B lymphocytes, when lacking HS1 expression, are severely impaired in their spontaneous migration capacity. *Conclusions*. HS1 interacts with several cytoskeleton adapters and components, likely participating in the regulation of cytoskeleton in B-lymphocytes. Specifically, the fact that HS1 complexes with HIP-55, Cortactin and ZAP-70 suggests that it may be involved in coupling antigen receptor induced signaling with cytoskeleton regulation in both normal and leukemic B cells. This might indicate a role in controlling shape and movement in B lymphocytes following activation. The impairment in B lymphocyte spontaneous migration in the absence of HS1, suggests that this molecule might be relevant in the regulation of CLL cells migration and homing into the lymphoid tissues and may represent a novel target for pharmacological intervention in leukemia.

0073

CLL TRANSFORMING TO RICHTER'S SYNDROME CARRY STEROTYPED HCDR3S AT VERY HIGH FREQUENCY (>50%) AND DISPLAY BIASED USAGE OF HOMOLOGOUS IGHV4-39 GENES

S. Valeria,[1] D. Capello,[2] R. Bomben,[3] F. Forconi,[4] L. Laurenti,[5] G. Del Poeta,[6] R. Marasca,[7] S. Pileri,[8] A. Carbone,[9] M. Paulli,[10] F. Bertoni,[11] G. Gaidano,[2] V.S. Gattei,[3] D. Rossi[2]

[1]Amedeo Avogadro University, NOVARA, Italy; [2]Division of Hematology, Amedeo Avogadro University, NOVARA, Italy; [3]Oncohematology Unit, CRO, AVIANO, Italy; [4]Division of Hematology, University of Siena, SIENA, Italy; [5]Division of Hematology, Catholic University of the Sacred Heart, ROME, Italy; [6]Division of Hematology, University of Tor Vergata, ROME, Italy; [7]Division of Hematology, University of Modena and Reggio Emilia, MODENA, Italy; [8]Istituto Seràgnoli, University of Bologna, BOLOGNA, Italy; [9]Division of Pathology, INT, MILAN, Italy; [10]Institute of Pathology, University of Pavia, PAVIA, Italy; [11]IOSI, BELLINZONA, Switzerland

Background. The prognostic value of specific IGHV gene usage is a well recognized feature of CLL. Usage of IGHV4-39 at CLL diagnosis appears to be an independent risk factor of transformation to Richter Syndrome (RS) in multivariate analysis (*Rossi, Br J Haematol 2008, in press*). The potential relevance of specific IGHV gene usage in RS transformation may be further supported by the identification of stereotyped B-cell receptors in RS. *Aims.* To investigate HCDR3 clustering in CLL transformed to RS. *Methods*. The study was based on 57 CLL transformed to RS. A consecutive series of 223 CLL was utilized as internal control group. Analysis of IGHVDJ sequences was based on the International ImMunoGeneTics resource (IMGT®, *http:\\imgt.cines.fr*). Cluster analysis was performed with a blind approach using the multiple sequence alignment ClustalX (1.83) software. HCDR3s of CLL transformed to RS and HCDR3s of CLL belonging to the internal control group were aligned to HCDR3s of 2984 CLL from our collaborative multicentric database (*Bomben, Blood 2007;110:909a*) and from a previously reported database (*Murray, Blood 2008;111:2083-90*). Cluster nomenclature was according to Stamatopoulos (*Blood 2007;109:259-70*) and Murray (*Blood 2008;111:2083-90*). Results. Cluster analysis revealed that 32/57 (56.1%) CLL transformed to RS carried stereotyped HCDR3s. Prevalence of stereotyped HCDR3s was significantly higher in CLL transformed to RS than in CLL of the internal control group considering: i) all cases (RS: 32/57, 56.1% *vs* CLL: 52/223, 22.3%; $p<0.001$); ii)

IGHV unmutated cases (RS: 24/39, 61.5% *vs* CLL: 30/78, 38.4%; p=.018); and iii) IGHV mutated cases (RS: 8/18, 44.4% *vs* CLL: 22/145, 15.1%; p=.006). In addition, the prevalence of stereotyped HCDR3s in CLL transformed to RS was significantly higher than in CLL from the two databases investigated (*Murray, Blood 2008;111:2083-90; Bomben, Blood 2007;110:909a*) when the analysis was conducted: i) for all cases (p=1.2x10^{-16} and p=7.7x^{9}, respectively); ii) for IGHV unmutated cases (p=0.008 and p=8.2x10^{-4}, respectively); and iii) for IGHV mutated cases (p=6.3x10^{-4} and 4.5x10^{-4}, respectively). Analysis of IGHVDJ revealed that CLL transformed to RS displayed a biased usage of IGHV4-39 (8/57; 14.0%) when compared to the consecutive CLL series used as internal control group (8/223, 3.6%) (p=0.002). The biased usage of IGHV4-39 in CLL transformed to RS was also confirmed when CLL from the two databases were used for comparison (Murray database: IGHV4-39 96/1967, 4.8%, p=0.002; Bomben database: IGHV4-39: 55/1426, 3.8%, p=1.6x10^{-4}). IGHV4-39 CLL transformed to RS entered a cluster in 7/8 cases (87.5%). According to the nomenclature by Stamatopoulos and Murray, five cases belonged to subset 8, and 1 case to subsets 10 and 33 each. IGHV4-39 CLL transformed to RS entered a cluster more frequently than CLL from the databases (Murray database: 31/96, 32.2%, p=.003; Bomben database: IGHV4-39: 19/55, 34.5%, p=0.007). *Conclusions*. The implications of these data are twofold. First, occurrence of stereotyped HCDR3s is a frequent feature of CLL that transform to RS, potentially suggesting an important contribution of antigen stimulation in driving CLL transformation to aggressive lymphoma. Second, these data expand the notion that IGHV4-39 preferentially associates with RS. The pathogenetic relevance of IGHV4-39 in RS transformation is further supported by evidence of stereotyped B-cell receptors in the overwhelming majority of RS cases utilizing IGHV4-39.

0074

THE METABOLISM OF MEVALONATE AS A SIGNALING PATHWAY INFLUENCING TUMOR-HOST INTERACTIONS AND DISEASE PROGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

M. Coscia,[1] S. Peola,[1] G. Matta,[1] F. Pantaleoni,[1] M. Foglietta,[1] C. Vitale,[1] D. Angelini,[2] S. Chiaretti,[3] C. Riganti,[4] A. Guarini,[3] D. Drandi,[1] M. Ladetto,[1] A. Bosia,[4] R. Foà,[3] L. Battistini,[2] M. Boccadoro,[1] J.J. Fournie,[5] M. Massaia[1]

[1]Department of Medicine and Experimental Oncology, Section of Hematology, TORINO, Italy; [2]Santa Lucia Foundation, Neuroimmunology Unit, ROMA, Italy; [3]Department of Cellular Biotechnologies and Hematology, Division of Hematology, ROMA, Italy; [4]Department of Genetics, Biology and Biochemistry, TORINO, Italy; [5]Departement Oncogénèse and Signalisation dans les Cellules Hématopoiétiques INSERM, TOULOUSE, France

Background. The mevalonate (Mev) pathway is essential for the post-translational modification of proteins involved in cell growth and differentiation. It also generates intermediate metabolites that are specifically recognized by the Vδ2 γδ T-cell subset. Vδ2 T cells play an important role in immune responses against tumor cells. They represent less than 5% of peripheral blood lymphocytes but can be efficiently expanded *in vitro* upon exposure to Zoledronic acid (Zol). *Aims*. The aim of this work was to evaluate whether the Mev pathway might be regarded as a signaling pathway influencing tumor-host interactions in CLL. *Methods.* Sixtyseven previously untreated CLL patients were evaluated for *in vitro* Vδ2 T cells expansion upon stimulation with Zol + interleukin-2 (IL-2). The IgVH mutational status was analyzed by cDNA PCR amplification and sequencing. The level of activity of the Mev pathway was determined by 1) the analysis of gene expression profile (GEP) data 2) the biochemical quantification of the intermediate metabolite Isopentenyl pirophosphate (IPP). γδ T cells subset distribution and natural killer receptors (NKRs) profile were evaluated by multicolor flowcytometry. *Results*. Based on the *in vitro* Vδ2 proliferative response to Zol+IL2, 60% of CLL patients were defined as responders (R) and 30% as non-responsders (NR). Interestingly, our data have shown a strict and significant correlation among the Vdelta2 proliferative response to Zol + IL-2 and the IgVH mutational status of the leukemic cell. Indeed, 100% of R patients were mutated (M), whereas 70% of NR patients were unmutated (UM). To gain further insight into this association, we evaluated the activity of the Mev pathway in tumor cells of M and UM patients. Both the GEP data and the biochemical analysis have shown a significantly higher activity of the Mev pathway in UM CLL cells. The higher amount of IPP produced by UM CLL cells most likely determines a chronic stimulation of Vδ2 T cells *in vivo*. Indeed, a predominance of effector memory and terminally differentiated effector memory (TEMRA) Vδ2 T cells expressing the inhibitory NKR ILT2 was observed in NR patients. The expression of ILT2 on Vδ2 T cells was paralleled by high level of expression of the corresponding ligand HLA-G on CLL cells. HLA-G expression is associated with an unfavorable outcome in CLL. The association of R/NR status with biological markers of disease aggressiveness (i.e., IgVH mutational status and HLA-G expression) prompted us to determine whether R/NR status might associate to other features of disease aggressiveness and to predict tumor progression in CLL patients. Results from this analysis showed a significantly higher frequency of poor-risk cytogenetic abnormalities and a significantly shorter time to first treatment in NR as compared to R patients. *Conclusions*. Based on these data, we propose that the high rate of activity of the Mev pathway in UM CLL cells might determine a chronic stimulation of Vδ2 T cells thus leading to their *in vivo* differentiation into functionally impaired TEMRA. Therefore, we have identified a novel mechanism of immune escape which is at least partially contributing to disease progression in UM CLL.

0075

THE PROLIFERATIVE RESPONSE TO CPG-ODN STIMULATION PREDICTS DISEASE PROGRESSION IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

L. Laurenti,[1] M. Tarnani,[2] I. Innocenti,[2] P.G. Longo,[3] S. De Matteis,[2] P. Chiusolo,[2] A. Mannocci,[2] S. Sica,[1] G. Leone,[2] D.G. Efremov[3]

[1]Policlinico A. Gemelli, ROMA; [2]Policlinico A Gemelli, ROMA, Italy; [3]ICGEB Monterotondo-Outstation, ROMA, Italy

Background. Chronic lymphocytic leukemia (CLL) B-cells from certain patients exhibit marked proliferation following stimulation with unmethylated CpG-oligodeoxynucleotides (CpG-ODN). We observed that proliferation induced by CpG-ODN occurs primarily in leukemic B-cells from patients with progressive disease and unmutated immunoglobulin VH genes. *Aims*. We correlated this proliferative response, IgVH, CD38, ZAP-70 and cytogenetic abnormalities to progression-free survival (PFS) to detect the prognostic value of a new biological marker. *Methods*. The proliferative response to CpG-ODN stimulation was investigated in 65 CLL patients by analysis of [^{3}H] thymidine incorporation. We evaluated the proliferative response based on the stimulation index (SI) (cpmCpG / cpmMedium). A value of SI greater than 3 was considered indicative of a proliferative response. We also studied IgVH mutational status, CD38, ZAP-70 and high risk and low risk chromosome alterations detected by FISH analysis. We performed K test to evaluate the grade of accordance among CpG-ODN and other biological parameters. *Results*. Thirty-nine patients were men and 26 were women. Median age was 65 years. At presentation 49 were Binet stage A, 12 stage B and 4 stage C. Proliferative response to CpG-ODN stimulation showed 31 proliferating cases and 34 non-proliferating. About IgVH 33 cases were mutated and 29 unmutated. CD38 was tested in 63 cases; 14 resulted positive. ZAP-70 was studied in 63 patients; 26 were positive. FISH analysis was performed in 59 patients, 49 patients were low-risk and 10 high risk. The biological data are shown in Table 1.

Table 1.

Biological parameters (cut-off)		*CpG-ODN proliferating*	*CpG-ODN non-proliferating*
IgVH (98%)	Unmutated	22 (71%)	7 (22%)
	Mutated	9 (29%)	24 (78%)
CD38 (30%)	Positive	11 (35%)	3 (9%)
	Negative	20 (65%)	21 (91%)
Zap 70 (20%)	Positive	17 (55%)	9 (29%)
	Negative	14 (45%)	23 (71%)
FISH (HR: 11q-; 17p-) (LR: +12; normal; 13q)	High risk	8 (29%)	2 (7%)
	Low risk	20 (71%)	29 (93)

Patients from the proliferating subset had a significantly shorter median PFS (44 months *vs* 87 months, p=0.002). By univariate analysis, the variables significantly associated with longer PFS were: mutated Ig VH genes (p=0.001), ZAP-70 expression (p=0.009) and proliferative response to CpG ODN stimulation (p=0.002). By multivariate analysis the only independent variable associated to longer PFS was mutated Ig VH genes status (HR = 3.553; 95% CI: 1.628-7.751). Kappa test showed the strongest grade of agreement between proliferative response to CpG ODN stimulation and IgVH genes mutational status (κ=0.47, p<0.0001).

We also evaluated PFS according to proliferative response and VH

gene mutation status. The combination of non-proliferating cases with mutated VH genes (38.7%) had a significantly longer median PFS (not reached at 199 months); non-proliferating cases with unmutated VH genes (11.4%) (60 months); proliferating cases with mutated VH genes (14.5%) (60 months); proliferating cases with unmutated VH genes (35.4%) (30 months), (Logrank=15.249; p=0.002; Breslow=14.978; p=0.002). *Summary and Conclusions*. Cases with a positive proliferative response have significantly shorter PFS, indicating that the proliferative capacity of the leukemic cells is an important determinant of the clinical course in CLL. These data confirm that the proliferative response to CpG-ODN stimulation is strongly correlated with adverse biological prognostic features, in particular with unmutates IgVH genes. A new biological information emerged by combination of IgVH and CpG. About 35% of patients with CpG non proliferating and IgVH mutated genes can be considered as *super stable patients*.

UDP-GLUCURONOSYLTRANSFERASE 2B17 GENE EXPRESSION IS A NOVEL MARKER FOR PROGNOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

M.G. Gruber,[1] M. Bilban,[1] D. Heintel,[1] H. Esterbauer,[1] C. Fonatsch,[1] C. Mannhalter,[1] K. Eigenberger,[1] A. Gaiger,[1] C. Skrabs,[1] E. Porpaczy,[1] T.L. Le,[1] A. Hauswirth,[1] S. Stilgenbauer,[2] U. Kroemer,[2] K. Vanura,[1] U. Jaeger[1]

[1]*Medical University of Vienna, VIENNA, Austria;* [2]*University of Ulm, ULM, Germany*

Background. UDP-glucuronosyltransferase (UGT) 2B17 glucuronidates androgens and their metabolites. UGT2B17 shows by far the most dramatic difference in gene expression between the Asian and Caucasian normal populations and is associated with an increased prostate cancer risk in Caucasians. Interestingly, Asians have a strikingly lower incidence of chronic lymphocytic leukemia (CLL). In previous microarray-analysis we found that UGT2B17 RNA is differentially expressed between high and low risk CLL. *Aims*. i) To evaluate UGT2B17 gene-expression as prognostic marker for CLL; ii) to determine the genetic background (UGT2B17 polymorphism) of Caucasian CLL patients. *Methods*. i) Real-time PCR results of 136 PBMC-samples of Austrian B-CLL patients were compared with clinical data and CLL risk factors. In addition, we analyzed CD19-sorted cells from selected CLL patients and normal controls. ii) Conventional hot start PCR with 214 DNA samples of Austrian CLL patients and 449 samples of Austrian age-matched healthy donors (307 men, 142 women) were compared regarding the distribution of UGT2B17 gene polymorphism. This polymorphism consists of deletions encompassing the entire *UGT2B17* coding region. (genotype: ins/ins, ins/del, or del/del). *Results*. *UGT2B17* gene-expression ranged from 0 - 264,12 (median: 2,026) compared to normal PBMC (set as 1). Expression correlated with LPL-expression (p<0,0002), mutational status (p=0,001), CD38-expression (p=0,007), LDH-elevation (p=0,009), Binet-stages B and C (p=0,013), and 14q aberrations (p=0,044), and showed inverse correlation with 13q-deletion (p=0,013). Time to first treatment was significantly shorter in patients with high UGT2B17-expression (>2,026; p=0,00003) (Figure 1). UGT2B17 levels were up to 3 logs higher in CD19+ selected CLL cells compared to CD19 negative cells. RNA expression was higher in ins/ins compared to ins/del patients, but was absent in del/del patients.

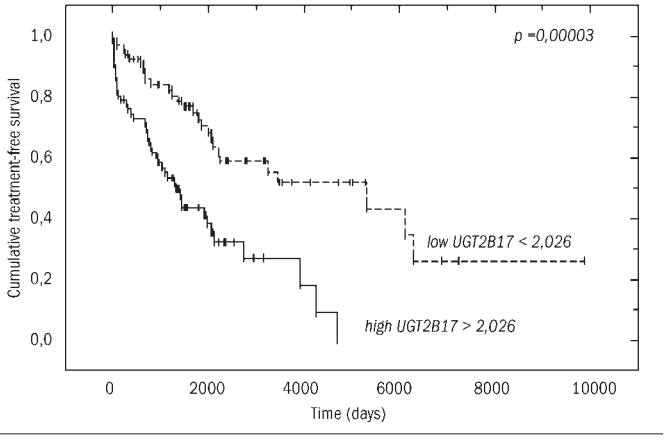

Figure 1.

Genotype frequencies in 214 CLL-patients were 38,97% ins/ins (♂ 35,04%, ♀ 44,87%), 49,74% ins/del (♂ 51,28%, ♀ 47,44%) and 11,28% del/del (♂ 13,68%, ♀ 7,69%), respectively. Within healthy donors we found 42,98% ins/ins (♂ 43,32%, ♀ 42,25%), 46,33% ins/del (♂ 45,60%, ♀ 47,89%) and 10,69% del/del (♂ 11,07%, ♀ 9,86%). There was no significant difference in polymorphism-frequency between CLL-patients and healthy subjects or gender. Double deleted patients showed a tendency for longer time to first treatment compared to ins/ins and ins/del genotypes albeit not statistically significant (p=0,051). *Conclusions*. UGT2B17 gene-expression is a prognostic marker for CLL patients and correlates with genotype. No difference in genotype distribution between CLL patients and controls was found in a Central European population. Impact of UGT2B17-expression on response to treatment is currently being investigated.

ALTERNATIVELY SPLICED TRANSCRIPTS OF ACTIVATION-INDUCED CYTIDINE DEAMINASE (AID) IN CHRONIC LYMPHOCYTIC LEUKEMIA. CORRELATION WITH IGHV GENE MUTATIONAL STATUS AND SURFACE IMMUNOGLOBULIN ISOTYPE EXPRESSION

F. Marantidou,[1] M. Chatzouli,[1] I. Athanasiadou,[2] V. Taxynopoulou,[2] A. Agathagelidis,[2] K. Valianatou,[1] E. Kostarelli,[2] A. Saetta,[3] N. Stavroyianni,[2] E. Manioudaki,[1] P. Korkolopoulou,[3] N. Laoutaris,[1] A. Anagnostopoulos,[2] K. Stamatopoulos,[2] C. Belessi,[1] E. Patsouris[3]

AID plays a key role in class switch recombination (CSR) and somatic hypermutation (SHM). Normal B-cells carry three different AID isoforms by alternative splicing of AID mRNA. AID1 mRNA encodes for the full-length protein and seems responsible for the enzymatic action; the AID3 isoform lacks amino acid residues critical for AID function. Dimerization of AID1 and AID3 may play a role in controlling AID activity. In the present study, we analyzed the patterns of AID splice variant mRNA expression in CLL and explored possible associations with IGHV gene mutational status and surface immunoglobulin (sIg) isotype expression. The study group included 187 patients with CLL, of which 119 (63.6%)%) carried IGHV genes with <98% homology to the closest germline gene (mutated), whereas the remainder (68/187 cases, 36.4%) carried unmutated IGHV genes. Twenty-two of 130 cases (16.9%) with available data expressed surface IgG; the remainder (108/130 cases; 83.1%) expressed IgM/IgD. Full-length AID transcripts (AID1) and 2 splice variants (AID2/AID3) were amplified by Real-time PCR in three different reactions with primers/probes specific for each isoform. ABL was used as a housekeeping gene and the results were expressed as AID copies /10.000 copies ABL. A cut-off value of 10 AID copies per 10,000 ABL copies was used for AID positivity. AID1/2/3 transcripts were detected in 114/94/99 patients, respectively. Seventy-six of 187 patients (40.5%) carried all three alternatively spliced AID transcripts; 57/187 patients (30.5%) carried one or two splice variants; finally, 54/187 patients (29%) were negative for any AID transcript. Co-expression of all three alternative splice variants was significantly more frequent among cases with unmutated IGHV genes (41/68 cases *vs* 35/119 cases with mutated IGHV genes; p<0.01). On the other hand, complete absence of AID splice variants was significantly more frequent among cases with mutated IGHV genes (42/119 cases *vs* 12/68 cases with unmutated IGHV genes; p=0.01). Expression of at least one AID isoform was significantly more prevalent among IgG *vs* IgM/D cases (20/22 *vs* 59/108 cases, respectively; p<0.01); 19/20 AID positive, IgG-switched cases, carried mutated IGHV genes. Of note, in IgG-switched cases, the AID3 transcript was always co-expressed with the AID1 and/or AID2 transcript. At the cohort level, the median values of AID1/2/3 transcripts were 51.5/48.3/50.3 copies per 10,000 copies ABL, respectively. *AID1/2/3* transcript levels varied between different cases up to 2-log. Significantly higher AID1 transcript levels were observed in IgG-switched cases (median, 138 copies per 10,000 copies ABL). In conclusion, co-expression of all three alternative AID splice variants in CLL patients with unmutated IGHV genes is indicative of functional inactivation of AID, possibly via formation of *AID1/AID3* or *AID2/AID3* dimers. Increased levels of full-length AID1 transcripts in IgG-switched/IGHV-mutated CLL cases alludes to the potential role of the AID1 transcript in both SHM and CSR, in keeping with normal B cells.

0078

REGULATION OF CXCR4 EXPRESSION BY VEGF AND SEMA3A IN B-CELL CHRONIC LYMPHOCYTIC LEUKAEMIA

B.P. Power,[1] P.M. Murphy,[2] J.H. Harmey,[1] P.T. Thornton[3]

[1]Royal College of Surgeons Ireland, DUBLIN; [2]Department of Haematology, Beaumont Hospital, DUBLIN; [3]Department of Haematology, Connolly Hospital, DUBLIN, Ireland

B-cell Chronic Lymphocytic Leukemia (B-CLL) is characterized by the accumulation of B-CLL lymphocytes in the blood, marrow and secondary lymphoid tissues. B-CLL cells have a long survival owing to alterations in the normal pathways of apoptosis. In the marrow and lymphoid tissues CLL cells are in close contact with stromal cells that constitute distinct microenvironments. The secretion of the *CXCR4* ligand *CXCL12* by stromal cells attracts B-CLL cells and provides protection from spontaneous or induced apoptosis. Studies in other cell types have shown VEGF signalling to be involved in regulating *CXCR4* expression levels. Our aim in this study was to examine the role of VEGF signalling in regulating CXCR4 levels in CLL cells. Expression levels of VEGF receptors (VEGFRs)-1 and 2 in CLL samples were determined by flow cytometry. Expression of the VEGFR co-receptor Neuropilin-1 (*NRP1*) in CLL samples was examined by Western blot. Informed consent was received from all patients. Treatment of CLL cells from patients with the NRP1 ligand SEMA3A which is a competitive inhibitor of VEGF binding to NRP1 resulted in decreased *CXCR4* expression levels as determined by flow cytometry (n=8, $p<0.05$). Culture of CLL cells with a VEGF blocking antibody resulted in a variable change in *CXCR4* levels which appears to correlate with VEGFR1 expression levels. Treatment of CLL cells with the VEGFR signalling inhibitor SU5416 caused a decrease in cell survival in a number of patient samples which also appears to correlate with VEGFR1 expression levels. These results show that signalling through VEGF receptors and the VEGF co-receptor *NRP1* plays a role in regulating CXCR4 levels in CLL cells. This pathway may therefore represent a target for future treatment in CLL.

ABERRANT GENE EXPRESSION PATTERN OF ANGIOGENESIS-RELATED FACTORS CHARACTERIZES B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

R. Maffei, S. Martinelli, I. Castelli, R. Santachiara, P. Zucchini, M. Fontana, S. Fiorcari, G. Bonacorsi, R. Marasca, G. Torelli

University of Modena and Reggio Emilia, MODENA, Italy

Background. Chronic lymphocytic leukemia (CLL) B cells display defective apoptosis and prolonged survival that are ascribed not only to intrinsic defects but also to aberrant microenvironmental signals. Emerging evidence suggests that angiogenic signalling pathways play important role in CLL. *Aims.* The aim of the study was to define the pattern of angiogenic factors expressed by circulating CLL B cells and then to investigate the ability of CLL to enhance the basal angiogenic potential when exposed to hypoxia condition. *Methods*. The spontaneous gene expression levels of several angiogenesis-related factors such as vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), angiopoietin-1 (Ang1) and -2 (Ang2) and thrombospondin-1 (TSP1) were measured by Real-time PCR in a cohort of 120 CLL patients and 5 normal controls. Ang2 plasma concentrations were detected using ELISA assay. The degree of bone marrow (BM) angiogenesis was quantified in 26 CLL patients by immunohistochemical staining using antibody to CD34 and by measuring the microvessel number. For hypoxia treatment, $CD19^+$ cells from 6 CLL patients were cultured in an air-tight chamber infused with a pre-analyzed air mixture containing 1% O2/5% CO2/94% N2. After 24h culture under either normoxic or hypoxia conditions, the expression levels of angiogenesis-related factors were evaluated by Real-time PCR. *Results.* Circulating CLL B lymphocytes spontaneously expressed increased levels of Ang2 and bFGF, similar level of VEGF and diminished levels of both TSP1 and Ang1, involved in angiogenesis inhibition, compared to normal B cells. Higher expression of Ang2 was detected in high-risk CLL patients characterized by Ig-unmutated genes ($p<0.0001$), CD38/ZAP-70 positivity ($p=0.019$), advanced clinical stage ($p=0.018$) and unfavourable cytogenetics ($p=0.031$). Likewise, 2-fold increase of Ang2 plasma concentration was observed in Ig-unmutated compared to Ig-mutated CLL subsets ($p=0.035$). Of interest, positive correlation was found between Ang2 expression and the degree of vascularization in BM compartment ($p=0.044$). Furthermore, CLL B cells were able to modulate their angiogenic potential in hypoxic conditions. Hypoxic treatment induced brisk up-regulation of VEGF expression, slight increase of Ang2 and down-regulation of bFGF in CLL B cells. Enhancement of VEGF in hypoxia was variable from patient to patient with stronger up-regulation in Ig-unmutated CLL (20-fold to several hundred-fold induction) than in Ig-mutated ones (14-, 3-, and 0-fold induction). Conclusion: We suggest the involvement of Ang2 and VEGF dysregulation in precocious switch to a vascular phase and in CLL disease progression.

A PROTEOMIC APPROACH TO INVESTIGATE TARGETS ASSOCIATED WITH B-CELL RECEPTOR SIGNALING IN CHRONIC LYMPHOCYTIC LEUKAEMIA

L. Eagle,[1] L. Cawkwell,[2] D. Allsup[3]

[1]University of Hull, HULL; [2]Post-Graduate Medical Institute, the University of Hull, HULL; [3]Department of Haematology, Hull Royal Infirmary, HULL, UK

Chronic Lymphocytic Leukaemia (CLL) results from the progressive accumulation of tumour cells which do not proliferate rapidly but fail to undergo death. Stimulation of the B-cell receptor (BCR) by antigen may prevent apoptosis of the malignant cells and has a relevant role in the disease with a poor prognosis. A good prognosis is associated with a characteristic BCR unresponsiveness and a bad prognosis is associated with a BCR that maintains the full capacity to respond to a triggering antigen, which the cells may be chronically exposed to. We have utilised proteomics as a way of investigating the BCR signaling pathways by identifying proteins which are differentially expressed in cells which have undergone sustained BCR stimulation. Protein was extracted from stimulated and unstimulated cells from clinical CLL samples. The extracts were separated using conventional two-dimensional polyacrylamide gel electrophoresis (2D-PAGE). The gels were stained with a visible total protein stain and analysed with statistical software. Proteins with a two-fold change in expression between stimulated and control samples were excised from the gels and analysed by matrix assisted laser desorption/ionisation with time of flight mass spectrometry (MALDI-TOF-MS). Changes in protein expression were detected in response to prolonged BCR stimulation. Targets found include ones which are associated with the activation of anaplastic lymphoma kinase (ALK), the plasma kallikrein-kinin system (KKS), the AKT-1 pathway, the MAPK pathways, the adenylate kinase system and involvement in the CD40-dependant activation of B-CLL cells. One of the protein targets found was increased by over two-fold in two independent clinical samples after sustained BCR stimulation. Confirmation work on this novel protein is presently being undertaken in a number of clinical samples. These biomarkers may be of interest for future therapeutic intervention or could be utilised as prognostic markers in a novel routine test.

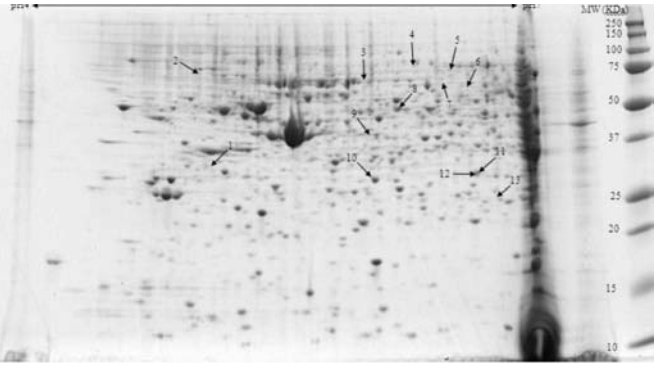

Figure 1. 2D gel showing differentially expressed proteins.

0081

CLL WITH T(14;18) : A DISTINCT DISEASE?

N.M.J. Put,[1] P. Meeus,[2] B. Chatelain,[3] M. Stul,[1] N. Boeckx,[4] C. Graux,[3] G. Bries,[5] C. Doyen,[3] C. Dubois,[6] S. Marichal,[7] P. Pierre,[8] A. Van Hoof,[9] J. Verschuere,[10] L. Harlet,[11] I. Wlodarska,[1] P. Vandenberghe,[1] L. Michaux[12]

Hart Hospital, ROESELARE - MENEN; [12]UZ Leuven/UCL St. Luc, LEUVEN / BRUSSELS, Belgium

Background. Balanced translocations are uncommon in chronic lymphocytic leukemia (CLL), and their significance remains poorly understood. *Aims.* The aim of the present study was to identify the characteristics of a population of patients with B-CLL and a t(14;18) or variant. Methods. Clinical and cytogenetic files from patients referred between 1990 and 2007 for cytogenetic characterization of CLL, and displaying a t(14;18)(q32;q21) or its molecular equivalent were reviewed. Morphology was centrally reviewed. FISH was performed to confirm involvement of BCL2. IgVH mutational status, VDJ family usage, and BCL2 breakpoint were assessed. *Results*. Thirty patients displayed a t(14;18) or variant in the karyotype and 3 in molecular analysis (representing < 2% of CLLs referred during the period of study). These were mainly males (ratio M/F: 23/10) ranging in age from 34 to 88 years (median 67). Staging data were available in 24 patients: 19 presented with Binet stage A, 2 with stage B and 3 with stage C. Follow-up data were available in 29 patients over a period ranging from 1-161 months (median 43). Sixteen/28 required therapy; two were refractory to therapy. Five died due to disease evolution, and 3 due to another disease, whereas 17 are still alive and 4 are lost to follow-up. Immunophenotype was compatible with CLL (Catov*s*ky score ≥3). Morphological review confirmed the diagnosis of classical CLL in all cases. The t(14;18) was the sole aberration in 10 cases, and was associated with other changes in 23 cases, i.e. +12 in 13 patients and del(13q) in 5 patients. Other abnormalities included +X, -X and del(6q) in one case each. Complexity (≥3 changes) was rare (n=4). The translocation involved most frequently the IgH locus, but variant cases involving the Ig κ or λ locus were observed in 3 and 5 cases, respectively. The *BCL2* breakpoint was in the major breakpoint region in 14 cases and in the minor cluster region in 1 case. In 10 cases, the breakpoint was located elsewhere. VH was mutated in 17 and unmutated in 3 cases. In 20 patients, the 4 following Ig VH families were used : VH3 in 14, VH5 in 4 (all 5.51), VH4 and VH1 each in one case. J and D usage was known for 18 patients. J4 was used in 11, J6 in 3, J5 in 2 cases and J1 and J3 each in one case. D usage was variable. In three patients D2-8 was seen, D3-10 in 3 patients, D3-16 and D1-26 each in 2 patients. The 8 remaining patients all displayed a different D usage. There were no recurrent VDJ combinations. *Conclusions*. CLL with t(14;18) represents a rare entity. Population characteristics are comparable to those of CLL patients in general (middle-aged patients, male predominance, typical immunophenotype and classical morphology). The t(14;18) was neither associated with aggressive disease nor with complex cytogenetic changes. In addition, the majority of the patients displayed mutated IgVH status, and responded to therapy.

0082

ANALYSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA CASES WITH STEREOTYPIC IMMUNOGLOBULIN'S RECEPTORS IN UKRAINIAN COHORT

N. Bilous, I. Abramenko, A. Chumak

Research Centre for Radiation Medicine, KIEV, Ukraine

Background. The biased repertoire of immunoglobulin heavy-chain variable (IgHV) gene found in CLL and additional identification of CLL subsets with stereotyped heavy chain complementarity determining region 3 (*HCDR3*) suggest about possible role of antigen(s) in the disease pathogenesis. The nature of antigens remains to be identified, however some data suggest that it might be auto-antigens, and microbial or viral antigens. *Aims*. Our aim was to analyze of CLL cases in Ukrainian cohort for distinguishing cases with stereotyped HCDR3s and gain inside the nature of possible antigens involved. *Methods*. Reverse transcription, polymerase chain reaction, and direct sequence.

Table 1.

Patient no	GenBank Access no.	IgHV gene	HCDR3 aa sequence	Antigen specificity

	46379	IgVH3-33	-- -N ----------	natural human anti-Sm antibody VH chain
	EU099240	IgHV3-30-3	-- -E- ----------	CLL case

Results. Single productive IgHV gene rearrangements from 218 CLL patients were analyzed. Unmutated IgHV sequences predominated in the group - 155 (71.1%) cases *vs* 63 (28.9%) mutated. Ten IgHV genes accounted for more than 60% of all cases, the most frequent genes were IgHV1-69 (20.6%), IgHV4-34 (7.3%), and IgHV1-02 (6%). Alignment analyses of the HCDR3 sequences revealed that sixty seven (30.7%) had HCDR3 homology (>60%) with sequences inside CLL cohort or with CLL sequences available from GenBank database. At that, 54 of them were referred to 23 of 48 previously described stereotyped CLL subsets. Another 13 cases along with homologous CLL cases available from database were referred to 8 subsets, which to our knowledge, had not been reported earlier. As each of that groups consisted of at least 3 cases, they might be considered as true CLL subsets. We found also, that several CLL cases from the cohort showed HCDR3 homology with anti-bacterial or anti-viral Igs (Table 1). Specifically, 4 cases (IgHV4-30-4, IgHV4-61, IgHV3-15, and IgHV3-11) shared similar HCDR3 with Igs specific to Streptococcus pneumoniae polysaccharides (PPS), at that, for 3 first cases we found homological CLL case from GenBank database. One IgHV-69 case showed *HCDR3* homology with Ig that recognizes capsular polysaccharide of Neisseria meningitides, and one IgHV4-59 case - with anti - staphylococcal protein A Ig. Three cases showed homology with anti-viral Igs: two IgHV1-02 sequences - with rotavirus-specific Igs, and one IgHV3-30-3 - with anti-rabies virus Ig. *Summary*. The restricted IgHV repertoire and high quantity of CLL cases with stereotyped immunoglobulin receptors strongly suggests a selection by restricted set of antigens. It is possible that bacterial and viral antigens might play a role in CLL pathogenesis.

0083

CD200 AS A TOOL FOR DIFFERENTIAL DIAGNOSIS BETWEEN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA AND MANTLE CELL LYMPHOMA

G.A. Palumbo,[1] G. Fargione,[1] N. Parrinello,[1] K. Cardillo,[2] A. Chiarenza,[1] S. Berretta,[1] C. Conticello,[3] L. Villari,[2] F. Di Raimondo[1]

[1]University of Catania, CATANIA; [2]Pathology Unit - Ospedale V. Emanuele, CATANIA; [3]Istituto Oncologico del Mediterraneo, VIAGRANDE (CT), Italy

A wide spectrum of B-cell lymphoproliferative disorders may become evident in leukemic phase and be misdiagnosed as Chronic Lymphocytic Leukemia (B-CLL), because of overlapping disease features. In particular, in the presence of a CD5 positive B-cell lymphocytosis, it is important to differentiate B-CLL from mantle cell lymphoma (MCL) as the latter is a more aggressive disease with poor response to conventional chemotherapy. Differential diagnosis between B-CLL and MCL is assessed by immunophenotypic analysis on freshly isolated cells and in this respect CD23 is considered a reliable marker because of its positivity in CLL and negativity in MCL. However, some cases where CD23 is not discriminant have been reported. In any case the diagnosis of MCL has to be confirmed by demonstration of cyclin D1 positivity or by the presence of the t(11;14)(q13;q32) chromosomal translocation detected by cytogenetics, fluorescence *in situ* hybridization (FISH), Western blot or Polymerase Chain Reaction (PCR) analysis. Even though these represent reliable methods, they are not widely available and time-consuming. Cyclin D1 detection can be accomplished on tissue biopsy only and not in cell suspension by flow cytometry; moreover, performing analysis on fixed tissues, CD5 and cyclin D1 may show equivocal or even negative results. In addition, the presence of the chromosomal translocation t(11;14) is not patognomonic for MCL. In fact, MCL patients without it are reported and the same translocation can be rarely found in B-CLL. Therefore, there is a need for finding new markers that allow an easier differential diagnosis between the two diseases. In this study we attempt to define the role of CD200 as a diagnostic tool. This antigen (previously referred to as OX2) is a membrane glycoprotein, belonging to the immunoglobulin superfamily, that seems to play an immunosuppressive role and regulates myeloid cell activity in a variety of tissues. It is expressed on a subset of T and all $CD19^+$ B lymphocytes (but not on NK cells), and highly on central and peripheral nerve tissue. Its expression has also been reported on human myeloma plasmacells and B-CLL cells. We evaluated CD200 in 91 patients with a CD5+ lymphoproliferative disease (79 B-CLL and 12 MCL in leukemic phase) by flow cytometry on fresh neoplastic cells. CD200 was positive in all B-CLL patients, while it was totally absent in 9 MCL patients and positive in 4, 7 and 16% of $CD5^+$ cells in the remaining 3. To confirm these results, we examined CD200 by immunohistochemistry on paraffin-embedded lympoid tissues and bone marrow (BM) trephine biopsies from 23 B-CLL and 44 MCL patients. Also with this technique all B-CLL neoplastic cells were positive for CD200 both in lymphnodes and in BM while all MCL cells were negative. Notably, in all MCL CD200-negative lympoid tissue biopsies, it was possible to observe CD200+ residual dendritic cells (useful as immunohistochemistry reaction positive control), as already known in tonsil and splenic follicular dendritic cells. Thus, in our series, there is a clearcut between MCL cells, in which CD200 is not expressed *vs* B-CLL, with high expression as reported by other authors. Therefore, adding CD200 in flow cytometry and immunohistochemistry routine panels could be of great help in distinguishing between these two entities, in particular in patients with a prevalent leukemic expression.

COMBINED THALIDOMIDE AND FLUDARABINE THERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA RESULTS IN DISTINCT MOLECULAR AND ANTILEUKEMIC EFFECTS

K. Giannopoulos,[1] K. Giannopoulos,[1] A. Dmoszynska,[1] M. Kowal,[1] E.W.K. Wasik-Szczepanek,[1] P. Wlasiuk,[1] A. Bojarska-Junak,[1] J. Rolinski,[1] S. Stilgenbauer,[2] L. Bullinger[2]

[1]Medical University of Lublin, LUBLIN, Poland; [2]University of Ulm, ULM, Germany

Background. Thalidomide (THAL) is a promising immunomodulatory drug that might not only target leukemia cells but also the tumor microenvironment. Moreover since angiogenesis plays important role in chronic lymphocytic leukemia (CLL) THAL based regiments might effectively treat disease. *Aims*. We aimed to treat CLL patients (pts) with THAL and fludarabine (FLU) and monitored effects of THAL treatment *in vivo* in sequential blood samples. *Patients and methods*. Forty patients were included in this study (median age 67, range 43-75 years). In total, 20 patients received THAL+FLU as first line (arm A) and 20 as second or third line therapy (arm B). Pts received THAL (100 mg po/day) starting at day 0 (d0). FLU was added for 5 consecutive days every 28 days (25 mg/m^2 iv/day) starting at day 7 (d7) for up to 6 cycles. TNF expression levels were assessed using a high sensitivity ELISA test, and T-cell subpopulations were analyzed by FACS analysis on d0, d7, and d12. To evaluate the influence of THAL on gene expression (GEP), 20 (10 from arm A and 10 from arm B) paired d0 and d7 samples were analyzed using U133plus2.0 microarrays. *Results*. The overall response rate (ORR) was 52,5%, 80% in arm A and 25% in arm B. 25% in arm A achieved CR but no CR in arm B was observed. THAL therapy was effective in decreasing the number of CLL cells ($CD5^+CD19^+$) as assessed by FACS from 51.75 G/L to 31.7 G/L after treatment on day 7. Subsequent 5 days of therapy with FLU reduced significantly the number of CLL cells to 16.8 G/L. The number of CD3 lymphocytes showed no significant change during THAL therapy (2599 cells/mL on day 0 and 2166 cells/mL on day 7). Addition of FLU decreased $CD3^+$ cells to 853 cells/mL on day 12 (p=0.01). Both $CD4^+$ and $CD8^+$ T cell subsets were significantly reduced after FLU therapy (p=0.008 and p=0.009, respectively). THAL induced no effect on $CD4^+$ as well as CD8+ T cell populations (p=0.44 and p=0.29, respectively). Interestingly, analyzing in detail CD4 T cells we found significant decrease in the number of CD4+CD25hiFOXP3+ T regulatory cells (Tregs) after THAL from 182 cells/mL to 114 cells/mL (p=0.05). Tregs were further reduced by FLU to 43.9 after FLU on day 12 (p=0.001). THAL therapy did not reduce the number of other T-cell subpopulations reported to possess regulatory properties such as $CD8^+CD28^-$, $CD4+GITR^+$, $CD4^+CD62L^+$ and $CD3^+TCR\gamma\delta^+$. In contrast addition of FLU to therapy decreased the number of $CD8^+CD28^-$ (p=0.012), $CD3^+TCR\gamma\delta^+$ (p=0.005) as well as $CD4^+GITR^+$ (p=0.058) and $CD4^+CD62L^+$ (p=0.27). The changes in Tregs during THAL therapy differed in responder *vs* nonresponder groups of CLL patients showing greater fold of Tregs reduction in patients who responded to therapy. However, we observed no significant changes in the plasma levels of TNF neither after THAL alone nor after FLU. No correlation was observed between serum TNF level and expression of TNF receptor 1 (*TNF R1*) nor TNF R2. Interestingly, the expression of TNF R1 was significantly higher in patients who did not responded to THAL as determined by WBC changes after 7 days of THAL therapy (19.98 *vs* 9.7, p=0.03).The nonresponder group tended to present with higher levels of TNF R2 when compared to patients who responded (51.6 *vs* 33.1, p=0.17). Paired supervised analysis of GEP data based on sample comparison before and during THAL treatment revealed a THAL induced signature comprising 123 differentially expressed genes (p<0.001). Comparison of GEP changes observed *in vivo* with the data contained in Connectivity Map, a public repository of GEP changes induced by *in vitro* treatment of cells with a wealth of different drugs, revealed a significant correlation of our signature with thalidomide induced changes in breast cancer cells (MCF7 cells). Interestingly, there was also a significant correlation with signatures induced by imatinib, valproic acid and prednisolone in MCF7 cells. Gene set enrichment analyses showed 22 deregulated pathways, including the apoptosis and FAS signaling pathway which involved expression changes of FAS, FADD, caspase 8 and caspase 3 (p<0.005). Furthermore, we observed a significant association with CD40L signaling which has been previously reported to play a role in immunomodulatory drug action. *Conclusions*. Combined THAL+FLU

therapy demonstrated significant efficacy previously untreated B-CLL and limited efficacy as salvage therapy with acceptable safety profile. Furthermore, our study provides novel biological insights into the molecular effects of THAL, which might act (i) by enhancing apoptosis of CLL cells and (ii) by reducing Tregs, thereby enabling T-cell dependent tumor rejection. THAL therapy revealed a superior safety profile in interaction with T cells when compared to FLU. Therefore THAL might represent an interesting therapeutic option for CLL patients.

0085

RITUXIMAB CONSOLIDATION AND MAINTENANCE THERAPY PROLONG RESPONSE DURATION IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

G. Del Poeta,[1] M.I. Del Principe,[1] A. Siniscalchi,[1] L. Maurillo,[1] F. Buccisano,[1] A. Venditti,[1] F. Luciano,[1] P. Niscola,[1] A. Zucchetto,[2] V. Gattei,[2] A.P. Perrotti,[1] P. De Fabritiis,[1] S. Amadori[1]

[1]Department of Hematology, University Tor Vergata, ROMA; [2]Clinical and Experimental Hematology Unit, IRCCS, AVIANO (PN), Italy

Monoclonal antibodies in combination with chemotherapy resulted in more complete responses and longer response duration in B-cell chronic lymphocytic leukemia (B-CLL), reducing disease burden to levels detectable only by flow cytometry. Moreover, low-dose rituximab decreases CD20 antigen loss and promotes enhanced targeting in CLL (*Williams, 2006*). We performed a phase II study adding rituximab to fludarabine (Flu) as therapy for symptomatic, untreated CLL. Remission status was assessed also by a multiparametric flow cytometric approach based on the detection of $CD19^+CD5^+CD79b$- B-CLL lymphocytes. IgVH mutational status, CD38, ZAP-70 and cytogenetics were obtained in all patients (pts) before treatment. We defined as high risk pts having at least two of these markers: unmutated IgVH, CD38>30%, ZAP-70>20%, intermediate/unfavorable cytogenetics (trisomy 12 or del11q or del17p). Ninety-five CLL pts, median age 61 years (range 37-79) received six monthly courses of Flu (25 mg/sm^2 for 5 days) and four weekly doses of rituximab (375 mg/m^2) starting after completion of Flu therapy.

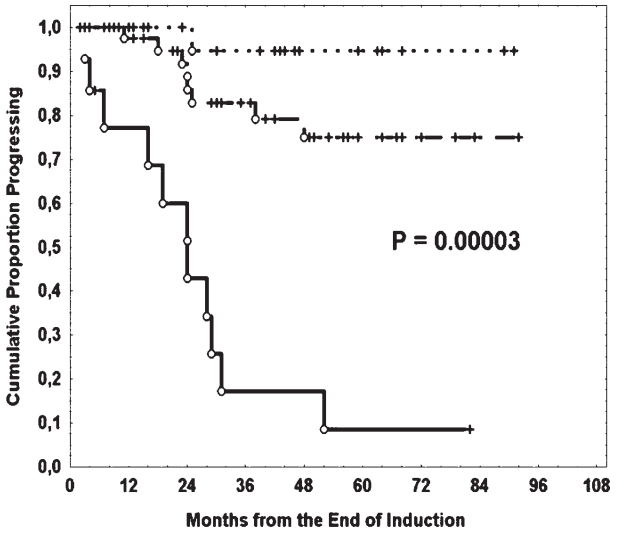

Figure 1. Response duration by Rituximab consolidation/maintenance.

Informed consent was obtained from all pts. According to modified Rai stages, 11 pts had a low stage, 81 an intermediate stage and 3 a high stage. Based on NCI criteria, 75/95 (79%) pts achieved a complete remission (CR), 16/95 (17%) a partial remission (PR) and 4/95 (4%) no response or progression. Four pts underwent grade 3 (WHO) infective lung toxicity, 1 patient acute fatal B hepatitis and 1 patient progressed towards Richter's syndrome. Hematologic toxicity included mainly neutropenia (grade 3 and/or 4 in 47 pts) and thrombocytopenia (grade 3 and/or 4 in 5 pts). Forty-one pts either in CR with $CD5^+CD19^+CD79b$- bone marrow (BM) cells >1% (MRD^+, n=15 pts) or in CR MRD negative with $CD5^+CD19^+$ peripheral blood lymphocytes (PBL) >1000/μL (n=14 pts) within 1 year after completion of the induction treatment or in PR (n=12 pts), underwent consolidation and maintenance therapy with four monthly cycles of rituximab at 375 mg/m^2 followed by twelve monthly doses of rituximab at 150 mg/m^2. The median follow-up duration was 48 months. All pts experienced a long progression-free survival (PFS) from the end of induction treatment (67% at 7 years). Nevertheless, CLL pts that underwent consolidation and maintenance therapy (n=41) showed a significantly longer response duration compared to MRD^+ not consolidated pts (n=14; 75% *vs* 9% at 6 years; p=0.00003, Figure 1). Noteworthy, BM and PBL persistently MRD negative (>1 year) pts (n=36) showed a very long response duration (95% at 6 years, Figure 1). A significant shorter PFS was observed within $CD38^+$ pts (29% *vs* 81% at 6 years, p=0.0002), unmutated pts (58% *vs* 89% at 4 years, p=0.003) and ZAP-70^+ pts (44% *vs* 85% at 6 years; p=0.00002). Notably, within the high risk subset (n=34), considering only MRD^+ pts in CR or PR (n=18), MRD^+ consolidated pts (n=11) showed a significantly longer response duration (58% *vs* 18% at 2 years, p=0.01) in comparison with MRD^+ not consolidated pts (n=7). Therefore, consolidation and maintenance therapy with rituximab prolong significantly the response duration in B-CLL, also within the high risk subset, thus potentially increasing overall survival.

FLUDARABINE PLUS THALIDOMIDE AS FRONTLINE THERAPY FOR NEWLY DIAGNOSED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL).

S. Ailawadhi, K.C. Miller, D. Depaolo, A. Whitworth, W. Brady, M. Czuczman, Z.P. Bernstein, F. Hernandez-Ilizaliturri, S. Padmanabhan, A. Chanan-Khan

Roswell Park Cancer Institute, BUFFALO, USA

Introduction. Chronic lymphocytic leukemia (CLL) is a malignant hematologic disorder characterized by proliferation of morphologically mature appearing lymphocytes and a dysregulated tumor microenvironment that supports tumor cell growth. Fludarabine (F) has demonstrated its clinical efficacy in CLL and is often used as the first therapeutic option in these patients. To further improve the clinical responses to F we combined it with thalidomide (T). We hypothesized that T will target the tumor microenvironment resulting in increased sensitivity of the tumor cell to F. Thus the FT regimen will concurrently target the tumor cell as well as its microenvironment. Here we report the efficacy and toxicity profile of the FT regimen in treatment naive CLL patients enrolled on a phase I/II clinical study at our center. *Methods*. All previously untreated CLL patients requiring treatment as per the NCI-WG (1996) were eligible for this study. F was given at a dose of 25 mg/m^2 IV for 5 consecutive days starting day 8 of each 28-day cycle for a maximum of 6 cycles. T was initiated on day 1 and was given every day continuously throughout the treatment (6 cycles). The phase I part of the study was concluded and did not demonstrate any dose limiting toxicity of this combination (*Chanan-Khan et al Blood 2006*). The phase II investigated T at 200 mg/day in combination with F. Response assessment was done as per the Revised NCI-sponsored Working Group Guidelines. Acyclovir 400 mg PO BID, Bactrim DS PO 3 times/week and weight-adjusted low-dose warfarin were given for prophylaxis of herpes zoster, PCP and venous thromboembolism, respectively. *Results*. A total of 35 patients (11 females, 24 males) with a median age of 63 years (range 35-78) have been enrolled. Rai stage distribution at initiation of treatment was stage I 31% (n=11) stage II 20% (n=7), stage III 29% (n=10) and stage IV 20% (n=7), respectively. The phase I part of accrual included 13 patients while 22 patients were accrued on the phase II of the protocol. Most common ≥ grade 3 hematologic toxicities included neutropenia (20%) and thrombocytopenia (11%). There were no ≥ grade 3 non-hematological toxicities with an incidence > 10%. Most common non-hematological toxicities were grade 1 or 2 nausea (23%) and constipation (20%). Tumor flare was noted in 14% patients (n=5). Response analysis showed that 29 patients were evaluable. Of these, 15 (52%) achieved a CR and 13 (45%) achieved a PR. Thus the ORR was 97%. *Conclusions*. FT is a novel and efficacious regimen for treatment naive CLL. This regimen demonstrated high CR rate compared to historical control (fludarabine alone).Toxicity was manageable and acceptable. Detailed and updated results of this study will be presented at the meeting.

0087

LUMILIXIMAB IN COMBINATION WITH FCR FOR THE TREATMENT OF RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): RESULTS FROM A PHASE I/II MULTICENTER STUDY

J. Byrd,[1] J. Castro,[2] I. Flinn,[3] A. Forero-Torres,[4] T. Kipps,[2] N. Heerema,[1] Y. Kasamon,[5] W. Wierda,[6] T. Lin,[1] H. Mu,[7] S. Tangri,[7] S. O'Brien[6]

[1]The Ohio State University Comprehensive Cancer Center, COLUMBUS; [2]Moores Cancer Center University of California San Diego, SAN DIEGO; [3]Sarah Cannon Research Institute, NASHVILLE [4]University of Alabama Birmingham Comprehensive Cancer Center, BIRMINGHAM; [5]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, BALTIMORE;[6]The University of Texas/MD Anderson Cancer Center, HOUSTON; [7]Biogen Idec, SAN DIEGO, USA

Background. Lumiliximab is an anti-CD23 monoclonal antibody that is being investigated for relapsed CLL. In a previous study, lumiliximab monotherapy given weekly was well tolerated, achieved sustainable CD23 receptor occupancy and showed clinical activity. *Aims.* A phase I/II, multicenter study was conducted to evaluate the safety and efficacy of lumiliximab in combination with fludarabine, cyclophosphamide, and rituximab (L+FCR) for patients (pts) with relapsed $CD23^+$ CLL. In addition, CD23 receptor occupancy on CLL cells and possible effects of elevated serum CD23 were evaluated. *Methods*. 31 pts received either 375 mg/m^2 (n=3) or 500 mg/m^2 (n=28) of L+FCR for up to six 28-day cycles. All pts completed treatment and follow-up is ongoing. A semi-quantitative flow cytometry method was used to measure CD23 receptor occupancy and serum CD23 was analyzed using an enzyme-linked immunosorbent assay. *Results*. Median age at study entry: 58 yrs, Rai Stage I/II: 71%, median # of prior regimens: 2 (1-10). Overall response rate was 65%: complete response (CR) 52% and partial response13%. 5 of the 8 pts with del (11q22.3) achieved CR. Based on median follow-up of 16.8 mos (1.5-37.6), KM estimated median progression-free survival (PFS) for all pts was 19.3 mos. Median PFS for all responders and CR pts were 23.4 mos and 30.4 mos, respectively. 23 pts (74%) reported a Grade 3 or 4 event. Compared with published FCR data, L+FCR has a similar safety profile with no additional toxicities. L+FCR sustained CD23 receptor occupancy which was not affected by elevated levels of serum CD23. *Conclusions*. L+FCR is an effective regimen for pts with relapsed CLL. L+FCR produced an impressive CR rate, an encouraging PFS and a similar safety profile to that of FCR. A large, randomized, global study of L+FCR *vs* FCR (LUCID) is ongoing to further evaluate the safety and efficacy of this regimen.

0088

IDENTIFICATION OF AN IN VIVO MOLECULAR SIGNATURE OF SENSITIVITY VS RESISTANCE TO FLUDARABINE IN B CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

E. Moussay,[1] V. El Khoury,[1] N. Aouali,[1] K. Van Moer,[1] B. Leners,[1] F. Bernardin,[1] A. Muller,[1] P. Nazarov,[1] M. Yatskou,[2] L. Vallar,[1] V. Palissot,[1] G. Berchem[3]

[1]CRP-Santé, LUXEMBOURG; [2]Université du Luxembourg, LUXEMBOURG; [3]Centre Hospitalier de Luxembourg, LUXEMBOURG, Luxembourg

Background. The B chronic lymphocytic leukemia (B-CLL), the most common hematological malignancy in Western countries, is characterized by the accumulation of $CD5^+$ $CD19^+$ $CD23^+$ B lymphocytes arrested in G0/G1 phase of the cell cycle. Leukemic B-cells do not fulfill their immunological role and do not undergo apoptosis anymore due to up-regulation of anti-apoptotic factors, thus resulting in progressive obstruction of organs, gradually leading to death of the patients. Due to their potential to kill non-dividing cells, purine nucleoside analogs, such as fludarabine, are often used in first line therapy to treat hematological malignancies. Although the effect of fludarabine against CLL cells is widely accepted, its mode of action on the molecular level *in vivo* is poorly understood. A short list of genes regulated by fludarabine *in vivo* was previously reported; all of them induced in B cells by p53 after 5 days of treatment. *Aims*. In this study, we compared the response, at the transcriptomic level, of B cells from CLL patients sensitive or resistant to fludarabine in the clinic. We investigated their response to fludarabine up to 9 days after the beginning of the treatment. *Design and Methods*. For this purpose, we purified B cells from blood puncture before fludarabine administration (day 0) and after 1, 2, and 9 days of treatment. All patients had signed a written informed consent. We then performed a whole-genome analysis with cDNA microarrays (loop design). Selected genes were submitted to real-time PCR confirmation. Furthermore, an array-based Comparative Genomic Hybridization (CGH) analysis was used to determine the genetic aberrations of the B cells from these CLL patients. Additionally, we compared the genomic and transcriptomic data obtained by high-throughput methods with the clinical data of the patients. Gene Ontology softwares were used to functionally classify these genes. *Results*. Statistical analysis and clustering led us to identify for each time-point tested a gene expression signature of *in vivo* sensitivity and/or resistance to fludarabine of B-CLL patients. Most of *in vivo*-regulated genes identified could be classified with gene ontology softwares as part of the cell death mechanisms, cell cycle regulation, DNA damage and repair, kinase activity, enzymatic activity, translation and the RNA and nucleotide metabolism. In addition to common losses (del13q14; del17p13), cytogenetic analysis revealed the presence of isochromosomes together with other abnormalities in fludarabine-resistant patients. *Conclusions*. Taken together, our data show significant distinct profiles between sensitive and resistant patients in response to fludarabine treatment and strongly argue in favor of the establishment of targeted PCR after 1-2 days of treatment as a reliable tool to early determine the outcome of the therapy of B-CLL patients by fludarabine.

0089

ABNORMAL SERUM FREE LIGHT CHAIN RATIOS IN CHRONIC LYMPHOCYTIC LEUKAEMIA ARE SIGNIFICANTLY ASSOCIATED WITH EARLIER DISEASE-SPECIFIC DEATH

J. Harding,[1] G. Pratt,[2] R. Holder,[2] C. Fegan,[3] C. Pepper,[3] D. Oscier,[4] G. Mead[2]

[1]The Binding Site, BIRMINGHAM, UK; [2]University of Birmingham, BIRMINGHAM; [3]Cardiff University, CARDIFF; [4]Royal Bournemouth Hospital, BOURNEMOUTH, UK

Background. Serum free light chains (FLC) have prognostic significance in monoclonal gammopathy of undetermined significance, solitary plasmacytoma of bone, smouldering myeloma, multiple myeloma, Waldenstroms macroglobulinaemia and AL amyloidosis. The incidence of abnormal FLC in other lymphoid malignancies including chronic lymphocytic leukaemia (CLL) is unclear with only one published report which found 8/18 CLL patients with an abnormal FLC. There have been no studies correlating FLC with other biological variables and clinical outcomes in CLL or lymphoma. *Methods*. This is a retrospective study that analysed 259 (Stage: A, 209; B, 23; C, 21; Male:Female ratio 1.6:1, mean age 75: range 29-98) archived patient sera. Sera had been collected before (n=181) or during (n=79) treatment. The levels of FLC and B2M were assessed using nephelometric immunoassays (The Binding Site) on the Dade-Behring BNTMII analyser. Previously recorded measurements for biological and clinical markers (age, sex, CD38, ZAP70, and VH mutational status) were used in Kaplan Meier Survival Hazards and Cox Regression analysis, outcome was described as alive, cause of death (COD) related to disease or COD unknown/unrelated.

Table 1. Serum free light chain and B2M in CLL.

	Patient Status			
	All	Alive	Disease specific COD	Unrelated COD
Kappa κ (mg/L)	28.0 (0.32-382)	22.5 (0.45-309)	56 (0.32-382)	30 (2.14-177)
Lambda λ (mg/L)	21 (0.82-216)	19.4 (1.63-216)	28 (6.82-179)	24 (2.83-113)
κ / λ ratio	3.5 (0.2-156.1)	2.4 (0.02-54)	11.2 (0.02-156)	1.9 (0.09-10)
B2M (mg/L)	4.5 (0.13-74.2)	3.6 (0.13-21.9)	9.3 (1.6-72.4)	4.9 (1.56-15.8)

Results. The population of CLL patients were analysed (Table 1). Using Kaplan Meier Survival Hazards, abnormal FLC ratio was a significant indicator of poorer survival (n=255, Log Rank Mantle-Cox p=0.006). Using Kaplan Meier Survival Hazards, abnormal FLC ratio was a significant indicator of poorer survival (n=255, Log Rank Mantle-Cox p=0.006). Using Cox Regression analysis (n=179, missing =63, with 17

cases excluded before the first event) we analysed age, stage, sex, CD38, ZAP70, mutational status and B2M and found 4 significant, independent, prognostic factors ZAP70 (p<0.001), mutational status (p<0.002), B2M (p<0.003) and abnormal ratio (p<0.006). Furthermore, analysis of patients with an abnormal λ ratio showed significant correlation (Spearmans ρ 0.396 p<0.01) with VH3-21, 48 and 53 usage. *Conclusions*. Elevated levels of κ and λ FLC are evident in CLL patients. An abnormal FLC ratio associated significantly to worse outcome and is independent of the established markers ZAP70, CD38 and mutational status. VH3-21, 48 and 53 are known to be indicators worse outcome in mutated patients, here we provide the first indication that an abnormal λ FLC ratio may be indicative of the VH usage. The importance of abnormal FLC ratios in CLL requires further studies as does the biological rationale for their occurrence.

0090

RAI AND BINET CLASSIFICATIONS FOR CHRONIC LYMPHOCYTIC LEUKEMIA SHOULD RECOGNIZE A ROLE FOR IMMUNE THROMBOCYTOPENIA, BUT NOT FOR AUTOIMMUNE HAEMOLYTIC ANEMIA

C. Visco, I. Giaretta, M. Ruggeri, E. Novella, E. Albiero, E. Pacquola, C. Borghero, F. Rodeghiero

Ospedale S Bortolo, VICENZA, Italy

Background. In the era of biologic markers, and of immuno-chemotherapy, Rai and Binet clinical staging systems provide reliable classification of patients with chronic lymphocytic leukaemia (CLL) into well-defined risk-groups. Patients presenting with a haemoglobin level inferior to 10 (Binet C) or 11 g/dL (Rai 3), and/or a platelet count less than 100x10^9/L (Rai 4, Binet C) are still classified as high risk. However, both Rai and Binet classifications do not distinguish between autoimmune haemolytic anemia (AHA)/immune thrombocytopenia (IT), and marrow infiltration as the cause for anemia or thrombocytopenia. *Aims*. To verify the prevalence and prognostic significance of IT and AHA in patients with CLL at presentation. *Methods*. Four-hundred twenty-five patients with CLL consecutively diagnosed and followed at our Institution in a 9-year period were analyzed for the occurrence of AHA and IT at presentation, or during the first year following diagnosis in those not requiring treatment. Overall survival (OS) of patients developing AHA or IT within the first year from CLL diagnosis was compared with remaining patients using Kaplan-Meyer method, starting from the time of CLL diagnosis. Criteria for diagnosis of IT and AHA were as reported in our previously published series (*Blood 2008;111:1110-6*). Rai and Binet stage was 3/4 or C in 15% and 14% of patients, respectively. Median follow-up was 62 months, with 60% of patients requiring treatment for CLL. *Results*. Considering the whole follow-up period, 23 patients were diagnosed with AHA (5,4%), and 25 with IT (5,8%). Median time to AHA was 44 months (range 0-94), while median time to IT was significantly inferior (14 months, range 0-82, p=0.01, by Log-Rank test). Thus, of the 23 patients with AHA, three developed this complication at the time of CLL presentation, and one in the first year after diagnosis (4/23, 17%). Conversely, IT occurred at CLL diagnosis in six patients, and in the first year after diagnosis in five (11/25, 44%), significantly more frequently than AHA (p=0.04). Median OS of the four patients developing AHA within the first year from CLL diagnosis was not different from other patients with CLL (90 *vs* 112 months, p=0.25), whereas patients with IT within the first year from CLL diagnosis shared a remarkably shorter OS (50 *vs* 112 months, p=0.0001), which was similar to patients with Rai 4 or Binet C (44 and 48 months, p=0.23). An un-mutated immunoglobulin heavy-chain variable-region was frequently observed both among CLL patients with IT (80%), and AHA (55%). *Conclusions*. Differently from AHA, rarely occurring at CLL presentation, and whose prevalence increased when advanced stages were more frequently observed, IT was not related to disease activity. According to our findings, IT should be recognized as a possible cause of thrombocytopenia at CLL presentation, and patients classified as high risk in Rai and Binet classifications, while AHA doesn't seem to retain a prognostic role in this setting.

0091

COMPARISON OF CLADRIBINE PLUS CYCLOPHSOPHAMIDE OR FLUDARABINE PLUS CYCLOPHOSPHAMIDE IN DIFFERENT AGE GROUPS IN PREVIOUSLY UNTREATED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (PALG-CLL3 STUDY)

T. Robak,[1] J.Z. Blonski,[1] J. Gora-Tybor,[1] K. Jamroziak,[1] L. Konopka,[2] B. Ceglarek,[2] M. Calbecka,[2] A. Kostyra,[2] B. Stella-Holowiecka,[2] J. Kloczko,[2] K. Warzocha,[2] I. Seferynska,[2] A. Dmoszynska,[2] M. Kowal,[2] K. Lewandowski,[2] J. Dwilewicz-Trojaczek,[2] E. Wiater,[2] K. Kuliczkowski,[2] S. Potoczek,[2] A. Hellmann,[2] A. Mital,[2] A. Skotnicki,[2] W. [1]*Med Univ of Lodz, LODZ, Poland;* [2]*PALG-CLL3, LODZ, Poland*

Background. Purine analogues, Cladribine (2-CdA) and Fludarabine (FA), are highly effective in treatment of chronic lymphocytic leukemia (CLL). This trial was designed to compare the efficacy and toxicity of 2-CdA and cyclophsophamide (CC regimen) with FA and cyclophsophamide (FC regimen) in different age groups of patients with CLL. *Patients and Methods*. The study was started in January 2004 and requirement was ended in May 2005. The efficacy and toxicity of CC *vs* FC were compared in two groups previously untreated patients with progressive or symptomatic CLL: aged less than 65 years (134 pts) and aged 65 years and more (151 pts). The primary endpoints of the analysis were overall response (OR) and complete response (CR). The secondary endpoints were progression free survival (PFS), overall survival (OS) and treatment-related toxicity. The treatment response and side effects were evaluated according to NCI-SWOG guidelines. The details of the treatment schedule were published previously (*Blood, 2006;108(2):473*). Results. The results of study are shown in *Table 1*.

Table 1

Characteristics		Treatment CC	Treatment FC	p value
Pts enrolled		145	168	
Pts evaluated		134	151	
	<65y	91	111	
	≥65y	43	40	
OR	<65y	77 (45%)	95 (55%)	0.50
	≥65y	41 (54%)	35 (46%)	0.19
CR	<65y	34 (39%)	54 (61%)	0.25
	≥65y	25 (54%)	21 (46%)	0.43
PFS (median)	<65y	2.294y	2.688y	0.33
	≥65y	2.676y	2.297y	0.60
Neutropenia	<65y	17 (37%)	29 (63%)	0.15
	≥65y	12 (60%)	8 (40%)	0.22
Thrombocytopenia	<65y	11 (48%)	12 (52%)	0.46
	≥65y	6 (55%)	5 (45%)	0.50
Infections	<65y	22 (42%)	30 (58%)	0.41
	≥65y	19 (56%)	15 (44%)	0.25
Death	<65y	11 (46%)	13 (54%)	0.33
	≥65y	5 (42%)	7 (58%)	0.60

Conclusions. CC and FC programmes used as first line therapy in B-CLL give similar response rates and PFS and OS in younger and older CLL patients. The chemotherapy toxicity is acceptable in both age groups and does not differ significantly between patients treated with FC and CC.

INCREASED SERUM BAFF (B-CELL ACTIVATING FACTOR OF THE TNF FAMILY) LEVEL IS A PECULIAR FEATURE ASSOCIATED WITH FAMILIAL CHRONIC LYMPHOCYTIC LEUKEMIA

S. Molica,[1] G. Digiesi,[2] F. Mauro,[3] R. Mirabelli,[1] G. Cutrona,[4] G. Vitelli,[2] F. Iuliano,[5] F. Morabito,[6] R. Foà,[3] M. Ferrarini[4]

[1]Azienda ospedaliera Pugliese-Ciaccio, CATANZARO; [2]Clinical Pathology, IRCCS REgina Elena, ROMA; [3]Hematology Institute, University La Sapienza, Rome, ROMA; [4]Medical Oncology, Istituto Nazionale Tumori Genova, GENOVA; [5]Medical Oncology, Ospedale Giannettasio, ROSSANO (CS); [6]Department Hematology, Az. Ospedaliera, COSENZA, Italy

Although serum levels of BAFF (B-cell activating factor of the TNF family) have been evaluated in a number of lymphoproliferative disorders information on B-cell chronic lymphocytic leukemia (CLL) are limited. With this background we sought to establish whether BAFF levels correlated with clinical characteristics of disease in a series of 84 CLL patients. In this patients' cohort we found that BAFF serum levels, as measured at the time of diagnosis using a commercial ELISA assay (R & D Systems, USA), were significantly higher in age- and sex-macthed healthy controls (i.e.,median, 695 ng/mL; range, 389-1040) in comparison to the general population of CLL patients (median, 376; range, 93-8914; $p<0.0001$). Moreover, we observed significantly lower levels of BAFF among patients with unmutated IgVH (295.5 ng/mL; range, 138-1823) in comparison with patients with mutated IgVH (415 ng/mL; range 93-8914: $p=0.0001$). These differences translated into a shorter time to first treatment observed in Binet stage A patients with lower soluble BAFF levels in comparison to patients with higher concentration ($p<0.0001$). When we examined the clinical characteristics of CLL patients with elevated BAFF levels (after setting as a cut-off the median value observed in healthy controls; i.e., 695 ng/mL) we found that 6 out of 15 (40%) of individuals with increased levels had a first-degree relative diagnosed with CLL. In contrast, only 5 out of 64 (7.2%; $p=0.0007$) patients with sporadic CLL displayed BAFF concentrations higher than median value found in controls. This difference translates into a six-fold hingher frequency of elevated BAFF levels in the familial CLL in comparison to sporadic CLL. To determine whether elevated BAFF levels correlated with features other than familial incidence, we compared clinico- biological caracteristics between patients with familial and sproradic CLL, respectively. The two groups were alike with respect to age ($p=0.82$), sex distribution ($p=0.97$), mutational status of IgVH ($p=0.682$), CD38-expression ($p=0.529$) and ZAP-70-expression ($p=0.85$). Finally, the only feature differentiating sporadic from familial CLL was serum BAFF level which was significantly higher in the latter (Sporadic CLL, 336 ng/mL; range 93-925; Familial CLL, 601 ng/mL; range, 138-8914; $p=0.002$). In conclusion our results indicate that in early B-cell CLL clinico-biological profile including among other parameters BAFF may provide a useful insight into the complex interrelationship of prognostic variables. As demonstrated by others in patients with familial lymphoproliferative disorders (J. Clin Oncol 2006, 24 : 983-987) we provide clear evidence that serum BAFF levels represent a peculiar biological feature of familial CLL.

LOW DOSE ORAL FLUDARABINE PLUS CYCLOPHOSPHAMIDE IN ELDERLY PATIENTS WITH UNTREATED AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

F. Forconi, A. Fabbri, M. Lenoci, E. Sozzi, M. Bocchia, A. Gozzetti, M. Tassi, D. Raspadori, F. Lauria

University of Siena, SIENA, Italy

Background. Fludarabine plus cyclophosphamide (FC) at conventional doses is highly effective in Chronic lymphocytic leukemia (CLL) and is currently indicated in first line therapy. Oral FC at reduced doses remains highly effective in elderly patients with low-grade non Hodgkin lymphomas other than CLL. *Aims.* to test tolerability and efficacy of oral FC at reduced doses in patients unfit for standard regimens. *Methods.* Twenty-five elderly patients with untreated (UT-CLL, n=13) or refractory CLL (R-CLL, n=12), requiring treatment according to 1996-NCI criteria, were given oral F (25 mg/m^2/day) and C (120 mg/m^2/day) in an outpatient regimen for 4 consecutive days every 4 weeks for a maximum of 4 cycles. Median age of the whole population was 70 years (range 61-80). Performance status was ≥1 in 80% patients. Tumor IGHV gene was unmutated in 90% cases. CD38 was positive in 68% and ZAP-70 in 68%. Chromosomal 11q or 17p deletions were documented in 25.5% patients. Median time from diagnosis or from prior treatment to FC was 24 months (range 1-77). Overall, biological risk and clinical characteristics were indicative of an aggressive behavior of the investigated cohort. Patients were evaluated after every cycle for toxicity and hematological response. Toxicity and responses were defined according to NCI criteria, with the exception of not repeating bone marrow aspirate after treatment termination. Progression, new treatment or death was defined as "event". *Results.* Patients received median 3 cycles (4 in UT-CLL, 3 in R-CLL). Nine-of-25 (36%) reduced the number of cycles because of fatigue (1 patient), heart failure (1), idiopathic thrombocytopenic purpura (1) in the UT-CLL (3/13) or infection (2), femur fracture (1), prolonged isolated thrombocytopenia or pancitopenia (2) and idiopathic thrombocytopenic purpura (1) in the R-CLL (6/12). Overall, 23/25 patients (92%) obtained a response (11/25 CR, 44%; 12/25 PR, 48%). Among UT-CLL, all responded to treatment (8/13 CR, 61.5%; 5/13 PR, 38.5%). Among R-CLL, 10/12 (83.5%) responded (3/12 CR, 25%; 7/12 PR, 58.5%; 2/12 NR, 16.5%). With a median follow-up of 23 months, 14/25 patients (56%) were event-free and 23/25 (92%) were alive. Among UT-CLL (median follow-up 12 months), 9/13 (69%) were event-free and all were alive. Among R-CLL (median follow-up 25 months), 5/12 (42%) were event-free and 10/12 (83%) were alive. Deaths occurred in the 2 R-CLL that had not responded to treatment, after 2 and 4 years, respectively. *Summary and Conclusions.* Despite the poor risk of the investigated population, this low-dose oral FC treatment showed good efficacy both in untreated and refractory/relapsed CLL. The treatment may be useful in elderly patients who cannot benefit of more aggressive or eradicating strategies and is easy to administer on an outpatient basis.

0094

ORAL FLUDARABINE PLUS RITUXIMAB RESULT IN HIGH COMPLETE REMISSION RATE IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

G. Del Poeta,[1] M.I. Del Principe,[1] L. Maurillo,[1] A. Siniscalchi,[1] F. Buccisano,[1] A. Coletta,[1] P. Bulian,[2] A. Venditti,[1] P. Niscola,[1] V. Gattei,[2] C. Simotti,[1] A.P. Perrotti,[1] P. De Fabritiis,[1] S. Amadori[1]

[1]Department of Hematology, University Tor Vergata, ROMA; [2]Clinical and Experimental Hematology Unit, IRCCS, AVIANO (PN), Italy

In the past two decades the treatment goal of chronic lymphocytic leukemia (CLL) shifted from symptom palliation to the attainment of maximal disease control, using the chemoimmunotherapy combinations incorporating purine analogs and monoclonal antibodies. Although intravenous (IV) fludarabine is effective against CLL, IV administration is inconvenient in an outpatient setting. The aim of this phase II study was to evaluate the efficacy and the toxicity of a regimen combining sequentially oral fludarabine phosphate (Flu) and rituximab in symptomatic, untreated CLL patients (pts). The primary end point was the overall response rate. Minimal residual disease (MRD) was assessed by a multiparametric flow cytometric method based on the detection of CD19$^+$CD5$^+$CD79b- residual B-CLL lymphocytes in bone marrow (BM). VH mutational status, CD38, ZAP-70 and cytogenetics by fluorescence *in situ* hybridization were obtained in all pts before treatment. Forty-six CLL pts, median age 65 years (range 50-79) received six monthly courses of Flu (35 mg/m^2 for 5 days) and four weekly doses of rituximab (375 mg/m^2) starting soon after completion of Flu therapy (median time 40 days). Informed consent was obtained from all pts. According to modified Rai stages, 9 pts had a low stage, 35 an intermediate stage and 2 a high stage. Eighteen of 46 (39%) pts were ZAP-70 positive, 13/46 (28%) were CD38 positive and 16/45 (36%) were IgVH unmutated. Eighteen of 46 pts (39%) showed a normal karyotype, 12/46 (26%) presented del13q and 16/46 (35%) an intermediate/high risk cytogenetic pattern (6 pts: del17p; 5 pts: del11q; 5 pts: trisomy 12). Based on NCI criteria, 37/46 (80%) patients achieved a complete remission (CR) and 9/46 (20%) a partial remission (PR). There were no differences between VH mutated and unmutated, or between ZAP-70$^+$ and ZAP-70 negative, or between CD38+ and CD38- subsets with regard to CR rate. Twenty-nine of 36 pts (80%) in clinical CR presented CD5$^+$CD19$^+$CD79b- BM cells <1% (MRD-). The main side effects were myelotoxicity and infections. Hematologic toxicity included mainly neutropenia (grade 3 and/or 4 in 16 pts), thrombocytopenia (grade 4 in 2 pts) and anemia (grade 4 in 1 patient). Five pts presented grade 3/4 (WHO) infective lung toxicity and 5 patients herpes zoster virus infection. Three patients received only oral fludarabine because grade 4 neutropenia and serious lung infections. Gastrointestinal toxicity was generally mild to moderate and did not require treatment. Although the median follow-up duration was still short (19 months), all B-CLL pts experienced a long progression-free survival from the end of induction treatment (90% at 2 years). In conclusion, the combination of oral fludarabine/rituximab provides a highly effective and well tolerable first-line option allowing us to achieve MRD negativity with a potential increase in survival time.

0095

RETROSPECTIVE COMPARISION OF EFFICASY AND TOXICITY OF FC AND FCR REGIMENS IN UNTREATED PATIENTS WITH B -CELL CHRONIC LYMPHOCYTIC LEUKEMIA

A. Nikitin,[1] A. Stadnik,[2] N. Salogub,[3] Yu. Lorie,[1] N. Tsyba,[1] A. Alexeeva,[4] N. Mashuk,[1] V. Biderman,[1] A. Zaritsky[2]

[1]Hematology Research Center of Russia, MOSCOW; [2]Center for Heart, Blood and Endocrihology, ST.PETERSBURG; [3]Pavlov Medical University, ST.PETERSBURG; [4]City Hospital 31, ST.PETERSBURG, Russian Federation

Background. Although no randomised trials have been published so far, phase II studies and retrospective comparisions have demonstrated that addition of rituximab to fludarabine containing regimens provides a significant advantage over FC or fludarabine alone in terms of response, PFS and even OS. In this retrospective study we have compared treatment outcomes in patients who received FC or FCR as initial therapy. *Aims*. The main tasks were assesement of toxicity, PFS and OS in patients treated with FC or FCR in real clinical practice. *Methods*. The study included 102 B-CLL patients who started treatment before the 1st of October, 2006 in four Russian centers. There were 69 males and 33 females. The median age was 56,5 yrs (range 40-78 yrs). Sixty two patients received FC and 40 FCR. The decision between FC and FCR was based predominantly on the availability of rituximab. FC was given in a standard 3-day schedule either intravenously (F 25 mg/m^2/d and C 250 mg/m^2/d) or per os (F 40 mg/m^2/d, C 250 mg/m^2/d). All patients in FCR group received 375 mg/m^2 of rituximab on day 1 of each cycle. *Results*. Overall and complete response rates were 87% and 39% in the FC group *vs* 95% and 60% in the FCR goup, respectively (p=0.03). The median progression free survival was 24 months in FC group and has not been reached in FCR group and the survival probability at 2 years was 75% (p=0,009). There was a clear trend in overal survival in favour of FCR, although differences were not significant (p=0,11). Pretreatment characteristics of two groups, such as stages, blood count, lymphocyte doubling time, LDH level, % of patients with bulk lymph nodes and mutational status were well matched, although there were two exceptions. First, the median time to treatment in FCR group was significantly shorter (14 months *vs* 28,5 months). Second, 35% (n=14) of patients in FCR group were younger than 50 years, while in FC group only 17% (n=11) were younger than 50 years. Multivariate Cox regression analysis using baseline characteristics showed that the addition of rituximab to FC reduced the risk of disease progression across all patient subgroups (age, time to treatment, stages) compared with FC. With adjustment on age and time to treatment, stage C and treatment without rituximab were independently associated with disease progression with hazard ratios of respectively 2.65 (CI-95% 1,7-4,0; p=0.02) and 2.3 (CI-95% 1,5-3,6; p=0.05). More patients in the FCR group experienced neutropenia grade III - IV (39% *vs* 29%). The rate of anemia and thrombocytopenia were similar in both treatment groups. Two patients in FC group developed autoimmine hemolytic anemia (AIHA). There were no cases of AIHA in patients receiving FCR. Infectious toxicity was similar, with febrile neutropenia being the most frequent event (12% of cycles in FC group and 9,5% of cycles in FCR group). *Conclusion*. The addition of rituximab to the FC regimen improves the clinical outcome in previously untreated patients with B-CLL without increased toxicity.

CHEMOIMMUNOTHERAPY REGIMEN OF FLUDARABINE, CYCLOPHOSPHAMIDE, AND RITUXIMAB FOLLOWED BY ALEMTUZUMAB AS INITIAL THERAPY FOR CHRONIC LYMPHOCYTIC LEUKAEMIA: A VALID APPROACH FOR ERADICATION OF MINIMAL RESIDUAL DISEASE

S. Galimberti, N. Cecconi, G. Cervetti, G. Buda, E. Orciuolo, F. Papineschi, F. Caracciolo, E. Benedetti, M. Petrini

Hematology, PISA, Italy

Background. Association of cyclophosphamide, fludarabine and rituximab has been reported as a very effective treatment for patients affected by chronic lymphocytic leukaemia (CLL), with 95% of overall responses (ORR) and 70% of complete remissions (CR) (*Keating MJ, JCO 2005*). Our Group previously reported that 62% of cases, persistently IgH-positive after fludarabine, achieved molecular remission after alemtuzumab administered subcutaneously, 10 mg, three times a week, for 12 weeks (*Galimberti S, J Immunotherapy 2004*). Moreover, Moreton and co-workers reported that alemtuzumab offered 20% of minimal residual disease (MRD)-negative responses, with median survivals significantly longer in MRD-negative patients compared with those achieving an MRD-positive complete remission, partial remission (PR), or not responsive (NR) (*Moreton P, JCO 2005*). *Patients*. On these bases, in the 2004 a new protocol for treatment of patients affected by advanced CLL, aged ≤65 years, started at Pisa Haematology. This protocol scheduled 4 cycles of fludarabine-cyclophosphamide-rituximab; cases in PR received further 2 cycles. Cases in CR MRD-negative underwent leukapheresis after Aracytin plus G-CSF, whereas patients in CR but still MRD-positive or in PR received alemtuzumab at the schedule above reported. After 60 days, patients were re-evaluated by molecular assays also; cases still MDR-positive received Rituximab again as *in vivo* purging before stem cell mobilization procedure. Patients MRD-negative after alemtuzumab directly underwent the stem cell mobilization. Cases achieving an MRD-negative CR stopped treatment and underwent clinical and molecular follow-up every three months for the first 3 years. Patients in CR but still positive or that became IgH-positive again after a PCR-negative phase or who harvested contaminated CD34$^+$ cells had to be considered for autologous transplantation. *Results*. Until December 2007, 16 patients have been treated according to this protocol; 11 were male, and the median age was 50 years. The median lymphocytic count was 13.1x10^6/L, median bone marrow infiltration was 43%; 25% of cases presented high β2-microglobulin levels or splenomegaly >5cm or were scored at high risk for CD38 high levels. No deletions of chromosome 17 were documented after FISH analysis. After 4/6 R-FC cycles, the ORR was 87%, with 74% of CRs. All patients completed treatment: toxicities included in half of patients WHO grade 3-4 neutropenia, 12% infections, and 10% of CMV reactivations (without disease). Ten out of the 16 patients resulted IgH-negative by fluorescent PCR assays and then underwent stem cell harvest. Seven of them mobilized >3×10^6 CD34$^+$ stem cells and 85% of harvests were uncontaminated. One patient in CR but MRD-positive, 3 patients in PR and one resistant received alemtuzumab. The patient in CR achieved the MRD-negativity, and the resistant patient achieved a good PR. Three cases received Rituximab before stem cells harvest, but they collected contaminated aphereses. With a median follow-up of 20 months, 11 patients are still in CR, 9 of them (82%) also PCR-negative. In univariate analysis, quality of response (CR *vs* PR/NR), splenomegaly and MRD-negativity after R-FC treatment were the most significant parameters conditioning PFS. In multivariate analysis, the molecular status and splenomegaly retained this significance. *Conclusions*. In conclusion, the R-FC regimen, followed by administration of alemtuzumab, allowed to achieve a very high rate of haematological complete responses and MRD eradication. Because even in the *alemtuzumab era* the eradication of minimal residual disease is associated with better overall and treatment-free survivals, the above reported combination could represent a valid approach for patients affected by advanced CLL.

0097

DEMOGRAPHICS AND SURVIVAL OF PATIENTS WITH STAGE 0 CHRONIC LYMPHOCYTIC LEUKEMIA (CLL-0) AND MONOCLONAL B CELL LYMPHOCYTOSIS WITH CLL-PHENOTYPE (MBL) IN A SINGLE CENTRE 1992-2007: EFFECT OF PROPOSED NEW DIAGNOSTIC CRITERIA

A. Yong,[1] G. White,[2] J. Stanley,[3] D. Buhrkuhl,[2] J. Phillips[2]

[1]Otago University, WELLINGTON; [2]Haematology, Wellington Hospital, WELLINGTON; [3]Public Health, University of Otago, WELLINGTON, New Zealand

Background. Little is known about the nature and prognosis of MBL or how this condition differs from early stage CLL. New diagnostic criteria to distinguish between CLL-0 and MBL have been proposed and are currently controversial.[1] *Aims*. To compare the demographics and survival of patients with CLL-0 and MBL diagnosed over 15 years in a single centre using both current and proposed new diagnostic criteria. Methods. We established a retrospective database from diagnostic immunophenotyping records and hospital clinical records for all patients with CLL or MBL (IWLLG criteria) diagnosed at Wellington Hospital 1992-2007. Dates of death were obtained from New Zealand Health Information Service. Results. 388 CLL and 44 MBL patients were identified. 203 CLL patients were Rai stage 0 at diagnosis. 154 were of unknown stage. Peripheral clone size at diagnosis was reported for 207/247 patients with CLL-0 or MBL. No significant difference was seen in demographics, CD38 status or overall survival between CLL-0 and MBL patients using current diagnostic criteria in which a lymphocyte count of 5x10^9/L is used to distinguish CLL-0 and MBL or proposed new criteria in which peripheral blood B cell clone size of 5×10^9/L is used (*Table 1*). For the 247 patients with either CLL-0 or MBL, projected medi-

an survival (Kaplan-Meier) was 8.2 yrs for patients with CD38 negative disease and 4.1 yrs for patients with CD38 positive disease (p=0.065, log-rank test). Conclusion. No significant difference in age distribution, sex ratio or proportion with CD38 positive disease was found between patients with CLL-0 and those with MBL using either current or proposed new diagnostic criteria. No significant difference in survival was found between CLL-0 and MBL patients regardless of whether peripheral blood clone size of 5×10^9/l or peripheral blood lymphocyte count of 5×10^9/l was used as a diagnostic criterion. In patients with early lymphoproliferative disease expressing a CLL immunophenotype (either CLL-0 or MBL), there was a non-significant trend to greater survival in patients with CD38 negative disease.

HCNT1 EXPRESSION AND PURINE ANALOGUE ACTIVITY: PHARMACOGENOMIC AND CLINICAL RESULTS IN CLL/SLL PATIENTS TREATED WITH 2-CDA AND RITUXIMAB

P. Bertazzoni, C. Rabascio, D. Laszlo, L. Calabrese, D. Radice, L. Orlando, L. Preda, P. Rafaniello, F. Gigli, S. Bassi, L. Nassi, G. Martinelli

European Institute of Oncology, MILAN, Italy

Background. The combination of purine analogue and rituximab represents an efficacy treatment for CLL/SLL pts. According to NCI-WG updating guidelines, a treatment failure or disease progression within 6 months to a purine analogue based regimen is defined as refractory disease (*high risk* pts) with a poor prognosis. The mechanisms of resistance are still unclear despite some preliminary suggestions seem to involve several proteins responsible for uptake and transport of nucleoside analogue into the tumour cells. *Aims*. To investigate the activity of 2-CDA and rituximab combination in CLL/SLL pts and to identify, by pharmacogenomic approaches, genetic factors that may predict clinical response for a risk adapted therapy. *Methods*. 35 pts with an active CLL (24 pts) or SLL (11 pts) were treated with a combination therapy with rituximab at a dose of 375 mg/m^2 on day 1 and 2-CdA at a dose of 0.1 mg/kg (subcutaneously) per day for 5 days. The treatment was repeated every 4 weeks for 4 cycles. The median age was 59 years (31-76). 43% of pts were pre-treated. All pts performed a CT scan of the abdomen at baseline and at the and of treatment. Minimal residual disease (MRD) assessment was evaluated by flow-cytometry and PCR methods. Using ABI PRISM 7000 Real Time PCR platform we investigated the hCNT1 expression encoding for concentrative nucleoside transporters protein. Relative quantification was performed using the Delta Ct calculation: the value of gene expression was normalised to the calibrator (healthy tissue cells and healthy donors peripheral blood cells). The pharmacogenomic analysis was done in bone marrow for SLL and in peripheral blood for CLL, in 19 pts (14 CLL and 5 SLL). Results. The overall response rate was 92% (49% CR and 43% PR). SLL pts achieved 100% of ORR. At baseline the abdomen CT scan was abnormal in 33 pts and it remains abormal at revaluation in 16 pts. 8 pts achieved a negative MRD by flow-cytometry. With a median follow-up of 16 months (1,5- 44) 13 pts progressed with a median TTP of 9,8 months (2-40). 50% of pts with abnormal CT scan experienced a PD with a median TTP of 3 months while 29% with a normal CT scan at the and of therapy progressed with a median TTP of 13 months. The pharmacogenomic analysis showed a significance difference in terms of hCNT1 expression levels between patients with a refractory and no refractory disease (p=0,0214). There was no statistical difference in terms of hCNT1 expression between CLL and SLL pts. *Conclusions*. The combination of 2-CDA and rituximab is associated with a high response rate. The high rate of relapse observed in pts with abnormal CT scan underlies the relevant role of this radiological examination. The low levels of hCNT1 expression measured in high risk patients need to be confirmed in a larger studies and correlated, if possible, with other negative prognostic factors such as the presence of del (17) (p13.1) to better understand the reduced efficacy of purine analogue in pts with refractory disease.

BCR/ABL ONCOGENIC KINASE INHIBITS MISMATCH REPAIR TO PROTECT FROM APOPTOSIS AND INDUCE POINT MUTATIONS

T.S. Stoklosa,[1] T. Poplawski,[2] M. Koptyra,[3] M. Nieborowska-Skorska,[3] G. Basak,[1] A. Slupianek,[3] M. Rayevskaya,[4] I. Seferynska,[5] L. Herrera,[4] J. Blasiak,[2] T. Skorski[3]

[1]The Medical University of Warsaw, WARSAW, Poland; [2]Department of Molecular Genetics, University of Lodz, LODZ, Poland; [3]Department of Microbiology and Immunology, Temple University, PHILADELPHIA, USA; [4]Department of Pediatrics/Hematology, Temple University, PHILADELPHIA, USA; [5]Department of Hematology, Institute of Hematology and Blood Transfusion, WARSAW, Poland

Background. BCR/ABL oncogenic tyrosine kinase transforms hematopoietic stem cells to induce chronic myelogenous leukemia (CML) and acute lymphocytic leukemia (ALL). BCR/ABL kinase can also increase DNA damage and compromise the fidelity of DNA repair causing genomic instability. Accumulation of genetic abnormalities is believed to be responsible for resistance to the small molecule inhibitors such as imatinib, dasatinib and nilotinib, and for transition of a relatively benign chronic phase (CML-CP) to the fatal blast crisis (CML-BC). Mismatch repair (MMR) system maintains genomic stability by removing mismatched bases from DNA and by inducing apoptosis in cells with excessive DNA damage, the role of MMR activity in leukemia cells remains unclear. *Aims*. Examining the role of mismatch repair system in genetic instability of CML cells. *Methods*. 32Dcl3, Baf3 murine IL-3-dependent cell lines and their BCR/ABL-transformed counterparts were used. Primary CML CD34$^+$ patient cells were used after receiving informed consent. For measurement of MMR activity the plasmid substrate was used containing EGFP gene with T:G mismatch-corrupted start codon. The mismatch can be corrected to T:A by MMR, which restores T-A match and EGFP expression as determined by flow cytometry measuring the number of EGFP$^+$ cells. N-methyl-N-nitro-N-nitrosoguanidine (MNNG) was used as a mutagen inducing MMR-sensitive DNA lesions and ouabain-resistance as an indicator of mutagenesis in Na^+/K^+ ATPase to further assess mutation rate and phenotype. Cell viability was assessed by trypan blue exclusion, clonogenic tests of cells surviving MNNG challenge were done in methylcellulose. MMR proteins expression was analyzed by Western blotting, while nuclear localization by immunofluorescence microscopy. *Results*. The efficacy of MMR was reduced 2-fold in BCR/ABL-positive cell lines and CD34$^+$ CML cells in comparison to normal counterparts as measured by MMR activity assay. Impaired MMR activity in leukemia cells was associated with better survival, resistance to apoptosis and accumulation of p53 but not of p73 after treatment with MNNG, which induces DNA lesions that recognized by the MMR pathway. In contrast, parental cells displayed accumulation of p53, p73, and activation of caspase 3 resulting in cell death (Figure 1).

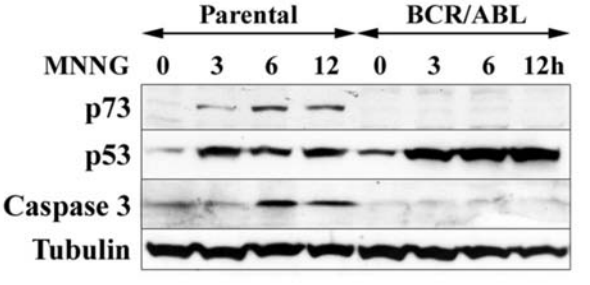

Figure 1.

BCR/ABL-positive cells, surviving the treatment with MNNG, displayed 15-fold higher mutation frequency than parental counterparts as determined by ouabain-resistance test. More than 70% of mutations in BCR/ABL cells were G:C'A:T and A:T'G:C transitions. Western blotting and immunofluorescence studies indicated that total and nuclear expression of MMR proteins (MSH2, MSH6, MLH1, PMS2) did not differ in BCR/ABL-positive and normal cells, but their nuclear co-localization in response to MNNG was severely impaired in the former cells. The

defects in activity of MMR system and interaction of MMR proteins in leukemia cells were reversed by inhibition of BCR/ABL kinase with imatinib. *Summary and Conclusions*. We observed reduced MMR activity in CML cells associated with higher mutation frequency. Deregulated MMR activity in CML cells may be directly responsible for generation of point mutations in bcr/abl kinase sequence (and in other genes) causing resistance to small molecule inhibitors and malignant progression of the disease. The precise effect of BCR/ABL kinase on MMR pathways requires further studies.

HIGH-RESOLUTION MAPPING OF DELETIONS OF CHROMOSOME 9Q+ IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA BY SNP-ARRAYS: WHICH GENES MATTER?

S. Colarossi,[1] A. Gnani,[1] S. Soverini,[1] F. Castagnetti,[1] G. Marzocchi,[1] S. Luatti,[1] A. Astolfi,[2] S. Formica,[2] I. Iacobucci,[1] E. Ottaviani,[1] F. Palandri,[1] A. Poerio,[1] M. Amabile,[1] G. Rosti,[1] A. Pession,[2] N. Testoni,[1] M. Baccarani,[1] G. Martinelli[1]

[1]Institute of Hematology and Medical Oncology Seràgnoli, BOLOGNA; [2]Pediatric Oncology and Hematology L. Seràgnoli, BOLOGNA, Italy

Background. Extensive submicroscopic deletions 5' to ABL and/or 3' to BCR on the derivative chromosome 9 (9q+) may be detected at diagnosis in a proportion of patients (pts) with chronic myeloid leukemia (CML). 9q+ deletions (del9q+) have been associated with adverse outcome in pts treated with chemotherapy of interferon, but whether or not they retain prognostic significance in the imatinib era still remains a matter of controversy. *Aims*. Last year we presented the results of a study conducted on 442 newly diagnosed CML pts enrolled in GIMEMA CML WP studies of imatinib between Jan 2004 and Jan 2006. The rates of complete cytogenetic response and major molecular response were shown not to differ significantly between pts with (n=55) and without (n=387) del9q+. It can be hypothesized that the size of the deleted region may be a confounding variable and that one or more critical genes lost in some cases and retained in others may be responsible for differences in pt response and outcome. In order to address this issue, we planned to use SNP-arrays to perform a high-resolution mapping the deleted region in the 55 pts who were known to carry del9q+ as assessed by FISH analysis. *Methods*. Genomic DNA could be extracted from bone marrow mononuclear cells archived at diagnosis in 42/55 pts. SNP-array-based karyotyping was perfomed using Affymetrix GeneChip Human Mapping 250K Nsp arrays. Copy number analyses were performed using 48 Hapmap normal individuals as reference set and Partek Genomic Suite software. *Results*. Results obtained in the subset of 13 pts analyzed so far show that the extension of genomic loss is variable in size. The deleted region spanned 600 kb to 2.3 Mb 5' to ABL and/or 150 kb to 7.8 Mb 3' to BCR, with overall deletion size ranging from 3 to 8 Mb. Detailed maps of genes involved were generated for each pt. The comparison of these maps highlighted clusters of genes (8 in the region 5' to ABL and 13 in the region 3' to BCR) that were lost in different subgroups of pts. On chromosome 9, they included the PP2A inhibitor SET; PPP2R4, encoding the regulatory subunit of PP2A; the oncogenic transcription factor *PRDM12*; *TOR1A* and *TOR1B*, two ATPases involved protein folding; hsa-mir-199b and hsa-mir-219-2 micro RNAs; on chromosome 22, they included MIF, a lymphokine involved in tumor cell motility; the splicing factors *TFIP11* and SF3A1; the *PIB5PA, PTPNS1L* and DUSP18 phosphatases; the *ADRBK2* receptor kinase; the mitotic spindle assembly checkpoint regulator *MAD1*; the regulator of chromatin *SMARCB1*; the Rgr oncogene, encoding a Ras activator; the *CHEK2* ser/thr kinase; the oncogenic transcriptional co-activator MN1. *Conclusions*. Molecular characterization of del9q+ has so far been performed only by FISH. To the best of our knowledge, this is the first study allowing a high-resolution mapping of sequences involved in del9q+. Analysis of pts is ongoing and complete results, including clinical correlations with Sokal risk and response to imatinib treatment will be presented at the meeting.

PHILADELPHIA -POSITIVE LEUKAMIA PATIENTS ALREADY HARBOURING ABL KINASE DOMAIN MUTATIONS HAVE A HIGHER LIKELIHOOD OF DEVELOPING FURTHER MUTATIONS UNDER THE SELECTIVE PRESSURE OF NOVEL TYROSINE KINASE INHIBITORS

S. Soverini,[1] A. Gnani,[1] S. Colarossi,[1] F. Castagnetti,[1] F. Palandri,[1] S. Paolini,[1] E. Abruzzese,[2] S. Merante,[3] M. Rondoni,[4] I. Iacobucci,[1] A. Poerio,[1] M. Amabile,[1] C. Papayannidis,[1] P. Giannoulia,[1] G. Rosti,[1] M. Baccarani,[1] G. Martinelli[1]

[1]Institute of Hematology and Medical Oncology L.e A. Seràgnoli, BOLOGNA; [2]Department of Hematology Tor Vergata UNIVERSITY OF ROMA; [3]Division of Hematology, PAVIA; [4]Hematology Unit, RAVENNA, Italy

Background. Resistance to the Bcr-Abl tyrosine kinase inhibitor (TKI) imatinib mesylate (IM) in patients (pts) with chronic myeloid leukemia (CML) and Philadelphia-positive (Ph^+) acute lymphoblastic leukemia (ALL) is often caused by selection of point mutations in the Abl kinase domain (KD) altering residues that are directly or indirectly critical for IM binding. To circumvent this problem, novel TKIs have been rationally developed. Each of them, however, can be expected to retain its own Achilles heels, including novel inhibitor-specific mutations. *Aims*. To assess a) which mutations develop *in vivo* under dasatinib or nilotinib treatment and b) how Abl KD sequences evolve under the selective pressure of sequential therapy with novel TKIs. *Methods*. We have monitored the mutation status of 95 IM-resistant pts before and during treatment with up to two consecutive novel TKIs (dasatinib, nilotinib). Forty-five pts (47%) had CML in chronic phase; 50 pts (53%) had CML in accelerated/blastic phase (AP/BP) or Ph^+ ALL. *Results*. At the time of IM failure, 51/95 (54%) pts had KD mutations. After switching to a 2nd TKI (n=95 pts), 19/51 (38%) pts who had mutations at baseline as against 7/44 (16%; p=.02) pts who did not have mutations at baseline subsequently relapsed with newly acquired mutations. Median time to relapse was 8 months (range, 1-22). Cloning showed that these mutations could either be acquired by the pre-existing mutated subclone or arise in an independent one. In addition, 14/51 mutated pts did not respond to the 2nd TKI because of the mutation they were harbouring at baseline. After switching to a 3rd TKI (n=16 pts), 10/13 mutated pts as against 0/3 non-mutated pts relapsed with newly acquired mutations. Median time to relapse was 3 months (range, 1-5). Switch to a 4th TKI (MK-0457, PHA-739358) has so far been attempted in 3 mutated pts, but observation time is still too short. Newly acquired mutations in pts who failed dasatinib were *T315I, F317L, V299L, T315A, F317I/S/V*. Newly acquired mutations in pts who failed nilotinib were *Y253H, E255V/K, L273M, T315I*. More detailed analyses will be presented. *Conclusions*. (a) In IM-resistant pts treated with 2nd/3rd TKIs, Abl KD mutations are often the mechanism by which the Ph^+ clone tries to escape from inhibition (90% of failures associated with presence/emergence of mutations). However, the spectrum of *critical* mutants is very limited as compared to that of IM. b) Pts already harbouring mutations, especially those with CML in AP/BC or with Ph^+ ALL have a higher likelihood of developing further mutations under the selective pressure of novel TKIs. It can be hypothesized that in these pts a higher genetic instability may foster rapid emergence of multiple mutations over time within the same or different Bcr-Abl-positive subclones, which are selected or de-selected depending on the sensitivity profile of the specific TKI employed. In this clinical setting combination therapies would probably be more effective than single-agent treatment for long-term disease control.

P210-DERIVED PEPTIDE VACCINATIONS IN CML PATIENTS INDUCE *NOT REGULATORY* $CD4^+$/ $CD25^{High+}$/$FOXP3^+$ AND $CD4^+$/$PERFORIN^+$ PEPTIDE-SPECIFIC T CELLS

M.B. Bocchia,[1] M. Ippoliti,[1] M. Tassi,[1] E. Abruzzese,[2] M. Defina,[1] M.M. Trawinska,[2] A. Gozzetti,[1] D. Raspadori,[1] R. Crupi,[1] F. Lauria[1]

[1]University of Siena, SIENA, Italy; [2]S. Eugenio Hospital, ROMA, Italy

Background. We have previously shown that vaccination of chronic myelogenous leukaemia (CML) patients with CMLVAX100 (a mixture of 5 p210-b3a2 breakpoint derived peptides) plus GM-CSF was able to induce an evident and durable peptide-specific $CD4^+$ T cell response in the majority of patients. Peptide-specific $CD4^+$ T cell proliferation was measured by standard [^{3}H] thymidine incorporation assay and this response was mainly mediated by a 25 mer long breakpoint peptide

(b3a2-25) included in the vaccine. In this pilot clinical trial we showed that about 60% of 32 CML patients vaccinated while on imatinib, showed a reduction of their long lasting molecular residual disease after immunization (first 6 vaccinations) and about 25% of them achieved in addition a complete molecular response. *Aims*. To investigate the contribute of this peptide specific $CD4^+$ T cell response in antitumor activity, we further characterize peptide-induced proliferating $CD4^+$ cells. *Methods*. Briefly, in 10 *CMLVAX100* vaccinated patients in which a strong b3a2-25 specific $CD4^+$ proliferation was previously observed, we freshly isolated peripheral blood $CD4^+$ T cells and we cultured them 4 days only in the presence or not of b3a2-25 vaccine peptide or control PR-25 peptide. Afterwards, each culture condition was analyzed both for the co-expression of CD25, perforin and *FOXP3* molecules and for standard [^{3}H] thymidine incorporation assay. *Results*. As expected all patients showed a strong b3a2-25 specific $CD4^+$ proliferation (mean stimulation index 43 -range 19 to 81-). When flow cytometric analysis was performed, we observed a consistent increase of two main $CD4^+$ T cells subsets only in the b3a2-25 stimulated $CD4^+$ T cells, not in *no peptide* or *control peptide* stimulated $CD4^+$ T cells. 1) a *small-size* $CD4^+$/perforin$^+$ T cell population (raising from a median of 1.% (range 0.21-5.2) to 2.3% (range 0.49-6.2) with potential cytotoxic activity 2) a *large-size* $CD4^+$/$CD25^{+high}$/$FOXP3^+$ T cell population (raising from 0.29 % (range 0.03-0.66) to 5.65% (range 0.71-9.5) with potential regulatory function. Since the large size of the latter cells and their high proliferative activity would argue against a regulatory features and considering that the immunophenotypic profile of Tregs in human is not yet fully defined, in 3 selected vaccinated patients we expanded the $CD4^+$/$CD25^{+high}$/$FOXP3^+$ population with further *in vitro* b3a2-25 peptide stimulations and then we performed a *functional test* to measure its potential regulatory activity. Hence, we evaluated the ability of expanded b3a2-25 peptide specific $CD4^+$/$CD25^{+high}$/$FOXP3^+$ T cells to inhibit the growth of CFSE labelled normal subjects naïve $CD4^+$ T cells stimulated with autologous CD3-depleted APCs and antiCD3 plus antiCD28 MoAbs. In our experimental conditions, naïve CFSE $CD4^+$ T cells equally proliferated in the presence of b3a2-25 specific $CD4^+$/$CD25^{+high}$/$FOXP3^+$ T cells (at various peptide-specific: naïve T cell ratios), *no peptide* $CD4^+$ cells or PR-25 control peptide stimulated $CD4^+$ cells and the rate of proliferation was similar to the one observed in co-culture experiments with allogeneic normal $CD4^+$ cells. *Conclusions*. Our data confirmed that CMLVAX100 vaccinated CML patients mount *in vivo* a strong $CD4^+$ proliferative response specific for the b3a2-25 peptide contained in the vaccine. Some $CD4^+$ cell are perforin+, but the majority are $CD4^+$/$CD25^{+high}$/$FOXP3^+$. The latter display no *regulatory* activity despite their phenotype. Whether and how these peptide-specific $CD4^+$ T cells directly exert an antitumor activity against CML cells is now under evaluation.

PATIENT-SPECIFIC IC50 ASSAYS IN IMATINIB-RESISTANT CML PATIENTS ARE HIGHLY VARIABLE AND MAY BE CLINICALLY RELEVANT

D. White,[1] V. Saunders,[1] S. Quinn,[2] T. Hughes[1]

[1]IMVS and Hanson Institute, ADELAIDE; [2]Novartis Pharmaceuticals, SYDNEY, Australia

Background. We have previously demonstrated that in-vitro measurement of patient specific sensitivity to imatinib induced kinase inhibition (IC50imatinib) provides a key predictor of molecular response in imatinib treated *de novo* CML patients.[1] While overall responses to imatinib in chronic phase CML patients are excellent, some 15-20% of patients fail to respond or develop secondary resistance. The choice of second line therapy has, until recently, been guided largely by drug availability or clinical trial access. *In vitro* modelling of more common kinase domain mutants may provide an indicator for second-line drug choice, but this approach provides little guidance in patients with less common mutations, multiple mutations, in resistant patients without mutations, or in whom mutations are undetectable. *Aims.* To assess the predictive value of the patient specific IC50 assay, for achievement of 1 and 2 log reduction in BCR-ABL respectively, and progression in a cohort of imatinib-resistant patients treated with nilotinib for up to 24 months. *Methods*. Blood was collected from 12 imatinib resistant patients, immediately prior to nilotinib therapy. The IC50nilotinib was determined *in vitro* by assessing the reduction in phosphorylation of the adaptor protein Crkl (p-Crkl), an immediate downstream partner of BCR-ABL1. *Results*. The median IC50nilotinib was 78nM (Range:35-250nM). Seven of 12 (58%) patients achieved a 1 log reduction in BCR-ABL over the treatment course and 5 of the 12 (42%) achieved a 2 log reduction in BCR-ABL. There was a marked difference in the IC50nilotinib between those patients who achieved, and those that failed to achieve these milestones (Table 1). Four of the 12 patients progressed on nilotinib (median time to progression 3 months). There was a significant difference in IC50nilotinib between these patients and those who did not progress (median time on study 21months) $p<0.001$ Table 1. Five patients had baseline mutations. Four of these mutations have been assessed by in-vitro modeling, and all 4 have low IC50 75, 13, 67 and 35 nM. The patient specific IC50nilotinib for this cohort were 66, 180, 210, 250 and 180nM. Interestingly, the IC50 in patients without baseline mutations range from 30 to105nM (Median 60nM), which is not significantly different from that observed in *de novo* CML patients (median 57nM; range 12-85nM n=40). Hence, substantial interpatient variation in IC50, not attributable to assay variability, is observed in patients with mutations, but not significantly in resistant patients without mutations. *Conclusion*. This small dataset suggests that the IC50 assay, developed for *de novo* patients, is also applicable to imatinib-resistant patients. This assay provides a measure of the intrinsic sensitivity to nilotinib induced kinase inhibition. It may provide a more accurate predictor of the subsequent response or risk of progression for individual patients than published IC50 data from modeled constructs, which address only the nilotinib sensitivity of the predominant mutated clone. This assay warrants further assessment regarding its predictive value for second line therapy in imatinib resistant patients.

Table 1. Demonstrating the median IC50nilotinib for patient.

	Median $IC50^{nilotinib}$	
Milestone :-	**Yes**	**No**
1 log reduction in BCR-ABL	66nM (45-78nM)* n=7	180nM (89-220nM)* n=5
2 log reduction in BCR-ABL	66nM (55-76nM)* n=5	110nM (56-203nM)* n=7
Progression	195nM {Range 105-250nM} n=4	63nM {Range 35-120nM} n=8

PHILADELPHIA CHROMOSOME POSITIVE (PH^+) LEUKEMIA CELLS ARE NOT ENRICHED IN THE PRIMITIVE ($CD34^+CD38^-$) STEM CELL FRACTION DURING TYROSINE KINASE INHIBITOR THERAPY

S. Mustjoki,[1] P. Rohon,[1] K. Rapakko,[2] S. Hernesniemi,[3] P. Koskenvesa,[3] T. Lundan,[3] K. Porkka[3]

[1]Hematology Research Unit, HELSINKI; [2]Genetics Laboratory, Department of Laboratory, Oulu University Hospital, OULU; [3]Hematology Research Unit, Department of Medicine, HELSINKI, Finland

Background. Targeted tyrosine kinase inhibitors (TKIs) efficiently induce rapid hematologic and cytogenetic remission in most chronic myeloid leukemia (CML) patients. However, a small population of resistant primitive leukemia stem cells remains even after years on therapy, as rapid leukemia relapse occurs in patients who discontinue TKI therapy. *In vitro* experiments have suggested that the most primitive CML stem cells reside in the $CD34^+CD38^-$ fraction of bone marrow (BM) and are relatively resistant to TKIs, but thus far there are no reports describing the prevalence of these cells in patients under TKI therapy. *Aims.* The aim of this project was to analyze the effect of TKI therapy on Ph^+ leukemia stem cells *in vivo*. *Methods*. Large volume (median 26 mL) of BM aspirate samples from chronic phase CML patients under TKI therapy were collected (n=14) and CD34 positive cells were separated with immunomagnetic columns. CD34 positive cells were further sorted into $CD34^+CD38^+$ and $CD34^+CD38^-$ cell populations with multicolor flow cytometry in order to analyze progenitor cell fractions of different mat-

uration stage. Proportion of Ph+ cells was determined with fluorescence *in situ* hybridization (FISH) by counting 1000 cells in each fraction. *Results*. Of 14 patients with CML 11 were in complete cytogenetic remission (CCyR) when assessed by metaphase FISH of non-fractionated BM cells. Only one patient had Ph^+ cells detectable in the $CD34^+$ fractions. In remainder of patients, all progenitor cell fractions, including the most primitive $CD34^+CD38$- cells, were negative for Ph^+ cells. Of 4 patients not in CCyR and thus with detectable Ph^+ cells in total BM fraction, three had Ph^+ cells in $CD34^+$ progenitor cell fractions. However, the proportion of Ph^+ cells was not increased in the most primitive $CD34^+CD38^-$ cell fraction, as expected, but was at the same (patient 5, Table 1) or lower level (patients 13 and 14, Table 1), as compared to non-fractionated BM. *Conclusions*. Based on our data, in chronic phase CML patients, TKI therapy eradicates most Ph^+ $CD34^+$ progenitor cells. Unexpectedly, leukemic stem cells were not enriched in the most primitive $CD34^+CD38^-$ cell fraction *in vivo*. These results differ from the *in vitro* studies, where $CD34^+CD38^-$ cells have been shown to be resistant to TKIs. This could be due to non-physiological conditions (growth factor sensitivity, other cytokines) in cell culture assays. Our data underline the tremendous proliferative potential of very rare stem cells in CML patients in CCyR, as is evident after discontinuation of TKI therapy. Future studies evaluating the kinetics of disappearance of Ph^+ cells from stem cell fractions during TKI therapy are warranted and may give important information on the depth of the therapy response.

Table 1.

Pt	Treatment	Months on TKI	% BCR-ABL/GUS	BM FISH (% of Ph+ cells)			
				Non-fractionated	CD34+ $CD38^{high}$	CD34+ $CD38^{med}$	CD34+ $CD38^{neg}$

FOXO TRANSCRIPTION FACTOR IS DELOCALIZED AND INACTIVATED IN CML PATIENTS BY BCR-ABL ONCOGENIC SIGNALLING

F. Messa,[1] C. Panuzzo,[1] F. Arruga,[1] P. Nicoli,[1] E. Messa,[1] A. Morotti,[1] A. Rotolo,[1] S. Carturan,[1] T. Kalebic,[2] I. Iacobucci,[3] G. Martinelli,[3] E. Bracco,[1] G. Saglio,[1] D. Cilloni[1]

[1]University of Turin, TORINO; [2]Novartis Oncology, EAST HANOVER, USA; [3]University of Bologna, BOLOGNA, Italy

Background. The FoxO family of transcription factors is regulated by PI3K/Akt induced phosphorylation resulting in nuclear exclusion and degradation. Nuclear FoxO transcribes proapoptotic molecules and cell cycle inhibitors. In CML cells the TK activity of Bcr-Abl leads to the abnormal activation of downstream effectors including PI3K/Akt. The aim of this study was to investigate the role of FoxO in Bcr-Abl induced apoptotic arrest and cell growth and the consequence of imatinib (IM) treatment on FoxO activity. *Methods*. BM cells were collected from 30 CML patients and 20 healthy donors. The expression levels of FoxO were tested by RQ-PCR, FoxO protein amount and localization by Western blot (WB) and immunofluorescence and DNA binding activity by EMSA. Foxo was analyzed also in CML cells and Ph+ cell lines after incubation with IM and LY294002. Finally, we transfected cells with FoxO constitutively activated and we evaluated cell growth and apoptosis. Finally we used our already set up model of Drosophila melanogaster (Dm) transgenic for human Bcr-Abl to study the pathways leading to FoxO inactivation. *Results.* We found that the amount of FoxO mRNA and protein is similar in CML cells and controls. FoxO protein is equally distributed in the nucleous and cytoplasm in controls but is completely cytoplasmatic in CML cells and it enters the nucleous during IM treatment.Additionally, FoxO DNA binding activity in CML patients is completely absent at diagnosis and reappears after IM or LY294002 treatment. Cells transfected with the mutant form of FoxO showed a decreased rate of apoptosis and increased proliferation. The progeny obtained from the crossbreeding of Bcr-Abl flies and flies transgenic for FoxO showed a rescue of FoxO phenotype demonstrating that FoxO inactivation is Bcr-Abl mediated. In addition, the crossbreeding between Bcr-Abl flies and flies carrying inactivated FoxO mutant results into a progeny showing a mild phenotype suggesting that FoxO mediates Bcr-Abl oncogenic pathway. *Conclusions*. Taken together these observations suggest that FoxO is inactivated in CML cells and its delocalization is mainly dependant from Bcr-Abl activity. This results in increased proliferation and reduced apoptosis and it may be crucial for Bcr-Abl oncogenic pathway. The antiproliferative activity of IM may be mediated by FoxO re-localization.

DOWN-REGULATION OF PROTEIN TYROSINE PHOSPHATASE γ (*PTPRG*) IN CHRONIC MYELOID LEUKEMIA (CML)

M. Della Peruta,[1] M. Martinelli,[2] M. Monne,[3] D. Pintani,[4] T. Grafone,[2] I. Iacobucci,[2] M. Murineddu,[3] F. Vinante,[5] C. Tecchio,[5] M. Vezzalini,[4] G. Piras,[3] A. Gabbas,[3] A. Mafficini,[4] C. Sorio[4]

[1]University of Verona, VERONA; [2]Institute of Hematology and Medical Oncology Lorenzo e Ariosto Seragnoli, BOLOGNA; [3]Centro di Diagnostica Biomolecolare e Citogenetica Emato-Oncologica San France, NUORO; [4]Department of Pathology/General Pathology Section; University of Verona, VERONA; [5]Department of Clinical and Experimental Medicine/Hematology Section; University, VERONA, Italy

Background. Chronic Myelogenous Leukemia (CML) is the most common myeloproliferative disease while Receptor Protein Tyosine Phosphatase Gamma (PTPRG) has been implicated as a candidate tumor suppressor gene being its expression reduced in various neoplasms and somatic mutation detected in colon cancer. *PTPRG* regulates murine hemopoiesis and is expressed in specific hematopoietic lineages including $CD34^+$ cells. *Aims*. Explore the possibility that *PTPRG* could be involved in the pathogenesis of CML. *Methods*. mRNA and protein levels were measured in cell lines, bone marrow and peripheral blood cells by real-time PCR and flow cytometry using a newly developed antibody specific for the extracellular domain of *PTPRG*. Proliferation, clonogenic and xenografting assays were used to study the effect of *PTPRG* cDNA transfection in CML cell lines. *Results*. We found that PTPRG expression was undetectable in two of four CML cell lines analyzed. Its loss correlates with higher clonogenicity and proliferation capabilities, while re-expression inhibits both parameters, reduces tyrosine phosphorylation and induces myeloid differentiation in stably transfected K562 cells. The oncosuppressive and differentiation-inducing effect of PTPRG was confirmed *in vivo* after xenotransplantation in a nude mice model. *PTPRG* is down regulated at mRNA and protein levels in leukocytes of CML (but not of chronic lymphocytic leukemia-CLL) patients in both peripheral blood and bone marrow, including $CD34^+$ cells, and is reexpressed following molecular remission of the disease. *Conclusions*. Loss of *PTPRG* expression is associated to the pathogenesis of CML and designate *PTPRG* as a new pharmacological target. Measurement of *PTPRG* expression levels might find clinical application for confirming diagnosis and for following progression of disease and treatment.

0107

ABL KINASE DOMAIN MUTATIONS ARE INFREQUENT IN EARLY-CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS RESISTANT TO IMATINIB

S. Soverini,[1] A. Gnani,[1] S. Colarossi,[1] F. Castagnetti,[1] F. Palandri,[1] E. Abruzzese,[2] E. Orlandi,[3] M. Breccia,[4] G. Specchia,[5] F. Gherlinzoni,[6] A. Poerio,[1] M. Amabile,[1] I. Iacobucci,[1] G. Rosti,[1] M. Baccarani,[1] G. Martinelli[1]

[1]Institute of Hematology and Medical Oncology L.e A. Seràgnoli, BOLOGNA; [2]Department of Hematology Tor Vergata, UNIVERSITY OF ROME; [3]Division of Hematology, PAVIA; [4]Department of Hematology La Sapienza, ROMA; [5]Department of Hematology, BARI; [6]Hematology Unit, TREVISO, Italy

Background. Point mutations in the kinase domain (KD) of the Bcr-Abl gene are generally regarded as the most frequent mechanism of resistance to the tyrosine kinase inhibitor (TKI) imatinib mesylate (IM) in patients (pts) with chronic myeloid leukemia (CML). Nearly all studies, however, have focused mainly on pts with advanced disease, where resistance is most often observed. Nowadays, the great majority of pts on IM are early chronic phase (ECP) pts receiving IM as front-line treatment. If, on one hand, the IRIS study demonstrated that response rates are high and relapse is infrequent in ECP, on the other hand we still know very little on the contribution of KD mutations to resistance in this subset of pts. *Aims*. To assess the incidence of ABL KD mutations in ECP. *Methods*. Between January 2005 and January 2008 we analyzed for the presence of Abl KD mutations one hundred and six ECP pts on IM who were referred to our laboratory because their response was defined either as failure (n=72 pts) or as suboptimal (n=34 pts) according to recently published recommendations (*Baccarani et al., Blood 2006*). *Results*. Twenty mutations were detected in 18/72 (25%) pts who failed IM. In particular, mutations were observed in 1/2 pts who showed no hematologic response (HR) at 3 months, 1/10 (10%) pts who showed less than partial cytogenetic response (PCgR) at 12 months, 4/25 (16%) pts who showed less than complete cytogenetic response (CCgR) at 18 months, 7/25 (28%) pts who lost CCgR, 5/10 (50%) pts who lost HR. Mutations were M244V (n=2), G250E (n=1), Y253H (n=4), E255K (n=1), T277A (n=1), E279K (n=1), F311I (n=1), T315I (n=1), M351T (n=3), E355D (n=1), F359V (n=1), H396R (n=3). In 7 pts who progressed to accelerated or blastic phase shortly after, four had mutations: Y253H (n=2 pts), E255K (n=1 pt) and T315I (n=1 pt). Four mutations were detected in 4/34 (13%) pts who had a suboptimal response to IM. In particular, a mutation was observed in 1/13 (9%) pts who showed less than PCgR at 6 months and in 3/21 (14%) pts who showed less than CCgR at 12 months. Mutations were E255K, F317L, M351T, F359V. In both groups no correlation was observed between likelihood of mutation selection and Sokal risk score. *Conclusions*. In ECP pts who receive IM as front-line treatment Abl KD mutations are not the major mechanism of drug-resistance, probably because mutations tend to accumulate during the natural course of the disease as a result of a progressively increasing genetic instability and are therefore a feature of CML clinical deterioration rather than a phenomenon observed only against a background of IM exposure. Our data highlight the need to find out which is the actual predominant mechanism(s) of resistance acting in the setting of ECP - which now gathers the overwhelming majority of CML pts on IM therapy - as a mandatory step towards the development of effective second-line treatment strategies.

THE EFFECT OF IMATINIB MESYLATE ON THE SIGNAL TRANSDUCTION CASCADE REGULATING TELOMERASE ACTIVITY IN K562 CELLS AND IN K562 CELLS RESISTANT TO IMATINIB MESYLATE

R. Mor,[1] O. Uziel,[2] O. Shpilberg,[3] J. Lahav,[4] P. Raanani,[3] E. Rabizadeh,[4] Y. Zimra,[4] M. Lahav,[5] G. Granot[2]

[1]Felsenstein Medical Research Center, PETAH-TIKVA; [2]Felsenstein Medical Research Center, Beilinson Hospital, PETAH-TIKVA; [3]Felsenstein Medical Research Center, Institute of Hematology, Beilinson Hospital, PETAH-TIKVA; [4]Felsenstein Medical Research Center, Hematology Laboratory, Beilinson Hospital, PETAH-TIKVA; [5]Felsenstein Medical Research Center, Medicine A, Beilinson Hospital, PETAH-TIKVA, Israel

Background. Imatinib mesylate (IM) is a tyrosine kinase inhibitor selective for bcr-abl, c-Kit, and PDGFR. IM inhibits kinase activity through competition for ATP binding and is indicated for the treatment of newly diagnosed chronic myeloid leukemia (CML) patients. Recent publications have demonstrated that IM may also target other cellular components. In light of the important role of telomerase in malignant transformation, we were interested in the effect of IM on telomerase activity (TA) and on the signal transduction cascade upstream of it. The signal transduction cascade we focused on was: PI3K activation occurs following growth factor binding to its receptor. Active PI3K phosphorylates PIP2 generating PIP3. The balance of cellular PIP3 is also regulated by PTEN, a phosphatase that reduces PIP3 levels. PIP3 promotes AKT translocation to the plasma membrane. There, altered conformation of the protein allows subsequent phosphorylation by PDK-1. AKT is one of the kinases known to phosphorylate and activate telomerase. Aims To evaluated the effect of IM on the signal transduction cascade leading to modulation of TA in the bcr-abl positive K562 cell line and also in an IM resistant K562 cell line (K562res). The effect of IM on TA in the K562res cells is unknown. Using these cells will enable us to study the connection between the signal transduction cascade activated by bcr-abl and the cascade leading to telomerase activation. *Methods*. TRAP assay was used for detecting TA. RT-PCR and Western blots were used to detect levels of RNA and protein of the different cascade members. FACS analysis was used for cell-cycle studies. *Results*. IM caused an 80% inhibition of TA in both K562 and K562res cell. Inhibition of TA was not caused by changes in the transcription level of hTERT (the catalytic subunit of the enzyme). Telomerase is also regulated at the post-translational level through phosphorylation by p-AKT. A 60-85% reduction in p-AKT level was observed following IM incubation in both cell lines. In addition, the expression of PDK-1, known to phosphorylate AKT, was downregulated, explaining the dephosphorylation of AKT observed in the presence of IM. The expression of PI3K, known to positively regulate AKT and PDK-1, was downregulated in both K562 and K562res cell following exposure to IM. *Conclusions*. Our results demonstrate the ability of IM to inhibit TA in bcr-abl expressing cell lines. TA inhibition was demonstrated in K562 cells as well as in K562 cells resistant to high concentrations of IM. Therefore, the inhibitory effect of IM on TA isn't necessarily mediated through the known tyrosine kinase targets of IM. The signal transduction cascade in both the K562 and the K562res cell lines appears to go through downregulation of PI3K which causes a downregulation of PDK-1 and p-AKT levels leading to inhibition of TA. This study supports previous studies demonstrating telomerase as an additional target of IM. In addition, this study shows that cells, known to be resistant to IM with regards to its effect on bcr-abl, could still be sensitive to IM treatment regarding other cellular components.

DYNAMICS OF MUTANT BCR-ABL POSITIVE CLONES AFTER CESSATION OF IMATINIB TREATMENT

B. Hanfstein, M.C. Mueller, S. Kreil, T. Schenk, C. Lorentz, U. Schwindel, A. Leitner, R.. Hehlmann, A. Hochhaus

Medizinische Fakultät Mannheim der Universität Heidelberg, MANNHEIM, Germany

Background. Mutations of the BCR-ABL tyrosine kinase are considered a major cause of imatinib resistance in chronic myeloid leukemia (CML). More than 50 different mutations have been described, conferring resistance by different molecular mechanisms. The concept of selection of resistant clones in the presence of imatinib is well understood. However, only few data have been presented on the changes of mutant BCR-ABL positive clones after cessation of imatinib treatment. The assumption of reversibility of clonal selection after removing the selective pressure of ABL tyrosine kinase inhibition seems to be plausible, but a general concept of deselection has not yet been established. *Aims*. We sought to determine the decline of resistant clones after cessation of imatinib treatment in CML patients expressing different BCR-ABL mutations. *Methods*. We examined peripheral blood samples of 53 patients (pts; 31 m, 22 f, median age 61 yrs) with imatinib resistant CML bearing BCR-ABL mutations detected by direct sequencing and receiving a subsequent treatment without tyrosine kinase inhibitors after cessation of imatinib (median interval of imatinib treatment 1.6 yrs, median interval to resistance 1.1 yrs). BCR-ABL specific nested RT-PCR of total leukocyte RNA was performed. The amplicon was subjected to mutation specific restriction digests. The proportion of mutant BCR-ABL was defined by a densitometry assay following agarose gel electrophoresis. *Results*. 16 pts (9 m, 7 f, median age 63 yrs; in chronic (n=8), accelerated (n=4) or blastic phase (n=4); mutations Y253F, n=1; Y253H, n=4; E255K, n=5; T315I, n=4; M351T, n=2) had a minimum follow up of 0.3 yrs after cessation of imatinib (subsequent treatment: hydroxyurea, n=10; cytarabine, n=2; mercaptopurine and anagrelide, n=1; thioguanine, n=1; busul-

fan, n=1; interferon alpha, n=1) and could therefore be monitored for deselection of the mutant clone. Median follow up after cessation of imatinib was 1.3 yrs (range 0.3-2.8). Median proportion of mutant BCR-ABL expression in the presence of imatinib was 98% (range 38-100). The difference between the proportions before and after cessation at the lowest point was 61% (median, range -5-100) over a period of 0.4 yrs (median, range 0.2-2.1). We observed a decline of 93% within 2.1 yrs (Y253F), medians of 97%/0.5 yrs (Y253H), 67%/0.4 yrs (E255K), 0%/0.6 yrs (T315I) and 48%/1.1 yrs (M351T). Three pts expressing the T315I mutation revealed the persistence of a 100% mutant BCR-ABL clone during follow up. Two pts (Y253H and E255K) showed a pattern of repeated rapid selection and deselection after resumption and second cessation of imatinib therapy. 6 of 16 pts (CP, n=1; AP, n=3; BC, n=2; Y253H, n=2; E255K, n=1; T315I, n=2; M351T, n=1) died during a median observation period of 3.6 yrs after onset of imatinib treatment, five of them dying in blast crisis. *Conclusions*. Deselection of mutant BCR-ABL clones after cessation of tyrosine kinase inhibition seems to be common and reproducible except in patients harboring T315I.

GENE EXPRESSION DOWNREGULATION BY HAPLOINSUFFICIENCY MECHANISM IN CHRONIC MYELOID LEUKEMIA WITH DELETIONS ON DER(9)

F. Albano,[1] A. Zagaria,[1] L. Anelli,[1] A. Pannunzio,[1] A. Russo Rossi,[1] F. Manodoro,[1] N. Coccaro,[1] V. Liso,[1] M. Rocchi,[2] G. Specchia[1]

[1]Hematology-University of Bari, BARI; [2]DI.GE.MI University of Bari, BARI, Italy

Background. Genomic deletions flanking the breakpoint on der(9)t(9;22) occur in 10%-15% of patients with chronic myeloid leukemia (CML). These microdeletions have a variable extension and involve sequences on chromosomes 9 and/or 22, located proximally to the ABL and distally to the BCR gene. The deletions on der(9) are associated with a poor prognosis on interferon α (IFN-α) therapy whereas controversal data are available about their influence on the response to imatinib. The molecular mechanisms responsible for this unfavourable prognosis are still unclear. We report a gene expression study performed by quantitative real-time polymerase chain reaction (qRT-PCR) on 30 CML patients bearing genomic microdeletions on der(9) chromosome. To date, an expression study of genes mapping within the deleted regions on der(9) has never been performed. *Methods*. 334 CML patients in chronic phase were analyzed by FISH experiments with probes specific for ABL and BCR genes. Sixty (18%) out of 334 cases showed genomic deletions on der(9) chromosome; a detailed characterization of deletions extension was performed by using specific BAC contigs. Because of RNA sample availability, gene expression studies were performed in 30 out of 60 CML patients bearing der(9) deletions and in a pool of 10 CML cases without microdeletions. A total number of 47 genes with known functions were found located inside the 9 and 22 chromosome regions most frequently deleted in CML patients. Among all selected genes, 37 resulted to be homogeneously expressed in normal bone marrow samples and were analyzed by qRT-PCR experiments. A total number of 28 genes was validated by efficient primers pairs; their expression was evaluated in 30 CML cases bearing der(9) deletions and compared to a pool of cDNA samples derived from 10 CML patients without sequence deletions (calibrator). To standardize the quantification of each target gene, β-glucuronidase (β-GUS) gene served as endogenous control. All samples were run in triplets as technical replicates. Results. All the 28 analyzed genes were found downregualted with respect to CML cases without deletions. However, the difference was statistically significant only for six: protein kinase PKN3 (*PKN3*, p=0.003), SH3-domain GRB2-like endophilin B2 (*SH3GLB2*, p=0.0018), protein phosphatase 2A regulatory subunit B' (*PPP2R4*, p=0.007), ankyrin repeat and SOCS box-containing 6 isoform (*ASB6*, p=0.002), ubiquitin specific protease 20 (USP20, p=0.010), and torsin family 1 member B (*TOR1B*, p=0.009). The expression levels of the downregulated genes were 0.096, 0.222, 0.223, 0.198, 0.222, and 0.293 for *PKN3*, *SH3GLB2*, *PPP2R4*, *ASB6*, *USP20* and *TOR1B*, respectively. All 6 downregulated genes are located on chromosome 9 sequences, centromeric to the ABL gene, and are implicated in crucial cellular pathways. *Conclusions*. We have showed for the first time an expression downregulation of genes located on der(9) chromosome in CML patients bearing genomic microdeletions. These findings support the haploinsufficiency hypothesis, suggesting that in these cases one allele is always not sufficient to ensure an adequate gene expression dosage. However, the biological meaning and clinical implications of this gene downregulation remain to be investigated.

EVIDENCE THAT PPAR ACTIVATION MAY CONTROL THE EXPRESSION OF THE IMATINIB TRANSPORTER HOCT1 IN CHRONIC MYELOID LEUKAEMIA

L. Wang, M. Austin, E. Clark

Department of Haematology, LIVERPOOL, UK

The tyrosine kinase inhibitor imatinib (Glivec) produces remarkable responses in chronic myeloid leukaemia (CML). However, many CML patients may not achieve cytogenetic benefit, or lose an initial cytogenetic response. We recently reported that the expression level of the imatinib uptake transporter human organic cation transporter 1 (hOCT1) is a critical determinant of outcome in imatinib treated CML. Patients with high pre-treatment hOCT1 expression had superior complete cytogenetic response (CCR) rates, progression free and overall survival. Upregulation of hOCT1 in hOCT1-low patients could potentially improve the efficacy of imatinib treatment for these patients, but nothing is known about transcriptional regulation of human OCT1 in haematopoietic or CML cells. It has been reported that in liver cells, the hOCT1 gene is transactivated by hepatocyte nuclear factor-4α (HNF-4α), and that peroxisome proliferator-activated receptors (PPAR) α and γ activation increases OCT1 expression in mouse hepatocytes. Here we investigate HNF-4α and PPAR in primary CML cells and cell lines. Hepatocyte nuclear factor-4α (HNF-4α) ---- HNF-4α gene expression was studies by RT-PCR in CML (*K562*, *KCL22* and *LAMA84*) and HepG2 (hepatocyte) cell lines. HepG2 cells which express HNF-4α isoforms 1,2,3,7,8 and 9 were used as a positive control for detecting HNF4α expression. It was found that HNF-4α was not expressed in K562, KCL22, *LAMA84* or 11 CML primary cell samples. Using two HNF-4α antibodies (G162 and E410) which bind to the D domain and C-terminal F domain on Western Blot (and thus cover all possible isoforms), no HNF-4α protein was detected in either CML primary cells or CML cell lines. These results indicate that hOCT1 expression is not regulated by HNF-4α in CML. Peroxisome proliferator-activated receptors (PPAR) ---- RT-PCR studies showed that both PPAR α and γ are expressed in 10 primary CML cell samples and in 4 CML cell lines (*K562, KCL22, LAMA84* and *KYO1*). KCL22 cells (low basal hOCT1 expression) and mononuclear cells from 5 chronic phase CML patients were treated with the PPAR α agonists clofibrate or WY14643 and the PPAR Á agonist ciglitazone. A treatment dose and time was chosen that had no effect on the viability of the cells (assessed by the MTT assay). hOCT1 gene expression levels were measured using real-time quantitative RT-PCR on LightCycler. Both PPAR α and γ agonists increase hOCT1 expression in KCL22 cells to 1.5-3.0 fold of the control level. In all 5 primary CML cell samples, the PPAR γ agonist ciglitazone increased *hOCT1* expression to 1.7 to 4.2 fold of control. In 3 of 5 cases, the PPAR α agonist clofibrate also increased hOCT1 expression. In summary, PPAR α/γ agonists can increase hOCT1 expression in primary CML cells and CML cell lines. PPAR agonists may potentially be of clinical use in CML patients failing imatinib.

0112

EFFECT OF TYROSINE KINASE INHIBITORS ON REGULATORY T-CELLS (TREGS) IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML)

P. Rohon,[1] K. Porkka,[2] S. Mustjoki[3]

[1]Hematology Research Unit, Biomedicum, Helsinki University Central Hospital (HUCH, HELSINKI, Finland; [2]Hematology Research Unit, Dept of Medicine, HUCH, HELSINKI, Finland; [3]Hematology Research Unit, Depts of Medicine and Clinical Chemistry, HUCH, HELSINKI, Finland

Background. Tyrosine kinase inhibitors (TKIs) are currently the standard treatment in patients with chronic myeloid leukemia (CML). In addition to BCR-ABL oncoprotein, they also inhibit other kinases (e.g. C-kit, *TEC, BTK, PDGFR, SRC*), some of which have important physiological functions in immune responses. However, the *in vivo* effects of TKIs on immune effector cells are mostly unknown. T regulatory cells (Tregs) play the key role in immune homeostasis and protection against autoimmunity. Tregs are involved in the immune recognition of tumor-related antigens and may suppress anti-tumor immune responses by inhibiting the function of other effector cells. Increased amounts of Tregs have been observed in patients with solid tumors, but in hematological malignancies only a few studies exist. *Aims*. We aimed at the characterization of the Tregs at diagnosis and during TKI therapy (imatinib, dasatinib) in chronic phase CML patients. *Methods*. A total of 130 peripheral blood (PB) and bone marrow (BM) samples were studied from CML patients at diagnosis (n=13) and during TKI therapy (n=28). Samples

from 12 healthy volunteers served as controls. Tregs were analyzed with multicolor flow cytometry using antibodies for CD4, CD25 and FoxP3. The proportion of Tregs is presented as a percentage of $CD4^+$ T-cells. *Results*. Proportions of Tregs in PB and BM were similar (median percentages 5.2 and 4.3, respectively, p=0.14) and the values correlated significantly (rs=0.46, p<0.001). In BM, the median percentage (range) of Tregs at diagnosis, during imatinib and dasatinib therapy was 2.0 (0.9-5.3), 5.6 (0.2-9.8) and 2.7 (1.6-5.8), respectively (p=0.008). The median percentage of Tregs in PB at diagnosis, during imatinib and dasatinib therapy and in healthy controls was 4.7 (1.3-8.8), 5.7 (0.6-10.3), 3.6 (1.0-7.6) and 5.3 (3.8-6.9), respectively (p=0.42). Proportion of Tregs was lower in females than in males (3.7 and 5.5, respectively, p=0.003). No correlation with age or the Sokal risk score at diagnosis was observed. *Conclusions*. We show that the relative numbers of BM Tregs are decreased at diagnosis in CML patients. Imatinib induces a rapid increase in the proportion of Tregs to levels found in healthy controls. In contrast, dasatinib therapy was associated with similarly low Treg levels as at the time of diagnosis. This dissimilarity may reflect varying effects of imatinib and dasatinib on immune effector cells and on immune responses. In contrast to studies in solid tumors, increased proportions of Tregs were not observed, which may reflect a different function of these cells in hematological malignancies.

OMACETAXINE INDUCES THE RAPID LOSS OF MCL-1 BUT NOT OTHER ANTI-APOPTOTIC BCL-2 FAMILY PROTEINS IN BCR-ABL POSITIVE CELLS

H. Segal,[1] S. Michaels,[2] D. Brown[2]

[1]Deakin University, GEELONG, Australia; [2]ChemGenex Pharmaceuticals, MENLO PARK, CA, USA

Background. The natural product alkaloid omacetaxine mepesuccinate (OMA; formerly homoharringtonine) is currently undergoing evaluation in clinical trials as a therapy for patients with tyrosine kinase inhibitor resistant chronic myeloid leukemia (CML). OMA has been shown to inhibit protein synthesis (putatively via inhibition the elongation step of polypeptide synthesis) and induce apoptosis in leukemic cells. Overnight treatment (>16 hr) of BCR-ABL positive leukemia cells with OMA modulates expression of bcl-2 family proteins and activates apoptosis via proapoptotic caspases; however the key early proapoptotic mechanisms activated by OMA have been incompletely characterized. *Aims*. To further delineate the early (<8hr) cellular events affected by OMA, we have investigated the expression of pro- and anti-apoptotic bcl-2 family proteins following OMA treatment in BCR-ABL positive leukemia cells. For comparison, bcl-2 family protein expression was also assessed in cells treated with imatinib mesylate. *Methods*. Using the K562 leukemia cell line, the expression of bcl-2 family proteins that are anti-apoptosis (Bcl-2, Mcl-1 and Bcl-XL) and pro-apoptosis (Bim and Bax) was examined by Western blot after exposure to 10nM OMA or 10uM imatinib mesylate for 1, 2, 4 and 6 hr. *Results*. Treatment of K562 cells with OMA rapidly induced the loss of Mcl-1 protein expression, which was readily detectable after 2 hr and was more pronounced 4 and 6hr after addition of OMA. In contrast, treatment with imatinib mesylate did not alter Mcl-1 expression in the first 6 hr after treatment. Expression of other anti-apoptotic proteins Bcl-2 and Bcl-XL or pro-apoptotic Bim or Bax proteins were not affected by OMA or imatinib mesylate. The OMA induced loss of Mcl-1 was dependent on proteasome activity as co-treatment of K562 cells with the proteasome inhibitor MG-132 (10 uM) prevented OMA induced Mcl-1 degradation. *Summary/Conclusion*. These results indicate that OMA but not imatinib mesylate induces a rapid loss of the anti-apoptiotic protein Mcl-1 protein in CML cells. Follow up studies are currently underway to further define the molecular pathways affected by OMA treatment of BCR-ABL positive leukemic cells.

ROLE OF IMATINIB MESYLATE IN OSTEOBLASTOGENESIS

D. Tibullo,[1] C. Giallongo,[1] P. La Cava,[1] S. Berretta,[1] F. Stagno,[1] A. Chiarenza,[1] C. Conticello,[2] G. Palumbo,[1] F. Di Raimondo1

[1]Division of Hematology, University of Catania, CATANIA; [2]Department of Experimental Oncology, Mediterranean Institute of Oncology, VIAGRANDE (CATANIA), Italy

Background. Imatinib mesylate (IM) is a tyrosine kinase inhibitor currently used in chronic myeloid leukaemia (CML). It has been reported that IM may affect bone tissue remodeling mainly by an inhibitory activity on osteoclastogenesis. We therefore evaluated possible effects of IM on osteoblatic differentiation of Mesenchymal Stem Cells derived from bone marrow (BM-MSCs). Methods. Osteogenic differentiation of hBM-MSCS was induced in presence of 0.2 mM ascorbic acid, 0.1 µm dexamethasone and 10 mM β-glycerophosphate (osteogenic medium, OM). Expression of osteoblast-associated genes such as osteocalcin (OCN), RUNX2 and Bone morphogenetic protein (*BMP-2*) were evaluated by reverse transcription-polymerase chain reaction (RT-PCR). Culture surnatant and serum levels OPG and RANKL were assayed using specific ELISA tests. *Results*. At 21 days, an extracellular mineralization was present in hBM-MSC cultures with OM or IM alone but it was more evident with the combination. The levels of OCN, Runx2/cfba1 and OPN expression were increased in cells treated with OM, IM and OM + IM in respect to control. In particular, levels of BMP2 were significantly higher in IM treated cultures respect to control (p<0.0007) and they were also higher in OM + IM treated culture respect to OM alone (p<0.002). The same differences applied for OCN and Runx2/Cfba1, although at less significat p values. *OPG/RANKL* ratio in the surnatant of the culture (p<0,005) and OCN levels (p<0,005) were increased in BM-MSCs samples cultured with IM in comparison to control (OM alone). In addition, we examined the *OPG/RANKL* ratio in serum of 41 serum samples from CML patients at diagnosis or treated with IM 400 mg from 3 to 24 months. The *OPG/RANKL* ratio in patients at diagnosis was higher in comparison to healthy voluntaries (p<0.004) and the ratio further increased after 3 and 6 months of IM treatment (p<0.004). However. the *OPG/RANKL* ratio returned at the basal level after 24 months of treatment with IM. *Conclusions*. In summary, our data show that IM increases osteogenic markers mRNA expression in BM-MSCs and increase the *OPG/RANKL* ratio and OCN level in surnatant of BM-MSCs cultured with IM. In addition, we have shown that CML patients treated with conventional doses of IM have a transient elevation of the serum *OPG/RANKL* ratio that return to the basal level after 24 months. Our data show that IM increased the expression of BMP-2 and Runx2/cfba1 mRNA and we hypothesize that the BMP/Runx2 axis can have an important role in the IM-mediated induction of osteoblasts.

NCK β ADAPTER COORDINATES BCR-ABL/SAM68 INTERMOLECULAR INTERACTION

E. Bracco,[1] E. Bracco,[2] E. Deklic,[1] V. Rosso,[2] S. Mussino,[2] F. Arruga,[2] R. Catalano,[2] S. Carturan,[2] F. Messa,[2] I. Defilippi,[3] C. Panuzzo,[2] P. Nicoli,[2] E. Messa,[2] A. Rotolo,[2] R. Pedrola,[2] D. Cilloni,[2] G. Saglio[2]

[1]University, ORBASSANO; [2]University of Turin, ORBASSANO; [3]University of Turin, ORBASSANO, Italy

Background. Ph^+ disorders, such as chronic myelogenous leukemia (CML) are characterized by the presence of abnormal chromosome rising from translocation between chromosome 9 and 22 thus giving birth to a chimeric oncogenic protein named Bcr-Abl. This oncogenic kinase displays constitutive tyrosine kinase activity which leads to tyrosine residues autophosphorylation, in turn recruiting SH2 and/or PTP containing proteins. Bcr-Abl targeted therapy has been successfully used in the last decade and among currently available drugs inhibiting Bcr-Abl activity Imatinb mesylate represents the most efficient. Despite the vast amount of data describing the effects of Imatinib on signal transduction pathways (ERK1/2, CrkL phosphorylation, PI3K) in Ph^+ leukemic cells rather few experimental evidences are available on the effects of Imatinib on adapter molecules. *Aims and Methods*. The significance of interactions occurring between Bcr-Abl and adapter molecules is still debated matter. Most of the interactions so far described (CrkL, Grb2, PI3K p85 regulative subunit etc) appear to play a role in mediating and integrating signals which lead to proliferation, cell survival and/or cytoskeletal organization and more recently few data are presented supporting the hypothesis of adapter molecules as Abl catalytic regulators. By means of an interactomic approach, based on proteomic strategy using GST-Pull Down assay with an array of SH2 containing proteins, we attempted to gain insight into the role played by adapter molecules and Bcr-Abl interactions. *Results and conclusions*. The data herein presented aims to demonstrate the presence of quaternary complex involving the SH2-SH3 containing adapter protein Nck beta, the oncogenic tyrosine kinase Bcr-Abl and the RNA binding protein Sam68. The experimental evidences we have collected support the hypothesis for an Imatinib-dependent interaction between Nck beta and Bcr-Abl. Furthermore, Pull Down experiments indicate intermolecular interaction between Nck-beta and Sam68, supporting the idea of a complex Bcr-Abl/Nck-beta/Sam68. Interestingly, Sam68 may modulate splicing of gene regulating apoptosis event, such as BclX. These data represent the first experimental evidences showing an interaction between Bcr-Abl and Sam68 leading to speculate a putative role played by Bcr-Abl in mRNA splicing sc

UNUSUAL SINGLE BAC COPY NUMBER CHANGES IN CHRONIC MYELOID LEUKEMIA: EXAMPLES FROM CELL LINES AND PATIENTS

A. Chanalaris, A. Chanalaris, D. Brazma, M. Valgañón, C. Grace, E.P. Nacheva

Royal Free & UC Medical School, LONDON, UK

Background. The advent of aCGH has enabled us compare two or more genomes and led to impressive discoveries in the variation of our genetic material. The plethora of cryptic numerical aberrations in diseases are discovered with relative ease, the discovery of copy number variations and the discovery of disease associated genomic loci by single nucleotide polymorphisms are the contributions of this technology. Previous studies have used aCGH in CML to discover common features among CML patients in order to elucidate the relevance of the genetic background in CML disease progression. By employing aCGH in CML patients and CML cell lines we came across consistent numerical changes of large areas adjacent to the BCR/ABL1 fusion and also single BAC numerical changes interspersed throughout the genome that are not compliant with the numerical changes of the neighbouring region. *Aims.* To characterise the unusual copy number changes we observed and to eradicate the possibility of aCGH artefact results. *Methods*. Patient and cell line material was analysed by 1Mb BAC array (SGI). The unusual numerical aberrations were confirmed by FISH and quantitative real time PCR. *Results*. In addition to detection of genome imbalances, affecting regions both large (detectable at chromosome level) and cryptic (as small as 100Kb) array CGH was instrumental in revealing complex structural rearrangements. (i) Amplification of the region downstream of ABL1 gene: A several fold copy number gain of an 800 kb region downstream of the ABL1 breakpoint at 9q34.12 region was identified by high resolution array CGH in the cell lines *MEG-01, MC3, EM2* and CML-T1. FISH mapping revealed that this genomic gain is a result of a structural change, namely a tandem duplication of the same amplicon. The latter shows a consistent proximal breakpoint at the ABL1, while its distal boundaries fall within the *RAPGEF1* gene. This amplicon contains several genes, including *NUP214, LAMC3* and *RAPGEF1*. Similar gains/amplifications were also identified by FISH in a subclone in the cell line KYO-1 and were seen in 5 out of 12 cases with double Ph. (ii) Discordant copy number changes: loss of single BAC locus within a gained region and visa versa. This phenomenon, clearly detectable at the graphic presentation of the array data, has been detected in several patients and cell line genome profiles alike. The most frequently seen are the ones at the regions of 9p21, 6q23-27 and 1q22-qter were further investigated and confirmed by FISH and qPCR. *Conclusions*. We are presenting some cases of unusual copy number aberrations, unusual in that they go against the numerical changes of the surrounding genomic area. These changes are not artefacts and we are currently investigating the possibility of a mechanistic reason behind their appearance.

Chronic myeloid leukemia - Clinical I

0117

NILOTINIB IN CHRONIC MYELOGENOUS LEUKAEMIA IN BLAST CRISIS (CML-BC) PATIENTS WITH IMATINIB-RESISTANCE OR -INTOLERANCE: UPDATED PHASE 2 RESULTS

J. Giles,[1] R.A. Larson,[2] H.M. Kantarjian,[3] P. Le Coutre,[4] F. Palandrini,[5] A. Haque,[6] N. Gallagher,[6] O.G. Ottmann[7]

[1]CTRC at the UT Health Science Center San Antonio, SAN ANTONIO, USA; [2]The University of Chicago Hospitals, CHICAGO, USA; [3]MD Anderson Cancer Center, HOUSTON, USA; [4]Humboldt-Universität, BERLIN, Germany; [5]Department of Hematology-Oncology, University of Bologna, BOLOGNA, Italy; [6]Novartis Pharmaceuticals, EAST HANOVER, USA; [7]Medizinische Klinik III, FRANKFURT, Germany

Background. Patients (pts) with CML-BC, for whom prognosis remains poor, may benefit from treatment with nilotinib, a potent and highly selective BCR-ABL inhibitor. Nilotinib has been approved in several countries including the US and Europe for the treatment of patients (pts) with Philadelphia chromosome-positive chronic myelogenous leukaemia (Ph^+ CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. *Methods*. This phase 2, open-label study evaluated the efficacy and safety of nilotinib in adult pts with Ph^+ CML-BC resistant or intolerant to imatinib. The primary endpoint was confirmed haematological response (HR). Imatinib resistance was defined as either treatment with imatinib > 600 mg/d with disease progression or no HR in bone marrow after 4 weeks. Imatinib intolerance was defined as no major cytogenetic response (MCyR) and discontinuation due to grade 3/4 adverse events (AEs), or grade 2 AEs persisting for > 1 month while on imatinib. In the absence of safety concerns, the initial dose of nilotinib 400 mg twice daily (BID) on an empty stomach, could be escalated to 600 mg BID for: failure to achieve a return to CP, loss of an achieved haematological or cytogenetic response, or progressive disease. *Results*. Safety and efficacy data are reported for 136 BC pts (myeloid, n=105; lymphoid, n=31), 82% were imatinib-resistant and 18% were imatinib-intolerant. Many had also received other prior therapies including interferon (34%), cytarabine (37%) and BMT (13%). At study entry, 38% of pts had ≥95% Ph^+ metaphases, with additional chromosomal abnormalities noted in 53% of pts. Confirmed HR occurred in 29 (21%) pts, with 15 (11%) achieving complete HR. MCyR was achieved in 55 pts (40%), with 40 (29%) having complete cytogenetic response (CCyR). Overall survival at 12 months was 42%. Patients with myeloid and lymphoid blast crises had similar response rates. Treatment with nilotinib is ongoing in 13 pts (10%); 71 (52%) pts discontinued treatment due to disease progression. The median duration of treatment was 84 days. Median dose intensity was 800 mg/day, the same as the planned dose. Although dose interruptions occurred in 38% of pts, the median total duration of dose interruptions was only 10 days. The most common grade 3/4 laboratory abnormalities were neutropenia (67%), thrombocytopenia (62%), and anaemia (42%). Non-haematological toxicities were mostly mild to moderate and included rash and nausea. Grade 3/4 pleural/pericardial effusions and pulmonary edemas were not observed. <1% experience had grade 3/4 GI bleeding and no CNS bleeding occurred. *Conclusions*. Nilotinib demonstrates clinical activity in pts with imatinib-resistant or -intolerant CML-BC and is generally well tolerated. Nilotinib represents a novel treatment option in a group of CML pts with very advanced disease and limited treatment options.

0118

NILOTINIB IN IMATINIB-RESISTANT OR -INTOLERANT PATIENTS WITH CHRONIC MYELOGENOUS LEUKAEMIA IN ACCELERATED PHASE (CML-AP): UPDATE OF A PHASE 2 STUDY

P. le Coutre,[1] F.J. Giles,[3] A. Hochhaus,[2] J. Apperley,[3] G. Ossenkoppele,[4] A. Haque,[5] N. Gallagher,[5] M. Baccarani,[6] J. Cortes,[7] H.M. Kantarjian[7]

[1]Charité, BERLIN, Germany; [2]Med. Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany, MANNHEIM, Germany; [3]Imperial College School of Medicine, Hammersmith Hospital, LONDON, UK; [4]Free University, AMSTERDAM, Netherlands; [5]Novartis Pharmaceuticals, EAST HANOVER, USA; [6]University of Bologna Institute of Hematology and Medical Oncology Seragnoli, BOLOGNA, Italy; [7]MD Anderson Cancer Center, HOUSTON, USA

Background. Nilotinib, a potent and highly selective BCR-ABL inhibitor, has been approved in several countries including the US and Europe for the treatment of patients (pts) with Philadelphia chromosome-positive chronic myelogenous leukaemia (Ph^+ CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. *Methods*. This phase 2, open-label study evaluated the efficacy and safety of nilotinib in pts with Ph^+ CML-AP with imatinib resistance or intolerance. Primary and key secondary endpoints were rate of confirmed haematological response (HR) and major cytogenetic response (MCyR), respectively. Nilotinib was started at 400 mg twice daily (BID) and escalated to 600 mg BID for inadequate responses, in the absence of safety concerns. *Results.* Included in the analysis were 136 pts who received at least 1 dose of nilotinib. Of these 136 pts, 109 (80%) were imatinib-resistant and 27 (20%) were imatinib-intolerant. Median age was 58 (22-82) yrs; median dose intensity was 781 mg/day; median treatment duration was 7 months. Of 129 pts, confirmed HR occurred in 69 (54%) and complete HR occurred in 34 (26%). In imatinib-resistant and -intolerant pts, confirmed HR occurred in 55/104 pts (53%) and 14/25 (56%), respectively. A majority of responding pts (82%) maintained HR for at least 12 months. MCyR occurred in 40/129 pts (31%) and 24/129 pts (19%) had complete CyR. Of imatinib-resistant pts, 30/104 pts (29%) had a MCyR, and 10/25 imatinib-intolerant pts (40%) had a MCyR. At 12 months, the estimated overall survival rate was 81%. At data cutoff, treatment was ongoing for 57/136 pts (42%). The most common grade 3/4 laboratory abnormalities were thrombocytopenia (41%), neutropenia (39%), anaemia (25%), and asymptomatic elevated serum lipase (16%). Grade 3/4 non-haematological AEs were rare and included nausea, fatigue, headache, and diarrhoea. There was no occurrence of QTcF prolongation >500 msec from baseline. Grade 3/4 fluid retention was rare, occurring in <1% of all pts. Grade 3/4 rate for any bleeding events is 2.2%. There was minimal nilotinib cross-intolerance in patients intolerant to prior imatinib treatment. *Conclusions*. The results of this study confirm that nilotinib induces significant and durable responses in CML-AP pts with imatinib resistance or intolerance. Nilotinib is well tolerated, with minimal occurrence of grade 3/4 AEs, and is an effective treatment option for this advanced CML population.

0119

DASATINIB IS ASSOCIATED WITH DURABLE TREATMENT RESPONSES IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA: LONG-TERM FOLLOW-UP FROM THE PHASE I TRIAL (CA180002)

J. Cortes,[1] C.L. Sawyers,[2] H.M. Kantarjian,[1] N.P. Shah,[3] R. Paquette,[4] E. Bleickardt,[5] P. Paliwal,[5] M. Talpaz[6]

[1]MD Anderson Cancer Center, HOUSTON; [2]Memorial Sloan-Kettering Cancer Center, NEW YORK; [3]University of California San Francisco School of Medicine, SAN FRANCISCO; [4]UCLA, LOS ANGELES; [5]Bristol-Myers Squibb, WALLINGFORD; [6]University of Michigan, ANN ARBOR, USA

Background. Dasatinib is a potent BCR-ABL inhibitor, approximately 325-fold more potent than imatinib and 16-fold more potent than nilotinib for *in vitro* kinase inhibition. Dasatinib was approved for the treatment of imatinib-resistant/-intolerant chronic myeloid leukemia (CML) in any phase or Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph^+ ALL) because of efficacy observed during a phase I trial (CA180002) and a series of phase II studies (the START program). Long-term follow-up is now available for patients with CML in chronic phase (CP) treated during the 002 study. *Aims*. To investigate the durability of dasatinib treatment responses and long-term tolerability of patients treated in a phase I study. Data have been assessed after a minimum follow-up of 27 months. *Methods*. Patients with CML-CP who had experienced hematologic resistance/relapse on imatinib or who had discontinued imatinib following toxicity were enrolled from November 2003 to April 2005. Dasatinib was administered at 15-180 mg/d on a QD or BID schedule according to a dose-escalation protocol, with most patients initially treated on a 5 d on/ 2 d off schedule (dasatinib 100 mg QD is now the approved dose for patients with CML-CP following imatinib resistance or intolerance). In addition to safety assessments, rates of complete hematologic response (CHR) or major/complete cytogenetic response (MCyR/CCyR), and duration of progression-free survival (PFS) or overall survival were evaluated. *Results*. Of 45 patients with late CML-CP, 91% had received prior interferon-α, 62% had received imatinib at a dose >600 mg/d, and 58% had received imatinib for >3 years. Most patients had responded initially to imatinib (CHR 78%, MCyR 42%, CCyR 18%), 80% eventually became imatinib resistant (20% intolerant), and 73% had baseline BCR-ABL mutations. Dasatinib was administered QD to 22 patients for a median of 31 months (range 3.6-38.5) and BID to 23 patients for median of 23 months (range 0.5-36.1). Response rates were similar for QD *vs* BID treatment (CHR: 95.5% *vs* 87.0%; MCyR 45.5% *vs* 60.9%; CCyR 45.5% *vs* 43.5%). Across all patients, median durations of CHR and MCyR were not reached (71% of responding patients had maintained MCyR at 33 months), and at 36 months, the PFS rate was 64% and the overall survival rate was 82%. In a landmark analysis, achieving a MCyR at any time on dasatinib was associated with higher 36-month PFS (87% *vs* 37%) and overall survival (95% *vs* 66%). At last follow-up, 62% of patients remained on dasatinib; 18% discontinued following disease progression, only 1 patient (2%) discontinued for toxicity, and 11% died. Grade 3/4 neutropenia and thrombocytopenia were each noted in 47% of patients. Nonhematologic side effects were typically mild to moderate. The most common grade 3/4 nonhematologic side effects were pleural effusion (11%), gastrointestinal bleeding (7%), and dyspnea or pulmonary edema (4%). *Summary and Conclusions*. Long-term follow-up from this early study confirms that dasatinib is associated with high rates of hematologic and cytogenetic responses in CML-CP following imatinib failure. Dasatinib treatment responses were durable and translated into favorable PFS and overall survival. Side effects rarely led to treatment discontinuation.

0120

INTERIM RESULTS FROM A PHASE I CLINICAL TRIAL OF THE BCR-ABL INHIBITOR XL228 IN DRUG-RESISTANT PH^+ LEUKEMIAS

P. Shah,[1] E. Asatiani,[2] J. Cortes,[3] R. L. Paquette,[4] J. Pinilla-Ibarz,[5] C. Kasap,[1] L. A. Bui,[6] Y. Yaron,[6] D.O. Clary,[6] M. Talpaz[7]

[1]UCSF, SAN FRANCISCO; [2]Georgetown University, WASHINGTON, D. C.; [3]MD Anderson Cancer Center, HOUSTON; [4]UCLA, LOS ANGELES; [5]Moffitt Cancer Center, TAMPA; [6]Exelixis, Inc., SOUTH SAN FRANCISCO; [7]University of Michigan, ANN ARBOR, USA

Background. Treatment of the Philadelphia chromosome-positive leukemias (CML and Ph^+-ALL) has been revolutionized through the development of inhibitors of the oncoprotein Bcr-Abl, a drug class pioneered by imatinib. Although long term remissions are commonly achieved with this agent, relapses occur due to several mechanisms, including point mutations in the BCR-ABL gene and emergence of drug-resistant clones. While the second generation Abl inhibitors dasatinib and nilotinib have been effective in treating many patients who have become resistant to imatinib, there are certain mutated forms of Bcr-Abl which are refractory to all three approved inhibitors, notably the gatekeeper substitution T315I. In patients who relapse after responding to dasatinib treatment, a T315I-harboring clone is commonly found. Patients found to harbor this mutation have very poor response rates to the approved Abl kinase inhibitors and a poor prognosis. XL228 is a protein kinase inhibitor with potent activity against wild-type and T315I isoforms of Bcr-Abl (wild type Abl, Ki=5 nM; T315I, Ki=1.4 nM) with additional activity against IGF1R and Src. XL228 blocks downstream signaling from Bcr-Abl T315I in cell lines and modulates pCrkL levels in mouse K562 xenografts consistent with inhibitory activity against Bcr-Abl *in vivo*. Based on these data, we have initiated a Phase I clinical trial in patients with CML or Ph^+-ALL who are resistant or intolerant to standard therapies. *Aims*. The primary objective is to determine the safety, tolerability, and maximum tolerated dose of XL228 in patients with chronic, accelerated or blast phase CML, or Ph^+-ALL. The secondary and exploratory objectives include evaluating the pharmacokinetics of XL228, pharmacodynamic correlates of drug treatment, the safety and tolerability of longer term dosing, and preliminary evaluation of efficacy. *Methods*. XL228 is administered as a weekly infusion. Three cohorts (11 subjects) have been enrolled and evaluated as of abstract submission. *Results*. When dosed at 0.45, 0.9, and 1.8 mg/kg, XL228 has proven to be well-tolerated with no dose-limiting toxicities or drug-related severe

adverse events reported to date. Preliminary, unaudited safety data include the following Grade 1 adverse events which may be drug related: warmness and pain at the infusion site, fatigue, nausea, and peripheral neuropathy (1 patient). At this time, patients currently on study have been dosed for up to 6 months. Pharmacokinetic analysis of the first cohorts has demonstrated an approximately dose-proportional exposure, with a mean terminal half life of 15 to 38 hours. The mean volume of distribution ranges between 14.2 and 15.4 L/kg, suggesting XL228 distributes widely into the tissues. Weekly dosing results in low to moderate accumulation. There are preliminary indications of pharmacodynamic activity based on transient shifts in phospho-CrkL determined through flow analyses of patient peripheral blood samples. While several patients have been classified as having stable disease, no significant decreases in BCR-ABL qPCR or white count have been measured as of abstract submission. Dose escalation is continuing. *Summary*. XL228 is a promising agent for treating drug-resistant CML and Ph^+-ALL, including patients harboring the T315I gatekeeper mutation. Clinical evaluation of XL228 is ongoing.

0121

EFFICACY OF NILOTINIB IN PATIENTS (PTS) WITH NEWLY DIAGNOSED, PREVIOUSLY UNTREATED PHILADELPHIA CHROMOSOME (PH)-POSITIVE CHRONIC MYELOGENOUS LEUKEMIA IN EARLY CHRONIC PHASE (CML-CP)

J. Cortes,[1] D. Jones,[1] S. O'Brien,[1] A. Ferrajoli,[1] G. Borhtakur,[1] J. Burger,[1] W. Wierda,[1] G. Garcia-Manero,[1] L. Letvak,[2] H. Kantarjian[1]

[1]MD Anderson Cancer Center, HOUSTON, USA; [2]Novartis, EAST HANOVER, USA

Background. Nilotinib is an oral tyrosine kinase inhibitor with increased selectivity against Bcr-Abl approximately 30-fold more potent than imatinib effective in CML after imatinib failure. We initiated a phase II study to evaluate the efficacy of nilotinib as 1st line therapy in pts with newly diagnosed CML-CP. *Aims*, To investigate the efficacy and safety of nilotinib as first-line therapy in CML-CP. *Methods*. The primary objective was to estimate the proportion of pts attaining major molecular response at 12 months (mo). Pts with untreated CML-CP were eligible and received nilotinib 400mg twice daily. *Results*. Thirty-five pts have been treated for a median of 6.5 months (mo). The median age was 47 years (yrs). At 6 months, 100% of patients reaching this time point (n=20) have achieved a complete cytogenetic response [CCyR]. The rate of complete cytogenetic response [CCyR] at 3, 6 and 12 mo compares favorably to those observed in historical controls treated with imatinib 400 mg or 800 mg daily (Table 1).

Table 1

Months on therapy	Percent with CCyR (No. evaluable)			p value
	Nilotinib	Imatinib 400mg	Imatinib 800mg	
3	96 (31)	37 (49)	62 (202)	< 0.0001
6	100 (20)	54 (48)	82 (199)	< 0.0001
12	100 (11)	65 (48)	86 (197)	0.0007

Major molecular response (MMR) was observed in 13% at 3 mo, 45% at 6 mo, and 45% at 12 mo. Grade 3-4 thrombocytopenia was observed in 6% and neutropenia in 3%. Other grade 3-4 adverse events included elevation of lipase in 9% and bilirubin in 9%. Fifteen (43%) pts had transient treatment interruptions (median 11 days) and 14 had dose reductions. The actual median dose is 800 mg daily. Thirty-two patients continue on study. *Conclusion*. Nilotinib 400 mg twice induces a CCyR in nearly all patients as early as 3 months after the start of therapy with a favorable toxicity profile. Accrual is ongoing.

0122

DASATINIB COMPARED WITH HIGH-DOSE IMATINIB IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA IN CHRONIC PHASE (CML-CP) AFTER FAILURE OF STANDARD-DOSE IMATINIB - A TWO-YEAR UPDATE OF THE START-R STUDY

P. Rousselot,[1] S. Corm,[2] R. Paquette,[3] E. Bleickardt,[4] D. Dejardin,[4] H.M. Kantarjian,[5] D. Niederwieser[6]

[1]Hôpital Mignot, VERSAILLES, France; [2]Hôpital Huriez, LILLE, France; [3]UCLA, LOS ANGELES, USA; [4]Bristol-Myers Squibb, WALLINGFORD, USA; [5]MD Anderson Cancer Center, HOUSTON, USA; [6]University of Leipzig, LEIPZIG, Germany

Background. Resistance to standard-dose imatinib and subsequent treatment failure is a well-established problem that affects many patients with CML-CP. High-dose imatinib may be a therapeutic option in such cases. Dasatinib may override multiple mechanisms of imatinib resistance. It is 325-fold more potent against native BCR-ABL than imatinib *in vitro*, and is active against imatinib-resistant mutations with the exception of T315I. Dasatinib has also demonstrated efficacy in patients with imatinib-resistant CML. *Aims*. To evaluate the efficacy and safety of dasatinib and high-dose imatinib in patients with CML-CP after failure of standard-dose imatinib with a minimum follow-up of 24 months. *Methods*. START-R is an international, randomized, phase II study. In total, 150 patients with CML-CP who failed imatinib 400-600 mg/d received either dasatinib 70 mg BID (n=101) or imatinib 800 mg/d (n=49). The primary endpoint was major cytogenetic response (MCyR) at 12 weeks. Patients without MCyR at 12 weeks, those who experienced confirmed progression, or those with intolerance despite dose reduction were permitted to cross over to the other study therapy. Doses of dasatinib could be escalated to 90 mg BID for patients with inadequate responses at 12 weeks or progression. The definition for progression was: increasing WBC count, loss of complete hematologic response/MCyR, confirmed accelerated/blast phase disease, or death. Data are now presented for a minimum follow-up (LPFV to database closure) of 24 months. *Results*. At 12 weeks, MCyR rates were significantly higher for patients receiving dasatinib than for those receiving high-dose imatinib (36% *vs* 29%; p=0.4025). At last follow-up, MCyRs had been achieved with dasatinib *vs* high-dose imatinib treatment by 53% *vs* 33% (p=0.017), with the difference being attributable to rates of complete cytogenetic response (44% *vs* 18%; p=0.0025). Moreover, MCyRs were more durable for dasatinib: after 18 months, 90% of dasatinib-treated patients maintained MCyRs, compared with 74% of imatinib-treated patients. At 24 months, dasatinib was also associated with significantly higher major molecular response rates (29% *vs* 12%; p=0.028), improved time to treatment failure (patients without failure at 24 months: 59% *vs* 18% p<0.0001), and extended progression-free survival (PFS rates at 24 months; 86% *vs* 65%; p=0.0012). The PFS superiority of dasatinib over high-dose imatinib was apparent for patients receiving prior imatinib both at 400 mg/d (p=0.0562) and 600 mg/d (p=0.0033). Grade 3-4 non-hematologic adverse-event rates were minimal for both treatment groups. Grade 3-4 cytopenia was more common in the dasatinib arm. Rates of toxicity-related treatment discontinuation were similar between treatments (dasatinib 22% *vs* imatinib 20%). *Conclusions*. These extended, 24-month follow-up data support earlier START-R reports: the overall benefit-risk assessment favors dasatinib over high-dose imatinib in patients with CML-CP patients who failed standard-dose imatinib. The current labeled dose of 100 mg QD was approved based on a subsequent phase III, dose-optimization study which showed comparable efficacy with improved tolerability compared with 70 mg BID.

0123

DATA FROM A MULTICENTER OPEN LABEL STUDY OF SUBCUTANEOUS (SC) OMACETAXINE MEPESUCCINATE (OMA) IN IMATINIB (IM)-RESISTANT CHRONIC MYELOID LEUKEMIA (CML) PATIENTS (PTS) WITH THE T315I MUTATION

J. Cortes,[1] H.J. Khoury,[2] S. Corm,[3] F.E. Nicolini,[4] A.C. Benichou,[5] A.R. Craig,[6] E. Humphriss,[6] H. Kantarjian[1]

[1]MD Anderson Cancer Center, HOUSTON, USA; [2]Emory University School of Medicine, ATLANTA, USA; [3]CHRU Hôpital Claude Huriez, LILLE, France; [4]CHU Hôpital Edouard Herriot, LYON, France; [5]Stragen France, LYON, France; [6]ChemGenex, MENLO PARK, USA

Background. Omacetaxine (homoharringtonine, HHT) is clinically active against Ph^+ CML, with a mechanism of action independent of

tyrosine kinase (TK) inhibition. Currently available TK inhibitors (TKIs) have not demonstrated activity in CML patients with T315I mutation. *Aims.* We are evaluating the safety and efficacy of OMA in Pts with IM-resistant T315I$^+$ Ph$^+$ CML. *Methods*. Eligible Pts- adult CML with confirmed T315I mutation following imatinib failure. All patients must provide informed consent to participate. Induction schedule: 1.25 mg/m^2 OMA SC twice daily (BID) for 14 days every 28 days until complete hematologic response (CHR) or hematologic improvement. Maintenance schedule: 1.25 mg/m^2 OMA SC BID for 7 days every 28 days, for up to 24 mos. *Results*. To date, 33 Pts have been enrolled, 87% having failed multiple prior TKIs; 19 in chronic phase (CP), 7 in accelerated phase (AP) and 7 in myeloid blast phase (BP). Median age: 58 yrs (19-83), median disease duration: 58 mos. (5-285). An independent data monitoring committee composed of 2 medical doctors and a PHD biostatistician has been assembled to evaluate all responses reported in the study. This committee has completed the first adjudication of the initial 10 CP patients enrolled in the study. Overall response in these 10 patients demonstrates a CHR rate of 90% and a complete cytogenetic response rate of 20%. In addition, 1 patient achieved a minor cytogenetic response. The median time to response was 2 mos. (range 1-5) and the median duration of response for both hematologic and cytogenetic response is currently 6 mos. (range 1-12+). All responding patients (N=9) remain active in maintenance OMA treatment. Safety data are available on 23 patients enrolled in all disease phases and OMA has been well tolerated with the primary toxicity being myelosuppresion (managed with adjustments to the number of dosing days per cycle). Incidence of treatment emergent grade 3/4 events in these patients include: thrombocytopenia 61%, neutropenia 44%, anemia 39%, febrile neutropenia 22% and pancytopenia 13%. Mild injection site pain (23%) and erythema (13%) have also been reported. Grade 3-4 treatment emergent non hematologic events have been infrequent with individual events occurring in less than 5% (1 patient/event) of patients. *Conclusions*. OMA therapy in T315I+ IM-resistant CML is well tolerated and is resulting in durable CHRs and cytogenetic responses in the initial 10 CP patients enrolled as determined by an independent Data Monitoring Committee.

0124

CHRONIC MYELOID LEUKEMIA IN BLAST CRISIS TREATED WITH IMATINIB 600 MG: OUTCOME OF THE PATIENTS ALIVE AFTER A 6-YEAR FOLLOW-UP

F. Palandri,[1] F. Castagnetti,[2] N. Testoni,[2] S. Bassi,[3] M. Breccia,[4] R. Varaldo,[5] A. Liberati,[5] G. Specchia,[5] E. Zuffa,[5] G. Rege-Cambrin,[6] M. Bocchia,[5] G. Saglio,[6] F. Pane,[7] G. Martinelli,[2] M. Baccarani,[2] G. Rosti[2]

[1]Department of Hematology Seragnoli, BOLOGNA; [2]Department of Hematology Seragnoli, BOLOGNA; [3]Division of Hematology, AIEOP, MILANO; [4]Department of Cellular Biotechnology and Hematology, University La Sapienza, ROMA; [5]Division of Hematology, GENOVA; [6]Department of Clinical and Biological Science, University of Turin at Orbassano, TORINO; [7]CEINGE Biotecnologie Avanzate and Department of Biochemistry and Medical Biotech, NAPOLI, Italy

Background. Management of Blast crisis Chronic Myeloid Leukemia (BC-CML) is the most challenging entity in the treatment of chronic myeloproliferative disorders. In 2000, the introduction of Imatinib mesylate (IM) has opened a new option in the treatment of BC-CML. Early results have shown the superiority of IM compared to conventional chemotherapy; however, the long-term outcome of these patients remains to be clarified. *Aims.* The GIMEMA (Gruppo Italiano Malattie Ematologiche dell'Adulto) CML Working Party conducted a phase II, multi-institutional prospective study (CML/003) to investigate the long-term effects of IM in BC-CML patients, treated with IM 600 mg daily. Ninety-two patients were enrolled. After a 6-year follow-up, we assessed the IM long-term efficacy, response duration and survival, and we characterized the prognostic factors associated with a favourable outcome. *Methods*. Patients were monitored for hematologic and cytogenetic response at 1-3 months intervals. A complete hematologic response (CHR) required the normalization of platelet and white cell differential count and absence of extramedullary involvement. The definition of return to chronic phase (RTC) required less than 15% blasts and less than 30% blasts plus promyelocytes in blood or bone marrow and less than 20% peripheral basophils. Cytogenetic analysis was performed with standard banding techniques and the response was rated as usual. *Results*. Forty-six out of 92 patients (50%) had a sustained RTC, and 24 patients (26%) achieved a CHR. RTC was subsequently lost by 22 patients, for a median duration of the second CP of 11 months (range 1-67). Sixteen patients lost the CHR, for a median duration of the CHR of 6 months (range 1-43). Sixteen patients (17%) had a cytogenetic response (9 complete, 1 partial, and 6 minor or minimal). CCgR was subsequently lost by all but 2 pts after 2 to 12 mos from its first achievement, for a median CCgR duration of 7 months. The Kaplan-Meier median survival time was 7 months, and the survival rates were 53% at 6 months, 29% at 12 months, 23% at 18 months and 11% at 36 months; for the 10 patients who achieved a MCgR, OS was significantly better (p=0.001) (Figure 1). After a median observation time of 66 months, 7 (8%) patients are alive: 3 patients are on IM treatment (1 in CHR, 1 in partial CgR and 1 in CCgR). Three patients are in complete remission after allogeneic transplant. One patient is alive in BC, after failure of a second-generation TKI. *Conclusion*. We confirm that IM as monotherapy was valuable and safe in the short-term, but relapse rate was high and the longer term clinical outcome was not significantly influenced.

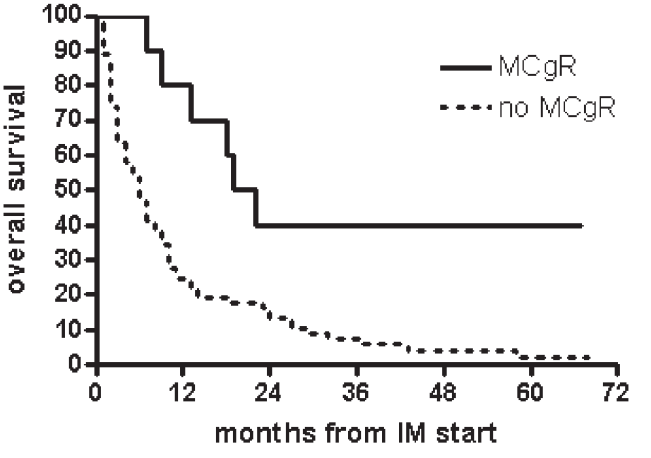

Figure 1. OS according to cytogenetic response.

Background. Imatinib mesylate (IM), a targeted inhibitor of the BCR-ABL tyrosine-kinase, is the standard of care for chronic myeloid leukemia (CML). In patients with CML in accelerated phase (AP-CML), the advent of IM significantly increased survival. However, few long-term data on the outcome of these patients based on large, prospective and controlled trials are available. *Aims*. The GIMEMA (Gruppo Italiano Malattie Ematologiche dell'Adulto) CML Working Party is conducting a phase II, multi-institutional prospective study (CML/003) to investigate the long-term effects of IM in AP-CML patients, treated with imatinib 600 mg daily. One hundred and eleven patients were enrolled; median follow-up of the 41 living patients is 82 months (range, 73-87). *Methods*. Patients were monitored for hematologic and cytogenetic response at 1-3 months intervals. A complete hematologic response (CHR) required the normalization of platelet and white cell differential count and absence of extramedullary involvement. The definition of return to chronic phase (RTC) required less than 15% blasts and less than 30% blasts plus promyelocytes in blood or bone marrow and less than 20% peripheral basophils. Cytogenetic analysis was performed with standard banding techniques. *Results*. In 107 patients (96%) was observed a RTC and 79 patients (71%) achieved also a CHR. Cumulative best rates of major cytogenetic response (MCgR) and complete cytogenetic response (CCgR) were 30% and 21%, respectively. CCgR was subsequently lost by 6 patients after 3 to 36 months from its first achievement (median,

10 months). A total of 90 patients (81%) discontinued IM, after a median time of 25 months (range, 1-86); only 7 patients (6%) discontinued IM because of adverse events. At last follow-up, 4 patients were alive in complete remission after allogeneic transplant, 16 patients have switched to second generation tyrosine kinase inhibitor and 21 patients were alive on IM therapy (13 in complete, 5 in partial, 1 in minor and 2 in null cytogenetic response). No late toxicities have been observed. The estimated rate of overall survival (OS) at 7 years was 43%, and was associated with the achievement of a MCgR (Figure 1). *Conclusion*. After a 7-year follow-up, IM continues to induce durable responses in patients with AP CML, with negligible toxicity.

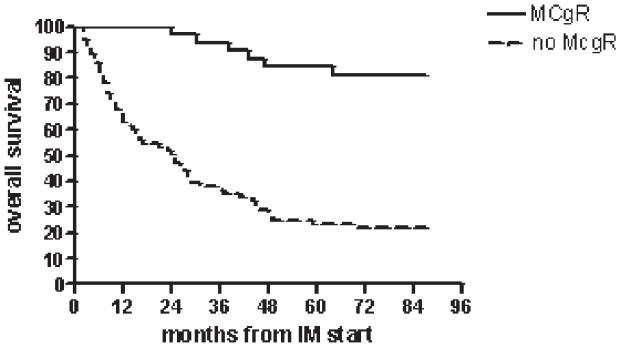

Figure 1. OS according to cytogenetic response

USE OF IMATINIB IN CHRONIC PHASE CML IN CLINICAL PRACTICE: THE UNIC STUDY

J.L. Steegmann,[1] M. Michallet,[2] E. Morra,[3] D. Marin,[4] G. Ossenkoppele,[5] G. Verhoef,[6] T. Kühr,[7] M. Björeman,[8] L. Van Bree,[9] K. Cerri[9]

[1]Hospital de La Princesa, MADRID, Spain; [2]Hôpital Edouard Herriot, LYON, France; [3]Ospedale di Niguarda Ca' Granda, MILAN, Italy; [4]Hammersmith Hospital, LONDON, UK; [5]VU University Medical Centre, AMSTERDAM, Netherlands; [6]University Hospital Leuven, LEUVEN, Belgium; [7]Klinikum Kreuzschwestern Wels, WELS, Austria; [8]University Hospital Örebro, ÖREBRO, Sweden; [9]Bristol-Myers Squibb International, BRAINE L'ALLEUD, Belgium

Background. Imatinib mesilate is widely used to treat chronic myeloid leukaemia (CML). *Aims*. The Unmet Needs in CML (UNIC) study aimed to address knowledge gaps on how CML patients are treated and monitored in clinical practice. Here, we present data on the use of imatinib in patients with chronic phase CML. *Methods*. UNIC was a cross-sectional study, with retrospective chart review of patients currently treated for CML or Philadelphia chromosome-positive acute lymphoblastic leukaemia (Ph^+ALL) across 8 European countries (Austria, Belgium, France, Italy, The Netherlands, Spain, Sweden, UK). Patients were recruited from September 2006 to March 2007. The study was designed to estimate the proportion of patients ever treated with imatinib and those imatinib-treated patients who have experienced imatinib resistance and/or intolerance (primary objectives). A secondary aim was to describe dosing patterns. A registry was collected of potentially eligible patients - those aged ≥18 years and treated for CML/Ph^+ALL at the participating centres (academic, non-academic, private clinic or other). Case Report Forms (CRFs) were completed for eligible patients until the recruitment target was reached. Data were collected at the most recent visit and retrospectively through clinical chart review. *Results*. CRFs were analysable for 1492 chronic phase CML patients, of whom 97% had received imatinib. Patients were defined as imatinib resistant/intolerant if resistance/toxicity led to a change in, or discontinuation of, imatinib use, as reported in their medical chart. Of the imatinib-treated chronic phase CML patients, 44.6% were imatinib resistant and/or intolerant at some time since imatinib initiation. A total of 20% of patients stopped and did not restart imatinib during the study period. Furthermore, 23% of patients stopped imatinib temporarily due to toxicity (median duration 22 days), of whom ~30% had >1 such interruption. In all, 41% (563/1366) of chronic phase CML patients had a dose increase and 33% (441/1352) had a dose decrease. The most common imatinib dose increase was from 400 mg to 600 mg (33%); the most common dose decrease was from 400 mg to 300 mg (39%). 16% of increases and 14% of decreases were both to and from imatinib doses <400 mg. Of the 520 patients with ≥1 dose increase, 17.5% were imatinib resistant just prior to dose change, of whom 63% were resistant at last observation. The median last imatinib dose was higher in imatinib-resistant patients (600 mg; n=149) than non-resistant patients (400 mg; n=1205). Of the imatinib-resistant patients, 41% had received doses≤400 mg. Of the patients with imatinib dose increases to 600 mg and 800 mg, 22% (62/284) and 32% (36/112), respectively, had a toxicity following the dose increase; and 88% (173/197) and 96% (64/67), respectively, of those without a cytogenetic response before the dose increase did not have a cytogenetic response after the increase. Summary/conclusions. A notable proportion of imatinib-treated chronic phase CML patients in this large observational study needed dose modification, where 41% had a dose increase and 33% had a dose decrease. Imatinib-resistant patients received higher imatinib doses than non-resistant patients.

EXPRESSION OF H-OCT1 PREDICTS FOR ACHIEVEMENT OF CCYR IN IMATINIB TREATED PATIENTS WHILE THE LEVEL OF PHOSPHO-CRKL INHIBITION IN CD34 POSITIVE CELLS SEEMS TO BE OF LITTLE PROGNOSTIC VALUE

S. Sorouri Khorashad, S. Wagner, D. Marin, A.G. Reid, D. Milojkovic, S. Willimott, G. Gerrard, L. Foroni, J.M. Goldman, J.F. Apperley

Imperial College of London, LONDON, UK

Background. About 15% of the patients who are treated with IM in chronic phase as first line treatment do not achieve complete cytogenetic response (CCyR). The mechanisms of failure to achieve CCyR in the majority of cases are unknown. Identification at diagnosis of patients who might subsequently fail to achieve CCyR would provide a considerable aid to clinical management. *Aims*. It has been suggested that measuring response to IM in CD34 cells from pre-IM samples might provide some information about patients' future response to therapy. We therefore assessed two such approaches for their predictive value: 1) measurement of the level of inhibition of Crkl phosphorylation (p-Crkl) by IM in CD34 positive cells; and 2) the level of h-OCT1 expression. Phosphorylation of the adaptor protein Crkl, which is a direct substrate of BCR-ABL, is known to be lower in patients responding to imatinib mesylate, and may therefore provide an in-vitro method of assessing likelihood of response. hOCT1 actively transports imatinib into cells, suggesting that patients with low baseline expression of hOCT1 may be unable to achieve adequate intracellular concentrations of imatinib, and hence fail to achieve a cytogenetic response. *Methods*. We analysed the level of P-Crkl inhibition by IM in CD34 positive cells from pre-IM samples and the level of h-OCT1 expression in 25 patients who had been treated with IM as first line therapy, 10 of whom failed to achieve CCyR during therapy with IM. Separated CD34 cells obtained before start of IM were cultured with and without 5 μM IM for 16 hours. The P-Crkl in the treated culture was calculated as a percentage of the untreated using flow cytometry. H-OCT1 transcript was measured by real time PCR and expressed as a ratio to the control gene which was G6PD in this study. *Results*. P-Crkl reduction was not significantly different in the patients who achieved CCyR from those who did not (p=0.53). Clinical response was not significantly different between the patients who had ≥50%reduction in P-Crkl and those who did not (p=0.97). The expression level of h-OCT1 in diagnostic samples was significantly associated with time to achievement of CCyR. The patients who had a h-OCT1/G6PD ratio >10 had RR of 4.2 to achieve CCyR than those for whom this ratio was less than 10 (p=0.027). Interestingly, there was no correlation between the inhibition level of P-Crkl and the level of h-OCT1 (p=0.86). This observation suggests that the level of h-OCT1 expression may not influence inhibition of P-Crkl by 5 μM IM. *Summary*. Level of *in vitro* inhibition of p-Crkl in CD34 positive cells by IM does not appear to predict for future response, however, the expression level of h-OCT1 shows a significant correlation with time to CCyR and warrants further investigation as a prognostic indicator.

0128

DASATINIB LACK OF CROSS INTOLERANCE TO IMATINIB IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA IN CHRONIC PHASE (CML-CP) WHO ARE INTOLERANT TO IMATINIB - A RETROSPECTIVE SAFETY ANALYSIS

F. Guilhot,[1] S.L. Goldberg,[2] R.M. Stone,[3] M. Mauro,[4] Y. Matloub,[5] T.T. Chen,[5] H.J. Khoury[6]

[1]CHU de Poitiers, POITIERS, France; [2]Hackensack University Medical Center, HACKENSACK, USA; [3]Dana-Farber Cancer Institute, BOSTON, USA; [4]Oregon Health & Science University, PORTLAND, USA; [5]Bristol-Myers Squibb, WALLINGFORD, USA; [6]Emory University School of Medicine, ATLANTA, USA

Background. Cross intolerance may be a barrier in the second-line treatment of imatinib-intolerant patients with CML-CP. Dasatinib is a BCR-ABL inhibitor structurally unrelated to imatinib; it is effective in patients with CML-CP intolerant to imatinib and is generally well tolerated. The most common adverse events of imatinib treatment are fluid retention, gastrointestinal intolerance, and cytopenias. *Aims*. To assess whether the type of intolerance to imatinib (hematologic or non-hematologic toxicity) predicts the safety of dasatinib. *Methods*. Pooled data from two multicenter studies, one phase II and one phase III, in patients with CML-CP were analyzed. Imatinib intolerance was defined as grade ≥3 non-hematologic toxicity or any grade 4 hematologic toxicity lasting >7 days. Dasatinib was administered according to one of four schedules: 70 mg BID, 100 mg QD (the approved dosing schedule), 50 mg BID, and 140 mg QD. Median duration of dasatinib therapy was 11.96 months (0.03-30.06 months). Cross intolerance between imatinib and dasatinib was evaluated using discontinuations due to NCI-CTAE grade 3-4 adverse events. Evidence for a correlation between fluid retention on imatinib and subsequent pleural effusions on dasatinib was examined. *Results*. In total, 271 patients with imatinib-intolerant CML-CP were eligible for analysis. The duration of imatinib therapy was <1 year in 58% of patients. Imatinib intolerance was related to hematologic toxicity in 46 patients and non-hematologic toxicity in 225 patients. The exact cause of imatinib intolerance related to non-hematologic toxicity was defined in 210 patients (Table 1).

Table 1.

Adverse events causing intolerance	No. of imatinib-intolerant pts	No. of dasatinib-intolerant pts	No. of pts discontinuing dasatinib
Rash	87	3	1
Hepatotoxicity	48	0	0
Myalgia/arthralgia	22	1	1
GI toxicities	15	2	0
Fluid retention	10	0	0
Pulmonary toxicities	10	0	0
Bone pain	5	0	0
Others (1 or 2 pts each)	13	3*	0
TOTAL	**210**	**9**	**2**

*Fatigue, headache, and cardiac toxicity

Nine (4%) patients experienced the same grade 3-4 non-hematologic toxicity on dasatinib as on imatinib, and only two (1%) discontinued dasatinib. Seven patients continued on dasatinib following dose reduction. Ten patients had fluid retention on imatinib, and none developed pleural effusion on dasatinib. Among the 46 patients who had discontinued imatinib due to hematologic toxicity, six (13%) discontinued dasatinib due to the same hematologic toxicity. *Conclusions*. In this large population of imatinib-intolerant patients with CML-CP, there was no evidence of cross intolerance between imatinib and dasatinib, suggesting that imatinib-intolerant patients may be successfully switched to dasatinib without being at risk of experiencing similar grade 3-4 toxicities. There was also no evidence to support a correlation between fluid retention with imatinib and pleural effusions with dasatinib.

0129

HAPLOIDENTICAL BLOOD AND MARROW TRANSPLANTATION IN ADVANCED CHRONIC MYELOID LEUKEMIA: A SINGLE-CENTER REPORT OF 35 PATIENTS

Z. Zhao, T. Wu, J.B. Wang, X.Y. Cao, Y.M. Ying, D.P. Lu

Beijing Daopei Hospital, BEIJING, China

Background. Chronic myeloid leukemia (CML) has substantially improved survival with the application of imatinib, however, the patients with advanced CML such as in accelerated phase (AP) or blast crisis (BC) have dismal prognosis even in the era of tyrosine kinase inhibitors. Allogeneic hematopoietic stem cell transplantation is still the only way to cure the patients with advanced CML. HLA mismatched / haploidentical blood and marrow transplantation (haplo-BMT) from family donor is a feasible alternative option for patients with hematological malignancies who need transplant but lack of matched either sibling or unrelated donor (*Lu DP et al. Blood 2006; 107:3065*). *Aims*. In current clinical study, the efficacy of haplo-BMT in the treatment of advanced CML was investigated. *Methods.* From November 2002 to October 2007, thirty-five patients with advanced CML without matched either sibling or unrelated donors received haplo-BMT. All patients or their guardians signed consent forms approved by the institutional review board. Eleven patients achieved the second or the third CP after treatment with imatinib or chemotherapy or both before pre-conditioning, but there were thirteen cases in AP and 11 patients in BC at the time of transplantation. The median age was 29 years (range 8 to 51 years). The regimens for pre-conditioning and GVHD prophylaxis have been published previously. G-CSF primed both bone marrow and peripheral blood were employed as the grafts. The median follow-up time among living patients was 25.5 months (range, 5 to 57 months). *Results.* The cases of HLA-antigen mismatched between donor and recipient as 1, 2, and 3 antigens were 1, 12, and 22 respectively. The mean mononuclear cells and $CD34^+$ cells were $7.19\pm1.37\times10^8$/kg and $2.54\pm1.50\times10^7$/kg. All but one patient achieved hematopoietic reconstitution. The median days for neutrophil and platelet engraftment were 13 (range, 8-22) and 17 (range, 9-151), respectively. Hyperacute GVHD occurred in 28.6% patients. The cumulative incidence of grade II to IV acute GVHD was 47.8%. Among 27 patients with survival longer than 100 days, 16 of them had chronic GVHD. Two-year cumulative overall survival rates were 75.0%, 26.6% in patients with CML-CP2 or CP3, CML-AP or BC, respectively (p<0.01). *Conclusions*. Haploidentical BMT is a feasible therapeutic mean for patients with advanced CML if they have no matched donor available. It is better to perform haplo-BMT at CML-CP2 or CP3 other than CML-AP or BC.

0130

BLASTS, EOSINOPHILS, SPLEEN ENLARGEMENT, AND CONCOMITANT DISEASE PROVIDE INDEPENDENT SIGNIFICANT PROGNOSTIC INFORMATION ON THE PROBABILTY TO LIVE MORE THAN NINE YEARS WITH CONSERVATIVE DRUG TREATMENT

M. Pfirrmann,[1] F. Waibel,[2] M. Lauseker,[1] S. Saussele,[2] M. Rohrbacher,[2] A. Leitner,[2] J. Hasford,[1] R. Hehlmann,[2] A. Hochhaus[2]

[1]Ludwig-Maximilians-University, MUNICH; [2]Medizinische Fakultät Mannheim der Universität Heidelberg, MANNHEIM, Germany

Background. 1477 newly diagnosed patients with chronic myeloid leukemia (CML) in chronic phase were recruited for German CML studies I, II and III between 1983-2001. Most patients (n=1094, 74%) received drug treatment as first-line therapy. 383 patients received allogeneic stem cell transplantation in first chronic phase and are not considered here. *Aims.* Based on a median observation time of 9.6 years for 238 living patients (22% of 1094) for the drug-treated patients, we sought to investigate which factors evaluated at diagnosis provide prognostic information with regard to survival beyond nine years after registration in one of the trials. *Methods*. To be able to determine the final outcome (dead or alive nine years after registration), living patients who were observed for <9 years were excluded (n=95). The prognostic influence of the candidate variables on the final outcome was examined by conditional logistic regression with *at least nine year survival* as response. Responders and non-responders were matched by allocated drug treatment (busulfan (BU), hydroxyurea (HU), interferon-α (IFN), combination therapy IFN+HU), sex, and age group (<50, 50-64, >64 years). To avoid too small strata, further 38 patients allocated to intensive chemotherapy were not considered. *Results.* The 961 patients of the final analysis sample comprised 684 patients randomised within the trials CML I and II: 164 patients were randomised to BU, 255 to HU, 102 to IFN, and 163 to

IFN+HU. The remaining 277 patients were part of the CML study III and allocated to receive IFN+HU as first-line therapy. Only drug treatment but not trial origin had an influence on survival. After nine years, 177 patients were still alive (18%): 12 (7%) allocated to BU, 31 (12%) to HU, 19 (19%) to IFN, and 115 (26%) to IFN+HU. Of 130 patients (73% of 177) who were still alive at last evaluation, 62 (48%) received second line imatinib therapy, 30 (23%) IFN, 22 (17%) HU, 11 (8%) no therapy, 2 (2%) other therapy, and for 3 (2%) therapy was unknown. With a significance level of 0.05, conditional logistic regression identified white blood cell count, the proportions of basophils, blasts, eosinophils, and erythroblasts in peripheral blood, hemoglobin, lactate dehydrogenase, spleen size, weight loss, and Karnofsky index to have a significant univariate association with survival outcome. In addition to these variables, the univariately non-significant parameters fever, general ill-feeling, concomitant disease, platelet count, and proportions of myelocytes and promyelocytes in peripheral blood qualified for multiple analyses. A backward and forward selection strategy yielded a final model with four independent variables: blasts, eosinophils, spleen enlargement, and concomitant disease. Apart from the latter one, these variables were also part of the Hasford score (*Hasford et al., JNCI 1998; 90:850-8*). *Conclusions*. Matched for allocated first-line treatment, sex, and age group, our results indicate that blasts, eosinophils, spleen enlargement, and concomitant disease provide independent, statistically significant prognostic information on the probability to live beyond nine years with conservative drug treatment.

0131

MEASUREMENT OF IMATINIB AND ITS METABOLITE, CGP-74588, IN TREATED CHRONIC MYELOID LEUKAEMIA PATEINTS BY HPLC

A. Davies, A. Hayes, K. Knight, S.J. Watmough, M. Pirmohamed, R.E. Clark

University of Liverpool, LIVERPOOL, UK

Background. Recent data have indicated that plasma imatinib levels might correlate with clinical outcome in chronic myeloid leukaemia (CML). Imatinib is mainly metabolised by the cytochrome P450 isoform (CYP3A4) to produce the N-desmethyl metabolite CGP-74588. Although equipotent, CGP-74588 has a longer half-life than imatinib, and may have longer lasting effects. A variety of concomitant medications and foodstuffs can either inhibit or induce drug metabolism pathways, in particular CYP3A4, and thereby alter the level of the interacted drug. It is therefore possible that plasma levels of CGP-74588, as well as imatinib, correlate with clinical outcome. *Methods*. We have developed a high performance liquid chromatography (HPLC) technique that will assay both imatinib and CGP-74588 simultaneously, using clozapine as the internal standard. Solid phase extraction (SPE) was used to prepare the plasma samples (200 μL). The samples were separated by UV-HPLC through a Gemini C6-Phenyl (150 mm x 4.6 mm ID; 5 μm) column (Phenomenex) under isocratic mobile phase conditions of MeOH:50mM ammonium acetate (65:35, v/v) at a flow rate of 1 mL/min and detected at 260 nm. *Results*. Complete separation of the imatinib and CGP-74588 peaks was observed with retention times of 5.5 and 3.7 minutes, respectively, during a run time of 17 minutes. Mean extraction recovery of imatinib and CGP-74588 are 89% and 96% respectively. Calibration curves are linear (r^2=0.9999) between 12,000 and 750 ng/mL. The limit of quantification (LOQ) is 100 ng/mL (<15% bias). Intra-day precision is demonstrated with CVs at or below 2% and 4.5% for imatinib and CGP-74588 respectively. The method is reproducible with mean inter-day CVs of less than 3.5% and 3% for imatinib and CGP-74588 respectively. Analysis of clinical samples has demonstrated contrasting plasma imatinib levels 22-26 hours after identical doses, with subsequent clinical outcome being more favourable with higher plasma levels. In addition, the ratio of imatinib to CGP-74588 was not constant, and may relate in part to the time since last dose of imatinib, and CYP3A4 activity. As predicted, levels of both imatinib and CGP-74588 are higher in samples 11-13 hours post dose than 22-26 hours post dose, and in patients receiving 600 or 800 mg daily doses compared to 400 mg daily dosing. Expansion of these findings with a wider dataset is currently in progress. *Summary*. The present entirely HPLC based method to assay both imatinib and CGP-74588 avoids the need for mass spectrometry and for radioactive laboratory standards, and can be used to monitor individual patient responses to imatinib and improve the prediction of clinical outcome in CML.

0132

COMBINED THERAPY WITH IMATINIB FOR INDUCTION AND INTERFERON AS CONSOLIDATION INDUCES A SUSTAINED CYTOGENETIC REMISSION THAT FACILITATES DISCONTINUATION OF ANTI LEUKEMIC THERAPY IN CHRONIC MYELOGENOUS LEUKEMIA

I. Hardan,[1] N. Amariglio,[1] L. Trachtenbrot,[1] A. Simon,[1] A. Shimoni,[1] I. Levi,[2] M. Koren- Michowitz,[1] Y. Binenbaum,[1] G. Rechavi,[1] A. Nagler[1]

[1]Sheba Medical Center, TEL HASHOMER; [2]Soroka Medical Center, BEER SHEVA, Israel

Imatinib Mesylate (IM, Gleevec) is capable of induction of cytogenetic and molecular response in a substantial proportion of newly diagnosed and previously treated chronic myelogenous leukemia (CML) patients. Discontinuation of therapy results in an early disease progression in most cases due to IM reduced activity on immature Ph+ progenitors. IM is therefore needed for lifelong, while the duration of response to tyrosine kinase inhibibitors and the adverse effects of long term use of these agents are yet unknown. Alpha Interferon (IFN) is capable of controlling immature Ph^+ progenitors, mainly in the set up of minimal residual disease (MRD), by mounting an autologous anti leukemic activity mediated by CML specific T cell clones. Therefore, unlike IM, IFN therapy discontinuation in responding patients often does not result in disease progression. *Aims*. We conduct a prospective clinical trial aims to study the efficacy of further eliminating residual Ph^+ progenitor cells in patients with IM induced complete cytogenetic remission (CCyR) and it's potential role in facilitating discontinuation of (and freedom from the need of) anti-leukemic therapy. *Methods*. Eligibility includes more than one year of documented CCyR on IM therapy and lack of history of IFN intolerance. PEG-IFN2α (Pegasys) was added to the IM therapy at enrolment for 12 month. IM therapy was discontinued after 9 month of IFN administration. Thus, 12 month after enrolment patients remain off anti leukemic therapy. Twelve patients (9 m, 3 f ; median age 47y, range 32-61) were enrolled. Median CML duration at enrolment was 61 month (range 24-108). Six patients were previously treated with IFN; one patient had a previous autologous and one an allogeneic BMT. Three patients had a previous documentation of accelerated phase CML. Hasford score at diagnosis was low in seven patients and intermediate/high in 3 and 2 patients respectively. Median duration of IM therapy was 54m (range 21-72). At enrolment seven patients had a major molecular response (MMR) in BM cells including one with undetectable BCR-ABL transcript (molecular remission, CMR). *Results*. One patient discontinued IFN therapy after 4 weeks due to side effects. 11 patients received 90-180 mg of PEG-IFN/week according to blood counts for 52 weeks and discontinued IM therapy 39 weeks after initiation of IFN therapy. Nine Of the 11 patients improved their molecular response (either to MMR or to CMR) during the IFN therapy (one remained in CMR and one in MMR). At the day of IM discontinuation 7 of 11 patients had a documented molecular remission (CMR). With a median follow up of 9 month from discontinuation of IM therapy (range 3-16m) two of 11 patients relapsed (at 8 and 9 month after IM discontinuation, and regained their base line response with IM therapy) while nine of the 11 patients remain in CCR off therapy. Four patients are >15 month from IM discontinuation (>12 month off all therapy). These four patients are in a sustained cytogenetic remission (two with CMR and two with MMR). *Conclusions*. An adition of one year of consolidation therapy with IFN can facilitate discontinuation of Imatinib (and all anti leukemic) therapy in patients with CML in cytogenetic remission. A longer follow-up and larger experience are needed to determine the off-therapy duration of remission and to define the sub-population of patients that may benefit from this strategy.

0133

TREATMENT OF PHILADELPHIA-POSITIVE CHRONIC MYELOID LEUKEMIA WITH IMATINIB: INTRODUCING THE CONCEPT OF STABLE MOLECULAR RESPONSE

F. Palandri,[1] I. Iacobucci,[2] S. Soverini,[2] F. Castagnetti,[2] A. Poerio,[2] N. Testoni,[2] G. Alimena,[3] M. Breccia,[3] G. Rege-Cambrin,[4] M. Tiribelli,[5] R. Varaldo,[5] E. Abruzzese,[5] B. Bruno,[5] F. Pane,[6] G. Saglio,[4] G. Martinelli,[2] M. Baccarani,[2] G. Rosti[2]

[1]Department of Hematology Seragnoli, BOLOGNA; [2]Department of Hematology Seragnoli, BOLOGNA; [3]Department of Cellular Biotechnology and Hematology, University La Sapienza, ROMA; [4]Department of Clinical and Biological Science, University of Turin at Orbassano, TORINO; [5]Division of Hematology, UDINE; [6]CEINGE Biotecnologie Avanzate and Department of Biochemistry and Medical Biotech, NAPOLI, Italy

Background. The achievement of a major molecular response (MMolR) at 12 months is a surrogate marker of progression to accelerated/blast phase free survival (PFS) in chronic myeloid leukemia (CML) patients treated with imatinib (IM). *Aims*. We evaluated the prognostic value of the long-term prospective evolution of the MolR based on a retrospective analysis of 130 late chronic phase patients, who achieved a complete cytogenetic response (CCgR) with IM 400 mg. *Methods*. Two hundred and seventy-seven patients were treated with IM 400 mg daily after Interferon-α (IFN-α) failure, and 153 (53%) patients obtained a CCgR. We have selected for this analysis 130 out of 153 patients (85%), on the basis of the following criteria: 1) a CCgR confirmed at least twice; 2) at least 3 molecular tests performed after achieving the CCgR (median number of evaluable molecular tests: 5; range: 3-8). Patients were monitored for cytogenetic and MolR every 6 months. Cytogenetic analysis was performed with conventional methods. MolR was assessed on peripheral blood by quantitative PCR (RQ-PCR, TaqMan) and results were expressed as a ratio of BCR-ABL:ABL %. MMolR was defined as a ratio BCR-ABL/ABL % less than 0.05; a complete MolR (CMolR) was defined as undetectable BCR-ABL transcript levels by RQ-PCR confirmed by nested PCR. *Results*. In 71 patients (55%) MolR was always major (stable MMolR); in 19 (15%) MolR was occasionally less than major (unstable MMolR) and in 40 patients (30%) MMolR was never achieved (never MMolR). Patients with stable MMolR had longer CCgR duration and better PFS compared to patients with absent or unstable MMolR. The achievement of a MMolR, if maintained continuously, conferred a marked long-term stability to the CCgR (rate of CCgR loss: 4%): the probability of remaining in CCgR after 6 years was calculated by the Kaplan-Meyer method (Figure 1) and was 95% for patients in stable MMolR and 67% for patients with unstable or never MMolR (p<0.0001, log-rank test).

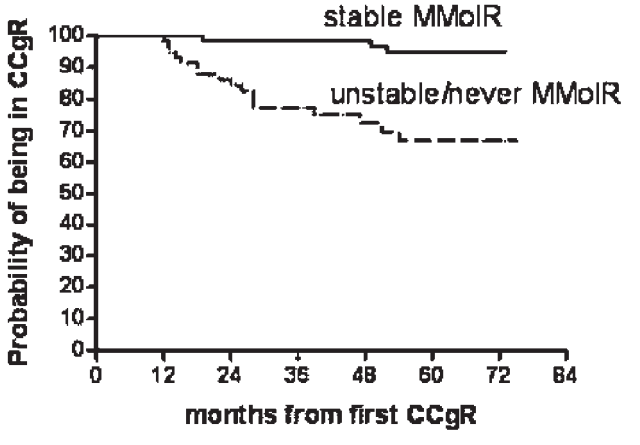

Figure 1. CCgR duration according to RQ-PCR categories.

Patients with stable MMolR have a significantly lower risk of losing the CCgR than patients with unstable (4% *vs* 21%, p=0.03) and never MMolR (4% *vs* 33%, p<0.0001). Finally, if a MMolR is not maintained continuously, the risk of losing the CCgR is higher but not significantly than if it is never achieved (33% *vs* 21% p=0.5). *Conclusion*. These data confirm that achieving a MMolR is prognostically important but point out that the prognostic value of achieving a MMolR is greater if the response is confirmed and stable.

EXPANDING NILOTINIB ACCESS IN CLINICAL TRIALS (ENACT) STUDY IN ADULT PATIENTS WITH IMATINIB-RESISTANT OR INTOLERANT CHRONIC MYELOID LEUKEMIA (CML): UPDATED SAFETY ANALYSIS

F. Nicolini,[1] G. Alimena,[2] Z. Shen,[3] H.-K. Al-Ali,[4] A. Turkina,[5] G. Smith,[6] R. Pasquini,[7] S. Jootar,[8] Y. Hsu,[9] M.L. Veronese,[9] B. Powell[10]

[1]Hôpital Edouard Herriot, LYON, France; [2]Cellular Biotechnology and Hematology, University La Sapienza, ROME, Italy; [3]Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, SHANGHAI, China; [4]Medizinische Klinik und Poliklinik II, Universitat Leipzig, LEIPZIG, Germany; [5]Hematological Scientific Center, MOSCOW, Russian Federation; [6]Leeds Teaching Hospital, LEEDS, UK; [7]Universidade Federal do Paraná, CURITIBA, Brazil; [8]Medicine, Mahidol University, SALAYA, Thailand; [9]Novartis Pharmaceuticals, EAST HANOVER, USA; [10]Comprehensive Cancer Center of Wake Forest University Baptist Medical Center, WINSTON-SALEM, USA

Background. Nilotinib, a potent and highly selective BCR-ABL inhibitor, has been approved in several countries including the US and Europe for the treatment of patients (pts) with Philadelphia chromosome-positive chronic myelogenous leukemia (Ph^+ CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. The ENACT study, which is an open label, multicenter, ongoing study, was initiated to provide expanded access to nilotinib and obtain additional safety information in pts with imatinib-resistant or -intolerant CML- chronic phase (CP), -accelerated phase (AP), or -blast crisis (BC). *Methods*. Pts received nilotinib 400 mg twice daily (BID). Dose escalation was not permitted. Pts who required dose reduction to 400 mg once daily due to toxicity were allowed to have a dose re-escalation to 400 mg BID after resolution of the adverse events (AEs) ≤grade 1, lack of response, or persistent disease at the investigator's discretion. Efficacy assessment was not an objective of this study. *Results*. To date, more than 1600 patients have been enrolled, with results for the first 1056 pts (CP, n=818; AP, n=120; BC, n=118) included for this analysis. Median age of pts was 53 years, and 69% were imatinib-resistant. AE data are available for 974 pts. At data cut-off (June 30, 2007), 710 pts (67%) were continuing on nilotinib. Median duration of nilotinib exposure was 124 (1-522) days for CP pts, 90 (10-361) days for AP pts, and 54 (1-354) days for BC pts; median dose intensity was 800, 783, and 785 mg/day, respectively. The main reasons for discontinuation were inadequate responses (13%), and AEs (11%). The majority of AEs were hematologic, with the most common grade 3/4 hematologic toxicities being thrombocytopenia (22%) and neutropenia (13%). Non-hematologic AEs were mostly mild to moderate and included headache, rash, and nausea. Deaths were reported for 28 (3%) pts, and occurred more frequently among those with BC (n=15). A low incidence of QT prolongation (QTcF > 500 msec, n=2, 0.2%) was observed overall. *Conclusion*. This updated analysis of a large expanded access study further demonstrates that nilotinib is generally well tolerated in heavily pretreated pts in all phases of CML with safety profile reported in ENACT being similar to that observed in the pivotal phase II registration study.

Chronic myeloid leukemia / Myeloproliferative disorders

DEVELOPMENT OF PROTOTYPE REFERENCE MATERIALS FOR BCR-ABL QUANTITATIVE RT-PCR

C.P. Cross,[1] A. Hochhaus,[2] M.C. Mueller,[2] G. Saglio,[3] S. Branford,[4] T.P. Hughes,[4] J. Gabert,[5] Y.L. Wang,[6] P. Metcalfe,[7] H.E. White[8]

[1]University of Southampton, SALISBURY, UK; [2]III Medizinische Klinik, MANNHEIM, Germany; [3]University of Turin, TURIN, Italy; [4]IMVS, ADELAIDE, Australia; [5]Université de la Méditerranée, MARSEILLES, France; [6]Weill Medical College of Cornell University, NEW YORK, USA; [7]NIBSC, SOUTH MIMMS, UK; [8]NGRL Wessex, SALISBURY, UK

Background. RQ-PCR is used routinely to quantify levels of BCR-ABL mRNA and thereby monitor the response of CML patients to treatment. Despite efforts to establish standardised protocols, there is still substantial variation worldwide in the way RQ-PCR for BCR-ABL is undertaken, what control gene is used for normalisation and how results are reported. An international scale (IS) has been established that is anchored to two key points defined in the IRIS trial: a common baseline (100% BCR-ABLIS) and major molecular response (0.1% BCR-ABLIS). Definition of the IS currently relies on relating results directly or indirectly to the Adelaide international reference laboratory. A more robust definition of the IS requires the development of internationally accredited reference reagents. *Aims*. To produce and assess the use of freeze dried cell lines and armored RNA constructs as candidate reference materials for the standardisation of BCR-ABL RQ-PCR protocols. *Methods*. Development of materials was co-ordinated by the National Genetics Reference Laboratory (Wessex) in conjunction with the National Institute of Biological Standards and Controls and Asuragen Inc. Field trial evaluation of the reagents was performed by 33 laboratories worldwide. (i) Freeze dried cell lines. In an initial assessment of 30 haemopoietic cell lines, HL60 and KG1 were found to express relative levels of BCR, ABL and GUSB (the three principal control genes used for normalisation of RQ-PCR results) that were closest to normal leukocytes and were therefore selected for further analysis and validation. Reference standards were prepared by diluting K562 cells (b3a2 BCR-ABL expressing cell line) into HL60 and KG1. Four levels of BCR-ABL in each negative cell line were produced and freeze dried at 3×10^6 cells/vial. The performance of the freeze dried cells was assessed by an international field trial (June - October 2007) that involved 14 laboratories (7 EU, 4 USA, 3 Asia/Australasia) using 7 different protocols and 9 different RQ-PCR platforms. (ii) Armored RNAs were produced for b2a2 and b3a2 BCR-ABL, plus BCR, ABL and GUSB as control genes and their performance was assessed in an international field trial (October-November 2007) that involved 29 laboratories (22 EU, 3 USA, 4 Asia/Australasia). Results RNA (median 30 μg/vial) was successfully extracted from freeze dried cell mixtures shipped worldwide at ambient temperature. The HL60/K562 and KG1/K562 cell mixes performed equally well producing coefficients of variation within and between laboratories that were comparable to those seen with patient samples. The aRNA trial showed good comparability of normalised %BCR-ABL/control gene results between laboratories. The reagents worked very well when directly heat lysed prior to cDNA synthesis but further modifications are required to ensure adequate yields following RNA extraction. *Summary*. Both freeze dried cells and armoured RNAs appear to be suitable for development of BCR-ABL reference reagents. We are planning large scale production of the freeze dried cell lines as 'higher order' internationally accredited reference materials. The armoured RNAs will undergo a further round of field trial evaluation with the aim of establishing them as secondary reference reagents.

0136

DASATINIB EARLY INTERVENTION AT CYTOGENETIC RATHER THAN HEMATOLOGIC RESISTANCE TO IMATINIB IS ASSOCIATED WITH MORE FAVORABLE RESPONSES

H. Kantarjian,[1] A. Quintas-Cardama,[1] S. O'Brien,[1] F. Ravandi,[1] G. Borthakur,[1] Y. Matloub,[2] D. Liu,[2] T.T. Chen,[2] J. Cortes[1]

[1]MD Anderson Cancer Center, HOUSTON; [2]Bristol-Myers Squibb, WALLINGFORD, USA

Background. In patients with chronic myeloid leukemia (CML) in chronic-phase (CP), development of resistance or intolerance to imatinib, or progression to advanced-phase disease, is associated with poor clinical outcome. Dasatinib, a BCR-ABL inhibitor that is 325-fold more potent than imatinib and 16-fold more potent than nilotinib *in vitro*, is an effective treatment for patients with CML in any phase or Philadelphia chromosome-positive acute lymphoblastic leukemia following imatinib resistance or intolerance. Treatment with dasatinib or other second-generation tyrosine kinase inhibitors is more effective when administered during CML-CP compared with during advanced-phase disease. Importantly, treatment after cytogenetic relapse on imatinib rather than after hematologic relapse, i.e. earlier intervention, is an independent prognostic factor for survival. *Aims*. To further assess the impact of early intervention with dasatinib following imatinib failure, clinical trial data in patients with imatinib-resistant CML-CP have been analyzed. The primary objective was to determine whether dasatinib treatment was associated with more favorable outcomes when administered following loss of major cytogenetic response (MCyR) on imatinib rather than following loss of both MCyR and complete hematologic response (CHR). *Methods*. Data from three phase II/III dasatinib clinical studies in imatinib-resistant CML-CP were analyzed retrospectively: CA180-013 (70 mg BID), CA180-017 (70 mg BID), and CA180-034 (100mg QD, 50 mg BID, 140 mg QD, 70 mg BID) (dasatinib 100 mg QD is now the approved dose for patients with CML-CP following imatinib failure). Assessments included complete cytogenetic response (CCyR) rate and progression-free survival (PFS). *Results*. The analysis identified 151 patients who received dasatinib treatment after confirmed loss of MCyR and 33 patients who received dasatinib after loss of both MCyR and CHR (n=33) during imatinib treatment. More than half of patients had received imatinib doses >600 mg/d and more than 65% had received imatinib for >3 years. Following dasatinib treatment, higher CCyR rates were achieved in patients treated after loss of MCyR (72%) than in those treated after loss of both MCyR and CHR (42%) (Table 1). Patients treated after loss of MCyR also had prolonged PFS (median PFS not reached) compared with those treated after loss of both MCyR and CHR (median PFS 18.5 months), with 24-month PFS rates of 89% and 29%, respectively. A third group of patients was identified who had confirmed loss of CHR (n=146). Among these patients, one quarter had also achieved MCyR but loss of MCyR was not recorded. Dasatinib was also effective after loss of CHR on imatinib, with a CCyR rate of 35% and a 24-month PFS rate of 64% (median PFS not reached) in this group. *Summary and Conclusions*. Dasatinib is an effective treatment for patients with CML-CP who have experienced imatinib failure. Response rates and PFS were improved when dasatinib was administered early after imatinib failure, i.e. after loss of MCyR rather than after loss of both MCyR and CHR. To increase treatment benefits associated with dasatinib, early intervention (at loss of MCyR) is recommended and close monitoring of response during imatinib treatment is required to identify when resistance first develops.

Table 1. Achievement of CCyR by patients treated dasatinib after loss of response to prior imatinib.

	Loss of MCyR		Loss of MCyR and CHR		Loss of CHR	
	n/N	%	n/N	%	n/N	%

RESPONSE TO NILOTINIB IN CHRONIC MYELOGENOUS LEUKEMIA PATIENTS IN CHRONIC PHASE (CML-CP) ACCORDING TO BCR-ABL MUTATIONS AT BASELINE

J. Radich,[1] D.-W. Kim,[2] G. Martinelli,[3] S. Soverini,[3] S. Branford,[4] M. Mueller,[5] A. Haque,[6] Y. Shou,[6] A. Hochhaus,[5] T. Hughes,[4] G. Saglio[7]

[1]Fred Hutchinson Cancer Research Center, SEATTLE, USA; [2]Catholic University of Korea, SEOUL, South-Korea; [3]University of Bologna, BOLOGNA, Italy; [4]Hanson Institute Centre for Cancer, ADELAIDE, Australia; [5]Medizinische Klinik III, MANNHEIM, Germany; [6]Novartis Pharmaceuticals, EAST HANOVER, USA; [7]University of Turin, TORINO, Italy

Background. Nilotinib (Tasigna®) is a potent and highly-selective BCR-ABL inhibitor approved in the US and Europe for the treatment of patients (pts) with Philadelphia chromosome-positive (Ph^+) chronic myeloid leukemia (CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. *Methods*. This subanalysis of a phase 2 study of nilotinib in imatinib-resistant or-intolerant CML-CP pts assessed the occurrence of baseline BCR-ABL mutations and their impact on treatment outcome following 12 months of therapy. The BCR-ABL kinase domain (amino acid 230-490) was amplified and mutations identified by direct sequencing that allowed for detection of > 20% minor alleles. *Results*. Of the 275 pts with mutation data available, 113 (41%) had BCR-ABL mutations at initiation of nilotinib therapy. Amongst imatinib-resistant patients, the frequency of mutations at initiation was 56%. After 12 months of therapy, major cytogenetic response (MCyR) was achieved in 60%, complete cytogenetic response (CCyR) in 42%, and major molecular response (MMR) in 25% of pts without baseline mutations, *vs* 50%, 32%, and 21% of pts with mutations, respectively, among the imatinib-resistant pts. Response rates in pts with mutations of ≤150 nM cellular IC50 (*M244V, L248V, G250E, Q252H, E275K, D276G, F317L, M351T, E355A, E355G, L387F, F486S*) and with mutations of unknown IC50 values had comparable response rates to those for pts without baseline mutations: MCyR were 62% and 58%, respectively, and CCyR were 40% and 42%, respectively. For patients (n=26) with less sensitive BCR-ABL mutations (*in vitro* cellular IC50 > 150 nM), MCyR was achieved in 1 of 8 pts (13%) with Y253H, 3 of 8 pts (38%) with E255K/V, and 1 of 10 pts (10%) with F359C/V. None of these patients achieved CCyR. *Conclusions*. A significant proportion of imatinib-resistant pts with BCR-ABL mutations at baseline respond to imatinib. Pts with sensitive BCR-ABL mutations exhibited response rates on nilotinib therapy comparable to those for patients with no baseline mutations. Less sensitive mutations represented <15% of the cohort and may be associated with less favorable responses. Larger cohort and longer follow-up are required to validate these findings.

0138

EPIDEMIOLOGICAL STUDY ON SURVIVAL OF CHRONIC MYELOID LEUKEMIA (CML) AND DE NOVO PH+ ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS WITH T315I MUTATION - A PRELIMINARY ANALYSIS

D.W. Kim,[1] W. Zhou,[2] G. Martinelli,[3] C. Chuah,[4] F. Yagasaki,[5] I. Dufva,[6] S. Peter,[2] M. Mauro,[7] F. Giles,[8] J. Cortes,[9] J. Pearson,[2] J. Goldman,[10] F. Nicolini[11]

[1]St. Mary's Hospital, The Catholic University of Korea, SEOUL, South-Korea; [2]Department of Epidemiology, Merck Research Laboratories, NORTH WALES, PA, USA; [3]Institute of Hematology and Medical Oncology „Seràgnoli„, University of Bologna, BOLOGNA, Italy; [4]Department of Hematology, Singapore General Hospital, SINGAPORE, Singapore; [5]First Department of Internal Medicine, Saitama Medical School, SAITAMA, Japan; [6]Department of Haematology, Herlev Hospital, University of Copenhagen, HERLEV, Denmark; [7]Oregon Health & Science University, Center for Hematologic Malignancies, PORTLAND, OR, USA; [8]Cancer Therapy & Research Center, Institute for Drug Development, ANTONIO, TX, USA; [9]Department of Leukemia, The University of Texas M.D. Anderson Cancer Center, HOUSTON, TX, USA; [10]Haematology Department, Hammersmith Hospital, Imperial College London, LONDON, UK; [11]Hematology Department, Hôpital Edouard Herriot, LYON, France

Background. T315I mutation is one of the major mechanisms of resistance to Imatinib and 2nd generation tyrosine kinase inhibitors (TKIs) and may be associated with poor survival. *Aims*. The objective of this study was to estimate overall survival (OS) and progression-free survival (PFS) for CML and Ph^+ ALL patients with T315I mutation. *Methods*. This is a retrospective, multi-center epidemiological study. Eligible patients were CML and Ph^+ ALL patients who were identified as possessing T315I mutation between the years 1999 and 2007. The medical records of approximately 200 patients are being abstracted for detailed clinical, treatment, mutation and survival information. Data on 62 patients from Korea, Italy, Singapore, USA, Denmark, and Japan were included in this preliminary analysis. Kaplan-Meier curves were used for survival analysis. Patients who received any new investigational drug were censored at the time it was started. *Results*. For the 62 patients, 24 were female, and the median age at T315I mutation detection was 42 years (range 19-76). Thirty seven patients were Asian, 24 were Caucasian, and 1 was multi-racial. At the time of diagnosis, 48 patients were in chronic phase (CP), 4 in accelerated phase (AP), 4 in myeloid or lymphoid blastic crisis (BC), and 6 were *de novo* Ph^+ ALL. All 6 *de novo* Ph^+ ALL patients were from one site in Italy. Nineteen patients had received IFN and 1 had stem cell transplantation prior to treatment with TKIs. Median time from diagnosis to onset of hematologic or cytogenetic resistance to TKI (using European Leukemia Network criteria) was 23 months (range 3-132), and to first detection of the T315I mutation was 34 months (range 3-164). Twenty-two CP patients progressed to AP or BC at the time of TKI resistance onset (Table 1).

Table 1. Overall survival and progression-free survival of CML and Ph+ ALL patients with T315I mutation.

Starting date: 1st time of TKI resistance*				
Disease phase	**Chronic (N=26)**	**Accelerated (N=15)**	**Blastic** (N=14)**	**Ph+ ALL (N=6)**
Median OS month	53.9	20.1	8.5	8.7
6-month OS rate	88%	92%	50%	75%
Median PFS month	17.0	5.3	3.5	3.2
6-month PFS rate	68%	47%	36%	25%
Starting date: 1st time of T315I mutation detection				
Disease phase	**Chronic (N=22)**	**Accelerated (N=15)**	**Blastic** (N=19)**	**Ph+ ALL (N=5)*****
Median OS month	21.2	Not reached	2.1	Not reached
6-month OS rate	73%	86%	18%	53%
Median PFS month	9.5	Not reached	2.0	0.9
6-month PFS rate	64%	64%	8%	20%

*: One missing data **Myeloid or lymphoid blastic crisis. ***One patient received new investigational drug before T315I mutation and was censored before the starting date.

After TKI resistance onset, 37 patients were on Imatinib, and 47 on 2nd generation TKIs. Fifteen patients were checked for mutation before the onset of TKI resistance, and 24 patients were checked for mutation within 3 months of TKI resistance onset. The median time between TKI resistance and T315I mutation was 7.2 months for CP, 4.4 months for AP, 0.8 month for BC, and 1.2 month for *de novo* Ph^+ ALL. At the 1st time of T315I mutation detection, T315I was the predominant clone in 50 patients, 20 patients also had other mutations (7 patients had P-loop mutations), and 24 patients had developed other mutations before T315I detection. OS and PFS from 1st time of TKI resistance and T315I mutation detection are summarized in Table 1; the median OS follow-up time was 17.5 months (range 0.2-40.6) from T315I mutation. Conclusion. These preliminary results suggest that survival of patients harboring a T315I mutation depended on the disease phase at the onset of TKI resistance or T315I mutation. T315I mutation was usually detected within a short period of time after TKI resistance, especially for patients in the advanced phases. These results will be verified when data collection is completed for the patient cohort.

0139

EFFICACY OF SUBCUTANEOUS HOMOHARRINGTONINE IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS RESISTANT TO TYROSINE KINASE INHIBITORS (TKI) AND HARBORING A BCR-ABL MUTATION

D. Marin,[1] F. Maloisel,[2] L. Legros,[3] F.E. Nicolini,[4] L. Roy,[5] P. Rousselot[6]

[1]Imperial College London, LONDON, UK; [2]CHU Hospice Civil, STRASBOURG, France; [3]CHU Hôpital Archet, NICE, France; [4]CHU Hôpital Edouard Herriot, LYON, France; [5]CHU Hôpital Jean Bernard, POITIERS, France; [6]Hôpital A. Mignot, LE CHESNAY, France

Background. Omacetaxine [OMA, semi-synthetic homoharringtonine] is an alkaloid active on CML cells by inhibiting protein synthesis and inducing the intracellular signals for apoptosis via mitochondrial release of cytochrome C and activation of caspases. *In vitro* studies demonstrated that OMA activity is not affected by the presence of BCR-ABL kinase domain (KD) mutations. *Methods*. We present here a retrospective analysis of the clinical experience acquired in 6 institutions for the SC OMA treatment of CML patients (pts) with at least one BCR-ABL KD mutation and various degrees of resistance to TKI therapy. *Results*. From February 2003 to August 2007, 20 patients fulfilled these criteria. All pts received one or multiple lines TKI therapy (IM 400-800 mg: n=19; dasatinib 140-200 mg: n=5; nilotinib: n=1), 14 patients had also been treated with interferon (IFN - n=7), SCT (n=3), or combined IM+ara-c (n=1), IM+IFN (n=1), IFN+ara-c (n=2). Prior to OMA, baseline characteristics were: mean age 56.9 years (111.9; range 26-74), sex ratio 9F/11M, mean disease duration 72 months (±41, range: 22-148). CML status was: CP with CHR with or without cytogenetic response (n=5; group A), CP without CHR (n=7; group B), AP (n=6; group C), or blast phase (BP - n=2; group D). KD mutation status included 15 pts with a single mutation (*M244V: 3; V244Q: 1; G250E: 1; Q252H: 1; Y253H: 2; T315I: 4; M351T: 1; F359V: 1; E453K: 1*), and 5 pts with combined mutations (*K247R+F317L; T315I+V379I; Y253F+M351T; F311I+T315I; Y253H+T315I*). This series includes so 12 pts harboring pejorative mutations: T315I (n=6), P-loop (n=5), or a combination of both (n=1). SC OMA was administered at 2.5 mg/m^2/day, for 1 to 6 days when combined with IM (n=7: 3 pts from group A and 4 pts from group B), and for up to 14 days when administered as monotherapy. In median, 5 OMA courses were administered (range: 1-20). In group A, all 5 patients (100%) maintained CHR. Of them, 1 pt with previous complete CyR improved his molecular response by 1.26 log reduction, 1 pt with partial CyR achieved complete CyR and improved his molecular response by 1.67 log reduction, and the T315I mutation was no longer detectable after 3 cycles in 2 additional pts. In group B, 5 pts (71%) achieved CHR (P-loop mutation: 2), and 2 pts (29%) did not respond. In group C, 3 pts (50%) achieved CHR, of them 2 pts with the T315I mutation also achieved a CyR (1 complete, 1 minor); 1 pt (17%) with T315I+V379I achieved NEL; and 2 pts (33%) with P-loop mutation did not respond. In group D, the 2 BP pts did not respond (1 T315I, 1 combined T315I+P-loop). Grade 3-4 myelosuppression was reported for 12 pts. OMA was otherwise well tolerated and led to discontinuation of treatment in 1 pt (grade 2 asthenia - combined OMA+IM). Conclusion: OMA is active in BCR-ABL mutated patients and so may be considered as an option for these patients when loosing sensitivity to TKI therapy. Ongoing prospective clinical trials are confirming its role for these patients.

0140

SINGLE NUCLEOTIDE POLYMORPHISMS WITHIN THE ABL KINASE DOMAIN OF CML PATIENTS - PITFALLS IN THE DETECTION OF RELEVANT BCR-ABL MUTATIONS

T. Ernst,[1] M.C. Müller,[2] J. Hoffmann,[2] P. Erben,[2] B. Hanfstein,[2] A. Leitner,[2] R. Hehlmann,[2] A. Hochhaus[2]

[1]Wessex Regional Genetics Laboratory, SALISBURY, UK; [2]III. Medizinische Klinik, Universitätsklinikum Mannheim, MANNHEIM, Germany

Background. The most frequently identified mechanism of acquired imatinib resistance in patients with chronic myeloid leukaemia (CML) is the emergence of point mutations within the BCR-ABL kinase domain. To date, more than 70 different mutations have been described. The BCR-ABL K247R change has been revealed as a rare single nucleotide polymorphism (SNP) occurring likewise in healthy controls and non-hematological cell types. Despite its juxtaposition to the P-loop, biochemical and cellular assays of imatinib and dasatinib sensitivity showed no alteration compared to non-mutated BCR-ABL. *Aims*. Since gene polymorphisms do not automatically necessitate a change in the therapeutic strategy, we systematically analysed if other changes in the BCR-ABL kinase domain should be considered as SNPs rather than acquired mutations. *Methods*. A total of 911 CML patients (501 m, 410 f; median age 58.1 years, range 15.5-85.3) after failure or suboptimal response to imatinib were screened for BCR-ABL kinase domain mutations by denaturing high-performance liquid chromatography (D-HPLC) and direct sequencing. Patients were in chronic phase (n=587), accelerated phase (n=151), myeloid (n=103), or lymphoid blast crisis/ALL (n=70). In comparison to acquired BCR-ABL kinase domain mutations, SNPs also have to occur in normal, untranslocated ABL alleles. Therefore, SNP analysis was based on the search for nucleotide changes in corresponding normal ABL alleles by ABL allele-specific PCR and subsequent D-HPLC/sequencing analysis. Nucleotide changes in normal ABL alleles were confirmed by cloning experiments. *Results*. BCR-ABL kinase domain mutations were detected in 456/911 patients (50%). Eighty-three different mutations affecting 60 amino acids were detected of those six nucleotide changes were uncovered as SNPs (GenBank accession No. U07563): 58758G/A (T240T, n=1), 58778A/G (K247R; n=9), 68708T/G (F311V, n=2), 68722T/G (T315T, n=1), 68736A/G (Y320C, n=1), and 74901A/G (E499E; n=73). A second patient harboring the substitution 68708T/G (F311V) in BCR-ABL alleles did not show any nucleotide change in normal ABL alleles. In this cohort of patients, the 74901G (E499E) change was the most common polymorphism with an allele frequency of 8.0%. The 58778G (K247R) polymorphism had a frequency of 1.0%, whereas the nucleotide changes 58758A, 68722G, and 68736G were detected once only leading to an allele frequency of 0.1% each. *Summary/conclusions*. The vast majority of BCR-ABL kinase domain mutations are acquired mutations and not SNPs. In addition to the previously described K247R polymorphism we uncovered five new SNPs, two of them led to amino acid changes. SNPs could theoretically contribute to primary but not to secondary resistance to tyrosine kinase inhibitors and must therefore be distinguished from acquired mutations. Novel point mutations should be confirmed by analysing the normal ABL alleles to exclude polymorphisms. Pre-existent polymorphisms not representing acquired mutations do not directly require a change in therapeutic strategy, unless there are indications of inadequate response to treatment.

0141

MINIMAL CROSS-INTOLERANCE BETWEEN NILOTINIB AND IMATINIB IN PATIENTS WITH IMATINIB-INTOLERANT CHRONIC MYELOGENOUS LEUKAEMIA (CML) IN CHRONIC PHASE (CP) OR ACCELERATED PHASE (AP)

A. Hochhaus,[1] H.M. Kantarjian,[2] M. Baccarani,[3] P. Le Coutre,[4] A. Haque,[5] N. Gallagher,[5] J. Cortes,[2] F. Giles[6]

[1]Med. Fakultät Mannheim der Universität Heidelberg, MANNHEIM, Germany; [2]MD Anderson Cancer Center, HOUSTON, USA; [3]Institute of Hematology and Medical Oncology Seragnoli, University of Bologna, BOLOGNA, Italy; [4]Campus Virchow, Charité, Humboldtuniversität, BERLIN, Germany; [5]Novartis Pharmaceuticals, EAST HANOVER, USA; [6]University of Texas Health Science Center, SAN ANTONIO, USA

Background. Nilotinib, a potent and highly selective BCR-ABL inhibitor, has been approved in several countries including the US and Europe for the treatment of patients (pts) with Philadelphia chromosome-positive chronic myelogenous leukaemia (Ph+ CML) in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. The current study examines cross-intolerance between nilotinib and imatinib among CP and AP pts enrolled in the phase 2 registration study of nilotinib. *Methods*. Imatinib-intolerance was defined as no prior major cytogenetic response (MCyR) and discontinuation of imatinib due to Grade 3/4 adverse events (AEs) or persistent (> 1 month) or recurrent (recurred > 3 times) Grade 2 AEs, despite optimal supportive care. Nilotinib-imatinib cross-intolerance was defined as treatment with nilotinib and occurrence (regardless of causality) of Grade 3/4, or persistence or recurrent Grade 2, of the same AE(s) that led to discontinuation of imatinib therapy. The planned starting dose of nilotinib was 400 mg twice daily (BID), which could be escalated to 600 mg BID for lack of response and in the absence of safety concerns. Patients with multiple AEs due to imatinib are counted for each AE. *Results*. 94 CP and 27 AP imatinib-intolerant pts were included in this analysis and the median duration of prior imatinib therapy were 14 and 9 months, respectively. The majority of pts received <600 mg/day of imatinib (66% in CP, 67% in AP). The median duration of nilotinib therapy in this cohort of pts was 13 and 5 months with median dose intensity being 701 and 755 mg/day in CP and AP pts, respectively. Although dose interruption occurred in 70% of CP and 56% of AP pts, the medi-

an percentage of days with dose interruption was only 6% and 7% of the total time on nilotinib, respectively. Of the 57 imatinib-intolerant CP pts with nonhaematological AEs, only 1 discontinued nilotinib due to cross intolerant AE (AST elevation). Of the 29 pts with haematological AEs, 7 discontinued nilotinib (thrombocytopenia). No AP pts discontinued nilotinib due to cross intolerance. Nilotinib was also efficacious in both imatinib-intolerant CML-CP pts (n=59; 63%) and CML-AP pts (n=10; 40%) who achieved MCyR. *Conclusions*. These results are consistent with previously reported findings of minimal nilotinib cross-intolerance in imatinib-intolerant CML-CP and CML-AP pts. Thrombocytopenia emerged as the only imatinib-intolerant laboratory abnormality leading to intolerance that may recur in some pts during nilotinib therapy. In the pivitol phase II registration study, nilotinib has been proven to be effective in Ph^+ CML patients with imatinib-resistance and intolerance. Nilotinib represents an important therapeutic option in CML patients with imatinib-intolerance.

0142

A NEW ASSOCIATION BEETWEN THE ALLELIC JAK2V617F BOURDEN AND THE PLATELET VOLUME IN POLYCYTEMIA VERA (PV) AND ESSENTIAL THROMBOCYTHEMIA (ET)

M. Sobas,[1] M. Pérez-Encinas,[1] C. Quinteiro,[2] T. González,[2] E. Ansoar,[1] S. Ordoñez,[1] J.L. Bello[1]

[1]Hospital Clínico Universitario de Santiago de Compostela, SANTIAGO DE COMPOSTELA; [2]Fundación Galega de Medicina Xenómica, SANTIAGO DE COMPOSTELA, Spain

Background. A differentiation between thrombocytosis caused by a PV, an ET, or a reactive disorder (RD) seems to be easier since the discovering of V617F-JAK2 mutation. However the distinction between an early phase of PV with thrombocytosis and the ET JAK2+ is not possible with the recently published criteria (WHO 2008). The platelet distribution width (PDW) and the mean platelet volume (MPV) are very simple tests useful for the differential diagnosis of thrombocytosis (*Van der Lelie J Clin Pathol 1986*). *Aims*. We evaluated the useful of PDW and MPV in the context of the new criteria diagnostic for PV and ET, in especial to try a better distinction between an early phase of PV and the ET JAK2+. *Methods*. We studied 16 PV and 89 ET patients with a platelet count ≥450×10^9/L diagnosed according the WHO 2008 criteria and followed-up in our Department. We used the JAK2 MutaScreenTMKit (IPSOGEN) for quantification of V617F mutation. MPV and PDW were made in whole blood anticoagulates with edetic acid using the Coulter LH 750 Analyzer. Only patients with a platelet volume analysis previous to treatment with hydroxiurea were included. *Results*. First, we confirmed that MPV and PDW value are higher in PV and ET respect to reactive disorders RD. Comparison of values of MPV and PDW showed a significantly higher PDW (17,75) and MPW (8,73 fl) in PV patients respect to ET patients (PDW (17,11; MPW 7,71 fl). Then we found a higher value of the platelet volume in the PV in comparison with the ET JAK2 +, and when we compared the platelet volume between the ET V617F-JAK2 positive and negative patients. Finally, when we created 3 groups of MPNs: negative with <2% of V617F mutation, between 2-31% and 31-100%, we have observed a statistically significant relation between the allelic ratio of V617F and MPV and PDW in MPNs patients: MPV and PDW increase with higher allelic ratio of V617F mutation. *Conclusions*. We confirm previous reports about the useful of PDW and MPV analysis in differential diagnosis of thrombocytosis. PV patients with thrombocytosis present significantly higher value of PDW and MPV that in ET. We first report the correlation between the JAK^+ status and the PDW and MPV in MPNs, that seem be independent of the platelet count. The study of the combination of *JAK2* status with the platelet volume analysis in a larger cohort of patients could help to do a easy index for the differential diagnosis between the PV and the ET.

Table 1.

	V617F	*Number*	*Mean*	*SO*	*p*
Platelet distribution width	Negative (<2%)	34	16,7794	,99690	,000
	2-31%	56	17,2429	,69252	
	>31%	13	17,7611	,56256

DECISIONAL FLOW WITH A SCORE SYSTEM TO START PLATELET-LOWERING TREATMENT IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA (ET): LONG-TERM RESULTS

R. Latagliata,[1] A. Rago,[1] A. Spadea,[2] C. Santoro,[1] I. Carmosino,[1] M. Breccia,[1] L. Napoleone,[1] A. Fama,[1] F. Biondo,[1] P. Volpicelli,[1] M.C. Petti,[2] G. Alimena,[1] M.G. Mazzucconi[1]

[1]Hematology- University La Sapienza, ROMA; [2]Hematology, Regina Elena IFO, ROMA, Italy

Background. Treatment of ET is still a matter of debate for the difficulty in deciding between platelet(plt)-lowering agents and a *wait and see* policy with anti-aggregating agents only: a main problem is to identify what patients are *at risk* to develop severe thrombotic events during the course of the disease. *Design and Methods*. We prospectively tested in ET patients at diagnosis with no clear indication to plt-lowering treatment a score system based on the following 6 variables: age, plt level, cardiovascular diseases, previous thrombotic events, smoking, dismetabolic diseases: the score was reassessed in each patient every 3 months during follow-up. *Results.* From 04/92 to 03/98, 168 consecutive adult patients (57 males and 111 females, median age 59.5 yrs, range 20.5 - 84.8, median plt value 1,010×10^9/L, range 587-2,714) with ET according to PVSG criteria were diagnosed at our Institution. Among them, a plt-lowering treatment was started in 32 patients considered *symptomatic* for the presence at diagnosis or within 6 months before of severe haemorrhages, vascular accident or severe disturbances of microcirculation; plt-lowering treatment was also started in all the 33 patients aged > 70 years at diagnosis. The remaining 103 patients were a*symptomatic* and aged <70 years and were classified according to our score system: thirty-two patients with a score ≥4 started plt-lowering treatment with hydroxyurea early after diagnosis. The remaining 71 patients had a score < 4 at diagnosis and received anti-aggregating agents only: of them, 24 (33.8%) started plt-lowering treatment during follow-up (18 for a score increase to ≥4 and 6 for the occurrence of thrombotic complications or symptoms) after a median time from diagnosis of 28 months (range 3-130) while 47 (66.2%) did not start any plt-lowering treatment. Thrombotic complications occurred in 9/103 patients (8.7%) scored at diagnosis: in particular, they occurred in 4/32 patients (12.5%) with score ≥ 4 receiving plt-lowering treatment since diagnosis and in 5/71 patients (7%) with score <4 under anti-aggregating agents only. Overall, 6 out of 103 scored patients died and 27 were lost to follow-up, with a 15-year cumulative survival of 88%. *Summary*. In conclusion, a decisional flow based on present score system appears effective in patients without a clear indication for plt-lowering treatment at diagnosis to discriminate subjects at different risk of thrombotic events and could be useful to decide when a plt-lowering therapy needs to be started.

0144

JAK2 MUTATION AND AN ADDITIONAL THROMBOPHILIC STATE ARE MAJOR PROTHROMBOTIC RISK FACTORS IN MYELOPROLIFERATIONS WITH THROMBOCYTHEMIA - DATA FROM A REGISTRY OF ANAGRELIDE-TREATED PATIENTS

J. Schwarz,[1] M. Penka,[2] M. Doubek,[3] Y. Brychtova,[3] O. Cerna,[4] P. Dulicek,[5] J. Kissova,[2] T. Pavlik[6]

[1]Institute of Hematology and Blood Transf, PRAGUE; [2]Dept. of Clinical Hematology, Masaryk University Hospital, BRNO; [3]Dept. of Internal Medicine/Hematooncology, Masaryk University Hospital, BRNO; [4]Dept. of Clinical Hematology, Charles University Hospital Kralovske Vinohrady, PRAGUE; [5]Dept. of Internal Medicine II. Dept. of Clinical Hematology, Faculty Hospital, HRADEC KRALOVE; [6]Center for Biostatistics and Analyses, Masaryk University, BRNO, Czech Republic

Background aim of the study. We have evaluted prospectively collected data of 336 Czech patients from an international registry of patients treated with anagrelide (ANG) for thrombocythemia in the setting of a myeloproliferative disease (MPD-T). *Patients*. The initial diagnoses (recorded largely according to PVSG criteria) were the following: essential thrombocythemia - 274 (81.5%), idiopathic myelofibrosis - 26 (7.8%), polycythemia vera - 24 (6.7%) and chronic myeloid leukemia - 3 (0.9%). The mean age at diagnosis and at database entry was 47 and 50 years (means: 45.3 and 49.1). The male/female ratio was 37:63%. A vast proportion of patients (80.7%) had been already pretreated with thromboreducing drugs: overall, 67 patients had received ANG, 121 had had interferon-alpha, 223 had been treated with hydroxyurea and 54 patients had received another drug. More than one line of previous thromboreductive therapy was recorded in 146 (43.5%) patients. Follow-

ing registration, 24.1% was receiving another thromboreducing drug in addition to Thromboreductin (ANG brand). The median platelet value was 1015 G/L at diagnosis, and 613 G/L (range 140-3325) at database entry. The treatment goal was achieving 600/400 G/l platelets in low-/high-risk patients. High-risk patients had either previous thrombosis, an additional thrombophilic state (mostly inherited), or JAK2 gene V617F mutation. *Results*. Pretreated and unpretreated patients responded to ANG equally well. In the latter, (n=65; median platelet count of 946 G/Lat day 0), the platelet counts at 3-6-9-12-36 months reached 565-444-451-421-441 G/L, respectively. High-risk patients had lower platelet counts (488-400-387-376-323 G/L; n=118) than good-risk ones (523-441-384-423-455 G/l; n=98) at the given above time points. The mean ANG dose at 3 months was only 1.8 mg/day (median, 1.5 mg/d), whereas onwards, the mean dose was quite stable within 2.2-2.3 mg/day interval (median, 2.0 mg/d). At the time of database entry, 65 (19.3%) patients had a history of a thrombotic event, and 30 (8.9%) had had hemorrhage. During the follow-up after entering the registry, only 11 (3.5%) patients had thrombosis (6 had a major and 5 a minor one). Likewise, there have been very few patients with a bleeding event reported: 2 patients experienced a major and 4 patients a minor event (altogether 1.9% of patients). Only 106 patients had the JAK2 mutation evaluated. Half of them (53 patients) carried the mutation (hetero-/homozygous). Of the 53 patients with the mutation, 21 (39.6%) had thrombosis (before or after registration). Thrombosis was significantly more rare in 53 patients without the mutation, in 9 cases only (17.0%; p=0.017, Fisher´s test, CI 95%). Of 50 evaluable patients with thrombosis, 19 (38.0%) were thrombophilia+, whereas of 147 patients without thrombosis, a thrombophilia+ state was demonstrated only in 31 cases (21.1%; p= 0.024). *Discussion and conclusions*. The database enables analyses of treatment tactics; e.g. it has shown that high-risk patients on ANG do not achieve the desired level of thromboreduction at 3 months. Analysis of thrombotic events confirmed that JAK2 mutation or additional thrombophilic states are major risk factors in MPD-T.

0145

ABSENCE OF THE JAK2 EXON 12 MUTATIONS IN PATIENTS WITH SPLANCHNIC VENOUS THROMBOSIS AND WITHOUT OVERT CHRONIC MYELOPROLIFERATIVE DISORDERS

A. Fiorini, E. Rossi, T. Za, A. Ciminello, P. Chiusolo, S. Sica, G. Leone, V. De Stefano

Institute of Hematology, Catholic University, ROMA, Italy

Background. Thrombosis of major abdominal veins has been reported in 5% to 10% of the patients with polycythemia vera (PV) or essential thrombocythemia (ET). Conversely, molecular hallmarks of chronic myeloproliferative disorders (CMD) can be recognized in a substantial portion of patients with splanchnic venous thrombosis not meeting all the criteria for diagnosis of PV or ET. We have previously reported the presence of the JAK2 V617F mutation in the absence of overt signs of CMD in 21% of overall patients with splanchnic venous thrombosis and in 43% of patients with extrahepatic portal vein thrombosis (*De Stefano et al, J. Thromb. Haemost. 5: 708, 2007*). Recently additional *JAK2* exon 12 mutations have been reported in PV patients *JAK2* V617F-negative (*Scott et al., N. Engl. J. Med. 356: 459, 2007*). *Aims*. The present study is aimed to investigate the prevalence of the JAK2 exon 12 mutations among patients with splanchnic venous thrombosis and without overt CMD. *Methods.* We investigated JAK2 exon 12 mutations in 42 patients (M/F 21/21) with splanchnic venous thrombosis and without overt CMD who had been previously tested for the JAK2 V617F mutation and resulted negative. The median age at the thrombotic event was 44 years (range 18-79). Thrombosis involved the extrahepatic portal vein in 20 patients, the superior mesenteric vein in 14, the hepatic veins in 7, and the splenic vein in 1. DNA samples was obtained from peripheral blood granulocytes. We used allele-specific PCR according to Scott *et al.* for screening JAK2 exon 12 mutations. We tested 41 patients for the F537-K539delinsL mutation, 37 for H538QK539L, 40 for K539L, and 35 for N542-E543del. *Results.* We did not find any mutation of the JAK2 exon 12 in this sample of patients with abdominal thrombosis and JAK2 V617F negative. *Conclusions.* Apparently the *JAK2* exon 12 mutations are not frequently detectable in patients with splanchnic venous thrombosis, unlike the *JAK2* V617F mutation. However, given the rarity of the *JAK2* exon 12 mutations as cause of PV, further multicenter studies on larger samples of patients are needed to confirm this finding.

0146

BLOOD P50 EVALUATION ENHANCES DIAGNOSTIC DEFINITION OF ISOLATED ERYTHROCYTOSIS

E. Rumi,[1] F. Passamonti,[1] L. Pagano,[2] M. Ammirabile,[2] L. Arcaini,[1] C. Elena,[1] A. Flagiello,[3] R. Tedesco,[3] C. Vercellati,[4] A.P. Marcello,[4] D. Pietra,[1] R. Moratti,[5] M. Cazzola,[1] M. Lazzarino[1]

[1]Department of Hematology, Fondazione IRCCS Policlinico San Matteo, Pavia, PAVIA; [2]U.O.C. Microcitemia, Dipartimento Oncoematologia; A.O.R.N.A. Cardarelli, NAPOLI; [3]CEINGE Biotecnologie Avanzate, NAPOLI; [4]Department of Hematology, Fondazione IRCCS Policlinico Mangiagalli Regina Elena, MILANO; [5]Department of Clinical Chemistry, Fondazione IRCCS Policlinico San Matteo, PAVIA, Italy

Background. High oxygen-affinity hemoglobin variants and 2,3-diphosphoglycerate (2,3-DPG) deficiency are inherited diseases generating low tissue oxygen tension and erythropoietin-driven erythrocytosis that compensates for hypoxia. Level of blood p50 is used to recognize these conditions, which are characterized by the presence of isolated erythrocytosis. However, more common diseases share this clinical finding, such as secondary erythrocytosis, polycythemia vera and idiopathic erythrocytosis. *Aims*. In order to enhance diagnostic definition of patients with isolated erythrocytosis, we evaluated venous blood p50 level in 102 consecutive patients with isolated erythrocytosis. *Methods*. The blood gas analyzer used (Radiometer ABL 800 Flex) was equipped with the FLEXQ module to automatically identify p50 value (normal range: 25 to 29 mmHg). Besides p50 evaluation, the initial diagnostic work-up included blood cell count, arterial oxygen saturation, serum erythropoietin measurement, screening for JAK2 mutations. WHO criteria were applied for polycythemia vera. Diagnosis of idiopathic erythrocytosis implied exclusion of secondary erythrocytosis and polycythemia vera. Patients with low level of p50 were further studied for high oxygen-affinity hemoglobin variants and 2,3-diphosphoglycerate (2,3-DPG) deficiency. Samples for molecular analysis were obtained after patient provided written informed consent. *Results*. Seven patients had relative erythrocytosis. Among 95 patients with absolute erythrocytosis, 4 (4.2%) had decreased p50 level. The extended study of family members revealed a familial inheritance. These patients were investigated for hemoglobin variants and deficiency of 2,3-DPG. Family 1 had Hemoglobin Malmö; Family 2 had Hemoglobin San Diego. In Family 3 the proband had a new high oxygen-affinity hemoglobin variant (Hemoglobin Safi) resulting from the transversion C'A at codon 81 of the β2-globin gene. In Family 4 a deficiency of 2,3 diphosphoglycerate mutase was found. Within the 91 patients with normal p50 values, 46 (51%) had secondary erythrocytosis, 13 (14%) polycythemia vera, and 32 (35%) idiopathic erythrocytosis. *Conclusions*. This study suggests to investigate blood p50 level in patients with isolated erythrocytosis.

0147

TREATMENT RESPONSE AND COMPLICATIONS OF PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA RECEIVING HYDROXYUREA

D. Sotiropoulos,[1] A. Papalexandri,[1] P. Tsirigotis,[2] A. Pouli,[3] P. Kyriazopoulos,[4] M. Protopapa,[5] I. Dervenoulas,[2] A. Fassas,[1] A. Anagnostopoulos[1]

[1]G Papanikolaou Hospital, THESSALONIKI; [2]Attikon Hospital, ATHENS; [3]St. SAVVAS, ATHENS; [4]Patision hospital, ATHENS; [5]Hospital of Serres, SERRES, Greece

Essential thrombocythemia (ET) is a myeloproliferative disorder characterized by persistent thrombocytosis. The frequency of JAK2V617F mutation is estimated at approximately 50% of the patients. Thrombotic episodes and bleeding complications are the most frequent events. Secondary malignancies can also occur. Hydroxyurea, anagrelide and interferon-a are available treatments. We studied retrospectively 197 patients, 79 male and 118 female with a median age of 58 years (19-85). Thrombosis at diagnosis presented in 33/197 patients and hemorrhage in 8/197. Median platelet count was 990*106/L (502-2500*106/L). Splenomegaly was present in 32 patients and fibrosis in 44.The majority of the patients received hydroxyurea (HU) as front-line therapy (125/197). 21 patients received anagrelide and 20 interferon-a, 4 received a combined therapy with HU and interferon-a while 27 patients received no therapy. *JAK2V617F* mutation was present in 37/72 patients (51%). There was no difference in age at diagnosis between V617F-positive and V617F-negative patients. An elevated WBC count was observed in V617F-positive patients at diagnosis (p=0,015). Hemoglobin level and platelet count were similar in the two groups of patients. The WBC and

PLT count was not correlated with thrombosis or bleeding at diagnosis. Of the patients receiving hydroxyurea, 94% had a response, a significantly higher percentage compared to the other therapy groups (p<0,001) .Response was considered when a patient didn't need a second-line therapy in a not otherwise refractory disease. Response at six months (PLT<600.000×10^6/L) was more frequently seen with HU compared with anagrelide (p<0,05). A quick response did not reduce the incidence of thrombotic or bleeding complications. No difference between thrombotic complications (6/66 patients, 9.01%) or hemorrhage (4/66 patients, 6.06%) was observed between the V617F-positive and V617F-negative patients. Secondary malignancies were observed in 6/197 patients (0,03%) with no correlation to HU therapy. In conclusion, our study showed a significant difference between the HU group of patients and those who did not receive HU as front line therapy with regard to therapy response. A response at six months did not affect the incidence of complications. There was no difference in hemoglobin level at diagnosis in V617F-positive and V617F-negative patients but a higher WBC count was observed in the V617F-positive group of patients.

0148

OCCULT T-CELL CLONES OCCUR IN THE MAJORITY OF PATIENTS WITH SUSTAINED AND UNEXPLAINED HYPEREOSINOPHILIA

G. Helbig,[1] M. Majewski,[2] J. Grzegorczyk,[3] J. Dziaczkowska,[1] B. Stella-Holowiecka,[1] J. Wojnar,[1] S. Krzemien[1]

[1]Silesian Medical University, KATOWICE; [2]Institue of Haematology and Transfusion Medicine, WARSAW; [3]Department of Immunology, LODZ, Poland

Background. The T-cell clone, which is thought to be the source of eosinophilopoietic cytokines (mainly IL-5), is identified by clonal rearrangement of the T-cell receptor (TCR) or/and by the presence of an abnormal T-cell immunophenotype. In some cases an unexplained eosinophilia may result from the response to exogenous cytokines produced by T-cells; the entity is termed *lymphoproliferative variant of hypereosinophilic syndrome* (L-HES). Material and methods. The blood samples from 32 patients with non-reactive hypereosinophilia were studied fo TCR rearrangement using the BIOMED-2 multiplex PCR. The FIP1L1-PDGFRA and ETV6-PDGFRB transcripts were detected by RT-PCR. T-cell subpopulation was assesed by flow cytometry. Results. There were 32 patients (16F/16M), at the median age of 54 years (range 17-77). Their median white blood cell (WBC) count was 11.3×10^9/L (range: 5.3-121) with the median eosinophil count of 3.9×10^9/L (range:0.7-99) and the median eosinophil bone marrow infiltration of 30% (range: 14-64). Seventeen patients (53%) demonstrated TCR clonality including TCRB in 16 patients, TCRD in 8 and TCRG in 8. The FIP1L1-PDGFRA fusion transcript was detected in 2 patients (6%), both of them presented TCR clonality. The *ETV6-PDGFRB* fusion protein was found in 2 TCR-positive patients. The immunophenotyping of T-cells revealed an atypical phenotype in 5 cases, all were TCR- positive. 2 out of these 5 patients had an increased lymphocyte count. There were no significant differences in serum levels of IL-4, IL-5 and tryptase between TCR^+ and TCR^- cases. No difference was found in blood eosinophil count, bone marrow eosinophil infiltration, serum IgE and vitamin B12 levels. During the follow-up one patient evolved in overt peripheral T-cell lymphoma and one in T-cell large granular leukemia. Conclusions. The T-cell clone was identified in a majority of studied patients with prolonged eosinophilia. Since the TCR positive cases may evolve in a full-blown T-cell lymphoma, the close monitoring of patients with occult T-cell clone is required.

0149

LOW DOSE SPLENIC IRRADIATION IN MYELOFIBROSIS: OUTCOMES AND TOXICITY OF THREE RADIATION SCHEDULE

M. Federico,[1] P. Guerrieri,[2] A. Russo,[3] G. Cardinale,[4] A. Giordano,[5] R. Lagalla,[6] P. Montemaggi,[2] G. Pagnucco[4]

[1]University of Palermo, PALERMO; [2]Radioterapia Ospedale Oncologico M. Ascoli, PALERMO; [3]Medical Oncology University of Palermo, PALERMO; [4]Ematologia Ospedale Oncologico M. Ascoli, PALERMO; [5]Pathology University of Siena, SIENA; [6]Radiology University of Palermo, PALERMO, Italy

Background. Splenectomy or splenic irradiation (SI) are the sole treatment modality to control drug resistant splenomegaly in patients with Myelofibrosis (MF). Even if splenectomy is associated with 10% risk of operative mortality, a morbidity rate close to 50% and a higher relative risk of blast transformation, it is generally preferred to SI for the longer period of symptoms relief that allows in compare to a single course of radiation. SI, on the opposite, has been considered only in poor surgical candidates with comparable response rates but with a shorter symptoms free interval. Furthermore SI has been associated to a significative incidence of post radiation life-threatening cytopenias. If splenectomy outcomes and complication rates are supported by large retrospective trials, for SI just a few papers have been published mostly on small number of patients with a significative variability among radiation treatments. *Aims*. Although a general agreement to low RT doses emerges from literature, there is not a precise definition of *low doses*. Aim of this work is to assess outcomes and complication rates of splenic irradiation in three cohorts of patients treated with different *low dose* irradiation schedule. Groups have been aggregated on the basis of the mean Normalized Tumor Dose (NTD10), a radiobiologic tool that allows comparing different RT fractionations by normalizing the delivered dose to a standard (2 Gy fraction) treatment.

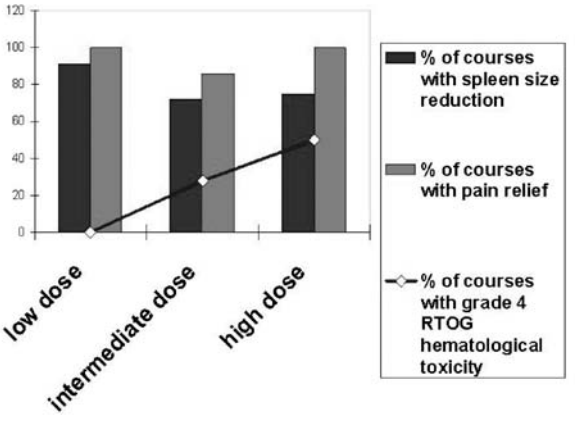

Figure 1. Outcome and toxicity.

Methods. We retrospectively reviewed 14 MF patients (9 M, 5 F) with symptomatic drug resistant splenomegaly and splenic pain; 11 patients (84%) had also constitutional symptoms as night sweets, febricula and an initial state of cachexya. Patients received RT five days per week continuously. The three groups of patients received respectively a mean NTD of 1.8 Gy (low dose group: 6 pts), 4.4 Gy (intermediate dose group: 4 pts) and 9.2 Gy (high dose group: 4 pts). Patients were considered responders if experienced a spleen reduction (≥50%) and a durable pain relief. Response evaluation was carried out 20 days after completing radiation. Treatment toxicity, limited to myelosuppression, was scored according the RTOG scale. *Results.* Patients in the low dose group received 11 RT courses and experienced an excellent outcome both in terms of spleen size reduction (91% of courses) and pain relief (100% of courses); no life-threatening cytopenias (grade 4 RTOG) occurred. Patients in the intermediate dose group received 7 RT courses and had comparable outcomes (72% and 86% of courses with spleen size reduction and pain relief) but a higher incidence (28%) of severe cytopenias (2 on 7 courses). Patients in the high dose group experienced a spleen size reduction in 75% of courses and a pain relief in all. The incidence of RTOG 4 cytopenias was 50%. No patient in this group had retreatment. *Conclusions*. NTD10 1.8 is a NTD value 2-3 fold lower than in other published series. Patients in this group experienced an excellent splenomegaly palliation without any relevant side effect. In this group patients were able to repeat safely splenic irradiation several times so prolonging the symptoms relief largely over than expected

POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMIA: JAK2V617F MUTATION IS MORE COMMON IN OLDER PATIENTS

M.L. Randi, E. Ruzzon, M. Scapin, F. Tezza, I. Bertozzi, F. Fabris

University of Padua, PADOVA, Italy

Background. Most patients affected by polycythemia vera (PV) and essential thrombocythemia (ET) carry a somatic JAK2 point mutation (V617F). At present, we know that *JAK2V617F* occurs in 90% of PV patients and it is more common in older than in younger ET patients. The aim of the present study is to evaluate the frequency of the mutation in PV and ET patients stratified on the basis of their age. *Patients and methods*. We evaluated 249 consecutive patients affected by myeloproliferative disorders (MPD)(92 males and 157 females, mean age 60±17 years at the time of the study) and regularly followed in our outpatients surgery. 112 were affected by PV and 126 by ET, diagnosed in agreement with the PVSG criteria. The patients were stratified in 4 groups on the basis of their age at the time of the study: younger than 40 years, 40-60 years, 60-75 years and >75 years. The *JAK2V617F* mutation was searched in peripheral blood granulocytes with DNA and allele- specific PCR and Bsa XI digestion. *Results*. Considering all the patients together, but also dividing PV and ET cases, the percentage of mutated *JAK2* patients increased progressively as shown in the Table 1. While around 50% of patients younger that 40 carried the mutation, all but few cases was wild type in the group > 75. Considering all the MPD patients, the increase of mutated cases was statistically significant comparing >75 with all other age groups (p=0.001 *vs* <40, p=0.009 *vs* 40-60 and p=0.03 *vs* 60-75). Within PV patients the comparison between <40 and >75 patients was statistically different (p=0.007) as well as comparing 40-60 patients and >75 (p=0.04). No statistical difference was found in the different groups of ET regarding the percentage of *JAK2V617F* mutated cases. *Conclusions*. The PVSG criteria seems to overestimate younger PV patients possibly because idiopathic erythrocytosis or not-recognized familial cases are more frequent in this age group. In contrast, *JAK2V617F* mutation is common in older patients with PV in agreement with the occurrence of PV mainly in middle-advanced age. We confirm that *JAK2V617F* is more common in older than in younger ET patients.

Table 1. Significant statistical difference respect >75.

Age (years)		PV	ET	TOT
<40	tot	15 *	23	38 *
	V617F	7 (46.6%)	13 (56%)	20 (52.6%)
40-60	tot	23 *	44	67 *
	V617F	14 (60.8%)	28 (63.6%)	42 (62.6%)
60-75	tot	44	39	83
	V617F	30 (68.2%)	26 (66.6%)	56 (67.4%)
>75	tot	33	17	50
	V617F	29 (87.8%)	15 (82.3%)	43 (86%)

0151

UNUSUAL VEIN THROMBOSIS IN PATIENTS WITH POLYCYTHEMIA VERA (PV) AND ESSENTIAL THROMBOCYTHEMIA (ET)

M.L. Randi, M. Scapin, F. Tezza, N. Candeo, I. Bertozzi, E. Duner

University of Padua, PADOVA, Italy

Background. Budd-Chiari (BD) syndrome and portal system thrombosis (PST) are complications of both PV and ET. Moreover, sometimes these patients can develop thrombosis of cerebral veins (CVT) otherwise uncommon. In most cases, the thrombotic event is the presenting feature of the myeloproliferative disorder (MPD) and the causal disease of thrombosis is often difficult to be recognized. The erythroid spontaneous colony (EEC) formation are well known to be associated with both BD and PST also before the clinical evidence of PV or ET. Recently, *JAK2V617F* mutation has been reported to be commonly associated with venous thrombosis in ET. *Aims.* The aim of our study is to clarify if the research of *JAK2V617F* and of EEC formation can help in identifying the presence of PV or ET in patients with uncommon vein thrombosis. *Patients and Methods*. We report 22 consecutive patients (15 females and 7 male, mean age 37.5±14.4 years) with 5 PVT, 3 CVT and 14 BC diagnosed with ultrasonography in the case of splancnic thrombosis and with cerebral magnetic resonance for SVT. In all patients JAK2V617F mutation was searched in peripheral blood granulocytes DNA and allele-specific PCR and Bsa XI digestion were used. Spontaneous erythroid colonies formation (EEC) from peripheral blood mononuclear cells was obtained with a standard method. Concurrently, the diagnosis of PV or ET was made in agreement with the WHO 2001 criteria. *Results*. Our 22 patients resulted affect by MPD (16 ET and 6 PV). JAK2V617F mutation was present in 18 cases (81.1%, 4 PV and 14 ET) while the remaining 4 had JAK2 wild type (WT); 1 PV patient was homozygous for the mutation, while the remaining 17 were heterozygous. EEC development was found in 14 (63.3%,11 ET and 3 PV). The concordance of the texts is resumed in the Table 1.

Table 1.

	$JAK2^{V617F}$ EEC+	$JAK2^{V617F}$ EEC-	$JAK2^{WT}$ EEC-
BC	10 (71.4%)	2 (28.5%)	2 (50%)
PST	3 (60%)	1 (20%)	1 (20%)
CVT	1 (33%)	1 (33%)	1 (33%)
total	14 (60%)	4 (20%)	4 (20%)

Conclusions. We confirm that PV or ET and an unusual vein thrombosis, included cerebral vein thrombosis, have a high prevalence of JAK2V617F mutation. In BC and in PST we found a strong association between the presence of JAK2V617F and development of spontaneous EEC that suggests to use these texts as first line diagnostic tools in patients with splancnic vein thrombosis of unknown origin.

0152

A TIME AND DOSE TO RESPONSE STUDY OF IMATINIB THERAPY FOR CHRONIC HYPEREOSINOPHILIC SYNDROMES

T. Intermesoli,[1] F. Delaini,[1] S. Salmoiraghi,[1] S. Acerboni,[1] V. Guerini,[1] A. Vannucchi,[2] S. Mappa,[2] G. Rossi,[3] V. Rossi,[3] E. Di Bona,[4] A. Carobbio,[1] T. Barbui,[1] A. Rambaldi,[1] R. Bassan[1]

[1]Ospedali Riuniti di Bergamo, BERGAMO; [2]AOU Careggi, FIRENZE; [3]Spedali Civili, BRESCIA; [4]Ospedale S. Bortolo, VICENZA, Italy

Background/Aims. Hypereosinophilic syndrome (HES), chronic eosinophilic leukaemia (CEL) and chronic idiopathic hypereosinophilia (CIH) are rare disorders characterized by unexplained chronic hypereosinophilia with/without organ damage. Imatinib mesylate (IM) may be a potent therapeutic agent for these diseases, mainly targeting an overexpressed PDGFR tyrosine kinase activity. *Methods*. This study aimed to assess 1) the response rate to escalating doses of IM administered for 12 total weeks, 2) timing to response, 3) diagnostic profile of IM-responsive cases, and 4) duration of response following drug withdrawal. Eligible patients had HES, CEL, or severe CIH with eosinophil (EO) count >5x10^9/L. Diagnostic work-up included marrow morphology, standard cytogenetics, molecular genetics to identify *FIP1L1-PDGFRα, ETV6-PDGFRβ* and *JAK2* rearrangements, and immunophenotypic detection (Vβ) of T-cell clones (TCC). IM was provided by Novartis Oncology, Italy, to be administered at 100 mg/d; in case of unsatisfactory response, the drug could be increased by 100 mg/d on a weekly basis and up to a maximum of 400 mg/d. After 12 weeks, IM was stopped and response re-evaluated. A complete response (CR) was defined by an eosinophil count <0.35x10^9/L, associated with disappearance of any previous clinical and hematological abnormality. *Results*. Between X/04-II/07, 25 patients were enrolled: 18 males, median age 53 yy (range 25-80 yy), with a disease history of 0.08-16 yy (median 3), and a previous treatment in 10 (40%). Blood eosinophilia was 0.71-17.5x10^9/L (median 2.3). The diagnosis was HES in 13, CEL in 6 and CIH in 6. Cytogenetics was abnormal in 6 (30%), a TCC was detected in 4 (21%), *FIP1L1-PDGFR4* in 6 (24%), ETV6-PDGFRβ in none and *JAK2* mutation in 1. Twenty-three cases were evaluable for response, while 2 quit the study . An early CR was documented in 11 cases (48%): 3 with CEL and t(4;8) (n=1) or chromosome 5 abnormalities (n=2), 6 with FIP1L1-PDGFRalpha rearrangements, and 2 with HES without rearrangements. No patient with TCC or JAK2 mutation responded. 2/6 (33%) patients with FIP1L1-PDGFRα fusion gene achieved a complete molecular response. As regards timing and dose relationships, a marked drop of blood EO as well as 10/11 CRs occurred after only 1 (92% EO reduction) and 2 (97% EO reduction) weeks of IM 100 mg/d (Figure 1), while a further CR patient received 400 mg/d on week 2 only due to abdominal illness. After 12 weeks, 10 evaluable patients were confirmed in CR (IM dosing: 100 mg/d in 7; 200 mg/d in 3, of whom one had 400 mg/d for one week only). After withdrawal, all cases lost rapidly their response, IM being restarted

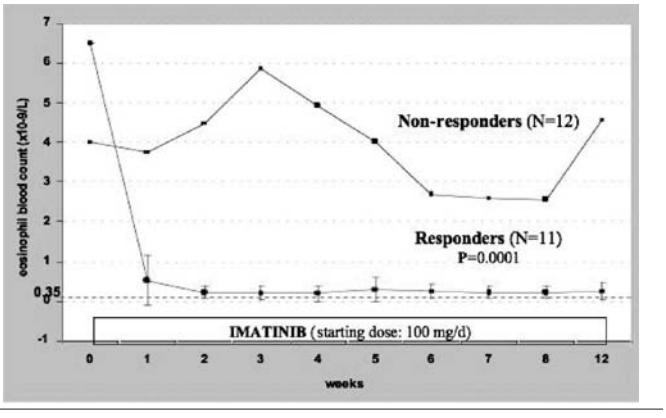

Figure 1.

Conclusions. Low-dose IM (100 mg/d) is confirmed to be rapidly effective in selected HES/CEL/CIH patients (*PDGFR* rearrangements, no abnormal T cell clone). A short therapeutic trial of low-dose IM may be indicated in idiopathic hypereosinophilia patients, particularly with concurrent organ damage, to identify IM-sensitive cases outside the predefined group of PDGFR-rearrangements, before the availability of complex diagnostic tests. Drug withdrawal is on the contrary associated with rapid relapse, so that long-term maintenance is required.

Cytogenetics and molecular diagnostics I

EUROPEAN STANDARDIZATION OF BCR-ABL MRNA QUANTIFICATION

M.C. Müller,[1] P. Erben,[1] G. Saglio,[2] S. Branford,[3] B. Hanfstein,[1] D. Gosenca,[1] T. Ernst,[1] R. Hehlmann,[1] N.C.P. Cross,[4] A. Hochhaus[1]

[1]Universitätsklinikum Mannheim, MANNHEIM, Germany; [2]Division of Hematology and Internal Medicine, University of Turin, TURIN, Italy; [3]IVMS, ADELAIDE, Australia; [4]Wessex Regional Genetics Laboratory, University of Southampton, SALISBURY, UK

Background. Comparability of molecular results between different laboratories is the prerequisite for their use within large studies and for optimal patient management. International recommendations have defined a standardized way to calculate and express individual results on an International Scale (IS). Utilization of the IS in different laboratories currently relies on comparison of a series of test samples to derive laboratory-specific conversion factors (CFs) which are then validated by exchange of a second set of samples. *Aims.* We sought to develop the IS in 40 European laboratories undertaking BCR-ABL mRNA quantification with highly diverse techniques, i.e. cDNA synthesis, PCR platforms, control genes, external standards, evaluation methods. *Methods*. Triplicates of WBC lysates (10%, 1%, 0.1%, 0.01% dilutions of a CML patients leukocytes in healthy donors leukocytes, n=480) were shipped on dry ice to 40 participating laboratories. A common RNA extraction protocol (TRIzol®) was applied followed by individual protocols for cDNA synthesis, RQ-PCR and evaluation. Results were compared with results from the central reference laboratory (Mannheim). After assessment of linearity, individual CFs were calculated (individual BCR-ABL result x CF = BCR-ABL result according to the International Scale). For validation of the CF 25-30 aliquots of patient WBC lysates were exchanged. *Results.* In 36 of 40 laboratories (90%) CFs were successfully calculated whereas 4 laboratories (10%) failed due to non-linear results. The coefficients of variation (CV) of individual results (n=36) improved from 0.87-1.85 before conversion to 0.28-0.43 after conversion. In order to validate the CFs, 35 of 40 laboratories (88%) provided patient samples which were analyzed in both test and reference laboratories. After conversion, 50% of results (median proportion of samples per laboratory) were within 2-fold of each other (range, 0.5-2.0), 77% were within 3-fold and 92% were within 5-fold. Recalculation of the CFs using Bland-Altman difference plots led to significantly higher concordance rates (<2-fold difference, median 72%, p=0.0002; <3-fold difference, median 89%, p=0.0002; <5-fold difference, median 96%, p=0.0011). Three labs appeared to achieve unsatisfying concordance rates (2-fold, <40%; 3-fold, <65%; 5-fold, 65-90%). *Conclusions*. We conclude that control rounds based on distribution of dilution samples represent powerful tools to check linearity of molecular quantification systems for BCR-ABL mRNA. Furthermore, they facilitate the calculation of CFs for participating laboratories, enabling the expression of results according to the International Scale. An expansion of these efforts to all European countries is ongoing within the European Treatment and Outcome Study (EUTOS) for CML.

0154

RESCUE OF GENOMIC INFORMATION IN 72% OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) WITH NORMAL/FAILED CYTOGENETICS AND IDENTIFICATION OF NF1 DELETION AS THE HALLMARK OF A SUBSET OF NOTCH1-MUTATED T-ALL. A GIMEMA STUDY

C. Matteucci,[1] G. Barba,[1] E. Varasano,[1] A. Vitale,[2] L. Elia,[2] M. Mancini,[2] V. Pierini,[1] R. La Starza,[1] B. Crescenzi,[1] S. Romoli,[1] V. Nofrini,[1] M.F. Martelli,[1] R. Foà,[2] C. Mecucci[1]

[1]Hematology, IBiT Foundation, University of Perugia, PERUGIA, Italy; [2]Hematology, University La Sapienza, ROMA, Italy

Background and Methods. Molecular cytogenetics and advanced wide-genome technologies have provided information on >80% of T-cell acute lymphoblastic leukaemia (T-ALL). We used Metaphase-, Array-CGH (M-, A-CGH), Fluorescence *in situ* hybridization (FISH) and mutational analysis to characterize 32 adult B-cell acute lymphoblastic leukaemia (B-ALL) and 40 T-ALL at diagnosis, from GIMEMA protocol 0496. All cases were non-classified genetically, because of failed conventional cytogenetic analysis, normal karyotype, and negative molecular studies for the most common genomic rearrangements. *Results*. M-CGH detected DNA copy number variations (CNV) in 25/40 T-ALL cases (62.5%) and

13/32 (40.6%) B-ALL. Gains frequently involved entire chromosomes 21 (six cases), 14 (four cases), and X (four cases, one with an Xp amplification) and the following chromosomal regions: 1q (six cases), 17/17q (five cases), 5/5p (four cases, one with a high level amplification at 5p13.2-p15.2). Losses frequently involved the regions of: 9p (eleven cases), 5q and 6q (eight cases each), 11q and 13 (four cases), 9q, 16/16q, 17p (three cases each). CNV were associated with specific lineages: 1q gain was found in 12.5% of B-ALL and 5% of T-ALL; X/Xp gain in 12.5% of B-ALL but not in T-ALL. 9p loss was detected in 6.2% of B-ALL and 22.5% of T-ALL; 5q loss was found in 3.1% of B-ALL and 20% of T-ALL. A-CGH, performed with commercial 3200-3600 BAC arrays with resolution of about 0.85-0.8 Mb, detected changes in 4/6 cases with normal M-CGH and identified additional imbalances in 6 abnormal cases. It revealed a deletion in 17q11.2/NF1 gene in 2 cases (the sole genomic imbalance in one; associated with chromosome 13 deletion in the other). In the latter, BAC array detected a cryptic four-clone deletion (RP11-229K15, RP11 353O18, RP11-142O6, RP11-41C23) on 17q11.2 of 0.5-2 Mb in size. FISH screening with probes for the NF1 gene on 42 cases of T- and B-ALL with fixed cells detected another case of T-ALL case with a cryptic del(17q11.2). None of the B-ALL cases was positive. A FISH screening in additional 20 cases of T-ALL belonging to different GIMEMA protocols showed 2 cases with a microdeletion at 17q11.2 region. Somatic mutations of the NOTCH1, FBW7 and NF1 genes were investigated using Denaturing High Performance Liquid Chromatography in the 5 cases with NF1 deletion. No mutation was detected at FBW7 gene while NOTCH1 was mutated in all cases. Moreover, one case showed a stop mutation at NF1 exon 22 of the nondeleted allele, confirming the tumorigenic mechanism of suppressor gene haploinsufficiency. Thus, NF1 deletion is a genomic event identifying a subgroup of NOTCH1-positive T-ALL. Conclusions. M- and A-CGH integrated failed/normal cytogenetics in T-ALL, rescuing 72% of genetically undefined T-ALL cases (M-CGH alone rescued 62.5 %). A-CGH detected a new microdeletion of the 17q11.2 region, which identified a subset of patients with NOTCH1-positive T-ALL. M-CGH, together with the added value of the higher resolution A-CGH, emerged as valid approaches for genomic characterization of T-ALL.

0155

CONSTITUTIVE ACTIVATION OF PDGFRA OR PDGFRB BY DIVERSE FUSION GENES CAN RAPIDLY BE DETECTED BY QUANTITATIVE RT-PCR

P. Erben,[1] M.C. Mueller,[2] D. Gosenca,[2] G. Metzgeroth,[2] H. Popp,[2] C. Walz,[2] E. Thomas,[2] R. Hehlmann,[2] N. Cross,[3] A. Hochhaus,[2] A. Reiter[2]

[1]University Hospital Mannheim, MANNHEIM, Germany; [2]III. Med. Klinik, Med. Fak. Mannheim, Univ. Heidelberg, MANNHEIM, Germany; [3]Salisbury District Hospital, SALISBURY, UK

Rapid identification of fusion genes involving PDGFRA or PDGFRB in chronic myeloproliferative disorders or myelodysplasia is compromised by the multitude and heterogeneity of partner genes. We therefore sought to establish quantitative RT-PCR assays (RQ-PCR) by amplification of 3´-mRNA sequences which are fully retained in PDGFRA fusion-gene positive patients (4 fusion genes; 38 patients, 35m, 3f, median age 54 yrs, range 33-75) or PDGFRB fusion gene-positive patients (4 fusion genes; 7 patients, median age 58 yrs, range 19-75). Except for FIP1L1-PDGFRA positive cases, all patients had chromosomal aberrations of bands 4q12 (*PDGFRA*) or 5q31-33 (*PDGFRB*) as assessed by conventional cytogenetics. As external standards for quantification, serial dilutions of plasmids containing non-rearranged *PDGFRA* and *PDGFRB* sequences were employed. ABL transcripts were quantified as an internal control and results were expressed as the ratios PDGFRA/ABL or PDGFRB/ABL. A cut-off point for overexpression of *PDGFRA* and *PDGFRB* (mean+2SD) was determined by analysis of a series of 30 healthy volunteers. At diagnosis, all patients in the study group showed significantly increased normalized transcript levels compared to patients with fusion-gene negative hypereosinophilic syndrome (HES) patients or healthy controls (*PDGFRA*, 0.8 *vs* 0.0062 *vs* 0.0064, $p<0.0001$; PDGFRB, 182 *vs* 3.41 *vs* 5.85, $p<0.0001$). The sensitivity of the assays measured by serial cell dilutions (EOL cells in HL60 cells) and mRNA dilutions from patients with known fusion transcripts differed for PDGFRA (1:1,000) and *PDGFRB* (1:10) quantification. The greater sensitivity for *PDGFRA* was due to the very low expression of this gene in normal leukocytes. Follow-up analyses of *FIP1L1-PDGFRA* positive patients during treatment with imatinib (n=23) revealed a decrease of *PDGFRA* expression to levels comparable to healthy controls in 21 of 23 (91%) patients after a median time of 13 weeks (range 8-67). These results were concordant to fusion gene specific nested RT-PCR which became negative in 19 of 21 cases after a median of 21 weeks (range, 28-67). The RQ-PCR assays may serve as useful adjuncts to diagnostic detection of imatinib-responsive fusions as well as powerful tools to help identify as yet unknown molecular aberrations involving these genes.

0156

MUTATIONS OF THE WT1 TRANSCRIPTION FACTOR ARE ASSOCIATED WITH INFERIOR OVERALL SURVIVAL-AN ANALYSIS IN 368 AML PATIENTS WITH NORML KARYOTYPE <60 YEARS TREATED IN THE AML96 PROTOCOL OF THE DSIL

C. Thiede, T. Illmer, S. Soucek, M. Schaich, G. Ehninger

University Hospital Carl Gustav Carus, DRESDEN, Germany

Background. In patients with AML and normal karyotype, several specific molecular abnormalities have been reported during the last years, including *FLT3-ITD*, *NPM1* and *CEBPA* mutations. The presence of these alterations has an impact on prognosis, and new strategies try to implement them for treatment stratification. More recently, mutations of the WT1 gene have been described in AML patients. Thus far, studies on this mutation are limited in sample size and the precise prevalence and the prognostic impact WT1 mutations is unknown. In an attempt to further characterize patients with AML and normal karyotype (NK-AML), we have studied WT1 mutations in NK-AML patients below the age of 60. We characterized mutations in the mutational hotspot regions of WT1 by high-resolution fragment analysis (Exons 1 and 7) or direct sequencing (Exon 9) in a total of 368 patients treated in the AML96 trial of the DSIL. Results were correlated with other mutations (e.g. FLT3; NPM1) as well as clinical parameters and outcome. *Results*. Mutations of the WT1 gene were found in 38/368 patients (10.3%). The mutations were predominantly located in exon 7 (n=25) and exon 9 (n=12), whereas only 3 mutations were found in exon 1; two patients had mutations in two exons. Among the clinical characteristics, *WT1* mutations were associated with younger age at diagnosis (median *WT1* wt: 49 yrs. *vs* WT1 mut: 42 yrs.; $p=.036$), higher LDH (median *WT1* wt. 434 U/l *vs* WT1 mut709.8 U/l; $p=.001$), but not with patient gender, BM-blasts or leukocyte counts. No significant association was further seen with the presence of FLT3-ITD, TKD or *NPM1* mutations. Patients with WT1 mutations had a comparable CR-rate after double induction chemotherapy (WT1-neg: 70% *vs WT1* pos: 65.8%). However, the probability of overall survival in patients with mutated WT1 was significantly lower (median WT1 neg: 22.6 mo. range: 16.1-29.2 *vs* WT1-mut: 11.5 mo. range 8.4-14.6; $p=0.027$). *WT1* had no significant impact on the probability of disease free survival and the rate of relapse. In a multivariate Cox-proportional hazard model including several clinical (age; WBC counts; LDH) or molecular parameters (NPM1/FLT3-ITD mutational groups), mutant *WT1* remained an independent predictor of inferior OS with a hazard ratio of 1.6 (range: 1.1-2.5). *Conclusions*. *WT1* mutations can be found in a significant proportion of patients with AML and normal karyotype. They are more common in younger patients and appear to be associated with a lower probability of OS. Thus, the detection of WT1 mutations might add further impact to the prognostic classification based on molecular alterations.

0157

MULTIPLEX LIGATION-DEPENDENT PROBE AMPLIFICATION (MLPA) IS A POWERFUL TECHNIQUE TO IDENTIFY PROGNOSTIC RELEVANT CHROMOSOMAL DELETIONS AND DUPLICATIONS IN CLL PATIENTS

M.-J.P.L. Stevens-Kroef,[1] A. Simons,[1] H. Gorissen,[1] T. Feuth,[1] D. Olde Weghuis,[1] A. Buijs,[2] R. Raymakers,[1] A. Geurts van Kessel[1]

[1]Radboud University Nijmegen Medical Centre, NIJMEGEN; [2]University Medical Centre Utrecht, UTRECHT, Netherlands

Background. B-cell chronic lymphocytic leukemia (B-CLL) is characterized by a highly variable clinical course. Characteristic genomic abnormalities such as deletions of the ATM and/or TP53 genes, deletions of the 13q14.3 region and trisomy 12 have shown to provide prognostic information (*Dohner et al. NEJM 343:1910-6*). *Aims*. The still widely and commonly applied karyotyping and FISH techniques for the detection of these aberrations are laborious and expensive. As an alternative, we set out to perform multiplex ligation-dependent probe amplification (MLPA) analysis using commercially available kits. This allowed us to analyze 56 genomic CLL-specific and risk-identifying targets, including the loci mentioned above, in a single experiment. *Methods*. MLPA data of 88 CLL patients were compared with interphase FISH data using the

ATM, centromere 12, RB1, D13S319, and TP53 specific probes in a double blinded fashion. *Results*. Overall, there was a perfect correlation between the MLPA and FISH data if the genetically abnormal clone was present in at least 10% of the cells. Only one case with 8% abnormal cells, as determined by FISH, was not detected by MLPA. Since multiple probes per tested locus and multiple loci were included in the MLPA assay, additional abnormalities not covered by the standard FISH probes used were detected by MLPA, i.e., trisomy of the short arm of chromosome 12, trisomy of chromosome 19 and gain of the MYCN gene. Furthermore in 3 patients small 13q14.3 deletions undetectable by FISH were identified and in another 10 patients deletions only partly covering the 13q14.3 locus were observed. In all these patients the deletions included the non-coding RNA locus DLEU, which represents an alternatively spliced transcript of BCMS gene. This gene has been proposed to be the most likely candidate tumor suppressor in 13q14 involved in the leukemogenesis of B-CLL. *Conclusions*. We have demonstrated that MLPA is a comprehensive and reliable diagnostic tool for the simultaneous identification of different clinically relevant and region-specific genetic aberrations in CLL. Furthermore MLPA has the potention to detect small critical regions of genomic loss or gain.

0158

PATTERN OF MENINGIOMA 1 GENE (MN1) EXPRESSION IN DIFFERENT GENETIC SUBSETS OF ACUTE AND CHRONIC MYELOID LEUKAEMIAS AND ITS POTENTIAL USE AS A MARKER FOR MINIMAL RESIDUAL DISEASE DETECTION

F. Arruga,[1] F. Messa,[1] E. Gottardi,[1] M. Fava,[1] S. Carturan,[1] C. Panuzzo,[1] E. Bracco,[1] E. Messa,[1] P. Nicoli,[1] A. Rotolo,[1] I. Iacobucci,[2] F. Lo Coco,[3] G. Martinelli,[2] G. Saglio,[1] D. Cilloni[1]

[1]University of Turin, TURIN; [2]University of Bologna, BOLOGNA; [3]University tor Vergata, ROMA, Italy

Background. Meningioma 1 (MN1) gene overexpression has been reported in acute myeloid leukaemia (AML) patients and identified as a negative prognostic factor. The Aims of the study are to characterize the patients presenting with MN1 overexpression and to establish if MN1 transcript could be a useful marker for MRD detection. *Methods.* MN1 has been quantified by RQ-PCR in 158 AML patients of different cytogenetic groups, in 30 CML patients at different phases of disease and in 50 normal controls. In 20 patients bearing a fusion gene transcript (FG) suitable for MRD assessment, we performed a simultaneous analysis of the MN1 and of the FG transcript during follow-up. Sequential MN1 and WT1 analysis was also performed in 10 AML patients lacking other molecular markers and RQ-PCR for NPM mutations in additional 7 cases. *Results.* The MN1 levels were extremely low in normal samples: median value of 136 MN1/104ABL copies in PB (range 9-300) and 254 in BM (range 80-500) and 12,9 (range 11-19) in $CD34^+$ cells. By contrast, about 50% of the AML samples with normal karyotype (NK) showed high MN1expression with a median of 5136 copies/104 ABL copies (range 852-90230) and 6780, (range 1367-15900) in PB. All samples carrying the CBFβ-MYH11 FG expressed a significantly higher amount of MN1 transcript as compared to controls (p<0,0001 in both BM and PB): median 46950, (range 2149-98000) in BM and 34500, (range 1400-67999) in PB. About 50% of the samples with AML1-ETO FG abnormally expressed MN1: median 16950, (range 3500-34000) in BM and 3475, (range 1260-56000) in PB. Finally, the APL samples expressed MN1 values comparable to those of healthy subjects in both BM (p=0,05) and PB (p=0,08). Paired analysis established a remarkable correlation between MN1 expression in PB and BM with a r value of 0,91. No association between FLT3 mutations and MN1 was demonstrated. In contrast, MN1 is typically overexpressed in patients with NPM mutations. 36 out of 47 $NPMc^+$ patients were characterized by abnormal MN1expression. We were unable to confirm the correlation between EVI-1 and MN1 expression (r= 0,06) reported in literature. Finally, MN1 is not expressed in CML in chronic phase (10 cases) but it is highly overexpressed during accelerated (n=10) and blast crisis (n=10) (median 49100 and 62741 respectively). Finally MRD has been detected by RQ-PCR by measuring MN1, FG, WT1 and in 7 cases without FG by NPM as well. In all cases characterized by FG transcript, the longitudinal pattern of MN1 expression always paralleled that of the FG. Furthermore, MN1 strictly paralleled WT1 and NPM in patients without any FG. In all the cases MN1 rose at least two months before relapse. *Conclusions.* these data show that 47% of patients with NK are characterized by abnormal MN1 expression. The overexpression is typical of AML with $NPMc^+$ and inv(16) and CML in accelerated and blastic crisis. MN1 could represent a marker for MRD. Increased MN1 expression in the BM during follow up was always found to be predictive of an impending hematological relapse.

INFANT ALL PATIENTS WITH T(4;11)/MLL-AF4 FUSION HAVE A DIFFERENT GENOTYPIC PROFILE THAN OLDER ALL CHILDREN

M. Bardini,[1] R. Spinelli,[2] L. Corral,[1] E. Mangano,[3] G. Fazio,[1] I. Cifola,[2] A. Biondi,[1] C. Battaglia,[4] G. Cazzaniga[1]

[1]M. Tettamanti Research Center, MONZA; [2]ITB-Segrate, CNR and Center of excellence CISI, Università degli Studi di Milano, MILANO; [3]CNR and Center of excellence CISI, Università degli Studi di Milano, MILANO; [4]Center of excellence CISI and Dip Science and Biomedical Techologies, MILANO, Italy

Background. Mice models and prenatal studies indicate that in childhood ALL the individual genetic lesions alone are insufficient to generate a full leukemic phenotype, and cooperating oncogenic lesions are required. Recently, genome-wide studies on childhood ALL (1-18 years) identified deletions at several loci, mainly affecting genes that play a critical role in regulating B-cell development and differentiation. By contrast, prenatal and postnatal steps in the pathogenesis of Infant ALL (<1 year at diagnosis) are not defined. Infant ALL is a very aggressive disease, with t(4;11)/MLL-AF4 fusion representing the major subgroup. Although the very short latency suggests that leukemogenic events occur prenatally, mice models indicate that MLL-AF4 alone is not sufficient to induce leukemia, and additional mutations may occur. Also unclear is whether the molecular pathways needed for lymphoid cell differentiation are altered in cases with an MLL rearrangement and, if so, whether these alterations differ between the leukemia of infants and older children. *Aims*. Aim of this study was to detect MLL-cooperating aberrations, undetectable by conventional techniques. More specifically, we searched for Loss of Heterozygosity (LOH) associated or not to copy number alterations. The identification of these lesions could help identifying leukemia pathogenesis, providing the basis for targeted therapy. *Methods*. We have analyzed 28 cases of Infant ALL with t(4;11) at diagnosis and their corresponding samples at remission and relapses, when available (n=18 and n=8 respectively) by using genome-wide single nucleotide polymorphism (SNP) analysis (100K SNP human mapping, Affymetrix). Data were analyzed by using dChip software, and confirmed by CNAG2.0. *Results*. Compared to older childhood ALL patients, a far limited number of deletions/amplifications has been found; only 4/28 patients showed deletions, namely 1p36.13-p36.31 in one patient, 3p11.1-p12.2 plus 7q22.1-q22.2 in another patient, 4q22.3 in a third patient and 8q24.11 plus 14q21.3 in another; while 24/28 Infant ALL did not present any visible structural variation at diagnosis. By contrast, several segmental copy-number neutral (CNN) LOH have been detected and in most cases the same homozygous trait found at diagnosis was also present at remissions. The extension and prevalence of the affected regions was variable; among them 14q21.2 (4/28), 7q31.33-q32.1 (3/28), 8q21.12-q21.3 (2/28) and 8q24.11 (2/28) have been further validated by direct sequencing. At relapse, additional alterations have been detected, such as deletion of 7p in 3 cases, associated to 7q duplication (iso7q) in 2/3 cases. *Summary and Conclusions*. Overall, these results confirm that Infant ALL with t(4;11)/MLL-AF4 fusion represents a biologically unique disease, different from other type of leukemia occurring in older children. While in older children a multistep mechanism (with the involvement of several genes) is required for the full leukemic phenotype, MLL rearrangements *per se* might play a major role on the leukemogenesis. By this approach it could not be excluded that different mechanisms could cooperate with MLL in transforming cells, including point mutations. The functional role of CNN-LOH still needs to be understood: they could either reflect the duplication of oncogenic mutations, or be related to epigenetic mechanisms. A role in the predisposition to leukemia could also be hypothesized.

COMBINED INTERPHASE FLUORESCENCE *IN SITU* HYBRIDIZATION IS A VALID TOOL FOR FULL GENOMIC INVESTIGATION AND DIAGNOSTIC SCREENING IN T-ALL. A GIMEMA STUDY

R. La Starza,[1] P. Gorello,[1] E. Varasano,[1] V. Pierini,[1] A. Guarini,[2] A. Vitale,[2] A. Bardi,[3] A. Cuneo,[3] M.F. Martelli,[1] R. Foà,[2] L. Elia,[2] C. Mecucci[1]

[1]Hematology, IBiT Foundation, University of Perugia, PERUGIA; [2]Hematology, University La Sapienza, ROMA, Italy; [3]Hematology, University of Ferrara, FERRARA, Italy

Background. In T-cell acute lymphoblastic leukemias (T-ALL) molecular lesions target regulators of cell cycle, proliferation, differentiation, survival and apoptosis in *multi-step* pathogenetic pathways. To identify events concurring in T-ALL development full genetic characterization is needed. *Aims*. To set-up and validate a molecular cytogenetic tool to integrate mutational analysis and PCR and provide a full genetic diagnosis of T-ALL. *Methods*. We designed a combined interphase fluorescence *in situ* hybridization (CI-FISH) assay to study 15 genes/loci that are involved in T-ALL leukemogenesis and validated it in 20 patients enrolled in the GIMEMA protocols with immunophenotype, cytogenetics, mutational analyses, and ALL Multiplex-PCR (*BCR-ABL1, PBX1-E2A, SIL-TAL1, MLL-AF4, MLL-ENL*, and *NUP98-RAP1GDS1*). Phenotypes were pre-T in 8 cases, cortical in 11 and mature in 1. Karyotyping succeeded in 13/20 cases and was abnormal in 6/13. *NOTCH1* mutations were detected in 7/18 cases (38%); FBW7 in 4/18 (16%). Multiplex-PCR detected one MLL-ENL and one SIL-TAL1 rearrangement. *Results*. CI-FISH gave abnormal hybridization patterns in 16/20 patients and detected multiple genomic changes in 10. Del(9p)/CDKN2A was found in 8 patients and del(6q) in five. No TCRA/D translocations were found even though they are estimated to be as frequent as TCRB translocations.1 TCRB was involved in translocations: t(7;11)(q35;p13)/TCRB-LMO2 in two cases, and inv(7)(p15q34)/TCRB-HOXA, t(7;9)(q34;q32) /TCRB-TAL2, and t(7;10)(q34;q24)/TCRB-HOX11 in one case each. Although the incidence of CDKN2A and of TCRB translocations was similar to other reports,[1,2] we found a higher incidence of del(6q) (25% *vs* 4-13%) which was probably due to the genomic clones selected for the minimal common deleted region. MLL-translocations were found in two cases, one of which had been found by Multiplex-PCR. In another patient CI-FISH hybridization signals indicated 6q23/C-MYB had undergone duplication and translocation suggesting a new cytogenetic mechanism may lead to C-MYB over-expression. CI-FISH detected the rare CALM-AF10 in one case and SIL-TAL1 in another. Previously unknown recurrent aberrations included trisomy of chromosome 9 in 1 case and of 11p in 2 cases and deletions involving 7q34 in 3 cases, 5q35/TLX3, 9q34/ABL1, and 12p13 in 2 cases each, and 14q11/TCRA/D in 1. In 2 cases with del(12p) of different extension, a common deleted region included several putative tumour suppressor genes such as *LRP6, DUSP16, DDX47, EMP-1, CREBL2,* and *CDKN1B*. Interestingly, *CDKN1B* haploinsufficiency was recently reported in T-cell prolymphocytic leukemia.[3] In 2/3 patients with del(7)(q34) which lost only the 3' *TCRB* flanking region we hypothesize a new cytogenetic mechanism whereby an unbalanced translocation activated unknown oncogenes. *Conclusions*. CI-FISH identified genetic abnormalities in 80% of cases and multiple changes in 50%. It reliably detected cryptic, rare, and new chromosome changes, TCR rearrangements, molecular lesions involving *promiscuous* genes and oncogene activation by diverse cytogenetic mechanisms. We propose using CI-FISH in the diagnostic screening of T-ALL to supplement mutational analysis and PCR studies and to validate the genetic classification of T-ALL in clinical studies.

THE COINCIDENCE OF THE JAK2V617F AND 5Q-DELETIONS IS ASSOCIATED TO VARIABLE MYELOPROLIFERATIVE AND MYELODYSPLASTIC PHENOTYPES: REPORT OF 13 CASES

U. Bacher,[1] T. Haferlach,[2] C. Haferlach,[2] T. Weiss,[2] W. Kern,[2] S. Schnittger[2]

[1]University of Hamburg, HAMBURG; [2]MLL Munich Leukemia Laboratory, MUNICH, Germany

Background. There are few studies on the coincidence of deletions of 5q and of the JAK2V617F in the literature. Ingram *et al.* (Leukemia, 2006) reported on 6 patients with initial stages of Myelodysplastic Syndrome (MDS) with this coincidence. *Aim of the Study*. To increase insights in this phenomenon, we evaluated retrospectively the frequency of the JAK2V617F mutation in 69 patients with different entities of MDS and chronic myeloproliferative diseases (CMPD) and a del(5q) and performed further characterization of the 13 patients who had both aberrations in coincidence. *Patients and Methods*. Between August 2005 and February 2008, mutational screening for the *JAK2V617F* was performed in 69 patients with a deletion of 5q as sole aberration or within non-complex aberrant karyotypes. Cases were analyzed by chromosomal banding combined by interphase fluorescence *in situ* hybridization (FISH) and by melting point based PCR analyses for the *JAK2V617F*. Cytomorphology and histopathology were additionally performed, and a diagnosis of chronic myeloid leukemia was excluded by interphase FISH for BCR-ABL. Finally, 13 patients with diverse CMPD and MDS subtypes were observed with a coincidence of del(5q) and *JAK2V617F*, and were further evaluated. *Results*. Frequency of coincidence: 13/69 patients (19%) with a deletion of 5q were positive for the *JAK2V617F* (11 at diagnosis, 2 during follow-up). Characteristics of the 13 patients with a coincidence of *JAK2V617F*/del(5q): There was a strong female preponderance (10 females: 3 males). Range of age was 45.9-86.1 years (median 71.9). Ranges of peripheral blood parameters were as follows: Leukocytes: 4 - 22×10^9/L (median 12.8×10^9/L), thrombocytes: 80 - 1195x10^9/L (median 592×10^9/L), hemoglobin: 90-160 g/L (median 12.8 g/L). Thrombocytosis was present in 6/10 cases, where data were available, 4/10 had anemia, and 5/10 presented with peripheral leukocytosis. 11/13 cases had an isolated del(5q), whereas in one case there was an additional del(20q)(q11), and in another case an additional del(12p)(p11p13). The proximal breakpoints of the deletion were localized in 9 cases at 5(q13-q15), in 4 cases at 5(q22-q23). The distal breakpoints were localized in 11 cases at 5(q33-q35) and in 2 cases at 5q31. Diagnoses of the 13 patients as assessed by cytomorphology, histopathology, and clinical and laboratory parameters were as follows: The most frequent disorder was MDS/CMPD overlap in 5 cases. Two cases each showed "classical"MDS/5q- syndrome, not classifiable CMPD (CMPD-U), or essential thrombocytosis (ET). One case had a CMPD in acceleration with 14% bone marrow blasts. (In one case classification was not possible, as diagnosis was performed during follow-up.) *Conclusions*. A considerable proportion of patients with a deletion of 5q (19% in this analysis) show a coincident *JAK2V617F*. In this study most patients with this coincidence had an overlap between myelodysplastic and myeloproliferative disorders, but there are also cases with the features of *classical* MDS/5q- or with *classical* ET. These variable phenotypes might be explained by additional mutational factors and deserve further investigation. Further studies should focus on the cooperation of the JAK2 and the del(5q) to increase insights in cooperative mechanisms in leukemogenesis in myeloproliferative and myelodysplastic diseases as in their overlap.

Hospital, Fac. of Medicine, Masaryk Univ., BRNO; [8]Institute of Experimental Biology, Faculty of Science, Masaryk University, BRNO, Czech Republic

Background. The presence of chromosomal aberrations detected by fluorescence *in situ* hybridisation in plasma cells is considered to be important prognostic factor for patients with multiple myeloma (MM). One of the newest mentioned factors is gain/amplification of chromosome band at 1q21. *Aims*. This study is aimed at comparison of incidence and assesment of prognostic impact of amp1q21, del13q14, del17p13, and translocations t(4;14) and t(11;14) in newly diagnosed MM patients. *Methods*. A total of 91 newly diagnosed patients with median age 58 years, median follow-up 33.9 months received 4 cycles of VAD followed by high dose of melphalan (200 mg/m^2) supported by peripheral blood stem cells. Cytoplasmic interphase FISH (cIg-FISH) analyses were assesed utilizing commercial DNA probes (Abbott-Vysis, Il, USA and Kreatech Biotechnology, NL, USA) in plasma cells labeled by the AMCA anti-IgL antibodies (Vector Laboratories, Inc.). *Results*. Chromosomal abnormalities were assessed in 91% MM patients. Amp1q21 was detected in 47% (43/91) patients, del13q14 and del17p13 were detected in 54% (48/89) and 29% (25/87) patients, respectively; t(4;14) and t(11;14) were detected in 31% (18/59) and 44% (35/79) patients, respectively. A significant association between amp1q21 and del17p13 incidences was observed (p=0.032). Similarly, a trend towards association between amp1q21 and del13q14 incidences was observed (p=0.088). Among patients with amp1q21 ORR (CR+PR) was 82.4% (14/17); among patients lacking amp1q21 ORR was 90.6% (20/22) (p=0.636). Similarly, no difference in ORR for any other studied aberration was observed. Comparison of PFS median in positive *vs* negative patients for each aberration was as follows: For amp1q21 reached 15.6 *vs* 37.5 months; p=0.013; for del13q14 reached 21.7 *vs* 30.1 months; p=0.614; for del17p13 reached 17.1 *vs* 31.7 months; p=0.059; for t(4;14) reached 18.1 *vs* 31.9 months; p=0.582 and for t(11;14) the PFS median was not yet reached *vs* 22.5 months; p=0.435, respectively. Comparison of OS median in positive *vs* negative patients for each aberration was as follows: For amp1q21 reached 28.0 *vs* 51.0 months; p<0.001; for del13q14 was not yet reached *vs* 40.8 months; p=0.388; for del17p13 reached 28.6 *vs* 47.7 months; p=0.095; for t(4;14) was not yet reached *vs* 38.2 months; p=0.701 and for t(11;14) reached 35.9 months *vs* not yet reached; p=0.663, respectively. *Summary and Conclusions*. Our data suggest that amp1q21 is associated with reduced PFS and OS intervals in patients treated with autologous transplantation. Similarly a trend towards shorter survival for del17p13 positive patients was observed. Moreover, negative prognostic impact of amp1q21 can be boosted by presence of any other studied chromosomal aberration, which implicates much poorer outcome for patients carrying those aberrations together (data not shown). Considering observation of negative impact of amp1q21 either with or without correlation of any other studied aberrations, amp1q21 seems to be the most powerful independent prognostic factor for MM patients.

GENE COPY NUMBER CHANGES IN MYELODYSPLASTIC SYNDROMES

I. Borze,[1] E. Juvonen,[2] E. Elonen,[2] S. Knuutila[1]

[1]Haartman Institute, HELSINKI, Finland; [2]Department of Medicine, Division of Hematology, Helsinki University Central Hosp, HELSINKI, Finland

Background. Myelodysplastic syndromes (MDS) are a group of bone marrow malignances characterized by dysplasia and ineffective hematopoiesis involving one or more myeloid lineages. MDS evolve to acute myeloid leukemia (AML) in many cases. These disorders occur predominantly in elderly people (median age is 50-70 years old). MDS can appear as *de novo* (without history of some toxic exposure) or as therapy-related (related to chemotherapy and radiotherapy) disorder. Cytogenetic abnormalities vary with MDS type, but are present in about 30-50% of all MDS cases. Specific chromosome abnormalities known in MDS are loss of whole 5 or 7, 5q-, 7q-, trisomy of 8, and Y-. Additionally can be observed: 20q-, 17p-. In special losses of chromosomal material are frequent. *Aims.* We screed the entire genome of 25 *de novo* MDS for gene copy number changes, in order to detect microdeletions and microduplications, using high-density 244k oligonucleotide-based array CGH (Agilent Technologies). *Methods.* DNA was extracted from archive bone marrow samples using standard methods. The digestion, labeling and hybridisation were done according to manufacture's protocol. The array slides were scanned with Agilent's cofocal scanner. The data was processed with Feature Extraction software v9.1 and analyzed with CGH Analytics software v3.4 (Agilent Technologies). *Results.* The array CGH results showed small chromosomal aberration in addition to that detected by karyotyping tehnique. In 56% of the cases we were able to point out new chromosomal microaberrations. The most common aberrations were deletions of 5q and 7q with common region located at 5q21.3q32 and 7q22.1q33. In three cases we found a complex molecularkaryotype, and in addition four cases exhibit only one or two new microalterations. *Summary.* Based on our array result and also of some previous reports, the aCGH is a powerful technique to reveal small chromosomal aberrations in MDS. In our data these new microaberrations were located at chromosome: 3q, 7q, 11q, 18q, 17q.

Finding of clonal chromosomal aberrations in plasma cells is considered as one of the most important and independent prognostic factor in patients with multiple myeloma (MM). The aim of the study was to assess the frequency and prognostic value of the most common chromosomal aberrations in a homogenous series of patients with newly diagnosed multiple myeloma enrolled to the phase III trial CMG 2002. In this study 208 patients enrolled until December 31, 2005 were included. All patients underwent single autologous bone marrow transplantation according to protocol of the trial after 4xVAD induction chemotherapy and were randomized after transplantation to two maintanance/consolidation treatment arms. All patients gave written informed consent to the proposed therapeutic procedure and to the provision of samples for research purposes. Cytoplasmic Ig-FISH (cIg-FISH) analyses were done on plasma cells labeled by the Amca Anti-Human kappa-chain, Amca Anti-Human lambda-chain and Amca Anti-goat IgG monoclonal antibodies (Vector Laboratories). cIg-FISH was done by locus-specific DNA probes (Abbott-Vysis, Des Plaines, Illinois, USA and Kreatech Biotechnology B.V, Amsterdam, The Netherlands). To rule out the presence of a false positive result, cut-off values were established at 20% for detection of deletions and at 10% for detection of translocations and gains, respectively. All patients were systematically examined by conventional G-banding technique and by cIg-FISH for the deletion/monosomy of chromosome 13 and IgH gene rearrangements. Consequently, in patients with previously proven rearrangement of IgH, cIg-FISH with LSI IGH/CCND1 and/or LSI IGH/FGFR3 probes for detection of translocations t(11;14)(q13;q32) and

t(4;14)(p16;q32) was performed. In addition, 137 patients were also screened for the deletion of 17p13 and 106 cases for amplification of 1q21 chromosomal region were examined. Chromosomal changes were observed in 83.6% of the patients. Aberrations of chromosome 13 and IgH rearrangement were present in 52.9% and 58.6% of cases, respectively. t(11;14)(q13;q32) was detected in 18.5% of cases (only in two of them as sole abnormality), and t(4;14)(p16;q32) in 15.8% of cases. Statistical analyses confirmed association of IgH aberrations with significantly shorter progression free survival (PFS, p=0.040). We did not confirmed better prognosis of t(11;14)(q13;q32). Prognostic impact of monosomy/deletion of 13q was not proved. Deletion of 17p13 was detected in 21.6% of patients, its association with shorter survival in this study was not found. Amplification of 1q21 was detected in 37.7% of cases, we confirmed its association with significantly shorter survival (OS, p=0.020 and PFS, p=0.001). Finding of cumulative two and more aberrations was in our cohort of patients with MM accompanied by significantly lower progression free and overall survival (p=0.007 and p=0.001, respectively). Comprehensive molecular cytogenetic analysis of genetic changes in plasma cells of patiens with MM should further extend our understanding of the disease, hopefully enabling improvements in the targeted treatment of the patients.

METHYLATION STATUS OF THE PROMOTER OF 25 TUMOUR SUPPRESSOR GENES IN CHRONIC MYELOMONOCYTIC LEUKAEMIA (CMML)

E. Such,[1] A. Valencia,[1] J. Cervera,[1] M.L. Senent,[1] I. Luna,[1] E. Marco,[1] M. Mallo,[2] F. Solé,[2] S. Oltra,[1] R. Collado,[3] A. Vicente,[4] V. Amigo,[5] J.C. Hernández-Boluda,[6] E. Luño,[7] O. Fuster,[1] E. Barragan,[1] P. Bolufer,[1] M.A. Sanz,[1] G. Sanz[1]

[1]Hospital Universitario La Fe, VALENCIA; [2]Hospital del Mar, BARCELONA; [3]Hospital General Universitario de Valencia, VALENCIA; [4]Hospital de La Ribera, VALENCIA; [5]Hospital Arnau de Vilanova, VALENCIA; [6]Hospital Clinico de Valencia, VALENCIA; [7]Hospital Central de Asturias, OVIEDO, Spain

Background. Epigenetic inactivation of tumour suppressor genes by promoter methylation is a common event in human cancers. In myelodysplastic syndromes (MDS) aberrant methylation of some tumour suppressor genes, such as p15INK4B, is a frequent event. The most common method for identifying this alteration is the methylation specific PCR (MS-PCR). As the number of genes hypermethylated in cancer is increasing a methylation-specific multiplex ligation-dependent probe amplification (MS-MLPA) technique has been recently developed. This technique allows the detection of the methylation status of 25 sequences that correspond to a set of tumor suppressor genes that are frequently silenced by methylation in different tumours in a single reaction. *Aims*. To study the methylation status of 25 tumour suppressor genes in DNA samples of 31 patients with CMML by means of MS-MLPA. *Patients and methods*. We studied 31 CMML bone marrow samples at the time of diagnosis [23M/8F, median age: 62 (range:52-85); median Hb: 11.1 g/dL (range: 7.2-14.1); WBC: 21.8×10^9/L (range: 3-42.8) and platelets: 196.5×10/L (range: 4.0-478)]. Genomic DNA was extracted using standard protocols (Qiamp DNA Mini kit). MLPA reagents were obtained from MRC-Holland (*www.mrc-holland.com*). Bone marrow DNA from healthy donors was used as negative control. CpGenome™ Universal Methylated DNA (Chemicon, Millipore) was used as a positive control. Quantification of the methylation status was done by dividing the peak area with the combined areas of the control probes lacking the target sequence of the HhaI. Finally, the relative peak area of each target probe from the digested sample was compared with those obtained from the undigested sample. Aberrant methylation was scored when the calculated methylation percentage was >10%. *Results*. The analysis of diagnosed CMML patients by MS-MLPA, showed aberrant methylation in p15INK4B (6/31, 19%), CDH13 (5/31, 16%), IGSF4 (3/31, 10%), FHIT (3/31, 10%) and RASSF1 (1/31, 3%) promoter regions. The vast majority of patients showed no methylation (18/31; 58%) or just one methylated sequence (8/31; 26%). By contrast, 13% (4/31) of patients showed two or three methylated genes. To validate these findings, MS-PCR was carried out to amplify CpG regions in p15INK4B. Methylation status of p15INK4B was confirmed by both methods in all the patients. The aberrant methylated genes found in the experiment belong to different molecular pathways involved in cell progression and differentiation: cell cycle (p15INK4B, RASSF1 and FHIT) and cell adherence (CDH13 and IGSF4). All of these genes are found frequently inactivated by aberrant methylation in haematological malignancies. No significant correlation was found between methylation status of the different genes and the clinical or biological characteristics. *Conclusions*. MS-MLPA appears to be a new valid method for multiplex detection of aberrant methylation patterns of CpG islands of several genes in just one assay. We found that methylation of these tumour suppressor genes is uncommon in patients with CMML. However, 13% of the patients show abnormal methylation in two or three genes. Clinical relevance of these findings should be explored.

Background. Myelodysplastic syndromes (MDS) are a group of clonal haematopoietic stem cell diseases characterised by dysplasia and ineffective haematopoiesis in one or more myeloid cell lines. More than 50% present cytogenetic aberrations at diagnosis time. Partial or complete deletion of the long arm of chromosome 5 is the most frequent abnormality in MDS; it supposes 10-15% of all *de novo* MDS. To note, there is a distinction between patients with 5q- as a sole alteration and patients diagnosed as *5q- syndrome*, a new MDS entity accepted by the WHO. Recently, a new drug (lenalidomide) has been approved in the US for the treatment of patients diagnosed of MDS with the 5q31 deletion. This drug can reduce transfusion requirements and reverse cytologic and cytogenetic abnormalities. *Aims*. The aim of the present study is to apply the FISH technique in patients diagnosed of MDS in which the conventional banding cytogenetics (CBC) study had shown a normal karyotype, absence of metaphases or an abnormal karyotype without evidence of del(5q). As a result, FISH would allow the detection of the 5q deletion in cases in which has not been detected by CBC. In consequence, these patients might be candidates to receive treatment with lenalidomide. *Patients and Methods*. We present a retrospective study based on 717 patients referred by institutions affiliated to the Spanish Haematological Cytogenetics Working Group (GCECGH). Patients were divided into two groups: Group A, includes 638 patients who did not present the 5q deletion at diagnosis by CBC and Group B (79 patients), in which CBC analysis revealed the 5q deletion (positive control group). In all of them, LSI EGR1 (5q31) SpectrumOrange/D5S23, D5S721 SpectrumGreen Probe (Abbot Molecular Inc.™) was applied to test the 5q deletion. We also performed whole chromosome paintings (Metasystems™) in order to define some karyotype aberrations. *Results*. In group A, the 5q deletion was detected by FISH in 38 cases (6%). Most of the positive cases were diagnosed as *5q- syndrome*. The deletion was observed in 13 cases with a normal karyotype, 11 without metaphases in the CBC study, nine with an aberrant karyotype with implication of chromosome 5, and five with altered cytogenetics and others chromosomes involved. In group B, the 5q deletion was observed by CBC and confirmed by FISH in all cases. We compared the proportion of cells with 5q- detected by CBC *vs* FISH; after applying a statistical analysis we did not find significant concordances in the detection of cells carrying 5q deletion by CBC or FISH. *Conclusions*. The application of FISH 5q31 improves the detection of 5q deletion in 6% compared with CBC. FISH 5q31 will be mandatory to apply when there is a suspected *5q- syndrome* by clinical and/or morphology (64.28%), CBC without metaphases (20.37%) or an aberrant karyotype with chromosome 5 involved (no 5q- chromosome) (81.81%). It would be recommendable to apply FISH 5q31 in any *de novo* MDS. FISH 5q31 might help in the selection of possible candidate patients to receive treatment with lenalidomide.

WHICH IS THE OPTIMAL DOSAGE OF VALGANCICLOVIR AS PRE-EMPTIVE THERAPY FOR CYTOMEGALOVIRUS INFECTION IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT?

A. Candoni, E. Simeone, M. Tiribelli, R. Fanin

Division of Hematology, UDINE, Italy

Introduction. CMV infection is a common complication after allogeneic hematopoietic stem cell transplant (HSCT). Valganciclovir (VGC) is a pro-drug of ganciclovir (L-Valyl ester), orally available, that was first approved for prevention of CMV disease in high-risk (donor positive, recipient negative) solid organ transplants (1800 mg/day as a standard dose). However the optimal dosage of the drug in HSCT has not been yet established. *Aim and Methods*. We report our experience using two different dosages of VGC as pre-emptive CMV therapy in HSCT. During a 12 months period VGC was administered on an outpatient basis to 30 consecutive HSCT recipients with a CMV positive antigenemia, detected after a median time of 86 days (range: 59-480) from transplant; 18/30 patients underwent HSCT from unrelated and 12/30 from related donors. Seventeen patients (57%) received a RIC regimen. At the detection of CMV infection, 21 patients (70%) had an acute or chronic GVHD for which they were receiving immunosuppressive therapy. The pp65 antigenemia assay were positive in all cases with a mean number of positive nuclei of 22,5±43. The first 15 cases received VGC 1800 mg/day (GROUP A) while the following 15 patients were treated with VGC 900 mg/day (GROUP B). The treatment with VGC was continued in all cases until the CMV antigenemia became negative in two consecutive samples, or until the treatment failure (increase of antigenemia in two consecutive samples). The two groups resulted well balanced, without significant differences in age, sex, underling diseases, transplant type, mean number of positive nuclei or CMV serology status at HSCT. *Results*. Overall, 27/30 (90%) cases obtained a complete clearance of antigenemia (14/15 in the GROUP A and 13/15 in the GROUP B). The median duration of VGC therapy was 18 (range 8-64) and 22 (range 8-61) days, respectively (p=ns). No cases of CMV disease were reported. A total of fifteen (50%) patients experienced one or more recurrence of CMV infection after discontinuation of VGC therapy, without significant differences in the two groups (8/15 *vs* 7/15). Seven cases required i.v. therapy with foscavir, but no patient developed CMV disease. Only three patient (2 in the GROUP A and 1 in the GROUP B) developed a mild deterioration of renal function that required dose halving (VGC 900 mg/day in the two from GROUP A, 450 mg/day in the GROUP B case). Overall, 14/30 patients (47%) experienced hematologic toxicity. Mild and transient neutropenia was reported in 12 cases (40%), transient anemia in 9 (30%) and transient thrombocytopenia in 12 patients (40%) respectively, without significant differences between two groups even if there was a trend toward higher incidence of hematological side effects in the 1800 mg/day dose group. *Conclusions*. Our experience confirms that pre-emptive therapy with VGC after allogeneic HSCT is safe and effective, with a rapid clearance of CMV antigenemia. However, in this outpatient setting, the relapse rate was not negligible (50% of cases) even if we did not observe any case of CMV disease. Our data suggest that a lower dose of VGC (900 mg/day) has comparable efficacy than the standard dose (1800 mg/day) in clearing CMV antigenemia. Therefore, in the setting of allogeneic HSCT, the suitable VGC dose for pre-emptive CMV therapy could be lower than the 1800 mg/day previously suggested. However, additional prospective and randomised studies with close monitoring of both pharmacokinetics parameters and CMV antigenemia and viremia are warranted to confirm these data and to allow the definition of the optimal dose and duration of VGC pre-emptive therapy in allogeneic HSCT recipients.

VORICONAZOLE PROPHYLAXIS AMONG AUTOLOGOUS STEM CELL TRANSPLANT PATIENTS

T. Gastinne, S. Le Gouill, F. Gay-Andrieu, A. Clavert, C. Touzeau, V. Safar, J.-L. Harousseau, P. Moreau

University Hospital of Nantes, NANTES, France

Invasive fungal infections remain one of the leading causes of death among recipients of hematopoietic stem-cell transplants (SCT), especially in allogeneic SCT but also in autologous SCT. Because of a long period of building works in our hospital, we initiated, in July 2005, a systematic administration of oral voriconazole in patients receiving high dose chemotherapy and autologous SCT. We performed a retrospective observational study to describe the incidence of IA and other invasive fungal infection in autologous SCT. We report no cases of IA among 99 SCT recipients who received voriconazole prophylaxis compared with a 5% (5/95) incidence among those receiving no systemic antifungals for prophylaxis (p<0.05). Thus, voriconazole was effective in preventing IA during neutropenia of patients, who underwent autologous HSCT. Between July 2005 and June 2006, eighty-seven patients underwent ninety-nine autologous SCT at the Hematology department of the Nantes University Hospital. Patient characteristics are included in Table 1.

Table 1. Characteristics of patients receiving voriconazole prophylaxis versus no prophylaxis.

	No prophylaxis group (n=87)	Voriconazole group (n=87)
Single autologous SCT	79	75
Double autlogous SCT	8	12
Number of HSCT	95	99
Mean age	54	54
Sex M (%)	47 (54)	48 (55)
Reason for transplant, n (%)		
Non hodgkin Lymphoma	41 (47)	42 (48)
Hodgkin'sdisease	12 (14)	13 (15)
Multiple myeloma	32 (37)	32 (37)
Other	2 (2)	-
Line of treatment, n (%)		
First	75 (79)	83 (84)
Second	19 (20)	15 (15)
Third	1 (1)	1 (1)
Conditionning regimen, n (%)		
BEAM	55 (58)	51 (52)
Melphalan 100	6 (6)	1 (1)**
Melphalan 200	31 (33)	39 (39)
Melphalan 220	0	3 (3)
Mitoxantrone-cytarabine	2 (2)	4 (4)
Other	1 (1)	1 (1)
IA, n (%)	5 (5)	0**
Invasive Zygomycosis	0	0
Mortality due to fungal	1	0

** P < 0,05

Forty-two patients were treated for non-Hodgkin lymphoma (48%), and thirty-two (37%) for multiple myeloma. The majority of the autologous SCT were performed during first line treatments. BEAM (BCNU, Etoposide, Aracytine and Melphalan) and Melphalan (200 mg/m^2) were the most common conditioning regimen. Median duration of neutropenia was 8 days. Out of these 99 autologous SCT, no patient met the criteria for definite or probable IA. The cohort of patients receiving voriconazole prophylaxis was retrospectively compared with autologous SCT recipients receiving no antifungal prophylaxis. Between July 2004 and June 2005, 95 autologous HSCT were performed on 87 patients and no patient received antifungal prophylaxis. These two cohorts did not significantly differ in terms of demographic characteristics, disease, type of conditioning or of duration of the neutropenia. In this non-prophylaxis group, 5 patients (5%) met the criteria for probable IA. The difference in incidence of IA among these 87 patients compared with those receiving voriconazole prophylaxis (0 on 99 autologous SCT) was statistically significant (p<0.05). In both groups, we encountered neither zygomycoses, nor candidosis. One patient receiving no antifungal prophylaxis presented a fatal hemoptysis. However, mortality related to fungi did not show a statistical difference, with no death in the voriconazole group compared to one death in the non-prophylaxis group. Thus, voriconazole was safe and effective in preventing IA during neutropenia of patients, who underwent autologous HSCT. Voriconazole offers an alternative for selected patients and for a short period of time.

IS DOMESTIC TAP WATER A RISK FACTOR FOR INFECTIONS IN NEUTROPENIC PATIENTS?

H. von Baum, M. Bommer, A. Forke, J. Holz, P. Frenz, N. Wellinghausen

Ulm University Hospitals, ULM, Germany

Background. It has been questioned whether tap water from the domestic environment of neutropenic patients poses a risk for infections with waterborne pathogens like *Legionella spp., P.aeruginosa*, nontuberculous mycobacteria (NTM) or moulds, respectively. *Aims.* We therefore conducted a prospective study to assess i) the prevalence of these pathogens in the tap water of hemato-oncologic patients and ii) the risk for acquiring an infection with the aforementioned pathogens at home. *Material and Methods*. Cold and warm tap water samples were collected in the bathrooms of neutropenic patients, decontaminated (for NTM culture) and

cultured quantitatively on several specific media. Species identification was performed using standard microbiological methods including 16S rDNA sequencing or line hybridization assays for NTM. If the patients were re-admitted to the hospital all infectious episodes were analyzed with regard to the pathogens of interest. *Results*. 65 patients were included into the study. *P. aeruginosa* or *Legionella spp.* were cultivated from the tap water of 7 (11%) and 6 (9%) homes, respectively. Cultures for NTM were completed in 45 cases yet with mycobacteria present in 42 samples (93 %). Species included *M. chelonae, M. diernhoferi, M. fortuitum, M. fluoranthenivorans, M. frederiksbergense, M. gilvum, M. gordonae, M. hodleri, M. mucogenicum, M. scrofulaceum, and M. tusciae*. Moulds could be cultivated from the water of 36 households (55%), *Aspergillus spp.* (2) and *Mucor spp.*(3) were isolated only rarely. During the observation period infections due to *P. aeruginosa* were noted in 7 patients and one patient had a bloodstream infection with *M. chelonae*. Typing of the clinical and water mycobacterial isolate is underway. No legionellosis was diagnosed. Moulds were recovered from only two clinical samples. In the case of one patient, however, *Cladosporium spp.* was identified in his bronchial lavage as well as in his domestic water sample. *Conclusions*. Community drinking water contains several facultative pathogens which can pose a risk to immunocompromised patients. Our preliminary data suggest that a minority of patients develops infectious complications due to bacterial pathogens acquired from water sources at home.

0170

LOW MORTALITY OF INVASIVE FUNGAL INFECTIONS IN PATIENTS UNDERGOING INTENSIVE CHEMOTHERAPY FOR ACUTE LEUKAEMIA: EXPERIENCE FROM A SINGLE INSTITUTION NOT USING ROUTINE ANTIFUNGAL PROPHYLAXIS

F.H. Hitz, K. Boggian

Kantonsspital St.Gallen, ST.GALLEN, Switzerland

Background. Patients undergoing intensive chemotherapy for acute leukaemia (AL) are at high risk for invasive fungal infections. Proven and probable fungal infections in this patient population range between 8% - 15% and are lethal in approx. 30% of cases. Recent reports therefore emphasise the importance of prophylactic antifungal therapy for the prevention of lethal invasive fungal infections. However, antifungal prophylaxis may favour the emergence of resistant fungal strains. As an alternative close clinical monitoring of AL patients with the prompt introduction of antifungal therapy in case of clinically suspected fungal infection may be equally effective to control the mortality due to fungal infections in neutropenic AL patients. *Aims*. Retrospectively analyse the incidence and mortality of fungal infections in neutropenic AL patients undergoing intensive chemotherapy in the absence of prophylactic antifungal treatment, and to compare this to the published incidence and mortality observed in the presence of antifungal prophylaxis. *Methods.* We retrospectively analysed 326 neutropenic episodes from 126 consecutive patients treated for *de novo* or relapsed acute leukaemia (AL) between 2001 and 2007. Median age at diagnosis was 52 years (range: 18-75 years). All patients received intensive cytotoxic therapy. Autologous stem cell transplantation was performed in 5 patients; no patients receiving allogeneic transplantations were included. The mean duration of neutropenia observed was 17.6 days. Antifungal prophylactic treatment or routine laboratory screening tests (e.g. galactomannan test) were not used. Patients were examined daily for clinical signs of infection, and infectious diseases specialists were routinely involved into clinical decision making. Antifungal therapy was initiated in case of persisting neutropenic fever in the presence of broad spectrum antibiotic treatment, or when radiologic imaging results from febrile, neutropenic patients were suggestive of invasive fungal infection. Proven, probable and possible fungal infections were defined according to EORTC guidelines. *Results.* Possible fungal infection was diagnosed in 20/326 (6.1%) neutropenic episodes (6 possible candida infections of liver/spleen and 14 cases of possible pulmonary aspergillosis). Proven invasive fungal infections were diagnosed in 16/326 (4.9%) neutropenic episodes. Invasive candidiasis was diagnosed in 7 patients, invasive aspergillosis in 8 patients while a generalised mucor infection was identified in one patient. Importantly, none of the suspected or proven invasive fungal infections in neutropenic AL patients was lethal. *Summary and Conclusions.* We performed a single-institution, retrospective analysis of the incidence and mortality of invasive fungal infections in AL patients undergoing intensive chemotherapy without receiving prophylactic antifungal treatment. Employing this strategy we observed 11% proven or suspected invasive fungal infections, which is similar to the incidence reported for this patient population when antifungal prophylaxis is performed. However, we did not observe mortality in any of the 36 proven or suspected invasive fungal infections. Our results suggest that close interdisciplinary clinical monitoring of AL patients during chemotherapy-induced neutropenia may be an effective strategy for controlling the rate of fatal fungal infections.

0171

IS SERUM INTERLEUKIN-8 (IL-8) A USEFUL MARKER TO DISCRIMINATE LOW OR HIGH PROBABILITY OF INFECTION IN HOSPITALIZED PATIENTS WITH NEUTROPENIC FEVER?

Y.H. Tromp

University Medical Center, GRONINGEN, Netherlands

Background. Chemotherapy-induced neutropenic fever is frequently noticed in patients treated with intensive chemotherapy. However, only half of the patients demonstrate a clinically or microbiologically proven infection. Recently, it was shown that patients in the out patient clinic with neutropenic fever can be categorized in subgroups with a low or high probability of infection. The low-risk group was characterized by the absence of clinical and physical abnormalities and an IL-8 level <60 ng/l (*JCO 2005;20:7437*). *Aims*. To demonstrate whether IL-8 in conjunction with CRP is a relevant parameter to select hospitalized patients with chemotherapy-induced neutropenic fever with a low or high probability of bacterial infection. *Methods*. Hospitalized patients treated with high-dose chemotherapy and developing chemotherapy-induced neutropenic fever (neutrophiles $\leq 0.5\times10^9$/L, or leucocytes 1.0×10^9/L in combination with temperature >38.5°C) were enrolled after informed consent. Before starting with intravenous antibiotic treatment, all patients underwent physical and radiological examination, blood samples for IL-8 and CRP, and bacteriological cultures were taken. Treatment with antibiotics was continued until the 5th afebrile day and was adapted according to culture results. In case of persistent fever without a pathogen, antifungal medication was added. IL-8 and CRP monitoring was repeated at day 1, 3, 5 and 7. Primary end point was the predictive value of serum IL-8 level in conjunction with CRP for the presence of a clinically (CDI) or microbiologically (MDI) documented infection or fever of unknown origin (FUO). Secondary end point was the IL-8 level in relation to response to treatment. *Results*. 93 febrile episodes in 74 patients were evaluated. Based on clinical and microbiological examinations, 43% of the febrile episodes were categorized as MDI, 10% as CDI and 47% as FUO. Median IL-8 was lower in the FUO group compared to CDI/MDI (70 respectively 214 ng/L, $p<0.0005$), whereas median CRP levels were equal (105 mg/L *vs* 135 mg/L, $p=0.1$). In 25% of the febrile episodes the IL-8 level was <60 ng/L, predominantly in the FUO group (43%) compared to CDI/MDI (8%). In 3 of 4 patients with CDI/MDI and serum IL-8 <60 ng/l at the start, the IL-8 level increased ≥60 ng/l after 2-3 days of follow-up. FUO and CDI/MDI patients with a serum IL-8 ≥60 ng/l and responsive on i.v. antibiotic treatment showed after 3 days a rapid decline of IL-8 levels, i.e. 92% and 72% respectively. In non-responding patients however, median IL-8 level remained ≥60 ng/l at day 3, i.e. 95 ng/L in FUO (n=15), and 113 ng/L in CDI/MDI (n=36). *Conclusions*. These results demonstrate that the serum IL-8 level is a useful marker to identify hospitalized FUO patients with neutropenic fever with low probability of infection especially when follow-up samples are obtained. These findings might in future be translated to limit the period of antibiotic treatment in this subgroup of patients.

0172

MATERNAL HIV INFECTION AND ITS IMPACT ON CORD BLOOD CYTOKINES AND B CELL ONTOGENY

I.G.H. Lorand-Metze, E. Borges-Almeida, M.M.S. Vilela, H. Milanez, B.M. Abramczuk, K. Metze

State University of Campinas, CAMPINAS, Brazil

Background. The introduction of antiretroviral therapy (HAART) in HIV+ pregnant women drastically decreased vertical transmission of HIV to their offspring. However, immunological deficiencies have been found in newborns of HIV+ mothers, affecting their response to vaccines given in the neonatal period. *Aims*. We studied the B lymphocyte maturation in cord blood from newborns of HIV+ mothers using HAART and compared it with that of normal newborns. We also examined the lymphocyte subsets and cytokine profiles in the cord blood and compared it to the values found in their mothers at the 35. week of gestation. *Methods*. cord blood from newborns of 36 HIV+ mothers (9 were drug users and were analyzed separately) and 15 newborns of healthy mothers was examined. All mothers were invited to participate and gave informed consent. Lymphocytes were analyzed by flow cytometry using the com-

binations: CD45/CD34/CD19/CD22, cCD79a/cIgM/ CD19/CD10, sIgM/CD34/CD19/CD10, CD5/CD19/CD45 and CD8/ CD4/CD3. The BCG-and PHA-stimulated production of IL2, IL4, IL7, IL10, IL12, IFN-gamma and TNF-α from mothers and infants were quantified using ELISA. *Results*. delivery took place in week 39 (36-41) in normal mothers and in week 38 (36-40) in HIV+ mothers. Mothers' age was similar in all three groups. Only 13 mothers had a detectable viral load: mean 2.7 logs (1.73-5.6). Concerning cord blood lymphocyte subsets, the 3 groups differed in the percentage of $CD3/CD8^+$ cells (higher in the newborns of drug users) and that of $CD19/CD5^+$ cells (higher in the newborns of all HIV^+ mothers). Maturation of B-lymphocytes was similar in newborns of normal mothers and HIV+ ones not using drugs, but in the offspring of drug users, increased numbers of immature cells were seen. In a multiple regression, the number of CD19/CD5+ cells could be calculated by the formula: % B CD5+ = 21.8 x "group"- 0.18 "IL-7 (cord)"+ 0.28 "INF (cord)"+ 6.3 "TNF (cord)"- 10.6 "(smoking mother)". Concerning the cytokine profile, there was a good correlation between cord and mothers' serum level, except for TNF-alpha. In mothers with drug abuse, very low levels of IL-7 and high levels of TNF were observed. *Conclusions*. exposed newborns present alterations in T and B subsets as well as in cytokine profile in cord blood. This may be due to exposure in utero to HIV proteins, maternal cytokine transplacental transfer, as well as the use of HAART by the mother during pregnancy. In newborns of drug users this effect is enhanced despite effective HAART treatment. These changes may affect effectiveness of neonatal vaccination.

INCIDENCE OF HUMAN HERPES VIRUS TYPE 7 (HHV-7) INFECTIONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES WHOSE DISEASE COURSE IS ACCOMPANIED BY NEUTROPENIA

G. Lejniece,[1] D. Auzina,[1] A. Lejnieks,[1] S. Kozireva,[2] S. Chapenko,[2] M. Chistjakov,[2] Z. Nora,[2] M. Murovska[2]

[1]*The National center of Hematology, Riga East Hospital, Clinic Linezers, RIGA;* [2]*A. Kirchenstein Institute of Microbiology and Virology Riga Stradins University, RIGA, Latvia*

Background. Neutropenia is form of host-defence dysfunction that is closely related to an increased risk of infections including herpes virus infections. HHV-7 is ubiquitous lymphotropic herpes virus which infects cells of immune system including $CD4^+$ and $CD34^+$ cells and modulates their functions. Like other herpes viruses HHV-7 undergo latency and in immunocompromised individuals may become reactivated leading to severe complications including neutropenia and contribute further toward immunosuppression. The aim of this work was to evaluate the frequency of HHV-7 infection in patients with hematological malignancies whose disease course is accompanied by neutropenia and to determine the possible involvement of HHV-7 in development of this dysfunction. Materials and methods. 82 patients with neutropenia including 25 MDS, 19 ALL, 9 NHL, 14 MM patients and 15 patients with other hematological diseases were enrolled in this study. 45 apparently healthy donors were examined as a control group. The presence of latent/persistent and active HHV-7 infection was determined by detection of HHV-7 DNA in whole blood and cell-free plasma, respectively, using nested PCR. The plasma levels of TNF-alpha and IL-6 were determined in 12 patients with active infection, 22 - with latent/persistent infection, 30 without HHV-7 infection and 10 blood donors using quantitative ELISA. Results. Latent/persistent HHV-7 infection was observed in 46 (56.1%) of 82 patients as well as in 26 (57.7%) of 45 blood donors. Active HHV-7 infection was detected in 20/46 (43.5%) patients and in 1/26 (3.8%) blood donors. The frequency of active HHV-7 infection was significantly higher in patients with neutropenia compare to the blood donors (20/46 *vs* 1/26 p=0.00030). Five patients with active HHV-7 infection had febrile neutropenia and splenomegalia. The mean level of TNF-α in patients with active HHV-7 infection was higher (40.2 pg/mL) than those in patients with latent/persistent (25.8 pg/mL) and patients without HHV-7 infection (25.5 pg/mL) as well as in blood donors (7.9 pg/mL). The mean level of IL-6 in patients with active (16.5 pg/mL) and latent/persistent (10.7 pg/mL) HHV-7 infection was similar to this in patients without HHV-7 infection (19.2 pg/mL). *Conclusion*. The results showed that active HHV-7 infection is frequent event in patients with hematological malignancies whose disease course is accompanied by neutropenia and leads to increase of TNF-alpha level. In some cases active HHV-7 infection could be the cause of febrile symptom and splenomegalia. Taking into account that HHV-7 is able promote maturation of granulocyte lineage in infected CD34+ cells we suggest that it could be implicated in the pathogenesis of neutropenia in such patients.

0174

IN HIGH RISK ACUTE LEUKEMIA PATIENTS EARLY ANTIFUNGAL THERAPY AND DIAGNOSTIC PROCEDURES IMPROVE THE OUTCOME OF INVASIVE MOULD INFECTIONS

A. Nosari, M. Riva, A. Volonterio, M. Montillo, L. Marbello, A. Brizio, A. Molteni, C. Vanelli, C. Gabutti, G. Nador, E. Morra

Niguarda Cà Granda Hospital, MILAN, Italy

Background. Most guidelines recommend empirical antifungal therapy (EAT) for persistent febrile neutropenia, but this recommendation is now controversial. Risk for invasive mould infections (IMI) is particularly elevated in patients during induction or salvage phase of chemotherapy in acute leukaemia (AL) setting. In selected patients at high risk for IMI, EAT could continue to be the most effective and safer choice. *Aims.* To evaluate efficacy and safety of EAT in acute leukaemia patients. *Methods*. We reviewed the records of 137 consecutive acute leukaemia patients (108 acute myeloid leukemia, 20 acute lymphoblastic leukemia, 6 myelodysplastic syndromes, 3 blastic crisis of chronic myeloid leukemia) treated from January 2003 to January 2008 with empirical antifungal therapy during induction or salvage phase of chemotherapy and therefore considered at very high risk of IMI. Prophylaxis with itraconazole oral solution 5 mg/kg/day was performed to all patients, except those with acute lymphoblastic leukemia. At the beginning of EAT early diagnostic procedures with chest CT scan (within 48 hours) and galattomannan antigen test for the first three alternate days were performed. *Results*. Amphotericin B (AMB)-based frontline EAT was administered at fourth day of fever with negative cultures in 126 pts, voriconazole in 4 pts and caspofungin in the other 7 cases due to previous nephrotoxicity. We found 56 FUO (40.9%), and 81 fungal infections, 52 possible , 22 probable and 7 proven (4 aspergillosis, 3 zygomycoses, 1 fusariosis, with a comorbility of Aspergillus Niger and Mucor infection in one patient). Seventynine patients (62.7%) changed AMB-based frontline therapy due to: nephrotoxicity (41 pts, 32.5%), infusional reaction (26 pts, 20.6%), cutaneous reaction (2 pts), no response to antifungal therapy (5 pts, 4%). Improvement or cure were seen in the majority of patients. Only 2 of 81 patients died during antifungal therapy. Fungal attributable mortality of our population was 2.5%. At discharge the patients were treated, if necessary, with oral voriconazole 400 mg/day (50 pts) or posaconazole (3 pts: 2 aspergillosis, 1 zygomycosis) until the disappearance of fungal lesions. During aplasia of the following chemotherapy cycles secondary prophylaxis with oral voriconazole or AMB-based treatment was administered. Fifteen patients, 2 with residual pulmonary lesions, underwent bone marrow transplantation (4 autologous, 6 related allogeneic, 4 unrelated allogeneic, 1 aploidentical stem cell transplants) with liposomal amphotericin 3 mg/kg/day as secondary prophylaxis; one of the 2 pts with residual pulmonary lesions died due to Aspergillus terreus reactivation during neutropenic phase of allogeneic transplant. *Conclusions*. Compared with our previous study (*Nosari et al, Am J Hematol 2001;68:231*) performed between January 1989 and July 1999, an earlier antifungal therapy and diagnostic procedures reduced mortality (27% *vs* 2,5%) and improved the outcome of high risk acute leukemia patients. Our observations probably reflect a better management of these patients mainly due to the use of new antimycotics and more effective diagnostic and therapeutic approaches.

CHANGING EPIDEMIOLOGY OF INVASIVE FUNGAL INFECTIONS AMONG HAEMATOLOGICAL PATIENTS: RESULTS OF 46 MONTH SURVEILLANCE STUDY

C. Cattaneo, E. Borlenghi, F. Bracchi, M.A. Capucci, M. Micheletti, A.M. Pelizzari, A. Re, G. Rossi

Spedali Civili, BRESCIA, Italy

Background. Invasive fungal infections (IFI) can cause severe morbidity and mortality among haematological cancer patients. Acute leukaemia (AL), particularly myeloid, during first induction, is the major predisposing factor outside allogeneic transplant. Aims. To evaluate the recent evolution of IFI epidemiology among haematological non-allotransplant patients. Methods. From April '04 to January '08, 2360 admissions to our Institution were monitored and all febrile/infectious episodes were prospectively recorded. Haematological diagnoses were mainly AL/myelodysplastic syndrome (MDS), lymphoma/chronic lymphocytic leukemia (CLL) and myeloma (35.4%, 35.2% and 18.1% respectively). Patients with >7-days expected neutropenia received antifungal prophylaxis with itraconazole 400 mg/day p.o. and nebulized amphotericin-B. Infections were considered "microbiologically proven" (MPI) when

microrganisms were isolated from infection sites. IFI were defined as probable/proven according to EORTC/MSG criteria. Infections were correlated with haematological diagnosis, status of disease, neutropenia and central venous catheter (CVC). Results. Among 952 fever/infections recorded, 385 were MPIs. They were more frequent in AL/MDS (50.1% and 53% of cases, respectively), than in lymphoma/CLL (31.9% and 31.4%) or myeloma (14.7% and 14.5%)). There were 34 probable/proven IFI, i.e. 8.8% of MPI. Thirty-five fungal pathogens were isolated (1 mixed). Aspergillus spp was responsible for 22 (64,7%) cases (12 A. fumigatus, 2 A. niger, 1 A. terreus, 1 A. flavus, 6 A. not specified), Candida spp for 6 (17,6%) (2 C. parapsilosis, 1 C. giullermondii, 1 C. famata, 1 C. kefyr, 1 C. tropicalis), Mucor spp for 2, and Cryptococcus spp, P. boydii, P. jirovecii and Fusarium spp for 1 case each. IFI occurred more frequently in patients with lymphoma/CLL (2% of admissions) and myeloma (1.6%) than in AL/MDS, where only 10 cases were diagnosed (1.2%), only 4 of which during induction. IFI occurred more in refractory/relapsed patients (61.8% of cases), than at diagnosis (17.6%), during postchemotherapy aplasia in AL (11.8%), or in patients without evidence of disease (8.8%). In 68% of cases patients developed IFI while on corticosteroids, whereas neutropenia was present in 53% of cases, and was not a statistically significant risk factor for IFI in febrile patients (3.2% *vs* 4.1%). By univariate analysis a diagnosis of lymphoma/CLL and active underlying disease were significant risk factors among patients with MPIs, both for the presence of IFI (14% *vs* 6.4%, $p<0.05$; 12.6% *vs* 2.2%, $p<0.01$, respectively) and for aspergillosis (9.9% *vs* 3.8%, $p<0.05$; 8.1% *vs* 1.4%, $p<0.01$ respectively), whereas neutropenia turned out to be protective for IFI (11.3% *vs* 7.4%, $p<0.01$), as well as diagnosis of AL/MDS both for IFI and aspergillosis (4.9% *vs* 13.3%, $p<0.01$; 2.7% *vs* 8.5%, $p<0.05$, respectively). Candidemia was not associated with CVC. Conclusions. This surveillance study completely redefined the epidemiology of IFI and aspergillosis among haematological non-allotransplanted patients admitted at our Institution, showing that IFI and aspergillosis are currently developing predominantly in those with active haematological disease, particularly lymphoma/CLL in advanced stage, often without neutropenia and on corticosteroids, whereas they do not significantly impact on patients with AL, even during induction treatment. The role of the prophylactic measures adopted as well as of other unrecognized local factors needs to be further explored.

0176

SINGLE INSTITUTION RETROSPECTIVE ANALYSIS OF BRONCHOALVEOLAR LAVAGE AS ETIOLOGICAL DIAGNOSTIC TOOL FOR PULMONARY INFILTRATES IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

F. Onida, P. Usardi, C. Annaloro, M.L. Ranzi, G. Saporiti, C. Olivares, C. Boschetti, L. Rosso, A. Maraschini, M. Colombi, A. Grancini, A. Della Volpe, N.S. Fracchiolla, G. Lambertenghi Deliliers

Ospedale Maggiore Policlinico Mangiagalli e Regina Elena, University of Milan, MILANO, Italy

Background. Due to both disease- and therapy-related immunodeficiency, patients with hematological malignancies are at high risk to develop severe respiratory infections, which bear to high mortality rates. Identification of the etiological causes is of extreme usefulness for selection of the most effective treatment. *Aims*. With this study we aimed to retrospectively evaluate the etiological diagnostic value of fiberoptic bronchoscopy with bronchoalveolar lavage (BAL) in febrile patients with hematological malignancies and radiological evidence of pulmonary infiltrates. *Methods*. From January 2004 to December 2007, 56 bronchoscopies with BAL were performed in 52 patients in whom pulmonary infiltrates were unveiled by CT scan. Six patients were untreated, whereas all the others had received a previous chemotherapy-based treatment, including hematopoietic stem cell transplantation (HSCT) in 25 patients (12 allogeneic, 13 autologous). Underlying diseases were acute leukaemias in 27 patients (9 ALL, 18 AML), blastic phase of CML in 3 patients (2 Philadelphia-negative), lymphomas in 13 patients, and other malignancies in 9 patients. *Results*. Overall, a microbiological positivity was documented in 34 BAL samples (60%) obtained from 30 patients. Findings were classified as due to possible contamination in 7 cases (21%), even though only in 3 of these the same microorganisms were detected by the weekly nasal and oropharyngeal surveillance swabs. Eight samples (23%) were positive for Aspergillus fumigatus, whereas gram-negative bacterial pathogens were found in 5 samples (15%). Pneumocystis carinii was isolated in 9 samples (26%), while in 1 patient there was identification of Mycobacterium tuberculosis. CMV-DNA was detected in two cases, one positive also for *Aspergillus*. Among the 5 patients who underwent more than one BAL, dissimilar microbiological findings were detected in 4. Early termination of bronchoscopy was required in one patient who experienced acute respiratory distress requiring intubation. Antibiotic treatment was modified as a result of microbiological findings in 55% of patients, whereas among patients whose BAL was negative only 8 did not require empirical modification of the antibiotic scheme. As far as the outcome of pneumonia is concerned, death as a consequence of infection-related respiratory failure occurred in 3 out of the 30 patients who had positive BAL findings (10%), and in 4 out of the 22 patients (18%) with sterile BAL. *Conclusions*. In neutropenic patients fiberoptic bronchoscopy represent the most feasible etiological diagnostic tool, while other methods are dangerous and of difficult execution. Regarding BAL findings, we did not observe significant differences between patients who were previously subjected to HSCT and patients who were not. Also, no differences were noted between patients having a single localized pulmonary infiltrate and patients with multiple lesions or diffuse infiltrates. The identification of pathogens (Candida, Gram-positive bacteria) whose causative association with infectious pulmonary lesions is doubtful raise the question as to how to define criteria to establish their actual etiological role. In this setting, periodical surveillance by mucosal swabs may be viewed as an useful tool.

0177

ITRACONAZOLE *vs* AMPHOTERICIN B AS EMPIRICAL ANTIFUNGAL THERAPY FOR PERSISTENT FEVER IN NEUTROPENIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES : EVIDENCE FROM A META-ANALYSIS OF 618 PATIENTS

M. Yoshida

Teikyo University School of Medicine, KAWASAKI, Japan

Background. There is still no consensus on the efficacy of antifungal therapy for persistent neutropic fever with hematological malignancies. *Aims*. To compare the efficacy and overall tolerability of itraconazole with those of amphotericin B as empirical antifungal therapy for persistent neutropenic fever in patients with hematological malignancy. *Methods*. This study is a meta-analysis of patients with persistent neutropenic fever with hematological malignancy from three comparative clinical trials of itraconazole and amphotericin B. *Results*. In this study, 618 patients with hematological malignancy were included. Publication bias and statistically significant heterogeneity was not observed among the analyzed studies. Itraconazole was statistically significant in response rate compared with amphotericin B [odds ratio (OR) = 0.63, 95% confidence interval (CI): 0.46-0.87](Figure 1).

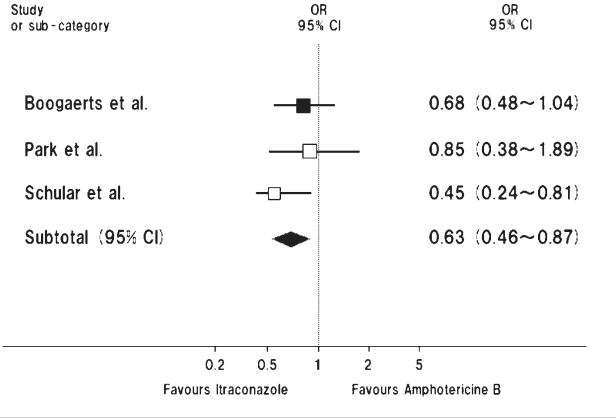

Figure 1. Result of the Meta-analysis: Response Rate.

Fewer patients were withdrawn due to the development of adverse effects associated with itraconazole when compared with amphotericin B [odds ratio (OR) = 0.30, 95% confidence interval (CI): 0.19-0.46]. Fewer patients were inferior in result of composite outcome score with itraconazole when compared with amphotericin B[odds ratio (OR) = 0.59, 95% confidence interval (CI): 0.42-0.84]. *Summary and Conclusions*. These data suggest that itraconazole is more effective than amphotericin B and also showed advantages regarding tolerability. This study confirm the role of itraconazole as useful and safe agent in empirical antifungal therapy of febrile neutropenic patients with hematological malignancy.

0178

NEUTROPHIL VOLUME DISTRIBUTION WIDTH: A NEW AUTOMATED HEMATOLOGIC PARAMETER FOR ACUTE INFECTION

A.E. Papakonstantinou,[1] A. Chondrothanasi,[2] E. Christodoulaki,[2] I. Grafakos,[2] A. Skourbouti,[2] A. Lavda,[2] P. Safioleas,[2] C. Manti[2]

[1]*Thriasion Hospital, ATHENS, Greece;* [2]*Thriassion Hospital, ELEUSINA, Greece*

Introduction. Review of peripheral blood smears can yield important diagnostic information through the identification of the morphologic changes characteristically seen in reactive neutrophils during infection. Such changes include the presence of toxic granulation, toxic vacuolization, and Döhle bodies in the cytoplasm. Younger forms (left shift), such as bands and metamyelocytes, also can be identified. This approach, however, is labor-intensive and time-consuming because it requires manual examination. Furthermore, the results are subjective because they depend on human interpretation, and only a few hundred cells can be analyzed for any given sample. The Coulter LH 750 hematology analyzer has a ability to measure specific parameters of neutrophil populations like mean and standard deviation (SD) of cell volume (MVI,SDVI), conductivity (MCI,SDCI), and light scatter (MSI, SDSI). These so-called positional parameters (PP) can detect morphologic changes in neutrophil population and can be an additional indicator for diagnosing acute infection. *Aims*. To investigate the value of the neutrophil SDVI, generated by VCS technology of the Coulter LH 750 hematology analyzer, as an additional predictor of acute infection. *Materials and Methods*. Total white blood cell count, percentage of neutrophils, and SDVI data from 64 patients with positive blood cultures for bacteria and from 54 age-matched healthy control subjects were prospectively analyzed. We then studied whether changes in SDVI correlated with patients' WBC counts (less or greater than 11000/μL)and neutrophil percentage (less or greater than 85%). The PP was obtained by the Coulter LH 750 hematology analyzer (Beckman Coulter, Fullerton, CA, USA). Comparisons between means were performed by analysis of variance. *Results*. A significant increase in the SDVI was observed in the bacteremic patients compared with the controls (26,8 *vs* 20, 63, $p<0,001$). Such increase was observed even in patients with white blood cell counts less than 11000/ μL) (25,4 *vs* 20,63, $p<0,001$) or with percentage of neutrophils less than 85% (25,8 *vs* 20,63, $p<0,001$). The more dramatic increases were seen in patients with leukocytosis (27,94 *vs* 20,63, $p<0,001$) or with neutrophilia (27,6 *vs* (27,6 *vs* 20,63, $p<0,001$).Tables 1 and 2.

Table 1.

	Control	Patients	P
Number	54	64	
SDVI mean	20.63	26,8	<0,001

Table 2.

	Control	Patients <11000	>11000	Neut perc <85%	>85%
Num	54	29	35	29	35
SDVI mean	20.63	25,4	27,94	25,8	27,6
P		<0.001	<0,001	<0.001	<0,001

Conclusions. The SDVI increases in acute infection 2) Using an SDVI cutoff of 23, as in bibliography, seems that SDVI is a good predictor of acute infection 3) The SDVI increase correlated significantly with leukocytosis and neutrophilia but was observed even in patients with white blood cell counts less than 11000/mL or with percentage of neutrophils less than 85%.4) As a quantitive parameter, the SDVI has potential for use as an additional indicator for diagnosing acute infection.

VORICONAZOLE AS SALVAGE THERAPY IN IMMUNOCOMPROMISED PATIENTS WITH PULMONARY ASPERGILLOSIS WHO RECEIVED FIRST LINEE ANTIFUNGAL THERAPY WITH CASPOFUNGIN

E. Simeone, A. Candoni, M. Chiozzotto, R. Fanin

Division of Hematology, UDINE, Italy

Introduction. The efficacy of voriconazole in the treatment of IFI (including CNS mycosis and rare mycosis) has been clearly demonstrated in large multicentric randomized trials. However, to date, limited preclinical and clinical studies are avaible about voriconazole salvage therapy after caspofungin.[1–3] *Patients and Methods*. Here we report the results of voriconazole salvage therapy in a small but omogeneous group of 14 hematologic patients (12 AML, 1 CML, 1 NHL) who had a proven (5) or probable (9) pulmonary Aspergillosis that received caspofungin as a first line therapy, without CR (6 PR, 1 SR, 7 NR). The loading dose of voriconazole was 6 mg/Kg intravenously or 400 mg b.i.d. orally, followed by maintenance therapy of 4 mg/kg intravenously or 200 mg b.i.d orally. *Results*. The median duration of voriconazole therapy was 37 days (range 14-68). Eight of 14 patients (57%) obtained a complete resolution (CR) of IFI and one, who was a non responder to CAS, obtained a SR. Table 1 reported the results of Voriconazole salvage therapy. No significant drug-related clinical adverse events were recorded. IFI-related death occurred in 3/14 cases (21%); IFI-unrelated death occurred in 2/14 (14%) patients, who died for complications related. *Conclusions*. voriconazole is an effective option as a salvage therapy for Aspergillosis with lung involvment (Complete Response rate 57%) after first line therapy with caspofungin. The tolerance was good without discontinuation of therapy due to advers events. However we have to underline that in our limited experience, the success of voriconazole salvage therapy was associated with neutrophils recovery in the majority (7/8) of responsive patients.

HOW COMPLEMENT AMPLIFICATION CAN BE STIMULATED AT THE ONSET OF A SYSTEMIC INFLAMMATORY RESPONSE IN SEPSIS

H.U. Lutz,[1] S. Fumiax,[1] J.S. Goede,[2] M. Fischler,[3] A. Luginbühl,[1] S. Frick,[4] P. Fodor[4]

[1]ETH Zurich, ZURICH; [2]University Hospital Zurich, Hematology Department, ZURICH; [3]University Hospital Zurich, Intensive Care Unit, ZURICH; [4]Stadtspital Zurich, Department of Internal Medicine, ZURICH, Switzerland

Background. The systemic inflammatory response syndrome (SIRS) in sepsis is triggered by excess C5a generation via the amplifying C3/C5 convertase, but it has remained unclear how complement amplification is stimulated. It is, however, known that neutrophils release elastase that becomes effective, despite the many plasma inhibitors, because small molecular weight elastase inhibitors ameliorate SIRS (Okayama *et al.* J Anesth. 2006;20:6-10). Elastase can cleave IgG to F(ab')2 (*Baici et al. Scand. J. Immunol. 1980;12:41-50*) and F(ab')2-containing immune complexes (F(ab')2-IC) of any specificity are known to stimulate complement amplification, but require an unknown plasma factor (*Reid. Immunology. 1971;20:649-658*). *Aims.* The aims were 1) to identify this plasma factor by *in vitro* experiments and 2) to investigate whether F(ab')2 fragments are generated in septic patients at the onset of SIRS and whether F(ab')2-IC play a role in complement amplification at the onset of SIRS. *Methods.* 1) We generated F(ab')2-IC from a naturally occurring antibody (NAb) to spectrin and spectrin dimer and studied their potency a) to form potent C3 convertase precursors (Jelezarova *et al.* J Biol. Chem. 2003;278:51806-1812) and b) to stimulate complement amplification by using radiolabelled C3 (Lutz *et al.* Blood 1996;88:184-193). 2) We gelfiltered plasma from controls and septic patients at the onset of SIRS and determined the total concentrations of F(ab')2 and of anti-hinge NAbs in three pools (enriched in immune complexes, IgG, or F(ab')2). On plasma of these patients we studied the concentration of released elastase and formation of factor Bb by using ELISA methods. *Results.* 1) We show that absorption of human plasma on F(ab')2 from human IgG prevented F(ab')2-IC from stimulating complement amplification and thus depleted the required plasma factor. The factor was purified from IVIG as those NAbs that bind to F(ab')2, but not to intact IgG. These *anti-hinge NAbs* restored complement amplification by F(ab')2-IC in absorbed plasma. Anti-hinge NAbs must have formed secondary immune complexes with F(ab')2-IC, in which the conformationally stabilized, shortened heavy chain captured dimeric C3b as shown by 2-D SDS PAGE with ester bond cleavage between the dimensions, implying generation of C3b2-F(ab')2-IC. Such complexes are as potent as C3b2-IgG complexes, which have a long half life and are 7-10 more effective C3 convertase precursors than immobilized C3b (*Lutz and Jelezarova. Mol Immunol. 2006;43:2-12*). This process may stimulate complement amplification at the onset of SIRS in humans. Indeed, plasma from nine septic patients at the onset of SIRS contained up to 3 µg/mL F(ab')2 fragments. The concentrations of F(ab')2 and of factor Bb correlated linearly with that of released elastase. Moreover, the F(ab')2 fragments migrated on Sephacryl S300 together with anti-hinge NAbs as ICs with MW of up to ~750kDa in all of the 9 patients studied. Conclusion: These findings provide for the first time a plausible mechanism of how complement amplification may be stimulated at the onset of a SIRS.

HBV MARKERS IN ACUTE LEUKAEMIA PATIENTS TREATED WITH MYELOSUPPRESSIVE CHEMOTHERAPY: A MONOCENTRIC EXPERIENCE

A. Ferrari,[1] M. Pacilli,[2] E. Conte,[3] E. Montefusco,[3] M.A. Aloe Spiriti,[2] C. Tatarelli,[3] R. Porrini,[3] M. Di Fonzo,[4] S. Angeletti,[4] M. Marignani,[4] B. Monarca[2]

[1]Un. La Sapienza II facoltà Az.Osp. Sant'Andrea, ROMA; [2]University La Sapienza II facoltà Az. Ospedaliera Sant'Andrea Hematology, ROMA; [3]University La Sapienza II facoltà Az. Ospedaliera Sant'Andrea Hematology, ROMA; [4]University La Sapienza II Facoltà Az. Osp. Sant'Andrea Gastroentherology Dep., ROMA, Italy

Background. Reactivation of hepatitis B virus (HBV) infection has been mainly described in patients with antibodies against HBV (anti-HBs and/or anti-HBc) undergoing chemotherapy or bone marrow transplantation for lymphoproliferative disorders. In these patients antibodies against HBV may be lost, and reappearance of markers of active viral replication (HBsAg, anti-HBcIgM, HBeAg and HBV-DNA) may occur. We describe our experience about HBV in patients treated for Acute Leukaemia (AL). *Aims and Methods*. From November 2003 to November 2007 were referred in our Hematology Unit 28 consecutive patients with AL, elegible for aggressive treatment (17 M, 11 F, median age 48 yrs, range 29-67, 18 AML, 10 ALL). At diagnosis, all patients were tested for HBV markers: of these, 13, diagnosed before 2005, were screened only for HbsAg, while the remaining 15, seen from 2005, were screened for the whole panel. All 28 patients underwent intensive chemotherapy +/- transplant procedures; follow-up for HBV serology were performed at least 6 - 12 months from diagnosis. *Results*. At diagnosis, among all patients,25 resulted negative for HBV serological pattern: of these, 9 died for progression disease within 6 months, while 16 mantained at follow up the negativity of HBV serological panel. Three out of 28 patients (10%) resulted positive for HBV screening at diagnosis with the following pattern: one was positive for HBcAb, HBeAb and HBsAb, another was positive for HBcAb and HBsAb, the last was positive only for HBcAb. During follow up of these 3 patients, the first one (ALL patient) started lamivudine prophylaxis before underwent cord blood transplant: he died because of transplant related event without showing HBV seroreversion. The other 2 patients showed an HBV seroreversion; both patients showed an HBsAg positivity and increase of serum HBV-DNA level, so that antiviral treatment with lamivudine was started. One patient (AML, in 1st CR from 9 months) experienced an acute flare hepatitis: in spite of lamivudine treatment he showed a progressive increase in bilirubine and liver enzymes; therapy with adefovir and steroids was added resulting an improvement of hepatic parameters. Three months later HBV-DNA level was < 200 copies/mL, with normal hepatic values. The other patient (AML in a dismielopoietic phase after autologous SCT) after three months of lamivudine had normal hepatic tests but a serum HBV-DNA level already > 200 copies/mL. *Conclusions*. Evaluation of complete HBV panel is important in patients treated with highly myelosuppressive chemotherapy because of the high mortality risk in HBV reactivation in acute leukaemia patients HBcAb positive and/or HBsAb positive. The question of antiviral prophylactic treatment remains still unresolved.

0182

HEPATITIS B VIRUS (HBV) REACTIVATION CAN OCCUR IN SPITE OF LAMIVUDINE PROPHYLAXIS IN HBV CARRIERS TREATED WITH CHEMOTHERAPY. AN ANALYSIS OF 17 CASES

M. Drera, A.M. Pelizzari, M. De Vecchi, A. Tucci, L. Bettini, M. Puoti, G. Rossi

Spedali Civili di Brescia, BRESCIA, Italy

Background. Prophylactic lamivudine has proven effective for preventing hepatitis B virus (HBV) reactivation during chemotherapy (CT). However HBV breakthrough viremia or hepatitis can still occur during prophylaxis or after its withdrawal, but its characteristics and outcome of such prophylaxis failures are largely unknown except for a few case reports. *Aims*. To analyse the characteristics and prognosis of a series of cases of HBV reactivation occurring during or after lamivudine prophylaxis in HBV onco-hematologic carriers. *Methods*. All cases of HBV reactivation observed from 8/1999 to 2/2008 in hematologic HBV-positive patients undergoing lamivudine prophylaxis at our Institution (100 mg/d from the start to 1-6 months after the end of CT) were retrieved. Viral breakthrough was defined as an at least one-log serum HBV-DNA copies increase, acute hepatitis as a sudden rise in serum ALT to >5x the UNL or >3x the baseline level. *Results*. Of 17 patients (pts) identified, 5 had HBV reactivation while on lamivudine prophylaxis for a median of 7 mos (range 3-10) (*breakthrough reactivation*). In 12 reactivation occurred 2,8 mos (range 1,5-3) after the end of lamivudine prophylaxis whose median duration had been 9,3 mos (range 3,5-17,5) (*late reactivation*). Median age was 60 ys (43-72); F/M was 0.54. Diagnoses included indolent NHL (6), CLL (5), aggressive NHL (3), AML (2) and myeloma (1). Antineoplastic treatment included high-dose CT with/without SCT (7), purine analogue-contaning CT (5), anthracyclin-based CT (2), chlorambucil (2). Monoclonal antibody (antiCD20/antiCD52) were used in 10 cases. At baseline all cases were anti-HBc-positive, 14/17 were HBsAg positive, 5/12 had detectable serum HBV-DNA and 3 had chronic hepatitis. HBV reactivation occurred as increase in HBV-DNA copies in the 5 pts with CLL, and as acute hepatitis in 12 cases, never as acute liver failure. YMMD mutation was found in 2/7 cases tested. *Breakthrough reactivation* during prophylaxis did not differ from *late reactivation*, except for a predominance of male sex (4/5) and of a diagnosis of indolent NHL/CLL (5/5). Reactivation was managed by continuing or resuming lamivudine (100 mg/d), with/without adefovir or tenofovir. Hepatitis resolved in 11/12 cases, one returned to chronic hepatitis. HBV-DNA decreased in all and normalized in 10/12 evaluable cases. After a median follow-up

of 21 mts (range 4-89) 15/17 pts are alive. Lamivudine has been stopped in 4 cases in remission after 8,5-18 mos and in 1 for inefficacy. It has been maintained in 10 cases, in 6 in combination with other antivirals. No liver-related death has occurred. Hematologic treatment could be continued with few modifications. Two pts have died of lymphoma but overall results do not differ from HBV-negative patients. *Conclusions*. HBV reactivation in spite of lamivudine prophylaxis is not rare. It appears mainly in pts with indolent NHL or CLL, a disease in which it seems to characteristically occur in the absence of significant hepatitis. Both *breakthrough* and *late reactivation* are generally mild and can be successfully managed in most cases by continuing or resuming lamivudine, alone or in combination. They do not seem to affect the overall prognosis of patients.

0183

EFFECTIVE SECONDARY ANTI-FUNGAL PROPHYLAXIS WITH VORICONAZOLE

L. Dignan, V. Grigoriadou, F. Maxwell, S. Evans, A. Riddell, B. Shaw, M. Ethell, J. Treleaven, G. Morgan, M. Potter

The Royal Marsden Hospital, SURREY, UK

Background. Systemic fungal infections (SFIs) are common in patients undergoing allogeneic transplant or intensive chemotherapy. There is also a high incidence of reactivation in those requiring further treatment. Voriconazole has proven efficacy against candida and aspergillus species, excellent oral bioavailability and compliance is generally good. A randomised controlled trial (RCT) has supported its use in treatment of SFI (Herbrecht R *et al.* NEJM 2002; 347: 408-15) but data in the prophylactic setting is limited. Small studies suggest that it may prevent fungal reactivation during further treatment in patients with leukaemia. (*Cordonnier C et al. BMT 2004;33: 943-8; Trifilo S et al. BMT 2007; 40(5)*:451-6). *Aims*. To assess whether voriconazole is an effective secondary antifungal agent in a larger group of patients with haematological malignancy. *Methods*. A retrospective chart review was undertaken to identify patients who had received voriconazole from Jan 2004 to June 2007. Patients were included if they had a possible, probable or proven SFI and went on to receive further treatment for haematological malignancy. All patients had their original CT scans independently assessed by a radiologist to confirm likelihood of fungal infection. CT changes were categorised as major e.g halos, air crest, cavitation or minor e.g. nodules. Patients who had normal CT scans or those with consolidation, effusions or ground glass changes only were excluded. Informed consent was undertaken as part of the consent to treatment of haematological malignancy. *Results*. Twenty-two patients received oral voriconazole 200mg bd during the study period (14 acute leukaemia, 4 lymphoma, 4 chronic leukaemia) . 20 patients had a previous diagnosis of possible fungal infection and 2 had proven infection according to European Organisation for Research and Treatment of Cancer criteria. 5 patients had major changes and 16 had minor changes on chest CT scan. 4 patients had complete remission of fungal infection at time of further treatment and 17 were in partial remission. 1 patient had candida in blood cultures but a normal CT. 5 patients underwent allogeneic BMT, 7 received steroid treatment (average 75mg of prednisolone) for graft versus host disease, 8 received chemotherapy for acute leukaemia or lymphoma and 2 received alemtuzumab and prednisolone for CLL. The average duration of treatment was 121 days (range 21-278). Patients generally tolerated voriconazole well. 3 patients developed deranged liver function tests, one had visual disturbance and one developed cerebellar signs. Voriconazole was stopped in 3 patients and an alternative anti-fungal agent used in 2 of these cases. Five patients received further IV anti-fungal treatment. 3 had worsening CT scan appearances and 2 were treated empirically. At 6 months following diagnosis of SFI, 2 patients had died. Causes of death were *E. Coli* septicaemia and myocardial infarction. *Summary/conclusion.* We report a retrospective review of patients receiving secondary antifungal prophylaxis with voriconazole which is, to the best of our knowledge, larger than that previously published. This review suggests voriconazole may be an effective secondary prophylactic agent in this high risk group. A RCT would be useful to further investigate this issue.

0184

THE ROLE OF BRONCHOALVEOLAR LAVAGE (BAL) IN EVALUATING NEW PULMONARY INFILTRATES ON COMPUTED TOMOGRAPHY IN HAEMATOLOGY PATIENTS WITH NEUTROPENIC FEVER UNRESPONSIVE TO BROAD-SPECTRUM ANTIBIOTICS

T. Todd, D. Enoch

Cambridge University Hospitals NHS Foundation Trust, CAMBRIDGE, UK

Background. Pulmonary complications are a significant cause of morbidity and mortality in immunocompromised haemato-oncology patients, with invasive fungal infection being one of the commonest. Chest computed tomography (CT) with bronchoalveolar lavage (BAL) for further investigation of new pulmonary changes identified on CT has emerged as a widely used approach in investigating patients with neutropenic fever unresponsive to broad-spectrum antibiotics. However, studies of BAL are conflicting with diagnostic yields of between 9 and 80%. Most studies suggest its role in diagnosing non-infectious aetiologies is limited. Complication rates are high in haematology patients (up to 15%) and recent studies have failed to demonstrate a beneficial impact on patient outcome of therapy changes made in response to BAL findings. The optimum role of BAL in the diagnostic pathway of this high risk population remains unclear. *Aims*. To establish the diagnostic yield, complication rate, therapeutic and outcome impact of BAL in neutropenic haematology patients with fever unresponsive to broad spectrum antibiotics and new pulmonary changes on CT. *Methods*. All haematology in-patients undergoing CT chest for antibiotic unresponsive neutropenic fever between September 2003 and December 2006 at our centre were retrospectively identified from a radiology database. The CT findings, microbiology, histopathology and admission records were reviewed. Specimen processing was audited against British Society for Medical Mycology (BSMM) guidelines. Death and admission length data were collected on all patients with new pulmonary changes on CT. Antigen tests were not available during the study period. *Results*. 191 patients (198 episodes) received chest CT scans, of which 68 had significant new radiological changes. All patients had received ≥3 daysof broad spectrum antibiotics (usually piperacillin-tazobactam, vancomycin and gentamicin in combination) and had commenced liposomal amphotericin B (n=66) or voriconazole (n=2). Median age was 33 years with equal sex distribution. The commonest underlying conditions were acute myeloid leukaemia (31), acute lymphoblastic leukaemia (12) and allogeneic stem cell transplant (10). 24 underwent BAL, three with transbronchial biopsy. Median time from CT to BAL was 7 days. In 4 cases no sample reached the laboratory, twenty had samples sent for microbiology, 12 for cytology and 3 for histology. Despite largely meeting BSMM standards (microbiology 95%, cytology 92% and histopathology 100%) no fungus was identified. Klebsiella, pseudomonas aeruginosa and herpes simplex virus were identified in 1 case each. The klebsiella and pseudomonas had also been grown on blood cultures and treatment was only altered for the herpesvirus. No non-infective diagnoses were established. Three patients had respiratory distress post BAL (none had had biopsy), one required ventilatory support. There was no significant difference in rate of death during admission or duration of admission between those who did or did not have BAL. *Summary/ Conclusion*. The diagnostic yield of BAL was low, there were life-threatening complications, the results infrequently changed treatment and patient outcome was not improved. A diagnostic strategy either excluding BAL or delaying it until antifungal therapy proves ineffective or newer fungal antigen detection techniques have proven negative may, for most of this patient group, be more appropriate.

Multiple myeloma - Biology

BISPHOSPHONATE RELATED OSTEONECROSIS OF THE JAW IS ASSOCIATED WITH POLYMORPHISMS OF THE CYTOCHROME P450 CYP2C8 IN MULTIPLE MYELOMA: A GENOME WIDE SINGLE NUCLEOTIDE POLYMORPHISM ANALYSIS

E. Sarasquete,[1] R. Garcia-Sanz,[1] L. Marin,[1] M. Alcoceba,[1] M.C. Chillon,[1] A. Balanzategui,[1] C. Santamaria,[1] J. Blade,[2] J. De la Rubia,[2] J. Petit,[2] M.T. Hernandez,[2] J. Lahuerta,[2] M. Gonzalez,[1] F. San Miguel[2]

[1]Hospital Universitario de Salamanca, SALAMANCA; [2]GRUPO ESPAÑOL DE MIELOMA GEM/PETHEMA. RED ESPAÑOLA DE MIELOMA (G03/136), SPAIN, Spain

Background. Bone destruction is probably the most representative hallmark of Multiple myeloma (MM). Bisphosphonates (BP) are the most widely used and effective antiresorptive agents for the treatment of disease associated with excessive osteoclast-mediated bone resorption. Recently, an increasing body of the literature has suggested the association between the use of bisphosphonates and the development of osteonecrosis of the jaws (ONJ). However, the reason why some patients develop ONJ (incidence between 2.4% to 12.8%) and why the majority do not remains unresolved. Several environmental factors have been related with a higher risk of ONJ developing, but no genetic variables have been describe to be associated with ONJ up to now. *Aims*. To asses the potential role of genetics in ONJ development. *Methods*. We performed a genome wide association study using 500.568 SNPs in two series of MM patients included in the same therapeutic protocol and which also received the same BP therapy: 22 cases (MM with ONJ) and 65 matched controls (MM without ONJ). Witten informed consent was obtained from all participants. *Results*. All patients included in this study were selected from the global population enrolled in the Spanish GEM-2000 protocol. Clinical and biological characteristics, response to treatment and survival rates were similar in both subsets of patients. For each SNP, we tested the allelic association with the ONJ presentation or not. The first analysis found four SNPs mapped within the cytochrome P450, subfamily 2C polypeptide 8 gene (CYP2C8) that could be associated with this complication (rs1934951, rs1934980, rs1341162 and rs17110453). The SNP rs1934951 (Intron 8) was significantly associated with ONJ (Overall P-value=1.07E-06? Pc, Bonferroni corrected P value =0.02). This SNP displayed an overrepresentation of the T allele in the group of cases (0.475 *vs* 0.125). Furthermore, the heterozygous genotype CT was present in 66% of the cases vs. 25% of the controls, whereas the homozygous genotype CC was more frequent in the control population, 75% vs, 19%. Even more, homozygote individuals for the T allele were exclusive of individuals with ONJ (14.3% vs. absence). On the other hand, rs1934980 and rs1341162 are allocated in the intron 5 whereas rs17110453 lies in the 5' near gene region. These SNPs showed a significant correlation with ONJ presentation ($p=4.23\times10^{-6}$, p=6.2210-6 and p=2.1510-6 respectively), although the association did not remain statistically significant after the Bonferroni correction (pc=0.09, pc=0.13 and pc=0.46 respectively). The calculated odds ratio of the risk conferred by the SNP rs1934951 assuming a dominant model of inheritance was 12.75 (95% confidence interval (CI) =3.7-43.5) associated with the presence of one or two T alleles. The odds ratios for rs1934980, rs1341162 and rs17110453 assuming the dominant model too, were as follows: 13.88 (95% CI =4.0-46.7), 13.27 (95% CI =3.5-49.9) and 10.2 (95% CI =3.2-32.1) respectively. *Conclusions*. Our data suggest that the rs1934951 polymorphism, as well as other SNPs in linkage disequilibrium with it, may play a role as a risk factor for developing ONJ in MM patients receiving BPs therapy. This data support genetic analyses in MM patients before starting the BP therapy.

ARRAY CGH HIGHLIGHTS GENETIC DIFFERENCES BETWEEN MGUS AND MYELOMA

L. Chiecchio,[1] G. Dagrada,[1] R.K.M. Protheroe,[1] D.M. Stockley,[1] G.J. Morgan,[2] N.C.P. Cross,[1] C.J. Harrison,[1] F.M. Ross[1]

[1]University of Southampton, SALISBURY, UK; [2]Institute of Cancer Research, SUTTON, UK

Multiple myeloma (MM) usually shows complex chromosome abnormalities, many of which are also seen in SMM and MGUS. In order to find potential changes mediating transformation from pre-malignant stages to MM, we analysed an initial set of 57 plasma cell dyscrasias on the Agilent 244k array comparative genomic hybridization (aCGH) platform. Interphase FISH (iFISH) was used to define different groups for aCGH analysis. The cohort comprised cases with t(4;14) (8 MM, 5 SMM, 2 MGUS); t(11;14) (1 PCL, 1SMM, 1 MGUS); t(14;16) (1 PCL, 7 MM, 5 SMM, 1 MGUS); t(14;20) (4 MGUS); hyperdiploid cases lacking immunoglobulin heavy chain rearrangements (IgHr) (1 PCL, 9 MM, 2 SMM, 7 MGUS); hypodiploid cases lacking IgHr (1 PCL, 1 MM). The iFISH results of patients at different stages of the disease were almost indistinguishable, while aCGH revealed marked differences in complexity. Surprisingly, the simplest profiles belonged to MGUS cases with t(14;20); all four of whom have been stable for at least four years. Among gained regions, 1q was more frequent in MM and PCL, 17/28 (61%) *vs* 10/28 (36%) in pre-malignant cases; three of the latter progressed to MM at 7, 33 and 44 months, while the other seven are still stable (median FU 41 mo). iFISH on 484 cases (376 MM, 41 SMM, 67 MGUS) confirmed the lower frequency in MGUS ($p=0.001$ *vs* MM) and significant associations with t(4;14) ($p<0.001$), deletion 13q ($p<0.001$) and t(14;20) ($p<0.007$). Two recurrent homozygous deletions (HD) involved members of the NF-kB pathway: TRAF3 (14q32.32; 3 cases) and BIRC2/BIRC3 (11q22.1; 2 cases). Other HD were 1p32.3 (CDKN2C & FAF1; 3 cases) and 9p21.3 (CDKN2A; 2 cases). Heterozygous deletions for the same loci were also detected. No HD were found in stable MGUS or SMM, although one SMM with TRAF3 HD progressed to active MM within a year. HD were also rare in hyperdiploid MM lacking IgHr. Multiple other NF-kB pathway genes are dysregulated in MM by loss or gain of function, leading to constitutive activation of the non-canonical pathway; among these only LTBR, on 12p13.31, was abnormal in our cohort (within one interstitial gain of 0.9Mb). iFISH in a further 237 patients (40 MGUS, 12 SMM, 185 MM) showed BIRC2/3 deletion in 9 (4.9%) MM cases with 6/9 (67%) HD, and TRAF3 deletion in 43 (20%) patients, including 6 MGUS and 3 SMM; all 6 HD were in MM cases. Both deletions were associated with deletion 13q (TRAF3 $p=0.0039$; BIRC2/3 $p=0.01$) and non-hyperdiploidy ($p=0.01$ for both). Occasional MM cases showed multiple gains and losses of discrete adjacent regions on a few chromosomes. Amplification was rare: one hyperdiploid case with no IgHr had amplified different regions of 8q including MYC and of 11q including CCND1. MYC amplification was also found in one PCL with t(11;14). It is clear that standard iFISH abnormalities are insufficient to predict progression of MGUS/SMM. This study suggests that different secondary genetic events contribute to this process and may preferentially occur in association with specific primary abnormalities.

0187

BASED ON DIFFERENTIAL EXPRESSION OF ANGIOGENIC GENES ALONE, BEING POLYCLONAL PLASMABLAST (PPC), BONE MARROW PLASMA CELL (BMPC) AND MULTIPLE MYELOMA CELL (MMC) CAN BE PREDICTED, BUT BEEING EARLY STAGE/ VS. THERAPY-REQUIRING MULTIPLE MYELOMA CAN NOT

D. Hose,[1] J. Moreaux,[2] T. Meiner,[3] J.-F. Rossi,[2] A. Benner,[4] K. Mahtouk,[2] A. Seckinger,[3] C. Hei,[4] M. Hundemer,[3] T. Rème,[2] J. Hillengass,[3] K. Herde,[5] U. Bertsch,[3] J. DeVos,[2] S. Wenisch,[5] V. Pantesco,[2] A. Jauch,[6] E. Jourdan,[2] H. Goldschmidt,[3] B. Klein,[2] T. Möhler[3]

Unfallchrurgie, Universitätsklinikum Giessen, GIESSEN, Germany; [6]Institut für Humangenetik, Universitätsklinikum Heidelberg, HEIDELBERG, Germany

Background. Angiogenesis is a hallmark of active multiple myeloma and a therapeutic target, e.g. by thalidomide. Others and we have shown this to be due to a differential and novo expression of

pro/antiangiogenic genes in MM as well as an effect of increased plasma cell number. *Aim* of this study was to investigate based on the expression of (anti)angiogenic genes alone (192 gene consensus list determined by medline search), i) whether for respective samples being PPC, BMPC or MMC can be predicted, ii) the expression differences between these entities, iii) if being early stage *vs* therapy requiring MMC can be predicted. *Patients and Methods*. 187 newly diagnosed MM/MGUS-patients (65 training (TG) / 122 independent validation group (VG)), 14 normal donors (ND) and 12 *in vitro* generates PPC samples were included. Bone marrow aspirates were CD138-purified by activated magnetic cell sorting. RNA was *in vitro* transcribed and hybridised to Affymetrix HG U133 A+B GeneChip (TG) and HG U133 2.0 plus arrays (VG). Expression data were gcrma-normalised and the empirical Bayes algorithm used. P-Values were adjusted using the Benjamini-Hochberg method (Bioconductor). The PANP-algorithm was used to identify expressed genes. iFISH was performed on purified MM-cells using probesets for chromosomes 1q21, 9q34, 11q23, 11q13, 13q14, 15q22, 17p13, 19q13, 22q11 and the translocations t(4;14) and t(11;14). Selected expression data were verified by real time RT-PCR and western blotting. *Results*. (i) On TG and VG, being BMPC or PPC is predicted by a 17 gene predictor (31 probe sets) without error. Being MMC is predicted with an error rate of 6.9/4.7 % with an overall-error rate of 5.8/4.3 % in TG/VG, respectively. (ii) 5 proangiogenic genes/7 probe sets (*HGF, ADM, CXCL2, IGF1, Met*) and 1 antiangiogenic/1 probe set (SerpinF1) are differentially expressed between these entities concordantly in TG and VG. Most patients with MGUS and MM display 1 or more over expressed angiogenic gene. (iii) Attribution of MMC to early *vs* therapy requiring MM can not be predicted. *Conclusion*. PPC, BMPC, and MMC differ in expression of (anti)angiogenic in a way that being either of the three can be predicted on the expression of these genes alone. To the contrary, the (rather small) expression differences between MMC of early-stage/therapy requiring MM-patients do not allow a prediction, giving evidence that angiogenesis related genes are activated early during disease progression. This can be taken as rationale for early intervention using antiangiogenic compounds.

BONE MICROENVIRONMENT CELLS REVEALS A DIFFERENT GENE EXPRESSION PROFYLING IN MULTIPLE MYELOMA PATIENTS AS COMPARED TO HEALTHY SUBJECTS: POTENTIAL RELATIONSHIP WITH THE BONE STATUS

K. Todoerti,[1] G. Lisignoli,[2] F. Morandi,[3] L. Agnelli,[1] S. Colla,[3] M. Crugnola,[3] C. Manferdini,[2] D. Verdelli,[1] K. Codeluppi,[2] G. Lambertenghi-Deliliers,[1] V. Rizzoli,[3] A. Neri,[1] N. Giuliani[3]

[1]*Università di Milano, Fondazione IRCCS Policlinico, MILANO;* [2]*Laboratorio di Immunologia e Genetica, Istituti Ortopedici Rizzoli, BOLOGNA;* [3]*Ematologia e Centro trapianti midollo osseo, Università di Parma, PARMA, Italy*

Background. Multiple myeloma (MM) is characterized by the high capacity to induce osteolytic bone lesions. Osteoblasts (OB) formation is impaired in MM patients mainly due to the block of the Runx2/Cbfa1 activity and consequently the suppression of the osteogenic differentiation of human mesenchymal cells (MSC)/osteoprogenitor cells. *Aims.* To find the gene expression alterations in the bone microenvironment cells and their potential relationships with the occurrence of bone lesions in multiple myeloma (MM) patients. *Methods*. MSC and OB cells were isolated, without *in vitro* differentiation, from bone biopsies obtained by iliac crest of 24 MM patients, 10 MGUS subjects and 8 healthy donors (N) who underwent orthopedics surgery. Bone status was determined by total X rays scan and MRI for the spine. Cell proliferation was evaluated in relationship with growth substrate (bone and glass) and cell phenotype by flow cytometry and immunohistochemistry. Gene expression profiling analysis of isolated MSC and OB cells was performed using GeneChip® Affymetrix HG-U133A arrays. Hierarchical agglomerative clustering and dendrogram generation were used to search for natural groupings in the profiles of the most variable genes across the whole panel using the dChip software. Supervised analysis was performed using the Significant Analysis of Microarrays software. *Results*. Both MSC and OB cells showed a higher cell doubling rate in MM patients as compared to N. Higher expression of alkaline phosphatase and *Runx2* was observed in OB as compared to MSC cells in both N and MM patients without osteolytic lesions, but not in osteolytic ones. An unsupervised analysis of the most variable genes across the dataset generated a hierarchical clustering with the two major branches distinguishing MSC and OB cellular types. A multi-class analysis of N, MGUS and MM patients identified 43 differentially expressed genes in MSC cells, mainly characterizing N *vs* MM and MGUS samples. A supervised analysis between N and MM samples identified 78 genes (57 up-regulated and 21 down-regulated) differentially expressed in MSC and 29 genes (16 up-regulated and 13 down-regulated) in OB. Notably, genes encoding the Homeobox class proteins, such as HOXB2-6-7, were up-regulated in both MSC and OB of MM patients as compared to N. As regards the bone status, a total of 36 up-regulated and 9 down-regulated genes were found differentially expressed in MSC from osteolytic *vs* non-osteolytic MM patients, whereas MGUS-MSC exhibited an intermediate transcriptional profile between osteolytic and non-osteolytic MM patients. A distinct pattern of gene expression profiling was also observed in MSC *vs* OB when osteolytic and non-osteolytic MM patients were compared (51 *vs* 20 differentially expressed genes, respectively). On the other hand, few genes were found differentially expressed in OB cells in relationship with the presence of bone lesions. CONCLUSIONS. A distinctive transcriptional fingerprint was identified in isolated MSC and OB cells of MM patients as compared to N subjects, which mainly correlated with cell proliferation. Moreover, a different gene expression profile was observed in MSC cells of MM patients according to the presence/absence of bone lesions, highlighting the critical role of the block of the osteogenic differentiation.

0189

THE TYROPHOSTIN ADAPHOSTIN (NSC680410) INHIBITS MULTIPLE MYELOMA BONE MARROW ANGIOGENESIS IN *IN VITRO* AND *IN VIVO*

K. Podar, J. Zhang, G. Tonon, M. Sattler, S. Vallet, M.S. Raab, D. Chauhan, K.C. Anderson

Dana-Farber Cancer Institute, BOSTON, USA

Background. Marked anti- proliferative activity of the tyrophostin adaphostin (NSC680410) was previously demonstrated in a variety of hematologic malignancies including chronic myelocytic leukemia (CML), chronic lymphocytic leukemia (CLL), acute myelocytic leukemia (AML), and Multiple Myeloma (MM). Specifically, in MM we identified a new mechanism by which drug- induced upregulation of c-Jun inhibits proliferation and induces apoptosis via caspase- triggered c-Abl cleavage. *Aims*. To demonstrate an antiangiogenic role for adaphostin in MM and to delineate molecular mechanisms mediating these effects. *Methods and Results*. Here we show that adaphostin (NSC680410), similar to bortezomib, additionally inhibits tumor angiogenesis within the MM bone marrow (BM) microenvironment. Specifically, adaphostin induces marked downregulation of total and nuclear c-Myc protein expression in MM cells followed by a significant Hif-1 decrease. Consequently, VEGF secretion is downregulated in a dose- and time-dependent manner. In contrast, neither specific knockdown of c-Abl expression nor exogenous overexpression of caspase- cleavage- induced c-Abl fragment abrogate adaphostin- induced c-Myc and Hif-1α downregulation. Taken together, these results indicate the existence of a c-Myc-/ Hif-1α- dependent, but c-Abl- independent, pathway modulating MM cell production and secretion of VEGF. Our data further demonstrate activity of adaphostin within the BM microenvironment. Specifically, adaphostin inhibits maturation of osteoclasts and, similar to bortezomib, VEGF secretion triggered by adhesion of MM cells to BMSCs and mature osteoclasts. Consequently, conditioned media derived from adaphostin-treated co-cultures markedly inhibit endothelial cell growth and tubule formation in a dose- dependent manner. In addition, adaphostin inhibits MM cell adhesion to extracellular matrix proteins vitronectin, fibronectin, and osteopontin. Functionally, these effects are predominantly mediated via adaphostin- induced downregulation of β3- integrin protein and activity and disturbance of lipid rafts within the plasma cell membrane as evidenced both by use of β3- integrin neutralizing antibodies and deletion of caveolin-1 by antisense methodology. Furthermore, we also demonstrate a direct anti- angiogenic effect of adaphostin induced by inhibition of endothelial cell proliferation, and the induction of cell apoptosis. Finally, these *in vitro* data were confirmed using an *in vivo* xenograft mouse model of human MM. Specifically, marked tumor growth inhibition was accompanied by both downregulation of Hif-1α and CD31 expression in tumors isolated from adaphostin- treated animals *vs* control animals as evidenced by western blot analysis, as well as immunohistochemistry. *Summary/conclusions*. In summary, these data identify new molecular mechanisms leading to VEGF production and secretion in the MM bone marrow microenvironment and provide the rationale for the clinical evaluation of adaphostin to target both MM cells and the BM milieu to improve patient outcome in Multiple Myeloma.

0190

EARLY CONSOLIDATION WITH BORTEZOMIB, THALIDOMIDE AND DEXAMETHASONE IN MM PATIENTS IN CR OR VGPR FOLLOWING AUTOLOGOUS TRANSPLANTATION INDUCES MOLECULAR REMISSIONS

A. Palumbo,[1] F. Cavallo,[1] G. Pagliano,[1] S. Ferrero,[1] L. Santo,[1] V. Magarotto,[1] P. Pregno,[2] M. Grasso,[2] A.M. Liberati,[2] T. Caravita,[2] F. Pisani,[2] T. Guglielmelli,[2] C. Crippa,[2] L. De Rosa,[2] D. Drandi,[1] M. Boccadoro,[1] M. Ladetto[1]

[1]A.O.U. San Giovanni Battista, TORINO, Italy; [2]Italian Multiple Myeloma Network, GIMEMA, ITALY, Italy

Background. Autologous transplantation (ASCT) is unable to induce molecular remission (MR) in MM as opposed to allogeneic transplantation. The achievement of MR is an important requisite for long-term disease control. It is unknown whether the use of new non-chemotherapeutic agents following ASCT might ensure further cytoreduction allowing patients to enter this status which seems associated with a reduced risk of relapse. *Aims*. In this study an early consolidation regimen including Bortezomib, Thalidomide and Dexamethsone (VTD) was employed in patients achieving CR or VGPR in the post-ASCT setting and strict molecular monitoring was performed by qualitative and quantitative PCR to evaluate if VTD may induce further cytoreduction and to verify if a proportion of those patients could enter MR. *Methods.* Patients were eligible if they had the following: 1) presence of a molecular marker based on the IgH rearrangment; 2) a documented complete or very good partial remission (CR or VGPR) following ASCT. The VTD had to be started within 6 months from ASCT for a total of 4 cycles. Each cycle consisted of: a) Bortezomib at the dose of 1.6 mg/m^2 as an IV injection once weekly (on days 1, 8, 15, 22) followed by a 13-day rest period (days 23-35); b) Thalidomide at the initial dose of 50 mg/day PO once daily, with increments of 50 mg every 7 days to acceptable tolerance (maximum 200 mg); c) Dexamethasone 20 mg/day PO once daily, on days 1 to 4, 8 to 11 and 15 to 18 followed by a 17-day rest period (days 19-35). Minimal residual disease (MRD) was evaluated on bone marrow samples at study entry, after 2 courses of treatment, at the end of treatment and then at six months intervals. MRD was evaluated using clone-specific primers by nested PCR and real time PCR. *Results.* 40 patients were enrolled and were valuable at study entry: 94% of them were PCR-positive following ASCT. 18% of patients did not receive the whole planned treatment, including one toxic death. 12 patients improved their responses from ASCT: 9 patients (36%) from VGPR to CR, 3 patients (12%) from nearCR to CR. 17% of patients converted to PCR negativity after 2 VTD courses and 27 patients are valuable at the end of the program with a PCR-negativity rate of 22%. Subsequent follow-up samples are available in 22 patients. MR persisted in all PCR-negative patients assessed at 6 months (four cases) and at 6 and 12 months (two cases). Seven relapses/progressions occurred and were all among PCR-positive patients. Real-time PCR has been performed in ten persistently PCR-positive patients with a >0.5 log tumor reduction in eight of them (median 1.2 log; range 0.2-2.1). *Conclusions*. VTD consolidation can convert a proportion of CR/VGPR MM patients from PCR-positivity to PCR-negativity and has a measurable anti-tumor effect also in persistently PCR-positive patients. In this study we demonstrate that new non chemotherapeutic agents have activity on MRD persisting following ASCT and indicate that MR is an achievable goal also outside the allogeneic transplantation setting.

0191

DISTINCT PATHOGENIC SUBGROUPS IN MULTIPLE MYELOMA DEFINED BY QUANTITATIVE GENE EXPRESSION, GENOMIC ABERRATIONS, AND VDJ GENE STRUCTURE

D. Kienle,[1] P. Liebisch,[1] C. Vatter,[1] E. Wiedenmann,[1] A. Brodbeck,[1] P. Lichter,[2] H. Döhner,[1] S. Stilgenbauer[1]

[1]University of Ulm, ULM; [2]German Cancer Research Center, HEIDELBERG, Germany

Background. Clinical course of multiple myeloma (MM) is highly variable. Recurrent chromosomal aberrations such as translocations, deletions or chromosomal extra copies may lead to a dysregulation of critical genes (e.g. affecting *CCND1, CCND3, FGFR3, MAF, TP53*) resulting in plasma cell immortalization. Some of these chromosomal abnormalities were associated with poor prognosis such as translocation t(4;14) and deletion 17p13, however, the mechanisms mediating the aggressive clinical course are poorly understood. Additionally, a restricted usage of specific VH genes has been reported implicating a role for specific B-cell receptor rearrangements in MM biology. *Aims*. To identify potential pathomechanisms and disease subgroups in MM patients based on the analysis of interrelations between genomic abnormalities, quantitative expression of genes involved in critical genomic regions and MM pathogenesis, and VDJ configuration. *Methods*. Purification of plasma cells of 117 patients to a median percentage of 85% was reached using immunomagnetic separation. FISH screening for the detection of genomic abnormalities at 1q21.2, 9q34, 11q25, 13q14, 17p13, and 14q32, as well as t(4;14), and t(11;14) was performed in all cases. Transcripts of the following candidate genes were quantified using real-time RT-PCR: *CCND1* (coding region and 3`UTR), *CCND2, CCND3, FGFR3, MAF, MMSET, MUM1, TACC, RB1, p16, E2F1, p27, p21, CDK4, TP53, ATM, MDM2, MCL-1, BCL-XL, BCL-2, c-MYC, BTBD3, ITGB7, CX3CR1, TYMS, FNTA, EIF3S12, and CXCL12*. VDJ configuration was analyzed in 100 cases by direct sequencing. *Results*. Major genomic subgroups could be defined by 1) t(4;14) (20% of all cases), or 2) t(11;14) (25%), or 3) no abnormality at 14q32 (14q32normal; 39%). In 16% of the cases the translocation partner remained unknown. Compared to 14q32normal cases, the t(4;14) subgroup showed a characteristic overexpression of *FGFR3* and *MMSET* (critical genomic region) but also of *CCND2* and CDK4. In addition to a high-level overexpression of *CCND1*, the t(11;14) subgroup was characterized by a significant overexpression of *CCND3* and BCL2, and a downregulation of *BTBD3*. Upregulation of *CCND1* was observed in approx. 50% of 14q32normal cases when compared with t(4;14) cases (median expression 80 *vs* 0.4) but was lower than in t(11;14) cases (median 915). No gene-dosage deregulation of RB1, TP53 or MCL1 transcript levels could be detected in cases harboring a genomic alteration at the respective locus (13q14, 17p13, 1q21). Most MM exhibited heavily mutated VH genes, (median VH homology 92.7%). The t(4;14) subgroup showed a significantly lower VH homology compared to the t(11;14) and the 14q32normal subgroup (median 89.2%, 93.2%, and 92.9%). VH gene usage was balanced between the genomic subgroups except for V3-21, which was exclusively observed in cases with t(4;14). *Conclusions*. Genomic subgroups defined by t(4;14), t(11;14), and 14q32normal were associated with highly characteristic gene expression patterns pointing to distinct biologic subgroups, which is supported by the non-random distribution of VH mutations and VH gene usage. Aberrant expression of candidate genes from critical genomic regions was associated with a deregulation of cell cycle and apoptosis regulators pointing to underlying pathomechanisms. To elucidate the clinical impact of these findings, clinical data will be supplemented and correlated with the molecular features.

EFFECT OF LENALIDOMIDE-BASED REGIMENS ON BONE REMODELING IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

E. Terpos,[1] D. Christoulas,[2] E. Kastritis,[2] E. Katodritou,[3] M.C. Kyrtsonis,[4] X. Papanikolaou,[4] D. Maltezas,[4] N. Stavropoulos,[4] K. Tsionos,[4] P. Repousis,[4] G.A. Pangalis,[4] K. Zervas,[3] O. Sezer,[5] M.A. Dimopoulos[2]

[1]251 General Air Force Hospital, ATHENS, Greece; [2]Department of Clinical Therapeutics, University of Athens Medical School, ATHENS, Greece; [3]Department of Hematology, „Theagenion Cancer Center, THESSALONIKI, Greece; [4]Greek Myeloma Study Group, GREEK SOCIETY OF HEMATOLOGY, Greece; [5]Department of Hematology and Oncology, Charité - Universitaetsmedizin Berlin, BERLIN, Germany

Background/Aims. Lenalidomide plus dexamethasone is very effective for the management of refractory/relapsed multiple myeloma (MM). However, there is very little information for its effect on myeloma bone disease. The aim of this study was to evaluate the effect of lenalidomide-based regimens on bone remodeling in relapsed/refractory MM. *Patients/Methods*. We evaluated 71 patients (44M/27F; median age 67 years) with refractory/relapsed MM: 58 received lenalidomide at the standard dose of 25 mg/day x 21d, every 28 days, with either high (n=38) or low (n=20) dose dexamethasone (RD), while 13 patients received the combination of lenalidomide (15 mg/day x 14d), low dose dexamethasone plus bortezomib (1 mg/m^2, on days 1,4,8,11 every 21 days; BDR). All but one patient were under zoledronic acid therapy; this patient had developed ONJ and refused to re-start bisphosphonate. The following serum indices were measured on cycle 1/day 1, and then on the last day of cycles 3, 6, and 9: (i) osteoblast inhibitor dickkopf-1 (Dkk-1); (ii) osteoclast regulators: *sRANKL* and osteoprotegerin (OPG); (iii) bone resorption markers: CTX and TRACP-5b; and (iv) bone formation markers: bone-specific alkaline phosphatase (bALP) and osteocalcin. These markers were also evaluated in 35 healthy controls of similar gender and age.

Results. At baseline, 21 patients had no lytic lesions (group A), while 11 had 1-3 lytic lesions (group B) and 39 had >3 lytic lesions and/or a pathological fracture (group C) in skeletal survey. Patients at baseline had increased levels of Dkk-1, sRANKL, and bone resorption markers (p<0.01) and reduced levels of osteocalcin (p<0.01) compared to controls. Group C patients had increased sRANKL/OPG, CTX, TRACP-5b, Dkk-1 and reduced OC compared with all others (p<0.02 for all comparisons). To-date, 50 patients have completed 3 cycles of therapy (38 RD and 12 BDR), while 26 have completed 6 cycles (19 RD and 7 BDR) and 12 (10 RD and 2 BDR) 9 cycles of therapy. The objective response was 58% in RD (34/58 patients) and 53% (7/13) in BDR. The administration of lenalidomide-based regimens produced a reduction of sRANKL and sRANKL/OPG ratio after 6 cycles of therapy (p=0.02) that continued after 9 cycles. Furthermore, a reduction of Dkk-1, which was started after 3 cycles (p=0.01) and continued after 6 and 9 cycles of therapy was accompanied by an increase in bALP during the same period (p<0.01). The reduction of Dkk-1 and the increase of bALP was higher in BDR than in RD (p=0.03 and 0.006, respectively). Moreover, BDR patients showed also a dramatic increase of osteocalcin after the 3rd cycle (p<0.001). During study period the patient who did not receive bisphosphonate had a pathological fracture during the 5th RD cycle. No other SREs were observed. *Summary and Conclusions*. Lenalidomide-based regimens affect bone metabolism through the reduction of sRANKL/OPG and Dkk-1 levels. BDR may have a stronger beneficial effect on bone formation than RD, reflecting the bone anabolic effect of bortezomib and/or the lower dose of dexamethasone used in these patients. Further studies are needed to exact final conclusions for the effect of lenalidomide on bone metabolism in relapsed/refractory MM.

0193

GENE EXPRESSION PROFILES FOR MOLECULAR CLASSIFICATION OF MUTLIPLE MYELOMA

A. Broyl,[1] D. Hose,[2] Y. Knegt, de,[3] H. Lokhorst,[4] H. Goldschmidt,[4] M. Duin, van,[1] P. Sonneveld[1]

[1]Erasmusmc, ROTTERDAM, Netherlands; [2]University of Heidelberg, HEIDELBERG, Germany; 3Erasmus University Medical Center, ROTTERDAM, Netherlands:[4]Utrecht University Medical Center, UTRECHT, Netherlands

Background. Multiple Myeloma (MM) is a malignant plasma cell disorder, characterized by presence of a monoclonal protein, immunodeficiency, anemia, renal failure and bone lesions. In newly diagnosed patients the median response rates vary from 50% with Melphalan/Prednisone to 80% with high-dose therapy (HDT). New agents like Bortezomib (Bor), a proteasome inhibitor, and Thalidomide (Thal), an antiangiogenic and immunomodulatory drug, have shown efficacy in 40% of patients with relapsed/ refractory MM and are now studied in first-line treatment. Classical prognostic classifications like serum beta2-microglobulin, albumin and chromosomal aberrations have insufficient predictive power to estimate long term outcome with these targeted agents. We have set out to design a prognostic index based on molecular and disease related markers of MM. *Aims. We* have included 800 patients with MM in a large multicenter, prospective phase III trial to evaluate the effect of targeted therapy with HDT. In order to gain new insights in the pathogenesis of MM to design a prognostic index based on molecular profiling, gene expression profiles (GEP) were assessed in purified myeloma cells obtained at diagnosis. Hierarchical clustering was performed to define subgroups of patients with unique pathogenetic events. *Methods*. GEP of 204 CD138 magnetic cell selected (MACS) myeloma plasma cells with a PC purity >80% was performed using Affymetrix GeneChip U133 plus 2.0 arrays. Analysis of the gene arrays included hierarchical clustering to subdivide groups of myeloma patients and identification of differentially expressed genes in the different groups using BRB-array tools, which we verified using RT-PCR. All patients were treated according to trial protocol with Bor in combination with Adriamycin, Dex (PAD, (arm A) followed by HDT or with Vincristine, Adriamycin and Dex (VAD, arm B) followed by HDT (HOVON65/GMMG-HD4). *Results*. Based on correlated GEPs and 3 known translocations involving the immunoglobulin heavy chain region at 14q32, we subdivided myeloma patients into clusters. We determined differentially expressed genes in the different clusters and correlated the clusters with chromosomal aberrations like 13q loss, 1q loss, gain of 9, 11 and 15 and with relevant clinical data like bone lesions. We describe the clusters showing distinct gene expression signatures in combination with specific chromosomal aberrations and clinical characteristics. *Summary/ Conclusions*. Hierarchical cluster analysis in combination with 3 known translocations involving the immunoglobulin heavy chain region at 14q32 led to the subdivision of myeloma patients into clusters, each with a specific molecular signature, and/or unique chromosomal patterns. The response and survival data of the molecular subgroups have been partly identified and will be further analyzed.

A CELLULAR PROTEOME MAP OF HUMAN MULTIPLE MYELOMA

W. Drach,[1] A. Slany,[2] V. Sagaster,[3] N. Gundacker,[2] V. Haudek,[2] H. Wimmer,[2] C. Zielinski,[3] C. Gerner[2]

[1]Medical University of Vienna, VIENNA; [2]Medical University of Vienna, Institute for Cancer Research, VIENNA; [3]Medical University of Vienna, Dept. of Medicine I, VIENNA, Austria

Background and Aims. Molecular profiling identifies proteins characteristically deregulated in malignant diseases. Characteristic biomarkers may be useful to support diagnosis and patient stratification, while the recognition of aberrant cell activities and cell survival strategies may lead to the development of specifically designed pharmacologic strategies. We therefore performed proteomic profiling of primary human multiple myeloma (MM) cells in order to define the impact of protein expression abnormalities in MM. *Methods*. Plasma cells were isolated from bone marrow of patients with MM or MGUS and forwarded to proteome analysis based on 2D gel electrophoresis in addition to shotgun analysis by nano-LC-MS/MS. Erythrocytes, platelets and plasma as well as quiescent and activated lymphocytes, monocytes, endothelial and dendritic cells from healthy donors were processed in an identical manner for comparative analysis. The resulting data were interpreted with the aid of a home-made SQL database. *Results*. Among about thousand proteins identified in MM cells, we found aberrant expression of proteins involved in fatty acid beta-oxidation (VLCAD), unfolded protein response/ER-stress (ARMET protein, cytosol aminopeptidase), oxidative stress (ste20/oxidant stress responsive kinase 1), interferon response (MX1), iron uptake (transferrin receptor/CD71), DNA modification (transforming protein ERG, methyltransferase-like protein 7A), apoptosis and survival (apoptosis-inducing factor 1, hsp75), protein synthesis (ribosome-binding protein, Unc-13 D), cell adhesion (CD9/tetraspanin-29, LYRIC/metastatic adhesion protein), signaling (sts-1) and cell-cell interaction (Cystatin F, basigin/collagenase stimulatory factor, stem cell growth factor, small inducible cytokine B7, PD-ECGF/Gliostatin). *Conclusion*. The presently applied proteome analysis strategy, based on the systematic investigation of purified primary human cells, allowed us to find characteristic alterations in MM cells. Several proteins directly relate to known aberrant cell activities such as elevated protein synthesis and secretion resulting in ER-stress, which makes the cells sensitive to proteasome inhibitor treatment. Work is in progress to use quantitative assessment of such proteins for patient stratification, identification of response predictors, and biomarkers for the distinction of MM and MGUS.

SERUM ANGIOPOIETIN-1 TO ANGIOPOIETIN-2 RATIO IS AN INDEPENDENT PROGNOSTIC FACTOR FOR SURVIVAL IN NEWLY DIAGNOSED PATIENTS WITH MULTIPLE MYELOMA: RESULTS FROM THE GREEK MYELOMA STUDY GROUP ON 174 PATIENTS

E. Terpos,[1] K. Anargyrou,[1] E. Katodritou,[2] E. Kastritis,[3] A. Pouli,[4] E. Michali,[5] S. Delimpasi,[6] E. Verrou,[2] D. Margaritis,[7] K. Tsionos,[1] K. Stefanoudaki,[8] K. Zervas,[2] M.A. Dimopoulos[3]

[1]251 General Air Force Hospital, ATHENS; [2]Department of Hematology, „Theagenion„ Cancer Center, THESSALONIKI; [3]Department of Clinical Therapeutics, University of Athens Medical School, ATHENS; [4]Department of Hematology, St Savvas Anticancer Hospital, ATHENS; [5]Department of Hematology, G. Gennimatas„ General Hospital, ATHENS; [6]Department of Hematology, Evangelismos General Hospital, ATHENS; [7]Department of Hematology, Democritus University of Thrace School of Medicine, ALEXANDROUPOLIS; [8]Department of Hematology, A. Fleming General Hospital, ATHENS, Greece

Background and Aims. Angiogenesis represents an essential step of disease progression in several hematological malignancies, including multiple myeloma (MM). Angiopoietin-1 (Ang-1) and its natural antagonist angiopoietin-2 (Ang-2), both ligands for the receptor tyrosine kinase Tie-2, are essential cytokines for angiogenesis process. Maturation and stabilization of the vascular wall are critically regulated by Ang-1 binding to Tie-2 receptor, while Ang2- antagonizes Tie-2 binding and induces vessel destabilization, which leads to the angiogenic sprouting. Vascular endothelial growth factor (VEGF), angiogenin and basic fibroblast growth factor (bFGF) are also potent stimulators of both physiological

and pathological angiogenesis. The aim of this study was to evaluate the serum levels of the above angiogenesis cytokines and explore possible correlations with clinical data, including survival, in newly diagnosed, untreated, MM patients. *Patients and Methods*. One hundred and seventy-four newly-diagnosed MM patients were evaluated (92M/82F; median age: 66 years, range: 40-94 years). According to ISS, 55 patients had stage 1, 61 stage 2 and 58 stage 3 myeloma. Serum levels of Ang-1, Ang-2, VEGF, VEGF-A (the major angiogenesis component of VEGF), angiogenin, and bFGF were evaluated using ELISA methodology (R&D Systems, Minneapolis, MN, USA, for all, except VEGF-A: Diaclone, Bensancon, France). *Results*. MM patients had increased serum levels of Ang-2 ($p<0.0001$) and angiogenin ($p<0.0001$), and a borderline increase of VEGF-A ($p=0.08$) compared with 21 controls of similar age and gender. Ang-1 levels were not different between patients and controls; thus the ratio of Ang-1/Ang-2 was reduced in MM. Patients with ISS 3 had increased serum levels of angiogenin and reduced Ang-1/Ang-2 ratio compared with all others ($p=0.003$ and 0.04, respectively). Interestingly, patients with lytic disease (n=97) had increased levels of Ang-2 compared with those who had no lytic lesions in skeletal survey ($p=0.008$). Ang-2 correlated with LDH (r=0.267, $p=0.0001$), CRP (r=0.24, $p=0.007$), VEGF (r=0.317, $p<0.0001$) and bFGF (r=0.29, $p=0.0001$), while angiogenin correlated with β2-microglobulin (r=0.249, $p=0.001$) and Hb (r=-0.265, $p=0.001$). The median survival of all patients was 47 months and the median follow-up was 19.6 months. The univariate analysis revealed that ISS stage ($p<0.001$), serum LDH ($p=0.003$), age ($p=0.02$), bone disease status ($p=0.0001$), serum creatinine ($p=0.017$), and the ratio of Ang-1/Ang-2 predicted for survival. Patients with serum Ang-1/Ang-2 of below or equal to the median value of 6.03 had a median survival of 27.8 months, while patients with Ang-1/Ang-2 values of above this median value had a median survival of 53 months ($p=0.033$). The multivariate analysis based on a Cox regression model revealed that only serum LDH ($p=0.001$), Ang-1/Ang-2 ratio ($p=0.001$) and bone disease status ($p=0.001$) could independently predict for survival in our cohort of patients. *Summary & Conclusions*. These results reveal for the first time in MM patients the correlation of reduced Ang-1/Ang-2 ratio with advanced disease and highlight the role of Ang-1/Ang-2 pathway in the biology of plasma cell growth as reflected by its influence on survival. These observations reveal Ang-1/Ang-2/Tie-2 system as a possible target for the development of novel anti-myeloma agents.

MICRORNA GENES ASSOCIATED WITH GENOMIC ALTERATIONS OR GENE EXPRESSION MODULATION CONTRIBUTE TO ENHANCE GENETIC HETEROGENEITY IN MULTIPLE MYELOMA

M. Lionetti, L. Mosca, L. Agnelli, D. Ronchetti, S. Fabris, A Andronache, L. Nobili, G. Ciceri, G. Lambertenghi-Deliliers, A. Neri

University of Milan, Fondazione IRCCS Ospedale Policlinico, MILAN, Italy

Background. Multiple myeloma (MM) is characterized by high genomic instability affecting both ploidy and structural rearrangements, as well as frequent copy number (CN) variations of specific chromosomal regions. It was reported that miRNA-genes often reside in regions representing hot spots for chromosomal abnormalities, which may contribute to their deregulation, and it was demonstrated that intronic miRNAs expression levels are frequently associated with those of the corresponding host-gene. *Aims*. Identification of molecular pathways potentially involved in MM pathogenesis using integrative analysis of genome-wide and gene expression profiling and micro-RNA expression data, in a panel of human myeloma cell lines (HMCLs). Methods. CN data were generated on Affymetrix GeneChip® Human Mapping 250K Nsp arrays, and the local DNA CN variations were calculated using the DNAcopy Bioconductor package based on circular binary segmentation. The miRNA expression data were generated on Agilent miRNA microarrays (representing 470 human mature miRNAs), and normalized using the AromaLight Bioconductor package. Gene expression data were generated on GeneChip® HG-U133A arrays, and normalized using the RMA Bioconductor package. Results. Our microarray analysis in a panel of 18 HMCLs revealed the presence of gains and losses involving entire chromosomes or specific regions, at a variable frequency up to 70%. We excluded miRNA-genes having multiple genomic locations and focused on miRNAs mapped within regions showing increased CN in at least 2 HMCLs, and we selected miRNAs having expression values of at least 2-fold their mean across the whole panel. Among the identified correlations, we report miR-92b (1q22) and miR-27a (19p13.12) in 4 HMCLs; miR-23a (19p13.12) in 3; and miR-520c (19q13.1), miR-214 (1q24.3), miR-22 (17p13.3) and miR-193b (16p13.12) in 2. Most of the identified miRNAs were already reported as deregulated in different human cancers, such as miR-23a in bladder cancer; miR-27a has oncogenic activity in MDA-MB-231 breast cancer cells, stimulating survival and angiogenesis; miR-214 decreases apoptosis in HeLa cells and is deregulated in ovarian cancer, where it induces cell survival through targeting PTEN; miR-520c is involved in tumor migration and invasion. The same integrative approach was used to detect correlations between miRNAs and the corresponding host-gene expressions, looking for those miRNAs whose variation (2-fold higher or lower) to the mean across the whole panel corresponded to the same variation of the host-gene in the gene expression profile panel. A strict correlation ($p<1\times10^{-5}$) was identified between miR-335 and MEST gene (mapped to 7q32.2), and miR-342 and EVL (14q32.2); the correlation coefficient on the whole panel were 0.86 and 0.88, respectively. A minor but significant correlation was identified between miR-625 and FUT8 (14q23.3) (R=0.53, $p<0.05$). These data suggest a strict influence of the same promoter activity on miRNA and host-gene expression. *Conclusions*. We showed that miRNAs expression in HMCLs could be affected by the presence of genomic lesions or may correlate with host-genes modulation suggesting a possible role in the molecular pathogenesis of MM. Our study represents the basis for further investigations aimed at functionally characterizing specific miRNAs in MM.

0197

IDENTIFICATION OF NEOPLASTIC PLASMA CELLS BY FLOW CYTOMETRY: LOOKING FOR THE BEST MARKER(S)

P. Mancuso, A. Calleri, P. Antoniotti, J. Quarna, A. Agazzi, S. Sammassimo, G. Pruneri, G. Martinelli, F. Bertolini

European Institute of Oncology, MILANO, Italy

Background. Bone marrow (BM) examination by trephine biopsy (BM-TB) is routinely performed during staging and follow-up of patients affected by plasma cells (PCs) disorders such as multiple myeloma (MM) and MGUS. The use of multiparametric flow-cytometry (FC) is currently restricted to clinical research studies. However, the presence of monoclonal antibodies specific for PCs (CD138, CD38), and the identification of markers candidate to discriminate normal *vs* neoplastic PCs makes this procedure suitable also for clinical applications. *Aims of the study*. To compare the phenotype of $CD45^{-/dim}$ PCs *vs* $CD45^{+}$ PCs and of monoclonal *vs* polyclonal PCs. 2) To identify which neoplastic PC marker identified by FC ($CD45^{-}$, $CD19^{-}$, $CD56^{-}$, cytoplasmatic λ/γ) better correlates with BM-TB. 3) To analyze discordance between FC and BM-TB. *Methods*. By four- (2000-2005) and six-color (2005-2008) FC, we analyzed 336 bone marrow aspirates from 130 MM patients before or after treatment. PCs were identified as $CD138^{+}CD38^{++}$. A panel of monoclonal antibodies including CD45, CD19, CD56, CD20, CD117, and CD126 and citoplasmatic λ/γ was used to characterize PC phenotype. At the same time, BM-TB was performed. *Results*. We compared the phenotype of $CD138^{+}CD38^{++}$CD45-/dim *vs* $CD138^{+}CD38^{++}CD45^{+}$ PCs for $CD19^{-}$ (92 *vs* 66%) $CD20^{+}$ (15 *vs* 12%) $CD56^{+}$ (72 *vs* 57%) $CD126^{+}$ (9 *vs* 16%) $CD117^{+}$ (46 *vs* 42%) expression and cytoplasmatic λ or γ chain restriction (94 *vs* 58%). When selected for light chain restriction *vs* polyclonal PCs, the phenotype was $CD19^{-}$ (92 *vs* 30%), $CD20^{+}$ (15 *vs* 7%), $CD56^{+}$ (71 *vs* 40%), $CD126^{+}$ (14 *vs* 8%) $CD117^{+}$ (49 *vs* 16%) $CD45^{neg/dim}$ (54 *vs* 8%). Concordance between FC and BM-TB was 80% according to light chain restriction, 77% according to CD19-, 66% according to $CD56^{+}$, 60% according to CD45-/dim PC phenotype. As light chain restriction showed the highest correlation with BM-TB, we analyzed in detailed the reason of discrepancy observed in discordant samples (20% of al samples). In 14.4 % of cases FC was positive and BM-TB negative. Fifty-two percent of these samples were performed after chemotherapy and the average frequency of monoclonal PC was 1% (range 0.2-3%). Among FC-BM-TB+ samples, the most frequent reason of discordance was the dilution of bone-marrow samples with blood, as confirmed by the absence of eritroblasts and myeloid precursor as reported by morphological assessment. *Conclusions*. Combined assessment of clonality and immunophenotype by FC is an useful tool for the diagnosis and follow up of PC disorders, and seems particularly promising for the investigation of the minimal residual disease. Light-chain PC restriction showed the best rate of correlation with BM-TB. However, FC sensitivity seems to be higher when the an aberrant PC phenotype (rather than clonality) is analyzed. Further studies are ongoing to evaluate the prognostic values of CD117+ PC.

0198

MICRO-RNA15A AND MICRO-RNA16 EXPRESSION IN MULTIPLE MYELOMA

S.L. Corthals,[1] Y. Knegt, de,[2] M. Schoester,[2] H.B. Beverloo,[2] K.H. Lam,[1] P. Sonneveld[1]

[1]Erasmus University Medical Center, ROTTERDAM; [2]Erasmus Medical Center, ROTTERDAM, Netherlands

Background. Multiple Myeloma (MM) is characterized by the accumulation of malignant plasma cells in the bone marrow (BM). MM has a profound genetic instability, leading to chromosomal abnormalities. Deletion of chromosome 13 is observed in more than 50% of MM cases and is an early event in MM pathogenesis. Because of its poor prognostic impact it has become clinical practice to diagnose the presence of chromosome 13 deletions by fluorescence *in situ* hybridization (FISH) in patients with newly diagnosed MM. The adverse prognostic role of these deletions suggests the presence of MM tumor suppressor gene(s) on chromosome 13q. Micro-RNAs (miRs) are a new class of small non-coding single stranded RNAs. MiRs negatively regulate gene expression by binding to partially complementary sites in messenger RNAs (mRNAs) and may function as tumor suppressors and oncogenes. miR-15a and miR-16-1, located on chromosome 13q14, are frequently down-regulated or deleted in B-cell chronic lymphocytic leukaemia (CLL). It has been shown that miR-15a and miR-16-1 are able to bind BCL2, an anti-apoptotic protein, and negatively regulate its function. Downregulation or deletion of miR-15a or miR-16-1 might therefore result in increased expression of BCL2, subsequently inhibiting apoptosis. *Aims.* The aim of this study is to evaluate the expression of miR-15a and miR-16 in Multiple Myeloma and assess their role in the pathogenesis of Multiple Myeloma. *Methods.* Thirty-four Multiple Myeloma samples were obtained from newly diagnosed MM patients. Abnormalities of chromosome 13q14 were determined using whole genome SNP analysis using the Illumina Infinium HumanHap550 Genotyping BeadChip and FISH analysis. Probes used in this study include retinoblastoma-1 (RB1) and D13S319. The mature miR-15a and miR-16 expression levels in CD138 magnetic cell selected (MACS) myeloma plasma cells (purity >80%) were determined using the TaqMan MicroRNA Assay. Cytospin slides with MM plasma cells were used for immunocytochemical analysis of Bcl2 protein expression. *Results*. FISH analysis showed a chromosome 13 deletion in 15 patients (44.1%). However, 17 patients (50%) were determined to have chromosome 13 deletion by whole genome SNPchip analysis, indicating 2 false negative cases by FISH analysis. Both miR-15a and miR-16 are expressed in all 34 MM samples, although the level of expression varies. There was no correlation between chromosome 13 status of the MM patients and miR-15a and miR-16 relative expression levels. The Bcl2 protein expression in MM plasma cells demonstrates variation within and between patient samples, however, didn't show correlation with miR-15a or miR-16 relative expression levels. *Summary and Conclusions.* In this study we determined whether loss of chromosome 13q14 is correlated with miR-15a and miR-16 expression in Multiple Myeloma patients. We did not observe such a correlation. All chromosome 13 deletions in this study are heterozygous, therefore, compensation by the non-deleted allele could explain the expression levels of miR-15a and miR-16 detected. Furthermore, the observed miR-15a and miR-16 expression levels could be due to the fact that a highly correlated cluster of miRs located on chromosome 3 continues to be expressed. These data suggest that miR-15a and miR-16 do not explain the poor prognosis associated with chromosome 13 deletions.

0199

FREQUENCY OF C3435T POLYMORPHISM IN A NORTHERN IRISH POPULATION AND ASSOCIATIONS WITH OVERALL SURVIVAL IN MYELOMA

S. Drain,[1] M.A. Catherwood,[2] M.B. Drake,[2] P.J. Kettle,[2] T.C.M. Morris,[2] H.D. Alexander[2]

[1]University of Ulster, COLERAINE; [2]Belfast City Hospital, BELFAST, UK

Background. Multi-drug resistance has been demonstrated as a significant factor in the successful management of malignancy. One major source of this resistance has been identified as the P-glycoprotein (P-gp) drug efflux pump, which has wide substrate specificity and is one of many characterised ATP-binding cassette (ABC) membrane transporters. As this protein is encoded by the gene *MDR-1*, functional aberrations within this genomic region (7q21) are of great interest. Single nucleotide polymorphisms (SNP) have been investigated within *MDR-1* with many contributing to a change in the amino acid. The *MDR-1* C3435T SNP, previously reported as silent, has been significantly associated with altered P-gp substrate specificity due to the generation of a rare codon, leading to conformational changes in the protein product. Previous publications have demonstrated associations with this SNP and the clinical outcome of haematological malignancy such as acute leukaemia. Recent studies of multiple myeloma (MM) patients have investigated this SNP within Italian and Dutch cohorts, with a lack of concordance with regard to outcome. Thus, the role of the SNP in outcomes in MM remains unclear. *Aims*. The aim of this study was to investigate the prevalence of the C3435T SNP in a Northern Irish (NI) MM cohort compared with a NI age matched normal cohort and to determine its effect on disease outcome. *Methods*. Patients with a diagnosis of MGUS or MM (n =140) and age and gender matched healthy controls (n =140) were recruited. Preliminary SNP analysis was performed by polymerase chain reaction - restriction fragment length polymorphism (PCR-RFLP) on 87 MM cases and 92 controls. Survival statistics were obtained using univariate cox proportional hazards regression analysis and Kaplan-Meier plots while the prevalence of the SNP within the NI cohort was determined using χ^2. *Results*. No significant difference was observed in the incidence of the C3435T SNP in the MM cohort compared with controls and the incidences in both groups concur with NCI recorded Caucasian prevalence. Longer overall survivals (OS) were observed for the CT and TT genotypes compared with patients with a CC genotype (p=0.014) (Figure1). Relative to CT, the hazard ratio (HR) for TT was 2.67 (95% CI, 0.96-7.40; p=0.059) and for CC was 4.75 (95% CI, 1.65-13.64; p=0.004). *Conclusions*. The prevalence of the C3435T SNP within our cohort is in keeping with NCI Caucasian data and indicates no correlation between the SNP and incidence of MM. However, overall survival of myeloma patients was significantly associated with genotype, with wild-type CC patients demonstrating shorter survival. Interestingly, the heterozygous CT genotype had longest OS, indicating an optimum phenotypic contribution for this genotype. This initial data is in concordance with previous work in an Italian MM patient cohort and supports the use of C3435T genotyping in the initial diagnosis and risk stratification of MM patients. Study of larger patient cohorts is required to confirm these findings and will allow the investigation of treatment strategy in relation to these survival trends.

VASCULAR ENDOTHELIAL GROWTH FACTOR, OSTEOPONTIN AND NF-kB/P65 EXPRESSION IN MULTIPLE MYELOMA

S. Stifter,[1] T. Valkovic,[2] A. Nacinovic-Duletic,[2] K. Matus an-Ilijas,[3] K. Lucin,[3] I. Seili-Bekafigo,[2] D. Rendic Petranovic,[2] N. Jonjic[3]

[1]School of Medicine, Medical University Rijeka, RIJEKA, Croatia; [2]Clinical Medical Center Rijeka, Internal Clinic, Department of Hematology, RIJEKA, Croatia; [3]Department of Pathology, School of Medicine, Medical University Rijeka, RIJEKA, Croatia

Background. Previous studies have provided insights into the pathogenesis of multiple myeloma (MM), and defects involving proliferation, apoptosis, and angiogenesis which are believed to be important. Since, chemoresistence is a major problem in the treatment of patients with MM the new strategies of therapy development have been pointed towards expansion of new molecular targets. The importance of the nuclear factor-κ B (NF-κB) in the proliferation and anti-apoptotic effect in normal and tumor cells has been determined. However, the role of NF-ÎB in the pathogenesis of the MM still remains unclear. *Aims.* The aim of this study was to analyze the angiogenic potential of myeloma cells by identification of vascular endothelial growth factor (VEGF) and osteopontin (OPN) expression in connection with NF-κB/p65 activity. *Methods*. The bone marrow trephine sections obtained from 48-patients (22 men and 26 women, median age, 68.3 years; ranged 48- 89) diagnosed with MM, including clinical data regarding clinical stage (13 stage I, 18 in stage II, and 17 in stage III, according to Durie), and therapy response were unrolled in this study. Angiogenesis was immunohistochemically evaluated by measuring the intratumoral microvessel density (MVD) with anti-CD34, while VEGF, OPN, Ki-67 and NÎF-B/p65 were analyzed by using double immunohistochemistry; CD138 being used for detection of myeloma cells. The VEGF and OPN expression was evaluated as VEGF H-score and OPN H-score, multiplying the intensity with the percentage of positive myeloma cells. *Results*. Statistical analyzes show significant correlation between VEGF expression and MVD ($p<0.001$, $rp=0.609$), and between OPN expression and activated NF-κB/p65 ($p<0.033$, $rp=0.325$). In addition, a co-expression in myeloma cell for VEGF and OPN was observed ($p<0.012$). A strong reverse correlation was found between VEGF and Ki-67 ($p<0.008$, $rp=-0.389$) and weak between OPN and Ki-67 ($p=0.098$, rp =-0.255). Cytoplasmic NF-ÍB/65 shows almost significant correlation with OPN ($p=0.055$, $rp=0.294$) and nearly opposite relationship with VEGF expression ($p=0.064$, $rp=-0.278$). *Conclusions*. Increased production of VEGF protein by myeloma cells confirmed the increased intratumoral vascularity or angiogenic potential of tumor cells. However, the autocrine mitogenic potential of VEGF and OPN by evaluating the expression of these proteins could not be established. Co-expression of these two investigated proteins, VEGF and OPN on myeloma cells should be better determined in order to elucidate their probably synchrony role in angiogenesis and other functions. Specially, since the OPN expression is associated with activated NF-κB/p65 what implies a diverse functional activity of these cells.

0201

ELEVATED SERUM TIMP-1 LEVELS CORRELATE WITH ADVANCED STAGE AND PREDICT REDUCED SURVIVAL IN NEWLY-DIAGNOSED MULTIPLE MYELOMA PATIENTS

E. Terpos,[1] M.A. Dimopoulos,[2] V. Shrivastava,[3] K. Leitzel,[3] D. Christoulas,[2] M. Migkou,[2] M. Gavrietopoulou,[2] E. Eleftherakis-Papaiakovou,[2] K. Anargyrou,[1] E. Kastritis,[2] P. Hamer,[4] W. Carney,[4] A. Lipton[3]

[1]251 General Air Force Hospital, ATHENS, Greece; [2]Department of Clinical Therapeutics, University of Athens Medical School, ATHENS, Greece; [3]Penn State University/Hershey Medical Center, HERSHEY, PA, USA; [4]Oncogene Science/Siemens HealthCare Diagnostics, CAMBRIDGE, MA, USA

Background and Aims. Tissue inhibitor of metalloproteinase-1 (TIMP-1) is a natural metalloproteinase (MMP) inhibitor that binds to and inactivates mainly MMP-9. TIMP-1 has multifunctional roles in tumorigenesis: inhibition of the catalytic activity of metalloproteinases, growth promotion, inhibition of apoptosis, and regulation of angiogenesis. Increased TIMP-1 has been associated with an unfavorable prognosis in many cancers including breast, colorectal, gastric, head and neck, lung cancer, and lymphomas. *In vitro* studies have revealed *TIMP-1* overexpression by myeloma cell lines. Furthermore, *TIMP-1* promotes myeloma cell invasion across basement membranes. The aim of this study was to evaluate the serum levels of TIMP-1 in newly-diagnosed, previous untreated myeloma patients and explore possible correlations with clinical and laboratory data, including survival. *Patients and Methods*. Fifty-five patients with newly-diagnosed myeloma (25M/30F, median age: 69 years) were evaluated. Eleven patients had stage 1 disease according to ISS, while 27 had stage 2 and 17 stage 3 myeloma. Serum TIMP-1 was determined before the administration of any therapy, including bisphosphonates, using ELISA (Oncogene Science/ Siemens HealthCare Diagnostics, Cambridge, MA, USA) along with a series of serum markers of bone remodeling (NTX, CTX, TRACP-5b, bALP and osteocalcin) and osteoblast/osteoclast regulators (dickkopf-1, sRANKL and osteoprotegerin). The above bone markers were also evaluated in 25 healthy controls of similar age and gender. *Results*. The mean serum TIMP-1 level of all patients was 431.9 ng/mL (SD 198.1 ng/mL). Twenty-six patients (17M/9F; 47%) had elevated values of TIMP-1 (upper normal limit 324 ng/mL for males and 454 ng/mL for post-menopausal women). Patients had also increased levels of dickkopf-1, sRANKL, sRANKL/OPG ratio and bone resorption markers (NTX, CTX, and TRACP-5b) ($p<0.01$ compared with healthy controls). TIMP-1 serum levels correlated with β2-microglobulin ($r=0.414$, $p<0.01$), albumin ($r=-0.416$, $p<0.01$), osteocalcin ($r=0.325$, $p=0.01$), CTX ($r=0.314$, $p=0.01$), NTX ($r=0.306$, $p=0.02$), and LDH ($r=0.295$, $p=0.03$). More importantly, *TIMP-1* correlated with ISS (ANOVA $p=0.005$). Patients with ISS 3 disease had higher levels of TIMP-1 (mean±SD 557.8±234 ng/mL) compared with those who had ISS 1 (311±90.6 ng/mL; $p=0.001$) or ISS 2 disease (405.5±165.6 ng/mL; $p=0.021$). Furthermore, patients with lytic disease (n=43) had increased levels of TIMP-1 (457.7±205 ng/mL) compared with all others (313.6±107.6 ng/mL; $p=0.05$). The median follow-up was 31 months after blood collection and 16/55 patients have died. The median survival since time of blood collection has not been reached yet. Patients who had TIMP-1 level of above the mean value had a median survival of 37 months, while in all others the median survival has not been reached yet ($p=0.04$). *Summary and Conclusions*. Our study provides evidence for the first time that increased serum level of *TIMP-1* correlates with advanced myeloma and predicts for reduced survival in myeloma patients. These results suggest that *TIMP-1* participates in myeloma pathogenesis and strongly support that serum TIMP-1 deserves further study to determine its predictive and prognostic biomarker potential in a larger cohort of myeloma patients.

0202

INCREASING FREQUENCY OF MCL-1 mRNA EXPRESSION THROUGH THE STAGES OF MULTIPLE MYELOMA

A.K. Mylin,[1] T. Rasmussen,[2] M. Lodahl,[2] I.M. Dahl,[3] L.M. Knudsen[4]

[1]Rigshospitalet, University of Copenhagen, COPENHAGEN, Denmark; [2]Herlev Hospital, University of Copenhagen, HERLEV, Denmark; [3]Tromsø University Hospital, TROMSØ, Norway; [4]Odense University Hospital, ODENSE, Denmark

Background. The protein Mcl-1 (Myeloid cell leukaemia-1), a member of the Bcl-2 (B-cell lymphoma/leukaemia-2) family of antiapoptotic proteins, is demonstrated to be critical for proliferation and survival of myeloma cells *in vitro*, suggesting that Mcl-1 is an attractive target for future therapies in multiple myeloma (MM) (1). Furthermore, a recent study has shown that overexpression of Mcl-1 protein in myeloma cells *in vivo* is associated with relapse and short event-free survival (2). *Aims.* Here, we investigated frequency and prognostic impact of Mcl-1 mRNA expression in myeloma cells from a large group of patients with different stages of MM including the premalignant stage monoclonal gammopathy of undetermined significance (MGUS). *Methods.* The study population consisted of 10 MGUS patients and 113 newly diagnosed MM patients with immunophenotypic aberrant plasma cells in BM aspirates. All MGUS patients had IgG or IgA isotype and were stable for minimum 24 months after BM sampling. Forty MM patients received intensive therapy with high-dose chemotherapy followed by autologous stem cell transplantation (ASCT), 63 MM patients received conventional therapy, and the remaining 10 MM patients were observed without treatment. All samples were obtained after informed consent according to the Helsinki II declaration. Five human myeloma cell lines (HMCL) were also investigated. After fluorescence activated cell sorting (FACS) of 100 immunophenotypic aberrant plasma cells directly into polymerase chain reaction (PCR) tubes, a cDNA archive was generated using global reverse transcription (RT)-PCR. Expression levels of Mcl-1, Bcl-2 and Bcl-xL normalized to β-actin were determined in each cDNA archive by real-time PCR. Normalized mRNA expression above 10-5 was considered positive. *Results.* Mcl-1 mRNA expression in myeloma cells was seen in 20% of MGUS patients compared to 72% of MM patients (p=0.0008) and all of the HMCL investigated (p=0.003). Among MM patients, there was a trend towards Mcl-1 expression being more frequent in patients with advanced disease defined by Durie-Salmon (DS) stage (64% DS I, 58% DS II, 80% DS III; p=0.049). The median level of mRNA expression did not differ among the groups investigated. Mcl-1 (p=0.03) and especially Blc-2 (p= 0.004) mRNA expression was associated with high age. The MM patients were followed for up to 116 months (median 29 months; range 1 - 116 months), and 74 deaths were registered. Mcl-1, Bcl-2 or Bcl-xL mRNA expression had no impact on overall survival. Forty MM patients receiving intensive therapy were followed for up to 77 months after ASCT (median 28 months; range 0 - 77 months). During this period, 18 patients experienced relapse or disease progression demanding reinstitution of therapy and 3 patients died. Mcl-1 mRNA expression at diagnosis lacked association with event-free survival after intensive therapy. *Summary and Conclusions*. Mcl-1 mRNA expression in myeloma cells rise in frequency through the stages of MM, but lack association with overall and event-free survival.

MOLECULAR CYTOGENETIC ANALYSIS OF WALDENSTROM'S MACROGLOBULINEMIA IN KOREA

J.W. Seo,[1] S.M. Bang,[2] K.U. Park,[2] S.S. Yoon,[1] D.S. Lee,[1] H.J. Kim,[3] K.H. Kim,[3] S.R. Cho,[4] H.C. Kim,[4] J.W. Song,[5] J.S. Kim,[5] K.W. Kim,[6] J.H. Lee,[6] J.J. Lee,[7] M.K. Shin,[7] C.W. Seo,[8] H.S. Chi,[8] D. Oh,[9] J.H. Won[10]

[1]Seoul National University Hosp., SEOUL; [2]Seoul National University Bundang Hosp., SEONGNAM; [3]Sunkyunkwann University College of Med., SEOUL; [4]Ajou University Hospital, SUWON; [5]Yeonsei University College of Medicine, SEOUL: [6]Gachon University Gil Hospital, INCHEON; [7]Chonnam National University Medical School, GWANGJU; [18]University of Ulsan College of Medicine, SEOUL; [9]Pochon CHA University College of Med., SEONGNAM; [10]Soonchunhyang University Hospital, SEOUL, South-Korea

Background. Waldenstrom's macroglobulinemia (WM) is a malignant lymphoproliferative disorder associated with infiltration of the bone marrow by pleomorphic B-lineage cells and monoclonal IgM production. High incidence of 6q deletion and rarity of IgH rearrangement discriminates WM from other B cell malignancy. *Aims*. To compare the molecular cytogenetic characteristics between WM and multiple myeloma (MM), we performed interphase fluoresecent *in situ* hybridization (FISH) study in Korean patients with WM and MM. *Mehtods*. Thiry nine patients who fulfilled the diagnosis of WM and 132 patients with MM were enrolled for the characterization of cytogenetic changes using conventional cytogenetics and FISH. The sex ratio was 3.9:1.0 (male 31, female 8) and the mean age at the diagnosis was 63 year (range form 40 to 87 year) in WM group. FISH analysis combined with cytoplasmic immunoglobulin light chain staining was performed on bone marrow mononuclear cells or air-dried bone marrow smear, using 6 kinds of probes (6q21, 6q23, IgH rearrangement, p16 gene, RB1 gene, 1q25), which included 2 different regions of long arm of chromosome 6. A cut-off of 10% or greater was used for the interpretation of FISH combined with immunophenotyping.

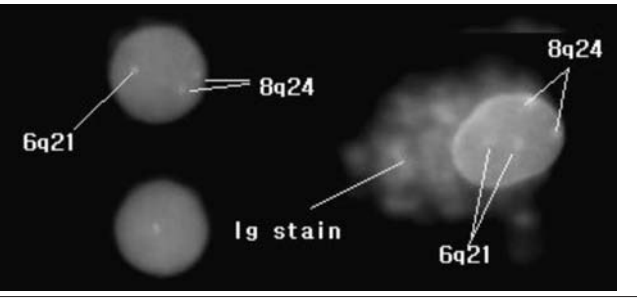

Figure 1. 6q deletion in only small lymphocyte

Results. Out of 23 successful karyotypes, 26% showed abnormal karyotypes, including 1 case of 6q deletion (4%). With FISH method, deletions of 6q23 were observed in 3/29 cases (10%), followed by deletions of 6q21 in 3/31 cases (10%), IgH translocation in 1/29 case (3%), gain of 1q in 1/26 case (4%). Deletion of 6q was hemizygous in all 3 cases. In one WM patient, 6q deletion was observed in only small lymphocytes, but not in plasma cells. In MM group, frequency of 6q deletion was 0% (0/30, FISH for 6q deletion was performed in 30 patients with MM), while RB1 deletion was most frequent change (45%, 59/132), followed by IgH translocation (41.8%, 55/132) , and gain of 1q (38.8%, 50/132). *Conclusions*. In Korean WM patients, deletion of long arm of chromosome 6 (10%) was lower than the reported frequencies of caucacians. WM showed markedly lower frequency of IgH translocation (3%) and trisomy 1q (4%), compared to those of MM (41.8% and 38.8%, respectively), which suggested that MM and WM are the different disease entites.

0204

PHENOTYPE OF PLASMA CELLS IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND MULTIPLE MYELOMA SUBJECTS

L. Kovarova,[1] I. Buresova,[1] R. Suska,[1] L. Pour,[2] L. Zahradova,[1] V. Sandecka,[1] M. Penka,[1] R. Hajek[3]

[1]University Hospital, BRNO, Czech Republic; [2]University Research Center - Czech Myeloma Group, Masaryk University, BRNO, Czech Republic; [3]Dept. of Hemato-Oncology, University Hospital, Brno and Faculty of Medicine, MU, BRNO, Czech Republic

Background. Flow cytometric immunophenotyping can identify $CD38^+CD138^+$ plasma cells (PCs) in monoclonal gammopathies. Monoclonal gammopathy of undetermined significance (MGUS) is the most common asymptomatic plasma cells disorder which eventually progress to symptomatic multiple myeloma (MM). *Aims*. The aim of this study was to find possibilities and limits of multicolour flow cytometry in diagnostics of monoclonal gammopathies and to evaluate whether or not the expression of CD19 and CD56 can distinguish between normal polyclonal and abnormal clonal PCs. *Methods*. Bone marrow of 78 newly diagnosed MM patients (average age 64,0±9,9 years) and 25 MGUS patients (64,0±8,1 years) was analysed. Group of MM patients consisted of 19 patients in clinical disease stage I - according to the D-S system - (MM I), 14 patients in stage II (MM II) and 45 patients in stage III (MM III). Plasma cells were identified by simultaneous expression of CD38, CD138, CD45, CD56 and CD19. Clonality of PCs was confirmed by light chain analysis in specific cases. *Results*. There was found lower number of $CD38^+CD138^+$ PCs in MGUS patients when compared with both whole group of MM patients (p<0,001) and individual MM groups (p<0,047; p<0,001 and p<0,001 respectively). See details in Table 1.

Table 1.

Parameter median (range) %	MGUS (n=25)	MM (n=78)	MM I (n=19)	MM II (n=14)	MM III (n=45)
$CD138^+$ $CD38^+$ cells	0,4 (0,0-4,2)	3,0 (0,0-47,7)	1,0 (0,0-14,6)	3,7 (0,2-18,7)	4,7 (0,0-47,7)
$CD19^+$ PC	15,0 (1,9-75,6)	1,2 (0,0-79,4)	4,7 (0,2-54,8)	0,8 (0,0-79,4)	0,9 (0,0-73,6)
$CD56^+$ PC	23,6 (6,3-91,8)	88,6 (0,1-99,8)	88,3 (0,5-99,4)	65,5 (0,5-99,7)	90,6 (0,1-99,8)

Surface markers CD19 and CD56 were chosen for discrimination between respectively normal residual PCs and abnormal neoplastic PCs. Higher number of polyclonal $CD19^+$ PCs was found in MGUS patients when compared with both whole group of MM (p<0,01) and individual groups of MM (p=0,002; p<0,001 and p<0,001 respectively). However $CD56^+$ PCs were found in predominance over residual $CD19^+$ PCs in 56% (14/25) of MGUS patients. The highest number of residual $CD19^+$ PCs was found in MM I (p=0,048) when all clinical stages of MM were compared with one another. A majority of PCs in MM patients were abnormal $CD56^+$ PCs and no significant differences for CD56 expression were found after comparison of all MM clinical stages with one another. There were found $CD19^+$ PCs in 2,6% (2/78) of patients with MM, these were $CD45^+$ with light chain restriction as well. PCs of 15,4% (12/78) of MM patients expressed neither CD19 nor CD56, but they were monoclonal. *Summary and Conclusions*. Lower number of PCs was found in MGUS patients when compared with MM patients and these PCs can be separated into subpopulations including normal residual $CD19^+$CD56- PCs and abnormal $CD56^+CD19^-$ PCs (alternatively $CD56^+CD19^+$ or CD56-CD19- in MM cases). Surface marker CD19 is a useful parameter for identification of normal residual PCs, but assessment of light chain restriction is recommended for verification of their normality, especially in $CD19^+$ MM cases.

INDUCTION WITH CYBORD PRODUCES HIGH COMPLETE RESPONSES IN NEWLY DIAGNOSED MULTIPLE MYELOMA

A.K. Stewart,[1] B. Reeder,[1] R. Fonseca,[1] P.L. Bergsagel,[1] A. Pirooz,[1] G. Hentz,[1] E. Boesiger,[1] G. Pisa,[2] V. Kukreti,[2] Ch. Chen,[2] S. Trudel,[2] R. Mikhael,[2] F. Leis,[1] E. Reece[2]

[1]Mayo Clinic, SCOTTSDALE, USA; [2]Princess Margaret Hospital, TORONTO, Canada

Background. The combination of oral cyclophosphamide, bortezomib and dexamethasone (CyBorD) is active in multiple myeloma (MM) producing rapid responses. *Aims.* The goal of this study was to determine the depth of that response in newly-diagnosed patients with multiple myeloma as assessed by CR, nCR and VGPR after 4 cycles of therapy. *Methods*. Patients with newly diagnosed MM were eligible if they had measurable or evaluable disease, were >18 years of age, had an ECOG PS <3 and were able to give informed consent. Treatment consisted of a single arm of cyclophosphamide 300mg/m^2 po days 1, 8, 15, 22, bortezomib 1.3 mg/m^2 IV days 1, 4, 8, 11 and dexamethasone 40mg po days 1-4, 9-12, and 17-20 of a 28 day cycle. A total of 4 cycles was planned with the goal of proceeding on to stem cell transplant. Growth factors were allowed after cycle 1. The primary endpoint was complete response with secondary endpoints of ORR, PFS and toxicity. *Results*. 33 patients have been enrolled and 23 are evaluable for response and toxicity at the time of writing. Patient characteristics included mean age of 60, 43 % female, and ISS stage II/III in 35/26 %. Prior to transplant the ORR is 100 % with 85 % achieving at least a VGPR. 64 % had a CR or nCR. Responses occurred rapidly with a mean reduction in M-Protein of 66 % and 83 % after 1 and 2 cycles. Grade 3 toxicities included neutropenia in 20%, thrombocytopenia in 9 %, hyperglycemia in 17 % and peripheral neuropathy (PN) in 5 %. Gr 1-3 PN occurred in 69%. There was no grade 5 toxicity. All patients that elected to proceed on to transplant were able to undergo successful stem cell harvests. *Conclusions*. The induction regimen CyBorD is highly active in the treatment of newly diagnosed MM and produces very good and complete responses exceeding those seen with other induction regimens, mimicking that seen with high-dose therapy and stem cell transplantation. The main toxicity is peripheral neuropathy.

0206

INCORPORATION OF THALIDOMIDE INTO UP-FRONT DOUBLE AUTOLOGOUS STEM-CELL TRANSPLANTATION FOR NEWLY DIAGNOSED MULTIPLE MYELOMA FAILS TO OVERCOME THE POOR PROGNOSIS IMPARTED BY CHROMOSOME 13 DELETION

M. Cavo,[1] C. Terragna,[1] N. Testoni,[1] P. Tosi,[1] M. Ceccolini,[1] A. Gorgone,[2] S. Annunziata,[2] C. Nicci,[1] M. Renzulli,[1] P.P. Fattori,[2] G. Leopardi,[2] E. Zamagni,[1] P. Tacchetti,[1] G. Perrone,[1] S. Ronconi,[1] A. Lazzaro,[2] M. Offidani,[2] M. Fiacchini,[1] D. Vertone,[2] P. Fabbri,[2] A. Brioli,[1] M. Pallotti,[1] L. Pantani,[1] L. Guardigni,[2] D. Mamone,[2] M. Baccarani[1]

[1]Seràgnoli Institute of Hematology and Medical Oncology, BOLOGNA, Italy; [2]Bologna 2002 Study, ITALIAN MYELOMA NETWORK, Italy

The phase II "Bologna 2002"clinical study incorporated thalidomide-dexamethasone (thal-dex) into melphalan-based (200 mg/m^2) double autologous stem-cell transplantation (ASCT) as up-front therapy for patients with symptomatic multiple myeloma (MM) and less than 65 years of age. By study design, thal (200 mg/d) and dex (40 mg/d x 4d every month, with two added courses on the 1st and 3rd month of therapy) were administered from the outset until the second ASCT. An analysis on an intention-to-treat basis was performed of 311 consecutive patients who entered the study and were followed for a median of 3 years. The rate of ≥ very good partial response (VGPR) increased from 29% after 4 months of primary induction therapy with thal-dex to 63% after the second ASCT. Median durations of relapse-free survival (RFS) and event-free survival (EFS) were 52 and 42 months, respectively. The probability of 5-year projected overall survival (OS) was 70%. A case-match comparison of 135 of these patients with an equal number of pair mates who entered the predecessor "Bologna 96"study and were randomly assigned to receive double ASCT alone showed a significant benefit from added thal to double ASCT in terms of increased ≥ VGPR rate (68% *vs* 49%, respectively; p=0.001), extended 5-year RFS (54% *vs*

32%; p=0.005) and prolonged EFS (median: 52 *vs* 33 months; p=0.01). All 311 patients were screened on purified CD138+ bone marrow plasma cells for the presence at diagnosis of chromosome 13 alterations [del(13)] (47% of cases) and t(4;14) (13% of cases). In a logistic regression analysis, both absence of del(13) (p=0.001) and low beta2- microglobulin (beta2-m) levels (p=0.007) were significantly related to attainment of ≥ VGPR after the second ASCT. In a multivariate analysis of all 311 patients, the most important and independent variable significantly extending time to progression (TTP), EFS and OS was the absence of del(13) (p=0.001, p=0.001 and p=0.007, respectively), along with attainment of ≥ VGPR after the second ASCT. OS was also significantly influenced by both β2-m (p=0.044) and hemoglobin concentration (p=0.05), whereas platelet count was an additional prognostic factor for TTP (p=0.025). In conclusion, in comparison with double ASCT alone, incorporation of thal into double autotransplantation as up-front therapy for symptomatic MM significantly improved the response rate (≥ VGPR), RFS and EFS, without adversely affecting postrelapse OS. The presence of del(13) by FISH analysis was the most important and independent variable adversely influencing attainment of ≥ VGPR, EFS and OS following added thal-dex to double ASCT. Incorporation of thal into double autologous stem cell transplantation failed to overcome the poor prognosis imparted by chromosome 13 deletion.

CIC, IBMCC (USAL-CSIC), SALAMANCA, Spain; [11]Millennium Pharmaceuticals, Inc., CAMBRIDGE, USA; [12]Johnson & Johnson Pharmaceutical Research & Development, L.L.C., RARITAN, USA; [13]Johnson & Johnson Pharmaceutical Research & Development, BEERSE, Belgium; [14]Dana-Farber Cancer Institute, BOSTON, USA

Background. Results from the phase III VISTA study in previously untreated MM patients ineligible for high-dose therapy demonstrate that VMP is superior to melphalan-prednisone (MP) in terms of response rates (82% *vs* 50%, respectively, by M-protein assessment, including 35% *vs* 5% immunofixation-negative M-protein complete response [CR]), time to progression (median 24.0 *vs* 16.6 months, HR=0.483, p<0.001), time to subsequent therapy (median not reached *vs* 20.8 months, HR=0.522, p<0.001), and overall survival (medians not reached, HR=0.607, p=0.0078). (Off-label use: bortezomib in front-line MM in a novel combination.) *Aims*. Time to response and duration of response (DOR) were secondary end points of VISTA. The analyses presented here compare time to first response, time to best response, and DOR with VMP and MP, and assess the impact of length of VMP therapy on quality of response and duration of CR. *Methods*. Patients were randomized to VMP (N=344) or MP (N=338); all provided written, informed consent. Treatment was administered for up to 54 weeks, and comprised nine 6-week cycles of melphalan 9 mg/m^2 and prednisone 60 mg/m^2, days 1-4, alone or in combination with bortezomib 1.3 mg/m^2 twice weekly (days 1, 4, 8, 11, 22, 25, 29, and 32), cycles 1-4, and weekly (days 1, 8, 22, and 29), cycles 5-9. M-protein analyses were performed by a central laboratory. Response, relapse, and progression in these analyses were determined using European Group for Blood and Marrow Transplantation (EBMT) criteria. Descriptive statistics were provided for responders only; p-values were based on stratified log-rank tests. *Results.* Responses were significantly more rapid with VMP; median time to first response was 1.4 months with VMP *vs* 4.2 months with MP (p<0.001). Nevertheless, late *de novo* responses occurred with VMP; 4% of first responses were seen beyond the initial 24 weeks of therapy (i.e. during cycles 5-9). Median time to best response was 2.3 months with VMP *vs* 4.9 months with MP, and median time to CR was 4.2 months *vs* 5.3 months, respectively (p<0.001), suggesting that quality of response improved with prolonged treatment. Notably with VMP, 28% of CRs as best response occurred during cycles 5-9. Responses were substantially more durable with VMP; median DOR was 19.9 months with VMP *vs* 13.1 months with MP, and median DOR in patients achieving CR was 24.0 months *vs* 12.8 months, respectively. For VMP patients achieving CR, continued treatment beyond initial CR resulted in prolonged CR. In patients who received ≤2 additional cycles, >2 additional cycles but <9 cycles in total, or all 9 protocol-specified cycles, median/25% quantile duration of CR was 16.9/7.4 months, not estimable/9.7 months, and 20.3/16.4 months, respectively. *Conclusions.* VMP results in significantly more rapid and substantially more durable responses than MP. Although many responses occur early with VMP, prolonged therapy results in additional first responses and improves quality of response, in particular maximizing the chance of achieving CR. Continued therapy also improves duration of CR with VMP, indicating that to maximize clinical benefit patients should not discontinue therapy early upon achieving CR.

0208

BORTEZOMIB IN COMBINATION WITH PEGYLATED LIPOSOMAL DOXORUBICIN AND THALIDOMIDE (VDT) FOR THE TREATMENT OF PREVIOUSLY UNTREATED MULTIPLE MYELOMA

S. . Ailawadhi, K.C. Miller, D. Depaolo, A. Whitworth, J. Yu, D.L. Trump, S. Padmanabhan, M. Czuczman, Z.P. Bernstein, F. Hernandez-Ilizaliturri, K. Lee, A. Chanan-Khan

Roswell Park Cancer Institute, BUFFALO, USA

Introduction. Addition of pegylated liposomal doxorubicin (PLD) is reported to enhance the efficacy of bortezomib. To further optimize the clinical efficacy of these agents we included thalidomide to the regimen. In a previous report we described the clinical efficacy of this novel, non-steroidal regimen that incorporated bortezomib (V), PLD (D) and thalidomide (T) in patients with relapsed or refractory multiple myeloma (MM). High clinical responses in heavily pretreated patients, even in the absence of steroids encouraged us to investigate this regimen in previously untreated MM patients. Here we report the efficacy and toxicity profile of the VDT regimen in treatment naive MM patients enrolled on a phase II clinical study at our center. *Methods*. All previously untreated MM patients were eligible for this study. Bortezomib (1.3 mg/m^2) was given on days 1, 4, 15, and 18, pegylated liposomal doxorubicin was given (20 mg/m^2) on days 1 and 15 and thalidomide (200 mg) was given daily continuously throughout the treatment. Patients received treatment on a 4-week cycle. Acyclovir 400 mg PO BID and low-dose warfarin were given for prophylaxis of herpes zoster and venous thromboembolism, respectively. *Results*. A total of 34 patients (median age 60; range 40-82 years), 21 M and 13 F have so far been enrolled. Advance (stage III) disease was noted in 69% of the patients. The median beta 2 microglobulin was 4 mg/L (range1.6-9.7), albumin was 4 g/dL (range 3.1-4.8) and LDH was 333 U/L (range 152-1057). Patients received a median of 5 treatment cycles (range 1-8). Toxicity: The most common grade 3 or 4 hematologic toxicities included lymphopenia (32%) and neutropenia (21%), while the non-hematologic toxicity included infections 21% (n=7). The incidence of grade 3 or 4 plantar palmar erythrodysthesia was 3% (n=1). Venous thromboembolism has not been observed in any patient to date. Grade 3 or 4 peripheral neuropathy was seen in only 1 patient (3%). Response: To date 28 patients are available for response assessment (EBMT criteria), 3 patients are too early for response assessment while 3 patients were not evaluable due to discontinuation of treatment. The ORR of this regimen is 68% with IFE negative CR observed in 4 patients (14%). Another 7 patients (28%) achieved a stable disease for an overall clinical benefit of 96%. Progressive disease was noted in 1 patient on the regimen so far. *Conclusion*. VDT is a novel non-steroidal regimen with clinical efficacy in previously untreated myeloma patients. Overall toxicity is manageable. Several patients remain on treatment and accrual is continuing on the study at present. Detailed and updated results of this study will be presented at the meeting.

0209

A RANDOMISED PLACEBO CONTROLLED STUDY WITH MELPHALAN/PREDNISONE *vs* MELPHALAN/PREDNISONE/THALIDOMIDE: QUALITY OF LIFE AND TOXICITY

N. Gulbrandsen,[1] A. Waage,[2] P. Gimsing,[3] I. Turesson,[4] G. Juliusson,[5] N. Abildgaard,[5] B. Bjørkstrand,[6] K. Carlson,[5] I.M. Dahl,[5] K. Forsberg,[5] L.M. Knudsen,[7] J. Lanng Nielsen,[5] U.H. Mellqvist,[8] I. Nesthus,[9] M. Strandberg,[5] F. Wisløff,[1] P. Fayers[10]

[1]Ullevål University Hospital, OSLO, Norway; [2]St. Olavs Hospital/NTNU, TRONDHEIM, Norway; [3]National Hospital, COPENHAGEN, Denmark; [4]Malmø University Hospital, MALMØ, Sweden; [5]Dep of Hematology, LUND, Sweden; [6]Dep of Hematology Huddinge, STOCKHOLM, Sweden; [7]Herlev, COPENHAGEN, Denmark; [8]Sahlgrenska, GOTHENBURG, Sweden; [9]Haukeland, BERGEN, Norway; [10]NTNU, TRONDHEIM, Norway

Background, methods. Previously untreated patients with multiple myeloma were included in this double-blind randomised trial. Patients not eligible for high dose treatment in Norway, Sweden and Denmark were recruited. The study started in 2002 and accrual of patients stopped 1st of May 2007. Date of analysis was 10th of October 2007. Median follow up is 36 months. Patients were randomly allocated to treatment with melphalan/prednisone/thalidomide or melphalan/prednisone/placebo. Starting dose of thalidomide was 200 mg escalating to 400 mg. *Aims*. Primary endpoint was overall survival, secondary endpoints were event free survival, response, time to progression and quality of life. *Results*. Altogether 363 patients were included and 357 patients were evaluable for analysis. In the thal and placebo arm respectively, the mean age was 75 (49-92) years (both arms), 52 % and 62 % were males, 65 % and 64 % had b2 microglobulin > 3,5 mg/mL, 28% and 32 % had WHO stage 3-4. The response rates were CR/nCR 6 *vs* 3 %, VGPR 9 *vs* 3 %, PR 27 *vs* 22 % at 6 months in the thal arm and placebo arm, respectively. Time to progression were 20 *vs*18 months ($p<0.05$). There was no significant difference in progression free survival (16 *vs* 14 months) and overall survival (29 *vs* 33 months). In patients above 75 years of age there was a tendency to higher early mortality in the thalidomide arm. Self reported quality of life was assessed with the EORTC QLQ-C30 questionnaire, version 3.0. Baseline form was filled in before randomisation, subsequent forms were sent out every 3 months. Registrations up to 39 months were analysed. There was improvement >10 units (considered to be important for patients) during the first 6 months for appetite, insomnia, pain, fatigue, social function, physical function, emotional function and global health status, but no difference between the two arms. There was marked increased constipation in the thalidomide arm. The mean difference was 16 units. There was significantly less diarrhea in the thalidomide arm. For appetite, pain, insomnia, fatigue, cognitive function, physical function, role function, social function, emotional function and global quality of life, there were no or small differences of borderline significance. Questions specifically addressing polyneuropathy symptoms were not included in the questionnaire. The analysis was made on an intention to treat basis, but will also be analysed with respect to the actual treatment periods with thalidomide. The incidence of venous thromboembolism was 8 % in both treatment arms. There was no recommendation for prophylaxis for venous thromboembolism in the study. Approximately 30% of the patients used salicylates, warfarin or heparin for other reasons. *Conclusion*. there was a marked increase in constipation, but not in other symptoms in the thalidomide arm. There was improvement for appetite, insomnia, pain, fatigue, social function, physical function, emotional function and global health status during the first 6 months in both arms.

BORTEZOMIB (VEL) BASED REGIMENS IN MULTIPLE MYELOMA (MM) PATIENTS WITH RENAL IMPAIRMENT (RI): A PRELIMINARY RETROSPECTIVE ITALIAN MULTICENTER STUDY

M. Gentile,[1] S. Ciolli,[2] M.T. Petrucci,[3] S. Galimberti,[4] G Mele,[5] A.F. Casulli,[6] D. Mannina,[7] E. Piro,[8] F. Morabito[1]

[1]Ematologia di Cosenza, COSENZA; [2]Dipartimento di Ematologia, Università e Ospedale Careggi, FIRENZE; [3]Dipartimento di Biotecnologie e Ematologia, Università La Sapienza, ROMA; [4]Dipartimento di Oncologia, Sezione Ematologia, Ospedale Santa Chiara, PISA; [5]Divisione di Ematologia, Presidio Ospedaliero A. Perrino,BRINDISI; [6]Struttura Complessa di Ematologia, Azienda Ospedaliera SS.Annunziata, TARANTO; [7]Divisione di Ematologia, Azienda Ospedaliera Papardo, MESSINA; [8]Divisione di Ematologia Ospedale Pugliese Ciaccio, CATANZARO, Italy

Background. Up to 30% of newly diagnosed MM patients have a RI at diagnosis, remaining a common and severe complication throughout the course of disease. Vel alone or in combination has been shown to be active and well tolerated in both relapsed and newly diagnosed MM with varying degrees of RI. *Aims*. To assess the safety and efficacy of Vel containing regimen in MM patients with different degrees of RI. *Patients Methods*. Between November 2003 and January 2008, 64 patients, either untreated (14 pts), or relapsed/refractory (50 pts) after a median of 2 therapies (range1-4) and with RI (CrCl<80 mL/min) were analysed. Median age was 71 years (range 58-81); 39% were female. Isotypes were IgG 42%, light chain 33%, IgA 23%, IgD 2%. Vel-based regimens utilized were: Vel alone in 7 patients, Vel+Dex in 30, VTD (Vel+Dex+Thal) in 7, PAD (Vel+Dex+Pegylated liposomial doxorubicin) in 6 patients, PAD+Thal in 4, MPTV (Melphalan+Prednisone+Thal+Vel) in 2 and VMP (Vel+Melphalan+Prednisone) in 8. All patients received Vel (median dose 1.3 mg/m^2, range 0.8-1.3) for 4 doses per cycle, administered on days 1, 4, 8 and 11 every 3 weeks in all schedules but VMPT (days 1, 8, 15 and 22 every 5 weeks). RI was evaluated by CrCl, using the Cockcroft-Gault formula, and cases were clustered accordingly into 3 subgroups: CrCl 51-80, 30-50 and <30 ml/min, corresponding to mild (9 pts, 14%), moderate (21 pts, 33%) and severe (34 pts, 53%) RI, respectively. Eight patients required dialysis. *Results*. A total of 332 cycles of Vel were administered with a median number of 5. Seven patients (11%) discontinued therapy (6 refractory and 1 relapsed) for WHO grade 4 neuropathy in 4 pts, diarrhoea in 1, pneumonia in 1, cardiotoxicity in 1. The rate of therapy discontinuation was 18%, 5%, 0% for severe, moderate and mild RI subgroups, respectively (p=ns). Fifteen patients (23%) required a Vel dose reduction (9 with severe and 6 with moderate RI). Overall 65 episodes of WHO grade III/IV toxicity were observed: 17 were non-hematological (neuropathy in 5 pts, gastrointestinal complications in 5, infections in 5 and cardiotoxicity in 2), and 48 were haematological (anemia in 15 pts, neutropenia in 10 and thrombocytopenia in 23). A higher rate of haematological SAEs were observed in severe RI patients than in those with moderate and mild RI (91% *vs* 52% *vs* 66%; p=0.004). ORR (>PR) was 71% (44/62 evaluable pts). Namely, 13 patients (20%) achieved a CR, 4 (6%) a nCR, 9 (14%) a VGPR and 18 (28%) a PR. The ORR was similar across renal subgroups. Reversal of RI was documented in 29/62 cases (47%) after a median time of 2.4 months (range 0.5-7.9). In 2/8 dialysed patients renal replacement therapy was discontinued after 1 and 4 months. After a median follow-up of 12 months, 18 patients died. PFS was 61% at 1 year. *Conclusions*. Vel-based regimens are safe and active in MM patients, inducing an high ORR and a prompt reversal RI in roughly half cases. Thus Vel-based regimens should be considered appropriate treatment options for the MM who have any degree of RI, including those requiring dialysis.

A MULTICENTER COMPARISON OF AUTOLOGOUS STEM CELL TRANSPLANTATION FOLLOWED BY REDUCED-INTENSITY ALLOGENEIC STEM CELL TRANSPLANTATION WITH TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA :THE KOREAN MULTIPLE MYEOMA WORKING PARTY (KMMWP)

C.K. Min,[1] H. Kim,[2] K. Kim,[3] J.Y. Kwak,[4] S.T. Lee,[5] J.H. Won,[6] S.S. Yoon,[7] J.H. Lee,[8] C. Suh[9]

[1]St. Mary's Hospital, The Catholic University of Korea, SEOUL; [2]Ulsan University Hospital, University of Ulsan College of Medicine, ULSAN; [3]Sungkyunkwan University School of Medicine, SEOUL; [4]Chonbuk National University Medical School, JEONJU; [5]Yonsei University College of Medicine, SEOUL; [6]Soon Chun Hyang University Hospital, SEOUL; [7]Seoul National University College of Medicine, SEOUL; [8]Gachon Medical School, INCHEON; [9]Asan Medical Center, University of Ulsan College of Medicine, SEOUL, South-Korea

Background. Autologous stem-cell transplantation (ASCT) after high-dose chemotherapy is regarded as the standard therapeutic approach for younger patients with multiple myeloma (MM) even if virtually all patients ultimately relapse following this procedure. Recently, tandem ASCT significantly improved overall survival (OS) and event-free survival (EFS) compared with single ASCT. Another strategy is to use reduced-intensity allogeneic stem cell transplantation (RISCT) earlier in the course of disease in chemosensitive patients. *Aims.* we retrospectively compared the outcomes after a planned tandem ASCT or RISCT in the patients who previously underwent ASCT. *Methods*. One-hundred twenty-six patients who received a high dose (140 to 200 mg/m^2) of melphalan as the conditioning regimen of the first ASCT were analyzed. Ninety-six patients (median age, 50.5 years) received a second ASCT, whereas 30 patients (median age, 46.5 years) underwent a RISCT (related in 28 patients and unrelated in 2 patients). The median interval between the first and second transplant was 131 days in ASCT group and 157.5 days in the RISCT group. The conditioning regimen for the tandem ASCT and RISCT consisted of high-dose melphalan±total body irradiation (TBI) and fludarabine + melphalan or TBI, respectively. The two groups were evenly matched with regard to other disease characteristics. *Results*. After a median follow-up of 664 days (range, 143-2904) from the first ASCT, the median event-free survival (EFS) and overall survival (OS) in all 126 patients were 878 days and 1838 days, respectively. The median EFS in the second ASCT *vs* RISCT group were 844 days (95% CI, 714-973) and 1342 days (95% CI, 813-1870), respectively (p=0.262). The median OS in the tandem ASCT *vs* RISCT group were 2160 days (95% CI, 1847-2832) and 1575 days (95% CI, 1202-1947), respectively (p=0.132). Disease-related mortality was not significantly different between the second ASCT *vs* RISCT groups (73.3% *vs* 60.0%, p=0.325) as well as treatment-related mortality between the 2 groups (26.7% *vs* 40%, p=0.358). On multivariate analysis, an achieving a good response (≤ VGPR) after the induction treatment predicted a better EFS compared to a poor response (≤ PR) (RR; 0.245, p=0.01). A good response after first ASCT or the second transplant was associated with a better EFS by univariate analysis but not by multivariate analysis (RR; 0.927, p=0.830 or RR; 0.772, p=0.453, respectively). *Conclusion*. In this retrospective analysis, ASCT followed by RISCT was not superior to the tandem ASCT, either EFS or OS. Disease-related deaths were not different between the 2 groups. Patients whose disease is sensitive to chemotherapy and who obtain a good response after induction treatment benefited the most from this tandem transplant therapy.

0212

INFLUENCE OF GLUCOCORTICOID RECEPTOR POLYMORPHISM G+647C ON EFFICACY OF VAD AND VD THERAPY IN PATIENTS WITH MULTIPLE MYELOMA

N.V. Stepanova, A. Voitovich, V. Larionova, S. Moiseev

St.-Petersburg State Medical University, SAINT-PETERSBURG, Russian Federation

Polymorphisms and mutations glucocorticoid receptor gene may be associated with an altered sensitivity to glucocorticoids in patients with lymphoid neoplasms. Efficacy of VAD therapy in dependency of polymorphisms G+647C glucocorticoid receptor gene (2 intron) was evaluated in 38 patients with multiple myeloma II-III stages. Patients received 4-6 courses of VAD therapy as first line therapy. Polymorphism glucocorticoid receptor gene was evaluated by PCR-RFLP analysis. CC genotype was revealed in 12 (38%), CG genotype - in 21 (55%), GG genotype - in 5 (13%) patients with multiple myeloma. Distribution of these polymorphisms in patients with multiple myeloma did not differ from distribution in population of St-Petersburg. Efficacy of VAD therapy in patients with multiple myeloma was dependent on glucocorticoid receptor G+647C polymorphisms. Uneffectiveness of therapy (progression disease) was revealed in 4 (19%) patients with CG genotype, in 4 (36%) patients with CC genotype and in 5 (100%) c GG genotype. Complete remission (CR) was received in 5 (24%) patients with CG genotype. None of the patients with CC and CG genotype reached CR. Not complete response (near CR, partial remission, minimal response, stabilization disease) was received in 12 (57%) patients with CG genotype, 7 (64%) patients with CC genotype and in none of the patients with GG genotype. 13 patients with multiple myeloma after ineffective VAD therapy as second line therapy received treatment by VD therapy (velcade (bortezomib) 1,3 mg/m^2 at 1, 4, 8, 11 days and dexametazone 20 mg at 1,2, 4,5, 8,9, 11,12 days every over 10 days). Patients received 8 such courses. 6 (46%) patients reached CR, 1(8%) patient - near CR, 2 (15%) - partial remission, 2 (15%) - stable disease, 2 (15%) - progression disease. Efficacy of velcade was not dependent on G+647C polymorphisms of glucocorticoid receptor gene (2 intron). Preliminary results may indicate that G+647C polymorphisms of glucocorticoid receptor gene influence on efficacy of VAD therapy but not influence on efficacy of therapy by velcade + dexametazone.

0213

MELPHALAN, PREDNISONE AND LENALIDOMIDE FOR NEWLY DIAGNOSED MYELOMA: KINETICS OF NEUTROPENIA/THROMBOCYTOPENIA AND TIME TO EVENT RESULTS

A. Palumbo,[1] P. Falco,[1] P. Corradini,[2] C. Crippa,[3] F. Di Raimondo,[4] A. Falcone,[3] N. Giuliani,[5] P. Musto,[6] P. Pregno,[7] G. Aitoro,[8] A. Luraschi,[9] A. Nozza,[10] R. Knight,[11] J.B. Zeldis,[11] M. Boccadoro,[1] M.T. Petrucci[3]

Background. Melphalan, prednisone and lenalidomide (MPR) has shown significant anti-myeloma activity in newly diagnosed myeloma patients. In a phase I/II study, neutropenia and thrombocytopenia were the most frequent adverse events while non-hematologic toxicities were infrequent. *Aims*. We analyzed the kinetics and risk factors for neutropenia and thrombocytopenia in newly diagnosed myeloma patients who received MPR at the maximum tolerated dose of melphalan (0.18 mg/Kg) and lenalidomide (10 mg/day). Efficacy end-points were also analysed. *Methods*. Twenty-one patients (median age 69 years) received lenalidomide (10 mg/day for 21 days) plus melphalan (0.18 mg/kg for 4 days) and prednisone (2 mg/kg for 4 days) every 4 weeks for a maximum of 9 cycles, followed by maintenance with lenalidomide alone (10 mg/day for 21 days every month). The occurrence of grade-3 neutropenia required G-CSF administration. The occurrence of grade-4 neutropenia despite G-CSF administration or any other grade-4 hematological toxicities required withholding of treatment and subsequent dose reduction at the start of the following cycle. A new cycle was allowed if the neutrophil count was >1x109/L and platelet count >50x109/L. A delay of 2 weeks was allowed, a delay beyond 2 weeks required dose reduction and a delay beyond 4 weeks required therapy discontinuation. *Results*. Grade-3 neutropenia was reported in 38.1% of patients, grade-4 neutropenia in 14.2% of patients, but febrile neutropenia was 9.5%. G-CSF was administered in 42.3% of patients. The mean neutrophil count at the start of each MPR cycle was 2.69×10^9/L (SD 1.4). The mean neutrophil count at nadir (day 15-21) of each cycle was 1.43×10^9/L (SD 1.0). The incidence and depth of neutropenia did not increase with the number of cycles. The mean neutrophil count during maintenance was 2.11×10^9/L (SD 1.0). Grade-3 thrombocytopenia was recorded in 14.2% of patients and grade-4 thrombocytopenia in 9.5%; one patient required platelet transfusion. The mean platelet count at the start of each MPR cycle was 174×10^9/L (SD 63.9). The mean platelet count at nadir (day 15-21) of each cycle was 121×10^9/L (SD 56.3). Thrombocytopenia was more pro-

nounced after the 9 MPR cycles. The mean platelet count at the end of the 9 cycles was 109×10^9/L (SD 53). The mean platelet count after 6 months of lenalidomide maintenance therapy was 158×10^9/L (SD 79.2). One patient reduced the dose of lenalidomide for severe neutropenia. Three patients discontinued therapy for severe thrombocytopenia and neutropenia. Grade 3-4 hematologic toxicity was more frequent in patients with low baseline neutrophil count and in those with Bence-Jones myeloma. More frequent grade-3/4 non-hematologic adverse events were febrile neutropenia (9.5%), cutaneous reaction (9.5%), thromboembolism (4.8%). After a median follow-up of 29.5 months, the median time-to-progression was 28.5 months, the median progression-free survival was 28.5 months and the 2-years overall survival was 90.5%. No death was reported in the first 18 months of treatment. *Conclusions*. Oral MPR is a promising first line treatment for elderly myeloma patients. Hematologic adverse events were frequent but manageable with the use of G-CSF.

0214

A PILOT STUDY TO EXPLORE THE TOLERABILITY AND EFFICACY OF THALIDOMIDE CONTAINING REGIMENS TO REDUCE TUMOUR CELL LOAD PRIOR TO AUTOLOGOUS TRANSPLANTATION IN MULTIPLE MYELOMA (MM)

N. Horvath,[1] D. Joshua,[2] J. Gibson,[2] A. Roberts,[3] J. Norman,[4] C. Underhill,[5] C. To,[1] L.B. To[1]

[1]IMVS, ADELAIDE; [2]Institite of Haematology. Royal Prince Alfred Hospital, SYDNEY; [3]Hepartment of Haematology, Royal Melbourne Hospital, MELBOURNE; [4]The Queen Elizabeth Hospital, ADELAIDE; [5]Hume Regional Integrated Cancer Service, ALBURY-WODONGA, Australia

Background. In multiple myeloma thalidomide has been found to be effective therapy in relapsed/refractory disease. In the early 2000s little was known about the efficacy of thalidomide as part of first line therapy particularly its use as debulking therapy prior to autologous transplantation. *Aims.* To explore the role of thalidomide in pre-transplant induction treatment in MM. *Patients and methods*. Between Sept 2002 and Dec 2006, 48 patients with advanced, de-novo MM were entered into a multicentre, phase 2 study of pre-transplant induction treatment after voluntary informed consent had been obtained. The regimen included DTx3 (pulse dexamethasone 32 mg TDS x 5d every 3 weeks PO and thalidomide 400 mg/d), followed by DT-PACEx2 (thalidomide 400 mg/d, dexamethasone 40 mg/d x 4 PO and cisplatin 10 mg/m^2/d, doxorubicin 10 mg/m^2/d, cyclophosphamide 400 mg/m^2/day, etoposide 40 mg/m^2/d as 4 day infusion administered 4 weeks apart. Stem cells were harvested at recovery from DT-PACE. Paraprotein and BJP responses, rate of CR, VGPR and PR according to international uniform response criteria1, OS and EFS were compared to a historical cohort of 46 unselected patients for whom prognostic and survival data could be retrieved who had been treated with VAD (same dexamethasone scheduling), mobilised with HD cyclophosphamide + G-CSF and proceeded to HDT and ASCT.

Table 1. Comparison of response to trial therapy and VAD+HD

	Median percent paraprotein/BJP present after each phase of treatment		Percent of subjects achieving CR and VGPR after each phase of treatment			
Therapy	Para/ BJP %	p	CR %	p	CR+VGPR %	p
DTx3 all p	12	0.031	2	0.167	44	0.078
DTx3 Tx p n=28	9	0.034	4	0.333	43	0.085

VAD x3	26		9		24	

Results. One patient withdrew himself before commencing therapy and has been excluded from all evaluations. There was no significant difference between age and international staging score of the two groups of patients. 32 patients completed study treatment. 11 patients were withdrawn (9 for adverse events) and 2 died (1 sepsis, 1 haemorrhage) during DT phase. Three patients were withdrawn after DT-PACE 1 (2 for adverse events and 1 for poor response). 29 had successful stem cell harvests. 28 patients were transplanted after completing trial therapy. Table 1 shows the comparison of response to trial therapy and VAD + HD cyclophosphamide 69 serious adverse events included 25 episodes of infection, 3 haemorrhage, 1 pulmonary embolus, 2 deaths and 1 late myelodysplasia. OS and EFS of the 47 evaluable patients at 3 years were 79% and 36% respectively (medians NR and 29 months). OS of the 28 patients who proceeded through all of study therapy and were transplanted *vs* the 46 historical controls were 96% *vs* 76% at 3 years respectively, (medians NR and 76 months, p=0.06) and EFS were 36% *vs* 37% at 3 years respectively (medians 30 months and 28 months, p=0.89). *Conclusion*. 1) Thalidomide plus dexamethasone followed by DT-PACE is associated with tolerable but not insignificant toxicity. 2) Thalidomide plus dexamethasone combination achieves a greater depth of response than VAD. 3) The addition of DT-PACE improves the pre-transplant CR and VGPR rate. 4) In spite of the improved pre-transplant responses, no survival benefit, either OS or EFS, has been demonstrated. 5) We question the validity of pre transplant response as a surrogate marker for outcome in patients treated with novel agents.

Background. Effective reduction of myeloma before autologous stem cell transplantation (ASCT) prolongs survival in multiple myeloma patients. Recently, incorporation of novel agents resulted in improved response rate and reduced side effect in newly diagnosed multiple myeloma. *Aims.* We studied efficacy and safety of sequential VAD and VTD as induction chemotherapy. *Methods.* Patients are planned to receive 2 cycles of VAD (vincristine 0.4 mg D1-4, adriamycin 9mg/m^2 D1-4, dexamethasone 40 mg D1-4, 9-12 every 3 weeks), and VTD (bortezomib 1.3 mg/m^2 D1, 4, 8, 11, thalidomide 100 mg daily, dexamethasone 40 mg D1-4, 9-12 every 3 weeks). High dose melphalan (200 mg/m^2) is used as a conditioning regimen for ASCT. Bortezomib (1.3 mg/m^2) as a maintenance treatment is administered weekly x 4 times every 6 weeks for 4 cycles after ASCT. Response was assessed by EBMT criteria, with additional category of nCR. Adverse events were graded by the NCI-CTCAE, Version 3.0. *Results.* At this interim analysis, 60 patients have been entered into the ongoing trial, and efficacy could be assessed in 54 patients. After 2 cycles of VAD, response rate was 63%. After VTD, six patients showed further improvement with additional CR, and an overall response was 94% with 19% CR. Especially, patients with poor prognostic cytogenetics (n=7) all responded after VTD. So far, autologous stem cells were successfully collected in all 35 patients with a median CD34$^+$ count of 6.5×10^6/kg (range, 2.17-44.7$\times10^6$/kg). In

34 patients who underwent autologous stem cell transplantation, seven patients gained additional CR. Seventeen patients completed bortezomib maintenance, and CR rate was 65%. The median follow-up duration was 10 months, and median time to response was 1.4 months, and median overall survival was not reached. Grade 3,4 hematologic toxicity was more frequently observed after VAD than VTD (anemia 15.8%, 4.6%, neutropenia 7.9%, 4.2%), and incidence of grade 2,3 peripheral neuropathy after VAD was lower (VAD 3.5%, VTD 9.6%). There was no thrombosis after VTD. *Conclusions.* Sequential VAD and VTD induction therapy in newly diagnosed multiple myeloma was highly effective, even in patients with poor prognostic cytogenetics, and did not prejudice stem cell collection. VTD could have contributed to increased RR and minimized side effects. An updated results will be presented at the EHA meeting.

LONG-TERM OUTCOMES OF AUTOLOGOUS TRANSPLANTATION IN 141 MULTIPLE MYELOMA PATIENTS: A SINGLE CENTRE EXPERIENCE

M. Krejci,[1] R. Hajek,[2] Z. Adam,[2] A. Krivanova,[2] L. Pour,[2] K. Kresova,[2] M. Holanek,[2] V. Sandecka,[2] M. Sahmani,[2] J. Mayer,[2] J. Vorlicek[2]

[1]IHOK University Hospital Brno and IHOK LF MU Brno, BRNO, Czech Republic; [2]University Hospital Brno, BRNO, Czech Republic

Background. Autologous stem cell transplantation (ASCT) has an important role in the treatment of multiple myeloma (MM) patients (pts). In this report, we describe the long-term outcome of a cohort of 141 pts with newly diagnosed symptomatic MM treated with ASCT in a single institution, median follow-up from transplant was 8.4 years (range: 5.1-12.1). We have specifically analysed those factors that might predict for long-term survival. *Methods*. A total of 141 MM pts were transplanted in our centre between 1996 and 2002. The conditioning regimen was high dose melphalan (200 mg/m^2) in all pts. At diagnosis of MM 75% of pts (105/141) had stage III according to Durie-Salmon, 16% (23/141) II and 9% (13/141) I, clinical stages according to ISS were the following: stage 1 in 58/132 pts (44%), stage 2 in 54/132 pts (41%) and stage 3 in 20/132 pts (15%). Types of monoclonal immunoglobulin were as following: 61% (86/141) IgG, 21% (30/141) IgA, 14% (20/141) light chain, 1% (2/141) IgD, 2% (4/141) non-secretory myeloma. Renal insufficiency was presented in 11% of pts (15/141). Median age at transplantation was 55 years (range: 28-69). When the symptomatic relapse of MM after ASCT was occured, pts were treated by alone chemotherapy (81 cases) or chemotherapy with thalidomide or bortezomib (33 cases). The next transplantation was performed at 59 pts. *Results*. Following ASCT, overall response rate (ORR) was 90% (121/134), 26% of pts (35/134) were in CR, 43% of pts (58/134) were in VGPR, 21% of pts (28/134) in PR, only 10% of pts (13/134) had SD. Median TTP from start of treatment was 40.7 months, median OS was 72.6 months. Nineteen percent of pts (27/141) are alive and disease free, 23% of pts (33/141) are alive with relapse and 57% of pts (81/141) died with median follow-up 8.4 years from ASCT. The subgroup of living pts without relapse had ORR 100% with high CR rate: CR in 70% of pts (19/27), VGPR in 15% of pts (4/27), PR in 15% of pts (4/27). Cytogenetic examination was performed at 59% of pts without relapse (16/27), all pts had normal karyotype. Significant prognostic parameters for poor survival after ASCT were: age at transplant over 60 years (p= 0.003), renal impairment with serum creatinine over 2mg/dL (p= 0.014), clinical stage III according to ISS (P under 0.001) and no achievement of CR after ASCT (P under 0.001). The status of disease before ASCT and type of paraprotein did not significantly affect OS after ASCT. Type of treatment of symptomatic relapse was influenced OS, pts treated with next autologous transplantation had significantly longer survival than others (p=0.032), as well as pts treated with thalidomide or bortezomib in comparing pts treated chemotherapy only (p under 0.001). *Conclusion*. ASCT is effective procedure in MM patients. The achievement CR after transplantation, no presence of stage 3 according to ISS and treatment of posttransplant relapse with thalidomide or bortezomib are the most significant parameters for long-term surviving.

RETROSPECTIVE COMPARISON OF BORTEZOMIB WITH VINCRISTINE-DOXORUBICIN-DEXAMETHASONE (VAD) AS INDUCTION TREATMENT PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE MYELOMA

C.K. Min,[1] B,S. Cho,[1] S. Lee,[1] K.S. Eom,[1] J.W. Lee,[1] W.S. Min,[1] C.W. Park,[2] C.C. Kim[1]

[1]St. Mary's Hospital, The Catholic University of Korea, SEOUL, South-Korea; [2]Kangnam St. Mary's Hospital, The Catholic University of Korea, SEOUL, South-Korea

Background. High-dose therapy followed by autologous stem cell transplantation (ASCT) is the standard treatment option for the treatment of younger patients with multiple myeloma (MM). Patients achieving high-quality responses, as reflected by CR (complete response) and VGPR (very good partial response) after transplant benefit from ASCT. Induction pre-transplantation treatment with vincristine, doxorubicin, and dexamethasone (VAD) is currently being replaced by new targeted agents with high antimyeloma activity. The use of this novel agent may increase the CR/VGPR rate before ASCT, which may improve post-transplantation response and survival. *Patients and methods*. We performed a retrospective analysis of 72 patients with MM who consecutively received bortezomib-containing regimens (n=30) or VAD (n=42) before collection of peripheral blood stem cells and ASCT. The median age was 53 (34-65) years and 38 (52.8%) were male. The 2 groups were comparable with respect to the major presenting variables known to potentially affect clinical outcome. Patients with untreated (n=16) or previously treated MM (n=14) received bortezomib alone or in combination with the other chemotherapeutic agents. In 42 patients, vincristine and doxorubicin (by continuous infusion at the doses of 0.4 mg/d and 9 mg/m^2/d, respectively, on days 1 to 4) in combination with dexamethasone were administered every month. *Results*. Objective response (OR, at least PR) prior to ASCT was documented in 27 patients (90%) of 30 who were treated with bortezomib-containing regimens. Among 14 previously treated patients, 7 patients had received only one prior treatment before bortezomib and 7 patients as the third line or more. The corresponding figure among patients who received VAD was 33 (78.6%) of 42. The difference between the 2 groups was not significant (p=.2) However, the high-quality response rate with VGPR or more in the bortezomib group was significantly higher compared to the VAD group (66.7% *vs* 35.7%, respectively, p=.01). The difference between the 2 groups did not reach the level of statistical significance with respect to the response after ASCT (p=.122). After ASCT, all patients had a successful engraftment. There was no significant difference between the 2 groups with respect to the median number of CD34+ cells collected, the median time until neutrophil and platelet regeneration. The severe (grade 3 or more) toxicity of VAD was hematologic, particularly granulocytopenia, and infection; bortezomib-related toxicities were thromobocytopenia and peripheral neuropathy. One patient of the bortezomib group died from severe mucositis and gastrointestinal bleeding 41 days after ASCT; 1 of the VAD group died of penumocytis carinii pneumonia 101 days after ASCT. *Conclusion*. Results of this retrospective comparison of bortezomib-containing regimens with VAD regimen as induction treatment prior to ASCT for MM provided demonstration of the superiority of bortezomib therapy in terms of achievement of high-quality response. PBSC collection and engraftment following ASCT were not affected by bortezomib treatment. Bortezomib may be considered an effective therapy compared to the VAD regimen as front-line therapy for MM patients who are candidates for subsequent ASCT.

VTD (VELCADE, THALIDOMIDE, DEXAMETHASON) REPRESENTS AN ACTIVE INDUCTION REGIMEN FOR PATIENTS WITH MULTIPLE MYELOMA

W. Drach,[1] V. Odelga,[2] J. Ackermann,[2] V. Sagaster,[2] H. Kaufmann,[2] N. Worel,[3] W. Rabitsch,[4] P. Kalhs,[4] C. Zielinski[2]

[1]Medical University of Vienna, VIENNA, Austria; [2]Medical University of Vienna, Dept. of Medicine I, VIENNA, Austria; [3]Medical University of Vienna, Dept. of Blood Group Serology & Transfusion Med, VIENNA, Austria; [4]Medical University of Vienna, Bone Marrow Transplant Unit, VIENNA, Austria

Background. VTD was reported to be an active salvage regimen in patients with relapsed/refractory multiple myeloma (MM). Since initial results with VTD as frontline therapy were also promising, we used

VTD as induction treatment prior to autologous stem cell transplantation in MM patients (pts), particularly in patients with poor prognostic features and/or high tumor burden. *Methods*. Bortezomib (Velcade) was administered at 1.3 mg/m^2 on days 1, 4, 8, and 11; thalidomide was given at a daily dose of 100 mg; dexamethasone (20 mg orally) was given on days 1, 2, 4, 5, 8, 9, 11, and 12. Four to six cycles were scheduled every 3 weeks. Concomitant treatment included prophylaxis against deep vein thrombosis (low dose aspirin, 100 mg daily) and herpes zoster reactivation. *Results*. We here report our experience with 12 pts (7 males, 5 females; median age 50 years, range, 36 - 67 years) with newly diagnosed MM (3 pts had failed prior VAD or thal/dex) treated with VTD. Pts had a high tumor mass at presentation (for example, pt 1: Bence-Jones kappa MM with 95% plasma cell infiltration, serum free-kappa light-chains 4000 mg/l; pt 2: IgG-kappa MM with serum IgG > 9000 mg/dL, bulky plasmacytomas in the iliac bones; pt 3: IgA-lambda MM with 70% plasma cells in the bone marrow, IgA 4500 mg/dL, plasmacytoma in the os sacrum > 10 cm in diameter) and/or cytogenetic abnormalities associated with high-risk disease (deletion of chromosome 13q in 5 pts; amplification of 1q21 (CKS1B) in 4 pts; translocation t(4;14) in 1 pt). VTD resulted in a rapid response already after 1 cycle in 10 of the 12 pts (83%), 7 pts (58%) achieved a complete response (CR)/near CR, and 3 pts had a partial response (including one very good partial response). Only one pt experienced disease progression. Rapid tumor mass reduction was not associated with signs of tumor lysis, and two pts had a significant improvement in renal function (reversal from dialysis in one pt; serum creatinine down from 2.4 to 1.3 mg/dL). 5 pts have already completed G-CSF primed peripheral stem cell collection (2.4 - 7.9 CD34+ cells/kg body weight) and high-dose melphalan (MEL200) plus autologous stem cell transplantation (all 4 evaluable pts achieved a CR after completion of high-dose therapy). Toxicity of VTD was mild (Grade 1-2 gastrointestinal side effects and peripheral neuropathy; one episode of deep vein thrombosis). Updated results will be presented at the meeting. *Conclusions*.Induction treatment with VTD results in rapid tumor mass reduction and a high remission rate (83%) in MM pts even with poor prognostic features. Stem cell collection was not compromised after VTD suggesting that VTD is an effective and safe induction treatment prior to autologous transplantation in MM.

0219

VTD INDUCTION CHEMOTHERAPY FOLLOWED BY MPT MAINTENANCE AS A FIRST LINE TREATMENT FOR THE PATIENTS WITH MULTIPLE MYELOMA WHO ARE NON-TRANSPLANT CANDIDATES

H.S. Eom,[1] Y.K. Kim,[2] J.S. Chung,[3] K.H. Kim,[4] H.J. Kim,[5] J.Y. Jin,[6] Y.R. Do,[7] S.J. Oh,[8] H.Y. Kim,[5] C.W. Suh,[9] C.M. Seong,[10] C.S. Kim,[11] D.S. Lee,[12] J.H. Lee[13]

Background. Bortezomib, thalidomide, dexamethasone (VTD) and melphalan, prednisone, thalidomide (MPT) chemotherapies have been known to be active regimens in patients (pts) with multiple myeloma (MM). *Aims*. The objective of this study is to examine response and toxicities and to estimate survival of pts with VTD followed by MPT, who are non-transplant candidates with previously untreated MM. *Methods*. Total of 34 pts were enrolled and informed consent was obtained from March, 2006 through February, 2008 and this study is still ongoing. 14 pts were men and 20 pts were women. The median age was 67 years (range, 61-75 years) and median follow up was 10 months (range, 1-21 months). Pts received bortezomib 1.3 mg/m^2 on days 1, 4, 8, 11, thalidomide 100 mg daily, dexamethasone 40 mg on days 1-4 every 3 weeks for a maximum of 6 cycles of treatment, and thereafter melphalan 4 mg/m^2 on days 1-7, prednisone 40 mg/m^2 on days 1-7, thalidomide 100 mg daily every 4 weeks for a maximum of 12 cycles. *Results*. In 28 pts who completed at least first two cycles of VTD, 96% of them showed responses 18% CR, 4% nCR, 11% VGPR, 64% PR, 3% SD. 24 pts completed 4 cycles of VTD and all of them showed 100% response rates 42% CR, 17% nCR, 33% VGPR, 8% PR. 20 out of 21 who completed 6 cycles of VTD showed 95% responses 57% CR, 10% nCR, 19% VGPR, 10% PR. Also 12 pts who completed 4 cycles of MPT showed 83% responses 76% CR, 8% nCR, 8% VGPR, 8% PR. Among them, 4 pts who had nCR and VGPR at VTD obtained CR. This indicates MPT further improved response rate after VTD. One and half year PFS and OS were 65% and 73%, respectively. 15 pts (44%) stopped protocol therapy because of consent withdrawal (2 pts), death (7 pts), disease progression (2 pts) and severe adverse reaction (4 pts). The causes of death were infection-related in 5 pts who had been in remission. Other 2 pts were unknown etiology. Although peripheral neuropathy affected 88% of pts, only 12% of the pts were grade 3. The most common side effects of the chemotherapies greater than grade 3 were pneumonia (27%), herpes zoster (2%), asthenia (6%), diarrhea (9%), nausea (3%), thrombocytopenia (15%), neutropenia (15%) and anemia (12%). *Conclusions*. As first-line therapy, VTD followed by MPT showed high response rates and manageable toxicities for nontransplant candidates. Although high dropout rate was observed due to complications such as infection and neuropathies, treatment was well tolerated in the majority of the patients. *Protocol Number: ClinTrials.gov. NCT00320476

THADD REGIMEN IS FEASIBLE AND EFFECTIVE IN AN UNSELECTED MULTIPLE MYELOMA POPULATION AGED 75 OR MORE YEARS

M. Offidani,[1] L. Corvatta,[2] C. Polloni,[3] M.-N. Piersantelli,[3] S. Gentili,[3] P. Galieni,[4] M. Catarini,[2] A. Mele,[5] M. Brunori,[2] A. Samori,[2] G. Visani,[4] N. Blasi,[2] M. Ferranti,[2] F. Alesiani,[6] M. Burattini,[2] R. Centurioni,[2] P. Leoni[3]

[1]Clinica Ematologia, ANCONA, Italy; [2]Divisione Medicina, FABRIANO, Italy; 3Clinica Ematologia, Ospedali Riuniti Ancona, ANCONA, Italy; [4]Divisione Ematologia, ASCOLI PICENO, Italy; [5]Divisione Ematolgia, TRICASE, Italy; [6]Unità Oncoematologia, SAN SEVERINO MARCHE, Italy

Background. Although more than 20% of multiple myeloma (MM) patients aged over 75 years, no specific treatment can be considered the golden standard for this population. However, recent data have shown that the MPT combination is able to improve the outcome of very elderly patients with newly diagnosed MM. *Aims*. We conducted a retrospective study to assess the efficacy and toxicity profile with ThaDD combination for very elderly MM patients. *Methods*. Unselected patients 75 or more years old received thalidomide 100 mg continuously, pegylated liposomal doxorubicin 40 mg/m^2 on day 1 every 28 days, dexamethasone 40 mg on days 1-4 and 9-12. They also were given prophylaxis with warfarin 1.25 mg day and ciprofloxacin 250 mg twice daily. Forty patients with MM (27 newly diagnosed and 13 advanced) were considered for this analysis. Median age was 77 years (range 75-91), 30 patients (85%) had ISS equal or higher 2, 13 (33%) PS (ECOG) > 2 and 10 (25%) had renal failure. Unfavourable cytogenetics was present in 34% of patients with a valuable test. *Results*. Overall, 31 patients (77.5%) obtained at least PR. Four patients achieved a CR (10%), 13 VGPR (32.5%), 14 PR (35%). Moreover, 3 patients obtained a MR, 4 progressed and 2 died early. Of note, patients with newly diagnosed MM achieved a higher quality of response if compared with advanced disease (≥VGPR 52% *vs* 23%). With a median follow up of 24 months, median TTP was 19 months for newly diagnosed and 17 months for advanced MM patients, PFS was 17 and 13 months for *de novo* and advanced MM, respectively. Median OS was not reached in newly diagnosed MM patients (75% at 2 years) and 19 months in relapsed/refractory ones. Three patients (10%) stopped treatment due to toxicity (one pulmonary embolism, one cardiotoxicity and one liver toxicity). Thalidomide was withdrawal in 6 patients (15%), mainly due to thromboembolic events. Non hematologic side effects included ≥ grade 2 peripheral neuropathy (12.5%), grade 3 constipation (7.5%) and DVT (20%, one pulmonary embolism). Regarding hematologic toxicity, grade 3-4 thrombocytopenia was reported in 5% of patients and grade 3-4 neutropenia in 12.5% of patients. Grade 3-4 infections occurred in 4 (10%) of patients without related deaths. Compared with younger patients included in the same ThaDD protocol, no significant differences in terms of compliance, non hematologic and hematologic toxicities were observed. *Conclusions*. Our study shows that ThaDD regimen is a suitable therapeutic option also in very elderly MM patients.

0221

SEQUENTIAL THERAPY WITH VAD, BORTEZOMIB AND CYCLOPHOSPHAMIDE AS INDUCTION THERAPY FOR MULTIPLE MYELOMA: A SEQUENTIAL PHARMACOLOGIC COMBINATION TO ACHIEVE COMPLETE REMISSIONS BEFORE STEM CELL TRANSPLANTATION

M. Postorino,[1] L. Pupo,[1] L. Di Caprio,[1] S. Campagna,[1] L. Franceschini,[1] D. Renzi,[1] M. Rizzo,[1] L. Gianni,[1] S. Faccia,[1] R. Cannarsa,[1] M. Ales,[1] F. Buccisano,[1] D. Venditti,[1] M. Cantonetti,[2] S. Amadori[1]

[1]Tor Vergata University, ROMA; [2]Tor vergata university, ROMA, Italy

Background. Multiple Myeloma (MM) remains an incurable disease despite intensive therapy such as high-dose melphalan and autologous stem cell transplantation (ASCT), that remains ,however, the gold standard therapy for patients (pt) without allogeneic donor. In multivariate analysis achieving complete remission (CR) before ASCT is a significant independent variable for Overall Survival and Time to Progression. *Aims.* Following this assertion, in a preliminary and feasibility study, we tried to obtain the best response as soon as possible by the induction therapy with a combinated and sequential therapy with VAD, Bortezomib and Cyclophosphamide. In fact using VAD or Bortezomib based regimen alone we obtained Complete Remision (CR/nCR) in 15% and 35% respectively; instead in our opinion their sequential use could permit a better tumor mass reduction and the exploitation of synergic role of Bortezomib in front of chemotherapy. *Material and methods*. From September 06 to December 07 we enrolled 7 pts with untreated MM; median age was 44 years (34 - 66), M/F was 2/5; the M-protein type was IgG in 3 pts, IgA in 4 pts.; the stage was IIA, IIIA and III B in 2, 4 and 1 pts .respectively; all pts showed bone marrow plasmocitosys > 50% and 5/7 pts showed extensive bone disease. Cytogenetic data were unfavourable in 3/7 pts. Patients underwent to VAD regimen (Vincristine 2 mg and Adriamicine 40 mg/m^2 on day 1 and dexametasone 40 mg day 1-4) for 2 cycles (day 1 -21); 15 days after last therapy, pts started bortezomib regimen (1.3 mg /m^2 on day 1,4,8,11) for 3 cycles and 15 days after last dose pts received Cyclophosphamide 4 g/m^2 and G-CSF for stem cell harvesting. *Results*. All patients achieved the partial remission after VAD scheme, while CR was achieved in 6/7 patients post Bortezomib. After Cyclophosphamide six patients were in CR and one was in near CR . All pts mobilized stem cells and they reached target of CD34+ (10x106/kg) with one and two apheresis in 5 and 2 patients respectively .Toxicity was low and mainly consisted of neutropenia (WHO grade I-II in 15 % of pts) and mild peripheral neuropathy (WHO grade I in 20% of pts). Conclusion. Since our experience was a preliminary and feasibility study, we think that the sequential therapy with combination of VAD, Bortezomib and Cyclophosphamide could be highly effective as up-front therapy in patients with MM; moreover it is associated with low toxicity and results in an excellent stem cell harvesting.

0222

PROMISING THERAPY RESPONSE IN MULTIPLE MYELOMA PATIENTS TREATED WITH INDUCTION CHEMOTHERAPY CONSISTING OF BORTEZOMIB, DOXORUBICIN AND DEXAMETHASONE FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION

W. Zinke-Cerwenka,[1] T. Stojakovic,[2] H. Sill,[1] E. Eibl,[1] W. Linkesch[1]

[1]Division of Hematology, GRAZ; [2]Clinical Institute of Medical and Chemical Laboratory Diagnostics, GRAZ, Austria

Background. Induction chemotherapy followed by high dose melphalane and autologous stem cell transplantation (ASCT) is considered the standard treatment for patients with multiple myeloma. Incorporation of new agents like the proteasome inhibitor bortezomib (PS-341) in combination with doxorubicin and dexamethasone (PAD) increases response rates in induction therapy significantly and may also contribute to improved results after autologous transplantation. *Methods*. After 4 cycles of PAD stem cell mobilisation was performed successfully in 24 patients with newly diagnosed multiple myeloma. All patients but one qualified for ASCT by achieving at least SD. Another patient discontinued therapy before ASCT. Until now, 22/24 patients underwent ASCT after conditioning with melphalane 200mg/m^2. The pre-transplantation remission status (EBMT criteria) of these patients was: 2 CR, 8 nCR, 10 PR and 2 SD. Evaluation of treatment response was performed 3 months after ASCT. Maintenance therapy after transplantation with thalidomide was determined for all patients who achieved only SD or PR before ASCT. *Results*. Twenty-one patients could be evaluated; one did not reach the first evaluation point yet. According to EBMT criteria, 3 patients achieved CR, 12 nCR and 3 PR. One patient died of pneumonia and two patients showed progressive disease. The median follow-up after ASCT is 9 months (range: 3-25). *Conclusion*s. These preliminary data show that improved response rates after PAD induction may translate into improved CR/nCR rates after single ASCT.

A COMPARISON OF TWO CONDITIONING REGIMENS FOR MULTIPLE MYEOLOMA. A SINGLE CENTER EXPERIENCE

J. Peñarrubia,[1] R. Cuello,[2] A. Cantalapiedra,[1] A. Dueñas,[1] E. Fontecha,[1] O. Gutierrez,[1] A. Silvestre,[1] J.M. Martin-Antoran,[1] J. Fernández-Calvo,[2] J. García-Frade[1]

[1]Hospital del Rio Hortega, VALLADOLID, Spain; [2]Hospital Clínico, VALLADOLID, Spain

Background. Different conditioning regimens have been used in myeloma patients treated with autologus stem cell transplantation (ASCT), but none has shown a clear advantage over any other. *Aims.* To assess differences in efficacy and toxicity of two conditioning regimens for multiple myeloma. *Methods*. 36 consecutive myeloma patients (male/female = 19/17; age: median = 54 years, range=33-67) transplanted at our institution between April-96 and June-05 were analyzed. Thirty two patients received the alternating chemotherapeutic regimen VBMCP/VBAD as induction treatment, and the remaining 4 received VAD. All patients were transplanted as front line therapy, immediately after being administered chemotherapy. 21 received melfalan 200mg/m^2 divided in 2 consecutive days (MEL200) and 15 patients received busulfan 12 mg/kg divided in four consecutive days plus melfalan 140 mg/m^2 on the fifth day (BUMEL). *Results*. There were no differences between the 2 groups in patient characteristics both at diagnosis or at transplant. The number of CD34 cells infused (x10^6/kg) in each conditioning group was statistically similar: median (range), BUMEL 2.5 (1.6-4.3), MEL 200 2.35 (1.8-7.8) (p=0.25). After ASCT, granulocyte and platelet recovery were similar for both groups. Time to platelet recovery (20x10^9/L) was 11 days in both groups and time to reach 50x10^9/L/L was 14 days in BUMEL and 15 days in MEL200 (p=0.11). Median hospital stay was 14 days in both groups (p=0.16). No patient died in the first 100 days post-ASCT. Both regimens yielded a similar response in reference to pre-ASCT myeloma status. The 5-year overall survival was 66.7% in BUMEL and 53% in MEL200 (p=0.66). The 5-year event-free survival was 66% in BUMEL and 26% in MEL200 (See Graph). After a median follow-up of 50 months, the median event-free survival was not yet reached in BUMEL, whereas it was 33 months in MEL200. These differences in event-free survival were close to statistical significance (p=0.08). No differences in the type or severity of toxicities were noted. A case of mild veno-oclusive liver disease occured in BUMEL. *Conclusions*. Our data show a trend towards a better anti-myeloma effect for the BUMEL conditioning regimen Vs MEL200 that might reach statistical significance with a larger number of patients. There appears to be no clear-cut differences in toxicity. Further study is warranted to confirm these data.

Myelodysplastic syndromes - Clinical I

0224

EFFECT OF AZACITIDINE (AZA) *vs* LOW-DOSE ARA-C (LDAC) ON OVERALL SURVIVAL (OS), HEMATOLOGIC RESPONSE, TRANSFUSION INDEPENDENCE, AND SAFETY IN PATIENTS (PTS) WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (MDS)

P. Fenaux,[1] N. Gattermann,[2] J. Seymour,[3] E. Hellström-Lindberg,[4] G.J. Mufti,[5] U. Duehrsen,[6] S. Gore7, F. Ramos8, O. Beyne-Rauzy,[9] H. Dombret,[10] A. List,[11] D. McKenzie,[12] J. Backstrom,[12] A. Allen,[12] C.L. Beach[12]

[1]Hôpital Avicenne, BOBIGNEY, France; [2]Heinrich-Heine-University, DÜSSELDORF, Germany; [3]Peter MacCallum Cancer Centre, EAST MELBOURSE, Australia; [4]Karolinska University Hospital, STOCKHOLM, Sweden; [5]King's College London, LONDON, UK [6]University Hospital Essen, ESSEN, Germany; [7]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, BALTIMORE, USA; [8]Servicio de Hematología, Hospital de León, LEÓN, Spain [9]Chu Purpan, TOULOUSE, France; [10]Hôpital Saint-Louis (APHP), PARIS, France; [11]Moffitt Cancer Center, TAMPA, USA; [12]Pharmion Corporation, OVERLAND PARK, USA

Background. LDAC is often used to treat MDS although no survival advantage has been established, and pts must be monitored carefully for myelosuppression (UK MDS Guidelines Group, Br J Haematol 2003;120:187). The large randomized phase III trial (AZA-001) confirmed AZA as the first MDS treatment to significantly prolong OS in higher-risk MDS pts compared with 3 conventional care regimens (CCR), including LDAC (*Fenaux, Blood 2007;110:Abstract 817*). *Aims*. To assess OS, hematologic response, transfusion independence, and safety in a subgroup analysis comparing pts receiving AZA *vs* LDAC. *Methods*. Higher-risk MDS pts (FAB: RAEB, RAEB-T, CMML; IPSS: Int-2, High) were enrolled. Before randomization, investigators selected 1 of 3 CCR (best supportive care, LDAC [20 mg/m^2/d x 14d every 28 days for ≥4 cycles], or intensive chemotherapy) for all pts. Then, if randomized to AZA, pts received AZA (75 mg/m^2/d SC x 7d every 28 days for ≥6 cycles) regardless of investigator selection; if randomized to CCR, pts received their investigator-selected treatment. All regimens were continued until study end, relapse, progression, unacceptable toxicity, or AML transformation. For this subgroup analysis, OS, hematologic response (IWG 2000), and transfusion independence (≥56 days) were compared between the AZA and LDAC groups This was an intent-to-treat analysis based on all randomized pts using Cox proportional hazard modeling stratified by IPSS and FAB subtypes, adjusting for baseline ECOG, RBC transfusions, FAB subtype, presence of -7/del(7q), LDH, and hemoglobin. Median OS was analyzed using Kaplan-Meier methods. Treatment by investigator-selection interaction was included in the model. Erythropoiesis-stimulating agents were not allowed. All pts gave informed consent.

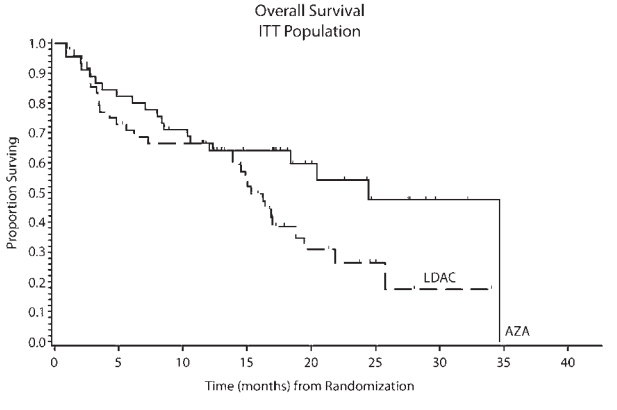

Figure 1.

Results. There were 94 pts selected by investigators to receive LDAC. Per randomization, 45 received AZA and 49 LDAC. Baseline characteristics were similar between the AZA and LDAC groups, respectively, e.g., median age: 69 years (42-82) *vs* 71 years (56-85); cytogenetics: intermediate (16% *vs* 25%), poor (29% *vs* 16%); IPSS: High (42% *vs* 43%); FAB classification: RAEB (60% *vs* 51%), RAEB-T (33% *vs* 39%). AZA was administered for a median of 9.0 (1-39) cycles, LDAC for 4.5 (1-15) cycles. More early discontinuations due to withdrawal of consent, adverse events, or progression were observed in the LDAC group (67%) *vs* the AZA group (39%). Median OS was 24.4 months (95% CI: 12.0-34.7) *vs* 15.3 months (95% CI: 13.9-18.8) in the AZA and LDAC groups, respectively (hazard ratio: 0.38 (95%CI: 0.21-068, p=0.001, Figure 1). The OS advantage with AZA *vs* LDAC, respectively, was supported by CR+PR rates (31% *vs* 12%, p=0.042), HI rates (major+minor: 53% *vs* 25%, p=0.006), and transfusion independence in baseline-dependent pts (45% *vs* 13%, p=0.011). Higher rates of grade 3-4 anemia were seen in the LDAC group (14%) *vs* the AZA group (7%). Rates of thrombocytopenia were similar. Deaths during study were higher in the LDAC group *vs* the AZA group: 59% *vs* 45%, respectively. *Summary/conclusions*. AZA significantly prolongs OS with a 62% reduced risk of death *vs* LDAC. The OS advantage with AZA was supported by significant improvements in hematologic response and improvement, and transfusion independence. AZA should be considered first-line therapy compared with LDAC in higher-risk pts with MDS.

0225

A PHASE II STUDY OF OUTPATIENT ADMINISTRATION OF DECITABINE FOR 5 DAYS EVERY 4 WEEKS TO ADULTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

P. Steensma,[1] M. Baer,[2] J. Slack,[1] R. Buckstein,[3] L. Godley,[4] J. Larsen,[5] M. Cullen,[5] S. Arora,[5] H. Kantarjian[6]

[1]Mayo Clinic, ROCHESTER, MN, USA; [2]Roswell Park Cancer Institute, BUFFALO, NY, USA; [3]Toronto Sunnybrook Regional Cancer Centre, TORONTO, ON, Canada; [4]University of Chicago, CHICAGO, IL, USA; [5]MGI Pharma, BLOOMINGTON, MN, USA; [6]MD Anderson Cancer Center, HOUSTON, TX, USA

Background. Decitabine, a DNA-targeted hypomethylating agent, is FDA-approved for treatment of patients with all FAB subtypes of MDS. An overall improvement rate of 30% in MDS patients (complete responses [CR] + partial responses [PR] + hematologic improvements [HI]) was reported with the approved dosing regimen of 15 mg/m^2 intravenously over 3 hours every 8 hours for 3 days, repeating every 6 weeks. An off-label regimen, in which decitabine is administered 20 mg/m^2 IV over 1 hour once daily for 5 consecutive days repeating every 4 weeks, permits the use of decitabine as outpatient therapy. The 5-day regimen showed promising efficacy in an initial trial (Blood. 2007;109:52), with 39% CR using the International Working Group [IWG] 2006 criteria. *Aims*. This multicenter, open-label, single-arm study evaluated the efficacy and safety of the 5-day decitabine dosing regimen in patients with all FAB subtypes of MDS. *Methods*. Eligible patients were enrolled at 28 sites in the USA and Canada. Inclusion criteria were ≥18 years of age, *de novo* or secondary MDS (including CMML with white count <12,000/mL), and International Prognostic Scoring System (IPSS) score ≥0.5. All patients received decitabine 20 mg/m^2 IV over 1 hour x 5 days, with cycles repeated every 4 weeks. The primary endpoint was overall response, assessed by both the IWG 2000 criteria (available at the time of study initiation and used to aid comparison with the approved 3-day dosing regimen), and with updated IWG 2006 criteria. *Results*. Ninety-nine patients enrolled: median age 72 years, 72% male, 89% *de novo* MDS, median time from diagnosis 22 weeks, and 27% with prior therapy for MDS. FAB classification was: RA, 20%; RARS, 17%; RAEB, 45%; RAEB-T, 6%; and CMML, 11%. This report includes data through 15 months after enrollment of the last patient. Patients received a median of 5 cycles of decitabine (range 1-20), with 38% of patients receiving ≥8 cycles. All 5 doses of decitabine were administered during 98% of cycles. Overall improvement rate in the intent-to-treat population was 43% by the IWG 2000 criteria (CR+PR+HI). Using the IWG 2006 criteria, the improvement rate was 51% overall (17% CR, 15% mCR and 18% HI). Median time to improvement (IWG 2006 criteria) was 1.7 months and 82% of patients that improved did so by Cycle 2. Median survival was 19.6 months and the 1-year survival rate was 66%. The most frequently observed grade 3 or higher adverse events attributed to the study drug were neutropenia (31%), thrombocytopenia (18%), febrile neutropenia (14%), anemia (12%), pneumonia (11%), and fatigue (5%). *Summary and Conclusions*. Administration of decitabine on the alternative 5-day dosing schedule in the outpatient setting demonstrated prompt clinical activity with a manageable toxicity profile, suggesting that both the approved 3-day regimen and this alternative 5-day regimen provide meaningful clinical benefit to patients with MDS.

0226

WELL-DIFFERENTIATED SYSTEMIC MASTOCYTOSIS (WDSM): A NOVEL FORM OF MASTOCYTOSIS

M. Jara-Acevedo,[1] A.C. García-Montero,[1] C. Teodosio,[1] L. Escribano,[2] I. Alvarez,[3] L. Sanchez-Muñoz,[4] C. Akin,[5] D.D. Metcalfe,[6] A. Orfao[1]

[1]Cancer Research Center, SALAMANCA, Spain; [2]Centro de Estudios de Mastocitosis de Castilla La Mancha, TOLEDO, Spain; [3]Centro de Estudios de Mastocitosis de Castilla la Mancha, TOLEDO, Spain; [4]Centro de Estudios de Mastocitosis de Castilla la Manca, TOLEDO, Spain; [5]Allergy and Clinical Immunology, University of Michigan, ANN ARBOR, USA; [6]Laboratory of Allergic Diseases, NIAID, NIH, BETHESDA, USA

Background. Mastocytosis are a heterogeneous group of disorders characterized by an abnormal expansion and accumulation of mast cells (MC) in one or more tissues. In 2001, the World Health Organization (WHO) proposed a combination of major and one minor criteria, or at least three minor criteria, for the diagnosis of systemic mastocytosis (SM). Major criteria was defined as presence of dense infiltrates of >15 MC in bone marrow (BM) and/or other extracutaneous organs. Minor criteria include, 1) dense infiltrates with >25% of MC showing abnormal morphology; 2) presence of KIT mutation at codon 816; 3) aberrant expression of CD2 and/or CD25 in BM MC; and 4) serum total tryptase >20ng/mL. However, a variable percentage of patients that present SM clinical-biological symptoms do not fulfill the SM WHO criteria. In 2004, a case of a novel form of mastocytosis-Well Differentiated Systemic Mastocytosis (WDSM)-was described; but so far the clinical-biological features of this type of SM have not been established. *Aims*. We propose to define the clinical-biological characteristics and the diagnostic criteria of this new subtype of SM. *Methods*. The study was performed at the reference centers of the Spanish Network on Mastocytosis (REMA) in a series of 14 selected patients (3M/11F) that could be included in the WDSM subtype. In addition, data from 3 patients were referred from the University of Michigan. *Results*. Only 9 patients fulfilled the WHO criteria for SM. 16 patients fulfilled the major criteria, but none showed >25% of MC with abnormal morphology. Typical KIT mutation (D816V) was found only in one patient, but 3 patients displayed other KIT mutation (I817V, N819Y and F522C). No aberrant CD2 and/or CD25 expression was found in BM MC, except for a case that displayed a dim CD2 expression in all MC and other 3 patients presenting weak CD25 expression restricted to a MC sub-population. High serum tryptase levels were persistently detected only in 5 patients. Apart from the WHO criteria, all patients showed typical skin lesions and hypergranulated MC. MC clonality was demonstrated by HUMARA test in all 7 female patients analyzed. Comparison of clinical characteristics observed in WDSM patients with those from 132 patients diagnosed with Indolent Systemic Mastocytosis (ISM), showed an earlier -pediatric- onset in WDSM patients (median 5 years old *vs* 29 years old in ISM). Interestingly, WDSM group showed neither anaphylactic episodes nor neuropsychiatry symptoms, whereas in ISM their frequency was 46% and 26%, respectively. Higher BM MC load was found in WDSM (median 0.11%) *vs* ISM (median 0.06%), while serum tryptase levels were lower in WDSM (median 12 ng/mL vs 29 ng/mL). *Conclusions*. WDSM is a subtype of mastocytosis with pediatric onset that typically shows mature large hypergranulate BM MC, absence of D816V KIT mutation, absence or dim expression of CD2 and/or CD25, and low serum tryptase levels. Despite presenting systemic involvement (BM and skin affectation), WDSM patients were not well classified using the actual SM diagnostic criteria (WHO criteria).

0227

5-AZA-2'-DEOXYCYTIDINE CAN INDUCE DIFFERENTIATION OF CLONAL ABNORMAL PROGENITOR CELLS FROM PATIENTS WITH MYELODYSPLASTIC SYNDROMES WITHOUT INDUCTION OF APOPTOSIS

S. Meers,[1] P. Vandenberghe,[1] M. Boogaerts,[1] G. Verhoef,[1] C. Verfaillie,[2] M. Delforge[1]

[1]University Hospital Leuven, LEUVEN, Belgium; [2]Stem Cell Institute, LEUVEN, Belgium

Background. The methyltransferase-inhibitors 5-azacytidine (AZA) and 5-aza-2'-deoxycytidine (DAC) are changing the treatment of high-risk myelodysplastic syndromes (MDS). To date, two major mechanisms of action have been postulated. One mechanism is selective induction of apoptosis in the abnormal progenitor cells allowing outgrowth of remnant normal progenitors. Alternatively, treatment with methyltransferase-inhibitors could (re-)induce differentiation of abnormal progenitors as they have been shown to do in leukemic cell lines. *Aims*. This study was designed to evaluate the *in vitro* effects of DAC and AZA on purified CD34$^+$ cells from patients with MDS and AML. We evaluated the effects of these drugs on (1) the viability and (2) the clonogenic capacity of CD34$^+$ cells. (3) In progenitor cells showing increased proliferation after treatment with DAC or AZA we determined their clonal origin. *Methods*. Bone marrow CD34$^+$ cells from 17 patients (11 MDS, 6 AML) and 11 healthy controls were purified using MACS columns and subjected to different concentrations of DAC (0.5 and 1.0 μM) and AZA (2.5 μM and 5 μM). After 24h, 48h and 72h, the cells were harvested and assessed for viability with trypane blue staining. Subsequently, equal numbers of living cells were cultured in standard clonogenic assays for 14 days. Single hematopoietic colonies were plucked from the methylcellulose medium to be evaluated with FISH. *Results*. (1) Incubation with DAC did not significantly influence the viability of primary bone marrow CD34+ cells from healthy controls. Similar results were found in progenitor cells from MDS patients. In contrast, we noted more apoptotic CD34+ cells from AML patients in the presence of DAC. The concentrations of AZA in this study lead to an increase in cell death in donors as well as in patients. (2) DAC did not significantly influence the number of colonies produced by normal CD34+ cells. In contrast, the concentrations of AZA we used lead to reduced number of colonies and especially the number of BFU-E. The number of colonies in cultures from AML-derived CD34$^+$ cells was low and was not significantly altered by previous culture with AZA or DAC. Only in 1 patients with RARS pre-culture of the CD34$^+$ cells for 72h with DAC resulted in a higher number of mature colonies and this was observed with 2 different concentrations of DAC. (3) This patient with RARS was known with the cytogenetic abnormality 45, X, -Y, DEL(1)(P12P33) (2 of 10 metaphases, others being 46,XY). We randomly picked 10 colonies from the 3 conditions (0, 0.5 μM and 1.0 μM DAC) and analyzed these colonies with FISH. All colonies were found to be derived from the abnormal clone. *Summary/conclusions*. Methyltransferase-inhibitors are increasingly used in the treatment of high-risk MDS. Our *in vitro* study suggests that differentiation-induction of abnormal progenitor cells rather than selective induction of apoptosis of these cells is responsible for their effect in MDS.

0228

IRON CHELATION THERAPY WITH DEFERASIROX (ICL670) REDUCES SERUM FERRITIN (SF) AND LABILE PLASMA IRON (LPI) IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

A.F. List,[1] M.R. Baer,[2] D. Steensma,[3] A. Raza,[4] J. Esposito,[5] J. Virkus,[5] J. Feigert,[6] E. Besa,[7] C. Paley[5]

[1]University of South Florida, TAMPA, USA; [2]Roswell Park Cancer Institute, BUFFALO, USA; [3]Mayo Clinic, ROCHESTER, USA; [4]Univerisity of Massachusetts, MASSACHUSETTS, USA; [5]Novartis Pharmaceuticals Corporation, EAST HANOVER, USA; [6]Arlington Fairfax Hematology/Oncology, ARLINGTON, USA; [7]Thomas Jefferson University, PHILADELPHIA, USA

Background. Transfusion-dependent patients with MDS may benefit from iron chelation therapy to prevent the morbidity and mortality associated with iron overload. The once-daily oral agent, deferasirox, has demonstrated efficacy and tolerability in patients with MDS. Here we report 12-month data from the US03 trial in patients with MDS treated with deferasirox. *Aims.* To evaluate the long-term efficacy and safety of deferasirox in patients with lower-risk MDS in study US03, an ongoing, Phase II, open-label, 3-year trial. *Methods*. Patients enrolled had Low- or Int-1 IPSS risk MDS, transfusional iron overload (SF ≥1000 μg/L and >20 units RBC transfusions), and serum creatinine (SCr) 2-fold the upper limit of normal (ULN). Deferasirox was initially dosed at 20 mg/kg/day, and could be increased to 40 mg/kg/day based on tolerability and response. SF was monitored monthly; LPI, the reactive species of non-transferrin-bound iron, was assessed quarterly. *Baseline results*. In 173 patients (102 men, 71 women) with a mean age of 70 years (range 21-90), IPSS risk groups were Low (46 patients; 27%), Int-1 (123; 71%) and other (four; 2%). Baseline parameters were: SF 3398 μg/L (863-36,280); LPI 0.4 μmol/L (0.0-3.6); mean lifetime transfusions prior to study 63; years of prior transfusions 3.5 (0-34). MDS therapy at study entry included: chemotherapy 22 patients; growth factors 46. Estimated creatinine clearance: normal (>80 mL/min) 77 patients; mild impairment (51-80 mL/min) 68; moderate impairment (30-50 mL/min) 25; severe impairment (<30 mL/min) two. Forty percent of patients had elevated LPI (≥0.5 μmol/L). Efficacy: Fifty-three patients have reached the 12-month treatment milestone in this ongoing trial. Over 12 months, the mean dose was 21 mg/kg/day and mean transfusion rate was 4.1 units/month. Mean SF±SD (μg/L) values were: baseline 3398±3088; 3 months 3065±1743; 6

months 2775±1355; 9 months 2759±1562; 12 months 2603±1336 (Figure 1). Sustained suppression of mean LPI to the normal range was achieved after 3 months' treatment (Figure 1).

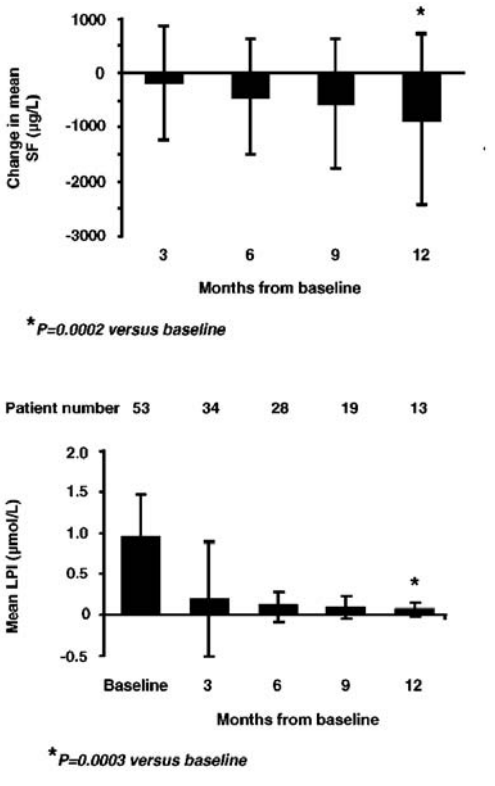

Figure 1.

Safety. Of 165 patients, 10 (6%) discontinued secondary to suspected adverse events (AEs), and seven (4%) serious AEs. There were 11 deaths (7%), all unrelated to deferasirox. Of 140 patients with normal baseline SCr, 35 (25%) increased >ULN (2.2 mg/dL max SCr). SCr increased >33% above baseline in 11 patients (8%) with abnormal SCr at baseline. Thrombocytopenia developed in 22 patients (13%) and neutropenia occurred in 52 (32%). Development of cytopenia was consistent with hematologic progression of MDS. *Summary and Conclusions*. Twelve months' treatment with deferasirox in these patients with MDS and elevated SF decreased mean SF by 859±1548 µg/L and normalized trough LPI in all patients, indicating 24-hour sustained suppression. A high baseline SF may also have contributed to the elevation of SCr. Deferasirox was generally well tolerated. Recent reviews show a 30% increase in hazard ratio for every 500 µg/L increase in SF >1000 µg/L, and NCCN guidelines recommend considering iron chelation therapy in iron-overloaded patients with MDS. Ongoing assessments in this study will evaluate the effect of deferasirox treatment on cardiac, hepatic and endocrine function in these patients with MDS.

0229

TRANSFUSION BURDEN, DISEASE DURATION AND AGE IDENTIFY NON-DELETION 5Q MDS PATIENTS HIGHLY RESPONSIVE TO LENALIDOMIDE TREATMENT

A.F. List,[1] K. Wride,[2] R. Knight[2]

[1]University of South Florida, H. Lee Moffitt Cancer Center and Research Institute, TAMPA, FLORIDA; [2]Celgene Corporation, SUMMIT, NJ, USA

Background. Lenalidomide is an immunomodulatory agent that was shown in the MDS-002 study of patients with non-deletion 5q (del[5q]) myelodysplastic syndromes (MDS) to reduce transfusion requirements in 43% of patients with 26% of patients achieving transfusion independence.[1] Multivariate analysis of this study showed that baseline transfusion burden and duration of disease were co-variates influencing hematologic response to lenalidomide.[1] We hypothesized that lenalidomide targets a disease profile in patients with non-del(5q) MDS that is clinically distinct, and perhaps characterized by an immune pathogenesis.[2] *Aims*. To investigate the demographic profile of patients with non-del(5q) MDS who have the greatest potential for benefit from lenalidomide treatment, we performed a secondary analysis of the MDS-002 multicenter Phase II trial. *Methods*. Transfusion independence rate and the duration of response were analyzed according to features previously linked to erythropoietin (EPO) response and MDS with a potential immune pathogenesis, i.e., transfusion burden (≤4 units RBC *vs* > 4 units in the 8 weeks prior to the study), MDS disease duration (≤2 years *vs* > 2 years) and age (≤60 years *vs* > 60 years). Fisher's exact test and a test for trend were used for the univariate comparisons. The duration of transfusion independence (TI) was estimated by the Kaplan-Meier method. *Results*. Among 214 patients treated with lenalidomide, 60 patients received ≤4 units RBC/8 weeks and had a diagnosis of MDS ≤2 years. Demographics were similar between these patients and those with higher transfusion burden/long-standing disease: median age, 72 years (range, 35-94) *vs* 73 (27-87); male, 60% *vs* 66%; low/int-1 IPSS category, 84% *vs* 77%, respectively. Of the patients who had low transfusion burden and short MDS duration, 43% (26/60) achieved TI with lenalidomide compared with 19% (30/154) of patients with greater transfusion burden or longer disease duration ($p<0.001$). There was a highly significant association between baseline transfusion burden and the frequency of TI response ($p<0.0001$, Figure 1). The frequency of TI to lenalidomide was higher in patients ≤60 years of age (12/29 [41%] *vs* 45/186 [24%], $p=0.069$). Median duration of response was 10.0 months (95%CI, 5.2-not yet reached; range, 1.9-39.5) for patients with low transfusion burden and disease duration ≤ 2 years compared with 9.5 months (95%CI, 4.9-14.0; range, 2.0-37.1) in the other group.

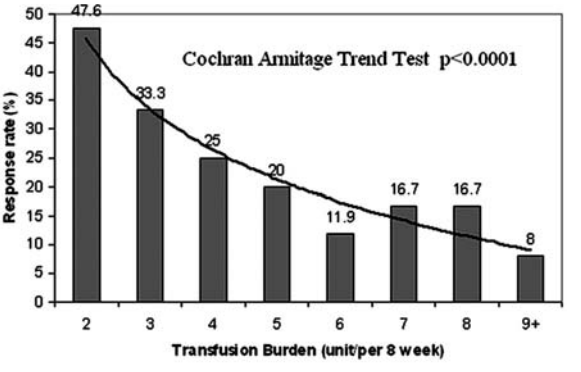

Figure 1. TI response by transfusion burden.

Conclusions. MDS patients with low transfusion burden and disease duration ≤2 years had high rates of transfusion independence with lenalidomide that compare favourably to EPO therapy.[3,4] The age dependent response favoring ≤60 years suggests that lenalidomide may restore T-cell homeostasis and offer an alternative to immunosuppressive therapy in this population. These data suggest that lenalidomide may offer a primary treatment alternative for the management of RBC transfusion dependent MDS patients.

A NEW EVALUATION OF THE POTENTIAL AETIOLOGICAL ROLE OF SMOKING HABIT IN PRIMARY MYELODYSPLASTIC SYNDROME: INBIOMED HEMA-001/2004 STUDY (PART ONE)

F. Ramos,[1] N. De Las Heras,[1] J.A. Rodriguez,[2] M. Megido,[2] J.R. Gonzalez,[3] L. Florensa,[4] M. Barbon,[1] C. Del Canizo,[3] M. Fuertes,[1] J. Gonzalez-Gallego[5]

[1]Hospital de León, LEÓN; [2]Hospital El Bierzo, PONFERRADA (LEÓN), Spain; [3]Hospital Universitario de Salamanca, SALAMANCA; [4]Hospital del Mar, BARCELONA; [5]INBIOMED, University of León, LEÓN, Spain

Background. Several studies have linked cigarrette smoking habit (SH) to the development of primary myelodysplastic syndromes (MDS). The average smoker is exposed to daily benzene doses 10-times higher than a non-smoker. Tobacco smoke induces oxidative DNA damage but at

least two detoxifying pathways may alleviate this challenge: glutation-transferases M1 and T1 (*GSTM1, GSTT1*) and NAD(P)H quinone-oxidoreductase (NQO1). Polymporphisms of the genes codifying for this enzymes are responsible for a reduction in the detoxifying capacity that has confers a higher risk of AML/MDS. The eventual interaction between SH and these polymporphisms has been analyzed in several human tumours, but it has not been explored so far in MDS. *Aims*. To clarify the role of SH and to check the eventual impact of concurrent polymorphisms in *GSTM1, GSTT1* and *NQO1* in the aetiology of MDS. *Methods*. We have recruited prospectively 241 patients at 3 spanish hospitals, for a case-control study. A case:control ratio of 1:3 was designed, to optimize recruitment. Sample size was estimated with the aim to detect an odds-ratio (OR) of at least 3.0. Sixty one consecutive MDS patients (FAB criteria) and 180 hospital controls participate in this study. Control patients were randomly selected among the patients of the Departments of Traumatology/Surgery. We excluded upfront those with MDS or other blood diseases, abnormal PB counts, previous cancer, previous treatment with radiotherapy, alkylating agents, or azatioprine and SH related-diseases. Life-long enviromental exposures were recalled with the use of self-administered ad-hoc questionnaire. SH has been calculated in *pack-years* and categorized in quintiles. Smoke exposure at enrollment was confirmed by plasma cotinine determination. The presence of a null genotype for *GSTM1* and *GSTT1* was studied by multiplex PCR, while *NQO1* genotyping was performed by RFLP-PCR. Crude and covariate-adjusted odds-ratios, were calculated for SH by single-step logistic regression analysis, after proper identification of target covariates following a hierarchical approach.

Table 1. Odds-ratio for MDS as a function of smoking habit, adjusted for relevant confounders and statistically significant first-order interactions. Q5 stand for 5th quartile of the distribution.

	n	Crude Odds-ratio	Adjusted Odds-ratio	95% CI
Non-smokers	116	1.00		
Smokers (any level)	127	1.38	1.48	0.77 - 2.86
Non-smokers	116	1.00		
Smokers Q4-Q5	48	2.36	3.10	1.38 – 6.96
Non-smokers	116	1.00		
Smokers Q1-Q3	76	0.93	0.91	0.41 – 2.01
Smokers Q4	23	1.53	1.97	0.64 – 6.06
Smokers Q5	25	3.23	4.39	1.49 – 12.99

Results. MDS tends to be a bit more frequent in smokers (OR 1.38; 95% CI 0.77 - 2.47) but a disequilibrium in inactivating polymorphisms of benzene detoxifying enzymes was not obvious (ORs ranged from 0.82 to 1.19). Patient stratification according to SH intensity reveals a clear-cut dose-effect relationship (Chi-square for lineal trend= 5.91, p=0.016) between the SH level and the *riskof* MDS (Table 1), with those exposed to >28 pack-years showing an adjusted-OR of 3.1 (95% CI 1.38-6.96), and those over 52 pack-years reaching 4.4 (95% CI 1.49-12.99). After stratification according to FAB, the effect of SH was limited to advanced MDS. Exposure to automobile exhaust at work showed a synergistic effect with SH, confering a higher risk of MDS (p=0.047). Finally, MDS patients harboring intermediate-risk cytogenetics (IPSS) were smokers more frequently than those with other cytogenetic subgroups (p=0.025, Fisher) and had been exposed to less cigarrette smoke (median exposure 0.0 *vs* 58.5 pack-years, p=0.004 Mann-Whitney). *Conclusions*. Smoking habit over 28 pack-years is a risk factor for advanced primary MDS. Intermediate-risk cytogenetics is more frequent among smokers. Concurrent exposure to automobile fuel exhaust, seems to increase the risk of MDS in smokers. The polymorphisms considered do not make a significant contribution to the problem, and eventual preventive initatives should be addressed to the general population.

5-AZACYTIDINE FOR THE TREATMENT OF ACUTE MYELOID LEUKEMIA: RESULTS IN 45 PATIENTS FROM THE ITALIAN PATIENT NAMED PROGRAM

P. Musto,[1] L. Maurillo,[2] A. Spagnoli,[3] M. Genuardi,[3] M. Lunghi,[3] N. Di Renzo,[3] G. Mele,[3] A. Levis,[3] A. D'Arco,[3] A. Gozzini,[3] M. Petrini,[3] M. Mianulli,[3] G. Sanpaolo,[3] A. Santagostino,[3] G. Pietrantuono,[3] F. D'Auria,[3] D. Ferrero,[3] G. Gaidano,[3] F. Ferrara,[3] V. Santini,[3] G. Leone,[3] A. Bosi,[3] A. Venditti[3]

[1]CROB, Centro di Riferimento Oncologico della Basilicata, RIONERO IN VULTURE (PZ); [2]S. Eugenio Hospital, Tor Vergata University, ROMA; [3]On behalf of ad hoc Italian Study Group, AZACYTIDINE IN MDS AND AML, Italy

Background. 5-azacytidine (AZA) is a hypomethylating agent approved in 2004 from FDA for the treatment of all types of myelodysplastic syndromes (MDS), including RAEB-T FAB subtype (marrow blasts between 21 and 30%), which are now classified as AML, according to WHO classification. Indeed, some recent reports have raised the question of a possible efficacy of AZA in selected patients with AML. *Methods*. In September 2007, we started a retrospective study aiming to register and analyse all Italian patients with MDS or AML who had received AZA for the treatment of their disease outside of clinical trials, on the basis of a national patient named program. Among a total of 218 patients treated in 31 different Italian Institutions since 2005, forty-five AML were collected. Most of them were elderly, unfit patients not eligible for more intensive therapies, often with hypocellular AML. Median age was 70 years (range 29-87), twenty-one pts were male. Unfavourable karyotype was present in 59% of assessable pts, while 66% of cases were secondary AML. Median time from diagnosis was 5 months (range 5-27). Thirty pts (66.7%) were pre-treated, 24.4% with one line and 42.3% with two lines of chemotherapy (CT) (12 low dose CT; 16 high dose CT, including autologous or allogeneic stem cell transplantation; 2 growth factors; 11 other therapies). The median number of monthly AZA cycles administered was 3 (range 1-11). Thirty-six pts (80%) received AZA 100 mg/d fixed-dose s.c., nine (20%) 75 mg/d/sqm s.c.. A seven-day per month schedule was employed in 32 pts (71.1%), while 13 pts (27%) received AZA for more than 7 days. One patient received the drug for 5 days. Twenty-four pts (53%) received AZA alone, twenty-one (47%) in various combinations with growth factors (n.1), valproic acid±ATRA (n.18), gentuzumab-ozogamycin (n. 2). *Results*. The most relevant toxicity observed (grade 3-4) was represented by further myelosuppression (15%), infections (24%: in particular, 1 fungal, 3 pneumonia and one septic shock) and gastro-intestinal adverse events (20%). Overall, complete remission (CR) occurred in 3 out of 41 assessable patients (7.4%). Partial response was observed in additional 10 pts (24.2%), so that overall response rate was 31.6%. Median response duration was 2 months (range 1-8). After a mean follow-up of 12 months, seventeen pts (38%) are still alive. A significant difference (p<0.019) in response rate in favour of 75 mg/sqm *vs* 100 mg fixed dose was observed. *Conclusions*. These data confirm, in the practical clinical setting, that AZA could has a role in treating selected patients with *de novo* or pretreated AML. Of interest, in our series the *standard* dose of 75 mg/m^2 for 7 days appeared to be more effective than 100 mg/d (one single vial) fixed dose.

0232

RAPID ONSET OF EFFECTIVENESS WITH THREE ALTERNATIVE AZACITIDINE (AZA) DOSING REGIMENS IN PATIENTS (PTS) WITH MYELODYSPLASTIC SYNDROMES (MDS)

R. Lyons,[1] T. Cosgriff,[2] S. Modi,[3] H. McIntyre,[45] I. Fernando,[4] J. Backstrom,[4] C.L. Beach[4]

[1]Cancer Care Centers of South Texas, SAN ANTONIO; [2]Hematology and Oncology Specialists, METAIRIE; [3]Joliet Oncology-Hematology Associates, JOLIET, USA; [4]Pharmion Corporation, OVERLAND PARK, USA

Background. At a dosing schedule of 75 mg/m^2/day SC for 7 consecutive days every 4 weeks, AZA is an effective and safe treatment for pts with MDS (*JCO 2002;20:2429*). An alternative dosing schedule that eliminates weekend dosing would be more convenient for pts and clinicians. Rapid onset of disease improvement is also important; the time to onset of hematologic improvement (HI) and red blood cell (RBC) transfusion independence (TI) in AZA-treated pts has not been formally studied. *Aims.* To assess the timing of HI or RBC TI using 3 alternative AZA dosing schedules that avoid weekend dosing. *Methods*. In this phase II, multicenter, open-label trial, pts with a diagnosis of FAB-defined RA, RARS, RAEB, RAEB-T, or CMMoL were randomized to 1 of 3 AZA alternative-

dose regimens that were repeated every 4 weeks for 6 cycles: AZA 5-2-2 (75 mg/m²/day x 5 days, followed by 2 days no treatment, followed by 75 mg/m²/day x 2 days), AZA 5-2-5 (50 mg/m²/day x 5 days, followed by 2 days no treatment, followed by 50 mg/m²/day x 5 days) or AZA 5 (75 mg/m²/day x 5 days). Pts with ≥6 days of treatment were evaluable for efficacy. Onset of HI and RBC TI in baseline transfusion-dependent pts, as defined by IWG 2000 criteria (Blood 2000;96:3671), was assessed by treatment cycle. *Results*. In all, 151 pts were randomized to AZA 5-2-2 (n=50), AZA 5-2-5 (n=51), or AZA 5 (n=50). Most pts were RA (43%) or RAEB (30%). Proportions of evaluable pts with HI (major + minor) were 44%, 52%, and 55% in the AZA 5-2-2, AZA 5-2-5, and AZA 5 groups, respectively, and onset of HI occurred within the first 2 treatment cycles for 82%, 58%, and 90% of pts, respectively (Table). Proportions of pts who achieved RBC TI after baseline dependence were 55%, 60%, and 63%, in the AZA 5-2-2, AZA 5-2-5, and AZA 5 groups, respectively, and onset of TI occurred within the first 2 cycles for 92%, 75%, and 75% of pts, respectively (Table 1).

Table 1. Onset of HI or TI by treatment cycle.

	AZA 5-2-2 n (%) pts		AZA 5-2-5 n (%) pts		AZA 5 n (%) pts	
CYCLE	Any HI (n=22)	RBC TI (n=12)	Any HI (n=23)	RBC TI (n=12)	Any HI (n=28)	RBC TI (n=16)
1	9 (41)	6 (50)	6 (26)	4 (33)	15 (54)	9 (56)
2	9 (41)	5 (42)	7 (30)	5 (42)	10 (36)	3 (19)
3	1 (5)	0	7 (30)	3 (25)	2 (7)	1 (6)
4	0	1 (8)	2 (9)	0	1 (4)	2 (13)
5	2 (9)	0	1 (4)	0	0	1 (6)
6	1 (5)	0	0	0	0	0

Onset of HI and TI continued to occur, however, during cycles 3 to 6. All three alternative dosing regimens were generally well tolerated with similar safety profiles to that seen with the approved AZA dosing schedule. *Summary/conclusions*. These data indicate the 3 alternative AZA dosing schedules are effective in the treatment of MDS. Moreover, these data demonstrate the rapid onset of action of AZA, with the majority of pts who achieve HI or RBC TI experiencing onset of effect within the first 2 treatment cycles. Although rapid onset of HI and TI occurred in the majority of pts, onset continued to be observed during later cycles.

0233

TREATMENT-RELATED MYELODYSPLASIA AND SECONDARY AML FOLLOWING FLUDARABINE COMBINATION CHEMOTHERAPY

A. Carney, A. Westerman, S. Tam, A. Milner, H. Prince, M. Kenealy, M. Wolf, E. Januszewicz, A. Ritchie, N. Came, F. Seymour

Peter MacCallum Cancer Centre, EAST MELBOURNE, Australia

Background. Fludarabine combination chemotherapy achieves high response rates in CLL and indolent lymphoma. Fludarabine inhibits DNA repair and augments the cytotoxic effect of DNA damaging agents such as cyclophosphamide and mitoxantrone. This mechanism may also affect marrow progenitor cells to increase the risk of myelodysplasia or secondary acute myeloid leukaemia (MDS/sAML). *Aims*. To investigate the incidence and characteristics of MDS/sAML after treatment with fludarabine in combination (F+) for lymphoproliferative disorders and identify risk factors for its development. *Methods*. Review of the Peter MacCallum Cancer Centre Pharmacy database form 1996-2006 identified 146 patients treated with fludarabine (F) combined with cyclophosphamide (C) and/or mitoxantrone (M)±rituximab (R) who have at least 12 months follow-up since starting treatment. Kaplan-Meier analysis was used to estimate MDS-free survival (MDSFS), defined as the time from first exposure to F+ to onset of MDS. The Mantel-Cox logrank test and Cox proportional hazards regression were used to estimate the effects of patient characteristics on MDSFS, including age, gender, disease type, treatment with alkylators at other times, treatment with radiotherapy, number of F containing treatment episodes, number of prior therapies, and addition of M to first F+ therapy. *Results*. 146 patients (pts) treated with fludarabine in combination (F+) were followed up for a median of 40 months. Ninety-six patients (66%) were male and the median age of all patients was 58 years (range 30-84 years). Disease type was CLL in 69 pts (47%), follicular lymphoma (FL) in 49 pts (34%), Waldenstrom's macroglobulinaemia or marginal zone lymphoma (WM/MZL) in 19 pts (13%) and MCL in 9 pts (6%). Seventeen cases of MDS/sAML have been identified for an overall rate of 11.6% (12 refractory cytopenia with multilineage dysplasia, 2 chronic myelomonocytic leukaemia, 1 refractory anaemia with excess blasts and 2 AML with multilineage dysplasia). Patients included 11 with FL (crude rate 22.4%), 2 with CLL (2.9%) and 4 with WM/MZL (21.1%). Most patients had other treatments but 2 with FL had F+ as their only line of treatment. Ten pts (7%) received M with first F+ treatment and half of these developed MDS. MDS/sAML was diagnosed at a median time of 46 months following commencement of F+ treatment. Karyotypic analysis was typically complex. Median overall survival post-MDS/sAML diagnosis was 11 months. The median MDSFS for this cohort of pts was estimated at 8.2 years (95% CI 8.0 - >9.2 years). Disease type had a significant effect on MDSFS (p=0.029) with the MDS-free rate at 6 years estimated at 100% for CLL, 69% for FL, 100% for MCL and 75% for WM/MZL. Median MDSFS was significantly shorter for those pts treated with F+M (p<0.001). The MDS-free rate at 6 years was 54% for F+M compared to 86% without M. Other variables did not have a significant effect on MDSFS. *Summary and Conclusions.* Fludarabine combination chemotherapy is associated with a moderate risk of MDS/sAML particularly in patients with follicular lymphoma and when combined with mitoxantrone. This complication should be considered when evaluating the potential benefit of this treatment in lymphoproliferative disorders.

0234

TREATMENT WITH VNP40101M (CLORETAZINE?) IN PATIENTS WITH HIGH RISK MYELODYSPLASTIC SYNDROMES (MDS): RESULTS OF A SUBSET POPULATION IN A PHASE II STUDY

G. Mufti,[1] D. Rizzieri,[2] N. Vey,[3] D. Hudak,[4] J. Karp,[5] F. Giles[6]

[1]King's College Hospital, LONDON, UK; [2]Duke University, DURHAM, NC, USA; [3]Institut Paoli-Calmettes, MARSEILLE, France; [4]Vion Pharmaceuticals, Inc., NEW HAVEN, CT, USA; [5]Johns Hopkins University, BALTIMORE, MD, USA; [6]CTRC University of Texas Helath Science Center, SAN ANTONIO, TX, USA

Background. Patients with high risk MDS have few effective therapeutic options. Hypomethylating agents have been approved with complete response rates of approximately 8% in patients with high risk MDS (IPSS score ≥ 1.5). VNP40101M is a novel alkylating agent which preferentially targets the O6 position of guanine resulting in DNA cross-links and has shown activity against AML and high risk MDS in clinical trials. *Aims*. 184 patients were treated in a multi-center Phase II study conducted to investigate the activity and safety of VNP40101M as a single agent in patients with AML or high risk MDS by FAB classification. The primary endpoint, overall response rate (ORR), was defined as CR and CRp according to the AML response criteria proposed by the International Working Group (*Cheson et al. JCO 2003*). A retrospective analysis of the safety and efficacy of VNP40101M treatment in a subset of high risk MDS patients is presented. *Methods*. VNP40101M was administered at 600 mg/m² as a single 30-60 minute IV infusion. A second treatment was allowed for patients who showed hematologic improvement or partial response. Patients who achieved CR or CRp could receive a consolidation course of 400 mg/m². High risk MDS patients enrolled to this study under FAB classification were retrospectively reclassified according to the WHO criteria. Safety and efficacy parameters were analyzed by each classification system. B classification were treated. These patients were categorized as follows: RAEB 12 patients (46%); RAEB-t 9 patients (35%); CMML 3 patients; and *unknown* 2 patients. 8 of 26 patients (31%) had received prior treatment for MDS. The median time from diagnosis to treatment with VNP40101M was 76 days (range 1-808). The median age of patients was 71 (range 59-82) with a median IPSS of 2. Eleven patients (42%) had unfavorable cytogenetics. All 26 patients received a first induction dose of VNP40101M; 8 patients also received a consolidation dose. Response (CR or CRp) was achieved in 10 of 26 patients (38%). Three of the 10 responders had received prior treatment for MDS. Median overall survival (OS) was 3.4 months (range 0.6 - 28.6). One patient died within 30 days of first induction treatment; 1 patient died within 30 days of consolidation. By retrospective reclassification, 17 of 26 patients were identified as having MDS according to WHO criteria. 6 patients were reclassified as AML, and 3 patients as MDS/MPD (CMML). ORR was 53% (9/17). Median OS was 3.9 months (range 0.6 - 28.6). *Summary and Conclusions*. VNP40101M is an active agent for patients with high risk MDS. Efficacy and tolerability is demonstrated regardless of classification by FAB or WHO criteria. Response can be achieved in patients with prior treat-

ment. Further investigation with VNP40101M as a single agent or in combination with other agents in frontline or as salvage treatment is warranted.

0235

PRE-TRANSPLANT SERUM FERRITIN AS AN INDEPENDENT PROGNOSTIC FACTOR IN MDS PATIENTS UNDERGOING REDUCED INTENSITY CONDITIONING HSCT

Z.Y. Lim, V.F. Fiaccadori, S.G. Gandhi, M. Kenyon, A.Y.L. Ho, A.P. Pagliuca, G.J. Mufti

Kings College London and Kings College Hospital, LONDON, UK

Background. Allogeneic haematopoeitic stem cell transplantation (HSCT) is at present the only potentially curative option for MDS. Recent studies have suggested a link between iron overload and post-transplantation liver toxicity, infectious susceptibility, and even overall survival. Iron overload, in terms of ferritin levels, has been studied by several groups and is now known to be an independent prognostic factor for patients undergoing myeloablative HSCT. *Aims*. We performed a retrospective analysis to assess the impact of pre-transplant ferritin on subsequent outcome of MDS patients undergoing reduced intensity conditioning(RIC) HSCT. *Methods*. 99 MDS patients treated between 1999 and 2004 were analysed. All patients were ineligible for conventional myeloablative HSCT due to either age or pre-existing comorbidities. The median age of patients was 51.1 years (range: 19-72). Based on the WHO classification, 3 patients had isolated Del 5q syndrome, 3 RARS, 28 RCMD, 1 RCMD-RS, 16 RAEB-1, 12 RAEB-2, and 36 with AML/MDS. Using WPSS 27 patients were in very high risk group, 50 in high, 16 in intermediate, 6 in low risk group; all patients were transfusion dependent at the time of transplant. We set 1000 ng/mL as the cut off value for pre-transplant serum ferritin, obtaining a group of 26 people with ferritin levels<1000 ng/mL, and a group of 62 with a level over the cut off. Median pre-transplant ferritin was 1991,5 ng/mL (range 6-9580). The RIC protocol consisted of 30 mg/m^2 intravenous (IV) fludarabine daily from day -9 to day -5; 20 mg IV alemtuzumab from day -8 to day -4; and a fixed dose of 4 mg/kg oral busulphan in four divided doses daily from day -3 to day -2. Post-transplant GvHD prophylaxis was achieved with cyclosporine. *Results and discussion*. At 2 years actuarial OS for the cohort was 53%. The DFS, TRM and relapse incidence were 48%, 24%, and 36% respectively. Patients with lower serum ferritin (<1000 ng/mL) showed a better outcome at 2 years in terms of OS (76% vs 43.2%, p=0.007), DFS (64.3% vs 39.5%, p=.015), relapse (23.5% vs 41.9%, p=0.024), but not TRM (15.7% vs 29.5%, p=.250). Serum ferritin correlated with IPSS score: of the 62 patients in high ferritin group, 46 were int-2 or high risk, and only 16 was low or int-1(p=.003); serum ferritin did not correlate with sex, age, cytogenetics, cell source, cell donor, and WPSS. On cox-regression analysis pre-transplant ferritin was an independent prognostic factor in terms of OS (HR=3.151,confidence interval 95%, p=.010), DFS (HR=2.422,CI=95%, p=.018), but not for relapse (HR=2.490, CI= 95%, p=.066) or TRM (HR=1.909,CI=95% p=.251). *Conclusions*. These findings suggest that ferritin levels pre-transplantation can aid in the predicting of subsequent transplantation outcomes in MDS patients undergoing RIC HSCT. Further studies are needed to evaluate the surrogacy of this association and whether iron chelation may play a role in the management of selected patients.

0236

EUROPEAN INTER-COUNTRY TREATMENT SELECTION DIFFERENCES DO NOT ALTER OVERALL SURVIVAL BENEFIT SHOWN WITH AZACITIDINE VS CONVENTIONAL CARE REGIMENS IN HIGHER-RISK MYELODYSPLASTIC SYNDROMES

V. Santini,[1] P. Fenaux,[2] N. Vey,[3] W.K. Hofmann,[4] T. Robak,[5] A. Bacigalupo,[6] L. Silverman,[7] M. Canales,[8] N. Scmitz,[9] P. Muus,[10] I. Fernando,[11] J. Backstrom,[11] L. Zimmerman,[11] C.L. Beach[11]

[1]University of Florence, FIRENZE, Italy; [2]Hôpital Avicenne, BOBIGNY, France; [3]Institut Paoli Calmettes, MARSEILLE, France; [4]Charité - University Hospital, BERLIN, Germany; [5]Medical University of Lodz, LODZ, Poland; [6]S. Martino's Hospital, GENOVA, Italy; [7]Mount Sinai School of Medicine, NEW YORK, USA; [8]University Hospital La Paz, MADRID, Spain; [9]Allgemeines Krankenhaus St. Georg, HAMBURG, Germany; [10]UMCN St. Radboud, NIJMEGEN, Netherlands; [11]Pharmion Corporation, OVERLAND PARK, USA

Background. Recently, a large, international, multicenter, randomized, Phase III trial (AZA-001) demonstrated that azacitidine (AZA) was the first drug treatment to significantly prolong overall survival (OS) in higher-risk pts with myelodysplastic syndromes (MDS) (Fenaux, Blood 2007;110:Abstract 817). The trial was designed to allow comparison of treatment with AZA with a control group receiving one of three frequently used treatments in higher-risk MDS pts. *Aims*. The purpose of this pooled, subgroup analysis was to assess country-specific treatment preselections across eight European countries (France, Germany, Italy, Spain, UK, Sweden, Greece, the Netherlands) to evaluate the effects of pre-randomization treatment selection on the consistency of the AZA-001 OS findings. *Methods*. Higher-risk MDS pts (FAB-defined RAEB, RAEB-T, or CMML; IPSS: Int-2 or High) were enrolled. Prior to randomization, investigators preselected the most appropriate treatment for individual pts from 3 conventional care regimens (CCR, best supportive care [BSC], low-dose ara-C [LDAC, 20 mg/m^2/d x 14d every 28 days for ≥4 cycles], or intensive chemotherapy [IC, 7+3 regimen]). Pts were then randomized to AZA or CCR. Regardless of investigator selection, those randomized to AZA received AZA at 75 mg/m^2/d x 7d, every 28 days for ≥6 cycles; pts randomized to CCR received their investigator-selected treatment. All pts provided informed consent. Investigator selection and OS were compared by practice patterns across the eight highest enrolling European countries. *Results*. Overall, 280 pts were enrolled (78% of the total AZA-001 patient population) across the eight EU countries. Baseline characteristics were consistent between AZA and CCR groups. Investigator selection showed profound selection differences across the countries. Pooled results from France and UK showed the highest preselection for LDAC (74% [62/84]) with 26 patients receiving AZA per randomization to AZA and 36 receiving LDAC per randomization to CCR. Pooled results from Germany, Italy, Spain, Sweden, Greece, and the Netherlands showed the highest preselection for BSC (79% [155/196]) with 80 patients receiving AZA per randomization to AZA and 75 receiving BSC per randomization to CCR. Survival analysis pooling France with the UK (where LDAC selection was highest) showed an OS advantage for the AZA group *vs* the CCR group similar to that observed in the overall AZA-001 OS analysis (Table 1).

Table 1. OS (median months) in France/UK (LDAC driven) and Germany/Italy/Spain/Greece/Sweden/Netherlands (BSC driven) compared with the overall AZA-001 findings.

Country	OS AZA	OS CCR	Difference	HR (95%CI)	Log-rank P
France/UK	24.5	16.4	8.0	0.44 (0.23-0.85)	0.012
Germany/Italy/Spain/ Greece/Sweden/ Netherlands	25.1	15.7	9.4	0.65 (0.43-0.97)	0.032
Overall AZA-001	24.4	15.0	9.4	0.58 (0.43-0.77)	0.0001

Survival analysis pooling results from Germany, Italy, Spain, Sweden, Greece, and the Netherlands (where BSC selection was highest) also showed an OS advantage for the AZA group *vs* CCR that was highly similar to that observed in the overall AZA-001 OS findings (Table 1). Comparison of OS results in the pooled LDAC group (France/UK, n=36) with the pooled BSC group (Germany/Italy/Spain/Sweden/Greece/the Netherlands, n=75) showed no differences: 16.9 months *vs* 17.2 months (HR: 1.01; 95% CI: 0.59-1.73; log-rank p=0.963). *Summary and Conclusions*. Regardless of investigator treatment selection preferences for LDAC (France/UK) or for BSC (Germany/Italy/Spain/Sweden/Greece/the Netherlands), differences in median OS between the AZA and CCR groups remained statistically significant and consistent with results from the AZA-001 trial. Treatment with AZA yielded significant benefit for OS compared with LDAC. LDAC provided no survival benefit *vs* BSC.

0237

TREATMENT OF LOWER RISK MDS WITH DEL 5Q WITH LENALIDOMIDE (LEN): CURRENT RESULTS OF THE FRENCH PATIENT NAMED PROGRAM (ATU)

F. Le Bras,[1] M. Sebert,[2] V. Eclache,[2] T. Lamy,[2] J. Dlaunay,[2] S. Visanica,[2] F. Dreyfus,[2] A. Banos,[2] M. Blanc,[2] C. Leyronnas,[2] C. Besson,[2] B. Derenzis,[2] X. Thomas,[2] C. Rodon,[2] N. Vey,[2] M. Gardembas,[2] M. Faron,[2] F. Bauduer,[2] J.F. Ramee,[2] D. Zajec,[2] A. Delmer,[2] D. Rea,[2] O. Beyne-Rauzy,[2] J. Ceccaldi,[2] P. Beaucournou,[2] J. Dugay,[2] P. Fenaux,[2] L. Ades[2]

[1]AP HP, PARIS, France; [2]Groupe Francophone des Myelodisplasies, PARIS, France for the groupe Francophone des myelodysplasies (GFM)

Background. LEN is very effective in lower risk MDS with del 5q (List *et al.*, 2006). A patient named program was launched by French health authorities to use LEN in low and int 1 risk MDS with del 5q and transfusion dependence (>2 RBC units/ 2 months). *Patients*. Patients received 10 mg of LEN /day,3 weeks on, 1 week off. Hematological response (IWG2006) was assessed after 16 and 32 weeks of treatment. *Results*. 40 pts were evaluable for response as of Feb 1st , 2008. Median age was 73 [range 45-92], M/F 40%, median interval from diagnosis to LEN treatment 44 months (range 4-165). At inclusion, 18 pts had del 5q syndrome, 9 RARS, 4 RCMD and 9 RAEB-1, 16 pts were IPSS low and 24 int-1. Del 5q was isolated, with 1 additional and > 1 additional abn in 27, 8 and 5 pts resp. 8 pts were untreated, while 32 had previously received EPO. Median transfusion requirement was 4,4 units/ 2 months. 30/40 (75%) pts achived erythroid response (IWG 2006), of whom 24 (60%) achieved transfusion independence (TI). Median time to TI was 15 weeks (range 8 - 32). TI was achived in 62%, 54%, 55%, 67%, 40% pts with IPSS low, IPSS int 1, isolated del 5q, del 5q+1abn, del5q + >1abn, resp, and 59% and 62% of EPO pretreated and EPO naive pts. Grade III-IV neutropenia and thrombocytopenia were seen in 68% and 35% pts resp, leading to reduction of LEN dosing in 72% . Other grade III-IV side effects were Lyell's syndrome (n=1), deep venous thrombosis (n=1) Quincke's edema (n=1).One patient died due to CNS bleeding following worsening of thrombocytopenia under treatment, while no pt died from sepsis due to neutropenia. With a still short median FU on treatment (24 weeks), no relapse has occured. No patient has progressed to AML. *Conclusions.* Our results confirm previous findings. An update on the > 100 patients now accrued in the program will be presented.

0238

5-AZACYTIDINE FOR THE TREATMENT OF INTERMEDIATE-2/HIGH IPSS RISK MYELODYSPLASTIC SYNDROMES: RESULTS IN 83 PATIENTS FROM THE ITALIAN PATIENT NAMED PROGRAM

L. Maurillo,[1] A. Spagnoli,[2] A. Gozzini,[2] N. Cecconi,[2] M. D'Argenio,[2] M. Lunghi,[2] S. Rocco,[2] G. Palumbo,[2] F. Rivellini,[2] M. Genuardi,[2] S. Sibilla,[2] F. Ferrara,[2] G. Mele,[2] N. Filardi,[2] G. Sanpaolo,[2] G. Specchia,[2] A. Tonso,[2] A. Santagostino,[2] M.T. Voso,[2] E. Balleari,[2] V. Cassibba,[2] P. Della Cioppa,[2] C. Mazzone,[2] E. Oliva,[2] L. Ciuffreda,[2] D. Russo,[2] S. Galimberti,[2] O. Villani,[2] F. D'Auria,[2] N. Di Renzo,[2] A.M. D'Arco[2]

[1]S. Eugenio Hospital, Tor Vergata University, ROMA; [2]On behalf of ad hoc Italian Study Group, AZACYTIDINE IN MDS AND AML; [3]CROB, Centro di Riferimento Oncologico della Basilicata, RIONERO IN VULTURE, Italy

Background. 5-azacytidine (AZA) is an hypomethylating agent approved in 2004 from FDA for the treatment of all types of myelodysplastic syndromes (MDS) and with still pending approval in Europe. *Methods*. In September 2007, we started a retrospective study aiming to register and analyse all Italian pts with MDS or AML who had received AZA for the treatment of their disease outside of clinical trials, on the basis of a national patient named program. Among a total of 218 pts treated in 31 different Italian Institutions since 2005, eighty-three were int-2/high IPSS risk MDS. Median age was 70 years (range 36-84), M/F ratio 58/25. According to WHO classification, there were 7 RCMD, 16 RAEB-1, 58 RAEB-2, 1 CMMoL, 1 MDS unclassified. Median time from diagnosis was 6 months (range 1-96). Sixty-three pts (76%) were transfusion-dependent, fifty-three (64%) had received prior treatment: approximately 25% had received low dose or AML-like chemotherapy. AZA was administered as single agent in 55 pts (66%), while in the remaining subjects the drug was variously combined with growth factors, valproic acid or other agents. Forty-five pts (55%) received a standard dose of 75 mg/d/sqm s.c., thirty-seven (45%) a fixed dose of 100 mg/d s.c.. Single cycle treatment duration was 7 days in 46 pts (58%), < 7 days in 29 pts (36%), > 7 days in 5 pts (6%), The median number of monthly cycles was 4 (range 1-11), with 46 pts who completed at least 4 cycles (55%). *Results*. The most relevant toxicity observed (grade 3-4) was represented by myelosuppression (54%), infections (18%) and gastro-intestinal adverse events (4%). According to 2006-updated IWG criteria, overall response rate in 74 assessable pts was 38% (43% in 46 pts who had completed at least 4 cycles). In particular, complete response, partial response and haematological improvement occurred in 12%, 19% and 7% of pts (13%, 26% and 4% of those treated with at least 4 cycles), respectively. Disease remained stable in 44% of pts, while progression or failure were observed in 18%. Response duration ranged from 1 to 14+ months. There were no significant differences in response rate according to dose and schedule employed, although a trend in favour of 75 mg/d/sqm for 7 days vs other schedules was observed (52 vs 25-35%, respectively). *Conclusions*. These independent, multicenter study data are consistent with the results recently presented for the phase III international AZA-001 trial and confirm, in the clinical practice, that AZA is a safe and effective drug for int-2/high IPSS risk MDS. An update of this series, including survival data, will be presented at the meeting.

MONOCYTES FROM PATIENTS WITH MYELODYSPLASTIC SYNDROMES ARE MORE RESISTANT TO THALIDOMIDE-MEDIATED TNF-α INHIBITION COMPARED TO MONOCYTES FROM CONTROL SUBJECTS

S. Meers,[1] L. Boon,[2] M. Boogaerts,[1] C. Verfaillie,[3] G. Verhoef,[1] M. Delforge[1]

[1]University Hospital Leuven, LEUVEN; [2]PanGenetics, UTRECHT, Netherlands; [3]Stem Cell Institute, LEUVEN, Belgium

Background. Many factors have been identified that contribute to bone marrow failure observed in patients with myelodysplastic syndromes (MDS). Our group has recently shown that monocytes are activated in patients and can contribute to bone marrow failure via CD40-CD40L interactions with T helper cells (*Meers et al Leukemia 2007;21:2411-9*). We also demonstrated that stimulation of the CD40-receptor on monocytes induces a significantly higher production of TNF-alpha in patients compared to controls. Thalidomide can induce hematopoietic responses in selected patients with MDS and inhibition of TNF-α production is one proposed working mechanism. However, this has never been studied *in vitro* using monocytes from MDS patients. *Aims*. This study was designed to determine (1) the production of the inflammatory cytokines TNF-α, IL-1beta, IL-6 and IL-10 by monocytes from patients after stimulation with either lipopolysaccharide (LPS) or CD40-agonists. (2) In addition, we evaluated the *in vitro* effects of thalidomide on production of these cytokines. *Methods*. With MACS columns, we purified $CD14^+$ cells from peripheral blood of 30 patients with MDS (22 RA, 5 RARS and 3 RAEB) and 28 aged healthy volunteers. $CD14^+$ cells were plated at a density of $3x10^5$ cells/mL in IMDM containing 15% fetal bovine serum. After 1 week, the medium was replaced with fresh medium supplemented with either LPS (at 1 µg/mL) or a mixture of clone 64 (agonist anti-human CD40 monoclonal antibody, PanGenetics, The Netherlands) at 10 µg/mL, and interferon-γ at a final concentration of 1000 IU/mL. Thalidomide was added in various concentrations (5-10-25 µg/mL) immediately thereafter. Supernatant was harvested after 24h and stored at -20°C. Cytokine concentrations were determined with commercially available ELISA-kits. *Results*. (1) We confirmed our previous observation that MDS monocytes produce significantly more TNF-α in response to CD40 stimulation than monocytes from healthy controls ($p<0.05$), whereas LPS induced similar TNF-α production in both groups. In addition, we found that compared to controls, stimulation of CD40 on MDS monocytes induced significantly more IL-1beta and IL-10. (2) Thalidomide inhibited TNF-α production after LPS stimulation in controls as well as in patients. But whereas in control monocytes stimulated with CD40-agonists, any concentration of thalidomide was able to significantly inhibit TNF-alpha production, in patients we observed a significant inhibitory effect only with the highest concentration (25 µg/mL) of thalidomide. We observed no inhibitory effect of thalidomide on the production of IL-1β, IL-6 or IL-10. *Summary and Conclusions*. We present the first *in vitro* data of the effects of thalidomide on cytokine production by monocytes derived from patients with MDS. We confirm that thalidomide is able to inhibit LPS-induced TNF-α production in MDS monocytes as efficiently as in control monocytes. However, the amount of TNF-α that MDS monocytes produce upon stimulation of the CD40 receptor can only be blocked in presence of high concentrations of thalidomide. Since in MDS TNF-α production induced by the CD40-CD40L pathway is probably clinically more important than LPS-induced production, this could explain the rather low response rates in MDS patients treated with thalidomide.

THE ORAL CHELATOR ICL670 REPRESSES SIGNALING THROUGH THE MTOR PATHWAY IN MYELOID LEUKEMIA CELLS BY ENHANCING EXPRESSION OF REDD1

J. Ohyashiki, C. Kobayashi, R. Kurashina, Y. Zhang, R.S. Hamamura, K. Ohyashiki

Tokyo Medical University, TOKYO, Japan

Background. Iron plays a central role in the regulation of many cellular functions. Dysregulation of its metabolism leads an iron overload situation and iron depletion leads to an inhibition of cell proliferation. Recent reports demonstrated that ICL670 (Novartis) acts as a potent NF-kappa-B inhibitor and improves hematological data in a subset of MDS patients (*Cilloni et al, Haematologica, s1: 238, 2007*). However, the precise mechanism of anti-cancer effect of ICL670 is still uncertain. *Aims.* To evaluate the effect of ICL670, and to identify the moleclular pathways responsible for the observed reduced transfusion requirement during chelation therapy, we performed gene expression profiling to focus on the pathway involved in the anti-cancer effect of ICL670. *Method*. A human myeloid leukemia cell line, K562, was incubated with 1-200 μM of ICL670. Fresh leukemia cells were also obtained from patients with *de novo* AML, as well as post-MDS AML, after obtaining an informed consent. Cell numbers at 48 h after incubation with or without ICL670 were assessed with the Cell Counting Kit-8 assay (Dojindo Molecular Technologies, Gaithersburg, MD, USA). Total RNA was extracted after 24 h incubation with or without ICL670 (10 μM and 50 μM), then, gene expression profiling was done using an Affymerix GeneChip (U133 Plus 2.0). Statistical analysis was done by GeneSifter (VizXlab, Seattle, WA, USA). *Results*. Inhibitory concentration (IC50) of ICL670 was 50 μM in K562 cells, while that in fresh leukemia cells was 100 to 200 μM. Gene expression analysis revealed up-regulation of genes related to apoptosis (i.e. BCL6, PHLDA1, and BNIP3L), genes regulating interferon (i.e. IFIT1, IFIT3), genes linked to DNA-damage responses (i.e. REDD1, GADD45B). Based on the results obtained from gene expression profiling, we in particular focused on the REDD1/mTOR pathway in ICL670 treated K562 cells. We found that enhanced expression of REDD1 and its downstream protein, tuberin. Notably, S6 kinase as well as phosphorylated S6 kinase, which is known to be a target of mTOR, was significantly repressed in ICL670-treated K562 cells, in a dose- dependent manner. *Conclusion*. Overall, the data support the conclusion that REDD1 functions up-stream of tuberin to down-regulate mTOR pathway in response to ICL670. ICL670 might have benefit for not only iron chelation but also be an anti-proliferative agent in some MDS patients.

0241

ALL-TRANS RETINOIC ACID (ATRA) COMBINED TO ERYTHROPOIETIN (EPO) FOR THE TREATMENT OF ANEMIA IN LOW RISK MYELODYSPLASTIC SYNDROMES (MDS)

R. Itzykson,[1] S. Ayari,[2] D. Vassilief,[2] E. Berger,[2] B. Slama,[2] N. Vey,[2] F. Suarez,[2] O. Beyne-Rauzy,[2] A. Guerci,[2] S. Cheze,[2] X. Thomas,[2] A. Stamatoullas,[2] M. Gardembas,[2] F. Bauduer,[2] M.C. Chaury,[2] A. Kolb,[2] L. Legros,[2] D. Damaj,[2] F. Hamza,[2] F. Dreyfus,[2] P. Fenaux,[2] L. Ades[2]

[1]Assistance Publique Hopitaux de Paris, Hopital Avicenne, Universite Paris 13, BOBIGNY, France; [2]Groupe Francophone des Myelodysplasies, BOBIGNY, France

Background. First line treatment of anemia in low-risk MDS largely relies on recombinant EPO, +/- G-CSF, but patients with high endogenous EPO levels or requiring frequent RBC transfusions have low probability of response (Nordic score, Hellström-Lindberg E *et al.*, BJH 2003). It has been reported that combining ATRA to EPO a) could yield erythroid responses in MDS with high endogenous EPO level, and b) could also improve other cytopenias (*Stasi R. et al., Blood 2002*). *Aims*. In order to further document this effect, we designed a phase II protocol combining EPO and ATRA in MDS with < 10% blasts and anemia (transfusion dependent or Hb < 10 g/dL) having failed EPO or with low probability of response to EPO or with additional cytopenias. *Patients*. Between 10/2004 and 04/2005, 65 patients (pts) (median age 72y; 16 RA, 21 RARS, 1 RCMD, 24 RAEB-1, 1 5q- syndrome, 1 unclassified; karyotype: 41 fav, 11 interm, unfav 7 NA 6; IPSS: 12 low, 37 int 1, 10 int 2 NA 6) were included, based on (several criteria in some pts): EPO level > 500 U/L (n=19), previous failure of an adequate regimen of EPO alone (ie. 60000 UI/week during 12 weeks; n = 31), other cytopenias (plts < 50 G/L and/or ANC< 1000/mm^3; n=30). 47 pts (72%) were transfusion dependent, 32 (49%) received >2 RBC units/month. Pts received EPO β (Neorecormon® 60 000 UI/week) and ATRA (45 mg/m^2/d every other week). Response was evaluated at 12 weeks. The primary endpoint was HI-E by IWG 2000 criteria (responses were subsequently reclassified per IWG 2006). *Results*. Six of the 65 pts included were not assessable (because of lethal cardiac failure n=1, other cancer n=2, progression n=1, lethal sepsis n=2). Of the remaining 59 pts, 70% achieved HI-E per IWG 2000 (26% Major, 44% minor) and 46% HI-E per IWG 2006. Response rates according to IWG 2000 and 2006 were, respectively, 57 % and 39% in patients with previous EPO failure, 61% and 39% in pts with endogenous EPO >500 U/L, 82% and 61% in pts transfused > 2 RBC/month, 83% and 58% in pts with the last 2 features (who would have expected a response rate to EPO + G-CSF of about 7% according to the Nordic score). Only 1 neutrophil response in 31 neutropenic and no platelet response in 20 thrombocytopenic patients were observed. After 24 weeks of treatment, response was maintained in 87% of responders by IWG 2000 criteria. EPO ATRA combination was well tolerated, with mainly grade ≤ 2 toxicities, the most frequent being skin and mucosal toxicity of ATRA. *Conclusions*. EPO-ATRA combination is safe and yields significant response rates in anemia of low-risk MDS patients having failed EPO alone, or unlikely to respond to EPO because of high endogenous EPO levels or high transfusion needs. However it has no effect on neutropenia and thrombocytopenia.

Non-Hodgkin's lymphoma - Biology and Clinical

P0242

GENOME-WIDE ANALYSIS OF DIFFERENT SUBTYPES OF B-CELL NON-HODGKIN'S LYMPHOMA USING HIGH-RESOLUTION GENOMIC MICROARRAYS

M. Kato,[1] K. Takeuchi,[2] G. Yamamoto,[1] Y. Nannya,[1] M. Sanada,[1] S. Chiba,[1] Y. Ishikawa,[3] S. Mori,[4] Y. Kobayashi,[3] M. Kurokawa,[1] S. Ogawa[1]

[1]The University of Tokyo Hospital, TOKYO; [2]National Cancer Center Hospital, TOKYO, Japan; [3]Cancer Institute Hospital, TOKYO; [4]The University of Teikyo, TOKYO, Japan

Background. B-cell type non-Hodgkin's lymphoma (B-NHL) is a comprehensive group of mature B-cell neoplasm. B-NHLs are categorized into subtypes including diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL) and mucosa-associated lymphoid tissue lymphoma (MALT-L), which is characterized by distinct pathological and molecular genetic features. These B-NHLs possess a wide variety of genetic alterations, such as gains, losses, and translocations, as well as abnormalities in allelic composition. These alterations may collectively comprise unique genomic profiles specific to different subtypes of B-NHL, which are tightly linked to the pathogenesis of each B-NHL subtype. Although various genetic abnormalities have been identified in each subtype, the detailed genomic profiles remain to be defined. *Aims*, In this study, in order to obtain a comprehensive registry of genomic abnormalities in B-NHLs, and in order to investigate the unique genomic profiles of different B-NHL subtypes, we performed genome-wide analysis of copy number change and allelic imbalances for 189 B-NHL samples. *Methods*. Recently, we have developed a novel algorithm, CNAG/AsCNAR, to detect copy number alteration and allelic composition using SNP-genotyping microarrays, without dependence on availability of self germline DNA (Nannya *et al.* Cancer Res, 2005). This robust algorithm also enabled sensitive detection of loss of heterozygosity (LOH), even in the primary samples contaminated by 70-80% of normal cells, by finding subtle distortions in allele-specific signals (Yamamoto *et al.* Am J Hum Genet, 2007). In this study, we performed SNP-chip and CNAG/AsCNAR analysis for 189 B-NHL specimens, including 65 cases of DLBCL, 61 cases of FL, and 63 cases of MALT-L. *Results*. A large number of gains and losses of chromosomal/genomic segments as well as allelic imbalances were identified. While individual genomic profiles are substantially variable among different cases, they collectively showed a characteristic genomic profile in each B-NHL subtypes; +1q, +2p and +18 are common to DLBCL and FL, while +3 and +11q were more frequently found in DLBCL and +11p was more characteristic to FL. MALT-L also showed +3 and +18, but rarely had +1q and +2p. CN neutral LOH due to mitotic recombination events are frequently found in DLBC (70%) and FL(54%), but less common in MALT-L. UPD most commonly involves 1p, 1q, 6p, 9p and 12q. In total, 29 loci of high-grade amplification were identified. Among these recurring amplifications were observed at 1q and 2p, which involves FCGR2B, and cRel genes, respectively. These amplifications were detected in both DLBCL and FL, but rare in MALT-L. Total 14 loci of homozygous deletion were also detected and differentially distributed among different B-NHL subtypes. *Summary/conclusions*. SNP-chip with CNAG/AsCNAR analysis revealed characteristic genomic signatures of distinctive B-NHL subtypes, implicating their unique pathogenesis.

0243

CHLAMYDOPHILA PSITTACI (CP) IS VIABLE AND INFECTIOUS IN THE CONJUNCTIVA AND PERIPHERAL BLOOD OF PATIENTS WITH OCULAR ADNEXAL MALT LYMPHOMA (OAML): RESULTS OF A PROSPECTIVE CASE-CONTROL STUDY

J.M. Ferreri,[1] R. Dolcetti,[2] P. Dognini,[1] L. Malabarba,[1] N. Vicari,[3] E. Pasini,[2] M. Ponzoni,[1] M.G. Cangi,[1] L. Pecciarini,[1] A. Giordano Resti,[1] S. Rossini,[1] C. Doglioni,[1] S. Magnino[3]

[1]San Raffaele H Scientific Institute, MILANO; [2]Cancer Bio-Immunotherapy Unit, Centro di Riferimento Oncologico, AVIANO; [3]National Reference Laboratory for Animal Chlamydioses, IZSLER, PAVIA, Italy

Background. Some lymphomas are linked to specific bacterial infections. Confirmation of these associations by bacteria isolation from patients' (pts) samples (second Koch's postulate) has been achieved for H. pylori, but not for other lymphoma-related bacteria. OAML is linked to Cp infection, but the viability and infectivity of this microorganism in OAML pts has not been investigated yet. *Aims*. A single-center prospective trial was conducted to assess the prevalence of Cp infection in 20 OAML pts and 42 healthy blood donors referred to our Institution in a 6-month period, and to define whether the Cp DNA and antigens previously detected in OAML pts correspond to a viable and infectious microorganism. *Methods*. 20 OAML pts and 42 healthy blood donors referred to our Institution in a 6-month period were intervisted for epidemiological and clinical features. Biological samples (conjunctival swabs and peripheral blood mononuclear cells - PBMC) of pts and donors were collected during interview. The presence of Cp on conjunctival swabs and PBMC was assessed by TETR-PCR and *in vitro* cultural methods. The presence of Cp was assessed also in lymphoma tissue. Differences in epidemiologic features and infection rates were compared by Fisher exact test. *Results*. Donors were more commonly young males living in urban areas, whereas OAML pts frequently reported a history of chronic conjunctivitis and prolonged contact with household animals (85% *vs* 38% of donors; p=0.00001). Cp was detected in lymphoma tissue of 15 (75%) pts. Cp DNA (TETR-PCR)was detected in conjunctival swabs and/or PBMC from 10 (50%) OAML patients and in PBMC from one (2%) donor (p=0.01). Viability and infectivity of Cp, demonstrated by growth in cell cultures, were confirmed in conjunctival swabs and/or PBMC from 5 (25%) OAML pts, but not in donors (p=0.002). *Conclusions*. This prospective case-control study demonstrates, for the first time, that Cp is viable and infectious in conjunctival swabs and/or PBMC of OAML pts. The association between Cp and OAML is now supported by a second Koch's postulate level. Epidemiological features in OAML pts are consistent with increased risk of Cp exposure.

0244

PATTERN OF ANGIOGENESIS-RELATED GENE EXPRESSION DURING IN VIVO GROWTH OF MANTLE CELL LYMPHOMA CELL LINE JEKO-1

J.M. Molinsky,[1] S.L Leahomschi,[1] M.H. Hulova,[1] T.S. Simonova,[1] R.P. Pytlik,[1] M.T. Trneny,[1] T.S. Soukup,[2] J.M. Mokry,[2] E.N. Necas,[1] J.Z. Zivny,[1] P.K. Klener[1]

[1]Charles University in Prague, 1st Faculty of Medicine, PRAHA; [2]Charles University in Prague, Faculty of Medicine in Hradec Kralove, HRADEC KRALOVE, Czech Republic

Background. The significance of angiogenesis for disease progression is well established in solid tumors. Alternatively, other mechanisms such as vasculogenic mimicry and vessel cooption were described to provide oxygen supply. The contribution of these processes and their molecular mechanisms in hematologic malignancies remains to be elucidated. *Aims*. To analyse expression profile of angiogenesis-related genes in human mantle cell lymphoma cell line JEKO-1 growing *in vivo* after subcutaneous xenotransplantation into immunodeficient mice in comparison to the JEKO-1 cell line cultured *in vitro*. *Methods*. We injected 5 millions of JEKO-1 cells subcutaneously into sublethally irradiated NOD/LtSz-Rag1null mice (n=4). Animals were killed when the tumors reached 2 cm in diameter and total RNA was isolated from the tumors. After reverse transcription, real time PCR analysis of angiogenesis-related gene expression was performed by using low density arrays (human angiogenesis panel). The results were normalized to GAPDH expression and two independent RNA isolations from *in vitro* growing JEKO-1 cells were used as calibrator sample. Flow cytometry analysis revealed that tumors consisted of 20-40 % of human CD45 positive cells. To rule out possible nonspecific detection of mouse genes, we separated human lymphoma cells from murine cells on magnetic column by anti human CD45 microbeads. CD45 positive and CD45 negative cell fractions were analysed as positive and negative controls, respectively. *Results*. The positive and negative controls confirmed the specificity of the array for human genes. The selected CD45 positive tumor cells showed similar expression levels as nonselected cells (i.e. the whole tumor cell population). No gene expression was detected in CD45 negative tumor cells. The most upregulated gene in all JEKO-1 tumors compared to *in vitro* growing JEKO-1 cells was platelet-endothelial cell adhesion molecule 1 (PECAM-1/CD31; 25-40 - fold increase). Other upregulated genes included brain-specific angiogenesis inhibitor 1 (BAI-1), fibulin 5 (FBLN5), vascular endothelial growth factor receptor 1 (VEGFR-1), angiogenin (ANG), connective tissue growth factor (CTGF), hepatocyte growth factor (HGF) and lymphangiogenic markers prospero-related homeobox 1 (PROX1) and CD44. Proangiogenic vascular endothelial growth factor (VEGF) and midkine were downregulated and expression of VEGFB didn´t change. No expression of VEGFC, angiopoietin-1,

angiopoietin-2 was detected as well as expression of receptors TIE-1, VEGFR-2, VEGFR-3 and fms-related tyrosine kinase 3 (FLT3). *Summary and Conclusions*. Our results revealed significant changes in gene expression of angiogenesis-related genes in JEKO-1 mantle cell lymphoma cell line after xenotransplantation into immunodeficient mice. Interestingly, the most upregulated gene was platelet-endothelial cell adhesion molecule 1, CD31/PECAM-1. Furthermore, we detected differential expression of several well-known proangiogenic factors (VEGF, ANG, CTGF, HGF) as well as inhibitors of angiogenesis (BAI-1, FBLN5 and VEGFR-1). The results suggest that regulation of angiogenesis by lymphoma cells might represent an important factor impacting growth and propagation of mantle cell lymphomas.

CRYPTIC REARRANGEMENTS OF THE ALK GENE IN ALK-EXPRESSING DIFFUSE LARGE B-CELL LYMPHOMA

K. Van Roosbroeck,[1] J. Cools,[1] D. Dierickx,[2] J. Thomas,[3] P. Vandenberghe,[1] P. Marynen,[1] J. Delabie,[4] C. De Wolf-Peeters,[4] I. Wlodarska[1]

[1]Department of Human Genetics, Catholic University of Leuven, LEUVEN; [2]Department of Hematology, Catholic University of Leuven,LEUVEN; [3]Department of Oncology, Catholic University of Leuven, LEUVEN; [4]Department of Pathology, Catholic University of Leuven, LEUVEN, Belgium

Background. ALK$^+$ DLBCL represents a recently described subtype of B-cell lymphoma, expressing the anaplastic lymphoma kinase (ALK). An aberrant expression of this protein tyrosine kinase is typically found in T/null-cell derived ALK$^+$ anaplastic large cell lymphoma (ALCL) which are characterized by 2p23/ALK rearrangements. So far, less than 40 ALK$^+$ DLBCL cases have been published. The majority of them is characterized by the t(2;17)(p23;q23)/ALK-CLTC rearrangement. *Aims*. The aim of our study was to identify and characterize ALK rearrangements in two DLBCL cases showing expression of ALK. *Methods*. Immunohistochemistry (IHC) was used to assess the expression pattern of ALK in two CD20-/CD138$^+$ DLBCL cases. Conventional cytogenetics, followed by FISH, was applied to identify and characterize the underlying 2p23 aberrations. The putative ALK partner was identified by 5' RACE PCR and RT-PCR followed by sequencing. *Results*. Case 1: cytoplasmic expression of the ALK protein, found by IHC, suggested a variant t(2p23). Cytogenetics revealed complex aberrations not involving 2p23, while FISH showed translocation of the 3'ALK region to 3q27 and translocation of the entire BCL6 gene (3q27) to 2pter. Further 5' RACE PCR detected an in-frame SEC31A-ALK fusion transcript in which exon 24 of SEC31A was fused to exon 20 of ALK. Interestingly, the 4q21 region harbouring SEC31A looked normal in the present case. Further multicolour karyotyping and FISH analysis identified the cryptic SEC31A-ALK fusion at 3q27. This rearrangement probably occurred by a t(2;3)(p23;q27) associated with a cryptic insertion of the 5'end of SEC31A upstream of the translocated 3'ALK. In addition, a duplication of the SEC31A-ALK fusion was found on a der(20). Case 2: IHC showed cytoplasmic and nuclear expression of ALK. Cytogenetics identified a t(2;2)(p23;q31) as a part of a complex karyotype. FISH with LSI ALK showed translocation of the 3'end of ALK to a normal-looking 5q35. This region harbours the NPM gene involved in a classical t(2;5)(p23;q35) which typifies approximately 75% of the ALK$^+$ ALCLs. Further FISH analysis showed a cryptic insertion of the 3'ALK into the NPM locus. This is the first ALK$^+$ DLBCL case in which a t(2;5)-independent NPM-ALK fusion has been detected. *Summary and Conclusions*. In summary, we identified two new rearrangements of ALK in ALK$^+$ DLBCL and confirmed the key role of this gene in the pathogenesis of this rare subtype of B-cell lymphoma. In both reported cases, ALK rearrangements were submicroscopic and generated by an insertion of either the partner gene, SEC31A, into the 3' end of ALK, or by an insertion of the 3' end of ALK into the partner gene (NPM/5q35). These cytogenetically cryptic rearrangements of ALK have never been described in ALK$^+$ DLBCL.

0246

EXPRESSION OF CXCR4 AND CD26 ON DENDRITIC LYMPHOPLASMACYTOID LYMPHOMA: A KEY FOR INTERPRETING SKIN HOMING OF NEOPLASTIC CELLS

L. Del Vecchio,[1] R. Franco,[2] A. De Renzo,[3] G. Cerciello,[3] F. Perna,[3] C. Lo Pardo,[4] V. Mettivier,[5] A.M. D'Arco,[6] G. Corazzelli,[7] P Mirabelli,[8] G. Abate,[8] M. Gorrese,[8] B. Rotoli[3]

Cardarelli, NAPLES;[5]Ematologia Ospedale A. Cardarelli, NAPLES; [6]Ematologia Ospedale Umberto I, NOCERA INFERIORE (SA); [7]Ematologia Istituto dei Tumori Pascale, NAPLES; [8]Ceinge Institute, NAPLES, Italy

Background. An unusual form of leukemia/lymphoma expressing HLA-DR, CD4, CD56 and CD123 (IL3R) has been recently described. Surface antigen mosaic and functional properties of these cells are similar to a fraction of normal dendritic cells, the DC2 or lymphoplasmacytoid subset. This type of neoplasia perfectly overlaps to CD4$^+$CD56$^+$ lymphoma previously named in WHO classification as *blastic NK* lymphoma. To date, two main types of patients affected by dendritic lymphoplasmacytoid lymphoma (DLPL) have been described: (i) cases with an acute leukemia-like picture and (ii) cases with initial skin involvement and subsequent leukemic or lymphomatous dissemination. *Aims*. The aims of this study were: (i) to define the exact immunophenotype of this rare type of neoplasia; (ii) to assess the real incidence of these cases; (iii) to correlate immunophenotype with clinical behavior. *Methods*. In this study we characterized 10 cases of DLPL by using an extended panel of monoclonal antibodies, flow cytometry (FCM) and immunohistochemistry (IH). Nine cases were studied by FCM and 8 by IH. The panel utilized for FCM characterization was the following: CD2, CD3, CD4, CD5, CD7, CD8, CD10, CD11a, CD11b. CD11c, CD13, CD14, CD15, CD16, CD19, CD20, CD22, CD23, CD24, CD25, CD26, CD29, CD33, CD34, CD36, CD37, CD38, CD40, CD41a, CD42b, CD43, CD44, CD45, CD56, CD57, CD58, CD61, CD69, CD71, CD80, CD86, CD103, CD184. *Results*. FCM characterization on bone marrow aspirates in 7 cases with heavy bone marrow involvement consistently evidenced the phenotype HLA-DR$^+$, CD4$^+$, CD56$^+$, CD36$^+$, CD103$^+$. Three cases with massive involvement of bone marrow and no cutaneous infiltration clearly showed CD26. All cases with bone marrow involvement were initially referred to our institution as acute myeloblastic leukemia (AML). During the same period in which we observed the cases reported here, we overall studied 2551 cases of acute myeloblastic leukemia. IH was performed on cutaneous biopsies in 5 patients, all of which expressed CD4, CD56, CD123 and TCL1, along with variable expression of CD68 and CD43. We studied also CXCR4 (CD184), since this receptor and its ligand CXCL12/SDF1 seem to drive metastasis in several cases of neoplastic disease. CXCR4 is antagonized by CD26, trough its enzymatic action on SDF1. CXCR4 was observed by IH in all cases, while convincing expression of CD26 was never found. One cutaneous fragment was also studied by FCM, confirming the CXCR4$^+$CD26$^-$ pattern. *Conclusions*. In conclusion, immunophenotype of this rare disease seems to be stable as regards HLA-DR, CD4, CD56, CD36 and CD103 display. CD26/DPPIV seems to counterbalance CXCR4 function based upon its activity on CXCL12, abundantly produced in the skin, which seems to represent the main destination of dendritic lymphoma spreading. CXCR4 and CD26 appear to be associated with tissue distribution of neoplastic cells, with CXCR4$^+$CD26$^-$ pattern corresponding to cases characterized by initial cutaneous involvement and metastatic potential, CD26 bright expression being restricted to acute leukemia-like disease.

FACS SORTING IS AN EFFICIENT, FLEXIBLE AND CONVENIENT CELL TARGETING STRATEGY: APPLICATIONS IN ROUTINE MOLECULAR DIAGNOSTICS OF MATURE B-CELL MALIGNANCIES

B. Maes, K. Hensen, F. Hillen, V. Peeters, J.-L. Rummens

Virga Jesse Hospital, HASSELT, Belgium

Background and aims. In non-Hodgkin lymphoma and multiple myeloma, the malignant cell populations are often situated within a background of benign lymphoid and non-lymphoid cells. In lymphoid tissues, lymphoma involvement may only be partial and/or reactive B- or T-cells may be abundantly present. Bone marrow or peripheral blood may show only minimal infiltration by lymphoma or myeloma. Detection of chromosomal or gene aberrations on any of these sample types, may be hampered by the abundance of non-malignant cells. A cell targeting strat-

egy may therefore be required, to allow a sufficient sensitivity of any genetic or cytogenetic method such as, FISH or gene- or expression array applications. Methods and *Results.* Within the past years we have successfully validated and implemented in routine diagnostics, the combined approach of FACS imunophenotyping, simultaneous cell purification by FACS directly on glass slides, followed by interphase FISH. FACS is a very flexible purification technique, as all populations of interest can be simultaneously sorted. Only small amounts of material and low numbers of the desired cell type are required for FACS. In our hands, purity of FACS sorting was significantly higher compared to magnetic bead sorting (95-99% *vs* 80 %). Efficiency was also substantially better for FACS sorting. Subsequent interphase FISH analysis can be applied for any genetic aberration of interest on FACS sorted cells. It is fast and non-laborious thanks to the purity of the investigated cell population and the absence of background cells or substances, and with reduced reagent costs as only a small amount of probe should be applied on the small cell spot generated by FACS. In CLL, we have demonstrated that the sensitivity of detecting deletion 17p positive CLL cells by FISH on FACS sorted CD19+CD5+ cells is 1 in 10exp5 to 1 in 10exp6 white blood cells. This sensitivity is as high as that of allele-specific oligonucleotide PCR and allows this methodology to be used for assessing MRD negative status. We have shown that plasma cells present in as low as 1 % of WBC in the bone marrow can be successfully investigated for the occurrence of IGH-translocations, deletion 13q and deletion 17p by this FACS-FISH approach. In addition, we have also shown that array-CGH and metaphase FISH is feasible on FACS purified plasma cells. In follicular lymphoma and mantle cell lymphoma, respectively FISH for the IGH/BCL2 fusion and FISH for the *IGH/CCND1* fusion is successfully performed on respectively $CD19^+CD10^+$ and the $CD19^+CD5^+$ cell populations sorted by FACS. Either blood, bone marrow or a cell suspension of an involved lymph node can be used for diagnosis or staging, or to sensitively detect residual bone marrow involvement after therapy. *Conclusions*. FACS-sorting is an efficient, flexible and convenient cell targeting strategy that allows adequate combination of immunophenotyping and detection of genetic aberrations by FISH in different types of B-cell malignancies. In addition, it is a promising technique in view of novel micro-array applications for B-cell malignancies, which will benefit from the high cell population purity obtained by FACS sorting.

REPEATED RADIOIMMUNOTHERAPY (RIT) WITH I-131 RITUXIMAB IN PATIENTS WITH RELAPSED OR REFRACTORY B-CELL NON-HODGKIN'S LYMPHOMA (NHL); PRELIMINARY RESULTS

H.J. Kang,[1] S.M. Lim,[1] G.J. Cheon,[1] C.W. Choi,[1] S.S. Lee,[1] I.I. Na,[1] B.Y. Ryoo,[1] W.S. Kim,[2] S.H. Nam,[3] Y.H. Park,[2] C. Suh,[4] H.S. Eom,[5] S.H. Yang[1]

[1]Korea Cancer Center Hospital, SEOUL, South-Korea; [2]Samsung Medical Center, SEOUL; [3]Seoul Veterans Hospital, SEOUL; [4]Asan Medical Center, SEOUL, South-Korea; [5]National CancerCenter, SEOUL, South-Korea

Background and Aims. Previously, we reported the results of single treatment with I-131 rituximab in relapsed or refractory B-cell non-Hodgkin's lymphoma (12th EHA abstract 0300). The study results showed modest response rate (35.0% in total patients; 55.6% in low-grade lymphoma, 18.2% in DLBCL.) with relatively short duration of response (median, 2.4 months; range, 1.0-31.6). Therefore, we designed a new protocol to investigate that the efficacy of RIT could be increased by repeated administration of I-131 rituximab as done with chemotherapy. *Methods*. Inclusion criteria were as follows: B-cell NHL with relapsed or refractory to primary standard therapy, measurable disease, adequate hematologic, renal, and hepatic function, informed consent. The rituximab (Mabthera, Roche) was radiolabeled with iodine-131 (I-131) using a modified chloaramine T method. All patients received unlabeled rituximab of 70 mg immediately prior to administration of therapeutic dose of I-131 rituximab (median 7.4 GBq; range, 4.44-9.73 GBq), and 1 months later tumor response was evaluated by contrast enhanced 18F-FDG PET/CT. RIT with I-131 rituximab was repeated in patients who did not progress after single treatment, and continued until disease progression or up to maximum six cycles. *Results*. 16 patients were enrolled (7 Mantle cell, 3 Marginal zone B-cell, 2 follicular cell, 4 diffuse large B-cell; median age, 61 years). Patients had been received one more than prior chemotherapy regimens (range, 1-4) and median treatment cycles of 6 (range, 5-15). A total of 50 cycles of I-131 rituximab (median 3; range, 1-6) were administered, and all patients were evaluated for response and toxicities. The total objective response rate was 68.8%, and 66.7% (5 CR, 3 PR) in low-grade lymphoma, 75% (3 PR) in DLBCL. The median duration of response was 6.6 months (range, 0.6-24.7 months). Adverse events were primarily hematologic toxicities; the incidence of grade 3 or 4 neutropenia and thrombocytopenia was 12.0% (23/50 cycles) and 18% (31/50 cycles), respectively. There was no treatment-related death. *Summary and Conclusions*. Compared to single treatment, repeated administration of I-131 rituximab can increase the duration of response and response rate in patients with relapsed or refractory B-cell NHL.

THE HAEMOPHAGOCYTIC SYNDROME (HPS) RE-VISITED: A SOUTHEAST ASIAN PERSPECTIVE

C. Tan, W. Hwang, Y. Loh, C. Chuah, H.J. Ng, L.H. Lee, S.L. Tien, L.C. Lim, Y.T. Goh, M. Koh

Singapore General Hospital, SINGAPORE, Singapore

Background. HPS is a clinicopathologic entity characterized by fever, cytopenia, liver dysfunction and coagulopathy due to dysregulated activation of non-neoplastic histiocytes. It is associated with a myriad of different causes, with geographical variations, and commonly results in an unfavorable outcome. Data pertaining to its approach is scarce. Advances in immunophenotyping have allowed better delineation of lymphoma-associated HPS. We report the clinical spectrum and outcome of 55 cases of HPS in an adult Asian population from a single institution. *Methods*. Patients(pt) with findings of haemophagocytosis on bone marrow morphology from year 2002 to 2007 were identified and clinical records of such patients were reviewed in this retrospective analysis. Only patients who fulfill the criteria of having HPS were included in the study. *Results*. There were 37/55 cases (67%) associated with malignant lymphoma. According to WHO classification, these include NK/T cell lymphoma, nasal-type (n=11), peripheral T-cell lymphoma (NOS) (n=8), anaplastic large T-cell lymphoma (ALTCL)(n=2), hepatosplenic Á‰ T-cell lymphoma (n=2), angioimmunoblastic T-cell lymphoma (n=1), diffuse large B-cell lymphoma(DLBCL) (n=9), indolent B-cell lymphoma (n=3) and Advanced Hodgkin's disease (n=1). Compared to pt with T or NK-cell lymphomas, pt with B-cell lymphoma were older (median age 69yrs vs 48yrs, p=0.02). Of 11 pt with NK/T-cell lymphoma, nasal-type, 9 had primary extra-nasal presentation, while 3 were extra-nasal relapses, with prior history of nasal involvement. Common to both the T and NK-cell lymphomas were the demonstration of EBV involvement by in-situ hybridization for EBV-encoded early small RNA or PCR for EBV DNA, absence of serological evidence of an active EBV infection and unremarkable tumour masses. Except for 2 cases of ALTCL, marrow infiltration by lymphoma was evident in all cases of T or NK-cell lymphomas. Only 4/9 cases of DLBCL had evidence of marrow involvement. Other causes of HPS (33%) included disseminated TB (n=5), autoimmune disease (n=3), viral infection (1 each for HIV, disseminated variecella, and dengue virus infections respectively), bacterial infection (n=1) and marrow metastasis (n=1).

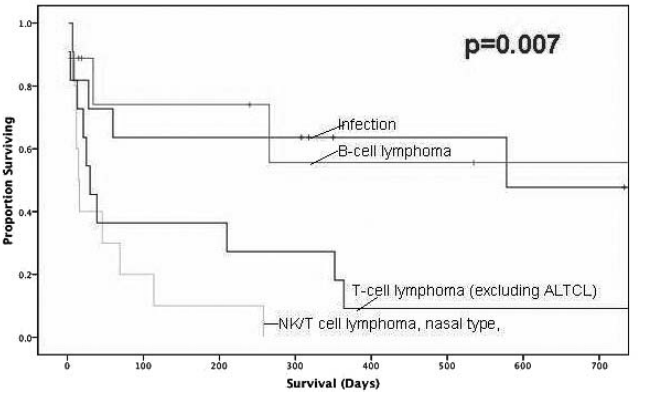

Figure 1. Overall survival by underlying causes of HPS.

Etiological cause of HPS could not be elucidated in 5 cases. Despite similar presenting features, prognosis of non-malignant causes of HPS was good once appropriate treatment was instituted. Two patients with disseminated TB who did not receive anti-TB treatment due to a delay in the diagnosis succumbed to HPS. Median overall survival for NK/T cell lymphoma, nasal-type, T-cell lymphoma (excluding ALTCL), B-cell

lymphoma and infective causes were 15 days, 30 days, 578 days and not reached respectively (p=0.007). Underlying etiology of HPS was a more important prognostic factor than age or performance status on multivariate analysis. *Conclusions*. Vigorous search for an underlying etiology is crucial. Infectious disease screening has to be guided by epidemiological data. A delay in diagnosis may compromise the outcome of a treatable infection like TB. EBV associated NK/T or T-cell lymphoma accounts for a disproportionate number of cases unique to the Asian perspective and prognosis remains dismal. HPS is the common end-point and contributory cause of mortality for all pt with NK/T lymphoma, nasal-type . This has implications in clinical trials.

TRANSCRIPTOME DEFINED PATHOGENESIS AND CLASSIFICATION OF B-CELL NON-HODGKIN LYMPHOMAS IDENTIFIES SIGNATURES THAT PROVIDE AVENUES FOR PROGNOSTIC MARKERS AND GENOMIC DRIVEN TARGETED THERAPIES

M. Aggarwal,[1] M.A. Piris,[1] E. Kimby[2]

[1]*Spanish National Cancer Center, MADRID, Spain;* [2]*Karolinska Institutet, STOCKHOLM, Sweden*

Background. The knowledge so far accumulated about B-cell lymphoma pathogenesis has not been sufficient to facilitate the development of targeted therapies. We analyzed a large series that includes all the major B-cell lymphoma types. *Aims*. Identification of commonly dysregulated pathways in B-cell non-Hodgkin's lymphomas. Identify heterogeneity in B-cell lymphomas in terms of functional pathways. To find out key driving mechanisms in the pathogenesis of B-cell lymphomas. To investigate the prognostic potential of biological markers of pathogenesis. To translate genomic profiling into discovery of targeted therapie. *Methods*. We used a combination of microarray; gene set enrichment analysis, tissue microarrays, gene silencing and multiple bioinformatics tools for our analysis.

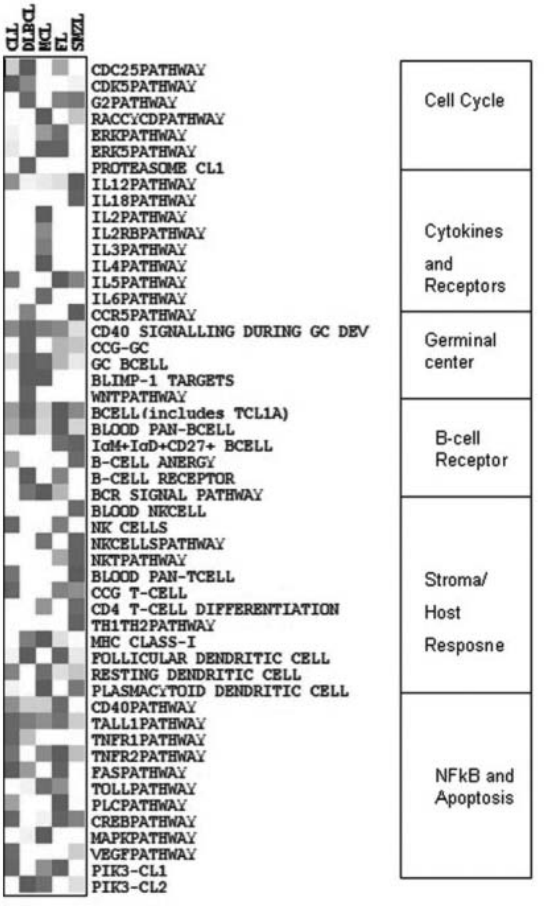

Figure 1. Functional pathways defining heterogeneity

Results. The functional signatures determining lymphoma classification were cell-cycle, apoptosis, cytokine-cytokine receptor interaction, T-cell receptor, B-cell receptor (BCR), cell adhesion, and NF-kB activation. These signatures reveal subclasses of diagnosed lymphoma types, suggesting the existence of a distinct functional heterogeneity within most lymphoma types, and particularly among CLL, MCL, and DLBCL. Functional signatures in B-cell lymphomas allow a better understanding of common mechanisms, and at the same time establish the biological basis of the clinical variability. The results identify the main pathways driving lymphoma growth, and reveal the existence of common survival mechanisms (B-cell receptor pathway) and genes (TCL1a oncogene) that are essential for lymphoma pathogenesis. We explored the functional pathways that define prognostic variance in CLL and other lymphomas. In CLL, using chemical genomic profiling techniques, we identified drugs that can potentially reverse the progression of disease. *Summary and Conclusions*. We identify lymphoma to be a result of multiple oncogenic lesions and deregulated pathways, the key drivers being altered BCR signaling and TCL1A expression acting via the calcium signal pathway in B-cells and T-cells. These findings helped us to explore targeted drugs using chemical genomic profiling in B-NHL.Additionally, we found markers with prognostic potential in MCL an CLL from profiling studies.

FOLLICULAR LYMPHOMA (FL) DIFFERS FROM FOLLICULAR HYPERPLASIA (FH) ALSO AT THE EPIGENETIC LEVEL

J. Paz Carreira,[1] R. Losada,[1] A. Garcia-Rivero,[1] M. Varela-Pérez,[2] A. Alvarez,[3] F. Bal,[2] J. Alba,[4] M. Gonzalez-López[3]

[1]*Centro Oncologico de Galicia, LA CORUÑA;* [2]*Xeral-Calde Hospital, LUGO;* [3]*Juan Canalejo Hospital, A CORUÑA;* [4]*POLUSA, LUGO, Spain*

Introduction. The distinction between benign follicular hyperplasia (FH) and follicular lymphoma (FL) can sometimes be challenging. Germinal centers (GC) are unique sites in peripheral lymphoid tissue where clonal selection of B cells takes place. This occurs as a response to stimulation by various antigens originating, sometimes, follicular hyperplasia (FH). GC have been known to be a major source of B-cell lymphomas including follicular and diffuse large cell. DNA methylation of tumor-suppressor genes is a mechanism of gene silencing involved in the pathogenesis of FL. Much less is known about the role of methylation in FH. We determined the methylation status of 5 tumor-suppressor genes in 20 patients with FL and 30 patients with BFH in order to see any differences between the pathological and the physiological state. Material and Methods. Genomic DNA extracted from paraffin-embedded samples of 20 FL and 30 BFH were analyzed by methylation-specific polymerase chain-reaction to determine promoter hypermethylation of DAP-k, SHP1, Rarβ, p14 and p15. FL samples were obtained from lymph nodes. BFH samples were obtained from lymph nodes and tonsils. Diagnosis was based on morphology and immunohistochemistry analysis. All cases were matched for age, sex and ethnic origin. *Results*. DAP-k, SHP1, p14, p15 and RARb promoters were methylated in FL and BFH. DAP-k and RARb promoter methylation occurred with higher frequency in FL (89% and 72%) than in BFH (44% and 39%) (p=0.004 and p=0.024). SHP1 is methylated in 89% FL vs 35% BFH (p=0.000). p14 was more frequently methylated in FL (100%) than in BFH (36%) (p=0.01), but only five samples were analyzed for this gene. p15 was methylated more frequently in FL than in BFH (39% vs 25%) but the difference was not statistically significant (p=0.388). *Conclusions*. Inactivation of DAP-K, SHP1 and Rarβ is present in FL with significantly higher frequency than in BFH. Therefore, it may have pathogenic significance. With our data, methylation of the cyclin dependent kinase inhibitor p15 is not a differential pathogenic event in FL with respect to FH. However, in the case of p14, in spite of the small size of the sample, it may represent a complementary route to disease progression.

0251

CUTANEOUS CCL27 EXPRESSION IN EARLY-STAGE MYCOSIS FUNGOIDES: ITS ROLE IN THE BALANCE BETWEEN THE TUMORAL INFILTRATE AND ANTI-TUMORAL IMMUNE RESPONSE, AND PROGNOSTIC UTILITY AS A PREDICTOR OF RECURRENCE

G. Goteri,[1] S. Rupoli,[2] A. Campanati,[3] S. Sabato,[1] L . Canafoglia,[2] G. Ganzetti,[3] P. Picardi,[2] A. Costagliola,[1] D. Stramazzotti,[1] S. Pulini,[4] A.R. Scortechini,[2] S. Serresi,[5] M. Ottaviani,[6] M. Nicolini,[6] A. Cellini,[3] G. Fabris,[1] A.M. Offidani,[3] P. Leoni[2]

[1]Institute of Pathology, ANCONA; [2]Clinic of Hematology, ANCONA; [3]Clinic of Dermathology, ANCONA; [4]Department of Hematology, PESCARA; [5]Division of Dermathology, I.N.R.C.A.-I.R.C.C.S., ANCONA; [6]Division of Dermatology, FABRIANO, Italy

Background. Recruitment of neoplastic T-cells in skin is a critical step in the pathogenesis of Mycosis Fungoides (MF) lesions. The chemokine CCL27 attracts memory CCR10-positive T cells to the skin. Increased CCL27 serum levels and skin epidermal expression have been observed in MF patients compared to normal controls, but the interactions between neoplastic cells and the skin immune system needs to be further elucidated. *Aims*. We investigated whether CCL27 expression in MF is related to the density of dendritic cells (DC), CD8+ lymphocytes and CD4+ neoplastic lymphocytes; moreover, whether it influences the clinical response to therapy, it is modifiable by therapy itself and if the changes eventually observed can predict the frequency of recurrences and event-free survival. *Material and methods*. CCL27 epidermal immunohistochemical staining was performed in 52 early stage-MF patients, 34 M/18 F, treated by PUVA plus interferon α for 14 months, with a complete follow-up data. Specimens were obtained at diagnosis and at the end of treatment. Formalin-fixed/paraffin-embedded tissue sections were immunostained with anti-CCL27, CD1a, CD8, CD4 antibodies. CCL27 immunoreactivity was graded as + (faint/moderate staining, limited to epidermal basal layer, as in normal skin); ++ (faint/moderate staining in the suprabasal layers; strong staining up to the lower two-thirds of epidermis); +++ (strong staining of full-thickness epidermis). Density of CD1a-positive DC and CD8+ lymphocytes was graded as + (few/isolated cells), ++ (small, ≤5 cell clusters), +++ (larger, >5 cell clusters). Density of CD4+ lymphocytes was graded as + (perivascular infiltrate), ++ (discontinuous subepidermal band), +++ (continuous band). Statistical analysis was also performed (chi2 test for tables of contingency; event-free survival curves (EFS) by Kaplan-Meier method). *Results*. At diagnosis, CCL27 expression was similar to normal skin in 16 cases and abnormal/suprabasal in 36, with 12 +++ cases. A normal/basal CCL27 expression tended to be correlated with a high DC density and with a low neoplastic infiltrate density (although p=NS). CCL27 at diagnosis was not correlated with clinical response (50 complete remission/CR, 2 partial remission). Treatment induced a significant CCL27 increase (suprabasal in 42 cases with 24 +++ cases; χ^2 test: p=0.004). Skin CCL27 expression at the end of treatment, but not at diagnosis, was related to recurrence and influenced EFS. During follow-up (median, 92.5 mo.s; range, 43-165), 33 patients relapsed (median EFS, 46 mo.s). A normal/basal CCL27 expression at the end of treatment, was correlated with a lower incidence of disease recurrence (3/9 compared to 30/41 with suprabasal expression; χ^2 test: p=0.022) and a longer median EFS (111 mo.s vs 39 mo.s with suprabasal expression; log rank test: p=0.031). *Conclusions*. Increased CCL27 expression in early-stage MF lesions might be related to a balance between neoplastic cells and immunomodulant dendritic cells. CR induction in almost all patients by treatment is not correlated with a CCL27 reduction, but a normal CCL27 expression after treatment designates a subset of patients (about 20%) with a favourable behaviour. The mechanisms involved in the increased CCL27 expression after therapy in the remaining 80% patients, which have a higher probability to recur, need to be further investigated

0252

MUTATION ANALYSIS OF IGVH GENES IN 18 SPLENIC MARGINAL ZONE LYMPHOMA (SMZL) CASES AND CORRELATION WITH CLINICAL AND IMMUNOPHENOTYPIC CHARACTERISTICS

C. Kalpadakis,[1] E. Dimitriadou,[2] T. Vassilakopoulos,[2] M. Angelopoulou,[2] M. Siakantaris,[2] F. Kontopidou,[2] H. Papadaki,[1] P. Panayiotidis,[2] G. Pangalis[2]

[1]University of Crete, HERAKLION; [2]University of Athens, Laikon General Hospital, ATHENS, Greece

Background. SMZL is a distinct entity. Current data suggest that there is an heterogeneous pattern of immunoglobulin (Ig) somatic hypermutation. The prognostic significance of these molecular findings is yet controversial. *Aims.* To evaluate the mutational status in a series of 18 SMZL patients and to correlate it with patients' features and outcome. *Methods.* DNA was extracted from mononuclear cells of spleen tissues and bone marrow. Polymerase chain reaction (PCR) was performed using 5' leader region specific primers for each one of the six VH families (VH1-VH6) and a 3'J consensus primer. Resultant PCR products were next ligated and cloned and plasmid DNA was isolated from overnight cultures of randomly selected colonies. At least five plasmids per case were sequenced for both orientations. Clinical, laboratory and outcome data of these patients were recorded and evaluated in relation to mutational status of IgVH genes. *Results.* In 9 of 18 cases (50%), IgVH genes were found mutated (<98% homology to the nearest germline configuration). Sixteen cases used the VH3 and the other two the VH1 family segments. Correlation of mutation status with clinical, laboratory and outcome characteristics of our pts disclosed no statistical significant findings. Sixteen cases (9 mutated and 7 unmutated) used the VH3 family, while the other two unmutated used the VH1-2 family. In order to determine whether mutations in IgVH regions were antigen driven, we further analyzed the mutation pattern of somatic hypermutation in the mutated cases (Table 1). p values of ≤0,05 according to the multinomial distribution model were considered statistically significant of antigen-selection, as it is currently accepted. In two of the nine mutated cases the R/S ratio in CDR was greater than expected by chance only, suggesting antigen selection. In three mutated cases the excess of R over S mutations targeted the FR regions rather than the CDR. In the remaining four mutated cases the pattern of R/S mutations in FR or CDR showed no evidence of antigen selection. *Summary and Conclusions*. Our results indicate that there are two types of SMZLs, one with mutated VH genes and one with unmutated. VH3 family was the most commonly used. In the mutated cases the ratio of R/S mutations displayed an heterogeneous pattern and in 4 of them antigen selection process could not be clearly supported. Prognostic significance of the VH family usage and mutational status has not been confirmed in this study.

Table 1.

VDJ gene in mutated patients (% numb. of mutations)	FR R/S	P value FR	CDR R:S	P value CDR
VH3-11 J4 D5-5 (97.57%)	3/0	0.28	3/0	0.022

LONG-TERM SURVIVAL OF PATIENTS DIAGNOSED WITH NON-HODGKIN LYMPHOMA AFTER A PREVIOUS MALIGNANCY

D. Pulte,[1] A. Gondos,[2] H. Brenner[2]

[1]Weill Cornell Medical College, NEW YORK, USA; [2]German Cancer Research Center, HEIDELBERG, Germany

Background. An increase risk of non-Hodgkin lymphoma (NHL) has been observed in survivors of several malignancies. Survival for patients with primary NHL has improved in the 1990s and early 21st century, but population-based survival data for patients diagnosed with NHL after a prior malignancy are sparse. One prior study of NHL after HD treated between 1981 and 1999 found generally poor outcomes, with overall survival of about 30% in this patient population, a much lower rate than that for patients with primary NHL treated during the same time period. *Aims*. To disclose changes in survival in patients with NHL after a previous malignancy between the 1990s and the early 21st century. *Methods*. We estimated trends in age specific 5- and 10-year relative survival

of NHL patients with prior malignancy in the United States from 1990-1994 to 2000-2004 from the 1973-2004 data base of the Surveillance, Epidemiology, and End Results (SEER) Program. Period analysis of survival was employed to disclose recent developments with minimum delay. *Results*. 10,605 patients were diagnosed with a NHL after a prior malignancy during the periods studied. The most common preceding malignancies were non-epithelial skin cancers other than melanoma (representing 35% of prior malignancies in this sex and age group) and prostate cancer (12%) for men aged 15-64, prostate (43.5% and 47.4%, respectively) and colon/rectum cancer (12.2% and 16.5%, respectively) in men 65-74 and 75+ years of age. Breast (33.1%) and cervical (19.4%) cancers were most common for women aged 15-64 while breast (41.9% and 42.0%, respectively) and colon/rectum cancers (13.3% and 20.2%, respectively) were most common among women aged 65-74 and 75+. Five and 10-year relative survival has strongly improved for NHL patients with prior malignancies between 1990-94 and 2000-04, from 38.0% to 54.1% and 24.4% to 41.0%, respectively. The increase was most pronounced among men below the age of 65 (from 17.7% to 58.6% and from 12.7% to 44.4%, respectively) but major increases were also seen in older age groups and among women. Despite a strong increase in relative survival, patients with prior malignancy continued to have a worse prognosis compared to those with no prior malignancy (Figure 1), although the gap in survival has lessened over time. *Conclusions*. NHL after a prior malignancy is common, with 1 in 7 cases of NHL occurring in patients with a history of prior malignancy. The prognosis of patients with secondary NHL has strongly improved in recent years, particularly among male patients below 65 years of age. The use of antibody therapy, active treatment for HIV, and other advances are likely to contribute to the improvements observed. A history of prior malignancy continues to be a marker of relatively poor prognosis in patients with NHL, but survival has improved greatly in patients with and without prior malignancy.

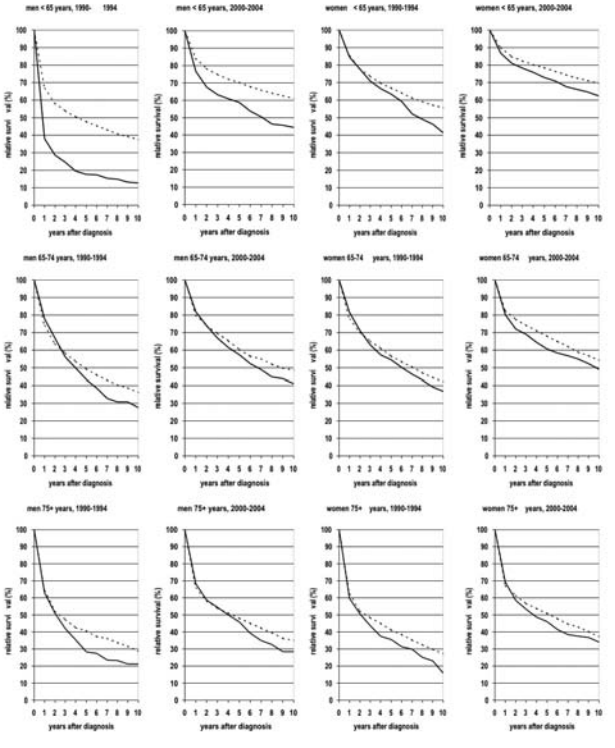

Figure 1. Relative survival rates after in patients diagnosed with NHL. Solid lines represent patients with prior malignancy, dashed lines patients without prior malignancy.

NT-PROBNP IS A POWERFUL AND INDEPENDENT PROGNOSTIC FACTOR FOR SURVIVAL IN ANTHRACYCLIN-TREATED LYMPHOMA PATIENTS

A. Salar, R Guerri, J Comín, A. Alvarez-Larrán, M Gomez, E. Gimeno, B Sanchez-Gonzalez, C. Pedro, E. Abella, L Molina, T. Gimenez, J Bruguera, C. Beses

Hospital del Mar, BARCELONA, Spain

Introduction. N-terminal pro-brain natriuretic peptide (NT-proBNP) has been shown to be a sensitive indicator of cardiac abnormalities. High blood levels of NT-proBNP have been associated with poor clinical outcome in patients with amyloidosis treated with conventional chemotherapy and/or autologous transplantation. However, its clinical value in lymphoma is unknown. *Aims.* To assess the value of NT-proBNP as a prognostic variable for survival in patients with lymphoma receiving anthracyclin-containing chemotherapy. *Patients and methods*. patients with Hodgkin´s (HL) and non Hodgkin´s lymphoma (NHL) candidate to receive anthracyclin-containing chemotherapy were included. Clinical heart examination, evaluation of cardiovascular risk factors, determination of NT-proBNP blood levels and high resolution echocardiography were done at diagnosis, at the end of therapy and annually thereafter. NT-proBNP levels were measured with electrochemiluminescence sandwich immunoassay (ECLIA; Roche) on an Elecsys System 2010. Clinical variables related with patient characteristics, lymphoma risk and cardiovascular risk were analyzed. *Results*. 81 patients have entered onto the study and 79 pts have been analyzed (2 early lost of follow-up). Patient characteristics: median age: 61 years (range: 18-85); male: 58%; NHL: 79%; HL: 21%; ECOG/PS ≥2: 25%; Ann Arbor III-IV: 57%; B-symptoms: 24%, bulky: 17%; LDH >1 nv: 34%; β2-microglobulin >1 nv: 53%; albumin <35 g/L: 32%; haemoglobin <105 g/L: 20%; extranodal disease ≥2: 17%; comorbidities ≥2: 44%; previous cardiac disease: 11%; median NT-proBNP: 100 pg/mL (9-9102); median left ventricular ejection fraction (LVEF): 65% (range 41-83). High blood levels of NT-proBNP were associated with: age, Ann Arbor stage, ECOG/PS, LDH, β2-microglobulin, albumin, haemoglobin, comorbidities and previous cardiologic history (but not with LVEF). Median follow-up from starting treatment was 18 m (0-45). Ten patients died. Overall survival (OS) at 12 and 24 months were 87% (95% CI: 80-94%) and 84% (95% CI: 80-88%) respectively. Table 1 shows sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and efficacy for several cut-off levels of NT-proBNP. Factors associated with worse OS in the univariate analysis were: NT-proBNP >900, ECOG/PS ≥2, LDH >1 nv, β2-microglobulin >1 nv, albumin <35 g/L, haemoglobin <105 g/L, number of comorbidities ≥2, previous cardiologic history, number of extranodal sites ≥2, B-symptoms, age >60. In multivariate analysis, the strongest factor predicting for survival was NT-proBNP >900 (HR 22, 95% CI: 4.1-119) (p<0.0001). *Conclusions*. NT-proBNP >900 is a strong and independent prognostic factor for survival in patients with lymphoma treated with anthracyclin-containing regimens. 2. Levels of NT-proBNP are not associated with LEFV in this study. 3. NT-proBNP is an easy, fast, widely available and well-standardized parameter that could be useful in addition to other well-established prognostic indexes.

Table 1.

Cut-off of NT- proBNP	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Efficacy (%)
> 330	90	78.3	37.5	98.2	79.8
> 500	80	82.6	44.4	96.7	84.8
> 900	80	82.6	72.7	97	93.7

T-CELL LARGE GRANULAR LYMPHOCYTE LEUKAEMIA: CLINICAL COURSE AND RESPONSE TO TREATMENT

F. Fortune,[1] A. Fortune*,[1] K. Kelly*,[1] J. Sargent,[2] S. McGuckin,[1] F. Quinn,[1] K. Haslam,[1] D. O'Brien,[1] E. Conneally,[1] P. Browne,[1] P. Thornton,[2] E. Vandenberghe[1] *Co first author

[1]St. James Hospital, DUBLIN, Ireland; [2]Mater Hospital, DUBLIN, Ireland

Background. Large Granular Lymphocytic Leukaemia (LGL) is an indolent T lymphoproliferative disorder. Molecular analysis of the T cell receptor (TCR) gene to define clonal T populations has made LGL diagnosis robust and thus clarified its natural history. *Aims.* We have reviewed the clinical course and treatment outcome of patients with LGL attending 2 large haematology services to clarify its natural history and assess response to treatment. *Methods*. The clinical features, laboratory findings and treatment response. Of 20 patients diagnosed between 2003-2007 with a clonal proliferation of T-LGL confirmed by morphology, flow-cytometry and molecular analysis. *Results*. Twenty patients with a median age of 66 (range 27-78) were referred to a haematology unit by their general practitioner with non-specific symptoms of fatigue (55%), recurrent infections (45%) and minor blood count abnormalities. The median time from symptom onset to diagnosis was 5 months. Thirteen (65%) patients were neutropenic, 6 had an absolute lymphocytosis (>5×10^6 /μL) and 7 (35%) were anaemic. Physical examination was normal in 60% of patients with splenomegaly noted in 15%. An excess of LGLs was seen on blood film with the following immunophenotype: $CD3^+$, CD7 weak, CD4:CD8 ratio reversal and CD56-. Clonality was confirmed using TCRβ, γ and δ Biomed probes, of which 18 had β, 18 γ and 9 δ gene rearrangements. Twelve (60%) patients needed treatment for symptoms or a neutrophil count <0.5×10^9/L, with a median time from diagnosis to treatment of 11 months. Six patients received cyclosporine as first line therapy, resulting in a temporary improvement in blood count in 3 patients. Methotrexate or Chlorambucil was used in 4 patients with no improvement. Eight patients were treated with the purine analogue 2'deoxycoformycin (Pentostatin); 4 receiving it as first line therapy. The overall response rate was 62.5% with a complete haematological response in 3 patients (including 2 molecular remissions) and a partial response in 2 patients. Two patients relapsed 18 months after Pentostatin, with 1 patient achieving a further remission with alemtuzamab and a second multiply treated patient with a 20-year history of LGL proceeding to allogeneic bone marrow transplantation. *Conclusions*. This case series confirms the clinically heterogeneous nature of this disorder, and suggests that it may be under-diagnosed resulting in non-specific morbidity in the community. Accurate diagnosis using molecular techniques is now possible. Pentostatin is an effective, well-tolerated treatment for symptomatic LGL. Clarity on indications for treatment and a logical treatment algorithm might improve the morbidity of this disease.

HYPOGAMMAGLOBULINEMIA AND NON-NEUTROPENIC INFECTION AFTER CHEMOTHERAPY COMBINED WITH RITUXIMAB. PREDICTIVE FACTORS AND CLINICAL SIGNIFICANCE

K. Filanovsky, L. Shvidel, M Shtalrid, A. Duek, M. Haran, E. Sigler, A. Berrebi

Kaplan Medical Center, REHOVOT, Israel

Rituximab is a chimerical human/ mouse monoclonal anti-CD20 antibody successfully applied in B-cell lymphoproliferative disorders. The suppression of B-lymphocytes may induce hypogammaglobulinemia and increased risk for infection. These complications are rarely observed as a result of monotherapy with rituximab but have been often noted following combination with aggressive chemotherapy or in the setting of autologous stem cell transplantation (ASCT). In an attempt to study the role of rituximab in induction of hypogamma, we analyzed the frequency of this phenomenon, its possible causes, infectious complications and infection-related mortality in lymphoma patients treated with different chemotherapy regimens with or without rituximab. We analyzed 182 patients with lymphoma; 136 of them received rituximab concurrently with chemotherapy (R-Chemo) and 46 patients treated with chemotherapy only, with follow-up period of up to five years. Following R-Chemo, 17 cases (12.5%) of severe hypogamma (defined as <60% of normal IgG range) were diagnosed, 21 patients (15.5%) had mild and moderate hypogammaglobulinemia, and 16 (12%) were found with decreased IgM alone. Multivariate analysis showed a significant increase of severe hypogamma when >6 doses of rituximab were given. Moreover, rituximab in >8 doses leaded to severe hypogamma in 50% of patients compared to 11.8% in patients treated with ≤8 doses (p .006) associated with 3 times more infections. The type of chemotherapy regimen didn't influence development of the hypogamma. Even myeloablative chemotherapy used in combination with rituximab before ASCT slightly increased the rate of severe hypogamma (p .065). Only the combination of fludarabine and rituximab (FR) compared to other Chemo-R, induced non-significant increase of severe hypogammaglobulinemia (21% vs 11%; p=0.02), and severe non-neutropenic infection 19.4% vs 5.0% (p .005) and infection-related mortality 24% *vs* 6% (p. 004). Multivariate analysis showed that patients post FR treatment were 6.4 times more prone to have severe infections than post other Chemo-R regimens (95% CI 1.49-27.0). Age and gender of patients, type of lymphoma, bone marrow involvement didn't affect the immunoglobulin level. We found a strong correlation between the IgG level and frequency of severe infections and mortality from infection (p<0.01). Finally, the pre-treatment hypogamma was not found as a risk factor for infection. However, the duration of this phenomenon was found important: patients with severe hypogamma lasted >6 months were 4.5 times more likely to have severe infection (95%CI 1.19-18.5). In conclusion, hypogammaglobulinemia is an important phenomenon leading to increase in infection and infection-related mortality rate in lymphoma patients receiving chemotherapy with or without rituximab. Rituximab given for >6 cycles significantly increases the incidence of severe hypogammaglobulinemia. Fludarabine-based chemotherapy combined with rituximab and the duration of hypogammaglobulinemia are independent predictive factors for severe infection and infection-related mortality.

INTERLEUKIN 10 (IL10) PROMOTER POLYMORPHISMS ARE ASSOCIATED TO THE EPSTEIN-BARR VIRUS STATUS IN CHILDHOOD BURKITT'S LYMPHOMA: PATHOGENIC CLUES FROM AN INTERMEDIATE RISK REGION

C. F. M. Fonseca Minnicelli, M.H.M. Barros, I.Z. Zalcberg, R.H. Hassan

National Institute of Cancer, RIO DE JANEIRO, Brazil

Background. IL10 is an immunoregulatory cytokine that exerts B cell proliferation effects. IL10 expression is influenced by several of EBV proteins. Moreover, EBV susceptibility seems to be related to IL10 promoter polymorphisms. *Aims*. To investigate the role of IL10 as a susceptibility factor in BL, related to EBV status. *Methods.* A case-control study was performed including 57 BL patients (1-16 years, median 6; M40:F17) and a group of 270 healthy controls (M148:F122), including 20 umbilical cord blood samples (age 0), 51 children (median age, 8 years) and 199 adults (median 26 years). EBV association was determined in BL samples by EBER-ISH and PCR. Genotyping was performed by allele specific (AS)-PCR and fluorescent STR-PCR for positions -1082(A/G) and -592(A/C) of the proximal haplotype and the IL10.G microssatelite, respectively. Analysis of the proximal haplotype -1082(A/G), -819(C/T),-592(A/C) was performed in 106 controls and 48 BL cases. *Results.* In the control group, genotypic frequencies were AA= 44.3%, GG= 9.9% e GA= 45.8% for the -1082 position and AA= 6.8%, CC=28.4% and AC= 64.8% for -592. In BL patients, -1082 genotypic and genic frequencies were GG=26.3%, GA=40.3% and AA=33.4%; G allele 0.46, and A allele 0.54. The -1082 GG genotype and G allele, belonging to the high IL10 expression GCC haplotype, were over-represented in BL compared to the control group (p= 0.006 and p=0.043, genotypic and genic respectively). When BL patients were grouped in EBV+ (n=31) and EBV- (n=24), the frequency of -1082 G allele was significantly higher in the EBV-group in relation to control (OR 2.38; CI95%: 1.34-4.22; p=0.0043). Analysis of the -592(A/C) position in BL group showed frequencies of AA=2.3%, AC=50% and CC=47.7%; A allele 0.27 and C allele 0.73. Genotypic frequencies were significantly different from controls, due to an over-representation of CC genotype (p=0.04). Such differences were not related to EBV status. The proximal IL-10 haplotypes for high, intermediate and low cytokine production, GCC, ACC and ATA, respectively were detected in control and BL groups. In BL, ATA/ATA (1%) and GCC/GCC (42%) were the less and most frequently found genotypes, compared to controls, with ACC/ACC (4.7%) and GCC/ACC (24.5%) as the less and most frequent genotypes. Statistical comparison showed a higher-than-expected frequency of homozygous GCC genotype in BL (p=0.066). The IL10.G CA tandem repeat polymorphisms showed a range of 18 to 25 in the BL group and 18 to 26 in control group, without significant differences. *Conclusions*. Our results suggest that IL10 inter-individual genetic variations have a role in BL predisposition and patho-

genesis. Differences between BL cases and controls were accounted by an over-representation of the GCC haplotype. -1082G allele and GG genotype were over-represented in EBV- BL. This study has the characteristic of evaluating similar number of EBV+ and EBV- cases originated in the same socio-geographical context, allowing to propose a differential effect of IL10 polymorphisms according to the virological status of BL. In EBV+ cases, genetically determined IL10 expression variation might be obscured by the potent EBV-mediated IL10 induction.

RISK OF FEBRILE NEUTROPENIA AND USE OF G-CSF PRIMARY PROPHYLAXIS IN NON-HODGKIN'S LYMPHOMA PATIENTS RECEIVING R-CHOP-21

C. Haioun,[1] U. Jaeger,[2] P. Lugtenburg,[3] R. Pettengell,[4] F. Principe,[5] F. Rossi,[6] A. Salar,[7] M. Schwenkglenks,[8] G. Verhoef,[9] S. Edmundson,[10] P. Bacon[11]

[1]CHU Henri Mondor, CRETEIL, France; [2]Universitatsklinikum, VIENNA, Austria; [3]Erasmus Medical Center, ROTTERDAM, Netherlands; [4]St George's University of London, LONDON, UK; [5]Hospital San Joao, PORTO, Portugal; [6]CTMO Fondazione OM PoMaRe IRCCS, University of Milan, MILAN, Italy; [7]Hospital del Mar-IMAS, BARCELONA, Spain; [8]European Center of Pharmaceutical Medicine, University Hospital, BASEL, Switzerland; [9]University Hospital Gasthuisberg, LEUVEN, Belgium; [10]Amgen Ltd, UXBRIDGE, UK; [11]Amgen Europe (GmbH), ZUG, Switzerland

Background. Three-weekly CHOP (cyclophosphamide, doxorubicin, vincristine, prednisone) chemotherapy with rituximab (R-CHOP-21) is the standard of care for aggressive Non-Hodgkin's Lymphoma (NHL) in many countries. CHOP regimens are myelotoxic, carrying a substantial risk of febrile neutropenia (FN). Current guidelines recommend granulocyte colony-stimulating factor (G-CSF) primary prophylaxis for patients at overall ≥20% risk of FN due to their chemotherapy regimen and patient-related factors. IMPACT NHL is an observational study assessing neutropenia and anaemia management with 2- and 3-weekly CHOP regimens in Europe and Australia. *Aims.* In this analysis, we report physician-assessed risk of FN at baseline in patients with aggressive and indolent B-cell NHL receiving R-CHOP-21 and the use of G-CSF primary prophylaxis. *Methods*. For this observational study of NHL management, data are collected both retrospectively and prospectively. This interim analysis focuses on retrospective data from consecutive NHL patients treated with R-CHOP-21 at 62 centres in 10 countries. Eligible patients were the five who had most recently completed treatment prior to the centre joining the prospective study. Patients received 1-8 cycles of R-CHOP-21. Physicians were asked to review patient records and assess FN risk prior to therapy using criteria from the EORTC guidelines on G-CSF use (i.e. total FN risk derived from R-CHOP-21 and any patient-related factors such as older age and advanced disease stage). Here, we present the proportion of patients assessed to be at ≥20% baseline FN risk and the use of G-CSF primary prophylaxis (defined by current practice as initiation up to Day 7 of cycle 1). The subsequent incidence of FN and the incidence of FN-related hospitalizations are also shown. *Results*. In total, 174 patients who began treatment with R-CHOP-21 between 01/2005 and 05/2007 were included in this analysis. About two thirds (61%) were male and the mean age was 61.2 years (range: 18-83; 83 [48%] were aged ≥65 years). Forty percent of patients had Stage IV disease; 12% had received prior treatment. Diffuse large B-cell lymphoma was the most common histological type (59%), followed by follicular lymphoma and mantle cell lymphoma. Ninety-one patients (52%) were judged to have been at ≥20% FN risk from R-CHOP-21 and patient-related factors; 44% of these patients received G-CSF primary prophylaxis (Table 1). The actual incidence of FN in this group of patients was 23%. Overall, 29% of patients received G-CSF primary prophylaxis (pegfilgrastim or daily G-CSF [mean±SD daily G-CSF prophylaxis doses in cycle 1: 4.55±1.80]). Twenty percent of patients eventually experienced FN. There were 38 hospitalizations primarily related to FN. *Conclusions*. In this analysis, physicians estimated over half of NHL patients receiving R-CHOP-21 to be at high (≥20%) risk of FN at baseline (according to guideline criteria). Less than half of these patients received G-CSF primary prophylaxis and 23% of them subsequently experienced FN. The overall incidence of FN for all patients was 20%. FN led to a substantial number of hospitalizations. This preliminary analysis suggests G-CSF primary prophylaxis should be considered for NHL patients receiving R-CHOP-21.

Table 1. Physician-assessed baseline FN risk, G-CSF primary prophylaxis and actual incidence of FN in NHL patients receiving R-CHOP-21.

	Assessed baseline FN risk <20%	Assessed baseline FN risk ≥20%	All patients
	N = 69	N = 91	N=174
G-CSF primary prophylaxis	10 (14%)	40 (44%)	50 (29%)
FN cycle 1	7 (10%)	7 (8%)	14 (8%)
FN in any cycle	13 (19%)	21 (23%)	34 (20%)
NB. No FN risk was assigned for 14 patients			

Non-Hodgkin's lymphoma - Clinical (indolent + miscellaneous)

THE (R)VAD+C REGIMEN IS A GOOD PREPARATIVE REGIMEN BEFORE PBSC TRANSPLANTATION FOR MCL PATIENTS TREATED IN FIRST LINE AND KI67 APPEARS AS AN EFFECTIVE INDEPENDANT FACTOR OF SURVIVAL: TEN YEARS EXPERIENCE OF THE FRENCH GOELAMS GROUP

R. Gressin,[1] S. Caulet Maugendre,[2] E. Deconinck,[2] O. Tournilhac,[2] M. Dartigeas,[2] M.P. Moles,[2] J. Dugay,[2] D. Guyotat,[2] J.F. Rossi,[2] S. Le Gouill,[2] G. Lepeu,[2] G. Damaj,[2] T. Lamy,[2] P. Solal Celigny,[3] H. Maisonneuve,[4] B. Corront,[4] J.P. Vilque,[2] P. Casassus,[2] J.L. Dutel,[4] J.P. De Jaurreguyberry,[5] F. Maloisel,[2] P. Rodon,[4] A. Thyss,[6] P. Feugier,[2] C. Le Maignan,[2] S. Cailleres,[4] V. Lucas,[4] i. Grulois,[4] A. Bellange,[4] M. Colonna,[7] P. Colombat[2]

[1]CHU Michallon, GRENOBLE, France; [2]CHU, RENNES; [3]Clinique Victor Hugos, LE MANS; [4]CHR, LA ROCHE SUR YON; [5]CH Sainte Anne TOULON; [6]Centre Lacassagne, NICE; [7]Cancer Register of Isère, GRENOBLE, France

Background. Consolidative PBSC transplantation appears as the best strategy for MCL patients who have responded to a first line treatment. Today there is no consensus for that first regimen. The overall survival (OS) of these patients depends on independent factors described in the recent MIPI score. Nevertheless this index doesn't integrate the proliferation index which has been often underlined in the literature as a potential factor for survival. *Aims.* to confirm the real efficacy of the (R)VAD+C regimen before PBSCT in MCL patients (Gressin Ann Oncol 1997) and to analyse the value of the MIB1 (KI67) on survival we present the results of two consecutive prospective phase II studies of the Goelams. *Methods.* Following informed consent, 113 patients were enrolled in one of the two studies opened between 1996 and 2005. MCL diagnosis was centrally reviewed and ki67/MIB1 expression systematically counted on 1000 cells (2x500). From 1996 to 2000, 74 patients received the VAD + C regimen (classical VAD followed by ten days of chlorambucil 12 mg/D from D20 to D29. Delay between each cycle was 35 D). After 4 cycles, the responders over 60 years received 4 additional cycles and those under 60 two additional cycles followed by PBSCT. Between 2001 and 2005, 39 patients aged less than 65 years received RVAD+C (rituximab 375 mg/m^2 D1 of each VAD) followed by PBSCT. The conditioning regimen associated alkeran 140 and a 8 grays TBI. Treatment response was defined according to the Cheson criteria after 4 cycles of (R)VAD+C. *Results.* the two patient series showed similar clinical and biological features at diagnosis and both overall and complete response rates (ORR 73% and CRR 46%). Significantly, grade ? haematological toxicity occurred in less than 5% of patients. 62% (49/79) of the young patients were transplanted. The response to the (R)VAD+C depends on 3 independent factors: lymphocytosis> 5G/L, LDH>N and B symptoms. With less than 2 factors, the ORR and CRR of 70% of the patients were 80 and 60%. OS was better in transplanted population (30 months vs 65 m). 4 independent factors of OS were determined by a cox regression : LDH>N, PS> 2, MIB1 > mean value 25 and B symptoms. 4 prognostic groups were defined with a median OS respectively at 112 m (no factor), 55 m (1 f), 40 m (2 f) and 11 months (3-4 f). The MIPI score distinguished three groups as defined in literature (low, intermediate and high risk) with a median OS of respectively 75 m, 42 M and 20 m. *Conclusion*. The (R)VAD+C regimen offers a good efficacy/tolerability ratio before PBSCT for MCL treatment. It is especially relevant for 70% of patients which appear with few factors of response at diagnosis. Despite the relevance of the new MIPI score for these patients treated by a less toxic regimen than the RCHOP, we believe that the MIB1/KI67 could better qualify these survival prognosis factors.

0260

PROLONGED SURVIVAL IN REFRACTORY/RELAPSED MANTLE CELL LYMPHOMA FOLLOWING EARLY-INTENSIFIED CHEMOTHERAPY WITH MULTIPLE AUTOLOGOUS HEMATOPOIETIC STEM CELL SUPPORT

S.C. Cortelazzo,[1] M. Mian,[1] T.C. Tarella,[2] A. Rossi,[3] M.M. Magni,[4] A.M.G. Gianni,[4] P.C. Patti,[2] M.S. Mirto,[2] B.F. Benedetti,[2] P.G. Pizzolo,[2] R.A. Rambaldi[3]

[1]Division of Hematology and [2]BMT, BOLZANO; [3]Hematology, TURIN, Italy; BERGAMO, Italy; [4]Oncology INT, MILANO, Italy

Background.Patients (pts) with Mantle Cell Lymphoma (MCL) resistant/relapsed after front-line therapy, generally had a short survival even though they were treated with high-dose chemotherapy supported by autologous peripheral blood progenitor cell (PBPC) transplantation (ASCT). *Aims*. To evaluate if an early intensified chemotherapy (HDS) with or without rituximab with multiple PBPC support could improve the clinical outcome of this poor-risk subset of pts. *Methods*. A cohort of 41 MCL pts, median age 55 years (range 36-69), M/F 26/15, resistant (N=19) or relapsed (N=22) after anthracyclin or fludarabine containing regimens with or without rituximab is the subject of this intention to treat retrospective analysis. The adverse features at enrolment in this salvage program were: blastoid variant (17%), bulky disease (23%), BM involvement (73%), age>60 yrs (32%), B symptoms (17%), elevated LDH (35%), advanced stage (90%), poor ECOG-PS (10%), >1 extranodal sites (42%), IPI>2 (33%). After 2-3 cycles of cisplatin-containing chemotherapy, pts received high dose (hd) cyclophosphamide (CTX) 7g/sqm, and hd-Ara-C (2g/sqm every 12 hours for 6 days) with PBPC support. Following HDS a conditioning program with hd-melphalan (180 mg/sqm) supported by PBPC and/or hd-mitoxantrone plus hd-melphalan (60 and 180 mg/sqm) with ASCT was planned. Rituximab (375 mg/sqm) was given to 66% of pts for a total of 6 doses, twice after hd-CTX and hd-AraC, as *in vivo* purging before CD 34$^+$ cell harvest and twice after ASCT. *Results*. 73% of pts completed the planned program. All pts mobilized enough cells CD 34$^+$ to support hd Ara-C and hd-melphalan and ASCT after mitoxantrone+melphalan. Following HDS 62% of pts achieved a CR. At completion of treatment the CR rate was 71%, and TRM at 100 days was 7%. After a median follow-up of 44 months (range 10-123) relapse occurred in 10/29 remitters (34%). By Chi-square test only BM involvement was associated with relapse. The rate of 2nd CCR was 49 % and the 5-year estimate of OS, EFS and DFS was 51, 46 and 59%, respectively. It is noteworthy that resistant and relapsed pts were equally sensitive to HDS in term of CR rate (63.vs 77%) and duration (5 year DFS, 62 *vs* 70%). Pts who received rituximab had a superior CR rate (78 *vs* 57%) and duration (5 year DFS, 62 *vs* 42 %) even if the small number of pts did not allow the achievement of statistical significance. Cox multivariate analysis failed to identify within potential prognostic markers factors predictive for OS and EFS. *Conclusions*. The present study showed that poor risk pts with resistant/relapsed MCL may benefit of early intensified chemotherapy and multiple PBPC support. It should be investigated whether the implementation of the use of rituximab in induction and/or maintenance could improve these promising results or if other active agents might be considered.

0261

ANALYSIS OF OUTCOMES AND FOLLOW-UP IN NON-HODGKIN LYMPHOMA PATIENTS TREATED WITH 90Y-IBRITUMOMAB TIUXETAN FOR RECURRENT OR REFRACTORY DISEASE. DATA OBTAINED FROM RADIOIMMUNOTHERAPY REGISTRY

P.G. Giraldo,[1] J. Gómez Codina[2]

[1]H. U. Miguel Servet, ZARAGOZA, Spain; [2]H. U. La Fe, VALENCIA, Spain

Background. 90Y Ibritumomab tiuxetan (90Y-RIT) is approved for the treatment of refractory or recurrent non-Hodgkin follicular lymphoma (NH FL). *Aims.* To analyze retrospectively the aggregate data of NHFL patients, from the Spanish-Portugal registry of patients treated with 90Y-RIT in clinical practice setting in terms of effectiveness and tolerability in order to provide a pragmatic approach to experimental data. *Methods.* Effectiveness endpoints retrospectively studied were: objective response rate (ORR), time to progression (TTP) overall survival (OS) and safety. Clinical prognostic factors were collected to asses their possible influence upon treatment effectiveness, by multivariate analyses. *Results.* 169 p from 51 centres (treated since commercial availability in Spain and Portugal until August 2007) were registered: M/F 57.7%/42.3%; mean age 59.6 years (19-83); ECOG 0-1 79.7%; 113 had FL (66.9%) and 56 non-

FL (33.1%). ORR was 66.9% (95%CI: 59.8, 74.0). According to FLIPI, ORR was: LR: 86.8%; IR: 65.5%; HR: 58.6%. According to IPI, ORR was: LR: 52.2%; ILR: 57.1%; IHR: 44.4%; HR: 33.3%. Median follow-up time was 6.6 months, median TTP was 10.1 months (95% CI:6.8-13.3) and median OS has not been achieved, with an estimated OS at 1 and 2 years of 74.1% and 51.0% respectively. Intermediate and high FLIPI score were significantly associated with worse response rate and more risk for progression than lower score: Odds Ratio 0.29 (95%CI: 0.09-0.88) and 0.25 (95%CI: 0.08-0.77), respectively; Hazard Ratio 3.01 (95%CI: 1.36-6.66) and 4.33 (95% CI: 1.98-9.49), respectively. More than 2 previous treatments, was also related with a worse response rate for FL p: OR 2.49 (95% CI: 0.87-7.08). Safety analysis is summarized in Table 1.

Table 1. Safety analyses.

Haematological % (G3-4)	
▪ Anemia	56.2 (23.7)
▪ Neutropenia	62.7 (45.6)
▪ Leucopenia	67.5 (37.3)
▪ Thrombocitopenia	85.2 (50.3)
▪ Febrile Neutropenia	10.1 (10.1)
Non haematological toxicity % (G3-4)	
▪ Asthenia	36.1 (8.3)
Treatment/interventions required (%)	
▪ Hospitalization	26.6
▪ G-CSF	43.8
▪ Red blood cell transfusions	29.0
▪ Platelet transfusions	30.8

Conclusions. Despite the limitations of the retrospective design of the Registry, these results obtained with 90Y-RIT for lymphoma patients treated within the clinical practice setting are similar to that obtained in clinical trials. Updated data will be presented at the meeting.

0262

LONG TERM OUTCOMES OF PATIENTS WITH ADVANCED-STAGE CUTANEOUS T CELL LYMPHOMA AND LARGE CELL TRANSFORMATION

S. Arulogun,[1] H.M. Prince,[1] J. Ng,[2] S. Lade,[1] G.F. Ryan,[1] O. Blewitt,[1] C. McCormack[2]

[1]Peter MacCallum Cancer Centre, EAST MELBOURNE; [2]St Vincent's Hospital, MELBOURNE, Australia

Background. Cutaneous T cell lymphoma (CTCL) is a rare disease, and only a small number of long-term follow-up studies worldwide have been performed on large cohorts of patients. Although typically an indolent disease, approximately one-third of patients present with, or progress to, advanced-stage disease (stages IIB-IVB). *Aims and Methods*. We aimed to define the outcome of patients with CTCL and determine the risk of progressing to advanced-stage disease. A 31-year retrospective analysis of our cutaneous lymphoma database, containing 297 patients with mycosis fungoides (MF) and Sezary syndrome (SS), of whom 92 patients had advanced-stage disease (ASD) and 22 patients had large cell transformation (LCT), was undertaken to study long-term outcomes and identify clinical predictors of outcome. LCT was diagnosed if at least one skin biopsy showed a population of large cells that were greater than 4 times the size of small lymphocytes exceeding 25% of the total lymphoid infiltrate. *Results*. The median age at diagnosis of ASD was 60 years. Two-thirds of patients with ASD presented with *de novo* ASD; the remaining one-third had a preceding diagnosis of early-stage MF. The median follow up was 4.4 years (0.1-33 years) for the entire MF/SS population. The median overall survival (OS) for ASD was five years with a 10-year predicted OS of 32%. Age at initial diagnosis (p=0.01), tumour stage (p=0.01) and clinical stage (p=0.0003) were found to be significant predictors of outcome of ASD. Patients who presented with *de novo* advanced-stage MF/SS demonstrated a non-statistically significant trend to better outcomes than those with a prior diagnosis of early-stage MF. Large cell transformation was diagnosed in 22/297 MF/SS patients (7.4%), and present at the time of initial MF/SS diagnosis in 7/22 patients (32%). With respect to patients who progressed to LCT, the rate was only 1.4% in patients with early-stage disease, compared with stage IIB (27%) and stage IV (56%-67%) disease, with a median time from initial diagnosis of MF/SS to LCT of 2.3 years (0.1-29 years). At the time of diagnosis of LCT, patients had plaque lesions (4), tumour lesions (16) and erythroderma (2). The median OS following the diagnosis of LCT was 2 years. *Conclusions*. In this group of patients with long-term follow-up, we demonstrate that the incidence of LCT is strongly dependent on tumour stage at diagnosis and demonstrate a much lower overall risk of LCT than previously reported, which likely reflects the community-based referral pattern of our cutaneous lymphoma clinic.

0263

RESULTS FROM A PHASE II STUDY INVESTIGATING THE EFFICACY AND SAFETY OF LENALIDOMIDE ORAL MONOTHERAPY IN RELAPSED OR REFRACTORY INDOLENT NON- HODGKIN'S LYMPHOMA

H.W Peter,[1] J.M. Vose,[2] T.D. Moore,[3] C.B. Reeder,[4] C.E. Cole,[5] G. Justice,[6] H.P. Kaplan,[7] M. Voralia,[8] D. Pietronigro,[9] K. Takeshita,[9] A. Ervin-Haynes,[9] J.B. Zeldis,[9] T.E. Witzig[4]

[1]New York Medical Center, NEW YORK, USA; [2]University of Nebraska, OMAHA, NE, USA; [3]Mid Ohio Oncology/Hematology Inc., COLUMBUS, OH, USA; [4]Mayo Clinic, SCOTTSDALE, AZ, USA; [5]Gundersen Clinic, LA CROSSE, WI, USA; [6]Pacific Coast Hematology/Oncology Medical Group, FOUNTAIN VALLEY, CA, USA; [7]Swedish Cancer Institute, SEATTLE, WA, USA; [8]Saskatoon Cancer Center, SASKATOON, SASKATCHEWAN, Canada; [9]Celgene Corporation, SUMMIT, NJ, USA

Background. Indolent non-Hodgkin's lymphoma (NHL) has a median survival of 10 years but is rarely cured. Lenalidomide (Revlimid®), an immunomodulatory drug of the IMiDs® class, is approved by the FDA and EMEA in combination with dexamethasone, for treatment of multiple myeloma in patients who have received at least 1 prior therapy, and by the FDA as a monotherapy for the treatment of transfusion-dependent anemia in patients with myelodysplastic syndromes associated with a deletion 5q cytogenetic abnormality. Lenalidomide also has activity in chronic lymphocytic leukemia and cutaneous T-cell lymphoma. *Aims*. This study was designed to assess the efficacy and safety of oral lenalidomide monotherapy in patients with relapsed or refractory indolent NHL. *Methods.* Patients with relapsed or refractory indolent NHL with measurable disease after at least 1 prior treatment regimen were eligible. Patients received 25 mg lenalidomide orally once daily on Days 1-21 every 28 days and continued therapy for 52 weeks as tolerated or until disease progression. Response and progression were evaluated using the IWLRC methodology. *Results*. Forty-three patients were enrolled in the study and included in this analysis. The median age was 63 (range 43-89) years and 17 patients were female. Median time from diagnosis to lenalidomide treatment was 4.5 (0.4-24) years and the median number of prior treatment regimens was 3 (1-15). Histologies included small lymphocytic lymphoma [SLL] (n=18), follicular center lymphoma [FCL] grades 1-2 (n=22), nodal marginal B-cell lymphoma (n=2), and extranodal marginal zone B-cell lymphoma of MALT type (n=1). Eleven of the 43 patients (26%) exhibited an objective response, including 2 complete responses, 1 complete response unconfirmed, and 8 partial responses. Fifteen patients had stable disease, 13 had progressive disease and 4 were not evaluable. Responses included 4/18 SLL patients (22%) and 7/22 FCL (32%) patients. Median time to response was 3.6 (range 1.7-4.1) months. Median progression free survival was 4.6 months for all patients, and at least 7.7 (range 4.4->13.5) months for responding patients and still ongoing. Sixteen patients (37%) required at least one dose reduction with a median time to first dose reduction of 2 (0.5-9.6) months. The most common grade 4 adverse event was neutropenia (14%), and the most common grade 3 adverse events were neutropenia (21%), and thrombocytopenia (12%). *Summary/conclusions*. Lenalidomide oral monotherapy is active in relapsed or refractory indolent NHL, resulting in a response in 26% of patients, with manageable side effects.

0264

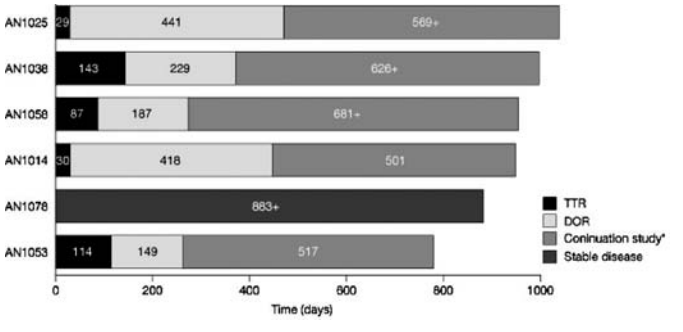
VORINOSTAT PROVIDES PROLONGED SAFETY AND CLINICAL BENEFIT TO PATIENTS WITH ADVANCED CUTANEOUS T-CELL LYMPHOMA (CTCL)

M. Duvic,[1] E.A. Olsen,[2] D. Breneman,[3] T.R. Pacheco,[4] S. Parker,[5] E.C. Vonderheid,[6] J.L. Ricker,[7] S. Rizvi,[7] C. Chen,[7] K. Boileau,[7] A. Gunchenko,[7] C. Sanz-Rodriguez,[7] L.J. Geskin[8]

[1]MD Anderson Cancer Center, HOUSTON; [2]Duke University, DURHAM; [3]University of Cincinnati Medical Center, CINCINNATI; [4]University of Colorado Health Sciences Center at Fitzsimons, AURORA; [5]Emory University, ATLANTA; [6]Johns Hopkins University, BALTIMORE; [7]Merck Research Laboratories, UPPER GWYNEDD; [8]University of Pittsburgh, PITTSBURGH, USA

Background. Vorinostat, an orally active histone deacetylase inhibitor, was approved in October 2006 by the FDA for the treatment of the cutaneous manifestations of CTCL in patients with progressive, persistent or recurrent disease on or following two prior systemic therapies. *Aims*.

To evaluate the activity and safety of at least 2 years' treatment with vorinostat in patients with advanced CTCL. *Methods*. Patients with stage ≥IB CTCL who had received at least two prior systemic therapies and recovered from all prior treatment-related toxicities were eligible for inclusion in an open-label, multicenter Phase IIb trial. All patients provided written informed consent before enrollment. Patients were treated with oral vorinostat 400 mg once daily for 7 days per week and remained on study medication until intolerable toxicity or progressive disease (PD). The primary endpoint was objective response rate measured by the severity weighted assessment tool. Secondary endpoints included time to response and duration of response. Safety and tolerability were also evaluated. Patients could continue to receive vorinostat in an extension study after the time of data cut-off. This post hoc subset analysis reports results from patients who had received vorinostat therapy for ≥2 years as of November 1, 2007. *Results*, Six of 74 patients enrolled in the original study had received vorinostat therapy for ≥2 years as of November 1, 2007 (Figure 1). This includes five responders (one complete responder, four partial responders) and one patient with prolonged stable disease. The median age was 65 years (range 57-74), the median number of prior therapies was 2.5 and the median time from diagnosis of CTCL to enrollment was 1.8 years (range 0.7-5.9). The most common drug-related adverse events (AEs) as determined by the study investigator were diarrhea (100%), nausea (83%), fatigue (67%), and alopecia (50%). One patient had a serious AE of pulmonary embolism, which resolved in 7 days and this patient is continuing therapy as of Day 955. One patient who experienced serious AEs of increased creatinine phosphokinase (CPK) [Day 490] and rash (Day 645) remained on therapy until Day 948. The only other grade ≥3 AEs were anorexia (n=1) and thrombocytopenia (n=1). One patient discontinued due to PD, one patient discontinued due to PD, rash, and increased CPK, and four are continuing therapy as of November 1, 2007 (one complete responder, two partial responders and one with stable disease). Three of the four patients continuing therapy had baseline CTCL stage IIB, while the fourth patient had stage IVA CTCL at study entry. Updated data on these patients will be presented. *Conclusions*. Vorinostat is a novel anticancer agent that has demonstrated prolonged safety and clinical benefit in these patients with advanced CTCL.



*During the follow-up study, patients who benefited from vorinostad continued on theraphy with ongoing clinical responses without formal mSwat assessment.

Figure 1. Time on study of patients on vorinostat therapy for ≥2 years (available data as of November 1,2007)

0265

FIRST-LINE TREATMENT WITH RITUXIMAB COMBINED WITH INTRAVENOUS OR ORAL FLUDARABINE FOR PATIENTS WITH EXTRANODAL MUCOSA ASSOCIATED LYMPHOID TISSUE (MALT) LYMPHOMA

A. Salar,[1] E. Domingo-Domenech,[2] C. Estany,[3] M.A. Canales,[4] C. Montalban[5]

[1]Hospital del Mar, BARCELONA; [2]ICO-Bellvitge, BARCELONA; [3]Mutua de Terrasa, TERRASA; [4]Hospital La Paz, MADRID; [5]Hospital Ramón y Cajal, MADRID, Spain

Background. Fludarabine as a single agent has shown activity in MALT lymphoma. The addition of rituximab to other drugs has improved outcomes in several types of NHL without a significant addition of toxicity. Our aim was to evaluate the safety and efficacy of rituximab combined with fludarabine in first-line therapy for extranodal MALT lymphoma. We also explore whether an early response evaluation could allow us a reduction from 6 to 4 cycles of treatment. *Methods*. This study enrolled adult patients with untreated extranodal MALT lymphoma who were candidate to receive systemic treatment. Patients received rituximab 375 mg/m^2 intravenously (IV) on day 1 and fludarabine 25 mg/m^2 (IV) given on days 1-5 (days 1-3 in > 60 years), every 4 weeks; after the first cycle, oral fludarabine was allowed to be given orally at 40 mg/m^2 with the same schedule. After three cycles, a work-up was done. Patients in CR received an additional cycle and, if PR, a total of 6 cycles was recommended. *Results*. 22 patients have started on therapy. Characteristics of the first 18 pts: median age: 59 years; 7 male, 11 female; PS 0 (94%); site of origin: stomach (61%), skin (16%), lung (11%), parotid gland (11%); stage: I (66%), II (16%) and IV (16%). A total of 82 cycles of R-F were administered; 2 pts received 2 cycles, 9 pts 4 cycles, 7 pts 6 cycles. 17 pts are evaluable for response. Overall response rate was 100% with 94% achieving CR. In the pt in PR, symptoms resolved and received no further treatment being in PR at last follow-up. One pt with parotid gland involvement at dx relapsed at 6 m from the end of treatment in two unaffected areas at dx (breast and bone marrow). Median follow-up from starting treatment is 15 m (range: 17-27). PFS rate is 93% (CI95%:79-100%) at 12 m and OS rate is 100% at 12 m. Tolerance to oral fludarabine was excellent with most patients preferring this formulation. Mild neutropenia was the most common toxicity, usually presenting after the third cycle. 1 pt developed a prolonged grade 4 neutropenia after the 6th cycle. No blood transfusions were required. 3 pts developed grade 2 respiratory infection, but none pt had to be admitted. *Conclusions*. These preliminary data indicate that the RF regimen, either with intravenous or oral fludarabine, was well tolerated even in elderly patients. This combination is very active for the treatment of untreated extranodal MALT lymphoma, even with fewer cycles than initially planned. Updated data will be presented.

0266

PRIMARY EXTRANODAL FOLLICULAR LYMPHOMA OF HEAD AND NECK (PEFLHN): A RARE DISEASE WITH A POOR CLINICAL OUTCOME (IELSG 23)

S.C. Cortelazzo,[1] M. Mian,[1] R. Tsang,[2] A. Rossi,[2] M.E. Cabrera,[2] F.M. Federico,[2] Z.E. Zucca,[2] M. Busetto,[2] R.A. Rambaldi,[2] C.F. Cavalli[2]

[1]Division of Hematology and BMT, BOLZANO, Italy; [2]TORONTO, Canada

Background. PFLHN is a rare disease whose clinical characteristics, treatment and outcome are scarcely known. *Aims.* To compare the clinical features and outcome of PFLHN patients (pts) with those of most frequent and well known primary extranodal MALT of head and neck (PEMLHN). *Methods*. From May 1986 to January 2007, 72 MALT and 44 FL were referred to 7 international cancer centers. The main site of presentation in MALT was the parotid and salivary glands (49%) followed by the Waldeyer's ring (32%), whereas in the FL-group prevailed the location of Waldayer's ring (58%) and less frequently parotid and salivary glands (27%). Both groups had comparable median age (60 yrs),age >60 years (53 *vs* 50%) and a low frequency of B symptoms (6 *vs* 5%), However, more PFLHN pts had the following: advanced stage (61 *vs* 42 %), elevated LDH (19 *vs* 2%), poor ECOG-PS (7 *vs* 3%), bulky disease (7 *vs* 3%) and MIPI>1 (49 *vs*30%). Regarding therapy more PEMLHN pts received radiotherapy in comparison with PFLHN (79 *vs* 54%; p=0.002), alone (16 *vs* 3) or with anthracyclin-containing chemotherapy (10 *vs* 6) and/or surgery (10 *vs* 15). *Results*. 93% of pts in both groups achieved a complete remission, 4.4 % a partial remission and 3% were resistant to therapy. Acute toxicity (G2-3) mostly consisted of xerostomia and none died of treatment-related mortality. Among 106 responders, 36 pts eventually relapsed (MALT 30%; FL 39%). More than sixty percent of relapses occurred in sites different from presentation. After a median follow-up of 44 months (range 2-152) the 1st CCR-rate was 71% in the MALT *vs* 61% in the FL pts. Forty-three per cent of PEMLH died of disease *vs* 61% in PFLHN. The projected 5-year estimate of OS, EFS, and DFS in MALT was 81%, 56% and 65% compared to 62%, 44% and 51% in FL pts, without plateau in both groups. Cox multivariate analysis failed to identify within potential prognostic markers factors predictive for OS and EFS. *Conclusions*. The present study showed that pts with primary indolent lymphoma of head and neck had an high relapse rate comparable to that of cases with advanced disease, without any evidence of cure. Moreover. PFLHN pts had more adverse features at presentation and a worse outcome than PEMLHN. The less intensive use of radiotherapy in FL pts could in part explain the different relapse rate in the two groups. These results suggest that a combined treatment including radiotherapy could improve the outcome of pts affected by this rare disease.

0267

A PHASE II INTERNATIONAL, MULTICENTER STUDY OF ORAL PANOBINOSTAT (LBH589) IN PATIENTS WITH REFRACTORY CUTANEOUS T-CELL LYMPHOMA (CTCL)

M.G. Bernengo,[1] F. Vanaclocha,[2] M. Duvic,[3] T. Kuzel,[4] F. Kerdel,[5] L. Pinter-Brown,[6] A. Bosly,[7] C. Okada,[8] D. Breneman,[9] P.L. Zinzani,[10] J. Becker,[11] L. Hughey,[12] M. Ardaiz,[13] J. Zain,[14] L. Zhang,[15] S. Hirawat,[15] G. Laird,[15] D. Johnson,[15] H.M. Prince[16]

Lurie Comprehensive Cancer Center, CHICAGO, IL, USA; [5]Florida Academic Dermatology Centers, MIAMI, FL, USA; [6]UCLA Medical Center, School of Medicine, LOS ANGELES, CA, USA; [7]UCL Mont Godinne, YVOIR, Belgium; [8]Oregon Health and Science University, PORTLAND, OR, USA; [9]University Dermatology Consultants, CINCINNATI, OH, USA; [10]University of Bologna, BOLOGNA, Italy; [11]Klinik der Universitat Wuerzburg, WUERZBURG, Germany; [12]University of Alabama at Birmingham, BIRMINGHAM, AL, USA; [13]Hospital J.M. Ramos Mejia, BUENOS AIRES, Argentina; [14]Columbia University, NEW YORK, NY, USA; [15]Novartis Pharmaceutical Corp., FLORHAM PARK, NJ, USA; [16]Peter MacCallum Cancer Centre, MELBOURNE, Australia

Background. Panobinostat (LBH589) is a potent deacetylase inhibitor (DACi) which induces apoptosis of tumor cells at nanomolar levels. Prince *et al*. noted encouraging panobinostat activity in patients with CTCL (*ASCO, 2007*). This phase II study seeks to confirm the efficacy in refractory CTCL patient population. *Methods*. This open label study is enrolling patients with stage IB-IVA CTCL from ~40 sites globally. Eligibility criteria include diagnosis of mycosis fungoides (MF) or Sezary syndrome (SS), treatment with ≥2 prior systemic regimens, adequate organ function and ECOG PS ≤2. Patients are excluded for significant cardiovascular abnormalities or QTcF >450 msec. Patients receive oral panobinostat on days 1, 3, and 5 weekly in 28 day cycles until disease progression or intolerance. Patients are being accrued to two groups. Group 1 includes patients previously treated with oral bexarotene, while group 2 are patients who are bexarotene naïve. Each group follows a Simon 2-stage design independently. The primary endpoint is response rate measured using a composite score. Intensive ECG monitoring for QTcF is incorporated in the study. *Results*. Sixty patients (group 1 - 36; Group 2 - 24) have been treated to date (median age 57 years [range 25-88]; 36 males, 24 females; 46 MF, 14 SS). Median number of prior treatment regimens is 4.5 for group 1, and 3 for group 2. Twenty-five patients (69.4%) in group 1 and 19 patients (79.2%) in group 2 had ?stage IIB disease at study entry. Patients have received 1-14+ cycles of treatment. Efficacy was evaluated by the composite score (modified Severity-Weighted Assessment Tool [mSWAT] to assess skin disease, and CT scan for evaluation of visceral and lymph node involvement, and circulating SS counts/flow cytometry of peripheral blood mononuclear cells for SS patients). In group 1, 3 of 27 patients with at least 2 post-baseline efficacy assessments have achieved an overall partial response, and 7 patients have achieved a skin response, including 1 complete response, assessed by mSWAT. In group 2, 2 of 15 patients with at least 2 post-baseline efficacy assessments have achieved a skin response. With most patients enrolled recently, many patients in both groups have not yet had disease evaluation for response. Twelve patients have progressed on treatment and ten patients discontinued treatment due to AEs. There has been no treatment-related death. The most common adverse events (all grades, regardless of drug causality) have been diarrhea (~53.3%), thrombocytopenia (~37%), nausea (~32%), fatigue (~27%), pruritus (~23%), asthenia, abdominal pain, and blood triglycerides increased (~20% each), headache (~18%), neutropenia, hyperglycaemia, and dysgeusia (~17% each). The most common Grade 3 or 4 adverse events (regardless of drug causality) have been neutropenia (~8%), thrombocytopenia (~8%), hypophosphataemia (5%), diarrhea (5%), and hyperglycaemia (5%), Among 2838 ECGs analyzed thus far, there has been no ECG with QTcF >500ms, two with QTcF >480ms, and three with QTcF >60ms increase from baseline. *Conclusions*. Encouraging activity is being observed in this ongoing study. Panobinostat has been generally well tolerated with no major safety concerns. Enrollment to the study is currently ongoing for both groups.

0268

90Y-IBRITUMOMAB TIUXETAN TREATMENT FOR RELAPSED AND/OR REFRACTORY B CELL NON-HODGKIN`S LYMPHOMA. MULTI-INSTITUTIONAL ARGENTINIAN STUDY

Background. 90Y-ibritumomab tiuxetan (Zevamab® ; ZEV; Bayer-Schering Pharma- Argentina) has been approved for the treatment of relapsed, refractory and transformed (high grade) follicular lymphomas. *Methods*. Between Sep. 2005 and Feb. 2008, 45 patients (pts) [22 F & 23 M; median age 62 yrs (45-83)] with refractory/relapsed lymphoma were enrolled. Diagnoses: 37 follicular lymphoma (FL), 5 were mantle cell lymphoma (ML) and 3 transformed lymphoma (TL); 18 pts had bulky disease, 8 had bone marrow involvement and 21 had stage III-IV disease. Median time from diagnosis was 5 yrs (0.5-29). Twenty two pts had received 1-2 previous treatments, and 23 pts had received 3-5 previous treatments including 5 pts with autologous bone marrow transplantation. All had previously received anti-CD20 monoclonal antibody therapy. Six pts received previous radiotherapy. ZEV was administered at 0.3 or 0.4 mCi, based on initial platelet count. Seven days before, and the same day of the ZEV administration, pts received standard rituximab 250 mg/m^2. In 3 pt, ZEV was part of the conditioning regimen of autologous bone marrow transplantation. *Results*. Forty pts were evaluable for response: 34 (86%) pts responded - 19 CR (48%), 15 PR (38%). Overall survival and PFS for the entire group at 18 months was 63% and 37% respectively, with a median follow-up of 12 months (1-29 months). Of the 45 patients, 5 pts (11%) had died before third month and response was not assessed, 6 pts (13%) did not respond, 3 (7%) died with response from other causes, 14 pts (31%) responded and subsequently relapsed. Finally 17 pts (38%) continue to be in response, 9 (20%) lasting more than twelve months (long lasting responders). Slight differences in duration of response and survival were observed between FL vs ML and TL favouring FL (RR 2.047). Forty six per cent of pts required filgrastim for neutropenia, 24% required platelet transfusions, 22% had neutropenia plus fever and were admitted for complicated pancytopenia, and 20% required red blood cells transfusion. Two patient died 30 & 40 days after treatment with hypoplastic bone marrow complicated with sepsis in the post autologous bone marrow transplantation period. Four pts with previous bone marrow transplantation required filgrastim, transfusions and 2/3 had febrile neutropenia. *Conclusions*. Our experience with ZEV in relapsed and refractory FL shows 48 % CR. Even heavily treated pts that had previous bone marrow transplantation were able to receive ZEV, although they required extra support. Our experience supports the use of ZEV in relapsed and refractory lymphomas even after autologous bone marrow transplantation.

0269

BORTEZOMIB AND INTERFERON IN ASSOCIATION IN THE TREATMENT OF ADVANCED OR REFRACTORY SÉZARY SINDROME: A SINGLE CENTER EXPERIENCE

M. Postorino,[1] L. Pupo,[1] L. Di Caprio,[1] L. Franceschini,[1] S. Campagna,[1] D. Renzi,[1] M. Rizzo,[1] L. Gianni,[1] S. Faccia,[1] R. Cannarsa,[1] M. Ales,[1] F. Buccisano,[1] D. Venditti,[1] G. Lombardo,[2] G. Baliva,[2] M. Cantonetti,[1] S. Amadori[1]

[1]Tor Vergata University, ROMA; [2]Istituto Dermatopatico dell'Immacolata, ROMA, Italy

Background. Sézary Sindrome (SS) is a chronic, lymphoprolipherative cutaneus disease. The conventional treatments as photoapheresis, alpha interferon, polichemoterapy and immunotherapy with monoclonal antibodies can induce a short partial remission with decreasing of tumor burden. The most recent data demonstrated a possible role of allogenic hemopoietic stem cells transplantation to obtain a continuous complete remission. The majority of patients with advanced or refractory disease receive palliative cares due to age, performance status and matched donor availability. The mechanisms responsible for the resistance of Sézary cells to a wide range of death-inducing agents remain largely unknown. Recently, the antitumor effects of proteasome inhibitors, mostly bortezomib, have been reported in different types of cancer. Several lines of evidence indicate that proapoptotic and antiproliferative effects of bortezomib on cancer cells result from an inhibition of the NFk-B pathway; this effect is enhanced by use of Interferon alfa (INF). *Aims.* The evaluation of efficacy and toxicity of a long-term treatment with bortezomib associated with alfa IFN is the main aim of our study. *Methods*. From November 2006 to dicember 2007 Six patients with SS were enrolled in our protocol: they were treated with bortezomib at the dose of 1.3 mg/m^2 weekly and Interferon 3x10^{6}UI twice a week for 12 weeks(induction phase).The patients, who achieved a complete remission,received the same dose of bortezomib every 2-3 weeks and continued IFN therapy(maintenance phase). In case of near Complete Remission (nCR: absence of cutaneous symptoms and very low count of Sezary cell) or good partial response (gPR: absence of cutaneous symptoms and reduction >60 % of circulating Sezary's cells) the bortezomib and Interferon dose remained weekly until the disease progression. Median age of patients was 53 years (range 43-67). All patients were resistant to first-line-therapy and to Interferon. At the enrolment, one patient showed hyperleukocytosis (WBC > 50000/uL) and unfavourable cytogenetic. Two patients, with matched donor, received the therapy to reduce the cutaneous and circulating Sezary's cells before the conditioning treatment; the other patients were candidated to long-term therapy. *Results*. All patients responded to the bortezomib-IFN association: two patients were in CR, at 3 and 16 months after the induction therapy and now they are in maintenance. Two patients were in nCR and one was in gPR at 14, 11 and 12 months respectively (one of the patients in nCR is going to allogeneic SCT). The patient with hyperleukocytosis obtained a partial remission but after 2 months he relapsed. All responder patients showed an important restore of normal clones of T lymphocytes and nobody presented infectious diseases. The protocol was well tolerated and any toxicity has been experienced. *Conclusions*. The association bortezomib-IFN seems effective and safe in reducing tumor burden in advanced SS patients. A longer follow up and a higher number of treated patients are requested for the response evaluation.

0270

PHASE I TRIAL OF ORAL VORINOSTAT IN COMBINATION WITH BEXAROTENE IN ADVANCED CUTANEOUS T-CELL LYMPHOMA

R. Dummer,[1] K. Hymes,[2] W. Sterry,[3] M. Steinhoff,[3] C. Assaf,[3] H. Kerl,[4] J. Ahern,[5] S. Rizvi,[5] J.L. Ricker,[5] S. Whittaker[6]

[1]Universitätsspital Zürich - Dermatologische Klinik, ZÜRICH, Switzerland; [2]NYU Medical Center, NEW YORK, USA; [3]Campus Charité Mitte des Universitätsklinikums Charité, BERLIN, Germany; [4]University Clinic of Dermatology, GRAZ, Austria; [5]Merck Research Laboratories, UPPER GWYNEDD, USA; [6]St John's Institute of Dermatology, LONDON, UK

Background The histone deacetylase inhibitor vorinostat and the RXR-selective retinoid bexarotene are each clinically active and safe as monotherapy in the treatment of cutaneous T-cell lymphoma. *Aims.* This study was performed to test whether the combination of vorinostat and bexarotene could be safely administered to patients with advanced cutaneous T-cell lymphoma. *Methods*. A Phase I trial of vorinostat (200, 300, or 400 mg daily) in combination with bexarotene (150, 225, or 300 mg/m^2 or 150 mg, daily) was conducted. Cycles were repeated every 28 days for ≤ 6 cycles until progressive disease or intolerable toxicity. Adult patients with stage ≥IB progressive, persistent, or recurrent cutaneous T-cell lymphoma refractory to ≥1 systemic therapy were eligible. Patients must not have received prior bexarotene within 3 months or prior histone deacetylase inhibitor treatment and must have adequate hematologic, hepatic, and renal function. The primary objective was to determine the maximum tolerated dose. Activity and safety of the combination regimen were also assessed. *Results*. Nineteen patients have been enrolled: median age, 58 years (range 33-77), median number of prior systemic therapies, 3 (range 1-14). Eighteen patients have received ≥1 dose and were evaluable for safety as of 11/1/07. Two patients (Cohort 2) experienced dose-limiting toxicity (Table 1).

Table 1.

Cohort	Vorinostat (mg)	Bexarotene	N	CTCL Stage	# of Cycles	Dose limiting toxicities	Best Response
1	200	150*	3	IB, IVA (2)	2, 5, 6	-	PD, SD (2)
2	300	150*	5	IIB (3), IVA, IVB	1, 1, 2, 3, 6	Grade 3 fatigue,Grade 3 hypertriglyceridemia (3)	PR, SD (4)
2a	200	225*	3	IIB, IVA (2)	3, 4, 6	-	CR, SD (2)
2b	200	300*	3	III, IVA (2)	6, 6, 6	-	PR, SD (2)
3	400	150†	5	IB, IIB (2), III, IVA	1, 1, 2, 5, 6	-	PR, SD (2), PD, NE

NE = not evaluable; PD = progressive disease; PR = partial response; SD = stable disease. *mg/m^2/day; †mg/day

The maximum tolerated dose has not been reached. The most common drug-related toxicities were hypertriglyceridemia (50%), hypercholesterolemia (28%), hypothyroidism (28%), and lethargy/fatigue (28%). Grade 3 drug-related adverse events included hypertryglyceridemia (17%) and neutropenia (11%). Two patients had drug-related serious adverse events (skin necrosis; lymphangitis and lymph node abscess) and both recovered. Twelve patients have discontinued treatment: only 2 due to adverse events (skin necrosis, fatigue). Preliminary data indicate that of 18 evaluable patients, 1 had a complete response, 3 had partial responses, 12 had stable disease, and 2 had progressive disease. *Conclusions*. Accrual continues to determine the maximum tolerated dose. The combination of vorinostat and bexarotene is tolerable and active in patients with advanced cutaneous T-cell lymphoma.

0271

RITUXIMAB MAINTENANCE SIGNIFICANTLY PROLONGS TIME TO PROGRESSION IN PATIENTS WITH RELAPSED FOLLICULAR LYMPHOMA AND ALSO ACHIEVES A LONG TERM DISEASE CONTROL IN *DE NOVO* FOLLICULAR LYMPHOMA

A. Salar, S. Saumell, C. Pedro, A. Alvarez-Larrán, E. Gimeno, E. Abella, T. Gimenez, A. Ferrer, B. Bellosillo, C. Beses

Hospital del Mar, BARCELONA, Spain

Background. Rituximab (R) maintenance has recently demonstrated survival improvement compared with observation in patients with relapsed or refractory follicular lymphoma (FL). The aim of this study was to retrospectively evaluate our experience with rituximab maintenance in *de novo* or relapsed FL. *Methods*. We have retrospectively evaluated 42 patients with FL who received R maintenance. Only patients in CR or PR were candidates for R maintenance. Treatment consisted of R 375 mg/m^2/week x 4 consecutive weeks every 6 months during 2 years (Maintenance type 1) or R 375 mg/m^2 every 3 months during 2 years (Maintenance type 2). Overall and progression free survival were calculated from the day of the first R infusion. Time to progression after R maintenance was compared to the time to progression of the immediately previous treatment between the same patients, using the non parametric Wilcoxon test. *Results* Forty patients were included, with 2 pts receiving rituximab maintenance in two different episodes. Median age: 64 years (range: 27-85); male 18 (43%). First line R in 24 pts (57%) and in second or third relapse in 18 pts (43%). Number of previous treatments: 1 in 24 pts (57%), 2 in 14 (33%) and 3 in 4 (10%). Immediately previous treatment: CVP±R in 5 pts (12%), CHOP± R 14 (33%), fludarabing-containing±R 9 (21%), R 5 (12%) and others±R 9 (21%). Status previous starting maintenance: CR in 36 (86%), PR in 6 (14%). Among pts in CR, 5 progressed and 1 died (pneumonia + progressive disease) during maintenance. Among pts in PR, 2 progressed and 4 pts converted to CR during maintenance. At a median follow-up since first R maintenance infusion of 38 months (1-70), 13 pts (31%) have relapsed. Overall and progression free survival at 3 years were 94% (CI95% 87-100%) and 69% (CI95% 62-76%), respectively. No differences were found with respect to: status previous maintenance, line of therapy (first vs subsequent lines) and type of maintenance administered. From 18 pts with relapsed FL, median time to progression from the immediately previous chemotherapy was 25 months vs 36 months after maintenance R (p= 0.017). Maintenance R therapy was prematurely withdrawn

in 2 pts (recurrent infections and delayed severe neytropenia). Hipogammaglobulinemia was present in 47% and 55 % of pts before and after R maintenance, respectively. Levels of IgM were significantly lower after R maintenance (p=0.03) but levels of IgG and IgA were similar. *Conclusions*. Time to progression after rituximab maintenance is significantly increased compared with the time to progression of the immediately previous treatment in patients with relapsed FL. Rituximab maintenance is safe either in first or subsequent lines of therapy.

0272

RITUXIMAB MAINTENANCE THERAPY CAN BE SAFELY ADMINISTERED VIA A RAPID INFUSION PROTOCOL: RESULTS FROM THE MAXIMA STUDY

M. Wenger,[1] F. De Marco,[2] U. Vitolo,[3] I. Poddubnaya,[4] D. Chamone,[5] P. Warburton,[6] B. Jezersek Novakovic,[7] J.M. Rowe,[8] H. Dresler,[9] D. Thurley[10]

[1]Roche, BASEL, Switzerland; [2]Divisione Universitaria di Ematologia, Cattedra di Ematologia, TORINO, Italy; [3]Divisione Ospedaliera di Ematologia A.O. S. Giovanni Battista, TORINO, Italy; [4]Cancer Research Centre of RAMS, MOSCOW, Russian Federation; [5]Hematology Department of the Clinic Hospital of the University of São Paulo, SÃO PAULO, Brazil; [6]Wollongong Hospital, WOLLONGONG, Australia; [7]Institute of Oncology Ljubljana, LJUBLJANA, Slovenia; [8]Department of Hematology & Bone Marrow Transplatation, RAMBAM Health Care Campus, HAIFA, Israel; [9]Roche Pharmaceuticals (Israel) Ltd, PETACH TIKVA, Israel; [10]Roche Products Pty. Limited, DEE WHY, Australia

Background. The benefit of maintenance therapy in follicular lymphoma (FL) has been reported recently by various groups. Sehn *et al.* (Blood 2007) have demonstrated that rituximab (R) can be administered via a rapid-infusion protocol. *Aims*. The current study is intended to extend the safety database for R-maintenance and to examine the safety of fast infusion protocols in a real-life setting. *Methods*. 500 patients with first-line or relapsed FL having achieved CR/PR after R-containing induction therapy were eligible to receive R at the standard dose for follicular lymphoma of 375 mg/m^2 every eight weeks for a maximum of 2 years. Primary endpoint is safety, with secondary endpoints being PFS, EFS, TTNL, and OS. The study aims to detect at least one rare event with a true incidence of 0.32% with 80% power. *Results*. 349 patients with FL have been enrolled at clinical cut-off: Median age is 56, 76% were treated in first remission, and 74% were in CR. Data on a total of 809 infusions was available. Except for one patient with preexisting history of recurrent cerebrovascular incidents who received rituximab at standard infusion speed and suffered from a TIA no SAEs were recorded within 24h of the maintenance infusion. Of all patients available for analysis, 82.5% used a standard-speed infusion regimen (approx 4-6h) for the first maintenance infusion. At one year of maintenance treatment, 54% of patients were receiving R via a rapid-infusion regime (approx 1.5h). A total of 9 SAEs were recorded in the 275 patients that received at least one infusion, all but one were considered unrelated. One patient with previously known cardiac arrhythmias died 13 days after the 4th infusion of unknown causes. After clinical cut-off, three other patients died of progressive lymphoma. Hematologic toxicity occurred in 9 patients, with three grade 3/4 events (neutropenia), one resulting in febrile neutropenia. Recruitment will be completed in March 2008. *Conclusions*. R-maintenance q 8 weeks in FL after R-containing induction therapy can be safely administered. We could reproduce the finding of others that rapid-infusion regimens are no worse than standard speed infusions.

0273

A PILOT STUDY WITH RITUXIMAB, BORTEZOMIB AND HYPER-FRACTIONATED CYCLOPHOSPHAMIDE (RBC REGIMEN) FOR THE TREATMENT OF ADVANCED MANTLE CELL LYMPHOMA IN ELDERLY PATIENTS

P.M. Musto,[1] R. Guariglia,[1] G. Pietrantuono,[1] O. Villani,[1] M.C. Martorelli,[1] F. D'Auria,[1] A. Zonno,[1] A. Zupa,[1] G. Bianchino,[1] G. Improta,[1] V. Grieco,[1] L. Digiovannantonio,[1] E. Feudale,[1] R. Lerose,[1] A. Pinto,[2] F. Ferrara[3]

[1]CROB, Centro Riferimento Oncologico Basilicata, RIONERO IN VULTURE; [2]Istituto Nazionale Tumori, Fondazione Pascale, NAPOLI, Italy; [3]Cardarelli Hospital, NAPOLI, Italy

Background. Mantle-cell lymphoma (MCL) represents a distinct clinicopathologic entity which accounts for 3-10% of all non-Hodgkin lymphomas and whose median overall survival generally does not exceed 3-4 years. Patients with MCL are typically older adults with a male predominance and usually present with stage IV disease. The neoplastic phenotype is characterized by CD20 and CD5 co-expression, while CD23 surface antigen is lacking. Translocation t(11;14)(q13;q32) and cyclin D1 overexpression are the cytogenetic and molecular hallmarks of the disease. Rituximab is a key component of the current, most diffused regimens for the treatment of MCL (in particular, in R-CHOP or R-HyperC-VAD). Autologous stem cell transplantation or observation after induction therapy may be indicated, depending on patient eligibility. However, considering that MCL is frequently diagnosed in elderly subjects with relevant co-morbidities, high dose chemotherapy or the use of drugs with potential cardiotoxicity, such as anthracyclines, may result not feasible in a significant proportion of patients. In this setting, recent data suggest that the proteasome inhibitor bortezomib is well tolerated and has significant single-agent activity in patients with MCL. *Methods*. We evaluated safety and efficacy of a 21-day cycle, anthracycline-free combination of rituximab (375 mg/m^2 d 1), bortezomib (1.3 mg/m^2 d 1, 4, 8, and 11) and hyper-fractionated cyclophosphamide (600 mg/sqm given as a double, three-hour infusion d 1-3) (RBC regimen) in elderly patients with advanced MCL. Diagnosis was made according to standard histological, phenotypic and molecular criteria. So far, 14 patients (9 males, 5 females) have entered the study. Mean age was 77.2 years (range 72-84). All patients had stage IV disease, evidencing extranodal localizations (n. 4) or marrow/leukemic involvement (n. 10). IPI score was 2 in 5 patients, 3 in 7 patients and 4 in 2 patient. Four patients received RBC as first line therapy, the others were treated at relapse, generally after (R)-CHOP or (R)-CHOP-like regimens. *Results*. Two patients are currently too early, being still on therapy. Two patients who presented with very high peripheral WBC count died during the first cycles due to progressive disease, while another patient did not tolerate first cyclophosphamide infusion and was therefore removed from the study. No other extra-hematological toxicities higher than grade 1 were observed.. Hematological toxicities consisted in grade 1-2 thrombocytopenia/neutropenia (nine patients), while 3 patients experienced grade 3 neutropenia, requiring G-CSF support. One patient showed an initial response in extranodal sites but then progressed before the fourth cycle. Among the 9 patients who received at least six RBC cycles, three achieved a partial response and 6 obtained a complete response (overall response rate 75%, on intention to treat analysis excluding patients still on therapy). In 2 patients, molecular remission using PCR for t(11;14) bcl-1/IgH determination could be demonstrated. All responders maintain their remission phase 6 to 14 months after the start of RBC treatment. *Conclusions*. Although still preliminary, these results indicate that RBC regimen is feasible, well tolerated and effective (including the possibility to obtain molecular response) in elderly patients with advanced MCL.

0275

BENEFIT OF RITUXIMAB BEFORE AUTOLOGOUS STEM-CELL TRANSPLANTATION (ASCT) AT TIME OF RELAPSE IN PATIENTS WITH FOLLICULAR LYMPHOMA (FL)

K. Belhadj,[1] Y. Hicheri,[2] C. Pautas,[2] T. El Gnaoui,[2] F. Hemery,[3] C. Copie-Bergman,[4] J-L. Beaumont,[5] J. Dupuis,[2] I. Gaillard,[2] C. Haioun[2]

[1]Hôpital Henri Mondor, CRETEIL; [2]Hématologie, Hôpital Henri Mondor, CRETEIL; [3]Unité d'Information Médicale, Hôpital Henri Mondor, CRETEIL; [5]Département de Pathologie, Hôpital Henri Mondor, CRETEIL; [5]Etablissement Français du Sang, CRETEIL, France

Background. During disease's course, high dose therapy followed by ASCT can be considered as an alternative to sequential chemotherapies. *Aims*. To evaluate ASCT in the pre and post rituximab era as consolidation. *Methods*. Between 1989 and 2004, 54 patients (pts), not previously treated with rituximab, received ASCT at relapse. At initial diagnosis, median age was 47 yrs (24-61) and FLIPI score was > 3 in 18%. ASCT was performed in 2nd remission in 43 pts and in 3rd remission in 11. TBI - based conditioning regimens was used in 42 pts. Patients treated at relapse before 1998 did not receive rituximab-based salvage regimens and those treated after 1998 received rituximab before ASCT. The main characteristics of the two populations were as shown on the Table 1. *Results*. After ASCT, 49 pts achieved CR, 4 PR and one pt progressed. With a median follow-up of 8 yrs, 28 pts (52%) relapsed after a median time of 13 months (range 4-95) and 20 pts died from lymphoma progression: 9 pts, secondary malignancy: 7 pts and late infection: 4 pts. Ten-year overall survival (OS) from initial diagnosis was 68% and 10-year OS and event-free survival from ASCT were 64 and 37%, respectively. After adjusting for follow-up (median follow-up of the rituximab-treated group: 7 yrs), comparison between the 2 groups shows a significantly better 10-year OS in the rituximab-treated group (80% vs 34%, p=0.001). *Conclusion* The prognosis of pts with FL is highly improved by rituximab incorporated in salvage treatment before consolidative ASCT. after 2nd or 3rd remission in FL.

Table 1.

	rituximab-naive group	rituximab-treated group
N	29	25
FLIPI at initial diagnosis (Low/Intermediate/High) %	41/48/11	27/46/27
Median age at ASCT (yrs)	50 (range 35-60)	52 (range 30-62)
ASCT performed in 2nd remission	23	20
ASCT performed in 3rd remission	6	5

0276

RESULTS OF MAINTENANCE THERAPY WITH RITUXIMAB IN FOLLICULAR NON HODGKIN LYMPHOMA

B. Soria,[1] M.T. Olave,[2] R. Rubio-Escuin,[1] A. Rubio-Martinez,[1] L. Palomera,[2] M.A. Fuertes,[2] P. Mayayo,[1] V. Recasens,[1] P. Giraldo,[1] Group By GEHMA[3]

[1]Miguel Servet University Hospital, ZARAGOZA; [2]Lozano Blesa University Hospital, ZARAGOZA; [3]I+CS, ZARAGOZA, Spain

Follicular non-Hodgkin's lymphoma (F-NHL) is rarely curable with standard chemotherapy, the natural history of disease is characterized by successive relapses. The addition of Rituximab to different induction chemotherapy regimens increases the response rate and progression-free survival (PFS), without significantly increase of toxicity in the schedules that not including Fludarabine. The administration of Rituximab as maintenance therapy could be an useful and safe option for patients in complete remission after induction therapy with regimens based in immuno-chemotherapy, nevertheless the best maintenance schedule is not yet defined. *Objective*. To present our experience with an homogeneous maintenance schedule with Rituximab administrate every 6 months for F-NHL. *Patients and methods*. Prospective, observational study in 48 F-NHL patients in complete remission after first line therapy with immuno-chemotherapy (R-CHOP, R-CF, R-MCF, R-COP) since January 2002 to April 2007. Maintenance schedule: Rituximab 375 mg/m^2 weekly x 4 every 6 months two years in an outpatient protocol of fast infusion (24 hours before the patient received anti H1 and H2 orally and steroids 40 mg, dexclorfeniramina 5mg and paracetamol 1 g IV previously to administration every Rituximab dose in a total volume of 250 mL. The first 50 mL is administered in 30 and 200 mL in 60 minutes), patients with severe previous reactions were excluded of this schedule and received Rituximab in slow infusion. Patients were evaluated previous to start maintenance and two months after 4 courses, CT scan, PET and molecular study of t(14;18) in bone marrow were performed. Side effects according to common toxicity criteria were evaluated. Overall survival and relapsed free survival were analyzed according Kaplan-Meier and Cox regression study. *Results.* 37 patients have completed maintenance therapy (25 F/12 M); Mean age 55.3(24-77). ECOG 0(60.8%), 1(34.7%), 2(4.3%); At diagnosis: B symptoms 44.4%; FLIPI 0(8.1%), 1(43.4%), 2(30.4%), 3(17.3%); stage I(8.6%), II(17.3%), III (39.1%), IV(34.7%); grade I(43.5%), II(56.5%); Bulky 14%; extra node disease 14%; Hb<10 g/dL (14%); LDH increased 14%; B2M increased 14%. R-CHOP (69.5%), R-CHOP+local Rx (8.7%), R-FCM (17.3%), R-FC (4.3%), R-COP (2.0%). 90% of patients have received maintenance fast infusion protocol. Adverse events 2 patients (8.6%) had mild skin erythema during infusion, 2 (8.6%) previously treated with Fludarabine+Rituximab developed neutropenia grade 3-4: Overall survival mean 29.2 months (95% CI: 12-63), RFS: mean 23.3 months (95% CI:6-55). Only two patients have relapsed (4.6%), one of them with lost of CD20 expression in 70% of B-malignant cells. *Conclusions*. Rituximab maintenance therapy in an outpatient protocol of fast infusion could be a good strategy to prolong RFS in F-NHL, the tolerance is acceptable and satisfactory in most of the patients. It is necessary a longer follow-up to consider the magnitude of the effect obtained.

5-ANDROSTENE-3β,17β-DIOL ADMINISTERED TO MICE EXPOSED TO TOTAL BODY IRRADIATION RESULTS IN RAPID RECONSTITUTION OF IMMATURE BONE MARROW PROGENITOR CELLS AND SYNERGIZES WITH TPO BUT NOT WITH G-CSF

F.S.F. Aerts Kaya,[1] T.P. Visser,[1] C.L. Reading,[2] J.M. Frincke,[2] D.R. Stickney,[2] G. Wagemaker[1]

[1]Erasmus University Medical Center, ROTTERDAM, Netherlands; [2]Hollis-Eden Pharmaceuticals Inc, SAN DIEGO, USA

Background. 5-AED (5-androstene-3β,17β-diol) is a naturally occurring adrenal cortical steroid and has been shown to display radioprotective effects in both rodents and non-human primates, resulting in accelerated multilineage hematopoiesis and enhanced survival after radiation, including accelerated $CD34^+$ cell reconstitution in bone marrow of non-human primates. Where pegylated granulocyte-colony stimulating factor (Peg-G-CSF) is known to stimulate recovery of neutrophils, thrombopoietin (TPO) specifically protects short-term spleen repopulating immature cells and promotes platelet recovery. *Aims*. We studied the effects of combined treatment with 5-AED and Peg-G-CSF or TPO delivered after total body irradiation (TBI) on reconstitution of multilineage hematopoiesis and recovery of specific immature repopulating cell subsets to both further elucidate the efficacy of 5-AED and explore possible additive or synergistic effects. *Methods*. For direct measurements of the radioprotective effect of 5-AED, BALB/c mice were exposed to the midlethal dose of 6 Gy TBI. Two hours after irradiation, mice were injected with a placebo IM, 40 mg/kg 5-AED IM, 0.225 µg TPO IP or 10 µg Peg-G-CSF IP. To measure the effect of 5-AED on immature repopulating cells, BALB/c donor mice were exposed to 3x2 Gy TBI, fractions separated by 24 h, and treated after each fraction with placebo IM, 40 mg/kg/d 5-AED IM, 0.7 µg TPO IP or a single injection of 10 µg Peg-G-CSF IP and examined 24 h after the last fraction for immature cells per femur by the assay for marrow repopulating cells (MRA) and the spleen colony test (day 12 CFU-S) in 8 Gy irradiated recipient mice. *Results*. After 6 Gy TBI, BALB/c mice treated with 40 mg/kg 5-AED displayed a remarkably accelerated recovery of white blood cells ($p<0.01$), blood platelets ($p<0.01$) and red blood cells ($p<0.05$), as well as increased bone marrow cellularity ($p<0.01$) and elevated numbers of colony forming cells ($p<0.01$) at 14 days post-irradiation in comparison to placebo-treated animals. Addition of 5-AED to either Peg-G-CSF or TPO treatment did not result in an additive effect. The fractionated 3x2 Gy TBI study revealed a 5- and 7- fold increase in CFU-S in the 5-AED and TPO groups, respectively, relative to radiation controls, and a synergistic increase of 20-fold when used simultaneously. A similar effect on CFU-s was not observed for G-CSF, and neither did it synergize with 5-AED. MRA, expressed as GM-CFU per femur 13 days after transplantation in 10 mice, revealed an approximately 5- to 6-fold increased marrow repopulating ability: 1002 (range 0-5785) for 5-AED *vs* 174 (5-360) for radiation controls, contrasting TPO that promotes CFU-S reconstitution at the expense of MRA cells.[1] *Conclusions*. 5-AED as a single agent stimulates multilineage hematopoiesis and increases bone marrow cellularity following irradiation. The effect is mediated by increased survival and/or reconstitution of immature repopulating cells in a pattern distinct from that of TPO. Consistently, 5-AED strongly synergizes with TPO at the level of immature cells from which reconstitution originates, thus revealing a novel mechanism of bone marrow protection in cytoreductive therapy.

A POTENT SMALL MOLECULE PIM KINASE INHIBITOR WITH IN VIVO ORAL AVAILABILITY AND ACTIVITY IN CELL LINES FROM HEMATOLOGICAL MALIGNANCIES

G. Berk, E. Gourley, X.H. Liu, J. Lamb, P. Severson, J. Bearss, C. Jones, H. Vankayalapati, S. Warner, D. Bearss

SuperGen, Inc., DUBLIN, USA

Background. A small family of serine/threonine kinases known as Pim-1, Pim-2, and Pim-3 are involved in various signaling pathways in which they act as downstream effectors and potent inhibitors of apoptosis. The Pim kinases are unique in that they are expressed as active kinases and therefore gene expression levels directly correlate to their activity in cells. Pim-1 and Pim-2 are expressed in cells of hematopoietic lineage and Pim-3 appears to be more important in cells of epithelial origin. In concordance with these different patterns of expression, Pim-1 and Pim-2 are commonly overexpressed in hematological malignancies such as leukemias and lymphomas, while Pim-3 overexpression has been noted in melanoma, pancreatic adenocarcinoma, gastric, and other epithelial tumors. Thus, the Pim kinases are interesting targets for drug development, which offer promising potential in the treatment of hematological and solid malignancies. *Aims*. Develop a potent and selective, orally available Pim kinase inhibitor. *Methods*. Utilizing the published Pim-1 crystal structure and our proprietary CLIMBTM process, we identified a subset of leads from a large, virtual library from which a series of optimal analogs were synthesized to produce SGI-1776. *Results*. The IC50 of this compound in a biochemical enzyme-based assay was 6.7 nM for Pim-1, 69 nM for Pim-3, and 363 nM for Pim-2. Cell-based activity, determined by an anti-proliferative assay using HEL, K562, MV-4-11, and other leukemia, lymphoma, and solid tumor cell lines shows IC50 values as low as 54 nM. MV-4-11 cells treated with SGI-1776 shows a dramatic decrease in phospho-BAD levels (a direct substrate of the Pim kinases) as determined by western blot with an EC50 value of 7.9 nM. In conjunction with the anti-proliferative and phospho-BAD data, cell death via apoptosis was observed in cells treated with SGI-1776. As a result of these data and favorable pharmacokinetic studies, SGI-1776 was introduced into various *in vivo* studies that yielded efficacy in mouse xenograft tumor models of hematological origin. In a MOLM-13 xenograft model, only one of eight tumors remained in the group treated at 270 mg/kg SGI-1776 (PO) after fourteen days, whereas all eight tumors remained in the vehicle group. In addition to efficacy studies, pharmacodynamics studies will be presented. *Summary and Conclusions.* SuperGen's SGI-1776 exhibits potent inhibition of Pim kinase activity, translating into potent inhibition of cellular signaling pathways, cancer cell proliferation, and *in vivo* tumor progression in non-clinical models.

THE PURINE NUCLEOSIDE PHOSPHORYLASE INHIBITOR FORODESINE INDUCES P53-INDEPENDENT MITOCHONDRIAL APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS THROUGH MCL-1 DOWNREGULATION AND INDUCTION OF P73 AND BIM

R. Alonso,[1] N. Villamor,[1] R. Upshaw,[2] S. Bantia,[2] C. Manz,[1] T. Mehrling,[3] E. Campo,[1] E. Montserrat,[1] D. Colomer[1]

[1]Hospital Clinic Barcelona, BARCELONA, Spain; [2]BioCryst Pharmaceuticals Inc., BIRMINGHAM, USA; [3]Mundipharma International Limited, CAMBRIDGE, UK

Background. Chronic lymphocytic leukemia (CLL) is a disease derived from the monoclonal expansion of $CD5^+$ B-lymphocytes. High ZAP-70 expression levels are associated with poorer overall survival, whereas p53 alterations convey drug resistance and short survival. Forodesine (BCX-1777) is a purine nucleoside phosphorylase inhibitor that induces an increase of plasma 2'-deoxyguanosine and intracellular accumulation of deoxyguanosine triphosphate and inhibition of DNA synthesis/repair, leading to cell death induction. Unlike other purine nucleoside analogs, Forodesine is not incorporated into DNA and represents a new selective anti-leukemic agent with a not yet fully explored mechanism of action. AIMS. To analyze the cytotoxic effect of Forodesine in CLL cells regarding their ZAP-70 levels as well their p53 status and to evaluate if the *in vitro* combination of Forodesine with Fludarabine, Bendamustine or Rituximab has a synergistic advantage. Finally, we characterized the mechanism of action of forodesine-induced apoptosis. *Methods*. The cytotoxic effect of Forodesine was analyzed by AnnexinV/PI staining in primary cells from 35 patients with CLL, 11 of them carrying p53 alterations. The synergistic or antagonic effect if combined with other drugs was analyzed using the combination index (CI) described by Chou and

Talalay. To further elucidate the mechanism of action of forodesine, several hallmarks of apoptosis were analyzed. *Results*. Pharmacologically achievable levels of Forodesine (2 μM) and dGuo (10-20 μM) induced apoptosis in CLL cells (mean cytotoxicity of 56.7±14.3 % with respect to control at 48 hours). No significant cytotoxic differences were observed between CLL cells regarding ZAP-70 expression levels (mean cytotoxicity of 57.6±10.2 % in 19 cases with ZAP-70 high *vs* 59.3±12.3 % in 16 cases with ZAP-70 low). CLL cases with 17p deletion showed a high sensitivity to forodesine (mean cytoxicity of 58.5± 20 %). A significative correlation between intracellular dGTP accumulation and forodesine-induced cytotoxicity was observed (p=0.0058). A high synergistic effect (CI<1) was observed between Forodesine and Bendamustine (mean CI=0.56) or Rituximab combination (mean CI=0.53). On the contrary, an antagonistic effect (CI>1) was observed with the combination of Fludarabine and Forodesine (mean CI=1.96). Forodesine induced an increase of the pro-apoptotic protein Bim, loss of mitochondrial membrane potential and generation of reactive-oxigen species (ROS). CLL cells express high levels of the anti-apoptotic proteins Mcl-1 and Bcl-2 that inversely correlate with *in vitro* and clinical response to chemotherapy. A decrease of the anti-apoptotic Mcl-1 protein, without affecting Bcl-2 was observed following Forodesine exposure. We demonstrated that p73 protein, which is activated upon DNA damage and ROS production and able to overcome resistance to apoptosis of CLL cells lacking p53, is induced after Forodesine incubation in both wild type- and p53 deleted CLL cases. *Conclusions*. Forodesine, as single agent or in combination with Bendamustine or Rituximab, might be highly effective in the treatment of CLL independent of the p53 and ZAP-70 status. Forodesine induced p73 and pro-apoptotic Bim, decreased the anti-apoptotic Mcl-1 protein leading to activation of the mitochondrial apoptotic pathway. No significant differences in these apoptotic markers were observed regarding p53 status, suggesting a common apoptotic pathway independent of p53-mediated cell death.

SAFETY AND TOLERABILITY OF VORINOSTAT - EXPERIENCE FROM THE VORINOSTAT CLINICAL TRIAL PROGRAM

D. Siegel,[1] M. Hussein,[2] C.P. Belani,[3] F. Robert,[4] S. Rizvi,[5] J. Wigginton,[5] S. Randolph,[5] J.L. Ricker,[5] J. Lis,[5] J. Garcia-Vargas,[5] C. Sanz-Rodriguez[5]

[1]Hackensack University Medical Center, HACKENSACK; [2]H. Lee Moffitt Cancer Center, TAMPA; [3]Penn State Cancer Institute, HERSHEY; [4]University of Alabama, BIRMINGHAM; [5]Merck Research Laboratories, UPPER GWYNEDD, USA

Background. Vorinostat is an orally active histone deacetylase inhibitor with anticancer properties when used alone or in combination. *Aims*. To present an overview of safety and tolerability data from patients who received vorinostat as monotherapy or in combination with other systemic therapies for solid and hematological malignancies. *Methods*. Safety data from patients in the Vorinostat Clinical Trial Program (Merck protocols 001, 002, 003, 004, 005, 006, 008, 011, 012, 013, 015, 016, 025, 029, 030, 048, 058, 066) were collated (cut-off date December 2007). *Results*. Data from 476 patients are included. A total of 341 patients received vorinostat as monotherapy for solid tumors (mesothelioma, head and neck, renal, thyroid, laryngeal, breast, colorectal, non-small-cell lung cancer [NSCLC], and gastric cancers) or for hematological malignancies (acute myeloid leukemia, chronic lymphocytic leukemia, or chronic myeloid leukemia, non-Hodgkin's lymphomas [including cutaneous T-cell lymphoma {CTCL}, peripheral T-cell lymphoma, diffuse large B-cell lymphoma, and follicular lymphoma], Hodgkin's disease, myelodysplastic syndrome or multiple myeloma). A total of 135 patients received vorinostat in combination with other systemic therapies: pemetrexed and cisplatin in advanced cancer, bortezomib in advanced multiple myeloma, bexarotene in advanced CTCL, erlotinib in relapsed/refractory NSCLC, or carboplatin and paclitaxel in chemonaïve NSCLC. As monotherapy, the most commonly reported adverse events (AEs) were fatigue (68.3%), nausea (60.1%), diarrhea (55.4%), and anorexia (49.9%). Grade 3-4 AEs included thrombocytopenia (15.2%), fatigue (13.5%), dehydration (8.5%), and anemia (7.9%). There were three drug-related deaths (ischemic stroke, tumor hemorrhage, unspecified) observed in patients who received vorinostat monotherapy. Of the 156 patients who received vorinostat monotherapy at 400 mg q.d. (the current FDA-approved dose in CTCL patients), 13 patients (8.3%) discontinued due to AEs (predominantly anorexia [1.3%], pulmonary embolism [0.6%], and weight decrease [0.6%]), and 24 patients (15.4%) required dose modifications (commonly due to thrombocytopenia [5.8%], diarrhea [1.9%], and nausea [1.9%]). In combination therapy, the most commonly reported AEs were nausea (52.6%), diarrhea (43.0%), and fatigue (41.5%). The most common grade 3-4 events included fatigue (16.3%), diarrhea (5.9%), dehydration (5.2%), and nausea (5.2%). There was one drug-related death (hemoptysis) that occurred in a patient with NSCLC. Discontinuation due to AEs occurred in 25 (18.5%) patients, commonly due to fatigue (3.0%) dehydration and nausea (both 2.2%), and 23 patients (17%) required dose modifications (commonly due to fatigue [5.9%], diarrhea [1.5%], and hypertriglyceridemia [1.5%]). *Conclusions*. Data from the Vorinostat Clinical Trial Program demonstrate that vorinostat has an acceptable safety and tolerability profile when used either as monotherapy or in combination with other systemic therapies in cancer patients. Dose modifications are usually not required in the majority of patients who receive vorinostat as monotherapy or in combination regimens.

EZN-2208, A NOVEL POLYETHYLENEGLYCOL-SN38 CONJUGATE, THERAPY RESULTS IN CURES OF ANIMALS BEARING AGGRESSIVE NON-HODGKIN'S LYMPHOMA MODELS

P. Sapra, M. Mehlig, J. Malaby, P. Kraft, H. Zhao, L. Greenberger, I. Horak

Enzon Pharmaceuticals, PISCATAWAY, USA

Background. Examination of the clinical utility of SN38 (10-hydroxy-7-ethyl-camptothecin), the highly active metabolite of CPT-11, has not been possible to date due to extremely poor solubility of SN38. We have generated, a novel polymer-drug conjugate, EZN-2208, made by linking SN38 reversibly with a multi-arm high molecular weight polyethylene glycol (PEG). *Aims*. The objectives of these studies were to evaluate the therapeutic efficacy of EZN-2208 in animals bearing non-Hodgkin's lymphomas. *Methods*. The *in vitro* cytotoxicity of EZN-2208 and CPT-11 were tested in human lymphoma (Raji, Daudi, DoHH2) cancer cell lines using the tetrazolium assay. Annexin V-FITC and propidium iodide staining followed by flow cytometry analysis were used to detect cytotoxicity at various apoptosis/necrosis stages. The therapeutic efficacy was evaluated in xenograft models of non-Hodgkin's lymphoma (Raji and Daudi and DoHH2). *Results*. *In vitro*, the IC50 of EZN-2208 ranged from 3-24 nM. EZN-2208 was about 30-45-fold more potent than CPT-11. In apoptosis assays, within 24 hours following treatment, the major mechanism of cell killing was late apoptosis and cell necrosis. When administered in a multiple dose regimen (q2d x 5), the MTDs of EZN-2208 and CPT-11 were 10- and 40 mg/kg respectively. In the Raji xenograft model, treatment with a single MTD of EZN-2208 resulted in a 500% improvement in life span (ILS) and 50% cures of animals compared with 19% ILS observed for mice treated with a single MTD of CPT-11. Multiple dose treatment of EZN-2208 resulted in 90% cures of animals compared with 63% ILS and no cures observed for the CPT-11 group. In an early disease Daudi xenograft model (treatment administered 24h postinjection of cells), a single injection of EZN-2208 treatment resulted in cures of 60% of animals and no cures were observed for CPT-11 group. Multiple injections of EZN-2208 cured 100% of animals. In the more aggressive late stage disease Daudi model (treatment administered 7 days postinjection of cells), a single dose of EZN-2208 caused 56% cures of animals, whereas CPT-11 treatment was completely ineffective. Multiple injections of EZN-2208 cured 100% of animals. Similar results were obtained in another model (DoHH2, t(14;18) chromosomal translocation), where EZN-2208 outperformed CPT-11 both in early and advanced disease models. *Conclusions*. EZN-2208 has excellent therapeutic efficacy and significantly greater antitumor activity than CPT-11 in several human NHL xenograft models. We have previously shown in solid tumor xenograft studies that EZN-2208 has prolonged circulation in the blood compared with CPT-11, resulting in high tumor exposure of free SN38. Therefore the dramatic antitumor activity seen in the NHL models may be attributed to a long circulation half-life and high exposure of the tumors to SN38. These studies merit the clinical evaluation of EZN-2208 in hematological malignancies. EZN-2208 is currently in Phase 1 clinical studies to identify optimal dose and schedule.

RITUXIMAB AND ALEMTUZUMAB IN COMBINATION, BUT NOT ALONE, INDUCE COMPLETE REMISSIONS IN A PRECLINICAL ANIMAL MODEL OF PRIMARY HUMAN ALL: RATIONALE FOR COMBINATION TREATMENT.

B.A. Nijmeijer, M.L.J Van Schie, S. Stevanovic, R. Willemze, J.H. Falkenburg

Leiden University Medical Center, LEIDEN, Netherlands

Background. Acute lymphoblastic leukemia (ALL) in adults has a poor prognosis, despite intensive chemotherapy or allogeneic stem cell transplantation. Further treatment intensification is limited by toxicity. Monoclonal antibodies display a relatively favorable toxicity profile. Rituximab (RTX) recognizing CD20, and alemtuzumab (ALM) recognizing CD52, have shown clinical activity in hematological malignancies. Precursor-B ALL (preB-ALL) may express CD20 and/or CD52. *Aims*. To evaluate the activity of RTX and ALM against preB-ALL in a preclinical *in vivo* model. *Methods*. Expression of CD20 and CD52 on preB-ALL cells was determined by staining with RTX or ALM followed by secondary anti-human-Ig antibody. Mean fluorescence intensity (MFI) was analyzed by flow cytometry. To investigate *in vivo* activity of RTX and ALM, NOD/scid mice were inoculated with primary human ALL cells. Three weeks later treatment was given by daily injection of 250 µg antibody. After 4 weeks of treatment, mice were sacrificed for analysis of peripheral blood (PB) and bone marrow (BM). *Result*s. Of 18 randomly selected primary human ALL, 10 expressed CD20 (56%, median MFI 102, range 97- 951) and 12 expressed CD52 (67%, median MFI: 324, range 111-633). All CD20 positive ALL expressed CD52. In 8 CD52 positive ALL distinct CD52 negative subpopulations were observed (0.1 to 4% of leukemic cells). Two of these cases (coded COA and VBK) that expressed CD20 and CD52 were selected for *in vivo* studies. In both cases, RTX cleared blast cells from the PB but at end-point leukemic cells persisted in BM (COA: 59% of nucleated cells *vs* 76% in control animals, VBK: 23% vs 86%, respectively). Persisting cells expressed a significantly decreased amount of surface CD20, all of which was occupied by RTX. Expression of CD20 on these cells was restored after engraftment into secondary recipient mice. To determine the cause of the decreased surface CD20 expression during RTX treatment, animals were engrafted with primary cells, received a single dose of RTX or vehicle alone, and were sacrified 24 hours later. Leukemic cell numbers were strongly reduced in PB (0.1% vs 7.4%) but not in BM (5.4% vs 8.4%), indicating limited elimination of ALL cells in the BM. Expression of CD20 on these cells was however reduced 13-fold, demonstrating that CD20 (or CD20-RTX complexes) had been removed from their surface. Likewise, ALM eliminated leukemic cells from PB of engrafted animals. At end-point leukemic cells persisted in BM (COA: 20% *vs* 76%, VBK: 74% *vs* 86%, respectively) and these cells displayed complete loss of CD52. However, CD52 expression was not restored after engraftment and expansion in secondary recipient mice. Thus, although both antibodies appeared to exert anti-leukemic activity, RTX activity was limited by down modulation of CD20 in the BM and ALM activity by the emergence of pre-existent CD52 negative cells. However, RTX treatment did not affect expression of CD52, and ALM treatment did not affect expression of CD20. Therefore, we evaluated combined administration of RTX and ALM in the same experimental setting. Combined treatment (250 µgRTX+250 µg ALM daily for 4 weeks) resulted in complete disappearance of leukemic cells from the BM of 6 out of 6 COA engrafted mice and in 4 out of 5 VBK engrafted mice. *Conclusions*. A combination of rituximab and alemtuzumab may be promising as treatment for patients with preB-ALL.

THE NOVEL HDAC INHIBITOR UCL67022 HAS POTENT ACTIVITY IN MULTIPLE MYELOMA CELLS AND REMAINS EFFECTIVE IN A BONE MARROW MICRO-ENVIRONMENT MODEL

R. Popat,[1] L. Maharaj,[2] H. Oakervee,[2] J. Cavenagh,[1] B. Middleton,[3] A. Rioja,[3] C. Marson,[3] S. Joel[2]

[1]St. Bartholomew's Hospital, LONDON; [2]Centre for Experimental Cancer Medicine, Barts and the London, LONDON; [3]University College London, LONDON, UK

Background. Histone acetylation and deacetylation are critical to gene expression in many cancers. Moreover, the enzymes that mediate the acetylation state of histones also alter the acetylation state of a number of other non-histone proteins. Histone deacetylase inhibitors (HDACI) represent a novel class of drugs that result in altered gene expression and the acetylation of key survival proteins such as HSP90. *Aims*. This study sought to investigate the effects of UCL67022 (a novel hydroxamic acid derived HDACI) on human multiple myeloma cell lines (HMCLs), patient derived myeloma cells and peripheral blood mononuclear cells (PBMCs). Drug activity in the presence of cytokines and stromal cells to mimic the bone marrow micro-environment was studied. Mechanisms of apoptosis resulting from HDACI exposure, and effects on ubiquitinated proteins were also examined. *Methods*. The HMCLs U266, RPMI 8226, MM1S and MM1R and the bone marrow stromal cell (BMSC) line HS-5 were used. Bone marrow aspirates from consenting patients were used to separate myeloma cells using a negative selection procedure and to generate BMSCs for co-culture studies. Cell viability and/or cell number were measured following 24 and 48hr incubations using both an ATP bioluminescence method and a fluorochrome based method. Immunofluorescence was performed by laser scanning confocal microscopy. HDACI effects on protein acetylation, caspase activation and HSPs were investigated by western blot analysis. *Results*. UCL67022 was approximately 10 fold more potent in reducing cell viability than SAHA in all HMCLs and 5 patient derived samples. IC50 values at 48 hours ranged from 45-118 nM for HMCLs and less than 360nM for patient samples. The cytotoxic effect was maintained when cells were supplemented with bone marrow derived cytokines such as IL-6 and IGF-1 and only minimally reduced when co-cultured with HS-5, BMSCs or patient derived BMSCs. In contrast, the presence of these cytokines, or BMSCs, abrogated the effects of dexamethasone. The effects of UCL67022 on BMSC cytokine production are currently being studied. UCL67022 had little effect on the viability of normal PBMCs at concentrations up to 30 µM or on BMSCs. Western blotting revealed acetylation of histone H3 and α-tubulin at 24hrs with 0.1 µM UCL67022 (compared with 1.0-10 µM SAHA) and cleavage of caspase 8 but not caspase 9. To investigate the potential HDAC6 inhibitory activity further, immunofluorescence studies were performed using acetylated α-tubulin and ubiquitin antibodies. UCL67022 caused the uniform hyperacetylation of α-tubulin which was able to disrupt bortezomib induced aggresomal formation. The combination of UCL67022 and bortezomib also altered the localisation of ubiquitinated protein to micro-aggregates. This disruption of protein homeostasis did not lead to an increase in HSP 27, 70 or 90 nor did it result in synergistic cytotoxicity by calcusyn analysis. *Conclusions*. UCL67022 is a novel hydroxamic based HDACI with potent activity in multiple myeloma. It is able to overcome the protective effects of the bone marrow microenvironment and induces apoptosis through activation of caspase 8. Finally it can disrupt bortezomib induced aggresome formation indicating HDAC6 inhibitory activity.

0284

METHYLSELENINIC ACID DEMONSTRATES ANTI-LEUKAEMIC ACTIVITY AND SENSITISES AML CELLS TO THE EFFECTS OF CYTOTOXIC AGENTS BY INITIATING THE UNFOLDED PROTEIN RESPONSE

J.M. Stevens, S. Juliger, K. Summers, J. Fitzgibbon, T.A. Lister, S.P. Joel

St Bartholomew's Hopsital, LONDONWEST SMITHFIELD, UK

Background. Evidence is accumulating that selenium modulates the activity of cytotoxic drugs and that the selenium species, methylseleninic acid (MSA) induces endoplasmic reticulum (ER) stress, initiating the unfolded protein response (UPR). *Aims*. To investigate the interaction between MSA and cytotoxic drugs in AML cell lines and evaluate the effect of MSA on markers of the UPR. *Methods*. A concentration-response curve was obtained for THP-1 and U937 cells exposed to MSA and 4 other cytotoxic agents (cytarabine, doxorubicin, etoposide and bortezomib). Subsequently cells were exposed to incremental concentrations of cytotoxic agent, combined with EC5 and EC10 concentrations of MSA. For the evaluation of chemosensitisation, results for cytotoxic drugs used as single agents were expressed relative to control viability and results for the combined effect were expressed relative to the effect of low concentration MSA alone. The concentration-response curves generated were compared using a one-way ANOVA test. Western blot (WB) and real time polymerase chain reaction (qRT-PCR) analysis were used to determine changes in the UPR (GRP78 upregulation, phosphorylation of eIF2α, splicing of XBP1 mRNA and GADD153). *Results.* MSA reduced the viability of THP-1 cell and U937 cells at 48 hours (EC50 18.2 µM and 3.9 µM respectively). Subtoxic concentrations of MSA sensitised cells to the effect of cytotoxic agents: significant supra-additive effects on viability were seen in THP-1 cells exposed to MSA in combination with cytarabine (p=<0.0001), etoposide (p=0.008), bortezomib (p=0.004) and doxorubicin p=0.03. MSA also sensitised U937 cells to etoposide (p=0.03) and bortezomib (p=0.0030), but not cytarabine or doxorubicin. Upregulation of GRP78, and phosphorylation of eIF2 were seen on exposure

of THP-1 cells to MSA. In U937 cells, GRP78 and phosphorylated eIF2α were maximally upregulated at baseline and did not change after exposure to MSA. Splicing of XBP1 mRNA and upregulation of GADD153 were demonstrated by qRT-PCR in both THP-1 and U937 cells after exposure to MSA, at both subtoxic and EC50 concentrations, in a time-dependent manner. *Conclusions*. These results demonstrate that MSA has activity against AML cells as a single agent, while at lower concentrations it sensitises cells to cytotoxic drugs and causes ER stress. However the effect is cell line specific; U937 cells were more sensitive to MSA but demonstrate less chemosensitisation by MSA than seen in THP-1 cells. This difference may be associated with the ER chaperone molecule GRP78, which exerts a cytoprotective effect against ER stress. GRP-78 was maximally upregulated at baseline in U937 cells, but was present at only low levels in THP-1 cells and could be upregulated further after exposure to MSA. This study suggests that subtoxic concentrations of selenium may be useful as a chemomodulating agent, in combination with conventional cytotoxic agents, in the treatment of AML.

0285

HIVTAT MEDIATED TRANSDUCTION OF COMPETITIVE PEPTIDES THAT DISRUPT THE BCR/ABL TETRAMERS INHIBITS THE PROLIFERATION OF PHILADELPHIA CHROMOSOME POSITIVE CELLS

A.A. Mian, M. Ruthardt, T. Beissert

Medical Clininc II/Hematology, FRANKFURT, Germany

Background. Philadelphia Chromosome (Ph) positive ALL and CML are characterized by the oncogenic BCR/ABL fusion tyrosine kinase (FTK). The BCR portion of the FTK harbors an N-terminal coiled-coil (CC) domain which induces the tetramerization of BCR/ABL. The BCR mediated tetramerization of ABL in the fusion protein leads to the constitutive activation of the ABL kinase. The subsequent permanent activation of multiple downstream signaling pathways induces the leukemic phenotype. The CC helical motif Helix-α-2 (Helix-2) represents the majority of the tetramer interface. Helix-2 is both, sufficient and necessary for BCR/ABL tetramerization. Targeted inhibition of BCR/ABL by the ABL kinase inhibitor Gleevec induces apoptosis in BCR-ABL transformed cells and leads to complete remission in Ph-positive leukemia patients. However, a large portion of ALL patients and CML patients in blast crisis relapse and acquire Gleevec resistant BCR/ABL mutations. We have previously shown that the coexpression of BCR/ABL and Helix-2 derived peptides reduces the transformation potential of Imatinib sensitive and Imatinib resistant BCR/ABL. Helix-2 peptides interfere with BCR/ABL tetramer formation and reduce the autophosphorylation of BCR/ABL. Our previous study provided a proove of concept that competitive Helix-2 peptides targeting the tetramerization domain represent a potential therapeutic approach for BCR/ABL positive leukemia. *Aims*. The aim of this study was to use the peptide transduction domain HIVTAT to deliver Helix-2 peptides (TAT-Helix-2) to Ph+ cells. We studied the proliferation of BCR/ABL-dependent Ph^+ cell lines in presence of TAT-Helix-2 as well as the autophosphorylation of BCR/ABL expressed in these cells. *Methods*. TAT-Helix-2 peptides were fused to GFP (TAT-Helix-2-GFP) and the STREP® tag. These fusion peptides were purified from bacterial lysates using the STREP® tag. The Ph-positive cell lines BV173, TOM-1 and K-562 and the Ph-negative cell line Nalm-6 were exposed to 1 μM of the TAT-Helix-2-GFP peptides. The successfull delivery to the cells was checked by FACS and western blots. The proliferation of the cells was assessed by dye exclusion and the viability by XTT assays. Anti-phospho-ABL specific immunoblotting was used to reveal the BCR/ABL autophosphorylation. All experiments were controlled using Helix-2-GFP peptides lacking a HIVTAT-domain and HIVTAT-tagged GFP devoid of Helix-2. *Results*. Here we report that i) TAT-Helix-2 peptides are efficiently delivered to Ph-positive hematopoitic cell lines; ii)) TAT-Helix-2 inhibits the growth and viability of Ph-positive cells, without affecting Ph-negative cells ; iii) the antiproliferative effects are enhanced in presence of chloroquine; iv) TAT-Helix-2 peptides decrease the autophosphorylation of BCR/ABL. *Summary and Conclusions*. Taken together these results show that cell permeable TAT-Helix-2 peptides are efficiently delivered to hematopoietic cells. Upon cellular uptake these peptides inhibit the ABL-kinase activity. TAT-Helix-2 peptides specifically inhibit the proliferation of Ph-positive patient-derived cell lines. This study provides first evidence that cell permeable Helix-2 derived peptides harbor a therapeutic potential for BCR/ABL positive leukemia.

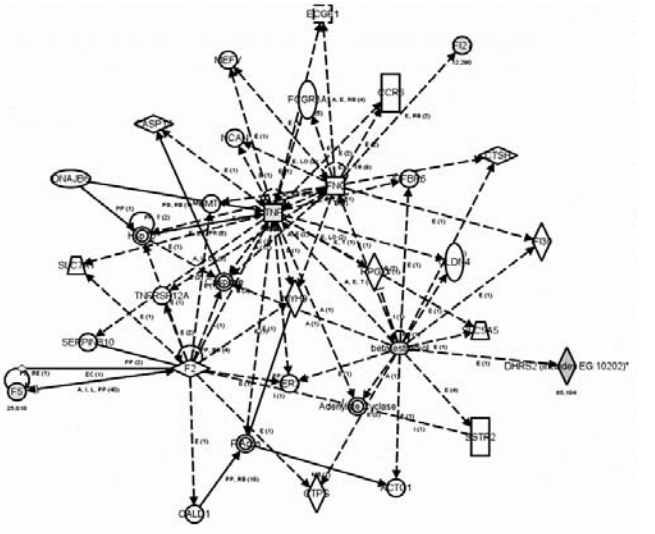
0286

HISTONE DEACETYLASE INHIBITOR ITF2357 EXERT SIGNIFICANT ANTI-PROLIFERATIVE AND PRO-APOPTOTIC EFFECTS ON THE P39 CELL LINE: A GENE EXPRESSION STUDY

S. Galimberti,[1] M. Canestraro,[1] H. Savli,[2] G. A. Palumbo,[3] B. Nagy,[4] F. Di Raimondo,[3] M. Petrini[1]

[1]Hematology, PISA, Italy; [2]Biology department, Kocaeli University, KOCAELI, Turkey; [3]Hematology Univeristy of Catania, CATANIA, Italy; [4]1st Department of Obstetrics and Gynecology, Semmelweis University, Budapest, BUDAPEST, Hungary

Background. ITF2357 is a new histone deacetylase inhibitor that has been recently reported to induce apoptosis Histone deacetylase inhibitors (HDAC inhibitors, HDI) are a class of drugs that interfere with the function of histone deacetylase.HDAC inhibitors are being studied as a treatment for cancer and neurodegenerative diseases. The exact mechanisms by which the compounds may work are unclear, but epigenetic pathways are proposed. Richon *et al.*found that HDAC inhibitors can induce p21 (WAF1) expression, a regulator of p53's tumor supressor .ITF2357, is a new histone deacetylase inhibitor, on multiple myeloma and acute myelogenous leukemia cells *in vitro* and *in vivo*. It induced histone acetylation, blocked proliferation and induced apoptosis in MM and AML cell lines. Also ITF2357 has anti-neoplastic activity *in vitro* and *in vivo* by induction of leukemic cell apoptosis.ITF2357 inhibits production of growth and angiogenic factors in IL-6 and VEGF. By this study, we assessed if ITF2357 would exert an anti-proliferative and pro-apoptotic effect on a myelo-monocytic cell line (the P39). *Methods*. Cell viability was assessed by MTT; apoptosis by the Annexin V/propidium cytofluorimetric analysis. ROS production was evaluated by dihydrorhodamine 123 (DHR) and flow-cytometry assay. Total RNA Samples were isolated using Qiamp RNA mini kit (Qiagen, Germany) and hybridized on Whole Human Genome Microarray platforms (Agilent). Obtained data imported into GeneSpring 6.1 software for analysis (GeneSpring 6.1,Silicon Genetics, Redwood City, CA, USA). The fold changes were analyzed by filtering the dataset using p-values <0.01 and a signal-to-noise ratio >2 for use in ANOVA statistical analysis. Additional filtering (minimum 2-fold change) was applied to extract the most these genes were analyzed using Ingenuity Pathways Analysis (IPA) Software (Ingenuity Systems, Redwood City, CA). Those genes with known gene symbols (HUGO) and their corresponding expression values were uploaded into the software. Each gene symbol was mapped to its corresponding gene object in the Ingenuity Pathways Knowledge Base. Networks of these genes were algorithmically generated based on their connectivity. Canonical pathways analysis identified the pathways, from the IPA library of canonical pathways, which were most significant to the input data set.



The significance of the association between the data set and the canonical pathway was determined based on two parameters: (1) A ratio of the number of genes from the data set that map to the pathway divided by the total number of genes that map to the canonical pathway and (2) a P value calculated using Fischer's exact test determining the

probability that the association between the genes in the data set and the canonical pathway is due to chance alone. Results have been confirmed by TaqMan® Low Density Array Human Apoptosis Panel using Real-Time PCR (Applera). *Results*. With an IC50 of 0.8 mcM, ITF2357 was able to inhibit proliferation and induce apoptosis (measured by Annexin V and presence of apoptotic bodies) of P39 cells, in a dose- and time-dependent way. ITF2357 blocked cell cycle in the G1 phase at low dose (0.5 mcM) and in the G2 phase at higher dose (0.8 mcM). Moreover, the production of reactive oxygen species (ROS) was significantly increased after exposure to this histone deacetylase inhibitor. In order to better understand the mechanism of apoptosis, we performed gene expression assays, by using both the TaqMan® Low Density Array Human Apoptosis Panel (Applied Biosystem), and Agilent platforms. The genes identified as de-regulated by ITF2357 were then analyzed for network and gene ontology by Ingenuity Pathway Analysis software. In the untreated P39, 84 of the 93 genes involved in the apoptotic pathway and represented in the Taqman Low-Density Arrays were expressed. Already after 12h-treatment, ITF2357 down-regulated 9 genes and up-regulated 11 genes. After exposure for 24 hours, ITF2357 down-regulated 48 genes and up-regulated 3 genes only. Among down-regulated genes, *BAD, BCLXL, BCL2, BCL2L10*, whereas APAF1 was significantly up-regulated. Moreover, microarray assays showed that the IL6, IL10, inflammation, *NF-kB, PDGF, TGFβ* and apoptosis were the pathways more significantly modified after exposure to ITF2357. Interestingly, among the significantly down-regulated genes, JUN, NF-kB, TNFA, IL1β could be clinically relevant. Indeed, IL1beta has been reported to induce activation of NF-kB, with consequent cell proliferation in acute leukemia; consequently, a down-regulation of IL1beta expression, in addition to the direct down-regulation of NF-kB, could suggest an anti-proliferative effect in MDS. Moreover, TNFalpha plays a well-known pathogenetic role in MDS: it induces apoptosis in the maturing cells causing pancytopenia, but also stimulates the proliferation of the primitive progenitors, accounting for the hypercellular bone marrow frequently observed in MDS. The ability of ITF2357 of down-regulating TNFα expression would be also relevant. *Conclusions*. In summary, biological results and gene expression assays suggest the possible use of histone deacetylase inhibitors in treatment of high-risk MDS. *in vivo* trials will be useful to confirm this hypothesis coming from our *in vitro* studies.

TARGETED THERAPY WITH ARSENIC TRIOXIDE AND INTERFERON ALPHA ERADICATES LEUKEMIC CELLS IN SCID MICE MODEL OF ADULT T-CELL LEUKEMIA/LYMPHOMA

A. Bazarbachi,[1] H. El Hajj,[2] H. Hasegawa,[3] M. El-Sabban,[2] G. Zaatari,[2] S. Saab,[2] R. Mahfouz,[2] R. Nasr,[2] Y. Kfoury,[2] O. Hermine,[4] H. De Thé,[5] W. Hall[6]

[1]American University of Beirut Medical Center, BEIRUT, Lebanon; [2]American University of Beirut, BEIRUT, Lebanon; [3]National Institute of Infectious Diseases, TOKYO, Japan; [4]Necker Hospital, PARIS, France; [5]Hopital Saint Louis, PARIS, France; [6]University College Dublin, DUBLIN, Ireland

Background. HTLV-I associated adult T-cell leukemia (ATL) is a severe, chemotherapy-resistant malignancy associated with poor prognosis. Recently, HTLV-I Tax transgenic mice, accurately reproducing human ATL disease were generated. To develop a more consistent and rapid model of disease development, direct transfer of Tax transgenic cells into SCID mice was assessed and showed that they die within 28 days, having developed both an extremely aggressive leukemia with characteristic flower cells, and extensive lymphomatous infiltration of the spleen, lymph nodes, bone marrow, liver, kidney and lung by malignant T lymphocytes highly expressing CD25. Furthermore, and as in ATL patients, we observed marked hypercalcemia and high level of LDH. *Aims and Methods*. We have previously identified *in vitro* several potential targeted therapies for ATL. To define the optimal schedule and drug combination to be evaluated in clinical trials, we tested the following drugs using the *in vivo* ATL SCID model: zidovudine, interferon α (IFN), arsenic trioxide, the proteasome inhibitor bortezomib, and the combinations of zidovudine and IFN, or of arsenic and IFN. *Results*. The combination of zidovudine and IFN had no effect on the survival of ATL SCID mice confirming the hypothesis that this combination targets the viral replication since these animals have Tax-transgenic leukemic cells but no entire HTLV-I retrovirus, contrary to ATL patients. Inhibition of NF-kappaB using bortezomib or arsenic alone almost doubled the mice survival but was not sufficient to eradicate ATL malignant cells. Strikingly, the most relevant effect on the mice survival was obtained when we used the combination of arsenic trioxide and interferon alpha, which targets both the HTLV-I Tax oncoprotein and the constitutive activation of the NF-kappaB pathway. Indeed, this combination cured 40% of treated mice after one cycle and 80% of treated mice after two cycles with evidence of total disease eradication. *Conclusions*. These impressive results suggest that double targeting of Tax and NF-κB by the combination of arsenic trioxide and interferon alpha may suffice to cure ATL. This combination is now tested in newly diagnosed ATL patients.

IN VITRO AND IN VIVO PROPERTIES OF PT-401, A NOVEL ERYTHROPOIETIN FUSION PROTEIN

J. Sytkowski,[1] J.Y. Jeong,[1] K.L. Davis,[1] A.L. Socha,[1] H.J. Gomez[2]

[1]Beth Israel Deaconess Medical Center, Harvard Medical School, BOSTON, MA; [2]DNAPrint Pharmaceuticals, Inc., SARASOTA, FL, USA

Background and Aims. Recombinant human erythropoietin (rhEpo, epoetin) is widely used for correction of anemia due to chronic kidney disease and other conditions. Modified forms of rhEpo and other erythropoiesis stimulating agents (ESAs) with higher efficacy and longer half-life have been and continue to be developed to overcome rhEpo's short *in vivo* half-life. Previously, we described a novel Epo fusion protein, PT-401, comprising identical head-to-tail repeats and a short linker. We now report that PT-401 exhibits unique *in vitro* characteristics and enhanced *in vivo* activity in mice compared to rhEpo. *Methods*. PT-401 was expressed in Chinese hamster ovary (CHO) cells stably transfected with a mammalian expression vector containing the PT-401 cDNA. We used quantitative immunoblotting analysis with the monoclonal anti-Epo antibody AE7A5 to identify and quantify PT-401 protein in the cell culture supernatant. Highly purified PT-401 was obtained by sequential column chromatography. The interaction of PT-401 with the Epo receptor (EpoR) was characterized using radioiodinated PT-401 and BaF3 cells stably expressing the human EpoR (BaF3/huEpoR). *Results*. The amount of PT-401 secreted into protein-free cell culture medium of cloned CHO cells varied between 4 and 40 mg/L. Clones producing PT-401 with the optimal glycosylation were identified based upon mobility in SDS-PAGE and isoelectric focusing, based upon the observation that the extent of glycosylation of Epo correlates with the *in vivo* half-life. The specific biological activity of purified PT-401 measure by *in vitro* bioassay was similar to that of freshly produced PT-401 in the cell culture supernatant, demonstrating that the biological activity of PT-401 was preserved during the purification process. PT-401 exhibited specific, saturable binding to the EpoR. The equilibrium dissociation constant (Kd) of PT-401/EpoR interaction was approximately 4 nM, higher than that for rhEpo (0.14 nM, determined in the same experiment), consistent with longer-acting ESAs. The specific activity of PT-401 determined by *in vitro* bioassay was lower than that of rhEpo, reflecting the higher Kd, also consistent with other longer-acting ESAs. Importantly, PT-401 increased the mean hematocrit of mice to significantly higher levels compared to rhEpo in all injection schemes tested (three injections with 300 IU/kg or 100 IU/kg, a single injection with 100 IU/kg), demonstrating the superior *in vivo* activity of PT-401. *Conclusions*. PT-401 exhibits *in vitro* characteristics consistent with a very long-acting ESA and an *in vivo* biological activity superior to that of rhEpo, suggesting important therapeutic advantages.

WOULD INACTIVATION OF GGTASE-I PREVENT THE DEVELOPMENT OF K-RAS-INDUCED MPD IN MICE?

A.-K. Sjögren, K.M.E. Andersson, B. A. Cutts, C. Karlsson, O. Khan, M. Liu, M.O. Bergö

Institute of Medicine, GÖTEBORG, Sweden

Background. We showed that inactivation of Pggt1b (the gene encoding geranylgeranyltransferase (GGTase-I)) reduces tumors and improves survival in mice with K-RAS-induced lung cancer.[1] In this model, K-RAS(G12D) is switched on not only in lung cells but also in myeloid cells, resulting in myeloproliferation. Interestingly, the inactivation of Pggt1b eliminated the myeloid phenotypes. To determine if inactivation of Pggt1b would prevent the development of a well-established myeloproliferative disase (MPD) model, we bred conditional Pggt1b knockout mice (Pggt1bfl/fl) with mice harboring a Cre-inducible K-RAS(G12D) allele (K) and a Mx1-Cre transgene (M). Injection of pI-pC in KM mice results in a lethal MPD.[2–4] Surprisingly, the inactivation of Pggt1b caused the mice to die more rapidly. One potential explanation for this finding is that mice with the K-RAS-induced MPD develop tumors in other tissues (e.g. lungs, gastrointestinal tract) due to *leaky* expression of K-RAS(G12D) and that the simultaneous inactivation of Pggt1b caused tissue damage. *Aims*. To test a tissue-specific model for K-RAS-induced

MPD and to use this model to define the impact of GGTase-I deficiency on disease phenotypes.

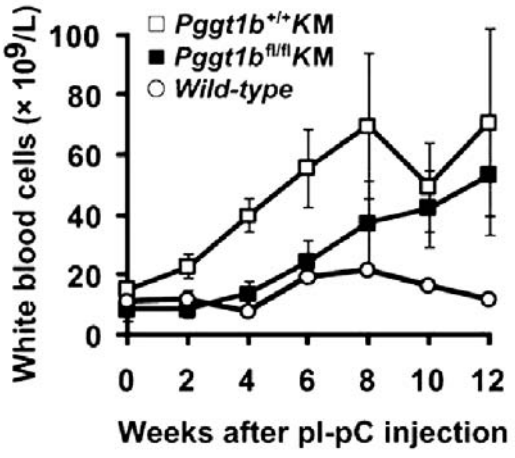

Figure 1. GGTasa-I deficiency reduces leukocytosis in mice with MPD. White blood cell counts in peripheral blood of mice receiving Pggt1b+/+ KM fetal liver cells (white rectangles, n=8-9 week 0-4; n=3-5 week 6-12), Pggt1bfl/flKM cells (black rectangles, n=8-10 week 0-4; n=4-5 week 6-12), and wild-type cells (white circles, n=3 week 0-4; n=1 week 6-12) were measured at different time points after pI-pC injection. Data are mean±SEM.

Methods. We isolate liver cells from Pggt1bfl/flKM and Pggt1b$^{+/+}$KM embryos and inject them into irradiated wild-type mice. Injection of pI-pC into mice receiving Pggt1b$^{+/+}$KM cells would turn on the expression of Cre - and K-RAS(G12D) - exclusively in the hematopoietic cells. We expected these mice to develop a K-RAS-induced MPD but not tumors in other tissues. In mice receiving Pggt1bfl/flKM cells, pI-pC should activate K-RAS(G12D) and simultaneously inactivate Pggt1b. In those mice we should be able to define the impact of inhibiting GGTase-I on the development of K-RAS-induced MPD. *Preliminary Results* Injections of pI-pC into mice receiving Pggt1b$^{+/+}$KM cells induced the development of MPD with leukocytosis, splenomegaly, and death, as predicted. K-RAS(G12D) expression was restricted to the hematopoietic cell compartment and no tumors have been detected in other tissues (n = 4 mice). Mice receiving Pggt1bfl/flKM cells showed reduced white blood cell counts (Figure 1) and splenomegaly, and improved survival. However, the mice still developed MPD, although with a prolonged latency. Genotyping of bone marrow from mice receiving Pggt1bfl/flKM (at 8 weeks) showed activation of K-RAS(G12D) but incomplete knockout of the Pggt1b allele. To overcome this incomplete Cre-inactivation of Pggt1b, we now use fetal liver cells with one conditional and one Pggt1b knockout allele (i.e, Pggt1bfl/-). In these cells, knockout of Pggt1b will be more efficient. *Conclusions.* We have tested a new approach to study mechanisms and treatment of K-RAS-induced MPD in mice. In this model, the potentially confounding effects of tumors in multiple other tissues are eliminated. We predict that we will now be able to define the impact of inactivating GGTase-I on the development of MPD in mice.

ANTILEUKEMIC ACTIVITY OF THE TYROSINE KINASE INHIBITOR BVT II +/- CYTARABINE OR DAUNORUBICIN IN ACUTE MYELOID LEUKEMIA

A Eriksson,[1] S. Bashir Hassan,[1] M. Höglund,[1] R. Larsson,[1] E. Lindhagen,[1] A. Åleskog,[1] K. Föhlenhag,[2] A. Jenmalm Jensen,[2] F. Lehmann,[2] A. Löthgren,[2] V. Parrow[2]

[1]Uppsala University, UPPSALA; [2]Discovery Research, Biovitrum AB, STOCKHOLM, Sweden

Backgroud. BVT II, a further development of the previously presented agent BVT I*, is a kinase inhibitor exhibiting activity against several receptor tyrosine kinases in enzymatic assays. *Aims*. Investigate the antileukemic activity of BVT II in hematological malignancies, as a single agent as well as in combination with two conventional antileukemic agents. *Methods*. To explore the *in vitro* activity of BVT II, the semiautomated fluorometric microculture cytotoxicity assay (FMCA) was used. The experiments were performed on a cell line panel as well as on primary tumor cells from 29 patients with hematological malignancies, (acute myeloid leukemia; AML; n=10), acute lymphocytic leukemia (n = 10) chronic lymphocytic leukemia (n = 9) and for comparison, normal peripheral blood mononuclear cells (PBMC; n=6). Combining BVT II with the AML drugs cytarabine and daunorubicin, possible synergistic effects, including sequence dependency, was studied using the FMCA In the *in vivo* experiments, semipermeable hollow fibers containing cells from 2 AML patients and the flt-3-positive AML cell line MV-4-11 were implanted subcutaneously in NMRI male mice. The animals were treated subcutaneously twice a day with 15 mg/kg of BVT II or vehicle only. The fibers were retrieved after 6 days and cell density assessed using the MTT-assay. *Results*. *In vitro*, cytotoxic activity was observed in cells from all hematological malignancies tested as well as in PBMC. AML tended to be the most sensitive cell type. Amongst the cell lines, the flt-3-positive AML cell line MV-4-11 showed the highest *in vitro* response towards BVT II in terms of EC50. *In vivo*, BVT II displayed significant antileukemic effect in both primary AML cells and MV-4-11 (Figure 1). No major toxicity, neither hematological nor non-hematological, was observed in the animals. Results from the combination studies (FMCA) suggest a sequence dependency, with better antileukemic activity when the cells were exposed to cytarabine or daunorubicin for 24 hours before adding BVT II. *Conclusions*. BVT II is a tyrosine kinase inhibitor displaying significant *in vitro* and *in vivo* effect in AML.

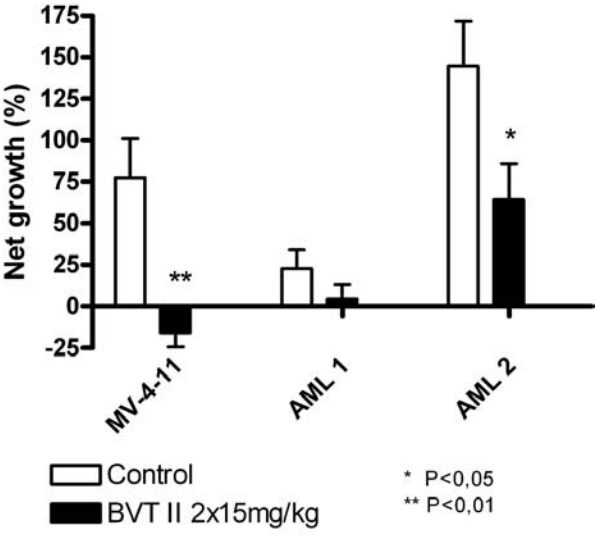

Figure 1. *In vivo* activity of BVT II against AML cells (cell line MV-4-11 and primary AML cells from two individual patients) in the mouse hollow fiber assay. Results are presented as net growth, defined as the percent change in cell density in the fibers during the 6 days of *in vivo* experiment.

RITUXIMAB THERAPY FOR AUTOIMMUNE DISEASES

L. Flenghi, M. Capponi, P. Minga, L. Marcomigni, L. Stocchi, F. Falcinelli

Hematology and Clinical Immunology, PERUGIA, Italy

Background. Standard therapy for autoimmune diseases (drugs with non-specific immunosoppressive capacities) is associated with infections and toxicity. As the anti-CD20 monoclonal antibody Rituximab induces complement- or cell-mediated lysis of autoreactive lymphocyte clones, we assessed its efficacy in patients who were resistant to standard therapy for primary and secondary autoimmune hemolytic anemia (AIHA), autoimmune thrombocytopenia (AT), mixed cryoglobulinema (MC) and pemphygus (PEM). *Methods*. Intravenous Rituximab 375mg/m^2 once a week for 4 weeks for primary AIHA, AT, MC and PEM. Rituximab 375 mg/m^2 combined with cyclophosphamide 1 gr iv every fortnight for two months for secondary AIHA. *Patients*. Primary AIHA in 4 patients (2 with warm antibodies, 2 with cold); AIHA secondary to lymphoproliferative disorders in 8 patients (5 non-Hodgkins Lymphoma (NHL), 3 chronic lymphocytic leukaemia). All patients had previously received steroid therapy; 8/12 had received cyclophosphamide. All secondary AIHA had received chemotherapy; 2/8 had undergone autologous bone marrow transplantation. AT: 11 patients had idiopathic thrombocytopenic purpura (ITP), 1 had NHL, another had Sjogren's disease. All had platelet counts < 10,000/mmc, and had received steroids and high dose, intravenous immunoglobulin. Two had received Azathioprine in the previous 2 months. Chemotherapy had failed in the patient with NHL and splenectomy in 4 patients with ITP. MC was idiopathic in 1 and associated with HCV-related chronic hepatitis in 2. All presented arthralgia, asthenia, petechial lesions of the leg. Previous treatment included interferon α, plasmapheresis and steroids. PEM: paraneoplastic pemphygus was secondary to NHL in 1 patient with mucosal and cutaneous lesions; pemphygus vulgaris with cutaneous lesions was present in another. Previous therapy included steroids and azathioprine (with severe side effects). *Results*. AIHA: Haemoglobin levels increased in 11/12 patients. Steroids were suspended. Two patients achieved full response but relapsed after 18 and 8 months, respectively. After retreatment with Rituximab, 1 is in complete response after 50 months; the other relapsed after 5 months and underwent splenectomy. 1 non-responding patient died of AIHA. 9/12 patients achieved full response (12 gr/dL haemoglobin) one month after therapy and maintain it at a median follow-up of 53 months (range 4 - 106). AT: 9/13 patients reached normal platelet counts and suspended steroid treatment. 1 good responder requested a second Rituximab cycle after 16 months and obtained a second response and normal platelet count after 110 months. Median follow - up is 28 months (range 4-129). MC: Rituximab was suspended in 1 patient because of a persistent urticaria-type reaction. Cryocrit dropped from 82.7% to 44.0% with little clinical benefit. In another patient cryocrit fell from 156% to <30%. Rituximab retreatment was needed after 19 months. Cryocrit normalized (follow-up 6 months). In the third patient cryocrit fell from 60% to the present negative value after 40 months. Symptoms disappeared in the two responders. PEM: In both patients lesions improved and clinical remission was sustained in 1 patient for 52 months (without therapy) and in the other for 36 months (until death due to NHL). *Conclusions*. Rituximab seems safe and successful in patients with these autoimmune diseases who were resistant to standard immunosuppressive drugs.

Platelets and thrombocytopenia

FAMILIAL THROMBOCYTOPENIA CAUSED BY A PRO-APOPTOTIC MUTATION OF CYTOCHROME C

M. Morison,[1] E.C. Ledgerwood,[1] E.M. Cramer,[2] P.L. Cheong,[1] G. Hughes,[1] A.J. Holyoake,[3] S. Fichelson[2]

[1]University of Otago, DUNEDIN, New Zealand; [2]Institut Cochin, INSERM U.567, PARIS, France; [3]Pacific Edge Biotechnology Ltd, DUNEDIN, New Zealand

Background. We have identified a large New Zealand family with mild thrombocytopenia, with normal MPV, inherited as an autosomal dominant condition. *Aims and Methods*. To determine the causative mutation and its mechanism, genetic, phenotypic, and biochemical assessments were performed. Results. To identify the causative mutation, linkage analysis and candidate gene sequencing revealed the first mutation of human cytochrome c, G41S. Recombinant G41S protein showed enhanced ability to activate caspase-3 within the intrinsic apoptotic pathway. In contrast, measures of its mitochondrial function and its structure were normal. Normal peripheral blood immature platelet fraction values indicated normal platelet survival. Electron microscopy of bone marrow showed intramedullary naked megakaryocyte nuclei and platelets indicative of dysregulated release into the marrow space rather than into sinusoids. Megakaryocytes were cultured from CD34$^+$ blood cells from two family members. Unusually numerous platelets, confirmed by EM, were produced as early as day 6. Normally CD34$^+$ cell-derived megakaryocytes produce visible platelets only after 10-12 days in culture. Flow cytometry showed a 10 fold increase in the ratio of platelet-like particles (CD41$^+$) to megakaryocytic cells at days 6 and 7 of culture. Conclusions. These results confirm the role of cytochrome c-mediated intrinsic apoptosis pathway activation in platelet formation. Affected individuals were otherwise healthy and long-lived indicating that thrombopoiesis is especially sensitive to changes in the intrinsic apoptosis pathway. Furthermore their phenotype implies that the presence of a more *active* cytochrome c has little or no effect on the apoptotic outcome in most organs during development and adult life.

0293

FIBRONECTIN FACILITATES VIABILITY EXPANSION AND MATURATION OF MEGAKARYOCYTE PROGENITORS AND CD34$^+$ HEMATOPOIETIC STEM/PROGENITOR CELLS FROM CORD BLOOD

V.R. Deutsch, E. Hubel, S. Kay, T. Ohayon, A. Many, E. Naparstek, D. Grisaru

Tel Aviv Medical Center, TEL AVIV, Israel

Background. Following cord blood (CBT) and bone marrow transplant (BMT) neutropenia and protracted thrombocytopenia remain serious clinical problems. CBT is primarily performed in children due to low numbers of hematopoietic stem/progenitor cells (HSPC) and megakaryocyte progenitors (MK-p). Platelet production following transplant depends on the availability of adequate numbers of cytokine responsive stem and megakaryocyte progenitor cells (MK-p). Thrombopoietin(TPO), had no clinical impact on thrombopoiesis in patients post BMT due to the paucity of MK-p in the grafts. If expanded, Mk-p would supply the appropriate target cells to maximize the effect of TPO and provide efficient earlier platelet engraftment. While CB CD34$^+$HSPC can be expanded, isolation of these cells from CB is not practical due to the limited number of stem and progenitor cells in the CB units. Additionally, MK expansion from purified stem cells requires long culture periods which are inappropriate for transplantation. *Aims*. To expand MK-p and HSPC, from small aliquots of whole CB, in short term cultures using progenitor enriched mononuclear cells (MNC). Growth conditions were designed to enhance viability and proliferation using fibronectin (FN), a major component of the bone marrow hematopoietic niche known to protect and stimulate HSPC, and new growth factor combinations which included the hematopoietic ARP peptide. *Methods*. Precursor enriched MNC (3) were expanded on fibronectin (FN) coated dishes in the presence of autologous plasma with various new cytokine combinations. These included r-hu-TPO, β- FGF, r-hu-SCF and ARP a peptide derived from the stress variant of acetylcholinesterase (AChE-R) recently discovered to have potent hematopoietic stem cell and MK growth factor activity (2,3). True expansion of MK, MK-p, HSPC and their subpopulations were characterized by high resolution flow cytometry on day 0 and 10 days of culture using SSC, CD45, CD41 and

CD34 and appropriate gating out of granulocyte and monocytes, which acquire CD41+ adherent platelets in culture. *Results*. High definition flow cytometry of the MK and myeloid progenitor subpopulation demonstrated that FN alone, increased the viability and expansion of MK, Mk-p (SSC^{low}/CD45-/^{dim}/$CD41^{high}$) and CD34+ HSPC. FN and ARP increased HSPC proliferation and drove Mk maturation measured by ploidy and GPIIb/IIIa expression. The combination of FN, thrombopoietin (TPO) and ARP produced a 4-6 fold increase in CD34+ HSPC, and a notable 40-70 fold increase in Mk-p, and CD34+/CD33+ HSPC. These conditions also enhanced CFU- Mk and multilineage CFU-GEMM. The MK-p expansion was calculated to potentially produce sufficient numbers of platelets to prevent bleeding in transplanted recipients. *Conclusions*. This study demonstrates for the first time that FN, maintains and expands thrombopoietic precursors and this effect is enhanced in the presence of TPO and ARP. High definition flow cytometry was used to resolve the true expansion of early MK and CD34+ progenitors and their subpopulations. We demonstrate that short term expansion of a small fraction of the CB unit is feasible, easy to perform and can comply with GTP regulations. Our novel approach may lead to improved cell therapy modalities to facilitate myelopoiesis and platelet production and shorten the neutropenia and thrombocytopenia post CBT.

0294

EFFICACY AND SAFETY OF REPEATED INTERMITTENT TREATMENT WITH ELTROMBOPAG IN PATIENTS WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP)

B. Psaila,[1] J. Bussel,[1] S. Vasey,[2] M. Aivado,[2] B. Mayer,[2] N. Stone,[2] M. Arning[2]

[1]*Weill-Cornell Medical College of Cornell University, NEW YORK, NY, USA;* [2]*GlaxoSmithKline, COLLEGEVILLE, PA, USA*

Background. REPEAT is an ongoing open-label phase II study evaluating the safety and consistency of response to repeated intermittent dosing of eltrombopag, a new oral non-peptide thrombopoietin receptor agonist, in adults with chronic ITP. *Aims*. This study was conducted to evaluate the safety and consistency of response to repeated intermittent administration of eltrombopag in patients with chronic ITP. *Methods*. Eltrombopag (50 mg) was administered to 66 patients with baseline platelet counts of 20K-50K/μL across 3 cycles of treatment. A cycle consisted of an on-therapy period of up to 6 weeks, followed by an off-therapy period of up to 4 weeks. Only patients responding (defined as platelets ≥50K/μL and 2x baseline) in Cycle 1 were allowed to continue with Cycles 2 and 3. The primary endpoint was consistency of response in Cycle 2 or 3, given response in Cycle 1. Written, informed consent was obtained from all study participants. *Results*. The median age of patients was 51 years; 71% were Caucasian; 68% were female; 44% and 45% had baseline platelet counts ≥20K-30K/μL and >30K-50K/μL, respectively; 30% were splenectomized; and 33% were receiving baseline ITP medication. 82% responded in Cycle 1, with 88% achieving the primary endpoint, 95% CI (72%, 97%). By Day 8 and 15 of each cycle, >60% and >75% of patients had responded, respectively. Off-therapy, median platelet counts remained ≥100K/μL 1 week after discontinuation and returned to near baseline after 2 weeks. A decrease in bleeding was observed in each on-therapy period vs baseline. Bleeding increased again during off-therapy periods, but remained lower than at baseline of Cycle 1. There were no SAEs reported. Headache was the most frequently reported AE (17%). After on-therapy periods, a transient decrease in platelet counts defined as *platelet count <10K/μL* or *<20K/μL and at least 10K/μL below baseline within 4 weeks of discontinuation of eltrombopag* was observed in 5/66 patients, and 13/66 patients, respectively. No bleeding AEs were reported in these patients during 4 weeks off-therapy. *Conclusion.* Repeated intermittent use of eltrombopag produced consistent and predictable responses in patients with chronic ITP. Eltrombopag appears well tolerated upon repeated administration with the same or greater counts with each subsequent cycle.

0295

DOSING LEPIRUDIN IN PATIENTS WITH HEPARIN-INDUCED THROMBOCYTOPENIA AND VARIOUS DEGREES OF RENAL FUNCTION IMPAIRMENT: A SINGLE-CENTRE EXPERIENCE WITH 68 PATIENTS

L. Alberio,[1] M. Tschudi,[2] B. Lämmle[2]

[1]*Department of Haematology and Central Haematology Laboratory, BERN, Switzerland;* [2]*Department of Haematology and Central Haematology Laboratory, Inselspital, BERN, Switzerland*

Introduction. Heparin-induced thrombocytopenia is a severe prothrombotic complication of heparin treatment. Lepirudin is a direct thrombin inhibitor approved for its treatment. Late in 2000 we observed that patients receiving the recommended doses of lepirudin were over-anticoagulated. *Aims.* To identify an adequate lepirudin dosing regimen for patients with various degrees of renal function impairment. *Methods*. Between 1.2001 and 2.2007 we treated 53 consecutive patients diagnosed with HIT administering lepirudin without initial bolus and reducing the recommended dose by 1/3. In addition, lepirudin dose was further adjusted according to calculated creatinine clearance (CCL). Intensity of anticoagulation was monitored with thrombin times (TT) and aPTT, its efficacy was assessed with measurements of the platelet count (PC) and D-dimers (DD). Based on this experience we defined an in-house regimen, which we prospectively validated from 3.2007 to 2.2008 treating 15 HIT patients. *Results*. Among the 53 patients of the first study phase, those with a normal renal function (CCL > 60 mL/min) which were within therapeutic range at first monitoring 4 hours after lepirudin start (17/29) received a median lepirudin dose of 0.078 mg/kg/h. The efficacy of this treatment was documented by a median aPTT-prolongation of 2.03 times at first control, by a PC increase from median 81 G/lL at d0 to 117 G/L (d1) and 272 G/L (d5), and by a decrease of DD from median 4599 mcg/L at day 0 to 1810 mcg/mL at follow-up. Patients with a moderately impaired renal function (CCL 30-60 mL/min) within therapeutic range at first monitoring (7/15) received a median lepirudin dose of 0.040 mg/kg/h. The efficacy of this treatment was documented by a median aPTT-prolongation of 2.09 times, by a PC increase from median 73 G/l (d0) to 82 G/L (d1) and 169 G/L (d5), and by a decrease of DD from median 3634 mcg/l to 1540 mcg/mL. Patients with a severely impaired renal function (CCL <30 mL/min) within therapeutic range (7/9) received a median lepirudin dose of 0.013 mg/kg/h. The efficacy of this treatment was documented by a median aPTT-prolongation of 2.11 times, by a PC increase from median 67 G/L (d0) to 82 G/L (d1) and 149 G/L (d5), and by a decrease of DD from median 2508 mcg/L to 1568 mg^3/mL. From these data we derived a dosing regimen (see conclusions), which was prospectively validated treating 15 HIT patients: all of them were within therapeutic ranges at first monitoring and experienced a resolution of the thrombocytopenia and a significant decrease of DD. *Conclusions*. The reported data confirm that the recommended dosage schedule for lepirudin is to high. We show that it is safe to avoid the first lepirudin bolus, and that administering lepirudin 0.08 mg/kg/h to patients with normal renal function, 0.04 mg/kg/h for those with moderate impairment and 0.01 - 0.02 mg/kg/h for those with severe impairment of renal function is an efficacious treatment for HIT.

0296

ORAL ELTROMBOPAG HELPS CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP) PATIENTS TO UNDERGO PROCEDURES WITHOUT BLEEDING OR ADDITIONAL TREATMENT TO RAISE PLATELET COUNTS

M. Tarantino,[1] J. Bussel,[2] M. Saleh,[3] N. Stone,[4] M. Arning[4]

[1]*Comprehensive Bleeding Disorders Center, PEORIA, ILA;* [2]*Weill-Cornell Medical College of Cornell University, NEW YORK, NY;* [3]*Georgia Cancer Specialists, ATLANTA, GA, USA;* [4]*GlaxoSmithKline, COLLEGEVILLE, PA, USA*

Background. Patients with chronic ITP may need additional treatment in preparation for planned diagnostic procedures or surgeries. Predictable, rapid platelet elevation for the duration of a hemostatic challenge would be instrumental in reducing dependence on transfusion and rescue medications. Eltrombopag is a new oral non-peptide thrombopoietin receptor agonist that has been shown to elevate platelet counts and reduce bleeding events in patients with chronic ITP. *Aims*. This analysis was conducted to determine whether eltrombopag treatment would allow patients with chronic ITP to undergo procedures without bleeding or additional treatment to raise platelet counts. Methods. Data collection on hemostatic challenges from 2 placebo (PBO)-controlled and 2 open-label eltrombopag trials (REPEAT and EXTEND) in patients with

pretreated chronic ITP. Written, informed consent was obtained from all study participants. *Results*. Data from 269 eltrombopag-treated patients and 67 PBO patients were analyzed. Three PBO patients and 22 eltrombopag patients had documented episodes of hemostatic challenges. In the PBO-controlled trials, 4 patients treated with eltrombopag had platelet responses >100K/µL and successfully managed 2 surgeries, 1 tooth extraction and 1 severe car accident without rescue medication or bleeding complications. Two PBO patients needed IVIg to elevate platelet counts prior to surgeries and 1 patient received tranexamic acid. In the open-label REPEAT study, 7 patients successfully managed hemostatic challenges without rescue therapy and unexpected bleeding (1 subject had both endoscopic sinus surgery and a cardiac catheterization, 1 patient each had TUR of the prostate and colon polypectomy, 2 patients had colonoscopies, and 2 patients had dental work). In EXTEND, 13 patients experienced ≥1 hemostatic challenge; 2 also faced a hemostatic challenge in a prior trial. The procedures included tooth repair, colonoscopies, arthroscopy, and uterine polypectomy. Two patients not responding to eltrombopag had rescue treatment (IVIg and cyclosporine) prior to the procedure; no unexpected bleeding was reported. *Conclusion*. Eltrombopag-stimulated platelet count elevation consistently allowed patients to successfully master hemostatic challenges without the use of rescue therapies, such as platelet transfusions; no excessive bleeding was reported indicating platelets produced in response to eltrombopag function normally.

0297

ELTROMBOPAG EFFECTIVELY ELEVATES PLATELETS IN PATIENTS WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP) REGARDLESS OF SPLENECTOMY STATUS

A. Newland,[1] J. Bussel,[2] N. Stone,[3] B. Mayer,[3] M. Arning[3]

[1]Barts and the London NHS Trust, LONDON, UK; [2]Weill Medical College of Cornell University, NEW YORK, NY, USA; [3]GlaxoSmithKline, COLLEGEVILLE, PA, USA

Background. Splenectomy is a standard second-line therapy for patients with chronic ITP. Patients who have refractory disease following splenectomy have a significant unmet medical need, with limited options for treatment. Eltrombopag is a new oral thrombopoietin receptor agonist that has been shown to increase platelet counts to ≥50,000/µL during short-term treatment (up to 6 weeks) in the majority of patients with chronic ITP. *Aims.* To evaluate the impact of splenectomy status on the response to eltrombopag in patients with chronic ITP. *Methods*. The importance of splenectomy status on response to eltrombopag in patients with chronic ITP was analyzed in 2 placebo-controlled trials that enrolled 164 patients to a starting dose of 50 mg eltrombopag once daily and 67 to placebo. Patients had at least 1 prior ITP therapy, which may have included splenectomy and a baseline platelet count of <30,000/µL. Prospective treatment comparisons were performed adjusting for stratification of splenectomy status at randomization. Written, informed consent was obtained from all study participants. *Results*. In the placebo-controlled trials, 28/67 placebo-treated patients (42%) and 46/106 eltrombopag-treated patients (43%) were splenectomized. Fifty-nine percent of splenectomized patients who received eltrombopag in the placebo-controlled trials achieved platelet counts ≥50,000/µL, compared with 64% of non-splenectomized eltrombopag-treated patients. Statistical significance was calculated and no significant interaction between response and splenectomy status was observed (p=0.661). *Summary and Conclusions*. This analysis demonstrated that with up to 6 weeks of treatement eltrombopag raises platelet counts to an equivalent degree in patients with chronic ITP regardless of splenectomy status. Eltrombopag may provide an effective treatment option for chronic ITP patients including those with refractory disease post splenectomy.

0298

SERUM THROMBOPOIETIN LEVELS IN PATIENTS WITH LIVER CIRRHOSIS; RELATION TO PLATELET COUNT, PLATELET FUNCTIONS SPLEEN SIZE AND SEVERITY OF THE DISEASE

M. Awad, S. EL- Sayed, M. EL-Nahas, H. EL-Askalany, T. Abdel- Hamid

Mansoura Unversity, MANSOURA, Egypt

Background. Thrombopietin (TPO) is an important regulator of megakaryocyte maturation and platelet production. The role of TPO (which is mainly produced by the liver) in thrombocytopenic cirrhotic patients is still under investigation. The aim of this study was to measure the serum TPO levels in cirrhotic patients and examine its relationship with circulating platelet count, platelet functions, splenic size and severity of disease. *Material and methods.* This study was conducted on 88 subjects, divided into 2groups, group 1 (patient group) included 72 patients with liver cirrhosis (diagnosed by combination of clinical, laboratory, ultrasound and histopathological data), they were further divided into 2 subgroups, group IA: included cirrhotic patients with thrombocytopenia (36 patients, 28 males and 8 females with age 50.3±years) , and group IB: included cirrhotic patients with normal platelet count (36 patients,26 males and 10 females, with age 50.64± 6.8 years) Group II comprised 16 healthy persons with matched age and sex used as a control group. AII included persons were subjected to: through history taking, full clinical examination, beside the following investigations: complete blood picture, kidney and liver function tests, Hepatitis Band C markers, platelet count and functions (aggregation to ADP, epinephrine and collagen) serum TPO level (Shinohara *et al.* 1996) and abdominal Doppler ultrasound. The following invasive investigation were done for group I(Patients) only: bone marrow aspiration, upper gastrointestinal endoscopy, sigmoidoscopy and liver biopsy (the latter was done for 21 patients only). Patients with pure schistosomal fibrosis were excluded from the study. Patients were classified according to the child- Pugh score into 3 classes of clinical severity: A, b and C. *Results*. Cirrhotic patients were thrombocytopenic in comparison to control (p<0.0001).Serum TPO levels were lower in cirrhotic patients (130.6±79 pg/mL) than control group (225.5±36 pg/mL) (p<0.0001) and also in patients with thrombocytopenia with normal platelet count (160.2±70.3 pg/mL) (p<0.0001). TPO had a significant positive correlation with platelet count (p=0.0001 for subgroup IA & p=0.04 for subgroup IB)TPO has significant positive correlation with platelet aggregation to ADP, epinephrine and collagen in group 1A and 1B but insignificant correlation in group 11. However serum TPO did not correlate with spleen size. Splenic size had a significant negative correlation with platelet count in cirrhotic patients (p=0.03 for subgroup IA& p=0.004 for subgroup IB). [In cirrhotic patients, serum TPO levels were found to be decreased as the disease progressed in subgroup IA, 188.25±23.28 pg/mI in class B and 51±26 pg/mL in class C ,while in group IB, 247.3±40.49 pg/mL in class A, 121.3±29.6 pg/mL in class C]. Child-Pugh score has a significant negative correlation with TPO level in both subgroups IA &IB (p=0.0001) and with platelet count (p=0.0001 for subgroup IA and 0.01 for subgroup IB) but no significant correlation with spleen size. In comparing class A, B C in both subgroups (IA & IB), spleen size was significantly larger in child class A of subgroup IA when compared to same class of subgroup IB (p=0.0001) with slight significant decrease in TPO in class A of subgroup I than class A of subgroup B (p=0.02). *Summary and Conclusion*. We concluded that low TPO production may play a role, along with hypersplenism, in the development of thrombocytopenia in patients with liver cirrhosis, In early stage of cirrhosis (Child- Pugh class A), splenomegaly and hypersplenism may be the main pathomechanism of thrombocytopenia. While advanced liver cirrhosis (Child- Pugh class B & C), causing more reduction in TPO production, plays a central role in the pathogenesis of thrombocytopenia.

0299

LESS CHRONIC ITP AFTER IVIG FOR ACUTE CHILDHOOD ITP ? A MATCHED PAIRS ANALYSIS FROM REGISTRY I OF THE INTERCONTINENTAL ITP STUDY GROUP (ICIS)

R.Y.J. Tamminga,[1] W. Berchtold,[2] M.C.A. Bruin,[3] G.R. Buchanan,[4] T. Kühne[5]

[1]University Medical Centre Groningen, GRONINGEN, Netherlands; [2]University of Applied Sciences of Aargau, BRUGG, Switzerland; [3]Wilhemina Children's Hospital, UTRECHT, Netherlands; [4]University of Texas, Southwestern Medical Center, DALLAS, TEXAS, USA; [5]University Children's Hospital, BASEL, Switzerland

Background and aims. Childhood immune thrombocytopenic purpura (ITP) is a bleeding disorder caused by destruction of platelets with a very small risk of a life threatening bleeding. ICIS Registry I was initiated in 1997 to obtain worldwide prospective data on the natural history of ITP in children. The first analyses of ICIS data showed that 25-47% of the children developed chronic ITP (defined as a platelet count < 150×10^9/L 6 months after diagnosis) depending on age. Previous studies in small numbers of patients suggested that intravenous immunoglobulin (IVIG) treatment at diagnosis might reduce the risk of chronic ITP. Therefore, the ICIS Registry I (with data on >2000 patients) was used to examine prognostic factors related to chronic ITP. *Methods and results*. Of the 2605 children with newly diagnosed ITP, between 3 months and 16 years of age, in 1984 the platelet count 6 months after diagnosis was known; 630 (32%) had a platelet count <150×10^9/L. Patient and clinical characteris-

tics associated with a significantly (univariate analysis, $p<0.001$) higher risk of chronic ITP were: age (<2 yrs: 22%; 2-10: 30%; >10:49%), platelet count at diagnosis (<10×10^9/L: 25%; 10-20: 37%; 20-50: 40%; >50:50%) and previous infection (yes: 27%; no 38%). Gender was not of prognostic significance. Investigating the effect of treatment, we performed a matched pairs analysis: two groups were composed, one with platelets >150×10^9/L (controls) and one with platelets <150×10^9/L (cases) at six months from diagnosis, but matched with regard to gender, age, previous infection, platelet count at diagnosis and country of origin. We identified 449 matched pairs. The group with chronic ITP had been more often treated at diagnosis with steroids and less often with IVIG than the controls; the difference between IVIG and steroid treatment was highly significant (p=0.003); patients who were treated with both IVIG and steroids behaved like those with steroids alone; patients without any initial drug treatment behaved in between. Odds ratio (OR) for not having chronic ITP was for IVIG: 1.8 (95% confidence interval: 1.25-2.64) and for steroids 0.60 (0.42-0.87). *Summary and conclusions*. Data from the worldwide ICIS Registry I also suggest that IVIG treatment of acute childhood ITP might reduce the risk for chronic ITP while steroids might increase that risk. However, caution is warranted because this study was not a randomized controlled trial, and a considerable number of patients could not be included in the final analyses. A prospective randomised study is needed to confirm these results.

Funding: this study was supported by an unrestricted grant from Baxter Healthcare Corporation

SPLENECTOMY FOR IMMUNE THROMBOCYTOPENIC PURPURA (ITP) OR TRAUMA AND RISK OF INFECTIONS, VENOUS THROMBOEMBOLIC EVENTS AND DEATH

W.M. Schoonen,[1] R.W. Thomsen,[2] D. Körmendiné Farkas,[2] A. Riis,[2] J.P. Fryzek,[3] H.T. Sørensen[2]

[1]Amgen, UXBRIDGE, MIDDLESEX, UK; [2]Aarhus University Hospital, AARHUS, Denmark; [3]Amgen Inc., THOUSAND OAKS, CA, USA

Background. Immune thrombocytopenic purpura (ITP) is an autoimmune disorder characterised by an increased risk of bleeding due to impaired production and increased destruction of platelets. Destruction of platelets primarily takes place in the spleen; therefore, splenectomy is used in treating ITP. Splenectomy is associated with an increased risk of infections and possibly other adverse outcomes, including death, pulmonary embolism and infarction. *Aims*. The risk of adverse outcomes among splenectomised ITP patients compared to unsplenectomised population controls was estimated. Additionally, to understand how these risks may differ for ITP patients *vs* patients splenectomised for other reasons, patients splenectomised due to splenic traumatic rupture were compared to population comparisons. *Methods*. We identified patients who underwent splenectomy for either ITP or traumatic rupture between 1996 and 2005 in Danish nationwide medical databases. For each splenectomised person we identified 10 un-splenectomised population comparisons, frequency-matched on age, sex, and index date of splenectomy. We determined occurrence of death, hospitalised infection overall and pneumonia in specific, and venous thromboembolic events in splenectomised *vs* un-splenectomised persons within 90 days, 91 to 365 days, and more than 365 days, using multivariate regression for confounder adjustment. *Results*. We identified 269 splenectomised ITP patients and 765 patients with splenectomy due to trauma. Compared to the general population, relative risk of all studied adverse outcomes was highest within 90 days of splenectomy for both the ITP and trauma patient groups. In this 90 day period, death was the adverse outcome with the highest risk for trauma patients (relative risk (RR)= 125.5; 95% Confidence Interval (CI) 61.0-258.1). In later time periods the risk declined but remained 2-fold increased. Risk of death was also increased among ITP patients within 90 days of splenectomy (RR= 33.07; 95% CI 7.4-146.3) but was non-significantly increased in later time periods (Table 1). Risk of hospitalised infections remained elevated across all time periods for both ITP patients and trauma patients. More than a year after splenectomy, relative risk of infections was 3.5-fold increased for ITP patients (95% CI=2.6-4.8), and 2.5-fold increased for trauma patients (95% CI=2.0-3.2). No splenic vein thromboses were observed. However, risk of any venous thromboembolic events was strongly increased for trauma as well as ITP patients. Within 90 days of splenectomy, risk was 52-fold increased for ITP patients and 41-fold for trauma patients. Again, risk declined in later time periods but remained 3-fold increased more than a year after splenectomy. *Summary/conclusions*. Splenectomy is associated with strongly increased relative risks of hospitalised infections, death, and thromboembolic events in the 90 days following the procedure. Although risks decline in later time periods, they remain elevated compared to the general population for both ITP and trauma patients.

Table 1. Risk of adverse outcomes of splenectomy.

THE BURDEN OF CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP) IN ADULTS: RESULTS OF A CHART REVIEW OF 600 PATIENTS IN EUROPE

F. Rodeghiero,[1] M. Michel,[2] J. Besalduch,[3] D. Provan,[4] M. Rummel,[5] M. Aivado,[6] K. Grotzinger,[6] N.L. Papo,[6] T. Hultsch,[7] N. Höbel[7]

[1]Ospedale S Bartolo di Vicenza, VICENZA, Italy; [2]Henri Mondor Hospital, CRETEIL, France; [3]Hospital San Dureta, PALMA DE MALLORCA, Spain; [4]Queen Mary's School of Medicine and Dentistry, LONDON, UK; [5]Universitaetsklinikum Giessen und Marburg GmbH, GIESSEN, Germany; [6]Glaxo-SmithKline Research & Development, COLLEGEVILLE, USA; [7]Kendle GmbH, MUNICH, Germany

Background. The investigation and management of patients with chronic adult ITP varies widely and there is a lack of data on current treatment strategies in Europe. *Aims.* To contribute to a better understanding of the treatment and healthcare resource utilisation of chronic ITP patients in France, Germany, Italy, Spain and the UK. *Methods.* This is part of a comprehensive project investigating the burden of chronic ITP and which involves both expert opinion as well as real patient data. A retrospective chart review for 600 patients was performed in 4 to 8 secondary and tertiary treatment centres in each participating country. Investigators were asked to include in the study the most recent 40 adults seen at their site from 31-Mar-2007 to 01-Jan-2005 with a diagnosis of chronic ITP lasting more than 12 months. Patients' demographics, medical history, current treatments and side effects, as well as medical resource utilisation were abstracted from the patient's medical charts for the 12 months prior to their most recent visit. *Results.* The mean age of the total patient sample was 54.1 years, with 67% women and 33% men. Median time from the first diagnosis of ITP to the start of the observational period was 36 months. Prior to the observational period, 23% of patients had been splenectomised and the most frequently reported treatment was corticosteroids. During the observational period, 60% of all patients were treated and received 1-12 different medical treatments (mean 2.7). The most frequent reasons given for treatment were platelet count (65%) followed by bleeding symptoms (17%). Corticosteroids represented 45% of treatments given, followed by IVIG (10%), azathioprine (7%) and rituximab (3%). Splenectomies (6% of patients) and platelet transfusions (2% of patients) were rarely performed during the observational period. A further 2% of patients refused to undergo splenectomy during the period.

In addition to regular monitoring of platelet levels, 85% of patients visited their haematologist 1 to 4 times during the year of observation. The remaining patients saw their physician 5 to 14 times (mean 2.7). Main reasons for a visit were a low platelet count (42% of visits) and bleeding (12% of visits). Overall, 11% of patients required hospitalisation; 6% of these were in an intensive care unit. 96% of hospitalisations were due to ITP (low platelet count, 65%, bleeding 35%) and 4% of hospitalisations were due to ITP treatment related side effects. Mean duration of hospitalisation was 10.7 days. *Conclusions*. This retrospective chart review of 600 patients is the largest study to date of its kind in ITP and provides the first results of actual treatment practices, outcomes and medical resource utilisation in 5 major European countries. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP even though two thirds of them were actively treated. Corticosteroids were the most widely used treatment, followed by IVIG. The study results clearly highlight the burden that ITP imposes on patients and on health care systems across Europe.

0302

TREATMENT SATISFACTION IN PATIENTS DIAGNOSED WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA

F. Rodeghiero,[2] A. Matzdorff,[3] J.F. Viallard,[4] N. Chowhan,[5] S.D. Mathias,[6] Z. Cong,[7] J. Isitt[1]

[1]*Amgen, Inc, NEWBURY PARK, USA;* [2]*Department of Hematology, S. Bortolo Hospital, VICENZA, Italy;* [3]*Dept. Hematology and Oncology, Caritasklinik St. Theresia, SAARBRUECKEN, Germany;* [4]*CHU de Bordeaux Hôpital, HAUT-LÉVÊQUE, France;* [5]*Cancer Care Center, Inc, NEW ALBANY, INDIANA, USA;* [6]*Health Outcomes Solutions, WINTER PARK, FLORIDA, USA;* [7]*The Pardee RAND Graduate School, LOS ANGELES, CALIFORNIA, USA*

Background. Immune Thrombocytopenic Purpura (ITP) in adults is often a chronic disorder that requires continuous monitoring of platelet counts, bleeding events, and treatment-related side effects. Current ITP treatment options for chronic ITP include corticosteroids, intravenous immunoglobulins (IVIg), rituximab, and clinical supervision in order to prevent bleeding events by appropriate treatments. Splenectomy is reserved for those patients who do not respond or relapse after these medical therapies, or require intolerable doses to achieve safe platelet counts. Treatment-related side effects may result in patient distress and negative outcomes. *Aims*. The purpose of this study is to demonstrate that treatment satisfaction in patients with chronic ITP does not significantly improve under current standard of care. *Methods*. We present the initial results from a prospective, observational, international multi-center study in patients' previously diagnosed with chronic ITP and consecutively enrolled in this study. Patients with a primary diagnosis of ITP were enrolled from both community-based clinics and academic/referral centers. Retrospective data from patients' charts provided date of 1st ITP diagnosis, treatments received, and medical history. ITP treatments, dose, response, and duration of response were collected prospectively for 12 months. Patients completed a validated self administered treatment satisfaction questionnaire for medication (TSQM) at enrollment and monthly thereafter for 12 months. The TSQM is composed of 14 items and consists of 3 domains (effectiveness, side effects, and convenience) and an overall satisfaction score.

Table 1.

Overall Treatment Satisfaction Score				
Treatment	TSQM Prior to Treatment	TSQM End of Treatment	Change	p-Value[1]
Corticosteroid	52.2	48.4	-3.8	0.46
Rituximab	68.5	72.6	4.2	0.59
IVIG	63.0	61.7	-1.3	0.12
Anti-D	55.0	56.4	1.4	0.62
Splenectomy	44.3	60.0	15.7	0.04

[1] For TSQM score prior to treatment vs. end of treatment, t-test on residuals for change scores adjusted for age, gender, number of treatments previously received, time since 1st chronic ITP diagnosis.

Higher scores signify greater patient satisfaction. Effects were estimated using linear regression with the final TSQM score as the dependent variable, and adjusting for age, gender, TSQM score before treatment starts, number of treatments previously received and time since 1st diagnosis of chronic ITP. *Results*. The first 165 patients enrolled in the study were from 38 U.S. centers (44% male; mean age 59 years). During the study evaluation period (at baseline or beyond), 39 patients (24%) were splenectomized and 128 (78%) received ITP-related treatments including corticosteroids (n=101), IVig (n=54), Rituximab (n=46), and Anti-D Antibody (n=40). Patient scores significantly increased in effectiveness (p=0.03) and overall satisfaction (p=0.04) in patients receiving a splenectomy (Table 1). Patient side effects scores decreased significantly in patients receiving corticosteroids (p=0.02), and increased significantly in patients taking IVIG (p<0.01), and Anti-D (p=0.04). No significant changes were observed in convenience scores among all treatments. *Summary and Conclusions*. Our study indicates that while patients receiving a splenectomy reported significant improvements in effectiveness and overall satisfaction, no other medication significantly improved patients' treatment satisfaction and corticosteroids significantly worsened in side effects scores. Novel ITP interventions are desirable to improve both treatment satisfaction and reported effectiveness in patients with chronic ITP.

0303

SHOULD THE THRESHOLD FOR PROPHYLACTIC PLATELET TRANSFUSION IN NEONATES BE STANDARDISED AT 20x10⁹/L

A. Murray,[1] A.G. Roberts,[1] A. Stanworth[2]

[1]*Imperial College, LONDON, UK;* [2]*National Blood Service, OXFORD, UK*

Background. Intraventricular haemorrhage (IVH) is the commonest major haemorrhage in neonates and is a leading cause of neonatal death and disability. Most IVH occurs in preterm neonates during the first week coinciding with their highest prevalence of thrombocytopenia. As a result thrombocytopenic neonates commonly receive prophylactic platelet transfusions (Tx). However no study has defined the appropriate trigger threshold in neonates. Therefore, neonates receive prophylactic platelet Tx over a wide range of counts, commonly between 20-60×10⁹/L,[1] without evidence of efficacy. *Aims.* To document major haemorrhage in neonates and assess its relation to severity of thrombocytopenia and platelet Tx. *Methods.* Prospective observational study of neonates with platelet counts <60×10⁹/L (NT<60) in 7 neonatal intensive care units (NICUs). Major haemorrhage was defined as grade 3/4 IVH (Papile grading) plus other fresh major haemorrhage (as below). Following parental consent neonates had daily recording of platelet count, haemorrhage, and platelet Tx. *Results.* 3498 neonates were admitted to participating NICUs. 194 developed NT<60 (5.5%) and 169 were enrolled: median gestational age 27 (range 23-41) weeks, birth weight 825 (427-3733) grams. Main associated conditions: sepsis n=71; maternal pre-eclampsia/fetal growth restriction (PET/IUGR) n=36; necrotising enterocolitis (NEC) n=9. Forty-five neonates had major haemorrhage. Twenty-six entered the study with grade 3/4 IVH but no previous NT<60 or platelet Tx. Twenty-seven (19 without previous haemorrhage, 8 with previous IVH) suffered major haemorrhage on study, at median 7 (range 2-61) days: IVH n=12, pulmonary n=7, PR n=3, abdominal n=2, haematuria n=2, IVH and pulmonary n=1. However, the platelet count nadirs in these 27 neonates, and their platelet counts prior to haemorrhage, did not trend towards the lower end of the 20-60×10⁹/L range (Figure 1).

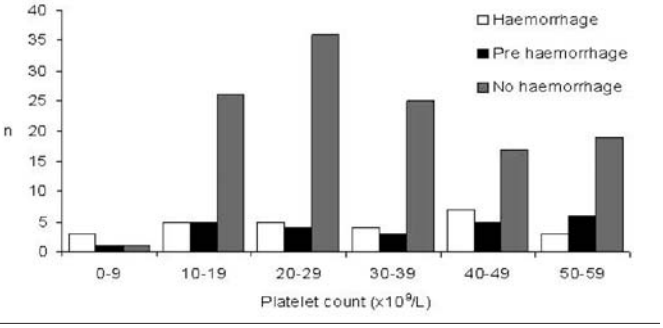

Figure 1. Lowest platelet counts in study neonates

Four hundred and fourteen platelet Tx were administered on study raising the median pre-transfusion count form 27 (range 2-75) to 79 (4-513)×10⁹/L. Neonates without major haemorrhage received 223 prophylactic Tx, those with major haemorrhage 115, 78 post-haemorrhage. Only 13 Tx were given to treat haemorrhage and 12 hours post transfusion manifestations of haemorrhage remained the same in 5 and reduced

in 8. The remaining 63 Tx were given for clinical reasons. Outcome differed by the cause of thrombocytopenia. Despite similar platelet nadirs, neonates with maternal PET/IUGR had on study bleeding and mortality rates of 4 and 7%, respectively, whereas those with sepsis/NEC had rates of 15 and 33%. *Conclusions.* These data suggest that in thrombocytopenic neonates without active bleeding the risk of major haemorrhage does not alter within the platelet count range 20-60×10⁹/L. Consequently prophylactic platelet Tx at thresholds above 20×10⁹/L may not alter outcome and Tx at these levels could be reserved for treatment of haemorrhage. Progress likely depends on reducing prophylactic Tx of doubtful benefit, and tailoring platelet Tx practice to the outcomes of different patient groups. Both objectives will require well-designed randomised controlled trials.

HEPATITIS C VIRUS INFECTION AND LOW PLATELET COUNT: A COMMUNITY-BASED STUDY IN A HEPATITIS B AND C ENDEMIC AREA

C.Y. Dai, C.K Ho, W.L Chuang, J.F Huang, M.Y. Hsieh, W.Y. Chang, M.-L. Yu

Kaohsiung Medical University, KAOHSIUNG, Taiwan

Background. Hepatitis C virus (HCV) infection has been considered as associated with abnormal blood count. *Aims.* To evaluate the association between virologic status and platelet count in individuals with HCV infection in a hepatitis B virus and HCV endemic area. *Methods.* A large-scale survey, enrolling 11,239 residents aged 40 to 65 years, was conducted in the Kaohsiung area of Taiwan. Platelet count, alanine aminotransferase (ALT) level, hepatitis B surface antigen (HBsAg) and anti-HCV were checked. For anti-HCV-positive subjects the serum HCV RNA was tested by using a standardized automated qualitative polymerase chain reaction assay. Non-invasive markers of fibrosis (FibroTest; FT) derived from five biochemical markers including α2-macroglobulin, apolipoprotein A1, haptoglobin, total bilirubin and γ-glutamyltranspeptidase by a quantitative assessment was computed on the website (http:\\www.biopredictive.com). *Results.* Overall, 703 (6.3%), 1536 (13.7%), 84 (0.7%) and 9,084 (80.8%) were positive for anti-HCV, HBsAg, and both anti-HCV and HBsAg, and negative for anti-HCV and HBsAg, respectively. Subjects with anti-HCV had significantly higher mean age and mean ALT value, lower mean platelet count, higher frequency of male sex, abnormal ALT and low platelet count than those who were anti-HCV-negative (all $p<0.001$). In multivariate logistic regression (MLR) analysis, the independent factors significantly associated with positive anti-HCV were lower age, female sex, abnormal ALT value and low platelet count. Subjects with positive HCV RNA had significantly higher mean ALT value, lower mean platelet count, lower frequency of positive HBsAg, and higher frequency of abnormal ALT value and low platelet count than those who were HCV RNA-negative (all $p<0.001$). In MLR analysis, the independent factors significantly associated with positive HCV RNA in anti-HCV subjects were abnormal ALT value, positive HBsAg and low platelet count. Subjects with a low platelet count had a significantly higher mean ALT value, higher frequency of abnormal ALT value and higher frequency of positive serum HCV RNA (all $p<0.001$). In MLR analysis, the independent factors significantly associated with low platelet count were abnormal ALT value and positive HCV RNA. A significant trend for higher prevalence of HCV RNA in patient groups with lower platelet count was demonstrated ($p=0.019$, chi-square for trend). The FT score was checked among 137 patients with positive anti-HCV (17 were HCV RNA-negative). When compared to patients with no or mild fibrosis, those with advance fibrosis had significantly lower platelet counts ($p=0.002$) and higher prevalence of positive HCV RNA ($p<0.001$). The mean platelet count was significantly lower and mean FT score and mean fibrosis stage were significantly higher among 120 HCV RNA-positive individuals than 17 HCV RNA-negative ones by univariate analyses (all $p<0.001$). In MLR analyses, lower platelet count and higher fibrosis stage were independent factors associated with positive HCV RNA. *Conclusions.* Based on this large-scale community study, our results implicate that platelets may be affected directly by HCV. Decreased platelet counts in anti-HCV-positive individuals strongly implies positive HCV RNA and is associated with elevated ALT levels, which indicates active HCV-related liver disease.

ORAL ELTROMBOPAG INCREASES PLATELET COUNTS AND REDUCES BLEEDING IN CHRONIC ITP PATIENTS: POOLED RESULTS OF PHASE II AND PHASE III TRIALS

M.N. Saleh,[1] J.B. Bussel,[2] N. Stone,[3] B. Mayer,[3] J. Jenkins[3]

[1]Georgia Cancer Specialists, ATLANTA, GA; [2]Weill-Cornell Medical College of Cornell University, NEW YORK, NY; [3]GlaxoSmithKline, COLLEGEVILLE, PA, USA

Background. Current treatments for thrombocytopenia have a poor risk-benefit profile and often have no level 1 evidence of their tolerability or efficacy profile. Eltrombopag is the first-in-class oral non-peptide thrombopoietin receptor agonist, being developed as treatment for various thrombocytopenias, including chronic idiopathic thrombocytopenic purpura (ITP). *Aims.*This pooled analysis assessed the efficacy and safety of eltrombopag treatment in adult patients with chronic ITP. *Methods.* Efficacy and safety data from two independent double-blind, placebo-controlled studies in adult patients with chronic ITP have been pooled [Bussel *et al.* New Engl J Med. 2007; Bussel *et al.* Haematologica. 2007]. In both studies, patients were required to have a baseline platelet count <30K/μL. The primary endpoint was the proportion of patients with a platelet count ≥50K/μL after up to 6 weeks of treatment. Secondary endpoints included platelet count pharmacodynamics (PD), incidence and severity of bleeding (WHO bleeding scale), and safety parameters. Written, informed consent was obtained from all study participants. The first study was a Phase II dose finding study. 117 patients were randomized to one of 4 arms to receive once daily oral doses of placebo (n=29), 30 mg (n=30), 50 mg (n=30) or 75 mg (n=28) eltrombopag for up to 6 weeks. The second study was a Phase III study in which 114 patients were randomized (2:1) to one of 2 arms to receive once daily oral doses of placebo (n=38) or 50 mg (n=76) eltrombopag for up to 6 weeks. Randomization was stratified by concomitant ITP medication, splenectomy status, and baseline platelet count (>/≤ 15K/μL). *Results.* (Table 1). *Conclusions*. Eltrombopag, administered as a once daily tablet for up to 6 weeks, is an effective therapy for the treatment of ITP, increasing platelet counts to safe levels in more than 60% of the patients, while reducing the incidence and severity of bleeding symptoms. There were no clinically meaningful differences in incidence or severity of AEs between patients treated with eltrombopag 50 mg compared to placebo.

Table 1. Pooled Safety and Efficacy Data

Baseline Characteristics	Placebo (n=67)	50 mg (n=106)
Age, median (range)	46 (18-85)	47 (19-84)
Female, n (%)	43 (64)	64 (60)
Concomitant ITP medication, n (%)	23 (34)	44(42)
Splenectomy status, n (%)	28 (42)	46 (43)
Baseline platelet count ≤15K/μL, n (%)	31 (46)	50 (47)
At least 3 prior ITP therapies, n (%)	30 (45)	60 (57)
Median platelet count at Day 1 (range), K/μL*	17 (3-29) (n=50)	18 (0-30) (n=86)
Patients with any bleeding at Day 1*	38 (59) (n=64)	63 (62) (n=102)
Efficacy	**Placebo (n=65)**	**50mg (n=101)**
Patients with platelet count ≥50K/μL), n (%)	9 (14)	62 (62)
Median platelet count at Week 6 (range), K/μL	18 (2-419)	84 (1-1,312)
Patients with any bleeding at Week 6, n (%)	34 (56)	44 (43)
Safety	**Placebo (n=67)**	**50mg (n=106)**
Number of patients with an adverse event (AE)	35 (52)	70 (66)
Number of patients with a drug-related AE	16 (24)	31 (29)
Number of patients with a serious adverse event (SAE)	8 (12)	12 (11)
Number of patients with a SAE leading to withdrawal	4 (6)	3 (3)

* Based on efficacy population.

ORAL ELTROMBOPAG SPARES CORTICOSTEROIDS AND REDUCES BLEEDING IN PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP)

J.B. Bussel,[1] G. Cheng,[2] M.N. Saleh,[3] B. Meddeb,[4] B. Mayer,[5] N. Stone,[5] M. Arning,[5] M. Aivado[5]

[1]Weill-Cornell Medical College of Cornell University, NEW YORK, NY, USA; [2]Prince of Wales Hospital, SHATIN, NT, Hong Kong; [3]Georgia Cancer Specialists, ATLANTA, GA, USA; [4]Hopital La Rabta, TUNIS, Tunisia; [5]GlaxoSmithKline, STOCKLEY PARK, UK

Background. Eltrombopag is a new oral non-peptide thrombopoietin receptor agonist shown to increase platelets and reduce bleeding symptoms during short-term placebo-controlled trials in chronic ITP patients. EXTEND is an ongoing, open-label study designed to assess the long-term clinical benefit of eltrombopag, including the potential for patients to reduce/eliminate concomitant ITP therapies. *Aims.* This analysis was conducted to determine the long-term clinical benefit of eltrombopag treatment, including the potential for patients with chronic ITP to reduce/eliminate the use of concomitant ITP therapies. *Methods*. In EXTEND, patients receive a starting dose of 50 mg eltrombopag/day that can be adjusted in response to platelet counts. Bleeding symptoms using the WHO Bleeding Scale were assessed at each visit. Written, informed consent was obtained from all study participants. *Results*. To date, 109 patients have received eltrombopag; at baseline, 37% were receiving concomitant ITP medication, 44% were splenectomized, 70% had baseline platelet counts <30K/μL, 17% between 30K-≤50K/μL, and 14% >50K/μL. 14 out of 40 patients (35%) taking concomitant ITP medications at baseline were able to stop ≥1 ITP med(s) (prednisone [n=10], danazol [n=4], and one subject each with dexamethasone, mycophenolic acid, and oxymetholone). The proportion of patients with any bleeding and any clinically significant bleeding (WHO Grade 2-4) decreased from baseline as platelet counts increased. At baseline, >60% of patients had any bleeding and >20% of patients reported clinically significant bleeding. After 12 weeks, <30% of patients had any bleeding and <5% had clinically significant bleeding. For the majority of weeks, the proportion of patients with any bleeding or clinically significant bleeding was reduced by approximately half from baseline. *Conclusion*. The findings from this ongoing study demonstrate the clinical benefit of eltrombopag during long-term treatment in patients with chronic ITP, as measured by reduction of both concomitant ITP medications and bleeding symptoms.

0307

RISK OF THROMBOEMBOLIC EVENTS AMONG PATIENTS WITH CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP)

I. Bennett,[1] U. Forssen,[1] C. Enger,[2] J. Nelson[1]

[1]GlaxoSmithKline, PHILADELPHIA, USA; [2]I3 Drug Safety, ANN ARBOR, USA

Background. ITP is a disease caused by inadequate platelet production as well as increased platelet destruction. There is very little published data on the risk of TE in ITP patients. *Aims*. To examine the risk of TE among patients with chronic ITP compared to a non ITP population. *Methods*. This was a retrospective database analysis using eligibility and medical claims data from a large U.S. health plan affiliated with i3 Drug Safety. Chronic ITP patients were defined using the following criteria: a) at least two physician claims separated by at least six months with ICD-9 CM diagnosis code 287.3x for primary thrombocytopenia, b) at least 12 months of continuous enrollment prior to the date of the diagnosis code eligibility, and c) at least 18 years of age between January 1, 2000 and September 30, 2006 with follow-up through December 31, 2006. The non ITP reference group was selected from the same time period. TE were defined as deep vein thrombosis (DVT), pulmonary embolism (PE), myocardial infarction (MI), unstable angina (UA), ischemic stroke (IS), transient ischemic attack (TIA), portal vein thrombosis (PVT), and other TE using ICD-9 CM diagnosis codes. Patients in both groups with a history of TE during the 12-month baseline period were excluded from the analysis. The incidence rate ratio (IRR) and 95% Confidence Interval (CI) of occurrence of TE comparing the ITP to non ITP populations was estimated using Poisson regression. *Results*. All chronic ITP patients (N=2,873) who met the above mentioned criteria formed the ITP cohort; N=116,933 non ITP patients created the reference group. Among the ITP patients, 197 (6.9%) patients experienced at least one TE during a median follow up of 15 months. Among the non ITP patients, 4,027 (3.4%) developed at least one TE during follow up (median 17 months). After adjusting for age, gender, history of hypertension, and past and recent history of steroid use, the cumulative IRR comparing the ITP to non-ITP patients for any TE was 1.65 (95% CI: 1.42-1.91). The adjusted cumulative IRR was significantly greater than one for the individual TE such as unstable angina (IRR 1.45; 95% CI: 1.11-1.89), ischemic stroke (IRR 2.21; 95% CI: 1.48 - 3.32), transient ischemic attack (IRR 1.70; 95% CI: 1.30 - 2.23), portal vein thrombosis (IRR 37.82; 95% CI: 12.39-115.41), and other TE (IRR 2.01; 95% CI: 1.60-2.53). There was increased risk for DVT (IRR 1.69; 95% CI: 0.88-3.25) and PE (IRR 1.52; 95% CI: 0.64-3.62) in chronic ITP patients *vs* the non ITP population that did not reach statistical significance. There was no increase in risk for MI (IRR 0.98; 95% CI: 0.66-1.45). *Summary*. The study found an association of increased risk for thromboembolic events in patients with chronic ITP compared to the non ITP population.

0308

RETROSPECTIVE SAFETY REVIEW OF IV RHO (D) IMMUNE GLOBULIN

C.J. Sinclair, C.J. Sinclair, C. Muller, H. Li, M.G. Genereux

Cangene Corporation, WINNIPEG, Canada

Background. Cangene IV Rho (D) Immune Globulin (IV RhIG), a purified human Anti-D immunoglobulin, has been licensed to treat immune thrombocytopenic purpura (ITP) for over 12 years in North America and recently in numerous European countires. In pivotal studies, IV RhIG demonstrated strong efficacy characteristics and duration of response, with common side effects being headache, chills and fever. Since licensure, rare haemolytic reactions have been reported through post-marketing surveillance, ranging from mild haemoglobin decrease to intravascular haemolysis (IVH) and its potential complications. *Aims*. Cangene evaluated the reporting rate of haemolytic reactions and assessed if there was any contribution of gender, age, dosing, or previous medical history to the severity of haemolytic reactions. *Methods*. Data from the Cangene's IV RhIG pharmacovigilance database was analyzed. Haemolytic reactions were characterized as definite, probable or possible IVH using an internal algorithm. Possible and probable cases are regarded as other haemolytic reactions. *Results*. Since January 1994 to December 2007, 57 Definite and 184 Probable or Possible IVH events have been reported. Using the estimated number of doses administered in this period (2,500,000), reporting frequency of definite IVH is 0.0023, and other haemolytic reactions are 0.0074, with an overall total of 0.0097. Gender was analyzed for 238 cases (3 unknown), of which females contributed 55%. Age group was analyzed for 216 cases (25 unknown), with 0-20, 20-50 and >50 years of age representing 31%, 20% and 49%, respectively. Dosing in (mcg/kg) was analyzed for 175 cases (66 cases were unknown), with 6%, 55% and 39% of patients receiving <40, 40-60 and >60 mcg/kg, respectively. The overall dose used in the IVH group was 60 mcg/kg and for patients with other haemolytic reactions was 56 mcg/kg. A review of medical history was conducted in 179 cases (62 cases did not have complete medical history) to evaluate whether specific conditions may increase the severity of haemolytic reactions. Pre-existing haematologic malignancies were reported in 15% of definite IVH cases and in 10% of other haemolytic reactions; hepatic dysfunction was reported in 19% of definite IVH cases and in 8% of other haemolytic reactions; pre-existing viral infection was reported in 19% of definite IVH cases and in 8% of other haemolytic reactions; autoimmune disorders were reported in 7% of definite IVH cases and in 5% of other haemolytic reactions. *Conclusions*. Based on a 12 year period of Cangene IV RhIG safety data, the reporting rate of overall haemolytic reactions such as definite IVH is rare. No significant reporting rate differences by gender or dose are apparent, while the relationship with age needs to be further analyzed. As reported in recent literature, pre-existing medical conditions including hepatic dysfunction, recent viral illness or haematologic malignancy may contribute to haemolytic events; however, the low number of cases and incomplete data reported in the passive system make conclusions difficult.

0309

ALTERATIONS OF MORPHO-FUNCTIONAL STATUS IN CIRCULATING PLATELETS ASSOCIATED WITH THROMBOCYTOPENIAS

I. Vasilenko,[1] I. Kastrikina,[1] E. Pustovaya[2]

[1]Institute of Rheumatology RAMS, MOSCOW, [2]Hematological Research Center, MOSCOW, Russian Federation

Quantitative platelet disorders are always associated with qualitative platelet alterations. The circulating platelet multiplicity reflects cell distinctions in size, density, metabolic, functional, biochemical features and the level of megakaryocyte polymorphism. The relation between this platelet attributes is extensively discussed but the some details are sufficiently unclear. The purpose of this study was to evaluate the various aspects of platelet heterogeneity and activity in patients with idiopathic thrombocytopenic purpura (ITP) and secondary thrombocytopenias. Platelet-rich plasma was separated from blood samples of healthy volunteers (20), patients with immune thrombocytopenic purpura (15) and secondary thrombocytopenias associated with antiphospholipid syndrome (APS) (15) and lupus erythematosus (LE)(12) by centrifugation at 1000 g for 10 min at room temperature. Morpho-functional status of peripheral blood platelet we determined by express-method of vital computer morphometry using computer phase-inteference microscope Cytoscan: height accuracy 0,5nm, coordinate accuracy 10nm, image area 256×256 pixels, optical magnification 1000, acquisition time 4-12 sec. The complex algorithm of morphometry included definition of optic and geometrical characteristics of unfixed and unstained living platelets, statistical analysis of data and creation of medical documents. We have analyzed the optic-geometrical parameters of each isolated living platelet and the distribution of platelets by sizes to detect the heterogeneity of cell population. It allowed to identify four platelet forms that have different morphological features and different parameters of size distribution. In the cell population we distinguished 4 morphologic forms of platelet with according to various activation levels. So 64% of resting platelets (discoid forms), 21% of platelets with low activation level, 12% of platelets with high activation level and 3% of degenerate functionally incomplete platelets were registered in healthy volunteers. In ITP, APS and LE patients had the high level of platelet activating state: 48, 50, 45%-the resting platelets; 41, 42, 45%-activating forms; 11, 8, 10%-degenerating forms, respectively). The average metric platelet parameters (diameter, perimeter, height, area and volume) in ITP were constituted 3,2±0,9 mkm; 9,4+/2,7 mkm; 1,1±0,4 mkm; 6,0±3,0 mkm^2; 2,9±2,0 mkm^3 (M±σ) contrary to 2,6±0,8 mkm; 8,2+/3,4mkm; 1,3±0,5mkm; 4,6±2,1 mkm^2; 1,8±1,3mkm^3 in norm (p<0,05). The average metric platelet parameters in APS and LE were constituted 3,2±1,2 mkm; 10,4+/5,1 mkm; 1,5±1,0 mkm; 7,5±3,7mkm^2; 3,3±2,9mkm^3 (M±σ) and 3,7±1,5 mkm; 12,0+/3,3 mkm; 0,9±0,4 mkm; 8,7±2,7 mkm^2; 2,5±1,7 mkm^3 (M±σ), respectively. It is important the values of phase height objectively reflected platelet granule contents in platelets. The subpopulation of giant platelets (with diameter>5 mkm) were revealed and described in patient with thrombocytopenias: 10, 18, 27% in ITP, APS and LE, respectively. Furthermore we discriminated giant platelets with low and high density corresponding cells with reduced or enlarged significances of phase high. The relation between the activating platelet status, platelet count and percentage of giant platelet is well established. Computer phase interference morphometry of living platelets provides the sufficient degree of objectivity and information for the real evaluation of the haemostatic state of patients and allowed to prognosticate the possible disturbances. Advances in the understanding of the platelet structure features in ITP and secondary thrombocytopenias will promote to improving our knowledge of pathogenesis for this diseases.

0310

RAPID INCREASE OF PLATELET COUNT WITH IGPRO10 IN CHRONIC IMMUNE THROMBCYTOPENIC PURPURA

A. Salama,[1] T. Robak,[2] L. Kovaleva,[3] Y. Vyhovska,[4] S.V. Davies,[5] M.G. Mazzucconi,[6] O. Zenker[7]

[1]Charité University Medicine Berlin, BERLIN, Germany; [2]Medical University of Lodz, LODZ, Poland; [3]Russian Academy of Medical Sciences, MOSCOW, Russian Federation; [4]Institute of Blood Pathology and Transfusion Medicine AMS, LVIV, Ukraine; [5]Taunton and Somerset Hospital, TAUNTON SOMERSET, UK; [5]University La Sapienza, ROMA, Italy; 7CSL Behring, BERN, Switzerland

Background. Immune thrombocytopenic purpura (ITP) is an autoimmune bleeding disorder with an estimated annual incidence of 55-66 new cases per 1,000,000 individuals. The condition is characterized with decreased counts of circulating platelets due to antibody-mediated platelet destruction. Intravenous immunoglobulin (IVIG) is a widely recommended treatment for both acute and chronic ITP. IgPro10 is a new 10% liquid IVIG product formulated with L-proline, which combines a ready-to-use formulation with the convenience of room temperature storage for its entire shelf life; both are considered advantages in IVIG therapy. *Aims*. The primary objective of this prospective, open-label, phase III trial was to evaluate the efficacy, safety and tolerability of IgPro10 in patients with chronic ITP. *Methods*. Fifty-seven patients aged 12-65 years with a platelet count of ≤20×10^9/L at screening were treated with 1 g/kg body weight of IgPro10 intravenously on each of two consecutive days. The primary efficacy parameter was the number of patients who respond to IgPro10 treatment with an increase of platelet count to ≥50×10^9/L within 7 days after the first infusion. Secondary efficacy endpoints included time to platelet response, duration of platelet response, platelet counts at specified time points, and regression of hemorrhages at defined bleeding sites. Regression of hemorrhages was defined as a decrease of severity of bleeding status from baseline. *Results*. IgPro10 therapy resulted in an increase of platelet count to ≥50×10^9/L in 46 (80.7%) of the 57 patients (95% CI: 69.2%, 89.3%) within 7 days after the first infusion. An important feature of the treatment was the rapid response: 43% of the patients achieved response with only one infusion. The median time for response was 2.5 days after start of IgPro10 administration (Figure 1).

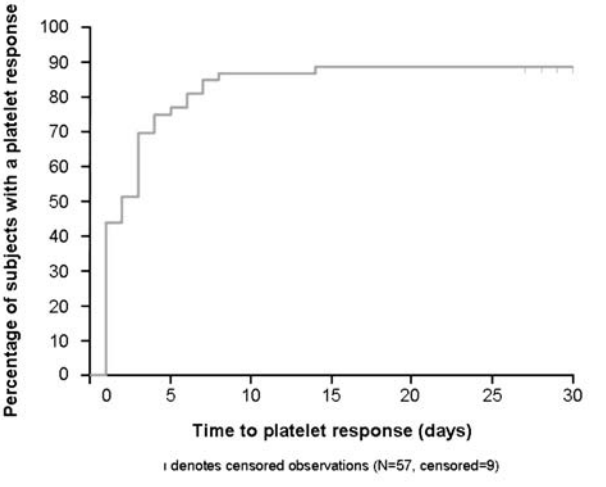

Figure 1.

Platelet response was sustained for a median time of 15.4 days (range, 1 to >82 days). In line with the almost instant increase of platelet counts, the bleeding status of patients improved rapidly. A significant reduction in the number and severity of hemorrhages was observed 2 days after treatment. By Day 8, the proportion of patients with bleeding events had dropped from 70.2% at baseline to 21.8% and most of the remaining hemorrhages were mild to moderate in severity. IgPro10 administration was well tolerated and 104 of the 114 infusions could be performed at the maximum allowed infusion rate of 4 mg/kg/min. Adverse events (AEs) were generally mild or moderate and typical for the disease and treatment. The most frequent AE was headache. *Summary/conclusions*. IgPro10 treatment produces a rapid increase in platelet counts to a safe level of ≥50×10^9/L and has a good tolerability.

Stem cell biology and microenvironment

COMPARISON OF TWO BONE MARROW (BM) CELL TYPES AND ADMINISTRATION ROUTES FOR THE TREATMENT OF HINDLIMB ISCHEMIA USING THE GFP-TIE2 TRANSGENIC MODEL: ANY OPTION WORKS BUT WITHOUT TRANSDIFFERENTIATION

F.M. Sanchez-Guijo,[1] E. Oterino,[1] M.V. Barbado,[1] S. Carrancio,[1] N. Lopez-Holgado,[1] S. Muntion,[1] P. Hernandez-Campo,[1] L.I. Sanchez-Abarca,[1] J.A. Perez-Simon,[1] J.G. Briñón,[2] J.F. San Miguel,[1] M.C. Del Cañizo[1]

[1]Hospital Universitario de Salamanca, SALAMANCA, Spain; [2]Departamento de Biología Celular. Universidad de Salamanca, SALAMANCA, Spain

Background. There is growing evidence suggesting that cells from BM contribute to revascularization in experimental models of ischemia and in phase I and II clinical trials. Nevertheless, there is no definitive clue regarding the best cellular type to be used, since some groups have employed selected stem cell populations (e.g. CD133$^+$ cells) whereas others have used BM mononuclear cells, all with encouraging results, but with no direct comparison between them. The same applies to the route of cell delivery, where intravenous (IV) and direct intramuscular (IM) administration in the ischemic area have proven their value. The mechanism of action of the transplanted stem cells is also controversial. *Aims.* To compare the neovascularization capacity of CD133$^+$ selected BM cells, which have been claimed as the primitive endothelial progenitor cell subset, and the whole myeloid (CD11b$^+$) population in a murine hindlimb ischemia model assessing, in addition, IV *vs* IM administration. Finally, we wanted to gain insight into the mechanism of action of the transplanted cells by using Tie2-GFP (Green Fluorescent Protein) transgenic mice as donors: any cell from these donor mice expresses GFP only if it activates the Tie2 promoter, a specific endothelial marker. *Methods.* Transgenic FVB-Tie2-GFP mice were used as donors. BM mononuclear cells from these mice underwent magnetic cell sorting to obtain CD133^1 cells and CD11b$^+$ cells independently. Wild-type FVB mice were used as recipients and underwent left iliac artery ligation and section. 24 hours later, 1×10^6 CD133$^+$ cells or 1×10^6 CD11b$^+$ selected cells were either intravenously administered or intramuscularly injected in the left quadriceps. Each one of the four experimental groups (CD133 IV, CD133 IM, CD11b IV, CD11b IM) contained 6 wild-type FVB ischemic mice, that were maintained for 7, 14 and 21 days after the transplant (72 recipient mice in total), and then sacrificed for tissue processing. A non-ischemic sham operated group was included as control, as well as a group with limb ischemia but treated with no cells. Peripheral blood flow (μL/sec) in the ischemic limb was assessed at days 7, 14 and 21 by laser-Doppler, and tissue analysis performed in the ischemic muscles (abductor and quadriceps) consisted on capillary density quantification and immunofluorescence analysis to find donor cells with endothelial phenotype, that would appear as GFP positive. *Results and Conclusions*. In all four experimental groups, blood flow significantly recovered compared to the ischemic mice that received no cells. There were no differences between groups, with the exception that flow recovery was significantly faster (at day +14) for the mice treated with CD133$^+$ cells either IV or IM. Capillary density showed again a significant improvement in all cell-treated mice compared with the control, but also without differences at day +21 between groups. Finally, we did not find significant numbers of GFP cells in the ischemic muscles analyzed. This fact indicates that the beneficial effects observed with either cell type or delivery route were not related to Tie2 expression, and therefore transdifferentiation of BM cells into endothelial cells is lacking in our experimental model.

ALDEHYDE DEHYDROGENASE ACTIVITY IDENTIFIES DISTINCT SUBCLASSES OF PRIMITIVE HEMATOPOIETIC CELLS IN MYELOID MALIGNANCIES

A. Bogen,[1] M. Pietschner,[1] C. Eaves,[2] W. Hiddemann,[1] C. Buske,[1] O. Christ[1]

[1]University of Munich, 3rd Dept. of Medicine, MUNICH, Germany; [2]Terry Fox Laboratory, British Columbia Cancer Agency, VANCOUVER, Canada

Background. The selection of cells with high aldehyde dehydrogenase (ALDH) activity in samples of normal human bone marrow, peripheral blood or umbilical cord blood has been shown to enrich for cells with colony-forming and *in vivo* repopulating potential. In human cord blood, usually 0.5-1 percent of all low-side scatter mononuclear cells show high ALDH activity. These rare cells have a predominantly primitive (CD34$^+$) phenotype and contain most of the short-term and the entirety of long-term repopulating cells present in these samples. However, little is known about the usefulness of ALDH activity as a marker of primitive cells in samples of leukemic hematopoiesis. *Aims*. In the present study, we aimed to functionally and phenotypically characterize subsets of acute (AML) and chronic (CML) myeloid leukemia cells with distinct levels of ALDH activity. *Methods*. Light-density (LD) cells were isolated from AML and CML samples and stained with the ALDEFLUOR fluorescent substrate. Cells were then sorted and analyzed for their CFC content, immunophenotype, and the presence of karyotype abnormalities using fluorescence *in situ* hybridization (FISH). *Results*. In all CML samples analyzed, ALDH$^+$ cells were detectable at higher percentages and with higher mean fluorescence intensities than in samples of normal hematopoietic cells. As in normal hematopoiesis, these cells were highly enriched for cells with a primitive phenotype and showed markedly increased colony forming activity. Preliminary studies using FISH suggest that in primary CML samples, selection for high ALDH activity may allow the isolation of the leukemic (Ph$^+$) subfraction within the most primitive (CD34$^+$CD38$^-$) population. Conversely, AML samples less consistently contained ALDH$^+$ cells, and the phenotype of these showed a considerable inter-sample variability. *Conclusions*. We and others have previously shown that selection of cells with high ALDH activity enriches for a variety of primitive cells with clonogenic and repopulating potential in populations of normal human hematopoietic cells. The results presented here show that high ALDH activity can be reproducibly found in samples of myeloid neoplasias, and that these cells contain the majority of phenotypically primitive and functionally immature cells. Assessment of ALDH activity appears to be a valuable tool for the selection of primitive cells in myeloid malignancies. Transplantation studies are underway to determine whether high ALDH activity is a specific feature of transplantable leukemic cells.

OPTIMAL CONDITIONS FOR MESENCHYMAL STEM CELLS EXPANSION IN A FBS-FREE MEDIUM

K. Chieregato, M. Maddalena, S. Castegnaro, M. Marchesi, D. Madeo, F. Rodeghiero

San Bortolo Hospital, VICENZA, Italy

Background. Mesenchymal stem cells (MSCs) are multipotent cells isolated from several tissues capable to differentiate into several cell lineages. They interact with hematopoietic stem cells and exert immunoregulatory function. These characteristics make MSCs excellent candidates for regenerative medicine and gene therapy. Due to their scarce quantity, MSCs require *ex vivo* expansion. To this aim there is a need to identify growth factors that might be used in serum-free formulations to avoid transmissible diseases. *Aims.* In this study we evaluated the effects of a pool of human recombinant growth factors (hr-GFs including Epidermal Growth Factor [EGF], basic-Fibroblast Growth Factor [bFGF], Granulocyte Colony-Stimulating Factor [G-CSF], Hepatocyte Growth Factor [HGF], Insulin-like Growth Factor I [IGF I], Platelet-Derived Growth Factor-bb [PDGFbb] and Transforming Growth Factor β1 [TGFβ1]) on MSCs obtained from human adipose tissue (AT) and umbilical cord (UC) cultured in standard conditions. *Methods.* MSCs at the end of fist passage were plated in a 96-well plate at 1500 cells/cm^2 in DMEM supplemented with human Platelet Poor Plasma (hPPP, 3%). On subsequent day cells were treated for 72 hours with different media containing respectively: Fetal Bovine Serum (FBS, 10%); Platelet Lysate (PL, 10%); hPPP; hPPP with hr-GFs at 5 or 10 or 30 ng/mL; hPPP with EGF at 10 ng/mL and other hr-GFs at 5 or 10 or 30 ng/mL. Cell proliferation was measured with BrdU incorporation. *Results.* In UC-MSCs cultures (fig. 1A-B) EGF, bFGF and PDGFbb increased fluorescence intensity respectively by 2,5 , 2,6 and 2,9 fold compare to control (hPPP at 3%), showing a similar effect of FBS, but lower than PL. Only when EGF and PDGF-bb were added together we obtained a proliferation rate near to PL; whereas the combination of EGF and bFGF had a moderate additive effect. HGF and G-CSF did not induce proliferative response when added alone; furthermore they reduced EGF-induced proliferation.The same effect was detected for IGF I. TGFβ1 induced a robust inhibition alone or in combination with EGF or EGF-bFGF-PDGFbb. In AT-MSCs cultures (Figure 1 C-D) EGF and PDGFbb had an effect similar to that of UC cells. b-FGF alone had a more remarkable proliferative effect than on UC-MSCs, and higher than PL. With EGF we did not appreciated a further increase of proliferation rate. G-CSF and HGF, alone and with EGF, had no effect. IGF I alone induced an increased cell proliferation, whereas

EGF did not. TGFβ1 caused inhibition in AT-MSCs too, but only when added alone, in fact with EGF it potentiated its proliferative effect.The addition of EGF, bFGF and PDGFbb represented the best condition for AT-MSCs growth, more than PL. *Conclusions.* AT and UC-MSCs showed a good expansion in a FBS-free medium containing hPPP and a mixture of hr-GFs. In particular a combination of EGF-PDGFbb (10 ng/mL) for UC-MSCs and EGF-bFGF-PDGFbb (10 ng/mL) for AT-MSCs has shown a proliferation rate higher than with FBS and similar to that obtained with PL addition. Further studies are required to investigate the uptake potential *in vivo* of expanded MSCs and their immunoregulatory capacity.

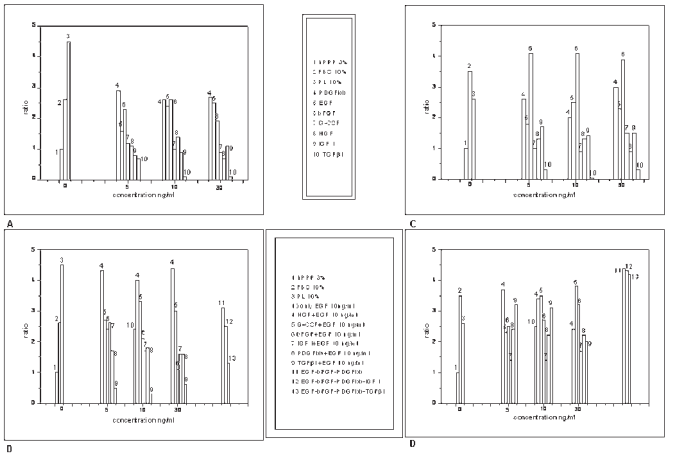

Figure 1 A-C Ratio between fluorescence of UC or AT MSCs, respectively, expamded in hPPP, or FBS, or PL, or with hr-GFs alone and control (hPPP 3%). B-D Ratio between fluorescence of UC or AT MSCs cultures in FBS, or PL or EGF (10 ng/mL) plus GFs and vehicle control.

OPTIMIZATION OF MESENCHYMAL STEM CELL EXPANSION PROCEDURES BY CELL SEPARATION AND CULTURE CONDITIONS MODIFICATION

S. Carrancio,[1] N. Lopez-Holgado,[2] F.M. Sánchez-Guijo,[2] E. Villarón,[2] V. Barbado,[3] S. Tabera,[2] M. Díez-Campelo,[2] J. Blanco,[4] J.F. San Miguel,[2] M.C. Del Cañizo[2]

[1]University Hospital of Salamanca, SALAMANCA; [2]Department of Hematology. University Hospital of Salamanca, SALAMANCA; [3]Cell Biology and Pathology Anatomy Deparment. University of Salamanca, SALAMANCA; [4]Department of Traumatology. University Hospital of Salamanca, SALAMANCA, Spain

Background. The use of mesenchymal stem cells (MSC) in gene and cell therapy holds promise as a potential therapeutic tool for several human diseases, and a number of clinical trials with MSC transplantation have been initiated in the last few years. The great numbers of these cells required for clinical approaches, together with the low percentage of them in adult bone marrow, make the *in vitro* expansion a mandatory process. Well-defined isolation, expansion and characterization protocols are required to facilitate comparison of MSC clinical results. Several methods have been proposed in order to improve the number and quality of MSC including the use of platelet lysate (PL) and low O2 tension but none of them has included a different isolation method. Some years ago, it was reported that a greater number of fibroblast progenitors was obtained when gravity sedimentation was used. We have hypothesized that within these progenitors MSC would be included and we propose a new approach for cell separation. *Aims.* The present study was designed to optimize the culture of MSC by combining and comparing several cell isolation methods and culture conditions. *Methods.* Human MSC were isolated from BM cells of eleven healthy volunteer donors after informed consent was obtained. Mononuclear cells (MNC) from bone marrow aspirates were obtained by both density gradient centrifugation (standard method) and gravity sedimentation. Cells were cultured with or without platelet lysate (PL) preparations and under different O2 concentrations until fourth passage. Time of expansion, number of cells obtained, morphology, cell surface markers and differentiation potential were evaluated. *Results.* The number of cells obtained by using gravity sedimentation was significantly higher (11.7×10^6, range from 5.52 to 20.4×10^6 cells/mL) than that obtained with density centrifugation (4.4×10^6, range from 2.0×10^6 to 6.4×10^6 cells/mL) ($p<0.05$). Morphologically, MSC expanded in the presence of PL were smaller and exhibited faster proliferation rates that those expanded in conventional culture medium. As shown in Figure 1, the number of MSC obtained by gravity sedimentation and cultured with PL (with or without hypoxia) were significantly higher than those obtained in the other groups ($p<0.05$) from P1 until P4. When the oxygen tension was studied, we could observe that reduced oxygen tension lead to a faster proliferation, particularly during the first passages and this fact led to a significantly shorter time of expansion when compared with other groups ($p<0.05$). MSC obtained by any of the different culture conditions expressed comparable inmunophenotype and were able to differentiate into osteoblasts, adipocytes and chondrocytes.*Conclusions.* MSC isolation by MNC gravity sedimentation together with culture medium supplementation with 5% of PL in a hypoxic atmosphere (5% O2) significantly improved MSC yield and reduced expansion time compared to the standard accepted protocols.

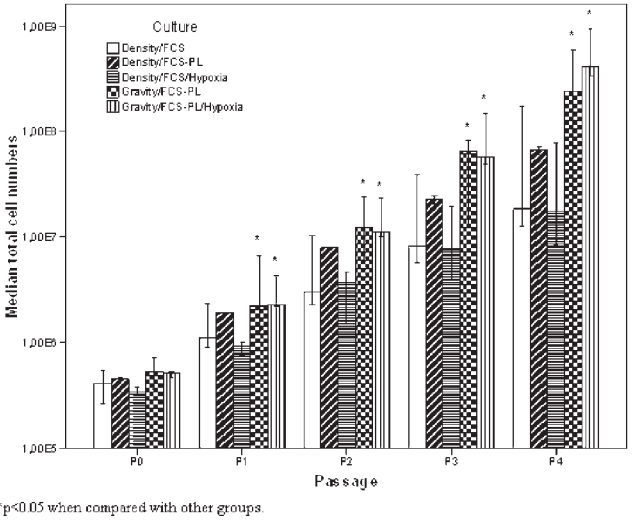

Figure 1. Effect of culture conditions on isolation and proliferation of BM MSC. Total number of adherent cells isolated at passages 0-4 from 10' BM mononuclear cells.

0315

IMMUNOPHENOTYPIC AND GENE EXPRESSION PROFILE CHANGES OF EX VIVO EXPANDED UMBILICAL CORD BLOOD CD34+ HEMATOPOIETIC STEM CELLS

D.L. Zanette

FMRP-USP-CTC, RIBEIRAO PRETO, Brazil

Background. The number of hematopoietic stem cells (HSC) in UCB samples is a limiting factor for its use in transplants and *in vitro* expansion of these cells seem promising. Nevertheless, the use of animal derived culture components and the adverse effects on cells viability and differentiation potential of commonly used expansion protocols hamper their clinical application. *Aims*. To allow future improvements, this study was carried in order to gain knowledge on molecular mechanisms acting on HSC upon culture conditions allowing the expansion of primitive sets of UCB HSC. Material and Methods. 13 samples of immune-magnetically purified UCB $CD34^+$ cells (mean purity 93.5%) were expanded in serum and stroma-free conditions with FLT3-lig, TPO, SCF and IL-6. Following purification (T0) and after 3 days of culture (T3), cells were evaluated by flow cytometry for the percentage of apoptotic cells (anexin V-expressing cells), of primitive cell subsets ($CD34^+/CD38^-$ and $CD34^+/CD90^+$) and of $CD34^+/CXCR4^+$ cells. Differentiation and clonogenic potential was accessed by methylcellulose assays. RNA extracted from samples were pooled to generate two independent gene expression profiles from cells at T0 and at T3 (total of four) using oligonucleotide microarrays encompassing over 10,000 genes. Differentially expressed genes were selected for validation based on multiple comparisons between both time points. Individual RNA samples were used to evaluate the expression level of IL9R, SMAD6, BIRC5 and CDC25C genes by real time quantitative PCR (dual-labeled probes, 2-ddCt comparative method). *Results*. A mean fold increase in

total cell counts of 2.8 was seen on day 3, with at least 80% of these cells expressing CD34. Absolute numbers of $CD34^+/CD38^-$ and $CD34^+/CD90^+$ subsets were increased two and six-fold, respectively. At T3 cultures had a greater percentage of viable cells, compared to T0 (mean 75% *vs* 63%). The percentage of $CD34^+/CXCR4^+$ cells was significantly lower at T3 (p=0.005). The absolute and relative number of colonies, as demonstrated by clonogenic progenitor assays, was not altered between T0 and T3, indicating that the differentiation capacity of cultured cells was maintained. Cell cycle related genes involved in mitosis were the most upregulated, such as CDC25C (fold=8), whereas the expression levels of known intrinsic regulators of HSC self-renewal such as HOXB4, Bmi-1 and STAT5B, did not change. In addition, the downregulation of CXCR4 (fold= -9), involved in homing, and the upregulation of genes such as IL9R (fold=56), associated with proliferation through JAK/STAT pathway, SMAD6 (fold=12), a negative regulator of TGF-β1 pathway and BIRC5 (fold=7), a negative regulator of apoptosis, were all confirmed by qPCR on the samples evaluated (p<0.05, Mann Whitney T test). *Conclusions*. Using a protocol free of animal derived components, we were able to expand, in a short period of time, the absolute numbers of cell subsets typically associated with HSCs, without affecting cell viability and clonogenic potential. Functional evaluation of the significant gene expression changes that accompany expansion the may help to improve protocols to expand HSC while maintaining desired characteristics.

IMPAIRED MOBILIZATION OF THALASSEMIC MICE DUE TO INCREASED SEQUESTRATION OF HEMATOPOIETIC STEM CELLS IN THE THALASSEMIC SPLEEN

N. Psatha, E. Yannaki, A. Tasouli, E. Athanasiou, G. Karponi, V. Constantinou, D. Bougiouklis, A. Papadopoulou, A. Xagorari, A. Anagnostopoulos, A. Fassas

Gene and Cell Therapy Center, Hematology-BMT Unit, George Papanicolaou Hospital, THESSALONIKI, Greece

Background. Gene therapy has recently been considered a therapeutic potential for thalassemia, therefore, there is a necessity to determine the most preferable source of autologous $CD34^+$ cells. It is well known that Granulocyte-Colony Stimulating Factor (G-CSF)-mobilized peripheral blood stem cells (PBSCs) provide a higher yield of stem cells than conventional bone marrow harvest. However, the administration of G-CSF in conditions of splenomegaly may not prove safe, as G-CSF is related to splenic enlargement rarely resulting in rupture. On the other hand, an enlarged spleen may potentially pool stem cells from the periphery and negatively affect mobilization. *Aims.* We decided to investigate the G-CSF effect in a thalassemic mouse model (HBBth-3) as compared to a normal strain (C57Bl6), in terms of safety, mobilization efficacy and distribution of stem cells among hematopoietic compartments. *Methods*. G-CSF was administered intraperitoneally at 200 μg/kg once a day for 7 days. Control mice received no G-CSF-treatment. Hematopoietic stem/progenitor cell (HSPCs) analyses were carried out by flow cytometry (FCM) and clonogenic assays (CFU-GM) on three hematopoietic tissues: peripheral blood, bone marrow, and spleen. HSPCs were defined as Lin-sca-1+c-kit+ cells by FCM. Histological and immunohistochemical analyses (MPO, TER-119, c-kit, Ki-67, Gomori) were performed into harvested tissues. Spleen and liver weight was determined as a ratio (x1000) to total body weight. *Results*. G-CSF caused dramatic alterations in the histology of thal spleens represented by excessive hypercellularity and intense trilineage hemopoiesis in a greatly expanded red pulp dominating over the white one. No death or splenic rupture in G-CSF-treated animals of either strain was observed (0/68), however, hemorrhagic infarcts could be detected in the spleens of G-CSF-treated HBBth-3 mice at the time of sacrifice (5/40). The size difference was significant in favor of thal spleens over normal ones, both at steady state (p<0,0001) and post G-CSF(p<0,0001), however, the G-CSF effect was stronger in normal than in thalassemic strain finally resulting in 133% increase as compared to 65% increase in the thal spleen size. Calculation of LSK+cells/μL blood and CFU-GM/mL blood demonstrated that the HBBth-3mice mobilized less effectively than C57Bl6 mice (p=0,01 and p=0.01, respectively) due to the sequestration of LSK+cells and CFU-GM progenitors in the spleen (p=0,007 and p=0.06 respectively). Splenectomy restored the mobilization efficacy in thal mice at comparable levels to the normal strain by increasing LSK+ cells in the blood by 2.5 fold and CFU-GM by 4.3 fold. The liver post splenectomy developed a compensatory increase of extramedullary hematopoiesis which became intense after G-CSF. *Conclusions*. Our data imply that in view of human gene therapy for thalassemia, multiple cycles of mobilization or bone marrow harvest may be required for a sufficient yield of transplantable HSCs in non-splenectomized patients and strategies to reduce the risk of G-CSF-induced infarcts in the spleen should be explored in a clinical setting.

CHOLESTEROL-ENRICHED DIET PROMOTES LEUKEMIA ENGRAFTMENT AND PROGRESSION

R. Fragoso,[1] T. Carvalho,[1] A. Gomes,[1] L. Martins,[2] J. Barata,[2] S. Dias[1]

[1]Portuguese Institute of Oncology, LISBON; [2]UBCA, Institute of Molecular Medicine, LISBON, Portugal

Subsets of acute leukemia patients have low cholesterol levels (hypocholesterolemia) associated with poor clinical outcome and evidence of extramedullary disease. In the present study, to address *in vivo* the contribution of cholesterol metabolism on leukemia development, we xenotransplanted T and B lymphoblastic leukemias into nod-scid mice subjected to a high fat diet (that results in increased cholesterol levels in the peripheral blood and in the bone marrow). We observed that the high fat diet condition worsened the disease, and significantly decreased the survival of leukemic mice. The increased mortality was due to an increased BM engraftment and, at the latter stages of the disease, to the early onset of extramedullary disease in organs, such as the spleen and the lungs. The increased BM engraftment in high fat diet mice was diminished by treating the mice with cholesterol lowering drugs (statins). According to these results we hypothesized that cholesterol levels may modulate the BM microenvironment, making it more permissive to leukemia cells engraftment (and, at the latter stages of the disease, to their exit). Mechanistically, we first focused on the effects of high cholesterol in endothelial cells. We started by performing trans-endothelial leukemia cell migration assays using endothelial cell monolayers pretreated or not with high levels of cholesterol. Importantly, we observed that cholesterol enrichment significantly increased leukemia cells trans-endothelial migration (~3 folds over control). We observed that some of the key molecules involved in leucocytes adhesion to endothelium (such as P-selectin, VCAM and I-CAM) were up-regulated by this cholesterol treatment, as well as the complement component factor C3a and C5 receptors, known to regulate endothelial monolayer permeability and adhesion. On the other hand, we observed that cholesterol treatment induces complement component factors C3a and C5 expression on leukemia cells, suggesting that cholesterol metabolism may modulate leukemia cells/BM microenvironment interaction through the complement pathway activation involving leukemia:endothelial cell interactions. Accordantly, blocking the complement pathway activation (with a C3a receptor antagonist) impaired cholesterol-induced leukemia trans-endothelial cell migration. Next, we sough to analyze the importance of the complement pathway in regulating leukemia engraftment and expansion *in vivo*, by inoculating different leukemia cells on nod-scid mice fed or not with a fat diet and treating or not with a complement inhibitor before/during leukemia BM engraftment and after, during leukemia progression. According to our results, complement pathway inhibition decreased BM engraftment and also prevented/delayed the onset of extramedullary disease on fat diet mice, by impairing endothelial cell permeability/survival in the BM and in the peripheral organs. Our results demonstrate for the first time the mechanisms by which a high-cholesterol diet may modulate the interaction between subsets of leukemia and BM endothelial cells, contributing towards increased leukemia onset and progression.

DIFFERENTIAL BCR EXPRESSION IN SEQUENTIAL STAGES OF MURINE HEMATOPOIETIC HIERARCHY

H.K. Khoury

Princess Margaret Hospital, TORONTO, Canada

Background. The BCR gene was originally cloned due to its involvement in the t(9;22) translocation found in CML and B-ALL. In this translocation the chimeric gene BCR-ABL is under the control of the promoter of BCR. Although BCR-null mice do not exhibit major defects in the development of definitive hematopoietic cells, they show abnormal stress responses to infective stimuli. It has been shown that BCR transcriptional activation is tissue and lineage specific. *Aims.* The goal of this study was to analyze BCR expression in sequential stages oh hematopoietic hierarchy in order to add insight into the importance of the potential role of BCR in normal hematopoiesis and the contribution

of its dysregulation to leukemic hematopoiesis. *Materials and Methods.* We quantified by real-time RT-PCR, the transcript level of this gene in different stages of maturation of the murine hematpoietic hierarchy that include long-term (LTR-HSCs), short-term repopulating hematopoietic stem cells (STR-HSCs), Multipotent B+, pentapotent, tetrapotent, the bipotent (pE/pMeg) and neutrophilic/macrophage (pNeut/pMac), unipotent (BFU-E, CFU-E, pMeg, pMac and pNeut) progenitors and, finally, the terminally differentiated cells (E, Meg, Mac, Neut, Mast , B and T). The LTR- and STR-HSCs are able to reconstitute the entire murine hematopoietic system for a period of 1 year or more and 3-12 months and have the phenotypes (Rho-Kit+Sca1+Lin-CD49b-) (Rho-Kit+Sca1+Lin-CD49b+), repectively. Complementary DNA was obtained from sorted cells (HSCs, mature B and mature T) or pooled at each stage of maturation from single cell precursors whose differentiation potential was determined by the outcome of cultured sibling cells (Multipotent B+ and myeloid progenitors and mature cells). *Results.* BCR transcript expression was biphasic. The first phase was restricted to the LTR-HSC and STR-HSC with BCR/GAPDH levels of 0.0027 and 0.0017, respectively. The second phase included mainly the bipotent progenitors (pE/Meg and pNeutro/Mac) with BCR/GAPDH ratios of 0.009 and 0.002, respectively. BCR Expression was not detected in the Multipotent B+, pentapotent, tetrapotent, unipotent or terminally-differentiated cells. Then we analyzed the BCR gene transcript levels in HSCs that are arrested at G0 phase and after stimulating them to undergo mitosis. Interestingly, LTR-HSCs and STR- HSCs in G1 phase showed 10-fold increase in BCR transcripts when compared to HSCs in G0. Moreover, this augmentation persisted during all stages of mitosis. *Conclusions.* Our findings suggest that BCR transcript levels are tightly regulated during murine hematopoietic differentiation; whether this regulation is achieved at the pre-transcriptional (through methylation of DNA regulatory regions or histone modification) or post-transcriptional (by microRNA) level is still to be determined. The increase in BCR levels during mitosis may indicate a potential role of BCR in mitosis or cell cycle, such a role is still to be fully deciphered. Moreover, our results may suggest that the abnormal stress response of $BCR^{-/-}$ mice is likely due to abnormal compensatory function of the pNeut/Mac progenitors rather than to defective function of the terminally maturing cells. It remains to be determined if the murine expression pattern is recapitulated in the human hematopoietic precursor hierarchy, and in particular whether the expression of the BCR-ABL fusion transcript and protein follow the same pattern in CML.

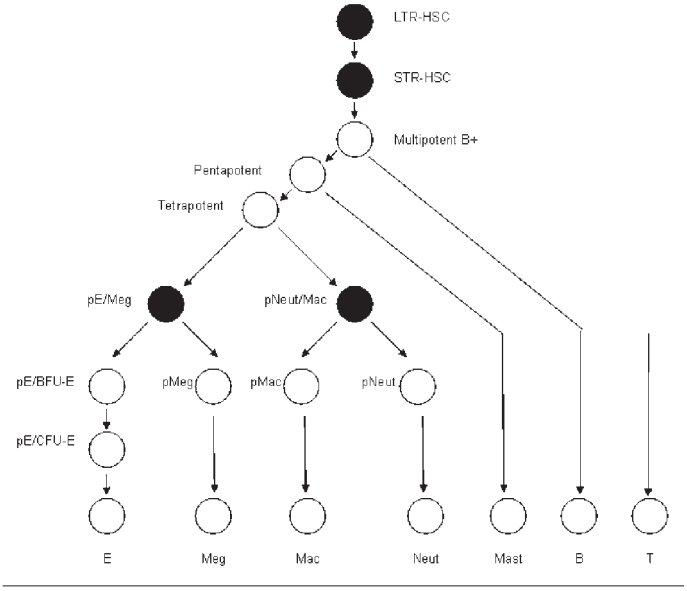

Figure 1. BCR expression in murine hematopoietic Hierarchy.

A QUALITATIVE AND QUANTITATIVE ANALYSIS OF THE CD68+ CELL MICROENVIRONMENT COMPONENT IN REACTIVE LYMPH NODES AND FOLLICULAR LYMPHOMA AT PRESENTATION AND RELAPSE

T. Todd,[1] S. Barrans,[2] K. Turner,[2] R. Tooze,[2] A.S. Jack[2]

[1]*Cambridge University Hospitals NHS Foundation Trust, CAMBRIDGE;*

[2]*HMDS, Leeds Teaching Hospitals NHS Trust, LEEDS, UK*

Background. The importance of the tumour microenvironment in follicular lymphoma (FL) has been highlighted by both gene expression profiling (GEP) and quantitative analyses of the $CD68^+$ cell component. However, whole tissue GEP does not distinguish the contribution of different cell types; and quantitation of a single, non-lineage specific marker, may be over simplistic. *Aims.* To determine phenotypic and quantitative differences in the CD68+ cell population between reactive lymph nodes, and FL presentation and relapse. *Methods.* Quantitative analysis of the $CD68^+$ cell population was performed by staining sections from 43 matched pairs of formalin fixed paraffin embedded lymph nodes of presentation and relapsed FL with anti-CD68 (PGM1) antibody using standard immunohistochemistry. Cells were counted at x1000 magnification in both the 5 most densely populated fields (as previously published) and 40 random fields per sample. The composite phenotype of $CD68^+$ cells was further investigated in 10 reactive, 10 presentation and 10 relapse FL lymph nodes using 2 or 3 colour immunofluorescence (MCIF). CD68 was used to identify the cells of interest in combination with antibodies against inflammatory factors (PU.1, CEBP/beta, COX2), markers of M1 (iNOS, IL23) and M2 (the novel markers Gas-3 and Cadherin-1) macrophage differentiation, transcription factors (IRF1, IRF2, IRF4, IRF8 , BCL6) and genes from prognostically significant groups previously determined by GEP and attributed to the microenvironmental component (LGMN, ACTN1, C1q, STAT1). S100 was used to identify non-macrophage antigen presenting cells (APC). *Results.*No quantitative difference in $CD68^+$ cells was identified between FL presentation and relapse. The composite phenotype of $CD68^+$ cells was unchanged between FL presentation and relapse but differed markedly between reactive and FL lymph nodes. In FL fewer cells expressed iNOS than in reactive lymph nodes (45% *vs* 85%), IL23 was unchanged though weaker, COX2 was virtually absent, IRF2 was expressed in a higher proportion of cells (25% *vs* 10%) and IRF1 in a lower proportion (63% *vs* 82%). Gas3 and Cadherin-1 were more frequently expressed in FL (84% vs 18% and 87% vs 10% respectively) as was LGMN. ACTN1 and LGMN were also expressed in tumour and normal lymphocytes. 5% of $CD68^+$ cells co-expressed S100. *Summary and Conclusions*. This study has demonstrated the potential utility of MCIF for evaluating the tumour microenvironment. We have shown that a proportion of $CD68^+$ cells are non-macrophage APCs and that some genes highlighted in prognostically significant gene expression profiles and attributed to the microenvironment are also expressed in tumour cells. No quantitative or phenotypic difference in the $CD68^+$ component of the microenvironment was demonstrable between presentation and relapse samples suggesting that the microenvironmental response to tumour remains constant. Clear phenotypic differences in $CD68^+$ cells between FL and reactive samples were demonstrated. FL showed diminished M1 and inflammatory marker expression but enhanced M2 marker and differing transcription factor expression. We have shown for the first time that Gas3 and cadherin-1 are expressed in markedly more $CD68^+$ cells in human FL compared to reactive lymph nodes. These findings may be of value in future evaluation of the microenvironment in this and other diseases.

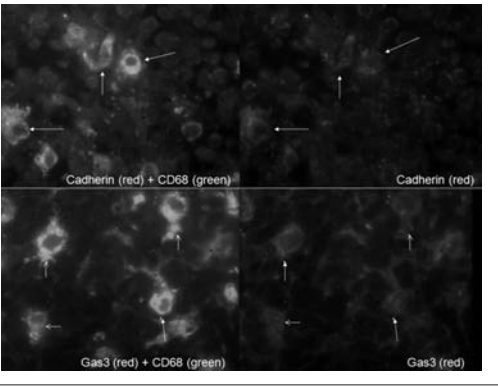

Figure 1. $CD68^+$ cells expressing Cadherin-1 and Gas3 in FL.

NOTCH1, GATA3 AND NF-KB PARTICIPATE IN A TRANSCRIPTION NETWORK THAT REGULATES PRIMITIVENESS OF HEMATOPOIETIC STEM CELLS

R.A. Panepucci,[1] L.H.B. Oliveira,[2] D.L. Zanette,[1] G.A. Molfetta,[1] R.C.V. Carrara,[1] V.C. Oliveira,[1] A.G. Araujo,[1] M.D. Orellana,[1] P.V.B. Palma,[1] C.C.B.O. Menezes,[1] D.T. Covas,[1] M.A. Zago[1]

[1]Fundacao Hemocentro de Ribeirao Preto (FMRP-USP), RIBEIRAO PRETO; [2]FCF-UNESP, ARARAQUARA, Brazil

Background. NFKB2 and RELB are sub-units of a transcription factor (TF) that mediates constitutive signaling of the nuclear factor kappa B (NF-kB) pathway. We have previously shown that the increased signaling of this pathway in umbilical cord blood (UCB) CD34$^+$ hematopoietic stem cells (HSC) as compared with bone marrow (BM) CD34$^+$ cells is probably related to their more primitive state, to which higher levels of NOTCH1 could also contribute. However, differences of the proportion of more primitive CD34$^+$ cells among BM and UCB CD34$^+$ HSC could also account for this finding. CD133 is a surface marker expressed in a more primitive sub-population of CD34$^+$ cells that are highly enriched in long-term culture-initiating and NOD/SCID-repopulating cells with a proposed hemangioblast potential. Aims. Identify molecular mechanisms related to the more primitive characteristics of UCB and CD133$^+$ HSC. Material and Methods. Human CD34$^+$ and CD133$^+$ cells were immunomagnetically purified from BM and UCB obtained from donors and from the placenta in term births. Oligonucleotide microarray gene expression profiles were carried out followed by in silico promoter analysis using the TELIS on-line tool. Real-time quantitative PCR for selected genes were carried on a total of 65 immunomagnetically purified samples. Interference RNA (iRNA) experiments were carried on BM CD34$^+$ HSC. Results. UCB CD34$^+$ cells contained a significantly higher proportion of CD133$^+$ than BM (70% and 30%, respectively). Cluster analysis of the expression profiles, encompassing around 10.000 genes, showed that UCB CD133$^+$ are more similar to UCB CD34$^+$ than to BM CD133$^+$ cells, whereas BM CD34$^+$ showed the lesser similarity to these cells, a result probably related to the cell sub-populations composition. Compared with CD34$^+$ cells, CD133$^+$ cells had a higher expression of many well-known factors related to the hemangioblast potential of primitive HSC. In fact, TFs such as RUNX1/AML1, GATA3, USF1, TAL1/SCL, HOXA9 and HOXB4 were all present at higher levels in CD133$^+$ HSC. Promoter analysis of these differentially expressed TF revealed a frequency of NF-kB TF binding sites on these genes significantly higher than the expected frequency for random selected genes, and included potentially novel NF-kB targets such as RUNX1, GATA3 and USF1. NOTCH1, GATA3, NFKB2 and RELB levels evaluated by real-time PCR were significantly higher (Mann-Whitney) for UCB (CD34$^+$ or CD133$^+$) samples than for BM CD34$^+$ samples. NOTCH1, GATA3 and NFKB2 levels were also higher on BM CD133$^+$ samples compared to BM CD34$^+$ samples. Significant positive correlations (Sperman's correlation coefficient) were demonstrated for the levels of all the transcripts evaluated, thus indicating that GATA3 levels in HSC can be regulated by NOTCH1 and NF-kB members. To further test this hypothesis, we used iRNA against NKFB2 in HSC. As a result, levels of NFKB2, GATA3 and RELB (a known target of NFKB2/RELB dimmers) were down-modulated, in comparison with cells transfected with control iRNA. Conclusions. Our results indicate that constitutive NF-kB signaling may act together with NOTCH1 to upregulate transcription factors related to a more primitive state of HSC. Supported by FAPESP, CNPq and FINEP.

0321

MAINTENANCE OF PRIMITIVE STEM CELL ACTIVITY DURING MASSIVE AMPLIFICATION OF COMMITTED PROGENITORS IN CLINICAL SCALE SERUM-FREE *EX VIVO* CULTURES OF THAWED CORD BLOOD CD34$^+$ CELLS.

Z. Ivanovic,[1] P. Duchez,[1] J. Chevaleyre,[1] M. Vlaski,[1] B. Dazey,[1] X. Lafarge,[1] E. Robert-Richard,[2] F. Mazurier,[2] J.M. Boiron[3]

[1]Etablissement Français du Sang Aquitaine - Limousin, BORDEAUX; [2]INSERM E0217, BORDEAUX; [3]Université V Segalen Bordeaux 2, BORDEAUX, France

Background. The *ex vivo* expansion of cord blood (CB) cells could potentially resolve the problem of the low cell content in the graft and of the long period of post-transplantation neutropenia, as was demonstrated for *ex vivo* expanded autologous peripheral blood CD34$^+$ cells (Boiron *et al.*, Transfusion 46:1934). We upscaled (Duchez *et al.*, J Hematother Stem Cell Res 12: 587, 2003) the experimental procedure (Kobari *et al.*, Exp Hematol 28: 1470, 2000) of CD34$^+$ cell expansion in clinical-scale cultures in presence of SCF, FLT3 ligand, MGDF (100 ng/mL each) and G-CSF (10 ng/mL). *Aims.* Since the long-term engraftment capacity is crucial after allogeneic transplantation, the activity of primitive stem cells was investigated before and after expansion of thawed cord blood CD34$^+$ cells in our culture system. *Methods.* Expansion of CD34$^+$ cells selected [(Isolex (Duchez *et al.*, J Hematother Stem Cell Res 12: 587, 2003) or Miltenyi, (Ivanovic *et al.*, Stem Cells. 22: 716, 2004)] from previously cryopreserved and thawed volume-reduced (Dazey *et al.*, Stem Cells Dev 14: 6, 2005) or non-reduced cord blood units was performed in two-step cultures (diluted 1:4 after 6 days ; VueLife culture bags) in the presence of SCF, FLT3 ligand, MGDF and G-CSF in Macopharma HP01 serum-free medium (Ivanovic et al, Transfusion 46: 126, 2006). The activity of stem cells was evaluated on the basis of detection of human cells in the bone marrow of NOD/Scid mice (primary recipients) 6-8 weeks after transplantation (i.v.). The maintenance of very primitive stem cells was studied by a serial engraftment: the secondary recipients were engrafted by an intramedullary injection of primary recipient bone marrow cells. Six weeks later, injected femurs were analyzed as in primary recipients : human CD45, CD33, CD19 as well as the number of clonogenic progenitors, (CFC), of human-origin. *Results.* The number of total cells, of CD34$^+$ cells as well as of committed progenitors were expanded ~500 fold, ~100 fold and ~150 fold, respectively. The activity of primitive stem cells (SRC : SCID Repopulating Cells) at the end of culture, was maintained at the Day-0 level as judged by the phenotypical markers (corresponding to relatively less primitive subpopulation of SRC), and doubled as judged by human CFC content in primary recipient bone marrow (SRC - CFC, representing relatively more primitive subpopulation of stem cells). The engraftment of secondary recipients (considered to be the measure of very primitive stem cells) was not impaired by culture whether judged by human phenotypical markers or by human CFC numbers. *Conclusions.* In the course of a massive expansion of hematopoietic progenitors from CD34$^+$ cord blood cells in this clinical-scale serum-free cultures, the activity of the primitive stem cells is not impaired. Furthermore, the activity a stem cell subpopulation (SRC-CFC) was enhanced. These data actualize the *ex vivo* expansion as an approach that could significantly improve the transplantation of cord blood stem and progenitor cells.

Stem cell transplantation - disease related

UNRELATED CORD BLOOD TRANSPLANTATION AFTER MYELOABLATIVE CONDITIONING IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA

J. Ooi, S. Takahashi, A. Tomonari, N. Tsukada, T. Konuma, S. Kato, S. Kasahara, A. Tojo, S. Asano

Institute of Medical Science, University of Tokyo, TOKYO, Japan

Background. Recently, unrelated cord blood has been increasingly used for an alternative stem cell source in adult patients. We previously reported promising results of a pilot study of unrelated cord blood transplantation (CBT) in adult patients with *de novo* acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS)-related AML. *Aims.* The main purpose of this study was to confirm the safety and efficacy of unrelated CBT for adult patients with AML after myeloablative conditioning regimen as well as to identify factors related to the transplant outcome. *Methods.* Between August 1998 and September 2007, 75 adult patients with AML were treated with unrelated CBT at The Institute of Medical Science, University of Tokyo. Written informed consent was obtained from all patients. Diagnoses at transplantation included *de novo* AML (n=56) and MDS-related secondary AML (n=19). 44 (59%) patients were transplanted in an advanced status of the disease (defined as AML in third or subsequent complete remission, relapse or refractory disease). All patients received four fractionated 12 Gy total body irradiation and chemotherapy as myeloablative conditioning. 72 patients received standard cyclosporine (CyA) and methotrexate, and 3 patients received CyA only as a graft-versus-host disease (GVHD) prophylaxis. Among the patients the median age was 45 years (range, 18-55 years), the median weight was 55 kg (range, 36-76 kg), the median number of cryopreserved nucleated cells was 2.44×10^7/kg (range, $1.16\text{-}5.29\times10^7$/kg) and the median number of cryopreserved CD34 positive cells was 1.00×10^5/kg (range, $0.15\text{-}8.97\times10^5$/kg). All patients received a single and HLA mismatched cord blood unit. *Results.* 71 patients had myeloid reconstitution and the median time to more than 0.5×10^9/L absolute neutrophil count was 21 days. A higher CD34 positive cell count was independently associated with faster neutrophil recovery (p=0.0001). A self-sustained platelet count more than 50×10^9/L was achieved in 67 patients at a median time of 37 days. Acute GVHD greater than or equal to grade III occurred in 7 of 71 evaluable patients and chronic GVHD occurred in 61 of 66 evaluable patients. Among 61 chronic GVHD patients, 19 patients were extensive type. 52 patients are alive and free of disease at between 7 and 115 months after CBT. With a median follow-up of 71 months, the probability of event-free survival (EFS) at 5 years was 67%. The 5-year cumulative incidence of transplant related-mortality and relapse was 11%, 25%, respectively. In multivariate analyses, advanced disease status was an adverse factor for EFS (p=0.01) and relapse (p=0.02). HLA compatibility had no impact on any transplant outcomes. *Conclusions.* These results suggest that adult AML patients without suitable related or unrelated bone marrow donors should be considered as candidates for CBT.

0323

MYELOABLATIVE HEMATOPOIETIC ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA IN FIRST OR SECOND COMPLETE REMISSION OR REFRACTORY DISEASE: A RETROSPECTIVE STUDY OF 168 PATIENTS ENROLLED IN TWO CONSECUTIVE FRENCH TRIALS

E. Bachy,[1] C. Pautas,[2] C. Cordonnier,[2] X. Thomas,[1] M. Michallet[1]

[1]Edouard Herriot Hospital, LYON; [2]Henri Mondor Hospital and Paris 12 University, CRETEIL, France

Background. Prognostic factors of acute myeloid leukemia (AML) at diagnosis are well identified in the literature. However, whether type of induction may impact on the outcome of myeloablative (MA) allogeneic stem cell transplantation (alloHSCT) is debated. Aims. The aim of this study was to confirm the role of pretransplant prognostic factors and of the induction regimen on overall survival (OS), disease free survival (DFS) and relapse rate (RR). Methods. We retrospectively analysed 168 patients (median age 36 (15-52) years old) enrolled in two consecutive prospective trials (ALFA 9000 trial and ALFA 9802 trial; database for transplantation obtained from Societe Francaise de Greffe de Moelle et de Therapie Cellulaire (SFGM-TC)) who underwent MA alloHSCT in first or second complete remission (CR1 or CR2) or in refractory disease (RD) stage between June 1996 and December 2004. Thirty-four patients received standard 3+7 induction with standard doses of cytarabine (Ara-C) and 134 patients received intensified (double or time-sequential) induction with intermediate doses of Ara-C. Statistical analyses were performed to evaluate the correlation between OS, RR, or DFS, and age at time of transplantation (before 40, n=108; after 41, n=60), cytogenetic status (available for 134 of 168 patients; favorable, n=11; intermediate, n=92; unfavorable, n=31), status at transplant (CR1, n=98; CR2 , n=29; RD, n=41), conditioning regimen (endoxan plus total body irradiation (EDX-TBI), n=96; endoxan plus busulfan (EDX-BUS), n=37; other, n=35), source of stem cells (peripheral blood, n=11; bone marrow, n=156; unknown, n=1), type of donor (matched related, n=133; matched unrelated, n=35). Results. Median OS and DFS were 1.10 and 0.86 years respectively. OS, RR, and DFS at 5 years were respectively 45.7%, 35.4% and 41.5%. By Kaplan-Meier univariate analysis, OS was significantly improved for patients receiving related matched alloHSCT (p=0.004) and bone marrow stem cells (p=0.012). While no significant correlation was found between OS and cytogenetic status or type of induction treatment or age at time of transplant, status at transplantation markedly correlated with OS (CR1 vs CR2 vs RD, p<0.0001), as well as type of conditioning regimen (EDX-TBI or EDX-BUS vs other, p=0.0004). By Cox multivariate analysis, only related (vs unrelated) matched donor (p=0.009) and status at transplantation (CR1 vs RD, p=0.041) were associated with a significant better OS. In a subgroup analysis of the 98 patients transplanted in CR1, OS was significantly improved for patients receiving standard vs intensified induction (p=0.031). However, no further association was found when adjusted for cytogenetic status in a Cox model mainly because patients who underwent HSCT in CR1 after 3+7 standard induction showed all more favorable cytogenetic features than those who received an intensified induction. Conclusions. We confirmed in this study that status at transplantation as well as matched related donor type remain strong prognostic factors. Furthermore, in univariate analysis, the outcome was better after CR1 if patients received standard induction. However, in multivariate analysis, after adjusting for potentially confounding factors, this trend was not confirmed. Further studies are needed to determine the role of intensified induction regimens before alloHSCT especially for patients with adverse cytogenetic characteristics at diagnosis.

0324

CLOFARABINE/ARA-C (CLARA) TREATMENT FOLLOWED BY REDUCED-INTENSITY CONDITIONING AND ALLOGENEIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK, RELAPSED, OR REFRACTORY ACUTE LEUKEMIA

S. Buchholz, J. Krauter, E. Dammann, S. Ehrlich, M. Port, E. Weissinger, M. Stadler, M. Eder, A. Ganser

Hannover Medical School, HANNOVER, Germany

Background. Allogeneic stem cell transplantation (SCT) is the most effective treatment for high-risk, refractory or relapsed AML and MDS. However, most AML and MDS patients are older than 50 years and not eligible for conventional myeloablative conditioning. Combined cytoreductive therapy with reduced-intensity conditioning regimen (RIC) is increasingly used for these patients, but limited anti-leukemic activity still results in significant relapse rates. Clofarabine, a nucleoside analogue with properties of both fludarabine and cladribine, has shown remarkable activity in relapsed AML and ALL. *Aims.* The aim of this pilot study is to evaluate the antileukemic and immunosuppressive effects of clofarabine/ara-C in the context of RIC allogeneic SCT for patients with high-risk AML, ALL, and MDS. *Methods.* Up to February 2008 fourteen patients (median age: 62, range 39 - 69, male/female: 10/4) with high-risk, relapsed or refractory acute leukemia or MDS (8 AML, 2 ALL, 4 MDS; high-risk cytogenetics n=4) were treated. At SCT, patients were in CR (n=3), in relapse (n= 5), refractory (n=3), and untreated (n=3). Cytoreductive therapy consisted of clofarabine 30 mg/m^2 and ara-C 1000 mg/m^2 for 5 days. After 3 to 5 days of rest, RIC was given with 4 Gy of total-body irradiation, 80 and 120 mg cyclophosphamide /kg for related and unrelated donors, respectively, and ATG. All patients were transplanted with unmanipulated G-CSF mobilised peripheral blood stem cells from matched (n = 7) and mismatched (n=3) unrelated or matched related (n = 4) donors. GvHD prophylaxis consisted of cyclosporine A and mycophenolate mofetil. *Results.* Overall, treatment was well tolerated and all but two patients are alive and in haematological remission (follow-up median day + 120, range day + 8 to 286). All but one (early death) patient engrafted (median day + 19 for ANC > 0.5 G/L, range: day +12 to 31). So far no acute GvHD > I° was observed with follow-up > 100 days for 7 patients. Non-hematological toxicity included reversible hepatotoxicity (increase in ALT and AST CTC II - III°) in 11 patients, CTC IV° in one patient, hem-

orrhagic cystitis in one patient, and mild to severe reversible hand-foot-syndrome in 9 cases. One patient suffered from veno-occlusive disease and infectious complications and died due to multiorgan-failure on day + 33, and one patient died due to candida septicemia on day +8. *Conclusions.* Antileukemic therapy with clofarabine and Ara-C followed by RIC allogeneic HSCT is feasible in elderly patients with high-risk acute leukemia or MDS with normal engraftment and no increase in GvHD. Non-hematological toxicity of this regimen mainly liver and skin is acceptable. Updated results of this ongoing pilot study will be presented.

UNRELATED TRANSPLANTS FOR POOR PROGNOSIS ADULT ACUTE LYMPHOBLASTIC LEUKEMIA: LONG-TERM COMPARATIVE ANALYSIS BASED ON THE HEMATOPOIETIC PROGENITOR SOURCE

C. Ferra,[1] J. Sanz,[2] R. Cámara,[2] G.F. Sanz,[2] A. Bermúdez,[2] D. Valcárcel,[2] M. Rovira,[2] M. Morgades,[2] I. Espigado,[2] I. Heras,[2] D. Serrano,[2] C. Barrenetxea,[2] C. Solano,[2] R. Duarte,[2] A. García-Noblejas,[2] A. Iriondo,[2] J.L. Díez,[2] E. Carreras,[2] J. Sierra,[2] M.A. Sanz,[2] J.M. Ribera[2]

[1]H. Germans Trias i Pujol - Institut Català d'Oncologia, BADALONA; [2]GETH and PETHEMA groups, VALENCIA, Spain

Background. Adults with high risk ALL features at diagnosis, slow responders or with recurrent disease have a poor outcome with standard chemotherapy and are considered for unrelated transplants in most centers if a matched sibling donor is not available. Unrelated cord blood (UCB) has emerged as an option for unrelated transplant in adult patients. Aim of the study: to compare the outcome of adult patients with unrelated transplant for poor prognosis ALL based on the hematopoietic source used for transplant. *Patients and Methods.* One hundred and thirty-seven adult patients (median 29 years [15-59], 82M/55F) with poor prognosis ALL received an unrelated transplant in 12 Spanish institutions from 2000 to 2007. ALL was of precursor B lineage in 73 (53%), T-cell lineage in 54 (39%) and undetermined lineage in 10 (7%) patients. ALL was in 1st CR in 76 (56%) patients, in 2nd CR in 33 (24%), in 3rd CR in 8 (6%) and with overt disease in 20 (14 %) patients. Both groups were comparable for the main clinical and biologic ALL features. Conditioning therapy consisted on TBI-CY in 63 (46%), BU-CY in 8 (6%), Thiotepa-BU-CY/FLU in 57 (42%) patients (all of them UCB transplants) and other regimens in 9 (7%) patients (6 of them were non-myeloablative conditioning). The source of hematopoietic progenitors was UCB in 61 (45%), mobilized peripheral blood in 37 (27%) and bone marrow in 39 (28%) patients. HLA compatibility requirements for selecting unrelated donors (bone marrow and mobilized peripheral blood) were 7-8 out of 8 allelic identities, and for UCB were 4-6 out of 6 A / B antigenic and DR allelic identities. *Results.* The median follow-up was 20 months (0.3-96). DFS estimated at 5 years for patients transplanted with any source were significantly better in transplants in 1st CR *vs* 2nd CR or more advanced disease (median 10 [2-19], 6 [0-13] and 3 [0-7] months, p=0.023). There was no statistical difference in OS or DFS at 5 years between UCB and conventional unrelated transplant (peripheral blood stem cell transplant [PBSCT] and bone marrow transplant [BMT]). TRM was significantly lower in UCB transplants.

Table 1.

	OS (5 y, IC 95%:)	Median OS (month, IC 95%:)	DFS (5y, IC 95%:)	Median DFS (month, IC 95%:)	TRM (5y, IC 95%:)
Whole series	23% (13-33)	10 (4-16)	20% (11-29)	7 (3-11)	57% (45-69)
PBSCT + BMT	18% (6-30)	7 (1-14)	18% (7-29)	5 (3-8)	67% (52-82)*
UCB transplant	31% (15-47)	11 (3-19)	23% (8-38)	9 (2-16)	40% (25-55)*
Patients in 1st CR	29% (14-44)	38 (28-49)	25% (11-39)	10 (2-19)	58% (44-72)
PBSCT + BMT	23% (4-42)	27 (3-50)	22% (4-40)	12 (2-21)	65% (44-86)
UCB transplant	35% (14-56)	10 (0-23)	28% (6-50)	10 (0-26)	50% (31-69)

*p=0.029

The relapse probability was 23% for the entire group without differences between both groups of unrelated transplants. *Conclusions.* UCB transplant, unrelated PBSCT and unrelated BMT are equivalent options for poor prognosis adult ALL patients without a sibling donor. However, all unrelated transplant modalities are associated with high transplant related mortality.

Supported in part with grants PEF-07 from the Jose Carreras Leukaemia Foundation and RD 06/0020/1014 from RETICS.

TREATMENT OF ACUTE LEUKAEMIA WITH UNMANIPULATED HLA-MISMATCHED/ HAPLOIDENTICAL BLOOD AND BONE MARROW TRANSPLANTATION

X.-J. Huang, D.-H. Liu, L.-P. Xu, K.-Y. Liu, H. Chen, W. Han, Y.-H. Chen, X.-H. Zhang, D.-P. Lu

Peking University Institue of Hematology, BEIJING, China

Background and aims. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains one of the best therapeutic options to cure acute leukaemia (AL). However, many patients lack a human leukocyte antigen (HLA) matched donor. HLA mismatched family donors are associated with insufficient long-term survival because of infection and GVHD if T cells are depleted. Recently, we developed a new method for HLA-mismatched/haploidentical transplantation without *in vitro* T-cell depletion (TCD). *Methods*. We analyzed the outcome of 250 consecutive patients with AL who underwent HLA-mismatched/haploidentical transplantation with 1-3 mismatched loci from family donor via our new transplant protocol. The factors that might influence the outcome of transplantation were discussed. *Results*. 249 patients achieved sustained, full donor chimerism. The incidence of grade 2-4 acute graft-versus-host disease (GVHD) was 45.8%, and that of grades 3 and 4 was 13.4% which was not associated with the extent of HLA disparity. The cumulative incidence of total chronic GVHD was 53.9% and that of extensive chronic GVHD was 22.6% in 217 evaluable patients. 150 of the250 patients survived free of disease recurrence throughout the follow-up of 862 days (range: 212-2207 days). 8 patients received DLI as a treatment for relapse after transplantation and all achieved leukemia free survival (LFS). The 2-yr probability of LFS for AML was 69.1% and 55.4% and for ALL was 68.9% and 17.5% in standard-risk and high-risk groups, respectively. Lower overall survival and LFS were associated with diagnosis of acute leukaemia in high-risk group (p< 0.005) and the occurrence of acute GVHD of grades 3 and 4 (p<0.02). *Conclusions*. Treatment of acute leukaemia with unmanipulated HLA-mismatched/haploidentical blood and bone marrow transplantation was feasible.

0327

STUDY OF WT-1 EXPRESSION AND ANALYSIS OF JH REARRANGEMENT MAY PREDICT RISK OF RELAPSE IN ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA SUBMITTED TO ALLOGENEIC BMT

M. Miglino, R. Varaldo, N. Colombo, R. Grasso, M. Clavio, L. Vignolo, C. Ghiggi, F. Ballerini, L. Canepa, I. Pierri, M. Gobbi

Chair of Haematology, GENOVA, Italy

The study of the monoclonal JH rearrangement is widely applied in the minimal residual disease (MRD) analysis of chronic and acute B-lymphoproliferative diseases, when a specific intrinsic marker is lacking. Patients who are JH positive at the end of therapy do not necessarily have an increased risk for relapse. Wilms' tumor gene (WT1) is a tumor suppressor gene involved in the regulation of cell growth and differentiation. WT1 transcripts and nuclear protein have been detected in the majority of human acute leukemias. The level of WT1 expression has been associated with the presence, persistence or reappearance of a leukemic clone. A significant association between WT1 level and prognosis has been shown in patients with acute myeloid leukaemia and acute lymphoblastic leukaemia (ALL) receiving chemotherapy. We analyzed both WT1 expression and JH rearrangement in 32 adult ALL patients submitted to allogeneic BMT to investigate whether the sequential monitoring of both markers is able to predict the outcome and improve the disease management. JH assay was performed by fingerprint method and WT1 expression by Real-time PCR , normalized on Abl expression . In this scenario WT1 expression could reflect a functional state of leukemic clone and predict relapse.14 males and 18 females, with a median age of 35 years (range, 19 to 51) have been studied . Ten patients showed t(9;22), 2 t(4;11), 1 a complex karyotype; 17 patients had a normal karyotype. All patient had received a conventional induction and consolidation therapy . Molecular study was performed before BMT, at day +100, and then every 3 months. In all the patients one or more JH monoclonal bands had been identified on the marrow sample studied at diagnosis .In the pre-BMT samples JH rearrangements have been detected in all the 32 patients, whereas WT1 expression was shown in 15 patients. In 3 patients in complete hematologic remission the high level of WT1 expression was predictive of an early relapse. At day +100 post BMT 9 patients were JH negative: 7 of these patients are alive and disease free, 2 have died, due to extensive GVHD, in complete remission. All these patients had normal levels of WT 1 expression . Twentythree

patients were JH positive : 7 had high level (≥100) of WT1 and experienced an early relapse, 2 had intermediate level (50-100) and both relapsed in extramedullary site, 14 patients had normal level of WT1 (< 50) and maintain CR with a median follow up of 24 months. Nine of these 13 received donor lymphocyte infusions for persisting JH positive molecular status: 4 of them developed cGVHD and one patient died of extensive cGVHD. In conclusion, our data suggest that elevated WT 1 level post BMT (day +100) may have an unfavorable prognostic value . JH negative status post BMT is always associated with a low level of WT1 expression and is associated with a very low risk of disease recurrence.

0328

ALLOGENEIC TRANSPLANTATION FOR MYELOFIBROSIS IN MYELOPROLIFERATIVE DISEASE -A SINGLE CENTER EXPERIENCE

M. Markova, J. Schwarz, A. Vitek, V. Valkova, D. Pohlreich, P. Cetkovsky

Institute of Haematology, PRAHA 2, Czech Republic

Background. Although new discoveries in gene mutations bring a new hope for future targeted therapy of myelofibrosis in the setting of myeloproliferative disease (MF-MPD), allogeneic hematopoietic stem cell transplantation (HSCT) still remains the only curative procedure. However, it is not devoid of causing quite high transplant-related mortality, especially when myeloablative conditioning regimens are used. *Aims*. To evaluate retrospectively the results of HSCT performed in a single institution for MF-MPD and to analyze the prognostic parameters at diagnosis and at time of transplant. *Patients and Methods.* 19 patients with MF-MPD underwent HSCT. 17 of them had primary myelofibrosis, 2 had postpolycythemic MF. The male/female ratio was 8:11, the median age was 49.3 years (38-63). The conditioning regimen used was myeloablative in 12 patients and 7 patients received a reduced intensity conditioning regimen (RIC); fludarabine plus busulphan was used in all but one patient. A matched related donor was used in 21.0% (4 pts), matched and mismatched unrelated and mismatched related donors were used in 78.9% (15 pts). The median post-transplant follow-up was 8 months (2-61 mos). Survival curves were constructed and evaluated by the Cox regression method (Mantel-Haenschel test). *Results.* Transplant-related mortality was 26.3% (5 patients), the projected overall survival (OS) was 57% at 2 years following HSCT. The regimen intensity did not translate to any difference in OS (p=0.38). The same was true for comparisons of related or unrelated (p=0.61) and HLA-matched and mismatched donors (p=0.76). Engraftment failure or graft rejection was seen in 21.0% (4 patients), all but one following RIC. OS seemed to be better in patients with a spleen of <10 cm below costal margin at the time of transplant (Fig. 1), albeit this has not reached statistical significance (p=0.35). The spleen size was also not significant for time to engraftment of leukocytes and thrombocytes (p=0.28 and p=0.23, respectively). Surprisingly, myeloablative conditioning led to earlier engraftment of leukocytes (median 16 days) than RIC (23 days; p=0.01, Mann-Whitney test). Venoocclusive disease (VOD) was present in 52.6% (10 patients), without any impact of the regimen intensity. However, the presence of VOD grade 2-3 significantly deteriorated the projected OS at 2 years (22.2% *vs* 75.0%; p=0.01). The presence of acute graft-vs-host disease (aGvHD) in 47% (9 patients) also tends to impair OS (23.8% vs 90.0%; p=0.07). The incidence of aGvHD significantly correlated with the incidence of of VOD (p=0.04). Among pretransplant characteristics, notably both patients with Lille score 2 died. Patients with erythroblasts in peripheral blood at diagnosis tended to have poorer OS (p=0.12). Alike, immature granulocytes at diagnosis seemed to predict worse OS (p=0.27). *Discussions and conclusions*. Allogeneic transplantation offers a chance for long-term OS for high-risk patients with primary myelofibrosis. Many of the weaker associations described above may become significant if a larger number of patients is studied. We believe that proper selection of patients for HSCT (without significant numbers of immature granulocytes and normoblasts, without gross splenomegaly, transfusion-independent) will substantially improve the long-term results.

0329

REDUCED INTENSITY CONDITIONING STEM CELL TRANSPLANTATION FOR HIGH RISK AML AND MDS - OUTCOME OF PATIENTS IN A SINGLE CENTER

M. Uzunov,[1] S. Wittnebel,[2] C. Boccaccio,[2] J.H. Bourhis[2]

[1]*Hopital Pitié-Salpetriere, PARIS;* [2]*Institut Gustave Roussy, VILLEJUIF, France*

Background. Reduced intensity conditioning (RIC) hematopoietic stem cells transplantation (HSCT) was developed in order to obtain long term disease control using graft-versus-disease (GVD) effect in a variety of patients unfit for a standard transplantation procedure. *Aims.* We aimed to assess the long term disease control after a RIC HSCT. *Methods.* We retrospectively assessed the medical records of 43 consecutive AML and MDS high risk patients transplanted in a single center between 2000 and 2006. *Results.* The majority of patients (97%) were older than fifty, median age of 56. RIC was proposed to the four younger patients because of invasive fungal infection (2patients), heart failure (1patient) and relapse after a previous standard HSCT (1patient). RIC was considered in older patients because of the high risk MDS or leukaemia: failure of first line chemotherapy (8 patients - 18.6% in 2nd complete remission), partial remission (6 patients -14%), poor risk cytogenetics (14patients - 32.5%) or molecular biology features(Flt3+ - 3patients - 6.9%), secondary leukaemia (8patients - 18.6%), detectable minimal residual disease (1patient - 2.3%). Thirty nine patients received a Fludarabine based conditioning regimen. Fludarabine was associated to TBI2Gy, Busulfan, ATG, Endoxan, Ida, Ara-C and 4 patients received 6 Gy TBI associated to 60mg/kg cyclophosphamide. 29 patients - 67% received SCT from an identical sibling, 11 patients- 26% from an MUD and 3patients- 7% from un unrelated cord blood. Post transplant immunosuppression consisted in CSA and/or MMF or short course MTX. Engraftement was achieved in 41 patients (96%) - 1 patient died on D10 and was not assessed for engraftement and 1 patient rejected his graft. Cumulative incidence of acute and chronic GVHD was 30% (13 patients). With a median follow up of 43 months (range 12-94) 22 patients (52%) are alive and 18 in complete remission (CR) and 21 died. Death was due to disease progression - 16 patients (37%), due to sepsis in the context of severe GVHD - 2 patients, to respiratory failure - 2 patients, fulminant hepatitis - 1 patient and due to complications of severe psychiatric disease - 1patient. The estimated OS for the whole group was 52% at 3 years and 48% at 4 years. For the AML patients the 3 years OS was 48%. The estimated 3 years OS was 49,6% for patients receiving a graft from an identical sibling and 64,3% from a MUD. Estimated 3 years DFS was 75% in patients experiencing either acute or chronic GVHD and 29% in the absence of GVHD. Durable remission was achieved in 57,9% of the pts in CR1 compared to 28.6% of pts beyond CR1. *Conclusions*. Less than 25% of patients older than 50 treated with chemotherapy alone are long term survivors, failure of first induction and bad risk blasts karyotype carries usually a dismal prognostic with a very high incidence of relapse. Our results support the use of RIC HSCT for patients having high risk myeloid malignancies which are not candidate for a conventional allogeneic HSCT. Transplant in CR1, GVHD and graft from a MUD seem to be associated with a better outcome

SINGLE UK CENTRE EXPERIENCE OF ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CHRONIC MYELOMONOCYTIC LEUKEMIA

Z.Y. Lim, P.K. Krishnamurthy, W. Nagi, M. Kenyon, A.Y.L. Ho, G.J. Mufti, A.P. Pagliuca

Kings College London and Kings College Hospital, LONDON, UK

Background. Chronic myelomonocytic leukemia (CMML) carries a relatively poor prognosis with a median survival of 20-40 months with transformation to acute myeloid leukaemia in up to a third of cases. Allogeneic stem cell transplantation is a potentially curative treatment for CMML but data regarding outcomes is limited. *Aims*. We performed a single centre retrospective analysis on the outcomes of 18 patients who have received allogeneic transplantation at King's College Hospital, London since 1988. *Patients and Methods*. The median recipient age was 54 years and the median Dupriez score was 2. 41 patients had CMML and 39% had Acute Myeloid Leukaemia (AML) transformed from CMML. 25% of the cohort had complex cytogenetic abnormalities. The median interval from diagnosis to transplant was 20.9 months. All but one patient received induction chemotherapy prior to transplant, with most patients receiving either one (53%) or two (12%) courses of a FLAG or FLAG-Ida containing regimen. Two patients had previously undergone autologous stem cell transplantation. Conditioning was with a T-cell depleted reduced intensity conditioning regimen, Fludarabine/Busulphan/Campath (FBC, 83% of patients) or Fludarabine/Busulphan/ATG (11%). 1 patient (6%) was treated with a myeloablative Bu/CY regimen. 56% of the transplants used male donors; 39% of the donors were HLA-matched siblings, 44% were HLA-matched unrelated donors, with 17% HLA-mismatched unrelated donors. The source of progenitor stem cells was peripheral blood in 67% of cases.

Results. The median time to neutrophil and platelet engraftment was d+17 and d+19 respectively. No patients experienced primary graft failure. The median follow-up of the cohort was 895 days. The 2-year survival of the cohort was 31%, with a relapse incidence of 43%. The median time to relapse was 202 days post-transplant. Transplant-related mortality at 2-years was 33% with the primary cause of death secondary to GvHD and infection. CMV reactivation occurred in 6 patients at a median of 45 days post-transplantation. Acute GvHD occurred in 39% of patients at a median of 65 days post-tramsplanation: skin GvHD (60%), gut GvHD (14%) or both. A total of 6 patients received DLI post-transplant (median: d+232 post transplant). The indication for DLI was loss of chimerism in 4 cases and for morphological relapse in the other 2 cases. 3 of the patients who received DLI subsequently developed GVHD. However, only 2 patients had a response to DLI (both with initial loss of chimerism), with restoration of chimerism. *Conclusions*. In a cohort of patients with high risk CMML, our data suggests that allogeneic transplantation is a feasible therapeutic option in patients with CMML, with durable responses achievable in a proportion of patients.

ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION FROM UNRELATED DONORS FOR CHRONIC LYMPHOCYTIC LEUKAEMIA: A POPULATION-MATCHED ANALYSIS FROM THE EBMT REGISTRY

M. Michallet,[1] P. Dreger,[2] A. Van Biezen,[2] M. Sobh,[3] D. Milligan,[2] D. Niederwieser,[2] L. Sutton,[2] A. Buzyn,[2] R. Tapani,[2] A. Nagler,[2] J. Schetelig,[2] V. Koza,[2] T. De Witte[2]

[1]Hôpital Edouard Herriot, LYON, France; [2]EBMT CLL Sub-committee CLWP, LEIDEN, Netherlands; [3]Edouard Herriot Hospital, LYON, France

We performed from the EBMT registry a population-matched analysis of allogeneic for CLL after either myelo-ablative or non myelo-ablative conditioning. Two hundred ninety four patients were studied, 161 from HLA identical siblings and 133 from unrelated donors. We matched the centre, the type of conditioning (standard or reduced intensity), recipient gender and age, HSC source, year of transplantation and we defined almost 3 common factors. We then obtained 120 pairs matched allotransplantations, 60 in each group (Table 1). In group 1, on 59 evaluable patients, 28(47%) developed acute GVHD with 15(25%) ≥grade II [12(20%) grade II and 3(5%) grade IV], on 58 evaluable patients, 21(36%) patients developed cGVHD [10limited and 11(19%) extensive]. At the last follow-up, 21(35%) patients relapsed and, 23 patients died and 37 are alive. In group 2, on 57 evaluable patients, 37(65%) patients developed acute GVHD with 24(42%) ≥grade II [15(26%) grade II, 7(12%) grade III and 2(4%) grade IV], on 50 evaluable patients 30(60%) developed cGVHD (15 limited and 15(30%) extensive). At the last follow-up 10 patients (17%) relapsed, 27died and 33 are alive. We found a very significant difference concerning the non relapse mortality with 12% (2-19) for group1 and 39% for group2 (p<0.001). In addition, we observed no significant difference concerning the probability of overall survival and event-free survival at 3 years: for group 1, 66% (54-81) and 56%(44-72) respectively with a median follow-up of 45 months (3-109) and for group2, 52% (39-68) and 46% (34-62) respectively with a median follow-up of 35 months (6-76) (p=0.11 and p=0.24). In conclusion, this study showed no difference between group 1 and group 2 due to higher non relapse mortality after unrelated transplantation and higher relapse rate after related transplantation for CLL.

Table 1.

Variables	Related (Group 1)	Unrelated (Group 2)
Gender : Male/Female	49 (81.6%) /11(18.4%)	48 (80%) / 12 (20%)
HSC Source BM/PBSC	5 (8.3%) / 55 (91.7%)	6 (10%) / 54 (90%)
Conditioning Std/RIC	6 (10%) / 54 (90%)	6 (10%) / 54 (90%)
ABO Compatibility Comp/Minor/Major	39(65%)/4(6.6%)/14 (23.4%)	26(43.3%)/11(18.3%)/19(31.6%)
Patients median age (Min-Max)	54 (37-66.5)	51.5 (35-66)

DOUBLE UMBILICAL CORD BLOOD TRANSPLANTATION IN PATIENTS WITH HIGH RISK HEMATOLOGICAL DISEASES: A SINGLE-CENTRE EXPERIENCE

A. Ruggeri,[1] R. Peffault de Latour,[2] V. Rocha,[2] M. Carmagnat,[3] J. Larghero,[4] A. Madureira,[2] M. Robin,[2] C.A. Rodrigues,[2] D. Rea,[4] R. Traineau,[5] P. Ribaud,[2] C. Ferry,[2] A. Devergie,[2] C. Rabian,[3] A. Toubert,[3] E. Gluckman,[2] G. Socié[2]

[1]Bone Marrow Transplantation unit, PARIS; [2]Service d'Hématologie Greffe, PARIS; [3]Service d'Immunologie, PARIS; [4]Unité de Thérapie cellulaire, PARIS; [5]Service d'Hémobiologie, PARIS, France

Background. Double cord blood transplantation (dUCBT) has extended cord blood use to adults with hematological disease. *Aims.*We report a phase II study on 35 dUCBT from 2004 to 2007. *Methods.* Twentythree patients had high risk hematological malignancies (ALL=6, AML+MDS=8, secondary AL=5, CML=2, Hodgkin disease= 2) and 12 high risk of rejection (SAA=5, PNH=1, Fanconi Anemia=6). Among all patients, 9 (28%) (3 AML, 3 SAA, 1 FA, 1 MDS and 1 CML) had undergone previous non-engrafted transplants. Previous transplant source was UCB and BM in 5 and 4 cases respectively. Analyses of T, B and NK cells phenotype were done once a month during first 3 months and ever 3 months until 12 months. Patient data were collected after obtaining informed consent.Median age was 35 years (6-55) median weight was 59kg (17-90). Median follow-up was 17 months (4-39). Half of patients (n=17) received myeloablative conditioning, reduced intensity regimen was performed mostly for second transplant and 22 patients received ATG. Most of cord blood units were 4/6 or 5/6 HLA A, B and DR match with the patient. GVHD prophylaxis consisted in cyclosporine+steroids in 21 patients (60%) and associated with mycophenolate in 14 (40%). Median infused cell doses were 4×10^7 NC/Kg (1.8-9.7) and 3×10^5 $CD34^+$cells/Kg (0.5-7.46). *Results.* Twentyfive patients (71%) engrafted at median time of 25 days (11-42). Before day 100, chimerism data were evaluable in 29 patients. A single UCB unit predominated in 18 patients showing full donor chimerism. Mixed chimerism was detected in 6 patients and 5 patients had autologous recovery. After day 100, 16 out of 19 evaluable patients mantained complete donor chimerism and 3 had evidence of both UCB units engraftment. Acute GVHD was observed in 18 patients (43%) (grade III-IV, n=6) and chronic GVHD in 15 out of 26 patients at risk. During the first 100 days 19 CMV reactivations were detected; 4 HSV (resistant to acyclovir); 1 HHV6-meningoencephalitis; 4 EBV reactivations; 3 adenovirus diseases, 4 VRS infections, 3 septicemias, 6 fungal infections, 2 toxoplasmosis. After day 100 we observed 5 CMV reactivations, 1 CMV disease, 1 HSV, 1 EBV-PTLD and 3 fungal infections. Delayed immune reconstitution was observed in all patients with important lymphopenia. Median numbers of lymphocytes were 352 mm^3 at 3 months (n=15); 460 at 6 months (n=13) and 703 at 9 months (n=13). Median numbers of CD3/CD4 at 3, 6 and 9 months were: 34, 40, and 49 mm^3, respectively; of NK cells 223, 294 and 368 mm^3 and of B cells were 1, 5 and 65 mm^3, respectively. At 12 months overall survival was 56 (±8%). Relapse occurred in 5/35 patients (18%) and was major cause of death in 3 of them. TRM at 6 months was 39%±9. Infection was a major cause of death in 7 subjects. Five out of 9 patients have been rescued of previous non-engraftment and are alive and well (5-37 months). Conclusion:dUCBT is an option to treat patients with high risk diseases lacking a suitable HLA matched donor despite a long lasting immune deficiency.

0333

HIGH DOSE IMMUNOSUPPRESSIVE THERAPY (HDIT) WITH AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION (AHSCT) IN MULTIPLE SCLEROSIS (MS): CLINICAL AND PATIENT-REPORTED OUTCOMES

Y.L. Shevchenko,[1] A. Novik,[1] A. Kuznetsov,[1] B. Afanasyev,[2] I. Lisukov,[3] O. Rykavicin,[4] T. Ionova,[5] V. Melnichenko,[1] D. Fedorenko,[1] S. Shamanski,[4] A. Kishtovich,[5] R. Kruglina,[1] A. Kondrashov,[1] R. Ivanov,[1] G. Gorodokin[6]

[1]Pirogov National Medical Surgical Center, MOSCOW, Russian Federation; [2]Department of Bone Marrow Transplantation, Pavlov State Medical University, ST. PETERSBURG, Russian Federation; [3]Institute of Clinical Immunology, Siberian Branch of Russian Academy of Science, NOVOSIBIRSK, Russian Federation; [4]Department of Haematology, Burdenko Central Military Hospital, MOSCOW, Russian Federation; [5]Unit of QoL Research in BMT, Multinational Center of Quality of Life Research, ST. PETERSBURG, Russian Federation; [6]New Jersey Center for Quality of Life and Health Outcome Research, NEW JERSEY, USA

During the last decade HDIT+AHSCT has been used with increasing frequency as a therapeutic option for MS patients. The goal of our research was to study long-term treatment outcomes in patients with different types of MS after early, conventional and salvage/late HDIT+AHSCT. Fifty-six patients with MS (secondary progressive - 27 patients, primary progressive -10, progressive-relapsing - 1, and relapsing-remitting - 18) from 6 medical centers were included in this study (mean age - 32.0, range: 17-51; male/female - 22/34). Fourteen patients underwent early AHSCT (EDSS 1.0-3.0), 38 patients - conventional (EDSS 3.5-6.5) and 4 patients - salvage/late AHSCT (EDSS 7.0-8.5). Median EDSS at base-line was 6.0 (range 1.5-8.0). The median follow-up duration was 18 months (range 6-84 months). Neurological and quality of life (QoL) evaluation was performed at baseline, at discharge, at 3, 6, 9, 12 months, and every 6 months thereafter following HDIT+AHSCT; MRI examinations - at baseline, at 6, 12 months, and at the end of follow-up. FACT-BMT and FAMS were used for QoL evaluation. Notably, no transplant-related deaths or unpredictable severe adverse events were observed. All of 45 patients included in the efficacy analysis experienced improvement (n=28) or clinical stabilization (n=17). Among the patients with improvement there were 15 SPMS, 4 PPMS, 8 RRMS and 1 PRMS; 9 SPMS, 4 PPMS and 4 RRMS stabilized. Among the patients with improvement there were 20 patients after conventional, 6 - after early and 2 - after salvage AHSCT. In the group with stabilization there were 15 patients after conventional AHSCT and 2 - after salvage AHSCT. Two patients (SPMS and PPMS; conventional AHSCT) deteriorated to a worse score after 18 months of stabilization; 2 others progressed after 12 and 30 months of improvement (RRMS, early AHSCT and SPMM, conventional AHSCT), respectively. Results of MRI scans were available in 37 patients. Sixteen patients (43.3%) had active lesions at baseline and all turned to inactive status except two cases. Of the 21 patients without active lesions pretransplant 20 remained inactive, whereas one patient showed disease activity after transplantation. No active, new or enlarging lesions were registered in patients without disease progression. Out of 24 patients included in QoL analysis 22 exhibited improved QoL 6 months post-transplantation. Further QoL improvement was observed at longer follow-up. All the patients with out disease progression were off therapy throughout the post-transplant period. In conclusion, HDIT+AHSCT appears to be an effective treatment for MS both in terms of clinical and patient-reported outcomes. The data obtained point to feasibility of early, conventional and salvage transplantation in MS patients. Further studies should be done to establish the best timing for transplantation and to validate regimens for early, conventional and salvage/late HDIT+AHSCT.

0334

IMPACT OF DONOR AND RECIPIENT BIRTH ORDER ON OUTCOME OF HLA-IDENTICAL SIBLING STEM CELL TRANSPLANTATION (SCT) IN ACUTE MYELOID LEUKEMIA (AML)

C. Dobbelstein, H. Kamal, E. Dammann, E. Weissinger, M. Stadler, J. Krauter, A. Ganser, M. Eder

Hannover Medical School, HANNOVER, Germany

Background. Among well established risk factors for outcome of SCT such as patient´s age, HLA-identity between donor (D) and recipient (R), stage of disease, the impact of primacy of birth in HLA-identical sibling transplantation has recently been described in a retrospective analysis (Bucher *et al.* Blood 2007). In this cohort, first-born patients had the best survival, the lowest incidence of acute graft-versus host disease (aGvHD), and a reduced relapse mortality rate. The underlying mechanism may include pre-existing microchimerism due to fetomaternal and transmaternal sibling cell trafficking in younger siblings. *Aims.* The aim of this study was to analyze the impact of relative birth order of recipients and donors on outcome of HLA-identical sibling SCT in AML. *Methods.* We retrospectively analyzed HLA-identical sibling transplantation for all consecutive evaluable patients with *de novo* AML from 1986 to 2007 at our centre. 123 patients transplanted from HLA-identical siblings were assigned to one of two groups: 61 recipients had an older sibling donor (D>R group), and 62 patients were older than their donors (R>D group). Data for age, sex, stage of disease, cytogenetics, transplantation date, conditioning regimen, stem cell source, T-cell depletion, incidence and severity of acute GvHD, relapse rate, relapse mortality (RM), overall survival (OS), and treatment-related mortality (TRM) were analysed. *Results.* Both groups were comparable for sex, transplantation date, high-risk cytogenetics, conditioning regimen, stem cell source, and T-cell depletion. In contrast, the R>D group encompasses slightly more patients with primary induction failure prior to SCT (10% *vs* 2%, p=0.05). Median age and follow-up (FU) were 38 years (range: 17-65 years) and 32 months (range: 0.3-187 months) for the D>R group, and 41 years (range: 21-66 years) and 34 months (range: 0.6-220 months) for the R>D group, respectively. In the D>R group, there was a trend for higher incidence of aGvHD ≥II° as compared to the R>D group: 33% *vs* 19% (p=0.09). In addition, relapse incidence in the D>R group seems to be higher than in the R>D group (30% *vs* 18%, p=0.12) with a higher RM (25% *vs* 8%, p=0.01) as compared to the D>R group. In contrast, TRM was not different among both groups (26% *vs* 27%). Finally, OS at 180 months was 60% ±7.1% and 39% ±7.9% for the R>D group and the D>R group, respectively. *Conclusions.* In AML, a trend to superior OS, lower incidence of aGvHD ≥II°, and lower relapse incidence and a reduction in RM were observed in recipients transplanted from younger sibling donors. These data on a homogeneous group of AML patients are in line with a previous report on a cohort of patients with heterogeneous diseases. Multi-centre studies for specific diseases are required to establish the impact of donor and recipients birth order on outcome of HLA-identical sibling transplantation.

0335

INFLUENCE OF GRAFT COMPOSITION ON OUTCOME OF ALLOGENEIC PERIPHERAL BLOOD STEM CELL TRANSPLANTATION. LOW CD34+ CELLS PREDICTED LOW TRM IN PATIENTS WITH STANDARD-RISK HAEMATOLOGICAL MALIGNANCIES

F. Bijou,[1] R. Tabrizi,[2] X. Lafarge,[1] M. Sauvezie,[2] J.M. Boiron,[1] K. Bouabdallah,[2] T. Leguay,[2] D. Fizet,[1] A. Pigneux,[2] G. Marit,[2] C. Foucaud,[2] S. Vigouroux,[2] M. Dilhuydy,[2] R. Bouzgarou,[1] B. Dazey,[1] C. Melot,[2] N. Milpied[2]

[1]Etablissement Français du Sang, BORDEAUX; [2]CHU de Bordeaux, Service Maladies du Sang, PESSAC, France

Many reports have studied factors associated with the donor influencing outcome of patients (pts) after allogeneic transplantation. We have reviewed the influence of cell subsets [CD34, B, T, NK] of granulocyte-colony-stimulating factor mobilized peripheral blood stem cells (G-PBSC) on clinical outcome in 78 allogeneic transplantations from January 2002 to December 2006 for pts with standard- risk myeloid and lymphoid malignancies in a single center. All grafts were monitored for CD34 median 6,8×10^6/kg (1,7-28.1), CD19: 45.2×10^6/kg (6-152), CD3: 180×10^6/kg (24-567), CD56$^+$cells: 25.3×10^6/kg(2-115)). Diagnoses included standard-risk diseases N= 78 (Chronic lymphocytic leukaemia, low grade lymphoma, high grade lymphoma in first CR, AML/ALL first CR, Refractory anaemia with ringed sideroblasts of myelodysplastic syndrome, chronic myeloid leukaemia first CP, multiple myeloma in CR or partial remission). G-PBSCs have been harvested from 54 matched related and 24 unrelated donors (MRD and MUD). The pts and donors median age was 53 yrs old (23-65) and 46 (24-67) respectively. Eleven myeloablative and 67 reduced intensity conditioning regimens were administered and followed by cyclosporine A alone or±mycophenolate mofetil or±methotrexate. The median follow-up was 19 months. 71 pts engrafted. Cumulative incidence (CI) of day 100 grade 2-4 aGVH and 3 years cGVH were 33 % and 61 % respectively. CI of TRM, Relapse, EFS and OS at 3 yrs were 27 %, 33 %, 53% and 59 % respectively. In univariate analysis, low TRM was correlated with low CD34 (p=0,02), low B cells (p=0,047) and MRD (p=0,005). Low relapse incidence (RI) was strongly associated with low NK cells number (p=0,007), donor chimerism

(p<0,001) and cGVH (p=0,05). Type of donor and cGVH predicted better EFS (p=0,001 and p=0,03) respectively. NK cells, cGVH and type of donor offered better OS respectively (p=0,03; p=0,005 and p=0,01). In multivariate analysis, low NK cells number is the only factor affecting independently RI [95% confidence interval, 1-7, RR=2,6 (p=0,05)]. cGVH is affecting independently OS (p=0,04). These results show a role of NK cells in relapse to be futher explored.

0336

OUTCOMES OF PATIENTS RELAPSING FOLLOWING T-CELL DEPLETED REDUCED INTENSITY CONDITIONING ALLOGENEIC TRANSPLANTATION FOR MDS OR AML

Z.Y. Lim, T. Munir, S.G. Gandhi, M. Kenyon, A.Y.L. Ho, A.P. Pagliuca, G.J. Mufti

Kings College London and Kings College Hospital, LONDON, UK

Background. Disease relapse following reduced intensity conditioning allogeneic stem cell transplantation remains one of the major causes of post-transplant mortality, particularly in patients with AML or MDS. Management of these patients poses a significant challenge and at present, it remains unclear as to the optimal form of treatment for this subgroup of patients. *Aims*. We retrospectively reviewed the outcomes of 162 consecutive patients treated with a uniform fludarabine/busulphan/alemtuzumab RIC allograft regimen at Kings College Hospital, London from 2003-2006. We identified 40 patients with high risk MDS and AML who had relapsed following allograft and proceeded to review the management and outcomes of these patients. *Methods.* The median recipient age of time of transplantation was 54.5 years. The diagnoses were MDS=18 (45%), AML=18 (45%), CMML=4 (10%). The stem cell source for the initial transplant was PBSC in 34 cases (85%), and bone marrow in 6 (15%). 16 patients (40%) received stem cells from a sibling donor with 24 from an unrelated donor (60%). The median number of courses of intensive chemotherapy received prior to transplant was 2 courses (range: 1-7). The median time to disease relapse post-HSCT was 259 days (range: 34-1034). 13 patients had cytogenetic relapse and 27 had frank morphological relapse of disease (>5% blasts in bone marrow). Patients were analysed according to 4 groups: 12 patients (30%) did not receive further treatment and only received supportive care. 6 patients (15%) were treated with escalating doses of DLI alone. 8 patients (20%) received chemotherapy alone. 14 patients (35%) received a combination of re-induction chemotherapy followed by DLI. *Results*. The median survival post-relapse was 162 days (95%CI: 57-266). There was no significant difference in recipient age, disease type, stem cell source, type of relapse (cytogenetic/morphological) or stem cell dose between the subgroups. The median survival of the 4 groups was: supportive care (35 days), DLI only (147 days), chemotherapy alone (207 days), intensive chemotherapy + DLI (1033 days). There was no significant difference in the survival outcomes between patients receiving chemotherapy or chemotherapy + DLI (p=0.57), but patients who received chemotherapy + DLI and a significantly improved outcome when compared with those receiving DLI alone (1 year actuarial survival: 62% *vs* 0%, p=0.02). *Conclusions*. Our findings are consistent with published data indicating that the use of DLI alone is ineffective for the treatment of AML or MDS patients with morphological relapse post-transplantation. However, the use of re-induction chemotherapy followed by DLI can potentially induce durable long-term remissions in a significant proportion of patients.

0337

RESPONSE TO COMBINED USE OF DONOR LYMPHOCYTE INFUSIONS AND IMATINIB MESYLATE IN PATIENTS RELAPSED AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR CHRONIC MYELOID LEUKEMIA

P. Bavaro,[1] F. Pompetti,[2] P. Olioso,[1] G. Papalinetti,[1] S. Santarone,[1] P. Di Carlo,[1] E. Di Bartolomeo,[1] P. Di Bartolomeo[1]

[1]Centro Trapianti Midollo Osseo, PESCARA; [2]Dip. Medicina Trasfusionale, Laboratorio Biologia Molecolare, PESCARA, Italy

Imatinib Mesylate (IM) is an effective drug against chronic myeloid leukemia (CML) and actually it has become the standard therapy for patients with newly diagnosed CML-chronic phase. IM is able to induce remission also in patients with CML who relapse following allogeneic stem cell transplantation (SCT). Nevertheless, IM should be continued indefinitely in responding patients because usually leukemia recurs when the drug is stopped. Donor lymphocyte infusions (DLI) are very successful in restoring complete remission for patients who relapse in chronic phase after SCT. Unfortunately, DLI can be complicated by potentially life-threatening graft-versus-host disease (GvHD) and myelosuppression. To study the possible synergy between DLI and IM, we assigned the CML patients with relapse after SCT to receive IM 400 mg/die and DLI in escalating doses of 1, 5 and 10×10^7 CD3+cells/kg given every 6 weeks provided there were persistence of relapse and absence of clinical signs of GvHD. It was scheduled to stop IM therapy after 3 months of continuous molecular remission (MR), defined as undetectable BCR/ABL transcripts PCR on bone marrow and peripheral blood samples. Four CML patients allografted from HLA-identical sibling between January 1998 and January 2001, who showed recurrent disease at a median of 62 months (range, 28-101) following SCT, entered this study. One patient was in molecular relapse, 2 in cytogenetic relapse, and 1 in hematologycal relapse. The median duration of IM therapy was 180 days (range, 170-220). The median number of DLI was 2 per patient (range, 2-3). The total $CD3^+$ cells dose infused per patient was $1,5\times10^7$/kg, $5,1\times10^7$/kg, 6×10^7/kg, and 15×10^7/kg, respectively. The first dose of DLI was reduced to 0.5×10^7 $CD3^+$ cells/kg because of limited chronic GvHD in the patient who was in molecular relapse. The subsequent dose was delayed by 12 weeks. The patient with haematological relapse underwent IM therapy for 4 years. He obtained the MR and 6 months later a reduction of IM to 200 mg/die was attempted. Following 12 weeks of treatment at this dosage, a molecular relapse was diagnosed. He received DLI and achieved a new MR which is maintained at 7 months after IM discontinuation. The other three patients started combined therapy with IM and DLI at a median of 2 months (range, 2-3) following diagnosis of relapse. They reached the MR at median of 3 months (range, 2-4) of treatment. All 4 patients are currently off-therapy. A continuous MR is maintained at a median of 7 months (range, 2-14). No signs of acute or chronic GvHD were observed and haematological values remained constantly in normal range. The combined therapy was generally well tolerated. In our small series, the fast achievement of a complete MR, the persistence of response after the IM discontinuation and the absence of GVHD are of interest. These observations suggest a potential synergy between cytoreductive ability of IM and immune-mediated cures of CML by DLI, despite the concern of reported immunosuppressive effect of the IM. These preliminary results are particularly encouraging and deserve further studies with more patients and longer follow-up.

0338

THE COMPARISON BETWEEN MATCHED RELATED DONOR AND ALTERNATIVE DONOR FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACQUIRED APLASTIC ANEMIA: KSBMT2007-02 STUDY

H. Kim,[1] H.H. Koo,[2] H. Kook,[3] B.S. Kim,[4] S.H. Kim,[5] H.K Kim,[6] H.J. Kim,[3] S.H. Bae,[7] J.J. Seo,[8] S.K Sohn,[9] H.J Shin,[10] H.S. Ahn,[11] J.H. Won,[12] S.S. Yoon,[11] Y.H. Lee,[13] D.C. Jeong,[14] D.Y. Jo,[15] Y.D. Joo,[16] M.S Hyun,[17] K.H. Lee[8]

Backgound. Although allogeneic hematopoietic stem cell transplantation (alloSCT) from matched related donor (MRD) is a standard therapy for severe acquired aplastic anemia (AA), alternative donor (AD) alloSCT is increasing and the survival of alloSCT from AD improves nowadays. *Aims.* We planned this study to review the recent result of alloSCT survival and to compare AD with MRD. *Methods.* A retrospective study comparing MRD and AD for alloSCT in patients with AA was conducted by Korean Society of Blood and Marrow Transplantation (KSBMT2007-02 study). *Results.* The patient population was AA, pure red cell aplasia, paroxysmal nocturnal hemoglobinuria, and they underwent alloHSCT from 1997 and 2007. Total 336 patients were enrolled in 24 Korean alloSCT centers. Survival analysis was done in 331 patients because data were not available in 5 patients. Two hundred five adult patients with AA were also analyzed to define the characteristics of adult AA patients. AA was 97.3% and median age at alloSCT was 20.4

(1-62) years old. Median time from diagnosis to alloSCT was 6.2 (0.2-248.4) months. Male was 48.9%. Seventy nine percent patients received bone marrow (BM) as a stem cell source. AD had longer time from diagnosis to alloSCT (p=0.049) and received more peripheral blood (PB) or cord blood (CB) as a stem cell source (16.3% *vs* 31.7%, p=0.004). Univeriate analysis showed MSD (p<0.001), age less than 15 years (p=0.010), BM as stem cell source (p=0.036) and disease duration less than 12 months (p=0.007) were significant predictor for better survival. However, multivariate analysis revealed that donor type was not significant factor (p=0.087) whereas age and BM was predictors for better survival. When 205 adult AA patients were analyzed, AD had more graft failure (p=0.005), delayed neutrophil engraftment (p=0.035), more acute graft versus host disease (GvHD; p=0.009). However, there were no different between AD and MRD in terms of platelet engraftment (p=0.618), incidence of SOS (p=0.735) and relapse rate (p=0.360). MRD (p=0.011), age less than 30Y (p=0.001), disease duration less than 12M (p=0.003), no prior immune suppression therapy, (p=0.007) and platelet transfusion less than 90U (p=0.010) significantly affected survival. Only age and platelet transfusion were significant factor for better survival in multivariate analysis. *Summary.* In conclusion, our study showed that donor type was not a significant factor for survival. Therefore, AD should be considered earlier when there is no MRD in patients with AA.

0339

CURRENT STATUS OF THE KOREA MARROW DONOR PROGRAM (KMDP) AND ITS INTERNATIONAL COOPERATIVE ACTIVITIES

J. Seo,[1] E. Choi,[1] H. Im,[1] B. Kim[2]

[1]Asan Medical Center, SEOUL; [2]Korea Marrow Donor Program, SEOUL, South-Korea

Background. The KMDP was established in March 1994 to facilitate the unrelated hematopoietic cell transplantation (HCT) in Korea. After the first case of unrelated HCT in July 1996, 1,000th case of unrelated HCT facilitated by the KMDP was achieved in October 2006. The need for HCT is steadily increasing, but the possibility of finding a matched related donor is becoming more difficult in Korea. *Aims*. We tried to evaluate the domestic and international coordinating activities of KMDP to enhance the feasibility of unrelated HCT in patients who do not have matched related donor. *Methods*. Data on unrelated HCT using unrelated adult donor and unrelated umbilical cord blood collected by KMDP until Dec. 2007 was analyzed retrospectively. *Results*. The cumulative number of patients who underwent unrelated HCT through the coordination of the KMDP doubled during recent 3 years. The cumulative number of volunteer donors registered at the Korea Network of Organ Sharing (KONOS) reached 144,970 by Dec. 2007. The match rate for a Korean patient who requested donor search through KMDP to find HLA-matched volunteer donor registered at KONOS was 72% in 2007. The most common cause of UBMT was AML followed by ALL, CML, SAA, MDS and other miscellaneous disorders in the descending order. The KMDP established the Korea Network for Cord Blood (KoreaCord) in June 2001, and 14,307 cord blood units are preserved at the KoreaCord by Dec. 2007. The number of cord blood transplantations in Korea reached 364 cases by the end of 2007, and it includes the 223 cases facilitated by KMDP using the units of the KoreaCord (197 pediatric patients, and 26 adult patients). The levels of HLA tests for volunteer donors registered at KONOS were serologic for HLA-A, -B, and DNA level for HLA-DR for those registered until early 2001. Since the latter half of 2001, all the volunteer donors are tested at DNA level for HLA-A, -B, -C, and -DR. The major international cooperations of KMDP with foreign registries has been with the Japan Marrow Donor Program (JMDP) and Buddist Tsu Chi Stem Cell Center (BTCSCC) of Taiwan. The international cooperation between KMDP and JMDP was started in March 1999, and 136 Korean patients underwent unrelated HCT using JMDP donors by 2007. Also the KMDP facilitated unrelated HCT in 14 Japanese patients using KONOS donors. One hundred thirty Korean patients received unrelated HCT using donors from BTCSCC by 2007, which includes 23 cases facilitated by KMDP. The KMDP signed contract to cooperate donor exchange activities with NMDP in 2005, and with Chinese Marrow Donor Program (CMDP) in 2007. *Summary*. The KMDP is expanding the number and quality of volunteer donor registry, and the match rate for a Korean patient to find a matched unrelated donor is increasing. The international cooperative activities with foreign registries together with continuous development of the KoreaCord will further enhance the feasibility of unrelated HCT for patients who can not find matched related donor for HCT.

Stem cell transplantation - miscellaneous

HOMING OF LIN- / CD117+ HEMATOPOIETIC STEM CELLS IN LETHALY IRRADIATED MICE

J. Vavrova,[1] M. Rezacova,[2] S. Filip,[2] J. Mokry,[2] Z. Sinkorova[1]

[1]Faculty of Military Health Sciences, University of Defence, HRADEC KRALOVE; [2]Charles University, Faculty of Medicine in Hradec Kralove, HRADEC KRALOVE, Czech Republic

Background. High doses of ionizing radiation damage not only hematopoietic system, but also other tissues, such as intestinal epithelium or thymus. Very little is known about effect of transplantation of primitive hematopoietic cells on regeneration of these tissues after lethal irradiation. *Aims.* In this report, we describe the homing of hematopoietic stem cells (HSCs) to non-hematopoietic tissues in lethally irradiated (9 Gy) hybrid mice transplanted intravenously with lineage-/ CD117$^+$ bone marrow cells from ROSA-26 mice (lacZ$^+$). Methods and *Results.* On day 8 post irradiation, we were able to demonstrate recovery of hematopoiesis as the the number of CD117$^+$/B220$^-$ cells in the bone marrow reached the level of non-irradiated controls. Bone marrow CFU-GM numbers did not reach levels found in non-irradiated controls even 33 days after transplantation. Regeneration of differentiated cells in peripheral blood was significantly slower. On 12th day regeneration of lymphocytes was observed, increase in granulocytes was detected as late as on 33rd day. Transplanted cells containing lacZ gene were detected in reciepient hybrid mice by histochemistry and their location in the thymus, liver, stomach and ileum was followed during 33 days post transplant. On day 8 and 33 after transplantation, we found massive presence of donor (lacZ$^+$) cells in the thymus cortex. In the stroma of small intestinal villi, the lacZ$^+$ cells could be demonstrated sporadically on day 8 post transplant; higher positivity was seen in the stromal villi and lower positivity in lamina propria mucosae were observed on day 33 post transplant. By day 33 individual lacZ$^+$ cells were dispersed in relatively great numbers throughout the liver parenchyme. *Conclusions*. Transplantation of sorted lin-/ CD117$^+$ effectively resulted in hematopoietic recovery ensuring survival of lethally irradiated animal. Hematopoietic stem cell transplantation led not only to recovery of hematopoietic and lymphoid tissues but also facilitated recovery of the small intestinal mucosa, which was significantly damaged by ionizing radiation.

0341

FEASIBILITY OF A NEW RQ-PCR APPROACH FOR QUANTITATIVE AND SENSITIVE MONITORING OF CHIMERISM POST-BMT

G. Cazzaniga, F. Colnaghi, A. Colombo, V. Rossi

Clinica Pediatrica Univ. Milano-Bicocca, MONZA, Italy

Background. Allogeneic-BMT is extensively used to treat patients with hematological and metabolic diseases. Monitoring post-transplantation by chimerism analyses predicts negative events and allows to set up the appropriate preventive therapeutics before clinical symptoms. In this context, a quantitative analysis of chimerism kinetics, instead of simple qualitative detection, would permit an accurate evaluation of the kinetics of host cells in the post-BMT period. Until now, fluorescent-based PCR analysis of short tandem repeats (STRs) is the technique most used to document chimerism after allo-BMT. However, the sensitivity of this method is relatively low (detection level of a minor genotype is around 1%), mainly as a consequence of PCR competition biases. *Aims.* We evaluated the feasibility of a new approach for determining mixed chimerism based on real-time quantitative PCR (RQ-PCR) detection of insertion/deletion (ins/del) polymorphisms by TaqMan technology. *Methods.* Ins/Del polymorphisms of 2 to 5 nucleotides were selected to have a high minor allele frequency; one TaqMan Genotyping Assay has been developed, and two allele-specific PCR assays plus an internal control reference were used for post-BMT monitoring. The genotype screening was based on the delta-delta-Ct method by a dual probe TaqMan Genotyping Assay. Twenty-four ins/del sequence polymorphisms belonging to human biallelic loci were selected with an average minor allele frequency of 0.35, that will contain at least one marker that can distinguish between >99.5% of unrelated sample pairs. Markers with completely different genotype between donor and recipient, or heterozygous in recipient will have high $\Delta\Delta$-Ct, and thus can be considered as informative. The most informative marker can then be selected to be used in the post-transplantation quantitative chimerism monitoring. The quantification assays was run by allele-

specific oligonucleotide (ASO) PCR assay in two separate tubes (one per allele), and a third assay, specific for RNAse P, was used for the DNA normalization and run in a separate tube using the same DNA. *Results.* We evaluated the 24 markers' informativity on DNA samples from 5 recipient/donor pairs, 3 unrelated and 2 related. In all of them discrimination between recipient and donor genetic profile was possible, and thus quantification of mixed chimerism feasible. By using serial dilutions of mixed DNAs, the method showed a linear correlation with r higher than 0.98 and a sensitivity of 0.1%. *Summary*. The main advantage of the new ins/del RQ-PCR method over STR-PCR chimerism assays, in addition to the quantification, is the absence of PCR competition and plateau biases, thus resulting in greater sensitivity and linearity. The chimerism detection and monitoring workflow is simple, and it appears promising for the detection and quantification of a minor DNA genotype in a major one, as required for chimerism quantitative evaluation. Fluorescent-based PCR of short tandem repeats (STR-PCR) and real-time PCR ins/del chimerism assay will be compared for a panel of post-BMT follow up patients samples and presented. In conclusion, this new assay has the potential to provide an accurate quantitative assessment of mixed chimerism that can be useful in guiding early implementation of additional treatments in hematopoietic and non-hematopoietic stem cell transplantation.

0342

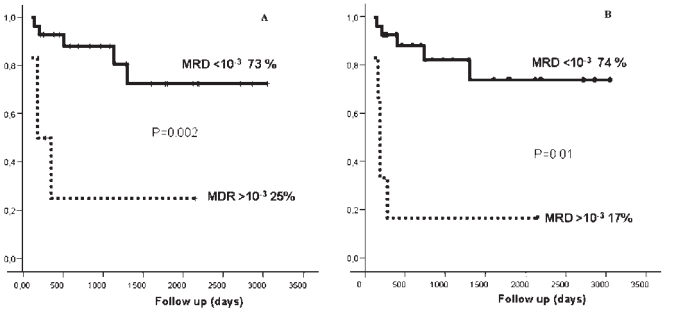
MINIMAL RESIDUAL DISEASE MONITORING AFTER ALLOGENEIC TRANSPLANTATION MAY HELP TO INDIVIDUALIZE POST-TRANSPLANT THERAPEUTIC STRATEGIES IN ACUTE MYELOID MALIGNANCIES

M. Díez-Campelo,[1] J.A. Pérez-Simón,[2] J.J. Pérez,[2] M. Alcoceba,[2] M.J. Arcos,[2] I. Graciani,[2] J. Richtmon,[2] C. Encinas,[2] M.D. Caballero,[2] F. Sánchez-Guijo,[2] M.C. López-Berges,[2] B. Vidriales,[2] J.F. San Miguel[2]

[1]Hospital Universitario, SALAMANCA; [2]Hematology, Hospital Universitario CIC, IBMCC (USAL-CSIC), SALAMANCA, Spain

Background. Allogeneic hematopoietic stem cell transplantation is a potentially curative treatment option for many patients with acute myeloid malignancies (acute myeloid leukemias (AML) and myelodisplastic syndrome (MDS)). However, relapse may occur in 15-50% of patients. Once relapse has occurred, rescue therapy usually remains unsuccessful. One of the most important factors which influence on the efficacy of the rescue therapy is tumor load at the time of relapse. In this regard, the monitoring of minimal residual disease (MRD) after transplant would allow to identify patients with impending relapse. *Aims.* The current study evaluates in 41 patients diagnosed with AML or high risk MDS the use of MRD monitoring before and after transplant in order to identify patients at high risk of relapse. *Results*. MRD assessment before and after transplant (days +21-56 and +100) allowed to discriminate different risk populations. Accordingly, the higher the MRD value, the worse the outcome, with MRD $</\geq 10^{-3}$ being the most significant cut-off values. Regarding relapse, results confirmed the importance of the negative predictive value (NPV) of MRD monitoring. Thus, the percentage of non relapses among patients with low MRD ($<10^{-3}$) at pre-transplant and at day +100 were 87 and 93%, respectively. Among 8 patients with positive MRD ($\geq 10^{-3}$) before transplant, all but 2 had died. Regarding 6 patients who displayed positive MRD on day +100 there were 5 events. The patient without event was the only one developing cGVHD. Fifty out of the 41 patients are currently alive. Overall TRM was 32% at 4 years. Projected overall and event free survival (EFS) at 4 years were 57% and 56%.

Figure 1. Impact of MRD on Overall (A) and Event free (B) survival at day +100.



Projected relapse free survival (RFS) at 4 years was 79%. Overall survival was 73% *vs* 25% at 4 years among patients with low ($<10^{-3}$) *vs* high MRD ($\geq 10^{-3}$) at day +100 after transplant, p=0.002; regarding EFS 74% of patients with low MRD were event free at 4 years as compared to 17% among patients with high MRD at day +100 (p=0.01) (Figure 1); finally, in terms of RFS 89% of patients with MRD $<10^{-3}$ were event free as compared to 40% among those with the higher value (p=0.003). Similar results were obtained with the same cut-off value at different days post-transplant (+21-56) and also in the pre-transplant analysis in terms of OS, EFS and RFS) (data not shown). In multivariate analysis MRD monitoring prior to transplant (HR= 6.3; (95% CI; 1.6-23.8), p=0.006) and at day +100 (HR= 30.2; (95% CI; 4-224.3), p=0.001) as well as chronic GVHD (HR=9.2; (95% CI; 2.1-39.3), p=0.003) had a favorable impact on EFS. *Summary*. In the present study we show that multiparametric flow cytometry evaluation of MRD during pre and early post-transplant period is a valuable tool for outcome prediction in patients with myeloid malignancies undergoing HCT and this method may allow early therapeutic intervention among patients identified as high risk.

0343

SURVIVAL IMPROVEMENT OF UNRELATED HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH REDUCED INTENSITY REGIMENS IN HIGH-RISK PATIENTS FOR AGE OR DISEASE (ON BEHALF OF GITMO)

A. Rambaldi,[1] A. Carobbio,[1] L. Lombardini,[2] T. Lamparelli,[3] S. Pollichieni,[4] R. Oneto,[3] R. Fanin,[5] F. Bonifazi,[6] P. Corradini,[7] G. Lambertenghi,[8] F. Ciceri,[9] P.E. Alessandrino,[10] P. Iacopino,[11] W. Arcese,[12] R. Scimè,[13] M. Falda,[14] F. Benedetti,[15] A. Bacigalupo,[3] A. Bosi[16]

[1]Ospedali Riuniti di Bergamo, BERGAMO; [2]Divisione di Ematologia, Policlinico Careggi, FIRENZE; [3]Azienda Ospedaliera Universitaria San Martino, GENOVA; [4]Italian Bone Marrow Donor Registry (IBMDR), GENOVA; [5]Clinica Ematologica DIRM, A.O. Universitaria di Udine, UDINE; [6]Istituto di Ematologia ed Oncologia Medica Seragnoli, Università di Bologna, BOLOGNA; [7]Istituto Nazionale dei Tumori, MILANO; [8]Fondazione IRCCS Ospedale Maggiore, MILANO; [9]Ospedale San Raffaele, MILANO; [10]Policlinico S. Matteo, PAVIA; [11]Azienda Ospedaliera Bianchi-Melacrino-Morelli, REGGIO CALABRIA; [12]Policlinico Universitario Tor Vergata, ROMA; [13]Azienda Ospdaliera V. Cervello, PALERMO; [14]Azienda Sanitaria Ospedaliera San Giovanni Battista, TORINO; [15]Ospedale Policlinico Giambattista Rossi - Borgo Roma, VERONA; [16]Policlinico Careggi, FIRENZE, Italy

Background. Despite reports on the feasibility of reduced intensity conditioning (RIC) transplants from unrelated donors (UD), there's no clear evidence of a survival advantage in a cohort of consecutive and unselected high-risk patients activating a donor search. *Aims.* To test prospectively survival rates of patients activating an UD search leading or not to a transplant (with two different RIC regimens) in a program involving all Italian transplant centers. *Patients and Methods*. Two categories of patients were eligible for this program. Category A) included elderly patients (age between 55-65) with a diagnosis of Acute Myeloid Leukaemia (AML, n=62), Acute Lymphoblastic Leukaemia (ALL, n=5), Chronic Myeloid Leukaemia (CML, n=11), Primary Myeloid Fibrosis (PMF, n=17) and Myelodysplastic Syndrome (MDS, n=20) while category B) included patients of any age with Hodgkin Disease (HD, n=105), Non Hodgkin Lymphoma (NHL, n=73) and Chronic Lymphocytic Leukaemia (CLL, n=34). Accordingly, 327 UD searches were activated between September 2002 and December 2004. UD transplant was performed in 121 cases (36%), and only two RIC regimens were allowed: one based on fludarabine, low dose TBI and alemtuzumab, and the other based on thiotepa and antithymocyte globulin. No relevant differences in terms of median age (48.4 *vs* 51.9 years) and diagnosis (HD 34% *vs* 31%, NHL 23% *vs* 22%, AML 21% *vs* 18%, CLL 7% *vs* 12%, MDS 4% *vs* 7%, CML 2% *vs* 4%, PMF 4% *vs* 2%, ALL 2% *vs* 1%) were registered among patients who eventually underwent UD transplant versus those who did not. *Results*. 121 patients were transplanted at a median interval of 168 days from the UD search. Of the 206 who did not receive an UD transplant, 169 (82%) stopped the UD search and 37 (18%) still have an ongoing search. The major causes for the 169 search interruptions were death (52%), disease progression (20%) or other treatments (19%). With a median follow up of 1.5 years (range 0-4.7), the 3-year Overall Survival (OS), calculated from the time of UD search activation to death or last follow-up visits, was 47% and 28% for transplanted and not-transplanted patients, respectively. Cox multivariable analysis considering UD transplant as time-dependent covariate was performed according to the different diagnoses. UD transplant was associated with a significant sur-

vival improvement in acute leukemia patients (HR=0.56, p=0.04), whereas only a favorable trend was observed for NHL, HD and CML/PMF patients (p=0.7, p=0.3 and p=0.9, respectively). Patients' outcomes and survival were not different according to the two RIC regimens adopted. *Conclusions*. This study confirms that UD transplants is feasible in high risk or elderly patients. A significant survival advantage is shown for UD transplants only for patients with acute leukemia. The impact of UD transplants on survival in patients with chronic lymphoid and myeloid malignancies is not statistically significant, and should be considered before activating an unrelated donor transplant program.

0344

BONE AS A REGULATOR OF HEMATOPOIETIC STEM CELL TRAFFICKING: BIOCHEMICAL MARKERS OF BONE REMODELING AND ANGIOGENIC CYTOKINES IN STEM CELL MOBILIZATION

M.K. Angelopoulou,[1] E. Terpos,[2] P. Tsirkinidis,[3] K. Anargyrou,[3] V. Pappis,[3] M. Moschoyiannis,[3] E. Chatzileonida,[3] O. Tsopra,[3] E. Papakostas,[3] M.-C. Kyrtsonis,[3] E. Dimitriadou,[3] F.N. Kontopidou,[3] T.P. Vassilakopoulos,[3] G.A. Pangalis[3]

[1]National and Kapodistrian University of Athens, ATHENS; [2]251 Air Force General Hospital, ATHENS; [3]National And Kapodistrian University of Athens, ATHENS, Greece

Background. Bone has been long considered as a structural, non-functional tissue supporting bone marrow hematopoietic stem cells (HSC). However recent evidence indicates an active interplay between bone and HSC. Endosteum-lining osteoblasts are an important component of the HSC *niche*. The mobilization and collection of peripheral blood stem cells (PBSC) is a standard procedure in the treatment of many hematologic malignancies, both in the autologous and allogeneic stem cell transplantation setting. The mechanisms of HSC mobilization implicate adhesion molecules, cytokines, chemokines and enzymes that lead to the disanchorage of HSC from bone marrow, through the endothelium to the circulating blood. However little is known regarding the significance of bone remodeling and metabolism in HSC mobilization in humans. *Aims.* To study biochemical markers of bone remodeling, osteoclast/osteoblast regulators and angiogenic cytokines in the process of PBSC mobilization of patients with lymphoma and myeloma. *Methods.* Twenty-four patients (10 with multiple myeloma, 5 with Hodgkin's Lymphoma and 9 with non-Hodgkin's lymphoma) were studied. Serum samples from each patient were collected at two different time points: before the initiation of mobilization (pre-mobilization sample) and on the day of PBSC collection, which coincided with the highest circulating CD34 counts (collection sample). The following molecules were measured by ELISA in patients' sera: i) osteoclast regulators: soluble receptor activator of nuclear factor kappa-B ligand (sRANKL), osteoprotegerin (OPG), and osteopontin; ii) osteoblast inhibitor dickkopf 1 (Dkk-1); iii) markers of bone resorption: C- and N- cross-linking telopeptide of collagen type I (CTX and NTX, respectively) and tartrate-resistant acid phosphatase isoform 5b (TRACP-5b); iv) markers of bone formation: osteocalcin (OC), and bone-specific alkaline phosphatase (bALP); and v) angiogenic cytokines: angiopoietin-1 (Ang1), angiopoietin-2 (Ang2) and angiogenin. Values between the two different time points were compared with non-parametric methods. Patients who had a successful PBSC collection ($CD34^+$ cells>2.0×10^6/kg) were considered as *good mobilizers*, while the remaining ones were classified as *poor mobilizers*. *Results.* The comparison of the molecules under study between the pre-mobilization and collection samples revealed the following: Soluble RANKL (p=0.000), OPG (p=0.003), bALP (p=0.000) and Ang2 (p=0.001) increased significantly, while OC (p=0.000), CTX (p=0.014) and Ang1 (p=0.001) decreased significantly between pre-mobilization and collection. The increase in sRANKL was more prominent than OPG, leading to an increased sRANKL/OPG ratio, indicating stimulation of osteoclast activity. The reduction of Ang1 and the concomitant increase of Ang2 resulted in a significant reduction of Ang1/Ang2 ratio indicating vessel destabilization. The comparison between good and poor mobilizers revealed that poor mobilizers had significantly higher CTX and NTX levels both at pre-mobilization (p=0.001 and p=0.02 respectively) and collection samples (p=0.001 and p=0.001 respectively), lower Ang-1 pre-mobilization (p=0.02) and higher OC at collection (p=0.03) compared to good mobilizers. *Summary and Conclusions.* Bone metabolism seems to be altered during PBSC mobilization, pointing to a more dynamic role of bone tissue in the trafficking of HSC. The results of our study show for the first time that vessel endothelial cell destabilization and osteoclast stimulation are two important events associated with the mobilization process. Moreover several of these markers, may identify poor mobilizers.

0345

CHRONIC KIDNEY DISEASE AFTER NON-MYELOABLATIVE STEM CELL TRANSPLANTATION IN ADULTS

S. Kersting, L. Verdonck

UMC Utrecht, UTRECHT, Netherlands

Background. Chronic kidney disease (CKD) after myeloablative stem cell transplantation (SCT) is a well-established problem. Little is known about CKD after non-myeloablative SCT. *Aims.* The aims of the present study were to evaluate the prevalence of CKD and to analyse risk factors for CKD in a large cohort non-myeloablative SCT recipients. Moreover, we wanted to study whether CKD influenced survival in these patients. *Methods.* We performed a retrospective cohort study of 108 adults who received non-myeloablative SCT with fludarabine (30 mg/m^2/day for 3 days) and/or total-body irradiation conditioning (200cGy). Renal function was assessed by estimating glomerular filtration rate (GFR) with the MDRD equation. CKD was defined as GFR <60 mL/min/1.73 m^2 if it persisted until death or last follow up. *Results.* CKD developed in 15% of patients after a median of 15 months. None of the patients required dialysis. Cumulative incidence of CKD was 7% at 12 months, 14% at 24 months, 16% at 36 months and 22 % at 48 months. Risk factors for CKD were female gender (p=0.021), older age (p=0.040) and lower GFR pre-transplant (p<0.001). Complications after SCT (graft-versus-host disease, cytomegalovirus reactivation, admission to intensive care unit, hypertension) were not associated with CKD. Stem cell transplantation nephropathy, a cause of CKD after myeloablative SCT, did not occur. Overall survival was 66%. There was no difference in survival between patients with or without CKD. *Summary and Conclusions.* CKD is a frequent complication after non-myeloablative SCT and is not related to SCT nephropathy. Women, patients above 50 years of age and patients with slightly decreased kidney function pre-transplant have the greatest risk of development of CKD. Identifying these patients is important, since CKD is associated with hypertension, anaemia and reduction in functional status.

0346

HEPATITIS B REACTIVATION IN PATIENTS UNDERGOING AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION: A SINGLE CENTRE EXPERIENCE

M. Esposito,[1] M.R. Villa,[1] S. Improta,[1] A. Lucania,[1] G.P. Izzo,[1] P. Correale,[1] A. Marrone,[2] L. Mastrullo[1]

[1]P.O. San Gennaro U.O.C. Ematologia, NAPOLI; [2]Medicina Interna e Epatologia II Università degli Studi di Napoli, NAPOLI, Italy

Background. Hepatitis due to reactivation of hepatitis B virus (HBV) is an important cause of liver related desease in patients undergoing autologous hematopoietic cell transplantation. It has been observed in patients positive for hepatitis B surface antigen (HBsAg) and in HBsAg negative patients who had HBV infection in the past (HBsAb and HBcAb positive). *Aims*. We investigated the incidence of hepatitis B reactivation in patients undergoing autologous hematopoietic cell transplantation in our centre between April 2005 and December 2007. *Methods*. We have studied 30 patients, 19 out of 30 were seronegative for HBV, 9 were anti HBs (HBsAb) and 2 were healthy carriers of hepatitis B surface antigen (HBsAg). Prior to transplant, all patients had normal levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase and total bilirubin. Liver function tests were carried out thrice weekly during the first 30 days of transplant, once a week during the next 30-60 days, and at 2 to 12 week intervals until their last follow up. The patients were followed for a median of 16 months after transplantation. *Results*. Hepatitis B reactivation developed in 3 patients after transplantation. One of these patients was HBsAg positive and two were HBsAb positive before transplantation. Hepatitis flare-up occurred at a median of 4-6 months after autologous transplantation. These patients become HBsAg positive, HBeAg and anti HBc IgM positive. HBV DNA was positive for all three patients. In two patients hepatitis was documented with an elevation of transaminase and bilirubin levels. Lamivudine treatment was started in all these patients. Two patients recovered completely after this treatment. One patient are still treated with lamivudine. *Conclusions*. Our result indicate that HBV reactivation post autologous hematopoietic cell transplantation is possible not only in HBsAg positive patients, but also in HBcAb o HBsAb positive patients. We suggest that a careful monitoring of HBV-DNA levels is important for prevent hepatic damage caused by HBV reactivation.

0347

SUCCESSFUL OUTCOME AFTER NON-MYELOABLATIVE ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH RENAL DYSFUNCTION

S. Kersting, L. Verdonck

UMC Utrecht, UTRECHT, Netherlands

Background. Non-myeloablative allogeneic HSCT is a transplantation approach that enables patients with co-morbid conditions to undergo allogeneic HSCT. Little is known about patients with reduced renal function as a single co-morbidity before HSCT. *Aims.* The aim of the present study was to assess the outcome of patients with mildly reduced renal function before non-myeloablative HSCT. *Methods.* Fifteen patients with a glomerular filtration rate (GFR) of less than 60 mL/min/1.73 m^2 before non-myeloablative HSCT were matched on gender, age and type of transplant to 30 controls with normal renal function. All patients received a non-myeloablative HSCT with fludarabine (30 mg/m^2/day for 3 days) and/or total-body irradiation conditioning (200cGy). Graft-versus-host disease (GVHD) prophylaxis consisted of mycophenolate mofetil and cyclosporine. Data on renal function, cyclosporine dose, cyclosporine trough levels, hypertension and GVHD were collected. *Results.* Of the 15 patients with impaired renal function, 8 patients (53%) improved or stabilized to a GFR ≥60mL/min/1.73 m^2 at last follow up. Five patients (33%) developed chronic kidney disease stage 3 (GFR <60 mL/min/1.73 m^2) compared to 5 patients (17%) in the control group (p=0,031). Survival was similar between cases and controls. There were no differences in complications after HSCT (acute renal failure, hypertension, acute GVHD, chronic GVHD or nephrotic syndrome). Furthermore, there were no differences in cyclosporine dose and trough levels. *Summary and Conclusions.* Non-myeloablative HSCT can be safely offered to patients with mildly reduced renal function. Cyclosporine can be administered at the same dose as patients without renal dysfunction, as long as cyclosporine trough levels and creatinine are monitored and dose adjustments are made if necessary.

THE STUDY OF $CD3^+CD4^+CD25^+$ T CELLS LEVEL AND IMMUNE RECONSTITUTION AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION IN HEMATOLOGICAL DISEASES

A.D. Moicean, A.M. Dumitrescu, V.M. Teleanu, D.N. Colita

Fundeni Clinical Institute, BUCHAREST, Romania

T regulatory (Treg) cells are an immunoregulatory cell type with suppressive effect in the course of immune response that the body uses to control autoimmunity in periphery through *dominant tolerance* By naturally occurring $CD4^+$ T regulatory (Trn or nTreg) which constitutively display CD25 several different Treg cell populations have been described in the past decade. These include cross-regulatory $CD4^+$ Th1 and Th2 cells, IL-10 producing $CD4^+$Tr1 cells and TGFb-producing $CD4^+$ Tr2/Th3 cells. Both Tr1 and Tr2/Th3 Treg cells can acquire CD25 expression. We have studied the $CD3^+CD4^+CD25^+$ T cells level at 1-24 months after hematopoietic stem cell transplantation on 32 consecutive patients with hematological malignant diseases. All patients received peripheral stem cells mobilized with G-CSF. Two patients received related myeloablative allotransplant for acute myeloblastic leukemia (AML), one patient received MUD myeloablative allotransplant for acute leukemia too, one patient received related nonmyeloablative allotransplant for AML and 28 received autotransplant (1 for AML, 5 for nonhodgkin lymphoma (NHL), 7 for Hodgkin Disease and 13 for multiple myeloma). All but NHL patients after autotransplant had an increase level of $CD3^+CD4^+CD25^+$ T cells (media 49.11%/Th, 31.95 - 80.52). The NHL patients had media 28.72% $CD3^+CD4^+CD25^+$ T cells/Th. Both patients with myeloablative allotransplant had a high level of $CD3^+CD4^+CD25^+$ T cells (media 77.19%/Th, 69.15 - 85.23). The patient with nonmieloablative allotransplant had low level of $CD3^+CD4^+CD25^+$ T cells (15.25%/Th). In conclusion, the level of $CD3^+CD4^+CD25^+$ T cells after HSCT seems to be different with stem cell source and conditioning regimen. For nonmieloablative allotransplant which creates a more immunological than hematological space for hematological stem cells homing the light suppressive activity of immune cells is the decisive factor for engrafting.

HHV-6 AND HHV-7 ACTIVATION IN EARLY PERIOD AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

G. Lejniece,[1] I. Puga,[2] A. Sultanova,[2] M. Murovska,[2] S. Chapenko[2]

[1]*The National center of Hematology, Riga East Hospital, Clinic Linezers, RIGA;* [2]*A. Kirchenstein Institute of Microbiology and Virology Riga Stradins University, RIGA, Latvia*

Background. Despite great advances in stem-cell transplantation, opportunistic infections remain a major cause of morbidity and mortality for transplant patients. Beta-herpesviruses - Human herpesvirus-6 and -7 (HHV-6 and HHV-7) are considered the immunomodulatory and immunosuppressive viruses that infect individuals persistently during lifetime and in a case of reactivation may be cause for subsequent development of different complication after transplantation. Although, the pathogenesis of HHV-6 is not well understood, recent evidence suggests that the virus is a potential life-threatening pathogen in the post-transplant period. The significance of HHV-7 activation in transplant patients remains poorly understood. The aim of this study was to examine activation of HHV-6 and HHV-7 before and in early period after auto-peripheral blood stem cell transplantation (auto-PBSCT). Methods. Forty patients (22 male, 18 female, mean age 31.6 years [range: 17 - 54]) with Hodgkin's lymphoma (26/40), non-Hodgkin's lymphoma (7/40) and myeloma (4/40) were examined for beta-herpesviruses activation before and a 10 - 14th day after auto-PBSCT. All patients had received prophylactic therapy with Valtrex (500 mg x 2 in the day) one month after PBSCT. Nested polymerase chain reaction (nPCR) with peripheral blood mononuclear cells and cell-free blood plasma DNAs as the templates were performed to detect of latent/persistent and active viral infection, respectively. Results. Latent/persistent HHV-6 and/or HHV-7 infection before transplantation was detected in 35 out of 40 patients (87.5%): HHV-6 - in 15/40 (37.5%) and HHV-7 - in 33/40 (82.5%) patients. From these 35 patients dual (HHV-6+HHV-7) viral infection in 13 (37.0%) patients was revealed. Active virus infection (HHV-7) was detected only in 3/35 (8.6%) patients. Activation of beta-herpesviruses after transplantation was detected in 17/35 (48.6%) patients. From these 17 patients HHV-6 activation alone was not revealed, HHV-7 activation alone was found in 14/17 (82.4%) and HHV-6 + HHV-7 activation - in 3/17 (17.7%) patients. The analysis of the data showed significantly higher frequency (p=0.0004) of beta-herpesviruses activation in early period after auto-PBSCT (48.6%) in comparison to the period before transplantation (8.6%). The frequency of HHV-7 activation alone was significantly higher (p=0.0043) after auto-PBSC (14/35, 40.0%) in comparison with those in the period before transplantation (3/35, 8.6%). Conclusion. The activation of HHV-6 and/or HHV-7 in the patients with Hodgkin's, non-Hodgkin's lymphoma and myeloma are not frequently observed after treatment with high-dose of chemotherapy before transplantation. However, in early period after auto-PBSCT, the frequency of viruses' activation, HHV-7 activation in particular, becomes significantly higher. HHV-7 reactivation after engraftment can be a risk factor for the activation of other herpesviruses and for subsequent development of viral associated complications in transplant recipients.

ALTERED EXPRESSION AND FUNCTION OF THE CHEMOREPELLENT/RECEPTOR PAIR SLIT/ROBO UPON MYELOID DIFFERENTION OF HEMATOPOIETIC STEM AND PROGENITOR CELLS

S.B. Geutskens,[1] W.A. Andrews,[2] S.E. De Haan,[1] J.G. Parnavalas,[2] P.L. Hordijk,[1] P.B. Van Hennik[1]

[1]*Sanquin Research and Landsteiner Laboratory, AMSTERDAM, Netherlands;* [2]*University College London, LONDON, UK*

Slit is an extracellular matrix molecule originally identified in the developing central nervous system (CNS). Here it transmits a repulsive cue to neuronal progenitors preventing axonal outgrowth via the transmembrane receptor Roundabout (Robo). Four Robo and three Slit homologues have been identified in vertebrates. While Slit1 is confined to the CNS, Slit2 and Slit3 are widely expressed and have been reported to inhibit the CXCL12-induced migration of breast cancer cells, myocardial progenitors and of mature hematopoietic cells, i.e. T-lymphocytes and monocytes. CXCL12 and its receptor CXCR4 are critical in the regulation of hematopoietic stem/progenitor cell (HSPC) migration to the bone marrow (BM) upon transplantation. We have set out to investigate whether a negative migratory cue, i.e. Slit and its receptor Robo, can modulate HSPC migration. We show that Slit2 and -3 were expressed in BM-derived endothelial and stromal cell lines, whereas Robo1 was

expressed by CD34+ HSPC derived from different sources. Interestingly, Robo1 mRNA and surface protein expression levels in HSPC were significantly higher as compared to CD14+ monocytes. Moreover, Robo1 expression was reduced during differentiation of HSPCs towards CD14+ cells *in vitro*. Slit3 inhibited the CXCL12-induced migration of Robo1-expressing HL60 and U937 cells, while it enhanced the directional migration of monocytes. HSPC migration was not affected under these conditions, but lower Slit3 concentrations inhibited directional HSPCs migration, which is in agreement with their higher Robo expression levels. Thus, the outcome of Slit responsiveness appears to be dependent on Robo expression levels. s.geutskens@sanquin.nl

CRITERIA FOR INTENSIVE CARE UNIT ADMISSION OF CRITICALLY ILL HAEMATOPOIETIC STEM CELL TRANSPLANT PATIENTS - A SCORING SYSTEM

C.L. Wong, J. Apperley, E. Kanfer, D. Marin, D. Milojkovic, A. Rahemtulla, K. Patel, E. Olavarria

Hammersmith Hospital, LONDON, UK

Background. There is only general guidance within our Haematology Department relating to patients referred to Intensive Care Unit (ICU). On average, approximately 15 patients are admitted into the ICU every year after undergoing Haematopoietic Stem Cell Transplant (HSCT) in our institution. There is a need for consistent criteria to be used in the assessment of critically ill patients so that appropriate referral pathways to ICU can be followed. *Aims.* The overall aims of the study were: 1) To identify critically ill Haematology patients using consistent criteria. 2) To assess the degree of illness severity according to the number of organ failures and the new SAPS II score (Simplified Acute Physiology Score). 3) To set a standard, using the data collected above, against which a patient can be assessed and referred to ICU appropriately. *Method*. The first phase of the study was conducted on 9 patients with haematological malignancies who were admitted into the ICU. It showed that critically ill patients could be defined as patients who fulfilled ≥2 of the following criteria: sepsis, haemodynamic instability, respiratory failure, acute renal failure, use of inotropes, liver abnormality, Glasgow Coma Scale <6 and/or acute grade III-IV GVHD. The number of organ failures and SAPS II score needed to be explored further to assess their reliability in discriminating patients who need to be referred to ICU and their outcome. Therefore, the second phase of the study was subsequently conducted on 40 consecutive patients who had undergone autologous or allogeneic HSCT over a period of six months. *Results*. There were 25 autografts and 15 allografts. 14 (35%) patients became critically ill as defined by the above criteria. 8 out of 14 (57%) critically ill patients were referred for ICU management, of which 4 were admitted into ICU. The mortality amongst patients fulfilling the definition of critically ill was 43%. All 14 critically ill patients had ≥2 organ failures although this was not found to be a useful factor for discriminating patients who needed to be referred to ICU. The SAPS II score, however, was very useful in predicting outcome. All patients with a SAPS II score of <56 points survived the critically ill episode without transfer to ICU. Patients with a SAPS II score >65 points had 100% mortality regardless of whether they were transferred to ICU or not. Finally, patients with a SAPS II score between 45-65 points were better managed in ICU, although the SAPS II score was not predictive of their survival. *Summary and Conclusions*. Critically ill patients after HSCT should be identified using ≥2 criteria as per study proforma. SAPS II score should be performed on all critically ill patients to help discriminating patients who need to be referred to ICU. A *window* of between 45 and 65 points was defined as the optimal range in which patients should be considered for ICU transfer.

COMPARISON OF IV BUSULFAN AND FLUDARABINE VS IV BUSULFAN AND CYCLOPHOSPHAMIDE AS CONDITIONING REGIMEN IN MYELOABALTIVE ALLOGENEIC STEM CELL TRANSPLANTATION

S. González de Villambrosia, A. Moretó, J. Núñez, A. Bermúdez, L. Yáñez, A. Insunza, A. Iriondo

Hospital Universitario Marqués de Valdecilla, SANTANDER, Spain

Objetives. To evaluate the effectiveness and toxicity of once-daily iv busulfan and fludarabine (BUFLU) compared to busulfan and cyclophosphamide (BUCY) as conditioning regimen for myeloablative allogeneic stem cell transplantation. *Methods and material*. Retrospective study of 40 patients who underwent allogeneic transplantation in our centre from May 2005 to January 2008. 20 patients received busulfan (3.2 mg/kg x 4 days; days -5 to -2) and fludarabine (40mg/m^2 x 4 days; days -5 to -2) as conditioning regimen. Busulfan (3.2 mg/kg x 4 days; days -7 to -4) and cyclophosphamide (60 mg/kg x 2 days; days -3 to -2) was given in 20 patients. There were no statistical significant differences between both groups comparing age, sex, diagnosis, comorbidity, lines of treatment, disease status, histocompatibility, donor type (55% unrelated in BUFLU *vs* 40% in BUCY), stem cell source (bone marrow 95% *vs* 80%) and G-CSF use (10% *vs* 15%). *Results.* Considering hematopoietic recovery, there were no differences in days to 100 and 500 neutrophil engraftment (13.55 *vs* 13.6; 16 *vs* 18) and to 20000 and 50000 platelet engraftment (16.40 *vs* 18.95; 26.5 *vs* 38) between BUFLU and BUCY groups. However, in the BUFLU group we found a shorter total duration of neutropenia below 100 (4.5 *vs* 8.9 days p=0.0001) and 500 (9.2 *vs* 14.77 days p=0.0015) and lower red blood cell and platelet transfusion requirements (2.15 *vs* 5.85 p=0.006 and 4 *vs* 14 p=0.029 respectively). Complete donor chimerism in day +30 was observed in 19 (95%) patients with the BUCY regimen and 8 (40%) patients with BUFLU (p=0.0002). In the latest group, more than 75% of donor chimerism was found in 9/12 patients with mixed chimerism and all patients, except one, reached complete donor chimerism by day +120. No patient developed neurological toxicity. Considering gastrointestinal toxicity (nausea, vomiting and early diarrhea), liver toxicity (OMS) and veno-oclussive disease (5% *vs* 5%) there were not significant differences between both groups. The incidence of severe mucositis was similar with both regimens (55% *vs* 50%) but median duration of parenteral nutrition was shorter with BUFLU (4 *vs* 7.5 days). There was less grade III/IV acute graft versus host disease (aGVHD) in the BUFLU group (25% *vs* 55% p=0.05). Mortality before day 100 was 13% (2/15) in the BUFLU group (both of them due to early relapse) and 5% (1/20) in the BUCY group (due to refractory aGVHD). No patient died because of toxicity in the BUFLU group. With a median follow up of 160 days in the BUFLU group and 381 days in the BUCY group, we found no significant differences in overall survival (90% *vs* 75% respectively) and relapse rate (20% *vs* 15% respectively). *Conclusions.* In our experience, iv BUFLU as mieloablative conditioning regimen in allogeneic stem cell transplantation is associated with lower early toxicity, neutropenia duration, transfusion requirements and severe aGVHD than iv BUCY. It is necessary a longer follow up to evaluate survival and relapse.

COMPARING TOXICITY PROFILES OF INTRAVENOUS BUSULFAN IN PRETRANSPLANT CONDITIONING -DIVIDED DOSES VERSUS SINGLE DAILY DOSE

S. Narayan, E. Thoulouli, G.S. Lucas, J. Burthem, J. Lee, M. Waller, H. Lenehan, J.A.L. Yin

Manchester Royal Infirmary, MANCHESTER, UK

Background. Oral busulfan has been used in pretransplant conditioning for many years. Its safety in clinical use however has been compromised by its unpredictable intestinal absorption, erratic bioavailability and high incidence of hepatic veno-occlusive disease (VOD). Introduction of a parenteral formulation ensuring 100% bioavailability with predictable pharmacokinetics has led to its increased use in clinical practice. Although pharmacokinetic monitoring allows individualization of drug dosage, it is not universally available. Intravenous Busulfan has demonstrated a good safety profile when administered at 0.8 mg/kg 6-hourly. Recent studies have used busulfan as once daily dosing at 3.2 mg/kg/day with no increased toxicity or end-organ damage despite higher plasma concentration times. We retrospectively analysed patients treated at Manchester Royal Infirmary with an intravenous busulfan-based conditioning regimen and compared toxicity profiles between 6-hourly and once daily dosing. *Patients and Methods.* Between May 2005 and January 2008 25 patients with haematological malignancies were transplanted using intravenous busulfan either at 0.8mg/kg/dose 6-hourly (group I; n=13) or 3.2 mg/kg once daily (group II; n=12). Regular clinical and laboratory indices of organ function and toxicity were monitored. No pharmacokinetic studies were performed. Conditioning regimens used were BuCy or FluBuCamp as per standard protocols. Phenytoin and LMWH prophylaxis were used in all patients. Azoles and Paracetamol were avoided until 48hours after completion of busulfan infusion. Organ toxicity was documented according the NCI-CTCAE version3 (National Cancer Institute's Common Toxicity Criteria for Adverse Events). Hepatic VOD was diagnosed based on Baltimore criteria. *Results and Discussions*. All patients engrafted. Median time to neutrophil engraftment in both groups was 12.5days. In group I, one patient developed secondary graft failure following an HLA-Cw mismatched unrelated donor trans-

plant. No infusion-related toxicities were observed. All patients developed mucositis, most commonly grade2-3. No neurotoxicity was seen. 4 patients in group I and 11 in group II developed transiently impaired renal function. Temporary renal replacement therapy was required in one patient in group II who had ongoing renal impairment following cadaveric renal transplant. In both groups 90% of patients developed hepatotoxicity (grades 1-3), most commonly manifesting as transient elevation of ALT and bilirubin. Hepatic VOD was suspected in one patient in group I, who later succumbed to accelerated CML. In group II, two patients developed VOD. One patient with multiple risk factors developed severe disease with hepatorenal syndrome which was fatal. *Conclusions*. Intravenous busulfan may be used with once daily dosing safely and efficaciously. Careful patient selection and choice of transplant regimen together with minimal use of concomitant hepatotoxic drugs may reduce the incidence and severity of regimen related toxicity. More studies are needed to evaluate safety of once daily busulfan, especially in heavily pretreated patients with multiple risk factors for organ toxicity.

0354

IMPACT OF MTOR INHIBITION ON LYMPHOID HOMING AND TOLEROGENIC FUNCTION OF NANOPARTICLE LABELED DENDRITIC CELLS FOLLOWING ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

R. Zeiser,[1] R. Reichardt,[1] C. Dürr,[1] D. Von Elverfeldt,[2] E. Jüttner,[3] B. Smith,[4] R.S. Negrin[4]

[1]Albert-Ludwigs University Freiburg, FREIBURG, Germany; [2]Department of Diagnostic Radiology and Medical Physics, FREIBURG, Germany; [3]Department of Pathology, Freiburg University, FREIBURG, Germany; [4]Stanford University School of Medicine, STANFORD, USA

Background. Dendritic cells (DC) play a major role in the pathogenesis of graft-versus-host disease (GvHD). Directed modification of surface molecules on DC that provide instructive signals for T cells may create a tolerogenic DC phenotype that affects GvHD severity. *Aims.* To investigate the impact of the mTOR inhibitor rapamycin (RAPA) on *in vivo* migratory capacities, tolerogenic function and B7 family member surface expression on DC following allogeneic hematopoietic cell transplantation (aHCT). *Methods.* To generate a platform for magnetic resonance imaging (MRI) and bioluminescence imaging (BLI) based cell trafficking studies we labeled luciferase transgenic DC with superparamagnetic iron oxide (SPIO) nanoparticles bound to a murine IgG antibody that allowed for Fc γ (R) receptor mediated endocytosis. *Results.* Locally injected luc+ DC could be tracked within their anatomical context at high resolution by BLI and MRI after aHCT, based on stable intracellular localization of SPIO-IgG complexes. RAPA preconditioned DC (DC-R) displayed reduced expression of MHC class II, B7-1 (CD80) and B7-2 (CD86) but not B7-H4 whose ligation of T cells has a profound inhibitory effect on their proliferation and cytokine secretion. DC-R of recipient genotype reduced GvHD severity as evidenced by improved survival and reduced allogeneic T cell expansion, which is compatible with their tolerogenic phenotype. CCR5, CCR7 and CD62L expression was not affected by mTOR inhibition which allowed for DC-R *in vivo* trafficking to secondary lymphoid compartments where immunregulation is required. *Conclusions.* This study is the first to delineate the impact of RAPA on DC migration and tolerogenic function after aHCT. Modification of the DC phenotype by mTOR inhibition may have therapeutic potential in an attempt to reduce GvHD following aHCT.

0355

RECONSTITUTION OF T CELLS AFTER *IN VIVO* T CELL DEPLETION WITH ALEMTUZUMAB IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

E.M. Wagner,[1] T. Schmitt,[2] S. Wenzel,[2] J. Hemmerling,[2] A. Konur,[2] K. Kolbe,[2] C. Huber,[2] W. Herr,[2] R.G. Meyer[2]

[1]Haematology and Oncology, MAINZ; [2]Johannes Gutenberg-Universität, MAINZ, Germany

Introduction. Targeting CD52 by alemtuzumab is frequently used for *in vivo* T cell depletion (TCD) in allogeneic stem cell transplantation (HSCT). We have recently introduced a protocol applying alemtuzumab-mediated TCD allogeneic HSCT followed by prophylactic application of CD8-depleted donor lymphocyte infusions (DLI) [Meyer, Blood 2007; 109: 374]. Here we provide data on the CD52-expression of reconstituting lymphocytes and monocytes as well as on the influence of DLI-application in patients in following this protocol. *Methods and Results*. Peripheral blood mononuclear cells of 20 patients after HSCT following conditioning with fludarabine, melphalan and alemtuzumab were monitored for the expression of CD52 by flow cytometry. Of these patients, 9 were treated with CD8-depleted DLI. Eleven patients did not receive DLI because of mild graft-versus-host disease (GVHD, n=9) or unavailability of the donor (n=2). The CD52-expression in monocytes, B and NK cells remained unaltered after transplantation and was not influenced by the application of CD8-depleted DLI. The majority of reconstituting CD4 T cells were CD52-negative after transplantation. In those patients who did not receive DLI, the majority of CD4 T cells remained CD52-negative throughout the first year after HSCT. This cannot be explained by a direct effect of alemtuzumab, because earlier studies have shown that the antibody is not present in active plasma concentrations beyond day +60 after HSCT. If CD8 depeted DLI were applied, they lead to the rapid re-establishment of CD52-positive CD4 T cell-populations. Hence, the proportion of CD52-positive CD4 T cells was significantly higher in patients who had received DLI compared to those who had not. Although the DLI were depleted from CD8 T cells, there was also a trend towards more CD52-positive CD8 T cells in patients who had received DLI. We further analysed the donor chimerism of CD52-positive and -negative CD4 T-cell subpopulations in two patients who received DLI as well as in one patient who did not. In all three patients, the CD52-positive subpopulations were mainly of host origin, whereas the majority of donor T cells were among the CD52-negative subpopulation. After the application of DLI, the CD52-positive CD4 T cell-populations switched to donor-type, indicating the proliferation of the transferred CD4 T cells *in vivo*. In contrast, in the patient who did not receive DLI, the percentage of donor chimerism of the CD4pos/CD52pos population remained considerably lower than in the CD4pos/CD52neg fraction. *Conclusions*. T cell depletion applying alemtuzumab leads to the reconstitution of CD52-negative T cell-populations, especially in the CD4-positive population. The majority of T cells remain CD52-negative beyond the presence of the antibody. By following the CD52-expression before and after CD8-depleted DLI, we demonstrated the *in vivo* proliferation of DLI-derived T cells. Spontaneously reconstituting CD52-positive CD4 T cells were mainly of host origin which might indicate a differentiated effect of alemtuzumab on CD4 T cell subsets.

0356

PROGNOSTIC FACTORS OF CHRONIC GRAFT VERSUS HOST DISEASE AFTER ALLOGENEIC BLOOD STEM CELL TRANSPLANTATION: NIH SCALE PLUS TYPE OF ONSET PREDICT SURVIVAL AND DURATION OF IMMUNE SUPPRESSIVE THERAPY

J.A. Pérez-Simón, C. Encinas, F. Silva, M.J. Arcos, M. Díez-Campelo, F. Sanchez-Guijo, E. Colado, J. Martín, L. Vazquez, C. Cañizo, D. Caballero, J.F. San Miguel

Hospital Universitario, SALAMANCA, Spain

Background. Chronic graft-versus-host disease (cGVHD) is a major complication after peripheral blood stem cell transplantation (PBSCT). Several grading systems have been developed trying to predict survival among patients with cGVHD. Nevertheless, most of these studies have been developed in the bone marrow transplantation (BMT) setting while the characteristics of cGVHD differ between PBSCT and BMT. The National Institutes of Health (NIH) have proposed a new clinical scoring system for assessment of cGVHD severity based on the number of organs involved and the degree of functional impairment. Nevertheless, this scoring system requires to be validated to assure its prognostic impact. *Aims.* In the current study we have evaluated the prognostic value of the NIH scoring system and searched for additional prognostic factors in a series of 171 patients consecutively undergoing PBSCT from a matched related donor. All patients received CsA plus MTX as GVHD propylaxis. 68 patients received myeloablative and 103 reduced intensity conditioning regimen. 37% were categorised as low risk according to disease status at transplant, 43% as intermediate and 20% as high risk. *Results.* Cumulative incidence of cGVHD was 70% among patients surviving > 100 days after transplant and 60% were cathegorized as having extensive cGVHD. Cumulative incidences of mild, moderate and severe cGVHD were 29%, 42% and 28%, respectively. Overall, sixty eight percent of patients were off immune suppression 5 years after transplantation. Absence of prior aGVHD [HR=2.7 (95% CI = 1.3-6), p=0.004] and mild cGVHD [HR=4.2 (95% CI = 1.4-12.12), p=0.007] significantly increased the probability of being off treatment at last follow up. With a median follow-up of 54 months overall survival at 5 years was 52%. Severe cGVHD according to NIH scoring system [HR=13.27 (95%

CI = 2.81 - 62.5), *p*=0.001] adversely influenced on outcome while *de novo* onset [HR=0.094 (95% CI = 0.02-0.43), *p*=0.003] had a favourable impact on survival. The combination of both variables allowed to identify 4 different subgroups of patients in terms of outcome, with OS of 82%, 70%, 50% and 25%, respectively. *Conclusions.* NIH scoring system is of prognostic value among patients undergoing PBSCT and, together with type of onset, must be considered in order to predict the outcome of patients who developed cGVHD. These parameters should be considered in order to adapt immune suppressive strategies to the risk of the patients.

0357

IMPACT OF NOD2/CARD15 POLYMORPHISMS ON TREATMENT OUTCOME IN *EX VIVO* T-CELL DEPLETED HAEMATOPOIETIC STEM CELL TRANSPLANTATION

W.J.F.M. van der Velden, N.M.A. Blijlevens, N.P.M. Schaap, H. Dolstra, J.P. Donnelly

Radboud University Nijmegen Medical Center, NIJMEGEN, Netherlands

Background. NOD2 is as an intracytosolic pattern recognition receptor sensing the microbial component muramyl dipeptide. It is expressed in Paneth cells, dendritic cells and monocytes and plays an important role in the innate immune defences and immune regulation at the epithelial surfaces of gut and lung. NOD2 polymorphisms (SNPs), resulting in dysfunction of NOD2, have been shown to influence the outcome of haematopoietic stem cell transplantation (HSCT). However, the impact of NOD2 polymorphisms in the setting of *ex vivo* T-cell depleted HSCT remains to be determined because contradicting data exist. Aims. To determine the impact of NOD2 polymorphisms on treatment outcome in *ex vivo* T-cell depleted HSCT. *Methods.* We performed a retrospective analysis in one hundred and twenty-five (n=125) Dutch patients and their donors admitted at our transplant unit between May 1996 and November 2005 for an HLA-identical sibling, *ex vivo* T-cell depleted allogeneic HSCT. All patients were treated according to the same protocol and received ciprofloxacin antimicrobial prophylaxis. We selected a homogenous group of eighty-five (n=85) patients all receiving a uniform conditioning regimen containing idarubicin, a regimen associated with the occurrence of severe mucositis. We assayed NOD2 polymorphisms SNP 8 (Arg702Trp), 12 (Gly908Arg) and 13 (Leu1007fsinsC) with the use of a Taqman real time PCR protocol. *Results.* The overall frequency of NOD2 SNPs was 18.8%. Allele frequencies were 6.2, 0.6 and 3.2% for SNP8, 12 and 13 respectively. In 22 pairs at least one mutation was present. In 4 pairs (4.7%) only recipients had a mutation, in 8 pairs (9.4%) only donors and in 10 pairs (11.8%) both donor and recipient. Mutations were associated with significant higher incidence of severe aGvHD (grade III-IV); mutation present 18.2% *vs* wt 3.2%, and in case of both recipient and donor mutated, 30% *vs* wt 3.2%. There was also a significant impact on the 1-year treatment related mortality (TRM) in pairs with both recipient and donor mutated; TRM 1- year 50% *vs* wt 11.1%. There seemed to be a trend towards a higher incidence in gram positive bacteraemia in the presence of these polymorphisms. No significant impact on disease relapse was found. *Conclusions*. We show a significant impact of NOD2 polymorphisms on the outcome of *ex vivo* T-cell depleted HSCT, regarding occurrence of aGVHD and TRM. Pre-transplant screening for these polymorphisms should be considered in order to select the most appropriate donor. Importantly, the impact of NOD2 polymorphisms seems to be determined by factors such as background incidence of aGVHD and mortality as well as the allele frequency of the NOD2 polymorphisms in the HSCT population.

CLOTTING FACTOR VIII AND RISK OF VENOUS THROMBOEMBOLISM IN CANCER PATIENTS - RESULTS OF THE VIENNA CANCER AND THROMBOSIS STUDY

R. Vormittag, R. Simanek, A.L. Chiriac, C. Ay, D. Dunkler, P. Quehenberger, C. Marosi, C. Zielinski, I. Pabinger

Medical University Vienna, VIENNA, Austria

Background. Malignancy represents a complex acquired condition of thrombophilia. VTE is a main determinant of cancer morbidity and mortality. The identification of reliable markers of risk prediction and individual risk stratification will be needed to treat patients selectively according to their risk profile in view of preventing thrombosis and improving survival. Elevated levels of clotting factor VIII (FVIII) are an established risk factor for primary and recurrent VTE. Up to now, no prospective data on FVIII as predictive parameter for VTE in cancer patients are available. *Aims*. The aim of this prospective study was to assess whether FVIII was a risk marker for VTE in cancer patients. *Methods*. Patients with newly diagnosed cancer and those with disease progression that did not recently have chemotherapy, radiotherapy or surgery were included in the prospective observational CATS and followed prospectively. In case of overt infection patients were not enrolled. Study endpoint was symptomatic, objectively confirmed VTE. Factor VIII activity was measured on a Sysmex CA 7000 analyzer using factor VIII deficient plasma (Hyland Baxter Immuno, Vienna, Austria) and Dade Actin-FS (Dade Behring, Marburg, Germany). Kaplan-Meier and Cox regression analyses were used for statistical evaluation. Multivariable Cox regression analyses included (continuous or dichotomized) FVIII, age, sex and treatment regimen. Treatment regimen (surgery and/or radiotherapy and/or chemotherapy) was included as time-dependent parameter. Elevated FVIII was a dichotomized variable indicating plasma levels above or below 230% (95th percentile of a group of 75 healthy, age- and sex-matched control individuals).

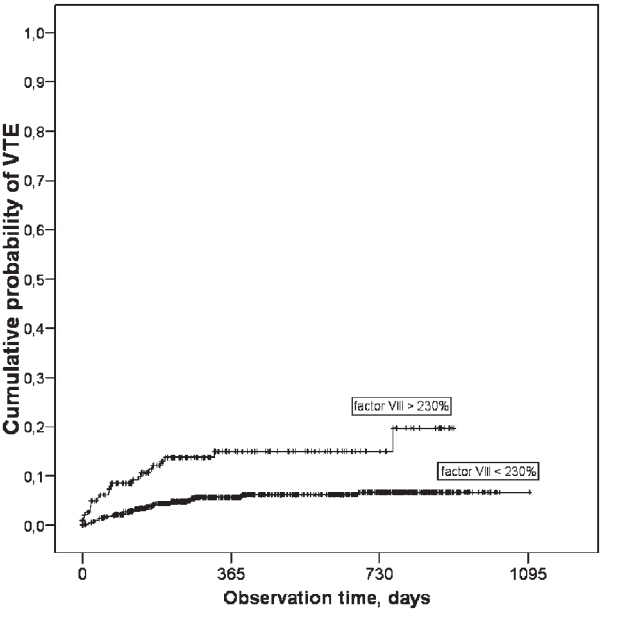

Figure 1.

Results. Data on 786 cancer patients (353 women/433 men) were available for analyses. Patients were followed for a median observation time of 422 days. 56 events were observed. Main tumour entities were malignancies of the breast (n=132), lung (n=100), gastrointestinal tract (n=141), pancreas (n=47), kidney (n=21), prostate (n=99) and brain (n=94); 109 patients had haematological malignancies and 43 other tumours. No relevant correlation between FVIII and the inflammatory marker fibrinogen was found (correlation coefficient 0.16). A twofold increase of FVIII was associated with a 3.0-fold [95% CI: 1.8-5.1] increased hazard ratio (HR) for VTE in univariate analysis and a 3.6-fold HR [2.1-6.2] in multivariable analysis. Elevated FVIII was present in 180 (22.9%) patients. Elevated FVIII was associated with a 2.7-fold increased HR [1.6-4.7] for

VTE in univariate analysis and a 3.0-fold [1.7-5.1] increased HR in multivariable analysis (Figure 1). *Conclusions.* FVIII was independently associated with an increased risk of VTE in cancer patients.

0359

HYPOFIBRINOLYSIS IS A RISK FACTOR FOR MYOCARDIAL INFARCTION IN YOUNG MEN

M.E. Meltzer,[1] C.J.M. Doggen,[2] P. De Groot,[3] F. Rosendaal,[2] T. Lisman[4]

[1]University Medical Center Utrecht/Leiden University Medical Center, UTRECHT / LEIDEN; [2]Leiden University Medical Center, LEIDEN; [3]University Medical Center Utrecht, UTRECHT; [4]University Medical Center Utrecht/University Medical Center Groningen, UTRECHT/GRONINGEN, Netherlands

Results of studies on the relation between the fibrinolytic system and arterial thrombosis have been conflicting. Previously, we demonstrated that hypofibrinolysis as measured by a plasma-based assay constitutes a risk factor for venous thrombosis. In the present study we investigated the effect of hypofibrinolytic activity on the risk of myocardial infarction (MI) using the same assay. We included 560 men with a first MI and 646 control subjects under the age of 70 who participated in the Study of Myocardial Infarctions Leiden (SMILE), a population-based case-control study. Participants filled in a questionnaire and provided a blood sample. Patients and controls using anticoagulants at time of blood draw were excluded, leaving 426 patients and 646 controls in present analyses. Lysis of a tissue factor-induced clot by exogenous tissue-type plasminogen activator was studied by monitoring changes in turbidity during clot formation and subsequent lysis. Using quartiles of clot lysis time (CLT) based on values found in control subjects, we found age-adjusted Odds Ratios (ORs) (95% confidence interval) of 1.7 (0.7-3.7), 3.1 (1.4-6.9), and 3.2 (1.5-6.7) for respectively the second, third, and fourth quartile compared with the first, in men below 50 years. After adjusting for lipid levels, blood pressure, C-reactive protein, body mass index, diabetes, smoking, and alcohol use, these ORs decreased to 1.2 (0.5-3.1), 2.1 (0.8-5.2), and 1.8 (0.7-4.8). In men above 50 years no clear association was found between CLT and MI-risk. The age-adjusted OR in these men with CLTs in the fourth quartile was 0.9 (0.6-1.3) compared with the first. After further adjustment for the cardiovascular risk factors described above, the OR was 0.7 (0.4-1.1). Our study shows that decreased fibrinolytic capacity increases the risk of a first MI in men under the age of 50.

This study was supported by the Netherlands Heart Foundation (Grant no. 2005B060 and 92.345).

0360

THE RISK OF PULMONARY EMBOLISM DUE TO PROXIMAL DEEP VENOUS THROMBOSIS OF THE LEGS DIFFERS IN PATIENTS WITH DIFFERENT KINDS OF INHERITED THROMBOPHILIA

E. Rossi, T. Za, A. Ciminello, G. Leone, V. De Stefano

Institute of Hematology, Catholic University, ROME, Italy

Background. It is uncertain whether the presence of inherited thrombophilia influences the risk of developing pulmonary embolism (PE) and whether different thrombophilic alterations are associated with different incidences of PE. *Aims.* The present study is aimed to investigate the risk of PE among patients with deep vein thrombosis (DVT) and inherited thrombophilia. Patients and *Methods.* We studied 920 patients (M/F 397/523) with proximal DVT of the legs with or without symptomatic PE referred for thrombophilia screening, after exclusion of patients with overt cancer and antiphospholipid antibodies; DVT was unprovoked in 315 patients and provoked by a triggering circumstance in 605 ones. The median age at the time of DVT was 37 years (range 0 to 85).Three hundred and fifty-three patients (38.3%) had deficiency of antithrombin (AT, n=16), protein C (PC, n=26), protein S (PS, n=22), factor V Leiden (FVL, n=168), prothrombin G20210A (PT-GA, n=87), or multiple abnormalities (n= 35), and 566 had no known defect. We analyzed the incidence of PE at the time of the first DVT in the patients with thrombophilia in comparison with those with no known defect. *Results.* First DVT was complicated by symptomatic PE in 242 patients (26%); the risk of PE was increased in patients with AT deficiency (relative risk, RR, 2.4, 95% CI 1.6-3.6) or with PT-GA (RR 1.5, 95% CI 1.1-2.0) and decreased in those with FVL (RR 0.7, 95% CI 0.5-1.0) in comparison with those with no known inherited defect. The increase in risk for PE associated with AT deficiency or PT-GA was more pronounced in women (RR 4.0, 95% CI 2.4-6.5 and 1.8, 95% CI 1.1-2.7, respectively) and in patients younger than 45 years (RR 3.6, 95% CI 2.3-5.6 and 2.0, 95% CI 1.3-3.0, respectively). In the subgroup of younger women the risk associated with AT deficiency was 4.9-fold increased (95% CI 2.6-9.2) and the risk associated with PT-GA was 2.3-fold increased (95% CI 1.3-3.9). *Conclusions.* The design of our study is susceptible of underestimation of the rate of PE among DVT patients. However, there is no reason to think that the pattern of underestimation should have differed among the patient groups, having the diagnostic procedures been carried out before the referral to the Thrombosis Center. Therefore, the estimate of the relative risk between patients is quite reliable. Our data suggest that patients with DVT have different risks of PE according to the genotype and that AT deficiency or PT-GA can lead preferentially to PE. The risk associated with such abnormalities is further increased in women and in younger individuals.

CANCER-RELATED VENOUS THROMBOSIS: RESIDUAL VEIN THROMBOSIS IMPROVES SCREENING FOR OCCULT CANCER

S. Siragusa, A. Malato, G. Saccullo, I. Abbene, D. Caramazza, L. Lo Coco

University Hospital of Palermo, PALERMO, Italy

Background. Clinical advantages of extensive screening for occult cancer in patients with idiopathic Deep Vein Thrombosis (DVT) is still debated since this approach improves early detection of cancer but not cancer-related mortality. Recently, we have demonstrated that patients with Residual Vein Thrombosis (RVT), 3 months after DVT, have a high risk for cancer in the subsequent 2 years (Siragusa S *et al.* Blood 2005;106(11):OC262). At the present it is unknown whether RVT assessment may be used to select patients, with idiopathic DVT, who require screening for occult cancer. *Objective of the study*. We conducted a prospective study evaluating whether a RVT-based screening for cancer is sensitive and influences cancer-related mortality. Study design. Prospective with two cohorts of DVT patients: the first cohort was monitored for clinical overt cancer only (Group A), while the second (Group B) received complete screening for occult neoplasm and subsequent surveillance. *Materials and methods*. Consecutive patients with a first episode of DVT who presented RVT after 3 month of anticoagulation and without signs and/or symptoms for overt cancer. Screening for occult cancer was based on: ultrasound and/or CT scan of the abdomen and pelvis, gastroscopy, colonoscopy or sigmoidoscopy, hemoccult, sputum cytology and tumor markers. These tests were extended with mammography and Pap smear for women and ultrasound of the prostate and total specific prostatic antigen (PSA) for men. All investigations had to be completed within four-weeks from the assessment of RVT. All patients were followed-up for at least 2 years. Incidence and cancer-related mortality was compared between the two groups by survival curves (Kaplan-Mayer) and related Breslow test for statistics. *Results*. Over a period of 6 years, 345 patients were included in the analysis: first cohort included 213 patients (Group A), second cohort 132 (Group B). Clinical characteristics between groups were homogenous. During the follow-up, 8.4% of patients developed overt cancer in group A; in group B, 8.3% of patients had diagnosed cancer at the moment of extensive screening while one new case (0.7%) occurred during the follow-up (Table). The sensitivity of this approach was 91.6% (95% confidence intervals 74.7-108.5). Cancer-related mortality was 6.5% in group A and 3.0% in group B ($p< 0.001$) (Table 1). *Conclusions*. Our study demonstrates that RVT-based screening for occult cancer improves early detection as well as cancer-related mortality.

Table 1. Cancer events.

Characteristic	Group A (n= 213)	Group B (N= 132)
Cancer, No (%) at screening time*	- -	10 (8.3)
Cancer, No (%) during clinical surveillance**	18 (8.4)	1 (0.7)
Density incidence (cases x 1000 p/y)	41.9	40.3
Mean time cancer diagnosis (months ±SD)	6.9 (1.3)	3.6 (0.7)
Cancer-related mortality, No (%)	14 (6.5)	4 (3.0)
Cancer-related mortality, mean time (months ±SD)	19 (3.4)	18 (2.8)

EFFECT OF FONDAPARINUX 2.5 MG ONCE DAILY ON ALL CAUSE MORTALITY: A META-ANALYSIS OF THROMBOPROPHYLAXIS TRIALS

J.W. Eikelboom,[1] A.G.G. Turpie[2]

[1]Hamilton Health Sciences-General Hospital, HAMILTON, ON; [2]Hamilton Health Sciences - General Division, HAMILTON, ON, Canada

Background. Compared with placebo, unfractionated heparin or low-molecular-weight heparins (LMWH), fondaparinux 2.5 mg once daily significantly reduced overall mortality by about 15% at 30 days in patients with acute coronary syndromes (OASIS-5 and -6). *Aims.* In order to determine whether this benefit was observed in other settings, we analyzed the effect of fondaparinux 2.5 mg on all-cause mortality in all phase III fondaparinux thromboprophylaxis trials. *Methods.* We performed a meta-analysis of 8 randomized, double-blind trials in patients undergoing major orthopedic (EPHESUS, PENTHIFRA, PENTAMAKS, PENTATHLON 2000, PENTHIFRA-PLUS) or abdominal (PEGASUS, APOLLO) surgery or in medical patients (ARTEMIS). In 5 trials, fondaparinux 2.5 mg once daily was compared with approved regimens of LMWH; in 3 trials, the comparator was placebo. Fondaparinux and comparators were administered for up to 31 days. The efficacy outcome was all-cause mortality up to day 32. *Results.* A total of 13,085 patients were analyzed. Compared with placebo or LMWH, fondaparinux demonstrated a non-significant reduction in all-cause mortality (p=0.058; test for heterogeneity: p=0.58). Consistent results were observed irrespective of the type of comparator (Table) and in subgroups according to gender, age, body-mass index, and a history of venous thromboembolism, myocardial infarction, stroke or cancer. In surgical trials, consistent results were also observed in patients in whom fondaparinux was initiated at least six hours after surgery. Fondaparinux tended to reduce similarly cardiovascular (OR 0.76, 95% CI: 0.55 to 1.06) and non- cardiovascular deaths (OR 0.81, 95% CI: 0.53 to 1.24). *Summary and Conclusions.* In thromboprophylactic settings, fondaparinux 2.5 mg once daily given for up to 31 days tended to reduce all-cause mortality relative to placebo/LMWH. This result is consistent with the long-term reduction in mortality observed with fondaparinux 2.5 mg in patients with acute coronary syndromes.

Table 1. Effect of fondaparinux on mortality.

Day 32	Fondaparinux 2.5 mg	Comparator	Odds ratio (95% CI)
versus placebo	2.0% (28/1405)	2.6% (36/1409)	0.77 (0.46 to 1.26)
versus LMWH	1.5% (77/5133)	1.9% (98/5138)	0.78 (0.58 to 1.06)
All studies	1.6% (105/6538)	2.1% (134/6547)	0.79 (0.60 to 1.01)

GESTATIONAL AGE-RELATED D-DIMER IN LMWH TREATED PREGNANT WOMEN WITH THROMBOPHILIA

U. Harbrecht, B. Enste, S. Flommersfeld, E. Höbert, H. Seidel, J. Oldenburg

Institute for Experimental Haematology and Transfusion Medicine, BONN, Germany

Background. D-Dimer is increasingly used to guide anticoagulation in pregnant women with thrombophilia and/or previous thrombosis. However, evidence in terms of onset, intensity and duration of anticoagulation is not well-established. Furthermore, gestational reference values for single D-dimer-tests are lacking. *Aims.* We investigated the course of D-dimer in low-molecular-weight heparin (LMWH) treated pregnants related to gestational age and intensity of anticoagulation. *Methods.* The study population comprised 292 women who had completed 323 pregnancies; 59% of patients had a history of thrombosis (n=171), 21% inherited (n=63) and 20% acquired (n=58) thrombophilia without thrombotic events. A subgroup of 24% (n=69) suffered from (recurrent) fetal loss. After risk stratification LMWH was given in prophylactic doses (n=303) at 40-100 AXaU/kg/d s.c. during entire or limited period of pregnancy and after delivery to achieve AXa-levels of 0.1-0.4 U/mL or in therapeutic dosis (100-200 AXaU/kg/d) in a few patients (n=20) with an AXa-target of 0.4-1.0 U/mL. D-dimer (Vidas D-Dimer®, Bio Merieux) and anti-factor-Xa (Heparin®, Instrumentation Laboratory) were measured at least once per trimester and in puerperium if possible. *Results.* Mean D-dimer (normal range 0-0.49 µg/mL) increased continuously under prophylactic LMWH regimen and was 0.44±0.29, 0.77±0.57 and 1.19±0.65 µg/mL in the first (week 8-13), second (week 14-26) and third trimester (week 27-40) and 0.57±0.65 (0.10-4.44) in puerperium (3-6 weeks after delivery). The corresponding AXa-levels were 0.27±0.12, 0.24±0.13, 0.26±0.13 and 0.40±0.17 U/mL, indicating antithrombotic therapy within the target range. In the therapeutic patient group D-dimer was considerably suppressed by LMWH. Two patients (0.6%) suffered from new thrombosis during LMWH therapy. *Conclusions.* D-dimer increases continuously with gestational age in heparin treated pregnants. Heparin appears to attenuate the natural increase of D-dimer dose-dependently.

0364

HEREDITARY AND ACQUIRED THROMBOTIC RISK FACTORS FOR CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION

C.L. Wong, R.M. Szydlo, S. Gibbs, M.A. Laffan

Hammersmith Hospital, LONDON, UK

Background. The role of thrombosis in the pathogenesis of chronic thromboembolic pulmonary hypertension (CTEPH) and non-CTEPH is not clear. Factor VIII (FVIII) is frequently elevated but previous studies have failed to identify a role for hereditary thrombotic risk factors. *Aims.* To analyse the frequency of both hereditary and acquired thrombotic risk factors in CTEPH compared to non-CTEPH. *Methods*. Between December 2005 and June 2006, 245 patients were investigated for pulmonary hypertension (PH) at Hammersmith Hospital. 45 had CTEPH and 200 had non-CTEPH. Patients were tested for antithrombin, protein C, protein S, Factor V Leiden (FVL) and prothrombin (PTG20210A) gene polymorphisms, antiphospholipid antibody (APA), lupus anticoagulant (LA), FVIII, von Willebrand factor (VWF) and fibrinogen. Ethnic group, blood group, WHO functional status and oxygen saturation were also recorded. *Results*. 9 out of 31 (29%) Caucasian patients with CTEPH *vs* only 10 out of 129 (5.15%) Caucasian patients with non-CTEPH were heterozygous for FVL (p=0.001). For the PTG20210A polymorphism, the frequency was not significantly different (p= 0.325) between the two groups, although the prevalence of 7.89% in CTEPH is similar to that in patients with thrombosis. In contrast to other studies, we have not found a significant increase in APA and LA. The incidence of elevated FVIII and VWF (>150 u/dL) was significantly increased in patients with CTEPH and non-CTEPH, although they were significantly higher (p<0.012) in the CTEPH group as compared to the non-CTEPH group. The ratio of blood group O to non-O between the 2 groups was found to be not significant (p=0.13). There was no correlation between fibrinogen and VWF levels in the CTEPH group (p=0.5), in contrast to the strong correlation between fibrinogen and VWF in the non-CTEPH group (p=0.001). There was no correlation between FVIII-VWF with WHO functional status in the CTEPH group although there was a strong correlation (p<0.001) between the two parameters in the non-CTEPH group. For equivalent WHO functional class, FVIII levels were higher in the CTEPH group. We have found no correlation between oxygen saturation and levels of FVIII and VWF in both groups of patients. *Summary and Conclusions*. The results indicate different pathophysiologies for CTEPH and non-CTEPH. This is the first study to find significantly increased prevalence of FVL polymorphisms and in association with the higher FVIII levels imply a role for thrombosis in the development of CTEPH. Higher levels of FVIII-VWF are not explained by differences in WHO functional class or oxygen saturation. The association between VWF and fibrinogen in the non CTEPH group suggests that elevation of VWF may be secondary to inflammation in this group and may also reflect associated disorders. The elevation of FVIII in the CTEPH group appears to be a primary phenomenon similar to that seen in patients with thrombosis and together with the increased prevalence of FVL in this group supports a primary role of thrombosis in aetiology.

0365

LEPTIN INDUCES THE EXPRESSION OF FUNCTIONAL TISSUE FACTOR IN HUMAN NEUTROPHILS AND PERIPHERAL BLOOD MONONUCLEAR CELLS THROUGH JAK2-DEPENDENT MECHANISMS AND TNFα INVOLVEMENT

S. Rafail,[1] I. Kourtzelis,[2] I. Mitroulis,[2] M. Speletas,[3] M. Doumas,[2] S. Giaglis,[4] K. Kambas,[2] G. Kartalis,[2] S. Konstantinides,[5] K. Schaefer,[5] K. Ritis[2]

[1]Democritus University of Thrace, ALEXANDROUPOLIS, Greece; [2]First Division of Internal Medicine, Medical School, Democritus University, ALEXANDROUPOLIS, Greece; [3]Department of Immunology and Histocompatibility, School of Medicine, University, LARISSA, Greece; [4]Foundation for Biomedical-Research of the Academy of Athens, Centre of Immunology, ATHENS, Greece; [5]Department of Cardiology and Pulmonary Medicine, Georg August University, GOETTINGEN, Germany

Background. Leptin is an adipocyte-derived cytokine primarily involved in the regulation of body weight and energy balance. Increased levels of plasma leptin have been observed in obese individuals and it is believed that hyperleptinemia may contribute to the atherothrombotic risk associated with obesity. *In vivo* studies suggest that leptin also promotes platelet aggregation and thrombosis in mice models. Furthermore, tissue factor (TF), the primary *in vivo* initiator of the extrinsic coagulation cascade, is expressed, among others, by inflammatory cells (activated endothelial cells and monocytes). Recently, polymorphonuclear (PMN) cells were also shown to produce functional TF. *Aims.* Inflammation and thrombosis are linked in many clinical disorders. Leptin is involved in the regulation of inflammation. We examined the effects of leptin on the expression of tissue factor in blood polymorphonuclear and peripheral blood mononuclear (PBMC) cells in an effort to elucidate the role of leukocytes as a source of circulating TF in hyperleptinemic disorders. *Patients and Methods.* PMN and PBMC from healthy donors (n=7) were incubated with leptin and the effects on TF expression were assayed functionally for TF activity, using a modified prothrombin time (mPT) as well as at mRNA and protein levels. Cell signalling inhibition studies were also performed in order to identify the molecular pathway involved in signal transduction. *Results.* Leptin stimulated PMN and PBMC induced a dose-dependent procoagulant activity as verified by mPT which could be completely blocked by the addition of a specific neutralizing antibody against TF. Moreover, leptin increased TF mRNA and protein expression levels in stimulated leukocytes, as determined by real-time RT-PCR, western blot, flow-cytometry and immunocytochemistry. Inhibition studies revealed that the effect of leptin on TF expression is mediated, at least in part, by JAK2 and PI3 kinase. At the same time, our findings, after neutralizing TNFα in supernatants of leptin treated cells, also suggest the involvement of TNFα in the leptin induced TF expression in leukocytes. *Conclusions.* Leptin appears to be capable of triggering the extrinsic coagulation cascade by upregulating the expression of TF in human leukocytes. These effects appear to be mediated by the leptin receptor and the JAK2-PI3 kinase intracellular signalling pathway and they may require, at least in part, the presence of TNFα. The contribution of PMN as a source for circulating TF via leptin suggests a possible novel link between obesity, inflammation and thrombosis.

0366

ENDOTHELIUM PROCOAGULANT AND ANGIOGENIC ACTIVITIES INDUCED BY ACUTE PROMYELOCYTIC LEUKEMIA (APL) CELLS ARE INHIBITED BY LOW MOLECULAR WEIGHT HEPARINS (LMWH)

A. Vignoli, M. Marchetti, L. Russo, D. Balducci, A. Falanga

Ospedali Riuniti, BERGAMO, Italy

Background. APL cells can stimulate endothelial cells to express procoagulant (PCA) and proangiogenic activities, which in turn contribute to the progression of the disease. LMWH have anti-inflammatory and antiadhesive properties on tumor cell/vascular cell interactions *in vitro*. Little is known on the possible effects of heparins on APL cell-induced endothelium procoagulant and angiogenic activities. Since endothelial Tissue Factor (TF) and its inhibitor TFPI are involved in the angiogenesis process, in a previous study, we demonstrated that LMWH dalteparin regulates the expression of TF and TFPI of microvascular endothelial cell (HMEC-1) stimulated by bacterial endotoxin (Vignoli *et al.*, Haematologica 2006). *Aims*. In this study we wanted to evaluate whether: 1. Two different LMWH (i.e. dalteparin and enoxaparin) may affect TF and TFPI of HMEC-1 exposed to APL cells; and 2. this effect may be associated to modulation of tumor-induced EC angiogenic response. *Methods.* HMEC-1 were incubated with tumor conditioned medium (CM) from the human APL cell line NB4, in presence or absence of LMWH dalteparin or enoxaparin (0.01, 0.1 and 1 IU/mL). After incubation, endothelial HMEC-1 were tested for TF activity by the one-stage clotting assay, released TFPI antigen by ELISA, and capillary-like tube formation by Matrigel assay. VEGF acted as standard proangiogenic factor. *Results*. NB4 CM induced a 47% increase in EC TF activity compared to control cells ($p<0.05$): this increase was dose-dependently inhibited by both LMWH, reaching a maximum of 70% and 78% mean inhibition with 1 IU/mL dalteparin and enoxaparin, respectively ($p<0.05$ for both LMWH vs NB4 CM alone). In addition, dalteparin and enoxaparin dose-dependently increased the release of TFPI by EC exposed to NB4 CM. In the same setting, both LMWH significantly ($p<0.05$) inhibited the capillary-like tube formation induced by NB4 CM, as well as by standard VEGF, giving a >80% inhibition at 1 IU/mL LMWH concentration against both stimuli. *Conclusions.* LMWH simultaneously counteract the prothrombotic features and the angiogenic response of microvascular endothelium elicited by APL cells. These results support a possible role for LMWH in controlling APL cell interaction with the vascular wall.

0367

PERIOPERATIVE MANAGEMENT OF ANTICOAGULATION WITH TAPERED DOSE WARFARIN

S. Schulman, B. Earl, M. Robinson

McMaster University, HAMILTON ON, Canada

Background. Controversy exists regarding optimal management of anticoagulation with warfarin before and after surgical procedures and randomized controlled trials are lacking. *Aims*. We have evaluated in a feasibility study tapered dose warfarin, which would eliminate the need for pre- and postoperative (low-molecular-weight) heparin injections. The intent was to achieve an International Normalized Ratio (INR) of 1.5 (range 1.2-1.7) on the day of the procedure, which maintains a certain degree of thromboprophylactic effect during the entire preoperative period, thereby obviating the need for bridging anticoagulation. *Methods*. We recruited at the HHS-General Hospital in Hamilton 70 patients on chronic treatment with warfarin and scheduled to undergo a variety of surgical procedures. Instead of stopping warfarin we tapered the dose by administering 50% of the maintenance warfarin dose for 5-6 days in patients with a baseline INR 3.0-3.5, for 4-5 days in patients with a baseline INR 2.1-2.9, for 3-4 days in patients with a baseline INR 1.9-2.0 and for 2 days in patients with a baseline INR 1.7-1.8. We obtained a new INR on the day before surgery and if possible also in the morning of surgery. In the evening of the day of surgery the patient took a double dose of warfarin, compared to maintenance, and thereafter the usual dose. The main outcome was the INR at the time of the procedure. *Results.* The baseline INR was 2.3±0.5. We attained a mean INR of 1.5±0.2 on the day before or the day of surgery with 86% within the desired range. Three patients (4%) had an INR of 2.0 or higher on the day of surgery. In a historical material with 200 patients stopping warfarin 5 days before surgery this happened in 3 cases (1.5%). Contributing to failure of reaching the intended INR range for surgery may have been misinterpretation of our instructions for dosing, since in 3 cases the INR increased and in 2 cases it remained unchanged from baseline.

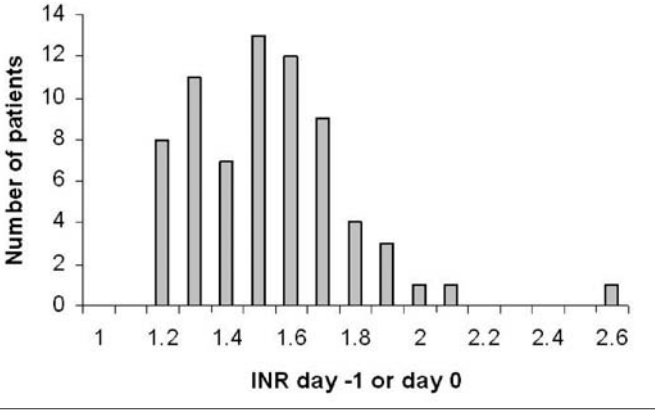

Figure 1.

Conclusions. Tapered dose of warfarin is an inexpensive alternative to bridging with heparins for invasive procedures. A small proportion of patients will remain in the therapeutic INR range by the time of surgery. This may be avoided by an INR the day before surgery and vitamin K 1 mg orally in case of unacceptable level, a strategy that we are now testing formally in a randomized controlled trial.

0368

LEONURUS HETERORHYLLUS SWEET (CHINESE MOTHERWORT HERB) EXTRACT INHIBITS TISSUE FACTOR EXPRESSION INDUCED BY THROMBIN ON HUMAN UMBILICAL VEIN ENDOTHELIAL CELLS

J. Yin,[1] GG Shi,[1] Y.J. Shen,[1] Z.W. Zhang,[1] X.G. Luo,[1] X.F. Wang,[2] H.L. Wang[2]

[1]Medical College of Shantou University, SHANTOU; [2]Shanghai Institute of Hematology, Ruijin Hospital, SHANGHAI, China

Background. Tissue factor (TF) is an initiator of coagulation and thrombosis as the receptor of clotting factor VII. Injured blood vessel endothelial cells release TF, which initiates thrombosis. In our previous study, we found that Chinese Leonurus Heterorhyllus Sweet (LHS) could inhibit thrombosis during heart ischemia. *Aims.* In this article, we investigated how LHS affected TF expression under the induction of thrombin on human umbilical vein endothelial cells (HUVECs). *Methods.* Twenty (20) grams of the dried herb (aerial part) was extracted. A stock solution of 250 mg raw material per milliliter was prepared from the freeze-dried powder of the herbal extract, from which a series of the diluted solutions were prepared in phosphate-buffered saline (PBS). Subconfluent proliferating HUVECs in 100-mm plastic dishes were incubated with thrombin (50 IU/mL) for 10 hours, and were sham-treated (control) or treated with the herbal extract (50 mg/mL for 48 hr at 37°C) in complete culture medium later. HUVECs were then washed twice with PBS to remove the herbal extract and harvested with help of trypsin for TF test. *Results.* LHS extract was effective in inhibiting TF transcription and expression induced by thrombin on HUVECs. The inhibitory action of the herbal extract was time- and dose-dependent, which reached its maximum when the final concentration of the herbal extract was 50 mg/mL and incubated with HUVECs for 48 hours at 37°C, a significant decrease of inhibitory action was shown when the drug exposure time was over 48 hours. TF activity was 31.17±3.78 U/10,000 cells (vs 58.19±4.17U/10,000 cells without LHS extract incubation, $p<0.01$), and TF antigen was 53.95±3.85pg/10,000 cells (*vs* 99.17±4.02pg/10,000 cells without LHS extract incubation, $p<0.01$) when the drug exposure time was 48 hours at 37°C and LHS extract final concentration was 50 mg/mL. Run-on assay showed that LHS extract down-regulated significantly TF gene transcription induced by thrombin on HUVECs. *Conclusions*. Leonurus Heterorhyllus Sweet was able to down-regulate TF expression induced by thrombin on human umbilical endothelial cells.

ELASTASE DEGRADATION PRODUCTS OF FIBRINOGEN AND VENOUS THROMBOEMBOLISM

F.J.L.M. Haas,[1] P. Meijer,[2] R.E.G. Schutgens,[3] D.H. Biesma,[3] K Cluft[2]

[1]St. Antonius Hospital, NIEUWEGEIN; [2]Gaubius Laboratory, TNO, LEIDEN; [3]UMC Utrecht, UTRECHT, Netherlands

Background. A specific enzyme immune assay (EIA) for degradation of fibrinogen (FgEDP) by proteases from polymorphonuclear leukocytes is capable of quantifying very low levels of split products. The levels have been found to be stable in individuals, but elevated during acute vascular events. The predictive value of elevated FgEDP for coronary and cerebral infarction is significant (odds between 3,8 -7,5 for highest quartiles). *Aims*. To evaluate FgEDP in patients with acute venous thrombosis. *Methods*. In 438 symptomatic outpatients, participants in a management study, investigating the use of D-dimer and a clinical decision rule in the exclusion of DVT, the FgEDP assay was tested and compared with the D-dimer EIA assay using the Moab FDP-14 (FbDP). From all patients the values of erythrocyte sedimentation rate (ESR) and white blood cell count (WBC) were known. *Results*. The relation between FgEDP and FbDP was significant in the thrombosis negative group (T^-) group ($p=0.03$), but not in the thrombosis positive (T^+) group. The area under the curve (AUC) of the Receiver Operation Characteristic (ROC) curve, as measure of the clinical accuracy of both assays, were 0.62 (95% CI 0.57 -0.67) for FgEDP and 0.90 (95% CI 0.88-0.93) for FbDP. From the ROC curve the optimal FgEDP cut-off point for exclusion of DVT was 200 µg/L with a sensitivity 96.9% and specificity 13.2%. The calculated negative and positive predictive values were 83% and 41%. There was no significant relation between FgEDP and age in the whole group ($p=0.17$) and in the T^+ group ($p=0.66$), but this relation was significant in the T- group ($p=0.007$). The relation FgEDP and ESR was significant at a 0.001 level in the whole group and both T^+ and T- groups. The relation with WBC was significant for the whole group ($p=0.01$), but not for the T+ ($p=0.37$) and T^- group ($p=0.07$). There was a significant difference ($p<0.01$) between the values of the FgEDP assay in the T+ and T- group: 306 (IQR 123) µg/L and 272 (IQR 114) µg/L respectively. Unadjusted logistic regression for quartiles of FgEDP, ESR and WBC showed odds ratio's of 3.05 (95% CI 1.67-5.55), 1.49 (95% CI 0.78 - 2.81) and 3.40 (95%CI 1.77-6.56) for the highest quartiles. After adjustment for age, gender and ESR and each other, the odds for FgEDP and WBC remained significant: 3.83 (95% CI 1.76-8.34) and 2.68 (95% CI 1.31-5.45). *Conclusions.* A significant odds ratio for elevated FgEDP and WBC indicate a role of inflammation in VTE. FgEDP appears the best discriminatory variable in this study. For clinical decision, however, inflammation variables are not useful and the accuracy of the FgEDP is too low for the exclusion of DVT, just as the predictive values.

0370

REVERSIBILITY OF THE ANTICOAGULANT EFFECT OF HIGH DOSES OF THE DIRECT THROMBIN INHIBITOR DABIGATRAN, BY RECOMBINANT FACTOR VIIA OR ACTIVATED PROTHROMBIN COMPLEX CONCENTRATE

J. van Ryn, D. Ruehl, H. Priepke, N. Hauel, W. Wienen

Boehringer Ingelheim Pharma GmbH & Co KG, BIBERACH, Germany

Background. Dabigatran is a potent, direct and reversible inhibitor of thrombin. Its antithrombotic and safety profile has been demonstrated in numerous *in vivo* models and in phase III clinical trials in DVT prevention after orthopedic surgery. However, concern regarding potential overdosing or uncontrolled bleeding has led to the testing of agents known to reverse hemostatic defects. *Aims.* This study investigated the effects of recombinant Factor VIIa (Novoseven®) or activated prothrombin complex concentrate (Feiba®) on the experimentally-induced bleeding by a high dose of dabigatran in anaesthetized rats. Reversal of anticoagulant activity monitored as the aPTT was also measured. *Methods.* Saline or dabigatran (1 µmol/kg bolus + 0.5 µmol/kg/h) was infused for 25 min. Novoseven® or Feiba® were administered as a bolus injection 20 min after infusion begin, i.e. 5 min prior to the bleeding determination. Bleeding was induced by a standardized incision with a Surgicutt® blade in the tail of anaesthetized rats. Blood sampling for aPTT was performed at the end of the infusion period. *Results.* Bleeding was 125±8 s (mean±SE) in control animals. High dose dabigatran elevated this to 1455±352 s. High doses of Novoseven® (1 mg/kg i.v.) or Feiba® (100U/kg i.v.) did not affect blood loss as compared to control. When administered with high dose dabigatran, Novoseven® (0.1 or 0.5 mg/kg) significantly reduced bleeding to 186±49 and 135±13 s, respectively. Similarly, Feiba® (50 or 100 U/kg) also significantly reduced bleeding to 146±11 and 174±18 s, respectively. Control aPTT was 7±0.5 s, after dabigatran this increased to 58±8 s. Addition of Novoseven® dose-dependently reversed the aPTT to 31±1.9 or 27±2 s. The aPTT was not shortened in the presence of Feiba®. *Conclusions*. Novoseven® as well as Feiba® at therapeutically relevant doses reversed the prolonged bleeding time in rats treated with a high dose of the direct thrombin inhibitor dabigatran. Novoseven® also reversed the prolonged aPTT, whereas Feiba® did not. This is consistent with previous data reported by others (Thromb Res 2001,101, 145). These data suggest that Novoseven® and Feiba® have the potential as antidotes for the oral direct thrombin inhibitor dabigatran etexilate in case of severe bleeding complications.

0371

EFFECTS OF DABIGATRAN, A DIRECT THROMBIN INHIBITOR, AS COMPARED TO ENOXAPARIN AND THE DIRECT FACTOR XA INHIBITOR, RIVAROXABAN, ON TISSUE FACTOR-INDUCED PLATELET AGGREGATION IN HUMAN PLATELET RICH PLASMA

J. van Ryn, M. Kink-Eiband, N. Hauel, H. Priepke, W. Wienen

Boehringer Ingelheim Pharma GmbH & Co KG, BIBERACH, Germany

Background. Direct thrombin inhibitors are potent inhibitors of platelet function when platelets are activated with thrombin. This action does not occur by direct binding of the DTI to the platelet PAR-1/-4 receptor, but indirectly, by inhibiting thrombin and thereby reducing its interaction with the receptor on the platelet. *Aims.* It was hypothesized that both direct thrombin and factor Xa inhibitors and enoxaparin could inhibit platelet aggregation, if the stimulus to initiate aggregation was higher in the cascade than factor Xa, such as tissue factor. Thus, the

direct thrombin inhibitor, dabigatran, the direct factor Xa inhibitor, rivaroxaban and enoxaparin were tested. *Methods.* Free flowing whole blood (60 mL) was obtained from an antecubital vein using an 18 gauge needle from healthy human volunteers and collected into 3.13% sodium citrate (1/10 dilution). This was centrifuged to obtain platelet rich plasma (PRP). Samples (300 µL PRP) were placed in a 6-channel light transmission aggregometer. Photometric tracings were continuously digitally recorded over 5 min following the addition of tissue factor and curves were evaluated as AUC and time to aggregation. PRP was incubated with 2 mg/mL Pefabloc®FG (Gly-Pro-Arg-Pro) to prevent fibrin polymerisation, 5 mM $CaCl_2$ and increasing concentrations of dabigatran, enoxaparin or rivaroxaban. Tissue factor (5-27 µl of 10 mL Innovin solution) was tailored for each individual, so that the minimum concentration resulting in maximum aggregation was used. As positive controls, aggregation was also performed after stimulating with ADP (10 µM), collagen (2 µg/mL), TRAP (20 µM) or ecarin (0.1 U/mL). *Results.* All substances inhibited tissue factor-induced platelet aggregation in a concentration-dependent manner. Dabigatran was the most potent inhibitor of platelet aggregation among the substances tested, with an IC50 of 35 nM, rivaroxaban followed with an IC_{50} of 312 nM and enoxaparin with 13µM. All substances had no effect on platelet aggregation induced by ADP, collagen and TRAP. Dabigatran was a potent inhibitor of ecarin-induced platelet aggregation, while rivaroxaban and enoxaparin had no effect, as expected from their mechanism of action. *Conclusions.* Thus, this study demonstrates that direct thrombin inhibitors (by inhibiting thrombin) and direct factor Xa inhibitors (by preventing thrombin generation) inhibit platelet aggregation, though dabigatran was more potent than rivaroxaban and enoxaparin under these experimental conditions. Thus, these substances may not only be effective in venous / stasis thrombotic episodes where fibrin formation plays an important role, but may also be effective in more platelet dominant, arterial thrombosis settings.

CIRCULATING PROCOAGULANT MICROPARTICLES IN PATIENTS WITH VENOUS THROMBOEMBOLISM

C. Ay,[1] J.M. Freyssinet,[2] T. Sailer,[3] R. Vormittag,[3] I. Pabinger[3]

[1]Division of Haematology and Haemostaseology, Department of Medicine I, VIENNA, Austria; [2]Université Paris-Sud, Le Kremlin-Bicêtre; Université Louis Pasteur, STRASBOURG, France; [3]Division of Haematology and Haemostaseology, Medical University of Vienna, VIENNA, Austria

Background. Circulating microparticles (MPs), small and phospholipid-rich vesicles released from the membrane of many cells upon activation or apoptosis, have been suggested to have an important role in coagulation. However, data from patients with venous thromboembolism (VTE) are scarce. *Aims.* The aim of our present study was to investigate the association of circulating procoagulant MPs with VTE in a population of high risk patients. *Methods.* We investigated procoagulant MPs in patients with a history of objectively confirmed recurrent VTE and in an age- and gender-matched control group of healthy individuals. All patients had at least one unprovoked event of deep venous thrombosis or pulmonary embolism. Plasma was obtained at least 3 months after the most recent event of VTE. The measurement of circulating procoagulant MPs was performed after capture onto immobilized annexin V and determination of their procoagulant potential with a prothrombinase assay. Comparison of categorical parameters among groups was done by Chi^2-test. T-test and Mann-Whitney-test were applied to compare metric variables with a normal or skewed distribution between patients and controls, respectively. Binary logistic regression analysis was applied to calculate the odds ratio (OR). *Results.* Hundred-sixteen patients (53 female / 63 male; mean age ±SD: 56±12 yrs) and 129 controls (66 female / 63 male; mean age ±SD: 53±11 yrs) were enrolled. Levels of MPs (nanomolar phosphatidylserine [nM PS]) were not statistically significantly elevated in patients compared to controls (median [interquartile range]: 5.35 [4.03-7.18] *vs* 5.30 [3.55-7.05], p=0.63). The OR of elevated MPs (cut-off at the 75th percentile of MPs level in controls) was 1.06 [95% CI: 0.59-1.88], p=0.85). *Conclusions.* In conclusion, we did not find an association between elevated procoagulant MPs and the risk of VTE, if studied during a chronic stage of the disease.

0373

INVESTIGATION OF THE ROLE OF PLATELETS IN CLOT BOUND THROMBIN ASSAYS AND THEIR CONTRIBUTION TO CLOT PROCOAGULANT ACTIVITY

P.M. Player, R. Luddington, S. MacDonald

Addenbrooke's Hospital, CAMBRIDGE, UK

Background. Thrombin bound to fibrin during the process of clot formation retains its activity and is still able to initiate further coagulation in the surrounding plasma as 95% of thrombin generation occurs after the moment of clotting. This is potentially of major clinical significance as a significant number of patients treated with anticoagulants following venous thromboembolism (VTE) have a second thrombotic event. By measuring the endogenous thrombin potential (ETP) the total amount of thrombin that a sample is capable of generating can be measured. *Aims*. The aim of this study is to determine Clot Bound Thrombin (CBT) activity and to investigate the procoagulant effects that these clots have on a plasma system. It has been shown that thrombin generation is initiated in platelet poor plasma (PPP) when in the presence of a plasma clot. In this study the role of platelet rich plasma (PRP) will be investigated to determine the role of platelets in the system and whether it is necessary to include them in an assay of CBT activity. Comparisons will also be made between thrombin generation assays with patients with a previous history of VTE and patients with known bleeding disorders. *Methods*. The experiment was a modification of the method described by Hemker, *et al.* (2003) (Pathophysiology of Haemostasis and Thrombosis 33, 4-15) using CBT to initiate thrombin generation. *Results.* The ETP relative fluorescence is greater in PRP (1088.75 FLU, SD=124.11) than in PPP (1011.5 FLU, SD=75.49) whereas the lagtime for PPP (18.81 min, SD=3.939969) is greater than PRP (10.53 min, SD=1.484192). The peak amount of thrombin produced for PPP (113.34 FLU, SD=9.077527) is greater than PRP (98.36 FLU, SD = 15.28028). The thrombin generation plot clearly shows that the ETP (area under the curve) is less for patients with a bleeding disorder (531.5 FLU.min, SD=91.92388) than the patients with a history of VTE (962 FLU, SD=158.8147). The VTE patients produce thrombin at an earlier time (14.80 min, SD=2.784526 *vs* 15.95 min, SD=1.774838) and at the greatest amount (124.3783 FLU, SD=20.60447 *vs* 53.315 FLU, SD=15.78969). *Summary/conclusions*. From this study platelets were shown to affect the single point and thrombin generation assays and represent a more physiological model. Varying the platelet count has also been shown to affect the results. The differences in platelet counts between patients will not give inaccurate results because this represents the patient's coagulation physiology and hence actual risk of bleeding or thrombosis. The results from the bleeding disorder patients show a decreased ETP level compared with patients with a history of VTE.

0374

THE INCIDENCE OF POSITIVE HIT ANTIBODIES IN A LARGE ICU, COMPARING THE USE OF UFH OR NORMAL SALINE FOR THE PATENCY OF THE ARTERIAL LINES

M. El-Ali, Th. Theodoridis, Ch. Kalpodimou, A. Pappas, B. Gerovasili, E. Angelopoulos, S. Poulaki, B. Markaki, D. Zervakis, S. Nanas, B. Christopoulou-Cokkinou

Evangelismos General Hospital, ATHENS, Greece

Aims. To compare the incidence of positive HIT antibodies during a period of 6 months of normal saline(NS) use instead of unfractionated heparin (UFH) for the patency of the arterial lines. *Material and Methods.* Two groups of patients (pts)were registered. The first group included pts hospitalized in the ICU from 01-01-07 to 30-06-07and UFH was routinely used. The second group included pts hospitalized from 01-07-07 to 31-12-07 and NS was used instead of UFH. HIT antibody detection was performed in cases of a clinical or laboratory suspicion. The ELISA method was used for the detection of HIT antibodies (Asserachrom HPIA, Diagnostica Stago, Asnieres, France). *Results.* In the first group 193 pts were included (64,2% survived), 38 pts (19,7%) had a clinical/laboratory suspicion of HIT(males: 23, females: 15, median age:63,3 years, median duration of hospitalization: 39 days, 38,9%survived),14pts of the 193 (7,3%) had positive HIT antibodies 232pts were included in the 2nd group (69,8%survived), 43 pts(18,5%) had a clinical or laboratory suspicion of HIT (males: 24, females: 19,median age: 62,9 years,median duration of hospitalization: 30,1 days and survival percentage 60,1%) ,positive HIT antibodies were detected in11pts of the232 (4,7%). *Conclusions.* The substitution of UFH by NS for arterial line flushing leads to a reduction in positive HIT antibodies. The difference is not statistically signif-

icant (p=0,18) but it is encouraging. Carefully planed studies of a larger scale are needed to confirm our results. Such a study has already been initiated by our research team.

0375

SYMPTOMATIC VENOUS THROMBOEMBOLISM IN MEDICAL IN-PATIENTS: A MULTICENTER ITALIAN SURVEY ON PREVALENCE, RISK ASSESSMENT, AND ATTITUDE TOWARDS PROPHYLAXIS

G. Gussoni,[1] M. Campanini,[2] M. Silingardi,[3] G. Scannapieco,[4] A. Mazzone,[5] G. Magni,[6] I. Iori[3]

[1]FADOI Study Centre, ROMA; [2]Internal Medicine, Maggiore Hospital, NOVARA; [3]Internal Medicine I, Arcispedale S. Maria Nuova, REGGIO EMILIA; [4]Internal Medicine, Cà Foncello Hospital, TREVISO; [5]Internal Medicine, Civile Hospital, LEGNANO; [6]QBGroup SpA, PADOVA, Italy

Background. Precise indications on epidemiology and prevention of venous thromboembolism (VTE) in medical in-patients are difficult to define because of the heterogeneity of design among available studies, and the complexity of patients population, frequently characterized by comorbidities and patient-specific multiple risk factors. The majority of in-hospital VTE occurs in medical services, and this trend is increasing over time, hence the need for up-to-date, real-world data on prevalence, risk profile and prophylaxis of VTE in medical in-patients. *Aims.* Objective of our study (GEMINI) was to contemporarily assess the epidemiology of symptomatic VTE in patients hospitalized in Internal Medicine (IM), to evaluate the impact of potential risk factors, and the attitude towards thromboprophylaxis. *Methods.* GEMINI was a prospective, observational study performed from March to September 2006 in 27 Italian Departments of IM adhering to FADOI (Italian Federation of Internal Medicine). Data from consecutive unselected patients admitted to IM were recorded during hospital stay, and a three-month follow-up was scheduled in patients with diagnosis of VTE and onset of symptoms later than 48 hours after admission (*hospital-acquired* events, primary study end-point). A sample size of 4500 patients was considered appropriate to document a reliable estimate of *hospital-acquired VTE,* by hypothesizing an event rate of 0.75±0.25%. *Results.* A total of 4846 patients were included (mean age 71.0±15.9, male 45.4%); the majority of patients (54.6%) had more than two active concomitant diseases at the time of admission. Symptomatic VTE was registered in 177 (3.65%) patients; of these, 26 cases (0.55%) occurred with onset of symptoms later than 48 hours after admission. In this group of patients no recurrent VTE was recorded, however a high rate of all-cause mortality (26.9%) occurred, at three-month follow-up. By means of multivariable regression analysis, previous VTE (Odds Ratio 8.52, 95% confidence interval 4.14-17.53) and bed resting (2.99, 1.91-4.71) were significantly associated with venous thromboembolism, while a trend for increased risk was documented in cancer patients. During hospital stay antithrombotic prophylaxis was administered in 41.6% of patients without VTE at admission (31.9% low-molecular-weight heparin, 8.7% oral anticoagulants, 0.8% unfractionated heparin, 1.0% other methods). Globally, 41.8% of GEMINI patients had indication to thromboprophylaxis according to 2004 Guidelines by the American College of Chest Physicians, and 58.7% of them actually received it. The choice of administering or not thromboprophylaxis appeared qualitatively adherent to indications from randomized clinical trials and international guidelines. As a specific finding, cancer patients were however less likely to receive thromboprophylaxis. Obesity and severe renal failure (conditions for which concerns have been raised on the appropriate use of heparins) were frequent in our unselected population (18.7% and 15.1%, respectively), therefore supporting the need for specific data on these patients, usually excluded from randomized clinical trials on thromboprophylaxis. *Summary and Conclusions.* VTE is a quite common finding in patients admitted to IM Departments, and recommended thromboprophylaxis is still under-used in this setting. Tough a difficult task to achieve, due to complexity of this population, further efforts are needed to reach a more systematic and appropriate use of prophylaxis in at-risk medical in-patients.

Vascular biology, bleeding disorders and transfusion medicine

REDUCTION IN PLASMA PROTEIN C & PROTEIN S LEVELS DURING VASO-OCCLUSIVE CRISIS IN CHILDREN WITH SICKLE CELL DISEASE

A. Piccin,[1] C. Mc Mahon,[2] C. Murphy,[3] E. Eakins,[3] O.P. Smith,[4] W.G. Murphy[5]

[1]Dept of Haematology Our Lady's Children Hospital, [2]Irish Blood Transfusion, DUBLIN; [2]Haematology Dept. Our Lady's Children Hospital, DUBLIN; [3]Irish Blood Transfusion Service, DUBLIN; [4]Dept of Haematology, Our Lady's Children Hospital, DUBLIN, Ireland

Background. Vascular occlusion is the main cause of crises in sickle cell anaemia (SCA). Recent studies suggest that the expression of phosphatidylserine and annexin V on sickle erythrocyte membranes together with increased micro-particle formation, may promote pro-coagulatant and inflammatory events that include: thrombin generation, endothelial cell adhesion, and vaso-occlusion. The protein C anticoagulant pathway serves as an *on demand* anticoagulant system. Thrombin binds to thrombomodulin results in a complex that rapidly converts protein C to activated protein C (APC). Activated protein C in complex with protein S functions as an anticoagulant by inactivating factors Va and VIIIa. Defects of this pathway are the most common basis for hereditary thrombophilia and infants born with homozygous protein C deficiency usually develop microvascular thrombosis of the skin (purpura fulminans). More recently, APC has also been shown to be cytoprotective to many cell types *in vitro* and *in vivo*. *Aims*. To compare plasma protein C and protein S levels in SCA patients in crisis with protein C and protein S levels in normal (age/ethnicity) matched controls and in SCA patients in steady state who were or were not receiving hydroxyurea or blood transfusion therapy. *Methods*. All patients and controls were of sub-Saharan African ethnicity. All SCA patients (n=119) had haemoglobin SS: 58 patients without history of crisis in steady state (mean age 5.3 years), 15 patients in sickle cell crisis (mean age 5.4 years), 31 patients on hydroxyurea (mean age 7.2 years) and 15 patients on transfusion therapy (6.5 years). Seventeen children of sub-Saharan African ethnicity of similar age (mean 4.6 years) were used as control group (haemoglobin AA). Protein C was analysed by chromogenic method and protein S by latex based assay. Data analysis was performed by a one-way analysis of variance. *Results*. Protein C values were significantly reduced in patients in crisis (mean=0.51 IU/mL; range 0.45-0.58; SD±0.11) compared to all other groups: controls (mean 0.70 IU/mL; range 0.64-0.76; SD± 0.12 p<0.001); hydroxyurea (mean= 0.66 IU/mL; range 0.62-0.70; SD± 0.12; p<0.001); steady state (mean =0.61 IU/mL; range= 0.58-0.64; SD± 0.11; range; p<0.05); and transfusion therapy (mean =0.63 IU/mL; range =0.59-0.68; SD±0.07; p<0.05). PS values showed a statistically significance between the control group (mean=0.77 IU/mL; range =0.68-0.86; SD± 0.17) vs crisis (mean= 0.54 IU/mL; range =0.45-0.64; SD± 0.17; p<0.001); control vs hydroxyurea (mean= 0.65 IU/mL; range =0.60-0.69; SD± 0.12; p<0.05); control vs transfusion(mean =0.62 IU/mL; range =0.54-0.69; SD±0.13; p<0.05) and crisis vs steady state (mean =0.67 IU/mL; range =0.64-0.71; SD±0.13; p<0.05). *Conclusions*. Plasma levels of protein C and protein S were significantly reduced in children during sickle cell crises but were normal in those patients on hydroxyurea and transfusion therapy. Protein C levels decrease dramatically in septic shock and the extent of the decrease is correlated with the risk of mortality and multi-organ failure. Although the absolute decrease protein C and protein S seen in sickle cell crises is not as dramatic as that seen in patients with sepsis, further studies are warranted to determine the clinical significance of these findings.

0377

ELECTIVE SPLENECTOMY IN CHILDREN WITH SICKLE CELL ANAEMIA: IS IT A CAUSE OF FURTHER CRISES?

A. Piccin,[1] R. Geoghegan,[2] H. Conroy,[2] H. Rizkalla,[3] M. Mc Dermott,[3] M. Corbally,[4] O.P. Smith,[2] C. Mc Mahon[5]

[1]1Dept of Haematology Our Lady's Children Hospital, 2Irish Blood Transfusion, DUBLIN; [2]Dept of Haematology, Our Lady's Children Hospital, DUBLIN, Ireland; [3]Dept of Pathology, Our Lady's Children Hospital, DUBLIN, Ireland; [4]Dept of Surgery, Our Lady's Children Hospital, DUBLIN, Ireland; [5]Haematology Dept. Our Lady's Children Hospital, DUBLIN, Ireland

Background. Acute splenic sequestration is a major cause of mortality in children with sickle cell anaemia (SCA). It is caused by intrasplenic trapping of red cells and is defined as a haemoglobin decrease of at least 2g/dL associated with a markedly elevated reticulocyte count and acutely enlarging spleen. Recurrent splenic sequestration is common and occurs at least in 50% of those who survive the first episode. Sequestration can occur in children as young as 5 weeks but is seen most often in children between the ages of 3 months and 5 years. Splenectomy (SP) is an accepted treatment for patients with recurrent splenic sequestration. Previous reports have suggested that SP increases the risk of developing further sickle cell events. *Aims*. Evaluating the outcome following splenectomy in SCA. *Methods*. We present a retrospective national study on children with SCA treated with elective SP. The medical notes of all children with SCA undergoing open SP at Our Lady's Children's Hospital, Dublin, between 2001-2007, were reviewed. The number of crises were recorded pre and post splenectomy. Blood values, obtained 4 weeks before SP in the absence of transfusion (T) therapy, were compared with values 3 months and 6 months after SP. White cell count (WCC), neutrophils (N), platelets (PLT), haemoglobin, haematocrit, mean corpuscular volume, bilirubin, lactic dehydrogenase (LDH), reticulocytes were recorded and variation (Δ) analyzed using Wilcoxon test (Graph Pad statistical package®). *Results*. Fifteen patients with SCA were identified: M=10, F=5 (M/F ratio=2) the median age was 5 years (range 13 months-15 yrs). All were of African ethnicity: 13 (86%) Nigerian, 1 (7%) from Congo and 1 (7%) from Angola. The indication for elective SP was recurrent splenic sequestration. Four patients had been started on hydroxyurea (HU) or Transfusion (T) before SP: one because cerebral stroke (T), 3 because chest crises (HU). All patients were transfused for 4 weeks prior to surgery to reduce HbS <30%. Sixty-six crises were recorded pre and 29 post SP. When splenic sequestration was excluded, there were 16 crises pre, and 36 post. The majority of crises were bone (62%) pre SP and abdominal (36%) post SP. Patients on HU/T did not develop further crisis. At 3 months post SP WCC, N and PLT values were all statistically significantly raised (ΔWCC p=0.03; ΔN p=0.03; ΔPLT p=0.0001). The trend continued at 6 months (ΔWCC p=0.001; ΔN p=0.002; ΔPLT p=0.002). Changes in haemoglobin, Hct and the markers of haemolysis (bilirubin, LDH and reticulocytes) were not statistically significant. *Conclusions*. Elective SP is a lifesaving therapeutic approach for children with recurrent splenic sequestration. However, this study demonstrates an increase in crises post SP. We suggest that the persistently elevated WCC, PLT, N values may be contributing factors. The adoption of disease modifying therapy, such as HU, may be needed to control these parameters in the future.

A CORRECT GATING STRATEGY PLAYS AN IMPORTANT ROLE IN RARE EVENT DETECTION OF ENDOTHELIAL PROGENITOR CELLS

J.L.A.J. Rummens, A. Daniels, H. Jongen, R. Koninckx, M. Hendrikx, P. Dendale, D. Hansen, K. Hensen

Virga Jesse Hospital, HASSELT, Belgium

Aims. In the present study, we aimed to optimise a six-colour multiparameter flowcytometric panel for EPC detection. Since EPC's are very rare in circulation, it is technically challenging to count such rare events and several layers of control were build in our analysis. Additionally, we investigated whether exercise could acutely increase the numbers of endothelial progenitor cells in circulation. Numbers of EPCs were compared between healthy volunteers and patients that underwent coronary artery bypass graft (CABG). Flow cytometric data were compared by the functional and morphological CFU-EC assay. *Methods*. Healthy volunteers (n=10) and post-op CABG patients (n=10) underwent an exhaustive bicycle exercise test. Age between groups were comparable. Blood (20 mL) was taken just before and 10 min after exercise. Mononuclear cells were isolated and samples were incubated using following combinations of monoclonal antibodies: CD3-FITC; CD15-FITC; CD133-PE; CD14-PerCP; CD34-PE-Cy7; VEGFR2-APC and CD45-APC-Cy7. In order to have a good estimate of non-specific binding of antibodies to cells, fluorochrome matched isotype controls were used in combination with fluorescence minus one (FMO). In addition, the FITC channel was reserved as dump channel using anti-CD3- and anti-CD15-FITC conjugated monoclonal antibodies. Approximately 2×10^6 events were acquired. Absolute cell numbers were determined with the single-platform method using TruCount Tubes (BD). To determine CFU-EC numbers, cells were grown in Endocult® following manufacturer's instructions. Statistical analysis was performed using *Analyse-it®* software. Pre- and post-exercise cell numbers were compared using Wilcoxon signed-rank test. Numbers between volunteers and patients were compared using the mann-whitney-U test. A p-value<0.05 was considered statistically significant. *Results*. An increase of EPC numbers before and after exercise could be obtained. The absolute number of $CD34^+/CD133^+/VEGFR2^+$ cells per mL blood in healthy volunteers changed nearly 2-fold (from 5,92±6.09 before exercise to 11.01±9.60 after exercise (p=0.04)). However, this increase was not statistically different for CABG patients (1.71±1.99 *vs* 7.19±15.14 p=0.38). Interestingly, the absolute EPC cell numbers in healthy patients is higher compared to CABG patients but only statistically significant after exercise (p=0.04).Different results were obtained when comparing the amount of CFU-EC colonies. There was almost no increase in the number of CFU-EC colonies after exercise. For healthy volunteers a mean of respectively 11.44±19.99 and 13.8±22.18 CFU-EC/106 cells before and after exercise was obtained (p=0.16). For CABG patients this number was only 1.03±1.00 and 1.39±1.45 (p=0.54). However the number of colonies between healthy volunteers and patients was significantly higher both before (p=0.008) and after (p<0.001) exercise. *Conclusions*. In conclusion, we developed a useful six-colour flowcytometric assay to detect EPCs in circulation. Our results show that physical exercise does increase circulating EPC numbers in both healthy volunteers and CABG patients. Moreover, our findings suggest that coronary arterial disease has a negative impact on the numbers of circulating EPC's and that after CABG operation numbers do not normalise. This study provides a basis to investigate the EPC numbers as a biomarker of cardiovascular status.

0379

RETROSPECTIVE EVALUATION OF DYSFIBRINOGENAEMIC PATIENTS AT A SINGLE CENTER: CLINICAL FEATURES AND LABORATORY FINDINGS

C. Santoro, A. Leporace, F. Biondo, P. Pignoloni, C. Mercanti, R. Foà, M.G. Mazzucconi

Hematology, ROMA, Italy

Background. Dysfibrinogenaemia is a very rare bleeding disorder in which the clinical phenotype is unpredictable. The literature consists predominantly of collections of case reports. A relatively recent compilation of over 250 patients, revealed that 53% were asymptomatic, 26% had haemorrhage and 21% had thrombosis, some of whom also had haemorrhage. *Aims.* To retrospectively investigate clinical features and laboratory findings of our dysfibrinogenaemic patients and to compare our data to literature's. *Methods.* Over the last ten years, 17 dysfibrinogenaemic patients were diagnosed at our centre [7 males, 10 females, median age at diagnosis 46.6 years (6.1-80.9), 8 families]. The reasons for admission were: finding of a reduction of fibrinogen activity in 12 patients, familial study in 5. Laboratory findings are shown in the accompanying Table 1.

Patients	Fibrinogen activity/antigen (mg/dL)	PT ratio 0.90-1.14	PTT ratio 0.92-1.16
1	112/380	1.07	1.1
2	Undetectable/250	1.3	1.2
3	36/192	1.2	1.3
4	66/250	1.17	1.12
5	52/140	1.2	1.06
6	57/140	1.1	1.02
7	62/380	1.16	0.9
8	70/250	1.04	1.08
9	50/470	1.3	0.9
10	98/226	0.9	1.09
11	Undetectable/195	1.14	1.1
12	Undetectable/250	1.2	1.04
13	Undetectable/250	1.09	1.32
14	Undetectable/250	1.2	1.06
15	56/192	1.2	0.9
16	Undetectable/215	1.28	1.04
17	Undetectable/400	1.28	1.15

Figure 1.

Results. Ten/17 (59%) patients experienced hemorrhagic symptoms, mostly mild: traumatic cutaneous bleedings in 7 patients; gastro-intestinal bleeding in 2; epistaxis in 3; gum bleeding in 2. One/17 patient (6%) experienced a cerebral ischemia (concomitant disease: acleisto-cardia). Twelve patients underwent surgery, eleven underwent dental extractions. Tranexamic acid was used as prophylaxis treatment of surgery in 2 patients. Only 1 patient bled after dental extraction. Eleven spontaneous deliveries and 3 cesarian sections were performed in 9 women without any prophylaxis treatment. No hemorrhagic or thrombotic complications were reported. No spontaneous abortions occurred. None of the 17 patients was transfused. *Conclusions.* We confirm that dysfibrinogenemia is a rare coagulation disorder. The prevalence of asymptomatic patients is inferior to literature data (35% vs 53%). Just 1 patient (6%) had a thrombotic event. Hemorrhagic patients (59%) experienced mostly mild symptoms. No one of them needed transfusion therapy.

0380

FIBRINOGEN OSTRAVA I AND OSTRAVA II

R. Kotlín,[1] A. Sobotková,[1] J. Suttnar,[1] T. Riedel,[1] B. Blazek,[2] P. Salaj,[1] J.E. Dyr[1]

[1]Institute of Hematology and Blood Transfusion, PRAHA; [2]Children`s Medical Clinic, University Hospital Ostrava, OSTRAVA, Czech Republic

Background. Fibrinogen is a 340 kDa glycoprotein which is composed of six polypeptide chains. It plays a crucial role in blood coagulation. Serine protease thrombin cleaves fibrinogen to fibrin monomer and releases N-terminal parts of Aalpha and Bbetachains, termed fibrinopeptide A and fibrinopeptide B, respectively. Hereditary dysfibrinogenemia is a disease wherein an inherited abnormality in the fibrinogen molecule results in defective fibrin clot formation. *Aim.* Aim of our study was to characterize a case of a gene defect causing dysfibrinogenemia in two unrelated families from Ostrava, Czech Republic. *Methods.* Fibrin polymerization and fibrinolysis were measured by turbidimetrical method. Kinetics of fibrinopeptide release was measured by HPLC method according to Suttnar *et al.*[1] In-gel digestion of separated fibrinogen chains was performed as described by Shevchenko *et al.*[2] Mass spectrometry was performed using Biflex IV mass spectrometer as described earlier.[3] Gene sequencing was performed by dideoxysequencing method. Scanning electron microscopy (SEM) was performed on VEGA Plus TS 5135 electron microscope as described earlier.[4] *Results.* Fibrinogen Ostrava I: The patients - 8 yr-old boy and his 2-yr-old brother - have prolonged thrombin time and low Clauss fibrinogen level (Table 1).

Table 1. Coagulation tests results .

	aPTT	PT	TT	fbg (Clauss)	fbg (Immuno)
Ostrava I	37,9 s	19,1 s	79,5 s	0,5 g/l	2,52 g/l
Ostrava I Brother	41,3 s	18,0 s	59,7 s	0,5 g/l	2,56 g/l
Ostrava I Mother	35,8 s	13,2 s	14,5 s	2,27 g/l	2,12 g/l
Ostrava II	n.d.	n.d.	156,9 s	0,68 g/l	3,58 g/l
Ostrava II Mother	159,5 s	n.d.	>180 s	0,75 g/l	1,72 g/l
Ostrava II Father	n.d.	n.d.	n.d.	2,1 g/l	2,82 g/l
Ostrava II Aunt	43,1 s	n.d.	30,2 s	0,83 g/l	2,68 g/l
Ostrava II Grandmother	170,7 s	n.d.	n.d.	1,17 g/l	4,13 g/l
Normal values	28,8 - 37,2 s	12 - 15 s	13 - 17 s	2,0 - 4,2 g/l	2,0 - 4,2 g/l

Fibrin polymerization was impaired and measurement of fibrinopeptide release showed higher rate of released fibrinopeptide B. The patient and his brother bear a heterozygous point mutation in exon 2 of FGA causing substitution of Aalpha 16 Arg to Cys. SEM revealed thicker fibres than control. Fibrinogen Ostrava II: The patient - 2 yr-old boy and his relatives have prolonged thrombin time and low Clauss fibrinogen level (Table 1). Fibrin polymerization was impaired and measurement of fibrinopeptide release showed higher rate of released fibrinopeptide B. The patient and his relatives bear a heterozygous point mutation in exon 2 of FGA causing substitution of Aalpha 16 Arg to His. SEM revealed thicker fibres than control. *Conclusions.* The patients were found to bear a point mutation in the fibrinogen Aalpha chain. Arg 16 is necessary for right fibrinopeptide A release by thrombin. Substitution Aalpha 16Cys was found to be more serious than substitution Aalpha 16His. Those mutations lead to impaired fibrinopeptide release and polymerization, abnormal fibrin clot and pathophysiologic coagulation.

This work was supported by a grant of The Grant Agency of the Czech Academy of Sciences nr. KAN200670701.

TRANEXAMIC ACID EFFECTS ON POSTOPERATIVE BLEEDING AFTER CARDIOPULMONARY BYPASS SURGERY: INFLUENCE OF PAI-1 GENE POLYMORPHISM

P. Machado, J.M. Raya, J.J. Jimenez, J.L. Iribarren, M.J. Rodriguez-Salazar, T. Martin, L. Morabito, M. Brouard, Y. Barrios, R. Martinez, M.L. Mora, J.M. Rodriguez-Martin

Hospital Universitario de Canarias, LA LAGUNA, Spain

Background. Excessive perioperative bleeding continues to complicate cardiopulmonary bypass (CPB) surgery and in some hospitals more than 25% of all blood products are assigned to open heart surgery. Postoperative hemorrhage is related to increased morbidity and mortality in patients undergoing cardiac surgery. Excessive postoperative bleeding (EPB) has been attributed to acquired platelet dysfunction, impaired coagulation, and increased fibrinolysis. The characterization of the hemostatic defects responsible for EPB is crucial for specific treatment and optimal clinical management of the patients. The plasminogen activator inhibitor-type1 (PAI-1) 4G/5G polymorphism is known to influence plasma levels of PAI-1, the main endogenous regulator of fibrinolysis, the 4G allele being associated with high levels and the 5G allele with low levels. *Aims.* To determine the effects of tranexamic acid (TA) on postoperative bleeding in CPB surgery according to 4G/5G PAI-1 gene polymorphism. *Methods.* We performed a prospective analysis on the postoperative bleeding effect of TA prophylaxis (2g), administered before and after CPB, according to PAI-1 polymorphism. We recorded data related to coagulation, fibrinolysis and bleeding, preoperatively, at admission (0-hr) to the intensive care unit (ICU), 4-hr and 24-hr postoperative. Excessive blood loss is defined as that above 1L/24 hours. For gene analysis, blood samples (3 mL) were collected before surgery in EDTA-containing tubes and subjected to DNA purification using proteinase K, phenol-chloroform extraction, and ethanol precipitation. Genotyping was performed in a blinded manner, without knowledge of any clinical data. Gene analysis of PAI-1 4G/5G polymorphism was performed in all patients using primers and restriction endonuclease digestion. In addition, neutral markers were genotyped to follow genomic control strategies that would detect spurious associations due to population substructure. SPSS v.15 was used for statistical analysis. *Results.* We studied fifty patients (24 with TA and 26 without TA). In patients not receiving TA, significant differences were found between PAI-1 genotype groups (4G/4G; 4G/5G; 5G/5G) in chest tube blood loss at 0-hr (p=0.03); at 4-hr (p=0.001) and at 24-hr (p=0.009). Fresh frozen plasma was required during ICU stay in 50% of 5G/5G, 25% of 4G/5G and none of 4G/4G carriers, (p=0.021). 4G/4G patients did not show significant differences in blood loss between TA and placebo groups. 4G/5G patients receiving TA had lower blood loss than placebo group at 0-hr (p=0.012), and at 24-hr after surgery (p=0.014). In contrast, 5G/5G patients receiving TA had significantly lower blood loss compared to placebo group at 0-hr (p=0.028), at 4-hr (p=0.008), and at 24-hr (p=0.004) after surgery. Fifty-five percent of 5G/5G patients in the placebo group received fresh frozen plasma during ICU stay compared with no patients in the TA group (p=0.014). *Conclusions.* In our experience, PAI-1 5G/5G homozygote patients who did not receive TA showed significantly greater postoperative bleeding than patients with other PAI-1 genotypes. 5G/5G homozygote carriers who received TA showed the greatest blood-sparing benefit. Finally, we consider that the main limitation of the study is the relatively small sample size, and that these findings require confirmation in larger series.

0382

THE COLLAGEN BINDING ASSAY IN THE DIAGNOSIS OF VON WILLEBRAND'S DISEASE

P.N. Badenhorst, S.M. Meiring, M. Kelderman

University of the Free State, BLOEMFONTEIN, South Africa

Background. Von Willebrand's disease (VWD) is a commonly inherited bleeding disorder caused by either a qualitative or quantitative defect of Von Willebrand factor (VWF). The standard assessment of VWF functional activity is the ristocetin cofactor assay (VWF:RCo), where dilutions of the patient's plasma are tested for their ability to promote platelet agglutination in the presence of the antibiotic ristocetin. Recently measurement of the collagen binding function of VWF (VWF:CB) was introduced as an additional functional test. Because VWF:RCo and VWF:CB measure different binding properties of VWF, the place of the VWF:CB assay in the diagnostic workup of VWD is still debatable. Furthermore, only one patient with a collagen binding defect of VWF has been reported in the literature. *Aims.* To determine the role of the collagen binding assay in the diagnosis VWD and to see how many patients in our comprehensive VWD testing facility had defective collagen binding as the only abnormality. *Methods*. For the first part of the study we tested 40 normal subjects; 10 with type 2A; 10 with type 2B; 14 with type 2M and 10 with type 1 VWD. We performed all prescribed laboratory tests for the diagnosis of VWD. These tests included the VWF antigen levels, ristocetin cofactor activity, collagen binding activity, multimer analysis with densitometric tracing, ristocetin induced platelet agglutination and the factor VIII binding assay. For the latter part of the study we performed the same tests on 105 patients referred to us with a history of bleeding. *Results.* We found the VWF:CB assay to be very sensitive to large VWF multimers with decreased values type 2A and 2B disease. The VWF:CB assay correlated well with the antigen levels in type 2M and type 1 VWD and contributes to the diagnosis of these sub-types. We found two patients with a collagen binding defect as the only abnormality. Both patients had a history of bleeding with normal VWF antigen levels; normal binding to platelets (ristocetin cofactor levels) and normal multimer patterns. However, the collagen binding activity of both patients was low compared to the antigen levels (CB/AG <0.3). An acquired defect due to the presence of autoantibodies to the collagen binding site of VWF was excluded by mixing studies with normal plasma. *Conclusions*. Our results suggest a definite place for the VWF:CB assay in the diagnosis of VWD and that it should be regarded as complementary rather than an alternative assessment of VWF functional activity. We also report two more patients with collagen binding defects that may be caused by mutations in the collagen binding (A3) domain of VWF. Genetic analysis is needed to confirm this.

REGRESSION OF ACQUIRED VON WILLEBRAND SYNDROME AFTER SUCCESSFUL TREATMENT OF LOW GRADE GASTRIC MALT LYMPHOMA

F. Biondo, A. Matturro, C. Santoro, P. Pignoloni, A. Leporace, A. Pulsoni, R. Foà, M.G. Mazzucconi

Hematology, ROME, Italy

Background. Acquired Von Willebrand syndrome (AVWS) is a rare bleeding disorder which mimics most of the clinical symptoms and laboratory features of the hereditary disease. Usually, this acquired syndrome occurs in persons with no personal or family history of bleeding; it is particularly frequent in lymphoproliferative or myeloproliferative diseases and it can also be associated with solid tumors, immunologic and cardiovascular disorders, and other miscellaneous conditions. Clinical history: A 48-year old woman was diagnosed with Von Willebrand Disease (VWD) in 2003 at another Institution following an episode of gastric bleeding. In that occasion, the endoscopy and biopsy showed a corrosive gastritis, without Helicobacter Pylori (HP) infection and no evidence of lymphoproliferative disease. The patient came to our attention in 2005 because of a second episode of gastric bleeding. She had no family history of hemorrhagic disorders and she had no personal history of bleeding (spontaneous or post-surgery) before 2002, when mucocutaneous symptoms (ecchimoses and menhorragia) occurred. Laboratory tests were as follows: aPTT ratio 1.15 (n.v. 0.92-1.16); PT ratio 0.90 (n.v. 0.90-1.14), bleeding time (BT) >13 minutes (n.v. <9 minutes), Ristocetin Cofactor Activity (VWF:RCo) 20% (n.v. 50-150), FVIII:C 52% (n.v. 48.5-120%), VWF:Ag 34% (50-126%), Collagen Binding Assay (CBA) 19% (n.v. 50-146%), Ristocetin Induced Platelet Agglutination (RIPA) 1.4 mg/mL (n.v. 0.8-1.2 mg/mL), VWF:RCo/Ag ratio 0.6 (discrepant <0.7); the diagnosis of VWD subtype 2A was therefore confirmed. A new gastric mapping endoscopy with multifocal biopsies was performed with desmopressin prophylaxis therapy and it showed an infiltration of low grade gastric MALT lymphoma B cells. Negativity of HP infection was demonstrated by serology and gastric biopsies. A bone marrow biopsy showed a <10% involvement; CT scan excluded other involved sites. The patient was classified as stage IVE according to the Ann-Arbor classification of extranodal non-Hodgkin's lymphomas (NHL). The patient underwent Rituximab immunotherapy at a dose of 375 mg/m^2 once weekly for four weeks. To prevent gastric bleeding, prophylactic treatment with Desmopressin 0.3 μg/Kg for 3 times a week was performed. *Results.* Restaging of the disease after Rituximab treatment indicated a partial remission; gastric biopsies showed the persistence of MALT lymphoma while the bone biopsy was negative. Maintenance treatment with Rituximab 375 mg/m^2 every three months for four doses was performed. Restaging documented a complete remission (absence of disease in the gastric biopsies and bone marrow). Since the start of Rituximab no gastric bleeding was recorded. On July 2007, reassessment of VWD was performed. Laboratory tests showed the following results: aPTT ratio: 0.87, BT 3 minutes, VWF:RCo 106%, FVIII:C 158%, VWF:Ag 110%, VWF:RCo/Ag ratio 0.96. To confirm these data, laboratory tests were repeated in October 2007. The results were: aPTT ratio 0.91, VWF:RCo 76%, FVIII:C 174 %, VWF:Ag 78%, VWF:RCo/Ag ratio 0.97. *Conclusions.* The normalization of the coagulative parameters in concomitance with a complete remission of the primary lymphoproliferative disorder allowed us to reach a diagnosis of acquired VWD in association with a low grade gastric MALT lymphoma. The successful treatment of the underlying primary disease was followed by a regression of the VWD.

EPIDEMIOLOGY OF TRANSFUSION RELATED ACUTE LUNG INJURY IN E-FIT, THE FRENCH HEMOVIGILANCE DATABASE : 1994 TO 2006. A STUDY OF THE FRENCH HEMOVIGILANCE NETWORK

P. Renaudier,[1] M.P. Vo Mai,[2] N. Ounnoughene,[2] P. Breton,[3] S. Cheze,[4] A. Girard,[5] L. Hauser,[5] J.F. Legras,[2] H. Odent-Malaure,[5] D. Rebibo,[5] S. Schlanger,[3] C. Waller,[5] B. Willaert,[2] C. Caldani[2]

[1]Unité d'Hémovigilance, LYON CEDEX 04; [2]AFSSaPS, SAINT DENIS; [3]DRASS, ROUEN; [4]CHU, CAEN; [5]EFS, CAEN, France

Background. Transfusion Related Acute Lung Injury (TRALI) is a life-threatening complication of allogenic blood transfusion, manifested typically by a non-cardiogenic pulmonary edema. However, the magnitude of the risk of TRALI remains unknown at this time, all the more so as a variety of other clinically similar respiratory complications can be associated with transfusion. Hemovigilance had been implemented in France since 1994. All adverse effects (AE) regardless of their severity should be notified on a normalized form to AFSSaPS, the French health products safety agency, as required by the French law. *Objective*. to describe TRALI observed in e-FIT, the French hemovigilance database. *Population and Methods.* AE possibly, probably or definitely associated with transfusion were considered for inclusion. As the item *TRALI* was explicitly present since 09/01/2001, we screened the database from 07/01/1994 to 09/01/2001 with *pulmonary edema AND fluid overload excluded*, or with free comments including the words *TRALI*, *anti-granulocyte antibodies*, *non-cardiogenic pulmonary edema*, *white lung syndrome*. The subsequent AE were considered for inclusion only if TRALI was the final diagnostic. *Results.* From 07/01/1994 to 12/31/2006, 85 812 AE were registered in e-FIT, corresponding to 35,423,172 labile blood products (LBP) transfused. 139 AE fulfilled the above criteria (1/81,000 LBP transfused). There were 74 men and 65 women, age = 0 to 86 (median 58). 111 patients presented with with dyspnea, 64 with chills and/or hyperthermia and 67 with a typical pulmonary edema. 15 TRALI were fatal, 101 were life-threatening and 23 were benign. 49 patients received only packed red cells, 8 only fresh frozen plasma and 51 only platelet concentrates. 29 patients received fresh frozen plasma either alone or associated with an other LBP ; the type of plasma was secured by quarantine for 27 (one donor) and treated by solvent-detergent (100 donors) for 2 (but associated with packed red cells and apheresis platelet concentrates and excluded). In no case, FFP treated with SD were involved. *Conclusions*. (1) TRALI is more frequent in elderly patients, as noted in other reports ; (2) Platelets concentrates remains the more frequently LBP involved, but packed red cells also contribute to nearly half of the TRALI reported ; (3) Plasma secured by quarantine is the only FFP involved ; (4). Besides the classical life-threatening presentation, a benign form of TRALI seems to exist

0385

THE DECLINING RISK OF ABO INCOMPATIBILITIES: TWELVE YEARS OF HEMOVIGILANCE IN FRANCE

P. Renaudier,[1] M.P. Vo Mai,[2] N. Ounnoughene,[2] P. Breton,[3] S. Cheze,[4] A. Girard,[5] L. Hauser,[5] J.F. Legras,[2] H. Odent-Malaure,[5] D. Rebibo,[5] S. Schlanger,[3] C. Waller,[5] B. Willaert,[2] C. Caldani[2]

[1]Unité d'Hémovigilance, LYON CEDEX 04; [2]AFSSaPS, SAINT DENIS; [3]DRASS, ROUEN; [4]CHU, CAEN; [5]EFS, CAEN, France

Background. ABO incompatibilities (ABOi) usually result from the failure to comply with Standard Operating Procedures (SOP). Continuous training (CT) is the main way to ensure their proper use in ultra-high security systems like civil aviation but little is known for transfusion. In France, SOP include a Beth-Vincent test at the bedside before the transfusion of Packed Red Cells (PRC). At the hospitals, Hemovigilance Officers (HO) are in charge of transfusion safety along with the settlement of traceability and the notification of all Adverse Effects (AE). If SOP and CT are requested by Law since 1993 for blood banks, they are only advised for hospitals even though the bedside Beth-Vincent test requires a special training. However, HO have more and more transposed the model of blood banks in hospitals especially since 2000. *Objective*. To describe time-trends of ABOi observed in e-fit, the French Hemovigilance database. *Population and Methods.* All AE with *acute ABOi* as the final diagnostic were considered. Time-trends were studied according to the Box and Jenkins model (ARMA). *Results.* From 07/01/1994 to 12/31/2005, 79 106 AE were registered in e-fit, corresponding to about 30,000,000 Labile Blood Products (LBP) transfused. 304 (0.4 %) were ABOi (1/107,850 LBP transfused). There were 183 men and 121 women with 81.3 % of whom more than 40 years old. 205 patients (67.4 %) received only PRC, 73 (24.0 %) Platelet Concentrates (PC), 22 (7.2 %) Fresh Frozen Plasma (FFP) and 4 (1.3 %) more than a single LBP. 18 ABOi were fatal, possibly (4 cases) probably (4 cases) or definitely (9 cases) associated with a PRC, and 1 doubtfully with a FFP. Time-trends displayed 3 periods : (1) from 1994 to 1997 ABOi increased concurrently with the frequency of all AE notifications, (2) from 1997 to 2000 reached a steady-state with 35 ABOi/year on average (1/70,000 LBP), (3) since 2001 regularly decreased of 14 %/year on average (13 ABOi for 2005 = 1/198,450 LBP). The localization of the failure to comply with SOP (i.e. hospital, blood bank or both) was studied for PRC. From 1997 to 2005, the liability of blood banks alone or along with hospitals remained stable (resp 0.42 and 2.58/year on average) whereas those of hospitals dramatically decreased (16.25/year from 1997 to 2000 and 8.6/year from 2001 to 2005). *Conclusions*. (1) ABOi are now 3 times less frequent than in 2000 ; (2) a notification bias is unlikely because both hospitals and blood banks are aware of traceability data that include the ABO phenotype for both the recipient and the LBP issued ; (3) CT applied on a nationwide basis seems to be the main factor to reduce ABOi in hospitals ; (4) a residual risk related to human errors seems to exist ; (5) the way to overcome that risk remains a matter of debate.

0386

EFFICACY OF RECOMBINANT HUMAN AND RHESUS THROMBOPOIETIN STIMULATED BLOOD TRANSFUSIONS IN COMPARISON TO UNSTIMULATED WHOLE BLOOD OR THROMBOCYTE TRANSFUSIONS IN A NON-HUMAN PRIMATE MODEL

F.S.F. Aerts Kaya,[1] T.P. Visser,[1] S.C.C. Hartong,[1] Z. Agur,[2] G. Wagemaker[1]

[1]Erasmus University Medical Center, ROTTERDAM, Netherlands; [2]Institute for Medical BioMathematics (IMBM), Bene-Ataroth & Optimata Ltd, RAMAT GAN, Israel

Background. Pre-treatment of allogeneic blood donors with thrombopoietin or other c-mpl ligands to increase thrombocyte counts would reduce apheresis volume, increase transfusion efficacy, decrease volume donated per recipient and the number of donors needed, and reduce the number of thrombocyte transfusions required and thus the cumulative risk of immune responses. *Aims.* We tested the efficacy of recombinant rhesus TPO (rrTPO) and human TPO (rhTPO) treatment of non-human primate blood donors on the total number of thrombocytes per transfusion and its effect on platelet and hematocrit increments in irradiated recipient monkeys. In addition, we used a pre-treatment regimen predicted by biomathematical modeling[1] for optimal efficacy and reduced immunogenicity, and measured the humoral immune response to TPO after up to 4 times challenging of donors. *Methods.* Healthy male rhesus monkeys (n=11) were treated with 5 µg/kg/d rrTPO or rhTPO (Genentech Inc.), administered subcutaneously for 4 consecutive days and served as donors up to 4 times for lethally or sublethally irradiated pancytopenic monkeys (n=21). Data were compared to regular thrombocyte transfusions or whole blood transfusions obtained from untreated animals and infused into irradiated control monkeys (n=23). Transfusions were collected in citrate and exposed to 20 Gy Á-rays delivered by a 137Cs source. Antibodies to TPO were demonstrated using a sensitive ELISA with a detection limit of 10 pg/mL. *Results.* Each transfusion was standardized to contain on average 1.0E+10 thrombocytes, independent of the source or stimulation status of the platelets. The average transfused volume was 10.3±4.2 mL for rrTPO stimulated transfusions, 14.6±3.4 mL for rhTPO, 32.1±6.4 mL (from 100 mL of blood) for regular platelet transfusions and 38.1±10.8 mL for whole blood transfusions. Transfusion with rrTPO or rhTPO stimulated blood products resulted in platelet increments of 33.4±26.0 and 28.0±19.7E+09/L, respectively, the former significantly different from 25.4±19.2E+09/L observed for regular platelet transfusions ($p<0.05$). Hematocrits were not affected by infusions of TPO stimulated platelet transfusions, contrasting an average 6.1% unstimulated whole blood transfusion. The average increment of thrombocytes per mL infused volume was 0.8±0.6E+09/L for both whole blood and thrombocyte transfusions and was significantly higher for both rrTPO with an increase of 3.4±2.4E+09/L ($p<0.01$) and rhTPO with an increase of 2.0±1.6E+09/L ($p<0.01$). Even after 4 cycles of rr or rhTPO pretreatment, antibodies to TPO were not detected using the regimen predicted by the biomathematical model. *Conclusions.* A mathematically predicted non-immunogenic TPO administration regimen adapted for multiple pre-treatment of blood donors resulted in a significant increase of blood platelets and in well-tolerated collection of the required 1.0E+10 thrombocytes per transfusion unit. Despite the 7- to 10-fold lower total volume obtained from the donor monkeys after TPO stimulation, platelet increments in recipients were significantly higher. These data demonstrate that use of TPO or a TPO-mimetic can considerably reduce blood volume required per recipient while significantly promoting transfusion efficacy.

VESICULATION DURING STORAGE OF RBCS - OXIDATION, PHAGOCYTOSIS AND FAS-RELATED SIGNALLING MOLECULES

A. Kriebardis,[1] M. Antonelou,[1] K. Stamoulis,[2] E. Economou-Petersen,[3] L. Margaritis,[1] I. Papassideri[1]

[1]University of Athens, ATHENS; [2]Blood Transfusion Center, NIKEA, PIRAEUS; [3]National Blood Center, ATHENS, Greece

Background. Red blood cells (RBCs) lose membrane *in vivo*, under certain conditions *in vitro* and during *ex vivo* storage. The vesiculation influences the viability of stored RBCs and the post transfusion performance. *in vivo*, the RBC-derived microvesicles expose PS and are rapidly removed from the circulation by means of scavenger receptors. At least a part of the apoptotic machinery that is active in nucleated cells exists in mature RBCs. They further suffer protein oxidative damages during storage and progressively exhibit most of the *aging* characteristics of signalling potential, namely the activation of caspases and membrane binding of IgGs. *Aims.* The concept of the protein oxidation, phagocytosis-associated and Fas-related signaling as a part of the RBC storage lesion has been supported by previous reports. Despite that, there is not an established connection between them and vesiculation during storage. The presently reported work aimed to investigate this probable connection. *Methods.* Vesicles were isolated from the plasma of twenty-one non-leukoreducted packed RBCs (pRBCs) units in CPDA, at eight different time-points of the storage period and shortly afterwards. The oxidation status and the composition of the vesicles were evaluated by means of immunoblot. Ghost membranes were also investigated as controls. *Results.* IgGs-specific bands were detected in vesicles beginning from the first days of storage while the CD47 membrane marker was found in them at two weeks onward. The vesicles contain Fas/CD95, FADD and full length caspase 3 and caspase 8. Low MW cleavage products of caspase 8 and caspase 3 were also increasingly detected in the vesicles at 10 days onwards. The protein oxidative indexes of vesicles stored up to 21 days were significantly greater compared to those of the corresponding membranes of origin. Some of the oxidized protein bands have been identified as actin, band 3 and stomatin. *Summary and Conclusions.* The IgGs composition of the vesicles closely resembles that of

pRBCs stored for long periods in CPDA. The presently reported high protein oxidation index of vesicles provides direct evidence for a link between the storage-induced protein oxidation and vesiculation processes. The findings suggest that the vesicles (i) represent a microenvironment of high oxidative stress or of gathering oxidatively damaged proteins and (ii) have the same mechanism of recognition with their parent and/or senescent RBCs, including the binding of autoantibodies. The presence of CD47 showed that the vesicles contain more than one phagocytosis-related signals. Hence, the effectiveness of their clearance could be related to both the type and the amount of signals exposing on their surface. Our novel findings commit substantiating data for the existence of Fas-dependent signaling components inside the vesicles released during storage and circumstantial evidence for the action of a Fas/FADD/caspase 8/caspase 3 complex. The gathering of oxidative proteins and reactive signalling components into vesicles strongly suggests that the vesiculation further operates as an effective way of discharging damaged or *dangerous* proteins produced in the pRBC units during storage.

RELATION OF PRESENTING FEATURES WITH CLINICAL AND LABORATORY OUTCOMES OF TTP/HUS PATIENTS

M.M. Yilmaz,[1] B. de Laat,[2] J.L. Kerckhoffs,[3] R.R.P. de Vries,[1] A. Brand[1]

[1]Dept of Immunohematology and Bloodtransfusion,Leiden University, LEIDEN; [2]Dept of Blood Coagulation,Sanquin Diagnostic Services, AMSTERDAM; [3]Dept of Hematology,Haha Hospital,, THE HAGUE, Netherlands

*Background.*Thrombotic thrombocytopenic purpura (TTP) is an uncommon hematological disorder characterized by severe thrombocytopenia, coombs negative hemolytic anemia with fragmented eritrocytes, fever and with renal and/or neurologic findings. Pathology for most forms of TTP is due to a severe defect in protease that cleaves von Willebrand factor (VWF). This metalloprotese is referred to as ADAMTS-13. However cases with acquired TTP, may have severe ADAMTS-13 deficiency secondary to the development of anti ADAMTS 13 antibodies. *Aims.* In the current study we analyzed retrospectively the ADAMTS-13 activity, antigen and inhibitor levels in plasma of TTP-HUS patients and thereby evaluated the possible association between ADAMTS-13 antigen, activity antibody and plasma exchange and the other presenting clinical features. *Methods*. This study is a retrospective analysis of TTP/HUS patients treated between 1984 and 2005 in Leiden University Medical Center and Haga Hospital ,the Netherlands. Measurement of the ADAMTS-13 activity in plasma was performed with TRETS assay (j. Thromb Haemost 2007,5:1330-1). Both for the activity and antigen assay a value of <30 was considered as decreased. The Antigen assay was newly developed by one of us (BdeL). Tecnozym ADAMTS13 inhibtor assay was used antibody assay. For the antibody data a titer of >15 is considered as positive. *Results.* We investigated 65 adult TTP-HUS patients, Fourty six (70.8 %) out of 65 TTP/HUS patients had a complete remission. The ADAMTS-13 activity in plasma were measured in 39, antigen and antibody in 37 patients. The ADAMTS-13 activity in 16 of 39 (41%) and antigen for 14 (37.8%) TTP-HUS patients had low (<30) levels. 24 of 37 (64.8%) TTP-HUS patients had high level of ADAMTS-13 antibody (>15). Three of them were secondary TTP-HUS patients. There was no statistical difference for antibody levels between early, moderate and late responder groups (p=0.642). And also there was no statistical difference for TPE volume between early and late responders group and early and moderate responders group (p=0.916) (p=0.262). But it was determined that in relapsed patients antibody levels were higher than in non-relapsed patients. This was statistically significant (p<0.0001). *Conclusions*. ADAMTS-13 antibody level at the beginning of the disease did not differ between early moderate and late responder groups but may help to predict patients who will possibly relapse.

0389

PREOPERATIVE INDIVIDUALIZED PROTOCOL REDUCE THE NEED FOR TRANSFUSION IN ELECTIVE TOTAL HIP OR KNEE ARTHROPLASTY

E. Colado, J.R. González-Porras, M.P. Conde, J. Martín-Sánchez, J. Olazabal, J. Alonso, L. López-Corral, M.P. Nieto, M. Corral

Hospital Universitario de Salamanca, SALAMANCA, Spain

Background. Individualized, patient based protocols can reduce Allogeneic Blood Transfusion (ABT) in elective surgery. *Aims.* To obtain a preoperative hemoglobin (Hb) level ≥14 g/dL and normal iron stores, and to reduce the number of ABT in major elective orthopedic surgery patients. *Methods.* Between January 2005 and September 2007, 305 patients were enrolled in an optimal use/blood-saving program (OU/BSP) based on the correction of preoperative iron-deficiency anemia or chronic inflammation anemia as soon as surgery was scheduled. Patients were classified according to Hb levels. Surgery was delayed in anemic patients with Hb ≤ 10 g/dL until the cause had been identified and properly treated. Patients with Hb 10-13 g/dL received recombinant human erythropoietin (rHuEPO) and/or oral or intravenous (IV) iron, depending on their iron metabolism parameters and time to surgery. Patients with Hb 13-15 g/dL were treated with IV or oral iron and autologous predonation was considered. Patients with Hb higher than 15 g/dL were given no treatment. We used the chi-square test and Student's t-test in the univariate analysis, and multivariate analysis was performed using multiple logistic regression (Forward method). P values < 0.05 were considered statistically significant. A cohort of 305 patients was enrolled and was compared to a matched historical control. No differences were observed when comparing age (68.1±10.6 *vs* 68.8±9.9 years), sex (Male 124 / Female 181 in both groups), weight (72±12.6 *vs* 74±10.5 kg), surgical procedure (46,6%, hip arthroplasty; 54,4%, knee arthroplasty in both groups), ferritin level (127±227 *vs* 129±126 ng/mL) or Hb levels (13.8±1.32 *vs* 13.8±1.4 g/dL) nor time to surgery. 80 patients (26.2%) required no therapeutic intervention, 145 patients (47,5%) were treated on oral iron therapy, 49 patients (16.1%) were treated with IV iron, 9 patients (3%) were treated with rHuEPO and iron, autologous predonation was performed in 20 patients (6.6%), loss of follow-up occurred in two patients (0.7%). *Results.* 80% of patients in our program obtained a preoperative Hb of 14 g/dL or more, compared with 60% of our historical cohort (p< 0.001). Subsequently, 18% of our patients received ABT whereas 31.8% of our historic control did (p<0.001). As expected, 40% of patients on autologous predonation program received blood transfusion. In the multivariate analysis, the variables independently associated with a higher risk of red blood cell transfusion were: weight > 70 kg (*vs* < 70 kg) [52% *vs* 10%, p= 0.003], hip arthroplasty (*vs* knee) [38.2% *vs* 11.7%, p= 0.003] and presurgical Hb < 14 g/dL (*vs* presurgical Hb > 14 g/dL) [47.6% *vs* 16.5%, p= 0.002]. *Conclusions*. Strategies aimed at reducing ABT should be individualized on a patient basis. Autologous predonation increases the overall risk of transfusion.

0390

USE OF A NOVEL POST-OPERATIVE CELL SALVAGE SYSTEM IN CARDIAC SURGERY

I.M. Anderson, I. Quasim, M. Steven, L. Soutar

Western Infirmary, GLASGOW, UK

Background. Cardiac surgery uses approximately 20% of US national blood stocks. With pressure on blood supplies and well documented risks associated with transfusion, there has been increased interest in minimising blood use by pharmacological or mechanical means. Intraoperative cell salvage has been used in cardiac surgery for many years however a recently introduced system (CardioPat) has been specifically designed to address some of the technical challenges presented by post-operative cardiac surgery; the system accurately measures blood loss and is able to apply a variable amount of suction to the drains. Traditionally blood collected postoperatively in chest drains has been discarded however the CardioPat system collects blood lost from mediastinal drainage, washes it, haemoconcentrates to approximately 80% and resuspends the red cells for autotransfusion. *Aims.* We aimed to assess the effectiveness of this system in postoperative patients who were felt to be bleeding excessively on their return from theatre. *Methods*. Patients who bled more than 80 mL in at least two consecutive 15 minute periods on their return from theatre were targeted and connected to the CardioPat system. Demographic details were collected as per normal audit procedure, as were details on admission and discharge Haemoglobin (Hb) concentrations. Total mediastinal blood loss was noted as was the amount of washed red cells returned to the patient. Blood bank transfusion details were collected at discharge from hospital. Transfusion triggers and routine clinical care were observed as per unit protocols. *Results.* In our institution, mean red cell use is 1.7 units per patient and mean postoperative mediastinal drain losses are 960 mL. The CardioPat device has been used postoperatively in 34 patients to date. Mean mediastinal drain losses were 2394mL in this group (range 780-7400 mL). The device produced an average of 295 mL of blood for re-infusion (range 15-2340 mL). This is equivalent to an average of 1.7 units of red cells (range 0.1-14.2). Mean homologous transfusion in this group was 6.7 units. This is similar to a group defined as bleeding excessively in a previous audit however discharge Hb in our patient group was higher (9.7 g/dL v 9.2). Admission and discharge Hb in this group of patients were similar to oth-

er cardiac patients (13.4 g/dL and 9.7g/dL respectively). *Conclusions*. The CardioPat has proved useful in this postoperative setting and can lead to considerable reductions in homologous transfusion. The current UK cost of a unit of red cells is £150 therefore use of the CardioPat has been cost-neutral. Universal cell salvage has been criticised for increasing costs; targeting this higher risk group allows cell salvage to become cost-neutral and even cost-saving.

CONTINUING EDUCATION IN TRANSFUSION MEDICINE: 12 YEARS OF EXPERIENCE IN THE UNIVERSITY HOSPITAL OF SALAMANCA

J. Martín-Sánchez,[1] E. Colado,[1] C. Encinas,[1] I. De la Fuente,[1] M.J. Rodriguez,[2] J.R. Gonzalez-Porras,[1] M.J. Nieto,[1] M. Corral[1]

[1]Hospital Universitario de Salamanca, SALAMANCA; [2]Hospital Nuestra Señora de Sonsoles, AVILA, Spain

Background. Demography and clinical context of our transfused population have radically changed in the past few years. These variables have influenced transfusion practice medicine in our setting. *Aims*. To analyze transfusion practice during the years 2004, 2005, 2006 and 2007, and compare it with our own experience since 1995. To assess the utility and impact of continuing transfusion education and analysis started in 1995, in the consecution of transfusion excellence and detection of new clinical problems related to transfusion. *Methods*. A prospective concurrent design was followed; a 2 month period was analyzed using a basic transfusion form. Local transfusion guidelines were created in 1995 and periodically reviewed afterwards. Widespread knowledge of the guidelines was guaranteed thanks to clinical sessions, speeches, personal case-by-case advice, department oriented clinical sessions, daily instruction, and the annual meeting of the hospital transfusion committee. Two independent analyzers reviewed every form and determined the adequacy of each transfusion event according to those guidelines. *Results*. We analyzed 1442 transfusion events in 726 patients. 1001 of the events corresponded to packed red blood cells (RBC) (289, 235, 218, 254 in 2004, 2005, 2006 and 2007 respectively), 305 to pooled or apheresis-obtained platelets (PT) (80, 118, 107 and 169; 2004, 2005, 2006 and 2007), and 8 to fresh frozen plasma units (FFP) (all in 2006). Median age of our population was 66 years (interquartilic semirange, IS, was 49-76 years), and 50.1% of our patients were older than 65. RBC receptors' median age was 71 (IS 57-78), *vs* 64 in 1995. PT receptors' median age was 55 (35-65). Hematology patients received 47.1% (680 transfusion events), and together with oncological patients accounted for 53.6% of all transfusions (764 events). Pretransfusional haemoglobin values have followed a declining trend during the last 3 years and since 1996: in 2007 they are 7.6g/dL. RBC transfusion inadequacy amounted to 3.8% (24 out of 733; 4.2%, 1.7%, 3.7%, 5,2% in 2004, 2005, 2006 and 2007 respectively). For PT the rate was 8% (38 out of 473 events), annual rates were 10% in 2004, 18.6% in 2005, 3.7% in 2006 and 2% in 2007. In 1995, the rate was 32% for RBC, but prompt educational intervention made it go as low as 5.8% with a first educational action in 6 months time (1996; $p<.0001$). This low rate of inadequate transfusions has been maintained as shown above with only one increase in 1998. A new educational intervention was effective again. *Summary and Conclusions.* We have demonstrated that a continuing education approach is the most valuable tool to achieve optimal use of blood components. Continuing transfusion education and assessment are unavoidable if we are to maintain our present quality standards, as new problems arise because of a changing clinical scenario. One of the problems is the risk of undertransfusion if haemoglobin transfusion thresholds descend even more. Another one, transfusing and ageing population. Thus, careful monitoring of haemoglobin trigger, quality of life and clinical state of the receptors must be a priority.

0392

TWO-YEAR AUDIT OF THERAPEUTIC APHERESIS ACTIVITY IN A TERTIARY REFERRAL CENTRE IN IRELAND: ANALYSIS BY 2007 AMERICAN SOCIETY FOR APHERESIS GUIDELINES

T. Swords,[1] R. Swords,[2] Z. Heetun,[2] C. Gibbons,[2] O. Langan,[2] K. Mulhall,[2] P. Hayden[2]

[1]University College Hospital Galway, GALWAY; [2]Galway University Hospital, GALWAY, Ireland

Aims. We performed a retrospective analysis of all patients undergoing therapeutic apheresis (TA) in a large tertiary referral centre over a 2 year period (2006-2007). The indications for TA were then classified using the 2007 guidelines of the American Society For Apheresis (ASFA) in order to determine the evidence base underlying current TA activity at our institution. *Methods*. The indications for TA were taken from the medical records of patients treated between January 2006 and December 2007 inclusive. Procedural details of each TA episode were also compiled from apheresis service records. *Results*. There were 27 patients treated during this 24 month period, 13 males (48%) and 14 females (52%). A total of 165 apheresis procedures were performed, of which 61 (37%) were for ASFA category 1 indications, 36 (22%) for category 2 and 68 (41%) for category 3 disorders. Of the procedures conducted, 85 were for neurological (52%) disorders, 36 for renal (22%), 20 for haematological (12%), 18 (11%) for autoimmune conditions and 6 (4%) for metabolic diseases. The most common conditions requiring plasmapheresis were Guillain-Barre syndrome and Myasthenia Gravis. The average procedure time was 72 minutes. A total of 128 (78%) of the TA procedures required the placement of Central Venous Access Devices. Peripheral venous access was sufficient in 37 (22%) of the cases. The main complications related to achieving venous access and fluctuating Access Pressures. Human Albumin Solution (4.5%) was the most commonly used replacement fluid (91% of procedures) and all patients had a single plasma volume exchange. *Summary and Conclusions*. The 2007 ASFA guidelines were useful in allowing for clear category assignment. The availability of fact sheets with details of the evidence base for TA in each given condition was helpful for the TA team, patients and clinical service users. The guidelines highlighted shortcomings in our practice particularly with respect to the number of category 3 procedures conducted. For individual cases, the choice of replacement fluid, number of apheresis procedures performed and plasma volumes exchanged in our practice were often at variance with the proposed guidelines. The authors have now adopted a revised approach to clinical apheresis, which closely follow the ASFA approach, in the hope of reducing the number of unnecessary procedures and improving cost effectiveness. This information will facilitate rational use of this limited resource in the future.

0393

MULTIPLATE IMPEDANCE AGGREGOMETRY AS A PREDICTOR OF POST-OPERATIVE BLOOD LOSS IN CARDIAC SURGERY

I.M. Anderson, S. Travers, I. Quasim, M. Steven, L. Soutar

Western Infirmary, GLASGOW, UK

Background. Surgery involving cardiopulmonary bypass is recognised to have a significant impact on platelet function both in terms of platelet dysfunction due to direct platelet damage from the bypass machine's roller pumps and also due to pharmacological effects of pre-operative antiplatelet medication. Accordingly there has been significant interest in point-of-care tests of platelet function. Various methods are available to assess platelet function. Impedance aggregometry was first described in 1979 but has recently been modified to allow multiple tests to be performed simultaneously and analysed by computer. The Multiplate analyser determines an area under the curve in response to stimulation of activation pathways and thus determines platelet function. *Aims.* We sought to assess the ability of Multiplate tests to predict post-operative bleeding in our cardiac surgical population. *Methods*. We tested 44 consecutive patients scheduled for elective cardiac surgery. Prior to cardiopulmonary bypass, all samples were submitted for a collagen activation test as an overall assessment of platelet function and a *TRAP* (thrombin receptor activating peptide) test to assess the effect of antiplatelet medication. An 'Aspi 'test±an ADP test was performed to specifically assess the effect of aspirin or clopidogrel where these drugs had been in use preoperatively; in our unit aspirin is continued until the day of surgery although clopidogrel is normally stopped 5 days before. On arrival in the Intensive Care Unit these tests were repeated postoperatively and the results noted. Post-operative drain losses were noted at 16 hours. *Results*. 44 patients were studied and included in the statistical database. Data was analysed by *Best Subsets* then multiple regression analysis using Minitab statistical software. No preoperative test was predictive of blood loss. The best predictor of excessive blood loss was a combination of the postoperative collagen and TRAP test results. However, these only accurately predicted blood loss in 43% of patients and were not independently significant. *Conclusions*. Multiplate analysis offers point-of-care testing. Initial results indicate better prediction in postoperative rather than pre-operative testing - perhaps not surprising in view of greater platelet dysfunction in this setting. Initial results have encouraged us to continue our study to obtain greater patient numbers.

0394

MONOCYTE SUBPOPULATIONS WITH DIFFERENT CYTOKINE RELEASE INDUCED BY LEUKOCYTAPHERESIS IN HEALTHY BLOOD DONORS

M. Hendelmeier, A. Oehring, E. Strasser, R. Zimmermann, R. Eckstein

University Hospital Erlangen, ERLANGEN, Germany

Background. Dendritic cells (DC) are the terminal stage of monocyte differentiation. Peripheral blood monocytes are a heterogenous population and consist of distinct subsets. The understanding of monocyte heterogeneity and the release of cytokines may have implications for the development of DC vaccines. *Aims.* Leukocytapheresis may be a stimulus for the release of cytokines by monocyte subpopulations. *Methods.* 12 healthy blood donors were investigated before and after leukocytapheresis procedures (COM.TEC cellseparator, Fresenius HemoCare, MNC program and COBE Spectra, Gambro, PBSC program). Additionally, apheresis products were examined and the release of cytokines was investigated by flow cytometry. *Results.* The leukocyte concentration of products ranged between 28×10^3 and 112×10^3 White blood cells (WBC) per microliter. The mean percentage of $CD14^{++}$ monocytes releasing IL-1 was 82.1 percent (range, 71.6% to 94.8%) and the mean percentage of $CD14^{+}CD16^{+}$ monocytes releasing IL-6 was 6.4 percent (range, 4.2% to 11.6%). The main population of $CD14^{++}$ monocytes showed a significant higher release of IL-1 in the pre- and postdonation blood counts compared to the $CD14^{+}CD16^{+}$ monocyte subpopulation releasing IL-1 (predonation: $p<0.001$ and postdonation: $p<0.002$). Subpopulations of $CD14^{+}CD16^{+}$ monocytes showed a significant higher release of IL-6 in the predonation blood counts compared to $CD14^{++}$ monocytes (4.8% *vs* 9.1%, $p<0.001$). The pre- and post-donation counts of $CD14^{+}CD16^{+}$ monocytes releasing IL-6 did not differed significantly, whereas the release of IL-6 by this subpopulation in the apheresis products increased significantly ($p<0.0001$). Compared to the initial concentration of $CD14^{++}$ monocytes releasing IL-1 in donors no cytokine release in apheresis products was found, whereas $CD14^{+}CD16^{+}$ monocytes releasing IL-6 were enriched by factor 2 in apheresis products (both $p<0.0001$). *Summary and Conclusions.* The $CD14^{++}$ monocytes releasing IL-1 were enriched in the postdonation blood counts. However, no $CD14^{++}$ monocytes releasing IL-1 were found in the apheresis products. $CD14^{+}16^{+}$ monocytes releasing IL-6 were increased in the apheresis products, but not in the postdonation blood counts. These results may suggest a cytokine release in different monocyte subpopulations induced by leukocytapheresis.

0395

PHARMACOKINETICS (PK) OF SUBCUTANEOUS FONDAPARINUX 1.5 MG IN PATIENTS WITH MODERATE RENAL IMPAIREMENT (MRI)

A.G.G. Turpie,[1] D. Boyle[2]

[1]Hamilton Health Sciences - General Division, HAMILTON, ONTARIO, Canada; [2]GlaxoSmithKline Upper Merion, KING OF PRUSSIA, PA, USA

Background. Fondaparinux is approved for the prevention of venous thromboembolism. Like low-molecular-weight heparins, fondaparinux is mainly eliminated via the kidneys. At the once-daily (od) dose of 2.5 mg, exposure to fondaparinux is increased in patients with MRI (creatinine clearance, CLcr: 20 to 50 mL/min). *Aims.* We looked for a reduced dose of fondaparinux able to achieve a similar level of exposure in patients with MRI and in patients with normal renal function (NRF).

Table 1.

AUC_{0-24} (mg*h/mL)	Day	1.5 mg od in MRI patients (n=3457)	2.5 mg od in MRI patients (n=3257)	2.5 mg od in NRF patients (n=16,543)
	1	2.9 (2.1-4.1)	4.8 (3.5-6.8)	3.2 (2.1-4.8)
	28	6.2 (3.9-10.5)	10.4 (6.4-17.2)	5.0 (2.8-8.9)

Geometric mean (5^{th}-95^{th} prediction intervals)

Methods. Using a population PK model based on data obtained in 756 major orthopedic surgery patients, we predicted the pharmacokinetics of fondaparinux based on the demographic characteristics and renal function of the patients enrolled in the Phase II/III thromboprophylactic trials. A total of 20,000 patients were simulated in order to predict exposure (AUC0-24) and peak plasma concentration (Cmax) on Days 1, 7 and 28 after the od administration of fondaparinux 1.5 mg or 2.5 mg in MRI or NRF patients. *Results.* Predicted AUC0-24 (Table 1) and Cmax in patients with MRI administered 1.5 mg od were very close to those in patients with NRF administered 2.5 mg od. In the low range of CLcr, the inter-individual variability in the plasma concentration of fondaparinux was lower with 1.5 mg than with 2.5 mg. *Summary and Conclusions.* Exposure to od fondaparinux was estimated to be similar in MRI patients administered 1.5 mg and in NRF patients administered 2.5 mg. Based on the results of these pharmacokinetic simulations, fondaparinux 1.5 mg od may be an appropriate thromboprophylactic dose in patients with MRI.

0396

NOVEL, GRADUALLY INCREASING AND LONG-LASTING ADHESIVE AND SECRETORY RESPONSES ELICITED BY LEUKOTRIENE B4 IN ENDOTHELIAL CELLS ARE MEDIATED VIA THE MAP KINASE PATHWAY

A.S.M. Johansson, J.Z. Haeggstrom, J. Palmblad

Karolinska Institutet, STOCKHOLM, Sweden

Leukotriene B4 (LTB4), a powerful chemotactic and immune modulating lipid, signals via distinct G-protein-coupled surface receptors, denoted BLT. The ensuing cellular responses are rapid in onset and short-lived. Recently, we reported that BLT1 is the predominating BLT expressed on human umbilical vein endothelial cells (HUVEC). LTB4 stimulation of HUVEC causes adhesion of neutrophils, up-regulation of E-selectin, ICAM-1 and VCAM-1, release of MCP-1 and IL-8, and of NO production. Since L-NAME inhibited the nitrite release, this is suggested to reflect NO production. The expected fast and transient adhesive and secretory responses (peaking after 15-30 min) were, unexpectedly, followed by sustained larger peaks after 3-7 h, similar in magnitude to those elicited by LPS. Moreover, LTB4 responses were mediated by the MAP kinase/Erk pathway, whereas no activation of NK-kB p65, c-jun or Elk-1 was observed. Thus, contrary to previous observations, LTB4 causes not only rapid but also long-lasting pro-inflammatory responses in endothelial cells, which is a novel observation. Since IL-8 and MCP-1 plays a role in neutrophil and monocytes recruitment our findings may have functional consequences in the early and sustained vascular responses to inflammation. Moreover, the results point to BLT receptors as potential targets for pharmacological intervention in vasculitides of various causes.

Background. MTX-based CHT is the conventional approach to PCNSL, but superiority of polyCHT over MTX alone is unproven. A benefit of adding araC to MTX has been suggested by a meta-analysis and a large retrospective series. *Aims.* To assess if MTX-araC combination is more active than MTX alone as primary CHT for PCNSL in a randomized comparison. *Patients*. PCNSL pts (HIV-; 18-75 ys; PS≤3; 2004-2007) were randomly allocated to receive 4 courses (interval 3 weeks) of MTX 3.5 g/mq (arm M) or MTX (same dose) + araC 2 g/mq x 2/d, d 2-3 (arm MA). CHT was followed by radiotherapy (RT). Pts were stratified based on IELSG score and centre RT policy for pts >60 ys in complete remission (CR) after CHT. CR rate (CRR) after CHT was the primary endpoint; planned accrual (alpha=.05; betta=.2) for P0 30% and P1 50% was 39 pts/arm. *Results.* 79 pts (median age 58 ys) were randomly assigned to receive M (N=40) or MA (N=39). IELSG risk was low in 22 (28%) pts, intermediate in 48 (61%) and high in 9; 14% of pts had ocular lesions and 7% had meningeal disease; no differences in presentation between arms were observed. 231 (73%) of the 316 planned courses were actually delivered (M 71%; MA 76%). CHT was interrupted due to PD in 20 (50%) M and 8 (21%) MA pts (p<0.001), toxicity in 1 (3%) M and 7 (18%) MA pts (p=0.009) and refusal in 2 MA pts. ≥25% dose reduction was indicated in 1 M and 17 MA pts. G4 neutropenia (10% *vs* 74%), G4 thrombocytopenia (5% *vs* 64%) and infections (3% *vs* 23%) were significantly higher in MA arm. All G3-4 non-hematological toxicities were <5%. One M pt (3%, cardiotoxicity) and 3 MA pts (8%, sepsis - hepatotoxicity) died of toxicity. After CHT, 7 M and 18 MA pts achieved CR (18% *vs* 46%; p=0.0002); 10 M and 9 MA pts achieved PR (ORR: 43% *vs* 69%; p=0.0002). After CHT-RT, 11 M and 25 MA pts achieved CR (28% *vs* 64%; p<0.0001). At a median f-up of 16 mo, 29 M and 22 MA pts experienced failure (PD, relapse, death), with a 3-yr EFS of 24% *vs* 35% (p=0.02). *Conclusions.* This is the first randomized trial on PCNSL with completed accrual. The addition of araC to MTX resulted in significantly better outcome and acceptable toxicity. MTX+araC may be the control arm for future randomized trials.

0398

CNS RECURRENCE IN AGGRESSIVE LYMPHOMA TREATED WITH MODERN CHEMOTHERAPY (CHOP-14) WITH OR WITHOUT RITUXIMAB: AN ANALYSIS OF CNS-EVENTS IN ELDERLY PATIENTS TREATED IN THE RICOVER-60 TRIAL OF THE GERMAN HIGH-GRADE NON-HODGKIN'S LYMPHOMA STUDY GROUP (DSHNHL)

N. Schmitz,1 V. Boehme,[1] S. Zeynalova,[2] E. Lengfelder,[3] M. Reiser,[3] H. Steinhauer,[3] M. Clemens,[3] C. Nickenig,[3] M. Loeffler,[2] M. Pfreundschuh[4]

[1]ASKLEPIOS KLINIK St. Georg, HAMBURG; [2]Institute of Medical Informatics, Statistics & Epidemiology, University Leipzig, LEIPZIG; [3]On behalf of the DSHNHL, HOMBURG; [4]Department of Internal Medicine I, Saarland University, HOMBURG/SAAR, Germany

Background. CNS recurrence of aggressive lymphoma remains a distressing and usually incurable event. In an analysis of patients on protocols of the German High-Grade Non-Hodgkin's Lymphoma Study Group (DSHNHL) between 1990 and 2000, the CNS relapse rate was 2.2% in 1693 patients treated with modern chemotherapy but without rituximab (Boehme *et al.*, Ann. Oncol 2007;18:149-57). We now analyzed the incidence and prognostic factors for CNS recurrence in the RICOVER-60 trial (Pfreundschuh *et al.*, Lancet Oncol 2008;9:105-16). *Patients and Methods*. From 2000-2005, elderly patients (pts.) between 61 and 80 years with CD20$^+$ aggressive lymphoma (all risk groups according to the IPI) were randomized to receive 6 or 8 cycles of CHOP-14 chemotherapy with or without 8 courses of rituximab. For patients with lymphoma manifestation in testes, bone marrow, sinuses or other head and neck locations deemed at high risk for CNS recurrence, the protocol asked for intrathecal (i.th.) prophylaxis with 15 mg methotrexate (MTX) twice in the first two cycles of chemotherapy. *Results*. 1217 patients were evaluable, of whom 58 patients (4.8 %) after a median time of 8 months (1-39) developed relapse or progression to the CNS with a median time of survival of 3 months (0.1-38). Multivariate Cox regresssion analysis identified involvement of more than one extranodal site (RR = 3.4; p< 0.001), the presence of B-symptoms (RR = 1.9; p= 0.025) and increased LDH (RR = 1.5; p= 0.146) as predictors of CNS recurrence. Patients with three characteristics had a CNS relapse rate of approximately 24% at 2 years, about 6-fold the incidence rate observed in all other patients. The addition of rituximab to chemotherapy reduced the risk of CNS recurrence (RR = 0.5; p= 0.025), whereas the number of treatment cycles (6 *vs* 8) did have no influence on the CNS-specific outcome. Of 210 patients (17%) with lymphoma involvement of testes, bone marrow or head (sinuses, orbita, oral cavity, tongue, salivary glands) 120 pts. received i.th. prophylaxis as intended per protocol whereas the remaining 90 patients were not treated with MTX due to protocol violation. Only seven of these patients (7/210 = 3.3%) developed meningeosis in the course of the disease. There was no difference in the incidence of meningeal relapse between the patients with or without prophylaxis. *Conclusions*. The incidence of CNS relapse in 1217 patients treated for aggressive lymphoma with CHOP-14 with or without rituximab was low (4.8 %) although slightly higher than reported in other recent series. The prognostic factors for CNS-disease and the poor prognosis of CNS relapse remained largely unchanged. Rituximab significantly reduced the incidence of CNS disease (3.6 *vs* 5.9%) and the risk of CNS recurrence (RR 0.5; p= 0.025) for the most part due to improved overall response after combined chemo-immunotherapy. The number of patients who experienced meningeosis was low (7 patients) and prophylactic i.th. therapy given to patients deemed at high risk for meningeosis did have no influence on the incidence of meningeal relapse. I.th. prophylaxis should no longer be recommended because with modern immuno-chemotherapy the incidence of CNS recurrence is low even in *high-risk* patients and there is no indication that the incidence of meningeosis could be reduced.

0399

RESULTS FROM AN INTERNATIONAL STUDY INVESTIGATING THE EFFICACY AND SAFETY OF LENALIDOMIDE IN RELAPSED OR REFRACTORY AGGRESSIVE NON-HODGKIN'S LYMPHOMA

C. Haioun,[1] C.B. Reeder,[2] J. Polikoff,[3] N.M. Chowhan,[4] I. Esseessee,[5] R. Greenberg,[6] A. Ervin-Haynes,[7] D. Pietronigro,[7] J.B. Zeldis,[7] T.E. Witzig,[2] M.S. Czuczman[8]

[1]CHU Henri Mondor, CRÉTEIL, France; [2]Mayo Clinic, SCOTTSDALE, AZ, USA; [3]Kaiser Permanente Medical Group, SAN DIEGO, CA, USA; [4]Cancer Care Center, NEW ALBANY, IN, USA; [5]Hematology Oncology Associates of Central Brevard, ROCKLEDGE, FL, USA; [6]Center for Cancer and Hematologic Disease, CHERRY HILL, NJ, USA; [7]Celgene Corporation, SUMMIT, NJ, USA; [8]Roswell Park Cancer Institute, BUFFALO, NY, USA

Background. Previous trials have shown that lenalidomide is active with manageable side effects in non-Hodgkin's lymphoma (NHL). *Aims.* The present study aims to confirm the activity and safety of lenalidomide in patients with relapsed or refractory aggressive NHL in an international setting. *Methods.* Patients with relapsed or refractory aggressive NHL with measurable disease (≥ 2 cm) after at least 1 prior treatment regimen were eligible. Patients received 25 mg lenalidomide orally once daily on Days 1-21 every 28 days and continued therapy as tolerated or until disease progression. Response and progression were evaluated using the IWG criteria. *Results.* As of August 25, 2007, 46 patients were eligible for response assessment and 79 for safety evaluation. Median age was 65 (21-84) years, 74% were male, and 96% had received prior rituximab. Median time from diagnosis was 2 (0.2-12) years and median number of prior treatment regimens was 3.5 (1-13). Histologies included diffuse large B-cell lymphoma [DLBCL] (n=29), follicular lymphoma grade 3 [FL] (n=1), mantle cell lymphoma [MCL] (n=13) and transformed lymphoma [TSF] (n=3). An objective response was observed in 13 patients (28%), including a complete response in 1 patient (2%) and partial responses in 12 patients (26%). Ten patients (22%) had stable disease. Responses were seen in each of the aggressive histologic subtypes studied: DLBCL (6/29), FL (1/1), MCL (5/13), and TSF (1/3). Most common grade 3 or 4 adverse events were neutropenia (24%), thrombocytopenia (16%), leukopenia (9%), anemia (6%), dehydration (5%), and fatigue (5%). *Summary and Conclusions.* Lenalidomide has activity in relapsed or refractory aggressive NHL, resulting in a response in 28% of patients with manageable side effects. Updated data will be presented at the meeting.

THE HOST PHARMACOGENETIC PROFILE IS AN INDEPENDENT PREDICTOR OF OUTCOME AND TOXICITY IN DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH R-CHOP21

D. Rossi,[1] S. Rasi,[1] S. Franceschetti,[1] D. Capello,[1] A. Castelli,[1] A. Chiappella,[2] L. De Paoli,[1] A. Ramponi,[3] E. Pogliani,[4] U. Vitolo,[2] A. Conconi,[1] G. Gaidano[1]

[1]Division of Hematology, Amedeo Avogadro University, NOVARA; [2]Division of Hematology, Azienda Ospedaliera S. Giovanni Battista, TURIN; [3]Division of Pathology, Amedeo Avogadro University, NOVARA; [4]Division of Hematology, University of Milano Bicocca, MONZA, Italy

Background. R-CHOP is the standard treatment for diffuse large B-cell lymphoma (DLBCL). Several tumor cell-related predictors of efficacy and toxicity have been so far identified for DLBCL treated with R-CHOP. Conversely, no information is available on the impact of the host's genetic background as a predictor of outcome and toxicity in this context. *Aims.* This study aimed at verifying whether relevant single nucleotide polymorphisms (SNPs) of the host may further refine the prognostic stratification and the prediction of toxicity in DLBCL patients treated with R-CHOP21. *Methods*. The study was based on a consecutive series of 106 DLBCL treated with R-CHOP21 and provided with a large and homogeneous dataset comprising clinical variables at diagnosis, chemotherapy doses and toxicity. All data were collected prospectively. Candidate SNPs belonged to genes known to be involved in the pharmacogenetics of cyclophosphamide, doxorubicin, vincristine, prednisone and rituximab, and included SNPs affecting: i) drug metabolism (cytochrome-P450: CYP2B6-25504C>T, CYP2B6-15630G>T, CYP2C19-19153G>A, CYP3A4--392A>G, CYP3A4-14365T>G, CYP3A5-6980G>A); ii) drug detoxification: (gluthatione-S-transferase: GSTA1--4621T>C, GSTM1-null, GSTP1-1374A>G, GSTP1-2264C>T); iii) drug transport (multidrug-resistance-related proteins: ABCC1-129623G>T, ABCC2-53394T>A, ABCC2-68692G>A, ABCB1-90855C>T, ABCB1-49691G>A, ABCG2-8824C>A, ABCG2-33G>A; and iv) drug pharmacodynamics (NADPH-subunits: NCF4--368A>G, RAC2-7418T>A, CYBA-4185C>T; TP53: p53-440G>C; Fcγ receptor: FCGR2A-4487A>G, FCGR3A-5092T>G, FCGR3A-1301T>G/A; Glucocorticoid receptor: GR-67G>A, GR-1087A>G, GR-1829C>G). Genotyping of candidate SNPs was performed on PBMC collected at DLBCL diagnosis by SNP-minisequencing (ABI Prism SNaPshot Multiplex kit, Applied Biosystem). Primary end points were event free survival (EFS) and toxicity. *Results*. Univariate log-rank analysis identified CYBA-4185C>T (3-year EFS CT/CC: 61.2% *vs* TT 41.7%; *p=0*.008), ABCC2-53394T>A (3-year EFS TT: 64.0% *vs* AT/AA: 34.1%; *p*=0.013), and GSTA1--4621C>T (3-year EFS CT/TT: 64.8% *vs* CC: 39.2%; *p*=0.027) as predictors of EFS. Multivariate analysis identified CYBA-4185TT (HR:2.57; *p*=0.010) and GSTA1--4621CT/TT (HR:0.44; *p*=.010), along with chemotherapy interruption (HR: 3.52; *p*=0.002), IPI3-5 (HR:2.81; *p*=0.006), and liver involvement (HR:3.07; *p*=0.006) as independent predictors of EFS after adjusting for ABCC2-53394T>A, marrow involvement, organ function (marrow, renal, liver, cardiac), comorbidities, dose intensity of cyclophosphamide and doxorubicin, and toxicity. The impact of SNPs was also evaluated for toxicity in 658 courses of R-CHOP21 by logistic regression analysis adjusted for age, sex, ECOG PS, IPI, comorbidities, organ function, and doses of cyclophosphamide, doxorubicin and vincristine. NCF4--368AG/GG was an independent predictor of low risk of hematologic toxicity G3-4 (HR:0.49; *p*=0.012), infection (HR:0.42; *p*=0.002), cardiac toxicity (HR:0.34; *p*=0.001), and neurological toxicity (HR:0.52; *p*=0.009). *Conclusions*. The implications of these results are twofold. First, host SNPs affecting doxorubicin and/or cyclophosphamide pharmacodynamics (CYBA-4185C>T) and detoxification (GSTA1--4621C>T) are independent predictors of outcome in DLBCL treated with R-CHOP21. Poor EFS heralded by CYBA-4185C>T, a nonsynonimous SNP of NADPH-oxidase p22phox, may be due to reduced production of reactive oxygen species (ROS) that mediate doxorubicin cytotoxicity. Favorable EFS associated with GSTA1--4621C>T may be related to reduced expression of glutathione-S-transferase A1, a phase II enzyme involved in cyclophosphamide and doxorubicin detoxification. Second, NCF4--368AG/GG, a SNP belonging to NADPH-oxidase p40phox and regulating ROS generation and granulocyte burst, has an independent protective role against both hematologic and non-hematologic toxicity.

0401

PRIMARY DIFFUSE LARGE B-CELL LYMPHOMA OF THE TESTIS: IMPROVED OUTCOME WITH RITUXIMAB-CHOP WITH CNS AND CONTRALATERAL TESTIS PROPHYLAXIS. FINAL RESULTS OF IELSG 10 STUDY

U. Vitolo,[1] E. Zucca,[2] A. Chiappella,[1] M. Martelli,[1] M. Balzarotti,[1] G. Benevolo,[1] P. De Masi,[1] A. Filippi,[1] M.K. Gospodarowicz,[2] A. Lopez-Guillermo,[2] G. Martinelli,[2] F. Merli,[1] T. Perrone,[1] P. Pregno,[1] A.H. Sarris,[2] S. Storti,[1] F. Cavalli[2]

[1]On the behalf of IELSG and IIL, Hematology, San Giovanni Battista Hospital, TORINO, Italy; [2]On the behalf of IELSG, IOSI, BELLINZONA, Switzerland

Background. Diffuse large B-cell lymphoma (DLBCL) of the testis (PTL) is a rare presentation of extranodal lymphoma at poor prognosis with a 5-yr overall survival of 40-55%. Contralateral testis, CNS and extranodal sites relapses are the main cause of failures. *Aims.* the IELSG10 study is a prospective phase II international trial for stage I or II PTL. It aimed at defining a standard treatment for PTL with a combined treatment of R-CHOP, intrathecal methotrexate and prophylactic scrotal radiotherapy (RT) with the addition, in stage II, of loco-regional RT. The trial was conducted by International Extranodal Lymphoma Study Group (IELSG) and Intergruppo Italiano Linfomi (IIL). The present analysis provides the final results of the whole study. *Methods.* Between June 2001 and December 2006, 53 untreated patients with stage I-II PTL were enrolled from 31 centres. Treatment was: R-CHOP21 (Rituximab 375 mg/mq, Cyclophosphamide 750 mg/mq, Doxorubicine 50 mg/mq, Vincristine 1.4mg/mq d 1 and Prednisone 40 mg/mq dd 1-5) for 6 or 8 (in stage II patients with slow response) courses; intrathecal methotrexate (IT-MTX) 15mg for 4 doses in courses 1 and 2; after chemotherapy 30Gy scrotal RT to the contralateral testis was planned to all patients reserving 30-36 Gy on loco-regional nodes for stage II disease. *Results.* median age was 64 years (22-80); 40 stage I and 13 stage II; 4 had bilateral testicular involvement and 6 LDH > normal. All received R-chemotherapy as planned. Fifty patients received adequate CNS prophylaxis (at least 4 IT-MTX); 3 less than 4 IT because of toxicity. Scrotal RT was given to 49 patients; 4 did not perform it (2 refusals, 1 progressive disease and 1 bilateral orchiectomy). Eight of the 13 stage II patients received nodal RT as planned. Fifty-two patients (98%) achieved a CR and 1 progressed after 4 R-CHOP. With a median follow-up of 36 months, 3-yr OS and 3-yr PFS (including progressions and deaths from any causes) were: 86% (95% CI 70-93%) and 82% (95% CI 66-91%) respectively. Eight patients relapsed or progressed: 2 in nodal sites, 4 in extranodal +/– nodal sites and 2 in CNS (1 isolated meningeal and 1 meningeal + nodal relapse). The actuarial risk of CNS relapse at 3 years was only 2% (95% CI 0-6%). No contralateral testis relapses were observed. Eight patients died: three because of DLBCL, 1 of heart failure, 1 of colon carcinoma and one of acute myeloid leukemia 4 and 21 months off therapy while in CR. The most severe (grade 3-4) toxicities were: leukopenia 27% and neurologic 13%. Infections were recorded in only 2 patients, no other extrahematological toxicities were observed. No toxic deaths occurred during treatment. *Conclusions.* the results showed that this combined treatment with R-CHOP21 and complete CNS and scrotal prophylaxis improves the outcome of PTL compared with data reported into the literature. An effective systemic control of the disease with no contralateral testis relapses and a reduced incidence of CNS relapse was achieved in a prospective population of PTL, mainly elderly, with a treatment with a low toxic profile.

Chronic myeloid leukemia - Clinical I

FIRST REPORT OF THE TOPS STUDY: A RANDOMIZED PHASE III TRIAL OF 400MG VS 800MG IMATINIB IN PATIENTS WITH NEWLY DIAGNOSED, PREVIOUSLY UNTREATED CML IN CHRONIC PHASE USING MOLECULAR ENDPOINTS

J.G. Cortes,[1] M. Baccarani,[2] F. Guilhot,[3] B.J. Druker,[4] R. Yu,[5] M. Rudoltz,[5] T. Krahnke,[6] T. Hughes[7]

[1]The University of Texas, HOUSTON, USA; [2]Institute of Hematology and Medical Oncology Seragnoli," University of Bologna, BOLOGNA, Italy; [3]Centre Hospitalier Universitaire, La Miletrie, POITIERS, France; [4]Oregon Health & Science University Cancer Institute, PORTLAND, USA; [5]Novartis Pharmaceuticals, EAST HANOVER, USA; [6]Novartis Pharma AG, BASEL, Switzerland; [7]Institute of Medical and Veterinary Science, ADELAIDE, Australia

Background. The IRIS study (imatinib vs interferon/Ara-C) established 400 mg imatinib (SD-IM) as standard of care for patients with newly diagnosed chronic myeloid leukemia in chronic phase (CML-CP). In the IRIS trial achievement of a MMR predicted for progression-free survival (PFS) benefit (Druker 2006). Phase II trials have suggested that high dose imatinib (HD-IM), 800 mg, increases the likelihood of achieving major molecular response (MMR) (Kantarjian 2004), and may improve long-term progression-free survival (PFS) (Aoki 2006). *Aims.* The Tyrosine Kinase Inhibitor Optimization and Selectivity Study (TOPS) aims to determine whether a higher initial dose of imatinib (800 mg *vs* 400 mg) improves the probability of achieving MMR among patients in early chronic phase. *Methods.* Adult patients with newly diagnosed, previously untreated Ph+ CML-CP were randomized to receive either HD-IM or SD-IM in a 2:1 ratio. Patients were stratified by Sokal score at diagnosis. The primary endpoint was MMR (BCR-ABL/control gene ratio of ≤ 0.1% according to the standardized international scale) at 12 months. The study was powered to demonstrate a 50% improvement in the rate of MMR at 12 months between the two arms (90% power assuming a response rate of 60% for the 800 mg and 40% for the 400 mg). Secondary evaluations included: CCyR rates at 12 months, dose intensity in each arm, evolution of hematologic, cytogenetic, and molecular response over time, and safety. Patients received regular clinical and laboratory evaluations, including Bcr-Abl transcript measurement at baseline and then every three months. *Results.* 476 patients were enrolled from 19 countries at 103 study sites from June 2005 to December 2006. First analysis of this study will be completed by the time of EHA congress. Data to be presented include MMR at 12 months, dose intensity, evolution of responses over time, relationship to Sokal score, and safety. *Conclusions.* This will be the first presentation of data from TOPS, the first controlled trial to evaluate HD-IM in newly diagnosed CML-CP patients of all Sokal risk categories. Achievement of MMR at an early time point will be correlated in future analyses with event-free, progression-free, and overall survival to determine if CML-CP patients may benefit long-term from treatment with an initial imatinib dose of 800 mg. Approximately 75% of 12 month molecular data used to determine the rate of MMR at 12 months have been analyzed in a blinded fashion at the time of this abstract submission. All 12 month molecular data will be unblinded and available in May 2008.

0403

BOSUTINIB (SKI-606) SHOWS HIGH TOLERABILITY AND CLINICAL ACTIVITY IN PATIENTS WITH PHILADELPHIA CHROMOSOME POSITIVE LEUKEMIAS

C. Gambacorti-Passerini,[1] J. Cortes,[2] H. Kantarjian,[2] D. Kim,[3] A. Turkina,[4] T. Fischer,[5] F. Cervantes,[6] S. Agarwal,[7] B. Hewes,[7] T.H. Brummendorf[8]

[1]University Milano-Bicocca, MONZA, Italy; [2]MD Anderson Cancer Center, HOUSTON, USA; [3]St Mary's Hospital, SEOUL, South-Korea; [4]Hematology Research Center, ST. PETERSBURG, Russian Federation; [5]University of Mainz, MAINZ, Germany; [6]Hospital Clinic Provincial, BARCELONA, Spain; [7]Wyeth Research, CAMBRIDGE, USA; [8]Universitätsklinikum Hamburg-Eppendorf, HAMBURG, Germany

Background. Bosutinib (SKI-606) is an orally available, dual Src/Abl kinase inhibitor. *Aims.* To assess safety and clinical activity of bosutinib (B) in patients (Pts) with Philadelphia chromosome positive (Ph+) chronic myelogenous leukemia (CML) or acute lymphocytic leukemia (ALL)

who are resistant/intolerant to Imatinib (I) or other TKIs, we conducted a phase 1/2 study. *Methods.* Pts received B at 400 to 600 mg/day, with a median age of 56 (CP), 53 (AP), 48 (BP), 60 (ALL) yrs. The planned duration of the study was 1 year, but it was subsequently extended in pts showing clinical response to B. *Results.* Pts evaluable for safety analysis are: 152 in CP-CML, 32 in AP-CML, 23 with BP-CML and 17 with ALL. The most frequent treatment emergent adverse events (AE) observed for CP were diarrhea (68%), nausea (43%), vomiting (28%), abdominal pain (27%), rash (24%) and for advanced phase were diarrhea (61%), nausea (43%) and vomiting (38%), pyrexia (29%), pain (29%); these effects usually subsided spontaneously within the first 4 weeks of treatment. Grade 3/4 AEs occurring in >5% of CP pts were diarrhea (7%) and rash (7%). G3/4 lab based abnormalities included [CP: thrombocytopenia (T, 14%), neutropenia (N, 9%), anemia (A, 1%) and increased ALT (7%) and advanced phase: T, 71%, A, 32%, N, 46%]. Only 3% of advanced phase pts observed G3/4 pleural effusion. Even pts with blast phase leukemia experienced moderate hem toxicity with G3/4 T in 78% (but 74% at baseline), G3/4 N in 61% (22% at baseline), and G3/4A in 30% (17% at baseline). In 115 I-resistant or intolerant CP-CML pts with no prior exposure to other TKIs, 89% had complete hematologic response (CHR, unconfirmed); 41% had major cytogenetic response (MCyR) and 33% achieved a Major Molecular response. CP pts with exposure to other TKIs had CHR and MCyR rates of 77% and 20%. AP-CML pts exposed to I only had CHR/MCyR rates of 50% and 44% while BP-CML and ALL pts had CHR/MCyR rates of 15% and 18%. Nineteen different Bcr-Abl mutations were detected in 37 CP pts and 13 in 27 advanced phase pts: activity was observed in all of them with the exception of T315I. *Conclusions.* Bosutinib was well tolerated in pts with Ph^+ leukemias, with primarily low-grade gastrointestinal and dermatologic AEs, and no related pleural effusion. Results updated to March 2008 and including response durations will be presented.

Background. Imatinib (IM) 400 mg daily is the standard treatment for chronic myeloid leukemia in early chronic phase (ECP): the results of the IRIS trial have shown a 72 months overall survival of 95%; the EFS and PFS were 83% and 93%, respectively. The complete cytogenetic response (CCgR) rate of the IM 400 mg arm was 25% at 3 months (at 6, 12, 18 and 60 months it was 51%, 69%, 76% and 87%, respectively). Nilotinib, a second generation TKI , has a higher binding affinity and selectivity for Abl with respect to IM, being 20 to 50 times more active in imatinib-sensitive cell lines and is highly effective in IM resistant patients, across every disease phase. Among 320 patients in late chronic phase, resistant or intolerant to IM, who received nilotinib 400 mg BID for at least 6 months, the rates of major and complete cytogenetic response were 56% and 40 %, respectively, with very few progressions. Based on these data, nilotinib is currently registered for the treatment of CML patients intolerant or resistant to IM, but it may compete with IM for the frontline treatments of ECP patients. *Aims*. To investigate the therapeutic efficacy and the safety of nilotinib 400 mg BID in ECP, Ph-pos CML patients. *Methods*. An open-label, single stage, multicentric, phase II study (ClinicalTrials.gov. NCT00481052), that was approved by the reference IEC in Bologna, S.Orsola-Malpighi University Hospital and by the IECs of each participating institution, was open to accrual in June, 2007; all patients provided written informed consent. The primary endpoint is the CCgR rate at 1 year; the kinetic of MR is studied by Q-PCR, baseline and after 1, 2, 3, 6, 9 and 12 months form starting the treatment. *Results*. Seventy-three patients have been enrolled from 20 Centres between June, 2007 and February, 2008. The median age was 51 years (range 18-83), 56% low, 32% intermediate and 12% high Sokal risk. Median follow-up is currently 75 days (range 1-210). Thirty-four patients completed 3 months on treatment: 33/34 achieved a CHR; 20/23 evaluable pts (11 pending) reached a MCgR (87%) with 18/23 in CCgR (78%). The MMR rate (BCR-ABL:ABL < 0.1% according to the International Scale) was 52% (13/25 evaluable patients - 9 pending). Adverse events (grade III/IV): hematologic toxicity was recorded in 2 pts (6% - only 1 epysode of grade IV neutropenia); non-hematologic AEs in 4 pts (12% - no grade IV) and biochemical abnormalities in 10 pts (29%, mainly transient increased bilirubin or transaminases - no grade IV). *Conclusions.* The results that have been achieved so far strongly support the hypothesis that in ECP, Ph-pos CML patients the response to nilotinib may be faster than the response to IM.

Background. Imatinib mesylate (IM), 400 mg daily, is the drug of choice for the frontline treatment of Ph pos CML. Several biologic findings and clinical observations suggest that increasing the dose of IM may result in improved therapeutic efficacy. The complete cytogenetic response (CCgR) rate to IM 400 mg is significantly affected by Sokal risk (49% in high risk patients at 1 year, IRIS study). Thus, newly diagnosed high risk patients, who account for 20 to 30% of all CML patients, may benefit from a dose increase front-line. *Aims.* To compare the effects of IM, 400 mg or 800 mg daily, in previously untreated, early chronic phase (ECP), Sokal high risk, Ph pos, CML patients. *Methods.* In an international, multicenter, prospective, randomized study (Italy, Scandinavian Countries and Turkey) (Clin. Trials Gov. NCT00514488), 215 patients were enrolled over a 3-year period and were randomized (1:1) to receive IM 400 or 800 mg daily. Cytogenetic response was assessed by chromosome banding analysis and FISH analysis of marrow cells, after 3, 6 and 12 months. Molecular response was assessed by RQ-PCR of blood cells, after 3, 6, and 12 months. The primary efficacy variable was the CCgR rate at 12 months, based on the intention-to-treat. *Results.* As of February 2008, 205/215 patients are evaluable for the primary efficacy variable, 103 in the 400 mg arm, and 102 in the 800 mg arm. The CCgR rates (400 mg *vs* 800 mg) were 20% *vs* 23% after 3 months, 53% *vs* 52% after 6 months, and 60% *vs* 63% after 12 months (primary efficacy variable). Treatment failures (non complete hematologic response or no CgR at 6 months, less than partial CgR at 12 months, or loss of hematologic response or of CgR at any time) were 19/103 (18%) in the 400 mg arm *vs* 16/102 (16%) in the 800 mg arm. In the 400 mg arm, the median administered dose was 400 mg, and there was no difference in outcome between the patients who received the full dose and those who received a dose ranging beteween 300 and 400 mg, with a CCgR rate of 67% and 76% respectively. In the 800 mg arm, the median administered dose was 700 mg, and the CCgR rate was 91% in those who received 600 to 800 mg *vs* 54% in those who received less than 600 mg. Treatment discontinuations for adverse events were 4/103 in the 400 mg arm *vs* 7/102 in the 800 mg arm. Molecular response data are under evaluation and will be presented at the meeting. *Conclusions.* In this international, prospective, randomized study of IM 400 vs 800 mg daily, in a selected, high risk population of patients with Ph pos CML, no difference could be detected overall, according to treatment arm, in the rate of CCgR, of failure, and of adverse events, during the first 12 months of treatment. A dose-

response relationship was observed in the 800 mg arm but not in the 400 mg arm. The patients will be followed for progression-free and overall survival. The data will be available for metanalyses.

Background. Recent phase II studies revealed that high doses of Imatinib (800mg/day) are capable to induce higher and earlier rates of cytogenetic and molecular responses, both in second line after failure to interferon alfa and in newly diagnosed chronic phase (CP) CML patients. *Aims.* We wanted to validate these data in a larger cohort of patients performing an international 2 arm phase III trial comparing the standard dose of Imatinib (400mg/day, arm A) with high dose Imatinib (800mg/day) for 6 months, followed by 400mg maintenance (arm B). *Methods.* Between February 2004 and December 2006 a total of 227 pretreated Ph+/BCR-ABL positive CP CML patients were randomized into this 2 arm phase III trial. The first planned interim analysis was performed after 50% of the patients had been treated for 12 months since randomisation. *Results.* There were no significant differences between treatment groups regarding sex (44.5% male, 55.5% female), age (median: 46 years for both groups), and different pretreatments, which included hydroxyurea (96%), interferon (72%), busulfan (17%) and *others* (26%; mainly AraC±combinations). Rates of complete haematological responses did not differ significantly between both arms at 3, 6 and 12 months (mo), respectively (53% arm A vs 59% arm B at 3 mo, 92% *vs* 85% (mo 6), 82% *vs* 90% (mo 12)). After 3 and 6 months, however, during the time where high doses of Imatinib (800mg/day) were applied in arm B, significantly ($p<0.05$) more patients achieved a major cytogenetic response (MCR; 21% arm A *vs* 37% arm B (mo 3); 34% *vs* 54% (mo 6) and a complete cytogenetic response (CCR; 6% arm A *vs* 25% arm B at 3 mo; 20% *vs* 44% at 6 mo). Moreover, significantly ($p<0.05$) more patients achieved a major molecular response (MMR) at 6 months in the Imatinib HD arm B compared to arm A (20% *vs* 7%). At 12 months, following dose reduction of Imatinib to 400 mg/d for *maintenance* at month 6 in the HD arm B, the rates of MCR (the primary endpoint of the study) were comparabel (57% arm A, 59% arm B). Nevertheless, there was still a clear trend to higher rates of CCR (37% arm A *vs* 48% in arm B) and MMR (16% arm A *vs* 21% arm B) in the HD arm, but at the time of the interim analysis these values did not reach statistical significance. In contrast to non-hematological toxicities, grade 3/4 hematological toxicities were significantly more common in the HD arm B (anemia: 2% (arm A) *vs* 14% (arm B); leukopenia: 24% *vs* 46%; thrombocytopenia 15% *vs* 39%). In spite of high rates of grade 3/4 leukopenias in the experimental arm B grade 3/4 infections were low in both arms: 2% (arm A), 3% (arm B). The cumulative median doses of imatinib were 400 mg (arm A) and 767 mg (arm B), respectively. *Conclusions.* These phase III data support the concept of more rapid and higher rates of cytogenetic and molecular remissions when higher doses of imatinib are applied.

SHORT TELOMERE LENGTH IS AN INDEPENDENT PREDICTOR OF SURVIVAL, PROGRESSION, RICHTER'S SYNDROME TRANSFORMATION AND RECURRENT INFECTIONS: AN ANALYSIS ON 421 CLL PATIENTS INCLUDING BLINDED VALIDATION ON 230 CASES

D. Rossi,[1] C. Lobetti Bodoni,[2] E. Genuardi,[2] L. Monitillo,[2] M. Cerri,[1] C. Deambrogi,[1] D. Drandi,[2] I. Ricca,[2] A. Rocci,[2] M. Boi,[2] S. Ferrero,[2] D. Capello,[1] L. De Paoli,[1] L. Bergui,[2] P. Omedè,[2] M. Massaia,[2] M. Boccadoro,[2] G. Gaidano,[1] M. Ladetto[2]

[1]Amedeo Avogadro University of Easten Piedmont, NOVARA; [2]University of Turin, TURIN, Italy

Background. In chronic lymphocytic leukemia (CLL) short telomeres have been associated to poor outcome. However validation on a large series is required to verify if TL is worth entering clinical practice. *Aims.* i) to definitely validate TL as an independent prognostic factor for time to first treatment (TTFT) and overall survival (OS) in a large CLL series (including a large blinded sample); ii) to assess TL impact on other relevant CLL endpoints, including Richter's syndrome (RS) transformation and infection risk. Methods. We used two consecutive series of 421 CLL (historical series n=191 from University of Turin; blinded validation series n=230 from Avogadro University). TL was assessed on PBMC collected at diagnosis by Southern blotting. Results. ROC analysis identified a cut-off point of 4650bp. Median TL was 6000bp (25th-75th:4614-7487bp). TL<4650bp was observed in 100/387 (25.8%) CLL. TL<4650bp associated with advanced Binet stage ($p=.003$), IGHV-homology>98% ($p<0.001$), del11q22-q23 ($p=.009$), CD38>30% ($p=.018$). Univariate log-rank analysis (UA) identified TL<4650bp as a risk factor (RF) of short TTFT (19.2 months *vs* 85.2 months; $p<0.001$), along with Binet B-C, IGHV-homology >98%, CD38>30%, ZAP70>20%, del11q22-q23, del17p13, +12, and absence of del13q14 ($p<.001$ in all instances). Multivariate analysis selected TL<4650bp as an independent TTFT predictor (HR:2.04; $p=.002$).

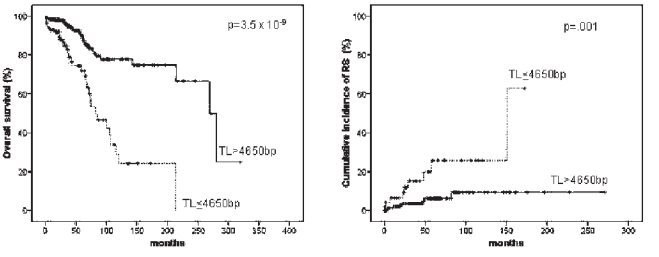

Figure 1.

UA identified TL<4650bp as a RF of short OS (82.2 *vs* 269.3 months; $p=3.5\times10^{-9}$ Figure 1A), along with age>65y, Binet B-C, IGHV-homology >98%, and del17p13 ($p<0.001$ in all instances). Multivariate analysis selected TL<4650bp as an independent OS predictor (HR:3.15; $p=<0.001$). TL<4650bp consistently identified a subset of patients with short TFS and OS, despite harboring favorable predictors as documented by bivariate log-rank test . Indeed, TL<4650bp segregated a CLL group displaying short TTFT despite being characterized by Binet A (1.7×10^{-8}), IGHV-homology<98% ($p=1.6\times10^{-10}$), CD38<30% ($p=1.4\times10^{-8}$), ZAP70<20 ($p=3.3\times10^{-11}$), and normal FISH or del13q14 only ($p=4.1\times10^{-11}$). Also, TL<4650bp segregated a CLL group displaying short OS despite having age<65y ($p=1.4\times10^{-7}$), Binet A ($p=0.001$), IGHV-homology <98% ($p=1.4\times10^{-6}$), and del17p13 absence ($p=6.2\times10^{-5}$). Results were superimposable in the historical and blinded validation series. The validation series (n=230) allowed the investigation of additional outcomes, namely RS transformation and infection risk. UA identified TL<4650bp as a RF for RS (5-year risk: TL<4650bp 35.8% *vs* TL>4650bp 6.3%; $p=0.001$. Multivariate analysis selected TL<4650 (HR:4.1, $p=0.007$) (Figure 1B) and lymphadenopathy >3cm (HR: 7.4, $p=2.1\times10^{-4}$) as independent predictors of RS. UA identified TL<4650bp as a RF of short time to recurrent infections (TL<4650bp 3.0 months vs TL>4650bp 26.3 months; $p=1.9\times10^{-4}$). Multivariate analysis identified TL<4650bp (HR:6.35; $p=0.002$) and IGHV-homology >98% (HR: 3.51;

p=0.007) as independent predictors of recurrent infections. Conclusions. This is the largest TL analysis so far in CLL and is provided with an independent and blinded validation cohort. The implications of our results are multifold. First, short TL is validated as an independent OS and TFS predictor. Second, short TL identifies a CLL subgroup with rapid disease progression and short survival despite the presence of favorable predictors. Third, short TL independently predicts RS and recurrent infections. Because short TL are the sole independent predictor of all CLL outcomes, we advise its more widespread clinical use.

0408

THE MOST FREQUENT T(14;19)(Q32;Q13)-POSITIVE B-CELL MALIGNANCY CORRESPONDS TO AN AGGRESSIVE SUBGROUP OF ATYPICAL CHRONIC LYMPHOCYTIC LEUKEMIA

F. Nguyen-Khac,[1] E. Chapiro,[1] I. Radford-Weiss,[2] C. Bastard,[3] I. Luquet,[4] C. Lefebvre,[5] E. Callet-Bauchu,[6] D. Leroux,[5] P. Talmant,[7] M.-J. Mozziconacci,[8] F. Mugneret,[9] S. Translocation t(14;19)(q32;q13) involving BCL3 and IGH was first reported in chronic lymphocytic leukemia (CLL) and then, together with variant BCL3-translocations, in other B-neoplasms. The Groupe Francophone de Cytogenetique Hematologique (GFCH) collected 43 chronic lymphoproliferative disorders with t(14;19) or variant in order to analyze to what extent this uncommon abnormality could define a subgroup among B-cell malignancies, and to document the consequences of the rearrangement. Clinical and biological patients' informations were gathered at diagnosis when available. The cytological, histopathological and immunological reviews were centralized and performed for 30/43 cases. All conventional cytogenetic data were reviewed by the GFCH. Detection of IG and BCL3 rearrangement, and recurrent abnormalities frequent in CLL were performed by hybridation *in situ* fluorescence. Genes expression was measured by RQ-PCR and IGHV mutation analysis were performed using published techniques. In our series the diagnosis felt more frequently in the CLL/SLL type (WHO classification) (n=30, 70%), with however atypical features when compared to common CLL: heterogeneous mixture of cells (70%) and signs of disease progression (80%), Matutes score < 4 (78%), high frequency of trisomy 12q and 6q deletion (67% *vs* 13.6-16%, p<10-11 and 19% *vs* 4.6-6%, p<0,02 respectively), low incidence of 13q deletion (14% *vs* 55-57.4%, p<10-5), high frequency of unmutated status of IGHV (90% *vs* 46%, p<0,001) and over-representation of the V4-39/D6-13/JH5 repertoire (25% *vs* 0.9-1.2%, p<0,001). BCL3 expression was also increased in all studied cases (median: 11.5% *vs* 2.9%, p=0.002). There were 64% Binet stage A and 36% stages B/C. The median time from diagnosis to initial therapy was 10 months for A stages, 1.3 months for all CLL stages, 2.3 months regarding CLL with trisomy 12, which was very short compared to the median treatment-free intervals for common CLL groups with 17p deletion (9 months), 11q deletion (13 months), 12q trisomy (33 months) and 13q deletion as the sole abnormality (92 months) reported in the literature. Finally, while t(14;19)(q32;q13) was more frequent in CLL, it may be observed in various types of B-cell lymphomas, mostly in marginal zone lymphomas (n=6, 14%). *Conclusions*. t(14;19)-positive CLL deserves to acquire the status of particular agressive subgroup defined by cell polymorphism and signs of disease progression, $CD5^+$ immunophenotype and Matutes score < 4, trisomy 12 and 6q deletion associated with t(14;19), unmutated IGVH status with an over-representation of the V4-39/D6-13/JH5 repertoire, and high BCL3 expression. These observations indicate the deregulation of the NFkB pathway in mature B-cell malignancies which could represent a therapeutic target.

0409

CD49D EXPRESSION IS AN INDEPENDENT RISK FACTOR OF PROGRESSIVE DISEASE IN EARLY STAGE CHRONIC LYMPHOCYTIC LEUKEMIA

D. Rossi,[1] A. Zucchetto,[2] F.M. Rossi,[2] D. Capello,[1] M. Cerri,[1] C. Deambrogi,[1] S. Cresta,[1] S. Rasi,[1] L. De Paoli,[1] C. Lobetti Bodoni,[3] P. Bulian,[2] G. Del Poeta,[4] M. Ladetto,[3] V. Gattei,[2] G. Gaidano[1]

[1]Division of Hematology, Amedeo Avogadro University, NOVARA; [2]Clinical and Experimental Onco-Hematology Unit, CRO, AVIANO; [3]Division of Hematology, University of Turin, TURIN; [4]Department of Hematology, University of Tor Vergata, ROMA, Italy

Background. Chronic lymphocytic leukemia (CLL) is a markedly heterogeneous disease. This notion is best exemplified by the variability in time to progression and in survival of Binet A CLL. The identification of prognostic subgroups within Binet A CLL is currently a major challenge. CD49d represents a novel CLL prognosticator, whose value in Binet A patients is unknown. *Aims*. This study aimed at verifying whether CD49d expression may further refine the prognostic stratification of Binet A CLL. Methods. The study was based on a consecutive series of 140 Binet A CLL representative of this disease stage and provided with a large and homogeneous dataset of biological and clinical variables. CD49d expression was assessed on PBMC collected at CLL diagnosis by three-color flow cytometry. A cut-off point of 30% was utilized to define positivity. *Results*. At diagnosis, CD49d>30% was observed in 54/140 (38.6%) Binet A CLL. CD49d>30% associated with markers of proliferating CLL, namely CD38>30% (p=3.9×10^{-6}), short telomere (p=0.021), high LDH (p=0.007) and β-2-microglobulin (p=.020). CD49d expression was not associated ($p>0.05$ in all cases) with IGHV homology, del11q22-q23 or del17p13, number of FISH lesions,TP53 inactivation by deletion and/or mutation, or ZAP70 expression. Also, CD49d expression was not associated ($p>0.05$ in all cases) with clinical markers of tumor burden. Univariate log-rank analysis identified CD49d>30% as a risk factor of progressive disease, in terms of time to progression (CD49d>30% 38.0 months *vs* CD49d<30% 66.7 months; p=4.7×10^{-4}), treatment free survival (TFS) (CD49d>30% 50.2 months *vs* CD49d<30% not reached; p=8.3×10^{-5}), and time to lymphocyte doubling (CD49d>30% 28.2 months *vs* CD49d<30% 53.0 months; p=.009). Multivariate analysis selected CD49d>30% as an independent TFS predictor after adjustment for biological (HR 2.39, p=0.019), clinical (HR 4.34, p=6.4×10^{-5}), and both biological and clinical variables analysed together (HR 2.59, p=0.032). Within Binet A subgroups harboring favorable predictors, CD49d>30% consistently identified a subset of patients with short TFS, as documented by bivariate log-rank test. Indeed, among patients harboring favorable biological predictors, CD49d>30% segregated a group of CLL displaying short TFS despite being characterized by IGHV homology <98% (p=.007), number of FISH lesions <2 (p=1.3 ×10^{-4}), normal FISH or del13q14 only (p=0.005), wild type TP53 (p=1.6 ×10^{-4}), telomere length >4250 bp (p=0.004), CD38<30% (p=0.005), or ZAP70<20% (p=0.003). Also, among patients harboring favorable clinical predictors, CD49d>30% identified a group of CLL displaying short TFS despite being characterized by Rai 0 (p=0.001), absence of splenomegaly (p=2.2×10^{-4}), lymphocytes <20 ×10^9/l (p=0.002), Hb >13 g/dl (p=2.7×10^{-5}), platelets >150×10^9/l (p=2.1×10^{-4}), BM lymphocytes <50% (p=0.009), non-diffuse BM pattern (p=0.001), β-2-microglobulin <2.5 mg/l (p=0.003), and LDH <1 x ULN (p=0.007). Conclusions. CD49d>30% is a marker of disease proliferation and dissemination in Binet A CLL. Our observations, along with the easiness of CD49d assessment, indicate CD49d>30% as a new marker for the initial prognostic assessment of Binet A CLL. In particular, CD49d>30% is useful for the identification a subgroup of Binet A CLL that displays rapid disease progression and need of treatment, despite being characterized at diagnosis by favorable predictors.

TP53 MUTATIONS AND DEL17P13 PREDICT SIMILAR OUTCOME AND CHEMOREFRACTORINESS IN CHRONIC LYMPHOCYTIC LEUKEMIA

M. Cerri,[1] C. Deambrogi,[1] D. Capello,[1] S. Cresta,[1] S. Rasi,[1] E. Sozzi,[2] L. De Paoli,[1] V. Gattei,[3] F. Forconi,[2] G. Gaidano,[1] D. Rossi[1]

[1]Division of Hematology, Amedeo Avogadro University, NOVARA; [2]Division Of Hematology and Bone Marrow Transplantation, University of Siena, SIENA; [3]Clinical and Experimental Onco-Hematology Unit, C.R.O., AVIANO, Italy

Background. Chronic lymphocytic leukemia (CLL) harboring del17p13 displays a dismal prognosis and a high risk of chemorefractoriness. The tumor suppressor TP53 is located on chromosome band 17p13 and loss

of TP53 is thought to be responsible for the poor prognosis of del17p13 CLL. Aims. This study aimed at verifying whether TP53 inactivation through mutation harbors the same prognostic role as del17p13. Methods. The study was based on a consecutive series of 224 CLL provided with a large and homogeneous dataset of biological and clinical variables. TP53 mutation status was assessed on PBMC collected at CLL diagnosis by direct sequencing of TP53 exons 2 to 10. *Results.* TP53 mutations were observed in 23/224 (10.3%) CLL, and included missense mutations in 20/23 (86.9%) cases, and insertions, short deletions and splicing site mutations in 1/23 (4.3%) cases each. TP53 mutations affected exon 4 in 1/23 (4.3%) cases, exon 5 in 4/23 (17.3%), exon 6 in 4/23 (17.3%), exon 7 in 5/23 (21.7%), and exon 8 in 9/23 (39.1%). No mutations were found in exons 2, 3, 9 or 10. Mutations targeted the TP53 DNA-binding domain in 21/22 cases. Functional codons targeted by mutations were TP53 DNA-binding codons (5/22) and zinc-ligand codons (2/22). All mutations predicted a reduction of trans-activation activity of the mutated p53 protein (median residual activity: 6.44% by http:\\p53.free.fr/Database/p53_recomendations.html). FISH karyotype was available in 213/224 cases. Overall, 29/213 (13.5%) CLL harbored TP53 inactivation through deletion and/or mutation: 11/213 (5.1%) CLL were TP53-mutated/del17p13, 10/213 (4.6%) were TP53-wt/del17p13, and 8/213 (3.7%) were TP53-mutated/no del17p13. Median residual TP53 trans-activation activity was similar between the TP53-mutated/no del17p13 and the TP53-mutated/del17p13 subgroups (9.54% *vs* 10.30% respectively; p=0.224). Univariate log-rank analysis identified TP53 mutations as a risk factor of short treatment free survival (TFS) (TP53-mutated: 17.2 months *vs* TP53-wt: 87.5 months; p=0.006), overall survival (OS) (TP53-mutated: 91.7 months *vs* TP53-wt: not reached; $p=1.1\times10^{-5}$), time to chemorefractoriness (TP53-mutated: 6.3 months *vs* TP53-wt: 75.4 months; $p=4.4\times10^{-5}$), time to alkylator refractoriness (TP53-mutated: 9.3 months *vs* TP53-wt: 68.0 months; p=0.002) and time to fludarabine refractoriness (TP53-mutated: 6.3 months *vs*TP53-wt: 82.1 months; $p=4.0\times10^{-4}$). TFS, OS and time to chemorefractoriness did not differ between CLL harboring TP53 mutations in the absence of del17p13 and CLL harboring del17p13 (TFS: TP53-mutated/no del17p13: 16.1 months, TP53-wt/del17p13: 1.0 months, TP53-mutated/del17p13: 18.3 months; OS: TP53-mutated/no del17p13: 94.7 months, TP53-wt/del17p13: 56.0 months, TP53-mutated/del17p13: 91.7 months; time to chemorefractoriness: TP53-mutated/no del17p13: 5.7 months, TP53-wt/del17p13: 55.0 months, TP53-mutated/del17p13: 5.5 months) (p>0.05 for all comparison). Multivariate analysis selected TP53 mutation as an independent predictor of TFS (HR:2.48; p=0.21), OS (HR:3.48; p=0.002), and chemorefractoriness (HR:4.20; p=0.001) after adjustment for IGHV gene homology, CD38 expression, FISH karyotype, and exposure to fludarabine. *Conclusions.* Mutation in the absence of del17p13 is the sole mechanism of TP53 inactivation in ~4% CLL. TP53 mutations carry the same prognostic relevance as del17p13 in terms of CLL progression, survival and risk of chemorefractoriness. Because of the practical implications for choice of therapy, screening for TP53 mutations, in addition to del17p13 assessment, should be included in the initial prognostic assessment of CLL.

CLINICAL AND BIOLOGICAL CHARACTERIZATION OF CIRCULATING ENDOTHELIAL CELLS IN CHRONIC LYMPHOCYTIC LEUKEMIA

G.M. Rigolin,[1] R. Maffei,[2] L. Rizzotto,[1] M. Ciccone,[1] O. Sofritti,[1] G. Daghia,[1] F. Cibien,[1] F. Cavazzini,[1] R. Marasca,[2] G. Castoldi,[1] A. Cuneo[1]

[1]Hematology - University of Ferrara, FERRARA; [2]Hematology Section - COM - University of Modena, MODENA, Italy

Background. Several studies have shown that bone marrow-derived endothelial cells (EC) may contribute to tumor angiogenesis and that in the peripheral blood of cancer patients there is an increased amount of circulating ECs (CECs) that may participate to new vessel formation. Recent data also showed that in B-cell neoplasms ECs are in part tumor-related reflecting a novel aspect of tumor angiogenesis. All together these observations suggest that tumors can elicit the sprouting of new vessels from existing capillaries through the secretion of angiogenic factors and that, in some cases, cancer cells can also mimic the activities of ECs by participating in the formation of vascular-like networks. *Aims*. To characterize the clinical and biological role of CECs in a series of 85 chronic lymphocytic leukemia (CLL) patients. *Methods*. CEC levels were evaluated by multiparameter flow cytometry and correlated with known clinical and biological parameters. For biological studies, CECs were first isolated by immunomagnetic sorting and then characterized by phenotypic studies with antibodies recognizing endothelial and CLL antigens, by FISH analyses with specific probes and by gene expression profiling comparing CLL CECs with CECs from normal subjects, and with monocytes and lymphocytes from the same CLL patient. *Results*. CEC levels were significantly higher in CLL patients in comparison to normal healthy subjects (p=0.037). Higher CEC levels were associated with advanced disease stage (p=0.012) and with lack of response to treatment or progressive disease (p=0.005). No association was demonstrated with CD38/ZAP70 expression and FISH/cytogenetic abnormalities. In all experiments more than 95% of immunomagnetically sorted cells were of EC origin as demonstrated by phenotypic analyses (VEGFR2$^+$, vWF$^+$, CD144$^+$, UEA1 lectin$^+$, CD45$^-$, CD14$^-$, CD5$^-$, CD19$^-$). FISH analysis showed that a significant proportion of sorted CECs was tumor-derived because they harbored the same genetic lesion as observed in neoplastic CLL cells. The fraction of CECs showing cytogenetic aberrations averaged 40.7% (range, 20-78%). More then 85% of CECs presented features of EPCs because they expressed CD133, a marker gradually lost during EC differentiation and absent in mature ECs. CLL CEC had a similar gene expression pattern for several genes characterizing CEC function such as CD144, CD34, CD133, CD146, CD31, VEGFR2, VEGFR3, VWF, and TIE2. Moreover, CLLCEC showed a strongly different gene expression pattern compared to normal CEC characterised by increased cell survival and proliferation including activation of Wnt and inhibition of Notch signalling pathways, reduction of cell adhesion to extracellular matrix and enhanced pro-angiogenic function. Gene expression profiling analysis also suggested that similarities exist with clonal CLL lymphocytes. *Conclusions*. These findings suggest that in CLL CECs are in part tumor related and with a gene expression profile that may indicate their contribution to tumor neovasculogenesis and possibly to the spreading and progression of the disease.

Stem cell transplantation in multiple myeloma

Giovanni Battista, TORINO; [17]Università di Torino, TORINO; [18]Divisione di Ematologia dell'Università di Torino, AOU San Giovanni Battista, TORINO, Italy,

Background. The dramatic reduction of transplant-related mortality (TRM) with nonmyeloablative conditionings has extended the eligible age for transplantation up to 65-70 years. Therefore the role of allografting in the treatment of multiple myeloma has to be redefined. *Aims.* At 15 Italian Centers, patients younger than 65 years with newly diagnosed multiple myeloma were enrolled in a prospective phase II study to evaluate the effect of non-myeloablative allografting on overall (OS) and event-free (EFS) survivals. From January 2000 to June 2005, 106 patients entered the study. Induction chemotherapy consisted of VAD-based regimens, followed by cyclophosphamide and growth factor mobilized peripheral blood stem cell harvest. To improve disease control an autograft with melphalan 200 mg/m^2 was planned 2-4 months before a low-dose (2 Gy) TBI-based allograft from HLA-identical siblings. Graft-*vs*-host disease (GVHD) prophylaxis included cyclosporin and mycophenolate mofetil. *Results.* One-hundred-two (96%) patients, median age 54 (30-65), completed the program whereas 4 withdrew their consent. Incidence of acute grade II-IV GHVD was 40% (4% grade IV), while chronic GVHD occurred in 52%. Cox models for the development of GVHD showed that the infusion of higher doses of donor CD34$^+$ cells correlates with higher incidence of acute, but not chronic, GVHD (HR 1.11, CI 1.03-1.19, p=0.004). Overall TRM was 14%. Fifteen % of patients died from disease progression, 3 from secondary tumor (3%). After a median follow-up of 5 (2.3-8.4) years, OS was not reached and median EFS was 37 (31-54) months post-transplant. Overall response, complete (CR) plus partial remission, was 91% (93/102), with 54 patients achieving CR. Disease relapse occurred in 45/102 patients, including 14/54 of those who reached CR post-transplant. By multivariate-analysis the achievement of at least a very good partial remission prior to allografting was significantly associated with longer OS (HR 0.24,CI 0.08-0.72, p=0.01) and longer EFS (HR 0.34,CI 0.18-0.65, p<0.01). Interestingly, chronic GVHD was not correlated with either the achievement of post-transplant CR (HR 0.88,CI 0.47-1.65, p=0.7) or its duration (HR 0.94,CI 0.55-1.6, p=0.8). Presence of del(13) was evaluated only in a subset of 39 patients: 13 carried del(13) and 26 did not. OS was not reached in the patients without del(13) and was 4.3 years in patients with del(13) (p=0.18). Summary and *Conclusions.* After 5 years of follow-up, this study shows that a tandem auto-allo approach is a treatment option for newly diagnosed multiple myeloma. Given the significant importance of pre-transplant disease reduction to enhance graft-versus-myeloma, a new multicenter trail that incorporates new drugs in the induction phase is currently in progress.

0413

REDUCED INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION (RIC ALLO-SCT) FOR PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM): A SURVEY FROM THE SOCIETE FRANCAISE DE GREFFE DE MOELLE ET DE THERAPIE CELLULAIRE

M. Mohty,[1] L. Quoc-Hung,[2] F. Nicolini,[2] F. Garban,[3] H. Esperou,[4] M. Attal,[5] N. Milpied,[6] B. Lioure,[7] P. Bordigoni,[8] I . Yakoub-Agha,[9] J.H. Bourhis,[10] B. Rio,[11] E. Deconinck,[12] M. Renaud,[13] J.L. Harousseau,[1] D. Blaise,[14] M. Michallet[2]

[1]CHU de Nantes, NANTES; [2]CHU de Lyon, LYON; [3]CHU de Grenoble, GRENOBLE; [4]Agence de Biomedecine, PARIS; [5]CHU de Toulouse, TOULOUSE; [6]CHU de Bordeaux, BORDEAUX; [7]CHU de Strasbourg, STRASBOURG; [8]CHU de Nancy, NANCY; [9]CHU de Lille, LILLE; [10]Institut Gustave Roussy, PARIS; [11]CHU Hotel-Dieu, PARIS; [12]CHU de Besancon, BESANCON; [13]CHU de Poitiers, POITIERS; [14]Institut Paoli-Calmettes, MARSEILLE, France

The results of RIC allo-SCT for MM are still under considerable debate. While EBMT data did not support the universal use of RIC for MM allografts, the Italian randomized multicenter study suggested that in newly diagnosed myeloma, survival in recipients of a hematopoietic stem-cell autograft followed by RIC allo-SCT from an HLA-identical sibling is superior to that in recipients of tandem stem-cell autografts. The aim of this multicenter retrospective national study was to identify prognostic factors for outcome of high-risk patients with MM after allo-SCT prepared by RIC. Data from 219 patients (median age 52 years, range 27-66), who received grafts from a sibling (n=197) or unrelated donor (n=22) were analyzed. At time of transplant, only 37 patients (17%) received RIC allo-SCT in CR or VGPR, while 134 patients (61%) were transplanted in PR. 48 patients were transplanted either in stable disease (n=15) or were in refractory/progressive disease (n=33). All patients have received at least one autologous transplant prior to RIC allo-SCT. The graft source was PBSCs in the majority of patients (n=183). 21% of the patients received the Seattle Fludarabine and low dose TBI RIC regimen, while 53% of patients received Fludarabine, Busulfan and ATG. 32 patients (15%) died of transplant-related complications. The incidences of grade 2-4 acute GVHD and extensive chronic GVHD were 37% and 20% respectively. At 3 years, overall and progression free survivals (OS, PFS) were 41% (95%CI, 34-49) and 19% (95%CI, 14-27) respectively. Disease status (CR, PR, SD *vs* progressive) was significantly associated with overall survival (p=0.0002; Figure 1). In multivariate analysis, disease status at time of RIC allo-SCT, was the strongest parameter associated with an improved OS and PFS (p=0.005 and p=0.004 respectively). Despite its obvious caveats, the relatively low TRM observed in this series, suggest that there is still space to investigate RIC allo-SCT for MM. However, RIC allo-SCT appears to result in a durable response only if it is applied early in the disease history, especially when patients are still chemosensitive. Since the latter results are also expected to be further improved with the systematic and early use of maintenance therapies (Bortezomib and/or Lenalidomide) after RIC allo-SCT, randomized or quasirandomized prospective studies are still warranted.

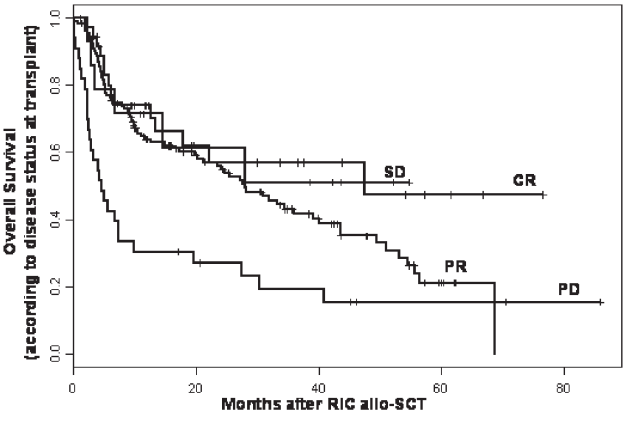

Figure 1.

0414

UPDATED ANALYSIS OF ALLOGENEIC HSCT AFTER RIC FOR HEMATOLOGICAL MALIGNANCIES FROM THE SOCIÉTÉ FRANÇAISE DE GREFFE DE MOELLE OSSEUSE ET DE THÉRAPIE CELLULAIRE (SFGM-TC) REGISTRY

M. Michallet,[1] M. Michallet,[2] Q. Le,[2] M. Mohty,[3] M. Sobh,[2] F.E. Nicolini,[2] J.-M. Boiron,[3] H. Espérou,[3] M. Attal,[3] N. Milpied,[3] B. Lioure,[3] P. Bordigoni,[3] I. Yackoub-Agha,[3] J. Bourhis,[3] B. Rio,[3] E. Deconninck,[3] M. Renaud,[3] N. Raus,[2] D. Blaise[3]

[1]Hôpital Edouard Herriot, LYON; [2]Edouard Herriot Hospital, LYON; [3]Société Française de Greffe de Moelle et de Thérapie Cellulaire, PARIS, France

This report updates a retrospective study from SFGM-TC registry concerning 1108 patients who underwent allogeneic hematopoeitic stem cell transplantation (HSCT) after reduced intensity conditioning (RIC) from HLA identical siblings (84%) and unrelated donors (16%) for hematological malignancies. At time of conditioning, 442 patients were in CR, 337 in PR, 107 in stable disease (SD) and 222 in progressive disease (PD). As conditioning, 255 patients received fludarabine and TBI (2 grays), 465 patients fludarabine, busulfan and ATG and 388 patients an other regimen. After transplant, 336 patients (30%) developed an acute GVHD grade II (grade II: 178, III: 80 and IV: 78). A chronic GVHD was present in 388 patients (35%) (185 limited and 203 extensive). With a median follow-up of 30 months, the 3 and 5-year probability of overall survival (OS) were 43.5% (40-47) and 32%(29-35) respectively and the 3 and 5-year probability of event-free survival (EFS) were 35%(31-39) and 28% (24.5-31) respectively. The TRM at 1 year, 2 years and 3 years was 15% (13-17), 18% (15.5-21) and 20% (17-23).

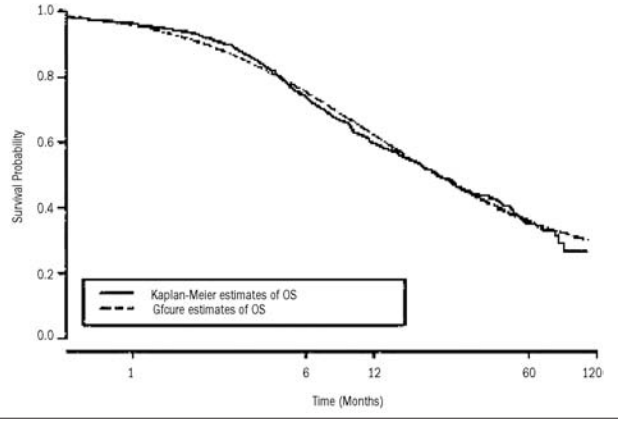

Figure 1.

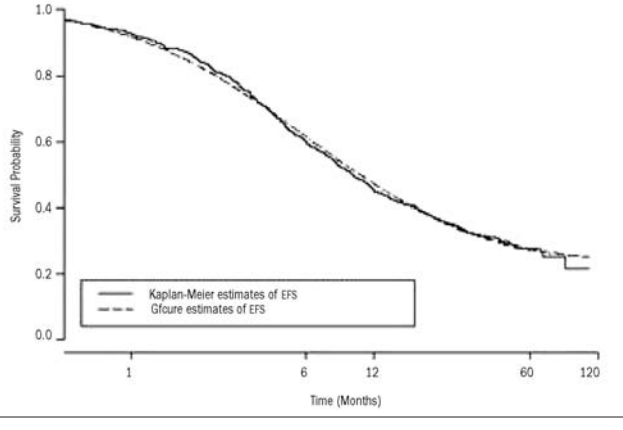

Figure 2.

A mixture model, gfcure with Splus statistical package determined the percentages of long-term survivors and its adequacy was verified graphically. The probability to be a long-survivor was 24% (17.5-32.5) (Figure 1) and to be a long event-free survivor was 23% (19-28) (Figure 2). The multivariate analysis has tested recipient and donor age, disease status pre-transplant, number of transplants before RICT, HSC source, sex matching, HLA matching, CMV status and ABO compatibility. The only factor which had a significant impact on long-term survival after RICT was the disease status just prior conditioning: PR *vs* CR: HR: 3.63 [1.14-9.18] $p<0.001$ and PD *vs* CR: HR: 4.35 [2.22-8.51] $p<0.0001$. In conclusion, these updated data demonstrate that allogeneic HSCT after RIC was able to possibly cure 23% of patients with haematological malignancies and the most important factor to take into account remains to be in CR pre-transplant.

0415

A PROSPECTIVE PETHEMA STUDY OF TANDEM AUTOLOGOUS TRANSPLANTATION *vs* AUTOGRAFT FOLLOWED BY REDUCED-INTENSITY CONDITIONING ALLOGENEIC TRANSPLANTATION IN NEWLY DIAGNOSED MULTIPLE MYELOMA

Clinico Universitario, SALAMANCA, Spain

Background. Two randomized trials showed that tandem autologous transplant (ASCT) results in a significantly longer EFS and OS in patients failing to achieve CR or near-CR with a single transplant, but there was no survival plateau. Promising results have been reported using dose-reduced intensity conditioning (Allo-RIC), especially after debulky with an autologous transplant. *Aims.* To investigate the efficacy in terms of response and survival from a second transplant intensification (2nd ASCT *vs* Allo-RIC) in patients with chemosensitive disease who failed to achieve CR or near-CR with a first ASCT. Patients and *Methods.* Patients diagnosed with MM from Oct 1999 to Dec 2004 younger than 70 years received 6 courses of VBMCP/VBAD and responding patients were intensified with busulphan/melphalan or MEL-200 followed by stem cell support. Patients not achieving CR or near-CR were planned to receive a second transplant (2nd ASCT with CVB - cyclophosphamide, etoposide and BCNU - or MEL-200 intensification or an Allo-RIC with fludarabine/MEL-140 conditioning, if sibling donor available). *Results.* Eighty-five patients received a 2nd ASCT while 25 underwent an Allo-RIC. The CR rate was significantly higher with allo-RIC (40% *vs* 11%, $p= 0.001$). There was a trend towards a higher TRM with the allogeneic procedure (5% *vs* 16%, $p=0.07$). The incidence of grade II-IV aGVHD was 32% and 14 of 21 (66%) patients at risk developed cGVHD. After a median follow-up from the second transplant of 5.2 years, there was a trend towards a longer progression-free survival (median 31 mos *vs* not reached, $p=0.08$) in favour of Allo-RIC with a plateau for allografting and none of the 10 patients who achieved CR after Allo-RIC ha relapsed. The overall survival was not significantly different (median 58 mos. Vs not reached, $p=0.9$), although there was a plateau for the Allo-RIC group not observed with 2nd ASCT. *Conclusions.* In patients with MM failing to achieve at least nCR with a first ASCT, the Allo-RIC offers more long-term benefit than a second ASCT.

0416

THE HEMATOPOIETIC CELL TRANSPLANTATION-SPECIFIC COMORBIDITY INDEX (HCT-CI) PREDICTS SURVIVAL AND NON-RELAPSE MORTALITY IN LYMPHOMA AND MYELOMA PATIENTS RECEIVING RIC ALLOGRAFT

L. Farina,[1] B. Bruno,[2] F. Patriarca,[3] F. Spina,[1] R. Sorasio,[2] M. Morelli,[1] R. Fanin,[3] M. Boccadoro,[2] P. Corradini[1]

[1]Istituto Nazionale Tumori, University of Milano, MILANO; [2]Ospedale San Giovanni Battista, University of Torino, TORINO; [3]Azienda Ospedaliera Universitaria, UDINE, Italy

Background. The allogeneic hematopoietic cell transplantation-specific comorbidity index (HCT-CI) has been recently developed to identify patients at high risk of morbidity and mortality after an allogeneic stem cell transplant (alloSCT). Reduced-intensity conditioning (RIC) regimens have decreased non-relapse mortality (NRM) in heavily pre-treated patients. Aims. We performed a retrospective study to assess whether comorbidities, according to HCT-CI, may influence the outcome of lymphoma and multiple myeloma patients undergoing a RIC alloSCT. Methods. Between 2000 and 2007, 197 patients received a RIC alloSCT from a HLA identical sibling (n= 123) or unrelated (n=74) donor in three Italian Transplant Units. Median age at transplant was 52 years (range, 17-69) and 41% of the patients were 55 or older. Diseases included non Hodgkin's lymphoma (n=103), multiple myeloma (n=68) and Hodgkin's lymphoma (n= 26). Median number of previous treatments was 3 (range, 0-8). Disease risk according to Kahl *et al.* (Blood 2007) was low, intermediate and high in 29%, 42% and 29% of patients, respectively. Thirty-three of 68 myeloma patients received a non-myeloablative conditioning regimen, whereas the others received a RIC regimen. The incidence of grade ≥2 acute graft-versus-host disease (aGVHD) was 35%. Patients with HCT-CI of 0, 1-2 and ≥3 were 64 (32%), 61 (31%) and 72 (37%), respectively. Variables included in multivariate analysis were age (<55 or ≥55), disease risk (low, intermediate and high), number of previous lines of therapy (≤ and >2), HCT-CI (0, 1-2 and ≥3), Karnofsky Perfomance Status (PS, >80% and ≤80%). Results. One-year OS and PFS were 87%, 60%, 60% and 91%, 75%, 70% in patients with HCT-CI of 0, 1-2 and ≥3, respectively. Cumulative incidence of NRM was 6%, 22%, 25% at 1 year and 6%, 24% and 27% at 2 years, whereas relapse mortality was 5%, 20%, 17% at 1 year and 7%, 27% and 23% at 2 years. By multivariate analysis only Karnofsky PS (p=0.00051) and HCT-CI (p=0.0038) were correlated with OS, whereas PFS was influenced by disease risk category (p=0.013), number of previous therapies (p=0.038), and both Karnofsky PS (p=0.031) and HCT-CI (p=0.0009). Interestingly HCT-CI was the only significant factor that could predict NRM (p=0.034) while Karnofsky PS failed to show a significant correlation (p=0.1). Of note, age (≥55) was not statistically significant either in OS, or PFS or NRM. The cumulative incidence of grade ≥2 aGVHD in patients with HCT-CI 0, 1-2, ≥3 was 26%, 35% and 41%, respectively (p=0.25). Myeloma patients with HCT-CI 0, 1-2 or ≥3 showed a similar OS whether they were transplanted with a non-myeloablative or RIC regimen (HCT-CI 0: p= 0.951, HCT-CI 1-2: p= 0.946; HCT-CI ≥3: p=0.063). Conclusions. Although the data need to be confirmed in prospective trials, these results showed that HCT-CI may be a useful tool to predict OS, NRM and also PFS after RIC alloSCT in lymphoma and myeloma patients. In the clinical setting HCT-CI and not age should be used for patient risk assessment.

Cytogenetics and molecular diagnostics

DIFFERENCES IN CYTO- AND MOLECULAR GENETIC ABERRATIONS BETWEEN YOUNG (<2YR) AND OLDER CHILDREN WITH ACUTE MYELOID LEUKEMIA

B.V. Balgobind,[1] I.H.I.M. Hollink,[1] D. Reinhardt,[2] J. Bradtke,[3] A. Teigler-Schlegel,[3] A.R. Von Bergh,[1] J. Cloos,[4] G.J.L. Kaspers,[4] E. van Wering,[5] Z. Zemanova,[6] J. Stary,[7] J. Cayuela,[8] A. Baruchel,[8] M.M. van den Heuvel-Eibrink,[1] C.M. Zwaan[1]

[1]Erasmus MC - Sophia's Children Hospital, ROTTERDAM, Netherlands; [2]AML-BFM Study Group, HANNOVER, Germany; [3]Children's University Hospital, GIESSEN, Germany; [4]VU Medical Center, AMSTERDAM, Netherlands; [5]DCOG, THE HAGUE, Netherlands; [6]General Teaching Hospital, PRAGUE, Czech Republic; [7]2nd Medical School, Charles University, PRAGUE, Czech Republic; [8]St. Louis Hospital, PARIS, France

Background. Young children (defined as <2 years old) with acute myeloid leukemia (AML) do not differ in outcome when compared with older children with AML. Previously, distinct cytogenetic aberrations specific for AML in young children have been reported, such as t(7;12), and t(1;22), which is found exclusively in FAB M7. Moreover, young children with AML are characterized by a high frequency of 11q23-rearrangements. However, so far, no information is available on differences in the molecular genetic background of these two age groups. *Aims*. We performed a retrospective analysis of the distribution of different cytogenetic and molecular aberrations in young (<2yr) and older children (≥ 2yr) with AML. *Methods*. 421 pediatric AML cases (age 0-19 yr) were screened for the recurrent cytogenetic aberrations (i.e. 11q23-rearrangement, inv(16), t(8;21) and (t15;17)) using FISH and PCR, next to standard karyotyping, which was done by the collaborative groups. Also molecular screening of the mutational hotspots was performed , including c-KIT (n=229), N- and K-RAS (n=187), FLT3/ITD (n=162), FLT3-TKD (n=230), PTPN11 (n=216), MLL-PTD (n=240), CEBPalpha (n=251) and NPM1 (n=291). *Results*. The predominant cytogenetic aberration in the young children with AML consisted of 11q23-rearrangements, which occurred in 44% of the young children *vs* 17% in the older children (p=<0.005). We also found significant differences in other cytogenetic subgroups of AML between young and older children, i.e. normal karyotype, 5% *vs* 18%, respectively (p=0.008) and complex karyotype, 12% *vs* 5% (p=0.03). t(7;12) (n=3) and t(8;16) (n=3) were only detected in young children, in contrast to t(15;17) (n=16) and t(8;21) (n=44), which were only seen in older children. For the molecular aberrations a significantly different age distribution was found for NPM1 mutations (0% young *vs* 9% in older children; p=0.05) and FLT3-ITD (0% *vs* 21%, respectively; p=0.005). Mutations in the other genes showed no clear correlation with age. Several non-random associations between molecular and cytogenetic aberrations were detected. 89% of c-KIT mutations were associated with core-binding factor AML in children ≥2 years old. In young children, 2/4 c-KIT-mutated cases were associated with an MLL-rearrangement. NPM1, CEBPalpha and FLT3-ITD mutations in older children were significantly correlated with normal karyotype AML (respectively 57%, 37% and 75%; p=<0.05). In young children, 71% of RAS mutations were associated with an 11q23-rearrangement *vs* 48% in older children (p=0.02). In older children however, 41% of the RAS mutations were associated with a normal karyotype. *Conclusions*. These data suggest that young children with AML are characterized by differences in the type and frequency of cytogenetic and molecular genetic abnormalities when compared with older children with AML, possibly reflecting differences in underlying biology between these age groups. These differences may become clinically relevant in the era of molecularly targeted therapy.

COMPREHENSIVE MOLECULAR ANALYSES OF TP53 GENE ALTERATIONS IN ACUTE MYELOID LEUKEMIA WITH COMPLEX KARYOTYPE

F.G. Rücker,[1] L. Bullinger,[1] C.-M. Kugler,[1] S. Miller,[1] H.A. Kestler,[1] P. Lichter,[2] H. Döhner,[1] K. Döhner[1]

[1]University of Ulm, ULM; [2]DKFZ, HEIDELBERG, Germany

Approximately 10 to 15% of acute myeloid leukemia (AML) cases exhibit a complex karyotype, defined by three or more chromosome abnormalities without presence of a specific fusion transcript. In order

to identify novel genomic regions of interest in this AML subgroup we applied comparative genomic hybridization to microarrays (array-CGH) allowing high-resolution genome-wide screening of genomic imbalances. Using this approach, we identified deletions of 17p13, affecting a genomic region that harbours TP53, in 48 of 100 unselected cases. Since TP53 is frequently involved as a tumor suppressor gene in numerous malignancies, we aimed to investigate its role in this AML subgroup. In 46 of the 48 patients 17p13 deletions were validated by FISH (fluorescence in-situ hybridization) using a TP53 locus specific DNA-probe. In a first series, 83 of the 100 cases were evaluated for TP53 mutations by direct sequencing of exons 4 to 9. In total, 47 mutations occurring in 34 cases were identified with a maximum of four mutations per case. Of these 47 mutations 14 were known polymorphisms [exon 6 (silent mutation) n=3, intron 9 n=4, intron 4 n=4, intron 7 n=3]; five cases exhibited known mutations in intronic splice sites (intron 4 and intron 8, n=2 each, and intron 6 n=1). In addition to 24 known mutations (missense n=23, nonsense n=1) four novel mutations were identified, one in intron 4 and three missense-mutations in exon 5. Combining the array-CGH findings with the mutation status, TP53 gene alterations were detected in 60% of the patients. Interestingly 19% of these cases showed biallelic mutations with deletion of one allele and a mutation in the remaining allele. In addition, TP53 gene alterations were associated with distinct genomic amplifications. All cases exhibiting amplifications in 8q24 or 12p13 (n=3 each) showed altered TP53, respectively, as well as three out of four cases with amplifications in 9p24 or 13q12, respectively. Correlation of these findings with global gene expression (GEP) data, which were available in a subset of cases (n=43), revealed specific expression patterns that were highly associated with TP53 alterations. For example the signature for biallelic TP53 mutations was enriched for genes involved in JAK-STAT signaling as gene set enrichment analysis (GSEA) provided significant associations with the BioCarta pathways *STAT3-signaling* and *IL22 soluble receptor signaling*. Furthermore, we also observed a significant enrichment for genes belonging to the *ARF-*, *VEGF-* and *Hypoxia/p53*-pathways, thereby suggesting that altered p53 function might indeed be of functional relevance in the affected AML cases. In conclusion, these data suggest that loss of normal p53 function plays an important role in the subgroup of AML with complex karyotype. Further analyses will facilitate to disclose the underlying pathways.

DIAGNOSTIC AND PROGNOSTIC IMPACT OF GENE EXPRESSION PROFILING BASED MOLECULAR MARKER PREDICTION IN CYTOGENETICALLY NORMAL AML

L. Bullinger,[1] T. Hielscher,[2] C. Stirner,[1] R. Kranz,[1] Y.H. Kim,[3] S. Fröhling,[1] R.F. Schlenk,[1] A. Benner,[2] K. Döhner,[1] J.R. Pollack,[3] H. Döhner[3]

[1]University of Ulm, ULM, Germany; [2]DKFZ, HEIDELBERG, Germany; [3]Stanford University, STANFORD, USA

Background. In acute myeloid leukemia (AML), cyotgenetics is one of the most powerful prognostic markers. The largest subset of patients, cytogenetically normal AML (CN-AML), comprises a heterogeneous group with intermediate prognosis. However, in the past few years, mutations in genes like FLT3, CEBPA and NPM1 have been identified in CN-AML, and the presence of such mutations carries important prognostic information. Furthermore, DNA microarray-based gene expression profiling (GEP) has been shown to powerfully capture the molecular heterogeneity of cancers, and has been applied to build classifiers and clinical-outcome predictors in AML. *Aims.* While prior studies have defined gene-expression patterns associated with NPM1, CEBPA, and FLT3, none has assessed the clinical-relevance of identified signatures. *Methods.* Here, we profiled a large set of clinically-annotated CN-AML specimens (n=142) entered within a multicenter trial for patients < 60 years (AMLSG HD98A trial) using 40k cDNA microarrays. In this data set we applied supervised analysis (LASSO penalized logistic regression) to define gene-expression patterns characterizing FLT3 internal tandem duplication (ITD), CEPBA and NPM1 mutations. Next, we evaluated the utility of the respective signatures with regard to CN-AML classification and prognostication in an independent data set of CN-AML cases (n=83, entered within our ongoing multicenter trial AMLSG 0704 for patients <60 years) analyzed by Affymetrix microarrays (Human Genome U133 Plus 2.0 Arrays). *Results.* While in the cDNA data we were able to define distinct signatures associated with NPM1, CEBPA and FLT3 consisting of 39, 27, and 47 genes, respectively, only the NPM1 signature revealed a high prediction accuracy of >95% in leave-one-out cross validated classification. Prediction of FLT3-ITD or CEBPA mutation performed less well with accuracies of 80% and 73%, respectively. However, for both CEBPA and FLT3-ITD the predicted mutation class labels performed slightly better than the marker itself with regard to the prognostic impact on overall survival (CEPBA: p=0.00635 *vs* p=0.00683, FLT3-ITD p=9.57e-06 *vs* p=5.11e-05; logrank test). For class prediction the signatures derived from our cDNA data performed equally well in our independent test set analyzed by Affymetrix microarrays taking into account the smaller cohort. Furthermore, in the independent data our classifier signatures also provided prognostic information in addition to the molecular markers. *Summary and Conclusions.* With regard to the GEP based *misclassifications* we speculate that the signatures identified cases with alternative genetic or epigenetic changes that either phenocopy or block the effects of the respective aberrations. Therefore, the signature genes provide a starting point to dissect these *mutations* pathways, and our findings underscore the potential clinical utility of a gene-expression based measure of clinically-relevant *mutation pathway activation*.

IMPROVED DETECTION AND MOLECULAR MONITORING OF FIP1L1-PDGFRA BY ANALYSIS OF PATIENT-SPECIFIC GENOMIC DNA FUSION JUNCTIONS

C. Score,[1] C. Walz,[2] J.V. Jovanovic,[3] A.V. Jones,[1] K. Waghorn,[1] C.E. Hidalgo-Curtis,[1] D. Grimwade,[3] F.H. Grand,[1] A. Reiter,[2] N.C.P. Cross[1]

[1]Leukaemia Research, SALISBURY, UK; [2]III. Medizinisch Klinik, MANHEIM, Germany; [3]Cancer Genetics Laboratory, Guy's Hosptial, LONDON, UK

FIP1L1-PDGFRA is a cytogenetically cryptic fusion seen in roughly 10% of patients with a provisional diagnosis of idiopathic hypereosinophilic syndrome (IHES). Previous studies have highlighted the importance of detecting FIP1L1-PDGFRA since positive patients are usually excellent responders to imatinib, however unambiguous detection of this fusion by FISH or RT-PCR is complicated by several factors. Heterozygous deletion of CHIC2 detected by FISH, a surrogate marker for FIP1L1-PDGFRA, is not always reliable since the proportion of cells carrying the abnormality may be low and overlap with the background false positive rate. In many cases the fusion mRNA is only detectable by nested RT-PCR, probably due to a combination of the heterogeneity of breakpoints within FIP1L1, the high degree of alternative splicing as well as highly variable levels of expression. We aimed to develop a more reliable method by which FIP1L1-PDGFRA could be detected, exploiting the fact that genomic breakpoints within PDGFRA are tightly clustered. We designed a multiplex Long Range PCR (LR PCR) assay with 15 forward primers spanning the breakpoint region within FIP1L1 (intron 5 to exon 16) and one reverse primer in PDGFRA intron 13. To date we have screened 202 samples with IHES or persistent unexplained eosinophilia and detected the genomic junction sequence in all RT-PCR positive samples (n=43). Genomic fusions were amplified by single step PCR in all cases whereas only 22 (51%) of these samples were single step RT-PCR positive. Importantly, FIP1L1-PDGFRA was detected in two cases that had been scored as RT-PCR negative. The ability to detect minimal residual disease (MRD) with high sensitivity is also important and therefore we designed patient-specific primer/probe combinations to quantify residual FIP1L1-PDGFRA positive cells from genomic DNA (gDNA). Absolute quantitation of the fusion at presentation (n=11) by gDNA RQ-PCR revealed a 40 fold variation between patients (range 0.027-1.1 copies of FIP1L1-PDGFRA per haploid genome). Comparison of gDNA RQ-PCR and nested RT-PCR for detection of MRD in follow up samples revealed large discrepancies with 47% (28/60) positive by gDNA RQ-PCR but only 29% (17/58) positive by nested RT-PCR, again highlighting the inaccuracies of the standard RT-PCR technique. Analysis of gDNA also gave a 1-2 log greater sensitivity than the analysis of cDNA by RQ-PCR. MRD assessment using gDNA showed that 11 of 12 patients achieved complete molecular response to imatinib within a median of 9 months (range 3-21) of starting treatment, with a sensitivity of detection of between 1 in 104 and 1 in 105 as assessed by quantitation of the ALB gene. We conclude that detection and quantitation of FIP1L1-PDGFRA from gDNA is more sensitive at both diagnosis and follow up compared to analysis of cDNA. Improved detection of this fusion is likely to lead to improved patient management.

EARLY ASSESSMENT OF MINIMAL RESIDUAL DISEASE (MRD) BY OPTIMIZED REAL-TIME QUANTITATIVE PCR (RQ-PCR) ASSAY FOR DETECTION OF WT1 TRANSCRIPTS PROVIDES AN INDEPENDENT PREDICTOR OF DISEASE RELAPSE IN ACUTE MYELOID LEUKEMIA: A EUROPEAN LEUKEMIANET (ELN) STUDY

Early assessment of minimal residual disease (MRD) by optimized real-time quantitative PCR (RQ-PCR) assay for detection of WT1 transcripts provides an independent predictor of disease relapse in acute myeloid leukemia: A European LeukemiaNet (ELN) study. *Background.* Quantitative RQ-PCR assays to detect leukemic fusion transcripts have been shown to identify reliably the acute leukemia patients at highest risk of relapse, allowing development of a more individualized treatment approach. *Aims.* To establish and evaluate an optimized RQ-PCR assay for quantification of Wilms' Tumor gene (WT1) expression which could provide a more precise measurement of disease response and quality of remission in patients lacking a leukemia-specific MRD target. *Methods.* Nine published and in house WT1 assays were systematically evaluated across a network of 11 European laboratories. Assays were excluded on the basis of lack of RNA specificity, inferior sensitivity or involvement of regions which are hotspots for mutation. An assay located within the 5 region affording the greatest sensitivity was ultimately selected and evaluated in 729 diagnostic samples from 588 patients, together with follow-up samples from 106 patients (median age 45 years) treated with intensive combination chemotherapy. *Results.* WT1 was over-expressed in the majority of AML cases, with comparable levels in PB and BM (PB - median 4637 WT1 copies/104 ABL copies, range 0-1132709; BM - median 7212, 0-750571), as compared to normal BM (median 19.8, 0-213), PB (median 0.01, 0.01-47.6) and PBSCs (median 6.1, 0-39). There was no correlation between WT1 expression at diagnosis and age, presenting WBC, NPM1 or FLT3 mutation status or cytogenetic risk group, although significantly higher expression was found in acute promyelocytic leukemia with t(15;17) (median 19195 range 280-177500, p=0.01). Cases with low WT1 expression were screened for mutations of the 5' region and in 40% mutations were detected. While Cox regression analysis showed no association between baseline WT1 level and relapse (p=0.3), a greater response in terms of WT1 transcript reduction following induction chemotherapy was associated with a significantly reduced risk of relapse (hazard ratio 0.54 per log reduction (95% CI 0.36-0.83), p=0.004), which remained significant when adjusting individually for age, presenting WBC and cytogenetic risk group. Failure to normalize WT1 transcript levels by the post-induction and post-consolidation timepoints was associated with a higher risk of relapse (100% and 67% respectively at 5 years, as compared to 44% and 42% for patients with WT1 levels within the normal range at these stages p=0.05, p=0.004). Analyses of sequential PB and BM samples from 15 AML cases with low WT1 expression (<250 copies) were undertaken, which showed no significant modulation in transcript level on regeneration after chemotherapy, indicating that in $WT1^+$ AML, transcript levels detected in follow-up samples reliably reflect disease status. *Conclusions.* This study suggests that normalization of WT1 transcripts as determined by an optimized RQ-PCR assay provides an independent predictor of disease relapse in AML Moreover, it lends support to the incorporation of early assessment of MRD to develop more robust risk scores, to enhance risk stratification and identify patients who may benefit from allogeneic transplant.

Gene therapy, cellular immunotherapy and vaccination

LENTIVIRAL GENE THERAPY OF HEMATOPOIETIC STEM CELLS RESULTS IN PHENOTYPE CORRECTION IN A MOUSE MODEL OF POMPE DISEASE

M. Stok,[1] N. van Til,[2] F.S.F. Aerts Kaya,[2] T.P. Visser,[2] M. Kroos,[3] M. de Waard,[4] E. Jacobs,[5] M. Willart,[6] P. van der Wegen,[5] B. Scholte,[5] B. Lambrecht,[6] D. Duncker,[4] A. van der Ploeg,[7] A. Reuser,[3] M. Verstegen,[2] G. Wagemaker[2]

[1]Erasmus MC, ROTTERDAM; [2]Hematology, Erasmus MC, ROTTERDAM; [3]Clinical Genetics, Erasmus MC, ROTTERDAM; [4]Experimental Cardiology, Erasmus MC, ROTTERDAM; [5]Cell Biology & Genetics, Erasmus MC, ROTTERDAM; [6]Pulmonary Medicine, Erasmus MC, ROTTERDAM; [7]Pediatrics, Erasmus MC, ROTTERDAM, Netherlands

Background. Pompe disease is a storage disorder characterized by progressive muscle weakness, caused by deposition of glycogen due to a reduced function of acid alpha-glucosidase (GAA). In the early onset form, death occurs within the first year of life by cardiac and respiratory failure. Available enzyme replacement therapy (ERT) does not provide a lasting cure and requires life-long administration. *Aims.* To develop a more efficient alternative for ERT we have explored the potential of lentivirus (LV) mediated gene transfer of hematopoietic stem cells (HSC) to correct glycogen storage in a Pompe (Gaa-/-) mouse model. *Methods.* Lineage negative HSC from Gaa-/- donor mice were transduced *ex vivo* with third generation self-inactivating (SIN) LV-SF-GAA or LV-SF-GFP (green fluorescent protein) as control, both driven by the promoter of the spleen focus forming virus (SF), and transplanted into sublethally irradiated Gaa-/- mice, 8-12 week of age. *Results.* Transplantation of SIN-LV-SF-GAA resulted in sustained (up to 1.5 year) high level expression of alpha-glucosidase in peripheral blood cells (PBC). Over-expression of the enzyme, as observed in PBC, resulted in reconstitution of alpha-glucosidase expression and clearance of glycogen in heart, diaphragm, stomach, uterus, liver and spleen. Skeletal muscle displayed a significant reduction of glycogen, although not as prominent as the other tissues. The large activity increase of alpha-glucosidase in heart tissue resulted in a near normalization of heart geometry and function, as visualized by echography. In addition, locomotor function and skeletal muscle strength, as well as respiratory function were significantly improved and stablized, proportional to the level of glycogen clearance. Adverse effects on the hematopoietic/immune system, measured at the progenitor and the end cell levels, were not observed. *Conclusions. Ex vivo* hematopoietic system mediated gene therapy corrects defects in the Pompe mouse model, indicating that the approach may provide a valid alternative for ERT in the treatment of Pompe disease. Codon optimization of the transgene is anticipated to provide a further elevation of enzyme levels. Current experiments aim at establishing the minimum cell dose and conditioning regimen required for optimal efficacy and long-term monitoring for potential adverse effects.

0423

AN ORIGINAL GENE THERAPY STRATEGY OF HEMOPHILIA B USING LENTIVIRALLY MODIFIED HEMATOPOIETIC STEM CELLS

M. Cambot,[1] C. Lavenu-Bombled,[1] J. Cossonière,[1] J.P. Rosa,[2] A. Dubart-Kupperschmitt[1]

[1]INSERM, LE KREMLIN-BICÊTRE CEDEX; [2]INSERM U689, PARIS, France

Gene therapy approaches involving Hematopoietic Stem Cell (HSC) could be used to cure genetic and infectious diseases affecting hematopoietic or non hematopoietic tissues. New developments have improved safety in using integrative viral vectors while they retain ability to stably and efficiently modify HSC. We chose hemophilia B, a monogenic bleeding disorder due to defects in the FIX gene, as a model to study gene therapy using modified HSC. Although the existing substitutive treatment is effective, high cost and side effects require the development of alternative treatments to improve patient's lives. Therefore, hemophilia B is the target of numerous gene therapy strategies. Despite encouraging therapeutic effects in animal models, clinical trials were very disappointing due to low and transient transgene expression. The strategy we develop should overcome several problems identified in former studies, such as the development of antibodies against FIX or

immune response against transduced cells, and should allow a bleeding correction, even in presence of pre-existing inhibitory antibodies. The permanence of the therapeutic effect will be ensured by engraftment of *in vitro* transduced HSC using an integrative lentivector encoding FIX. FIX expression, driven by a megakaryocytic specific promoter, will be restricted to differentiated megakaryocytes (Mk). Fusion to a peptide derived from Platelet Factor 4 (PF4) will target FIX into α-granules of Mk and platelets. Thus, the rFIX stored in platelet α granules will be locally delivered on the site of vascular injury, in response to platelet activation. The global efficacy of this strategy is studied in three different models. Human HSC *in vitro* differentiated into Mk are used to assess the biological activity of the therapeutic FIX synthesized by Mk and stored in α-granules, a non-physiological situation. FIXko mice are used to study the therapeutic efficacy of the strategy. And a preclinical model in the macaque is developed to study gene therapy approaches using HSC in the long term. In these three models, we showed that human GPIbα promoter restricts the expression of a transgene to differentiated Mk and that a 4 amino-acid peptide derived from PF4 is sufficient to target transgenic FIX to α-granules of Mk. For macaque HSC transplantation, we focus on improving the conditions of HSC transduction and on pre-conditioning the animals for an optimal and permanent engraftment. We reproducibly obtain efficacies of transduction at a mean of 50% using an HIV-derived vector encoding GFP. For *in vivo* studies, the sub-myeloablative protocol tested is not fatal to animals and induces a bone marrow aplasia and an immuno-suppressive effect necessary for HSC engraftment. After 600 days, GFP^+ cell engraftment is low (1%) but stable for one year in bone marrow and peripheral blood. The follow-up of engrafted animals is ongoing to study lentiviral integration sites, evolution of the clonality of hematopoietic reconstitution. In future experiments comparing modified HSC engraftment after myelo-ablative or sub-myelo-ablative conditioning, we will study efficacies and kinetics of hematopoietic reconstitution, persistence of transgene expression, immune response and safety concerns.

0424

REDIRECTING T-CELLS AGAINST CANCER CELLS BY TRANSFER OF BROADLY TUMOR REACTIVE GAMMA-DELTA-T-CELL RECEPTORS

J.H.E. Kuball, V. Marcu-Malina, M. Theobald

UMC Utrecht, UTRECHT, Netherlands

Background. Adoptive transfer of alpha-beta-T-lymphocytes is a promising treatment for a variety of malignancies, but often not feasible due to difficulties in generating T-cells reactive with the targeted antigen from patients. To facilitate rapid generation of cells for therapy, T-cells can be programmed with genes encoding for an antigen-specific alpha-beta-T-cell receptor (TCR). However, this concept is limited by the low affinity of most tumor-reactive alpha-beta-TCR chains. One attractive alternative to mediate a selective anti-tumor-reactivity with a high-affinity TCR arises from the ability of gamma-delta-T-cells to mediate anti-tumor-reactivity while ignoring healthy-environment. The gamma-delta-T-cell-receptor (TCR) itself is not effected by rigors of negative selection and is supposed to mediate this intriguing property. Gamma2delta2-TCRs recognize non-classical antigens including metabolites of the mevalonate pathway. *Aims and Methods.* To test the ability of gamma2delta2-TCRs to redirect alpha-beta-T cells selectively against tumor cells, the gamma2delta2-TCR was retrovirally transduced into human alpha-beta-T cells. *Results.* Strong surface-expression of introduced gamma2delta2-TCRs was observed while endogenous alpha-beta-TCR chains were down-modulated. Functional analysis revealed that a gamma2delta2-TCR efficiently reprograms both, $CD4^+$ and $CD8^+$ T-cells against a broad panel of cancer cells while ignoring normal cells. Moreover, tumor-specific T-cell proliferation, cytokine secretion and killing were significantly enhanced by additional application of biphosphonates. *Summary*. In summary, gamma2delta2-TCRs are an attractive alternative to redirect alpha-beta-T cells against cancer cells with both, an improved efficacy and safety profile as compared to currently used alpha-beta-TCRs.

0425

REGULATORY T CELLS ARE RESISTANT TO PROTEOSOME INHIBITOR MEDIATED APOPTOSIS AND CAN BE EXPANDED *in vitro* IN UPON CULTURE WITH BORTEZOMIB

J.A. Pérez-Simón, B. Blanco, L.I. Sánchez-Abarca, M. Díez-Campelo, S. Tabera, P. Hernández-Campo, S. Gutierrez-Cosio, C. Rodriguez-Serrano, F. Sanchez-Guijo, C. Cañizo, J.F. San Miguel

Hospital Universitario, SALAMANCA, Spain

Background. We have previously shown that bortezomib selectively induces apoptosis among alloreactive T-cells after mixed lymphocyte reaction (MLR) (Blanco, Blood 06). Using this approach, it could be possible to induce a selective ablation of immune response against host antigens. On the other hand, regulatory T cells (Treg) play a crucial role in keeping an appropriate homeostasis of the immune response in steady state and also contribute to decrease the risk of GVHD after allogeneic transplantation. Some studies have been reported describing alternative methods to induce *in vitro* allodepletion although, those which have been evaluated into the clinical setting , have failed to obtain a clear benefit in terms of lowering the risk of GVHD, at least in part due to the fact that Tregs may also be affected by *in vitro* depletion. *Aims.* In the current study we have evaluated the effect of bortezomib on Treg viability. *Results.* Firstly, we analyzed the effect of bortezomib on Treg viability after MLR using anexin/7-AAD staining. While viability significantly decreased among activated (alloreactive) T-cells, both resting and regulatory T cells remained unaffected (Figure 1A).

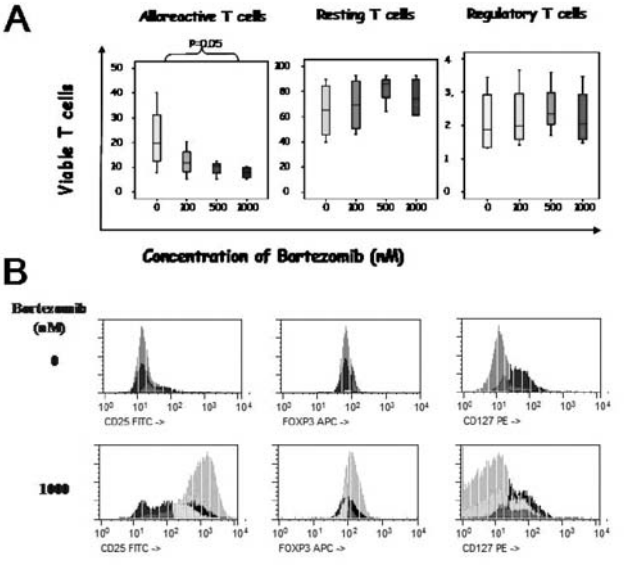

Figure 1.

Since activated T-cells were sensitive and Treg were resistant to the pro-apoptotic effect of bortezomib, we asked whether we could obtain a purified Treg population after *in vitro* expansion with antiCD3-CD28 plus IL2 (50 U/mL) in the presence of the drug. Interestingly, after 4 weeks of culture, T cells had a significantly higher expression of FoxP3 and CD25 and lower expression of CD127 upon culture with bortezomib (Figure 1B). We next evaluated the effect of *in vitro* expanded T-cells on the proliferation of effector T-cells (Teff) stimulated with antiCD3-CD28. Functional assays confirmed that T-cells expanded in the presence of bortezomib (Tr) inhibited Teff proliferation while this effect was not observed when we used bortezomib-untreated *in vitro*-expanded T-cells, with a mean (SD) of 27.3% (7.3) *vs* 68.7% (9.6) of non-proliferating Teff after co-culture with bortezomib-untreated *vs* treated (Tr) *in vitro*-expanded T-cells ($p<0.001$). Furthermore, Tr significantly decreased the production of IFN among Teff as assessed by intracytoplasmic-IFN staining (16 *vs* 3% IFN^+ Teff after stimulation with antiCD3-CD28 and co-culture with bortezomib-untreated *vs* treated T-cells). According to these data, the presence of bortezomib allowed to obtain T-cells with immunoregulatory properties (Tr). Finally we asked whether bortezomib allowed to expand the Treg already present in the initial culture or did modify the functional characteristics of T-cells allowing to obtain a new *in vitro*-generated Tr population. For this purpose, we selected CD25 negative T-cells and expanded these cells as previously described in the presence of bortezomib. Interestingly, Tr

were also obtained using this approach, which showed similar characteristics in terms of phenotype and functionality as compared to Tr obtained from unpurified T-cells. *Conclusions.*Treg are resistant to the pro-apoptotic effect of bortezomib. Furthermore, *in vitro* expansion in presence of bortezomib allowed to obtain Tr which showed immunoregulatory properties. This effect may be useful in the allogeneic transplant setting

Hematology, Univ. of Antwerp, WILRIJK (ANTWERP), Belgium; [4]Lab. of Molecular Diagnostics in Hematology, EDEGEM (ANTWERP), Belgium; [5]Division of Hematology, Antwerp University Hospital, EDEGEM (ANTWERP), Belgium; [6]Radboud Univ. Nijmegen, Dep. of Tumor Immunology, Centre for Mol. Life Sciences, NIJMEGEN, Netherlands; [7]Weatherall Inst. of Mol. Med., Univ. Oxford, J. Radcliff Hosp., OXFORD, UK; [8]Division of Hematology and CCRM, Antwerp University Hospital, EDEGEM (ANTWERP), Belgium

Background. To date, Wilms tumor protein (WT1) is acknowledged as a valuable target for active specific immunotherapy in several solid and hematological malignancies, such as leukemia. Preclinical data from our laboratory and that of Hans Stauss have shown that WT1 RNA-electroporated dendritic cells (DC) stimulate WT1-specific T cells *in vitro* (Van Driessche A *et al.* Leukemia 2005;19:1863-1871). *Aims.* We started a phase I/II dose-escalation trial in which patients with acute myeloid leukemia (AML) in remission received intradermal injections with WT1 RNA-loaded DC. Feasibility, safety and immunogenicity of the vaccine were investigated. *Methods.* Eight patients received four biweekly DC vaccines. A delayed-type hypersensitivity (DTH) test was performed 2 weeks following the last vaccination. Patients underwent an apheresis and monocytes were isolated using CD14-labeled magnetic beads by CliniMACS. DC were generated in 6-day cultures in clinical-grade medium supplemented with serum, GM-CSF and IL-4 and maturated with PGE2 and TNF-a. Keyhole limpet hemocyanin (KLH) was added during maturation as a $CD4^+$ helper antigen. Mature DC were harvested, electroporated with WT1 mRNA and used as vaccines. Patients were monitored for minimal residual disease (MRD) by analyzing WT1 RNA expression in peripheral blood by qRT-PCR. When the patient was HLA-A2+, tetramer staining was performed to detect WT1-specific CD8+ T cells. Before and after the vaccination cycle, peripheral blood was collected for immunomonitoring purposes. *Results.* There was successful DC generation and vaccine production in all patients selected. No serious adverse events or toxicity was seen. A decrease in WT1 RNA expression was observed during the course of the vaccination in 4/6 patients who had an increased WT1 mRNA level in peripheral blood at the start of DC vaccination. A vaccine-specific immune response was demonstrated in 8/8 patients by an *in vivo* DTH reaction both to KLH as well as to WT1. By tetramer analysis, detectable levels of WT1-specific CD8+ T cells could be demonstrated during the course of the vaccination both in the peripheral blood as well as in the expanded DTH-infiltrating T cells from the skin biopsies. Preliminary data from immunomonitoring in pre- and post-vaccination T cell samples from 4 patients show a mixed T helper (Th)1/Th2 response towards the KLH and the WT1 protein following vaccination. *Conclusions.* We conclude that vaccination of AML remission patients with WT1 RNA-loaded DC is feasible and safe. Furthermore, the vaccine elicits anti-vaccine T-cell responses *in vivo* and a decrease in WT1 RNA expression levels was observed during MRD monitoring in some vaccinated patients.

ANGIOGENESIS AND VEGF-/RECEPTOR EXPRESSION IN MYELOPROLIFERATIVE DISEASES: CORRELATION WITH CLINICAL PARAMETERS AND JAK2-V617F MUTATIONAL STATUS

M. Medinger, A. Gratwohl, A. Theocharides, A. Buser, D. Heim, R. Skoda, S. Dirnhofer, A. Tichelli, A. Tzankov

University Hospital, BASEL, Switzerland

Angiogenesis is essential for malignant tumor growth. This has been documented for solid tumors and there is emerging evidence that progression of haematological malignancies also depends on the induction of new blood vessels. The most important pro-angiogenic factor is vascular endothelial growth factor (VEGF), activating the VEGF receptor 1 (VEGFR-1) and receptor 2 (VEGFR-2). Therefore VEGF and its receptors may provide a target for therapy in hematological malignancies. In Bcr-Abl negative myeloproliferative diseases (MPD) there are only few data about the role of angiogenesis. We studied 100 patients with MPD, including polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) by immunohistochemical assessment of microvessel density (MVD) and the expression of VEGF and its receptors VEGFR-1, VEGFR-2 and VEGFR-3 in bone marrow (BM) sections (Table 1). The normal controls (NC) consisted of 10 BM which were free of abnormalities. MVD, as assessed by CD34 staining, was calculated as the mean number of stained vessels in 5 fields at 200 magnification. Expression of VEGF/-receptors was assessed as mean of the number of positively staining cells in 5 fields. Our study showed a significantly higher degree of angiogenesis in PMF, PV and ET compared with NC (Table 1; $p<0.001$, $p<0.0007$ and $p<0.001$, respectively). Angiogenesis was higher in PMF than PV and ET ($p<0.001$ and $p<0.001$). Increased angiogenesis correlated with higher VEGF expression compared to NC ($p<0.009$). VEGFR-2 expression was significantly higher in MPD than in NC ($p<0.001$) and, in particular, in PMF ($p<0.001$) and PV ($p<0.001$). There were no significant differences between VEGFR-1 and VEGFR-3 expression compared to NC. MVD and VEGF expression was significantly higher in JAK2-V617F mutation positive MPD [30 (12-39) *vs* 22 (9-31) mean vessels per 1 mm^2 field (range); $p<0.001$ and 49% (20-65) *vs* 32% (19-42) mean %VEGF positive (+) cells (range); $p<0.001$] than in negative MPD, but there was no difference regarding VEGF receptors expression. In conclusion, this study showed increased angiogeneis in MPD patients as expressed by increased VEGF and VEGFR-2 expression. Patients with the JAK2-V617F mutation had a higher MVD and VEGF expression than patients without the JAK2-V617F mutation. Our data support the hypothesis of an autocrine VEGF/VEGFR-2 loop in the pathogenesis of MPD. Inhibition of angiogenesis could constitute a novel strategy for the treatment of MPD.

Table 1.

	PMF (n=45)	PV (n=30)	ET (n=25)	NC (n=10)
Age years (range)	59 (37-68)	64 (48-70)	60 (24-72)	62 (45-68)
Sex (M/F)	25/20	18/12	10/15	5/5
MVD Mean vessels per mm^2 field (range)	32 (13-79)	19 (11-59)	17.5 (7-23)	8 (1-15)
VEGF Mean %VEGF(+) cells (range)	51 % (10-75)	46% (15-70)	50% (10-75)	5% (0-9)

MANAGEMENT OF REPRODUCTIVE EVENTS IN FEMALES WITH GAUCHER DISEASE

A. Zimran,[1] N. Belmatoug,[2] S. Granovosky-Grisaru,[1] R. Heitner,[3] D.A. Hughes,[4] P. Kaplan,[5] V. Malinova,[6] E. Mengel,[7] E. Morris,[8] M. Mrsic,[9] S. vom Dahl[10]

[1]Shaare Zedek Medical Centre, JERUSALEM, Israel; [2]Nadia, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris, CLICHY, France; [3]Johannesburg Hospital, JOHANNESBURG, South Africa; [4]Royal Free & University College Medical School, LONDON, UK; [5]Children's Hospital of Philadelphia, PHILADELPHIA, USA; [6]Charles University & General Teaching Hospital, PRAGUE, Czech Republic; [7]Univeristy Clinic, MAINZ, Germany; [8]Addenbrookes Hospital, CAMBRIDGE, UK; [9]Clinical Hospital Centar Rebro, ZAGREB, Croatia; [10]St. Franziskus Hospital, COLOGNE, Germany

Background. The principal manifestations of type 1 (non neuronopathic) Gaucher disease include increased risk of bleeding, anaemia, splenomegaly, hepatomegaly and bone disease. An effective disease-specific treatment for type 1 disease has been available since 1991 in the form of alglucerase (enzyme replacement therapy) and later its recombinant form, imiglucerase. Treatment goals and monitoring guidelines for imiglucerase provide the basis for a disease management strategy (Andersson *et al.*, 2005; Pastores *et al.*, 2004; Weinreb *et al.*, 2004). These goals and guidelines, however, do not make specific reference to females for whom the manifestations of Gaucher disease could have significant impact during reproductive events such as menarche and menstruation; fertility; pregnancy, parity, delivery and lactation; and menopause. *Aims.* To examine the reciprocal effects of reproductive events and Gaucher disease in untreated and enzyme-treated females to identify an optimal management approach. *Methods.* A panel of international clinicians experienced in the management of Gaucher disease convened to review and present evidence from the peer-reviewed literature, a pharmacovigilance database on alglucerase and imiglucerase, and their own clinical experience to support discussions and recommendations. Data from further recent surveys were also reviewed. *Results.* Menarche may be delayed in symptomatic girls with Gaucher disease who are not treated with enzyme replacement therapy. Menorrhagia seems to be more common than in the non-Gaucher population. There is no evidence of decreased fertility in Gaucher disease. Pregnancy and delivery are not trivial in Gaucher disease. Women with Gaucher disease may be at increased risk of complications because of peripartum bleeding and worsening bone involvement. Therapy with alglucerase or imiglucerase before and during pregnancy may help reduce the rate of spontaneous abortion and risk of complications in the peripartum period. There is no evidence of any teratogenic effect of alglucerase and imiglucerase on the foetus, or of any adverse effect on infants breast fed by mothers receiving imiglucerase. Breast feeding may present a physiological challenge to mothers with Gaucher disease. There is a lack of information on menopause in women with Gaucher disease. *Conclusions.* Menarche and pregnancy are the main issues to be considered in women with Gaucher disease. Neither is a contraindication to enzyme replacement therapy. Planned conception, and a multidisciplinary approach to the management of pregnancy, is the most desirable route to parenthood for women with Gaucher disease. Ideally, for symptomatic patients who require enzyme replacement therapy, therapeutic goals should be achieved before conception to help ensure women are in an optimal clinical state to withstand the physiological demands of pregnancy and the post partum period. Patients treated with imiglucerase prior to pregnancy should be allowed (or encouraged) to continue imiglucerase treatment throughout pregnancy and breast feeding (despite the package insert warning). Disease monitoring during reproductive events should be vigilant to the risk of exacerbated bone disease, especially osteoporosis, and peripartum bleeding associated with Gaucher disease. The impact of Gaucher disease on menopause is poorly understood and requires further study especially in relation to bone mineral density and appropriate treatments.

HEALTHY BLOOD DONORS WITH A POSITIVE COOMBS TEST: NATURAL ANTI-C3 AND FRAMEWORK-SPECIFIC ANTIBODIES TOGETHER INHIBIT COMPLEMENT DEPENDENT PHAGOCYTOSIS OF SENESCENT RED BLOOD CELLS

H.U. Lutz,[1] B.M. Frey,[2] P. Stammler,[1] A. Siderow,[2] M. Kradolfer,[1] V. Alaia[1]

[1]ETH Zurich, ZURICH; [2]Regional Blood Transfusion Service SRK, SCHLIEREN, Switzerland

Background. Coombs-positive red blood cells (RBC) or RBC with a positive direct agglutination test (DAT-positive RBC) from healthy blood donors carry elevated numbers of IgG molecules as is known for many years (for a review see: Garratty. Gerontology. 1991;37:68-94). In almost all cases this phenomenon is not an early sign of an autoimmune hemolytic anemia. The reason for this opsonization has remained elusive. Aims and *Methods.* By studying the specificity of IgG molecules eluted from density separated RBC (Lutz *et al.* Biochim.Biophys. Acta 1992;1116:1-10) and by performing phagocytosis experiments we tried to identify the specificities of bound IgG molecules. We compared the specificities of eluted IgG molecules with those of a pair of naturally occurring antibodies (NAbs), which we have characterized earlier (Jelezarova and Lutz, Mol. Immunol. 2005;42:1393-1403) and studied the concentration of the two types of NAbs in plasma from these donors by ELISA. *Results.* The majority of RBC-associated IgG molecules was on dense RBC from Coombs-positive healthy blood donors. These blood donors had increased numbers of dense RBC as compared to aged-matched controls and some of their RBC were even denser than the densest cells of controls. Their densest cells were in fact older than the oldest cells of controls based on the band 4.1a/b ratio. Phagocytosis of senescent RBC from these donors was 1.5 to 2 fold higher than that of senescent control cells, implying that Coombs-positive old RBC carried more opsonins than those of controls. In contrast to this, their old RBC were less efficiently phagocytosed than senescent control cells in an *in vitro* assay in which FcR-mediated phagocytosis was suppressed by physiological concentrations of whole human IgG. The additional IgG molecules on Coombs-positive RBC from healthy blood donors comprised primarily anti-C3 and framework-specific anti-idiotypic NAbs. This was evident from immunoblots with IgG molecules eluted from senescent RBC after dissociation of IgG complexes. The increased binding of the pair of these NAbs to their senescent RBC was most likely due to the fact that healthy blood donors with a positive Coombs test had increased concentrations of the two types of NAbs in their plasma at the same ratio as in controls. Suppression of complement-dependent phagocytosis occurred by binding of this pair of NAbs to senescent RBC via two possible modes: 1) by binding to senescent cell-associated anti-band 3 NAbs (Lutz *et al.* Blood Cells 1988;14:175-195), which otherwise would have preferentially captured C3b (Lutz *et al.* J. Biol.Chem. 1993;268:17418-17426), and 2) by binding to C3 fragments on senescent RBC. *Conclusions.* Binding of anti-C3 NAbs together with framework-specific anti-idiotypic NAbs to senescent RBC may have suppressed their complement-dependent phagocytosis and thereby prolonged their *in vivo* life span.

HOME BLOOD AND PLATELET TRANSFUSIONS AS PART OF A DOMICILIARY PROGRAM OF SUPPORTIVE CARE IN PATIENTS WITH BLOOD MALIGNANCIES: AN ITALIAN SINGLE-CENTRE EXPERIENCE

P. Alfieri

Division of Haematology, MODENA, Italy

Home care has achieved a relevant role in the global management of patients with blood malignancies improving quality of life and reducing health care costs. Transfusion therapy is of major impact in this clinical setting. In our department a home care service supported by AIL (Italian Association against Leukaemia-Lymphoma-Myeloma) is operating in order to assist haematologic patients that are fragile, unfit, not self-sufficient, in different stages of disease (terminal, advanced, chronic, in causal therapy). Here we share a single-centre experience in home transfusion assistance throughout a 9-yrs period (July 1999 - February 2008), by describing patients' characteristics, clinical indications, operating procedures and safety issues. All patients undergone home transfusions were eligible for domiciliary program of supportive care. Transfusions were requested to blood bank according to haemoglobin levels (Hb < 8 g/dL), platelet count (PLT <10.000/mcl) and main clinical indications. Informed consent was obtained before first home transfusion. Anti-

allergic premedication with hydrocortison and clorfenamine was routinely administered before any platelet transfusion so as to minimise risks of adverse reaction. Consultant haematologist was responsible for clinical surveillance during transfusion, by home-assisting patients in the first fifteen minutes of infusion and after then being telephonically available in case of emergency Among the 335 patients enrolled in the AIL home care program, 156 (46.5%) received at least one home transfusion. Patients (male=75, female=81, median age=75, in terminal phase=80, with advanced disease=43, chronically ill=24, in causal therapy=9) were affected by acute myeloid leukaemia (26%), myelodisplastic syndrome (15%), chronic myeloproliferative disorders (15%), multiple myeloma (14%), non-Hodgkin's lymphoma (13%), chronic lymphocytic leukaemia (7%), acute lymphoid leukaemia (3%), Hodgkin's lymphoma (3%), aplastic anaemia (2%), other chronic anaemias (3%). Total number of transfusion was 2012: packed red blood cells (RBC) were 1369 (68%) while platelet concentrates (PC) were 643 (32%). 65 patient were transfused both for RBC and PC; 83 patients received only RBC, 8 were patients transfused only with PC. The average number of transfusions per patient was 13 (min 1 - max 131). Patients with myelodisplasia, acute leukaemia and myeloproliferative disorders had higher transfusion requirement, accounting respectively for 18, 14 and 14 transfusions per patient throughout an entire period of home assistance. No serious adverse reaction was reported. The consultant haematologist was contacted on-call in 107 cases (about 5% of all transfusions) because of the onset of fever < 38°C (15 cases), nausea and/or vomiting (11 cases), skin rash (9 cases) and above all extravasation (72 cases). Home transfusions are a valid option in the effort to increase the accessibility and convenience of care in the setting of haematologic patients. The major concern about out-of-hospital transfusions is represented by the difficult emergency medical care in case of severe reactions. In our operating model these risks are severely diminished through a careful patients' selection and a clinical appropriateness, and obviously by a strict collaboration between the local Division of Haematology and Transfusion Centre. The role of fundraising organisations like AIL is nowadays essential to sustain these programs. Several issues, such as those regarding standard operating protocols and cost analysis, remain open.

THE BURDEN OF CHRONIC IDIOPATHIC THROMBOCYTOPENIC PURPURA (ITP) IN ADULTS: RESULTS OF A DELPHI PANEL OF 32 EUROPEAN CLINICAL EXPERTS

F. Rodeghiero,[1] M. Michel,[2] J. Besalduch,[3] D. Provan,[4] M. Rummel,[5] M. Aivado,[6] K. Grotzinger,[6] N.L. Papo,[6] S. Stamenitis,[7] N. Höbel[7]

[1]Ospedale S Bartolo di Vicenza, VICENZA, Italy; [2]Henri Mondor Hospital, CRETEIL, France; [3]Hospital San Dureta, PALMA DE MALLORCA, Spain; [4]Queen Mary's School of Medicine and Dentistry, LONDON, UK; [5]Universitaetsklinikum Giessen und Marburg GmbH, GIESSEN, Germany; [6]Glaxo-SmithKline Research & Development, COLLEGEVILLE, USA; [7]Kendle GmbH, MUNICH, Germany

Background. The investigation and management of patients with chronic adult ITP varies widely and there is a lack of data on current treatment strategies in Europe. *Aims.* To provide insights into current treatment practices and preferred treatment strategies for chronic ITP in Europe (France, Germany, Italy, Spain and the UK). *Methods.* This is part of a comprehensive project investigating the burden of chronic ITP which involves both expert opinion and real patient data. Treatment centres with large ITP patient loads were identified in each country. A physician from each centre and experienced in treating ITP was invited to participate in a Delphi panel. The Delphi Method is a structured process for collecting and distilling knowledge from a group of experts by means of a series of questionnaires interspersed with controlled opinion feedback. Thirty-two haematologists/oncologists (France 8, Germany 8, Italy 7, Spain 7 and UK 2) were interviewed individually and remained anonymous to each other. The interviews consisted of 49 questions (43 of which were open-ended) about ITP treatment patterns, evaluation of current treatment options and rationale for ITP treatment choices. The questionnaire was developed by 5 ITP clinical experts in conjunction with a clinical research organisation (CRO) and study sponsor, and was administered by the CRO. *Results.* There was strong consensus for the use of corticosteroids as a first choice treatment (29/32, 91%) to prevent bleeding in non-splenectomised patients and to a lesser extent in splenectomised patients (66%). Physicians focused on increasing patients' platelet levels, but did not agree on a specific target level (from 10,000 - 30,000/μL, median 20,000/μL). The second choice treatments were splenectomy for 75% of experts, IVIG for 72% and rituximab for 25%. If patients were already splenectomised, the second choice treatments were immunosuppressants for 69% of experts, IVIG for 50%, rituximab for 44% and others (danazol, dapsone) for 19%. The physicians' choice of treatment was based on their prior clinical experience (91% of experts) and on official guidelines (American Society of Hematology, 72% of experts). The experts perceived patients' comorbidities (75% of experts) and refusal of splenectomy (75% of experts) as their main reasons for deviating from their usual patient management. Improved treatment tolerability was reported as the most important unmet medical need in chronic ITP, because of the poor side effect profile of current treatments (88% of experts). The greatest impact of chronic ITP on patients in terms of health-related quality of life (HRQoL) was perceived by the experts to be patients' fear of bleeding (66% of experts) and treatment side effects (60% of experts). The impact of ITP on HRQoL was compared to that of diabetes (53% of experts) and chronic heart disease (38% of experts). Conclusion: Corticosteroids were the most commonly used treatment for chronic ITP across all participating countries. The positioning of splenectomy and rituximab in treatment strategies was more controversial and differed among countries. Physicians highlighted the need for new ITP treatments with improved tolerability. This study provided some of the first insights into current ITP treatment practices and perceptions in Europe.

Non-Hodgkin's lymphoma - Indolent

0432

PHASE 3 STUDY OF PATIENTS WITH RELAPSED, REFRACTORY MANTLE CELL LYMPHOMA: COMPARISON OF TREATMENT WITH TEMSIROLIMUS *vs* INVESTIGATOR'S CHOICE THERAPY

E. G. Verhoef,[1] G. He,[2] J. Romaguera,[3] R. Herbrecht,[4] M. Crump,[5] A. Strahs,[6] O. Hanushevsky,[6] F. Binlich,[6] B. Hewes,[6] B. Coiffier[7]

[1]University Hospital Gasthuisberg, LEUVEN, Belgium; [2]Johannes Gutenberg-Universität, MAINZ, Germany; [3]MD Anderson Cancer Center, HOUSTON, TX, USA; [4]Hôpital de Hautepierre, STRASBOURG, France; [5]Princess Margaret Hospital, TORONTO, Canada; [6]Wyeth Research, CAMBRIDGE, MA, USA; [7]Hôpital Lyon Sud, PIERRE BÉNITE, France

Background. Mantle cell lymphoma (MCL) is characterized by an 11;14 translocation that results in overexpression of mRNA of cyclin D1, a key cell cycle regulatory protein. Translation of cyclin D1 mRNA is regulated by the mammalian target of rapamycin (mTOR). Temsirolimus, a specific inhibitor of mTOR, has produced tumor responses in patients with relapsed MCL (Witzig *et al.* J Clin Oncol 23:5347, 2005). *Aims.* In this phase 3, randomized, open-label study, we compared the antitumor activity of temsirolimus with investigator's choice therapy (IC) in patients with relapsed and/or refractory MCL. *Methods.* Patients with confirmed MCL must have received 2-7 prior lines of therapy and received an alkylating agent, an anthracycline, and rituximab. All patients provided written informed consent. Patients were randomly assigned (1:1:1) to 1 of 2 schedules of IV temsirolimus, 175 mg weekly 3 times followed by either 75 mg (175/75 mg, arm 1) or 25 mg (175/25 mg, arm 2) weekly, or to IC (arm 3), which included the single agents gemcitabine (42%); fludarabine (26%); chlorambucil, cladribine, etoposide (6% ea); cyclophosphamide, thalidomide, vinblastine (4% ea); or alemtuzumab, lenalinomide (2% ea). The primary endpoint was progression-free survival (PFS) based on central independent review of radiologic and clinical data. Accrual of 177 patients to achieve 105 PFS events was planned to test the hypothesis that temsirolimus would increase PFS compared with IC. Power was 80% and α=0.025 comparing temsirolimus with IC (assuming medians of 6.2 and 3.0 months, respectively). *Results.* We report final results for 162 patients (54 patients per arm): median age 67 years, 81% male, 50% >3 prior regimens, 32% prior stem cell transplantation, and a median of 2 prior rituximab and other immunotherapy regimens.

Table 1.

Parameter	Temsirolimus		IC
	175/75 mg Arm 1	175/25 mg Arm 2	Arm 3
Progression-free survival, independent assessment			
Median mo (97.5% CI)	4.8 (3.1, 8.1)	3.4 (1.9, 5.5)	1.9 (1.6, 2.5)
Increase in median *	153%	79%	
HR (97.5% CI)*	0.44 (0.25, 0.78)	0.65 (0.39, 1.10)	
p-value, log-rank test*	0.0009	0.0618	
Overall survival

*Arm 1 or arm 2 : arm 3

After 105 PFS events, patients treated with temsirolimus 175/75 mg had significantly longer PFS than those treated with IC (p=0.0009, Table 1); patients treated with temsirolimus 175/25 mg did not have significantly longer PFS than those treated with IC (p=0.0618). Patients treated with temsirolimus 175/75 mg showed a trend toward longer overall survival compared with those treated with IC (p=0.0714). The objective response rate for patients treated with temsirolimus 175/75 mg and IC was 22% and 2%, respectively (p=0.0019). The most frequently occurring grade 3 or 4 adverse events were thrombocytopenia (arm 1: arm 2: arm 3, 59%: 52%: 36% patients), anemia (20%: 11%: 17%), neutropenia (15%: 22%: 26%), and asthenia (13%: 19%: 8%). The mean relative dose intensity (actual dose/assigned dose) for the 3 doses of temsirolimus 175 mg for arms 1 and 2 was 0.74 and 0.70, respectively, and for temsirolimus 75 mg and 25 mg was 0.69 and 0.86, respectively. *Conclusions.* Administration of IV temsirolimus, 175 mg per week for 3 weeks followed by weekly 75-mg doses, to patients with relapsed, refractory MCL resulted in an acceptable safety profile and significantly increased PFS and objective response rate compared with IC.

0433

RESULTS FROM THE RANDOMIZED PHASE 3 FIRST-LINE INDOLENT TRIAL (FIT) OF CONSOLIDATION OF FIRST REMISSION WITH 90Y-IBRITUMOMAB TIUXETAN IN ADVANCED FOLLICULAR NON-HODGKIN'S LYMPHOMA (FL)

J.A. Radford,[1] F. Morschhauser,[2] A. Van Hoof,[3] U. Vitolo,[4] P. Soubeyran,[5] H. Tilly,[6] P.C. Huijgens,[7] A. Kolstad,[8] M. Kunz,[9] A. Hagenbeek[10]

[1]Christie Hospital, MANCHESTER, UK; [2]Hôpital Huriez, LILLE, France; [3]General Hospital St-Jan, BRUGGE, Belgium; [4]Azienda Universitaria Ospedaliera S.Giovanni Battista, TORINO, Italy; [5]Institut Bergonié, BORDEAUX, France; [6]Centre Henri Becquerel, ROUEN, France; [7]Vrije Universiteit Medisch Centrum, AMSTERDAM, Netherlands; [8]The Norwegian Radium Hospital, OSLO, Norway; [9]Bayer Schering Pharma AG, BERLIN, Germany; [10]UMC Utrecht/HOVON, UTRECHT, Netherlands

Background. Radiolabeled monoclonal antibodies are highly effective in first-line treatment of FL and may improve the quality of response when used in consolidation therapy. *Aims.* We conducted an international, prospective, controlled, randomized phase 3 trial to evaluate the efficacy and safety of consolidation with 90Y-ibritumomab tiuxetan (Zevalin; Zev) radioimmunotherapy in patients with advanced FL in first remission after induction treatment. This study evaluated Zev for an off-label indication. *Methods.* Major patient eligibility criteria included: CD20+ grade 1 or 2 FL, stage III/IV at diagnosis, normal peripheral blood cell counts, <25% bone marrow involvement, CR/CRu or PR after first-line induction therapy, and informed consent. After induction, patients were randomized to receive either Zev (250 mg/m^2 rituximab on day -7 and day 0 followed on day 0 by Zev 14.8 MBq/kg; max 1184 MBq) or no further treatment (control). The primary end point was progression-free survival (PFS), calculated from the time of randomization (approximately 2 weeks prior to Zev administration). *Results.* 414 patients (Zev, n=208; control, n=206) were enrolled at 77 centers in 13 European countries and Canada. Patient demographics (Zev/control) were: median age 55/53 yrs; stage IV 64%/66%; B-symptoms 22%/20%; high-risk FLIPI 24%/21%. Induction therapies were also well balanced and included: chlorambucil n=39; CVP n=106; CHOP n=122; CHOP-like n=61; fludarabine combinations, n=22; rituximab combinations, n=59. After a median observation period of 3.5 yrs, the median PFS significantly increased from 13 mo (control) to 37 mo (Zev; p<0.0001; hazard ratio [HR] 0.465). For patient subgroups in PR or CR after induction, median PFS was 6 *vs* 29 mo (p<0.0001; HR 0.304) and 29.5 *vs* 54 mo (p=0.0154; HR 0.613), respectively. FLIPI scores were retrospectively determined for 71% of patients in this study. For the subgroup with low-risk FLIPI, median PFS was 24 mo in the control arm and not reached in the Zev consolidation arm (p=0.0502; HR 0.599). For patient subgroups with intermediate-risk and high-risk FLIPI scores, median PFS was 11 *vs* 54 mo (p<0.0001; HR 0.227) and 6.5 *vs* 24 mo (p=0.0789; HR 0.587), respectively. After Zev consolidation, 77% of patients in PR after induction converted to CR. As expected, toxicity associated with Zev was primarily hematologic, and grade 3 or 4 infections occurred in 8% of patients (2% in the control arm). *Conclusions.* In patients with advanced FL responsive to first-line induction treatment, consolidation with Zev resulted in high PR to CR conversion rates regardless of type of first-line induction treatment, prolonged PFS by 2 years overall, and extended PFS in all FLIPI subgroups.

0434

BRIEF CHEMOIMMUNOTHERAPY WITH RITUXIMAB (R)-FND ± R MAINTENANCE AS FIRST LINE TREATMENT IN ADVANCED FOLLICULAR LYMPHOMA (FL) IN ELDERLY: PRELIMINARY ANALYSIS OF A PROSPECTIVE RANDOMIZED TRIAL

U. Vitolo,[1] M. Ladetto,[1] C. Boccomini,[1] E. Gamba,[2] I. Alvarez,[1] L. Baldini,[1] M. Ceccarelli,[3] A. Chiappella,[1] P. Corradini,[1] A. De Renzo,[1] F. Di Raimondo,[1] A. Gallamini,[1] A. Guarini,[1] B. Mantoan,[1] M. Martelli,[1] V. Naso,[1] G. Parvis,[1] M. Petrini,[1] P. Pinto,[1] S. Pozzi,[1] A. Pulsoni,[1] L. Rigacci,[1] C. Tarella,[1] A. Tucci,[1] F. Zaja,[1] E. Gallo[1]

[1]Intergruppo Italiano linfomi (IIL), Hematology, S Giovanni Battista, HOSPITAL AND UNIVERSITY TORINO; [2]Roche, MONZA; [3]Unit of Cancer Epidemiology, CPO Piemonte, TORINO, Italy

Background. FL is common in elderly and the aim of treatment is usually palliation. *Aims.* in order to plan a treatment specifically devised for elderly patients with a reduced amount of chemotherapy, we investigated the efficacy and safety of a brief chemo-immunotherapy R-FND + Rituximab consolidation followed by randomization between Rituximab maintenance or observation. *Methods.* From January 2004 to December 2007, 235 patients (age 60-75) with untreated advanced stage FL were enrolled into 33 IIL centres. Patients gave their written informed consent. Treatment plan was: 4 courses of R-FND (Rituximab 375 mg/m^2 day 0, Fludarabine 25 mg/m^2 dd1-3, Mitoxantrone 10 mg/m^2 day 1, Dexamethasone 10 mg dd 1-3) every 28 days followed by 4 weekly Rituximab (375 mg/m^2); responding (CR+CRu+PR) patients were randomized to receive Rituximab maintenance (375 mg/m^2 every 2 months for 4 doses) or observation. PCR analysis for IgH/Bcl-2 rearrangement was performed on bone marrow (BM) samples at diagnosis, after R-FND, after Rituximab consolidation and during maintenance/observation phase. An interim analysis was planned to evaluate safety and response of chemo-immunotherapy before randomization, after the first 80 randomized pts (January 2004 to December 2005). This analysis included 95 patients recruited within this time frame. *Results.* Median age was 65 (60-75); advanced stage II 14%, stage III 16% and stage IV 70%; 63% had BM involvement and 20% B symptoms; FLIPI Low 10%, Intermediate 30%, High 60%. PCR analysis was done in 91 patients at diagnosis: 56% were Bcl-2+. Eighty patients were randomized between maintenance or observation; 15 patients were not due to: progressive disease 6, stable disease 2, adverse events 3, concomitant neoplasia 1, withdrawal of consent 2, lost 1. Overall response, CR rate and PCR negativity associated with CR after R-FND and Rituximab consolidation are shown in the following Table 1.

Table 1.

	N	ORR	CR	PCR negativity associated to CR (46 patients Bcl2+ evaluable)
Baseline	95	-	-	-
R-FND x 4	95	86 (90%)	51 (54%)	18 (39%)
Rituximab Consolidation	88	80 (84%)	68 (72%)	31 (67%)

Nineteen patients (54%) of 35 PRs after R-FND were converted to CR with Rituximab consolidation. PCR negativity increased from 39% to 67% with Rituximab consolidation after R-FND. A high CR rate was achieved also in poor prognosis patients (CR according to FLIPI: Low 75%, Intermediate 88%, High 81%). The most frequent CTC grade 3-4 toxicity was neutropenia in 25% of the courses, with only 6 serious infections. Pulmonary and cardiac toxicities were < 1%. No toxic deaths occurred. Any grade Rituximab related reactions were seen in 9% of the courses with Rituximab discontinuation in only 2 patients. So far 91 patients are alive and 4 died of lymphoma. *Conclusions.* A brief chemo-immunotherapy R-FND + Rituximab consolidation is safe and effective with a high CR rate and PCR negativity in elderly patients with untreated FL even in FLIPI high risk. Rituximab consolidation converted to CR 54% of PRs after R-FND and increase Bcl2 rearrangement negativity rate. The whole study will provide insights on the role of Rituximab maintenance after R-chemotherapy.

0435

ROMIDEPSIN INDUCES CLINICALLY SIGNIFICANT AND DURABLE RESPONSES IN RELAPSED OR REFRACTORY CTCL: A NCI INTERNATIONAL, MULTICENTER STUDY

S. Bates,[1] R. Piekarz,[1] R. Frye,[1] S. Allen,[2] M. Craig,[3] L. Geskin,[4] L. Hutchins,[5] D. Joske,[6] M. Kirschbaum,[7] J. Leonard,[8] M. Prince,[9] C. Reeder,[10] J. Nichols[11]

[1]National Cancer Institute, BETHESDA, USA; [2]North Shore Univ Hospital, MANHASSET, USA; [3]West Virginia University, MORGANTOWN, USA; [4]University of Pittsburgh, PITTSBURGH, USA; [5]Arkansas Cancer Research Center, LITTLE ROCK, USA; [6]Sir Charles Gairdner Hospital, PERTH, Australia; [7]City of Hope Cancer Center, DUARTE, USA; [8]Cornell University, NEW YORK, USA; [9]Peter MacCallum Cancer Centre, EAST MELBOURNE, Australia; [10]Mayo Clinic, SCOTTSDALE, USA; [11]Gloucester Pharmaceuticals, CAMBRIDGE, USA

Background. Romidepsin, an HDAC inhibitor, has previously demonstrated activity as a single agent in patients with T-cell lymphomas. *Aims.* To evaluate the efficacy and tolerability of romidepsin in the treatment of advanced CTCL. *Methods.* A Phase II, open-label, multi-arm multicenter study enrolled 71 CTCL patients from the NCI and 9 extramural sites. Patients with relapsed or refractory CTCL (Stages IA-IVB) with either < 2 prior systemic therapies (Arms 1, 5) or > 2 prior systemic therapies (Arm 3), received romidepsin at 14 mg/m^2 over 4 hrs on Days 1, 8 and 15 q 28 days. Responses were assessed by Investigators using a composite endpoint that evaluated changes in skin (via an overall skin assessment tool), lymph nodes, extranodal visceral lesions and abnormal circulating T-cells. Separately, Investigators assessed responses using the composite endpoint with skin changes based on target lesion measurements. To account for inter-observer variability, disease response was also assessed by an Independent Response Review Committee (IRRC) that was composed of 3 physicians who were experts in the field of CTCL. *Results*. 71 patients [48(67.6%) male and 23(32.4%) female; mean age of 56.0 + 13.0 yrs] were eligible. 63 patients were included in the evaluable population (defined as having received a minimum of two cycles of therapy). The mean number of prior therapies received was 3.4 (range 1-10), with patients receiving on average 2.4 (range 1-7) prior systemic and 1.8 (range 1-3) skin-directed therapies. Objective response rates (ORR) in the evaluable population are summarized in the Table 1 below by stage.

Table 1.

Clinical Stage	N	ORR (CR + PR)	CR	PR
ALL	63	25 (39.7%)	4 (6.3%)	21 (33.3%)
IA-IIA	8	5 (62.5%)	0 (0.0%)	5 (62.5%)
IIB-IIIB	21	10 (47.6%)	1 (4.8%)	9 (42.9%)
IVA-IVB	34	10 (29.4%)	3 (8.8%)	7 (20.6%)

IRRC determined ORR was 29% (18/63). ORR using the composite endpoint with skin changes based on target lesion measurement was 35% (23/65). The median duration of response was 336 days (11 months) and the maximum duration of response as of data cut-off was 5.5+ years. Treatment emergent study drug-related AEs were reported in 70 patients, with Grade 3 and Grade 4 events reported in 58 (81.6% and 15 (21.1%) patients, respectively. Two (2) deaths were considered possibly related to treatment. The most frequent drug-related AEs (all grades) were nausea (81.7%), fatigue (73.2%), electrocardiogram T-wave amplitude decreased (69.0%), hemoglobin decreased (59.2%), platelet count decreased (59.2%), anorexia (53.5%) and hypocalcaemia (53.5%). Serious AEs considered possibly, probably or likely related to treatment were reported in 26 (36.6%) patients. *Conclusions.* This study demon-

strates durable clinical benefit (ORR of 39.7% and median duration of response of 11 months) and tolerability of romidepsin in patients with recurrent or refractory CTCL. Significant responses were observed at all stages of disease, including an ORR of 29.4% in Stage IV patients.

0436

SUMMARY OF THE CLINICAL BENEFIT OF VORINOSTAT IN RELAPSED/REFRACTORY CTCL

E.A. Olsen,[1] S. Rizvi,[2] J. Garcia-Vargas,[2] C. Sanz-Rodriguez,[2] J. Viscusi,[2] M. Gates,[2] M. Duvic[3]

[1]Duke University Medical Center, DURHAM; [2]Merck Research Laboratories, UPPER GWYNEDD; [3]MD Anderson Cancer Center, HOUSTON, USA

Background. Vorinostat is an orally active, potent inhibitor of histone deacetylase. Two completed Phase II studies have evaluated the clinical benefit of vorinostat in patients with cutaneous T-cell lymphoma (CTCL). *Aims*. Here we report corroborative conclusions on the efficacy and safety of vorinostat in CTCL based on the results from two Phase II studies. *Methods*. An initial study exploring several vorinostat dosing regimens and a second pivotal study using a 400 mg qd dose, enrolled patients with advanced CTCL who were refractory to and/or intolerant of other therapies. Patients in the initial study must have received ≥1 prior systemic therapy for CTCL compared with ≥2 in the pivotal study. Only those patients in the initial study that were treated with vorinostat 400 mg qd (the FDA-approved dose of vorinostat in CTCL) are included in the comparison. The primary endpoint in both studies was objective response rate (ORR). *Results.* The two studies were similar with respect to baseline characteristics. A total of 87 patients were included in the combined analysis of the initial and pivotal studies (13 and 74 patients, respectively). At baseline, 72 patients had CTCL Stage IIB or higher. The median number of prior systemic therapies at baseline was five in the initial study *vs* three in the pivotal study. ORRs were comparable between the patients taken from the initial study and the pivotal study overall (30.8% and 29.7%, respectively) and in patients with Stage IIB or higher (36.4% and 29.5%, respectively). In addition, several patients who did not meet the objective response criteria achieved pruritus relief and/or prolonged stable disease. Median time to objective response ranged from approximately 2 to 3 months; 88 days and 55 days in the initial and pivotal studies, respectively. Median duration of response (DOR) was 113 days in the initial study *vs* in excess of 4 months (upper range: 322 days) in the pivotal study (DOR not reached, study ongoing for duration). The median time to progression was clinically meaningful in the overall patient population for both studies (initial study: 85 days; pivotal study: not reached, but estimated to exceed 5 months). Of particular interest was the clinically meaningful reduction in pruritus in patients who were symptomatic at baseline in the initial and pivotal studies (72.7% and 31.9%, respectively reported pruritus relief). Furthermore, complete resolution of pruritus was observed in 9.1% and 11.1% of patients, respectively. Three drug-related grade 3/4 AEs were observed in the initial study: thrombocytopenia, anemia and dehydration (all 8%). Twenty-one patients (28%) in the pivotal study had drug-related grade 3/4 AEs. The most common were fatigue (5%), pulmonary embolism (5%), thrombocytopenia (5%), and nausea (4%). One patient in the initial study and 9 in the pivotal study discontinued due to AEs. *Conclusions.* Even though required prior treatment and the method for evaluating response differed between the two studies, response rates were similar and clinically meaningful in a substantial proportion of patients with CTCL (Stage IB and above), who had progressive, persistent, or recurrent disease subsequent to prior therapies.

Multiple myeloma: improving standard therapy for elderly

0437

A PHASE IB, MULTI-CENTER, OPEN-LABEL, DOSE-ESCALATION STUDY OF ORAL PANOBINOSTAT (LBH589) AND I.V. BORTEZOMIB IN ADULT PATIENTS WITH MULTIPLE MYELOMA (MM)

O. Sezer,[1] M. Kaiser,[1] D. Siegel,[2] I. Prosser,[3] M.V. Mateos,[4] M. Kangas,[5] M. Jalaluddin,[6] P. Bourquelot,[5] J. Bladé,[7] J. San Miguel,[4] K. Anderson,[8] J. Bradner[8]

[1]Charité, BERLIN, Germany; [2]Hackensack University Medical center, HACKENSACK, NJ, USA; [3]The Canberra Hospital, CANBERRA, Australia; [4]Hospital Universitario de Salamanca, SALAMANCA, Spain; [5]Novartis Pharma AG, BASEL, Switzerland; [6]Novartis Pharmaceuticals Corp, FLORHAM PARK, NJ, USA; [7]Hospital Clinic I Provincial de Barcelona, BARCELONA, Spain; [8]Dana Farber Cancer Institute, BOSTON, MA, USA

Background. Panobinostat (LBH589) is a pan-deacetylase inhibitor (pan-DACi) targeting epigenetic and multiple oncogenic pathways. Pan-DACi activity has been associated with a decrease in oncoprotein stability (BCR-ABL, HER-2, AR, ER) via HSP-90 inhibition, tumor cell motility and invasion (α tubulin), and angiogenesis (HIF-1α). Cell death is also promoted by induction of apoptosis (P53) and cell cycle arrest mediated by histone hyperacetylation. Currently the agent is under clinical investigation as a single agent and in combination for a range of solid and hematologic malignancies. *In vitro* studies have shown panobinostat to induce cytotoxicity at low nanomolar concentrations in multiple myeloma (MM) cell lines resistant to dexamethasone, melphalan and doxorubicin. Additional *in vitro* and *in vivo* experiments have demonstrated potent synergy of panobinostat with bortezomib via cytotoxicity and MM tumor growth delay. Collectively, these data provide a strong rationale for the first clinical trial of this combination in MM patients. *Aims.* The primary objective of this phase I study is to establish the maximum tolerated dose (MTD) of panobinostat with bortezomib in a second-line setting. Safety, tolerability, pharmacokinetic pharmacodynamic profiles and preliminary efficacy of the combination will be assessed as secondary objectives. *Methods.* Up to 40 adult patients with relapsed MM (IMWG criteria) who have received at least one prior line of therapy, will be enrolled. Key exclusion criteria include prior exposure to an HDACi, primary refractory MM, peripheral neuropathy (greater than Grade 1) and impaired cardiac function. Informed consent is required of all patients. The study consists of dose-escalation and dose-expansion components. Escalation commences with 10mg of panobinostat administered 3 times weekly in combination with 1.0mg/m^2 of bortezomib on Days 1, 4, 8 and 11 over a 21 day cycle. A six-parameter, adaptive Bayesian logistic regression model guides the escalation to MTD with each dose-combination being studied in cohorts of six patients. Dose-limiting toxicities (DLT) are defined as adverse events or abnormal laboratory values assessed as clinically relevant, occurring during Cycle 1, and meeting pre-specified criteria. At the MTD, additional patients will be enrolled into a dose-expansion cohort to obtain further safety and tolerability information. For patients with worsening disease after Cycle 1, dexamethasone can be added. Responses are assessed using the International Uniform Response Criteria for MM. *Results.* As of 11 February 2008, Cohort 1 (10mg LBH589 + 1.0mg/m^2 bortezomib) has been successfully completed with none of six patients enrolled experiencing DLT. Hematological AEs included CTCAE Gr 2 anemia, Gr 2-4 neutropenia and thrombocytopenia (1 patient required a single platelet transfusion). Non-hematological AEs included fatigue (1; CTCAE Gr 3) and infection (1); no grade 4 events were recorded. A total of five SAEs have occurred during cycle 1, with one event (hospitalization due to pyrexia and pain) considered to be study treatment-related (bortezomib only). Given the observed safety data, panobinostat dose has been escalated to 20 mg in the combination treatment with bortezomib in cohort 2. Updated information on this and any subsequent cohorts will be presented. *Conclusions.* 10 mg panobinostat with 1.0mg/m^2 bortezomib (first dose level) was well tolerated.

0438

BORTEZOMIB, PEGYLATED-LYPOSOMAL-DOXORUBICIN AND DEXAMETHASONE AS INDUCTION PRIOR TO AUTOLOGOUS TRANSPLANT, FOLLOWED BY LENALIDOMIDE AS MAINTENANCE IN ELDERLY NEWLY DIAGNOSED MYELOMA PATIENTS

A. Palumbo,[1] P. Falco,[1] C. Crippa,[2] V. Montefusco,[2] F. Patriarca,[2] M. Ruggeri,[1] A. Larocca,[1] F. Cavallo,[1] A.M. Liberati,[2] F. Rossini,[2] N. Giuliani,[3] T. Guglielmelli,[2] G. Benevolo,[2] C. Cangialosi,[2] T. Caravita,[2] G. Rossi,[2] P. Corradini,[4] M. Boccadoro[1]

[1]A.O.U. San Giovanni Battista, TORINO; [2]Italian Multiple Myeloma Network, GIMEMA, ITALY; [3]Cattedra e UO Ematologia e Trapianto Midollo, Università degli Studi di Parma, PARMA; [4]Divisione Ematologia, Istituto Nazionale Tumori, MILANO, Italy

Background. New agents have been introduced as induction treatment prior to autologous stem cell transplant (ASCT) and as consolidation or maintenance thereafter to improve complete response (CR) rates. Melphalan at 100 mg/m^2 has been suggested as reduced-intensity conditioning regimen for elderly patients. *Aims.* In this prospective multicenter phase II study, we evaluate Bortezomib in combination with Pegylated-Lyposomal-Doxorubicin and Dexamethasone (PAD) as induction before reduced-intensity ASCT, followed by Lenalidomide and Prednisone (LP) as consolidation and Lenalidomide alone as maintenance in elderly multiple myeloma (MM) patients. Primary endpoints were safety (any Grade-3 non-hematologic toxicity < 30%) and efficacy (near complete response rate, nCR > 35%). *Methods.* Newly diagnosed MM patients aged 65-75 years were eligible. The induction included four 21-day PAD cycles (Bortezomib 1.3 mg/m^2 on days 1, 4, 8, 11, Pegylated-Liposomal-Doxorubicin 30 mg/m^2 on day 4 and Dexamethasone 40 mg/day on days 1-4, 8-11, 15-18 for cycle 1 and on days 1-4 for cycles 2-4). Cyclophosphamide (3 g/m^2) plus G-CSF was used to harvest stem-cells. Patients were then conditioned with tandem Melphalan 100 mg/m^2 and stem-cell support (MEL100). After ASCT patients received four 28-day LP cycles (Lenalidomide 25 mg/day on days 1-21 plus Prednisone 50 mg every other day) followed by Lenalidomide alone (10 mg/day on days 1-21 every 28 days) as maintenance. *Results.* One-hundred and one patients (median age 67) were enrolled. After the 4 PAD cycles 95% of patients achieved at least partial response (PR), 60% at least very good partial response (VGPR), 23% at least nCR, and 13% CR. After tandem MEL100, 95% of patients showed PR, 80% at least VGPR, 60% at least nCR, and 33% CR. After LP consolidation regimen all patients achieved PR, 89% at least VGPR, 78% at least nCR, and 56% CR. During induction therapy, 25% of patients experienced grade 3-4 hematologic toxicity therapy, while more frequent grade 3-4 non-hematologic toxicities were peripheral neuropathy (17%) and infections (11%). During LP consolidation one DVT and one discontinuation due to prolonged anemia and thrombocytopenia were recorded. *Conclusions*. PAD as induction pre ASCT followed by LP as consolidation induced a high response rate with a 56% CR rate recorded at the end of a reduced intensity ASCT regimen for elderly patients. Updated results will be presented at the meeting.

0439

RECOVERY OF RENAL IMPAIRMENT BY BORTEZOMIB-DOXORUBICIN-DEXAMETHASONE (BDD) IN MULTIPLE MYELOMA (MM) PATIENTS WITH ACUTE RENAL FAILURE. RESULTS FROM AN ONGOING PHASE II STUDY

P. Ludwig,[1] Z. Adam,[2] R. Greil,[3] F. Keil,[4] N. Zojer,[5] J. Thaler,[6] H. Gisslinger,[7] A. Lang[8]

[1]Wilhelminenspital, VIENNA, Austria; [2]Department of Hematooncology, University Hospital,, BRNO, Czech Republic; [3]Department of Internal Medicine III, Hospital Salzburg, SALZBURG, Austria; [4]Department of Internal Medicine and Intensive Care, Hospital Leoben, LEOBEN, Austria; [5]Department of Medicine I, Wilhelminenspital, VIENNA, Austria; [6]Department of Internal Medicine IV, Hospital of Mercy Sisters, WELS, Austria; [7]Department of Internal Medicine I, University Hospital Vienna, VIENNA, Austria; [8]Department of Internal Medicine, Hospital Feldkirch, FELDKIRCH, Austria

Background. Acute light chain induced renal failure (ARF) is a severe complication of progressive MM, often leading to permanent renal dysfunction and dependence on chronic hemodialysis in a substantial proportion of patients. Reversal of kidney failure can only be achieved by fast and substantial suppression of pathogenic light-chains by effective anti-MM therapy. *Aims.* To evaluate the efficacy of the BDD regimen in restoring renal function and in achieving tumor control. *Methods.* Up to now 57 patients have been enrolled. Documentation is available for 40 patients (age: median 64 years, range 41-82 years, DS stage I: 4%, II: 10%, III: 76%. 60% of pts presented with *de novo* MM, and 40% with progressive disease. ARF was defined in newly diagnosed patients as reduction of GFR to <50mL/min due to MM nephropathy and in previously treated pts with signs of tumor progression and a GFR of >60 mL/min within the last 4 weeks as a reduction of GFR by >25% to <60 mL/min. Treatment regimen: Bortezomib (1.3 mg/m^2, d 1, 4, 8, 11 until the first safety analysis and thereafter of 1.0 mg/m^2 d 1, 4, 8, 11), doxorubicin (9 mg/m^2, d 1, 4, 8, 11 until first safety analysis and thereafter of 9 mg^2, d 1, and 4) and dexamethasone 40 mg (d 1, 4, 8, 11). Cycles were repeated every 21 days. *Results.* 32 patients have completed at least 2 cycles and are evaluable for response as yet. Nine patients achieved CR/nCR, 9 VGPR, 4 PR and 2 MR (CR-PR: 69%, CR-MR: 75%): Median GFR at baseline was 16.8 mL/min (range: 4 to 48mL/min) and improved to 154mL/min (range: 19 - >180mL/min). Improvement of GFR correlated weakly with tumor response. Median GFR was 59 mL/min (19->180 mL/min) in 18 pts with CR/nCR and VGPR, 35 mL/min (20->180 mL/min) in 4 pts with PR, and 46/min (39-43mL/min) in 2 pts with MR. Toxicity was assessed in 29 pts. Three pts died during the first treatment cycle; 2 from pneumonia (including 1 with sepsis) and 1 pt (age 81 years) from myocardial infarction. Grade 3-4 toxicities: infections (16%), neutropenia (16%), cardiovascular (10%) and weakness (10%) and thrombopenia and acute hearing loss in 5%. Grade 1-2 toxicities: infections 21%, neutropenia 16% and weakness, diarrhoea, GI bleeding in 5%. Of note, 4 of the 7 infectious complications were due to herpes virus infections/reactivations. This led to a protocol amendment with reduction of doxorubicin treatment to days 1 and 4 (instead of d 1, 4, 8, 11) and of bortezomib dose reduction to 1.0mg/m^2 and to mandatory antibacterial and antiviral prophylaxis. *Summary*. Overall response rate was 75% (CR-MR), with 28% of the 32 evaluable pts achieving CR/nCR and 28% VGPR. A significant renal response (GFR >50mL/) was obtained in 14 (43%) and an >200% improvement in GFR to levels between 30-50 mLmin was noted in additional 6 (19%) patients. Renal response correlated weakly with myeloma response. Dose reduction of the regimen after initial untoward toxicity led to favourable tolerance in the subsequently treated patients.

0440

MELPHALAN + PREDNISONE *vs* MELPHALAN + PREDNISONE + THALIDOMIDE IN INDUCTION THERAPY FOR MULTIPLE MYELOMA IN ELDERLY PATIENTS: FIRST INTERIM RESULTS OF THE DUTCH COOPERATIVE GROUP HOVON

P. Wijermans,[1] M. Schaafsma,[2] Y. Van Norden,[3] R. Ammerlaan,4 P. Sonneveld,[5] S. Wittebol,[6] H. Sinnige,[7] P. Huijgens,[8] M. van Marwijk Kooy,[9] R. van der Griend[10]

[1]Haga Hospital, THE HAGUE; [2]Mediasch Specrum Twente, ENSCHEDE; [3]HOVON datacentre, ROTTERDAM; [4]Hovon datacenter, ROTTERDAM; [5]Erasmus MC, ROTTERDAM; [6]Meander MC, AMERSFOORT; [7]Jeroen Bosch Hospital, DEN BOSCH; [8]Free University MC, AMSTERDAM; [9]Sophia Hospital, ZWOLLE; [10]Diakonessen Hospital, UTRECHT, Netherlands

Background. The Dutch cooperative group HOVON started a randomised phase III study in elderly myeloma patients in September 2002 comparing the standaard Melphalan and Prednisone treatment with the combination Melphalan, Prednison and Thalidomide (HOVON 49 study). Patients with a multiple myeloma > 65 years of age with a stage IB or higher were candidates for this study. *Methods*. Melphalan was given in a dose of 0.25 mg/kg and prednisone 1 mg/kg for 5 days every 4 weeks. Thalidomide was given daily with ina dose of 200 mg. A maximum of 8 cycles was planned. If there was still a response further therapy was allowed till a plateau phase was reached. When a good response and a plateauphase was reached the patients who were randomised for Thalidomide received maintenance therapy with Thalidomide 50 mg/day till progression of their disease. It was planned to enter 420 patients in the study. However accrual decreased significantly due to positive outcome of other studies with Thalidomide. Therefor the study was stopped after the inclusion of 344 patients. This is the first analysis based upon the data of the first 320 patients. *Results*. 344 patients were entered. The first 320 patients were analysed for this report. 7 patients were non-eligible due to either being stage IA or not having a measurable tumor parameter. From one patient there was not a signed informed consent available. Eleven patients were excluded from this analysis because of insufficient data available at the time of evaluation. Thus data are presented of 301 patients; 149 in the M+P arm and 152 in the M+P+T arm. The median age was 72 years in both groups. The arms were well matched for age, sex, stage of the disease, performance status and type of M-protein. The best response on protocol was as folows M+P response rate 47% (with a CR 1%, VGPR 8% and PR 38% respectively) and for M+P+T arm a response rate of 63% (with a CR 1%, VGPR 28% and PR 34%) which was significantly better (p<0.001). There was a significant difference in the Event Free Survival in favour of the M+P+T arm (p< 0.001) but no difference was observed for the Progression Free Survival (p=0.08) and Overall Survival (p=0.28). *Toxicity*. Only one third of all the patients received cycle 3 of Melphalan and Prednison according the planned protocol. In all the other patients the doses had to be reduced and or delayed. Grade 2,3 and 4 toxicity of any type was seen in 59% of the patients in the M+P arm and in 87% of the M+P+T patients. This difference was mainly due to grade 2 and grade 3 neurotoxicity. After three cycles only 36% of the patients used the full Thalidomide dose and after 6 cycles this was only 28%. No differences between the two arms were seen for other toxicities. *Conclusions*. In this randomised phase III study we did observe a significant improvement in the Resonse Rate, the quality of the responses and time to response in favour of the M+P+T arm. This did translate in an improvement of the Event Free Survival but not in the Overall Survival. The toxicity of the five days schedule with 0.25 mg/kg/day Melphalan led to a substantial number of patients who did not received the planned therapy. Thalidomide added significantly to the toxicity (mainly neurotoxicity) of the treatment. We were unable to confirm the positive effect with Thalidomide as part of front-line therapy on Overall Survival as it was seen in other studies

0441

OVERALL SURVIVAL WITH DEXAMETHASONE IN PHASE III MULTIPLE MYELOMA TRIALS AFTER ADJUSTMENT FOR CROSS-OVER TO LENALIDOMIDE

J. Morgan,[1] K. Ishak,[2] B. Deniz,[2] T. Drayson,[3] M. Dimopoulos,[4] M. Weber,[5] M. Augustson,[6] J. Child,[7] R. Knight,[8] G. Begum,[9] A. Dunn,[9] A. Shearer,[10] J. Caro[2]

[1]The Royal Marsden NHS Foundation Trust & The Institute of Cancer Research, SURREY, UK; [2]United BioSource Corporation, MONTREAL, Canada; [3]University of Birmingham, BIRMINGHAM, UK; [4]University of Athens School of Medicine, ATHENS, Greece; [5]Anderson Cancer Center, HOUSTON, TX, USA; [6]Sir Charles Gairdner Hospital, NEDLANDS, Australia; [7]University of Leeds, LEEDS, UK; [8]Celgene, SUMMIT, NJ, USA; [9]Warwick Medical School, COVENTRY, UK; [10]Celgene UK, LONDON, UK

Background. In pivotal trials (MM-009/010) evaluating lenalidomide plus high dose dexamethasone (Len+Dex) *vs* Dex alone, 47% of the latter switched to Len±Dex at disease progression or following ethical study unblinding. Given the significantly better efficacy of Len+Dex, survival with Dex alone is overestimated. *Aims.* Use external data on survival to adjust Dex survival for the cross-over to Len±Dex. *Methods.* Pooled data from the UK Medical Research Council (MRC) MM IV, V, VI, and VIII trials enrolled between 1980 and 1997 were used to derive an equation predicting survival with second-line conventional therapies (including VAD, ABCM, Melphalan and cyclophosphamide), according to patient and disease characteristics. Applying this equation to MM-009/010 Dex patients yielded their expected survival without cross-over to Len±Dex. This was used to estimate survival for this subgroup in a lifetime simulation by adjusting the scale parameter of the post-progression survival equation estimated from MM-009/010. Since survival patterns change with additional lines of treatment, further calibration was necessary for multiple prior therapies. As patient-level data for this subgroup were not available from MRC, published Mayo clinic data on median survival with conventional therapies for patients with two prior therapies (12.6 months) was used to adjust the predicted median from the trial-based, MRC-calibrated equation. The simulation model was then used to compare long-term survival with Len+Dex *vs* Dex alone without cross-over. *Results.* Of 873 MRC patients who initiated second-line conventional treatment, 826 had died, with 17.6 months median survival from starting second-line treatment. Survival did not differ significantly between Dex- and non-Dex-containing regimens (p-value=0.79). Exponential survival with age, performance status, M-protein, B2M and time to progression as predictors provided best fit to the data. Application using this equation to predict survival for MM-009/010 Dex patients with one prior therapy yielded a median survival of 16.2 months (95%CI: 13.1-20.1) compared to 33.6 months (95%CI: 27.1-NE) observed with cross-over to Len±Dex. The median survival for patients with multiple prior therapies was 12.6 months (95%CI: 10.2 - 15.6), compared to 27.3 months (95%CI: 23.3-33.3) with cross-over to Len±Dex. The calibrated lifetime simulation yielded estimated mean survival of 2.2 life-years with Dex alone compared with 5.6 life-years with Len+Dex for patients with one prior therapy, and 1.5 life-years for Dex alone compared with 4.2 life-years for Len+Dex for patients with multiple prior therapies. *Conclusions*. Lenalidomide delivers significantly larger survival gains in this life-limiting orphan disease when appropriate adjustment has been made for the cross-over that occurred in the trials.

FAMILIAL ERYTHROCYTOSIS ASSOCIATED WITH A MUTATIONAL HOTSPOT IN THE HIF2A GENE

M.J. Percy,[1] P.A. Beer,[2] G. Campbell,[3] A.W. Dekker,[4] A.R. Green,[2] D. Oscier,[5] M.G. Rainey,[6] R. van Wijk,[4] M. Wood,[3] T.R.J. Lappin,[7] M.F. McMullin,[7] F.S. Lee[8]

[1]Belfast City Hospital, BELFAST, UK; [2]University of Cambridge, CAMBRIDGE, UK; [3]Essex Rivers Healthcare NHS Trust, COLCHESTER, UK; [4]University Medical Center Utrecht, UTRECHT, Netherlands; [5]Royal Bournemouth Hospital, BOURNEMOUTH, UK; [6]Vale of Leven District General Hospital, ALEXANDRIA, UK; [7]Queen's University of Belfast, BELFAST, UK; [8]University of Pennsylvania School of Medicine, PHILADELPHIA, USA

Background. Erythrocytosis is characterized by an increased hematocrit, a raised hemoglobin and variable serum erythropoietin (Epo) levels. It can arise from defects in the oxygen sensing pathway, which result in elevated Epo synthesis. Mutations have been previously described in both the von Hippel Lindau (VHL) and the prolyl hydroxylase domain 2 (PHD2) proteins in individuals with erythrocytosis. Epo synthesis is regulated by a negative feedback mechanism involving the kidneys and the hypoxia inducible factor (HIF). Although the alpha subunit of HIF is constitutively expressed it is degraded by the proteasome in the presence of oxygen. The prolyl hydroxylase domain family of proteins (of which PHD2 is a member) modify the proline in a LXXLAP (where underlining indicates site of hydroxylation) motif in HIF-α. This allows the VHL protein to bind and to ubiquitinate HIF-α for proteasonal degradation. There are three isoforms of HIF-alpha and mouse studies have indicated that HIF-2α is the critical regulator of Epo synthesis. However in man it is unresolved which isoform controls Epo production. Recently, we identified a heterozygous HIF-2alpha mutation, Gly537Trp, in three generations of one family with erythrocytosis. Functional studies confirmed this particular mutation impacted significantly on the ability of HIF-2alpha to be targeted to the proteasome, thereby stabilizing HIF-2α. *Aims.* To analyse the HIF2A gene for mutations in a cohort of erythrocytosis individuals with serum Epo levels above the normal range and establish whether HIF2A is a significant cause of erythrocytosis. *Methods.* DNA was isolated from peripheral blood and PCR-direct sequencing of exon 12 of the HIF2A gene was performed. *Results.* Sequencing the HIF2A gene identified four individuals with two novel heterozygous mutations (Met535Val and Gly537Arg). All patients presented with erythocytosis at a young age with raised serum Epo levels, similar to the first case of HIF-2alpha mutation. There is no evidence of a von Hippel Lindau like syndrome in these patients. Furthermore two individuals had a clinical history of thrombosis as seen with the first family who possessed the Gly537Trp HIF-2α mutation. *Summary*. To date four of the five independent HIF2A mutations are located at Gly-537 suggesting a mutational hotspot associated with erythrocytosis. Both Met-535 and Gly-537 amino acids are located close to the hydroxylacceptor Pro-531 in HIF-2alpha. Pro-531 forms part of the conserved LXXLAP motif but interestingly none of the mutations detected thus far directly involve this motif. Examination of the three-dimensional structure of VHL bound to hydroxylated HIF-1alpha suggests that these mutations may impact on the association of HIF-2alpha with VHL. Furthermore, these results support a major role for HIF-2alpha in the regulation of Epo production in man and identify HIF2A mutations as a significant cause of erythrocytosis.

THE ETV6-PDGFRβ AND FIP1L1-PDGFRα FUSION PROTEINS ESCAPE UBIQUITINATION AND DEGRADATION

F. Toffalini,[1] A. Kallin,[1] L. Michaux,[1] P. Vandenberghe,[1] P. Pierre,[2] J. Cools,[1] J.B. Demoulin[1]

[1]Université Catholique de Louvain, BRUSSELS; [2]Cliniques du Sud-Luxembourg, ARLON, Belgium

Chimeric receptor tyrosine kinase genes are created by chromosomal rearrangements associated with chronic leukemia. These genes encode fusion proteins in which the intracellular kinase domain is fused to the N-terminal part of a partner protein that is replacing the receptor ligand binding domain. The constitutive activation of the kinase domain in the hybrid leads to constitutive signaling and uncontrolled cell proliferation. The TEL-PDGFRB (TPβ) hybrid protein is produced by the t(5;12) translocation between TEL/ETV6 and the platelet-derived growth factor receptor beta (PDGFRB) genes, and it is found in a sub-set of patients with chronic myelomonocytic leukemia (CMML). FIP1L1-PDGFRA (FPα) results from a deletion on chromosome 4q12 and it is the hallmark of chronic eosinophilic leukemia (CEL). In contrast to wild-type PDGFRα and β, which are quickly degraded upon activation, we observed that TPβ and FPα escaped down-regulation resulting in stabilization of the proteins in Ba/F3 cells. High stability of FPα hybrid was confirmed in peripheral blood mononuclear cells derived from a patient with eosinophilic leukemia. Similar data were obtained in cells expressing ZNF198-FGFR1, another fusion protein associated with the 8p11 myeloproliferative syndrome. CBL-mediated ubiquitination of receptor lysines targets them for lysosomal degradation. Ubiquitination of TPβ and FPα was much reduced compared to wild-type receptors despite marked CBL phosphorylation in cells expressing hybrid receptors. Treatment with proteasome inhibitors slightly increased TPβ stability and revealed a modest TPβ polyubiquitination. Deletion of the pointed (PNT) domain in TPβ, which is required for its polymerization and activation, strongly destabilized the protein, indicating that TPβ clustering also prevents its degradation. Stability assays with TPβ and FPα kinase inactive forms revealed that signaling is not responsible for the hybrid increased stability. In conclusion, chimeric receptor tyrosine kinases escape efficient down-regulation through lysosomes and proteasomes, by a mechanism that may involve altered ubiquitination and protein clustering.

THE SELECTIVE JANUS KINASE (JAK) INHIBITOR, INCB018424, SHOWS EFFICACY IN A PHASE I/II TRIAL IN PATIENTS WITH PRIMARY MYELOFIBROSIS (PMF) AND POST POLYCYTHEMIA VERA/ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS (POST-PV/ET MF)

S. Verstovsek,[1] H. Kantarjian,[1] A. Pardanani,[2] D. Thomas,[1] J. Cortes,[1] R. Mesa,[2] W. Hogan,[2] J. Redman,[3] R. Levy,[3] K. Vaddi,[3] J. Fridman,[3] A. Tefferi[2]

[1]M.D. Anderson Cancer Center, HOUSTON, TEXAS; [2]Mayo Clinic, ROCHESTER, MINNESOTA; [3]Incyte Corporation, WILMINGTON, DELAWARE, USA

Background. Mutations in JAK2 and MPL have been recognized in Philadelphia chromosome-negative myeloproliferative disorders, including PV, ET and PMF, making JAK a therapeutic target for these diseases. INCB018424 is a potent, selective and orally bioavailable JAK inhibitor with an excellent safety profile supporting its clinical evaluation. *Aims.* The purpose of this study was to evaluate the safety and tolerability of INCB018424 and determine the MTD and preliminary efficacy in patients with PMF and Post-PV/ET MF. *Methods.* A phase I/II dose-escalation trial of INCB018424 was conducted with a PO BID continuous schedule. Responses are defined by the International Working Group (IWG) consensus criteria for treatment response in myelofibrosis with myeloid metaplasia (IWG-MRT). *Results.* Overall characteristics of the 32 patients enrolled include median age of 65 yrs; 67% males; 47% PMF, 38% post-PV and 15% post ET; and 87% with JAK2V617F mutation. The starting dose of 25 mg PO BID was demonstrated to be the maximum tolerated dose (MTD) (N = 6 pts). Two patients had grade 4 thrombocytopenia during the first cycle in the 50 mg PO BID cohort (N = 5 pts) which defined the dose limiting toxicity. Myelosuppression has been the only toxicity assessed to be related to drug thus far and this is an on-target effect. An expanded cohort of 21 additional patients has also been enrolled at the MTD, all of whom completed at least 3 months of therapy. A rapid and significant reduction in splenomegaly was observed in the group of 28 patients with palpable spleens at baseline. Sixteen patients have met the IWG criteria for splenic clinical improvement (CI) with a median time to response of <1 month. No patients have progressed after an initial response and based on the current follow up, the median duration of response is greater than 3 months. In addition, the majority of patients had improvement in their ECOG PS to 0 and their constitutional symptoms resolved or were significantly reduced. Laboratory correlates with treatment have included a marked reduction in proinflammatory and angiogenic cytokines, significant increases in hematopoietic growth factors and normalization of systemic JAK/STAT signaling. Follow up is too short to make valid conclusions regarding effects on anemia, V617F allele burden, bone marrow histology and cytogenetics. *Conclusions.* Treatment with INCB018424 results in marked spleen size reduction and symptom improvement without significant toxicity. Clinical improvements occurred regardless of mutation status or prior MPD diagnosis. Updated results for all 32 patients followed for at least 6 months will be available by the time of the meeting. Further dose modifications and schedules are being explored.

0445

THE CLINICAL PHENOTYPE OF PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA HARBORING MPL 515W>L/K MUTATION

E. Antonioli,[1] A. Pancrazzi,[2] P. Guglielmelli,[2] A. Bosi,[2] G. Barosi,[3] M. Ruggeri,[4] G. Specchia,[2] F. Lo Coco,[5] T. Barbui,[6] A.M. Vannucchi[2]

[1]University of Florence, FIRENZE; [2]Dept of Hematology, FLORENCE; [3]IRCCS Policlinico S. Matteo, PAVIA; [4]Ospedale San Bortolo, VICENZA; [5]Policlinico universitario Tor Vergata, Roma, ROMA; [6]Ematologia, Ospedali riuniti, BERGAMO, Italy

Background. A 515W>L/K mutation in MPL (MPLmut) has been described in 5-10% of patients (pts) with myelofibrosis, in some cases also associated with JAK2617V>F allele. We previously reported that among 217 subjects with myelofibrosis, the 18 MPLmut pts were more severely anemic than MPL wild-type (MPLWT) pts (Guglielmelli *et al.*, BJH 2007). MPL 515W>L mutation has been reported also in 1% of pts with essential thrombocythemia (ET). Aim and Methods. Aim of the study was to determine the frequency of MPL W515L/K mutation in 995 patients with ET and to correlate clinical and laboratory characteristics with MPL mutation. We have collected 31 MPLmut pts (3.1% of total) in an unselected series of 995 ET pts according to PVSG and WHO criteria. A novel quantitative real-time PCR assay for 515W>L and 515W>K allele in granulocyte DNA has been designed; detection limit was 0.01% for W>L allele and 0.1% for W>K allele. Results. 18 pts were 515W>L and 12 were 515W>K; 8 pt with W>L and 6 pts with W>K allele were homozygous for mutant allele. Mean mutant allele burden was 53(±26)% and 37(±23)% for W>K and W>L, respectively. In one patient a novel MPL mutation was identified that results in the substitution of tryptophan for arginine (515W>A). Eight MPLmut pts (26%) also harbored JAK2617V>F allele, as compared to 527/964 of MPLWT (57%; p=0.001); mean 617V>F allele burden was significantly lower in MPLmut (11±8%) than in MPLWT pts (27±15%; p=0.002). At diagnosis, hemoglobin level was lower in mutated pts (p=0.02) while platelet count, MCV and LDH level were significantly higher in MPLmut pts. There was no difference in splenomegaly, systemic symptoms and major thrombosis between MPLmut and MPLWT pts; however, pts with microvessel disease were significantly more frequent among MPLmut (61% *vs* 30%; p=0.0005). Among mutated pts, those with W>L were older (p=0.004) than W>K. We observed that W>L mutation was preferentially associated with lower haemoglobin level, while a significantly higher platelet count was found in patients with W>K. Bone marrow (BM) biopsy at diagnosis of MPLmut pts was reviewed blinded; total BM cellularity was significantly lower in MPL mutant pts, while there was no difference in the mean reticulin grade. On the other hand, presence of MPL mutation significantly affected the megakaryocytic lineage: the number of both megakaryocytes and megakaryocyte clusters per mm^2 of bone marrow area were significantly increased in MPL mutant pts (p= 0.006 and p=0.0002. respectively), while the mean number of megakaryocytes per cluster did not differ compared to MPL-wt pts. There was also an increase in the number of small megakaryocytes/mm^2 (p<0.0006), that represented 28.1±14.4% of all megakaryocytes in MPL mutant patients compared to 18.6±12.2 in MPL-wt patients. *Conclusions.* Frequency of MPL mutation in this large series of ET is higher than originally reported, and although some intriguing correlation with clinical and hematologic parameters could be evinced, MPL mutant patients did not constitute a defined sub-group within the spectrum of ET. MPL mutational screening is relevant in the diagnostic work-up of suspected ET as a tool to demonstrate occurence of clonal myeloproliferation, since a sizable proportion (≈8%) of JAK2 wild-type patients actually present a mutation at codon 515 of MPL.

0446

PEGYLATED INTERFERON-α-2A INDUCES COMPLETE HEMATOLOGICAL AND MOLECULAR RESPONSES WITH LOW TOXICITY IN POLYCYTHEMIA VERA: RESULTS OF THE PV-NORD PVN1 STUDY

J.J. Kiladjian,[1] B. Cassinat,[2] P. Turlure,[3] N. Cambier,[4] M. Roussel,[5] S. Bellucci,[5] S. Chevret,[2] B. Grandchamp,[6] C. Chomienne,[2] P. Fenaux[1]

[1]AP-HP, Hôpital Avicenne, BOBIGNY; [2]APHP, Hopital Saint-Louis, PARIS; [3]CHU Dupuytren, LIMOGES; [4]CHRU de Lille, Hopital Huriez, LILLE; [5]AP-HP,Hôpital Lariboisiere, PARIS; [6]AP-HP, Hopital Bichat; INSERM U656, PARIS, France

Background. Interferon-α (IFNα) is a non-leukemogenic treatment of polycythemia vera (PV), also able to induce cytogenetic remissions. Its use is nevertheless limited by toxicity, leading to treatment discontinuation in about 25% of patients within the first year. *Aims and Study design*. We completed a phase 2 multicenter study of pegylated-IFNα-2a in 40 PV patients. Objectives included evaluation of efficacy, safety, and monitoring of residual disease using JAK2V617F quantification in circulating granulocytes (%V617F). The PVN1 study was approved by the IRB of Paris 13 University, and by the French Health Products Safety Agency. Informed consent was provided according to the Declaration of Helsinki. *Results*. Median follow-up was 31.4 months. After 12 months of treatment, all the 37 evaluable patients had hematological response, including 94.6% complete responses (CR), and only 3 (8%) patients had stopped treatment. After the first year, 29 patients remained in hematological CR, including 24 still on pegylated-IFNα-2a, and 5 who had stopped treatment for 3 to 18 months (and without any other cytoreductive treatment). Sequential samples for %V617F monitoring, available in 29 mutated patients, showed %V617F decrease in 26 (89.6%). Median %V617F decreased from 45% before pegylated-IFNα-2a to 22.5%, 17.5%, 5%, and 3% after 12, 18, 24, and 36 months, respectively (p<0.0001). Molecular CR (JAK2V617F undetectable) was achieved in 7 patients, lasting from 6 to 18 months, and persisting after pegylated-IFNα-2a discontinuation in 5. Kinetics of decrease and final %V617F level were independent of baseline JAK2V617F level, and of presence of 9p LOH. Finally, no vascular event was recorded in the whole cohort after 31.4 months of median follow-up. *Conclusion*. Those results show that pegylated-IFNα-2a yields high rates of hematological and molecular CR in PV with limited toxicity, and could even eliminate the JAK2 mutated clone in selected cases.

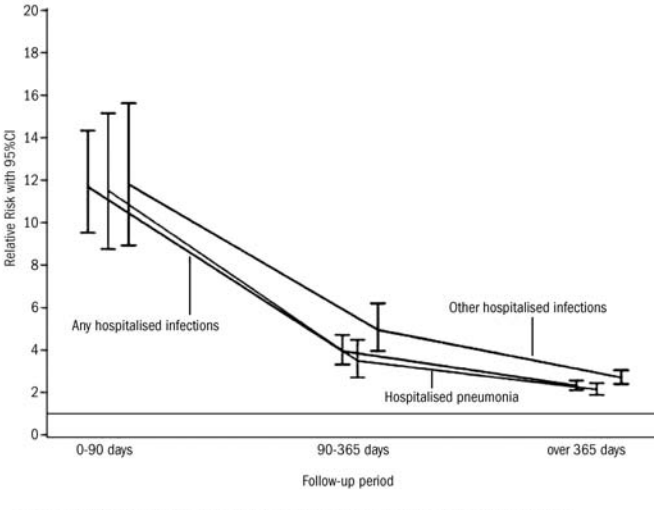
INCIDENCE OF INFECTIONS IN SPLENECTOMISED PATIENTS AND GENERAL POPULATION COMPARISONS: NATIONWIDE COHORT STUDY IN DENMARK

W.M. Schoonen,[1] R.W. Thomsen,[2] D. Körmendiné Farkas,[2] A. Riis,[2] J.P. Fryzek,[3] H.T. Sørensen[2]

[1]Amgen, UXBRIDGE, MIDDLESEX, UK; [2]Aarhus University Hospital, AARHUS, Denmark; [3]Amgen Inc., THOUSAND OAKS, CA, USA

Background. Splenectomy is indicated for a variety of medical conditions. Two surgical procedures are available; open splenectomy (OS) or laparoscopic splenectomy (LS). The spleen is important in filtering and removal of blood-borne pathogens such as Streptococcus pneumoniae. Splenectomy has been associated with a high incidence of subsequent infections, but the risk compared to the general population has not been quantified. Further, LS may confer a lower risk of infection, but this has yet to be investigated. *Aims.* To estimate the risk of infection by time since surgical procedure for all splenectomised patients and LS patients separately, compared to the general population in Denmark. *Methods.* All individuals who underwent splenectomy from 1996 to 2005 were identified in nationwide Danish medical databases. For each splenectomised person we identified 10 population comparisons, frequency-matched on age, sex, and index date of the splenectomy. The outcomes of interest were hospitalised infections overall and hospitalised pneumonia in specific. For a subset of data from Northern Denmark we had additional data on microbiologically confirmed bacteraemia episodes. We compared rates of infection in splenectomised *vs* un-splenectomised individuals within 90 days, 91-365 days, and more than 365 days after the index date, using multivariable techniques to adjust for age, sex and comorbid diseases present at the index date. *Results*. We identified 3812 individuals with splenectomy (median age 60 (interquartile range 41-72) years, 43% females) and 38120 population comparisons. Overall, 21.9% of splenectomised individuals had a hospitalised infection at any point in time after splenectomy (median follow-up time 2.6 years), *vs* 10.8% of the population comparisons. The relative risk (RR) of any hospitalised infection from splenectomy was highest within 90 days when 6.7% had an event (RR=11.7, 95% confidence interval (CI) 9.5-14.3). The relative risk remained four-fold elevated during 91-365 days, and more than two-fold one year or longer after the splenectomy (Figure 1).



*Relative risk during follow-up in patients with splenectomy compared with population comparisons.
Risk estimates are shown both for infections overall and stratified by pneumonia and other infections.

Figure 1. Adjusted relative risk of hospitalised infections*

A similar pattern was observed for hospitalised pneumonia, with 12.3% having an event in the splenectomised group *vs* 6.5% of the comparisons. More than one year after splenectomy, risk of hospitalised infections other than pneumonia appeared to be relatively higher than risk of pneumonia (Figure 1). In our regional subcohort, bacteraemia was observed in 13.1% of 418 splenectomised subjects and in 1.2% of the 4180 comparisons The adjusted relative risk of bacteraemia was 177-fold (95% CI 50-624) increased within 90 days, 7.9 times (2.7-22.9) and 3.8 times (1.8-8.1) increased after 91-365 days and more than 365 days, respectively. Laparoscopic splenectomy was performed on 33 patients, two of whom had a hospitalised infection within 90 days (*vs* zero population comparisons) and a further five had a hospitalised infection one year or more after the splenectomy (*vs* 13 population comparisons). *Summary and conclusions.* Splenectomised individuals are at increased risk of hospitalised infection, in particular bacteraemia, compared to the general population. Relative risk of infection was highest in the 90 days following splenectomy and remained more than two-fold elevated more than a year after splenectomy. Data on laparoscopic splenectomy were limited but we did observe infections in those patients.

0448

IMPACT OF PRIOR INVASIVE PULMONARY ASPERGILLOSIS (IPA) ON OUTCOME IN PATIENTS RECEIVING REDUCED INTENSITY CONDITIONING (RIC) ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-SCT)

J. El cheikh, L. Wang, C. Faucher, S. Furst, P. Berger, D. Blaise

[1]Department of Haematology, Unité de Transplantation et de Thérapie Cellulaire (UTTC), Institut Paoli-Calmettes, Marseille, France

Background. Invasive Pulmonary Aspergillosis (IPA) is a major cause of morbidity in patients with hematological malignancies. The aim of this single centre retrospective study was to determine the impact of prior IPA on outcome after RIC Allo-SCT. *Methods.* All cases of proven or probable IPA diagnosed prior to performance of RIC Allo-SCT at the Paoli-Calmettes Institute Cancer Centre from 1 January 2000 through 31 December 2007 were included. 28 patients were identified among 434 patients undergoing Allo-SCT. Patients' data were collected from a maintained database and by retrospective clinical chart review. *Results.* Twenty eight cases were identified. Gender: M/F (16/12); median age at diagnosis was 53 years (18-65). 23 patients (82%) had acute myeloid leukemia. In all patients, IPA was diagnosed according to standard procedures. IPA therapy included: 20 patients (71%) were receiving Voriconazole; 4 patients Itraconazole, and 4 patients with an association of different antifungal drugs including Caspofungine, Liposomal Amphoteracinre-B, or Posaconazole. The median duration of treatment prior to RIC was 8 months range (1-16). The median time between the diagnosis of IPA and transplantation was 6 months (1-27); 20 patients (71%) received a graft from a family donor, 4 patients had a MUD, and 4 patients received cord blood cells donors. 21 patients (75%) received a conditioning regimen with Fludarabine Busulfan and ATG, and 4 patient (14%) received a conditioning with Fludarabine Cyclophosphamide and TBI, 3 patients (11%) Fludarabine and TBI, Most patients (n=25; 89%) received or continued a secondary prophylaxis against aspergillosis at time of Allo-SCT: 17 (68%) had a prophylaxis with Voriconazole; 3 patients Itraconazole, 2 patients Posaconazole. After RIC transplantation only 4 patients (14%) had reactivation of their IPA. The latter 4 patients were experiencing severe acute GVHD treated with high dose corticosteroids. None of these patients died of IPA. Actually 18 patients (64%) are still alive with a median follow up of 23.5 months (12.6-48.5). Overall survival at 2 years was 59% [95%CI, 43-83]. In all, 3 patients died from other causes not directly related to IPA, 2 patients because of relapse or disease progression, and one due extensive chronic GVHD. *Conclusions.* In comparison to literature in standard myéloablative allo-SCT setting, these data suggest that adequately treated and controlled IPA prior to RIC Allo-SCT do not worsen outcome. The latter is likely due to multiple changes in transplantation practice, including the RIC nature of the conditioning regimens, the infusion of peripheral blood stem cells, rapid diagnosis of IPA, and use of modern efficient antifungal drugs.

HBV REVERSE SEROCONVERSION AND INTERVENTION WITH VACCINATION AFTER ALLOGENEIC HSCT IN PATIENTS WITH PREVIOUS HBV INFECTION

M. Onozawa, S. Hashino, R. Morita, K. Kahata, T. Kondo, J. Tanaka, M. Imamura, M. Asaka

Hokkaido University Hospital, SAPPORO, Japan

Background. Appearance of anti-hepatitis B surface antigen antibody (anti-HBs) and clearance of hepatitis B virus (HBV) from serum usually indicate resolution of hepatitis in patients infected with HBV. However, in most patients in whom HBV has been eliminated from serum, HBV DNA is still detectable in the liver using polymerase chain reaction. Reactivation of this dormant HBV in the liver is known as reverse seroconversion (RS). Previously, we reported that HBV-RS after allogeneic hematopoietic stem cell transplantation (allo-HSCT) was a frequent late-onset complication that can be predicted by careful monitoring of progressive disappearance of anti-HBs (Onozawa M *et al.* Transplantation. 2005.79(5):616-9). RS hepatitis after allo-HSCT is thought to be a phenomenon caused by naive donor immunity after loss of recipient-oriented immunity against HBV. We speculated that vaccination could prevent reactivation of HBV in allo-HSCT recipients. Safety and efficacy of recombinant HBV vaccine in allo-HSCT recipients have already been confirmed. *Aims.* We conducted post-transplant recombinant HB vaccine intervention to immunize naïve donor immunity and determine clinical impact to prevent post-HSCT HBV-RS. *Methods.* Allo-HSCT recipients who underwent transplantation in our hospital from Feb. 1990 to Mar. 2007 and who were followed for at least 1 year after HSCT were enrolled. Thirty-eight recipients were serologically considered to have previous HBV infection in pre-HSCT evaluation. From Mar. 2003 we started hepatitis B vaccine intervention for HSCT recipient after cessation of immunosuppressant administration. Thirteen recipients who underwent transplantation after Mar. 2003 were immunized by HB vaccine by a standard 3-dose (0, 1, 6 month) regimen (vaccine group: M/F, 6/7; age, 24-68 years (median, 50 years); follow-up period, 20-60 months (median, 37 months)). Twelve recipients who underwent transplantation after Mar. 2003 were observed without intervention (non-vaccine group: M/F, 5/7; age, 22-65 years (meidan, 47 years); follow-up period, 12-55 months (median, 23 months)). Thirteen recipients who underwent transplantation before Mar. 2003 and were observed without vaccine intervention were considered as controls (historical control group: M/F, 9/4; age, 22-52 years (median, 36 years); follow-up period 17-116 months (median, 59 months)). We studied transition of anti-HBs and incidence of HBV-RS. *Results.* Progressive decreases in titers of anti-HBs were observed in all pre-HSCT anti-HBs positive recipients. Eight of the 13 historical control group recipients and 3 of the 12 non-vaccine group recipients suffered HBV-RS after loss of anti-HBs, but none of the 13 vaccine group recipients suffered HBV-RS. Cumulative risks of HBV-RS at 3-years after HSCT in the historical control, non-vaccine group and vaccine group were 41%, 39% and 0%, respectively (p=0.022). *Conclusions.* All recipients with previous HBV infection should be considered to be at high risk for RS after allo-HSCT. Intervention with recombinant HBV vaccines is effective for prevent post-transplant HBV-RS in allo-HSCT recipients.

CLINICAL VALUE OF SCREENING DETECTION OF 1,3-BETA-D GLUCAN (BG) FOR EARLY DIAGNOSIS OF INVASIVE FUNGAL INFECTIONS (IFI) IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES - RESULTS OF A PROSPECTIVE STUDY

Z. Racil,[1] I. Kocmanova,[2] B. Weinbergerova,[1] J. Winterova,[1] M. Lengerova1, J. Mayer1

[1]*University Hospital Brno and Masaryk University, BRNO;* [2]*University Hospital Brno, BRNO, Czech Republic*

Background and Aims. BG - the major cell wall component of various medically important fungi - can be used as a target for early detection of IFI. The aim of our study was to evaluate usefulness of BG detection for screening of IFI in hemato-oncological patients in routine clinical use. *Methods.* Between January 2005 and July 2007, blood samples for BG screening were obtained from patients in intermediate to high risk of IFI. The BG was detected by FungitellTM test (Associates of Cape Cod, USA). Only proven and probable cases of IFI were considered to calculate sensitivity, specificity, and positive and negative predictive values (PPV, NPV). *Results.* BG screening was performed in 1154 blood samples obtained during 104 anticancer treatment cycles: treatment of AML, n = 46 (44.2%); allogeneic HSCT, n = 40 (38.5%); autologous HSCT, n = 17 (16.4%); other, n = 1 (0.9%). The incidence of IFI in our study was 17.3% (n=18) and probable or proven IFI was detected in 9 cases (8.6%). The highest sensitivity, specificity, PPV, and NPV (88.9%, 40.7%, 13.6% and 97.2%) were obtained when cut off of 80 pg/mL and one positive result were used. For routine clinical use, positive results in two consecutive samples are usually more relevant. Thus, when consecutive positivity of the test was required, cut off of 60 pg/mL was found more useful (sensitivity 66.7%, specificity 47.7%, PPV 11.8%, and NPV 93.2%). Low PPV, caused by frequent false positive results, was identified as the main limitation of this assay. Fifty-one (59%) treatment cycles were positive if a criterion of one sample above 80 pg/mL was used. If consecutive positivity with cut off 60 pg/mL was used, 45 (52%) of them were positive. Approximately 90% of these BG positive cycles were false positive. We did not find any correlation between positive BG assay result and frequency of empirical antifungal treatment, frequency and grade of mucositis, yeast colonization, administration of selected antibiotics, or infusion solutions or bacteremia. *Summary and Conclusions.* Our comprehensive analysis reflecting routine use of BG test for panfungal screening of IFI showed limited usefulness of this assay in patients with hematological malignancies. Low sensitivity together with poor PPV are the major limitations of this test, which, based on these results, cannot be recommended for screening purposes.

HIGH-DOSE ACICLOVIR FAILS TO PREVENT CYTOMEGALOVIRUS INFECTION AND DISEASE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

N. Duncan, D. Stocken, H. Osman, J. Ward, P. Moss, M. Cook, C. Craddock

University Hospital Birmingham NHS Foundation Trust, BIRMINGHAM, UK

Background. Cytomegalovirus (CMV) disease remains an important cause of morbidity and mortality following allogeneic stem cell transplantation (SCT).(1) It has been demonstrated that administration of high-dose aciclovir during the post-transplant period can reduce the incidence of CMV infection and disease(2,3) and we therefore wished to examine the impact of its use at a major regional allograft centre. *Aims*. To determine the effect of high-dose aciclovir prophylaxis on the incidence of CMV infection and disease, time to reactivation and survival in patients undergoing allogeneic stem cell transplantation. *Methods*. Data on incidence and outcome of CMV infection were collected for 144 consecutive at-risk patients undergoing allogeneic SCT between January 2002 and December 2006. Until July 2004, patients received low-dose aciclovir (200mg qds until day +35) as herpes simplex prophylaxis but no CMV prophylaxis. From July 2004 onwards, patients received aciclovir until day+100 at a dose of 800mg qds orally (sibling donors) or 500mg/m^2 tds IV until mucositis resolved, then 800mg qds orally (matched unrelated donors). *Results*. Data were collected for 144 patients, 73 of whom received high-dose aciclovir prophylaxis. The remaining 71 patients (control group) received low-dose aciclovir. The majority of patients (70%) received pre-transplant alemtuzumab for T-cell depletion. The overall incidence of CMV reactivation (up until day +100) was 40% in the high-dose aciclovir group and 44% in the control group (p=0.74). There were no significant differences between the groups in

the time to first reactivation (median 36 days in both groups), incidence of CMV disease (7% in both groups) and day +100 survival (84% *vs* 83%). Seronegative patients were found to have a low incidence of reactivation (13%) but of those patients who reactivated, 75% developed CMV pneumonitis. Multivariate (logistic regression) analysis demonstrated that three factors all significantly impacted on the risk of CMV infection: T-cell depletion [odds ratio 7.42 (2.4-21.9)], recipient CMV seronegativity [odds ratio 0.14 (0.04-0.51)] and a diagnosis of CML [odds ratio 4.58 (1.26-16.72)]. However, the use of aciclovir did not demonstrate any significant benefit. Using the model, a predictive equation for calculating probability of CMV reactivation for an individual patient was determined. The equation was subsequently validated in a cohort of 44 patients at risk of CMV reactivation. *Summary and Conclusions*. In this study, the use of high-dose aciclovir prophylaxis failed to reduce the incidence of CMV infection and disease in a high-risk population of patients undergoing allogeneic SCT and alternative prophylactic strategies should be considered. We have developed a novel method that allows the risk of CMV reactivation to be calculated for an individual patient. This predictive equation will be of value in identifying and targeting high-risk patients who require more intensive prophylactic strategies.

TIME TO LEUKAEMIA (TTL) ASSESSED IN NOD/SCID MICE TRANSPLANTED WITH PRIMARY ALL LEUKAEMIA CELLS DETERMINES EARLY RELAPSE IN PATIENTS AND IS IDENTIFIED BY A SPECIFIC GENE SIGNATURE

H. Meyer,[1] S.M. Eckhoff,[1] M. Queudeville,[1] M. Zimmermann,[2] A. Schrauder,[3] G. Lahr,[1] K. Holzmann,[1] M. Schrappe,[3] K. Stahnke,[1] K.-M. Debatin[1]

[1]University of Ulm, ULM; [2]Medical School Hannover, HANNOVER; [3]University Hospital Schleswig-Holstein, KIEL, Germany

Poor response to induction therapy is the major risk factor identified in ALL and is used within the ALL BFM study to identify patients at high risk for relapse (e.g. prednisone poor response, PPR: more than 1000 blasts/µl peripheral blood after treatment with prednisone systemically for 8 days and MTX intrathecally once on day 1). Despite the efforts achieved by the stratification strategies the majority of relapses are recruited from the group of initially good responding patients (in ALL BFM the standard and medium risk, SR and MR groups) emphasising the need for additional independent stratification factors. In our study we transplanted primary leukaemia cells from 50 children with newly diagnosed B cell precursor ALL (BCP-ALL) into NOD/SCID mice. Time to leukaemia was determined for each patient sample transplanted as weeks from date of transplant to date of clinical manifestation of the disease. Leukaemia was verified in spleen and bone marrow by flow cytometry staining for human CD19. Time to leukaemia of less than 10 weeks (short TLL) was observed in 6 patient samples whereas 44 leukaemia samples took clearly more than 10 weeks until appearance of leukaemia (long TTL). A clear cut in relapse free survival (Kaplan Meier analysis, N=50, log rank: $p<0.0001$) was found for patients whose leukaemia cell samples showed short TTL (N=6, mean survival: 13.1 months, SE: 4.1, CI: 5.0-21.2) in contrast to patients with long TTL (N=44, mean survival: 50.7 months, SE: 1.9, CI: 47.1-54.4). Of note, the same distinct difference in relapse free survival was observed considering the SR and MR groups only (N=40, log rank $p<0.0001$, long TTL: 52.4 months; short TTL: 12.6 months). By multivariate analysis (N=50, relapse free survival) patients exhibiting short TTL in the xenotransplant model exhibited a strongly increased risk for relapse with a risk ratio of 44.59 (CI: 8.42-236.11, $p<0.0001$). Interestingly, patients in our cohort showing prednisone poor response known as important clinical risk factor revealed only a risk ratio of 8.71 (CI: 1.75-43.44, $p= 0.008$). None of the patients with long TTL encountered early relapse. These findings in 50 directly transplanted samples were confirmed transplanting different cryopreserved BCP-ALL samples. In order to further characterise the biological properties of the leukaemia cell in the two groups, gene expression profiles of samples with short or long TTL in the xenograft model were investigated using a human whole genome array (Affymetrix U133 Plus 2.0). We identified a signature of differentially expressed genes distinguishing both groups. The differential expression was confirmed for selected genes by quantitative RT-PCR. Taken together, estimation of time to leukaemia (TTL) of leukaemia samples transplanted onto NOD/SCID mice is a new promising factor in paediatric ALL. Using an expression array approach patient samples displaying short TTL can be discriminated from those with long TTL by a unique gene expression signature. This allows direct identification of patients with increased risk for relapse by this new independent risk factor avoiding transplant in the mouse model.

UNIQUE DNA METHYLATION PATTERNS SEPARATE DISTINCT SUBTYPES OF MLL REARRANGED INFANT ALL

D.J.P.M. Stumpel,[1] P. Schneider,[1] R.X. Menezes,[1] E.H.J. van Roon,[2] T.C.M. Peters,[1] J.M. Boer,[2] R. Pieters,[1] R.W. Stam[1]

[1]Erasmus MC Rotterdam-Sophia Children's Hospital, the Netherlands, ROTTERDAM; [2]Leiden University Medical Center, Center for Human and Clinical Genetics, LEIDEN, Netherlands

Background. Acute Lymphoblastic Leukemia (ALL) in infants (<1 year of age) is characterized by chromosomal rearrangements involving the MLL gene (~80%) that are associated with a poor prognosis. The most frequent MLL translocations in infant ALL are t(4;11), t(11;19) and t(9;11). Based on gene expression profiling, MLL rearranged ALL (MLL) represents a unique type of leukemia clearly distinguishable from other ALL

subtypes. Whether MLL also displays unique epigenetic features like aberrant silencing of (tumor suppressor) genes induced by promoter CpG island hypermethylation remains unkown. *Aims.* Therefore, the present study was designed to unravel specific DNA methylation patterns associated with the different types of MLL translocations found among infant ALL patients. *Methods.* For this, we applied Differential Methylation Hybridization (DMH) using both custom spotted 9K CpG island microarrays (Huang *et al.*, 2002), and commercially available 244K CpG arrays (Agilent), on primary infant ALL samples carrying t(4;11) (n=21), t(11;19) (n=17) or t(9;11) (n=6). The obtained DNA methylation patterns were compared with the patterns found in infant ALL samples without MLL rearrangements (n=13). Healthy pediatric bone marrow samples (n=9) were included as a reference. *Results.* Both CpG microarray platforms revealed that t(4;11) and t(11;19) positive samples are characterized by abundant promoter CpG island hypermethylation as compared with normal bone marrow. This aberrant DNA methylation pattern appeared to be largely absent in t(9;11) positive samples as well as in infant patients carrying germline MLL genes. Based on unsupervised cluster analysis, these latter subgroups consistently cluster together with healthy bone marrow samples (Figure 1). Subsequently, the obtained CpG array data were compared with gene expression profiles (Affymetrix) from corresponding patients. For several hypermethylated genes we observed down-regulated gene expression. However, we also repetitively found that genes significantly hypermethylated in t(4;11) and t(11;19) positive samples show silencing in all samples tested, including healthy bone marrow. Possibly t(4;11) and t(11;19) samples display hypermethylation of genes already methylated (or otherwise silenced) among hematopoietic cells. In rare occasions we observed the opposite; despite severe hypermethylation, some genes retain high expression levels. *Summary and Conclusions.* Unique DNA methylation patterns are present among different subtypes of MLL rearranged infant ALL, separating t(4;11) and t(11;19) positive infant ALL patients from patients carrying t(9;11) and wild-type MLL genes. Clearly, translocations t(4;11) and t(11;19) are associated with severely hypermethylated leukemias, whereas translocation t(9;11) seems to be less capable of inducing aberrant DNA methylation patterns. This study provides the first epigenetic insights into the complex biology of MLL rearranged ALL in infants.

Seràgnoli", BOLOGNA; [3]Department of Genetics and Microbiology, University of Bari, BARI; [4]Hematology, University of Turin at Orbassano, ORBASSANO, TURIN; [5]CEINGE, University of Naples Federico II, NAPLES; [6]"La Sapienza" Unversity, ROME, Italy

Background. The Ph chromosome is the most frequent cytogenetic aberration associated with adult ALL and it represents the single most significant adverse prognostic marker. The constitutively active tyrosine kinase encoded by BCR-ABL blocks the B-cell differentiation, prevents apoptosis and also causes genetic instability. Recently, the introduction of array-based analysis of single nucleotide polymorphism (SNP) has allowed the rapid determination of genome-wide allelic information at high density for a DNA sample. *Aims.* To identify, at submicroscopic level, genetic lesions which can escape standard cytogenetic observations and may provide new insights into the alternative process underlining leukemogenesis and resistance in Ph+ ALL. *Methods.* We profiled, until now, the genomes of 36 out of 55 Ph+ ALL patients. The median age was 55 years (range, 18-76) and the median blast percentage was 90% (range, 76-100%). 250 ng of genomic DNA were processed on 500K SNP array according to protocols provided by the manufacturer (Affymetrix Inc., USA). Copy number state was calculated with respect to a set of 48 Hapmap normal individuals and a set of samples obtained from acute leukaemia cases in remission using Partek® Genomics Suite. Fluorescence *in situ* hybridization (FISH), real-time quantitative PCR and western-blot analyses were performed to validate our results. *Results.* We identified region of high level amplification and homozygous deletion in all patients, with deletions outnumbering amplification almost 3:1. Copy number alterations most frequently involved chromosome 7 and 8. Lesions varied from loss or gain of complete chromosome arms (trisomy 4, monosomy 7, loss of 9p, 10q, 14q, 16q and gain of 1q and 17q) to microdeletions and microduplications targeting genomic intervals. Sub-microscopic lesions encompassing single or only few genes were observed with relative high frequency. Many of these copy number alterations were associated with cellular proliferation and/or apoptosis [e.g. CDKN2A and CDKN2B (n=8), GADD45A (n=2), FAS (n=2), BTG1(n=2)]. We also frequently observed anomalies in genes involved in early B-cell differentiation. These include the paired box gene PAX5 (9p13, n=5) which is a critical determinant of B-lineage commitment; the B-cell adapter containing a SH2 domain protein BLNK (10q23.2-q23.33, n=1); the pre-B lymphocyte gene VPREB1 (22q11.22, n=8) and the transcription factor IKZF1 (7p13-p11.1, n=9), which is required for normal lymphoid development. Reverse transcriptase-PCR and western-blot analysis for IKZF1 showed that in some cases this deletion was associated with the expression of the dominant-negative isoform Ik6 with cytoplasmatic localization. Other recurring copy number abnormalities with relevance to leukemogenesis included deletions of BTLA, TOX, MDS, PBX1, RUNX1, ETV1 and PTEN. It is noteworthy that some lesions felt in regions lacking annotated genes. *Conclusions*. High-resolution SNP-based genomic profiling is a reliable and valid method for the identification of genomic anomalies and genes relevant for the development of leukaemia. Multiple independent copy number anomalies were frequently observed in genes involved in cell cycle regulation and B-cell differentiation, suggesting that these processes could contribute to the poor prognosis of Ph+ ALL.

MONOALLELIC LOSS AND FREQUENT MUTATION OF THE SECOND ALLELE OF PAX5 ARE GENETIC HALLMARKS OF DIC(9;20) CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

S. Strehl, K. Nebral, M. König, D. Krehan

CCRI, Children's Cancer Research Institute, VIENNA, Austria

Background. About 1.5% of childhood B-cell precursor acute lymphoblastic leukemia is associated with the presence of a dic(9;20)(p13;q11) chromosome. In about 40% of the cases dic(9;20) is the sole karyotypic change suggesting that this aberration is the primary leukemogenic event. However, so far all efforts to delineate the genes involved in this specific genetic aberration have failed. This is mainly due to the observation that the breakpoints in both chromosomes are heterogeneous and thus neither a specific gene is affected on either chromosome nor has the formation of a fusion gene been observed. In general, the formation of a dicentric chromosome results in hypodiploidy, which however can be masked by nonrandom gains of chromosomes. Owing to the fact that dic(9;20) not always results in monosomy 20q the crucial gene(s) are more likely to be located at 9p. In this respect, it has been observed that dic(9;20) is frequently associated with homo- or heterozygous deletion of CDKN2A. Recently, it has been shown that hypodiploid ALL has one null PAX5 allele and a significant proportion of cases harbor point mutations in the other PAX5 allele. *Aims and Methods.*In order to determine whether deletion and/or mutation of PAX5 are associated with dic(9;20) leukemia we analyzed 7 cases for their PAX5 status by fluorescence *in situ* hybridization (FISH) using PAX5-specific probes, mutation screening of all PAX5 coding exons, and expression of PAX5 isoforms. *Results*. FISH analysis using PAX5 flanking BAC clones showed that in 7/7 cases with a dic(9;20) one allele of PAX5 was consistently deleted. Sequence analysis of all coding exons of the retained allele revealed mutations in PAX5 in 4/7 (>50%) cases. These mutations comprised two in exon 3 encoding the paired DNA-binding domain, namely P80R (2 cases) and T75A (1 case), and a T311A mutation in exon 8 encoding the N-terminal part of the transactivation domain of PAX5. To exclude inherited germline mutations remission samples of all four cases were analyzed and showed that all PAX5 mutations were indeed somatically acquired. Moreover, evaluation of the expression pattern of N- and C-terminal PAX5 isoforms revealed that in one of the unmutated cases no full-length transcript was present. All other cases expressed full-length PAX5 and different isoforms in variable patterns and levels. However, to date it remains elusive whether the expression of such PAX5 isoforms is leukemia-associated or reflects specific stages of B-cell development. Regarding the CDKN2A status, FISH analysis revealed a heterozygous in three, a homozygous in two, and a mixed pattern of homozygous and heterozygous loss in one of the cases. In the remaining case, CDKN2A was lost from the dic(9;20) chromosome but a signal was observed on a der(12) marker chromosome suggesting a complex rearrangement, which resulted in a dic(9;20) without concomitant loss of CDKN2A. *Conclusions*. Together, our data suggest that haploinsufficiency of PAX5 and mutation of the second allele may play a crucial role in the leukemogenesis of dic(9;20) leukemia.

0456

IDENTIFICATION OF CANCER STEM CELLS IN B-CELL LYMPHOID HEMATOLOGIC MALIGNANCIES

H. Nishida

The Institute of Medical Science, The University of Tokyo, TOKYO, Japan

Background. Although cancer stem cells (CSCs) have already been identified in acute myeloblastic leukemia, current data on CSCs in lymphoid hematologic malignancies are conflicting. B-cell acute lymphoblastic (B-ALL) cells capable of long-term proliferation were reported to be $CD34^+/CD10^-$ or $CD34^+/CD19^-$ cells, suggesting that these cells are progenitors of B-ALL (Castor 2005, Cox 2004). *Aims*. In order to overcome this disease, molecular targeted therapy against CSCs is essential, but specific positive markers for them other than CD34 have not been identified yet. The purpose of this study was to determine the positive CD marker for the efficient isolation of CSCs in B-ALL. *Methods*. We evaluated the stem cell properties of B-ALL cell lines and primary pediatric pre-B ALL samples *in vitro* and *in vivo*. *Results.* we first performed extensive FACS analysis of cell surface antigen markers (total 101) in 7 B-cell leukemia/lymphoma cell lines. We found that especially three B-lineage precursor leukemia cell lines; YAMN90 (t(1;19) positive), REH(t(12;21) positive), ARH77 (normal karyotype) consisted of heterogeneous populations in marker expressions. Moreover, small subpopulations of $CD9^+$/high cells in these cell lines were shown to have stem cell characteristics within the clone *in vitro* and *in vivo*. Sorting & Culture assay revealed that $CD9^-$ cells repopulated only $CD9^-$ cells, whereas $CD9^+$ cells repopulated not only $CD9^+$ cells but also $CD9^-$ cells to reconstitute the original pattern of the cell line. We then transplanted $CD9^+$ and $CD9^-$ cells into immunodeficient NOG mice to compare the tumorigenicity of each population. The mice injected with $CD9^+$ cells died of leukemia within 30-40 days, however, those injected with $CD9^-$ cells survived, which leukemic engraftements were not successful. Next, we isolated leukemia cells from spleens or bone marrow of the transplanted mice and $CD9^+$ cells were shown to be serially transplantable onto secondary, tertiary mice. For further investigation, we also examined primary samples of childhood pre B-ALL patients and discovered that $CD9^+$ cells were found in all cases of peripheral blood or bone marrow and showed significant correlation with CD34 expression in many cases. In addition, gene expression profile between $CD9^+$ and $CD9^-$ cells using Affymetrix gene chips revealed that there are several affected genes related to stem cell characters and leukemia development. *Conclusions*. our data indicate that B-ALL cells with tumorigenicity onto NOG mice express CD9, and suggest that CD9 is a new positive marker for efficient isolation of CSCs in some cases of B-cell lymphoid hematologic malignancies including B-ALL.

Background. Cytogenetically normal AML (CN-AML) accounts for 20-25% of childhood AML. In an earlier array-based CGH study on 43 childhood CN-AML samples, we identified an 11p13-deletion that includes the Wilms' tumor 1 (WT1) gene in one patient. Its other WT1 allele carried a mutation. Recently, 10% of adult CN-AML patients were also found to carry WT1 mutations. *Aims*. To investigate the frequency of WT1 mutations, their association with clinical characteristics and their prognostic value in a large cohort of childhood AML. *Methods.* We screened 298 diagnostic childhood AML samples using PCR-based direct sequencing of exons 7-10. We also screened exons 1-6 in a selected CN-AML subgroup. Additionally we screened 39 paired diagnostic-relapse samples. *Results.* WT1 mutations were detected in 35/298 (12%) of the samples. In 18/35 (51%) of the WT1-mutated samples, we detected more than one WT1 mutation that included another WT1 mutation (n=14), a homozygous mutation (n=3), or a deletion of the other allele (n=1). Mutations were predominantly found in exon 7, but also in exons 1, 2, 3, 8, 9 and 10. Strikingly, the mutational hotspots were located within areas used for WT1-based MRD detection. Moreover, 4/28(14%) diagnostic-relapse pairs with a wild-type WT1 at diagnosis gained a mutation at relapse, which also has consequences for MRD detection. Regarding patient characteristics, WT1 mutations clustered in the CN-AML subgroup (21/93=22.6%; p=<0.001); fewer (14/205=6.8%) being found in the other cytogenetic subgroups. WT1-mutated patients had a higher diagnostic WBC (median 57.2x10E9/l; p=0.007). No significant differences were found for median age, gender and FAB classification between WT1-mutated *vs* wild-type patients. WT1 mutations were more frequently associated with an FLT3/ITD (40%; p=0.002) and a CEBPalpha mutation (26%; p=0.007), but did not carry simultaneously NPM1 mutations (0%; p=0.09). Prognostic univariate analysis within the CN-AML patients identified WT1 mutations as a poor prognostic factor (WT1-mutated *vs* wild-type patients: CR rate 74% *vs* 91%; p=0.05, pOS 45% *vs* 72%; p=0.02 and pEFS 32% *vs* 51%; p=0.04). Multivariate analysis including other known prognostic factors in childhood AML is currently being performed. *Conclusions.* WT1 mutations cluster in childhood CN-AML, and are a new poor prognostic marker in this subgroup. The presence of these mutations may complicate the WT1-based MRD detection currently used.

MIR-125B: RELEVANCE IN CHILDHOOD ACUTE MEGAKARYOBLASTIC LEUKEMIAS

K. Boehmer, J.H. Klusmann, D. Reinhardt

Hannover Medical School, HANNOVER, Germany

Background. Children with Down's syndrome (DS) are at high risk to develop transient leukemia (TL) or acute myeloid leukemia (ML-DS). Acquired mutations of the hematopoietic transcription factor GATA1 have been identified in leukemic blasts from virtually all patients with ML-DS or TL. Five miRNAs (miR-99a, miR-125b-2, miR-155 and let-7c) are known to be encoded on chromosome 21. We investigated the role of miR-125b-2 in the development of TMD and ML-DS. *Patients and Methods.* To elucidate their role in the development of TL and ML-DS, we first measured their expression level in sorted cells from patient samples [ML-DS (n = 4), TL (n = 4), non-DS AMKL (n = 4)], and in megakaryocytes from healthy donors (n = 3) by qRT-PCR. The expression of miR-125b was clearly elevated in ML-DS (10-fold), TL (5-fold) and non-DS AMKL (3-fold) compared to normal megakaryocytes (ppatients *vs* control <0.01). This was confirmed in microRNA low density array [ML-DS (n = 5), TMD (n = 5), non-DS AMKL (n = 3)]. To define the relevance of miR125b-2 for proliferation the miRNA was transduced into human $CD34^+$ stem cells. Proliferation was analysed by MegaCult and CollagenCult. Inhibition of miRNA125b was evaluated by transfection of anti-miRNA 125 into cell lines (CMK, M07, K562), blasts and stem cells. Cell cycle of the transfected cells was examined by BrdU-flow-Kit. With Gene Set Enrichment Analysis (GSEA), we analysed the regulation of putative target genes of mi-R125b-2 predicted by Targetscan and PicTar databases in the gene expression profile of ML-DS in comparison to non-DS AMKL. *Results.* By retroviral overexpression, we could show that ectopic expression of miR-125b markedly enhanced proliferation of myeloid progenitor cells (MPC, $CD34^+CD33^+$) (MPCmiR-125b) *in vitro*. In colony-forming assays, the number of MPCmiR-125b derived colonies exceeded the number of MPCvector derived colonies (empty vector) by 4-fold (<0.01). All MPCmiR-125b derived colonies contained a mixture of immature cells (CFU-GEMM) indicating an affected differentiation. This could also be confirmed by immunophenotyping of MPC cultured in liquid medium containing various cytokines (percentage $CD34^+CD33^+$ 26% *vs* 9%). The silencing of miR-125b-2 resulted in a significant inhibition of proliferation of megakaryoblastic cell lines, and primary blasts, whereas $CD34^+$ human stem cells and K562 remains unaltered (ANOVA; p<0.05). Approximately 10% of M07 cells transfected with anti-125b were in G2-cell phase comparison to 16% of control cells. GSEA of ML-DS (n=22) compared to AMKL (n=30) revealed a decreased expression of putative target genes of mi-R 125b-2. As predicted, silencing of miR-125b shows the upregulation of 347 target genes of mi-R125b-2 in sample of cells (M07, CMK). *Conclusions*. miR-125b seems to be involved in the leukemogenesis of trisomy 21 associated leukemia by mediating the proliferation of MPC while repressing differentiation.

GENOME-WIDE SNP ANALYSIS IDENTIFIES GENOMIC ABNORMALITIES IN ACUTE MYELOID LEUKEMIA WITH NORMAL KARYOTYPE

J. Kronke,[1] L. Bullinger,[1] C. Schön,[1] K. Urlbauer,[1] S. Miller,[1] C. Senger,[1] K. Holzmann,[2] R. Schlenk,[1] K. Döhner,[1] H. Döhner[1]

[1]University of Ulm, ULM; [2]Microarray Core Facility, University of Ulm, ULM, Germany

Approximately 45% of patients (pts) with acute myeloid leukemia (AML) exhibit a normal karyotype on conventional chromosome banding analysis. To further characterize this heterogeneous group of cytogenetically normal (CN)-AML, we applied the microarray-based technology of single nucleotide polymorphism (SNP) analysis which provides a powerful tool to identify copy number alterations (CNA) and uniparental disomies (UPD) that result from the exclusion of the wild-type allele without change of chromosomal copy number. We performed paired SNP-chip analysis in a total of 126 CN-AML pts: in 80 pts the Affymetrix 50k Hind and in 62 pts Affymetrix 250k Sty and Nsp (together 500k) arrays were used;.in 16 pts a comparative analysis on both the 50k and 500k platform was done. In all pts bone marrow samples taken at the time of complete morphological remission was used as an intra-individual control to distinguish acquired somatic aberrations in AML blasts from germline polymorphisms. Data analysis was performed by using the CNAG 2.0 software. In total, 42 aberrations (deletions n=16; gains n=6; UPDs n=20) were identified in 31 cases. Two small deletions, one in 2p21 (0.7 Mb) and a second in 11p13 (0.26 Mb), were detected only by the 500k platform, thereby demonstrating the superiority of the 500k over the 50k assay. Other deletions occurred in 3p13 (n=4), 12p13 (n=2), 12q21 (n=1), 12q24 (n=1), 2p21 (n=1), 4q24 (n=1), 8q21 (n=1), 8q23 (n=1) 9q21 (n=1), 11p13 (n=1), 11q23 (n=1), and 13q12 (n=1). Recurrent deletions on 3p were confirmed by fluorescence *in situ* hybridization (FISH) and the commonly deleted region was delineated to a genomic segment of approximately 2 Mb. Genomic gains were identified in 6 pts and were restricted to single cases [4q22 (n=1), 8q12 (n=1), 9p23 (n=1), 14q32 (n=1), 18q12 (n=1) and 22q11 (n=1)]. Furthermore, acquired UPDs ranging from 28 Mb to 96 Mb in size were detected in 16% of the pts [6p (n=5), 11p (n=5), 13q (n=5), 1p (n=2), 2p (n=1), 11q (n=1) and 19q (n=1)]. All pts exhibiting an UPD on chromosome 13q had homozygous FLT3-ITD (internal tandem duplication) mutations. The UPD on 19q was associated with a homozygous CEBPA mutation. Our data demonstrate the power of high resolution SNP-chip analysis in CN-AML for the detection of novel regions of interest

as well as the definition of areas affected by UPDs, thereby supporting non-random mechanism of acquired mitotic recombination events in AML.

THE LEUKEMOGENIC TRANSCRIPTION FACTOR ERG COLLABORATES WITH GATA1S TO IMMORTALIZE MEGAKAROCYTIC PRECURSORS: A MOUSE MODEL FOR THE PATHOGENESIS OF SPORADIC AND DOWN SYNDROME ASSOCIATED ACUTE MEGAKARYOBLASTIC LEUKEMIAS

S. Izraeli,[1] S. Salek-Ardakani,[2] J. De Boer,[2] N.J. Sebire,[2] L. Rainis,[1] S. Lee,[2] O. Williams,[2] S. Izraeli,[3] H.J.M. Brady[2]

[1]Sheba medical center, RAMAT GAN, Israel; [2]Institute of Child Health, LONDON, UK; [3]Sheba Medical Center, RAMAT GAN, Israel

Background. Although, numerical chromosomal aberrations (aneuploidy) are prevalent in cancer, very little is known of their role in carcinogenesis. The most common constitutional aneuploidy with predisposition to leukemia is trisomy 21, also known as Down Syndrome (DS). DS children have a 20-fold increased risk of childhood acute lymphoblastic leukemia (ALL) and a 500-fold increased risk for acute megakaryoblastic leukaemia (AMKL)3. Around 10% of DS newborns have a transient myeloproliferative disorder (TMD) that resolves spontaneously but approximately 20% of TMD patients will progress to develop AMKL during early childhood. Somatic mutations acquired during fetal hematopoiesis in the GATA1 transcription factor are detected in megakaryoblasts from all the DS patients with either TMD or AMKL. *Aims.* To investigate the hypothesis that the chromosome 21 gene ERG-3 collaborates with mutated GATA1 in megakaryobastic transformation and leukemias. *Methods. In vitro* and *in vivo* transformation and transplantation assays with mouse fetal liver hematopietic progenitors (HPCs) transduced with ERG and mutated GATA1 (GATA1s). *Results.* Transduction with both ERG and GATA1s (but not with each of them alone) was necessary and sufficient for immortalization of fetal megakaryocyte progenitors with the phenotype of AMKL megakaryoblasts. We show that ERGpromotes megakaryopoiesis and acts as an oncogene and that progenitor cells harboring a GATA1s mutation plus ERG or ERG alone lead to rapid development of invasive megakaryoblastic leukemia *in vivo*. The addition of GATA1s resulted in a less differentiated AMKL compared with ERG alone. *Conclusions.* Our data support a model where trisomy 21 overexpressed genes that promote fetal megakaryopoiesis co-operate with GATA1s mutations that arrest differentiation and lead to DS AMKL. It is also the first demonstration in-vivo of the direct leukemogenic role of ERG, whose high level of expression in human myeloid leukemias are associated with particularly poor outcome.

0461

IDENTIFICATION OF THREE TYROSINE RESIDUES OF IMPORTANCE FOR SURVIVAL SIGNALING OF FLT3 ITD THROUGH GAB2

K. Masson, T. Liu, J. Sun, L. Rönnstrand

Lund University, MALMÖ, Sweden

The receptor tyrosine kinase Flt3 is normally expressed in hematopoietic progenitor cells and has been implicated as major cause of transformation in acute myeloid leukemia, where it in approximately 30% of cases is constitutively active. Intracellular signals mediated by Flt3 play pivotal roles in cell fate determination and survival and previous studies have shown that signaling via the mutant Flt3 ITD (internal tandem duplication) promotes enhanced cell growth as compared to the wild type receptor. In this study, we have identified tyrosines 768, 955 and 969 of Flt3 as phosphorylation sites and mediators of Grb2 interaction, leading to the association of the scaffolding protein Gab2 and contributing to proliferation and survival. We used murine hematopoietic Ba/F3 cells stably transfected with either the wild type Flt3 or the ITD, with or without a triple mutation of the Grb2 binding sites, and have characterized the cells in terms of proliferation, survival and apoptosis. Interestingly, we found that the Flt3 ITD promotes increased survival and when mutating the tyrosines 768, 955 and 969 to phenylalanine, this phenotype is lost. When looking into different downstream pathways, we observed that this effect is mainly caused by decreased PI3-kinase/Akt as well as STAT5 signaling, and the Flt3 ITD carrying the triple mutation of the Grb2 binding sites show less Akt and STAT5 activation as compared to the regular Flt3 ITD receptor. siRNA mediated knockdown of Gab2 in the Flt3-ITD expressing AML cell line MV4-11 strongly suppressed Erk, Akt and Stat5 phosphorylation. These findings not only reveal new phosphorylation sites in Flt3 but contribute to the understanding of the molecular mechanism by which Flt3 ITD functions in pathological conditions.

OPPOSING EFFECTS OF PROTEIN KINASE A AND C CAUSES DIFFERENTIAL PHOSPHATIDYLSERINE EXPOSURE IN A CD47 RECEPTOR MEDIATED ERYTHROCYTE APOPTOTIC PATHWAY

P. Jeremy,[1] F. Gilsanz,[2] J. Delaunay,[3] N. Avent[1]

[1]University of the West of England, BRISTOL, UK; [2]Hospital '12 de Octubre' 'Instituto National de la Salud, MADRID, Spain; [3]Service d'Hématologie, d'Immunologie et de Cytogénétique, PARIS, France

Erythrocyte apoptosis, like nucleated cell death, is characterised by phosphatidylserine exposure at the outer membrane leaflet. Our group has previously reported that ligation of a monoclonal antibody, BRIC-126 can mediate red cell apoptosis and subsequent PS exposure, through a CD47 receptor mediated pathway. We have also demonstrated that several membrane proteins are involved in this pathway and one such interaction is a direct protein: protein interaction between CD47 and protein 4.1R. Further studies have shown that red cells deficient in protein 4.1R undergo increased PS exposure in response to BRIC-126 than do normal cells, suggesting that protein 4.1R is critical to this pathway. In order to further elucidate the CD47 apoptotic pathway we have inhibited Protein Kinase A and Protein Kinase C whilst ligating CD47 with BRIC-126, as these kinases are known to interact with protein 4.1R at specific serine residues and are often implicated in cell signalling cascades, especially apoptosis. We have used flow cytometry in conjunction with an annexin V-FITC binding assay to compare mean percentage annexin V positive cells whilst inhibiting protein kinase A and protein kinase C using the cell permeable specific inhibitors Bisindolylmaleimide I, Go 6976 and KT 5720. Our findings suggest opposing effects of Protein kinase A and Protein Kinase C compared with control erythrocytes. We observed that PS exposure was decreased in cells with the specific cell permeable PKC inhibitors Bisindolylmaleimide I and Go 6976 present but increased in cells with the specific PKA cell permeable inhibitor KT5720 present. The increase in PS exposure when PKA inhibitor KT5720 is present is similar to the effect seen in individuals deficient in protein 4.1R. The difference in PS exposure between PKC inhibition and PKA inhibition suggests opposing effects of PKA and PKC during CD47 ligation and a possible interaction with protein 4.1R, this may also suggest that specific phosphorylation events on protein 4.1R are critical to the CD47 apoptotic pathway. Ongoing studies are investigating isoform specific inhibition of PKC and PKA along with 2D phosphoimmunoblots to look at changes in PI before and after ligation of BRIC 126.

CHARACTERISATION OF TINF2 MUTATIONS IN A LARGE COHORT OF PATIENTS WITH DYSKERATOSIS CONGENITA AND RELATED BONE MARROW FAILURE SYNDROMES

J. Walne, T. Vulliamy, R. Beswick, M. Kirwan, I. Dokal

Institute of cell and molecular sciences, LONDON, UK

Background. Dyskeratosis congentia (DC) is a multi-system syndrome which displays marked clinical heterogeneity. Patients present with a wide range of haematological and non-haematological features including nail dystrophy, abnormal skin pigmentation, leucoplakia and aplastic anaemia (AA). Many patients can first present with AA and the diagnosis of DC may not be clinically obvious. The genetic basis of DC remains unknown in >50% of patients. Mutations have been found in genes encoding components of the telomerase complex, namely TERC (the RNA component), TERT (the enzymatic component) and dyskerin (DKC1) and NOP10 both of which encode proteins in the small nucleolar ribonucleoprotein particle. Recently TINF2, a component of the shelterin complex has also been shown to be mutated in a small number of patients with DC *Aims*. The aim of this study was to determine the contribution to the pathology that mutations in exon 6 of TINF2 may make in patients with DC and other related syndromes including aplastic anaemia (idiopathic and constitutional, IAA and CAA, respectively) and myelodysplasia/acute myeloid leukaemia. This exon was the focus of the study as previous work identified mutations only in this region of the gene. *Methods*. To date 302 families are entered into the Dyskeratosis Congenita Registry at Barts and The London, London, UK. In this large collection of patients, 185 remain genetically uncharacterised. Analysis failed on 12 patients, and the remaining 173 were screened for mutations in exon 6. Heteroduplex analysis was performed using denaturing high performance liquid chromatography following PCR amplification. Any abnormal shifts were sequenced to determine the nucleotide change involved. We also screened 111 patients with IAA, 77 with CAA, 15 with myelodysplasia/acute myeloid leukaemia and 41 with related disorders as well as 91 healthy individuals. *Results*. Coding changes were found in 31/173 previously uncharacterised DC index cases. In this group, 21/31 mutations affected amino acid arginine 282, mutated to either cysteine (n=7) or histidine (n=14). Of the remaining 10 mutations, 7 were mis-sense and 3 resulted in a frame-shift and premature stop codons. 8 coding changes were also seen in the 244 non-DC patients analysed. Of these, 5 resulted in the polymorphic Gly237Arg substitution. The remaining 3 were unique mis-sense mutations. Apart from the known polymorphism none of these changes were seen in the healthy control group. Segregation analysis in the DC families showed that of the 16 cases where both parents are available, 15 are *de novo* and in only one case is the mutation is inherited. *Summary and conclusions*. In this large series, TINF2 mutations in exon 6 account for ~11% of DC (31/290), with the majority being *de novo* cases. Patients with TINF2 mutations have severe disease with a high incidence of aplastic anaemia usually presenting below 10 years of age. In the non-DC patient group TINF2 mutations may have a minor pathological role (3/244). The prevalence of TINF2 as a cause of DC is second only to dyskerin (~30%, 86/290).

0464

EVIDENCE OF A SUB-CLINICAL LYMPHOPROLIFERATIVE DISEASE IN PATIENTS WITH 'IDIOPATHIC' AUTOIMMUNE HEMOLYTIC ANEMIA

F.R. Mauro, M.S. De Propris, I. Del Giudice, D. Armiento, S. Coluzzi, I. Della Starza, M.C. De Nicolo', M.C. Arista, L. Quattrocchi, G. Girelli, A. Guarini, R. Foa'

University "La Sapienza", ROME, Italy

Background. Idiopathic autoimmune hemolytic anemia (AHA), which accounts for about half of cases, is diagnosed in the absence of a concomitant disease. A lymphoproliferative disease is frequently associated or can follow AHA. *Aims*. The aim of this study was to better define the clinical features of cases defined as *idiopathic* AHA. *Methods*. Fifty consecutive patients with *idiopathic* AHA were diagnosed at the Institute of Hematology of "La Sapienza"University of Rome. In all patients, except for anemia associated with laboratory signs of hemolysis and a positive DAT test, no evidence of an associated disease emerged by the clinical examination and the medical history. Before starting steroid treatment, the following examinations were performed: immunohematologic study; total body CT scan or a chest XR with abdomen ultrasound; HBV and HCV serology; autoantibody screening (anti-nucleous; anti-cardiolipin; anti-gastric parietal cell; anti-beta 2-glycoprotein-I); peripheral blood (PB) immunophenotype. *Results*. The median age of the 50 patients was 66 years (range: 20-84), Thirty-two patients were females. The immunohematologic study revealed an anti-erythrocyte auto-antibody in all cases (IgG: 27; IgM:15; IgG + IgM: 7; IgA:1). An idiopathic AHA was confirmed in 26 cases (52%), while in 24 (48%) a concurrent disease was diagnosed (tumor: 4; HCV hepatitis: 2; autoimmune disease: 2). In 16 cases (32%), all with a normal lymphocyte count, the PB immunophenotype revealed the presence of a small B-lymphocyte clone, with a chronic lymphocytic leukemia phenotype, $CD5^+/CD19^+$, $CD23^+$, in 3 cases and a lymphoma phenotype, $CD5^+/CD19^+$, $CD23^-$ or $CD5^-/CD19^+$, $CD23^-$, in 13. The median number of clonal B lymphocytes in the PB was 0.5×10^9/L (range: 0.03-1.9×10^9/L). Clonality was confirmed by PCR Ig gene rearrangement analysis. The same clonal population was detected in the bone marrow aspirate of all evaluated cases. No other signs ascribable to a lymphoproliferative disease were detected, except for a patient with an enlarged abdominal lymph node. *Conclusions*. Our findings indicate that about one third of newly diagnosed patients with otherwise defined *idiopathic* AHA show an underlined B-lymphocyte clone, suggesting the presence of a subclinical lymphoproliferative disease which may play a role both in the pathogenesis of the autoimmune disorder and in the subsequent occurrence of a lymphoma. The detection of such clones should be considered in the diagnostic work-out and address the treatment strategy of patients with AHA.

0465

DOUBLE CORD BLOOD TRANSPLANTATION FOR PATIENTS WITH INHERITED AND ACQUIRED BONE MARROW FAILURE SYNDROMES

A. Ruggeri,[1] R. Peffault de Latour,[2] V. Rocha,[2] C.A. Rodrigues,[2] M. Robin,[2] J. Larghero,[3] R. Traineau,[4] P. Ribaud,[2] C. Ferry,[2] A. Devergie,[2] E. Gluckman,[2] G. Socié[2]

[1]Bone Marrow Transplantation unit, PARIS; [2]Service d'Hématologie Greffe, PARIS; [3]Unité de Thérapie cellulaire, PARIS; [4]Service d'Hémobiologie, PARIS, France

Background. The outcome of severe aplastic anemia (SAA), refractory to immunosuppressive therapy or related to Fanconi anemia (FA), is usually poor in the absence of hematopoietic stem cell transplantation. Single cord blood is an alternative stem cell source for patients without matched related or unrelated donors, but is associated with high transplant related mortality due to the low cell dose infused. *Aims.* We performed double cord blood transplantation (dCBT) in 14 patients (6 male and 8 female) with a median age of 16 years (6-31), diagnosed with bone marrow failure syndromes (BMFS) (8 FA, 5 SAA and 1 PNH), from 2004 to 2007. All patient data were collected after informed consent. *Methods.* Median disease duration before dCBT was 31 months (5-240). At transplant, median neutrophil and platelet count were 0.3×10^9/L (0.0- 1.1) and 21×10^9/L (3-93), respectively. All patients were highly transfused before transplant. Six patients (43%) received a dCBT as a rescue of previous rejected transplants (2 SAA and 4 FA). All patients received a fludarabine-based regimen, with TBI (2 Gy) for 4 patients. Cord blood units were 4/6 or 5/6, HLA A, B and DR match with the patient, except one which was 3/6. Graft versus host disease (GVHD) prophylaxis consisted in cyclosporin+mycophenolate mophetile for 5 patients. Steroids were given from day 7 to day 14 and stopped in absence of GVHD. Median cell doses infused were 4.8×10^7 NC/Kg (1.8-9.7) and 2.9×10^5 $CD34^+$cells/Kg (0.5-7.46). *Results.* Graft rejection was observed in 6 patients (3 previously allotransplanted). Among the remaining 8 patients the median time to achieve absolute neutrophils count >500 was 28 days (range 14-42) and median time to a platelet count > 20,000 was 83 days. At day 100, donor-recipient chimerism analysis was evaluable in 10 patients (72%). Seven patients (70%) showed a full donor chimerism, 2 patients (20%) were mixed chimeras and 1 patient (10%) had an autologous recovery. In six out of 8 patients, the predominant UCB unit was the first one infused. Acute GVHD grade II-III was scored in 9 patients (70%) (6 grade II, 3 grade III). One patient presented acute GVHD grade IV. All the FA group patients (8 out of 14) developed aGVHD. Six patients out of 8 developed chronic GVHD (3 limited and 3 extensive). Six patients died (2 GVHD, 2 fungal infections, 1 thrombotic microangiopathy, 1 sepsis). With a median follow-up of 13 months (range 5- 22), the overall survival (OS) was 57% (±13%) for all patients. According to disease category, the predicted 1-year OS for patients with acquired BMF (SAA and PNH) and inherited BMFS (FA and CD) was 80 (±17%) and 44 (±16%), respectively.The median survival of patients who were transplanted twice was 50% (±13%). *Conclusions.*dCBT seems to be an option to treat patients with bone marrow failure syndromes and without matched HLA donors. Those results need to be confirmed in a prospective study to warrant the inclusion of dCBT in the treatment strategy of diseases with high risk of rejection.

0466

EFFECTS OF STAT5A PHOSPHORYLATION ON PROLIFERATION AND DIFFERENTIATION OF MYELOID HEMATOPOIETIC PROGENITORS IN HEALTHY INDIVIDUALS AND IN PATIENTS WITH SEVERE CONGENITAL NEUTROPENIA

J. Skokowa, K. Gupta, A. Müller Brechlin, K. Welte

Hannover Medical School, HANNOVER, Germany

Background. Severe congenital neutropenia (SCN) is characterized by the onset of recurrent life-threatening infections in early childhood due to a *maturation arrest* of myeloid progenitors at the promyelocytic stage with a few or no mature neutrophils in the bone marrow and blood. SCN patients are at increased risk of developing AML or MDS. The cumulative incidence of AML/MDS is 21% after 10 years. The leukemic transformation occurred in both autosomal dominant (with ELA2 mutations) and autosomal recessive (with HAX1 mutations) groups of SCN patients. The pathogenesis of SCN, the mechanisms underlying malignant transformation in these patients as well as the role of G-CSF treatment in this process are still unknown. Since AML/MDS are not observed in cyclic (CyN) or idiopathic neutropenia patients treated with G-CSF, an underlying defect downstream of G-CSFR signaling rather than G-CSF therapy *per se* predisposes to malignant transformation in SCN. Recently we found that downregulation of LEF-1 transcription factor and its target gene C/EBPβ are a common pathomechanism of SCN irrespective of mutation status. *Aims.* In the present study, we aimed to evaluate the association between increased G-CSF-triggered phosphorylation of STAT5, low levels of LEF-1 and leukemic transformation of hematopoiesis in SCN. *Methods.* We investigated the effects of G-CSF on phosphorylation status of STAT5 in $CD34^+$ and in $CD33^+$ bone marrow progenitor cells from healthy individuals and SCN patients. We also compared expression patterns of LEF-1 and C/EBPβ in the presence of constitutively activated STAT5a (mutant of STAT5a, (STAT5A[1*6]) in these cells and evaluated the mechanisms of STAT5: LEF-1 interaction. *Results.* We found that G-CSF stimulation resulted in a significantly higher phosphorylation of STAT5 in $CD33^+$ bone marrow myeloid progenitors of four SCN patients (two harbouring ELA2 mutations and two with HAX1 mutations), as compared to two patients with cyclic neutropenia, two patients with idiopathic neutropenia and four healthy volunteers. Transduction of constitutive activated STAT5a in $CD34^+$ or in $CD33^+$ cells of healthy individuals resulted in 20-fold downregulation of LEF-1 expression. A screen of the 10kb upstream region of LEF-1 gene revealed two putative STAT5a binding sites (-3913 bp to -3894 bp and -3728 bp to -3709 bp). The specificity of the STAT5a binding to the LEF-1 promoter in nuclear extracts of $CD34^+$ cells and in two myeloid leukemia cell lines (HL-60, U937) was confirmed in a chromatin immunoprecipitation (ChIP) assay. More intriguingly, to analyse the mechanisms of LEF-1 inhibition, we generated reporter gene constructs containing 4000 bp upstream regulatory region with promoter of human LEF-1 gene. We found, that co-transfection of 293 HEK cells with LEF-1 cDNA and β-catenin cDNA resulted in a considerable elevation of LEF-1 promoter activity, suggesting a strong autoregulation of LEF-1 gene by LEF-1 protein. Additional co-transfection with constitutively activated STAT5a significantly abrogated LEF-1-dependent activation of LEF-1 promoter. Moreover, we found that constitutively activated STAT5a also abrogated LEF-1/β-catenin effects on TOPglow reporter construct, containing four LEF-1/TCFs binding sites. Similar inhibitory effects of STAT5A[1*6] on LEF-1 transcriptional activity has been observed by the analysis of the reporter construct of known LEF-1 target gene, cyclin D1. *Conclusion*. G-CSF induced a strong phosphorylation of STAT5 in hematopoietic progenitors of SCN patients, as compared to patients with other types of neutropenia and to healthy individuals. Constitutively activated STAT5a binds directly to the promoter of LEF-1 gene and inhibits its expression by disturbing the LEF-1-autoregulatory loop. These intracellular events may contribute to the malignant transformation of myelopoiesis in SCN.

Hodgkin's lymphoma

[1]University Hospital of Cologne, COLOGNE; [2]German Hodgkin Study Group, COLOGNE, Germany

Background and Aims. The HD15 multicenter trial of the German Hodgkin Study Group (GHSG) included advanced-stage Hodgkin lymphoma patients. Patients were prospectively randomized to either 8 or 6 cycles of BEACOPPescalated or 8 cycles time-condensed BEACOPP-baseline. Beside the reduction of chemotherapy one other main study endpoint was the prognostic value of 18F-fluorodesoxyglucose (FDG) positron emission tomography (PET) following chemotherapy. The aim was to specify the negative predictive value of PET (NPV) in patients with residual tumour mass after chemotherapy. *Methods.* Inclusion criteria for the PET question were partial remission (PR) after the end of chemotherapy with at least one involved nodal site measuring 2.5 cm or more in diameter by computed tomography (CT). Exclusion criteria included diabetes, elevated blood sugar levels and skeletal involvement with risk of instability. Calculations were restricted to those cases with either progressive disease (PD) or relapse within 12 months after PET or at least 12 months of follow-up. A total of 275 patients were eligible for this analysis. The assessment was based on those patients confirmed by an expert panel as being PET-negative. CT verification was performed to identify false positive PET findings. The NPV was defined as the proportion of patients without progression or relapse within 12 months. *Results.* 9/216 patients with PET-negative residues and 9/59 patients with PET-positive residues had PD or relapse within one year of follow-up. The NPV was 0.958% (95% CI 0.931 - 0.985%). 244/245 patients with PET-negative residual masses, received not further irradiation. 62/66 patients with PET-positive residues, received additional radiotherapy. Progression/relapse rates were significantly different between those patients with residual mass being PET-negative or PET-positive (p=0.0053). PET-negative patients, who were assessed as partial response by CT, had a prognosis similar to those in complete remission. There was no significant difference in the progression free survival in this trial and the prior GHSG trials HD12 (arms pooled) and HD9 (arm C) for advanced-stage HL (p=0.266). Importantly, the proportion of patients receiving radiotherapy decreased from 70% (HD9-C) to 39% (HD12) and 12% (HD15). *Conclusions*. The high NPV of PET suggests that radiotherapy following 6 or 8 cycles of BEACOPP might be restricted to those patients who are PET-positive after chemotherapy.

Istituto Nazionale Tumori, University of Milano, MILANO, Italy

Background. Allogeneic stem cell transplantations (allo-SCT) with reduced intensity conditioning (RIC) regimens are increasingly performed in lymphomas. The number of studies on RIC allografting in Hodgkin lymphoma (HL) remains quite limited, several groups reported conflicting results, and no clear data exist on the clinical role of allo-RIC as an effective salvage option. HL patients relapsing after autologous SCT (auto-SCT) have a very dismal outcome with no therapeutic options able to obtain a durable disease control. *Aims*. To investigate the role of RIC allo-SCT in HL patients relapsing/progressing after auto-SCT. All our analysis was based on the commitment of the attending physician to perform an allo-SCT and therefore we retrospectively evaluated only those patients undergoing a HLA-typing immediately for the failure of auto-SCT. We compared patients receiving allogeneic transplantation (donor group) with those not having a suitable donor (no donor group) receiving a conventional treatment. *Patients and Methods*. 97 patients were retrospectively evaluated. For all patients, a search for a sibling or matched unrelated donor (MUD) was started at time of relapse/progression. 56 patients had a donor: 31 HLA-identical siblings (53%), 19 MUD (32%), 6 haploidentical family donor (15%). Thiotepa and fludarabine based regimens were used before allogeneic transplantation in all patients. Patients with no donor (n= 41) were treated according to the common policy of each center. All of them received chemo- and/or radiotherapy. *Results*. The median age of patient population was 30 years (17-62). After a median follow-up of 23 months (0-110), 29 patients are alive (52%) in the donor and 13 in the no donor group (32%). For all patients, the median overall (OS) and progression free survival (PFS) were 31 and 15 months, respectively. The 2-year OS and PFS were 60% and 29% respectively. The transplant-related mortality was 12% in the donor group. The 2-y OS and PFS were significantly better in the donor compared to the no donor group (OS 68% *vs* 50%, p 0.003, long rank test; PFS 31% *vs* 26%, p 0.03, Wilcoxon test). A pre allo-SCT positive PET scan correlated with a poor outcome. *Conclusions*. This retrospective study shows that RIC allogeneic transplantation is a feasible and useful option for HL patients failing an auto-SCT.

Giovanni and Paolo Hospital, VENEZIA, Italy; [15]Padoa University, PADOA, Italy; [16]Modena University, MODENA, Italy; [17]Palermo University, PALERMO, Italy; [18]National Institute of Tumours, MILAN, Italy; [19]University of Genoa, GENOA, Italy; [20]University of Turin, TURIN, Italy

Background. FDG-PET scan has been demonstrated as the only factor able to predict treatment outcome in advanced-stage HL patients treated with ABVD with much more efficacy than International Prognostic Score (IPS) (Gallamini JCO 2007). We present hear the updated result of this trial, on behalf of Intergruppo Italiano Linfomi and Danish Lymphoma Group. *Patients and methods.* Patients prospectively enrolled in the trial were treated with standard ABVD therapy x 6 courses. Consolidation radiotherapy was given in case of bulky presentation or residual tumour mass. Conventional radiological staging and FDG-PET scan were performed at baseline (PET-0) and after two courses of ABVD (PET-2). No treatment change was allowed based on the PET-2 results except in case of overt disease progression. Positive and minimally positive PET-2 scans were centrally reviewed. PET 2 was considered negative if the scan was negative o minimally positive (MRU^+). A study was defined as MRU^+ in presence of a non-focal uptake with a SUV lower, equal or slightly higher than mediastinal blood pool structures. *Results.* Two-hundred-sixty patients were enrolled in the study and are available for analysis. After a median follow-up of 3.15 years (0.6-6.3), 203 patients were in continued CR (cCR), 2 patients were in PR; 43 patients progressed during therapy, and 12 relapsed. Fifty-two patients were PET-2 positive and 208 patients were PET-2 negative. 44/52 PET-2 positive patients (84.6%) showed treatment failure (36 showed progression and 8 relapse) while 7 were in cCR and one in PR at the latest follow-up. 198/208 PET-2 negative patients (96.6%) were in cCR and one patient in PR at the latest follow-up, while 11 patients had experienced treatment failure. The 5-year FFS for PET-2 positive patients was 24.5% and for PET-2 negative 96.0% ($p<0.0001$). The sensitivity, specificity and overall accuracy of PET-2 for predicting 2-year PFS were 77%, 96%, and 92%, respectively. The positive predicting value (PPV) was 85% and the negative predicting value (NPV) was 95%. In univaried analysis the factors confirmed to be significant for FFS were PET scan, IPS (0-2 *vs* > or =3), stage IV, bulky disease and extranodal sites. In multivariate analysis the factors remaining significant were stage IV (HR 2.2) and PET (HR 21.8). In a matched 2-year PFS analysis, this study showed no prognostic value of IPS when the information from PET-2 is added. *Conclusions.* Since most if not all HL treatment failures are recorded within 3 years from diagnosis, PET-2 is able to predict with great efficiency the majority of treatment failures. For these reasons we propose to consider ABVD-treated HL patients with a PET-2 positive a distinctive HL subset characterized by a very poor outcome, requiring very aggressive therapy as early as possible during the course of the disease.

CNS HODGKIN LYMPHOMA: AN INTERNATIONAL PRIMARY CNS LYMPHOMA COLLABORATIVE GROUP (IPCG) REPORT OF 18 CASES

R. Gerstner,[1] L.E. Abrey,[2] D. Schiff,[3] A.J.M. Ferreri,[4] A. Lister,[5] S. Montoto,[5] R. Tsang,[6] E. Thiel,[7] F. Graus,[8] D. Behringer,[9] G. Illerhaus,[10] S. Weaver,[11] P. Wen,[12] N.L. Harris,[1] T.T. Batchelor[1]

[1]Massachusetts General Hospital, BOSTON, MA, USA; [2]Memorial Sloan-Kettering Cancer Center, NEW YORK CITY, USA; [3]University of Virginia, CHARLOTTESVILLE, USA; [4]San Raffaele H Scientific Institute, MILAN, Italy; [5]St. Bartholomew's Hospital, LONDON, UK; [6]Princess Margaret Hospital, TORONTO, Canada; [7]Charité-Campus Benjamin Franklin, BERLIN, Germany; [8]Hospital Clinic, BARCELONA, Spain; [9]Augusta-Kranken-Anstalt, BOCHUM, Germany; [10]University Hospital Freiburg, FREIBURG, Germany; [11]Albany Medical Center, ALBANY, USA; [12]Dana Farber Cancer Institute, BOSTON, USA

Background. Hodgkin lymphoma (HL) involves the central nervous system (CNS) in only 0.2-0.5% of all cases. Most published reports consist of single cases so there is little guidance for clinicians on how to manage this rare disease. *Aims.* To better understand the natural history of CNS involvement of HL. *Methods.* We collected detailed clinical data on 18 patients with meningeal or parenchymal CNS involvement of HL (CNS-HL) treated at 12 international centers from 1972-2007. *Results.* All 18 patients had classical HL: 8 classic HL not otherwise specified, 7 nodular sclerosis HL, and 3 mixed cellularity HL. Fourteen of the 18 patients had histological confirmation of CNS-HL by biopsy, resection, or autopsy and 4 patients had neuroimaging findings consistent with secondary CNS-HL. Only 1 patient had primary CNS-HL. In 7 patients, CNS-HL was discovered simultaneously with or prior to the diagnosis of systemic HL. For the remaining 10 patients, CNS-HL appeared an average of 10.3 months (range 4-189 months) after the diagnosis of systemic HL. Four of these 10 were in *systemic* CR when CNS-HL was discovered. Patients presented with a variety of symptoms at the time of CNS-HL diagnosis: pain/sensory symptoms (5/18), weakness (4/18), altered mental status (3/18), headache (4/18), and seizure (3/18). Lumbar puncture was performed in 11 patients and 6 had elevated protein in the CSF. Two patients had *atypical* cells, in 1 of these 2 the cells stained positive for CD30. Thirteen patients had intraparenchymal disease and 5 had dural-based lesions without parenchymal involvement. Multifocal disease was found in 5 patients, 2 of whom had brain, spinal cord, and meningeal involvement. Seven patients were treated with chemotherapy and radiation resulting in 2 PRs and 5 CRs; 5 received chemotherapy alone resulting in 3 CRs and 2 PDs; 4 received radiation alone (3 WBRT, 1 stereotactic radiosurgery) resulting in 3 CRs and 1 PR; 1 patient underwent gross total resection alone, and 1 patient had an unknown treatment history. In addition, 4 patients were given intrathecal chemotherapy with methotrexate or cytarabine and 2 patients received PBSCT. Radiographic response to any type of treatment was observed in 15/17 patients. Ten patients have died and the median overall survival is 55.8 months (range 4.5-235 months) after first diagnosis of HL (either systemic or CNS) and 39 months (range 2.2-46.8 months) after diagnosis of CNS-HL. Seven patients died from progressive HL, 1 patient died of a pulmonary embolism with evidence of systemic and CNS-HL at the time of autopsy, and 2 died of unrelated causes in CR. Only 2 of the 10 patients with CNS-HL at relapse are alive at 35 and 273 months of follow-up. *Summary and Conclusions.* CNS-HL is rare and our series of 18 patients is the largest one reported to date. Our data indicate that CNS-HL can affect any part of the CNS and can occur in the setting of widespread disease or when disease is well controlled. Although there is no established standard of care for CNS-HL, 15/17 treated patients achieved a radiographic response and long-term survival is possible.

MUTATION IN TMPRSS6, A SUPPRESSOR OF HEPCIDIN GENE EXPRESSION, IN FAMILIAL IRON DEFICIENCY ANEMIA

M.A. Melis,[1] M. Cau,[1] R. Congiu,[1] S. Barella,[1] A. Cao,[1] M. Westerman,[2] M. Cazzola,[3] R. Galanello[1]

[1]University of Cagliari, CAGLIARI; [2]Intrinsic LifeSciences, LA JOLLA, USA; [3]University of Pavia, PAVIA, Italy

Background. While genetic hemochromatosis is a common inborn error of iron metabolism, inherited disorders with defective iron absorption are extremely rare in humans. *Aims*. We studied a large Sardinian family in which microcytic anemia due to defective iron absorption and utilization is inherited as a recessive character, with the aim of identifying the mutant gene. *Case report and methods*. Three of the five patients were referred to hospital between 8 and 12 months of age because of anemia, while the other two were found to be moderately anemic during the study of the family. Anemia was severely microcytic (MCV from 50 and 55 fL) and hypochromic (MCH from 15 to 17 pg). Evaluation of body iron status showed low serum iron, normal TIBC and normal serum ferritin. Serum transferrin receptor levels were elevated, indicating a defective iron supply to the erythroid marrow. This condition is refractory to oral iron, and only partially responsive to parenteral iron administration. *Results*. Genome-wide scanning by microsatellites and single nucleotide polymorphisms showed a multipoint LOD score of 5.6 on chromosome 22q12.3, where the TMPRSS6 gene is located. Its murine counterpart (Tmprss6) has been recently found to be a suppressor of hepcidin gene expression, required for normal uptake of dietary iron. In fact, a splicing error in Tmprss6 has been detected in Mask mice, which have a recessive chemically induced phenotype characterized by progressive loss of body hair and severe iron deficiency due to reduced absorption. Sequencing analysis of TMPRSS6 revealed a homozygous mutation, predicting a splicing error, in affected members of the Sardinian family. Despite iron deficient erythropoiesis, a condition in which hepcidin concentration is expected to be almost undetectable, homozygous subjects had normal to high serum hepcidin levels. *Conclusions*. These observations suggest that the TMPRSS6 mutation leads to overproduction of hepcidin, and in turn to defective iron absorption and utilization. More generally, findings of this study confirm in humans the inhibitory effect of TMPRSS6 on hepcidin synthesis already demonstrated in Mask mice.

BIALLELIC MUTATIONS IN THE TELOMERASE COMPONENT NHP2 CAUSE THE PREMATURE AGEING SYNDROME DYSKERATOSIS CONGEINTA

J. Vulliamy,[1] R. Beswick,[1] M. Kirwan,1 A. Marrone,[2] M. Digweed,[3] A. Walne,[1] I. Dokal[1]

[1]Barts and The London School of Medicine and Dentistry, LONDON, UK; [2]Imperial College School of Medicine, LONDON, UK; [3]Institut fur Humangenetik, BERLIN, Germany

Background. Dyskeratosis congenita (DC) is a bone marrow failure syndrome characterized by a triad of muco-cutaneous features. A range of other somatic abnormalities may also be observed, including signs of premature ageing (early greying, dental loss), osteoporosis and malignancy. DC is genetically heterogeneous, but is unified by the fact that the mutations identified to date all affect molecules involved in telomere maintenance. These include components of the telomerase complex (dyskerin, the RNA component TERC, the reverse transcriptase component TERT and NOP10) which is responsible for maintaining telomere length. More recently, mutations have also been identified in a component of shelterin (TIN2), the telomere-associated protein complex. *Aims*. Many DC patients remain genetically uncharacterized. Here we describe the analysis of two other proteins, NHP2 and GAR1 that together with dyskerin and NOP10 are key components of telomerase and small nucleolar ribonucleoprotein (snoRNP) complexes. *Methods*. Mutation analysis has been performed by denaturing HPLC screening followed by direct DNA sequencing. Telomere lengths have been measured by Southern blot analysis. TERC levels and the effects of siRNA knockdown of gene transcripts have been assessed by quantitative real-time PCR measurements. *Results*. We have identified the first biallelic mutations in NHP2 and shown that can cause autosomal recessive DC. In contrast, we have not found any GAR1 mutations. Patients with NHP2 mutations, in common with patients bearing dyskerin and NOP10 mutations have short telomeres and low TERC levels. SiRNA mediated knockdown of NHP2 in human cells also led to a reduction in TERC levels, but this was not observed following GAR1 knockdown. *Summary and conclusions.* These findings suggest that in human cells GAR1 has a different impact on the accumulation of TERC compared to dyskerin, NOP10 and NHP2. Most of the mutations so far identified in patients with classical DC impact either directly or indirectly on the stability of RNAs. Specifically, patients with dyskerin, NOP10 and now NHP2 mutations have all been shown to have low levels of telomerase RNA in their peripheral blood providing direct evidence of their role in telomere maintenance in humans.

Background. MP has been the standard of care for newly diagnosed MM patients ineligible for high-dose therapy with stem cell transplantation (HDT-SCT). However, rates of complete response (CR) are low and median overall survival (OS) is typically 2-3 years. In a phase I/II trial of VMP in 60 elderly newly diagnosed patients, CR rate was 32%, and 3-year OS rate was 85%. *Aims*. The phase III VISTA study compared VMP with MP in previously untreated MM patients ineligible for HDT-SCT. Off-label use: bortezomib in front-line MM in a novel combination. Methods: Between December 2004 and September 2006, 682 patients from 151 centers in 22 countries in Europe, North and South America, and Asia were randomized (1:1) to 54 weeks treatment with VMP (N=344) or MP (N=338); stratification was by baseline β2-microglobulin and albumin, and region. All patients provided written, informed consent. Patients received nine 6-week cycles of melphalan 9 mg/m^2 and prednisone 60 mg/m^2, days 1-4, alone or with bortezomib (1.3 mg/m^2: days 1, 4, 8, 11, 22, 25, 29, 32, cycles 1-4; days 1, 8, 22, 29, cycles 5-9). The primary end point was time to progression (TTP). M-protein analyses were performed by a central laboratory. Progression was determined using European Group for Blood and Marrow Transplantation (EBMT) criteria. *Results*. Median age was 71 years; 30% of patients were aged ≥75 years, 34% had KPS ≤70%, 33% had β2-microglobulin >5.5 mg/L, and 34% had ISS Stage III disease. Based on a protocol-specified interim analysis, the Independent Data Monitoring Committee recommended the study be stopped, as the pre-specified statistical boundary for the primary end point (TTP) had been crossed. M-protein objective responses (≥50% reduction) were seen in 82% and 50% of patients receiving VMP and MP, respectively, including 35% and 5% immunofixation-negative M-protein CR. VMP was superior to MP for all time-to-event end points, including TTP (median 24.0 *vs* 16.6 months; HR=0.483, $p<0.001$), OS (median not reached in either group, HR=0.607, $p=0.0078$), and time to subsequent therapy (median not reached *vs* 20.8 months, HR=0.522, $p<0.001$). TTP superiority was seen consistently across patient subgroups defined by age, sex, race, region, β2-microglobulin level, albumin level, and ISS stage. VMP efficacy (M-protein CR rate - see table, TTP, and OS) was not affected by age (<75 *vs* ≥75 years), cytogenetics (high-risk vs standard risk), or creatinine clear-

ance (≥60 *vs* <60 mL/min). VMP was well tolerated; patients remained on therapy for a median of 46 weeks (8 cycles) versus 39 weeks (7 cycles) with MP. The rate of serious AEs was higher with VMP (46% *vs* 36%), but rates of grade 4 AEs (28% *vs* 27%) and treatment-related deaths (1% *vs* 2%) were similar. Grade 3/4 sensory neuropathy occurred in 13% of VMP patients; 74% of peripheral neuropathy events resolved/improved in a median of 2 months. Conclusions: VMP is significantly superior to MP in newly diagnosed MM patients ineligible for HDT-SCT. These results establish VMP as a new standard of care in this patient population.

Table 1.

VMP patients	M-protein CR rate
All patients (N=336)	35%
Aged ≥75 years (n=106)	33%
Aged <75 years (n=230)	36%
High-risk cytogenetics (n=26)	35%
Standard-risk cytogenetics (n=142)	32%
Creatinine clearance <60 mL/min (n=182)	35%
Creatinine clearance ≥60 mL/min (n=154)	34%

Background. Children with Down Syndrome (DS) have a markedly increased risk for acute megakaryoblastic (AMKL) and lymphoblastic (ALL) leukaemias. DS-AMKL is uniquely characterized by an acquired mutation in GATA1. The existence of similar collaborating mutations in DS-ALL has remained elusive. Constitutive activation of JAK/STAT pathway occurs in several hematopoietic malignancies. We hypothesized that mutations in JAK2 might be a common molecular event in DS-ALL. *Aims*. To characterize the prevalence, the specificities and functional consequences of JAK2 mutations in DS-ALL. *Methods*. We analyzed JAK2 DNA analysis by denaturing high-performance liquid chromatography and sequencing was performed on 89 diagnostic DS-ALL and on 216 sporadic ALL, DS-AMKL and essential thrombocythemia samples obtained from major European Leukemia Groups. The functional consequences of identified mutations were studied in mouse pro-B cells. *Results*. Acquired JAK2 mutations were identified in 16 (18%) DS-ALL patients; The only non-DS ALL patient with JAK2 mutation had an iso-chromosome 21q, later shown to be a DS mosaic. Children with a JAK2 mutation were significantly younger (mean 4.5 *vs* 8.5 yrs, $p<0.001$) at diagnosis. Five mutant alleles were identified, each affecting a highly conserved arginine residue (R683). Modeling of JAK2 pseudokinase domain revealed that R683 is situated in an exposed conserved patch separated from the one involved in MPDs. The mutations caused constitutive JAK/STAT activation and cytokine independent growth of BaF3 cells that was sensitive to treatment with JAK2 inhibitors. *Conclusions*. Somatically acquired R683 JAK2 mutations define a distinct ALL subgroup which is uniquely associated with trisomy 21. JAK2 inhibitors may be useful for treatment of these leukemias. There is a striking genotype-phenotype association between the type of somatic mutation within the JAK2 pseudokinase domain and either B-lymphoid or myeloid neoplasia.

IFN-α PROMOTES PROLIFERATION OF DORMANT HSCS *IN VIVO*, MAKING THEM SUSCEPTIBLE TO ELIMINATION BY CHEMOTHERAPY

M.A.G. Essers,[1] S. Offner,[2] W.E. Blanco-Bose,[2] Z. Waibler,[3] U. Kalinke,[3] M. Duchosal,[4] A. Trumpp[2]

[1]ISREC, School of life sciences, EPFL, EPALINGES, Switzerland; [2]ISREC, School of Life Sciences, Ecole Polytechnique Fédérale de Lausanne (EPFL), EPALINGES, Switzerland; [3]Paul Ehrlich Institute, LANGEN, Germany; [4]Centre Hospitalier Universitaire Vaudois, LAUSANNE, Switzerland

The life-long maintenance of blood is dependent on the activity of bone marrow haematopoietic stem cells (HSCs), which are multipotent and display long term self-renewal capacity. In the mature organism, stem cell activity is retained in a reservoir of dormant HSCs, which do not significantly contribute to the daily haematopoiesis. However, upon haematopoietic injury these cells can be efficiently recruited into the cell cycle actively supporting the recovery of the haematopoietic system. Up to now, the signals, which promote the exit of HSCs out of the dormant stage, are largely unknown. Here we show that HSCs efficiently exit G0 and enter the cell cycle in response to treatment with interferon-alpha (IFNα) *in vivo*. IFNα treatment results in the phosphorylation of STAT1 and PKB/Akt, and expression of IFNα target genes in HSCs, as well as stem cell antigen (Sca-1) up-regulation at their surface. HSCs lacking IFNAReceptor, STAT1 or Sca-1 do not show increased proliferation in response to IFNα stimulation. Priming of HSCs with IFNα followed by treatments with the anti-proliferative chemotherapeutic agent 5-FU causes lethality due to HSC exhaustion, indicating that 5-FU resistant dormant HSCs can be sensitized to this drug by pre-treatment with IFNα *in vivo*. These results demonstrate a novel role for IFNα on activation of dormant stem cells in vivo and, since dormancy is thought to be a typical feature of certain haematological tumour cells as well, may help to clarify the so far unexplained clinical effects of IFNα on dormant leukaemic stem cells.

LCK IS A CRITICAL SIGNALING EFFECTOR IN NUP214-ABL1 POSITIVE T-ALL

K. De Keersmaecker, M. Porcu, O. Gielen, J. Cools

K.U.Leuven, LEUVEN, Belgium

Background and Aims. T-ALL is characterized by the presence of different types of mutations leading to cell cycle defects, impaired differentiation, abnormal proliferation and unlimited self-renewal. Fusion genes involving the tyrosine kinase ABL1 were identified as mechanisms that provide a proliferation and survival advantage to leukemic cells. The NUP214-ABL1 fusion gene is the most common ABL1 fusion in T-ALL, found in 6% of T-ALL patients. NUP214-ABL1 is sensitive to the ABL1 kinase inhibitor imatinib, and proliferation of NUP214-ABL1 expressing Ba/F3 and ALL-SIL cells is inhibited by imatinib. However, treatment of NUP214-ABL1 positive patients with imatinib might result in development of imatinib resistance, similarly to what has been described in imatinib treated BCR-ABL1 positive patients. In this study, we aimed at identifying critical signaling proteins downstream of NUP214-ABL1 that could be used as alternative therapeutic targets for treatment of NUP214-ABL1 positive T-ALL. *Results.* The SRC family kinase LYN is known to be required for BCR-ABL1 induced B-ALL development. We observed that the NUP214-ABL1 positive T-ALL cell line ALL-SIL was sensitive to the SRC family kinase inhibitor PP2, suggesting also a critical role for one or more SRC family kinases in NUP214-ABL1 signaling. Analysis of expression and phosphorylation of all SRC family members in ALL-SIL cells suggested that the PP2 induced effects in this cell line were due to inhibition of LCK and/or FYN. We confirmed that LCK phosphorylation was inhibited by PP2, and that siRNA mediated knock-down of LCK resulted in a marked reduction of cell viability, similar to the effect observed by inhibition or knock-down of NUP214-ABL1 itself. In contrast, siRNA mediated knock-down of FYN only resulted in a weak inhibitory effect on the proliferation of ALL-SIL, indicating that this SRC family kinase was not critically required. PP2 treatment or knock-down of LCK expression had no significant effect on T-ALL cell lines not transformed by NUP214-ABL1, suggesting that LCK activation is specific to NUP214-ABL1 transformed T-cells. *Summary and conclusions.* Although imatinib efficiently inhibits NUP214-ABL1 activity, we expect that NUP214-ABL1 positive T-ALL patients treated with this drug might develop imatinib resistance. Our data indicate that LCK activity is critical for NUP214-ABL1 signaling and that LCK could represent an alternative therapeutic target for treatment of NUP214-ABL1 positive T-ALL. Further *in vivo* analysis of the potential of LCK as a target in NUP214-ABL1 positive T-ALL is warranted.

UNINTENTIONAL TRANSPLANTATION OF T CELL LYMPHOBLASTIC LEUKEMIA OF THE DONOR TO THREE DIFFERENT ORGAN RECIPIENTS WITH SIGNIFICANT HLA INCOMPATIBILITIES

W. Jedrzejczak,[1] J. Dwilewicz-Trojaczek,[1] A. Dmoszynska,[2] L. Konopka,[3] B. Ziarkiewicz-Wroblewska,[1] E. Chmarzynska-Mroz,[1] G. Charlinski,[1] A. Gronkowska,[1] B. Kaczmarek,[1] H. Stanczak,[1] M. Nowaczyk,[1] A. Sadowska[1]

[1]Medical University of Warsaw, WARSAW; [2]Medical University of Lublin, LUBLIN; [3]Institute of Hematology and Transfusion Medicine, WARSAW, Poland

Background. Despite the performance of hundred thousands organ transplantations in the world we failed to find a report of the transplantation of leukemia of organ donor together with transplanted solid organ. It is commonly assumed that unlike cells of solid tumors, leukemic cells are readily available to the immune system of the recipient, that under conditions of multiple HLA incompatibilities is still able to destroy them, despite posttransplant immunosuppression. *Description of cases*. In June 2005 four patients received organs from 19-year old previously healthy male donor that died accidentally. No donor autopsy was performed but examination of some adipose tissue adjacent to the transplanted liver revealed the presence of T cell lymphoma $CD3^+$,Tdt^+, MIB^+, $CKMNF^-$, $CD10^-$,$CD20^-$, while liver itself seemed not to be affected. The heart recipient died soon thereafter, but recipients of the liver (30 yr old male with Wilson disease) and both kidneys (32 yr old male and 59 yr old female with renal insufficiency) survived. In all these patients in January 2006 (i.e. 6-7 months after transplantation) T cell lymphoblastic leukemia bearing the same phenotype as T cell lymphoma earlier found in donor tissue was diagnosed. In two patients it was also found that this leukemia (HLA type of the donor) had the same cytogenetic abnormalities [46, XY, t(1;14)(p32;q11),del (9)(q32)], while one of these recipients was a female. HLA typing has revealed that between the donor and all recipients existed some shared specificities. Between the donor and recipient of the liver there was compatibility of one class I antigen, between the donor and female kidney recipient compatibility of one class I and one class II antigen. Finally, between the donor and male kidney recipient there was compatibility of one class I and two class II antigens. This means that the recipients have been incompatible with the donor at 5/6, 4/6, and 3/6 antigens respectively, and yet leukemia developed in all of them at almost the same time. All patients after transplantation received tacrolimus in standard doses. All have been treated for leukemia with chemotherapy, and all promptly achieved complete remission. This remission is still maintained in the recipient of the liver. Male recipient of the kidney had one relapse and is in the 2nd complete remission, while female kidney recipient died of fungal infection during an attempt to induce the fourth complete remission. Transplanted organs are functioning in two surviving patients and also in succumbed patient the kidney was functioning almost until death in January 2007. *Conclusions.* These data indicate, that T lymphoblastic leukemia is transplantable despite large HLA incompatibilities and low tumor load. Immune system seem to be unable to reject such leukemia at least when depressed by tacrolimus.

GENOME PROFILE OF PH POSITIVE ALL IN ADULT PATIENTS

A. Chanalaris,[1] D. Brazma,[1] L. Rai,[1] A. Chanalaris,[1] J. Howard,[1] M. Valgañón,[1] C. Grace,[1] L. Foroni,[2] E.P. Nacheva[1]

[1]Royal Free & UC Medical School, LONDON; [2]Imperial College London, Hammersmith Campus, LONDON, UK

Background. Acute lymphoblastic leukemia (ALL) accounts for 15% of all leukaemias in adults. Philadelphia positive (Ph^+) ALL is the most common form of adult ALL accounting for 15-30% of adult ALL. Ph^+ ALL patients have the most unfavourable prognosis with overall disease free survival of less than 10%. *Aims.* As there is limited information in the genomic profile of adult ALL we employed aCGH to complete a genome profile of Ph^+ ALL. *Methods.* 21 patients with Ph^+ ALL were investigated by comparing DNA from presentation and remission bone marrow samples using oligonucleotide array CGH at resolution of 65kbp. FISH and RT-PCR assessed the presence of BCR/ABL1 fusion in all presentation samples. Additionally, G-banding analysis was carried out in 5 patients. *Results.* Copy number aberrations (CNA) were detected in all samples. Six genome segments, ranging in size from 120kb to over 1Mb were recurrently affected and over 200 single locus imbalances were found in 3 or more (~30%) samples. Some 65% of all CNA were found to involve regions within the resolution of the cytogenetic analysis. In order of frequency the whole chromosome CNA found are: gain/loss of X (8/14); gain of 8 (6/14); gain of 4 (5/14); gain of 14(5/14); gain of 21 (3/14). Lack of correlation between the aCGH and karyotype data is apparent in many samples, but further work is required to build up a precise map of these discrepancies. Among the most frequent segmental changes is the loss of a common region within 14q32 (105.350-105.480) that contains part of the Immunoglobulin heavy chain locus, as seen in 9/21 samples. In further 7 samples the loss included the TCR-alpha chain sequences (14q32 141.94-141.99). Deletions at 9p21, covering a common region (21.36-22.69) were found in 5/21 samples. The 135kb region, that houses the genes CDCN2A&2B, interferon α 1,2,8 & e1 and the BC015960 (p16) genes, is several fold smaller than the 9p loss identified recently by 1Mbp BAC aCGH in 58 patients with B and T/ ALL (Strefford *et al.*, 2007). Loss of 9q34 and 22q11 sequences consistent with deletions of der(9)t(9;22) were found in 2/21 cases (~10%), while genome gains associated with double Ph chromosome were less than expected (14%). In addition to gains of either the whole chromosome 8 or the 8q arm, an ~ 700kb segment from 8q24.3 (145.00-145.70) was found amplified in two samples. Containing several genes this amplicon differs from the ones described in AML (Storlazzi *et al.*, 2005) and CML (Brazma *et al.*, 2007). Finally, over 15 single locus imbalances detected in 6 or more patients, have been reported as polymorphic markers (CNVs) in disease free individuals. Their identification as secondary aberrations in sequential Ph^+ ALL samples adds new aspects to the cur-

rent concept about the biological role of this polymorphism. *Conclusions*. These findings generate an unique genome profile for Ph+ ALL, substantially different from both ALL and CML to merit further investigations.

0479

IDENTIFICATION BY OLIGONUCLEOTIDE ARRAYS OF A SUBSET OF T-ALL PATIENTS WITH MYELOID-LIKE GENE PATTERN: POTENTIAL MECHANISMS OF TRANSFORMATION

S. Chiaretti, M. Messina, S. Tavolaro, V. Fulci, I . Della Starza, R. Maggio, A.D. Negulici, V. Di Maio, A. Vitale, G. Macino, A. Guarini, R. Foà

University Sapienza, ROMA, Italy

Background. Until recently, few molecular aberrations were recognized in acute lymphoblastic leukemia of T-cell origin (T-ALL). The scenario is rapidly changing; novel lesions are emerging and they include rearrangements (i.e. SIL/TAL1, CALM/AF10 and NUP214/ABL), gene overexpression (i.e. LYL, TLX1, TLX3, TAL1) and mutations (NOTCH1, PTEN). Furthermore, it is now clear that there is a certain degree of overlap between acute myeloid leukemia (AML) and T-ALL: it was recently described that CEBPA hypermethylation induce, in a subset of AML patients, an increased expression of T-cell-related genes. In this context, gene expression profiling is useful in identifying previously unrecognized subentities. *Aims*. To identify, using gene profiling, novel entities of T-ALL and to investigate their clinico-biologic features. *Methods*. Within the MILE study (Microarray Innovations in LEukemia, sponsored by Roche Molecular Systems) we evaluated, using HGU133 Plus 2.0 arrays, 52 adult patients with T-ALL at diagnosis: 3 patients harbored SIL/TAL, 2 BCR/ABL, 1 NUP/ABL1, 1 CALM/AF10 and 2 a rearrangement involving ALL1. Statistical analysis ,performed using the dChip software, was based on unsupervised analysis; real-time quantitative PCR (Q-PCR) was used to validate the results obtained on a set of genes. *Results*. By unsupervised clustering we identified at least 3 T-ALL subgroups. The first distinct cluster included SIL/TAL+ patients; the second cluster included all cases exhibiting high levels of HOXA gene expression: in agreement with previous reports, the 2 ALL1+ and the CALM/AF10+ patient were included in this branch. Finally, the third group (defined for simplicity *myeloid T-ALL*) included 5 patients whose gene profile resembled that of AML cases. In fact, they were characterized by the overexpression of a large set of myeloid-related genes: 1) surface antigens; 2) transcription factors, namely CEBPA, CEBPB, CEBPD, MNDA and MAFB; 3) granule proteins, as myeloperoxidase (MPO) and lysozime. Flow cytometry confirmed that they were undoubtedly of T derivation, being all CyCD3 and CyCD7+. Cytogenetic analysis was not available; however, molecular screening did not reveal the presence of typical myeloid fusion products. In order to validate gene expression results, we performed Q-PCR on MPO, CEBPA and CEBPB: for all the 3 genes teste, and their overexpression was confirmed (T-ALL *vs* myeloid T-ALL p=0.0001, 0.005 and 0.0002, respectively). Given the overexpression of several members of the CEBP family, and in particular of CEBPA, we also sought to evaluate the expression levels of miR-223, known to be regulated by CEBPA and to have a role in myeloid differentiation: these cases had significantly higher levels of miR-223 when compared to remainder T-ALL (p=0.0002), comparable to those observed in AML. *Conclusions*. By gene profiling it is possible to identify a subset of T-ALL patients, representing 10% of those analyzed, who display myeloid features. Notably, these cases were not recognized by standard approaches, underlying the importance of gene profiling. Since these cases are characterized by the overexpression of CEBPA and miR-223, further studies are warranted to understand the relation between these 2 RNAs and to evaluate potential epigenetic modifications involved.

ETV6/RUNX1 INTERFERES WITH SPINDLE CHECKPOINT FUNCTION AND TP53 SURVEILLANCE THEREBY PROMOTING TETRAPLOIDIZATION

E. Panzer-Grümayer,[1] A. Inthal,[1] R. Joas,[1] L. Orel,[1] G. Fuka,[1] A. Haas,[2] G. Krapf[1]

[1]Children's Cancer Research Institute, VIENNA; [2]St. Anna Kinderspital, VIENNA, Austria

Background. The chromosomal translocation t(12;21)(p13;q22) occurs in about 25% of childhood B cell precursor (BCP) ALL and generates the ETV6/RUNX1 fusion gene (also known as TEL/AML1). This gene rearrangement is an initiating event in leukemia development but requires further genetic alterations for the clinical manifestation of the leukemia. Unlike all other BCP ALL subtypes ETV6/RUNX1 positive ALL may display a near tetraploid karyotype suggesting that the fusion protein and/or its ensuing secondary mutations interfere with cell cycle regulation and TP53 surveillance. The most important control for mitotic failures during cell division is the spindle-assembly checkpoint (SAC). Its activation in pro- and promethaphase delays onset of anaphase via inhibition of the anaphase promoting complex/cyclosome until all kinetochors are attached to microtubules. The aim of this study was to elucidate the mechanism by which ETV6/RUNX1 impacts on SAC thereby causing polyploidization. Experimental set up: Stably ETV6/RUNX1 expressing clones of the murine pro-B cell line Ba/F3 and human leukemic cell lines (REH, AT-1, AT-2, which carry the ETV6/RUNX1 fusion gene) were used as model systems. To assess the functionality of the major control systems that prevent aneuploidy SAC activation and TP53 protein phosphorylation were evaluated. Furthermore, key regulatory proteins of SAC were analyzed upon chemical activation by microtubule-altering drugs (i.e. nocodazole and paclitaxel). TP53 activation was studied via double strand break induction using the TopoII inhibitor VP16. *Results.* Expression of ETV6/RUNX1 induced tetraploidization in Ba/F3 clones while controls containing several other constructs remained diploid. We then went on to study the effects of ETV6/RUNX1 on SAC activity but also on protein levels of its key components. SAC was attenuated in fusion gene carrying leukemic cell lines upon chemical activation, as indicated by a reduced mitotic index. Furthermore, these cells also showed *slippage* into G1 phase without increase in apoptosis. At the protein level, ETV6/RUNX1 expressing cells had reduced amounts of MAD2L1 and BUBR1, the major key players of the mitotic checkpoint complex, compared to controls. In keeping with recent reports indicating that reduced MAD2L1 and BUBR1 protein levels inhibit also DNA damage-induced mitotic arrest and consecutive cell death, we showed that this could also be the case for ETV6/RUNX1 positive cells based on reduced phosphorylation of TP53 at S15 after DNA damage. Based on our findings we assume that the chimeric protein ETV6/RUNX1 attenuates the spindle checkpoint and TP53 activity and thereby sensitizes cells to polyploidization. As only a small proportion of t(12;21) positive ALL have a near tetraploid karyotype, it is tempting to speculate that ETV6/RUNX1 leads to the manifestation of this phenotype only in collaboration with particular secondary events or predisposing factors. Studies are under way to test this hypothesis.

CO-ADMINISTRATION OF 2-DEOXY-D-GLUCOSE ALLOWS DEXAMETHASONE DOSAGE REDUCTION IN THE INDUCTION THERAPY OF LYMPHOBLASTIC LEUKEMIA

K. Eberhart,[1] K. Renner,[2] I. Ritter,[2] C. Hellerbrand,[3] B. Timischl,[2] R. Kofler,[4] P. Oefner[2]

[1]University of Regensburg and Tyrolean Cancer Research Institute, REGENSBURG, Germany; [2]University of Regensburg, Institute of Functional Genomics, REGENSBURG, Germany; [3]University of Regensburg, Department of Internal Medicine, REGENSBURG, Germany; [4]Tyrolean Cancer Research Institute, INNSBRUCK, Austria

Background. Glucocorticoids (GC) are used in the therapy of acute lymphoblastic leukemia (ALL) in combination with other chemotherapeutics because of their ability to induce apoptosis and cell cycle arrest. However, GC exert severe side effects and resistance develops frequently. Hence, there is a demand for improved treatment protocols. Our gene expression profiles of patients undergoing GC monotherapy suggested that the enzyme phosphofructokinase/fructosebiphosphatase-2 (PFKFB2) may play a crucial role in GC-induced apoptosis via alterations in glucose utilization. *Aims.* The development of a new treatment to reduce the effective dose of GC by amplifying the glycolytic disturbances and harm preferentially cancer cells. To this end, we investigated the combinatory treatment of GC and 2-deoxy-D-glucose (2-DG), in a concentration tolerated by cancer patients, when systemically administered. 2-DG is a nonmetabolizable glucose analog, which accumulates intracellularly as 2-deoxy-glucose-6-phosphate (2-DG-P). *Methods.* Acute lymphoblastic T-cells (CCRF-CEM-C7H2) and pre-B ALL cells (preB-697) were treated with 100 nM dexamethasone and either 3 mM or 1 mM 2-DG, respectively. Apoptosis was determined by Annexin V/PI stain and sub G1-peak detection. Intracellular accumulation of 2-DG-P was determined by CE-ESI-MS. Lactate and glucose concentrations in the supernatant were analyzed by enzymatic assays, ATP by a luciferase assay. Mitochondrial function was examined by high-resolution respirometry. Hexokinase II expression was analyzed by RT-PCR and

immunoblotting after cellular fractionation. Primary lymphoblasts of patients were co-cultured with fibroblasts. *Results.* T- and preB-ALL cell lines were dramatically sensitized to GC-triggered apoptosis by the co-administration of 2-DG, allowing a 20-fold reduction of the effective dose of GC. 2-DG treatment resulted in a 2-fold doubling time. Human primary resting and activated lymphocytes showed no effect on sole 2-DG treatment and no synergistic effect on the combinatory treatment. 2-DG accumulated intracellularly 2-DG-P (200 nM/mg protein). The combination of 2-DG and GC resulted in a reduction of glycolysis, mitochondrial oxidative phosphorylation and ATP levels. This ATP drop might be partially responsible for the synergism of 2-DG and GC, since restoring ATP level by the administration of pyruvate could prevent this effect in preB cells. In T-ALL cells we could not elevate ATP concentration by the administration of pyruvate. Mitochondrial bound hexokinase II expression was reduced at mRNA and protein levels, leading to membrane alterations and release of pro-apoptotic factors. Preliminary data suggest additional alterations in the lipid composition of the mitochondrial membrane. Hexokinase II reduction in combination with the observed decrease in glucose up-take might explain the decline in energy metabolism. First patient samples treated *ex vivo* are under investigation. *Conclusions.* GC as well as 2-DG disturb the energy metabolism, thereby amplifying each others effects. Since cancer cells are strongly dependent on glycolysis, the observed glycolytic changes suggest that cancer cells are harmed preferentially. The co-administration of 2-DG and GC holds the promise of an improved therapy protocol for the treatment of ALL.

0482

RARE INCIDENCE BUT EXTREME DIVERSITY OF PAX5 FUSION GENES IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

K. Nebral,[1] M. König,[1] G. Mann,[2] O.A. Haas,[2] S. Strehl[1]

[1]CCRI, Children's Cancer Research Institute. St. Anna Kinderkrebsforschung, WIEN; [2]St. Anna Children's Hospital, WIEN, Austria

Background. PAX5 encodes the B-cell lineage specific activator protein (BSAP) and is required for B-cell development and lineage maintenance. Pax5 fulfills a dual role by activating B-cell specific genes and simultaneously repressing lineage-inappropriate genes. In B-cell non-Hodgkin's-Lymphoma with a t(9;14)(p13;q32), PAX5 is juxtaposed to the IGH locus, which results in overexpression of PAX5. In acute lymphoblastic leukemia (ALL) it has been shown that PAX5 can fuse to FOXP1 (3p13), AUTS2 (7q11), ELN (7q11), ETV6 (12p13), PML (15q24), ZNF521 (18q11), and C20orf112 (20q11). *Aims and Methods.* To determine the overall incidence of PAX5 rearrangements in childhood ALL dual-color split-apart FISH assays using BAC clones flanking the PAX5 gene as well as PAX5 exon-specific cosmid probes were used. This FISH approach allows for the detection of all PAX5 rearrangements independent of the partner gene, including also those resulting in juxtaposition of PAX5 under regulatory elements of a partner gene. Novel fusion partners were identified by 5' and 3' RACE. The presence of a specific fusion gene was verified by RT-PCR and sequence analysis or fusion gene-specific FISH. *Results*. In a retrospective study, more than 400 patients enrolled in the Austrian ALL-BFM 2000 study were screened for PAX5 rearrangements. Six patients showed a separation of the PAX5 FISH probes and three showed PAX5-3' deletions as well indicating PAX5 rearrangements. Out of these 9 patients, one each has been previously shown to harbor a dic(9;12)(p13;q13)/PAX5-ETV6 and a t(9;15)(p13;q24)/PAX5-PML aberration. Of the remaining 7 cases, in one patient showing a PAX5-3' deletion, fusion gene-specific FISH and RT-PCR detected a PAX5-C20orf112 fusion. In four patients 5' or 3' RACE identified novel PAX5 chimeric transcripts and subsequent RT-PCR confirmed that PAX5 was fused to HIPK1 (1p13), POM121 (7q11), DACH1 (13q21), and BRD1 (22q13.33). The remaining two cases were extensively analyzed by FISH, RT-PCR and RACE, but no fusion gene could be delineated so far. All hypothetical fusion proteins fuse the C-terminal region or even the entire protein of the fusion partner to the PAX5 paired DNA-binding domain, or parts of the transactivation domain. Thus, all PAX5 fusion proteins are predicted to retain the ability to bind to PAX5 target genes, but would no longer provide normal transcriptional regulatory functions. *Conclusions*. We could determine that in childhood ALL PAX5 rearrangements occur at an incidence of about 2% and have identified the fusion partners in seven cases, which included four with novel PAX5 in-frame fusions to HIPK1, POM121, DACH1, and BRD1. Our data show that PAX5 fusions, though a rare event, fuse PAX5 to a broad range of different partner genes with diverse functions including not only transcription factors but also structural proteins.

0483

NK-LIKE HOMEODOMAIN PROTEINS ACTIVATE TRANSCRIPTION OF POLYCISTRONIC MIR-17-92 AND INHIBIT ETOPOSIDE-INDUCED APOPTOSIS IN T-ALL CELLS

S. Nagel,[1] L. Venturini,[2] G.K. Przybylski,[3] P. Grabarczyk,[4] C. Corinna,[1] H.G. Drexler,[1] C.A. Schmidt,[4] R.A.F. MacLeod,[1] M. Scherr[2]

[1]DSMZ, BRAUNSCHWEIG, Germany; [2]Medical School Hannover, HANNOVER, Germany; [3]Polish Academy of Sciences, POZNAN, Poland; [4]University of Greifswald, GREIFSWALD, Germany

Background. Homeobox genes code for transcription factors, impacting developmental processes and oncogenesis if mutated or dysregulated. The NK-like familiy of homeobox genes includes TLX1, TLX3 and NKX2-5 which are ectopically activated in T-cell acute lymphoblastic leukemia (T-ALL) cells mostly via chromosomal aberrations. The pathologic function of these closely related genes is still unclear. Here we analyzed their effect on the C13orf25 gene, containing the miR-17-92 cluster. Micro RNAs (miRNAs) are a class of deeply conserved small non-coding RNAs which regulate gene expression by hybridization to complementary sequences usually located in the 3´untranslated region of coding transcripts. The primary transcripts (pri-mRNA) are processed to short mature miRNAs, mediating either inhibition of mRNA translation or mRNA cleavage. Aberrant expression of specific miRNAs is involved in oncogenesis as recently described for several human malignancies. The miR-17-92 polycistron encodes miRNAs which reduce E2F1 and PTEN protein expression. Transcription of both E2F1 and miR-17-92 is induced by MYC, itself a target of E2F1, generating a highly regulated interactive network. Depending on the cellular context, E2F1 performs conflicting tasks by triggering proliferation or inducing apoptosis. *Aims.* Here we investigated expression and function of the miR-17-92 cluster in T-ALL cells. *Results.* Real-time RT-PCR analysis of both miR-17-92 pri-mRNA and mature miRNAs revealed different expression levels in these cells, suggesting a possible implication of the NK-like homeodomain proteins in the regulation of the miR-17-92 cluster in T-ALL. HELA cells transfected with TLX1 or NKX2-5 expression constructs showed elevated miR-17-92 pri-mRNA expression, demonstrating an activating effect. Lentiviral-mediated overexpression of NKX2-5 in the T-ALL cell line MOLT-4 consistently showed increased miR-17-92 pri-mRNA levels and decreased E2F1 protein amounts. For functional analysis of these downstream targets, another T-ALL cell line (PEER) was lentivirally transduced with expression constructs for either miR-17-92 or E2F1, resulting in reduced or elevated E2F1 protein levels, respectively. Overexpression of miR-17-92 or E2F1 did not significantly influence cell proliferation. However, induction of apoptosis by treating these cells with etoposide, an inhibitor of topoisomerase II, indicated that overexpression of miR-17-92 and E2F1 resulted in enhanced and reduced cell viability, respectively, as analyzed by MTT assay. Furthermore, expression analysis of miR-17-92 pri-mRNA in primary T-ALL samples positive for TLX1/3 expression, respectively, displayed elevated levels in comparison to control samples. *Conclusions*. In summary, these data indicate an activatory effect of oncogenic NK-like homeodomain proteins on miR-17-92 expression, reducing E2F1 protein levels and thereby enhancing survival of leukemic T-cells.

CHARACTERIZATION OF NUP214-ABL1 POSITIVE T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA REVEALS GENOMIC HETEROGENEITY OF THE FUSION GENE PRESENTATION

C. Graux,[1] N. Dastugue,[2] M. Lafage,[3] F. Mugneret,[4] S. Struski,[5] M.J. Grégoire,[6] N. Nadal,[7] E. Lippert,[8] M. Stevens-Kroef,[9] P. Vandenberghe,[10] L. Michaux,[10] A. Bosly,[1] I. Wlodarska,[10] I. Lahortiga,[10] K. De Keersmaecker,[10] J. Cools,[10] A. Hagemeijer,[10] H.A. Poirel[1]

[1]UCL, YVOIR, Belgium; [2]Hôpital Purpan, TOULOUSE, France; [3]Institut Paoli-Calmettes, MARSEILLES, France; [4]CHU Dijon, DIJON, France; [5]CHU Strasbourg, STRASBOURG, France; [6]CHU Nancy, NANCY, France; [7]CHU St Etienne, ST ETIENNE, France; [8]CHU Bordeaux, BORDEAUX, France; [9]Academisch Ziekenhuis, NIJMEGEN, Netherlands; [10]KUL, LEUVEN, Belgium

Background. The t(9;22) generating the BCR-ABL1 fusion is the hallmark of CML, and also characterizes 25% of B-ALL cases. BCR-ABL1 is extremely rare in T-ALL, but we recently identified a NUP214-ABL1 fusion in about 6 % of T-ALL cases. A unique feature of NUP214-ABL1 is its presence on extrachromosomal amplified material (episomes). To

date, only 1 NUP214-ABL1 positive T-ALL case has been described without episomes, but with an intrachromosomal amplification of the fusion gene on chromosome 2. In the current study we analysed 16 additional NUP214-ABL1 positive T-ALL cases and 3 T-ALL cell lines to characterize their clinical and genetic presentations. *Methods*. In collaboration with the GFCH, we retrospectively collected 346 T-ALL bone marrow, blood or pleural fluid samples from 15 different centres. FISH and/or RT-PCR were performed to determine the presence and genetic presentation of the fusion gene. *Results*. We identified 16 NUP214-ABL1 positive T-ALL cases. Median age was 15,5 years (3 to 45) with a male predominance (12:5). The 12 samples with available information showed an HOX11 or HOX11L2 abnormality as assessed by FISH or RT-PCR confirming the specific occurrence of NUP214-ABL1 with HOX11 or HOX11L2. Among the 14 cases with available data on outcome, we observed 1 primary refractory and 5 relapse cases of which 4 occurred early. FISH analysis of these cases revealed a variable pattern of NUP214 and ABL1 signals. Thirteen of the 15 samples that could be evaluated by FISH showed episomal amplification. In 1 case, episomal and intrachromosomal amplification of the NUP214-ABL1 fusion was observed. One other case was characterized by episomes, intrachromosomal amplification and an additional insertion of the non amplified NUP214-ABL1 fusion on 14q. One case only demonstrated intrachromosomal amplification. Finally, 1 case showed no detectable rearrangement of NUP214 or ABL1 by FISH, but was positive by RT-PCR. Three cell lines with the NUP214-ABL1 fusion only showed the presence of an intrachrosomal amplified NUP214-ABL1 fusion on 9q34. *Conclusions*. Our work stresses the interest of combining both FISH and RT-PCR for the identification of the NUP214-ABL1 fusion, since the fusion gene may only be present in a fraction of the cells. Our data confirm that the NUP214-ABL1 fusion is in most cases associated with episomal amplification, but that also intrachromosomal amplification or insertion into random chromosomes can occur. This heterogeneous presentation of the NUP214-ABL1 fusion provides insight in the mechanisms of episome formation, amplification and optionnal reintegration. It underlines also that NUP214-ABL1 is supported by episomes that have the property to amplify and we have to take this into account when discussing the interest of adding imatinib to the treatment of these patients. The NUP214-ABL1 fusion is mainly detected together with HOX11 or HOX11L2 positive T-ALL, and could influence the outcome in these subgroups. Our data raise the question of the impact of variable NUP214-ABL1 genomic presentations on the outcome of this subgroup of T-ALL. Finally, during the screening we did not detect any other ABL1 fusion variants, indicating that the NUP214-ABL1 fusion is the most frequent ABL1 abnormality in T-ALL.

0485

ALTERNATIVE SPLICING OF IKAROS MRNA IS RESPONSIBLE FOR THE EXPRESSION OF DIFFERENT ABERRANT ISOFORMS IN PHILADELPHIA CHROMOSOME-POSITIVE (PH+) ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA (ALL) PATIENTS

A. Lonetti,[1] I. Iacobucci,[1] R. Zuntini,[2] S. Ferrari,[2] D. Cilloni,[3] F. Messa,[3] E. Ottaviani,[1] F. Arruga,[3] F. Salmi,[1] S. Paolini,[1] C. Papayannidis,[1] P.P. Piccaluga,[1] P. Giannoulia,[1] S. Soverini,[1] G. Saglio,[3] F. Pane,[4] A. Vitale,[5] S. Chiaretti,[5] R. Foà,[5] M. Baccarani,[1] G. Martinelli[1]

Seràgnoli, BOLOGNA; [2]Medical Genetics Unit, S.Orsola-Malpighi University Hospital, BOLOGNA; [3]Department of Clinical and Biological Science, University of Turin, ORBASSANO, TURIN; [4]CEINGE and Department of Biochemistry and Medical Biotechnology, NAPLES; [5]Department of Cellular Biotechnologies and Hematology, "La Sapienza" Universit, ROME, Italy

Background. Ikaros is a zinc finger transcription factor required for normal hemopoietic differentiation and proliferation, particularly in the lymphoid lineages at multiple stages, that acts both potentiating and repressing gene expression. By means of alternative splicing, Ikaros encodes several proteins that differ that differ in their abilities to bind to a consensus DNA-binding site. Shorter, DNA non-binding isoforms exert a dominant negative effect, inhibiting the ability of longer heterodimer partners to bind DNA. An excess of short DNA nonbinding isoforms has been described in different human haematological malignancies. *Aims.* To detect and quantify different Ikaros transcript variants in Philadelphia-positive (Ph+) adult acute lymphoblastic leukaemia (ALL) patients by performing a high-throughput method based on capillary electrophoresis. *Methods*. We analyzed 46 adult *de novo* Ph+ ALL patients. Ikaros cDNA, obtained from bone marrow or peripheral blood, was amplified with two pairs of oligonucleotides, the forward primer of each couple conjugated with a fluorescent dye (fluorescein) at its 5' end. PCR products were then loaded on the ABI Prism 3730 DNA Analyzer for automated capillary gel electrophoresis and the results were plotted with the AbiPrism GeneMapper v3.5 software (Applied Biosystems). The GeneMapper electrophoretograms display information about transcript length, peak height and peak area. The emitted fluorescence at each peak position reflects the number of amplified target sequence: peaks heights are correlated to the quantity of amplified PCR product and used as an indication of the Ikaros level expression in a sample. *Results.* In 19/46 (41%) of patients we identified a single peak of 255 bp corresponding to DNA non-binding isoform Ik6. In the remaining 59% patients we observed the co-expression of many fragments, corresponding to the different functional (Ik2) and non functional (Ik4, Ik4A, Ik5A, Ik6, Ik6Δ, Ik8) Ikaros transcript variants. Furthermore, a recurring 60-bp insertion immediately downstream of exon 3, was frequently detected in Ik2 and Ik4 isoforms either alone or together with an in-frame 10-amino acid deletion, due to a 30- bp deletion at the end of exon 7. Both the alterations are due to the selection of alternative splice sites which determine an impairment ability to form dimers and to bind the DNA target sequence. *Summary and conclusions.* Taken together, our findings demonstrated that alterations of the transcription factor Ikaros, involving both short spliced oncogenic isoforms and aberrant full-length isoforms are a common feature of Ph+ ALL. Because of the leukemic role of short and/or aberrant Ikaros splice variant, it is more important to use a sensitive method to detect them: in this study we develop a fast, sensitive, high-throughput method, to both detect and quantify splice variants.

GLUCOCORTICOID-MEDIATED EFFECTS IN LEUKEMIA CELLS: INVOLVEMENT OF MICRORNAS

R. Mitlohner, P. Rhein, R. Ratei, W.D. Ludwig, L. Karawajew

RRK, Helios Klinikum Berlin, Charité, BERLIN, Germany

Background. Glucocorticoids (GCs) are the principal therapeutic agents in acute lymphoblastic leukemia (ALL), but molecular targets of GCs are still under discussion. MicroRNAs (miRNAs) are a recently discovered class of small noncoding RNAs with the potential to target the messages of protein-coding genes. *Aims.* Identification and function of miRNAs involved in GC-specific signaling in human precursor B-cell ALL (PBC-ALL). *Methods.* This study has been performed using human ALL cell lines (TOM-1, REH), primary ALL blasts at initial diagnosis, and ALL engrafted in NOD/SCID mice. miRNA profiling of GC treated *vs* untreated cells was performed using a set of 157 human miRNA assays. Expression of candidate miRNAs was validated by real-time RT-PCR. For the functional analysis, cells were nucleofected with miRNA precursor oligonucleotides. MS-5 stromal cells have been used for culturing of nucleofected primary cells. *Results.* miRNA expression profiling of ALL cells has demonstrated GC-induced modulation of miRNA expression in different cell systems. GC-induced upregulation (1.6-3.5 fold) of miR-29b has been a common event in GC-sensitive (TOM-1, primary and NOD/SCID engrafted leukemia cells) but not in GC-resistant (REH) cells. In TOM-1 cells, an overexpression of miR-29b alone was sufficient to induce apoptosis 24h after transfection. Moreover, considerable apoptosis rates (17%) have been achieved in NOD/SCID engrafted cells after transfection with miR-29b precursor molecules. Of note, overexpression of miR-29b was able to induce apoptosis in REH cells and, therefore, to overcome GC-resistance in PBC-ALL. *Conclusions*. Our data demonstrate a pro-apoptotic activity of miR-29b which is potentially involved in GC-specific signaling.

IDENTIFICATION OF MULTIPLE NOVEL IGH@ TRANSLOCATIONS IN ADOLESCENT ACUTE LYMPHOBLASTIC LEUKAEMIA

L. Russell, C.J. Harrison

Newcastle Universtiy, NEWCASTLE UPON TYNE, UK

Chromosomal translocations lead to oncogene activation or gene fusion in hematological malignancies, where they play an important role both in diagnosis and as an indicator of prognosis. Chromosomal translocations involving the immunoglobulin heavy chain locus (IGH@) at chromosome band 14q32 are frequently observed in mature B-cell neoplasia, although a number are now emerging in B-cell precursor acute lymphoblastic leukemia (BCP-ALL). The partner genes differ from those observed in mature B-cell ALL, although their expression is always dereg-

ulated due to the juxtaposition of transcriptional enhancers within the locus. We have identified an increasing number of partners, including recurrent translocations involving 6p (ID4) (n=13) and 19p (EPOR) (n=2), as well as individual cases involving 4p (ZNF595), 5q (novel gene), 7q (TRG@), 15q (novel gene or MEIS2) and 17q (IGF2BP1). Fluorescence *in situ* hybridization and/or long-distance inverse polymerase chain reaction identified partner genes with upregulation of target gene mRNA shown by quantitative real-time PCR. A novel subgroup of 13 IGH@ positive BCP-ALL patients with t(6;14)(p22;q32) showed deregulated expression of ID4 in cooperation with loss of CDKN2A and PAX5, frequently as a result of i(9)(q10). Breakpoints were scattered over a 19kb region centromeric of ID4. Two patients showed a recurrent, reciprocal translocation involving IGH@ with the breakpoint at 19p13, in one patient, 3kb centromeric of EPOR. Analysis of EPOR expression showed increased mRNA levels of this receptor associated with the specific IGH@ translocation, t(14;19)(q32;p13), at diagnosis and relapse in one patient. Overexpression of BCL2L1, CIS and PIM-1 in this patient suggested activation of the JAK-STAT pathway signifying a block in apoptosis and increased proliferative advantage, the two main hallmarks of cancer. Individual patients were also identified by FISH mapping to have IGH@ translocations involving multiple chromosomes and target genes highlighting the promiscuity of this locus, in which all partners may be linked to common pathways in the pathogenesis of leukaemia. The age of these patients ranged from 1-48 yrs, 4 were <10 yrs, 12 were 10-19yrs and 4 were >20 yrs (median - 15yrs) at diagnosis. This is consistent with previous findings of IGH@ translocations being frequently observed in adolescents and young adults. Although patient numbers are small, preliminary survival data suggest that this subgroup may be associated with a good response to therapy.

WHICH TECHNIQUE(S) TO USE WHEN STUDYING MINIMAL RESIDUAL DISEASE AT DAY 35 IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: A MULTICENTER APPROACH

B.J. de Moerloose,[1] K. Swerts,[1] M. Bakkus,[2] A. Uyttebroeck,[3] N. Boeckx,[3] A. Van Damme,[2] P. Vandenberghe,[3] B. Verhasselt,[1] J. Philippé,[1] Y. Benoit[1]

[1]Ghent University Hospital, GHENT; [2]University Hospital Brussel, BRUSSELS; [3]University Hospital Leuven, LEUVEN, Belgium

Background. Detection and quantification of MRD in pediatric ALL patients is important for monitoring response and detection of early relapse. Currently, different methodologies are available (multiparameter flow cytometry (FC), detection of fusion genes using real-time quantitative (RT-)PCR, and competitive PCR-based quantification of clonal immunoglobulin or T-cell receptor gene rearrangements (genescan)). *Aims.* In this multicenter study, MRD detection rates of these techniques were compared and relationships between MRD results and clinical outcome were studied. *Methods.* At the end of induction (day 35), bone marrow samples from 260 patients, treated according to EORTC protocol 58951, were analyzed using at least one method (see above). *Results.* More MRD positive patients were identified by (RT-)PCR (8/78; 10%) or FC (21/258; 8%) compared to genescan (13/214; 6%) or cytomorphology (6/254; 2%). 13/21 patients positive by FC were positive by at least one other technique; likewise 5/8 and 7/13 children positive by (RT-)PCR or genescan scored positive for at least one other method. 14 patients suffered from early relapse, whereas CCR above 30 months was reached in 155 children (median follow-up: 69 months). MRD results of these 169 patients were used to calculate positive predictive value (PPV) and negative predictive value (NPV) at day 35. PPV of FC, (RT-)PCR and genescan was 36%, 33% and 50%. Highest PPV (60%) was reached combining FC and genescan. NPV's of single or combined tests were at least 94%. *Conclusions*. Genescan analysis is superior to FC or (RT-)PCR in identifying patients at risk of early relapse. MRD rates by (RT-)PCR and FC are higher than those obtained by genescan. However, FC and (RT-)PCR have a relatively high false positive rate (PPV=33% and 36%) and MRD by (RT-)PCR detection of fusion genes was only possible in 30% of our patients. Therefore, it is advisable to combine techniques in order to optimize the predictive value of MRD testing.

MOLECULAR CHARACTERIZATION OF CHROMOSOMAL ALTERATIONS IN T-CELL NEOPLASMS BY COMBINING OF FT-CGH AND LM-PCR

G.K. Przybylski,[1] K. Dittmann,[2] P. Grabarczyk,[2] S. Gesk,[3] W. Siewert,[3] R. Siebert,[3] C.A. Schmidt[2]

[1]Institute of Human Genetics, POZNAN, Poland; [2]Universität Greifswald, GREIFSWALD, Germany; [3]Institut für Humangenetik, KIEL, Germany

Background. Dysregulation of gene expression due to chromosomal aberrations plays a key role in malignant transformation. Translocations are routinely found in cancer cells using cytotogenetic methods, but only few of them have been further characterized on the molecular level due to time and labour consuming genomic cloning methods. To better understand the pathogenesis of malignant diseases novel rapid high throughput approaches for determination of the sequence of chromosomal breakpoints are needed. *Aims.* In this study combination of fine tiling comparative genomic hybridization (FT-CGH) and ligation mediated PCR (LM-PCR) was used for cloning and molecular characterization of novel chromosomal breakpoint regions and gene rearrangements in primary T-cell acute lymphoblastic leukaemia (T-ALL) and in a T-cell Non-Hodgkin Lymphoma cell line (K384). *Methods.* A custom fine-tiling oligonucleotide array of 385,000 oligonucleotides (NimbleGen) covering 24 Mb of different genomic areas, including the T-cell receptor alpha/delta locus (TCRAD) on 14q11.2, was designed for comparative genomic hybridization (CGH). All DNA losses within TCRAD were further analyzed by LM-PCR. Since chromosomal translocation involving the TRAD locus are usually accompanied by DNA losses due to TRAD rearrangements, we assumed that using LM-PCR T-cell acute lymphoblastic leukemia we will be able to amplify unknown translocation partners. *Results.* FT-CGH analysis revealed several mono- and biallelic DNA losses in the TCRAD locus in the primary T-ALL sample and in the K384 cell line. Using LM-PCR with sets of nested primers located at the borders to the deleted regions amplification products were obtained differing from the germline control. Sequence analysis of the non-germline LM-PCR products revealed two physiological TCRD rearrangements, TRDV2-J3 and TRDD2-J3, and a 4.6 kb deletion next to the TRAV41 region. In the T-ALL sample on one allele a normal TRAV30-J42 rearrangement was found, while on the other allele an error occurred during the TCRD deleting rearrangement, which is a pivotal step in alpha/beta T-cell development and generates the T-cell receptor excission circles (TREC). The TCRD recombining element (dREC) and the TRAJ61 segment, which normally are joined together, were abberantly cross fused with regions located on chromosome 12q23. Sequence analysis reveald that the rearrangement disrupted the hypothetical gene C12orf42, and was accompanied by a 1.3 kb deletion between the breaks. The identification of a reciprocal translocation t(12;14)(q23;q11.2) was in line with a split observed with fluorescence in-situ hybridization (FISH) probes for the TRAD locus in 39% of cells. *Summary and Conclusions.* We have shown that the combination of FT-CGH and LM-PCR allows the amplification and molecular characterization of gene rearrangements and chromosomal translocation in cell lines and even in patient samples with limited percentage of malignant cells harboring a distinct chromosomal aberration.

TAF1-NUP214 IS A NEW RECURRENT FUSION IN A SUBSET (~3%) OF ADULT T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Gorello,[1] L. Elia,[2] R. La Starza,[1] L. Brandimarte,[1] E. Varasano,[1] A. Vitale,[2] V. Pierini,[1] M. Longinotti,[3] G. Del Poeta,[4] M.F. Martelli,[1] R. Foà,[2] C. Mecucci[1]

[1]Hematology, IBiT Foundation, University of Perugia, PERUGIA; [2]Hematology, University La Sapienza, ROME; [3]Hematology, University of Sassari, SASSARI; [4]Hematology Division, Sant'Eugenio Hospital, Tor Vergata University, ROME, Italy

Background. In T-cell acute lymphoblastic leukaemia (T-ALL) oncogene deregulation occurs through TCRB or TCRA/D juxtaposition or gene fusions. Cytogenetic mechanisms underlying oncogene activation are often cryptic and are detected only by molecular techniques such as FISH, CGH, array-CGH, and gene expression profiling. *Aims.* To characterize the molecular events underlying a cryptic del(9)(q34) in two cases of T-ALL and to establish its incidence in adult T-ALL. *Methods.* A panel of 15 FISH probes was used in a pilot study on 29 adults with T-ALL. A cryptic del(9)(q34)emerged in 2 cases. To delineate the cryptic del(9)(q34)/ABL1, we used four DNA clones for 9q34 ordered as fol-

lows from centromere to telomere: RP11-216B9, RP11-550J21, RP11-143H20, RP11-544A12. For PCR analyses TAF-I-NUP214 fusion transcripts were amplified using primers SET_540F (exon 6) (GAAGAGGCAGCATGAGGAAC) + CAN_2916R (exon 21) (TACTTTGGGCAAGGATTTGG) for the first amplification round and SET_747F (exon 7) (TGACGAAGAAGGGGATGAGGAT) + CAN_2601R (exon 19) (ATCATTCACATCTTGGACAGCA) for nested PCR. Isoform-specific PCR was also performed using CAN_2916R (exon 21) as reverse primer and either TAFIα42F (GAAACCAAGACCACCTCCTG) for the TAF-I alpha isoform, or TAFIβ38F (AGCTCAACTCCAACCACGAC) for TAF-I beta. Reverse primer CAN_2601R (exon 19) and either TAFIα42F or TAFIβ38F were used for the nested PCR. The PCR products were sub-cloned into the pGEM-T easy vector (Promega), sequenced and analyzed using the Blast sequences program (NCBI, http:\\www.ncbi.nim.nih.gov/) and BLAT Search Genome (http:\\genome.ucsc.edu/cgi-bin/hgBlat). To include TAF-I-NUP214 fusion in molecular screening we set-up a multiplex RT-PCR using primers SET-540F and CAN-2916R for the first reaction step and SET_747F and CAN_2601R for the second. Our assay was applied to study 73 patients with T-ALL who were enrolled in the Italian Multicentric GIMEMA studies LAL-0496, LAL- 2000, and LAL-0904. *Results*. The 5'TAF-I and the 3'NUP214 appeared to be juxtaposed as the four 9q34 DNA clones defined the del(9)(q34) endpoints centromerically at the 3' of TAF-I and telomerically at the 5' of NUP214. RT-PCR gave a 802 bp product in one case and a 643 bp product in the other. In the second round a 280 and 121 bp amplification product respectively was detected. Cloning experiments and sequence analysis revealed fusion of nucleotide 813 (exon 7) of TAFI with nucleotide 2389 (exon 17) in 1 case and with nucleotide 2548 (exon18) of NUP214 in the second. To our knowledge, TAFI exon 7/ NUP214 exon 17 fusion has never been described. Moreover the presence of TAFI-alpha/NUP214 and TAFI-beta/NUP214 fusion transcripts was observed in both patients. Multiplex-PCR detected 1/73 TAF-I-NUP214 positive T-ALL. *Conclusions*. Cryptic interstitial del(9)(q34)TAF-I-NUP214 produces the TAF-I-NUP214 fusion transcript which is a new recurrent molecular lesion in adult T-ALL. Since we found 3 cases of TAF-I-NUP214 positive T-ALL when a total of 102 adult patients were screened, the incidence was estimated as 2.9%.

THE GENERATION OF SENSITIVE, PATIENT SPECIFIC MOLECULAR PROBES IS FEASIBLE IN MOST ADULT ALL PATIENTS AND ALLOWS THE DEFINITION OF A RISK ADAPTED POSTCONSOLIDATION TREATMENT STRATEGY

O. Spinelli, M. Tosi, B. Peruta, T. Intermesoli, E. Oldani, R. Bassan, A. Rambaldi

Ospedali Riuniti, BERGAMO, Italy

Background. Several studies have shown the importance of a molecular evaluation of minimal residual disease (MRD) to predict outcome in childhood acute lymphoblastic leukemia (ALL) but in the setting of adult ALL, only a few studies define a risk adapted treatment strategy on the basis of MRD results. *Aims*. To generate at least 1 sensitive allele specific oligonucleotide (ASO) probe derived from TCR and IG gene rearrangements for RQ-PCR evaluation of MRD in adult ALL patients lacking a translocation derived chimeric transcript. The availability of sensitive molecular probes were instrumental for the definition of risk adapted post consolidation therapy. *Methods*. One hundred and eighty patients with B-lineage ALL, 107 T-lineage ALL, 5 B-and 18 T-Lymphoblastic Lymphomas enrolled in a Phase II clinical study (ALL 09/2000) of the Northern Italy Leukemia Group (NILG) were evaluated following the ESG-MRD-ALL (European Study Group on MRD detection in ALL) methodology. TCR and IG gene rearrangements were identified by PCR amplification, heteroduplex analysis and direct sequencing of clonal bands. Two or more ASO primers were designed on the specific junctional regions and their sensitivity were evaluated at different annealing temperatures (from 60 to 69°C) on serial dilution of diagnostic material by quantitative PCR. *Results*. TCR gamma (TCRG) gene rearrangements were detected by PCR in 49% (n=88) of B-lineage ALL and in 73% (n=77) of T-lineage ALL, while TCRD gene rearrangements in 40% (n=72) and in 47% (n=50) of B- and T-ALL respectively. IgH gene rearrangements were detected in 59% (n=106) of B-lineage and in 4% (n=4) of T-lineage ALL cases. IGK-Kde gene rearrangements were investigated only in B-lineage ALL and the percentage of positivity for clonal bands was 32% (n=57). TCR beta clonality was studied only in T-ALL patients and it was found in 65% (n=64) of cases. The distribution of the clonal rearrangements were similar in the lymphoblastic lymphomas. A total of 484 ASO primers were designed and tested by quantitative PCR at different temperatures to reach a sensitivity suitable for MRD evaluation. We obtained a sensitivity of 10^{-5} in 48% (n= 232) of tested ASO primers, 10^{-4} in the 35%(n=167) and 10-3 in 16% (n=79). Overall, we were able to monitor MRD in 81% of the studied cases, with 2 or 1 ASO probes in 49% (n=135) and 32% (n=90) of cases, respectively. *Conclusions*. In combination with probes generated on translocation derived chimeric genes, more than 90% of adult ALL enrolled into the NILG ALL 09/2000 protocol were suitable for a molecular evaluation of MRD. Therefore, our data show the feasibility of a MRD based definition of risk adapted post consolidation treatment strategy in adult ALL.

0492

ADDITIONAL GENETIC FEATURES OF NUP214-ABL1 POSITIVE PEDIATRIC T-ALL

M. Pisecker,[1] M. König,[1] R. Ullmann,[2] S. Strehl[1]

[1]CCRI, VIENNA, Austria; [2]MPIMG, BERLIN, Germany

Background. T-cell acute lymphoblastic leukemia (T-ALL) is a high-risk malignancy of thymocytes, and accounts for 10-15% of pediatric ALL cases. In T-ALL genetic analyses have elucidated an enormous heterogeneity in genetic abnormalities including chromosomal translocations, deletions, amplifications, and mutations. In about 5-10% of the cases an episomal amplification of a 500 kb DNA fragment normally located at 9q34 that fuses NUP214 and ABL1 has been observed. This genetic aberration is always accompanied by either TLX3 or TLX1 rearrangement. *Aims and Methods*. This study was aimed at the identification and characterization of genetic events accompanying the occurrence of the NUP214-ABL1 fusion in pediatric T-ALL. Genomic DNA of 102 childhood T-ALL patients and 12 matched relapse samples was subjected to BAC tiling path array CGH. Samples showing an amplification of 9q34 were further analyzed by FISH and RT-PCR to confirm the amplification/fusion event. In addition, the TLX3 rearrangement-status in these patients was investigated by FISH and other associated genetic events determined by array CGH were subjected to bioinformatic analysis. *Results*. Array CGH analysis revealed a gain of 9q34 in 5 samples, two of which were relapse samples and showed the amplification only at this stage of the disease. Subsequent FISH analysis confirmed these results and detected a reintegration of the NUP214-ABL1 amplicon into the genome in one of the relapse samples. Amplification of the NUP214-ABL1 by RT-PCR revealed that the fusion gene was also present in those two diagnostic specimens in which array CGH failed to detect the amplification and FISH analysis showed ambiguous results with a minor fraction (<3%) of positive cells. At diagnosis all five patients showed a TLX3 rearrangement by FISH in more than 60% of the cells. Detailed analysis of the array CGH data revealed five regions of minimal overlap (RMO) shared by at least two cases located at 1p36, 6q16, 9p21 and 11p13 (losses) and 18q21 (gain), which together contained 34 known genes. In four of the cases CDKN2A was homozygously deleted, whereas the remaining case showed a heterozygous deletion. The del(11p13) encompassed only the WT1 gene, which has tumor suppressive function, and was present in three patients two of which had a relapse. These two cases showed the deletion also at diagnosis, a stage of the disease in which the NUP214-ABL1 fusion was not detectable by array CGH. *Conclusions*. Neither FISH nor array CGH are the appropriate methods to unambiguously uncover the presence of a NUP214-ABL1 fusion, and thus reliable detection of this genetic aberration requires high-sensitive RT-PCR approaches. Moreover, together our data suggest that fusion and amplification of NUP214-ABL1 is not a primary genetic event in the development of pediatric T-ALL.

T-LYMPHOCYTE LEUKEMIA CELLS MOLT-4: RESISTANT TO TRAIL, BUT VERY SENSITIVE TO IONIZING RADIATION. COULD LOW DOSES OF RADIATION INCREASE SENSITIVITY TO TRAIL?

M. Rezacova

Charles University, Faculty of Medicine in Hradec Kralove, HRADEC KRALOVE, Czech Republic

Aims and Background. T-lymphocyte leukemia cells MOLT-4 are resistant to TRAIL, but very sensitive to ionizing radiation. The aim of the study was to evaluate effect of ionizing radiation on senzitization of MOLT-4 cells to TRAIL. *Methods and Results.* T-lymphocyte leukemia cells MOLT-4 are very sensitive to ionizing radiation. We determined D0

value (the dose after which survives 37% of cells) 0,8 Gy. As soon 2 min after irradiation by the dose of 1.5 Gy we detected ionizing radiation inducing foci containing gammaH2A.X, 53BP1 and Nbs1, which were formed around double-strand breaks of DNA. However, we did not detect phosphorylated form of Nbs1. Inability to phosphorylate Nbs1 could be the reason of high radiosensitivity and low repair capacity. High doses of ionizing radiation (5 and10 Gy) caused decrease of repair proteins Mre11, Rad50 and Nbs1. Our study further demonstrates that cells of acute T-lymphoblastic leukemia MOLT-4 do not express receptors for TRAIL (tumor necrosis apoptosis inducing ligand) DR5 and are TRAIL resistant. Ionizing radiation in the therapeutically achievable dose of 1 Gy significantly sensitizes TRAIL-resistant cells MOLT-4 to the TRAIL-induced apoptosis by increase in death receptor for TRAIL DR5. *Conclusions*. When TRAIL is applied after the irradiation in the time of increased DR5 positivity induced by ionizing radiation (1 Gy) more efficient cell killing by apoptosis is achieved and resistance to TRAIL is nullified.

INCREASED RISK OF ACUTE LYMPHOBLASTIC LEUKAEMIA IN BRAZILIAN INDIVIDUALS WITH NAD(P)H:QUINONE OXIDOREDUCTASE 1 (NQO1) AND CYTOCHROME P450 A1 (CYP1A1) GENE DEFECTS

G. Yamaguti,[1] G. Lourenco,[1] V. Silveira,[2] L.G. Tone,[2] L.F. Lopes,[3] C.S.P. Lima[1]

[1]State University of Campinas, CAMPINAS; [2]School of Medicine of Ribeirao Preto, University of Sao Paulo, RIBEIRAO PRETO; [3]Hospital do Cancer A. C. Camargo, SAO PAULO, Brazil

Background. Acute lymphoblastic leukaemia (ALL) has been linked to chronic exposure to benzene and tobacco's polycyclic aromatic hydrocarbons (PAH). The NAD(P)H:quinone oxidoreductase 1 (NQO1) is an enzyme that detoxifies benzene-derived quinones and reduces oxidative stress on hematopoietic cells. A C'T substitution polymorphism at nucleotide 609 of the NQO1 gene has been linked to a decreased activity of the coded enzyme. On the other hand, PAH are bioactivated by the cytochrome P450 A1 (CYP1A1) enzyme. An A'G substitution polymorphism at nucleotide 4889 and a T'C substitution at nucleotide 6235 of the CYP1A1 gene lead to the production of an enzyme with increased activity in PAH metabolism. Moreover, environmental-related diseases resulting from exposure to benzene and tobacco-related diseases have been described as serious health problems in south-eastern Brazil. *Aims.* The aim of this study was to evaluate the influence of the NQO1 C609T and CYP1A1 A4889G and T6235C polymorphisms for ALL risk in individuals of the south eastern region of Brazil. *Methods.* Genomic DNA from 93 ALL patients (median age: 4.33, range: 0.4-17; male: 47, female: 46; Caucasian: 82, African-American: 11) and 93 gender and race-matched controls (median age: 53, range: 40-60; male: 47, female: 46; Caucasian: 82, African-American: 11) were analysed using the polymerase chain reaction (PCR) and enzymatic digestion. The differences between groups were calculated by the chi-square or Fischer exact test. Logistic regression analysis was used to obtain gender and ethnic origin adjusted odds ratios (ORs). *Results.* Controls' samples but not patients' samples were in Hardy-Weinberg (HW) equilibrium for the NQO1 locus (X2=2.04, p=0.15, X2=5.16, p=0.02, respectively). The frequency of the NQO1 609CT+TT genotype was significantly higher in ALL patients than in controls (49.5% *vs* 50.5%, p= 0.001). Carriers of the NQO1 variant allele (T) were under a 2.8-fold increased risk of ALL (95% CI: 1.53-5.29). Both controls' and patients' samples were in HW equilibrium for the CYP1A1 A4889G and T6235C loci (X2=0, p=1.00, X2=0.46, p= 0.50; X2= 3.38, p=0.07, X2=0.64, p=0.42; respectively). Similar frequencies of the CYP1A1 4889AG+GG and 6235TC+CC genotypes were seen in patients and controls (38.7% *vs* 26.9%, p=0.09; 39.7% *vs* 31.2%, p=0.22; respectively). Controls and patients with the distinct genotypes of the CYP1A1 A4889G (OR=1.72, 95% CI:0.92-3.19) and T6235C (OR=1.46, 95% CI: 0.80-2.67) were under similar risks for ALL. However, the frequency of the combined variant genotypes NQO1 609CT+TT and 4889AG+GG was higher in patients than in controls (33.3% *vs* 7.5%, p< 0.001). Carriers of the two variant alleles were under a 8.6-fold increased risk for ALL (95% CI: 3.35-21.86). Conclusion: These results suggest a role for the NQO1 609TT+CT and CYP1A1 4889GG+AG genotypes in increased risk for ALL in individuals of south eastern Brazil. Since the variant alleles of NQO1 C609T and CYP1A1 A4889G polymorphisms are prevalent in the general population, the identification of individuals with the variant genotypes may provide a useful public health approach for prevention of ALL. Financial support: CNPq

DETECTION OF PROTEIN PATTERNS IN PLASMA OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA USING FUNCTIONALIZED MAGNETIC BEADS AND LINEAR MALDI-TOF MASS SPECTROMETRY

N. von Neuhoff,[1] T. Oumeraci,[1] B. Hirsch,[1] M. Kostrzewa,[2] M. Schrappe,[3] B. Schlegelberger,[1] G. Cario[3]

[1]Hannover Medical School, HANNOVER; [2]Bruker Dalton GmbH, LEIPZIG; [3]University Hospital Schleswig-Holstein, Campus Kiel, KIEL, Germany

Background. Proteomic profiling of body fluids is a promising novel tool for the identification of protein signatures in order to stratify the risk and to monitor treatment outcome. Different methods have been developed to isolate and fractionate plasma proteins and to determine discriminative protein signatures. However, it is still challenging to obtain highly reproducible and distinctive protein patterns for the reliable detection of disease specific biomarkers. *Aims.* The present study describes a novel technology for plasma proteome analysis using functionalized beads to fractionate proteins and peptides, matrix-assisted laser desorption/ionization-time of flight-mass spectrometry (MALDI-TOF-MS) and specialized software tools. This has resulted in distinctive and highly reproducible plasma proteome signatures from children with acute lymphoblastic leukemia (ALL) investigated at four timepoints before and during chemotherapy. *Methods.* EDTA plasma samples from 12 patients with childhood ALL treated according to the ALL-BFM2000 protocol were taken before and at different timepoints during treatment (day 0, week 1, week 5, week 12). Plasma proteins were fractionated using functionalized magnetic beads. Beads with different surface functionalities (e.g. hydrophobic interaction, cationic exchange and anionic exchange) were used to enrich and to purify different protein/peptide subclasses. Proteomic profiles were acquired in a linear microflex MALDI-TOF mass spectrometer. To ensure reproducibility, each purified sample was processed independently four times and each fraction was spotted four-fold onto MALDI targets. For spectra acquisition, 500 single shots were accumulated from each of the corresponding target positions. The acquired patterns were analyzed using the ClinProTools 2.1 software (Bruker Daltonik, Leipzig) to discriminate data sets and discover reliable candidate proteins. Data sets obtained by different bead functionalities were analyzed separately. Depending on the sample and magnetic bead functionality, up to 343 masses were detected in the range from 1 kDa to 10 kDa. *Results.* Distinct signatures were identified for all applied magnetic bead functionalities. Comparing the spectra from four independently processed fractions of each sample showed a very high reproducibility of the obtained data. The best classification was achieved after cationic exchange fractionation of the plasma samples. Using this technology, an almost complete separation of the four timepoints before and during chemotherapy was achieved. The discrimination was based on up to 12 different masses and resulted in a recognition capability of 100% overall and of 94.4% in cross-validation. *Conclusions*. Based on a novel technology for the fractionation of plasma proteins using functionalized magnetic beads, MALDI-TOF-MS and specialized software tools, proteome signatures were reliably able to distinguish plasma probes from children with ALL obtained at four different timepoints before and during chemotherapy. Work is in progress to identify the discriminative peptides and proteins and to clarify their cellular function and possible role in chemotherapy response. Further studies will focus on the potential value of measuring these plasma protein signatures for monitoring individual treatment response in childhood ALL.

TIME-DOMAIN OPTICAL IMAGING OF AML XENOGRAFTS WITH NEAR-INFRARED CONJUGATED MONOCLONAL ANTIBODIES

E. Mc Cormack, M. Mujic, B.T. Gjertsen

Institute of Medicine, BERGEN, Norway

Background. The 5-year survival for acute myeloid leukaemia (AML) has changed little in the last two decades and while molecular targeted and neoadjuvant therapies have provided some promise more recently, the clinical impact upon survival has been limited. The methods employed to authenticate these prospective targets *in vivo* tend to be quite protracted with validation and preclinical testing remaining the rate-limiting step in translating these treatments to the clinic. Molecular imaging has now become a critical facet of not only drug development but also clinical and preclinical disease monitoring. *Aims.* Using an innovative mode of *in vivo* optical imaging we have described a novel methodology of time domain (TD) optical imaging and its implementation in preclinical detection and longitudinal monitoring of fluorescent proteins in AML. However, imaging of fluorescent proteins or bioluminescent enzymatic reporters is problematic due to high tissue absorption at visible wavelengths. Thus we propose the development of novel imaging strategies in relevant animal models of AML, which exploit the near-infrared region (NIR) of light. Through development monoclonal antibodies (mAb)s targeted NIR optical probes we propose to interrogate AML biology and monitor treatment efficacy with TD optical imaging. *Methods.* Using mouse anti-human mAbs against human myeloid markers (CD45, CD13 and HLA-ABC) we conjugated NIR dyes and employing imaging phantoms in a commercial TD optical imaging system we optimised the degree of labelling for *in vivo* imaging. We established several preclinical xenograft models of AML (NB4, HL60, MOLM-13) and compared the ability to monitor disease progression with fluorescent/bioluminescent proteins and our NIR-mAb probes with TD optical imaging. *Results.* The combined use of TD optical imaging and NIR labelled mAbs proved to be superior to both fluorescence and bioluminescence for earlier and more quantitative imaging of xenograft models of AML. TD imaging of distinct fluorescence lifetimes of NIR labelled mAbs also permitted the discrimination of specific and random binding of the fluorescent probe. *Summary*. The combined use of TD optical imaging and NIR labelled mAbs provided an excellent mode of disease detection and longditudinal monitoring of human xenograft models of AML. In the future it should be possible to use this technology to detect distinct subsets of AML populations *in vivo* and monitor functional therapeutic response e.g. Immunotherapy.

COAGULATION ACTIVATION IN ACUTE PROMYELOCYTIC LEUKEMIA TRANSGENIC MICE MODEL HCG-PML-RAR?

M.C.T. Pintao, B.A.A. Santana-Lemos, F.G. Mangolini, L.L. Figueiredo-Pontes, F.P. Saggioro, C.L.A. Silva, P.S. Scheucher, G.A.S. Santos, M.S. Baggio, A.B. Garcia, E.M. Rego

Medical School of Ribeirão Preto - University of São Paulo, RIBEIRÃO PRETO, Brazil

Background. Acute promyelocytic leukemia (APL) is associated with a coagulopathy characterized by disseminated intravascular coagulation (DIC), fibrinolysis and proteolysis. Primary hyperfibrinolysis is considered to be responsible for the severe bleeding in APL. However, the bulk of evidence, particularly elevated levels of D-dimer, suggests that excess fibrinolysis is secondary to excess thrombin generation. In addition, properties of the malignant leukemic cells themselves and their interactions with host defense mechanisms, including increased expression of procoagulant activity, expression of fibrinolytic and proteolytic properties and secretion of proinflammatory cytokines, play a role in APL coagulopathy. *Aims*. We took advantage of the transgenic mice (TM) hCG-PML-RARα generated by Pandolfi´s group (He *et al.*, 1997) to characterize coagulation and cytokine pattern in leukemic (leu) in comparison to non-leukemic-TM (non-leu) and wild type (WT) controls. *Methods*. Blood was obtained by cardiac punction of 12 leu-TM, 14 non-leu-TM and 12 WT mice using syringe with citrate 3.2% with proportion adjusted to 9:1 (blood:citrate). Plasma was separated by centrifugation and stored at -80° until analysis. Brain, kidney, lungs, heart, spleen, liver and bone marrow (BM) where obtained for histological analysis. Coagulation activation was analyzed by measurement of thrombin-antithrombin complex (TAT-ELISA), fibrinolysis was analyzes by measurement of plaminogen activator inhibitor-1 (PAI-1) activity (ELISA) and interleukins (IL-6, IL-10, MCP-1, INF-Á, TNF and IL-12p-70) where measured by BD Cytometric Bead Array mouse inflammation kit (CBA). Fibrin deposition where evaluated by histochemistry using Mallory's phosphotungstic acid-hematoxilin (PTAH) stain. Statistical analysis was performed by ANOVA. *Results*. Leu-TM presented anemia, thrombocytopenia and leucocytosis associated with BM infiltration by leukemic cells resembling promyelocytes (56±19%; 9,5±3.6%; and 8.4±2.4% in leu-TM, non-leu-TM and WT, respectively. Spleen size (median± SD) was higher in leu-TM (0.956± 0.583g), compared to non-leu TM (0.136±0.071g) and WT mice (0.094± 0.011g). PAI-1 activity was higher in leu-TM in comparison to non-leu-TM and WT (mean±SD): 16.5±11.2 ng/mL; 2.1± 6.0 ng/mL and 2.4±5.2 ng/mL (p<0.001), respectively. TAT levels were non significantly higher in leu-TM, but since the detected levels in all 3 groups were higher than the reported in literature, we can not rule out that there was activation during heart puction. In addition, intravascular fibrin deposition was not detected by histochemic evaluation. Analysis of interleukin pattern showed elevated TNF in leu-TM in comparison to non-leu-TM and WT (mean±SD): 20.50±9.2 pg/mL; 4.4±0.8 pg/mL (p<0.001) and 4.6±1.4 pg/mL (p<0.001), respectively. IL-6 was also elevated in leu-TM in comparison non-leu-TM and WT (mean±SD): 6.9±5.8 pg/mL; 2.5±0.7 pg/mL (p<0.001) and 3.4±2.0 pg/mL (p<0.05). *Summary and conclusions*. In conclusion, the leukemia developed by hCG-PML-RARαTM is associated to elevated PAI and elevated IL-6 and TNF cytokines, thus reinforcing the importance of fibrinolysis and cytokines in APL associated coagulopathy. Our results demonstrate that the TM model that mimics the APL coagulopathy and is a very useful tool for testing new drugs and understanding the physiopathology of the disease.

Background and Aims. The nucleophosmin (NPM1) gene mutation is one of the most common genetic alterations in adult acute myeloid leukemia (AML), accounting for 50-60% of AML cases with normal karyotype. Despite molecular heterogeneity, all variants lead to common changes in the NPM1 protein causing an increased nuclear export of the nucleophosmin leukemic mutant and its aberrant accumulation in the cytoplasm. AML with mutated NPM1 shows distinctive biological and clinical features, suggesting that AML with mutated NPM1 represents a new disease entity. Experimental evidence of the oncogenic potential of the nucleophosmin mutant is, however, still lacking, and it is unclear whether other genetic lesion(s), such as FLT3-ITD, cooperate with NPM1 mutations in generating the leukemic phenotype. The multi-step theory of carcinogenesis was conceived after mathematical modelling demonstrated that the increasing cancer incidence with age can be explained by several stochastic events needed for tumorigenesis. An analysis of the age-specific incidence, together with mathematical modelling of AML epidemiology, can help to uncover the number of genetic events needed to cause leukemia. *Methods*. National registry-based AML incidence data with details of NPM1 mutation status are not available. Therefore, we collected data sets at five major European Institutions: the Laboratory of Cytogenetic and Molecular Diagnostic, University Hospital Ulm, representing the German-Austrian AML study Group; the Laboratory of Hemopathology, Institute of Hematology, University

of Perugia, representing GIMEMA group; the Laboratory for Molecular Diagnostics, University Hospital Carl Gustav Carus, Dresden, Germany, representing the Deutsche Studieninitiative Leukämie; the Munich Leukemia Laboratory, and the Department of Hematology, Erasmus University Medical Center. We determined the age-specific incidence of AML with mutated NPM1 (a total of 1444 cases) for each country. We then adapted a previously designed mathematical model of hematopoietic tumorigenesis to analyze the age incidence of AML with mutated NPM1. Finally, we confermed the predictions of equations with direct computer simulation of the stochastic process. *Results*. Linear regression of the curves representing age-specific rates of diagnosis per year showed similar slopes of about 4 on a doubly logarithmic scale. The one-mutation model generated slopes similar to real age-specific incidence curves from patients (Figure 1) from Germany, The Netherlands, and Italy. Since FLT3-ITD frequently associates with NPM1 mutations and appears to abrogate the favourable prognostic effect of NPM1 mutations in AML, we determined whether the age incidence of NPM1-mutated AMLs with FLT3-ITD differs from cases with wild-type FLT3. No significant difference emerged in the slopes of FLT3-ITD-positive and -negative AML with mutated NPM1. *Summary and Conclusions*. The model fits the NPMc+ AML age-specific incidence curve for plausible parameter choices supporting the hypothesis that a single genetic event, or two sinchronous events, are sufficient to cause this type of leukemia. No difference can be detected between the slopes of the age specific incidence of FLT3-ITD-positive and -negative NPMc+ AML, supporting the view that NPMc+ AML is a homogeneous group irrespective of the FLT3 mutational status. Since NPM1 mutations are associated with haploinsufficiency of wild-type NPM in leukemic cells, an attractive hypothesis would be that the two alterations act together to cause NPMc+ AML.

COMPLEX AMPLIFICATION OF CHROMOSOME 21 MASKING A NOVEL CRYPTIC RUNX1 GENE FUSION IN AN AML CELL LINE (OCI-M2)

S. Chen,[1] B. Schneider,[2] S. Nagel,[2] R. Geffers,[3] H. Quentmeier,[2] M. Kaufmann,[2] H. Drexler,[2] R. MacLeod[2]

[1]DSMZ'German Collection of Microorganisms and Cell Cultures, BRAUNSCHWEIG; [2]DSMZ'German Collection of Microorganisms and Cell Cultures, BRAUNSCHWEIG; [3]Helmholtz Centre for Infection Research, BRAUNSCHWEIG, Germany

Background. Recently, a novel complex recurrent genomic amplification targeting part of the long arm region of chromosome - amp21q2 - was described in a subset of acute myeloid leukemia (AML) patients (Baldus *et al.*, Proc Natl Acad Sci USA 101: 3915, 2004). Array comparative genomic hybridization (CGH) combined with expression profiling highlighted several gene amplification targets on 21q, notably APP (amyloid beta precursor protein), while RUNX1 (alias AML1) at 21q21 was excluded as a direct target. *Aims.* We have identified an erythromegakaryocytic cell line - OCI-M2, established from a 56-year old patient with AML-M6 secondary to myelodysplastic syndromes (MDS), to serve as a model for investigating this novel leukemic entity. *Methods.* OCI-M2 Cells were subjected to conventional and molecular cytogenetic analysis by fluorescence *in situ* hybridization (FISH) using BAC and fosmid clones. Array-CGH was performed using 100k arrays, and expression profiling with U133 Plus 2.0 arrays (Affymetrix). Gene expression was confirmed by reverse transcription (RT)-PCR, and quantified by qRT-PCR. Random amplification of cDNA ends (RACE) was used to detect RUNX1 fusion transcript. *Results.* Conventional cytogenetic analysis showed the following karyotype: 51,XX,der(X)t(X;8)(q23;q23),+6,+9,der(9)add(9)(p23)del(9)(p12p21)t(9;21)(p23;q22)t(21;19)(q21.2;q13)add(19)(hsr),t(10;12)(p12;p12),del(17)(q11q21.1),+20,der(21)add(21)(q22)(hsr),+3mar. FISH analysis revealed extensive amplification of material from chromosomes 19 and 21 on both der(9) and der(21) marker chromosomes forming homogeneously staining regions. Array-CGH showed that amplification of chromosome 21 peaked (~4X) the ~37-47Mbp, followed by 15-18 Mbp and 27-35 Mbp (both ~3X), but spared the interval closest to RUNX1. Thus, chromosome 21 amplification in OCI-M2 closely resembles that described by Baldus *et al.* FISH using BAC and fosmid clones confirmed that the 21q21 breakpoint inside der(9) lay within RUNX1, close to intron 6. Both der(9) and der(21) markers carried extensive homogeneously staining regions. FISH using chromosome 19 BAC/fosmid clones showed both chromosomes 19 and 21 to be amplified within these markers. The chromosome 19 amplicon was focused on the 33-45Mbp interval flanked by breakpoints on der(9) at 19q12 (33.0 Mbp) inside a gene-poor region, and at 19q13 (45 Mbp) near RPS16 - a ubiquitously expressed 40S ribosomal protein gene. Discrepant bands from 3´-RACE using RUNX1 templates were excised and sequenced. Sequencing confirmed fusion of 5´-RUNX1 with 3´-RPS16. Western blotting with N-terminus antibody to RUNX1 confirmed the translation of both wild type and enlarged 70 kDa mutant bands, consistent with formation of a novel fusion protein. RPS16 belongs to the emergent family of ribosomal proteins recently implicated as a target of 5q deletions in AML/MDS. *Conclusions.* Taken together, our findings: 1) document a novel RUNX1 translocation; 2) increase the number of RUNX1 translocations documented in AML cell lines from four (partnering ETO at 8q22, ETV6 at 12p13, EVI1 at 3q26, LRP16 at 11q13) to five; 3) implicate a new ribosomal protein gene in leukemogenesis; 4) provide a novel tool for investigating the role of RUNX1 rearrangement in leukemogenesis; and 5) identify a cell line model for characterizing the gene target(s) of chromosome 21 amplification in AML.

VEGF MRNA LEVELS, PROTEIN CONCENTRATION AND MICROVESSEL DENSITY IN AML PATIENTS, AT DIAGNOSIS AND IN REMISSION

A. Avgitidou,[1] E. Ioannidou,[1] A. Tsiga,[1] E. Vlachaki,[1] F. Klonizakis,[1] St. Dimoudis,[1] M. Diamantidis,[1] S. Haralambidou,[1] I. Venizelos,[2] I. Klonizakis[1]

[1]Hippokration Hospital, AUTH, THESSALONIKI; [2]Department of Pathology, Hippokration Hospital, THESSALNIKI, Greece

Background. Angiogenesis is the formation of new blood vessels from pre-existing vessels and is involved in the growth of solid tumours. Haematologic malignancies do not develop in the same way as solid tumours so the requirement of angiogenesis has not been as clearly

recognised as for other malignancies. However, in the last years, many studies evaluated the importance of angiogenesis in heamatologic malignancies, like AML, indicating a possible role in its pathogenesis. Although, many angiogenic factors have been identified in AML, the most important is Vascular Endothelial Growth Factor (VEGF). VEGF plays an essential role in normal and pathologic angiogenesis, but its clinical role in AML remains unclear. *Aims.* The aim of our study was to investigate the expression of VEGF in the bone marrow of AML patients at diagnosis and in remission, and thus to assess the role that angiogenesis play in the progression of the disease. *Methods*. Total RNA was isolated from bone marrow cells of 50 AML patients (median age 54,4 years) and 10 individuals, of the same age, with normal haematopoiesis that used as controls. Thirty one patients were at the onset of the disease, whereas 19 patients were in complete remission (<5% bone marrow blasts). Real-Time Semi-Quantitative RT-PCR assay was performed in order to detect the mRNA levels of VEGF. The regulation of the target gene was estimated as an expression ratio. Serum concentrations of VEGF in 50 AML patients and in 10 control samples were measured by ELISA assay. Bone marrow biopsies from 23 newly diagnosed AML patients were assayed for microvessel density (MVD), using anti-CD34 monoclonal antibody. MVD was estimated by counting the number of vessels per 400x high power field (HPF) using light microscopy. *Results.* Increased expression levels of VEGF were found in the serum from patients with AML at diagnosis (365,65pg/μl, $p<0,05$) and in remission (579,08pg/μl, $p<0,05$) compared with the levels found in control group (69,48pg/μl). Interestingly, there is a significant increase ($p<0,05$) in VEGF concentration at patients in remission compared to patients at diagnosis. Immunohistochemical staining showed a significant increase of the bone marrow MVD in newly diagnosed AML patients (6,276 vessels/HPF, $p<0,05$) compared with controls (1,6 vessels/HPF). Finally, the mRNA levels of VEGF were significantly lower in newly diagnosed untreated patients (1,37 fold, $p<0,001$) compared to controls. There is no significant difference between remission patients (1,097 fold, $p>0,05$) and controls, but VEGF mRNA levels were significantly higher in remission patients compared with newly diagnosed patients ($p=0,001$). *Summary and Conclusions.* There is evidence of increased MVD in the bone marrow of AML patients, which supports the hypothesis of an important role of angiogenesis in AML. Our data show a discrepancy between bone marrow angiogenesis and VEGF expression, both in mRNA and protein level. This suggests that angiogenesis in AML likely represents a response to bone marrow microenvironmemt and that VEGF expression in not an intrinsic property of leukemic cells but can be produced also by normal cells. Further investigation in this field is recommended in order to better determine VEGF function in AML.

SECONDARY GENETIC ABBERATIONS AND THEIR EFFECT ON PROGNOSIS IN CORE BINDING FACTOR - ACUTE MYELOID LEUKEMIA (CBF-AML)

J. Markova,[1] Z. Trnkova,[2] J. Maaloufova,[2] J. Stary,[3] P. Cetkovsky,[2] J. Schwarz[2]

[1]Institute of Hematology & Blood Transf., PRAGUE 2; [2]Institute of Hematology & Blood Transfusion, PRAGUE 2; [3]Dept. of Pediatric Hematology & Oncology, Faculty Hospital Motol, PRAGUE 5, Czech Republic

Background. Patients with CBF-AML carrying AML1/ETO or CBFb/MYH11 are considered to have good prognosis, albeit about 50% of them relapse. Secondary genetic aberrations associated with poor outcome occur in this patient subset. Mutations in FLT3 and particularly in C-KIT receptor tyrosine kinases have been frequently described in CBF-AML. Mutations in exon 17 of C-KIT more often occur in patients with the AML1/ETO fusion and according to some authors, negatively affect both the incidence of relapse and overall survival (OS), while a strong association between C-KIT exon 8 mutations and CBFb/MYH11+ AML has been reported. *Aims.* To perform mutational analysis of C-KIT in order to check its incidence and prognostic relevance in patients with CBF-AML. *Patients and Methods.* A cohort of 60 CBF-AML cases was studied. The median patients' age was 29.3 years (range: 1.6-72.2), the male/female ratio was 38/22. The presence of AML1/ETO and CBFb/MYH11 at diagnosis (and futher during treatment) was detected by real-time RT-PCR. C-KIT mutations (in exons 8, 9, 10, 11, 17 and 18) and FLT3/ITD were determined by gel electrophoresis and direct sequencing. FLT3 D835 point mutations were analysed by restriction analysis using EcoR V and verified by direct sequencing. To detect the JAK2 V617F mutation, an allelic discrimination real-time RT-PCR assay was employed. *Results.* The median WBC count of CBF-AML patients was 20.5 G/L. Cases with the AML1/ETO fusion had lower WBC than those with CBFb/MYH11 (medians: 13.3 *vs* 66.0, $p=0.001$). Of 34 patients with AML1/ETO, 4 had C-KIT exon 17 mutation, involving C-KIT D816 in 75% cases. Two patients had ITD in exon 11 and only one presented with a mutation in exon 8. FLT3 ITD and D835 mutations were found in 3 and 2 cases, respectively. Two patients had JAK2 V617F mutation. C-KIT mutations were detected in 14/26 patients with CBFb/MYH11: 9 of them in exon 8, 5 in exon 17 (in one patient, mutation was present in both exons). No mutation was detected in exon 11. Four patients with CBFb/MYH11 had a point mutation in FLT3 D835 and one FLT3/ITD was found in this group. JAK2 V617F mutation was not detected in CBFb/MYH11-positive patients. Although CBFb/MYH11-positive patients with a C-KIT mutation had higher median WBC counts, this was not significant ($p=0.24$). The C-KIT mutation did not affect WBC counts in AML1/ETO-positive cases. Of 33 CBF-AML patients with unmutated C-KIT, 12 (36%) relapsed ; of C-KIT mutated cases, 7/17 (41%) relapsed ($p=0.37$). No difference in the mutational status of C-KIT gene was found when AML1/ETO and CBFb/MYH11-positive patients were evaluated separately ($p=0.36$ and $p=0.43$, respectively). Of 3 AML1/ETO cases with the exon 17 D816 mutation, 2 relapsed ($p=0.10$). *Conclusions.* We were unable to confirm any major prognostic impact of assaying C-KIT mutations in CBF-AML patients. The only result indicating a trend to prognostic significance applies to AML1/ETO patients with the D816 mutation in exon 17. However, in our experience, these patients are quite rare (3 of 34 patients). In the future, we plan to test solely the D816 mutation in AML1/ETO positive patients.

Supported by the Czech Ministry of Health research project 00237360001.

ESCAPE-MECHANISM IN CHILDHOOD ACUTE MEGAKARYOBLASTIC LEUKEMIAS

O. Hummel, I. Fränzel, K. Reinhardt, D. Reinhardt

Hannover Medical School, HANNOVER, Germany

Background. About 5 to 10% of the children with Down Syndrome showed a transient leukemia and had 400-fold risk to suffer myeloid leukemia (ML-DS) within the first 4 years of life. Both leukemias are characterized by megakaryoblastic differentiation and mutations of the hematological transcription factor GATA1. The incidence of acute megakaryoblastic leukemias (AMKL) in children without Down syndrome is 6% only. In ML-DS and AMKL severe myelofibrosis is a typical problem, whereas TL could be complicated by a liver fibrosis. As previously shown transforming growth factor beta (TGFb), secreted preferentially by megakaryoblasts, was supposed to induce myelofibrosis. As a TGFb usually inhibited cell proliferation, we hypothesized that the dominating leukemic blasts, used an *escape* -mechanism as proliferation advantage. *Methods.* Expression of the TGFb-receptors I,II,III (TBR I,II,III), the pseudoreceptor BMP and activin membrane-bound inhibitor (BAMBI), thrombopoietin-receptor (c-mpl), cytokine.receptor CXCR4 and BMP2 were analysed by qPCR, gene expression profiling and immunophenotyping (if applicable) in primary AML-blasts and megakaryoblastic cell lines (CMK derived from a TL, M07 derived from AMKL, HL60 as control). Further we analysed the TGFb-receptor regulation by increasing concentrations of TGFβ(10 to 50 ng/mL) in patient derived bone marrow stroma-cell - CMK/M07/HL60/blasts/CD34$^+$ stem cell co-cultures. *Results.* Myeloid blasts from patients with TL, ML-DS and AMKL showed significantly decreased expression of TBR III, SDF-1 and CXCR4 and an increased expression of BAMBI, c-mpl and BMP2. Further, the WNT-, TGFb- and Cadherin-signalling pathways were activated in all three entities. In co-cultures, proliferation of CMK and M07 cell line was slightly inhibited. A TGFb dependent down regulation of TBR III and an up regulation of Bambi could be demonstrated. Interestingly, CXCR4 expression was strongly induced in both CMK cells and bone marrow stroma cells. *Conclusions.* The preliminary results support the hypothesis that TGFb is in involved in an escape mechanism of childhood megakaryoblastic leukemias

MOLECULAR CHARACTERIZATION OF THE MLL-SEPT6 FUSION GENE IN ACUTE MYELOID LEUKAEMIA: IDENTIFICATION OF NOVEL FUSION TRANSCRIPTS AND CLONING OF GENOMIC BREAKPOINT JUNCTIONS

N. Cerveira,[1] F. Micci,[2] J. Santos,[1] M. Pinheiro,[1] C. Correia,[1] S. Lisboa,[1] S. Bizarro,[1] L. Norton,[1] A. Glomstein,[2] A.E. Åsberg,[3] S. Heim,[2] M.R. Teixeira[1]

[1]Portuguese Oncology Institute, PORTO, Portugal; [2]Radiumhospitalet-Rikshospitalet Medical Center, OSLO, Norway; [3]St. Olav University Hospital, TRONDHEIM, Norway

Background and Aims. Abnormalities of 11q23 involving the MLL gene are found in several haematological malignancies, including acute lymphoblastic leukaemia (ALL) and acute myeloid leukaemia (AML). One of the more than 52 different MLL fusion partners so far identified is the SEPT6 gene, which belongs to an evolutionarily conserved family of genes, the septins. In this work we aimed to characterize at both the RNA and DNA levels three AML cases with chromosome banding and/or molecular cytogenetics evidence of a rearrangement between 11q23 and Xq24 (the SEPT6 locus). *Design and Methods.* Three AML cases were studied by a combination of cytogenetic (chromosome banding and/or fluorescence *in situ* hybridisation), molecular (RT-PCR, LD-PCR, HN-PCR and sequencing), and bioinformatic methodologies. *Results.* Karyotyping and molecular cytogenetics showed, in all cases, a chromosomal recombination between 11q23 and Xq24. Molecular analysis led to the identification of several MLL-SEPT6 fusion transcripts in all cases, including a novel MLL-SEPT6 rearrangement (MLL exon 6 fused with SEPT6 exon 2) and several alternative splicing variants. Genomic DNA breakpoints were found inside or near Alu or LINE repeats in the MLL breakpoint cluster region, whereas the breakpoint junctions in the SEPT6 intron 1 mapped to the vicinity of GC-rich low-complexity repeats or near Alu repeats. In addition, a topoisomerase II consensus cleavage site was detected in SEPT6 intron 1. *Interpretation and Conclusions.* We characterized a novel MLL-SEPT6 rearrangement in childhood AML. Our findings suggest that a non-homologous end-joining repair mechanism may be involved in the generation of MLL-SEPT6 rearrangements in AML.

INHIBITION OF THE PROLIFERATIVE AND ANGIOGENIC ACTIVITY OF FLT3 INTERNAL TANDEM DUPLICATION MUTANTS FROM ACUTE MYELOID LEUKEMIA CELL LINES BY A TYROSINE KINASE INHIBITOR

L.A. Luis Arístides,[1] N. Barbarroja,[2] M.J. Luque,[2] R.M. Carretero,[2] A. Torres,[3] V. Velasco,[3] Ch. Lopez-pedrera[2]

[1]Hospital Reina Sofía, CÓRDOBA; [2]Unidad de Investigación, CÓRDOBA; [3]Servicio de Hematología, Hospital Reina Sofía, CÓRDOBA, Spain

The Flt3 gene encodes a haematopoietic class III receptor tyrosine kinase (RTK) involved in the proliferation and differentiation of the haematopoietic stem cells. Activation of the Flt3 by different types of mutations plays an important role for proliferation, resistance to apoptosis, and prevention of differentiation of leukemic blasts in acute myeloid leukemia (AML). At least one type of such mutations -an internal tandem duplication in the Flt3 juxtamembrane domain (Flt3/ITD)- has been associated with an unfavourable prognosis. RTK signaling pathways are normally highly regulated. However, their over activation has been shown to promote the growth, survival, and metastasis of tumour cells. Over expression of vascular endothelial growth factor (VEGF, a major angiogenesis regulator), and its specific tyrosine kinase receptors, VEGFR1 (Flt1) and VEGFR2 (KDR), are detected in a variety of haematological malignancies, including AML, were they contribute to poor survival and negative progression of the malignancy. In the last years, many laboratories embarked on projects aimed at generating compounds that specifically inhibited the activity of these aberrant signalling cascades triggered by tyrosine kinases involved in tumorigenesis. The aim of the present study was to analyze the molecular and cellular effects of Flt3 inhibition in AML cell-lines representative of the different Flt3 genotypes, by using both chemical inhibitors (AG1296 and AG1295) or gene silencing (by using a lentiviral system). Four cell lines were analyzed: NB4 and THP-1 (Flt3/wt), Molm13 (Flt3ITD/wt), and MV411 (Flt3ITD/-). *Results.* AG1296 selectively and potently inhibited autophosphorylation of constitutively activated Flt3 in Flt3-ITD cell lines (MV411 and Molm13) in a dose-dependent manner. Concomitantly, cell proliferation was prevented and apoptosis was induced. Moreover, the constitutive activation in AML cells of Flt3-mediated intracellular kinases (ERK, AkT and STAT5) was inhibited in the cell lines holding the mutated receptor. Furthermore, AG1296 was shown to be involved in the blockage of VEGF/VEGFRs expression, resulting in inhibition of VEGFRs activity. Combined RNAi-induced downregulation of Flt3 expression and treatment with the chemical inhibitors of RTK activity, leaded to higher efficiency in the inhibition of both cell proliferation and angiogenesis, as well as to the prevention of the apoptosis induction in AML cells. *Conclusions*. Their activity against Flt3 and their potent antiangiogenic activity, suggest a potential therapeutic application of AG1296 or similar drugs, in combination with RNAi-induced down-regulation of Flt3 expression, in the treatment of AML involving deregulated Flt3-tyrosine kinase activity.

AKT AND PKC ARE POSSIBLE REGULATORS OF TELOMERASE ACTIVITY DURING DIFFERENTIATION OF MYELOID LEUKEMIC CELLS

O. Yamada,[1] K. Ozaki,[1] M. Nakadake,[2] M. Akiyama,[3] K. Kawauchi,[4] R. Matsuoka[1]

[1]Tokyo Women's Medical University, TOKYO, Japan; [2]Institut Gustave Roussy, VILLEJUIF, France; [3]Jikei University School of Medicine, TOKYO, Japan; [4]Tokyo Women's Medical University Medical Center East, TOKYO, Japan

Background. Telomerase is active in immature somatic cells and tumor cells, but is suppressed in differentiated cells. Several mechanisms of telomerase regulation, including transcriptional, translational, and post-translational mechanisms, have been reported, suggesting that the regulation of telomerase activity is a complex process. *Aims.* To determine the mechanisms modulating telomerase activity during granulocytic and monocytic differentiation of hematopoietic cells. *Methods.* A human acute myeloblastic leukemia cell line (HL60) was induced to undergo monocytic differentiation by exposure to VD3, while granulocytic differentiation was induced by exposure to ATRA or Am80 (an RAR-α/β-selective retinoid that does not bind and activate RAR-γ and RXRs). Changes of several signaling proteins during differentiation were examined. Telomerase activity, expression of human telomerase reverse transcriptase (hTERT) protein and mRNA, and epigenetic factors within the telomerase promoter region were also examined. *Results.* Rapid down-regulation of telomerase transcription occurred during early differentiation of HL60 cells into both lineages prior to G1 arrest. Akt kinase activity was transiently suppressed after 6 hours of differentiation along with inhibition of telomerase activity. Because significant suppression of Akt activity occurred while telomerase protein expression was maintained, the post-translational regulation of telomerase activity was suggested. Each of the three differentiation agents caused a significant increase of signaling proteins (including Akt, PKC-α, mTOR, Rictor, and p21) and a decrease of bcl-2 at 3 days after the initiation of differentiation. To further assess the transcriptional regulation of telomerase, a chromatin immunoprecipitation (ChIP) assay was performed. This showed that acetyl-Histone H4, which binds to the hTERT promoter, underwent deacetylation during differentiation. *Conclusions.* There was a decrease of telomerase activity and hTERT (protein and mRNA) expression during granulocytic and monocytic differentiation stimulated by ATRA and Am80 or VD3, respectively. Active forms of Akt, PKC-α, mTOR, and mTOR-associated Rictor protein showed an increase at 3 days after the induction of differentiation. It has been reported that Akt promotes the transcription of hTERT and post-translational activation of telomerase. Modulation of acetyl-Histone H4, which regulates transcription of the telomerase gene, was observed before the activation of Akt occurred at 3 days after the start of differentiation, which suggests that epigenetic control of telomerase transcription takes place before Akt activation occurs during differentiation. PKC was also reported to activate telomerase post-translationally, and recombinant PKC-α caused a dose-dependent increase of telomerase activity in HL60 cells. In differentiated cells, telomerase protein disappeared before the activation of PKC-α occurred. These results indicate that telomerase activity is regulated by at least two mechanisms during granulocytic and monocytic differentiation, with one being transcriptional and the other being post-translational and involving Akt and PKC.

TAP- AND PROTEASOME-DEPENDENT ENDOGENOUS ANTIGEN LOADING OF HLA CLASS II IN AML BLASTS INTRODUCES 'REVERSE' CROSS-PRESENTATION AND A PROMISING NEW TARGET FOR GENERATING LEUKEMIA-SPECIFIC CD4+ T CELLS

M.M. van Luijn,[1] M.E. Ressing,[2] E.J. Wiertz,[2] S. Ostrand-Rosenberg,[3] Y. Souwer,[4] G.J. Ossenkoppele,[1] A.A. Van de Loosdrecht,[1] S.M. Van Ham[4]

[1]VU Medical Center, AMSTERDAM, Netherlands; [2]Leiden University Medical Center, LEIDEN, Netherlands; [3]University of Maryland, BALTIMORE, USA; [4]Sanquin Research and Landsteiner Laboratory, AMSTERDAM, Netherlands

Background. According to classical HLA class II antigen loading, exogenous antigens are processed in the endosomal/lysosomal pathway and associate with HLA class II after exchange with the class II-associated invariant chain peptide (CLIP). For this, the Invariant Chain (Ii) is required for targeting of HLA class II to the lysosomes. We recently showed that Ii knock-down in AML blasts resulted in a decline in CLIP amount per HLA-DR molecule (Van Luijn *et al.*; Abstract EHA 2008). Absolute HLA-DR amount was also lowered on these blasts, which is in line with the need of Ii for exogenous antigen loading on HLA class II. In other types of AML blasts however, Ii knock-down did not affect HLA-DR expression. *Aims.* To elucidate the Ii-independent pathway of HLA class II-restricted antigen presentation in AML. *Methods.* Ii expression was silenced in HLA-DR+ KG-1 and Kasumi-1 AML cell lines by RNA interference. Both cell lines were additionally transduced with UL49.5, a BHV-1-encoded protein that blocks peptide transport into the endoplasmic reticulum (ER) by interfering with the function of the transporter associated with antigenic processing (TAP). After FACS-sorting of TAP-deficient HLA-DR- and HLA-DR+ cell populations, Ii expression was determined by flow cytometry. Furthermore, MG-132 was used to abrogate proteasome activity and confirm endogenous antigen processing. *Results.* Ii silencing in the Kasumi-1 cell line lead to a drastic decline in HLA-DR expression on the plasma membrane (13.9-fold decrease in MFI). Surprisingly, HLA-DR levels on KG-1 cells were hardly affected by Ii silencing. As HLA-DR expression does require peptide binding, Ii-independency may be achieved by endogenous antigen loading. To test this hypothesis, supply of endogenously derived peptides into the ER was blocked by viral proteins that interfere with the function of TAP. In line with previous findings, TAP inhibition in KG-1 cells by UL49.5 (which degrades TAP and changes it conformation) resulted in a significant down-regulation of HLA class I (7.7-fold MFI decrease). Most interestingly, this modulation also lead to a clear HLA-DR- (52.3%; MFI=1.4) KG-1 population next to HLA-DR+ (36.5%; MFI=288.9) KG-1 cells. Upon sorting of both populations, TAP-deficient HLA-DR- and HLA-DR+ cells contained a respectively lower (2.4-fold MFI decrease) and higher (3.0-fold MFI increase) amount of intracellular Ii as compared to wild type cells. Moreover, silencing of Ii expression in TAP-deficient HLA-DR+ cells caused a strong decline in HLA-DR expression, both intracellularly (1.5-fold MFI decrease) and extracellularly (2.3-fold MFI decrease). Finally, specific inhibition of the proteasome also resulted in a marked down-regulation of HLA-DR expression on KG-1 cells in contrast to Kasumi-1. At the less toxic concentration, MG-132 treatment caused a 2.1- and 2.7-fold MFI decrease, respectively. This confirms that a least part of the antigens presented by HLA class II in KG-1 are derived from endogenous sources. *Summary and Conclusions.* These data reveal a TAP- and proteasome-dependent 'reverse' cross-presentation pathway of endogenous antigens on HLA class II molecules. Modulation of this pathway in AML blasts might enhance HLA class II-restricted presentation of leukemic antigens, leading to leukemia-specific activation of CD4+ T effector cells.

DISRUPTION OF TGF-β SIGNALING IN ACUTE PROMYELOCYTIC LEUKEMIA DEPENDS ON NUCLEAR PML FUNCTION

L.L. Figueiredo-Pontes, B.A.A. Santana-Lemos, R.H. Jácomo, A.S.G. Lima, A.I. Dore, F.U. Ferreira, A.A. Goes, R.A. Panepucci, D.T. Covas, A.M. Fontes, R.P. Falcao, E.M. Rego

Medical School of Ribeirao Preto, RIBEIRAO PRETO, SAO PAULO, Brazil

PML is a tumor suppressor that, among its physiological roles, acts as a regulator of the TGFβ pathway. Recently, Lin, Bergman and Pandolfi have demonstrated that Pml-null mouse embryonic fibroblasts are resistant to TGFβ-dependent growth arrest, apoptosis and cellular senescence. In the absence of PML, induction of TGFβ target genes and phosphorylation of TGFβ-signaling proteins Smad2 and Smad3 are impaired. Restoration of a cytoplasmic isoform of PML (cPML) in these cells reverts TGFβ defects, suggesting that it is an essential modulator of TGFβ signaling. In acute promyelocytic leukemia (APL), the expression of the PML-RARα oncoprotein leads to PML delocalization and functional impairment. Therefore, deregulation of TGFβ pathway may play a role in APL pathogenesis. However, PML-RARα is expressed mainly in the nucleus, and its effect on TGFβ and TGFβ-target genes transcription is unknown. In this context, our aim was to study the role of nuclear PML-RARα in TGFβ signaling. A conditional retroviral model in which PML-RARα expression is regulated by doxycycline was generated in the NIH/3T3 fibroblastic murine lineage. In this model, PML-RARα full-length cDNA was cloned in a retroviral vector containing a tetracycline-responsive element. Both the responsive recombinant vector and a regulatory vector containing the reverse tetracycline transactivator were transfected in the EcoPack293 packaging cell line. The resulting virus-containing supernatants were used to serially infect NIH/3T3 target cells, which were then treated and selected with vector resistant antibiotics. After recovery, transduced NIH/3T3 cells were submitted to treatment with doxycycline (2000ng/mL) during 72 hours. Total RNA was obtained and reverse transcribed. Real Time PCR for the expression of PML-RARα, Tgfβ and Smad3 was performed. Results showed that doxycycline induced an eight fold increase of PML-RARα gene expression. In the presence of PML-RARα, the expression of Tgfβ and its mediator and target Smad3 was repressed, thus suggesting that the transcription of TGFβ is PML-RARα dependent. Western blot analysis of Tgfβ expression in the nuclear fraction of doxycycline-treated and untreated controls revealed no difference. Therefore, PML-RARα oncoprotein can antagonize not only cPML but also nuclear PML (nPML) function leading to disruption of TGFβ signaling in both nucleus and cytoplasm. We can hypothesize that, in the nucleus, PML-RARα may interrupt the interaction of nPML with Smad2/3/4 complex leading to blockade of TGFβ transcriptional activity. Although the disruption of TGFβ pathways itself is not sufficient to initiate malignant transformation, it may be a critical second step that contributes to leukemia progression. In this context, the modulation of TGFβ signaling may have therapeutic interest in APL.

POLYMORPHISMS OF THE DNA REPAIR GENE XRCC1 (399) AND XPD (751) CORRELATES WITH RISK OF ACUTE MYELOID LEUKEMIA IN TURKISH POPULATION

A. Ozcan,[1] M. Pehlivan,[2] E. Karaca,[1] C. Ozkinay,[1] F. Ozdemir,[1] S. Pehlivan[3]

[1]Ege University, IZMIR; [2]Gaziantep University department of hematology, GAZIANTEP; [3]Gaziantep University Department of Medical Biology, GAZIANTEP, Turkey

Background. The DNAs of all organisms are continuously under the threat of internal and external factors causing DNA damages. The aim of DNA repair mechanism is to protect genome integrity. Polymorphisms that occur in DNA repair genes affect DNA repair capacity and constitute a risk factor in hematological malignities. X-ray repair cross-complementing group 1 (XRCC1) and Xeroderma pigmentosum complementation group D (XPD), the DNA repair genes, work in the base excision repair (BER) mechanism and the nucleotide excision repair (NER) mechanism. Polymorphisms of XRCC1 gene codon 399 and XPD gene codon 751 in polymorphic regions affect DNA repair capacity. *Methods.* In this study, X-ray repair cross-complementing group 1 (XRCC1) gene codon 399 and Xeroderma pigmentosum complementation group D (XPD) gene codon 751 polymorphisms were researched by the polymerase chain reaction-enzyme cutting (PCR-RFLP) method in 100 patients with hematological malignity (HM) (36 acute myeloid leukemia [AML], 64 lymphoid malignities [LM]) and 100 healthy controls and the distributions of genotypes and allels were compared in patient and control groups. *Results.* 46 of the patients with HM are females while 54 of them are males and the median age is 46 (16-82). When the genotype and allel frequencies among the HMs and healthy controls, XPD-751Gln variant, were arranged and compared according to age and sex, it was detected that Gln/Gln genotype, reported as a protector, decreased significantly in AML (p=0.042) and that there was no relation between allel frequencies (p=0.054). In XRCC1-399, it was detected that Gln/Gln genotype decreased significantly in AML (p=0.014) and in all HMs (p=0.033) and that Gln allel was present at a lower ratio in AML (p=0.046). No statistical significance was found according to age and sex in the distribution of polymorphisms of both genes. In leukemias with early relapse, XPD 751 Lys/Lys genotype was observed to be at a statistically higher ratio (p=0.042). When both genes were evaluated togeth-

er, the presence of a relationship among MHs was detected upon a decrease in Gln/Gln+Lys/Gln haplotype frequency (p=0.048). *Conclusions.* With this study, it was put forth that a decrease in Gln/Gln genotype and Gln allel reported to be a protector among XRCC1 codon 399 and XPD codon 751 polymorphisms in AML and an increase in Lys/Lys genotype in acute leukemias were related to early relapse.

PROGNOSTIC SIGNIFICANCE OF MOLECULAR MARKERS IN NORMAL KARYOTYPE -AML: A SINGEL CENTER EXPERIENCE

O. Spinelli, M. Tosi, V. Guerini, P. Zanghì, M. Franchi, I. Taboni, M. Magri, C. Zanotti, T. Intermesoli, E. Oldani, R. Bassan, A. Rambaldi

Ospedali Riuniti, BERGAMO, Italy

Background. Cytogenetic alterations well define the outcome of Acute Myeloblastic Leukemia (AML). In Normal Karyotype (NK) AML other molecular markers are needed to predict the prognosis and to drive clinical decisions. In the last decade some molecular markers have been proposed, but the clinical significance of some of them is still not well defined. *Aims*. To verify the clinical significance of the presence or absence of molecular markers in predicting the outcome of NK-AML patients enrolled in sequential clinical studies in our center. *Methods*. Diagnostic samples derived from 105 NK-AML patients (age<60y) enrolled in 4 sequential clinical study (STT, BXIII. BXIV, LAM2000) were analyzed for FLT3-ITD, FLT3-TKD, NPM1, WT1 (exon 7 and exon 9), MLL-PTD and CEBPA mutations. *Results*. The prevalence of each mutation was the following: FLT3-ITD 32% (30/94), FLT3-TKD 7% (7/97), NPM1 49% (44/90), WT1 9% (7/77), MLL-PTD 6% (3/53), CEBPA 16% (8/51). The CR rate of this group of patients was 88%. With a median observation time of 21,1 months the Overall Survival (OS) and Disease Free Survival (DFS) of this group of NK-AML patients were 40% and 43%, respectively. By univariate analysis, OS was decreased in the presence of FLT3-ITD (26% *vs* 48%, p=0.015) while it was apparently increased by the presence of CEBPA mutation (100% *vs* 44%). Patients carrying WT1 gene mutations showed an inferior OS (28% compared to 43% of WT1 negative patients) but this difference did not reach a statistical significance (p=0. 4). The DFS was significantly inferior in FLT3-ITD positive patients (30% *vs* 51%, p= 0.006) and a 75% DFS was seen in CEBPA positive patients compared to 48% in CEBPA negative patients (p= 0.2). The probability to achieve a CR was superior in NPM1 positive patients (93% *vs* 78%, p=0.04) while no significant difference was associated with the presence of other mutations. By multivariate analysis (CEBPA and MLL-PTD were excluded for the limited number of patients), the presence of FLT3-ITD independently predicts a worse DFS (HR 2.19, CI 1.03-4.66, p=0.041). On the contrary, the presence of NPM1 mutation predicts a better CR rate (OR 6.17, CI 1.01-37.52, p= 0.048) and showed also a positive trend for a better DFS (HR 0.48, CI 0.22-1.06, p= 0.07) and a better OS (HR 0.54, CI 0.26-1.1, p=0.09). The presence of WT1 gene mutations was associated with a worse OS (HR 2.8, CI 0.86-9.5, p= 0.08). *Conclusions*. In a cohort of NK-AML patients, sequentially treated with intensive chemotherapy protocols in a single center, we confirmed the adverse prognostic impact of FLT3-ITD and WT1 gene mutations, and the favorable outcome associated with CEBPA and NPM1 gene mutations. All these markers should be identify in each case in order to better define the prognostic profile of each patient and the best post remission consolidation treatment strategy.

PTK 787/Z222485, A POTENT INHIBITOR OF VASCULAR ENDOTHELIAL GROWTH FACTOR RECEPTOR TYROSINE KINASE PHOSPHORYLATION, MIGHT CONSTITUTE A NEW EFFECTIVE THERAPY TO ACUTE MYELOID LEUKEMIA

N. Barbarroja,[1] L.A. Torres,[2] M.J. Luque,[2] R.M. Carretero,[2] A. Torres,[3] F. Francisco,[4] Ch. López-Pedrera[2]

[1]Hospital Reina Sofia, CÓRDOBA; [2]Unidad de Investigacion, CORDOBA; [3]Servicio de Hematología, CORDOBA; [4]Servicio de Hematologia, CORDOBA, Spain

Angiogenesis plays an important role in the pathogenesis of acute myeloid leukemia (AML) and the vascular endothelial growth factor (VEGF) is a crucial, positive regulator of this process. The biological activity of VEGF is mediated by two different receptor tyrosine kinases: VEGFR-1/Flt-1 and VEGFR-2/KDR. Many studies have shown that high levels of VEGF protein are correlated with short survival and poor prognostic of patients with AML. This fact has encouraged the study of specific inhibitors of VEGF and its receptors as alternative therapy. Currently, new antitumoral drugs inhibitors of VEGFRs activity are being analyzed. PTK787/ZK 222584 is an oral angiogenesis inhibitor targeting vascular VEGF receptor tyrosine kinases, including VEGFR-1, VEGFR-2, VEGFR-3/Flt-4, the platelet-derived growth factor receptor tyrosine kinase and the c-kit protein tyrosine kinase. Clinical trials have demonstrated the efficiency of this compound in the cell proliferation inhibition and in the induction of the cell apoptosis in various solid tumours. However, there are still unknown its effects in AML blast. *Objective*. To investigate the role of the VEGFRs inhibitor PTK787/ZK222584 on cell proliferation, survival and angiogenesis in AML cells, and the effect of the combined treatment with a chemotherapeutic drug, idarrubicin. *Material and Methods.* Four AML cell lines (MV4-11, MOLM-13, NB4 and THP-1) were treated with PTK787 (2.5, 5, 10, 20 and 40 μM), given alone or combined with idarrubicin (2 ng/mL) for 24 and 48 hours. Then, cell apoptosis was analyzed by flow cytometry, and cell proliferation was detected using an XTT colorimetric assay. The effects on the activation of VEGFRs and several intracellular pathways (ERK, Akt and STAT5) were studied by western blot. The VEGF levels in the cellular supernatants were evaluated by ELISA assay. *Results.* PTK787 reduced the cell proliferation and induced apoptosis in a dose-dependent manner in the four cell lines. At the molecular level PTK787 inhibited the constitutive activation of ERK, Akt and STAT5. These effects were stronger in MV4-11 and MOLM-13 cells. Moreover, PTK787 reduced the VEGF expression levels and inhibited the phosphorylation of VEGFRs. On the other hand, the combined treatment with PTK787 and idarrubicin promoted an additive effect in the induction of cellular apoptosis, inhibition of cell proliferation and reduction of VEGF expression. *Conclusions.* Our overall results encourage the use of PTK787/ZK 222584 in association with low doses of chemotherapic agents in clinical trials for the treatment of AML.

CHOLESTEROL-RICH DOMAINS REGULATE FLT-1 ACTIVATION SIGNALS IN ACUTE MIELOID LEULKEMIA CELLS

C. Casalou, J.F. Moura Nunes, S. Dias

Portuguese Institut of Oncology, LISBON, Portugal

Cholesterol-rich domains (i.e. lipid rafts and caveolae) have been implicated in several cellular processes. By concentrating several molecular components they function as platforms for cell signaling. Caveolin-1, the major protein component of caveolae, has been implicated in intracellular cholesterol transport. We have found that vascular endothelial growth factor receptor-1 (FLT-1) and caveolin-1 mRNA expression levels are up-regulated by PLGF/VEGF binding in AML cells. Also, FLT-1 mRNA expression level is also regulated by cellular-cholesterol content. Increased cellular cholesterol levels on AML cells up-regulate FLT-1 and caveolin-1 expression. Moreover, FLT-1 protein phosphorylation is abolished by treatment of AML cells with β-cyclodextrin, a cholesterol depletion agent or by nystatin, an inhibitor of lipid raft endocytosis. Co-localization FLT-1 with caveolin-1 in AML cells is also affect by cholesterol cellular content. In addition, by sucrose-gradient fractionation we have found that FLT-1 co-sediments with lipid-raft protein components together with Rac-1 and Hsp90 proteins. These results show that on leukaemia cells FLT-1 Is associated with lipid rafts/caveolae and this association is crucial for FLT-1 expression and signaling on acute leukaemia cells. Furthermore, a soluble portion of caveolin-1 was found in the subcellular-fractionation of AML cells and by immuno-electron microscopy we localized caveolin-1 primarily inside mitochondria of PLGF-stimulated leukemia cells. Analysis of mitochodrial extracts showed that cholesterol depletion removes caveolin-1 from mitochondria and by opposition, a large acumulation of caveolin-1 inside leukemia cell mitochondria was found after increased cellular cholesterol levels. These studies suggest a regulation of cholesterol intracellular-trafficking exerted by FLT-1-activation after VEGF/PLGF stimulus and implicate an unexpected role for this signaling pathway in mitochondria function (i.e. aerobic metabolism).

VASCULAR ENDOTHELIAL GROWTH FACTOR PLAYS AN IMPORTANT ROLE FOR THE RECOVERY OF NORMAL HEMATOPOIESIS AFTER CHEMOTHERAPY IN ACUTE MYELOGENOUS LEUKEMIA CASES

H. Haruko, M. Noguchi, R. Shirasaki, T. Sugao, Y. Oka, K. Kawasugi, Y. Akiyama, N. Shirafuji

Teikyo University School of Medicine, TOKYO, Japan

Objective. The serum vascular endothelial growth factor (VEGF) level is decreased in aplastic anemia cases. We investigated VEGF system at the onset and after chemotherapy of acute myelogenous leukemia (AML) cases, and determined whether VEGF system influenced the prolonged bone marrow suppression observed in some of these cases. *Materials and Methods.* Sera and bone marrow cells were prepared from 40 informed AML patients including 12 cases of AML (M3) at the onset of the disease, and the recovery periods after chemotherapy including the prolonged hematopoietic suppression periods observed in some of the cases, and the concentration of VEGF in sera of the patients and in the conditioned media obtained from non-adherent bone marrow-cell cultures was measured with ELISA kit (Quantikine; R&D Systems). The expression of VEGF, VEGF receptor type-1 (VEGFR-1) and VEGF receptor type-2 (VEGFR-2) was analyzed with RT-PCR. The biological effect of VEGF on the bone marrow cells which showed the prolonged suppression after chemotherapy was analyzed with colony-formation assay. *Result and Discussion*. As was reported previously, VEGF levels were significantly increased in all of M3 cases. In other types of AML cases the levels of VEGF varied. When patients were given chemotherapy and the sustained bone marrow suppression was observed, the production of VEGF was significantly decreased less than that observed in AML cases with normal bone marrow recovery. In M3 cases that were treated with all-trans retinoic acid and the prolonged bone marrow-suppression was observed, VEGF production was also significantly suppressed. In these sustained suppression cases, when normal hematopoiesis was observed after the long duration, VEGF levels were recovered to be increased. The expression of VEGFR-2 was demonstrated in bone marrow cells from prolonged bone marrow suppression cases; however, the expression of VEGFR-1 was not observed. In these cases, when bone marrow cells were cultured with VEGF, synergistic effects with G-CSF, EPO and Stem Cell Factor and FLT-3 Ligand were observed with colony-formation assay. These observations indicate that VEGF works on the important role for the normal hematopoietic recovery after chemotherapy in AML cases.

PROTEOMIC MODIFICATIONS INDUCED BY VALPROIC ACID IN AML1/ETO POSITIVE LEUKEMIA CELLS

V. Santini,[1] F. Buchi,[2] G. Ferrari,[2] E. Spinelli,[2] A. Gozzini,[2] T. Lunghi,[2] A. Bosi[2]

[1]University of Florence, FIRENZE; [2]AOU Careggi, University of Florence, FLORENCE, Italy

Background. Alterations in chromatin organization are a common mechanism in leukemogenesis. Many drugs affecting epigenetic modulation of gene expression have been proposed as therapy of haematopoietic neoplasms, unfortunately frequently without selection on a molecular basis of disease types more prone to respond to these agents. *Aims.* On the basis of our previous findings, we think that HDAC inhibitors could be remarkably effective in the treatment of some forms of acute myeloid leukemias, i.e. CBF-AML. *Methods.* We analysed the effects of the short chain fatty acid derivative valproic acid (VPA 2mM) on the proteome of AML1-ETO-positive, AML blast cells. We also analysed the differences in response to VPA shown by AML1/ETO-inducible U937-A/E-9/14/18 cells, with and without expression of AML1/ETO protein. VPA is suitable for oral administration and is the HDACi most easily available for clinical use in Europe. Total cell protein extracts of treated and untreated AML1-ETO-positive cells were separated by two dimensional electrophoresis (2DE) on non-linear pH gradient 3-10. The 2D gels were analysed by adequate software (Image Master TM Platinum), for spot detection and quantification. 2D gels were virtually superimposed and aligned for proteomic comparison. *Results.* Significant differences both qualitative and quantitative in protein spots appeared between treated and untreated cells. Moreover, spot differences were increasing throughout the period of culture (24-72 hours) in the presence of VPA and subsequent histone acetylation (determined by western blot), inhibition of proliferation (cell cycle analysis, MTT test) and apoptosis (annexin -V expression). MALDI-TOF MS analysis (PMF and/or MS/MS experiments) of the most representative protein spots indicated that the correspondent identified proteins may be divided into functional categories: DNA binding/signal transduction proteins, metabolic enzymes, heat shock proteins and chaperones. Proteins induced by VPA were: enolase-1, laminin -binding protein Siah-interacting protein (SIP). VPA significantly enhanced the expression of the following proteins: nucleophosmin, EEF1D protein, stathmin 1, activator of HSP-90 ATPasi, tumor rejection antigen (gp 96). VPA inhibited the expression of cofilin-1 and calreticulin precursor variant , as well as that of proteasome subunit alpha and beta. *Conclusions.* There is growing evidence of the importance of nucleus-cytoplasm trafficking in neoplastic cells. Therefore, the identification of a significant modulation by VPA of proteins regulating cell trafficking and of chaperone proteins indicates a fundamental role of this agent in affecting the function of AML1/ETO positive leukemic cells. Moreover, common proteins with different spot distribution were identified, leading to the hypothesis of the presence of different isoforms or post translational modifications of the same protein. The effects of VPA, like other HDACi, appeared significant in AML1-ETO-positive cells where the stability of DNMT/HDAC repressor complex binding to DNA was reduced, strongly suggesting to consider therapy with HDACi for AML molecular subtypes, such as CBF-AML, in which chromatin-organizing proteins are involved in the pathogenesis of disease. Thus, the treatment with HDACi, possibly in combination with hypomethylating agents, as we also observed, may specifically influence the natural history of leukaemia by interfering with the molecular mechanisms of leukaemogenesis.

PROTEOMIC MODIFICATIONS INDUCED BY AZACITIDINE IN AML1/ETO POSITIVE LEUKEMIA CELLS

V. Santini,[1] F. Buchi,[2] G. Ferrari,[2] E. Spinelli,[2] T. Lunghi,[2] A. Gozzini,[2] A. Bosi[2]

[1]University of Florence, FIRENZE; [2]AOU Careggi, University of Florence, FIRENZE, Italy

Background. Alterations in chromatin organization are a common mechanism in leukemogenesis. Many drugs affecting epigenetic modulation of gene expression have been proposed in clinics, mostly without selection on a molecular basis of disease types more prone to respond to these agents. On the basis of our previous findings, we think that some forms of acute myeloid leukemias, i.e. CBF-AMLs, could be specifically sensitive to DNMT inhibitors AZA has been shown to prolong survival in MDS and has been used also in AML therapy. *Aims.* We analysed the effects of the hypomethylating agent azacitidine (AZA 1uM) on the proteome of AML1-ETO-positive, AML blast cells. We also analysed the differences in response to AZA shown by AML1/ETO-inducible U937-A/E-9/14/18 cells, with and without expression of AML1/ETO protein. *Methods.* Total cell protein extracts of treated and untreated AML1-ETO-positive cells were separated by two dimensional electrophoresis (2DE) on non-linear pH gradient 3-10. The 2D gels were analysed by adequate software (Image Master TM Platinum), for spot detection and quantification. 2D gels were virtually superimposed and aligned for proteomic comparison. Methylation of p15 promoter (methylation specific-PCR), histone acetylation (Western blot), inhibition of proliferation (cell cycle analysis,) and apoptosis (annexin-V expression) were evaluated in parallel. *Results.* AZA inhibited cell proliferation and induced significantly higher levels of apoptosis in AML1-ETO expressing cells. At proteome analysis, significant differences both qualitative and quantitative in protein spots appeared between AZA treated (24-72 hours) and untreated cells. Total spots number was 620 in untreated cell lysates, and 486 in AZA treated. 400 spots were matching, and MS identified 31 proteins with different level of expression in treated *vs* untreated cells. MALDI-TOF MS analysis (PMF and/or MS/MS experiments) of the most representative protein spots indicated that the correspondent identified proteins could be divided into 4 functional categories: DNA binding/signal transduction proteins, metabolic enzymes, heat shock proteins and chaperones, structural proteins. Proteins induced by AZA were: calmodulin and Cypa /Hvgpia. AZA significantly enhanced the expression of the following proteins: NM23a , hPCNA, both DNA binding proteins and the structural protein muscle Z-line. AZA inhibited the expression of ER60 protease, VCP protein, proline-4-hydroxylase. Heat shock proteins like HSP90, 60, 70 gp96, but also tubulin and enolase 1 had different spot distribution in AZA treated lysates *vs* untreated, indicating post translational modifications induced by the hypomethylating agent. Western blots with specific antibodies for single identified proteins were performed to confirm quantitative and qualitative results. *Conclusions.* We observed a significant modulation by AZA of proteins regulating cell trafficking and of chaperone proteins. The role of these proteins in maintaining the transformed phenotype in AML1/ETO positive leukemic cells has to be ascertained, because indeed the characterization of their activity could be important in identifying markers of sensitivity to DNMTinhbitors.

Acute myeloid leukemia - Clinical II

SAFETY AND EFFICACY EXPERIENCE OF SNS-595 IN RELAPSED/REFRACTORY ACUTE LEUKEMIA PATIENTS = 60 YEARS OLD COMPARED TO < 60 YEARS OLD: RESULTS OF A PHASE 1 STUDY

C Michelson,[1] J. Lancet,[2] H. Kantarjian,[3] F. Ravandi,[3] F. Giles,[4] G. Michelson,[1] J. Karp[5]

[1]Sunesis Pharmaceuticals Inc, SOUTH SAN FRANCISCO; [2]H Lee Moffitt Cancer Center, TAMPA; [3]M. D. Anderson Cancer Center, HOUSTON; [4]UT-San Antonio, SAN ANTONIO; [5]Johns Hopkins Sidney Kimmel Cancer Center, BALTIMORE, USA

SNS-595 is a novel naphthyridine analog, a subclass of quinolones not previously used for the treatment of cancer. SNS-595 has a specific, saturable interaction with DNA and is a topoisomerase II poison, causing replication-dependent site-selective double strand DNA damage, irreversible G2 arrest and rapid apoptosis. SNS-595 is not a substrate for P-glycoprotein, thereby evading a common drug-resistance mechanism, and has low potential for CYP450-mediated drug-drug interactions. SNS-595 is in phase 1 and 2 clinical trials in acute myeloid leukemia and ovarian cancer, with clinical responses in these indications as well as in NSCLC and SCLC. A phase 1 dose escalation study was recently completed (Proc ASH 2007) and the MTD on the weekly schedule (qw) was 72 mg/m^2 and on the twice weekly schedule (biw) was 40 mg/m^2. A review of the safety and efficacy data by age group is presented. *Methods.* SNS-595 was administered as a slow IV push on days 1, 8, 15 (qw) or days 1, 4, 8, 11 (biw). Patients were assessed at least weekly for safety and hematologic recovery. *Results.* Across both schedules, 70 patients (pts) were enrolled and are evaluable. 27 pts were < 60 years old (yo) (median=43 yo; range: 21-59 yo) and 43 pts were ≥60 yo (median=69 yo, range: 60-85 yo). Pt demographics were comparable between the two treatment schedules: most pts were males (63%) and white (74%), ECOG PS=0 or 1 (91%), and had relapsed or refractory AML (83%). For the 27 pts who were < 60 yo, the most common grade 3 or higher AEs were: febrile neutropenia (31%), thrombocytopenia (19%), neutropenia (15%), and stomatitis (15%). Similarly, among the 43 pts who were ≥60 yo, the most common grade 3 or higher AEs were: febrile neutropenia (31%), neutropenia (24%), thrombocytopenia (21%), and stomatitis (12%). The DLT for both schedules was oral mucositis with similar incidence of stomatitis among those < 60 yo and ≥60 yo. There were 5 total CR/CRps across both schedules: 4 CR/CRps in the qw schedule (2 were in pts < 60 yo, 2 were in pts ≥60 yo); and 1 CRp in a pt on the biw schedule ≥60). In addition, there was one CRi in the ≥60 yo group. All the CR/CRps in the qw schedule had previously failed anthracyclines and cytarabine and had intermediate or unfavorable cytogenetics. Linear pharmacokinetics was observed across both patient age groups and antileukemic activity was associated with time above a 1 μM threshold. *Conclusions.* SNS-595 appears to be generally well tolerated in pts with advanced leukemias in pts ≥60 yo and <60 yo. Complete remissions have been observed in both age groups. Given this safety profile, a single agent study of SNS-595 as front line treatment for AML pts ≥60 yo is underway as is a combination study with cytarabine for relapsed/refractory AML in pts ≥18 yo.

EXTRA-MEDULLARY MYELOID TUMOR: A RETROSPECTIVE CLINICOPATHOLOGICAL STUDY OF 32 CASES.

T. Todd, M. Besser, J. Craig, R. Marcus

Cambridge University Hospitals NHS Foundation Trust, CAMBRIDGE, UK

Background. Extra-medullary myeloid tumour (EMMT, also granulocytic sarcoma, myeloid sarcoma or chloroma) is characterized by collections of immature myeloid cells outside the bone marrow. High rates of misdiagnosis have been shown in multiple studies in the previous century although no studies have examined the impact of this on outcome. Current UK guidelines recommend treatment of EMMT in the same fashion as acute myeloid leukaemia but a recent European study (clinical follow up of 67 patients) suggests EMMT has a very poor outcome (long term survival rate 11%) and recommends allogeneic stem cell transplantation as first line therapy in all patients. *Aims*. To assess the current rate of, and reasons for, misdiagnosis, the possible impact of this on patient outcome and survival, and survival in patients not treated with allogeneic transplant. *Methods*. Cases of extramedullary myeloid tumour (EMMT) diagnosed at our institution between 01/01/1997 and 15/06/07 were identified by search of an electronic database. Case notes and pathology for these patients were reviewed. *Results*. 32 patients were identified. 15 (47%) had pre-existing or simultaneously diagnosed myeloid malignancy and 17 (53%) were *de novo* isolated EMMT. Misdiagnosis occurred only in the latter group (10/17, 59%) most commonly as lymphoma (6/10) and sarcoma (2/10). The initial pathology report highlighted difficulty of diagnosis in all cases. Nine of nine EMMT cases tested were strongly positive for MIB1, 6 of 6 for bcl-2, 3 of 3 for vimentin and 2 of 18 for CD79a. All the bcl-2 positive cases were misdiagnosed as Non-Hodgkin's lymphoma and 2 vimentin positive cases as sarcoma. No misdiagnosed case was initially tested for chloroacetate esterase or myeloperoxidase, though in 9/10 subsequent testing showed one or both to be positive. Overall survival for all patients from presentation was 14 months. Patients with lymphadenopathy (n=17) did significantly worse (median survival 8 months *vs* 27 months; log rank test $p<0.01$). There were no long term survivors in whom the mass was >10 cm at diagnosis (n=7) and only 1 long term survivor from 6 patients initially given non-AML chemotherapy. This patient switched to AML therapy within 7 days. 9 (28%, 7 adults, 2 children) cases were long term survivors (median follow up 1640 days). Two of these received local excision and radiotherapy only. The others received intensive AML chemotherapy, and one received allogeneic stem cell transplant. *Conclusions*. Despite older studies highlighting this issue, isolated *de novo* EMMT continues to present considerable diagnostic difficulty. Expression of markers such as vimentin or bcl-2 which are often seen in other malignancies contributes to this. Staining for myeloperoxidase and chloroacetate esterase in cases of diagnostic difficulty of solid tumours or lymphoma is suggested. Lymphadenopathy, mass size >10cm and incorrect initial therapy seem to adversely affect overall survival. Our series, with almost identical median follow up to the study quoted above, has a much higher long term survival rate despite only one patient receiving allogeneic stem cell transplantation. Our data do not support a need for allogeneic transplant as routine first line therapy.

0517

SEQUENTIAL TREATMENT WITH LOW DOSES OF RETINOIC ACID (LOATRA)±VALPROIC ACID(VPA) FOLLOWED BY LOW DOSES ARAC(LODAC) IN ELDERLY ACUTE MYELOID LEUKAEMIA(AML) PRELIMINARY CLINICAL AND BIOLOGICAL RESULTS

S. Fenu,[1] C. Nobile,[2] C. Nervi,[3] A. Chierichini,[1] P. Anticoli-Borza,[1] B. Anaclerico,[1] V. Bongarzoni,[1] R. Bruno,[1] S. Cortese,[1] P. Iacovino,[1] F. Pauselli,[1] C. Tozzi,[1] G. Cimino,[4] L. Annino[1]

[1]AZ. Osp. S.Giovanni-Addolorata, ROME; [2]Campus biomedico university, ROMA; [3]San raffaele Bio-medical Park Foundation, ROMA; [4]Department of cellular Biotechnolgy and hematology university La sapienza, ROMA, Italy

Background . Recent reports indicated the biological therapeutic potentiality and the clinical feasibility of epigenetic treatments with VPA+ATRA or ATRA alone in AML, and suggested their capability in sensitizing leukemic cells to chemotherapy. Therefore, we designed a single centre induction schedule with LoDAC preceded by VPA+LoATRA or LoATRA alone sequential administration to treat AML patients aged >65years or not eligible for intensive therapy. *Aims.*The aims of this study were to evaluate the clinical efficacy (in term of response rate and toxicity) and the biological changes occurring in leukemic blasts in relation to haematological response. *Methods.* From September 2006 to December 2007 we enrolled 14 consecutive AML patients (median age 66years, range: 44-81); of these 7 were *de novo* AML, 2 secondary AML and 5 were in ≥1 relapses. At treatment onset BM blasts ranged from 30% to 81%. As cytogenetics 6 patients had normal karyotype, 4 a complex one and 4 presented other abnormalities (Dup1, t(2;13), t(8;21), -y). Induction schedule consisted of VPA (in escalating dosage from 10 mg/kg/die to 30 mg/Kg/die) d1-55, LoATRA 25 mg/m^2 d7-55; LoDAC 40 mg t.d./die s.c. d10-16 and d45-51. Therapy was repeated every 20 days up to 3 cycles. Five patients (2=*de novo*; 3=relapsed) received VPA+LoATRA+LoDAC whereas 9 patients (5=*de novo*; 2=sAML ;2=relapsed) received LoATRA+LoDAC because of concomitant dysmetabolic(6) and psychiatric diseases(3). PB and BM samples for biological studies (morphology, cytochemistry, immunophenotype, cell cycle and apoptosis, histone acetylation status, gene expression analysis) were sequentially collected at days 0,7,14,28,35,55. Response was evaluated after the first cycle according to IWG criteria. *Results.*Haematological response was observed in 8 patients: 5 achieved complete remissions, 2 partial remissions and 1 minor haematological improvement. Of the remaining 6 pts: 1 died during induction and 5 were no responders. Thus the Overall Response Rate(ORR) was 50%. In the 8 responder patients,

PB recovery (Hb>9g/dL;PMN>1000/m3and PLTS>50.000/m^3) and BM blasts clearance occurred at d42 (range35-50) and at d35 (range25-50), respectively. No patient had extra-haematological toxicities WHO grade 3 or 4, and in all cases treatment was applied on out-patient basis. Preliminary results of biological assays showed a significant difference in responder patients *vs* no responders occurring before LoDAC administration: 1)increasing rate of S phase cells (p=0.02 at d+7 and p=0.03 at d+14); 2)cytochemical changes (increasing MPO/CAE expression); 3)progressive decreasing of early myeloid markers (HLA-DR, CD34, CD117) expression and a concomitantly increasing of late myeloid (CD11b, CD15 or CD14) differentiation markers (Figure1). As of January 2008 of the 8 responder patients, 1 is in 1stcontinuous CR and 2 in PR for +6,+10,+10 months, 5 of them relapsed in a median time of 6 months (range 5-9), two of them achieved a 2nd CR.Seven out of the 14 patients are still alive; median OS was 8 months (range 2-14). *Conclusions*. Sequential VPA and/or LoATRA+LoDAC are feasible, well-tolerated and safe treatment that enabled a 50% of responses. These treatments also induce AML blast phenotypical changes that may increase their sensitivity to LoDAC. However a larger number of cases are required to confirm these results.

0518

IN VITRO CHEMOSENSITIVITY OF 'NON LEUKEMIC' CFU-GM, IN AML PATIENTS, IS CORRELATED WITH CD34$^+$ MOBILIZATION AND MAY IDENTIFY GROUPS WITH DIFFERENT DISEASE FREE SURVIVAL

G.S. Sortino, G.M. Milone, G.A. Avola, G.L. Leotta, A.S. Strano, M.G. Camuglia, M. Poidomani, S. Coppoletta, A. Triolo, S. Toscano, M.P. Azzaro

Hematology, CATANIA, Italy

Background. An high number of CD34$^+$ cells in P.B. during mobilization has been associated in AML patients in CR to a high relapse rate and to greater amount of minimal residual disease (Keating, Feller 2003). A different pharmacokinetics of chemotherapy drugs administered during induction or an intrinsic chemoresistence of normal bone marrow precursors have been hypothesized as possible explanations for the observed association between mobilization of non leukemic CD34$^+$ cells and leukaemia residual disease. *Methods.* With this background we assessed in a group of AML in CR the *in vitro* chemosensitivity of non leukemic BM cells to Maphosphamide and Etoposide and correlated it to mobilization strength as well as to DFS. 37 patients affected by AML have been prospectively studied, all were treated using a same induction and consolidation chemotherapeutic regimen. Sensitivity to Maphosphamide and to Etoposide of CFU-GM, BFU-E, CFU-E, CFU-GEMM obtained from bone marrow in 1st CR was studied 2-4 weeks after PBSC mobilization. *Results.* Chemosensitivity of CFU-GM to ASTA-Z as well as to Etoposide and of CFU-GEMM to ASTA-Z, expressed as residual colony growth in comparison to untreated cells, was significantly correlated with peak of CD34$^+$ cells in P.B. during mobilization (R=0.639, p=0.0001 at 75 mcg/mL of ASTA-Z).To study relationship between chemosensitivity of non leukemic CFU-GM and survival we splitted patients in the 3 groups according to their chemosensitivity in respect to normal controls. Survival at 6 months was 0% for hyposensitive group, 60% in normosensitive group and 78% in hypersensitive group (log rank: 0.064). The survival of hyposensitive patients was significantly lower than the remaining patients (log rank: 0.01). Sensitivity of CFU-GM to 100 mcg/mL to ASTA-Z was found important for DFS also when studied in Cox proportional hazard model (Likehood ratio p=0.03). In a stepwise selection, sensitivity to ASTA-Z but not CD34$^+$ peak during mobilization was selected as important for DFS, moreover ASTA-Z sensitivity of normal non leukemic CFU-GM was found important for DFS also in group of AML pts having at diagnosis a normal cytogenetic. *Conclusions.* We have found that in AML patients sensitivity of normal non leukemic CFU-GM to maphosphamide and to Etoposide is highly variable and significantly correlated to CD34$^+$ cells peak reached during mobilization. Chemosensitivity of normal non leukemic CFU-GM was also found to be related to DFS.

0519

LEUKEMIA-FREE SURVIVAL (LFS) AS A SURROGATE FOR OVERALL SURVIVAL (OS) IN AML PATIENTS IN REMISSION (CR): A TRIAL OF A NOVEL IMMUNOTHERAPY WITH HISTAMINE DIHYDROCHLORIDE PLUS LOW-DOSE IL-2 (HDC/IL-2)

M.E. Buyse,[1] P. Squifflet,[1] S.E. Allard,[2] D. Bhagwat,[2] J.M. Rowe[3]

[1]*International Drug Development Institute (IDDI), LOUVAIN-LA-NEUVE, Belgium;* [2]*EpiCept Corporation, TARRYTOWN, NY, USA;* [3]*Rambam Medical Center, HAIFA, Israel*

Background. The goal of cancer therapies is to cure disease and extend OS. However, due to the number of patients and length of follow-up required, OS as a clinical trial endpoint is often impractical. Disease-free survival has been shown to be a valid surrogate for OS in clinical trials of novel therapies for some solid tumors (Buyse *et al.* Biostatistics, 2000 and JCO, 2007). LFS is a well-accepted endpoint in trials of remission maintenance therapies in AML. In such trials, the OS endpoint is particularly exposed to confounding factors that include different post-relapse therapies and unrelated deaths, particularly in older patients. *Aims.* To investigate whether LFS is an acceptable surrogate for OS in AML patients in CR by re-examining data from a clinical trial of remission maintenance immunotherapy with HDC/IL-2 *vs* no active therapy. *Methods.* A randomized multinational trial of 320 adults with AML compared HDC/IL-2 self-administered for up to 18 months to standard-of-care (no treatment) (Brune *et al.* Blood, 2006). A significant benefit of HDC/IL-2 was demonstrated for the primary endpoint of LFS for all patients and for patients in first CR (n=261) (log-rank test p= 0.008 and p= 0.011, respectively). OS was a secondary endpoint, and the corresponding log-rank test P-values were 0.21 and 0.16, respectively. Whether LFS is an acceptable surrogate for OS was assessed by performing weighted linear regression analyses (WLRA) between LFS and OS, and between the estimated effects of HDC/IL-2 on LFS and OS. Coefficients of determination (R^2) quantified the proportion of variance explained by the regression.

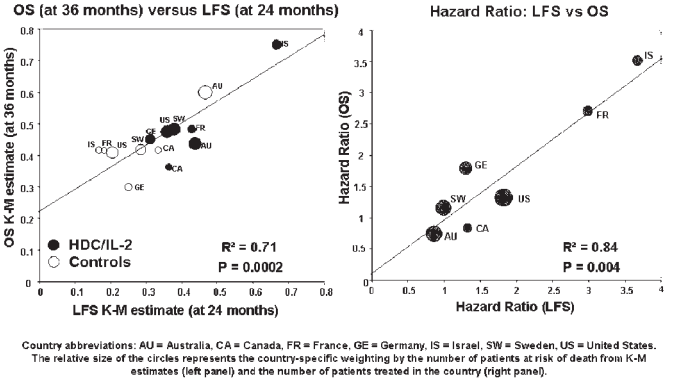

Figure 1.

Results. Country-specific Kaplan-Meier (K-M) estimates of 24-month LFS were highly correlated with 36-month OS in both treated and untreated groups (R^2 = 0.71; p=0.0002) (left panel in Figure 1). The WLRA equation was OS(36) = 0.22 + 0.70 x LFS(24). Similar correlations were found between 24-month LFS and 48-month or 60-month OS. Country-specific hazard ratios (HR), reflecting the effect of HDC/IL-2 on LFS and OS, were also highly correlated (R^2 = 0.84; p=0.004) (right panel in Figure 1) with a WLRA equation HR(OS) = 0.10 + 0.86 x HR(LFS). *Conclu-*

sions. Our analyses confirm that in AML, LFS is strongly associated with OS. Additionally, in this trial of HDC/IL-2 immunotherapy for remission maintenance, the treatment effect on LFS was strongly associated with the treatment effect on OS. Taken together, these observations support the claim that LFS may be a valid surrogate for OS in AML patients in CR.

0520

5-AZACYTINE IMPROVES SURVIVAL IN RELAPSED/REFRACTORY AML, RESULTS OF A MONOCENTRIC ANALYSIS OF 21 CASES

S. Ayari, T. Guillaume, P. Chevallier, E. Brissot, T. Gastinne, M. Mothy, J.L. Harousseau, J.D. Delaunay

University Hospital, NANTES, France

Refractory or relapsed AML have very poor prognosis with a survival of few weeks. 5-Azacytidine, a DNA hypomethylating agent with cytotoxic activity, results in clinical response in high risk MDS and AML. *Patients and Methods*. Since August 2006, 21 patients with refractory/relapsed AML (10F/11M) median age 66 (range 27-80) years received 75mg/m^2 5-azacytidine sc for 7days every 28 days. Relapsed and refractory AML were present in 11 (52%) and 10 (48%) patients respectively, secondary AML in 14 (66%) pts. Median number of chemotherapy cycles prior to 5- azacytidine was 3 (range 1-9). First line therapy was intensive chemotherapy in 12 (57%) patients, three of them received allogeneic transplantation. Low dose cytarabine and other alternative therapy had been received by 5(23%) and 4(19%) cases respectively. Unfavourable and intermediate cytogenetics were observed in 11(52 %) and 10 (48%) pts respectively. Median WBC prior to treatment was 4 (range 1.1-111)×10^9/L. Transfusion dependent anemia and thrombocytopenia were present in 19 (90%) and 14 (66%) pts respectively. Hematologic response was assessed according to the international working group criteria for AML first at 3 cycles of 5-azacytidine and then at 6 cycles or at the end of treatment. Because of early death, two patients (one died from pneumonia and the other from progression of disease) were not evaluable for response. *Results*. Median number of cycles received was 3 (2-14) with a total of 96 treatment cycles performed. Four (21%) pts have achieved response: 1 complete remission and 3 partial responses. Thirteen (68%) pts were in stable disease while 2 (10.5%) progressed. The median number of courses to achieve response was 3 (range 3-6). Tolerance of treatment was acceptable. Infections, including 6 bacteraemia episodes and 3 pneumonias, were the most common non-hematologic complications requiring admission to the hospital with a median days of hospitalisation of 15 (3-34). Median number of erythoid units and platelet units transfused per cycle of treatment was 5 (2-8) and 4 (0-7) respectively. The median follow-up of 11 months. Despite a low rate of response, one year overall survival was 41% (CI 18-62%) with a median survival of 5.8 months for all patients. Durable remission and low toxicity allowed two patients (1CR and 1PR) to proceed to non ablative allogeneic stem cell transplantation with continuous CR at 3 and 8 months following transplantation. The median survival was only 5.4 months in the unfavourable cytogenetics group whereas was not reached in the intermediate cytogenetics one. *Conclusions*. In this report, 5-azacytidine appears to improve overall survival of patients with refractory/relapsed AML despite a low response rate. In addition, pts with intermediate cytogenetics had better outcome.

THE INCIDENCE AND SURVIVAL OF ACUTE DE NOVO LEUKEMIAS IN ESTONIA AND IN A WELL-DEFINED REGION OF WESTERN SWEDEN DURING 1997-2001: A SURVEY OF PATIENTS AGED 16-64 YEARS

L. Wennstrom,[1] E. Holmberg,[1] D. Stockelberg,[1] S. Safai-Kutti,[1] K. Vaht,[1] E. Luik,[2] H. Everaus,[2] K. Palk,[3] M. Varik,[3] I. Viigimaa,[3] J. Kutti[1]

[1]Sahlgrenska University Hospital, GÖTEBORG, Sweden; [2]Tartu University Clinics, TARTU, Estonia; [3]Regional Hospital, TALLINN, Estonia

Estonia regained its independence in 1991 after having been occupied by the Soviet Union for 5 decades. In view of political/socio-economic differences in between Estonia and a neighbouring country, a well-defined Region of Western Sweden, in a recent study (Leuk Lymphoma 2004; 45:915-921) we retrospectively compared the incidence and survival of *de novo* acute leukemia (AL) patients aged 16-64 years over three 5-year periods (1982-1996) in the two countries. Estonia and the so-called Western Swedish Health Care Region are well comparable area-wise (45,000 km^2 and 27,000, respectively) as to population (1.38 million inhabitants and 1.65, respectively). The age standardized incidence rate regarding total *de novo* AL was slightly, but not significantly, lower in Estonia than in Western Sweden (1.49/100,000/year for Estonia and 1,76 for Sweden, respectively). However, the survival data for the two countries were highly different (p<0.001). Thus, the relative survival for the total group of *de novo* AL in Estonia at 1 year was 20.7% and at 5 years 3.6%, respectively. The corresponding figures for the Swedish patients were considerably higher, 65.2% and 29.4%, respectively. Further, the 5-year survival significantly (p<0.05) increased for the Swedish patients over the 3 consecutive 5-year periods. No such improvement was recorded for the Estonian patients. In view of the dismal outcome for Estonian patients we decided to prospectively compare the results for incidence and outcome of *de novo* AL between the two countries over forthcoming 5-year periods. Herein we report on the results of the 5-year period comprising 1997-2001. All hospital records were carefully reviewed and only *de novo* AL were identified. The current report deals only with patients aged 16-64 years. The patients were categorized into 3 groups: those with unequivocal (1) acute myeloblastic leukemia (AML), (2) acute lymphoblastic leukemia (ALL), and (3) non-classifiable, undifferentiated or biphenotypic acute leukemia (uAL).The total number of *de novo* AL encountered in the Estonian population aged 16-64 years was 83 (43 males and 40 females), the corresponding figure for the Swedish population being 125 (65 males and 60 females). As regards Estonia the subgroups were: AML n=58, ALL n=22, and uAL n=3. The corresponding figures for Sweden were: AML n=95, ALL n=28, and uAL n=2. In Estonia, the yearly age standardized incidence per 100,000 inhabitants for *de novo* AL was 1.77 (1.38-2.16); for Western Sweden the figure was 2.17 (1.78-2.57). As compared to our previous study (cf. above) the survival data for the two countries were still highly different. Thus, in Estonia the relative survival at 1 year was 52.3% (40.9-62.4%) and at 5 years 16.4% (9.3-25.4%), respectively. The corresponding figures for the Swedish patients were considerably higher, 75.5% (66.9-82.2%) and 36.9% (28.4-45.5%), respectively. However, whereas in the current study the survival at 5 years for *de novo* AL in Estonia had improved significantly, there was no change as regards relative survival at 5 years for the Swedish patients.

COMPLEX REARRANGEMENTS RESULTING IN LOSS OF BOTH 20Q AND 17P IN AML

J. Julie,[1] J.D. Howard,[1] M. Valgañón,[1] C. Grace,[1] H. Mazzulo,[1] M. Griffith,[2] P. Nacheva[1]

[1]Royal Free & UC Medical School, LONDON; [2]University of Oxford, OXFORD, UK

Background. Deletions of the long arm of chromosome 20 (del 20q) are a recurring abnormality associated with haematological malignancy (Mitelman 1995, Sandberg 1991, Heim and Mitelman,1995, Asimakopoulos & Green, 1996). The 20q deletions are seen in approximately 10% of the cases with PV and IMF, 4% of cases with myelodyspalstic syndrome (MDS) (Fenaux *et al.*, 1996), 1-2% of patients with acute myeloid leukaemia (AML) as well as other myeloproliferative disorders (MPD) (Bench *et al.* 2000). Deletions of chromosome 20q are well recognised in myeloid disorders and have been seen alone or as part of a complex karyotype (Johansson *et al.*, 1993, Schoch *et al.* 2002). Loss of 17p, via deletion, unbalanced translocation and isochromosome formation have been associated with the *17p-syndrome* (Lai *et al.* 1995, Soenen

et al. 1998). However these two aberrations are thought to occur independently and not usually seen with in the same karyotype (MacKinnon *et al.* 2007). *Results.* Here we present 9 patients characterised by a *classical* del(20)(q11.2) accompanied by cryptic (masked) loss of 17p within a complex karyotype. Molecular cytogenetic investigations revealed in 7/9 patients an unbalanced t(17;20)(p11;q11.2) with loss of the 17p11-pter genomic region. The remaining two cases showed more complex, three-way rearrangements albeit resulting in the same genomic loss. While the loss of TP53 appears to be consistent in these patients the break point on 20q is variable within the band 20q11. *Conclusions.* Importantly, the simultaneous loss of 17p and 20q due to the t(17;20) was identified in cases with clinically overt AML, most commonly preceded by MPD or MDS.

0523

A PHASE I STUDY OF TIPIFARNIB AND BORTEZOMIB IN THE TREATMENT OF POOR RISK ADULT ACUTE MYELOID LEUKEMIA

S. Paolini, E. Ottaviani, B. Lama, F. De Rosa, C. Laterza, P. Giannoulia, I. Iacobucci, C. Papayannidis, S. Parisi, P.P. Piccaluga, F. Salmi, M. Baccarani, G. Martinelli

Istituto di Ematologia e Oncologia Medica L. e A. Seràgnoli, BOLOGNA, Italy

Background. Outcome of older adults with acute myeloid leukemia (AML) is poor due to both disease and host-related factors. Tipifarnib (Zarnestra,) and bortezomib (Velcade) are new, promising targeted-treatments for hematological malignancies that might improve current results. In particular, tipifarnib is an oral, non-peptidomimetic farnesyltransferase inhibitor which has been shown to be effective in acute myeloid leukemias, allowing complete remission (CR) rates ranging from 8 to 22%, when used as single agent. Bortezomib is a proteasome inhibitor approved for multiple myeloma therapy, that determined hematological improvements in acute leukemia patients in phase I study. Interestingly, *ex vivo*, tipifarnib and bortezomib were proved to be synergistic in AML cell lines, above all overcoming environment-mediated resistance. *Aims.* We designed a phase I study aiming to investigate the maximum tolerated dose (MTD) and dose-limiting toxicity (DLT) of ascending doses of bortezomib in association with standard dose of tipifarnib in patients with AML aged >18 years and unfit for conventional chemotherapy, or aged >60 years and in first or subsequent relapse. *Methods*. Bortezomib was administered as weekly infusion for three consecutive weeks (days 1, 8, 15) in a 28 days cycle, starting from 0.7 mg/m^2 and increasing by 0.3 mg/m^2, to cohorts including a minimum of 3 patients until the DLT was reached in one out of six patients. Tipifarnib was administered at the daily dose of 600 mg BID for 21 consecutive days in a 28 days cycle. Dose reduction of tipifarnib was scheduled in case of grade III/IV extra-hematological toxicity. *Results*. From April to June 2007 a total of 12 patient were enrolled; 11/12 actually received at least one dose of treatment and were then evaluable. Five patients have been treated with bortezomib at the dosage of 0.7 mg/m^2 without reporting DLT. The adverse events were nausea (n=1) and skin rash (n=1), both of grade II; the first occurred within the first 15 days of treatment and was considered tipifarnib-related, resolving with transient drugs interruption. The latter occurred 21 days after the first course and slowly resolved by adopting specific measures; in this case the treatment was definitively stopped. Six patient have been treated with bortezomib at the dosage of 1.0 mg/m^2. In the first cohort (n=3), DLT was reached, due to grade III central neurological toxicity. In particular, mental confusion occurred in one patient after ten days of therapy and resolved 36 hours after treatment withdrawal. Other adverse events were grade II skin rash (n=1) and grade I diarrhea (n=1), not requiring for dose modification. In consideration of this DLT another cohort of three patient was treated at the same dosage of bortezomib without any adverse event. As concern treatment response, one patient receiving bortezomib 1.0 mg/m^2 obtained a CR, while no response was documented in other cases. *Conclusions*. We conclude that the MTD of bortezomib administered once a week for three consecutive weeks every 28 days in association to standard dose of tipifarnib is 1.0 mg/m^2. A phase II study has been then planned and is currently ongoing.

INCIDENCE AND CHARACTERISTICS OF CD56+ ACUTE MYELOID LEUKEMIA IN ADULTS AND CHILDREN: CD56 EXPRESSION IS HIGHER INCIDENCE AND STRONG ASSOCIATION WITH CNS INVOLVEMENT IN CHILDHOOD ACUTE MYELOID LEUKEMIA

H.R. Lee, I.H. Kim, S.S. Yoon, S.Y. Park, B.K. Kim, H.J. Kang, H.Y. Shin, H.S. Ahn, H.K. Kim, M.H. Park, H.I. Cho, D.S. Lee

Seoul National University College of Medicine, SEOUL, South-Korea

Background. CD56 is the membrane-bound glycoprotein, an isoform of the neural cell adhesion molecule (NCAM) and CD56 is used as a natural killer (NK) cell marker in immunophenotyping of leukemia. Several studies reported the association of CD56 expression and poor prognosis in acute myeloid leukemia (AML), however, most of these studies were confined to adult AML. *Aims.* To investigate the clinical difference between CD56+AML and CD56-AML in adults and children, we examined the incidence of CD56+AML and analyzed several clinical and biological characteristics (age, sex, WBC count, and median blast count in peripheral blood), cytogenetic features, immunophenotypic features, and clinical prognosis of CD56+AML and CD56-AML. *Methods.* 213 patients (177 adults, 36 children) with *de novo* AML in Seoul National University Hospital were enrolled. FAB subtypes were 4 M0 (2.3%), 26 M1, (12.2%), 78 M2 (36.6%), 27 M3 (12.8%), 43 M4 (20.2%), 15 M5 (7.1%), 14 M6 (6.6%), and 5 M7 (2.4%). Immunophenotyping was performed by immunohistochemical stain or multiparameter flow cytometry. The association between CD56 expression and variables (age, sex, WBC count, median blast count, cytogenetic features, extramedullary involvement, disease free survival, and overall survival) was analyzed by the fisher's exact test, chi-square test and T test, and Kaplan-Meier method. All statistical calculation was performed using SPSS system. *Results.* CD56 was detected in 6 of 177 adults (3.4%) and in 9 (25.0%) of children, showing significantly higher in children group (p<0.001). The CD56 expression was significantly frequent in M7 subtype (p=0.003). The other clinical characteristics, such as sex, WBC count, median blast count in peripheral blood, were not significantly associated with CD56 expression. The frequency of central nervous system (CNS) involvement was significantly higher in CD56+AML (p=0.025), although the frequency of overall extramedullary involvement did not differ between CD56+AML (3/15, 20.0%) and CD56-AML (27/198, 13.6%). Three patients in CD56+ AML presented extramedullary involvement at initial diagnosis or relapse. They were all children, and the involved sites were all CNS (Table 1). Among cytogenetic changes, AML1/ETO rearrangement was significantly associated with CD56 expression (p=0.024). When CD56 expression was analyzed by age group, AML1/ETO rearrangement was not associated with CD56 expression in children group (p=1.000). However, AML1/ETO rearrangement was significantly associated with CD56 expression in adults group (p=0.002). Aberrant expression of one or more lymphoid markers was observed in 42.9% (6/15 CD56+AML) and 45.2% (80/198 CD56-AML), showing no difference between CD56+AML and CD56-AML. Median disease free survival was 7 months in CD56+AML and 19 months in CD56-AML, showing no significant difference in two groups (p=0.247). Median overall survival was not reached in CD56+AML and 25 months in CD56-AML (p=0.164). *Conclusions.* The incidence of CD56+ AML was higher in childhood AML. We consider that CD56+ AML have unique biologic behavior, showing strong association with CNS involvement in childhood AML and AML1/ETO rearrangement in adult AML. To our knowledge, this is the first report on the higher incidence of CD56 expression in childhood AML compared to adult AML.

Table 1. Extramedullary involvement of CD56+ vs CD56- AML.

Total (n=213)	CD56+ n=15 (7.0%)	CD56- n=198 (93.0%)	*p*
Extramedullary involvement	3 (20.0%)	27 (13.6%)	0.450
Adult	0	19	
Child	3	8	
CSF involvement	3 (20.0%)	7 (3.5%)	0.025
Adult	0	4	
Child	3	3

MOLECULAR MONITORING OF BAALC AS A MINIMAL RESIDUAL DISEASE MARKER IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LEUKEMIA

Y. Najima, K. Ohashi, T. Yamashita, H. Akiyama, H. Sakamaki

Tokyo Metropolitan Komagome Hospital, TOKYO, Japan

Background. Although expression of the gene BAALC (brain and acute leukemia, cytoplasmic) predicts outcome in acute leukemia (AL), there is little information about clinical implication of molecular monitoring of transcripts of this gene as an assessment of minimal residual disease (MRD). *Aims.* To assess the clinical role of molecular monitoring BAALC gene expression in AL without well-known MRD markers. *Methods.* A real-time quantitative reverse transcriptase-polymerase chain reaction (RQ-PCR) was used to quantify BAALC gene expression in 21 patients (pts) with newly diagnosed AL. Bone marrow (BM) samples, obtained pretreatment and post chemotherapy, were serially analyzed to quantify these transcripts. Peripheral blood (PB) samples were also obtained to evaluate the correlation between BM and PB samples. These transcripts levels were compared with that of Wilms' tumor gene (WT1) in 14 pts without well-known MRD markers. In 7 pts with PML/RARα, AML/ETO or BCR/ABL carrying AL, these specific translocation markers were also monitored in parallel. GAPDH transcripts were used as an internal control and the ratio BAALC was thus estimated for evaluating the kinetics of residual clones. *Results.* BAALC expression levels showed clear correlation between BM and PB samples (r=0.945), and was seen in PB of healthy controls with a median expression level of 2.89x10exp-4/GAPDH. While, AL patients showed increasing BAALC transcript levels with 3 logs higher than the background level, and following induction chemotherapy the number of BAALC transcript was reduced along with pts obtaining hematological remission. In one patient with chemotherapy refractory AL, allogeneic bone marrow transplantation caused a significant reduction of the BAALC transcripts near the cutoff level. Comparative monitoring of MRD by RQ-PCR for WT1 and specific translocation markers demonstrated that BAALC had a closed kinetics to WT1 but not to specific translocation markers. *Conclusions.* The quantitation of the BAALC gene expression made it possible to assess MRD in pts with AL. To our knowledge, this is the first report concerning the use of BAALC mRNA expression for MRD monitoring.

LOW DOSE GENTUZUMAB OZOGAMICIN, AFTER INTENSIVE INDUCTION IN OLDER AML PATIENTS: RESULTS IN 13 PATIENTS IN A SINGLE CENTRE INSTITUTION

A. Poloni,[1] S. Trappolini,[1] B. Costantini,[1] D. Capelli,[1] E. Troiani,[1] G. Mancini,[1] G. Discepoli,[2] M. Montanari,[1] G. Gini,[1] I. Scortechini,[1] P. Leoni,[1] A. Olivieri[1]

[1]Clinica di Ematologia, ANCONA; [2]Istituto di Citogenetica, ANCONA, Italy

Background. The optimal post-remission treatment for elderly patients with acute myeloid leukemia (AML) is presently unknown. Gemtuzumab ozogamicin (GO) is a humanized anti-CD33 monoclonal antibody conjugated to calicheamicin, that is rapidly internalized after binding to CD33. So GO is a more selective agent for acute myeloid leukemia (AML), because the CD33 antigen is expressed on AML, while it is not expressed on normal hematopoietic stem cells and non hematopoietic tissues. However, some studies indicated that this agent was often ineffective in patients with refractory AML cells via various mechanisms even though these preliminary data have been obtained during the induction phase of therapy. *Aims.* We evaluate the efficacy of low dose GO as post-remission approach after complete remission (CR), in order to eliminate the minimal residual disease in elderly patients enrolled in a pilot prospective study. *Methods*. We enrolled in an intensive induction protocol 78 elderly AML patients, eligible for aggressive chemotherapy. Fifthy-seven (73%) achieved CR; among these 48 (84%) received first consolidation with intensive chemotherapy and were planned to receive a further consolidation with ASCT or low dose GO in case of PBSC collection failure: 21 patients successfully achieved PBSC collection and 19 undergo ASCT: in this subset we observed 4 TRD (21%) with 9 patients relapsing and 6 patients still alive in CR with a median follow-up of 60 months (range, 7-100). Thertheen patients, that failed PBSC mobilization, have been furtherly consolidated with GO at the dose of 3 mg/m^2 for three times, monthly, with a median follow-up was 23 months (range, 6-62). *Results.* WHO grade III/IV adverse events included hematological toxicity (n = 13), hypertransaminasemia (n = 1), and anaphylactic syndrome (n=3). There were no major adverse events. Two patients relapsed and eventually died after 7 and 13 months. One patient relapsed 29 months after, but achieved a second complete remission after a reinduction regimen; GO was added again for three times and now he is in complete remission after 5 months. Eleven patients out of 13 are alive and 12 in continuous complete remission. *Conclusions.* Our preliminary data indicate a potential role for GO in the consolidation therapy in old patiens with AML in CR after intensive induction and first consolidation chemotherapy. After the first consolidation course patients allocated to the transplantation arm showed an high transplant related mortality and a very high relapse rate. Conversely we observed a superior OS and LFS in those patients who received consolidation with GO compared with those who received consolidation with ASCT (p=0.003). These preliminary data encourage the use of low dose GO as consolidation therapy of MRD in older patients with AML; it remains to establish if the PBSC collection failure after CR represents an independent favourable prognostic factor in this subset of patients.

Chronic lymphocytic leukemia - Prognostic factors

0527

HIGH CD54 CELL SURFACE EXPRESSION ON B CELLS IN CHRONIC LYMPHOCYTIC LEUKEMIA IS AN INDEPENDENT PREDICTOR OF POOR OUTCOME

P. Bulian,[1] M.I. Del Principe,[2] A. Zucchetto,[1] L. Maurillo,[2] R. Bomben,[1] F. Buccisano,[2] M. Dal Bo,[1] F. Luciano,[2] F.M. Rossi,[1] A. Venditti,[2] M. Degan,[1] S. Amadori,[2] V. Gattei,[1] G. Del Poeta[2]

[1]IRCCS CRO, AVIANO; [2]Dipartimento di Ematologia, Ospedale S.Eugenio, Universita' Tor Vergata, ROMA, Italy

Background. The intercellular adhesion molecule-1 (ICAM-1, CD54) is expressed in B Chronic Lymphocytic Leukemia (B-CLL) at lower intensity compared to other chronic leukemic B-cell disorders. Higher expression was found in patients with marked lymphadenopathy and/or splenomegaly, with Binet stages B and C, and with rapid lymphocyte doubling time (LDT). Preliminary reports investigating the prognostic relevance of CD54 in B-CLL suggested that patients expressing CD54 in more than 30% of the neoplastic component experienced shorter time to treatment (TTT) and overall survival (Hjalmar, Eur J Haematol, 2002), although so far no one has tested the independence of CD54 as prognosticator in the context of other prognostic factors. Aims. To test the independent contribution of CD54 to prognosis estimation as measured by TTT, we performed a multivariate analysis, adjusting for modified Rai stage (mod.Rai), beta-2 microglobulin, LDT, CD38 and ZAP-70 expression. Methods. All variable were measured at diagnosis or prior to start of protocol therapies. Patients treatments were established following the National Cancer Institute Working Group criteria. Expression of CD38 and CD54 was analysed by three-colour immunofluorescence with CD19 and CD5. Irrelevant antibodies were used to determine *Background.* Expression was reported as percent of $CD5^+CD19^+$ CLL cells above *Background.* Flow-cytometry detection of ZAP-70 was performed in four colour by using a PerCP-Cy5.5 CD19, APC CD5, PE CD3/CD56 and Alexa-488 ZAP-70. ZAP-70 expression was reported as percent of CD19+ CLL cells expressing the protein above a marker set at the left tail of ZAP-70 fluorescence distribution of T cells. Results. CD54 expression in 231 B-CLL cases showed a skewed distribution ranging from 2% to 99%, with a median of 43%. Sixty-six percent of patients expressed CD54 above 30%. Median CD38 expression was 9%, with 37% of patients above 30%. Median ZAP-70 expression was 17%, with 41% patients above 20%. Modified Rai stage was I in 37% of patients, II in 61% and III in 3%. Median beta-2 microglobulin was 1.97 g/L, ranging from 1 to 10 g/L. A LDT shorter than 12 months was present in 13% of patients. Fifty-three percent of patients were treated, with a median TTT of 64 months (54-90). In univariate analysis all factors were significant at $p<0.05$, the hazard ratio (HR) was 4.44 for LDT<12 months, 4.30 for a mod.Rai stage>= 2, 3.06 for CD54>=30%, 2.38 for CD38>=30, 2.07 for ZAP-70>=20 and 1.55 for 1 gr/L increment of beta-2 microglobulin. After multivariate analysis the HR for LDT was 2.59 ($p=0.002$), for mod.Rai 3.06 ($p<0.0001$), for CD54 2.08 ($p=0.0064$), for CD38 1.48 ($p=0.07$), for ZAP-70 1.43 ($p=0.09$), for beta-2 microglobulin 1.26 ($p=0.0026$). Conclusion. Surface membrane expression of CD54 on B-CLL cells has a prognostic power greater than CD38 and ZAP-70 expression, even after adjustment for Rai stage, lymphocyte doubling time and beta-2 microglobulin concentration.

0528

MICRORNA-34A IS SIGNIFICANTLY DOWN-REGULATED IN B-CLL PATIENTS WITH P53 ABNORMALITIES

M. Mraz,[1] J. Kotaskova,[2] B. Tichy,[2] K. Malinova,[2] M. Trbusek,[2] Y. Brychtova,[2] J. Mayer,[2] S. Pospisilova[2]

[1]Medical Faculty MU and University Hospital Brno, BRNO; [2]Medical Faculty MU and University Hospital Brno, Department of Hematooncology, BRNO, Czech Republic

Background. MicroRNAs (miRNAs) are small RNA molecules acting as post-transcriptional regulators of gene expression. They are dynamically regulated during cell differentiation, proliferation and apoptosis. Many studies have shown that miRNAs are aberrantly expressed in cancer cells, suggesting that they might act as a novel class of oncogenes or tumor suppressors. A possibility to use microRNA signatures for a specific cancer classification has also been demonstrated. *Aims*. The aim of this study was to identify miRNAs, which could have a potential role in B-CLL pathogenesis and might be useful as prognostic markers. We primarily focused on the identification of microRNAs abnormally expressed in a B-CLL subtype with poor prognosis harbouring a deletion/mutation of the TP53 gene. *Methods*. Peripheral blood samples from 30 B-CLL patients were collected (del/mut TP53 n=13: unmut IgVH n=8; mut IgVH n=3, polyclonal n=2; wt TP53 n=17: mut IgVH n=9; unmut IgVH n=8). B-CLL lymphocytes were separated by RosetteSep™ Human B Cell Enrichment antibody cocktail (obtained purity was >90% of $CD5^+19^+$ B-CLL cells). Real-time PCR (ABI TaqMan MicroRNA Assays) was used to detect the expression of 35 microRNAs, which were chosen based on target prediction, using the software miRanda, TargetsScan and literature data. The obtained values were correlated with functional status of the p53 (deletion/mutation of TP53 or wt TP53) and other known standard prognostic markers, such as mutation status of IgVH, del13q, expression of ZAP70 and expression of CD38. *Results*. We observed a statistically significant down-regulation of miR-34a in the TP53-abnormal samples (p=0,00015; non-parametric Mann-Whitney U test). This most differently expressed microRNA was ~15-fold down-regulated in B-CLL cells with TP53 abnormalities compared to the samples with wt TP53. MiR-34a has been recently reported to be directly regulated by p53 protein *in vitro* and these data show, to our knowledge for the first time, that this microRNA is abnormally expressed in leukemic patients and its expression is directly dependent on the p53 functional status. We also detected the down-regulation of miR-34a in p53 abnormal cells in tumor cell lines with different p53 status. In addition, we also identified several other microRNAs, whose expression correlates with B-CLL prognosis, for instance miR-18a expression is related to the IgVH mutation status and is significantly lower (p=0,025) in samples harbouring the unmutated IgVH. *Summary and Conclusions*. Our results show that microRNAs expression varies in the B-CLL prognostic subtypes. B-CLL patients with a deletion/mutation of the TP53 gene display significantly lower expression of miR-34a targeting anti-apoptotic gene Bcl2. Consequently, this miRNA could potentially play an important role in the pathogenesis of chronic lymphocytic leukemia subtypes.

INFERIOR OVERALL SURVIVAL IN CLL PATIENTS WITH TP53 MUTATIONS AND MDM2 SNP309 POLYMORPHISM

R.H. Linderholm,[1] K. Willander,[2] K. Karlsson,[3] P. Söderkvist[2]

[1]Linköping University Hospital, LINKÖPING; [2]Dept Clinical and Experimental Medicine, Linköping University Hospital, LINKÖPING; [3]Dept of Haematology, Lund University Hospital, LUND, Sweden

Background. Patients with CLL harbouring 17p deletions, the chromosomal location of TP53, have a dismal prognosis, indicating the importance of a functional p53. There are several ways to inactivate p53 where deletions and gene mutations are obvious causes. The MDM2 protein impair p53 activity and an increased expression of MDM2 is implicated as a susceptibility factor for different forms of cancer. A single nucleotide polymorphism (SNP) at nucleotide +309 (T>G) in intron 1, the promotor region of the MDM2 gene, is associated with an increased expression of the protein and subsequently impaired p53 function. *Aims.* In the present work we have focused on the clinical impact of the MDM2 SNP309 polymorphism and TP53 mutations in CLL.

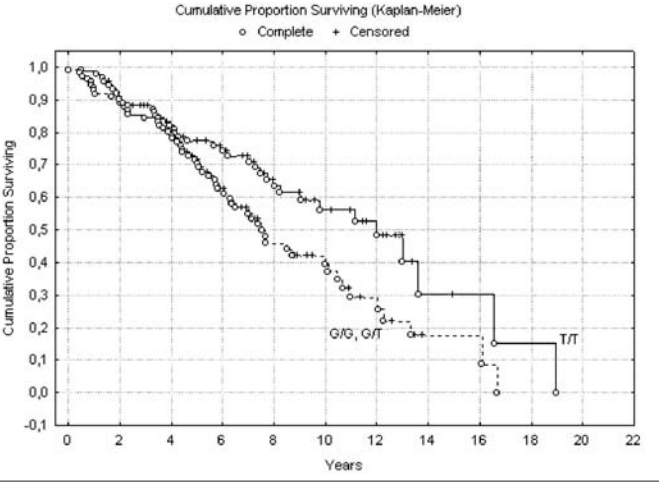

Figure 1. OAS according to MDM2 SNP309 status

Methods. In 213 patients with B CLL, we have investigated MDM2 SNP309, TP53 mutations in exon 5-8, and the mutational status of the IgVH gene and correlated with clinical parameters, such as, Binet stage, age of onset, time from diagnosis to first treatment, time from first to second treatment and overall survival (OAS). *Results.* There were 148 males and 65 females with a median age of 62,8 years. At diagnosis the number of patients in Binet stages A, B, and C were 101, 43, and 50, respectively. In 103 of 154 (67 %) patients, an unmutated (<98% homology with germline) IgVH gene was found. The median (range) follow up time was 6,6 (1,6-15,0) years. The OAS among 95 non-surviving patients was 4,7 (0-19,0) years. In total, 8,1 % out of 211 patients examined were homozygous for the G-allele of SNP309 (G/G) and 48,3 % were heterozygous (G/T). Somatic mutations of the TP53 was demonstrated in 19/213 (8,9 %) patients. Patients with MDM2 SNP309 G/G or G/T genotypes had a signficantly shorter survival (log rank test, p=0.016), as compared with patients with T/T genotype (Figure 1). The difference was approximately two years in median OAS. Patients with somatic mutations of the TP53 disclosed an even shorter OAS, as previously shown. *Conclusions*. CLL patients with mutations in the TP53 and/or 17p deletions have a short OAS. The SNP309 polymorphism of the MDM2 gene seems to add prognostic information in CLL possibly by an attenuation of the p53 pathway. Trials with MDM2 antagonists might be of particular interest in this subset of patients.

0530

GENE EXPRESSION PROFILE OF CLL PATIENTS TREATED WITH DNA-DAMAGING AGENTS IDENTIFIES BIOLOGICAL PATHWAYS IMPLICATED IN RESPONSE ACHIEVEMENT AND RELAPSE

N. Villamor,[1] F. Bosch,[1] A. Ferrer,[2] M. Aymerich,[1] A. Muntañola,[1] P. Jares,[1] D. Colomer,[1] E. Montserrat,[1] E. Campo[1]

[1]Hospital Clínic, BARCELONA; [2]Laboratori de citologia hematològica. Pathology Department, Hospital del Mar, BARCELONA, Spain

Background. P53 abnormalities are the only well established biomarker for poor response to therapy in patients with CLL treated with DNA damaging agents. In addition, other markers such as CD38 and ZAP-70 expression or IgVH mutational status have been associated with a shorter duration of the response. The mechanisms underlying the variability of the response in patients with CLL have not been fully investigated. *Aims.* To identify biological factors associated to response to treatment in patients with CLL by means of an extensive analysis of genomic expression. *Methods.* Magnetically purified CLL cells from 22 previously untreated patients receiving fludarabine, cyclophosphamide and mitoxantrone (FCM) were hybridized to oligonucleotide HGU133 Plus 2.0 arrays (Affymetrix). Gene expression measures were normalized using RMA methodology from the Affy package (Bioconductor project). Unsupervised and supervised analyses were performed with dChip v2.6. Patients achieving a MDR-negative status or a complete response (CR) were compared to other responses. Also relapsing patients were compared to continuous CR. *Results.* Fourteen patients achieved CR (8 MDR-negative and 6 MDR-positive), six patients achieved partial response and two failed to respond. The supervised analysis identified 268 genes differentially expressed between patients achieving CR and the remaining patients. Among these genes we found transporters (ABCA7, SLC16A7, SLC26A2. TMC6), transcription regulators (HDAC6, IFI16, ILF3, VEZF1), tumor suppressor genes (LATS2, MTSS1, RAP1A), metabolism of nucleotides (ARHGEF1, GNAI2), cytoeskeleton (MACF1, MICAL1, TUBAC3) or apoptosis regulators genes (BCL2, HRK, CDKN2A, PRKCE, CARD11 PDCD4). When comparing patients achieving MRD-negative CR and those obtaining other degrees of response 105 genes differentially expressed were identified. Interestingly, six genes (including MTSS1, GLT8D1, IFI16, MAP4K1) were found differentially expressed when comparing CR *vs* non-CR patients and MRD-negative CR *vs* other responses. Among patients who obtained CR, 64 genes were differentially expressed in MDR-negative and MRD-positive CR cases, 15 of them in common with the 105 found between MDR-negative CR and the rest of responses. These common genes included MAP4K1, DGKQ, MTSS1, TARBP1, GPSM3, UGT8, KTN1, PICALM and AMICA1 that are involved in apoptosis, guanosine metabolism, movement of cells and microfilaments, and adhesion and invasion of cells. At diagnosis, overexpression of ZAP70, TNFRSF1B, IL27RA, LAT2, or underexpression of PDCD4, GMNN, HSPA4, ABCA1 or NFKBIE were associated to relapse, among 159 differentially expressed between relapsing and non-relapsing patients. *Summary*. Response to treatment in patients with CLL seems to imply, besides classical apoptosis and cell cycle regulation, other multiple cellulars pathways. Interestingly, among these other pathways are included genes regulating transport, cytoeskeleton, adhesion, transcription or metabolism of nucleotides.

CLL PATIENT COMPARISON ACCORDING TO ZAP70 MRNA LEVEL: NEW PROGNOSTIC FACTORS, DIFFERENCES IN MICRORNA EXPRESSION AND DISTINCT INTERACTION CAPACITIES WITH THE MICROENVIRONMENT

B. Stamatopoulos, H.B. Haibe-Kains, N. Meuleman, D. Bron, P. Martiat, L. Lagneaux

Laboratory of Experimental Hematology, Institut Jules Bordet, Université Libre de Bruxelles (ULB), Brussels, Belgium

Background. Gene expression profile is a powerful tool to better understand the biology, the clinical outcome and the molecular mechanism implicated in chronic lymphocytic leukemia (CLL). This disease presents an extremely variable clinical course with overall survival times ranging from months to decades. Therefore a plethora of prognostic factors which classified patients in poor or good behaviour have been investigated. Zeta-associated protein 70 (ZAP70) is one of the most promising prognostic factors to predict CLL evolution. Furthermore, we previously described a quantitative real-time PCR (qPCR) method to measure ZAP70 and demonstrated its prognostic power (Stamatopoulos *et al.*, Clin. Chem., 2007). *Aims.* In this study, we compared gene expression profile of patients expressing high *vs* low ZAP70 mRNA level in order to find genes not only associated with prognosis but also with cell biology. We also confirmed some microRNA differentially expressed between these two groups and linked them to treatment-free survival (TFS) and overall survival (OS). *Methods.* ZAP70 was evaluated by qPCR in a cohort of 108 patients ; two groups of 7 patients were chosen in the top-20 of patients expressing high and low level of ZAP70 mRNA and their gene expression profiles were compared using Affymetrix technology. Selected genes were verified by qPCR in an extended patient cohort (n=85) with a median follow-up of 72 months. Adhesion/migratory capacities into a stromal microenvironment or in response to conditioned medium were also evaluated. Finally, we investigated the differential expression of some microRNA by qPCR in a cohort of 61 patients with a median follow-up of 74 months. *Results.* 43 probe sets were differentially expressed with a FDR<10%, 135 with a p<0.001 and 932 with a p<0.05 with a fold change of >1.5 (increase or decrease). Several of these genes were TFS and/or OS significant predictors: PDE8A and FCRL family genes were downregulated in ZAP70$^+$ patients and can predict TFS and OS; ITGA4 mRNA was upregulated in ZAP70$^+$ patients and can significantly predict OS. Moreover pathway analysis reveals an over-representation of adhesion/migration genes. CXCR4/SDF1-alpha pathway was one of them. We observed a downregulation of CXCR4 in stromal-adherent cells only in ZAP70$^+$ patients indicating that only these patient cells can respond to microenvironment stimulus. Furthermore, ZAP70$^+$ patient cells can significantly better adhere to fibronectin and ZAP70$^+$ cells have better migratory capacities in response to conditioned medium. MicroRNA comparison confirmed the differential expression of miR-29c and miR-223 and we showed for the first time that these two microRNA had a TFS and OS individual prognostic power. *Conclusions.* This study identifies new prognostic factors (genes and microRNA) and shows the better adhesion/migratory capacities of ZAP70$^+$ cells in their microenvironment explaining their better survival and the aggressiveness of the disease.

QUANTITATIVE GENE EXPRESSION ANALYSES OF SURROGATE MARKERS FOR GENETIC RISK GROUPS AND SURVIVAL IN CLL

D. Kienle,[1] A. Benner,[2] C. Läufle,[1] D. Winkler,[1] A. Bühler,[1] A. Habermann,[1] T. Zenz,[1] R. Dalla-Favera,[3] P. Lichter,[2] H. Döhner,[1] S. Stilgenbauer[1]

[1]University of Ulm, ULM, Germany; [2]German Cancer Research Center, HEIDELBERG, Germany; [3]Columbia University, NEW YORK, USA

Background. In chronic lymphocytic leukemia (CLL), a number of gene expression surrogate markers for genetic features such as VH mutation status have been described. Their detailed relation to the most important genetic subgroups, i.e. VH mutation status, V3-21 usage, del11q22-q23 (11q-), and del17p13 (17p-), and their value as prognostic markers in the context with established prognostic factors is largely unknown. *Methods.* Transcript levels of 18 candidate genes (ADAM29, ATM,

CLLU1, DMD, GLO1, HCSL1, KIAA0977, LPL, MGC9913, PCDH9, PEG10, SEPT10, TCF7, TCL1, TP53, VIM, ZAP70, ZNF2) were determined by real-time quantitative RT-PCR (RQ-PCR) in CD19-purified as well as unpurified patients samples. Their predictive value regarding individual genetic subgroups, an integrated genetic risk model, treatment free (TFS) and overall survival times (OS) was investigated in 151 CD19 purified patients samples including multivariate analyses. In a subset of 55 cases ZAP-70 expression was determined by FACS for comparison with RQ-PCR data. *Results.* The strongest association with the VH mutation status was observed for LPL (correct prediction of 84% of cases) and ZAP70 (84%), followed by TCF7 (74%), a marker being overexpressed in VH mutated CLL. Additional significant associations were observed between the 11q- subgroup and ATM (downregulation), and between the 17p- subgroup and TCL1, TCF7, ZNF2, and ADAM29 (all downregulated). Patients at genetic risk (VH unmutated or V3-21 usage or 11q- or 17p-) were best assigned by ZAP70, whereby a determination by RQ-PCR yielded better results compared to the FACS method. When assessing a hierarchical risk model integrating the relevant genetic subgroups (risk 17p- > 11q- > VH unmutated or V3-21 usage > VH mutated) high misclassification rates occurred with any individual marker (42% for ZAP70), which was mainly due to the impossibility of separating cases with 11q- and 17p- from VH unmutated cases without these abnormalities. This was improved using a marker combination (misclassification rate 30% for a combination of LPL, TCF7, ZAP70, ZNF2, and ATM). Still, a discrimination of 11q- or 17p- from VH unmutated patients without these abnormalities was achieved in only approx. 50% of 11q- and 17p- cases. In multivariate analyses including all candidate genes, LPL was the strongest OS predictor, whereas TFS was best predicted by ZAP70 and TCF7. When genetic factors were included in multivariate OS and TFS analyses, the surrogate markers lost their independent prognostic significance. *Conclusions.* Screening for patients at genetic risk can be performed using the individual markers ZAP70 or LPL. Usage of a marker combination reduces misclassifications especially regarding the highest risk groups 11q- and 17p-. However, a reliable distinction of these risk groups is not achieved and the prognostic impact of the surrogate markers remains inferior compared to the established genetic factors.

A DISTINCTIVE TRASCRIPTIONAL PROFILE CHARACTERIZES THE CHROMOSOME 17P LOSS IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

S. Fabris,[1] L. Mosca,[1] K. Todoerti,[1] G. Cutrona,[2] S. Matis,[2] M. Colombo,[2] L. Agnelli,[1] M. Lionetti,[1] D. Intini,[1] M. Gentile,[3] M. Mauro,[4] V. Callea,[5] G. Festini,[6] S. Molica,[7] G. Lambertenghi-Deliliers,[1] F. Morabito,[3] M. Ferrarini,[8] A. Neri[1]

[1]Università di Milano, Fondazione IRCCS Policlinico, MILANO; [2]Istituto Nazionale per la Ricerca sul Cancro, IST, GENOVA; [3]Azienda Ospedaliera di Cosenza, COSENZA; [4]Azienda Ospedaliera S. Martino, GENOVA; [5]Azienda Ospedaliera, Reggio Calabria, REGGIO CALABRIA; [6]Azienda Ospedaliero-Universitaria, Ospedali Riuniti di Trieste, TRIESTE; [7]Azienda Ospedaliera Pugliese- Ciaccio, CATANZARO; [8]Università degli Studi di Genova, GENOVA, Italy

Background. Distinct genetic abnormalities such as TP53 deletion at 17p13.1 have been identified as having an adverse prognostic relevance in B-cell chronic lymphocytic leukemia (B-CLL). Conventional cytogenetic studies have shown that TP53 deletion in B-CLL is associated predominantly with 17p loss (17p-) resulting from different complex chromosomal rearrangements such as unbalanced translocations or isochromosome 17q formation. *Aims*. The purpose of this study was to characterize a deletion-mapping of chromosome 17p in a subset of 17p- B-CLLs using genome-wide DNA profiling and Fluorescence in-situ hybridization (FISH) analyses. Additionally, gene expression profiling analysis was performed to identify specific transcriptional patterns or altered molecular pathways associated with 17p aberrations, which may have biological and clinical relevance in 17p- B-CLL. *Methods*. A panel of 71 untreated Binet A B-CLLs (18 of which carrying a TP53 monoallelic deletion) was characterized for the most recurrent genomic aberrations (trisomy 12 and deletions of 13q14, 11q22.3 and 17p13) and for the major prognostic markers. The genomic profile of chromosome 17p was investigated with GeneChip® Human Mapping 50K Xba 240 arrays in 12/18 17p- B-CLLs. Inferred copy numbers were derived from a Hidden Markov Model (HMM) based algorithm implemented in CNAT 4.0.1 software (Affymetrix). FISH probes covering a region of approximately 6 Mb in 17p11.2-p12 was selected to validate the array results. The transcriptional profiles of the 60 B-CLLs (7 carrying 17p-) have been generated on Affymetrix GeneChip® U133A arrays. The identified transcriptional fingerprints of the 17p- cases was validated on an independent dataset of 100 B-CLL cases (Haslinger *et al.*, 2004) using a Multi-class Prediction Analysis. Polymerase chain reaction was used to define the mutational status of the TP53. *Results*. Genome-wide DNA analysis of TP53 -deleted samples showed 17p loss in 11/12 cases, with distinct deletion patterns scattered along the 17p11.2-p12 region. FISH analysis confirmed these findings and revealed 17p loss in a small fraction of leukemic cells in the remaining TP53 -deleted case. In addition, FISH indicated 17p loss in the 6/18 cases not investigated by SNP. Mutations in exons 5 to 9 of the remaining TP53 allele were found in 9/12 deleted samples. Gene expression profiling of 60 B-CLLs, including 7 patients with 17p loss, identified 40 differentially expressed genes in 17p- *vs* 17p normal samples, 35 of which were down-regulated in 17p- tumors: the majority (30/35) of these transcripts, including putative tumor suppressor genes (GABARAP, GPS2 and OVCA1) mapped to 17p, indicating a remarkable gene dosage effect. *Conclusions*. Our study confirms and extends previous observations indicating that TP53 deletion in B-CLL patients is associated with the loss of chromosome 17p. Gene expression profiling showed that chromosome 17p loss is associated with significant down-regulation of genes located on 17p, indicating a gene-dosage effect. The potential coordinated loss of tumor suppressor genes on 17p other than TP53 , may represent an important mechanism for the negative clinical outcome associated with this lesion in B-CLL and warrants further investigation.

INTEGRATIVE GENOMIC ANALYSIS OF TRISOMY 12 ABNORMALITY IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

L. Mosca,[1] K. Todoerti,[1] S. Fabris,[1] G. Cutrona,[2] S. Matis,[2] M. Colombo,[2] L. Agnelli,[1] M. Lionetti,[1] M. Gentile,[3] M. Spriano,[4] V. Callea,[5] G. Festini,[6] S. Molica,[7] G. Lambertenghi-Deliliers,[1] F. Morabito,[3] M. Ferrarini,[8] A. Neri[1]

[1]Università di Milano, Fondazione IRCCS Policlinico, MILANO; [2]Istituto Nazionale per la Ricerca sul Cancro, IST, GENOVA; [3]Azienda Ospedaliera di Cosenza, COSENZA; [4]Azienda Ospedaliera S. Martino, GENOVA; [5]Azienda Ospedaliera, Reggio Calabria, REGGIO CALABRIA; [6]Azienda Ospedaliero-Universitaria, Ospedali Riuniti di Trieste, TRIESTE; [7]Azienda Ospedaliera Pugliese- Ciaccio, CATANZARO; [8]Università degli Studi di Genova, GENOVA, Italy

Background. B-cell chronic lymphocytic leukemia (B-CLL) is a genetically heterogeneous disease with a high variable clinical course. Trisomy 12 (+12) is frequently associated with the disease (approximately 20%) and it has been reported to be correlated with an intermediate prognosis. Despite the recent remarkable progresses in the understanding the molecular pathogenesis of B-CLL, the biological significance of trisomy 12 remains to be fully elucidated. *Aims.* To identify signalling pathways and additional lesions associated with tumorigenesis in +12 B-CLLs. Methods. A panel of 80 Binet A untreated B-CLLs including 18 patients with trisomy 12 was investigated. This series was characterized for the most recurrent genomic aberrations (deletions of 13q14, 11q22.3 and 17p13) and for the major prognostic markers. Gene expression profiles were generated on Affymetrix GeneChip® U133A arrays. The identified transcriptional fingerprint of +12 was generated and then validated on an independent dataset of B-CLL cases (Haslinger *et al.*, 2004) by a Multi -class Prediction Analysis. Furthermore, genome-wide profiling data were generated by means of Affymetrix GeneChip® Human Mapping 250K Nsp SNP arrays in a subset of 45/80 B-CLLs including 9 patients with +12. Inferred copy numbers were derived from a Hidden Markov Model (HMM) based algorithm implemented in CNAT 4.0.1 software (Affymetrix). Results. The transcriptional analysis revealed 140 genes as the best classifier for the +12 B-CLLs. 92 out of the 118 genes up-regulated in +12 patients mapped on chromosome 12, most of which (86%) on the long arm. The remaining 26 genes and the 22 genes down-regulated in +12 samples showed different chromosomal localizations. The transcriptional fingerprint validation on an independent cohort of 100 B-CLL patients showed a global classification rate of 92.5%. A functional analysis of the deregulated genes revealed the involvement in transcriptional regulation, DNA, mRNA and protein metabolism. Many genes (ANAPC5, CCT2, CCT4, CDK2AP1, CDKN1B, CHFR, MCRS1, PCTK2) were also related to regulation of cell-cycle, cell death (ATXN1, CD63, DNM1L, DYRK2, HRK, OPTN, TEGT) and immune response (CKLF, CD58, CTLA4, HDAC9, IL21R) as well as to different cellular metabolic processes (AMPD3, CS, LDHB, NUDT4). Consistent with FISH data,

genome-wide DNA analysis showed that +12 is never found to be associated with the other most recurrent aberrations of B-CLL. Moreover, SNPs analysis identified, among the +12 patients, other recurrent copy number variations, such as gains of 14q32, 15q11, 17q21 and losses of 11p15, 14q11, 14q32 and 15q11: however, this correlation did not reach a statistically significant level. Conclusions. Trisomy 12 appears to affect gene expression in B-CLL not only by a dosage effect but also by influencing the expression of genes located on different chromosomes leading to the deregulation of multiple cellular functions. None of the copy number alterations identified by SNP genomic analysis appeared to be tightly correlated with +12.

0535

ANALYSIS OF TP53 MUTATION IN A LARGE COHORT OF CLL PATIENTS BEFORE FIRST-LINE TREATMENT: ANALYSIS OF THE GENETIC PROFILE WITHIN THE CLL4 TRIAL (F *vs* FC) OF THE GCLLSG

T. Zenz,[1] T. Denzel,[1] S. Häbe,[1] D. Winkler,[1] A. Bühler,[1] R. Busch,[2] B. Eichhorst,[3] M. Hallek,[3] H. Döhner,[1] S. Stilgenbauer[1]

[1]University of Ulm, ULM; [2]Institute of Medical Statistics and Epidemiology, Technical University, MUNICH; [3]University of Cologne, COLOGNE, Germany

CLL patients with 17p deletion have a dismal prognosis after treatment. The exact prognostic role of TP53 mutations in the absence of 17p deletion and any differential impact of the mutation in cases with 17p deletion (*vs* sole deletion) is currently unclear. *Aims.* To assess the incidence, profile and prognostic impact of TP53 mutations as assessed by sensitive DHPLC followed by direct sequencing in a well characterized and homogeneous patient population from a prospective trial (CLL4 trial GCLLSG). *Methods.* We studied 342 of 375 CLL4 trial patients with available material. The population is well characterized and detailed genetic characteristics are available (FISH, VH-Status). We used DHPLC to detect TP53 mutations in the coding exons (2-11). Aberrant profiles were confirmed by sequencing including the use of fragment collection in cases with low grade mutations. *Results.* We found an overall incidence of TP53 mutations of 8.2 % (28/342 patients). The mutations were exclusively located in the DNA binding domain. We observed 2 splice site mutations, 3 deletions, 2 insertions but the majority of mutations were missense mutations in exons 5-8. Two patients had 2 different mutations. Fourteen of 16 patients with 17p deletions also had a TP53 mutation (87.5 %). Interestingly, both patients with a 17p deletion where no TP53 mutation was identified, showed a low proportion of 17p- cells (19-21%) suggesting that detection limits of the technique might explain this finding. We found TP53 mutations in the absence of 17p deletions in 4.3% (14/326). The proportion of mutated allele in cases without 17p deletion ranged from 10 to 90 percent. In two patients with follow-up samples we found evidence of clonal evolution at the time of relapse. The genetic profile of cases with TP53 mutation showed a high incidence of 17p deletions (13/28 cases), but also included cases with 11q deletion 3/28, 13 deletion as the sole abnormality (5/28) and normal karyotype (4/28). The majority of cases with TP53 mutations had an unmutated VH status (n=21)(75%), while 6 of 28 had a mutated VH status (V3-21: n=1). Correlation with baseline parameters and clinical outcome is currently being performed and will be presented. *Conclusions*. In this first line treatment trial population, TP53 mutations without 17p deletion occurred in 4.3% (14/326) of patients and the majority of cases with 17p deletion also have TP53 mutations. The demonstration of clonal evolution in cases with TP53 mutation without 17p deletion after F-based therapy points to the biological and clinical significance of TP53 mutations in CLL.

0536

SCREENING FOR COPY-NUMBER ALTERATIONS AND LOSS-OF-HETEROZYGOSITY IN CHRONIC LYMPHOCYTIC LEUKEMIA - A COMPARATIVE STUDY OF FOUR DIFFERENTLY DESIGNED, HIGH RESOLUTION MICROARRAY PLATFORMS

R. Gunnarsson,[1] J. Staaf,[2] M. Jansson,[3] A.M. Ottesen,[4] H. Göransson,[5] U. Liljedahl,[6] U. Ralfkiær,[7] M. Mansouri,[3] A.M. Buhl,[8] K. Ekström Smedby,[9] H. Hjalgrim,[10] A.C. Syvänen,[6] A. Borg,[2] A. Isaksson,[5] J. Jurlander,[8] G. Juliusson,[11] R. Rosenquist[3]

[1]Lund University, LUND, Sweden; [2]Department of Oncology, SCIBLU Genomics, Lund University, LUND, Sweden; [3]Department of Genetics and Pathology, Uppsala University, UPPSALA, Sweden; [4]Department of Growth and Reproduction, Juliane Marie Centre, Rigshospitalet, COPENHAGEN, Denmark; [5]Department of Medical Sciences, Uppsala University, UPPSALA, Sweden; [6]Department of Medical Sciences, Molecular Medicine, Uppsala University, UPPSALA, Sweden; [7]Danish Cancer Society, Laboratory of Cancer Genomics, COPENHAGEN, Denmark; [8]Department of Hematology, Leukemia Laboratory, Rigshospitalet, COPENHAGEN, Denmark; [9]Department of Medicine, Clinical Epidemiology Unit, Karolinska Institutet, STOCKHOLM, Sweden; [10]Department of Epidemiology Research, Statens Serum Institut, COPENHAGEN, Denmark; [11]Stem Cell Center, Hematology and Transplantation, Lund University, LUND, Sweden

Background and Aims. Screening for gene copy-number alterations (CNAs) has improved by applying genome-wide microarrays, where SNP-arrays also allow analysis of loss-of-heterozygozity (LOH). Few comparative studies of high-resolution platforms have thus far been performed and there is a current need to compare platforms in order to understand the pros and cons with the differently designed arrays. Here we investigated chronic lymphocytic leukemia (CLL) samples by applying four differently designed microarrays for evaluation of: 1) baseline variation and ratio response to FISH-validated genomic aberrations, 2) detection of known recurrent and novel CNAs and concordance between platforms, and 3) detection of LOH with the Illumina and Affymetrix SNP-arrays. *Materials and Methods*. We screened 10 CLL samples using four different high-resolution platforms: BAC-arrays (32K), oligonucleotide-arrays (185K, Agilent), and two SNP-arrays (250K, Affymetrix and 317K, Illumina). Baseline variation and copy-number ratio response was calculated on normalized array-data. Analysis of CNAs and LOH was performed applying the Bio Array Software Environment (BASE) and dChip software, respectively. *Results*. Evaluation of baseline variation and copy-number ratio response showed the best performance for the Agilent platform and confirmed the robustness of BAC-arrays. Accordingly, these platforms demonstrated a higher degree of platform-specific CNAs. The SNP-arrays displayed higher technical variation, although this was compensated by high density of elements. Cross-platform comparison revealed 29 concordantly detected CNAs, including FISH validated known recurrent alterations, which confirmed that all platforms are powerful tools when screening for large aberrations. However, detection of 32 additional regions present in 2-3 platforms illustrated a discrepancy in detection of small CNAs, which often involved reported copy-number variations. LOH-analysis using dChip revealed concordance of mainly large regions, but showed numerous, small non-overlapping regions and LOH escaping detection. Affymetrix detected a higher degree of CNAs compared to Illumina, while the latter showed a lower noise level and higher detection rate in the LOH analysis. *Conclusions*. Usage of high resolution microarrays will improve the possibility to detect new recurrent microevents in CLL leading to identification of new important subgroups potentially refining the prognostic hierarchy established by FISH. If only copy-number data is preferred, oligonucleotide-arrays such as Agilent provide a high sensitivity of this type of analysis. If LOH-analysis is desirable, SNP-arrays are the preferred choice but, parallel improvement of analysis tools is required for an in-depth analysis of allelic imbalances.

0537

CYTOGENETIC ABNORMALITIES DEL(17P) AND DEL(11Q) IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): A PROSPECTIVE STUDY ON 156 YOUNG PATIENTS IN DIFFERENT PHASES OF THE DISEASE

I. Del Giudice, F.R. Mauro, M. Nanni, M.S. De Propris, S. Santangelo, M. Marinelli, N. Peragine, F. Mancini, D. Armiento, L. Quattrocchi, A. Guarini, R. Foa'

University La Sapienza, ROMA, Italy

Background. In chronic lymphocytic leukemia (CLL), the presence of del(17p) is associated to chemotherapy resistance and poor prognosis. p53 function can be impaired by del(11q)/ATM mutations, which also confer an unfavorable outcome. In previously published series, the incidence of these abnormalities ranges from 10% to 32% for del(11q) and 3% to 27% for del(17p), depending on the stage of the disease and whether or not treatment was administered. *Aims*. To assess the incidence of del(17p)/del(11q) in CLL patients in different phases of their disease, the correlation of these abnormalities with other biologic parameters and their impact on treatment requirement. *Methods*. From November 2002 to December 2007, 156 young CLL patients (<60 years-old) were included in this study. Three different cohorts were prospectively evaluated: 79 cases at diagnosis with stable disease for at least 12 months (group 1), 53 at first progression (group 2), 24 at progression after one or more therapies (group 3). Cytogenetic abnormalities, ZAP-70 and CD38 expression, as well as IgVH mutational status were analyzed. *Results*. The distribution of unfavorable prognostic markers in the 3 different groups is summarized in the Table 1. The incidence of del(17p) (cut off >20% cells) raised progressively from group 1, to groups 2 and 3 (0%, 6% and 26%, respectively; $p<0.001$). The incidence of del(11q) (cut-off >10%) increased significantly from group 1 to 2 (5% and 16%; p 0.04), though it was not higher in group 3 (5%). The proportion of unmutated IgVH (<98% homology) cases also increased progressively in the 3 groups, 24% in group 1, 52% in group 2 and 71% in group 3 ($p<0.001$). The same trend was found for CD38 >7% ($p<0.001$) and ZAP-70 >10% expression (p 0.03). Patients with del(17p) or del(11q) almost exclusively showed unmutated IgVH ($p<0.001$) and were mostly CD38$^+$ (p 0.003) and ZAP-70+ (p 0.01). Focusing on previously untreated patients with progressive disease (group 2), they required treatment after a median time of 39 months (range 1-144) from diagnosis. Cases with del(17p) or del (11q) had a treatment-free interval (TFI) that was on average half of that of cases without these abnormalities (23 *vs* 40 m), as well as cases with IgVH unmutated *vs* mutated (18 *vs* 50 m), CD38 pos *vs* neg (21 *vs* 40 m), ZAP-70 pos *vs* neg (26 *vs* 41 m). *Conclusions*. Del(17p) and del(11q) occur in CLL cases with other adverse biologic features, as unmutated IgVH, ZAP-70+ and CD38$^+$, and show a rapidly progressive course. They represent a small subgroup of cases in the early phases of disease, which progressively raises with more advanced disease. Thus, their incidence, as well as that of other biologic factors with adverse prognostic impact, changes considerably when patients in different phases of the disease are investigated. This has to be considered in the design of clinical trials. Moreover, reassessment of chromosomal abnormalities during the course of CLL is warranted, especially after treatment.

Table 1.

	CLL diagnosis		CLL 1st progression			CLL Previously treated/refractory		
	N° cases	%	N° cases	%	p	N° cases	%	p
IgVH mutated (≥98%)	59/78	76%	25/52	48%	.001	7/24	29%	.001
IgVH unmutated (<98%)	19/78	24%	27/52	52%		17/24	71%	
CD38 ≥7%	11/79	14%	23/52	44%	.001	17/24	71%	.001
ZAP-70 ≥10%	26/74	35%	28/50	56%	.02	10/17	59%	.03
del(17p) >20%	0/78	0%	3/51	6%	.03	5/19	26%	.001
del(11q) >10%	4/78	5%	8/51	16%	.04	1/19	5%	.09
del(17p)+ del(11q) pooled	4/78	5%	11/51	22%	.004	6/19	32%	.019

SPONTANEOUS CLINICAL REMISSION IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICAL AND BIOLOGIC FEATURES OF 9 CASES

I. Del Giudice, F.R. Mauro, S. Chiaretti, S. Tavolaro, S. Santangelo, M. Marinelli, R. Maggio, M.S. De Propris, F. Mancini, L. Quattrocchi, D. Armiento, A. Guarini, R. Foa'

University "La Sapienza", ROME, Italy

Background. Spontaneous clinical remission in chronic lymphocytic leukemia (CLL) is an exceptionally rare phenomenon, the biologic features of which have not been reported. *Aims and Methods*. Aiming at a better definition of the biologic profile of such cases, we report on 9 patients with CLL who underwent a spontaneous clinical remission of the disease over a median follow-up of 11 years (range 3-28). At diagnosis, all cases were Binet stage A, the median lymphocyte count was 11.8×10^9/L (range 8.7-27.6) and the proportion of CLL cells in the peripheral blood (PB) was 78% (range 65-82%). At the time of the study, the median lymphocyte count was 3.16×10^9/L (range 1.3-4.9) and the proportion of CLL cells in the PB was 44% (range 5-53%). *Results*. At the time of regression, CD38 expression was less than 7% in all cases. PCR analysis of the variable IgVH region showed a mutated status in all 7 cases evaluated, with a mean mutation frequency of 7.2%±2.8 (median 7.4%, range 2.7-10.7%). IgVH usage was restricted to the VH3 family in all cases but 1, with the following gene distribution: VH3-30 in 2 patients, VH3-07 in 1, VH3-15 in 1, VH3-33 in 1, VH3-72 in 1, VH4-34 in 1. The light chain variable region genes, mutated in 6/8 cases, were: Vκ4-1 in 3 patients, Vκ2-30 in 1, Vκ3-15 in 1, Vλ1-47 in 1, Vλ1-51 in 1 and Vλ2-11 in 1. The Vκ4-1 cases had highly homologous LCDR3 amino acid sequences. Microarray analysis revealed a distinctive genomic profile for such cases with an over-representation of BCR-related genes, ribosomal genes, regulators of signal transduction and transcription. No significant differences were observed between CLL in spontaneous remission and healthy individuals in the absolute number of activated T lymphocytes producing IFN-γ, TNF-α and IL-4, whilst a significant lower amount of TNF-α producing T cells was found in spontaneous remission, stable CLL and healthy individuals compared to progressive CLL. *Conclusions*. We confirm that in CLL spontaneous regressions up to a state of protracted clinical remission can occur despite the persistence of the neoplastic clone at microsopic levels. Biologic features of these cases include negative CD38, mutated VH3-30 and Vk4-1 usage with an identical LCDR3 common motif, as well as a peculiar gene profile, suggesting that the activation of BCR-related and translation-associated genes is the most significant change occurring in the regressing leukemic clone.

P53 EVALUATION IN CLL BY P53 ARRAY: A SIMPLE, SENSITIVE AND SPECIFIC METHOD THAT UNRAVELS A HIGH PERCENTAGE OF POLYMORPHISMS AND MUTATIONS

S. Chiaretti,[1] S. Tavolaro,[1] M. Messina*,[1] M. Marinelli,[1] I. Del Giudice,[1] F.R. Mauro,[1] S. Santangelo,[1] N. Peragine,[1] S. Truong,[2] M.S. De Propris,[1] M. Nanni,[1] A. Guarini,[1] R. Foà[1]

[1]*University La Sapienza, ROMA, Italy;* [2]*Roche Molecular Systems, PLEASANTON, USA*

Background. Chronic lymphocytic leukemia (CLL) is an heterogeneous disease. Several biologic parameters are relevant prognostic markers; among these, p53 mutations are relatively rare events, usually detected in the late stages of disease, highly predictive of unfavorable outcome and associated with Ritcher's syndrome. *Aims*. To evaluate the specificity, sensitivity and advantages of the AmpliChip p53 Test array - a product currently under development at Roche Molecular Systems, Inc - and to correlate the results with the most relevant clinico-biological parameters. *Patients and Methods.* Forty-eight untreated CLL patients were evaluated; 35 had progressive disease: 16 were IgVH germline and 19 mutated. Thirteen had a stable disease and were IgVH mutated. Concordance between IgVH status and ZAP70 expression was 77%; CD38 proved positive in 78.6% IgVH germline patients and in 16% IgVH mutated cases. TP53 sequencing revealed 2 mutations, 2 polymorphisms and 1 heterozygosis within progressive cases, and 1 polymorphism within stable patients; p53 protein accumulation was identified in 2 cases. Finally, FISH analysis revealed 13q deletions in 64% patients, no aberrations in 20% and trisomy 12, 11q and 17p deletions in 12%. The p53 array allows sequencing of exons 2-11: 50 ng of genomic DNA are amplified in two separate PCR reactions. Subsequently, PCR products are fragmented, hybridized, stained and scanned. The whole procedure requires roughly 8 hours. Each array queries 1268 nucleotide positions that are investigated by individual probesets that contain five probes: 1 for wild-type sequence, 3 for possible substitutions and 1 for deletion. Each probe contains multiple copies of an oligonucleotide sequence. The mutation detection algorithm detects single base pair substitutions and deletions. *Results*. The p53 array detected 7 mutations (14.5%), involving exon 5 in 2 patients (with 1 case harboring 2 different mutations), exon 8 in 2, exon 9 and exon 7 in 1, respectively. P53 array also detected the following polymorphisms: codon 72 in 17 patients (35%), codon 213 in 4 (8%) and codon 36 in 2 (4%). There was no significant association between p53 mutations and IgVH mutational status, ZAP-70 and CD38expression, and cytogenetic findings. From a clinical standpoint, mutations were only detected in progressive cases and there was not a statistical association between codon 72 polymorphisms and clinical behavior (Fisher exact test = 0.32). Although the numbers are small, similar conclusions can be drawn for codon 213. Comparison with TP53 sequencing highlighted a higher sensitivity of the AmpliChip p53 Test array: in fact, the mutations that were identified by sequencing were also detected by p53 array, while 3 additional mutations, at exon 5, 7 and 9 were not detected by TP53 sequencing: this discrepancy will be further investigated. *Conclusions*. The p53 array represent a highly reliable and non-time consuming tool for mutational analysis of TP53. Using this new approach, our results corroborate that p53 mutations occur exclusively in progressive patients and are not associated with other prognostic parameters. Furthermore, p53 array highlights a high percentage of codon 72 polymorphisms in CLL patients, regardless of the clinical behavior, whose role needs to be further investigated.

PRESENCE OF HETEROZYGOUS ATM DELETION MAY NOT BE CRITICAL FOR THE RESPONSE OF CLL CELLS TO FLUDARABINE

M. Trbusek,[1] S. Cejkova,[1] L. Rocnova,[1] D. Potesil,[2] J. Smardova,[1] J. Malcikova,[1] D. Zezulkova,[1] M. Doubek,[1] Y. Brychtova,[1] S. Pospisilova,[1] J. Mayer[1]

[1]*University Hospital Brno, BRNO;* [2]*Masaryk University, Faculty of Science, BRNO, Czech Republic*

Background. Abnormalities of the TP53 or ATM, two co-operating tumor-suppressor genes, significantly deteriorate prognosis and treatment options in CLL patients. Although their aberrations seem to be mutually exclusive in CLL cells, the inactivation of the former gene leads to a much shorter survival and a higher drug resistance. Association between the ATM mutation and resistance of CLL cells to fludarabine has recently been reported and a similar observation has also been noted in cases manifesting a low level of Atm protein. *Aims.* (i) to assess an *in vitro* effect of fludarabine on CLL cells with heterozygous ATM deletion in comparison to TP53-abnormal and wild-type cases (ii) to monitor the activation of the p53 pathway in the corresponding cells. *Methods.* Interphase FISH was used for a determination of the TP53 and ATM deletions. Functional FASAY analysis coupled to sequencing was employed to supplement the screening also for the TP53 mutations. Metabolic WST-1 assay monitored a cell viability after fludarabine administration (25; 6.3; 1.6 and 0,4 μg/mL). Western blot analysis was used to detect the p53 stabilization and real-time RT-PCR was employed to monitor the activation of the p53-downstream targets, PUMA, BAX and p21. *Results.* A representative series of 59 CLL cultures was used. Fludarabine provided a clear concentration-dependent curve after 48 h cultivation in most of the samples, with the exception of some strongly resistant cases (harboring abnormal TP53). The sensitivity to fludarabine was assessed at the concentration of 1.6 μg/mL, since it had provided the most significant differences among individual samples. The TP53-abnormal samples (n=20) were remarkably more resistant to this drug than the remaining CLL (p=0.012; Mann-Whitney U-test), whilst there were no significant differences between the ATM-deleted (n=21) and wt (n=18) subgroups (p=0.71). All ATM-deleted (n=6) and wt (n=4) samples tested by the Western blot showed a clear stabilization of the p53 protein after fludarabine exposure. On the contrary, two of the three tested, ATM-deleted cases, did not induce the p53 after the administration of doxorubicin, a known activator of Atm kinase through the dsDNA breaks. Q-RT-PCR analysis confirmed the induction of the p53-downstream target genes, i.e. PUMA, BAX and p21, in virtually all tested ATM-deleted (n=7) and wt (n=6) samples. The TP53-abnormal samples were devoid of any induction, what again supported a view that a clear borderline distinguishes the TP53-abnormal samples from the remaining CLL, as it regards the response to fludarabine. *Summary and Conclusions.* Presence of ATM deletion in CLL cells should not be considered a priori as a marker of fludarabine resistance. The Atm kinase does not seem to be critical for the activation of the p53 pathway after fludarabine administration.

CYTOTOXIC EFFECT OF SDX-308, ANALOGUE OF R-ENANTIOMER OF ETODOLAC, IN COMBINATION WITH PURINE ANALOGUES OR MONOCLONAL ANTIBODIES ON *EX VIVO* B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

P. Robak, T. Robak, P. Smolewski, A. Linke, B. Cebula

Medical University of Lodz, LODZ, Poland

Background. Non-steroidal anti-inflammatory drugs (NSAIDs) were recently found to inhibits proliferation and invasive growth or inducing cell apoptosis in several tumors, including some hematologic malignancies. One of those agents, non-cyclooxygenase 2-inhibiting R-enantiomer of etodolac (SDX-101) was found to be very active against chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) cells. The indole-pyran analogue of SDX-101, SDX-308 (CEP-18082), showed even more potent cytotoxicity than SDX-101 against MM cells and inhibits orthoclase formation and activity of mature osteoclasts. The *Aims.* In this report we demonstrate activity SDX-308 in combinations with purine analogues or monoclonal antibodies against CLL cells. Material and *Methods.* Cytotoxic effects of SDX-308 alone and in combinations with purine analoques, fludarabine (FA) or cladribine (2-chlodeoxyadenozine, 2-CDA), and monoclonal antibodies, anti-CD52 (campath, alemtuzumab, ALT) or anti-CD20 (rituximab, RTX) was assessed *ex vivo* in samples obtained from 50 untreated CLL patients. *Results.* SDX-308 was found to be very active against CLL cells, inducing apoptosis-based cytotoxicity. In preliminary experiments, SDX-308 was evaluated in concentrations 3,4-340 μg/mL, with 50% cytoxicity (IC 50) gained at the dose of 34 μg/mL after 24 hours of incubation. Based on these data, SDX-308 in concentrations 8,5-25,5 μg/mL have been chosen for further experiments. All combinations of SDX-308 occurred to provide either synergistic or additive cytotoxic effects. Namely, 24 hour incubation with 25,5 μg/mL of SDX-308 used alone induced mean control-compensated cytotoxic index (CCI) - 22.3%. In these settings FA (1 μg/mL) and 2-CdA (50 μg/mL) induced mean CCIs 4.2% and 5.5%, respectively. RTX and ALT, in cells initially cross-linked with secondary IgG antibodies, induced mean CCIs 3.2% and 9.3%, respectively. Mean CCI in response to combination of 25,5 μg/mL SDX-308 with FA was 45.1% (*vs* effects of single agents - $p<0.001$). Mean CCI for 2-CdA was 45.9% and for SDX-308+RIT (for both -$p<0.001$). Finally, SDX-308 combined with ALT exerted mean CCI 46.9% ($p<0.005$). The main mechanism of SDX-308 action was apoptosis. The agent triggered significant activation of caspase-3 (*vs* untreated controls - $p=0.003$), upregulating Bax protein expression. Moreover, SDX-308 induced overexpression of p73 protein, whereas expression of p53 was not significantly triggered. All combinations upregulated expression of proapototic Bax ($p<0.05$) in CLL cells, increasing the Bax/Bcl-2 ratio. Further investigations of detailed mechanisms of these interactions are currently ongoing in our institution. Conclusion: These data indicate that combinations of SDX-308 with 2-CdA, FA and both monoclonal antibodies, RIT or ALT, exert synergistic or additive, proapototic effects against CLL cells. This suggest feasibility of such treatment in this disease.

THE VARIANCE IN PATIENT-REPORTED NONADHERENCE WITH IMATINIB TREATMENT IN CHRONIC MYELOID LEUKEMIA IS ATTRIBUTABLE TO BOTH PHYSICIANS AND PATIENTS - RESULTS FROM THE ADAGIO STUDY

L. Abraham,[1] L. Noens,[2] R. De Bock,[3] G. Verhoef,[4] P. Zachee,[5] Z. Berneman,[6] Ph. Martiat,[7] Ph. Mineur,[8] K. Van Eygen,[9] M.-A. Van Lierde,[10] K. MacDonald,[1] S. De Geest,[11] T. Albrecht,[12] I. Abraham[13]

[1]Matrix45, EARLYSVILLE, USA; [2]UZ Gent, GENT, Belgium; [3]ZNA Middelheim, ANTWERPEN, Belgium; [4]UZ Gasthuisberg, LEUVEN, Belgium; [5]ZNA Stuivenberg, ANTWERPEN, Belgium; [6]UZA, ANTWERPEN, Belgium; [7]Institut Jules Bordet, BRUXELLES, Belgium; [8]Hopital St. Joseph, GILLY, Belgium; [9]AZ Groeninge, KORTRIJK, Belgium; [10]Novartis Pharma, VILVOORDE, Belgium; [11]University of Basel, BASEL, Switzerland; [12]Matrix45 & University of Virginia, EARLYSVILLE, VA, USA; [13]Matrix45 & University of Arizona & University of Pennsylvania, EARLYSVILLE, VA, USA

Background. Imatinib therapy for chronic myeloid leukemia is a long-term treatment potentially compromised by patient nonadherence. Nonadherence is often seen as a patient problem. Studies tend to ignore the statistically hierarchical and partially dependent relationship between physicians and patients. A given physician may treat several patients enrolled in a study, and thus these patients share common treatment practices as a result of being *nested* under a given physician. Quantifying the proportions of variance attributable to patients and physicians may reveal the impact of class effects. *Aims*. To quantify the relative proportions of variance in patient-reported nonadherence with imatinib treatment for chronic myeloid leukemia that are attributable to physicians before any patient determinants are considered. *Methods*. The ADAGIO study1 is a prospective, 90-day observational, open-label, multicenter study of patients with chronic myeloid leukemia (CML) and treated with imatinib. Sample of 169 evaluable pts who had been on imatinib for a minimum 30 days at enrollment and treated by 46 physicians. Patients rated their nonadherence on a visual analog scale (0-100) as part of routine clinical practice. Hierarchical (multilevel) modeling was used to examine the fixed effect of physician on patient-reported nonadherence and to calculate the associated intraclass correlation coefficient (ICC), which quantifies the relative proportion of variance attributed to the hierarchically higher class (in this case physicians). *Results*. A statistically significant model for the fixed effect of physician on patient-reported nonadherence was retained ($p<0.0001$) with intercept (patients' average nonadherence rating on scale 0-100) of 4.59 (95%CI 3.16 to 6.01). The ICC associated with the class effect for clinicians was 0.346. *Summary and conclusions*. In a fixed effects analysis, 34.6% of the variance in patient self-reported nonadherence was accounted for by the class effect of clinician. Conversely, the remaining 65.4% of variance remains attributable to patients. This shows the significant effect that treating physicians may have on patients' medication behavior. Instead of routinely attributing all causes of nonadherence to patients, physicians should be cognizant of their potential role if they observe their patients to be nonadherent. Further research is needed to define and explicate both physician- and patient-related determinants of nonadherence with imatinib therapy for chronic myeloid leukemia.

IMATINIB PLASMA LEVELS CORRELATE WITH MOLECULAR RESPONSE IN CML PATIENTS

E. Faber, D. Friedecky, J. Tomkova, S. Rozmanova, P. Rohon, I. Skoumalova, T. Adam, M. Jarosova, K. Indrak

University Hospital, OLOMOUC, Czech Republic

Background. Examination of imatinib plasma levels are recommended in the CML patients with suboptimal response or failure. However, there are reports suggesting that imatinib plasma through levels correlate both with cytogenetic and molecular response of the patients and may be used for routine management of the treatment. *Aims.* In order to analyse the impact of imatinib plasma levels on treatment results we have introduced the examination of imatinib plasma levels into our laboratory follow-up of CML patients in 2007. All patients have signed informed consent before blood sampling. *Methods.* High performance capillary electrophoresis for determination of imatinib was used. Separation of drug

and desmethylated metabolite in methanol deproteinated plasma was performed in 50 mmol/L citrate buffer adjusted with γ-amino-n-butyric acid to pH 3.6. Limit of detection of the method was 10 nmol/L and recovery and imprecision were better then 86.7 % and 4.68 %, respectively. *Results.* We report here the results of the first comparison of plasma drug levels in the CML patients with optimal (ratio of BCR-ABL/ABL lower than 0.06%) and suboptimal (ratio of BCR-ABL/ABL higher than 0.06%) molecular response. Total 115 samples from 76 CML patients were examined. However, only 18 samples from patients with major and better molecular response and 17 samples from patients with suboptimal molecular response were chosen for the final comparison. The actual sample was eligible for analysis providing patient had been treated with standard dose 400mg daily for at least one year, there was no other evident cause of the suboptimal response (any presence of additional cytogenetic abnormalities or BCR/ABL mutation) and the sample was taken between 24±6 hours after the ingestion of the drug. Other medication, the actual duration of the therapy (providing it was longer than one year), time interval between the dose and the meal ingestion, weight, body-mass index, body surface area or co-morbidity of the patients were not taken into the account. All patients except the two in the suboptimal group have achieved the complete cytogenetic response and in addition to that other two patients in the suboptimal group have progressed, while there were any such patients in the optimal group. The results of drug level measurements showed considerable variability between the patients. However, the imatinib plasma levels in the optimal group median 2.93 μmol/L (range of 1.33-5.61) were found significantly higher that in the suboptimal group 1.75 μmol/L (range of 1.04 - 3.41) $p<0.001$, t-test. Moreover, patients with negativity in quantitative RT-PCR testing showed a trend for even higher drug plasma levels: median 3.54 μmol/L (range of 1.60-5.61) $p<0.007$, t-test. *Conclusions.* Imatinib plasma levels measured according to our methodology are in CML patients associated with molecular response to therapy. Further studies are needed in order to establish the exact role of imatinib plasma levels measurement in the management of CML patients.

Background. Nilotinib, a potent and highly selective BCR-ABL inhibitor, has been approved in several countries including the US, Mexico, and Europe for the treatment of patients (pts) with Ph+ CML in chronic phase (CP) and accelerated phase (AP) who are resistant or intolerant to prior therapy including imatinib. *Aims.* To describe the baseline mutational analysis in Mexican imatinib-resistant or-intolerant CML pts before starting treatment with nilotinib. *Methods.* The study population included adult pts with imatinib-resistant or -intolerant Ph+ CML, most were in advanced phases of the disease. Physical exam, EKG, bone marrow aspiration, karyotyping and BCR-ABL mutation screening were performed in all pts before starting nilotinib. All pts signed an informed consent. Nilotinib was administered orally at a dose of 400mg twice daily (BID). *Results.* In Mexico, between October 2006 and June 2007, 53 pts were included in the nilotinib compassionate use program (CUP). The median age was 41.7 (22-68) years; 19 (44%) were men. Most pts (20/53; 47%) had accelerated phase (AP), 15 (35%) had chronic phase(CP) and 8 (19%) had blastic crisis (BC). The median duration since CML diagnosis was 73.8 (14-183) months. The median duration of prior imatinib use was 27.6 months. 37 (86%) pts were imatinib-resistant. For this analysis, only 44 (100%) pts had available data. Before starting nilotinib, a plasma-based ABL mutational analysis was performed. The ABL kinase domain was amplified in the semi-nested PCR followed by direct sequencing using ABI/prism Big-Dye terminator cycle sequencing kit on automated capillary DNA sequencer (Quest Diagnostics, ABL Kinase domain mutation): 29 (66%) pts did not have detectable mutations and 15 (34%) pts had BCR-ABL mutations at baseline. The mutational types detected were: 1 (2.3%) pt each with F359[V,F], Y253H, G250E, E355G and E255K respectively; 2 (4.5%) pts with F317L; 2 (4.5%) pts with M351T; 3 (6.8%) pts with F486S and 3 (6.8%) pts with T315I. The 12 month follow-up analysis showed that 1 pt with F359[V,F] lost the mutation. 1 pt without baseline mutation developed a new E255[K,E] mutation (pt also had progressive disease). 12 pts remain without any mutations. There are some pending mutational reports that will be available at the time of the meeting. The overall hematology response to nilotinib was 79%. The Table 1, summarizes the baseline mutational status and the current pt status. *Conclusions.* Resistance to imatinib in CML has an heterogeneous pattern. 34% of Mexican pts included in this program had detectable mutations. Nilotinib is an effective treatment option for pts with imatinib-resistant Ph+ CML regardless of the presence or absence of BCR-ABL mutations. Additional follow-up is warranted in these pts.

Table 1. Baseline mutations and most recent status.

Baseline mutational status	*Status on 15 Feb 2008*	*N (%)*
Mutation detected	Alive	8 (18%)
Without detectable mutation	Alive	22 (50%)
Mutation detected	Dead	7* (16%)
Without detectable mutation	Dead	7 (16%)
Total		44 (100%)

*3 (6.8%) pf pts had T315I mutation at baseline

0545

MANAGEMENT OF CHRONIC MYELOID LEUKAEMIA IN CLINICAL PRACTICE IN FRANCE: RESULTS OF THE FRENCH COHORT OF THE UNMET NEEDS IN CML (UNIC) STUDY

M. Michallet,[1] F. Maloisel,[2] C. Chaleteix,[3] M. Hacini,[4] F. Huguet,[5] A. Oukessou,[6] B. Bregman,[6] A. Guerci[7]

[1]Hôpital Edouard Herriot, LYON; [2]Hôpital Civil, STRASBOURG; [3]Hôpital Hôtel-Dieu, CLERMONT FERRAND; [4]Centre Hospitalier, CHAMBERY; [5]CHU Purpan, TOULOUSE; [6]Bristol-Myers Squibb, RUEIL-MALMAISON; [7]CHU Brabois, VANDOEUVRE LES NANCY, France

Background. The prevalence of chronic myeloid leukaemia (CML) and its treatment with imatinib in France have been reported in two studies (Tardieu S, *et al.*, 2005; Corm S, *et al.*, 2006), but few data exist on current practical CML management patterns or extent of imatinib resistance and/or intolerance. *Aims.* The Unmet Needs in CML (UNIC) study, conducted across eight European countries including France, aimed to: estimate proportions of (i) patients ever treated with imatinib and (ii) imatinib-treated patients who have experienced imatinib resistance and/or intolerance (primary objectives); and assess disease management patterns, including imatinib dosing, and proportions of patients tested for treatment response. Here, we present a restricted analysis of the French cohort. *Methods.* UNIC was a cross-sectional study, with retrospective chart review of patients currently treated for CML (recruited September 2006-March 2007). A registry was collected of potentially eligible patients - those aged ≥18 years and treated for CML at participating centres. Case Report Forms (CRFs) were completed for eligible patients until the recruitment target was reached. Data were collected at most recent visit and retrospectively through clinical chart review. *Results.* Of the 1266 French patients, CRFs were completed for 767 CML patients. Analysis was restricted to 654 chronic phase (CP) CML patients, of whom 627 (96%) had received imatinib at some point during follow-up. In total, 22.8% of CP-CML patients in the French cohort discontinued imatinib therapy (Table 1). By last observation, 44.2% of imatinib-treated CP-CML patients needed a change in imatinib dose; 35.2% had a dose increase and 27.6% a decrease (patients could have both). A patient was defined as imatinib resistant if reported as such by the physician in the medical chart, and intolerant to imatinib (or other concurrent treatment) if toxicity led to

a change in imatinib use, as reported in the medical chart. Rates of reported imatinib resistance or intolerance in the French CP-CML cohort were similar to those in the total European population (Table 1): 38.3% of CP-CML patients in the cohort from France were reported as imatinib resistant and/or intolerant at some time. Of CP-CML patients, 39 (6.2%) discontinued imatinib due to toxicity. In the French CP-CML cohort, median (Q1-Q3) daily dose of imatinib was 400 (397-410) mg in the total sample (N=627), 390 (322-442) mg in patients who had ever experienced imatinib resistance/intolerance (N=240), and 400 (400-400) mg in those who had never experienced imatinib resistance/intolerance (N=387). With respect to disease monitoring, 70% (424/604) of CP-CML patients had < 4 PCR analyses to assess molecular response in the last 12 months. Furthermore, 46% (40/93) of imatinib-resistant CP-CML patients had not been assessed for mutations since diagnosis. *Summary and Conclusions.* In this large observational study of CML patients in France, nearly all patients were exposed to imatinib therapy. Nearly half needed a change in imatinib dose, 38.3% experienced imatinib resistance and/or intolerance and 22.8% discontinued imatinib according to physician criteria. Molecular monitoring of disease appeared to be used less often in clinical practice in France than according to recommendations.

Table 1.

Imatinib-treated patients, n/N (%)	French chronic phase CML cohort	Total European chronic phase CML sample
Discontinued imatinib during the follow-up period	143/627 (22.8)	289/1441 (20.1)
At least one change in imatinib dose by last observation	263/595 (44.2)	677/1370 (49.4)
Imatinib dose increase	209/594 (35.2)	563/1365 (41.2)
Imatinib dose decrease	163/591 (27.6)	441/1352 (32.6)
Imatinib resistance / intolerance reported in the medical chart		
Resistant	93/627 (14.8)	206/1441 (14.3)
Intolerant	197/627 (31.4)	552/1441 (38.3)
Resistant and/or intolerant	240/627 (38.3)	643/1441 (44.6)
Resistant and intolerant	50/627 (8.0)	115/1441 (8.0)

MULTICENTER OPEN LABEL STUDY OF SUBCUTANEOUS (SC) OMACETAXINE (OMA) IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS (PTS) THAT ARE RESISTANT OR INTOLERANT TO TWO OR MORE TYROSINE KINASE INHIBITORS (TKIS)

J. Cortes,[1] M. Wetzler,[2] L. Akard,[3] J.H. Lipton,[4] A.C. Benichou,[5] A.R. Craig,[6] E. Humphriss,[6] H. Kantarjian[1]

[1]MD Anderson Cancer Center, HOUSTON, USA; [2]Roswell Park Cancer Institute, BUFFALO, USA; [3]Indiana Blood and Marrow Transplantation Center, BEECH GROVE, USA; [4]Princess Margaret Hospital, TORONTO, Canada; [5]Stragen France, LYON, France; [6]ChemGenex, MENLO PARK, USA

Background. Omacetaxine mepesuccinate (semi-synthetic homoharringtonine, HHT) is clinically active against Ph^+ CML, with a mechanism of action independent of tyrosine kinase (TK) inhibition. The development of TKI resistance and intolerance is an emerging problem. Patients who have failed multiple TKIs may benefit from an alternative therapy for CML. The development of BCR-ABL mutations may result in increased resistance to currently available TKIs. *Aims.* We are evaluating the safety/efficacy of SC OMA in CML Pts that have failed or are intolerant to 2 or more TKIs and do not harbor the T315I BCR-ABL KD mutation. *Methods.* Adult pts with CML following failure or intolerance to at least 2 TKIs are eligible. All enrolled patients are provided informed consent prior to commencing OMA treatment. Induction schedule: 1.25 mg/m^2 SC twice daily (BID) for 14 days every 28 days until complete hematologic response (CHR) or hematologic improvement (HI); patients may receive maintenance OMA therapy with 1.25 mg/m^2 BID for 7 days every 28 days, for up to 24 mos. *Results.* To date, 18 Pts have been enrolled, 9 in chronic phase (CP), 7 in accelerated phase (AP) and 2 in myeloid blast phase (BP). Patients have received a median of 2 prior TKIs (range 2-4). Four patients have entered the trial with BCR-ABL mutations identified; one of these patients had multiple mutations (G250E/V299L); the others harboring the N331S, G250E and F317L mutations, respectively. Median age: 45 yrs (29-67), median disease duration: 26 mo. (16-36). Response data are available for 4 CP patients, 2 AP patients and 4 BP patients. After median follow-up on therapy of 3 mo. (1-6), overall hematologic response rate: CP 75% (3/4, 2 CHR, 1 HI) with one minor cytogenetic response, AP 100% (2/2, both CHR) with one patient achieving a partial cytogenetic response and then discontinuing therapy to receive bone marrow transplant, and BP 50% (2/4, 1 return to chronic phase, 1 HI). Median time to response is 1 mo. (range 1-2 mo); median duration of response is 6 mo. (range 1-9 m.o). Preliminary safety data are available (N=7). OMA therapy has been well-tolerated with myelosuppression the primary toxicity observed, (managed with adjustments to the number of dosing days per cycle). Incidence of treatment emergent grade 3/4 events: neutropenia 57%, thrombocytopenia 14% and anemia 14%. *Conclusions.* OMA therapy in CML Pts who have failed or are intolerant to multiple tyrosine kinase inhibitors has been well tolerated and has resulted in cytogenetic and hematologic responses.

LONG-TERM SURVIVAL IN CHRONIC MYELOCYTIC LEUKEMIA AFTER A FIRST PRIMARY MALIGNANCY

D. Pulte,[1] A. Gondos,[2] H. Brenner[2]

[1]Weill Cornell Medical College, NEW YORK, USA; [2]German Cancer Research Center, HEIDELBERG, Germany

Background. Within the past 10-15 years, advances in therapy of chronic myelocytic leukemia (CML), including stem cell transplant (SCT) and tyrosine kinase inhibitors (TKI), have entered clinical practice, resulting in strong improvements in survival rates for patients with CML. The risk of CML is increased after a number of malignancies, including breast and thyroid cancer and lymphoid malignancies. Few studies of survival in patients with CML occurring after a prior malignancy are available.

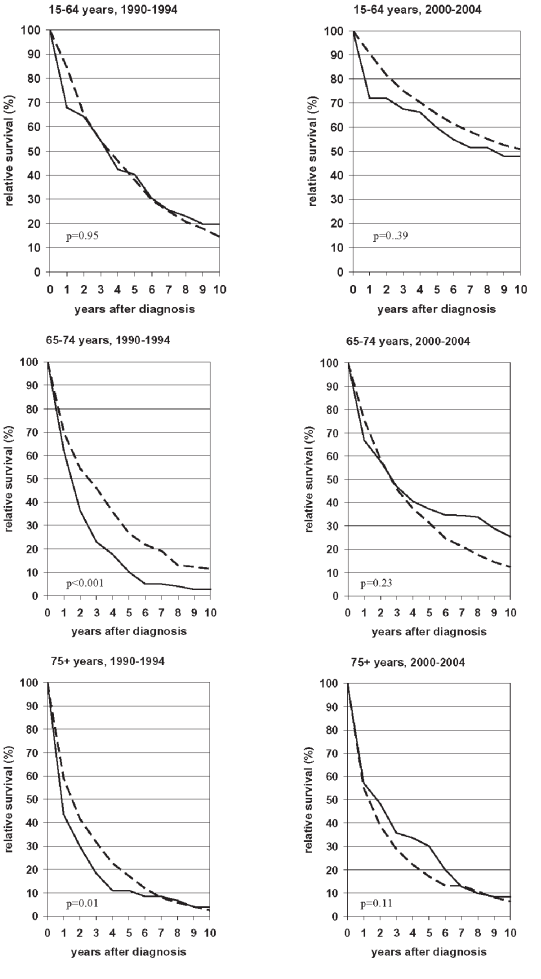

Figure 1. Ten-year relative survival curves according to calendar period and age group for CML patients with a prior malignancy (solid curves). Survival curves for patients with primary CML are given for comparison (dashed curves).

Aims. To examine survival on a population level of patients diagnosed with CML after a prior malignancy. *Methods.* We estimated trends in age specific 5- and 10-year relative survival of patients with secondary CML in the United States from 1990-1994 to 2000-2004 using the Surveillance, Epidemiology, and End Results Program database. Period analysis was employed to disclose recent developments with minimum delay. *Results.* Eight hundred eighty-three patients diagnosed with CML after a previous malignancy during the period of interest were identified. The most common preceding cancers were prostate (22.3% of preceding malignancies overall), breast (17%), and colon/rectum (15.1%). Cervical cancer was also relatively common among younger patients (9.9% among patients aged 15-64). Overall, 5-year relative survival increased from 17.6% to 37.7% (p<0.0001), and 10-year relative survival increased from 7.6% to 23.8% (p<0.0001) between 1990-94 and 2000-04. Patients experienced particularly strong improvements in 10-year relative survival (from 19.8 to 48.0%) in age group <65 and in 5-year survival (from 10.2 to 37.5%) in age group 65-74. Even in age group 75+, 5-year relative survival increased from 11.0 to 30.2%. In 1990-94, patients aged 65-74 and 75+ who were diagnosed with CML after a prior malignancy had a distinct survival disadvantage compared with patients diagnosed with CML without a prior malignancy. By 2000-04, this survival disadvantage was overcome and tentatively reversed (Figure 1). *Conclusions.* Survival for patients with CML diagnosed after a prior malignancy improved greatly in all age groups between 1990-94 and 2000-04. The survival disadvantage for patients aged 65+ with prior malignancy observed in 1990-94was absent and possibly reversed in 2000-04. This change in survival may be due to the availability of less toxic treatments such as TKI, which, unlike SCT, can be used even in patients with relatively poor health, as may be more common in older patients who have survived a prior malignancy.

SEQUENTIAL MOLECULAR MONITORING OF PATIENTS WITH CHRONIC PHASE MYELOGENOUS LEUKEMIA DURING IMATINIB MESYLATE TREATMENT. CLINICAL SIGNIFICANCE AND PREDICTIVE VALUE

H Kamel,[1] Y El-Nahas,[1] M Abdel Moaty,[1] R Abdel Fattah,[1] M El Emary,[1] W. ElMetnawy[2]

[1]*National Cancer Institute, Cairo University, CAIRO, Egypt;* [2]*Cairo University, medical School, CAIRO, Egypt*

Background and Purpose. To determine the value of regular sequential determinations of bcr-abl transcripts by RT Q-PCR in identifying the pattern of long term response to IM in Egyptian patients with chronic phase CML, correlation with hematologic and cytogenetic response. *Patients and Methods.* Seventy five Egyptian patients with CP CML , treated with a daily oral dose of IM 400 or 600mg were followed for a median follow up (FU) period of 20.6 months (range 6-43 months) . RT Q-PCR was performed at regular intervals every 3 months during the whole FU period ,cytogenetic analysis by conventional karyotyping or FISH was performed every 3 or 6 months. *Results.* The median Bcr-Abl/Abl ratio before the start of therapy was 12.3 (range: 0.23-20). Analyses of the results showed that 70 patients (93%) had hematologic response, 53 patients (70%) achieved partial and complete cytogenetic response (PCR &CCR) by 12 months. Among these 53 patients only 36 patients (48%) who achieved major molecular response (3 log reduction from initial Bcr-Abl/Abl ratio), and Bcr-Abl transcripts became undetectable in 19 (25%) of them through 24 months follow up period with more than 4.5 log reduction from initial Bcr-Abl/Abl ratio upon consequetive measurements. Four patients (5%) attained major molecular response (3 log reduction) after 18 months and were considered late responders. A suboptimal response was observed in 13 patients (17%) who maintained 2 log reduction with partial cytogenetic response along 18-43 months follow up, and five of them demonstrated a reincrease of Bcr-Abl transcripts as detected by Q-RT PCR .Only one of the 5 patient could gain major molecular response upon increasing the dose of IM to 600 mg. Primary resistance was observed in 18 (24%) of the 75 patients who have not demonstrated any molecular or cytogenetic response since the start of treatment. *Study of the abl kinase mutations.* T 315 I, P 311 L , E 255 K and the M 351 T was performed by AS PCR in 12 patients. The M 351 T mutation was found in 3 cases out of 7 with primary resistance, the same mutation was also found in one out of 3 patients with suboptimal response. One patient relapsed during treatment did not have any of the studied mutations but had clonal evolution with acquisition of a new chromosomal abnormality. *Conclusions*. Molecular monitoring of bcr-abl transcripts during IM treatment of patients with CP CML is a reliable predictive method of the course of the disease. The inferior response to IM in this sample of Egyptian population may be either attributed to the limited sample size or more likely, to differences in biology from the western population.

MULTICENTER EXPERIENCE WITH IMATINIB MESYLATE IN 202 NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA (CML) PATIENTS

A.M. Carella,[1] E. Orlandi,[1] M. Lazzarino,[1] M. Annunziata,[1] F. Ferrara,[1] E. Pungolino,[1] E. Morra,[1] C. Baratè,[1] M. Petrini,[1] M. Miglino,[2] M. Gobbi[2]

[1]*Hematology Division, GENOA;* [2]*Institute of Hematology, GENOA, Italy*

Background. Imatinib mesylate (IM) is a powerful and selective p210 Bcr-Abl tyrosine kinase inhibitor that has been demonstrated to be effective for the treatment of CML. *Aims.* An Italian multicenter study was performed to investigate the safety, efficacy, tolerance and compliance of IM in newly diagnosed CML patients. *Methods.* From February 2000 through February 2007, we collected 339 CML patients in different phases of disease and previously treated with Interferon-alpha and/or other therapies. Two hundred and two untreated Ph+ CML patients received Imatinib at diagnosis at a dose of 400 mg orally per day; 119 were male and 83 female with a median age of 50 (range, 17-84) years. Sokal risk: low 39,6%, intermediate 44,6% and high 15,8%. *Results.* Complete hematological remission was achieved in 94% of patients. The estimated rate of complete cytogenetic remission (CCR) was 78,7% after 12 months; with a median follow up of 38 months the rate of CCR raised to 86,8%. Levels of Bcr-Abl transcripts had fallen by at least 3 log in 52% of cytogenetic remitters patients at 12 months; after a median follow up of 38 months, 26% of these patients achieved complete molecular remission (CMR). The most commonly reported adverse events after IM were edema (including peripheral and periorbital edema) (50%), muscle cramps (37,7%), diarrhea (40,7%), fatigue (38,8%); moreover in 8 (5,2%) patients grade 3-4 events were observed consisting of pancitopenia and/or elevated liver enzymes. Eight (5,2%) patients died: 2 patients for progressive disease after allografting, 2 patients of cardiac infarction, 1 patient of severe necrotic fascitis, 1 patient of metastatic colon cancer and 2 patients of blastic crisis. In summary, at 84 months 194/202 (96%) patients are alive and 175 (87%) of them are still receiving IM. Nineteen (13%) patients discontinued Imatinib: 7 patients for adverse events grade 3-4 and 12 patients for progressive disease. *Conclusions.* These data are comparable to those of IRIS study and confirm the safety and efficacy of IM in newly diagnosed patients.

0550

NILOTINIB IS ACTIVE IN IMATINIB RESISTANT AND INTOLERANT CHRONIC MYELOID LEUKEMIA (CML) PATIENTS

M.K.M. Koren-Michowitz,[1] P. Le Coutre,[2] J. Duyster,[3] C. Scheid,[4] J.M. Rowe,[5] N. Goldschmidt,[6] E. Ribakovsky,[1] A. Nagler[1]

[1]*Chaim Sheba Medical Center, RAMAT GAN, Israel;* [2]*Campus Virchow Klinikum Charité, BERLIN, Germany;* [3]*Dept. of Internal Medicine III, Technical University of Munich, MUNICH, Germany;* [4]*Klinik I für Innere Medizin Universität zu Köln, KÖLN, Germany;* [5]*Rambam Medical Center, HAIFA, Israel;* [6]*Hadassah - Hebrew University Medical Center, JERUSALEM, Israel*

Background. Nilotinib is active in imatinib resistant pts and in those with imatinib intolerance. Here, we report the results of 63 CML pts treated with niltoinib within 2 phase 2 trials (CAMN107AIL01, Israel and ENACT, Germany). *Pts and Methods.* Mean age of the pts was 56 years (range 25-77), the mean disease duration was 64 months (range 2-55) and the mean number of prior therapies was 2.18 including imatinib. Forty pts had chronic phase (CP), 12 had blast crisis (BC) and 11 accelerated phase (AP) CML. Forty-three pts were imatinib resistant and 20 intolerant to imatinib. Thirteen pts were treated with a second generation TKI prior to nilotinib (dasatinib [11] INNO406 [1] SKI606 [1]). Fifteen pts (28% with available data) had 16 ABL KD mutations at trial entry including F359V (2), M244V (2), Y253H, L387M, E355K, T277A, T315I, G250E (2), F317L, L248V, T315I, Q252H, E279K. *Results.* After a median follow up of 12 months (range 2.5-28) CHR was achieved in 24 pts without a CHR at baseline (57%), 56% in CP, 67% in AP and 42% in BC (1 additional BC pt has returned to CP). CCyR was newly achieved in 40% of pts, 40% in CP, 20% in AP and 42% in BC and MMolR was achieved in 27% pts without a MMolR at baseline, 28% in CP, 11% in AP and 25% in BC. Best response according to baseline features is presented in Table 1. Nilotinib therapy was discontinued in 26 pts (50% of pts with available data) due to disease progression (N=11), side effects (N=9), referral for Allo SCT (N=3) and other reasons (N=3). The mean duration of treatment was 7.5 months (range 0.4- 24). Grade 3-4 hematological toxicity was seen in 32% of pts, 39% in advanced phase disease and 27% in CP (p=0.3). The most common non-

hematological adverse events were rash (N=10), fever / infection (N=8), bone pain (N=5), elevation of liver enzymes (N=5), indirect hyperbilirubinemia (N=8) and asymptomatic hyperglycemia (N=6). Grade 3-4 non-hematological toxicity was observed in 19% necessitating drug withdrawal in 6. There were no cases with pleural effusions. *Conclusions.* Nilotinib therapy can result in cytogenetic and molecular responses in CML pts including those in advanced stage, those harboring ABL KD mutations and those failing prior 2nd generation other TKIs.

Table 1.

	CHR	PCyR	CCyR	MMolR	No response/ progression
Disease Phase (N)					
CP no baseline CHR (23)	6	1	2	3	11
CP baseline CHR (8)	2	1	3	2	
CP baseline PCR (4)			1	3	
CP baseline CCR (4)			1	3

NONADHERENCE WITH IMATINIB TREATMENT IN CHRONIC MYELOID LEUKEMIA IS A FUNCTION OF DISEASE, HEALTH, KNOWLEDGE, AND SOCIAL FACTORS - RESULTS FROM THE ADAGIO STUDY

L. Abraham,[1] L. Noens,[2] R. De Bock,[3] G. Verhoef,[4] P. Zachee,[5] Z. Berneman,[6] Ph. Martiat,[7] Ph. Mineur,[8] K. Van Eygen,[9] M.-A. Van Lierde,[10] K. MacDonald,[1] S. De Geest,[11] T. Albrecht,[12] I. Abraham[12]

[1]Matrix45, EARLYSVILLE, USA; [2]UZ Gent, GENT, Belgium; [3]ZNA Middelheim, ANTWERPEN, Belgium; [4]UZ Gasthuisberg, LEUVEN, Belgium; [5]ZNA Stuivenberg, ANTWERPEN, Belgium; [6]UZA, ANTWERPEN, Belgium; [7]Institut Jules Bordet, BRUXELLES, Belgium; [8]Hopital St. Joseph, GILLY, Belgium; [9]AZ Groeninge, KORTRIJK, Belgium; [10]Novartis Pharma, VILVOORDE, Belgium; [11]University of Basel, BASEL, Switzerland; [12]Matrix45 & University of Virginia, EARLYSVILLE, VA, USA; [13]Matrix45 & University of Arizona & University of Pennsylvania, EARLYSVILLE, VA, USA

Background. Imatinib therapy for chronic myeloid leukemia is a long-term treatment potentially compromised by patient nonadherence. There is little evidence of the determinants of patient nonadherence. Identifying determinants of nonadherence may assist in improving patients' medication behavior and thus treatment outcomes. *Aims*. To quantify the multivariate associations among two nonadherence measures and disease, health, knowledge, and social factors and to model their relative contribution to patient nonadherence. *Methods*. The ADAGIO study[1] is a prospective, 90-day observational, open-label, multicenter study of patients with chronic myeloid leukemia (CML) and treated with imatinib. Sample of 169 evaluable pts who had been on imatinib for a minimum 30 days at enrollment. Canonical correlation analysis was used to model the multivariate relationship between nonadherence and baseline determinants. Measurements included two vectors: (1) nonadherence at 90 days vector: Basel Assessment of Adherence Scale for patients (0/1 with 1=nonadherent); and percent of imatinib taken per pill count (subtracted from 100 to reflect nonadherence); (2) Determinants vector: age; months since CML diagnosis; months since initiation of imatinib treatment; knowledge of CML disease, treatment, and imatinib; general health (SF-8); and living status (alone Y/N). Nonadherence was defined as a two-element vector so as to increase measurement reliability and decrease the biases associated with various methods of adherence assessment used in routine clinical practice. *Results*. Two canonical correlations were generated: 0.389 (Bartlett's Chi-squared=25.572, p=0.012) and 0.213 (Bartlett's Chi-squared= 5.661, p=0.341); the second canonical correlation was deleted because it was not statistically significant. The canonical loadings (or structure coefficients) for the retained model were: age 0.951; months since CML diagnosis 0.203; months since initiation of imatinib treatment 0.143; general health 0.027; knowledge of disease, treatment, and imatinib -0.366; and living alone 0.121. *Summary and Conclusions*. The patient nonadherence vector was related to the determinants vector as follows: nonadherence increased as patients were older, had been diagnosed with CML for a longer period of time, and had been on imatinib treatment for a longer period time. Taken together, these three variables may refer to disease chronicity. Nonadherence increased if patients were in slightly better health at enrollment, perhaps reflecting some self-neglect behavior as patients felt less ill. Living alone was associated with higher nonadherence, and may suggest the importance of social support and daily assistance. These variables may be warning signs for nonadherence for clinicians to consider in practice, given the long-term nature of imatinib treatment. Better patient knowledge of disease and treatment, a clinically modifiable determinant, was associated with a decrease in nonadherence. In summary, clinicians should be aware of potential nonadherence in CML patients on imatinib who present with the following risk factors: older age, longer disease duration and imatinib treatment duration, poor knowledge of disease and treatment, living alone, and relatively good health.

FLOW CYTOMETRIC ANALYSIS OF ONCOGENIC SIGNAL TRANSDUCTION PATHWAYS IN PRIMARY LEUKAEMIC CELLS

A. Beel,[1] B. Wasag,[1] V. Van Duppen,[1] J. Cools,[1] D. Bron,[2] L. Michaux,[3] G. Verhoef,[1] P. Vandenberghe[1]

[1]KULeuven, LEUVEN; [2]Institut J.Bordet, BRUSSELS; [3]University Hospitals St-Luc, WOLUWE, Belgium

Background. The development of small molecule inhibitors is one of the most exciting developments in recent cancer treatment and established oncogenic tyrosine kinases as prime targets for therapy. As the efficiency of molecular inhibitors critically depends on target inhibition, and underlined by the emergence of molecular resistance, it becomes crucial to assess the activation status of oncogenic signalling. *Aims*. 1. to develop a flow cytometric alternative for measuring intracellular protein phosphorylation status in CML and Ph$^+$) ALL. 2. to predict or confirm sensitivity or resistance to TKI on functional grounds. *Methods*. Fresh cells were incubated with imatinib (IM) or dasatinib (DAS). After fixation and permeabilisation, they were incubated with phospho-epitope specific antibodies or whole protein antibodies, and counterstained with Alexa647-conjugated secondary antibodies. Experimental conditions were fine-tuned in BCR-ABL transfected BaF3 cells and validated with western blotting. PBL were obtained by venipuncture or therapeutic leukapheresis, and density centrifugation. Measurements were performed on a FacSCanto cytometer (Becton Dickinson). *Results*. In BCR-ABL transfected BaF3, P-CRKL was reduced by 54% and 38% by IM 1 and 10 µM respectively. T315I BCR-ABL BaF3 were completely resistant, consistent with the known resistance profile. Q252H BCR-ABL BaF3 showed an intermediate response. These changes in CRKL phosphorylation were confirmed by Western blot. We tested 16 CML patients in early chronic phase (ECP), 4 patients with CML in acceleration phase/blast crisis (AP/BC), 3 CML patients in complete cytogenetic remission (CCyR), 2 patients with T315I and 2 ALL patients with t(9;22)(q34;q11). The relevant cell population was identified by surface coimmunostaining. In ECP, incubation with IM at a concentration of 1µM induced a clear-cut decrease of CRKL phosphorylation in CD34$^+$ cells, neutrophils, but not in lymphocytes. Likewise, DAS induced a reduction in CRKL phosphorylation at a concentration of 10 nM. Total CRKL immunostaining was not altered by incubation with a TKI. In samples from patients with CML in CCyR, AML or reactive neutrophil leukocytosis, and from healty controls, CRKL phosphorylation remained unchanged. P-ERK and P-TYR decreased in some, but not all patients. Other downstream targets (P-CBL, P-FAK, P-STAT5,) did not reveal a response to TKI. In 2 patients with a T315I mutation, CRKL phosphorylation was entirely resistant to IM and DAS. In one, *in vitro* sensitivity to IM/DAS was restored after IM discontinuation. Sequencing and RT-PCR of the BCR-ABL kinase domain with allele-specific primers showed a concomitant decrease and later on disappearance of the T315I clone. A *de novo* Ph$^+$ ALL was sensitive to IM/DAS, while a relapsing Ph$^+$ ALL under imatinib was entirely resistant to IM but sensitive to DAS. Kinase

domain mutation analysis is pending here. *Conclusions*. This assay reliably measures the activation status of BCR-ABL, and allows a *signalling* diagnosis of CML in patient material. Moreover, it allows to explore and monitor clinical resistance to kinase inhibitors *in vitro*, and may assist in therapeutic choices. Given the limited dynamic measurement range, its potential to predict the long-term outcome under TKI is uncertain.

COMPARISON OF ALLOGENEIC STEM CELL TRANSPLANTATION AND IMATINIB FOR CHRONIC MYELOID LEUKEMIA: RESULTS FROM CAMELIA REGISTRY

E. Faber,[1] J. Muzik,[2] V. Koza,[1] E. Demeckova,[1] J. Voglova,[1] L. Demitrovicova,[3] J. Chudej,[1] I. Markuljak,[4] E. Cmunt,[5] T. Kozak,[6] E. Tothova,[1] M. Jarosova,[1] L. Dusek,[7] K. Indrak[1]

[1]University Hospital, OLOMOUC, Czech Republic; [2]Institute Biostatistics and Analyses, BRNO, Czech Republic; [3]National Oncology Institute, BRATISLAVA, Slovakia; [4]FD Roosevelt Hospital, BANSKÁ BYSTRICA, Slovakia; [5]1st University Hospital, PRAGUE, Czech Republic; [6]University Hospital Kralovske Vinohrady, PRAGUE, Czech Republic; [7]Institute of Biostatistics and Analyses, BRNO, Czech Republic

Background. CAMELIA is an international population-based registry for patients with chronic myeloid leukemia (CML) treated at 10 major centers in the Czech Republic and Slovakia. *Aims.* To compare the results of imatinib therapy and allogeneic stem cell transplantation used as the first or second-line treament for CML patients in CAMELIA Registry. *Methods.* Patients were selected from the cohort of 242 women and 272 men with Ph-positive CML patients (median age 50; range 15-83) diagnosed after 2000. Comparison was performed as a retrospective study. Registry-procedures were fully in accord with country legal and ethic requirements. *Results.* Median duration of the patients' follow-up was 3.2 years (range: 0.1-7.9 years). Imatinib was used for the first and second-line therapy in 244 and 189 patients after median of 34 and 407 days (range 0-127 and 103-2660) from diagnosis, respectively. There were no statistically significant differences between both groups with respect to age, phase of CML and Sokal score, however, there were significantly more patients with high-risk Hasford score in the group treated with first-line imatinib (p<0.001). The rate of complete cytogenetic and major molecular response did not differ between the both groups, however, there were more patients progressing 40 *vs* 62 (16.4 *vs* 32.8%; p<0.001), more patients treated with second-generation tyrosine kinase inhibitors 13 *vs* 20 (5.3 *vs* 10.6%) or transplanted 15 *vs* 17 (6.2 *vs* 8.9%) in the second-line group. As the result both overall survival and progression free survival were better in the group treated with first-line imatinib (p=0.046 and 0.054; Figure 1).

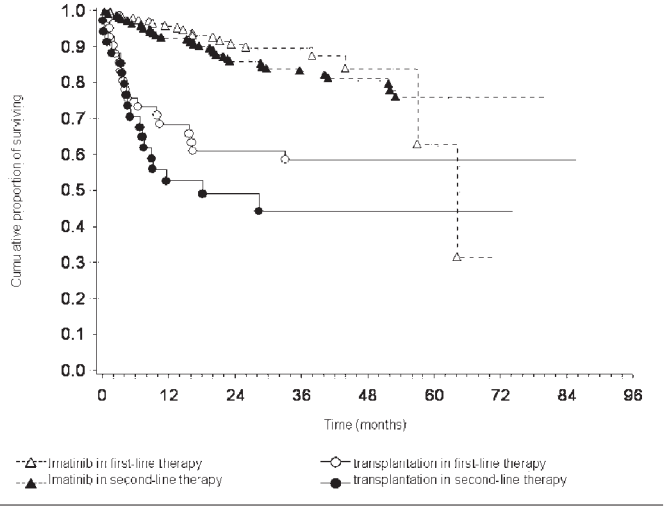

Figure 1.

Allogeneic stem cell transplantation was used as the first and second-line treatment modality in 41 and 34 patients aged 18-59 and 17-59 years (median 34 and 36) (p<0.001; Mann-Whitney test; in comparison with patients treated with imatinib). Most patients were transplanted from the related donor 43 (57.3%) after myeloablative conditioning 58 (77.3%) and using peripheral stem cell grafts 53 (70.7%). For primary and secondary transplantation median interval from diagnosis to transplant was 153 and 516 days, respectively. Complications of transplantation were the most frequent cause of death in both groups (16 and 7 patients, respectively), however, higher number of patients died after CML progression in the group where transplantation was performed as second-line treatment (1 and 8 patients, respectively). Both first and second-line imatinib therapy showed significantly better overall and event-free survival when compared with the transplantation used as the first or second-line treatment modality (p<0.001; Log-rank test Figure 1). *Conclusions.* Our analysis from the population-based registry of CML patients diagnosed after 2000 has confirmed previous reports from other studies and proved the benefit of early imatinib treatment after the diagnosis and also the clear superiority of imatinib over allogeneic stem cell transplantation in the first-line therapy of CML.

Supported by the project of CAMELIA Registry.

IMATINIB IN THE FIRST-LINE CML TREATMENT: AN ANALYSIS OF A COMPREHENSIVE NON-COMMERCIAL DATABASE OF ALL CONSECUTIVE PATIENTS IN A DEFINED POPULATION

J. Mayer,[1] H. Klamova,[2] D. Zackova,[1] M. Doubek,[1] P. Cetkovsky,[2] J. Rulcova,[2] K. Machova,[2] J. Moravcova,[2] D. Dvorakova,[1] T. Jurcek[1]

[1]University Hospital, BRNO; [2]Institute of Hematology and Blood Transfusion, PRAGUE, Czech Republic

Background. Imatinib has changed the paradigm of CML treatment. Moving imatinib into the first-line CML therapy is based predominantly on excellent results of IRIS trial. Population-based real-life data, however, are still scarce. *Aims*. To describe the efficacy and toxicity of imatinib in the first-line setting on an unselected population of CML patients. *Methods*. Data about CML patients in the first chronic phase from the region of about 6 million inhabitants who were treated with imatinib were collected into the database called INFINITY (tyrosine kinase Inhibitors iN the FIrst aNd followIng CML Treatment). One of the main goals was to include all consecutive patients. The database is quite detailed: there are 85 entry parameters and up to 106 parameters during the different visits in the follow-up. The BCR/ABL examination was centralized into 2 labs: one used B2M and the second one ABL as a control gene. Comparison of both methods (serial dilution of cell-line K562, and the blinded patients' samples) revealed that the results obtained from both laboratories were comparable up to 10% of BCR-ABL. The study so far is a voluntary activity with no company sponsorship. *Results*. 105 patients (pts) have been included (51 males and 54 females) aged 54 y (median; 20-77). 103 pts received initially hydroxyurea and 11 underwent leukapheresis. The Hasford score distribution was: low, 14%; intermediate, 52%; high, 34%. Median follow-up at the date of the analysis is 18 month (3-60). The median actually administered imatinib dose was 400 mg. After 12 months of therapy, the response rates were: complete hematological response 92%, complete cytogenetic response 70%, partial cytogenetic response 12%, complete molecular response 4%, and major molecular response 42%; twelve months BCR/ABL expression was 0.25% (median; 0%-31%). The improvement of ECOG performance status during the first year of therapy was striking: ECOG PS 0 increased from 25% to 79%, and PS 2 decreased from 25% to 4%. Non-hematological toxicity of any grade decreased from 80% (month 3) to 34% (month 12) with edema and cramps being the most prevalent. At 12 months, 16% of pts had hematological toxicity of any grade with anemia being dominating. In total, 14 patients stopped the treatment for various reasons: 5 pts underwent allogeneic hematopoietic stem cell transplantation, 6 pts changed the tyrosine kinase inhibitor for imatinib failure (dasatinib, n=5; nilotinib, n=1), and 3 patients were switched to dasatinib for intolerable non-hematological toxicity. There was only one death, however, linked to the alcohol intoxication. *Summary*. In this non-study population of CML patients, we can confirm, that imatinib therapy leads to the excellent disease control in a majority of patients in the first chronic phase, and these results are surprisingly well comparable to the results of IRIS trial.

0555

THERE ARE NOT ONLY POINT MUTATIONS BUT ALSO SPLICING DEFECTS IN BCR-ABL GENE IN CML PATIENTS TREATED BY IMATINIB

A.V. Misyurin, M.V. Suchkova, A.A. Krutov, E.V. Aksenova, V.V. Tikhonova, A.G. Turkina, N.D. Khoroshko

National Research Center for Hematology, MOSCOW, Russian Federation

Background. Emergence of BCR-ABL kinase domain mutations in CML patients is considered the major course of inadequate response or loss of response to treatment by tyrosine kinase inhibitors. It is recommended that if level of BCR-ABL transcripts in CML patients treated by imatinib appears to be rising and if repeat test shows that the level has risen by 0.5 or 1.0 log, the next step should be to search for such mutations. More than 50 different point mutations of BCR-ABL kinase domain and a splice BCR-ABL isoform associated with the L248V mutation are reported in CML patients with acquired resistance to imatinib. *Aims.* To search for mutations in BCR-ABL kinase domain in CML patients that prone to lose response for imatinib treatment according to data of RQ-PCR quantification. Patients and *Methods.* Chronic phase CML patients has been treated by imatinib and monitored by means of RQ-PCR (BCR-ABL/ABL)x100%). At even weak signs of BCR-ABL level increasing, the mutational analysis has been performed by means of direct PCR fragment sequencing. We have used original primers that enable to search for mutations in the area spanning from a3 to a11 ABL exons of BCR-ABL gene (the whole BCR-ABL kinase domain and flanking regions). *Results.* Sequencing has been performed for 117 CML patients that were suspected to acquire imatinib resistance according to BCR-ABL expression quantification. 33 point mutations of 13 different types have been detected, among them 730A>G(Met244Val)- (2/33-6%), 742C>G(Leu248Val)- (4/33-12%), 749G>A(Gly250Glu)- (8/33-24%), 756G>T(Gln252His)- (1/33-3%), 763G>A (Glu255Lys)-(2/33-6%), 764A>T (Glu255Val)-(2/33-6%), 835G>A(Glu279Ala)-(1/33-3%), 944C>T(Thr315Ile)-(5/33-15%), 949T>C (Phe317Leu)-(1/33-3%), 949ë>G (Phe317Leu)-(1/33-3%), 1064A>C (Glu355Gly)-(1/33-3%), 1075T>G (Phe359Val)-(3/33-9%) and 1187A>G (His396Arg)-(2/33-6%). Interestingly, all 4 cases with 742C>G (Leu248Val) point mutation have additional abnormal variant of BCR-ABL gene as a splicing isoform lacking 81 bp of exon a4. The point mutation 742C>G exchange the motif CAAGCT for CAAGGT and the latter is a strong splice acceptor site. The same structure of acceptor splicing site is responsible for excision of intron sequence between exons a4 and a5. It seems that this cryptic splice acceptor site in the middle of 4a exon carrying 742C>G point mutation may compete with natural splice acceptor site from 4th intron. It gives rise to two BCR-ABL transcripts: one carrying a point mutation and the other one with 81 bp's deletion of the 3'end of exon 4a, without frameshift. We have also observed two novel cases of splicing defects in BCR-ABL gene. In one of the patients there has been found a 72 bp's deletion of the 5'end of exon a7. In this case there is also occurred no frameshift of the CDs. On the 3'end of this deletion there is a pyrimidine-rich region followed by AG dinucleotide. There is also GT sequence on 5'end of the remnant of exon a7. The motif AG/GT is believed a typical splice donor site and that is a possible explanation of the molecular mechanism that underlies this deletion. This deleted form of BCR-ABL gene has been the only one in this patient. After a temporary and slight increasing of BCR-ABL expression this patient regain major molecular response without escalation of imatinib dose. The last case of BCR-ABL splicing defects detected in CML patients was of arbitrary nature. In this patient with primary imatinib resistance mutational analysis has revealed an insertion of 35 bp (actttgataaccgtgaagaaagaacaagatagaag) between exons a8 and a9. This insertion adds 9 novel amino acids to the BCR-ABL protein encoded up to a8 exon and then there is incorporated a stop-codon giving rise to a truncated form of BCR-ABL protein. The imatinib has been exchanged for dasatinib for this patient; nevertheless, it gives rise to only partial molecular response (1 log). It turned out that this insertion sequence is originated from the middle of 8th intron. Conclusion: The most common BCR-ABL molecular defects connected to imatinib resistance are point mutations of BCR-ABL kinase domain. However, there may be less frequent structural abnormalities of other nature that should be also considered. Here we report 3 types of splice BCR-ABL isoforms, two of them are novel. The other that was reported earlier, namely, 81 bp's deletion of a4 exons seems to always accompany 742C>G point mutation.

HAS SIMULTANEOUS PREGNANCY NEGATIVELY INFLUENCED PROGRESSION AND TREATMENT RESPONSE IN CML?

H. Klamova, J. Moravcova, K. Machova, J. Brezinova, M. Markova

Institute of Hematology and Blood Transfusion, PRAGUE, Czech Republic

Background. Although it is not very frequent to make a simultaneous diagnosis of chronic myeloid leukaemia during pregnancy, it occurs. The incidence of CML and concurrent pregnancy is estimated 1/ 75 000. The treatment of pregnant CML patients is not easy but it is possible at the present time. It contains risk for the embryonic development on one hand, on the other one an untreated CML can jeopardise both the mother and the unborn baby. No standard treatment proposal has been introduced so far. *Aims.* Evaluation of possibilities and the results of CML treatment in simultaneous pregnancy and in the period after physiologic delivery. Patients and *Methods.* From the total number of 298 patients with CML treated in our department, 84 women were in childbearing age. Of them 7 (8%) became pregnant. The pregnancy confirmation was either made together with diagnosis of CML, or during CML treatment. Two patients decided abortion, 5 women decided to continue pregnancy, which was closely monitored by obstetricians. In these 5 patients (age 29-36 years) the history of the CML disease during pregnancy and 6-57 months after childbirth is followed up. The achievement of haematologic (CHR), cytogenetic (CgR) and molecular (MMoR) response was evaluated together with quality of life. Informed consent was obtained. *Results.* In 4 patients the diagnosis of CML was set together with pregnancy confirmation, lasting 9-14 weeks. In one patient, who had been already treated with imatinib for 10 months, the pregnancy was confirmed in the 21.week of its duration. During first trimester leukodepletion was the only treatment, when needed. In the 2.and 3.trimester all the patients were treated with interferon (INF) and eventually leukodepletion. All mothers gave birth to completely healthy new-borns in 38.-39.week of pregnancy, as expected. The haematological remission was achieved in all 5 patients in 3 months after INF initiation, which lasted in 4 patients during the whole pregnancy. One patient lost the haematological remission 3 weeks before expected delivery, which was solved by INF dosage augmentation together with leukodepletion. After the delivery all the patients started to be treated with imatinib 400 mg/day. In 2 of them complete cytogenetic remission (CCgR) was achieved 6 and 12 months after the imatinib initiation, one patient has major cytogenetic response in 6 months of treatment. Other 2 patients did not have optimal response to imatinib, in one of them Y253H mutation was found. After switching to 2nd generation thyrosine kinase inhibitor (dasatinib), CCgR was achieved 6 and 12 months of treatment. Major molecular response was achieved in 4 patients. The quality of life is very good (PS ECOG =0) in all 5 patients 10 to 86 months from diagnosis. *Conclusions*. We conclude that in our patients simultaneous pregnancy did not negatively influenced further response to CML treatment. CML diagnosis in pregnancy is not conclusive reason for abortion, though it is always high-risk process. The treatment of CML in pregnant women is effective. Close collaboration of haematologist and obstetrician is necessary.

THE OCCURRENCE OF PLEURAL/PERICARDIAL EFFUSIONS IN PH+ CML PATIENTS FAILING PRIOR TYROSINE KINASE INHIBITORS (TKI) BEFORE STARTING NILOTINIB - ANALYSIS OF DATA FROM COMPASSIONATE USE PROGRAM

P. le Coutre,[1] E. ODwyer,[2] L. Mendes,[3] C. Woodman[3]

[1]*Charité, BERLIN, Germany;* [2]*University College Hospital, GALWAY, Ireland;* [3]*Novartis Oncology, FLORHAM PARK, NJ, USA*

Background. There are now three TKIs approved for the treatment of patients with Ph+ CML (imatinib, nilotinib and dasatinib). Although each of these drugs inhibits Bcr-Abl, their safety profiles are different, especially regarding fluid retention events. *Aims.* Evaluate the occurrence of pleural/pericardial effusions in resistant or intolerant CML patients who had failed either imatinib therapy only or imatinib and dasatinib therapy. *Methods.* Between June, 2006 and January 2008, pts with Ph+ CML (CP, AP, BC) were evaluated for compassionate use approval of nilotinib for the treatment of resistance or intolerance to either imatinib therapy alone or imatinib followed by dasatinib. The majority of pts (98%) had not previously received nilotinib therapy. Resistance and intolerance as well as CML phase were defined using similar criteria as that previously reported in the nilotinib pivotal phase I/II registration study. At the time of medical review for compassionate use approval safety information including the presence of or the history of pleural/pericardial effusions was collected along with dosing information for imatinib and dasatinib. *Results.* A total of 621 pts were evaluated for nilotinib through the compassionate use program. The median age was 52 yrs (range, 12-88); 16 pts (2%) were < 18 yrs of age. 491 (79%) pts had failed imatinib alone (78%, resistant; 22%, intolerant) and 130 (21%) pts had failed imatinib and dasatinib therapy (53%, resistant; 47%, intolerant). For the complete dataset , 359 (58%) pts had CP, 152 (24%) pts had AP, and 110 (18%) pts had BC. For the pts treated with imatinib only, 4 pts (<1%) had pleural effusions alone (n=1) or in combination with pericardial effusions (n=3). For the pts treated with imatinib followed by dasatinib, 38 pts (29%) had pleural effusions alone (n=34) while 4 pts (3%) had pleural and pericardial effusions. Of the pts with dasatinib-associated effusions; 15% occurred on daily doses > 140 mg, 35% on doses of 140 mg, 24% on doses of 100 mg and 24% on doses of < 100 mg. There were 9 additional pts who developed effusions in which the dasatinib dose at the time of the effusion was not available. Of the 24 pts with effusions on dasatinib daily doses of 140 mg, 15 pts discontinued therapy due to an effusion and 5 pts had effusions persist despite a reduction in dasatinib dose. One pediatric pt (age 12 yr) developed a pleural effusion on a dasatinib dose of 100mg QD. None of the pts who developed a pleural/pericardial effusion on dasatinib had a history of pleural/pericardial effusion on imatinib. *Conclusions.* This large dataset supports earlier reports that pleural/pericardial effusions occur commonly in CML pts treated with dasatinib and that the occurrence of effusions with dasatinib may occur even at daily doses <140 mg, and in some cases with daily doses <100 mg.

USEFULNESS OF *IN VITRO* SENSITIVITY TESTING OF LEUKEMIC CELLS TO KINASE INHIBITORS FOR THE MANAGEMENT OF TREATMENT WITH IMATINIB AND DASATINIB IN CML PATIENTS

R. Solna,[1] J. Veselovska,[1] S. Rozmanova,[2] E. Faber,[2] M. Jarosova,[2] M. Holzerova,[2] K. Indrak,[2] V. Divoky[1]

[1]*Department of Biology, Faculty of Medicine, Palacky University, OLOMOUC;* [2]*Department of Hemato-oncology, University Hospital, OLOMOUC, Czech Republic*

Background. Second generation Abl tyrosine kinase inhibitors (TKIs), such as dasatinib (DAS) or nilotinib, are currently available for the treatment of patients with chronic myeloid leukemia (CML) resistant or intolerant to imatinib (IM) therapy. The efficacy of TKIs can be evaluated *in vitro* by degree of inhibition of phosphorylation of selected signaling molecules downstream Bcr-Abl after incubation of leukocytes with the drug. *Aims.* To evaluate functional assay that enables the clinicians to predict therapy responses and the degree of resistance/sensitivity of Bcr-Abl-positive leukemia patients to TKIs. *Methods*. Quantitative real time RT-PCR (Q-RT-PCR) was performed to monitor the level of BCR-ABL transcripts. BCR-ABL mutational status was assessed using sequencing of the RT-PCR products. The *in vitro* test of sensitivity to TKIs was based on detection of inhibition of phosphorylation of Crkl and Phospho-Src Family kinases (SFK, Tyr416). The pellet of leukocytes was washed with Optimem I (Gibco) and incubated in RPMI (Sigma) with10% fetal bovine serum (Gibco) and with or without 10 μM IM or 250 nM dasatinib at 37°C/5% CO2 for 1 hour. After cultivation the cells were washed two times with ice-cold PBS and lysed in IP buffer with phosphatase and protease inhibitors. Protein lysates were subjected to electrophoresis SDS-PAGE and western blot with immunodetection with primary antibody anti-Crkl 32H4 (Cell Signaling), Phospho-Src Family (Tyr416) Antibody (Cell Signaling), and with secondary antibody (Stabilized Goat Anti-Mouse/Anti-Rabbit HRP-conjugated, PIERCE) and detection substrates (Super Signal West Dura/Femto Chemiluminiscence Substrate, PIERCE). *Results*. Sixty patients were analyzed using the test, some of them repeatedly. The extent of inhibition of phosphorylation of Crkl and SFK in this assay correlated with the clinical status and the numbers of BCR-ABL-positive cells assessed by FISH and/or Q-RT-PCR. The patients' cells with Y253H and T315I mutations showed a complete or partial failure to inhibit Bcr-Abl TK by IM, based on the ratio of mutant and wild-type clones. DAS in these patients did not inhibit Bcr-Abl TK, but completely inhibited SFK, suggesting, that in these patients SFK were not activated downstream Bcr-Abl. Patient with E255K mutation showed resistance to IM but sensitivity to DAS, which correlated with his *in vivo* responses to these drugs. Some IM-resistant patients lacking mutation of BCR-ABL proved sensitivity to higher dosage of IM or to DAS in this assay, which lead to appropriate therapeutical intervention. In one patient, BCR-ABL clone was eradicated on IM therapy; however, a Ph-negative myeloproliferative disorder associated with a high activation of SFK persisted, suggesting activation of an alternative signaling pathway not inhibited by IM and independent of Bcr-Abl. The patient developed resistance to DAS, which corresponded with a failure to inhibit SFK in *in vitro* phosphorylation assay. *Conclusions*. *In vitro* test of sensitivity of Bcr-Abl-leukemia cells to TKIs allows direct evaluation of the Bcr-Abl protein inhibition and reflects both the (possible) mutational status of Bcr-Abl as well as other mechanisms of resistance intrinsic to the cell. It could serve as a simple test for indication of these inhibitors in a patient-specific manner.

DASATINIB PHARMACOKINETICS AND EXPOSURE-RESPONSE (E-R): RELATIONSHIPS TO EFFICACY AND SAFETY IN PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA IN CHRONIC PHASE (CML-CP)

C. Nicaise,[1] X. Wang,[1] A. Roy,[1] M. Pfister,[1] T.T. Chen,[1] E. Bleickardt,[1] A. Hochhaus,[2] N.P. Shah,[3] F.E. Nicolini,[4] R.E. Clark,[5] G. Saglio,[6] H. Kantarjian[7]

[1]Bristol-Myers Squibb, WALLINGFORD, CONNECTICUT, USA; [2]Universität Heidelberg, MANNHEIM, Germany; [3]University of California San Francisco School of Medicine, SAN FRANCISCO, USA; [4]Hôpital Edouard Herriot, LYON, France; [5]Royal Liverpool University Hospital, LIVERPOOL, UK; [6]University of Torino, ORBASSANO-TORINO, Italy; [7]MD Anderson Cancer Center, HOUSTON, TEXAS, USA

Background. Dasatinib is 325-fold more potent than imatinib and 16-fold more potent than nilotinib against BCR-ABL *in vitro*. In a randomized, phase III, dose-optimization study in patients with CML-CP (CA180-034), a 100 mg QD schedule was associated with similar efficacy but greater tolerability (less frequent pleural effusion, cytopenia, and dose reduction/interruption) than three other dosing regimens (50 mg BID, 140 mg QD, 70 mg BID). *Aims.* To characterize the relationship between dasatinib pharmacokinetic exposure, efficacy (major cytogenetic response [MCyR]), and tolerability (pleural effusion) with data from the four dosing regimens evaluated in study CA180-034. *Methods.* Patients (n=670) were randomized to dasatinib 100 or 140 mg/d, and to a QD or BID schedule, using a 2x2 factorial design. Exposure was characterized by a population-pharmacokinetic (PPK) model and was used to derive the individual estimates of steady-state concentration (Cavg), steady-state trough concentration (Cmin), and steady-state peak concentration (Cmax). Pleural effusion E-R was described using a Cox proportional-hazards model. Covariates assessed were age, gender, body weight (PPK only), and history of cardiac disease (E R only). MCyR E R was described using logistic regression.

Table 1.

	Dosing schedule			
	100 mg QD	*70 mg BID*	*50 mg BID*	*140 mg QD*
Mean C_{min} ng/mL (CV%)	2.69 (26)	6.9 (24)	5.13 (24)	3.86 (28)
Mean C_{max} ng/mL (CV%)	66.85 (56)	53.71 (46)	37.6 (48)	94.09 (55)
Mean C_{avg} ng/mL (CV%)	14.16 (20)	20.34 (17)	14.32 (18)	19.96 (18)
	C_{min} ng/mL			
		<2.5	2.5-<5.0	≥5.0
Pleural effusion (%)		4	14	25
Dose reduction (%)		26	45	59
Dose interruption (%)		51	64	75
Major cytogenetic response (%)		69	63	62

Results. Samples from 567 of the 670 randomized patients were available for the PPK analysis. Of the patients participating in the PPK analysis, 94 experienced pleural effusions, 271 required dose reduction, and 376 required dose interruption. The PPK analysis demonstrated that dasatinib exposure was independent of age, gender, or body weight, but was dependent on dosing schedule. E-R analysis showed that the risk of pleural effusion increased with Cmin (2.33-fold for each doubling of Cmin; $p<0.001$) and age (1.93-fold for each ten years of life; $p<0.001$). Cmax and Cavg were not found to be significant predictors of pleural effusion. Cmin also correlated with dose reduction or interruption, but not with efficacy, which was related to Cavg, duration of dose interruption, and age. *Conclusions.* Cmin appears to correlate strongly with dasatinib toxicity, but not with efficacy. The lowest Cmin is achieved with a 100 mg QD dosing schedule, previously shown to have the optimal benefit'risk assessment among the tested dosing schedules.

A NOVEL MGB PROBE-BASED ASSESSMENT OF MINIMAL RESIDUAL DISEASE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA CARRYING NPM1 (NUCLEOPHOSMIN) EXON 12 MUTATIONS

D. Dvorakova, D. Ohlidalova, J. Pospisilova, M. Lengerova, J. Mayer

University Hospital Brno, BRNO, Czech Republic

Background. Insertions into exon 12 of NPM1 gene represent the most frequent molecular aberration in the subgroup of patients with acute myeloid leukemia (AML) otherwise showing normal karyotype. These mutations appear to be stable and can be detected in the majority of patients at relapse. Therefore, NPM1 mutant may be used as a marker for quantification of minimal residual disease (MRD). *Aims*. As an alternative to published methods that employ mutation-specific primers (either forward or reverse) and common TaqMan probe, we propose here a novel approach for long-term follow-up of residual leukemia cells based on mutation-specific probe with minor groove binder (MGB) at the 3´end. *Methods*. We designed reverse and forward primers on the exon 12 that are common for wild-type and mutant alleles and three mutation-specific short MGB probes. MGB probes include VIC/MGB probes for mutant A and mutant B allele, and one FAM/MGB probe that is specific for wild-type allele of NPM1. This approach based on allelic discrimination is highly specific and we did not observed any cross reactivity in clinical samples. For rapid screening of A or B mutation that represents approximately 78 and 12% of NPM1 mutations, respectively, we used two independent TaqMan assays involving two sets of MGB probes: FAM/wild-type probe with VIC/mutation A probe or FAM/wild-type probe with VIC/mutation B probe. For absolute quantification of each individual allele, we used one corresponding MGB probe in separate assay. All assays were performed using 7300 Sequence Detector System (Applied Biosystems). For all NPM1 targets, the best amplifications were obtained using 62°C annealing temperature. For absolute quantification, standard curve with serial dilutions of a plasmid containing the target sequences was used. The mutation value was normalized on the number of albumin gene copies. *Results.* We determined that quantitative detection of mutations A and B is highly specific without any background caused by the amplification of wild-type genomic DNA. Sensitivity of the assay was tested using 10-fold serial dilutions of genomic DNA obtained from NPM1-mutated patient at diagnosis in DNA pool from peripheral blood leukocytes of six healthy donors. At least 10-4 sensitivity was reached in all cases. Furthermore, sensitivity of the assay was tested on 10-fold serial dilution of plasmid with type A mutation, type B mutation, and wild-type NPM1 sequences, respectively. Maximal reproducible sensitivity was 10 plasmid molecules. *Conclusions.* Here we propose highly sensitive and reproducible method that could be used for long-term follow-up of MRD and represents suitable alternative for the standard routine laboratory evaluation. Our method employing highly mutation-specific short MGB probes is based on allelic discrimination assays of NPM1 mutant alleles. We suggest that MGB probes that could be successfully employed for genotyping of single nucleotide polymorphisms represent efficient approach for specific detection of NPM1 mutations without any amplification of wild-type allele.

THE POOR PROGNOSIS ASSOCIATED WITH GAIN/AMPLIFICATION OF 1Q21 IN RELAPSED MULTIPLE MYELOMA PATIENTS MAY BE OVERCOME BY VELCADE BASED REGIMEN IN CONTRARY OF THALIDOMIDE BASED REGIMEN

P. Nemec,[1] H. Greslikova,[1] J. Smetana,[2] R. Zaoralova,[3] R. Kupska,[3] K. Berankova,[2] H. Filkova,[4] D. Kralova,[3] M. Krejci,[5] L. Pour,[5] L. Zahradova,[5] V. Sandecka,[5] Z. Adam,[5] P. Kuglik,[2] R. Hajek[5]

Hospital, Fac. of Medicine, Masaryk Univ., BRNO, Czech Republic

Background. The presence of chromosomal aberrations detected by fluorescence *in situ* hybridisation (FISH) in plasma cells is considered to

be an important prognostic factor for patients with multiple myeloma (MM). However for relapsed patients, it is unknown whether or not the negative impact of these aberrations can be eliminated by treatment based on the new drugs like Velcade or thalidomide. *Aims.* This study is aimed at comparison of ability to overcome the negative prognostic impact of the most common cytogenetic aberrations by treatment regimens based on Velcade or thalidomide. *Methods.* Velcade group: A total of 40 patients (median age 65.1 years; median follow-up 10.4 months; median of previous therapy lines 2 (range 0-3, 37.5% in first and 45.0% pts. in second relapse) were treated by Velcade based regimen (48% together with glucocorticoids and alkylating agens; 30% with anthracycline±dexamethasone; 22% with dexamethasone only). Thalidomide group: A total of 34 (median age 65.1 years; median follow-up 16.2 months; median of previous therapy lines 1 (range 0-4, 64% pts. in first and 20.6% in second relapse) were treated by thalidomide based regimen (94% together with dexamethasone and cyclophosphamide; 6% with dexamethasone only). Both groups were separately examined by cytoplasmic interphase FISH (cIg-FISH) for presence of 1q21 gain/amplification, del13q14, del17p13, t(4;14) and hyperdiploidy/nonhyperdiploidy. *Results.* Chromosomal abnormalities were assessed in 78.4% of all relapsed MM patients. *Results for patients treated by Velcade based regimen.* Amp1q21 was detected in 66% (21/32) patients, del13q14 and del17p13 were detected in 64% (25/39) and 24% (9/37) patients, respectively. Translocation t(4;14) was detected in 34% (11/32) and nonhyperdiploidy in 61% (14/23) patients. A total of 55% (22/40) of patients achieved ORR (CR+PR). Comparison of ORR of positive *vs* negative patients for any aberration was not significant. Comparison of TTP median of positive *vs* negative patients for each aberration was as follows: For amp1q21 reached 8.9 *vs* 7.9 months; p=0.803; for del13q14 reached 7.6 *vs* 8.5 months; p=0.570; for del17p13 reached 5.2 *vs* 9.2 months; p=0.170; and for t(4;14) reached 7.9 *vs* 8.4 months; p=0.525. *Results for patients treated by thalidomide based regimen.* Amp1q21 was detected in 56% (15/27) patients, del13q14 and del17p13 were detected in 45% (14/31) and 6% (2/31) patients, respectively. Translocation t(4;14) was detected in 39% (11/28) and nonhyperdiploidy in 63% (10/16) patients. A total of 67.7% (23/34) of patients achieved ORR. It seems to be a trend towards worst treatment response, whereas 46.7% (7/15) of amp1q21 positive patients achieved ORR *vs* 83.3% (10/12) of patients lacking amp1q21 (p=0.093). ORR was not influenced of any other named chromosomal abnormalities. Comparison of TTP median of positive *vs* negative patients for any aberration was as follows: For amp1q21 reached 8.1 *vs* not yet reached; p=0.015; for del13q14 reached 10.0 *vs* 8.0 months; p=0.906; for del17p13 TTP was not yet reached for positive *vs* 9.2 months; p=0.610; and for t(4;14) reached 9.8 *vs* 9.2 months; p=0.491. *Summary and Conclusions*. Both new drugs can overcome negative prognostic impact of all named chromosomal abnormalities except amp1q21. The difference in TTP median in amp1q21 positive and negative patients treated by thalidomide based regimen suggests that thalidomide is not able to overcome negative prognostic impact of amp1q21 in contrary of treatment based on Velcade regimen, which probably may overcome poor prognosis of amp1q21.

Backgrounds. The biologic characteristics of childhood acute lymphoblastic leukemia (ALL) is different from those of adult ALL. Tumor suppressor genes, p16, p14, and p15 gene are inactivated either by promoter methylation, deletion or mutation, however, in leukemia, promoter methylation and deletion are the main mechanisms of inactivation. *Aims.* To compare the alteration status of p16, p14, and p15 gene in childhood and adult ALL, we analyzed the incidences and the prognostic significances of deletion and hypermethylation of p16, p14, and p15 in childhood and adult B-ALL. The association between alterations of those genes and known cytogenetic prognostic factors (BCR-ABL, TEL-AML, MLL rearrangement, and numerical changes) were also assessed. *Methods.* A total of 91 newly diagnosed B-ALL patients (61 children, 30 adults) were studied. Interphase fluorescent *in situ* hybridization study (p16, BCR-ABL, TEL-AML, MLL) and methylation specific PCR were performed using bone marrow mononuclear cells. Numerical changes were assessed by FISH and chromosome analysis. Chi-square test, Fisher's exact test, Kaplan and Meier method and Cox proportional hazards regression were applied for statistical analysis. *Results.* The frequencies of homozygous deletion of p16, p14, and p15 were 11.5% in children and 30.0% in adult, showing higher incidence in adults (p=0.029). In overall survival study, homozygous deletion was associated with the worse prognosis in adults (Figure 1, p=0.019), but not in childhood. The incidences of promoter methylation of p16, p14, and p15 were as follows: 34.4%, 14.8%, and 34.4% in children; 26.7%, 10.0%, and 40.0% 26.7% in adults, respectively, with no statistical difference between two groups. No significant association was observed between deletion and hypermethylation. Childhood ALL showed inactivation of p16 (39.3%), p14 (24.6%), and p15 (42.6%), while adult ALL showed inactivation of p16 (46.7%), p14 (33.3%), and p15 (56.7%), with the same order of frequencies, but with higher tendency of methylation in adult ALL. In p14 unmethylated adults, the homozygous deletion had adverse effect on overall survival (OS) (p=0.036). There was no significant association between chromosomal aberrations and promoter methylation in childhood and adult ALL. The children with sole MLL rearrangement showed poorer disease free survival (DFS) than those with sole homozygous deletion with low statistical significance (p=0.059). Homozygous deletion was translated into poor prognosis in OS in adults without MLL rearrangement (p=0.011). Adult with normal karyotype showed shorter OS when accompanied by homozygous deletion, although p value was 0.051. *Summary and Conclusions.* We performed a comprehensive analysis of deletion and hypermethylation of p16, p14, and p15 genes in both childhood and adult B-ALL. Homozygous deletion was more frequent in adults, showing association with shorter OS in adults, but not in children. This difference of distribution and prognostic value between childhood and adult ALL could be one of the explanations for the disparity of clinical outcome. Our results suggest that homozygous deletion is an independent prognostic factor in adult ALL.

CHROMOSOMAL INSTABILITY IS CORRELATED WITH PROGNOSIS IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

Ch.E. Heilig,[1] H. Löffler,[1] A. Jauch,[2] U, Mahlknecht,[3] A.D. Ho,[3] A. Krämer[1]

[1]Deutsches Krebsforschungszentrum (DKFZ), HEIDELBERG; [2]Institute of Human Genetics, University of Heidelberg, HEIDELBERG; [3]Department of Medicine V, University of Heidelberg, HEIDELBERG, Germany

Background. Chromosomal Instability (CIN) has been proposed to play a pivotal role in both early malignant transformation and tumor progression (Lengauer *et al.* Nature 1998; 396: 643-649). However, data on the presence and extent of CIN in primary malignant cells are lacking. *Aims.* We sought to evaluate the role of CIN in the evolution of myelodysplastic syndromes (MDS), the progression of MDS to acute myeloid leukemia (AML), and the prognosis of patients with these malignancies. *Methods.* We isolated CD34-positive cells from 18 patients with MDS and 27 patients with AML not receiving cytostatic treatment, from 9 healthy controls, and from 9 control patients with malignancies not involving the bone marrow. We performed fluorescence *in situ* hybridisation (FISH) hybridising centromeric probes for chromosomes 1, 6, 7, and 8 to the $CD34^+$ cells and quantitated the cell-to-cell variability of the chromosome content by determining the modal chromosome number of each chromosome and the median percentage of cells whose chromosome number differed thereof. The average of these percentages then was correlated with clinical data. *Results.* Although the CIN values did not differ significantly between subgroups, there was a small number of patients in our cohort with CIN values that were elevated more than 2 SD relative to the mean of healthy control subjects (5.8+3.0%) (Figure 1). Surprisingly, in the group of patients with MDS, all three patients with an elevated CIN value reached the endpoint, defined as progression to AML (2 patients) or death (1 patient) within 4.9, 10.2, and 12.3 months after sample collection, respectively, whereas in the remaining 15 patients with normal CIN values there was only one case of death (3.9 months after sample collection), but no progression to AML after a median follow-up of 10.7 months (range 0-18.3 months). In the group of patients with AML following MDS there were 2 additional samples with clearly elevated CIN values, one of which was from the patient who progressed from MDS. Most remarkably, the CIN value of this patient's CD34-positive cells quickly rose within one month to nearly 50% to remain at this level until 4 months later, when a diagnosis of AML was made. This patient received an allogeneic bone marrow transplant and is alive 13 months after the progression to AML, whereas the other AML patient with an elevated CIN value succumbed to his disease after 4 months. *Conclusions*. The preliminary results of our investigation point out a possible role for CIN in the progression of MDS to AML. Furthermore, our data suggest that the quantification of CIN might be valuable for identifying patients with high-risk MDS more reliably.

AN ANALYSIS OF FMS-LIKE TYROSINE KINASE IN CHILDHOOD ACUTE LEUKAEMIAS

A.S. Leow,[1] H. Ariffin,[2] S.K.Y. Kham,[1] T.C. Quah,[1] A.E.J. Yeoh[1]

[1]National University of Singapore, SINGAPORE, Singapore; [2]University of Malaya, KUALA LUMPUR, Malaysia

Background. FMS-like tyrosine kinase 3 (FLT3) receptor is pivotal in mitogenic pathways of progenitor cells and is expressed in most childhood leukaemias. Certain genetic subgroups demonstrate high-level expression involving a significant percentage harbouring activating mutations, typically FLT3 internal tandem duplication (ITD) and activating loop mutation (ALM). A prevalence of 15-20% of childhood acute myeloid leukemia (cAML) patients harbours either or both mutations contributory to constitutive proliferation and poorer prognosis. Conversely, these mutations may be infrequent or absent in childhood acute lymphoid leukemia (cALL), yet FLT3 over-expression harbours good prognosis in hyperdiploid ALL and infant MLL, showing irrelevance with FLT3 mutation status. *Aims.* We aim to evaluate FLT3 receptor mutations in acute leukaemias in predominantly Asian children; and its associations with any clinical or biological characteristics in these patients. *Methods.*We screened 479 leukemia patients (cAML: n=153; cALL: n=326) for the presence of FLT3 mutations. We screened codon 835 variant using PCR and restriction enzyme digest, and nucleotide change was determined by sequencing. Qualitative and quantitative analysis of FLT3-ITD was performed using Genescan (ABI 377). FLT3 expression was evaluated in 167 patients (cAML: n=95; cALL: n=72) and correlate with age, initial WBC, cytogenetic and FAB classifications, using quantitative real-time PCR (ABI 7900) and normalized with housekeeping gene ABL. The composition in the 95 cAML cohort by FAB classification were: n(M2)=34; n(M3)=14; n(M4)=11; n(M7)=12; whilst cases in each of the remaining subgroup was <7. In 72 cALL cases classified by cytogenetic subtypes, 26 were hyperdiploids, 4 were t(1;19), 12 were t(12;21), 4 were t(9;22), and 26 with no oncogene fusion. *Results.* In cAML, 12.6% (17/153) harbored ITD mutations of varying insertion lengths (15-63bp), whilst 7.2% (11/153) harbored codon 835 variants. Of 17 cAML FLT3-ITD positive, 4 (23.5%) were PML-RARA, 2 (11.8%) were AML1-ETO and 1 (6%) showed 11q23. Low allelic wildtype/ITD ratio (AR: <0.5) constitutes 23.5% (4/17). Two patients harboured both FLT3-ITD and codon 835. High expression levels of FLT-3 in cAML were significantly associated with leukocytosis (TWC>50×10^9/L; p=0.01), and age (3-9yrs > above 9yrs > below 3yrs; p=0.013). FLT3 expression in AML-M7 is significantly down-regulated (mean=0.8; median=0.02; range=0.001-4.4; p=0.022). In cALL, none exhibited FLT3-ITD mutation; only 1.5% (5/326) had codon 835 variant. High expression levels in cALL were significantly associated with age (below 3yrs > 3-9yrs > above 9yrs; p=0.03), and hyperdiploid cytogenetic subtype. *Conclusions*. Our results show a high incidence of 18.3% (28/153) in cAML and a low frequency in cALL, 1.5%. Low AR of FLT3-ITD comprises of 23.5% in our cohort, and this has been shown to have inferior prognosis in adult AML. In cAML, FLT3 expression is significantly down-regulated in AML-M7 subtype, but significantly up-regulated in the 3-9yrs age group and leukocytosis at presentation. In cALL, FLT3 expression is up-regulated in hyperdiploid cALL which is concordant with other published data. We are unable to validate this association in infant ALL due to small sample size.

GAINS OF CHROMOSOME 1Q IN PATIENTS IN RELAPSE AND PROGRESSION OF MULTIPLE MYELOMA

J. Balcarkova, H. Urbankova, V. Scudla, M. Holzerova, J. Bacovky, M. Zemanova, K. Indrak, M. Jarosova

University Hospital Olomouc, OLOMOUC, Czech Republic

Chromosomal abnormalities have biologic and prognostic significance in multiple myeloma (MM), especially among patients with relapsed and refractory disease. Abnormalities of chromosome 1 are one of the most recurrent chromosomal changes in patients with MM and are found in approximately 45% of patients. Recent publications have shown that 1q gain, consistently involving 1q21, is associated with complex karyotypes and poor-risk genetic features. One of the genes mapping to the band 1q21 is CKS1B that plays a critical role in cell cycle progression. In addition, other oncogenes as BCL9, PDZK1, IRTA1 and IRTA2 were up-regulated by the gain of 1q. It has been suggested that the region 1q21 harbors one or more target genes associated with malignant phenotype of MM, although the critical genetic region and the tar-

get genes for chromosomal gain involving 1q rearrangement in MM remains unknown. In the present study we used FICTION method, arrayCGH or CGH (comparative genomic hybridization) to delineate the minimal region included in 1q gain in 30 bone marrow samples from MM patients, 10 in a progression and 20 with a relapse of MM (14 males and 16 females). Using FICTION method with locus specific probe 1q21/1p36 (Kreatech Biotechnology B.V, The Netherlands) we detected copy number changes of 1q21 in 14 (47 %) out of 30 samples. FICTION method to detect chromosomal changes with known prognostic impact, such as deletion of RB1, IgH translocations and trisomies of chromosomes 7, 9, 11, 15, 17 was done by locus-specific DNA probes (Abbott-Vysis, Des Plaines, Illinois, USA). CGH or 1Mb arrayCGH were performed in 5 selected cases and except other multiple abnormalities revealed gains of whole arm 1q. For rapid mapping of gained region in the other patients we used FICTION method with BAC-derived probes flanking a few selected candidate oncogenes as SF3B4, BCL 9, IRTA 1, ASPM, and ARF1. All patients with proved 1q gains had other cytogenetic abnormalities: deletion of RB1 gene and t(4; 14) were found in 3 (10 %) patients, deletion of RB1 gene and deletion of IgH gene in 2 (7 %), trisomies of examined chromosomes in 5 (17 %), single t(4; 14) in 1(3 %) and complex karyotype in 3 (10 %) patients. We will summarize and discuss our molecular cytogenetic findings with respect to the 1q gains and possible over expression of candidate oncogenes located in this region.

FLT3-ITD, NPM1 MUTATIONS AND WT1 HYPEREXPRESSION IN CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML)

E. Such,[1] J. Cervera,[1] A. Valencia,[1] O. Fuster,[1] M.L. Senent,[1] I. Luna,[1] E. Marco,[1] M. Mallo,[2] F. Solé,[2] E. Barragán,[1] R. Collado,[3] A. Vicente,[4] V. Amigo,[5] J.C. Hernández-Boluda,[6] E. Luño,[7] S. Oltra,[1] P. Bolufer,[1] M.A. Sanz,[1] G. Sanz[1]

[1]Hospital Universitario La Fe, VALENCIA; [2]Hospital del Mar, BARCELONA; [3]Hospital General Universitario de Valencia, VALENCIA; [4]Hospital de La Ribera, VALENCIA; [5]Hospital Arnau de Vilanova, VALENCIA; [6]Hospital Clinico de Valencia, VALENCIA; [7]Hospital Central de Asturias, OVIEDO, Spain

Background. Chronic myelomonocytic leukemia (CMML) is a heterogeneous disease sharing features of myelodysplastic syndromes (MDS) and chronic myeloproliferative disorders (cMPS). Recent analysis driven to characterize cMPS have shown the important role that tyrosine-kinase cell signalling pathways play in their pathogenesis. However neither comprehensive studies on these pathways nor reports about valid new prognostic factors for MDS and AML applied to CMML are available. FLT3-ITD has been primarily found in patients with AML. However, the fact that approximately 20% of CMML patients develop secondary AML and the high prevalence of FLT3 mutations in myelomonocytic and monocytic variants of *de novo* AML (subtypes M4 and M5 according to the French-American-British [FAB] classification) led us to explore the presence of activating FLT3 mutations in patients with CMML. On the other hand, NPM1 mutations have been detected in patients who had CMML and a short (<1 year) survival, with rapid progression to AML (Caudill, 2006). Additionally, WT1 gene expression in leukemia cells is approximately 105 times higher than in normal peripheral blood (PB) cells and has been inversely correlated with the prognosis of acute leukemia and MDS (Barragán *et al.*, 2004). *Aims.* To study the frequency of FLT3-ITD, NPM1 mutations and WT1 hyperexpression in CMML. *Patients and Methods.* NPM1/FLT3-ITD mutations were studied in PB samples from 66 patients with CMML according to FAB criteria [50M/16F; median age: 72 yr. (range: 37-96); median WBC: 13.5×10^9/L (range: 2.4-170); median Hb level: 10.6 g/dL (range: 6.5-14.7); and median platelet count: 134×10^9/L (range: 4-928)] using a multiplex PCR assay followed by capillary electrophoresis. Genomic DNA was amplified using specific NPM1 and FLT3 primers. PCR products were followed by capillary electrophoresis to simultaneously analyze NPM1 and FLT3 gene alterations on an ABIPRISM 310 DNA Analyzer (Applied Biosystems, Foster City, CA). RNA samples for determining WT1 hyperexpression was available in 31 patients. cDNA was amplified using the kit TM universal Master Mix and specific WT1 primers and probe by real-time quantitative PCR on a LightCycler 1.5 (Roche Diagnostics). *Results.* None FLT3-ITD/NPM1 mutations were found in any of the 66 cases. By contrast, WT1 hyperexpression was identified in 8/31 cases (25%). Due to low numbers no specific clinical correlation or prognostic significance of this finding could be established. *Conclusions.* Our results indicate that FLT3 and NPM1 mutations are uncommon in CMML. By contrat WT1 hyperexpresion is observed in 25% of the cases. Prognostic value of this finding should be explored in large series.

MINIMAL RESIDUAL DISEASE (MRD) MONITORING IN CML PATIENTS: COMPARISON BETWEEN AUTOMATED FISH ANALYSIS AND RQ-PCR

G. Calabrese,[1] D. Fantasia,[1] F. Pompetti,[2] R. Di Gianfilippo,[3] P. Guanciali-Franchi,[1] D. Romagno,[1] E. Morizio,[1] M. Alfonsi,[1] S. Pulini,[4] A. Spadano,[4] R. Di Lorenzo,[4] P. Di Bartolomeo,[4] A. Iacone,[2] G. Palka[3]

[1]University of Chieti, CHIETI SCALO; [2]Dip. Medicina Trasfusionale, Pescara Hospital, PESCARA; [3]Medical Genetics, Pescara Hospital, PESCARA; [4]Dip. Ematologia, Pescara Hospital, PESCARA, Italy

Background. Real-time quantitative PCR (RQ-PCR) is acknowledged as the gold standard approach for MRD monitoring in CML patients during follow up. *Aims*. To compare RQ-PCR method with a novel FISH analysis approach based on a fully automated FISH slide scanner and image analyzer (Duet BioView, Israel) for picking up rare cell events. *Methods*. Fifty-one CML patients in clinical and cytogenetic remission following imatinib (IM) therapy (44 patients), or bone marrow transplantation (BMT; 7 patients) were investigated. Ninety samples, 75 from bone marrow and 15 from peripheral blood, were tested with both RQ-PCR using TaqMan protocol (Applied BioSystems, USA), and Duet BioView FISH slide scanner by scoring 1600-4500 cells for BCR-ABL rearrangement using a dual-color, dual-fusion FISH probe combination (Kreatech, Denmark). Leukemic cell levels in the samples were arbitrarily grouped in three classes: >1%; 0,99%-0,04%; and <0,04% of scored cells. *Results*. FISH/RQ-PCR concordance was 100% for class >1%, 96% for class 0,99%-0,04%, and 84% for class <0,04% leukemic cells. Samples with FISH/RQ-PCR discordant results showed leukemic cells as evidenced by FISH close to the detection limit of FISH procedure itself (i.e. 0,04%). The discordant cases had <0,01% BCR-ABL transcript level and no recurrence of *molecular* disease in the following 18 months of treatment. In two patients FISH analysis unravelled 3/1900 (0,16%), and 8/3800 (0,21%) leukemic cells carrying two copies of BCR-ABL fusion, i.e. double Ph, which are undistinguishable from those with a single copy of BCR-ABL rearrangement when investigated by RQ-PCR. IM dose escalation (800 mg/day) resulted in disappearance of double BCR-ABL leukemic cells, which are still absent 24 and 30 months from high-dose therapy start, respectively. Peripheral blood samples also showed FISH/RQ-PCR concordant results when >3000 cells were scored by FISH. *Conclusions*. Present data show that automated FISH analysis by scoring >1600 bone marrow or >3000 peripheral blood cells/sample provides useful information for MRD monitoring in CML patients, being FISH results largely overlapping with those obtained with RQ-PCR approach. Furthermore, early occurrence of double Ph-positive cells can also be recognized allowing appropriate therapy protocol modification.

ANALYSIS OF FLT3-ITD IN 147 PATIENTS WITH ACUTE MYELOGENOUS LEUKEMIA

L. Zamora,[1] M. Cabezón,[2] J. Grau,[2] J. Ayats,[3] M. Morgades,[2] S. Marcé,[2] B. Patiño3, D. Dominguez,[2] I. Granada,[2] N. Ruiz-Xivillé,[2] M. Xandri,[2] A. Cisneros,[2] A. Serrano,[2] N. Lloveras,[2] J. Juncà,[2] A. Oriol,[2] M. Arnan,[3] C. Boqué,[3] R.F. Duarte,[3] A. Fernández de Sevilla,[3] J.M. Ribera,[2] F. Millá,[2] E. Feliu[2]

[1]Hospital Germans Trias I Pujol - ICO, BADALONA; [2]Hospital Germans Trias i Pujol - ICO, BADALONA; [3]Hosptial Duran i Reynals - ICO, HOSPITALET, Spain

Background. Cytogentic aberrations are one of the most important independent prognostic factors in AML. However 40-50% of the patients have a normal karyotype conferring an intermediate risk, but their survival is highly variable. A growth factor gene called FMS-like tyrosine kinase3 (FLT3) play an important role in this group of patients. This gene can harbour internal tandem duplication (ITD) or mutations in 25% of adult patients with AML, much of them with normal karyotype. The presence of these FLT3 aberrations is associated with an unfavourable prognosis. Some recent studies have described that increased values of the ITD/wild-type (WT) allele ratio confer a worse outcome. The aim of the present study was to characterise the prognostic significance of the ratio of ITD/WT alleles and the size of the ITD allele. *Patients and Methods.* Bone marrow or peripheral blood samples at diagnosis from 147 patients with AML were retrospectively analysed. They included 86 patients with non promyelocytic AML, 15 with acute promyelocytic leukaemia (APL), 35 AML with multilineage dysplasia and 11 with secondary AML (6 therapy-related and 5 blast crisis of Ph' negative CMPD). Cytogenetic studies were performed from unstimulated bone marrow at diagnosis and karyotypes were described according to ISCN 2005. The presence of FLT3-ITD was performed on genomic DNA using published primer molecules with few modifications (Nakao M *et al.* Leukemia 1996). Polymerase chain reaction (PCR) products were analyzed on standard 3% agarose gels. Patients with ITD were reanalysed by Genescan analysis using PCR primer FLT3 11F labelled with 6-FAM. PCR setup was identical to the standard PCR. This methodology allowed us to establish the mutant to wild-type FLT3-ITD ratio as well as the size of the duplications. *Results.* From the 147 patients, 81 have an abnormal karyotype (55.1%) and 27 harbour an ITD (18.4%). Twenty-one of these 27 patients (78%) had a normal karyotype. FLT3-ITD/WT ratio ranged from 0.041 to 5.431 (median 0.52). FLT3-ITD size ranged from 14.69 to 188.68 (median 43.97). In patients with normal karyotype the presence of FLT3 ITD was associated with inferior OS (p=0.040) but not DFS. Neither the FLT3-ITD/WT ratio nor the FLT3-ITD size had impact on DFS or OS in the present series. *Conclusions.* Although FLT3-ITD had poor prognostic significance in patients with AML and normal karyotype, the FLT3-ITD/WT ratio and the FLT3-ITD size did not have impact on prognosis in patients from the present series.

MOLECULAR CYTOGENETIC STUDY OF CHILDHOOD T-ALL

L. Babicka,[1] E. Malinova,[1] Z. Zemanova,[1] A. Berkova,[1] J. Tajtova,[1] J. Zuna,[2] E. Mejstrikova,[2] J. Stary,[3] K. Michalova[1]

[1]General Faculty Hospital and 1st Faculty of Medicine, Charles University, PRAGUE; [2]CLIP, 2nd Faculty of Medicine, Charles University, PRAGUE; [3]Uneversity Hospital Motol and 2nd Faculty of Medicine, Charles University, PRAGUE, Czech Republic

Background. T-cell acute lymphoblastic leukemia (T-ALL) represents 10-15% of pediatric ALL cases and differs from B-lineage ALL by clinical, biochemical, immunological and chromosomal features. Acquired cytogenetic aberrations are present in 90% of newly diagnosed B-ALL patients and some of them became an independent prognostic factor. In contrast to leukemia of B-cell origin, chromosomal changes are observed in approximately 30-50% of T-ALL only, and their prognostic implication in patient's outcome still remains unclear. *Aims.* The aim of this study was to - retrospectively and prospectively - analyze by conventional and molecular cytogenetic methods bone marrow cells of children with T-ALL, to evaluate the significance of chromosomal aberrations and to assess prognostic impact of recurrent genomic changes. *Methods.* Karyotypes of all patients were analyzed at the time of diagnosis by G-banding and FISH methods. For detection of the most frequent chromosomal changes, i.e. rearrangements of TCR loci (TCRαδ-14q11, TCRβ-7q34, TCRγ-p15), deletion of p16 (9p21) and amplification of ABL (9q34), we used interphase FISH with locus-specific BAC clones or commercially available probes (DakoTM, Abbott VysisTM). Complex chromosomal rearrangements were proved by multicolor FISH with the *24XCyte* probe kit with combinatorially labeled painting probes specific for each chromosome (MetaSystemsTM). *Results.* During the years 1995-2007 we examined 55 pediatric patients with T-ALL. Archived material was available in 27 of them (9 girls and 18 boys with an average age 8,5 years). Rearrangements of TCR loci were found in 12 children (44%)-TCRαδ in 10 and TCRβ in 2 cases. Deletion of p16 was proved in 11 patients (41%)-homozygous in 8 and heterozygous in 3 cases respectively. Amplification of ABL gene was detected in one patient and in three others a supernumerary copy of this gene was revealed. Twenty one patients are living in the first complete remission. Six children died and none of them showed the rearrangements of TCR loci. The results will be discussed at the poster in detail. *Conclusions.* T-ALL remained for a long time in the shadow of B-ALL because of low incidence and normal karyotype in common. During past decade molecular cytogenetic and genetic methods have been instrumental in finding cryptic chromosomal rearrangements, which have led to the identification of several important oncogenes. In our cohort we detected by molecular cytogenetic methods chromosomal abnormalities in 82% of patients, *vs* 44% by conventional cytogenetic. However, prognostic impact should be evaluated in larger cohorts of patients and longer period of time. Thus, our work attempts to clear up the significance of chromosomal aberrations related to childhood T-ALL in order to facilitate the patients' stratification into prognostic groups similarly like it has been adopted in B-ALL.

MIRNA PROFILING MAY BE APPLIED TO THE DIAGNOSIS OF ACUTE LEUKEMIAS

I. Sánchez-Ortega, M. Carricondo, A. Lasa, E. Bussaglia, C. Canals, A. Aventín, J. Sierra, J. Nomdedéu

Hospital de la Santa Creu i Sant Pau, BARCELONA, Spain

Background. MicroRNAs (miRNAs) are 18-22 nucleotide non-protein-coding RNAs with regulatory functions. Some miRNA play important roles in development, cell proliferation, differentiation and apoptosis. They can also function as oncogenes and tumor suppressors in multiple cancers. miRNA expression has been shown to be informative in acute leukemias diagnosis based on their differential expression in hematopoietic cell lineages and development stages. *Aims*. To test the potential clinical utility of miRNA profiling, we analyzed the expression of miRNA128a, miRNA128b, miRNAlet7b and miRNA223 in an unselected and consecutive series of acute leukemia cases. *Methods*. Forty-one consecutive acute leukemias diagnosed at the Hospital de la Santa Creu i Sant Pau in Barcelona from 2005 to 2007 were included in the study. For each case morphologic, immunophenotypic, cytogenetic and molecular data were available. The series included: 21 acute myeloid leukemias (FLT3-ITD 2 cases, MLL-ITD 1 case, AML1-ETO 1 patient, PML-RARα 2 cases, CBFβ-MYH11 1 case, complex karyotype 2 cases, other: 12 cases), 18 acute lymphoblastic leukemias (T-cell lineage 2 cases and B cell lineage 16 cases: 2 cases with bcr-abl rearrangements, 1 AF4-MLL+, 1 E2A-PBX+, 12 others) and 2 biphenotypic acute leukemias according to the EGIL criteria (Myeloid-B-cell lineage). Five normal bone marrow samples were used as controls. miRNA128a, miRNA128b, miRNAlet7b and miRNA223 quantification was performed using a stem-loop RT-PCR assay in an ABI PRISM® 7700 genetic analyzer and calculated employing the ΔΔCT method. *Results*. The assessment of the miRNA patterns were useful as cell lineage markers in nearly half of AML cases (10/21) (specificity: 100%) and in fifty percent of ALL patients (9/18) (specificity: 100%) as follows: 1) AML pattern: up-regulation of miRNAlet7b (Ct <22) and miRNA223 (Ct <15) together with the down-regulation of miRNA128a (Ct >31) or miRNA128b (Ct >32). 2) ALL pattern: relative up-regulation of miRNA 128a (Ct <29) and miRNA128b (Ct <31). *Summary*. In the light of our findings, miRNA expression signature of four miRNAs can distinguish AML from a ALL in a subgroup of patients. The use of scoring systems based on the miRNA expression could improve the currently employed immunopenotypic cell-lineage assignment.

HIGH FREQUENCY OF RUNX1 MUTATIONS IN DE NOVO ACUTE MYELOID LEUKEMIA WITH PARTIAL TANDEM DUPLICATION OF MLL

D.C. Liang,[1] L.Y. Shih,[2] C.F. Huang,[2] T.L. Lin,[2] Y.S. Shih,[1] M.C. Kuo,[2] T.H. Lin,[2] C.L. Lai[2]

[1]Mackay Memorial Hospital, TAIPEI; [2]Chang Gung Memorial Hospital, TAIPEI, Taiwan

Background. Transcription factor AML1/RUNX1 is essential for normal hematopoiesis. RUNX1 mutations have been described in patients with AML-M0 and were rarely found in non-M0 AML. There was no report of RUNX1 mutations in AML with partial tandem duplication of MLL (MLL-PTD). *Aims.* We aimed to investigate the RUNX1 mutations in AML patients with MLL-PTD. Patients and methods. Bone marrow samples from 82 patients with MLL-PTD were examined for RUNX1 mutations. MLL-PTD was screened by Southern-blot analysis followed by RT-PCR or detected by real-time quantitative PCR. Mutation analysis of RUNX1 gene was performed by direct sequencing of all RT-PCR products amplified with 3 overlapping primer pairs which cover the entire coding sequences of RUNX1b gene from exon 3 through exon 8. Samples with abnormal sequencing results were subjected to repeated PCR using genomic DNA with alternative primers. *Results*. RUNX1 mutations were detected in 21 patients (25.6%). Three patients had two RUNX1 mutations. Taken together, 24 mutations were detected; 12 mutations were located in RHD (exons 3-5) and 12 mutations at C-terminal region (exons 6-8). The patterns of 24 mutations consisted of 5 missense mutations, 3 nonsense mutations, 15 frameshift mutations, and 1 silent mutation. Of the 3 patients carrying two RUNX1 mutations, clonal analysis showed that one patient had combined missense and frameshift mutations on the same allele, the other patient had two missense mutations on different alleles, and another patient had combined missense and silent mutations on the same allele. RUNX1 mutations were detected in 2 of 5 patients with AML-M0, 6 of 20 M1, 8 of 36 M2, 3 of 14 M4, 2 of 4 M5 and none of 3 M6 patients with MLL-PTD. Acquired trisomy 21 was found in 2 patients with RUNX1 mutations. Seven of the 23 patients with a duplication of exons 2 to 8(e8e2) had RUNX 1 mutations compared with 14 of 59 patients with exons 2 to 6 duplication (e6e2) (p=0.579). There were no differences in age, sex, blood counts, percentages of blasts in bone marrow or peripheral blood, FAB subtypes, or treatment outcome between patients with and without RUNX1 mutations. Twenty-eight of 44 patients who received induction chemotherapy achieved a complete remission and 15 had leukemia relapse. Twelve patients had relapse samples available for reanalysis, 5 patients harboring RUNX 1 mutations at diagnosis relapsed with the identical mutants, 6 patients had no RUNX 1 mutations at both diagnosis and relapse phases, and the remaining one acquired a C-terminal mutation at relapse. *Conclusions*. Our results showed that patients with *de novo* AML and MLL-PTD had a high frequency of RUNX 1 mutations with frameshift mutations at C-terminal region being the most frequent patterns. RUNX1 mutations play a role in the development and relapse of leukemia in a subset of AML patients with MLL-PTD.

HIGH EXPRESSION OF ETS-RELATED GENE, ERG, PREDICTS POORER OUTCOME IN AML INTERMEDIATE RISK PATIENTS WITH ABNORMAL KARYOTYPE

V. Kairisto,[1] M. Hämäläinen,[2] V. Juvonen,[1] T. Lakkala,[2] J. Johansson,[1] T.-T. Pelliniemi,[1] T.T. Salmi,[3] K. Remes[4]

[1]Tykslab, TURKU; [2]University of Turku, TURKU; [3]Dept. Paediatrics, Turku University Hospital, TURKU; [4]Dept. Medicine, Turku University Hospital, TURKU, Finland

To date, two studies have suggested that overexpression of the ETS-related gene (ERG) is associated with poor outcome in normal karyotype AML. We investigated the effect of ERG expression on AML survival in a retrospective group of 92 unselected consecutive Finnish AML patients treated at the University Hospital of Turku. The six pediatric patients were treated according to the Nordic NOPHO protocol. Patients, aged 17-65 years, were treated according to the protocols of the Finnish Leukaemia Group. Patients older than 65 yrs were treated with less intensive treatments which typically included low-dose cytarabine for 5-7 d and idarubicine±thioguanine. ERG expression was analysed at presentation in bone marrow mononuclear cells of all patients. Analysis of ERG expression was carried out by quantitative PCR as previously described (Baldus *et al.* PNAS 2004;101:3915) using ABL transcript quantification as the point of reference for each sample. In addition to routine haematological and cytogenetic investigations the mutation analyses for FLT3 length and codon 835 point mutation and nucleophosmin (NPM1) mutation were done for all patients. The cytogenetic classification of the patients was based on the Medical Research Council criteria. 21/92 patients were classified into the favourable cytogenetic group (t(8,21), inv(16) or t(15;17)). Seven patients in this group also had the FLT3 length or point mutation, but none of them had NPM1 mutations. The median ERG/ABL transcript ratio was 6.7 (range 2.6-19.2). 15/92 patients were classified into the adverse prognostic group (-5/5q-, -7, 3q abnormalities or complex karyotypes with >4 abnormalities). One of them had FLT3 codon 835 mutation and one NPM1 mutation. The median ERG/ABL transcript ratio in this group was 6.8 (range 0.05-17.6). The intermediate prognostic group was the largest patient cohort in this study including 56/92 patients. 18/56 patients had abnormal and 38/56 normal karyotypes. 22 patients had mutated NPM1 gene, 15 had the FLT3 length mutation and two the codon 835 point mutation. Of the 22 intermediate risk patients with nucleophosmin mutation all except one had normal karyotype. The median ERG/ABL transcript ratio in this group was 5.2 (range 0.05-15.9). The survival analysis in this retrospective patient group could be done with the endpoint of two years for all patients. To study the effect of ERG expression on survival, each of the above mentioned subgroups were split into two halves using the subgroup specific median ERG/ABL ratio as the cut off -limit. In the intermediate group the high ERG expression tended to associate with poor survival. However, the only statistically significant difference in survival was confined to the subgroup of intermediate risk patients with abnormal karyotype (Figure 1). It is of interest that the previous observations about the clinical significance of ERG expression in AML have been limited to patients with normal karyotype. The only statistically significant effect on survival we could observe was for the patients with abnormal karyotype in the intermediate prognostic group. It remains to be investigated whether this effect is also linked to some additional molecular abnormalities. The Figure 1 below shows overall survival of all intermediate risk group AML patients (left) and of those with abnormal karyotype (right). Solid curves show survival of patients with ERG expression below median and the broken lines of those with ERG expression above median. The difference of the Kaplan-Meier curves on the right is statistically significant (p=0.038).

IN VITRO AND *IN VIVO* STUDY OF TREATMENT WITH THE HDAC INHIBITOR VALPROIC ACID (VPA) IN TWO PATIENTS AFFECTED BY ACUTE MYELOID LEUKAEMIA POST MYELODYSPLASTIC SYNDROME

C. Tatarelli,[1] M.A. Aloe Spiriti,[1] F. Saltarelli,[1] E. Conte,[1] E. Montefusco,[1] G. La Verde,[1] A. Ferrari,[1] B. Monarca,[1] C. Nervi[2]

[1]Azienda Ospedaliera Sant'Andrea, ROME; [2]Departments of Histology and Medical Embryology, University of Rome La Sapienza, ROMA, Italy

Background. Acute myeloid leukaemia (AML) and myelodysplastic syndrome (MDS) are clonal myeloid diseases that predominantly affect elderly patients, for which therapeutic options are limited. Since both disorders are characterized by impaired maturation of hematopoietic progenitor cells, differentiation induction is an attractive treatment strategy. Histone deacetylase (HDACs) inhibitors are able to induce acetylation of the core histones, allowing recruitment of transcription factors complexes and leading to transcriptional reactivation. Recently it has been demonstrated that treatment with the HDACs drug valproic acid (VPA) potentiates or restores retinoic acid (RA) induced myeloid differentiation in fresh AML blasts from patients. Several works reported a well established efficacy and clinical benefit of VPA or associated with RA in patients with MDS, and in poor risk or chemotherapy- resistant AML patients.Aims.In this work we analyzed the effect of VPA monotherapy in two untreated cases of AML secondary to MDS (sAML/MDS) *in vitro* and *in vivo*. *Patients and Methods*. One 81 year old AML-M2 woman (patient#1) and one 81 year old AML-M6 72 year old men (patient#2), both uneligible for intensive chemotherapeutic regimens, received oral VPA as compassionate treatment. Preclinical *in vitro* studies on the effect of differentiation, proliferation, apoptosis were done five days before starting the *in vivo* treatments. The effect of RA was tested for the eventual *in vivo* administration, in case of resistance to VPA. Serum VPA concentrations were mantained within the therapeutic limits established for the treatment of patients with epylepsy (50-110 ug/mL). Mononuclear cells were isolated for both patients for the *in vitro* study at day -5 and for the *in vivo* study at day 0,7,14,21,28,42,53 for patient #1, and at days 7,14,21,28,43,100 for patient # 2 of treatment from BM and/or PB, and evaluated by: morphology, Flowcytometry, Acetylation of Histones, RNA expression by Real time PCR, Cell Cycle analysis. VPA serum levels were measured at the same above days. Results. VPA alone or with RA (RA+VPA) *in vitro* induced the appearance of cells with meta-myelocte morphology-like morphology in both cases. Moreover the treatment with these agents induced a reduction of the percentage of blasts, that was more evident for the AML-M2 type. Cell cycle analysis revealed a slight increase of cells in G0/G1 phase and G2/M and a decrease of the S-phase of the cell cycle with the RA, VPA and RA+VPA treatments in both patients. The addition of RA, VPA and both agents to the culture of blast cells reduced the percentage of $CD34^+$ cells in AML-M2, a marker present on leukemic blasts. A reduction of the % of the CD235 marker expressed in erythroid AML-M6 blasts, was found after culturing cells with VPA. Moreover, the gene expression analysis showed that myeloid differentiation genes are up-regulated by VPA, in particular MPO and GM-CSF for AML-M2 and G-CSF and GM-CSF for AML-M6.The overall *in vitro* results represented a good rationale for the transcriptional/differential treatment with VPA of these patients *in vivo*. Here we show that achievement of VPA therapeutic serum levels (50ug/mL) correlates with global hyperacetylation of histone H3 and H4 in leukemic blasts and clinical/biological responses in AML patients. Survival from VPA treatment was 85 days for patient #1 and 244 for patient #2. A major neutrophil response (MaR-N) in patient #1 was associated, at the cellular level, with a widespread histone acetylation of the peripheral blood leukemic blasts. In patient#2 the acetylation status correlates with the VPA level that paralleled the increase of the neutrophil count. In this patient a higher proportion of reduction blasts was observed (35%), although he presented a minor neutrophil response (MiR-N). Moreover in this patient a 4 cm diameter lesion at the left upper pulmonary tract visible at a CT chest, that was performed at the time before treatment, disappeared at a subsequent CT thoracic scan after the VPA treatment. While the biospy of the mass was not done because of the low platelet count, and no antibiotics or antifungines were administered between the two CT scan, the lesion was strong suggestive for lung cancer. Valproic has been shown to induce differentiation of bronchial epithelial cells, and regression of lung metastasis of breast carcinoma in animal mice *in vivo* treated with valproic acid has been previously observed. Conclusion.This is the first biological and clinical study that showed that differentiation/transcriptional therapy with VPA was of clinical benefit in these two old patients.

IDENTIFICATION OF NOVEL EPIGENETICALLY SILENCED TUMOUR SUPPRESSOR GENES IN HODGKIN AND NON-HODGKIN LYMPHOMA

S. Röhrs,[1] J. Romani,[1] A. Rosenwald,[2] W. Dirks,[1] H.G. Drexler,[1] H. Quentmeier[1]

[1]DSMZ - Deutsche Sammlung von Mikroorganismen und Zellkulturen, BRAUNSCHWEIG; [2]University of Würzburg, WÜRZBURG, Germany

Background. Epigenetic inactivation of tumour suppressor genes (TSGs) by promoter CpG island hypermethylation is a common hallmark of human cancer. It is generally agreed that CpG island hypermethylation profiles are specific for different tumour types. Therefore, the methylation patterns of TSGs might prove useful in cancer diagnosis and are potentially valuable for unravelling causes of tumourigenesis. *Aims.* Here, we set out to elucidate whether the methylation profile of TSGs would allow the classification of diverse lymphoma entities, as well as the identification of novel epigenetically silenced genes in these diseases. *Methods.* We analysed the methylation status of 24 different TSGs in combination with copy number changes. Thirty-nine lymphoma cell lines were tested, representing Hodgkin lymphoma plus five distinct subtypes of non-Hodgkin lymphoma (anaplastic large cell lymphoma, Burkitt lymphoma, diffuse large B-cell lymphoma, follicular lymphoma, mantle cell lymphoma). For this approach we used a methylation-specific MLPA (Multiplex Ligation-dependent Probe Amplification) assay. The obtained data were validated at the expression level by quantitative real time PCR. *Results.* Using the MLPA assay, we identified a group of TSGs generally methylated or deleted in all analysed lymphoma cell lines (e.g. CDH13, DAPK1, IGSF4, RARbeta). We also found several TSGs that were preferentially methylated in specific lymphoma subtypes. For example, CD44 is epigenetically silenced in all analysed lymphoma entities except for mantle cell lymphoma. Methylation of RASSF1 is characteristic for Hodgkin and Burkitt lymphomas. The inhibitory effect of promoter hypermethylation on transcription could be confirmed at the expression level. Furthermore, expression of methylated genes was reinducible by treatment of cells with the demethylating agent 5-aza-2'-deoxycytidine. *Conclusions.* Our studies on the methylation status of TSGs in lymphoma cell lines support previous methylation analyses (e.g. for RARbeta and RASSF1) performed on primary lymphoma patient material (1, 2), confirming the applicability of cell lines as model systems. In addition, we identified novel methylation patterns and report lymphoma subtype specific methylation of individual TSGs not hitherto described. Future investigations will show, whether our results on lymphoma cell lines can be verified with patient material.

EPIGENETIC REGULATION OF WNT PATHWAY BY ABERRANT HYPERMETHYLATION OF WNT ANTAGONISTS IN ACUTE MYELOID LEUKEMIA (AML)

A. Valencia,[1] J. Román-Gomez,[2] J. Cervera,[1] E. Such,[1] E. Marco,[1] E. Barragan,[1] P. Bolufer,[1] M.L. Senent,[1] F. Moscardo,[1] M.A. Sanz[1]

[1]Hospital Universitario La Fe, VALENCIA; [2]Hospital Universitario Reina Sofia, CORDOBA, Spain

Background. The canonical Wnt pathway is evolutionary highly conserved and plays a critical role during the cell fate and differentiation decisions during embryogenesis and in adult stem cells such as the self-renewal and proliferation of haematopoietic stem cells. Deregulation of its activity is associated with a variety of human cancers, and several target genes of Wnt act either as tumour suppressor genes or protooncogenes. This signalling pathway is controlled by a number of natural Wnt antagonists that interfere with ligand-receptor interactions that activate the pathway, including members of the Dickkopf (DKK) family and the secreted Frizzled-Related Proteins (sFRP) family. Interestingly, aberrant methylation of Wnt antagonists has been found in some haematological malignancies, leading to activation of the Wnt pathway. *Objectives*.

Given that hypermethylation of CpG islands in the promoter region of several genes is an epigenetic pathway that appears to be common in AML, we studied the role of aberrant gene methylation of a panel of soluble Wnt antagonists including, sFRP1, sFRP2, sFRP4, sFRP5, DKK1 and DKK3 in the activation of the canonical Wnt pathway in AML, as well as the expression of the downstream genes regulated by the Wnt pathway, TCF1 and LEF1, and the Wnt target gene, cyclin D1. *Methods.* We selected 184 AML bone marrow samples at the time of diagnosis (110 male/74 female, median age: 60 yr, range: 16-92). Genomic DNA and RNA were extracted using standard protocols. After bisulphite treatment DNA was PCR amplified with primers specific for the methylated and unmethylated alleles of the genes. LightCycler Fast Start DNA Master SYBR Green I (Roche Diagnostics GmbH Mannheim) was used to detect gene expression by real-time PCR technique. *Results.* Hypermethylation of the gene promoters was observed in all Wnt inhibitors. Among the 184 patients, the methylation frequencies were as follows: 42% sFRP1, 32% DKK1, 31% sFRP2, 22% sFRP5, 16% DKK3 and 4% sFRP4. None methylated gene or just one were found in 56% of patients (Group I) and two or more methylated genes in 44% (Group II). Expression of TCF1, LEF1 and cyclin D1 was significantly higher in patients that had methylation of at least one gene (p=0.015, 0.01 and 0.002, respectively). In order to determine the clinical relevance of the methylation profile we compared patient characteristics between both groups. There were no differences in age, sex, presenting WBC, FAB subtype, cytogenetics risk groups and FLT3 or NPM1 mutations. In univariate analysis patients younger than 60 years with intermediate cytogenetics belonging to the Group II had a significantly reduced disease free survival than Group I at 4 years (49% *vs* 27%, respectively, p=0.001) and relapse free survival (61% *vs* 28%, respectively, p=0.03). In multivariate analysis considering age, sex, WBC, FLT3-ITD and NPM1 mutations and methylation profile of the Wnt antagonist, the combination of FLT3-ITD/NPM1 mutations was the only variable that retained an independent adverse significance. *Conclusions*. We demonstrated that hypermethylation of Wnt antagonists is a frequent event in AML and is associated with activation of the Wnt pathway as demonstrated by the up-regulation of the Wnt target genes. The methylation profile defines a group with a significantly worse prognosis in young patients with intermediate cytogenetics risk.

EPIGENETIC CONTROL OF MHC2TA TRANSCRIPTION IN HUMAN T CELL ACTIVATION AND IN T LEUKEMIA CELLS

P.J. van den Elsen, M.C.J.A. Van Eggermond, D.R. Boom, T.M. Holling

Leiden University Medical Center, LEIDEN, Netherlands

The co-activator CIITA, encoded by the MHC2TA gene, is essential for transcriptional activation of all MHC-II genes. In humans, activated T cells express CIITA and MHC class II molecules. Expression of CIITA in human activated T cells is associated with chromatin modifications involving the MHC2TA multipromoter region (CIITA-PI, -PII, -PIII and -PIV). By using chromatin immunoprecipitation (ChIP) assays we show that the levels of trimethylated lysine 27 in histone H3 are reduced upon T cell activation. This modification is associated with compact chromatin and transcriptional silent genes and is resulting from the activity of the histone methyltransferase EZH2, a member of the polycomb group protein family. At the same time a strong increase is noted in the levels of histone H3 and H4 acetylation and in triple methylation of lysine 4 in histone H3, modifications which are associated with transcriptional active genes. Bisulfite sequencing showed that DNA methylation of CIITA-PIII and CIITA-PIV is absent in unstimulated T cells lacking CIITA and MHC class II molecule expression. Together these data reveal that epigenetic histone modifications and not DNA methylation modifications are involved in transcriptional activation of MHC2TA during T cell activation. These results are corroborated by the observations made in T leukemia cells lacking CIITA and MHC class II molecule expression. However, in these tumor cells DNA methylation modifications were also noted in addition to the triple methylation modification of lysine 27 in histone H3. To evaluate the contribution of the various epigenetic DNA and histone modifications, we have generated Jurkat T leukemia cells by transfection of a modified histone H3 with a lysine to arginine mutation at position 27. Using these altered Jurkat cells and inhibitors for DNA methylation and histone deacetylase activities we are investigating the contribution of the various epigenetic processes involving DNA and histone methylation in transcriptional silencing of MHC2TA in T leukemia.

MICRORNA IMPLICATION IN EVI1 OVEREXPRESSION IN ACUTE MYELOID LEUKEMIA

M. Gomez-Benito, I. Vazquez, C. Vicente, A. Conchillo, N. Marcotegui, E. Bandres, M.D. Odero

CIMA, University of Navarra, PAMPLONA, Spain

The EVI1 (ecotropic virus integration site-1) gene codes for a zinc finger transcription factor with important roles both in normal development and in leukemogenesis. High levels of EVI1 expression is a poor prognostic factor in *de novo* acute myeloid leukemia (AML) with and without 3q26 rearrangements. However, its precise role in myeloid disorders is not completely yet understood, and little is known about the pathways by which it promotes leukemic transformation. EVI1 can bind to specific DNA sequences through both of its zinc finger domains independently, and also interacts with transcriptional coactivators and corepressors. In addition, EVI1 has been implicated in signaling through the PI3K/Akt pathway and in blocking JUNK and stress-induced apoptosis. Nonetheless, additional mechanisms may also exist. MicroRNAs are a new class of evolutionary conserved small RNAs affecting gene expression at the post-transcriptional level. miRNAs have been found to participate in regulatory circuits that control development and lineage-differentiation fate of hematopoietic cells. To date, little information is available on transcription factors modulating miRNA transcription and expression at the basal or tissue specific level. Our aim was to study the possible implication of miRNAs in both EVI1 expression levels regulation (mRNA and protein) and EVI1 downstream pathways. miRNA expression, as well as EVI1, is highly regulated and shows restricted expression profiles in adult tissues. We screened the expression of 250 mature miRNAs by real-time RT-PCR in 9 AML cell lines (4 expressing EVI1 and 5 not), and performed a statistical analysis of the two groups. We found 6 miRNAs significantly upregulated in EVI1-expressing cells. Three of these miRNAs have been previously described as having important roles in cell development, proliferation and apoptosis. Besides, the seed region of two of them is entirely complementary to the EVI1 3´UTR, suggesting a possible minicircuitry EVI1-miRNAs and so, a possible implication of these miRNAs in EVI1 regulation. When stably overexpressing EVI1 in cells we have detected an increase in these two miRNA levels, although no change was detected when transient silencing EVI1. We are currently making stably EVI1 silencing to evaluate its effects on miRNA levels. We have also overexpressed these miRNAs and inhibited their activity in AML cells, detecting downregulation and a slight increase of EVI1 protein levels, respectively. Nevertheless, further functional studies must be performed in order to asses their contribution to the leukemic phenotype. In conclusion, even though a lot of interesting data about the functions and ways of action of EVI1 have already been collected, a lot of open questions remain. The miRNA implication in EVI1 overexpression and its functional study could contribute to understand the role EVI1 is exerting in AML development and to identify new EVI1 direct and indirect target genes, which could be of interest for therapeutic approaches.

THE SECOND SIGNAL IN ANTIGEN-PRESENTING CELLS: COMPLEMENTARY JAK/STAT AND CD40 SIGNALLING MEDIATE PRO-INFLAMMATORY ACTIVATION

T. Luft,[1] M. Conzelmann,[2] E. Rodionova,[1] M. Hess,[1] A. Zota,[2] T. Giese,[3] S. Breit,[4] P. Dreger,[1] T. Luft[1]

[1]University of Heidelberg, HEIDELBERG; [2]DKFZ, HEIDELBERG; [3]Insitute of Immunology, University of Heidelberg, HEIDELBERG; [4]Dept. Paediatrics, University of Heidelberg, HEIDELBERG, Germany

CD40L represents a strong endogenous danger signal associated with inflammation. CD40L induces pro-inflammatory activation of CD40 expressing antigen-presenting cells; however, CD40 activation alone is insufficient to induce IL-12p70 secretion. Cytokines such as IL-4, GM-CSF and IFNg complement the CD40 signal with a JAK/STAT signal, thereby permitting IL-12p70 secretion and at the same time reducing IL-10 secretion. Global inhibition of the JAK/STAT pathway resulted in the loss of IL-12p70 secretion and increased IL-10 secretion. siRNA studies revealed that JAK1, JAK2 and JAK3 enhance whereas Tyk2 inhibits IL-12p70 secretion. In addition, JAK1 directly inhibited IL-10 secretion. The mechanism of JAK/STAT modulation of CD40 signals in DC involved transcriptional regulation of mRNA of IL12p35, p40 and IL-10.

IFNg induces a strong JAK1/JAK2-phosphorylation and a rapid p35mRNA-induction, whereas IL-4 acts with slower kinetics due to a weaker JAK1/JAK2 signal and a stronger Tyk2 signal. Therefore, IL-4 signalling has to persist much longer than IFNg signalling in order to induce similar amounts of IL-12p70. This different dependence on signalling persistence may explain the distinct biological characteristics of Th1- and Th2-cytokines, which both induce IL-12p70 via activation of the same JAKs. Complementary CD40 and JAK/STAT activity is essential for IL-12p70 secretion by all human antigen-presenting cells as it was similarly observed in DC, monocytes and B cells. This strict requirement of both complementary signals opens a new way of interfering with CD40 effects by modulating the *second signal* JAK/STAT.
