European Hematology Association (EHA)

The European Hematology Association (EHA) aims to promote excellence in clinical practice, research and education in European hematology.
EHA was founded in June 1992 and today – with over 3,000 members from 100 countries – is a consolidated representative of European hematologists.

Our aim

- Become the official European representative of hematology and hematologists – especially where research, education and regulatory issues are concerned – and to become a conduit for European harmonization.
- Promote the creation of a highly attractive market for practitioners and researchers in Europe thus fostering the mobility of hematologists in and to Europe.
- Reach out and offer a platform to countries that wish to further develop excellence in hematology.
- Promote education, training and scientific research in hematology in Europe.
- Exchange and disseminate knowledge and scientific information in the field of hematology.

Our activities

- Organizing of annual scientific and educational congresses in major European cities.
- Dissemination of medical research, both basic and clinic, through the Haematologica/The Hematology Journal.
- Collaborating with other leading organizations in the field of hematology and oncology.
- Providing postgraduate education through the annual congress, tutorials and workshops and scientific meetings.
- Supporting junior basic and clinical researchers in the development of their careers through the EHA Fellowship Program.
- Strengthening the quality and professional status of hematology throughout Europe by accrediting scientific meetings and providing CME accounts.

EHA Membership

If you recognize the need for a strong European Hematology Association and would like to take advantage of the various activities of the Association, you may wish to become a member of EHA and contribute to its objectives.

Benefits of EHA membership:

- Subscription to Haematologica/ The Hematology Journal, including on-line access
- Special EHA Member rate for the EHA Annual Congress
- Eligible to apply for the EHA Fellowship Program and the EHA-ASH Translational Research Training in Hematology (TRTH) Award
- EHA Newsletter, the official newsletter for members of EHA, published in May and November.
- EHA monthly e-bulletin
- Access to the job-posting section on the website
- Access to the online EHA membership database
- Priority access to webcast sessions of the EHA Annual Congress
- Vote in election of board of directors

17TH CONGRESS
JUNE 14 - 17, 2012
AMSTERDAM

Word of welcome

On behalf of the EHA Board and the Scientific Program Committee we are pleased to present the Abstract Book of the 17th Congress of EHA.

The Scientific Program Committee has compiled an exciting and topical program of Simultaneous Sessions and Poster Sessions from over 2,000 submitted abstracts. Please join our expert moderators for a walk along the posters in your field of interest on Friday and Saturday. The six best abstracts have been selected for presentation during the Presidential Symposium on Saturday, June 16.

On behalf of the EHA Board, the committees and all the people involved in this years' EHA congress, we thank you for coming to Amsterdam.

DIFFERENTIAL CHEMOKINE RECEPTORS EXPRESSION IN RELAPSE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA (ALL): A ROLE FOR CXCR3 IN RELAPSES

M Ramírez[1], A Gómez-García[1], C Martínez-Laperche[1], A Luque[1], J Martínez-Palacio[2], F Casco[1], N Lozano[1], A Lassaletta[1], L Madero[1], S Hortelano[3]

[2]Medioambientales y Tecnológicas, CIEMAT., Madrid, Spain
[3]Instituto de Salud Carlos III. Majadahonda, Spain, Spain

Background. Leukemic relapses remain the major cause of treatment failure in childhood acute lymphoblastic leukemias (ALL). Resistance to chemotherapy may be intrinsic to lymphoblasts, but it is also possible that the environment may minimize the effects of antileukemic drugs. Leukemic blasts may infiltrate areas where the levels of chemotherapies are suboptimal. In addition, the environment may provide prosurvival signals to the leukemic cells. There is scant information on the molecular basis of these processes. Identifying molecules that allow the leukemic cells to localise and survive in special niches may help in finding new targets for those patients at high risk for relapses. **Aims.** To assess whether chemokines expressed by ALL blasts may have a role in relapses. **Methods.** We compared the levels of chemokine receptors in marrow samples from 94 children with ALL, under an approved protocol. Clinical data were collected from each patient for statistical analysis. Eighty-two samples were drawn at the time of diagnosis, and 15 at relapse. Only 3 patients had samples corresponding to diagnosis and to relapse. We quantitated the levels of chemokines in central system fluid (CSF) samples by ELISA or by Bioplex assays. The functional role of specific chemokines was studied *in vitro* and *in vivo*. Chemotaxis was assessed in standard transwell assays. The influence of chemokines on chemotherapy-induced apoptosis was assessed by flow cytometry, western blotting and caspase activity assays. Immunodeficient mice transplanted with human leukemia cells were treated with a specific antagonist to test the effects of inhibition *in vivo*.Results. Leukemic blasts from patients with T-ALL and marrow relapses expressed CCR5, CXCR3 and CXCR5 at higher levels compared to those who did not relapse. Patients with T-ALL and central nervous system (CNS) relapses expressed higher levels of CCR3, CCR5, CCR7 and CXCR3 compared to those with no CNS relapse. In patients with T-ALL, the levels of CXCL10 (a CXCR3 ligand) in CSF were significantly higher among patients with CNS relapses. Higher expression of CCR5 and CCR8 were found among patients with B-ALL and marrow relapses than among those who did not relapse. Children with B-ALL and CNS relapses expressed higher levels of CCR3, CCR5 and CCR8 in their blasts than those with no CNS relapses. The role of CXCR3 was further studied in functional assays. Signaling through CXCR3 induced chemotaxis in leukemic cell lines and in primary leukemic cells, depending upon the levels of CXCR3 expression. CXCL10 specifically diminished chemotherapy-induced apoptosis on ALL cells expressing CXCR3, partially inhibiting caspase activation and maintaining the levels of the antiapoptotic protein Bcl-2. Finally, immunodeficient mice engrafted with a CXCR3-expressing human leukemic cell line, showed decreased infiltration of marrow, spleen and CNS after receiving a CXCR3-antagonist molecule. **Summary and Conclusions. .** The expression of some chemokine receptors was upregulated upon leukemic relapse, both in B- and in T-ALL, and in cases of medullary and extramedullary involvement. CXCR3 signaling may have a dual function in relapses: chemotactic for the localisation of leukemic blasts in specific niches, and it may also confer resistance to chemotherapy

INHIBITION OF MCL1 AND GLYCOLYSIS SYNERGISTICALLY SENSITIZES TO PREDNISOLONE IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

M Ariës, R van den Dungen, R Pieters, M Den Boer
Erasmus MC - Sophia Childrens' Hospital, Rotterdam, Netherlands

Background. Prednisolone resistance is one of the main prognostic factors of precursor B acute lymphoblastic leukemia (ALL). Overcoming prednisolone resistance would improve survival rates. Recently, we demonstrated that knockdown of the anti-apoptotic gene *MCL1* sensitized leukemic cell lines to prednisolone. We also discovered that 2-deoxyglucose (2-DG), an inhibitor of glycolysis, had the same effect. **Aims.** Because glycolytic and apoptotic pathways are related and tightly regulated survival pathways, we investigated a possible synergistic mechanism of *MCL1* and glycolysis in prednisolone resistance. In addition, we tested a newly developed locked nucleic acid against MCL1 (LNA-MCL1). **Methods.** Leukemic cells of prednisolone sensitive and resistant pediatric ALL patients were treated *in vitro* for 48h with 1 µg/ml or 250 µg/ml prednisolone. Hereafter, protein was isolated and reverse phase protein array was performed. MCL1 knockdown was achieved by lentiviral silencing and LNAs in two different leukemic cell lines and the effect was assessed with RTQ-PCR and Western blot. Cell viability and cell count were analyzed by MACSQuant. Glucose consumption was measured using a glucose assay kit (Sigma). A suboptimal concentration of 0.5 mM 2DG was used to inhibit glycolysis in MCL1 silenced cells. Cytotoxicity of cells towards prednisolone was determined by the *in vitro* 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide drug resistance assay. Statistical Mann-Whitney tests were performed in SPSS. **Results.** Exposure of primary patients' leukemic cells to prednisolone significantly reduced the MCL1 protein levels in prednisolone-sensitive compared to prednisolone-resistant cases ($P<0.05$; 2.6 to 2.9 -fold reduction in sensitive cells). Exposure to 3 LNA-MCL1 antagonists resulted in a highly efficient knockdown of MCL1 protein levels by 82+/-16% which was similar to the silencing of MCL1 by 2 lentivirally delivered shRNAs, 72+/-12%. Silencing of MCL1 in leukemic cells by either LNA-MCL1s or shMCL1s decreased the proliferation rate by 1.9 to 9-fold ($P<0.05$), increased the apoptosis-rate by 1.4 to 4.7-fold ($P<0.05$) and sensitized to prednisolone by 1.8 to 80.8-fold ($P<0.05$). Interestingly, silencing of MCL1 by LNA-MCL1s or shMCL1s both stimulated the consumption of glucose by 1.1-2.5-fold ($P<0.05$), indicating that cells with silenced MCL1 upregulate the glycolytic process to enable survival. In correspondence, inhibition of glycolysis by 2-DG reduced the proliferation rate of MCL1-silenced cells by 1.3 to 3.9-fold ($P<0.05$). Most importantly, silencing of MCL1 and inhibition of glycolysis synergistically sensitized leukemic cells to prednisolone by 1.7+-0.6 fold. **Summary and Conclusions. .** MCL1 is a potent target to therapeutically convert drug resistance in pediatric acute leukemia. However, MCL1 silenced cells upregulate glycolysis to circumvent apoptosis. Silencing of MCL1 and inhibition of glycolysis synergistically sensitized leukemic cells to prednisolone. These data therefore provide evidence for concomitant causes of resistance, and indicate that MCL1 and glycolysis should be targeted simultaneously to modulate prednisolone resistance in acute leukemia.

0003

HIGH-THROUGHPUT FISH SCREENING REVEALS THE ACCURATE INCIDENCE OF IGH@ TRANSLOCATIONS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKAEMIA

J Russell[1], L Jones[1], A Erhorn[1], C Schwab[1], K Laczko[2], C Harrison[1]
[1]Newcastle University, Newcastle upon Tyne, United Kingdom
[2]Leica Microsystems, Gateshead, United Kingdom

Chromosomal translocations lead to oncogene activation or gene fusion in hematological malignancies, where they play an important role both in diagnosis and as an indicator of prognosis. Translocations involving the immunoglobulin heavy chain locus (*IGH@)* in B-cell precursor acute lymphoblastic leukaemia (BCP-ALL) have recently been characterised and found to be different from those reported in the mature B-cell malignancies, although their expression is always deregulated due to the juxtaposition of transcriptional enhancers within the locus. The *IGH@* locus rearranges with multiple genes including: the *CEBP* family of transcription factors, cytokine receptors: *EPOR* and *CRLF2,* and the inhibitory transcription factor, *ID4*. We have developed a high-throughput screening approach to ascertain the true incidence of *IGH@*

translocations in BCP-ALL. We have screened an entire childhood clinical treatment trial (ALL2003) using the Vysis LSI IGH break-apart rearrangement probe (Abbott Molecular) with automated scanning using the CytoVision 7.2 SPOT counting system (Leica Microsystems). We optimised slide set up, hybridisation and scanning templates for capture and automated scoring of 200 cells in over 2000 patients. We have identified *IGH@* translocations in 4% (115/2580) of childhood ALL with the translocation positive population ranging from 5% (cut off value of 3%) to 100% of nuclei. A median age of 10 years and white cell count of $11x10^9$/L was observed in patients with *IGH@* translocations. The median age was significantly higher than all patients entered to this trial (5 years). This is consistent with our previous findings of *IGH@* translocations being frequently observed in adolescents and young adults. We identified the involvement of *CRLF2* in 19%, the *CEBP* gene family in 5%, and *ID4* in 6% of the *IGH@* translocations. DNA was available for Multiplex Ligation-dependent Probe Amplification (MLPA) from 43 *IGH@* translocation patients. Copy number alterations were investigated using the MLPA kit P335-A1 (MRC Holland), which includes probes for *IKZF1, CDKN2A/B, PAX5, EBF1, ETV6, BTG1, RB1*, and the PAR1 region: *CRLF2, CSF2RA, IL3RA*. We identified deletions in 40%, 30%, 19%, 7%, 9%, 12% and 9%, respectively. The number of gene deletions ranged from zero (37%), one (28%), two (26%), three (7%) and five (2%) deleted in the same patient. We have also screened an entire adult trail (MRC UKALLXII) for the presence of *IGH@* translocations, identifying 8% (58/690) of patients whose outcome was inferior to other BCP-ALL subtypes. Interestingly, in 70% and 57% of *IGH@* positive children and adults, respectively, the translocation partner remains to be elucidated, suggesting the presence of as yet unidentified cryptic rearrangements. Characterisation of these partners is necessary to identify additional oncogenes that may be involved in leukaemogenesis or provide potential therapeutic targets.

0004

THE TRANSPHOSPHORYLATION OF BCR IN THE RESISTANCE OF BCR/ABL HARBORING THE T315I MUTATION

M Ruthardt, A Mian, A Metodieva, A Rafiei, H Serve, O Ottmann, M Ruthardt
Goethe University, Frankfurt, Germany

Background. In Philadelphia chromosome positive (Ph+) leukemia, the t(9;22) encodes for the BCR/ABL fusion protein. BCR/ABL is a constitutively activated kinase which induces the leukemic phenotype because of the aberrant activation of multiple signaling pathways. Targeted inhibition of BCR/ABL by ABL-kinase inhibitors (AKI) such as Imatinib, Nilotinib or Dasatinib induces apoptosis in BCR/ABL transformed cells and leads to complete remission in Ph+ leukemia patients. However, the “gatekeeper” mutation T315I confers resistance against all actually approved ABL-kinase inhibitors. It seems not only to decrease affinity for kinase inhibitors but to confer additional features to the leukemogenic potential of BCR/ABL. In our previous studies we determined the role of T315I in the resistance and its contribution in the leukemogenic potential of BCR/ABL. We studied its influence on loss-of-function mutants with regard to the capacity to mediate factor-independence. We found that resistance of BCR/ABL-T315I was accompanied by the trans-phosphorylation of endogenous BCR at tyrosine 177. **Aims.** In order to further disclose the mechanisms of resistance mediated by T315I we investigated the role of the transphosphorylation of endogenous BCR. Therefore we studied the effects of T315I in both BCR/ABL mutants lacking functional domains in the BCR portion indispensable for the oncogenic activity of BCR/ABL such as the N-terminal coiled coil (CC), the tyrosine phosphorylation site Y177 and the serine/threonine kinase domain (ST), as well as on the ABL-portion of BCR/ABL (#ABLT315I). **Methods.** All mutants were retrovirally expressed iin Ba/F3 cells and tested for their capacity to mediate factor independence in the absence and presence of Imatinib. The transformation potential was studied in untransformed Rat-1 fibroblasts by focus formation assays and colony formation in semi-solid medium. BCR-expression was targeted by RNA interference. **Results**. Here we report that i.) T315I restored the capacity of loss-of-function mutants of BCR/ABL to confer factor-independence and their transformation potential in Rat-1 cells; ii.) Short hairpin (sh) RNA against endogenous BCR reduced expression of endogenous BCR; iii.) shRNA against endogenous BCR abrogated the capacity of loss of function mutants of BCR/ABL-T315I to mediate factor independent growth of Ba/F3 cells and to strongly reduce their transformation potential in Rat-1 cells. **Summary**. Our data show that the T315I restores the capacity of loss-of-function mutants to transform cells which is dependent on the transphosphorylation of the endogenous BCR suggesting endogenous BCR as a therapeutic target to overcome resistance by T315I.

NOVEL ACTIVATING MUTATIONS LACKING CYSTEINE IN TYPE I CYTOKINE RECEPTORS IN ACUTE LYMPHOBLASTIC LEUKEMIA

C Shochat[1], N Tal[1], O Bandapalli[2], G Cazzaniga[3], A Kulozik[2], A Biondi[3], M Muckenthaler[2], D Bercovich[4], S Izraeli[1]
[1]Sheba Medical Center, Tel Aviv University, Ramat Gan, Israel
[2]Department of Pediatric Oncology Hematology , University of Heidleberg, Heidleberg, Germany
[3]Centro Ricerca Tettamanti, Clinica Pediatrica, University of Milano-Bicocca, Monza, Italy
[4]Department of Human Molecular Genetics, Tel Hai Academic College, Kiryat-Shmona, Israel

Interleukin 7 receptor alpha (IL7R) is required for normal lymphoid development. IL7R can dimerize with cytokine receptor-like factor 2 (CRLF2) to form the receptor to thymic stromal lymphopoietin (TSLP), or with interleukin-2 receptor gamma (IL2RG) to form the receptor to IL-7. We and others have recently reported activating mutations in IL7R and CRLF2 in acute lymphoblastic leukemia (ALL). The addition of a cysteine to the extracellular or transmembrane domains of the receptor, characterizing these mutations activate the receptor by causing ligand- independent receptor dimerization via s-s bonds between the mutated cysteines.Here we report the discovery of a novel type of activating mutations lacking cysteine in IL7R and CRLF2 in ALL. IL7R mutations were found in 3 T-ALL patients and CRLF2 mutation was found in one B-Cell precursor ALL. Three of these mutations were small in-frame indels and one a missense mutation. All were located in the C-terminal region of the transmembrane domain (TMD), in contrast to the more common cysteine insertion mutations, located in the N-terminal region of the TMD. The mutations in IL7R were: 254 insertion (ins) EKV, 254 ins GEA and V253G. The CRLF2 mutation was 244 ins EIM.To decipher the effect of IL7R and CRLF2 ‘non cysteine‘ mutations, we generated interleukin 3 dependent mouse pro-B cells (BaF3) and the mouse IL7 dependent MOHITO cell line that expressed either the wt receptors or the mutated constructs. We demonstrate that the mutated constructs lead to cytokine independent growth associated with phosphorylation of STAT5 and JAK1. As expected, unlike the cysteine mutated protein, no homodimerization was observed in Western Blot under non reducing condition.We have thus identified a novel mechanism for constitutive activation of cytokine receptors in leukemia. Given the presence of similar receptors in multiple cell lineages, such mutations may occur in other neoplastic disorders.

0006

MOLECULAR CHARACTERIZATION OF TP53 MUTATIONS IN B-ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL) REVEALS MISSENSE SUBSTITUTIONS, ABERRANT EXON-JUNCTIONS AND INTRON RETENTION EVENTS

I Iacobucci[1], A Ferrari[1], A Lonetti[2], C Papayannidis[1], S Trino[3], C Venturi[1], A Ferrarini[4], L Venturini[4], M Abbenante[1], S Parisi[1], F Cattina[5], S Soverini[1], D Russo[5], M Vignetti[6], F Pane[7], M Delledonne[4], M Baccarani[1], G Martinelli[1]

Recently, copy number and sequence alterations of *TP53* has been shown in 12.4% of pediatric B-ALL in which they independently predicted high risk of treatment failure (Hof J et al. JCO 2011). Since the pattern, frequency and significance of *TP53* aberrations in adult B-ALL have still to be determined, in this study we set-up a sensitive assay to address this issue.Deletions and uniparental disomy (UPD) involving *TP53* were assessed in 146 DNA samples from adult Philadelphia-positive (Ph+)(n = 126) and Ph-negative (n = 20) ALL by Genome-Wide Human SNP 6.0 array (Affymetrix). UPD events were not detected whereas losses of *TP53* occurred in 2% of cases.Mutations of *TP53* were thereafter investigated in 69 adult B-ALL samples (60 Ph+ and 9 Ph-negative). Since the majority of the studies in leukemia were focused on DNA and resulted in low rate of *TP53* mutations, we aimed to identify RNA mutations and aberrant isoforms. To this purpose three overlapping shorter amplicons covering the entire coding cDNA sequence (GenBank NM_000546.4) and the untranslated exon 1 [amplicon 1 (491 bp): exons 1-5; amplicon 2 (482 bp): exons 5-8; amplicon 3 (498 bp): exons 8-11)] and a longer amplicon (1,317 bp)

starting from exon 1 and ending to exon 11 were sequenced by Sanger method. *TP53* mutations were detected in 7 cases (10.1%), suggesting that these alterations are apparently rare events in B-ALL. They included 4 missense substitutions in the DNA binding and carboxyl-terminal tetramerization domains: C135Y (ex 5), A234T (ex 7), R290C (ex 8) and A347T (ex 10). Interestingly, in two cases aberrant transcripts were identified: 1) a *TP53* isoform characterized by retention of introns 5-6-7 and predicted to encode for a truncated protein due a premature stop codon; 2) a *TP53* isoform in which the DNA binding domain is lost due to an exon conjunction between the exon 4 and the 3' untraslated region (UTR)(ex4-3'UTR: 7579533-7572842, GRCh37/hg19).Next, in order to investigate if low rate of mutations were detectable, we also analyzed whole transcriptome data obtained using next generation sequencing technology (Illumina/Solexa Genome Analyzer) in 3 Ph+ ALL patients. All patients harbored clones ranging from 45% to 94% with *TP53* mutations in the DNA binding and tetramerization domains: C182W (ex 5), T231A (ex 7), L330R (ex 9) in the first patient and Stop394S, D393V/H and G389Y/V (ex 11) in the second one. Moreover, in the first and third patient we detected 10 and 13 base exchanges, respectively, located in intron 6 within 7578166-7578142 region, suggesting a retention of the intron 6 in the primary transcript and the dysfunction of the DNA-binding domain. In conclusion, we demonstrate for the first time that *TP53* alterations at the RNA level (missense substitutions, aberrant exon junctions and intron retentions) are highly frequent in adult B-ALL patients and that testing for *TP53* mutations with a sensitive assay based on RNA analysis is required.Supported by ELN, AIL, AIRC, Fondazione Del Monte Bologna e Ravenna, FIRB 2006, Ateneo RFO grants, PIO program, Programma di Ricerca Regione-Università 2007-2009.

ROLE OF MIR-29A IN THE MOLECULAR PATHOPHYSIOLOGY OF ALL: SYSTEMATIC IDENTIFICATION OF TARGET TRANSCRIPTS

L Oliveira, M Fráguas, J Schiavinato, A Araújo, P Palma, L Oliveira, R Vilar, F Meirelles, D Covas, M Zago, R Panepucci
INCTC, Hemotherapy Center and Faculty of Medicine of Ribeirão Preto, University, Ribeirão Preto, Brazil

Background. Several microRNAs (miRs) have been implicated in leukemogenesis, since they play important roles in the control of self-renewal and differentiation, by controlling, the translation or degradation of its target. Recent studies revealed miR-29a as an important player in the regulation of hematopoietic (HSC) and leukemic stem cells (LSC). For instance, reduced levels of miR-29a have been associated with more aggressive disease and worst prognosis in chronic lymphocytic leukemia, mantle cell lymphoma and acute myeloid leukemia (AML). A preliminary database analysis revealed that miR-29a levels in Jurkat (JKT) cells and in acute lymphoblastic leukemias (ALL) are extremely reduced (as compared to normal T-cells). Intriguingly, overexpression of miR-29 in mouse B-cells or HSC results, respectively, in the development of leukemia with B-CLL characteristics or, AML, by converting myeloid progenitors into self-renewing LSC. **Aims.** To explore the role of miR-29a in the molecular pathophysiology of ALL, by carrying a systematic identification of its target transcripts. **Methods.** Synthetic pre-miR-29a, inhibitory anti-miR-29a and respective control molecules were independently electroporated into JKT and 48h post-transfection gene expression profile was obtained using Agilent microarrays. Transcripts simultaneously down-regulated by the pre-miR and up-regulated by the corresponding anti-miR, were compared to the set of predicted targets to identify confident targets. To identify pathways and biological processes modulated by the miR-29a, we used a Functional Annotation Tool (DAVID) and selected targets were validated using qRT-PCR. The functional effect of restoring miR-29a in JKT was evaluated by flow cytometry for apoptosis using annexin V and propidium iodide (PI). Finally, flow-cytometry was used to evaluate the global levels of chromatin 5-hmC and 5mC in Jurkat cells, after pre-miR and anti-miR transfections. **Results.** Among pathways with a statistically significant enriched number of miR-29a target transcripts, we identified: Apoptosis (FAS, BIRC2), WNT (WNT8B/16, FZD4/10, LRP6, TCF7L1), TGF-beta (TGFB3, ACVR2A **BMP8A, SMAD2, BMPR1** LEFTY2,), Jak/Stat (LIF, LIFR, SPRY1) and cancer (MDM2, APC, NRAS, PTEN, PTENP1, RARB, FOS). Further inspection revealed central components of active demethylation (including TET1/2/3 and TDG) and maintenance of DNA methylation following cell division (DMNT3b). qRT-PCR confirmed the significant down-regulation of TET1/2/3 and DMNT3b after pre-miR transfection (pValue<= 0.05, n=3). Functional analysis revealed an increase in the levels of spontaneous apoptosis (Fold=3) and of hydroxy-methylation (34,9% to 59,2% of 5-hmC) in JKT cells, after treatment with pre-miR and anti-miR, respectively. **Summary/ Conclusions.** Both, oncogene hypomethylation or tumor suppressor hypermethylation can lead to oncogenic transformation. For instance, mutations in the DNMT3A (leading to hypomethylation) or the TET family (leading to hypermethylation) are found in a significant fraction of myeloid disorders. We have identified several target transcripts of miR-29a that are associated with pro-oncogenic pathways. Moreover, we show that increased levels of miR-29a leads to increased apoptosis in Jurkat cells. Taken together, reduced miR-29a levels found in ALL may contribute to the molecular pathophysiology of the disease; trough the consequent increase in the level of its target transcripts, which include central components involved in the epigenetic control of transcription by *de novo* methylation or active demetylation. **Support**. OVARIAN INFILTRATION IS CELL LINE SPECIFIC AND ASSOCIATED WITH HIGH CXCR4 EXPRESSION IN A XENOGRAFT MODEL OF PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKAEMIA

Y Yousafzai[1], M Williams[1], Z Macqueen[1], F Menzies[1], B Gibson[2], S Nelson[1], R Nibbs[1], G Graham[1], C Halsey[1]
[1]University of Glasgow, glasgow, United Kingdom
[2]Royal Hospital for Sick Children, Glasgow, United Kingdom

Background. Acute lymphoblastic leukemia (ALL) is the commonest hematological malignancy in children. With improved treatment a high cure rate has been achieved, however management of relapsed disease and reduction of treatment-related toxicity remain major challenges. Although ovarian involvement is commonly detected at post-mortem in female patients with relapsed disease, little is known about the mechanisms underlying leukemic infiltration of this tissue. As well as being of interest to the pathogenesis of relapse, understanding ovarian involvement also has implications for fertility preservation such as the use of cryopreserved ovarian tissue for post remission re-implantation in girls with previous ALL.We hypothesize that leukemic cell dissemination to extramedullary sites such as the ovaries is associated with the abnormal expression of chemokine receptors which play important roles in governing physiological leukocyte trafficking as well as in metastasis of many types of cancer. To test this we have developed a xenograft model of extramedullary ALL using human leukemic cell lines and immunodeficient (NOD/SCID/IL2R gamma null) mice. Using this model we have identified two Philadelphia positive pre-B ALL cell lines which differ in their capacity to home to the ovaries with one producing striking ovarian infiltration (SupB15) and the other (SD1) showing no signs of ovarian involvement but producing aggressive disease elsewhere. **Aims.** To identify chemokine receptors associated with homing of acute lymphoblastic leukemia to the ovaries. **Methods.** Initial screening was performed by quantitative PCR for 17 candidate chemokine receptors in the ovarian homing (SupB15) and non-homing (SD1) cell line. Promising candidates were further evaluated by flow cytometry and functional assays. Expression of the corresponding chemokine ligands in murine ovarian tissue was assessed by qPCR. **Results.** Only two chemokine receptors were up-regulated in SupB15 cells compared to SD1 cells; CXCR4 and CCR9. High levels of CXCR4 expression by SupB15 were confirmed by FACS and immunofluorescence. In addition SupB15 cells were shown to bind the CXCR4 ligand CXCL12 using fluorescently labelled chemokine and showed efficient chemotaxis towards CXCL12 in transmigration assays. Migration could be inhibited by use of the CXCR4 antagonist AMD3100. In contrast SD1 cells showed lower levels of CXCR4 expression by FACS and no directional migration to CXCL12. We could not confirm CCR9 surface expression by FACS on SupB15 cells or transmigration in response to its ligand CCL25. This data is further supported by qPCR analysis of chemokine ligand expression by murine ovaries which show high levels of CXCL12 and only very low levels of CCL25 in resting tissue. Further work will investigate the effect of CXCR4-inhibition on the ability of SupB15 to infiltrate the ovaries *in vivo*. **Summary.** Despite both carrying the t(9:22) translocation these two cell lines produce distinct patterns of extramedullary spread with a striking difference in their ability to infiltrate the ovaries. Here we provide evidence that the chemokine receptor CXCR4 and its ligand CXCL12 may be important in determining spread to this important sanctuary site.

GENE EXPRESSION-BASED IN SILICO SCREENING FOR GLUCOCORTICOID-SENSITIZING THERAPEUTICS IN MLL-REARRANGED INFANT ALL IDENTIFIES PI3K INHIBITORS AS POTENTIAL MODULATORS OF PREDNISOLONE RESISTANCE

A Spijkers-Hagelstein, S Mimoso Pinhancos, P Schneider, R Pieters, R Stam
Erasmus Medical Center - Sophia Children's Hospital, Rotterdam, Netherlands

Background. Obtaining successful treatment results for *MLL*-rearranged Acute Lymphoblastic Leukemia (ALL) remains challenging, to some extent due to poor glucocorticoid (e.g. prednisone and dexamethasone) responses. Thus, overcoming resistance to these drugs may be a crucial step towards improving prognosis. However, despite intensive research, little is known about the

mechanisms of resistance. **Aims.** Therefore we aimed to produce a gene expression signature associated with *in vitro* prednisolone resistance in *MLL*-rearranged infant ALL, and identify therapeutic agents that reverse the profile and induce prednisolone sensitivity. **Methods.** By comparing gene expression profiles (Affymetrix HU133plus3.0 GeneChips) from *MLL*-rearranged infant ALL patients either sensitive or resistant to prednisolone *in vitro*, we defined a gene signature associated with prednisolone resistance. Using this signature, we applied Connectivity Map analysis to perform an *in silico* screen for agents potentially capable of reversing the prednisolone-resistance profile and induce sensitivity. **Results.** Connectivity map analyses revealed that LY294002, a PI3K inhibitor, would potentially fulfill this task. Subsequent validation experiments demonstrated that indeed LY294002, as well as other known PI3K inhibitors, markedly sensitized otherwise resistant *MLL*-rearranged ALL cell to prednisolone *in vitro*. Using quantitative real-time PCR analyses, we validated the modulating effects of LY294002 on the expression of the genes present in our prednisolone-resistance profile. This showed that the prednisolone-sensitizing actions of LY294002 are indeed mediated by inhibition of PI3K, as one of the genes down-regulated in response to LY294002, *i.e. PARVB*, represents a known PI3K target. **Conclusions.** We conclude that implementing FDA-approved PI3K inhibitors in current treatments may potentially improve the GC-response, as well as the prognosis, for patients with *MLL*-rearranged ALL.

FREQUENCIES AND PROGNOSTIC IMPACT OF RAS MUTATIONS IN MLL-REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA IN INFANTS

E Driessen[1], E van Roon[1], J Spijkers-Hagelstein[1], P Schneider[1], P de Lorenzo[2], M Valsecchi[2], R Pieters[1], R Stam[1]
[1]Erasmus MC/ Sophia Children's Hospital, Rotterdam, Netherlands
[2]University of Milano-Bicocca, Monza, Italy

Background. Acute Lymphoblastic Leukemia (ALL) in infants represent an aggressive malignancy associated with a high incidence (~80%) of *MLL* translocations like t(4;11) generating MLL-AF4 fusion proteins. Recent attempts to mimic MLL fusion-driven leukemogenesis in mice raised the question whether or not these MLL fusions require secondary hits to induce leukemia. Based on previous reports, *RAS* mutations may represent likely candidates, but results are inconclusive and contradicting on the incidence of these mutations in *MLL*-rearranged ALL. **Aims.** Therefore, our aim was to elucidate the precise frequencies and the potential role (in terms of disease aggressiveness and clinical outcome) of *RAS* mutations in *MLL*-rearranged infant ALL patients, and their relation with known (e.g. WBC, age, and glucocorticoid response) and putative (e.g. *HOXA* expression) prognostic factors.

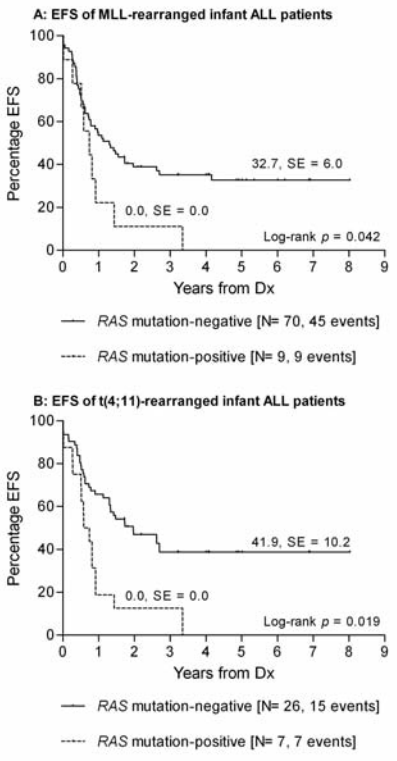

Figure 1. Survival of RAS mutated and non-mutated infants .

Methods. For this, PCR and sequence analysis were used to screen a large cohort (>100 samples) of infant ALL cases for the presence of *RAS* mutations, and studied our results in relation with various clinical parameters and prognostic impact. **Results.** *RAS* mutations were detected in ~14% of all cases tested, with a significantly higher frequency of ~24% in t(4;11)-positive patients (p=0.04). The presence of a *RAS* mutation was associated with a poor outcome in both the *MLL*-rearranged infant ALL patients, as well as in t(4;11)-positive cases alone (Figure 1). The 5-year EFS rates for the *RAS* mutation-positive and negative *MLL*-rearranged cases was 0· 0±0· 0 % vs. 32.7±6.0%(p=0.042). Furthermore, we identified the presence of a *RAS* mutation as an independent predictor (p=0.019) for poor outcome in *MLL*-rearranged infant ALL, with a hazard ratio of 3.194 (95% confidence interval: 1.211-8.429). Also, *RAS*-mutated patients appeared to have significant higher white blood cell counts at diagnosis (p=0.013), and are significantly more resistant to glucocorticoids *in vitro* (p<0.05). Finally, we demonstrate that *RAS* mutations, but not the lack of *HOXA9* expression nor the expression of *AF4-MLL* are associated with poor outcome in t(4;11)-rearranged infant ALL. **Summary and Conclusions. .** We conclude that *RAS* mutations represent genuine secondary hits in *MLL*-rearranged infant ALL and are an independent predictor for clinical poor outcome in this already unfavorable type of childhood leukemia. Moreover, we propose future risk-stratification based on abnormal *RAS*-pathway activation and that *RAS*-mutated infants could benefit from additional treatment with *RAS*-pathway inhibitors.

TAGONES, MINOR MATURE NK AND T LYMPHOCYTE SUBPOPULATIONS INTERFERING WITH MRD T-ALL ANALYSIS - A NOVEL STRATEGY PROPOSED

G Paterakis[1], A Taparkou[2], A Ampatzidou[3], G Avgerinou[3], C Papassarandi[4], D Koliouskas[2], P Vasileiou[4], S Polychronopoulou[3]
[1]„GEORGIOS GENNIMATAS„ GENERAL HOSPITAL OF ATHENS, Athens, Greece
[2]Pediatric Oncology Department, Hippokration General Hospital, Thessaloniki, Greece
[3]Department of Paediatric Haematology-Oncology, „Aghia Sofia„ Children's Hospital, Athens, Greece
[4]Flowdiagnosis Laboratory, Athens, Greece

Background. In Acute T Lymphoblastic Leukema (T-ALL), minimal residual disease identification by multiparameter flow cytometry, has been based on simultaneous assessment of cytoplasmic and surface CD3 antigen along with combinations of CD7 and CD45 common connecting antigens. In the individual protocols there are used specific antigens that mainly characterize immature epitopes like Tdt, CD99, CD34, CD117, CD10, CD1a etc. Recently however ı Roshal et al, Cytometry B Clin Cytom. 2010 May;78(3):139-46, showed that immediately post treatment those antigens are significantly down modulated, providing false negative results in MRD identification based on these immature antigens. In contrast mature T lymphocyte antigens like CD7, CD2, CD4, CD8, CD5, TCRab, TCRgd, appear to retain their expression during therapy. AIM The aim of this study was to evaluate a novel gating strategy based on mature antigens, initially using as a control cohort, samples of non-T ALL receiving therapy. **Methods.** We analyzed 25 non T-ALL marrow samples from patients recovering from therapy (B-ALL, AML, Lymphomas) as well as 12 normal blood and reactive marrows. **Results.** We located minor mature NK and T cell subpopulations interfering in presumed T-ALL empty spaces. 1) CD45 bright NK cells CD16+ or CD56+ with cytoplasmic CD3 epsilon expression, CD7+, CD2, CD5-, TCR- and surface CD3 negative 2) CD45 bright T4 and T8 lymphocytes with down regulated surface CD3 and TCRab expression, CD2+, CD5+. 3) NK2 CD56bright lymphocytes with reduced CD45 intensity. All the above populations were consistently found in regenerating and normal condition in minus log3 and log4 concentrations and interfered with our MRD T-ALL analysis. In comparison to hematogones in B-ALL they were named for simplicity tagones. The novel strategy of MRD analysis was planned with five color combinations using as common backbone antigens, surface and cytoplasmic CD3, CD7, CD16 and CD45, while tested antigens were all mature (CD2, CD4, CD5, CD8, TCRαβ, TCRγδ, CD56). Within this analysis platform, tagone patterns were consistently similar between non-T-ALL subjects. We then prospectively applied this strategy in the evaluation of T-ALL MRD patterns (n=18). MRD was considered positive, when there were noted deviations from the tagones pattern of expression. They were quantitated up to -log4 concentration. **Conclusions.** We provide a feasible strategy of multiparameter MRD detection in T-ALL based on the concept of discrimination from the patterns normal minor populations of mature T and NK cells, imitating expressions of antigens found in T-ALL

0012

TP53 MUTATIONS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) ARE RELATIVELY FREQUENT IN MOLECULARLY NEGATIVE CASES OF BOTH B- AND T-LINEAGE AND CORRELATE WITH POOR RESPONSE TO INDUCTION THERAPY

S Chiaretti[1], F Brugnoletti[1], S Tavolaro[1], S Bonina[1], F Paoloni[2], M Marinelli[1], I Della Starza[1], A Negulici[1], A Vitale[1], MS De Propris[1], L Elia[1], M Vignetti[1], M Bonifacio[3], M Kropp[4], S Sica[5], R La Starza[6], G Pizzolo[3], S Molica[4], G Leone[5], G Meloni[1], AM Testi[1], A Guarini[1], R Foà[1]

[5]Department of Hematology, Catholic University of the Sacred Heart, Rome, Italy
[6]Hematology, University Hospital S. Maria della Misericordia, Perugia, Italy

Background. *TP53* mutations occur in several cancers including hematologic malignancies, particularly chronic lymphocytic leukemia (CLL) and acute myeloid leukemia (AML), where the incidence is of 5-10% and 7%, respectively. While in these neoplasms *TP53* mutations have been widely investigated and correlate with a poor prognosis, their incidence and role in acute lymphoblastic leukemia (ALL) remain controversial. **Aims.** To investigate the incidence of *TP53* mutations and their correlation with known molecular aberrations and outcome, we analyzed a cohort of 98 newly diagnosed adults with ALL. In 10 cases, we also analyzed paired relapse samples. **Methods.** Genomic DNA was extracted from mononuclear cells of patients enrolled in different GIMEMA protocols. All samples contained at least 70% of leukemic blasts. In 10 cases paired diagnosis-relapse material was analyzed. Sixty-two patients had a B-lineage ALL (B-ALL) and 36 a T-ALL. Molecular screening showed that, within B-ALL cases, 25 harbored the *BCR/ABL*, 9 the *ALL1/AF4* and 4 the *E2A/PBX* transcripts. The remaining patients were negative for the presence of the aforementioned fusion genes. Within T-ALL, 4 cases harbored the *SIL/TAL1, 1 NUP98/RAP1GDS1* and *1 SET/NUP214* rearrangement.*TP53* mutation analysis was performed using a microarray-based sequencing assay, the AmpliChip p53 Research Test (Roche Molecular Systems), which allows sequencing of the entire coding region of the *TP53* gene, including exons 2-11 splice sites. Results were validated by direct sequencing. **Results.** The AmpliChip p53 assay identified *TP53* missense mutations in 8 patients (8.16%) studied at diagnosis. Within the mutated patients, 4 had a B-ALL (6.4%): 3 cases (12.5%) had no known molecular abnormality and 1 harbored the *BCR/ABL* rearrangement (4%). No mutations were found in *E2A/PBX1+* and *ALL1/AF4+* cases. Within the T-ALL group, 4/36 carried *TP53* mutations (11.1%): none of these cases harbored known molecular aberrations. Overall, *TP53* mutations were found in 13% of ALL cases without known molecular abnormalities.Sanger sequencing confirmed all the mutations but one, suggesting the presence of a sub-clonal population. Furthermore, of the 10 paired patients studied, 2 acquired the mutation at relapse (20%): one patient had a *BCR/ABL+* B-ALL and the other a T-ALL. Patients harboring *TP53* mutations were predominantly males (M/F= 6/2) and were younger than *TP53* wild-type (wt) cases (*TP53* mut 30 *vs TP53* wt 36.5 years).Since the majority of the mutations occurred in molecularly negative patients, response to induction was evaluated in this subset: of the 47 evaluable patients, 12 were refractory to induction and, remarkably, 25% were *TP53* mutated. **Conclusions.** These results indicate that *TP53* mutations frequency in ALL at the onset of the disease is similar to that reported in CLL and AML. Furthermore, they indicate that, within patients without known molecular aberrations of both T- and B-lineage, *TP53* alterations can be detected in 13% of cases and therefore could be particularly useful for the prognostic stratification of these subgroups. Indeed, although statistical significance was not reached because of the small number of *TP53* mutated patients, our results indicate that *TP53* mutations have a deep impact on response to induction treatment and achievement of complete remission.

0013

SRC KINASE INDUCED PHOSPHORYLATION OF ANNEXIN A2 MEDIATES GLUCOCORTICOID RESISTANCE IN MLL-REARRANGED ACUTE LYMPHOBLASTIC LEUKEMIA

A Spijkers-Hagelstein, S Mimoso Pinhancos, P Schneider, R Pieters, R Stam
Erasmus Medical Center - Sophia Children's Hospital, Rotterdam, Netherlands

Background. Glucocorticoids (e.g. prednisone and dexamethasone) are commonly used in the treatment of childhood acute lymphoblastic leukemia (ALL). Unfortunately, infants with ALL (<1 year of age) characterized by translocations of the *MLL* gene are frequently resistant to these drugs. As poor glucocorticoid responses are firmly associated with therapy failure, overcoming glucocorticoid resistance may be a crucial step towards improving prognosis. In search of insights into glucocorticoid resistance mechanisms, we generated a gene expression signature associated with *in vitro* prednisolone resistance in *MLL*-rearranged infant ALL. One of the genes strongly discriminating between resistant and sensitive patients appeared to be *ANXA2*, encoding human annexin A2. **Aims.** Here we aimed to functionally study the role of annexin A2 in prednisolone-resistant *MLL*-rearranged ALL. **Methods.** *ANXA2* expression was validated by quantitative RT-PCR and immunoblotting in *MLL*-rearranged cells. To study the role of annexin A2, Src kinases or p11 in prednisolone resistance, we performed RNAi experiments using lentiviral constructs expressing either a non-targeting shRNA or shRNAs directed against *ANXA2*, Src kinases or *S100A10*. *In vitro* prednisolone response was determined by MTT assays. **Results.** *MLL*-rearranged cells resistant to prednisolone *in vitro* expressed elevated levels of annexin A2 and its phosphorylated form (active). Further investigation demonstrated that the underlying factor of this association was the presence of Src kinase induced phosphorylation (activation) of Annexin A2, a process requiring the adaptor protein p11 (encoded by *S100A10*). shRNA-mediated knock-down of annexin A2, FYN, LCK, or p11, all led to inhibition of annexin A2 phosphorylation and resulted in marked prednisolone sensitization in otherwise resistant *MLL*-rearranged ALL cells. Likewise, exposure of prednisolone-resistant *MLL*-rearranged ALL cells to various known Src kinase inhibitors exerting high specificity towardsFYN and/or LCK had similar effects. **Conclusions.** In conclusion, we here present a novel mechanism of prednisolone resistance in *MLL*-rearranged ALL, and propose that inhibition of annexin A2 phosphorylation embodies an attractive therapeutic strategy for overcoming resistance to glucocorticoids in this highly aggressive type of leukemia.

0014

THE POTENTIAL OF AURORA KINASE B AS A THERAPEUTIC TARGET IN CHILDHOOD ACUTE LEUKEMIA

S Hartsink-Segers[1], M Zwaan[1], C Exalto[1], M Luijendijk[1], V Calvert[2], E Petricoin[2], W Evans[3], D Reinhardt[4], V de Haas[5], H Caron[6], R Pieters[1], M Den Boer[1]
[1]Erasmus MC, Rotterdam, Netherlands
[2]George Mason University - Center for Applied Proteomics and Molecular Medicine, Manassas, United States of America
[3]St. Jude Children's Research Hospital, Memphis, United States of America
[4]Medical School Hannover, Hannover, Germany
[5]Dutch Childhood Oncology Group, The Hague, Netherlands
[6]Emma Children's Hospital - AMC, Amsterdam, Netherlands

Background. Aurora kinases (AURK) A and B are known regulators of mitosis and are overexpressed in a large number of human cancers, including leukemia. Several AURK-inhibitors have shown anti-tumor activity *in vitro* and *in vivo*. However, the efficacy of AURK inhibition in the treatment of childhood acute leukemia is largely unexplored. **Aims.** We investigated the effect of inhibiting AURKA and AURKB in leukemic cells of children with newly diagnosed acute lymphoblastic leukemia (ALL) and acute myeloid leukemia (AML), to determine the potential of these two kinases as new targets for therapy. **Methods.** Affymetrix gene expression data of 297 ALL, 237 AML and 8 normal bone marrow (nBM) samples were analyzed for AURKA and B mRNA expression levels. Protein expression levels in 172 pediatric ALL and 10 nBM samples were determined with a reverse phase protein array. Functional studies were performed in ALL and AML cell lines, in which AURKA and B were silenced using a short hairpin RNA with a lentiviral delivery system or LNA-containing oligonucleotides. Sensitivity of leukemic cell lines and primary patient samples to the AURKB-selective inhibitor Barasertib-HQPA (AZD1152-HQPA) was tested *in vitro* with an MTS assay. **Results.** AURKA and B mRNA levels were low in ALL and AML patients. In contrast, Aurora A and B proteins were expressed to a greater extent in patients ($p<0.0002$), especially in ALL cases with an E2A-PBX1 translocation ($p<0.002$), than in nBM mononuclear cells. Silencing of AURKA by shRNA and by LNA-oligonucleotide caused no or only minor growth delay in several cell lines reflecting genetic subtypes typically found in pediatric

ALL and AML. In contrast, silencing of AURKB resulted in proliferation arrest and apoptosis in these cells. Furthermore, 18 out of 20 ALL and AML cell lines tested were highly sensitive to the AURKB-selective inhibitor Barasertib-HQPA in the nanomolar range (IC50 = 19-233 nM), and differential sensitivity was observed between primary patient samples. **Summary and Conclusions. .** In adult AML, clear responses are observed with Barasertib in early clinical trials. In agreement, we show that inhibition of Aurora B by shRNA, LNA-based mRNA antagonist and Barasertib-HQPA has an anti-proliferative and pro-apoptotic effect on childhood acute leukemia cells, whereas targeting Aurora A did not have a major effect. Aurora B could therefore be a promising new target for therapy in the treatment of pediatric ALL and AML.

0015

GENE EXPRESSION PROFILING, HIGH-DENSITY GENOME-WIDE GENOTYPING AND COPY NUMBER ANALYSES OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

M Sanders, A Schelen, J Koenders, Z Ristic, P Van Geel, B Löwenberg, P Sonneveld, J Cornelissen, A Rijneveld, P Valk
Erasmus MC, Rotterdam, Netherlands

Background. Acute lymphoblastic leukemia (ALL) is a malignant disease characterized by a clonal proliferation of malignant lymphoblasts, which is characterized by accumulation of genetic alterations in B or T lymphoid precursor cells. ALL is the most common leukemia in children, but is a rare disease in adults. In recent years this disease has been extensively studied in children using various genome-wide molecular approaches, however, studies in adults are lacking. **Aims.** We have analyzed a cohort of 71 paired, i.e. diagnosis and remission, adult ALL cases using gene expression profiling with Affymetrix HGU133 Plus 2.0 Genechips and genome-wide genotyping and copy number analyses using Affymetrix 6.0 DNA Mapping GeneChips. These high-resolution SNP-arrays enable the determination of recurrent focal, possibly cryptic, genetic lesions. **Methods.** In paired diagnosis and remission samples genotype calls per SNP were determined using the Birdseed algorithm and copy numbers per SNP using dChip. The ALL cohort included 53 B-ALL cases and 18 T-ALL cases, which were all extensively molecularly characterized, i.e., all known recurrent ALL specific molecular aberrations were determined. Unsupervised analyses of the ALL cases based on gene expression profiling data demonstrated that besides the separation of B-ALL and T-ALL, various molecularly-defined ALL subsets carried distinct gene expression profiles. **Results.** Genome-wide genotyping demonstrated (1) recurrent aberrations involving *CDKN2A/B* (65%), *IKZF1* (29%), *PAX5* (29%), BTG1 (23%) and *RB1* (7%) at higher frequencies than previously shown by others, (2) that all T-ALL cases carried a copy number change involving the CDKN2Apathway (two cases that did not carry an allelic loss of *CDKN* had lesions in *CDKN2A-IP* or *CDKN2A-IPNL*), (3) additional recurrent aberrations in *MKKS* (9%), resulting in significant down regulation of gene expression, and *KRAS* (7%), (4) selected cases with unbalanced translocations involving *BCR-ABL*, *NUP214-SET*, *NUP214-SQSTM1* and *TCF3-HLF*, as well as illegitimate V(D)J recombination involving *CRLF2* and *STIL*, (5) genetic aberrations involving *SUZ12*, i.e., a core component of the Polycomb Repressive Complex 2 (PRC2), in 3 T-ALL cases. This ensued sequencing of the *SUZ12* gene, i.e., the region encoding the Zn-finger and VEFS-box (EZH2 interaction domain) in 200 ALL cases, resulting in the identification of missense or nonsense *SUZ12* mutations in 3 T-ALL cases. **Conclusions.** We have demonstrated that high-quality/high-resolution SNP-arrays grants the ability to determine submicroscopic genetic lesions and unbalanced translocations. Additionally, we have shown that many known recurrent ALL-specific copy number variants are found at a higher frequency than previously reported. Finally, we have also identified novel aberrations, such as those in the *SUZ12* gene, which are currently subjected to mutational analyses.

Acute lymphoblastic leukemia - Clinical

IMPACT OF MINIMAL RESIDUAL DISEASE LEVEL DURING THE FIRST-LINE IMATINIB THERAPY ON LONG-TERM OUTCOMES OF ALLOGENEIC STEM CELL TRANSPLANTATION IN ADULTS WITH PH-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

S Lee, DW Kim, YJ Kim, N Chung, JH Yoon, SH Shin, S Yahng, SE Lee, BS Cho, KS Eom, HJ Kim, CK Min, JW Lee, WS Min, CW Park
Catholic BMT Center, The Catholic University of Korea, Seoul, South-Korea

Background. The combination of imatinib with chemotherapy as a front-line treatment has demonstrated an improved complete response rate and an increased applicability of allogeneic stem cell transplantation (SCT), thus allowing a better short-term outcome in adults withPhiladelphia chromosome-positive acute lymphoblastic leukemia (Ph-positive ALL). However, with prolonged follow-up, a substantial proportion of transplants and practically almost all non-transplants continue to die as a result of relapse. Most published studies in the imatinib era include quantitative minimal residual disease (MRD) findings, but the long-term outcome in relation to molecular response to any given therapeutic approach remains to be determined in Ph-positive ALL. **Aims.** Here, with a more sizable patient population and a longer follow-up, we conducted a systemic re-evaluation to identify risk factors that affect long-term transplantation outcome in the imatinib era, and focused particularly on the prognostic relevance of MRD level at each pre-SCT treatment stage. **Methods.** Between September 2000 and December 2009, 95 adults [median age, 34 years (range, 15 to 59 years)] with newly diagnosed Ph-positive ALL who received a uniform treatment protocol of allogeneic SCT following imatinib (400 mg/d for 4 weeks at each cycle) plus conventional chemotherapy (alternating modified hyper-CVAD and high-dose cytarabine/mitoxantrone) were included in this analysis. All patients were transplanted from a fully matched sibling or a suitably matched (≤2-allele mismatched) unrelated donor after the completion of the second imatinib cycle. MRD monitoring for BCR-ABL1 transcript is centrally evaluated by real-time quantitative PCR (4.5 log sensitivity) through handling of bone marrow samples from all patients (Research Institute of Molecular Genetics, The Catholic University of Korea,Seoul,Korea). All patients in the study provided written informed consent, and the study protocol was approved by the institutional review board of The Catholic University of Korea. **Results.** After the first imatinib cycle, 33 of the 95 patients (34.7%) achieved at least major molecular response [MMR; including 12 complete molecular response ($CMR^{4.5}$)]. Frequencies of achieving a reduction in BCR-ABL1 transcript levels of 1% to <0.1% and <1% at this stage were 27 (28.4%) and 35 (36.8%), respectively. After the second imatinib cycle, 68 patients (71.6%) achieved at least MMR (including 27 $CMR^{4.5}$), and the remaining 27 patients showed an insufficient molecular response [1% to <0.1% (n=9; 9.5%) and <1% (n=18; 18.9%), respectively]. Eighty-eight (92.6%) of the 95 patients received SCT in first complete response. After a median follow-up of 60 months, the 5-year cumulative incidence of relapse and nonrelapse mortality were 24.9% and 18.8%, respectively, and the 5-year disease-free survival and overall survival rates were 61.5% and 65.8%, respectively. The most powerful predictive factor affecting relapse, disease-free survival, and overall survival was the achievement of good quality of molecular response (MMR or $CMR^{4.5}$) after the second imatinib cycle ($P<0.001$). **Summary and Conclusions. .** In the era of tyrosine kinase inhibitors, prospective assessment of the extent of MRD reduction may allow us to identify subgroups of Ph-positive ALL transplants at high risk of relapse and provide potential guidelines for the development of new risk-adapted, MRD-based therapeutic approaches.

Background. Risk stratification has led to a tremendous improvement of the 5-year overall survival rates in childhood acute lymphoblastic leukemia (ALL). The average risk group 1 (AR1), consisting of all non-very low risk and non-very high risk B-cell lineage ALL patients, is the largest patient group accounting for 57% in our experience. Despite the good overall survival, the total number of relapses observed in this AR1 group is considerable. **Aims.** In this study, we aimed at identifying a marker able to predict relapse, at the stage of diagnosis. To this end, we focused on the recently discovered microRNAs of which their expression has been reported to hold prognostic power in other cancer types. **Methods.** A total of 693 microRNAs were profiled using automated high-throughput quantitative stem-loop RT-PCR in a cohort of diagnostic bone marrow samples from AR1 pediatric precursor B-cell ALL patients in continuous complete remission (follow-up>6 years) and patients who experienced relapse. All patients were treated according to the EORTC-CLG protocol 58951 (December 1998-August 2008). The ethical committee approved the study and informed consent was obtained from the patients and/or their parents. Statistics were performed using SPSS17 and R (Bioconductor). **Results.** Logistic regression analysis and Prediction Analysis of Microarray allowed us to identify a 19-microRNA signature, prognostic for relapse within this group. The signature has an accuracy, sensitivity and specificity of 77%, 69% and 84%, respectively. Currently, the signature is evaluated in an independent validation cohort. Notably, several of the microRNAs present in this signature are known oncogenes or tumor suppressor genes. Multivariate analysis, including the microRNA signature, white blood cell count and age, shows that the 19-microRNA signature is an independent prognostic factor. **Conclusions.** The identified 19-microRNA signature is a unique and powerful tool for further risk-stratification. The method and signature are suitable for routine laboratory testing and will be further evaluated in a prospective study. **Correspondence to:** farzaneh.ghazavi@ugent.be

Background and Aims. Among elderly patients with ALL, those with Ph+ had historically a poorer prognosis. Excellent short-term results have been obtained with TKI inhibitors together with minimal or moderate amount of chemotherapy, but a continuous pattern of relapses has been observed over time. A comparison of two prospective parallel trials conducted by the Spanish PETHEMA Group in elderly patients with Ph+ or Ph- ALL is herein performed. **Patients and Methods.** Patients older than 55 yr. were included in the ALLOLD07 and ALL OPH07 trials if they have Ph- or Ph+ ALL, respectively. ALLOLD07 trial (derived from the Elderly ALL trial from the EWALL Group [Göckbuget et al, Blood 2008; 112: Abstract 304]) included induction with vincristine (VCR) dexamethasone (DXM) and idarubicin (IDA), in phase 1, and cyclophosphamide (CPM) + cytarabine (ARA-C) in the Phase 2. Consolidation included 6 alternating cycles with intermediate-dose methotrexate (MTX)+asparaginase (ASP) (odd cycles) and ARA-C (even cycles). Maintenance therapy included merpatopurine (MP)+MTX up to 2 yr, with monthly reinduction cycles with VCR and DXM during the first year. ALL OPH07 tiral included induction with imatinib, VCR and DXM and maintenance with imatinib+MP+MTX up to 2-yr, with monthly reinduction cycles with VCR and DXM during the first year. Imatinib therapy was given during the third year. **Results.** Between July 2007 and December 2011, 28 valid patients were included in the ALLOLD07 and32 in the ALLOPH07 trial. Both groups of patients were comparable for the main clinical and biologic characteristics of ALL. Early death was observed in 3(11%) of patients in the ALLOLD07 trial vs. 4 (13%) in ALL OPH07, failure occurred in4 pts (14%) vs. 1(3%), and CR was attained in 21(84%) vs. 26(96%), respectively. With a median follow-up of 17 (1-52) months in both protocols, 3 patients withdrawn from the ALLOLD07 (vs. none in the ALLOPH07), 10 (48%) relapsed (vs. 9[35%]) and 1(5%) (vs. 2 [8%]) died due to treatment-related mortality. In all, 7 patients (25%) (vs 15 [47%]) are alive in first CR.The medians (95%CI) of CR duration were 27(13-41) months in ALLOLD07 trial vs. 37(13-43) in the ALLOPH07, and the medians of OS were 16(8-23) months (vs. 22[9-35]), without significant differences between the two protocols. The duration of neutropenia in induction was significantly longer in the ALLOLD07 trial, as was extramedullary grade III-IV toxicity, especially infections. No differences in the post-induction toxicity were observed on comparison of both protocols. **Conclusions.** From the data of these two parallel protocols, Ph+ ALL in the elderly is not associated with poorer prognosis in the TKI era. However, improvement in the therapy of both Ph+ and Ph- ALL in elderly patients is clearly needed.Supported by grants RD06/0020/1056 from RTICC, PI10/01417 from FIS, Instituto Carlos III, and P-EF-11 from Jose Carreras Leukemia Foundation.

BONE MARROW CLEARANCE OF LEUKEMIC BLASTS ON DAY 14 OF INDUCTION DETERMINES PROGNOSIS AND HELPS IN STRATIFICATION OF ADOLESCENTS AND ADULTS WITH *de novo* ACUTE LYMPHOBLASTIC LEUKEMIA

S Mohamed, K Ibrahim, H EL-Zahrany, M Bakr, M Shaheen, G El-Dossary, S AbuJafar, S Khalil, F Al-mohareb, E Colcol, T Abulhassan, M Al-Jurf, F Hussain, F AlSharif, N Chaudari
KFSHRC, Riyadh, Saudi Arabia

Background. early clearance of leukemic blasts after induction had been shown to correlate with prognosis and to help in stratifying ALL therapy. Timing and methodology as well as methods of quantification of residual leukemic blasts varied significantly. **Aims.** to assess the impact of clearance of marrow leukemic blasts on day 14 of induction on prognosis and its value in stratifying *de novo* ALL in adolescents and adults. **Patients and Methods.** 163 (53 female, 110 male) consecutive patients were treated between 2003-2011 with a unified CALGB-based induction (Adriamycin 50mg/m^2 d1-3, Cyclophsphamide 1.5gm/m^2 d1, vincristine 1.4/m^2 d1,8,15,22, Prednisone d1-28 , L-aspaaraginase) followed by HIDAC consolidation. Cytomorphology and flow-cytometry of bone marrow aspirates and biopsies (BMA) was reported as BMA- if blasts <5% and BMA+ if ≥5%. Those with high risk features [high WBC count (>100K in T- or >30K in PreB-), CNS+, high risk cytogenetics (Ph+) or >4 weeks to achieve remission or BMA+.] were offered Allo-HSCT if available. Salvage was tried in BMA+. Day 28 BM biopsy was done to assess complete remission (CR) status. Of the 163 patients, 72% were PreB- vs. 28% T-ALL. Median age was 21-y (14-63). Median follow up of survivor was 21 mo(0.68-96.5). **Results.** 134 (82%) were BMA -ve and 29 (18%) BMA+ with no difference in phenotype (p 0.65), high WBC count (p 0.95), age (p.95). BMA+ had more Ph+ (28% vs. 10%;p=0.015), CNS (28% vs. 10%;p=0.03) and a trend of male dominance (79% vs. 65%; p= 0.06). 50% of BMA- carried high risk features while all (100%) BMA+ were considered high risk. Of BMA-, 130 (97%) achieved CR1 vs. 16 (57%) of BMA+(p=0.005) and 50% from BMA- received alloHSCT (BMA-BMT+) vs. 54% of BMA+ (BMA+ BMT+)(p 0.95). OS of BMA- was 49.5%+0.05 vs. 20.3%+0.08 for BMA+ (p 0.002; HR=2.2+0.26). OS values of different groups in relation to AlloHSCT (BMT) were: BMA-BMT+ 57% +0.06, BMA-BMT-: 41.4+/-0.07; (p=0.06) and BMA+BMT- of 33.3%+/-0.12 vs. BMA+ BMT- of zero% (P=0.002). CIR for BMA- was 0.56 (95% CI=0.54-0.57) vs. 0.69 (95% CI=0.66-0.72) for BMA+ (P=0.2) with a HR of 1.5 (0.85-2.67; p=0.2) .Using Competing risk regression modeling (CRR) by Fine & Gray, BMT had insignificant lowering of CIR in BMA- (0.61+/-0.005 vs. 0.5 +/- 0.005; p=0.3) but significant in BMA+ (0.86+0.026 vs. 0.47+0.018; p=0.01). BMA- had a trend for better DFS vs. BMA+(0.36+0.04 vs. 0.22+0.08; p=0.1). The impact of alloHSCT in improving DFS was greatly evident in BMA+ (BMT- 0%, BMT+ 0.33+/-0.12; p=0.02) vs. BMA- (BMT- 0.3+/-0.06, BMT+0.42+/-0, 06; p=0.2). In the BMA- , there was no significant impact of other high risk factors including age (p=0.45), WBC (p=0.2), CNS+ (p=0.2), poor cytogenetics (p=0.9) or BMT (p=0.2). **Conclusions.** persistence of ≥5% marrow leukemic blasts on day 14 of induction is a strong prognostic and stratification tool in ALL and is associated poor outcomes. AlloHSCT improves outcome of *de novo* ALL and is the only option for meaningful survival for those with significant residual disease on day 14 of induction.

MINIMAL RESIDUAL DISEASE DETECTION IN CHILDHOOD B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA. MULTICOLOR FLOW CYTOMETRY AND PCR OF FUSION GENE TRANSCRIPTS DATA COMPARISON

A Popov[1], G Tsaur[2], T Verzhbitskaya[1], T Riger[1], E Shorikov[2], L Saveliev[3], L Fechina[1]
[1]Regional Children's Hospital, Ekaterinburg, Russian Federation
[2]Research Institute of Medical Cell Technologies, Ekaterinburg, Russian Federation
[3]Ural State Medical Academy, Ekaterinburg, Russian Federation

Background. Minimal residual disease (MRD) monitoring by flow cytometry (FC) or polymerase chain reaction (PCR) is a strong tool for risk-adapted treatment in childhood acute lymphoblastic leukemia (ALL). IgH/TCR rearrangements monitoring by real-time quantitative PCR (RQ-PCR) is very laborious and costly approach. Hence other methods - FC and PCR of fusion gene transcripts (FGt) - can be used for long-term MRD monitoring. **Aims.** To evaluate qualitative concordance between MRD data assessed by FC and PCR of FGt in children with ALL. **Methods.** Concurrent detection of MRD by multicolor FC, RQ-PCR and RT-PCR was performed in 331 follow-up bone marrow samples from 77 children. Among them 34 patients (pts) carried *ETV6-RUNX1* FGt, 4 pts - *TCF3-PBX1*, 1 pt - *BCR-ABL*, 3 pts - *SCL-TAL1* while in other 35 pts various types of *MLL*-rearrangements were detected. 29 pts had CD10(-), 45 pts - CD10(+) B-lineage ALL and 3 pts - T-ALL. 115 samples were obtained during remission induction while 216 - during consolidation/intensification. **Results.** Sensitivity of FC MRD detection varied from 0.01% to 0.001%. PCR sensitivity ranged from 5×10^{-5} to 1×10^{-5}. 100 of 331 samples were MRD-negative by both methods, 36 (10.87%) - were negative by FC but positive by RT-PCR, while in 8 samples (2.42%) tumor cells were detected by FC only. Remaining 187 samples were MRD-positive by both techniques. Qualitative concordance of 86.71% between FC and PCR data was found. Concordance in *MLL*-rearranged(88.51%), *ETV6-RUNX1*-positive(88.00%) and *TCF3-PBX1*-positive(91.67%) cases was very similar (p=0.879). Samples with and without normal B-cell precursors (BCP) were analyzed separately, because presence of BCP in follow-up samples is known to be an obstacle for FC data analysis. Qualitative concordance in BCP-negative and BCP-positive samples was very similar (84.21% and 90.53% respectively, p=0.123). In contrast, concordance of FC and PCR data in samples obtained during remission induction and during consolidation/intensification was significantly different (78.26% and 91.20% respectively, p=0.002). As long as FC data analysis in CD10(+) and CD10(-) B-lineage ALL patients bases on different approaches, these types of leukemia were also analyzed separately. High qualitative concordance was found in samples from both B-lineage ALL types (85.37% and 89.81% respectively, p=0.300). Direct comparison of quantitative FC and RQ-PCR data is impossible but MRD values in FC-negative/PCR-positive samples were lower than in samples, where tumor cells were detected by both methods (median 0.011%, range 0.001-0.413% and median 0.534, range 0.001-56.491% respectively, p<0.0001). So FC appears to be better for the quantitative MRD evaluation however FGt detection by PCR is more appropriate for qualitative MRD assessment. Hence, FC is more applicable for MRD monitoring during early treatment phases, when the precise MRD value is essential while PCR for FGt is more useful for later time-points when any MRD-positivity corresponds to poor outcome of childhood ALL. **Conclusions.** Qualitative concordance between PCR-based FGt detection and FC data achieved 86.41%. Tandem application of FC at early time-points and FGt detection by PCR at later time points seems to be a useful tool for long-term MRD monitoring in childhood ALL.

[8]Department of Hematology, La Sapienza University, Rome, Italy

Background. The treatment of Central Nervous System (CNS) relapse/ resistence in pediatric acute Leukemia (AL)/lymphoma remains a challenging clinical problem. Liposomal Cytarabine (LC) (DepoCyte) is a new intrathecal (IT) formulation characterized by slow-releasing of free Cytarabine into the cerebrospinal fluid (CSF), resulting in longer drug exposure and possibly higher response rate. Severe neurotoxicity has been recently reported during LC treatment.

Table 1.

Patients' characteristics (N = 30).

Characteristic	No.
Gender:	
Male/Female	21/9
Median age at diagnosis (yrs) (range)	6.0 (0,3-17)
Median age at Liposomal Cytarabine treatment (yrs) (range)	9.4 (0,8-18)
Underlying neurological disease (Down's syndrome)	1
Diagnosis:	
Acute Lymphoblastic Leukemia (4 infant)	22
Acute Myeloid Leukemia (3 infant)	6
Non Hodgkin-Lymphoma	2
N. of CNS relapse at Liposomal Cytarabine treatment:	
First relapse	15
Second relapse	7
≥Third relapse	6
CNS Resistance	2
Type of relapse:	
Isolated CNS relapse/resistance	18
Combined relapse	12
Median Liposomal Cytarabine administration	4 (2-9)
N. of Liposomal Cytarabine administration for CR	3 (1-4)
Dose Level per patients and age:	
20 mg (< 1 years)	4
25 mg (1-3 years)	3
35 mg (3-14 years)	17
50 mg (> 14 years)	6
CNS response (%):	
Complete response	25 (83.4)
Partial response	3 (10.0)
Not Applicable	2 (6.6)
Neurological toxicity ≥ grade 3 (%):	4 (13.3)
Posterior reversible encephalopathy syndrome	1
Strabismus and clonie at right inferior limbs	1
Aphasia, Ataxia, hypostenia of left hemylate, corea	1
Partial seizures after CNS hemorrhagic stroke	1
Toxicity < grade 3 (%):	9(30.0)
Headache grade III	4
Irritability	3
Fever	2
Concurrent systemic HD-MTX/ARA-C (%)	21 (70.0)
Previous cranial RT/TBI (%)	8 (26.6)
Subsequent RT/TBI (%)	7 (23.3)
Subsequent SCT (%)	12 (40.0)
Outcome:	
Death from sepsis	2 (6.6)
Death from TRM	2 (6.6)
DOD	11 (36.7)
Alive in CCR	11 (36.7)
Alive in CR after subsequent relapse	4 (13.3)
Median follow-up (mths) (range)	30.5 (2-58)

CNS: central nervous system; HD-MTX/ARA-C: high dose Methotrexate/ Cytarabine; yrs: years; mts: months; CCR: complete continuous remission; CR: complete remission; RT: radiotherapy; TBI: total body irradiation; TRM: transplant related mortality; SCT: stem cell transplantation; DOD: died of disease

Aims. We retrospectively evaluated the safety and activity profile of IT LC in a cohort of 30 pediatric patients with CNS recurrence/resistance. **Methods.** From May 2005 to July 2011, 30 patients (21 males/9 females; median age 9.4 years) with CNS relapse/resistance (22 ALL, 6 AML and 2 NHL) were treated with IT LC at dosages ranging from 20 to 50 mg/dose depending on age, in eight AIEOP Centers. Patients concomitantly received oral administration of Dexamethasone (DEXA) at a dosage of 0.2 mg/kg twice a day for 5 days, associated with IT DEXA in ten children. Twenty seven out of 30 patients were simultaneously treated with systemic chemotherapy and 21 with concurrent high dose cytarabine or methotrexate. LC was started upon CNS relapse and was administered every 15 days, regardless of aplastic phase and underlying chemotherapy until CSF negativity in two subsequent lumbar punctures. Table 1 resumes the patients' clinical characteristics. LC treatment was discontinued when neurotoxicity appeared or in the presence of severe adverse events. Toxicity was evaluated according to Common Toxicity Criteria, version 3.0. **Results.** Twenty-five patients (83.4%) achieved a CNS cytological complete response (CR); three patients (10%), who presented radiological meningeal involvement at LC treatment, showed PR (negative CSF with persistence of less than 50% at neuroimaging) and two patients were not evaluated for IT pre-treatment. A median of four LC administrations were given (range, 2-9), with CSF negativity after three median IT administrations. Neurological toxicity > grade 3 was observed in 4 patients (13.3%); one patient experienced posterior reversible encephalopathy syndrome, the second had strabismus and clonus in the lower right limb, the third had partial seizures after CNS hemorrhagic stroke during the aplastic phase and the last one showed aphasia, ataxia, hypostenia of the left hemibody, corea. Two of these 4 patients resumed LC after CNS event resolution without complications. Other neurological adverse events < grade 3 were reported in 9 patients (30%), namely mild headache (n=4), irritability (n=3) and fever (n=2). No permanent sequelae were observed. Median overall survival was 20.9 months and the probability of being alive at 5 years was 45.7%. **Conclusions.** These encouraging data suggest that intrathecal IT LC is well tolerated and effective, as it can induce continuous CNS CR in a relevant proportion of children with relapsed/refractory leukemia/lymphoma. Despite its potential neurotoxicity, LC remains an interesting formulation since it reduces the frequency and total number of IT administrations. These characteristics associated with efficacy can improve compliance and quality of life in young patients. Further prospective studies on larger pediatric series are needed to confirm our observations and define optimal dosage and best timing administration of the drug in the pediatric setting.

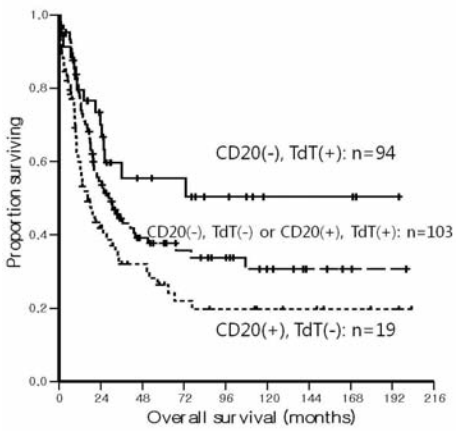
0022

PROGNOSTIC SIGNIFICANCE OF IMMUNOHISTOCHEMICAL BIOMARKERS INCLUDING CD20, CD13 AND TDT IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

DY Kim, JH Lee, JH Lee, HS Park, HJ Park, HJ Park, SH Paek, J Mijin, K Young-Ah, YS Lee, M Seol, AR Jung, YJ Lee, SS Jang, CJ Park, HS Chi, KH Lee
Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

Background. Recently, targeted therapies with monoclonal antibody, such as rituximab which targets CD20 have been administered to the treatment of adult acute lymphoblastic leukemia (ALL), and promising results of reducing relapse rate and improving overall survival (OS) have been reported. Therefore, prognostic and predictive meanings of frequently-expressed cell surface markers of adult ALL have become important. **Aims.** We analyzed the prognostic significance of cell surface markers which are commonly expressed on the ALL cells for the treatment including allogeneic hematopoietic cell transplantation (allo-HCT). **Methods.** Patients who were diagnosed as ALL and treated in Asan Medical Center, Seoul, Korea, from 1995 until 2011 were included in this retrospective analysis. Patients with L3-type (Burkitt leukemia), lymphoid blast crisis of chronic myeloid leukemia were excluded. 'High risk' was defined as 'age≥35 years' or 'WBC count at diagnosis≥30x10^6/L' or 't(9;22) or BCR-ABL(+)'. Immunohistochemical markers were defined as positive when their expression was ≥20%. **Results.** Median age of 230 patients (male: female= 116: 114) included in this analysis was 38.0 (range 18-75) years, 28% of patients were Philadelphia-positive (Ph+), and 76% were high risk. Positivity of each immunohistochemical marker was 87.0% (CD19), 45.6% (CD20), 63.9% (CD22), 82.6% (CD10), 80.5% (terminal deoxynucleotidyl transferase; TdT), 66.8% (CD34), 39.2% (CD13), and 33.0% (CD33), respectively. Of 230 patients, 84% were treated with a combination chemotherapy consisting of vincristine, prednisolone, daunorubicin (VPD), and L-asparaginase, and 16% were treated with VPD plus tyrosine kinase inhibitor (imatinib, nilotinib or dasatinib). CR rate was 92%, which was not different between those with Ph+ and Philadelphia-negative (Ph-) ALL. AlloHCT was performed for 124 (54%) patients, during their first CR (80%) or more advanced stage. After 45.4 months of median follow-up period of surviving patients, 2-year and 5-year RFS was 48.3% and

36.2%, respectively. For overall survival (OS), 2-year and 5-year OS were 57.0% and 39.4%, respectively. When patients were divided into groups by prognostic factors, risk group (standard vs. high, 41.2 vs. 22.9 months, *p*=0.041), age (<45 vs. ≥45 years, 26.2 vs. 19.7 months, *p*=0.026), CD20 positivity (negative vs. positive, 30.8 vs. 19.3 months, *p*=0.007), CD13 positivity (negative vs. positive, 19.7 vs. 34.5 months, *p*=0.005), and TdT positivity (negative vs. positive, 17.5 vs. 30.7 months, *p*=0.05) significantly affected OS of patients. In the multivariate analysis with Cox-proportional hazard model, CD20 (HR 1.95, 95% CI 1.33-2.95, *p*=0.001), CD13 (HR 0.62, 95% CI 0.41-0.94, *p*=0.024) and TdT (HR 0.57, 95% CI 0.36-0.90, *p*=0.015) positivity were significantly associated with OS, as well as risk group (HR 1.76, 95% CI 1.11-2.79, *p*=0.017). When patients were categorized into 3 groups according to the positivity of CD20 and TdT, 5-year OS rate of each group was 36.1, 25.4, and 9.0 months, respectively (*p*=0.0003) (Figure 1). **Conclusions.** Positivity of common immunohistochemical cell surface antigen of adult ALL, especially of CD20, CD13, and TdT was an useful and discriminative prognostic biomarker.



Figuure 1. Overall survival curve according to the positivity of CD20 and TdT

NORMAL KARYOTYPE PREDICTS BETTER SURVIVAL IN ADULT PH-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA - RESULTS OF THE RUSSAIN ACUTE LYMPHOBLASTIC LEUKEMIA(RALL)STUDY GROUP

E Parovichnikova[1], Y Davidyan[1], G Kliasova[1], E Mavrina[1], S Bondarenko[2], T Kaporskaya[3], T Ryltzova[3], E Kondakova[4], O Baranova[5], G Savchenko[1]
[1]National Research Center for Hematology, Moscow, Russian Federation
[2]State Medical University, St.Petersburg, Russian Federation
[3]Regional Clinical Hospital, Irkutsk, Russian Federation
[4]District Clinical Hospital, Surgut, Russian Federation
[5]National Oncological Center, Moscow, Russian Federation

Background. Adult ALL is characterized by higher frequency of unfavorable biological features, slower molecular response, more toxicity followed by less compliance, translating in less efficacy compared with childhood ALL. So called "pediatric approach"applied in adult ALL is now considered to be more reasonable especially in the younger adults. **Aims and Methods.** RALL has initiated a prospective multicenter trial for adult Ph-neg ALL based on: 1) evaluation of b/m blast clearance after 7 days of Prednisolone (PRD) prephase and its substitution by Dexamethasone (DEXA) if b/m blast count was >25%; 2) continuous 2,5 years treatment schedule with prolonged L-asparaginase (Σ=590.000 IU); 3)evaluation of the impact of the late intensification (2 courses of HD of methotrexate and ARA-C) on MRD clearance. The study is registered on the ClinicalTrials.gov public site; NCT01193933. **Results.** From Nov, 2008, till Jan, 2012, 24 centers enrolled 150 pts: median age 28y (15-55), 62f/88m, 67%=B-lin, 33%=T-lin. Cytogenetics was evaluable in 60% of pts (n=90) and 47% of them (n=42) were with normal karyotype (NK). 26% of patients were in the standard risk (SR) group (WBC <30 for B-Lin, <100 for T-Lin, EGIL BII-III, T-III; LDH < 2N, No late CR, t(4;11)-negative), 59% - in the high risk (HR) group (WBC >30 for B-Lin, >100 for T-Lin, EGIL BI, T-I-II-IV; LDH > 2N, No late CR, t(4;11)-positive), 15% were not qualified. The analysis was performed in January, 2012.+8day b/m blast count was reported in 111 pts and has shown b/m blasts >25% in 64% of pts. The portion of non-responders to PRD was 50% in SR and 69% - in HR groups (p=0,04). In 118 analyzed pts CR rate was high in both risk groups (SR=94,1%; HR=91,0%) with total 7 induction deaths (5,9%) and 3 resistant leukemias(2,5%). L-asparaginase was stopped due to toxicity in 19% of patients, but it did not influence OS and DFS. With a median follow-up of 11 mo (1-36 mo) death in CR was reported in 6/108 (5,5%)pts, relapses - in 18/108 (16,6%). OS at 36 mo was 72,4%, DFS-60,5%.MRD analysis for clonal IgH and TCR rearrangements was carried out in 25 pts. And as in our previous studies (ASH 2006, abstr 2294) the clearance was slow with only 41,6% pts negative for MRD at day +133 (4mo) of the protocol. Two late intensification courses (day +157 = 5 mo) increased MRD negativity only up to 50%.Age, WBC, immunophenotype, LDH, risk group, +8 day b/m blast count, time without treatment (<>8days), L-asparaginase cessation did not influence survival. OS and DFS differed in pts with NK vs all other abnormalities: 84,6% vs 71,9%,(p=0,04) and 89% vs 70% respectively(p=0,03). **Conclusions**. So, our data demonstrated that in adult Ph-neg ALL normal karyotype is a favorable prognostic factor comparing to any abnormality and late intensification did not influence MRD clearance.

0024

WHITE MATTER ANISOTROPY AND NEUROCOGNITIVE OUTCOME IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA SURVIVORS TREATED WITH 3 DIFFERENT PROTOCOLS

S El-Alfy, I Ragab, I Azab, S Amin, M Abdel Maguid
Ain Shams University, Cairo, Egypt

Background. Patients with childhood ALL achieve long-term disease-free survival yet neurocognitive outcome could affect the quality of life of survivors. The study aimed to assess the prevalence of neurocognitive dysfunction in survivors of childhood ALL treated with different protocols. **Patients and Methods.** Sixty ALL survivors aged 5-16 years; 2-9 years at diagnosis, CNS1, treated through 1998-2008 with chemotherapy only and regularly followed up in childhood cancer survivors clinic were compared to 60 healthy age and sex matched controls. Revision of scholastic achievement , type and risk of ALL, protocol of treatment, number, type and doses of intrathecal chemotherapy and high dose I.V methotrexate. Patients diagnosed between JAN 1998 to DEC 2000 were treated with Modified BFM 83; those between JAN 2001 to JUN 2004 with BFM 90 , and those from JUL 2004 to JUN 2008 with CCG 1991 for standard risk and CCG 1961 for high risk patients. Neurocognitive functions were tested using Wechsler Intelligence Scale for Children ,Benton visual retention (BVR) test and Trail making tests were done. MRI Brain was performed using diffusion weighed images and diffusion tensor magnetic resonance imaging (DTI). **Results.** Survivors treated with CCG protocol showed a significant decrease in all cognitive tests compared to control (p<0.05). BFM 90 group had a significant lower total IQ, verbal IQ, TMT-partA, compared to both control and Modified BFM 83 group, and a significant decrease in performance IQ, BVRT and TMT-partB compared to control. No significant difference in results of cognitive tests between Modified BFM 83 and control group. Both left and right frontal apparent diffusion coefficient (ADC) was significantly higher in CCG group compared to control BFM 90 and modified BFM 83 groups (p<0.05) and a significant decrease in fraction anisotropy (FA) of right frontal cortex in CCG group compared to control, BFM 90 and Modified BFM 83 groups (p<0.05). Right frontal FA was significantly lower in BFM 90 and Modified BFM 83 groups compared to control group. No significant correlation between IQ tests with age at diagnosis, length of treatment, duration from the end of therapy, number of IT doses. By comparing survivors according to duration since end of therapy, group I (1-2 years from end of chemotherapy) and II (2-5 years)of survivors showed a significantly lower full scale IQ, PIQ and correct BVRT compared to control group, and no significant difference in group III (5-10 years) compared to control ; left frontal ADC was significantly higher in group I and II of survivors compared to control and significant higher right frontal ADC in all three groups compared to control; left frontal FA was significantly lower in group I and III of survivors compared to control and the right frontal FA of survivors was significantly lower compared to control. **Conclusions.** CCG treated patients showed the worst neurocognitive outcome among three assessed protocols. Regressive course of neurocognitive dysfunction in chemotherapy-only treatment need to be prospectively addressed. Frontal lobe FA may be a useful marker for the assessment of neurotoxicity in childhood ALL survivors.

0025

ACUTE NEUROLOGIC COMPLICATIONS IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

A Meral Günes, M Sezgin Evim, B Baytan
Uludag University, Bursa, Turkey

Background. In recent years, 5 years event-free survival in children with acute lymphoblastic leukemia (ALL) has increased to 80% with the use of intensive chemotherapy protocols. It has been noted that the frequency of the side effects also increased. One of them is neurotoxicity reported in 3-13% of children with ALL. The most common neurological complications are convulsions, cerebrovascular accidents (bleeding, stroke), infections, posterior reversible encephalopathy (PRES), peripheral neuropathy and long term neurocognitive defects. **Aims.** This study analyzed acute central nervous system (CNS) complications occurred during ALL treatment. **Patients and Methods.** A total of 265 children diagnosed as ALL between 1995 and 2010 were enrolled into the study. They all completed the full courses of ALL-BFM-95 and ALL-BFM-2000 chemotherapy protocol. We retrospectively evaluated their clinical records and collected neurological events occurred during treatment. Patients with CNS leukemic infiltration and peripheral neuropathy at diagnosis and post-treatment late-onset encephalopathy or neurocognitive defects were excluded from the study. Neurological exam, cranial magnetic resonance imaging (MRI), electroencephalography (EEG), lumbar puncture (LP) and metabolic screening for differential diagnosis were performed. None of the patients had a history of neurological abnormalities prior to the onset of ALL. **Results.** Twenty-three(5%) out of 265 children (F: 13,M:10) had developed CNS complication during therapy. Their median age at diagnosis was 4.8±2.3 years (range, 1-17.5 years). None of them presented CNS leukemic involvement at diagnosis or at the time of the neurologic event. The events were convulsion(n:12), intracranial aspergillosis (n:4), PRES(n:3), sinus vein thrombosis (n:2), inadequate ADH syndrome (n:1) and transient ischemic attack (n:1). Ten children (43%) experienced neurologic events during the induction phase. In 8 cases (34%), the events occurred during reinduction and in 5 (21%), it occurred during the consolidation phase. Outcome of the 23 patients developed CNS complications, 14(60%) stayed healthy and 9 (39%) became epileptic. One (4%) died after the development of CNS complication. **Conclusions.** CNS complications are frequent events during ALL therapy, and require rapid detection and prompt treatment to limit permanent damage.

0026

SCREENING SURVIVORS OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA FOR OBESITY, METABOLIC SYNDROME AND INSULIN RESISTANCE

N Sarper, H Karakurt, S Çaki Kilic, S Aylan Gelen, E Zengin
Kocaeli University, Kocaeli, Turkey

Bacground. Acute lymphoblastic leukemia (ALL) survivors have severe or life threatening chronic medical conditions 3.7 times more than their siblings. Among these medical conditions cardiovascular disease are quite frequent. **Aims.** Screening ALL survivors for obesity, metabolic syndrome (MS), insulin resistance (IR), hypothyroidism, insulin-like growth factor-1 (IGF-1), insulin like growth factor binding protein-3 (IGFBP-3) and prevention of cardiovascular disease by recommending healthy diets and increasing physical activity. **Methods.** Forty-four ALL survivors in first remission were enrolled. Twenty-six of them received 12-18 Gy cranial radiotherapy (RT). Patients' body mass indexes (BMI) at diagnosis and during the study were compared. BMI of the survivors were also compared with siblings. MS evaluation was performed in patients, parents and siblings older than six-years. HOMA index of the survivors was also calculated. In survivors with impaired fasting glucose levels, oral glucose tolerance test (OGTT) was performed. Thyroid functions, IGF-1 and/or IGFBP-3 levels of the irradiated survivors were also measured. **Results.** Median age was 6 years (2.5-17.5) at diagnosis and 11.5 years (6-23) during the study. Mean time following diagnosis was 5.4 (3-10) years. At diagnosis mean BMI percentile was 46.7 (3-95) and mean z score was -0.09±1.14; during the study these values raised to 71.1±25.6 (3-100) and 0.8±0.94, respectively (p<0.001). Twenty-five percent (n=11) and 48% (n=21) of the patients were obese/overweight at diagnosis and during the study respectively. At diagnosis only two patients (4.5%) had obesity whereas nine survivors (20%) had obesity (p=0.005). Survivors had significantly higher BMI-percentile and BMI-z score compared to their siblings (p=0.006 and p=0.011) (Figure 1). There was no correlation between survivors' obesity and obesity of the mother and father (p=0.3 and p=0.6 respectively). In three survivors (%6.8) there was MS. MS of the survivors had no correlation with maternal and paternal MS (P=0.1, P=0.5). In survivors exposed to RT, obesity/overweight ratio was 13/26 (50%) and MS incidence was 7.4%. Obesity/overweight and MS had no correlation with RT (p=0.7 and p=1). Among survivors exposed to RT, only three (11.5%) had thyroid dysfunction. Out of 26 survivors exposed to RT, 5 were obese and only one of these five survivors had thyroid dysfunction. There was no correlation between obesity and thyroid dysfunction (p=0.4). Out of 12 survivors with both IGF-1 and IGFBP-3 deficiency, 5(41.6%) were obese/overweight. There were no correlation between obesity/overweight and IGF-1 and IGFBP-3 deficiency (p=0.4). In 27.2% of the survivors there was IR and in 18% there was impaired fasting glucose. OGTT revealed abnormal glucose regulation and/ or IR in four of the survivors. **Summary and Conclusions. .** The incidence of obesity/overweight was significantly high in ALL survivors compared to their BMI at diagnosis and their siblings. Incidence of obesity was not correlated with RT, thyroid dysfunction and IGF-1 and IGFBP-3 levels. Incidence of MS was also higher than the normal population. Screening survivors for obesity, MS and IR and trying to improve these cardiovascular risk factors may prevent long-term morbidity and mortality.

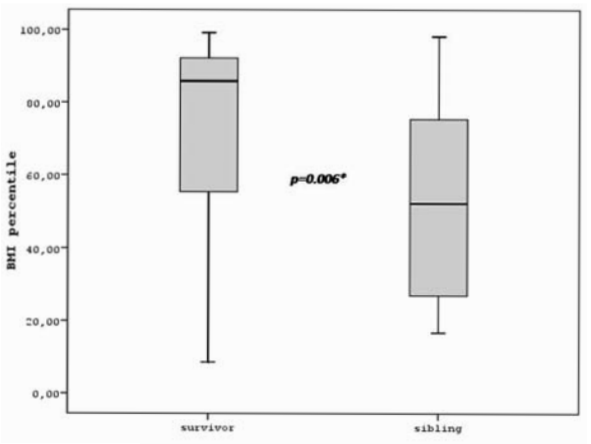

Figure 1. Body mass index of survivors and siblings.

0027

DELETIONS IN IKAROS BUT NOT ABERRANT CRLF2-EXPRESSION ARE ASSOCIATED WITH AN UNFAVORABLE PROGNOSIS IN BCRABL1 POSITIVE CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

A van der Veer[1], M Willemse[1], V de Haas[2], A Veerman[2], W Kamps[2], R Pieters[1], M den Boer[1]
[1]Erasmus MC - Sophia Children's Hospital, Rotterdam, Netherlands
[2]Dutch Childhood Oncology Group (DCOG), The Hague, Netherlands

Background. In contrast to the high success rate to effectively treat children with precursor B-ALL, the prognosis of the 3% subset of *BCRABL1*-positive patients remains poor despite high-risk treatment regimens. Deletions in *Ikaros* (*IKZF1*) and high level of expression of *CRLF2* have been associated with a poor prognosis in childhood precursor B-ALL. However, whether these markers are also prognostic in *BCRABL1* positive ALL is unknown. **Aims.** We aimed to determine the prognostic value of *IKZF1*-deletions and aberrant *CRLF2*-expression in children with *BCRABL1* positive ALL since these markers may be of potential benefit to improve risk-stratification of these patients. **Methods.** Leukemic cells of newly diagnosed *BCRABL1* positive patients enrolled in Dutch Childhood Oncology Group studies were analyzed for *IKZF1* and *CRLF2*-status. The multiplex ligation dependent probe amplification (MLPA) p335-assay (MRC Holland) was used for discovery of *IKZF1*-deletions. Data were validated by array-CGH (Agilent, 180k chip) and a second MLPA-assay (p202, MRC Holland). *CRLF2*-expression level was determined by Affymetrix U133 plus 2.0 gene expression arrays. *BCRABL1* negative precursor B-ALL cases (n=558) served as reference. A high level of *CRLF2*-expression was assigned to 10% of all cases ranked by *CRLF2*-expression level. **Results.** Deletions in *IKZF1* were found in 62% of the cases (16/26) of which 12 with a partial deletion and 4 with a complete deletion of IKZF1. Patient characteristics revealed that *IKZF1*-deleted cases had a higher leukocyte count compared to unaffected cases (p=0.007). The cumulative incidence of relapse (pCIR) with death as a competing event indicated that *IKZF1*-deleted *BCRABL1*-positive cases had an increased risk of relapse compared to those with an unaffected *IKZF1*-gene (56.3% versus 12.5%, p=0.03).The *CRLF2*-expression was median of 703 arbitrary units (p25-p75:609-739) in *BCRABL1*-positive cases versus 683 arbitrary units (p25-p75:586-847) in the *BCRABL1*-negative cases (p>0.05). Hence, high expression of *CRLF2* cannot explain the poor prognosis of *BCRABL1*-positive cases. **Conclusions.** Our data suggest that a deletion of *IKZF1,* but not high expression level of *CRLF2,* can serve as unfavorable prognostic factor within

the subset of children with *BCRABL1*-positive precursor B-ALL. In a collaborative international study the independent prognostic value of *IKZF1*-deletions in *BCRABL1* positive ALL is currently being evaluated and will be presented at the meeting.

0028

OUTCOME OF HYPERFRACTIONATED CYCLOPHOSPHAMIDE, VINCRISTINE, DOXORUBICIN AND DEXAMETHASONE (HYPER-CVAD) CHEMOTHERAPY FOR 125 ADULT PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA IN AN ASIAN POPULATION

R Yiu, H Than, Y Loh, G Wong
Singapore General Hospital, Singapore, Singapore

Background. Hyperfractionated cyclophosphamide, vincristine, doxorubicin and dexamethasone (Hyper-CVAD) chemotherapy has been commonly used for adult patients with acute lymphoblastic leukaemia (ALL) in our institution. Earlier study from Kantarjian *et al.* reported complete response rate of 92% and 5-year survival rate of 38%. Clinical response data is lacking in Asian population. **Aims.** We report our data on the efficacy of hyper-CVAD chemotherapy regimen in adult patients with ALL and the baseline characteristics of these patients in our Asian population. **Methods.** Total 125 patients aged 18 years or above were diagnosed to have ALL from January 1998 to August 2010 and received hyper-CVAD chemotherapy regimen. Forty-seven patients underwent allogeneic haematopoietic stem cell transplantation (HSCT) and their survival data were censored at the time of HSCT. Clinical, haematologic and cytogenetic data were collected retrospectively. Treatment response and survival outcome were analyzed using SPSS version 17.0. **Results.** Median age of the cohort was 39 years (range 18-67). There were 100 Chinese, 18 Malays and 4 Indians. Complex cytogenetic aberrations, t(4;11)(q21;q23), low hypodiploidy and Philadelphia (Ph) chromosome were detected in 24%, 4%, 1% and 30% of patients respectively. T-cell phenotypes were detected in 12.8% of patients. Complete remissions (CRs) were achieved in 78.4% of patients. The median time to CR was 28 days. The presence of Ph chromosome predicted poor CR rate (62% versus 89% in Ph negative ALL; p=0.017). Twenty-two of 37 Ph positive ALL patients were given imatinib concurrently with hyper-CVAD and their CR rate was better (77% versus 40% in those who did not receive imatinib; p=0.012). Five patients (4%) died during the first 2 induction cycles due to infections. Relapses occurred in 32 patients. With median follow-up of 24 months (range 1-157), the estimated 5-year survival rate was 42%. Median overall survival was 21.3 months. The median survival was significantly influenced by cytogenetic risk categories (not reached for standard-risk, 10 months for Ph chromosome, and 11 months for other high-risk cytogenetics; p=0.016). Further analysis of Ph positive ALL did not reveal any survival benefit for patients who received imatinib (with median survival 10 months versus 8.7 months for those who did not receive imatinib; p=0.98) although imatinib improved the CR rate. Among 22 patients who received imatinib, 13 of them underwent HSCT following hyper-CVAD and imatinib. With an extended median follow-up of 51 months, an improved median survival (49.6 months) was observed in Ph positive ALL patients who underwent HSCT (p=0.002). **Conclusions.** Compared to earlier data, the CR rate of 78% was lower in our adult ALL patients who were treated with hyper-CVAD regimen. This may be accounted for by a higher percentage (30%) of Ph positive ALL in our series. The 5-year survival rate of 42% in our study was otherwise comparable to results from earlier studies. The survival outcome for high-risk cytogenetic subgroup including Ph positive ALL was disappointingly poor although imatinib and allogeneic HSCT were able to improve the overall long term survival in patients with Ph positive ALL.

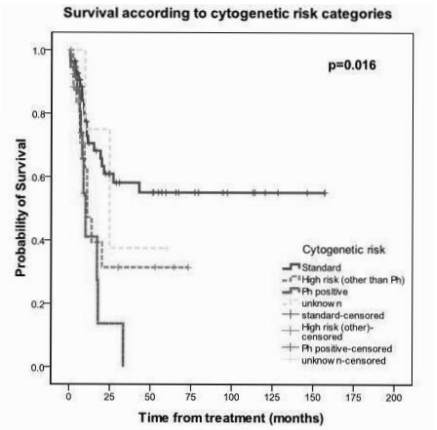

Figure 1. Survival according to cytogenetic risk categories.

0029

HONEY AND A MIXTURE OF HONEY, BEESWAX AND OLIVE OIL-PROPOLIS EXTRACT IN TREATMENT OF CHEMOTHERAPY-INDUCED ORAL MUCOSITIS: A RANDOMIZED CONTROLLED PILOT STUDY

S Elbarbary[1], A Abdulrhman[1], A Amin[2], S Ebrahim[1]
[1]Ain Shams University, Cairo, Egypt
[2]Department of Pediatrics, Cairo, Egypt

Objectives. In spite of being one of the most investigated subjects among supportive care in cancer, no therapy has been found effective in treatment of chemotherapy-induced oral mucositis. Based on the observations that honey bees products have anti-inflammatory and wound healing effects, the present study tried to evaluate the effect of topical application of honey and a mixture of honey, olive oil-propolis extract and beeswax (HOPE) in treatment of oral mucositis. **Methods.** This was a randomized controlled clinical trial conducted on 90 patients with acute lymphoblastic leukemia and oral mucositis grades 2 and 3. The mean age of enrolled patients was 6.9 yr. The patients were assigned into three equal treatment groups: Honey, HOPE and control groups. Topical treatment for each patient consists of honey, HOPE and benzocaine gel for honey HOPE and control groups, respectively. **Results.** Recovery time in grade 2 mucositis was significantly reduced in the honey group as compared with either HOPE or controls ($p < 0.05$). In grade 3 mucositis, recovery time did not differ significantly between honey and HOPE ($p=0.61$) but compared with controls, healing was faster with either honey or HOPE ($p<0.01$). Generally, in both grades of mucositis, honey produced faster healing than either HOPE or controls ($p<0.05$). **Conclusions.** Based on our results which showed that honey produced faster healing in patients with grade 2/3 chemotherapy-induced mucositis, we recommend using honey and possibly other bee products and olive oil in future therapeutic trials targeting chemotherapy-induced mucositis.

Table 1. Recovery time among studied patients.

	Recovery time (days) Mean ± SD			p		
Grade of mucositis	Group 1 (honey)	Group 2 (HOPE)	Group 3 (control)	Honey vs HOPE	Honey vs control	HOPE vs control
2	3.6 ± 0.8	4.2 ± 0.7	4.6 ± 0.9	0.0324	0.0017	0.1750
3	5.4 ±1.1	5.8 ± 2.6	8.6 ± 1.0	0.6108	0.0001	0.0012
2 and 3	4.25 ±1.25	5.75 ± 2.57	6.10 ± 2.47	0.0056	0.0005	0.5928

[7]Department of Pediatric Hematology and Oncology, Collegium Medicum, Bydgoszcz, Poland
[8]Chorzów Center of Pediatrics and Oncology, Chorzów, Poland
[9]Department of Pediatrics, Hematology and Oncology, Pomeranian Medical University, Szczecin, Poland

Background. Liposomal cytarabine for intrathecal administration is characterized by prolonged activity and better penetration to central nervous system

(CNS). This makes it promising medicine for treating children with hematopoietic malignancies relapsing in CNS or with refractory CNS disease. **Aims of the study**. The study aimed at retrospective evaluation of the effectiveness of liposomal cytarabine (Depocyte®) administrated intrathecally as a part of the treatment of hematopoietic malignancies in Polish children and adolescents. **Patients and Methods.** The study group consisted of 24 patients, 13 boys and 11 girls, treated in the centers of Polish Pediatric Leukemia/Lymphoma Study Group, including 19 patients with acute lymphoblastic leukemia (ALL), 3 patients with acute myeloid leukemia (AML) and two children with high grade Non-Hodgkin's Lymphomas (NHL). The median age of the children was 10.9 years (range: 1.3 to 18 years). Liposomal cytarabine treatment was administered on compassionate basis to 21 children with relapsed acute leukemia / NHL, a single child with secondary leukemia, one patient with severe neurotoxicity after intrathecal Methotrexate during front-line treatment and in one child with large granulocytic sarcoma, penetrating into CNS. Fourteen patients received liposomal cytarabine dosage of 50 mg, while the remaining 10 children were exposed to the doses of 25-35 mg, all in association with prophylactic dexamethasone administration. The number of liposomal cytarabine injections ranged from 1 to 11, mean 5 doses per patient. **Results.** The clearance of CNS disease was achieved in 17 of 24 patients (71%). Eleven children were alive during the follow-up procedure, including 7 patients in complete remission after treatment completion. Grade IV neurotoxicity was observed in five children, which might be also partly related to CNS malignancy. Another side effects occurred in 4 patients, including headache, vertigo, paresthesias and seizures. **Conclusions.** Liposomal cytarabine administered intrathecally is effective treatment for CNS disease in children with relapsed acute leukemia/NHL with acceptable toxicity profile.

0031

ASSESSMENT OF HEALTH RELATED QUALITY OF LIFE IN CHLDREN WITH CANCER DURING THERAPY

M Beshir, M Hesham, E El-Safy, H Zordok
Faculty of Medicine, Zagazig Univerity, Zagazig, Egypt

Background. the increased survival o cancer patients may be accompanied by long term burden for some individuals related to the unique characteristics of their cancer diagnoses and its treatment on their educational, psychological and social development. Thus the identification of subgroups of childhood cancer survivors at risk for poor HRQoL is important for development of new strategies as well as determination of treatments promoting long term survival and reducing risk for poor HRQoL outcomes will be a goal. **Aims.** to assess quality of life (QoL)of children with newly diagnosed cancer at one and three months of starting therapy, and to obtain effects of sex, age, type of malignancy, stage of the disease and treatment on quality of life of those children. **Patients and Methods.** A descriptive study was carried out on the newly diagnosed children with cancer during treatment at Pediatric Hematology Oncology Unit, Zagazig University Children Hospital during period between Jan 2011 and Jan 2012. In this study we use PCQL-32 questionnaires to measure HRQoL in pediatric cancer patients. This scale defines HRQoL in five items that measures impact of disease and treatment on the individual's physical, social, psychological, cognitive functioning and disease/treatment -related symptoms. It assesses both patient's and parent's perceptions of child' HRQoL. **Results.** This study was conducted on fifty newly diagnosed cancer patients, their mean age was 9±2.5 years old, 54% of them were males and 46% females. Thirty patients were diagnosed as leukemia, while twenty cases as solid tumors. Eighty % of our patients were received chemotherapy, while 14% were received Radiotherapy and only 6% received combined therapy. QoL of children at three months was significantly better than QOL at one month of therapy in all functioning and there was Strong correlation between child and mother report at one and three month in all functioning of QOL. No significant difference between two types of malignancy and child QoL at one and three months of therapy. There was a better quality of life in children received radiotherapy only than other types of treatment at one month, while at three month children received only chemotherapy had better QoL. There was significant difference between age groups in cognitive function, with better functioning in the youngest age at one and three months of therapy. There was no significant difference between both sex at 1&3 months. There was a significant difference among birth order groups with worst of the 4th or more order. QoL of children to the youngest mothers and highly educated parents was better than those to older mothers or low educated parents respectively. **Conclusions.** HRQoL in childhood cancer survivors mainly affected by time elapsed since diagnosis, stages of cancer and type of treatment while most of sociodemographic factors has no or little effect which limited to one month only, this indicates that to improve QoL of those children, we have to improve their treatment and psychological support for both children and parent to facilitate their coping with disease and its treatment.

Acute myeloid leukemia - Biology 1

Background. Acute myeloid leukemia with normal karyotype (AML-NK) corresponds to a heterogeneous disease with diverse clinical outcomes, thus requiring an efficient risk-stratification. Recently Single-nucleotide polymorphism array (SNP-A) analyses have revealed previously unrecognized copy number abnormalities (CNA) and uniparental disomy (UPD) that might be helpfull for a better risk-stratification in this subset of AML. **Aims.** Analysis of the prognostic significance of SNP-A-based karyotyping in a homogenous treated cohort of older AML-NK (50-70 years) with a previously untreated *de novo* AML. **Patients and Methods.** We performed Affymetrix SNP6.0 array analysis in a cohort of 117 AML-NK enrolled in the randomized multicentric phase 3 ALFA0701 trial (NCT00927498) comparing induction with daunorubicine and cytarabine without (DA-arm) or with Gemtuzumab-Ozogamicin (GO)(DAGO-arm). **Results. :**Median age of our patients was 61 years (range, 50 to 70 years) and 54 patients (46%) were male and 63 (54%) were female. We demonstrate the presence of 69 cryptic genomic aberrations in 47 patients (40%) consisting of 13 deletions (13 patients), 11 gains (11 patients) and 45 regions of UPD (33 patients). The median size of deletions was 2 Mb (0.15Mb-18Mb) and of gains was 0.5Mb (0.12-1.4Mb).The median size of UPD's was 42 Mb (3Mb-158Mb). Chromosome 13(q12.11-q34) and 1(p36.31-p36.21) were the most frequently affected with UPD observed in 8 and 5 patients, respectively. All 8 patients with UPD of chromosome 13 had this occurrence in sub-clones and all harbored *Flt3-ITD*. There were no significant correlations between the presence of genomic aberrations and age, sex, WBC, or mutations *in NPM1, CEBPA, TET2, IDH1*/2, *FLT3*-ITD or *DNMT3a*.The median duration of follow-up from time of diagnosis of the study group was 17.5 months (range 1-43). Patients with abnormal SNP-A lesions compared to those without, did not show a significant different complete remission rate (87% vs 93%;p=0.34) or a 2 year cumulative incidence of relapse (56.6% vs 56.9%;p=0.46). Resulting EFS did not differ significantly in patients with abnormal SNP (HR=1.52, 95%CI:0.93-2.48; p=0.10). By contrast, overall survival (OS) was shortened in AML with SNP-A lesion (HR=1.85, 95%CI:1.02-3.34;p=0.043). Patients with number of abnormalities (≥2) had a highly worse OS (HR=2.41, 95%CI:1.15-5.06; p=0.020) and EFS (HR= 2.41,95%CI:1.25-4.63; p=0.008). DA-arm when compared to DAGO-arm, have a significantly shorter OS (HR= 0.54, 95%CI: 0.29-0.99; p= 0.046) and EFS (HR=0.50, 95%CI 0.30-0.83; p=0.007). In DA-arm we found a very poor prognosis impact of SNP-lesions on both OS (HR= 2.93, 95%CI:1.33-6.46; p= 0.008) and EFS (HR= 2.89, 95%CI:1.45-5.78;p=0.003). By contrast, DAGO-arm erase the prognostic value of the SNP lesions on both OS (HR= 1.49, 95%CI: 0.60-3.72; p= 0.39) and EFS (HR=1.26, 95%CI: 0.59-2.68; p= 0.56). Similarly none genes mutations studied (*NPM1, CEBPA, TET2, IDH1*/2, *FLT3*-ITD, *DNMT3a*) impact on OS and EFS of DAGO-arm patients. Very interestingly a significantly shorter EFS in DAGO-arm was restricted to patients with ≥2 SNP-A abnormalities (HR=2.58, 95%CI: 1.08-6.13; p=0.032). **Conclusions.** We conclude that SNP-A Karyotyping improve outcome prediction in older AML-NK. In particular a number of SNP-A abnormalities ≥2 is a strong poor prognosis marker.

LYSOPHOSPHATIDIC ACID (LPA) ENHANCES MOTILITY AND PROLIFERATION OF HEMATOPOIETIC STEM CELLS AND CONTRIBUTES TO THE PATHOGENESIS OF ACUTE MYELOID LEUKEMIA (AML)

C Ortlepp, S Koch, T Schildberg, C Heiderich, S Brenner, M Bornhäuser, G Ehninger, C Thiede
University Hospital Dresden, Dresden, Germany

Activating mutations of the FLT3 receptor tyrosine kinase, especially the internal tandem duplication (FLT3-ITD) are among the most common abnormalities in adult AML. These mutations induce ligand independent constitutive activation of the receptor and downstream signaling pathways, including RAS/ERK, PI3K and STAT5-signaling. Several lines of evidence suggest that FLT3-ITD

mutations induce an aggressive disease, characterized by a high rate of disease recurrence and poor clinical outcome.To better understand the specific phenotype induced by FLT3-ITD mutations, we performed microarray expression analysis of primary leukemic samples from patients with different types of FLT3-mutations. One gene specifically upregulated in FLT3-ITD+ AML was *ENPP2* coding for Autotaxin (ATX). The ATX protein acts as a secreted lysophospholipase D (lysoPLD) by converting lysophosphatidylcholine (LPC) to the lipid mediator lysophosphatidic acid (LPA), which signals via G-protein coupled LPA receptors (LPAR1-6) and has important functions in cell migration and proliferation. The current study demonstrates that ATX expression is specifically upregulated and functionally active in acute myeloid leukemia (AML) harboring an internal tandem duplication (ITD) mutation of the FLT3 receptor gene.ATX expression was evaluated in different leukemic cell lines and hematopoietic stem cells using RT-Q-PCR, Western blot, and functional assays. Chemotaxis was studied with transwell migration assays and clonogenic potential was determined with colony-forming assays. Results were verified by retroviral transduction of ATX into ATX-negative THP-1 cells. In addition, the effect of ATX inhibition was evaluated using a novel ATX-specific inhibitor, ACD-0708.ATX was found to be highly expressed in AML cells, especially in cells harboring FLT3-ITD. Comparable ATX expression levels were also found in CD34+ cells, whereas mature cells showed significantly lower ATX expression. ATX-expression led to increased migration towards LPC, whereas ATX neg. cells showed no significant response. LPC-mediated migration in MV4-11 cells could be blocked by PKC412, a tyrosine kinase inhibitor, indicating the causative role of FLT3-ITD. Moreover, LPC-induced chemotaxis was blocked upon JUN dephosphorylation and inhibition of ATX using the small molecule inhibitor ACD-0708, respectively. LPA increased chemotaxis in human leukemic cell lines and CD34+ progenitors in a dose dependent manner by at least 50%. The LPC/LPA-induced chemotaxis in MV4-11 cells was sensitive to inhibition by pertussis toxin and Ki16425, a LPAR1/3 selective LPA-inhibitor. The observation that LPA3 was not expressed in MV4-11 cells indicates that migration is dependent on the presence of LPAR1. Moreover, ATX expression increased colony-forming capacity in the presence of LPC or LPA by 40% and 75%, respectively. Vice versa, inhibition of ATX using ACD-0708 selectively induced killing of ATX-expressing cell lines.Our data indicate that the ATX-LPA axis contributes to proliferation and migration of hematopoietic stem cells and that aberrant ATX expression may support the pathogenesis of FLT3-ITD positive AML.

DEEP SEQUENCING REVEALS ALLELE-SPECIFIC HYPERMETHYLATION AT 14Q32 IMPRINTED DOMAIN IN ACUTE PROMYELOCITIC LEUKAEMIA (APML)

F Manodoro, J Marzec, J Wang, T Chaplin, B Young, S Debernardi
Barts Cancer Institute, London, United Kingdom

BackgroundEmerging evidences have showed that epigenetic alterations, including DNA methylation, occur at a very early stage of the tumorigenic process. Therefore the identification of specific loci that undergo DNA methylation changes might identify genes and factors important for disease progression. In chromosome 14q32, the DLK1/DIO3 domain harbors differentially methylated regions (DMRs) that regulate the expression of imprinted genes by the modulation of the allelic CpG methylation pattern. The intergenic DMR (IG-DMR), located between the genes DLK1 and MEG3, is the imprinting control region (ICR) and operates hierarchically on the secondary MEG3-DMR that resides in the MEG3 promoter. Previous studies showed that a subset of microRNAs clustered downstream MEG3 and regulated coordinately with MEG3 is overexpressed in APML only.AimsThe aim of the study is to determine whether the methylation profile of IG-DMR and MEG3-DMR is altered in APML leading to overexpression of miRNAs. Furthermore, since DNA methylation is differentially distributed between the two alleles, we aim to obtain the allelic methylation pattern of the DMRs.MethodsNine regions overlapping IG-DMR and MEG3-DMR were selected for high-throughput amplicon sequencing with Roche 454 GS FLX Titanium. Amplicon libraries were obtained from bisulfite treated genomic DNA from APML cases, including diagnostic and remission sample pairs, healthy donors and additional acute myeloid leukaemia (AML) subclasses. Sequence output was analysed with QUMA (http://quma.cdb.riken.jp). UCSC database (http://genome.ucsc.edu/) was used to search for SNPs among the regions selected.ResultsWe generated 1,093,266 sequence reads with an average read length of 399 bp. Reads were aligned to the germline sequence and, after filtering out the reads that did not meet the quality criteria, 923,981 sequences were used to determine the methylation status of a total of 202 CpGs. Unsupervised hierarchical clustering showed that APML was predominantly hypermethylated as compared to normals. Pair wise T-test performed between diagnosis/remission APML sample pairs confirmed that the onset of the disease was associated with increase of DNA methylation in 14q32. CpGs affected by aberrant methylation were not randomly distributed across the regions, but organized in a specific pattern included in the MEG3-DMR. Notably, statistical analysis performed on the IG-DMR did not provide any evidence of DNA methylation changes affecting the ICR. We next identified heterozygous SNPs in the selected regions and conducted allele-specific methylation analysis. Results showed that hypermethylation arises in a mono-allelic manner, retaining a conservative pattern on the other allele (Figure 1). **Summary and Conclusions. .** APML is associated with allele-specific hypermethylation at the MEG3-DMR, a regulatory region embedded in DLK1/DIO3 imprinted domain. In contrast, the methylation profile of the ICR remains unchanged. These findings indicate that in APML aberrant epigenetic profile might lead to altered expression of regulated genes without imprinting disruption.

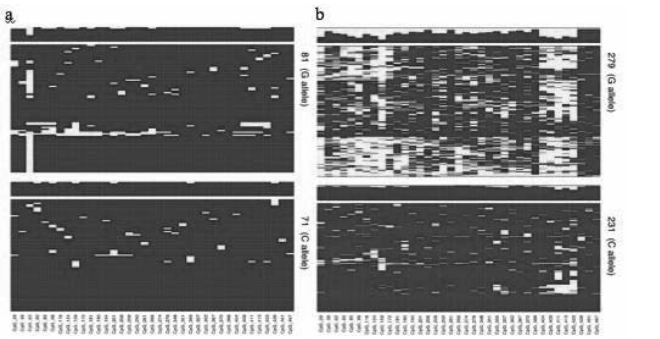

Figure 1. Allele-specific hypermethylation in APML. a) diagnosis; b) complete remission. Grey, methylated; white, not methylated.

THE EFFECTS OF HISTONE DEACETYLASE INHIBITORS ON THE MALIGNANCY OF T(6;9)-DEK/CAN-POSITIVE LEUKEMIA

M Ruthardt, C Oancea, A Romanski, S Ahmad, M Heinssmann, A Vogel, S Wietbrauk, J Roos, H Serve, G Bug, M Ruthardt
Goethe University, Frankfurt, Germany

Background. Acute myeloid leukemia (AML) is characterized by an abnormal accumulation of hematopoietic progenitors in the bone marrow (BM). The AML phenotype is maintained by an accelerated proliferation due to a differentiation block that prevents progenitors from reaching the post-proliferative stage of blast cells. This is supported by the aberrant stem cell capacity of poorlydefined leukemic stem cells (LSC). Specific chromosomal translocations, such as t(8;21), t(15;17), t(6;9) represent the leukemia initiating event. The related AML associated fusion proteins (AAFPs) such as PML/RAR, AML-1/ETO or DEK/CAN recapitulate the leukemic phenotype *in vitro* and *in vivo*. Most of the AAFP interfere with the epigenetic regulation of transcription by modifying key processes of chromatin modeling such as histone acetylation and methylation as well as DNA methylation. In the DEK/CAN fusion protein all the chromatin binding domains of DEK are conserved and we recently showed that DEK/CAN is associated to chromatin and strongly interferes with chromatin modeling by inhibiting the decondensation of chromatin and accessibilityto transcription. **Aims.** Here we investigated, whether it is possible to revert the leukemogenic potential of DEK/CAN by histone-deacetylase (HDAC) inhibitors (HDACi) such as Valproic acid (VPA), Dacinostat and Vorinostat. **Methods.** The effects of the HDACi on histone acetylation and methylation were studied by Western blotting and intracellular FACS on DEK/CAN-expressing human U937 cells. Modifications of the differentiation potential and the stem cell capacity was assessed in retrovirally transduced primary murine HSC in liquid culture, by replating efficiency and colony forming unit spleen day 12 (CFU-S12) assay, respectively. Furthermore we used a mouse model of DEK/CAN-positive leukemia and a xenograft model based on human t(6;9) positive cells inoculated in NSG mice. **Results.** Here we show that i.) DEK/CAN interferes with thee chromatin decondensation by Dacinostat in U937 cells; ii.) HDACi with the exception of VPA induce differentiation of DEK/CAN-positive murine HSC and reduced their replating efficiency; iii.) Dacinostat most efficiently as compared to the other HDACi abolished the stem cell capacity of DEK/CAN-positive leukemic stem cell as revealed by a strongly reduced number of colonies in a colony forming unit spleen day 12 assay (CFU-S12), in which DEK/CAN was not anymore detectable even by RT-PCR upon exposure to HDACi; iii.) exposure to the HDACi prevented leukemia induction in the xenograft model, without interfering with the engraftment. **Summary.** Our here presented results suggest that the HDACi even with different efficacy are able to reveert with the malignancy of DEK/CAN-positive leukemic cells.

GENOME-WIDE GENOTYPING OF *de novo* AND THERAPY-RELATED ACUTE MYELOID LEUKEMIA WITH T(9;11)(P22;Q23) REVEALS NOVEL RECURRENT GENOMIC ALTERATIONS

M Kühn[1], L Bullinger[1], J Edelmann[1], J Krönke[1], S Gröschel[1], F Rücker[1], P Paschka[1], V Gaidzik[1], K Holzmann[2], R Schlenk[1], H Döhner[1], K Döhner[1]

[2]Microarray Core Facility, University of Ulm, Ulm, Germany

Background. Rearrangements of the mixed-lineage leukemia (*MLL*) gene play an important role in the development of acute leukemia. In acute myeloid leukemia (AML), translocation t(9;11)(p22;q23) *MLLT3-MLL* is the most common genetic alteration involving *MLL.* Translocation t(9;11) can be found in *de novo* AML as well as in therapy-related AML (t-AML). Clinically, t(9;11)-associated AML is characterized by a broad heterogeneity and secondary genetic events have been discussed to underlie these heterogeneous phenotypes. **Aims and Methods.** To identify additional genetic alterations in t(9;11)-positive AML, we performed single nucleotide polymorphism (SNP)-array analysis of 40 diagnostic leukemia samples [*de novo* AML: n=22; t-AML: n=14, unknown: n=4]. Control-DNA from remission bone marrow or peripheral blood was available for paired analysis in 15 cases (38%). Data were processed using reference alignment, dChipSNP, and circular binary segmentation. In addition, gene mutation/expression status was determined for a set of genes, known to be frequently altered in AML (*FLT3* [ITD and TKD], *NPM1*, *IDH1*/2, *DNMT3A*, *TET2*, *NRAS*, and deregulated expression of *EVI1*). **Results.** Paired analysis revealed a mean of 1.9 somatic copy number alterations (CNAs) per case (range: 0-12); 50 % of cases lacked any CNAs. There were no significant differences in the mean number of CNAs between *de novo* and therapy-related cases [*de novo* AML: 1.1 (range: 0-4); t-AML: 2.8 (range: 0-13); *p*=0.78]. Recurrent deletions were detected at chromosomal bands 7q36.1-36.2 (n=2; *de novo*: n=1; t-AML: n=1) and at the chromosomal translocation breakpoint 11q23 (n=4; *de novo*: n=3; t-AML: n=1). The del(7)(q36.1-36.2) partly overlapped with the minimally deleted region that we previously identified in 8% of core-binding factor AML. The only gene located in both regions was *MLL3*, a member of the mixed-lineage leukemia gene family. The most recurrent gain was trisomy 8 [n=8 (20%)], which was also detected by conventional cytogenetics in all cases. Trisomy 8 was more commonly found in *de novo* AML than t-AML (6/22; 27% vs. 1/14; 7%). Novel recurrent focal gains were identified at 9p22.1 (n=2; size: 341 Kb) and at 13q21.33-q22.1 (n=2; size: 1021 Kb) with each region harboring genes potentially involved in cancer pathogenesis (*ACER2* in 9p; *KLF5* in 13q). Notably, no copy number neutral loss-of-heterozygosity (CN-LOH) was detected in the 40 cases. Mutation analysis revealed mutations in *FLT3* (ITD; 2/36 (6%); TKD; 3/29 (10%); *NPM1* 2/31 (7%), and deregulated *EVI1* expression in 8/16 (50%) patients; none of the cases showed mutations in *IDH1*/2 [0/29], *DNMT3A* [0/19], *TET2* [0/15], and *NRAS* [0/6]. **Summary and Conclusions.** AML with t(9;11) is characterized by remarkably few CNAs; we found no substantial differences between *de novo* and therapy-related cases with regard to lesion-/mutation type or frequency. Nevertheless, we were able to identify new recurrent lesions as e.g. deletions in 7q36.1-36.2. Determining their functional role in leukemogenesis and drug resistance will provide new insights into the pathogenesis of t(9;11)-rearranged AML.

PHENOTYPICAL AND FUNCTIONAL ABNORMALITIES OF MESENCHYMAL STEM CELLS FROM ACUTE MYELOID LEUKEMIA PATIENTS

J Domenech[1], T Charbonnier[1], L Desbourdes[2], A Iltis[1], J Javary[2], A Gauthier[2], E Gyan[1], O Herault[1]
[1]University of Tours & CHRU Tours, Tours, France
[2]University of Tours, Tours, France

Background. Contribution of stromal cell compartment to the leukemogenesis process remains controversial. Thus, although abnormalities of stromal cells (which do not belong to malignant clone) have been reported in acute myeloid leukemias (AML), recent data from animal models suggest that genetic changes in stromal cells can induce myelodysplastic syndromes and secondary leukemias (Raaijmakers et al. Nature 2010;464: 852-7). **Aims.** In the present work, we studied the phenotypical and functional properties of mesenchymal stem cells (MSCs) from AML patients compared to normal controls. **Methods.** Bone marrow-derived MSCs have been obtained from 12 AML patients (5 AML0/1, 3 AML3, 4 AML4/5) and from 6 normal controls (harvested during orthopedics surgery). MSCs were cultured in alphaMEM medium supplemented with 10% FCS and 1ng/mL FGF2. The following analyses have been performed : proliferative capacity (evaluated by population doubling time or PDT), cloning efficiency (evaluated by CFU-F assay), immunophenotypical characteristics (CD45, CD34, CD14, CD90, CD73, CD105, CD106, CD271, CD146, CD31, CD309, CD49d, CD49e), mesenchymal differentiation capacity (towards adipocytic, osteoblastic and chondrocytic lineages), and secretion capacity of essential niche factors including SDF-1 (CXCL12), SCF (stem cell factor) and Ang-1 (angiopoietin-1). All these analyses have been carried out at the end of the 2nd passage. **Results.** While no evident differentiation deficiency towards adipocytic, osteoblastic or chondrocytic pathways was found, a clear decrease of CFU-F frequency was noted in most of the AML patients (8/12 patients). These 8 patients (AML-Clono^{low}) were present in all FAB groups and did not display any particular feature, considering age, sex, cytogenetic and molecular, abnormalities, or clinical evolution. Compared to normal MSCs, MSCs/AML-Clono^{low} tended to display prolonged PDT (p=0.071) and were associated with lower expression levels of VCAM-1 (p=0.014). Compared to MSCs/AML-Clono$^{norm/high}$, MSCs/AML-Clono^{low} displayed decreased PDT (p=0.041) with decreased secretion capacity of SDF-1 (p=0.007) and in a lesser extend of Ang-1 (p=0.027) without clear change in SCF secretion (p=0.126). **Summary and Conclusions.** Our study showed that BM-derived MSCs from most of AML patients display proliferative and clonogenic deficiency. These abnormalities are associated with a decreased expression of niche factors which are essential for hematopoietic stem cell control. To better characterize MSCs from AML patients, large and middle scale studies of gene expression profile are in progress together with their normal and leukemic hematopoiesis supportive capacity.

[4]P.O. „S.Vincenzo„, Taormina, Italy
[5]Policlinico Università degli Studi di Palermo, Palermo, Italy
[6]Università degli Studi di Catania, Catania, Italy

Acute myeloid leukemia (AML)represents a heterogeneous disorder with recurrent chromosomal alterations and molecular abnormalities. Among AML with normal kariotype (NK-AML)FLT3 activating mutation, internal tandem duplication (FLT3-ITD), is present in about 30% of patients, conferring unfavorable outcome. Our previous data demonstrated specific up-regulation of miR-155 inFLT3-ITD+ AML. miR-155 is known to be directly implicated in myeloid hyperplasia and/or hematopoiesis. Our aim was to integrate data from different source as GEO gene expression database and MIR@NT@N prediction tool to achieve a model about the role of miR-155 inFLT3-ITD+ AML and to validate this by experimental analysis. In this study we applied a four steps strategy. At the first step, using gene expression dataset from GEO database, we generated the transcription factors co-regulation network acting in FLT3 mutated AML and at the same time, we predicted the miR-155-TF connections by MIR@NT@N. In the second step, we extracted, from the general network, the module of transcription factors connected to miR-155. At the third step, we compared the mir-155 module with the canonical pathways. At the final step, using a new cohort of newly diagnosed AML patients, we verified the expression levels of most intriguing hubs and correlated them to miR-155 expression levels. From these analyses, we derived a sub-network, called “miR-155 module”that describes functional relationship among miR-155 and transcription factor in FLT3-ITD+ AML. We confirmed a strong up-regulation of miR-155 in the FLT3-ITD+ AML. We found that “miR-155 module”is characterized by the presence of six transcription factors as central hubs: four miR-155 regulators (JUN, RUNX1, FOSb, JUNB) and two targets of miR-155 (PU.1, CEBPB) all known to be “master”genes of myelopoiesis. We found, in FLT3-ITD+ AML, a significant down-regulation of miR-155 target genes *CEPB-beta* and *PU.1* (respectively 0.354 fold p=0.000 and 0.404 fold p= 0.000) and up-regulation of miR-155 regulator genes JUN and RUNX1 (2,597 fold p=0.0210 and 2,64 fold p<0.0001 respectively). We described, for the first time, a regulatory pathway that connects FLT3-ITD mutation, a poor prognostic marker for AML, to reduced expression of TFs master regulators of myelopoiesis. Our results suggest that activating mutation of FLT3 in AML can lead, through the induction of JUN, to increased expression of miR-155, which then causes down-regulation of *PU.1* and *CEBP-beta* and consequently causes block of myeloid differentiation. More simply, FLT3- ITD → ↑JUN → ↑miR-155 → ↓PU.1 ↓CEBPbeta → ↓Myelopoiesis. In conclusion our study consolidates data on miR-155 association with FLT3-ITD+ AML, describes an integration of sequence-based prediction analysis with expression network that individuates vertices involved in the molecular pathogenesis of FLT3 mutated AML, suggests a molecular pathway

that starting from in FLT3 activating mutation, through miR-155, damages myeloid differentiation. We also suggest that miR-155 deregulation may act as central hub in the multi-steps mechanism of FLT3 mutated leukemogenesis offering new therapeutic strategies.This work was supported by a grant of Associazione Italiana Ricerca sul Cancro (Project IG 10701 AIRC)

DIFFERENTIAL DNA METHYLATION IN AML PATIENTS WITH WILD-TYPE AND MUTATED DNMT3A AND PROGNOSTIC IMPACT OF DNA METHYLATION

H Hájková[1], J Marková[1], C Haškovec[1], R Petrboková[1], I Šárová[1], O Fuchs[1], A Kostecka[1], P Cetkovský[1], K Michalová[2], J Schwarz[1]
[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic
[2]General University Hospital and 1st Faculty of Medicine, Prague, Czech Republic

Introduction. DNA methylation has been established as a mechanism playing an important role during the process of leukemogenesis. Mutations in *DNA methyltransferase 3A (DNMT3A)* gene have been found in patients with acute myeloid leukemia (AML) and have been shown to be associated with adverse clinical outcome. **Aims.** We studied the relationship between DNA methylation status of selected genes and *DNMT3A* mutational status and also the impact of DNA methylation on the patients' prognosis. **Patients and Methods.** We examined 79 AML patients at diagnosis (intermediate and high cytogenetic risk) and 20 healthy donors for the presence of aberrant DNA methylation of 12 tumor suppressor genes (TSG) (*CDKN2B*, *CALCA*, *CDH1*, *ESR1*, *SOCS1*, *MYOD1*, *DAPK1*, *TIMP3*, *ICAM1*, *TERT*, *CTNNA1*, *EGR1*) by MethyLight and for mutations in the gene *DNMT3A* by direct sequencing. We also studied methylation status of 24 HOX genes using methylation-restriction endonucleases followed by RQ-PCR arrays in 10 AML samples compared to 4 healthy donor samples. **Results.** Sequencing of cDNA between amino acids 300 and 930 revealed that 32 of 79 AML patients had *DNMT3A* mutation. MethyLight assessment of 12 TSG showed the following frequencies of hypermethylation: *CDKN2B* (47%), *CALCA* (43%), *CDH1* (22%), *SOCS1* (24%), *MYOD1* (18%), *ESR1* (14%). The remaining 6 genes were weakly methylated in less than 10 % AML patients at diagnosis and were therefore excluded from further analysis. Comparing overall cumulative DNA methylation levels and numbers of simultaneously hypermethylated (HM) genes to mutational status of *DNMT3A* gene, we found lower levels of DNA methylation (P<0.0001) as well as lower numbers of concurrently hypermethylated genes (P<0.0001) in patients with *DNMT3a* mutations. We observed the same trend also in DNA methylation levels of HOX genes when comparing AML patients with mutated (n=4) versus wild-type (n=6) *DNMT3A*. Furthermore, DNA methylation levels or numbers of HM genes were independent of age, gender, percentage of blasts (PB and BM) or cytogenetic risk group (intermediate versus high risk). When assessing DNA methylation impact on prognosis we found a correlation between higher DNA methylation (cumulative levels and numbers of HM genes, respectively) and increased overall survival (OS) (P=0.03 and P=0.01, respectively) as well as lower incidence of relapse (P=0.05 and P=0.01, respectively). For individual genes, *SOCS1* was found to be significantly linked with better OS (P=0.04). **Conclusions.** Our results show that numbers of simultaneously hypermethylated genes and DNA methylation levels of selected TSG as well as HOX genes differs between AML patients with wild-type and mutated *DNMT3A*. Increased DNA methylation of these TSG is linked with better prognosis in AML patients.This study is a part of the COST Action BM0801 (EuGESMA) and is supported by the Czech Ministry of Education, Youth and Sports (MŠMT) OC10042 grant.

TEL2/ETV7 IS A COOPERATING FACTOR IN THE LEUKEMOGENIC TRANSFORMATION OF MN1-TEL T(12;22)(P13:Q11) KNOCK-IN MURINE MYELOID CELLS *IN VITRO*

M Numata, I Klein-Geltink, S Surtel, C Grosveld
St.Jude Children's Research Hospital, Memphis, United States of America

The MN1-TEL fusion oncoprotein in human myeloid leukemia is a product of t(12;22)(p13;q11) chromosomal translocation and consist of N-terminal MN1 and C-terminal of TEL1/ETV6 sequences. Previously, our studies have shown that MN1-TEL knock-in mice, in which the *MN1-TEL* transgene is under the control of the *Aml1* regulatory sequences, developed T-lymphoid tumors with 30% penetrance after a long latency period. Furthermore, 90% of mice receiving transplants of Hoxa9-transduced MN1-TEL knock-in BM succumbed to acute myeloid leukemia much more rapidly than mice receiving transplants of control Hoxa9-transduced BM. These results indicated that the leukemogenic effect of MN1-TEL in our knock-in mice is pleiotropic and the cooperating secondary mutation determines the type of leukemic disease outcome. *TEL2/ETV7* is highly homologous to the ETS transcription factor *TEL1/ETV6*, a frequent target of chromosomal translocation in human leukemia. We have shown that TEL2 cooperates with Myc in B lymphomagenesis and ectopic expression of TEL2 in mouse bone marrow causes myeloproliferative disease with a long latency, indicating that TEL2 is a hematopoietic oncoprotein requiring cooperating mutations to induce leukemic transformation. However, the molecular mechanism of TEL2-mediated leukemogenesis in myeloid cells remains to be clarified. *TEL2* expression is upregulated in 70% of ALL or AML samples and 3 out of 3 leukemic MN1-TEL BM samples showed a 2-16 fold upregulation of *TEL2* expression compared with normal BM. Thus, we wished to determine if elevated TEL2 expression cooperated in the leukemogenic transformation in our MN1-TEL mouse model. Here, we focus on the tumorigenic function of TEL2 in context of MN1-TEL knock-in murine bone marrow cells *in vitro*. To induce elevated TEL2 expression, we transduced lineage-negativeBM cells of MN1-TEL$^{+/-}$ mice with lentiviruses encoding *TKp-TEL2-IRES-YFP* or *TKp-IRES-YFP*, which were then cultured in medium supplemented with myeloid cytokines (mIL3, hIL-6 and mSCF). After long-term culture, TEL2-expressing myeloid cells doubled 2-fold faster than control cells in an IL-3-dependent manner. Annexin V staining showed that the rate of apoptosis in TEL2-myeloid cells was 5-fold lower than in control cells. Moreover, TEL2-myeloid cells were more resistant to cytokines withdrawal-induced cell death than control cells. Using quantitative RT-PCR, the expression level of *Bcl-2* was slightly but significantly elevated in TEL2-myeloid cells. In silico analysis identified a highly conserved putative ETS-binding site in *Bcl-2* promoter region. ChIP assay with anti-TEL2 antibody using U937T-TEL2 human monocyte cell line showed that TEL2 specifically bound to the conserved ETS binding site in the human *Bcl-2* promoter region, suggesting that TEL2 directly upregulates *Bcl-2* expression in myeloid cells. These results suggest that TEL2-mediated upregulation of Bcl-2 in MN1-TEL-expressing myeloid cells causes inhibition of apoptosis and might convey a proliferative advantage to MN1-TEL-positive AML cells.

[2]National Taiwan University, Taipei, Taiwan
[3]National Taiwan University Hospital, Taipei, Taiwan

Background. Phosphoinositide 3-kinases (PI3Ks)/Akt cascade has been found to regulate cell survival, proliferation, and differentiation in a variety of cells. Taking-over upstream signaling from receptor tyrosine kinases (RTKs) or G protein-coupled receptors (GPCRs), activated PI3K further transfers signals to downstream components such as PDK1 and Akt constructing a classical PI3K/AKt pathway. Recent comprehensive genomic analyses of cancers have linked genetic mutations or alterations of critical components in PI3K pathway together with several human cancers. This pathway therefore appears an opportunity for cancer therapy target. PI3K pathway aberration has also been found in patients with acute myeloid leukemia (AML), implicating as a causal

factor in leukemogenesis and drug resistance in AML. **Aims.** Akt makes up one of the major nodes in PI3K pathway so that it has been an important target for specific inhibitors developed by many pharmaceutical companies and academic laboratories. The purpose of this study was to characterize the therapeutic potency and antitumor mechanisms of MK-2206, a specific allosteric Akt inhibitor, in AML. **Methods.** Human leukemia cell lines U937, OCI/AML3, MV-4-11 as well as MOLM-13 and primary AML blast cells from patient were used as *in vitro* and *ex vivo* models for this study. MTS assay was used to determine the effect of MK-2206 on cell viability in AML cells. Western blotting, flow cytometry and quantitative real-time PCR were applied to clarify molecular mechanisms of MK-2206 in AML cells. **Results.** We found that MK-2206 exerted more cytotoxic effect to AML cells in comparison with normal PBMC (IC_{50}: 0.6-2.5 μM vs. 18.8-19.5 μM) suggesting a drug potency with biosecurity. Treatment of MK-2206 results in dose-dependent cell cycle arrest at G1 phase and/or apoptosis induction in all AML cells we tested and primary AML blasts. Further analysis of pro- or anti-apoptotic proteins after MK-2206 treatment revealed that MK-2206 exerts a fast and lasting effect on down-regulation of Mcl-1 in all AML cells we tested. Further elucidating the mechanism how to modulate Mcl-1 expression was explored. We found that MK-2206 treatment did not affect Mcl-1 mRNA expression even at 10 μM for 24hrs, completely ruling out the transcriptional regulation of MK-2206 to Mcl-1 in this issue. We also found that MK-2206 could decrease inactive form of GSK3β (p- GSK3β) accompanying with decreased Mcl-1 within 2 hrs after treatment, suggesting a post-translational mechanism involved. MG-132, a proteasome inhibitor, could rescue Mcl-1 down regulated by MK-2206, confirming the effect of MK-2206 associated with proteasome-dependent degradation. Lithium, an inducer of GSK3β phosphorylation, could also rescue Mcl-1 down regulated by MK-2206, demonstrating that the effect of MK-2206 on modulating Mcl-1 levels is through GSK3β signaling. Taken together, these data highlight a mechanism that MK-2206 would inhibit the Mcl-1 accumulation through activating GSK3b activity and enhancing subsequent proteasome-dependent degradation of Mcl-1. **Conclusions.** MK-2206 showed therapeutic potency in AML treatment and this effect is trough a GSK3b-mediated proteasome-dependent pathway. These data highlight the anti-tumor mechanisms of MK-2206 in AML cells and may help appropriate application of MK-2206 to future clinical trials in AML.

COMPLEX MOLECULAR REARRANGEMENTS IN CHILDHOOD ACUTE MYELOGENEOUS LEUKEMIA WITH TRANSLOCATION T(10;11)(P12;Q23) REVEALED BY PAIRED-END MAPPING

S Ghosh
Medical Faculty, Heinrich-Heine-University, Düsseldorf, Germany

Background. In up to 20% of all pediatric AML cases rearrangements involving the *MLL* gene on chromosome 11q23 have been reported. Reciprocal translocations t(10;11)(p12;q23) and other more complex rearrangements in 10p and 11q have been detected in 10-15% of pediatric patients with MLL rearranged AML. This cohort depicts a subgroup of AML in children with a very poor clinical outcome with a 5 year overall survival less than 30%. In most cases complex rearrangements with three or more breaks result in a fusion gene consisting of MLL and MLLT10. **Aims.** In this study we report on sequencing results of six pediatric AML patients with variant forms of t(10;11). Paired-end sequencing was performed to give a detailed genetic "map"of the leukemic samples in order to characterize the malignancy and detect further structural variants (translocations, deletions and inversions). **Methods.** DNA was isolated from peripheral blood lymphocytes and paired-end sequencing was performed on an Illumina platform. Patient fragment libraries with insert sizes of ~ 350 bp were sequenced on the GAIIx (2x 36 bp) or the HiSeq 2000 (2x 50 bp), respectively. Reads were aligned using BWA and unique reads with high mapping quality served as input for the structural variation detection tool GASV. Only variants not appearing in the remission sample or the Database of Genomic Variants were reported for closer inspection. Furthermore copy number variations were detected with the tool FREEC. **Results.** The GAIIx produced 96.000.000 to 287.000.000 total reads per sample (2-6 lanes on one flow cell), the HiSeq2000 201.000.000 to 670.000.000 total reads per sample (1-2 lanes on one flow cell). In each sample >90% of reads could be aligned and >90% of the genome was covered by fragments. In five out of six patients MLLT10/MLL was detected and the breakpoint region was identified. In the sixth patient FISH revealed MLLT10/MLL; paired-end-sequencing detected another translocation t(10;11) instead, resulting in a fusion gene consisting of RNF169 and MLLT10. In selected samples, PCR amplification and subsequent capillary sequencing could validate these results. Furthermore, we detected numerous additional structural variants. False positive variants could be reduced after having established an in-house database. Copy number analysis was performed to detect gains and losses of chromosomal regions; in addition, we identified the genetic background of marker chromosomes and were able to visualize complex rearrangements (see figure) .**Summary and Conclusions.** By means of paired-end sequencing we were able to characterize complex genomic structural variants in pediatric patients suffering from t(10;11) AML. Newly detected structural variants in our patients are subject to further analyses in other cohorts to find pathogenic similarities between different entities and characterize prognostic subgroups.

[3]Mackay Memorial Hospital, Taipei, Taiwan
[4]Chang Gung Children's Hospital, Taoyuan, Taiwan
[5]Chang Gung University, Taoyuan, Taiwan

Background and Aims. Minimally differentiated acute myeloid leukemia (AML-M0) is a rare subtype of AML with poor prognosis. Novel genetic aberrations are increasingly reported in AML but have not been studied comprehensively in AML-M0. We aimed to examine the genetic alternations in patients with AML-M0 and to determine their clinical relevance. **Materials and Methods.** Sixty-eight patients diagnosed as *de novo* AML-M0 with median age of 49.0 (0.3~97.9) and median follow-up duration of 4.6 (0~176.6) months were enrolled. We analyzed a wide spectrum of gene mutations including class I of signaling and RAS pathways (*FLT3*, *C-FMS*, *C-KIT*, *N-RAS*, *K-RAS*, *PTPN11*, *JAK2*^{V617F}), class II affecting transcription and differentiation (*RUNX1*, *MLL*-PTD, *NPM1*, *CEBPα)*, class III of tumor suppressor genes (*WT1*, *P53*), and class IV of epigenetic regulators (*IDH1/2*, *ASXL1*, *DNMT3A)* on bone marrow cells from AML-M0 patients at initial diagnosis. Gene mutational analysis was performed with PCR-based assays followed by direct sequencing. **Results.** Fifty-three of 68 (77.9%) patients were found to have at least one mutation: 50.8% (33/65) patients had class I mutations which were mutually exclusive, 33.3% (22/66) had class II, 9.2% (6/65) had class III and 35.4% (23/65) had class IV mutations. The most frequent gene mutations were *FLT3* (28.4%, 15 *FLT3*-ITD and 4 *FLT3*-TKD), *IDH1/2* (27.7%, 4 *IDH1*-R132, 5 *IDH2*-R140, 9 *IDH2*-R172), *RUNX1* (23.9%), *N-RAS/K-RAS* (12.3%), *ASXL1* (10.9%), *DNMT3A* (10.3%) and *MLL*-PTD (9.1%). *PTPN11*, *WT1*, *P53*, *C-FMS*, *JAK2*^{V617F}, *NPM1*, and *CEBPα* occurred sporadically with lower frequencies. Taken together, 26 of 53 patients (49.1%) had more than one mutation. Four of the 6 patients with *DNMT3A* and 3 of the 7 patients with *ASXL1* mutations also had *IDH2* mutations. *IDH* and *RUNX1* mutations were associated with older age (p=0.006 and p=0.011). *RAS* mutation was associated with higher circulating blasts whereas patients with *DNMT3A* mutations had a significantly lower WBC counts and lower circulating blasts. In univariate analysis, survival was affected by old age (HR 1.019, 95% CI 1.009~1.029, p=<0.001), cytogenetic risk group (intermediate vs. high risk, HR 0.486, 95% CI 0.237~0.996, p=0.049) and the presence of class III mutations (HR 1.512, 95% CI 0.985~2.321, p=0.059). Old age (HR 1.014, p=0.005) and class III mutations (HR 1.638, p=0.026) had adverse impact on event-free survival. In multivariate

analysis, old age (HR 1.021, 95% CI 1.008~1.034, *p*=0.001) and *RUNX1* mutation (HR 2.712, 95% CI 1.241~5.930, *p*=0.012) remained the adverse factor for inferior survival. **Conclusions.** The present study showed a high frequency of class IV mutations (*IDH1/2, ASXL1* and *DNMT3A,* single or in combination*)* in AML-M0 in addition to *FLT3* and *RUNX1* mutations. Most patients harbored multiple mutations. *RUNX1* mutation was associated with a poor outcome. Supported by grants NSC100-2314-B-182-023-MY3, NHRI-EX96-9434SI and MMH-E-99009.

KPT-SINE (SELECTIVE INHIBITORS OF CRM1 MEDIATED NUCLEAR EXPORT) EXHIBIT STRIKING ANTI-LEUKEMIC ACTIVITY AGAINST AML AND T-ALL CELLS WHILE SPARING NORMAL HEMATOPOIETIC CELLS

J Etchin[1], A Kentsis[1], T Sanda[1], A Kung[1], R Stone[1], D McCauley[2], M Kauffman[2], S Shacham[2], A Look[1]
[1]Dana-Farber Cancer Institute, Boston, United States of America
[2]Karyopharm Therapeutics, Natick, United States of America

Background. CRM1 is the major nuclear exporter that mediates transport of a variety of molecules, including proteins involved in tumor suppressor and cellular proliferation pathways. CRM1 is upregulated in a range of solid and hematologic malignancies and its overexpression is correlated with poor prognosis and with resistance to chemotherapy. The crystal structure of CRM1, in complex with its export cargo, Snurportin 1, has been recently resolved. The molecular understanding of the CRM1-cargo binding interface has led to the development of novel small molecule inhibitors of CRM1-cargo interaction, termed KPT-Selective Inhibitors of Nuclear Export (SINE). **Aims.** KPT-SINE are potent CRM1 inhibitors that irreversibly inactivate the CRM1-directed protein export by covalent modification of the essential CRM1-cargo binding residue Cys528. The inhibition of the CRM1 nuclear export has been shown to lead to selective apoptosis in cancer cells when compared to normal hematopoietic cells and normal cells. Here, we assess the efficacy of the KPT-SINE in human AML, T-ALL, and normal hematopoietic cells. **Methods.** The viability of a panel of human AML and T-ALL cell lines upon treatment by the KPT-SINE was assessed. Dose-response measurements were done using serial dilutions of KPT-SINE from 1 μM to 0.3 nM and luminescent cell viability assay. Apoptosis was measured using Annexin V staining and TUNEL assays. **Results.** KPT-SINE induces rapid apoptosis in 12 AML and 14 T-ALL cell lines with IC50s of 15-170 nM. In the KPT-SINE-sensitive cell lines, BCL2 overexpression suppresses KPT-SINE-induced apoptosis, indicating its intrinsic pathway mediation. Importantly, oral administration of KPT-SINE compounds, either KPT-251 at 75 mg/kg or KPT-330 at 15 or 25 mg/kg, induced remarkable growth suppression in MV4-11 human AML cells engrafted into immunodeficient NSG mice with minimal toxicity to normal mouse hematopoietic cells after 35 days of treatment. Bone marrow biopsies of KPT-treated mice were remarkable in that they showed normal hematopoietic cell morphology and cellularity after 35 days of treatment. Significant survival benefit was observed in mice treated with either KPT-251 or KPT-330, compared to vehicle-treated mice. Studies to address the potency of the KPT-251 and KPT-330 on MOLT-4 human T-ALL cells *in vivo* are ongoing. **Conclusions.** These studies emphasize the clinical promise of the KPT-SINE as a novel and selective drug candidate for the treatment of AML and T-ALL.

0045

VECTORIZED ANTICANCER DRUG F14152, USED ALONE OR IN COMBINATION WITH ARAC, DEMONSTRATES POTENT ANTILEUKEMIC ACTIVITY IN AML *in vivo* MODELS DERIVED FROM PATIENTS

M Annereau, A Pillon, L Creancier, I Vandenberghe, B Gomes, V Brel, C Ricome, C Bailly, A Kruczynski, N Guilbaud
Centre de Recherche et de Développement Pierre Fabre, Toulouse, France

Background. Drugs specifically vectorized to cancer cells should offer a reinforced activity, tackle tumor cells while preserving normal cells, resulting in an improved therapeutic index. In this context, the selective targeting of tumor cells with polyamine-containing drugs has been considered and the most promising compound in this category is arguably the spermine-podophyllotoxin conjugate F14512. F14512, that contains a spermine chain in place of the C4 glycosidic moiety of etoposide, displays an enhanced anti-proliferative activity on a large panel of tumor cell lines (10 fold) as compared to etoposide and exploits the polyamines transport system (PTS) to accumulate into cells. In a previous study, we established a clear correlation between the expression of the PTS system in 13 leukemia cell lines and their sensitivity to the cytotoxic action of F14512. This antitumor activity has encouraged the set up of a phase 1 clinical study with F14512 in patients with acute myeloid leukemia (AML). **Aim.** Although standard cytotoxic chemotherapy induced complete remissions in AML patients, relapse rates are still very high, resulting in a poor outcome in most cases. **Methods.** We evaluated the antitumor activity of F14512 alone, and in combination with the reference drug AraC, against novel *in vivo* AML models, collected from 3 different patients, and established onto NSG mice (LAM-2, LAM-7 and LAM-18). **Results.** These 3 AML samples exhibited a normal karyotype, with FLT3-ITD, NPM1 and DNMTA3 mutations which proved their stability over serial transplantations *in vivo*. After multiple i.v. administrations of F14512, 3 times a week for 3 weeks, an extensive reduction of AML cell number (98-99%) was observed in LAM-2 and LAM-7 -bearing mice. This antileukemic activity was recorded on the basis of flow cytometry, q-PCR and histology assessments. Mechanisms of F14512-induced cell death are currently investigated, and preliminary data suggest that senescence is involved. We also demonstrated *in vitro* and *in vivo* synergistic effects of F14512 in combination with AraC, one of the frontline chemotherapeutic agents for AML. The antileukemic effects of F14512 on LAM-18 bearing mice were marginal with an inhibition of AML cell growth of 42%. **Summary and Conclusions.** Collectively, these results demonstrate that F14512 exhibits a marked *in vivo* antileukemic activity in these AML models derived from patients, supporting its clinical development, which is currently in progress.

0046

A SPECIFIC MICRORNA SIGNATURE CHARACTERIZES ACUTE MYELOID LEUKEMIA WITH TRANSLOCATION T(6;9) (P23;Q34)/DEK-NUP214

M Díaz Beyá[1], A Navarro[2], M Pratcorona[1], R Tejero[2], L Magnano[1], M Monzo[2], J Esteve[1]
[1]Hospital Clinic Barcelona, Barcelona, Spain
[2]Molecular Oncology and Embryology Laboratory, Human Anatomy Unit, University, Barcelona, Spain

Background. Acute myeloid leukemia (AML) with translocation t(6;9)(p23;q34) is a rare (1%) high-risk AML subtype characterized by the fusion of nuclear phosphoprotein DEK in chromosome 6 with the nucleoporin encoding gene *NUP214* (*CAN*) in chromosome 9. This fusion gene in der(6) chromosome induces transformation by altering growth characteristics, nucleo-cytoplasmic transport, and protein synthesis of hematopoietic stem cells. MicroRNAs (miRNAs) are small non-coding RNAs that play an important regulatory role in many biological processes. Nonetheless, to date, little is known on the role of miRNAs in t(6;9) (p23;q34) DEK-NUP214 AML subtype [t(6;9) AML]. **Aims.** The main objective of this study was to examine if t(6;9) AML harbors a miRNA signature associated with DEK/CAN fusion gene assembly. **Methods.** We have analyzed the miRNA profile of 117 AML patients with 10 different AML subtypes, including eight cases of t(6;9) AML, and three CD34+ bone marrow specimens from healthy donors. The expression of 670 mature miRNAs was assessed using TaqMan Human MicroRNA Arrays v2.0 (Applied Biosystems) in an ABI 7900 HT sequence detection system. Statistical analyses were performed with TiGR MultiExperiment Viewer and R software. To identify molecular pathways potentially altered by the expression of multiple miRNAs we used Diana-mirPath, which performs an enrichment analysis of multiple miRNA target genes, comparing each set of miRNA targets to all known KEGG pathways. **Results.** Supervised analysis by means of t-test based on multiplex permutations and SAM analysis revealed a distinctive miRNA signature in t(6;9) AML patients. When the miRNA expression in t(6;9) AML was compared with miRNA expression in all other AML subtypes and also specifically with other high-risk AML subtypes, we found that a miRNA signature specifically associated with t(6;9) AML. This specific signature is composed of 30 differentially expressed miRNAs, 28 of which are upregulated in comparison with other leukemia subtypes. Some of these miRNAs have been previously described as players in several cancers (let-7a and let-7e, miR-143, miR-145, miR-451, miR-330-5p, miR-194, miR-99, miR-132, miR-199, miR-494 or miR-98), and others have been related to acute leukemia (miR-223, miR-451,miRNA-181a*). In addition, several HOX-related miRNAs were upregulated (miR-10a, miR-10a* and miR-10b). Interestingly, three miRNAs of the signature are located in or near the genomic region of NUP214 (9q34): miR-181a* (9q33), let-7a (9q34) and miR-199b-5p (9q34). The Diana-mir-Path analysis found that some of the miRNAs in our signature may regulate genes involved in the KIT, MAPK/AKT2, and RUNX1 signaling pathways, both of which are deregulated in AML.**Conclusions**We have identified for the first time a specific miRNA signature related to t(6;9) AML, with an overall upregulated profile. Some of the miRNAs in the signature may impact the leukemogenic process by altering essential pathways involved in cell differentiation and proliferation. Our findings thus contribute some insight into the biological profile of t(6;9) AML. Nonetheless, further investigation is warranted to determine the mechanisms leading to this miRNA signature and to identify the specific targets of the miRNAs.

IDENTIFICATION OF TARGET GENES OF THE TRANSCRIPTION FACTOR HB9 IN HEMATOPOIETIC CELLS AND ITS ROLE IN HEMATOPOIESIS

D Ingenhag[1], S Wildenhain[2], C Ruckert[3], Ö Degistirici[2], M Dugas[3], R Meisel[2], A Borkhardt[2], J Hauer[2]
[1]Heinrich Heine University Duesseldorf, Center for Child and Adolescent Health, Duesseldorf, Germany
[2]Department of Pediatric Oncology, Center for Child and Adolescent Health, Duesseldorf, Germany
[3]Institute of Medical Informatics, University of Münster, Muenster, Germany

Background. The transcription factor HB9, encoded by the *homeobox gene B9* (*HLXB9*), is involved in the development of pancreatic beta- and motor neuronal cells. In addition, *HLXB9* is recurrently rearranged in young children with Acute Myeloid Leukemia (AML) characterized by a chromosomal translocation t(7;12)-*HLXB9/TEL* and concomitant high expression of the unrearranged, wildtype *HLXB9* allele.Hence in this study we aimed to identify target genes of HB9 in hematopoietic cells and its role in hematopoiesis. **Methods and Results.** In this study, we used ChIP-on-chip analysis together with expression profiling and identified prostaglandin E receptor 2 (PTGER2) as a direct target gene of HB9 in a hematopoietic cell line. The functional HB9 homeodomain is essential for binding of HB9 to the *PTGER2* promoter region and enables downregulation of *PTGER*2 expression. Functionally, HB9 conducted downregulation of *PTGER2* results in a two-fold repression of intracellular cAMP mobilisation when cells were stimulated with butaprost and a four-fold decrease when stimulated with prostaglandin E2. The decreased gene expression is valid in *HLXB9* expressing primary murine hematopoietic stem cells as well as in bone marrow cells from translocation t(7;12) positive patients. Furthermore, among the primary and secondary target genes of HB9 in the myeloid cell line HL60, 78% of significantly regulated genes are downregulated, indicating an overall repressive function of HB9. Differentially regulated genes were preferentially confined to pathways involved in cell-adhesion and cell-cell interactions, similar to the gene expression footprint of *HLXB9* expressing cells from t(7;12) positive patients. **Conclusions.** The present results indicate a regulative function of HB9 in cell-adhesion and cell-cell interaction in hematopoietic cells. Future experiments will analyse the role of *HLXB9* in the regulation of bone marrow homeostasis using an in-vivo model of primary murine HSCs and a transgenic Nestin-GFP positive mouse strain to model the hematopoietic niche.

0048

CLINICAL IMPLEMENTATION OF A NOVEL HIGH-THROUGHPUT SCREEN OF PRIMARY LEUKEMIA CELLS TO PERSONALIZE THERAPY FOR RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA (AML)

M Frattini, D Shum, M Heaney, R Brentjens, P Maslak, J Jurcic, H Djaballah
Memorial Sloan-Kettering Cancer Center, New York, United States of America

Background. For most patients with relapsed and refractory acute myeloid leukemia, therapeutic success is unpredictable with current cytotoxic chemotherapeutic regimens. Moreover, multiple courses of therapy have been shown to result in co-morbid conditions, which can often preclude the patient from being able to receive the potentially curative therapy of allogeneic bone marrow transplantation. **Aims.** With the goal of identifying a successful chemotherapy regimen for these patients, based on patient-specific myeloid blast cell chemo-sensitivities, we have developed a high-throughput screening assay that utilizes primary (patient-derived) leukemia cells and tested for chemo-sensitivity and resistance against a panel of established chemotherapeutic agents as well as novel agents. **Methods.** This assay was developed in 1536 well format and initially optimized against a panel of leukemia and lymphoma cell lines to help determine optimal concentration of cells to be used. Standard twelve point dose response curves were performed in duplicate for all compounds tested. Alamar Blue was used as an indicator of cell viability and death. **Results.** Using this assay with primary patient samples of AML, we were able to identify *in vitro* resistance against the various drugs already clinically administered, including cytarabine, etoposide, and anthracyclines. Importantly, we were also able to show *in vitro* sensitivity to chemotherapy agents that had not been previously administered. The index patient was a 32-year-old woman with primary refractory acute myeloid leukemia who had received six different therapeutic regimens prior to our testing, all of which demonstrated *in vitro* resistance using our assay. The blasts were sensitive, however, to 6-thioguanine with an inhibitory concentration (IC_{50}) of 70 nM. Based on the *in vitro* data, the patient began a combination treatment regimen containing oral 6-thioguanine as her white blood cell (WBC) count had increased to greater then 50,000 cells/ml on her previous therapy. Following a maintenance regimen with these agents, her circulating blast count decreased to less then 10,000 cells/ml, and she had partial recovery of the neutrophil count, resulting in a dramatic decrease in the overall leukemia burden. This result was not seen with her previous treatment regimens. Importantly, the majority of this therapy was administered in the outpatient setting. After over six months of combination therapy, her WBC began to rise again and repeat testing was performed on her cells. Importantly, the results indicated resistance to 6-thioguanine with IC_{50}>10 microM, confirming the response seen *in vivo*. Subsequently, we have collected samples from more than fifteen patients with AML and used this screening assay to predict their response to various chemotherapeutics. In each case, we have accurately predicted the *in vivo* clinical response (both sensitivity and resistance) to different chemotherapeutic agents. **Conclusions.** These data demonstrate that the technology described here to screen drug therapy for patients with relapsed and refractory AML is clinically useful and has a potential role in designing individualized drug treatment regimens for these patients.

0049

DIFFERENTIAL EXPRESSION OF NPM1 SPLICE VARIANTS IN ACUTE MYELOID LEUKEMIA

M Zajac[1], A Dolnik[2], K Dohner[2], L Bullinger[2], K Giannopoulos[1]
[1]Department of Experimental Hematooncology, Medical University of Lublin, Lublin, Poland
[2]Department of Internal Medicine III, University of Ulm, Ulm, Germany

Background. Acute myeloid leukemia (AML) is one of the most common types of leukemia among adults. Recently, gene mutations and deregulated expression of genes have been described, providing insights into the mechanisms of leukemogenesis and unraveling the enormous molecular heterogeneity, in particular within the group of cytogenetically normal (CN) AML. Of particular importance are mutations of the necleophosmin-1 (*NPM1*) gene, which identify a group of CN-AML patients with favorable prognosis in case of no concomitant FMS-like tyrosine kinase 3-internal tandem duplication (*FLT3*-ITD). Notably, wildtype *NPM1* encodes for three alternatively spliced isoforms: R1 (B23.1), R2 (B23.2), R3 (B23.3). **Aims.** Since splicing variants play an important role in cellular function, the current project aimed to characterize the expression pattern of *NPM1* splice variants in AML patients. **Methods.** For 96 AML patient samples (44 CN-AML and 52 samples with cytogenetic aberrations) qRT-PCR was performed. Total expression (Rt) as well as levels of the three splicing variants of *NPM1* were evaluated: R1 translates exon 1 to 9 and 11 to 12, R2 contains exons 1 to 10 and R3 lacks exons 8 and 10. To investigate the distribution of splicing variants the R1/Rt, R2/Rt and R3/Rt ratios were calculated, respectively.

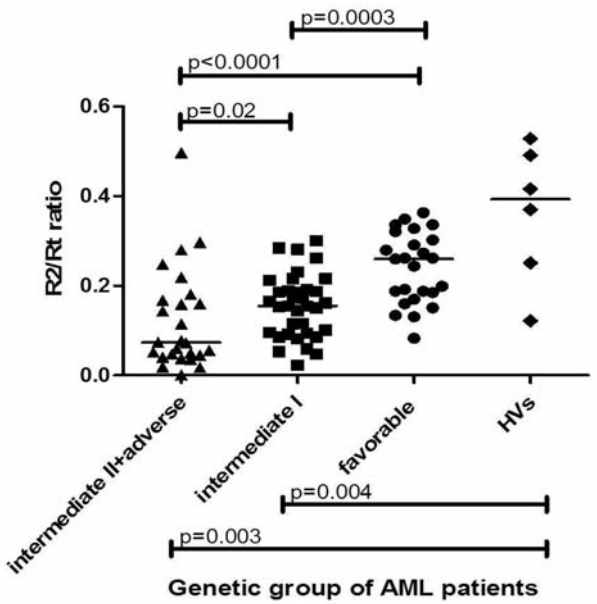

Figure 1. Differential expression of R2/Rt ratio in the total AML cohort with different prognosis. Favorable (t(8;21), inv(16), *NPM1+/FLT3*-ITD-), intermediate I (*NPM1+/FLT3*-ITD+, *NPM1-/FLT3*-ITD-, *NPM1-/FLT3*-ITD+), intermediate II and adverse (t(9;11), complex karyotype, cytogenetic abnormalities not classified as favorable or adverse).

Results. Total expression Rt as well as expression of splice variants R1 and R3 were significantly higher in all AML patients compared to healthy volunteers (HVs) with a median expression of 1.323 vs 0.5175 (p=0.004), 2.98 vs 0.5485

(p=0.0072), and 2.821 vs 0.108 (p<0.0001), respectively. The expression of R2 splicing variant was elevated in AML patients with *NPM1* mutations (*NPM1*+) compared to patients without *NPM1* mutations (*NPM1*-) with a median expression of 0.829 vs 0.385 (p=0.0426). Significant differences with regard to the splicing variant distribution were found between HVs, CN-favorable (*NPM1*+/*FLT3*-ITD) and CN-intermediate (*NPM1*+/*FLT3*-ITD+; *NPM1*-/*FLT3*-IDT-; *NPM1*-/*FLT3*-ITD+) groups. The ratios of R1/Rt and R2/Rt within the CN-intermediate group were significantly lower in comparison to HVs (median 0.231 vs 0.48, p=0.0048 and 0.155 vs 0.393, p=0.0038, respectively), while the R3/Rt ratio was increased in CN-intermediate and CN-favorable groups compared to HVs (median 0.617 vs 0.084, p= 0.0002 and 0.3555 vs 0.084, p=0.0007). Interestingly, in all AML patients the R2/Rt ratio was the highest in groups with favorable prognosis and was decreased in groups with poor outcome (Figure 1). **Conclusions.** *NPM1* mutations play an important role in the biology of the CN-AML bearing both prognostic and predictive value. Interestingly, the expression and the distribution of *NPM1* splice variants might be of biological importance for the entire AML cohort, as we found an imbalance in the distribution among all AML patients, not only CN-AML. Notably, there was a great reduction of a *NPM1* splice variant R2 that lacks exons 11 and 12 (R2/Rt), where the mutation appears.

0050

THE LEUKEMIA ASSOCIATED NUCLEAR CO-REPRESSOR ETO HOMOLOGUE GENES ARE REGULATED DIFFERENTLY IN HEMATOPOIETIC CELLS

P Kumar, R Ajore, R Dhandha, U Gullberg, I Olsson
Lund University, Lund, Sweden

Backbround. *ETO, MTG16,* and *MTGR1* are nuclear transcriptional corepressors of the human ETO protein family. The ETO homologue genes are 3´participants in leukemia fusions generated by chromosomal translocations responsible of hematopoietic dysregulation. **Aims.** We tried to compare structural and functional promoter elements of *ETO*, *MTG16* and *MTGR1* genes in order to find associations between their regulation and hematopoiesis. **Methods.** 5´ deletion examinations and luciferase reporter gene studies were used to identify the proximal promoter. Binding of transcrition factor to the TFBS site was confiemed by *in vitro* antibody enhanced electrophoretic moblity shoft assay and *in vivo* chromatin immunoprecipitation. Overexpression study was used to confrim the effect of transcription factor on expression of genes. **Results.** An evolutionary conserved region of 228 bp revealed potential cis-elements involved in transcription of ETO. While, TATA- and CCAAT-less MTG16 promoter with a GC box close to the start site showed strong reporter activity when examined in erythroid/megakaryocytic cells. Mutation studies showed that an evolutionary conserved GATA consensus-binding site present at -636 and -301 site of MTG16 and MTGR1 promoter respectively, repressed promoter function of MTG16 and MTGR1. Furthermore, results from *in vitro* antibody-enhanced electrophoretic mobility shift assay and *in vivo* chromatin immunoprecipitation validated the binding of GATA-1 to the GATA site. The overexpresion of GATA1 futher increased the activity of *ETO* and *MTGR1* promoer in reporter assay. In case of MTGR1, TATA-less and CCAAT-less promoter retained most of the transcriptional activity in a GC box-rich sequence containing multiple SP1 binding sites reminiscent of a housekeeping gene with constitutive expression. However, mutations of individual SP1 binding sites did not repress promoter function; multiple active SP1 binding sites may safeguard constitutive *MTGR1* transcriptional activity. The leukemia associated *AML1-ETO* fusion gene suppressed *ETO, MTG16* and *MTGR1* promoter activity. **Conclusions.** An evolutionary conserved GATA binding site is critical in transcriptional regulation of the *ETO* and *MTG16* promoter. In contrast, the *MTGR1* gene depends on a GC box-rich sequence for transcriptional regulation and ubiquitous expression. Our results demonstrate that the ETO homologue promoters are regulated differently consistent with hematopoietic cell-type-specific expression and function.

Acute myeloid leukemia - Clinical 1

ADDITION OF MINIMAL RESIDUAL DISEASE (MRD) ASSESSMENT BY FLOW CYTOMETRY FOR FURTHER RISK STRATIFICATION WITHIN THE EUROPEAN LEUKEMIA NET FAVORABLE RISK GROUP IN ADULT AML

T Köhnke[1], D Sauter[2], K Ringel[2], M Hubmann[2], S Bohlander[2], S Schneider[2], A Dufour[2], J Braess[3], W Hiddemann[2], K Spiekermann[2], M Subklewe[2]
[1]Klinikum der Universität München, München, Germany
[2]Medizinische Klinik und Poliklinik III, Klinikum der Universität München, München, Germany
[3]Klinik für Onkologie und Hämatologie, Krankenhaus Barmherzige Brüder, Regensburg, Germany

Background. In adult AML, most patients receiving intensive induction chemotherapy achieve complete hematologic remission. However, the majority of these patients will experience subsequent relapse. Therefore, determination of relapse risk is of particular interest to guide therapeutic decisions for post-remission therapy. To date, cytogenetic and molecular markers are able to provide risk stratification at primary diagnosis. However, the value of MRD is emerging and might play an increasing role in risk stratification beyond genetics. MRD assessment by flow cytometry is possible in virtually all cases, even those where molecular markers are not available.AimsIn order to further improve existing and well described risk stratification, we analyzed whether the addition of MRD-assessment by flow cytometry after induction chemotherapy in patients achieving complete remission is capable of determining groups of patients which, within each cytogenetic and molecular risk group, might have an elevated risk of relapse. **Methods**. From the database at the Laboratory of Leukemia Diagnostics at our clinic patients with newly diagnosed AML treated between 2000 and 2011 were analyzed. At least two samples of bone marrow blood (at primary diagnosis and during or after treatment) had to be available for MRD assessment by 3-color-flow cytometry at our laboratory. Leukemia associated immunophenotypes (LAIPs) were determined by gating on aberrant expression of a well-defined set of antigens (Kern et al., 2003). MRD positivity was defined as ≥0,3% LAIP positive cells after induction therapy. Cytogenetic and molecular risk stratification was assigned in accordance to the European LeukemiaNet (ELN) guidelines. **Results**. 662 patients fulfilled the inclusion criteria and 472 (71%) achieved a complete remission. 346 (73%) of these patients had MRD data by flow cytometry available after induction chemotherapy and in 319 cases ELN risk stratification was available. The median age at diagnosis in this group was 53 years (18-85) and 94, 86, 95 and 44 patients were assigned to the ELN favorable, intermediate I, intermediate II and adverse risk group, respectively. For the entire cohort, LAIP positivity resulted in a significantly shorter Relapse Free Survival (RFS) (median 12,4 vs. 19,9 months, log-rank test p=0,016), whereas Overall Survival (OS) was not significantly different (48,9 vs. 38,1 months, p=0,132). However, within the favorable risk group both RFS (78,2 vs. 20 months, p=0,016) and OS (median not reached vs. 49,6 months, p=0,019) were significantly worse in case of MRD positivity. **Summary.** In adult AML, therapeutic decisions guiding post-remission treatment strategies are mostly based on molecular and cytogenetic risk at primary diagnosis. Here we could show that MRD assessment by flow cytometry after induction therapy can further divide the ELN favorable risk group into two distinct subgroups. This might lead to improved risk stratification to guide post-remission therapeutic decisions. However, the value of MRD assessment needs to be confirmed in prospective studies.

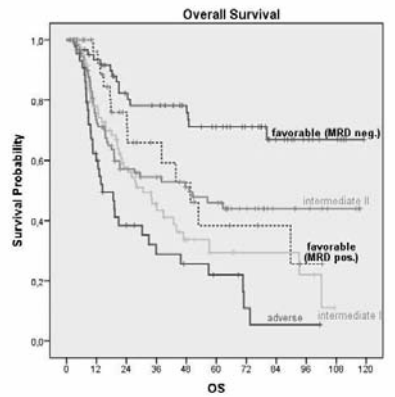

Figure 1. Overall survival showing subgroups within the ELN favorable risk group by MRD status (log rank test p<0.00001)

MICRORNA LET-7A-3 PROMOTER METHYLATION IS ASSOCIATED WITH KARYOTYPING, CEBPA PROMOTER METHYLATION AND SURVIVAL IN ACUTE MYELOID LEUKEMIA

Y Ko[1], ML Teo[2], CY Hu[2], YS Chen[2], CY Chen[3], HF Tien[3], LI Lin[2]
[1]Yuanpei University, Hsinchu, Taiwan
[2]National Taiwan University, Taipei, Taiwan
[3]National Taiwan University Hospital, Taipei, Taiwan

Background. Epigenetic dysregulation plays an important role in oncogenesis. In acute myeloid leukemia (AML), a number of genes, such as *CDKN2B (p15), p73, SOCS1* and *CEBPA,* are aberrantly methylated. MicroRNAs (miRNAs) are endogenous small non-coding RNAs. They target the 3' untranslated regions of certain mRNAs and repress their expression post-transcriptionally. The miRNA let-7a is involved in oncogenesis by targeting growth-control genes. It is transcribed from three different loci, the *let-7a-1*, *let-7a-2*, and *let-7a-3*, where *let-7a-3* is located in a CpG island and is epigenetically regulated. *Let-7a-3* is differentially methylated in normal and tumor tissues, and hypermethylation of *let-7a-3* is correlated with favorable prognosis in ovarian cancer. However, the significance of epigenetic phenotype of *let-7a-3* in AML has not been addressed. **Aims.** We examined the methylation status of *let-7a-3* promoter in AML cell lines and patients and evaluated the association of the methylation level to clinical features and survival of AML patients. **Methods.** A total of 90 patients diagnosed with AML were enrolled in this study. This study was approved by the Institutional Review Board of the NTUH, and written informed consents were obtained from all the participants. Bisulfite-treated DNA was used in the DNA methylation analysis which was designed to cover a 723-bp region containing 33 CpG sites including two *Bst*UI sites (CGCG) in the *let-7a-3* gene. DNA methylation status was assessed by combined bisulfite restriction analysis (COBRA) and bisulfite sequencing PCR (BSSP). **Results.** We showed that *let-7a-3* promoter was heavily methylated in AML cell lines and most of the AML patients. *Let-7a-3* was methylated at 93%, 80%, 71%, and 90% of the CpG sites in AML cell lines including HEL, HL60, K562 and U937 cells, respectively. *Let-7a-3* was designated as methylated in 81.1% (73/90) patients, as partially methylated in 12.2% (11/90) patients, and as unmethylated in 6.7% (6/90) patients. To evaluate the clinical significance of *let-7a-3* methylation, chi-square test was applied to correlate the methylation status and clinical data of 84 AML patients. *Let-7a-3* methylation status was correlated with patients' karyotypes but not with age, gender, and FAB subtypes. In patients with favorable karyotypes [t(15;17), t(8;21), and inv(16)], 40% (4/10) acquired hypermethylated *let-7a-3*, whereas in patients with intermediate (normal and others) and unfavorable (-5, -7, +8 and complex) karyotypes, the frequency was 83% (49/59) and 86% (13/15), respectively. The transcription factor C/EBPα is a tumor suppressor essential for early myeloid differentiation. Mutation and epigenetic silencing of *CEBPA* are both linked to AML development. We found that methylation status of *let-7a-3* was inversely correlated with methylation of *CEBPA* distal promoter region (-1423 to -1121), which is crucial for *CEBPA* expression. In patients with unmethylated *CEBPA*, 88% (56/64) harbored hypermethylated *let-7a-3*; however, in patients with hypermethylated *CEBPA*, only 50% (10/20) did. Using Kaplan-Meier survival analysis, we demonstrated that *let-7a-3* hypermethylation was associated to better 5-year survival in AML patients with intermediate karyotype or unmethylated *CEBPA*. **Summary and Conclusions.** Our study proposed a prognostic role for *let-7a-3* methylation in AML and indicated an inverse correlation between the methylation status of *let-7a-3* and *CEBPA*.

0053

DETERMINATION OF THE MAXIMUM TOLERATED DOSE OF PANOBINOSTAT IN COMBINATION WITH A 5-DAY SCHEDULE OF AZACITIDINE IN HIGH RISK MYELODYSPLASTIC SYNDROME AND ACUTE MYELOID LEUKAEMIA: A PHASE IB/II STUDY

P Tan[1], K Reed[1], P Walker[1], S Avery[1], S Patil[1], A Grigg[2], P Mollee[3], O Gervasio[4], I Winiger[5], D Honemann[6], A Wei[1], A Spencer[1]

[3]Princess Alexandra Hospital, Brisbane, Australia
[4]Novartis Pharmaceuticals Australia, Sydney, Australia
[5]Novartis Pharma AG, Basel, Switzerland
[6]Celgene Pty Ltd, Melbourne, Australia

Background. The therapeutic options for patients with high risk myelodysplastic syndrome (MDS) or acute myeloid leukemia (AML) who are not eligible for intensive chemotherapy remain limited. The combination of hypomethylating agent and deacetylase inhibitor (DACi) has been shown to be synergistic, both in terms of leukemia cell killing and gene reactivation *in vitro*. **Aims.** To investigate the safety, tolerability and preliminary efficacy of combining the oral pan-DACi panobinostat (LBH589) with azacitidine in newly diagnosed MDS or AML, not fit for standard induction therapy. **Methods.** Phase Ib/II multi-center open label dose-escalation and expansion study. Inclusion criteria: untreated IPSS intermediate-2 or high risk MDS, or AML (marrow blasts ≥20%), not eligible for standard induction therapy. Patients received azacitidine 75 mg/m^2 SC on days 1-5 of each 28-day cycle with either 10, 20, 30 or 40mg panobinostat orally 3 days per week (M/W/F) for 7 doses per cycle commencing on day 5. Treatment schedule contained 6 cycles of combination therapy, and continued if there was no disease progression or unacceptable toxicity. The safety and tolerability of the combination was assessed. **Results.** 40 patients gave informed consent and were enrolled into the study, with a median age of 70 years (36-82). 30 AML patients had intermediate (18/30) or poor cytogenetic risk (12/30); 10 MDS patients with intermediate-2 (7/10) or high risk (3/10) IPSS. Patients entered panobinostat dose-escalation cohorts of 10mg (4 patients), 20mg (7), 30 mg (6) or 40mg (6); and expansion study 30mg (17). All grade non-hematologic adverse events regardless of relatedness to study treatment (>10%) were fatigue (50%), injection site reaction (50%), nausea (38%), diarrhea (33%), anorexia (28%), febrile neutropenia (15%), constipation (13%), dyspnea (13%), fever (13%), and vomiting (13%). There were no unexpected adverse events or drug reactions. The principal dose-limiting toxicity (DLT) was fatigue. In the dose-escalation phase, the grade 3/4 DLTs were: panobinostat 10mg cohort (0/4 DLT), panobinostat 20mg cohort (1/7 DLT; grade 3 fatigue), panobinostat 30 mg cohort (1/6 DLT; grade 3 fatigue), panobinostat 40mg (4/6 DLTs; all grade 3: fatigue (1), syncope (1), hyponatremia (1) and somnolence/reduced level of consciousness (1)). Therefore, in combination with the 5-day schedule of azacitidine, the maximum tolerated dose (MTD) of panobinostat was defined at 30mg; this dose level was selected for expanded accrual. The median number of treatment cycles initiated was 5 (1-20). There was an overall response rate (ORR) (CR+CRi+PR) in AML patients of 8/30 (27%) (2 CR, 1 CRi, 5 PR). In MDS patients the ORR was 5/10 (50%) (2 CR, 3 PR). After a median follow-up of 10.6 months, the median OS was 8.0 months (0.7-20.5). **Conclusions.** In previously untreated MDS/AML, panobinostat and azacitidine is well tolerated and the MTD of panobinostat was 30mg when in combination with a 5-day azacitidine schedule at 75mg/m^2 daily. This combination demonstrates clinical activity and warrants further clinical evaluation.

[6]Sheffield Teaching Hospitals NHS Trust, Sheffield, United Kingdom
[7]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background. Graft-versus-host disease (GVHD) and disease relapse are the major causes of treatment failure in adults with Acute Myeloid Leukaemia (AML) who undergo a reduced intensity conditioned (RIC) allograft. Strategies which reduce the risk of disease relapse and GVHD are urgently required. The demethylating agent 5-azacitidine (AZA) has well documented anti-leukaemic activity in AML and has been shown to reduce the risk of GVHD in animal models. **Aims.** We wished to study the tolerability of post-transplant AZA and its impact on GVHD and disease relapse in patients undergoing a RIC allograft for high risk AML. **Methods.** Adults with AML who underwent allogeneic transplantation using a conditioning regimen consisting of fludarabine (30 mg/m^2 IV x 5 days), melphalan (140 mg/m^2 IV), and alemtuzumab (10 mg IV x 5 days) were eligible for this study. All patients received GVHD prophylaxis using cyclosporine. Patients with sustained neutrophil and platelet engraftment commenced treatment with AZA (36 mg/m^2 x 5 days) which was administered every 28 days until one year post transplant. All patients gave informed consent and the trial was registered as #ISRCTN36825171. **Results.** 37 patients (median age 59 yrs) commenced treatment with AZA at a median of 55 days (range 40 to 194) post-transplant. 25 patients were transplanted from matched (7 or 8/8) unrelated donors and 12 patients were transplanted from HLA identical related donors. 32 patients were in remission at the time of transplant (CR1=24, CR2=8) and 5 patients had active disease (2 primary refractory AML, 3 relapsed AML). 21 patients had intermediate risk cytogenetics and 9 poor risk cytogenetics at diagnosis. Post transplant AZA was well tolerated and 31 patients completed at least 3 cycles. Haematological toxicities were modest and only 4 patients experienced treatment delay due to neutropenia or thrombocytopenia. The most common grade >3 non-haematological toxicity was infectious complications which occurred in 9 patients.

5 patients developed Grade 2 acute GVHD and no patient developed >Grade 2 acute GVHD. 3 patients developed limited chronic GvHD and no patient developed chronic extensive GVHD. To date 11 patients have relapsed at a median of 7 months (4-15 months) after transplantation. Of the 16 patients treated with AZA until one year post transplant, 15 are in complete remission at the time of last follow up. **Conclusions.** Prolonged administration of AZA is well tolerated immediately after a RIC allograft in an elderly population of patients. Our data demonstrate that administration of AZA after allogeneic SCT appears to be associated with a low risk of acute and chronic GVHD and a reduced risk of disease relapse. These observations identify a potential strategy to improve outcome after allogeneic stem cell transplantation in high risk AML but require confirmation in a randomised clinical trial.

0055

HIGH GATA2 EXPRESSION IS A POOR PROGNOSTIC MARKER IN PEDIATRIC ACUTE MYELOID LEUKEMIA

M Luesink[1], I Hollink[2], V van der Velden[3], R Knops[4], J Boezeman[4], V de Haas[5], J Trka[6], A Baruchel[7], D Reinhardt[8], B van der Reijden[4], M van der Heuvel-Eibrink[2], M Zwaan[2], J Jansen[4]

[7]Hematology, Hopital Saint-Louis, Paris, France
[8]Acute Myeloid Leukemia-Berlin-Frankfurt-Munster (AML-BFM) Study Group, Hannover, Germany

Background.Acute myeloid leukemia (AML) is a clinically and genetically heterogeneous disease that accounts for 15% to 20% of childhood leukemia. Over the past decades, the prognosis for children with AML has improved considerably as a result of better (risk-adapted) therapeutic strategies. Risk-group classification has mainly been based on cytogenetic aberrations and response to induction chemotherapy. More recently, novel genetic defects and expression patterns have been discovered that enable the further refinement of risk-category assignment for individual patients. **Aims.** The transcription factor GATA binding protein-2 *(GATA2*) gene, located at chromosome 3q21, plays an essential role in the regulation of myeloid lineage determination. In the current study we investigated the relevance and prognostic value of *GATA2* expression and mutations in pediatric AML. **Methods.** In a large cohort of *de novo* pediatric AML patients, mutation screening of *GATA2* was performed using Sanger sequencing. *GATA2* expression was determined using gene expression profiling (Affymetrix HGU133 Plus 2.0 microarray) and quantitative real-time PCR. Informed consent was obtained after Institutional Review Board approval according to local laws and regulations, and in accordance with the Declaration of Helsinki.Results*GATA2* mutations were detected in 5/230 pediatric AML cases, representing a frequency of 2.2% overall, and 9.8% in cytogenetically normal (CN-)AML. Co-occurrence of *GATA2* mutations with various other recurrent mutations was observed in all cases (*N-RAS* mutations (N=4), *NPM1* mutations (N=2), *CEBPA* double mutations (N=2), and *WT1* mutations (N=1)). The clinical significance of *GATA2* mutations should be determined in a larger cohort. Both at diagnosis and clinical relapse, *GATA2* expression was heterogeneous. In 151 out of 237 patients (64%), *GATA2* expression at diagnosis was higher than in normal bone marrow. In a subgroup of 38 patients, *GATA2* expression was studied during follow-up. In complete remission, normalization of *GATA2* expression was observed, whereas *GATA2* expression levels stayed high in patients with refractory disease.Importantly, high *GATA2* expression at diagnosis proved to be an independent poor prognostic factor for event free survival (HR 2.1, p=0.001) and disease free survival (HR 2.2, p=0.005), with a trend towards worse overall survival (HR 1.7, p=0.056). The prognostic impact of *GATA2* was particularly high in specific morphologic and genetic AML-subgroups. High *GATA2* expression identified a group of patients with a significantly worse outcome among patients with high *WT1* expression. Moreover, in patients with FAB-M5 morphology and inv(16), pronounced differences in survival were observed between patients with high vs. normal *GATA2* expression. **Summary and Conclusions. .** We conclude that high *GATA2* expression is a novel poor prognostic marker in pediatric AML, which identifies patients with a severely dismal prognosis in specific AML subgroups. Since *GATA2* was a potent poor prognostic factor for overall survival, event free survival and disease free survival, *GATA2* expression may be a useful marker for better risk-group stratification and risk adapted therapy in the future.

Background. The prognosis of patients with acute myeloid leukemia (AML) refractory to first induction therapy is poor and highly dependent on response to salvage therapy as well as subsequent allogeneic hematopoietic stem cell transplantation (HSCT). Best outcome can be achieved after allogeneic HSCT performed in complete remission (CR). Therefore, improvement of response to salvage therapy is mandatory. **Aims.** The primary goal of the AMLSG 05-04 trial of the German Austrian AML Study group (NCT00143975; ClinicalTrials.gov) was to assess the response rate and overall survival (OS) in patients < 61 years of age with primary refractory AML treated with high-dose cytarabine and mitoxantrone in combination with all-*trans* retinoic acid (ATRA) and gemtuzumab ozogamicin (GO).Here we report the final results including long-term survival data. **Methods.** Patients with AML refractory to first induction were eligible for enrollment. All patients gave informed consent.Salvage therapy (GO-A-HAM) consisted of GO 3mg/m^2, iv on day 1; cytarabine 3mg/m^2, iv bid. days 1-3; mitoxantrone 12mg/m^2, iv days 2 and 3 and ATRA 45mg/m^2, po days 4-6 and 15mg/m^2 po days 7-28.In all patients an allogeneic HSCT was intended after completion of salvage therapy. **Results.** 93 patients were enrolled between July 2004 and June 2007. All patients received prior intensive induction therapy with idarubicin, cytarabine and etoposide. Median age at enrollment was 48 years (range: 22-62), type of AML was *de novo* n=77; secondary, n=4, and therapy-related n=12. Distribution of cytogenetic risk groups revealed n=7 (8%) favorable risk, n=51 (58%) intermediate risk, and n=30 (34%) high risk patients. *FLT3*-ITD and *NPM1* mutations were present in n=18 (22%) and n=12 (15%) patients, respectively. CD33 (>20% expression measured by flow cytometry) was expressed on leukemic blasts in 87% of the patients.Results after GO-A-HAM were as follows: CR was achieved in n=28 (30%), CR with incomplete platelet recovery (CRi) in n=19 (20%), partial remission (PR) in n=10 (11%), refractory disease (RD) in n=33 (35%), and n=3 patients (3%) died. Major toxicities CTC > grade 2 were infections (65%), gastrointestinal symptoms (14%), and neurological impairments (8%). Seventy (75%) patients proceeded to an allogeneic HSCT (n=16, MRD; n=49, MUD; n=5, haplo-identical donor) all within 3 months after GO exposure. Nine cases of veno-occlusive disease (VOD) after HSCT occurred, 5 (7%) of them were graded moderate/severe.Median follow-up was 48.6 months, 4-year OS rate was 32% (95%-CI 24%- 44%). Best OS rate was achieved in patients attaining CR, CRi or PR after GO-A-HAM who received subsequent allogeneic HSCT (n=50) with 47% (95%-CI, 35-64%). In contrast, OS rate was poor in patients without response to GO-A-HAM and subsequent allogeneic HSCT (n=20) or those not receiving an allogeneic HSCT irrespective of response to GO-A-HAM (n=23) with 12% each. (95%-CI 3-45%; 4-42%)No prognostic marker for response to salvage therapy or survival was identified. **Conclusions.** GO-A-HAM is an effective treatment option for primary refractory AML patients leading to high response rates. The combination with subsequent allogeneic HSCT was feasible without increased VOD rate. Survival of responding patients after allogeneic HSCT was promising.

[3]Hematology, Catania University, Catania, Italy

Aims. We designed a phase II study to assess the antitumor efficacy of the combination regimen with low-dose lenalidomide and low-dose cytarabine in patients with acute myeloid leukemia (AML) aged more than 70 years. **Methods.** Thirty-three patients (median age 75 years, range: 70-85) were consecutively enrolled in the study. Median white blood cell count at diagnosis was $5.5x10^9$/l (range: 0,59-46,$8x10^9$/l), whereas median haemoglobin was 9,4 g/dl and median platelet count was $29x10^9$/l. Ten out of 33 patients had a normal karyotype, 19/33 an intermediate or unfavourable karyotype and 4/33 were not evaluable. Sixteen patients had a *de novo* AML, whereas 17 patients had a secondary AML (12 after MDS, 2 after a CMPD, 1 after myelofibrosis, 2 after chemo-radiotherapy for a breast cancer). Patients received low-dose lenalidomide (10 mg/day orally, days 1-21) and low-dose cytarabine (20mg twice day subcutaneously, days 1-15). Therapy was repeated every 6 weeks, up to 6 cycles. **Results.** Seven out of 33 patients died in aplasia while receiving the first induction cycle of therapy, and are not evaluable for response; one is not evaluable due to death while receiving chemotherapy (acute heart failure). Four patients are too early. Twenty-two patients completed at least one cycle of therapy and are evaluable for response. Among these patients, 11/22 (50%) obtained complete remission (CR) after the first cycle, recovering normal WBC, hemoglobin and platelets values after a median of 32 days (range: 25-44) from the start of chemotherapy. Eight out of 11 responding patients are still in morphologic, cytogenetic and FISH CR after 24, 22, 20,14, 11, 10, 5 and 3 months from the start of therapy, respectively. Two patients died while in CR after receiving, respectively, the second and the third cycle of therapy due to a multi organ failure after an infectious complication. One patient relapsed 3 months after the first cycle and died with active leukemia. The other 11 patients who completed at least one cycle of therapy did not respond at all and rapidly died due to progressive disease. At present, with a median follow up of 13 months for surviving patients, 8/22 (36%) are alive in continuous CR, 2/22 died in CR and 1/22 died due to relapse. Notably, all responding patients presented with low blast count and unfavorable cytogenetics at diagnosis. **Conclusions.** Low-dose lenalidomide has high activity in addition to low-dose cytarabine, in a subset of very elderly AML patients with extremely poor-prognosis. Considering the low compliance of very elderly, frail AML patients to high-dose therapy, this low dose schedule seems to be particularly profitable for patients with low blast count and unfavorable cytogenetics. The study was registered at EMA with the EUDRACT no 2008-006790-33.**Acknowledgements:** Celgene is acknowledged for providing Lenalidomide for the patients. The study was supported in part by AIL Pesaro Onlus.

HIGH BONE MARROW EXPRESSION OF LGALS3, THE GENE ENCODING GALECTIN-3, IS AN INDEPENDENT UNFAVORABLE PROGNOSTIC FACTOR FOR OVERALL SURVIVAL IN PATIENTS WITH *de novo* ACUTE MYELOID LEUKEMIA

CL Cheng, MC Lee, JY Jhuang, HA Hou, WC Chou, HF Tien
National Taiwan University Hospital, Taipei, Taiwan

Background. Galectin-3, a β-galactoside-binding lectin, plays an important role in cancer cell progression, adhesion, apoptosis, transformation, angiogenesis and metastasis. A lot of researches also demonstrated an important role of galectin-3 expression in several types of malignancies. However, the studies concerning clinical implications of galectin-3 expression in patients with acute myeloid leukemia (AML) are scarce. **Aims.** In this study we aimed to determine the clinical implication of the expression of *LGALS3,* the gene encoding galectin-3, in adult *de novo* non-M3 AML patients. **Methods.** We investigated the expression of *LGALS3* in the bone marrow (BM) by reverse-transcriptase real-time polymerase chain reaction in a test cohort consisting of 280 adults 15 years of age or older with newly diagnosed *de novo* non-M3 AML at the National Taiwan University Hospital and correlated the results with clinical features and outcomes of the patients. The prognostic impact of BM *LGALS3* expression was also validated in an independent cohort comprised 42 *de novo* non-M3 AML patients. **Results.** Among 280 patients, those with higher BM *LGALS3* expression were older (P<0.001), more frequently had French-American-British (FAB) M4 and M5 subtypes (both P=0.003), and CD14 expression on leukemic cells (P=0.009), but less commonly had FAB M1 subtype (P<0.001). In addition, higher *LGALS3* expression was closely associated with *PTPN11* mutation but negatively associated with *FLT3-ITD* and *CEBPA*$^{\text{double mutation}}$. There was no correlation between the cytogenetic abnormalities and BM *LGALS3* expression. Survival analysis was performed in 211 non-M3 AML patients who received standard intensive cure-intent chemotherapy. Patients with higher BM *LGALS3* expression, compared to those with lower expression, had lower CR rates (61.5% *vs.* 82.5%, P=0.001) and higher primary refractory rates (23.1% *vs.* 10.8%, P=0.023). With a median follow-up time of 69.5 months, patients with higher BM *LGALS3* expression had a shorter overall survival than those with lower expression (median 16.3 months *vs*. 39.8 months, P=0.02). Moreover, multivariate analysis demonstrated that higher BM *LGALS3* expression was an independent poor prognostic factor for overall survival among total patients and patients with normal karyotype. The unfavorable prognostic impact of higher BM *LGALS3* expression was also confirmed in the independent validation cohort. A scoring system incorporating high BM *LGALS3* expression and nine other prognostic factors, including age, white blood cell count, cytogenetics, *NPM1/FLT3-ITD*, *MLL-PTD*, *CEBPA*$^{\text{double mutation}}$ and mutations of *AML1/RUNX1* and *WT1*, into survival analysis was proved to be very useful to stratify AML patients into different prognostic groups (P<0.001). **Summary and Conclusions.** Our research provides evidences that BM *LGALS3* expression is associated with distinct biologic and clinical characteristics in AML. Higher BM *LGALS3* expression is significantly correlated with poor prognosis in AML patients. BM *LGALS3* expression may serve as a new biomarker to predict clinical outcome. Galectin-3 may be a potential target for the treatment of AML patients with higher expression of this factor.

0059

THE INCIDENCE OF CENTRAL NERVOUS SYSTEM INVOLVEMENT IN ACUTE MYELOID LEUKEMIA

N Alakel, F Stölzel, M Kramer, S Parmentier, M Bornhaeuser, G Ehninger, M Schaich
University Hospital Dresden, Drsden, Germany

Background. Acute myeloid leukemia (AML) is able to affect the central nervous system (CNS). However, so far most studies examined paediatric patients or reported about small numbers of patients. Thus, little is known regarding the clinical aspects and treatment outcome of CNS-involvement in adult AML. **Aims.** To analyze the clinical appearance, risk factors and impact of CNS involvement in a large series of adult patients with AML treated within the studies of the Study Alliance Leukemia (SAL) at initial diagnosis or relapse. **Methods.** 3530 AML patients with a median age of 57 years (range 15-87) included in the prospective AML96, AML2003 and AML60+ trials of the SAL study group were evaluated for CNS involvement. Patients with neurological symptoms were referred to an aspiration of the cerebrospinal fluid (CSF) and CNS involvement was proven depending on morphology and/or flow cytometry of the CSF. Prophylactic CNS therapy was not regularly performed within these treatment protocols. CNS involvement was treated using intrathecal triple chemotherapy (ITC). **Results.** A total of 50 of 3530 patients had proven CNS involvement with an overall incidence of 1.4%. Patients with CNS involvement were similar to patients without CNS involvement with respect to gender, age, *FLT3/NPM1* mutations and AML-therapy.The incidence of extramedullary AML other than CNS was significantly higher in patients with CNS involvement (n=26, 52 % *vs.* n=246, 7%, *p<0.001*). AML FAB M5 occurred more frequently in patients with CNS involvement (n=16, 32% *vs.* n=452, 13%, *p<0.01*). Furthermore, patients with CNS involvement had significantly higher lactate dehydrogenase (LDH) levels (1049 *vs.* 421 IE/l, *p<0.001*), higher white blood cell count (WBC) (64 *vs.* 11 Gpt/l, *p<0.001*) and had a more often trisomy 8 (n= 8, 16% *vs.* n= 277, 8%, *p=0.03*). Comparing patients with CNS involvement with patients without CNS involvement at diagnosis no significant difference in overall survival at 2 years (40% *vs.* 41%) and event free survival at 2 years (20% *vs.* 26%, respectively) was observed.20 patients had CNS involvement at time of initial presentation and 30 patients had CNS involvement at first, second or third relapse. Only 6 of 20 patients (30%) with CNS involvement at initial diagnosis developed systemic relapse, similar to patients without CNS involvement (n=1243, 35%). Furthermore, none of the patients in this group developed CNS involvement at the time of relapse. On the contrary all patients with CNS involvement at relapse developed again systemic, as well as CNS relapse (n=30,100%). **Conclusions.** CNS involvement in AML is a rare entity and it is accompanied with higher incidence of other sites of extramedullary AML. Factors associated with an increased risk of CNS involvement include: trisomy 8, FAB M5, higher LDH levels and higher WBC count at diagnosis. Patients with CNS disease at initial diagnosis of AML have similar survival outcomes as compared to those without CNS disease if treated with intrathecal therapy, whereas extramedullary relapse within the CNS is associated with a poor outcome.

0060

POSITIVE PROGNOSTIC IMPACT OF > 4 LOG REDUCTION OF NPM VALUE AFTER INDUCTION AND CONFIRMED MOLECULAR REMISSION IN DENOVO CYTOGENETICALLY NORMAL AML PATIENTS WITH NPM MUTATIONS

M Clavio[1], M Miglino[2], C Marani[2], N Colombo[2], R Grasso[2], F Guolo[2], G Pica[2], F Ballerini[2], E De Astis[2], F Cruciani[2], G Pastori[2], L Mitscheunig[2], M Bergamaschi[2], S Aquino[2], P Minetto[2], C Ghiggi[2], M Sessarego[2], AM Carella[2], M Gobbi[2]
[1]Hematology and Oncology, IRCCS Ospedale S Martino IST, Genova, Italy
[2]IRCCS Ospedale S Martino IST, Genova, Italy

Background and Aims. In the subset of NPM-mutated denovo AML patients (NPM-AML), the study of NPM mutations has been proposed as a means to assess response to therapy and monitor minimal residual disease (MRD). We compared the clinical value of MRD monitoring by cytofluorimetric methods, WT1 expression and by the study of NPM mutations in a series of NPM-AML patients. **Patients and Methods.** Bone marrow samples of 26 consecutive normal karyotype NPM-AML patients (median age 54 years) achieving CR after conventional chemotherapy were studied. A four-color flow cytometer (FCM) was used to perform immunophenotype (IF). NPM A mutations and WT1 expression were studied by a quantitative Real Time PCR. Immunophenotypic complete response (IF-CR) was defined as the absence of clonal cells by FCM. Lack of NPM mutation was defined as NPM molecular complete response (NPM-CR), whereas the normalization of WT1 expression defined WT1 molecular complete response (WT1-CR). If the undetectability of the NPM mutation was confirmed in two consecutive samples, the response was defined as confirmed NPM-CR. **Results.** The relapse risk was not affected by the achievement of IF-CR and WT1-CR after consolidation therapy, but it was significantly lower in patients achieving a confirmed NPM-CR (3/10 in confirmed NPM mol-CR and 15/16 in patients without confirmed NPM mol-CR, p<0.03). The projected DFS of patients achieving a < 4 log or ≥ 4 log reduction in NPM values after induction therapy were 12.6% and 50%, respectively at 36 months (p=0.009). Moreover, DFS was clearly affected by the achievement of a confirmed NPM-CR (36 month-projected DFS is 63% for patients who reached confirmed NPM-CR and 0% for those who did not, p 0.001). Cox regression analysis showed that DFS was influenced only by the achievement of confirmed NPM-CR (p 0.004) and by blast count at diagnosis (p 0.003). Furthermore, FLT3-ITD status at diagnosis had no impact on DFS in the cohort of patients reaching NPM-CR or in those with confirmed NPM-CR. The projected OS of patients achieving a < 4 log or ≥ 4 log reduction of NPM values after induction therapy was 19.6% and 100%, respectively, at 36 months (p = 0.01) (Figure 1). The reappearance of clonal cell at FCM analysis (IF-rel), WT1-molecular relapse (WT1 rel) and NPM-molecular relapse (NPM rel) were always followed by hematologic relapse (H-rel). The median interval between IF-rel, WT1-rel and NPM-rel and H-rel was 0.8 months (range 0-4.6), 1.2 months (range 0-4.7) and 4.4 months (range 0.9-8.4), respectively. The interval between NPM-rel and H-rel was significantly longer than the interval between IF-rel and H-rel (p<0.01) or WT1-rel and H-rel (p<0.03). **Conclusions.** In NPM-AML DFS and OS were mainly affected by the kinetics of the clearance of NPM mutated cells (> 4 log reduction or NPM-CR after induction) and by the achievement of confirmed NPM-CR after consolidation. Furthermore studying NPM mutations in the follow up period allows for early prediction of H-rel compared to FCM and evaluation of WT1 expression.

[15]Univerité Paris 7, Paris, France

Aim. Previous studies with conventional doses of GO have reported prolonged thrombocytopenia as a frequent adverse event. The ALFA-0701 trial demonstrated the efficacy of adding 5 doses of 3 mg/m2 GO on day 1, 4 and 7 of a standard 7+3 induction and day 1 of two consolidation courses in patients with *de novo* AML aged 50-70 years (median, 64y) (Castaigne et al., ASH meeting 2011). However, despite the use of fractionated small doses prolonged thrombocytopenia were more frequent in the GO arm B than in control arm A. We report here on their incidence and prognostic significance. **Methods.** According to IWG criteria, complete remission with incomplete platelet recovery (CRp) is defined as CR with a platelet count (PLTC) <100.109/L. Prolonged thrombocytopenia was defined here as no PLTC >100.109/L recovery on day 45 following the onset of previous chemotherapy course (grade 1-2, PLTC >50 and <100.10.9/L; grade 3-4, PLTC ≤ 50.109/L). **Results.** The CR/CRp rate was 104/139 (74.8%) in arm A and 113/139 (81.3%) in GO arm B. (P=0.25), with more CRp in arm B (11 vs 4). During induction, 3 patients in arm A and 4 in arm B died with haemorrhage. Among CR/CRp patients, 86.5% in arm A and 76.1% in arm B received the 2 planned consolidation courses (P= 0.07). The reason for not receiving consolidation therapy was prolonged thrombocytopenia in 8 arm B patients. Overall, 19 (14 grade 1-2 and 5 grade 3-4) and 74 (53 grade 1-2 and 21 grade 3-4) episodes of prolonged thrombocytopenia were observed in 14 arm A and 48 arm B patients, respectively (P<0.0001), either after induction (4 arm A and 12 arm B), first (7 arm A and 28 arm B), or second consolidation (8 arm A and 34 arm B). Thrombocytopenia resolved within 2 to 29 months (median, 5 months) in 4/19 and 34/74 episodes in arm A and B, respectively (P= 0.07). In the other cases, thrombocytopenia was still present at the time of relapse, death, or transplant. Median number of platelet transfusion episodes was significantly higher in arm B after the 3 chemotherapy courses. One CRp patient died with haemorrhage in arm B. Grade 3-4 bleeding events occurred in 4/139 (2.9%) in arm A and 12/139 (8.6%) in arm B (P= 0.07). In arm B, RFS was similar in CR and CRp patients (2-year RFS, 50.1% [40.3-62.2] vs 51.9% [28.7-93.9]; P=0.88). Based on univariable analyses in the 217 responders, persistent thrombocytopenia was only associated with liver toxicity (44% in patients with liver toxicity vs 25% of those without, P= 0.03). Among the 208 responders alive at 6 months, 57 (11 arm A, 46 arm B) had previously experienced prolonged thrombocytopenia, but this did not modify their survival (2-year OS, 71.7% vs 53.2%.; HR= 0.63 [0.35-1.13]; P= 0.12) and was even associated with an improved RFS (2-year RFS, 51.2% vs 31.5%; HR= 0.61 [0.39-0.96]; P= 0.03). **Conclusions.** prolonged thrombocytopenia, even if frequently observed after GO treatment, does not confer an adverse prognosis.

0062

CD56 ANTIGEN EXPRESSION AS THE MOST IMPORTANT PROGNOSTIC FACTOR IN NORMAL KARYOTYPE ACUTE MYELOID LEUKEMIA WITHOUT THE FLT3-ITD MUTATION

I Djunic[1], M Virijevic[1], A Novkovic[2], N Kraguljac-Kurtovic[1], V Djurasinovic[1], N Colovic[1], A Vidovic[1], N Suvajdzic-Vukovic[1], D Tomin[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinical Hospital Center Zemun, Belgrade, Serbia

Background. Patients with normal karyotype acute myeloid leukemia (NK-AML) without the FLT3 internal tandem duplication (FLT3-ITD) mutation account

for approximately 30% of all AML cases and exhibit a heterogeneous clinical outcome. The prognostic factors in this subgroup of AML patients are still unknown. **Aims.** The aims of this study were to estimate the prognostic factors for complete remission (CR) rate, overall survival (OS) and disease-free survival (DFS) in patients with NK-AML in the absence of the FLT3-ITD mutation as well as to determine the relevance of CD56 antigen expression, an immunophenotypic marker, on outcome in this cohort of patients. **Methods.** The study involved 112 subjects with NK-AML without the FLT3-ITD mutation during a follow-up period of 42 months. As risk factors for rate of CR, OS and DFS in months in this cohort of patients the following were evaluated: age, ECOG performance status (PS), leukocytosis (<30x10^9/L vs ≥3010^9/L), lactate dehydrogenase (LDH) more than 1.5 x upper limit of normal, and CD34 expression (<10% vs ≥10%). For CD56 antigen expression, detected by flow-cytometry, the cut-off value ≥20% was taken as positive (CD56+). Patients were treated by the Medical Research Council (MRC) 12 regimen. Risk factors were identified using univariate and multivariate analysis. **Results.** The mean age of the patients was 55 years (range 21-79). Univariate analysis showed that the following risk factors were significant for CR rate: age ≥55 years (p = 0.012), ECOG PS ≥2 (p = 0.011), leukocytosis (p = 0.030), LDH (p = 0.011), and CD56+ (p = 0.025). Multivariate analysis indicated CD56+ as the most important risk factor for CR rate: p = 0.005, HR 0.266 (95%CI 0.086-0.765). Significant factors for OS in univariate analysis were: age ≥55 years (p = 0.013), ECOG PS ≥2 (p = 0.020), leukocytosis (p = 0.046), LDH (p = 0.050) and CD56+ (p = 0.024). Multivariate analysis indicated CD56+ as the most important risk factor for OS: p = 0.008, HR 2.180 (95%CI 1.352-3.962). CD56+ was not significant for DFS in this subset of patients. **Conclusions.** This study showed that CD56 antigen expression on leukemic cells in patients with NK-AML without the FLT3-ITD mutation predicts shorter OS and a lower rate of CR in comparison with patients from the same subgroup without CD56 positivity. Therefore, more intensive therapeutic regimens should be considered in such cases.

0063

THE ROLE OF MAINTENANCE THERAPY IN ACUTE PROMYELOCYTIC LEUKEMIA - A SYSTEMATIC REVIEW AND META-ANALYSIS

E Muchtar[1], L Vidal[2], A Gafter-Gvili[2], R Ram[2], O Shpliberg[2], P Raanani[2]
[1]Rabin Medical Center, Petah tikva, Israel
[2]Institue of Hematology, Petah Tikva, Israel

Background. Acute promyelocytic leukemia (APL) is the most curable type of AML, with a cure rate over 80%. A consensus exists regarding the administration of both induction and consolidation treatments, albeit different approaches. However, there is conflicting evidence regarding the effect of maintenance treatment on survival. **Aims.** Objectives of this review were to examine the efficacy and safety of maintenance therapy in patients with APL and to establish the best regimen for maintenance in these patients. **Methods.** We performed a systematic review and meta-analysisof randomized controlled trials assessing maintenance treatment in patients with newly diagnosed APL in first complete remission. We searched *The CochraneLibrary*, MEDLINE, EMBASE, LILACS, conference proceedings, databases of ongoing trials, and references of published trials until September 2011. As different comparator arms were used during maintenance, we pooled data for the following comparisons: any maintenance *vs.* observation; ATRA-based maintenance *vs.* non- ATRA based maintenance and ATRA alone *vs.* ATRA and chemotherapy. Primary outcomes were overall survival (OS) and disease-free survival (DFS). Hazard ratios (HR) with 95% confidence intervals (CI) were estimated and pooled using random-effects model. **Results.** Nine randomized controlled trials enrolling 2012 patients were included in the meta-analysis. According to the three above designed comparisons, there is no evidence that maintenance therapy improves OS (HR for any maintenance *vs*. observation 1.07, 95% CI 0.23-4.86; HR for ATRA-based maintenance *vs*. non- ATRA based maintenance 0.98, 95% CI 0.64-1.51; HR for ATRA alone maintenance *vs*. ATRA and chemotherapy 1.13, 95% CI 0.62-2.07). However, DFS was improved with any maintenance compared to observation (HR 0.63, 95% CI 0.41-0.97); (5 trials, 1209 patients). Moreover, ATRA based regimens improves DFS compared to non-ATRA based regimens HR 0.61 95% CI 0.46-0.83); (4 trials, 749 patients), with further benefit for ATRA and chemotherapy maintenance compared to ATRA alone (HR 1.47 95% CI 1.03-2.1; 4 trials, 1028 patients). The report on major adverse events was scarce, precluding meta-analysis of clinically relevant adverse events. However, increased rates of grade 3/4 adverse events were noted for any maintenance *vs*. observation and for ATRA and chemotherapy *vs*. ATRA alone. **Conclusions.** Results of the present meta-analysis suggest that maintenance therapy improves DFS in APL patients compared to observation and does not support an OS benefit. The significance of this finding is limited due to significant clinical and statistical heterogeneity between studies (I^2 of heterogeneity=72%). ATRA based regimens improve DFS but not OS compared to non-ATRA based regimens, with further benefit for ATRA and chemotherapy compared to ATRA alone. The discrepancy between the advantage in terms of DFS and the lack of influence on OS in all comparisons might be explained by an increased toxicity of maintenance which might negatively balance the improved DFS or by effective salvage protocols for relapsing patients. The effect of maintenance therapy should be further evaluated in the various prognostic groups, and the different induction and consolidation regimens.

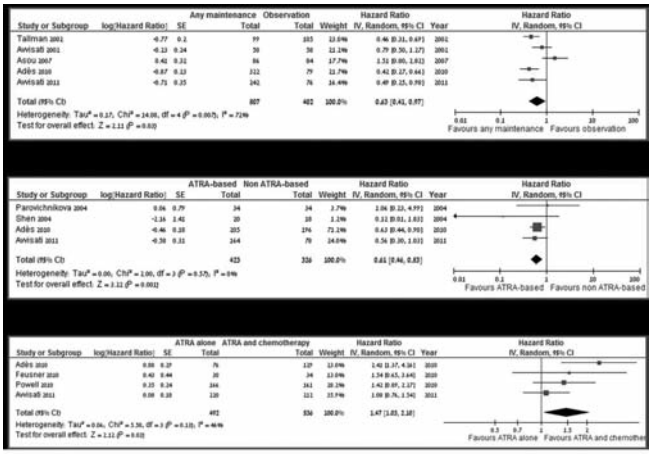

Figure: disease-free survival (DFS) for the 3 designed comparisons. Black squares represent the point estimate, their sizes represent their weight in the pooled analysis, and the horizontal bars represent the 95% CI. The black diamond at the bottom represents the pooled point estimate. ATRA, all-trans retinoic acid; CI, confidence interval; SE standard error.

TIME FROM DIAGNOSIS TO INTENSIVE CHEMOTHERAPY INITIATION MIGHT NOT ADVERSELY IMPACT THE OUTCOME OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Bertoli[1], E Berard[2], F Huguet[3], A Huynh[3], S Tavitian[3], F Vergez[4], E Delabesse[4], C Demur[4], A Sarry[3], V Lauwers-Cances[5], C Récher[3]
[1]Toulouse University Hospital, Toulouse, France
[2]Department of Epidemiology, Health Economics and Public Health, UMR 1027, Toulouse, France
[3]Department of Hematology, Toulouse University Hospital, Toulouse, France
[4]Hematology Laboratory, Toulouse University Hospital, Toulouse, France
[5]Department of Epidemiology, Health Economics and Public Health, Toulouse, France

Background. Although acute myeloid leukemia (AML) is a therapeutic emergency, initiation of chemotherapy is sometimes delayed because of medical, geographical or administrative constraints, with unknown consequences. A recent study (Sekeres *et al*., Blood 2009) tended to show that a 5-day or more delay had a negative impact on response rate and overall survival of patients aged 60 or younger. This conclusion is now cited in international guidelines (Döhner *et al*., Blood 2010). **Methods.** We retrospectively studied the impact on outcome of the time from diagnosis to treatment (TDT) in 552 consecutive patients treated with intensive chemotherapy in Toulouse University Hospital between 2000 and 2009 for non-promyelocytic newly diagnosed acute myeloid leukemia. TDT was transformed using restricted cubic spline method to obtain a continuous function. **Results.** The median age of our cohort was 57 years (range, 16-83), with 61% being 60 or younger. Secondary and hyperleukocytic AML (*ie*. WBC > 50 G/L) counted for 20% and 24% respectively. According to the European LeukemiaNet classification 22%, 29%, 26% and 23% of patients were classified in favorable, int-I, int-II and adverse categories. ECOG performance status > 1, tumoral syndrome, leukostasis and infection at diagnosis were found in 13%, 26%, 4% and 13% respectively. The induction chemotherapy was homogeneous since 94% of patients received either daunorubicin (60 mg/m²/d for three days) or idarubicin (8 g/m²/d for five days) in combination with standard doses of cytarabine (100 or 200 mg/m²/d for seven days according to age. The median TDT was seven days (range, 1-73) with 331 (60%) patients having a TDT longer than 5 days. In the 331 patients whose chemotherapy was delayed more than 5 days, the main causes were diagnosis out of Toulouse University Hospital (26%), an awaited karyotype result (12%), diagnosis out of leukemia unit (12%) or infection at diagnosis (8%). 54 (10%) early deaths occurred in our series. TDT was not significantly associated with early death, both in non-adjusted analysis (p=0.06) and after adjustment (p=0.15). CR or CRi was obtained in 399 patients (72%). After adjustment, TDT was not significantly associated with response rate (p=0.1675 for younger patients and WBC ≤ 50 G/L). The median overall survival was 18 months (12 in older and 28 in younger). TDT was associated with overall survival (p=0.047): the non-adjusted risk of death is U-shaped with a nadir to day 6 (Figure 1a). However, after adjustment for age, secondary AML, WBC, ECOG performance

status, ELN risk groups and type of consolidation, TDT was no longer associated with OS (p=0.74) (Figure 1b). TDT did not have an impact on OS regardless of age and WBC. **Conclusions.** We did not find any harmful signal concerning the effect of TDT on OS, early death and response rate, both in younger and older patients with newly diagnosed AML. Since personalized therapies based on particular genetic features are going to be developed, our study suggests that waiting for specialized laboratory tests does not seem unreasonable, except for well-known early complications.

IDARUBICIN OVERCOMES MULTIDRUG RESISTANT 1 INDUCED CHEMORESISTANCE WITH HIGHER INDUCTION REMISSION RATE THAN DAUNORUBICIN IN *DE NOVO* ACUTE MYELOID LEUKEMIA PATIENTS

B Xu[1], Z Zha[1], F Chen[2], P Shi[2], X Guo[2], F Fan[1], H Huang[1]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China
[2]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China

Background. Multidrug resistance 1(MDR1) mediated chemoresistance was extensively considered to play an important role in treatment failure in acute myeloid leukemia(AML). Idarubicin(IDA), a synthetic daunorubicin(DNR) analog, was reported to have a distinct advantage over that of DNR for remission induction combined with cytarabine(Ara-C) in AML. But the underlying molecular mechanisms remained unclear. **Aims.** This study is aiming to determine if IDA can overcome MDR1 induced chemoresistance in *de novo* acute myeloid leukemia patients. **Methods.** Clinical data of 125 patients aged between 12 to 80 years who have received daunorubicin (DNR at 35~45mg/m^2/d, 3 days) or idarubicin (IDA, 6~8 mg/m^2/d, 3 days) in combination with cytarabine (Ara-c 100~200 mg/m^2/d, 7 days) for remission induction were retrospectively analyzed. The patients were subdivided into high and low MDR1 expression groups according to the median expression of MDR1 mRNA in their pre-treated bone marrow cells. Comparisons were performed using X^2 test and independent-samples T test. **Results.** Treatment with IDA and DNR in combination with Ara-C resulted in satisfactory CR rates of 82.5% and 57.4% CR respectively. Patients with high MDR1 expression had a significantly lower CR rate than those with low MDR1 (59.7% vs 77.8%, p=0.029). We then subdivided the patients into IDA/high MDR1, DNR/ highMDR1, IDA/low MDR1, and DNR/low MDR1 groups and compared the CR rate. Results showed CR rate in the IDA/high MDR1 group (23/28, 82.1%) was higher than the DNR/ highMDR1 group (14/34, 41.2%)(P=0.001), while there were no statistical difference between IDA/low MDR1 (24/29, 82.8%)and DNR/low MDR1 group(25/34, 73.5%)(P=0.380), suggesting IDA may overcome MDR1 induced chemoresistance. Besides, the IDA arm was also superior to DNR arm on CR rate in favorable (21/23(91.3%) vs 15/25(60.0%), P=0.012) or intermediate cytogenetic risk groups(22/27(81.5%) vs 20/35(57.1%), P=0.042). To investigate whether MDR1 also has an impact on induction remission in favorable or intermediate risk groups, patients were further divided into high and low MDR1 subgroups in favorable and intermediate risk groups. MDR1 expression level between the two risk groups was not of statistical significance (p=0.645), but CR rate in IDA/favorable/high MDR1 group (9/10, 90.0%) was higher than DNR/favorable/high MDR1 group (4/11, 36.4%) (p=0.011). Similarly, CR rate in IDA/intermediate/high MDR1 group (12/15, 80.0%) was higher than DNR/intermediate /high MDR1 group (8/19, 42.1%)(p=0.026), suggesting overcoming MDR1 induced chemoresistance also potentiated IDA remission induction superiority in favorable or intermediate risk groups. **Conclusions.** IDA was superior to DNR for remission induction with a significantly higher CR rate. Overcoming MDR1 induced chemoresistance and improving the CR rate in favorable and intermediate cytogenetic risk groups potentiated IDA the superiority. A larger prospective clinical trial is needed to further confirm this point of view.

THE CLINICAL FEATURES AND PROGNOSTIC IMPACT OF DNMT3A GENE MUTATION IN JAPANESE PATIENTS WITH *de novo* AML

S Wakita, H Yamaguchi, T Ryotokuji, J Takeuchi, I Omori, T Hirakawa, T Kitano, Y Mitamura, F Kosaka, K Inokuchi, K Dan
Division of Hematology, Department of Internal Medicine, Nippon Medical School, Tokyo, Japan

Background. and Aims. The *DNA methyltransferase 3A* (*DNMT3A*) gene mutation was identified by whole-genome sequencing in patients with acute myeloid leukemia (AML). *DNMT3A* encodes for the enzyme DNA (cytosine-5)-methyltransferase 3A and belongs to the family of other methyltransferases. These enzymes are involved in adding methyl groups to the cytosine residue of CpG dinucleotides and thus play an important role in epigenetic regulation of genes, but the mechanism of *DNMT3A* mutation -associated leukemogenesis was still unknown. About clinical impact of *DNMT3A* mutation, several groups reported that *DNMT3A* mutation have been associated with adverse outcome. We analyzed clinical features and prognostic impact of *DNMT3A* mutation in patients with Japanese patients with AML. **Methods.** We retrospectively analyzed 188 cases of *de novo* AML treated at Nippon Medical School Hospital and its affiliated facilities from 2000 to 2010. We analyzed 188 samples at initial presentation and 70 samples at relapse. **Results.** *DNMT3A* mutations were detected in 35 cases (18.6%) at initial presentation, and 12 cases (17.1%) at relapse. Most frequently, codon R882 located in exon 23 was mutated, and 32 cases (91.4%) of these mutations were located within methyltrasferase domain.We evaluated the correlation of clinical and genetic characteristics with *DNMT3A* mutations. The frequency of higher white blood cell count (p= 0.044), M5 in FAB classification (p= 0.039), and intermediate risk karyotype (p<0.001) in patients with *DNMT3A* mutations were significantly higher than those in patients without them. Also, patients with *DNMT3A* mutations had a mutation in *NPM1* (p<0.001), *FLT3ITD* (p<0.001), and *IDH1/2* (p=0.016) more frequently.We next assessed the prognostic impact of *DNMT3A* mutations. For total cohort of patients with AML, complete remission rate and rates of relapse free survival (RFS) at 5 years were not statistically different between AML patients with and without *DNMT3A* mutations. However the overall survival (OS) at 5 years in patients with *DNMT3A* mutation (11.0%) was significantly lower than those in patients without them (28.9%) (p=0.003). Among the intermediate risk karyotype or *FLT3ITD* negative AML patients, RFS at 5 years were not statistically different between AML patients with and without *DNMT3A* mutations, but OS at 5 years in patients with *DNMT3A* mutation (intermediate risk karyotype: 12.6%, *Flt3ITD* negative: 11.6%) was significantly lower than those in patients without them (intermediate risk karyotype: 23.9%, p=0.035, *FLT3ITD* negative: 30.9%, p=0.009). Finally *DNMT3A* was an independent adverse prognostic factor by multivariate analyses (Hazard ratio 2.573, 95% CI 1.036-6.386, p=0.042). **Conclusions.** This study shows that *DNMT3A* mutation is an important adverse prognostic factor among intermediate risk karyotype or *FLT3ITD* negative AML patients. Recently *TET2* and *IDH* 1/2 gene mutations in *de novo* AML were reported. These genes including *DNMT3A* play an important role in epigenetic regulation of genes such as methylation etc, and mutations of these genes may be associated with leukemogenesis of AML. Now we are analyzing *TET2* mutations among same our AML cohort, and we will show the prognostic impact of *TET2*, *IDH1/2* and *DNMT3A* mutations in patients with *de novo* AML.

EPIDEMIOLOGY AND OUTCOMES OF APL IN A LARGE POPULATION-BASED CANADIAN COHORT

C Paulson[1], A Serebrin[1], D Turner[1], J Bergeron[2], S Couban[3], D Jones[3], S Mahmud[1], C Meloche[2], M Sabloff[4], M Savoie[5], J Storring[6], M Seftel[1]
[1]University of Manitoba, Winnipeg, Canada
[2]Hôpital Maisonneuve-Rosemont, Montreal, Canada
[3]Dalhousie University, Halifax, Canada
[4]University of Ottawa, Ottawa, Canada
[5]University of Calgary, Calgary, Canada
[6]McGill University, Montreal, Canada

Background. Acute promyelocytic leukemia (APL) is a rare but highly curable sub-type of acute myeloid leukemia (AML). Recent epidemiologic studies suggest that APL incidence may be rising, and that outcomes of this disease are substantially worse than those reported in clinical trials. We hypothesized that in Canada: (1) that the incidence of APL is increasing and (2) in a universal health system with regional acute leukemia referral centres, outcomes would be as favorable as those suggested by clinical trials. **Aims.** To determine the incidence and mortality of APL using the population based Canadian Cancer Registry. **Methods.** New cancer diagnoses and deaths are required to be reported to provincial cancer registries in Canada. The Canadian Cancer Registry (CCR) collects data from provincial cancer registries, resulting in a national comprehensive, population-based database of cancer incidence and mortality. We reviewed all new diagnoses of APL in Canada between 1993 and 2007 to determine trends in incidence and mortality. **Results.** A total of 399 cases were identified, representing 3.01% of all AML cases. The age adjusted incidence of APL was 0.073 cases per 100,000. Incidence was higher in older patients (>50 years) (0.136/100,000, as compared to 0.057/100,000 for younger pts <50). There was an increased incidence in younger pts between 2005 and 2007 compared to the previous years (incident rate ratio 1.42, 95% confidence interval 1.07 - 1.88). For all patients, 30 day survival was 78.2%, and did not improve over the study period. In younger pts, 30 day survival was 89.3%, as compared to 64.5% in older adults. 5 year survival was 73.3% in younger adults, as compared to 29.1% in older adults. A logistic regression model was conducted in each subgroup, and there was no trend towards decreased early or late mortality with treatment in more recent years. **Conclusions.** In this, the largest complete national study of APL, the overall incidence was similar to previously published studies, but was higher in older adults. In younger adults, an increased incidence was noted in more recent years. The early death rate of 35.5% in patients over age 50 and 10.7% in patients younger than 50 are similar to previously published cohorts. This further confirms that early death rate (as a surrogate for therapy related mortality) is higher than suggested by clinical trials. Patient selection and rigorous attention to supportive care might account for this difference. The very high early death rate in older adults is concerning, and further efforts are required to determine how to improve outcomes for this group. We also recommend further close surveillance of APL in view of the recent increase in incident cases.

Acute myeloid leukemia - Clinical 2

THE CLINICAL RELEVANCE OF BAALC AND ERG EXPRESSION LEVELS IN PEDIATRIC AML

M Hermkens[1], M van den Heuvel-Eibrink[1], S Arentsen-Peters[1], A Baruchel[2], J Stary[3], D Reinhardt[4], M Zimmerman[4], V de Haas[5], R Pieters[1], M Zwaan[1]
[1]Erasmus MC, Rotterdam, Netherlands
[2]Robert Debré Hospital, Paris, France
[3]2nd Faculty of Medicine, Charles University, Prague, Czech Republic
[4]Hannover Medical School, Hannover, Germany
[5]Dutch Childhood Oncology Group, The Hague, Netherlands

Background. Pediatric AML is curable in approximately 70% of patients. Its prognosis is determined by genetic aberrations and early treatment response, although 20% of pediatric patients lack cytogenetic aberrations (CN-AML). In adult CN-AML patients, prognosis is worse when there is high expression of either *BAALC* (Brain And Acute Leukemia Cytoplasmic; chromosome 8q22) or *ERG* (E26 transformation-specific-related; chromosome 21q22). **Aims.** We studied expression levels of *BAALC* and *ERG* in children in different cytogenetic subgroups aimed at improving risk group stratification and thereby also risk-adapted treatment and survival in this subgroup. **Methods.** Using gene expression profiling (Affymetrix Human Genome U133 Plus 2.0 Array) we studied *BAALC* and *ERG* expression in 294 *de novo* pediatric AML patients, who had been fully characterized for molecular aberrations. Validation was done using RT-qPCR, where we found high correlations between GEP and RT-qPCR for *BAALC* (R_s=0.809, P<0.001) and *ERG* (R_s=0.798, P<0.001) expression levels. *BAALC*^{high} was defined as above-median and *ERG*^{high} as above the 75th percentile. **Results.** The CBF-AML group had significantly higher *BAALC* expression levels (P<0.001) than non-CBF-AML. However, there was no difference in expression levels between the CN-AML group and all other cases. *ERG* expression levels were found to be higher in t(15;17) cases (P<0.001) than in all other cases. *ERG* expression was not associated with outcome in any subgroup, nor in the total cohort. In CN-AML, high *BAALC* expression was a poor prognostic factor for OS (*BAALC*^{high} vs *BAALC*^{low}; 47±11% vs. 76±10%; P=0.03), and a trend for EFS (29±10% vs. 50±11%; P=0.07) and CIR (62±11% vs. 37±10%; P=0.07). However, multivariate analysis, including *NUP98/NSD1* translocations and *NPM1* mutations, did not identify *BAALC* expression as an independent risk factor for OS in CN-AML.Summary/ **Conclusions.** Hence we conclude that *BAALC* and *ERG* expression have no prognostic significance in pediatric AML.

0069

PHASE I STUDY OF PLERIXAFOR IN COMBINATION WITH CLOFARABINE IN PREVIOUSLY UNTREATED OLDER ADULT PATIENTS WITH ACUTE MYELOGENOUS LEUKEMIA (AML) UNLIKELY TO BENEFIT FROM STANDARD INDUCTION CHEMOTHERAPY

J Burger, E Jabbour, M Sivina, F Ravandi, J Cortes, M Andreeff, M Konopleva, S Pierce, M Brandt, M Marris, S Faderl, H Kantarjian
The University of Texas MD Anderson Cancer Center, Houston, Texas, United States of America

Background. Older patients with AML have inferior treatment outcomes including high treatment related mortality, lower CR rates and shorter remission durations. Clofarabine (CLO) is among the most active anti-leukemic agents in elderly AML patients with an approximate overall remission rate (ORR = CR + CRp) of 40%. AML cells express CXCR4 chemokine receptors which cause leukemia cell retention in the marrow microenvironment, where AML cells are protected from cytotoxic drugs. To achieve AML cell mobilization and sensitization to CLO, we designed a combination trial of plerixafor, a small-molecule CXCR4 antagonist, with CLO. Primary endpoint was to determine safety of this drug combination. **Methods.** This is a single arm Phase I study for adults with untreated AML who were ≥60 years with at least one of the following adverse prognostic factors: age ≥70 years, AHD, PS=2, and/or intermediate/unfavorable risk karyotype. Plerixafor was dose-escalated in a 3+3 design, starting at 240 mcg/kg, and proceeding to dose levels of 320 mcg/kg, and 400 mcg/kg. Plerixafor was given daily as subcutaneous (SQ) injection on days 1-5, 4-6 hours prior to CLO, which was given at doses of 30 mg/m^2 intravenously (IV) during induction and 20 mg/m^2 during re-induction/consolidation. Dose-limiting toxicities (DLT's) were assessed during the first cycle. Correlative laboratory studies included characterization of AML cell mobilization and immunophenotype changes. **Results.** The median duration of follow up in surviving patients at time of this analysis was 16 weeks. Median duration of remission (DOR) was 49

weeks. The median overall survival was 38 weeks. Of 13 enrolled patients, 6 (46%) achieved a response (4 CR, and 2 CRp), 5 had resistant disease (38%), and 2 were not evaluable due to early death from infectious complications (30 day all-cause mortality 15%). We did not notice any prolonged myelosuppression, the median time to ANC and platelet recovery was 29 and 25 days, respectively, without prolonged time to recovery at higher plerixafor doses. Sequential CBCs demonstrated mobilization of AML cells into the peripheral blood, accounting for a 107 ± 30% increase in peripheral blasts at 2 hours (n=8), a 218 ± 105% increase at 4 hours (n=9), and a 264 ± 94% increase at 8 hours (n=11) after plerixafor injection. Immunophenotype studies did not reveal any significant surface marker changes on the AML cells, particularly no CXCR4 up-regulation. Drug-related adverse events were nausea, febrile neutropenia, diarrhea, rash, and bilirubin and ALT elevations. Most treatment-related events were Grades 1-2 (except 2 cases of grade 3 ALT elevation). **Summary and Conclusions.** These data indicate that the combination of plerixafor with CLO is active and well-tolerated in treatment-naïve, older AML patients with ≥1 adverse prognostic factor. Safety data from this study are consistent with previously reported studies of single-agent CLO in older patients. Importantly, we did not notice any prolonged myelosuppression. Accrual into the expanded last dose cohort is expected to finish shortly, and the complete Phase 1 experience will be presented at the meeting. A Phase 2 study of plerixafor plus CLO is underway to determine the efficacy of this new drug combination (NCT01160354).

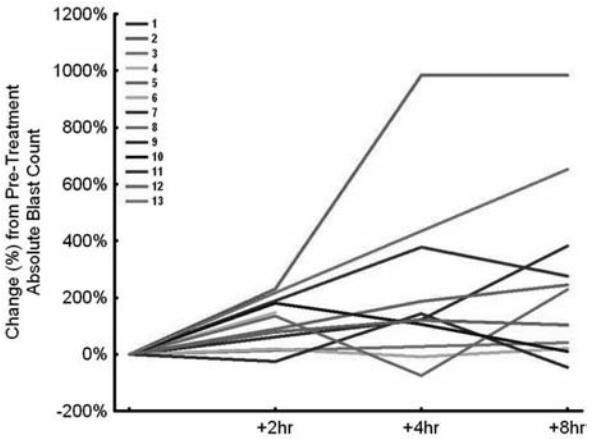

Figure 1. Blast increase (%) in the PB after plerixafor in individual AML patients.

PREDICTION OF MORTALITY AND SURVIVAL OF PATIENTS WITH ACUTE MYELOGENOUS LEUKAEMIA IN THE INTENSIVE CARE UNIT - A SINGLE CENTER EXPERIENCE

N Thoennissen, M Pohlen, C Hullermann, G Thoennissen, J Oberfeld, P Lebiedz, M Stelljes, T Kessler, J Waltenberger, C Müller-Tidow, U Krug, W Berdel
University of Muenster, Münster, Germany

Background. Patients with haematological neoplasms including acute myelogenous leukaemia (AML) display a dismal outcome when transferred to Intensive Care Unit (ICU) for life-threatening complications. Therefore, it is crucial to identify parameters with prognostic significance. **Aims.** To identify potential risk factors for mortality and survival in patients with AML admitted to ICU. **Methods.** In critically ill patients with AML treated in the University Hospital of Muenster, Germany, between 11/2004 and 06/2011, the following demographic and clinical parameters were evaluated for risk prediction by an explorative approach: Age, sex, *de novo* versus secondary AML, cytogenetic and molecular risk according to the ELN 2010 classification, disease status (relapsed / refractory versus others), previous allogeneic stem cell transplantation (alloSCT), reason for ICU admission (sepsis versus others), paO2, mean arterial blood pressure, urine production, Glasgow coma scale (GCS), haematocrit, lactate and left ventricular ejection fraction (LVEF) at the time of ICU admission, as well as days between hospital admission and ICU admission and (for survival after ICU discharge only) days spent in ICU. Parameters were evaluated by univariate analysis for correlation with death during ICU and with survival after ICU discharge; only parameters with a *P*-value < .1 were selected for subsequent multivariate analysis. **Results.** Of n=187 AML patients admitted to our ICU, 108 (58%) succumbed while in ICU. Prognostic factors independently associated with death on ICU were: good risk according to ELN 2010 classification (Hazard Risk [HR]: 0.25; 95% CI: 0.09 - 0.67), hypoxia with paO2 < 72 mmHg (HR: 5.9; 2.6 - 12.5), sepsis (HR: 10.5; 4.7 - 23.8), lactate > 3 mmol/L (HR: 3.0; 1.4 - 6.3) and LVEF ≤ 60% (HR: 2.5; 1.18 - 5.3). Based on these parameters, a score predicting ICU mortality of AML patients was calculated, showing a goodness of fit of AUC=0.86 in the receiver operator characteristics (ROC), compared to 0.72 for the SAPSII score. Accuracy of prediction could also be demonstrated by comparing the median predicted ICU mortality with the observed mortality in quarters of patients by predicted mortality: 1st quarter, predicted 10% versus observed 18% (9/49 patients), 2nd quarter: predicted 49% versus observed 43% (19/44), 3rd quarter: predicted 77% versus observed 77% (37/48), 4th quarter: predicted 94% versus observed 94% (43/46). In comparison, the 79 AML patients (42%) surviving the ICU showed a 3-year survival of 64% (95% CI: 51 - 77%). Disease status, a previous alloSCT, days from hospital admission to ICU admission, days spent on ICU, an oliguria/anuria, GCS ≤ 7 and a hematocrit ≤ 25% were independent prognostic factors in a multivariate cox regression analysis. A prognostic index based on these factors was able to separate three distinct risk groups with 3-year survival rates of 100% in the low risk group (n=26), 67% (95% CI: 45 - 89%) in the intermediate risk group (n=26) and 24% (95% CI: 0 - 48%) in the high risk group (n=27), *P*<0.0001. **Conclusions.** With this large analyzed cohort of AML patients, we were able to identify independent risk factors for both mortality during and survival after ICU stay.

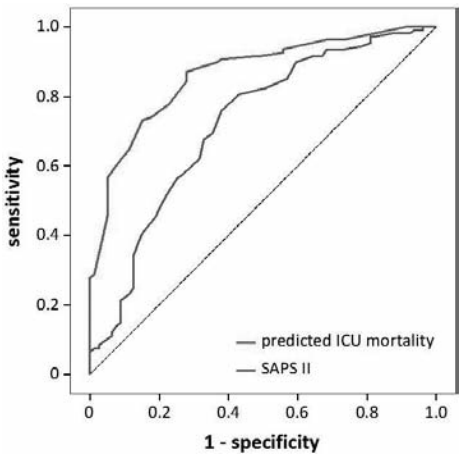

Figure 1. predicted ICU mortality.

MICROTRANSPLANTATION AS POSTREMISSION THERAPY FOR ACUTE MYELOID LEUKEMIA: LONG-TERM FOLLOW-UP

H Ai[1], G Mei[1], Y Chang-Lin[1], Q Jian-Hui[1], S Qi-Yun[1], H Kai-Xun[2], S Wan-Jun[3], W Juan Wang[4], S Xu-Liang[5]
[1]Affiliated Hospital of Academy of Military Medical Sciences, Beijing, China, Beijing, China
[2]Affiliated Hospital of Academy of Military Medical Sciences, Beijing, Beijing, China
[3]Second Artillery General Hospital, Beijing, Beijing, China
[4]Centre Hospital of Cangzhou City, Cangzhou, China
[5]Chang Zhi Medical Colledge, Chang Zhi, China, Chang Zhi, China

ABSTRACT**Background.** Despite best current therapy, about half patients with acute myeloid leukemia in first complete remission (AML-CR1) who had no HLA-identical donors relapsed. Whether the HLA-mismatched stem cell microtransplantation as a novel postremission therapy in such patients will improve survival and avoid graft-versus-host disease (GVHD) is still unknown. **Aims.** To evaluate effects and toxicity of the microtransplantation in AML-CR1 as a novel postremission therapy. **Methods.** 101 AML-CR1 patients (9-65 years old) from the four treatment centres, received programmed infusions of granulocyte colony-stimulating factor-mobilized HLA-mismatched donor peripheral blood stem cells following each of three cycles of high dose cytarabine chemotherapy conditioning without GVHD prophylaxis. Donor chimerism and microchimerism and $WT1^+$ $CD8^+$ T cells were analyzed. **Results.** The 6-year leukemia-free survival (LFS) and overall survival (OS) were 84.4%, and 89.5% in the low-risk group which was no significantly different from the intermediate-risk group (59.2% and65.2%, *p*=0.272 and p=0.308). The 6-year DFS and OS were 76.4% and 82.1% in the patients who received high dose of donor $CD3^+$ T cells (>$1.1x10^8$/kg) in each infusion which was significantly higher than those (49.5% and 55.3%, p=0.091 and p=0.041) in lower dose (<$1.1x10^8$/kg). No GVHD was observed in all of the patients. Sustained donor microchimerism (2

days to 1020 days) was detected in 20 of the 23 female patients who were available for detection of Y chromosome. A significant increase of $WT1^+$ $CD8^+$ T-cells (from 0.2% to 4.56%) was observed in 33 of the 39 patients with positive HLA-A*0201 antigen by a pentamer analysis. **Conclusions.** The microtransplantation as postremission therapy may improve outcomes but avoide GVHD in AML-CR1 patients.

0072

ORAL CLOFARABINE PLUS LOW-DOSE CYTARABINE IN PREVIOUSLY TREATED AML AND HIGH-RISK MDS PATIENTS =60 YEARS OF AGE

M Pagel[1], R Sandhu[2], T Gooley[2], B Scott[2], K Shannon-Dorcy[2], C Dean[2], R Appelbaum[2], H Estey[2]
[1]Fred Hutchinson Cancer Research Center, Seattle, WA, United States of America
[2]FHCRC, Seattle, WA, United States of America

Background. For many older patients with AML or high-risk MDS, the risks of standard induction chemotherapy may outweigh the benefits. The combination of intravenous (IV) clofarabine and cytarabine (ara-C) appears well tolerated and active in older or relapsed adults with AML. A randomized trial in untreated patients age ≥60 suggested that IV clofarabine plus low-dose ara-C (LDAC) was more effective than clofarabine alone. Oral clofarabine offers advantages to older patients and a phase II trial in higher-risk MDS patients confirmed the drug's activity, leading us to combine oral clofarabine with LDAC in a dose-escalation phase I/II study for patients age ≥60 with relapsed/primary refractory AML or high-risk MDS. **Aims.** Our goals were to estimate the maximum tolerated dose (MTD) and to assess complete remission (CR) rates. **Methods.** Oral clofarabine was administered daily on days 1-5 together with once daily subcutaneous (SQ) LDAC at 20 mgBID on days 1-10. Adults age ≥60 years with AML or high-risk MDS were eligible if they had primary refractory disease or failed one prior therapy and disease recurred within 1 year of CR date and had ECOG performance status 0-2. Informed consent was obtained from all patients. **Results.** Twenty-nine patients have been enrolled to date. Median age was 72 (range, 62-82) years. Eight patients (28%) had secondary AML. The median performance status was 1 (range, 0-2) and median time from diagnosis to trial entry was 12 (range, 2-67) days. Cytogenetics (SWOG criteria) were unfavorable in 13 patients (45%), intermediate in 9 (31%), favorable in 1 (3%), and unknown in 6 (21%). The MTD of oral clofarabine when given with LDAC was determined to be 20 mg and the dose-limiting toxicity was cardiac dysfunction. Number of cycles given: 23 patients - 1 cycle, 4 patients - 2 cycles, 1 patient - 3 cycles, 1 patient - 4 cycles. Twenty-six patients were treated as outpatients and 14 patients were hospitalized during the course of treatment including 11 for fever. Seven patients (24%) have achieved a CR. Based on previous MD Anderson data (Blood 1996; 88:756), the expected CR rate with HiDAC, FLAG *etc* would be 15%. Three patients (10%) achieved CR with incomplete blood count recovery and 1 (3%) a partial remission. Four of the 10 patients who achieved CR or CRi have relapsed at a median of 4 months. The other 6 have been in CR/CRi for a median of 3.5 months (range, 0-13.5 months). Fifteen patients (52%) died after treatment, 10 due toAML. **Conclusions.** Oral clofarabine at 20 mg daily for 5 days plus LDAC appears to be well tolerated and can generally be delivered in an outpatient setting. The CR rate appears higher than expected. While accrual is on-going, these results warrant further study.

0073

LATE PHYSIOLOGIC AND PSYCHOSOCIAL OUTCOMES AMONG LONG-TERM ADULT SURVIVORS OF ACUTE PROMYELOCYTIC LEUKEMIA

J Park, D Douer, M Heaney, E Berman, P Maslak, J Jurcic, E Stein, M Frattini, M Tallman
Memorial Sloan-Kettering Cancer Center, New York, NY, USA

Background. Since the introduction of all-trans retinoic acid (ATRA) and arsenic trioxide, acute promyelocytic leukemia (APL) has become the most curable adult leukemia with cure rates now exceeding 80%. In addition, APL affects younger patients compared to other subtypes of AML (median age at diagnosis 44 vs. 65). This has resulted in a growing population of APL survivors that did not exist just a few decades ago. However, little is known about the late effects of treatment on APL survivors. **Aims.** We conducted a single institution retrospective survey to examine the late physiologic and psychological outcomes among adult APL survivors. **Methods.** Patients with newly diagnosed APL treated at Memorial Sloan-Kettering Cancer Center between 1992 and 2007 were identified. Patients who are alive at 5 years or more from the date of diagnosis and remain in continuous remission were classified as APL survivors. Individual medical and pharmacy records were reviewed to analyze treatment-induced cardiac toxicity, second malignancies, and psychosocial outcomes as assessed by presence of depression, anxiety, social functioning and the use of anti-depressants and/or sedatives. **Results.** 52 adult APL survivors were identified with a median follow-up of 9 years (range, 5 - 19 years). The median age at diagnosis was 44 years. All received induction therapy with ATRA +/- anthracyclines. The median cumulative dose of doxorubicin isotoxic equivalents was 420 mg/m^2 (range, 0 - 792). Serial echocardiograms were obtained in 16 patients (30.8%) during the follow-up period. Twelve patients (23%) experienced late cardiac toxicity, consisting of congestive heart failure (n=2), left ventricular hypertrophy (n=1), and recurring episodes of syncope, dizziness, and palpitations (n=9). Two patients who experienced congestive heart failure had a known history of coronary artery disease and hypertension but with normal cardiac function prior to APL treatment. Chronic anxiety, depression and difficulty returning to work were documented in 13 patients (25%), 8 of whom required anti-depressants and/or counseling. Two patients developed second malignancies: localized prostate cancer 3 years after APL treatment at age 65, and metastatic lung adenocarcinoma 9 years after APL treatment at age 69. **Summary and Conclusions.** This study demonstrates an unusually high rate of long-term cardiac toxicity and chronic emotional and social difficulties among adult APL survivors. This result indicates that long-term follow-up should be standardized for adult leukemia survivors similar to those applied to childhood cancer survivors, which will allow studies to evaluate the actual incidence of adverse physiologic and psychosocial outcomes in a larger cohort. Because APL is the only highly curable subtype of adult AML with a relatively young median age at diagnosis, it is the best disease-model to focus on identification, prevention and control of the late and long-term adverse effects of leukemia treatments.

0074

FLUDARABINE-BASED INDUCTION THERAPY DOES NOT OVERCOME THE NEGATIVE PROGNOSTIC ROLE OF BAALC OVER-EXPRESSION IN ACUTE MYELOID LEUKEMIA

M Tiribelli[1], A Geromin[1], L Marin[1], D Fabbro[2], A Franzoni[2], E Simeone[1], A Candoni[1], R Fanin[1], G Damante[2], D Damiani[1]
[1]Division of Hematology and Bone Marrow Transplantation, Udine, Italy
[2]Institute of Genetics, Department of Medical and Biological Sciences, Udine, Italy

Background. Despite progresses in understanding leukemia pathogenesis and in supportive care, the prognosis of acute myeloid leukemia (AML) remains dismal, as with conventional therapy long-term survival is attained in less than 30% of patients. Among factors negatively impacting on prognosis, multidrug resistance (MDR) protein ABCB1 (PGP) over-expression plays an important role. Inclusion of fludarabine in induction therapy overcome MDR effect, increasing remission rate and survival in ABCB1+ patients. However, less is known on the impact of fludarabine on other recently identified molecular alterations associated to negative prognosis. **Aims.** We evaluated the impact of various molecular factors on the outcome of 140 patients with AML treated at our Institution with a fludarabine-based induction protocol. **Methods**. One hundred forty consecutive patients with non-promyelocytic AML treated with a fludarabine-based induction chemotherapy and at least one consolidation course with high-dose cytarabine between 2004 and 2011, were included in our analysis. Blast cells immunophenotype and MDR proteins (ABCB1, ABCG2) expression were evaluated by multiparametric flow cytomety. Molecular analysis for FLT3-ITD and NPM1 mutations were performed by standard methods, and BAALC expression was calculated by real time PCR, with the cut off value set at 50th percentile. **Results.** Median age was 55 (range: 20-84) years, and 44 patients (31%) had secondary leukemia. Karyotype was evaluable in 130 patients: 7 (5%) favorable, 83 (64%) intermediate and 40 (31%) unfavorable. MDR proteins ABCB1 and ABCG2 were over-expressed in 39/140 (28%) and 60/140 (43%) cases, respectively. FLT3-ITD and NMP1 mutations were present in 38/140 (27%) and 36/140 (26%) patients, while BAALC was over-expressed in 61/140 (44%). After induction therapy, 101 (72%) patients achieved complete remission (CR), while 39 (28%) were refractory. In multivariate analysis, CR was negatively affected by secondary leukemia (P=0.003) and BAALC over-expression (P=0.035). Thirty-one of 101 (31%) patients relapsed, at a median of 14 months from diagnosis. Relapse probability was affected only by ABCG2 over-expression (P=0.03). Four-years overall survival (OS) was 49% (95% CI: 40-60). Lower survival probability was associated with older age (P=0.0001), high ABCG2 (P=0.003) and BAALC over-expression (P=0.02) while no association was found with FLT3 and NPM1 mutations or ABCB1 over-expression. However, subdividing patients according to FLT3, NPM1 and BAALC status, we could identify three groups with significantly different OS: FLT3-/NPM1+/BAALC± patients showed the best survival, FLT3+/NPM1-/BAALC±, FLT3+/NPM1+/BAALC+ or FLT3-/NPM-/BAALC+ patients had the worst survival, while FLT3-/NPM1-/BAALC- and FLT3+/NPM1+/BAALC- patients displayed intermediate OS (P=0.002). **Summary and Conclusions.** Our data suggest that BAALC

over-expression has a negative impact on CR attainment and OS in AML patients, irrespectively of cytogenetics and, to a lesser extent, FLT3 and NPM1 mutational status, whit the exception of the FLT3+/NPM1- subset. Fludarabine is confirmed to overcome the negative impact of high ABCB1 and FLT3-ITD mutation, but seems to have no impact on BAALC over-expression.

0075

CLINICAL AND BIOLOGICAL CHARACTERISTICS OF ISOCITRATE DEHYDROGENASE 1 AND 2 MUTATIONS IN ACUTE MYELOID LEUKEMIA

M Koszarska[1], N Meggyesi[1], A Bors[1], A Feczko[1], S Nahajevszky[2], A Batai[2], E Adam[2], A Kozma[2], T Orban[3], N Lovas[2], Z Matrai[2], A Sipos[2], S Fekete[2], T Masszi[2], A Tordai[1], H Andrikovics[1]
[1]Hungarian National Blood Transfusion Cervice, Budapest, Hungary
[2]St. Istvan and St. Laszlo Hospital, Budapest, Hungary
[3]Hungarian Academy of Science, Budapest, Hungary

Background. Mutations of isocitrate dehydrogenase 1 and 2 (*IDH1 and 2)* are novel genetic alterations identified in the background of acute myeloid leukemia (AML). *IDH1 and 2* mutations act through the neomorphic production of 2-hydroxy-glutarate (2HG) resulting in the competitive inhibition of several 2-oxoglutarate (2OG) dependent enzymes, causing comparable methylation profile changes and gene expression patterns. On the other hand, some reports suggest that different *IDH* mutations may have distinctive clinical features and affect differently treatment outcome. **Aims.** To investigate the frequency, clinical associations and the prognostic effect of *IDH* mutations in the entire patient population, followed by the detailed analyses of particular *IDH* mutations in a Hungarian cohort of patients with AML. **Methods.** 376 AML patients (180 males/196 females; median age: 51; range: 16-93 years) diagnosed and followed between 2001-2009 were enrolled in the study. Remission and relapse rates, and survival were analyzed for 314 patients younger than 60 years and treated with curative intention. *IDH* mutations were screened using allele-specific PCR. Positive results for AS-PCR were confirmed by high resolution melting and sequencing. **Results.** *IDH1* and *IDH2* mutations were mutually exclusive, detected in 32 (8.5%) and 28 cases (7.5%). All mutations were in heterozygous form. In *IDH1*, R132C (n=14, 43.7%) and R132H (n=10, 31.2%) substitutions were the most frequent. In *IDH2*, R140Q (n=20, 71.4%) and R172K (n=8; 28.6%) were identified. *IDH* mutations combined were associated with: older age (p=0.001), higher average platelet counts (p=0.001), intermediate karyotype (p<0.0001), *NPM1* mutation (p=0.022) as well as with a lower mRNA expression level of *ABCG2* gene (p=0.006) at diagnosis. The same findings remained significant for the *IDH1* and *IDH2* mutants analyzed separately vs. *IDH1 and 2* wild type combined (n=316) comparisons, except for *ABCG2* expression in the *IDH1* comparison which showed only a tendency (p=0.062) and *NPM1* mutation in the *IDH2* comparison, which was not significant (p=0.17). Interestingly, particular *IDH* mutations differ in association with *NPM1* mutations: double *IDH* and *NPM1* mutations occurred in 14.3% (2/14) of *IDH1* R132C vs. 70% (7/10) R132H carriers (p=0.02) and in 47.4% (9/20) of *IDH2* R140Q vs. 0% (0/8) R172K carriers (p=0.02). Remission rate, relapse rate, overall survival (OS) were not different in *IDH1* mutant (n=24) vs. *IDH1 and 2* wild type (n=269) or in *IDH2* mutant (n=21) vs. *IDH1 and 2* wild type. *IDH1* R132H (n=9) negatively influenced OS compared to *IDH1 and 2* wild type (p=0.02) or to R132C (n=9, p=0.019). No differences were found comparing various IDH2 mutations with respect to treatment outcome. ***Summary and* Conclusions.** *IDH1 and 2* mutations are associated with distinct clinical characteristics, although alterations in NPM associations suggest differences between particular mutations. *IDH* substitutions are generally considered as a weak prognostic factors influencing survival in an inconsistent way in different AML subgroups, which may originate from different amino acid changes affecting outcome in opposite ways. Our observations may suggest that specific mutations might differ in the level of 2-HG production or they might act differently on other pathways besides blocking 2OG-dependent enzymes.

0076

ROLE OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MONOSOMAL KARYOTYPE

Y Choi, SD Kim, DY Kim, JH Lee, KH Lee, M Seol, YS Lee, YA Kang, M Jeon, AR Jung, JH Lee
Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

Background. Monosomal karyotype (MK), defined as at least two autosomal monosomies or one single autosomal monosomy with one or more structural cytogenetic abnormalities, has been associated with dismal outcomes in acute myeloid leukemia (AML) in previous reports. **Aims.** We analyzed the clinicolaboratory characteristics and prognostic significance of MK in patients with AML and we also evaluated the possible role of allogeneic hematopoietic cell transplantation (HCT) in patients with MK. **Methods.** We retrospectively analyzed 749 patients with newly diagnosed AML, who received intensive induction chemotherapy between 1990 and 2010 at a single institute. Patients with acute promyelocytic leukemia were excluded in this study. Patients were classified as having good, intermediate, or poor risk cytogenetics according to the NCCN guideline, and MK status was also determined. **Results and Summary.** MK was found 71 patients (9.5%) and it was more frequent in 50 years or older patients (12.3%) or patients with secondary AML (19.1%) compared to patients younger than 50 years (7.1%; p=0.015) or patients with *de novo* AML (8.2%; p=0.001), respectively. MK was mostly associated with poor risk cytogenetics: 1/123 (0.8%) patients with good risk karyotype, 1/463 (0.2%) patients with intermediate risk karyotype, 9/59 (15.3%) patients with poor risk non-complex karyotype, and 60/104 (57.7%) patients with poor risk complex karyotype. Patients with MK had significantly lower initial leukocyte counts (p<0.001) and lower bone marrow blast percentage (p=0.039) than those without MK. Induction chemotherapy regimen was cytarabine plus daunorubicin or idarubicin in most patients. The rate for complete remission (CR) was significantly lower in MK (n=31, 43.7%) compared to non-MK (n=534, 78.8%; p<0.001). Allogeneic HCT in the first CR was performed in 14 patients with MK and 192 patients without MK. Overall survival (OS) and relapse-free survival (RFS) was significantly lower in MK patients compared to non-MK patients (OS, median, 6.5 vs. 25.7 months, p<0.001; RFS, median, 10.0 vs. 21.5 months, p=0.005). Multivariate analyses showed that MK was an independent risk factor for lower CR rate (hazard ratio [HR], 0.228 compared to intermediate risk cytogenetics, p<0.001), inferior OS (HR, 2.878, p<0.001), and inferior RFS (HR, 2.213, p=0.001). When only the patients with MK were analyzed, performance of allogeneic HCT in the first CR was independent prognostic factor for higher OS (HR, 0.374; p=0.032) and higher RFS (HR, 0.372; p=0.044). The median OS and RFS of the patients with MK who received allogeneic HCT in the first CR were 22.2 months and 16.8 months, respectively. **Conclusions.** Our study confirmed dismal outcomes of the AML patients with MK. Performance of allogeneic HCT in the first CR improved the outcomes of the patients with MK, but the survivals after HCT were still low.

Table 1. Multivariate analysis.

FERTILITY IN LONG-TERM SURVIVORS OF ACUTE MYELOID LEUKEMIA

K Brånvall, Å Derolf, E Johansson, M Hultcrantz, K Bergmark, M Björkholm
Karolinska University Hospital, Stockholm, Sweden

Background. Acute myeloid leukemia (AML) survival rates have improved considerably since the 1970:s, especially for younger patients. In Sweden today just over half of the patients diagnosed in their fertile age (20-44 years) are long-term survivors (surviving for more than five years). This creates a growing group of young adults living with potential sequelae of the disease or its treatment, and consequences on their family situation. The average age of giving birth to/fathering one's first child is also steadily rising, further increasing the group of young AML patients who have not yet had the children they want when they start their treatment. Risk factors for treatment-related infertility are well described mainly in leukemia of late childhood and adolescence. Few studies concerning the incidence of pregnancies in adult AML survivors have been published. **Aim.** To evaluate the impact of AML and its treatment on fertility and family situation in adult long-term survivors. **Methods.** Using the Swedish population registries, we identified 311 adult (≥20 years) patients who were diagnosed with AML within the Leukemia Group of Middle Sweden (LGMS) 1973-2003, and survived for more than five years. A questionnaire including items on reproductive concerns, family situation and infertility-related distress was used for data collection. One hundred of the 161 survivors (62%) still alive at study start in May 2010 and included in this study complet-

ed the questionnaire. After excluding women >45 years and/or postmenopausal women and men >55 years, 22 women and 38 men were included in the final analysis. Male patients were divided in two age groups: 20-45 years and 46-55 years. Written informed consent was obtained from all patients. **Results**. Despite a rather high (34 years) median age of women, 9 of them (41%) tried to get pregnant after treatment but only three succeeded. In addition, another of them adopted a child. Five (83%) of the unwillingly childless women reported "a moderate"or "a lot"of distress caused by this impairment. Among men in the same age group, all six who wanted children after treatment succeeded, three using assisted reproductive therapy and three without any additional assistance. None of the men 46-55 years old cryopreserved their sperm or tried to father a child. Among the patients that wanted children after AML treatment, 46% of women and 40% of younger men reported that they were not, or not fully, informed about fertility and fertility-related issues before or during treatment. In contrast, among men 46-55 years, none reported they would have wanted more information. **Summary and Conclusions.** Infertility after AML treatment caused a substantial degree of distress among females. Young men succeeded in fathering the children they wanted. Many young survivors felt that they were not adequately informed about therapy-related fertility aspects. Infertility among young female AML survivors remains an important clinical problem and there is a need for improved clinical counseling and education in this area.

0078

VECTORIZATION OF F14512, A NOVEL TARGETED CYTOTOXIC AGENT, TOWARDS LEUKEMIC CELLS: FUNCTIONAL BIOMARKER IMPLEMENTATION DURING A MULTICENTRIC PHASE 1 TRIAL IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS

G Zorza[1], C Dumontet[2], I Tagoug[2], S Amsellem[3], C Roumier[4], MC Jacob[5], M Merlin[6], M Mohty[7], J Annereau[1], P Ferré[1]

[3]Institut Gustave Roussy, Villejuif, France
[4]Claude Huriez Hospital, Lille, France
[5]Grenoble Hospital, La Tronche, France
[6]Alphabio Laboratories, Marseille, France
[7]Hôtel Dieu Hospital, Nantes, France

Background. F14512, a novel anticancer polyamine (spermine)-epipodophyllotoxin conjugate, is targeted towards tumor cells via the polyamine transport system (PTS). The PTS is an energy-dependent machinery generally hyperactive in cancer cells with a high demand for polyamines. In the absence of sufficient molecular knowledge on human PTS, a functional test was investigated to assess the uptake of F14512 into cancer cells. F17073, a proprietary fluorescently-labelled polyamine, was selected as a surrogate probe for PTS activity. Fluorescent microscopy and flow cytometry analysis demonstrated that F17073 uptake was modulated in competition with spermine or F14152, and thus specific of the PTS. As preclinical proof of concept, F17073 accumulation was correlated with the sensitivity to F14512. A flow cytometric-based assay was developed to measure F17073 uptake in acute myeloid leukemia (AML) fresh samples, for use as a functional biomarker in clinical trials. **Aims.** To assess the PTS activity in leukemic cells from patients accrued in the first multicentric phase 1 trial of F14512, as a functional biomarker of drug vectorization. **Methods.** After cross-validation of 6 hematology laboratories using a control blood pool, probe incorporation into patients' blast cells and lymphocytes was determined during the first phase 1 trial of F14512. Briefly, fresh peripheral blood (PB) and/or bone marrow (BM) samples collected at baseline were immediately transferred and processed in each hematology laboratory with a triplicate incubation (F17073 and CD45 Antibody ; 1hr ;37°C). Processed samples were shipped to a central hematology laboratory for flow cytometry reading within 24hr. The cellular accumulation of F17073 was measured as the mean fluorescence intensity detected in blast cells and lymphocytes. **Results.** During the cross-validation step, F17073-associated fluorescence was similar whether blood pool was processed in the central or in each hematology laboratory. The immediate processing of fresh samples associated with a centralised flow cytometry reading was therefore feasible in the multicentric phase 1 trial.As of december 2011, on 40 evaluable patients, F17073 fluorescence was higher in blast cells than lymphocytes in 80% of the samples, with no difference between the PB (n=35) or BM (n=32) origin of the samples. As compared to lymphocytes of the same patients, about 50% higher fluorescence was evidenced in blast cells ($p<0.001$) suggesting a preferential accumulation of the probe into AML cells.Potential relationships between PTS activity and F14512 cytotoxicity will be presented on mature data at the recommended dose. **Conclusions.** A functional test, usually highly dependent on cell viability and experimental conditions, has been here successfully implemented into a multicentric setting. Those results demonstrate that F17073 accumulates preferentially in leukemic cells for most of the AML patients eligible for F14512 administration. This functional biomarker confirms that F14512 is vectorized towards leukemic cells of such patients, and is therefore likely to further express its cytotoxic activity.

RELEVANT PROGNOSTIC VALUE OF WILM'S TUMOR GENE EXPRESSION REDUCTION AFTER THE FIRST INDUCTION COURSE IN 82 CONSECUTIVE NON M3 AML PATIENTS

M Clavio[1], M Miglino[2], C Marani[2], N Colombo[2], R Grasso[2], F Guolo[2], G Pica[2], F Ballerini[2], E De Astis[2], G Pastori[2], G Beltrami[2], M Bergamaschi[2], L Mitscheunig[2], S Aquino[2], C Ghiggi[2], D Lovera[2], I Pierri[2], L Canepa[2], M Sessarego[2], F Cruciani[2], P Minetto[2], AM Carella[2], M Gobbi[2]
[1]Hematology and Oncology, IRCCS Ospedale S Martino IST, Genova, Italy
[2]IRCCS Ospedale S Martino IST, Genova, Italy

Background. Most patients with acute myeloid leukaemia (AML) show increased levels of Wilms' tumor gene (WT1) expression at diagnosis. The aim of this study was to evaluate if the kinetics of reduction of WT1 expression may impact on relapse rate and disease free survival (DFS). **Patients and Methods.** In 82 consecutive non M3 AML patients (72 *de novo* and 10 secondary, median age 58 years, range 17-81 years) we studied WT1 gene expression on bone marrow samples at diagnosis and after one induction course. A quantitative Real Time PCR was used for the study of WT1 expression. Only patients with WT1 expression greater than 100 copies ($WT1/Ablx10^3$) at diagnosis were included. To evaluate the kinetics of reduction of WT1 expression we calculated the difference between the logarithm of WT1 value at diagnosis and WT1 level after induction (deltaWT1 = logWT1 at diagnosis - logWT1 post induction). DFS was evaluated from the date of the first CR to the date of the last follow-up for patient in CR or to the date of relapse or death for any cause. For patients submitted to bone marrow transplantation (BMT), the DFS was censored at the date of BMT. **Results.** DeltaWT1was less than 1 in 38 patients (46.3%), ranged between 1 and 2 in 22 (26.8%) and was ≥ 2 in 22 (26.8%). Hematologic response rate, relapse rate and DFS were significantly affected by deltaWT1. Among 38 pts with deltaWT1 < 1, 16 patients failed to achieve CR, 19 relapsed, 1 died in remission and 2 had a complete remission length of 1 and 3 months. Among 22 pts with a deltaWT1ranging between 1 and 2, 10 relapsed (DFS median 6 months, range 1-34 months), 5 patients were offered BMT in first CR and 7 maintain CR (median DFS 13 months, range 1-55 months). Among 22 patients with deltaWT1≥ 2 , 8 patients relapsed (median DFS 9.5 months, range 3-17 months), 2 patients underwent BMT and 12 are alive and disease free (median DFS 38.5 months, range 3-85 months). The projected DFS at 60 months of patients with deltaWT1 < 1, ≥ 1 and < 2, and ≥ 2 were 0 %, 27.8% and 51.9%, respectively ($p = 0.000$) (Figure 1).We tried to define a significant deltaWT1cut off level and found that deltaWT1 ≤ 1,5 was associated with higherfailure rate (response less than CR or relapse). Thirty-five of 38 (92%) patients with deltaWT1 < 1.5 did not respond or relapsed, whereas 19 of the remaining 44 pts (43,2%) with deltaWT1 > 1.5 ($p = 0.000$). **Conclusions.** our study shows that in AML patients response rate, relapse rate and DFS were affected by the kinetics of WT1 expression reduction. In particular patients with deltaWT1 < 1.5, though in CR, should be offered more intensive chemotherapy or BMT due to a high risk of relapse.

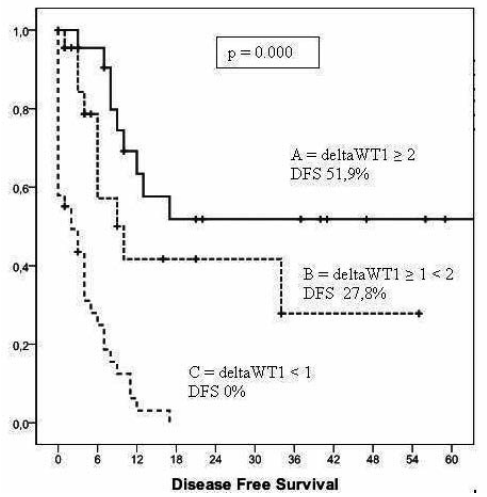

Figure 1. DFS according to delta WT1.

Background. Outcome of elderly patients with relapsed/refractory acute myeloid leukemia (R/R AML) is extremely poor. Subsequent hematopoietic stem cell transplantation (HSCT) in patients with R/R AML may improve survival. **Aims.** We have previously reported the efficacy and safety outcomes of the CLASSIC I study in older patients with R/R AML (Kantarjian, EHA 2011). In this report, we evaluate the outcomes of subsequent HSCT after Clo+Ara-C or Ara-C alone in the CLASSIC I trial. **Patients and Methods.** CLASSIC I was a prospective, randomized, double-blind, placebo-controlled trial comparing Clo+Ara-C to Ara-C alone in patients ≥55 years old with R/R AML. Patients were randomized to either Clo 40 mg/m^2 or placebo followed by Ara-C 1 g/m^2 for 5 consecutive days. While the primary endpoint of overall survival in the CLASSIC I study did not differ between treatment arms, there were statistically significant improvements in the Clo+Ara-C arm in secondary efficacy endpoints (ORR, CR,EFS)In this post-hoc analysis, patient characteristics and safety were analyzed for those patients who underwent HSCT. We performed a series of landmark analyses to assess the extent of association (rather than cause and effect) between HSCT and overall survival (OS).

Table 1. Impact of HSCT on OS and HSCT-Related Safety.

	Overall (N=66)	CLO+Ara-C (N=34)	Ara-C (N=32)
Impact of HSCT on Overall Survival; HR (95% CI)			
Naïve estimate	0.30 (0.22, 0.40)	--	--
Landmark analysis across groups on FAS patients at 4 months	0.59 (0.37, 0.92)	--	--
Landmark analysis by group on CR patients at 4 months	0.72 (0.41, 1.27)	0.81 (0.40, 1.63)	0.61 (0.23, 1.60)
Landmark analysis by group on CR patients at 8 months	0.49 (0.31, 0.77)	0.50 (0.24, 1.01)	0.40 (0.16, 0.99)
HSCT-Related Safety; n (%)	**N=66**	**N=34**	**N=32**
100-day post-HSCT mortality	9 (13.6%)	4 (11.8%)	5 (15.6%)
Acute GVHD	11 (16.7%)	5 (14.7%)	6 (18.8%)
Acute Grade ≥3 GVHD	3 (4.5%)	1 (2.9%)	2 (6.3%)
Chronic GVHD	1 (1.5%)	1 (2.9%)	0 (0.0%)
VOD Complications	1 (1.5%)	0 (0.0%)	1 (3.1%)

HSCT, hematopoietic stem cell transplantation; FAS, full analysis set; CR, complete remission; GVHD, graft-vs-host disease; VOD, veno-occlusive disease

Results. Among 320 patients with centrally confirmed AML(age, median 67 yrs), 66 (21%; median age 63 years) underwent subsequent HSCT [Clo+Ara-C arm: n=34; Ara-C arm: n=32]. Of which, 47 patients (71%) proceeded to HSCT in CR; 36 in CR from study drug [Clo+Ara-C arm: n=22 and Ara-C arm: n=14 patients] and 11 in CR from additional therapy. 64 patients received an allogeneic transplant [sibling donor: n=46 (70%), unrelated donor: n=18 (27%)] and 2 (3%) were autologous transplants. Preparative regimens included myeloablative in 23 (33%) patients and reduced intensity conditioning/non-myeloablative regimens in 43 (66%) patients. Median time to HSCT was 3.8 months (range 1.6-14.8 months) from the initiation of the study drug, Multiple analyses were consistent with a survival benefit of HSCT - a naïve estimate comparing OS in patients with and without HSCT [HR 0.30 (95% CI 0.20, 0.40) *p<.0001*]; a 4-month landmark analysis comparing OS past 4 months in patients with and without HSCT [HR 0.59 (95% CI 0.37, 0.92) *p=.023*]; and landmark analyses assessing the impact of HSCT on OS for patients who achieved CR at 4 months [HR .72 (95% CI .41, 1.27) *p=0.255*] and at 8-months [HR 0.44 (95% CI 0.25,0.76) *p=.004*]. Although there was evidence that HSCT was associated with longer survival, there was little evidence of a differential effect across the treatment arms (interaction p=0.32). Post-HSCT safety findings were similar across treatment groups (Table 1) and raised no new concerns. **Conclusions.** Approximately 20% patients (median age 63 yrs) with R/RAML underwent subsequent HSCT in the CLASSIC I trial. More patients in the Clo+Ara-C arm proceeded to HSCT in CR from study drug. Overall, this post-hoc analysis of the CLASSIC I study demonstrated that subsequent HSCT in elderly patients with R/RAML was feasible and was associated with longer survival; though there was little evidence of a differential effect across treatment arms.

0081

BAALC OVEREXPRESSION IN AML IS ASSOCIATED WITH POOR PROGNOSIS IN ALL CYTOGENETIC RISK CATEGORIES

M Tiribelli[1], D Damiani[1], D Fabbro[2], A Michelutti[1], A Franzoni[2], M Cavallin[1], E Simeone[1], E Toffoletti[1], R Fanin[1], G Damante[2]

[1]Division of Hematology and Bone Marrow Transplantation, Udine, Italy
[2]Institute of Genetics, Department of Medical and Biological Sciences, Udine, Italy

Background. In the past years many molecular alteration have been associated with prognosis in adult myeloid leukemia with normal cytogenetic (CN-AML). Among them, overexpression of brain and acute leukemia cytoplasmic (BAALC) gene confers poor prognosis. Less defined is its role in AML with cytogenetic abnormalities. **Aims.** Objective of this study was to evaluate the role of BAALC over-expression in the outcome of adult patients with AML, irrespectively of karyotype. **Methods.** We analyzed 210 patients with AML treated at the Division of Hematology of Udine between 2005 and 2011. Median age was 60 years (range: 20-87) with 102 males and 108 females. One hundred forty patients had *de novo* AML while in 73 cases leukemia developed from a previous myeloproliferative disease or after exposure to chemo/radiotherapy. Karyotype at diagnosis was available in 186 patients: favorable in 23, intermediate in 109 (normal in 79) and unfavorable in 54. Quantitative BAALC expression was determined by real-time PCR and expressed in arbitrary units after normalization to ABL; the cut off value between high and low expression was set at 50th percentile. **Results.** BAALC was overexpressed in 89/210 (42%) patients. No association was found between BAALC positivity and sex, age, type of leukemia (*de novo* vs secondary), WBC count, FLT3-ITD status or CD56 expression. High BAALC expression was associated with CD34 positivity (71/89, 80%), while among 121 BAALC-negative patients only 49 (40%) were CD34+ (P<0.00001). Considering cytogenetic subgroups, BAALC overexpression was lower in patients with favorable karyotype (4/23, 13%) than in all others cytogenetic groups (67/163, P=0.05). Considering intensity of expression, higher BAALC levels were found in CD34+ vs CD34- cases (44.79±89.6 vs 9.05±31.6, P=0.0004) and in patients with intermediate karyotype, compared to those with favorable or unfavorable abnormalities (35.8±85.6, vs 10.2±25.6, P=0.04 and vs 14.3±29.4, P=0.05). One hundred ninety-one out of 202 patients (8 cases with promyelocytic leukemia were excluded from analysis) were evaluable for therapy response. In univariate analysis, BAALC overexpression showed a negative impact on complete remission achievement (P=0.002), as well as age, CD34 expression, and secondary AML; CD34+, age and BAALC retained their statistical significance also in multivariate analysis. BAALC did not influence relapse probability, nonetheless had a strong impact on overall survival (OS): 3-years OS was 50% (95% CI: 38-62) in BAALC negative patients, compared to 36% (95% CI: 24-47) in patients over-expressing BAALC (P=0.001). Karytotype per se did not influence survival probability, but subgrouping patients according to cytogenetic risk and BAALC expression we could identified three groups with different prognosis: favorable karyotype + low BAALC (3-years OS 75%, 95% CI: 64-87), intermediate karyotype irrespective of BAALC and unfavorable karyotype + low BAALC (3-years OS 48%, 95% CI: 38-56) and patients with favorable or unfavorable cytogenetic + high BAALC (3-years OS 34%,, 95% CI: 27-43) (P=0.02). **Summary and Conclusions**. BAALC over-expression identified AML patients with poor prognosis in all the cytogenetics group. Though relatively rare, positivity of BAALC in patients with favorable or unfavorable karyotype significantly worsened survival.

0082

A PHASE I TRIAL OF LENALIDOMIDE IN COMBINATION WITH INTERMEDIATE DOSE CYTARABINE (IDC) IN RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA (AML) PATIENTS

E Vigil, A Griffiths, E Thompson, E Brady, M Dickey, A Ford, S Wang, M Wetzler
Roswell Park Cancer Institute, Buffalo, United States of America

Background. Lenalidomide, an oral immunomodulator, has been studied as a single agent in the treatment of relapsed/refractory AML. In a recent study, five (16%) of 31 patients (pts) achieved complete remission (CR), and all three pts with karyotype aberrations achieved cytogenetic CR. The drug was safely escalated to 50 mg daily for 21 days and was active with relatively minimal toxicity (Blum et al, JCO 2010). These low single-agent CR rates suggest that combining lenalidomide with chemotherapy might improve outcomes. Since IDC induces CR in approximately 17% of relapsed/refractory AML pts (Faderl et al, JCO 2012), we performed a phase I study to assess the safety and preliminary efficacy of IDC followed by lenalidomide in this patient population. **Aims.** To determine the maximum tolerated dose (MTD) of lenalidomide following IDC therapy in relapsed/refractory AML patients in the dose finding phase. To evaluate the safety and preliminary anti-leukemic activity of this combination in the dose expansion phase. **Methods.** The study was designed as a two phase study: a dose finding, and expansion phase. IDC was administered at 1.5 gm/m^2/day on days 1-5 of a 28 day cycle followed by lenalidomide initially given days 6-10 (6-10d) and then days 6-26 (6-26d). Lenalidomide dose range was 25mg, 15mg and 10mg. A maximum of two such inductions were allowed. Once CR was achieved, lenalidomide maintenance was then given daily for 28 days until disease progression. **Results.** As of January 20th 2012, 20 pts with a median age of 70 (range 34-79) years have been accrued to the dose finding arm of this study. Two patients have insufficient follow-up to report treatment results and adverse events. Thirteen pts (72%) had received more than two previous therapies. The number of pts with dose limiting toxicities (DLTs) at each dose level (DL) was: 0/4 pts in DL 1 (25 mg/d; 6-10d), 4/6 all grade 3 non-blistering macular-papular rash in DL 2 (25 mg/d; 6-26d), 3/7 pts grade 3 AST, grade 3 anorexia, grade 3 bilirubin in DL 3 (15 mg/d; 6-26d), and 0/3 pts in DL 4 with no DLT at present time and 2 pts with no information available (10 mg/d; 6-26d). Severe (grade 3-5) adverse events (SAEs) were observed in 17 of 18 pts. The most frequent hematological SAEs were thrombocytopenia (89%). anemia (83%) and neutropenia (61%). The most frequent non-hematological SAEs included nausea and vomiting (61%), skin rash (39%) and fatigue (33%). Two patients achieved CR and 1 patient demonstrated CR without platelet recovery (CRp) for an overall CR/CRp rate of 17% (3/18 evaluable patients). Three patients had stable disease. **Conclusions.** IDC and lenalidomide can safely be administered to refractory/relapsed AML pts. The dose expansion phase is ongoing at 10mg daily and will be reported at the meeting.

0083

ISTH DIC SCORE = 6: A NEW PREDICTOR OF EARLY DEATH IN ACUTE PROMYELOCYTIC LEUKAEMIA

M Mitrovic, N Suvajdzic, A Bogdanovic, N Kraguljac Kurtovic, A Sretenovic, I Elezovic, D Tomin
Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. Despite the improvements in acute promyelocytic leukemia (APL) treatment, early death (ED) remains a problem, with recently reported rates between 17 and 29%. **Aims.** To report ED in 49 *de novo* APL patients and to identify pretreatment factors predictive for ED. **Methods:** We retrospectively analyzed data on ED in 49 newly diagnosed, t(15;17)(q22;q12) or PML-RARA positive APL patients (median age 42 years, range 19-69; 23/26 female/male ratio) managed in the Clinic of Hematology from 2004 to 2011 with all-trans retinoic acid combined with anthracyclines. Patients with International Society of Thrombosis and Haemostasis Scoring System for diseminated intravascular coagulation (ISTH DIC score) ≥5 were considered to have overt DIC. ED was defined as death from any cause from the first day of hospitalization up to 30 days from therapy initiation. **Results.** Median time from the first symptoms to diagnosis was 20 days (range: 5-90). Pretreatment patients characteristic were as follows: ECOG PS 1, 2, 3, 4 had 17/49 (34%), 16/49 (33%), 14/49 (29%) and 2/49 (4%) patients respectively; median WBC count 3.9x10^9/L (range: 0.6-183); median platelet count 29x10^9/L (range: 4-101); hypergranular form in 43/49 (88%) patients; Sanz' s risk stratification: high 19/49 (39%), intermediate 19/49 (39%), low 11/49 (22%); median D-dimer 2426 µg/L (range 551-11340); median PT 62% (range 34-129); median fibrinogen level 2.35 g/L (range 0.57-6.5). DIC was confirmed in 42/49 (86%) patients, median ISTH DIC score was 6 (range: 2-7). Bleeders at diagnosis had higher WBC (29.3x10^9/L vs. 9.4x10^9/L, P=0.02), higer percentage of peripheral blood promyelocytes (36% vs. 14%, P=0.04) and higer median ISTH DIC score (6 vs. 4, P=0.0007) comparing to the non-bleeders. ISTH DIC score ≥5 was predictive for bleeding (P=0.034208).Therapy **Results.** ED occured in 10/49 (20.4%) patients due to: differentiation syndrome (DS) 3 (30%), endocranial bleeding 5 (50%) and infection 2 (20%). We did not register any death before diagnosis or due to misdiagnosis, but 3/49 (6%) of patients died before therapy initiation. Predictors of ED were: WBC >10x10^9/L (P=0.05), ECOG ≥3 (P=0.0006), fibrinogen level <2 g/L (P=0.02617), PT <50% (P=0.007292), ISTH DIC score ≥6 (P=0.00529) and DS occurrence (P=0.04). It is of note that DS occurred in 12 (27%) of patients, severe form in 9/12 (75%). **Conclusions.** High ED rate in our series is in line with current reports. Our results suggests that ISTH DIC score is a more sensitive predictor for ED compared to single parameters such as fibrinogen level, PT and D-dimer and can be used together with Sanz' s score to identify patients at very high risk for ED. Moreover an integrative prognostic risk score including WBC, ISTH score and ECOG PS might be even more sensitive. Further large population based studies for testing new score systems and refinements therapeutic approaches for APL are needed.

[3]University of Michigan, Ann Arbor, United States of America
[4]Stanford University Medical Cancer, Stanford, United States of America
[5]Dana Farber Cancer Institute, Boston, United States of America
[6]University of TX Health Science Center, San Antonio, United States of America

Background. NEDD8 activating enzyme (NAE) initiates the NEDD8 conjugation pathway and is required for activity of cullin ring ubiquitin ligases (CRLs). Activation of CRLs controls timed degradation of substrates involved in cell cycle regulation, signal transduction, DNA replication and stress responses. MLN4924 is an investigational, small molecule NAE inhibitor which forms a covalent adduct with NEDD8, thereby blocking ubiquitination and proteasomal degradation of CRL substrates such as chromatin licensing and DNA replication factor 1 (CDT1). Preclinical tumor models treated with MLN4924 resulted in tumor regression and supported Phase I clinical development. **Aims.** Evidence of target inhibition and downstream pathway modulation was a secondary objective in the MLN4924 AML phase I study C15003. Patients were treated on days 1, 3, 5 of a 21 day cycle at doses ranging from 25 to 83 mg/m^2. Required bone marrow aspirate or biopsies (BMA) were taken at screening and on day five at 3-6 hours post dose. Here we describe the development and clinical implementation of IHC pharmacodynamic (PD) assays measuring MLN4924-NEDD8 covalent adduct (adduct) and CDT1 expression in pre and post dose BMAs from AML patients. **Methods.** THP-1 AML tumor xenograft models were treated with MLN4924. Tumors were collected for IHC at multiple post-dose time points. CDT1 and adduct antibodies were detected with a HRP polymer or a biotin labeled secondary, respectively. Antibody staining was quantified as a percent positive pixel count. The CDT1 assay for patient BMA biopsies was supplemented with a cocktail of CD34 and CD117 antibodies for tumor cell identification. Six slides for each biopsy were stained and Definiens software algorithms used to calculate the percent CD34/CD117 cells positive for CDT1. A mixed effects model was used to estimate the within subject coefficient of variation (CV) in tumor CDT1 levels. A population PK model was used to predict cumulative MLN4924 plasma AUC at day 5. **Results.** Pre-clinical AML models treated with MLN4924 demonstrated presence of adduct within 30 minutes lasting up to 24 hours post dose, indicating that MLN4924 rapidly distributes and persists in tumor tissue. IHC assays detected accumulation of CDT1 in xenograft tumors at 2-8 hours post treatment, demonstrating successful inhibition of NAE. IHC staining for adduct in BMA pairs from 21 patients confirmed presence of drug in 100% of the post-dose BMAs and absence pre-dose. Statistical assessment of the CDT1/CD34/CD117 IHC assay identified the minimum evaluable tumor burden with 20 out of 21 BMAs containing sufficient tumor. Sixteen of the twenty patients (80%) showed a statistically significant ($p<0.05$) increase in CDT1 expression in the post dose sample with a fold change of 1.48 or greater including 3/3 patients who achieved a complete response in the PD evaluable cohort. PK data was available for 18/20 patients however; no statistical correlation between CDT1 fold change and MLN4924 plasma AUC was identified. **Summary.** These data demonstrate inhibition of NAE and downstream pathway modulation in BMA from patients with AML who were treated with MLN4924 on days 1, 3, 5 in a phase I clinical trial at doses as low as 25 mg/m^2.

0085

CXCR4 MAY BE A PROGNOSTIC MARKER IN ACUTE MYELOGENOUS LEUKEMIA (AML)

G Battipaglia[1], I Migliaccio[1], M Raia[2], G Scalia[2], F Grimaldi[1], M Grasso[1], F Pane[1], L Del Vecchio[2], A Camera[1]
[1]Federico II University, Naples, Italy
[2]Department of Clinical and Sperimental Cytometry, CEINGE Federico II University, Naples, Italy

Background. CXCR4 and its ligand CXCL12 are involved in the maintenance of homeostasis of the homing of hematopoietic stem-cells in the bone-marrow microenvironment. In leukemia, CXCR4/CXCL12 axis is known to play a role in the attraction of leukemic blast cells in the bone marrow niches creating an occult source of minimal residual disease that could be responsible for leukemia relapse over time. **Aims.** This study analyses the CXCR4 expression on leukemic blast cells and its prognostic role evaluating disease-free (DFS) and overall survival (OS) of the patients with AML. Methods: Bone marrow samples at diagnosis from 84 consecutive patients with AML were analyzed by flow-cytometry (FACS) for the expression of CXCR4 on leukemic blasts. The cutoff of 10% was used in order to distinguish positive (CXCR4 >10%, Group A) from negative (CXCR4 ≤10%, Group B) cases to correlate antigen expression and survival outcome of the patients. DFS and OS were estimated by the Kaplan-Meier method, while survival curves were compared by the log-rank test. **Results.** The median age was 67 years (range, 17-86). Fifty-six patients (67%) suffered from a de novo AML, whereas 28 (33%) showed a previous hematological disorder (sAML from myelodysplasia, n=22; therapy related-AML, n=3; sAML from myeloproliferative disease, n=3). According to cytogenetics and molecular results, prognosis was favorable in 13, intermediate in 22 and unfavorable in 27 patients. 22 patients were unclassifiable. In most cases treatment consisted of cytarabine+anthracycline based induction regimen (group A, n=16; group B, n=41), while 19 (23%) patients received other cytoreductive therapies (hydroxyurea, n=8; low-doses cytarabine, n=4; 5'-azacitidine, n=7). Three patients received the best supportive care. Thirty-eight (45%) patients achieved the complete remission. Twenty patients were eligible for a stem cell transplant (SCT): 11 patients received allogeneic SCT, while 9 received autologous SCT. Median OS of the whole patient population was 12 months, while at the last f-up on December 2011 the median DFS was not reached. Group A (n=29) and Group B (n= 55) showed a median expression of CXCR4 of 24% (range, 11%-92%) and 3%, respectively. Median OS in the Groups A and B were 6 and 21 months, while DFS was 21 months for Group A and was not reached for Group B. By the log-rank test a significant correlation was found between the two Groups both for OS (p<0.011) and DFS (p<0.031). OS and DFS Hazard ratio were 2.298 (CI: 1.216-4.345) and 2.991 (CI:0.9185-9.736), respectively. **Conclusions.** Our findings showed a striking correlation between CXCR4 expression and the overall survival time in a heterogenous patient population affected by AML. These results agree with the reported biological role of the CXCR4/CXCL12 axis concerning the protection of leukemic cells in the hematopoietic niches. If these data will be confirmed in a larger cohort of patients, CXCR4 detection could be considered useful during the diagnostic work-up in AML.

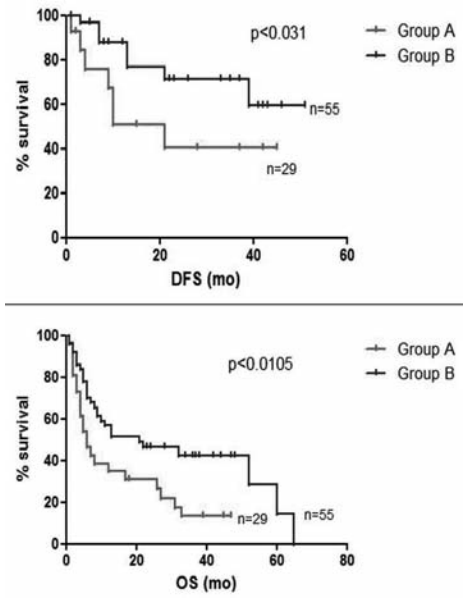

Figure 1.

0086

ALLOGENIC STEM CELL TRANSPLANT (ASCT) AS INITIAL SALVAGE FOR PATIENTS (PTS) WITH ACUTE MYELOID LEUKEMIA (AML) REFRACTORY TO HIGH-DOSE CYTARABINE-BASED INDUCTION CHEMOTHERAPY

M Cornelison[1], N Daver[1], M De Lima[1], H Kantarjian[1], F Ravandi[1], S Pierce[1], I Khouri[1], S Giralt[2], B Oran[1], G Garcia-Manero[1], E Jabbour[1]
[1]MDACC, Houston, United States of America
[2]MSKCC, New York, United States of America

Background. Outcomes of pts with AML who are refractory to High-dose Cytarabine (HiDAC) based induction are dismal. ASCT as initial salvage may be effective and potentially superior to repeat induction with combination chemotherapies in such pts. **Methods.** 1597 AML pts were treated with HiDAC-based induction at our institution between 1995 and 2009 and 285 primary refractory pts were identified. 28 (10%) of these underwent ASCT as initial salvage and were reviewed. **Results.** Median age was 56 years (36 to 77) and 50% were males. Median ECOG PS was 1 (0-2). Antecedent hematological disorders were present in 14 pts (50%). Median white cell count, hemoglobin, platelet count and bone marrow (BM) blast percentage at diagnosis were 3.5 x 10^9/L (0.6 to 73.6), 7.8 g/L (6.5 to 11.4), 44x10^9/L (9 to 615), and 43% (6-82), respectively. 9 pts (32%) had complex cytogenetics. FLT3 mutations were identified in 2 (15%) of 13 evaluated pts. All pts were refractory to HiDAC-based induction. HiDAC was combined with an anthracycline in 16 pts (57%) and non-anthracycline in 12 pts (43%).Median time from induction to ASCT was 76 days (28 to 184). Median BM blast and peripheral blast at ASCT were 28% (3 to 82) and 4% (0 to 41). 21 pts (75%) had matched related donors (18 sibling and 3 haploidentical) and 7 (25%) had matched unrelated donors. Conditioning regimens were melphalan-based, busulfan-based, fludarabine-based or others in 7 (25%), 10 (36%), 8 (29%) and 3 pts (10%); respectively. Complete remission (CR) was achieved in 23 of 28 pts undergoing ASCT (CR = 82%) with median time to CR of 31 days (26 to 134). 12 pts relapsed with median time to relapse of 5 months (2 to 19). 8 pts remain alive with median follow up of 80 months (28 to 118). Median overall survival (OS) for the entire group is 20 months (5 to 118). In historical series of pts with AML refractory to HiDAC-based induction, salvage chemotherapies induced CR rates of 22% with median OS of 4 months. **Conclusions.** Initial salvage with allogenic SCT is feasible and yields superior outcomes to salvage chemotherapy in primary HiDAC refractory AML pts. Randomized studies are warranted to further explore this treatment option.

0087

G8 OR MULTIMODAL GERIATRIC ASSESSMENT (MGA) FOR THE SCREENING OF OLDER PATIENTS WITH MALIGNANT HEMOPATHIES ?

S Dubruille, M Maerevoet, M Roos, S Vandenbossche, N Meuleman, Y Libert, D Bron
Institut Jules Bordet, Brussels, Belgium

Background. Although malignant hemopathies among older patients remain curable diseases, in some cases, their treatment can precipitate geriatric syndromes. To manage this risk, hematologists have to detect unsuspected health problems, to estimate survival and to predict tolerance to the treatment in order to optimizer the treatment (full dose chemotherapy, reduced-dose or palliative treatment). Growing evidences suggest that a Multimodal Geriatric Assessment (MGA) could help hematologists to achieve this goal but is time consuming and expensive. Short-screening tool (G8) could allow screening for fragile patients but is under evaluation. **Aims.** 1) To evaluate the respective usefulness of G8 and MGA to predict mortality in a selected population of consecutive « fit » older inpatients referred for the treatment of malignant hemopathies in a cancer centre. 2) To assess the usefulness of G8 to predict the initial treatment choice and the tolerance to chemotherapy. **Methods.** Between October 2009 and February 2012, a G8 and a full MGA assessment were performed in 60 consecutive older inpatients (≥65 years). These patients were considered «fit » enough by the referral physicians to receive chemotherapy. We excluded from the analyses patients for whom the disease does not require treatment or patients who refused the treatment. The normal cut-off for G8 assessment has been defined ≥15/17. Patients' initial treatment choice, tolerance to chemotherapy (therapeutic changes during treatment), death and cause of death were extracted from medical files. **Results.** G8 screening score was abnormal in 85% (n=51) of our inpatients. Differences between normal and abnormal G8 scores are not associated with one year survival (p=0.665). Causes of G8 abnormal score were primarily denutrition and psychological distress. MGA showed that a probable mild cognitive disorder (MMSE) (p=0.013) and a slow motion (Time Up and Go test) (p=0.014) are associated with a higher risk of death in the first year of treatment. Difference between normal and abnor-

mal G8 scores was curiously not associated with initial treatment choice (p=0.757) and tolerance to chemotherapy (p=0.481). **Conclusions.** Among older inpatients with hematological malignancies, G8 may be too sensitive to select older patients susceptible to benefit from full dose chemotherapy. In our small series of «fit» older patients, a poor G8 score does not allow to predict tolerance to chemotherapy and not translate into a worse survival. The leading cause of death (92%) remains the progression of the disease. Prospective trials are needed to determine whenever a lower threshold of G8 score could better identified -in malignant hemopathies- patients at risk of treatment related death. Prospective trials are also needed to assess the usefulness of MGA and to improve multidisciplinary care of older patients with malignant hemopathies.

0088

BURDEN OF ILLNESS OF FLT3-MUTATED ACUTE MYELOID LEUKEMIA (AML) IN THE UNITED STATES

M Sotak[1], M Marin[1], J Coombs[2], G Schiller[3], A Teitelbaum[1]
[1]OptumInsight Life Sciences, Chicago, United States of America
[2]Novartis Pharmaceuticals Corporation, East Hanover, United States of America
[3]UCLA Medical Center, Los Angeles, United States of America

Objective. Patients with FLT3-mutated AML have poor prognoses due to short survival, high incidence of relapse, and a lack of durable effective treatment options. Limited information is published on the burden of AML, especially for FLT3-mutated disease. **Aims.** This study reviewed the literature and estimated the burden of FLT3-mutated AML in the US. **Methods.** A systematic literature review was conducted in PubMed to identify relevant publications from 2000-2011. 607 citations were identified and 35 articles abstracted. Epidemiologic data were also sought from the Surveillance, Epidemiology and End Results (SEER) database. Estimates of the epidemiology of FLT3-mutated AML were calculated from SEER data and US Census projections. An Excel model was developed to estimate the BOI of FLT3-mutated AML. Resource utilization estimates were obtained from the literature and expert opinion. **Results.** No direct estimates for the incidence or prevalence of FLT3-mutated AML in the US were identified in the literature. The prevalence of AML in 2008 was obtained from SEER data (27,813 patients aged ≥20 years). In 2010, it was estimated that 784 adults <60 years and 1,622 adults ≥60 years were diagnosed with FLT3-mutated AML.In patients age <60 years, the literature reported FLT3 mutations in up to 30% of AML cases. Per the literature review, FLT3-mutated AML is associated with a poorer prognosis: median overall survival estimates of 15.2-15.5 months for patients age <60 years, compared to 19.3-28.6 months for patients with FLT3-WT disease. Five-year survival for age <60 years ranged from 15% for high FLT3/ITD levels to 31% for low FLT3/ITD levels vs. 42% for FLT3-WT.Three studies were identified which reported information on the impact of AML on quality of life (QoL), though none described the QoL impact of FLT-3 mutated AML. One study specifically examined the <60 year old population, noting that patients receiving stem cell transplants had significantly worse long-term impact on QoL vs. patients receiving conventional chemotherapy. No studies quantifying the impact of AML on productivity were identified.The US BOI of FLT3-mutated AML was estimated at $251 million in 2010, including $191 million in direct costs and $60 million in lost productivity. Inpatient hospitalizations accounted for 36% of direct costs and stem cell transplants for 38%. The cost per newly diagnosed patient with FLT3-mutated AML <60 years was estimated at $114,193 vs. $105,819 for patients with FLT3-WT AML (statistical significance not tested). For newly diagnosed patients <60 years, the burden of FLT3-mutated AML was estimated at $90 million in 2010. A sensitivity analysis using American Cancer Society incidence data (n=13,780) yielded an estimate of $125 million in 2010 for newly diagnosed patients <60 years with FLT3-mutated AML. As early mortality and early retirement were not included in indirect costs, these costs are likely underestimated. **Conclusions.** FLT3-mutated AML potentially represents a greater per-patient burden than FLT3-WT AML due to shorter survival and greater use of stem cell transplantation. Investigational treatments targeting the FLT3 mutation may provide additional therapeutic options, with the potential to improve clinical outcomes.

Cellular Immunotherapy and vaccination

EFFECTIVE PROPHYLAXIS OF CMV DISEASE IN RECIPIENTS OF ALLOGENEIC HAEMOPOIETIC STEM CELL TRANSPLANTS USING ADOPTIVE T CELL TRANSFER - LONG TERM FOLLOW-UP OF 50 PATIENTS

E Blyth[1], L Clancy[2], R Simms[3], J Burgess[3], C Ma[3], P Shaw[4], P Micklethwaite[1], J Gottlieb[3]
[1]Westmead Hospital, Westmead, Australia
[2]Sydney Cellular Therapies Laboratory, Westmead, Australia
[3]University of Sydney, Westmead, Australia
[4]Children's Hospital Westmead, Westmead, Australia

Background. We investigated the use of donor-derived cytomegalovirus (CMV) specific cytotoxic T cells administered early post transplant to prevent CMV disease. **Methods.** CMV CTL were generated from CMVseropositive haemopoietic stem cell donors by three methods**.** Cohort 1: donor monocyte derived dendritic cells (mo-DC) from peripheral blood were used to present the CMV peptide NLVPMVATV to autologous donor T cells. Cohort 2: mo-DC transfected with an adenoviral vector containing the CMV pp65 gene (Adpp65) were used to stimulate autologous donor T cells. Cohort 3: as for cohort 2 but the stem cell harvest product was the source of effector T cells. A single cell infusion of $2x10^7$ cells/m^2 was administered to transplant recipients from day 28. Patients were assessed for infusional safety, transplantation outcomes and CMV directed immune function. **Results.** We infused 50 patients with CMV CTL between 2003 and 2011 (cohort 1 n=10; cohort 2 n=33, cohort 3 n=10). Indications for transplantation were AML (n=30; 17 in CR1, 11 in CR2 and 2 with persistent disease), ALL (n=7), MDS (n=3), NHL (n=5), Hodgkin's lymphoma (n=1), multiple myeloma (n=2) and non-malignant conditions (n=2). 20 patients received myeloablative conditioning and 30 received reduced intensity conditioning. 50% of patients received *in vivo* T cell depletion with anti-thymocyte globulin (n=22) or alemtuzumab (n=3). There were 36 sibling donors and 14 unrelated donors. 45/50 were fully HLA matched and 5/50 had 1 antigen mismatch. Donor/recipient CMV serostatus was pos/pos (n=36) and pos/neg (n=14). Median follow up was 26 months post transplant (range 2 to 80). 50% of patients reactivated CMV within 100 days post transplant (17/25 pre-infusion, 8/25 post infusion). There were no cases of CMV reactivation post day 100. Reactivation rates were not different from those observed in 168 historical controls at our institution. Median peak CMV titre was <600 copies/mL in reactivating patients (below the limit of linearity of the assay). Three patients (6%) required treatment with intravenous ganciclovir post T cell infusion (compared with 46% requiring CMV pharmacotherapy in controls). Only one patient developed CMV disease (pneumonitis) (compared with 9% CMV infection rate in controls). He died despite treatment with ganciclovir. 38% (19/50) developed acute GVHD (grade I-II 15/19, III-IV 4/19). Of these, 10 followed cell infusion (grade I-II 7/10, III-IV 3/10). Two patients (4%) died of acute GVHD post T cell infusion. Median follow-up was 18 months post transplant (range 2 to 80). At 5 years post transplant, progression free survival was 69% and overall survival was 70%. **Conclusions.** In this non randomised study, adoptive transfer of CMV specific CTLs appeared to reduce the requirement for CMV specific pharmacotherapy with ganciclovir or foscarnet without affecting the rate of CMV reactivation. A low rate of CMV disease was observed. We postulate that infused cells are able to limit viral reactivation and prevent progression to tissue infection.

RAPID ANALYSIS AND SELECTION OF MINOR HISTOCOMPATIBILITY ANTIGENS WITH THERAPEUTIC RELEVANCE BY MICROARRAY GENE EXPRESSION ANALYSIS

M Griffioen, M Pont, M Honders, A Kremer, E Lurvink, S van Luxemburg-Heijs, C van Bergen, J Falkenburg
Leiden University Medical Center, Leiden, Netherlands

Background. Patients with hematological malignancies can be successfully treated with allogeneic hematopoietic stem cell transplantation. Beneficial Graft-versus-Leukemia (GvL) reactivity, however, is often accompanied with undesired Graft-versus-Host Disease (GvHD). GvL and GvHD are mediated by donor T-cells recognizing minor histocompatibility antigens (MiHA). Donor T-cells recognizing ubiquitously expressed MiHA may induce GvL as well as GvHD, whereas MiHA with hematopoietic restricted expression may be selectively targeted in GvL. We previously developed a method based on whole genome association scanning for high throughput discovery of novel MiHA, and new strategies are now required for rapid analysis and selection of MiHA with therapeutic relevance. **Aims.** The aim of the study was to investigate

whether MiHA with therapeutic relevance can be rapidly selected based on cell type specific expression patterns as determined by microarray gene expression analysis. **Methods.** Malignant and non-malignant hematopoietic cells of different origins were isolated by flowcytometry based on expression of specific markers. Non-hematopoietic cell types included isolated or cultured skin derived fibroblasts (FB) and keratinocytes, proximal tubular epithelial cells, hepatocytes and small intestine, colon and lung epithelial cells. Various non-hematopoietic cell types were also cultured in the presence of IFN-g to mimick the pro-inflammatory cytokine milieu of the early post-transplantation period. Total RNA was isolated and processed for gene expression profiling. T-cell recognition of primary (malignant) hematopoietic and (cytokine treated) non-hematopoietic cell types was measured by IFN-g ELISA. **Results.** The quality of the microarray gene expression database was validated by demonstrating expression of specific markers for each cell type, and confirming expression patterns of well-known hematopoietic restricted MiHA. Next, we used microarray gene expression analysis to investigate the cell type specific expression profiles of 12 MiHA as recently discovered by whole genome association scanning. T-cell experiments demonstrated that 7 of these 12 MiHA were recognized on skin derived FB, of which 6 MiHA were only recognized after pre-treatment with IFN-g. T-cell clones for the remaining 5 MiHA failed to recognize (cytokine treated) FB. Microarray expression analysis demonstrated that all genes encoding MiHA that are recognized on (cytokine treated) FB exhibited broad expression profiles. Of the 5 MiHA that were not recognized on (cytokine treated) FB, 3 genes showed ubiquitous expression, indicating that gene expression is required, but not always sufficient for T-cell recognition, and that other factors such as antigen processing and presentation and surface expression of adhesion and costimulatory factors also play a role. The genes encoding the remaining 2 MiHA displayed hematopoietic restricted expression patterns. These genes include ARHGDIB, which is expressed in a large variety of (malignant) hematopoietic cell types, and EBI3, which is selectively expressed on mature dendritic cells. T-cell experiments confirmed surface expression of the HLA-B*0702 restricted LB-ARHGDIB-1R on primary leukemic cells of different origins, illustrating the therapeutic relevance of this MiHA. **Summary and Conclusions.** Our data demonstrate that microarray gene expression analysis allows rapid analysis and selection of MiHA with therapeutic relevance for development of novel T-cell therapies with the aim to induce a more favorable balance between GvL/GvHD in alloSCT.

HLA-CLASS II UPREGULATION DURING AN ONGOING VIRAL INFECTION CAN LEAD TO HLA-DP DIRECTED GRAFT-VERSUS-HOST DISEASE AFTER HLA-DPB1 MISMATCHED CD4+ DONOR LYMPHOCYTE INFUSION

S Stevanovic, C Van Bergen, S Van Luxemburg-Heijs, J Harskamp, C Halkes, M Griffioen, F Falkenburg
Leiden University Medical Center, Leiden, Netherlands

Background. In allogeneic hematopoietic stem cell transplantation (alloSCT), T-cell depletion of the graft prevents severe acute Graft-versus-Host Disease (GvHD), but impairs post-transplant anti-tumor and anti-viral immunity. Early intervention with donor lymphocyte infusion (DLI) after T-cell depleted alloSCT (TCD-alloSCT) is frequently associated with reintroduction of GvHD. However, administration of CD8+ T-cell depleted DLI has been associated with conversion to donor hematopoiesis, disease remissions in patients with relapsed malignancies and improved immune reconstitution against pathogens, in the absence of severe GvHD, providing a rationale for exploration of CD4+ T-cell based immunotherapy as treatment modality for hematological malignancies. AIMWe recently initiated a clinical study in which patients with hematological malignancies are treated with prophylactic CD4+ DLI at 3 months after HLA-matched unrelated donor TCD-alloSCT. Two patients with acute myeloid leukemia converted to full donor chimerism with concomitant Grade-1/2 skin and Grade-3/4 colonic acute GvHD after a single infusion of $0.5*10^6$ purified CD4+ T-cells/kg following 10/10 HLA-matched, but HLA-DPB1 mismatched, TCD-alloSCT. We performed detailed analysis of the clinical course and specificity of T-cell immune responses to investigate the immune mechanisms underlying development of the beneficial and detrimental clinical responses in these patients. **Methods.** Based on co-expression of HLA-DR, activated CD4+ and CD8+ T-cells were clonally isolated from peripheral blood samples obtained during GvHD after, and tested for recognition of patient- and donor-derived target cells using IFNg-ELISA. **Results.** From patients 1 and 2, we isolated in total 19 (2,5%) and 16 (5,6%) CD4+ T-cell clones, which were alloreactive as illustrated by specific recognition of patient-, but not donor-, derived hematopoietic cells. Blocking studies with specific monoclonal antibodies and retroviral transduction of donor EBV-LCL with patient mismatched HLA-DPB1 alleles confirmed allorecognition of patient HLA-DPB1 alleles by all alloreactive CD4+ T-cell clones. The majority of HLA-DPB1 specific CD4+ T-cell clones from both patients recognized patient-derived skin-fibroblasts expressing HLA-class II molecules induced by pre-treatment with pro-inflammatory cytokines. Alloreactivity was demonstrated for only one CD8+ T-cell clone (0,3%) from patient 2, which was restricted by HLA-C and failed to recognize patient-derived cytokine-treated skin-fibroblasts. At the time of CD4+ DLI, both patients were in complete remission and complete donor chimerism was shown in the B-cell and myeloid compartments, whereas predominantly patient chimerism (89-100% patient) was observed in the T-cell compartments. In both patients these residual patient-derived T-cells were activated as reflected by expression of HLA-class II, and most of these T-cells were CMV-specific T-cells as a consequence of CMV reactivations. Summary and Conclusions. Our data indicate a direct role for alloreactive HLA-DP directed CD4+ T-cells as mediators of profound clinical responses after prophylactic HLA-DPB1 mismatched CD4+ DLI. We postulate that (local) release of pro-inflammatory cytokines by patient-derived CMV-specific T-cells expanded as a consequence of CMV reactivation induced HLA-class II expression on non-hematopoietic cells, thereby making them targets for alloreactive HLA-DPB1 specific CD4+ T-cells in GvHD. In conclusion, our results suggest that active viral infections at the time of prophylactic CD4+ DLI play a relevant role in development of GvHD after HLA-class II mismatched TCD-alloSCT.

0092

DONOR T-CELLS SPECIFIC FOR HEMATOPOIETIC-RESTRICTED MINOR HISTOCOMPATIBILITY ANTIGENS ARE INDUCED IN PATIENTS IN WHICH GRAFT-VERSUS-LEUKEMIA REACTIVITY IS ACCOMPANIED WITH GRAFT-VERSUS-HOST DISEASE

M Pont[1], E Lurvink[2], C Van Bergen[2], M Honders[2], S van Luxemburg-Heijs[2], M Kester[2], J Falkenburg[2], M Griffioen[2]
[1]LUMC, change to Leiden University Medical Center, Leiden, Netherlands
[2]Leiden University Medical Center, Leiden, Netherlands

Background. Patients with hematological malignancies can be effectively treated with allogeneic hematopoietic stem cell transplantation (alloSCT) and donor lymphocyte infusion (DLI). In HLA-matched alloSCT, donor T-cells can mediate beneficial Graft-versus-Leukemia (GvL) reactivity due to recognition of minor histocompatibility antigens (MiHA) on patient malignant cells. MiHA are peptides in HLA-molecules that differ between patient and donor due to single nucleotide polymorphisms. Donor T-cells may also induce Graft-versus-Host Disease (GvHD) when MiHA with ubiquitous expression on hematopoietic and non-hematopoietic tissues are recognized. Development of broadly applicable T-cell therapies to selectively stimulate GvL reactivity after HLA-matched alloSCT without GvHD requires identification of multiple MiHA with hematopoietic-restricted expression in common HLA class I molecules.**Aim**The aim of the study was to analyze whether hematopoietic-restricted MiHA can be identified in patients with combined GvL and GvHD reactivity. **Methods.** Patient 1 with acute myeloid leukemia and patient 2 with chronic myeloid leukemia entered complete remission following DLI after HLA-matched alloSCT. In both patients, induction of GvL reactivity coincided with GvHD. Single CD8+ T-cells were isolated from peripheral blood obtained 6-9 weeks after DLI based on CD137 expression after 48 hours of stimulation with patient-derived EBV-B cells (patient 1) or CML cells *in vitro* modified into professional antigen presenting cells (CML-APC; patient 2). T-cell recognition of hematopoietic cells and (cytokine-treated) fibroblasts (FB) was measured by IFN-γ ELISA. MiHA were identified by whole genome association scanning (WGAs) and expression profiles were determined by microarray gene expression analysis using (malignant) hematopoietic and (cytokine-treated) non-hematopoietic cell types that are targeted in GvL and GvHD. **Results.** A total number of 399 T-cell clones were isolated from the two patients. All T-cell clones were tested for recognition of patient-derived EBV-B cells (patient 1) or CML-APC (patient 2) as well as donor EBV-B cells, and 170 T-cell clones were shown to be specific for MiHA. All MiHA specific T-cell clones were subsequently analyzed for reactivity against a mixture of peptides of previously identified MiHA. T-cell clones specific for LB-GEMIN4-1V and ZAPHIR were isolated from patient 1, and T-cell clones for LB-ADIR-IF and LRH-1 from patient 2. These MiHA are ubiquitously expressed, except for LRH-1 which has a hematopoietic-restricted expression profile. Finally, all MiHA specific T-cell clones were tested against patient-derived FB, and the majority of T-cell clones were shown to recognize these cells after pre-treatment with IFN-γ. We identified 5 novel MiHA by WGAs, which were all ubiquitously expressed as demonstrated by microarray gene expression analysis. However, a minority of T-cell clones showed no recognition of (cytokine-treated) FB, and are currently under investigation for identification of MiHA with potential therapeutic relevance. **Summary and Conclusions.** The data show that donor T-cells recognizing hematopoietic-restricted MiHA can be induced in patients with combined GvL and GvHD reactivity. Our strategy of efficient isolation of MiHA specific CD8+ T-cell clones followed by rapid identification and expression analysis of MiHA by WGAs and microarray gene expression analysis for T-cell clones which fail to recognize patient-derived (cytokine-treated) fibroblasts is therefore relevant for discovery of novel hematopoietic-restricted MiHA with therapeutic relevance.

0093

PRODUCTION OF LEUKEMIA-REACTIVE T-CELLS VIA A GOOD MANUFACTURING PRACTICE PROCEDURE FOR TREATMENT OF PATIENTS WITH ACUTE OR CHRONIC B-CELL MALIGNANCIES AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

I Jedema, C Hoogstraten, P Van Liempt, M Van de Meent, J Falkenburg
Leiden University Medical Center, Leiden, Netherlands

Donor T-cells recognizing malignant cells of the recipient can mediate a potent therapeutic graft-versus-leukemia (GvL) effect. However, due to the broad repertoire of specificities, application of unselected donor T-cells at the moment of allogeneic stem cell transplantation (alloSCT) or by donor lymphocyte infusions (DLI) early after transplantation harbors a high intrinsic risk of inducing severe GvHD. Moreover, the poor immunogenicity of most leukemias may further limit the potential therapeutic effect of DLI. These limitations may be overcome by the adoptive transfer of in-vitro generated leukemia-reactive T-cells containing a selected population of donor T-cells with specificities skewed towards recognition of (malignant) hematopoietic cells of the patient.In this study, we developed a Good Manufacturing Practice (GMP) procedure to generate potent leukemia-reactive T-cells for adoptive transfer into patients with recurrent or persistent B-cell malignancies after alloSCT.Primary malignant B-cells harvested from peripheral blood (PB) or bone marrow (BM) of patients with chronic lymphocytic leukemia (CLL), acute lymphoblastic leukemia (ALL), or mantle cell lymphoma (MCL) were transformed in-vitro into antigen presenting cells (APC) by crosslinking of CD40 using a 2-step strategy consisting of CpG/IL4 pre-activation of the malignant cells followed by co-culture with irradiated CD3/28 activated donor T-cells expressing CD40-ligand. Next, naïve donor T-cells enriched from the donor leukapheresis product depleted of CD14+ monocytes and CD25+ regulatory T-cells were stimulated with the malignant APC (T-cell/APC ratio 50/1) and cultured for 14 days in IMDM supplemented with heat-inactivated human serum, 10 ng/mL IL-7 and only 0.1 ng/mL IL-15. After a second stimulation with the malignant APC (T-cell/APC ratio 25/1) leukemia-reactive T-cells were isolated based on their expression of the activation marker CD137 using a clinical grade CD137-biotin reagent, anti-biotin beads and cliniMACS isolation (Miltenyi Biotec). Post-isolation culture was performed in IMDM supplemented with heat-inactivated human serum, 10 ng/mL IL-7 and 0.5 ng/mL IL-15 and irradiated donor PB mononuclear cells. The functional reactivity of the isolated T-cells against primary malignant B-cells, malignant APC and donor PBMC was tested at 7-10 days after isolation using flow-cytometry-based quantitative cytotoxicity assays and analysis of specific cytokine production. Sufficient numbers of phenotypical appropriate malignant APCs expressing CD40, CD80 and CD86 could be reproducibly generated from primary malignant B-cells both harvested at diagnosis or at a later stage after initial treatment. CD137+ fractions after cliniMACS isolation contained >50% CD137+ T-cells. Isolated leukemia-reactive T-cells contained an oligoclonal T-cell receptor (TCR) repertoire, as measured by analysis of TCR-beta chain expression, and showed profound cytotoxic activity (>50% lysis at 3/1 E/T ratio) against the primary malignant B-cells as well as against the malignant APC and no reactivity against donor cells. All T-cell products produced in the large scale testruns under GMP conditions met the pre-defined criteria for quality control and release for clinical application.We have developed a GMP-approved procedure for the generation of leukemia-reactive T-cells. A clinical phase I/II study is initiated to demonstrate the feasibility and safety of administration of these leukemia-reactive T-cells to patients with recurrent or persistent mature B-cell neoplasms after allo-SCT.

A SUBSET OF NAIVE T-CELLS SHOWS HLA-RESTRICTED AUTO-REACTIVITY AGAINST UNPULSED AUTOLOGOUS DENDRITIC CELLS HAMPERING ENRICHMENT OF LOW-FREQUENCY ANTIGEN-SPECIFIC T-CELLS BY *IN VITRO* PRIMING

TS Lam, M Van de Meent, J Falkenburg, I Jedema
Leiden University Medical Center, Leiden, Netherlands

BackgroundAdoptive transfer of in-vitro selected antigen-specific T-cells is an elegant strategy to treat persistent disease after allogeneic stem cell transplantation. In these cases, induction of primary immune responses from the naive donor T-cell repertoire is required. Priming of antigen-specific naive T-cells by in-vitro stimulation with peptide-loaded autologous monocyte-derived dendritic cells (autoDCs) has been shown to be feasible, but poorly reproducible. An observed unexpected proliferative response of naive T-cells following stimulation with autoDCs in the absence of exogenously loaded peptides (the 'autologous mixed lymphocyte response' (autoMLR)) hampers the enrichment of low-frequency antigen-specific T-cells.AimTo unravel the autoMLR phenomenon by investigating the frequency, nature, and specificity of naive T-cells responding to unpulsed autoDCs.MethodsPurified human naive T-cells (CD3+CD45RO-CD27+) were labeled with the fluorescent dye PKH and stimulated with unpulsed autoDCs (R/S ratio 1/1) in medium containing 5 ng/mL IL-7 and 0.1 ng/mL IL-15. Proliferation, as indicated by PKH dilution, was monitored 7-10 days after stimulation. Based on their proliferative response, autoDC-reactive (PKH-low) and non-reactive (PKH-high) T-cells were isolated single cell/well or in bulk by flow cytometric cell sorting. Secondary stimulations were performed with autologous or allogeneic HLA-matched and mismatched stimulator cells with or without HLA-blocking antibodies.ResultsThe autoDC-reactive T-cell population, comprising a polyclonal population of CD4+ and CD8+ T-cells, represented 1-3% of the total naive T-cell pool, which was similar in adult and cord blood-derived naive T-cells. The autoDC-reactive T-cells acquired CD45RO expression, while the non-reactive counterparts remained naive in response to stimulation with autoDCs, but could still respond to allogeneic stimulator cells. Increasing the number of autoDCs enhanced the proliferation rate of the autoDC-reactive T-cells without affecting the frequency of responding cells. Although both CD4+ and CD8+ naive T-cells showed autoDC reactivity, we could only generate CD4+ clones retaining their reactivity against autoDCs. The autoDC-reactive CD4+ clones produced IFN-γ and/or IL-4 and down-regulated their TCR/CD3 complex upon stimulation, but most T-cell clones were not cytotoxic against autoDCs. Interestingly, the autoDC-reactive T-cell clones showed profound reactivity against autologous monocytes, immature DCs, and primary myeloid leukemic cells (AML), but not against non-myeloid cells including EBV-LCL, PHA-blasts, and (activated) B-cells, indicating the myeloid-lineage specificity of the autoDC reactivity. Importantly, lack of reactivity against autologous EBV-LCL cultured in medium supplemented with the cytokine cocktail used for DC generation excluded the possibility of recognition of cytokines or medium components presented by stimulator cells. Analysis of reactivity against a panel of allogeneic DCs and primary AML cells matched for one or more of the HLA class II molecules and HLA blocking experiments revealed HLA-restriction of the autoDC reactivity. From individual donors both HLA-DP, -DQ and -DR restricted autoDC-reactive clones were isolated, further illustrating the polyclonality of this reactivity.ConclusionsIn conclusion, we demonstrated the existence of T-cells in the naive repertoire from healthy donors showing HLA-restricted auto-reactivity against autoDCs. These T-cells show myeloid lineage-specific reactivity against HLA-matched allogeneic cells. Removal of these autoDC-reactive T-cells is essential for in-vitro enrichment of low-frequency antigen-specific T-cells from the naive repertoire using antigen-loaded DCs as stimulator cells.

0095

DONOR LYMPHOCYTE INFUSIONS (DLI) CD3+ AFTER REDUCED INTENSITY CONDITIONING (RIC) ALLOGENEIC STEMS CELLS TRANSPLANTATION; SINGLE CENTRE EXPERIENCE

J Elcheikh, R Crocchiolo, S Furst, P Ladaique, C Faucher, AM Stoppa, A Granata, R Devillier, C Oudin, D Coso, B Calmels, C Lemarie, R Bouabdallah, C Chabannon, D Balise
Institut Paoli Calmettes, Marseille, France

Donor lymphocyte infusions (DLI) can induce remission in patients with hematologic malignancies who relapse after allogeneic stem cells transplants (alloSCT). However Graft versus Host Disease (GvHD) remains the major complication of this strategy. We have been using escalating doses of DLI for many years, and wanted to assess risk factors for GvHD and transplant related mortality (TRM) as well as disease outcome according to reason of DLI.We analyzed 77 patients who received a total of 87 DLI, for different reasons and at different intervals from transplant. The median number of DLI was 2 (1-4) the median interval between transplant and DLI was 9 months (1-41), the median number of infused CD3+ cells /kg of recipients body weight was 2,8x10^7 ($1x10^6$- $11,8x10^7$). The diagnosis were multiple myeloma (n=25), acute leukemia (n=19), lymphoma (n=18), chronic myeloid leukemia (n=5), myelofibrosis (n=3), myelodysplastic syndrome (n=2), other diagnosis (n=5). Median patient age was 48 years (20-67). The cause of DLI was relapse or progression in 40 patients (52%), residual disease in 11 patients (14%), prophylactic in 13 patients (17%), and the presence of mixed chimerism in 13 patients (13%). Factors studied for an association with GvHD and TRM were donor type (siblings/alternative donors), year of DLI (</> 2006), maximum dose of DLI (</> $1x10^7$), recipient age (<=/>50 years), number of DLI (</> 1), interval transplant-DLI (</> 6 months), cause of DLI (relapse vs. prophylaxis vs. mixed chimerism vs. residual disease), disease type and recipient gender. Seven patients (9%) developed acute GvHD grade II-IV, and 5 patients (6%) developed an extensive chronic GvHD. In univariate analysis we could identify the interval transplant-DLI <= 6 months, the dose of DLI (>=$1x10^7$) and DLI number as a predictors factors of acute GvHD: In multivariate analysis this result was confirmed only for the interval transplant-DLI <= 6 months with HR=0.10 (0.02-0.51) (p=0.006). With a median follow up of 43 months (9-132), 43 patients are alive

(56%). The primary cause of death was relapse of the original disease in 29 patients (38%), whereas 4 died of TRM (5%). Only the interval transplant DLI <= 6 months was identified as a factor predicting TRM in univariate analysis. The overall survival (OS) at 5 years was 45% [CI 95% (34-56)]; the progression free survival (PFS) at 3 and 5 years was 24% [CI 95% (13-33)] and 17% [CI 95% (8-26)] respectively. PFS after DLI significantly differed according to reason of DLI. In this relatively large series of consecutive DLI, the risk of GvHD was relatively low, and we could identify only the interval transplant-DLI less than 6 months as significant predictor of acute GvHD and TRM. At a preliminary analysis, DLI seem to show efficacy when administered as prophylaxis, for mixed chimerism and residual disease but not for overt relapse. Our findings indicate that this form of adoptive immunotherapy is well tolerated and induces a low incidence of GvHD and TRM, supporting further investigation as an upfront modality to enhance graft versus tumor response in high risk patients.

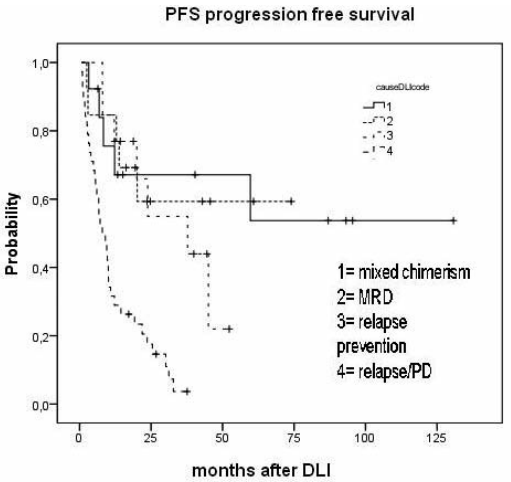

Figure 1. PFS.

***IN VITRO* GENERATION OF CD4+CD25HI LYMPHOCYTES EXPRESSING HIGH LEVELS OF FOXP3 AND GITR FROM UMBILICAL CORD BLOOD NAÏVE T-CELLS**

R Haddad[1], J Schiavinato[1], F Saldanha-Araujo[1], A Araujo[1], P Palma[2], C Menezes[2], D Covas[2], M Zago[2], R Panepucci[2]
[1]HCFMRP-USP, Ribeirão Preto, Brazil
[2]Fundação Hemocentro de Ribeirão Preto, Ribeirão Preto, Brazil

Background. The generation of induced regulatory T-cells (iTregs) *ex-vivo* holds promise in the clinics, in light of its potential immunotherapeutical use in conditions involving transplant rejection and autoimmune disorders. Nevertheless, reports from the literature are conflicting and are mainly derived from mouse or human peripheral blood. **Aims.** Evaluate the potential *in vitro* generation of iTregs from umbilical cord blood. **Methods.** CD4+CD45RA+ naïve cells were isolated from umbilical cord blood by negative selection and were activated with anti-human CD2/CD3/CD28 beads (1:2) in the presence of IL-2 (10, 50 or 100 U/ml) with (CD4med) or without combinations of TGF-beta (5 or 10 ng/ml) and atRA (50 or 100 nM) for 5 days. CD4+ gated lymphocytes were analyzed by flow cytometry, for the expression of CD25, FoxP3, TNFR2, GITR. CD4+CD25hi cells were sorted and tested for its ability to suppress proliferation of CD3+ cells (CFSE staining). Methylation analysis of FoxP3 TDSR region was also performed. **Results.** In the presence of atRA (100 nM), the percentage of CD25hi cells increased till the 3rd day, in all treatment conditions. In the 5th day, cell death occurred with low IL-2 levels (10U/mL), irrespective of TGF-beta concentration, while, at higher IL-2 levels (100U/ml), a higher concentration of TGF-beta (10 ng/ml) caused cell death. At optimal IL-2 levels (50U/ml), presence of atRA resulted in increased generation of CD25hi cells, reaching up to 30% of CD4+ cells, as compared to only 3% observed in the absence of atRA. Moreover, without atRA, cell death was noticeable at low TGF-beta concentration. Cells activated in the presence of 50 U/ml IL-2, 5ng TGF-B and 100mM atRA ($CD4_{TGF/atRA}$) showed the highest percentages of CD25hi T cells after 5 days of culture. From day 1 to day 5, the percentage of FoxP3+ cells in the CD25hi population increased in both conditions, but with higher percentages in $CD4_{TGF/atRA}$, reaching 99%; and only 50% in $CD4_{med}$. Importantly, while in $CD4_{med}$, FoxP3+ cells were almost absent in the CD25- population; in $CD4_{TGF/atRA}$ this percentage reached up to 55%. Similarly, in the 5th day, GITR+ cells were almost absent in $CD4_{med}$ in the CD25- population, while this percentage reached up to 32% in $CD4_{TGF/atRA}$. TNFR2 expression was restricted to CD25+ cells, with higher percentage of positive cells in the CD25hi population. Intriguingly, while TNFR2 was steadily expressed, in all days, in around 70% of the CD25hi cells in $CD4_{med}$; in $CD4_{TGF/atRA}$ this percentage decreased from 61% in day 1, to 9% in the 5th day. Finally, TDSR region was fully methylated and the suppressive capacity of CD4+CD25hi cells sorted from $CD4_{TGF/atRA}$ could not be observed. **Conclusions**. We show that high percentages of Foxp3+ CD4+CD25hi T-cells expressing GITR can be generated *in vitro*, from umbilical naïve T cells. Despite the high levels of Foxp3+, methylation of FoxP3 TDSR and inability to suppress proliferation of activated lymphocytes indicated that additional stimuli is necessary to drive full differentiation of CD4+ naïve cord blood cells into functionally capable regulatory T cells. **Support.** FAPESP and CNPq.

MULTIPOTENT STROMAL CELLS INDUCE DIFFERENTIATION OF MONOCYTES TOWARDS AN IL-10 PRODUCING PHENOTYPE IN AN IL-6 DEPENDENT MANNER, AND PREVENT DIFFERENTIATION TOWARDS DENDRITIC CELLS

S Melief, S Geutskens, H Roelofs, W Fibbe
LUMC, Leiden, Netherlands

Multipotent stromal cells (MSC) have been studied because of their immunomodulatory capacities, which make these cells interesting candidates for further clinical application. One of the proposed effects of MSC is the inhibition of dendritic cell differentiation. Both IL-6 and IL-10 interfere with the differentiation of monocytes to (immature) dendritic cells and skew the monocytes into the macrophage lineage. Since macrophages produce higher levels of IL-10 than monocytes, this induces an autocrine loop. We hypothesized that IL-6 and IL-10 may play a role in the inhibitory effect of MSC on the differentiation of monocyte towards dendritic cells.$CD14^+CD1a^-$ monocytes are cultured in RPMI containing 10% fetal calf serum, IL-4 (10 ng/mL) and GM-CSF (5 ng/mL) in the presence or absence of culture-expanded bone marrow derived MSC. Significantly lower numbers of $CD14^-CD1a^+$ immature dendritic cells (iDC) were generated in cultures containing MSC than in control cultures without MSC (15.1% versus 70.6%, $p < 0.01$). Similar results were obtained in cultures that contained MSC-conditioned medium. In co-cultures with allogeneic $CD4^+CD25^-$ T cells, iDC ($CD14^-CD1a^+$) displayed a higher allostimulatory capacity than $CD14^+CD1a^-$ cells derived from MSC-containing cultures. Conditioned media from co-cultures of monocytes and MSC contained higher levels of IL-6 and IL-10, in comparison with cultures without MSC (IL6: 221.6 pg/ml versus 11.9 pg/ml, $p < 0.001$, $n = 6$; IL-10: 984.6 pg/ml versus 333.4 pg/ml, $p < 0.01$, $n = 4$). We showed that IL-10 is produced by the monocytes in these cultures and not by MSC. In cultures containing saturating concentrations of neutralizing antibodies to IL-10, no effect on the MSC-induced inhibition of monocyte-to-iDC differentiation was observed. In contrast, this process was significantly inhibited by neutralizing antibodies to IL-6. The differentiation of monocyte-to-iDC could be inhibited by both IL-6 and IL-10. IL-6 was constitutively expressed at high levels by MSC and this factor was responsible for the enhanced IL-10 expression and secretion by monocytes.We conclude that i) differentiation of monocytes towards iDC is inhibited by MSC through the production of IL-6 and ii) IL-6 induces the formation of IL-10 producing monocytes, which exhibit a reduced allostimulatory capacity. Our results indicate a crucial role for monocytes in the immunomodulatory properties of MSC.s.m.melief @lumc.nl

MULTIPOTENT STROMAL CELLS MODULATE MONOCYTES TO INDUCE THE GENERATION OF CD4+CD25HIFOXP3+ REGULATORY T CELLS

S Melief[1], Schrama[1], M Tiemessen[1], M Hoogduijn[2], H Roelofs[1], W Fibbe[1]
[1]LUMC, Leiden, Netherlands
[2]Erasmus MC, Rotterdam, Netherlands

Multipotent stromal cells (MSC) have been shown to possess immunomodulatory capacities and are therefore explored as novel cellular therapy. In this study we investigated the role of MSC in the generation of regulatory T cells. We focused on the cellular interactions and secreted factors that are essential in this process.In an *in vitro* culture system (RPMI containing 10% fetal calf serum) of PBMC we showed that significantly more $CD4^+CD25^{hi}FoxP3^+$ T cells (Tregs) were generated in the presence of culture-expanded bone marrow derived MSC than in cultures without MSC (21.0% versus 2.7%, $p < 0.001$; n=5). Similar results were obtained with MSC-conditioned medium, indicating that this process is dependent on soluble factors secreted by the MSC. The

MSC-induced PBMC, containing Tregs, were functionally suppressive since they were able to suppress the proliferation of $CD4^+CD25^-$ T cells stimulated with αCD3/αCD28 beads. Removal of monocytes from the PBMC by MACS or adherence, completely prevented the generation of Tregs. This shows that the interaction between MSC and monocytes is essential for generating the population of Tregs. We showed that MSC enhanced the survival of monocytes within the PBMC population and induced skewing of the monocytes into a M2-macrophage-like phenotype. The generation of Tregs by MSC was significantly suppressed by addition of neutralizing antibodies directed against the TGF-β1 receptor but not by anti-IFNγ antibodies. These results indicate that TGF-β1, but not IFNγ, is involved in this process. Since TGF-β1 is constitutively secreted by MSC, it is conceivable that the MSC-induced generation of Tregs is mediated by TGF-β1 and that TGF-β1 secretion is independent of the interaction between MSC and PBMC. Experiments with inhibitors of heme oxygenase 1 (SnPP) and prostaglandin E2 (indomethacin) did not reveal a significant contribution to the MSC-induced generation of Tregs.In summary, we report that i) MSC promote the generation of regulatory T cells and ii) the induction of Tregs requires the presence of monocytes and of TGF-β1.s.m.melief@lumc.nl

EFFECTIVENESS OF WT1 PEPTIDE VACCINATION IN COMBINATION WITH IMATINIB THERAPY FOR AN IMATINIB-RESISTANT CML PATIENT

M Narita[1], M Masuko[2], A Yamahira[2], T Ida-Kurasaki[2], S Kitajima[2], T Kitajima[2], K Takai[3], T Koike[4], M Takahashi[1]

[3]Niigata Citizen Hospital, Niigata, Japan
[4]Nagaoka Red Cross Hostital, Niigata, Japan

Background. Although tyrosine kinase inhibitors (TKIs) have brought a dramatic improvement of the prognosis of CML, the extermination of CML stem cells is not yet achieved. It is well known that the induction and long-term maintenance of CTLs is inevitable for the eradication of cancer stem cells or MRD. WT1 is highly expressed in various types of leukemia including CML and WT1 protein is one of the most promising leukemia associated antigens for induction of CTLs. CML in CP in which the amount of CML cells was decreased remarkably by TKI is an ideal phase for the examination of effectiveness of immunothearpy. Therefore, in order to clarify the safety and effectiveness of WT1 peptide vaccination for the patients with CML, we started WT1 peptide vaccination in combination with imatinib therapy for a patient with CML. We could confirm the suppression of residual CML cells and the obvious existence of WT1 specific CTLs still over 3 years after discontinuation of vaccination. **Materials and Methods.** A 51 years-old male with CML in CP had been treated with 400 mg imatinib for 4 years. bcr-abl transcripts decreased transiently but gradually increased to more than 1,000 copies thereafter. HLA-A*2402-restricted 9mer WT1 peptides (CYTWNQMNL; a.a. 235-243), which had been identified to possess an anti-tumor immunogenicity, were administered subcutaneously at the dose of 1 mg/day every 2 weeks in combination with 400 mg imatinib for first 5 months and thereafter every 4 weeks for 12 months. The vaccination was undertaken 22 times totally. This protocol had been approved by ethical committee of Niigata University. The appearance of WT1-specific CTLs in PB was confirmed by evaluating the frequency of MHC/WT1 $tetramer^+CD8^+$ T cells by using mixed lymphocyte peptide culture (MLPC). **Results.** Although bcr-abl transcripts increased up to more than 2,000 copies after the the initiation of WT1 vaccination every 2 weeks, the transcripts have decreased to less than 500 copies by the administration of WT1 peptides every 4 weeks. After seven months from the cessation of WT1 peptide vaccination bcr-abl transcripts decreased to the level of major molecular response (MMR), which is lasting thereafter for 37 months. While WT1-specific CTLs were not detected in PB before WT1 peptide vaccination, the CTLs appeared after the second vaccination and remained at the level of nearly $15/10^6$ $CD8^+$ T cells thereafter. The MHC/WT1 $tetramer^+$ cells showed cytotoxicity against only the cells expressing WT1 and HLA-A*2402. Because the CML cells have not increased in molecular level after the cessation of vaccination, change of the treatment from imatinib to second-generation TKI is not planned now. **Conclusions.** WT1 peptide vaccination for an imatinib-pretreated CML patient is feasible and effective, which is due to the long-lasting amplification of WT1-specific CTLs with cytotoxicity against WT1-expressing leukemia cells. Tumor antigen specific peptide vaccine therapy in combination with molecular targeted therapy is one of the potent methods for eradicating leukemic stem cells.

[2]Laboratory of Experimental Immunology, University of Copenhagen, Copenhagen, Denmark
[3]Department of Microbiology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark
[4]Allo-HCT Laboratory, Department of Hematology, Rigshospitalet, Copenhagen, Denmark

Background. Cytomegalovirus (CMV) is an important human pathogen in immunocompromised hosts causing severe disease in hematopoietic cell and solid organ transplant recipients. Both CD4+ and CD8+ T cells are important for long-term control of the virus. Identification of CMV specific T cell epitopes has primarily focused on CD8+ T cell epitopes. **Aims.** To characterize the repertoire of CMV-specific CD4+ and CD8+ T cell responses against immediate early antigen 1 and 2 (IE1 and IE2) in healthy CMV+ donors. **Methods.** Using intracellular cytokine secretion (ICS) and IFN-γ ELISPOT assays, PBMCs from CMV+ donors were screened for recognition of overlapping 15mer peptides spanning the entire IE1 and IE2 proteins. To identify CD8+ T cell epitopes, the optimal peptide length and HLA-class I restriction of the 15mer peptides were predicted using the predictor, HLArestrictor, and validated by tetramer staining. To identify CD4+ T cell epitopes, peptide-HLA class II affinity measurements guided the production of HLA class II tetramers, and these were used to validate CD4+ T cell epitopes. **Results.** We have identified and validated 12 CD8+ T cell epitopes (5 novel) representing HLA-A, -B, and -C alleles. We have also identified 29 HLA class II restricted CD4+ T cell epitopes (20 novel) and validated 7 of these with HLA class II tetramers. **Conclusions.** We have found multiple novel HLA class I and II T cell epitopes in IE1 and IE2. In IE1, we found both CD4 and CD8 epitopes, whereas CD4 epitopes dominated in IE2. In general, each individual donor recognized more CD4 epitopes than CD8 epitopes, but the frequencies of CD8+ T cells were often higher than the frequencies of CD4+ T cells. Interestingly we have found 5 dominant CD4 epitopes that were recognized by many donors and restricted to several different HLA class II molecules. These could be promising candidates for T cell targeted vaccine development and adoptive T cell transfer.

[3]Kyowa Hakko Kirin, Tokyo, Japan

Background. Early lymphocyte development is highly dependent on complex interactions within bone marrow microenvironment. Although the involvement of several categories of proteins has been reported, evaluating roles of individual stromal products in lymphocyte regulation is still informative to understand normal/malignant proliferation and differentiation of lymphocytes. **Aims.** We aimed to identify new key players to regulate lymphocyte development *in vivo*.Methods and **Results.** As the first screening, we comprehensively identified cell surface or secreted molecules produced by MS-5 stromal cells with signal trap **Methods.** The 5'-portion of MS-5-derived cDNA fragments were cloned into a HPC4-TF/pEFBOS vector, which produces chimeric proteins composed of cDNA-proteins, a HPC4-epitope tag, and tissue factor transmembrane. Cell surface expression of the chimeric proteins was detected by reactivity against anti-HPC4 antibodies with flow cytometory. The cDNA library was transfected into COS7 cells, and then cells expressing a HPC4-epitope on their surface were collected by cell sorting, followed by recovery of plasmids from the sorted cells. After three-time enrichment of cDNAs carrying signal sequences, the recovered plasmids were transfected into E. coli, and then 5,000 individual colonies were picked and stored. Based on HPC4-antibody recognition, 21 kinds of proteins carrying signal peptides, such as osteopontin, proliferin, osteoblast stimulating factor (OSF)-1, OSF-5, pre PDGF receptor, collagens, and 2 unknown proteins were identified. As the second screening, we selected proliferin, OSF-1, and OSF-5 by northern blots showing dominant expression on stromal cells and by information about expression in hematopoitic tissues and relationship with proliferation or differentiation. As the third screening, we generated transgenic chimera (Tg) mice, which produce these three molecules respectively under control of the immunoglobulin-kappa chain promoter to investigate *in vivo* effects. Tg mice are characterized by expression of proposal proteins in mature B cells without any influence on ontogeny. OSF-5-Tg mice showed significantly decreased number of blood cells in peripheral blood, spleen, and bone marrow as compared with control mice while either OSF-1- or proliferin-Tg mice did not. Flow cytometry of lympho-hematopoietic organs revealed that all Tg mice showed normal patterns of staining for T cells (CD4 and CD8 in thymus; CD3 in spleen) and myeloid cells (Mac1 in BM). In B cells, only OSF-5-Tg mice showed great decrease of $B220^+$ cells in peripheral blood, spleen, and bone marrow. OSF-5-Tg bone marrow cells have normal number of hematopoietic stem ($lineage^-Sca\text{-}1^{high}c\text{-}kit^{high}$) and pro-B ($CD43^{high}B220^+$) cells, but very few pre-B ($CD43^{dull}B220^+$) and immature B ($CD43^-B220^+$) cells. Thus, OSF-5 is likely to be a novel regulator of B lymphocyte development *in vivo*. OSF-5 is known to have two splicing variants, a secreted variant 1 and an intracellular variant 2. Our RT-PCR analysis revealed that OSF-5 variant 1 was expressed by stromal cells and OSF-5 variant2 by hematopoietic cells although OSF-5 mRNA was detected in a variety of organs. We have established *in vitro* culture systems using early lymphocyte progenitors and are now investigating roles of each OSF-5 variant. **Conclusions.** We successfully identified OSF-5 as a novel bone marrow component, which preferentially regulates early B lymphocyte development.

RESOLUTION OF NUCLEAR FACTOR I-A CHROMATIN SIGNATURE BY POLYCOMB AND MICRORNA PROMOTER TARGETING ACTIVITIES DIRECTS HUMAN GRANULOPOIESIS

C Nervi[1], G Zardo[1], A Ciolfi[1], L Vian[1], M Billi[2], S Racanicchi[2], C Maresca[1], F Fazi[1], N Noguera[3], M Mancini[1], M Nanni[1], G Cimino[1], F Lo Coco[3], F Grignani[2]
[1]University of Rome La Sapienza, Latina, Italy
[2]University of Perugia, Perugia, Italy
[3]University of Rome Tor Vergata, Roma, Italy

Background. Stem/progenitors lineage commitment is accompanied by chromatin modifications at gene promoter "bivalent domains"with overlapping repressive H3K27me3 and activating H3K4me3 marks. This bivalency postpones cell commitment and, contemporaneously, maintains progenitor cells primed for alternate lineage fates. Polycomb (PcGs) and trithorax (TrxGs) proteins are responsible for the tri-methylation of H3K27 and H3K4, respectively. PcGs also possess RNA binding properties. Non-coding RNAs can be required for PcG recruitment to DNA, promoting chromatin remodeling and transcriptional gene silencing. The non-coding RNA family includes microRNAs (miRs), mainly mediating post-transcriptional gene silencing through limited base-pairing to complementary mRNA sequences. We previously found miR-223 functionally involved in a regulatory circuitry directing human granulopoiesis and identified Nuclear factor I-A (NFI-A) as a post-transcriptional miR-223 target and as a regulator of human hematopoietic stem cell/progenitor (HSC/HPCs) lineage choice. Up-regulation of NFI-A levels induces differentiation along the erythroid lineage while its down-regulation shifts HSC/HPCs fate towards the granulocytic lineage. **Aims.** To investigate whether epigenetic modifications affecting genes controlling stem cell identity and lineage choice could be responsible for the NFI-A gene silencing during maturation/differentiation of myeloid progenitors and the role of miR-223 in these events. **Methods.** The cellular models were: i) bone marrow, peripheral blood and CD34+-HSC/HPC, from informed healthy donors; ii) primary acute leukemia blasts from 20 patients; iii)HL60, HL60R, K562, NB4, NB4-MR4 cell lines in their wild-type form, ectopically expressing miR-223 or knocked out for miR-223 or Suz12, Dicer1, Ago1. NFI-A and miR-223 gene expressions were tested by qRT-PCR. Cell differentiation was investigated by morphological and immunophenotipical assays. MiR-223 association with the PcGs-RNAi complex, nuclear localization and NFI-A promoter targeting activity were visualized by confocal microscopy, co-immunoprecipitation and chromatin immunoprecipitation (ChIP) assays. ChIP assay using H3K27me3 and H3K4me3 antibodies revealed chromatin status on NFI-A promoter, whereas bisulphite sequencing addressed NFI-A promoter methylation. **Results.** We found that during human granulopoiesis miR-223 localizes inside the nucleus and locates on its complementary sequences present on NFI-A promoter near binding sites of PcG members YY1 and Suz12. The *in vivo* formation of a nuclear repressive complex, composed by miR-223 and YY1-Dicer-1 at YY-1 binding sites on NFI-A promoter, induces NFI-A transcriptional gene silencing through the resolution of promoter chromatin bivalent domains and heterochromatin formation. The integrity of evolutionarily conserved miR-223 complementary seed-matches on NFI-A promoter is required for NFI-A transcriptional gene silencing. Interestingly, the ectopic expression of miR-223 in human myeloid progenitors channels granulopoiesis and induces heterochromatic silencing of NFI-A gene, whereas miR-223 silencing produces the opposite effects. **Summary and Conclusions.** Our work identifies a novel cooperative pathway of site-specific regulation of gene expression acting on the NFI-A gene promoter triggered by the promoter recognition and transcriptional targeting activity by miR-223 and PcGs (YY1 and Suz12), which is relevant for HSC/HPCs granulocytic lineage determination. Thus, besides regulating translation of their mRNA targets, endogenous miRs affect gene expression at the transcriptional level, functioning at a critical interface between chromatin remodeling complexes and the genome to direct cell fate lineage determination of human hematopoietic cells.

[10]MRC Molecular Haematology Unit and Department of Haematology, Oxford, United Kingdom

Background. Constitutional trisomy 21 (T21) causes Down syndrome (DS). There is a striking increase in childhood acute leukaemia in DS; both myeloid (ML-DS) and B-lymphoblastic (B-ALL). DS leukaemias display distinct characteristics which support a crucial role for T21 in their pathogenesis, and for ML-DS at least, there is evidence to suggest initiation in fetal life. We have previ-

ously reported that by the second trimester, the T21 fetal liver (FL) myeloid progenitor compartment is abnormal and in addition B lymphopoiesis is impaired. We hypothesized that perturbation of FL HSC or multipotent progenitor proliferation and lineage-commitment may be responsible for these defects in FL myelo- and lymphopoiesis. **Aims.** To determine the effects of T21 on FL HSC and multipotent progenitors (MPP and LMPP) **Methods.** We performed detailed immunophenotypic analysis, clonogenic and lymphoid differentiation cultures and gene expression studies of HSC/MPP/LMPP and committed myeloid and B-lymphoid compartments of second trimester human T21 FL and compared these with normal FL of the same gestation. **Results.** Compared to normal FL (n=13), the frequency of HSC in T21 FL (n=8) was increased (T21: 7.8±0.9 vs. normal: 2.3±0.4%;p=0.0026) as was the frequency of MEP (T21: 46.3 ± 7.6 vs. normal: 18.0 ± 2.0%; p=0.005) whereas MPP and GMP were reduced (T21 vs. normal: 3.7±0.4% vs. 5.7±0.7%; p=0.0484 and 7.0 ± 2.9% vs.14.3 ± 1.0%; p=0.036 respectively). Although the frequencies of lymphoid primed multipotent progenitors (LMPP) and early lymphoid progenitors (ELP) were comparable; there was a marked reduction in the CD34+CD19+ committed B progenitors (CBP) in T21 compared to normal FL (T21: 3.1±1.3%vs.normal: 10.7±1.3%; p=0.0026), suggesting a block to B-lymphoid differentiation. *In vitro* clonogenic assays of flow-sorted HSC and progenitors showed increased clonogenicity of T21HSC (5-fold p<0.01), CMP (2.7-fold p<0.05) and MEP (2.5-fold p<0.05) compared to normal FL. Lineage output from T21 HSC, MPP, CMP and MEP showed marked skewing towards the megakaryocyte-erythroid lineage with increased megakaryocyte, megakaryocyte-erythroid and erythroid blast colonies. Although normal FL HSC, LMPP and ELP generated CD34-CD19+ B cells in MS5 co-cultures, their T21 FL counterparts demonstrated marked impairment in B-cell differentiation with very few CD34-CD19+ cells generated in MS5 co-cultures. T21 FL HSC expressed a multilineage gene expression programme but showed marked reduction in expression of early lymphoid genes (*FLT3, ETS1, MEF2C, NOTCH1* and *HES1)* compared to normal FL HSC. T21 FL LMPP, ELP and CBP also failed to upregulate early lymphoid genes (*FLT3*, *NOTCH1*, *IKAROS* and *RUNX1)* and this was accompanied by reduced expression of several key B-lymphoid genes (*EBF, IGH@, CRLF2, IL7R*A) compared to normal FL. **Conclusions.** We report the first evidence in primary human FL cells that T21 causes perturbation of immunophenotypically-defined HSC/MPP/LMPP. Expansion of HSC is accompanied by megakaryocyte-erythroid bias and extensive dysregulation of B-cell development. Therefore, in T21 FL, multiple defects in the HSC compartment with downstream effects on the committed myeloid and B-lymphoid progenitor compartments, may underlie the increased susceptibility of T21 haematopoietic cells to both myeloid and lymphoid leukaemic transformation.

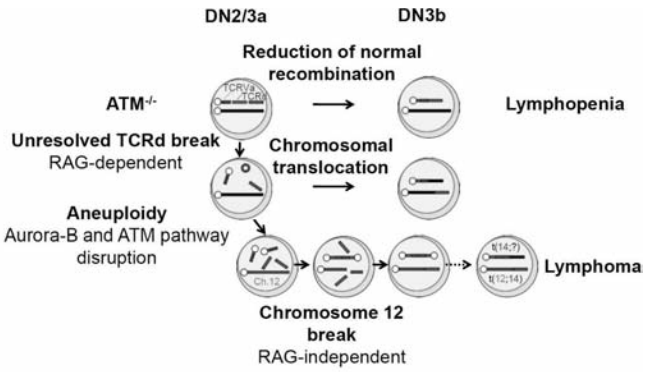
IMMUNE DEFECT AND VISUALIZATION OF CHROMOSOME 14 BREAKS AND TRANSLOCATIONS INVOLVING TCR A/D LOCI DURING EARLY T-CELL DEVELOPMENT LACKING ATM

T Isoda[1], M Takagi[1], J Piao[1], S Nakagama[1], M Sato[1], K Masuda[2], T Ikawa[2], T Morio[1], H Kawamoto[2], S Mizutani[1]
[1]Tokyo Medical and Dental University, Tokyo, Japan
[2]Laboratory for Lymphocyte Development, RIKEN, Yokohama, Japan

Background. Ataxia telangiectagia mutated (ATM) protein localizes at RAG mediated DNA DSBs and stabilizes DNA ends during V(D)J recombination. ATM deficient ($ATM^{-/-}$) mice are known to be predisposed to T-cell lymphopenia and T-cell lymphoma often associated with chromosome 14 translocation involving TCRd loci. $ATM^{-/-}$ mouse reportedly has a failure of T-cell development from double positive (DP) to single positive (SP) differentiation due to inefficient T-cell receptor a (TCRa) recombination. However, biological features of T-cell development at double negative (DN) phase and the timing of chromosome 14 translocation formation in $ATM^{-/-}$ mice have not been fully elucidated. **Aims.** We tried to understand how T-cell differentiation fails in thymocytes lacking ATM. Additionally, we tried to visualize when clomosomal breaks and translocations are generated during thymocytes development. **Methods.** We employed *in vitro* T-cell differentiation assay for obtaining metaphase spread from DN phase thymocytes. BM-progenitors were cultured on OP9-DLL1 cells with high-dose cytokine including Flt3-L, IL-7 and SCF. This culture condition halts T-cell differentiation at DN2-3a phase just before b-selection. Then, by reducing the concentration of Flt3-L and IL7, the differentiation arrest was released, leading to differentiation of thymocytes from DN3a to DN3b. **Results.** We demonstrate that $ATM^{-/-}$ thymocytes show a developmental failure at the transition phase from DN3a to DN3b in both ab and gd-lineages *in-vivo*. Consistent with *in-vivo* profiles, bone marrow (BM) progenitors of $ATM^{-/-}$ mice cultured with OP9-DLL1 show a delay at b-selection checkpoint in chronological order. This transitional failure was due to recombination failure of TCRb or d loci. We attempted to monitor when chromosome 14 translocation involving TCRa/d locus is generated during DN phase by using *in-vitro* culture system. Chromosome 14 breaks at TCRa/d locus were shown in 5% of $ATM^{-/-}$ DN2-3a cells, and these breaks persisted in 2.5% of $ATM^{-/-}$ DN3b-4 cells. Chromosome 14 translocation involving TCRa/d locus was detected in 0.8% of ATM-/- DN2-3a cells. The frequency of chromosome 14 translocation increased up to 11% of $ATM^{-/-}$ DN3b-4 cells. Chromosome 14 breaks and translocations were not detected in WT, $RAG2^{-/-}ATM^{+/-}$ nor $RAG2^{-/-}ATM^{-/-}$ thymocytes. These results suggest that in ATM deficient thymocytes generation of chromosome 14 breaks and translocations involving TCRa/d locus depend on RAG proteins, which mediate DNA DSB during b and gd selection. Additionally aneuploidy and dicentric chromosome 14 (dic(14:14)) with TCRVa amplification as well as sister chromatid breaks and translocations of chromosome 12 (t (12:14)) were also observed in minor population of $ATM^{-/-}$ cells. These snapshots might capitulate the RAG independent process for TCRVa amplification by breakage fusion breakage cycle and formation of recurrent chromosomal translocation toward thymic lymphoma in ATM deficiency. **Summary and Conclusions.** Our findings provide the first evidence that T-lymphopenia and chromosomal translocations in ATM deficiency derive from shared events involving a defect of repair of Rag dependent DNA breaks during early T-cell development. For lymphomagenesis Rag independent chromosomal instability processes are additionally involved in ATM deficiency.



Model for early thymocytes development lacking ATM
Schematic illustration for the impaired thymocyte development and creation of a translocation involving the TCR locus.

DEFICITS IN THE NF-KB ALTERNATIVE PATHWAY RESULT IN BOTH HEMATOPIETIC STEM CELLS AND MARROW STROMA FUNCTIONAL DEFECTS

M Ramírez[1], A González[1], L Fernández-Casanova[1], C Sánchez-Valdepeñas[2], S Baena[1], L Madero[1], R Schmidt[3], M Fresno[2]
[1]Hospital Universitario Niño Jesús, Madrid, Spain
[2]Centro de Biología Molecular Severo Ochoa, Madrid, Spain
[3]II. Medizinischen Klinik und Poliklinik, Munich, Germany

Background. The activation of NF-κB-inducing kinase (NIK) is generally known as the alternative (or non-canonical) NF-κB pathway, and drives the post-translational processing of p100 to mature p52, which results in the translocation to the nucleus of p52-containing complexes such as p52/RelB. The role of the alternative NF-κB pathway in the biology of hematopoietic stem cells (HSCs) is not known. The functions of HSCs in steady-state and under stress are controlled by a variety of molecules, which may provide different contribution to each process. The marrow microenvironment has a well established role in modulating the functions of HSCs. **Aims.** To study the functional capacities of HSCs and marrow stroma in mice deficient for two components of the alternative NF-κB pathway: NIK or p52. **Methods.** We studied HSCs and marrow stroma separately. The more immature hematopoietic compartment of marrow cells was characterised by flow cytometry. The amount of clonogenic progenitor cells in the marrow was assessed in standard CFU-GM cultures. The proliferative capacity of HSCs was assessed in *in vitro* liquid cultures with cytokines. The functional capacity of HSC was assessed *in vivo* in competitive repopulation assays. In vitro marrow stromal layers were generated from total bone marrow cells. We tested the ability of these stromal cultures for maintaining HSC function by seeding irradiated stromal layers with wild type HSCs. **Results.** The proportions of marrow cells with the immunophenotype of HSCs (lineage-depleted Sca1-positive ckit-positive cells, LSK, or CD150 positive CD48 negative cells) in either NIK-deficient or p52-deficient mice were similar to those in control mice. We found no differences in CFU-GM numbers in any of the mice

studied. Liquid cultures started with NIK-deficient marrow cells produced significantly less numbers of cells and CFU-GM, compared with those started with wild type marrow. NIK- or p52-deficient HSCs repopulated the B-, T- and myeloid-lineages but at significantly lower levels when compared to wild type HSCs. Total donor CD45.2 cells and total CD45.2 LSK cells were also significantly lower in the marrows of mice transplanted with NIK- or p52-deficient HSCs versus those of controls. When studying the effects of NF-κB alternative pathway defects on stromal cells, we observed that the stroma formation was delayed compared with that of control. The numbers of wild type CFU-GMs recovered 4 weeks after seeding were significantly lower in the NF-κB-deficient stromal cultures compared to those of controls.**Conclusions.** These results suggest that the NF-κB alternative pathway plays a role in the function of HSC that may be important under stress conditions. The pathway is also involved in the function of the hematopoietic stroma.

BONE MARROW CD14+ MONOCYTES AND MACROPHAGES POLARIZATION TOWARD M2 PHENOTYPE PROMOTE MULTIPLE MYELOMA TUMOROGENICITY VIA THE CXCR4/CXCL12 AXIS - A NOVEL POTENTIAL PATHWAY FOR TARGTED THERAPY

K Beider[1], M Abraham[2], H Wald[2], I Weiss[3], E Ribakovsky[1], M Leiba[1], A Shimoni[1], A Peled[2], A Nagler[1]
[1]Sheba Medical Center, Ramat Gan, Israel
[2]Biokine Therapeutics Ltd., Ness Ziona, Israel
[3]Goldyne Savad Institute of Gene Therapy, Hebrew University Hospital, Jerusalem, Israel

Background. Multiple myeloma (MM) is B-cell malignancy characterized by proliferation of plasma cells in the bone marrow (BM). Interaction between MM and BM microenvironment cells is critical for homing, growth and chemotherapy resistance of the tumor cells. Research to date has largely focused on the role of BM stromal cells (BMSCs) in MM progression. However, monocytes/macrophages may also contribute to MM growth. Macrophages are frequently found to infiltrate tumors. Tumor-associated macrophages (TAMs) exhibit predominantly M2-like phenotype and have been linked to diverse tumor-supporting activities. Elucidating the mechanisms involved in MM-macrophages interactions may have novel therapeutic applications. **Results.** MM cells specifically attracted peripheral-blood CD14+ monocytes. Interaction of MM with BMSCs significantly increased the ability of MM to recruit monocytes ($p<0.01$). We identified CXCL12 chemokine, produced by both MM and BMSCs, as critical regulator of CXCR4-positive monocytes migration. CXCL12 production was up-regulated in MM-BMSCs co-culture conditions, whereas blockage with anti-CXCR4 neutralizing antibodies significantly abrogated monocyte recruitment toward MM-derived conditioned medium ($p<0.01$). Furthermore, analyzing MM BM biopsies, we detected elevated levels of CXCL12 in comparison to normal BM samples, whereas malignant MM cells often represented the source of increased CXCL12 in BM. Next, the functional consequence of MM-macrophage interactions was examined. We showed that macrophages effectively induced MM proliferation and protected malignant cells from chemotherapy-induced apoptosis. Moreover, incubation with macrophages strongly induced the expression of various factors in MM cells, including chemokines CXCL12, CCL2 and CCL4, pro-inflammatory cytokine IL-1β and pro-angiogenic factors IL-8 and VEGF. Importantly, IL-10 secretion by MM cells was significantly up-regulated following the interaction with macrophages or BMSCs. These results suggest the possible role of MM cells in macrophage education and polarization. To further explore the modulatory effect of MM on macrophage polarization, we tested the expression of various M2 markers by macrophages following their interaction with MM cells. We found, that expression of M2-related chemokine CCL17, chemokine receptors CXCR1 and CXCR2 and scavenger receptor CD206 were up-regulated in macrophages following interaction with MM cells. Furthermore, MM cells fully blocked LPS-induced TNFa secretion from macrophages (a hallmark of M1 response), but further increased IL-10 secretion. Moreover, we analyzed the presence of M2-type macrophages in BM samples of MM patients. We detected increased numbers of CXCR4-expressing CD163+ CD206+ macrophages in MM BM (n=18) comparing to normal specimens (n=5). Finally, to explore the role of CXCR4/CXCL12 pathway in MM-mediated macrophage recruitment *in vivo*, a xenograft model of peritoneal macrophage migration was established. NOD/SCID mice were injected i.p. with CXCL12-expressing MM cell line RPMI8266 and F4/80+ macrophage recruitment into peritoneal cavity was measured. Injection of MM cells strongly increased the number of migrated macrophages, whereas CXCR4 blockade with neutralizing antibodies significantly suppressed macrophage migration. **Conclusions.** Taken together, these results identify macrophages as important players in MM tumorogenicity, demonstrate the role of MM in macrophage recruitment and M2 polarization and recognize CXCR4/CXCL12 axis as critical regulator of MM-stroma interactions and microenvironment formation. Our data provide the basis for future targeting MM-BMSCs and MM-macrophage interactions with anti-CXCR4 agents as therapeutic strategy in MM.

QUANTITATIVE BUT NOT QUALITATIVE IMPAIRMENT OF MATURE FETAL B CELL DEVELOPMENT IN DOWN SYNDROME IS CELL-INTRINSIC AND ASSOCIATED WITH A MATURATION BLOCK AT THE PRO-B LEVEL

G Cowan[1], K Goudevenou[1], A Roy[1], A Chaidos[1], K O'Donoghue[2], C Mattar[3], J Chan[3], A Karadimitris[1], I Roberts[1], G Bohn[1]
[1]Imperial College, London, United Kingdom

[3]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background. Children with Down syndrome (DS) have lymphopenia associated with an increased risk of autoimmune disease and susceptibility to infections. In conjunction with an increased risk of B acute lymphoblastic leukaemia, these observations suggest that trisomy 21 (T21) may specifically perturb B-lineage development. Consistent with this, we have recently found that in second trimester DS fetal liver (FL), early B cell development is characterised by a marked reduction in the frequency of Pre-proB and Pro-B committed B-progenitors suggesting that T21 impairs B-lymphoid development early in fetal life. Whether the effects of T21 are confined to the progenitor compartment or also affect mature B cell function and development in fetal life is unknown. **Aims.** To investigate mature B cell development in T21 FL, fetal bone marrow (FBM) and cord blood (CB). **Methods.** Frequency and immunophenotype of mature B cells from T21 and disomic (control) FL, FBM and CB samples were analysed by multiparameter flow cytometry. B cell receptor (BCR) repertoire was investigated by CDR3 length analysis using spectratyping. B cell development potential of T21 vs disomic $CD34^+$ cells was assessed in NOD/SCID/IL-$2Rg^{-/-}$ (NSG) xenograft assays. **Results.** The frequency of mature B cells ($CD34^-CD19^+$) was drastically reduced in T21 FL (n=8) compared to normal FL (n=5, 0.87±0. 27% vs. 7.66±2.9% respectively, p=0.03). Similar differences were observed in FBM (DS: n=3, 10.9±4.3% vs normal: n=3, 41.3±9.8%, p=0.049) and CB (DS: n=6, 4.6±2.1% vs normal: n=15, 14.3±2%, p=0.01). Despite the reduced B cell frequency, phenotypic maturation of B cells was similar in T21 and disomic samples. While nearly all B cells in normal and T21 fetal samples displayed a transitional phenotype ($CD34^-CD19^+CD10^+CD27^-$), CB samples contained mainly naïve ($CD34^-CD19^+CD10^-CD27^-$) cells with no significant difference in the proportion of naïve, transitional and memory cells between normal and T21 CB. Analysis of the BCR repertoire of $CD34^-CD19^+$ B cells by IgH spectratyping showed that fetal T21 mature B cells develop a fully diversified BCR repertoire comparable to that of gestation-matched disomic B cells consistent with a maturation block in DS at the Pro-B progenitor level prior to Ig gene rearrangement. To investigate whether the quantitative defect in B cell development is cell-intrinsic we transplanted 30,000 $CD34^+$ cells into NSG mice. Only 25% of T21 FL and none of the T21 FBM vs 100% of disomic samples showed BM engraftment after 12 weeks. Furthermore, while disomic FL $CD34^+$ cells gave rise predominantely to $CD34^-CD19^+$ BCs (77.8%±2.8% within the human $CD45^+$ population), engrafted T21 $CD34^+$ cells showed reduced ability to generate B cells (15.1% of the human $CD45^+$ cells) recapitulating the B cell ontogeny of human T21 fetal haemopoiesis consistent with the T21 fetal B cell differentiation defect being cell intrinsic. **Conclusions.** T21 and disomic mature fetal B cells display similar phenotypic patterns of differentiation and a fully diversified BCR repertoire. However, overall frequency of mature B cells in DS is severely reduced and results from a cell intrinsic process that leads to a maturation block at the Pro-B cell level.

TRAIL IMPAIRS STEM CELL SURROGATES OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA IN PRECLINICAL TRANSPLANTATION ASSAYS

I Jeremias[1], L Quintanilla Fend[2], C Castro de Alves[1]
[1]Helmholtz Zentrum München, Munich, Germany
[2]Universität, Tübingen, Germany

Background. Cancer stem cells represent the most important target cells for anti-tumor therapy as they are uniquely capable to maintain tumor growth and to induce relapse. TRAIL (TNF-related apoptosis-inducing ligand) is a member of the TNF family which induces apoptosis in a wide variety of tumor cells while sparing normal cells. TRAIL is currently tested in phase I and II clinical trials, yet its ability to target cancer stem cells is currently unknown. **Aim.** Here we aimed to evaluate the effect of TRAIL on LICs using tumor cells derived from

children with precursor B-cell acute lymphoblastic leukemia (pre-B ALL). **Methods.** Primary ALL cells were passaged through NSG mice, freshly stimulated with TRAIL *in vitro* and subjected to limiting dilution transplantation assays *in vivo*. After 12-16 weeks, mice were evaluated for leukemic engraftment. **Results.** In all 3 pre-B ALL samples tested, *in vitro* treatment with TRAIL prior to transplantation of cells into mice significantly reduced their engraftment capability. TRAIL disabled leukemic engraftment by > 95 % in all 3 samples and increased the time to engraftment and completely disabled it. In a second, additive approach, TRAIL was used in a preclinical mouse model. Pre-B ALL samples were engrafted in NSG mice and leukemia-bearing mice were treated with TRAIL systemically at 7.5 mg / kg daily i.p. for 10 days. In this preclinical *in vivo* model, TRAIL treatment completely cured a proportion of animals harbouring patient-derived pre-B ALL xenografts. In mice developing ALL despite of TRAIL treatment, ALL cells required prolonged incubation periods upon secondary transplantations. **Summary and Conclusions.** Taken together, TRAIL significantly disabled the leukemia-initiating function of LICs from patient-derived pre-B ALL xenografts *in vitro* and eliminated LICs *in vivo*. Our data show that it is feasible, although technically demanding, to test apoptosis sensitivity of LICs. We conclude from these data that TRAIL constitutes an attractive future drug for treatment of ALL.

0109

MATRIX PROTEIN ?IGH3 FUNCTION IN HEMATOPOIETIC STEM AND PROGENITOR CELLS

S Klamer[1], P van Hennik[2], M von Lindern[2], C van der Schoot[2], C Voermans[2]
[1]Sanquin Research, Amsterdam, Netherlands
[2]Sanquin Research, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands

Background. Adult hematopoietic stem and progenitor cells (HSPC) reside in specific niches in the bone marrow (BM). Within this specialized microenvironment, the interactions of HSPC with adhesion molecules on neighbouring cells and extracellular matrix (ECM) components are thought to be crucial for the maintenance of the HSPC population.Comparative gene-expression profiling of purified HSPC in homeostatic and regenerative conditions identified the ECM protein βigh3 as being upregulated in regenerative BM. **Aims.** The aim of this project is to study the function of the ECM protein βigh3 inHSCself-renewal and differentiation. **Methods.** Cord-blood derived $CD34^+$ cells and/or bone-marrow derived mesenchymal stromal cells (MSC) were transduced by lentivirus to obtain overexpression or knock-down of βigh3 and these cells were analyzed in various colony-assays, differentiation-assays and (co)cultures. **Results.** High endogenous expression of βigh3 was observed in MSC, whereas expression in HSPC is low and increases as cells differentiate to monocytes.Overexpression of βigh3 in HSPC (on average 80-fold) accelerated megakaryopoiesis and increased the percentage of mature megakaryocytic cells from 16%±6% to 30%±7 (n=4). In contrast, overexpression of βigh3 in HSPC reduced granulocytic proliferation (80%±11 reduction at day 7, n=3) and decreased the number of early colony-forming-unit-granulocyte-monocyte (CFU-GM) progenitors (21%±7 reduction, n=7), while the erythrocytic differentiation was not affected. Together these data indicate that overexpression of βigh3 differentially affects distinct hematopoietic lineages. Overexpression of βigh3 resulted in a progressive reduction over time of the quality of HSPC, determined as the long-term-culture-colony-initiating-cells (LTC-CFC) formation after co-culture (in week 2, 4 and 6 respectively a reduction of 23%, 61% and 92%), indicating again that βigh3 drives differentiation of HSPC.Knock-down of βigh3 in HSPC resulted in a more than 2-fold reduction of CFU-GM formation and an even more pronounced decrease (3.3-fold) in the number of colony-forming-unit-erythrocyte, which is explained by reduced proliferation of βigh3 knock-down cells. Accordingly, knock-down of βigh3 resulted in reduced cell numbers in MSC as well as HSPC cultures (at day 13 from 20- to 6-fold, per input cell), in addition to a reduction in the percentage of cells in cell cycle progression and reduced expression of cell cycle genes. Together these data indicate that βigh3 plays a role in cell proliferation.Interestingly, knock-down of βigh3 in HSPC increased the potential of HSPC to form cobblestone-areas under a layer of stromal feeder cells. The increased number of cobblestone-area-forming-cells (CAFC) detected at week 4 (1.7-fold) and 6 (1.8-fold) in this assay, and the increase in LTC-CFC formation (15.5-fold) indicated that reduction of βigh3 levels maintains renewal capacity of HSPC.**Summary and Conclusions.** βigh3 affects lineage commitment of HSPC and is an important factor in HSPC proliferation. Overexpression of βigh3 in HSPC accelerates megakaryocytic differentiation, while decreasing granulocytic proliferation and CFU-GM formation, suggesting that βigh3 drives lineage commitment of HSPC. Knock-down of βigh3 in HSPC stimulates CAFC formation, indicating that decreased βigh3 levels maintain undifferentiated HSPC. We postulate that the levels of βigh3 have to be tightly regulated in the (regenerative) bone marrow microenvironment to balance the self-renewal and differentiation of HSPC.

PROTECTION OF HEMATOPOIETIC STEM CELLS (HSC) AND PROGENITORS AGAINST OXYDATIVE STRESS BY CXCR4/SDF-1 AXIS

M Wittner[1], A Betems[2], H Abdelouahab[2], Y Zhang[2], E Kwarteng[2], D Jouni[2], C Marty[2], S Patel[2], I Plo[2]
[1]Gustave Roussy Institute, Villejuif, France
[2]INSERM U1009, Villejuif, France

Background. Reactive Oxygen species (ROS) are a heterogeneous group of molecules and free radicals derived from diatomic oxygen. Many physiologic and pathological states such as aging, infections or cancer are accompanied by excessive cellular ROS production leading to a state known as oxidative stress. The chemokine receptor CXCR4 and its ligand Stromal cell Derived Factor 1 (SDF-1) have been shown to provide a key role in the control of HSC and hematopoietic progenitor biology. We have recently shown that disruption of the CXCR4 receptor induces progressive loss of HSC and progenitors in the peripheral blood, leading to a sharp decline in CXCR4-/- hematopoiesis over time. **Aims.** We hypothesized that exhaustion of the bone marrow (BM) stem cell pool in CXCR4 -/- mice is due to increased oxidative stress in HSC and progenitors and that CXCR4/SDF-1 confers stress resistance to HSC. **Methods.** We induced *in vitro* oxidative stress in mature and primitive c-kit+Sca1+ lineage low/- (LSK) hematopoietic cells with the oxydant L-buthionine sulfoximine (BSO). The effect of SDF-1 on BSO-induced ROS level increase was evaluated with 2',7'- dichlorofluorescein (DCF), a molecular probe for general ROS detection. The capacity of BM cells or purified BM subpopulations to give rise to hematopoietic progenitors was quantified by seeding treated and untreated cells on semi-solid medium. DNA double-strand breaks induced by BSO were evaluated in the absence and presence of SDF-1 by immunofluorescence microscopy using an antibody specific for phospho-histone gamma H2AX. To evaluate CXCR4 functions on oxidative stress *in vivo*, CXCR4 chimeric mice were generated by transplanting embryonic day 14.5 CXCR4+/+ and CXCR4-/- foetal liver cells to lethally irradiated mice. Stably reconstituted mice were supplemented or not with N-acetylcysteine (NAC), a known ROS scavenger (H_2O_2), in the drinking water for one month. Cell cycle status, apoptosis, ROS level, DNA double-strand breaks and hematopoietic progenitors as well as phenotypically defined HSC-SLAM (LSK CD150+CD48-) numbers were quantified in BM and blood. **Results.** : i) Basal ROS production is heterogeneous in hematopoietic cells, LSK and LSK-SLAM cells presenting very low ROS levels compared to more mature cells. ii) SDF-1 or NAC addition to the culture medium prevents BSO effects on ROS augmentation and rescues BSO-induced decrease in hematopoietic clonogenic function. BSO-induced DNA damage is rescued by SDF-1 at the HSC level. iii) CXCR4-/- chimeric mice treated with NAC exhibited lower HSC ROS levels and higher numbers of medullary HSC, indicating that NAC treatment prevents exhaustion of the medullary stem cell pool. In the BM, CXCR4-/- SLAM cells are hyper proliferative in both, NAC treated and untreated mice, suggesting that the rescue effect of NAC is independent from cell cycle status. In contrast, NAC treatment results in reduced apoptosis and DNA damage in primitive cells. **Conclusions.** CXCR4/SDF-axis signalling is essential for protection of hematopoietic progenitors and HSCs against acute and chronic oxidative stress.

THE EXTRACELLULAR MATRIX PROTEIN SLIT3 PROMOTES ERYTHROPOIESIS

K Brussen, A van Stalborch, A Klok, M von Lindern, C Voermans, P van Hennik
Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands

Background. Slit extracellular matrix proteins are expressed by bone marrow (BM) stromal cells, whereas their receptors, the Roundabout (Robo) proteins, are expressed by hematopoietic stem- and progenitor cells (HSPC). We previously showed that homing of HSPCs to the BM was enhanced when the HSPCs were pre-treated with Slit3. **Aims.** The aim of this study was to determine whether and by what molecular mechanism Slit3 affects the proliferation and differentiation of HSPCs. **Methods.** The role of Slit3 was examined at distinct levels in the hematopoietic hierarchy. To investigate the role of Slit3 at the level of various stem and progenitor cell subsets, a colony-formation-unit-in culture assay was performed. To this end, cord blood (CB)-derived HSPCs and CB and BM-derived HSPCs subsets, i.e. hematopoietic stem cells (HSCs), common myeloid progenitors (CMPs), megakaryocyte-erythrocyte progenitors (MEPs) and granulocyte-monocyte progenitors (GMPs), were plated in semi-solid medium supplemented with growth factors in the presence or absence of Slit3. Next, to examine whether Slit3 affects the differentiation of HSPCs, the HSPCs were cultured in the presence or absence of Slit3 in serum-free liquid medium containing TPO, SCF and Flt3. We also investigated the role of Slit3

during differentiation of HSPCs towards erythroblasts in the presence of EPO, SCF and IL3. To unravel the cellular signaling induced by Slit3, we transfected HEK cells with Robo1 and Nck2, performed immunoprecipitation to identify interacting proteins and analyzed the phosphorylation status of all proteins in the complex. **Results.** Slit3 did not change the number of colony-forming units in the granulocyte-monocyte lineage or the megakaryocytic lineage, but increased the number of the burst-forming unit erythroid (BFU-E) progenitors by 2.7-fold. BFU-E colony formation from the HSC, the CMP and the MEP population increased in the presence of Slit3, whereas BFU-E colonies did not grow out from the GMP fraction as expected. During liquid culture of HSPC, Slit3 slightly increased the total number of nucleated cells and the number of cells with an immature erythroblast phenotype ($CD34^-CD45^-CD36^+CD71^+$) at day 11 by 1.8-fold. In the absence of EPO, the cells did not differentiate to more mature glycophorin A/$CD235^+$ erythroblasts. Notably, the frequency of BFU-E increased after 4, 7 and 11 days of culture with a maximal increase of 4.2-fold at day 7. During erythroblast differentiation culture, the number of $CD235^+$ cells was increased in the presence of Slit3 at day 7 and day 11 of culture, with a maximum of 2.3-fold at day 11. Concerning the molecular mechanism, we observed that Robo1 interacts with the adaptor proteins Nck and p130Cas. Slit3 decreased the tyrosine phosphorylation of Robo1 and increased the tyrosine phosphorylation of p130Cas, resulting in recruitment of the tyrosine kinase Lyn to the Robo1-Nck-p130Cas complex. Interestingly, this member of the Src family of tyrosine kinases is implicated in the regulation of erythropoiesis. **Conclusions.** Together, our data indicate that Slit3 promotes expansion of the erythroid progenitor compartment which results in an increased output of erythroid cells. Downstream of Slit3 this may involve activation of the Lyn kinase.

0112

CENTRAL MEMORY CD8 T CELLS REGULATE HEMATOPOIETIC STEM CELL FUNCTION

C Brandao[1], A de Bruin[2], M Nolte[1]
[1]Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands
[2]Academic Medical Center, Amsterdam, Netherlands

After immune activation, effector T cells, including virus-specific CD8 T cells, are known to migrate to the bone marrow (BM); however their function at this site is unknown. Since depletion of T cells from allogenic BM grafts compromisesHSCengraftment, we hypothesize that T cells can directly influence the balance between differentiation and self renewal of hematopoietic stem cells (HSCs). To test the ability of T cells to affect hematopoiesis, we performed liquid co-cultures of HSCs and T cells isolated from mouse BM. Here we show that T cells localized in the BM are able to enhanceHSCdifferentiation as well as their self-renewal capacity. This feature is specific for BM central memory (CM) CD8 T cells, since other T cell subsets are not able to affect HSCs to the same extent. Moreover, depletion of CM CD8 T cells from the total BM T cell pool abrogates the impact onHSCdifferentiation and self-renewal. In vitro studies showed that BM CM CD8 T cells do not affect quiescence ofHSCs, but do enhance their proliferative capacity. We also show that supernatant from CM CD8 T cells is sufficient to increaseHSCsnumbers *in vitro*. Interestingly, competitive transplantation assays showed thatHSCscultured with CM CD8 T cells-derived supernatant contribute much better to leukocyte formation than medium-treated HSCs. This effect is seen in both the myeloid and lymphoid compartment, indicating that CM CD8 T cells are able to release soluble factors that support and enhance the multilineage reconstitution capacity of HSCs. Functional studies with blocking antibodies or knock-out mice showed that the supernatant-mediated effect is not caused by the hematopoietic cytokines IL3, IL6, IL21, GM-CSF, TNF-a or IFNg. Preliminary data indicate that this feedback mechanism of the immune system on the hematopoietic process in the bone marrow is also present in the human situation, since autologous BM T cells increase the numbers of human HSCs, as well as their differentiation capacity.Overall, these findings demonstrate that T cells have an important function in the BM and that CM CD8 T cells can directly influenceHSChomeostasis. We postulate that virus-specific CD8 T cells migrate to the BM after infection in order to enhance the function of HSCs in their ability to replenish theHSC/progenitor cell compartment and restore blood cell numbers.

G PROTEIN-COUPLED RECEPTOR CROSSTALK IN HEMATOPOIETIC STEM AND PROGENITOR CELLS: ROLE OF HOMOLOGOUS AND HETEROLOGOUS DESENSITIZATION

R Möhle, A Drost, U Krauβ, L Kanz
University of Tübingen, Tübingen, Germany

Background. Hematopoietic stem and progenitor cells (HPC) express a variety of G protein-coupled receptors (GPCR), which all could play important roles in HPC trafficking. In other cell types, a complex network of crosstalk between different GPCR has been described. In HPC however, mechanisms regulating differential expression and function of GPCR are largely unknown. **Aims.** We analyzed crosstalk of CXCR4 and CysLT1, the two GPCR with the strongest cellular responses, in mobilized CD34+ HPC, using calcium signaling and actin polymerization as a functional read-out, and characterized the underlying signal transduction pathways. **Methods.** Human mobilized CD34+ HPC were isolated from the peripheral blood. Calcium fluxes and actin polymerization in response to receptor activation were measured using a fluorescent calcium indicator and phalloidin-FITC. Phosphorylation of kinases involved in signal transduction was assessed by Western blot. **Results.** Activation of CXCR4 as well as CysLT1 resulted in homologous desensitization as measured by absence of calcium fluxes and actin polymerization after repeated stimulation. Regarding calcium fluxes, heterologous cross-desensitization of CXCR4 by preceeding activation of CysLT1 and vice versa of CysLT1 by activation of CXCR4 was not observed. In contrast, heterologous desensitization of CysLT1-mediated actin polymerization was induced by preceeding activation of CXCR4, but not vice versa. This observation correlated with the inhibitory effect of protein kinase C (PKC) blocking with BisI and PKCzeta pseudosubstrate, which was observed analyzing actin polymerization in response only to CXCR4, but not to CysLT1 activation. Calcium fluxes mediated by either CXCR4 or CysLT1 could not be blocked with BisI and PKCzeta pseudosubstrate. Interestingly, Pyk2 phosphorylation was abrogated by pertussis toxin (Gi protein inhibitor) only after activation of CXCR4, but not CysLT1, revealing also a differential involvement of G proteins. **Conclusions.** In CD34+ HPC, homologous desensitization, which is required for rapid termination of receptor activation, occurs after activation of CXCR4 and CysLT1, and is due to receptor internalization, as both calcium fluxes and actin polymerization are inhibited. Heterologous desensitization of CysLT1 after preceeding activation of CXCR4 is restricted to actin polymerization and mediated by PKC signaling rather than receptor internalization. As signaling of CXCR4 is not influenced by preceeding CysLT1 activation, and actin polymerization represents a prerequisite for cell migration, a hierarchy exists in the control of HPC migration by different GPCR, with a dominant role for CXCR4. These findings confirm the particular importance of CXCR4 in the regulation of stem cell trafficking.

0114

IRRADIATION INDUCED GROWTH FACTOR FOR HEMATOPOIETIC MICROENVIRONMENT

A Bigildeev, I Shipounova, N Drize
Hematological Scientific Centre, Moscow, Russian Federation

Background. Mesenchymal stem cells (MSCs) are capable to transfer hematopoietic microenvironment. After implantation of femur bone marrow plug under the renal capsule of syngeneic recipients the ectopic hematopoietic foci are formed. Stromal cells in such foci are derived from donor MSCs while hematopoietic cells have the recipient's origin. The size of the foci formed (estimated by nucleated cell number) is proportional to the femur equivalent transplanted. It is known that the foci are enlarged 2-3 times in (sub)lethally irradiated recipients. It was shown that soluble factor that stimulates the growth of stromal microenvironment of the foci is produced in and secreted into the blood serum by irradiated bones.The aim of the study was to determine the nature of this stromal growth factor. **Methods.** The expression level of 75 genes associated with MSCs was analyzed in murine normal and irradiated bones by RQ-PCR. The expression levels of only 2 genes coding soluble secreted factors-IL-1beta and VEGF were elevated in irradiated bones (134 and 4 times, respectively). To verify the ability of IL-1beta to increase the size of ectopic foci it was administered to syngeneic (C57Bl x CBA) F1 recipients of bone marrow plugs implanted under their renal capsules. IL-1beta have been injected in transplanted mice intraperitoneally and subcutaneously in doses 25, 100, 200 and 400 pg per mouse once a day for the first 3 weeks after implantation of the bone marrow plug. Dose was guided by the concentration of IL-1beta measured by ELISA in the serum of irradiated mice. The size of each focus was determined 6 weeks after implantation by nucleated cells count and by weighting the bone shells.Results. The size of ectopic hematopoietic foci in control group was 6.5 $\pm 0.5 \cdot 10^6$ cells while it was larger in every injected groups - 7.2±0.8, 10.8± 0.5,

10.6, and 7.7±1.2·10^6 of nucleated cells for 25, 100, 200 and 400 pg of IL-1beta, respectively. Thus the effect was dose-dependent with the optimal dose of IL-1beta for stimulating hematopoietic microenvironment being 100 pg. The weight of bone shells was 2.8±0.1 mg for control group, 3.7±0.1, 4.8±0.1, 3.5 and 2.3 ±0.3 mg for each experimental group, respectively. These results demonstrate that injections of 100 pg of IL-1beta lead to the formation of larger foci of hematopoiesis with both higher number of nucleated cells and larger bone shells. **Conclusions.** Here we demonstrate, for the first time, the ability of IL-1beta to stimulate the development of hematopoietic microenvironment *in vivo*. IL-1beta could be not the single protein to induce the growth of stromal precursor cells. Another potential stromal growth factor *in vivo* could be VEGF, moreover IL-1beta might stimulate the production of some other factors capable of promoting the growth of hematopoietic microenvironment. The investigation of the mechanisms of IL-1beta action may help in determining the hierarchy of MSCs. Such novel stromal growth factor may be useful for treatment of several diseases affecting either hematopoietic microenvironment or bone defects.

EXPRESSION OF PSTAT5 IN CD34+/CD38- STEM CELLS IN JAK2 V617F+ MYELOPROLIFERATIVE NEOPLASMS (MPN)

E Hadzijusufovic[1], F Schur[2], S Cerny-Reiterer[1], E Pecnard[3], F Gouilleux[3], P Valent[1]
[1]Ludwig Boltzmann Cluster Oncology, Vienna, Austria
[2]Medical University of Vienna, Vienna, Austria
[3]UMR7292 Génétique, immunothérapie, chimie et cancer, Tours, France

Signal transducer and activator of transcription 5 (STAT5) has recently been implicated as a major regulator of growth and survival of neoplastic cells in various myeloid malignancies. In essential thrombocytosis (ET), polycythemia vera (PV) and primary myelofibrosis (PMF), the JAK2 V617F mutant is often detectable, and is considered to lead to activation of STAT5 in the cytoplasm of neoplastic cells. We examined the expression and function of STAT5 in primary neoplastic cells obtained from patients with ET, PV, and PMF, and in the JAK2 V617F+ erythroid leukemia cell line HEL. As assessed by immunocytochemistry, primary neoplastic JAK2 V617F+ cells and HEL cells expressed phosphorylated (p) STAT5 in their cytoplasm as well as in their nuclei. Western blot analysis confirmed that both the cytoplasmic as well as the nuclear extracts of HEL contain pSTAT5. We next examined pSTAT5 expression in CD34+/CD38- stem cells in 9 patients with JAK2 V617F+ myeloproliferative neoplasms (MPN) by flow cytometry. In all patients tested, the CD34+/CD38- stem cells were found to express pSTAT5, whereas CD34+/CD38- stem cells in the normal/reactive bone marrow did not express pSTAT5. In a next step, we applied the STAT5-targeting drugs piceatannol and pimozide. As assessed by ^{3}H-thymidine uptake, both drugs were found to inhibit the proliferation of HEL cells and of primary neoplastic cells in a dose-dependent manner. Both drugs were also found to induce apoptosis in HEL cells as determined by active caspase 3 staining. In summary, our data show that neoplastic cells in JAK2 V617F+ neoplasms express pSTAT5 in their cytoplasm and in their nuclei, and that targeting of STAT5 may be a novel interesting approach to control the expansion of neoplastic cells in MPN. Since pSTAT5 is also expressed in stem cell-enriched (CD34+/CD38-) fractions of neoplastic cells, STAT5 may serve as a promising new target in JAK2-mutated MPN.

Granulocytes

CONGENITAL AND CYCLIC NEUTROPENIA WITH ELANE MUTATIONS: GENOTYPE-PHAENOTYPE CORRELATION

C Zeidler
Severe Chronic Neutropenia International Registry (SCNIR), Hannover, Germany

Background. Mutations in the neutrophil elastase gene (*ELANE*) can be detected in more than 80% of cyclic neutropenia patients (CyN) and in the majority of patients suffering from autosomal dominant or sporadic congenital neutropenia (CN). **Aims and Methods.** Based on the data of the European Branch of the Severe Chronic Neutropenia Registry (SCNIR), we analysed genotype-phenotype correlation in ELANE-CN and ELANE-CyN - in particular with regard to the course of blood counts, bone marrow results, infections, response to therapy, risk of leukaemia and long term prognosis. **Results.** To-date, the SCNIR has collected data on 332 CN and 69 CyN patients from 23 European countries. Molecular genetic testing was performed in 125 of 332 and 32 of 69 CyN patients. In 83 out of 125 tested CN patients and in 26 out of 32 tested patients *ELANE* mutations were found. *ELANE* mutations are spread over all parts of the gene in both, CN and CyN, subtypes. So far, a number of mutations are present in CN or CyN only, but there are also shared mutations for both clinical subtypes. Therefore, the identified *ELANE* mutation does not allow discrimination between CN and CyN. Diagnosis is still depending on the clinical course of neutrophils. Differences between ELANE-CN and ELANE-CyN can be found in response to G-CSF treatment, bone marrow morphology, type of infections as well as risk of leukemic transformation. To-date, approximately 11% of the CN and none of the CyN patients developed leukaemia. In general, patients requiring higher doses of G-CSF are at greater risk.Intriguingly, in two patients in addition to *ELANE* we detected homozygous mutations in *G6PC3* and *HAX1*, respectively (digenic mutations).Due to the good treatment response to G-CSF, life expectancy is now prolonged: 41 of the 83 ELANE-CN and 15 out of the 26 ELANE-CyN patients have reached adulthood so far. A first survey on parenthood revealed that nine ELANE-CN (5 men, 4 women) and four ELANE CyN (2 men, 2 women) patients have children. Thirteen out of these 21 children suffer from neutropenia too (10/13 of ELANE-CN parents and 3/8 of ELANE-CyN parents). **Conclusions**. Based on the detected *ELANE* mutation it is not possible to assign to ELANE-CN or ELANE-CyN or determine the patient's risk for leukemic transformation.

0117

ACETYLATION OF MYELOID-SPECIFIC TRANSCRIPTION FACTOR C/EBP ALPHA

I Kuznetsova, K Welte, J Skokowa
Hannover Medical School, Hannover, Germany

Previously, we described new mechanism of G-CSF-triggered granulocytic differentiation via activation of the enzyme Nicotinamide Phosphorybosyltransferase (Nampt) leading to NAD$^+$ production and activation of NAD$^+$-dependent protein deacetylases SIRT1 and SIRT2.In order to investigate the mechanism of Nampt-triggered myeloid differentiation, we investigated whether myeloid-specific transcription factor C/EBPα could be acetylated. We found that SIRT1 and SIRT2 bind to and activate C/EBPα. We found that C/EBPa is acetylated on Lys 161 and generated rabbit polyclonal antibody specifically recognised acetyl-Lys 161 C/EBPa. We further analysed intracellular localization of acetylated C/EBPa and found that in acute myeloid leukemia cell lines NB4 and HL60 as well as in primary hematopoietic CD34$^+$ cells acetylated C/EBPa was localized in the nucleus. G-CSF treatment of CD34$^+$ cells or ATRA treatment of NB4 cells resulted in the deacetylation of C/EBPa. To evaluate the involvement of Nampt in the deacetylation of C/EBPa we treated NB4 and HL60 cells with the specific inhibitor of Nampt, FK866 and found dramatically elevated levels of acetylated C/EBPa after inhibition of Nampt. Similarly, inhibition of SIRT2 using specific inhibitor AC93253 also resulted in elevated levels of acetylated C/EBPa. Moreover, Nampt and SIRT1 significantly enhanced C/EBPa-triggered activation of reporter gene constructs of C/EBPa target genes G-CSF and G-CSFR, and by this induced granulocytic differentiation. Taken together, Nampt/SIRT dependent deacetylation of C/EBPa is involved in granulopoiesis.

SECRETORY LEUKOCYTE PROTEASE INHIBITOR (SLPI) PLAYS AN IMPORTANT ROLE IN MYELOID DIFFERENTIATION

O Klimenkova, W Ellerbeck, A Gigina, J Skokowa, K Welte
Hannover Medical School, Hannover, Germany

Secretory Leukocyte Protease Inhibitor (SLPI) is a cationic serine protease inhibitor with antiprotease, primarily anti-Neutrophil Elastase (NE), activities. Moreover, SLPI modulates intracellular signal transduction pathways such as NF-kB and Erk. The molecular interaction and the balance between NE and SLPI is tightly regulated. On the one side, NE upregulates the SLPI expression and at the other hand SLPI inhibits the NE-induced degradation of proteins.In severe congenital neutropenia (CN) patients with ELA2 mutations, mutated NE protein may activate unfolded protein response (UPR) and by this induce apoptosis and diminished differentiation of hematopoietic cells. In the present study we aimed to measure the amount of NE inhibitor, SLPI in myeloid cells and in plasma of CN patients.We identified severe diminished levels of SLPI mRNA in $CD33^+$ myeloid cells and in PMNs of CN patients, as compared to patients with cyclic neutropenia (CyN) and to healthy individuals. SLPI protein levels in plasma of CN patients were also significantly reduced. We further analysed whether diminished levels of SLPI are associated with the "maturation arrest" of myeloid cells seen in CN patients. We inhibited SLPI in the myeloid cell line NB4 and in hematopoietic $CD34^+$ cells using lentivirus-based transduction with SLPI-specific shRNA and analysed ATRA- or G-CSF-triggered myeloid differentiation, respectively. Indeed, myeloid differentiation was diminished in NB4 cells and in $CD34^+$ cells transduced with SLPI-specific shRNA, as compared to control shRNA transduced cells, which was accompanied by G_0/G_1 cell cycle arrest of SLPI shRNA transduced cells.We next analysed the mechanisms of diminished myeloid differentiation after inhibition of SLPI. SLPI is known to be involved in phosphorylation of Erk1/2 protein. Erk1/2 protein is involved in myeloid differentiation. We found that ATRA treatment of NB4 cells transduced with ctrl shRNA resulted in phosphorylation of Erk1/2 with a maximum on day 2 of treatment. Interestingly, we measured reduced Erk1/2 phosphorylation in ATRA-treated NB4 cells transduced with SLPI shRNA. Moreover, it has been shown that Erk1/2 phosphorylates LEF-1 transcription factor, essential for granulocytic differentiation and we found diminished levels of phosphorylated LEF-1 in SLPI shRNA transduced cells. Previously, we demonstrated severe diminished LEF-1 expression levels in myeloid cells of CN patients. Therefore, we concluded that SLPI is involved in myeloid differentiation by regulation of Erk1/2 dependent LEF-1 expression.

A ROLE OF GADD45B PROTEIN IN MYELOID DIFFERENTIATION AND STRESS RESPONSE OF HUMAN HEMATOPOIETIC CELLS

G Karachunskiy, A Gigina, K Welte, J Skokowa
Hannover Medical School, Hannover, Germany

Growth arrest and DNA-damage-inducible, beta (GADD45b) protein modulates stress responses in mouse myeloid cells. Recently, we demonstrated, that in patients with severe congenital neutropenia (CN) daily treatment with high doses of G-CSF stimulated C/EBPß-dependent emergency stress-induced granulopoiesis.Based on these findings, we assumed that GADD45b could play a role in the induction of granulopoiesis in CN patients. We assessed GADD45b expression levels in "arrested"promyelocytes of CN patients and surprisingly found severe downregulation of GADD45b expression in CN promyelocytes, in comparison to cyclic neutropenia patients and to G-CSF-treated healthy individuals. Expression of GADD45b target genes (e.g. cyclin B1, p27, CDK6, CDK4, bcl-xl) was also significantly reduced. We further evaluated a possible involvement of GADD45b in myeloid differentiation and stress response of human myeloid cells. GADD45b protein is known to be activated and to migrate into the nucleus after induction of DNA damage (e.g. ultraviolet (UV) irradiation). We found that UV irradiation of the NB4 but not THP1 acute myeloid leukemia cell line induces nuclear GADD45b. Therefore, we further analysed functions of GADD45b in myeloid differentiation and DNA damage in NB4 cells. We found that GADD45b was activated and migrated into the nucleus upon treatment of NB4 cells with ATRA. Inhibition of GADD45b in these cells led to dramatically reduced ATRA-triggered myeloid differentiation, which was in line with diminished expression of myeloid-specific transcription factor C/EBPß, which triggers "stress-induced" myeloid differentiation, but also of C/EBPa, responsible for "steady-state" granulopoiesis. Moreover, transduction of NB4 cells with GADD45b shRNA resulted in significantly enhanced sensitivity to UV irradiation, as documented by elevated apoptosis and reduced proliferation. This was in line with diminished mRNA expression of anti-apoptotic genes bcl-2, mcl-1, survivin as well as elevated mRNA expression of pro-apoptotic gene bad in GADD45b shRNA transduced cells, as compared to ctrl shRNA transduced cells. p21 mRNA expression was also significantly downregulated after inhibition of GADD45b mRNA.Taken together, GADD45b plays an important role in myeloid differentiation and stress response of acute myeloid leukemia cell line NB4. Studies of the effects of GADD45b in myeloid differentiation of primary hematopoietic cells in healthy individuals and in CN patients are ongoing.

NAMPT-DEPENDENT DEACETYLATION OF THE HEMATOPOIETIC-SPECIFIC LYN-SUBSTRATE 1 (HCLS1)

B Samareh Abolhasani, A Klaus, K Welte, J Skokowa
Hannover Medical School (MHH), Hannover, Germany

Recently, we demonstrated an essential role of the hematopoietic cell-specific Lyn substrate 1 (HCLS1 or HS1) protein in myeloid differentiation of human and mouse hematopoietic cells. HCLS1 is an interaction partner of HAX1, which is mutated in patients with severe congenital neutropenia (CN). In these patients HCLS1 expression and functions are severely downregulated, leading to "maturation arrest"of myelopoiesis. We also described the new pathway of myeloid differentiation downstream of G-CSF in healthy individuals and in CN patients: G-CSF induced Nampt and NAD^+, which activated NAD^+-dependent protein deacetylases, sirtuins. A huge amount of proteins are post-translationally modified by acetylation or deacetylation. However, it is unclear whether changes in the acetylation status activates or suppresses functions of proteins.In the present study we analyzed if HCLS1 protein could be de-/acetylated and if de-/acetylation of HCLS1 affects its functions during myeloid differentiation. We found that HCLS1 is acetylated on three lysines in the acute myeloid leukemia cell lines NB4 and HL60 as well as in $CD34^+$ hematopoietic cells. We also found that SIRT1 and SIRT2 interacted with HCLS1 protein in NB4 cells. Moreover, specific inhibition of Nampt (FK866) in NB4 cells led to enhanced acetylation of HCLS1 on Lys 123 and 241. Inhibition of SIRT2 (AC93253) resulted in elevated HCLS1 acetylation on Lys 123 and 192. Moreover, treatment of $CD34^+$ cells with G-CSF induced interaction between SIRT2 and HCLS. Effects of Nampt/SIRT-triggered deacetylation on HCLS1 functions remain to be investigated.

[6]Istituto Toscano Tumori, Firenze, Italy

Background. The force that drives the transformation of a normal cell into a neoplastic cell is the accumulation of a discrete set of somatic mutations. The occurrence of mutations is an inherent risk associated with DNA replication and cell division. Estimates of the human somatic mutation rate (μ) have been previously obtained from studies on dermal fibroblasts and on lymphoblastoid cells: however, the methodology required has been laborious and did not lend itself to the analysis of large numbers of samples. We have previously shown that the X-linked gene *PIG-A*, since its protein product is required for numerous glycosyl-phosphatidylinositol-anchored proteins to become surface bound, is a good sentinel gene for studying the frequency of spontaneous somatic mutations. **Aims.** To establish that a parameter related to μ, namely the frequency *f* of mutant cells, can be reliably and reproducibly measured on peripheral blood samples by flow cytometry analysis of granulocytes. **Methods.** 5 millions granulocytes, separated by a double density gradient, were stained with a mixture of 3 PE-moAbs that recognize 3 different GPI-linked proteins (CD59, CD55, CD24), plus one pan-leukocyte marker (anti CD45-APC) and one granulocyte marker (anti-CD11b-FITC). Granulocytes that are deficient in GPI-anchored proteins because of a *PIG-A* gene mutation are counted by FACS analysis. Mutant frequency, *f*, was calculated as the number of GPI-negative events per million cells. **Results.** We found that two independent measurement of *f* on the same sample (split samples) were very similar, with a coefficient of variation (CV) of 44.7%. From 32 volunteers we have collected 3 repeat samples with time intervals from 2 to 14 weeks (repeat samples): the CV of *f* in these repeat samples was 44.3%. Finally, we have studied *f* as a biological variate in 142 normal subjects. We have found that in this normal human popula-

tion Log *f* has a normal distribution. The variability of *f* spans a 80-fold range, from less than 1 to 37.5x10^{-6}, with a median value of 4.9x10^{-6}, and with 80% of values below 10.2x10^{-6}. **Conclusions.** We have shown that we can accurately measure, from a small sample of peripheral blood, the proportion of *PIG-A* mutant granulocytes (*f*). Since split samples and repeat samples have an almost identical CV (44.7 vs. 44.3%), we can infer that *f* is a relatively stable individual characteristic. The normal distribution of Log *f* is reminiscent of that of fundamental quantitative traits, such as height and many others. The methodology we describe will lend itself to investigating genetic factors that underlie the variation in the somatic mutation rate, as well as environmental factors that may affect it, including chemotherapy. It will be also possible to test whether *f* correlates with the risk of cancer.

[7]Teva Pharmaceuticals, Inc., Netanya, Israel

Background. Patients receiving cancer chemotherapy are at an increased risk of neutropenia. Recombinant granulocyte colony stimulating factors (G-CSFs) have been developed to stimulate proliferation and differentiation of neutrophils. Pegfilgrastim is a pegylated recombinant G-CSF that allows for once-per-cycle dosing. Balugrastim is a long-acting G-CSF composed of a genetic fusion between recombinant human serum albumin and G-CSF. **Aims.** The objective of this study was to compare the efficacy and safety of balugrastim and pegfilgrastim in patients with histologically or cytologically confirmed breast cancer who were scheduled to receive doxorubicin and docetaxel. **Methods.** In this double-blind, randomized, active-comparator, noninferiority trial, patients with ≥1.5x10^9 neutrophils/L, and ≥100x10^9 platelets/L were randomly assigned to subcutaneous injections of balugrastim 40 mg (n=153) or pegfilgrastim 6 mg (n=151) with stratifications for weight, prior chemotherapy exposure, and global location. The primary efficacy endpoint was the duration of severe neutropenia (days with an absolute neutrophil count <0.5x10^9 cells/L) during cycle 1 for the population of patients who did not have major protocol violations. **Results.** Mean duration of severe neutropenia in cycle 1 was 1.1 days in the balugrastim group and 1.0 days in the pegfilgrastim group (95% CI for difference between groups -0.13 to 0.37). Fifty-eight percent of patients in the balugrastim group and 59% in the pegfilgrastim group had severe neutropenia during cycle 1 (95% CI for difference between groups -11.98% to 10.41%). Two and 4 patients, respectively, had febrile neutropenia during cycle 1; no patients in either group had febrile neutropenia during cycles 2-4. Twenty percent of patients in the balugrastim group and 19% in the pegfilgrastim group had adverse events that the investigator considered to be related to study medication. Six and 7 patients, respectively, had serious adverse events. **Conclusions.** The results of this study support the noninferiority of balugrastim versus pegfilgrastim, demonstrating that both compounds have comparable efficacy. There were no unexpected safety events.

[3]Georgios Gennimatas General Hospital, Athens, Greece
[4]Polykliniki General Hospital, Athens, Greece
[5]University of Athens School of Medicine, Athens, Greece

Background. Gaucher disease (GD) is a lysosomal storage disease characterized by a genetic disruption in the metabolic breakdown of glucocerebroside caused by the lack of the enzyme beta-glucocerebrosidase. Bone complications are common in the non-neuronopathic form of GD and lead to considerable pain, limitations in mobility and negative impact on the quality of life. Skeletal manifestations include bone marrow infiltration, bone loss, lytic lesions and osteonecrosis. Magnetic resonance imaging (MRI) is the most sensitive procedure for assessing skeletal involvement in patients with GD and semi quantitative MRI is a very useful procedure for evaluating the bone marrow burden. **Aims.** The aim of this study was to develop a semi quantitative scoring system, based on MRI, to evaluate the bone marrow involvement in non-neuronopathic GD. **Methods.** We studied 27 adult patients (15M/12F, median age 44.5 years, range: 18-71 years) with the non-neuronopathic type of GD. MRI of the femoral bones was performed in all patients. We implemented T1-weighted spin echo (T1W) sequences, proton density sequences with fat suppression (PDFS) to further evaluate the detected changes on T1W sequence and short time inversion recovery (STIR) sequences for the evaluation of disease activity. We also performed a thorough comparison of T1W and PDFS images targeting in the detection of the remodeling process of the affected bone. In all patients we performed evaluation of bone infiltration on T1W images in affected areas as opposed with those of healthy regions and in conjunction with measurements taken from subcutaneous fat of both thighs of the same patients. We also studied 27 healthy individuals who had MRI scans for various other reasons, i.e. undiagnosed femur pain to exclude arthritis. **Results.** The MRI findings were independently evaluated by two experienced MR imaging specialists. The normal rate of subcutaneous fat of both healthy and affected individuals was fluctuated from 210-400 pixels and those of bony fat tissue from 120-180 pixels. On the contrary the affected values were found to vary from 15-80 pixels. In order to reduce the possibility of false positive and false negative values we combined all the region of interest (ROI) measurements with the degree of infiltration detected on T1W images. At the end we combined the above MRI findings and introduced the following classification: stage I: ROI 1/2 of normal values and bone infiltration up to 30%; stage II: ROI 1/3 of normal values and bone infiltration from 30 to 60%; stage III: ROI 1/4 of normal values and bone infiltration from 60% to 80% and stage IV: detection of epiphyseal infiltration, osteonecrosis and deformity regardless of the ROI'S values. All but one patient had abnormal MRI findings: 3 (11%) had stage I MRI abnormalities, 18 (66%) had stage II, 3 (11%) stage III and 2 (7%) stage IV. **Summary and Conclusions.** Our study suggests that the above semi quantitative MRI method is relatively easy to be performed compared to all other available methods for the non-neuronopathic GD. Furthermore, this sensitive MR technique would be useful for the evaluation of bone marrow involvement in this GD type.

Chronic lymphocytic leukemia - Biology 1

0124

MONOCYTIC POPULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA SHOWS ALTERED COMPOSITION AND PROANGIOGENIC, IMMUNOSUPPRESSIVE AND INVASIVE PROPERTIES

R Maffei[1], J Bulgarelli[1], S Fiorcari[1], L Bertoncelli[1], S Martinelli[1], C Guarnotta[2], I Castelli[1], S Deaglio[3], G Debbia[1], S De Biasi[1], G Bonacorsi[1], P Zucchini[1], F Narni[1], M Luppi[1], C Tripodo[2], A Cossarizza[1], R Marasca[1]

[2]University of Palermo, Palermo, Italy
[3]University of Turin and Human Genetics Foundation, Turin, Italy

Background. Macrophages are highly versatile cells and are prominent in the stromal compartment of virtually all types of malignancies. When migrating into tumor sites, they are exposed to stimuli of tumor cells that "educate"them to acquire a distinct phenotype of immunosuppression, angiogenesis and invasiveness. Macrophages reside in tissues infiltrated by chronic lymphocytic leukemia (CLL) B-cells and the extent of infiltration is associated with adverse prognostic factors. Moreover, nurse-like cells (NLCs), that differentiate from CD14+ monocytes into large/adherent cells, protect CLL from undergoing spontaneous or drug-induced apoptosis. **Aims.** We investigated whether CLL cells may influence the phenotype of monocytic population to promote a protective, pro-angiogenic and invasive profile. **Methods.** We first characterized the monocyte population in peripheral blood (PB) of 26 CLL and 13 healthy donors by flow cytometry. Furthermore, we evaluated monocyte migration by using Transwell assays and up-regulation of interleukin-10 (IL10), IL8 and MMP9 by qPCR and ELISA assays. Finally, we compared the gene expression profiles between monocytes collected from PB of 5 CLL patients and 5 healthy donors by using whole-genome microarrays. **Results.** Significant increase in nonclassical CD4+CD16++ monocytic subpopulation was detected in CLL compared to normal controls (10.4%±1.1% vs. 7.0%±1.1%) (p=0.04). Moreover, CLL patients with high risk genomic abnormalities were characterized by increased nonclassical monocytes (13.6% ± 2.5% vs. 8.5% ± 1.0%) and decreased classical monocytes (74.7% ± 3.1% vs. 68.3% ± 2.8%) compared to low risk FISH CLL (p=0.038). In addition, CLL patients displayed increased number of circulating monocytes expressing Tie2 receptor (TEMs) compared to normal controls (84.5 vs. 39.9/µl respectively, p=0.02). TEMs in CLL patients with adverse genomic aberrations were increased in comparison to low risk FISH CLL (157.9 ± 50.2/µl vs. 57.1 ± 17.9/µl) (p=0.04). We also confirmed that TEMs were present in CLL-infiltrated lymph nodal compartment by immunohistochemical staining.We identified 65 genes significantly up-regulated and 48 genes down-regulated in CLL monocytes compared with monocytes from normal controls (FC=2, p<0.05). The most up-regulated gene in CLL-derived monocytes is the GTPase-activating protein RAP1GAP (FC=6.5), able to inactivate RAP1 protein involved in phagocytosis. Conversely, we found a 12- and 3-fold down-regulation of tubulins TUBB3 and TUBB2 as well as a 2-fold decrement of CDC42EP3, a Rho GTPase effector protein involved in actin assembly at nascent phagosomes. In addition, we detected a 3.8-fold down-regulation of the chemokine ligand 5 (CCL5) involved in M1 polarization and a 3.2-fold down-regulation of prostaglandin reductase 2 (PTGR2), which catalyzes the reaction for inactivating the immunosuppressive prostaglandin E2 (PGE2).Ultimately, we found that CLL cells were able to attract monocytes and to induce the up-regulation of IL10, a Th2-derived cytokine able to inhibit inflammatory response, IL8, a pro-angiogenic chemokine, and MMP-9, a proteolytic proenzyme involved in degradation of extracellular matrix.**Conclusions.** These alterations further contribute to characterize the complexity of factors potentially involved in acquired immune deficiency of CLL patients. Overall, our findings indicate that the CLL-mediated "education"of immune elements may also include the establishment of a dysfunctional, immunosuppressive, pro-angiogenic and invasive phenotype in monocytes/macrophages.

[6]Dept.of Hematology, Catholic University Hospital A. Gemelli, Rome, Italy

Background. Chronic lymphocytic leukemia (CLL) cells from clinically aggressive cases (i.e. expressing unmutated, UM, IGHV) have a greater capacity to respond to external microenvironmental stimuli, including those transduced through Toll-like Receptor 9 (TLR9). In CLL, several studies has identified certain microRNAs as either implicated in disease pathogenesis, or as part of a microRNA signature predicting clinical outcome or drug resistance. However, little is known regarding the capacity of external stimuli to modulate the expression of specific microRNAs and/or microRNA families. **Aims.** To investigate the modulation of microRNAs upon TLR9 triggering in CLL. **Methods.** Freshly-isolated negatively-selected CLL cells from 16 CLL patients (8 with UM and 8 with mutated, M, IGHV) were stimulated with CpG (18 hours), or left unstimulated or stimulated with anti-IgM as further control. miRNA and Gene Expression Profiling (GEP) were performed and validated by qRT-PCRs and transfection of miR/antagomiR in primary negatively purified CLL cells. **Results.** Concomitant microRNA and GEP in CLL cells expressing either UM or M IGHV genes, selected microRNAs from the *miR-17~92* family as significantly upregulated and responsible for modifications in the gene expression profile in CpG-stimulated UM-CLL, but not in M-CLL cells. In addition, the *miR-17* gene regulator *MYC* and the MYC target genes *CAD*, *PGK1* and *TFAM* were also upregulated in CpG-stimulated UM-CLL cells. Notably, neither the *MYC*/*miR-17~92* pair nor the MYC target genes were upregulated in UM/M CLL upon BCR triggering. Time-course experiments using primary UM-CLL cells showed that *MYC* and *miR-17* were upregulated by CpG stimulation following different kinetics: a rapid and transient induction for *MYC*, and a slow and sustained up-regulation for *miR-17*. These findings, indicate an associative interactions between *MYC* and *miR-17~92* in CLL, as described in other cell systems. Negatively purified UM-CLL cells transfected with pri-miR-17 showed a significant increase in *miR-17* expression levels compared to scrambled control (*P=0.003*), along with the down-regulation of *miR-17* target genes. By evaluating these cells for apoptosis and viability in serum-deprived cultures, *miR-17*-transfected UM-CLL cells showed a higher percentage of viable cells, already evident at 24 hours (*P=0.021*) and peaking at 48 hours (*P=0.010*) of culture. In complementary experiments, purified UM-CLL cells were transfected with a mixture of antagomiRs against *miR-17*, *miR-18a*, *miR-20a* and *miR-20b* or scrambled sequences, as negative control. In samples transfected with the negative control, CpG-stimulation increased the levels of *miR-17~92* microRNAs and induced leukemic cell proliferation, as evidenced by BrdU incorporation. The antagomiR mixture inhibited the CpG-induced increase of microRNA levels and concomitantly reduced the percentage of BrdU-positive CLL cells. The *miR-17* expression level, analyzed in a series of 83 CLL, was significantly higher in UM CLL (*P=0.032)*, in ZAP-70+ CLL (*P=0.026*), or UM/ZAP-70+ CLL (*P=0.015*) compared to their relative counterparts. **Conclusions.** These data reveal a role for the axis *MYC*/*miR-17~92* family in regulating pro-survival and growth-promoting responses of UM-CLL cells to TLR9 triggering and indicate that TLR9 and BCR triggering operate through different non-redundant stimulation pathway.

TUMOR DYNAMICS OF CHRONIC LYMPHOCYTIC LEUKEMIA CASES WITH MULTIPLE PRODUCTIVE IGHV-IGHD-IGHJ REARRANGEMENTS

K Plevova[1], H Skuhrova Francova[1], N Darzentas[2], K Burckova[1], K Brazdilova[2], J Kabathova[2], L Jurackova[1], M Doubek[1], Y Brychtova[1], J Mayer[1], B Tichy[2], S Pospisilova[2]
[1]University Hospital Brno, Brno, Czech Republic
[2]Central European Institute of Technology, Brno, Czech Republic

Background. Due to the currently routine testing of IGHV mutational status in chronic lymphocytic leukemia (CLL) patients, evidence of cases with multiple productive immunoglobulin heavy genes rearrangements (MP-IGH) has

emerged. Several mechanisms, such as lack of allelic exclusion at the IG loci, or the presence of two clonal populations have been linked with the MP-IGH phenomenon. However, the true biological and clinical implications are currently unknown. Moreover, over-time clonal drift, a dynamic process of alterations in malignant clones recently observed in other lymphoid malignancies, has not been studied in these cases. **Aims.** Our study aimed to obtain molecular insight into the biological causes of MP-IGH in CLL and to perform a systematic study of the clonal drift in such cases. **Methods.** Separated B-lymphocytes from peripheral blood of 31 patients with MP-IGH were obtained. IGHV-IGHD-IGHJ, IGKV-IGKJ and IGLV-IGLJ rearrangements were analyzed from cDNA following described protocols. In available samples, PCR was repeated using gDNA; partial IGHD-IGHJ gene rearrangements and KDE rearrangements inactivating IGK loci were assessed. Detailed immunophenotypization was also performed. For the molecular monitoring of clonal dynamics, allele-specific oligonucleotide PCR assays (ASO-qPCR) were used. **Results.** Thirty one CLL cases with MP-IGHs were analyzed (two or three IGH rearrangements were detected in 26 and 5 patients, respectively). Firstly, we sought to unravel the possible causes underlying the presence of MP-IGH by performing a detailed immunophenotypic and molecular profiling. By coalescing all such results, we categorized the MP-IGH cases as follows: (i) definite co-existence of two clonal B-cell populations: 9/31 cases, with differing immunophenotypic light chain restriction; (ii) highly likely co-existence of more clonal populations with homogenous phenotype: 16/31 cases, where the number of detected IG rearrangements exceeded genomic capacity of single cell IG loci; (iii) indeterminate as to one or more CLL-like populations: 6/31 cases, in which we failed to obtain conclusive evidence of more than one clone. Furthermore, repeated MP-IGH analysis was performed in 23/31 patients (median interval from first to last analysis 24 months, range 8-74 months) to evaluate over-time changes in proportion of clones. Based on fragment analysis, detected IGH were considered as (i) persistent (stable in subsequent samples), (ii) appearing (originally undetectable), or (iii) diminishing (decreasing proportion in subsequent samples). In 11/23 patients, ASO-qPCR was used to confirm and quantify such changes. Interestingly, we observed clonal drift in MP-IGH cases: appearing of a new clone in three patients; diminishing of a clone in 18 patients. Moreover, analysis of molecular features of detected IGH revealed that selection of IGH tends to favour (i) higher IGHV identity to germ-line and/or (i) longer HCDR3. This tendency was more striking in cases where stereotyped BCR was selected.**Summary**: Our study allowed us to obtain novel insight into the biological causes of MP-IGH in CLL by categorizing patients according to the evidence of more than one B-lymphocyte clones. Importantly, we observed clonal drift favouring specific BCR molecular features, which might eventually provide further insight into disease evolution with implications for patient monitoring and therapy. PHOSPHOPROTEOMIC ANALYSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA AND B-CELL RECEPTOR SIGNALING SUGGESTS NOVEL THERAPEUTIC TARGETS

T Butler, D Taussig, P Cutillas, J Gribben
Barts Cancer Institute, London, United Kingdom

Background. Chronic Lymphocytic Leukemia (CLL) is currently incurable using conventional therapies. CLL is similar to many malignancies in its dependence on microenvironmental survival signals, but almost unique in that CLL appears to utilise antigen as a pro-survival ligand. Studies suggest that antigenic ligation of the B-cell receptor (BCR) plays a fundamental role in disease pathogenesis. Few consistent BCR signaling abnormalities have been noted. **Aims.** We sought to examine BCR signaling abnormalities in CLL by comparing with signaling in healthy B-cells. BCR signaling differences via IgM and IgD isotypes were also sought. We used the high-throughput method of mass-spectrometry (MS) based phosphoproteomics to analyse multiple signaling pathways simultaneously to provide an overview of active signaling pathways without *a priori* knowledge of which pathways to investigate. **Methods.** Apoptosis assays, calcium flux and western blotting were performed after BCR crosslinking using $F(ab')_2$ fragments to IgM or IgD. The BCR of CLL and tonsillar B-cells were stimulated for 5 minutes followed by lysis, peptide digestion, enrichment for phosphopeptides (typically 75%) using TiO_2 beads and analysis using HPLC-MS/MS (Orbitrap). IgD and IgM signaling was compared, and signaling in 6 CLL (3 *IGHV* gene mutated, 3 unmutated) was compared to BCR signaling in 4 control healthy tonsil B-cells.4. **Results.** 4,575 unique phosphopeptides were identified and quantified using a label-free technique based on extracted ion currents. Phosphosite quantifications were compared between CLL and tonsil samples, at baseline and after stimulation. 174 phosphoproteins ($p<0.001$, fold change up to >4000-fold) were overexpressed in CLL relative to healthy B-cells. These included components of RNA processing complexes, cytoskeletal regulators and MAPK signaling pathway components. Kinase prediction based on phosphoprotein substrates confirmed activation of kinases known to be active in CLL (such as AKT1, ERK1/2, casein kinase 2), but several novel kinases (such as CaMK1, CRIK, ROCK1 and BCKDK) were also active in CLL relative to healthy controls.Evaluation of differentially expressed phosphoproteins after BCR ligation suggested a limited number of phosphosites altered by BCR signaling. These included components of the spliceosome, regulators of the cytoskeleton, as well as known BCR signaling components. Kinase prediction suggested high constitutive activity of ERK and LYN kinases, consistent with their known roles in CLL, and BCR-induced kinase activities included CDK family members, MAPKs, BCKDK and others.Finally, incubation of the PI3 kinase inhibitor CAL101 resulted in different drug sensitivities in the 6 leukemia samples, the degree of apoptosis only partly correlated with AKT1 activity (a downstream marker of PI3K activity).5. **Summary and Conclusions.** Mass-spectrometry based phosphoproteomics is beginning to offer powerful methods for interrogating intracellular signaling, with networks of phosphorylation characterising the topology of pathways. BCR signaling in healthy B-cells has not previously been studied using this approach, and comparisons with CLL highlight known pathways as well as suggesting novel treatment targets. The goal is to identify kinases active in CLL that will provide rational and effective drug combinations.

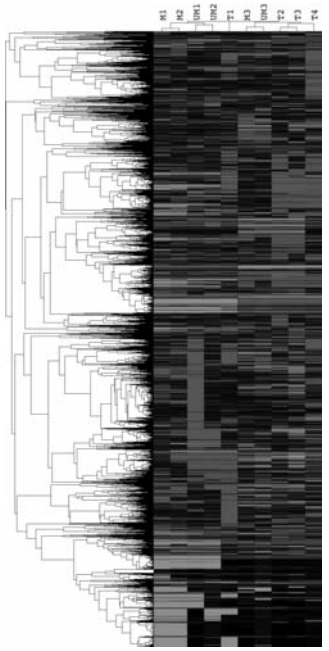

Figure 1. Unsupervised hierarchical clustering of phosphopeptides in unstimulated cells.

[2]University Hospital Brno, Brno, Czech Republic

Background. Abnormalities of *ATM* gene are frequent in chronic lymphocytic leukemia (CLL) patients and represent important predictive and prognostic factor. *ATM* defects are commonly assessed through monitoring of 11q deletion (11q-) using I-FISH. However, there are two aspects which may hamper setting aside affected patients properly: (i) 11q deletion does not mean ATM inactivation if the other allele remains intact (ii) there are patients who harbor *ATM* mutation without accompanying 11q-. Mutation analysis of *ATM* is complicated due to the extreme gene size and lack of preferential (hot-spot) mutations. Nevertheless, knowledge of *ATM* mutation status should significantly improve patient stratification. **Aims.** The aims were to establish an efficient and convenient system to detect *ATM* mutations and assess their frequency in high-risk CLL patients. **Methods.** We used the following complementary methodologies: (a) resequencing microarray (Affymetrix platform), which was designed to detect

1-nt substitutions (i.e. missense mutations, nonsense mutations, and substitutions in splicing sites) (b) western blotting (WB) to disclose patients with null ATM protein (c) functional testing based on induction of *CDKN1A* (p21) and *BBC3* (PUMA) genes after treatment of CLL cells with fludarabine and doxorubicin in parallel; in case of *ATM* mutation, the former drug leads to the gene expression induction, while the latter does not. **Results.** The resequencing on microarray was performed in 107 CLL patients. We detected 16 *ATM* mutations (13 missense, 2 nonsense, and 1 splicing) in 15 patients (14%). In parallel analysis, 11 out of 107 patients (10%) showed null ATM protein on WB; among these patients, there were six with mutation detected on microarray, two patients with three mutations together identified by direct Sanger sequencing only (two short deletions, one missense), and in remaining three patients a suspect mutation is still under investigation by direct sequencing. In total, there were 20 patients (19%) with demonstrable ATM defect (presence of mutation and/or null protein level). Our third test consisting of the ATM functional assessment (see Methods) indicated mutation in 12 patients; in 9 cases the mutation has already been identified. Not all identified mutations in our study, however, resulted into "ATM dysfunctional status". Proportions of patients with ATM defect in subgroups divided according to the presence of high-risk genetic features were following: 6 % (3/49) in patients having *TP53* mutation and/or deletion 17p; 32 % (13/41) in patients with 11q-; 24% (4/17) in patients without any adverse genetic defect. This observation confirms the previous data showing an exclusivity of *ATM* and *TP53* defects (although not strict) and suggests that the frequency of *ATM* mutations may not be dramatically different between the subgroups with or without 11q-. **Summary and Conclusions.** Our data confirms that *ATM* mutations do not automatically overlap with 11q- in CLL patients and are rare in *TP53*-defected subgroup. Several complementary methodologies should preferably be used to effectively assess *ATM* status. The work was supported by grants NS 9858-3, MUNI/A/0784/2011, and CZ.1.07/2.3.00/20.0045.

DIFFERENTIAL REGULATION OF NOTCH ISOFORMS AND INDUCTION OF APOPTOSIS IN CLL CELLS BY GLIOTOXIN

R Hubmann, M Hilgarth, S Schnabl, E Ponath, D Demirtas, M Reiter, C Zielinski, U Jäger, M Shehata
Medical University of Vienna, Vienna, Austria

Background. Members of the NOTCH gene family (NOTCH1-4) encode highly conserved transmembrane receptors that modulate many cellular differentiation processes and are also involved in tumor initiation and progression. We and others have reported that CLL cells express constitutively activated NOTCH2 which is associated with enhanced cell viability. Moreover, gain of function mutations in the NOTCH1 gene were found in a subset of CLL patients suggesting a significant role for NOTCH1 and NOTCH2 in the pathogenesis of CLL and as potential therapeutic targets. However, the clinically relevant class of NOTCH regulators, ie. γ-secretase inhibitors, appears to be only effective in a small proportion of CLL cases *(Hubmann et al; BJH 2010)*. In addition, there is no information on the expression and regulation of the other NOTCH family members in CLL. **Aims.** The aim of this study was to explore the effect of the NOTCH2 transactivation inhibitor gliotoxin (WO 2006/135949) on the viability of CLL cells and how gliotoxin regulates other NOTCH family members. **Methods.** To maintain NOTCH2 activity *in vitro*, CLL cells were cultured in suspension in the presence of PMA (*PMA model*) or under co-culture conditions using primary bone marrow stromal cells (BMSC) *(Microenviroment model; Shehata et al., BLOOD 2010).* The nuclear NOTCH activity was analysed by electrophoretic mobility shift assays (EMSA). FACS analysis was used to quantify the surface expression of the NOTCH2 target gene CD23 and to evaluate apoptosis. RT-PCR experiments were performed to analyse the effect of gliotoxin on the transcription of NOTCH and apoptosis related genes. **Results.** Gliotoxin completely blocked the formation of DNA-bound NOTCH2 complexes in all tested CLL cases (n=21) at nanomolar concentrations after 24 hours of incubation. The inhibition of NOTCH2 signaling by 200 nM gliotoxin was associated with induction of apoptosis (mean: 67±31 SD versus 13±14 SD) and downregulation of *CD23A* transcription and CD23 surface expression (mean: 42±32 SD versus 83±17 SD). Exceptionally, one CLL case with a recently described *NOTCH1* gain of function mutation was found to be less sensitive to gliotoxin. Short term (4 hours) exposure of CLL cells revealed that the induction of apoptosis by gliotoxin is independent of NFκB activity and the expression of the antiapoptotic genes *BCL2* and *MCL1*. Exposure to gliotoxin resulted in downregulation of *NOTCH1*, *NOTCH2* and *NOTCH4* mRNA expression. In contrast, gliotoxin induced the expression of *NOTCH3*, its target gene *HEY1,* and *NR4A1* (activation induced cell death mediator). In addition, giotoxin selectively abolished the supportive effect of BMSC on CLL cells under co-culture conditions. **Summary and Conclusions.** The data show that CLL cells differentially express all NOTCH family members and that gliotoxin is an efficient NOTCH isoform modulator in CLL cells. The induction of *NOTCH3, HEY1* and *NR4A1* expression by gliotoxin reveals the complex role of different NOTCH genes in the regulation of apoptosis in CLL cells. Thus, gliotoxin may have a potential therapeutic value and a beneficial effect in CLL patients which warrants further evaluation.

[7]Department of Laboratory Medicine, Lund University, Lund, Sweden

Background. The advent of global investigations has begun to unravel the functional involvement of DNA methylation in leukemogenesis. Previously, we identified divergent chronic lymphocytic leukemia (CLL) subgroups, IGHV-mutated and unmutated CLL, to have differential methylation patterns effecting key canonical pathway, proliferation and apoptotic genes. Despite these advances, in CLL cells, little to no knowledge exists regarding the extent to which DNA methylation changes with respect to time and exposure to different microenvironments. **Aims.** Our specific aims were, to compare the global DNA methylation profiles of IGHV mutated and IGHV unmutated CLL patients, to asses DNA methylation changes over time and investigate DNA methylation in CLL cells derived from different anatomical compartments. **Methods.** Using high-resolution 450K DNA methylation arrays, the DNA methylation profiles of 9 IGHV-mutated and 9 IGHV-unmutated peripheral blood diagnostic samples were analyzed. A second follow-up sample derived from these same patients collected ~5-8 years later, were additionally analyzed to study DNA methylation over time. Between the first and second sampling time-points, IGHV-unmutated patients were treated, whilst IGHV-mutated patients remained untreated. To study the effect of the microenvironment on CLL cell DNA methylation, 10 patient-matched peripheral blood (PB) and lymph node (LN) samples were also investigated. **Results.** On a larger scale to our previous 27K array study, we revealed 2239 CpG sites as differentially methylated between IGHV-mutated and unmutated CLL patients. Interestingly, the majority of sites were positioned outside CpG islands and promoters. Novel findings include differential DNA methylation of CpG sites within known differentially expressed CLL prognostic genes *CLLU1* and *LPL,* where methylation was notably higher in IGHV-mutated cases. Additionally, genes occupying TGF-ß and NF-κB/TNFR1 pathways and large numbers of polycomb target genes were shown to be differentially methylated. Over time, few large recurrent DNA methylation changes were noted among the subgroups. Although a larger number of non-recurrent differentially methylated sites were identified in IGHV-unmutated relative to IGHV-mutated cases over time, these changes equated to a low (<1%) global change. Similarly, few global recurrent and non-recurrent changes were identified between the patient-matched PB and LN compartment cases. **Conclusion**In summary, we confirm and extend the distinct methylation profiles of CLL subgroups. For the first time, we ascertain global DNA methylation to be relatively stable over time independently of treatment status, and demonstrate DNA methylation to be remarkably similar in CLL cells derived from different anatomical compartments.

[3]Department of Internal Medicine III University of Ulm, Ulm, Germany
[4]Department of Hematooncology and BMT Unit Medical University of Lublin, Lublin, Poland
[5]Department of Clinical Immunology Medical University of Lublin, Lublin, Poland

Background. The programmed death-1 (PD-1) molecule is an immunoreceptor, which through an interaction with its ligand (PD-L1), controls peripheral tolerance by limiting activation, development and effector functions of T lymphocytes. PD-1/PD-L1 pathway was found to be one of the potential tumor escape mechanism from the immunosurveillance and its expression was described on exhausted T lymphocytes. **Aims.** We assessed a mRNA level and surface expression of PD-1 and PD-L1 in CLL patients since the aberrant expression of PD-1 and PD-L1 might represent a novel T-cell feature on the lymphocytic B-cells. It might also define a possible prognostic marker. In the functional studies, the PD-1 expression was investigated under conditions mimicking influence of microenvironment in germinal centers.**Patients and Methods.** Quantitative reverse transcriptase PCR (qRT-PCR) was performed for the PD-1 transcript in 182 CLL patients and 10 healthy volunteers (HVs). For four PD-1 splicing variants as well as for PD-L1 and one splicing variant qRT-PCR was made in 43 CLL patients. For characterization of the surface expression of PD-1 and PD-L1 on leukemic B-cells in a group of 45 CLL patients, magnetic separation of $CD19^+$ cells followed by five parameter flow cytometric analysis was used. In functional studies, cells from 21 CLL patients and 11 HVs were stimulated with IL-4 and CD40L, and analyzed for the expression of CD38 and PD-1 using flow cytometric afterwards. **Results.** The median level of PD-1 transcripts in CLL patients was higher in comparison with HVs (p=0.0176, n=182). Additionally, expression of a truncated PD-1 splicing variant lacking of exons 2, 3 and 4 was lower in CLL patients compared with HVs (p=0.0007, n=43). The PD-1 transcript level was comparable between PBMC (n=149) and BM (n=140) samples. No difference of PD-L1 expression between CLL patients and HVs on mRNA level was observed. In flow cytometric analysis, we confirmed the presence of PD-1 and PD-L1 on the CLL cells surface. Notably, both PD-1 and its ligand were expressed on the same CLL cells. Median PD-1 expression was higher on $CD5^+CD19^+$ cells of CLL patients in comparison to control B cells of HVs (47.2% vs. 14.81%, p<0.0001). Notably, levels of PD-1 on healthy B cells were similar in HV and in $CD19^+CD5^-$ B cells of CLL patients. Expression of PD-L1 was observed at similar levels in CLL and HVs. Interestingly, the mean fluorescence intensity values of PD-L1 reflecting the expression levels on CLL cells were higher when compared to HVs (p=0.017). There was no difference of time to progression and overall survival in groups of patients characterized by low and high PD-1 and PD-1L expression. After stimulation with IL-4 and CD40L, protein expression of PD-1 was significantly increased in samples that responded and up-regulated CD38 in comparison to not responding samples (p=0.0093). **Conclusions.** PD-1 is a novel immunotolerant molecule expressed on CLL cells on both mRNA and cell surface levels, additionally being up-regulated on CLL cells with the immunophenotype reflecting proliferative potential. The PD-1 might be involved in the pathomechanism of CLL and provide a novel target for future therapies.

SYSTEMATIC EVALUATION OF LYMPHOCYTE SUBPOPULATION INBALANCES AND BONE MARROW CHANGES IN CLL PATIENTS TREATED WITH THE FCR REGIMEN: FOCUS ON CYTOTOXIC CELL EXPANSIONS AND ASSOCIATED DYSHEMATOPOIESIS

M Iskas[1], A Papalexandri[1], L Marinos[2], N Stavroyianni[1], B Tachynopoulou[1], K Kotta[1], M Papathanasiou[1], A Tsompanakou[1], K Stamatopoulos[1], T Papadaki[2], A Anagnostopoulos[1]
[1]G. Papanicolaou Hospital, Thessaloniki, Greece
[2]Evangelismos Hospital, Athens, Greece

A sizeable proportion of lymphoma patients treated with Rituximab-based regimens develop late onset neutropenia (R-LON) of as yet undefined cause(s). As we have previously shown, at least some R-LON cases may be attributed to autoimmune myelopathy/myelodyplasia arising in a context of cytotoxic T cell expansions with a large granular phenotype (CD3+CD8+CD57+). However, the retrospective character of all previous studies dealing with R-LON, including ours, created uncertainty as to whether the findings could be disease- and/or treatment-biased, as the relevant cohorts included cases with different diagnoses who were also treated with different CHI regimens. Here we present the results from the analysis of peripheral blood (PB) lymphocyte subpopulations and the detailed histopathological and immunohistochemical examination of bone marrow biopsy (BMB) samples of 23 CLL patients treated uniformly with the FCR regimen. The study group included 17 males and 6 females with a median age of 59 years (range, 29-72). Twenty-one cases received 6 FCR cycles, whereas the remaining 3 discontinued at cycle 5 because of Grade III hematologic toxicity. One month after the completion of the last FCR cycle, hemoglobin and platelet values were normal in all cases. In contrast, neutrophil counts were often low, with a median neutrophil count of $0.8x10^9$/l (range, 0.3-1.7). Neutrophil counts eventually normalized in all cases, however, 3/23 cases (13%) developed Grade III-IV LON at a median of 6 months after the completion of therapy. PB examination by 4-color flow cytometry (FACS) after the last FCR cycle identified residual CLL cells in 8/23 cases (35%). Eighteen cases were also systematically subjected to T cell subpopulation analysis with the following. **Results.** (i) T8 cells >1.0x109/l, 2/18 cases (11%); (ii) T4/T8 ratio <0.7, 7/18 cases (39%); (iii) >20% CD3+CD8+CD57+CD28- (T-LGL), 10/18 cases (55%): in cases with expanded T-LGLs, TRBV clonality assessment by flow cytometry did not reveal dominant epitopes. Notably, T cell subset imbalances were observed irrespective of whether the patients developed LON or not. BMB examination for assessment of response was performed in all cases after the last FCR cycle. The main findings are as follows: (i) minimal infiltration with small CD20-CD79a+CD5+CD23+CD3- B cells in 8/23 cases (35%), representing residual disease; (ii) mild-to-moderate infiltration by small CD3+CD5+CD45RO+CD20-CD79a- T cells in 19/23 cases (82%); (iii) hyperplasia of the erythroid and megakaryocytic series with concomitant dysplastic changes in 17/23 (74%) and 16/23 (69%) cases, respectively; (iv) hyperplasia or hypoplasia of the granulocytic series in 11 and 12 cases, respectively, with shift-to-the-left, always with less than 2% CD34+ cells, effectively ruling out the possibility of therapy-related myelodysplasia. In the three cases with R-LON, BMB examination was also performed at onset of neutropenia: 2/3 cases had hyperplasia whereas the remaining case had hypoplasia of the granulocytic series; all 3 cases had pronounced shift-to-the-left. In conclusion, our findings show that T cell subset imbalances are frequent after FCR treatment for CLL with variable effects on the hematopoietic marrow. Furthermore, they support the notion that R-LON may represent the end of a spectrum of dyshematopoiesis associated with immune-mediated myelodysplasia/myelopathy.

0133

MOLECULAR DISSECTION OF SIGNALS PROVIDED BY ACTIVATED T CELLS TO CLL CELLS INDICATES MAJOR ROLE FOR IL-21 AND CD40 IN CONTROLLING PROLIFERATION AND CHEMORESISTANCE

E Eldering[1], F Pascutti[1], J Tromp[1], M Jak[1], G van Bochove[1], I Derks[1], A Kater[1], S Pals[1], M van Oers[1], R van Lier[2]
[1]Academic Medical Center, Amsterdam, Netherlands
[2]Sanquin Research, Amsterdam, Netherlands

Background and Aim. Chronic Lymphocytic Leukemia (CLL) cells accumulate in peripheral blood (PB) but proliferate in secondary lymphoid organs, where they display increased resistance to apoptosis. The signals involved in CLL proliferation and chemoresistance *in vivo* remain unknown to date. In the proliferation centra (PC), CLL B cells are in close contact with activated $CD40L^+$ $CD4^+$ T cells. *In vitro* stimulation of PB CLL cells with CD40L results in chemoresistance and an apoptotic profile resembling the LN situation, but generally fails to induce proliferation. Activated T cells and follicular helper T cells can also secrete IL-21, which has an essential role in providing help to healthy B cells. Here, we dissected the signals provided by activated T cells versus 3T40L-stimulation to CLL with respect to proliferation and drug resistance. **Methods and results.** CLL cells were purified from PB and cultured with autologous T cells activated with anti-CD3/anti-CD28 antibodies (Tact) resulting CLL proliferation which depended both on CD40L- and IL-21-signaling. Remarkably, gene expression profiling revealed that Tact or CD40L induced a highly similar gene signature in CLL cells. An overlap of 1242 differentially expressed genes compared to PB CLL indicated that CD40L-signals play a major role in the Tact system. *In vitro* stimulation with only 3T40L+IL-21 also resulted in proliferation of CLL cells. Surprisingly, IL-21 abrogated the resistance induced by CD40L to certain drugs (fludarabine, roscovitine and bortezomib) but not to the BH3-mimetic ABT-737. Detailed analysis of the changes in the pro-/anti-apoptotic balance after IL-21 stimulation demonstrated this was due to a decrease in Bcl-2 and Bcl-xL expression. In addition, microarray analysis showed that 129 genes were differentially regulated by IL-21, among which were components of the JAK-STAT (STAT3), and apoptosis pathways (Bcl-2, Bcl-xL) as well as GZMB (Granzyme B). Of these genes, 80 were also different between 3T40 vs Tact stimulation. Finally, we wished to ascertain whether IL-21 is being produced *in*

vivo in CLL, and performed IHC stainings on paraffin LN samples from untreated patients, as well as Q-PCR analyses. Scattered among small lymphocytes, we observed IL-21 immunostaining in large cells. IL-21 mRNA was detectable in CLL LN samples, with highest levels comparable to *in vitro* TCR cell stimulation assays.These results indicate that activated T cells from CLL patients provide strong CD40L and IL-21 stimulation to CLL cells. This combination leads to proliferation and specific changes in gene expression, related to migration and susceptibility to apoptosis. If this scenario is representative of the situation in LNs, this would imply that proliferating CLL cells are more susceptible to certain drugs than the bulk of resting cells, which are protected by interaction with stromal cells. Lastly, we uncovered stong indications for expression of IL-21 in CLL LN tissue. **Conclusions.**These results are not only important for understanding the biology of CLL but might also open new treatment venues.

0134

NON-RECURRENT GENETIC ABERRATIONS IN CHRONIC LYMPHOCYTIC LEUKAEMIA: RELATIONSHIP TO RECURRENT GENETIC ABERRATIONS AND CLINICAL BEHAVIOR

M Pantic[1], K Zirlik[2], A Keppler-Hafkemeyer[2], R Kunzmann[2], H Veelken[3], D Pfeifer[2]
[1]University Medical Center, Freiburg, Germany
[2]Department of Hematology/Oncology, Freiburg University Medical Center, Freiburg, Germany
[3]Department of Hematology, Leiden University Medical Center, Leiden, Netherlands

Background. Recurrent genomic aberrations like del13q14, del11q22, del17p13 and trisomy 12 are well described as important prognostic parameters in CLL and therefore routinely tested in the diagnostic -work-flow of CLL. The prevalence and prognostic relevance of additional recurrent and non-recurrent genomic aberrations as defined by higher resolution technology still needs to be investigated. **Aims.** To detect the most frequent additional and novel non-recurrent genomic aberration using high resolution SNP arrays and to correlate their effects to the different groups of CLL recurrent aberrations. **Methods.** We analyzed copy number alterations (CNAs) in 240 consecutive CLL patients using high resolution Affymetrix SNP arrays. To determine the importance of small, tumor associated genomic imbalances and loss of heterozygosities (LOHs) we performed matched pair analyses of CD19+ B-cells and PB neutrophils in 120 patients. **Results.** In total, 407 CNAs were detected in 213 patients (89%) and among these, 203 (85%) had at least one of the recurrent aberrations. However, 77 patients (32%) had non-recurrent CNAs in addition to the recurrent aberrations. Among 166 non-recurrent CNAs, losses (66%) and gains (34%) were distributed with different frequencies among recurrent groups: 25%, 42%, 92%, and 93% in the group with del13q14, trisomy 12, del11q22 and del17p13, respectively. The median was 0.73 of non-recurrent CNAs per patient with the range from 0.35 in the group of CLL with del13q14 to 2.9 in the group with del17p13. The most frequent non-recurrent CNA is the gain of 2p found in 13 patients (5%) mostly with unmutated VH genes (10/13). Consistent with previous reports, gain 2p was exclusively found in combination with one of the recurrent aberration, del13q14 (n=5), del11q22 (n=3), del13q/del11q22 (n=3), del17p13 (n=2) strongly indicating disease evolution. A common minimal 3.5 Mb gain of 2p16 spans the *REL* and *BCL11A* oncogenes, implicating their importance in the pathogenesis of CLL. Moreover, novel non-recurrent aberrations were discovered in 10 CLL cases (4%). Those aberrations mostly affect chromosomal regions, for example del14q23.1-q32 and gain 17q21.33-q22, that overlap with non-recurrent CNAs occuring in combination with the recurrent lesions. Seven tumor associated, copy number neutral LOHs present in CD19+ cells, but not in PB neutrophils were identified in 6 CLL patients. Although tumor associated LOHs are a rare event, they span chromosomal regions (11q, 13q, 19p) that may harbor novel imprinted genes or loss-of-function alleles with importance for the pathogenesis of CLL. **Conclusions.** In conclusion, comprehensive screening for non-recurrent genomic aberrations in CLL by high-resolution SNP array analysis reveals the genomic complexity of CLL and suggest that some of the most frequent non-recurrent aberrations like gain 2p16 and del14q23.1-q32 should be included into the standard diagnostic FISH panel for genetic testing of CLL in order to determine their prognostic significance.

0135

THE ROLE OF STROMAL FIBROBLASTS IN THE REGULATION OF TUMOR MICROENVIRONMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Jarvinen, S Liyanarachchi, R Klisovic, E Hertlein, J Byrd, A De la Chapelle
Ohio State University Comprehensive Cancer Center, Columbus, OH, United States of America

Background. Compelling evidence supports the pivotal role of stroma, or microenvironment, derived signals in tumor progression. Chronic lymphocytic leukemia (CLL) cells *in vivo* evade apoptosis which might depend on their ability to secrete molecules that favorably manipulate the surrounding microenvironment. CLL cells occur throughout the hematopoietic system including the bone marrow (BM) where they have an opportunity to interact with stromal cells, such as fibroblasts (FB). Studies suggest that these FBs are neither part of the malignant clone nor of hematopoietic origin. We hypothesize that BM FBs might be functionally altered and play a role in microenvironmental fine-tuning through differential gene expression. Previous studies have highlighted the role of chemokine signaling in the regulation of the microenvironment. We hope to identify mechanisms other than chemokines that favor the survival of CLL cells. **Aims.** We hypothesize that similar to other malignancies, genetic changes occur not only in the cancer cells, but in the interacting stromal cells as well. By characterizing putative changes in stromal cell gene expression between CLL patients and control subjects we aim to identify molecular events that can be targets of therapeutic interventions. **Methods.** BM aspirates from well-characterized CLL patients (total n=125) and healthy controls (total n=10) were used to establish *in vitro* primary FB cultures. Confluent cultures were split three times. Total RNA was isolated from 14 patients and 10 controls. Samples were hybridized to the Agilent SurePrint G3 Human GE 8x60K microarrays. After background correction and normalization of the data, differentially expressed genes between patient and controls were identified by applying random variance model t-test using BRB-Array Tool software. Network, functional and canonical pathway analyses of differentially expressed genes were performed using Ingenuity Pathway Analysis software. The most up- or downregulated genes were validated using real-time qRT-PCR on total RNA from arrayed samples. **Results.** Expression levels in patients were either increased or decreased at least 1.5-fold [range 6.8-(-5.8); $p \leq 0.05$] for over 500 genes as compared to those in controls. A set of chemokines and chemokine ligands were among the most upregulated genes in patients. In line with this, canonical pathway analysis identified chemokine signaling to be a significant differentiating factor between patients and controls. There were several non-chemokine genes demonstrating strong up- or downregulation in patients. Interestingly, among these was a member of the RUNX gene family, known for its oncogenic potential, showing significant downregulation (-2.4-fold; $p=1.97 \times 10^{-4}$) in patients. Among the classes of significantly altered biological functions were cellular movement, growth and proliferation; cell-cell signaling and interaction; and cell death. Validation data produced by real-time qRT-PCR were in keeping with the array results.**Conclusions.** We have shown that stromal FBs derived from CLL patients have different gene expression profiles compared to controls. In agreement with previous reports, pathway analysis suggested differences in chemokine signaling to be important, whereas functional analysis identified genes involved in cell-cell interactions. The functional mechanisms of the genes and pathways involved in the survival of CLL B-cells remain to be studied by *in vitro* experiments and in coculture with BM FBs.

THE CYTOMEGALOVIRUS PROTEIN PUL32, WHICH IS RECOGNIZED BY B-CELL RECEPTORS ENCODED BY THE 1-69 GENE IN CLL, IS HIGHLY CONSERVED AMONG CLINICAL VIRUS STRAINS

K Vanura[1], F Rieder[1], MT Kastner[1], M Sandhofer[1], T Le[1], R Strassl[1], E Puchhammer[1], C Steininger[1], K Stamatopoulos[2], W Graninger[1], U Jäger[1], C Steininger[1]
[1]Medical University of Vienna, Vienna, Austria
[2]G. Papanicolaou Hospital, Thessaloniki, Greece

Background. Recently, we could show that recombinant antibodies (rAbs) of chronic lymphocytic leukemia (CLL) patients, encoded by the IGHV-1-69 gene, bind to the cytomegalovirus (CMV) large tegument protein pUL32 (pp150) (1). pUL32 is a highly immunogenic CMV protein with multiple epitopes dispersed over the 150 kDa protein. Analogous to other CMV antigens, host immune pressure to generate genetic diversity in the UL32-gene could be expected. Particularly CMV strains in CLL patients might be considered to be under strong selective pressure through a postulated persistent interaction of pUL32 with certain leukemic clones (1). The available information on the genomic diversity of this gene among clinical strains, however, is very limited. **Aim**. To determine UL32 genomic diversity in a clinical setting. **Methods.** We screened 200 consecutive

CLL patients for the presence of CMV-DNA and sequenced the UL32 gene to determine the genomic diversity among clinical CMV strains. Results were analyzed with respect to CMV-seropositivity and sequence of the Ig expressed on leukemic cells. As references, CMV UL32 sequences detected in patients with primary CMV infection (n=5) were used, in additional CLL patients treated with an anti-CD52 antibody (n=4), or sequences previously studied and available via PubMed (n=14). **Results.** CMV-DNA was detected in 3% and CMV-specific IgG antibodies in 71.5% of the 200 CLL patients. Interestingly, CMV-DNA was detectable in 2 CMV-seronegative patients. IgHV gene usage was associated neither with detection of CMV-DNA nor with CMV-seropositivity. Phylogenetic analysis of a total of 28 UL32 sequences, including 5 sequences from CLL patients, revealed low sequence variability (<1%). Moreover, the variability of UL32 observed between clinical strains was not restricted to specific stretches of the gene, rather it was uniformly distributed over the entire analyzed sequence. **Summary and Conclusions.** In contrast to other CMV antigens, such as glycoprotein B, pUL32 was found to be highly conserved among clinical CMV strains, including those from CLL patients. The function of pUL32 thus appears to be essential for CMV, considering the low genomic divergence of UL32 despite a presumed strong host immune pressure. The observed binding activity of distinct CLL rAbs to the same protein may hence be based on binding to different epitopes of the same protein.

REARRANGEMENT OF NOTCH1 OR BCL3 CAN INDEPENDENTLY TRIGGER PROGRESSION OF CLL

K De Keersmaecker[1], L Michaux[2], A Bosly[3], C Graux[3], J Finalet Ferreiro[2], P Vandenberghe[2], J Cools[1], I Wlodarska[2]
[1]KU Leuven - VIB, Leuven, Belgium

[3]Mont-Godinne University Hospitals, Yvoir, Belgium

Background. Recent data indicate that *NOTCH1* mutations significantly increase the risk of CLL progression towards Richter syndrome (RS) and chemoresistance, and that activation of *NOTCH1* at time of CLL diagnosis is an independent prognostic factor of poor survival. **Aims.** Our study aimed at identification of genetic defects triggering two consecutive progression events observed in a patient with CLL during 8 years of follow up. **Methods.** The applied techniques included conventional cytogenetic analysis, FISH, aCGH, qRT-PCR, Western blotting and Sanger sequencing. **Results.** The patient, a 58 year old male, was diagnosed with CLL (unmutated *VH*) in RS in June 2003. Karyotyping identified two related clones: (i) with an isolated +12 and (ii) with +12 and dic(9;14)(q34;q32). FISH and aCGH analysis showed that dic(9;14)(q34;q32) resulted in juxtaposition of 3'*IGH* and 5'*NOTCH1,* that was associated with loss of sequences distal to the involved loci. qRT-PCR analysis demonstrated a 10-fold upregulation of *NOTCH1* mRNA and a low expression of the neighboring genes (*GPSM11, CARD9, DNL2*). Immunoblotting of a cell lysate from lymph node with a NOTCH1 antibody recognizing active, cleaved NOTCH1 (Val1744), identified a band corresponding to activated intracellular NOTCH1. This finding suggested an additional truncating mutation that was further identified by sequence analysis. The detected two basepair deletion, ΔCT7544-7545/P2515fs, occurred in the nucleotide sequence encoding the PEST domain of NOTCH1. The patient was treated and achieved complete remission. In 2007, however, CLL relapsed and an examination of bone marrow (BM) identified a clone with a sole +12 negative for ΔCT7544-7545/P2515fs. Two years later, CLL progressed and BM revealed an evolved clone with complex aberrations including +12 and t(14;19)(q32;q13)/*IGH-BCL3* but lacking dic(9;14)(q34;q32). Of note, BM was again positive for ΔCT7544-7545/P2515fs. Despite treatment, evolving subclones with +12 were seen in the analyzed BM (06/2011) positive for ΔCT7544-7545/P2515fs. Four months later, the patient developed fatal peripheral T cell lymphoma. **Conclusions.** We deduced the sequence of multiple genetic defects driving development and progression of CLL in the presented case. An initial clone with +12, likely present at a presymptomatic CLL phase, later acquired an activating mutation of *NOTCH1*. Subsequent acquisition of dic(9;14)/*IGH-NOTCH1* triggered Richter transformation. After a few years, a persistent chemorefractory *NOTCH1*-mutated clone underwent another hit, t(14;19)/*IGH-BCL3*, which initiated the second progression that was followed by CLL-unrelated T-cell lymphoma. Our findings confirm the risk of activating mutations of *NOTCH1* in Richter transformation of CLL, particularly CLL with +12, and highlight that a residual chemotherapy-resistant *NOTCH1*-mutated clone is at risk of acquiring further progression-associated hits. Besides the known t(14;19)(q32;q13)/*IGH-BCL3,* we also identified dic(9;14)(q34;q32)/*IGH-NOTCH1* which so far has not been reported in B-cell leukemia/lymphoma, as a novel genomic aberration capable of triggering RS.

VORINOSTAT (SAHA) INDUCED DOWNREGULATION OF C-FLIP CAUSE'S APOPTOSIS IN CD40L/IL-4 ACTIVATED CHRONIC LYMPHOCYTIC LEUKAEMIA

A Catherwood[1], H Wheadon[2], W Jamison[3], D Longley[4]
[1]Belfast City Hospital, Belfast, United Kingdom
[2]College of Medicine, Veterinary & Life Sciences Institute of Cancer Sciences Uni, Glasgow, United Kingdom
[3]University Of Ulster, Coleraine, United Kingdom
[4]Queens University of Belfast, Belfast, United Kingdom

Background. Chronic Lymphocytic Leukaemia (CLL) is the most common form of leukaemia in adults in the western world. First line chemotherapy treatment of CLL has prolonged first remission; however disease progression and chemotherapy resistance occurs. Studies have shown that the microenvironment is essential in maintaining CLL cell cycle progression and can contribute to drug resistance. Cellular Flice like inhibitory protein (c-FLIP) is a protein that has been linked to drug resistance. It inhibits the activation of caspase 8 thereby inhibits apoptosis. **Aims.** To examine if the pan-HDAC inhibitor Vorinostat (Saha) can induce apoptosis of primary CLL cells stimulated via CD40L/IL-4. **Methods.** CLL cell lines CII (UM) and PGA (M) were treated in a dose dependant manner and expression of c-FLIP isoforms are assessed by RQ-PCR and western blotting. Caspase inhibitors were used to investigate the dependency cell death mechanism. CD19+ cells were purified from peripheral blood of CLL patients by Miltenyl-automac, IGHV and cytogenetic status was determined. Cells were placed into a co-culture system with mouse fibroblasts (previously irradiated) expressing human CD40L and 10ng/mL IL-4 added. CLL primary Cells were treated with Saha in a dose dependant manner simultaneously or following previous CD40L/IL-4 stimulation. Samples assessed for apoptosis via Annexin V/PI staining. Expression of known pro-survival proteins was assessed using western blotting. Primary cells were treated with Fludarabine or Saha while in CD40L/IL-4 system and apoptosis assessed. **Results.** CLL cell lines showed downregulation of c-FLIP protein levels and activation of caspase 8 following Saha treatment. The accompanying cell death was shown to be rescued by pan-caspase and caspase 8 specific inhibitors but not with caspase 9 inhibitors. CD40L/IL-4 activated CLL cells showed significant upregulation of pro-survival proteins important in both the extrinsic and intrinsic death pathways, most notably Bcl-2, Mcl-1, Bcl-xL and c-FLIP. CLL (not in co-culture) cells treated with Saha showed a decrease in cell viability within 24hrs of initial treatment in a dose dependant manner with further decreased viability following r-TRAIL treatment. Additionally, primary CLL cells from 19 patients treated whilst in the CD40L/IL-4 system for 24hrs show significant levels of apoptosis. Furthermore, time course experiments showed that Saha inhibits the upregulation of c-FLIP when cells are in the co-culture system. Moreover previously co-cultured cells become apoptotic after Saha treatment. Finally Saha treatment alone of patient cells in CD40L/IL-4 show significantly more apoptosis compared to Fludarabine treatment alone. **Summary.** c-FLIP appears to be frequently upregulated in CLL patient samples with CLL (UM) cell lines showing higher levels. CD40L/IL-4 stimulation individually or in combination results in upregulation of expression of anti-apoptotic proteins including c-FLIP. Saha has been shown to downregulate c-FLIP expression and our results show stimulated/previously stimulated patients it inhibits upregulation. This results in reduction of CLL cell viability and an increase in apoptosis. These results indicate that Saha can overcome pro-survival interactions found in the CLL microenvironment and cause apoptosis through the resultant activation of Caspase 8. Therefore, Saha may be a potential therapeutic strategy for the treatment of CLL.

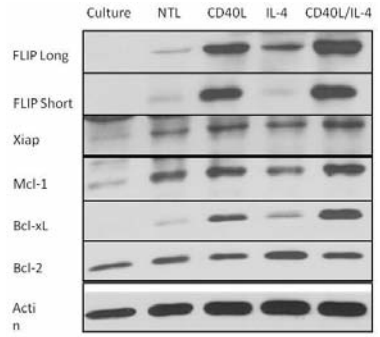

Figure 1. Combination of CD40L and Interleukin 4 on CLL primary cases causes synergistic upregulation of some pro-survival proteins compared to single.

IDENTIFICATION OF INTERLEUKIN-4 (IL-4) TARGET GENES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

MJ Alcaraz-Garcia, N Ruiz-Lafuente, S Sebastian-Ruiz, C Gonzalez-Garcia, MJ Majado, A Parrado
Hospital Virgen Arrixaca, Murcia, Spain

Background. Interactions of the malignant B lymphocytes with microenvironment play a crucial role in the pathogenesis of chronic lymphocytic leukemia (CLL). In this context, the cytokine interleukin 4 (IL-4) makes an essential contribution to B-cell differentiation and survival. In follicular lymphoma, a CLL-related disease, gene expression profile (GEP) studies suggest that a preeminent IL-4-dependent T-B cell axis sustains tumorigenesis. Activation of the IL-4 pathway might also contribute to CLL pathogenesis. In this study, the response of CLL cells to IL-4 in terms of GEPs was investigated. **Aims.** To identify the IL-4 target genes in CLL cells and normal B cells. **Methods.** Whole blood from 10 controls with normal lymphopoiesis and 10 chronic lymphocytic leukemia (CLL) patients was obtained prior informed consent. B cells were purified by negative isolation procedures. Aliquots of purified B cells were processed for total RNA obtention (Pre sample), or cultured for 12 hours in the presence of human recombinant IL-4 (IL-4 sample) or nothing (Ctrl sample). Two-color Whole Human Genome Microarrays (4 × 44k) were performed and analyzed with appropriate software for normalized extraction of data sets and statistics.Identification of IL-4 targets in CLL and normal B cells was performed using the 1-way ANOVA test ($p<0.05$) with posthoc Tukey HSD analysis. The IL-4 targets were found in the intersection between IL-4 vs Pre and IL-4 vs Ctrl comparisons. These analyses were followed by functional, pathway and network analyses. **Results.** Microarray analyses identified 203 IL-4 target genes in CLL (146 up, 57 down) and 343 IL-4 target genes in normal B cells (237 up, 106 down), being 84 genes common to both groups (76 up, 10 down). They included known and novel IL-4 targets. Top up-regulated genes in CLL were CCL17 (23-fold), RASL10A (21-fold), SLC24A3 (21-fold), HOMER2 (16-fold), SLC39A8 (11-fold), TLR7 (9-fold), QSOX1(9-fold), and CLDN1 (9-fold), and in normal B cells CCL17 (44-fold), IL4I1 (19-fold), RASL10A (15-fold), BATF (14-fold), IGSF3 (10-fold), MFI2 (9-fold), AHRR (8-fold), and TGM2 (8-fold). Down-regulations were weaker than up-regulations. Gene regulation by IL-4 was consistent with activation of STAT6 in both CLL and normal B cells, and NOTCH1 in normal B cells. In spite of the known pro-survival effect of IL-4 on CLL, confirmed by our own data, functional annotation of IL-4 targets predicted increased activation state of cell death in CLL and normal B cells (regulation z-scores of 1.998 and 1.861, respectively, near the cut-off level of 2). Significant canonical pathways for IL-4 targets included JAK/Stat and GM-CSF for both groups, signaling by CXCR4, phospholipase C, p70SK6, IL-8, IL-2, and RhoA for CLL, and Notch1 for normal B cells. **Summary and Conclusions.** GEP studies demonstrate that IL-4 is active in CLL cells and in normal B cells. However, the IL-4 targets identified in both groups partially overlapped, suggesting activation of common and divergent functional pathways in CLL and normal B cells. These results suggest that IL-4 stimulation in the CLL niche may sustain tumorigenesis.mariaj.alcaraz4@carm.es

DELETION (13Q14.3) AND/OR MIR15A-16-1 DOWNREGULATION: AN ALMOST CONSTANT FINDING IN CHRONIC LYMPHOCYTIC LEUKEMIA ?

A Godon[1], F Genevieve[1], M Truchan-Graczyk[1], L Baranger[1], O Blanchet[1], A Coutolleau[2], N Ifrah[1], M Zandecki[1], P Guardiola[2]
[1]University Hospital, Angers, France
[2]Genomics Platform STE, INSERM U872, Angers, France

Background. Del(13q14.3) is the most frequent deletion reported so far in B-CLL. It was recently shown that two micro-RNA genes (mir15a and mir16-1) are deleted in almost all cases carrying the deletion. However, large fluorescent in situ hybridization (FISH) studies fail to detect del(13q14) in up to 40-45% of B-CLL cases. Comparative genomic hybridization (CGH) technologies have substantially improved resolution, but are limited by noise, leading to mask small changes. **Aims.** To determine wether SNP random bead-arrays (Illumina, hybridization with oligonucleotides probes immobilized onto beads, that correspond to Single-Nucleotide Polymorphisms along the human genome, followed by single-base enzymatic primer extension) are more sensitive than interphase-FISH to detect del(13q14), or not. To discriminate between signal and noise, we also studied relationship between del(13q14) and mir15a/16-1 expression. **Methods.** A blood sample from 24 patients with B-CLL at diagnosis was analysed simultaneously using LSI D13S319(~130kb) (Abbott) and 13q14.3(~400 kb)/13q ter (Cytocell) FISH probes, SNP bead-array and miRNA expression. Blood samples from 24 healthy donors were used as negative controls. I-FISH: an average of 6% nuclei of normal lymphocytes showed loss of signal (truncated nuclei or random colocalized signals), and the cut-off to ascertain a chromosomal deletion was defined over 10% (m+3DS). SNP-array: 200 ng DNA was hybridized on the Illumina HumanCNV370 BeadChips, which assess ~373,397 markers (4.9 kb median marker spacing). miRNA: 200 ng total RNA was processed with Illumina's MicroRNA Expression Profiling Panel. **Results.** In 18 (75%) patients, del(13q14) was discovered using both I-FISH [13-95% nuclei; mean=47%; including 4 biallelic deletions] and SNP-arrays (size: 0.49-33 Mb). A clear-cut correlation was observed between percentage of I-FISH del(13q) nuclei and either SNP-arrays signals intensity [log*R* ratio and allele frequency (AF)] or reduced expression of mir15a/16-1 (greater amplitude in patients demonstrating biallelic deletion). In 5 other patients beadchips discovered del(13q) which was not detected after I-FISH, corresponding to cryptic del(13q14.3) (39-82 kb) in 3 patients (including 1 biallelic deletion) [displaying clear-cut correlation between SNP-arrays signals intensity and reduced mir15a/16-1 expression level]; and to (4-30Mb) deletions encompassing 13q14.3 in 2 patients with low clonal infiltration (respectively mono- or biallelic in 9% or 1% nuclei) [a clonal expansion was detected by I-FISH performed 6-12 months later]. In the last patient from this series del(13q) was undetected after both I-FISH and SNP-arrays, but mir15a and mir16-1 expression levels at <10% of normal cells were observed. **Summary and Conclusions.** Using BeadArray platform, we demonstrated del(13q14.3) and/or mir15a-16-1 downregulation in all B-CLL tested, even when FISH failed to detect an abnormality. Resolution and sensitivity as high as respectively 39 kb and 1% tumoral cells could be reached, with signals unambiguously discriminated from noise. We undertake a SNP-array study on a larger CLL cohort del(13q) negative by I-FISH. The presence of a deletion or another genetic abnormality located at 13q in all patients from this series leads to hypothesize a primary transforming lesion in lymphomagenesis, irrespective of prognostic features.

TARGETING PROLIFERATING CHRONIC LYMPHOCYTIC LEUKAEMIA CELLS WITH A NOVEL SYNTHETIC LOW DENSITY LIPOPROTEIN DRUG DELIVERY SYSTEM

G Jorgensen[1], E Cosimo[1], A Michie[1], T Holyoake[1], M Elliott[2], G Halbert[2], A McCaig[3]
[1]University of Glasgow, Glasgow, United Kingdom
[2]University of Strathclyde, Glasgow, United Kingdom
[3]Royal Alexandra Hospital, Paisley, United Kingdom

Background. Chronic lymphocytic leukaemia (CLL) currently remains incurable without stem cell transplantation, an option for only the minority of patients. Despite advances in chemotherapy, most patients relapse owing to the persistence of minimal residual disease (MRD). Substantial evidence has accrued to suggest that the tumour microenvironment is central to disease progression in CLL, with the bone marrow (BM) and lymph nodes (LN) acting as sanctuary sites for MRD. Whilst peripheral blood CLL cells are cell cycle arrested, significant rates of clonal proliferation occur in the BM/LN wherein acquisition of deleterious cytogenetic abnormalities such as 17p deletion may arise. Further, CLL cells co-cultured *in vitro* on stroma with CD154/IL-4 to give a proliferative signal, are chemoresistant to first line therapies. As proliferating cells require lipids for membrane synthesis, we hypothesise that proliferating CLL cells will have greater requirement for low density lipoprotein (LDL) compared to circulating CLL cells, and also that of normal resting lymphocytes providing a potentially differential cellular property to attack. Proof of concept of drug-loaded synthetic (s)LDL nanoparticles has been provided in glioblastoma and CML. We propose that drug loading into sLDL nanoparticles will allow selective targeting of proliferating CLL cells within the BM/LN proliferation centre, will protect drugs from plasma binding proteins, and will ultimately raise intracellular drug concentrations in the protective microenvironmental niche, to overcome chemoresistance. **Aims.** To determine (a) the extent of sLDL uptake by CLL cells compared to normal; and (b) whether sLDL uptake by CLL cells changes under proliferative conditions mimicking the proliferation centre. This will determine whether proliferating CLL cells have increased sLDL uptake compared to non-cycling CLL cells or normal B lymphocytes. **Methods.** sLDL uptake was assessed by flow cytometry, measuring the mean fluorescence intensity in the FITC channel owing to the stable incorporation of dioctadecyloxacarbocyanine (DiO) into the formulation. Internalisation was confirmed by deconvolution fluorescence microscopy. Primary CLL and normal donor samples were enriched for CD19+ B-lineage cells by magnetically activated cell sorting. Cells were cultured in media on tissue culture plastic or NT-L mouse fibroblasts with or without CD154/IL4. Lymphoid cells were stained with CellTrace Violet® to track cell division in response to proliferative signals (CD154/IL4 stroma). **Results.** HG3, a human lymphoblastoid cell line, avidly took up sLDL nanoparticles in a concentration (0-50 ng/mL cholesterol) and time (0.5-24h) dependent manner. Normal donor peripheral blood B-cells and CLL cells cultured on plastic did not actively take up sLDL but maintained their viability even in the highest concen-

tration sLDL tested. Actively proliferating CLL cells on CD154/IL4 stroma could be targeted with sLDL unlike their non-cycling counterparts; interestingly even the minor population of cells that had remained undivided on stroma were also found to be sLDL positive. **Summary**. CLL cells can be selectively targeted by sLDL nanoparticles with respect to their non-cycling counterparts. We next will investigate the *in vivo* targeting of sLDL which we hypothesise, by virtue of their size, will home to lymphoreticular organs, sanctuary sites for CLL MRD.

IDENTIFYING NOVEL PROGNOSTIC BIOMARKERS IN CHRONIC LYMPHOCYTIC LEUKEMIA USING PROTEOMICS: A POSSIBLE ROLE FOR KININOGEN

O Kashuba[1], J Bailey[2], G Eagle[3], D Allsup[2], L Cawkwell[3]
[1]Hull York Medical School/University of Hull, Hull, United Kingdom
[2]Queens Centre for Oncology and Hematology, Castle Hill Hospital, Hull, UK, Hull, United Kingdom
[3]Cancer Biology Proteomics Group, Post Graduate Medical Institute, University of, Hull, United Kingdom

Background. Disease progression in Chronic Lymphocytic Leukemia (CLL) is characterized by a high degree of heterogeneity. Some CLL patients have an indolent disease course with normal life span and die of unrelated causes whilst other patients have an aggressive disease progression with comparatively rapid fatal outcome. The lack of predictive factors for disease progression is the catalyst for identification of reliable and affordable biomarkers. The hyper reactivity of the B cell Receptor (BCR) to unknown antigen stimulation is associated with malignant B-cell survival. The identification of novel protein expression which is correlated to BCR stimulation may have diagnostic, prognostic and therapeutic value. **Aims.** We aimed to employ proteomics to identify novel proteins associated with BCR stimulation in CLL samples. The expression of putative biomarkers would be correlated with clinical data in a large series of samples. **Methods.** Following ethical approval, blood samples were collected from CLL patients who had not received treatment within 3 months. Peripheral blood mononuclear cells (PBMCs) were extracted and stimulated by crosslinking the BCR with 10 µg/ml $F(ab)_2$ goat anti-human IgM $Fc_{5\mu}$ fragmentat 37ºC. Cells treated with isotype control were included as untreated control. Two-dimensional gel electrophoresis (2DE) with MALDI-TOF mass spectrometry (MS) was used to identify proteins associated with BCR stimulation in 3 CLL samples. Immunoblotting was used to confirm KNG overexpression in BCR-stimulated samples. Following this, a series of 52 CLL samples was screened for basal Kininogen (KNG) expression using immunoblotting. Survival and Time To First Treatment (TTFT) data were available for all CLL samples. Basal KNG expression was correlated with overall survival, TTFT and other prognostic biomarkers. **Results.** Proteomic analysis by 2DE/MALDI-TOF MS revealed upregulation of KNG after 5.5 hours of BCR stimulation in 3/3 clinical samples. Upregulation of KNG after prolonged stimulation was confirmed by immunoblotting in 4 samples, including 2 which were previously analyzed using proteomics. There are 2 major forms of KNG: low molecular weight KNG (LMWK) and high molecular weight KNG (HMWK). The peptides identified in MALDI-TOF MS best matched the sequence of LMWK. The analysis of basal LMWK by immunoblotting revealed positive expression in 69% (36/52) of CLL samples. No statistical significance was found with preliminary clinical correlations however there was a trend towards shorter median survival in LMWK positive cases (152 months as opposed to 264 months for LMWK negative cases) (p=0.161). **Conclusions.** Our study demonstrates for the first time that CLL B-lymphocytes express KNG and that the expression level differs between samples. KNG is an important protein of the Kinin-Kallikrein System and is the substrate for proteolytic cleavage of Bradykinin, which is a mediator of inflammation and pain and also facilitates the increase of vascular permeability. Further research into the expression of LMWK and HMWK and the association with BCR stimulation will determine the potential role of KNG as a prognostic biomarker in CLL.

DETAILED MUTATIONAL ANALYSIS OF TP53 GENE REVEALS HIGH INCIDENCE OF ADDITIONAL MINOR PROPORTION MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

B Kantorova[1], J Malcikova[1], M Trbusek[1], J Smardova[2], J Lochmanova[1], L Sebejova[1], S Pavlova[1], M Doubek[2], J Mayer[2], S Pospisilova[1]
[1]Central European Institute of Technology, Masaryk University, Brno, Brno, Czech Republic
[2]University Hospital Brno, Brno, Czech Republic

Background. Presence of aberrations in the tumor suppressor gene *TP53* is one of the strongest prognostic markers of chronic lymphocytic leukemia (CLL). Besides 17p deletion the individual *TP53* gene mutations were recently associated with unfavorable CLL prognosis. In addition to clonal *TP53* mutations, minor mutations may be detected in some CLL patients. Nevertheless, frequency and importance of mutations present in minor cancer clones wasn't investigated up to now. **Aims.** We employed sensitive *TP53* mutational screening to determine the incidence of minor mutations in CLL patients. **Methods.** For precise mutational testing the combination of functional analysis (FASAY) and denaturing high-performance liquid chromatography (DHPLC; Varian) in connection with direct sequencing was used. Selected samples were investigated by ultra-deep next generation sequencing (NGS; GS Junior System, Roche). **Results.** Mutational status of the *TP53* gene was assessed in 198 samples from 185 selected CLL patients (12 patients were analyzed repeatedly). We found 96 mutations in 63 patients. Notably, in 15 patients with major clonal mutation 20 minor gene mutations were clearly detected (1-3 mutations per patient). Among them, 10 missense mutations, 7 splicing mutations and 3 frameshift mutations were identified. The detected minor mutations were evaluated by ultra-deep NGS in 7 patients, and presence of all 11 tested mutations was confirmed (mutation proportion 3,24% - 6,62%). Interestingly, the patients with minor *TP53* mutations were more frequently pre-treated by chemotherapy in comparison with patients who carried a sole mutation (P = 0.0031). **Conclusions.** Clonal *TP53* mutations are often accompanied with additional minor mutations, particularly in patients after chemotherapy. Our results further support the role of treatment in selection of *TP53* mutations in CLL patients. Evaluation of clinical impact of these minor clones requires systematic long-term analysis of large patients' cohort.This study was supported by research proposal MSM0021622430 and projects CZ.1.05/1.1.00/02.0068, CZ.1.07/2.3.00/20.0045, CZ.1.07/2.4.00/17.0042, MUNI/A/0784/2011.

[6]Department of Hematology, Oncology, Immunology, Hospital Munich-Schwabing, Munich, Germany

Background. A variety of first-line and relapse therapy regimens for patients with advanced chronic lymphocytic leukemia (CLL) have been established in the past years. Though ESMO guidelines recommend to repeat first-line therapy if relapse occurs later than 24 months after first-line chemoimmunotherapy, these recommendations have not been confirmed by clinical trials so far. However, the most beneficial composition and sequence of regimens (antibody-based, chemoimmunotherapy, CHOP-like regimen) regarding patients´ treatment-free and overall survival remains unclear. **Aims.** The aim of this meta-analysis was to evaluate whether special therapeutic regimens have a positive impact on treatment-free and overall survival. **Methods.** From 1659 consecutive patients included in five different study protocols for first-line and relapse of the GCLLSG (CLL4, CLL5, CLL8, CLL2L (Fludarabine + Cyclophosphamide + Alemtuzumab; first-line and in relapse) and CLL2M (Bendamustine + Rituximab; first-line and in relapse) trial) we selected 1558 patients who received at least one therapeutic regimen. 101 patients had to be excluded never having received treatment in one of the trials. Patients were assigned to different treatment categories. For statistical analysis Kaplan-Meier estimators and curves were used including log-rank tests. **Results.** The median age at the beginning of first-line treatment of the whole series (n=1558, 1113M/425F) was 61 (30-81) years.At first, patients were stratified according to the first-line treatment they received. Comparing the different regimens according to the study generations of the last two decades (first generation: CLL 4 - fludarabine monotherapy vs. fludarabine + cyclophosphamide; CLL 5 - chlorambucil monotherapy vs. fludarabine monotherapy; second generation: CLL 8 - fludarabine + cyclophosphamide vs. fludarabine + cyclophosphamide + Rituximab) treatment-free and overall survival steadily increases along with the advances in clinical CLL research (see Figure 1a).Thereafter we focused on different treatment regimens that have been administered at any time during the course of disease. Patients who received an antibody-based regimen at least once during their therapeutic course (n=909) had a significantly longer overall survival than all other patients who had never been treated with antibody-containing therapy (OS after 60 months: 75.7% vs. 64.1%, p=0.006, see Figure 1b).

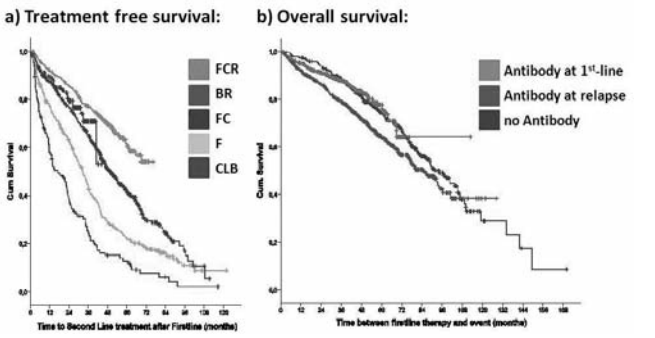

Figure 1. a) Treatment-free survival for patients with different first-line therapies b) OS of pts. with antibody-based regimen vs.pts.with antibody-free regimen.

This was independent from the time point of administration (first-line or relapse).The CHOP-regimen (Cyclophosphamide, Vincristine, Doxorubicine and Prednisolone), which was often chosen as relapse treatment due to its assumed efficacy especially in high-risk situations (early relapse, unfavourable prognostic markers), was used in 202 patients. The overall survival in the CHOP-collective was significantly shorter than in the comparative group ($p<0.0001$) although median observation time was not significantly different. However, this observation might reflect a bias in the selection of high risk patients for this relapse treatment. No influence on survival was observed in patients receiving a mitoxantrone-containing regimen at any time during the treatment course. **Summary and Conclusions.** This meta-analysis shows that the advances in the development of strategies for first-line therapies result in prolongation of treatment-free and overall survival for patients with CLL and need of treatment. Chemoimmunotherapies prolong the survival independently of the time point of chemoimmunotherapy administration (for first-line therapy or relapse).

Background. The advent of chemo-immunotherapy associations has substantially improved the overall response rate (ORR), time to progression, and overall survival of chronic lymphocytic leukemia (CLL). However, CLL remains incurable and patients (pts) eventually relapse. The development of an effective therapy that is not cross-resistant with the treatment strategies currently available as front-line treatment is one of the clinical unmet needs in CLL. **Aims.** Within the GIMEMA network, we conducted a phase II, non-comparative, multicenter study (CLL0809) to assess the efficacy and safety of the combination of bendamustine and ofatumumab in relapsed/refractory CLL. **Methods.** Pts with active CLL, pre-treated with no more than two lines of therapy, were eligible. Therapy consisted of bendamustine (70 mg/m^2) for two consecutive days every 28 days and ofatumumab (300 mg on day 1 and 1000 mg on day 8 at the first cycle and 1000 mg on day 1 at the subsequent cycles). Treatment was administered up to 6 cycles. The response was assessed after 3 cycles and at the end of treatment. An extensive biological characterization was performed in all pts. **Results.** Fifty pts have been registered from 14 centers. One patient was ineligible due to active HBV infection. The median age was 66 years (46-81); 71% of pts were in Binet stages B/C and 30%had bulky adenopathy ≥ 5 cm. FISH analyses detected del(13q), del(11q), +12 or del(17p) in 47%, 12%, 20% and 20% of pts, respectively; 20% of pts carried a p53 mutation and 16% had NOTCH1 mutations; 59% of pts had unmutated IGHV genes,

whereas ZAP-70 and CD38 were positive in 65% and 43% of cases. Previous treatments were fludarabine, rituximab or alemtuzumab-based therapy in 71%, 53% and 12% of pts, respectively; 39% of pts were pre-treated with two lines of therapy.The response was assessable at the 3rd cycle in 35 patients and at the 6th cycle in 18 pts. The ORR was 89% at the 3rd cycle and 79% at the 6th cycle, with respectively 26% and 16% of complete remissions. At the 3rd cycle, pts with 17p- and/or p53 mutation had an ORR of 83%.Hematologic toxicity was the most common adverse event. Grade 3/4 neutropenia, thrombocytopenia and anemia occurred in 65%, 18% and 4% of pts. A total of 3 severe infections were reported, including 2 fatal sepsis. Grade 3 infusion reactions to the first administration of ofatumumab occurred in 4 pts (2 skin rash, 1 sinus bradycardia, 1 hypotension plus dyspnoea).Eight pts went off study: two pts did not start treatment (1 for lack of drug supply and the other for informed consent withdrawal); 3 pts died during therapy (2 deaths were due to sepsis, while 1 patient died owing to a duodenal ulcer hemorrhage); in the remaining 3 pts therapy was stopped because of severe neutropenia, acute myocardial infarction or increased troponine levels. **Conclusions.** This preliminary analysis shows that the combination of ofatumumab and bendamustine is feasible and substantially effective in relapsed/refractory CLL patients with high risk clinical and biological features.

0146

CHLORAMBUCIL FOR THE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) - SYSTEMATIC REVIEW AND META-ANALYSIS

L Vidal[1], R Gurion[2], A Gafter-Gvili[2], P Raanani[2], O Bairy[2], T Robak[3], O Shpilberg[2]
[1]Rabin Medical Center, Israel, Israel
[2]Davidoff Center, Rabin Medical Center, Petah Tikva, Israel
[3]Department of Hematology, University of Lodz, Copernicus Memorial Hospital, Lodz, Poland

Background. Many trials assessing treatment for patients with CLL/SLL compares chlorambucil to different regimens, including other alkylating agents, purine analogues, and alemtuzumab. So far, none of these regimens improved overall survival as compared to chlorambucil, though improved response rates were shown with purine analogues. **Aims.** To assess the effect of chlorambucil on overall survival compared to other therapeutic regimens in patients with CLL/SLL requiring therapy. **Methods.** Systematic review and meta-analysis of randomized controlled trials that compared chlorambucil to other therapeutic regimens for patients with CLL/SLL requiring chemotherapy. We searched *The CochraneLibrary*, MEDLINE, LILACS, conference proceedings, and databases of ongoing trials. The primary outcome wasoverall survival. Secondary outcomes: complete response (CR) and overall response (complete and partial) rates, adverse events. Relative risk (RR) for dichotomous data and hazard ratio (HR) for time to event data were estimated and pooled. **Results.** We identified 18 trials recruiting patients between the years 1978 and 2006 randomizing 4662 adult patients, with previously untreated CLL/SLL. In 16 of the trials the mean/median age was less than 65 years. Indications for treatment were advanced disease (Binet stage B/C or Rai stage III/IV) or progressive disease at any stage. Chlorambucil was compared to fludarabine or cladribine; cyclophosphamide, vincristine, prednisone (COP); cyclophosphamide, adriamycin, vincristine, prednisone (CHOP); bendamustine; and alemtuzumab. Chlorambucil had a similar effect on overall survival as other chemotherapeutic regimens (HR 1.01, 95% CI 0.90 - 1.13, 15 trials, 4119 patients, random-effects model, Figure 1). Figure 1 depicts the effect of specific regimens compared to chlorambucil on overall survival. Sub-group analysis of overall survival showed a similar effect in different age groups, different comparators, and year of publication. Overall response rate did not differ between the allocated treatment groups. CR rate was inferior for chlorambucil compared to other chemotherapy regimens (RR 0.58 95% CI 0.36, 0.96, 4050 patients, 16 trials). Subgroup analysis of CR rate demonstrated that CR was inferior for chlorambucil compared to purine analogues, but not compared to COP or CHOP. Risk of grade 3/4 adverse events decreased with chlorambucil treatment (RR 0.59 95% CI 0.48 - 0.72, 3304 patients) as well as that of adverse events requiring discontinuation of chemotherapy (RR 0.45 95% CI 0.30 - 0.67, 3545 patients). **Conclusions.** Our systematic review showed with the perspective of time that chlorambucil remains a viable therapeutic option for patients with CLL/SLL due to similar effect on overall survival and overall response rate and a lower toxicity profile compared to other regimens in all age groups. Fludarabine containing regimen may be preferred in younger patients due to a higher complete remission rate. These results are limited by heterogeneity of the chemotherapeutic protocols, the wide range of study years, and the low quality of some of the included trials. None of the allocated treatments contained rituximab, which is currently the standard of care for first line treatment in CLL/SLL. Ongoing trials currently compare the effect of different chemotherapeutic regimens combined with rituximab to chlorambucil and rituximab.

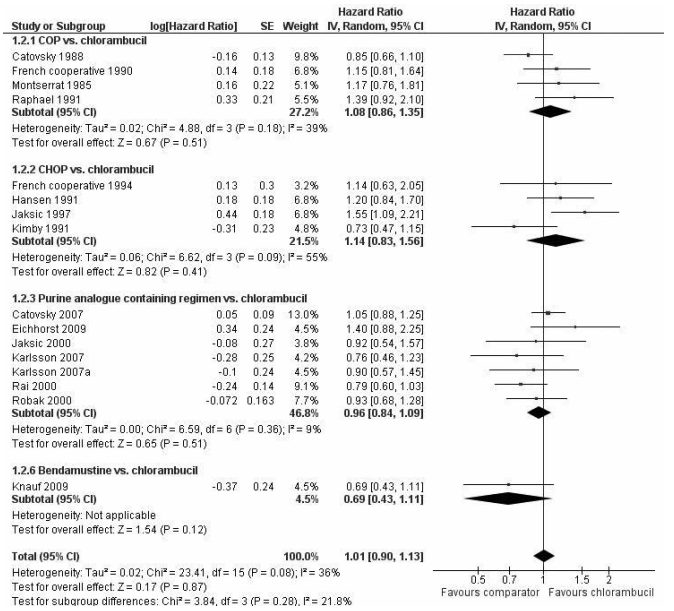

Figure 1. Effect of chlorambucil compared to other chemotherapeutic regimens on overall survival in CLL.

Background. Despite a substantial improvement of treatment outcomes in patients with CLL due to development of more efficacious combination therapies and introduction of rituximab, almost all patients will eventually relapse. According to ESMO guidelines, repetition of 1st-line therapy is a reasonable approach only in case of a relapse >24 months after initial treatment (Eichhorst et al., Ann Oncol., 2011). Little is known which therapy should be chosen in case of an earlier relapse. **Aims.** The purpose of this analysis was to evaluate the outcome of different 2nd-line therapies after early relapse in order to identify potent 2nd-line regimen. **Methods.** A total of 1558 patients were treated within 5 trials of the GCLLSG. Three trials evaluated 1st-line therapies for physically fit (CLL 4 and CLL8) and elderly patients (CLL5), another 2 trials included 1st-line and relapsed patients (CLL2M and CLL2L). 315 of these patients required 2nd-line therapies within 24 months. **Results.** First-line therapies of these 315 patients included fludarabine, cyclophosphamide (FC, n=100), fludarabine (F, n=85), chlorambucil (Clb, n=62), FC with rituximab (FCR, n=34) or bendamustine and rituximab (BR, n=17).Second-line therapies applied in these early relapsing patients were quite heterogeneous. Common therapies were the combination of cyclophosphamide, doxorubicine, vincristine, and prednisolone either with rituximab (CHOPR, n=32) or without (CHOP, n=24), followed by alemtuzumab (A, n=27), FC (n=26), BR (n= 20), FCR (n=16) or FC

with mitoxantrone (FCM, n=16). Less intense treatment approaches with single-agent chemotherapies, such as F (n=37), Clb (n=21) or bendamustine (B, n=15) were chosen in 87 patients. 10 patients receiving a stem cell transplantation, experimental drugs, irradiation or splenectomy were excluded from further analyses.Treatment regimen were allocated to three different relapse treatment groups: combined chemo(immuno)therapy or single-agent antibody-treatment (e.g. A, FC, FCR, BR), single-agent chemotherapies (e.g. F, B, Clb) and chemo (immuno) therapy with anthracyclines and/or ≥3 cytotoxic agents (e.g. CHOPR, CHOP, FCM). Median treatment free survival (time from 2nd-line to 3rd-line therapy or death) was 24.5, 18.7 and 16.4 months respectively (p=0.009). These inequalities in treatment efficacy translated into a significant difference in overall survival (OS): the median OS was 78.3 and 58.2 months in patients treated with either combined chemo(immuno)therapies/single agent antibody-therapies or single-agent chemotherapies, whereas patients with combined chemo(immuno)therapies containing anthracyclines and/or ≥3 chemotherapies had the worst median OS of 42.0 months (p=0.012). A higher median age in the single-agent chemotherapy group (67 versus 60 and 61 years) might have biased the treatment selection. All other patient characteristics, such as prognostic markers (IgHV status, cytogenetics, thymidine kinase and ß2-microglobuline), response to 1st-line therapy, time between 1st- and 2nd-line therapy and ECOG status did not differ between the three groups. **Summay and Conclusions.** Patients with a relapse <24 months who received therapies that contain ≥3 cytotoxic agents and/or anthracyclines had an impaired OS. Therefore, therapies such as CHOPR, CHOP or FCM appear to be inferior in comparison to standard chemoimmunotherapies or single-agent alemtuzumab. However, the worse outcome of early relapsing patients underscores the need for alternative treatment approaches with either allogeneic stem cell transplantation or use of novel drugs.

[2]University Hospital Heidelberg, Heidelberg, Germany

Background. With the increasing complexity of recurrent mutations in chronic lymphocytic leukemia (CLL), the clinical application and translation of genetic information is challenging. As CLL patients with *TP53* abnormalities require alternative treatment approaches, there is an urgent need for rapid and reliable assessment of genetic lesions that can easily be transferred to clinical practice. **Aims.** Our aim was to apply state-of-the-art technology to genotyping of leukemia. **Methods.** We designed a sensitive and reliable multiplex PCR system to analyze recurrent mutations in CLL. Based on a test set (n=59) with parallel Sanger sequencing, we developed a 454-based next-generation sequencing (NGS) approach to rapidly profile a panel of mutations in CLL-relevant and cancer consensus genes (*BRAF, EZH2, KRAS, MYD88, NOTCH1, NRAS, PIK3CA, SF3B1, TP53*). We validated the performance of the assay in a separate validation set (n=181) and thus contribute to mapping of the genetic profile of CLL. Exons with hotspot mutations in candidate genes and *TP53* (exons 4-10) were amplified for sequencing in 2 multiplex PCRs. We aimed at a minimum coverage of 30 reads per amplicon and achieved a medium coverage of 175 reads per amplicon. **Results.** We found a total of 40 non-synonymous sequence variants in the initial patient set. The most common mutations were found in *TP53* (17/40)*, SF3B1* (11/40), and *NOTCH1* (9/40) (Figure 1). To confirm the assay performance and CLL mutation profile, we used a validation set of 181 CLL patients. The incidence of mutations and the most commonly mutated genes were similar in both data sets. All variants were verified by Sanger sequencing. In addition to known recurrent mutations in CLL, we also identified rare (but in part targetable) mutations in *BRAF* (1/40), *MYD88* (1/40), and *KRAS* (1/40) (Figure 1). Importantly, mutations in small subclones were only detectable using our newly established multiplex PCR and 454 sequencing approach. **Summary and Conclusions.** Our results provide evidence that recurrent gene mutations can be analyzed robustly with higher sensitivity than Sanger sequencing by using a NGS approach based on multiplex PCR. The in-depth analysis of the genetic profile of patients with CLL is a prerequisite for the design of genotype-specific treatment approaches. In accordance with previous studies, we show that *TP53*, *SF3B1,* and *NOTCH1* are commonly mutated in CLL.

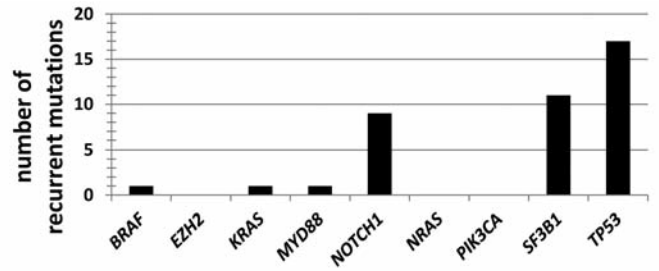

Figure 1. Distribution of recurrent mutations in CLL patients.

[14]Willamette Valley Cancer Institute and Reserach Center, Springfield, United States of America

Background. Btk supports activation, survival, and proliferation of malignant B cells in CLL and B-NHL. AVL-292 is an oral, potent (IC_{50} < 0.5nM), selective small molecule covalent inhibitor of Btk. **Aims.** To characterize the safety, dose limiting toxicity (DLT), maximum tolerated dose (MTD), pharmacokinetics (PK), pharmacodynamics (Btk occupancy), recommended phase 2 dose, and preliminary efficacy of AVL-292 in CLL and B-NHL. **Methods.** Following informed consent, patients (pts) with previously treated CLL or B-NHL received AVL-292 in escalating doses of 125, 250, 400 or 625 mg po QD per cohort using a 3+3 design in continuous 28 day cycles until progressive disease (PD) or toxicity. Plasma AVL-292 levels were assessed by LC-MS-MS. Btk occupancy by AVL-292 was assessed by covalent probe assay in blood mononuclear cells. **Results.** 16 pts have enrolled (3 each @ 125 and 250 mg, 6 @ 400 mg, and 4 @ 625 mg: 8M/8F; median age 66 years (range 45-79); median 2 prior therapies (range 1-10)) including 9 CLL (2 with del17p, 2 with del11q22, 2 with both del17p/del11q22; 2 mutated *IGHV*, 5 unmutated *IGHV*, 2 missing) and 7 B-NHL (1 diffuse large B cell lymphoma (DLBCL); 3 follicular (FL); 2 marginal zone (MZL); 1 mantle cell). Median time on treatment is 94 days, range 15-204. Thir-

teen of 16 pts continue treatment: 1 pt discontinued (dc'd) for PD after 6.75 cycles (CLL); 1 dc'd for PD after 1 cycle (DLBCL); and 1 dc'd for DLT (Gr 4 thrombocytopenia; 400 mg QD; FL). No other DLTs or grade 4 adverse events (AEs) have occurred and MTD has not been reached. Treatment emergent AEs (at least 2 subjects regardless of dose) reported as related to AVL-292 include transient diarrhea (5/16; 31.3%), and nausea and urticaria (2/16 each; 12.5%). Related Gr 3 AEs include 1 thrombocytopenia (possibly related) and 1 ANC low (probably related). Eight of 9 CLL patients have achieved best response of stable disease (SD) with median 28% decrease from baseline lymph node measurement (range 4-55% decrease; 1 pt > 50% decrease). One pt who achieved SD progressed after 6.75 cycles of AVL-292; and 1 pt is too early to evaluate for response. Six of 9 pts with CLL experienced > 10% increase in ALC over baseline in cycle 1, median increase 89.5% (range 50-212%), apparently due to re-distribution of CLL cells into the blood. Two of 7 NHL pts have SD (both MZL), 1 PD (DLBCL), 1 not evaluable due to DLT (FL), and 3 too early to evaluate. Full Btk occupancy was achieved with dose levels ≥ 250 mg. PK exposure (AUC_{last})was dose-proportional with no accumulation from Day 1 to 15. **Summary and Conclusions.** AVL-292 was well tolerated at 125, 250, and 400 mg po QD and early efficacy analysis in CLL and B-NHL shows 10/11 efficacy evaluable pts with best response of SD. Full Btk occupancy was achieved with ≥ 250 mg QD and PK was predictable with no accumulation. Additional study of 625 mg QD is ongoing. MTD cohort expansion is planned.

0150

THE INCIDENCE OF SECONDARY TUMORS IS NOT HIGHER IN PATIENTS TREATED FOR CLL COMPARED TO THE UNTREATED COHORT OF PATIENTS BUT IT IS HIGHER IN OLDER COMPARED WITH YOUNGER TREATED PATIENTS

M Trneny[1], P Obrtlikova[2], D Maluskova[3], J Muzik[3], L Dusek[3]
[1]Institute Hematology Blood Transfusion, Praha, Czech Republic
[2]Charles University General Hospital, Praha, Czech Republic
[3]Institute biostatics, Brno, Czech Republic

It is generally accepted that patients with CLL are in the higher risk of secondary tumors compared to the nonCLL population. Moreover, it has been demonstrated that some of the antileukemic treatments can be associated with secondary malignancies. There is however lack of data comparing treated and untreated populations.We have performed population based analysis of CLL patients diagnosed between 1977-2009 and recorded in the National Cancer Registry. Standard descriptive (median, percentile range) and epidemiological (crude incidence rate) statistics were used. The cumulative incidence of multiple malignancies developed over the time was estimated using standard KM estimates. Different cohorts were compared using Gray's test.Altogether 14408 pts with median age 70 years were included into the analysis. The crude incidence of tumors in this population was 2137 pts (14.9%). Out of these pts 861 (6,0%)were diagnosed before or concurrently with the CLL diagnosis. Altogether 1276 were diagnosed after the CLL diagnosis. Out of tumors after CLL dg , most frequent secondary malignancies were: lung cancer (18.8%), colorectal cancer (16.0%), prostate cancer (9.1%), renal cancer (7.4%), urine bladder cancer (5.8%), melanoma (5.1%). The cumulative incidence of secondary tumors at 5, 10 and 15 years resp. was 10, 14 and 16% resp. There was no significant difference between treated and untreated population in all time points, 9 vs 11%, 13 vs 15% and 15 vs 17% resp (ns p=0.228). We analysed two cohorts of pts - younger and older than 60 from the time of CLL dg. We have demonstrated trend (however no significant and inverse) in difference of cumulative incidence of sec. tumors between the young pts treated vs untreated in all time points (12 vs 13% at 10y, p = 0,068,) as well as in the the older population (17% vs 13% at 10y, p = 0.059). We have analysed both cohorts with the landmark analysis for treated pts from the time of first treatment and the cumulative incidence of secondary tumors in the younger cohort vs older cohort was statistically significantly different (p = 0.013), at 5, 10 and 15 y respectively it was 9% vs 14%, 13 vs 17% and 16 vs 18% resp. **Conclusions.** We have demonstrated in this population-based analysis the cumulative incidence of secondary malignancies in treated CLL patients at 15 y 17%, which is not significantly higher compared with untreated patients. The incidence is however significantly higher in older compared to younger patients. The underlying CLL seems to be more important for the onset of secondary malignancies compared to the treatment itself.

0151

LOW-DOSE FCR IN THE TREATMENT OF ELDERLY/COMORBID PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA/SMALL LYMPHOCYTIC LYMPHOMA (CLL/SLL): UPDATED RESULTS OF PROJECT Q-LITE BY CZECH CLL STUDY GROUP

L Smolej[1], Y Brychtova[2], M Spacek[3], M Doubek[2], M Motyckova[1], D Belada[1], E Cmunt[4], V Prochazka[5], P Rohon[5], H Poul[6], K Klaskova[3], T Kozak[3]

[6]Hematology/Tranfusiology Department, Hospital, Pelhrimov, Czech Republic

Background. Combination of fludarabine, cyclophosphamide and rituximab (FCR) is currently considered the treatment of choice in physically fit patients (pts) with chronic lymphocytic leukemia (CLL). However, many patients cannot tolerate this aggresive approach because of advanced age and/or serious comorbid conditions leading to unacceptable toxicity. For these patients, chlorambucil remains so far the standard of treatment. However, regimens based on low-dose fludarabine have recently demonstrated promising results in small studies. **Aims.** to assess efficacy and safety of low-dose FCR regimen used in elderly/comorbid patients with CLL/SLL: updated results are presented. **Patients and Methods.** Between March 2009 and February 2012, we treated 169 pts with active disease and efficacy/safety data are currently available on 145 pts (CLL, n=137, SLL, n=8, males, 59%, median age, 69 years [range, 58-87], median Cumulative Illness Rating Score 4.5 [range, 0-14], median creatinine clearance, 67 ml/min) by low-dose FCR at 17 centers cooperating within Czech CLL Study Group. Dose reduction of chemotherapy in comparison to regular FCR regimen was following: 50% of fludarabine dose (12 mg/m^2 i.v. or 20 mg/m^2 orally on day 1-3) and 60% of cyclophosphamide dose (150 mg/m^2 i.v./p.o. on day 1-3). Rituximab was administered in standard schedule (375mg/m^2 i.v. day 1 in 1st cycle, 500mg/m^2 i.v. day 1 from 2nd cycle). Treatment was repeated every 4 weeks. Antimicrobial prophylaxis with sulfamethoxazol/trimethoprim and aciclovir or equivalents was recommended. A total of 50% pts were untreated, remaining half had relapsed/refractory disease (median previous lines 1, range, 1-6). Advanced Rai stages (III/IV) were present in 61% pts; 39% had bulky disease. IgVH genes were unmutated in 74%; according to Doehner´s FISH hierarchical model, del 11q was present in 34% and del 17p in 6%. **Results.** Based on intention-to-treat principle, the overall response/complete response rate (including clinical CR [without bone marrow biopsy] and CR with incomplete blood count recovery) was 81/43% in first line and 69/35% in relapse. Serious (CTCAE grade III/IV) neutropenia occurred in 53%, thrombocytopenia in 12% and anemia in 12% of pts. Serious infections developed in 10% of pts. Median follow-up of living patients was 13 months (range, 2-31). Twenty-five patients have died; the most common causes of death were CLL progression and infections. Longer follow-up is necessary for PFS/OS and quality of life data. **Conclusions.** Treatment of elderly/comorbid CLL/SLL patients with low-dose FCR demonstrated promising results in first line as well as relapsed/refractory setting. Toxicity was acceptable and manageable. Recruitment in the study is ongoing and updated results will be presented. Supported by research project MZO 00179906 from Ministry of Health, Czech Republic.

RELAPSES IN HAIRY CELL LEUKEMIA

L Al-Radi[1], A Pivnik[2], S Kravchenko[1]
[1]Research Center for Hematology, Moscow, Russian Federation
[2]Medical Center „Genotehnology„, Moscow, Russian Federation

Background. Hairy cell leukemia (HCL) is an indolent lymphoproliferation effectively treated with purin analogous. However, relapses occurs and different treatment, including rituximab-containing regimens are tested. **Aims.** To estimate prognostic factors leading to relapse and survival benefit produced by addition of rituximab to purin analogous therapy. **Methods.** Between January 1995 - December 2011 196 HCL pts were treated with 2-CdA. Treatment schedules were standard. Relapse rate and its relationship to HCL form, patients clinical characteristics and results of relapse treatment were analyzed. *Results.* By February 2012r data on 165 patients was available (M:F=2,4:1, 72% classical HCL, median age 49 years, range 25-81). We detected 44 relapses in 38 (23%)

patients (M:F=2,4:1, median age 41 years (range 25-73), 71% classical HCL, 74% had 1st CR). Relapses developed within 1,5 - 12 years after 2-CdA treatment (median 3 yrs). Frequency of relapses has increased with duration of follow up from 8% in patients observed for 2 months - 6,5 years (median 3 yrs), to 61% in patients with follow up for 10 - 16 years (median 14,6 yrs). Patients with relapses (n=38) and those keeping remission (n=127) didn't differ authentically on quality of the previous remission (complete or partial), on HCL form (typical or variant), on gender (M or F). The only authentic difference was the patient's age at the moment of disease occurrence, as relapses has happened in 28 (49%) out of 57 patients younger then 45 yrs., in comparison with only 10 (9%) relapses in 108 patients older than 45 yrs. The median of disease free survival in young patients was 64 months while in older patients it was twice more and equaled 133 months However, the overall survival remained identical. What is the reason of the raised risk of relapse at the "young HCL patients"isn't clear yet. 2-CdA was administrated for relapsed HCL again, and has led to remission in 30 (91%) of 33 patients. Nevertheless the second relapse has developed later in 6 patients (5 of them young patients). Eight patients died - 3 in the 2nd CR for other then HCL reasons, 5 due HCL (2 from infections before treatment and 3 of inefficient application of 2-CdA). It has appeared that the results of the treatment of relapsed HCL depend on application rituximab if the first remission was short (remission duration less than 4 yrs). So, in 15 relapsed patients who have received only 2-CdA, the 2nd relapse developed in 5 of 7 patients (71%) with early relapse, and only in 1 of 8 patients (14%) with late relapse. However, in 11 relapsed patients who received 2-CdA plus subsequent course of rituximab the 2nd relapse hasn't developed not in 9 patients with early relapses, nor in 2 patients with late relapses with a median of observation after 2-CdA 33 months and after rituximab 12 months. *Conclusions.*We consider that 2-CdA should be followed by rituximab in HCL patients with early relapses or to prevent the relapse in HCL patients younger than 45 yrs.

OTHER CANCERS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA FOLLOWED AT THE M.D. ANDERSON CANCER CENTER FOR LONGER THAN 10 YEARS

A Ferrajoli, L Falchi, M Keating, S Lerner, S Strom, W Wierda
MD Anderson Cancer Center, Houston, United States of America

Background. Pts with chronic lymphocytic leukemia (CLL) have an increased incidence of other cancers (OC). However, detailed description of their occurrence in pts with prolonged follow-up has not been reported. **Aims.** Report the frequency, stages, time relationship with the diagnosis of CLL, impact on survival, and types of OC occurring after treatment in pts with follow-up >10 years. **Methods.** We reviewed our database and selected untreated pts with CLL and survival >120 months from referral to MD Anderson Cancer Center. We identified pts with an OC either before or after the diagnosis of CLL.

Table 1. Distribution of OC in 694 pts with CLL and follow-up >10 years.

	ALL OC[1]				OC excluding NMSC[2]

[1]other cancers; [2]non-melanoma skin cancer; [3]gastrointestinal; [4]head and neck; [5]therapy-related myelodysplastic syndrome/acute myeloid leukemia; [6]uterus-vagina-vulva; [7]peripheral nervous system; [8]non-Hodgkin lymphoma (excluding Richter's syndrome)

Results. We identified 694 pts with CLL, referred between 1959 and 2001, untreated and with complete follow-up. We identified 210 individual OC in 166 pts (24%). Sixty six/166 pts (40%) had prior history of OC at the time of diagnosis of CLL or an OC diagnosed concomitantly with CLL, whereas 100 pts (60%) were diagnosed with an OC after CLL. Four hundred thirty pts (62%) required treatment, 264 (38%) were on watch-and-wait. Among treated pts 102 (24%) were diagnosed with OC, among pts on watch and wait 64 (24%) had an OC. In the treated pts, 35 (8%) had an OC detected before/concomitantly and 67 (16%) had an OC after the diagnosis of CLL. Among pts on watch and wait: 30 (11%) and 34 (13%) had an OC before/concomitantly and after CLL, respectively. The frequency, type and timing of OC are shown in Table 1. Non-melanoma skin cancers (NMSC) were excluded from subsequent analyses as all of them were localized and prognostically irrelevant. Median time to first OC was 116 (1-352) months for the entire population, 121 (4-352) in treated pts and 56 (1-273) in pts on watch and wait. In terms of survival, median overall survival (OS) is 153 (121-361) months in pts with OC, whereas it has not been reached in pts without OC with a median follow-up of 155 months (214/579, 37% dead). Moreover, median OS was 160 (121-361) months in pts who developed OC after the diagnosis of CLL and it has not been reached in pts with a history of OC prior to or at the time of CLL (median follow-up of 143 months, 19/44, 43% dead). To further identify differences between the latter two groups, we reviewed the stage of OC, excluding NMSC and hematological OC. The presence of metastases to either lymph nodes or distant organs was recorded in 6/46 pts (13%) with an OC before/concomitantly with CLL and in 17/79 pts (21%) who developed OC after CLL. **Summary and Conclusions.** In pts with CLL and >10 years of follow-up, the incidence of OC is similar in treated and watch-and-wait pts. Time to first OC is longer in pts treated for CLL compared to pts on watch-and-wait. Interestingly, the median survival of pts who developed OC after the diagnosis of CLL is 153 months, whereas it has not been reached pts without OC at a median follow-up of 155 months.

0154

CUMULATIVE ILLNESS RATING SCALE (CIRS) IS A VALUABLE TOOL TO ASSESS AND WEIGH COMORBIDITY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS FROM THE CLL8 TRIAL OF THE GERMAN CLL STUDY GROUP

V Goede[1], R Busch[2], S Stilgenbauer[3], E Winter[4], A Fink[4], K Fischer[4], M Hallek[4]
[1]University of Cologne, Cologne, Germany
[2]Institute of Medical Statistics and Epidemiology, Technical University Munich, Munich, Germany
[3]Department III of Internal Medicine, University of Ulm, Ulm, Germany
[4]Department I of Internal Medicine, Center for Integrated Oncology, University of, Cologne, Germany

Background. A significant number of patients with chronic lymphocytic leukemia (CLL) have additional health problems, but a threshold at which comorbidity starts to influence survival and treatment toxicity is unknown. This lack of evidence makes it difficult for (i) clinicians to anticipate the impact of comorbidity on treatment outcome of individual CLL patients and (ii) scientists to define trial eligibility criteria which allow the stratification of CLL patients by medical fitness. **Aims.** To investigate whether the Cumulative Illness Rating Scale (CIRS) or other comorbidity scores are appropriate to predict mortality and treatment toxicity among the 817 subjects enrolled on the CLL8 trial of the German CLL Study Group (FC versus R-FC). **Methods.** A pretherapeutic CIRS assessment performed by the local investigators in all trial participants was used to extract information on the total score (CIRS-TOT), numbers of involved organs systems (CIRS-SYS), and organ-specific severity scores (CIRS-ORG). The Charlson Comorbidity Score (CCS) and the NCI Comorbidity Score (NCI-CS) were abstracted from the CIRS and from additional comorbidity data captured on the trial database. **Results.** The median (range of) CIRS-TOT, CCS and NCI-CS was 1 (0-8), 0 (0-4) and 1 (0-5), respectively. Of the 817 patients, 8% presented with more than 3 organ systems affected by comorbidity (CIRS-SYS >3) and 18% with at least one organ system affected by comorbidity of moderate or higher grade (CIRS-ORG =2-4). By univariate analysis, higher scores of CIRS-TOT, CIRS-SYS, CIRS-ORG, CCS, and NCI-CS all were associated with increased mortality. Predictors of reduced overall survival (OS) were CIRS-TOT >3 vs. 0-3 (HR 1.9, 95%CI 1.4-2.7, p<0.001), CIRS-SYS >3 vs. 0-3 (HR 2.5, 95%CI 1.6-3.7, p<0.001), CIRS-ORG 2-4 vs. 0-1 (HR 1.9, 95%CI 1.4-2.6, p<0.001), CCS >0 vs. 0 (HR 1.6, 95%CI 1.1-2.2, p=0.006), and NCI-CS >3 vs. 1-3 vs. 0 (HR 2.6, 95%CI 2.3-4.9, p=0.004; HR 1.5, 95%CI 1.1-2.0, p=0.006). Among these, CIRS-SYS and CIRS-ORG were the most powerful predictors of mortality in a Cox regression model. Three risk groups were identified: CIRS-SYS 0-3 and CIRS-ORG 0-1 (median OS: not reached), CIRS-SYS >3 or CIRS-ORG 2-4 (median OS: 69.7 months), CIRS-SYS >3 and CIRS-ORG 2-4 (median OS: 42.4 months). Theses CIRS parameters kept their independent prognostic value (p<0.001) in a Cox regression model including other survival factors (sex, age, performance status, Binet stage, serum factors, genomic aberrations, IGHV mutation status). Patients with CIRS-ORG 0-1 vs. 2-4 differed in their

risk of grade 3-4 toxicity (66% vs. 81%, p<0.001). **Conclusions.** This study establishes CIRS as a helpful assessment tool in CLL by identifying thresholds at which comorbidity impact on mortality and toxicity of patients treated with FC or R-FC.

PHASE I FEASIBILITY TRIAL OF CYCLOPHOSPHAMIDE, ALVOCIDIB (FLAVOPIRIDOL) AND RITUXIMAB (CAR) IN PATIENTS WITH HIGH-RISK B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)/SMALL LYMPHOCYTIC LYMPHOMA (SLL)

M Stephens, K Maddocks, L Andritsos, R Baiocchi, J Jones, M Phelps, A Johnson, L Smith, M Grever, J Byrd, J Flynn
The Ohio State University Medical Center, Columbus, OH, United States of America

Background. Specific genomic [del(17p 13.1), del(11q22.3), un-mutated IgVH] and clinical [age ≥70 years] risk factors are strongly associated with poor outcomes in CLL patients. Fludarabine-based immunochemotherapy regimens, such as fludarabine, cyclophosphamide, and rituximab (FCR), have been the mainstay of therapy for CLL, despite lack of effectiveness in high-risk CLL patients and the propensity for profound immune suppression. In contrast, alvocidib, the cyclin-dependent kinase inhibitor, is effective in this high-risk group and does not promote the same cellular immune suppression typically seen with fludarabine. Additionally, cyclophosphamide has been shown to be effective specifically in patients with del(11q22.3). **Aims.** Our aim was to develop an effective regimen for nucleoside analog-naive patients, which combines the efficacy of cyclophosphamide, alvocidib, and rituximab (CAR) in a schema designed to mitigate toxicities such as tumor lysis syndrome (TLS) and cytokine release syndrome (CRS). Our primary goals were to determine the tolerability and feasibility of frontline administration of combination CAR therapy to patients with high-risk CLL. **Methods.** We conducted a phase I trial of CAR in symptomatic CLL/SLL patients with high genomic or clinical risk disease. All patients had ≤1 prior therapy, ECOG performance status of 0-2, and adequate organ function. Patients in all cohorts received rituximab 100mg IV day 1 (of 21) of cycle 1 and 375 mg/m^2 IV on day 2 of cycle 1 and day 1 of cycles 2-6. Patients received either 300 mg/m^2 (cohorts 1 and 2) or 375 mg/m^2 (cohort 3) of IV cyclophosphamide on days 1-3. Patients received 30 mg/m^2 IV alvocidib over 30 minutes, followed by 30 mg/m^2 (cohort 1) or 50 mg/m^2 (cohorts 2 and 3) IV alvocidib over 4 hours day 8 of cycle 1 and days 1 and 8 of cycles 2-6. Standard 3x3 design was utilized with nine patients completing therapy, three in each cohort. **Results.** Median age was 55 years (range 43-77 years) and 7 were male. Patients had the following high risk features: del(17p 13.1) (*n*=3), del(11q22.3) (*n*=4), un-mutated IgVH (*n*=7), and age >70 years (*n*=2). All patients completed 6 planned cycles with exception of one patient in cohort 2, who stopped therapy after cycle 4 due to lack of response. Dose limiting toxicity was not reached. Toxicities observed were typical of those reported with the three individual drugs and were manageable. Importantly, there were no instances of TLS or significant CRS.All 9 patients were evaluable for response by 2008 IWCLL criteria. Three patients achieved CR, 4 achieved PR, 1 had stable disease, and 1 had progressive disease (PD). The patient with PD was 77 years old and had del(17p13.1) and un-mutated IgVH cytogenetics. **Conclusions.** Combined therapy with CAR is well tolerated in patients with genomic and clinical high-risk CLL. The known severe side effects of TLS and CRS were not observed with the novel timing of alvocidib in this regimen. This combination could offer advantages over standard frontline therapies for CLL patients in this high-risk group. Further study of this regimen is warranted in the setting of a phase II clinical trial.

0156

PROGNOSTIC RELEVANCE OF CD49D EXPRESSION ON B LEUKEMIC CELLS IN CHRONIC LYMPHOCYTIC LEUKEMIA. META-ANALYSIS OF PUBLISHED AND UNPUBLISHED INDIVIDUAL DATA FROM 3146 PATIENTS.

P Bulian[1], T Shanafelt[2], C Pepper[3], C Fegan[3], G Del Poeta[4], D Rossi[5], G Gaidano[5], L Cro[6], L Baldini[6], H Nückel[7], J Burger[8], V Gattei[1]

[6]Ospedale Maggiore, Milano, Italy
[7]Department of Haematology, University of Duisburg-Essen, Essen, Germany
[8]University of Texas MD Anderson Cancer Center, Houston, United States of America

Background. A number of investigators have provided data supporting the value of CD49d expression on B leukemic cells in chronic lymphocytic leukemia (CLL) as independent prognostic variable. These studies used a variety of clinical end points including overall survival (OS), time to treatment (TTT) or treatment free survival (TFS). The factors included in multivariate analyses of these studies also differed. Unresolved issues regarding the prognostic value of CD49d assessment in CLL included the choice of the optimal cut-off to define positivity and CD49d prognostic value in patients subsets defined by other standard prognostic factors. **Aim.** To perform meta-analysis using individual patient level data from studies of CD49d expression to evaluate its ability to predict OS (primary end-point) and TTT/TFS (secondary end-point). **Methods.** Studies published by 30 April 2011, reporting an association of high CD49d expression on B CLL cells, measured by flow cytometry, and end-points were identified by Medline search. Additionally, we performed a manual review of abstracts presented at the congress of the American Society of Hematology from 2006 to 2010. CD49d was used as a categorical variable, as coded in original studies.*Results.* We identified 6 published studies and one abstract for inclusion. All authors agreed to provide individual data on the patients in these publications as well as unpublished data on additional patients to be used for replication analysis. Four authors also submitted updated follow-up data. We collected the following variables: date of diagnosis, OS, TTT/TFS, CD49d, CD38, ZAP-70, immunoglobulin mutational (IGHV) status, del17p and del11q chromosomal aberrations, age, stage, ALC, and β2 microglobulin concentration. Data from 3146 individual patients was available with 261 subsequently excluded due to missing end point and/or CD49d data. Of 2771 patients with valid data, 1405 (51%) were included in the previous publications and 1366 (49%) were unpublished. Before starting analyses a decision was made to perform meta-analysis on published data and use data from previously unpublished data as a validation cohort. Pooled CD49d hazard ratio for OS was 2.62 (1.88-3.64). In bivariate analysis, the prognostic value of CD49d was confirmed and of comparable value in patients subsets defined by CD38 and ZAP-70 expression, IGHV status, unfavorable chromosomal aberrations. Finally, we performed a multivariate analysis including CD49d, CD38, ZAP-70, IGHV status, del17p and del11q. CD49d was significantly associated with shorter overall survival in this adjusted model, with a hazard ratio of 2.47(1.17-5.21). Inspection of Martingale residuals plots of CD49d in each study failed to show a recognizable cut-point. Accordingly, rather than using a data driven approach, these analyses suggest choosing a cut-point on pure distributional criteria or by a data independent approach. Analysis using such a strategy is underway with plans for validation in the cohort of 1366 unpublished patients. **Conclusions.** Preliminary results of a meta-analysis using individual patient data from >1400 patients confirm the association of high CD49d expression with short OS independent of other prognostic parameters. These findings may have implication for patient's stratification in future prospective studies and potential therapeutic efforts to target CD49d or CD49d signaling.

0157

APPLICATION AND FEASIBILITY OF ALLOGENEIC STEM CELL TRANSPLANTATION IN T-PROLYMPHOCYTIC LEUKEMIA: A SINGLE INSTITUTION EXPERIENCE OF 27 PATIENTS

N Sulai, L Oliveira, P Ketterling, S Zent, G Call, D Shanfelt, J Hogan, R Litzow, L Patnaik
Mayo Clinic, Rochester, United States of America

Background. T- prolymphocytic leukemia (T-PLL) is an aggressive T cell neoplasm associated with a poor response to chemotherapy and a median survival of < 1 year. Therapy with alemtuzumab has improved overall response (51-76%) and complete remission rates (40-60%); however the median survival continues to remain short. Finally, recent data has pointed towards potential benefit in patients with T-PLL from allogeneic hematopoietic stem cell transplantation (HSCT) within a short interval from diagnosis using a preparative regimen including total body irradiation (TBI). **Aims.** We undertook this study to estimate the feasibility and outcomes related to chemo-immunotherapy and HSCT in patients with T-PLL. **Methods.** 27 consecutive patients with T-PLL were seen at the Mayo Clinic from 1997 through 2011. All patients underwent peripheral blood flow cytometry, bone marrow examination and cytogenetic evaluation at diagnosis. T-PLL cells were characterized by a CD2+, CD3+, CD5+, CD7+ phenotype positive for CD4 and/or CD8. Cytogenetic studies included FISH analysis for *TCL1* at 14q32, deletion 11q23 (*ATM*), trisomy 8 and deletion 17p (*TP53*). All clinical and demographic data were retrospectively abstracted. Cox proportional regression method was used for multivariable analysis. **Results.** Of the 27 study patients, 14 (51%) were female and median age was 65 years (range, 40-86). The median (range) hemoglobin was 13.2 gm/dl (6-15.9), white cell count 74 x10^9/L (7-551), absolute neutrophil count [ANC] 6 x10^9/L (1-21), absolute lymphocyte count [ALC] 70 x10^9/L (2.7-540) and platelet count 153 x10^9/L (29-299). On FISH analysis 15 (56%) had abnormalities of 14q32 and 3 of these had +8 (11%). At last follow up 22 (81%) deaths were recorded. Two patients (7%) have an indolent disease that has thus far not necessitated ther-

apy. Seventeen patients were treated with alemtuzumab based regimens, while 8 received purine nucleoside analogues (cladribine/fludarabine/pentostatin). The median survival in the patients receiving alemtuzumab was 7 months compared to 4 months (p=0.5). Eight patients (30%) were >70 years of age and hence not eligible for HSCT. Of the 19 transplant eligible patients, 14 were unable to proceed to transplantation due to either progressive disease or lack of a suitable donor source [3 (22%)]. Thus only 3 (11%) transplant eligible patients were able to undergo an allogeneic HSCT (3 myeloablative matched unrelated donor HSCT). Two of the 3 transplanted patients died within 9 months from complications related to disease relapse. In a univariate survival analysis, high white count at presentation, high ALC, low ANC and cytogenetic abnormalities in addition to those involving 14q32 were predictive of a shorter survival, whereas in a multivariable model only the low ANC retained significance [p=0.04, HR 0.123-2.65]. **Summary and Conclusions.** Although transplant is considered the only therapy that offers long-term disease control for patients with T-PLL, only ~10% of patients in this series were able to proceed with allogeneic HSCT because of i) inadequate disease control with induction, ii) advanced age and iii) limited donor options. Better induction chemoimmunotherapy and the use of alternative donor sources (haploidentical/umbilical cord blood) need further exploration.

0158

COMPARISON BETWEEN THE INTERNATIONAL STANDARDISED APPROACH AND A SINGLE TUBE TEN COLOUR FLOW CYTOMETRIC ASSAY FOR DETECTION OF MINIMAL RESIDUAL DISEASE IN CLL

M Sartor, D Gottlieb
Westmead Hospital, Sydney, Australia

Background. The eradication of minimal residual disease (MRD) in CLL predicts for improved outcome. Approaches to CLL MRD detection vary in sensitivity and cost. Historically, CD5/CD19 co-expression with demonstration of clonality has been the principal method of MRD evaluation in CLL. However this approach is limited by the identification of normal hemopoietic cells and the inability to demonstrate light chain restriction with very low B cell numbers. More recently, an international standardised approach (ISA) to the assessment of MRD in CLL that utilises 10 monoclonal antibodies in a 4 tube test system and permits a sensitivity of 0.01% (Rawstron et al, Leukemia 2007) was published. **Aims.** To develop a single tube 10 colour flow cytometric assay based on the ISA methodology to be used in a centralised flow cytometry laboratory providing results for a multicenter clinical trial of lenalidomide treatment for MRD following FCR chemotherapy. The method was designed to minimise the requirement for cell numbers in patients with relative leucopenia following chemotherapy.Method: Peripheral blood (n=51) and bone marrow (n=20) was collected from patients at various time points post treatment for CLL (including bone marrow from 3 patients day 30 post-allogeneic stem cell transplant). Immunophenotyping was performed using a Gallios flow cytometer (Beckman Coulter). Monoclonal antibodies were used either according to the ISA (antibody/fluorochrome combination as per Rawstron et al) or in a single tube incorporating all of the following monoclonal antibodies: CD3 ECD, CD5 PercP5.5, CD19 eFluor, CD20 APC CY7, CD81 FITC, CD22 PE, CD43 PECY7, CD79b APC, CD38 A700, CD45 KO. A whole blood or bone marrow lyse method was used and analysis was performed according to the published ISA methodology or for the single tube using templates based on the ISA approach. Results from the two methods were compared. **Results.** Levels of residual disease in the 71 samples analysed varied from <0.01 to 22%. Twenty-four samples showed residual disease of <1%. Analysing all samples showed an excellent correlation between the two methods slope = 0.989, intercept =0.1 and R(2)=0.992. There was also excellent correlation for disease levels below 1.0%, (median 0.03 range <0.01-0.63%, n=24) slope = 1.15, intercept =0.007 and R(2)=0.994. Bland Altman analysis showed a mean of 0.008 +/- 0.058 (2SD) for values below 1%. **Conclusions.** The single tube ten colour flow cytometric assay for detection of MRD in CLL gives equivalent results to the ISA. There is a potential for improved sensitivity resulting from the removal of CD19+/CD3+ contaminating events and by increasing the total number of events acquired since there is no need to divide the sample into multiple tubes, particularly post-treatment when cell numbers are frequently limiting. The single tube assay is also simple, rapid and cost effective.

0159

A HIGH NUMBER OF LOSSES IN 11Q CHROMOSOME IS ASSOCIATED WITH A WORSE SURVIVAL IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA. PRELIMINARY RESULTS OF DATABASE OF CLL OF SPANISH GROUP OF CYTOGENETICS

Background. Cytogenetic abnormalities in CLL patients define groups of patients with different prognosis. Recently, three independent groups have reported that a high number of losses in 13q14 is related with a worse prognosis as well as it can be observed in patients with CLL and 17p deletion associated or not with *TP53* mutation. CLL patients with 11q deletion have a bad prognosis, although with a variable outcome. **Aims.** To analyze in a Spanish multicentric study if the number of losses in 11q chromosome in patients diagnosed with CLL can influence in overall survival (OS) and time to the first therapy (TFT). **Methods.** A total of 1.303 patients registered in DataBase of CLL of Spanish Group of Cytogenetics (GCECGH) and Spanish Group of CLL (GELLC) were included. All the clinical data as well as FISH information (13q, 12, 11q, 14q and 17p probes) and molecular studies were carried out. **Results.** One hundred and thirteen patients (8.67%) had 11q deletion, although the analysis was limited to 66 cases (52 men) due to lack of clinical data or inappropriate follow-up. Median OS of patients with 11q- was 85 months (CI 95%, 59-109) and TFT was 33 months (CI 95%, 18-48). At the moment of analysis, 30% (20/66) of patients had died and 64% (42/66) had progressed. In 28 out of 66 patients (42%) loss of 11q was the sole cytogenetic aberration at diagnosis. Most of patients (62%) were in clinical stage A of Binet. Interestingly, in the subgroup of patients with ³ 40 % of cells with loss of 11q (54 cases, 81%), the OS was 84 months (CI 95%, 67m-101m), while in the group with < 40 % of losses in 11q, the OS has not been reached (CI 95%, 99m-132m) (P= 0.045). In the univariate analysis for OS, a high serum LDH level (P= 0.026), a high serum $\beta_2$microglobulin level (P= 0.022) and unmutated *IGVH* pattern (P= 0.045) were associated with a worse survival, and a trend in advanced stages of Binet (P= 0.10) and lymphocyte blood count >30 x 10^9/L (P = 0.11) was observed. In the multivariate analysis for OS, the only significant variable included in the final model was a high serum LDH level (P= 0.043). Regarding the time to first therapy, in the group with ≥40% of losses in 11q the median TFT was 20 months (CI 95%, 1-41) while in the group of patients with <40% of 11q- cells it was 52 months (CI 95%, 32-72) (P = 0.087). In the TFT univariate analysis differences were observed in cases of high serum LDH (P = 0.003) and lymphocyte blood count >30 x 10^9/L (P = 0.033). **Conclusions.** In our series, the incidence of 11q deletion is less than described in the literature. Our results suggest that in patients with CLL, a high number of losses in 11q is inversely related to OS and shows a trend to a short TFT.

CISPLATIN CONTAINING SALVAGE TREATMENT OF P53 DYSFUNCTIONAL CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH BULKY DISEASE IS HIGHLY EFFECTIVE AND RESULTS IN TAP73 MEDIATED APOPTOSIS

S Tonino[1], M van Gelder[2], C Mulkens[1], J van Laar[1], G Suo[3], M van Oers[1], JY Wang[3], A Kater[1]
[1]Academic Medical Center, Amsterdam, Netherlands

[3]Moores Cancer Center, University of California, San Diego, United States of America

Background. In CLL, loss of function of p53 is highly associated with fludarabine-refractory disease and poor outcome. We recently reported activity of a cisplatin containing regimen (R-DHAP; rituximab, dexamethasone, cytarabine and cisplatin) in CLL in a retrospective analysis[1]. In solid tumors the activity of platinum-based compounds such as cisplatin was found to be independent of p53 function and mediated by the p53 family member TAp73. **Aims.** We further analyzed efficacy of a platinum-based regimen in fludarabine-refractory CLL patients and studied the role of TAp73 in cisplatin induced apoptosis. **Methods.** We performed an interim-analysis of a nation-wide multi-center phase 2 clinical trial in which fludarabine-refractory CLL patients with progressive disease receive 3 cycles of R-DHAP prior to allogeneic stem cell transplantation. Next, the mechanism of action of cisplatin was studied in patient derived p53 dysfunctional CLL cells and in the pro-lymphocytic cell line MEC1. Informed consent was obtained in accordance with the Declaration of Helsinki. **Results.** A response (according to IWCLL 2008 criteria) was obtained in 9 of 15 patients (60%) treated with R-DHAP; 4 of 8 patients (50%) with bulky disease responded. *In vitro* treatment of quiescent peripheral blood derived CLL cells with cisplatin did not result in cell death. However, cisplatin did induce apoptosis in p53 dysfunctional CLL cells which were brought to proliferate by combined stimulation with CD40-ligand and CpG (as a model for the lymph node (LN) environment).The prolymphocytic cell line MEC1 is p53 dysfunctional and has an activated NF-κB signature and can hence function as a model for p53 dysfunctional CLL cells in the LN environment. In MEC1 cells, cisplatin treatment resulted in cell cycle arrest, apoptosis and also increased sensitivity to FAS (CD95)- and fludarabine-induced cell death. At the molecular level, treatment with cisplatin induced c-Abl dependent protein expression of TAp73 and its downstream targets p21, Bid, Puma and CD95. TAp73 RNA interference markedly decreased sensitivity to cisplatin, supporting a role for TAp73 in apoptosis regulation in these p53 dysfunctional cells.Clinical relevance of these findings is supported by the observation of increased expression levels of TAp73 in lymph node derived CLL cells as compared to peripheral blood derived cells. Moreover, expression of TAp73 was observed in primary patient derived CLL cells upon stimulation with CD40-ligand (and CpG), suggesting that TAp73 induction in primary CLL cells is restricted to the activated compartment. Lastly, in p53 dysfunctional CLL cells isolated 24 and 48 hours after *in vivo* treatment with cisplatin, a clear induction of TAp73 was observed. This correlated with a rapid decrease in peripheral blood leukocyte count and lymph node size. **Conclusions.** These data indicate that platinum-based compounds are active in fludarabine-refractory (p53 dysfunctional) CLL. The activity of cisplatin in p53 dysfunctional CLL may at least in part be mediated by induction of TAp73; especially in the context of proliferation as occurs in the LN environment.

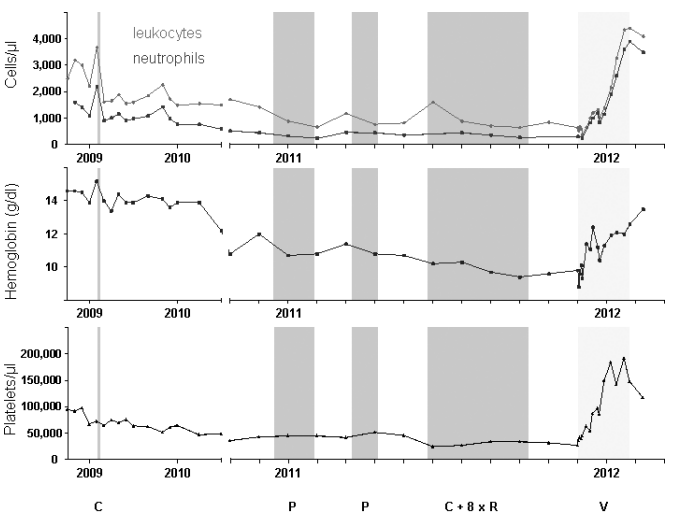
Background. Targeted intervention against driver mutations is about to open a new era in cancer treatment. An activating mutation of the BRAF serine/threonine protein kinase, BRAF V600E, occurs in a significant proportion of malignant melanomas, colorectal, thyroid, and other cancers. In hairy-cell leukemia (HCL), BRAF V600E is nearly always present, suggesting disease-specific oncogene dependence. **Methods.** Here, we present a patient with chemotherapy-refractory HCL who was treated with a short course of vemurafenib, a specific inhibitor of mutant BRAF. The activating *BRAF* V600E mutation in the HCL clone of this patient was demonstrated by DNA sequencing and a mutation-specific antibody. **Results.** Before vemurafenib treatment, no objective response could be achieved by three lines of purine analogue-based treatment regimens (cladribine, pentostatin and rituximab/cladribine). At the time of treatment initiation with vemurafenib, the patient had a BM infiltration of 70%, massive splenomegaly (24.8 x 8.3 cm), severe pancytopenia (leukocytes, 680/μL; hemoglobin, 10 g/dL; platelets, 36,000/μl) and a serum CD25 (soluble interleukin 2 receptor) level of 24,800 U/ml (normal rage, <900 U/mL). Treatment was started with 240 mg twice daily after a single loading dose of 960 mg and slowly escalated to 1,920 mg/d, the dose established in treatment of melanoma. Within two days of treatment with 480 mg/d, the spleen softened and decreased in size. On day six and 17 of vemurafenib treatment, the spleen size had shrunk to 18.8x6.9 cm and 14x5 cm, respectively. Platelets, hemoglobin and neutrophils normalized rapidly (neutrophils ≥1,500/μL on day 36; hemoglobin ≥12 g/dL on day 43; platelets ≥100,000/μL on day 28; Figure 1. Serum CD25, a reliable marker of HCL load, fell rapidly below 900 U/l by day 28. There was no clinical evidence of a tumor lysis syndrome associated with the rapid response to vemurafenib treatment. On day 43 of treatment, complete remission (CR) criteria were achieved. Treatment was terminated on day 56. At this point, there was no evidence of disease persistence based on immunophenotyping of the peripheral blood and BM histological findings, but a small HCL clone (<0.1%) was detected by flow cytometry of the BM sample. Final BM evaluation on day 70 confirmed CR while peripheral counts remained stable. **Conclusions.** The striking therapeutic activity of vemurafenib in our patient provides the first functional evidence to substantiate *BRAF* V600E as a driver oncogene *in vivo* and to validate mutant BRAF as a therapeutic target in HCL, thereby adding to the recent success of molecular mechanism-based therapies in other kinase-driven malignancies. Given the rarity of HCL, introducing new therapeutic modalities may be challenging. Future studies are needed that compare short-term inhibition of BRAF with low doses of vemurafenib (or alternative BRAF inhibitors) with standard therapy.



(C: cladribine, P: pentostatin, R:rituximab). With start of vemurafenib (V) treatment, the peripheral blood counts normalized rapidly to normal levels.

POOR PROGNOSIS OF HODGKIN VARIANT OF RICHTER'S TRANSFORMATION IN CHRONIC LYMPHOCYTIC LEUKEMIA TREATED WITH CLADRIBINE

K Jamroziak, O Grzybowska-Izydorczyk, D Jesionek-Kupnicka, J Gora-Tybor, T Robak
Medical University of Lodz, Lodz, Poland

It is generally believed that chronic lymphocytic leukemia (CLL) transformation to Hodgkin lymphoma (Hodgkin variant of Richter's transformation, Hodgkin-RT) has superior outcome than more common Richter's transformation to diffuse large B-cell lymphoma (DLBCL-RT). However, recent observation suggested that Hodgkin-RT in patients in whom CLL had been treated with fludarabine have very poor survival (Bockorny et al, 2012). In order to evaluate the clinical course of Hodgkin-RT in patients treated previously with cladribine we performed a single-center retrospective analysis to compare Hodgkin-RT incidence, characteristics and outcome with those of DLBCL-RT. We searched electronic databases of the Departments of Hematology and Pathology of the Medical University of Lodz to identify patients who developed biopsy- or fine-needle aspiration-proven RT between January 2000 and November 2011. Hospital records and ambulatory charts were reviewed to determine clinical, laboratory and pathologic features, treatment and outcome of CLL and RT. Hodgkin-RT and DLBCL-RT characteristics were compared by Fisher exact test or Mann-Whitney test. Survival after transformation was plotted using the Kaplan-Meier method and comparisons made by the log-rank test. **Results.** Among 786 patients with CLL admitted to our center since January 2000, 40 (5.1%) patients developed RT including 33 (4.2%) DLBCL-RT, six (0.8%) Hodgkin-RT and one plasmablastic lymphoma. There were 23 male and 17 female patients with a median age of 67.2 years (range 35.8-84.9). RT was diagnosed after a median of 2.6 years (range 0-12.3) from CLL diagnosis. Median survival after transformation was 1.1 years, 95% confidence interval (95%CI) 0.4-1.8 years. Of the patients with Hodgkin-RT, there were five men and one woman with a median age of 70.6 years (range 55.8-76.3). All patients received cladribine-based regimens before transformation. Treatment in Hodgkin-RT was mostly HL-type therapy including ABVD, COPP an COP. Two partial remissions were achieved, while four patients did not respond to chemotherapy. During the follow-up period five patients died of disease progression at 0.5, 2, 4 and 11 months from transformation, whilst one patient remained alive after 7 months of observation. Most of DLBCL-RT patients received rituximab-based immunochemotherapy. The comparison of patients with DLBCL-RT and Hodgkin RT indicated similar presenting characteristics and time to transformation in both types of RT, Interestingly, we found significantly shorter survival after transformation in Hodgkin-RT compared to DLBCL-RT (p=0.019) (Figure 1). In conclusion, the results of this study indicate that Hodgkin-RT in cladribine-treated CLL patients is characterized by very short survival, even compared to DLBCL-RT. This may be due to common choice of alkylator-based HL-type therapy that is likely suboptimal for Hodgkin-RT in patients exposed to purine analogs. We propose that more intensive treatment, such as immunochemotherapy with rituximab or alemtuzumab should be considered for Hodgkin-RT in CLL patients who had been previously treated with purine analogs.

Introduction. The DNA damage response axis plays a crucial role in chemoresistance in CLL, as indicated by the prognostic impact of deletions of 17p (locus of *TP53*) and 11q (locus of *ATM*). These deletions coincide with mutations in the remaining allele, although frequency, especially for *ATM* varies. Functional read-outs of the p53 axis might add clinical relevant information on the actual DNA damage response. Currently, different p53 function analyses are being developed. These assays are either based on measurement of (i) RNA expression levels of a single gene (RT-PCR*p21*) or gene sets (RT-MLPA), or protein expression levels (FACSp53-p21) after DNA damage by irradiation or etoposide/nutlin exposition or (ii) gene expression levels at base-line (RT-PCR *miR34a*). To what extent these different assays correlate is currently unknown. **Aims.** Detailed side-by-side analysis of available p53 functional assays in well characterized CLL samples **Methods.** Freshly frozen PBMC's of 15 different CLL samples (CD19/CD5>90%) were exchanged between 5 research groups that developed the following p53 functional assays: RT-PCR*p21* (Ulm), RT-MLPA (*bax*, *puma*, *p21* and *CD95*; Amsterdam), FACSp53-p21 (Paris) and RT-PCR *miR34a* (Salzburg/Brno). FISH-analysis (11q, 17p, 13q and 12) was performed on all samples. In addition mutations in *TP53* were determined by FASAY, DHPLC and Sanger sequencing and *ATM* mutations were assessed by Sanger sequencing. **Results.** RNA expression levels showed significant correlation (p-value < 0,01) between the different P53 functional assays with high correlation coefficients (range: 0,7-0,94). Based on combination of FISH-analysis, FASAY and Sanger sequencing the investigated CLL samples could be distinguished into 6 different categories; 1. 17p-with *TP53* mutation (n=5), 2. Sole *TP53* mutation (n=1), 3. 11q- with *ATM* mutation (n=1), 4. 11q- in absence of *TP53/ATM* mutation (n=4), 5. 17p- with both *TP53* mutation and *ATM* mutation (n=1) and 6. No 17p- and 11q- in absence of *TP53/ATM* mutation (n=3). All p53 functional assays showed absent to minimal induction of expression of respective target genes in samples with a cytogenetic abnormality combined with a *TP53/ATM* mutation (category 1, 3, 5). In contrast, samples without a cytogenetic abnormality in absence of *TP53/ATM* mutations (category 6) showed a marked increase in expression of respective target genes in all the assays. The patient with a sole *TP53* mutation (category 2) showed a normal DNA damage response in all assays except for FACSp53-p21. Samples with an 11q-in absence of *TP53/ATM* mutation (category 4) showed high inter-assay variation. The two assays with predefined cut-off values (RT-MLPA and FACSp53-p21) assessed 13 samples equally (9 p53 dysfunctional and 4 p53 functional), except for 2 patients (category 2, 3 respectively). Reproducibility of these assays is currently being determined. **Discussion.** For the first time a comparative side-by-side analysis of different available p53 functional assays was performed, which demonstrated strong correlations between the different assays. All assays could detect samples with expected disturbed and normal DNA-damage responses. To what extent these p53 functional assays could be of clinical relevance especially with respect to chemo-responsiveness, should be further studied in prospective studies.

Chronic myeloid leukemia - Biology

CBL DOWNREGULATION PLAYS A CRITICAL ROLE IN THE INCREASE OF AXL AND LYN TYROSINE KINASE LEVELS MEDIATING RESISTANCE OF CHRONIC MYELOID LEUKEMIA CELLS TO NILOTINIB

JM Pasquet[1], R Gioia[1], C Treogat[1], V Lagarde[1], V Prouzet-Mauléon[1], E Lippert[1], A Sirvent[2], S Roche[2], FX Mahon[1], JM Pasquet[1]
[1]INSERM U1035, Bordeaux, France
[2]CRBM CNRS 5237, Montpellier, France

The second generation of Abl tyrosine kinase inhibitor (TKI) nilotinib has been developed to overcome the resistance to imatinib, which was up to now the gold standard treatment of chronic myeloid leukemia (CML). Nilotinib has been approved recently as the front line treatment of CML but in rare situations, primary and secondary resistances are observed. We generated nilotinib-resistant K562 CML cells and characterized the mechanism responsible for nilotinib resistance in these cells : overexpression and increased activity of the Src-like tyrosine kinase Lyn (Mahon et al, 2008). A quantitative phosphoproteomic analysis performed by "Stable isotope labeling with amino acids in cell culture"(SILAC) further showed that this activity of Lyn is mediated by overexpression of the tyrosine kinase Axl and the hyper activation of the Spleen tyrosine kinase Syk (Gioia et al, 2011). The step by step inhibition of these tyrosine kinases confirmed the relevance of each of them in the resistance to nilotinib. Similar mechanisms were detected in primary cells from nilotinib-resistant CML patients. The mechanism of deregulation of Lyn is still currently unknown. Down-regulation of Axl by a specific shRNA strategy in nilotinib-resistant K562 cells (K562-rn), which overexpressed Axl, abolishes resistance that correlates with a decrease of Lyn overexpression and an increase of Cbl expression. Interestingly, from the SILAC analysis we observed a down-regulation of several signaling proteins including the ubiquitin E3-ligase c-Cbl. Since Cbl targets several tyrosine kinases for lysosomal recycling or proteosomal degradation, we addressed whether Cbl inhibition plays a role in Lyn and Axl protein accumulation. Cbl depletion in K562 cells by a specific shRNA strategy induced a large increase of Axl and Lyn protein levels. In addition, the depletion of Cbl also induced an emerging resistance to nilotinib as assessed in viability and apoptosis assays. Conversely, the overexpression of Cbl in nilotinib-resistant K562 cells (K562-rn) dramatically reduced Axl and Lyn levels and these effects were dependent upon an intact E3-ligase activity of Cbl. Last, Cbl expression re-sensitized K562-rn cells to nilotinib. Altogether, these results indicate that Cbl down-regulation plays a critical role in the increase of Axl and Lyn levels that control resistance to nilotinib in CML cells.

0165

DASATINIB MAY OVERCOME THE NEGATIVE PROGNOSTIC IMPACT OF KIR2DS1 IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA

[3]Liverpool Royal infirmary, Liverpool, United Kingdom

Natural killer (NK) cells are an important component of the allo-immune effect following allogeneic stem cell transplantation and have been shown to exert direct cytotoxicity against primitive quiescent CD34+ Philadelphia positive cells *in vitro*. The balance between signals received from inhibitory and activating cell surface receptors determines the cytotoxic activity of NK cells. These receptors include the killer immunoglobulin-like receptors (KIR).We recently reported on the relationship between KIR genotype and outcome in a large homogeneous cohort of newly diagnosed patients with CML in chronic phase (CP) treated with imatinib (Marin, Leukemia 2011). We showed that patients carrying the activating KIR gene *KIR2DS1* have a significantly lower probability of achieving CCyR, and lower 2-year probabilities of progression-free survival (PFS) and overall survival (OS) compared with those who are *KIR2DS1* negative. This effect was independent of Sokal risk score and was validated in a second independent large cohort of 174 patients with CML-CP treated with first-line imatinib in the multi-center UK SPIRIT 1 trial. The impact of the *KIR2DS1* genotype on the probability to achieve CCyR was even greater when the expression of this gene was considered together with the presence or absence of the ligand for the corresponding inhibitory KIR receptor (KIR2DL1), suggesting that in the presence of the HLA ligand, the corresponding inhibitory KIR may neutralize the effect of the activating KIR. We concluded that *KIR2DS1* may predict response to imatinib and identify patients at greater risk of treatment failure.In this study, we aimed to investigate whether *KIR2DS1* could also predict response to treatment with dasatinib. Dasatinib, a second generation TKI with potent BCR-ABL inhibitor activity, induces deeper and faster clinical responses than imatinib. Dasatinib also inhibits a wide variety of other kinases such as SRC and TEC, known to be key regulators of immune response.We studied 130 patients with CML in CP treated with first-line dasatinib on the UK multi-center trial (SPIRIT 2) for whom genomic DNA samples were available for analysis. All patients gave written informed consent for the use of their data for this analysis. The median follow-up was 18 months and 25% of the patients have been followed for at least 24 months. During follow-up 122 (93.8%) patients achieved CCyR and 94 (72.3%) major molecular response (MMR). We found no significant impact of KIR genotype on outcome. Specifically, the probabilities of CCyR, MMR and CMR for patients who were *KIR2DS1* allele positive was not statistically different, although marginally better compared to those patients who were negative for this gene, namely RR= 1.398 (p=0.09), RR= 1.003 (p=0.98) and RR= 1.526 p=0.64 respectively. These data indicate that dasatinib may overcome the negative prognostic impact of *KIR2DS1* on CCyR in newly diagnosed patients with CML treated with imatinib. Longer follow-up is needed to assess whether dasatinib also overcomes the negative impact of *KIR2DS1* genotype on PFS and OS.Functional and phenotypic studies to determine the differential impact of imatinib and dasatinib on KIR2DS1 expressing NK subsets are currently under way.

A DNA METHYLATION CLASSIFIER PREDICTS RESPONSE TO IMATINIB IN PRE-TREATMENT CML SAMPLES

A Bazeos[1], R Lowe[2], J Apperley[1], D Marin[1], G Nteliopoulos[1], H de Lavallade[1], K Rezvani[1], E Bray[1], S Loaiza[1], N Mahmud[2], C Mein[2], G Gerrard[1], L Foroni[1], J Goldman[1], V Rakyan[2]
[1]Imperial College London, London, United Kingdom
[2]Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background. Despite the consistent nature of the BCR-ABL1 fusion gene identified at diagnosis, CML is clinically heterogeneous as exemplified by the predictive value of Sokal scores and the variable response to tyrosine kinase inhibitors (TKI). We speculated that aberrant epigenetic programming and in particular differential DNA methylation might underlie the variations in outcome and variable responses to imatinib. **Methods.** $CD34^+$ cells were purified from the blood of 46 patients with CML-CP at diagnosis. Patients were treated with imatinib (400 mg/day) and classified as responders (n=29) if they achieved durable complete cytogenetic response (CCyR). Responders were subjected to leukapheresis following G-CSF mobilization. Non-responders (n=17) never attained major cytogenetic response (MCyR) (n=13) or lost a previously attained CCyR despite continuing imatinib (n=4). Using the Illumina Infinium HumanMethylation450 BeadChip to scrutinize 429,231 CpG dinucleotides within the genome, the pre-treatment genome-wide methylation profiles of the responders were compared with those of the non-responders as well as with the corresponding paired CCyR sample. Analogous methylation signatures were obtained from $CD34^+$ cells collected from healthy donors (in excess of requirement) treated with G-GSF to yield cells destined for allogeneic stem cell transplantation. Using Random Forest (RF), an ensemble classifier (supervised learning algorithm), a model was developed to define the CML-CP methylome and to separate imatinib responders from non-responders based on their genome-wide DNA methylation profile. With a permutation test it was then possible to select individual probes that separated these two groups ($p<0.01$). **Results.** Unsupervised hierarchical clustering of all samples using Ward's method showed that genome-wide DNA methylation analysis clearly distinguishes between CML-CP, CML-CCyR and normal $CD34^+$ cells. Two clusters, one derived from diagnostic CML samples and the other from the controls and CCyR samples (i.e. minimal or no leukemia) were identified. In the latter cluster CCyR samples were distinct but epigenetically much closer to normal $CD34^+$ cells than CML-CP samples. 534 different probes separated responders from non-responders. Using these 534 probes a 'leave-one-out' cross-validation procedure was repeated 100 times to estimate their prediction accuracy; their use correctly predicted all responders. **Conclusions.** The work so far has identified consistent differences in genome-wide methylation patterns between patients with untreated disease versus normal controls indicating a possible common epigenetic pathway in the leukaemic transformation to leukaemia. The study has also defined a 534-probe DNA methylation classifier, which predicts overall response to imatinib in CML patients. Validation with a second independent patient cohort is currently in progress.

0167

ABLATION OF ATG7 AUTOPHAGY GENE EXPRESSION AUGMENTS TKI EFFECTS AND ENHANCES CML CELL DEATH

M Karvela, C McKay, A Mukhopadhyay, E Allan, G Helgason, T Holyoake
University of Glasgow, Glasgow, United Kingdom

Background. Imatinib, a BCR-ABL tyrosine kinase inhibitor (TKI), has revolutionized treatment of chronic myeloid leukaemia (CML). Despite imatinib's auspicious effects, it fails to cure the disease due to CML stem cells' refractoriness and development of resistance (e.g. BCR-ABL^{T315I}). Although second (dasatinib, nilotinib) and third (ponatinib) generation TKIs inhibit imatinib-resistant BCR-ABL mutants, they still fail to overcome disease persistence. Autophagy is a cytoprotective catabolic process activated under stressful conditions and can be inhibited by chloroquine (CQ), a non-specific autophagy/lysosome inhibitor. We have previously shown that TKIs induce autophagy in CML and CQ-mediated autophagy inhibition enhances TKI efficacy. However, fundamental questions still remain unanswered: 1) is autophagy inhibition enhancing TKI efficacy in CML stem/progenitor cells, and what is the effect of TKIs combined with autophagy inhibition on normal stem/progenitor cells. 2) TKIs are known to additionally affect other kinases within the cell, such as PDGFR/c-Kit (imatinib), VEGF/Src (dasatinib), c-Kit/Arg (nilotinib) that could potentially affect autophagy independently of BCR-ABL. **Aims.** We aim to determine synergy between TKIs and specific autophagy ablation and investigate the specificity of TKIs in inducing autophagy by: 1) analysing the effect of TKIs combined with *ATG7* knockdown in CML and normal stem/progenitor cells, 2) investigating if TKIs induce autophagy solely through BCR-ABL inhibition or through other targets as well. **Methods.** In order to evaluate if ablation of autophagy enhances TKI effects, we inhibited autophagy pharmacologically with CQ, and in a specific manner by knocking down *ATG7* (a pivotal autophagy gene) stably, via lentiviral delivery, or transiently, via nucleofection. To achieve this, we developed a pLKO.1-GFP-shATG7 vector-based lentiviral system that reached up to 70% knockdown. A pool of siATG7 clones achieved 50% ATG7 knockdown after nucleoflection.In order to explore if TKI-induced autophagy is exclusively through BCR-ABL inhibition or not, we investigated the activity of the mammalian target of rapamycin (mTOR), a negative autophagy regulator, in BaF3 cell lines (parental, BCR-ABL and BCR-ABL^{T315}) following TKI treatment, by measuring the phosphorylation levels of its downstream effector RPS6. **Results.** Addition of CQ to ponatinib decreased survival of progenitor cells by 12% compared to ponatinib treatment alone (p=0.033) in a clonogenic assay. Additionally, lentiviral inhibition of autophagy enhanced TKI-induced death in CML CD34+ cells. Presence of *ATG7* knockdown in combination with dasatinib resulted in 24% increase in apoptosis and 40% decrease of the colony formation ability compared to TKI treatment alone in K562 cells. Experiments in primary human normal and CML stem cells are under way.Our data suggest that mTOR activity is essentially regulated by BCR-ABL and TKI-induced autophagy in CML cells is mainly driven by BCR-ABL inhibition. However, we observed that dasatinib-induced autophagy could partially be attributed to non-BCR-ABL targets. **Summary and Conclusions.** Autophagy is induced in CML upon TKI inhibition of BCR-ABL and facilitates survival. Our findings suggest that autophagy inhibition enhances TKI-induced cell death in CML stem/progenitor cells and underline the importance of ATG7 as a therapeutic target. Future development of specific autophagy inhibitors in combination with TKIs could target the fraction of persistent CML stem/progenitor cells.

CHARACTERIZATION OF THE BCR-ABL 3'UNTRANSLATED REGION

B Chereda[1], J vaz de Melo[1], D Hewett[2]
[1]University of Adelaide, Adelaide, Australia
[2]Centre for Cancer Biology, Adelaide, Australia

Background. The formation of the BCR-ABL gene is observed in a number of leukemias, but is most notably in chronic myeloid leukemia (CML). Recent studies have correlated BCR-ABL "dosage"with disease phenotype. However control of BCR-ABL expression is poorly understood. BCR-ABL transcription is driven by the BCR promoter, and contains the ABL1 3'untranslated region (3'UTR). The 3'UTR is an important regulator of gene expression, and is modulated by a number of factors such as non-coding RNAs and RNA-binding proteins. Therefore, we are investigating the role of the BCR-ABL 3'UTR in its expression. **Aims.** To characterize the BCR-ABL 3'UTR and identify mechanisms that affect BCR-ABL expression. **Methods.** Luciferase assays were used to map regulatory regions within the BCR-ABL 3'UTR. We also performed 3'RACE to look for 3'UTR shortening and measured the half-lives of BCR, BCR-ABL and ABL1. We used bioinformatics to predict microRNA-3'UTR interactions. Luciferase assays and microRNA over-expression in cell lines was carried out to test the bioinformatics predictions. **Results**. Using an ABL 3'UTR luciferase reporter we showed that the 3'UTR was repressive in a number of CML and non-CML cell lines. We also mapped two negative regulatory elements within the 3'UTR. Additionally, we observed post-transcriptional control of the 3'UTR, and that BCR-ABL and ABL have shorter half-lives than BCR. 3'RACE of the ABL1 3'UTR containing genes (ABL1 and BCR-ABL) identified a shortened 3'UTR. In patient samples, this 3'UTR variant was observed in approximately 2% of ABL1 3'UTR transcripts. MicroRNA-29, -30, -196 and 203 were predicted by Targetscan to interact with species-conserved regions of the BCR-ABL 3'UTR. Luciferase assays provide evidence that miR-29, and -196 interact with the 3'UTR. Over-expression of miR-29 and 196b in CML cell lines did not affect BCR-ABL expression. However, miR-196b reduced proliferation of myeloid cell lines. We are also establishing a system to isolate RNA-binding proteins bound the ABL 3'UTR. **Conclusions.** We have shown that the BCR-ABL 3'UTR is repressive and contains two negative regulatory elements. With the repression involving post-transcriptional control, current work is focused on identifying any microRNA or RNA-binding protein interactions with the 3'UTR. We envisage that our research will contribute to a better understanding of the biology of chronic myeloid leukemia and alternative forms of targeted therapy.

BCR-ABL TYROSINE KINASE SUSTAINED MDS1 AND EVI1 COMPLEX LOCUS (MECOM) EXPRESSION IN CHRONIC PHASE CHRONIC MYELOID LEUKAEMIA

G Jorgensen[1], S Roy[2], P Roy[2], M abed el Baky[2], J Melo[3], G Strathdee[4], T Holyoake[1], C Bartholomew[2]
[1]University of Glasgow, Glasgow, United Kingdom
[2]Glasgow Caledonian University, Glasgow, United Kingdom
[3]University of Adelaide, Adelaide, Australia
[4]University of Newcastle, Newcastle, United Kingdom

Background. Enhanced expression of MDS1 and EVI1 complex locus (*MECOM*), a proto-oncogene located on chromosome 3q26, is frequently observed in blast crisis (BC) of chronic myeloid leukaemia (CML), implicating this zinc finger transcription factor in disease progression. Shown to have a role in self-renewal, proliferation and the repopulating capacity of murine haemopoietic stem cells in *MECOM* null mice, MECOM's role in CML has not been fully determined. **Aims.** In this study we investigated *MECOM* gene expression, the effect of imatinib mesylate (IM) treatment and the biological activity of this gene in primary chronic phase (CP)-CML CD34+ progenitor cells as well as CML derived cell lines. **Methods.** K562 cells transduced with lentiviral vectors encoding non-target (NT) control or shRNAs targeting *MECOM* were selected by puromycin resistance. Q-PCR for *BCR-ABL*, *MECOM* isoforms and *GAPDH* was performed on an OPTICON 2 DNA engine. Colony forming cell (CFC) assays were performed in Methocult and scored after 12 days in culture. Primary CD34+ cells were enriched by positive magnetically activated cell selection (CliniMACS) to >90% purity and cryopreserved; thawed samples were cultured in IMDM with five growth factors (IL3, IL6, SCF, GCSF and Flt3L). **Results.** Knockdown of *MECOM EVI1* (E) and *MECOM MDS1-EVI1* (ME) isoforms: reduced K562 cell division at low cell density and if cells did divide, they turned over less frequently than parental or NT control cells; inhibited CFC by 34%; and moderately reduced BCR-ABL mRNA and protein expression but not tyrosine kinase activity. IM treatment of K562 in which *MECOM E* and *ME* were knocked down partially restricted differentiation as measured by Glycophorin A+ colonies plucked from CFC. Both *MECOM E* and *ME* transcripts were expressed in CD34+ selected cells of both CP-CML and non-CML (BCR-ABL negative) origin. Indeed CD34+ cells expressed high levels of *MECOM* and both *E* and *ME* transcripts were present in CML cells at similar levels to normal (allogeneic donor) and non-CML cells, with *ME* more abundant than *E*. Further, the splice variants with 324 internal amino acids (*324aa*), Δ*324*aa (missing zinc fingers 6 and 7 and part of the intervening region), *+9aa* (with nine amino acids in the repressor region) and Δ*9aa* were all detectable in CP-CML CD34+ cells at different levels. Furthermore, *MECOM* mRNA and protein expression was repressed by IM treatment of CP-CML CD34+ cells, K562 and KY01 cell lines but had no effect in non-CML CD34+ cells. Summary: The level of *MECOM* gene expression was not elevated by BCR-ABL kinase relative to non-CML and normal primitive haemopoietic cells. However, inhibition of *MECOM* expression by IM establishes for the first time a link between BCR-ABL kinase activity and *MECOM* expression in CP-CML progenitor cells suggesting that BCR-ABL partially mediates its biological activity through MECOM. Our results suggest that BCR-ABL tyrosine kinase activity sustains *MECOM* gene expression in CP-CML progenitor cells contributing to CML pathogenesis.

DASATINIB TREATMENT CAUSES ALTERATIONS IN BONE METABOLISM IN A JUVENILE RODENT MODEL

J Tauer, A Ulmer, L Hofbauer, M Suttorp
University Hospital Carl Gustav Carus, Dresden, Germany

Background. In children following treatment failure of chronic myeloid leukemia (CML) by imatinib (IMA) the second generation TKI Dasatinib (DASA; Sprycel®, BMS) represents another option. Similar to IMA this TKI specifically inhibits BCR-ABL but also shows off-target effects on PDGFR and c-FMS involved in bone metabolism (Vandyke K et al. Blood 115:766, 2010; Vandyke K et al. J Bone Miner Res 25:1759, 2010). In adult CML patients disturbances in bone and mineral metabolism (hyperparathyroidism) are reported during IMA therapy while in pediatric patients longitudinal growth retardation was observed (Shima H et al. J Pediatr 159:676, 2011). Pediatric clinical reports on bone side effects exerted by DASA have not been published yet. **Aims.** In a juvenile rat model we investigated the influence of DASA on the metabolism of the growing bone. **Methods.** Juvenile male Wistar rats (milestones of development: end of weaning: age 3 weeks, entering puberty: age 7 weeks) were chronically exposed to varying concentrations of DASA via the drinking water (controls: water; group A: 25 mg/L DASA; group B and C: each 50 mg/L DASA) from age 4 weeks to age 14 weeks. While group A and B were exposed continuously, group C received DASA intermittently (3 days 'ON', 4 day 'OFF'). Animals were sacrificed at age 6 weeks (prepubertal), 8 weeks (pubertal) and 14 weeks (postpubertal), respectively, and the following factors were analyzed: bone length, trabecular and cortical bone mass density (BMD), and bone-specific metabolic serum markers. **Results.** DASA was tolerated at all concentrations and no alterations in animals overall development and behavior were observed. Rats of group A, B, and C exhibited reduced femoral and tibial length and dose-dependently this effect was most pronounced in group B (figure 1). Femoral BMD analysis revealed reduced trabecular BMD postpubertally in all exposed groups while cortical BMD generally was unaffected. Tibial trabecular BMD was slightly decreased at prepubertal age in groups A and B but normalized under ongoing treatment. Tibial cortical BMD was not altered. Also no changes were found in vertebrae. Biochemical markers of bone resorption (CTX-I and TRAP) indicated no significant differences. Bone formation marker osteocalcin was reduced prepubertally by 20 % (group A), 30 % (group B), and 28 % (group C), respectively, followed by normalization during puberty. Parathormone and inhibin B levels remained normal. Growth hormone levels were found elevated during DASA exposure, however, IGF-BP3 was highly significantly lowered in all groups and at all ages. **Conclusions.** This juvenile rodent model is useful to mimic side effects of TKI treatment observed in still growing pediatric patients. As has been shown before for IMA (Tauer JT et al. EHA 2011 Abstract #0670; Tauer JT et al. ASH 2011, Abstract #3741) DASA also alters bone modeling and mandates pediatricians to carefully monitor osseous side effects in not yet outgrown patients. Suttorp M et al. Hematology ASH Educ Program 2010:368; Suttorp M et al. Curr Hematol Malig Rep 2012, in press.

AUTOPHAGY GENES SUPPRESSED IN CML ARE UP-REGULATED FOLLOWING BCR-ABL INHIBITION WITH TKI

A Mukhopadhyay[1], N Sahasrabudhe[1], M Karvela[1], E Allan[1], E Chan[2], G Helgason[1], T Holyoake[1]
[1]University of Glasgow, Glasgow, United Kingdom
[2]University of Strathclyde, Glasgow, United Kingdom

Background. Treatment of Chronic Myeloid Leukaemia (CML) has been radically transformed by introduction of Tyrosine Kinase Inhibitors (TKI), imatinib, dasatinib and nilotinib, which are capable of inhibiting constitutively active BCR-ABL kinase. But survival of residual CML stem cells after TKI treatment is a major obstacle for the elimination of the disease in patients. We have shown that autophagy is one of the mechanisms for survival of CML stem cells following TKI treatment. In vitro, autophagy can be inhibited by the lysosomotrophic agent chloroquine that inhibits lysosomal degradation of autophagosomes [1], [2]. CHOICES, (CHlorOquine and Imatinib Combination to Eliminate Stem cells), a randomised Phase II trial is ongoing to evaluate the response to autophagy inhibition in patients (ClinicalTrials.gov Identifier: NCT01227135). Autophagy can be induced as a survival mechanism following many conventional chemo and radio therapies. Therefore understanding of transcriptional regulate: on of this process is critical for targeted therapy against autophagy.AimAutophagy serves as a rescue mechanism in CML cells following TKI treatment. The aim of this project was to identify autophagy genes that were differentially regulated in CML versus normal cells at baseline and in response to TKI.MethodIn this study we have investigated the expression of a panel of 14 autophagy genes using Reverse Transcription quantitative Polymerase Chain Reaction (RT-qPCR) in primary CML and non-CML CD34+ cells and in CML cell lines. The protein expression was analysed by western blot.ResultsWe demonstrated that BCR-ABL+ CML progenitor cells have significantly lower expression of autophagy genes compared to non-CML progenitor cells. Following TKI mediated inhibition of BCR-ABL kinase activity, expression of key autophagy genes such as Ulk1, Ulk2, Vps34 and GabarapL was significantly up-regulated. Constitutive expression of BCR-ABL was sufficient to maintain the low basal expression of these genes in CML cell lines even after growth factor withdrawal for 24 hours, but growth factor withdrawal combined with TKI treatment induced the expression of the same genes in these cells. In a T315I mutant cell line where BCR-ABL is not inhibited by conventional TKIs the genes were only up-regulated following treatment with third generation TKI, Ponatinib, known to effectively inhibit T315I mutant BCR-ABL kinase activity.ConclusionTaken together it appears that BCR-ABL suppresses the transcription of autophagy genes in CML cells. Autophagy is up-regulated following TKI mediated inhibition of BCR-ABL, not only as indicated by protein markers, but also results in significant induction of transcription of autophagy genes. The study will allow us to identify critical genes controlling TKI mediated autophagy that can be targeted for future pharmacotherapy in CML and other malignancies for wider application.

NUP98/HOXA13 FUSION GENE AND HIGH MSI2 GENE EXPRESSION IN BLASTIC PHASE CHRONIC MYELOID LEUKEMIA

D Di Giacomo[1], V Pierini[1], F Arcioni[1], L Brunetti[1], G Barba[1], P Gorello[1], E Gottardi[2], C Mecucci[1]
[1]University of Perugia, Perugia, Italy
[2]University of Turin, Turin, Italy

Background. In hematopoietic malignancies, such as acute myeloid leukemia (AML), myelodysplastic syndromes, chronic myeloid leukemia in blast crisis (BC-CML), T-cell acute lymphoblastic leukemia, recurrent balanced translocations and inversions cause *NUP98* (11p15) to fuse with a partner gene. All fusion transcripts maintain the 5'-end of *NUP98* and the 3'-end of the partner gene, at least 28 of which have been identified to date. They are either homeobox (HOX), with a homeodomain region, or non-homeobox genes. NUP98/

HOX proteins retain the homeodomain with its DNA binding ability. Some also retain a short ANWL motif, which binds the transcriptional cofactors of the PBX family. The best characterized *HOX* partner is found in the *NUP98-HOXA9* fusion from a *t*(7;*11*)(p15;p15) and was first identified in AML (Nakamura et al Nature Genetics 1996). Subsequently, cooperation of NUP98/HOXA9 with BCR-ABL (Moore et al. *Ann.N.Y.Acad.Sci.* 2007) was proven. Recently Ito et al. (*Nature* 2010)and Kharas et al. (*Nature Medicine* 2010) showed that murine *Nup98/HoxA9* binds the *Musashi2* gene transcription start site, leading to over-expression, downstream NUMB-NOTCH1 pathway deregulation, loss of myeloid cell differentiation and increased proliferation. **Aims.** To investigate *MSI2* gene expression regulation in BC-CML bearing *NUP98/ HOXA13* fusion. **Methods and Patients.** Conventional Cytogenetics and FISH studies were performed on peripheral blood cells at diagnosis of BC-CML in a 39-year old man. Karyotype was 46,XY,t(7;11) (p15;p15),t(9;22) (q34;q11). FISH and RT-PCR confirmed the *BCR/ABL1* fusion. Given the 11p15 breakpoint, we performed a break-apart FISH assay with clones RP11-348A20 and CTD-3234F16 for *NUP98* gene (Gorello et al *Haematologica* 2008). The 7p15 breakpoint was investigated with probes RP1-170O19 and RP1-167F23 spanning the *HOXA* cluster genes. Nested-PCRs used *NUP98*-specific forward primers and specific reverse primers for the hypothetical partner genes: *HOXA9, HOXA11* and *HOXA13*.qRT-PCR was performed on the patient's cryopreserved bone marrow RNA sample. Additional samples included 13 BC-CML, 3 CP-CML, 4 AML (3 NPM+FLT3+ and 1 NPM+FLT3-) Controls were 3 non-neoplastic bone marrow samples. Quantitative PCR was performed using TaqMan probes (Applied Biosystems) Hs00292670_m1, for *MSI2*, and Hs00245445_m1 for the endogenous reference control, *ABL1*. Expression levels were normalized with the Universal Human Reference RNA (Stratagene). **Results.** Three splicing variants of the in frame fusion transcript *NUP98/HOXA13* were identified, all with the breakpoint between exon 16 (nt 2322) of *NUP98* and exon 2 (nt 952) of *HOXA13* gene. *MSI2* was over-expressed in the *NUP98/HOXA13* patient (6.21) another BC-CML case with complex karyotype (5.27), and 2/4 AML cases, both NPM+FLT3+ (6.69 and 6.92). Median values were: 1.96 for BC-CML, 3.14 for CP-CML and 3.55 for controls. **Conclusions.** We show for the first time that, in addition to *NUP98/HOXA9*, also the *NUP98/HOXA13* fusion gene underlies *Musashi2* over-expression in BC-CML. As *MSI2* was over-expressed in another BC-CML case with a complex karyotype and no evidence of t(7;11), we are now investigating its molecular lesions. *MSI2* over-expression in two NPM+FLT3+ AML confirmed previous results in a subset of AML (Griner et al. *Cancer Biology and Therapy* 2010). High *MSI2* expression could be one critical pathway in acute myeloid proliferation and may underlie BC progression in Ph-positive CML.

Background. Although most patients in chronic phase CML (CP-CML) respond to tyrosine kinase inhibitor therapy, the kinetic of response and - for patients reaching stable complete molecular response - the probability to maintain response after therapy cessation, are different. To date, clinical heterogeneity of CML is only assessed by pre-treatment scoring such as the Sokal score. It is believed that this clinical heterogeneity depends on the inherent nature of the disease and may be related to genetic heterogeneity of CML progenitors at diagnosis. **Aims.** To clarify the biological significance of Sokal score and to increase predictive value of pre-treatment scores, especially for patients of intermediate risk, using high-resolution genetic characterization. **Methods.**We collected 100 CD34+/fibroblasts paired samples at CP-CML diagnosis from bone marrow aspirates, and have performed Genome-Wide Human SNP 6.0 array (Affymetrix) for SNP-A karyotyping analysis on a subset of 40 pairs. **Results.** For this pilot study 40 of 100 patients have been analyzed (14 low risk, 22 intermediate risk, and four high risk patients). We have detected somatic alterations widely distributed among all chromosomes: 206 losses; 225 gains; 396 loss of heterozygoty/ uniparental disomy [LOH/UPD]. These lesions are of relatively small size, ranging from 100 to 1000 Kb, and from 1041 to 9000 Kb for gains/loss and LOH/UPD, respectively.Statistical analysis revealed lack of significant correlation between Sokal score and age, and type of alteration (i.e., LOH, gains, and losses). Interestingly, a lower Sokal score tends to have more genetic lesions, and vice versa (p=0.068). Of note, the number of patients with high Sokal score is very low in this preliminary analysis, and thus not allowing a definitive conclusion. However, this observation suggests that it is not the number of lesions (probably randomly distributed) but likely the type of affected region which may be relevant. Indeed, we have found 9q22.32-22.33 and 17p11.2 recurrent UPD among two out of the four high scored patients, both regions include candidate genes known to be involved in tumorogenesis or cell proliferation. Interestingly, the 17p11.2 region is also subject to parental imprinting. **Conclusions.** Our preliminary results confirm the genetic heterogeneity of CML at diagnosis with genetic instability-related alterations randomly distributed. But the inherent nature of CML (illustrated by the Sokal score) may more likely be related to the type of alteration, with only few relevant alterations related with higher pre-therapeutic score, rather than to the number of genetic lesions (i.e. level of genetic instability). Next generation sequencing strategies of candidate genes within these recurrent UPD regions, if these results are confirmed on the entire cohort with increased number of high Sokal score, will then be further investigated.

THE MATRICELLULAR PROTEIN CCN3 REDUCES NOTCH SIGNALING IN CHRONIC MYELOID LEUKEMIA

S Suresh[1], L McCallum[2], A Irvine[1]
[1]Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom
[2]School of Biomedical and Biological Sciences, University of Plymouth, Plymouth, United Kingdom

Background. Notch is a key regulator of hematopoiesis. Active Notch maintains hematopoietic stem cells in an undifferentiated state and inhibition of Notch signaling is required for differentiation to proceed. Deregulated Notch has been associated with Leukemia, although its role in Chronic Myeloid Leukemia (CML) is not well established. Previously, we reported BCR-ABL downregulation of the matricellular protein Ccn3 in CML; Ccn3 is a Notch ligand. This study examines the Notch-Ccn3 signaling axis in CML. **Aims.** To characterize the Notch-Ccn3 signaling pathway in CML. **Methods.** Western blotting was used to determine Notch1 and Ccn3 expression in CD34+ progenitors, mononuclear cells and neutrophils from CML and normal bone marrow (n=5). K562, KCL22 and LAMA cells (none of which express significant Ccn3 as a consequence of Bcr-Abl activity) were used as CML model systems. K562 cells stably overexpressing CCN3 (K562/CCN3) were used to study signaling mechanisms. Using siRNA, BCR-ABL was silenced in K562 cells and expression of Notch1 full length (FL), Notch1 intracellular domain (ICD), downstream targets c-Myc and Hes1 were evaluated. CML cell lines K562, K562/CCN3, KCL22 and LAMA were treated with gamma secretase inhibitor (GSI) to block Notch signaling (25 nM-1 μM) and viability measured by CellTiter-Glo®. Additional functional readouts were clonogenic assays and cell cycle analysis. All experiments were performed in triplicate. **Results.** Normal bone marrow cells homogeneously express Notch1, whilst Ccn3 is moderately expressed in CD34+ and mononuclear cells and reduced in neutrophils, consistent with a role for Ccn3 inducing myelopoietic differentiation. In CML, Notch1 is highly expressed in CD34+, mononuclear cells and neutrophils whereas Ccn3 is absent in CD34+ cells and neutrophils. Silencing BCR-ABL in K562 cells reduced Notch-FL and completely inhibited Notch-ICD cleavage, c-Myc and Hes1 ($p<0.001$). Notch1 mRNA levels were comparable in K562 and K562/CCN3 cells whereas Notch FL, Notch-ICD and Hes1 were reduced in K562/CCN3 cells ($p<0.01$). Co-immunoprecipitation showed Ccn3 interacting with Notch extracellular domain. GSI treatment of K562, KCL22 and LAMA cell lines had no effect on cell viability but reduced K562/CCN3 proliferation (100 nM GSI, 50.9±6.75 %, $p<0.01$). GSI treatment significantly decreased expression of Notch-FL and Notch-ICD in K562/CCN3 cells but in K562 cells Notch-FL was stabilized and Notch-ICD unchanged. Cell cycle analysis showed a subtle but significant increase in the

sub G0 population in K562/CCN3 cells (~2 fold, p<0.05) and notably formed fewer colonies with all concentrations of GSI (25 nM GSI, 11.6±0.43 in K562/CCN3 and 80.6±1.38 in K562 cells, p<0.001). Treatment with recombinant Ccn3 (rCcn3) reduced Notch-ICD and Hes1 expression in K562 cells (p<0.01). rCcn3 sensitized K562 cells to GSI with 30.2±1.04% reduction in viability (100 nM GSI, p<0.01). **Conclusions.** In CML, Bcr-Abl upregulates Notch1 simultaneously downregulating Ccn3, which disrupts the Notch-Ccn3 axis. Our study demonstrates Ccn3 as a negative regulator of Notch in CML and suggests Notch-Ccn3 signaling as an essential pathway maintaining normal hematopoietic function. Further understanding of Notch-Ccn3 axis may provide basis for novel treatment strategies in CML.

Background. Several lines of evidence associate ROS and antioxidant enzymes, which appear to play a major role not only in leukemogensis but display therapeutic implications in CML: bcr-abl tyrosine kinase induces the production of ROS in hematopoietic cells (Sattler et al 2000). Previously, our Lab. had found that peroxiredoxins (Prxs) are a ubiquitous family of multifunctional antioxidant thioredoxin-dependent peroxidases that have roles in the reversible inactivation of PTPs and PTEN in cells stimulated by growth factors and protect cells against oxidative stress and modulate intracellular signaling cascades (Rhee et al. Current Opinion in Cell Biology 17;183-189,2005). Recently, Agrawal-Singh et al (Blood 2011, Dec) had reported that PRX2 may be a tumor suppressor gene based on genomic wide analysis in myeloid leukemia primary cells. **Aims.** In this study, we investigated the changes of the levels of H_2O_2-removing enzymes (ie Prxs, glutathione peroxidase 1 (Gpx1), and catalase) during IM therapy in newly diagnosed CML and in the Ph positive K562 cell line with Imatinib treatment *in vitro* as well. **Patients and Methods.** Newly diagnosed CML BM samples were analyzed. This study was approved by the institutional review board. Patients were given written informed consents according to institutional guidelines. 400 mg or 600 mg of Imatinib was given to the chronic phase and accelerated/blast crisis samples respectively. Pairs of bone marrow sample at the diagnosis and at cytologic complete remission status of CML patients were evaluated for detection of intracellular ROS using dichlorodihydrofluorescein diacetate (DCFH-DA), the Immunohistochemical expression of PRX on single cell level and immunoblot assay for the expression of Prx1-6 and Gpx1. K562 cells were treated with Imatinib for 48 hours and RT-PCR and Immunoblot assay for PRX1-2 were performed. **Results.** Samples of newly diagnosed CML patients showed significantly decreased levels of Prx 2, but revealed increased level of catalase. As the level of Philadelphia chromosomes decreased with IM treatment, the expression levels of Prx II and catalase were restored to the levels of normal individuals. Interestingly, the Immunohistochemical expression of PRX on single cell level was well correlated with western blot results of PRX. Meanwhile, with the treatment of Imatinib into K562 cell line for 48hrs at 10 , there were significant elevations of PRX2, which may be supportive findings for the observations on CML patients during Imatinib treatment *in vivo*. In contrast, there were no obvious changes of PRX1 or PRX3 on protein level in K562 cells after treatment of Imatinib.**Conclusions.** Decreased Prx 2 and elevated catalase levels at the time of diagnosis are closely correlated with the elevated bcr/abl kinase level in newly diagnosed CML. The aberrant expression of those antioxidant enzymes were back to the level of normal individuals after IM treatment. Understanding the molecular mechanisms of changes on antioxidant may be potent tools to develop more effective new drugs in CML patients especially for Imatinib resistant patients.

INVOLVEMENT OF HEME OXYGENASE 1 IN THE MECHANISMS OF RESISTANCE TO IMATINIB MESYLATE IN CHRONIC MYELOID LEUKEMIA CELLS

D Tibullo, I Barbagallo, C Giallongo, N Parrinello, P La Cava, L Vanella, G Palumbo, F Stagno, G Li Volti, F Di Raimondo
University of Catania, Catania, Italy

Chronic myeloid leukemia (CML) is a stem cell disease in which BCR/ABL promotes the survival of leukemic cells. Identification of imatinib mesylate (IM) as a potent inhibitor of the Abl kinase and the subsequent findings that this compound displays growth inhibitory and pro-apoptotic effects in Bcr-Abl+ cells has deeply conditioned CML treatment. Unfortunately the initial striking efficacy of this drug has been overshadowed by the development of clinical resistance. Although the majority of Ph+ CML patients benefit from IM treatment, a substantial number of patients are either initially refractory to treatment or develop resistance during the course of treatment. A wide variety of molecular mechanisms can underlie resistance mechanisms. In the recent years, heme oxygenase-1 (HO-1) expression has been reported as an important protective endogenous mechanism against physical, chemical and biological stress and this cytoprotective role has already been demonstrated for several solid tumors and acute leukemia. To investigate the effect of HO-1 expression on cell proliferation and apoptosis in chronic myeloid leukemia cells, K562 and LAMA-84 cell lines were incubated for 24h with IM (1μM) or in combination with an inducer or inhibitor of HO-1 (Hemin and SnMP). In addition, cells were also treated with HO byproducts, bilirubin and carbon monoxide (CO), or with a protease inhibitor (Ed64). After pharmacological treatments we evaluated cell viability and HO-1 expression by real-time PCR. Pharmacological induction of HO-1 was able to overcome the effect of imatinib. The cytoprotective effect of HO-1 was further confirmed after silencing HO-1 by siRNA. Interestingly, neither bilirubin nor CO were able to protect cells from IM-induced toxicity. The protective effect of HO-1 was mitigated by the addition of Ed64, preventing HO-1 nuclear translocation. We also analyzed 96 kinase genes using *TaqMan® Low Density Array Human Kinases Panel* and found that induction of HO-1 in combination with IM increased seven different kinases. Finally, IM was able to increase the formation of cellular reactive oxygen species. This effect was reversed by HO-1 induction or the addition of N-acetylcisteine. In conclusion, the protective effect of HO-1 on IM-induced cytotoxicity does not involve its enzymatic by-products, but rather the nuclear translocation of HO-1 following proteolytic cleavage. Migration of HO-1 into the nucleus activates several kinases which may be responsible for mitogenic signals activation.

Background. Introduction of tyrosine kinase inhibitors (TKI) into clinical practice transformed chronic myeloid leukemia (CML) into truly chronic disorder. Although in the majority of cases remissions are durable, there is still a significant group of patients who develop resistance to the treatment and progress to blast crisis. Hence, there are still some unsolved clinical problems, including lack of reliable factors predicting rise in BCR/ABL level and disease progression. B*aculoviral* IAP repeat-containing (BIRC) is a family of eight functionally- and structurally-related proteins, which serve as endogenous inhibitors of apoptosis. Overexpression of various *BIRC* genes has been associated with cancer progression, multidrug resistance, poor prognosis and short survival in several types of neoplasms including hematological malignancies. In CML blast crisis survivin (*BIRC5*) and XIAP (*BIRC4*) were upregulated in comparison to chronic phase. However, there is no data on the role of other *BIRC* family members in prediction of CML progression. **Aims**. Analysis of the expression of *BIRC* genes at various stages of CML as potential markers allowing predicting disease progression in patients treated with TKI.MethodsRelative expression of family of *BIRC* genes was tested using RT-qPCR in sequential samples of cDNA from peripheral blood leukocytes (PBL) obtained from CML patients at various stages of the disease (from diagnosis to progression to blast crisis) simultaneously with regular *BCR/ABL* expression monitoring. Blood samples were taken after informed consent. The results were confirmed in larger group of cDNA samples obtained from patients in chronic phase or blast crisis as well as healthy blood donors. RT-qPCR experiments were performed according to MIQE guidelines. The changes of BIRC proteins level were observed in West-

ern blotting experiments performed on PBL lysates from CML patients and healthy blood donors.ResultsAs previously described, *BIRC5* expression was upregulated in patients in blast crisis in comparison to patients in chronic phase. In turn, the other *BIRC* genes were differentially expressed and did not follow expected pattern (Figure 1), i.e. *BIRC1* expression was significantly increased in blast crisis, the expression of *BIRC2*, *BIRC3*, *BIRC4* and *BIRC6* was barely changed in the course of the disease, whereas *BIRC7* expression was at the limit of detection. Unexpectedly, massive drop of *BIRC8* expression was observed in blast crisis samples in comparison to samples obtained from patients in chronic phase and healthy blood donors. Downregulation of *BIRC8* in blast crisis was observed also at the protein level. **Summary.** This is the first study covering a complete set of *BIRC* gene family expression in various stages of CML. Among the studied genes, expression changes in blast crisis in comparison to chronic phase were observed for three genes: a significant upregulation of *BIRC1* and *BIRC5* as well as downregulation of *BIRC8*. Hence, after validation, they may serve as markers of progression in CML. However, elucidation of the role of *BIRC8* downregulation in the progression of CML requires further studies.

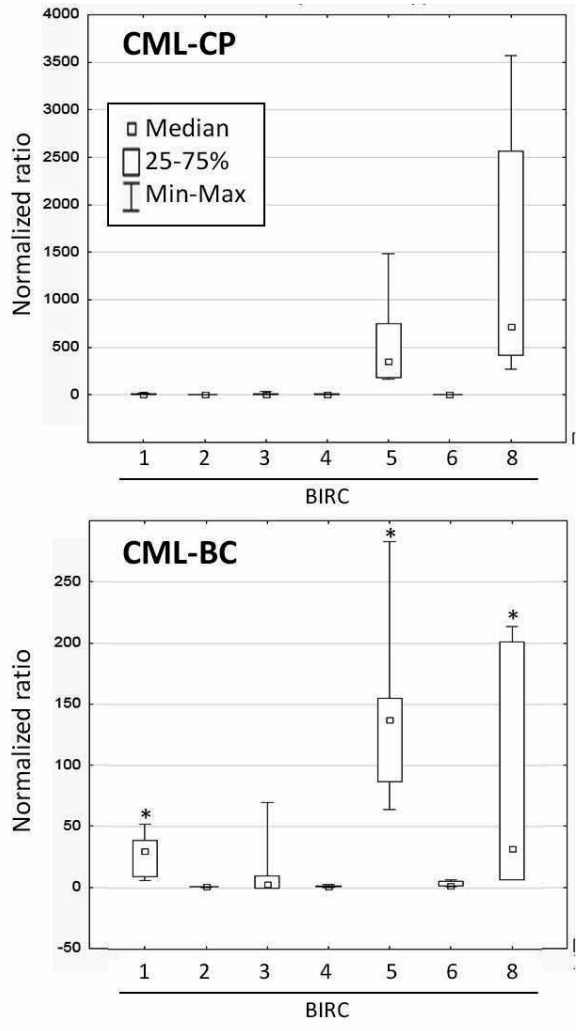

Figure 1. Expression of BIRC genes in chronic phase (CML-CP) and blast crisis (CML-BC). *p<0.05 vs. expression in CML-CP

[4]Oncology Centre - M. Sklodowska-Curie Institute, Warsaw, Poland

Background. Philadelphia chromosome is a main marker of the chronic myelogenous leukemia (CML) and occurs as a result of reciprocal translocation t(9;22)(q34;q11). In about 10-15% of the cases formation of Ph-chromosome is caused by complex translocations involving one or more additional chromosomes. *Aim* of this study was to determine frequency of complex translocations in CML and chromosomes involved. **Methods.** Cytogenetic investigations were performed in 212 patients with CML. Methods used were conventional cytogenetics and fluorescent *in situ* hybridization (FISH). *Results.* Of 212 patients with cytogenetically confirmed diagnosis of CML, 192 (91%) had Ph-chromosome formed by the standard translocation t(9;22)(q34;q11), whereas other 20 (9%) - had complex translocations. In 18 patients of the latter group complex translocations were revealed in all Ph-positive metaphases; other 2 patients had cells with both typical and complex translocations. In all of the 20 cases of complex translocations chromosomes 9 and 22 were involved with breakpoints typical for CML - 9q34 and 22q11. Except for the typical chromosomes 9 and 22, in 17 of complex translocations only 1 additional chromosome was involved; in 1 case - 3 chromosomes; in 1 more case - 4 chromosomes were engaged. The origin of additional chromosome was not determined in 1 case. Chromosome 2 was found to participate in three cases of complex translocations; chromosomes 1, 3, 4 and 17 - in 2 cases; and chromosomes 5, 6, 8, 9, 10, 11, 12, 13, 14, 16 and 19 - were involved in 1 case. The following breakpoints were engaged in the detected complex translocations: 1p36, 1q32, 2p13, 2q13, 2q36, 3p21, 3q25, 4p16, 4q12, 5q31, 6p21, 8q24, 9q22, 10q24, 11q13, 12q22, 13q13, 14q24, 16q23, 17p11, 17q23, 19q13. In one of the cases exchange of the material between der(22) and chromosome 5 was revealed which resulted in atypical morphology of der(22) and localization of *BCR/ABL* gene on derivative of chromosome 5. In this case gene *ABL/BCR* was located on der(9). It may be assumed that in 3 cases the mechanism of formation of complex translocations (including cells with different types of translocations as well as the case of t(9;22;5)(q34;q11;q31) resulting in atypical localization of *BCR/ABL*) was a two-step process. Whereas in the remaining 17 cases it was a one-step event. **Conclusions.** In our study frequency of complex translocations was found to be 9%, which is comparable to the data reported in the literature. It was found that complex translocations apart from chromosomes 9 and 22 can involve almost all chromosomes of karyotype with various breakpoints engaged. However, most frequent additional chromosomes were chromosome 2 (15% cases), 1, 3, 4 and 17 (10% of complex translocations each). Complex translocations involved more than 1 additional chromosome in 10% of cases. Probability of both one-step and two-step mechanisms of complex translocation occurrence was shown with respective frequency of 85% and 15%. Presence of secondary complex translocation may result in modifications of morphology of der(22) and localization of *BCR/ABL* gene and may be the sign of clonal evolution.

COMPARATIVE PHENOTYPIC ANALYSIS OF NK RECEPTORS ON 25 CP-CML PATIENTS WITH SUSTAINED COMPLETE MOLECULAR RESPONSE (CMR) AND MAJOR MOLECULAR RESPONSE (MMR)

G Binotto, AL Crispino, E Boscaro, S Carraro, M Castelli, M Cavraro, A Colpo, L Pavan, L Trentin, R Zambello, G Semenzato
University of Padua School of Medicine, Padova, Italy

Background. The critical role of BCR-ABL kinase activity in chronic myeloid leukemia (CML) pathogenesis has prompted tyrosine kinase inhibitors (TKIs) to become the gold standard of CML treatment. Although targeted therapy effectively induces and sustains cytogenetic and molecular responses, low levels of disease often persists, and TKIs can be safely discontinued only in a small subset of patients. Why a proportion of CMR patients do no relapse remains poorly understood and immunologic control of leukemic clone has been advocated. Several studies demonstrated that NK cells exert antileukemic activity through “missing self”recognition, which is regulated by a balance between NK inhibitory or activatory receptors signals. Previous reports have outlined the role of NKG2D in susceptibility of CML to NK cell-mediated cytotoxicity, which is par-

adoxically counterbalanced by imatinib negative modulation. **Aims.** The aims of the study were to assess whether a specific pattern of NK receptors (NKR) correlated with the achievement of complete or major molecular response. In addition, we investigated the presence of distinct NKR profiles within CMR patients group. **Methods.** Peripheral blood samples were collected from 25 CP-CML patients treated with imatinib. 10 patients with sustained CMR (median age 52 years, 35-75; mean disease duration 84 months; mean treatment duration 68 months, 19-117; mean response duration 52.7 months, 24-87), 15 patients with MMR (median age 56 years, 33-73; mean disease duration 68 months; mean treatment duration 57 months, 17-96; mean response duration 23.6 months, 12-42).NK receptors expression (Killer Immunoglobulin-like Receptors, KIR: p70, p140, p58/p50; Killer Lectin-like Receptors, KLR: CD94, NKG2A, NKG2C/A, NKG2D; Natural Cytotoxicity Receptors, NCR: NKp30, NKp44, NKp46, NKp80; Co-receptors: 2B4; LIR1/ILT2, GPR56) was analyzed by flow cytometry in CD3-/CD16+ subset.4. **Results.** WBC count, lymphocyte count and NK cell percentage were comparable between the two groups. No statistical differences in KIR profile were observed; interestingly, lower expression of p70 was documented compared to healthy controls (% positive cells: 3.9 and 5.4 respectively vs 17.1); NCR receptors were uniformly expressed in the two groups and were similar to healthy controls; lower expression of KLR NKG2A was observed when compared with normal population.As we observed a wide intragroup variability of NKG2D (33% of CMR patients were NKG2D negative) we performed a subanalysis of CMR patients based on NKG2D expression. Remarkably, activating receptors were preferentially expressed in NKG2D+ group: NKG2C (12.5% vs 7%; p=0.014), 2B4 (50% vs 38%; p=0.019), NKp46 (9.5% vs 4.5%; p=0.021). **Conclusions.** Although no NK receptor profiles seems to correlate with achievement of CMR or MMR (probably because these are not really distinct populations since some MMR patients will obtain CMR with time), we identified two subpopulations of CMR patients, based on NKG2D expression, with distinct activating receptor profile. This data suggest that NKG2D mediated cytotoxicity and, possibly, resistance to imatinib negative modulation, might account for CML residual disease control by NK cells in a subset of CMR patients. We are planning to evaluate the prognostic value of NKG2D expression in terms of complete molecular response maintenance after therapy discontinuation.

[2]National Research Center for Radiation Medicine, Kyiv, Ukraine

Background. Despite the successes of tyrosine kinase inhibitor (TKI) therapy, some patients with newly diagnosed chronic phase (CP) of chronic myeloid leukemia (CML) have inadequate response to treatment. The main causes of resistance are BCR-ABL mutations and clonal evolution. However, there are other mechanisms of resistance including hyperexpression of transmembrane glycoprotein Pgp-170, that is a a marker of multidrug resistance. **Aims.** the aim of study was to determine the features of expression of glycoprotein Pgp-170 in CML patients treated by TKI. **Methods.** We included 46 patients with CP-CML in study. Median age of patients was 35.3 years (range 19-65). Diagnostics and monitoring of CML were perfomed on the basis of cytogenetic examination of bone marrow cells by G-banding, and also molecular-genetic research of bone marrow and peripheral blood. The efficiency of TKI application was evaluated after 12 months of therapy. 36 patients have received imatinib (40% of them as the first line therapy), 10 patients have taken nilotinib (20% of them as first line therapy, the others have taken nilotinib after failure of imatinib treatment). The patients with suboptimal response to therapy and treatment failures were classified as resistant patients. The immunological studies were conducted on a FACscan flow laser cytometer. The number of $CD33^+$, $CD34^+$ cells in peripheral blood and bone marrow expressing Pgp-170 in CML patients was determined. **Results.** Results of study suggested that the number of $CD33^+$ hemopoietic cells with co-expression of transmembrane glycoprotein Pgp-170 was increased in CML patients who had resistance to TKI comparing with patients with optimal response on therapy ($p<0.05$). Comparing analysis has shown that in CML patients with resistance to therapy the number of $CD34^+Pgp\text{-}170^+$ hemopoietic cells in bone marrow and peripheral blood was also increased ($p<0.05$). The direct correlation between the number of $CD33^+$ $Pgp\text{-}170^+$ and Ph^+ bone marrow cells have been determined ($r = 0,893$, $p<0,0001$). **Conclusions.** The results of our study confirm the role of Pgp-170 in the development of resistance to TKI therapy in CML patients treated by TKI.

IS DETECTION OF CYP3A5*3 ALLELE IN CHRONIC MYELOID LEUKEMIA PATIENTS PRIOR TO TREATMENT WITH IMATINIB MESYLATE RELEVANT?

F Vrbacky, P Belohlavkova, J Voglova, J Malakova, J Nekvindova, Z Jiruchova, P Zak, J Maly, L Smolej
Faculty of Medicine and University Hospital, Charles University, Hradec Kralove, Czech Republic

Background. Imatinib mesylate (IM) is known to be metabolized by CYP3A subfamily members of cytochrome P450 family. When expressed, CYP3A5 can represent up to 50% of CYP3A protein and its inactivation can lead to significant variation of CYP3A mediated IM metabolism. Inactive allele CYP3A5*3 is predominant in Caucasian population. This single nucleotide polymorphism (SNP) A6986G (rs776746) forms cryptic splicing site and leads to incorporation of intron into mRNA, premature termination of translation and expression of truncated protein. Active allele CYP3A5*1 is very rare in Caucasian population, but there are significant differences in distribution of CYP3A5 allelic variants in different ethnic groups. **Aims.** To determine frequency of CYP3A5*3 allele in our cohort of IM-treated patients and assess the relevance of CYP3A5*3 allele detection prior to IM treatment. **Methods.** We retrospectively analyzed therapeutical response to IM (400 mg /day) according to European LeukemiaNet (ELN) recommendations in a cohort of 64 patients diagnosed in chronic phase of CML. Patients with treatment failure due to mutations in kinase domain of ABL were not included. CYP3A5*3 was detected by TaqMan SNP genotyping assay. IM plasma levels were detected by liquid chromatography from samples taken 24 hours (+/- 2 hours) after the last imatinib dose. **Results.** Our cohort consisted of 58 CYP3A5*3 homozygotes, 5 heterozygotes and 1 wild type homozygote, leading to the frequency of allele different than CYP3A5*3 5.7%. Major molecular response at 18 months after diagnosis was not associated with CYP3A5*3/*3 genotype ($n = 63$, $p = 0.191$) but heterozygous or wild type individuals for CYP3A5*3 allele showed a trend towards failure of complete cytogenetical response at 12 months ($n = 64$, $p = 0.053$). Plasma levels of IM were not altered by CYP3A5*3/*3 genotype ($n = 56$, $p = 0.656$). **Conclusions.** Our study did not confirm any association of heterozygous or wild type genotype for CYP3A5*3 allele and suboptimal response or failure of IM treatment according to ELN but heterozygous or wild type individuals for CYP3A5*3 allele displayed a trend towards failure of complete cytogenetical response at 12 months after diagnosis. Thus, cheap and fast genotyping of CYP3A5*3 in Caucasian population could be relevant but further study with larger patient cohorts are needed to confirm our findings. This study was supported by research project MZO 00179906 from Ministry of Health, Czech Republic.

Chronic myeloid leukemia - Clinical 1

T315I MUTATIONS ARE CLUSTERED WITH ADVANCED PHASES CONTRARY TO OTHER ABERRATIONS IN CML PATIENTS RESISTANT TO TKI THERAPY

J Malcikova[1], T Jurcek[2], F Razga[1], D Dvorakova[1], D Zackova[2], N Darzentas[1], L Sebejova[2], J Smardova[2], A Oltova[2], L Jurackova[2], M Trbusek[1], M Doubek[2], S Pospisilova[1], J Mayer[2], Z Racil[2]
[1]CEITEC, Masaryk University, Brno, Czech Republic
[2]University Hospital Brno and Masaryk University, Brno, Czech Republic

Background. Various mechanisms of resistance to tyrosine kinase inhibitors (TKIs) in chronic myelogenous leukemia (CML) patients were described. Among them, mutations within *BCR-ABL1* kinase domain are the most frequently studied, since they affect binding of TKI molecule. However, mechanisms leading to subsequent progression are still not fully elucidated. Inhibition of BCR-ABL1 by imatinib was suggested to induce p53 pathway, therefore, p53 inactivation could possibly influence therapy response. Beside this, mutations in genes involved in myeloid transformation (e.g. *ASXL11* and *CBL*) were identified, and their role in disease progression is under investigation. **Aims.** We analyzed genomic aberrations and mutations in *BCR-ABL1*, *TP53*, *ASXL1* and *CBL* genes in patients with primary or acquired resistance to TKIs therapy. **Methods.** Only patients that lost or never achieved major cytogenetic response were included in the study. Mutations in *BCR-ABL1* kinase domain were detected using direct sequencing and T315I-specific ligation PCR. *TP53* mutational status of exons 4-10 was examined by functional analysis (FASAY) coupled to direct sequencing. Mutational analysis of *ASXL1* (exon 12) and *CBL* (exons 8, 9) genes was performed by direct sequencing of gDNA. Genomic changes were detected using conventional metaphase cytogenetics and Affymetrix 2.7M Cytogenetic arrays. **Results.** In total, 26 TKI-resistant CML patients were investigated. 6 patients were examined at the time of blast crisis and 4 in the accelerated phase. In 12 patients *BCR-ABL1* mutation was identified at the time of genomic analyses, among them, 6 patients carried mutation T315I. Remaining patients (n=20) were additionally examined using T315I-specific ligation PCR, and this mutation was identified in 2 patients thereafter. Remarkably, from patients with T315I mutations (n=8), 7 were in advanced disease phase. Additional genomic aberrations were identified in 13/26 of patients. The detected changes included commonly observed large alterations (+8, -Y, i(17q)), cryptic copy number changes and uniparental disomy. Disruption of the p53 pathway was observed in 3 patients: one patient had *TP53* gene deletion caused by i(17q), one harbored biallelic deletion of *CDKN2A* that codes for a protein stabilizing p53 protein, and in one patient a *TP53* mutation was detected. The *TP53* mutation was present after progression to the blast crisis and was not detected in chronic phase, when TKIs resistance was manifested. Mutation in the *ASXL1* gene was identified in 9/26 patients, however, no mutation in the *CBL* gene was detected. Distribution of observed genetic and genomic lesions in individual CML patients is shown in the Figure 1. Mutation T315I clustered with advanced phases, while other changes seem to be distributed randomly. **Conclusions.** Patients with primary or acquired resistance to TKIs showed different pattern of gene mutations and genomic aberrations. TKI resistance in CML patients is probably not associated with alterations in the p53 pathway. Additional changes potentially influencing treatment response were found. However, most important event facilitating disease progression is likely the presence of T315I mutation in *BCR-ABL1*, as this mutation was identified in almost all patients that progressed to advanced phases.This work was supported with CZ.1.05/1.1.00/02.0068, CZ.1.07/2.3.00/20.0045, CZ.1.07/2.4.00/17.0042, MSM0021622430, and MUNI/A/0784/2011.

ETV6/ABL1 FUSION IN CHRONIC MYELOID LEUKEMIA

K Gancheva[1], D Brazma[2], J Howard-Reeves[2], H Mazzullo[2], N Zareian[1], P Partheniou[2], P Kotzampaltiris[2], C Grace[1], A Virchis[3], E Nacheva[1]
[1]UCL, Cancer Institute, London, United Kingdom
[2]Royal Free NHS Trust Hospital, London, United Kingdom
[3]Barnet NHS Hospital, Barnet, Herts, United Kingdom

Background. Chronic myeloid leukemia (CML) patients usually present with the Philadelphia (Ph) chromosome that results from t(9;22)(q34;q22) or variants, giving rise to a BCR/ABL1 fusion gene. Occasionally ABL1 forms chimeric products with 6 other genes. Of these, the ETV6/ABL1 fusion gene is the most common and has been reported not only in CML patients, but also in other haematological malignancies. **Aims.** To analyze the formation of the fusion gene ETV6/ABL1 in a female CML patient with t(9;12)(q34;p13) as sole bone marrow chromosome abnormality at presentation.METHODS and CASE REPORT: The BM G banding analysis failed to detect a Ph chromosome in a sample from a 42-year-old female who presented with CML. Instead a major cell population was found with a karyotype of 46,XX,t(9;12)(q34;p13) [8/10]. FISH using commercial probes did not show ABL1 changes (D-FISH/BCR/ABL1, Vysis), but revealed rearrangement of the ETV6 (ETV6/BA, Vysis). Whole genome screening was performed by a customized oligonucleotide x400K array (*Agilent Technologies*) and RT-PCR to search for rearrangements of ABL1 and ETV6 genes. A range of BAC probes was applied to obtain a comprehensive FISH map of the t(9;12)(q34;p13) products. **Results.** FISH showed rearranged ETV6 with 9q34 being the translocation partner. RT-PCR using published primers (*Van Limbergen et al., Genes, Chrom & Cancer 30:274-282, 2001*) confirmed the presence of ETV6/ABL1 both type A and B transcripts. However, such transcripts are unlikely to result from a direct rearrangement via t(9;12)(q34;p13) because of the contra orientation of the ETV6 and ABL1 genes. It is has been previously suggested that other genome changes affecting either of the partners are required before the formation of this fusion. In our case the genome array analysis provided a clue. The genome screening carried out with oligonucleotide arrays covering primarily exonic areas of over 2,000 genes revealed two main facts: (i) deletions within ETV6 consistent with rearrangements but unexpectedly, gains and losses within the NOTCH gene at 9q34.3 and (ii) a high level of genome instability evidenced by multiple cryptic imbalances affecting regions that harbor genes with known role in myeloid proliferation such as JAK2 (9p24.1), SYK (9q22.2), CCND1 (11q13.3), NTRK3(15q25.3) and RUNX1 (21q22.12) among others. We 'walked' with BAC probes along the 9q34 region and identified the breakpoint within NOTCH. Taken together, the array and FISH mapping data suggests a multistage mechanism for the formation of the ETV6/ABL1 fusion: firstly, translocation after breaks within NOTCH1 at 9q34 and within ETV6 at 12p13, followed by an inversion within the der(9) chromosome that results in formation of the ABL1/ETV6 fusion.SUMMARY: ETV6/ABL1 is a rare fusion gene in hematological malignancies, associated high genome aberration load and poor prognosis. We show that the formation of this rearrangement involves a third partner, the NOTCH1 gene and multiple cryptic genome lesions. These findings are reviewed in the context of 23 other similar cases published so far.

[5]Hospital Pulau Pinang, Penang, Malaysia
[6]Department of Medicine and Cell Therapy Centre, UKM Medical centre, Kuala Lumpur, Malaysia

Background. Despite the successful introduction of Imatinib Mesylate (IM) in Chronic Myeloid Leukemia (CML) treatment, success of this agent has been hampered by issues of clinical resistance and variability in treatment response. Various mechanisms for interindividual response variation have been described involving BCR-ABL1 dependent and BCR-ABL independent pathways. BCR-ABL dependent mechanism usually involves point mutations in the Tyrosine Kinase Domain (TKD) and amplification of BCR-ABL gene. BCR-ABL independent pathway still remains unclear with several postulated mechanisms. The HOX gene network encodes master regulators in haematopoiesis and

DNA methylation has been implicated to have an important role in aberrant control of HOX gene expression. Methylation of HOXA4 and HOXA5 has been strongly associated with progression to blast crisis and poor response to IM in CML patients. **Aims.** We hypothesized that DNA methylation of HOXA4 and HOXA5 might be associated with IM response variation. ABCB1 and ABCG2 are genes involved in IM transport and it was hypothesized that SNPs in ABCB1 and ABCG2 genes could also influence the efficacy of absorption or elimination of IM and modulate response variation. We explored the contribution of TKD mutations of BCR-ABL gene, methylation status of HOXA4 and HOXA5 genes, and SNPs of ABCB1 (T1236C, G2677T/A, C3435T) and ABCG2 (G34A, C421A) genes in affecting variation in response to IM in Malaysian CML patients. **Methods.** We employed dHPLC followed by sequencing for mutation analysis in 44 IM resistant CML patients, MS-HRM for methylation profiling and PCR-RFLP for genotyping of the 5 SNPs in 72 CML patients involving both IM good response and resistant CML patients. **Results.** Point mutations in the BCR-ABL were detected in 10/44 patients (22.7%). Six different types of mutations consisting of T315I(5), E255K(1), Y253H(1), M351T(1), V289F(1), E251G(1) were detected with T315I as the most predominant mutation. Point mutations in BCR-ABL TKD appeared to be a dominant BCR-ABL dependent mechanism accounting for resistance. Regarding BCR-ABL independent mechanism, HOXA5 was hypermethylated in both good response and resistant CML patients whereas HOXA4 methylation was higher in IM resistant (n=34) than IM good response CML patients (n=23) but the difference was insignificant (p=0.077). Some of the genetic variations of ABCB1 and ABCG2 correlated with response to IM. The genotype frequency of ABCB1 T1236T was significantly higher among good responders (p=0.039) whereas ABCB1 C1236C was higher among resistant group (p=0.0006). Likewise, ABCG2 C421C was significantly higher among resistant groups (p=0.004) but ABCG2 C421A was significantly higher among good responders (p=0.034). Other genotypes showed no significant difference between the two groups. **Summary and Conclusions.** Even though some of these SNPs influence IM response, our data are not significantly conclusive to translate into individual drug dose adjustment. The effect of IM depends on several genes and hence larger studies involving multiple genes exploring the potential effects of gene-gene interactions are clearly needed to elucidate the real impact of candidate gene polymorphisms and methylation profile on IM response and to what extent the use of second generation TKIs may eventually overcome the resistance imposed by genetic and epigenetic alterations.

Background. CML is characterized by the t(9;22)(q34;q11) chromosomal translocation, which leads to the constitutively activated BCR-ABL tyrosine-kinase (TK). Current treatment of CML is tyrosine-kinase inhibitor (TKI) therapy: Imatinib, Dasatinib and Nilotinib. Although most of the patients achieve complete cytogenetic and major molecular responses, the others get a suboptimal response or may show a TKI resistance. The main cause is the appearance of BCR-ABL TK point mutations, which impair and interfere with drug binding. Patients showing a TKI-specific mutation are eligible to alternative TKI treatment. Rare cases of splicing events inducing deletion or insertion of multiple nucleotides into ABL TK have been describe. **Aims.** We characterized the ABL deletions/insertions in 24 CML patients that showed Imatinib resistance. **Methods.** A total of 830 patients, treated in front-line therapy with Imatinib, were monitored by RQ-PCR, according to ELN recommendations. In 225 suboptimal or failure patients the ABL sequence of Bcr-Abl gene was analyzed by DHPLC and Sequencing. Deletions/insertions of ABL were confirmed by ARMS-PCR. Based on wild type BCR-ABL crystallography, mutated sequences were analyzed by homology modeling both to generate 3D structures and to predict TKI bindings. Informed consent was obtained from all patients. **Results.** We detected ABL mutations in 118 out of 225 (52%) tested patients: 80% of them reported single aminoacid substitutions in ABL, whereas the remaining patients show ex7-9 ABL deletion (19%) or insertion (1%). Among this 20% of patients no differences were observed in terms of age (median 52±18, range of 26-78), sex and WBC count.We observed ABL D363-R386del in 4 patients and homology modeling reveals that the entire activation loop have been lost, without modification in Dasatinib H-bonds. Moreover, we identified some mutations do not modify TKI interactions in ABL, i.e. ABL t1143del causing a C-terminal truncated ABL protein; a simultaneously insertion of ABL 293-1P and Lys294Gln exchange. In this last case, the insertion seems to attenuate the Imatinib-bond power, probably due the steric hindrance by proline. Indeed, the ins293-1P clone became predominant during Imatinib therapy, whereas it disappears during Dasatinib treatment. Homology modeling showed that 15 deletion of 177-336 nucleotides and one insertion of 1 nucleotide events caused frameshift and early truncation of ABL with loss of 3 out 5 Imatinib and all two Dasatinib H-bonds. Among these 15 patients, 7 switched to Dasatinib and died of advanced phases, while the remaining patients continued Imatinib or switched to Nilotinib and are still alive in cytogenetic complete response. Two patients with a complex BCR-ABL rearrangement (ex4-9 ABL deletion and ex13 BCR insertion) lost the mutated clone during Imatinib treatment. **Conclusions.** The TK domain is significantly altered in the majority of the detected ABL deletion/insertion alterations and Ph+ mutated cells are prone to add further alterations giving survival advantages to the leukemic clone. In conclusion, screening for deletion/insertion ABL mutation associated with homology modeling analysis to predict TKI binding, may be an experimental tool to help tailoring therapy for patients with CML.

Background. The introduction of Imatinib has significantly improved the outcome for patients with Ph+ CML. According to current recommendations, Imatinib (IM) should be continued indefinitely. However, optimal responders can be eligible for investigational trials of treatment discontinuation or modification. **Aims.** This study (ClinicalTrials.gov NCT 00858806) describes the effects of a policy of intermittent Imatinib (INTERIM) treatment (one month on/one month off) in patients ≥ 65 years old with Ph+ CML and stable complete cytogenetic response (CCgR), previously achieved with at least 2 years of standard (continuous) imatinib treatment. The primary endpoint of the study was the proportion of patients who maintained CCgR after 1 year of INTERIM (study core). **Methods.** Cytogentic and molecular responses were monitored by FISH and RT-Q-PCR every 3 months. Chromosome Banding Analysis (CBA) of marrow metaphases was performed at baseline, then only in case of FISH positivity (BCR-ABL positive nuclei > 1%) to define the loss of CCgR. The maximum tolerable rate of CCgR loss was statistically eastblished to 5%. **Results.** Seventy-six patients were enrolled, and were treated and monitored for a minimum of 12 months (study core). The clinical course was uneventful, in particular, no patient progressed to AP or BP, or lost complete hematologic response (CHR). No patient asked to resume the continuous treatment. At the end of the study-core (12 months), 6 patients (8%) lost CCgR (CBA-positive) and the probability of maintaining CBA-negativity was 92% (95% CI 86-98%). None of the patients who lost CCgR developed ACA in Ph+ cells. None of the factors which were examined by univariate and multivariate analysis was found to be asso-

ciated with CBA data, with the exception of the duration of imatinib therapy (HR=0.23, 95% CI 0.008-0.73, p=0.01). All the six patients who lost CCgR (CBA-positive) resumed continuous imatinib treatment at the same dose and returned in CCgR (CBA negative) after 3 to 9 months.At baseline, all patients but one (99%) were in MMR (MR 3.0), and 63 patients (83%) were in CMR (MR 4.0). At the end of the study core, these percentages were reduced to 76% and 58%, respectively. The probability of maintaining CMR (MR 4.0) was 63% (95% CI 52-75%) and MMR (MR3.0) was 76% (95% CI 67-86%). The percentage of patients in less than MMR (MR3.0) increased from 1% to 22% but no BCR-ABL mutations was found. None of the factors which were examined for a relationship with molecular response loss was found to be significant. After 12 months, the remaining 70 patients were allowed either to resume continuous treatment or to continue the intermittent treatment. Fifty-seven (75%) patients continue on INTERIM after 24 months, all in MMR (MR3.0) or in CMR (MR4.0). **Conclusions.** In summary, INTERIM produced a reversible loss of CCgR in 8% of patients but caused an increase of residual molecular disease in many more patients. However, INTERIM did not induce early a greater risk of disease progression and resistance to imatinib. **Acknowledgments.** EuropeanLeukemiaNet through the European Treatment and Outcome Study (EUTOS) and by Cofin 2009.

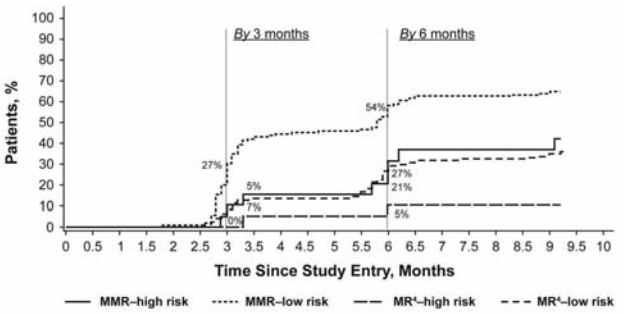
Background. Nilotinib, a potent selective inhibitor of BCR-ABL, was approved for the treatment of patients with newly diagnosed Ph+ CML-CP on the basis of data from ENESTnd. **Aims.** This phase IIIb, open-label study evaluated the efficacy and safety of nilotinib 300 mg BID as first-line therapy in patients with newly diagnosed Ph+ CML-CP. The primary endpoint was the rate of molecular response (MR^4,defined as detectable disease at ≤ 0.01% according to the international scale [IS] or undetectable disease in cDNA with ≥ 10,000 ABL transcripts) at 18 months as assessed in 13 European Treatment and Outcomes Study (EUTOS) laboratories to improve the sensitivity and standardization of RT-PCR for low-level BCR-ABL transcript detection. Secondary endpoints included MMR and CCyR at 12 and 24 months and rate of adverse events after achievement of MR^4. **Methods.** Patients with Ph+ CML-CP were administered nilotinib 300 mg BID. The MR^4 rate, defined above, was measured in peripheral blood leukocytes by quantitative RT-PCR, in 13 EUTOS laboratories. This is the first interim analysis of 200 patients who have reached 6 months. **Results.** To date, 1046 patients were recruited at 438 sites in 26 countries. 206 patients with at least 6 months follow up are presented here. Overall, 34%, 37%, and 18% of patients were classified as low, intermediate, and high Sokal risk; 80% and 9% of patients were classified as low and high EUTOS risk; remaining patients did not have available risk scores. In 191 patients with evaluable molecular samples, the CCyR rates by 3 and 6 months were 28% and 72%, and the MMR rates by 3 and 6 months were 22% and 52%, respectively. The MR^4 rates were 5% by 3 months and 19% by 6 months. Patients with low EUTOS risk had higher rates of both MMR and MR^4 by 3 and 6 months (Figure). Overall, 28% of patients had prior imatinib therapy (65% had > 6 weeks but < 3 months as allowed by protocol), and molecular responses were similar regardless of prior imatinib exposure. By 6 months, no patient had progressed to AP/BC. Adverse events (AE) were mostly grade 1-2 and manageable with dose interruptions/reduction: rash (22%), pruritus (17%), alopecia (12%), fatigue (12%), headache, and nausea (10%). Grade 3-4 hematologic AEs were uncommon. Grade 3-4 biochemical laboratory abnormalities included lipase increase (2%) and hyperbilirubinemia (2%). Treatment-related serious AEs were reported in 9% of patients. At 6 months, 89% of patients remained on study; 8% discontinued due to AEs. **Summary and Conclusions.** Current data demonstrate efficacy and safety of nilotinib 300 mg BID similar to that reported in other frontline trials, including ENESTnd. Through methodological improvements of RT-PCR, a network of EUTOS laboratories defined and measured MR^4 in a standardized manner. These efforts may further define deep molecular response to help identify patients potentially eligible for tyrosine kinase inhibitor discontinuation in future studies.



*n = 191 treated patients with evaluable molecular response data and typical transcripts.
EUTOS, European Treatment and Outcomes Study; MMR, major molecular response; MR^4, molecular remission with a sensitivity of 4 logs.

FREQUENT AND SUSTAINED DRUG-FREE REMISSION IN THE AUSTRALASIAN CML8 TRIAL OF IMATINIB WITHDRAWAL

M Ross[1], S Branford[1], J Seymour[2], C Arthur[2], A Schwarer[2], P Dang[1], J Goyne[1], P Bartley[3], C Field[1], C Slader[4], R Filshie[2], A Mills[2], J Melo[1], D White[1], A Grigg[2], T Hughes[1]
[1]SA Pathology, Adelaide, Australia
[2]Australasian Leukaemia & Lymphoma Group, Melbourne, Australia
[3]Flinders University, Adelaide, Australia
[4]Novartis Oncology, Sydney, Australia

Background. Selected patients with chronic myeloid leukaemia (CML) in stable complete molecular remission (CMR) on imatinib are able to stop treatment and may remain in remission. The prospective ALLG CML8 trial completed its accrual of 40 patients in August 2011. **Aims.** To identify risk factors for relapse when imatinib is stopped. **Methods.** Patients receiving imatinib for chronic phase CML were eligible if they were in CMR (no detectable BCR-ABL mRNA using real-time quantitative RT-PCR (RQ-PCR) with a sensitivity of at least 4.5-log) for ≥2 years. After giving informed consent patients stopped imatinib, and were monitored by RQ-PCR in a central laboratory: monthly for 12 months, 2-monthly in the second year, and 3-monthly thereafter. **Results.** 21 patients received imatinib after interferon therapy (IFN-IM cohort). 19 patients received imatinib frontline (IM cohort). The median follow-up was 33 months (IFN-IM 36mo; IM 33mo). 22 patients have met the study definition of relapse (BCR-ABL detected by RQ-PCR in two consecutive tests), while 18 patients remain in stable CMR after 5-66mo (median 33mo). Most relapses occurred within 6mo of stopping imatinib (median 3mo), but 7 relapses occurred later (range 6-24mo). Notably, late relapses generally did not show a rapid, exponential rise in BCR-ABL, whereas early relapses did. Imatinib treatment was recommenced at confirmed molecular relapse: 21/22 patients regained CMR, and the remaining patient was in MMR at last follow-up (14mo). No patient developed a kinase domain mutation. The actuarial molecular relapse-free survival was 42% (95% confidence interval 25-57%) at 33mo. This was similar between cohorts (IFN-IM 50%; IM 32%). We examined potential predictive factors for relapse (Table 1). Continuous variables were dichotomised about the median. In univariable analysis high risk Sokal score was associated with increased relapse risk (LO-INT 10/20; UNKNOWN 7/ 15; HI 5/5), as was a shorter duration of IFN treatment (in IFN-IM patients). Highly sensitive (6.2-log) and patient-specific BCR-ABL DNA PCR was used to monitor the level of minimal residual disease (MRD) in a subset of 25 patients with suitable diagnostic DNA available. 19/25 patients in CMR had detectable BCR-ABL DNA prior to stopping imatinib. Surprisingly, MRD detected by BCR-ABL DNA was **not** predictive of relapse risk, since 8 of these 19 patients remained in stable CMR with follow-up of 8-66mo. In stable CMR BCR-ABL DNA was detectable either intermittently or at a stable low level, around 1-log below the detection limit of RQ-PCR. With pro-

longed follow-up every patient had detectable MRD at least once while in CMR. No patient has become persistently DNA-negative so far. **Conclusions.** This study demonstrates that patients in stable CMR on imatinib can safely stop treatment with close molecular monitoring, and around 40% of these patients will remain in a durable CMR. These results are similar to the French STIM study, and are an important independent confirmation of the safety of this approach. DNA PCR studies suggest that the level of MRD is not the sole determinant of relapse risk. Further study is required to understand the biology of drug-free CMR.

EFFICACY AND SAFETY OF DASATINIB VS IMATINIB IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP): EUROPEAN SUBPOPULATION ANALYSIS OF THE PHASE 3 DASISION TRIAL

J Mayer[1], K Warzocha[2], F Huguet[3], F Stegelmann[4], J Steegmann[5], C Gambacorti-Passerini[6], C Lofgren[7], D Dejardin[7], A Hochhaus[8]

[5]Hospital Universitario de la Princesa, Madrid, Spain
[6]University of Milano Bicocca, S.Gerardo Hospital, Monza, Italy
[7]Bristol-Myers Squibb, Paris, France
[8]Universitätsklinikum Jena, Jena, Germany

Background. In the phase 3 DASISION trial of dasatinib vs imatinib in patients with newly diagnosed CML-CP, dasatinib demonstrated higher 12-month rates of complete cytogenetic response (CCyR) and major molecular response (MMR), lower rates of transformation, and was well tolerated (Kantarjian NEJM 2010 362 2260). **Aims.** Assess efficacy and safety of dasatinib vs imatinib in European patients from DASISION. **Methods.** After informed consent, patients were randomized to dasatinib 100 mg once daily (n=259) or imatinib 400 mg once daily (n=260). 170 patients enrolled were from European countries (France: n=41; Spain: n=30; Czech Republic: n=22; Poland: n=20; Italy: n=14; Germany n=12; Belgium: n=9; Hungary: n=6; The Netherlands: n=6; Austria: n=4; Denmark: n=4; Greece: n=2), with 74 and 96 patients receiving dasatinib and imatinib, respectively. Primary endpoint was confirmed CCyR (cCCyR) by 12 months. **Results.** In the European subpopulation and total population, 82% vs 75% and 77% vs 66% of dasatinib vs imatinib patients achieved cCCyR by 12 months, respectively. After 24 months, 73% and 72% of European patients and 77% and 75% of total patients receiving dasatinib and imatinib, respectively, remained on therapy. Respective 24-month cumulative rates of MMR in the European subpopulation and total population for dasatinib vs imatinib were 61% vs 48% and 64% vs 46%, respectively. Median time to MMR calculated using competing risk analysis in European patients was shorter for dasatinib (12 months) than imatinib (30 months). Among European patients, no patient receiving dasatinib transformed to accelerated/blast phase (AP/BP) on study or during follow-up after discontinuation, compared with four (4.2%) patients receiving imatinib. In the total population, nine (3.5%) vs 15 (5.8%) patients receiving dasatinib vs imatinib transformed. Drug-related adverse events (AEs) are shown (Table 1). Grade 3/4 non-hematologic AE rates were ≤1%. For dasatinib vs imatinib, in the European population (total population), 43% vs 29% (59% vs 43%) had dose interruption, 22% vs 16% (28% vs 15%) had dose reduction, and 11% vs 6% (7% vs 5%) discontinued due to AEs. Minimum 36-month follow-up will be presented. **Conclusions.** After 24 months dasatinib showed higher efficacy compared with imatinib, lower transformations to AP/BP, and was generally well tolerated. The efficacy and safety of dasatinib in the European subpopulation was similar to the total population, supporting first-line dasatinib use in European patients with newly diagnosed CML-CP.

0191

THE HIGH RATE OF BLAST CRISIS IN IMATINIB TREATED CHRONIC MYELOID LEUKAEMIA WITH HIGH CIP2A LEVELS IS NULLIFIED BY FIRST LINE DASATINIB OR NILOTINIB.

E McDonald, C Lucas, R Harris, R Clark
University of Liverpool, Liverpool, United Kingdom

Background. We have shown that a high CIP2A protein level at diagnosis of chronic myeloid leukaemia (CML) is a prospective biomarker of the development of blast crisis (Lucas et al Blood 2011; 117: 6660). CIP2A acts by inhibiting PP2A (a phosphatase and tumour suppressor which regulates cell proliferation, differentiation and survival) resulting in stabilisation of both PIM1 and c-Myc, predisposing patients to blast crisis. However the effect of second generation tyrosine kinase inhibitors (2G TKI) in high CIP2A patients is unknown. **Aims.** To investigate the progression rate in patients with a high CIP2A protein level at diagnosis, when treated with the 2G TKI dasatinib or nilotinib from initial diagnosis. **Methods.** CIP2A, PP2A, pY^{307}-PP2A, PIM1 and c-Myc proteins were assessed by flow cytometry in 59 newly diagnosed chronic phase patients, of which 31 patients received imatinib and 18 received dasatinib or nilotinib as first line treatment. Patients were stratified according to their CIP2A protein level at diagnosis. High CIP2A patients were defined as those patients with a CIP2A protein MFI >7 (Lucas et al Blood 2011; 117: 6660). **Results.** Of the 18 patients who received a 2G TKI from original diagnosis, all have achieved complete cytogenetic remission (CCR). All 11 of these who had a high CIP2A level at original diagnosis are alive and have not progressed, with a median follow up of 31 months; in stark contrast to the 100% actuarial progression rate in patients with high CIP2A treated with imatinib (Figure 1).

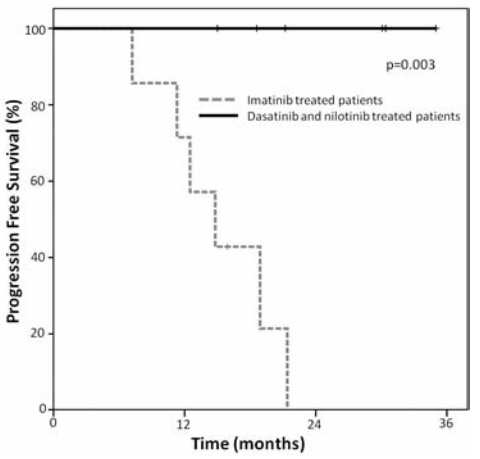

Figure 1.

High CIP2A patients treated with a 2G TKI had a trend towards a slower time to achieve MMR, compared to low CIP2A patients. At latest follow-up, no high CIP2A patient receiving a 2G TKI has yet achieved molecular negativity at the 4 log level (MR4.0), compared to 58% of low CIP2A patients (p=0.025).In K562 cells treated *in vitro* with TKI's at concentrations corresponding to Cmax, both dasatinib and nilotinib decrease CIP2A levels. In clinical samples, CIP2A protein level decreases in patients treated with either 2G TKI, and this is accompanied by an increase in PP2A activity and importantly a decrease in c-Myc serine 62 phosphorylation, thereby reducing its oncogenic activity. **Conclusions.** Patients presenting with high CIP2A levels have a very high risk of progression to blast crisis if treated with imatinib, but this risk is removed by using a 2G TKI as first line therapy. However, high CIP2A patients treated with 2G TKI have a lower probability of achieving deep molecular responses than those with low CIP2A levels, at least in the first 31 months of follow-up, and may merit more frequent observation. While these findings need independent confirmation, we hesitate to recommend imatinib for patients with high CIP2A protein levels at diagnosis unless very closely monitored.

Background. In the randomized phase 3 DASISION trial of dasatinib vs imatinib in patients with newly diagnosed CML-CP, dasatinib showed higher 12-month rates of complete cytogenetic response (CCyR) and major molecular response (MMR), lower transformation rates, and acceptable tolerability (Kantarjian NEJM 2010 362 2260). Recent reports indicate molecular responses of ≤10% BCR-ABL levels after three months of imatinib therapy are associated with increased overall survival and progression-free survival (PFS), and lower risk of failure (Hanfstein Blood 2010 116 abstract 360 and 2011 118 abstract 783; Marin JCO 2012 30 232). **Aims.** Analyze BCR-ABL kinetics in DASISION. **Methods.** After informed consent, patients received dasatinib 100 mg once daily (n=259) or imatinib 400 mg once daily (n=260). Typical BCR-ABL transcripts (b2a2 and b3a2) in peripheral blood were assessed using real-time quantitative PCR by a central independent laboratory. MMR was defined as BCR-ABL ≤0.1% on the international scale (IS; ≥3-log reduction from the standardized baseline). For PCR negative samples, ≥4.5 log sensitivity was confirmed (ABL level ≥25,614/reaction volume cDNA). **Results.** 24-month cumulative response rates in all patients calculated by competing risk analysis were higher for dasatinib vs imatinib: MMR: 65% vs 47%, P<0.0001; MR^4 ($BCR\text{-}ABL \leq 0.01\%$, ≥4-log reduction): 29% vs 19%, P=0.0053; $MR^{4.5}$ ($BCR\text{-}ABL \leq 0.0032\%$, ≥4.5-log reduction): 17% vs 9%, P=0.0032. Fewer patients receiving dasatinib (3.5%) transformed to accelerated/blast phase (AP/BP) vs imatinib (5.8%), on study or after discontinuation. The advantage in MMR rates for dasatinib over imatinib was maintained between 12 months (47% vs 28%) and 24 months (65% vs 47%). The advantage for dasatinib over imatinib at deeper levels of response ($MR^{4.5}$) increased between 12 months (5% vs 3%) and 24 months (17% vs 9%). Median time to MMR in all patients calculated by competing risk analysis was shorter for dasatinib (15 months) vs imatinib (35 months). Equivalent median BCR-ABL levels were achieved six months earlier with dasatinib than imatinib (Table 1).

Table 1.

BCR-ABL Kinetics		
	Median BCR-ABL level (IS), %	
	Dasatinib	Imatinib
3 Months	1.26	5.51
6 Months	0.30	1.01
12 Months	0.13	0.39
18 Months	0.06	0.15
24 Months	0.04	0.09

At three months, 84% vs 64% of evaluable patients receiving dasatinib vs imatinib achieved ≤10% BCR-ABL levels. Compared with patients who had >10% BCR-ABL levels at three months, patients achieving ≤10% had lower probability of transformation to AP/BP (dasatinib: 1.5% vs 8.1%; imatinib: 2.6% vs 9.4%), higher probability of 24-month PFS (dasatinib: 97% vs 83%; imatinib: 96% vs 85%), and higher probability of MMR by 24 months (dasatinib: 76% vs 16%; imatinib: 66% vs 19%). In this exploratory analysis, baseline characteristics were generally similar for patients achieving ≤10% and >10% BCR-ABL levels at three months. Compared with patients achieving ≤10% BCR-ABL levels, patients with >10%, had trends for intermediate/high Hasford risk scores, a greater proportion of splenomegaly, a larger spleen size among patients with splenomegaly, and higher WBC counts. Minimum 36-month follow-up will be presented. **Conclusions.** First-line dasatinib results in deeper and faster molecular responses vs imatinib, which are sustained with longer follow-up. In this exploratory analysis, earlier and deeper molecular responses appear associated with lower transformation rates and better long-term outcomes.

Background. The outcome of Philadelphia positive (Ph+) chronic myeloid leukemia (CML) patients has been significantly improved by the introduction of tyrosine kinase inhibitors (TKIs). Nilotinib (NIL) is a 2nd generation TKI with superior efficacy to imatinib (IM) approved as frontline therapy of CML in many countries. Until recently, the prognosis of CML patients has been evaluated using prognostic scores developed in the chemotherapy and in the interferon era. A new scoring system based on the analysis of a large cohort of CML patients treated with IM in early chronic phase (ECP), has been proposed by the European Leukemia-Net (ELN); the 2 variables included are basophils percentage and spleen size (Hasford J et al. Blood 2011;118:686-692). **Aims.** To investigate the prognostic value of the EUTOS score in a cohort of ECP CML patients treated frontline with NIL-based regimens. **Methods.** The patients were enrolled in two phase 2 multicentric studies conducted by the GIMEMA CML WP (ClinicalTrials.gov. NCT00481052 and NCT00769327) or were treated with NIL as initial treatment at the Bologna University Hospital. Definitions: complete cytogenetic response (CCgR) was defined as the absence of Ph+ metaphases over at least 20 metaphases examined by conventional banding analysis or <1% BCR-ABL+ nuclei over 200 nuclei examined by I-FISH; major molecular response (MMR) was defined as $BCR\text{-}ABL < 0{,}1\%^{IS}$; failures were defined according to 2009 ELN criteria; progression was defined as the transformation to accelerated or blastic phase; deaths, for any reason and at any time. All the calculations were performed according to the intention-to-treat principle. **Results.** 215 patients were included; the median age was 53 years (range 18-86). The median follow-up was 29 months (range: 18-43 months). The patient distribution according to the different scoring systems was as follows: EUTOS score 95% low and 5%; Sokal score 38% low, 44% intermediate and 18% high; Euro score 39% low, 56% intermediate and 5% high. The cumulative CCgR rate was 93%; the cumulative MMR rate was 89%; the failure-free survival was 90%; the progression-free survival was 93% and the overall survival 94%. Patients with low EUTOS score achieved a significantly higher cumulative rate of MMR than patients with a high EUTOS score (91% vs. 60%, p=0.01). Moreover, and more importantly (Figure 1), the patients with low EUTOS score had higher failure-free survival (91% vs. 70%, p=0.02), higher progression-free survival (94% vs. 80%, p=0.05) and higher overall survival

(95% vs. 79%, p=0.04) than the patients with a high EUTOS score. The Sokal score was able to predict differences in terms of MMR at any time and of failure-free survival, but not in terms of progression-free survival or overall survival. The Euro score failed to detect any response and outcome difference. **Conclusions.** The proportion of the patients who failed on NIL was small, reflecting the efficacy of the drug. In spite of that, the EUTOS score, developed from IM-treated patients, was able to identify this small group of patients, better than the Sokal and the EURO scores. **Acknowledgements.** European LeukemiaNet, COFIN,BolognaUniversity, BolognAIL

Background. Patients with fluctuating values of MRD have been observed after imatinib (IM) discontinuation in CML (Chronic Myelogenous Leukemia) patients (pts) in complete molecular response (CMR) for more than 2 years (STIM study, Mahon *et al*. Lancet Oncol. 2010). **Aims.** We analysed pts who stopped IM following a maintained CMR. Those patients were not included in the STIM study and were offered to restart therapy upon loss of major molecular response (MMR). We aimed to validate the loss of MMR as a criteria to restart IM. **Methods.** CP-CML pts were eligible if they were in CMR (CMR[4.5]: *BCR-ABL/ABL IS* <0.0032%) or UMRD (undetectable *BCR-ABL*) under IM therapy during 2 years. Some of these patients differed from the patients enrolled in the STIM study because they experienced one positivity of the *BCR-ABL/ABL* ratio during the 2 years follow-up. The criteria for restarting imatinib was the loss of MMR (BCR-ABL/ABL IS ratio >0.1%). We thus were able to calculate relapse free survival (RFS) using different criteria as end-points: loss CMR/UMRD defined by one occurrence MRD positivity, loss of CMR/UMRD using the STIM definition (two consecutive increasing values) and loss of MMR. **Results.** 58 CP-CML pts were included. Median follow-up after IM discontinuation was 17.2 months. Sex ratio (M/F) was 57% with a median age of 55.1 years. Sokal score distribution was 55.6%, 29.6% and 14.8% for low, intermediate and high risk respectively. 34 out of 58 (58.6%) pts received interferon therapy prior to IM. Median duration of IM therapy and median duration of CMR/UMRD prior to discontinuation was 77.2 months (30.1-145.4) and 37.1 months (24.7-96) respectively. Of note 31 out of 58 pts (53%) had a least one MRD positivity after the achievement of CMR/UMRD. We identified 18 patients (31%) who experienced repeated low levels of MRD after IM discontinuation without losing their MMR with a median follow-up of 23 months. We next analysed relapse free survival (RFS) using the loss of MMR criteria (RFS-MMR). Median RFS-MMR was not reached, compared to median RFS using the loss of CMR/UMRD criteria (4.8 months) and median RFS using the STIM criteria (13.7 months) (p=0.003). As a consequence, 65.6% of the patients remain treatment free at 2 years using the loss of MMR criteria. We then asked if prior therapy with interferon before IM may influence treatment free survival (TFS). Duration of IM therapy and Sokal score risk distribution were comparable in pts who received interferon or not. We observed a significantly longer TFS in interferon pre-treated pts as compared to patients who received IM first line (72% versus 55% at 2 years respectively, p=0.017). **Conclusions.** We validated the loss of MMR as robust criteria for restarting IM. We were able to identify up to 31% of pts in long term MMR with fluctuating values of BCR-ABL after IM discontinuation. We observed a better treatment free survival in patients previously treated with interferon before IM compared to patients who received IM as first line therapy emphasizing the putative role of interferon on CML stem cells.

INTRODUCTION: Nilotinib is a second-generation tyrosine kinase inhibitor (TKI) that demonstrated higher and faster responses and lower progression rates compared to imatinib in early chronic phase chronic myeloid leukemia patients (ECP CML). Early cytogenetic and molecular responses have been associated to a better outcome for imatinib treated patients (Jabbour et al. Blood 2011; Marin et al. JCO 2011). Few data are available concerning the relationships between the rapidity of the responses and the probability of subsequent progression to accelerated-blastic phase (AP/BP) after nilotinib-based regimens frontline. **Aims.** to evaluate the rate of progression and to identify early predictors of progression in ECP CML patients treated with nilotinib-based regimens. **Methods.** Two hundred fifteen patients were enrolled in two multicenter phase 2 studies conducted by the GIMEMA CML WP (ClinicalTrials.gov. NCT00481052 and NCT00769327) or were treated at the Department of Hematology and Oncological Sciences of S.Orsola-Malpighi Hospital - University of Bologna, with nilotinib 400 mg BID or 300 mg BID as initial treatment. The median age was 53 years (range 18-86). The median follow-up was 29 months (range: 18-43 months). Definitions: complete cytogenetic response (CCgR)

was defined as the absence of Ph+ metaphases over at least 20 bone marrow metaphases examined by conventional banding analysis or <1% BCR-ABL nuclei in peripheral blood by FISH (≥200 nuclei examined, I-FISH); molecular response was defined as the BCR-ABL/ABL ratio according to IS; progression was defined as the transformation to AB/BP. All the calculations were performed according to the intention-to-treat principle. **Results.** Overall, 8/215 (3,7%) patients progressed: 7/8 progressions occurred during the first year (2 patients at 4 months, 2 at 6 months, 2 at 10 months, 1 at 12 months and 1 at 13 months). At diagnosis 2 patients had clonal chromosome abnormalities; 2/8 patients had high EUTOS score, 6/8 intermediate (3) and high (3) Sokal score, 5/8 intermediate EURO score. At the time of progression the ABL mutational status was: 3 wild-type, 4 T315I, 1 Y253H. In order to identify early predictors of progression to AB/BP we analysed the cytogenetic and molecular response rates at 3 months in patients with and without subsequent progression. Seventy-four per cent (159/215) of the patients obtained a CCgR at 3 months, 3/159 progressed (1.9%); on the other hand, 26% (56/215) of the patients did not obtained a CCgR at 3 months (n=33) or were not evaluable (n=23), 5/56 (8.9%) progressed (p=0.0298)*. Eighty per cent (173/215) of the patients obtained a BCR-ABL/ABL ratio ≤ 1% at 3 months, 4/173 (2.3%) progressed; on the other hand, 20% (42/215) of the patients had a BCR-ABL/ABL ratio at 3 months > 1% (n=23) or were not evaluable (n=19), 4/42 (9.5%) progressed (p=0.0487)* **Conclusions.** In patients treated frontline with nilotinib-based regimens a CCgR and a BCR-ABL/ABL ratio ≤ 1% at 3 months correlated in univariate analysis with significantly reduced rates of progression to ABP. **Acknowledgements.** European LeukemiaNet, COFIN, Bologna University, and BolognAIL.

Background. Omacetaxine mepesuccinate ("omacetaxine") is an investigational, first-in-class cephalotaxine protein synthesis inhibitor that facilitates tumor cell death without depending on BCR-ABL signaling. Efficacy and safety were investigated in two phase 2, open-label, multicenter studies of patients with treatment-resistant chronic myeloid leukemia (CML) who had failed at least prior imatinib, many of whom were also resistant to or intolerant of dasatinib and/or nilotinib. **Aims.** This analysis of patients with CML and prior therapy with ≥2 tyrosine-kinase inhibitors (TKIs) assessed the efficacy and tolerability of omacetaxine across 3 groups: patients who had never achieved or had lost response to ≥2 TKIs (resistant group), were intolerant of ≥2 TKIs (intolerant group), or were resistant to 1 and intolerant of another (resistant/intolerant group). **Methods.** A subset of data from the phase 2 studies included patients in chronic phase (CP) and accelerated phase (AP) who were resistant/intolerant to ≥2 approved TKIs. All patients provided informed consent. Omacetaxine 1.25 mg/m^2 was given subcutaneously twice daily: ≤14 consecutive days/28-day cycle for induction, ≤7 days/cycle as maintenance. **Results.** Of 81 CP patients, 20% achieved major cytogenetic response (MCyR) for a median of 17.7 months (Table). Of these, 8 (10%) achieved complete cytogenetic response. Of 41 AP patients, 27% achieved major hematologic response (MaHR) for a median of 9 months (Table 1); none achieved a MCyR. Median cycles of exposure, study duration, and overall survival for each disease phase are also shown in the Table. Of 66 (81%) CP patients with treatment-related grade 3/4 adverse events (AEs; 54 resistant, 7 intolerant, 5 resistant/intolerant), the most common were thrombocytopenia in 44 resistant, 6 intolerant, and 4 resistant/intolerant patients and neutropenia in 32 resistant, 4 intolerant, and 1 resistant/intolerant patient. Fifteen CP patients had an AE leading to discontinuation (10 resistant, 2 intolerant, 3 resistant/intolerant), primarily disease progression. There were 10 deaths (the most common were disease progression and sepsis), 8 resistant, 1 intolerant, 1 resistant/intolerant; 2 were considered related to treatment (both sepsis). Of 28 AP (68%) patients with treatment-related grade 3/4 AEs (23 resistant, 3 intolerant, 2 resistant/intolerant), the most common were thrombocytopenia in 15 resistant, 2 intolerant, and 2 resistant/intolerant patients and anemia in 10 resistant, 3 intolerant, and 1 resistant/intolerant patients. Sixteen AP patients had an AE leading to discontinuation (16 resistant, 0 intolerant, 0 resistant/intolerant), primarily disease progression. There were 10 deaths due to AEs (the most common were disease progression and cerebral hemorrhage), 9 resistant, 1 resistant/intolerant; 2 were considered related to treatment (pancytopenia and febrile neutropenia). **Summary and Conclusions.** This subset analysis of patients with CML and prior therapy with ≥2 TKIs shows that omacetaxine provides efficacy and tolerability in both CP and AP across TKI-resistant, intolerant, and resistant/intolerant groups. Interpretation of the intolerant and the resistant/intolerant group data was limited by small sample sizes.Support - Teva Pharmaceutical Industries Ltd.

Background. Bosutinib is an orally active, dual competitive Src/Abl kinase inhibitor. The BELA trial compared the safety and activity of bosutinib with imatinib in newly diagnosed chronic phase chronic myeloid leukemia (CP CML). **Aims.** This analysis summarizes the safety profile and toxicity management of each agent after ≥24 months of follow-up; updated data including ≥30 months of follow-up will be presented. **Methods.** Patients aged ≥18 years with newly diagnosed (≤6 months) CP CML were randomized to receive bosutinib 500

mg/day (n = 250) or imatinib 400 mg/day (n = 252). **Results.** Median age was 48 years (range, 19-91 years) for bosutinib and 47 years (range, 18-89 years) for imatinib (n = 252). Median treatment duration was 27.5 months for both arms, with 63% bosutinib patients and 71% imatinib patients still receiving therapy; 25% and 9% of patients discontinued treatment due to an adverse event (AE). Deaths occurred in 7 bosutinib patients versus 13 imatinib patients (including 1 and 2 CML-related deaths); of these, 2 and 4 deaths occurred within 28 days of treatment discontinuation. Bosutinib was associated with higher incidences versus imatinib of gastrointestinal toxicities (diarrhea [70% vs 25%], vomiting [32% vs 16%], upper abdominal pain [14% vs 7%]) and pyrexia (18% vs 12%), and lower incidences of edema (peripheral edema [4% vs 11%], periorbital edema [1% vs 15%]) and musculoskeletal events (myalgia [6% vs 12%], muscle cramps [4% vs 22%], bone pain [4% vs 10%]). Diarrhea (12% vs 1%, respectively) and elevated alanine aminotransferase (ALT; 18% vs 3%) were the most common non-hematologic grade 3/4 AEs.Diarrhea typically occurred during the initial month of treatment, with a median time to first event of 3.0 days on bosutinib (n = 173) and 43.0 days on imatinib (n = 62), and a median duration of an event of 3.0 days and 5.5 days, respectively. Diarrhea was managed with antidiarrheal medication (bosutinib, 69%; imatinib, 42%), temporary dose interruption (bosutinib, 23%; imatinib, 10%), and/or dose reduction (bosutinib, 8%; imatinib, 0%). Of the patients with a temporary dose interruption due to diarrhea, 36/39 bosutinib patients and 6/6 imatinib patients were rechallenged without recurrence of diarrhea or permanent treatment discontinuation due to diarrhea.Despite the higher incidence of ALT and aspartate aminotransferase (AST) elevations with bosutinib, most events occurred during the first 3 months of treatment and were transient (Table 1). AEs of ALT and AST elevation were managed with dose modification and/or concurrent medication, and the majority of events had resolved at the time of this analysis (Table 1). Eleven patients discontinued bosutinib and 1 patient discontinued imatinib due to ALT elevation; no patients discontinued due to AST elevation. No cases met Hy's Law criteria (ALT/AST ≥3xULN [upper limit of normal] and bilirubin ≥2xULN), led directly to hospitalization, or were associated with permanent hepatic injury or liver-related deaths. **Conclusions.** Bosutinib and imatinib had acceptable but distinct safety profiles in newly diagnosed CP CML. Bosutinib was mainly associated with gastrointestinal AEs and transient ALT/AST elevations that were managed with dose modification and/or concomitant medication.

Table 1.

	ALT elevation		AST elevation	
Parameter	Bosutinib	Imatinib	Bosutinib	Imatinib
No. patients who experienced an AE	79	21	66	22

Background. Nilotinib is a potent and selective BCR-ABL inhibitor approved for the first line treatment of CML. The ENESTnd trial (24 months follow-up) showed higher and faster molecular responses and lower rates of progression to accelerated-blastic phase of nilotinib vs. imatinib. With imatinib 400mg (IRIS trial) the rate of events and progression to AB/BP were higher during the first 3-4 years. Consequently, a confirmation of the durability of responses to nilotinib after 4 years is extremely relevant. **Aims.** To evaluate the long-term outcome of patients treated with nilotinib 400mg BID as frontline therapy. **Methods.** A multicenter phase 2 trial was conducted by the GIMEMA CML WP (ClinicalTrials.gov.NCT00481052). Four years minimum follow-up data for all patients will be presented; data cut off for this analysis was December 31st 2011. Definitions: $MR^{3.0}$ (Major Molecular Response) as a BCR-ABL/ABL ratio <0,1%IS; $MR^{4.0}$, undetectable transcript levels with ≥10,000 ABL transcripts; failures: according to the revised ELN recommendations; events: failures and treatment discontinuation for any reason. All the analysis has been made according to the intention-to-treat principle. **Results.** 73 patients enrolled: median age 51 years; 45% low, 41% intermediate and 14% high Sokal risk. The cumulative incidence of CCgR at 12 months was 100%. CCgR at each milestone: 96% and 92% at 12 and 24 months, respectively. The overall estimated probability of $MR^{3.0}$ was 99%, while the rates of $MR^{3.0}$ at 12 and 24 months were 85% and 82%, respectively. Two out of 73 patients never achieved a $MR^{3.0}$, 1 who progressed to ABP (see below) and 1 in stable and confirmed CCgR at 36 months. Only 3 patients had a confirmed loss of MMR due to low adherence (all 3 still on nilotinib, 1 patient re-obtained a MMR). The overall estimated probability of $MR^{4.0}$ was 79%, while the rates of $MR^{4.0}$ at 12, 24 and 36 months were 12%, 27% and 30%, respectively. One third (22/73 pts) showed a stable $MR^{4.0}$ (defined based on 3 consecutive $MR^{4.0}$ samples 4 months apart). Only one patient progressed at 6 months to AP/BP and subsequently died (high Sokal risk, T315I mutation). The last daily dose was 600 mg or higher for 49 patients (67%). Six patients discontinued permanently nilotinib: 1 patient progressed to AP/BP; 3 patients had recurrent episodes of amylase and/or lipase increase (no pancreatitis); 1 patient had atrial fibrillation (unrelated to study drug) and 1 patient died after 32 months of mental deterioration and starvation (unrelated to study drug). During the fourth year of therapy (median follow-up of 45 months) no new events occurred; the estimated probability of overall survival, progression-free survival and failure-free survival was 97%, the estimated probability of event-free survival was 91%. **Conclusions.** Given the very low rate of failure and the stable molecular responses observed the outcome is expected to be optimal for most of patients after 4 years of nilotinib. **Acknowledgements.** European LeukemiaNet, COFIN, Bologna University, BolognAIL

[5]MD Anderson Cancer Center, University of Texas, Houston, Texas, United States of America
[6]Bristol-Myers Squibb, Paris, France
[7]Universitätsklinikum Jena, Jena, Germany

Background. Dasatinib, a potent BCR-ABL tyrosine kinase inhibitor (TKI), demonstrated significant efficacy in patients with imatinib-resistant and -intolerant CP-CML and is an approved second-line therapy. Recommended dosing is 100 mg once daily (QD), based on the CA180-034 dose-optimization study. Six-year analysis of CA180-034 provides the longest follow-up of patients with CP-CML treated with a second-line TKI. **Aims.** Investigate long-term safety and efficacy of dasatinib in patients with CP-CML resistant or intolerant to imatinib. **Methods.** Study design and endpoints have been described (Shah 2008, JCO). After informed consent, patients (N=670) were randomized to dasatinib 100 mg QD (n=167), 50 mg twice daily (BID; n=167), 140 mg QD (n=168), or 70 mg BID (n=168). **Results.** Results are based on five-year data; minimum six-year follow-up will be presented. After five years minimum follow-up, 205 (31%) patients remain on study drug (71% resistant to imatinib and 29% imatinib-intolerant). In the 100 mg QD arm, 57 patients (35%) remain on treatment (41 imatinib-resistant and 16 imatinib-intolerant). Patients still receiving study drug in the remaining treatment arms are as follows: 50 mg BID: n=52 (31%); 140 mg QD: n=44 (27%); 70 mg BID: n=52 (31%). 5-year efficacy results are presented (Table 1). In a landmark analysis, 85% and 83% of patients achieving major molecular response (MMR) and complete cytogenetic response (CCyR) at six months, and 85% and 79% of patients achieving MMR and CCyR at 12 months were alive and progression-free at five years, respectively. This represents a better outcome compared to patients with no cytogenetic response at six and 12 months (31% and 35% were alive and progression-free at five-years). For 100 mg QD, grade 3/4 hematologic adverse events (AEs) generally first occurred within 12 months of treatment and all-grade non-hematologic AEs generally first occurred within 24 months of treatment. Five-year rates of non-hematologic AEs (all-grades) for 100 mg QD vs other treatment arms include headache (33% vs 28%), diarrhea (28% vs 31%), fatigue (26% vs 23%), and pleural effusion (24% vs 32%). Dose/schedule modifications were permitted to manage AEs. Analysis of dosing by last dose available demonstrates that, across all arms, 151 (74%) patients were on QD dosing, of which 85 (56%) were receiving ≥100 mg QD. Association of long-term outcome and pre-therapeutic factors (age, best response to imatinib, baseline mutations, highest imatinib dose) will be presented. **Conclusions.** The majority of patients receiving dasatinib after five years continue on QD dosing. Long-term follow-up of dasatinib 100 mg QD demonstrates durable efficacy and a generally well-tolerated safety profile for patients with CP-CML following prior imatinib therapy.

Table 1.

Five-year efficacy rates								
	100 mg QD (N=167)		140 mg QD (N=167)		50 mg BID (N=168)		70 mg BID (N=168)	
	Imatinib resistant (n=124)	Imatinib intolerant (n=43)	Imatinib resistant (n=123)	Imatinib intolerant (n=44)	Imatinib resistant (n=124)	Imatinib intolerant (n=44)	Imatinib resistant (n=126)	Imatinib intolerant (n=42)
Major molecular response	41.7%	52.5%	32.7%	75.0%	36.1%	58.5%	39.5%	56.8%
Progression free survival	56. 2%	62.7%	39.9%	82.9%	63.7%	75.3%	55.8%	79.5%
Overall survival	76.7%	81.8%	75.5%	87.6%	72.7%	82.4%	69.9%	81.4%

Background. Approximately 50% of chronic phase (CP) chronic myeloid leukemia (CML) patients who received Imatinib (IM) achieve complete molecular response (CMR) at 6-7 years. The recent data from a study showed that in patients with a CMR lasting at least 2 years, the probability of persistent CMR at 12 months was 41%, and suggested IM can be safely discontinued, at least in some patients with sustained CMR. However, to define whether discontinuation of IM can be safely employed, further validation and much longer follow-up are needed. **Aims.** This prospective study is performed to identify safer and more concrete indicators of successful discontinuation and explore contributing factors for sustained undetectable transcript. **Methods.** In our prospective, multicenter study, CP CML patients who were treated with IM for more than 3 years in sustained $MR^{4.5}$ or undetectable transcript for at least 2 years were enrolled. Our objectives were to evaluate the probability of persistent undetectable molecular residual disease (UMRD), $MR^{4.5}$, and major molecular response (MMR) at 12 months after discontinuation and to identify contributing factors for sustained MMR. After discontinuation, molecular response was monitored using RQ-PCR assay every month up to 6 month, every 2 months up to 12 month, and every 3 months thereafter. The loss of MMR, MR4.5, and UMRD were defined on 2 consecutive assessments. **Results.** Up to 14 Feb 2012, 32 patients (15 men and 17 women) were enrolled in this study. With a median age of 37.5 years (range, 19 - 74), the percentages of patients with low, intermediate and high Sokal risk scores were 28%, 28% and 13%, respectively with unknown Sokal risk scores in 31%. There were previous histories of allogeneic stem cell transplantation (SCT) in 12 patients and interferon (IFN) therapy in 3 patients, while 19 patients received first-line IM. The median time on IM therapy and the median duration of sustained CMR were 84 months (range, 40 - 113) and 54 months (range, 24 - 105), respectively, prior to discontinuation.After a median follow-up of 12.9 months since discontinuation of IM, loss of MMR was observed in 4 patients after a median time of 3.7 months (range, 2.9 - 3.8) of treatment discontinuation. Loss of $MR^{4.5}$ and UMRD were detected in 7 patients and 8 patients, respectively. The 12-month probability of sustained MMR, $MR^{4.5}$ and UMRD were 83.2%, 71.7%, and 69.1%, respectively. By the univariate analysis, previous SCT, the time from IM therapy to UMRD, and the UMRD duration before discontinuation of IM were potential factors on sustained MMR. Among 20 patients without previous SCT, the time from IM therapy to UMRD and the UMRD duration before discontinuation of IM were potential predictive factors.**Conclusions** Our data showed a higher 12-month probability of sustained UMRD compare with previous discontinuation studies. Overall, of the 12 patients with previous SCT, no patient lost MMR. Through subgroup analyses in the cohort excluding previous SCT recipients, we found that the time from IM therapy to UMRD and the UMRD duration before discontinuation of IM were potential predictive factors.

Hodgkin's lymphoma

DIMINISHING PROGNOSTIC ROLE OF PREEXISTING DIABETES MELLITUS FOR PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA IN THE RITUXIMAB ERA

HJ Lu
Taipei Veterans General Hospital, Taiwan, Taipei, Taiwan

Background. Rituximab reforms the treatment of diffuse large B cell lymphoma (DLBCL) and the prognostic significance of baseline patient features should be reevaluated. Few population-based studies have investigated the association of diabetes mellitus (DM) and outcomes of lymphoma; however, the results remain inconclusive. **Aims.** To delineate the prognostic role of DM in DLBCL **Materials and Methods**. From January 2000 to December 2009, a total of 468 consecutive newly-diagnosed DLBCL patients receiving first-line chemotherapy with CHOP or rituximab plus CHOP (R-CHOP) were enrolled. Preexisting DM was defined according to medical history, use of anti-diabetic medications, or any record of an abnormal hemoglobin A1c test. Progression-free survival (PFS) and overall survival (OS) were estimated and compared using the Kaplan-Meier method with a log-rank test. **Results.** CHOP was administered in 194 patients, and 274 patients received R-CHOP. DM was identified in 16.2% (76/468) of patients. Diabetic patients were older and more performance-restricted, compared to the non-DM patients in both the CHOP and R-CHOP groups. In the CHOP group, 5-year PFS and OS were inferior in DM patients (PFS 32.4% vs. 50.0%, p = .045; OS 38.2% vs. 62.5%, p = .008). However, outcomes were similar for both DM and non-DM patients in the context of R-CHOP treatment (PFS 69.0% vs. 57.3%, p = .104; OS 78.6% vs. 70.7%, p = .197). The response rate of chemotherapy in DM patients was also improved to a level similar to non-DM patients with rituximab use. **Conclusions.** The prognostic significance of preexisting DM in DLBCL patients is changing in the rituximab era. The potentially additional benefit of rituximab in DM patients merits further investigation.

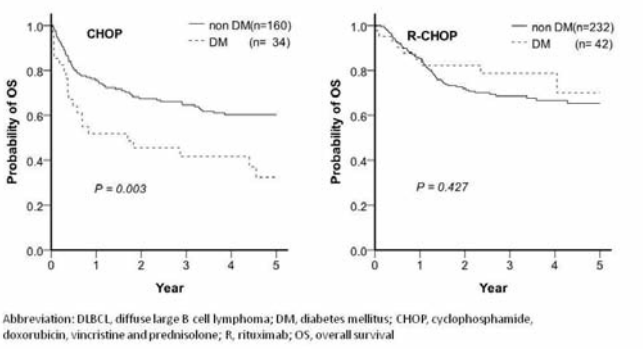

Figure 1. Overall survival of DLBCL patients with or without DM under CHOP/R-CHOP.

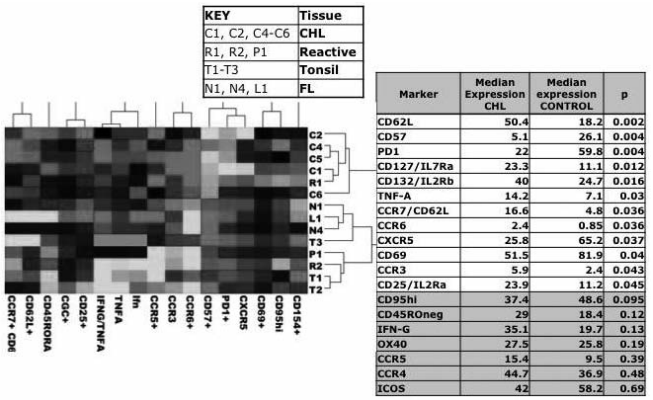
0202

DOMINANCE OF NAÏVE AND CENTRAL MEMORY CD4+ T CELLS IN THE CLASSICAL HODGKIN LYMPHOMA MICROENVIRONMENT PROVIDES A DISTINCTIVE SIGNATURE WITH IMPLICATIONS FOR PATHOGENESIS AND CLINICAL DIAGNOSIS

P Greaves, S Iqbal, G Rosignoli, J Matthews, A Wilson, D Taussig, J Gribben
Barts Cancer Institute, London, United Kingdom

Background. The microenvironment of classical Hodgkin lymphoma (CHL) is dominated by CD4+ T cells. The functional interactions of this infiltrate with the malignant Hodgkin-Reed-Sternberg (HRS) cell and other microenvironment components including macrophages and FOXP3-expressing Tregs have prognostic and pathophysiological significance. **Aims.** Using CD4+ T cell-expressed markers of known or proposed functional importance in CHL, we characterized dominant markers at diagnosis, identifying those which discriminate CHL-infiltrating from benign or other germinal centre B cell malignant node-infiltrating CD4+ T cells and hence determine a CHL-specific CD4+ T cell phenotype to functionally and clinically validate. **Method**. Frozen single cell suspensions (SCSs) from diagnostic lymph node biopsies (CHL=5, FL=3, tonsil=4, reactive=3) were thawed and immunofluorescent staining was performed for CD3/CD4 along with 42 markers chosen for their functional importance in CHL (immunoglobulin/tumour-necrosis-factor superfamily members, chemokine receptors, memory, TH2, TH1, T-Follicular-Helper (TFH)-associated markers, activation, senescence, immunosuppressive mediators and cytokines with TH1, TH2, immunosuppressive and HRS stimulatory properties (Figure 1). Flow cytometry was performed, markers expressed as a % total CD3+CD4+ population and medians calculated for each tissue (CHL vs. FL vs. tonsil vs. benign). T tests determined significant differences between CHL and other tissue-derived cells. Additionally, expression levels for each sample was entered into unsupervised hierarchical cluster analysis applying Pearson correlation/complete linkage. **Results.** Markers of central memory (CD62L, CCR7 and IL7Ra/CD127), naivety (CD45RO-neg), RANTES-receptor CCR3 and TH1-associated CCR5 (as well as IFN-G and TNF-alpha) and IL2 receptor components (CD132 and CD25) were overexpressed in CHL-derived CD3+CD4+ cells compared to controls, but there was no evidence of TH2 cytokines or IL10 expression. Markers of early activation (CD69, CD95), chronic activation/senescence (CD57&PD1) and TFH cells (CXCR5&PD1) were underexpressed. Treg/TH2-marker and CHL-associated TARC-receptor CCR4 was heterogeneously expressed in CHL (15-75%) as were receptors for HRS-expressed TNFRSF members (OX40: 25-60% and ICOS: 30-75%) but median expression was not significantly greater than in any control nodes. Unsupervised hierarchical clustering analysis identified two groups, one containing all CHL samples, the other FL and benign samples suggesting that the extended phenotype of the CD3+CD4+ compartment alone is characteristic of CHL. **Conclusions**. CHL-infiltrating CD3+CD4+ cells appear distinct from those infiltrating other reactive and malignant nodes with a phenotype suggesting overrepresentation of markers of central memory and naivety, and absence of early inflammatory or senescence markers, discriminating its phenotype from other malignant or benign node-derived CD3+CD4+ cells. As expected, expression of TARC-receptor CCR4 is increased but not in association with TH2-defining cytokines nor at levels significantly different to other malignant and benign reactive nodes. This dominant component suggests an expansion of the interfollicular T cell zone by central memory and naïve T cells perhaps through passive attraction into CHL-involved nodes, providing an explanation for the cell mediated immune defect in CHL, and a potentially diagnostic CD3+CD4+ signature for further clinical validation.



Marker	Median Expression CHL	Median expression CONTROL	p
CD62L	50.4	18.2	0.002

PERSISTENCE OF CD30 EXPRESSION IN CD30-POSITIVE LYMPHOMAS FOLLOWING TREATMENT WITH BRENTUXIMAB VEDOTIN (SGN-35)

W Chen, N Nathwani, S Forman, L Popplewell, A Krishnan, C Gomez, C Karanes, E Smith, L Farol, S Thomas, Y Kim
City of Hope National Medical Center, Duarte, United States of America

Background. Hodgkin Lymphoma (HL) and systemic Anaplastic Large Cell Lymphoma (sALCL) are two lymphomas that express CD30 on their cell surface. CD30 is a member of the tumor necrosis factor receptor superfamily. Brentuximab vedotin (SGN-35), an antibody-drug conjugate, consists of microtubule disrupting agent monomethyl auristatin E (MMAE) attached to the CD30-specific antibody, cAC10, by a protease cleavable dipeptide linker. The effect of brentuximab vedotin exposure on CD30 expression in patients undergoing treatment and post treatment are unknown. To examine the impact of brentuximab vedotin on CD30 expression, we performed a retrospective analysis of patients (pts) with HL and sALCL who received brentuximab vedotin at City of

Hope National Medical Center (COH), then subsequently underwent tumor biopsies upon disease progression. **Methods.** Between October 2009 and July 2011, 8 pts with relapsed/refractory HL or sALCL received brentuximab vedotin IV every 3 weeks at COH. Following disease progression, tumor biopsies were obtained. CD30 immuno-staining was performed using the monoclonal mouse anti-human CD 30, clone Ber-H2 (No M 0751), and visualized with the DAKO Envision/HRP kit. **Results.** While receiving treatment with brentuximab vedotin, 6 pts with HL and 2 with sALCL achieved disease control. The median age was 32 (range: 24-43). The median number of 3-week cycles of brentuximab vedotin was 6.5 (range: 2-10). 3 pts achieved a best response of CR, 4 patients achieved PR, and 1 pt achieved SD. 4 pts who had achieved a PR or SD had progressive disease while on brentuximab vedotin treatment. 4 additional pts who had achieved a CR or PR discontinued brentuximab vedotin treatment because of peripheral neuropathy (1), went onto allo-HCT (2), or changed salvage therapy to ICE while in PR (1). These 4 pts later developed progressive disease. All pts underwent biopsy of their lymphoma at the time of progression, 8/8 revealed ongoing CD30 expression. (Figure 1, IHC from 6 pts shown) **Conclusions.** These data suggest that relapsed or progressive HL expresses CD 30 even after prior exposure to brentuximab vedotin.

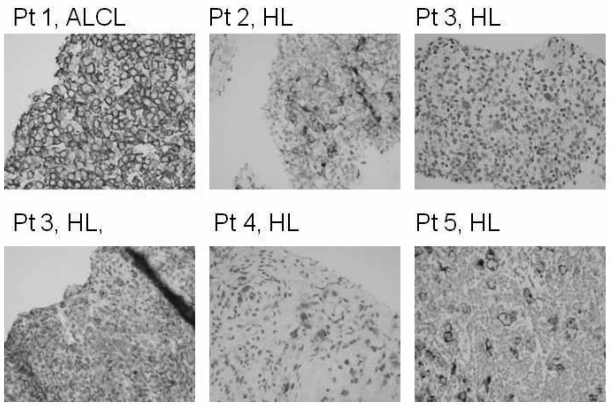

Figure 1.

HEALTH STATE UTILITIES FOR RELAPSED/REFRACTORY (REL/REF) HODGKIN LYMPHOMA (HL) AND SYSTEMIC ANAPLASTIC LARGE-CELL LYMPHOMA (SALCL)

P Swinburn[1], S Shingler[1], Y Liu[2], H Huang[2], S Acaster[3]
[1]Oxford Outcomes (An ICON plc Company), Oxford, United Kingdom
[2]Millennium Pharmaceuticals, Inc., Cambridge, United States of America
[3]Oxford Outcomes Inc., San Francisco, United States of America

Background. There is a paucity of effective treatment options for individuals with rel/ref HL and sALCL. Recent advances in targeted therapies have shown promise in inducing disease remission. Due to increasing pressure on limited healthcare resources, many countries now seek to undertake a review of cost-effectiveness for newly developed therapies. Mechanisms for this evaluation process vary internationally but typically require the benefits of a treatment to be expressed in quality-adjusted life years (QALYs). This approach seeks to capture the value of a treatment in terms of change in both survival and quality of life (QOL). If formal assessment of QOL has not been undertaken in a trial, this provides a challenge in determining suitable data to support the evaluation process. **Aims.** The aim of this study was to capture QOL data for outcomes associated with receiving therapy for rel/ref HL and sALCL. These data were expressed as health state utility values ranging from 0 (dead) to 1 (full health) (Brazier et al, Eur J Health Econ 2011), suitable for supporting economic evaluation. **Methods.** Health state descriptions were developed depicting different rel/ref HL and sALCL treatment outcomes. These included descriptions associated with extent of disease symptoms (B-symptoms) and clinical response (complete or partial response, stable or progressed disease). Descriptions were based upon a review of published literature, discussions with five clinical experts, and five patient interviews. Once devised, the draft descriptions were reviewed by six experienced specialist clinicians to assess their clinical realism, accuracy, and degree of representativeness, before being piloted with six members of the general public. The health states were then valued by a representative sample of members of the UK (n=100) and Australian (AUS, n=75) general public using the time trade-off (TTO) task. This exercise elicits a utility value by examining an individual's willingness to trade-off years of life to avoid the consequences of living in a presented state. **Results.** The utility values elicited for the health state descriptions are presented in the table. Any treatment response was viewed by participants as being associated with a notable improvement in QOL (higher mean utility values), with the increase for partial response versus stable disease being +0.084 (UK) and +0.109 (AUS). The improvement suggested by the complete response utility value is particularly marked, representing a +0.196 (UK) and +0.224 (AUS) increase over stable disease. The presence of residual B-symptoms following treatment affected QOL, as evidenced by the lower mean utility value for stable disease with B-symptoms compared with stable disease without B-symptoms (difference of -0.124 for UK, and -0.110 for AUS). **Conclusions.** Societal valuation of health states for rel/ref HL and sALCL reveals the notable perceived benefit of a treatment response, while the experience of residual B-symptoms can be associated with a substantial decline in QOL. Health state utility values from the UK and Australia TTO valuations were broadly similar, with identical ordering in terms of preference (highest to lowest utility values).

Table 1. UK and Australian utility values for the health state descriptions.

Response	Complete	Partial	Stable	Stable (plus B-symptoms)	Progressed
UK data, mean (SD)	0.906 (0.08)	0.794 (0.17)	0.710 (0.20)	0.586 (0.27)	0.382 (0.28)
AUS data, mean (SD)	0.889 (0.16)	0.774 (0.22)	0.665 (0.26)	0.555 (0.32)	0.319 (0.31)

ACTIVITY OF BRENTUXIMAB VEDOTIN IN PATIENTS WITH RELAPSED OR REFRACTORY HODGKIN LYMPHOMA OR SYSTEMIC ANAPLASTIC LARGE-CELL LYMPHOMA: COMPARISONS WITH META-ANALYSES OF HISTORICAL CHEMOTHERAPY DATA

A Gualberto, AX Chi, Y Liu
Millennium Pharmaceuticals, Inc., Cambridge, United States of America

Background. Brentuximab vedotin (SGN-35) has been shown to have antitumor activity in terms of overall response rate and complete remission (CR) rate in two single-arm pivotal phase 2 trials in relapsed or refractory (rel/ref) Hodgkin lymphoma (HL; SG035-0003) and systemic anaplastic large-cell lymphoma (sALCL; SG035-0004). **Aims.** In the absence of suitable comparator regimens for these trials, and per the ICH E10 (CHMP/ICH/364/96) guideline, we conducted meta-analyses of historical chemotherapy data to compare the activity of brentuximab vedotin to other therapies used for treatment of rel/ref HL and sALCL. **Methods.** CR rate was the endpoint since achieving a CR may be predictive for long-term clinical benefit in HL and aggressive non-Hodgkin's lymphoma (NHL). For the rel/ref HL meta-analysis, PubMed searches identified prospective trials and retrospective case series in which ≥10 adult HL patients with rel/ref disease were treated with gemcitabine alone/in combination (one of the most commonly used systemic therapies beyond second-line treatment in HL). Trials were classified as post-autologous stem cell transplant (ASCT; ≥33% of enrolled patients), or ASCT-naïve. For the rel/ref sALCL meta-analysis, a PubMed search identified all trials since 2001 of aggressive rel/ref NHL that included at least one sALCL patient. Quantitative statistical meta-analyses were carried out per pre-specified plans, and performed using random effect models; estimates (95% CI) of overall CR rate were provided. **Results.** For the rel/ref HL meta-analysis, 16 trials (N=605 patients) were identified, including nine post-ASCT trials (n=296, median of three prior regimens) in which a median of 44% (range 15-64%) of patients had prior ASCT, and seven ASCT-naïve trials (n=309, median of one prior regimen). CR rates are shown in the figure. Estimated overall CR rate in the post-ASCT subgroup was 15% (95% CI: 6.5, 23.5), which was significantly lower than the CR rate of 34% (95% CI: 25.2, 44.4; p=0.003) seen with brentuximab vedotin in SG035-0003, in which all patients had prior ASCT and the median number of prior regimens was 3.5. In the ASCT-naïve subgroup, estimated overall CR rate was 35% (95% CI: 16.9, 52.2); however, these patients had less advanced disease and were less heavily pretreated. Considering all trials, estimated overall CR rate in patients with rel/ref HL was 24% (95% CI: 14.2, 33.9), with a trend towards

lower activity versus brentuximab vedotin in patients with post-ASCT rel/ref HL (p=0.148). For the rel/ref sALCL meta-analysis, 19 trials (N=752 NHL patients) were identified, which included 48 sALCL patients. The estimated overall CR rate, 18% (95% CI: 11.3, 24.5), was significantly lower than with brentuximab vedotin in patients with rel/ref sALCL (versus CR rate at time of meta-analysis: 53% [95% CI: 39.9, 66.7], p<0.0001; updated CR rate [ASH 2011]: 59% [95% CI: 45, 71]). **Conclusions.** The anti-tumor activity of brentuximab vedotin, in terms of CR rate, appears to exceed that of gemcitabine-based therapies in rel/ref post-ASCT HL patients, and also appears to exceed that of other treatment options for aggressive rel/ref NHL, including sALCL. These meta-analyses suggest that brentuximab vedotin may provide meaningful long-term clinical benefit in rel/ref HL and sALCL.

[4]Center of Hematology & Bone Marrow Transplantation, Bucharest, Romania
[5]Medical University of Gdansk, Gdansk, Poland
[6]University Hospital Brno, Brno, Czech Republic

Background. Resminostat (R) is an oral pan-histone deacetylase (HDAC) inhibitor that has shown anti-tumor activity in a broad panel of preclinical models and revealed a favorable safety and efficacy profile in a first-in-man phase I study in patients (pts) with various solid tumor types. R is currently in phase II clinical development in pts with hepatocellular carcinoma (HCC), colorectal carcinoma (CRC) and Hodgkin lymphoma (HL). **Methods.** The open label, single arm, phase II SAPHIRE trial included HL patients who had progressed after prior therapy or were refractory to treatment. R was administered once daily at 600 mg or 800 mg. Pts were treated in cycles of 5 consecutive days followed by a 9 day treatment-free period (5+9 schedule), constituting a 14 day treatment cycle. Pts underwent assessment of their disease status by PET/CT. Primary endpoint of the study was the overall objective response rate (ORR). Secondary endpoints included efficacy, safety and tolerability and the analysis of pharmacokinetics of both doses for up to 6 h post-dose during the 1st and 3rd treatment cycle. Similarly, the effect of different doses of R on pharmacodynamic biomarkers such as HDAC enzyme inhibition and changes in expression levels of selected target genes was determined in peripheral blood cells (PBMC). In addition, plasma levels of the CC thymus and activation-related chemokine TARC (CCL17), a potential prognostic factor in HL, were determined. **Results.** The SAPHIRE study enrolled 37 patients of which 35 were eligible for efficacy evaluation. R at 600 mg or 800 mg daily dose was well tolerated with grade 2-3 anemia and thrombocytopenia in 35% and 27% of pts as most frequent AEs. Peak plasma levels of R were achieved at T_{max} = 2 h post-dose in both 600 mg (n=19) and 800 mg (n=18) dose cohorts. C_{max} and AUC increased proportionally to dose. Single and repeat PK profiles in both dose cohorts were comparable. Inhibition of HDAC enzymatic activity was time dependent and fully reversible within 72 h post-dose and reached a maximum of up to 94% inhibition at about 2 h post-dose corresponding to R peak plasma levels. Baseline TARC plasma levels of median 8400 pg/ml (range 35 pg/ml to >100 000 pg/ml) were substantially reduced after three cycles of R to a median of 2800 pg/ml, with a reduction of ³50% in 12 of 27 pts tested. Lower baseline TARC plasma levels were associated with clinical benefit to R treatment. Expression analysis of a set of 10 genes in pts PBMCs showed a correlation to drug plasma levels with strongest effects on transcription 5 h post-dose reflecting the delayed biological response to target inhibition. **Conclusions.** PK/PD data from the phase II SAPHIRE study indicate good bioavailability and efficient *in vivo* HDAC inhibition by resminostat at daily doses of 600 mg and 800 mg. Resminostat treatment also resulted in biological relevant downstream effects like transcriptional modulation and TARC plasma level reduction in heavily pre-treated HL patients. These findings may now be explored for their potential to predict clinical responses.

0207

SURVIVAL OF HODGKIN'S LYMPHOMA PATIENTS IN GERMANY

D Pulte[1], L Jansen[2], A Gondos[2], K Emrich[3], B Holleczek[4], A Katalinic[5], H Brenner[2]
[1]Thomas Jefferson University, Philadelphia, United States of America
[2]German Cancer Research Center, Heidelberg, Germany
[3]Johannes Gutenberg University Mainz, Mainz, Germany
[4]Saarland Cancer Registry, Saarbruecken, Germany
[5]Cancer Registry Schleswig-Holstein, Luebeck, Germany

Background. Hodgkin's lymphoma (HL) is a rare, highly treatable lymphoma. Previous publications have demonstrated high overall rates of survival for HL patients in Germany but no published information is available regarding survival by age, gender, or histologic subtype. **Aims.** To evaluate 5-year relative survival of patients with HL in Germany. **Methods.** Data was derived from 11 cancer databases throughout Germany, representing a total of about 33 million people. Patients diagnosed in Germany with HL (ICD 10 code C81) in 1997-2006 were included in the analyses. Period analysis was used to calculate 5-year relative survival rates for the time period of 2002-2006, overall and by gender, age, and histology. Similar calculations using data from the Surveillance, Epidemiology, and End Results database in the United States (US) were performed for comparison. A comparison of survival in 2002 versus 2006 was performed to evaluate recent changes in survival. **Results.** 5835 cases were identified, with a 9.15% of cases identified by death certificate only, leaving 5300 cases for analysis. Overall 5-year relative survival for patients with HL in Germany was 84.3%, compared with 80.6% in the US. Survival in Germany was highest in patients aged 15-29 at 97.9% and decreased with age to 57.5% at age 60+. Survival was about equal for men and women in Germany (84.7% in women versus 84.1% in men) but higher for women in the US (83.6% and 78.2%, respectively). Nodular lymphocyte predominant HL (NLPHL) had a higher survival than other types, with 5-year relative survival ranging from 72.2% for ages 60+ to 100.3% for ages 15-29. Survival was higher in Germany than in the US for all histologic sub-types except for NLPHL, with differences ranging from -0.9% units to +11.6% units. Survival improved in 2006 compared to 2002 for patients age 30-39, reaching almost 98% in 2006, and for patients with NLPHL, but was stable for other ages and histologies. Thus, in 2006, patients age 30-39 had a survival equal to patients age 15-29. **Conclusions.** Five year survival for patients diagnosed with HL in Germany is high, reaching nearly 98% for younger patients, but decreases with age. Survival did not significantly vary by gender in Germany but was worse for men in the US. These findings suggest that further concentration on treatment of HL in older patients and possibly a greater focus on how women are being treated may further improve survival for patients with HL.

0208

SAFETY AND EFFICACY OF BENDAMUSTINE THERAPY IN WALDENSTROM MACROGLOBULINEMIA

G Benevolo[1], C Lobetti-Bodoni[2], L Orsucci[1], B Botto[1], A Chiappella[1], P Riccomagno[1], C Ciochetto[1], R Bruna[2], L Bergui[2], M Ladetto[2], U Vitolo[1]
[1]Haematology 2 AUO san Giovanni Battista, Turin, Italy
[2]Haematology 1 AUO San Giovanni Battista, Turin, Italy

Background and Aims. Waldenstrom Macroglobulinemia (WM) is a rare low-grade lymphoma characterized by the presence of lymphoplasmacytic cells in

the bone marrow and monoclonal IgM in peripheral blood. Bendamustine is a bifunctional alkylating agent that is approved for treatment of lymphocytic leukaemia and indolent non-Hodgkin's lymphomas. So far few data are available on its role in WM. Aim of the study was to test the efficacy and safety of Bendamustine +/- Rituximab therapy in untreated or relapsed WM afferred to our institution. **Methods.** A retrospective analysis was performed on 15 WM patients who received therapy with Bendamustine from June 2009 to November 2011 in a single Italian Centre. Eleven patients were male, median age was 74 years (58-81) and all patients had stage IV disease. Based on the Morel ISS-WM study, 3 (20%) patients were high risk, 4 (27%) were intermediate risk, and 8 (53%) were low risk. Six patients received Bendamustine at diagnosis, while 9 patients as second or subsequent lines of treatment (2 in second,3 in third, 4 patients >3 previous lines respectively). Bendamustine was administered at the standard dose of 90 mg/mq day 1-2 every 28 days in 11 patients, whereas four patients received a dose reduction of 70 mg/mq. Only two patients didn't receive Rituximab due to refractory disease. Median number of delivered cycles was 4 (2-6). **Results.** After a median follow up of 10 months (2-31), 13 patients were eligible for efficacy analysis (two patients are still on therapy). The ORR was 92%. We observed eleven (85%) partial response (PR), one complete response (CR) and one stable disease (SD). CR was obtained in one patient with low-risk ISS treated at diagnosis. We observed a reduction of M protein >50% in 11/13 (85%) patients, whereas in 7/13 (54%) we obtained a reduction of M protein >75%. Moreover, a reduction of >50% of adenopathies and splenomegaly was showed in 12/13 (92%) patients. The therapy with Bendamustine was well tolerated with a low incidence of adverse events, mainly of G1. Three patients developed a G1 or more neutropenia and one of them interrupted therapy for prolonged G4 neutropenia. Three patients were treated with G-CSF. Two pts developed G2 thrombocytopenia. No patients developed a ≥G3 thrombocytopenia. The most common non-haematological adverse events were G1 fatigue (one patient) and infections (two exacerbation of herpes zoster infection requiring treatment were described). **Conclusions.** In our retrospective analysis therapy with Bendamustine +/- Rituximab was well tolerated and effective for WM patients both at diagnosis and at progression. Based on these observations, larger prospective studies to evaluate the role of Bndamustine plus Rituximab in WM patients are warranted.

[3]Medicine Oncology Centre Bydgoszcz, Bydgoszcz, Poland
[4]Centre Antoine Lacassagne, Nice, France
[5]CHU l'Archet, Nice, France
[6]Ospedale San Camillo, Roma, Italy
[7]Ospedale S.Antonio e Biagio, Alessandria, Italy
[8]Ospedale S.Martino, Genova, Italy

Background. Interim ^{18}F-FDG-PET (iPET) is the most important prognosticator in advanced-stage ABVD-treated Hodgkin Lymphoma (HL), but in early stage with or without bulky lesion a low PPV of iPET was reported. Moreover, a single residual FDG-avid mass (SFAM), commonly found at treatment (Tx) end in HL, was shown to reduce the specificity of PET in Tx response evaluation. Dual-point PET scan (2P-PET) has been proposed to discriminate unspecific inflammatory from neoplastic FDG uptake. **Aims.** we report here preliminary results from a cohort of HL patients (p), scanned with 2P-PET with the aim to increase specificity and PPV. **Methods.** from December 2008 till January 2012 25 HL p from Italian, French and Polish centers, most of them with bulky lesions, underwent 2P-PET at baseline (2P-PET-0), after 2 ABVD (2P-PET-2) and at Tx end (2P-PET-end). 2P-PET scan consisted in 2 consecutive image acquisitions 60' (+60) and 120'(+120) after single, standard-dose FDG injection. Tx was ABVD (x4 or x6) or BEACOPP (4+4) ± consolidation/involved-field radiotherapy (RT). In 23/25 p no Tx change was done based on iPET results and in 2 according to protocol. Bulky was defined as a mass with largest diameter ≥5 cm. Scans were reviewed by 2 expert readers in a consensus session. Standardized-Uptake Value $(SUV)_{MAX}$ was calculated both in +60 and +120 using single or multiple Volume of Interest regions (VOIs) drawn to encompass a single or multiple spots of FDG uptake within a single or multiple nodal mass. Retention Index (RI) was defined as $[(SUV_{MAX}+120-SUV_{MAX}+60)/SUV_{MAX}+120]$%. In case of multiple spots inside a single node or within different nodes, only the single focus with FDG uptake increase was considered. **Results.** In 25 p (1 stage I,13 II, 4 III, 7 IV), 35 2P-PET were done. 10 p underwent 2P-PET-0: in 10/10 SUV_{MAX} increased from +60 to +120 (ΔSUV_{MAX} 1-4.3). 15 p had a 2P-PET-2: 12 with a mean-follow-up of 18.36 months were evaluable. 3 were excluded because of too short (+1, +5, +6 months) follow-up. 7/12 p showed an average RI reduction of 55% (200-14): all are in continuous CR (CCR). 5/12 p. showed an average 20% (11-26) RI increase: all progressed +1 to +9 months after Tx end. Overall 3/12 cases (1 false positive, 2 false negative, with a Deauville score of 4 and 2,3 respectively) were correctly classified after 2P-PET scan. Ten p with a SFAM had a 2P-PET-end: in the 6/10 with an increased average RI of 23% (9-43) a biopsy proved HL relapse. In 4/10 an average reduced RI of 29% (9-45) was found: in 2 biopsy disclosed presence of residual thymic along with inflammatory tissue and 2 were in CCR +4 to+10 months after Tx end. **Conclusions.** SUV_{MAX} increased in all patients scanned at baseline and at Tx end in relapsing HL, and decreased in patients remaining in CCR. This suggest that a mounting and dropping FDG avidity with time reflects presence of viable tumour cells and non-neoplastic tissue, respectively. The PPV and a PNV of 2P-PET were 100%.

[8]Division of Medical Oncology A National Cancer Institute, Aviano (PN), Italy
[9]Clinic of Hematology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. Hodgkin lymphoma (HL) is characterized by the presence of CD30-positive Hodgkin Reed-Sternberg cells. The antibody-drug conjugate brentuximab vedotin (BV) delivers the highly potent antimicrotubule agent monomethyl auristatin E to CD30-positive malignant cells. In a pivotal, phase 2, single-arm, multicenter study with BV the overall response rate (ORR) was 75% and the complete response (CR) rate was 34% (Chen et al, ASH 2010). Moving from these results eligible patients in Italy were granted early access trough a Named Patient Program (NPP). **Aims.** To evaluate the effectiveness and safety of BV as single agent in patients with relapsed/refractory HL treated under the NPP. Here we report preliminary results. **Methods.** A multicenter retrospective/prospective observational study is ongoing at 9 Italian hematology centers. Response to therapy was assessed by Revised Response Criteria for Malignant Lymphoma and any adverse events occurred during was recorded and classified for type, grade and relationship with BV. **Results.** The sample for this preliminary analysis consisted of 65 patients with median age at diagnosis of 27,5 years (range 12-71). Approximately half of the patients were male (52%). Eastern Cooperative Oncology Group performance status at baseline was 0 (37%) or 1 (40%) or 2 (23%). All patients but 8 had previously received an autologous stem cell transplant and the median number of prior chemotherapy regimens was 4 (range 2-13). More than 60% of the patients had primary refractory disease and 81% was also refractory to the most recent salvage therapy. At the last update, the median number of cycles was 6 (range 1-13). Consistent with findings from the pivotal phase 2 study, after the first evaluation (interim PET after 3 cycles, 60 evaluable patients) 12 (20%) patients had CR and 32 (53.3%) patients obtained a partial response (PR) with a global ORR of 73.3%; PET evaluation after 8 cycles (20 evaluable patients) showed 5 (25%) CR and 3 (15%) PR. To date, 9 patients were allowed to received an allogeneic stem cell transplant after treatment with BV. Grade 3-4 treatment-related adverse events (AEs) reported were neutropenia (9%), peripheral sensory neuropathy (9%), thrombocytopenia (8%) and hyperglycemia (2%). No related Grade 5 events were observed. **Conclusions.** BV was associated with manageable adverse events and, based on investigator assessment, demonstrated encouraging activity in heavily pretreated patients with relapsed or refractory HL. These preliminary results confirm the important tumor shrinkage, ORR and CR rate also in everyday clinical practice.

0211

EARLY HODGKIN LYMPHOMA THERAPY, BASED ON PREDEFINED RISK FACTORS AND EARLY INTERIM PET/CT. ISRAELI H2 PROTOCOL: PRELIMINARY REPORT

E Dann[1], O Bairey[2], R Bar-Shalom[1], T Mashiach[1], M Izak[3], A Korenberg[3], L Akria[4], D Attias[5], K Filanovsky[6], U Abadi[7], R Abdah-Bortnyak[1], N Goldschmidt[8], R Epelbaum[1], I Avivi[1], D Lavie[8], J Rowe[9], O Shpilberg[2], O Paltiel[8]

[5]Bnai Zion Medical Center, Haifa, Israel
[6]Kaplan Hospital, Rehovot, Israel
[7]Meir Medical Center, Kfar Saba, Israel
[8]Hadassah Medical Center, Jerusalem, Israel
[9]Shaare Zedek Medical Center, Jerusalem, Israel

Background. The current goal of treatment for Hodgkin lymphoma (HL) is to maximize response and minimize long-term toxicity. **Aims.** This study was aimed to prospectively evaluate the outcome of patients with HL whose therapy is chosen based on baseline prognostic factors and is tailored depending on the results of PET/CT imaging performed after 2 cycles of chemotherapy. **Methods.** In this multicenter ongoing study, initiated in 2006, we escalate the intensity of therapy for patients with suboptimal early response evidenced by PET/CT. Patients with classic HL aged 18-60 years, stages IA-IIA are eligible. Individuals with early disease stage are categorized according to the German Hodgkin Study Group criteria for early favorable and unfavorable HL. Following 2 cycles of ABVD (adriamycin, bleomycin, vinblastine, dacarbazine), patients with early favorable disease (EF) and a negative PET/CT undergo involved nodal radiation therapy (INRT 25.2Gy) and those with early unfavorable disease (EU) receive 2 more cycles of ABVD (a total of 4 cycles) followed by INRT(27.2-30Gy for bulky mediastinal mass). Patients whose interim PET/CT remains positive are given 2 additional cycles of ABVD (a total of 4-6 cycles), followed by radiation therapy. Patients with putative large irradiation field and interim negative PET/CT could have additional 2 X ABVD and radiation therapy could be spared. **Results.** One hundred and twenty three patients were enrolled, 113 had interim PET/CT. Eighteen patients had early favorable and 105 early unfavorable disease. Median patients' age was 33 years. Nine patients (two with EF and seven with EU HL) had disease progression; 2 of them despite augmentation of therapy and 7 patients who had interim negative PET/CT. The positive predictive value of interim positive PET/CT and negative predictive value of negative studies were 2/15(13%) and 89/96 (93%), respectively. Fifteen patients had escalation of therapy following positive interim PET/CT and 2 of them had disease progression. Ninety six patients with early disease had negative interim study and were treated with the minimal therapy considered to be safe. Eighty nine of them are yet in remission. After a short follow-up, (median of 23 months; range 7- 63), the current study appears to demonstrate a 3-year progression-free survival (PFS) of 92%. While the negative predictive value for the patients with negative interim study was 93%, the majority of relapsing patients had a negative interim PET/CT. **Conclusions.** The current preliminary results suggest that interim PET/CT has a low sensitivity, indicating that augmentation of therapy based on positive PET/CT should be mild in patients with HL stages IA-IIA. Further follow-up evaluating the late effect of INRT is required.

0212

COMPARING BRENTUXIMAB VEDOTIN OVERALL SURVIVAL DATA AGAINST PUBLISHED OUTCOME DATA IN PATIENTS WITH RELAPSED/REFRACTORY HODGKIN LYMPHOMA POST-AUTOLOGOUS STEM CELL TRANSPLANT (ASCT)

J Thompson[1], L Barcena[1], B Woods[1], Y Liu[2], H Huang[2], C Hatton[3]
[1]Oxford Outcomes, Oxford, United Kingdom
[2]Millennium Pharmaceuticals, Inc., Cambridge, United States of America
[3]Churchill Hospital, Oxford, United Kingdom

Background. Treatment options for relapsed/refractory (rel/ref) Hodgkin lymphoma (HL) post-ASCT are limited. At this late stage life expectancy is short, and the few treatment options available are associated with high morbidity. Brentuximab vedotin represents the first therapy directed against the CD30 surface antigen expressed by HL cells and other haematologic malignancies. Brentuximab vedotin has been studied in HL patients who had relapsed following ASCT (SG035-0003; see Younes et al, ICML 2011, for response/safety data). This single-arm phase II trial formed the basis for the accelerated approval of brentuximab vedotin by the US FDA for HL patients post-ASCT or after ≥2 prior multi-agent chemotherapy regimens in non-ASCT patients. **Aims.** To compare the overall survival (OS) of rel/ref HL patients receiving brentuximab vedotin post-ASCT to OS associated with other treatments in this setting. **Methods.** A systematic review of English-language studies in rel/ref HL post-ASCT was carried out in Embase, Medline, Medline In-Process and CENTRAL from database inception until October 2010. ASH, EHA, ESMO and ASCO conference proceedings were also searched. More than 80% of the population in each study had to be HL patients who had failed ≥1 ASCT. No restrictions regarding study design or treatment were imposed. Treatments were broadly divided into two groups: second (mostly allogeneic) stem cell treatments (SCTs) and non-SCTs (radiotherapy, chemotherapy, palliative care). Where available, percentages of patients alive at six-monthly intervals for up to five years were extracted. Comparative graphs were produced, with proportions of patients alive in each study plotted against the time period of reporting, and each point sized to reflect number of patients per study, akin to a forest plot. **Results.** In total, 35 of the 49 studies retrieved by the systematic review reported OS. Of these, 31 provided retrievable data. *S*econd SCTs and non-SCTs performed similarly in years 1-2; however, a higher proportion of patients receiving second SCTs were alive in years 3-5 versus non-SCTs. Results varied substantially between studies; however, data from the largest studies, such as Martinez 2010 (second SCTs, n=133; non-SCTs, n=294) and Robinson 2008 (second SCTs, n=285), appeared representative, with data around the median of the observed range. At 1.5 years brentuximab vedotin showed promising outcomes, with an OS of 79% (n=102; data cut-off March 2011). This compares favourably with data from Martinez 2010 and Robinson 2008 for both second SCTs (1.5-year OS: 74% and 61%) and non-SCTs (1.5-year OS: 47%). Similar survival advantages were seen versus the remaining studies, except for two small non-SCTs studies (n=17, n=34) and three small second SCT studies (n=38, n=14, n=10). Producing a comparison between treatment types is hampered by the lack of randomised evidence and variation in patients' baseline characteristics, including exposure to further lines of systemic therapy post-ASCT. **Conclusions.** The 1.5-year OS for brentuximab vedotin of 79% is high relative to other published data for rel/ref HL patients post-ASCT. Further follow-up of SG035-0003 is required to determine if this improvement is maintained. Analyses adjusting for potential confounders would be required to robustly compare brentuximab vedotin to treatment options currently used.

[9]Washington University, Siteman Cancer Center, St. Louis, United States of America

Background. Brentuximab vedotin comprises an anti-CD30 antibody conjugated by a protease-cleavable linker to a microtubule-disrupting agent, MMAE. In pivotal phase 2 studies in patients with relapsed/refractory Hodgkin lymphoma (HL) or systemic anaplastic large cell lymphoma (sALCL), objective response rates were 75% and 86% and median durations of response were 6.7 and 12.6 months, respectively. **Aims.** A phase 2 study was initiated to investigate if patients who have previously responded to brentuximab vedotin could achieve another remission with retreatment (ClinicalTrials.gov #NCT00947856). **Methods.** Patients had a CD30-positive hematologic malignancy, achieved an objective response (per Cheson 2007) with prior brentuximab vedotin treatment, and experienced relapse after discontinuing treatment. Informed consent was obtained for all patients. Brentuximab vedotin was administered IV 1.8 mg/kg every 21 days; antitumor activity was assessed by the investigator. **Results.** 14 HL patients and 8 sALCL (5 ALK-negative) patients were enrolled (median age 34 years, range 16-72). Patients had received a median of 4 prior chemotherapy regimens (range 2-12). Median time since the previous brentuximab vedotin treatment was 6.9 months (range 1-44). Median number of retreatment cycles was 7 (range 1+ to 32+). Adverse events (AEs) in >25% of patients were nausea (41%), fatigue (36%), peripheral sensory neuropathy (36%), and diarrhea (27%). The most common Grade 3/4 AEs were anemia, fatigue, and hyperglycemia (3 patients each). Of the 11 patients who had pre-existing peripheral neuropathy, 3 (27%) had worsening with retreatment. Best clinical responses

in patients with HL were 3 CR, 5 PR, 3 SD, 3 PD. Among patients with sALCL, 5 achieved a CR, 1 had PD, and 2 were not yet evaluated. Of the 8 patients with CR in retreatment, previous best responses to brentuximab vedotin treatment were 4 PR and 4 CR. Median duration of retreatment response was 10.8 months (range 0+ to 10.8), and in patients who achieved CR, the median duration of response was not reached (range 0+ to 10.5 months); 11 patients remain on retreatment. **Conclusions.** Retreatment with brentuximab vedotin was generally well tolerated. Objective responses were observed (13 of 20; 65%) in this heavily pretreated population. Enrollment to the phase 2 retreatment study is ongoing.

[7]Hopital de la Pitie, Paris, France
[8]CHU Brabois, Nancy, France

Background. Hodgkin lymphoma (HL) is a curable disease in up to 80% of patients but for the remaining relapsed or refractory (rel/ref) patients no standard salvage therapy exists. Thus new chemotherapeutic agents are needed for HL in relapse following autologous stem cell transplant (ASCT). Bendamustine is a bifunctional alkylating agent, recently FDA approved for the treatment of chronic lymphocytic leukemia and indolent B-cell non-Hodgkin lymphoma. Limited data supports the use of bendamustine in HL (Borchmann, et al. Ann Oncol 1998). **Aims.** This retrospective study evaluate the activity of single-agent bendamustine in rel/ref HL for ASCT failures, non myeloablative transplant (NMT) failures, or patients (pts) who are ineligible for transplant. Our primary outcomes are response rate, toxicity and, progression free survival (PFS) (calculated from the first dose to progression). **Patients and Methods.** From July 2009 to july 2011, 28 patients (16M/12F) with a median age of 25 years (18 -64y) received at least one dose of bendamustine in 7 french centers. First line chemotherapy was ABVD in 25 cases and 12 patients were primary refractory to ABVD and 7 patients received radiation therapy. The median number of previous chemotherapy lines was at 5 (4 - 8) and 4 patients never received ASCT because of no response, 24 received ASCT (tandem autotransplant in 9 cases) and 6 NMT before treatment with Bendamustine. Before the first dose of bendamustine 17/28 patients were "on"chemotherapy and all had platelet counts over 150 G/l. Bendamustine was given for 2 days at 120 mg/m² in 8 patients and 90 or 100 mg/m² in the remainings, it was associated with rituximab in4 pts, vinorelbine in one pt.RESULTS.Two patients received only one course of Bendamustine for grade 4 thrombopénia (bone marrow involvement in one pt) and died rapidly from progressive disease.7 ptsreceived 1-2 cycles,10 ptsreceived 3-4 cycles,9 ptsreceived 5-6 cycles and2 ptsreceived 8 & 12 cycles. 5 patients experienced at least one grade 4 thrombopenia and G-CSF was used in 5 patients.The maximal response (evaluated with PET in 13 cases) was CR/CRu in9 ptsand 6 PR with an overall response rate of 53%. The median PFS was at 8 months (range 1 -18+) and three patients received subsequent consolidation (REVLIMID n =1 Chlorambucil n = 1 & NMT n =1). At the stopping date(December 2011), 10 patients had died from the disease. **Conclusions.** Bendamustine is effective in this heavily pretreated group of patients (mostly end-stage HL) even if the PFS is short. An earlier use should be explored in rel/ref HL, most likely in combination with other drugs such as liposomal doxorubicine or brentuximab vedotine.

[3]Haematology Department, University of Athens, Athens, Greece
[4]Pathology Department, University of Athens, Athens, Greece
[5]Haematology Department, 401 Military Hospital, Athens, Greece
[6]Pathology Department, Evangelismos Hospital, Athens, Greece

Background. CD5- MBL is a rare and not very well described entity. Based on the absolute lymphocyte counts (ALC), it can be divided in low count CD5(-) MBL (with normal ALC) and clinical CD5(-) MBL (ALC>5000/μL). **Aims.** To further analyze the clinical and laboratory characteristics as well as the clinical course of CD5- MBL and to compare the 2 subcategories. **Methods.** Inclusion criteria were detection of CD5- monoclonal B-cell population in blood without any evidence of other organ involvement. Clinical and laboratory data was analyzed along and bone marrow was evaluated by morphology and immunohistochemistry , while FISH analysis was performed for detection of trisomy 3,18,12,del7q and del17p. All patients underwent whole body CT scanning and gastroscopy was performed in 20 patients. Informed consent has been obtained from all patients. **Results.** The studied population included 43 patients with a median age of 69 years. 21 of them had ALC<5000/μL and 22 presented with lymphocytosis. The clinical and laboratory characteristics are shown on table 1. No significant differences were noticed between the 2 groups besides paraproteinemia which was more common in low count MBL. Cytopenias and B-symptoms were absent. According to IPI most patients ranked in the low or low-intermediate risk group. Paraproteinemia was a common finding (20/43). Lymphoma cells presented moderate to strong expression of CD20, moderate expression of FMC-7, CD5 negativity while CD23 was positive in 12, CD11c in 14, CD25 in 6, SIgκ in 26 and SIgλ in 17 cases. Bone marrow was infiltrated in all patients and the pattern of infiltration was interstitial in 11, nodular in 6, intrasinusoidal in 7 and mixed in 13 (nodular and intrasinusoidal in 7, nodular and interstitial in 4, nodular and diffuse in 2) with no significant differences between the two subgroups. FISH analysis was performed in 8 pts and only in one of them deletion of 17p was detected. Among patients with low count MBL none of them required therapy at a median follow up of 27 months: 19 had stable CBC, 2 presented a gradual increase of ALC, while in one patient MBL regressed a year later. In the clinical MBL group at a median follow up of 48 months 10 pts had stable CBC, 9 had a gradual increase of ALC and 2 of them developed cytopenias 57 and 79 months after diagnosis respectively, while 1 patient developed splenomegaly and pancytopenia 130 months later. These 3 patients were treated with rituximab and achieved complete response. Furthermore, 2 patients had resolution of lymphocytosis 6 and 24 months after diagnosis respectively. 1/3 rituximab responders relapsed and died 117 months after diagnosis due to disease progression. **Conclusions.** CD5- MBL displays many similarities with marginal zone lymphomas. Patients with low counts MBL present an indolent natural course with excellent outcome, while clinical MBL seems to have a more aggressive clinical course and it may represent a distinct entity, as we have previously described with the term primary bone marrow marginal zone lymphoma.

Table 1.

	All pts	MBL <5000/μL	MBL >5000/μL

VALIDATION OF THE INTERNATIONAL PROGNOSTIC SCORE IN PATIENTS WITH ADVANCED HODGKIN LYMPHOMA TREATED WITH ANTHRACYCLINE-BASED CHEMOTHERAPY

T Vassilakopoulos[1], A Kanellopoulos[1], G Pangalis[2], N Constantinou[3], G Boutsikas[1], S Kokoris[1], Z Galani[1], M Dimou[1], M Siakantaris[1], K Petevi[1], E Dimitriadou[1], M Dimopoulou[1], G Georgiou[1], C Kalpadakis[1], F Kontopidou[1], MC Kyrtsonis[1], T Tzenou[1], V Pappi[1], O Tsopra[1], M Moschogiannis[2], X Yiakoumis[2], I Vardounioti[1], V Karali[1], G Gainaru[1], T Ntalagiorgos[1], P Flevari[1], K Koutsi[1], E Bitsani[1], NA Viniou[1], P Panayiotidis[1], M Angelopoulou[1] , I Meletis[1]
[1]Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece
[2]Department of Haematology, Athens Medical Center, Athens, Greece
[3]Department of Haematology, Theagenion Hospital of Thessaloniki, Thessaloniki, Greece

Background. The International Prognostic Index (IPS), based on the analysis of 5023 patients treated before 1992, remains the most widely accepted prognostic system for advanced Hodgkin lymphoma. Nevertheless, IPS needs to be verified in independent patient series homogeneously treated with anthracycline-based chemotherapy (mostly ABVD) with or without radiotherapy. Few validation studies have been published so far with conflicting results**. Aims.** To assess the applicability of IPS in a relatively large series of patients with advanced HL under treatment with ABVD or equivalent regimens. **Methods.** In this retrospective study, we analyzed an homogeneous series of 510 patients with advanced Hodgkin lymphoma (stage IIB / III / IV) who were diagnosed and treated with anthracycline-containing therapy in 3 participating hospitals. Complete data for all parameters of IPS were available in 416 patients (82%), while at least half of the remaining patients were suitable for pooled analysis of the IPS (<3 versus ≥ 3 or <2 versus ≥ 2). Endpoints of the study were freedom from progression (FFP) and overall survival (OS). **Results.** Among 510 patients, 149 (29%) had stage IIB, 212 (42%) stage III, and 149 (29%) stage IV. The frequency of adverse IPS factors were: age ≥ 45 years 30%, male gender 57%, stage IV 30%, Hb <10.5g/dl 26%, leukocytosis ≥15x10^9/L 24%, severe lymphocytopenia 16% and albumin <4g/dl 65%. Only 23/416 patients (6%) had ≥5 risk factors. At a median follow up time of 81 months (6-308), 153 patients had refractory disease or relapsed and 107 had died. The 5-year FFP was 70% and the 10-year OS 73%. Among individual IPS factors, only stage IV was significantly correlated with FFP (p=0.0001), while the significance of hypoalbuminemia was marginal (0.05<0.0001 and p=0.02, respectively). Overall, the IPS was a statistically significant predictor of OS (p=0.01) but not FFP (p=0.11), as shown in the table. Instead, the discriminating ability of IPS was significantly improved for both OS (p<0.0001) and FFP (p<0.0001), when 306 patients with stage IIA were incorporated in the analysis. **Summary and Conclusions.** In an adequately sized series of patients with truly advanced stage HL, the IPS predicted OS and -less satisfactorily- FFP, without identifying subgroups of patients with very good or very unfavorable prognosis. Other conventional, biological or functional imaging-related factors need to be co-evaluated in order to identify sizeable subgroups of patients with sufficiently poor or favorable outcomes, suitable for treatment intensification or de-escalation respectively.

Table 1.

Comparison of FFP and OS in relation to IPS between the present study and the original publication (Hasenclever & Diehl, NEJM, 1998)

HEALTH OUTCOMES IN HODGKIN'S LYMPHOMA SURVIVORS: INCIDENCE OF LATE COMPLICATIONS WITH A FOCUS ON CARDIOVASCULAR DISEASE AND IMPACT OF SCREENING AND INTERVENTION

HU Hahn[1], A Keenan[2], T Price[2], M Borg[2], H Thomas[3], G Tucker[3], P Bardy[1]
[1]SA-Pathology/The Queen Elizabeth Hospital, Adelaide, Australia
[2]The Queen Elizabeth Hospital, Adelaide, Australia
[3]Health Statistics Unit, Epidemiology Branch, Government of South Australia, Adelaide, Australia

Background. More patients die from late effects of curative combined therapy modalities than disease progression in Hodgkin lymphoma (HL). Identification of risk factors and methods of risk reduction are of paramount importance to further improve long-term health outcomes. **Aims.** The primary aim of this study was to define the incidence and impact of late complications especially cardiovascular disease in patients cured of HL treated in a metropolitan health region over a period of 31 years.3. **Methods.** Patients were identified using the South Australian Cancer Registry and individual Hospital Cancer Registry. Patients older than 18 years and diagnosed after 1975 and in CR for 5 years were eligible to participate. The study was approved by the local Human Research Ethical Committee and informed consent obtained. Late complications and risk factors were assessed using modified Children's Oncology Group guidelines.4. **Results.** This program identified 158 patients with HL of which only 72 were fully evaluable at cut-off date (01.12.2011). The median age at diagnosis was 35 and at inclusion 52 years. Of all evaluable patients, 50 were alive at cut-off. 41 were not aware of late complications, and life-style and other factors modifying the risk. A long-term health plan existed for 9 patients only still seen by their hematologist/oncologist. The most frequently detected risk factors not including treatment were hypercholesterolemia (32), obesity (20), smoking (16) and hypertension (12). Late effects were common and led to significant morbidity and mortality. Second cancers occurred in 24, causing death in 17 patients. Screening revealed early cancer of breast, thyroid and bowel, respectively in 3 patients and one had relapse of HL. All underwent potentially curative surgical and medical treatment. Overt cardiovascular and cerebrovascular disease was detected in 15 and 6 patients, respectively of which 2 had not been diagnosed before. 2 patients died instantly from cardiac arrest due to myocardial infarction. 4 patients had asymptomatic valve disease and 3 atherosclerotic plaques now being reviewed for progressive disease annually. Hypertension increased the risk of cardiovascular disease, p=0.05. Radiotherapy, smoking, hypertension and hypercholesterolemia increased the risk of death from any cause, p<0.009.The SIR for secondary cancer was significantly raised as compared to the normal age-matched South Australian population (13.2). The same was true for cardio- and cerebrovascular disease (4.0 and 16.6, respectively). Radiotherapy appeared to be the single most important risk factor for cardiovascular disease in a chi square analysis with a p=0.015 using the Fisher Exact Test.5. **Summary and Conclusions.** Late effects are frequent and lead to excess and premature morbidity and mortality. A surprisingly high number of survivors are unaware of this risk. Reduction or avoidance of radiotherapy and management of risk through life-style choices such as smoking and other personal risk factors e.g. obesity, hypertension are of utmost importance as shown. Better means of follow-up, patient educationand retention, and integration of general practitioners in the treatment plan are a prerequisitefor successsful programs and need to be supported. Reduction of radiotherapy is being taken into account by current treatment concepts.

[2]Department of Haematology, Athens Medical Center, Athens, Greece
[3]Department of Nuclear Medicine/PET, Evangelismos General Hospital, Athens, Greece
[4]Department of Nuclear Medicine/PET, HYGEIA Hospital, Athens, Greece
[5]Department of Nuclear Medicine, Biomedical Research Foundation,Academy of Athens, Athens, Greece

Background. Patients with HL who become PET/CT(-) after ABVD chemother-

apy are expected to have a very favorable prognosis. Nevertheless, it is known that relapse risk persists for prolonged time periods. Prognostic factors determining the outcome of PET/CT(-) patients have not been adequately studied, although they may be very important for patient monitoring and counseling. **Aims.** The aim of this study was to identify relevant prognostic factors in this specific subgroup of HL patients. **Methods.** 341 patients with HL were treated with 4-8 ABVD cycles from December 2004 to mid 2011. 268 responders (CR, CRu, PR) underwent PET/CT after ABVD, while 40 did not due to technical reasons. There were missing data for 8 patients, 4 died prematurely and 21 rapidly developed progressive disease before PET/CT. Among the 268 responders who were evaluated by PET/CT, 212 patients became PET/CT(-) after ABVD, forming the patient population of the present study. **Results.** The median age of 212 PET/CT(-) patients was 29.5 years (15-78), 51% were males, 98% had classical HL, 26% had stage III/IV, 30% had B-symptoms, 21% had ≥5 involved sites, 37% had anemia, 15% significant leukocytosis, 9% severe lymphocytopenia, 48% had ESR ≥50 mm/h, 54% albumin <4 g/dL, 20% elevated LDH and 25% high IPS (≥3). Eleven patients relapsed and 1 died in 1st CR. The median follow-up (after PET/CT) for the remaining 201 patients was 34 months (1-80). 96% of stage I/II patients received additional radiotherapy (median 3000 cGy). In contrast, 88% of advanced stage patients were not irradiated. Relapse free survival (RFS) was 98%, 96%, 94% and 92% at 1, 2, 3 and 4-6 years after the negative PET/CT scan respectively. Among the above potential predictive factors, univariate analysis demonstrated that an inferior RFS was predicted by advanced stage (3-year RFS 98% vs. 83% for stages I/II vs. III/IV, p=0.0002) and involvement of ≥5 sites (97% vs. 84%, p=0.02). Especially for the 19 stage IV PET/CT(-) patients, the 3-year RFS was only 72% vs. 89% for the 35 stage III patients. In multivariate analysis only stage III/IV was an independent prognostic factor for RFS (hazard ratio 8.8, p=0.006). At least 2/3 relapses in stages I/II and 1/8 in stages III/IV were detectable by clinical examination only; 1/8 advanced stage patients relapsed in a previously bulky site, which could have been irradiated. **Summary and Conclusions.** Patients with HL achieving a negative PET/CT after ABVD, have an approximately 8% cumulative risk of relapse during the subsequent 5 years. A negative PET/CT after 4-6 cycles of ABVD predicts an excellent short/mid-term outcome in patients with stages I/II, who are typically irradiated. On the contrary, stage III/IV patients rendered PET/CT(-) after 6-8 cycles of ABVD, who are not usually irradiated, still remain in a considerable risk of relapse approaching 20% within the initial 3 years. Therefore, although stage III/IV PET/CT(-) patients may require regular monitoring with imaging studies, this can probably be avoided in stage I/II PET/CT(-) patients who have received radiotherapy, in order to minimize further exposure to radiation and save health care costs.

[3]Department of Experimental Oncology, Mediterranean Institute of Oncology, Viagrande, Catania, Italy
[4]Ospedale Garibaldi, Division of Onco-Hematology, Catania, Italy
[5]Division of Radiology, Ospedale Cannizzaro, Catania, Italy

Background. ABVD (doxorubicin, bleomycin, vinblastine, and dacarbazine is considered the gold standard for Hodgkin`s lymphoma (HL), but a small fraction of patients fails to achieve long term disease control for either resistant or relapsing disease. BEACOPP (bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone) has been proposed for a better disease control, despite immediate and long term side effects. Thus, new biomarkers to identify risk-adapted strategies are an emerging need, including interim-PET after two courses of chemotherapy (PET-2). The ratio between absolute lymphocyte and monocytes count ALC/AMC in peripheral blood at diagnosis has been recently suggested. We have already demonstrated that a circulating sub-population of immunosuppressive myeloid cells (MDSC) has the ability to suppress T-cell immune response, and are increased in the peripheral blood of HL patients,In this retrospective study we evaluated sensibility and specificity of interim-PET, ALC/AMC and MDSC-count in peripheral blood at diagnosis to predict progression free survival (PFS). **Methods.** From September 2008 to October 2011, 52 consecutive patients affected by classical HL were evaluated. All patients were treated with standard ABVD therapy followed by consolidation radiotherapy in case of bulky presentation or residual tumor mass. Both baseline and PET-2 were performed using standard technique. In peripheral blood, we evaluated ALC/AMC ratio and circulating levels of immature MDSC by flow cytometry defined as $CD45^+$, $CD34^+$, $CD11b^+$, $CD13^+$, $CD14^-$. **Results.** After a median follow-up of 19.2 months (range, 3.5-36.4 months), 44 patients (84.6%) were in continued complete remission (cCR), 8 failed treatment (15.4%) after a median of 11.2 months.PET-2 was available for all patients. 6/52 patients (11.5%) were PET-2 positive and all of them shifted to BEACOPP scheme. PET-2 had sensitivity for predicting 2-year PFS of 50% (95% CI%, 15.7 to 84.3%) and a specificity of 95.5% (95% CI, 84.5% to 99.4%).48/52 patients had high ALC/AMC-DX ratio>1.1, defined in accord to Porrata, 2012, with sensitivity for predicting 2-year PFS of 93.8% (95% CI, 69.8 to 99.8), but a low specificity of 9.1% (95% CI, 4.2% to 16.5%).HL patients at diagnosis showed higher levels of MDSC when compared to matched for sex and age healthy controls (3.02±0.25 vs 1.62 ± 0.16, p<0.0001), with return to normal values within the first 2 cycles of chemotherapy (1.81 ± 0.31, p=0.013). High MDSC count was associated with a lower PFS. MDSC count had sensitivity for predicting 2-year PFS of 75% (95% CI%, 34.9 to 96.8%) and a specificity of 86.4% (95% CI, 72.7% to 94.8%). **Conclusions.** A low ALC/AMC-DX ratio correlates with a good prognosis, but in our series we were not able to confirm the high specificity of this marker and its predicting value was certainly inferior to PET-2. Despite the therapy switching in case of PET-2 positivity, PET-2 still maintained high sensitivity and specificity for predicting 2-year PFS. MDSC count had high sensitivity and specificity for predicting 2-year PFS, comparable with PET-2, with the advantage of low cost and immediate availability at diagnosis.

Background. PET/CT is crucial in the post-treatment evaluation of patients with HL, while several studies support the implication of interim PET/CT in the design of treatment strategy. Although baseline PET/CT is recommended, it is not considered mandatory for the initial staging of HL. Furthermore, the effect of baseline PET/CT on the choice of the first-line treatment has not been systematically studied so far. **Aims.** To compare the results of conventional clinical staging (CS) and PET-based staging (PET-S) in patients with previously untreated HL. **Methods.** Sixty-seven patients with HL, who were selected based solely on the availability of baseline PET/CT results, were evaluated by conventional and PET-based methods**. Results.** The median age of the 67 patients was 33 years; 40/67 were males. Based on CS, 8, 25, 17 and 17 patients had stage I, II, III and IV. The median number of involved anatomic sites was 1, 2 (1-5), 5 (2-14) and 7 (4-11) for patients with CS I, II, III and IV respectively. Based on PET/CT results, the corresponding figures were 2 (1-5), 3 (2-9), 7 (2-14) and 11 (5-14). The number of involved anatomic sites as determined by CS or PET-S were highly correlated (Spearman's rho 0.80). Compared to CS, PET-S resulted in stage change in 20/67 patients (30%): 17 were upstaged (25%) and 3 were downstaged (5%), as shown in the Table 1. Similarly, PET-S revealed more sites of involvement than CS in 50/67 patients (67%). Among 20 patients with potential stage shift, major treatment modifications could have been justified in 16 (24% of the total) based on PET-S. However, in only 7/16 a different therapeutic strategy was actually applied due to PET/CT findings. Among 33 patients with CS I/II, 21 (64%) actually received wider field irradiation, based on the identification of more involved sites by PET/CT. With respect to bone marrow (BM) findings, 43 patients had no evidence of bone/BM uptake and all of them had negative BM biopsies. A diffuse BM uptake was observed in 11 patients: 2/11 (18%) had histologically proven BM involvement. Multifocal bone/BM uptake was noted in 13 patients: 5/13 (38%) had histologically proven BM involvement. **Conclusions.** PET-S resulted in the identification of more disease sites in the majority of patients with HL. A stage shift was noted in 30% of patients, with the majority of them being upstaged. In everyday practice only 10% of the patients had their treatment strategy changed due to PET/CT findings, although less radical changes did occur in 2/3 of early stage patients due to the widening of radiotherapy fields. The variable use of PET/CT for the initial staging of HL and its heterogenous effect on treatment decisions

may render comparisons of retrospective series difficult. Furthermore, PET/CT-based design of radiotherapy may lead to the use of larger fields, in an era that minimization of radiotherapy is warranted. The optimal use of baseline PET/CT in HL needs to be further evaluated.

Table 1. Stage distribution according to conventional methods or PET/CT in 67 patients with HL.

		PET/CT-based stage				
		I	II	III	IV	Total
Clinical Stage	I	3	2	2	1	8
	II	0	16	1	8	25
	III	0	3	10	4	17
	IV	0	0	0	17	17
Total		3	21	13	30	67

BEACOPP-14 VS BEACOPP-ESC IN PATIENTS WITH HODGKIN'S DISEASE FROM POOR-PROGNOSIS GROUP: INTERIM ANALISYS OF PROSPECTIVE RANDOMIZED MULTICENTER STUDY

I Kriachok[1], I Titorenko[1], K Filonenko[1], E Aleksyk[1], O Novosad[1], V Oliynik[2], V Stratiyenko[3], V Kovtun[2]
[1]National Cancer Institute, Kyiv, Ukraine
[2]Zaporozhsky Onkodispanser, Zaporizhzhya, Ukraine
[3]Regional clinical hospital, Kherson, Ukraine

Background. treatment results in patients with high risk Hodgkin's lymphoma (HL) still are insufficient. The treatment intensification could be promised approach in this group of patients. **Aims.** To compare the treatment efficacy and toxicity with BEACOPP-14 and BEACOPP-esc regimens in patients with HL from high risk group. **Methods.** Since September 2008 until now 151 patients in 6 Ukrainian centers from 18 to 65 years old (median 29 year), 58 male and 93 female with stage IIB with≥1 unfavorable factor and stage III-IV were included to the study. Patients were randomized to receive BEACOPP-14 (67 patients, totally received 424 cycles, 6,32±1,09 cycles per patient) or BEACOPP-esc (84 patients, totally received 459 cycles, 5,46±0,92 cycles per patient). The treatment efficacy in both groups was evaluated according to Cheson criterias (1999, 2007). Toxicity rate was evaluated with NCI-CTC criteria V.3.0. After completion of chemotherapy patients with initial sites >5 cm, residual lymph nodes >2 cm and PET-positive sites received radiotherapy (30-36 Gy). Additionally the similar group of patients, who received the therapy with ABVD, was selected for the historical control from National Cancer-Register.

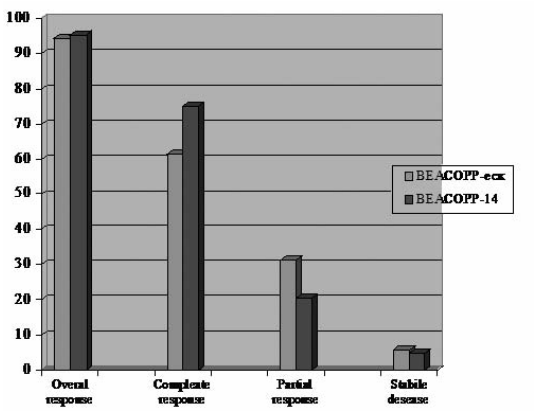

Figure 1.

Results. The treatment of patients from high risk group with both regimens was high-efficient. The response rate after the completion of chemotherapy is offer on the diagram. The ORR after the end of the treatment was 95,32 % in the group of BEACOPP-14 and 94,29 % in the group of BEACOPP-esc, CR rate was 75 % and 61,4 %, respectively (p>0,05). Observation period was 4-41 months (median 24 months). 2-year OS was 95.55% in the group of BEACOPP-esc and 100 % in the group of BEACOPP-14 (p> 0.05). In the group of historical control ORR was 80.39% (p<0.05), 2-year OS was 91,8% (p> 0.05). 2-year PFS was 94.91% in the group BEACOPP-esc, 97.95% in the group of BEACOPP-14 (p> 0.05) and was significantly lower in the group of ABVD (84,6 %, p<0.05). Toxicity of the therapy with BEACOPP-esc was higher then BEACOPP-14 due to hematological toxicity. The rate of anemia was higher in the group of BEACOPP-esc (63.18% vs. 54.25%, p<0,05), but the anemia of grade 3-4 was comparable 18,08 vs. 19,45%, respectively (p>0.05). The rate of neutropenia was also higher in the group of BEACOPP-esc (72.33% vs. 62.09%, p<0,05), but the neutropenia of grade 3-4 was comparable 46,3 vs. 42,48 % (p> 0.05). Thrombocytopenia rate was comparable in both groups (27.65% vs. 19.9%, p>0.05). In the treatment with BEACOPP-esc the rate of infectious complications was higher (13.09% vs. 4.47%, p<0,05)**. Conclusions.** ORR, CR and PFS were comparable in both groups of BEACOPP-esc and BEACOPP-14 and was significantly lower in the group of ABVD treatment. OS was comparable in all groups of patients. Toxicity rate was significantly higher in the group of BEACOPP-esc. These results need to be better studied in larger series with a longer follow-up.

0222

EXTRANODAL DISEASE IN HODGKIN'S LYMPHOMA: A RETROSPECTIVE ANALYSIS OF CLINICAL FEATURES AND OUTCOME

F Gaudio[1], T Perrone[1], V Fesce[1], A Spina[1], S Scardino[1], F Laddaga[1], A Gentile[2], P Pedote[3], G Specchia[1]
[1]Hematology - University of Bari, Bari, Italy
[2]Pathology - University of Bari, Bari, Italy
[3]Radiology - University of Bari, Bari, Italy

Background. Hodgkin's lymphoma (HL) is a highly curable disease and 5-year survival is improving, being currently 86%. Cure rates of more than 90% for early HL and more than 70% for those with advanced HL are expected. At presentation, HL is usually supradiaphragmatic, with contiguous spread often occurring predictably from one nodal group to the next along the lymphatic pathways. HL is usually almost entirely confined to the lymph nodes. Extranodal involvement is much less common in HL than in non-Hodgkin lymphoma. Extranodal invasion of adjacent tissue is seen in up to 15% of cases. **Aims and Methods.** To further assess the presenting features and the prognostic significance of extranodal disease in HL we performed a retrospective single institution study of 524 cases with a median follow-up of 12 years.The median ages were 40 years (range, 14-83 years) for men and 34 years (range, 16-77 years) for women; 393 (75%) were younger than 45 years of age. Stages III-IV were present in 340 pts (65%), bulky disease in 204 pts (38%), extranodal disease in 61 (12%), 303 pts (58%) had an IPS score 0-2 (low-risk) and 214 (41%) had a score >2 (intermediate-high-risk). Combined radio-chemotherapy was administered in 340 pts (65%) and chemotherapy alone in 184 (35).

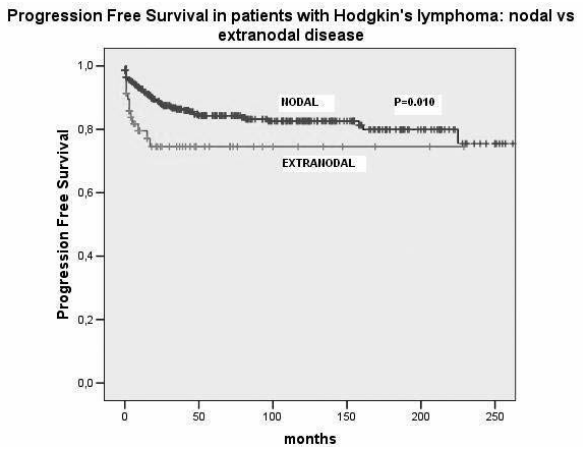

Figure 1.

Results. Extranodal disease was documented in 61 pts (12%) with a median age of 38 yrs (14-83 yrs), 39 (63%) had B symptoms, 27 (44%) had bulky disease, 29 (48%) had stage IV. Extranodal sites included the lung in 28 (41%), bone in 17 (25%); liver in 15 (21%), kidneys in 4 (6%), pleura in 4 (6%), pancreas in 1 (1%). The 61 patients with extranodal disease had poor prognosis compared with the nodal group (5 year progression-free survival [PFS], 73% versus 82%; p=0.010). Compared with the nodal subset, the extranodal patients presented more frequently with advanced stage disease (79% vs 21% p<0.001), a significantly higher (>2) HD-score (35.5% vs 10.3% p<0.001), B symptoms (63% vs 46% p=0.020), had a higher serum lactate dehydrogenase level (38% vs 18% p=0.014), a higher βeta2microglobulin level (33% vs 15% p=0.003), and a higher ESV level (64% vs 37% p=0.001). Complete remission (CR) rates in the extranodal and the nodal subsets of patient were 56% vs 71% (p=0.003), respectively. **Conclusions.** In our study extranodal disease in pts with HL is a rare occurrence (12%) associated with a poor clinical outcome. Further multicentric studies are needed to confirm our data.

[3]Oncology Hospital, Nizhniy Novgorod, Russian Federation

Introduction: Intensified chemotherapy with eight cycles of $BEACOPP_{escalated}$ or BEACOPP-14 in advanced stage Hodgkin Lymphoma (HL) is highly effective but also associated with relevant treatment related toxicity. High level pulmonitis in patients after bleomycin-consider cycles, especially with additional radiotherapy for mediastinal lymph nodes decrease quality of life. The clinical trial realized of the GHSG presented that exception of bleomycin from ABVD don't decrease efficiency of treatment. We excluded bleomycin from BEACOPP-14, the number of cycles reduced tosix, but dose of doxorubicin increased to 50mg/m^2 - EA(50)COPP-14. The program includes 6 EA(50)COPP-14± RT for initial bulky and residual mass. **Methods.** Between July 2008 and May 2011, 98 patients with newly diagnosed, histology-proven HL, aged 17-48 years, in Ann-Arbor stage II with mediastinal bulky or extranodal lesions, or those in stage III or IV were included. Sixty four patients finished their complete treatment in January 2011 they follow up 4 months after the end of treatment. The median follow-up consisted 19 months (from 9 to 31 months). Toxicities estimated in 77 patients, who finished chemotherapy in May 2011. Five patients were excluded from evaluable due to different reasons. **Results.** Complete (CR) and uncertain complete remissions (uCR) achieve in 60 (94%) of patients, partial response - in 3 (5%), progressive disease - in 1 (1%). One patient has early relapse after PET-negative CR. Secondary neoplasm was detected in 1 patient. In May 2011 all patients are alive.Hematological toxicities estimated in 77 patients. Particularly, neutropenia of III-IV grades was determined in 58 (75%) of patients, thrombocytopenia III-IV - in 12 (15%), anemia III-IV - in 52 (67%). The most frequency of hematological toxicities occurred after 4-5 cycles. Severe infection complications appeared in 22% of patients. **Conclusions.** The first preliminary results of treatment EA(50)COPP-14±RT showed high immediate efficiency and moderate toxicity.

CIRCULATING CELL-FREE DNA IS A GOOD PROGNOSTIC BIOMARKER FOR HODGKIN LYMPHOMA

M Giachelia, A Cuccaro, E Cupelli, G Massini, F D'Alò, MT Voso, G Leone, S Hohaus
Università Cattolica del Sacro Cuore, Rome, Italy

Background. Circulating cell-free DNA (cfDNA) derived from both neoplastic cells and inflammatory microenvironment has been shown to be significantly higher in cancer patients compared to healthy individuals and to decrease progressively during cancer remission. We have previously demonstrated that levels of plasma DNA were significantly higher in patients with lymphomas compared to controls and described associations to patient characteristics and prognosis (Hohaus et al, Ann Oncol 2009; 20:1408). **Aims**. In this study, we extended our previous observation on cfDNA levels in a limited cohort of HL patients to a larger prospectively evaluated group of HL patients, and correlated cfDNA levels in addition to clinical characteristics and prognosis to other biological parameters, as cytokine levels and tumor-associated macrophages. Methods cf DNA levels have been studied in pre-treatment plasma samples of 136 consecutive HL patients (62 males and 74 females) recruited at our Institution between 2004 and 2011, and 63 healthy volunteers (28 males and 35 females). Quantitative analysis of cfDNA has been assessed by a Sybr-Green based- qPCR assay for the *β-globin* gene (GenBank accession number U01317) and results are expressed as ng/mL. The coefficients of variability intra- and inter-assay were both <0.01. **Results.** The median plasma levels of cfDNA for HL patients were 23.56 ng/ml (range 1.05-656.04 ng/mL) and resulted significantly higher compared to controls (median 12.28 ng/mL, range 0.43-34.72 ng/ml; patients vs controls p<0.001). Plasma cfDNA levels at diagnosis were indicative of the tumor burden in our population, and were higher in patients with advanced disease (stage IIB-IV vs I-IIa, p=0.03), presence of B-symptoms (p<0.001), increased LDH levels (p<0.001), and an IPS score >2 (p=0.002). Moreover, levels of cfDNA correlated with plasma levels of the cytokines IL-6 (b=0.35, p<0.001), and IL-10 (available in 68 patients; p=0.02) and there was a trend for higher cfDNA levels in pts with a infiltration of tumor-associated macrophages (CD68+ cells) > 5% (available in 84 patients, p=0.06). Using the 95% upper level of controls as cut-point, patients with elevated cfDNA levels had an inferior event-free survival (EFS) (p=0.0001) and an inferior overall survival (OS) (p=0.009). In a multivariate analysis including advanced stage and adjusting the analysis for the type of chemotherapy regimen, elevated levels of cfDNA remained a prognostic factor for EFS (HR 8.2; C.I. 1.8-37.9; p=0.007) and OS (HR 6.3; 95% C.I. 1.3-33.3; p=0.03). **Conclusions.** The quantitative evaluation of plasma cell-free DNA provides a potential non-invasive biomarker for Hodgkin lymphoma, with a significant prognostic impact on patients' outcome.

INTERDISCIPLINARY EVIDENCE-BASED GUIDELINE FOR DIAGNOSIS, THERAPY AND FOLLOW-UP OF ADULT HODGKIN LYMPHOMA PATIENTS

N Skoetz, B von Tresckow, T Halbsguth, M Rancea, K Behringer, D Wongso, B Boell, B Klimm, I Thielen, D Eichenauer, P Borchmann, A Engert
University Hospital of Cologne, Cologne, Germany

Background. Hodgkin Lymphoma (HL) is one of the most common malignancies in young adults and has become curable for the majority of patients even in advanced stages. So far, there is no national or international evidence-based guideline giving recommendations for clinical practice in the treatment of HL patients. To improve and standardize diagnosis, therapy and follow-up for these patients, a clinical practice guideline was developed and consented by all major medical societies. This guideline was funded by the German Program for Guidelines in Oncology Implementation. **Aims.** To emphasize the clinically most relevant guideline recommendations related to diagnostics, treatment and follow-up of adult HL patients. **Methods.** Based on systematic literature searches in CENTRAL and MEDLINE, the currently available literature was classified, appraised for quality criteria and summarized in evidence tables. The intensive collaboration between the methodological experts in the Cochrane Haematological Malignancies Group, the clinical experts in the multi-disciplinary working-groups and the German Hodgkin Study Group ensured high quality as well as clinically relevant and up-to-date guideline drafts. The recommendations generated this way were graded for clinical and quality aspects and discussed in an interdisciplinary consensus-conference, and subsequently have been adapted and finalized. At the final consensus conference, a total of 180 evidence-based recommendations were issued. **Results.** There is a strong consensus that all patients should be offered the possibility to be treated within a clinical trial. Chemotherapy is the mainstay of treatment for all stages of HL. Two cycles of ABVD followed by involved-field radiotherapy (IF-RT) at 20Gy are strongly supported by the available evidence in early favorable stages. Early unfavorable stages should be treated with 2 cycles of BEACOPP escalated followed by 2 cycles of ABVD and IF-RT of 30Gy. The current recommendation for advanced stage patients is 6 cycles of BEACOPP escalated followed by 30Gy radiotherapy on PET-positive residual mass. There is unclear evidence for the additional value of PET, and the recommendations differ between staging, interim and follow-up evaluations. Specific guidelines are given for relapsed patients, those with nodular lymphocyte predominant HL, elderly patients and those with co-morbidities such as HIV. Health care professionals should encourage patients to exercise and should discuss the potential harms of complementary medicine with the patient. Moreover, fertility aspects have to be discussed with the patients before starting any treatment. Structured follow-up care should be provided and should, in particular, detect relapses, long-term organ toxicities and secondary malignancies. **Summary and Conclusions.** The first evidence-based guideline on the treatment of patients with HL translates scientific evidence and expert knowledge into precise recommendations for these patients into clinical practice. In addition to this clinical value, the guideline will enable healthcare professionals to improve patient information and quality management.

[2]Henri Mondor, Creteil, France
[3]Necker Hospital, Paris, France
[4]Lyon-Sud, Pierre Benite, France
[5]Hotel Dieu, Paris, France
[6]Lacassagne Center, Nice, France
[7]CHU Mont Goddine, Bruxelles, Belgium
[8]Lausanne Hospital, Lausanne, Switzerland

Background. Some biomarkers evaluable in the serum of diffuse large B-cell lymphoma (DLBCL) patients have been identified as prognosis factors and some of them can be routinely tested. These markers reflect the secretion or components of the tumor cells, nutritional status, tumor microenvironment, or can be related to secretion of pro-inflammatory cytokines. Elevated Serum free light chain (FLC) has been recently associated to an unfavorable prognosis in DLBCL. **Aims.** The aim of this study was to determine the clinical and prognostic relevance of a quantitative assessment of intact circulating immunoglobulin (Ig) using Ig heavy chain/light chain pairs (HLC) serum measurements in DLBCL patients. **Patients and Methods.** 407 adult patients (median age: 59y, 18-93) included in the LNH03-B clinical trial program with confirmed DLBCL were analyzed. The program initiated in 2003 included five clinical trials designed according to age and age-adjusted international prognostic index (aaIPI), providing a large cohort of patients with a long follow-up and being representative of the DLBCL population treated by rituximab (R) and anthracycline-based regimens. 244 were treated by R-CHOP/ R-mini-CHOP and 163 by ACVBP/R-ACVBP regimens. Serums were collected at the time of inclusion before any chemotherapy and used for FLC/HLC measurements performed by FREELITE™ and HEVYLITE™ assays. Published reference ranges were used to define an elevated FLC, an abnormal Kappa (K)/Lambda (L) FLC ratio and abnormal Ig(A-G-M) K/L ratios. **Results.** An abnormal K/L FLC ratio was observed in 38 patients (9.4%). 17 patients (5%) displayed an elevation of both K and L FLC and 76 (18.8%) an elevation of K or L FLC. Abnormal IgAK/L, IgMK/L and IgGK/L ratios were observed in 12 (2.9%), 78 (19%) and 26 (6.4%) patients, respectively. Patients with abnormal IgMK/L or abnormal FLC ratio displayed more frequently adverse characteristics including elevated LDH level (p =0.007), older age (p<0.001), elevated Beta2 microglobulin (p<0.001), or high IPI (p<0.001). No correlation was observed between lymphocyte count, creatinine level, albuminemia and FLC/HLC measurements. Patients with abnormal IgMK/L ratio had an inferior PFS in the overall cohort (5y-PFS CI95% 44.9% vs 69.4%, p = 0.0003) and OS (5y-0S CI95% 50.8% vs 78.3%, p=0.0003) and in the R-CHOP cohort (5y-0S CI95% 43.5% vs 70.6%, p=0.003) as compared with patients with normal ratio. Elevated FLC (5y-OS CI95% 36.6% vs 74.4%, p<0.001), abnormal K/L FLC and abnormal IgGK/L ratio were also associated to an unfavorable outcome. In a multivariate analysis including abnormal IgMK/L ratio, elevated FLC and aaIPI, an abnormal IgMK/L ratio (HR =1.6 CI95% 1.1-2.3, p=0.02) remains predictive of a shorter OS. Gene expression profile was performed in a subset of 58 patients using microarrays (Affymetrix U133+2). Patients with abnormal IgMK/L ratio tend to belong more frequently to the ABC subtype (p=0.1) and expressed at a higher level the Cμ gene (p=0.01), indicating that IgMK/L ratio measurement is partially driven by tumor biology. **Conclusions.** Both elevated serum FLC and abnormal IgMK/L ratio are associated with unfavorable outcome in DLBCL treated by immunochemotherapy and can be used as simple circulating biomarkers.

0227

DECREASED B AND T CELL REPERTOIRE DIVERSITIES ARE ASSOCIATED WITH INFECTIOUS RISK IN DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) PATIENTS

L Baseggio[1], G Salles[1], S Dupire[1], A Nondé[2], A Larnaud[1], O Filipe-Santos[2], S Moulle[1], A Grives[2], T Rabeony[2], G Parmentier[2], L Karlin[1], N Plantier[2], L Lebras[1], J Mouret[2], N Pasqual[2]
[1]Hospices Civils de Lyon - Université Lyon1, Pierre Benite, France
[2]ImmunID Technologies, Grenoble, France

Background. Despite the progress made in the management of patients with lymphoid malignancies, infections remain a frequent complication encountered during or after therapy. Beside chemotherapy induced neutropenia, immune dysfunctions may also contribute to the emergence of infections. Serum immunoglobulin levels are frequently altered and changes in T cell populations and functions are described in the context of several B cell neoplasms such as inverse circulating CD4/CD8 ratio, skewed distribution of regulatory T-cells (Treg) CD4+, all of them potentially contributing to infection vulnerability.Aims : In order to better characterize the adaptive immune cells and the infectious risk in patients with lymphoid malignancies, detailed molecular analyses of B- and T-cell receptor repertoires were analyzed on PBMC samples at diagnosis and correlated with the occurrence of infection. **Methods.** In a retrospective study, DNA extracted from PBMC obtained from 83 patients with lymphoid malignancies (CLL n=27; DLBCL n=21; follicular lymphoma n=37) at diagnosis (and 10 controls) was analyzed using a standardized investigation kit (ImmunTraCkeR). This device was designed to analyze the entire IGHVJ and TCRB VJ genes combinatorial diversity using multi-N-plex PCR amplification. The distribution of the IGH and TCRB combinatorial diversity was plotted together with CD19+ and CD3+ lymphocytes, respectively. Results were correlated with the occurrence of WHO grade 2 or higher infections during the first 6 months of the disease. **Results.** Both the IGH and TCRB repertoire were found to be profoundly altered at diagnosis. The median percentages of IGH combinatorial diversity were 20.83%, 46.88% and 39. 58 % in CLL, DLBCL and FL patients, respectively. The median percentage of TCRB combinatorial diversity were respectively 33.33%, 13.04% and 9.06%. All these values (except for IGH in DLBCL patients) were significantly different (Willcoxon test) from those observed in healthy individuals (54.17% and 59.60% for IGH and TCRB, respectively).Using ROC curve analysis, we attempted to determine optimal thresholds of IGH and TCRB diversity associated with the risk of infections. In DLBCL patients (but not in FL and CLL patients), IGH diversity below 51% and TCRB diversity below 10% were determined as optimal threshold for the occurrence of infections. When combining these 2 parameters (IGH < 51% and TCRB < 10%), a highly significant difference in the risk of developing an infection during the 6 first months of treatment was observed (Log-rank test, P=.026). Of note, lymphopenia at diagnosis was not associated with this risk in this cohort. **Conclusions.** These early results indicate that 1) both the B- and T-cell receptors repertoires are profoundly modified in patients with lymphoid malignancies at diagnosis 2) these modifications could be associated in DLBCL patients with the risk of developing an infection during treatment. A prospective series to further expand and confirm these findings is currently under way. Such confirmation may eventually help to consider anti-infectious prophylaxis or treatment choice in patients with lymphoid malignancies. These analyses may also prove to be useful to investigate if the immune cells dysfunctions may also be associated with the clinical outcome of patients.

0228

PROTEIN KINASE CK2 INHIBITORS CAUSE MANTLE CELL LYMPHOMA CELL APOPTOSIS AND SYNERGISTICALLY ENHANCE THE CYTOTOXIC ACTIVITY OF PROTEASOME INHIBITOR BORTEZOMIB

S Manni, A Brancalion, F Zaffino, L Quotti Tubi, A Colpo, G Semenzato, F Piazza
University of Padova, Padova, Italy

Background. Bortezomib (BZ) is a proteasome inhibitor currently employed in the therapy of multiple myeloma and in relapsed/refractory mantle cell lymphoma (MCL). However, in MCL complete remission rates are low and the duration of response relatively short. BZ causes cell apoptosis through different mechanisms, which are only partially known. Mechanisms of BZ resistance could involve the upregulation of pro-survival signaling cascades. Protein kinase CK2 is a growth-promoting protein that has been implicated in human solid and hematologic tumors; phase I clinical trials are ongoing utilizing oral ATP-competitive CK2 inhibitors in multiple myeloma and other malignant neoplasias. Despite CK2 has been shown to regulate signalling pathways playing a relevant role in MCL patho-biology, it is currently unknown whether this druggable kinase could promote MCL survival and be involved in BZ-induced cell death.

Aims. In this study we have investigated CK2 expression, cellular localization and its role in MCL survival. We analyzed whether CK2 takes part in BZ-induced MCL cell apoptosis and we studied whether blocking CK2 could influence pro-survival signalling pathways, which could account for cell resistance to BZ.METHODSBZ-sensitive (Jeko-1 and Granta-519) and BZ-resistant (Rec-1) MCL cell lines and freshly isolated B lymphocytes from healthy donor and MCL patients were cultured as per standard methods and exposed to different doses of two CK2 inhibitors (K27 and CX4945) and BZ. Cell proliferation was measured by [^{3}H]-thymidine incorporation assay and the combination index was calculated to determine whether CK2 and BZ inhibition has a synergistic effect. Cell growth and viability was assessed upon the different treatments by annexin V and propidium iodide staining, evaluation of mitochondrial potential depolarization and FACS analysis, western blotting of PARP cleavage and apoptosis related protein expression. Survival signaling pathways were studied with western blot analysis. **Results.** CK2 was highly expressed in MCL cells and its inhibition caused apoptosis and cell proliferation arrest. Simultaneous inactivation of CK2 (using two different inhibitors) and the proteasome resulted in a synergic anti-lymphoma effect with a calculated combination index inferior than 1 both in BZ-sensitive (Jeko-1) and in BZ-resistant (Rec-1) cell lines. The rate of BZ-induced MCL cell apoptosis was significantly increased by the simultaneous inhibition of CK2 and the proteasome in all the MCL models tested. The synergistic effect between the proteasome and CK2 inhibition was not present in healthy donor derived C19 B lymphocytes. Mechanistically, CK2 inhibition produced a reduction of phospho Ser 536 and phospho Ser 529 p65 NF-κB subunit levels in MCL cells. Remarkably, the simultaneous treatment with BZ and CK2 inhibitors determined a further reduction of this phosphorylated proteins. **Summary and Conclusions.** These results indicate that protein kinase CK2 is essential for MCL survival, protects from BZ-induced apoptosis and modulates pivotal growth promoting signaling pathways in MCL cells, such as the NF-κB cascades. Our findings suggest that CK2 inhibition could represent a rational therapeutic option for MCL and offer the groundwork to design novel combination treatments for this disease.

0229

IMPROVED OUTCOME OF ELDERLY DLBCL PATIENTS WITH 6XCHOP-14 AND 8 RITUXIMAB (R) APPLICATIONS GIVEN OVER AN EXTENDED PERIOD (SMARTE-R-CHOP-14 DSHNHL TRIAL) IS DUE TO BETTER RESULTS OF MALE PATIENTS

N Murawski, G Held, S Zeynalova, C Mueller, V Poeschel, A Viardot, M Haenel, U Keller, M Reiser, M Ziepert, N Schmitz, M Pfreundschuh
DSHNHL, Homburg/Saar, Germany

Background. 6xCHOP-14 with 8xR given over an extended period improved 3-year EFS (67% vs. 54%; p=0.030) and OS (80% vs. 67%, p=0.034) of poor-prognosis patients (IPI=3-5) in the SMARTE-R trial compared to the RICOVER-60 trial where patients received 8xR every 2 weeks. **Aims.** Because we had recently shown (Mueller et al., Blood 2012) that elderly male patients have a faster R clearance (12.68 ml/h vs. 8.21 ml/h; p=0.003) and shorter serum elimination half life ($t_{1/2ß}$=24.7 vs. $t_{1/2ß}$=30.7 days; p=0.003) than females, we analyzed whether these differences translated into different outcomes by comparing the results achieved by elderly female and male patients in the RICOVER-60 and SMARTE-R trials. **Methods.** In SMARTE-R, 189 evaluable elderly (61-80 y) pts. with DLBCL received 6 cycles of 2-weekly CHOP-14 combined with 8xR on days -4, -1, 10, 29, 57, 99, 155, and 239. The primary endpoint was event-free survival (EFS). 306 pts treated within the RICOVER-60 trial with 6xCHOP-14 + 8 R given on days 1, 15, 29, 43, 57, 71, 85 and 99 served as controls. **Results.** The 3-year EFS of 51 poor-prognosis male patients in SMARTE-R was 67% compared to 47% of 66 poor-prognosis male patients treated in RICOVER-60 (p=0.037); the respective figures were 71% vs. 53% (p=0.051) for PFS and 80% vs. 60% (p=0.027) for OS. In contrast, female poor-risk patients had only a small benefit from the extended rituximab exposure in SMARTE-R (n=48) compared to RICOVER-60 (n=57): 67% vs. 61% (p=0.354) for EFS; 71% vs. 67% (p=0.489) for PFS; and 80% vs. 76% (p=0.528) for OS. **Conclusions.** Elderly male patients with poor-prognosis DLBCL who have a faster R clearance and shorter R serum elimination half life than female patients benefit significantly from the longer R exposure in SMARTE-R with a gain of 20% in 3-year OS, while the outcome of female patients was only slightly improved. Even though R maintenance has failed to demonstrate any benefit in the primary treatment of DLBCL to date, these results underline the importance of a minimum exposure time of R in order to exploit its full therapeutic potential in DLBCL. *Supported by Deutsche Krebshilfe.*

THE CANADIAN TOSITUMOMAB AND I131 TOSITUMOMAB (TST/I131-TST) EXPERIENCE: FIVE YEAR SURVIVAL DATA

J Olney[1], M Freeman[2], J Mangel[3], D Steward[4], D White[5], G Gaudet[6], J Elia-Pacitti[2]
[1]Centre Hospitalier de l'Université de Montréal, Montreal, Canada
[2]GlaxoSmithKline Inc., Toronto, Canada
[3]London Health Sciences Centre, London, Canada
[4]University of Calgary and Tom Baker Cancer Centre, Calgary, Canada
[5]QEII Health Sciences Centre, Halifax, Canada
[6]Hôpital du Sacré-Coeur, Montreal, Canada

Background. Indolent NHL is characterized by relapses and remissions, responding less to each successive line of therapy. Radiotherapy in NHL is generally limited to localized disease or palliation, toxicity increasing with field size. CD20 immunotherapy has revolutionized NHL specifically targeting B cells. Combining these modalities as radioimmunotherapy is highly active but remains to be fully characterized. Mature survival data in this setting is very limited. The Canadian experience with 5-year follow-up can now provide some insights in this regard. **Aims.** Assess overall survival (OS) and progression free survival (PFS) at 5 years from treatment with TST/I^{131}-TST, explore predictors of OS and PFS, and update toxicity. **Methods.** The largest phase II open label study of TST/I^{131}-TST in indolent NHL was conducted at 12 Canadian centres. Patients with >2 prior lines of therapies, at least one including rituximab, responding to their last treatment were enrolled from April 2004 to February 2007. **Results.** 93 patients were included in the intent-to-treat population analysis. Median age was 59 years (32-78). ECOG status was0 in 55.9% and1 in 37.6%. Follicular NHL was present at original diagnosis in 94.6%, 78.5% with pathologic grade 1/2 histology. Bone marrow involvement was documented in 25.8%. The median duration of disease was 4.9 years (0.8-22.7). The median number of prior therapies was 5 (2-14) with 39.8% enrolled within 6 months of their last therapy. 25.8% had received prior radiotherapy.Study defined 6 months response rate was 43.0% (95% CI 32.8-53.7; 4.3% CR), 50% (38.6 - 61.4) in 80 evaluable patients. With 5 years of follow up, the median duration of response was not reached (95% CI 17.4-NR). Median PFS was 12.0 months (95% CI 7.7-17.5). Median OS was 59.8 months (95% CI 31.7-NR, 1.2-62.9+ months, Figure 1). In multivariate analyses hemoglobin (<120g/L), bulky disease (>5cm), and BSA (>2.2 m^2) were identified as significant predictors of OS, whereas LDH (>ULN), bulky disease (>10 cm), BSA (>2.2m^2), and number of prior therapies (>4) predicted PFS.There were 47 deaths, 40 of progressive disease and 7 of other causes (4 infectious, 1 aspiration, 1 leukemic transformation of MDS, 1 respiratory failure) with 5 of these 7 having prior progression. While on study (to 6 months), treatment was well tolerated. 13 patients (14%) had at least one SAE, six considered related to study medication by investigators. 33% had a grade 3/4 AE, including neutropenia (1%/5%), anemia (3%/0%) and thrombocytopenia (0%/1%). One febrile neutropenia was observed. After 6 months, there were four further SAEs reported in three patients, including MDS (2 cases), fatal sepsis (in one MDS patient), and left ventricular dysfunction. The MDS patients had 3 and 6 treatment lines prior to receiving TST/I^{131}-TST. Median TSH remained normal. Nine (9.7%) patients had two consecutive TSH measurements above UNL. **Conclusions.** Treatment with TST/I^{131}-TST was associated with durable responses as well as prolonged OS and PFS, with no unexpected toxicities in these heavily pretreated indolent NHL patients. Predictors of outcome included tumour bulk, BSA, hemoglobin, LDH and prior number of therapies.

[9]Internal Medicin, Hospital, Biella, Italy
[10]Hematology, Spedali Civili Hospital, Brescia, Italy

Background. Diffuse Large B-cell Lymphoma (DLBCL) patients with poor prognosis (age-adjusted International Prognostic Index, aa-IPI 2-3), had a dismal prognosis if treated with conventional chemotherapy. Some phase II studies and preliminary data of randomized phase III study conducted in Rituximab-era suggested that the addition of rituximab to high-dose chemotherapy was effective in DLBCL with poor prognosis at diagnosis, but results are controversial. **Aims.** of this study was to perform a long term follow-up of a series of patients included in a multicenter phase II Italian study (Vitolo U et al, Haematologica 2009) and to analyze the risk of central nervous system (CNS) relapses and the incidence of late toxicities. **Methods.** Inclusion criteria were: young patients (age, 18-60) with stage III-IV diffuse large B-cell lymphoma at aa-IPI 2-3. Treatment plan was: four courses of bi-weekly Rituximab-intensified CHOP (R-iCHOP14) followed by two courses of rituximab plus mitoxantrone, high-dose cytarabine and dexamethasone (R-MAD) and high dose chemotherapy BEAM plus autologous stem cell transplantation (ASCT). Updated data regarding of survival, CNS relapses and late toxicities were recorded on November 2011. **Results.** From 2002 to 2005, 112 patients were treated according to the phase II trial. Clinical characteristics were: median age 47 (36-52) years; aa-IPI 3 44%; bone marrow involvement 21%. With a median follow-up of five years, 5-year Overall Survival was 79% (95% CI: 70% - 86%). In a multivariate analysis, the risk of death was adversely influenced by age with a progressive increase of five years at diagnosis (p.008) or aa-IPI3 (p.001). Three patients experienced CNS relapses. Only one of the three patients received CNS prophylaxis with intrathecal Methotrexate, even if all of them were at risk for CNS relapse according to Italian Society of Hematology guidelines. Cumulative incidence of CNS recurrence at 10 years for R-iCHOP14+R-MAD+BEAM and ASCT was 3.6% (0 to 7.8). Most frequent late toxicities were dyslipidemia and secondary amenorrhea. Regarding to secondary malignancies, myelodisplasia or acute myeloid leukemia were recorded in two patients, at a median time of seven years off therapy. The actuarial risk of secondary malignancies at 10 years was 4.2% (0 to 10). **Conclusions.** The addition of Rituximab to dose-dense iCHOP followed by R-MAD and high-dose chemotherapy plus BEAM and ASCT improved the outcome in young untreated DLBCL patients at poor prognosis, with an acceptable risk of secondary malignancies and late toxicities. A careful identification of patients at risk could avoid the risk of CNS relapse.

[4]Busan Paik Hospital, Busan, South-Korea
[5]Kyung-sang National University Hospital, Jinju, South-Korea
[6]Gosin Gaspel Hospital, Busan, South-Korea

Background. Front line use of radiotherapy produced superior survival compared to initial chemotherapy in localized extranodal NK/T cell lymphoma (ENKTCL) in previous studies. Poor drug delivery owing to tissue necrosis related to angiodestruction and frequent expression of multidrug resistance (P-glycoprotein-positive) phenotype might be the important contributing factors. The use inadequately accurate imaging for radiation therapy volume delineation might lead to missed tumor or irradiation of excess volumes of normal tissues. Recently, PET/CT would be a promising tool for the radiotherapy planning to active lesion for ENKTCL. Furthermore, it was very difficult to obtain local control of the bulky lymphoma in a recent study.Aim. The objective of the present study is to investigate whether metabolic tumor volume (MTV) would be a prognostic factor in limited stage ENKTCL **Methods.** Seventy-four patients with ENKTCL in nasal area underwent PET-CT at diagnosis were enrolled for the present study. Treatment modality were given as follows: chemotherapy (CT) followed by radiotherapy (RT) (34 patients), RT followed by CT (20 patients) and CT alone (20 patients). MTV was delineated on the PET/CT images by extranodal region of nasal area equal or greater than standard uptake volume (SUV) 2.5. The final MTV was calculated by using fusion software (Syntegra, version 2.1E, Philips Co.).Results. ROC curve analysis was used to calculate the accuracy of ideal cut-off value to distinguish between low MTV and high MTV group. Various cut-off values of MTV were used to obtain a reasonable balance of sensitivity and specificity. 31.2 cm^3 of various values acquired a sensitivity of 90.3% and specificity of 58.1%. The median age was 58.5 years (range, 23-74 years) and male : female ratio was 45 : 29. The patients of ECOG performance status above grade 2 were 9 patients. Patients including stage IE and IIE were 42 : 33. The clinical outcomes were compared according to several prognostic factors such as age, high performance status (PS) grade above 2, high stage such as IIE, high international prognostic index (IPI) above 2, high LDH level above upper normal limit, local tumor invasiveness (LTI), up-front radiotherapy (RT) and high MTV above 31.2cm^3. Univariate analysis revealed that other seven factors except age had significant prognostic values in PFS and OS (PFS, high PS [p=0.006], High stage [p=0.044], high IPI [p=0.010], high LDH [p=0.017], LTI [p=0.003], up-front RT [p=0.003] and high MTV [p<0.001]; OS, high PS [p=0.004], high stage [p=0.017], high IPI [p=0.010], high LDH [p=0.009], LTI [p=0.001], up-front RT [p=0.002] and high MTV [p<0.001]). In multivariate analysis, up-front RT (PFS, HR=0.232, 95%CI=0.068-0.798, p=0.020; OS, HR=0.214, 95% CI=0.050-0.926, p=0.039) and high MTV (PFS, HR=2.962, 95%CI=1.101-7.968, p=0.032; OS, HR=3.345, 95% CI=1.276-8.708, p=0.014) were significant prognostic factors in PFS and OS.Conclusion. The present study showed that up-front RT and tumor burden at diagnosis measured by PET/CT had a significant prognostic values in ENKTCL.

[5]Universitätsklinik Mannheim, Mannheim, Germany
[6]Universitätsklinik Bonn, Bonn, Germany

Background: Clinical and pharmacokinetic data suggest that the effect of rituximab could be improved by prolonged exposure to the drug. To test for this hypothesis we performed a prospective randomized trial of rituximab maintenance therapy versus observation in patients (pts) with CD20+ B-cell Non-Hodgkin-Lymphoma. **Methods.** After completion of standard treatment, pts with $CD20^+$ B-cell lymphoma were randomized to either observation or maintenance therapy with rituximab (375 mg/m^2) administered every 3 months for 2 years. Both pts after first line therapy and pts after relapse treatment were included in the study. Pts with aggressive lymphoma were enrolled if they had achieved a complete response (CR) after initial treatment. Pts with aggressive lymphoma with residual tumor mass underwent positron emission tomography (PET) and qualified for randomization if this examination showed no signs of tumor activity. Pts with indolent lymphoma were eligible for the study if at least a partial response (PR) was achieved. Primary endpoint of the study was progression free survival (PFS), secondary endpoints were time to progression (TTP), overall survival (OS) and response to treatment. **Results.** 326 pts were included in the trial. Complete data sets of 294 pts were available for analysis on an intention-to-treat basis. We here report on the subset of 145 patients with diffuse large B cell lymphoma (DLBCL). 73 pts were randomized to the treatment group and 72 pts to the observation group. 77 (53%) pts were male and 68 (47%) female, with no significant gender differences between treatment and observation groups (p=0.74, Fisher's exact test). The median age was 58.6 years. 130 pts had received one previous therapy, 12 pts two, and two pts three previous lines of therapy. At study entry, 116 pts were in CR, 15 pts in unconfirmed CR and 14 pts in PR. Age, sex, number of previous therapies and remission status were well balanced between the treatment and the observation group (p≥0.48). After a median follow up of 30 months, PFS was excellent with 91% in the treatment group and 86% in the observation group (p=0.38). There was no difference in OS between the two groups. In a multivariate Cox model, OS

and PFS were not different between men and women. The estimated hazard ratio of female vs. male was HR(F:M)=0.90 (p=0.90) for OS and HR(F:M)=0.49 (p=0.20) for PFS. However, interestingly there was a significant interaction (p=0.02) between therapy group and gender in regards to PFS with significant more events in men than in women in the observation group (HR(F:M) = 0.12; 95% confidence interval (CI) =(0.02, 1.00)), and no differences between men and women in the treatment group (HR(F:M) = 2.71 ; 95%CI=(0.50,14.9)). **Conclusions.** In this study, rituximab maintenance therapy did not improve PFS or OS in patients with DLBCL in general. However, in male patients a significant better PFS was found in the treatment group compared to the observation group (HR=0.21; p=0.03), suggesting a benefit of rituximab maintenance therapy for male patients with DLBCL.

0234

A PHASE II TRIAL ADDRESSING EFFICACY OF HELICOBACTER PYLORI-ERADICATING THERAPY AS UP-FRONT TREATMENT IN EARLY-STAGE GASTRIC DIFFUSE LARGE B-CELL LYMPHOMA: IMPLICATIONS OF ONTOGENETIC CLASSIFICATION

[11]AO Santa Maria Nuova, Reggio Emilia, Italy

Background. *Helicobacter pylori* (*Hp*) infection is associated with both marginal zone lymphoma of MALT-type and diffuse large B-cell lymphoma (DLBCL) of the stomach. While *Hp*-eradicating antibiotic therapy is the standard treatment for limited-stage MALT lymphoma, the role of this strategy in gastric DLBCL is still controversial and resulting successful from a few case reports and small monoinstitutional retrospective series. **Aims.** This is the first multicentre phase II trial addressing safety and efficacy of *Hp*-eradicating therapy as exclusive treatment for limited-stage gastric DLBCL in Western countries. **Methods.** Inclusion criteria were histopathologic diagnosis of DLBCL with or without concomitant MALT-type areas; gastric *Hp* infection; stage-I disease with or without concomitant perigastric lymph nodes diameter <1.5 cm; hemoglobin ≥9 g/dl; normal LDH serum level. Registered patients received clarithromycin 500 mg bid, tinidazole 500 mg bid and omeprazole 20 mg bid, for 7 days. Objective response and bacterial eradication were assessed by gastric endoscopy-ultrasonography, biopsies and breath test after one and two months from antibiotics. Patients who achieved complete remission (CR) were referred to observation, patients in partial response (PR) received four doses of rituximab and patients with stable (SD) or progressive (PD) disease received anthracycline-based chemotherapy ± radiotherapy. Immunohistochemical ontogenic classification of DLBCL (i.e. Germinal center-GCB) versus non-germinal center (i.e., non-GCB) followed criteria proposed by Hans et al. **Results.** Sixteen patients (median age 70; range 38-87; 11 males) were registered. Five patients presented concomitant MALT areas; ten patients had perigastric lymphadenopathies. *Hp* eradication was achieved in all cases. Histopathological material for Hans' classificationwas available in 14 cases. CD10, bcl-6, bcl-2, and MUM1 immunoreactivity was detected in 4 (29%), 10 (71%), 12 (86%), and 7 (50%) cases, respectively. Accordingly,7 patients displayed a GCB phenotype and 7 showed non-GCB phenotype. Median Ki-67 (MIB1) proliferation index was 70% (range 30-99%).Lymphoma regression was complete in 8 (50%) patients, and partial in 3 (ORR= 69%; 95%CI= 47%-91%), one patient had SD and 4 PD. Two of the three PRs achieved CR after rituximab (CRR= 63%; 95%CI= 39%-87%). At a median follow-up of 66 months (range 13-104), nine of the 10 CRs were relapse-free, with a median DFS of 74+ months. The non-responder patients and the relapsed one received R-CHOP-like chemoimmunotherapy ± radiotherapy, and remained disease-free at 13-90 months (median 46+). Response and relapse rates were not associated with the presence of concomitant MALT areas, perigastric lymphadenopathies or Hans' classification results. Fourteen patients are alive, with a 5-yr OS of 94%; no patient died of lymphoma. Two patients (77 and 78 years old) died of cardiac failure after salvage treatment and gallbladder cancer at 13 and 90 months, respectively. **Conclusions.** Patients with limited-stage, *Hp*-associated DLBCL ± MALT of the stomach can be safely managed with antibiotics alone. Responses were recorded both among GCB and non-GCB lymphomas as well. Half of treated patients achieved long-term remission without chemotherapy, a critical issue considering that two-thirds of patients are old. Unresponsive patients can be safely salvaged with conventional chemo-radiotherapy with unaltered chances of cure.

0235

IMMUNO-CHEMOTHERAPY CONTAINING RITUXIMAB IS ASSOCIATED WITH IMPROVED SURVIVAL IN PRIMARY CNS B CELL LYMPHOMA

P Gregory[1], A Arumugaswamy[2], T Leung[3], KL Chan[4], M Abikhair[5], D Kipp[3], C Tam[4], A Bajel[3], L Cher[2], H Gan[2], A Grigg[2], D Ritchie[6], S Opat[5]

[4]St Vincent's Hospital, Melbourne, Australia
[5]Southern Health, Melbourne, Australia
[6]Peter MacCallum Cancer Centre, Melbourne, Australia

Background. Primary central nervous system lymphoma (PCNSL) is a rare and biologically distinct subset of non-Hodgkin lymphoma. Due to its low incidence, optimal treatment strategies remain uncertain and are currently based upon outcomes from retrospective series and small phase-II studies. In addition to improving survival outcomes in systemic B cell lymphomas, rituximab penetrates the CSF after intravenous administration and also reduces CNS relapse in high-risk systemic DLBCL. However its role in PCNSL remains uncertain. We report the results of a retrospective study examining the impact of rituximab, methotrexate, cytarabine and radiotherapy in patients managed with curative intent at four university teaching hospitals between 1996-2011. **Methods.** A retrospective study of consecutive cases of PCNSL treated at the participating institutions was performed in accordance with institutional ethical guidelines. Patients were included if they were HIV negative and had a first presentation of biopsy-proven primary CNS lymphoma or intravascular large B cell lymphoma according to WHO 2008 criteria. Patients were excluded if they were HIV positive or not treated with curative intent. Survival correlates were assessed by Cox regression using SPSS.

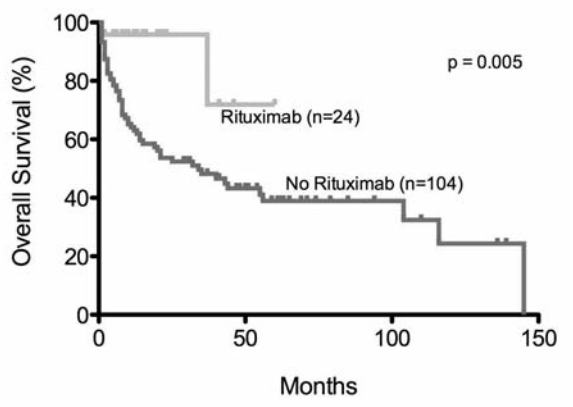

Figure 1. Overall survival of patients that were treated with curative intent and received rituximab.

Results. Of 164 patients, 30 were treated with palliative intent; 134 patients met the criteria for the study. The median age was 65 years (range 21-81), 49% male. At diagnosis, 31% had an ECOG performance status (PS) >1 and 43% an elevated serum lactate dehydrogenase (LD). Deep lesions, multiple lesions and cytology positive CSF involvement were found in 63%, 52% and 14% respectively. There was no difference in base-line characteristics between rituximab recipients and non-recipients. Histological diagnosis was DLBCL (122), T cell lymphoma (4), low-grade B cell lymphoma (1), indeterminate (3) and intravascular large B cell lymphoma (4).Chemotherapy regimens included single agent high-dose methotrexate (HD-MTX, ≥2g/m^2; n=83), combination chemotherapy including HD-MTX and cytarabine (37), other combination chemotherapy including HD-MTX (5) and combination chemotherapy without HD-MTX (8). Other front-line therapies included intrathecal MTX (43), radiotherapy (32) and rituximab (24). The median follow-up of surviving patients was 22 months. The 5 year overall survival (OS) was 44%.Univariate analysis revealed age ≤60 years (p=0.029), ECOG PS 0-1 (p=0.012), normal LD (p=0.027), diagnosis after 2004 (p=0.020), and treatment with high-dose MTX (p=0.045), cytarabine (p=0.013) and rituximab (p=0.005) as predictive of favourable OS. Cox regression analysis identified only rituximab (HR 5.3, 95% CI 1.3-21.9; p=0.002) and ECOG PS (HR 1.9, 95% CI 1.1-3.1; p=0.026) to be independent predictors of OS. At census, 22 of 24 patients treated with rituximab-containing regimens were still alive with a median follow up of 15 months. No differ-

ence in survival was observed between patients receiving HD-MTX 8 g/m^2 versus 2-3.5g/m^2 (p=0.81). Radiotherapy and intrathecal MTX were not associated with improved survival (p=0.444 and p=0.529). **Conclusions.** This retrospective analysis suggests that the addition of rituximab to HD-MTX based chemotherapy in patients with aggressive B-cell PCNSL was associated with an improved OS. Further studies are underway to validate these findings prospectively.

Aims. The toxicity and efficacy of non-pegylated liposomal doxorubicin (NPLD) when substituted for conventional doxorubicin in the CHOP regimen (Doxorubicin, Cyclophosphamide, Vincristine, Prednisone) were prospectively evaluated in the treatment of 129 consecutive elderly patients with newly diagnosed aggressive B-cell non-Hodgkin lymphoma (NHL). **Methods.** Patients were split in 2 groups according to the Multidimensional Geriatric Assessment (MDGA). Thirty-nine patients with an Activities of Daily Living (ADL) = 6 were addressed to receive dose-dense R-COMP every 2 weeks (14), whereas 90 patients with an ADL < 6 were addressed to receive R-COMP every 3 weeks (21). The median age of patients was 74 years (range: 65-89). At baseline 94/129 (73%) patients had stage III-IV disease, and 60/129 (46%) patients had an intermediate or high risk International Prognostic Index score. Median performance status was WHO 1 (range 0-3) and median number of comorbities was 2 (range 1-6). The median left ventricular ejection fraction (LVEF) before starting chemotherapy was 59% (range 40-73). A total of 715 cycles of chemotherapy were administered (234 R-COMP 14 and 481 R-COMP 21). All these variables were comparable between the 2 groups (14 vs 21). **Results.** All patients were evaluable for response. The overall response rate was 89% (complete response 73%, partial response 16%). With a median follow-up of 24 months (range 2-20) as of January 2012, 87/129 patients (67%) are alive and disease free, whereas 32/129 (25%) are dead and 8/129 (6%) are alive with active disease. Log rank analysis showed high risk IPI (4/5; p=0.02) to be a variable predictive for shorter event-free survival (EFS), whereas again high risk IPI (4/5; p=0.04), age >70 years (p=0.009), advanced-stage disease (stage III-IV; p=0.01) and performance status 2-3 (p=0.003) were all predictive of shorter overall survival (OS). The Cox proportional hazards regression model identified age >70 years (p=0.03) and perfomance status 2-3 (p=0.02) as the variables with a negative impact on OS. Finally, no statistically significant difference in terms of response was observed within the two groups (14 vs 21).Toxicity was mainly hematological in both groups. Grade 3/4 neutropenia occurred in 11% and 22% of cycles in the R-COMP 14 and 21 groups respectively, with an incidence of febrile neutropenia of 3% and 8% respectively. The relative dose intensity for the regimens was 93% for the R-COMP 14 group and 90% for the R-COMP 21 group, respectively. Regarding cardiotoxicity, only 8/129 patients presented a grade II-IV WHO toxicity. **Conclusions.** Up to now, this is the largest series of elderly aggressive NHL patients treated with NPLD instead of conventional doxorubicin reported in literature. Our data strongly suggest that NPLD induces a high rate of long-lasting complete response (CR) in a population of elderly patients with relevant comorbidities. The overlapping rate of CR between the dose-dense R-COMP 14 group and the standard R-COMP 21 group suggest that the use of NPLD outruns the impact of a dose-dense regimen in a substantial proportion of very elderly patients, representing a therapeutic opportunity for a category of patients not suitable for a dose-dense treatment.

ORAL LENALIDOMIDE PLUS 4 DOSES OF RITUXIMAB INDUCED PROLONGED REMISSIONS IN A COHORT OF PATIENTS WITH DLBCL AND GRADE 3 FOLLICULAR LYMPHOMA: A COMPLETED PHASE II CLINICAL TRIAL

M Wang, N Fowler, N Wagner-Bartak, F Hagemeister, S Neelapu, M Fanale, A Younes, L Zhang, L Sun, M Badillo, M Bejarano, R Champlin, L Kwak, L Feng, C Byrne, N Bell, J Zeldis, J Romaguera, L Fayad
University of Texas M.D. Anderson Cancer Center, Houston, United States of America

Background. The oral immunomodulatory agent lenalidomide has been shown to have significant single-agent activity with good tolerance in patients with diffuse large B-cell lymphoma (DLBCL). Its combination with monoclonal antibody rituximab might be more effective. After studying the combination in a phase I/II clinical trial in relapsed/refractory MCL patients (Wang et al, Lugano, 2011), we report our data from a Phase II clinical trial in relapsed/refractory DLBCL treated at the MTD. **Aims.** To evaluate the efficacy and safety of lenalidomide plus rituximab in patients with relapsed/refractory DLBCL. **Methods.** The study population includes patients with DLBCL (*de novo* or transformed) and Grade 3 follicular lymphoma. Patients received 20 mg oral lenalidomide daily on days 1-21 of every 28-day cycle and 375mg/m^2 intravenous rituximab weekly for 4 doses during cycle 1. Treatment continued until disease progression or severe toxicity. All patients signed an IRB-approved informed consent. The Kaplan-Meier method was used to calculate progression-free survival and response duration. **Results.** Forty five (45) patients with DLBCL were enrolled. Median number of prior therapies was 3 (range 1-4). Grade 3 and 4 toxicities, regardless of relationship to study therapy, included neutropenia (n = 24), thrombocytopenia (n=15), and lymphopenia (n=18). Other G3/4 events occurring in ≥ 2 patients include fatigue, rash, edema, embolism, elevated LFT, elevated LDH and electrolyte abnormalities. Four patients came off study because of toxicity and 12 required dose reductions. Overall response rate was 37% with a complete remission (CR + CRu) rate of 20% (CR rate of 16% and CRu rate of 4%) and partial remission (PR) rate of 13%. Median duration of response (CR/PR) was 10 months (95% CI). The median progression-free survival was 4 months (95% CI). After a median follow-up time of 16 months (7-41 months), the median overall survival was 11 months (95% CI). **Conclusions.** Oral lenalidomide plus rituximab was well tolerated and effective in patients with relapsed/refractory DLBCL and Grade 3 follicular lymphoma. Adding rituximab to lenalidomide might be superior to lenalidomide alone. A randomized clinical trial is needed for conclusive evidence.

0238

EVALUATION OF THE USE AND EFFICACY OF RITUXIMAB (R) MAINTENANCE REGIMENS IN US PATIENTS DIAGNOSED WITH FOLLICULAR LYMPHOMA (FL): DATA FROM THE NATIONAL LYMPHOCARE STUDY 2004-2007

L Nastoupil[1], R Sinha[1], M Byrtek[2], X Zhou[3], M Taylor[2], J Friedberg[4], B Link[5], J Cerhan[6], K Dawson[2], C Flowers[1]
[1]Winship Cancer Institute/Emory University, Atlanta, United States of America
[2]Genentech/Roche, South San Francisco, United States of America
[3]RTI Health Solutions, Research Triangle Park, United States of America
[4]James P. Wilmot Cancer Center, University of Rochester, Rochester, United States of America
[5]University of Iowa, Holden Comprehensive Cancer Center, Iowa City, United States of America
[6]Department of Health Sciences Research, Mayo Clinic, Rochester, United States of America

Background. Rituximab maintenance (RM) following induction therapy has been demonstrated to increase progression-free survival (PFS) in randomized trials in both first-line and relapsed settings (ECOG 1496, EORTC 20981, and PRIMA), and RM has frequently been used in clinical practice in the US and other countries. **Aims.** To examine the various approaches to RM used by practicing physicians, the correlates for use of RM, and the 'real-world' effectiveness of RM compared with observation (Obs) in patients with FL. **Methods.** The National LymphoCare Study (NLCS) is a multicenter, longitudinal, observational study of newly diagnosed FL patients enrolled from 2004 to 2007. All patients gave consent and were treated according to the enrolling physicians' preference; patients were followed for disease progression, retreatment, and overall survival (OS). Patients who achieved complete response, partial response, or stable disease following induction treatment with R-based therapy and had not initiated second-line therapy during the 215-day period following the date of last dose of induction therapy were categorized as Obs in this analysis, and those who started maintenance treatment during the 215-day period composed the

RM group.Predictors for receiving RM were identified using multivariate logistic regression analysis with backward stepwise selection. RM and Obs groups were compared for PFS, time to next treatment (TTNT), and OS using Cox proportional hazards models. **Results.** Of 2727 evaluable NLCS patients, 1204 completed R-based induction therapy and met all inclusion criteria for this analysis. 538 patients started RM treatment in the 215-day post-induction period and 666 patients were observed. The mean time to first RM dose was 4 months and mean duration of RM was 18 months. A total of 82% of RM patients completed their planned maintenance treatment regimen, 13% prematurely discontinued, and treatment was still ongoing for 5%. Predictors (p<0.05) for receiving RM over Obs were histology grade (1/2), stage (III/IV), geographic region (other than West), and center type (community practice). PFS and TTNT in the RM group were longer than those in the Obs group. With a median follow-up of 53 months after induction, OS was comparable between RM and Obs groups (HR=0.79; p=0.27). Adjusting for factors, including the Follicular Lymphoma International Prognostic Index, RM was associated with superior PFS (HR=0.69; p=0.003), longer TTNT (HR=0.73; p=0.03), but there was no difference in OS compared with Obs. The efficacy of RM treatment was not affected by the type of frontline regimen. At the time of analysis, 22% of RM patients had received second-line treatment; of these, 33% received R-monotherapy and 32% R-chemotherapy. In the Obs group, 25% received second-line treatment, 41% R-monotherapy, and 27% R-chemotherapy. The response rate for second-line treatment was similar between groups. **Conclusions.** NLCS data on physician-directed strategies following R-based induction provide useful information for comparing the effectiveness of RM and Obs in clinical practice. In this setting, RM treatment following R-based induction therapy produced significantly longer PFS and TTNT compared with Obs. Longer follow-up is required to determine whether this will produce differences in OS.

0239

IMPACT OF RELATIVE DOSE INTENSITY (RDI) IN TWO-WEEKLY DA-EDOCH14 COMBINED WITH RITUXIMAB ON SURVIVAL IN POOR PROGNOSIS DIFFUSE LARGE B-CELL LYMPHOMA

E Flores Ballester[1], J Garcia Suarez[2], M Callejas[2], I Arribas[2], J Gil Fernandez[2], N Curto[2], E Magro[2], H Guillén[2], C Casco[2], Y Martin[2], G Olmedilla[2], C Burgaleta[2]
[1]Hospital universitario principe de asturias, Barxeta, Spain
[2]Principe de Asturias University Hospital, Alcala de Henares, Spain

Background. It has been pointed out that maintenance of relative dose intensities (RDI) is related to survival prognosis in patients with poor prognosis diffused large B-cell lymphoma (DLBCL); however, little information is available from routine clinical practice regarding how well dose intensity is maintained with modern infusional regimens such a as 3-weekly R-EPOCH. The aim of the present study was to explore a R-DA-EPOCH-like regimen, which is delivered every 2 weeks (two-weekly DA-EDOCH14-R) for the treatment of prognosis DLBCL and to compare the average RDI with that achieved by poor prognosis DLBCL patients treated on the prior 3-weekly DA-EPOCH-R protocol conducted by our group. **Patients and Methods.** Forty five patients (median 49.81 years old; range 18-70) with newly diagnosis of poor-prognosis DLBCL (age-adjusted IPI ³2) were enrolled: 18 patients were treated with 6 cycles of two-weekly DA-EDOCH14-R (from 10/08 to 01/12), and 27 with 6-8 cycles of standard 3-weekly DA-EPOCH-R (from 11/02 to 05/06). Two-weekly DA-EDOCH14-R was supported on day 5 by pegfilgrastim 6 mg s.c, and 3-weekly DA-EPOCH-R was supported by filgrastrim, at a dose of 5 µg/kg/day s.c from day 6 until day 11. The primary objective of our chart review was to calculate the delivered dose intensities of chemotherapy for these 45 poor-prognosis DLBCL patients, and determine if a higher RDI resulted in better responses to chemotherapy and 3-year survival rates. RDI was calculated as the delivered dose intensity (total dose delivered/total time of therapy) divided by standard dose intensity calculated for each regimen and compared to progression-free survival (PFS) and overal survival (OS). Multivariate recursive partitioning survival analysis was utilized. **Results.** The two-weekly DA-EDOCH14-R group had a higher incidence of extranodal sites involved ≥2 (60% vs. 26%, respectively; p=0.018), and high aa-IPI score (70% vs. 37%, respectively; p= 0.02) than the patients treated with the prior 3-weekly DA-EPOCH-R regimen. Table **1** lists the dose intensity by Treatment Group. The median RDI was significantly lower with two-weekly DA-EDOCH14-R regimen (0,97 vs 1,21, with R-EPOCH14 p < 0.001, respectively). Response rates showed a near-significant trend towards a better CR rates with the two-weekly DA-EDOCH14-R regimen (90% vs. 66.6% with the 3-weekly DA-EPOCH-R combination, p=0.09). At a median follow up of 29 months, the estimated 3-year progression-free and overall survival rates were higher in the two-weekly DA-EDOCH14-R group (95% vs. 74% in the 3-weekly DA-EPOCH-R group; p=0.08). **Conclusions.** Our data suggest shortening of intervals between standard doses with modern infusional regimens (two-weekly R-EDOCH14) in comparison with increasing doses and fixed intervals (3-weekly DA-EPOCH-R), seems to be more effective than dose intensification in patients with poor prognosis DLBCL. This preliminary data must be demonstrated in further studies.

Table 1.

	ADI	RDI	Cum dose mg/m2
R-EDOCH-14	127,12254	0,96852652	
Doxorubicine			248,139111

90YTTRIUM ZEVALIN FOLLOWED BY BEAM (Z-BEAM) AND AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) FOR THE TREATMENT OF HIGH RISK RELAPSED/RESISTANT AGGRESSIVE NON HODGKIN'S LYMPHOMA (NHL)

B Botto, C Ciochetto, M Bello, R Passera, G Benevolo, C Boccomini, A Chiappella, R Freilone, F Giunta, M Nicolosi, R Novelli, L Orsucci, C Pecoraro, P Pregno, P Riccomagno, A Tonso, G Bisi, U Vitolo
AOU San Giovanni Battista, Turin, Italy

Background. High dose chemotherapy (HDC) and ASCT is actually considered an effective treatment for relapsed aggressive NHL. Standard dose Zevalin (0.4 mCi/kg) combined with conventional BEAM (Z-BEAM) is a promising conditioning regimen for the treatment of high risk relapsed/resistant NHL. **Aims.** We performed a single institution phase II study to determine the feasibility and to explore the possible sinergic effect of the addition of standard dose Zevalin to a BEAM high dose regimen in pts with high risk advanced stage NHL, with different histology, who relapsed or failed to respond after first line chemotherapy. A matched cohort analysis with a group of patients treated with standard BEAM without Zevalin was planned as secondary end point. **Methods.** Between October 2006 and May 2011 thirty pts were treated with Zevalin (day -14) followed by standard dose BEAM (day -7 to -1) and ASCT. Patients were included into the study and considered at high risk of failure if showed: progression or early relapse (<1 year) from previous therapy or multiple relapses. Standard dose DHAP or ICE with Rituximab were used as salvage chemotherapy and mobilizing regimen. **Results.** Clinical characteristics were as follows: 15 refractory and 15 early or multiple relapse; 8 grade I-II follicular, 17 PML/DLBCL, 3 MCL, 2 indolent non follicular; 7 stage II and 23 stage III-IV; 15 bone marrow involvement and 9 LDH level above normal. 14 patients received only one previous line of treatment and 16 were treated with 2 or more lines before Z-BEAM, all containing Rituximab. Only 5/30 patients received a reduced dose of 0.3 mCi/kg Zevalin because of low platelets counts. Response status before RIT was: 14 CR (47%), 10 PR (33%), 6 SD/PD (20%). At the end of treatment response status was: CR 19 (63%),PR 7(23%),PD 3 (10%) and TD 1 (4%). Median CD34+ cells infused was 7.26 10^6/kilograms (range 4.43-8.9). All pts engrafted with median time to platelet and neuthrophils count higher than $20x10^9$/L and $0.5x10^9$/L of 11 and 10 days respectively. With a median follow up of 27 months from salvage therapy 2-year progression free survival (PFS) is 63% and overall survival is 67%. 11 pts relapsed or progressed after Z-BEAM and 10 pts died, 8 of them for lymphoma, one because of lung Aspergillosis and H1N1 infection during BEAM and one for late encephalitis. We retrospectively compared this population with a matched-paired group of 21 pts treated with BEAM alone. No differences in clinical presentation at relapse were showed, apart the number of previous therapies: ≥2 only in 2 pts (9%) in BEAM group vs 16 pts (53%) in Z-BEAM group. ORR in BEAM group was 62% vs 86% in Z-BEAM group. A trend in favour of Z-BEAM was observed for PFS (63% vs 52%). **Conclusions.** In this group of pts with relapsed/resistant NHL at high risk of further relapse Z-BEAM+ASCT is able to achieve a good response with engraftment and toxicity not different from standard BEAM. 2-year PFS is promising, updated analysis with a longer follow-up is ongoing.

0241

THE PROGNOSTIC VALUE OF INTERIM POSITRON EMISSION TOMOGRAPHY BASED ON THE DEAUVILLE 5-POINT CRITERIA AFTER 3 OR 4 CYCLES OF RITUXIMAB PLUS CHEMOTHERAPY IN NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

JY Kwak[1], SK Yim[1], HY Yhim[1], YH Han[1], SY Jeon[1], NR Lee[1], EK Song[1], HS Kim[2], MH Sohn[1], CY Yim[1]
[1]Chonbuk National University Hospital, Jeonju, South-Korea
[2]Woosuk University Department of Nursing, Wanju, South-Korea

Background.Whole body positron emission tomography (PET) with ^{18}F-fluoro-2-deoxy-D-glucose is proposed as a reliable tool to predict treatment outcome in diffuse large B-cell lymphoma (DLBCL). However, there was a lack of uniform and reliable criteria for interpreting interim PET in DLBCL. In some studies, international harmonization project has been used for the interpretation of interim PET, but it was originally meant for assessment after termination of treatment. Recently, Deauville 5-point criteria has been recommended for interpretation of interim PET, but the prognostic data is limited. **Aim.** The aim of this study is to investigate the impact of interim PET using Deauville 5-point criteria on clinical outcomes in patients with DLBCL in terms of progression-free survival (PFS) and overall survival (OS). **Methods**. We consecutively enrolled 83 DLBCL patients treated with rituximab plus chemotherapy and performed an interim PET after 3 or 4 cycles of treatment in Chonbuk National University Hospital from Jan 2006 to Apr 2011. PET interpretation was done by two nuclear medicine specialists. **Results.** Total of 74 patients were included in this study. Nine were excluded because they had no initial PET data or had a single lesion excisioned before initial PET. The median age was 66 years (range 15-85) with 48 patients (64.9%) over 60 and 24 (32.4%) were female. The Ann Arbor stage was III in 16 (21.6%) and IV in 18 (24.3%) with nine involving bone marrow. ECOG performance status (PS) was 0 or 1 in 56 patients (75.7%), serum lactate dehydrogenase (LDH) level was elevated in 44 (59.5%) and B symptoms were present in 13 (17.6%). Bulky disease was identified in six patients (8.1%). Total of 16 patients (21.6%) were in the high risk International Prognostic Index (IPI).According to Deauville criteria 23 (31.1%) patients had 1 point, 25 (33.8%) had 2 points, 10 (13.5%) had 3 points, 15 (20.3%) had 4 points and one (1.3%) had 5 points. Those who had higher score than 4 (positive result in the Deauville criteria) were 16 (21.6%). After a median follow up of 22.4 month (range 6.0-69.1), the 3-year PFS and OS was 73.3±6.0% and 71.8±6.5%, respectively. The 3-year PFS and OS were significantly worse in patients having a positive interim PET (PFS, 30.1% vs 88.1%, *P*<0.001; OS, 26.4% vs 86.3%, *P*<0.001), respectively. The clinical variables associated with worse OS were as follows: age >60 years (*P*=0.004), Ann Arbor stage III or IV (*P*<0.001), ECOG PS 2 to 4 (*P*<0.001), presence of B symptom (*P*=0.002), elevated serum LDH level (*P*=0.026), extranodal involvement >2 (*P*=0.002), high IPI (*P*<0.001), positive interim PET (*P*<0.001). In multivariate analysis for OS, a positive interim PET (HR, 4.59; 95% CI, 1.33-15.7) and high IPI (HR, 5.83; 95% CI, 1.43-23.8) were independent prognostic factors for shortened OS. **Conclusions**. Interim PET analysis using Deauville 5-point scale in DLBCL is strongly predictive of survival outcomes. Further prospective studies are required to validate our results and optimize treatment strategies incorporating interim PET status to improve outcomes in patients with poor prognosis.

0242

SERUM CCL3 AND CCL4 LEVELS FUNCTION AS NOVEL PROGNOSTIC MARKERS IN DIFFUSE LARGE B CELL LYMPHOMA

K Takahashi, M Sivina, LX Xiao, YO Oki, L Fayad, S Neelapu, L Kwak, H Kantarjian, M Keating, XH Huang, J Burger
The University of Texas MD Anderson Cancer Center, Houston, United States of America

Background. B cell receptor (BCR) signaling is a critical pathway in various B cell malignancies, including diffuse large B cell lymphoma (DLBCL). Upon BCR stimulation, malignant B cells secrete the chemokine CCL3 and CCL4 (MIP-1α and β) to foster B cell interactions with accessory cells. CCL3 and CCL4 serum and plasma levels can readily be quantified using standard ELISAs, and are elevated in patients with chronic lymphocytic leukemia (CLL), where they function as an independent prognostic marker. Gene expression profiling in DLBCL revealed distinct signatures, such as the activated B cell (ABC) signature, which have prognostic implications. *SCYA3*, the gene coding for CCL3, is part of the ABC signature and associated with an inferior outcome. We therefore hypothesized that CCL3 and CCL4 serum levels may have prognostic impact in DLBCL. **Aims.** To determine the independent prognostic significance of serum CCL3 and CCL4 levels in untreated DLBCL patients. **Methods.** Serum samples from untreated DLBCL patients were analyzed for CCL3 and CCL4 levels by ELISA. Fisher's exact test was performed to evaluate the association between 2 categorical values. Spearman's correlation coefficiency was computed to correlate 2 continuous variables. Survival data were plotted according to Kaplan-Meier method, and group comparisons were made using the Log-rank test. Cox proportional hazard regression analysis was applied for multivariate analysis. **Results.** 102 patients from MD Anderson with untreated DLBCL were retrospectively analyzed. The median age of the cohort was 58 years old (range: 22 to 86) and median follow up duration was 14 months (1 to 33). 34 (33%) patients had an Ann Arbor Stage I or II, and 63 (67%) had III or IV disease. 65 patients (64%) had low International Prognostic Index (IPI) scores (0 to 2) and 37 (36%) patients had high scores (3 to 5). 95 (93%) patients received CHOP-like regimen with rituximab, and 7 patients (7%) received autologous stem cell transplantation as salvage therapy. Mean serum CCL3 and CCL4 levels were 49.9 ± 3.63 and 224 ± 17.4 pg/ml, respectively. High serum CCL3 levels (≥40) correlated with high IPI scores (p = 0.05), high LDH (p<0.01), and high β2 microglobulin (p<0.01). High serum CCL4 level (≥225) correlated with advanced Ann Arbor stages (p<0.01), high IPI scores (p<0.01), high LDH levels (p<0.01) and high β2 microglobulin (p<0.01). One year overall survival (OS) of the cohort was 91% (95% CI: 85-97), and 1 year progression free survival (PFS) was 81% (95% CI: 74-90). Log-rank test demonstrated that high CCL3 levels were associated with a significantly shorter PFS (p=0.029), and high CCL4 levels were associated with shorter OS (p<0.01) and PFS (p<0.01). Multivariate analysis revealed that high CCL4 level (HR: 3.2, p=0.03) and high IPI score (HR: 2.5, p=0.04) were significant and independent predictors for PFS. **Conclusions.** High serum CCL3 and CCL4 levels correlate with established prognostic markers and were associated with inferior outcome in DLBCL. CCL3 and CCL4 levels therefore should be considered for prognostication in DLBCL, particularly in the new era of BCR-targeting therapies.

LYMPHOMA OCCURRING OVER THE AGE OF 90: CLINICAL PRESENTATION AND OUTCOME

A Trebouet[1], T Marchand[1], E Gyan[2], H Monjanel[3], F Broussais-Guillaumot[4], Y Guillermin[5], S Le Gouil[6], S Boulanger[7], S Le Guyader[8], T Lamy[1], R Houot[1]
[1]Centre Hospitalier Universitaire de Rennes, Rennes, France
[2]Centre Hospitalier Universitaire de Tours, Tours, France
[3]Hôpital Saint Louis, Paris, France
[4]Insititut Paoli Calmettes, Marseille, France
[5]Centre Léon Bérard, Lyon, France
[6]Centre Hospitalier Universitaire de Nantes, Nantes, France
[7]Université de Bourgogne, Dijon, France
[8]Institut Bergonié, Bordeaux, France

Background. The incidence of lymphoma increases with age. Meanwhile, life expectancy continues to progress (>4 years at the age of90 inFrance). Thus, lymphoma in very elderly patients is not uncommon, and its frequency should increase with time. Despite few reports on lymphoma in very elderly patients (>80 years), no data are available for patients over the age of 90, rendering the management of lymphoma in this particular population very challenging. **Aims.** The purpose of our study is to describe the clinical presentation, management and outcome of lymphoma occurring in patients over the age of 90. **Methods.** In a retrospective, multicenter study, we analyzed 143 patients with Hodgkin (HL, n=5) or Non-Hodgkin (NHL, n=138) lymphoma diagnosed at the age of 90 or above, between 1990 and 2011. **Results.** Among the 143 patients, the median age at diagnosis was 92 years (range=90-99), 59% of patients were female. Thirty-three percent of NHL were indolent and 67% were aggressive. The most frequent histologies were diffuse large B cell lymphoma (45%), marginal zone lymphoma (10%), and follicular lymphoma (8%). At the time of analysis, full clinical and biological characteristics were retrieved for 46 patients. At diagnosis, 83% (38/46) of patients were still living at their home, 9% (4/44) had dementia, 41% (19/46) had a low (<i*e.* ≤2) Charlson index, 57% (23/40) had a low (<i*e.* ≤1) performance status, and 28% (12/43) had B symptoms. Treatment choices were the following: no treatment or corticosteroids alone in 10 (22%) of cases, surgery or radiotherapy in 4 (8.5%) cases, monochemotherapy in 11 (24%) cases, polychemotherapy with anthracycline in 4 (9%) cases or without anthracycline in 17 (37%) cases. Median overall survival (OS) for the entire cohort (n=143) was 6.6 months. Patients with indolent lymphoma had a significantly longer survival than patients with aggressive lymphoma with a median OS of 14.6 months *versus* 5.4 months (p=0.002), respectively (Figure 1). Causes of death were analyzed for 33 patients so far: death was due to lymphoma in 15 (46%) cases, treatment in 4 (12%) cases, other cause in 10 (30%) cases, unknown cause in 4 (12%) cases.**Conclusions**Lymphomas diagnosed at the age of 90 or over are frequently aggressive. In this case, the prognosis is poor. The outcome of patients with indolent lymphoma is significantly better. The main cause of death is lymphoma progression whereas toxic deaths are less frequent. This raises the hypothesis that a more "intensive"therapeutic approach may be beneficial to a subset of patients in this population. Our results will be updated for the meeting presentation.

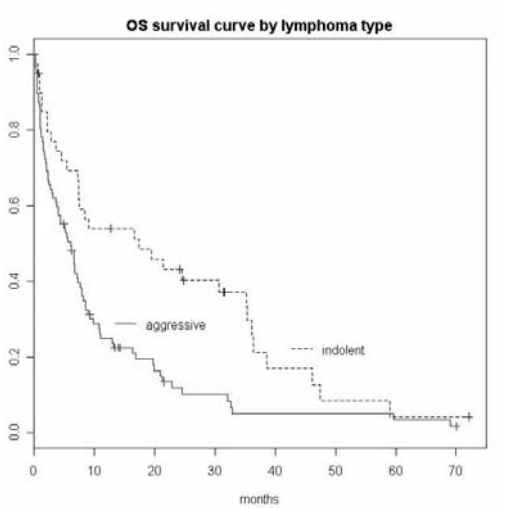

Figure 1. OS survival curve by lymphoma type.

[3]Oncologia Ospedale Figline, Figline Valdarno, Italy
[4]Oncologia, Empoli, Italy

Background. Autologous stem cell transplantation (ASCT) is considered the standard salvage therapy for relapsed or refractory non-Hodgkin lymphoma (NHL). 18F-fluoro-deoxyglucose positron emission tomography (FDG-PET) was largely used to explore the predictive value in early evaluation of treatment and at the end of therapy. **Aims.** The aim of this study was to evaluate the role of FDG-PET performed before and after ASCT.Between January 2005 and August 2010 in the Transplant Unit of our centre were performed 82 autologous stem cell transplantation (ASCT) in patients with relapsed or refractory NHL. Fourthy eight out 82 transplanted patients performed an FDG-PET before ASCT and 44 performed FDG-PET after ASCT procedures. This is the group of patients analysed in the study. **Results.** The median age was 53 years (range 21-67 years); 32 were male and 16 female. At time of transplant 26 pts (54%) were in complete remission (CR) , 15 pts (31%) in partial remission (PR) and 7 pts (15%) presented a refractory disease. The FDG-PET before ASCT was negative in 29 pts (60%) and positive in 19 pts (40%). After a median period of observation of 29 months (range 1-83 months) the overall survival (OS) was 93% in the FDG-PET-negative group and 43% in the FDG-PET positive group (p: 0.002). After a median time of observation of 26 months (range 0-83 months), the progression free survival (PFS) was 88% and 42% (p : 0.001) respectively for pts with FDG-PET negative and positive (figure 1).After three months form ASCT 44 out 48 patients performed an FDG-PET for restaging, the FDG-PET was negative in 27 pts (61%) and positive in 17 pts (39%). The PFS was 88% in the FDG-PET-negative group and 28% in the FDG-PET positive group (p: 0.000) and the OS was 92% and 26% respectively in FDG-PET negative and FDG-PET positive scans (p:0.000). **Conclusions.** Our results confirm that in NHL a negative pre-transplant FDG-PET is associated with a better OS and PFS but a significant rate of patients with positive FDG-PET (42%) did not progress. Moreover our data confirm that in NHL the higher prognostic value of FDG-PET is associated with post-transplant or final result. Patients with a positive FDG-PET after transplantation is associated with a poor prognosis and should be considered for alternative treatments

[6]Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Sait, Kawagoe, Japan
[7]Department of Internal Medicine, Division of Rheumatology, Keio University, Tokyo, Japan

Background. Recent studies have highlighted the specific group of lymphoproliferative diseases (LPDs), other iatrogenic immunodeficiency-associated LPDs (OIIA-LPDs), especially in patients with rheumatoid arthritis(RA). Methotrexate (MTX) is one of the most potent drugs that can be mediated LPDs. Numerous attempts to uncover the mechanism of OIIA-LPDs-RA, the pathogenesis remains unclear. In addition, the strategy of therapeutic approach for OAIIA-LPDs and anti-RA treatment after LPD development is not delineated. **Aims.** To address the clinocopathogenesis of OIIA-LPDs-RA, we analyzed data on OIIA-LPDs-RA patients treated at our institution, with a focus on determining the preferred anti-RA medication protocol after LPD development. **Methods.** Data on 23 patients with RA who developed LPD and were treated at our institution were retrospectively analyzed. **Results.** Patients of MTX associated LPDs in patients with RA were categorized into 3 groups; 1) MTX-Regressive-LPDs, LPD regression occurred after withdrawal of MTX, 2) MTX-Persistent-LPDs, LPD persisted after MTX withdrawal, 3) Other-Mediated-LPDs, LPD developed only after MTX was discontinued (Figure 1).

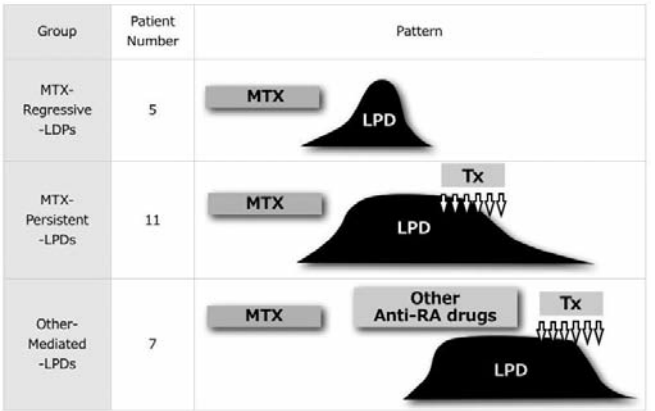

Figure 1. Three distinct subtypes of methotrexate associated lymphoproliferative

The patient's background of 3 groups showed a similarity regarding age, the duration of MTX treatment and the MTX total dose. Eleven of 23 patients were diagnosed with DLBCL, and various lymphomas including Hodgkin lymphoma and B/T- cell lymphomas were seen. The clinical stages and the laboratory data of LDH, CRP and sIL-2 in serum on the development of the LPDs in the MTX-Persistent-LPDs and Other Mediated-LPDs groups indicated significantly aggressive state of LPDs than those in MTX-Regressive-LPDs. The overall survival(OS) of all patients was 74% at 5 years, and those of 3 groups were 100%, 64%, and 60%, respectively. In 6 deceased patients, the delay in LPD detection was demonstrated in 4 patients because of the time lag in consulting with specialists from other hospitals. Some cases showed rarely LPD phenotypes: one case of DLBCL in MTX-Persistent-LPDs had a CD20 defect, and the other case of DLBCL in MTX-Persistent-LPDs was CD4 and CD30 positive. In 14 cases of karyotype analysis, 9 abnormal karyotype were detected. Of particular interest, the patient in the MTX-Regressive-LPDs showed a complicatedly abnormal karyotype that nonetheless vanished after MTX withdrawal. In the Other Mediated-LPDs group, MTX was not administrated at the LPDs development; azathioprine, bucillamine, salazosulfapyridine, tacrolimus and etanercept were given, and 3 drugs (tacrolimus, salazosulfapyridine, and etanercept) were given to the patients after LPD development; however, no patients showed LPDs regrowth. **Summary and Conclusions.** Of the data on 23 RA patients with LPDs, patients were categorized into three groups. The patients in MTX-regressive LPDs seemed a good prognosis, and OIIA-LPDs-RA itself appeared to have a better prognosis than other more common types of lymphomas. LPDs in OIIA-LPDs-RA might have a unique behavior. Various anti-RA drugs were given to the patients after developing LPDs, but no recurrent patients were documented.

USE OF EPSTEIN-BARR VIRUS DNA MONITORING AS A SURROGATE MARKER OF DISEASE ACTIVITY IN POST TRANSPLANTATION LYMPHOPROLIFERATIVE DISEASE

C Phipps[1], CG Lim[1], YS Lee[1], K Tay[2], Y Loh[1], D Tan[1]
[1]SingHealth Services / Singapore General Hospital, Singapore, Singapore
[2]National Cancer Center Singapore, Singapore, Singapore

Background. Epstein-Barr virus (EBV) DNA levels from blood can be quantified using real-time polymerase chain reaction (RT-PCR). Monitoring of these levels after an organ transplant may allow for immune-modulation as a pre-emptive measure to reduce the incidence of post-transplant lymphoproliferative disease (PTLD), but evidence for doing this is mostly confined to the paediatric and bone marrow transplant populations. The utility of monitoring EBV DNA levels in adults who have received a solid organ transplant remains largely undefined. We present here our study using EBV DNA levels to follow disease activity once PTLD has been diagnosed. **Aims.** To evaluate the role of EBV DNA levels as a surrogate marker of disease activity in PTLD. **Methods.** This was a single center study at a major transplant hospital in Singapore. Consecutive patients with newly-diagnosed PTLD were prospectively followed with serial EBV viral load monitoring using a quantitative real-time polymerase chain reaction (PCR) targeted at the conserved region of EBNA-1 gene of EBV from whole-blood samples. These were paired and correlated with imaging studies done at diagnosis, and at assessment of response (by IWG criteria) as well as upon disease relapse. **Results.** Fifteen patients with newly-diagnosed PTLD were identified from 2005 - 2011, all were post-renal transplant. The median age was 62 years and median follow-up was 16 months. Histology was centrally reviewed for consistency according to WHO 2008 classification of PTLD. Thirteen patients had monomorphic PTLD (9 with diffuse large B-cell lymphoma [DLCL], 1 peripheral T-cell lymphoma [PTCL], 1 Burkitt lymphoma, 2 plasmablastic lymphoma) while 2 had CD20 negative polymorphic PTLD. Eight of fifteen patients had EBV-associated PTLD based on histological staining for EBER and LMP1. These 8 patients also had elevated EBV DNA titers at diagnosis. There were 3 other patients with detectable EBV titres at diagnosis despite being EBV-negative on tumor histology. The sensitivity of EBV PCR detection from blood in our PTLD group was 73.3%. Treatment which included the tapering of immune suppression, rituximab and CHOP chemotherapy was administered at the discretion of the treating physician. Eleven of fifteen patients achieved complete remission (CR), 2 had partial remissions, and another 2 had progressive disease as documented by CT or PET imaging. There were 2 relapses. All patients who had detectable EBV in blood at diagnosis and whom achieved a CR had negative titres at completion of therapy. A diminution of EBV titers correlated with partial responses at interim staging. In the 2 patients who suffered relapse, one (who was in CR) had reappearance of EBV in blood while another (in PR) had a rise in EBV titres at relapse.**Summary and Conclusion.** In our patients with a positive EBV DNA at diagnosis, monitoring these levels accurately predicted clinical response as well as relapse in PTLD. Our numbers are small as this is a single center experience and PTLD is a relatively rare disease in adults. Larger studies are needed to confirm our findings.

THE ADDITION OF BORTEZOMIB TO STANDARD DOSE CHOP CHEMOTHERAPY SIGNIFICANTLY IMPROVES SURVIVAL IN RELAPSED MANTLE CELL LYMPHOMA

A Rule[1], M Furtado[1], H Eve[1], R Johnson[2], A Kruger[3], D Turner[4], S Bullard[5]
[1]Derriford Hospital, Plymouth, United Kingdom
[2]St James Hospital, Leeds, United Kingdom
[3]Royal Cornwall Hospital, Truro, United Kingdom
[4]South Devon Hospital, Torbay, United Kingdom
[5]Lymphoma Trials Office, Plymouth, United Kingdom

Background. Bortezomib has demonstrable activity in mantle cell lymphoma and is licensed in the US for this indication based on a single arm phase II tri-

al. Randomised trials with Bortezomib in this disease have not been published although a European registration study is on-going. We report the interim analysis of a UK NCRN randomised trial which subsequently lead to the discontinuation of the study. **Aims.** To explore the addition of Bortezomib to CHOP chemotherapy in relapsed MCL. **Methods.** This was a parallel phase II randomised trial of CHOP chemotherapy versus CHOP with Bortezomib (VCHOP) in patients at first relapse with MCL. The Bortezomib was administered at 1.6 mg/m^2 on days 1 and 8 of standard dose CHOP chemotherapy. Full dose vincristine was given in both arms. There was no stratification. The primary end point was overall response rate with secondary end points of PFS, OS and toxicity and tolerability of the 2 therapies. Rituximab was not used as this was not widely available in the UK when the trial was initiated. **Results.** 46 patients have been treated, 23 in each arm. The arms were well balanced (CHOP v VCHOP) by median age, 71yrs v 69yrs, median WCC 5.1 v 6.1, median time from diagnosis 19.7 v 24.7 months. Almost all patients had stage IV disease with WHO performance status 0-1. There were more men in the CHOP arm 91% v 65% and more patients has received prior rituximab in the CHOP arm 44% v 17%. Almost all of the patients had previously received fludarabine and cyclophosphamide with or without Rituximab as their initial therapy.The overall response rates were 43.4% (22% CR) for CHOP and 82.6% (35% CR) for VCHOP p=0.03. At a median follow up of 24.2 months the PFS is 8.2 months CHOP and 15.7 months VCHOP (p=0.07) with an overall median survival of 16.4 months CHOP and 36.1 months VCHOP (p=0.026, estimated hazard ratio is 0.4)There was no significant difference in severe sensory neuropathy (Gd III/IV) between the two arms, 3 cases with VCHOP compared with 2 with CHOP. However there was more Gd I/II sensory neuropathy with VCHOP, 10 v 3 cases and in addition there were 2 cases of Gd I/II motor neuropathy seen in the Bortezomib arm.There was more Gd III/IV haematotoxicity in the VCHOP arm; anaemia 8 v 4 cases, neutropenia 13 v 11 cases and thrombocytopenia 9 v 8 cases. There was no difference in other observed toxicity apart from 2 DVT's in the VCHOP arm.Summary: The addition of Bortezomib to standard CHOP chemotherapy significantly increases response rates and overall survival in relapsed MCL with modest additional toxicity.

0248

CONVENTIONAL CYTOGENETIC (CC) IN MANTLE CELL LYMPHOMA (MCL) IS A STRONG PROGNOSTIC TOOL INDEPENDENT OF THE MCL INTERNATIONAL PROGNOSTIC INDEX (MIPI) AND USEFUL TO ISOLATE INDOLENT MCL AT DIAGNOSIS

C Sarkozy[1], F Jardin[2], C Bastard[2], S Rigaudeau[1], SP Pilorge[1], H Farhat[1], P Rousselot[1], D Panther[2], I Radford[3], F Morschhauser[4], C Roche-Lestienne[4], D Bouscary[5], O Hermine[3], R Delarue[3], H Tilly[2], S Castaigne[1], S Chevret[6], C Terré[1]
[1]Centre Hospitalier de Versailles, Le Chesnay, France
[2]Centre Hospitalier H.Becquerel, Rouen, France
[3]Necker Hospital, Paris, France
[4]Centre Hospitalier de Lille, Lille, France
[5]Cochin Hospital, Paris, France
[6]Saint Louis Hospital, Paris, France

Background. MCL is characterized by the t(11;14)(q13;q32) and has an aggressive evolution with a median survival of 5 years. However, few patients, hardly recognizable at diagnosis, do have an "indolent"disease (iMCL) with a long survival without intensive therapy. To date, MIPI, blastoid variant and proliferation index (ki67) are commonly used as prognostic factors. Many studies highlight the role of additional genetics abnormalities (AA), but these abnormalities are not routinely tested and do not yet influence treatment decision. **Aims.** Therefore, we evaluated, in a cohort of t(11;14) MCL, the prognostic impact of AA detected by CC and their relationship with MIPI. **Methods.** All MCL cases diagnosed according to WHO criteria, between 1995 to 2011, were retrospectively selected, from 4 institutions, on the basis of an informative karyotype with t(11;14) at diagnosis. To isolate iMCL at diagnosis, we derived an "indolent score", based on clinical and cytogenetic characteristics that were selected as jointly associated with survival without intensive treatment (TFS) on a multivariate Cox model. Strength of association was assessed by hazard ratio (HR). **Results.** A total of 125MCL patients were included in this study. They were mostly male median age of 64 years; 87% displayed a stage IV disease, 68% a nodal presentation (lymph nodes >1cm), 55% an extranodal disease, 53% a spleen enlargement, 19% a blastoid variant and 48% a Ki67>30% (27/56 evaluated patients). The MIPI distribution was 33%, 27%, 40% for low, intermediate and high score respectively. CC analysis showed a total of 637 AA (range:0-37); 20% had isolated t(11;14), 16% one AA, 11% two, 53% a complex karyotype (CK), 6% a near tetraploid karyotype. Losses were more frequent than gains. Most frequent AA were del13q (24.8%), del9p (20.4%), del9q (19.2%), del17p (18.4%), del6q (19.2%), del1p (17.6%), del10p (12.8%), del10q (12.8%), del11q (8.8%) and tri3q (9.6%). Median follow-up was 35 months, median survival estimation 74 months. In a multivariable Cox model, high MIPI (HR=3.8, 95%IC:1.99-7.39, p<0.0001), CK (HR=2.37, 95%IC:1.17-4.79, p=0.017) and blastoid variant (HR=2.58, 95%IC:1.30-5.12, p=0.007) were independltly associated with a shortened survival.At time of analysis, among the 125 patients, 14 were alive without intensive treatment, 111 either received intensive therapy (n=106) or died before any intensive therapy (n=5); median TFS was 39 days (95%CI:31-59). Based on a multivariable Cox model, 4 variables were selected as associated with the outcome, namely spleen enlargement (HR=1.7, 95%CI:1.07-2.56), nodal presentation (HR=3.8, 95%CI:2.25-6.30), extranodal involvement (HR=2.4, 95%CI:1.57-3.76) and CK (HR=2.10, 95%CI:1.29-3.28). This allowed distinguishing two main groups of patients: "indolent"patients were defined as those who had no more than one risk factor excluding nodal presentation (n=18, whose median TFS was 53 months), and the remainders (median TFS: 1 month). **Conclusion.** In this multicentric cohort of t(11;14)MCL, complex karyotype, high MIPI and blastoid variant are 3 independent prognostic factors. With an "indolent score", relying on clinical and cytogenetic characteristics, we could discriminate iMCL at diagnosis. Therefore, besides being a tool for diagnosis, CC could be useful for the treatment decision in MCL.

0249

THE ADDITION OF STEM CELL TRANSPLANTATION FOLLOWING INDUCTION CHEMOTHERAPY IMPROVES OVERALL SURVIVAL IN MANTLE CELL LYMPHOMA PATIENTS WHO ACHIEVE A COMPLETE RESPONSE

M Vose, R Loberiza, J Bierman, G Bociek, O Armitage
University of Nebraska Medical Center, Omaha, United States of America

Background. The role of high-dose chemotherapy and stem cell transplantation (SCT) in first complete remission (CR1) for patients with mantle cell lymphoma (MCL) remains controversial. We evaluated 135 patients with MCL who were treated with anthracycline containing regimens or HyperCVAD/alternating with methotrexate/cytarabine (M/A) and obtained a CR. Based on physician preference, some patients subsequently received high dose chemotherapy and SCT. **Aims.** The aims of the analysis were to describe the characteristics of MCL patients who obtained a CR with induction chemotherapy. The risk of progression, progression-free survival (PFS), and overall survival (OS) were evaluated in patients who received induction chemotherapy +/- high dose chemotherapy with SCT. **Methods.** A total of 162 patients with newly diagnosed MCL were treated between 2000 and 2010. Of those patients, 135 obtained a first CR with induction chemotherapy. Patients were divided into two groups - Group 1 received an anthracycline containing chemotherapy (ex: CHOP +/- Rituximab (R)(N=62) and Group 2 received HyperCVAD/-M/A (+/- R) (N=73). Within each group, patients were evaluated for PFS, OS, and a multivariate analysis for risk of progression, treatment failure and death.

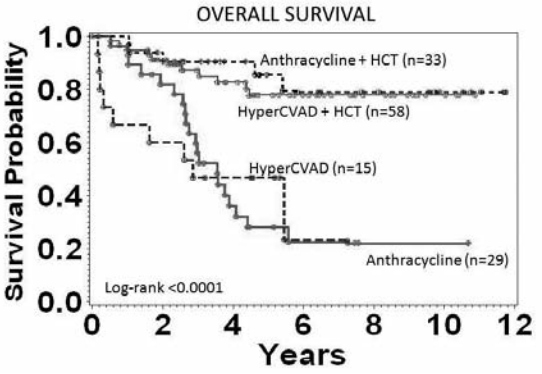

Figure 1. Overall survival.

Results. With a median follow up of 5 years (range 1-12 years), Group 1 consisted of 29 patients who received an anthracycline containing regimen alone (median age 70 years -[range 55-86]) while 33 patients received an anthracycline + SCT (median age 58 [range 39-75]). The 5-year OS for patients receiving anthracycline alone was 28% (95% CI, 13-46%) compared to 86% (95% CI, 65-94) for those patients receiving an anthracycline regimen followed by SCT in CR1 (p<0.001). Group 2 patients had a median follow up of 6 years (range 2-13 years), 15 patients received HyperCVAD- M/A alone (median age 53 years [range 32-75]) and 58 patients received HyperCVAD -M/A followed by SCT (median age 56 years [range 35-70]). The 5-year OS for patients receiving HyperCVAD- M/A alone was 47% (95% CI, 21-69%) compared to 78% (95% CI, 63-87%) for those receiving HyperCVAD-M/A with ASCT (p=0.03). In

multivariate analysis, both groups had a decreased hazard risk of death with the addition of SCT (anthracycline group, p=0.02) and (HyperCVAD- M/A, p=0.001). The only other significant covariate for the risk of death was age (p=0.01). **Conclusions.** For patients with MCL that achieve a complete remission with either an anthracycline or HyperCVAD- M/A, the use of high dose chemotherapy and SCT improved the overall survival when used as a consolidation therapy.

0250

TEMSIROLIMUS IN PATIENTS WITH RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA: DOES PROGNOSTIC RISK AFFECT OUTCOMES?

G Hess[1], L Kang[2], P Moran[2]
[1]Johannes Gutenberg University, Mainz, Germany
[2]Pfizer Inc, Cambridge, MA, United States of America

Background. Temsirolimus (TEM) is a selective inhibitor of mammalian target of rapamycin approved for treatment of relapsed or refractory mantle cell lymphoma (MCL) in Europe, Israel, Serbia, Australia, Hong Kong, Taiwan, and the Philippines. In the pivotal phase III trial (*J Clin Oncol* 2009;27:3822-9), TEM 175/75 (175 mg for first 3 weeks then 75 mg weekly) significantly prolonged progression-free survival (PFS) versus investigator's choice of therapy (INV) (4.8 vs 1.9 months, respectively; hazard ratio [HR]=0.44; *P*=.0009). TEM 175/25 (175 mg for first 3 weeks then 25 mg weekly) also showed longer PFS versus INV, but this difference was not significant (3.4 vs 1.9 months; respectively; HR=0.65; *P*=.06). However, at the time of the trial, patients were not categorized according to prognostic risk group at baseline. More recently, the simplified MCL International Prognostic Index (MIPI) was validated as a good predictor of survival (*Blood* 2008;111:558-65; *Blood* 2010;115:1530-1533). **Aims.** In this post hoc study, patients were retrospectively assigned simplified MIPI prognostic scores and outcomes were analyzed according to risk category. **Methods.** All patients (N=162) were classified (at study entry) as low, intermediate, or high risk using simplified MIPI scores, which are based on 4 independent prognostic markers: age, Eastern Cooperative Oncology Group performance status, lactate dehydrogenase level, and white blood cell count. Median PFS and overall survival (OS) were calculated using Kaplan-Meier estimates; significance of the treatment effect was indicated by log-rank P values ≤.05. The phase III study was not powered for this analysis, and statistical analyses shown are for explanatory purposes. **Results.** Distribution was relatively even across MIPI categories (55 patients low, 59 intermediate, 48 high). MIPI distributions in both TEM arms were: 175/75 (n=54: 28% low, 43% intermediate, 30% high); 175/25 (n=54: 28% low, 33% intermediate, 39% high). Relative to the TEM arms, the INV arm (n=54) had a higher proportion of low-risk patients (46% low; 33% intermediate; 20% high). Treatment with TEM 175/75 resulted in a significant improvement in median PFS (independent assessment) versus INV in high-risk patients (*P*=.003); trends toward improvement were observed for intermediate-risk and low-risk patients (*P*=.06 in each group). By investigator assessment, TEM 175/75 significantly improved median PFS versus INV by 7.9 months in the low-risk category (*P*=.0007) and by 2.8 months (*P*=.06) and 1.1 month *(P*=.001) in the intermediate-risk and high-risk categories, respectively. In all risk categories, more patients who received TEM 175/75 mg achieved stable disease compared with INV. In this study, simplified MIPI was a good predictor of OS in patients with relapsed/refractory disease. A trend toward longer OS was observed in low-risk patients treated with TEM 175/75 versus INV (*P*=.05). In both the TEM 175/75 and INV groups, grade 3/4 anemia, thrombocytopenia, and infection occurred more commonly in high-risk than low-risk patients. In the low-risk category, a higher incidence of grade 3/4 thrombocytopenia and anemia was observed with TEM 175/75 versus INV. **Conclusions.** Temsirolimus is effective for all risk groups of patients with relapsed/refractory MCL. Low-risk patients may potentially derive the greatest clinical benefit.

0251

ULTRA-RAPID 60 MINUTE INFUSION OF RITUXIMAB IN NON-HODGKIN'S LYMPHOMA -IMPLICATIONS FOR PRACTICE AND RESOURCES

J Horn, S Palmer
NHS Grampian, Aberdeen, United Kingdom

Background. Rituximab is an anti-CD20 monoclonal-antibody and core component of non-Hodgkin's lymphoma (NHL) therapy. It is frequently given in combination with cytotoxic chemotherapy and as a maintenance therapy in follicular lymphoma.Infusion related reactions are a common complication of rituximab therapy, particularly on the first infusion where it is recommended to be given following an escalating rate schedule. Subsequent infusions are given more quickly with an average infusion time of 2 ½ hours. There is increasing evidence to support the administration of subsequent doses by 'rapid infusion' over 90 minutes, but evidence for 60 minute infusion safety is more limited. **Aim.** This audit aims to establish the safety of 60 minute infusion of non-first dose rituximab in patients with NHL, and to evaluate the impact that this may have on manpower and resources. **Methods**.100 60 minute rituximab infusions in 33 patients with NHL were audited both prospectively and retrospectively. First doses were given using the recommended escalating rate schedule, but subsequent doses were infused over 60 minutes. Data collected included sex, diagnosis, chemotherapy regimen, incidence and nature of adverse infusion reaction on cycle 1 and incidence of infusion reactions on subsequent cycles. **Results.** 100 60 infusions were audited in 33 individual patients, 13 female and 20 male. Lymphomas were 20 follicular, nine diffuse large B cell, two marginal zone, one T-cell rich B-cell and one high grade B-cell not otherwise specified. Rituximab was given as part of R-CHOP (15) R-CVP (eight) R-FC (one), R-Chlorambucil (one) and as single agent maintenance (nine). One patient had two treatment lines. All patients received 10mg IV chlorphenamine and 1g oral paracetamol as standard but steroids were only given when as part of the planned chemotherapy schedule (80 infusions = 80%). Seven (21%) patients experienced infusion related reactions on cycle 1, all but one were of NCI grade 1-2. One (3%) patient experienced NCI grade 3 reaction (on R-CHOP). On subsequent cycles only this patient (3%) experienced an adverse infusion reaction (grade 2, flushing, urticaria and temperature of 38.c). This resolved following administration of IV hydrocortisone and the infusion completed safely over 90 minutes thereafter. **Conclusions.** In NHL, non first dose rituximab can be safely infused in 60 minutes without significant increase in infusion related adverse reactions. Only one patient failed to tolerate the 60 minute infusion, also having experienced the only identified grade 3 reaction on cycle 1. In one year, with a catchment population of 600,000, our service gave 535 doses of rituximab that would be eligible for 60 minute infusion. Considering an average dose of 700mg infused over 150 minutes, we project that the ability to administer 97% of these infusions in 60 minutes would provide a saving of up to 778.5 day-case chair hours and nursing hours per annum. Such significant savings promote more efficient use of day-case treatment resources and of the nursing workforce in day-case areas that are experiencing increasing pressures and demands.

[13]Rio Ortega University Hospital, Valladolid, Spain
[14]MD Anderson Cancer Center Madrid, Madrid, Spain

Background. Patients with Mantle cell lymphoma (MCL) have an adverse outcome after relapse due to refractory disease with conventional treatments. Bendamustine (B), a nitrogen mustard compound chemically related to alkylating agents, has demonstrated high efficacy with a low toxicity profile in reported clinical trials. **Aims.** To analyze the Spanish experience in patients with relapsed/refractory MCL treated with Bendamustine. **Methods.** Retrospective analysis of spanish experience using Bendamustine alone or in combination in the relapse setting. This study was approved by local ethical committees. **Results.** Forty-three patients have been registered from May to December 2011. *Patients'characteristics*: 67% male, median age 65 years old (range 41-88), 77% ECOG≤ 1, 77% Ann Arbor stage IV, 35% high risk MIPI and 12% blastic variant. Previous regimens were CHOP or CHOP like ± R in 41.5%, Hyper-CVAD/MtxAraC ± R in 39%, R-CVP in 10% and other regimens in 9.5%. Median number of previous treatments were 2.5 (range 1-6), 93% patients had received prior Rituximab and 73% had chemosensitive disease to the last treatment. Bendamustine regimen was R-B (R-375mg/m^2 D1, B-90 mg/m^2 D1-2) in 74% patients, R-B with B-70 mg/m^2 in 9%, B alone in 5%, R-B-Bortezomib in 2% and R-B plus consolidation with stem cell transplant or Y^{90}Ibritumomab-tiuxetan in 9%. Median number of cycles was 4.62 (range 1-8). G- CSF support was administered in 46% of cycles. *Response*: Overall response rate was 80%, with 46% CR & uCR and 34% PR. *Survival:* Median progression free survival (PFS) was 18 months (95% CI: 7.6-28.4), data that compares favourably with patients' PFS to previous therapy (12 months, 95% CI: 9.4-14.5). Median PFS for patients who achieved CR/uCR was 35.9 months (95% CI: 19.3-52.7) versus 8.4 months in patients with PR (95% CI: 4.7-12.2). With a median follow-up for surviving patients of 14 months since Bendamustine treatment, the estimated OS at 3 years is 48% (+ SD 11%). In the whole series median overall survival from diagnosis is 11.8 years (range: 5.3-18.3 years) without plateau. *Toxicity:* No treatment related mortality has been described. Over 194 cycles, there were 9 hospitalizations due to febrile neutropenia. No tumoral lysis syndrome has been reported. **Conclusions.** Our results with Bendamustine, alone or in combination, confirm the efficacy of this agent in the treatment of MCL, even in the setting of unselected patients previously exposed to multiple therapies including Rituximab.

0254

INTERIM FDG-PET/CT DOES NOT PREDICT OUTCOME IN NEWLY DIAGNOSED MANTLE CELL LYMPHOMA PATIENTS TREATED WITH CHEMOTHERAPY ALONE OR ASCT

E Ribakovsky[1], M Kedmi[1], I Avivi[2], N Benyamini[2], T Davidson[1], E Goshen[1], R Bar Shalom[2], T Tadmor[3], A Nagler[1], A Avigdor[1]
[1]Sheba Medical Center, Te-Hashomer, Israel
[2]Rambam Medical Center, Haifa, Israel
[3]Bnai-Zion Medical Center, Haifa, Israel

Background. Mantle cell lymphoma (MCL) is a rare disease, accounting for about 6% of all new lymphoma patients per annum. It is considered an incurable disease; nevertheless, a small proportion of patients may have long term remission after upfront autologous stem cell transplantation (ASCT). FDG-PET/CT scans are often used to evaluate patients with MCL at diagnosis, interim and end of therapy, although the impact of PET results on their outcome is not well established. **Aims.** In this study we looked for correlation between interim PET results and outcome in a retrospective cohort of MCL patients. We also attempted to identify the predictive value of interim and pre-ASCT PET in a subgroup of MCL patients who underwent upfront consolidation with high-dose chemotherapy and ASCT. **Methods.** We retrospectively reviewed the demographics, clinical features and outcome of 58 consecutive MCL patients who were treated at three medical centers between 1998 and 2011. PET/CT scans, performed after 3-4 cycles and at the end of first line chemotherapy (prior to ASCT), were reviewed and correlated with response and long-term outcome. Scans were scored as positive or negative based only on visual assessment, according to the revised response criteria adopted in 2007. **Results.** Fifty eight patients were included. Forty nine were male and 9 female. Median age at diagnosis was 59 years (yrs) (range 41-88). All but three patients had stage 3/4 disease. Forty four (76%) patients received RCHOP or RCHOP-like chemotherapy for induction, and 23 (40%) patients were treated by BEAM followed by ASCT as part of their upfront consolidation. After a median follow-up of 3.3 yrs (0.67-13.1) the estimated overall survival (OS) and progression free survival (PFS) at 3 yrs for the entire cohort were 84% and 48 %, respectively. In the subgroup of patients (n=23) who received ASCT consolidation, the Kaplan-Meier analysis demonstrated 82% OS and 68% PFS at 3 yrs. MIPI group (low, intermediate or high) predicted OS and PFS ($p<0.05$). Interim PET was performed in 51/58 patients. The interim-PET positive (n=31) and PET-negative (n=20) patients did not differ in gender, MIPI, stage or presence of B symptoms. However, older age (≥60) was significantly more common in the interim-PET positive group (p=0.02). The estimated 3 yr OS for interim-PET negative and interim-PET positive patients were 85% and 90%, respectively (p=NS). The 3 yr PFS for interim-PET negative and positive were 57% and 44%, respectively (p=NS). A subset analysis of the patients who received consolidation with upfront ASCT showed that neither OS at 3 years (75% for PET negative vs. 90% for PET positive) nor PFS at 3 years (80% for PET negative vs. 66% for PET positive) were predicted by interim PET results. Similarly, the pre-transplant PET results did not correlate with the outcome in this subgroup of patients. **Conclusions.** We conclude that negative interim PET is more likely to be found in younger MCL patients. However, interim FDG-PET/CT results do not predict OS and PFS. In patients, who received consolidation with upfront transplant, neither interim nor pre-transplant PET results predict outcome.

0255

THE PROGNOSTIC ROLE OF MANTLE CELL INTERNATIONAL PROGNOSTIC INDEX (MIPI) IN PATIENTS TREATED WITH RITUXIMAB AND HIGH DOSE CHEMOTHERAPY PLUS AUTOLOGOUS STEM CELL TRANSPLANT

A Chiappella[1], S Ferrero[2], C Frairia[1], B Puccini[3], L Arcaini[4], I Baldi[5], G Benevolo[1], C Boccomini[1], B Botto[1], C Ciochetto[1], C Gabutti[6], C Lobetti Bodoni[2], M Mian[7], L Orsucci[1], P Pregno[1], M Ladetto[1], U Vitolo[1]
[1]Hematology 2, San Giovanni Battista Hospital and University, Torino, Italy
[2]Hematology 1, San Giovanni Battista Hospital and University, Torino, Italy
[3]Hematology, Careggi Hospital, Firenze, Italy
[4]Hematology, Policlinic and University, Pavia, Italy
[5]Unit of Cancer Epidemiology, University of Torino and CPO Piemonte, Torino, Italy
[6]Hematology, Niguarda Hospital, Milano, Italy
[7]Hematology, Bozen Hospital, Bolzano, Italy

Background. Mantle cell lymphoma (MCL) had dismal prognosis, with continuous relapses. In young patients promising results were obtained with first line chemoimmunotherapy followed by high-dose cytarabine containing regimens and high dose chemotherapy plus autologous stem cell transplantation (HDC

plus ASCT). The Mantle Cell Lymphoma International Prognostic Index (MIPI) had an established role in predicting survival in MCL patients treated with conventional chemotherapy. **Aims.** of the study was to investigate the prognostic role of MIPI in a retrospective group of MCL patients treated with Rituximab-chemotherapy and HDC plus ASCT. **Methods.** Between 1999 and 2009, 105 untreated MCL patients <70 years were consecutively treated with Rituximab-chemotherapy followed by high-dose cytarabine and HDC plus ASCT. Histology was centrally reviewed and Ki-67 evaluation was performed. MIPI and MIPI-biological were calculated according to simplified formulas according to Hoster 2008. International Prognostic Index (IPI) was calculated and considered as standard prognostic index. Overall Survival (OS) curves were estimated and stratified by MIPI. Differences between curves were tested using the 2-tailed log-rank test. In order to quantify the predictive discrimination of MIPI, MIPI-biological and IPI scores, a Cox's model analysis and univariate logistic models (with death and failure event as binary outcomes) were fitted and the area under the receiver operating characteristic (ROC) curves (c-index) was estimated. **Results.** Clinical characteristics were: median age 61 (34-70) years, 87% stage IV, 84% with bone marrow involvement, 22% with blastoid variant. Patients at high-risk (HR) were 47% according to MIPI, 42% according to MIPI-biological and 44% according to IPI. With a median follow-up of 59 months, 4-year Overall Survival by increasing MIPI risk was 92% for low risk (95% Confidence Interval: 85%-100%), 71% for intermediate risk (CI: 47%-100%) and 63% for high risk (CI: 44%-89%); log-rank test for Overall Survival was: p-value = 0.0001 (Figure 1). In order to quantify the predictive discrimination of MIPI, MIPI-biological and IPI scores, c-index and Cox-index for death event and for failure event were calculated. Logistic c-index for Overall Survival was as follows: MIPI 71.2%, MIPI-biological 62.2%, IPI 72.4%; for Progression Free Survival was: MIPI 63.1%, MIPI-biological 59.5%, IPI 68.8%. Cox-index for death event was: MIPI 73.2%, MIPI-biological 66.8%, IPI 71.7%; cox-index for failure event was: MIPI 68.7%, MIPI-biological 64.5%, IPI 66.7%. **Conclusions.** MIPI score should be a good predictor of death event in patients affected by MCL and treated at diagnosis with Rituximab-chemotherapy followed by HDC plus ASCT. In this retrospective series of patients MIPI had a clear role in predicting survival; the real role of MIPI as predictor of death should be validate in prospective series of patients treated with Rituximab-chemotherapy followed by HDC plus ASCT.

FLUDARABINE-BASED COMBINATION CHEMOTHERAPY IN RELAPSED MANTLE CELL LYMPHOMA - THE EXPERIENCE OF A SINGLE CENTER

F Moita, J Santos, MG da Silva
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal

Background. Mantle cell lymphoma (MCL) is a rare subtype of lymphoma associated in most cases with poor prognosis and progressive resistance to chemotherapy. Treatment of relapses depends on regimens used as first line but the efficacy is usually limited. Fludarabine-based regimens have shown to be effective, although associated with significant hematological toxicities. **Aims.** To evaluate the clinical benefit and toxicities of fludarabine-containing regimens in relapsed MCL patients. **Methods.** A retrospective analysis of MCL patients diagnosed in our institution between 1999 and 2011 was conducted. The diagnosis was established by histopathological criteria, including cyclin D1 positivity, and/or detection of t(11;14). Response was classified according to *Cheson et al.* revised criteria. Toxicity was graded according to the common toxicity criteria, version 3.0. **Results.** Ninety-two MCL patients were identified in this period. Among the 57 who relapsed, 34 were salvaged with fludarabine based-regimens (56% associated with antracyclins and 65% with rituximab). The remaining were either candidates to high-dose chemotherapy and autologous stem cell transplant or unsuitable for fludarabine due to comorbidities or poor performance status. There were no significant differences regarding age, gender, stage, MIPI score, histological subtype and β2-microglobulin, between patients who received fludarabine-based regimens and the overall MCL patient population. In most cases (70.6%; n=24) fludarabine-based regimens were used as second line treatment (1-5 prior treatments), at a median time after diagnosis of 27 months; the majority (85.3%, n=29) of these patients received CHOP-like regimens as first line, associated with rituximab in 22 cases. 31 out of 34 fludarabine-treated patients were evaluable for response, with an overall response rate of 51.6% and complete remission rate of 19.4%. Median duration of response was 14 months and the median survival of responding patients was 21.5 months; however, the median time to next treatment for the whole population was only 3 months. With a median follow up of living patients of 7 months after starting fludarabine, the median survival was 8.5 months. Most patients (70%) experienced hematological toxicity, 62% of those graded 3/4. Febrile neutropenia occurred in 29% of patients (n=10/34), 6 requiring hospital admission. Treatment was prematurely discontinued in 45.5% (n=15/34) of cases, 9 due to toxicity and 6 due to disease progression with only 55% (n=18/33) patients receiving the intended treatment. **Conclusions.** In this small series of relapsed MCL patients, fludarabine-based regimens were associated with reasonable response rates and response duration. However, this did not translate in significant survival benefits for the whole population and was achieved at the expense of significant toxicities which determined therapy discontinuation in nearly half of patients, limiting the potential benefits to a selected population. This non-comparative study raises the question whether the benefit outweighs the potential risks of fludarabine therapies for relapsed disease, as it was recently shown for first line patients, when other active agents are being investigated in this setting.

0257

RELAPSED OR REFRACTORY SYSTEMIC ANAPLASTIC LARGE-CELL LYMPHOMA (ALCL) - A BURDEN OF ILLNESS ANALYSIS

S Baculea[1], J Eaton[1], T Illidge[2]
[1]Oxford Outcomes, Oxford, United Kingdom
[2]University of Manchester / Christie Hospital NHS Foundation Trust, Manchester, United Kingdom

Background. Systemic ALCL (sALCL) is a subtype of peripheral T-cell lymphoma (PTCL), a subset of the T-cell lymphomas, which in turn are a subtype of non-Hodgkin's lymphoma (NHL). sALCL accounts for approximately 3% of NHL cases. Between 25-45% of sALCL patients relapse following or are refractory to first-line therapy; there is no standard of care in these relapsed or refractory (rel/ref) patients. As a result of the small patient numbers, research into the epidemiology and disease burden of rel/ref sALCL is very limited. **Aims.** To describe the burden of sALCL, in terms of its epidemiology and humanistic burden, and to estimate current costs of treatment of patients with rel/ref sALCL. **Methods.** A literature search for sALCL epidemiology data was conducted. A systematic literature review of the clinical effectiveness and safety of available therapies in rel/ref sALCL was conducted in Medline/Medline in Process, Embase and the Cochrane Library, and targeted searches for treatment guidelines were conducted. To estimate the costs of rel/ref sALCL, a treatment pathway in patients with rel/ref sALCL in the UK was built based on guidelines recommendations and clinical experts' opinions. An annual cost per patient was estimated, including costs of drug acquisition and administration, monitoring costs, and costs relating to stem cell transplant (SCT), adverse events (AEs), and long-term care. **Results.** sALCL is a rare disease. There are an estimated 1,500 new sALCL cases per year in the EU5, of which approximately 285 are in the UK. Of these, approximately 86 were estimated to be incident rel/ref cases. The systematic review of treatments for rel/ref sALCL showed that there is no standard of care. Among novel therapies recommended for PTCL in the US National Comprehensive Cancer Network Clinical Practice Guidelines for NHL are pralatrexate, romidepsin, and, more recently, brentuximab vedotin (systemic ALCL only). The treatment pathway for sALCL at relapse includes chemotherapy regimens such as gemcitabine, GEM-P (gemcitabine, cisplatin, methylprednisone), ICE (ifosfamide, carboplatin, etoposide), G-CVP (gemcitabine, cyclophosphamide, vincristine, prednisone), DHAP (dexamethasone, cisplatin, cytarabine), and ESHAP (etoposide, methylprednisolone, cytarabine, cisplatin), as well as pralatrexate or romidepsin. In 80% of patients achieving complete response and 30% achieving partial response to re-induction

chemotherapy, allogeneic or autologous SCT was included as consolidation therapy (based on expert opinion). The estimated annual cost of current treatment for incident and prevalent cases of rel/ref sALCL in the UK is approximately £2 million (£17,000 per patient). The main cost components are transplant (44%), drugs and administration (22%), AEs (17%), and long-term care (up to 2 years follow-up; 18%). **Conclusions.** sALCL is a rare disease with no standard of care in the rel/ref setting. Evidence from the systematic review showed that conventional chemotherapy approaches are not curative and are associated with poor outcomes. Autologous and allogeneic SCT may provide long-term benefit in patients with chemosensitive disease, but their utility is limited due to the inability of standard salvage treatments to deliver high complete response rates. Therefore, new efficacious therapies are needed. The budget impact of current treatments is relatively small due to low patient numbers.

0258

NON-HODGKIN LYMPHOMA IN PREGNANCY TENDS TO INVOLVE THE REPRODUCTIVE ORGANS: MYTH OR REALITY?

N Horowitz, B Brenner, N Benyamini, I Avivi
Rambam Health Care Campus, Haifa, Israel

Background. Hematological malignancies during gestation present a complex clinical scenario for mother and fetus. Data on pregnancy-associated non-Hodgkin lymphoma (PANHL) are scarce, limited to case reports and small retrospective series. Furthermore, PANHL pathological subtypes and organ involvement have not been fully characterized. **Aims.** The current study reviewed all trials and case reports published between 1967-2011, aiming to determine epidemiology, clinical presentation, management and outcome of PANHL. **Methods.** A systematic search for articles published since 1967 in PubMed, Medline and Google scholar databases regarding PANHL was performed. The words 'cancer', 'lymphoma', 'pregnancy' and 'gestation' were used as discriminator terms. Data on mother's age, gestational stage, histological lymphoma type, organ involvement, timing of therapy applied and mother and fetal outcomes were recorded and analyzed. Cases where lymphoma was diagnosed prior to pregnancy and those defined as Hodgkin or lymphoblastic lymphoma, were excluded from the analysis. **Results.** One hundred twenty two cases, reported in 85 papers, were analyzed. Patient's median age at diagnosis was 28 years, ranging between 15-42 years. Fourteen women (11.5%) were diagnosed during the 1st trimester of pregnancy and 41 (34%) in 2nd and 3rd trimesters each. Trimester of pregnancy was unmentioned for 26 cases. Indolent lymphomas accounted for 4.1% (n=5), aggressive NHLs for 42.6% (n=52; 39 -DLBCL, 13 - T cell lymphomas) and highly aggressive NHLs (HA-NHLs) for 43.4 % (n=53). The latter included 39 cases of Burkitt lymphoma (BL), 19 of them endemic, 9 unclassified HA-NHLs and 5 cases of immunoblastic lymphoma. Histological subtype was undetermined for 12 cases. Reproductive organ involvement (ROI), reported in 44.3% of patients (54/122), was most predominant in patients with BL. Sixty nine percent (n=27) of pregnancy-related BL presented with breast involvement: 25 with bilateral and 2 cases with unilateral masses. Additionally, 12 BL patients had ovarian involvement (5 bilateral and 7 unilateral) and 4 had uterus involvement, accounting for ROI (including breast, ovary and uterus) in about 84.6% (n=33) of BL patients. Notably, ROI was significantly higher in endemic BL (100%) vs non-endemic BL (70%) (p=0.02). The incidence of ROI in women diagnosed with PANHL other than BL was 25.3% (n=21, including T cell - 46.2%, immunoblastic - 40%, DLBCL - 23.1%, low-grade lymphoma - 40%, unclassifiable high-grade lymphoma - 22.22%); however, this percentage is still higher than reported in non-pregnant woman. Chemotherapy was administered during gestation in 54 cases (42.2%): 9 during the first trimester, 26 during the 2nd and 19 in 3rd trimester. A delayed (postpartum) treatment strategy was applied in 54 patients and 8 patients were not treated. Ninety nine pregnancies ended successfully (81.15%). Sixteen pregnancies were terminated early [spontaneously (n=5) or electively (n=11)] and 5 pregnancies ended in intrauterine fetal death. Within a median follow-up of 6 months from diagnosis, 68 patients (55.7%) survived and 53(43.44%) died, 31 in the HA-NHLs (58.5%). **Conclusions.** PANHL represents a unique entity, with frequent involvement of reproductive organs, mainly in BL. Collaborative prospective studies are required to characterize the epidemiology, delineate the mechanisms and evaluate the optimal management of these patients.

HISTONE DEACETYLASE INHIBITOR INDUCED ANTI-MYELOMA ACTIVITY IS MEDIATED PRINCIPALLY VIA CLASS I DEACETYLASE INHIBITION

S Mithraprabhu[1], A Kalff[2], H Quach[3], T Khong[4], A Andrew[5]
[1]Monash University / Alfred Health, Melbourne, Australia
[2]Malignant Hematology and Stem Cell Transplantation (MH&SCT), Alfred Hospital, Melbourne, Australia
[3]Department of Clinical Hematology (DCH), Monash University, Clayton, Australia
[4]Australian Centre for Blood Diseases (ACBD), Monash University / Alfred Hospital, Melbourne, Australia
[5]ACBD, MH&SCT and DCH, Alfred Hospital / Monash University, Melbourne, Australia

Background. Histone deacetylases (HDACs) are a highly conserved group of enzymes that regulate a myriad of cellular functions through deacetylation of histones, transcription factors and molecular chaperones. Altered HDAC expression is significantly associated with a poor prognosis in a variety of malignancies, however, the expression pattern of HDAC and any potential correlation with patient outcome has not been characterized in multiple myeloma (MM). Furthermore, while HDACs inhibitors (HDACi) undergo continued therapeutic evaluation in MM, it is still not clear which HDAC(s) represent the optimal inhibitory target to induce maximal MM cell death. **Aims.** (i) Determine and compare HDAC expression in purified MM and normal plasma cells (PC) and correlate MM PC HDAC expression with overall survival (OS - diagnosis to death) and progression-free survival (PFS - diagnosis to first relapse/progression/death).(ii) Identify the HDAC that needs be inhibited to maximise HDACi-induced MM cell death. **Methods.** Quantitative RT-PCR was performed for *HDAC1-11* in normal (n=10) and MM PC (n=55) purified from patient bone marrow aspirates following appropriate consent. The OS and PFS of MM patients with high gene expression levels (>75th centile) compared to low levels (span75th centile) were derived utilising Kaplan-Meier survival plots. To determine the most suited HDACi for MM therapy, genetically heterogeneous myeloma cell lines (HMCL) and bone marrow mononuclear (BMMN) cells from MM patients were treated with a diverse range of HDACi for 48 hours (Figure 1).

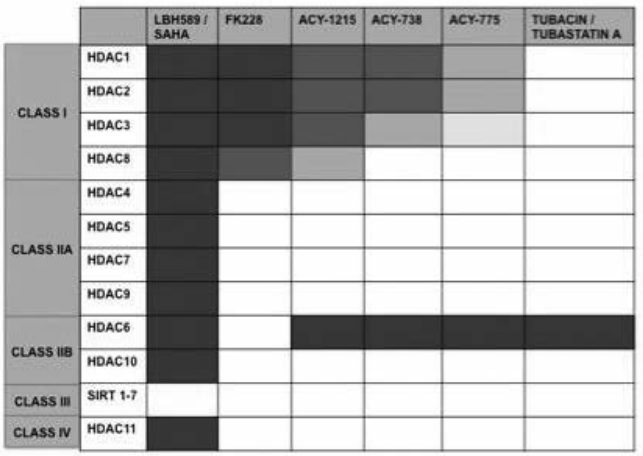

Figure 1. Image depicting inhibitory activity of HDACi against recombinant HDAC isoforms.Dark to lighter shades indicates strong to relatively weaker inhibition.

HDACi induced cell death of HMCL and primary MM cells was evaluated through flow cytometric enumeration of propidium iodide positive (PI+) or CD38hi/CD45neg/APO2.7pos cell populations, respectively. **Results.** *HDAC1, HDAC2 and HDAC6 over expression correlates with poor patient outcome*- Analyses of gene expression levels of *HDAC* in MM cells and normal PC revealed that median levels of all HDACs, with the exception of *HDAC1* and *HDAC11*, were significantly elevated in MM PC when compared to normal PC and that patients with the highest *HDAC1, 2* and *6* levels had a significantly shorter PFS from diagnosis.*Class I inhibition is critical to induce maximal MM*

*cell death*Six HMCLs (U266, OPM2, LP-1, RPMI8226, ANBL6 and XG-1) were treated with LBH589, FK228, ACY-1215, ACY-738 and ACY-775 and Tubastatin A for 48 hours. Measurement of PI+ cells at 48 hours indicated that in 6/6 cell lines tested, ACY-1215 and ACY-738 (both 10μM) caused cell death comparable to LBH589 and FK228 (both 50nM). ACY-775 and Tubastatin A induced comparable cell death in only 1/6 cell lines tested. Treatment of BMMN cells (n=10) with LBH589, SAHA, FK228 or tubacin also indicated that inhibiting Class I HDAC induced maximal MM cell death (75-90%) in 7/10 patient samples tested while inhibiting HDAC6 alone promoted killing comparable to the other HDACi inhibitors in only 5/10 patient samples tested. **Conclusions.** This study has established that altered *HDAC* levels correlate to poor outcome in MM patients and compounds with Class I HDAC inhibitory action induce maximal MM cell death. This fact not withstanding, specific HDAC6 inhibition demonstrates activity against some MM cells and this requires further evaluation.

[3]Department of Clinical Therapeutics, University of Athens School of Medicine, Athens, Greece
[4]Intrinsic LifeSciences LLC, La Jola, California, United States of America

Background. Hepcidin is a liver-derived hormone with a central role in iron regulationand in anemia of inflammation. Recently, it has been demonstrated that hepcidin is involved in the pathogenesis of anemia in Multiple Myeloma (MM). Furthermore, our group has recently shown in a small study of MM patients under treatment that, serum hepcidin may serve as a surrogate marker for MM and as a predictor for response to treatment. **Aims.** The aim of this study was to explore if serum hepcidin, measured at diagnosis, has a prognostic impact on overall survival (OS) and if it correlates with established adverse prognostic variables of MM in a large cohort of newly diagnosed patients. **Methods.** We studied 206 newly diagnosed, symptomatic MM patients: 105M/101F, median age 68 years (range: 33-91 years); 112 patients had IgG, 56 IgA, 32 light chain and 6 non-secretory MM. Sixty-four patients had ISS-1 MM, 69 ISS-2 and 73 ISS-3. Regarding frontline anti-myeloma treatment, 35 patients received MP, 28 patients receive bortezomib-based combinations (12 VD and 16 PAD), 90 received thalidomide-based regimens (32 CDT, 12 TVAD, 7 TD and 39 MPT), 23 received lenalidomide-based combinations (7 RD and 16 MPR), 11 patients received VDT and 19 patients received VAD. Sixty-three patients received autologous transplantation as a part of their initial MM treatment. All studied variables were measured before the administration of any kind of treatment, using fresh serum samples except for hepcidin and ferritin that were measured in frozen samples. Serum hepcidin was measured using a C-ELISA methodology, as previously described (Ganz et al. Blood 2008). Mann-Whitney U-test, One-Way ANOVA and Pearson's χ^2 test were used for correlations. Cox-regression was used to determine possible independent predictive factors for OS. *p* value <0.05 was considered as statistically significant. **Results.** The median serum hepcidin levels for all patients were 145ng/mL (range 0.01-2336ng/mL). Serum hepcidin positively correlated with ISS (p<0.001), serum creatinine (p<0.001; r=0.7) LDH (p=0.002; r=0.2), β2M (<0.001; r=0.6), C-reactive protein (p=0.03; r=0.2) ferritin (p=0.006; r=0.4) and transferrin saturation (p=0.002; r=0.4). Serum hepcidin also showed negative correlations with albumin (p<0.001; r=0.4), hemoglobin (p<0.001; r=0.5) and platelet counts (p=0.002; r=0.2). The univariate analysis showed that serum hepcidin, age, ISS, creatinine, LDH, β2M, albumin and hemoglobin were significant predictors for OS (p<0.05 for all parameters), whereas type of MM, C-reactive protein, platelet counts and free-light chain ratio did not predict for OS (p>0.05). The multivariate analysis showed that serum hepcidin, albumin and age, independently predicted for OS [(p<0.001) (95% CI:1.001-1.002),(p=0.001) (95%CI:0.34-0.75) and (p=0.003) (95%CI:1.011-1.057), respectively]. With a cut-off value of baseline serum hepcidin 286ng/mL, which represents the adult 95% upper normal limit- as previously described -and with a median follow-up of 47 months, the OS of patients with hepcidin >286ng/mL was 32 months (95% CI: 25-40) and of patients with normal serum hepcidin (≤286ng/mL) 62 months (95% CI: 39-84; p<0.001). **Conclusions.** Serum hepcidin strongly correlates with adverse clinical and biological myeloma features and is a strong predictor for survival in newly diagnosed symptomatic MM patients.

DEREGULATION OF SIRTUINS PRESENTS IT AS NOVEL THERAPEUTIC TARGETS IN MYELOMA

S Mithraprabhu[1], A Kalff[2], H Quach[3], T Khong[4], A Andrew[5]
[1]Monash University / Alfred Health, Melbourne, Australia
[2]Malignant Hematology and Stem Cell Transplantation (MH&SCT), Alfred Hospital, Melbourne, Australia
[3]Department of Clinical Hematology (DCH), Monash University,, Clayton, Australia
[4]Australian Centre for Blood Diseases (ACBD), Monash University / Alfred Hospital, Melbourne, Australia
[5]ACBD, MH&SCT and DCH, Alfred Hospital / Monash University, Melbourne, Australia

Background. The silent information regulator 2 (Sir2) family are highly conserved genes consisting of seven mammalian members (SIRT1-7). SIRTs orchestrate a variety of cellular functions including gene silencing, cell cycle and apoptosis, genomic stability and energy homeostatis through deacetylation and ADP ribosylation of proteins. Therefore, they are associated with numerous pathologies including metabolic diseases, neurodegenerative disorders and cancer. Evidence indicates that SIRT1-3 play contradictory roles in cancer and can function as a context-dependent tumor suppressor or oncogenic factor. This dual role renders them attractive therapeutic targets for anti-cancer therapy. In multiple myeloma (MM) the potential correlation of *SIRT* expression with patient outcome and the impact of modulating SIRT activity has not yet been determined. **Aims.**(i) Determine and compare *SIRT* expression levels in purified MM cells and normal plasma cells (PC) and correlate expression with overall survival (OS - diagnosis to death) and progression-free survival (PFS - diagnosis to first relapse/progression/death) of MM patients.(ii) Determine the impact of modulating SIRTs in genetically heterogeneous human myeloma cell lines (HMCL).**Methods.** Bone marrow aspirates from MM and normal patients were obtained following consent. Total RNA and cDNA were prepared from purified normal (n=10) and MM PC (n=55) and quantitative RT-PCR performed for *SIRT1-7*. The OS and PFS of MM patients with high gene expression levels (>75th centile) compared to low levels (<75th centile) were derived utilising Kaplan-Meier survival plots. To determine the impact of inhibiting SIRTs, HMCL were treated with commercially available SIRT inhibitors, EX-527 (inhibits SIRT1) and salermide (inhibits SIRT1 and SIRT2) for 48 hours and the proportion of cell death was determined through flow cytometric enumeration of propidium iodide positive (PI+) cells. **Results.** Gene expression analysis revealed that median levels of *SIRT1, 3, 5* and *7* were significantly elevated in MM PC compared to normal PC (p<0.01). MM patients exhibiting elevated *SIRT1* (1334 vs 2188 days; p=0.039)*, SIRT2* (844 vs 2272 days; p=0.003) and *SIRT5* (809 vs 2272 days; p=0.0004) displayed shorter OS compared to patients with lower *SIRT* levels, while patients with elevated *SIRT2* also displayed shorter PFS (649 vs 1050 days; p=0.038). Since *SIRT* gene expression levels were upregulated in MM PC from patients, the potential of inhibiting SIRTs in HMCL was explored. Six HMCLs (U266, OPM2, NCIH929, OCIMY1, ANBL6 and XG-1) were treated with EX527 and salermide (both at 25μM, 50μM and 100μM) for 48 hours. Measurement of PI+ cells at 48 hours indicated that EX527 induced cell killing in 6/6 cell lines tested at the highest dose (100 μM; 20-40%), while salermide was able to promote higher cytotoxicity at a lower dose (50μM; 50-75%), suggesting that inhibition of both SIRT1 and SIRT2 is superior to SIRT1 inhibition alone in inducing MM cell death. **Conclusions.** Augmented *SIRT* levels in MM patients correlate to poor outcome in patients signifying that SIRTs may represent novel predictors of adverse outcome in newly diagnosed MM patients. Furthermore, inhibiting SIRT1 and SIRT2 promotes MM cell death, providing a rationale for the exploration of SIRT inhibitors as anti-MM agents.

0263

HIF-1α INHIBITION PROMOTES CELL CYCLE ARREST IN MULTIPLE MYELOMA

G Perrone, E Borsi, C Terragna, M Martello, M Mancini, M Aluigi, MA Santucci, G Martinelli, M Baccarani, M Cavo
Department of Hematology and Oncological Sciences, University of Bologna, Bologna, Italy

Background. Hypoxia-inducible factor-1 alpha (HIF-1α) plays a critical role in survival and angiogenesis and is associated with poor prognosis in solid tumors. The role of HIF-1α in hematological malignancies is not completely known. In particular in multiple myeloma (MM) HIF-1α is constitutively expressed in about 35% of patients, and HIF-1α knockdown cell lines have shown higher sensitivity to standard chemotherapy, suggesting HIF-1α inhibition as a possible therapeutic strategy. **Aims**. In the present study, we explored the effect of EZN2968, an locked nucleic acid antisense oligonucleotide against HIF-1α, as a molecu-

lar target in MM. **Methods.** A panel of MM cell lines (MM1S, U266, OPM2, RPMI8226) and primary samples from MM patients were cultured *in vitro* in the presence of EZN2968 (20 μM) in normoxia ($p0_2$ 21%) and hypoxia ($p0_2$ 1%) condition. **Results.** Baseline expression of HIF-1α was initially investigated on MM cell lines and primary samples from MM patients. Under normoxia culture condition, HIF-1α mRNA and protein expression was detectable in all MM cell lines tested and in $CD138^+$ cells from newly diagnosed MM patients samples. Significant up-regulation of HIF-1α protein expression was observed after a short incubation with IL6 or IGF-I, confirming that HIF-1α can be further induced by biological stimuli. EZN2968 efficiently induces a selective and stable down-modulation of HIF-1α mRNA and protein expression either in normoxia or hypoxia conditions, without affecting the expression of other family members of hypoxia inducible transcription factors (HIF2 α). Moreover, we tested whether vascular endothelial growth factor (VEGF), a key transcription factor downstream target of HIF-1α, was modulated by EZN2968. The secretion of VEGF released by MM cell lines cultured in the presence or absence of EZN2968 decreased in a time dependent manner in the treated compared to untreated samples. Treatment with EZN2968 (up to 72hrs) gave rise to a progressive accumulation of cells in the S-phase and a concomitant reduction of G2/M phase. In addition, the subG0 phase was moderately increased. The analysis of p21 and p27, two keys cyclin-dependent kinase inhibitors controlling cell cycle check point, showed upregulation of protein levels. These results suggest that HIF-1α inhibition is sufficient for cell cycle arrest in normoxia. We next evaluated cell death induced by HIF-1α inhibition. AnnexinV/PI staining showed that incubation with EZN2968, moderately increased the percentage of Annexin V positive cells compared to untreated cells (30% vs 8%, respectively after 72h of treatment). In a time course experiment, we observed cleavage of PARP after 48 hours of treatment with EZN2968, suggesting the activation of an apoptotic pathway in response to HIF-1α depletion. **Summary.** In this study we provide evidence that HIF-1α, even in the absence of hypoxia signal, is expressed in MM plasma cells and is further inducible by bone marrow milieu stimuli, and that its inhibition is sufficient to induce a permanent cell cycle arrest. Our data support the idea that HIF-1α inhibition may suppress tumor growth by preventing proliferation of plasma cells through p21 activation.

A FISH STUDY TO CONFIRM THAT ISOLATED 7Q DELETIONS AND ISOLATED MONOSOMIES 7 SHOULD BE NO MORE INCLUDED WITHIN THE SAME PROGNOSTIC CATEGORY

P Bernasconi, I Dambruoso, M Boni, P Cavigliano, I Giardini, B Rocca, R Zappatore, C Calvello, M Caresana
Divisione di Ematologia, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. In MDS isolateddel(7q) and -7 are included in different categories by the "New Comprehensive Cytogenetic Scoring System". **Aims.** The present study was aimed at evaluating whether a series of BAC and commercial probes exploring bands 7q22, 7q31, 7q34-q35-q36 were able to reveal cryptic chromosome 7 lesions in 79 chromosomally normal patients and in 24 del(7q) patients. An additional goal was to assess whetherdel(7q) and -7 determined a significant different overall survival and a progression-free interval. **Methods.** The 121 patients (79 with a normal karyotype, 24 with an isolated 7q- and 18 with an isolated -7) analysed by the present study were included in a series of 637 patients who came to our observation in the period January 2000-December 2010. FISH probes obtained from Kreatech (Amsterdam, NL), Abbot Molecular Inc. (Chicago, Il,USA),BACPACResourcesCenter at C.H.O.R.I. (Oakland,USA). FISH was carried out as previously described. The following probes were used: ON MDS 7q- (7q22/7q35), RP11-51M22 (7q31), RP11-122A11 (7q34), RP11-992C19. I-FISH cut-off values, obtained after analysing 300 nuclei from ten normal samples, were fixed at 10%. **Results.** CC revealed a -7 and adel(7q) in 18 and 24 patients respectively. In 7 of these last patients (29.2%) FISH did not confirmdel(7q). Noteworthy, among the 79 chromosomally normal patients 8 (10.1%) presented an abnormal FISH pattern: 2 patients (one RCMD, one RAEB-1) showed a -7, 5 patients (one RA, 3 RCMD, one RAEB-1) adel(7q) and one RA patient an amplification of band 7q35. The chromosomal bands most commonly involved in deletions were 7q22 (15 patients) and 7q22 (7 patients). Interestingly, a RA patient with adel(7)(q22) at clinical diagnosis showed a progressive increase in the extension of the deleted area and eventually developed a -7. Thus, isolated chromosome 7 abnormalities were revealed in a total of 43/121 patients (35.5%): 20 (16.5%) presented a -7 and 22 (18.2%) adel(7q). There were 15 females and 27 males, median age 63 years (range 28-89). Median follow-up was 10 months (range 1-103). According to WHO classification, 4 patients were classified as RA, 14 as RCMD, 12 as RAEB-1 and 13 as RAEB-2. According to IPSS 2 patients were considered low-risk, 8 intermediate-1 risk, 20 int-2 risk and 13 high-risk.Del(7q) was associated with higher platelets counts, early MDS (11/22 versus 7/20) and lower IPSS risk subtypes (6/22 versus 3/20). Death occurred in 9 (41%) 7q- patients and in 10 (50%) -7 patients (p=0.01), whereas clinical evolution occurred in 12 (54.5%) and 14 (70%) patients respectively (p=0.01). Considering the 8 patients with a cryptic chromosome 7 defect on FISH studies, one -7 patient died and 4 patients, two each with a -7 and adel(7q), progressed to AML. The RA patient with a 7q35 amplification presented a stable disease. **Conclusions.** i) FISH is an effective method to reveal cryptic chromosome 7 defects and should be routinely applied with CC; ii) 7q deletions and -7 should be included within different prognostic categories as proposed by the NCCSS.

MINIMAL RESIDUAL DISEASE BY MULTIPARAMETRIC FLOW CYTOMETRY IS A USEFUL APPROACH TO IDENTIFY PATIENTS AT DIFFERENT RISK OF PROGRESSION AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA

P Stoyanov, P Ganeva, T Dikov, A Michova, I Tonev, L Garcheva, G Balatzenko, G Arnaudov, G Michaylov, M Guenova
NSHATHD, Sofia, Bulgaria

Background. High dose therapy with autologous stem cell support is considered standard for multiple myeloma (MM) patients eligible for the procedure. Most of the patients, however, will eventually relapse. Maintenance therapy is an option for sustaining response but at certain hazards. It is therefore important to define biomarkers of potential aid for the identification of patients at high risk of progression that might benefit additional treatment. **Aims.** To estimate the amount of residual myelomatous plasma cells by MFC in the bone marrow of MM patients after autologous stem cell transplantation (ASCT) and the impact on the course of the disease. **Methods.** Minimal residual disease (MRD) was assessed by 8-color MFC on day +100 in bone marrow aspirates of 39 MM patients who underwent ASCT using panels of monoclonal antibodies designed on the basis of the individual phenotypes at diagnosis, including CD138, CD38 and CD45 for gating purposes, and CD19, CD20, CD27, CD28, CD56, and CD117 to detect plasma cells (PC) [FACSCanto II (BD), Infinicyt software (Cytognos)]. In addition, the proportion of abnormal PC (APC) out of total PC in the sample was determined. Response assessment was performed at day+100 and at the end of the study after a mean of 12 months of follow up (range 4-32) applying the IMWG 2006 criteria. Time to progression (TTP) was calculated from the day of the autograft infusion to the day of relapse or progression. The impact of major demographic, clinical, laboratory and therapeutic variables was assessed by Kaplan-Meier and log-rank test. **Results.** FCM showed detectable abnormal PCs in all patients enrolled in the study. The median MRD level was 0.03% (range 0.002%-8.55%) from all cells acquired. These comprised 1.88% to 99.4% (median 22.9%) within the total PC compartment. At latest follow-up, 12 (30%) patients suffered disease progression and 27(70%) patients sustained their response. Data analysis showed that only ISS stage (log rank, p=0.042) and complete response (CR) at day+100 (Pearson chi-square, p<0.000) had statistically significant impact on TTP and persistent remission at final follow up respectively, while age, gender, initial phenotype, chemotherapy regimens prior to transplantation had no prognostic influence. On the other hand, MRD levels significantly influenced TTP. None of the 18 patients with MRD <0.02%, even those who failed to achieve CR at day+100, relapsed at the end of the study, while 12/21 patients with higher MRD levels, irrespective of CR at day+100, suffered disease progression after a median TTP of 13 months (0% vs. 57%, log rank p=0.0016). In addition, the proportion of ACP of all PCs also emerged as an important predictive marker for unsustained therapy response as 5% value proved to be the most discriminative regarding TTP (log rank p=0.036). **Conclusions.** Our results show that MRD evaluation by MFC is a very useful approach to identify patients at different risk of progression. Higher MRD levels are predictive of inferior TTP. MFC may contribute to evidence based therapeutic decisions for "patient-specific maintenance therapy". **Acknowledgements.** The study was supported by National Science Fund, Ministry of Education, Youth and Science.

CXCR4 PROMOTES MALIGNANT PHENOTYPE AND TUMORIGENESIS OF MULTIPLE MYELOMA AND NON HODGKIN LYMPHOMA IN VITRO AND *in vivo* IN ANIMAL MODEL

K Beider[1], M Abraham[2], H Wald[2], I Weiss[3], M Leiba[1], A Shimoni[1], A Peled[2], A Nagler[1]
[1]Sheba Medical Center, Ramat Gan, Israel
[2]Biokine Therapeutics Ltd., Ness Ziona, Israel
[3]Goldyne Savad Institute of Gene Therapy, Hebrew University Hospital, Jerusalem, Israel

Background. CXCR4/CXCL12 axis regulates a diverse array of cellular processes, including leukocyte trafficking, HSCs homing and B-cell lymphopoiesis. CXCR4 has been also implicated in the progression of hematological malignancies. CXCR4 is highly expressed by a variety of B cell neoplasms, such as CLL, MM and NHL. CXCR4 is critical regulator of MM homing. In addition, CXCR4 mediates migration, survival and chemoresistance of CLL cells. However, further investigation is required to reveal the role of CXCR4 in tumor-initiating cell phenotype and unravel the specific molecular mechanisms regulated by the CXCR4/CXCL12 axis in B cell malignancies. **Results.** Surface CXCR4 is commonly down-regulated in MM cell lines. To study the functional role of CXCR4 in MM we stably over-expressed CXCR4 in MM cells ARH77 and RPMI8226. As complementary research strategy, we blocked endogenous CXCR4 in Burkitt lymphoma cell line BL-2, that highly express surface CXCR4, using anti-CXCR4 shRNA construct. Enhanced CXCR4 expression in MM cell lines significantly increased their *in vitro* survival in serum-deprivation conditions ($p<0.01$). In addition, we found that elevated CXCR4 increased chemoresistance of MM cells to melphalan and bortezomib. Also, up-regulation of CXCR4 promoted MM soft-agar colony formation, significantly increasing colonies number and size. This reflects increased tumorigenic capacity of CXCR4-expressing cells. Respectively, CXCR4 blockade with shRNA inhibited the survival of lymphoma cells *in vitro*. Elevated CXCR4 prominently increased CXCL12-dependent transwell migration of MM cells ($p<0.01$), as well as their adhesion to fibronectin, laminin and BMSCs. In accordance, adhesion of BL-2 cells with silenced CXCR4 was significantly abrogated ($p<0.01$). Moreover, we found that enhanced CXCR4 significantly elevated cell-surface integrin VLA-4 on RPMI8226 cells. Moreover, we observed direct correlation between CXCR4 and VLA-4 expression levels on primary malignant cells in BM samples from MM and NHL patients. Next, we found that elevated CXCR4 increased the basic levels of pERK1/2 and pAKT in MM cells, and promoted their prolonged activation in response to CXCL12. Accordingly, increased resistance of CXCR4-expressing cells to ERK and PI3K inhibitors was observed. Importantly, JNK and Jak/STAT inhibitors effectively blocked RPMI8226-CXCR4 cell growth, identifying JNK and Jak/STAT pathways as potential therapeutic targets in CXCR4-promoted tumorigenesis. Lastly, we determined the role of CXCR4 in tumor development *in vivo*. CXCR4-expressing MM cells and CXCR4-silenced BL-2 cells, as well as corresponding parental cell lines, were subcutaneously injected into NOD/SCID mice. CXCR4-expressing, but not parental, MM cells produced detectable rapid-growing tumors already 10 days after the injection. Oppositely, CXCR4 silencing in BL-2 cells significantly ($p<0.001$) inhibited local tumor growth and fully prevented NHL spread to BM. These findings indicate that CXCR4 provides aggressive phenotype of MM and NHL *in vivo*. **Conclusions.** Taken together, our findings clearly demonstrate the important pathophysiologic role of CXCR4 in B cell malignancies. Furthermore, for the first time, we provide the evidence for CXCR4 oncogenic potential in MM, showing that CXCR4 promotes the clonogenic growth of MM cells. Our model may further serve to elucidate CXCR4-regulated molecular events involved in the pathogenesis of MM and NHL, and strongly support targeting CXCR4 as therapeutic tool in B cell neoplasms.

Background. Bortezomib has become established as a standard treatment for MM, both in relapsed patients and the newly diagnosed, but a proportion of patients are resistant to the drug. To further explore the *ex vivo* pharmacology of this drug, bone marrow samples from 150 patients diagnosed with MM were evaluated in a cell-based assay to determine the ability of bortezomib to induce cell death in the malignant population. The *ex vivo* efficacy and potency of bortezomib was determined, alone and in drug combinations that represent current treatment protocols. **Aims.** This study sought to identify patient samples that were resistant to bortezomib in an *ex vivo* test and to determine possible alternative treatments by evaluating the *ex vivo* pharmacology of the drug. **Methods.** Working with 16 hospitals across Spain, bone-marrow samples from patients diagnosed with MM were obtained, having first received informed consent, and processed within 24 hours of extraction. The sample was diluted in its entirety (retaining erythrocytes and plasma) and plated into 96-well assay plates containing the pharmacological agents. The plates were incubated for 48-hours, and then prepared for analysis by our flow cytometry-based ExviTech© platform. The percentage of plasma cell death was determined via labeling with appropriate monoclonal antibodies and AnnexinV-FITC. Dose/response curves of bortezomib were run to establish the efficacy and potency for each patient. Dexamethasone, melphalan, prednisolone, cyclophosphamide and doxorubicin were also tested, alone and in combination with bortezomib, as a reference to current treatment protocols.

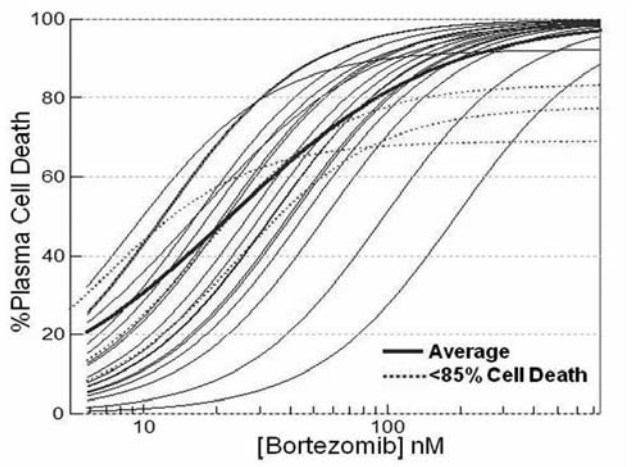

Figure 1. Twenty-two representative *ex vivo* dose/response curves to Bortezomib.

Results. Bortezomib eliminated over 90% of malignant cells in 97% of samples at high doses (Figure 1). In three samples a population of 15-30% of malignant cells was not killed with bortezomib (dashed lines), even at high concentrations, thus identifying the emergence of a potential bortezomib-resistant clone. There was a very wide spread in the bortezomib potency across the patient population, the EC50 ranging from 1 to 200nM (average of 30nM). The other drugs tested varied even more in efficacy (from <20% to >90% cell death) and potencies ranged over more than three orders of magnitude, displaying wide variations from sample to sample. For all patients tested, at least one drug, or one

drug-combination reached an efficacy of >85% cell death, suggesting a potentially efficacious treatment. **Conclusions.** The results of this study displayed a wide variability in the *ex vivo* activity of drugs, which corresponds to the wide a range of responses that are seen in the clinical outcome of the patients. By testing the drugs used in the treatment protocols for MM directly on patient samples, a pharmacological based model could be developed to infer drug resistance or sensitivity, patient by patient. This is similar to the Individualized Tumor Response Testing that has been documented over the last 20 years, albeit using a flow cytometry based assay and incorporating drug combinations evaluated in whole blood. The ultimate goal would be the development of a personalized medicine test for MM. This test would also provide an opportunity to explore reported synergy between bortezomib and other drugs such as doxorubicin and melphalan.

0268

GENETIC, EPIGENETIC AND DNA DAMAGE RESPONSE ALTERATIONS AS MOLECULAR PREDICTORS OF RESPONSE TO MULTIPLE MYELOMA THERAPY

M Gkotzamanidou[1], E Terpos[1], P Sfikakis[1], M Dimopoulos[1], V Souliotis[2]
[1]National & Kapodistrian University of Athens-School of Medicine, Athens, Greece
[2]Institute of Biological Research and Biotechnology, National Hellenic Research, Athens, Greece

Background. Multiple myeloma (MM) is a plasma-cell malignancy in which several genetic and epigenetic changes that are implicated in the biology of the disease. **Aims.** To evaluate epigenetic modifications and alterations in cellular DNA damage response pathways in myeloma patients who underwent high dose chemotherapy and autologous transplantation (ASCT). **Methods.** We studied 12 healthy volunteers (7M/5F; median age 41 years) and 70 MM patients (25M/45F; median age 53 years) who underwent high-dose melphalan therapy with ASCT. All patients provided informed consent according to institutional guidelines. Forty-eight patients achieved an objective response to ACST (responders) and twenty-two patients did not (non-responders). Peripheral blood mononuclear cells (PBMCs) were isolated prior to chemotherapy andwere *ex vivo*treated with melphalan. Three molecular end-points (chromatin condensation, transcription activity, DNA repair in both transcribed and non-transcribed DNA strands) were measured in four genomic loci (beta-actin, p53, N-ras and delta-globin genes). Furthermore, accumulation of p53 protein, inhibition and recovery of total RNA synthesis, as well as induction of apoptosis were also studied. **Results.** In all subjects, beta-actin, p53 and N-ras genes were transcriptionally active. Importantly, delta-globin gene was silent in all healthy volunteers, while an induction of the transcription activity of this gene was found in 49/70 (70%) of MM patients.In all subjects, 5'- to 3'-end gradients of chromatin condensation and repair efficiency were observed along the transcribed strand of the active genes, with higher looseness of chromatin structure and faster repair at the 5'-end. Nosignificant difference in the repair efficiency was found between MM patients in regionsoutside the genes as well as in the non-transcribed strand of active genes. Notably, responders showed a much slower repair efficiency of the transcribed strand than non-responders, with the difference being greater and statistically significant at the 5'-end ($p<0.001$).PBMCs from all healthy volunteers showed evidence of p53 protein accumulation at doses as low as 10 µg/mL melphalan, responders at 75 µg/mL, while non-responders required doses of at least 100 µg/mL. These results suggest that cells with lower repair activity (PBMCs from responders) are more sensitive to melphalan-induced p53 accumulation than PBMCs from non-responders having higher levels of preferential repair.PBMCs from non-responders had almost fully recovered total RNA synthesis to control levels by 6h following exposure to 100µg/ml melphalan. In contrast, PBMCs from all healthy volunteers and most responders (39/48) showed a more extensive and prolonged inhibition of RNA synthesis, suggesting that, the ability to preferentially repair the transcribed strand of the active genes correlates with rapid recovery of total RNA synthesis.Finally, induction of apoptosis was evident following 10µg/ml melphalan in all healthy volunteers, 75µg/ml in most responders (35/48) and at least 100 µg/mL in non-responders, suggesting that PBMCs from responders correlated with an increased susceptibility to melphalan-induced apoptosis. **Summary and Conclusions.** This study provides new data on the prediction value of specific genetic alterations, epigenetic changes and key components of DNA damage response pathways for response to high dose melphalan and ASCT in myeloma patients. These results can be translated in novel biomarkers for prediction of response to MM therapy.

EVIDENCES OF EARLY SENESCENCE IN MULTIPLE MYELOMA BONE MARROW MESENCHYMAL STROMAL CELLS (MM BM-MSCS)

T André[1], N Meuleman[2], B Stamatopoulos[2], C De Bryun[2], K Pieters[2], D Bron[2], L Lagneaux[2]
[1]Jules Bordet Institute - ULB, Brussels, Belgium
[2]Jules Bordet Institute, Brussels, Belgium

Background. It is now well established that the bone marrow (BM) constitutes a microenvironment required for differentiation, maintenance, expansion, and development of drug resistance of the multiple myeloma (MM) cell clone. Previous studies have suggested that direct and indirect interactions between MM plasma cells (MM-PCs) and BM-MSCs result in constitutive abnormalities in BM-MSCs. **Aims.** The aims of our study were to further investigate the constitutive differences of MM BM-MSCs compared to healthy donors (HD) BM-MSCs and to evaluate the impact of actual treatments on MM BM-MSCs. **Methods.** We carried out microarray analysis on BM-MSCs derived from MM patients (Untreated or previously treated with Thalidomide, Lenalidomide and Bortezomib) and healthy donors with an Affymetrix Genechip Human Genome U133 Plus 2.0 Array. In addition, we evaluated diverse characteristics of MM-MSCs such as proliferation capacity (CFU-F, doubling time), osteoblastogenesis (calcium deposits, ALP activity), cytokine and chemokine expression profile (ELISA), hematopoietic support (Bl-CFL, LTC-IC) and immunomodulatory activity (MLR). **Results.** We demonstrated that MM BM-MSCs, compared to HD BM-MSCs, presented an early senescent profile with expression of senescence-associated β-galactosidase (68.10 vs 20.23% of positive cells; $p=0.0002$; $n=11$), increased cell size (32.55 vs 31.32 µm; $p<0.0001$; $n=10$), reduced proliferation capacity (7156 vs 200298 CFU-F at passage 1; $p=0.0173$; $n=6$) and characteristic expression of members of the senescence associated secretion profile (SASP). We observed alterations in the osteoblastogenesis with a reduction of calcium deposits (8.74 vs 14.81 mg/µg of protein; $p=0.0023$; $n=7$) and an early rise of ALP activity (0.037 vs 0.018 U/µg of protein; $p=0.0126$; $n=9$). Finally, the hematopoietic support and immunomodulatory activity of MM BM-MSCs were also altered. For all these experiments, the actual MM treatments were able to partially reduce the MM BM-MSCs abnormalities (secreted factors, proliferation). **Conclusions.** We hypothesize that MM-PCs and MM BM-MSCs are co-dependent since separated *in vitro* cultures induce apoptosis or senescence and co-cultures permit the survival of both. So, it is of great importance to evaluate the impact of the MM-PCs eradication (complete and partial remissions) and of the treatments responsible of this eradication on MM BM-MSCs. Indeed, the disturbance of the bone marrow environment by senescent MM BM-MSCs would be sufficient to induce relapse or secondary cancers such as myelodysplasia and leukemia.

HYPOMETHYLATION OF ENDOGENOUS RETROTRANSPOSONS IS CORRELATED WITH FREQUENT CHROMOSOMAL DELETIONS AND POOR PROGNOSIS IN MULTIPLE MYELOMA

H Yasui[1], Y Aoki[1], M Nojima[1], H Suzuki[1], Y Maruyama[1], R Maruyama[1], E Yamamoto[1], M Itagaki[2], H Ikeda[1], T Hayashi[1], H Asaoku[2], K Imai[3], T Ishida[1], Y Shinomura[1]
[1]Sapporo Medical University, Sapporo, Japan
[2]Hiroshima Red Cross and Atomic-bomb Survivors Hospital, Hiroshima, Japan
[3]The Institute of Medical Science, The University of Tokyo, Tokyo, Japan

Background. Aberrant genome-wide hypomethylation is thought to be related to tumorigenesis through its promotion of genomic instability. Since the methylation of endogenous retrotransposons, which make up at least 42% of the human genome, including long interspersed nuclear element 1 (LINE-1) and short interspersed element Alu, plays an important role in the silencing of transposon-mediated mutagenesis, hypomethylation of retrotransposons in human tumors may lead to their reactivation. However, the role of the methylation of retrotransposons in multiple myeloma (MM), characterized by various chromosomal aberrations, remains to be elucidated. **Aims.** In this study, we investigated the methylation levels of retrotransposons, their correlation with the chromosomal aberrations, and their clinical relevance in predicting prognosis. **Methods.** We analyzed the methylation levels of LINE-1 and Alu as well as DNA copy number alterations in purified bone marrow plasma cells from patients with MM (n=74), patients with monoclonal gammopathy of undetermined significance (MGUS, n=7), and normal plasma cell providers (NPC, n=4) using bisulfite-pyrosequencing and array-based comparative genomic hybridization (aCGH), respectively. **Results.** We found a progressive and significant methylation decrease in Alu and LINE-1 from normal controls to MGUSs and MMs. Secondarily, the numbers of deleted probes of aCGH were significantly inversely correlated with the methylation levels of LINE-1 as well as of Alu. Important-

ly, hypomethylation of LINE-1 was well associated with frequent chromosomal deletions, including the deletion of chromosome 13. Finally, we observed significantly poorer prognosis in the lower LINE-1 methylation group compared with the higher group. **Summary and Conclusions.** Our data suggest that the hypomethylation of retrotransposons, especially LINE-1, correlates significantly with malignant levels, the frequency of chromosomal deletions, and prognosis in MM, and that LINE-1 methylation could be a useful marker for risk stratification.

RECONSTRUCTING THE HUMAN HEMATOPOIETIC NICHE: OPPORTUNITIES FOR STUDYING NORMAL AND MALIGNANT HEMATOPOIESIS

R Groen[1], W Noort[1], R Raymakers[1], H Prins[1], L Aalders[1], F Hofhuis[1], B van Kessel[1], P Moerer[1], H Rozemuller[1], JJ Schuringa[2], J de Bruijn[3], M de Weers[4], P Parren[4], H Lokhorst[1], T Mutis[1], A Martens[1]
[1]UMC Utrecht, Utrecht, Netherlands
[2]UMC Groningen, Groningen, Netherlands
[3]Xpand Biotechnology BV, Bilthoven, Netherlands
[4]Genmab BV, Utrecht, Netherlands

Background. Interactions with the hematopoietic niche in the bone marrow (BM) microenvironment are essential for hematopoietic stem cell (HSC) self-renewal. In addition, in hematological malignancies this niche is considered to serve as a sanctuary site for leukemic stem cells during chemotherapy, and to contribute to disease relapse. Although many advances have been made in understanding how the niche regulates HSC self-renewal and confers therapy resistance, most of this knowledge is based on genetic loss- or gain-of-function murine models. **Aims.** Since current models do not recapitulate the human physiology, there is a need for models that more closely resemble the human niche. **Methods.** We developed a unique humanized model, by implementing a novel scaffold-based technology for generating a human bone environment in RAG2$^{-/-}$gc$^{-/-}$-mice that facilitated engraftment of normal and malignant hematopoietic cells **Results.** Inoculation of mice carrying a humanized environment, with normal human CD34^{+} hematopoietic progenitor cells, isolated from umbilical cord blood, resulted in homing to the human bone environment and the generation of human hematopoietic cells of distinct lineages, but more importantly also the engraftment of CD34^{+} cells themselves. In a next series of experiments the supportive nature of the humanized niche was further investigated with patient-derived acute myeloid leukemia (pAML) and multiple myeloma (pMM) cells, two hematopoietic malignancies that are highly dependent on the BM microenvironment for survival and growth. Inoculation of the humanized mice with pAML cells, obtained from a poor-risk patient (M1; complex karyotype) or cells from a good risk AML patient (M4; inv(16)) revealed the ability of the reconstructed human bone environment to support outgrowth of the leukemia with the cells having a similar phenotype as those from the patient sample. Interestingly, engraftment of good risk AML samples, including inv(16), has been reported to be very difficult in the NOD/SCID-based AML xenotransplant model. Retransplantation of leukemic cells harvested from the scaffolds after passage 1, again engrafted in secondary scaffolds and showed after passage 2, identical outgrowth as in passage 1. The humanized model that we developed was further substantiated by the ability to support the outgrowth of pMM from 7 out of 7 patients. MM is a hematological malignancy that fails to grow in mouse tissues without extra support, *e.g*. fetal human bone chips. Moreover, the outgrowth of pMM in our humanized model is accompanied by an increase in osteoclast activity, indicating the presence of bone resorption, one of the most relevant clinical sequelae of MM.In addition, by gene-marking pMM cells with luciferase and using bioluminescent imaging, we were able to follow myeloma outgrowth in time. Treatment of pMM-bearing mice with identical drugs as given to the patients showed that the pMM cells growing in the humanized environment in the mice responded similar as the MM patients. **Conclusions.** This novel human-mouse hybrid model creates unprecedented opportunities to investigate species-specific microenvironmental influences on normal and malignant hematopoietic development, and to develop and personalize cancer treatment strategies

THE USE OF CD138 POSITIVELY SELECTED MARROW SAMPLES INCREASES THE APPLICABILITY OF MINIMAL RESIDUAL DISEASE ASSESSMENT BY PCR IN PATIENTS WITH MULTIPLE MYELOMA

N Puig, M Sarasquete, M Alcoceba, A Balanzategui, M Chillón, E Sebastián, M González-Díaz, J San Miguel, R García-Sanz
University Hospital of Salamanca, Salamanca, Spain

Background. In patients with multiple myeloma, the use of ASCT and novel agents is associated with high rates of complete response (CR) and thus, new methods assessing higher degrees of disease eradication are required. Minimal residual disease (MRD) detection by immunoglobulin heavy-chain real-time quantitative PCR (IGH RQ-PCR) and multiparameter flow cytometry (MFC) has proved to be of prognostic value in MM patients. Compared with MFC, RQ-PCR seems to have higher sensitivity but lower applicability due to inadequate diagnostic samples and/or lack of a suitable molecular marker. New strategies aimed at improving the applicability and performance of the PCR are thus needed. **Aims.** We have evaluated the use of CD138 positively selected bone marrow samples to identify a molecular target for MRD assessment by PCR in patients with MM. A fraction of each sample was used for CD138+ selection and the rest served as a reference control. **Methods.** Cell samples were obtained from bone marrow aspirates of 25 patients included in GEM/PETHEMA protocols. CD138+ plasma cell isolation was carried out using the AutoMACs separation system. High molecular weight DNA was isolated using DNAzol reagent. All samples were tested for amplification of complete (VDJ), incomplete (DJ) and Kde (Vk-Kde/intronRSS-Kde) rearrangements according to the BIOMED-2 Concerted Action. Germline IGH genes from complete VDJ and partial DJ rearrangements were identified using public IMGT/V-QUEST and BLAST databases, respectively. Kde and intron-RSS segments were identified by direct comparison with their corresponding germline sequences and Vk segments by using the IMGT database. **Results.** We first assessed clonality in all the 25 samples by amplifying VDJ, DJ and Kde rearrangements. Within the CD138+ selected group, VDJ rearrangements were detected in all cases (100%), DJ in 16 (64%) and Kde in 18 (72%) cases, whereas in the control samples VDJ, DJ and Kde rearrangements were detected in 19 (76%), 11 (44%) and 12 (48%) cases, respectively. As a result, all samples within the CD138+ selected group were suitable for sequencing, whereas only 21 (84%) of the reference samples were so. VDJ sequencing was successful in 22 samples (88%) within the CD138+ selected group and in 12 of the 19 (63%) unselected samples. By contrast, only minor differences in sequence efficacy were observed for DJ (seven and five cases were successfully sequenced among the CD138+ and unfractionated samples, respectively) and Kde (11 and nine cases in each group). In summary, 96% (24/25) of cases within the CD138+ selected group were suitable for PCR-based MRD assessment, 14 (56%) of them having two or more potential specific markers while in the unselected samples only 60% (15/25) of cases were suitable for MRD studies, with eight (32%) of them having two or more markers available. **Summary and Conclusions.** We conclude that the use of CD138 positively selected bone marrow samples increases the applicability of MRD studies by PCR in patients with MM (in our study, from 60% in unselected samples to 96% in CD138+ selected samples) and propose that it should be considered for inclusion as part of routine practice.noepuig@gmail.com

THE ROLE OF TUMOR PROMOTING IMMUNE SUPPRESSIVE MYELOID CELLS IN THE MULTIPLE MYELOMA BONE MARROW MICROENVIRONMENT

G Gorgun[1], T Hideshima[1], N Raje[2], N Munshi[1], P Richardson[1], K Anderson[1]
[1]Dana-Farber Cancer Institute, Boston, MA, United States of America
[2]Cancer Center, Adult Oncology, Massachusetts General Hospital, Boston, United States of America

Background. The interaction of myeloma (MM) cells with bone marrow accessory cells and/or the extracellular matrix induces genomic, epigenomic and functional changes which promote tumor development, progression, cell adhesion mediated-drug resistance (CAM-DR), and immune suppression. To develop the most efficient anti-MM treatment strategy and prevent tumor escape from immune recognition, both enhancing anti-MM effector immune response and overcoming MM-induced immune suppression is essential. Suppressive immune cells including myeloid derived suppressor cells (MDSC), regulatory T cells (Treg) and IL-17 secreting Th (Th17) cells act as tumor promoters and suppressors of effector immune response, and therefore represent a significant barrier to current anti-tumor therapeutic strategies. **Aims.** Since we and others have reported increased numbers of Treg and Th17 cells in MM, we here assessed tumor promoting, immune suppressive role of MDSCs in both peripheral blood (PB) and bone marrow (BM) of patients with MM compared to healthy donors. **Methods.** MDSCs were phenotypically characterized using flow cytometry analysis. MDSCs and autologous T cells were isolated from MM-PB or MM-BM by magnetic Ab selection or FACS sorting. Bone marrow stroma cells (BMSCs) were generated from fresh MM-BM. Cell growth was determined using 3H-thymidine incorporation or MTT assays. **Results.** Phenotypic analysis by flow cytometry showed a significant increase in $CD14^{-}CD11b^{+}HLA\text{-}DR^{low}CD33^{+}CD15^{+}$ MDSCs in fresh PB and BM from MM patients compared to healthy donors ($p<0.01$). MDSCs are highly heterogeneous cell populations, and they can be characterized by their tumor promoting, immunosuppressive functions. To determine whether the $CD14^{-}CD11b^{+}HLA\text{-}DR^{low}CD33^{+}CD15^{+}$ myeloid cell population represents functional MDSCs, we first assessed tumor promoting role of MDSCs in the MM microenvironment. MM-BMSCs were cocultured, with or without depletion of MDSCs with MM cell lines. When MDSCs were depleted from BMSC microenvironment, BMSC-mediated MM growth was significantly decreased to baseline levels of MM cells alone. Moreover, when isolated MDSCs from MM-BM were cultured with MM cell lines, there was a marked increase in MM cell growth, compared to MM cells alone. Since, the interaction between tumor and stromal accessory cells is bidirectional, we next analysed the impact of MM cells on MDSC development. MM cell lines cultured with PBMCs from healthy donors induced a 7 fold increase in MDSCs. Next, immune suppressive function of MDSCs was assessed in the culture of autologous T cells and isolated MDSCs from MM-PB or MM-BM. Importantly, freshly isolated MDSCs from both MM-PB and MM-BM induced significant inhibition of autologous T cell proliferation. Finally, we analysed the role of MDSCs in CAM-DR for bortezomib and lenalidomide. Culture of MDSCs with MM cell lines, with or without bortezomib (5nM) and lenalidomide (1uM), demonstrated that bortezomib induced less cytotoxicity against MM cells in the presence of MDSCs. **Summary and Conclusions.** Overall our preliminary data suggest that MDSCs are increased in MM microenvironment and play an important role in microenvironment mediated MM pathogenesis and immune suppression. Ongoing characterization of their direct impact on tumorigenesis, stromal tumor promotion, and in drug resistance will provide new therapeutic approaches in MM.

[8]Akirta University Graduate Shool of Medicine, Akita, Japan

Background. Multiple myeloma (MM) is characterized by the accumulation of a population of malignant plasma cells within the bone marrow. MM is generally responsive to conventional chemotherapy followed by myeloablative doses of alkylating agents and autologous stem cell transplantation. Cytotoxic chemotherapy-based treatment is not curative, however, and the disease eventually recurs. Although currently available anti-MM strategies are effective at targeting the bulk of tumor cells, it is not clear that these agents are targeting the tumor-initiating subpopulation, including side population (SP) cells. SP cells express high levels of various members of the ABC transporter family, which are responsible for their drug resistance. A recent work by Jakubikova et al (2011) demonstrated that SP cells in MM have shown to exhibit stem cell like characteristics as well as high tumorigenicity. **Aims.** The aim of our study is to identify gene/proteins specifically expressed in myeloma SP cells, which could be essential therapeutic targets. **Methods.** We isolated SP cells from MM cell lines by use of Hechest 33342 dye to examine potential of tumorigenicity (transplantation SP cells into NOD/Shi-scid IL-2γnul mice). Gene expression analysis of SP and non-SP cells were performed against 5 MM cell lines (RPMI 8226, AMO1, KMS11, KMS-12BM and JJN3) and 8 primary samples (n=6 fresh samples, n=2 relapsed samples). Aurora kinase inhibitor (VX-680), 3-deazaneplanocin A(DZNep), and a proteasome inhibitor, bortezomib were exposed to RPMI 8226 and AMO1. **Results.** We found that myeloma SP cells expressing CD138 exhibit greater tumorigenetic potential than non SP cells. Gene expression analysis of 5 cell lines and CD138-positive primary samples revealed that, in SP cells, expression of cell cycle (e.g. *CCNB1, CDC25C, CDC2, CDC20, GTSE1*)-, microtubule attachment (e.g. *BIRC5, CENPE, SKA1)*-, mitosis or centrosome (e.g. *AURKB, KIF2C, KIF11, KIF15*)-, proliferation (e.g. *TOP2A, ASPM*)-, polycomb (e.g. *EPC1, EZH2*)- and ubiquitin-proteasome (e.g. *UBE2D3, UBE3C*, *PSMA5*)- genes was significantly stronger than in non-SP cells. On that basis, we used an aurora kinase inhibitor (VX-680 for AURKB), histone methylation inhibitor (DZNep for EZH2) and a proteasome inhibitor (bortezomib for S20/S26 proteasomes) against RPMI 8226 and AMO1. Of these, bortezomib reduced the SP fraction more effectively than the other agents due to its ability to reduce levels of phospho-histone H3, EZH2 and PSMA5. This suggests bortezomib has a greater range of targets than other agents and could include cell cycle, centrosome, polycomb and proteasome genes/proteins. **Conclusions.** We found that myeloma SP cells exhibit strong tumorigenicity *in vivo*, and showed that they more strongly express cell cycle (G_2/M)-, centrosome-, polycomb- and ubiquitin-proteasome-related genes than non-SP cells. We also demonstrated that reducing transcription of all these genes is necessary when targeting myeloma SP cells, and that bortezomib is capable of shrinking the myeloma SP by downregulating the aforementioned genes. Our approach could be useful for screening new agents with which to target a population possessing strong tumor initiating potential in MM.

FUNCTIONALLY ACTIVE MYELOID-DERIVED SUPPRESSOR CELLS ARE INCREASED AFTER LENALIDOMIDE PLUS DEXAMETHASONE TREATMENT IN PREVIOUSLY UNTREATED MULTIPLE MYELOMA PATIENTS

K Muthu Raja[1], L Rihova[2], R Hajek[3]
[1]Masaryk University, Brno, Czech Republic
[2]Dept. of Clinical Hematology, University Hospital, Brno, Czech Republic
[3]Dept. of Internal Medicine, Hematooncology, University Hospital, Brno, Czech Republic

Background. Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of immature cells and reported to be expanded in pathological conditions including cancer, infectious diseases and some autoimmune diseases. Recently, a large number of studies showed MDSCs expansion and their suppressive function in tumor models and non-hematological malignancies. Multiple myeloma (MM) is a plasma cell malignancy associated with immunological impairments. **Aims.** To evaluate frequency of MDSCs and their suppressive function in MM patients at baseline and after lenalidomide plus dexamethasone (LD) treatment. **Patients and Methods.** A cohort of 16 untreated MM patients was included after obtaining signed informed consent forms according to Helsinki declaration. Median age of the studied cohort was 60 years (range, 36-67). According to international staging system (ISS) patients were staged as: ISS1, 8/16 (50%); ISS2, 5/16 (31%); and ISS3, 3/16 (19%). All patients received LD for 4 cycles as induction therapy (lenalidomide, 25mg on days 1-21; dexamethasone, 40mg on days 1, 8, 15, 22). Using multi-parameter flow cytometry (CD4-FITC, CD11b-PE, CD33-PerCpCy5.5, CD14-PECy7, HLA-DR-APC and CD8-PB), we assessed MDSCs, total lymphocytes, CD4 and CD8 T cells from PB of MM patients at baseline and after each LD treatment cycle. As controls, 11 healthy volunteers (HVs) PB samples were also assessed. Functional activity of MDSCs was studied using CFSE based T cell proliferation assays from 4 MM patients (3 untreated and 1 LD treated) and 3 HVs. Further, we profiled supernatants from proliferation assays for pro-inflammatory (IFN-γ, TNF-α) and immunosuppressive (IL-10) cytokines. **Results.** MDSCs were identified as CD33+CD11b+CD14-HLADR-. Frequency of MDSCs was significantly increased and total lymphocytes were reduced in MM patients at baseline compared to HVs (median% of MDSCs, 0.33 vs.0.08; P=0.001 and median% of lymphocytes, 16.10 vs. 36.13; P=0.01). However, baseline CD4 and CD8 T

cells from MM patients did not differ significantly from HVs. When we compared MDSCs from baseline and post-LD treatment, significant increase was observed after the 4th cycle but similar frequency was observed after 1-3 cycles (median% of MDSCs, 0.33 vs. 0.57; P=0.033). Functional studies revealed that MDSCs from MM patients and HVs suppressed CD3 T cell proliferation in concentration dependent manner (1:1, 1:5, 0:1). Suppressive function of MDSCs was comparable between HVs, untreated and LD treated patients. Cytokine data from MM and HVs showed that in the presence of MDSCs in proliferation assays, the level of IFN-γ, TNF-α and IL-10 was reduced significantly compared to proliferation assays without MDSCs (P=0.05). Comparison of MM and HVs cytokine data from proliferation assays (in presence or absence of MDSCs) showed no significant difference in the level of IFN-γ and TNF-α. But IL-10 level was 3-fold increased in proliferation assays (without MDSCs) from MM patients compared to HVs (mean pg/ml: 960.88 vs. 368.36; P=0.045). **Conclusions.** Our findings suggest that MDSCs are expanded and functional in MM. LD treatment in MM did not reduce MDSCs and their suppressive function. Expansion of these cells might enhance immune suppression in MM and thereby progress the disease.This study was supported by GACRGAP304/10/1395, MSM0021622434, LC06027, IGA: NS10406 and NS10408.

MYELOMA PLASMA CELL CD45 NEGATIVITY CORRELATES WITH DRUG RESISTANCE AND MORE AGGRESSIVE BIOLOGY WHEN COMPARED TO CD45 POSITIVE COUNTERPARTS

C Lin[1], T Khong[2], S Mithraprabhu[2], K Monaghan[2], A Cuddihy[2], R Grumont[2], S Gerondakis[2], A Spencer[2]
[1]Monash University, Alfred Hospital, Melbourne, Australia, Prahran, Australia
[2]Australian Centre for Blood Diseases, Monash University, Alfred Hospital, Melbourne, Australia

Background. Multiple myeloma (MM) is an incurable plasma cell (PC) malignancy predominantly negative for the protein tyrosine phosphatase CD45. Limited human data has demonstrated that the presence of proportionally greater numbers of $CD45^{-ve}$ rather than $CD45^{+ve}$ MM PCs confers shorter patient survival and murine data suggests that disease progression correlates with the transition from predominantly $CD45^{+ve}$ to predominantly $CD45^{-ve}$ disease. Based on these observations we hypothesised that CD45 negativity may be associated with increased drug resistance and a more malignant phenotype. **Aims.** To characterise and investigate the biology of MM PCs based on CD45 expression. **Methods.** U266 is an IL-6 secreting human MM cell line (HMCL) comprised of both $CD45^{+ve}$ and $CD45^{-ve}$ PC populations. These subsets were separated and analysed for differences in growth, surface phenotype, cytokine production, cell signalling, drug resistance and gene expression. **Results.** $CD45^{+ve}$ and $CD45^{-ve}$ PCs expressed similar levels of IL-6R, IGF-1R, CD49d and CD95, whereas the $CD45^{+ve}$ PCs expressed more CXCR4 and ICAM-1 (both $p<0.001$). Neither population produced IGF-1 and IL-6 was only produced by the $CD45^{-ve}$ population. Furthermore, upon IGF-1 stimulation, a 3-fold increase in IL-6 secretion ($p=0.04$) by the $CD45^{-ve}$ subset was observed. The $CD45^{+ve}$ cells displayed more rapid growth kinetics than the $CD45^{-ve}$ subset over 72hrs. But, comparable rates of $CD45^{-ve}$ PC growth were generated when the $CD45^{-ve}$ PCs were exposed to conditioned media (CM) from the $CD45^{+ve}$ PCs. Conversely, no change in growth was noted in the $CD45^{+ve}$ cells in the presence of CM from the $CD45^{-ve}$ cells. Basal p-AKT/p-STAT3/p-ERK expression was similar between the two subsets whereas both NOTCH and NFkB signalling was relatively increased in the $CD45^{-ve}$ PCs. Exposure to CM from the $CD45^{-ve}$ PCs resulted in a modest increase in p-AKT and p-ERK expression and a 3.5-fold increase in p-STAT3 in the $CD45^{+ve}$ subset whilst no change in signalling was detected in the $CD45^{-ve}$ PCs exposed to $CD45^{+ve}$ CM. The $CD45^{+ve}$ PCs exhibited a 2.9 fold and 2.1 fold increase, respectively, in bortezomib and marizomib induced cell death when compared to the $CD45^{-ve}$ PCs but no difference was observed following treatment with melphalan. Finally, comparative gene expression profiling ($CD45^{+ve}$ versus $CD45^{-ve}$) demonstrated increased expression of a range of tumour suppressor genes prone to promoter hypermethylation. Conversely, the $CD45^{-ve}$ PCs preferentially expressed a range of oncogenes known to be associated with metastasis and a more aggressive clinical phenotype in the context of solid tumour biology. **Conclusions.** Utilising the U266 HMCL as a model of CD45 expression we have demonstrated 1. co-operativity between $CD45^{+ve}$ and $CD45^{-ve}$ populations, suggesting that tumour heterogeneity within the context of MM may play a critical role in the promotion of the disease, and 2. that $CD45^{-ve}$ PCs exhibit increased drug resistance , increased activation of known oncogenic pathways and express a range of oncogenes known to be associated with metastasis and disease progression in solid tumours and that have not been previously described in MM.

OSTEOCLASTOGENIC INHIBITORY PROPERTIES OF SMALL IMMUNOGLOBULIN COMPLEXES AND THEIR POTENTIAL AS A THERAPEUTIC FOR THE TREATMENT OF OSTEOLYTIC BONE DISEASE IN MULTIPLE MYELOMA

K Thümmler[1], S Kitson[1], N Cody[1], R Soutar[2], C Goodyear[1]
[1]University of Glasgow, College of Medical, Veterinary and Life Sciences, Glasgow, United Kingdom
[2]Beatson West of Scotland Centre, Haemato-oncology Service, Gartnavel Hospital, Glasgow, United Kingdom

Background. Multiple myeloma (MM) is concomitant with severe bone destruction. This destruction, driven by osteoclasts, is in part due to the osteoclastogenic properties of myeloma cells. However, this is not a unidirectional process but rather a complex inter-dependent process where osteoclasts also produce survival factors that support myeloma cell survival. Novel approaches targeting osteoclastogenesis in MM may therefore not only be beneficial for the treatment of osteolytic bone disease but also have an indirect inhibitory effect on tumour burden. Recent studies within our laboratory have shown that small immunoglobulin complexes of *Staphylococcal aureus* Protein A and Immunoglobulin G (SIC) can inhibit RANKL-driven osteoclastogeneis. **Aims.** To investigate the inhibitory potential of SIC on myeloma-driven osteoclastogenesis and the subsequent impact on myeloma cell survival. **Methods.** Primary myeloma cells were isolated from bone marrow aspirates of active, untreated MM patients using $CD138^{+}$ magnetic selection. Myeloma cells, or myeloma cell line U266B1, were co-cultured with human $CD14^{+}$ monocytes or pre-osteoclasts (M-CSF and RANKL cultured monocytes) in the presence or absence of SIC. Myeloma-driven osteoclastogenesis was assessed by tartrate-resistant acid phosphatase (TRAP) staining and osteolytic capacity by bone slice cultures. Myeloma cell survival was determined via flow cytometry. **Results.** To investigate whether or not SIC could inhibit osteoclastogenesis induced by myeloma cells we treated myeloma cell/pre-osteoclast co-cultures with SIC or relevant controls. The addition of SIC to co-cultures significantly inhibited the osteoclastogenic potential of both primary myeloma cells and the U266B1 human myeloma cell line. Interestingly, the source of osteoclast pre-cursors (allogenic or autologous) did not have an impact on the osteoclastogenic potential of myeloma cells or the inhibitory capacity of SIC. The osteolytic activity of cells in the presence of SIC, as determined by bone slice cultures, was also substantially reduced. This inhibitory effect was dose dependent and reversible.SIC binding studies revealed that SIC could not directly interact with myeloma cells. However, to determine whether the treatment of co-cultures could have an indirect effect on myeloma cell survival, due to alterations in the supportive environment, we evaluated the number of dead (Annexin V^{+} $7AAD^{+}$) myeloma cells after 7 days in co-culture in the presence or absence of SIC. The viability of U266B1 myeloma cells was markedly increased in the presence of pre-osteoclasts. The addition of SIC, however, abolished this supportive effect resulting in increased myeloma cell death. **Summary and Conclusions.** SIC directly interfere with myeloma-osteoclast interactions: inhibiting both myeloma-driven osteoclastogenesis and osteoclasts-driven myeloma cell survival. Thus, our data supports the idea that SIC might be a potentially novel therapeutic treatment strategy for multiple

0278

MICRO-RNA EXPRESSION IS ASSOCIATED WITH EXPRESSION OF DNA METHYLTRANSFERASES AND ANTI-APOPTOTIC GENE MCL-1 IN MULTIPLE MYELOMA AND MONOCLONAL GAMMMOPATHY WITH UNDETERMINED SIGNIFICANCE (MGUS)

H Handa, H Hattori, Y Sasaki, T Saito, N Takahashi, H Koiso, T Mitsui, Y Osaki, N Sato, T Kamio, M Mihara, H Iriuchishima, S Akio, M Takizawa, T Sekigami, T Hoshino, A Yokohama, N Tsukamoto, H Murakami, Y Nojima
Gunma University, Maebashi, Japan

Background. Micro RNAs (miRs) are small non-coding RNAs of 19-25 bases in length having the ability to modulate the expression of other genes. MiRs are frequently involved in carcinogenesis and its expression analysis to predict the phenotype of malignancies has been shown. DNA methyltransferase (DNMT) is an enzyme that adds methyl group to cytosine of DNA keeping tumor suppressor genes (TSG) silent. It has been demonstrated that miR-15, miR-16, miR-29 family down-regulate DNMT and anti-apoptotic gene Mcl-1 expression then influence the survival of cancer cells *in vitro*. Many studies evaluate miR expression and its association with chromosomal abnormalities and the prognosis of multiple myeloma (MM), but the relationship between miR and its target gene expression in the patients has not been reported. **Aims.** In this study, we examine the relationship between miR-15, 16, 29 family expression and DNMT, Mcl-1 expression in MM and MGUS *in vivo* in patients. **Methods.** MM cell lines and BM samples obtained from 26 of MM patients, 16 of MGUS patients are subjected to the study after informed consent. Sequential BM samples during the treatment were obtained from 6 patients. RNA and miR were extracted from plasma cells separated by CD138 antibody and magnetic beads. MiR15a, 15b, 16, 29a, 29b, 29c and mRNA expression of DNMT1, 3A, 3B, Mcl-1 were quantified by Taqman-probe and real time PCR. **Results.** The expression level of miR15a and 16 was reduced in plasma cells of MM (6.4±3.1, 19.5±7.5) than of MGUS (34.8±15.4, 72.1±36.5) and of normal subjects(74.4±1.5, 25.5±12.9)(p=0.02, p=0.02). MiR 15b, 29a, 29b, 29c expressions were not significantly different among MM, MGUS and normal subjects. Conversely, DNMT1, 3A and Mcl-1 expression were elevated in MM (7.2±4.5, 8.5±3.3, 594±314) than in MGUS (0.8±0.2, 1.7±0.6, 41.4±41.2) and normal subjects (0.4±0.3, 2.1±1.8, 44.0±8.7) (p=0.03). DNMT3B expression was not different. In the MM cell lines, miR 29a and 29b expression were inversely correlated with DNMT1 mRNA expression (r=0.96, p=0.0003: r=0.86, p=0.014). In the patient samples, DNMT1 was inversely correlated with miR15a, miR15b, miR16, miR29a, miR29b (r=-0.435, p=0.003; r=-0.341, p=0.02, r=-0.332, p=0.03, r=-0.419, p=0.005, r=-0.407, p=0.006), DNMT3A was inversely correlated with miR15a, miR29a, miR29b, miR29c (r=-0.365, p=0.02; r=-0.315, p=0.04; r=-0.371, p=0.01; r=-0.315, p=0.04), DNMT3B was inversely correlated with miR15a, miR15b, miR29a, miR29b (r=-0.418, p=0.005; r=-0.385, p=0.01; r=-0.353, p=0.02; r=-0.358, p=0.02), and Mcl-1 was inversely correlated with miR29a (r=-0.028, p=0.03). Four of 6 patients' plasma cells showed decreasing miR 15a, 15b, 16 and 29 families and increasing DNMT1 and Mcl-1 expression during the treatment. Those patients acquired drug resistance. One patient's sample whose miR expression increased during the treatment showed reduced DNMT1 and Mcl-1 expression. **Conclusions.** We found that miRs decreased in MM and possibly associated with MM progression. Negative correlation with the expression level of the DNMTs, Mcl-1and miRs in MM cell lines and patients' samples were seen, which is consistent with previous reports about solid cancers. The sequential samples during the treatment suggest that miRs regulate its target gene expression *in vivo* in patients and thus related to MM prognosis.

Background. Recently, genome-wide association studies have identified and confirmed associations of glioma, chronic lymphocytic leukemia (CLL), breast, prostate, bladder, colorectal and ovarian cancer with several variants within a 600-Kb region of a longer, 1.18-Mb sequence, on chromosome 8q24. The 8q24 locus is devoid of genes, but telomeric to region 5 lies the MYC gene and a possible interaction among genetic variants of the 8q.24 region and MYC expression or activation have bas been reported. Since genetic factors are thought to be involved in Multiple Myeloma (MM) pathogenesis we postulated the hypothesis that variants in the 8q24 region could play a role also in MM risk. **Aims.** The aim of this study was to investigate whether genetic variants in the 8q24 region are associated with MM risk. **Methods.** We selected 20 SNPs spanning the 8q24 region and which showed associations in GWAS on CLL, breast, prostate, ovarian, bladder and colorectal cancer. The selected SNPs were genotyped in a population of 1188 MM cases and 2465 controls, ascertained through the IMMEnSE consortium and the Heidelberg Myeloma Group. **Results.** The carriers of the G allele of rs2456449 showed a statistically significant increased risk of MM ($OR_{carriers}$=1.21, 95%CI 1.05-1.40, P_{value}=0.009, P*trend*=0.030). Subdividing for recruitment center, in the population from Heidelberg, the observed association reached the study-wise significant threshold ($OR_{carriers}$=1.37, 95%CI 1.12-1.68, P_{value}=0.0022 P*trend*=0.0030) (Table 1).

Table 1. Distribution of genotypes of the 8q24 SNP rs2456449 in MM cases and controls.

8q24 SNP	Cases	Controls	OR*	95%C.I.*	P-value
rs2456449		IMMEnSE Consortium

				p-trend	***0.030***

Genotype distribution among MM cases and controls in the IMMEnSE consortium, in the Heidelberg Myeloma Group and in the overall population. *OR=Odds Ratio, C.I.=Confidence Intervals. OR are adjusted for age, gender and region of origin. Differences in samples numbers are due to failures in genotyping. Results in bold show p<0.05.

Conclusions. We found a statistically significant association between the G allele of rs2456449 and an increased risk of MM. This association is intriguing because the rs2456449 has been shown to be associated with CLL and monoclonal B-cell lymphocytosis risk. The rs2456449 G allele could therefore represent a risk factor shared by several B-cell malignancies through a common regulatory mechanism. The observed effect of genetic variants within the 8q24 locus and Myc transcription/expression could represent the functional basis of the reported association. In conclusion these data provide further evidence that the genetic variability in the 8q24 region might be associated with cancer risk and in particular with B-cell malignancies.

Myeloma - Clinical 1

Background. The IFM 2009-02 study aimed to determine the impact of the combination of pomalidomide (oral 4 mg daily) and dexamethasone (oral 40 mg weekly) in pts characterized with advanced myeloma (MM) resistant/refractory to lenalidomide and bortezomib. We have also analyzed the efficacy of pomalidomide and dexamethasone as compared to the respective last prior line of therapy. **Aims.** To compare the efficacy of pomalidomide and dexamethasone with that of the last prior line of therapy in patients with refractory myeloma.**Method.** This phase 2 multicenter study randomized MM patients who were non-responsive (≤ SD) or refractory (relapsed ≤ 60 days of last dose) to the last line of lenalidomide and/or bortezomib, as per IMWG criteria. Patients received pomalidomide 4 mg 21/28 days or 28/28 days plus dexamethasone. The primary objective was ORR (PR and better). All responses were reviewed by an independent committee (IRC). All patients had venous thromboembolism prophylaxis. All analyses are performed as ITT.

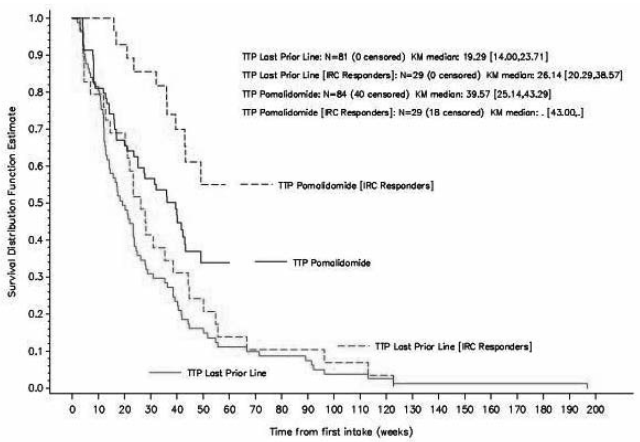

Figure 1. Comparison between TTP on-protocol and TTP on last prior line (ITT n=84).

Results. Eighty four patients (57 male and 27 female) were enrolled; 43 in arm 21/28 and 41 in arm 28/28. The median (min-max) age was 60 years (42-83). The median time from diagnosis to randomization was 70.5 months (9-277). The median number of prior lines of therapy was 5 (1-13), and 100% of the patients had received bortezomib and/or lenalidomide; 73% had received alkylating agents and thalidomide. As the last prior line of therapy, 38% had bortezomib-, 35% had lenalidomide-, 11% had bortezomib and lenalidomide-, 10% had thalidomide-, and 37% had an alkylating agent-based regimen. At the cut-off of March 1st 2011, the median follow-up for surviving pts was 10.4 months (2-14), the median number of cycles administered was 8 and6 in arm 21/28 and 28/28 respectively. The ORR was 35% in arm 21/28 and 34% in arm 28/28; 40% and 48% of patients had SD respectively. The median PFS was 6.3 months in both arms, and the median duration of response was 11.4 months and 7.9 months respectively. The median PFS was 3 times longer in responders versus patients that had a SD. Across both arms, patients refractory to the last line of therapy and to lenalidomide as the last prior line of therapy had a similar ORR and median PFS as compared to the entire study population, 32% and 23%, and 5.5 months (4-9) and 6.3 months (3-10), respectively. Regardless to whether patients responded to their last prior therapy, TTP on pomalidomide +dexamethasone was prolonged in the overall populations, from 5 months (3.5-6) to 10 months (6-11) and in patients who achieved a response, from 6.5 months (5-9.5) to NR (11—) (Figure 1). Updated efficacy and safety to be presented at EHA 2012. **Conclusions.** Pomalidomide and dexamethasone is active and generally well tolerated in heavily pre-treated patients with refractory multiple myeloma. This study provides further evidence that pomalidomide has no-cross resistance with lenalidomide and suggests that it can provide benefit for patients who have relapsed after other novel therapies including lenalidomide and bortezomib.

Background. The synergistic effects of vorinostat (VOR), an oral multi-histone deacetylase inhibitor, and bortezomib (BTZ) were shown in preclinical studies and confirmed in independent phase 1 trials in patients with relapsed/refractory multiple myeloma (MM). **Aims.** We conducted a global, randomized, placebo-controlled, phase 3 trial to investigate the benefits of VOR in combination with BTZ for the treatment of relapsed/refractory MM patients. **Methods.** Eligible patients (≥18 years, measurable MM, 1-3 prior regimens, ECOG ≤2) were randomized 1:1 to receive 21-day cycles of BTZ (1.3 mg/m^2 intravenously; days 1, 4, 8, 11) in combination with oral VOR (400 mg/d) or matching placebo, on days 1 to 14. Patients with prior resistance to BTZ were excluded, and additional use of corticosteroids for the treatment of MM was not allowed during the trial. All randomized patients were treated until disease progression, unacceptable toxicities, or withdrawal of consent. The primary end point was progression-free survival (PFS; after the occurrence of ~412 PFS events); all responses and progressions were determined according to the European Bone and Marrow Transplantation Group criteria and confirmed by an independent adjudication committee. **Results.** The trial enrolled 637 patients in 174 centers from 33 countries, making this trial one of the largest studies conducted in relapsed/refractory MM. The median age was 61 years (range 30-85 years), and patients had received a median of 2 prior regimens (range 1-3). Patients treated with VOR + BTZ compared with BTZ alone had a significant improvement in objective response rate (56% vs 41%; P<0.0001) and clinical benefit rate (71% vs 54%; P<0.0001). The durations of the induced responses were similar in both arms (8.5 vs 8.4 months); PFS and time to progression were signif-

icantly improved with VOR + BTZ compared with BTZ alone, with hazard ratio (HR) reductions of 23% (*P*=0.01) and 21% (*P*=0.02), respectively. With only 151 deaths, a favorable, nonsignificant trend in overall survival for VOR + BTZ was observed compared with BTZ alone (14% HR reduction; *P*=0.35). As expected, the most common treatment-emergent adverse events in both arms were predominantly hematologic and gastrointestinal disorders, with a significant increase for grade ≥3 thrombocytopenia (45% vs 24%; *P*<0.001) and grade ≥3 diarrhea (17% vs 9%; *P*=0.003) in the VOR + BTZ arm compared with BTZ alone. Mean exposure to study treatment was higher in the VOR + BTZ versus BTZ alone arm (7 vs 6 cycles); no differences in discontinuation rates were observed between the study arms (21% vs 22%, respectively). The combination was generally well-tolerated, and side effects were clinically manageable. Despite the increased incidence of grade ≥3 thrombocytopenia, no clinically relevant bleeding events have been reported. **Summary and Conclusions.** As the combination of VOR + BTZ induces significantly higher response rates and prolongs PFS in comparison with BTZ alone, VOR + BTZ may provide a new treatment option for relapsed/refractory MM patients. Subgroup analyses of high-risk patients will be presented at the meeting.

Background Multiple myeloma (MM) is the most relevant hematologic tumor in the elderly population. Median age at diagnosis is 70 years; 37% of patients are older than 75 years and 30% of patients present at diagnosis at least one co-morbid condition. The introduction of novel agents, bortezomib, thalidomide and lenalidomide, have changed the treatment paradigm of elderly MM, but side effects are frequent and full-drug doses less tolerated. Up to 90% of at least one serious adverse event (AE), with a subsequent 40% of drug discontinuation has been reported. **Aims.** A retrospective analysis evaluating 1435 individual patient data from 4 European phase III trials was conducted. We analyzed the impact of age, organ damage, treatment-related AEs and drug discontinuation as predictors of outcome. **Methods.** Patients with newly diagnosed MM, not eligible for autologous transplantation due to age (≥65 years) or co-morbidities, received melphalan-prednisone (MP), MP-thalidomide (MPT), MP-bortezomib (VMP), bortezomib-thalidomide-prednisone (VTP) or VMP-thalidomide (VMPT). Patients enrolled in the GISMM-2001 MP vs. MPT (331 patients), HOVON 49 MP vs. MPT (333 patients), GEM05MAS VMP vs. VTP (260 patients) and GIMEMA MM0305 VMP vs. VMPT (511 patients) trials were included in this meta-analysis. Trials were registered at ClinicalTrials.gov or controlled-trials.com. **Results.** Of the 1435 patients analysed, 332 did not receive novel agents (MP), 332 received thalidomide (MPT), 387 bortezomib (VMP), 384 thalidomide and bortezomib (VTP/ VMPT). Patients ≥75 years were 36%, equally distributed in the 4 groups. The proportion of patients with ISS III was lower in the MP group; renal failure was higher in the MP and MPT groups, due to less stringent selection of these protocols.The incidence of any grade 3-4 non-hematologic AEs was 29%, higher in MPT (43%) compared with VMP (24%) or VTP/VMPT (32%) groups. The most frequent were infections (10%), peripheral neuropathy (8%), cardiac (6%) and gastro-intestinal complications (5%). Drug discontinuation for toxicity was 27%, higher in MPT (35%) compared with VMP (16%) or VTP/VMPT (29%) groups.After a median follow-up of 33 months (95% Confidence Interval [CI] 10-56 months), 513/1435 patients (36%) died, the median overall survival was 50 months (95% CI 46-60 months). The causes of death were disease progression (76%) and toxic effects (24%), mainly infections, cardiac complications, second primary malignancies, and venous thromboembolism. The risk of death was increased in patients ≥75 years (Hazard Ratio [HR] 1.44, 95% CI 1.20-1.72, P<0.001), in patients with renal failure (HR 2.02, 95% CI 1.51-2.70, P<0.001), in those who experienced grade 3-4 cardiac, infective, or gastrointestinal AEs during treatment (HR 2.53, 95% CI 1.75-3.64, P<0.001) or requiring drug discontinuation due to AEs (HR 1.67, 95% CI 1.12-2.51, P=0.01). The risk of death increased in patients receiving more complex approaches with the combination of bortezomib-thalidomide. **Conclusions.** Age ≥75 years or renal failure at presentation, occurrence of cardiac, infective or gastrointestinal AEs negatively affected survival. An appropriate screening for vulnerability, assessment of organ function and less-intense personalized approaches are suggested in elderly unfit MM patients, to improve tolerability and optimize efficacy.

Smoldering Multiple Myeloma (SMM) is an asymptomatic proliferative disorder of plasma cells (PCs) defined by a serum monoclonal component (MC) of 30 g/L or higher and/or 10% or more plasma cells in the bone marrow (BM). There are several risk factors predicting high-risk of progression to symptomatic disease: >10% of PCs in BM, serum MC >30g/L, >95% aberrant PCs by immunophenotyping, or abnormal free-light chains. Standard of care of SMM is no treatment until progression disease.In this phase III trial, SMM patients at high-risk of progression were randomized to receive Len-dex as induction followed by Len alone as maintenance vs no treatment in order to evaluate whether the early treatment prolongs the time to progression (TTP) to symptomatic disease.Len-dex arm received an induction treatment consisting on nine four-weekscycles of lenalidomide at dose of 25 mg daily on days 1-21 plusdexamethasone at dose of 20 mg daily on days 1-4 and 12-15 (totaldose: 160mg), followed by maintenance until progression disease withLenalidomide at dose of 10 mg on days 1-21 monthly up to two years.The 124 planned patients were already recruited, and 118 were evaluable (six patients didn't meet inclusion criteria).On an ITT analysis (n=57), based on IMWG criteria, the overallresponse rate during induction therapy was 81%, including 56% PR, 11% VGPR, 7% CR and7% sCR. 51 patients have completedthe nine induction cycles, and the ORR was 87%, including 12% VGPR, 8% CRand 8% sCR. After a median of 15 cycles of maintenance therapy (2-31), the sCR increased to 16%.After a median follow-up of 32 months (range: 5-42),nine patients progressed to symptomatic disease in the Len-dex arm: four of them during maintenance therapy and the other five progressed after early discontinuation of the trial due to personal reasons. In the therapeutic abstention arm, 37 out of 61 patients (59%) progressed to active MM. The estimated hazard ratio was 6· 0 (95%CI= 2· 9-12.6), corresponding to a median TTP from inclusion of 23

monthsfor the not treatment arm vs median not reached in the treatment arm (p<0.0001). Estimated 3-years overall survival (OS) from the inclusion in the trial was 93% for Len-dex arm and 76% for no treatment arm (p=0· 04) and this difference was more evident if we evaluate the OS from the moment of diagnosis (HR: 5; 95% IC (1-22); p=0.03).As far as toxicity is concerned, during induction therapy, only one infection G4 was reported. The G3 adverse events (AEs) most frequently reported were: anemia (1), asthenia (4), diarrhea (1), skin rash (2) and infections (4).In conclusion, this analysis shows that in high-risk SMM patients, early treatment with Len-dex as induction followed by Len as maintenance significantly prolonged the TTP to symptomatic disease (HR: 6· 0), resulting into a benefit in overall survival. In addition, tolerability is acceptable. Moreover, biological progressions occurring under maintenance have remained controlled over a prolonged period of time.

[9]Onyx Pharmaceuticals, South San Francisco, United States of America

Background. We have previously reported safety and efficacy data of the combination of CFZ, LEN (Revlimid®), and low-dose DEX (CRd) from a phase 1/2 study of patients with NDMM (Jakubowiak et al. ASH 2011, Abstract 631). CRd provided rapid reduction of disease (68%) after cycle 1, and after a median of 8 cycles, 94% of patients achieved ≥partial response (PR), including 65% with ≥very good PR and 53% with ≥near complete response (nCR). In patients who received at least 12 cycles of CRd, the rate of ≥nCR improved to 79%. The regimen was well tolerated. **Aims.** To examine the clinical impact of prolonged CRd treatment, including maintenance therapy. **Methods.** Patients with NDMM were treated in 28-day cycles with CFZ 20-36 mg/m^2 IV (d1, 2, 8, 9, 15, 16), LEN 25 mg PO (d1-21), and DEX 40/20 mg (cycles 1-4/5-8) PO weekly. After cycle 4, autologous stem cell transplant (ASCT) candidates achieving ≥PR could undergo stem cell collection but then continued CRd with the option to proceed to ASCT. After cycle 8, patients continued CRd on a maintenance schedule using the last tolerated doses, with LEN/DEX at the same schedule but a modified CFZ schedule (d1, 2, 15, 16). Response was assessed by IMWG criteria with the addition of nCR. **Results.** As of November 30, 2011, 53 patients were enrolled with a median follow-up of 14 months (range 4-25) and a median number of treatment cycles of 13 (range 1-25). Overall, 33 (62%) patients achieved ≥nCR with a stringent CR (sCR) rate of 42%. The rate of sCR improved with the duration of treatment. At the completion of 4 cycles, 41% of patients were in ≥nCR with only 6% in sCR. Of 36 patients who completed 8 cycles and continued with CRd maintenance, 72% were in ≥nCR with 64% in sCR. Minimal residual disease (MRD) was assessed by multiparameter flow cytometry in 22 patients in CR with no evidence of MRD in 20 (91%) of these patients. The progression-free survival (PFS) rate was 97% at 12 months and 92% at 24 months. All patients who achieved sCR have maintained response for a median of 9 months (range 1-20). Extended treatment with CRd was well tolerated. During CRd maintenance, the most common toxicities (all grades) were lymphopenia (30%), leukopenia (26%), and fatigue (25%). Peripheral neuropathy was infrequent (11%) and mild to moderate in severity (grades 1/2). There were no treatment discontinuations due to toxicity during maintenance and limited dose modifications (CFZ 19%, LEN 28%, DEX 31%).**Summary and Conclusions.** Data from this study indicate that after a rapid initial response, prolonged CRd treatment steadily improves the depth of response with most patients eventually achieving sCR and a significant proportion of patients without evidence of MRD. Responses were durable with very promising PFS. These results compare favorably to other frontline regimens and support further development of CRd in this setting.

0285

GMMG MM5 TRIAL IN NEWLY DIAGNOSED MULTIPLE MYELOMA TO EVALUATE PAD VS VCD INDUCTION PRIOR TO HDT FOLLOWED BY LENALIDOMIDE CONSOLIDATION AND MAINTENANCE - FIRST INTERIM ANALYSIS ON INDUCTION

H Goldschmidt[1], H Salwender[2], U Bertsch[3], T Hielscher[4], M Hänel[5], D Hose[3], A Jauch[3], J Dürig[3], I Blau[6], W Lindemann[7], H Bernhard[5], M Zeis[8], M Hoffmann[5], M Görner[5], K Neben[3], K Weisel[3], C Scheid[3]

[5]Klinikum, Chemnitz, Germany
[6]Charité, Berlin, Germany
[7]Kath. Krankenhaus, Hagen, Germany
[8]Asklepios Klinik St. Georg, Hamburg, Germany

Background. The MM5 phase III trial of the German-Speaking Myeloma Multicenter Group (GMMG) was designed to address two independent primary objectives: 1.) Demonstration of non-inferiority of VCD (bortezomib, cyclophosphamide, dexamethasone) induction compared to PAd (bortezomib, adriamycin, dexamethasone) induction therapy with respect to response rate (very good partial response or better). 2.) Determination of the best of four treatment strategies with respect to progression-free survival (PFS). The four treatment strategies are defined by PAd vs. VCD induction treatment, high dose melphalan followed by autologous stem cell transplantation and maintenance treatment with lenalidomide for 2 years vs. lenalidomide until complete response (CR). During the induction phase the patients are treated with 3 cycles of PAd or VCD. PAd was dosed as bortezomib 1.3 mg/m^2, days 1, 4, 8, 11, doxorubicin 9 mg/m^2, days 1-4, dexamethasone 20 mg, days 1-4, 9-12, 17-20 (repeated every 28 days). VCD consisted of bortezomib 1.3 mg/m^2, days 1, 4, 8, 11, cyclophosphamide 900 mg/m^2 day 1, dexamethasone 40 mg, days 1-2, 4-5, 8-9, 11-12 (repeated every 21 days). **Methods.** An interim analysis with respect to response rates after induction treatment and a safety analysis were done in the first 150 patients (75 per regimen) as described in the protocol. Responses were assessed according to the response criteria of the International Myeloma Working Group, IMWG. **Results.** Patients treated with PAd or VCD were equally distributed for ISS and Durie-Salmon disease stage, age, kidney function and the cytogenetic abnormalities translocation t(4;14) and gain 1q21. Deletion17p13 was found more frequently in patients of the PAd group (17.1% vs. 6.1%). Seventy-one of 75 patients (94.7%) in the PAd group and 74 of 75 patients (98.7%) in the VCD group completed induction treatment. Response rate was similar in both induction regimens (PAd vs. VCD) with complete response (8% vs 9.3%), ≥ very good partial response (40% vs. 34.7%) and ≥ partial response (78.7% vs. 78.7%). The proportion of patients with any adverse event was comparable in PAd versus VCD (66.2% vs. 69.3%), but more serious adverse events (SAEs) were observed during PAd induction (32.4% vs. 22.7%). VCD led to a significantly higher proportion of leukocytopenia and neutropenia CTCAE °3 and 4 (PAd: 9.5% vs. VCD: 40%). The number of infections (≥ CTCAE °2) was higher during PAd induction (31.1% vs. 13.3%). Compared to the infection rate (≥ CTCAE °2) of 49% during PAD (dexamethasone 40 mg days 1-4, 9-12, 17-20) in the HOVON65/GMMG-HD4-trial, a reduction in MM5 during induction is observed. **Conclusions.** Both induction treatments in the current MM5 trial show relevant efficacy and no early non-inferiority of VCD compared to PAd was shown. PAd and VCD are well tolerated with more than 90% of the patients receiving the three planned induction cycles.

[9]Nottingham University Hospitals, Nottingham, United Kingdom
[10]Western General Hospital, Edinburgh, United Kingdom
[11]Royal Devon and Exeter Hospital, Exeter, United Kingdom

Background. Bisphosphonates (BP) are a standard of care for patients with

osteolytic lesions from multiple myeloma (MM). The MRC Myeloma IX study revealed significant overall survival (OS) and progression-free survival (PFS) benefits for the intravenous amino-BP, zoledronic acid (ZOL) over oral clodronate (CLO) in patients with MM (N = 1960) initiating chemotherapy (Morgan GJ, et al. *Lancet.* 2010). This trial was designed to include BP therapy at least until disease progression, and may provide insights into long-term effects of BP treatment as well as discontinuation of BPs before or upon disease progression. **Aims.** To assess the potential effects of discontinuing BP (ZOL) treatment on PFS and OS in patients with MM. **Methods.** Newly diagnosed MM patients were randomized to ZOL (4 mg IV q 21-28 days) or CLO (1600 mg/day PO) plus antimyeloma therapy. BP therapy was to be continued at least until disease progression. PFS and OS were estimated using Kaplan-Meier methodology. Hazard ratios (HR) were calculated using stratified Cox models. Exploratory post hoc Cox regression models including BP discontinuation as a time-dependent variable were used to assess potential correlations between stopping BP treatment on-study and long-term PFS or OS in ZOL-treated patients. **Results.** The MRC Myeloma IX trial now has a median follow-up of 5.9 years in 1960 evaluable patients. Median duration of BP treatment was 380 days (interquartile range, 153-716 days) before disease progression. BP therapy was discontinued before documented disease progression in 272 patients (28%) in the ZOL group and 204 patients (21%) in the CLO group. Notably, rates of treatment discontinuation for renal insufficiency or renal failure were low and similar across groups (~5% in each). Disease progression or death was documented in 856 patients (87%) in the ZOL arm vs 867 patients (89%) in the CLO arm. Relative improvements in PFS and OS with ZOL vs CLO were 11% (HR = 0.89; *P* = .02) and 14% (HR = 0.86; *P* = .01) respectively. Trends for improved PFS and OS (from baseline and after disease progression) with ZOL vs CLO were maintained in patients receiving BPs for ≥2 years (n = 539) but were not statistically significant. Exploratory Cox models including discontinuation of BP as a time-dependent variable suggest that stopping BP therapy did not affect PFS (*P* = .88) or OS (*P* = .42) in the ZOL arm. **Conclusions.** PFS and OS improvements with ZOL vs CLO (from baseline and after documented disease progression) were maintained during long-term follow-up in the MRC Myeloma IX study. Exploratory analyses in the ZOL arm suggest that on-study discontinuation of BP therapy did not significantly affect outcomes, but should be interpreted with caution because the trial did not collect BP discontinuation data after disease progression (ie, for these exploratory analyses, all patients receiving BPs at the time of first documented disease progression were assumed to have continued BP treatment until death). Further studies are required to determine the optimal duration of BP treatment.

0287

PHASE I/II STUDY OF CARFILZOMIB PLUS MELPHALAN-PREDNISONE (CMP) IN ELDERLY PATIENTS WITH *DE NOVO* MULTIPLE MYELOMA

P Moreau[1], C Hulin[1], D Caillot[1], L Benboubker[1], M Tiab[1], N Blin[1], X Leleu[1], M Roussel[1], C Chaleteix[1], M Attal[1], JL Harousseau[2], T Facon[1], B Kolb[1]
[1]University Hospital, Nantes Cedex 01, France
[2]Institute of Cancerology, Saint Herblain, France

Background. Melphalan-Prednisone + Thalidomide (MPT) or Bortezomib (MPV) are approved in frontline MM patients (pts) >65 years. Both regimens demonstrated significant benefit over MP alone in terms of PFS and OS but this benefit could be hampered by the risk of peripheral neuropathy (PN). Carfilzomib (Cfz) is a novel proteasome inhibitor that has demonstrated promising activity and favorable toxicity profile, with low rates of PN. This phase I/II study was designed to determine the maximum tolerated dose (MTD) of CMP, to assess safety and evaluate efficacy of this combination in newly diagnosed MM >65.Methods: In Phase I, Cfz was the only escalating agent starting at 20 mg/m2 (level 1) with maximal planned dose 36 mg/m2 (level 3), given IV on days 1, 2, 8, 9, 22, 23, 29, 30 for nine 42-day cycles. Oral melphalan 9 mg/m² and prednisone 60mg/m² were given on days 1 to 4, for all dose levels. Based on toxicity assessment, the study was amended to add dose level 4 (Cfz 45 mg/m2). MTD determination was based on occurrence of Dose limiting toxicities (DLTs) during the first cycle only. DLTs were defined as any grade 4 hematologic toxicity or preventing administration of 2 or more of the 8 Cfz doses of the first treatment cycle except grade 4 thrombocytopenia without bleeding or grade 4 neutropenia lasting ≤ 7 days; or grade ≥ 3 febrile neutropenia; or any other grade ≥ 3 nonhematologic toxicity. **Results.** As of February 12th 2012, 24 pts have been enrolled in the phase I: 6 pts at level 1 (Cfz 20), 6 at level 2 (Cfz 27), 6 at level 3 (Cfz 36), and 6 at level 4 (Cfz 45). There were 2 DLTs at level 4 (fever and hypotension not related to sepsis) and the MTD was considered to be 36 mg/m². Then, 16 additional pts were included in the phase II at level 3. Overall, 40 pts have been enrolled into the phase I/II study. The protocol is ongoing, and results will be updated during the meeting. In the current report, the median number of cycles analyzed is 5 (2-9), and 28 patients are still on therapy. Thus, all patients received at least 2 cycles and were considered evaluable for response. The ORR was 92% including 40% at least VGPR. These results, probably underestimated due to the dose-escalation design of the study and ongoing therapy, compare favorably to those achieved with MPV, MPT, MPR or lenalidomide-dex (ORR 71, 76, 80 and 85%, respectively) in the same population of patients. **Conclusions.** Frontline carfilzomib (36 mg/m^2) + MP is a tolerable and very effective combination in elderly MM pts. Treatment is ongoing, with updated toxicity and efficacy data to be presented at the meeting.

Background. Patients with multiple myeloma (MM) relapsed/refractory after bortezomib and lenalidomide have limited treatment options and poor outcome. Pomalidomide and dexamethasone showed significant activity in this setting. The efficacy and safety of Pomalidomide in combination with Cyclophosphamide is unknown. **Aims.** This phase I/II study aimed to evaluate the safety and efficacy of Pomalidomide-Cyclophosphamide-Prednisone (PCP) in relapsed/refractory MM patients. **Methods.** We evaluated the maximum tolerated dose (MTD) and efficacy of Pomalidomide (4 dose levels: 1, 1.5, 2 and 2.5 mg/day) in combination with Cyclophosphamide (50 mg every other day) and Prednisone (50 mg every other day) for six 28-day cycles, followed by Pomalidomide-Prednisone as maintenance. Dose Limiting Toxicities (DLTs) were: grade 4 neutropenia>3 days, grade 4 thrombocytopenia, any grade 3-4 non-hematologic adverse events (AEs). The MTD was the dose that achieved a DLT in 25% of patients, according to the Bayesian Continual Reassessment Method. Patients who received 1-3 prior lines of therapy and were relapsed/refractory to Lenalidomide were eligible. All patients received aspirin or low-molecular weight heparin as thromboprophylaxis. **Results.** A total of 41 patients were enrolled. DLTs occurred in 1 patient at 1.5 mg (grade 4 thrombocytopenia) and in 3 patients at 2.5 mg (grade 3 neuropathy, grade 3 hepatic toxicity and grade 4 thrombocytopenia). The MTD was 2.5 mg with an estimated DLT probability of 0.258 (95% credibility interval: 0.101-0.468). Overall, 29 patients received 2.5 mg. Twenty-nine patients were evaluable. The median age was 69 years (41-80), 45% had ISS 2-3 and 21% was at high risk by FISH (presence of at least one of the following: t(4;14) or t(14;16) or del 17p13). Median time from diagnosis was 64 months. Patients had received a median of 3 prior regimens, including Lenalidomide (100%), Bortezomib (72%), Thalidomide (17%), stem cell transplant (38%). A partial response or better (ORR) was reported in 72% of patients, including 21% very good partial response and 7% complete response. A clinical benefit (ORR + minimal response + stable disease) was observed in 97% of the patients, including 8% of minimal response and 17% of stable disease. The ORR for patients who received ≤2 prior ther-

apies was 90%. In responding patients, median time to ORR was 2 months (range 1-6). After a median follow-up of 7.3 months, 24/29 patients (82%) are free of disease progression and 27/29 (93%) are alive. Toxicity consisted primarily in myelosuppression. Grade 4 AEs included neutropenia (17%), thrombocytopenia (7%) and thromboembolism (3%); grade 3AEs were rash (10%), peripheral neuropaty (3%), infections (3%). Discontinuations for toxicity were 10% (grade 3 hepatic, grade 4 central neurologic toxicity and thromboembolism). **Conclusions.** Pomalidomide in combination with Cyclophosphamide and Prednisone showed clinical activity with limited toxicities in patients relapsed/refractory to Lenalidomide. Updated data will be presented at the meeting.

0290

ESCALATED WEEKLY DOSE OF BORTEZOMIB WITH LENALIDOMIDE AND DEXAMETHASONE FOLLOWED BY LENALIDOMIDE MAINTENANCE IN FIRST RELAPSE OF MULTIPLE MYELOMA. INTERIM ANALYSIS OF THE HOVON 86 TRIAL

P Sonneveld[1], O De Weerdt[2], M Levin[3], W Ghidey[4], E Vellenga[5], S Wittebol[6], J Doorduijn[1], P Wijermans[7], MJ Kersten[8], G Bos[9], H Lokhorst[10]

[7]HAGA Hospital, The Hague, Netherlands
[8]AMC, Amsterdam, Netherlands
[9]Maastricht Medical Centre, Maastricht, Netherlands
[10]UMCU, Utrecht, Netherlands

Background. The combination of bortezomib (1.3 mg/m^2) and lenalidomide (10-25 mg) with dexamethasone (VRD) is effective in newly diagnosed and relapsed multiple myeloma (MM). Lenalidomide maintenance has been shown to prolong progression-free survival (PFS) but not overall survival (OS). **Aims.** This investigator-sponsored two-step phase 2 trial was designed to evaluate escalating dosages of bortezomib (B) given once weekly and daily lenalidomide (L) combined with weekly dexamethasone (D) (eVRD) followed by L maintenance in patients with first relapse MM. **Methods.** Dose levels were B 1.3 mg/m^2, L 10 mg, (level 1); B 1.6 mg/m^2, L 10 mg (level 2); B 1.6 mg/m^2, L 15 mg (level 3); B 1.6 mg/m^2, L 20 mg (level 4). Dexamethasone was dosed 20 mg days 1-2, 8-9, 15-16. Patients with symptomatic MM, aged 18-80 in first relapse after initial treatment were eligible. The primary endpoint was response (overall response (ORR), complete response (CR) according to IMWG criteria, serum free lite-negative CR (sCR), very good partial response (VGPR) and partial response (PR)) with PFS, OS and toxicity as secondary endpoints. **Results.** Eighty-one patients were included, i.e. 13 patients in dose levels 1, 2 and 3, followed by 68 patients in the phase 2 part. This interim analysis was performed on 13 patients in the dose escalation phase and 22 patients in phase 2. Median age was 66 years, with 62/33/5 per cent presenting with ISS stages I/II/III, respectively.The Maximum Tolerated Dose (MTD) was reached at dose level 3 when the maximum of 3 SAEs in 5 patients was observed. The second phase of the trial was performed at MTD minus 1 dose level, i.e. with weekly B 1.6 mg/m^2 for 3 weeks, L 10 mg days 1-21 and D 20 mg days 1-2,8-9,15-16 for 8 cycles of 28 days followed by L maintenance 10 mg days 1-21. The median number of cycles was 6 in the dose-escalation phase and 7 cycles in phase 2. 7/13 (62%) patients in the dose-escalation and 13/22 (59%) patients in phase 2 started lenalidomide maintenance. Full dose B/L was administered in 102/139(73%) and 125/139(90%) of cycles. Non-hematological toxicity included peripheral neuropathy (PNP) grade 2 in 14% of patients and grade 3 in 18%. The median time to first occurrence of PNP was 92 days. Gastro-intestinal symptoms grade ≤2 were observed in 36% of patients.At a median follow-up of 12.3 months, the overall response rate was 82% with 39% CR/nCR, 18% VGPR and 25% PR. Median time to response was 1.1 cycle. Actuarial PFS at 12 months was 70% and OS was 82%. Four patients died from MM and 2 from other causes. One second primary tumor was observed in dose level 3. FISH data are being completed to assess relative risks. **Summary and Conclusions.** Escalated VRD followed by Lenalidomide maintenance is effective and feasible in patients with first relapse MM. Responses are induced rapidly. This trial was registered as Eudract nr 2007-002533-37. Financial support was provided by the Dutch Cancer League KWF, Janssen and Celgene.

Background. The development of novel agents, including the proteasome inhibitor bortezomib, has resulted in dramatic improvements in survival for patients with multiple myeloma (MM). However, MM remains an incurable disease, and there continues to be a significant unmet need in the relapsed and refractory setting. Thus, there is considerable interest in the discovery of effective agents and combination strategies for patients with relapsed and refractory MM. Panobinostat is an oral pan-deacetylase inhibitor with synergistic antimyeloma activity in combination with bortezomib, which may occur through dual inhibition of both the aggresome and proteasome pathways. A phase Ib study of panobinostat and bortezomib demonstrated clinical activity (≥ minimal response) in 40 of 62 (64.5%) patients with relapsed or relapsed/refractory MM, with a recent phase II study confirming this activity in bortezomib refractory MM. **Aims.** The primary objective of PANORAMA 1, a global, randomized, double-blind, phase III study of panobinostat + bortezomib + dexamethasone versus placebo + bortezomib + dexamethasone, is to evaluate the impact of panobinostat on progression-free survival in patients with relapsed MM. Secondary endpoints include overall survival, response rate, safety, and quality of life. Here, we report the patient demographics and the updated results of a blinded safety analysis from this study. **Methods.** Patients (N = 762) with relapsed or relapsed/refractory MM (1-3 prior lines of therapy) have been enrolled in the trial. Patients with bortezomib-refractory MM were not eligible. The study is composed of 2 treatment phases and follow-up during and after treatment until disease progression. Treatment phase 1 consisted of eight 3-week cycles of panobinostat or placebo (20 mg, oral) administered thrice weekly and bortezomib (1.3 mg/m^2, intravenous) administered twice weekly for 2 of 3 weeks. Dexamethasone (20 mg, oral) was administered on days of and after bortezomib. Patients who achieved clinical benefit proceeded to treatment phase 2, which consisted of four 6-week cycles with similar administration of panobinostat and dexamethasone and a modified once-weekly bortezomib schedule. **Results.** Preliminary demographic and blinded safety data from the first 536 randomized patients and 525 treated patients are now available, with treatment ongoing in 257 patients (47.9%). Median age was 63 years (32-84 years). Approximately half of patients (51.7%) received 2-3 prior lines of therapy and 57.3% received prior stem cell transplant. Adverse events of any grade included thrombocytopenia (47.6%), diarrhea (45.7%), fatigue (32.6%), anemia (30.5%), constipation (24.8%), and nausea (24.4%). Common grade 3/4 adverse events were thrombocytopenia (36.2%), diarrhea (14.5%), anemia (13.0%), fatigue (12.2%), neutropenia (11.4%), and hypokalemia (11.0%). Of

interest, peripheral neuropathy was observed in 24.6% of patients at any grade and 5.3% of patients at grade 3/4. **Conclusions.** Preliminary review of blinded pooled safety data in 525 patients treated in PANORAMA 1 suggested a comparable safety profile with respect to previously published clinical experience with bortezomib + dexamethasone. The data monitoring committee recommended that the study continue as planned. Enrollment of 762 patients was completed in February 2012. Updated blinded safety data will be presented.

0292

CLINICAL AND MOLECULAR ANALYSIS OF BORTEZOMIB- AND THALIDOMIDE-INDUCED PERIPHERAL NEUROPATHY (PN) IN MULTIPLE MYELOMA (MM): ANALYSIS FROM THE GIMEMA-MMY-3006 TRIAL

P Tacchetti[1], C Terragna[1], F Patriarca[2], MT Petrucci[2], E Zamagni[1], G Rossi[2], M Offidani[2], F Narni[2], C Cellini[2], L Pantani[1], L Baldini[2], T Caravita di Toritto[2], C Nozzoli[2], L Masini[2], M Martello[1], D Derudas[2], V De Stefano[2], G Catania[2], A Pezzi[1], F Ferrara[2], F Nobile[2], M Baccarani[1], G Cavaletti[3], M Cavo[1]
[1]Seragnoli Institute of Hematology, Bologna, Italy
[2]GIMEMA Italian Myeloma Network, Udine, Italy
[3]Dept Neuroscience and Biomedical Technologies, Monza, Italy

Background. PN is an important complication of MM and its incidence has been further increased after the introduction of the novel agents thalidomide and bortezomib. **Aims.** We performed a subanalysis of the phase 3 GIMEMA-MMY-3006 trial aimed to assess clinical and molecular features of treatment-emergent PN, in newly diagnosed MM patients treated with Thalidomide-Dexamethasone (TD) or Bortezomib-TD (VTD) as induction therapy prior to, and consolidation after, double autologous stem-cell transplantation. **Methods.** The primary adverse event endpoint was treatment-emergent PN of at least NCI CTCAE grade 2, since grade 1 PN may be misinterpreted and does not interfere with daily activities. Overall, 474 patients (236 randomized to VTD and 238 to TD) were stratified according to the development of grade ≥2 PN. Gene expression profiles (GEP) of pre-treatment CD138+ bone marrow plasma cells were analyzed in a subset of 122 VTD-treated patients (44 with and 78 without treatment-emergent grade ≥2 PN). **Results.** Occurrence of PN was higher in VTD arm compared to TD. In particular, the rate of grade ≥2 PN was 35% vs 10% ($p<0.001$), and grade ≥3 was 15% vs 2.5% ($p<0.001$), respectively. The median time to onset of grade ≥2 PN was 83 days on VTD and 37.5 days on TD ($p=0.04$) and most of the events occurred during the induction phase (52% on VTD and 71% on TD). PN resolved in 88% of patients on VTD and 95% on TD within a median time of 73 and 61 days, respectively. In both arms, development of grade ≥2 PN did not adversely affect rates of complete or near-complete response, time to progression and progression free survival. By univariate analysis, baseline patient characteristics, including age, MM isotype, ISS stage, cytogenetic abnormalities, and pre-existing neuropathy, were not predictive for treatment-induced PN in both arms. By GEP analysis, grade ≥2 VTD-induced PN was characterized by 1461 differentially expressed probe sets ($p<0.05$, one-way ANOVA Partek Genomic Suite, version 6.4), 690 up-regulated and 771 down-regulated. The genes with the highest changes in expression arrays included genes that are etiologically linked to the development and function of the nervous system such as *NRN1* and *BASP1*. GeneGO® pathway analysis of differentially expressed genes showed enrichment of genes mainly implicated in cytoskeleton remodeling (*MAP3k1*, *XIAP*, *ACTA2*), and clathrin-coated vesicle cycle (*VAMP7* and *AP2A2*). Moreover, analysis of biological networks showed involvement of genes implicated in regulation of cytoskeleton rearrangement, neurogenesis and axonal guidance (*TNK2, ARHGAP4, ARGEF12, ACTA2, SEMA6A, SEMA4D, EPHA5, NEFH, DCTN1, DCX*). **Conclusions.** VTD incorporated into double ASCT was associated with a higher incidence of PN compared with TD. Treatment-emergent PN was reversible in the majority of patients in both arms and did not adversely affect treatment efficacy and outcomes. No relationship between development of PN and both patient demographics and disease characteristics was observed. Conversely, GEP results provide new insight into potential molecular mechanisms underlying VTD-induced PN and suggest a correlation with a myeloma genetic profile characterized by the significant deregulated expression of genes involved in the cytoskeleton rearrangement and nervous system development and function.

[5]Hospital de Donostia, San Sebastián, Spain
[6]Millennium Pharmaceuticals, Inc., Cambridge, United States of America
[7]Winship Cancer Institute of Emory University, Atlanta, United States of America

Background. MLN9708 is an investigational oral, potent, reversible, and specific 20S proteasome inhibitor undergoing clinical investigation for the treatment of hematologic malignancies and solid tumors. The proteasome inhibitor bortezomib in combination with melphalan plus prednisone (MP) is recommended for patients with previously untreated multiple myeloma (MM) that are not eligible for transplant. Here we report phase 1 results of the first study of MLN9708 in combination with MP in patients with previously untreated MM (NCT01335685). **Aims.** To determine the safety, maximum tolerated dose (MTD), recommended phase 2 dose (RP2D), pharmacokinetics (PK), pharmacodynamics (PD), and anti-tumor activity of MLN9708 administered once- or twice-weekly in combination with MP in patients with previously untreated MM. **Methods.** Adults with previously untreated MM with measurable disease but ineligible for transplant were enrolled. All patients provided informed consent. Patients received twice-weekly (TW) or weekly (W) oral MLN9708: TW schedule, MLN9708 on days 1, 4, 8, 11, 22, 25, 29, and 32, and MP (9 mg/m^2 and 60 mg/m^2, respectively) days 1-4 of 42-day cycles; W schedule, MLN9708 on days 1, 8, and 15 and MP (6 mg/m^2 and 60 mg/m^2, respectively) days 1-4 of 28-day cycles. Dose-escalation proceeded from a fixed dose of 3 mg in both schedules using a standard 3+3 schema based on the occurrence of dose-limiting toxicities (DLTs) in cycle 1. **Results.** At data cut-off (Jan 27, 2012), 13 patients had been enrolled and included in the safety population, 7 to the TW (3 mg and 3.7 mg dose levels), and 6 to the W (3 mg and 4 mg dose levels) schedules. Median age was 78 years (range 65-84) and 73 years (range 66-81) for the TW and W schedules, respectively; 29% and 50% were male, and 71% and 83% had ISS stage I/II disease. Patients are ongoing on treatment, with a median duration of treatment of 2.2 cycles for the TW and 3 cycles for the W schedule at time of data cut-off. One patient receiving 3.7 mg TW experienced DLTs of subileus and grade 3 rash. The MTD for MLN9708 has not been reached for either schedule. Safety data are shown in the Table 1.

Table 1.

	MLN9708 TW (n=7)	MLN9708 W (n=6)
Drug-related AEs, n (%)	7 (100)	6 (100)
Most common drug-related AEs, n (%)		
Neutropenia	4 (57)	4 (67)
Thrombocytopenia	4 (57)	4 (67)
Pyrexia	3 (43)	1 (17)
All-cause grade ≥3 AEs, n (%)	7 (100)	4 (67)
Drug-related grade ≥3 AEs, n (%)	6 (86)	2 (33)
Most common drug-related grade ≥3 AEs, n (%)		
Neutropenia	3 (43)	2 (33)
Thrombocytopenia	2 (29)	0 (0)
Serious AEs, n (%)	3 (43)	2 (33)
Discontinuations due to PD, n (%)	1 (14)	0 (0)
On-study deaths, n	0	0

Most common drug-related grade ≥3 adverse events (AEs) were neutropenia and thrombocytopenia; neutropenia occurred in 5 patients (3 on the TW schedule and 2 on the W schedule) and thrombocytopenia in 2 patients (both on the TW schedule). Three TW patients experienced drug-related serious AEs of neutropenia, subileus, vomiting, and pneumonia; 2 patients had serious AEs with W MLN9708, both unrelated. Thus far, of 6 TW response-evaluable patients, 4 patients achieved ≥PR (2 at each dose level, including 1 CR). Of 5 W response-evaluable patients, 3 achieved a PR. Dose escalation is ongoing.

Updated data, including assessment of PK interaction, will be presented. **Conclusions.** These preliminary phase 1 data suggest that weekly and twice-weekly MLN9708 in combination with MP is generally well tolerated with manageable toxicities. Preliminary anti-tumor activity in patients with previously untreated MM was observed.

Background. Vorinostat (VOR) is an oral, multi-histone deacetylase inhibitor that affects pathways regulating cell proliferation and apoptosis in various tumor types. Phase 1/2 trials in MM have indicated clinical activity of VOR as both a single agent and in combination with bortezomib (BTZ) and immunomodulatory drugs (IMiDs). **Aims.** This global, open-label, single-arm, multicenter, phase 2b study was designed to determine efficacy and tolerability of oral VOR in combination with standard doses of BTZ in MM patients considered refractory to novel myeloma agents (eg, BTZ and IMiDs). **Methods.** Eligible patients were ≥18 years, received ≥2 prior regimens, and were BTZ-refractory (<25% response on therapy, progression during or <60 days after completion of therapy) and refractory to, intolerant of, or ineligible for IMiD-based therapy regimens. Patients received 21-day cycles of BTZ (1.3 mg/m^2 intravenously; days 1, 4, 8, 11) + oral VOR (400 mg/d; days 1-14); oral dexamethasone 20 mg on the day of and day after each dose of BTZ could be added to patients with progressive disease after 2 cycles or no change after 4 cycles. The primary endpoint was overall response rate (ORR; ≥ partial response). Responses and progression were determined according to the IMWG and the EBMT criteria for MM; efficacy data were confirmed by an independent adjudication committee. Patients were treated until disease progression, unacceptable toxicities, or withdrawal of consent, and monitored for safety. **Results.** A total of 143 patients were enrolled from 41 centers in 12 countries. In this heavily pretreated population, median duration of MM was 4.7 years, and 69% had received ≥4 prior regimens. Consistent with protocol inclusion criteria, all patients were considered refractory to prior BTZ. Of enrolled patients exposed to IMiDs, 99.3% had received ≥1 IMiD, 87% were considered refractory to ≥1 and 40% refractory to ≥2 different IMiDs, and 3% were ineligible for further IMiD-based therapy. ORR was 16.9%, with median duration of response of 170 days, corresponding to median progression-free survival of 3.13 months (95% CI: 2.40, 4.33); clinical benefit rate (≥ MR response) was 31.0%. Median overall survival (OS) was 11.23 months (95% CI: 8.47, 14.43), with a 2-year survival rate of 32%. Frequently reported adverse events were thrombocytopenia (69.7%), nausea (57.0%), diarrhea (53.5%), anemia (52.1%), and fatigue (48.6%); the overall safety profile was consistent with BTZ and VOR. Median exposure to study medication was 4 cycles, but in the absence of early disease progression patients tolerated the study treatment up to a mean of 6.2 cycles (range: 1-26). **Summary and Conclusions.** The combination of VOR + BTZ is active in MM patients refractory to novel treatment modalities and offers a new therapeutic option for this difficult-to-treat patient population. Additional high-risk and OS subgroup analyses will be presented at the meeting.

0295

A PHASE I/II TRIAL OF CYCLOPHOSPHAMIDE, CARFILZOMIB, THALIDOMIDE AND DEXAMETHASONE (CYCLONE) IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

J Mikhael[1], C Reeder[1], E Libby[2], L Costa[3], A Mayo[1], L Bergsagel[1], F Buadi[4], N Pirooz[1], J Lubben[1], A Dueck[1], A Stewart[1]
[1]Mayo Clinic Arizona, Scottsdale, United States of America
[2]University of Washington/Fred Hutchison Cancer Research Center, Seattle, United States of America
[3]Medical University of South Carolina, Charleston, United States of America
[4]Mayo Clinic Rochester, Rochester, United States of America

Background. Carfilzomib is a proteasome inhibitor that irreversibly binds its target with a favorable toxicity profile that has shown significant activity in relapsed multiple myeloma (MM). Here we combined carfilzomib with a well known international regimen of cyclophosphamide-thalidomide-dexamethasone (CTD) in patients eligible for stem cell transplant (SCT). This would also reserve both bortezomib and lenalidomide for later in the course of the disease. **Methods.** We conducted a Phase I safety run in 6 patients with no DLT observed before expanding to Phase II. The phase II regimen is shown below. Treatment was for 4 cycles with expected SCT post induction. For the phase II portion of this trial, the primary endpoint is the proportion of patients who have ≥very good partial response to treatment. All patients received herpes zoster prophylaxis and ASA daily.Treatment schema was as follows on a 28 day cycle:Carlfilzomib 20 mg/m^2 cycle 1 (27 mg/m^2 ≥ cycle 2) IV Days 1,2,8,9,15,16Thalidomide 100 mg PO Days 1-28Cyclophosphamide 300 mg/m^2 PO Days 1,8,15Dexamethasone 40 mg PO Days 1,8,15,22**. Results.** Twenty seven patients were enrolled. Median age was 65 (range 27-74). Best overall response rate during 4 cycles of CYCLONE for evaluable patients (n=19) at phase II dosing is 100%: CR 32%, VGPR 47%, PR 21%. Grade 3 toxicity was reported in 52% of patients and 19% experienced grade 4 toxicity. Grade 3/4 toxicities occurring in >5% of patients included fatigue, neutropenia, lymphopenia, thromboembolism, and generalized muscle weakness. Two cases of pneumonia required hospitalization. Toxicities of any grade seen in >20% of patients included fatigue, constipation, lethargy, thrombocytopenia, somnolence, neutropenia, increased creatinine, malaise, sensory neuropathy, and depressed level of consciousness. Seven patients (26%) developed grade 1 sensory neuropathy; no higher grade or painful neuropathy was evident. All but one patient advancing to SCT successfully collected stem cells. One patient with t(4;14) disease who was not transplanted has progressed and one has died. **Conclusions.** The 4 drug CYCLONE regimen has remarkable efficacy (79% ≥VGPR, 100% ≥PR) and manageable toxicity in newly diagnosed patients with multiple myeloma. Especially notable was the low incidence of neuropathy and depth of response (CR 32%) after only 4 cycles. Given the relative lack of toxicity an extension of this regimen at higher doses of carfilzomib (20/45mg/m^2) has been initiated. Adding carlfilzomib to CTD as induction therapy is feasible and effective.

0296

INCORPORATION OF THALIDOMIDE-DEXAMETHASONE INTO DOUBLE AUTOTRANSPLANTATION FOR MULTIPLE MYELOMA: UPDATED ANALYSIS WITH A LONG-TERM FOLLOW-UP

M Cavo[1], F Di Raimondo[2], E Zamagni[1], F Patriarca[2], L Catalano[2], N Testoni[1], F Casulli[2], S Volpe[2], C Terragna[1], Angelucci[2], L Masini[2], A Ledda[2], A Brioli[1], P Galieni[2], A Pezzi[1], C Califano[2], A Gozzetti[2], C Cellini[2], B Zannetti[1], P Tosi[2]
[1]Seragnoli Institute of Hematology, Bologna, Italy
[2]Bologna 2002 Study Italian Myeloma Network, Catania, Italy

Background. Recent incorporation of novel agents into autologous stem-cell transplantation (ASCT) has enhanced the rate of high-quality responses, PFS and, albeit less frequently reported, OS. However, a limited number of studies assessing these outcomes with a long-term follow-up have been reported so far. **Aims.** To address this issue, we performed an intention-to treat analysis of 357 newly diagnosed MM patients who were followed for a median of 7 years from starting thalidomide-dexamethasone (TD) and subsequent double ASCT. **Methods.** Details of this multicenter phase 2 study were previously reported (Cavo et al, *J. Clin. Oncol* 2009). TD was given from the outset until the second ASCT. The cut-off date for the present analysis was December 31, 2011. **Results.** The rate of CR-nCR and ≥VGPR to induction therapy was 14.85% and 31.37%; the corresponding values after double ASCT were 36.69% and 60.78%. The median duration of CR was 53.1 months. Overall, median values of PFS and OS were 47.2 and 109.6 months, respectively. In addition to standard poor prognostic variables at baseline, both del(13q) (PFS: p=0.0001, OS: p=0.0002) and t(4;14)±del(17p) (PFS: p=0.0073, OS: p=0.0028) adversely affected clinical outcomes, the worst prognosis being associated with del(17p) [4-year PFS and 8-year OS estimates, 10% each vs 31% and 43%, respective-

ly, for patients who carried t(4;14) but lacked del(17p)]. Patients with del(13q) alone had a higher risk of relapse or progression (54% and 76% at 4 and 8 years) than those without any cytogenetic abnormality (p=0.0339), but similar PFS and OS curves due to the favourable effect of salvage therapies (median post-relapse OS: 30 vs 31 months, respectively). On multivariate analysis, failure to ever achieve at least VGPR, low Hb, high β2-m and t(4;14)±del(17p) were found to be independent variables predicting for poorer outcomes. In particular, a shorter OS was seen for patients ever lacking high-quality responses (HR: 0.35, 0.23-0.54, p<0.0001) and with t(4;14)±del(17p) (HR: 0.51, 0.33-0.79, p=0.0030). Overall, 20% of patients survived for more than 8 years; their median duration of CR was 77.5 months and the 8-year PFS estimate was 47%. The 8-year OS rate after relapse or progression was 72%, as compared with a median of 23 months for non long-term survivors (p<0.0001). On multivariate Cox and logistic regression analysis, attainment of high-quality responses predicted for, and was independently associated with, long-term survival (HR: 0.027, p=0.0050). **Conclusions.** With a median follow-up of 7 years, TD plus double ASCT extended PFS and OS up to the median values of 4 and 9 years, respectively. The corresponding figures with VAD plus double ASCT (Cavo et al, *J Clin Oncol* 2007), as updated at this meeting with a median follow-up of 5 years, were 3 and 6 years. Despite these advances, high-risk cytogenetics, particularly del(17p), retained their adverse influence on prognosis. Long-term (>8 years) OS probability was in the 20% range, with sustained CR in 24% of patients. Achievement of high-quality responses was the most important and independent variable affecting long-term OS. Prolonged survival after relapse was a contributing factor to long-term OS.

0297

CLINICAL FEATURES AND OUTCOME OF NEWLY DIAGNOSED, SYMPTOMATIC PATIENTS WITH MULTIPLE MYELOMA =80 YEARS OF AGE: AN ANALYSIS OF THE GREEK MYELOMA STUDY GROUP

[10]Gennimatas General Hospital, Athens, Greece
[11]University of Patras, Patras, Greece

Background. Multiple myeloma (MM) is mainly a disease of the elderly and it has become common to treat patients of ≥80 years of age. However, octogenarians are often excluded from clinical trials due to comorbidities, very poor performance status or socioeconomic reasons. **Aims.** To describe the disease characteristics and identify prognostic factors in MM patients ≥80 years of age. **Methods.** We searched the database of the Greek Myeloma Study Group to identify patients with symptomatic myeloma who were ≥80 years of age at the time of initial therapy and who were treated in the novel agent era (between 1/1/2003 and 31/12/2010.) **Results.** Among 682 patients we identified 155 (23%) patients ≥80 years of age. Most octogenarians were males (57%) and had a poor ECOG performance status (PS ≥2) (60%); 70% had lytic bone disease, 53% anemia (Hb<10 mg/dl), 17% low platelet counts (<130x10^9/L), 11% elevated serum LDH (≥300 IU/L), while 59% had ISS-3, 34% ISS-2 and only 7% had ISS-1 MM (p=0.001). RI was common: 31% had serum creatinine ≥2 mg/dl but 63% had an eGFR <60 ml/min and 32% an eGFR <30 ml/min. When compared to patients <80 years of age, octogenarians had more often poor PS (p=0.001), anemia (p=0.006), elevated serum creatinine and low eGFR (p<0.001), low serum albumin (p<0.001) and elevated beta2-microglobulin (p<0.001). Upfront therapy with novel agents was given in 49% of octogenarians *vs*. 70% of patients <80 years (p<0.001). Response to first line therapy (≥PR) was lower in patients ≥80 years (58% *vs.* 78%; p<0.001). The median survival of patients ≥80 years was 22 months *vs.* 46 months for patients 66-79 years and 81 months for patients ≤65 years (p<0.001). Among octogenarians, 14% died ≤2 months from initiation of therapy *vs.* 3% for patients ≤80 years. In the univariate analysis, poor PS (16 months *vs.* 29 months, p<0.001) and elevated LDH ≥300 IU/L (9.4 *vs.* 27.5 months, p=0.016) were associated with poor survival in octogenarians. There were no significant differences in the characteristics of patients who were treated with novel agents or with conventional chemotherapy (CC). The median survival of octogenarians who were treated upfront with CC was 17 months *vs.* 26 months (p=0.3) for those who received upfront novel agents. Early death rates were similar. In an analysis, that excluded patients who died early (<2 months), response to first line therapy was associated with improved survival (29 *vs.* 16 months, p<0.001). In multivariate analysis, poor PS was the most important prognostic factor; upfront therapy with novel agents was independently associated with improved survival (HR: 0.64, 95%CI: 0.41-0.98, p=0.042), while male gender and ISS-3 MM were independently associated with poor survival. **Conclusions.** Patients ≥80 years of age with symptomatic myeloma often present with high risk features. Their median survival is <2 years and early mortality is high. Upfront use of novel agents is associated with significant survival benefit; however, reduced doses and aggressive supportive care are needed in order to reduce early mortality and to improve safety and patients' survival.

0298

SAFETY PROFILE AND MANAGEMENT IN MM-015 COMPARING LENALIDOMIDE-MELPHALAN-PREDNISONE FOLLOWED BY LENALIDOMIDE MAINTENANCE (MPR-R) WITH MP AND MPR IN NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM)

M Delforge[1], M Dimopoulos[2], Z Adam[3], R Hajek[3], Z Yu[4], L Herbein[4], C Jacques[4], A Palumbo[5]
[1]Katholieke Universiteit Leuven, Leuven, Belgium
[2]University of Athens School of Medicine, Alexandra Hospital, Athens, Greece
[3]University Hospital Brno, Brno, Czech Republic
[4]Celgene Corporation, Summit, United States of America
[5]University of Torino, Torino, Italy

Background. Lenalidomide is an IMiD® immunomodulatory agent with a dual mechanism of action comprised of tumoricidal and immunomodulatory effects. MM-015 is a pivotal, phase 3, randomized, double-blind, placebo-controlled trial comparing MPR-R with MP and MPR in transplant-ineligible NDMM patients. Interim results demonstrated significant median progression-free survival (PFS) improvements with MPR-R (31 months) vs. MP (13 months; *P*<.001) or MPR (14 months; *P*<.001). **Aims.** This analysis focused on the MM-015 safety profile and adverse event (AE) management; median follow-up was 41 months. **Methods.** Treatment details have been presented (Palumbo A, et al. *Blood*. 2011). AEs were graded according to the National Cancer Institute Common Terminology Criteria for AEs (V.3.0). For grade 4 hematologic and ≥ grade 3 non-hematologic AEs, treatment was withheld for the remainder of the cycle and restarted at a lower dose in subsequent cycles. Granulocyte colony-stimulating factor (G-CSF) or erythroid-stimulating agents were encouraged for grade 4 neutropenia or anemia. All patients received low-dose aspirin or other thromboprophylaxis where aspirin was contraindicated.

Table 1. Grade 3-4 hematologic and non-hematologic adverse events occurring in ≥ 10% of patients.

Treatment Arm	MPR-R		MPR		MP	
Age, years	65-75 (n = 114)	> 75 (n = 36)	65-75 (n = 116)	> 75 (n = 36)	65-75 (n = 116)	> 75 (n = 37)
Any hematologic, n (%)	90 (79)	33 (92)	86 (74)	32 (89)	58 (50)	18 (49)
Neutropenia	81 (71)	28 (78)	72 (62)	28 (78)	37 (32)	10 (27)
Thrombocytopenia	43 (38)	16 (44)	48 (41)	14 (39)	16 (14)	5 (14)
Anemia	27 (24)	12 (33)	27 (23)	16 (44)	22 (19)	4 (11)
Febrile neutropenia	5 (4)	5 (14)	3 (3)	1 (3)	0 (0)	0 (0)
Any non-hematologic, n (%)	64 (56)	23 (64)	59 (51)	26 (72)	50 (43)	18 (49)
Infections	10 (9)	7 (19)	14 (12)	8 (22)	10 (9)	5 (14)
Hypokalemia	3 (3)	4 (11)	2 (2)	4 (11)	0 (0)	1 (3)

Results. A total of 152, 153, and 154 patients were randomized to MPR-R, MPR, and MP, respectively. Grade 3-4 non-hematologic AEs occurring in ≥10% are listed (Table 1). During induction in the MPR-R, MPR, or MP arms, G-CSF was used in 100 (67%), 87 (57%), and 46 (30%) of patients. Only 1%, 4%, and 1%, respectively, discontinued any drug due to neutropenia. Regarding thrombocytopenia, no bleeding events were reported. Platelet transfusions were required by 51 (34%), 41 (27%), and 25 (16%) of MPR-R, MPR, and MP patients, respectively. Discontinuation of any drug for thrombocytopenia was infrequent: 3%, 5%, and 0%. With thromboprophylaxis, grade 3-4 deep-vein thrombosis (DVT) occurred in 3% (lenalidomide-treated) patients and 1% (MP) during induction. Discontinuation from induction due to AEs occurred in 16% (MPR-R), 14% (MPR), and 5% (MP) of patients. During lenalidomide maintenance, newly occurring or worsening grade 3-4 AEs were infrequent. Grade 4 neutropenia and thrombocytopenia were reported in 2/88 (2%) and 5/96 (6%), respectively. There were no reports of grade 3-4 febrile neutropenia or bleeding events. G-CSF was administered to 27 (31%) patients; 9 (10%) patients

received platelet transfusions. During maintenance, DVT was reported in 2 (2%) MPR-R and 1 (1%) MPR patients. Only 8% discontinued lenalidomide maintenance due to AEs. For induction and maintenance, discontinuation of any drug due to neutropenia was infrequent (2%, 4%, and 1%, for MPR-R, MPR, and MP, respectively). Similarly, only 3%, 5%, and 0% of patients discontinued any drug due to thrombocytopenia. Twelve (MPR-R), 10 (MPR), and 4 (MP) invasive second primary malignancies were reported, corresponding to low incidence rates per 100 patient-years of 3.04, 2.57, and 0.98, respectively. **Conclusions.** MPR induction AEs were manageable with dose reductions, G-CSF, and platelet transfusions, allowing the majority of patients aged 65-75 years to proceed to maintenance phase. Lenalidomide maintenance was generally well-tolerated in these patients with little evidence of cumulative toxicities, permitting continuous long-term therapy. In all patients, MPR-R treatment significantly extended median PFS vs. fixed-dose MP and MPR (*P*<.001 for both comparisons).

0299

LONG TERM SURVIVAL (> 10 YEARS) AFTER UP-FRONT SINGLE OR DOUBLE AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA: RESULTS FROM A PROSPECTIVE CLINICAL TRIAL

E Zamagni[1], P Tosi[2], A Pezzi[1], C Cellini[2], P Tacchetti[1], S Ronconi[2], S Volpe[2], L Pantani[1], L Catalano[2], M Fiacchini[1], A Gozzetti[2], F Narni[2], A Lazzaro[2], M Baccarani[1], M Cavo[1]
[1]Seragnoli Institute of Hematology, Bologna, Italy
[2]Bologna '96 Study Italian Myeloma Network, Rimini, Italy

Background. Survival of patients with multiple myeloma (MM) has been extended with the introduction of autologous stem cell transplantation (ASCT). More recently, availability of highly effective novel agents has further improved patient outcomes. However, it is still the matter of debate whether a proportion of patients treated with ASCT can enjoy a long term survival (> 10 years) while sustaining prolonged high quality response. **Aims.** A large multicentre prospective clinical trial of single versus double ASCT was conducted in Italy from January 1996 to December 2001. To more carefully evaluate long-term clinical outcomes and to identify those variables which were related to long-term survival we performed a post-hoc analysis.*Methods:* A total of 321 patients were randomly assigned to receive either a single or double ASCT, as previously described (Cavo M et al, JCO 2007). Results were updated as of 30 December 2011 and compared with those previously reported. All the analyses were performed on an intention-to-treat basis. **Results.** After a median follow-up of 61 months for the entire treatment population and 120 months for survivors, both TTP and PFS remained significantly longer with tandem versus single ASCT (median 41 vs 25 months, P= 0.004 and 37 vs 25 months, P= 0.012, respectively), while OS was similar in the two groups (median 71 vs 67 months). Median OS after relapse or progression was 35 months in the entire population. 47% and 33% of the patients in the double and single ASCT group achieved a CR+nCR. Overall, in 24% and 11% of the patients CR+nCR was sustained for more than 5 and 10 years, respectively. In a multivariate Cox regression analysis, best response (CR+nCR) ever achieved was the most important variable significantly extending PFS (P= 0.003) and OS (P=0.050); random assignment to double ASCT was an additional variable predicting for prolonged PFS(P= 0.026). Overall, 23% of patients were alive over 10 years (long-term survivors). Median TTP and PFS of long-term survivors were 73 and 74 months, respectively, versus 26 and 25 months for the rest of the population (P= 0.0000). Median duration of CR+nCR was 70 months in the long-term survivors group in comparison with 21 months in the remaining patients (P= 0.0000). The 10-year estimate of OS after relapse or progression in this subgroup of patients was 58%, in comparison to a median value of 24 months for the control group (P= 0.0000). In a logistic regression analysis, best response ever achieved (CR+nCR) (OR: 1.8, 1.06-3.01, P= 0.03), haemoglobin level greater than 10 g/dL (OR: 2.0, 1.04-3.90, P= 0.04) and platelets count greater than 150.000/mmc (OR: 5.3, 1.59-17.66, P= 0.007) at diagnosis were independent variables predicting for long term survival. **Conclusions.** Twenty three per cent of the patients undergoing up-front single or double ASCT without novel agents were alive after 10 years from start of treatment, with 25% of patients remaining relapse free. Attainment of CR+nCR was the leading independent variable predicting for long-term OS. Prolonged survival after relapse was a contributing factor to long-term OS.

Background. Defects in T cell function in cancer patients might influence their capacity to mount efficient anti-tumor responses to therapeutic vaccines. Previously, tumor infiltrating T cells (TILs) in patients with follicular lymphoma (FL) have been shown to have impaired immunologic synapse formation and T cell receptor signaling. **Aims.** 1) Identify effector cytokine signaling pathways specifically suppressed in FL TILs. 2) Determine whether T cell inhibitory receptors are differentially expressed on FL TILs. **Methods.** Single cell flow cytometry measurements of cytokine signaling were acquired for lymph node specimens from patients with FL (N=22), diffuse large B cell lymphoma (DLBCL; N=12) and mantle cell lymphoma (MCL; N=22). For comparison, blood samples from healthy donors (N=6) or from patients with chronic lymphocytic leukemia (CLL; N=14) were included. Phosphorylation of STATs were measured after activation with cytokines IL-4, IL-7, IL-10 or IL-21 in $CD3^+CD5^+$ T cells or in different T cell subsets using additional markers, including CD4, CD8, CD45RO, CD62L and PD-1. **Results.** We identified impaired IL-4-induced phosphorylation of STAT6 as well as impaired IL-10- and IL-21-induced phosphorylation of STAT3 in FL TILs as compared to DLBCL, MCL, CLL and healthy T cells. By combining phospho-protein specific flow cytometry with several T cell subset markers, we identified that CD4 T effector memory cells (T_{EM}; $CD62L^-CD45RO^+$), the major T cell subset present in malignant FL lymph nodes, was largely non-responsive to cytokines. This was not a general feature of $CD4T_{EM}$ cells since the majority of peripheral blood CD4 T_{EM} cells from FL patients could respond normally to cytokines. We observed high expression of the inhibitory receptor PD-1 in FL TILs, but not in autologous peripheral blood T cells in patients without leukemic disease. Importantly, detection of PD-1 expression in combination with p-STAT6 in FL LN samples stimulated with IL-4 revealed that $PD\text{-}1^{hi}$ FL TILs had lost their responsiveness, whereas $PD\text{-}1^-$ cells within the same sample had normal cytokine signaling responses. FL tumor cells were negative for PD-L1 and PD-L2, but tumor-infiltrating macrophages were $PD\text{-}L1^+$. Furthermore, disruption of the tumor microenvironment and *in vitro* culture for at least 24 hours was sufficient to restore cytokine signaling capacity in $PD\text{-}1^{hi}$ FL TILs, indicating that TILs *in vivo* seem to be getting the negative message through PD-1. **Conclusions.** FL TILs had impaired signaling downstream of key effector cytokines, including IL-4, IL-10, and IL-21. As the suppressed cytokine signaling was associated high expression of PD-1, our results suggest that therapies blocking PD-1 signaling activity might benefit FL patients.

MOLECULAR CHARACTERIZATION OF IMMUNOGLOBULIN GENE REARRANGEMENTS IN DIFFUSE LARGE B CELL LYMPHOMA: A POSSIBLE ROLE FOR ANTIGEN SELECTION

E Sebastián
Hospital Universitario de Salamanca, Salamanca, Spain

Background. Diffuse large B cell lymphoma (DLBCL) is an aggressive lymphoma that accounts for about 40% of adult B cell non-Hodgkin lymphomas (B-NHLs). However, ~25-30% of adult B-NHLs remain as DLBCL not otherwise specified (NOS). Immunostaining approaches allow these entities to be classified into GCB or non-GCB subtypes based on their presumed cell of origin. However, DLBCL pathogenesis remains partially unknown and the molecular features of immunoglobulin heavy chain (IGH) rearrangements may provide important information about the ontogeny and the role of antigen selection in DLBCL B cells. **Aims.** To study the IGH gene repertoire, mutation features,

and the stereotyped VH CDR3 patterns in order to contribute to a better understanding of the ontogeny and biology of DLBCL. **Patients and Methods.** A total of 165 patients diagnosed with DLBCL, NOS were included. Clonal IGH rearrangements were amplified according to the BIOMED-2 protocol and PCR products were directly sequenced. Germline IGH genes from complete IGHV-IGHD-IGHJ (V-D-J) and partial IGHD-IGHJ (D-J) rearrangements were identified using public IMGT/V-QUEST and BLAST databases, respectively. The canonical criteria for somatic hypermutation (SHM) (*Messmer et al. Blood 2004*) were analyzed in the global series as well as in the DLBCL subtypes and the most common IGHV genes. The criteria for stereotyped patterns (*Darzentas et al. Leukemia 2010*) in all complete VDJ sequences were carried out. **Results and Discussion.** Partial D-J rearrangements were present in 68/165 (41%), with 12% of them mutated (cut-off, 2%). Complete V-D-J rearrangements were identified in 130/165 (79%) patients. Most cases (89%) were highly mutated, but 12 sequences were truly unmutated or minimally mutated (100% or 97-99.9% germline identity, respectively). SHM was consistent with the canonical criteria, suggesting that the conventional machinery for mutations is used. A strong bias at the IGHV gene usage was observed, with IGHV4-34, IGHV3-23 and IGHV4-39 genes accounting for 1/3 of the cohort. The IGHV4-34 gene was overrepresented in our series (15.5% overall), appearing at a higher frequency than in normal B cells (3.9%, p<0.01). Finally, six cases were found to bear stereotyped sequences, three of them belonging to previously described subsets.Patients showing IGHV4-34 rearrangements shared several common features: 1) all but one were highly mutated; 2) all belonged to the non-GCB subgroup; 3) those in whom sequence could be obtained from the leader region conserved the specific FR1 motif (W7 and AVY 24-26), implying that these cells may retain the ability to bind to and be activated by superantigens, despite intense SHM activity. **Conclusions.** In DLBCL, IGHV gene usage is biased and bear stereotyped sequences, which imply an antigen-driven origin. The particular features in the sequence of the immunoglobulins suggest the existence of different biological subgroups within the non-GCB subtype. Their frequency and their possible clinical significance in DLBCL need to be analyzed in large independent series, which should be considered for future international collaborative efforts.

Background. MicroRNAs are small RNA molecules that play an important role in micromanaging gene expression. They have been strongly implicated in the pathogenesis of a variety of lymphomas. Their remarkable stability in both paraffin embedded formalin fixed (FFPE) tissue and peripheral blood make them excellent candidates as novel prognostic and disease response biomarkers with wide-spread applicability across lymphoma types. **Aims**. a) To identify microRNAs that are differentially expressed between a range of malignant and benign lymph nodes; b) To test whether highly expressed lymphoma-associated microRNAs had potential as circulating prognostic and disease response biomarkers in patients with high-risk DLBCL patients receiving R-CHOP chemo-immunotherapy. **Methods**. Agilent microRNA array (v2 and v3 chips) was performed on 23 DLBCL, 24 post-transplant lymphoma proliferative disorder (PTLD), 14 Hodgkin Lymphoma (HL) and 8 benign lymph nodes. A false discovery rate cut-off of 0.005 was applied. Real-time (RT-PCR) was used to confirm array findings. MicroRNAs consistently over-expressed in malignant nodes, regardless of histologic type, were then quantified in plasma using real-time RT-PCR, using a miR *Cel-39* spike in for normalisation. Plasma was obtained from patients enrolled into ALLG's prospective NHL21 study. This is a phase II clinical trial of high-risk DLBCL (IPI 2-5 and/or bulky disease), in which blood samples are taken at fixed time-points pre-therapy and post-cycle 4 of R-CHOP at time of interim PET/CT. 110 patients have been recruited to date. Informed consent was obtained for all trial participants. **Results.** miR-638 and miR-494 were consistently up-regulated across DLBCL, PTLD and HL nodes as compared to a benign lymph node signature. Levels of microRNAs 638 and 494 were markedly increased in the plasma of patients with high-risk DLBCL compared to normal controls (p<0.001 and p=0.003). Patients remaining PET/CT FDG-avid at the interim time-point had significantly higher pre-therapy plasma microRNAs (p=0.036) compared to patients who achieved a negative interim-PET/CT. Similarly at post-cycle 4, microRNAs were higher in those with a positive interim-PET/CT. **Summary and Conclusions.** A number of microRNAs are consistently differentially expressed between malignant and benign lymph node tissue. Circulating cell-free microRNAs in patients with high-risk DLBCL receiving R-CHOP show promise as prognostic and disease response biomarkers.

QUANTITATIVE ASSESSMENT OF DAPK1 PROMOTER METHYLATION IN FOLLICULAR LYMPHOMA IS A PREDICTIVE PARAMETER OF DISEASE OUTCOME

M Giachelia, V Bozzoli, F D'Alò, G Massini, MC Tisi, E Maiolo, F Guidi, MT Voso, G Leone, S Hohaus
Università Cattolica del Sacro Cuore, Rome, Italy

Backgroud. Transcriptional silencing of tumor suppressor genes, due to aberrant promoters' methylation, is a common epigenetic event in B-cell Lymphomas, including Follicular Lymphoma (FL). Using a qualitative analysis, we have previously reported that promoter hypermethylation of the pro-apoptotic death-associated kinase-1 (DAPK1) is a frequent epigenetic alteration in FL and correlates with an unfavorable outcome. **Aims**. The aim of our study was to study whether quantification of DAPK1 methylation levels could provide additional and more accurate prognostic information. **Methods.** We retrospectively studied 107 patients (49 males and 58 females), diagnosed at our Institution for FL in the period 2001-2011 of whom 91 patients were treated with immunochemotherapy (63 R-CHOP, 8 R-CVP, 11-R-FM, 9 other). DAPK1 promoter methylation, was determined on BM specimens by Methylight-PCR. As controls we included normal BM specimens obtained from 10 patients with ITP (Idiopathic Thrombocytopenic Purpura) and 10 PB samples from healthy volunteers. Quantitative results are expressed as percentage of methylation and the lower limit of detection of our assay was 0,1%.

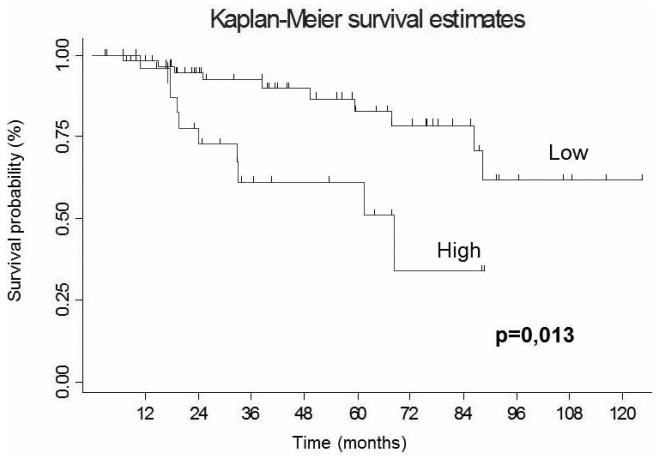

Figure 1. Unadjusted Kaplan-Meier plot of EFS according to DAPK1 methylation levels (high, >1.64%). p value of log-rank test is adjusted for treatment.

Results. In line with ourprevious data, we found DAPK1 promoter methylation in 73,8% of bone marrow samples of FL patients at diagnosis, while no methylation was found in our control group. The quantitative analysis demonstrated significantly higher methylation levels in patients with bone marrow infiltration (*p=0.0003*). Methylation levels were lower in patients with low risk disease according to both FLIPI and $FLIPI_2$ score (FLIPI 0-1 vs other: median 0,23% vs 0,53%; *p=0,0014*; $FLIPI_2$ 0 vs other: median 0,25% vs 1,12%; *p=0,025*). Levels of DAPK1 methylation were also associated to low histological grade (G1-G2 vs G3; medians: 0,41% vs 0,17%; *p= 0,004*). Bcl2/Igh rearrangement was present in 43.8% of our population, but no correlation was observed with DAPK1 methylation levels (bcl2/IgH positive vs bcl2/IgH negative; medians: 0.41% vs 0.24%; *p=0,35*). Interestingly, we found a significant higher level of methylation in patients not reaching Complete Remission (CR) after immunochemotherapy (*p=0,012*), suggesting a prognostic role for DAPK1 as epigenetic biomarker. Dividing in quartiles, methylation levels above the 75° percentile value of 1,64% predicted a significantly poorer outcome in terms of EFS (HR 3,2; 95% CI, 1,3-7,80; p=0,013 Figure 1; analysis adjusted for treat-

ment regimen). Including the FLIPI score into a multivariate analysis high levels of DAPK1 methylation (>1,64%) retained their impact on EFS as independent risk factor (HR: 2,8; 95% CI, 1,1-7,3; p=0,03). **Conclusions.** Our study indicates that the quantitative analysis of DAPK1 promoter methylation is a promising biomarker for Follicular Lymphoma, with prognostic impact on patients' outcome.

0304

LEVELS OF THE AUTOPHAGY ADAPTOR PROTEIN P62/SQSTM1 ARE NEGATIVELY CORRELATED WITH BCL-2 EXPRESSION IN HUMAN FOLLICULAR LYMPHOMA

C Mc Carthy, J Clear, G Gribben, C Jia
Barts Cancer Institute, London, United Kingdom

The autophagy adaptor protein p62/SQSTM1 delivers autophagy substrates, including itself, to autophagosomes for degradation. Accumulation of p62 within cells is therefore a marker of autophagy deficiency and elimination of p62 by autophagy has previously been proposed to suppress tumourigenesis. Since previous studies have suggested that the anti-apoptotic protein Bcl-2 can also inhibit autophagy, this study aimed to determine if Bcl-2 overexpression in human follicular lymphoma (FL) results in autophagy inhibition. We used p62 protein levels as a marker of autophagy and compared levels of p62 between FL and non-malignant reactive controls to ascertain the autophagy status of these cells.Using tissue microarrays (TMAs), p62 protein expression levels were determined in 156 reactive lymph node controls, 283 diagnostic FL and 154 matched relapse FL cores. By comparison to reactive lymph node controls, diagnostic and relapsed FL patients showed significantly decreased expression of p62 in germinal centres ($p < 0.001$). Bcl-2 positive FL patients (n=61) showed significantly reduced expression of p62 compared with Bcl-2 negative patients (n=25, $p < 0.001$). However, p62 expression levels neither predicted nor correlated with overall survival or time to relapse in FL patients.To examine this in more detail and to examine the cellular localisation of p62 in FL, levels of p62 and LC3-II, the generic autophagy marker, were examined in primary FL and reactive lymph node cells by Western blotting. Results showed an increased expression of LC3-II and decreased p62 expression in primary FL cells compared to reactive lymph node controls. The intracellular distribution of LC3 and p62 within FL and reactive lymph node cells was determined by immune-fluorescent microscopy. FL cells displayed higher numbers of LC3 punctate (LC3-II) and a diffuse distribution of p62, indicating active autophagy. However, LC3 staining of reactive control cells showed a diffuse, cytoplasmic pattern indicating non-autophagic LC3 (LC3-I) while greater numbers of larger p62-containing speckles were detected in these reactive cells. Together, these results demonstrate that FL patients have increased autophagy activity compared with reactive lymph node controls. We find no evidence to support an anti-autophagic role of Bcl-2 in primary FL cells.We therefore propose that overexpression of Bcl-2 in FL is negatively associated with p62 protein levels, suggesting that Bcl-2 does not inhibit autophagy in FL cells. Moreover, FL p62 protein levels are not associated with clinical outcome. Increased autophagy activity within FL may enhance resistance to chemotherapy.

0305

CKS1 IS REQUIRED FOR TUMOR CELL PROLIFERATION BUT NOT SUFFICIENT TO INDUCE HEMATOPOIETIC MALIGNANCIES

A Höllein[1], S Kratzat[2], F Bassermann[2], C Miething[2], V Nikolova[2], S Schoeffmann[2], C Peschel[2], L Quintanilla-Fend[3], J Duyster[2], U Keller[2]
[1]Technische Universität München, Klinikum Rechts der Isar, München, Germany
[2]III. Medical Department, Technische Universität München, München, Germany
[3]Institute of Pathology, Eberhard-Karls-Universität Tübingen, Tübingen, Germany

Background. Cks1 is an activator of the SCFSkp2 ubiquitin ligase complex that targets the cell cycle inhibitor p27Kip1 for degradation. Loss of Cks1 results in p27Kip1 accumulation and decreased proliferation. Cks1 expression is elevated in various B cell malignancies including Burkitt lymphoma and multiple myeloma. We have previously shown that loss of Cks1 results in elevated p27Kip1 levels and delayed tumor development in a mouse model of Myc-induced B cell lymphoma. Surprisingly, loss of Skp2 in the same mouse model also resulted in elevated p27Kip1 levels but exhibited no impact on tumor onset. **Aims.** To test the hypothesis that Cks1 has yet unknown p27Kip1-independent functions in controlling cell cycle progression and to investigate the intrinsic ongogenic activity of Cks1 to induce hematopoietic disorders. **Methods.** Mouse embryonic fibroblasts of Cks1-/- and p27-/- genetic backgrounds were examined regarding growth, cell cycle distribution, Cyclin/CDK status and CDK activity. To challenge the oncogenic role of Cks1 we have overexpressed Cks1 in the hematopoietic system using a retroviral bone marrow transduction-transplantation system. **Results.** We identify a function of Cks1 in mammalian cell cycle regulation that is independent of p27Kip1 and other SCFSkp2 regulated CKIs. Specifically Cks1-/-; p27Kip1-/- mouse embryonic fibroblasts still show defects in the G1-S phase transition that are coupled with decreased Cdk2-associated kinase activity, and defects in proliferation that are associated with Cks1 loss. Furthermore, concomitant loss of Cks1 does not rescue the tumor suppressor function of p27Kip1 that is manifest in various organs of p27Kip1-/- mice. By contrast, defects in mitotic entry and premature senescence of Cks1-/- cells are p27Kip1 dependent. Regarding the oncogenic activity of Cks1 we show that despite potent ectopic overexpression, Cks1 was unable to promote B cell hyperproliferation, B cell lymphomagenesis, or to induce myeloid malignancies. This was at variance with c-Myc overexpression, which caused acute myeloid leukemia. **Conclusions.** Our studies reveal p27Kip1-independent functions of Cks1 in the regulation of the G1-S transition and an important role for Cks1 in tumor cell proliferation. Despite being overexpressed and associated with a poor prognosis in various hematological malignancies, sole Cks1 expression is insufficient to induce lymphoma or a myeloproliferative disease *in vivo*.

0306

HOST GENETIC POLYMORPHISMS IN TNF ALPHA, LYMPHOTOXIN ALPHA, AND IL-10 INFLUENCE RISK OF DIFFUSE LARGE B-CELL LYMPHOMA

O Yri[1], PO Ekstrøm[1], V Hilden[1], K Liestøl[2], G Gaudernack[1], E Smeland[1], H Holte Jr.[1]
[1]Oslo University Hospital/Institute for Cancer Research, Oslo, Norway
[2]University of Oslo/Department of Informatics, Oslo, Norway

Background. Polymorphic variants in genes encoding cytokines and involved in immune responses may alter the host's capability to fight cancer development. Tumor necrosis factor alfa (TNFa), lymphotoxin alfa (LTA), and interleukin-10 (IL-10) are key proteins involved in the regulation of immune responses and have potent effects on several types of immune cells. Polymorphisms in genes encoding these proteins have been studied with regard to how these polymorphisms may influence the risk of developing lymphoma and the response to lymphoma treatment in different populations. Altered risk for diffuse large B-cell lymphoma (DLBCL) have been found for specific variants of these genes, however, the numbers of included patients and controls are often small and the effect size often varied and conflicting. **Aims.** To investigate the impact of single nucleotide polymorphisms (SNPs) in selected cytokine genes on risk for developing DLBCL in a large population cohort. **Methods.** We genotyped 448 DLBCL patients (age 18-83 years) and 1056 blood donors as controls for polymorphisms in the genes *TNFa* (rs1800629, rs361525), *LTA* (rs909253), and *IL-10* (rs1800890, rs1800896), using PCR-amplification for the gene segments of interest and constant temperature capillary electrophoresis for analysis of the genotypes. **Results.** The *TNFa* rs1800629 A-allele was associated with increased risk of DLBCL (*TNFa* AG/AA combined vs. GG; OR 1.59 (1.27-2.00), p<0.001). The *LTA* G-allele, and *IL-10* rs1800896 A-allele were associated with decreased risk of DLBCL (*LTA* AG/GG vs. AA; OR 0.76 (0.60-0.95), p= 0.02, *IL-10* rs1800896 AT/AA vs. TT; OR 0.76 (0.59-0.98), p=0.04). For the *IL-10* SNPs, the control group was not in Hardy-Weinberg equilibrium, thus the interpretation of the results for the SNP *IL-10* rs1800896 should be made with caution. **Summary and Conclusions.** An increased susceptibility for DLBCL by polymorphisms in genes encoding TNFa, LTA and IL-10 was confirmed in a large cohort of patients and controls. The results support previous findings in other populations, and add evidence to the link between dysregulation of immune responses and risk of developing lymphoma.

Table 1.

A HUMAN LYMPHOMA TH17 CELL LINE MODEL

S Ehrentraut[1], B Schneider[2]
[1]DSMZ, Braunschweig, Germany
[2]Universität, Rostock, Germany

Ehrentraut S, Schneider B, Nagel S, Quentmeier H, Kaufmann M, Meyer C, Kadin ME, Drexler HG, MacLeod RAFT-helper(Th)17 cells play key roles in autoimmune disease, notably psoriasis, Crohn's disease, juvenile diabetes, multiple sclerosis, and rheumatoid arthritis. Existing Th17 models are largely mouse based. Although the characteristics of human Th17 cells remain less well defined, it is apparent that human and mouse Th17 cells diverge both in their respective origins (CD161+ *vs* CD161- cells), and polarizing cytokines (IL-1β + IL-23 *vs* IL-6 and IL-1). Here we describe the characterization of a set of human cutaneous lymphoma cell lines deriving from a common T-cell clone to serve as a human *in vitro* model for those investigating Th17 biology. The donor patient initially presented with benign lymphomatoid papulosis followed later by Hodgkin lymphoma for which he received radiation treatment. Progressive skin disease returned, subsequently developing into a cutaneous T-cell lymphoma when the first cell line (MAC-1) was established. Two years later the patient developed a fatal anaplastic large cell lymphoma, from which two additional cell lines (MAC-2a and MAC-2b) were established. Microarray transcription analysis, validated by real time PCR, revealed that all three cell lines displayed conspicuous expression profiles highlighting genes expressed in T-effector cells. One terminal-phase cell line (MAC-2A) bore unmistakeable stigmata of Th17 cells, including conspicuous expression of IL-6, IL-17F, IL-22, ROR-a, STAT3 and TGFb. Prominent Th17 cytokine secretion was confirmed by ELISA and shown to be contingent upon JAK-STAT signalling. IL-17F expression was regulated by IL-6 signalling as reported in physiological conditions, since IL-6 receptor blockade effected by Tocilizumab treatment was accompanied by severe IL-17F downregulation. Conversely, when accompanied by treatment with the DNA methyltransferase inhibitor 5-azacytidine, exposure of chronic-phase MAC-1 cells to IL-6 stimulated IL-17F expression. Similar effects were produced by treatment with IL-2, a cytokine not hitherto implicated in Th17 development. Thus, MAC-1 cells display plasticity reminiscent of naïve T-cells and, together with MAC-2A cells present key aspects of T-effector cell development. Aryl hydrocarbon receptor (AHR) signaling reportedly supports IL-17 expression, and experiments performed on MAC cell lines confirmed the potential role of AHR signaling in IL-17 regulation. As well as providing an insight into human Th17 biology, our data support parallels between lymphoma development and T-cell polarization. We propose that analysis of MAC cells may reveal novel potential therapeutic targets and an *in vitro* model with which to test their druggability.

0308

INCIDENCE AND CHARACTERIZATION OF ADDITIONAL CHROMOSOMAL ABNORMALITIES IN MANTLE CELL LYMPHOMA (MCL) BY G-BANDING AND MOLECULAR CYTOGENETIC APPROACH.

F Oliveira, A Rodrigues-Alves, F Silva, V Lipoli, R Falcão
Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil

Background. Mantle cell lymphoma (MCL) is a distinct subtype of malignant lymphoma characterized by the translocation t(11;14)(q13;q32), resulting in overexpression of cyclin D1 and cell cycle dysregulation. Additional chromosomal abnormalities are present in 55~60% of patients and are associated with a potential role in the oncogenic process. **Aims.** We applied *G-banding*, FISH and spectral karyotype analysis (SKY) to better characterize the cytogenetic profile of secondary chromosomal abnormalities in 96 samples of blastoid MCL. **Methods.** Bone marrow and peripheral blood cells were used for *G-banding*, FISH and SKY analysis. Metaphase cells were obtained by using standard procedures and the subsequent cytogenetic analysis and interpretation of the data were made according to the ISCN (2009). FISH for detection of t(11;14)(q13;q32), including probes for del(6q), 8q23 rearrangements, del(13q)(*RB1* 13q14), and del(17p) *TP53* was performed on samples. Additionally we applied SKY analysis for those patients with complex karyotype (≥ 3 abnormalities). In order to confirm the molecular consequence of t(11;14)(q13;q32) and 8q23 rearrangements we evaluated the expression profile of cyclin D1 and *MYCC*, by real time PCR. **Results.** Secondary chromosomal abnormalities were present in 81.2% of patients. Structural abnormalities were more frequently observed than numerical (71,8% and 28,1%, respectively). Most of the structural rearrangements included balanced translocations. Abnormalities involving 6q (deletions and balanced translocations) represented 40.6% of the cases (n=39), by *G-banding* analysis. 6q abnormalities were also confirmed by FISH and those cases with complex karyotype we used SKY. On the other hand, deletions of 13q14 were observed in 45.8% of the patients (n=44), and FISH identified heterozygous deletions of *RB1* in all samples (n=44). Additionally, rearrangements involving 8q23 band represented 21.8% of the patients (n=21). However, among the profile of 8q23 rearrangements obtained, only ten patients presented Burkitt's like translocations [t(2;8)(p12;q24) and t(8;14)(q24;q32)]. *MYCC* hyperexpression was noted only in samples with t(2;8)(p12;q24) and t(8;14)(q24;q32). The remaining samples that displayed 8q23 rearrangements (n=11), we found normal levels of *MYCC*, compared with controls. Deletions of 17p were observed in 7 patients, by *G-banding* analysis. However, FISH for *TP53* identified loss of this gene in 14 samples investigated. SKY analysis and FISH helped to clarify the cytogenetic profile of samples with complex karyotype, including those, whose chromosome morphology was not suitable for *G-banding*. **Conclusions.** In conclusion, our findings demonstrate that the combination of *G-banding* and molecular cytogenetic approach, as for example FISH and SKY are important for detection and better characterization of secondary abnormalities in MCL. We noted that some specific abnormalities, such as 6q, 8q23 rearrangements and del(13q)(*RB1* 13q14) were more frequently observed in our samples than other studies involving secondary/additional chromosomal abnormalities in MCL, and reflect a consequence of genomic instability, disease progression and poor prognosis. This finding has important implications to predict outcome in MCL and should be considered in routine hematology laboratories.Financial support: FAPESP (Proc. 2007/52462-7 and 2011/01647-2).

HAIRY CELL LEUKEMIA CELL LINES DISPLAY B-CELL RECEPTOR SIGNALS CHARACTERISTIC OF PRIMARY TUMOR CELLS BUT LACK THE SIGNATURE BRAF MUTATION TO REVEAL UNREPRESENTATIVE ORIGINS

N Weston-Bell[1], D Hendriks[1], G Sugiyarto[1], N Bos[2], J Kluin-Nelemans[2], F Forconi[1], S Sahota[1]
[1]University of Southampton, Southampton, United Kingdom
[2]University of Groningen, Groningen, Netherlands

Background. In rare diseases such as Hairy cell leukemia (HCL), tumor-derived cell lines provide important models to study disease characteristics. A number of HCL derived cell lines have been generated and used successively to study key aspects of cellular function. Validation of these cell lines as representative of primary HCL disease remains incomplete. Recently the *BRAF* V600E mutation was established as a diagnostic molecular marker for typical HCL, identified in >99% of 350 HCL cases, mainly as a heterozygous mutation. **Aims.** To validate HCL cell lines as disease models of HCL by assessing B-cell receptor (BCR) function and the *BRAF* V600E mutation. **Methods.** We examined 6 HCL cell lines: Hair-M, HCLL-7876, EH, Eskol, HC-1 and HCLv-07. Surface marker and immunoglobulin (Ig) phenotype was performed by flow cytometry. Response to BCR stimulation with isotype specific goat $F(ab')_2$-anti-human Ig antibodes was assessed by measuring release of intracellular Ca^{2+} using fluo3-AM. ERK phosphorylation was assayed using the BD Phosflow method. Apoptosis was determined using ApoStat or Apo2.7 assays. For functional comparisons, tumor cells were selected in primary HCL by $CD19^+$, $CD11c^{HI}$, $CD103^+$ gating. *IGHV* genes were amplified from mRNA, cloned and sequenced. *BRAF* V600E mutation was analyzed in gDNA and mRNA by amplification and Sanger sequencing. **Results.** All cell lines expressed a single pre- or post- switched isotype, together with disease associated markers CD11c and CD103, although at a level of expression generally lower than in primary tumors, and were CD27 negative to mirror primary hairy cells. A single clonal somatically mutated *IGHV* gene was identified in 6/6 cell lines, again paralleling findings in the bulk of HCL tumors. BCR signals mediated Ca^{2+} flux and ERK phosphorylation in 4/4 cell lines, and in 2/2 lines were shown to trigger a marked apoptosis. These features recapitulated findings following BCR stimuli in primary HCL tumors, the data revealing that BCR function in cell lines is comparable to HCL disease. Strikingly however, we found that the *BRAF* V600E mutation was absent in all 6 cell lines, while readily confirmed in 4/4 primary s-HCL tumors. This reveals a clear divergence in the origin of the cell lines when compared with primary HCL. **Conclusions.** Although phenotype and BCR function in these cell lines reflects key features of primary malignant cells, the absence of the signature *BRAF* mutation clearly raises questions about their reliability as representative tools for the study of HCL disease. The findings furthermore illustrate the relevance and significance of molecular insights from next generation sequencing of tumor genomes when evaluating disease models.

[3]Department of Pathology, Oslo University Hospital,, Oslo, Norway
[4]Department of Informatics, University of Oslo, Oslo, Norway
[5]Department of Immunology, Institute for Cancer Research, Oslo University Hospit, Oslo, Norway

Background. Epigenetic changes are increasingly recognised as an important mechanism for altered gene expression in malignant cells. Altered DNA-methylation patterns may serve as biomarkers for cancer detection, assessment of prognosis, and prediction of response to therapy. **Aims.** Identify epigenetically regulated genes in B-cell lymphoma. **Methods.** We generated gene expression profiles from 11 B-cell lymphoma cell lines treated with 5-aza-2'deoxycytidine and trichostatin A and their normal counterparts. Further we analyzed the gene expression profiles of Non-Hodgkin-Lymphoma patients (n=638) and healthy controls (n=5). Epigenetically regulated candidate genes were subject to further analysis by methylation-specific PCR (MSP), bisulfite sequencing and quantitative MSP. **Results.** In the present study we identified epigenetically regulated genes by comparing gene expression profiles of 5-aza-2'deoxycytidine- and trichostatin A-treated cell lines to their untreated counterparts. Further we matched the upregulated genes after an epigenetic treatment with the gene expression profile of NHL patients and healthy controls. Only genes which were downregulated in patients and upregulated after epigenetic treatment in cell lines were subjected to further studies.We analyzed the methylation status of 30 candidate genes in lymphoma cell lines. Moreover, eight genes with a methylation frequency over 70% in cell lines were validated in NHL patients (n=56) and healthy controls, representing various stages of B-cell development. Preliminary results indicate that those genes are methylated in B-cell lymphoma patients and show no promoter methylation in healthy controls. We further analyzed the prognostic value of the candidate genes and found a correlation to survival. **Conclusions.** In conclusion, our results demonstrate that the analyzed genes might be suitable for early detection and monitoring of NHL.

MOLECULAR CHARACTERIZATION OF THE 6Q23-27 REGION IN SEZARY SYNDROME

K Izykowska[1], P Grabarczyk[2], F Braun[2], M Delin[2], M Möbs[3], M Beyer[3], W Sterry[3], C Schmidt[2], G Przybylski[1]
[1]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland
[2]Clinic for Internal Medicine C, University Greifswald, Greifswald, Germany
[3]Department of Dermatology and Allergy, Skin Cancer Center, Charité - Universität, Berlin, Germany

Background. Sezary's syndrome (SS) is a rare form of cutaneous T-cell lymphoma characterized by erythroderma and the presence of Sezary cells (CD3+, CD4+, CD8-) in skin, lymph nodes, and peripheral blood. Chromosomal instability is characteristic of this lymphoma and related to bad prognosis, but no specific abnormalities that may be directly involved in the development of the disease have been found yet. Over the past few decades cytogenetic and molecular cytogenetic findings revealed many genetic alterations in patients with SS, including recurrent losses in the 6q region, which is frequently altered in different cancer types and might carry genes important in oncogenesis. Detailed molecular characterization of DNA changes has the potential to reveal genes being deregulated and possible gene fusions. **Aims.** The purpose of this project was to analyze the 6q23-27 region at the molecular level in 12 Sezary syndrome patients and Sezary syndrome cell line (SeAx). **Methods.** High resolution Fine-Tiling Comparative Genomic Hybridization (FT-CGH) was performed for the 6q23-27 region and deletions were detected in 6 patients and SeAx cell line. Previous studies had shown that copy number changes detected by the FT-CGH, might be associated with small structural aberrations, like inversions or translocations, at the breakpoint. In order to sequence each breakpoint and identify possible rearrangements, samples with deletions were further analyzed by Ligation-Mediated PCR (LM-PCR). Moreover, in two samples paired-end next-generation sequencing was performed on the HiSeq2000 Illumina platform. **Results.** Using those techniques 37 breakpoints were characterized (28 in SS patients and 9 in SeAx), and 21 new rearrangements were identified, including 7 simple deletions, 8 inversions, 3 translocations (with chromosomes 3, 10 and 12) and 3 transpositions. 14 genes were disrupted as a result of those rearrangements, and two of them: oncogene *MYB* and *IL22RA2*, were affected more than once. **Conclusions.** In summary, the combination of FT-CGH and LM-PCR, as well as the high-throughput paired-end sequencing approach revealed numerous different rearrangements, including inversions and translocations, associated with the deletions in the 6q23-27 region in Sezary syndrome. Further studies are needed to unravel the effect of the identified alterations on the biology of SS cells and their possible role in the malignant transformation.

0312

ONO-WG-307, A POTENT INHIBITOR OF BRUTON'S TYROSINE KINASE (BTK), INDUCES TUMOUR SUPPRESSION IN ABC-DLBCL (TMD-8) XENOGRAFT MODEL

T Yoshizawa[1], R Kozaki[1], T Yasuhiro[1], S Hotta[1], J Birkett[2], M Narita[1], K Kawabata[1]
[1]Ono Pharmaceutical Co., Ltd, Osaka, Japan
[2]Ono Pharma UK, London, United Kingdom

Background. Bruton's tyrosine kinase (Btk) is a key regulator of B-cell receptors (BCR), which play a central role in signal transduction pathways regulating survival, activation, proliferation, and differentiation of B-lineage lymphoid cells. Abberant BCR signaling is implicated in the survival of malignant B-cells and recent studies indicate that targeting Btk may be effective in the treatment of B-cell lymphoma. **Aims.** ONO-WG-307 is a highly potent and selective Btk inhibitor with an IC50 in the sub-nmol/L range. The activated B-cell-like (ABC) subtype of diffuse large B-cell lymphoma (DLBCL) is associated with poor prognosis and new therapies, preferably chemo-sparing therapies, or as add-on to existing treatment regimens, are required to help treat patients with ABC-DLBCL. Therefore, Btk constitutes an interesting therapeutic target, thus the activity of ONO-WG-307 was evaluated in an ABC-DLBCL xenograft model. **Methods**. TMD-8 tumour cells were implanted subcutaneously into female SCID mice and ONO-WG-307 was administered orally, twice a day (BID) at doses of 1 mg/kg, 3 mg/kg and 10 mg/kg. Treatment with ONO-WG-307 was initiated when the mean tumour volumes reached 100-200mm^3. In order to investigate the activity of ONO-WG-307 in more established tumours, ONO-WG-307 was administered at a dose of 10 mg/kg BID in animals with mean tumour volumes of 300-400 and 500-600 mm^3. Animals were euthanized when the tumours reached a maximum volume of 2,000 mm^3 or after a maximum period of 2 months. **Results.** Treatment with ONO-WG-307 resulted in a dose-dependent inhibition of tumour growth in the TMD-8 xenograft model. Furthermore, parallel analysis of a pharmacodynamic marker using peripheral blood mononuclear cells (PBMCs), measuring phosphorylated Btk (P-Btk), further supported that Btk was inhibited and the level of P-Btk inhibition was correlated with the observed decreased tumour volumes in the TMD-8 model. **Conclusions.** ONO-WG-307 is a highly potent and selective oral Btk inhibitor with evidence of efficacy in the ABC-DLBCL TMD-8 xenograft model, with Btk inhibition further supported by using a PD marker from PBMCs. Given the need to treat and overcome disease resistance especially in ABC-DLBCL, the use of a Btk inhibitor is a novel, mechanistic approach to treating B-cell malignancies and these results warrant further development of ONO-WG-307 in clinical studies. Additional combination studies are underway using the TMD-8 xenograft model testing ONO-WG-307 in combination with various agents.

0313

LYTIC PHASE REPLICATION OF EPSTEIN-BARR VIRUS IN REPLICATION COMPETENT LEUKEMIA/LYMPHOMA CELL LINES

C Uphoff[1], J Weste[2], S Denkmann[1], H Drexler[1]
[1]Leibniz Institute DSMZ, Braunschweig, Germany
[2]University of Magdeburg, Magdeburg, Germany

Epstein-Barr virus (EBV) is widespread in human populations and associated with diverse malignant tumors, including Burkitt, Hodgkin and T/NK-cell lymphoma, nasopharyngeal and gastric carcinoma. EBV is also widely used for the *in vitro* immortalization of human B-cells to establish B-lymphoblastoid cell lines (B-LCL). The gammaherpesviruses persist latently in the form of covalently closed circular episomes in B-cells, expressing various latent phase genes. In a number of B-LCL or EBV-infected leukemia/lymphoma cell lines a fraction of the cells enter the lytic phase of infection, producing active viruses spontaneously or after induction with particular stimuli. The mechanisms of virus reproduction, especially the formation of the packaged linear virion DNA from the circular episomes, are not well understood. The linear genomes are characterized by repetitive terminal sequences at the 5´- and 3´-end of the EBV genome. Until now, a concatemeric replication of the episomal DNA was postulated according to the appearance of terminal repeat (TR) regions of variable length

reflecting the numbers of repetitive exons. To determine which cell lines are able to enter the lytic phase of reproduction, we applied different methods to differentiate cell lines restricted to the latent phase from those containing cells in the lytic phase. In contrast to latent phase cell lines all cell lines with lytic cells showed a laddering in Southern blots, resulting from viral genomes with different numbers of TRs. Hybridizing the blots with probes from the 5´- or 3´-prime end of the EBV genome revealed free DNA ends with TRs as well as fused TRs. However, the fused TRs also showed a marked laddering, whereas the episomal genomes of the latent cells displayed a single band of fused TRs only. Additionally, applying pulsed-field gel electrophoresis to separate large DNA fragments revealed no linear DNA with a number of consecutive ca. 170 kb EBV genome units. Comparing the episomes of various lytic phase cell lines, most of them display different numbers of TRs which is, however, constant within a given cell line. Cloning and sequencing the TR region of various fused genome ends of the phorbolester- and sodium butyrate-stimulated B95-8 cell line demonstrated TR structures identical to the episomal TR structure. This indicates that always complete TR units are either "lost"during replication by sequence specific events (for instance looping out) or are actively excised during or after the replication process. However, the results clearly disprove the concatemeric replication of EBV. The elucidation of the exact replication mechanism might uncover an Achilles heel of EBV or even all herpesviruses which might be used to eliminate these viruses and to preclude many hematopoietic and other malignant tumor.

[2]Dept. of Hemato-oncology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic
[3]Dept. of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic
[4]Dept of Pathology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

Background. Recent data show that host antitumor immunity is actively suppressed by cancer cells in many ways. The key mediator of immune tolerance is IL-2 stimulating differentiation of host CD4+ cells into suppressive CD4+CD25+ T-regulatory cells. Soluble IL-2 receptor is generated exclusively by the proteolytic cleavage of membrane IL-2R. Soluble complex IL2R-IL-2 leads to prolonged persistence of IL-2 signaling. **Aims.** To analyze the prognostic impact of pretreatment sIL-2R levels on FL patients' survival in the rituximab era.Methods: We studied 88 patients with newly diagnosed FL (median age 57 years). The FLIPI risk groups were: high 43%, intermediate 27%, low 30%. Most patients (77%) had advanced-stage disease; bulk >7cm was present in 49%. Almost half of them had elevated B2M level (>3mg/L, 45%). The mean (median) sIL-2R level at diagnosis was 188.5±174.3 kU/L (132.6 kU/L); elevated sIL-2R ≥115 was detected in 48/88 patients (55%). The GELF criteria were met by 79 (90%) patients. Treatment was applied with respect to their disease: CHOP/CHOP-like regimen in low-intermediate-risk FL (n=40, 50%) and more intensive protocol (Promace-Cyta-BOM/adequate intensity protocol) in intermediate-risk patients with additional unfavorable risk factors (high B2M, s-TK or bulky; n=10, 13%). Nineteen (24%) patients were treated with upfront ASCT (conditioning BEAM 200) due to very high-risk disease. Rituximab was added to frontline therapy in 66% and maintenance immunotherapy with rituximab (or interferon) was applied in 31% (39%) of cases. Patients with high sIL-2R share more unfavorable prognostic features than low sIL-2R group: H-FLIPI (60% vs 23%, p<0.001), bulky disease >7cm (70% vs 28%, p<0.001), advanced clinical stage (92% vs 60%, p<0.001), elevated B2M (60% vs 28%, p=0.002). No differences were observed between both groups in terms of age distribution, rituximab or maintenance application. Patients with high sIL2R needed more intensive therapy approaches: 25/29 (86%) patients treated with intensive protocol or ASCT were from high sIL2R group. By contrast, all 9 patients with no need for therapy had low sIL2R (p=0.01). **Results.** Complete remission rate was 83% and was comparable in both groups (81% vs 85%, p=0.67). After a median follow-up of 67 months (5.6 yrs), only 25/48 (52%) high-sIL-2R patients are alive in the 1st CR, compared to 29/40 (73%) in low sIL-2R group. Five-year progression-free survival was 54% (95% CI 0.39-0.68) in high-sIL-2R group, compared to 66% (95%CI 0.49-0.83, p=0.05) in high-sIL-2R group. Overall survival was not significantly different between both groups (p=0.14) despite more than twice as many events observed in high-sIL-2R group (13 vs 5 deaths). **Conclusions.** Soluble IL-2R plays an important biological role in tumor immunosurveillance. This fact reflects the presence of advanced disease features such as bulky disease, high B2M and higher FLIPI scores. Despite application of more intensive treatment approaches, the outcome of patients with high sIL-2R is less favorable. This parameter should be considered an adverse negative prognostic factor.Supported by grants from Czech Ministry of Education (MSM 6198959205) and Faculty of Medicine and Dentistry, Palacky University Olomouc (LF-2011-006).

SERUM BETA2-MICROGLOBULIN IS AN INDEPENDENT STRONG PREDICTOR OF OS IN A POPULATION OF DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) PATIENTS TREATED WITH R-CHOP

A Conconi[1], S Franceschetti[1], G Margiotta Casaluci[2], A Stathis[3], F Bertoni[3], M Ghielmini[4], F Cavalli[3], G Gaidano[1], E Zucca[3]
[1]Division of Hematology, Amedeo Avogadro University of Eastern Piedmont,, Novara, Italy
[2]Division of Hematology, Amedeo Avogadro University of Eastern Piedmont, Novara, Novara, Italy
[3]Divisions of Research, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland
[4]Division of Oncology, Oncology Institute of Southern Switzerlan, Bellinzona, Switzerland

Background. Stratification of diffuse large B-cell lymphomas (DLBCL) patients (pts) according to clinico-pathological features at diagnosis represents a major challenge. **Aims and Methods.** We retrospectively analyzed the clinical variables at diagnosis and outcome of a population of consecutive pts with confirmed diagnosis of DLBCL from the databases of the Oncology Institute of Southern Switzerland in Bellinzona (Switzerland) and the Division of Hematology of the Amedeo Avogadro University of Eastern Piedmont, Novara (Italy).Results. Among 2,426 non Hodgkin's lymphoma pts treated since 1980 to 2011, 813 cases of DLBCL were selected and, among these, 364 patients (187 male, 177 female), treated with combination of rituximab and CHOP (or CHOP-like) chemotherapy, were identified. In this pts subset, median age at diagnosis was 66 years (18-89);209 pts(57%) had stage III-IV, extranodal disease was reported in147 pts(40%), serum LDH was elevated in190 pts(54% of 352 tested pts),193 pts(60% of total321 pts) had elevated serum beta2-microglobulin; 161 pts (45% of the 360 cases in whom the data was available) had intermediate-high/high International Prognostic Index (IPI) risk. The distribution of351 ptsevaluable according to the revised-IPI (R-IPI) was the following:36 pts(10%) had low risk,159 pts(46%) had intermediate risk,156 pts(45%) had high risk. After median follow-up of 3.4 years, median OS was not reached yet, projected 3-yrs OS was 75% (95%CI:70-90), 5-yrs OS was 66% (95%CI:59-72) and 10-yrs OS was 53% (95%CI:37-66). The serum beta2-microglobulin level significantly predicted OS (P<0.0001. Figure 1). The projected 5-years OS was 83% (95%CI:73-90) in pts with low beta2-microglobulin at diagnosis and 55% (95%CI:45-64) in cases with high levels. The IPI and R-IPI prognostic models confirmed their capacity to predict the outcome in this pts population (P<0.0001 for both models). Beta2-microglobulin retained its

prognostic significance at multivariate analysis controlling for the single variables included in the prognostic models (IPI and R-IPI) and for each single model as a whole [HR: 2.39 (95%CI: 1.33-4.32) for the comparison with R-IPI]. **Conclusions.** In an era in which more and more genomic markers are suggested the prediction of prognosis of DLBCL pts according to clinical variables at diagnosis still has a major role in everyday clinical practice. In our series, the serum beta2-microglobulin was an important and independent prognostic marker of OS in R-CHOP treated pts in addition to R-IPI score. Beta2-microglobulin remains a reliable tool to be included in new prognostic indexes.

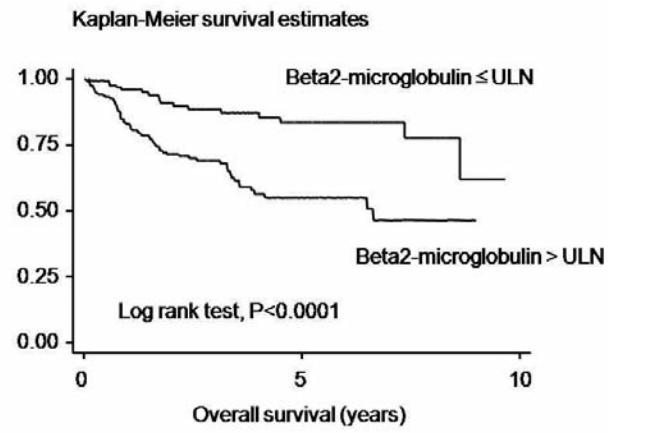

Figure 1.

0317

CLINICAL SIGNIFICANCE OF SUPPRESSOR OF CYTOKINES SIGNALLING-3 EXPRESSION FROM PATIENTS WITH NON HODGKIN LYMPHOMA UNDER CHEMOTHERAPY

F Attia, A Hasan, N Elmaraghy, G Hussin
Faculty of Medicine, Ismailia, Egypt

Introduction. To date, little is known about blood immune marker changes that may be related to the development of Non Hodgkin Lymphoma (NHL) and treatment response. And there are few circulating biological markers that could be useful in follow up of the patients. Objective: To study, by means of reverse-transcription polymerase chain reaction (RT-PCR), the expression of suppressor of cytokine signalling-3(SOCS-3) gene at the mRNA level in peripheral mononuclear cells from patients with NHL and to correlate with clinical pathological features and response to treatment. **Patients and Methods.** Thirty patients with NHL and 20 healthy controls were enrolled in the study. The SOCS-3 mRNA level in peripheral blood mononuclear cells (PBMCs) was detected by semi-quantitative real-time polymerase chain reaction. Quantification of cytokines such as interleukin 6 and tumor necrosis factor alpha (IL- 6 & TNF-α) were performed using sandwich enzyme-linked immunosorbent assays (ELISA). Main **Results.** Increased expression of SOCS-3 mRNA in peripheral blood plus increased serum levels of IL- 6 and TNF alpha from NHL cases with no complete remission after therapy. Higher levels of expression of SOCS-3 are associated with advanced disease, bone marrow involvement, extranodal involvement, poor performance status, B cell symptoms and high serum lactate dehydrogenase level which are evaluated by international prognostic index (IPI). Complete responses occur in 60% of patients with normal expression of SOCS-3 gene. Increased expression of SOCS-3 is common in diffuse large B cell lymphoma, CLL/small lymphocytic B cell lymphoma and follicular lymphoma. **Conclusions.** Elevation of mRNA expression of SOCS-3 correlates with advanced disease and poor response to treatment. Peripheral SOCS-3 expression might be used to monitor response during treatment. **Keywords.** Suppressor of cytokine signaling-3 expression; IL-6, TNF-α and non-Hodgkin's lymphoma

0318

ABSOLUTE MONOCYTE COUNT IS ASSOCIATED WITH ADVERSE PROGNOSIS IN DIFFUSE LARGE B-CELL LYMPHOMA: A VALIDATION STUDY IN A COHORT OF 219 PATIENTS FROM TWO CENTERS.

T Tadmor[1], N Benyamini[2], I Avivi[2], D Attias[1], A Polliack[3]
[1]Bnai-Zion Medical Center, Haifa, Israel
[2]Rambam Health Care Campus, Haifa, Israel
[3]Hadassah University Hospital, Jerusalem, Israel

Background. There is an emerging and growing interest regarding the role of monocytes and monocytic-derived cells in lymphoproliferative disorders. Recently it has been shown that high peripheral blood monocyte count is an independent prognostic value associated with poor prognosis and decreased overall survival in patients with diffuse large B-cell lymphoma (DLBCL). **Aims.** To evaluate the prognostic significance of monocytosis in a large cohort of newly diagnosed patients with DLBCL, to verify possible correlations with other well established prognostic factors, and to determine whether the administration of rituximab abrogates the adverse effect of elevated monocyte counts. **Material and Methods.** We reviewed clinical and laboratory data of consecutive untreated patients with DLBCL followed and treated at two medical centers in Israel between1993-2010. Monocytosis was defined as a count of > 800 cells/ mm^3 based on the count before starting treatment .This parameter was also evaluated for possible correlations with other prognostic and clinical factors including age, gender, B symptoms, stage, extra nodal involvement, serum LDH, bone marrow involvement, and the IPI score. All patients were treated with CHOP or rituximab (R)-CHOP regimens. A bivariate analysis for monocytosis and rituximab vs non-rituximab based therapy in relation to overall survival was performed.We conducted Kruskall-Wallis and Chi-Square Tests when appropriate. Log-rank tests was performed for survival analysis and a Cox proportional hazards regression model was used to determine the significance of the prognostic factors in a multivariate analysis. **Results.** 219 patients from two different medical centers in the north of Israel were evaluated. The median age at diagnosis was 59 years (range 18-96 yrs). The median follow-up time after diagnosis was 67.5 months (range, 1 to 332 months). In order to evaluate the relevance of monocytosis we compared the two categories (> 800 and < 800 cells/ mm^3) with other prognostic parameters. Monocyte counts above 800 cells /mm3 were associated with older age (66 vs 57 years) p=0.018, presence of B symptoms (40 % vs 23%) (p= 0.025), elevated LDH levels (67.4% vs 50%) (p=0.043), and high IPI score (26.6% vs 9.8%) (p=0.029). There was no correlation between monocyte count, gender and lymphopenia (lymphocyte count<1000 mm^3).The 5 years OS of the entire cohort was 78.7% and patients with monocytes above 800 / mm^3 had a 5 years OS of 63%, compared to 83% in those with monocytes<800/ mm^3 (p<0.01). Fifty seven patients (26.6%) were treated with CHOP alone, while 157 (73.4%) received R-CHOP. The addition of rituximab to CHOP combination chemotherapy did not abolish the adverse effect of monocytosis (p=0.73). **Conclusions.** This validation study in a larger patient cohort confirms the results reported in an earlier study and shows that monocytosis, a simple and readily available prognostic parameter, can easily be applied routinely to evaluate newly diagnosed patients with DLBCL and identify those with an higher risk for poor survival. The addition of rituximab, an agent with a well-recognized immuno-modulatory effect on the microenvironment, including monocytes , did not abrogate the negative adverse effect of monocytosis.

0319

TELOMERE LOSS IS AN EARLY AND PERSISTENT ABNORMALITY IN LEUKOCYTES FROM PATIENTS TREATED WITH CONVENTIONAL CHEMOTHERAPY BUT NOT FROM THOSE EXPOSED TO RITUXIMAB ALONE

A Gueli[1], A Risso[2], M Ruella[1], T Spatola[2], H Hu[1], D Gottardi[1], A De Crescenzo[1], S Buttiglieri[2], C Tarella[1]
[1]Hematology and Cell therapy, Mauriziano Hospital and University of Torino, Torino, Italy
[2]Molecular Biotechnology Center, Dep. Onc. Sp, University of Torino, Italy, Torino, Italy

Background. Patients with lymphoproliferative disease very often require treatments with chemotherapy. Several recent reports suggest that the exposure of leukocytes to chemotherapeutic drugs, may induce premature cell ageing. A good indicator of cell replication history is the length of telomeres. Indeed, telomere shortening and/or telomere dysfunction have been documented in patients receiving chemotherapy. The loss of telomere sequences has been linked to the increased risk of developing secondary malignancy in subjects previously treated with chemotherapy. However, the cell type involved and the time course for the onset of chemotherapy-induced telomere shortening remain to be elucidated. In the present study changes in telomere length (TL) before and after cytotoxic drug exposure were evaluated. **Aims.** Main aims of the study were: i. to verify whether TL shortening is a phenomenon induced by extensive chemotherapy treatments or it may occur even after minimal drug exposures; ii. to identify possible cell populations that are particularly susceptible to drug-induced telomere; iii. to define whether TL shortening following chemotherapy is reversible or permanent; iv. to investigate the different effect of chemoimmuno- or immunotherapy alone. **Methods.** Peripheral blood (PB) cells were obtained from 15 lymphoma patients undergoing chemoimmunotherapy (8 R-CHOP, 3 ABVD, 2 R-Bendamustine, 1 R-MINE, 1 R-OXDHA) and 5 patients with primary immune thrombocytopenia (PTI) treated with the anti-CD20 Rituximab (R). Median age of patients was 45 years. All but two lymphoma patients were at their first treatment line. TL was assessed on granulocyte (GN), mononuclear cell (MNC) and on total leucocytes (total PB) before and after each chemotherapy course. In 9 lymphoma patients and in all PTI, TL was assessed also at long term since last therapy. TL was evaluated by southern-blot analysis. **Results.** A marked reduction in TL was detected in 14/15 (93.3%) patients undergoing conventional chemotherapy in all PB cells investigated. As shown in Figure 1, a marked TL loss following chemotherapy compared to pre-treatment values was observed in granulocyte (p=0.0001), although a TL reduction was detectable also in MNC (p=0.003) and total PB (p=0.0009). In most patients TL shortening was detectable already after the first (9 pts) or the second (3 pts) chemotherapy course. In addition, TL shortening remained virtually unchanged up to 6 months since the last therapy in all 9 patients evaluated at long-term. Among different chemotherapy schemes evaluated, TL shortening was less pronounced in R-CHOP treated patients compared to patients receiving the other schemes, although the difference was not statistically significant. No difference in TL was detected before and after drug exposure in the five patients receiving R monotherapy, even in patients followed up to 10 months since last R infusion (Figure 1). **Conclusions.** Results indicate that telomere shortening: i. can be detected early following chemotherapy exposure and is persistently detectable for several months since chemotherapy; ii. can be most easily detectable in granulocytes; iii. is less evident in RCHOP treated patients compared to other therapy; iv. is not observed in patients affected by PTI treated with Rituximab.

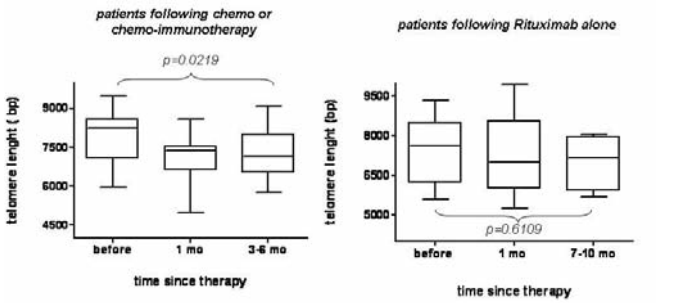

Figure 1. Changes of telomere in patients following chemo or chemo-immunotherapy and in patients treated with Rituximab alone.

THE HIGHEST PROGNOSTIC IMPACT OF LDH AMONG INTERNATIONAL PROGNOSTIC INDICES IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA IN THE RITUXIMAB ERA

JH Park, C Suh, DH Yoon, SM Kim, DY Kim, S Kim, J Kim, KA Kim, SW Lee, C Park, J Huh
Asan medical center, Seoul, South-Korea

Background. The International Prognostic Index (IPI) has been the primary clinical tool used to predict outcome for patients with diffuse large B-cell lymphoma (DLBCL). Although the IPI is considered as the standard prognostication system currently used, heterogeneity in prognosis still exists among patients with the same IPI score or risk group. Furthermore, the relative significance of each clinical factor of the IPI in same prognostic group has not been previously evaluated. **Aims.** We aimed to investigate the prevalence and relative prognostic impact of each risk factor of IPI in DLBCL patients with the same IPI scores. **Methods.** We retrospectively analyzed 387 patients treated with the standard R-CHOP as front-line therapy in a single center between February 2002 and February 2010. Patients with each IPI score were assigned to subgroups according to the combination of presenting risk factors comprising IPI: A (age ≥60 years), L (elevated serum LDH level), P (ECOG performance ≥2), S (Ann-Arbor stage ≥3), and E (extranodal sites ≥2). Then we investigated the frequency of the subgroups and compared their efficacy outcomes including complete response (CR) rate, 5-year event-free survival (EFS) rate, and 5-year overall survival (OS) rate. **Results.** The IPI remained predictive of EFS (p <0.01) and OS (p <0.01) in this study cohort. And the frequency of each IPI score was: 0 - 23.3% (n=90), 1 - 23.0% (n=89), 2 - 19.4% (n=75), 3 - 19.6% (n=76), 4 - 12.1% (n=47), 5 - 2.6% (n=10). Elevated LDH (n=209, 54.0%) was the most common risk factor in total, followed by S (n=207, 53.5%), A (n=142, 36.7%), E (n=111, 28.7%) and P (n=36, 9.3%). And in each IPI score of 1 to 4, A (n=36, 9.3%), LS (n=36, 48.0%), LSE (n=36, 47.4%), and ALSE (n=30, 63.0%) were the most predominant subgroups. Patients with elevated LDH tended to have lower CR rate, inferior EFS and/or OS irrespective of the IPI scores. Especially, patients with high LDH among those with IPI score of 2 had lower CR rate (73.1% vs. 95.2%, *p*=0.024), 5-year EFS (57% vs. 87%, *p*=0.014) and 5-year OS rates (58% vs. 82%, *p*=0.027) with statistical significance. **Conclusions.** Heterogeneity in prognosis among patients with the same IPI score still exists. Among the risk factors of IPI, LDH seems to be the most prevalent and potentially most significant prognostic factor for patients with DLBCL, which requires further validation though.

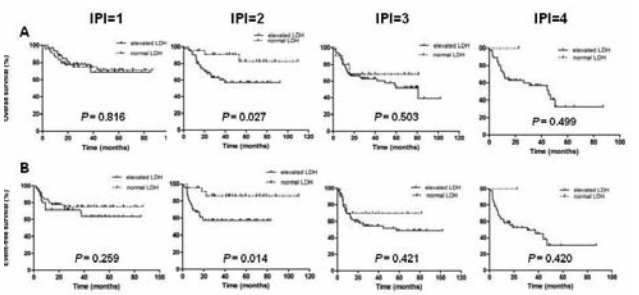

Figure 1. Overall survival (A) and event-free survival (B) of IPI score 1 to 4 by LDH level.

Myelodysplastic syndromes - Biology

Background. Aberrant DNA-methylation in the CpG sites of several tumor suppressor genes is considered the dominant pathogenetic mechanism in MDSs and the main cause of progression to AML. The use of hypomethylating agents significantly modified the therapeutic approach to MDS patients, primarily in higher-risk MDS patients. In lower-risk MDSs the use of 5-AZA hypomethylating agent is less understood. **Aims.** We prospectively evaluated the efficacy and safety of 5-AZA low-dose in Low or Int-1 risk MDS patients who were symptomatic and/or unresponsive to previous treatments. Furthermore, we studied the genetic profile by single nucleotide polymorphism (SNP) arrays and the molecular effects of 5-AZA on PI-PLCbeta1 promoter methylation, in order to identify these biological factors possibly correlated with the response to 5-AZA. **Methods.** 5-AZA was administered at a dose of 75 mg/mq/daily s.c for 5 consecutive days every 28 days for a total of 8 cycles. Final response was checked at the end of the 8th course. SNP microarray analysis was performed from mononuclear cells isolated from bone marrow aspirate samples before treatment. PI-PLC beta1 gene expression was evaluated on peripheral blood samples from patients at baseline, and monthly until the 8th cycle of 5-AZA administration. **Results.** Between September 2008 and February 2010, 32 MDS patients with IPSS risk Low- or Int-1 were enrolled into the study. Most patients had a normal karyotype (63%) by metaphase cytogenetics, were BRC transfusion-dependent (81%), receiving a median of 4 units/mo, and were previously unresponsive to treatment including ESAs (69%). Twenty-six patients (81%) completed the treatment plan (8 cycles). The Overall Response Rate after the 8th cycle was 58% (15/26 pts) whereas 42% of patients maintained a stable disease; no patient progressed towards a high-risk MDS or AML. Five (19%) patients reached a complete remission whereas 10 (38%) achieved an hematological improvement. Transfusion independent was achieved in 8/26 patients (31%). The median duration of the response was 10 months; five patients maintain their response, that is CR in 2 cases (+24 and +30 months) and HI-E in 3 cases (+14, +25,+26 months) without any treatment or supportive therapy. All but one patients (14/15) who achieved an hematologic response during treatment with 5-AZA showed a statistically significant increase in PI-PLCbeta1 mRNA expression. In all patients the increase of PI-PLCbeta1 levels anticipated the clinical response obtained at the 8th cycle. SNP array karyotyping identified genomic abnormalities in all analyzed patients (100%) compared with only 9/26 (35%) with metaphase cytogenetics; although, SNP array-based assay has been demonstrated to enable the identification of genetic abnormalities in all analyzed patients, the type and the number of copy number abnormalities were not correlated with clinical response to 5-Aza. By contrast, LOH alterations showed to have a trend with stable disease. **Conclusion**s. The current results of our study showed that 5-Aza low-dose schedule may be a safety and effective treatment for low risk MDS pts and may induce durable responsesThe correlation between the hematologic response and the PI-PLCβ1 expression indicate that PI-PLCβ1 may be a realiable marker of response to AZA.

Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of chronic myeloid neoplasms showing a predisposition to acute myeloid leukemia (AML). Although a number of gene mutations have been reported in MDS, they are common in many myeloid neoplasms and therefore, the molecular pathogenesis that is unique to MDS has not been fully elucidated. In this point of views, the recent discovery of novel pathway mutations of the RNA splicing machinery in myelodyplasia provided a new insight into the pathogenesis of MDS. These splicing pathway mutations are frequent (45-85%) in, and largely specific to MDS and related myeloid neoplasms. However, currently, the relationship between these splicing pathway mutations and other common genetic alterations as well as their clinical impacts in MDS has not been elucidated. **Aims.** To explore the genetic interaction of splicing pathway mutations with other genetic lesions and its impact on clinical outcomes, we analyzed genome-wide copy number lesions and common gene mutations that may coexist with splicing pathway mutations in a set of 313 cases with myelodysplasia, using SNP array karyotyping, including 190 cases with target sequencing of analyzing next-generation sequencer about common gene targets in MDS. The effects of the splicing pathway mutations and other genetic lesions on survivals were also evaluated. **Results.** Splicing pathway mutations were identified in 182 (58%) among 8 components of the splicing machinery, which occurred in a mutually exclusive manner. SNP array karyotyping revealed 151 cases (48%) showing copy number alterations, in which 7q- and/or 5q- were the most frequent abnormalities. Interestingly, the splicing pathway mutations were found at a significantly lower frequency among patients with 7q- and/or 5q- ($p<0.0001$), where multivariate analysis revealed that 7q- and/or 5q- were independently and significantly associated with the lower frequency of spliceosome mutation ($p = 0.001$ for 7q- and $p = 0.029$ for 5q-). Although 7q- and/or 5q- with complex karyotypes were associated with a significantly poor prognosis ($p = 0.025$, log-rank test) as a whole, they did not seem to be a risk of poor prognosis among those patients carrying a splicing pathway mutation.In total, 216 mutations, 135cases were identified among 190 cases, including 49 *TET2* (26%), 34 *RUNX1* (18%), 28 *ASXL1* (15%), 29 *RAS* (15%), 24 *TP53* (13%), 19 *IDH1/2* (10%), 11 *CBL* (6%), 12 *EZH2* (6%) and 10 *ETV6* (5%) mutations. No specific association between splicing pathway mutations and other coexisting mutations, except for the higher number of coexisting mutations in *SRSF2*-mutated cases. **Summary and Conclusions.** Splicing pathway mutations are rare in MDS cases with complex karyotypes and predict better clinical outcomes in this subgroup.

Background. In refractory anemia with ring sideroblasts (RARS), the iron deposited in the perinuclear mitochondria of ring sideroblasts is present in the form of mitochondrial ferritin (FtMt), which is expressed in the early stages of erythroid differentiation. However, it is unknown whether FtMt overexpression

is the cause or the result of mitochondrial iron deposition, and the mechanism of FtMt expression regulation remains unclear. **Aims.** Our aim was to investigate the possible influence of experimentally induced FtMt overexpression on erythroid differentiation and its capacity to induce a sideroblastic phenotype using a model system based on normal human hematopoietic progenitor cells. **Methods.** Lentivirus FtMt-transduced CD34+ bone marrow cells from 7 healthy donors were cultured for 21 days in a liquid medium with a cytokine cocktail according to a well established procedure that allowed the expansion of high numbers of erythroid progenitors and the *in vitro* production of erythrocytes. At various days samples of cultured cells were removed for biological studies including flow cytometry analysis to evaluate erythroid differentiation and STAT5 activation, ferritin expression, clonogenic assays, proliferative activity, apoptosis, heme content measurement and reactive oxygen species detection. In addition, the effect of the FtMt-transduction on iron metabolism and JAK2/STAT5 pathway activation was analyzed in K562 erythroleukemic cells. **Results.** Variable amount of FtMt (30-100 ng/mg of total proteins) was observed in FtMt-transduced cells, whereas FtMt protein was not detectable in wild type or GFP-transduced control cells. FtMt overexpressing normal erythroid progenitors were characterized by reduced cytosolic H ferritin levels and increased CD71 expression, indicative for cytoplasmic iron depletion, as well as by diminished heme content, and higher apoptotic rate, in comparison with the FtMt negative controls (P=0.0001). FtMt transduction did not inhibit proliferative activity nor did it abrogate cell ability to terminally differentiate, but the growth of clonogenic BFU-E was tendentially lower in FtMt-transduced samples; the appearance of Perls positive ring granules was noticed in rare late cells, after prolonged iron exposure. Significantly lower levels of STAT5 phosphorylation following Epo stimulation were found in FtMt positive erythroid progenitors compared to FtMt negative cells (P=0.03). On the contrary, no significant changes in comparison with the controls were observed after transduction with a mutant FtMt lacking ferroxidase activity. In the K562 cell line, FtMt overexpression reduced reactive oxygen species, STAT5 phosphorylation, and the anti-apoptotic Bcl-XL transcript, and determined cytosolic iron starvation, whereas the transferrin receptor 1 transcript increased due to the activation of the IRE/IRPs machinery. **Conclusions.** Experimental FtMt overexpression may modify mitochondrial iron availability, impair heme synthesis and trigger the pathogenic mechanism that leads to sideroblast formation and to ineffective erythropoiesis, at least in part, through the inhibition of the JAK/STAT pathway, which is central to erythroid differentiation. The antioxidant properties of FtMt might play a role in this inhibition. Thus, our data appear relevant to the pathophysiology of RARS. They have also considerable clinical implications, as they might provide the rationale for therapeutic strategies based on FtMt gene silencing of RARS progenitors to revert the pathological phenotype.

THE ROLE OF AUTOPHAGIC CELL DEATH IN RIBOSOMOPATHIES

A MacInnes[1], M Bierings[2], H Heijnen[2], R Van Wijk[2], H Gazda[3], A van de Loosdrecht[4]
[1]Hubrecht Institute, Utrecht, Netherlands
[2]UMC Utrecht, Utrecht, Netherlands

[4]VUmc, Amsterdam, Netherlands

Background. A significant percentage of myelodysplastic syndrome (MDS) patients carry a deletion in the 5q chromosome. Recently, 5q-MDS was classified as a "ribosomopathy", given the critical role of ribosomal protein gene S14 loss in this deletion. Ribosomopathies are characterized by hypoplastic anemia, bone marrow failure, and a predisposition to cancer (especially acute myeloid leukemia). In addition to 5q-MDS, ribosomopathies include Diamond-Blackfan anemia, Shwachman-Diamond syndrome, and some forms of dyskeratosis congenita. All these disease are linked to mutations in genes that function at various stages of ribosome biogenesis. While the loss of hematopoietic stem cells in these patients has conventionally been attributed to activation of the p53 tumor suppressor, several recent reports have alluded to the existence of a p53-independent mechanism of cell death. **Aims.** The aim of this work was to test the hypothesis that autophagy, the cellular process of self-digestion, is a p53-independent mechanism of death in cells with ribosome biogenesis impairments. **Methods and Results.** We used zebrafish models of ribosomal protein gene loss to determine that the widespread cell death observed is not associated with p53 stabilization or caspase activation, even upon DNA damage. Electron microscopy of these mutant embryos identified the presence of autophagosomes, and western blotting established the conversion of LC3-I to LC3-II (a hallmark of autophagy activation). These techniques in addition to confocal microscopy were then used to verify the activation of autophagy in human cells derived from ribosomopathy patients. **Conclusions.** Our results suggest that the p53-independent mechanism of death in cells with ribosome biogenesis impairments is linked to the activation of autophagy. We go on to discuss our prediction that acquired impairments in the function of autophagy may be linked to the malignant transformation of these patients to AML. This work suggests that autophagy plays an unappreciated role in the pathogenesis of ribosomopathies and may also shed light on why patients with these diseases are predisposed to malignancies.

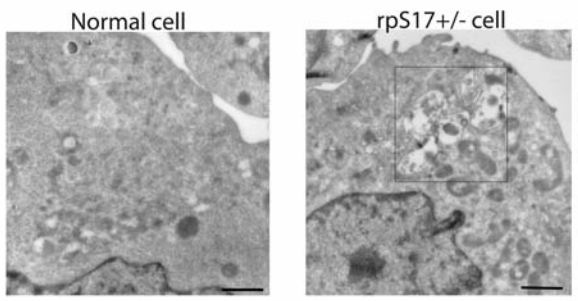

Figure 1. Autolysosomes (boxed area) are visible in ribosomopathy patient cells carrying an rpS17+/- mutation compared to normal controls.

MASSIVE PARALLEL SEQUENCING OF T-CELL RECEPTOR BETA CHAINS REVEALS A MAINLY PUBLIC REPERTOIRE IN CHILDREN WITH VERY SEVERE APLASTIC ANEMIA

P Krell[1], S Reuther[2], U Fischer[2], T Keller[3], T Bakchoul[4], C Ruckert[5], S Weber[3], M Gombert[2], F Schuster[2], C Asang[2], R Meisel[2], M Dugas[5], J Stoye[6], A Borkhardt[2]

[3]Acomed Statistics, Leipzig, Germany
[4]Medical Faculty, Justus Liebig University, Giessen, Germany
[5]Institute of Medical Informatics, University of Muenster, Muenster, Germany
[6]Genome Informatics, Faculty of Technology, Bielefeld University, Bielefeld, Germany

Background. Very severe aplastic anemia (vSAA) is caused by the destruction of CD34+ bone marrow stem cells by autoreactive T-cells. The antigenic target on stem cells is still unknown and may vary between individuals. Only few putative pathologic T-cell clones have been identified yet. **Aims.** The general objective of this study was to comprehensively assess the overall diversity of the TCR repertoire of patients newly diagnosed with vSAA by a deep sequencing approach. Expanded TCR β sequences should be identified that may indicate candidate autoreactive T-cell clones associated with the pathogenesis of the disease. These findings should be correlated with patient-specific screens for autoreactive antibodies and gene expression analyses of CD34+ stem cells previously performed. **Methods.** High coverage, massive parallel Roche/454 sequencing of T-cell receptor β-chain amplicons was employed to analyze the T-cell receptor repertoire of bone marrow-derived CD8+ T-cells from children newly diagnosed with vSAA (n=7) and healthy controls (n=5). β-chain amplicons were characterized by automated analysis regarding gene segment usage, length and encoded amino acid sequence as well as sequence diversity. This information was integrated into a novel complexity score to assess overall T-cell diversity. **Results.** The TCR repertoire of vSAA patients was severely restricted and detected mainly as a low background of not expanded clonotypes. TRBV and TRBJ gene segment usage was different from normal individuals. A low number of specific TCR clonotypes frequently found also in healthy controls (so called "public"sequences) was dominantly expanded. 17% of all unique CDR3 amino acid sequences in vSAA patients were public sequences, in comparison, only 1.9% in normal controls. High coverage sequencing also identified several TCR β-chain sequences present exclusively in the cohort of vSAA patients that may indicate candidate clonotypes involved in the pathogenesis of the disease. In 4 of 6 patients integrin-reactive antibodies were detected and in 5 of 5 cases gene expression profiling revealed a significant downmodulation of integrin GPVI and the integrin complexes GPIa/IIa, GPIIb/IIIa, GPIB/GPIX/GPV on surviving CD34+ stem cells. **Summary and Conclusions.** T-cell receptor repertoire analysis based on next-generation-sequencing is a useful tool to evaluate and to monitor the restriction of patients' T-cell repertoire. In vSAA patients antigen recognizing sequences could be identified that may be involved in the autoimmune pathogenesis of the disease. The finding of an otherwise mainly public T-cell receptor repertoire in these patients may indicate a state of chronic immune stimulation that could finally lead to exhaustion and depletion of antigen-specific T-cells. It remains to be tested whether the dominant expansion of specific pub-

lic sequences, however, is associated with the pathogenesis of the disease. It may be speculated that common antigens may be overrepresented or pathologically presented in vSAA patients. Analyses of greater cohorts will be necessary to clarify whether these disease-associated clonotypes are rather patient-specific or structurally related and directed against common autoantigens such as integrin receptors targeted by auto-antibodies in these patients.

[7]Fundación Pública Galega de Medicina Xenómica Hospital Clínico Universitario, Santiago de Compostela, Spain
[8]Hospital Cínico Universitario de Valencia, Valencia, Spain
[9]Centro Nacional de Investigaciones Oncológicas, Madrid, Spain

Background. Deletion 5q is observed in 20% of karyotypically abnormal myelodysplastic syndromes (MDS) cases, and it is associated with good prognosis. Lenalidome is a drug effective in this subset of patients but 25% of the patients did not respond. However, not many genetic predictors of response to lenalidomide have been studied in MDS with deletion 5q.**Aim**In MDS 5q deleted patients, to identify differences between responders and non responders to treatment with lenalidomide.**Patients and methods**Fifty two MDS patients with 5q deletion treated with lenalidomide were selected. All were studied by conventional cytogenetics (CC) and SNP arrays with Genome-Wide Human SNP Array 6.0 (n=47) or GeneChip Human Mapping 250K Nsp Array (n=5). Most of them were studied by direct genomic sequencing for: *CBL*, *TET2*, *ASXL1*, *IDH1*, *IDH2* and *TP53* genes. Arrays results were verified by FISH in cases with available fixed Carnoy cells. Also, we assessed the copy number status of *TP53* by FISH.For treatment response (hematological) we considered two groups: responders (complete or partial remission, n=37) and non responders (stable disease, failure or progression, n=11). **Results.** By CC, 37 showed isolated 5q deletion, seven a deletion 5q + 1 aberration, and four a complex karyotype (≥3 alterations). Two cases were normal and two non informative with a deletion 5q detected by FISH.The deletion 5q was identified by SNP-A in all patients. It detected additional lesions in 27.03% of patients with isolated deletion 5q by CC. Two cryptic recurrent lesions were detected by SNP-A: deletion on 12p13.2-p13.1 and on 15q26.1. SNP-A identifies most of the 5q deletions starting at q14. All but one were interstitials; the CDR extended from q22.3 to q31.1 (120,438,462-134,989,521; 14.5 Mb) with a median deleted size of 69.7 Mb. FISH technique with commercial or BACs probes confirmed results (mainly losses) detected by SNP-A.Number of lesions detected by CC (0-1 *vs* ≥2) shows a significant correlation with treatment response (P=0.005), as well as, the 280x10^3/L platelet count cut-off point (P=0.006). Both variables were validated in a multivariate analysis (P=0.018 and P=0.036, respectively). However, additional aberrations detected by SNP-A seems not to be related with treatment response (P=0.288).Direct genomic sequencing identified one mutation in *CBL*, one in *IDH2*, eight in *TET2* and five in *TP53*. Mutations on *TP53* shows a trend to predict no hematological response (P=0.061). However, it is not related to cytogenetics response (P=0.150) but none of the mutated cases achieved complete cytogenetics response. Two of the mutated cases had *TP53* gene deleted in a low proportion (only detectable by FISH). None of them responded and one evolved to acute myeloid leukemia. **Summary.** Low karyotypic complexity (by CC) and a high baseline platelet count (>280x10^3/L) are associated with the achievement of hematological response. However, *TP53* mutations show a trend for lenalidomide treatment failure. **Acknowledgements.** Grants: FI 07/00107, PI 11/02010, RD07/0020/2004, R06/0020/0031, SGR 541, BES2008-008053, "PROMETEO"2011/025, Beca de Investigación de la Fundación Española de Hematología y Hemoterapia, and COST BM0801. IMPAIRED CLEARANCE OF APOPTOTIC CELLS LEADS TO HMGB1 PROTEIN RELEASE IN THE BONE MARROW OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND INDUCES TLR4-MEDIATED PROINFLAMMATORY CYTOKINE PRODUCTION

M Velegraki, E Papakonstanti, I Mavroudi, M Psyllaki, C Kalpadaki, C Tsatsanis, H Papadaki
University of Crete School of Medicine, Heraklion, Greece

Background. Excessive pro-inflammatory cytokine production in the bone marrow (BM) has been recognized as a prominent pathogenetic mechanism for the disturbed hematopoiesis in patients with myelodysplastic syndromes (MDS). However, the upstream pathways, the exact cellular source and the triggering events related to cytokine excess in MDS BM remain unknown. **Aims.** To investigate the possible involvement of toll-like receptors (TLRs) and their endogenous ligands in the induction/maintenance of the inflammatory process in MDS BM. **Methods.** TLR expression was evaluated in the BM of MDS patients (n=27) and healthy controls (n=25) using flow-cytometry. Quantitative PCR analysis of 84 genes related to TLR-mediated signal transduction was performed using a commercially available PCR array in immunomagnetically sorted CD14$^+$ BM cells of patients and controls. Results were confirmed by testing separately three significantly over-expressed genes. The pro-inflammatory cytokine production by patient monocytes treated with autologous plasma in the presence/absence of a TLR4 inhibitor were measured with chemiluminescence and the levels of the high mobility group box 1 (HMGB1) protein, a TLR4 endogenous ligand, were assayed by ELISA in long-term BM culture (LTBMC) supernatants. To examine whether the excess of HMGB1 in patients' BM is due to macrophage dysfunction we used a fluorescent microscopy-based assay and we estimated the macrophage capacity to phagocytose apoptotic cells. We also assessed the HMGB1 levels in co-cultures of patient macrophages with different numbers of apoptotic cells. **Results.** A statistically significant increase in the proportion of TLR4$^+$ cells within the CD14$^+$ BM cell fraction was observed in patients (6.10%±5.27%) compared to controls (2.01%±1.38%) (P <0.0001) along with an up-regulation of TLR4 expression as was indicated by the TLR4 MRFI in MDS patients (P=0.0002). Fifty-three out of 84 TLR-related genes displayed at least a four-fold increase mRNA expression in MDS patients compared to controls. The relative mRNA expression of MyD88, TRIF/TICAM1 and TRAM/TICAM2 was significantly increased in MDS patients (2.39±1.26, 2.23±2.28 and 0.08±0.03, respectively) compared to controls (0.76±0.43, 0.89±0.60 and 0.01±0.009, respectively) (P=0.0001, P=0.0159 and P<0.0001, respectively). Incubation of patient monocytes with autologous BM plasma resulted in a TLR4-dependent production of proinflammatory cytokines as was indicated by the significant decrease of IL-1β, IL-6 and TNFα levels in the presence of the TLR4 inhibitor compared to cultures treated with the BM plasma alone (P=0.0313, P=0.0313 and P=0.0313, respectively). HMGB1 levels were significantly increased in LTBMC of patients compared to controls suggesting that HMGB1 might constitute an endogenous TLR4-activating ligand in MDS BM. Patient-derived macrophages displayed impaired capacity to engulf apoptotic cells (12.00%±2.00%) in comparison to healthy individuals (36.70%±4.81%; P=0.0079). HMGB1 release by MDS BM macrophages loaded with increasing numbers of apoptotic cells for different time periods was dependent on the apoptotic cell load (P<0.001) and incubation time (P=0.0417). **Summary and Conclusions.** A primary apoptotic cell clearance defect of BM macrophages might contribute to the inflammatory process in MDS BM through aberrant release of TLR4-inducing molecules such as HMGB1, from the apoptotic/necrotic cells present in patients' marrow microenvironment.

[5]Departments of Laboratory Medicine, National Taiwan University Hospital, Taipei City, Taiwan

Background and Aims. Mutations of the Enhancer of Zeste Homologue 2 (*EZH2*) gene, which encodes the histone methyltransferase, were recently

found in patients with myelodysplastic syndrome (MDS). The clinical and prognostic relevance of these mutations in MDS are unclear. **Methods.** A total of 272 *de novo* MDS patients diagnosed according to French-American-British (FAB) criteria at the National Taiwan University Hospital who had cryopreserved bone marrow cells for study were recruited into mutational analyses. Mutations in *EZH2* gene at exon 2-20 were analyzed by polymerase chain reaction and direct sequencing. The results were correlated with clinical features, cytogenetics, other gene mutations and treatment outcomes. **Results.** Among the 272 patients, 94 patients (34.6%) had refractory anemia (RA), 16 (5.9%) had RA with ring sideroblasts (RARS), 94 (34.6%) had RA with excess blasts (RAEB), 32 (11.8%) had RAEB in transformation (RAEBT), and 36 (13.1 %) had chronic myelomonocytic leukemia (CMMoL) according to the FAB classification. The disease of 204 patients fulfilled the criteria of MDS according to 2008 WHO classifications. *EZH2* mutations were detected in 17 (6.3%) of the 272 patients diagnosed according to the FAB classification and in 7(3.4%) of the 204 according to 2008 WHO classification.*EZH2*-mutated patients had higher WBC counts at diagnosis than *EZH2*-wild patients (median 8840/μL *vs.* 3915/μL, P=0.002). According to FAB classification, patients with CMMoL had the highest incidence (22.2%) of *EZH2* mutations, followed by RAEBT (6.3%), RA (4.3%), RAEB (3.2%), while none of the RARS patients had this mutation (P=0.001). There was no difference in the distribution of 2008 WHO classification, karyotype, and international prognostic scoring system (IPSS) between patients with and without *EZH2* mutations.To investigate the interaction of gene mutations in the pathogenesis of MDS, a mutational screening of 10 other genes was also performed. Among the 17 patients with *EZH2* mutations, 15 (88.2%) showed additional molecular abnormalities at diagnosis including eight with concurrent both *ASXL1* and *AML1/RUNX1* mutations, five *ASXL1* mutation, one *ASXL1* and *FLT3*/ITD and one both *ASXL1* and *NRAS* mutations. All but one patient with *EZH2* mutation showed concomitant mutation of *ASXL1,* a gene involved in the regulation of histone methylation, compared with 22.3% in those without *EZH2* mutation (P<0.001). The patients with *EZH2* mutation also had a significantly higher incidence of *AML1*/*RUNX1* mutation than those with *EZH2*-wild type (50.0% *vs.* 11.5%, P<0.001).With a median follow-up of 61months (range, 0.1-250.7 months), there was no significant difference in overall survival between patients with and without *EZH2* mutation by either FAB or 2008 WHO classifications (18.7 months *vs*. 30.5 months, P=0.493 and 33.8 months *vs*. 44.6 months, P=0.348, respectively). Subgroup analyses in patients with different-cytogenetic risk and in patients with different IPSS scores could not demonstrate prognostic impact of *EZH2* mutation, either. **Summary and Conclusions.** The highly close association of *EZH2* mutation with *ASXL1* mutation suggests that the two mutations may interact with each other in the pathogenesis of MDS. Further studies are necessary to disclose the mechanism of their concerted action in the development of MDS.

[6]Hospital U. Germans Trias i Pujol, Badalona, Spain
[7]Hospital U. de la Arrixaca, Murcia, Spain
[8]Hospital U. La Fe, Valencia, Spain

Background. Some 15% of MDS patients present with a hypocellular bone marrow. This fact has driven research towards eventual underlying immunological mechanisms, in analogy to severe aplastic anemia. Immune-induced cell damage and increased apoptosis might not be mutually exclusive, but even causally linked, and immune response may explain the clinical effectiveness of immunomodulators in some MDS patients. **Aims.** The aim of this study was to analyze serum levels at diagnosis of 6 cytokines and 3 chemokines in lower-risk MDS patients, as well as to evaluate their correlation with hemoglobin concentration at diagnosis, erythrocyte transfusion need during their first 16 weeks of follow-up, and overall survival (OS). **Methods.** Eighty-three lower-risk (IPSS<1.5) MDS patients (51 M and 32 F), prospectively recruited at 8 spanish GESMD sites and classified according to WHO-2008 (RCUD 5, RARS 6, RCMD 50, RAEB-1 12, 5q- syndrome 9, unclassifiable 1) were studied. The study was approved by the IRB at each study site and all patients gave written informed consent. Cytological diagnosis and cytogenetic evaluation followed standard operating procedures of the GESMD. Age, gender, hemoglobin, serum albumin, LDH, ferritin, beta2m, EPO, IL-2p70, IL-1beta, IL-10, IL-8, TNF-alpha, MIG, MCP1 and IP-10 levels (ELISA) were evaluated at diagnosis. Lee's Comorbidity Index (LCI, JAMA 2006) and the number of erythrocyte concentrates transfused in the first 16 weeks from diagnosis were also collected. Median follow-up was 17.9 months (range 4.4-35.2, IQR 11.4-21.4). During this time, 6 patients (7.2%) progressed to acute leukemia, 12 (14.5%) died and 4 (4.8%) were lost to follow-up. Kaplan-Meier estimates were calculated by using median as cutoff, and Logrank test for contrast. When median values were statistically significant, Logrank test-for-trend, using p25, p50 and p75 values, was also calculated. **Results.** According to their very network relationship, most of cytokines/chemokines levels were correlated among them. Serum levels of IL-6, IL-10, MIG and IP-10 showed a statistically significant correlation with age, LCI, albumin and beta2m, but strikingly only IL-10 correlated as well with Hb at diagnosis (Rho=-0.378; p<0.001) and transfusion need during the first 16 wks (+0.379; p<0.001). IL-1beta, TNF-alfa and IP-10 serum levels showed a negative correlation with LDH serum levels, but none of the cytokines/chemokines analyzed correlated with serum ferritin or EPO levels at diagnosis. Kaplan-Meier analysis showed that both EPO and IL-10 serum levels (see figure), but not IL-6, TNF-alfa or other cytokines/chemokines predicted OS in this lower-risk population. The mechanisms underlying the observed association are unclear, but might be mediated by endogenous GM-CSF production suppression and subsequent BFU-E growth inhibition, that seem to explain rHuEPO resistance in some CRF Patients (Cooper AC, J Am Soc Nephrol 2003; Oehler L, Blood 1997).The prognostic value of IL-10 serum levels seems independent of IPSS, but warrants further investigation in a larger series of patients. **Conclusions.** IL-10 serum levels correlate with hemoglobin concentration, transfusion need and OS in lower-risk MDS patients. This effect seems independent of EPO serum levels.*Spanish MDS Group (GESMD). This study was supported by a grant from Celgene, S.L., Madrid (project INBIOMED HEMA-001/2006).*

MYELODYSPLASIA TO ACUTE LEUKAEMIA: THE COMBINATION OF MICROARRAY GENE EXPRESSION DATA AND SHRNA KNOCKDOWN SCREENS TO UNDERSTAND THE PROGRESSION OF MDS TO AML.

F Liberante, K Mills
Queen's University Belfast, Belfast, Northern Ireland

Myelodysplastic syndromes (MDS) are bone marrow disorders resulting in ineffective haematopoiesis. However, a significant subset of patients will transform into Acute Myeloid Leukaemia (AML), which typically has a very low short-term survival rate. This study has identified and modulated genes whose expression changes prior to AML transformation to understand the molecular mechanisms that drive it.Microarray data, a subset of the international MILE study, from patients with a diagnosis of MDS was used to develop a gene expression-based prognostic classifier which identified 3 MDS groups with low (>36 months), intermediate (18-36 mo.) and high (<18 mo.) risk of AML transformation. This study has examined microarray gene expression across five groups (the three risk groups with the addition of normal bone marrow and normal/complex karyotype AML) using ANOVA. Genes were selected whose expression varied significantly across the groups (FDR-adjusted p-value <0.05) and also consistently increased or decreased with progression. A second microarray dataset from Pellagatti et al. 2006 that analysed the $CD34^+$ component from MDS and healthy bone marrow was used as a validation study.The overlap between these expression studies identified 343 genes, several of

which had previously established roles in *de novo* AML, such as HOX genes and WT1. However, several genes were identified whose potential role in leukaemia or MDS to AML progression had yet to be characterised. Pathway analysis of these novel genes suggested both central and peripheral involvement in non-canonical ubiquitin signalling. The gene list was further refined by examining only those genes that showed a high expression in AML and MDS cell lines. An shRNA knockdown screen (with at least three shRNA per gene) of these genes in those same cell lines has reinforced the significance of a deregulated ubiquitin pathway in MDS to AML progression.This study highlights the ubiquitin pathway in the transformation of MDS to AML providing an innovative therapeutic target for MDS patients at risk of transformation.

[3]CHU, Toulouse, France
[4]Hôpital Cochin, Paris, France

Background. Single nucleotide polymorphism arrays (SNP-As) allow the identification of chromosomal defects undetected by metaphase cytogenetics (MC), such as acquired copy-neutral loss of heterozygosity (CN-LOH) and offers higher resolution of unbalanced chromosomal defects. Myelodysplastic syndromes (MDS) are characterized by recurrent chromosomal abnormalities and molecular lesions that predict outcomes. **Aims.** A genome-wide scanning to identify known and new cryptic genomic abnormalities in a cohort of lower-risk MDS patients selected for their resistance to erythroid stimulating agents and prospectively treated in a phase 2 study, comparing treatment with azacitidine alone or in combination with epoetin-beta. **Patients and methods.** We performed Affymetrix SNP6.0 array analysis on 79 low-risk and intermediate-1 MDS patients, all enrolled in the GFM azaepo2008-1 study (NCT01015352). Median age was 70 years (range 42-85). Diagnosis according to WHO were RARS (n=36), RCMD-RS (n=14), RCMD (n=7), RAEB (n=10), RA (n=5), CMML (n=6) and 1 unclassified. MC results were available for 78 patients (one failed) and 55 (71%) had a normal cytogenetics (NC). **Results.** We identified 37 copy number abnormalities: 15 gains (median 146Mb; range: 1Mb-243Mb), and 22 losses (median 23Mb; range: 1.2Mb-78Mb). The most recurrent gain observed was trisomy of chromosome 8 (n=10). Losses preferentially concerned chromosomes 5 (n=4), 20 (n=4) and Y (n=3) and 4 (n=2). Thirteen CN-LOH were detected, most frequently on chromosomes 4 and 14, with a median size of 73Mb (range:2Mb-117Mb). Overall, 22 patients had one SNP-A lesion, 8 had 2 and 4 had 3 lesions. Regions of losses and/or CN-LOHs contained likely candidate genes (i.e. *DNMT3A, TET2, CBL, ASXL1* and *RUNX1*). Combining MC and SNP-A karyotyping lead to higher diagnostic yield of chromosomal defects as compared to MC alone (44% vs 29%;p=0.06). Indeed, additional chromosomal lesions were identified by SNP-A in 20% of patients with NC by MC and in 27% of patients with abnormal MC. MC did not detect sub-clonal trisomies 2 and 12, and partial duplications of chromosomes 2 [dup(2)(q12.3q14.3)] and 19 [dup(19)(p13.3p13.3)]. One monosomy 19 and two large deletions of chromosome 13 [del(13)(q14.13q22.1)] and 20 [del(20)(q11.22q13.2)] were similarly not detected by MC. In the remaining six NC by MC, microdeletions of a size ranging from 1.2Mb to 2.2Mb were identified by SNP-A. In addition, analysis of the patient with unsuccessful MC by SNP-A enabled the detection of a microdeletion encompassing *TET2* gene. SNP-A analysis also reveals 5 patients with unfavorable cytogenetics (4 complex karyotypes and one del(7q)) compared to none by MC. If we assume that genomic aberrations detected by SNP-A carry a similar prognostic value to those detected by MC, six patients by SNP-A analysis should then be switched to a higher IPSS risk category. Deep sequencing of previously known and new genes mutations is in process in this cohort of lower risk MDS patients to allow better risk-stratification with combined techniques. **Conclusions.** Our study demonstrated that SNP-A reveals unrecognized chromosomal abnormalities that may explain the clinical heterogeneity of lower-risk MDS patients. Use of SNP-A in clinical practice could improve prognostic classification and ensure a more appropriate management of individual patients.

GLOBAL DNA METHYLATION PREDICTS THE RESPONSIVENESS TO AZACITIDINE IN HIGH-RISK MYELODYSPLASTIC SYNDROMES

A Poloni[1], G Goteri[2], A Zizzi[2], F Serrani[1], B Costantini[1], S Trappolini[1], M Mariani[1], P Leoni[1]
[1]Clinica di Ematologia, Ancona, Italy
[2]Anatomia Patologica, Ancona, Italy

Background. Simultaneous promoters hypermethylation of CpG nucleosides in DNA is believed to be a key contributor to the molecular pathophysiology of Myelodysplastic Syndromes (MDS) by inactivating genes involved in the control of normal cell growth, differentiation, apoptosis, adhesion and cell motility. Aberrant DNA hypermethylation is associated with a poor prognosis in MDS that can be accounted for by more rapid progression to Acute Myeloid Leukemia (AML).Epigenetic therapy using DNA hypomethylating agents, such as azacitidine, is clinically effective for the treatment of MDS. **Aims.** We investigated the association between global DNA methylation in MDS patients with clinical outcome. Results were compared to an age-matched control group of healthy subjects and to a group of *de novo* and secondary AML patients. Then we focused on the role of global DNA methylation to predict the clinical response to azacitidine. **Methods** Bone marrow biopsy and mononuclear cells from 128 patients affected by MDS, comprising all subgroups, and 14 patients with high risk MDS treated with azacitidine were examinated. Immunochemistry was performed on paraffin-embedded sections using anti-5-methylcytosine/5mc antibody. Double immunostainings were performed for nuclear 5-methylcytosine/5mc and one of four cytoplasmic/cell membrane markers: CD34 for precursors, MPO for myeloid cells, Glycophorin-C for erythroid cells, Factor VIII for megakaryocytes. LINE-1 sequences were measured by COBRA methodology and by Pyrosequencing technology. **Results.** Our results showed that in MDS the global DNA methylation was intermediate between normal controls and AML and significantly correlated with age, blast count and karyotype.Moreover we identified at multivariate analysis only global methylation and age as significant independent prognostic factors affecting overall survival (OS).When we evaluated the global DNA hypermethylation in patients treated with azacitidine, we observed that it decreased in 10 responder patients and anticipated the haematological response, whereas it didn't in 4 patients with stable disease. **Conclusions.** Our data confirmed that DNA hypermethylation in MDS correlates with the clinical outcome. Also, we demonstrated, not only that global DNA methylation could be used to monitor the effect of azacitidine, but also may anticipate the haematological response. A longer follow-up is needed to make any correlation with prognosis and overall survival.

Background. Myelodysplastic syndromes (MDS) are a group of acquired clonal hematopoietic disorders, characterized by cytopenias, dysplasia in one or more of the myeloid cell lines and an increased risk of development of acute myeloid leukemia. Cytogenetic abnormalities identified by metaphase cytogenetics (MC) are observed in approximately 50% of MDS cases, and have an important diagnostic and prognostic role. In some MDS patients MC may fail to provide results because of the growth of none or few metaphases, with the

consequently loss of its important prognostic information. Fluorescence *in situ*hybridization (FISH) may complement the MC study, however, its utility is limited to the detection of particular lesions. SNP-A-based karyotyping, that only requires DNA extraction for its performance, could resolve MDS cases with non-informative MC. **Aims.** To apply SNP-A karyotyping in MDS patients with an unsuccessful routine cytogenetic to search for genomic aberrations and to study the potential usefulness of this technique to improve the diagnosis and prognostication of these patients. **Methods.** We studied 40 patients with primary MDS whose bone marrow (BM) karyotype showed no mitoses (n=38) or less than 10 analyzed metaphases (n=2). Diagnosis of MDS was made according to the 2008 WHO classification (Table 1). DNA was extracted from peripheral blood (PB) (n=14) or BM (n=26) at time of diagnosis. Samples were processed with the Affymetrix®Genome-Wide Human SNP Array 6.0. **Results.** SNP-A results are summarized in Table 1. SNP-A analysis enabled the detection of aberrations in 19 (47.5%) patients. Seven out of 19 aberrations were detected in PB samples and 12 in BM ones. SNP-A abnormalities were most frequently found in chromosomes 3, 5, 7 and 11. In five cases we observed a complex karyotype (≥3 numerical aberrations) by SNP-A. We observed four cases involving deletion of 5q (all confirmed by FISH) and three cases with 7q affected (a deletion and two CN-LOH). Median follow-up was 8.4 months (range 1-83.1). Median overall survival for the entire cohort was 67.8 months (95% CI 11.2-124.4). We analysed the survival of patients with CNAs detected by SNP-A and it was worse compared to those in whom no CNA were detected (median 7.7 months [95% CI: 6.4-9.0] *vs.* 67.8 months [95% CI: 0.5-135.1]; *P*=0.003). We tentatively assessed the IPSS risk group of the 35 patients with clinical and morphological data available, using the CNAs information obtained by SNP-A to determine the cytogenetic risk category. We clustered the patients into low/intermediate-1 risk and intermediate-2/high risk and we observed differences in survival between the two groups (OR 5.87 [95%CI 1.64-21]; *P*=0.007). **Conclusions.** SNP-A could be used successfully in PB samples. The identification of CNAs by SNP-A would improve the diagnostic and prognostic evaluation of MDS patients with non informative MC. Recurrent areas of acquired CN-LOH are lesions widely presented in MDS, their definitive impact awaits a formal prognostic analysis in larger series.This work was supported by grants from the ISCIII, Ministerio de Sanidad y Consumo, Spain (FI07/00107, PI07/1009 and PI 11/02010); RTICC (FEDER RD07/0020/2004), SGR 541, Acción COST BM0801, INBIOMED HEMA-001/2006 and Celgene Spain.

Purpose. Progressive cytopenias are the cause of death for the majority of patients with Myelodysplastic syndromes (MDS). In order to investigate if proliferative activity of CD34+ cells in MDS bone marrow correlates with prognosis, we measured expression of the proliferation inhibitor CDKN1C (P57KIP2). **Patients and Methods.** Two independent patients cohorts were recruited for investigating mRNA expression profiles (n=183) and p57 protein expression in immunohistochemistry of bone marrow biopsies (n=93) of patients with MDS. Overall survival was correlated with CDKN1C/P57KIP2 expression. **Results.** In purified CD34+ cells, mRNA expression of p57kip2 correlated with higher risk and poorer overall survival of patients with MDS (p=0.0006, n=183). Furthermore, increased CDKN1C expression was associated with loss of CD38 as well as loss of cyclins and cyclin-dependent kinases underlining the role of p57kip2 as a proliferation inhibitor within a left shifted stem cell compartment. Similarly, protein expression of P57KIP2 in immunohistochemistry independently predicts poor prognosis of patients with MDS (p=0.0003, n=93). This marker also has prognostic impact in RAEB-2 patients and after AML-like chemotherapy. In contrast, P57KIP2 does not predict outcome after allogeneic stem cell transplantation. Multivariate cox regression analysis with the confounding co-variates: age, cytopenias, cytogenetic risk profile, blast count and primary versus secondary MDS confirmed the impact of P57KIP2 expression on OS. Most importantly the interaction term P57KIP2 expression and blast count did not remain significant in the final model, providing evidence that P57KIP2 expression is an independent risk factor. P57KIP2 protein expression could also be demonstrated in sorted CD34+ cells of MDS patients and was significantly higher expressed than in CD34- cells. **Conclusions.** Low CD38 and high p57kip2 expression in CD34+ cells suggest a left shifted hematopoietic stem cell (HSC) compartment with a reduced fraction of proliferative and increased numbers of dormant HSC. Exhaustion of proliferative and accumulation of dormant HSC may therefore form the basis of the progressive cytopenias of late, non-leukemic MDS.

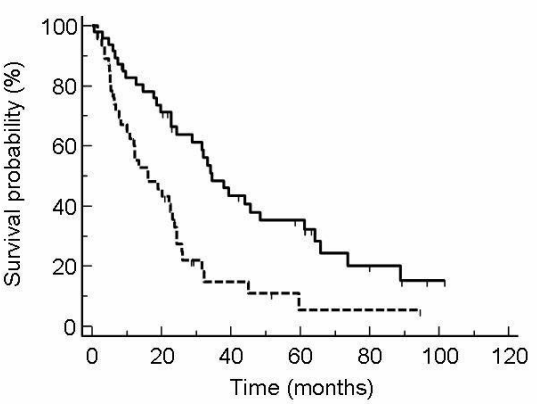

Figure 1 Impact of p57 expression in trephine biopsies on overall survival in patients with MDS.

DISTINCT PHENOTYPIC CHARACTERISTICS OF MDS WITH DEL(5Q) ABNORMALITIES MEASURED BY 8-COLOR FLOW CYTOMETRY

U Oelschlaegel, B Mohr, K Sockel, C Klotsche, M Bornhäuser, S Parmentier, C Thiede, G Ehninger, U Platzbecker
University Hospital Dresden, Dresden, Germany

Background. Patients (pts) with myelodysplastic syndrome (MDS) harbouring a deletion of the long arm of chromosome 5 (del(5q)) often display characteristic morphological features in the bone marrow (BM). Besides, 4-colour based flow cytometry (FCM) has become a valuable tool in the general diagnostics of pts with MDS, although it is still unknown, whether aberrations detected by FCM differ between certain cytogenetic subtypes. **Aims.** Using an 8-color FCM diagnostic panel we aimed to investigate potential differences in antigen patterns between MDS pts with and without del(5q) abnormalities. **Methods.** BM samples of 123 MDS pts with either del(5q) (IPSS low/int-1=32, int-2/high=25) or non-del(5q) MDS (IPSS low/int-1=50, int-2/high=16) were investigated. FCM was performed on a FACS Canto and standardized including the analysis of all samples after overnight storage and erythrocytes lysis prior to antibody staining. Thresholds were set according to median ± 2SD and/or ½ log differences compared to healthy BM samples. FCM score (FCSS) by Wells et al. 2003 and modified by van de Loosdrecht et al. 2008 into different groups (0-1 low, 2-3 moderate, >3 high) was applied. **Results.** When comparing low/int-1 MDS pts significantly more del(5q) pts had a moderate FCSS (67% vs. 31%; p=0.013) and less pts expressed aberrant lymphoid antigens (48% vs. 75%, p=0.048). Within granulopoiesis del(5q) pts showed less abnormalities (p=0.028), a higher lymphoid-to-myeloid ratio (p=0.021) reflecting a higher lymphocyte (19% vs. 10%, p=0.002) as well as a lower granulocyte (62% vs. 72%, p=0.009) count, and a higher degree of hypogranularity (p=0.023). Of note, within the monocytes significantly less del(5q) pts presented with aberrant lymphoid CD56 antigen expression (19% vs. 53%, p=0.014). Whereas aberrant CD56 expression on blasts was not different within IPSS low/int-1 pts, it was exclusively present in int-2/high del(5q) MDS vs. non-del(5q) MDS pts (63% vs. 0%, p<0.001). Interestingly, the amount of B-lymphoid progenitor cells (lyPC) was higher indel(5q) compared to nondel(5q) MDS (4.0% vs. 2.0%, p=0.030) and myeloid progenitors (myPC) showed a lower MFI for CD13 (p=0.033). Considering low/int-1 MDS with "isolated del(5q)"only, the above mentioned differences were even more pronounced: e.g. lymphoid-to-myeloid/monocytic ratio (p=0.003; p=0.018), higher grade of hypogranularity of granulocytes (p=0.006), and higher percentage of lyPC (p=0.002).Furthermore, during disease monitoring phenotypic characteristics such as percentage of CD34+ myPC, abnormal lymphoid-to-myeloid ratio, CD10- granulocytes or CD71 expression in erythrocytes disappeared in patients with a cytomorphological response. By contrast, characteristics like decreased CD19 or aberrant CD56 expression in CD34+ cells or percentage of CD45++ lymphocytes were rather unaffected by lenalidomide treatment. **Conclusions.** Eight-colour based FCM is a valuable tool in the diagnostics of MDS. It might also be able to distinguish del(5q) MDS from other MDS subtypes. The value of flow cytometric disease monitoring remains to be further analysed.

Myelodysplastic syndromes (MDS) are a heterogeneous stem cell bone marrow disorders characterized by the underproduction of one or more blood cells types, due to hematopoiesis dysfunction, and higher risk of leukemic transformation. Our previous results and indirect evidences from other studies suggest a role for oxidative stress (OS) in MDS etiology and pathogenesis. OS, resulting from an imbalance between Reactive Oxygen Species (ROS) production and antioxidant defenses, contributes to cell damage, apoptosis and ineffective hematopoiesis. On the other hand, our previous studies also show that CDKN2A and CDKN2B, two closely linked tumor suppressor genes involved in cell cycle regulation, which encode, respectively, for p16 and p15 cyclin-dependent kinase inhibitors, are inactivated by methylation. Although the cause of altered patterns of DNA methylation in cancer remains unknown, oxidative stress might influence DNA methylation profile.In this context, we investigate the relation between oxidative stress and p15 and p16 methylation status as risk factors and prognostic marker in MDS patients.For this purpose we have examined the expression levels of ROS, peroxide and superoxide anion, and the antioxidant defense GSH, in CD34 bone marrow cells collected at diagnosis from 24 patients with *de novo* MDS. The expression of these oxidative stress parameters was evaluated by flow cytometry using the fluorescent probes, H2DCF-DA, DHE and mercury orange, respectively. Genomic DNA was isolated from bone marrow aspirates by standard protocols and modified by sodium bisulphite. The MS-PCR for p15 and p16 promoter methylation was performed using two sets of primers, one for methylated DNA and other for unmethylated DNA. The patient group median age was 77 years (33-84), gender M/F=13/11, WHO subtypes: RCMD (n=8), RA (n=5), RAEB-1 (n=2), RAEB-2 (n=6), 5q- syndrome (n=1), LMMC (n=2) and IPSS: low (n=6), intermediate-1 (n=13) and intermediate-2 (n=5).Our previews results show that CD34 MDS cells had higher expression of peroxide, although a significant lower expression of superoxide anion and GSH levels, compared to controls. However, ROS and GSH expression were subtype-dependent (EHA09). On the other hand, 50% of MDS patients have at least one methylated gene and 21% have both methylated genes. MDS patients who have at least one methylated gene show a significant increase in peroxide expression levels (565±699 MFI) when compared with patients with p15 and p16 unmethylated genes (230±352 MFI). This fact is substantiated in patients with both methylated genes (878±743 MFI). Beside that, superoxide and GSH levels were lower in patients with at least one (O_2^{-}, 180±109 MFI; GSH, 165±136 MFI) or both methylated gene (O_2^{-}, 183±130 MFI; GSH, 156±143 MFI), compared patients with unmethylated genes (O_2^{-}, 256±136 MFI; GSH, 331±569 MFI). Moreover, patients with high peroxide levels have an increase frequency of gene methylation (43%) and a lower survival, compared to patients with normal/low levels (12%).This study suggests a correlation between oxidative stress, mainly peroxide levels, and gene methylation profile in MDS patients, since MDS patients with higher peroxide levels have higher frequency of gene methylation and lower survival.*This work was supported by CIMAGO (Project 22/09).*

PTEN/PI3K/AKT PATHWAY DYSREGULATION IN MYELODYSPLASTIC GRANULOCYTES

F D'Alò, E Fabiani, M Giachelia, L Fianchi, G Falconi, R Boncompagni, M Criscuolo, F Guidi, MT Voso, G Leone
Università Cattolica del Sacro Cuore, Rome, Italy

Background. Patients with Myelodysplastic Syndromes are at increased risk of infections not only because of the reduced number of granulocytes, but also for their functional abnormalities. Myelodysplastic neutrophils were shown to present impaired fungicidal and bactericidal activities and reduced chemotaxis. PTEN/PI3K/AKT pathway plays a crucial role in mediating cellular response to chemotactic stimuli. **Aims.** To study gene expression of PTEN/PI3K/AKT signaling pathways in myelodysplastic granulocytes compared to the normal counterpart. **Methods.** We evaluated PTEN mRNA expression in peripheral blood granulocytes isolated by Ficoll gradient centrifugation and osmotic erythrolysis from 30 patients with MDS and 12 normal controls by Sybr Green-based real-time RT-PCR, using Abl as reference gene. Data were expressed as $2^{-\Delta Ct}$. DNA methylation of two regions of the PTEN promoter (from -1223 bp to -1123 bp and from -300 bp to -128 bp) was studied by Methylation-specific PCR on bisulfite-treated DNA from 19 MDS and 6 controls. The gene expression profile of 84 genes belonging to the PTEN/PI3K/AKT signaling pathway was studied on granulocytes from 10 MDS patients and 10 matched normal control using the Human PI3K-AKT Signaling Pathway RT² Profiler® PCR Arrays (SABiosciences, Qiagen). Patients' cohort used for PCR arrays included the following MDS subtypes: 2 RCMD, 2 RAEB1, 4 RAEB2, 1 CMML and 1 t-MDS. Selected housekeeping genes were GAPDH, RPL13A and HPRT1. Data analysis was performed using the RT² Profiler® PCR Array Analysis Template v3.3. **Results.** PTEN mRNA was significantly down-regulated in myelodysplastic versus normal granulocytes (median 157,59 and 401,22, respectively, *p*=0.029). No significant differences in PTEN mRNA levels were observed in different MDS subtypes. PTEN promoter was not methylated in MDS and control granulocytes. Ten genes belonging to the PTEN/PI3K/AKT signaling pathway were found to be significantly down-regulated in MDS versus controls, including NFKBIA, FOS, AKT1, MAPK3, RBL2, RPS6KA1, GRB2, PIK3CG, RAF1 and ADAR (fold change less than -2 and p<0.05). Among studied genes, the most significantly suppressed was NFKBIA (fold change: -5,63, *p*=0.004) which encodes for the NFKB inhibitor-α, whose reduction might contribute to deregulated signaling across the PI3KT-AKT pathway in myelodysplastic granulocytes.**Summary/ Conclusions.** Deregulation of PTEN/PI3K/AKT signaling pathway can contribute to granulocytic dysfunction in MDS.

[3]CHU Purpan, Toulouse, France
[4]Centre H Becquerel, Rouen, France

Background. Del(5q) is the most frequent cytogenetic abnormality in myelodysplastic syndrome (MDS) and is associated with good prognosis when isolated or associated with only one other abnormality, on the other hand del(5q) in complex karyotype is associated with an increase risk of leukemic transformation. Recently, *TP53* mutations were found in 18 % of MDS with isolateddel(5q) and no excess of marrow blasts, especially in patients failing to respond or progressing after response to Lenalidomide. **Aims.** To assess the incidence of *TP53* mutations detected by direct sequencing and of del(17p) detected by Fluorescence *in situ* hybridization (FISH), their correlation and prognostic value in a cohort of Myelodysplastic Syndromes, and Acute Myeloid Leukemia (AML) withdel(5q). **Methods.** Bone marrow of 43 patients with MDS or AML anddel(5q), including 20 with isolateddel(5q) (or with one additional abnormality), and 23 with complex karyotype were selected. Three patients were also studied during follow up. **Results.** In patients with isolated del(5q) or one additional abnormality, no 17p deletion was found by FISH and 3 of the 18 cases analyzed (17 %) had *TP53* mutation. In patients with complex karyotype, 17 p abnormalities including del(17p), der(17) or monosomy 17 were observed by conventional cytogenetic (CC) in 15 of 23 cases, *TP53* deletion was confirmed by FISH in 10 of them. *TP53* mutation was found in 6 of the 13 patients tested (46%), only 3 of whom had del(17p). In the whole patient series, *TP53* mutations were associated with shorter survival (p=0.07)**. Conclusions.** We confirm the existence of *TP53* mutations in 17% of MDS with isolated del(5q). In patients with del(5q) and complex karyotype, FISH and sequencing are complementary techniques to analyze *TP53* abnormalities Our findings further suggest that, in MDS with del(5q), those abnormalities may occur in a defined order, with initial mutation of one *TP53* allele, followed by deletion of the second allele through del(17p), the latter event generally concomitant with appearance of a complex karyotype. These results encourage us to pursue *TP53* studies in larger cohort to determine patients with better chance to respond to Lenalidomide treatment.

LENALIDOMIDE INFLUENCES THE FUNCTIONAL CAPACITY OF MESENCHYMAL STROMAL CELLS IN PATIENTS WITH MYELODYSPLASTIC SYNDROME

R Ferrer, M Wobus, G Ehninger, M Bornhäuser, U Platzbecker
Medical Clinic and Polyclinic I, University Hospital, Dresden, Germany

Background. Lenalidomide (LEN) has been introduced as an effective drug capable of generating transfusion independency in a high percentage of low to intermediate-1 risk myelodysplastic syndrome (MDS) patients. While the direct mechanisms of action of the drug on the malignant cells have been intensively studied, its effects on the stromal compartment of the bone marrow (BM) have not been investigated so far systematically. **Aims.** Therefore, we investigated the in-vitro effects of LEN on human mesenchymal stromal cells (MSC) as a relevant cellular component of the BM microenvironment and if drug treatment influences functional capacities of these cells. **Methods.** Primary MSC from MDS patients (n=17) with different subtypes, including MDS-5q, and age matched healthy donors were incubated with LEN at concentrations of 0.1 and 1 µM for every experiment. Vitality and proliferation were quantified by Trypan Blue and MTT assay, respectively. Apoptosis (Annexin V staining) and cell surface marker expression were investigated by FACS. Cells were submitted to osteogenic and adipogenic induction to study differentiation capacity. A Boyden chamber assay was used to test the migration capacity of primary CD34+ hematopoietic cells towards conditioned medium of LEN treated or untreated MSC, and the concentration of SDF-1 in these supernatants were determined by ELISA. The MSC support of hematopoietic CD34+ cells was tested a coculture assay quantifying cobble-stone forming area cells after 4 weeks (CAFC). The ability of treated and untreated MSC to sensitize KG-1A cells to TNF-alpha was investigated by Annexin V staining after 24 h of coculture. **Results.** We could demonstrate that normal as well as MDS-MSC treated with LEN at clinically relevant concentrations retain their ability for proliferation, adipogenic and osteogenic differentiation and expression of distinct cell surface markers. The SDF-1 secretion by MSC was significantly reduced in healthy donors and MDS-5q groups, and this correlated with decreased induction of migration of CD34+ cells. The supportive capacity for hematopoiesis was also affected by LEN as demonstrated by a significantly lower number of CAFC after 4 weeks. MDS-MSC treated with LEN sensitized leukemic blasts (KG-1A cell line) to TNF-a induced apoptosis in direct coculture. **Conclusions.** Our in-vitro study suggests that LEN treatment at therapeutically relevant concentrations does not affect the proliferation and differentiation capacity of MSC from healthy donors and patients with MDS. Important functional activities of MSC were influenced by LEN: support of hematopoietic cells and SDF-1 secretion were reduced, and induction of TNF-alpha sensitivity of KG-1A cells cocultured with MDS-MSC, a defective feature in MDS, was rescued. These findings point to an indirect mechanism of action of LEN in MDS possibly via modulation of the microenvironment.

0340

ACUTE MYELOID LEUKEMIA (AML) ARISING FROM THE GPI-NEGATIVE HEMATOPOIETIC CELL POPULATION IN A PATIENT WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH)

M Sica[1], A Carpaneto[2], G Talini[1], R Caporale[3], M Berardi[1], M De Angioletti[4], M Montanaro[2], L Luzzatto[5], R Notaro[1]

[3]Flow Cytometry Unit, Careggi Hospital, Firenze, Italy
[4]Core Research Laboratory-ITT and ICCOM-CNR, Firenze - Sesto Fiorentino, Italy
[5]Istituto Toscano Tumori, Firenze, Italy

Background. PNH is a rare acquired disorder of the hematopoietic stem cell (HSC), characterized by a somatic mutation in the X-linked *PIGA* gene. This results in deficiency on the cell membrane of all proteins anchored by the glycosylphosphatidylinositol (GPI) molecule. In all PNH patients a clone arising from a GPI-negative (*PIGA*-mutant) HSC has undergone expansion. Although one might regard this very fact as a pre-leukemic condition, the estimated frequency in PNH of hematological malignancies, mostly AML, is between 0.6% to 2.9% of patients. In PNH most of hematopoiesis is supported by the GPI-negative clone, but residual GPI-positive cells exist in most cases: therefore it is not trivial to ask whether leukemia arises from within the GPI-negative clone or not: until now this has been determined only in very few cases. **Aims.** To identify the origin of leukemia arisen in a patient with classic hemolytic PNH. **Methods.** Phenotype and genotype of leukemic cells have been investigated by flow-cytometry and DNA/RNA sequencing. **Results.** *Case report*. A 71 years old former stonemason developed anemia, and was found to have PNH, with a large PNH clone (GPI-negative granulocytes: 98%). Neutrophil and platelet counts were normal. A bone marrow aspirate revealed erythroid hyperplasia and a normal karyotype. High reticulocyte counts, very high LDH levels and occasional hemoglobinuria were consistent with classic hemolytic PNH. The patient required approximately 3 units/month of packed-RBC. Just over 2 years after PNH diagnosis an increase in transfusion requirement (up to 6 units/month of packed-RBC) was noted, and there was evidence of iron overload. Six months later the patient developed acute leukemia (WBC 11,000/µL with 84% blasts in peripheral blood) with an immature myeloid phenotype: CD34+CD33+CD38+CD13+CD117+CD71+HLA-DR+CD7+. The patient was offered palliative cytoreductive treatment and unfortunately died within weeks. *Molecular studies*. Sequence analysis of the *PIGA* gene on DNA from PNH granulocytes before leukemia onset revealed a mutation in exon 2 (715G>T). This mutation predicts an amino acid replacement G239W; in addition, since this mutation destroys the canonical "donor site"at the distal end of exon 2, we anticipated it would affect splicing. Indeed, PCR amplification of mRNA revealed an aberrant *PIGA* transcript resulting from the use of a cryptic "donor site"(548 of intron 3). The translation of this aberrant transcript results in a non-functional truncated protein (118 amino acids) that is responsible for the GPI-negative phenotype. *Studies on the leukemic blasts*. All blasts were negative for the GPI-linked molecule CD59, indicating that leukemia arose from within the PNH clone. On DNA obtained from leukemic blasts we found exactly the same exon 2 mutation that was present in granulocytes before the leukemia onset. **Comments.** There are only a handful of cases in the literature in which it has been shown that AML in PNH arose from within the PNH clone. To the best of our knowledge, this is the first case in which this is formally proven by detecting the same mutation in leukemic blasts and in non-leukemic granulocytes from the same patient before he developed AML.

0341

BALANCE OF NK, NKT CELLS AND MAIN CYTOKINES - POSITIVE AND NEGATIVE REGULATORS OF HAEMOPOIESIS - IN PATIENTS WITH APLASTIC ANAEMIA AT DIFFERENT STAGES: RELAPSE AND REMISSION

V Glazanova, E Rozanova, V Chubukina, R Shilova
Research institute of hematology and transfusiology, Saint-Petersburg, Russian Federation

Background. In the basis of pathogenesis of aplastic anaemia (AA) lays immune-mediated disturbance of haemopoiesis, related to dysbalance of cytokines, produced by immune cells, including NK and NKT cells. A possible role of these cells in development of aplasia of hemopoiesis in AA patients now is being broadly studied. Nevertheless, their level and, especially, dynamics during the disease course are not well established yet. Considering that normally haemopoiesis is provided by balanced complex of positive and negative cytokine signals, the AIM of our study was to determine ratio of main opposite cytokines produced by mononuclear cells of AA patients, and their relations with levels of NK and NKT cells at different stages of the disease: relapse and remission. **Methods.** We have examined 23 patients with AA in dynamics. Percentage of NK and NKT cells was evaluated using flow cytometry (Beckman Coulter, FC500). Production of cytokines was evaluated in supernatants of peripheral blood mononuclear cells after 24-hour incubation at 37°C using ELISA. We have studied levels of the following cytokines: IL-1β and IL-6 (positive factors), TNFα (negative regulator of haemopoiesis), IL-4 (TNFα antagonist) and IL-2 (T-cell growth factor). **Results.** The level of natural killer cells in peripheral blood was 9,78±1,9%. that was significantly lower than norm (13,7±1,0%), while NKT cell level was 11,1±2,1% being 2-fold higher than norm (5,5±0,7%). Relapse of the disease was characterized by significant decrease of NK cells to 4,98±1,2% and increase of NKT cells up to 10,1±2,3%. In remission NK cells increased up to 12,40±0,9%, while level of NKT cells decreased to 9,15±1,3%, nevertheless being statistically significantly higher than normal. We have revaeled that normally the intensity of synthesis of positive haemopoietic factor IL-6 prevails over synthesis of other cytokines. At the same time, in AA priority of synthesis of hemopoietic factors shifts towards inhibitory cytokine - TNFα, which production exceeds normal level (44.2 pg/mL) more than 10-fold. Relapse of the disease is characterized by progression of all disturbances in cytokine balance, which were revealed in AA. Thus, significant increase of IL-1β and IL-2 production is accompanied by extremely increased, dominating over all other cytokines, intensity of synthesis of negative hemopoetic regulator - TNFα (18-fold higher than normal) and decreased production of its antagonist - IL-4. Complete clinical-hematological remission is characterized by a tendency to normalization of cytokine ratio. Thus, during remission there occurs a shift in priority of cytokine production from negative regulator - TNFα towards IL-6. The intensity of synthesis of this positive factor begins to dominate over other cytokines, similar to that revealed in norm. Nevertheless, even during complete clinical-hematological remission a production of TNFα by mononuclear cells remains increased. **Conclusions.** The fact that increased amount of NKT cells in relapse of AA was accompanied by marked increase of TNFα and decrease of IL-4, and that decrease of NKT cells in remission was accompanied by decreased TNFα and increased IL-4 can be the evidence of a role that NKT cells play in pathogenesis of AA.

EPIGENETIC REGULATION AND DEREGULATION OF VAULTRNA1-3 IN MDS

A Soegaard[1], M Treppendahl[1], A Aggerholm[2], M Skov Holm[2], G Liang[3], K Groenbaek[1]
[1]Rigshospitalet, Copenhagen Oe, Denmark
[2]Aarhus University Hospital, Aarhus, Denmark
[3]University of Southern California, Los Angeles, United States of America

Introduction. The role of non-protein encoding RNAs (ncRNAs) in normal cellular function has been widely recognized in the past decade, and perturbations in their expression can have great consequences in the initiation and progression of cancer. Also, epigenetic marks are essential for normal gene regulation and have a profound role in the pathogenesis of cancer. We have recently shown that a specific ncRNA, of the class of vaultRNAs (vtRNA2-1), is a prognostic factor in AML (Treppendahl et al., Blood, 2012). This project aims to investigate the epigenetic regulation and deregulation of the three other vtRNA members in myelodysplastic syndrome (MDS). **Materials, Methods and Results.** Treatment of the myeloid cell line, HL60, with demethylating drugs (azacytidine and decetabine) showed that vtRNAs are regulated by DNA methylation, and that vtRNA1-3 could be cancer-specifically silenced by DNA methylation. vtRNA1-3 is located in a region commonly deleted in MDS (5q33.3), indicating that it may function as a tumor suppressor. Initial analysis of the vtRNA1-3 methylation status in MDS patients (n=54, mixed IPSS groups) did not yield a significant difference in survival between patients with hypermethylated or unmethylated vtRNA1-3 promoters (P=0.15). However, analysis of the patients within the low and intmerdiate-1 risk groups (n=26), did show that patients with vtRNA1-3 hypermethylation did have a decreased survival compared to patients with unmethylated alleles (P=0.02), indicating that vtRNA1-3 may be involved in the pathogenesis of low/intermediate-1 risk MDS.Secondly, this project investigates the overall epigenetic structure of the vtRNA promoter regions. vtRNAs are RNA polymerase III transcripts, and have a unique combination of promoter elements not seen elsewhere in the genome. Our preliminary results indicate that vtRNAs have a unique and unexpected positioning of nucleosomes at their promoters and that histone modifications may also regulate their expression. **Conclusions.** These initial studies show that epigenetics can regulate the expression of vtRNAs, and that aberrant DNA methylation of the vtRNA1-3 promoter may be involved in the pathogenesis, and prognosis, of low and intermediate-1 risk MDS.

FISH ANALYSES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS) AND HEALTHY CONTROLS SUGGEST THAT THE LOSS OF A Y CHROMOSOME RESULTS FROM A COMBINATION OF AGE-AND DISEASE-RELATED FACTORS

C Ganster[1], F Braulke[1], K Shirneshan[1], D Kämpfe[2], U Platzbecker[3], U Söling[4], S Machherndl-Spandl[5], S Süßner[6], C Bramlage[1], M Koziolek[1], T Legler[1], D Haase[1], J Schanz[1]

[4]Outpatient Clinic, Kassel, Germany
[5]Krankenhaus der Elisabethinen, Linz, Austria
[6]Österreichisches Rotes Kreuz, Landesverband OÖ, Linz, Austria

Background and Aims. An isolated loss of the Y chromosome is associated with a very good prognosis in myelodysplastic syndromes (MDS). Remarkably, the prognosis in these patients is better than that of a normal karyotype, even if the mean age in the affected group is higher as compared to the typical MDS cohort (Ganster et al. ASH 2010). Despite this, it is still a matter of debate whether the loss of the Y chromosome is an age-related phenomenon or a clonal abnormality in MDS. Thus, the main goal of the study presented here was to examine this question in a multicentric study. **Methods.** We hypothesized that a disease related Y-loss would be present in CD34+ clonal cells, but not in CD3+ T-cells not belonging the MDS clone. Therefore, we determined the frequency of cells with Y-loss in CD34+ and CD3+ cells of MDS patients and of control persons not suffering from hematopoietic diseases. CD34+ and CD3+ cells were enriched by immunomagnetic or fluorescence activated cell sorting (FACS). The frequency of cells with Y-loss was determined by Fluorescence In Situ Hybridization (FISH) analysis. We analyzed CD3+ and CD34+ peripheral blood cells of 23 MDS patients (median age 78 years) and CD3+ peripheral

blood cells of 25 younger (median age 27 years) and of 25 elderly (median age 74 years) control persons. Additionally, CD34+ bone marrow or peripheral blood cells of 10 elderly control persons (median age 73 years) were analyzed so far. **Results.** In elderly MDS patients, the number of cells with Y-loss was significantly increased in CD34+ compared to CD3+ cells. The median clone size was 51% (range 8%-97%) in CD34+ cells and 5% (range 1%-14%) in CD3+ T-cells (p<0.01). Regarding the fact that MDS is extremely rare in young men below 35 years, we were not able to analyze the differences in CD3+ versus CD34+ cells in this group. Analyzing healthy controls, we found that a Y-loss in CD3+ cells of young men below the age of 35 is very infrequent. The median frequency was 0.5% (range 0%-2%), as compared to 2% (range 0%-14%) in CD3+ cells of elderly men (p<0.01). In the latter group, a Y-loss was observed in 8% (median) of CD34+ cells (range 2%-16%). To date, the analysis of CD34+ cells from the peripheral blood of young healthy men is pending. **Conclusions.** The absence of Y-loss in CD3+ cells of young healthy men compared to up to 14% Y-loss in CD3+ cells of elderly men implies an age related Y-loss in T-cells. Y-loss in up to 16% of CD34+ cells of healthy controls suggests an age-related Y-loss in CD34+ cells too. To improve diagnostic accuracy, we now aim to establish an age-matched laboratory threshold for the Y-loss in CD34+ cells. We conclude that the Y-loss in MDS patients is not just age-related or clonal but often a combination of both.

CHRONICALLY TRANSFUSED MYELODYSPLASTIC SYNDROMES (MDS) PATIENTS HAVE SEVERE IRON BURDEN: DEFERASIROX TREATMENT REDUCES IRON OVERLOAD AND IMPROVES LIVER FUNCTION

N Gattermann[1], P Greenberg[2], A Urabe[3], D Habr[4], E Kpamegan[4], J Porter[5]
[1]Heinrich-Heine-Universitat, Düsseldorf, Germany
[2]Stanford University Medical Center, Stanford, United States of America
[3]Kanto Medical Center, Tokyo, Japan
[4]Novartis Pharmaceuticals, East Hanover, United States of America
[5]University College London, London, United Kingdom

Background. Diagnosis and monitoring of iron overload, and the effect of iron chelation therapy in MDS patients, is often based on serum ferritin (SF) assessment, which is easily measured and accessible for most patients. Limited data on liver iron concentration (LIC) assessment exist in MDS, primarily due to biopsy-related risk of bleeding and infections in these patients. LIC is a more clinically robust and direct measure of body iron burden, and with increasing availability of non-invasive magnetic resonance imaging (MRI) techniques to measure LIC, it is becoming more practical to use in the management of transfused MDS patients. **Aims.** This pooled analysis assesses the degree of iron burden in a large cohort of MDS patients, focusing on LIC assessments in patients enrolled and completing 1-year deferasirox treatment. Relationships between LIC, SF and alanine aminotransferase (ALT) (a marker of liver function) are also examined. **Methods.** Data were pooled from iron-overloaded patients with MDS having Low/Int-1 risk or a life expectancy >1 year and who were enrolled in four open-label single-arm deferasirox studies. LIC was assessed in three of four studies using R2-MRI. In one study, LIC was assessed by ultrasound-guided percutaneous liver biopsy or by magnetic liver susceptometry using a superconducting quantum interference device (SQUID). LIC values obtained by SQUID were multiplied two-fold to correct for the underestimation of LIC by SQUID compared to biopsy (Porter *et al. EJH* 2008). Correlations were evaluated using Pearson's correlation coefficient.

Table 1. LIC, SF, and ALT parameters after 1-year deferasirox treatment in patients with MDS.

	n	Baseline	EOS	Change from baseline
Mean ± SD LIC, mg Fe/g dw				
Overall	71	20.5 ± 14.6	13.9 ± 13.1	−6.6 ± 10.3
Baseline LIC <7 mg Fe/g dw	15	4.1 ± 1.6	5.1 ± 2.5	1.0 ± 2.8
Baseline LIC ≥7 mg Fe/g dw	56	24.9 ± 13.4	16.2 ± 13.7	−8.6 ± 10.7
Median serum ferritin (range), ng/mL				
Overall	71	2620 (538 to 12,639)	2035 (158 to 10,520)	−630 (−9188 to 4834)
Baseline LIC <7 mg Fe/g dw	15	1593 (954 to 4950)	1938 (733 to 7073)	278 (−2630 to 4834)
Baseline LIC ≥7 mg Fe/g dw	56	2745 (538 to 12,639)	2036 (158 to 10,520)	−851 (−9188 to 3162)
Mean ± SD ALT, IU/mL				
Overall	71	55.9 ± 37.8	38.9 ± 27.7	−17.0 ± 36.7
Baseline LIC <7 mg Fe/g dw	15	29.4 ± 22.9	38.1 ± 27.3	8.7 ± 26.3
Baseline LIC ≥7 mg Fe/g dw	56	63.0 ± 38.0	39.1 ± 28.1	−23.9 ± 36.2

Results. Overall, 124 patients had LIC assessment at baseline (57.3% males; mean age, 65.4 years). Majority of patients had severely elevated LIC (<7 mg Fe/g dw, 15.3%; ≥7-≤15 mg Fe/g dw, 28.2%; and >15 mg Fe/g dw, 56.5%). SF levels were also elevated (baseline SF: ≤2500 ng/mL, 48.4%; >2500-≤5000 ng/mL, 35.5%; and >5000 ng/mL, 16.1%).Of the 124 patients, 71 patients also had end-of-study (EOS) LIC measurements, allowing efficacy assessment after 1-year deferasirox treatment. Mean deferasirox dose was 19.6 ± 6.5 mg/kg/day. Mean baseline LIC was 20.5 ± 14.6 mg Fe/g dw. In patients with baseline LIC ≥7 mg Fe/g dw, LIC was reduced by -8.6 ± 10.7 mg Fe/g dw by EOS, and 58.9% of patients achieved an LIC decrease of ≥30%. SF and ALT levels also decreased (Table 1). In patients with LIC ≥7 mg Fe/g dw, 32.1% had normal ALT levels at baseline, improving to 71.4% by EOS.At baseline, LIC and SF had a moderately strong correlation (R=0.546; P<0.001). Baseline LIC and ALT correlated to a lesser extent (R=0.361; P=0.002). Change in LIC correlated with change in both SF (R=0.336; P=0.0042) and ALT (R=0.397; P=0.0006). **Summary and Conclusions.** LIC was severely elevated in a high proportion of this large cohort of transfusion-dependent MDS patients. LIC decreased and the proportion of patients with normal baseline ALT levels increased after 1-year deferasirox treatment, particularly in patients with baseline LIC ≥7 mg Fe/g dw. Reductions in SF and ALT correlated with those of LIC. These results indicate that reduction of moderate-to-severe iron overload may be associated with improved liver function in MDS patients.

PROGNOSTIC ANALYSIS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA TRANSFORMED FROM MYELODYSPLASTIC SYNDROMES: WHO CAN BENEFIT FROM WHICH THERAPY?

N Okuyama[1], K Kadar[2], S Bakker[3], G Szombath[2], H Handa[4], H Tamura[1], A Kondo[1], K Dan[1], J Várkonyi[2], A van de Loosdrecht[3], K Ogata[1]
[1]Nippon medical school, Tokyo, Japan
[2]Semmelweis University, Budapest, Hungary
[3]VU university, Amsterdam, Netherlands
[4]Gunma university School of Medicine, Gunma, Japan

Background. Myelodysplastic syndromes (MDS) often transform into acute myeloid leukemia (AML). Such transformed patients (AML-MDS patients) have genetic backgrounds different from that of *de novo* AML patients. Risk-scoring systems, such as the International Prognostic Scoring System (IPSS) and the WHO classification-based prognostic scoring system (WPSS), are used to predict AML transformation in MDS. However, no established data exist to help predict the survival of AML-MDS patients. Similarly, there are few data on selecting available therapies, such as conventional chemotherapy (CC), allogeneic stem cell transplantation (allo-SCT), and best supportive care (BSC). **Aims.** To analyze the survival after the transformation in AML-MDS patients, in particular in association with treatment before and after transformation. **Methods.** We retrospectively analyzed data from 136 patients with AML-MDS at 4 different centers from Japan, Hungary and The Netherlands. Their initial diagnoses at the MDS stage included 17 refractory cytopenia, 5 refractory anemia with ringed sideroblasts, 42 refractory cytopenia with multilineage dysplasia, 63 refractory anemia with excess blasts , and one 5q- syndrome. Univariate survival analysis as a function of clinical variables was performed using the Kaplan-Meier method combined with the log-rank test. The variables included parameters at initial diagnosis and at AML transformation (e.g., age, sex, blood cell counts, blast percentages in the bone marrow, karyotype, IPSS, and WPSS) and treatment before and after transformation. Multivariate analysis for survival was performed using Cox proportional hazards regression analysis. **Results.** In univariate analysis, age, percentage of blasts in peripheral blood, and performance status (PS) at AML transformation as well as application of CC before AML were associated with survival time after AML transformation in all patients. In multivariate analysis, older age and higher percentages of blasts in peripheral blood at transformation were associated with significantly shorter survival. Age had the most significant effect on survival when the patients were divided into age ≥ 60 years (n = 106, older group) and < 60 years (n = 30, younger group). In the older group, 47 patients received CC, 46 received BSC, 6 received allo-SCT, and 7 received other therapies. The choice of therapy did not affect the survival time in this group. However, in the younger group, allo-SCT (n = 16) showed superior survival time compared with CC and BSC (P < 0.0001). **Conclusions.** Older age and high percentages of circulating blasts at AML transformation were poor prognostic factors. The IPSS and WPSS at the MDS stages and karyotypes at AML transformation did not predict the survival after the transformation. Furthermore, cytotoxic therapies, except for allo-SCT in the younger group, showed little survival benefit.

[8]La Sapienza University, Roma, Italy
[9]San Giovanna Addolorata Hospital, Rome, Italy
[10]S.Eugenio Hospital, Rome, Italy
[11]Policlinico Tor Vergata, Rome, Italy

Background. Myelodysplastic syndromes (MDS) are the most common hematologic malignancy in elderly patients and their onset is usually around the age of 70. Recombinant human erythropoietin (EPO) has been widely used to treat anemia in lower risk MDS patients, but few data are known about EPO treatment in the very elderly patient group. **Aims of the study** The objective of this study was to investigate the role of EPO treatment in terms of response, overall survival and toxicity in a very elderly MDS patient group. **Methods.** Ninety-three MDS patients (M/F 57/36) who were treated with EPO when aged ≥ 80 years were selected among MDS cases enrolled in a retrospective multicenter study by the cooperative group GROM (Gruppo Romano Mielodisplasie) from 01/2002 to 12/2010. Diagnosis was made according to FAB and WHO Criteria; responses were evaluated according to IWG criteria (2006). The IPSS score was used for prognostic stratification. **Results.** Median interval from diagnosis to EPO start was 2.8 months (IR 0.7 - 10.2). At EPO start, median age was 82.8 years (IR 81.2 - 84.7) with a mean haemoglobin level of 8.8 g/dl (SD +/-0.98). According to FAB classification, there were 61 (65.5%) patients with RA, 6 (6.5%) with SA and 26 (28.0%) with RAEB. According to WHO classification, there were 15 (16.1%) patients with RA, 2 (2.1 %) with SA, 39 (41.9%) with RCMD, 4 (4.2%) with RCMD-S, 17(18.3%) with RAEB-1, 9 (9.6%) with RAEB-2 and 7 (7.8%) with isolated del5q. The IPSS score was calculated in 60 patients with an available karyotype: 28 (46.6%) patients were low-risk, 26 (43.3%) int-1 and 6 (10.1%) int-2. Creatinine level was normal in 73 (78.5%) cases and elevated in 20 (21.5%) cases; 40 patients (43.0%) had a previous transfusion requirement. Median serum EPO level was 37.1 mU/L (IR 22.1 - 75.0). The initial dose of EPO was 40.000 UI/week in 34 (36.5%) patients and 80000 UI/week in 59 (63.5%) patients. An erythroid response was observed in 62 (66.6%) patients, which was major in 54 (58.0%) and minor in 8 (8.6%). No thrombotic event was reported during the treatment. Predicting factors for erythroid response were hemoglobin level at baseline > 8 g/dl (p = 0.03), ferritin levels < 250 ng/ml (p=0.007) and no previous transfusion requirement (p < 0.001). On the other hand, serum EPO levels at baseline < 50 mU/l (p=0.199) and normal creatinine levels (p=0.138) were not predictive for response. Median overall survival from EPO start was 48 months (CI 95% 27,5 - 68,4) in responders versus 30.6 months (CI 95% 7,3 - 53,8) in resistant patients (p= 0.185). Overall, toxicity was observed only in 4 responders.**Conclusions** Our data outline that EPO treatment is safe and effective also in very elderly MDS patients. However, further prospective and larger studies are warranted to confirm these data and to evaluate if EPO treatment could be worthwhile in terms of quality of life and cost-efficacy in very old patients.

Background. Cytogenetic evaluation of bone marrow samples in myelodysplastic syndromes (MDS) is a very important step not only to confirm the diagnosis but it is invaluable in defining the classification, the prognosis, the expected survival, as well as the risk of progression to acute myeloid leukemia (AML). The validation of cytogenetic risk groups based on WHO categories may provide useful information to define model for risk stratification.*Objective:* We aimed to improve focus on the value of cytogenetic evaluation in classification, staging and in order to predict clinical outcomes in MDS. In this way we developed a pilot clinical project to offer a service of conventional cytogenetic analysis for any patients with a suspected MDS that were examined from 11 medical centres of the Puglian Haematology Network. This pilot project was called ANDROMEDA that is an Italian acronym of ANalysis of cytOgenetics alteRatiOn in the MyEloDysplAstic syndromes. Another aim of the Andromeda service will be create a collaborative network between the medical centres involved in order to integrate their experience and to select risk-adapted stratification in MDS. **Methods.** We analyzed the cytogenetic and clinical characteristics from consecutive *de novo* MDS patients (n=146) admitted in medical centers between January 2011 and December 2011. All bone marrow tissues were collected from patients with suspected MDS and they were sent by the treating physician to a skilled Central Cytogenetic Laboratory to undergo classical and FISH cytogenetic analysis. Peripheral blood, bone marrows smears and core biopsy slides from all cases were reported in a case report form (CRF) through a central database in anonymity . All patients gave their informed consent to participation. **Results.** Overall there were 75 (51.4%) men and 71 women (48.6%) included in the ANDROMEDA program and median age was 74 years. The overall incidence of clonal chromosome abnormalities was 38.2%. Identified single abnormalities included del(5q) isolated (9 cases, 17.0%), +8 (6 cases, 11.3%), -7 (2 cases, 3.8%), nevertheless majority of 5q-, 8+, -7 cases combined with additional cytogenetics abnormalities (32.0%, 24.5% and 13.2% respectively). Complex karyotypes were detected in 12 cases (22.6% of abnormal karyotype). Only 6 (4.1%) bone marrow samples were not unqualified for cytogenetic analysis. Patients were classified in WHO subtypes as 27.5% refractory anemia (RA), 9.2% refractory neutropenia (RN), 2.5% refractory anemia with ring sideroblasts (RARS), 30.8% refractory cytopenia with multilineage (RCMD), 10.8% refractory anemia with excess of blast-1 (RAEB-1), 11.6% refractory anemia with excess of blast-2 (RAEB-2), 4.2% MDS with deletion 5q (MDS 5q-) and 3.3% MDS unclassifiable (MDS-U). **Conclusions.** These preliminary data demonstrated the feasibility and effectiveness of a project like Andromeda. The data collected may be associated with environmental and genetic factors of its territory in such a manner as to constitute a valid basis for epidemiological studies on MDS.

0348

TELOMERASE GENE SCREENING AND TELOMERE OVERHANG DETECTION IN CHINESE PATIENTS WITH MYELODYSPLASTIC SYNDROME

S Yan, B Han, YJ Wu, YQ Zhao
Peking Union Medical Colleague Hospital, Beijing, China

Background. Human telomeres are the long DNA TTAGGG repeats at the ends of chromosomes. Telomere dynamics and telomerase expression are fundamentally involved in cellular aging and cancer. The telomeric 3'-G rich overhang is a crucial telomeric structural component responsible for the t-loop formation. Loss of telomerase function also leads to short telometric overhangs, potentially resulting in chromosome instability. Shortened telomeric overhang was noticed in aplastic anemia patients with telomerase gene mutations and seem to correlate with poor response to immunosuppressive therapy. **Aims.** To

better understand the role of telomerase gene mutations and overhang length in the progression of myelodysplastic syndrome. **Methods.** We screened bone marrow samples from 62 Chinese patients with myelodysplastic syndrome (MDS) for variants in telomerase reverse transcriptase(TERT) and telomerase RNA component(TERC) gene. We also investigated the length of telomeric overhangs in those patients and 46 healthy individuals, using Southern blot analysis. Cytogenetic status, disease severity and short time survival rate in patients with MDS were evaluated. **Results.** Our cohort included 16 RA, 6 RAS, 2 RCMD, 15 RAEB I, 14 RAEB II, They were 36 males and 26 females, age was 56 (17-79), medium follow-up time was 12 months (4-36 months). All patients were evaluated with IPSS and WPSS scoring system. Neither TERT nor TERC mutations was identified in patients with MDS. Telomeric overhang length decreased as IPSS or WPSS value increased (Tables 1 and 2). Patients with higher risk IPSS or WPSS had shorter telomere overhang length compared to those with lower risk. Multivariate regression analysis showed telomeric overhang length, as well as IPSS and WPSS, is an independent prognostic factor for patients with MDS (IPSS P=0.001 overhang P=0.02; WPSS P=0.001 overhang P=0.012). **Conclusions.** Telometic overhang lengths change in accordance with IPSS and WPSS in patients with MDS. Short overhang length may be an independent factor for poor response and shorter survival in patients with MDS. These findings would have to be confirmed in large, prospective studies.

Table 1. Telomere overhang length in MDS patients with different IPSS.

	No. of cases	Overhang length Average ± SD	P value
Low risk*	24	200.9±70.9	NS between *and **
Intermediate I**	18	189.7±55.1	
Intermediate II***	8	138.2±32.9	NS between *** and ****
High risk****	12	133.1±30.1	
A= *+**	42	196.1±64.1	P=0.0001 when compare A and B
B= ***+****	20	135.1±30.5	

NS: No significant difference.

Table 2. Telomere overhang length in MDS patients with different WPSS.

	No. of cases	Overhang length Average ±SD	P value
1. Very low risk (score 0)	8	193.2±32.8	NS between 1 and 2 and 3
2. Low risk (score 1)	23	190.4±67.9	
3. Intermediate risk(score 2)	6	252.6±54.1	
4. High risk (score 3-4)	19	146.9±35.8	NS between 4 and 5
5. Very high risk (score 5)	6	112.1±46.8

EVALUATION OF AZACITIDINE IN TRANSFUSION-DEPENDENT, EPO-REFRACTORY PATIENTS WITH LOWER-RISK MDS

M Tobiasson[1], L Brandefors[2], I Dybedahl[3], H Garelius[4], M Grovdal[5], I Hogh-Dufva[6], L Kjeldsen[7], C Marcher[8], L Nilsson[9], A Olsnes Kittang[10], A Porwit[1], L Saft[1], M Skov Holm[11], L Mollgard[1], E Hellstrom-Lindberg[1]
[1]Karolinska University Hospital, Stockholm, Sweden
[2]Sunderbyn Hospital, Luleå, Sweden
[3]Rikshospitalet University Hospital, Oslo, Norway
[4]Sahlgrenska University Hospital, Gothenburg, Sweden
[5]Södersjukhuset, Stockholm, Sweden
[6]Herlev University Hospital, Copenhagen, Denmark
[7]Rigshospitalet University Hospital, Copenhagen, Denmark
[8]Odense University Hospital, Odense, Denmark
[9]Lund University Hospital, Lund, Sweden
[10]Bergen University Hospital, Bergen, Norway
[11]Århus University Hospital, Århus, Denmark

Background. Transfusion-dependency (TD) in patients with low- and int-1-risk MDS is associated with increased morbidity and mortality (Malcovati, JCO 2007). Around 30% of such patients respond to Epo +/- G-CSF with a median duration of two years (Jadersten, Blood 2005). Azacitidine (Aza) has been reported to induce transfusion-independence (TI) in patients with lower-risk MDS (Silverman, JCO 2002; Lyons, JCO 2009; Musto, Cancer 2010). However, this treatment has not been systematically evaluated in patients resistant to Epo +/- G-CSF, neither has the benefit of the combination of Aza and Epo been assessed in a prospective study. **Methods.** This prospective open-label, non-randomized phase II study included 30 consecutive patients with IPSS low- or int-1 risk MDS and a RBC transfusion need of ≥4 units q 8 weeks. Patients were either refractory to full-dose Epo + G-CSF for >8 weeks, or considered ineligible for such treatment according to a previously published predictive model (Hellstrom-Lindberg, Br J Hem 2003). Enrolled patients were treated with Aza 75 mg/m^2/d for five days q 28 days for six cycles. Patients remaining TD after six cycles were treated with another three Aza cycles, with the addition of Erythropoietin 60,000 units/week. Primary endpoint was number of patients achieving TI after six cycles and secondary endpoints were number of patients achieving TI after Aza+Epo, effect on bone marrow morphology, peripheral blood parameters, and safety profile. **Results.** Thirty patients were enrolled from January 2010 until September 2011. See Table 1 for patient characteristics. Eighteen patients were previously treated with Epo+G-CSF whereas remaining patients scored “low” in the predictive model and were thus considered refractory upfront. Median number of transfusion units needed was 7 (4-14) q 8 weeks preceding inclusion. Median platelet and ANC count pre-treatment was 220x10^9 (22-1468) and 2.1x10^9 (0.3-15.1), respectively. Severe thrombocytopenia (<30) and neutropenia (<0.5) was observed in 3 and 3 patients, respectively.Ten patients pre-terminated the study; five due to sustained cytopenia; two due to death (one sudden death and one neutropenic septicemia); two due to patient’s wish and one due to investigators choice. Twenty-nine serious adverse events were reported in 16 patients with infection (n=19) being most common. Nadir values after each cycle of Aza were seen at week 3 for thrombocytes (median 130x10^9) and at week 4 for neutrophils (median 1.2x10^9), respectively.Twenty-four patients were evaluable for treatment with Aza alone and 14 patients for Aza+Epo. TI was achieved in 5 patients (21%) after Aza alone and in one more patient after Aza+Epo. Three of 6 responding patients had a karyotype including trisomy 8. In a multivariate analysis, trisomy 8 was significantly (p=0.01) associated with response.

Table 1. Patient characteristics.

Median (range) Age	69y (55-80)	Significant fibrosis (grade ≥ 2), n	4
Gender (M/F)	21/9	Median (range) cell percentage	70% (20-100)
Median duration of disease	2y (0-20)	Median (range) blast count	2% (0-9)
Median transfusion units q 8 weeks	7 units (4-14)	IPSS, Low / Int-1, n	6/24
WHO classification, n		WPSS, Low / Int / High, n	3 / 14 / 13
RA / RARS / RCUD	1 / 2 / 2	IPSS Cytogenetics Favorable / Intermed./ Adverse, n	20 / 10 / 0
RCMD / RCMD-RS	13 / 5	Karyotype including trisomi 8, n	4
RAEB-I / MDS 5q-	3 / 1	Median S-epo	443 u/L (25-2313)
MDS/MPD	3	Median S-ferritin	1891 µg/L (220-6230)

Discussion. Aza can induce TI in patients with TD lower-risk MDS, but response rate is lower in this cohort of documented EPO-G-CSF-refractory patients compared to previous reports of less well-controlled cohorts. Since toxicity is substantial, candidate patients for this treatment must be selected carefully. Patients with trisomy 8 show a significantly higher response rate. The combination of Aza and Epo can be effective in rare cases.

0350

TRANSFUSION-DEPENDENT MYELODYSPLASTIC PATIENTS RECEIVING DEFERASIROX: A LONG-TERM FOLLOW UP

S Improta[1], MR Villa[1], A Volpe[2], N Cantore[2], L Mastrullo[1]
[1]UOC Ematologia ASL Napoli 1 Centro, Naples, Italy, Naples, Italy
[2]Divisione di Ematologia e U.T.I.E. A.O. San G. Moscati, Avellino, Italy

Background. Blood transfusion is the only supportive therapeutic chance in MDS patients refratory to other treatments. Several studies have demonstrated that patients with LOW-RISK MDS (IPSS: LOW, INT-1) have an elevated morbidity and mortality risk after the transfusion of more than 100 units of blood red cells. The use of iron chelators could reduce or prevent the iron overload damage. Deferasirox is a once-daily oral iron chelator that has demonstrated good efficacy and acceptable safety profile. **Aims.** We investigated the effectiveness and the safety of deferasirox therapy in reducing the iron overload in polytrasfused LOW-RISK MDS patients. **Methods.** We have treated 55 patients affected by LOW-RISK MDS refractory to any treatment modality and blood transfusion dependent form at least 1 year. All patients (35 male and 20 female, median age 71 years) showed before the beginning of the iron chelator treatment more than 2000 ng/ml of ferritinemia and a mean blood transfusion request of 1 unit of red blood cells every week in order to maintain Hgb levels higher than 8g/dl. All patients received deferasirox 10mg/kg p.o. once-a-day. A dose escalation to 20 mg/kg and then to 30 mg/kg p.o. once-a-day was performed after respectively one and three months from the beginning of the treatment.Results. After 6 months from the beginning of the therapy with deferasirox all the patients showed a reduction of ferritinemia (an about 60% decrease, r: 58-65%). Interestingly, after 12 months from the beginning of deferasirox therapy, a reduction of the transfusion request (50%) was recorded in 16 patients and one patient was transfusion-independent. To date (48 months of starting therapy) we found a maintenance of efficacy with a persistent reduction of transfusion requirements in about one third of patients. Furthermore, we found no toxicity and/or significant adverse events. **Conclusions.** Our results confirm the effectiveness of the therapy with deferasirox in reducing the iron overload in polytrasfused LOW-RISK MDS patients with acceptable toxicity profile. Moreover, our results show a significant reduction of the transfusion request in about one third of patients, persisting also after 48 months of iron chelation therapy with deferasirox. The positive effect on haemopoiesis of iron-chelation is already known and is due to the reduction of toxicity caused on haemopoietic precursors by an excess of free-iron in the bone marrow. Moreover, recent studies suggest a therapeutic role of deferasirox in MDS, independently of its iron chelating action: deferasirox seems to act as a potent NFkB inhibitor and this property could explain the improvement of the Hgb level.

0351

OUTCOMES OF CONTINUED AZACITIDINE TREATMENT FOR PATIENTS WITH MYELODYSPLASTIC SYNDROME IN IPSS LOW AND INTERMEDIATE-1

JH Moon[1], SK Sohn[1], YY Cho[2], YK Kim[3], HJ Kim[3], MK Kim[4], YR Do[5], MK Song[6], WK Lee[7], SM Lee[7], H Kim[8], JH Won[9], J Deok Yeon[10]

[3]Chonnam National University Hwasun Hospital, Chonnam, South-Korea
[4]Youngnam University Medical Center, Daegu, South-Korea
[5]Keimyung University Dongsan Hospital, Daegu, South-Korea
[6]Pusan National University Hospital, Pusan, South-Korea
[7]Inje University Busan Paik Hospital, Pusan, South-Korea
[8]Ulsan University Hospital, Ulsan, South-Korea
[9]Soon Chun Hyang University Hospital, Seoul, South-Korea
[10]Chungnam National University Hospital, Daejeon, South-Korea

Background. Hypomethylating agents improved clinical outcomes of myelodysplastic syndrome (MDS) patients. However, the treatment duration of azacitidine has not been determined yet, especially in lower risk patients. **Aims.** The current study compared the outcomes of MDS patients with continued azacitidine therapy and those off the treatment in MDS with IPSS low and intermediate-1. **Methods.** A total of 140 MDS patients who treated with azacitidine more than 4 cycles were included in the present study. **Results.** One-hundred six patients were treated with azacitidine 4 to 8 cycles then off the treatment (group-1) and 34 patients were treated more than 8 cycles with median 11 cycles (range 9-40)(group-2). Overall response rate (67.6% vs. 29.2%, p<0.001) and clinical benefit rate (82.4% vs. 53.8%, p=0.003) were higher for group-2 than group-1. Median overall survival (OS; 890 vs. 612 days, p=0.014) and progression free survival (PFS; 659 vs. 398 days, p=0.002) time were significantly longer for group-2 than group-1. Ninety-one patients were IPSS low and intermediate-1 groups. Continued azacitidine therapy improved OS (median 890 vs. 668 days, p=0.063) and PFS (median 685 vs. 433 days, p=0.020) in patients with lower risk IPSS. Survival rates after relapse to azacitidine treatment in lower risk IPSS patients (n=31, 34.1%) were poor and intensive treatment (1-year OS, 54.7%) did not improve the outcome compared to best supportive care (1-year OS, 59.9%; p=0.977). **Conclusions.** Azacitidine improved survival rates in IPSS low and intermediate-1 patients, however, most of the patients progressed with time despite continued azacitidine treatment. Plus, treatment outcomes for patients relapsed to azacitidine were poor despite intensive therapy. So, early implementation of allogeneic transplantation may be incorporated for MDS patients with IPSS low and intermediate-1.

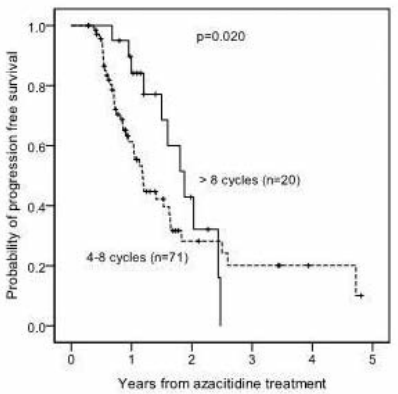

Figure 1. PFS of patients treated with azacitidine more than 4 cycles in IPSS low/intermediate-1 group.

IRON CHELATION THERAPY INDUCES HEMATOLOGICAL RESPONSE IN TRANSFUSION DEPENDENT PATIENT WITH MYELOID MALIGNANCIES

A Ricco[1], P Casieri[1], C Spinosa[1], E Laddaga[1], C Pasciolla[1], M Longo[1], S D'agostino[1], F Di Maso[1], G Specchia[1], N Sgherza[2]
[1]University of Bari, Bari, Italy
[2]Hematology, University of Bari, Italy, Italy

Background. Iron overload is well known to have a negative impact on survival in chronically transfused MDS patients, that is more striking in lower-risk categories, so that transfusion dependence was included in the WHO Prognostic Scoring System (WPSS) for MDS.Moreover several studies are currently exploring the potential benefits and the mechanisms of action of iron chelation therapies (ICT) on erythropoiesis, due to the increasing number of observations of haematopoietic recovery after ICT in bone marrow failure disorders. **Aims.** We report the results of a retrospective analysis of the hematologic response observed in a cohort of polytransfused patients treated in our institution in the last 10 years, who received ICT. **Methods.** Of 48 unselected polytransfused patients who received ICT, 18 were considered not evaluable, being in treatment with ICT for less than 3 months, ESAs for less than 6 months, 5-Aza for less than 1 year. Of the 30 evaluable patients, 24 were affected by myelodysplastic syndromes (MDS), 5 by myelofibrosis, 1 by severe aplastic anemia. One patient received Deferiprone as ICT, 4 deferoxamine, 28 deferasirox (2 after deferoxamine treatment, 1 before). The median serum ferritin level at the beginning of ICT was 1645 ng/ml (range 1068-6433), the median transfusion requirement was of 3 pRBC units/month (range 2-6); 4 patients also had severe symptomatic thrombocytopenia. **Results.** We observed a cumulative rate of 30% hematologic response (9 of 30 patients), evaluated according to the IWG 2006 criteria as HI-E in 8 patients (1 in deferoxamine and 7 indeferasirox treatment), 5 of whom achieved complete transfusion independency, 1 HI-E+HI-P, 1 HI-P in a patient who, interestingly, did not achieve any erythroid response. The median time to response was 3 months, ranging from 3 to 12, for deferasirox and 3 months for the only patient who experienced HI-E under deferoxamine treatment (following 2 months of previous deferasirox treatment, stopped due to intolerance). The median ferritin level at the time of response was 1760 ng/ml (range 361-2747), showing that the hematological response

was not merely related to the normalization of ferritin the levels.**Conclusion.** In our experience the rate of erythroid response among patients treated with ICT was similar to that reported in literature with standard dose epoetin therapy, in a setting of heavily transfused MDS patients, refractory to standard therapy.Further studies are required to investigate the potential mechanisms of action of iron chelators in inducing hematopoietic response, to determine the clinical and biological features of patients who would gain benefit and to analyze differences between groups of patients showing hematopoietic recovery or not after chelation therapy.

ERYTHROPOIETIN ALPHA VS BIOSIMILAR ERYTHROPOIETIN ALPHA PLUS LIPOFER AND B12 AND FOLATES IN PATIENTS WITH REFRACTORY ANEMIA. TWO CENTER PROSPECTIC STUDY

G Giordano[1], P Mondello[2], R Tambaro[1], N Perrotta[3], F D'Amico[1], G Sticca[1], C Di Falco[1]
[1]Fondazione „G.Paolo II„, Campobasso, Italy
[2]Policlinico „G.Martino„, Messina, Italy
[3]Università „G.D'Annunzio„, Chieti, Italy

Background. Biosimilar drugs have a similar, but usually not inferior although not hidentical effects of old registred drugs. Safety is hidentical to old registred drug**. Aims.** Aim of this study is to verify if in MDS patient with refractory anemia biosimilar erythropoietin alpha is not inferior to erythropoietin alpha in terms of safety, efficacy and costs. **Methods.** Between july 2008 and december 2011, 86 patients affected by refractory anemia were studied. Median follow-up was 18 months (R10-28).Patients were randomized 1:1 to receive in group A erythropoietin alpha 40000 IU sc/weekly.In group B patient received biosimilar erythropoietin alpha 40000 IU sc/weekly. In both arms patients received lipofer 14 mg 2 tablets orally/day calcium levofolinate 7.5 mg/day orally + Vitamin B12: 400 mg/day orally. In group A median age was 70 years (R63-73), M/F: 15/28. In group B median age was 64 years (R60-70), M/F: 24/19. IPSS was low in 30 patients and int-1 in 12 patients, karyotype showed -Y in two patient, del 20q in one patient, trisomy 8 in two patients in group A.IPSS was low in 32 patients and int-1 in 10 patients, karyotype showed -Y in one patients, del 20q in one patient in group B.Patients with 5q- were excluded from this study.Median level of haemoglobin was 9 g/dl in group A (R8-11) and 8.7 g/dL (R8.5-10.5) in group B. Cost of every month of erythropoietinic therapy was calculed dividing for each patient the sum of complete erythropoietic therapy for each month of follow-up, then in each group of patients median cost of erythropoietic therapy was calculed. **Results**. Group A patients increased Hb level of 1 g/dL after

0355

DOES BONE MARROW FIBROSIS AFFECT THE CLINICAL OUTCOME OF PATIENTS WITH MYELODYSPLASTIC SYNDROME OR SECONDARY ACUTE MYELOID LEUKAEMIA TREATED WITH AZACITIDINE?

R Yiu, Z Lao, YJ Lim, A Ho, G Kam
Singapore General Hospital, Singapore, Singapore

Background. Azacitidine improves the overall survival of patients with higher risk myelodysplastic syndrome (MDS) compared with conventional care regimens, but its clinical efficacy is limited in primary myelofibrosis. Bone marrow fibrosis is a common histological feature detected in MDS and confers an adverse prognosis. There is paucity of data about the influence of marrow fibrosis on the clinical effect of azacitidine in MDS. **Aims.** We performed a retrospective analysis in patients with MDS and secondary acute myeloid leukaemia (sAML) with background myelodysplasia or preceding MDS treated with azacitidine. We aim to determine if the degree of marrow fibrosis in MDS would influence the clinical outcome after azacitidine treatment. **Methods.** Total 27 patients who had MDS (n=18) and sAML (n=9) received azacitidine (administered subcutaneously at 75mg/m^2 daily for 7 days with repeat cycle every 4 weeks) with or without oral valproic acid (50mg/kg in 3 divided doses per day for 7 days, given concurrently with azacitidine) from December 2009 to December 2011 in our institution. The clinical, haematologic and cytogenetic data were collected. The bone marrow fibrosis grading system was adopted from Bauermeister (1971). Clinical response and survival outcome were compared between patients with marrow fibrosis less than grade 2 (marrow fibrosis<2) and those with marrow fibrosis of grade 2 to grade 4 (marrow fibrosis≥2). Statistical analysis was performed using SPSS version 17.0. **Results.** Sixteen patients had marrow fibrosis<2 and 11 patients had marrow fibrosis≥2. The median age of the whole cohort (n=27) was 67 years (range 41-82; median age of 68 years for marrow fibrosis<2 and 65 years for marrow fibrosis≥2). Seventeen patients were older than 65 years at the time of first treatment cycle. Cytogenetic risk categories were favourable (n=8), intermediate (n=10) and high (n=9). Among the high-risk cytogenetic category, 7 patients had marrow fibrosis≥2 and 2 patients had marrow fibrosis<2. A correlation of the cytogenetic risk categories and the degree of marrow fibrosis was observed in our cohort (p=0.016). The median numbers of treatment cycles delivered were 3 for marrow fibrosis<2 and 4 for marrow fibrosis≥2. Overall response rates were similar with 44% for marrow fibrosis<2 and 45% for marrow fibrosis≥2 (p=0.93). Age, gender and cytogenetic risk category had no impact on the overall response rate. The median overall survival was 10 months for the whole cohort. The median survival for marrow fibrosis<2 was 19 months and for marrow fibrosis≥2 was 10 months, but the difference in survival was not statistically significant (p=0.465). Further analysis of our cohort of patients showed an improved median survival in patients who had favourable cytogenetic risk (p=0.042), received at least 3 cycles of azacitidine (p<0.001) and/or achieved overall response to treatment (p=0.021). **Conclusions.** This retrospective analysis indicates that bone marrow fibrosis does not impact on the overall response and survival outcome in our small series of patients with MDS or sAML with background myelodysplasia treated with azacitidine. Study of a larger cohort of MDS patients treated with azacitidine is necessary to confirm this finding.

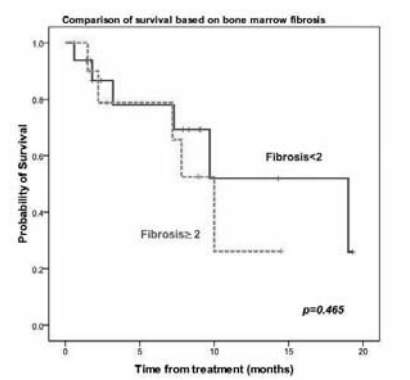

Figure 1. Survival based on bone marrow fibrosis.

0356

CONGENITAL BONE MARROW FAILURE SYNDROMES - DISEASES NOT EXCLUSIVE OF CHILDREN

J Carda, T Maia, M Benedito, J Pereira, M Duarte, C Menezes, M Ribeiro
Centro Hospitalar de Coimbra, Coimbra, Portugal

Background. The congenital bone marrow failure syndromes (BMFc) are a heterogeneous group of diseases characterized by a defect in hematopoyesis, that may affect one or more blood lineages, and a high oncogenic susceptibility. In the last decades many of the genetic abnormalities implied in these diseases had been clarified, allowing a better understanding of some of the mechanisms involved in normal hematopoyesis. Many patients with BMFc have typical phenotypic abnormalities and the majority is diagnosed in childhood. However, the phenotypes severities are heterogeneous and a growing number of patients are being diagnosed in adulthood. **Aims.** Analyze the clinical and laboratory findings at diagnosis, the evolution to bone marrow failure or to hematological malignancies and survival of patients with BMFc diagnosed in our department. **Methods.** Retrospective and descriptive study of clinical records of patients diagnosed with BMFc between 1996 and 2010. Collected data: sex, age, phenotypic abnormalities and cytopenias at diagnosis, family history, screening tests, clinical evolution, with or without allogenic stem cell transplantation, and survival. **Results.** Among 23 patients with BMFc diagnosed in a 15 years period, we found 8 Fanconi anemias (FA), 6 Blackfan Diamond syndromes (BD), 3 Shwachman-Diamond syndromes (SD), 2 Absent Radius Thrombocytopenia syndromes (ART), 1 Congenital amegacaryocytic thrombocytopenia (amega.T) and 3 osteopetrosis. The median age at diagnosis was 4.5 years; one female was diagnosed with BD at the age of 50 years, at the same time of her 10 years son, following an investigation of a macrocitic anemia. Eleven patients showed cytopenias at presentation, 13 were studied due to phenotypic abnormalities or positive family history. Eight patients with FA evolved to marrow failure, 2 of them to acute myeloblastic leukemia (AML) and 5 were submitted to allogenic stem cell transplantation. Of the 15 remaining BMFc, 4 evolved to marrow aplasia and only 3 patients were transplanted. In this group of 23 patients, 3 died, all with FA.The results are summarized in Table 1. **Summary.** All patients with FA evolved to bone marrow failure, 2 of them to AML, which is consistent with the literature. We did not observe non-hematological neoplasms. Eight patients were submitted to allogenic stem cell trans-

plantation, 5 with FA, 1 with BD, 1 with amega.T and 1 with osteopetrosis. This approach is an imperative attempt to increase patients's survival. BMFc are traditionally underdiagnosed and its identification remains a challenge mainly because their phenotypic characteristics and severity are heterogeneous. BMFc are known as children's diseases but as we can see in this study, some patients have been diagnosed in the adulthood. This is also true because they are expected to have multiple phenotypic and hematological abnormalities, which we show it is not always verified.

0357

MONITORING OF MORPHOLOGICAL FEATURES OF HEMATOPOIESIS IN MDS PATIENTS UNDERGOING EPIGENETIC THERAPY

V Dvirnyk, A Kokhno, E Glasko, O Dyagileva, E Parovichnikova
Hematology Research Center, Moskow, Russian Federation

Background/introduction: Treatment with inhibitors of DNA-methylases restores expression of cellular oncosupressor genes in MDS cells and drives them into differentiation to the mature cellular elements. However, therapy with hypomethylating agents may cause severe myelosuppression.**Purpose:** to study morphological features of hematopoiesis in bone marrow aspirates and trephine biopsies of MDS patients taken at different time points after decitabine therapy.**Materials and Methods.** 75 bone marrow aspirates and 67 trephine biopsies from 13 high risk MDS patients have been analyzed before and after 2, 4 and 8 decitabine courses of therapy. **Results.** Complete remission was achieved in 6/13 (46 %) of patients. In most cases decitabine treatment lead to a hypoplasia, characterized by the reduction of granulocyte lineage at the first stages of treatment and its subsequent restoration observed in the patients who have reached remission. In 4/6 (66,7%) of CR patients small prevalence of erythroid lineage persisted as detected by threphine biopsy and became normal - by cytology. The megakaryocytic lineage in 11/12 (92 %) of patients was expanded before treatment and was narrowed to normal or below normal level after therapy in 75 % of patients. Signs of myelodysplasia decreased in complete remission or disappeared in all cell lineages in the majority of patients. **Conclusions.** If CR is achieved after decitabine, almost all morphological features of dysplasia disappears. Cumulative analysis of bone marrow aspirates and trephine biopsies is required to objectively estimate morphological features of hematopoiesis in these patients.

Table 1. Dynamics of hematopoietic lineages while decitabine therapy.

Hematopoietic lineages Bone marrow aspirates	before n=13	after 2 courses n=13	after 4 courses n=7	after 8 courses n=4
Granulocyte cells (normal values 50-70%)	29,3% (16,0-49,6)	17,9% (3-32,6)	34,4% (5,0-50,4)	45,7% (36,5-58,0)
Erythroid cells (normal values 20-30%)	28,5% (2,0-74,5)	33,0% (4,0-67,4)	20,4% (1,0-37,8)	19,6% (8,8-35,5)

CLINICAL EXPERIENCE WITH AZACITIDINE IN CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) BASED ON 27 PATIENTS FROM A SPANISH STUDY

P Gonzalez Navarro[1], R García[2], A Bailén[3], J Muñoz[4]
[1]Hospital San Celcilio, Granada, Spain
[2]H. Universitario Virgen de la Victoria, Málaga, Spain
[3]H. Carlos Haya, Málaga, Spain
[4]H. Universitario Puerta del Mar, Cádiz, Spain

Background. Chronic myelomonocytic leukemia (CMML) is a clonal disorder of hematopoietic stem cells often occurring in elderly patients (Greco et al. Mediterr J Hematol Infect Dis. 2011). According to the 2008 WHO classification, CMML is a myelodysplastic/myeloproliferative neoplasm (MDS/MPN) further subdivided according to % of blasts in peripheral blood and bone marrow (BM) as CMML-1 (<5% blasts in peripheral blood and 5-9% blasts in BM) and CMML-2 (<10% blasts in peripheral blood and 10-19% blasts in BM) (Vardiman et al. Blood. 2009)Azacitidine (AZA) is a hypomethylating agent approved in Europe for treatment of myelodysplastic syndromes (MDS) with an intermediate to high risk of progressing to acute myeloid leukemia (AML) or death, CMML and AML that has developed from a myelodysplastic syndrome (Prescribing Information EMA 2011). Until its approval in May 2009, AZA was used in Spain under compassionate use in clinical trials.AZA produces a direct decrease of DNA methyltransferase activity *in vitro* and *in vivo*, reverting aberrant DNA methylation and increasing the expression of silenced genes, leading to cellular differentiation and/or apoptosis (Greco et al. Mediterr J Hematol Infect Dis. 2011). **Aims.** To assess the effectiveness of AZA in the treatment of CMML. **Methods.** We report the results (Response, Overall Response, Overall Survival and Progression Free Survival) of a retrospective, longitudinal, multicenter Spanish study of 27 patients: **Results.** Eighteen (66.6%) patients had CMML-1 and 8 (29.6%) had CMML-2. Median age at diagnosis was 69 years. Male/female ratio was 19/8 and ECOG performance status was 1-2 in 96.3% of patients. AZA was initiated at 75 mg/m^2 in 21 patients (78%) and 50 mg/m^2 in 5 (18.5%) patients. The mean number of cycles received was 8.3 (95% CI - 5.91; 10.73). Among the 23 patients evaluable for response, overall response was 39.1% consisting of: 13 % complete response (CR), 13 % partial response (PR), 4 % complete marrow response (mCR) and 8.7% hematological improvement (HI). Stable disease (SD) was noted in 26% and 34.8% had progressive disease (PD). 33.3% patients were alive at the end of treatment with AZA. Median overall survival was 11.70 months (95% IC 7.80, upper limit not reached) (Figure 1). **Conclusions.** Our results show that AZA is an active drug in the treatment of patients with CMML, with similar response rates described in the published literature. These findings corroborate clinical findings from other studies as AZA-001.tatumgonzalez@hotmail.com

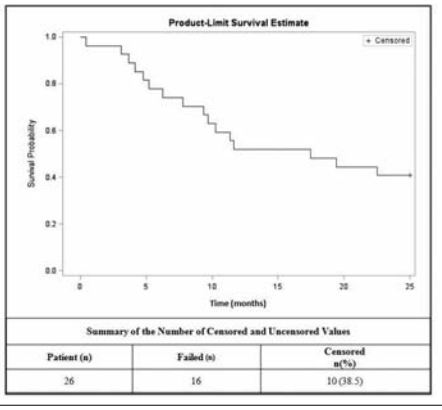

Figure 1. Overal survival.

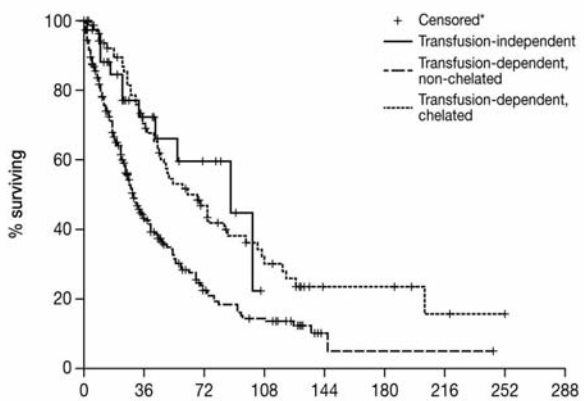
0359

THE IMPACT OF IRON CHELATION THERAPY ON CLINICAL OUTCOMES IN REAL-WORLD LOWER-RISK PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS): RESULTS FROM THE DÜSSELDORF REGISTRY

J Neukirchen[1], U Germing[1], F Fox[1], S Glaser[2], N Gattermann[1]
[1]Heinrich-Heine-Universität, Düsseldorf, Germany
[2]Novartis Pharma AG, Basel, Switzerland

Background. Over time, complications of chronic transfusions and subsequent iron overload can become significant for many patients with MDS, and iron chelation therapy (ICT) will need to be considered. Retrospective evidence of the benefit of ICT on MDS patient clinical outcomes has been previously reported (Fox *et al. Blood* 2009; Rose *et al. Leuk Res* 2010). Established in 1982, the Düsseldorf registry is the largest European database containing information on patients with MDS. Data collected allow examination of the impact of transfusion and ICT practices on long-term clinical outcomes in patients with MDS. **Aims.** This was a retrospective survey of the Düsseldorf registry to assess the impact of transfusion and ICT on clinical outcomes in real-world lower-risk MDS patients. **Methods.** Data were collected from patients with lower-risk MDS diagnosed since 1990, with serum ferritin measurements, who were not chelated or who had received deferasirox and/or deferoxamine (DFO). Patients were considered transfusion-independent or transfusion-dependent, based on their transfusion requirements at or after diagnosis (>2 units of red blood cells/8 weeks). Transfusion-dependent patients were considered to be chelated if they received ≥6 months of chelation therapy, cumulatively. Transfusion-dependent patients were subsequently assigned to either chelated or non-chelated groups, and compared to transfusion-independent patients for the purposes of this analysis. Data were evaluated up to 30 June 2011, corresponding to date of last follow-up. Kaplan-Meier estimates were used to calculate overall survival from time of MDS diagnosis. **Results.** Data from 417 patients were analyzed in the three groups: transfusion-independent patients (n=43; mean [SD] age, 66.0 [11.5] years; 79.1% males), and transfusion-dependent, non-chelated (n=289; 68.9 [12.4] years; 52.2% males) and chelated patients (n=85; 62.7 [10.3] years; 49.4% males). Overall 28 patients received deferasirox; 43 received DFO; 14 received deferasirox and DFO. Data on comorbidities were collected only at patient entry; cardiac (34.9, 23.2, 22.4%), hepatic (16.3, 4.2, 7.1%) and renal (7.0, 11.8, 8.2%) conditions were present among transfusion-independent, non-chelated and chelated patients, respectively.By study cut-off, 27.9% of transfusion-independent patients had died (median [25th, 75th percentile] time to death, 88 months [33, 101]). Among transfusion-dependent patients, 62.3% of non-chelated and 60.0% of chelated patients had died. In non-chelated patients, time to death was 30.0 months (13, 68), compared with 67 months (33, 126) in chelated patients (Figure 1). Overall, 4.7% of transfusion-independent patients progressed to acute myeloid leukemia (AML). Among transfusion-dependent patients, 16.6% of non-chelated patients and 14.1% of chelated patients had progressed.



Patients, n									
Transfusion-independent	43	15	7	0	0	0	0	0	0
Transfusion-dependent, non-chelated	289	81	29	17	2	1	1	0	0
Transfusion-dependent, chelated	85	52	28	16	5	5	2	1	0

*All patients who did not die are censored. If a patient is ongoing in the registry, the patient was censored at the cut-off date.

Figure 1. Kaplan-Meier survival curve for patients with lower-risk MDS from the Düsseldorf registry.

Summary and Conclusions. Transfusion-independent patients with lower-risk MDS had better overall survival and lower AML progression than transfusion-dependent patients. Among transfusion-dependent patients, overall survival was higher in chelated patients than non-chelated patients. Patients were selected based on knowledge of their transfusion need and availability of serum ferritin measurements; transfusion-independent patients were difficult to identify, hence the low numbers. The impact of comorbidities during follow-up could not be assessed since data were collected at entry only. The benefit of ICT on clinical outcomes needs confirmation with well-designed prospective trials.

0360

LONG-TERM OUTCOME OF ACQUIRED APLASTIC ANEMIA: COMPARISON BETWEEN BONE MARROW TRANSPLANTATION AND IMMUNOSUPPRESSIVE THERAPY

L Tukic[1], D Stamatovic[1], O Tarabar[1], M Elez[1], Z Tatomirovic[2], B Balint[3], A Zivanovic Ivic[1], N Kuljic Kapulica[4], O Radic Tasic[2], M Malesevic[1]
[1]Clinic of hematology, Military Medical Academy, Belgrade, Serbia
[2]Institute for Pathology, Military Medical Academy, Belgrade, Serbia
[3]Institute for Transfuziology, Military Medical Academy, Belgrade, Serbia
[4]Institute for Microbiology, Military Medical Academy, Belgrade, Serbia

Background. Both immunosuppressive therapy (IST) and bone marrow transplantation (BMT) are accepted treatments for patients (pts) with aplastic anemia (AA). Choosing one of these therapies depends on many factors. The aim of this retrospective study was to compare survival rates and long-term complications after IST or BMT in pts with AA and to identify prognostic factors associated with improved survival. **Patients and Methods.** between 2/1986 and 2/2012 55 pts with newly diagnosed AA were treated either with allogeneic BMT (20 pts) or with IST (35 pts). The median time from diagnosis to therapy was 2 months (range 1 to 17) in IST and 2.5 months (range 1 to 16) in BMT group. There was no statistical difference between 2 treatment groups in sex, severity of AA, disease duration, previous transfusion support, except age (pts in BMT group were younger). Twenty three allogeneic BMT were performed in 20 pts. All donors were HLA-identical sibling (1 donor was identical twin). Source of stem cells was bone marrow in 17 (3 with second transplants) and peripheral stem cell in 3 BMTs. Conditioning regimens were based on cyclophosphamide (CY) with antithymocyte (ATG) in 17 and Flud with CY and ATG in 3 BMTs. Twenty two pts received combined IST with ATG or ALG (antilymphocyte globuline), cyclosporine A and steroids and 13 pts ATG with steroids (from which 5 were splenectomized). **Results.** engraftment was documented (median time 19 days) in 19 transplanted pts (95%). In the first 100 days died 3 (15%) transplanted pts: one without engraftment (5%) on +23 days with gram-negative sepsis, the other developed steroid-refractory aGvHD grade 3-4 with invasive fungal infection and died on 78 days and the third died on 60 days with pneumonitis interstitialis (CMV+). Three pts (15.7%) who rejected allograft after 7 months (range 6 to 9), were retransplanted: 2 successfully, 1 died 8 days following the second BMT. One female pt (5.2%) developed cGvHD. In IST group responded 29 pts (82.8%) and 7 of them (24%) had two cycles IST. Five pts (14.2%) from IST group died, major causes of death were infection and hemorrhage. Aplasia recurred in 6 pts (20.6%) with partial response following IST in 24 months. Long-term complications of IST were: an evolution in MDS/AML after 76 months at 2 pts (6.8%), in PNH after 80 months at 1 (3.4%), avascular necrosis of hip at 5 pts (17.2%) and Ca prostate gland (after 150 months) at 1 pt (3.4%). Between groups did not difference in probability 12-years overall survival (BMT group 59.2%±0.12, IST group 73.4±0.08). Difference in survival was found in pts with/without response/engraftment ($p<0.001$). An improvement of peripheral blood counts was faster following BMT (median 19 days) related to IST (median 4 months) ($p<0.001$). **Conclusions.** This study indicates that over 60% of pts with AA can be successfully treated with either BMT or IST. Long-term overall survival does not differ in the two treatment groups. Questions still remains.

Myeloproliferative neoplasms - Clinical

0361

LONG-TERM FOLLOW UP OF A PHASE 1/2 STUDY OF SAR302503, AN ORAL JAK2 SELECTIVE INHIBITOR, IN PATIENTS WITH MYELOFIBROSIS (MF)

J Gotlib[1], A Pardanani[2], C Jamieson[3], J Cortes[4], M Talpaz[5], R Stone[6], G Gao[7], J Zhang[7], F Neumann[7], C Lebedinsky[7], A Tefferi[2]
[1]Stanford Comprehensive Cancer Center, Stanford, United States of America
[2]Mayo Clinic, Rochester, United States of America
[3]University of California San Diego, La Jolla, United States of America
[4]University of Texas MD Anderson Cancer Center, Houston, United States of America
[5]University of Michigan Comprehensive Cancer Center, Ann Arbor, United States of America
[6]Dana Farber Cancer Institute, Boston, United States of America
[7]Sanofi Oncology, Cambridge, United States of America

Background. SAR302503 is a potent, oral, JAK2-selective inhibitor being studied for the treatment of high- or intermediate-risk primary, post-polycythemia vera (PV), or post-essential thrombocythemia (ET) MF. We conducted a dose-escalation study (NCT00631462) followed by an extension study in patients who continued treatment beyond 6 cycles (NCT00724334) to evaluate the long-term effects of orally administered SAR302503 in MF (primary, post-PV, post-ET). Interim safety and efficacy results have been published (JCO 2011;29:789-796). **Aims.** The aim of this analysis is to report updated safety and efficacy data from the cohort remaining on study, including an assessment of the JAK2V617F allele burden. **Methods:** SAR302503 was administered orally once daily in 28-day cycles. Eligibility criteria included age ≥18 years and a platelet count ≥50x10^9/L. Patients were allowed into the extension study if treatment was deemed beneficial and well tolerated. The assigned dose of SAR302503 was the same as the last received in the dose escalation/confirmation study, but not to exceed the maximum-tolerated dose (MTD). All patients provided written informed consent. **Results.** Patients (N=59) were enrolled between February and October 2009: 44 had primary MF, 12 post-PV MF, and 3 had post-ET MF. The median age was 64 years, 51/59 patients (86%) were JAK2V617F-positive, and the median palpable spleen size was 18 cm at enrollment. Twenty-eight out of 59 patients (47%) were treated in the dose-escalation cohort (30-800 mg), 31/59 (53%) were treated at the MTD (680 mg), and 43/59 (73%) completed 6 cycles and continued on the extension study. As of June 30, 2011, 23/59 patients (39%) remained on treatment; the median number of cycles was 30 (range, 13-44), and the median current dose was 440 mg. As previously reported, spleen responses were seen within the first 3 cycles, with ≥50% patients in each dose level ≥240 mg/day showing a durable ≥50% decrease in palpable spleen size. The proportion of patients with a ≥50% reduction in spleen size was 54% at 6 months (n=57); 67% at 12 months (n=42); 53% at 18 months (n=36); 55% at 24 months (n=31); and 61% at 30 months (n=18). After 24 cycles of treatment, patients who had a JAK2V617F allele burden >20% at study entry had a persistent decrease in the median percentage JAK2V617F allele burden compared with baseline (21% [n=12] vs 60% [n=23]; P=0.03). Of the 34 patients who had leukocytosis at baseline, about 50% achieved a normalization of white blood cell counts across cycles. Of the 11 patients, who had thrombocytosis at baseline, platelet counts normalized in up to 86% of patients over time. Treatment-emergent toxicities were dose-dependent and generally alleviated with dose-reduction. Most frequently reported adverse events included nausea, diarrhea, vomiting, anemia, and thrombocytopenia. **Summary and Conclusions.** An updated interim analysis of this phase 1/2 study shows that treatment with SAR302503 reduced spleen size and the JAK2V617F allele burden, with an acceptable safety profile in patients with primary MF, post-PV MF, or post-ET MF. A phase 3 trial of SAR302503 in this setting was initiated in December 2011 (JAKARTA, NCT01437787). Sponsored by Sanofi.

BURDEN OF ILLNESS OF AGGRESSIVE SYSTEMIC MASTOCYTOSIS (ASM) IN THE UNITED STATES

M Sotak[1], M Marin[1], J Coombs[2], A Teitelbaum[1]
[1]OptumInsight Life Sciences, Chicago, United States of America
[2]Novartis Pharmaceuticals Corporation, East Hanover, United States of America

Background. Per the 2008 WHO report on the spectrum of mast cell disease, ASM is a severe and debilitating subtype of systemic mastocytosis (SM); mast cell leukemia is an aggressive variant of the disease. Limited information has been published on the epidemiology and burden of ASM. **Aims.** This study reviewed the epidemiologic, clinical, humanistic and economic literature on ASM in order to estimate the burden of ASM in the US. **Methods.** A systematic literature review was conducted in PubMed to identify English language publications regarding ASM published 2000 - 2011. 181 citations were identified, 156 abstracts screened, and 6 articles abstracted. The US population-level burden of ASM was estimated using an Excel model. Direct treatment costs were calculated from treatment patterns described in identified publications. **Results.** ASM involves multiple organ systems, resulting in potentially severe symptoms/conditions including anaphylaxis/allergic reactions, osteoporosis, hepatomegaly, splenomegaly, gastrointestinal symptoms, fatigue, and weight loss. There is no known cure for ASM. Treatment focuses on symptom reduction with antihistamines, bisphosphonates, glucocorticoids, proton pump inhibitors and mast cell stabilizers. Medications to control the disease include interferon-alpha, cladribine (2CdA), hydroxyurea, and imatinib or investigational agents in clinical trials. Median survival was 41 months in a published cohort study.No publications were identified providing US epidemiology data. Two estimates were calculated for the prevalence of ASM in the US in 2010: 616 and 1,220. A global ASM prevalence estimate of 0.2 cases/100,000 individuals resulted in an estimate of 616 prevalent cases. An SM prevalence rate of 3.3 cases/100,000 individuals and assumption that ASM accounts for 12% of SM cases resulted in a US prevalence rate of 0.4 cases/100,000 individuals and an estimated 1,220 ASM cases. Incidence was estimated at only 111 cases in 2010 using an SM incidence rate of 0.3/100,000 (again assuming ASM accounts for 12% of SM cases). The proportion of ASM/SM cases ranged from 7-18% in the literature with 12% from the largest study.Two studies examining the burden of mastocytosis on patient quality of life or productivity were identified. In one study, 82% of SM patients stated they suffer from a disability, with 28% reporting it as severe or intolerable. A recently published study reported 64% of mastocytosis patients commented that the disease moderately to severely restricted their quality of life. No studies were identified examining the economic burden of ASM. In this model, direct monthly per-patient costs were estimated between $5,232 and $8,741. These are likely underestimated as a result of limited resource utilization information in the literature. **Conclusions.** These results provide preliminary estimates for the burden of ASM in the US. Additional research can assist in further quantifying these estimates. Due to the variety of symptoms experienced by ASM patients, the lack of a curative therapy, impact on quality of life and short survival, it is likely that patients with ASM experience indirect costs (e.g., limitations in functioning or productivity) that may exceed the direct costs of treatment; further evaluation is warranted to estimate the total economic burden.

0363

THE COST OF BLOOD TRANSFUSION IN LOW-RISK PATIENTS WITH MYELODYSPLASTIC SYNDROMES (MDS): AN ECONOMIC ANALYSIS FOR THE CASE OF GREECE

B Fragoulakis[1], N Maniadakis[1], P Panagiotidis[2]
[1]National School of Public Health, Athens, Greece
[2]First Department of Propedeutic Medicine, Laikon General Hospital, Athens, Greece

Background. Myelodysplastic Syndromes (MDS) represent a heterogeneous group of acquired clonal bone marrow disorders with a diverse spectrum of presentations. Frequently, anemia represents the principal underlying cause of symptoms for MDS. In accordance with the National Comprehensive Cancer Network (NCCN) as well as European guidelines, the National guidelines in Greece recommend the use in selected patients groups of Red Blood Cell (RBC) transfusion for the management of anaemia in MDS patients. Nonetheless, the numbers of blood units donated in Greece by volunteer donors are insufficient to cover the existing needs. In addition, this treatment option carries risks and it also represents a costly option, especially for those who need long-term care, such as patients belonging to the low risk group. **Aims.** Given that healthcare resources are scare, especially in the presence of a serious economic crisis, an economic analysis was undertaken to assess the annual cost per patient of RBC transfusion in low risk MDS patients from the National Health System (NHS) perspective. **Methods.** A micro-costing bottom up approach was used based on a structured questionnaire filled by clinicians. Annual cost accounts for the cost of Blood Collection and Testing (BCAT), the cost of transfusion (CT) and the cost of the iron chelation (IC). Due to lack of robust local data, the cost of adverse events was not considered. The cost of BCAT (per two units) includes the cost of transfusion bag, molecular testing for HIV and hepatitis B/C, the cost of blood separation, group typing cost and storage cost. For the preparation of blood, two hours work by technicians (nurses-biologists) was considered, according to expert advice. The cost of CT per patient includes: the cost of cross-matching, the cost of white-blood-cell removal filters and one day admission in outpatient department (approximately six hours). The cost of

IC is expected in all patients after 25-30 blood transfusions. To deal with uncertainty, bias-corrected uncertainty intervals (UI) were calculated using the percentile method of non-parametric bootstrapping. Drug prices and the unit cost of healthcare resources were taken from local sources. **Results.** The average cost of RBC transfusion per patient year was estimated at €21,759 (95%UI: 20,768 - 22,758). The annual cost of CT was estimated at €2,589 (95%UI: €2,500 -€2,678), while the cost of BCAT was limited to €311 (95%UI: €264-€359). The cost of IC was estimated at €1,977 (95%UI: €1,948 -€2,008) per month and accounts for 86% of total cost. Finally, the cost of transfusing 2 units of blood was estimated at €906 (95%UI: €846-€948). **Conclusions.** Despite the fact that RBC transfusion represents the cornerstone treatment for MDS patients, the availability of blood as well as the cost related to RBC transfusion remain major issues. According to our analysis, the cost of regular blood transfusion in low risk MDS patients is substantial in Greece. This cost in reality could be even higher if the cost of adverse events was also considered. In addition, further investigation is needed in regards to the impact of poor compliance for IC therapy.

Table 1. Cost per item used in the analysis.

Blood collection and testing (2 units)	Cost (€)
Transfusion bag	5
Molecular testing for HIV/ hep B/C	5
Cost of separation	3
Cost of blood group typing	1
2hours of nurse/technician	20
Blood storage cost	3
Cost of blood transfusion (2 units)	
Cross-matching	3
WBC Removal Filter/ vein catheter	2.8
1 day admission cost	280
Cost of Iron chelation therapy (per month)*	
Desferrioxamine**	€0.048 per mg

**This type of cost was calculated only for those patients who need Iron Chelation after 20-30 units of Blood Transfusion*
***Mean dose was estimated as: 20mcg/per kg per day for an adult (70 kilograms)*

Background. Ruxolitinib is a potent and selective oral JAK1/2 inhibitor approved in the United States that has demonstrated rapid and durable reductions in splenomegaly and improved disease-related symptoms and quality of life in the 2 phase 3 COMFORT studies. Efficacy may be further enhanced with combinations of agents. Panobinostat, a potent oral pan-deacetylase inhibitor, has shown spleen size reduction, symptomatic improvement, and, in some cases, reversal of marrow fibrosis in MF patients in phase 1/2 trials. Synergistic anti-MF activity was shown in combination with ruxolitinib in JAK2-mutation-driven MF murine models. **Aims.** This study will determine a recommended phase 2 dose (RP2D) and/or maximum tolerated dose (MTD) and evaluate the pharmacokinetics (PK) of ruxolitinib and panobinostat in patients with MF. **Methods.** This is a phase 1b dose-finding study of the combination of ruxolitinib and panobinostat for the treatment of PMF, PPV-MF, and PET-MF (NCT01433445). Patients must be intermediate-1, -2, or high risk by International Prognostic Scoring System (IPSS) criteria and have palpable splenomegaly ≥5 cm below the costal margin. Dose escalation will be guided by a Bayesian logistic regression model with overdose control and will depend on dose-limiting toxicities (DLTs) in the first cycle as well as other safety findings. Each dosing cohort will consist of ≥ 3 evaluable patients. Data for ≥ 9 patients at any given dose level are required to determine the RP2D and/or MTD. Serial blood samples collected following a single dose of ruxolitinib alone on day 1 and in combination with panobinostat on days 2 and 6 were evaluated for plasma concentrations by LC-MS/MS. PK parameters were derived using noncompartmental analysis. **Results.** The first cohort of 5 patients (PMF, n = 2; PET-MF, n = 3) was treated with ruxolitinib 5 mg twice daily (BID) and panobinostat 10 mg 3 times a week, every other week (TIW/QOW); the second cohort of 8 patients (PMF, n = 4; PET-MF, n = 2; PPV-MF, n = 2) was treated with ruxolitinib 10 mg BID and panobinostat 10 mg TIW/QOW. Spleen and symptom responses for patients in the first 2 cohorts are shown (Table 1). In the first cycle, 1 DLT (grade 4 thrombocytopenia) and 1 severe adverse event (grade 3 nausea and diarrhea) were reported, and 2 patients had grade 1 elevations of creatinine. No clinically significant EKG abnormalities have been observed to date. The inter-individual variability in ruxolitinib AUC is ~40%. Mean ruxolitinib AUC on day 1 was comparable to AUC when combined with dose 1 panobinostat on day 2, but increased by 30% following 3 doses of panobinostat on day 6 in cohort 2. **Conclusions.** The combination of ruxolitinib and panobinostat appears to be well-tolerated and synergistic with promising efficacy results. Careful dose titration with additional cohorts will be necessary to confirm the optimal dosing strategy for this promising combination in the treatment of MF patients.

Table 1. Response to the combination of Panobinostat and Ruxolitinib for individual patients.

	Spleen		Constitutional Symptoms	
	Response	Time	Response	Time
Cohort 1 (n = 5)				
Patient 1	50% reduction	End of week 2	Complete resolution	End of week 2
Patient 2	50% reduction	End of week 2	Complete resolution	End of week 2
Patient 3	42% reduction	Start of cycle 4	No change	Start of cycle 4
Patient 4	17% reduction	Start of cycle 3	No change	Start of cycle 4
Patient 5[a]	No change	Start of cycle 4	No change	Start of cycle 4
Cohort 2 (n = 8)				
Patient 1	83% reduction	During week 1	Complete resolution	After 48 hours
Patient 2	30% reduction	After week 2	Complete resolution	After 72 hours
Patient 3	20% reduction	End of week 2	Significant improvement	End of week 2
Patient 4	20% reduction	End of week 2	Significant improvement	End of week 1
Patient 5	75% reduction	End of week 2	Complete resolution	End of week 2
Patient 6[b]	50% reduction	End of week 3	No change	End of week 3
Patient 7	No change	End of week 3	Complete resolution	End of week 3
Patient 8	Complete resolution	End of week 3	No change	End of week 3

[a] Patient experienced rising blast counts and was taken off study to undergo stem cell transplantation.

[b] Patient experienced grade 4 thrombocytopenia and was taken off study due to DLT criteria.

GERMLINE ACTIVATING JAK2-MUTATION IN A FAMILY WITH HEREDITARY THROMBOCYTOSIS

J Mead[1], M Rugless[2], O Chowdhury[3], A Dusa[4], P Woll[3], R Clifford[2], C Pecquet[4], D Atkinson[3], R Gale[5], S Henderson[2], S Constantinescu[4], S Jacobsen[3], A Schuh[2]
[1]Weatherall Instititute of Molecular Medicine, Oxford, United Kingdom
[2]Oxford BRC/NHS Haemato-Molecular Diagnostic Laboratory, John Radcliffe Hospital, Oxford, United Kingdom
[3]Hematopoietic Stem Cell Laboratory, Oxford, United Kingdom
[4]Ludwig Institute for Cancer Research, Université catholique de Louvain, Brussels, Belgium
[5]UCL Cancer Institute, University College London, London, United Kingdom

Background. The association between somatic JAK2 mutation and myeloproliferative neoplasms is now well established. However, JAK2 mutations are associated with heterogeneous clinical phenotypes and have been described both as primary and secondary genetic events, making it challenging to understand their exact role in disease pathogenesis. **Aims and Methods.** We have

identified a family with germline JAK2-V617I mutation and have characterised the clinical and biological impact of the mutation **Results.** JAK2-V617I-mutation was detected by pyrosequencing and was present at heterozygous levels in peripheral blood (PB) and germline DNA in six members of the same family. The mutation segregated with hereditary mild/moderate thrombocytosis in a high penetrance, autosomal dominant pattern. Vascular events were frequent in older affected individuals. Bone marrow (BM) examination demonstrated megakaryocyte hyperplasia but no evidence of myelofibrotic or leukaemic transformation.Whole exome sequencing (one case) and screening for MPN-associated mutations by targeted sequencing (four cases) did not reveal evidence of additional genetic events. Furthermore, copy number abnormalities or areas of uniparental disomy were excluded by SNP array in four cases. In addition, we carried out XCIP clonality analysis on two potentially informative cases with no evidence of clonal haematopoiesis.Previous studies have suggested that the JAK2-V617I mutation is constitutively activating in retrovirally transduced cell lines (PMID:18326042). However, patients with heterozygous JAK2-V617I did not show cytokine-independent colonies, suggesting that the impact of JAK2-V617I on signalling might be distinct from V617F. Indeed, in autonomous EpoR-Ba/F3 JAK2-V617I cells, constitutive STAT3 and STAT5 activation was much weaker for JAK2-V617I than V617F, and no activation of STAT1 was observed. In response to Epo stimulation, however, V617I resulted in markedly increased downstream signalling in comparison with wild-type JAK2 and comparable to JAK2-V617F. In order to confirm aberrant signalling in the JAK2-V617I patients, we investigated pSTAT3 levels in their PB cells. Baseline pSTAT3 level was not altered, however, following GCSF stimulation, JAK2-V617I-positive PB CD33+ myeloid and CD34+ stem/progenitor cells demonstrated a marked increase in pSTAT3 levels in comparison with controls.Phenotypic haematopoietic stem cells (Lin-CD34+CD38-CD90+CD45RA-) were increased in the PB and BM of JAK2-V617I positive patients and CD34+ cells showed normal engraftment in xenotransplantation assays. This is particularly noteworthy as the impact of JAK2 mutations on stem cells in mouse models is controversial. There were no significant differences in numbers of other phenotypically defined progenitor populations. In comparison with controls, CFU-GM were increased in the PB and BM of V617I-positive cases but BFU-Es were not affected, and CFU-Mks were non-significantly increased. **Summary and Conclusions.** Germline JAK2-mutation is a previously unreported cause of inherited haematopoietic disease. The high penetrance and homogeneous phenotype, together with cytokine hyper-responsive JAK2-dependent signaling in the presence of JAK2-V617I, provides compelling evidence of the causative nature of the mutation. Our findings highlight the need to routinely screen for non-JAK2-V617F mutations, and to exclude germline mutation in selected cases. Whilst these are likely to be rare families, we predict that other germline JAK2 mutations will now be detected, and genotype-phenotype correlations will be highly informative for understanding of JAK2-mutation biology.

Background. Symptom burden in MPNs is severe and a risk factor for mortality in some disease subtypes (Blood 2010;115(9):1703-8). A recent trial comparing JAK2 treatment to best available therapy revealed that patients receiving conventional MPN therapies experienced no difference or worsening of symptoms (Blood 2011;118(21):a6501). No studies have evaluated the specific associations of conventional therapies on individual MPN symptoms using a validated patient-reported measure of symptom burden. **Aims.** We aimed to assess associations between conventional therapies on specific MPN symptoms using the MPN-SAF TSS (Blood 2011;118(21):a3839). **Methods.** Patient demographics, symptom burden and disease traits including therapies were collected from MPN patients and physicians at a single time point during therapy. MPN-SAF TSS included "worst"fatigue from the BFI and MPN-SAF items of concentration, early satiety, inactivity, night sweats, itching, bone pain, abdominal discomfort, weight loss and fever. MPN-SAF TSS was calculated as the total 10-item score, reported in a range of 0 to 100 for patients completing at least 6 of the 10 items. **Results.** *Demographics*: 1433 MPN patients were prospectively enrolled, including 594 essential thrombocythemia(ET), 538 polycythemia vera(PV) and 293 myelofibrosis(MF) patients from 11 countries. Of these, 1408 patients completed at least 6 of the 10 required items. Patients were 54% female with a median age of 63.*Therapies:* Common therapies included hydroxyurea/hydroxycarbamide(47.7%), salicylates(43.8%), interferon/pegylated-interferon(9.4%), and phlebotomies(5.3%) with 12.6% receiving no therapy. MPN-SAF TSS variations were observed between patients receiving and not receiving each therapy, although only one reached statistical significance (Table 1).

Table 1. Number of respondents and average MPN-SAF TSS Score by type of MPN treatment (N=1,408).

			MPN Treatment

*ET and MF not assessed
**Student's t-test indicated a significant difference in MPN-SAF TSS between PV patients who received interferon therapy compared to those who did not (p=0.04).

Overall Treatment Effects: When comparing the overall effects of current therapy, worst fatigue was significantly more severe among PV patients undergoing treatment as compared to patients not receiving treatment (4.5(n=497) vs. 3.4(n=30), p=0.03). Among MF patients, abdominal comfort was significantly worse among patients not receiving therapy (3.3(n=57) vs. 2.3(n=230),p=0.02) .*Aspirin:* ET patients receiving aspirin reported significantly less weight loss than patients not receiving salicylates (0.62(n=298) vs. 0.98(n=283),p=0.03). Additionally, aspirin among ET patients reduced pruritus (1.5(n=296) vs. 2.0(n=284),p=0.02). PV patients receiving aspirin reported more concentration difficulties than patients on a non-aspirin regimen (3.0(n=254) vs. 2.4(n=264),p=0.01). MF patients receiving aspirin reported decreased bone pain (1.5(n=58) vs. 2.4(n=228),p=0.04) and abdominal discomfort (1.9(n=58) vs. 2.7(n=229),p=0.04). *Hydroxyurea/hydroxycarbamide*: PV patients receiving hydroxyurea/hydroxycarbamide reported decreased itching than patients not on this therapy, although this effect was of borderline significance (2.5(n=272) vs. 3.0(n=255),p=0.05). *Phlebotomies:* PV patients being given phlebotomies had significantly decreased problems with concentration compared to non-phlebotomized patients (1.9(n=71) vs. 2.8(n=447),p=0.02). *Interferon/pegylated-interferon*: PV patients receiving interferon therapy reported increased early satiety (3.1(n=69) vs. 2.4(n=257),p=0.04), fever (0.7(n=67) vs. 0.3(n=455), p=0.02), and MPN-SAF TSS (25.5(n=69) vs. 21.2(n=460),p=0.04) than non-interferon-receiving counterparts. **Conclusions.** Few significant effects in overall symptom burden were observed in patients undergoing traditional MPN therapies. Though some effects reached nominal statistical significance, a portion

may be spurious given the large number of tests performed. Further studies are needed to determine whether treatments impart additional symptom burden or if patients with specific symptom characteristics are selected to receive a particular treatment. Prospective serial assessment of conventional therapy impact is ongoing as part of a new clinical trial.

IMPROVED SURVIVAL IN YOUNGER PATIENTS WITH PRIMARY MYELOFIBROSIS OVER TIME, A STUDY OF 1,048 PATIENTS DIAGNOSED WITH PRIMARY MYELOFIBROSIS IN SWEDEN 1973-2008

M Hultcrantz
Karolinska University Hospital, Stockholm, Sweden

Background. Primary myelofibrosis (PMF) is the subtype associated with the worst prognosis of the myeloproliferative neoplasms (MPNs), overall median survival has been reported to be five to six years. Recent prognostic scoring systems all include age >65 years as an indicator of poor prognosis. We recently reported that there has been no major overall improvement in survival in PMF patients during the last three decades. However there is limited detailed information regarding the impact of age on survival over time. **Aims.** To assess patterns of survival in PMF patients of different age groups in a population-based setting in Sweden during a study period of 36 years. **Methods.** Patients with PMF were identified through the Swedish Cancer Register from 1973-2008 with follow-up until 2009. Relative survival ratios (RSRs) were computed as measures of survival. Five-, 10-, and 15-year RSRs with 95% confidence intervals(CIs) were calculated for PMF patients during four calendar periods:1973-1982, 1983-1992, 1993-2000, and 2001-2008 and for five different age groups; younger than 50, 50-59, 60-69, 70-79, and 80 years and older. Information on the number of allogeneic stem cell transplantations (SCTs) was obtained from the European Group for Blood and Marrow Transplantation Register. **Results.** A total of 1,048 PMF patients were identified (56% males, median age at diagnosis 71 years) were reported to the Swedish Cancer Register 1973-2008. Fifty-eight patients were younger than 50 years at diagnosis. During the study period, 43 allogeneic SCTs were carried out in patients with PMF in Sweden.Survival was lower in PMF patients compared to expected survival in the general population, reflected in 5-, 10- and 15-year RSRs of 0.39 (0.35-0.43), 0.21 (0.18-0.25), and 0.11 (0.08-0.15), respectively. During the first calendar period there was no distinct difference in relative survival between the age groups. However, during the years 1983-2008, patients younger than 50 years at diagnosis had a superior survival compared to the other age groups (Figure 1).

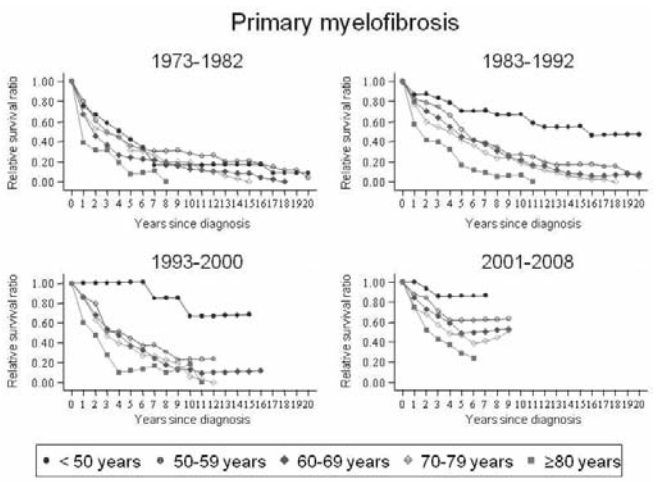

Figure 1. Cumulative relative survival in patients with primary myelofibrosis in relation to age and calendar period at diagnosis.

Five-year survival improved over time in patients <50 years at diagnosis and was 0.42 (0.15-0.67), 0.71 (0.47-0.85), 1.01 (1.01-1.01; no deaths occurred) and 0.86 (0.53-0.97) for the calendar periods 1973-1982, 1983-1992, 1993-2000, and 2001-2008, respectively. Additionally, in the same age group the 10-year RSR also improved and was 0.17 (0.03-0.42), 0.67 (0.44-0.84), and 0.67 (0.18-0.93) in 1973-1982, 1983-1992 and 1993-2000, respectively. **Summary and Conclusions.** In this large population-based study of over 1,000 PMF patients, we found patients under 50 years at diagnosis to have a better survival compared to patients aged 50 or above. Importantly, survival improved in younger PMF patients. There were no major changes in the classification system between 1983 and 2000. However, the introduction of prefibrotic PMF in 2001, including also early stage PMF patients in this group, might have influenced RSRs for the better during the most recent calendar period. In addition, the increasing number of allogeneic SCTs, the decrease in use of leukemogenic drugs and better supportive care has most likely contributed to the improvement in survival in young PMF patients.

[13]Hospital Dr Negrin, Las Palmas, Spain
[14]Hospital General, Castellon, Spain

Background. Patients with essential thrombocythemia (ET) and polycythemia vera (PV) have an increased incidence of new hematologic and nonhematologic malignancies as compared to the general population. However, information on the factors determining the risk of such complication is limited. Recently, inherited variations in DNA repair efficiency have been implicated in the predisposition to *de novo* and therapy-related acute myeloid leukemia (AML), as well as in the increased susceptibility to a variety of nonhematologic cancers.

Aims. To evaluate whether constitutional genetic variation in DNA repair predisposes to leukemic transformation and new nonmyeloid neoplasias in patients with ET and PV. **Methods.** Case-control studies for the predisposition to both types of malignancies were nested in a cohort of 422 subjects diagnosed with ET or PV during the period 1973-2010 in several institutions in Spain. A total of 64 incidence cases of AML and 50 of primary nonmyeloid cancers were accrued. Genotyping analysis of five single nucleotide polymorphisms located in four DNA repair genes involved in the nucleotide excision repair (*ERCC2* [also known as *XPD*], *ERCC5* [*XPG*], *XPC*) and base excision repair (*XRCC1*) pathways was performed by real-time PCR. **Results.** By conditional regression analysis, adjusted for other potentially predisposing factors, the Gln/Gln genotype in the *XPD* codon 751 (OR: 4.9; 95% CI: 2.0-12; P=0.001) and exposure to cytoreductive agents (OR: 3.5; 95% CI: 2.0-6.2; P<0.001) were identified as risk factors for leukemic transformation, whereas the Gln/Gln *XPD* genotype (OR: 4.2; 95% CI: 1.5-12; P=0.007) and patients' age (OR: 2.0; 95% CI: 1.4-2.8; P<0.001) predicted for the development of new nonmyeloid malignancies. Presence of the *JAK2* mutation retained a trend to be independently associated with development of a new primary cancer (OR: 2.5; 95% CI: 1.08-5.9; P=0.04) after adjustment for age and the *XPD* genotype. **Conclusions.** The present study shows that a single nucleotide polymorphism in the *XPD* gene predisposes individuals with ET and PV to develop AML and new primary nonmyeloid malignancies. These results, if confirmed in an independent series, could allow the identification of high-risk patients who would benefit from close surveillance and individualized therapeutic approaches.

[11]University of Florence, Florence, Italy

Background. Ruxolitinib, a potent and selective oral JAK1/2 inhibitor, has demonstrated rapid and durable reductions in splenomegaly and improved MF-related symptoms and quality of life in 2 phase 3 studies in patients with PMF, PPV-MF, or PET-MF. There is considerable experience in patients who develop thrombocytopenia on study, and ruxolitinib is well tolerated with dose adjustment. However, there is limited experience in patients with baseline thrombocytopenia as those with low PLTs (<100×10^9/L) were excluded from the phase 3 protocols. **Aims.** The EXPAND (Evaluating RuXolitinib in Patients with Low Baseline PlAtelet CouNts Diagnosed with Myelofibrosis) study is evaluating the safety of ruxolitinib to establish the maximum safe starting dose (MSSD) in thrombocytopenic patients with MF. **Methods.** Phase 1b, open-label, dose-finding study (NCT01317875) in patients with PMF, PPV-MF, or PET-MF and baseline PLTs 50-100x10^9/L. A Bayesian logistic regression model will be used to guide dose-escalation decisions; intrapatient dose escalation is allowed during the study. Study consists of 2 phases: dose-escalation and safety-expansion. Starting dose of ruxolitinib is 5mg twice daily (BID) with a maximum of 15mg BID. In the dose-escalation phase, cohorts will be: 5mg BID, 5mg am/10mg pm, 10mg BID, 10mg am/15mg pm, and 15mg BID; initially patients with PLTs 75-100x10^9/L (first stratum) will be enrolled. Once safety is established at the first 2 dose levels (5 mg BID; 5mg am/10mg pm), patients with PLTs 50-75x10^9/L will be included (second stratum). Each dose level in the second stratum will be open only if both that dose and the following one are deemed safe in the first stratum. In the safety-expansion phase, 20 patients (10 in each stratum) additional to those treated at the MSSD during dose escalation will be treated at the respective MSSD for their stratum. **Results.** Seven patients (PMF, n=4; PPV-MF, n=3) are currently enrolled; 4 in cohort 1 (5 mg am/5 mg pm) and 3 in cohort 2 (5 mg am/10mg pm). At baseline, all patients had an ECOG of 0 or 1, and spleen size ranged from 12-30cm below the costal margin. Six patients completed >28 days of treatment and are consequently evaluable; the seventh patient discontinued at day 6 due to granulocytic sarcoma and was nonevaluable. Of the 6 evaluable patients, 1 patient discontinued treatment on day 57 due to deterioration of general condition and underwent splenectomy on day 64. Reported AEs were similar to those previously seen with ruxolitinib. Three patients experienced grade 3/4 AEs (only 2 anemia events were study-drug related), and 2 patients experienced serious AEs (Table 1).

Table 1. Grade 3 or 4 AEs reported for all patients.

	AE or SAE	Grade	Relationship to Study Drug	SAE	Outcome	Action
Patient 1	Deterioration of general condition	3	Unrelated	No	Recovered/resolved	Discontinued
	Worsening of back pain, radiating to pelvis and hip	3	Unrelated	No	Recovered/resolved	None
	Worsening of neuropathic pain both legs	3	Unrelated	No	Recovered/resolved	None
	Anemia	4	Related	Yes	Recovered/resolved	None
	Splenectomy	4	Unrelated	No	Recovered/resolved	Discontinued
Patient 2	Anemia	3	Related	Yes	Recovered/resolved	None
Patient 3 (nonevaluable)*	Paralysis of oculomotor nerve	3	Unrelated	No	Recovered/resolved with sequelae	Discontinued
	Granulocytic sarcoma in sellar region	3	Unrelated	No	Recovered/resolved	Discontinued
	Asthenia	3	Unrelated	No	Not recovered/not resolved	None

* Patient discontinued after 6 doses and was therefore nonevaluable.

No hemorrhagic events were observed. The lowest PLT counts across all patients ranged from 29-67x10^9/L; no patient discontinued because of thrombocytopenia. No dose-limiting toxicities were observed. Reductions in palpable spleen length from baseline to the most recent postbaseline assessment were reported for 5/6 patients. **Conclusions.** In this phase 1b study of ruxolitinib in thrombocytopenic patients with MF, no DLT has occurred at the first 2 dose levels in patients with PLTs 75-100x10^9/L; thus, additional patients are being recruited for both strata. Updated results will be reported.

[6]Shire Pharmaceuticals, Basingstoke, United Kingdom
[7]Uppsala University, Uppsala, Sweden

Background. The Evaluation of Xagrid Efficacy and Long-term Safety (EXELS) study is an observational cohort study of essential thrombocythemia (ET) in high-risk patients. It is being conducted in 13 European countries: Denmark, Finland, France, Germany, Greece, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, and UK. The study is designed to monitor the safety and efficacy of cytoreductive therapies in routine clinical practice. The study is sponsored by Shire Pharmaceuticals. **Aims**. The objective of this analysis was to observe the disease characteristics and cytoreductive treatment patterns of ET across Europe. **Methods.** High-risk patients (>60 years of age; history of thrombosis; platelet count >1000x10^9/l) with ET who were receiving cytoreductive therapy at the time of registration were enrolled, following informed consent. The choice of cytoreductive therapy was determined prior to study registration and patients were managed according to local practice. Data were collected from each patient at the time of registration and every 6 months thereafter for 5 years, using an electronic data capture system. Here we describe findings from a data-cut taken in September 2011, scheduled 2.5 years since the last patient was enrolled. Approximately 70% of the patients were continuing in the study at this data-cut. **Results**. A total of 3643 patients, 61.3% females and 38.7% males, across a wide range of ages (<40 years, 6.9%; 40-59 years, 25.5%; ≥60 years, 67.6%) were enrolled into the study. The majority of patients (80.6%) had been previously treated with a cytoreductive therapy at the time of registration. Time from diagnosis to study registration was 0-<2 years for 32.9% of patients; 2-<5 years for 26.8%; 5-<10 years for 24.5%; and ≥10 years for 15.8% of patients. Hydroxycarbamide and anagrelide were the two main cytoreductive treatments prescribed as monotherapy in 65.1% and 22.2% of patients, respectively. 'Other' treatments included interferon, busulphan, pipobroman, 32P, and hydroxycarbamide and anagrelide in combination. At registration, a greater proportion of patients in the anagrelide group were <60 years (59.3%), relative to those taking hydroxycarbamide (19.3%). The full distribution of patient age according to treatment type were as follows: hydroxycarbamide (<40=2.4%; 40-59=16.9%; ≥60=80.7%); anagrelide (<40=16.3%; 40-59=43.0%; ≥60=40.8%); others (<40=12.9%; 40-59=39.4%; ≥60=47.7%). The number of patients and type of treatment at registration, per country, is displayed in Figure 1.

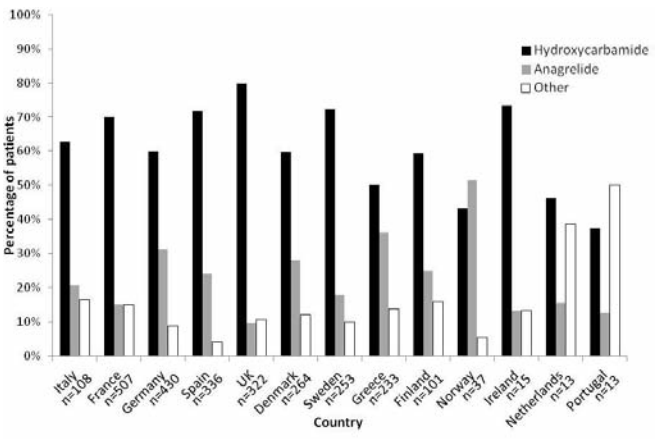

Figure 1. Type of treatment at registration per country.

The treatment pattern between countries was notably different, with rates of use showing marked variation; hydroxycarbamide 38-80%, anagrelide 10-51%, other 4-50%. **Summary and Conclusions.** This study provides real-world evidence regarding the cytoreductive treatment patterns of ET across Europe, taken from the largest observational cohort of high-risk patients with ET. Hydroxycarbamide was the most frequent treatment of choice in nearly all of the participating countries across Europe, but patient age strongly influenced the choice between hydroxycarbamide and anagrelide therapy. In general, the treatment pattern is in accordance with expert recommendations in Europe. The study is due to be completed in June 2014, and is expected to provide valuable information on long-term safety and efficacy of different cytoreductive treatments, with regard to disease-related events and toxicity.

[17]Incyte Corporation, Wilmington, United States of America

Background. Ruxolitinib is a JAK1/JAK2 inhibitor that has demonstrated significant clinical benefit in patients with myelofibrosis in the COMFORT-I study. **Aims.** To assess adverse events after interruption or discontinuation of study therapy and to evaluate the return of myelofibrosis-related symptoms after interruption of ruxolitinib therapy in the COMFORT-I study. **Methods.** COMFORT-I (NCT00952289) is a phase III, randomized (1:1), double-blind, placebo-controlled study in 309 adults patients with International Prognostic Scoring System intermediate-2 or high-risk primary myelofibrosis, post-essential thrombocythemia myelofibrosis, or post-polycythemia vera myelofibrosis. Patients assessed myelofibrosis-related symptoms daily using the modified Myelofibrosis Symptom Assessment Form v2.0; Total Symptom Score (TSS) was calculated from individual scores for abdominal discomfort, pain under left ribs, early satiety, night sweats, itching, and bone/muscle pain. Therapy was interrupted if platelet or absolute neutrophil count fell below 50,000/μL or 500/μL, respectively. Adverse events were evaluated after treatment interruption and treatment discontinuation. The study protocol suggested an optional tapering strategy and possible addition of steroids if ruxolitinib therapy was discontinued for reasons other than thrombocytopenia. All patients provided written informed consent. **Results.** The mean duration of treatment interruption was 16 days in the ruxolitinib group and 9 days in the placebo group. In ruxolitinib-treated patients with treatment interruption, TSS gradually returned to baseline levels over approximately 1 week. The most common adverse event leading to treatment interruption or discontinuation in each group was thrombocytopenia (n=11, ruxolitinib) and abdominal pain (n=4, placebo). Of these, only 1 ruxolitinib-treated patient discontinued therapy for thrombocytopenia. A summary of new onset/worsening of adverse events after treatment interruption or discontinuation is presented (Table 1). Of 103 patients who interrupted study treatment, 6 patients (n=3, ruxolitinib; n=3, placebo) experienced a total of 8 serious adverse events (4, ruxolitinib; 4, placebo). Of 58 patients who discontinued study treatment, 23 patients (n=10, ruxolitinib; n=13, placebo) experienced a total of 43 serious adverse events (19, ruxolitinib; 24, placebo). Analysis of serious adverse events of each patient showed that there was no specific pattern or difference between treatment groups after treatment interruption or discontinuation. Four of 21 ruxolitinib-treated patients had dose tapering following study drug discontinuation.**Summary/ Conclusions.** Apart from the expected return of myelofibrosis-related symptoms, there was no pattern of adverse events to suggest that interruption or discontinuation of ruxolitinib therapy is associated with a specific withdrawal syndrome. *Supported by Incyte Corporation.* Dr. Deininger is currently at the Division of Hematology and Hematologic Malignancies and Huntsman Cancer Institute, University of Utah, Salt Lake City, UT.

Table 1. Summary of adverse events (AEs) and serious adverse events (SAEs) after treatment interruption or discontinuation in COMFORT-I

	Ruxolitinib (N=155)	Placebo (N=151)
Treatment interruption, n	49	54
Grade ≥3 AEs, n	8	7
SAEs, n	3	3
	Gastrointestinal hemorrhage; Fatigue, neutropenic fever; Urosepsis	Anemia; Pulmonary edema; Hepatic encephalopathy, acute gout
Treatment discontinuation, n	21	37
Grade ≥3 AEs, n	12	17
SAEs, n	10	13
	Fall, splenic hemorrhage; Subdural hematoma; Pyrexia; Pneumonia, respiratory failure, septic shock; Acute myeloid leukemia (AML); Thrombocytopenia, renal failure; Pneumonia, Clostridial infection, sepsis; Pneumonia; Fatigue, muscular weakness, splenic infarction; Thrombocytopenia, AML	Staphylococcal infection; Gastrointestinal hemorrhage; Abdominal pain; Colitis, pulmonary embolism; Urinary tract infection, pneumonia; Dehydration, fall, splenic hematoma, subdural hematoma, cardiac failure, leukocytosis, pneumonia, renal failure, sepsis; Abdominal pain; Myelofibrosis; Renal failure; Pulmonary edema, multiorgan failure; Disease progression; Disease progression; Intestinal ischemia

NOTE: AEs and SAEs reported are as of the data cutoff for the primary endpoint of the study.

0372

COMPARISON OF THE EFFICACY OF PLACEBO AND BEST AVAILABLE THERAPY FOR THE TREATMENT OF MYELOFIBROSIS IN THE COMFORT STUDIES

R Mesa[1], S Verstovsek[2], F Cervantes[3], A Sirulnik[4], E Mendelson[4], W Sun[5], V Sandor[5], R Levy[5], C Harrison[6]

[4]Novartis Pharmaceuticals Corporation, East Hanover, United States of America
[5]Incyte Corporation, Wilmington, United States of America
[6]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background. Ruxolitinib is a potent and selective oral JAK1/2 inhibitor that has been approved in the US and has demonstrated rapid and durable reductions in splenomegaly and improved disease-related symptoms and quality of life (QoL) in 2 phase 3 studies (COMFORT-I and -II) in patients with primary MF, post-polycythemia vera-MF, or post-essential thrombocythemia-MF. Compared with the control group in each study (COMFORT-I, placebo; COMFORT-II, best available therapy [BAT]), a significantly higher proportion of patients receiving ruxolitinib achieved a ≥35% reduction in spleen volume at week 24 (COMFORT-I and -II; *P*<.0001) and week 48 (COMFORT-II; *P*<.0001). **Aims.** This analysis compares the efficacy outcomes between the placebo arm from COMFORT-I and the BAT arm from COMFORT-II. **Methods.** COMFORT-I is a randomized (1:1), double-blind, multicenter study comparing ruxolitinib 15 or 20mg twice daily (BID) with placebo, and COMFORT-II is a randomized (2:1), open-label, multicenter study comparing ruxolitinib 15 or 20mg BID with BAT (investigator-selected therapy, including no treatment). QoL was measured using patient responses with the EORTC QLQ-C30 as an exploratory endpoint in both studies. **Results.** In the COMFORT-I and COMFORT-II studies, 154 patients received placebo (ruxolitinib, n=155), and 73 patients received BAT (ruxolitinib, n=146), respectively, and were included in the primary efficacy analyses. The demographic and baseline characteristics were similar between the control arms of the 2 studies including spleen size below the costal margin (mean [standard deviation], 16.4 [6.27] cm and 15.8 [6.71] cm in placebo and BAT, respectively). Only 1 patient (0.7%) who received placebo and no patients who received BAT had a ≥35% reduction in spleen volume from baseline at week 24 (Figure). The median percent increases in spleen volume from baseline to week 24 in both the placebo and BAT groups were numerically similar (placebo, 8.5% [range, -46.4% to 48.8%]; BAT, 5.1% [range, -33.3% to 29.7%]). In contrast, almost all patients who received ruxolitinib

had a reduction in spleen volume from baseline at week 24 (COMFORT-I: median, -33.0%; COMFORT-II: median, -27.5%).The QLQ-C30 provides a measurement of QoL and MF-related symptoms, including fatigue, pain, dyspnea, insomnia, and appetite loss. At 24 weeks, neither the placebo nor BAT arms had clinically meaningful changes from baseline (10 points [Osoba et al. *J Clin Oncol*. 1998]) in global QoL (decreases indicate worsening) or symptom scales (increases indicate worsening) (Table). Although differences exist between the placebo and BAT arms in the mean change from baseline, between-group comparison was not performed because of the large standard deviations that complicate any comparisons between the 2 groups. **Conclusions.** This post hoc analysis shows that patients who received BAT in the COMFORT-II study fared no better in clinically meaningful QoL responses and had numerically similar increases in spleen size as those who received placebo in COMFORT-I. No clinically meaningful improvements in QoL or symptoms were seen on either the placebo or BAT arms. These new data strongly suggest that traditional therapies for MF provide little improvement in spleen size, symptoms, or QoL as compared with placebo.

Table. Mean EORTC QLQ-C30 Global Health Status and Subscale Results at Week 24 i the Placebo and BAT Arms (Observed Cases)[a]

	Placebo		BAT	
	n	Mean change from baseline at week 24 (SD)	n	Mean change from baseline at week 24 (SD)
Global health status/QoL	104	-3.4 (21.53)	37	5.2 (23.76)
Fatigue	107	1.8 (24.71)	39	-1 (23.57)
Pain	104	8.3 (27.47)	39	3 (28.06)

Background. Ruxolitinib is a potent and selective JAK1/2 inhibitor approved in the United States based on results of the phase 3 COMFORT studies. Ruxolitinib demonstrated rapid and durable reductions in splenomegaly and improved MF-related symptoms and quality of life of patients with MF. **Aims.** To determine the correlation between changes in mutant allele burden (%V617F) with spleen size reduction in COMFORT-II. **Methods.** COMFORT-II is a randomized, open-label, phase III study comparing ruxolitinib 15 or 20 mg twice daily (BID) with BAT. The primary endpoint was a ≥ 35% reduction in spleen volume from baseline at week 48. Change in %V617F was measured by allele-specific qPCR. Patients were stratified by absolute reduction in %V617F (< 10%, 10% to 20%, > 20%) and results were correlated with achievement of the primary endpoint. **Results.** More patients in the ruxolitinib arm had ≥ 10% V617F reductions compared with BAT (41% vs 5%; *P* = .01; Table). The majority of reductions > 20% were gradual and progressive over the course of the study; 2 patients had rapid reductions from 48% to 1% and 45% to 9% over 48 weeks (Figure). In the ruxolitinib arm, significantly more patients with a > 20% V617F reduction achieved the primary endpoint compared with patients with a < 10% reduction (79% vs 30%; *P* = .004). For patients with < 10% reductions (15 mg BID, n = 16; 20 mg BID, n = 24), the average total daily dose (TDD) of ruxolitinib was 29.6 mg; patients with > 20% reductions (15 mg BID, n = 3; 20 mg BID, n = 11) had a TDD of 35.3 mg. **Conclusions.** Patients who received ruxolitinib had larger reductions in *JAK2*V617F allele burden compared with BAT. %V617F reductions were gradual over the course of the 48-week study; longer follow-up is needed to determine the extent of allele burden reduction.

Table. Reductions in *JAK2*V617F Allele Burden at Week 24 and Week 48.

n (%)		Ruxolitinib (n = 145)[a]	BAT (n = 69)[a]
*JAK2*V617F positive at baseline		110 (76) Mean: 73.5 Median: 84.5 Range: 5-96	49 (71)[b] Mean: 69.1 Median: 81 Range: 1-95
*JAK2*V617F positive with week 24 data available		75 (68)	24 (49)
%V617F reduction	Median	-6.0%	0.5%
	< 10%[c]	46 (61)	24 (100)
	10% to 20%	15 (20)	0
	≥ 20%	14 (19)	0
*JAK2*V617F positive with week 48 data available		68 (62)	22 (45)
%V617F reduction	Median	-7.0%	0%
	< 10%[d]	40 (59)	21 (95)
	10% to 20%	14 (21)	1 (5)

Background. Philadelphia negative myeloproliferative neoplasms (MPN) are rare in patients younger than 40 years, and information on the natural history of disease is lacking in this setting. In particular, the available evidence suggests that these patients might have distinct vascular complications whose proper understanding is crucial for clinical decision making.The *aim* of this study, performed under the auspices of the Gruppo Italiano Malattie EMatologiche dell'Adulto (GIMEMA), was to evaluate thrombotic events and their risk factors in a large cohort of patients with MPN diagnosed between 16 and 40 years of age. **Material and Methods.** Nine Italian hematological centers completed an ad-hoc supplied electronic sheet, reporting the clinical and laboratory data of their young patients with MPN (age range 16 and 40 years). The final cohort included 1161 patients (61% females, median age at diagnosis 32.8 years) of whom 929 with ET and 232 with PV diagnosed between 1960 and 2011. Diagnostic criteria used were those in effect at the time of initial diagnosis; the Polycythemia Vera Study Group (PVSG) criteria were preferentially used for diagnoses prior to 2006 (570 patients), while the WHO criteria were for diagnoses thereafter (592 patients). We applied X^2 test for categorical variables and Mann-Whitney U for continuous variables. To evaluate risk factors for thrombosis we applied logistic regression analysis.

Table 1.

	Unusual site N=76	DVT or PE N=31	Univariate p
General characteristics			
Sex F (%)	52 (68%)	19 (61%)	0.67
Median age at diagnosis	30.4	34	0.114
Median follow up (years)	10.6	11.7	0.382
WBC x 10^9/L	9.9±4.2	10.6±5.5	0.856
Hb g/L	14.7±2.7	15.3±2.5	0.542
HT (%)	43.8±8.8	46.7±6.5	0.338
Platelets x 10^9/L	649±389	727±302	0.123
JAK2V617F	51/57 (89%)	13/23 (56%)	0.005

Results. In a total of 203 patients (17.4%) arterial (n=96, 8%) or venous (n=107, 9%) thrombosis was recorded, with higher prevalence in those with PV (27 % vs 15%, p<0.05). Considering venous thrombosis, 76 were thrombosis at unusual site (67 splanchnic vein thrombosis and 9 cerebral vein thrombosis) and 31 were deep vein thrombosis (DVT) or pulmonary embolism (PE), as reported in the table. Venous thrombosis was the presenting feature of MPN in 41 (38%) patients and thrombosis at unusual site was more common than DVT as presenting feature of MPN (p=0.009). Multivariable analysis identified diagnosis of PV (RR 2.9, 95% CI 1.2-6.9) and presence of *JAK2* (V617) (RR 5.5, 95% CI 1.6-18.9) as a significant risk factors for thrombosis at unusual site, and this was true also for female gender within ET patients (RR 7.8, 95% CI 1.02-60.2). The only predictor of DVT or PE seemed to be leukocytosis (>11x10^9/L; 3.0, 95% CI 0.96-9.4) without reaching statistical significance. Among arterial events, TIA or stroke occurred in 5% of ET and 6 of PV and acute coronary syndrome in 2% and in 7% respectively with the latter difference statistically significant (p<0.001). The presence of cardiovascular risk factors was the only predictor for arterial thrombosis in ET patients. **Discussion.** The most common phenotypic manifestation of venous thrombosis in young patients with MPN is thrombosis at unusual site, particularly in ET females, thus suggesting a possible interaction with hormonal risk factors. Most of these cases of atypical vein thrombosis occur in patients carrying the *JAK2* (V617F) mutation. Overall, PV has a more aggressive clinical course, characterized by an increased prevalence of thrombosis compared to ET.

Background. Chronic myeloproliferative neoplasms and myelodysplastic syndromes can evolve to secondary acute myeloid leukemia (sAML). It has been shown that sAML can arise either on the background of the chronic phase founder clone, or as an independent event, resembling *de novo* AML (dnAML). The leukemogenesis in sAML is poorly understood and these patients have poor prognosis. **Aims.** The main aim of the study was to compare genetic lesions in sAML and dnAML patients, and identify those with the most prominent impact on the overall survival (OS). Furthermore, we aimed to analyze the interplay of genetic aberrations in different genomic regions and their potential use in patient stratification. **Methods**. High-resolution genotyping and loss of heterozygosity mapping was performed on DNA samples from 86 sAML and 117 dnAML patients, using Affymetrix SNP 6.0 arrays. TP53, RUNX1, CBL, IDH1/2, NRAS, NPM1 and FLT3 genes were analyzed individually for mutations in all patients. OS comparisons were performed using the log-rank test, and multivariate survival analysis using Cox's regression model. Mutual information and interaction information analysis were performed using the R package "infotheo". **Results.** Patients with sAML showed higher karyotype complexity than dnAML (P<0.001), and more rarely a normal karyotype (P=0.002). We identified a total of 669 deletions, gains and acquired uniparental disomies (UPD). There were 36 recurrent aberrations (>5 events), most of which associated with sAML. High number of events allowed fine mapping (<1Mb) of target genes, such as JARID2, IKZF1, NF1. Mutations in TP53, 9pUPD, and del7q (harboring CUX1) were significantly associated with sAML, while NPM1 and FLT3 mutations were significantly associated with dnAML. Mutations in IDH1/2 were mutually exclusive with TP53 and NRAS mutations.Patients with sAML had worse 3-year OS rate (11.3%±4.9%) compared to dnAML (35.2%±5.3%; P=0.003). We analyzed the influence of features not associated with chronic phase or dnAML on OS of sAML patients. SAML patients with TP53 mutations showed a significantly shorter OS (1.8 months, 95%CI, 0.8-2.8) compared to patients with wtTP53 (5.6 months, 95%CI, 1.5-9.7). Patients carrying TP53 mutations demonstrated a lower 1-year OS rate then those with wtTP53 (7.1%±6.9% vs. 32.9%±7.1%; P=0.002). Complex karyotype, del7q (CUX1) and del7p (IKZF1) showed no significant effect on survival of sAML patients. Multivariate analysis confirmed that mutation in TP53 was the only independent adverse prognostic factor for OS (hazard ratio 2.41; 95%CI, 1.20-4.82; P=0.013) in sAML.The mutual information analysis showed that del5q and TP53 mutations, del12p (ETV6) and del5q, 11q gains and del17q, associate with respect to diagnosis. The negative interaction information analysis, indicating exclusivity to sAML, showed association for del5q and 9pUPD, del5q and TP53 mutations, as well as del20q and del4q (TET2). **Conclusions.** Our data suggests that distinct genetic lesions drive leukemogenesis in sAML, compared to dnAML. High karyotype complexity of sAML patients does not influence their OS, and indicates the presence of mainly passenger aberrations. Somatic mutations in TP53 are the only independent adverse prognostic factor in sAML. The mutual information and interaction analysis identified several potential markers for genetic stratification of patients with AML.

THE PROGRESSIVE BURDEN OF MYELOFIBROSIS (MF) IN UNTREATED PATIENTS: AN ASSESSMENT OF PATIENT-REPORTED OUTCOMES IN PLACEBO-TREATED PATIENTS FROM COMFORT-I

R Mesa[1], A Shields[2], T Hare[3], S Erickson-Viitanen[3], W Sun[3], S Verstovsek[4]
[1]Mayo Clinic, Scottsdale, United States of America
[2]Adelphi Values (formerly Mapi Values), Boston, United States of America
[3]Incyte Corporation, Wilmington, United States of America
[4]MD Anderson Cancer Center, Houston, United States of America

Background. COMFORT-I is a Phase III randomized, double-blind, placebo-controlled study of ruxolitinib in patients with MF, which incorporated patient-reported outcomes (PROs) and other quality of life measures to assess MF symptom burden. The placebo arm provides a controlled setting to assess changes in symptom burden among patients not receiving MF therapy. **Aims.** To assess the changes in PROs among patients from the COMFORT-I study not receiving treatment for MF. **Methods.** Informed written consent was obtained from all enrolled patients. Adult patients with intermediate-2 or high-risk MF (primary MF, post-polycythemia vera MF, and post-essential thrombocythemia MF) by International Prognostic Scoring System classification with ≥6 months life expectancy were randomized to placebo or ruxolitinib (1:1) after a 28-day washout of previous MF therapies. Individual MF symptom severity (night sweats, itching, abdominal discomfort, pain under ribs on left side, early satiety, and bone/muscle pain) were reported by the patient using the modified Myelofibrosis Symptom Assessment Form v2.0 electronic diary, and a Total Symptom Score (TSS) was calculated based on the sum of daily individual symptom scores. Other PRO measures included the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 (EORTC QLQ-C30 [100-point normalized scale; lower scores indicate poorer quality of life]); Patient Reported Outcome Measurement Information System (PROMIS) Fatigue Scale (100-point normalized scale; higher scores indicate greater fatigue); and Patient Global Impression of Change (PGIC; 7-point scale: 1=very much improved, 4=no change, 7=very much worse). Spleen volume was measured using MRI or CT and evaluated by a central blinded reviewer at baseline and every 12 weeks. Patients in the placebo group who had a ≥25% increase from baseline in spleen volume accompanied by worsening MF symptoms (early satiety with weight loss or worsening spleen pain requiring daily narcotic use) before database lock were eligible for unblinding and cross over to ruxolitinib. Patients who withdrew or crossed over to ruxolitinib before a study visit were not included in analyses for that visit or subsequent visits. **Results.** The COMFORT-I placebo arm included 154 patients with a median of 2.5 years since diagnosis; 35% were intermediate-2 and 65% high-risk. By week 24, mean TSS worsened by 42% from baseline. EORTC QLQ-C30 Global Health Status and functional subscale scores also worsened from baseline to week 24, with the greatest changes in Role Functioning (mean change = -11.1) and Social Functioning (mean change = -9.0); mean PROMIS Fatigue score worsened by 9.1%. Mean PGIC score was 4.2 at week 24; 40.2% of patients perceived their condition to be worse and 29.9% unchanged. The majority of patients experienced an increase in spleen volume; median increases at weeks 12 (n=132), 24 (n=106), and 36 (n=46) were 6.1%, 8.5%, and 9.7%, respectively. **Conclusions.** Patients receiving placebo reported worsening of MF symptoms and other PROs. Increases in spleen volume over time were also observed. These findings illustrate the progressive and debilitating nature of MF and suggest that early intervention with effective therapy should be considered. *Supported by Incyte Corporation.*

0377

TELOMERE LENGTHS IN PATIENTS WITH JAK2V617F: AN AGE-ADJUSTED MODEL

YM Lin[1], ML Teo[2], CY Hu[2], TH Chuang[3], CY Chen[3], HF Tien[3], LI Lin[2]
[1]National Taiwan University, Taipei, Taiwan, Taipei, Taiwan
[2]National Taiwan University, Taipei, Taiwan
[3]National Taiwan University Hospital, Taipei, Taiwan

Background. Myeloproliferative neoplasms (MPNs) exhibit the overproduction of peripheral blood cells caused by clonal disorders in the hematopoietic cells. An acquired mutation, *JAK2*V617F, has become the most common molecular abnormality in 95-97% of polycythemia vera (PV), 50-60% of essential thrombocytosis, and 50% of primary myelofibrosis. Telomeres are thousands of repeated sequences (TTAGGG)n capped at the end of chromosomes, essential for protecting chromosome from the fusion events. Recently, the reduction of telomere length has been found in the MPN patients with *JAK2*V617F. However, the individual telomere length might be modulated by several factors, such as the age, the cell type. These factors might challenge the accuracy of the comparisons between the MPN patients and the healthy controls. **Aims.** To generate a formula for the telomere length measurement based on age and to assess the variation of telomere length in patients with *JAK2*V617F.Method: A total of 255 normal controls and 63 patients diagnosed with MPN were enrolled in this study. This study was approved by the Institutional Review Board of the NTUH, and written informed consent was obtained from all the participants. Quantitative-PCR accompanying with ratio of telomere product (T) to single-copy gene product (S) were used. **Results.** Among 255 normal individuals, 219 were males and 36 were females and with the age of 9 to 81. The T/S ratios of males were lower than those of females (0.76 ± 0.38 vs. 0.94 ± 0.41, p=0.0037). There were no significant difference of T/S ratios between paired DNA from granulocytes and mononuclear cells (0.97 ± 0.37 vs. 0.83 ± 0.27, p=0.3601). When divided into 4 groups based on age (<27 y/o, 27-45 y/o, 46-64 y/o, >64 y/o), there were significant difference among these four groups by using one-way ANOVA test (p<0.0001). Therefore, the relationship between the age and the telomere length need a scientific model. The R-program implemented in the S-plus software (TIBCO Software Inc) was applied to fit the regression curve between ages and telomere lengths for the 255 normal individuals and the polynomial with third degree did have the best significance rather than the polynomial with first and second degrees (Figure 1). The formula of this polynomial was $y=9.06*10^{-5}x^3-0.0011x^2+0.0251x+1.13$. The p-value of F-statistic which tested the significance of this regression curve was 0.0015 and the proportion which could be explained by the fitted model was 0.363. Of 63 patients with MPN, 35 patients (55.6%) were positive of *JAK2*V617F. The telomere length of each MPN patient with *JAK2*V617F was compared with the corresponding age-matched T/S generated by the formula of the regression line, demonstrating a significant difference from the normal control cohort (0.42 ± 0.18 vs. 0.72 ± 0.20, p=0.0363. sensitivity = 0.77). Furthermore, the T/S ratios displayed a significant difference between paired DNAs from granulocyte and mononuclear cell in *JAK2*V617F patients (0.52 ± 0.44 vs. 0.89 ± 0.45, p=0.0287). **Conclusions.** We concluded that adjusted with age, the telomere lengths of patients with *JAK2*V617F were shorter than those of normal controls and displayed a significant difference between granulocytes and mononuclear cells.

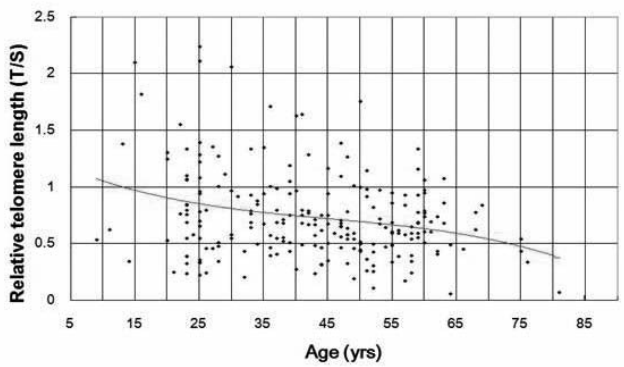

Figure 1. The spots displayed a wide variation in the same age, and predicted polynomial of third degree was showed on the scatter plot.

[11]IRCCS Policlinico San Matteo Foundation, Pavia, Italy
[12]University of Florence, Florence, Italy
[13]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background. Ruxolitinib has demonstrated rapid and durable reductions in splenomegaly and improved disease-related symptoms and QoL in 2 phase 3

studies (COMFORT-I and -II) in patients with primary MF (PMF), post-polycythemia vera-MF (PPV-MF), or post-essential thrombocythemia-MF (PET-MF) and has been approved in the US. The prevalence of individual symptoms among these patients has not been defined. **Aims.** This analysis evaluated baseline HRQoL and symptoms among patients enrolled in COMFORT-II. **Methods.** COMFORT-II is a randomized, open-label, multicenter, phase 3 study comparing ruxolitinib with best available therapy. HRQoL and symptoms were assessed at baseline using the European Organisation for the Research and Treatment of Cancer QoL Questionnaire-Core 30 (EORTC QLQ-C30) and Functional Assessment of Cancer Therapy-Lymphoma (FACT-Lym); this analysis summarizes these scores for all patients, regardless of assigned treatment. **Results.** In COMFORT-II (N = 219), 52% of patients were aged > 65 years and 57% were male. By International Prognostic Scoring System criteria (Cervantes et al. *Blood.* 2009), 40% had intermediate-2-risk MF, and 60% had high-risk MF.Patients had a mean palpable spleen length of 15.2 cm (range, 5-37 cm) below the costal margin. Patients with PMF or PPV-MF had larger spleens (mean, 15.8 cm; 95% CI, 14.6-16.9 cm and 16.2 cm; 95% CI, 14.5-17.9 cm, respectively) than those with PET-MF (11.4 cm; 95% CI, 9.7-13.1 cm).The most frequent symptoms (reported as "quite a bit"or "very much") were fatigue (54%), dyspnea (30%), insomnia (30%), pain (29%), night sweats (23%), and itching (21%), and there were differences in baseline symptoms across MF subtypes (Table, upper panel). Mean EORTC QLQ-C30 functioning, global health status/QoL, and symptom scores were comparable to or worse than those that have been reported for patients with acute myeloid leukemia (AML), chronic myeloid leukemia (CML), and breast cancer (Table, lower panel). **Conclusions.** This analysis shows that patients with MF experience severe disease-related symptoms and have diminished HRQoL similar to those with AML, but because patients with MF have a longer life expectancy (an average of 2.3 to 4 years for high- and intermediate-2-risk patients, respectively), they may suffer with a reduced QoL for many years.

Table. Prevalence of Symptoms at Baseline in COMFORT-II by MF Subtype (upper panel); Mean EORTC QLQ-C30 Scores at Baseline in COMFORT-II and for Patients With AML, CML, and Breast Cancer (lower panel).

% "quite a bit" or "very much"	MF (N = 219)	PMF (n = 116)	PPV-MF (n = 68)	PET-MF (n = 35)

[11]Hospital Clínic, IDIBAPS, Barcelona, Spain

Background. Ruxolitinib is a potent and selective oral JAK1/2 inhibitor that has been approved in the United States. Ruxolitinib has demonstrated rapid and durable reductions in splenomegaly and improved disease-related symptoms and quality of life (QoL) in two phase 3 studies (COMFORT-I and -II) in patients with primary MF (PMF), post-polycythemia vera-MF (PPV-MF), or post-essential thrombocythemia-MF (PET-MF). **Aims.** This analysis evaluated associations between cytokine levels and spleen size reductions in the COMFORT-II study. **Methods.** COMFORT-II is a randomized (2:1), open-label, phase 3 study comparing the safety and efficacy of ruxolitinib with BAT. Spleen volume was measured by MRI every 12 weeks and spleen length by palpation at each study visit. Plasma samples were analyzed using Rules-Based Medicine's Human MAP®v1.6; 89 cytokines were measured at baseline and weeks 4, 24, and 48. Simple linear regression was used to evaluate the correlation between baseline or change from baseline in cytokine levels with percent change of spleen size and change in FACT-Lym symptom scores in a univariate manner. **Results.** In the ruxolitinib arm, association was found between changes in TNF-α and leptin levels and percent spleen volume reduction at weeks 24 and 48 that were not observed with BAT and were independent of *JAK2*V617F status. A decrease from baseline TNF-α was associated with greater spleen volume reduction at weeks 24 and 48 (Figure A). Higher baseline leptin levels were associated with greater percent spleen length reductions at week 48. Larger increases in leptin at week 4 were also associated with enhanced spleen response. Higher baseline leptin levels were associated with improvement in FACT-Lymphoma symptom self-assessment of weight loss at week 24 ($P < .01$) and week 48 ($P = .02$). A clear trend was observed for increased leptin levels at week 4 that preceded weight gain on ruxolitinib treatment (Figure B). **SUMMARY/ Conclusions.** This analysis has shown statistically significant associations between both changes in TNF-α and spleen size reduction, and leptin levels and spleen size reduction/weight gain.TNF-α levels have been shown to be elevated in patients with MF, independent of *JAK2*V617F status. TNF-α is known to suppress the growth of hematopoietic progenitors and to promote the growth of mutant clones, contributing to cytopenias associated with MF. The reduction of TNF-α by ruxolitinib has the potential to modify the disease through suppression of the mutant clone. (Fleischman et al, *Blood.* 2011; 118 (24): 6392-6398.)Patients with MF have abnormally low leptin levels due to disease-associated cachexia. The increase in leptin levels on study precedes weight gain. Further analyses are required to understand whether the leptin increase is an early marker of symptom resolution or a surrogate for JAK2 inhibition that may play a regulatory role in leptin production, rather than a causal effect. These observations require confirmation in an independent data set. In addition, a multivariate approach to fully explore the relationship between cytokines and clinical changes will be presented.

MANAGEMENT OF MYELOFIBROSIS: A SURVEY OF CURRENT PRACTICE IN THE UNITED KINGDOM

M Qureshi[1], C Maclean[2], M McMullin[3], C Harrison[1]
[1]Guy's Hospital, London, United Kingdom
[2]Addenbrooke's Hospital, Cambridge, United Kingdom
[3]Queen's University Hospital, Belfast, United Kingdom

Background. Myelofibrosis is characterised by progressive anemia, pancytopenia, hepatosplenomegaly, fatigue, and night sweats. With the exception of stem cell transplantation (SCT), standard care focuses on palliation. There has been no previous evaluation of current management strategies in the UK. **Aims.** To assess current practices in management of Myelofibrosis in the UK.**Methods.** An internet based survey was designed to assess clinical need in Myelofibrosis, current management strategies and their success. This was emailed to over 800 Haematology clinicians and senior nurses within the UK. 105 healthcare professionals who had managed Myelofibrosis during the last 2 years responded.**Results.** Our survey confirmed that existing treatment options for Myelofibrosis are often unsatisfactory. When asked "In your experience, what are the three most common issues that need to be addressed during routine clinical reviews?", the majority (79%) of respondents replied that bothersome symptoms constituted the most common problem. Another 19% of respondents gave poor efficacy of medications as the most common issue. Moreover, Myelofibrosis particularly in advanced stages is a resource-intensive disease: patients with intermediate-risk 2 or high risk Myelofibrosis attended hospital every 3 to 4 weeks, according to 51.5% of respondents. Transfusion of blood products constituted the most common reason for hospital admission (43%) but sepsis (22.1%) and disease management (22.1%) were also significant.The most common complications of Myelofibrosis in over 50% of patients were anemia (68.1% of respondents), increased transfusion requirements (48.9%), and debilitating constitutional symptoms (30.9%). Splenic complications were also significant, however thrombosis and infection were uncommon.Current treatment tools for Myelofibrosis include splenectomy, SCT and drug therapies. Our study found that both splenectomy and SCT are rare treatment modalities. Regarding conventional drug therapies, our survey examined both their employment and their limitations. A wide variety of different therapies are utilised (Figure 1), suggesting there is a lack of treatment standardisation, and none of these treatments are uniformly successful. Indeed, only 32.1% of respondents stated therapy for anemia achieved its objective partially or completely in over 50% of patients. Moreover, the majority (78.8%) asserted that 50% or less of their patients maintained that response for over a year. A major finding was that many respondents thought there was no effective therapy for constitutional symptoms. For instance, a significant proportion of respondents considered there was currently no effective therapy for debilitating fatigue (40.7%), weight loss (34.6%), night sweats (25.9%) or fever (23.5%). **Conclusions.** This study constitutes an important source of information regarding current UK clinical practice. It identifies anemia, increased transfusion requirements and debilitating constitutional symptoms as the most frequent complications of Myelofibrosis. Two principal trends in management are prominent. Firstly, respondents used a wide variety of drugs, suggesting lack of standardisation and poor outcome. Secondly, effective management of symptom control is lacking. Further research is needed to clarify current treatment practices in the UK, and to assist the production of clinical guidelines.

EFFECTIVENESS OF INTERFERON ALPHA THERAPY IN ESSENTIAL THROMBOCYTHEMIA

N Pugliese, L Marano, C Quintarelli, M Gherghi, G Ciancia, B De Angelis, S Errichiello, B Izzo, A Peluso, V Martinelli, F Pane
University of Naples Federico II, Napoli, Italy

Background. Interferon-alpha (IFN) has shown significant activity in MPN. In Essential Thrombocythemia (ET) this drug is able to rapidly normalize platelet and leukocyte counts, as well as organomegaly. IFN is the only therapy known to induce complete molecular remission with the reduction or the suppression of tumor burden.Despite its effectiveness, many patients discontinue IFN therapy due its side effects. Their incidence and severity are dose-related and the most common are flu like syndrome, myalgia, headache, fatigue, myelosuppression, liver abnormalities, autoimmune disease and depression. IFN has no leukemogenic effects and is safe in pregnancy.We hereby report our monocentric experience. **Methods.** From 1992 until today, the Division of Hematology of the Federico II University Medical School, Naples, Italy, followed 365 ET patients (diagnosis according to PVSG criteria and subsequently with 2008 WHO criteria); 257 patients were treated with cytoreduction: 64.5% with hydroxyurea, 23.5 % with IFN, 10% with anagrelide and 2% with busulfan.Patients treated with IFN received subcutaneous injection at induction dose of $3x10^6$ units 5 times a week, reduced on the basis of clinical-hematological response. **Results.** After a median follow up of 36 months, of the 60 patients receiving IFN, 60% achieved complete hematological response (CHR) according to the European Leukemia Net criteria; of these 13% were taken off therapy and 39% are still receiving very low doses of IFN ($3x10^6$ units every 7-15 days). As many as 20% experienced partial hematological response (PHR). The median time to response was 2.6 months.Response was not influenced by age (p=0.06), gender (p=0.4), baseline values of hematocrit and hemoglobin normalized for the gender, platelet count (p=0.29), WBC count (p=0.1). Furthermore $JAK2^{V617F}$ mutational status does not influence the response.Under IFN therapy no patients had thromboembolic or hemorrhagic event, independently of their cardiovascular risk. As many as 22 patients experienced flu-like symptoms, 3 dermatitis, 3 alopecia, 7 autoimmune thyroiditis; of them only 2 patients had hypothyroidism and had to suspend IFN treatment.Average spleen volume at the baseline was 495 ml; after a median follow-up of 18 months it was 472 ml, with no differences in volume enlargement in CHR/PHR compared to non responsive patients.Bone marrow fibrosis grade (according to Thiele) did not worsen after IFN treatment in either patients who achieved CHR or PHR. We are unable to evaluate data about non responsive patients, because this parameter could be influenced by their second line treatment. **Conclusions.** IFN was safe and effective for patients with ET. The ability of IFN therapy to control and modify the clinical course of the disease is confirmed by our data. This response is sustained for prolonged periods in some patients, even after therapy discontinuation. IFN should be considered as election treatment even in young patients, for its lack of leukemogenic and teratogenic effects.

0382

IS MISCARRIAGE IN ESSENTIAL THROMBOCYTHEMIA (ET) A PROGNOSTIC FACTOR FOR THROMBOSIS?

I Bertozzi, E Duner, E Bonamigo, C Santarossa, F Fabris, M Randi
DIMED, Internal Medicine, CLOPD, University of Padua, Padova, Italy

Background. Essential thrombocythemia (ET) is a myeloproliferative neoplasm typical of median age with an increased risk of vascular complications. However, ET is also observed in young adults and major thrombotic events may occur also in these patients, who are predominantly women; some of them are diagnosed at childbearing age and their pregnancies have an increased risk of complications represented mainly by fetal loss. Thrombotic occlusion of placental circulation is considered an important mechanism of miscarriage. Relation between thrombosis and JAK2V617F or pregnancy complications and JAK2V617F is strongly suspected. **Aim and Scope.** We retrospectively studied a large cohort of young females with ET to evaluate if pregnancy complications and thrombotic events are related. **Materials, Methods and Patients.** Our study includes 57 consecutive pregnancies (age at conception 32.5±5.4 , range 23-41 years) in 34 females affected by ET (age at diagnosis 29.4 ± 5.8 years, platelets count 851 ±350 x 10^9/L). JAK2V617 mutation was searched with allele specific PCR. Statistical analysis was performed by X^2 test.**4. Results.** Evaluation of JAK2 gene was available in 24 females and 13 (54%) were mutated. Thirty-six (64%) uneventful deliveries were observed, while 21 (36%) pregnancies had a negative outcome (13 first trimester abortions and 8 advanced fetal loss). 27 pregnancies (13 uneventful and 14 fetal loss) (67.5%) occurred in JAK2V617F positive females and 16 (13 uneventful and 3 miscarriages) (32.5%) in JAK2 wild-type (p=0.03).Ten females at mean age of 37.5 ± 5.7

years (30 - 47) had a thrombotic complications: 3 arterial thrombosis (1 myocardial infarction, 1 stroke and 1 intestinal infarction), in all cases at least 10 years after pregnancy and 7 unusual veins thrombosis (1 cerebral, 2 portal and 4 supra-hepatic veins) which occurred in post-partum or no more than two years after delivery. Nine out of the 10 females (90%) with thrombosis had at least one complicated pregnancy.The correlation between pregnancy outcomes and thrombotic events is summarized in the Table 1. **Conclusions.** *JAK2*V617F mutation is confirmed as a negative prognostic factor for pregnancy complications. Our data show that thrombosis occur more frequently in patients who have already had negative pregnancy outcomes. Knowing that a previous thrombosis is a validated risk factor for further cardiovascular event and that placental thromboses have a basic role in pregnancy failures, we suggest that fetal loss should be considered as a thrombotic risk factor for stratification of ET patients. Prospective studies are need to confirm our hypothesis.

Table 1.

RUXOLITINIB IN CLINICAL PRACTICE FOR THERAPY OF MYELOFIBROSIS: SINGLE USA CENTER EXPERIENCE AFTER FDA APPROVAL

G Holly, E Knight, K Barr, R Tibes, V Fauble, J Camoriano, P Noel, R Scherber, R Mesa
Mayo Clinic, Scottsdale, United States of America

Background. Ruxolitinib was approved for commercial use for the therapy of intermediate and high risk myelofibrosis (MF) in the USA in November 2011. **Aims.** We sought to assess the initial clinical experience with the use of Ruxolitinib (outside of the clinical trial setting) at our high-volume MPN program. **Methods.** Patients with MF prescribed Ruxolitinib at our center within the first three months after FDA approval were included in this analysis. Baseline disease information, treatment history, dynamics of Ruxolitinib dosing, impact on cytopenias, splenomegaly, and symptoms were assessed. Results from the first four months of therapy are discussed in this abstract. Future results will be presented at the conference. **Results.** A total of 22 patients with MF (post-ET MF (n=6), post-PV MF (n=6) and primary MF (n=10)) began Ruxolitinib between November 2011 and January 2012. Seventeen patients carried the JAK2V617F mutation. The average spleen size prior to starting was 12 cm (0-22 cm). DIPSS-Plus scoring included patients with intermediate-1 risk (n=9), intermediate-2 risk (n=7), and high risk (n=6). Twenty-one patients had received previous therapies with hydroxyurea (68%), anagrelide (22%), interferon-alpha (18%), erythropoietin (13%), JAK-2 experimental agents (13%), danzol (9%) or immunomodulatory agents (9%). Patients had been diagnosed with MF an average of four years prior to initiating Ruxolitinib (0.2-17 years). Initial symptoms included fatigue (63%), nightsweats (59%), abdominal pain (50%), weight-loss (50%), pruritis (22%), early satiety (13%), bone pain (13%) and fevers (9%). The average hemoglobin was 10.9 g/dL (7.6-13.8). Platelet counts averaged 288 x 10^9 (32-844). Four patients had platelet counts less than 100 x 10^9; two patients had values less than 50 x 10^9. Fourteen patients were concurrently receiving MF therapy at the time Ruxolitinib was initiated. Sixteen patients began therapy at 20 mg BID with the remaining starting at a lower dose due to baseline cytopenias. Four patients have undergone dose changes for various symptoms including anemia, thrombocytopenia, hyperkalemia, fatigue and dizziness. One patient discontinued the medication for worsening transfusion-dependent anemia. Two patients required the addition of anagrelide or hydroxyurea for platelet counts >1,000 x 10^9/L. By week three, data from 17 patients was available for review. Six patients had been seen in follow-up and described a decrease in weight loss (n=4), fatigue (n=3), night sweats (n=2), abdominal pain (n=2) and pruritis (n=2). Five had marked reduction of their splenomegaly >5 cm, four of which were non-palpable. By week 4, nine patients had experienced a decrease in hemoglobin values, five of which had more than a 2 g/dL decrease and two requiring a dose reduction. Ten patients had experienced a reduction in platelet counts but all values remained above 100 x 10(9)/L.**Conclusions.** Randomized controlled studies have proven Ruxolitinib's efficacy in reducing debilitating symptoms, splenomegaly, and quality of life in MF patients. This study represents the first evaluation of Ruxolitinib use in clinical practice after FDA approval. Ruxolitinib use in clinical practice appears to mirror the controlled environment of recent clinical trials.

0384

BASELINE DATA FROM A MULTICENTER, PEDIATRIC DISEASE REGISTRY STUDY IN ESSENTIAL THROMBOCYTHEMIA

M Putti[1], J Sevilla[2], R Coll[3], J Smith[3], B Abhyankar[3], M Randi[1]
[1]University of Padua, Padua, Italy
[2]Hospital Infantil Universitario Niño Jesús, Madrid, Spain
[3]Shire Pharmaceuticals, Basingstoke, United Kingdom

Background. Essential thrombocythemia (ET) is a myeloproliferative neoplasm characterized by an overproduction of platelets. It is associated with an increased risk of thrombohemorrhagic complications and may evolve into myelofibrosis or acute leukemia. Although the median age of presentation is 60-65 years in adults, a significant number of cases have been described in children. However, limited information is available regarding disease complication rates, management approach and treatment outcomes in a pediatric population. **Aim.** The objective of the European pediatric disease registry study (ELLIOT STUDY) is to observe the disease characteristics and management of ET in a pediatric population. Baseline characteristics are described from the most recent data-cut. **Methods**. Children aged 6 to <18 years with ET, were enrolled into the ELLIOT study, after informed consent was obtained. This study is sponsored by Shire Pharmaceuticals. Data were collected at study enrollment and will continue to be collected at all routine clinic visits, for the study observation period (up to March 2016). At least 60 patients are planned to be enrolled into the study by March 2013. **Results.** A total of 51 patients recruited from 26 sites across 6 countries are currently included in the study. Data are described for 26 patients, 61.5% females (n=16) and 38.5% males (n=10), included in the data-cut taken in September 2011.Laboratory and clinical data are summarized in Table 1, comparing features at diagnosis and at study enrollment.

Table 1. Laboratory and clinical data comparing features at diagnosis and at study enrollment.

	At diagnosis	At enrollment
Age (years) Mean (SD)	9.1 (±4.9)	13.9 (±3.3)
Platelets (10^9/L) Median (range)	1251 (1.2–3762)	763 (1.0–2897)
Hb (g/dL) Median (range)	13.1 (10.7–14.4)	13.5 (11.8–15.1)
Hct Median (range)	39.1 (35–43.3)	40.6 (35.4–42)
WBC (10^9/L) Median (range)	11.8 (6.9–14270)	9.1 (5.4–13.6)
Symptoms and complications		
Asymptomatic; n ° (%)		10 (38.5)
Abdominal pain, tiredness, upper respiratory symptoms; n ° (%)		1 (3.8)
Headache; n ° (%)		11 (42.3)
Dizziness; n ° (%)		2 (7.7)
Paresthesia; n ° (%)		2 (7.7)
Foot and hand pain; n ° (%)		1 (3.8)
Nose bleeds and bruising; n ° (%)		1 (3.8)
Photophobia; n ° (%)		1 (3.8)
Thrombohemorrhagic event; n ° (%)		2 (7.7)
Twitching; n ° (%)		1 (3.8)
Splenomegaly; n ° (%)		1 (3.8)
Venous thrombosis; n ° (%)		1 (3.8)

Hb – Hemoglobin; Hct – Hematocrit; WBC – White blood cells

The most common complication observed was headache, experienced by 42.3% of patients (n=11). *JAK2* status was reported in only 4 patients (V617F positive, n=1).Bone marrow evaluation was performed in 17 cases by aspirates (65.4%); cytogenetic analysis was performed in 16 patients (61.5%), of which 1 was abnormal. In 9 patients trephine biopsies were performed: 7 had abnormal megakaryocytes, and fibrosis assessment in 7 patients showed grade 1 in 6 patients and grade 2 in 1 patient.The majority of patients (65.4%, n=17) did not receive cytoreductive treatment at or prior to study enrollment. Of the 9 patients who received cytoreductive treatment, a similar proportion had previously been treated with anagrelide (n=6) and/or hydroxycarbamide (n=5). Only four patients were still receiving cytoreductive treatment at study enrollment (all anagrelide). The median duration of anagrelide and hydroxycarbamide treat-

ment was 668 days (range, 185-2174) and 337 days (range, 32-1382), respectively. In the whole patient cohort, the most common concomitant medication at or prior to study enrollment was aspirin (38.5%, n=10). **Summary and Conclusions.** This study provides valuable epidemiological data concerning the clinical presentation and the management of children with ET, as observed in European pediatric hematological centers. The results show that while most patients do not receive cytoreductive treatment, approximately one-third of children are treated at some stage with anagrelide and hydroxycarbamide in similar proportion, even in the absence of major thrombohemorrhagic complications. Further information is required to understand factors affecting treatment choice and clinical management of ET in pediatric patients. This study highlights the need for guidance in the treatment of ET for pediatric patients. The study is ongoing.

0385

ANEMIA AND THE USE OF ERYTHROPOIETIC-STIMULATING AGENTS (ESAS) WITH RUXOLITINIB IN THE COMFORT-II STUDY

MF McMullin[1], C Harrison[2], D Niederwieser[3], H Demuynck[4], N Jäkel[3], A Sirulnik[5], M McQuitty[6], V Stalbovskaya[6], JJ Kiladjian[7], HK Al-Ali[3]

[2]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom
[3]University of Leipzig, Leipzig, Germany
[4]H Hartziekenhuis, Roeselare, Belgium
[5]Novartis Pharmaceuticals Corporation, East Hanover, United States of America
[6]Novartis Pharma AG, Basel, Switzerland
[7]Hôpital Saint-Louis et Université Paris Diderot, Paris, France

Background. Ruxolitinib is a potent and selective JAK1/2 inhibitor approved in the US based on results of the phase 3 COMFORT studies. Ruxolitinib demonstrated rapid and durable reductions in splenomegaly and improved disease-related symptoms and quality of life. Consistent with ruxolitinib's known mechanism of action, anemia was one of the most frequently reported adverse events (AEs) but was generally manageable and led to discontinuation in only 1 of 146 patients. In clinical practice, anemia can sometimes be managed with ESAs, which promote red blood cell proliferation via cytokine receptors that signal through the JAK pathway. Because these agents act upstream of ruxolitinib inhibition, it is important to determine their effect on the safety and efficacy of ruxolitinib and vice versa. **Aims.** This post hoc analysis evaluated the safety and efficacy of ruxolitinib in patients receiving concomitant ESAs in COMFORT-II. **Methods.** COMFORT-II is an open-label, randomized (2:1), multicenter, phase 3 study comparing ruxolitinib with best available therapy (BAT) in patients with primary MF, post-polycythemia vera MF, and post-essential thrombocythemia MF. Use of ESAs, though not prohibited, was discouraged for patients receiving ruxolitinib because these drugs can increase spleen size, which could confound efficacy analyses. **Results.** ESA use was reported for 9 of the 146 patients receiving ruxolitinib (+ESA group; darbepoietin-alpha, 1.4%[n=2]; epoetin-alpha, 4.8%[n=7]; median exposure, 22.1 weeks). Overall, the median duration of ruxolitinib exposure was 51.4 weeks, and median dose intensity was similar in the +ESA group compared with the non-ESA group (39.2 vs 30.0 mg/day). The mean change in spleen volume from baseline at week 48 was similar in both groups (+ESA, -29.8%; non-ESA, -30.1%); 44.4% (4/9) of the +ESA group and 27.0% (37/137) of the non-ESA group achieved ≥35% reduction in spleen volume from baseline at week 48. The mean number of packed red blood cell units received per month while on treatment was similar in both groups (+ESA, 0.78; non-ESA, 0.86). AEs reported in both groups were similar; serious AEs (SAEs) were reported for 4 patients in the +ESA group. SAEs determined to possibly be related to ruxolitinib (respiratory infection and decreased general condition) occurred in 1 patient who discontinued the study; this patient died from respiratory infection. At baseline, the +ESA and non-ESA groups had median creatinine levels of 70.2 and 75.4 µmol/L, respectively. Median changes from baseline at week 48 were similar for reticulocytes (+ESA, -13.6%; non-ESA, -9.1%) and hemoglobin (+ESA, -5.8%; non-ESA, -5.7%). The +ESA group had higher median levels of erythropoietin at baseline (39.0 vs 7.0 pg/mL) and a larger increase at week 48 (485.0% vs 185.2%). **Conclusions.** Ruxolitinib provides significant reduction in spleen size compared with BAT, and in these analyses, concomitant ESA use did not appear to affect these reductions. No substantially different AEs were reported in patients receiving ruxolitinib and ESAs. Concomitant use of ESAs may have allowed for an increased dose of ruxolitinib. Because the use of ESAs is common in clinical practice, further analyses are warranted.

0386

RED CELL MASS DETERMINATION IN PATIENTS WITH CLINICALLY SUSPECTED DIAGNOSIS OF POLYCYTHEMIA VERA OR ESSENTIAL THROMBOCYTHEMIA

A Ancochea, A Alvarez-Larrán, A Angona, L Martínez-Avilés, B Bellosillo, C Besses
Hospital del Mar, Barcelona, Spain

Background. WHO criteria for diagnosis of polycythemia vera (PV) include the presence of hemoglobin >16.5 g / dL in women, 18.5 g / dL in men or other evidence of increased red cell volume. In patients with clinically suspected diagnosis of essential thrombocythemia (ET) or PV who do not reach the WHO Hb level for PV diagnosis, the indication of red cell mass assessment is not well established. **Aims.** To identify the cut-off for hemoglobin (Hb) or hematocrit (Hct) that indicate the need for a red cell mass study in patients with a presumptive diagnosis of PV or ET. **Methods.** Red cell mass, by isotopic ^{51}Cr, was determined in 179 patients (91 women, 88 men) with clinically suspected diagnosis of ET or PV and a Hct higher than 0.42 L/L (females) or 0.45 L/L (men). Receiving operating characteristic (ROC) curves were performed to evaluate the diagnostic accuracy of Hb and Hct in order to distinguish a normal or an increased red cell mass. We determined the specificity and sensitivity of each Hb and Hct value. The cut-off was selected doing the sensitivity prevailing over the specificity in order to reduce the number of false negative cases. **Results.** An increased red cell mass was documented in 114 patients (64 males, 50 females). The ROC curves showed a greater area under the curve (AUC) for Htc than for Hb [AUC for Htc = 0.92 (95%CI: 0.88-0.96) and AUC for Hb= 0.88 (95%CI: 0.84-0.93)] with similar results being observed when patients were stratified by gender. The best value of Hct to indicate a red cell mass study was 0.48 L/L in women (specificity 73%, sensitivity 94%) and 0.50 L/L in men (specificity 75%, sensitivity 87.5%). Lowering the Htc threshold to 0.48 L/L in males increased the sensitivity up to 95% with only 3 false negative cases and an acceptable number of false positives (14 cases with Htc > 0.48 L/L out of 24 cases with normal red cell mass). The Hb cut-off points proposed in the WHO classification for diagnosis of PV showed a high specificity but a low sensitivity, resulting in a great number of false negatives (26 women and 27 men) that would be misdiagnosed as essential thrombocythemia if a red cell mass study was not performed. **Conclusions.** In patients with clinically suspected diagnosis of ET or PV who do not reach WHO defined Hb values to establish the diagnosis of PV, a red cell mass study should be performed when the Hct is higher than 0.48 L / L.

CLINICAL SIGNIFICANCE OF CLONALITY ASSESSMENT IN JAK2V617F-NEGATIVE ESSENTIAL THROMBOCYTHEMIA

L Martínez-Avilés, A Álvarez-Larrán, G Navarro, E Torres, R Longarón, A Angona, C Pedro, L Florensa, S Serrano, C Besses, B Bellosillo
Hospital del Mar, Barcelona, Spain

Background. JAK2V617F-negative essential thrombocythemia (ET) is a heterogeneous disease including patients with clonal hematopoiesis demonstrated by mutations in different genes or by X-chromosome inactivation patterns (XCIP) and others without molecular markers of clonality. It is unknown if patients with evidence of clonality have a different clinical outcome than those in whom clonal hematopoiesis cannot be demonstrated. **Aim.** To evaluate the clinical significance of clonality demonstration in a cohort of JAK2V617F-negative ET patients. **Methods.** In this study, 73 JAK2V617F-negative cases out of 186 subjects consecutively diagnosed with ET, in a single institution, were assessed for clonality by means of the *HUMARA* assay and analysis of the mutational status of *MPL* (exon10), *TET2* (whole coding sequence) and *ASXL1 (*exon 12). **Results.** Clonality by *HUMARA* assay was demonstrated in 21 patients (46%) out of 46 assessable females whereas mutations in *MPL*, *TET2* and *ASXL1* were observed in 7, 4, and 2 cases out of 73, respectively. The detection of any mutation (*MPL*, *TET2* or *ASXL1*) was more frequently observed in patients with clonal *HUMARA* (8 mutations out of 20 clonal cases) than in those with polyclonal hematopoiesis (1 case out of 23 polyclonal cases) being the difference statistically significant (p=0.007).With a median follow-up of 8 years, death, thrombosis, bleeding and disease transformation were registered in 7, 10, 8, and 6 patients (5 myelofibrosis, 1 myelodisplasia), respectively. No differences in thrombosis, bleeding or survival were observed according to the presence of clonality assessed either by *HUMARA* assay or mutational status. The probability of disease transformation at 10 years was higher in patients showing clonal hematopoiesis by *HUMARA* analysis (35% versus 0% in patients with polyclonal hematopoiesis, p< 0.004), and in those with presence of mutations in either *MPL*, *TET2* or *ASXL1* (64% versus 2% in patients without mutations, p<0.001). **Conclusions.** In conclusion, patients with JAK2V617F-negative ET who show clonal hematopoiesis demonstrated by the *HUMARA* assay or by the presence of mutations in the *MPL*, *TET2* and *ASXL1* genes, have a higher probability of disease transformation. **Acknowledgements**This study was supported in part by grants EC10-136, FISPI10/01807 and AECC Catalunya 2011

[5]Department of Clinical Chemistry and Toxicology, Pharmaceutical Sciences School,, Sao Paulo, Brazil
[6]Hematology/Oncology Department, Santa Casa Medical School, São Paulo, Brazil

Background. Hereditary hemochromatosis (HH) is one of the most common genetic diseases, and may be associated with excessive absorption of dietary iron in some cases. If untreated, progressive iron accumulation in key organs leads to toxicity, resulting in tissue damage and organ dysfunction. Iron overload (IOL) can be readily managed in most patients by therapeutic phlebotomy. However, patients with underlying anemia and/or difficult venous access may not tolerate this treatment. In addition, compliance may be variable over time as a result of the inconvenience of frequent visits and the discomfort associated with the procedure. Clinical studies have demonstrated the efficacy, safety, and tolerability of deferasirox (DFX) in patients with a variety of conditions associated with transfusional IOL. Studies reporting iron chelation therapy in patients with primary (nontransfusional) IOL are limited, but data are encouraging. Aims and Methods : DFX at the starting dose of 10 mg/kg/day was administered orally for 1 year in patients with HH (C282Y/C282Y, C282Y/H63D or H63D/H63D gene mutation) and IOL (defined as transferrin saturation [TS] ≥45% and serum ferritin [SF] level ≥ 500 µg/L confirmed at two visits and liver iron concentration (LIC) by MRI ≥ 5 mg Fe/g dw at study entry) who were unable or unwilling to comply with a regimen of phlebotomy. The study objectives were to evaluate the changes in TS, SF and LIC levels and the efficacy (% of SF reduction from baseline and/or achievement of SF < 300 µg/L) and safety of DFX. Efficacy was assessed monthly by measuring changes from baseline in TS and SF levels. Safety was evaluated monthly based on the incidence and type of adverse events and changes in laboratory parameters, including serum creatinine and liver enzyme. LIC by MRI was measured at baseline and after 1-year of treatment or when SF was < 300 µg/L. **Results.** A total of 10 adult patients were included and all of them completed the 1-yr treatment period. Median age was 52.0 years; 60% female, 100% caucasian, 70% with C282Y/C282Y HFE gene mutation. Median SF levels(µg/L) reduced significantly at 12 months compared to baseline (from 1608.5 to 300.0, p<0.001). Median LIC significantly dropped at 12 months compared to baseline (from 14.5 to 5.5, p<0.001). The median time to achieve a SF reduction ≥ 50% compared to baseline was 7.53 months. The most common drug-related AEs were mild, transientdiarrhea (5 patients) and nausea (2). No patient experienced increases in serum creatinine that exceeded the upper limit of normality. **Conclusions.** Our preliminarydata confirm that deferasiroxis effective in reducing body iron burden and well tolerated in patients with HH, with a clinically manageable safety profile when used at appropriate dose, and could be a safe treatment option to phlebotomy in selected patients.

I.V. IRON USAGE IN CHEMOTHERAPY-INDUCED ANEMIA: AN OBSERVATIONAL, PAN-EUROPEAN STUDY

P Gascon[1], O Hermine[2], C Hoffmann[3], M Aapro[4]
[1]Hospital Clinic Barcelona, Barcelona, Spain
[2]Service d'Hématologie Adultes, Hôpital Necker - Enfants Malades, Paris, France
[3]Vifor Pharma, Glattbrugg, Switzerland
[4]IMO Clinique de Genolier, Genolier, Switzerland

Background. Intravenous (I.V.) iron supplementation is superior over oral or no iron for the treatment of chemotherapy-induced anemia, a frequent comorbidity in cancer patients. International guidelines recommend I.V. iron to prevent/reduce blood transfusions and doses of erythropoiesis-stimulating agents (ESAs). However, recommendations on the optimum I.V. iron treatment schedule are still lacking. **Aims.** This study evaluated current I.V. iron treatment practice and its link to anti-cancer treatment. **Methods.** Onco-hematologists in France, Germany, Spain, UK and Switzerland (March-May 2011) reported data on patient demographics, hemoglobin (Hb) levels, iron parameters, and therapies of anemic cancer patients on chemotherapy who had received their first I.V. iron treatment and had available records for at least 3 months prior and after this treatment. Results are shown as percentages of all patients. **Results.** 32 Onco-hematologists reported 101 cases of which 87% had solid or hematologic tumours (68% stage IV) and 13% myelomas (54% ISS III). In 68%, the first iron infusion took place within one year after cancer diagnosis and in 41% on the day of anemia diagnosis. Anemia assessment intervals were ≤4 weeks in 94%. Before first I.V. iron treatment, 62% of patients had Hb <9.0 g/dL (96% tested), 50% had serum ferritin ≤30 µg/L (82% tested) and 60% a transferrin saturation <20% (25% tested). In 46%, I.V. iron was given as monotherapy (Spain 77%, Switzerland 71%), additional ESA or oral iron was given in 7% each. 25% had a transfusion at any time during the observation period (most frequently in UK 48%); 14% were switched from blood transfusion(s) to I.V. iron. Another 14% were switched from I.V. iron to ESA.Reasons for initiation of I.V. iron treatment were lack of response (20%) or intolerance (12%) to prior treatment. Mean Hb levels decreased from 9.6 to 8.7 g/dL during 3 months prior the first I.V. iron administration, and improved to 10.2 g/dL in the following 3 months when 61% received I.V. iron as sole anemia treatment. Mean total I.V. iron dose per patient was 732 mg. 49% received more than one I.V. iron dose and those with initial iron doses ≥500 mg (22%) showed a trend for a longer mean interval until the second I.V. iron dose (35.4 vs. 29.2 days) compared to those with initial doses <500 mg. Use of initial iron doses below or above 500 mg was independent of baseline Hb. Taxane-based chemotherapies were given in 28% of patients, anthracycline-, cisplatin- and oxaliplatin-based therapies in 19, 18 and 15%, respectively. In 58%, chemotherapy and I.V. iron were given within 1-3 days, although most physicians (85%) perceived the treatments as not connected. **Conclusions.** Practice in I.V. iron use, particularly the dosing strategy, varies considerably between countries, suggesting a need for updating anemia treatment guidelines with iron-specific aspects. Earlier initiation of I.V. iron treatment may prevent the decrease of already low Hb levels in patients with chemotherapy-induced anemia. Iron doses ≥500 mg may reduce treatment frequency. TSAT is still underused as iron status parameter. Intravenous iron was given in combination with most common chemotherapies.

POST-HOC ANALYSIS OF HEMATOLOGIC RESPONSES INCLUDING TRANSFUSION INDEPENDENCE IN IRON-OVERLOADED APLASTIC ANEMIA PATIENTS TREATED WITH DEFERASIROX

JW Lee[1], SS Yoon[2], ZX Shen[3], A Ganser[4], H-C Hsu[5], A El-Ali[6], D Habr[7], N Martin[6], J Porter[8]
[1]The Catholic University of Korea, Seoul, South-Korea

[5]Taipei Veterans General Hospital, Taipei, Taiwan
[6]Novartis Pharma AG, Basel, Switzerland
[7]Novartis Pharmaceuticals, East Hanover, United States of America
[8]University College London, London, United Kingdom

Background. Reports of iron chelation therapy in aplastic anemia (AA) patients have mainly focused on efficacy and safety of excess iron removal. The 1-year, EPIC study enrolled 116 iron-overloaded AA patients; deferasirox significantly reduced iron overload as assessed by serum ferritin levels. As iron overload has a suppressive effect on erythroid progenitors and may increase transfusion requirements, it is of interest to evaluate hematologic responses with iron chelators in AA. **Aims.** To evaluate hematologic parameters in iron-overloaded AA patients treated with deferasirox. **Methods.** EPIC study design and inclusion/exclusion criteria have been previously described (Cappellini *et al. Haematologica* 2010). For this *post-hoc* analysis, UK treatment guideline criteria for AA diagnosis were used (2 or 3 of the following: hemoglobin [Hb] <100g/L, platelets <50x10^9/L, neutrophils <1.5x10^9/L) with hematologic response criteria reported by Camitta (*Acta Haematol* 2000). Bone marrow and reticulocyte data were not recorded in EPIC, hence patients were classified as 'severe' AA based on fulfillment of platelet/neutrophil criteria. For severe AA patients, hematologic response was defined as: no response=still severe; partial response=transfusion independence, and no longer meeting criteria for severe disease; complete response=normal Hb for age, neutrophil count >1.5x10^9/L and platelet count >150x10^9/L. For 'non-severe' AA patients, response was defined as: no response=worse/not meeting criteria for partial/complete response; partial response=transfusion independence (if previously dependent), or doubling or normalization of at least one cell line, or increased Hb >3 g/dL if initially <6g/dL, or increased neutrophils >0.5x10^9/L if initially <0.5x10^9/L,

or increased platelets >20x10^9/L if initially <20x10^9/L; complete response=same as severe. Each criterion was confirmed with no measure within 28 days that disproved the response. Transfusion independence was defined as at least one 8-week period without transfusion in patients transfusion-dependent during the study. Patients with no transfusions in the year prior to study entry were excluded from transfusion responders. **Results.** Evaluable hematologic parameters were recorded in 72/116 (62.1%) iron-overloaded AA patients; nine (12.5%) and 63 (87.5%) with severe and non-severe AA, respectively. Twenty-four (33.3%) patients received deferasirox without concomitant immunosuppressive treatment (IST) and 48 (66.6%) patients received ≥1 concomitant IST during the study. Partial responses were observed in 30 (41.7%) patients (Figure); 11/24 (45.8%) patients without and 19/48 (39.6%) with concomitant IST. All 11 patients achieving a partial response without concomitant IST had non-severe AA and became transfusion-independent (11/24, 45.8%); two patients had an additional platelet response and one patient achieved a platelet and Hb response. Most patients achieving a partial response with concomitant IST also became transfusion-independent (15/19, 78.9%); two patients had an additional neutrophil response (one patient with non-severe and one with severe AA), one had an additional platelet and Hb response (non-severe AA) and one had an additional neutrophil, platelet and Hb response (severe AA). **Summary and Conclusions.** Deferasirox may improve hematologic parameters in AA patients if it is administered concomitantly with IST or not. The most common response was transfusion independence, as also observed in patients with other bone marrow failure conditions (Guariglia *et al. Leuk Res* 2011). Additional studies to confirm these results and to clarify mechanisms are required.

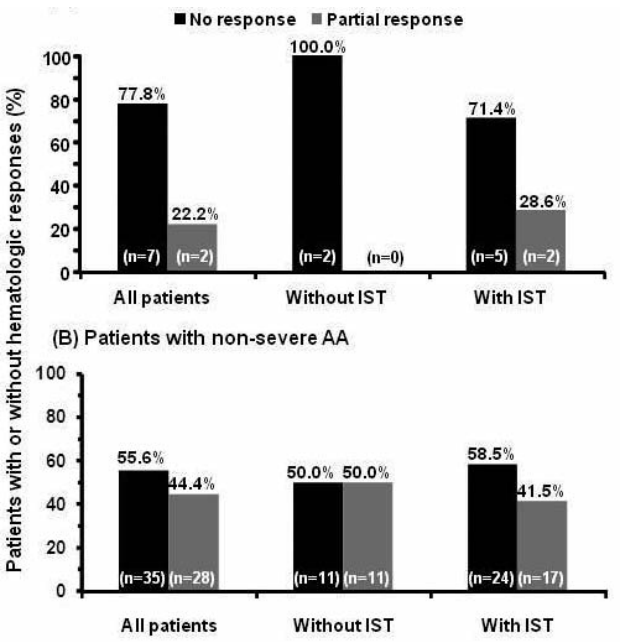

Figure 1. Hematological responses with or whitout IST in patients with (A) severe AA and (B) non-severe AA (A) patients with severe AA.

PHENOTYPE OF HETEROZYGOUS TMPRSS6 DEFECTS IN 4 DUTCH FAMILIES SUGGESTS THAT IRON REFRACTORY IRON DEFICIENCY ANEMIA IS A CO-DOMINANT DISEASE

A Donker[1], E Wiegerinck[1], S Klaver[1], T de Witte[1], D Bakkeren[2], M Nijziel[2], T Vlasveld[3], M Janssen[1], P Brons[1], D Swinkels[1]
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands
[2]Máxima Medisch Centrum, Veldhoven, the Netherlands, Veldhoven, Netherlands
[3]Bronovo Hospital, The Hague, the Netherlands, The Hague, Netherlands

Background. Iron Refractory Iron Deficiency Anemia (IRIDA) is a rare hereditary disease characterized by microcytic hypochromic anemia with low transferrin saturation (TSAT), not or only partially responsive to oral iron. The genetic substrate of IRIDA is the *TMPRSS6* gene (transmembrane protease serine 6), encoding the protein matriptase-2. *TMPRSS6* defects lead to increased levels of hepcidin, inappropriate for the low body iron status, resulting in decreased intestinal iron absorption and iron utilization by degradation of the cellular iron exporter ferroportin.Inheritance of IRIDA is still under debate. Most data from the literature indicate that IRIDA is an autosomal recessive disease. However, anecdotic reports describe heterozygous pathogenic TMPRSS6 mutations resulting in clinical apparent disease.In this abstract we report on 4 index cases with heterozygous pathogenic *TMPRSS6* defects resulting in mild IRIDA phenotypes. Family screening of the index cases showed only TMPRSS6 heterozygotes without the IRIDA phenotype. These data support the hypothesis that IRIDA is a co-dominant disease with variable penetrance. **Aims.** Description of inheritance and clinical and biochemical spectrum of IRIDA in index cases and relatives heterozygous for a pathogenic *TMPRSS6* defect. **Methods.** Case series**. Results.** Four index cases presented with mild microcytic hypochromic anemia with low transferrin saturation (TSAT), not or only partially responsive to oral iron supplementation. In 3 out of 4 index cases serum hepcidin, analysed by time-of-flight mass spectrometry, was inappropriately high relative to the low TSAT, suspicious of IRIDA (range TSAT/hepcidin ratio 0.3 to 1.0 %/nM; reference ranges men 1.7-256%/nM, premenopausal women 2.0-330%/nM, postmenopausal women 1.5-73.4%/nM; www.hepcidinanalysis.com). In the other index case the TSAT/hepcidin ratio was 2.1%/nM.DNA sequencing of the coding regions of the *TMPRSS6* gene between 2009 and 2012 showed a heterozygous pathogenic defect in all index cases (p.Cys702Phe, n=2; c.863+1G>T, in the 5' splice site of intron 7, n=1; p.Gly442Arg, n=1) Family screening of the 4 index cases was performed and showed 6 first degree relatives with the heterozygous pathogenic *TMPRSS6* defect.All these 6 heterozygous relatives were asymptomatic with Hb, MCV and TSAT/hepcidin ratio within reference ranges. This heterogeneity in phenotype could not be explained by modulating *TMPRSS6* polymorphisms cis or trans of the affected allele. Also there was no evidence for environmental factors influencing the biochemical /clinical penetrance in the affected index cases, such as hypermenorrhoe or chronic inflammation. **Summary and Conclusions.** We conclude that IRIDA is a co-dominant disease with variable clinical penetrance due to still unknown genetic and/or environmental factors, indicating that the inheritance of IRIDA still needs elucidation.

0392

ENDOTHELIAL DERIVED-MICROPARTICLES AS MARKER OF ENDOTHELIAL INJURY IN ABO - HEMOLYTIC DISEASE OF THE NEWBORN

H Awad, A Tantawy, R El-Farrash, E Ismail
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. ABO blood group incompatibility between mother and the fetus is currently the most frequent cause of hemolytic disease of the newborn (HDN). The ABO antigens are expressed on the surfaces of red cells and many other tissues, including vascular endothelium. Circulating endothelial microparticles (EMPs) are complex vesicular structures shed from activated or apoptotic endothelial cells and play a remarkable role in coagulation, inflammation, endothelial function, and angiogenesis contributing to the progression of vascular diseases. **Aims.** This work aimed to study circulating EMPs in ABO-HDN as a marker of endothelial activation , to examine the hypothesis of possible endothelial injury in neonates with ABO blood group incompatibility, and its relation to the occurrence and severity of hemolytic disease. **Methods.** Sixty-five full term neonates with HDN; 45 with ABO incompatibility and 20 with Rh incompatibility were compared to 20 healthy neonates with ABO and Rh matched mother and infant blood groups (controls). All neonates were studied stressing on blood grouping, markers of hemolysis ,and investigations were done to exclude other causes of neonatal hemolytic disease. Circulating EMPs ($CD144^+$) were measured by flow cytometry , before and after therapy (phototherapy and/or exchange transfusion). Patients with HDN were further subdivided according to the age-specific total serum bilirubin nomogram and disease severity into 3 subgroups; mild, moderate and severe HDN. **Results.** There was no significant difference between ABO and Rh HDN patients regarding birth weight,gestational age,hemoglobin,LDH, and bilirubin , however neonates with Rh HDN had higher reticulocytic count levels (p=0.008), and all (100%) had positive direct and indirect antiglobin test , compared to 17.8% and 15.6% in ABO HDN (p<0.001 and p=0.067,respectively). Pre-therapy EMPs levels were elevated in ABO and Rh HDN compared to controls (p<0.001, and p=0.02, respectively) ,being significantly higher in ABO compared to Rh HDN (p=0.02) . In ABO HDN , pre-therapy EMPs levels were significantly elevated in severe disease compared to moderate and mild disease (p<0.001),meanwhile, no significant difference was observed in EMPs levels in neonates with Rh-HDN in relation to disease severity (p=0.09) . Neonates with severe ABO-HDN had the highest pre-therapy EMPs compared to Rh-HDN (p<0.001). Multilinear regression analysis revealed that hemoglobin, reticulocytic count ,LDH and indirect bilirubin were independently correlated to pre-therapy EMPs levels in ABO HDN (r^2=0.834, p<0.001) , while in Rh HDN only hemoglobin and LDH were strongly significant (r^2=0.877, p<0.001). Post-therapy EMPs levels were significantly decreased after phototherapy as well as after exchange transfusion compared to pre-therapy levels (p<0.001) ,observed in both ABO and Rh-HDN groups , however, the decline in EMPs levels was remarkably evident

after exchange transfusion in neonates with severe ABO-HDN (p<0.001). **Conclusions.** We suggest that elevated EMPs in ABO-HDN may reflect an IgG-mediated endothelial injury parallel to the IgG- mediated erythrocytes destruction and thus could serve as a surrogate marker of vascular dysfunction and disease severity in those neonates. The proof of this concept remains to be fully elucidated and poses important challenges for risk stratification and therapeutic response.

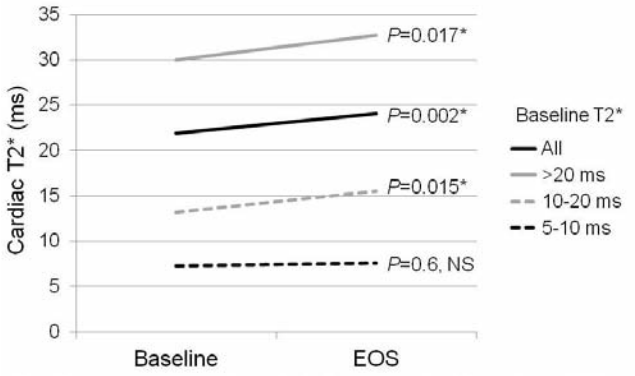
[6]University of Western Australia, Perth, Australia
[7]Dept. Radiology, Royal Adelaide Hospital, Adelaide, Australia
[8]Novartis Pharmaceuticals Australia Pty Ltd, Sydney, Australia
[9]Thalassaemia Services Victoria, Monash Medical Centre, Melbourne, Australia

Background. Cardiac failure is the leading cause of death in patients with thalassemia major. However, the introduction of new monitoring techniques, such as cardiac iron Magnetic Resonance Imaging (MRI) may lead to the improvement of patient care and prolong survival. The examination of the effect of iron chelators such as deferasirox on cardiac iron reduction is crucial in the development of treatment protocols, while the clinical consequences of cardiac iron accumulation in myelodysplastic syndromes (MDS) is still controversial. **Aims.** The primary objective of this study is to investigate the effect of single agent deferasirox on cardiac iron levels and cardiac function in a cohort of patients receiving regular red blood cell transfusions. **Methods.** Patients with transfusional siderosis were enrolled in this study and received deferasirox up to 40 mg/kg/day for 53 weeks. The primary endpoint was to investigate the change in cardiac T2* at 53 weeks compared to baseline (power and sample size calculation based on previously published literature). Secondary efficacy endpoints included change in left ventricular ejection fraction (LVEF), liver iron concentration (LIC) by R2-MRI and serum ferritin. All analyses were performed for all subjects in the full analysis population that included patients with hemoglobinopathies and MDS. Informed consent was obtained from all patients.



Results are presented as the adjusted means on back-transformed T2* values after the analysis model. *Statistically significant. NS: non-significant. EOS: end of study.

Figure 1. Change in cardiac T2* after 1 year.

Results. Results were available for 40 patients with hemoglobinopathies (36 thalassemia major, 4 sickle cell disease) and 6 patients with MDS (inferential statistics, all 46 patients with baseline and post-baseline cardiac T2* values). An overall increase in cardiac T2* from 21.9 to 24.1 ms was observed (10% increase, 95% CI=4 to 16%, *P*=0.002). Further analysis was performed based on T2* baseline values: 5-10 ms, no significant change (n=5; 7.3 to 7.6 ms; *P*=0.6); 10-20 ms, improvement of 18% (n=9 from 13.2 to 15.5 ms; *P*=0.015); >20 ms, increase of 9% (n=32; 30 to 32.7 ms; *P*=0.017). Descriptive statistics showed that in the subgroup of cardiac T2* 5-10 ms, patients had either received mean doses of deferasirox <30 mg/kg/day, or had a baseline LIC >25 mg Fe/g dry tissue. All patients in the MDS subgroup had baseline cardiac T2* >20 ms (descriptive analysis, median 30 ms; 24.4 to 33.2 ms), with a non-statistically significant increase in cardiac T2* after one year (12%; 29.3 to 32.7 ms, *P*=0.18). Statistically significant reductions in LIC were observed for the overall patient population (9.7 to 7.4 mgFe/g dry tissue *P*=0.037), especially for those with baseline LIC >7 mgFe/g dry tissue (20.2 to 15.1 mgFe/g dry tissue; *P*=0.003). A statistically significant reduction in serum ferritin of 7.6 µg/L/week was observed in the overall patient population (*P*=0.009). Safety marker analyses were consistent with previous reports. Results on LVEF will be presented. **Conclusions.** These results showed that once-daily deferasirox administered over 1 year induced a statistically significant increase in cardiac T2* levels, and a reduction in LIC and serum ferritin. This confirms previous reports showing that single agent deferasirox is an effective therapy for maintenance and reduction of cardiac iron levels, especially for patients with cardiac T2* >10 ms.

0394

FEATURES OF TREATMENT AND PROGNOSIS OF NON-ST ELEVATION ACUTE CORONARY SYNDROME IN PATIENTS WITH IRON DEFICIENCY ANEMIA

S Skotnikov, L Vertkin, A Vilcoviskii
Moscow State Medical-Stomatological University, Moscow, Russian Federation

The aim of the study was to determine features of clinical course and prognosis of non-ST elevation acute coronary syndrome in patients with iron deficiency anemia and high risk of bleeding. The authors analyzed the medical histories of 2473 patients admitted to the coronary care department from October 2006 to October 2009 year with diagnosis of non-ST elevation acute coronary syndrome, and 339 conclusions of post-mortem examination. Based on analysis of archival data shows, that the frequency of occurrence of anemia in patients with non-ST elevation acute coronary syndrome is 64,5%. Physicians rarely assess the risk of bleeding in these patients, and therefore antithrombotic therapy is appointed only in 62,6% of cases. In addition, at patients with hemoglobin below 90 g/l antithrombotic therapy is carried out in only 30,7% of cases. The opposite situation is observed with respect to the correction of iron deficiency anemia. Patients with non-ST elevation acute coronary syndrome and low level of hemoglobin are appointed iron preparations in 44,9% of cases, while patients with mild iron deficiency anemia - only in 6,5% of cases. Meanwhile, the incidence of myocardial infarction and mortality of these patients depends on the initial level of hemoglobin, as well as from ongoing antithrombotic therapy. Without it, antithrombotic complications occur in 22,1% of cases in the structure of all fatal events. In addition, demonstrated, that in patients with non-ST elevation acute coronary syndrome the incidence of myocardial infarction and mortality while severe anemia are 97,3% and 78,1% respectively. Proved that the highest frequency of fatal (22,1%) and non-fatal (37,4%) thrombotic complications occurs in patients with non-ST elevation acute coronary syndrome and iron deficiency anemia, which antithrombotic therapy in the hospital was not carried out. In these patients the frequency of hemorrhagic complications is equal to 4,3%. We demonstrated that using of antithrombotic therapy by low-molecular-weight heparin (dalteparin natrium) on the background correction of iron deficiency by aqueous complex of polynuclear iron (III)-hydroxide (Venofer ®), reduces mortality, risk of bleeding, symptoms of iron deficiency anemia and frequency of myocardial infarction development in patients with non-ST elevation acute coronary syndrome

[3]Department of hematology Memorial Sloan Kettering Cancer Center, New York, United States of America
[4]Divisione di Ematologia, Sapienza Univeristà di Roma, Rome, Italy
[5]Department of Haematology, Hassad Medical School, Jerusalem, Israel
[6]Istituto Toscano Tumori, Firenze, Italy

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a disease char-

acterized by hemolytic anemia, cytopenias and a high risk of venous thrombosis. Splenomegaly is not common: when it occurs, it is usually the consequence of splenic or portal vein thrombosis. PNH patients who have splenomegaly may also have thrombocytopenia, or neutropenia, or both, which may reflect hypersplenism. The management of this complication is challenging because splenectomy is hazardous in the presence of portal hypertension and it may be complicated by further thrombosis. **Aims.** Aim of this study was to test the safety and efficacy of selective splenic artery embolization (SAE), as an alternative to splenectomy, in patients with PNH who had thrombosis, splenomegaly and thrombocytopenia (TST). Our purpose was to devitalize part of the spleen without incurring in the risks of abdominal surgery. **Methods.** Four PNH patients had: (a) multiple thrombosis involving the portal system, (b) splenomegaly and (c) severe thrombocytopenia (median PLTS 15 x 10^9/L), presumed to be at least in part secondary to hypersplenism; 3 of the 4 patients also suffered from disabling recurrent episodes of abdominal pain. All 4 patients underwent SAE through interventional radiology, whereby branches of the main splenic artery, that are end-arteries distal to the splenic hilum, were occluded, causing infarction of the splenic parenchyma. In order to avoid an abrupt infarction of the entire spleen, which may be complicated by splenic rupture, splenic abscess, pneumonia or sepsis, SAE was carried out in steps, at several weeks or months intervals. **Results.** All patients witnessed a reduction/normalization of the spleen size. The 3 patients who suffered from recurrent episodes of abdominal pain experienced a resolution of the symptoms. Three out of 4 patients had a clinically significant increase in platelet counts: in 1 patient this took place already after the first SAE procedure and in 2 after 3 procedures. The procedures were uneventful, except for a pleural effusion in 1 case. With a follow-up time of 3 to 12 years, in 3 patients the clinical and hematological improvement was long-lasting. In the patient whose thrombocytopenia was not corrected, the reason was clearly bone marrow failure in addition to hypersplenism: this patient subsequently underwent a successful hematopoietic stem cell transplantation. In 1 patient, who was on eculizumab and had evidence of extravascular hemolysis, after SAE we observed, in addition to a remission of her thrombocytopenia, also a significant reduction in transfusion requirement. **Summary.** In conclusion, we have shown that SAE, carried out in sequential steps, is of benefit to patients with PNH who have the TST complex. A clinically significant resolution of pain was seen in all cases and an objective response was documented in terms of spleen size (4/4 cases) and of platelet counts (3/4 cases). In addition, for patients who, on account of the extravascular hemolysis remain transfusion dependent on eculizumab, SAE may be beneficial and probably a preferable alternative to splenectomy.

0396

THE VALUE OF RADIOCHROMATED ERYTHROCYTES IN DEMONSTRATING GASTROINTESTINAL TRACT BLOOD LOSS AS A SILENT CAUSE OF IRON DEFICIENCY

E Modebe[1], A Ellmann[2], L Wood[3], P Jacobs[3]
[1]Tygerberg Hospital, Parow, South Africa
[2]Stellenbosch University and Tygerberg Hospital, Parow, South Africa
[3]The Haematology Research Group, Pathcare, Claremont, South Africa

Background. Occult blood loss from the gastrointestinal (GI) tract, causing iron deficiency often with anaemia, can be diagnostically and therapeutically challenging. This is because stool testing may be negative, endoscopy poorly informative in view of intermittent bleeding while barium studies can potentially overlook superficial lesions. These limitations can be approached using two different radioactive isotopes to first reliably demonstrate the appearance of significant label in the stool and then localise the site anatomically.

Table 1. Summary of demographics and results of radionuclide studies.

Study	Age (years)		Sex		Result		
	Range	Mean	F	M	Positive	Negative	Total
Cr-51 RBC	1.5-81	50	36	21	30 (53%)	27 (47%)	57
Tc-99m RBC	36 -81	65	8	7	12 (80%)	3 (20%)	15

Aims. To demonstrate the usefulness of chromium-51 (^{51}Cr) labeled red blood cell (RBC) in detecting and quantifying blood loss from the GI tract and aiding in timing of Technetium-99 (^{99m}Tc) labeled RBC study, improving the sensitivity of the study to localize the site of GI bleeding. Finally to correlate these findings with clinical outcome. **Methods.** In this retrospective review, records of patients referred for evaluation of possible GI blood loss were reviewed, in each; daily recovery of radiochromium from stool was measured in the whole body counter. In those cases exceeding 50 ml/day, a technetium-99m (Tc-99m) localization study was performed.These studies were correlated with clinical findings. **Results.** 36 female and 21 males (n = 57) participated with institutional and ethics committee approval. In 30 (51 %) the radiochromium result was positive. In 15 of these, 12 (80%) technetium imaging then successfully defined a specific anatomical site: Ten of the latter were evaluable and half diagnosed with small-bowel angiodysplasia **Summary and Conclusions.** This sequential twin isotope method is practical in revealing otherwise silent intestinal haemorrhage. It has good patient acceptability and clinical as well as diagnostic utility in management.

0397

USE OF CAPILLARY BLOOD SAMPLES TO PERFORM CONFIRMATORY TESTS. AN AID FOR AN EARLIER DIAGNOSIS OF HEREDITARY SPHEROCYTOSIS (HS) IN NEONATES AND SMALL INFANTS

R Crisp[1], D Gammella[1], L Solari[1], G Schvartzman[2], C Rapetti[3], H Donato[3]
[1]Hospital Nacional Profesor Alejandro Posadas, Buenos Aires, Argentina
[2]Consultorios de Hematología Infantil, Buenos Aires, Argentina
[3]Hospital del Niño de San Justo, San Justo, Buenos Aires, Argentina

Background. Blood volume required to perform confirmatory tests for HS may be hard or even not feasible to collect in neonates or infants due either to difficulty inherent to the sampling procedure or to the inconvenience of withdrawing large blood volumes in small infants. Moreover, some patients with severe hemolytic anemia may require either red blood cells transfusions or exchange transfusions; in these cases, confirmatory tests must be delayed for some time. As a consequence, etiological diagnosis of hemolytic anemias may be delayed several weeks or months. Although capillary blood sampling is an easy procedure, its use to perform HS laboratory tests has not been reported in the literature. We have separately evaluated the accuracy of capillary blood for hypertonic cryohemolysis (CH), eosin-5'maleimide-flow cytometry (5'EMA-FC), and flow cytometric osmotic fragility (OF-FC), concluding that results showed no difference with the use of venous blood. In this study, we simultaneously performed the three tests. **Aims.** To assess the reliability of capillary blood samples for HS diagnosis. **Methods.** Twenty nine children, aged 2 days to 7 years (median 7 months), with hemolytic anemia or with a relative with HS were studied. Blood samples were collected by digital or heel punction in heparinized microhematocrit tubes. Six tubes (300 µL) per patient were collected for performing all tests. Our reference cut-off values for HS diagnosis are: CH >2.8%; 5'EMA-FC: gmean decrease >17; and OF-FC <22.8% residual red cells. All tests were performed within 24 hours from sampling. Criteria to confirm HS diagnosis was presence of spherocytes in the blood smear associated to positive results in at least two tests. **Results.** HS was diagnosed in 18 cases. Either CH or 5'EMA-FC were positive in 17 of them (94%), whereas OF-FC was positive in 16 of 16 HS children in whom the test was performed (100%). The only false positive result was CH in a newborn with hemolytic disease of the newborn secondary to ABO incompatibility. Most HS patients were positive for all performed tests. Only two of them presented one normal result, either for CH or for 5'EMA-FC tests. **Conclusions.** Neonatal jaundice is often the first manifestation of HS, associated to anemia in 50-80% of cases. Moreover, HS currently is a recognized cause of kernicterus. Therefore, HS is one main differential diagnosis to take into consideration when evaluating a neonate with hemolytic anemia. However, HS is usually underrecognized as a cause of neonatal hyperbilirubinemia. Our results show that the simultaneous use of these three tests allows confirming the diagnosis of HS in 100% of patients. Sensitivity was 94% for CH and 5'EMA-FC, and 100% for OF-FC, in agreement with those reported for the standard use of venous blood. The use of very small blood volumes allows an earlier etiological diagnosis in neonates and small infants. These results need to be confirmed in larger populations including HS and non-HS patients.

0398

DEVELOPMENT, IMPLEMENTATION AND FOLLOW-UP OF A NEW MANAGEMENT TOOL TO IMPROVE BLOOD TRANSFUSION SAFETY

G Duarte[1], E De Paula[2], JF Marques[2]
[1]Centro de Hemoetarpia Celular em Medicina de Campinas, Campinas, Brazil
[2]Centro de Hemoterapia Celular em Medicina de Campinas, Campinas, Brazil

Background. Assuring transfusion safety is an essential element of health

care in all countries, requiring government commitment and a legal framework. Fundamental transfusion safety strategies include selection of low risk donors, Good Manufacturing Practices in preparation of blood components, and appropriate clinical use of blood products including avoidance of unnecessary transfusions. To assure the latter, most centers employ an educational approach focused on the prescribing physician, associated with pre-transfusional audits of transfusion adequacy. However, the implementation of these laborious measures is often insufficient to prevent the unnecessary use of blood components, so that measures to monitor the efficacy of these strategies are key to blood transfusion services. **Aims.** Here we evaluate the efficacy of the utilization of a simple and straightforward management tool developed fours years ago, and used ever since, to monitor the use of blood components and enhance blood transfusion safety, in a private transfusion service in Campinas, SP, Brazil **Methods.** In our Institution, all transfusion requests are audited by a transfusion medicine physician prior to transfusion, and classified as "proper"or "non-proper"based on internationally-adopted guidelines regarding transfusion indications. "Non-proper"requests are then adapted to suit these protocols. From April to October 2008, requests for red blood cells (RBC), were additionally analyzed in order to identify recurrent characteristics that could be associated with "non-proper"requests. Two characteristics were associated with a higher likelihood of "non-proper"indication: (1) pre-transfusion hemoglobin higher than 9.0 g/dL, and (2) absence of information on hemoglobin levels. These two markers were then considered as surrogate markers of adequate use of RBC. These two characteristics were then used to calculate the so-called "RBC transfusion adequacy index"(RAI), which represents the proportion of RBC transfused in which any of these two characteristics were present. RAI was monitored prospectively from november 2008 to january 2012, as an indicator of the efficacy of other measures implemented to promote adequate use of blood products. **Results.** During the first part of the study, 1495 transfusions requests were analyzed, of which12,9% were classified as "non-proper". In the second part of the study, from november 2008 until january 2012, the RAI was used as a surrogate monitor of adequate use of blood transfusion monthly and the mean value was 85,46 % ± 2,42(SD). Regardless of the knowledge that blood transfusions are associated with significant risks, inadequate use of blood is still a problem. Available tools to avoid unnecessary transfusions are hard to implement in day-to-day practice. The acceptable RAI can vary significantly from service to service according to hospital complexity, social-economic issues and resources in different institutions. Summary: The optimal management of blood transfusion and patient related risks are a on course task. Here we have, prospectively shown that, RAI can be helpfull in transfusion services to monitor the efficacy of adequate use of blood components.

REDUCING THE RISK OF VCJD TRANSMISSION: A SAFETY TRIAL OF PRION-FILTERED VERSUS STANDARD RED CELLS TRANSFUSION IN SURGICAL PATIENTS (PRISM)

M Elebute[1], A Mora[2], L Choo[3], C MacRury[4], C Llewelyn[2], S Purohit[5], V Hicks[5], M Malfroy[2], A Deary[2], T Reed[2], S Meredith[3], L Manson[4], L Williamson[5]
[1]King's College Hospital, London, United Kingdom
[2]NHS Blood and Transplant/ MRC Clinial Studies Unit, Cambridge, United Kingdom
[3]MRC Clinical Trials Unit, London, United Kingdom
[4]Scottish National Blood Transfusion Service, Edinburgh, United Kingdom
[5]NHS Blood and Transplant, Colindale, United Kingdom

Background. Variant Creutzfeldt-Jakob (vCJD) is a fatal disease which can rarely be transmitted via blood transfusion. No reliable screening test exists for blood donors, and in animal models leucodepletion of donated red cells does not completely remove prion infectivity. A red cell filter device P-Capt™ (Macopharma) incorporating a resin designed specifically to remove prions has been CE marked for use inEurope. **Aims.** The PRISM study was designed to examine: 1. possible serious clinical sequelae in patients following transfusion of red cells that have been P-Capt® filtered, namely an increase in the formation of new, clinically significant red cell antibodies and; 2. an increase in atypical or previously recognised transfusion reactions. All outcome variables were measures of safety. **Methods.** Adult surgical patients in 9UK hospitals who required transfusion support were entered into a multicentre, non-randomised, open, controlled trial. All patients gave informed consent. Most patients had complex or re-do cardiac or vascular surgery. Patients who received at least 1 unit of filtered red cells were compared with a control cohort of patients who received standard red cell units only. The primary outcome was the development of red cell antibodies at 8 weeks or 6 months post-transfusion. Secondary outcomes included transfusion reactions and atypical symptoms arising during or post-transfusion. Imputability of these to transfusion was allocated after central review. **Results.** 917 P-Capt® filtered and 1336 standard red cell concentrate (RCC) units were transfused into 590 patients. 291 patients received standard red blood cells only, and 299 patients received at least one unit of P-Capt® filtered red blood cells. 26 new red cell antibodies were detected in 20 patients (10 standard arm; 10 filtered arm) with an overall alloimmunisation rate of 4.4% for patients who provided at least one follow up blood sample (78% of those transfused). Analysis by exact logistic regression showed that neither the treatment arm nor the number of units transfused had a significant effect on the proportion of patients who developed new clinically significant antibodies (OR 0.93, 95% CI 0.3, 2.5) and (OR 0.95, 95% CI 0.8, 1.1) respectively. No pan-reactive antibodies or new red cell antibodies formed specifically against P-Capt® filtered red cells were detected.Only 1 of 26 reported transfusion-related events was considered a probable transfusion reaction (febrile reaction, standard arm). A further 17 were considered possibly or unlikely to be transfusion-related (6 standard arm, 11 filter arm, p = 0.369), and 8 further events, all in the filter arm, were considered to be unrelated to the transfusion. None of the SAEs reported in the study (134 standard arm; 114 filtered arm) was considered clinically unexpected for this population or directly related to transfusion. **Conclusions.** Transfusion of P-Capt® filtered cells does not appear to increase the rate of red cell alloimmunisation and there were no transfusion reactions or adverse events clearly related to the filter in this study. Our findings suggest that these filters do not reduce the overall safety of transfusion, but post-marketing surveillance would be needed if implemented.

PREVALENCE AND PATTERN OF HEPATITIS B VIRAL MARKER DETECTION IN BLOOD DONORS AT CANADIAN BLOOD SERVICES HALIFAX/PEI

C Sharpe, M Bigham, D Anderson, I Sadek, N McLaughlin, E Kahwash
Canadian Blood Services, Halifax, Nova Scotia, Canada

Background. Current Canadian Blood Services (CBS) testing for the presence of the Hepatitis B virus (HBV) in blood donors involves universal screening for HBV DNA, Hepatitis B surface antigen (HBsAg) and Hepatitis B core antibody (anti-HBc). Supplementary testing includes Hepatitis B surface antibody (anti-HBs). **Methods.** A retrospective review of donor files testing positive for a HBV marker at CBS Halifax/PEI from January 1, 2011 to February 1, 2012 was undertaken to characterize the test result pattern. All donors denied prior hepatitis and vaccination within the past three months on their Record of Donation. Information about previous HBV vaccination was obtained from donors who contacted CBS about their HBV-positive test results. **Results.** Thirty-six donors tested negative for HBV DNA but reactive to one or more HBV seromarkers during the study period. Six donors tested anti-HBc repeat-reactive (RR) only. Twenty-seven donors tested RR for both anti-HBc and anti-HBs (17 new and 10 returning donors). Of the 10 returning donors who tested RR for anti-HBc and anti-HBs, 4 were documented to be HBsAg-negative < 3 months prior to the reactive donation. Another four out of the 27 RR anti-HBc and anti-HBs reactive donors were documented to have had HBV vaccination remotely. Three scenarios were observed for three donors who tested HBsAg-RR: HBsAg neutralization negative with reactive anti-HBs; HBsAg neutralization positive with non-reactive anti-HBs; and HBsAg neutralization negative with anti-HBs not tested. The donor testing RR for HBsAg (HBsAg neutralization positive) and anti-HBs non-reactive received a vaccination within days of donation. **Conclusions.** The majority of donors testing positive for a HBV seromarker were found to be RR for anti-HBc and reactive for anti-HBs which in conjunction with a non-reactive HBsAg and negative HBV DNA, most likely reflects previous, resolved acute HBV infection. An isolated RR anti-HBc result among 6 donors likely reflects either a false-reactive anti-HBc or a remote, resolved acute HBV infection with loss of anti-HBs. Recent HBV vaccination may cause a transient reactive HBsAg. Acquiring information from donors on the status of prior HBV vaccination may be of use in interpreting HBV test results.

THE EFFICACY AND SAFETY OF CRYOPRECIPITATE FOR FIBRINOGEN REPLACEMENT IN ACUTE AND CHRONIC ACQUIRED HYPOFIBRINOGENAEMIA

J Winthrop[1], M Sweeney[1], G Balendran[1], A Hadjinicolaou[1], S Idris[2]
[1]Cambridge University, Cambridge, United Kingdom
[2]Addenbrooke's Hospital, Cambridge, United Kingdom

Background. Fibrinogen is essential for coagulation especially in the context of acute haemostatic challenge such as surgery or haemorrhage. Cryoprecipitate is a source of fibrinogen and established as a treatment for acquired hypofibrinogenemia. It is produced from pooling of plasma fractions from a number of donors. In recent years, virally-inactivated fibrinogen concentrates have become available and are now considered the treatment of choice for congenital hypofibrinogenemia based on greater predictability of response and

safety profile. Despite its common use there is limited data on the efficacy and safety of cryoprecipitate in patients with acute and chronic hypofibrinogenemia. **Aims.** This retrospective study examines the efficacy and safety of cryoprecipitate in raising plasma fibrinogen concentrations and improving coagulation and clinical parameters in the treatment of patients with acute and chronic acquired hypofibrinogenemia. **Methods.** A retrospective analysis of data collected for all patients receiving cryoprecipitate at a large teaching hospital in the UK between October 2009 and August 2010 was undertaken. Overall, 132 cryoprecipitate transfusion events occurred over the study period. Of these, 79 episodes met the inclusion criteria. Plasma fibrinogen levels, Prothrombin Time (PT) and activated Partial Thromboplastin Time (aPTT) were recorded prior to cryoprecipitate administration and subsequent levels were noted at both 24 and 72 hour time-points. Medical records were consulted to determine the indication for cryoprecipitate administration, clinical response and any subsequent transfusion-related morbidity and mortality. The patients were followed up to a period of 1 year to detect any transfusion-acquired infections. Statistical analysis was carried out using non-parametric paired tests (Wilcoxon test). **Results.** On average 2 pools of cryoprecipitate - constituting a typical adult dose - were transfused at each event. Across all groups cryoprecipitate significantly raised the plasma fibrinogen level by a median of 0.8 g/L (P<0.001) though there was variation in the individual response of patients. Coagulation parameters also improved with significant reductions in both the PT (P<0.01) and aPTT (P<0.001). Correction in coagulation parameters correlated with improvement in clinical condition and cessation of bleeding in most cases. No increase in morbidity or mortality was observed attributable to cryoprecipitate transfusion. Additionally, after a year of follow up there were no reports of transfusion-related infections in any of the patients. Interestingly, the rise in plasma fibrinogen was particularly marked in patients who were bleeding acutely and had no evidence of a pre-existing coagulopathy. Patients with chronic hypofibrinogenemia had a significantly lower and less sustained response to cryoprecipitate. **Conclusions.** Cryoprecipitate remains an effective method of increasing the plasma fibrinogen level and subsequently improving the clotting of patients who are bleeding acutely with a low fibrinogen level. It is most effective in patients with no chronic underlying cause for their hypofibrinogenemia. However, the fibrinogen content of a pool of cryoprecipitate can vary significantly and clinical response may therefore be less reliable than with the use of purified fibrinogen concentrates. In addition, concerns regarding the theoretical risk of transfusion-related infection with the use of pooled cryoprecipitate remain, especially in the context of virally-inactivated concentrate now being readily available at a comparable cost.

Table 1. Fibrinogen response to cryoprecipitate transfusion in acute and chronic hypofibrinogenemia.

		Fibrinogen Level (g/L)

0402

STUDY OF EFFICACY RED BLOOD CELL TRANSFUSIONS AND THEIR INFLUENCING ON QUALITY OF LIFE IN HEMATOLOGICAL MALIGNANCIES PATIENTS WITH ANEMIA

N Romanenko
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Anemia in hematological malignancies (HM) patients is a frequent symptom, decreased survival rate and overall quality of life (QoL). Red blood cell (RBC) transfusions are routinely used to correct severe anemia increasing hemoglobin (Hb), improving patient's status and QoL in a short time. **Aims.** 1. To study the efficacy RBC transfusions. 2. To investigate QoL before and after RBC transfusions in anemic patients. **Methods.** HM patients (n=61) with anemia: non-Hodgkin's lymphoma (n=5), chronic lymphocytic leukemia (n=12), multiple myeloma (n=14), primary myelofibrosis (n=8), myelodysplastic syndrome (n=11), acute myeloid (n=9) and lymphoid leukemia (n=2). The median age of patients was 64.0 years (range 21-82). Transfusion threshold was Hb concentration <8.0 g/dL (for young patients; n=50) and <9.5 g/dL (for elderly patients; n=11). The Hb level was studied before and after every transfusion. QoL was assessed using FACT-An questionnaire: all patients filled up the special forms of questionnaire before the first RBC transfusion and after the latest one. Most patients were receiving chemotherapy according their diagnoses. The target Hb level was >8.0-9.9 g/dl. **Results.** Mean baseline Hb concentration was 7.0±1.2 g/dL (4.0-9.2 g/dl). A number of transfusions was 1-9 (median 3) during the hospitalization period (4-35 days). The Hb concentration significantly increased from baseline to 9.3±0.9 g/dl (8.0-10.2 g/dl; p<0.01). In whole group of patients Hb concentration increased at 2.8±1.3 g/dL after all RBC transfusions. Every blood unit increased Hb level at 0.9±0.3 g/dL on average. Only 28 patients (45.9%) increased Hb ≥1.0 g/dL after every transfusion, but 33 (54.1%) - 0.1-0.9 g/dL. Out of them were five chemotherapy refractory patients (8.2%), who increased Hb only at 0.1-0.4 g/dL per unit, and twenty eight ones (45.9%) who increased Hb at 0.5-0.9 g/dL, they were patients after high dose chemotherapy (n=6), progression of disease and refractory to chemotherapy (n=18), and severe hemolysis (n=4). FACT-An demonstrated that RBC transfusion reduced symptoms (items) of anemia in most cases (Figure): 1) I feel fatigued; 2) I feel weak all over; 3) I feel listless ("washed out"); 4) I feel tired; 5) I have trouble starting things because I am tired; 6) I have trouble finishing things because I am tired; 7) I have energy; 8) I have trouble walking; 9) I am able to my usual activities; 10) I need sleep during the day; 11) I feel lightheaded; 12) I get headaches; 13) I have been short of breath; 14) I have pain in my chest 15) I am too tired to eat; 16) I am interested in sex; 17) I am motivated to do my usual activities; 18) I need help doing my usual activities; 19) I am frustrated by being too tired to do the things I want to do; 20) I have to limit my social activity because I am tired. But statistically significance (p<0.05) were observed in 1-6 and 11-13 items (points reduced from 2.50 to 1.41 on the average). **Conclusions.** The study has shown that RBC transfusions not only are effective increase Hb level in anemic HM patients but also improve QoL.

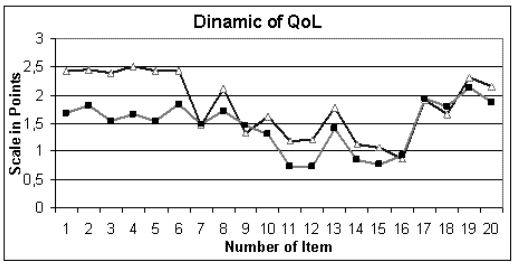

Figure 1.

0403

STUDY QUALITY OF LIFE IN LYMPHOPROLIFERATIVE DISORDERS PATIENTS WITH ANEMIA TREATED ERYTHROPOIETIN

N Romanenko, L Margaryan, I Kostroma, E Khromova, I Karamatskaya, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Anemia in lymphoproliferative disorders (LPD) patients is a frequent symptom and can decrease the efficacy of antitumor chemotherapy, survival rate and overall quality of life (QoL). Its pathogenesis is based on suppression by proinflammatory cytokines and decreasing erythroid precursor's sensitivity to serum erythropoietin. Therefore recombinant human erythropoietin (rHuEPO) are used as a pathogenetic therapy of anemia in patients with LPD which significantly increase hemoglobin, reduce a number of RBC transfusions and improve QoL. **Aims**.To study the efficacy of rHuEPO and improvment QoL in LPD patients with anemia. **Methods.** There were done this interventional prospective study to investigate the efficacy of rHuEPO in reducing RBC transfusion-dependency, increasing Hb concentration and QoL in patients (n=103) with low-grade non-Hodgkin's lymphoma (n=18), chronic lymphocytic leukemia (n=23) and multiple myeloma (n=62). The median age of patients was 65.5 years (range 24-84). rHuEPO was injected subcutaneously on 450 IU/kg weekly. Before start of rHuEPO treatment all patients have being received two or

more cycles of antitumor chemotherapy. The patients with Hb concentration <8.0 g/dL received RBC transfusions before rHuEPO treatment. The target Hb level was 12 g/dL. The duration of treatment with rHuEPO was planned within 16 weeks. Positive response was estimated as increasing Hb concentrating ≥2.0 g/dL or achieving target Hb level (12 g/dl) during the period of rHuEPO therapy and so achieving RBC transfusion-independency. QoL was assessed using the FACT-An questionnaire. **Results**. Mean baseline Hb concentration was 8.71±1.46 g/dl (3.7-10.0 g/dl). Before rHuEPO-therapy 31 patients had received RBC transfusion (1-17 units) during last 3-6 months because of low Hb (3.7-8.0 g/dl). The period of rHuEPO-therapy was from 4 to 16 weeks (mean 9.5±3.7 weeks). During the study period 14 patients (45.2%) followed RBC transfusions after rHuEPO treatment and 17 patients (54.8%) showed transfusion-independency. Whole we observed positive response in 67 patients (65.0%), their Hb concentration increased from baseline to 12.5±1.0 g/dl (11.2-15.7 g/dL; p<0.001). FACT-An demonstrated that rHuEPO-therapy significantly (p<0.02) reduced a range of anemic symptoms (Items 1-6 and 13; Figure): 1) I feel fatigued; 2) I feel weak all over; 3) I feel listless ("washed out"); 4) I feel tired; 5) I have trouble starting things because I am tired; 6) I have trouble finishing things because I am tired; 7) I have energy; 8) I have trouble walking; 9) I am able to my usual activities; 10) I need sleep during the day; 11) I feel lightheaded; 12) I get headaches; 13) I have been short of breath; 14) I have pain in my chest 15) I am too tired to eat; 16) I am interested in sex; 17) I am motivated to do my usual activities; 18) I need help doing my usual activities; 19) I am frustrated by being too tired to do the things I want to do; 20) I have to limit my social activity because I am tired. **Conclusions.** The study has shown that rHuEPO is effective treatment of reducing RBC transfusion-dependency, increasing Hb and improving QoL in LPD patients with anemia.

PHARMACOECONOMIC BURDEN FOR DELIVERY OF ANTI-RETROVIRAL TREATMENT: WHAT ARE WE IN FOR?

I Al Zakwani[1], A Balkhair[1], S Alkindi[2], N Al-Obaidani[1], A Pathare[1]
[1]Sultan Qaboos University Hospital, Muscat, Oman
[2]Sultan Qaboos University, Muscat, Oman

Background. Although the safety of transfused blood products has been continuously improving, even today, we still see transfusion transmitted viral infections. **Objective**: Our objective was to assess the pharmacoeconomic impact of antiretroviral therapy and highlight the occurrence of transfusion transmitted diseases [TTD]. **Methods.** Retrospective analysis of our Hemophilia A database. HIV1 and 2 were tested by ELISA followed by further testing with western Blot in retrovirus positive samples. Retrovirus viral load was monitored by quantitative PCR, and CD4 counts before and during treatment. CD4 counts were monitored by flow cytometry. **Results.** Amongst 93 Hemophilia A patient in our database since 1992, 17 (18.3%) had TTD. 13 (76.5%) patients had Anti-HCV positivity [6 HCV RNA PCR positive]; 2 (11.75%) were HIV-1 positive by western blot [both were retrovirus RNA PCR positive]; and 2 (11.75%) were HBV positive [both were also HBV DNA positive]. Two of these patients were positive for all the three viruses together. The two retrovirus RNA PCR positive cases, achieved a sustained virological remission [SVR] on the currently recommended HAART regimen following treatment over 27 and 32 months respectively. Furthermore, the CD4 counts have also normalized following SVR. Interestingly, we also observed an increased tendency for bleeding, especially when treatment was intensified by using boosted darunavir in one patient, which was controlled with prophylactic Factor VIII:C transfusions. The current cost of treatment [US dollars] for these two patients has been 16,120 and 15,172 over the past 12 months of treatment, respectively. Furthermore, the cost [US dollars] of prophylaxis with Factor VIII:C [15-25 units/kg, twice a week is 41,967 (annual) for the 2 patients. **Summary and Conclusions.** We report here SVR in two retroviral infections with RNA PCR negativity in both the treated patients. However, anti-retroviral treatment is ongoing according to the currently recommended international guidelines along with Factor VIII:C prophylaxis. Thus, the pharmacoeconomic burden with the average current cost of treatment for antiretroviral therapy and Factor VIII:C prophylaxis is about 36,630 USD, per patient in the long term.

0405

EVALUATION OF A SINGLE 1000 MG IRON DOSE FERRIC CARBOXYMALTOSE FOR IMPROVEMENT OF FATIGUE IN IRON DEFICIENT, NON-ANEMIC, PREMENOPAUSAL WOMEN IN THE RANDOMIZED, PLACEBO-CONTROLLED STUDY PREFER

B Favrat[1], K Balck[2], C Gasche[3], M Hedenus[4], A Mezzacasa[5], C Küng[5], C Breymann[6]
[1]Department of Ambulatory Care and Community Medicine, University Lausanne, Lausanne, Switzerland
[2]Private practice for internal medicine, Meine, Germany
[3]Medical University Vienna, Vienna, Austria
[4]Hematology Unit, Sundsvall Hospital, Sundsvall, Sweden
[5]Vifor Pharma, Glattbrugg, Switzerland
[6]Obstetric Research & Feto-maternal Hematology Res. Group, Univ. Hospital Zurich, Zürich, Switzerland

Background. In iron-deficient, non-anemic (IDNA) women, repeated iron administration can reduce symptoms of fatigue. **Aims.** This study evaluated the efficacy and safety of a single 1000 mg iron dose of intravenous (i.v.) ferric carboxymaltose (FCM) in healthy premenopausal women suffering from symptomatic unexplained fatigue and iron deficiency. **Methods.** Eligible women had to be iron deficient (serum ferritin <50 ng/mL and transferrin saturation TSAT <20%, or serum ferritin <15 ng/mL) but non-anemic (hemoglobin ≥11.5 g/dL) and present with a total score ≥5 on the Piper Fatigue Scale (PFS). Patients with major depressive disorder, any active or unstable concurrent medical condition, known infections, chronic inflammation, use of iron preparations within 4 weeks prior screening or a body weight <50 or >90 kg were not included. Participants were blinded to the study drug, randomized to receive a single dose of FCM (1000 mg iron) or saline solution (placebo), and followed-up after 7, 28, and 56 days. **Results.** 290 of 294 treated women were included in the analysis (FCM 144, placebo 146). Baseline characteristics were similar in both groups. Total PFS score improved (decreased by ≥1 point from baseline to Day 56) in 65.3% (FCM) and 52.7% (placebo) of patients (primary endpoint, odds ratio 1.68, 95%CI 1.05-2.70; p=0.03). The calculated improvement in total PFS was statistically significantly higher in the FCM (2.2±2.1 points) vs. the placebo group (1.4±2.0 points) (mean±SD; p=0.0007) and also consistent for all subscores on behavioral (2.46±2.31 vs. 1.56±2.26; p=0.001), affective (2.52±2.33 vs. 1.55±2.26; p<0.001), sensory (2.14±2.34 vs. 1.38±2.26; p=0.003) and cognitive mood (1.70±2.06 vs.0.98±1.94; p=0.003) aspects. Also computerized visual analogue scale (VAS) scores of self-rated alertness (14.2±18.0 vs. 8.9±17.9; p=0.007) and contentment (9.3±16.8 vs. 4.6±16.16; p=0.023) improved better after FCM compared to placebo treatment; differences in self-rated calmness showed a strong trend in favor of FCM (10.0±20.5 vs. 5.0±18.2; p=0.077). Correspondingly, the SF-12 mental score improved by 5.8±9.8 vs. 2.8±8.9 points (p=0.006). Notably, significant improvements in the different scores were associated with baseline TSAT <20%. At Day 56 after FCM treatment, serum ferritin levels were normal (≥50 ng/mL) in 99.3% of FCM-treated patients (placebo 2.1%), and 76.4% (placebo 32.9%) had a normal TSAT of 20-50%. Treatment emergent adverse events (114 with placebo and 209 with FCM) were mainly mild in intensity (63.2% and 66.5%, respectively). **Conclusions.** A single dose of FCM (1000 mg iron) effectively reduced fatigue symptoms and improved patient-rated mental quality of life as well as cognitive function in iron-deficient but otherwise healthy and non-anemic women. The results of this placebo-controlled study confirm that iron deficiency even without anemia, particularly if TSAT is below 20%, can affect women's health, and emphasize the importance of maintaining a normal iron status independent of Hb levels.

Hemoglobinopathy 1

EFFECT OF COMBINED ANTIOXIDANT THERAPY ON LIVER IRON CONCENTRATIONS AND HEPATIC FIBROSIS IN BETA-THALASSEMIA MAJOR PATIENTS

S El-Alfy[1], A Attia[2], A Adly[1], F Ibrahim[2], A Mahmoud[2], A Sayed[2]
[1]Ain Shams University, Cairo, Egypt
[2]National Research Center, Cairo, Egypt

Background. Repeated blood transfusions lead to oxidative tissue injury in β-thalassemia major (β-TM) due to iron overload which may enhance liver injury and fibrosis. **Aims.** to assess the effects of combined vitamin therapy on oxidant-antioxidant capacity, hepatic status and hemoglobin derivatives in β-TM patients. **Methods.** Prospective follow up study for 12 months involved 60 β-TM patients aged 4-17 years compliant on deferiprone (> 85% of calculated dose) compared to 60 healthy controls. Patients with initial low serum vitamins E, C, A (group1) were treated with therapeutic oral vitamin doses. Investigations done included: vitamins (A,C,E) levels, liver transaminases, serum ferrittin, percentage of erythrocyte hemolysis, hepatic fibroscan elastography (TE) for liver fibrosis and hepatic MRI R2* for liver iron concentration (LIC) were performed before, after 6 and 12 months of therapy. Antioxidant capacity assessed using reduced glutathione, malondialdehyde (MDA), catalase, superoxide dismutase and glutathione enzymes. **Results.** In β-TM group1 (n=39); baseline vitamin A, E, C, hemoglobin and reduced glutathione levels were significantly lower while MDA was significantly higher compared to controls (p<0.001). Correlation studies revealed that basal MDA level in β-TM was positively correlated with basal LIC (r=0.44,p<0.001) and ALT(r=0.52,p<0.001) while it was negatively correlated with basal vitamin A(r=-0.74,p<0.001), vitamin C(r=-0.65,p<0.001), vitamin E levels(r=-0.63,p=0.001) and glutathione peroxidase (r=-0.32, p=0.04). Initial serum ferritin level was negatively correlated with basal levels of vitamin A (r=-0.28, p=0.04) and vitamin E(r=-0.36,p=0.04). Basal LIC values were negatively correlated with vitamin A(r=-0.38,P=0.002), vitamin E(r=-0.45, p<0.0001) and vitamin C(r=-0.27, p=0.0), while it was positively correlated with basal ALT(r=0.43,p=0.001). Stepwise regression analysis was done and revealed that the most significant effect on MDA level in studied thalassemics were the initial values of LIC, vitamin A followed by AST levels. Follow up of sttudied thalassemics revealed that; vitamins, reduced glutathione and hemoglobin levels were significantly elevated and paralleled by progressive decline in MDA, reticulocytic count and serum ferritin levels during antioxidant therapy (p<0.001). Liver transaminases, superoxide dismutase levels were significantly decreased while glutathione reductase was significantly elevated during antioxidant therapy (p<0.001). Minimal Improvement of hepatic fibrosis as 23% of patients had TE (>12kPa) at baseline compared to 20.5% after 12 months, while 48.7% initially had TE (>6kPa) compared to 51.2%, 56.4% at 6 and 12 months. While LIC values were significantly decreased (mean; 16.4, 11.3, 8.9 mg/gm at baseline, after 6, 12 months, p<0.001) after antioxidant therapy. **Conclusions.** increased oxidative damage in β-TM may be due to depletion of lipid soluble antioxidant vitamins. Combined vitamins; A,C and E therapy improves the antioxidant status, reduce hemolysis rate and improve the hepatic status both by decrease LIC and to less extent the degree of liver fibrosis in β-TM compliant on deferiprone.

CIRCULATING PLATELET AND ERYTHROCYTE MICROPARTICLES IN SICKLE CELL DISEASE: RELATION TO CLINICOPATHOLOGICAL CHARACTERISTICS AND VASCULAR COMPLICATIONS

A Tantawy, A Adly, N Mamdouh, E Ismail
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. Sickle cell disease (SCD) is characterized by a complex vasculopathy, consisting of endothelial dysfunction and increased arterial stiffness, with a global effect on cardiovascular function. The hypercoagulable state and thromboembolic complications in those patients may result from multiple implicated factors, including chronic hemolysis and circulating cell-derived microparticles which originate from activated platelets and erythrocytes. **Aims.** This study aimed to measure the levels of platelet and erythrocyte-derived microparticles (PMPs and ErMPs) in young children and adolescents with sickle cell disease ,and their relation to the clinicopathological characteristics and aortic elastic properties. **Methods.** The study is a cross sectional study ,included 40 patients with sickle cell disease (aged 5-17 years) regularly followed in the Pediatric Hematology Unit,Ain Shams University , in Cairo,Egypt ,compared to 40 age and sex matched healthy controls. Patients were studied stressing on frequency and severity of sickling crisis, transfusion therapy, hydroxyurea and chelation therapy, as well as hematological profile, hemoglobin electrophoresis, D-dimer assay and antithrombin III (AT III) .Circulating platelet microparticles PMPs ($CD41b^+$) and erythrocyte-derived microparticles ErMPs (glycophorin A^+) were determined by flow cytometry. Echocardiography was performed with assessment of aortic elastic properties: aortic stiffness and distensibility. **Results.** Both PMPs and ErMPs were significantly increased in SCD patients compared to healthy controls (p<0.001). The highest MPs levels were found in patients with sickle cell crisis compared with those in steady state (p<0.001). SCD patients on hydroxyurea therapy showed lower values compared with untreated patients (p<0.001). Both types of MPs were inversely correlated with hemoglobin level (p=0.01) and positively correlated with lactate dehydrogenase (p=0.001), indirect bilirubin (p= 0.001), and D-dimer levels (p<0.05).Only ErMPs levels were positively correlated with serum ferritin (p=0.02). Echocardigraphic findings showed that systolic left ventricular function was preserved in all studied patients, while 14% of SCD patients had diastolic dysfunction. Aortic distensibility was significantly decreased while aortic stiffness was significantly increased in SCD compared to controls (p<0.05,for both). Aortic distensibility was negatively correlated with transfusion index in SCD patients (P=0.001). Aortic stiffness index was positively correlated to disease duration,PMPs, ErMPs, LDH and serum ferritin levels in studied patients (p<0.05). Aortic stiffness was positively correlated with intial Hb S% at time of diagnosis and with severity and numbers of sickling crisis in SCD patients(P=0.01, p=0.02 respectively). **Conclusions.** We suggest that increased circulating PMPs and ErMPs may be considered potential biological markers for vascular dysfunction and disease severity in SCD and may be implicated in the pathogenesis of coagulation abnormalities encountered in these patients. Their levels are closely related to markers of hemolysis, sickling severity, fibrinolysis and iron overload.

0408

SOLUBLE CD163 AS A BIOMARKER OF DISEASE SEVERITY IN YOUNG SICKLE CELL DISEASE PATIENTS AND THEIR TRAIT SIBLINGS

A Tantawy, A Adly, E Ismail
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. CD163 is a member of the Scavenger-receptor Cysteine-rich family of proteins. It is expressed on cells of monocyte-macrophage lineage and is the main hemoglobin-haptoglobin receptor ,and mediates the interaction between macrophages and erythroblasts . In SCD ,inflammation and monocyte activation are predisposing factors to vaso-occlusion crises. Siblings of patients with SCD may have the same pathophysiology without displaying severe symptoms of SCD. Soluble CD163 (sCD163) is a valuable biomarker in diseases with monocyte-macrophage involvement. Its clinical relevance in sickle cell disease (SCD) and trait remains elusive. **Aims.** This study aimed to assess (sCD163) levels in children with SCD and their sickle cell trait (SCT) siblings in relation to clinicopathological characteristics and to investigate its value as a potential marker for disease severity and hydroxyurea treatment response. **Methods.** 60 SCD patients, 30 SCT siblings and 30 healthy controls (median age : 9 years,7.3 years,and 7.5 years, respectively) were included. SCD patients were studied in the steady state excluding patients who had sickling crisis or other inflammatory conditions within one month prior to the study . All were subjected to history taking stressing on frequency of sickling crisis, transfusion requirements and response to hydroxyurea therapy. Investigations included hematological profile, hemoglobin electrophoresis,serum ferritin and measurement of serum sCD163 levels(ELISA). One year clinical and laboratory follow-up was done for studied patients and siblings. **Results.** Serum sCD163 levels were elevated in SCD patients and SCT siblings compared to controls (p<0.001), levels in untreated SCD were higher than in SCT siblings (p<0.001). sCD163 levels were higher in SCD patients who developed sickling crisis during one year study period (p<0.05). Patients on hydroxyurea therapy had lower sCD163 compared to untreated patients (p<0.001). There was significant positive linear relationships between sCD163 and age, disease duration, total leucocytic count and HbS with negative correlations with mean hemoglobin and HbF levels in SCD (p<0.05) . In siblings, sCD163 was positively correlated with age, HbS and negatively correlated with hemoglobin and HbF (p<0.05). Stepwise regression analysis showed that total leucocytic count, HbS and HbF were independently related to sCD163 in SCD (r2 =0.968, p<0.001). ROC curve analysis showed that the cutoff value of sCD163 at 1400 ng/mL could be considered a predictor for sickling crisis differentiating patients with and without the occurrence of this complication with a sensitivity of 92.3% and specificity of 94.1% (AUC, 0.98; 95% CI, 0.95-1.01; p<0.001) . **Conclusions.** sCD163 levels are related to SCD patients' clinical condition and can be considered a prognostic biomarker for early crisis prediction and to monitor response to hydroxyurea therapy .Elevated sCD163 in trait siblings could reflect increased risk of sickling in challenging situations.

0409

FLOW CYTOMETRY ASSESSMENT OF CIRCULATING PLATELET AND ERYTHROCYTE MICROPARTICLES IN THALASSEMIA MAJOR PATIENTS: RELATION TO CLINICAL, LABORATORY AND ECHOCARDIOGRAPHIC FINDINGS

A Tantawy, A Adly, N Mamdouh, E Ismail
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. Thalassemia is a hereditary hemolytic anemia caused by mutations in the globin gene complex. Circulatory disturbances including arterial and venous thrombosis have been reported. Aggregability of abnormal red cells and the high level of membrane-derived microparticles stemming from activated platelets and other blood cells are thought to be responsible for the associated thrombotic risk. Hemolysis is also thought to be an important pathophysiological prothrombotic risk, particularly through the formation of circulating vesicles. **Aims.** This study aimed to measure the levels of platelet and erythrocyte-derived microparticles (PMPs and ErMPs) in children and adolescents with β-thalassemia major (TM), and their relation to the clinical and laboratory parameters as well as aortic elastic properties and echocardiograpic findings. Methods:The study is a cross sectional study ,included 40 patients with β-thalassemia major (TM) (aged 8-19 years) regularly followed in the Pediatric Hematology Unit, Ain Shams University, in Cairo, Egypt ,compared to 40 age and sex matched healthy controls. Patients were studied stressing on transfusion and chelation therapy,splenectomy, history of thrombotic events, as well as hematological profile, hemoglobin electrophoresis, D-dimer, antithrombin III (AT III). Circulating platelet microparticles PMPs ($CD41b^+$) and erythrocyte-derived microparticles ErMPs (glycophorin A^+) were determined by flow cytometry. Echocardiography was performed with assessment of aortic elastic properties: aortic stiffness and distensibility . **Results.** Both PMPs and ErMPs were significantly increased in TM patients compared to healthy controls ($p<0.01$). Splenectomized TM patients had higher levels of PMPs and ErMPs thannonsplenectomized patients with significant positive correlation of PMPs levels to the duration since splenectomy ($p=0.04$). Levels of both types of MPs were inversely correlated with hemoglobin level and positively correlated with markers of hemolysis (lactate dehydrogenase and indirect bilirubin), and D-dimer levels in TM patients ($p<0.05$, for all). ErMPs levels were positively correlated with serum ferritin in TM patients($p=0.02$). History of thrombotic events was associated with significantly higher levels of both PMPs and ErMPs ($p<0.001$).Patients non-compliant to chelation therapy(receiving ≤ 60% of the chelating therapy dose) and patients with serum ferritin > 2500 ng/ml had significantly higher levels of PMPs and ErMPs compared to compliant patients and patients with serum ferritin less than 2500 ng/mL ($p<0.001$, for both). Echocardiographic findings showed that systolic left ventricular function was affected in 16% of studied patients, while 22% of patients had diastolic dysfunction. Aortic distensibility was significantly decreased while aortic stiffness was significantly increased in thalassemia patients compared to controls ($p<0.05$). Aortic distensibility was significantly lower in splenectomized thalassemic patients compared to non-splenectomized($P=0.001$). Aortic stiffness index was positively correlated to disease duration, PMPs, ErMPs, LDH and ferritin levels in studied thalassemics ($p<0.05$). **Conclusions.** We suggest that increased PMPs and ErMPs may be considered as potential biological markers for vascular dysfunction and hypercoagulable state in thalassemia patients increasing their risk of thrombotic events.

0410

SERUM ANGIOGENIN LEVEL IN PATIENTS WITH BETA THALASSEMIA AND SICKLE CELL DISEASE

M Matter[1], A Abdelmaksoud[2], A Shams El Din El Telbany[3], K Bebawy[1]
[1]Pediatric Department, Ain Shams university, Cairo, Egypt
[2]Pediatric Department, Ain Shams University, Cairo, Egypt
[3]Clinical Pathology department, Ain Shams University, Cairo, Egypt

Background. The role of angiogenin as a marker of angiogenesis has not been investigated in thalassemia or sickle cell disease patients. **Aims.** To estimate the serum angiogenin level in children and adolescents with beta thalassemia and sickle cell disease, and its relation to possible risk factors related to increased angiogenesis in those patients. **Methods.** This study was conducted at the pediatric Hematology Clinic, Children's Hospital, Ain Shams University on 32 β-Thalassemia major (β-TM) patients(mean age 14.2±3.8 years; 18 splenectomized), 20 β-thalassemia intermedia (β-TI) patients (mean age of 14.3±4.8 years; two splenectomized) and 20 sickle cell disease(SCD) patients (mean age of 14.1±2.4 years; 4 splenectomized).SCD patients were subdivided into 8 with (HbSS) and 12 with sickle thalassemia (HbS/β-thalassemia). Thirty five age and sex matched healthy individuals served as controls. After taking informed consent, patients were subjected to clinical assessment, complete blood count, Hb electrophoresis, serum ferritin and serum angiogenin level was done by ELISA. **Results.** The angiogenin level was significantly higher in patients with SCD [250(100-300)pg/ml] compared to β-Thalassemia group [180(140-230)pg/ml] and controls [89(80-103) pg/ml] ($p<0.001$) especially those with HbSS disease ($p=0.06$). We found no significant difference in angiogenin level between β- TM and β-TI ($p=0.88$) or splenectomized and non splenectomized patients ($p=0.19$). There was a significant inverse correlation between angiogenin level and the age of patients in β-TM($p<0.001$) and β-TI ($P=0.009$) and significant negative correlation between angiogenin level and age of disease onset in β- TM ($r=-0.414$, $p=0.019$) and in β- TI ($r=-0.486$, $p=0.30$) but not in SCD. There was a significant inverse correlation between angiogenin level and ferritin in β- TI group($r=-0.573$, $p=0.008$). Moreover; a highly significant inverse correlation between serum angiogenin and total duration of chelation was detected in β- TI ($p<0.001$) and β- TM ($p=0.003$) groups. In SCD, there was a significant inverse correlation between angiogenin level and both frequency of blood transfusion ($r=-0.731$, $p<0.001$) and hydroxyurea duration of therapy ($p=0.017$). **Conclusions.** A significantly higher angiogenin level was detected among patients with SCD especially in severe form of SCD. Regular blood transfusion and hydroxyurea therapy may negatively influence angiogenin level in patients with SCD, while early starting age of blood transfusion and chelation therapy may decrease angiogenin level in patients with β-thalassemia major.

0411

RETROSPECTIVE ANALYSIS OF MUSCULOSKELETAL COMPLICATIONS IN ADULTS WITH SICKLE CELL DISEASE ATTENDING A SINGLE INSTITUTION OVER 21 YEARS

N Igbineweka, E Drasar, SL Thein
King's College London School of Medicine, London, United Kingdom

Background. Musculoskeletal complications are common in patients with sickle cell disease (SCD). There is also a perception that the prevalence of connective tissue disease (CTD) in increased compared to populations without SCD. It is uncertain to what extent the presence of CTD affects the severity of SCD in these patients. **Aims.** This study assesses the prevalence of musculoskeletal complications including CTDs in the sickle cell adult cohort attending a teaching London hospital. In addition, it evaluates whether the presence of CTD correlates with increased severity of clinical course in patients with SCD. **Methods.** A retrospective investigational study was undertaken to assess musculoskeletal disease prevalence using serological and clinical documented evidence over a 21-year period, from 1999 - 2010. For the latter two years of our study period, patients with HbSS or HbSB0 (considered as sickle cell anemia, SCA) and CTD were compared against two markers of disease severity: a) number of hospital admissions and b) length of hospital stay. **Results.** 722 patients with SCD were included in the study group with 411 (57%) being women and 311 (43%) male. Genotype distribution shows hemoglobin S/S (HbSS) (n = 451), HbSC (n = 225), HbSB+ (n = 33) and HbSB0 (n = 13). 135 patients (18.7%) had ≥ 1 musculoskeletal disease(s) amongst the SCD population within the study period. Avascular necrosis (AVN) was the most prevalent musculoskeletal disease affecting 10% (n = 72), of the SCD population. Documented evidence of CTD was present in 3.1% (n = 23) of patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) being the most common at 2% (n = 14) and 0.3% (n = 2), respectively. Antinuclear antibody (ANA +ve) was found in 15% (n = 108) of patients and anti-smooth muscle antibody (ASM) present in 8% (n = 60) of patients. Within the latter two year period of the study, SCA patients with any positive autoimmune serology and/or CTD (n = 102) had a mean of 1.9 (±SD 2.7) admissions compared to a mean of 1.5 (±SD 2.7) admissions in those without autoimmunity and/or CTD (n = 210). The mean length of hospital stay in admitted patients was 6 days (±SD 4.1) in those with autoimmunity and/or CTD (n= 46) compared to 7 days (±SD 11.4) in those without (n = 108). **Conclusions.** Almost 1 in 5 patients in the SCD adult cohort had evidence of musculoskeletal disease. CTD prevalence of RA and SLE were greater in the SCD population in relation to prevalence reported in the existing literature in populations of similar ethnicity. There were no statistically significant differences in number of admissions or hospital stay between SCD patients with autoimmunity and/or CTD compared to those without. A considerable proportion of SCD patients were ANA +ve thus emphasizing the need for diagnostic vigilance in determining CTD in the patient with SCD.

[13]Epidemiology and Biostatistics Unit, Institute of Clinical Physiology, CNR, Pisa, Italy

Background. In thalassemia major (TM), myocardial fibrosis has been detected using the late gadolinium enanched (LGE) cardiovascular magnetic resonance (CMR) technique and a positive correlation with anti-HCV antibodies has been described. However, HCV-induced cardiomyopathy is still controversial. **Aims.** The aim of our study was to verify a possible correlation between myocardial fibrosis detected by LGE CMR and chronic hepatitis C in a large retrospective cohort of TM patients. **Methods.** We analyzed 434 TM patients (233 males, mean age 31±9 years) consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) study. LGE images were acquired to detect myocardial fibrosis. HCV-RNA tests were sensitive to detect more than 50 copies/mlL **Results.** Ninety out of 434 TM patients (21%) were found to have myocardial fibrosis by LGE CMR technique. Among the 312 patients tested for HCV RNA there was a significant correlation between the presence of myocardial fibrosis and a chronic hepatitis C (P=0.011). Among the 62 patients with myocardial fibrosis tested for HCV RNA, we found a significant higher prevalence of diabetes mellitus in CHC patients versus the no CHC patients (P = 0.049). In all patients DM was developed after the HCV infection diagnosis **Conclusions.** Our finding supports the hypothesis that in the multi-transfused TM patients HCV infection can be involved in the pathogenesis of myocardial fibrosis through both myocarditis directly and the pancreas and liver damage with the development of diabetes indirectly. These patients could therefore benefit from therapeutic interventions directed towards the eradication of virus.

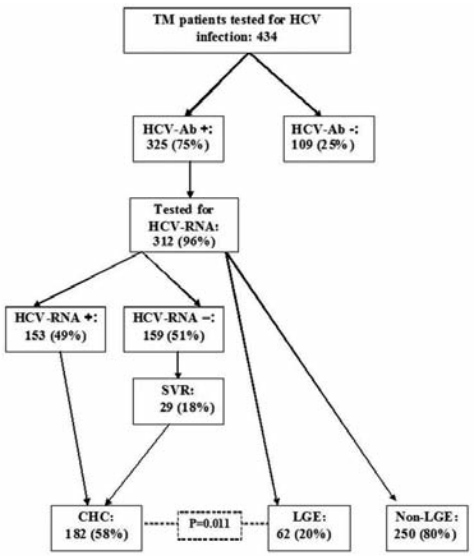

Figure 1. Flow chart of the test results.

MATERNAL COMPLICATIONS AND THE ASSOCIATION TO BASELINE VARIABLES IN PREGNANT PATIENTS WITH SICKLE CELL DISEASE

K Al-Khabori, N AL-Huneini, S Al-Farsi, M Al-Riyami
Sultan Qaboos University Hospital, Muscat, Oman

Background. Sickle cell disease (SCD) is an inherited hemoglobinopathy with multisystem complications. In pregnancy, it has been associated with multiple maternal complications. Studies addressing this issue have been limited in number and sample size. We planned to estimate the incidence of different maternal complications and the impact of baseline variables on the incidence. **Methods.** We retrospectively reviewed 68 consecutive pregnant patients with SCD followed at the obstetric clinic in a tertiary center from June 2006 to August 2011. We collected different baseline variables including age, gravidity, parity, baseline hematological parameters, history of splenectomy and cholecystectomy. We gathered the information on the number of SCD related admissions, emergency visits, intensive care admissions, acute chest syndrome, blood transfusions, pregnancy induced hypertension, preterm labor, maternal morbidity (eclampsia, uterine rupture and or post-partum hemorrhage), infection and maternal mortality. We used multivariable logistic regression to estimate and adjust the impact of baseline variables (age, parity, baseline hemoglobin F, history of splenectomy, cesarean section and the SCD genotype) on major maternal complications (define as a composite outcome of maternal mortality, morbidity, infection and pregnancy induced hypertension). **Results.** We analyzed 68 patients. The mean age was 30 years (standard deviation [SD] 3.8, range 22-40). The median gravidity and parity were 2 (range 1-6) and 1 (range 0-5) respectively. Sixty-two patients had SS genotype. The initial mean hemoglobin was 9.5 g/dl (SD 1.1, range 7.2-11.9). The mean baseline hemoglobin F was 10.2% (SD 6.6, range 0.7-29). All patients were on penicillin prophylaxis and folic acid. Five and eight patients had history of splenectomy and cholecystectomy respectively. Twelve patients delivered by cesarean section and only 1 patient had preterm labor. During pregnancy, 65 patients required admission for SCD and or pregnancy related complications (96%, confidence interval [CI] 91-100). The median number of admissions was 3 (range 0-20). Fifty-four patients (79%, CI 70-89) had at least 1 visit to emergency room with a median of 3.5 (range 0-75). Eight patients needed admission to intensive care unit (12%, CI 4-20). Fourteen patients developed acute chest syndrome (21%, CI 11-30). Infection was seen in 17 patients (25%, CI 14-36). Blood was given to 61 patients (90%, CI 82-97) with a median of 4 units (0-18). Pregnancy induced hypertension was observed in 8 patients (18%, CI 4-20) while 5 patients (7%, CI 1-14) had preterm labor. One patient developed eclampsia and 1 had uterine rupture. Only 1 patient died due to post partum hemorrhage. The multivariable logistic regression model showed that none of the factors included were statistically significant on the impact on the major maternal complications composite outcome. **Conclusions.** Patients with SCD can go through pregnancy with low mortality and pregnancy-related morbidity. However, SCD related morbidity and the need for blood transfusion remain high. Baseline variables don't predict SCD and pregnancy related complications. The study is limited by the small sample size and the retrospective nature of the design. Further larger prospective studies are needed to confirm the finding.

0414

EVALUATION OF SUBCLINICAL CENTRAL NERVOUS SYSTEM INVOLVEMENT IN THE THROMBOPHILIC CONTEXT OF NON TRANSFUSION DEPENDENT THALASSEMIA SYNDROMES

A Teli[1], M Economou[1], D Zafeiriou[1], J Rudolf[2], V Gourtsa[1], A Papastergiopoulos[1], E Kontopoulos[1], M Athanassiou - Metaxa[1], N Gombakis[1], F Papachristou[1]
[1]Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece
[2]Papageorgiou General Hospital of Thessaloniki, Thessaloniki, Greece

Backround. Beta thalassemia is known to be characterized by a hypercoagulable state, especially in thalassemia intermedia patients. Bibliographically, thalassemia intermedia patients also present with subclinical central nervous findings on neuroimaging examination, findings correlated to increasing age, negative thansfusion history and low levels of hemoglobin. **Aims.** To evaluate subclinical involvement of central nervous system in young non transfusion - dependent thalassemic patients, as well as frequency of coagulation abnormalities and a possible correlation of the two entities. **Methods.** Thirty one patients aged 4-21 years (mean age 12±4.7 years) participated in the study, 25 patients (Group A) with thalassemia intermedia and 6 patients (Group B) with haemoglobin H disease. All patients underwent inherited and acquired coagulation defect testing, neuroimaging and neurophysiologic evaluation. Patients aged 6-16 also had intelligence scores measured. **Results.** With regards to coagulation, a decrease in protein C and protein S activity was found in 13/25 (56%)

and 12/25(48%) of patients in Group A, respectively. In Group B 2/6 patients also had decreased protein S activity. Increased D-dimers, thrombin-antithrombin complex (TAT) and prothrombin fragment (F1 + 2) values were found in 2/25, 16/25 and 2/25, of patients in Group A and 2/6, 5/6 and 2/6 patients of Group B, respectively. Heterozygosity and homozygosity for the methylenetetrahydrofolate reductase mutation was found in 12/25 and 3/25 of patients in Group A and 3/6 and 0/6 of patients in Group B, respectively. Heterozygosity for factor V Leiden and G20210FII was found in 2/25 (8%) and 3/25 (12%) of patients in Group A, with increased prevalence compared to Greek population. Neuroimaging evaluation was normal in all patients. Neurophysiologic evaluation revealed abnormal findings in 9/25 of patients in Group A and 1/6 patients in Group B on electroencephalogram (EEG), 4/25 in Group A and 1/6 patients in Group B on brain auditory-evoked potentials (BAEPs) and 1/21 in Group A and 2/6 patients in Group B on somatosensory evoked potentials (SEPs). Visual-evoked potentials (VEPs) were normal in all patients. Significantly lower protein C values were found in patients with abnormal EEG of Group A (p=0.012). Transcranial Doppler (TCD) measurements revealed increased peak systolic velocities in 19/21 patients in Group A and 4/6 patients in Group B and decreased mean velocities in 7/21 patients in Group A and 3/6 patients in Group B. Patients with pathological findings on TCD study in Group A had significantly increased levels of F1+2 (p"□="□0.015) compared to patients with normal measurements. With regards to intelligence scores 2/18 of patients in Group A and 2/6 patients in Group B demonstrated IQ below 85. Additionally, 6/18 of patients in Group A and 1/6 patients in Group B presented mild neuropsychologic dysfunction. **Conclusions.** The study results confirm the early presence of hemostatic changes in young patients with non transfusion-depended thalassemic syndromes. Additionally, they demonstrate subclinical CNS involvement starting at childhood. For such involvement detection, in addition to commonly performed neuroimaging, neurophysiological and neuropsychological evaluation is warranted.

0415

NEONATAL CORD BLOOD SCREENING: CORRELATION OF HB BARTS QUANTITATION WITH GENESCAN AND MOLECULAR STUDIES

S Alkindi[1], A Al Zadjali[2], S Ambusaidi[1], A Misquith[2], H Al Haddabi[1], D Gravell[2], N Al Abri[1], R Krishnamoorthy[3], V Pathare[2]
[1]Sultan Qaboos University, Muscat, Oman
[2]Sultan Qaboos University Hospital, Muscat, Oman
[3]INSERM, UMR _S 763, Hopital Robert Debre, Paris, France

Background. Alpha-thalassaemia is highly prevalent in the Sultanate of Oman. Presence of Hb Barts in significant amounts in a neonate is pathognomonic for the presence of underlying alpha thalassaemia gene. **Aims.** To correlate significantly high Hb Barts levels obtained by quantitative high performance liquid chromatography [HPLC] in the neonatal cord blood screening programme with Gene Scan studies and validate by molecular characterization of alpha thalassaemia. **Materials and Methods.** In a prospective study, consecutive cord blood samples from 7837 neonates, which showed abnormally high Hb Barts by a quantitative high performance chromatography (alpha thalassaemia short program, Biorad Laboratories, Hercules, CA, USA) were screened with Genescan studies. Samples with a single peak, (suggestive of a deletion lesion) were subjected to sequencing by GAP PCR for α2 and α1 genes. Samples that showed two peaks, (indicative of a non-deletional lesion) were initially screened for common defects like alpha T-Saudi by Fast PCR. If negative, these samples were then studied for rarer non-deletional defects by direct sequencing for **α**2 and **α**1 genes using ABI 3100 Genetic Analyzer®. (Applied Biosystems, Foster City, CA, USA).

Table 1. Distribution of Hb, Red cell indices & alpha genotype in the three subgroups of Hb Barts.

Hb Barts		Hb g/dl	RBC x10^{12}/L	Hct (%)	MCV (fl)	MCH (pg)	MCHC (g/dl)	RDW (%)	HbF %	Genotype
<1% N= 625	Mean ± SD 0.9 ± 0.48 IQRange:0.7-1.1	15.81 ±1.58	4.54 ±0.52	49.92 ±5.03	105.72 ±5.64	34 .0 ±2.27	33.03 ±1.23	16.27 ±1.24	89.55 ±10.2	(αα/αα)
1 -3% N= 1847	Mean ± SD 1.4 ± 0.42 IQRange:1.2-1.7	15.78 ±2.03	4.74 ±0.66	48.25 ±6.99	101.57 ±5.44	33.38 ±2.69	32.71 ±1.17	16.25 ±6.46	84.65 ±9.75	(αα/−α$^{3.7}$)*
3 -10% N= 1323	Mean ± SD 5.6 ± 2.1 IQRange:4.3-7.2	14.96 ±2.01	5.29 ±0.69	47.46 ±6.8	89.87 ±5.39	28.47 ±2.1	31.65 ±1.39	17.3 ±1.82	81.42 ±9.5	(−α$^{3.7}$/−α$^{3.7}$)#

* 5.9% of these subjects had additional non-deletional mutation increasing the Hb Barts level.
# 5.6% of these subjects had additional non-deletional mutation increasing the Hb Barts level.

Results. Overall there were 3795 samples (48.42%) with Hb Barts indicative of the presence of α-thalassaemia. Amongst these, 3170(83.5%) subjects showed a significant amount of Hb Barts (>1%) ; with Genescan studies showing one peak in 1229 cases(38.77%) and two peaks in 1941 cases(61.23%). These results showed a 100% concordance with GAP PCR for α2 and α1 genes showing deletional (-α3.7/-α3.7) and non-deletional type (αα/-α3.7) in subjects with one and two peaks respectively. Furthermore, Hb Barts levels in the three groups also correlated significantly with red cell parameters and the alpha genotype (Table 1)**. Conclusions.** The amount of Hb Barts in neonates was proportional to the number of deletional **α** thalassaemia alleles. Furthermore, additional non-deletional mutation was associated with a further rise in Hb Barts. Genescan and DNA sequencing by GAP PCR showed a good correlation with elevated Hb Barts in the neonate.

0416

SAFETY AND EFFICACY OF HYDROXYUREA IN CHILDREN AND ADOLESCENTS WITH SICKLE/BETA-THALASSEMIA: THE GREEK EXPERIENCE

E Papadopoulou, M Economou, A Teli, D Zafeiriou, M Athanassiou-Metaxa, N Gompakis, F Papachristou
Thalassemia Unit, 1st Pediatric Department of Aristotle University of Thessalon, Thessaloniki, Greece

Background. Hydroxyurea is a cytotoxic, antimetabolic and myelosuppresive drug that has been used over the last years in adult patients with sickle cell disease (SCD), resulting in reduction in pain crises, hospitalizations and need for transfusions. Hydroxyurea has also been used, during recent years, in the treatment of children with severe SCD. However, data on young patients with a mild clinical course, such as usually present in sickle/beta-thalassemia (S/b-thal), is limited. **Aims.** To evaluate the safety and efficacy of hydroxyurea in Greek children and adolescents with Sthal. **Patients and Methods.** 13 patients (8 girls and 5 boys) with thal, aged 9.4±4.5 years (3.5-18), were included in the study. Hydroxyurea's daily dose ranged from 15-25 mg/kg, with a mean of 18.6 mg/kg. Treatment was given for 12 months. Laboratory follow-up consisted of white blood cell count, hemoglobin, hematocrit, red blood cell indices, reticulocyte count and platelets count measured every 2 weeks, biochemistry measured every 2 months and hemoglobin F measured every two to three months. Patients were clinically evaluated on every visit. Clinical course and adverse events were reported for the study period. **Results.** A reduction of pain crises as compared to the year before treatment (median:2, 0-5 vs median:0, 0-3, p=0.003) as well as of hospitalizations (median:1, 0-3 vs median:1, 0-1, p=0.014) was noted. None of the patients presented with a severe clinical event (acute chest syndrome, avascular bone necrosis, stroke, splenic sequestration crisis) during the study period. With regards to hematological parameters, an increase in hemoglobin (9.2±0.7 vs 9.7±0.8 g/dl, p=0.048), fetal hemoglobin (9.1±5.9 vs 23.4±8.9 %, p<0.001), mean corpuscular volume (66.5±3.7 vs 86.5±9.5 fl, p<0.001) and mean corpuscular hemoglobin (21±1.1 vs 27.5±2.9 pg, p<0.001) and a decrease in reticulocyte count (9.4±4.5 vs 4.2±2.3 %, p<0.001), white blood cell count (9854±3402 vs 7607±3401 k/ul, p=0.013), platelet count (382153±184509 vs 290307±135675 k/µl, p=0.005), total bilirubin (2.2±1.4 vs 1.3±0.6 mg/dl, p=0.019) and indirect bilirubin level (1.8±1.2 vs 1±0.5 mg/dl, p=0.016) was noted. With regards to adverse events, 2 patients had mild transaminasemia, 2 had mildly elevated serum creatinine levels, one transient thrombocytopenia and one transient leukopenia with neutropenia. All of the above mentioned toxicities were short-term and dose-dependable. **Conclusions.** To the best of our knowledge, this is the first study to specifically assess the effect of hydroxyurea therapy in young patients with S/b-thal and of the same ethnic origin. The study shows that hydroxyurea treatment is safe and efficacious in this patient cohort, however, long-term follow up and evaluation of possible protective effect on organ dysfunction is warranted.

0417

THE ROLE OF ULTRASOUND IN DIFFERENTIATING ACUTE OSTEOMYELITIS FROM VASO-OCCLUSIVE CRISIS IN CHILDREN WITH SICKLE CELL DISEASE

A Oyewo, F Brokke, K Jogeesvaran, B Inusa
Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background. In the acute stage, vaso-occlusive sickle crisis and osteomyelitis present with similar symptom such as pain, tenderness and swelling over the affected area with or without a fever; there may also be an associated rise in laboratory markers of infection such as white cell count (WCC) and C-reactive protein (CRP), without an obvious source of infection. These non-specific signs make distinguishing between both conditions a challenge for clinicians. Prompt diagnosis and treatment of osteomyelitis with surgical incision and drainage of affected sites when indicated, and extensive antibiotic therapy is crucial to prevent further complications. However, incorrect diagnosis of osteomyelitis in a child with vaso-occlusive crisis will result in unnecessary antibiotic treatment

and lengthy inpatient admission. The gold standard for diagnosing osteomyelitis is a positive blood culture or joint aspirate, however blood cultures are not always positive and joint aspiration is a rather invasive procedure which can be difficult to undertake in paediatric patients. **Aims.** The aim of this study was to examine the use of ultrasound as a tool in aiding early diagnosis in children with sickle cell disease presenting acutely with non-specific symptoms such as bone pain, fever or swelling which are typical of acute osteomyelitis or vaso-occlusive crisis arising due to bone infarction. **Methods.** We reviewed the clinical notes, radiological and laboratory reports of all children with sickle cell disease who were admitted to our department from October 2003 to December 2010 with a diagnosis of osteomyelitis or vaso-occlusive crisis based on symptoms at presentation and results of radiological and laboratory investigations. Thirty-seven cases with osteomyelitis and fifty-eight cases with vaso-occlusive crisis were reviewed. **Results.** A positive ultrasound finding for diagnosis of osteomyelitis was defined as evidence of periosteal elevation and/or fluid collection. A negative ultrasound finding was described as normal with no evidence of periosteal elevation or fluid collection. Positive ultrasound findings were observed in twenty-eight of the thirty-seven patients (76%) with osteomyelitis who had an ultrasound examination on day 0 - 6 of admission. Periosteal elevation was ≥4mm in nine of the twenty-eight (32%) patients with positive findings. Nine of the thirty-seven patients (24%) in the osteomyelitis group had a negative initial ultrasound scan; three of these patients had repeat ultrasound scans between days 4 - 7 of admission, all of which showed subperiosteal fluid collections ≥4mm in depth which is consistent with a diagnosis of osteomyelitis. Overall, ultrasound scan was positive in thirty-one out of thirty-seven patients (84%) in the osteomyelitis group. Initial ultrasound findings were negative in 91% of patients with vaso-occlusive crisis. **Conclusions.** Ultrasound is a useful, cost-effective diagnostic modality which is relatively easy to perform; it should be one of the first-line investigations in children where there is initial clinical confusion regarding the diagnosis of acute osteomyelitis or vaso-occlusive crisis. In cases where ultrasound is negative or inconclusive and clinical concern prevails, we would suggest a repeat ultrasound and/or MRI scan to guide the diagnosis.

0418

THE XMNI POLYMORPHISM AND BCL11A SNPS MAY HELP PREDICT HYDROXYUREA RESPONSE IN IRANIAN β-THALASSEMIA PATIENTS

M Banan[1], H Bayat[1], A Azarkeivan[2], S Mohammadparast[1]
[1]University of Social Welfare and Rehabilitation Sciences, Tehran, Iran
[2]Blood Transfusion Organization, Tehran, Iran

Background. Hydroxyurea (HU), a drug which can reactivate fetal hemoglobin (HbF) production, is frequently prescribed to β-thalassemia patients. However, transfusion requirements of only a subset of patients are reduced upon HU treatment. Because of its side-effects, targeted prescription of HU is imperative. **Aims.** The aim of this study was to identify genetic markers that correlate with HU response. Determination of these markers could be beneficial for targeted drug prescription. **Methods.** We carried out a retrospective association study of single nucleotide polymorphisms (SNPs) in three HbF quantitative trait loci (QTLs)"the XmnI polymorphism, Bcl11A, and the HBS1L-MYB intergenic region"with the response to HU in a cohort of 89 transfusion-dependent Iranian β-thalassemia patients. An increase in blood transfusion intervals post-treatment was used as a basis for drug response. **Results.** The XmnI T/T genotype and presence of the Bcl11A rs766432 (and rs4671393) minor alleles correlated strongly with the response to HU (P<0.001). This correlation was even stronger upon presence of both markers [P<0.001; odds ratio (95% confidence interval) = 40.8 (10.0-166.4)]. **Conclusions.** The XmnI polymorphism and Bcl11A SNPs may be used to accurately predict the HU-response of Iranian β-thalassemia patients.

0419

HAEMOGLOBINOPATHY SCREENING AND PREVENTION IN NORTHERN GREECE. A 10 YEARS SURVEY

S Theodoridou[1], M Alemayehou[1], N Prappas[1], T Daglis[1], V Aletra[1], O Karakasidou[1], T Vyzantiadis[2], T Theodoridis[2], E Boutou[3], A Balassopoulou[3], K Sinopoulou[3], V Delaki[3], C Vasilakos[1], A Agapidou[1], A Manitsa[1], A Loutradi[3], E Voskaridou[3]
[1]Hippokration Hospital, Thessaloniki, Greece
[2]Aristotle University, Thessaloniki, Greece
[3]National Thalassaemia Centre, Athens, Greece

Greece is a Mediterranean country with a high frequency of thalassaemia and haemoglobinopathies. Beta thalassaemia (β-thal) carrier frequency is approximately 8%, while 1.5% of the population is heterozygous for the HbS gene. Since 1974 a nation wide program for Thalassaemia prevention has been implemented in our country. The aim was to educate and to increase awareness of the public concerning these hereditary anaemias, to screen couples for haemoglobinopathies, to give genetic counselling and perform prenatal diagnosis. The spectrum of mutations we observe recently, is influenced by the number of immigrants from different geographic areas who have settled down in Greece the last two decades. Through population screening and prenatal diagnosis program that is performed,natives and immigrants are screened and counselled free of charge.We report the results of the prevention program in Northern Greece, over a 10-year period (2002-2011). A total of 25.520 subjects have been screened for haemoglobinopathies. Among them a total of 2602 couples were screened and counselled in our Thalassaemia Prevention Unit. In 259 cases (9,9%), both partners carried an abnormal haemoglobin gene and genetic counselling was offered. 248 out of 278 pregnancies, (including 5 twins pregnancies) were at risk of giving birth to a sick offspring carrying either the homozygous or doubly heterozygous forms of the mutations under discussion. 32 pregnancies involved couples who were heterozygous for mutations that did not cause severe clinical disease, and were exempted from prenatal diagnosis. These gene interactions were β-thal / α-thal, HbE / HbE, HbE-Saskatoon / HbS , HbE-Saskatoon / β-thal, HbO-Arab / HbO-Arab, HbD-Punjab / α-thal, HbD-Punjab / β-thal. Prenatal diagnosis was carried out by chorionic CVS at 11-12 weeks of gestation (n=218), in few cases by amniotic fluid sampling, at 16-18 weeks (n=21). Very few late-comers were tested by foetal blood sampling at 20-24 weeks of gestation (n=4), In two cases prenatal diagnosis was performed with chorionic CVS and amniotic fluid sampling and in one case with CVS and foetal blood sampling testing. In three cases a transvaginal procedure was performed. There has been one obstetric complication out of 248 procedures.It was the case of a transvaginal collection of CVS that provoked rapture of the membranes and automate abortion. 63 (26%) foetuses were found to be homozygotes or double heterozygotes for clinically significant mutations. These couples were informed of the danger of having a sick child but, as to the termination or continuation of the pregnancy, it was left to the couples to decide for themselves. Nevertheless, all the couples preferred termination of the pregnancies. Our conclusion is that, wide spread population screening for thalassaemia, in a country like Greece with a high frequency of the thalassaemia gene and that of other haemoglobinopathies, and the implementation of prenatal diagnosis in at risk couples, have both decreased the incidence of children born with Thalassaemia Major and Sickle Cell disease. This Thalassemia screening program has proved successful in our case as it has in many other countries that have implemented it.

0420

FETAL OUTCOMES IN PREGNANT PATIENTS WITH SICKLE CELL DISEASE

M Al Huneini, M Al Khabori, S Al Farsi, M Al Riyami
Sultan Qaboos University Hospital, Muscat, Oman

Introduction. Sickle cell disease (SCD) is an inherited hemoglobinopathy with multiple complications and multisystem involvement. Fetal outcomes in pregnant patients with SCD are not well studied. We therefore looked into the fetal outcomes in a single institute tertiary care setting and analyzed the impact of baseline variables on those outcomes. **Methods.** We retrospectively analyzed the fetal outcomes of 68 consecutive pregnant SCD patients followed at the obstetric clinic in our hospital from June 2006 to August 2011. We collected different baseline variables including age, gravida, parity, previous pregnancy outcomes including intrauterine growth restriction (IUGR), preterm labor, prematurity, intrauterine fetal death (IUFD), abortions, low birth weight , maternal morbidities (eclampsia, uterine rupture and or post-partum hemorrhage) baseline hematological parameters, history of splenectomy and cholecystectomy. We used multivariable logistic regression to estimate and adjust the impact of baseline variables on major fetal complications. **Results.** We analyzed 68

patients. The mean age was 30 years (standard deviation [SD] 3.8, range 22-40). The median gravidity and parity were 2 (range 1-6) and 1 (range 0-5) respectively. Mean gestation age was 37 weeks (SD 1.88, range 32-41)Sixty-two patients had SS genotype. The initial mean hemoglobin was 9.5 g/dl (SD 1.1, range 7.2-11.9). The mean baseline hemoglobin F was 10.2% (SD 6.6, range 0.7-29). None of the patients were on Hydroxyurea during pregnancy, but eight patients were on Hydroxyurea prior to pregnancy. Twelve patients had prior cesarean section. Only one patient had previous preterm labor, none had previous premature babies, five women had previous IUFD, no IUGR reported previously.Eleven cases (16%) of IUGR were noted (95% confidence interval [C.I]:0.07-0.25, 19 cases of fetal distress (28%; 95%CI: 0.16-0.38) Five cases (7%) had elective cesarean section and 24 (35%) needed emergency cesarean section.Low birth weight was seen in 22 cases (32%, 95% C.I: 0.21-.44) with a mean weight of 2.6 Kg (SD 0.47, range 1.2-3.92. There were two neonatal deaths.Sixteen newborn babies required admission to neonatology intensive unit (23.5%). On multivariate logistic regression for a composite of fetal outcomes that included IUGR, low birth weight, perinatal mortality and admission to neonatology units, none of those variables was of statistical significance. **Conclusions.** Our study shows that the adverse fetal outcomes in pregnant patients with sickle cell disease are high despite the fact that they were followed up a tertiary care centre with high risk obstetric care clinic along with specialized haematology follow up.We where not able to identify significant difference in the fetal outcome between SCD, SS genotype versus others likely owing to small number of other subtypes. Larger sample size may help to show if there is any significant difference.

0421

IMPORTANCE OF DIAGNOSIS OF NON-DELETIONAL ALPHA-THALASSEMIA

F de la Fuente-Gonzalo, J Martínez-Nieto, L Vinuesa, P Ropero, E Fontanes, C Seri, E Bolaños, F González, A Villegas, J Díaz-Mediavilla
Hospital Clínico San Carlos, Madrid, Spain

Background. The molecular basis of α-thalassemias are mainly deletions in α-globin genes, however, about 5-10% of cases are due to mutations in these genes. Most of these mutations are exclusive to each family, but some mutations as Nco and Hph are more common in some populations. Diagnosis of less frequent variants of this disease is essential in order to be applied to genetic counseling and prenatal diagnosis. **Aims.** In this paper we present the cases of non-deletional α-thalassemia diagnosed in our department from January 2009 to December 2011. **Methods.** Between January 2009 and December 2011 were studied 1127 patients collected by our center for study of α-thalassemia by presenting microcytosis with normal HbA_2 and HbF and without iron deficiency. The geographical origin of patients covered all the spanish territory.Molecular study required the extraction of genomic DNA. Deletions were ruled by α-globin StripAssay. The rest of patients were studied by automatic sequencing specific for both α_2 and α_1 genes.Results606 of the patients had α-thalassemia, of which 544 showed deletions (89.77%) and 62 patients (10.23%) mutations. Point mutations are set out in Table 1.

Table 1. Summary of point mutations in both 2 and 1 genes that are responsibles of a non-deletional alpha-thalassemia phenotipe in our study.

MUTATION NAME	AFFECTED GENE	GENE LOCATION	NUMBER OF CASES
Hph	α_2	IVS I -5nt	23
Hb Agrinio	α_2	CD29 CTG→CCG (Leu→Pro)	11
Hb Groene Hart	α_1	CD119 CCT→TCT (Pro→Ser)	11
CD23	α_2	CD23 GAG→TAG (Glu→AMB)	4
nt+778 C→A	α_1	nt+778 C→A	3
IVS-I-38 C→T	α_1	IVS-I 38 C→T	2
Hb Q-Thailand	α_1	CD74 GAC→CAC (Asp→His)	2
Hb Plasencia	α_2	CD125 CTG→CGG (Leu→Arg)	1
IVS-I-1 G→A	α_2	IVS I-1 (G→A)	1
T-Saudí	α_2	PolyA AATAAA→AATAAG	1
Constant Spring	α_2	CT TAA→CAA (Stop→Gln)	1
Hb Tunis-Bizerte	α_1	CD129 CTG→CCG (Leu→Pro)	1
Poly A	α_2	PolyA AATAAA→AATGAA	1

Conclusions. The identification of 13 different point mutations variants reveals the molecular heterogeneity of non-deletional α-thalassemia cases in our environment. This heterogeneity may have important implications in terms of its phenotypic expression, to be able to interact with other forms of deletional and non-deletional α-thalassemia more common and that are increasing in our country by migratory changes.However, five variants (Hph, Hb Agrinio, Hb Groene Hart, CD23 and nt +778 C>A) reflects the 84.07% of cases of non-deletional alpha-thalassemia. This fact has been seen in studies on other populations. For example, in Iranian population three variants (Hph, Hb Taibe and T-Saudí) account for 83.26% of non-deletional alpha-thalassemia collected cases.Integration of different molecular techniques, especially the automatic sequencing, is of great importance for the clinical diagnosis of thalassemia syndromes, mainly in the rare cases of non-deletional α-thalassemia. However, if variants mentioned above will be introduced in the available screening methods, it would allow an improved initial screening, which would result in a economic-saving and less time-consuming diagnosis.

0422

VITAMIN D STATUS IN PATIENTS WITH THALASSAEMIA MAJOR AND INTERMEDIA: ITS CORRELATION WITH IRON STATUS AND IMPACT ON OUTCOME

K Al-Farsi, M Al-Khabori, M Al-Huneini, V Kumar, M Zachariah, S Daar
Sultan Qaboos University Hospital, Muscat, Oman

Background. Vitamin D deficiency is common in patients with thalassemia. However, data on its impact on outcome and its correlation with iron load is limited. **Aims.** We aimed to investigate the prevalence of vitamin deficiency and insufficiency in patients with thalassemia major and intermedia and the study relationship between vitamin D status and iron overload. In addition, we planned to report the impact of vitamin D status on bone health in these patients. **Methods.** 25OH vitamin D (D25OH), albumin adjusted calcium, phosphate, alkaline phosphatase, parathyroid hormone (PTH) and ferritin levels were measured on all patients with thalassemia major and intermedia who are being followed at our institution. Data on age, gender and body mass index (BMI) were collected as well as data on cardiac T2* and liver iron concentration by MRI (LIC), bone density measurement (BDM) and fractures. We classified patients depending on their vitamin D levels into: sufficient (>50 nmol/L), insufficient (25-50nmol/L) and deficient (<25 nmol/L). We used multivariate ordinal regression to study the relation between vitamin D status and ferritin, cardiac and liver iron status, gender, BMI and BDM. **Results.** A total of 123 patients with thalassemia major (106) and thalassemia intermedia (17) were evaluated. There were 64 females and 59 males. Median age was 23±7.9 years (range:5-58) with mean BMI of 21.5±4.8 (13.7-37.2), median ferritin 1182 ng/mL (not normally distributed, range: 76-10500), cardiac T2* 30.3±13 (5.5-60) and LIC 7.1±6.7mg/g dry weight (1-32). Nine patients had insulin dependent and 9 had non-insulin dependent diabetes mellitus while 27 patients had hypoparathyroidism. Mean D25OH was 48.8±23nmol/L (12-131) with 47% having vitamin D insufficiency and 12% vitamin D deficiency. Hypocalcemia was seen in only 3 patients and hypophosphatemia in 2 patients. Of 63 patients over the age of 20 who had BDM, 25 (40%) had osteopenia (lumbar Z score and/or femoral Z score <-1.0 to >-2.5): 3 vitamin D deficient and 13 insufficient, while 32 patients (51%) had osteoporosis (lumbar Z score and/or femoral Z score <-2.5): 4 deficient and 7 insufficient . Four patients had fractures: 2 vertebral and 2 extremity; 1 in the osteopenic group, 1 in the osteoporotic group and 2 in patients less than the age of 20. Three of the 4 fractures occurred in patients with vitamin D deficiency and/or insufficiency. On the multivariate ordinal logistic regression, only ferritin had a significant correlation with vitamin D status (OR 1.2; 95% CI 1.1-1.3; p 0.001). There was no significant correlation between vitamin D status and cardiac or liver iron load. In patients over 20, there was no significant correlation between vitamin D status and BDM status. **Conclusions.** Vitamin D deficiency and/or insufficiency state is common in patients with thalassemia with a significant correlation with ferritin levels. Its contribution to osteoporosis and osteopenia requires further studies. The impact of vitamin D replacement in patients with thalassemia major and intermedia needs to be studied prospectively.

0423

SAFETY AND EFFICACY OF ERYTHROPOIETIN IN PATIENTS WITH SICKLE CELL ANEMIA AND CHRONIC RENAL INSUFFICIENCY

D Pulte, S Ballas
Thomas Jefferson University, Philadelphia, United States of America

Background. The use of recombinant erythropoietin (epo) in sickle cell anemia (SCA) is controversial. However, use of epo to improve hemoglobin in patients with renal failure is well established and renal failure is common in SCA. Because SCA results in increased filtration, renal function is often worse than it appears based on serum creatinine. Furthermore, some authors have found an increase in fetal hemoglobin in patients with SCA after administration of epo. Therefore, the use of epo in patients with SCA and chronic renal failure is attractive, although there are no randomized controlled trials definitively demonstrating benefit. **Aims.** To examine the safety and efficacy of epo usage in SCA and renal insufficiency. **Methods.** Charts of patients at the Thomas Jefferson University hematology clinic who were treated with epo for SCA with low reticulocyte count thought to be due to chronic renal insufficiency were reviewed. Data were extracted including hemoglobin and reticulocyte count at baseline and after treatment with epo, serum creatinine, pre-treatment erythropoietin level, and clinical status. Hemoglobin F level was recorded, when available. **Results.** Six patients received weekly or semiweekly recombinant erythropoietin or darbepoietin injections. Five of the six took hydroxyurea (HU). One did not due to intolerance. All patients had hypoplastic anemia with decreased baseline hemoglobin, with mean hemoglobin of 6.2 gm/dl, range of 5.5-7.9 gm/dL and low baseline reticulocyte count, mean 178,000 cells/µL, range 109-272,000 cells/µl. All patients had adequate iron stores as assessed by serum iron, iron binding capacity, and ferritin levels. All responded to epo administration with an increase in hemoglobin (mean hemoglobin on erythropoietin 9.1 g/dl, range 6.7-11.3) and reticulocyte count (mean on epo 204,000 cells/µl, range 140-273,000 cells/µl). Mean creatinine was in the normal range at a mean of 1.1 mg/dl (range 0.3-1.7 mg/dl). Baseline erythropoietin levels were elevated at a mean of 81.3 mIU/ml, but lower than expected for the degree of anemia seen. Fetal hemoglobin was measured both pre- and post-erythropoietin in two patients and no change was seen for either patient. Two patients who were transfusion dependent prior to starting epo no longer required regular transfusions after treatment. The patient not taking HU suffered a stroke while on therapy and therapy was changed to chronic exchange transfusions. No other patient suffered major toxicity from treatment with epo. **Conclusions.** Erythopoietin supplementation can be useful in patients with SCA and chronic renal insufficiency. Serum creatinine is an unreliable marker of renal function and may underestimate the possibility of hypoplastic anemia in patients with SCA. The decision to start epo should be made based on the overall clinical picture, including erythropoietin level, hemoglobin, and reticulocyte count. Epo should be used only with caution in patients with SCA and our experience suggests that epo should not be used in patients not receiving concurrent HU. Formal phase III studies to confirm the safety and efficacy of epo with HU in SCA with chronic renal insufficiency would be helpful for delineating the optimal timing and dosing of epo in SCA.

0424

INTRACRANIAL BLOOD FLOW VELOCITIES IN LEBANESE PATIENTS WITH SICKLE CELL DISEASE AND ?-THALASSEMIA INTERMEDIA

A Taher[1], M Abboud[1], J Maakaron[1], R Khoury[1], H Tamim[1], M Shehab[1], F Haddad[1], R Adams[2]
[1]American University of Beirut, Beirut, Lebanon
[2]Medical University of South Carolina, Charleston, United States of America

Background. Thalassemia intermedia (TI) and sickle cell disease (SCD) represent two common forms of hereditary anemias that share many clinical manifestations in developing cerebral infarctions [1, 2]. Transcranial Doppler ultrasonography (TCD) detects patients with SCD who are at an increased risk of developing infarction but its role in identifying high risk patients with TI has not been evaluated [3]. **Aims.** The aim of this study is to compare the mean maximal cerebral blood flow velocities (MBFV) in patients with SCD and TI. **Methods.** Between January 2011 and October 2011, a total of 60 patients with SCD and 20 patients with TI were examined. After obtaining informed consent, the right and left, middle and anterior cerebral arteries (RMCA, LMCA, RACA, LACA) were insonated using a temporal window approach. The MBFV of each artery was recorded separately. Demographic and recent laboratory information was collected for each patient. **Results.** Table 1 shows the baseline characteristics of the 2 groups of patients along with the averages and standard deviations of MBFV in the measured arteries. The 2 groups were matched for sex and hemoglobin concentration. However, TI patients were significantly older. Fifty-four out of the 60 sickle cell patients have SS (90%) while 6/60 (10%) have Sβ°, and 48/60 (80%) were on hydroxyurea. MBFV in the RACA was significantly higher in the sickle cell patients (p = 0.006). This difference was borderline significant in the case of the LMCA (p = 0.056), and not significant in the RMCA and LACA.**Conclusions**This is the first report to compare MBFV in TI and SCD patients. Sickle cell patients have been found to have higher MBFV than the normal population in several studies [3, 4]. Several mechanisms have been implicated including anemia, deficiency of nitric oxide synthesis, and endothelial dysfunction. The pathophysiology of SCD and TI includes disruption of these mechanisms. In this study, the mean MBFV values in 20 TI patients were lower than those of 60 SCD patients, despite similar hemoglobin levels, yet they were still higher than those reported for the normal population [5]. The difference was statistically significant for the RACA despite the fact that 48/60 (80%) of our SCD patients were on hydroxyurea treatment which is known to lower MBFV values. Larger scale studies with longer follow up are warranted to validate these findings and define any risk in the TI population.

Table 1. Baseline characteristics of 20 TI and 60 SCD patients with their measured maximal cerebral blood flow velocities.

	Thalassemia Intermedia	Sickle Cell Disease	p-value
N	20	60	
Age	28.0 ± 11.1 [10 – 47]	13.8 ± 8.2 [2 – 42]	p<0.01
Sex (F/M)	13/7	32/28	p=0.264
Hemoglobin	8.9 ± 2.0	9.2 ± 1.2	P=0.294
Hydroxyurea treatment	-	48/60 (80%)	
RMCA	93 ± 28 [39 – 155]	106 ± 28 [55 – 173]	p=0.94
LMCA	91 ± 28 [35 – 148]	104 ± 25 [50 – 169]	p=0.056
RACA	64 ± 18 [34 – 99]	80 ± 22 [41 – 143]	p=0.006
LACA	71 ± 18 [41 – 115]	76 ± 20 [36 – 117]	p=0.395

PHARMACOKINETIC ASSESSMENT OF POSACONAZOLE SUPPORTS AN EFFECTIVE ANTI-FUNGAL PROPHYLAXIS IN ACUTE MYELOID LEUKEMIA PATIENTS

M Gotti, MC Da Vià, P Zappasodi, M Bonfichi, M Cusato, M Regazzi, M Cazzola, C Castagnola
Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. Posaconazole (PSC) is an effective broad-spectrum anti-fungal triazole recommended for prophylaxis of Invasive fungal diseases (IFDs) in induction of acute leukemia patients and in GVHD phases of allogeneic transplant; the pharmacokinetic of PSC is linear and absorption strongly depends on gastric pH and nutrition. The registered schedule for IFDs' prophylaxis consists of 200 mg tid and preliminary studies suggest that ideal plasma concentrations for the best efficacy should be ≥0.7 µg/mL. **Aims.** To evaluate the effect of anti-fungal prophylaxis with PSC 200 mg bid in acute myeloid leukemia (AML) patients, supported by pharmacokinetic analysis. **Methods.** Sixty-four patients (32M/32F, aged 18-75 years) treated for AML at the Haematological Unit of the Foundation S. Matteo Pavia from January 2010 to December 2011 were enrolled. All patients received a dosage of 200 mg bid during neutropenic phases of induction, consolidation and reinduction therapy and serum levels were monitored on a weekly basis (at least 4 samples for each pts). PSC was administered with fatty food, while proton pump inhibitors or H2 antagonist were avoided during the entire prophylactic treatment. Plasma samples, taken at the steady-state, just before administration of PSC and during treatment levels, were measured on HPLC-UV. In term of efficacy, we compared the incidence of IFDs occurred in studied patients with that of 93 AML patients treated in the previous biennium who didn't receive any anti-fungal prophylaxis. **Results.** We analyzed 283 plasma samples. A high variability in PSC through levels was observed. During treatment, 55/283 (19%) of measurements resulted below 0.7 µg/mL, 189/283 (67%) ≥1 µg/mL and 39/283 (14%) were ranged between 0.7 and 1 µg/mL. Patients achieving a PSC measurement ≥0.7 µg/mL were 56 (88%).Median Ctrough was 1.43 µg/ml (0.14-5.92). PSC plasma levels increased after 48 hours from the first administration (1.7±1.64 vs 0.52±0.09 p<0.001) and by food intake (1.74±1.64 *vs* 0.58 ± 0.37 p<0.001). No relationship was observed between alanine aminotransferase, aspartate aminotransferase, bilirubin or creatinine levels and PSC levels. No relevant side effects were observed. In term of efficacy we observed a significant reduction of IFDs incidence in posaconazole group with respect the cases without prophylaxis (9,2% vs 22,6% p=0.03). **Conclusions.** Posaconazole 200 mg bid resulted in median plasma drug concentrations achieving therapeutic range in almost 90% of patients with a good tolerability. Plasma levels varied in time from the initial dose and were influenced by food intake. For these reasons we support the therapeutic drug monitoring during treatment. Finally, this prophylactic schedule allowed a significant reduction of invasive fungal infection.

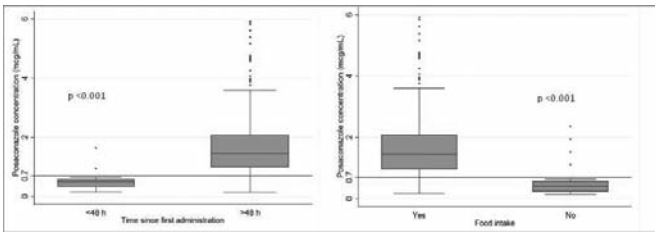

Figure 1. PSC serum level according to time since first administration and food intake.

0426

THE ROLE OF PET-CT FOR THE DIAGNOSIS OF INFECTIONS IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND PERSISTENT FEBRILE NEUTROPENIA

A Gafter-Gvili, M Paul, H Bernstine, L Vidal, R Ram, P Raanani, M Yeshurun, B Tadmor, O Shpilberg, D Groshar
Rabin Medical Center, Petah-Tikva, Israel

Background. Patients with hematological malignancies and prolonged febrile neutropenia are at high risk for bacterial and invasive fungal infections (IFIs). **Aims.** We aimed to evaluate the role of PET-CT for detection of such infections among these patients. **Methods.** Prospective cohort study of patients with hematological malignancies given intensive conventional chemotherapy and hematopoietic-cell transplantation (HCT). All consecutive, consenting patients with neutropenia (<500/mm^3) and persistent or breakthrough fever despite broad spectrum antibiotics (>5days) had a PET-CT examination. The CT component of the PET-CT was a contrast-enhanced diagnostic CT. Blinded evaluation of chest and sinus CT and the full PET-CT scan were compared with the final clinical diagnosis 30 days after neutropenia resolution, as determined by an expert panel consisting of a hematologist and an infectious diseases expert. **Results.** Between January 2008 and January 2011, 91 PET-CT examinations were performed in 79 patients. Median age was 56 (range: 21-85) years. PET-CT was performed after a median of 10 days from last chemotherapy (range: 0-255). Patients were neutropenic for a median of 11 (range:1-100) days.Most patients had acute leukemia (71 episodes), 7 patients underwent allogeneic HCT and 6 patients with lymphoma underwent autologous HCT.The types and number of individual diagnoses are listed in the table: Of the 91 PET-CT examinations, 23 episodes had two or more diagnoses, most commonly a combination of bacterial and fungal infection. Of 28 microbiologically documented infections (MDIs), bacteremia was the diagnosis in 20 episodes, most commonly without a focal source. Fifteen episodes were classified as fever of unknown origin.The sensitivity to detect any infection or non-infectious pathology in chest/sinus CT, was 58.8% (60 /102 diagnoses). The respective sensitivity for-PET- CTwas 85.3% (87/102). The difference in sensitivity was 26.5% (95% confidence interval 21.4% to 31.6%), matched sample p<0.001. The specificities of CT and PET-CT were not significantly different, 66.7% (10/15 episodes of FUO) and 60% (9/15), respectively. Of note, all 7 proven or probable fungal infections were FDG- positive.In 28 cases, PET-CT demonstrated findings which were not detected on chest/sinus CT (27.5% of diagnoses). These were mainly abdominal infections (as appendicitis, diverticulitis, etc.) and abscesses (perianal, splenic, etc.).When we compared PET-CT to total body (chest, sinus and abdomen) CT, we found that 7 of these cases were found only on PET-CT. The sensitivity of total body CT to detect disease was 78.4% (80/102).PET-CT resulted in modifications of patients' management in 46 (55%) cases. These included change in antibiotics (14 cases), change in antifungals (14), change in both (5), an invasive diagnostic procedure (7), a surgical procedure (i.e appendectomy, 3) and abscess drainage (4). **Conclusions.** PET-CT has a higher sensitivity with no loss of specificity compared to chest/sinus CT in patients with persistent febrile neutropenia. The increase in sensitivity afforded by PET-CT was mainly due to the addition of abdominal CT.

Diagnostic Category	Number of diagnoses (total 117)	Positive findings on PET/CT (positive findings with FDG uptake)	Positive findings on chest/sinus CT
Fever of unknown origin =no disease	15	6 (3)	5
Disease (Infectious causes):			
• Clinically documented infection (CDI)	34	31 (25)	14
• microbiologically documented infection (MDI)	28	16 (13)	9
• Possible invasive fungal infection (IFI)	20	20 (16)	19
• Probable/proven IFI	7	7 (7)	7
Disease due to primary malignancy or non-infectious causes	13	13 (10)	12

AT HOME TREATMENT AFTER HIGH DOSE CHEMOTHERAPY IS SAFE AND FEASIBLE, AND LEADS TO SIGNIFICANT COST SAVINGS

MJ Kersten, A Mank, C Schoonenberg, C Bleeker, S Heijmenberg, K De Heer, R De Haan, M Van Oers
Academic Medical Center, Amsterdam, Netherlands

Background and aim of the study. The necessity of keeping patients in hospital during neutropenia after high dose chemotherapy is under discussion. A prospective, nonrandomized, single center clinical study was performed to examine the safety and feasibility of ambulatory care in patients undergoing consolidation chemotherapy for acute leukemia, or autologous stem cell transplantation following high dose chemotherapy for lymphoma or multiple myeloma. In addition, patient satisfaction, costs and use of hospital resources were evaluated. **Patients and methods**. Patients fulfilling the eligibility criteria were discharged into ambulatory care the day after the last chemotherapy administration, or the day after reinfusion of the stem cells. Eligibility criteria included, but were not restricted to: adequate performance status, adequate fluid intake, understanding of risks and procedures, availability of a caregiver and travel time to the hospital <1 hour. Patients visited the ambulatory care unit 3 times a week for monitoring of signs, symptoms and laboratory results. Patients were asked to fill out a questionnaire with 21 questions on logistics, information, commu-

nication and patient perception.*Results*During the study period, 165 patients were admitted for 208 chemotherapy cycles. 76 patients in 89 cycles could not be included in the ambulatory care program, most frequently either because their medical situation did not allow for early discharge (58%), or because they had no care giver (15%), or had to travel a large distance to the hospital (15%).The 89 patients in the ambulatory care group (37 AML, 20 NHL, 17 ALL, 12 MM, 3 Hodgkin lymphoma), who underwent 119 cycles of high dose chemotherapy, spent almost 70% of the neutropenic phase at home. 37 out of 89 patients (46 cycles) were never readmitted to the hospital. None of the patients in the ambulatory care group had to be admitted to the intensive care, and there was no treatment related mortality. The most frequent reason for readmission was fever, and the median duration of readmission was 6 days (range,1-21 days). In the hospital group, 2 patients died, one because of pneumonia and one because of invasive aspergillosis. Ambulatory care led to significant cost savings, also when corrected for visits to the day care unit, and increased the capacity for admissions to the hematology department. Patients and their caregivers felt safe and comfortable at home, and the vast majority preferred home care over in-hospital treatment and would recommend it also to other patients. **Conclusions**. This study demonstrates the safety and feasibility of managing carefully selected patients in an ambulatory care setting after high dose chemotherapy. In addition, ambulatory care leads to significant cost savings, more efficient use of hospital beds, and a high degree of patient satisfaction.

0428

CLINICAL AND MICROBIOLOGICAL ASPECTS OF DISCONTINUATION OF QUINOLONE PROPHYLAXIS IN HAEMATOLOGICAL PATIENTS WITH CHEMOTHERAPY-INDUCED NEUTROPENIA: A SINGLE-CENTRE EXPERIENCE

A Verlinden, I Vrelust, H Jansens, A van de Velde, Z Berneman, W Schroyens, A Gadisseur
University Hospital Antwerp, Edegem, Belgium

Background. Routine use of quinolone prophylaxis in neutropenic haematological patients is widespread. Although it has been reported to result in significant survival advantages, emergence of bacterial resistance has become a concern. **Objectives** The aim of this study was to evaluate the clinical and microbiological impact of discontinuing ciprofloxacin prophylaxis (CP) in haematological patients with prolonged neutropenia. **Methods**. Between August 2009 and July 2011 a total of 269 consecutive admissions for polychemotherapy treatment followed by prolonged neutropenia were evaluated in this retrospective study. 43 were excluded due to documented infection or antibiotic treatment in the week prior to the start of treatment. Three sequential periods of 8 months were analysed: on-going routine use of CP, discontinuation of CP and reintroduction of CP. Patient characteristics were comparable between groups. Clinical endpoints were occurrence of neutropenic fever, bacteraemia, severe sepsis, septic shock and infection related mortality. Microbiological analysis included inventarisation of bacterial isolates from stool and blood cultures and their resistance pattern. Total per protocol antibiotic use for treatment of neutropenic fever and duration of hospitalisation were also analysed. **Results.** The incidence of neutropenic fever was significantly lower in patients receiving CP (55.1% versus 69.1%; p=0.049). However, the incidence of bacteraemia, severe sepsis, septic shock and infection related mortality did not differ significantly between groups. Routine microbiological screening of stools showed a higher prevalence of pathogens in the group not receiving CP (87.2% versus 47.0%; p<0.001). However, these were more frequently multisensitive (56.1% versus 10.9%, p<0.001). After CP discontinuation quinolone resistance disappeared very rapidly (7.3% versus 72.7%; p<0.001) with also a clear decrease in the presence of ESBL producing isolates (9.8% versus 34.5%; p=0.005). As stated before the overall incidence of bacteraemia did not change with discontinuation of CP, but there was a significantly higher proportion of gram-negative blood culture isolates (55.5% versus 21.1%; p=0.009). But again these isolates more often showed a multisensitive pattern (54.5% versus 0%; p=0.012) and less quinolone resistance (9.1% versus 100%; p<0.001). Antibiotic consumption and duration of hospitalisation did not differ significantly between groups. **Conclusions.** Because of increasing quinolone resistance, routine ciprofloxacin prophylaxis in patients with chemotherapy-induced neutropenia was discontinued. This did not lead to an increase in serious infectious complications nor to an increase in antibiotic consumption, although there was an increased incidence of neutropenic fever. Quinolone resistance disappeared very rapidly after discontinuation of ciprofloxacin prophylaxis and also reappeared very quickly after reintroduction. Analysis of this data has led us to suspend routine ciprofloxacin prophylaxis indefinitely.

0429

RECURRENCE OF BLOODSTREAM INFECTIONS AMONG ACUTE LEUKAEMIA PATIENTS DURING CONSECUTIVE TREATMENT: IMPACT ON EPIDEMIOLOGY AND OUTCOME

C Cattaneo, E Borlenghi, F Antoniazzi, F Schieppati, C Pagani, C Carbone, AM Pelizzari, A Re, G Rossi
Spedali Civili, Brescia, Italy

Introduction. Antibiotic prophylaxis with fluoroquinolones (Fq) in Acute Leukaemia (AL) patients (pts) receiving chemotherapy is a well established practice. Nevertheless, some pts experience more than one episode of bloodstream infection (BSI) caused by the same pathogen during the entire program of chemotherapy. **Aims.** In order to better define the actual risk of developing BSI recurrence (BSI-R) during subsequent phases of treatment, we analyzed all BSI occurring to consecutively treated AL pts at our Institute during a period of 7 years. **Patients and Methods.** Since June 2004 a program of active epidemiological surveillance is ongoing at our Institute. Data concerning infections occurring during chemotherapy-induced cytopenia in AL pts were analysed. All pts showing fever or signs/symptoms of infection underwent at least two sets of blood culture. **Results.** From June 2004 to May 2011, 258 cases of AL (197 acute myeloid leukaemia, 58 acute lymphoblastic leukaemia, and 3 blastic plasmacytoid dendritic cell leukaemia), were diagnosed and treated with at least one induction cycle followed by consolidation and with reinduction cycles in relapsing/refractory pts. Overall, 1263 chemotherapy cycles were delivered; 234 pts received more than 1 cycle. Two hundred and fifty BSI were observed (20.2%) in 139 pts receiving more than 1 cycle of chemotherapy (median 5, range 2-13); in 39/139 (28.1%) pts BSI recurred (median relapses: 1, range 1-4). Gram-negative (G-) bacteria accounted for 59.6% of BSI in 99 pts, Gram-positive (G+) for 34.4% in 68 pts and polymicrobic for 6% in 14 pts. Among G- BSI, *E. coli* and *P. aeruginosa* were the more frequent pathogens (115, 46% and 32, 12.8%, respectively), among G+, Coagulase Negative Staphylocci (CoNS), viridans streptococci and enterococci (38, 15.2%; 29, 11.6% and 21, 8.4%, respectively). *E. coli*, *P. aeruginosa*, CoNS and *S. viridans* were the four type of pathogens involved in recurrence. G- were significantly more frequent among BSI-R in comparison with other BSI (72.3% vs 50.6%, p =0.0009); in particular, *E. coli* accounted for 70.2% of BSI-R vs 33.3% for non relapsing BSI (p=<0.0001). All but 3 pts with BSI-R were neutropenic and previously treated with Fq prophylaxis; all relapsing pathogens showed Fq resistance (FqR). BSI-R did not correlate neither with type of AL nor with phase of disease, whereas it correlated with more than 4 delivered courses (84.6% vs 59%, p<0.0049). Fourteen out of 139 pts died within 30 days from BSI (10.1%); mortality was higher, although not significantly so, among pts with BSI-R (6/39, 15.4%) in comparison with pts without (8/100, 8%), particularly for pts with *P. aeruginosa* BSI-R (3/6, 50% vs 3/18, 16.6%). **Conclusions.** Among AL pts, BSI-R is frequent and often associated to FqR G- bacteria, particularly *E. coli*; this phenomenon is responsible for a shift towards G- epidemiology. Neutropenic pts treated with more than 4 courses were at risk for relapsing BSI. Mortality due to BSI recurrence seems to be higher in comparison with pts who do not experience it. Further observational studies are warranted in order to assess if prophylactic strategies other than Fq could be worthwhile.

0430

REVERSIBLE SKELETAL DISEASE AND HIGH FLUORIDE SERUM LEVELS IN HEMATOLOGIC PATIENTS RECEIVING VORICONAZOLE

B Gerber[1], R Guggenberger[1], D Fasler[1], G Nair[1], M Manz[1], G Stussi[2], U Schanz[1]
[1]University Hospital Zurich, Zürich, Switzerland
[2]Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background. Recently case reports of periostitis and skeletal disease in solid organ recipients with long-term voriconazole treatment have been published. **Aims.** We here investigate the occurrence of fluoride-intake associated alterations in patients with hematologic disease on triazol antifungal medication. **Methods.** We describe clinical, laboratory and radiology data of overall 43 patients with hematologic malignancies taking voriconazole (n=20), posaconazole (n=8), and itraconazole (n=4), and a hematologic patient control group (n=11). **Results.** Bone pain and radiologic evidence of periostitis was exclusively observed in patients receiving long-term voriconazole. Secession of treatment led to clinical improvement in all cases. In line with clinical evidence, fluoride serum concentration was elevated in patients receiving voriconazole (median 156.5 µg/l, interquartile range 96.8 µg/L; normal <30 µg/L) but not in the other treatment groups (p <0.001 for all comparisons against voriconazole).Summary/ **Conclusions.** Serum fluoride levels were elevated on average five-fold above normal levels in hematological patients receiving voriconazole. Clinical relevant skeletal disease was associated with

renal insufficiency and above ten-fold elevated fluoride levels, and was reversible upon termination of voriconazole treatment.

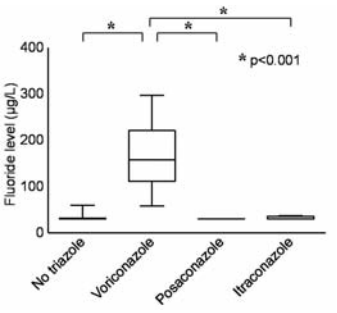

Figure 1.

0431

ASSOCIATION OF TNF-?, IL-6 AND IL-10 GENETIC POLYMORPHISMS AND IL-10 HAPLOTYPES WITH INFECTION SUSCEPTIBILITY AND OUTCOMES IN PATIENTS WITH MULTIPLE MYELOMA SUBMITTED TO ASCT

F Trigo[1], M Luizon[2], Y Muniz[2], H Dutra[3], H Scaffo[2], A Simões[2], A Maiolino[3], M Nucci[3], B Simões[2]
[1]University of São Paulo, Sertãozinho, Brazil
[2]FMRP-USP, Ribeirao Preto, Brazil
[3]UFRJ, Rio de Janeiro, Brazil

Background. The number of onco-hematological patients undergoing stem cell transplantation (SCT) has increased significantly in recent years; however bacterial, viral and fungal infections are major obstacles to its success. SCT increases patient's vulnerability to infections due to immunological changes related to the conditioning regimen. Multiple myeloma is a plasma cell neoplasm characterized by production of a monoclonal protein, bone destruction and susceptibility to infections. The introduction of Autologous Stem Cell Transplantation (ASCT) increased the overall survival of these patients, but infection still remains an important complication of the procedure. The increased levels of cytokines expression have an important relationship with the response immune. Studies have show that these Single Nucleotide Polymorphisms (SNPs) in the promoter region of cytokine genes are responsible for altering the levels of expression, affecting the stage of the disease and the immune response. **Aims.** Evaluate the association of the SNPs in the TNF-α, IL-6 and 10 genes and their haplotypes, with the infection susceptibility. **Methods.** Genomic DNA was extracted from mobilized peripheral-blood stem cells of 148 patients from the Bone Marrow Transplantation unit of Federal University of Rio de Janeiro. Genotyping was carried out for the SNPs IL-6 (-174G/C), IL-10 (-1082A/G, -592A/C e -819T/C) and TNF-α (-308G/A) using the Real-time PCR assay and PCR followed by restriction length fragment polymorphism (PCR-RFLP). Haplotype frequencies were estimated with Haplo.stats® and all the other statistical analysis were performed with SPSS®.**Results.** To evaluate the results we find all the alleles in Hardy-Weinberg equilibrium. The TNF-α polymorphism was significantly associated with fever of unknown origin (*p=0.03*), IL-6 polymorphism was associated with fungemia (p=0.04) and death during neutropenia (p=0.02), and IL-10 polymorphism was associated with superinfection (*p=0.02*). From the studied IL-10 haplotypes, the ACC haplotype was associated with Gram-negative bacteremia (*p=0.04*) and superinfection (*p=0.048*). **Summary and Conclusions.** The results showed that despite the primary predisposition to infection typical of multiple myeloma, the presence of the variants studied significantly affected susceptibility to serious infections and outcomes.

0432

PROTECTIVE EFFECT OF ANTI-FUNGAL AND ANTI-BACTERIAL PROPHYLAXIS IN AML THERAPY: A SINGLE CENTER EXPERIENCE

B Gerber[1], J Koeppel[2], M Paul[3], F Hoffmann[2], G Nair[1], U Schanz[1], M Manz[1]
[1]University Hospital Zurich, Zürich, Switzerland
[2]Division of Haematology, University Hospital Zurich, Zürich, Switzerland
[3]Institute for Social and Preventive Medicine Division of Biostatistics, Universi, Zürich, Switzerland

Background. Supportive therapy for patients with acute myeloid leukemia undergoing intensive chemotherapy has improved during the last decades. However, infections remain a major concern and the optimal strategy to reduce infection related morbidity and mortality is still a matter of debate and efficacy might be largely dependent on local settings. At our institution we did not apply prophylaxis until March 2010, when we introduced an anti-infective chemoprophylaxis scheme with posaconazole, levofloxacin and trimethroprim/sulfamethoxazole in combination with antiemetic prophylaxis with dexamethasone for all patients. **Aims.** To assess the impact of the newly introduced primary prophylaxis scheme on the incidence of fungal infections and bacterial infections, respectively. **Methods.** Retrospective single-center study performed at the leukemia ward (normal ventilation) and hematopoietic stem cell transplantation unit (air filtration and positive-pressure) of the University Hospital Zurich between 2009 and 2011. All Patients >=18 years with AML or high-risk MDS (IPSS>1.5) receiving intensive chemotherapy were included. Statistical analysis compared the patient cohorts before and after introduction of the prophylaxis scheme in March 2010. Invasive fungal infections (IFI) were classified according to the EORTC/MSG guidelines. **Results.** The study comprised 88 patients receiving a total of 203 therapy cycles. Baseline characteristics were similar in the non-prophylaxis and the prophylaxis cohort. The median age of the study population was 51.3 years (IQR 20.7), 45 (51%) of all patients were male. Five and 7 patients in the non-prophylaxis and prophylaxis cohort were diagnosed with IFD before the start of chemotherapy and were excluded from the analysis. Aplasia time was significantly longer in the non-prophylaxis cohort beeing 20 (IQR 10) and 17.5 (IQR 8.8) days, respectively (p=0.011). In the non-prophylaxis cohort more chemotherapy cycles were performed at the stem cell transplantation unit (29.3% and 9.6%, respectively; p=0.012). Adherence to the new prophylaxis scheme was 81.7% for posaconazole and 69.5% for levofloxacin, respectively. Overall survival at 100 days was 88.4% in the non-prophylaxis and 84.4% in the prophylaxis period, respectively. Invasive fungal infections were significantly more common in the non-prophylaxis period than in the prophylaxis period (88.9% and 55.3%; p=0.0032). In both groups IFI were classified as possible' (EORTC/MSG) in the vast majority of all cases (93.5% and 81%). In multivariate analysis chemoprophylaxis a well as treatment in the hematopoietic stem cell transplantation unit both led to a significant reduction in IFI (p<0.0001 and p=0.0021, respectively). No difference in bacteremia incidence was observed (32.6% and 34.6% in all chemotherapy cycles in the non-prophylaxis and the prophylaxis group, respectively). However, bacteremia in the prophylaxis group was more likely to be caused by gram-positive bacteria than in the non-prophylaxis-group (91.5% vs. 71.8%).Summary/ **Conclusions.** Our data confirm, that our combined antifungal and antibacterial primary prophylaxis with posaconazole and levofloxacin as well as treatment in a positive-pressure ward resulted in a significant reduction of possible IFI, however it did not reduce the incidence of bacteremia.

A COMPARATIVE STUDY OF PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA RECEIVING ALL-TRANS RETINOIC ACID WITH AND WITHOUT VORICONAZOLE: EFFECT ON DIFFERENTIATION SYNDROME

N Barreto, J Kuth, C Peskey, M Patnaik
Mayo Clinic, Rochester, United States of America

Background. The differentiation syndrome (DS) is a potentially fatal complication related to all *trans*-retinoic acid (ATRA) use in induction chemotherapy for patients with acute promyelocytic leukemia (APL). The reported incidence and mortality rates range between 2-31% and 1-33% respectively. The metabolism of ATRA is mediated through human cytochrome P450 (CYP) enzyme pathways, most notably CYP2C9 and CYP3A4. Triazole derivatives, such as voriconazole, are potent antifungal agents that act by inhibiting the CYP enzyme mediated conversion of lanosterol to ergosterol. Voriconazole is known to be a strong inhibitor of CYP2C9 and CYP2C19 in contrast to fluconazole which has less potent CYP interactions. **Aims.** With the increasing use of voriconazole for fungal prophylaxis, we wished to evaluate and contrast the inci-

dence and outcomes of ATRA-induced DS in patients with APL. **Methods.** Forty-six consecutive patients with APL undergoing induction-phase chemotherapy utilizing ATRA were seen at Mayo Clinic from 2000 through 2011. All patients provided consent for research participation. All patients underwent bone marrow examination with cytogenetic and molecular evaluation including FISH and RT-PCR for *PML-RARA*. DS was defined in accordance with other studies. Comparisons between the groups for categorical outcomes were made using Pearson's chi-square or Fisher's exact test. Two-sample t-tests or Wilcoxon rank-sum tests were used for continuous outcomes. A Cox proportional hazards model measured the association of voriconazole use and body mass index (BMI) with DS occurrence, where voriconazole use was considered a time-dependent covariate. **Results.** Of the 46 study patients, 27 (58%) were male with a median age of 56 years (range, 18-80 years). Thirty-one patients (67%) received a chemotherapy regimen including ATRA coinciding with voriconazole administration and 15 patients underwent chemotherapy treatment including ATRA without fungal prophylaxis. There was no difference in age, gender, Sanz risk assessment, combination chemotherapy regimen, white blood cell count, platelet count, creatinine clearance and LDH levels amongst patients in the two groups. The only heterogeneity was with the BMI, which was higher in patients receiving voriconazole (HR 1.04, CI 1.001-1.078, p=0.0427). The overall incidence of DS was 35% (n=16), with patients receiving voriconazole being more likely to experience the same (HR 2.31, CI 0.78-6.874, p=0.1308). After adjusting for BMI, patients receiving voriconazole had a higher tendency to experience DS (especially severe DS; 13 of 16 cases [81%]), however due to small numbers this trend was not statistically significant (HR 1.96, CI 0.65-5.94, p=0.23). Seven patients (44%), 5 of whom had received voriconazole, needed ICU admission for management of severe DS. Mean length of ICU stay was 4 days (range, 1-7 days) with no patients requiring intubation but 29% receiving vasopressor support. There were zero deaths attributable to DS and the Kaplan-Meier curve provided estimates days from initiation of voriconazole to diagnosis of DS. **Conclusions.** A trend towards increased incidence and severity of the ATRA mediated DS was seen in APL patients receiving voriconazole as fungal prophylaxis during induction therapy, contributing to the morbidity. Statistical significance was not reached due to small sample size; however this finding warrants larger studies addressing this important issue.

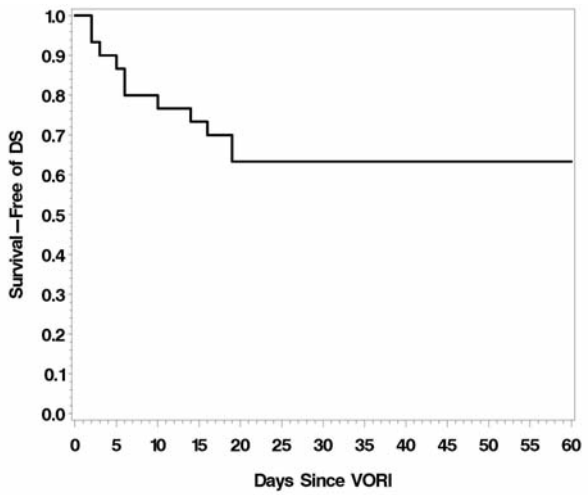

Figure 1.

EARLY DIAGNOSIS OF INVASIVE FUNGAL DISEASE IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES. PROSPECTIVE EVALUATION OF BIOLOGICAL MARKERS

E Yebra[1], M Cuétara[1], C Bombín[1], M Requena[1], E Anduaga[1], R Riaza[1], R Rodriguez[1], A Saez-Rosón[2], M Moragues[2], P Sánchez-Godoy[1]
[1]Hospital Universitario Severo Ochoa, Leganés, Spain
[2]Universidad del País Vasco/Euskal Herriko Unibertsitatea (UPV/EHU), Bilbao, Sri Lanka

Background. Invasive fungal disease (IFD) is an important cause of morbidity and mortality in patients with hematologic malignancies. Last years, the detection of biomarkers has become indispensable for the early diagnosis of fungal infections in these patients.OBJECTIVE. We evaluated the accuracy of serum galactomannan antigen (GM), (1-3) β-D-glucan antigen (BG) and antibodies against *Candida albicans* germ tubes (CAGT) for early diagnosis of IFD in patients with hematologic malignancies. **Methods.** A total of 500 serum samples from forty five hematology patients at high or intermediate-high risk for IFD as defined by Prentice et al. were collected twice weekly, from January 2008 through December 2010 ina single center. Quantitative detection of GM (Platelia *Aspergillus*®; Bio-Rad), BG (Glucatell® test) and antibodies to CAGT (*C. albicans* IFA IgG Vircell®test) were performed in every sample as surveillance test. In the presence of signs or symptoms suggestive of IFD or in case of positive test, patients were assessed and diagnosed according to the European Organization for Research and Treatment of Cancer/Invasive Fungal Infections Cooperative Group and the National Institute of Allergy and Infectious Diseases Mycosis Study Group (EORTC/MSG) Consensus Group.RESULTS. Seventy two episodes were assessed in the entire group. Median age of patients was 62 years (range 31-80). The most frequent underlying disease was acute myeloid leukemia (n=31). Four proven IFD and eight probable IFD were diagnosed in ten patients (22,2%). *Aspergillus* spp. was isolated in two patients, *Candida* spp in two patients and *Saccharomyces cerevisiae* in one patient. Pneumonia was the most common infection, ten of twelve IFD diagnosed.Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of GM monitoring at a cutoff of 0.5 were 100% (CI 95%: 93.7-100%), 57.5% (CI 95%: 40-74%), 32% (CI 95%: 11.7-52.2%), 100% (CI 95%: 97.5-100%) respectively, with an area under the curve (AUC) of 0.841. The sensitivity, specificity, PPV and NPV of BG monitoring at a cutoff of 120 pg/ml were 44.4% (CI 95%: 6.42-82.46), 57.5% (CI 95%: 39.2-75.9%), 22.2% (CI 95%: 0.24-44.2%), 80% (CI 95%: 60.8-97.5%) respectively, with an AUC of 0.6128. The diagnostic value of detection of antibodies to CAGT was not analyzed due to the low incidence of invasive candidiasis (two cases). False-positive results from GM and BG test occurred in 26.6% and 25% cases respectively.Of note, the combined results of GM and BG resulted in an improvement in the diagnostic accuracy of the tests to predict IFD, with sensitivity 57.5%, specificity 88.2%, PPV 43% and NPV 85.7%. **Conclusions.** The prospective screening of GM, BG and antibodies to CAGT is a useful and non-invasive tool for early diagnosis of IFD in high or intermediate-high risk adult hematologic patients. The combined use of GM and BG detection results in a more accurate strategy compared to the single determination of any of them, by increasing the specificity and the PPV whereas keeping a high NPV.

A MULTICENTER, PROSPECTIVE STUDY FOR INVASIVE FUNGAL DISEASE IN CHINESE PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

XJ Huang
Institute of Hematology, Peking University, Beijing, China

Background. The morbidity and mortality of invasive fungal diseases (IFDs) in patients with hematological malignancies undergoing chemotherapy remain high despite of new early diagnostic methods and antifungal prophylaxis. **Aims.** To better understand the epidemiology, diagnosis and treatments practice of IFDs in patients with hematological malignancies in China. **Methods.** This is the first multicenter, prospective observational study conducted in hematological centers in China. Patients admitted on the 1st to 10th day of each month from January to August 2011 and received intravenous chemotherapy for treatment of leukemia, hodgkins lymphoma, non-hodgkins lymphoma (NHL), myelodysplastic syndrome, and multiple myeloma were enrolled from 35 hospitals. Patients were followed through discharge and to the next course of chemotherapy. Underlying disease, previous IFD, medical history, antifungal prophylaxis and treatment during hospitalization were collected for all enrolled patients regardless of antifungal therapy. Patients diagnosed as proven or probable IFDs were followed up for an additional 6 weeks. **Results.** A total of 4816 patients were enrolled. Patient's age ranged from 1 to 90 yrs with median of 43 yrs, males accounted for 59%. Acute myeloid leukemia (AML) (27.8%), NHL (27.6%) and Acute lymphocytic leukemia (ALL) (19.7%) were the major underlying hematological diseases. Twenty percent of patients received first induction chemotherapy. One-third of the patients had ANC<500/mm^3, and 5.5% of the patients had previous invasive fungal infection.During hospitalization 18.8% of the p atients received antifungal prophylaxis, and the most commonly used agents for prophylaxis were azoles (94%). Among patients received antifungal prophylaxis, one-fifth received therapeutic antifungal treatment later. A total of 609 (12.6%) patients received therapeutic antifungal treatment, among them empirical therapy (88%) is the most common strategy when initiating antifungal therapy, pre-emptive and definitive therapy accounted for 8% and 4%, respectively. The most common agents for initiating treatment were azoles (80.8%), polyenes and echinocandins accounted for 10.2% and 11.8% respectively. After initial antifungal treatment 33.8% patients has adjusted treatment protocol, mainly because of lack of effectiveness (50.5%). The median duration of antifungal treatment was 14 days.A total of 8.6% of the patients were diagnosed as IFD, 172 (3.6%) patients were diagnosed as proven or probable IFD. The top three underlying diseases with high morbidity of IFD (proven or

probable) were AML (7.1%), MDS (4.1%) and ALL (3.7%). Univariate analysis showed that the previous IFDs, lower ANC, higher ECOG score, renal dysfunction and low albumin were associated with the development of IFDs.The overall mortality is 1.4%, while the mortality in patients with proven or probable IFD was 11.1%. **Conclusion.** The incidence of IFDs is relatively high in patients with hematological malignancies undergoing chemotherapy in China, which was similar to findings from Europe and U.S. The mortality rate in IFD is significantly higher than overall patients. The proportion of empirical antifungal therapy is higher in China which could be due to difficulties of early diagnosis of IFDs.

THE DETECTION OF 1,3-?-D-GLUCAN DETECTION IN BRONCHOALVEOLAR LAVAGE FLUID FOR THE DIAGNOSIS OF INVASIVE PULMONARY ASPERGILLOSIS IN HEMATOLOGICAL PATIENTS

M Toskova, S Timilsina, I Kocmanova, J Mayer, Z Racil
University Hospital Brno, Brno, Czech Republic

Background. Invasive pulmonary aspergillosis (IPA) is a severe infectious complication of hematological patients and its early diagnosis can contribute to the improvement of survival of affected patients. **Aims.** To evaluate the contribution of 1,3-β-D-glucan (BG) performed from bronchoalveolar lavage (BAL) fluid to IPA diagnosis. **Methods.** A retrospective analysis of BG detection in BAL fluid performed in 163 hematological patients between 1/2007 and 12/2011. Proven IPA (EORTC/MSG 2008 criteria) was documented in 2.6% (5 pts.), probable IPA in 10.7% (20 pts.) and possible IPA in 40.0% (75 pts). 46.7% (87 pts.) without evidence of IPA were considered as negative control. Pneumocystis pneumonia was diagnosed in 7.0% (13 cases) and positive culture from BAL fluid for *Candida sp*. was in 4.8 % (9 cases). Oral cavity colonization with *Candida sp*. was detected in 33.7% (63 cases). **Results.** 187 samples were included in the analysis. 48% (12/25 pts) of samples from proven/probable IPA pts were positive (> 80 pg/ml) and 12% (3/25) were intermediate (60-80 pg/ml). 37% (32/87) samples from pts without IPA were positive and 2% (2/87) were intermediate. After the exclusion of samples with pneumocystis pneumonia, the number of positive and intermediate results decreased to 32%.The mean BAL BG for patients with proven and probable IPA was 79 pg/ml (range 0-1145), for possible IPA 13 pg/ml (range 0-534) and for negative control 55 pg/ml (range 0-1477).The frequency of false positive results (>80 pg/ml) in our study was 29%. There was no difference between the mean BAL BG in the control group with or without oral cavity colonization with *Candida sp*. (43 vs. 32 pg/ml respective).The performance of glucan in BAL fluid tested at various cutoffs is presented in the table. **Summary and Conclusions.** The performance of glucan in BAL fluid has acceptable sensitivity, but a low specificity and positive predictive value for the diagnosis of invasive pulmonary aspergillosis. Moreover, due to "panfungality"of the assay it is necessary to use a combination of methods (ie galactomannan or PCR) for the confirmation of IPA.Supported by Masaryk University MUNI/A/0784/2011.

Table 1. The performance of glucan in BAL fluid tested at various cutoffs.

Proven and probable IPA vs. control group without pneumocystis pneumonia		
Sensitivity	88.0% (67.6 - 96.8%)	76.0% (54.4 - 89.9%)
Specificity	68.9 (56.9 - 78.9%)	70.2% (58.8 - 80.0%)
PPV	48.9% (33.9 - 64.0%)	46.3% (30.9 - 62.3%)
NPV	94.4 (83.6 - 98.5%)	89.6% (78.1 - 95.7%)

BRAIN ABSCESS AND FULMINANT SEPSIS CAUSED BY BACILLUS CEREUS IN PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES: CLINICAL EPIDEMIC FEATURES AND OUTCOMES

T Ugai, K Iwama, M Yamakura, M Takeuchi, H Sugihara, Y Nishida, K Matsue
Kameda Medical Center, Chiba, Japan

Background. Patients with haematological malignancies develop several kinds of bacteraemia due to intensive cytotoxic chemotherapy and immunosuppressive treatments. *Bacillus cereus* has emerged as a gram-positive pathogen that causes serious infection in haematological patients. However, the risk factors and characteristics have not been fully elucidated. **Patients and Methods.** We performed a retrospective chart review of the clinical and epidemiological feature of *Bacillus* bacteraemia in haematological and non-haematological patients at our hospital. In patients with sepsis, we also reviewed their charts to obtain clinical information, including insertion of a central venous catheter, neutrophil count, prior chemotherapy or steroid treatment.We also investigated clinical signs at febrile events, such as CNS involvement, unstable vital signs, gastrointestinal symptoms, antibiotic use and drug sensitivity of *Bacillus* species.We used univariate analysis and assessed the risk factors for fatal prognosis and brain abscess by *B. cereus*. Statistical analysis included χ^2 and Fisher's exact tests. All calculation were performed using the program R 2.12.1. **Results.** At our institution, we identified 56 patients with positive blood cultures for *B. cereus*, 17 with and 39 without haematological disease, during the period from April 2004 through December 2011. Bacteraemia was defined by the isolation of *B. cereus* from more than two blood culture sets. If a single blood culture yielded *B. cereus* without clinical symptoms, it was considered due to contamination. With respect to underlying haematological malignancies, 9 patients had leukaemia, 4 had myeloma, 3 had lymphoma and one had other haematological malignancies. Meningitis and brain abscess occurred in 3 of the 17 patients with haematological malignancies, but in none of those without haematological malignancies. Similarly, we noted that 5 of 17 patients with and 4 of 39 patients without haematological malignancy showed unstable vital signs caused by septic shock. Of the 17 patients with haematological malignancies, 3 patients died of *B. cereus* sepsis within few days, and 1 patient died of *B. cereus* meningitis and brain abscess despite receiving appropriate antibiotic therapy. In contrast, only 1 of the 39 patients without haematological malignancies died of *B. cereus* sepsis. Potential risk factors for brain abscess development in patients with *Bacillus* septicaemia included neutrophil count < 500/mm^3, corticosteroid use within 14 days and haematological malignancies. (P=0.003, P=0.007, P=0.003, respectively). Compared with the patients without malignancies, *B. cereus* septicaemia in patients with haematological malignancies was significantly associated with fatal outcome (P = 0.03). **Conclusions.** This study indicated that *B. cereus* causes fulminant meningitis, brain abscess and fatal prognosis in patients with, but not in those patients without, haematological malignancies. Therefore, early therapeutic intervention against *B. cereus* sepsis is important in the treatment of haematological malignancies.

0438

PNEUMOCYSTIS JIROVECI PNEUMONIA IN HEMATOLOGICAL PATIENTS: A SINGLE INSTITUTION EXPERIENCE

S Mancuso, G Franco, A Augello, G Iovine, G Saccullo, V Abbadessa, S Siragusa
University of Palermo, Palermo, Italy

Background. Pneumocystis jiroveci pneumonia (PJP) is usually documented in HIV infection and, in general, in patients with compromised immune system. It has been reported an incidence of PJP infection in hematological malignancies higher than in solid tumors. **Aims.** To establish the frequency and clinic characteristics of PJP infection in consecutive patients with hematologic neoplasms over a period of 2 years **Methods.** Patients population comprised consecutive HIV negative adult patients with hematological cancer and clinically suspected of PJP during the period 2008-2010. The diagnosis was done using PCR for PJ performed on oral wash. All the cases with microbiologically documented PJP were analyzed considering the following variables: demographic data, underlying hematological malignancy, relationship between chemotherapy and diagnosis of PJP, clinical parameters and radiological reports related to pneumonia and lymphocyte count. We obtained informed consent for samples taking and related analyses. **Results.** Among 86 consecutive subjects with hematologic malignancies, 24 resulted affected by PJP (27.9%). Mean age was 59±18.8 years; 14/24 (58.3%) of them were male and 10/24 (48.7%) female. The underlying hematologic diseases were: Non-Hodgkin lymphoma (66.7%), Hodgkin lymphoma (20.8%), Acute Myeloid Leukemia (8.3%) and aplastic anemia (4.2%). All the patients received chemotherapy (as single therapy or in combination); the most common regimens were FCR, CHOP and ABVD. No one received bone marrow transplantation at the time of present analysis. Diagnosis of PJP infection was established before chemotherapy in 14.5%, during treatment in 37.5% and after chemotherapy in the remaining 48% of the patients. Trimethoprim/sulfamethoxazole (TMP-SMZ) prophylaxis was performed in 5 PJP patients only. Mean value of lymphocyte count was 0.86 x 10^9/L (r. 0.10 -2.36 x 10^9/L; ±0.615). At the time of diagnosis, a statistical difference in median lymphocyte count was observed between patients < or > 65 years old [median count: 0.60 (± 0.42) x 10^9/L vs 1.13 (L ± 0.68) x10^9/, p < 0.005]. After a mean of 27.6 days (± 30.9), oral wash test became negative in cases assessed after PJ therapy. None of patients died or had serious adverse events. **Conclusions.** The incidence and clinical characteristics of PJP in hematological patients receiving chemotherapy is still under investigation; we found a broad spectrum of hematologic diseases complicated by PJP. In our population, diagnosis of PJ infection was established in > 10% of patients before the beginning of the first cycle of chemotherapy. Because of non-invasive oral washes PCR examination, appropriate designed studies should address the clinical advantages of the early diagnosis of PJ infection (and its treatment before chemotherapy) in heamatological malignancies.

Stem cell transplantation - Clinical 1

0439

CO-MORBIDITY SCORING IS A CRITICAL DETERMINANT OF OUTCOME AFTER ALEMTUZUMAB BASED REDUCED INTENSITY ALLOGRAFTS IN PATIENTS OVER THE AGE OF 60: A BSBMT STUDY

E Nikolousis[1], S Nagra[2], R Pearce[3], J Perry[3], K Kirkland[3], J Byrne[4], B Shaw[5], F Dignan[5], E Tholouli[6], J Yin[6], M Gilleece[7], D Milligan[1], N Russell[4], T Littlewood[8], G Cook[7], C Craddock[2]
[1]Heart of England NHS Trust, Birmingham, United Kingdom
[2]University Hospital Birmingham Queen Elizabeth, Birmingham, United Kingdom
[3]BSBMT Data Registry Guy's Hospital, London, United Kingdom
[4]Nottingham University Hospital, Nottingham, United Kingdom
[5]Royal Marsden Hospital, Sutton,Surrey, United Kingdom
[6]Manchester Royal Infirmary, Manchester, United Kingdom
[7]Leeds Teaching Hospital, Leeds, United Kingdom
[8]John Radcliffe Hospital, Oxford, United Kingdom

Introduction. Reduced intensity allogeneic transplants represent a curative therapy in older patients with haematological malignancies. However acute and chronic graft-versus-host disease (GVHD) remain major complications, particularly in older patients, and there is increasing use of *in vivo* T cell depletion using alemtuzumab or ATG in this patient population. Such a manoeuvre is associated with delayed immune reconstitution and increased infectious complications but there has been no analysis of factors predicting survival after a T cell depleted allograft in older patients. **Aims.** We therefore wished to identify factors determining overall survival (OS) and non-relapse mortality (NRM) after an Alemtuzumab based RIC allograft in patients with a haematological malignancy over the age of 60. In addition to standard transplant criteria the Seattle Co-morbidity score was applied in order to study the impact of pre-transplant co-morbidity on patient outcome. **Patients and Methods.** 215 patients with a haematological malignancy underwent allogeneic transplantation using an alemtuzumab based RIC regimen. The median patient age was 63 years (range 60-73). 134 patients had a Seattle Co-morbidity score of 0 or 1 and 57 a score of 2 or more (data unavailable in 24). 165 patients underwent transplantation for a myeloid malignancy (AML n=92, MDS n=60, miscellaneous n=11) and 50 for lymphoid malignancies (CLL n=20, NHL n=15, miscellaneous n= 15). 138 patients underwent a transplant from a matched (7/8 or 8/8) unrelated donor and 77 from a matched sibling donor. All patients were transplanted using alemtuzumab based conditioning (Fludarabine/Melphalan/alemtuzumab n=141, miscellaneous (including BEAM alemtuzumab and busulphan/alemtuzumab n=74). The median follow up was 24 months (range 2-100). **Results.** The one year and five year overall survival was 56% (49-63%) and 36% (27-45%) respectively. The one year non relapse mortality (NRM) was 27% (21-34%). The one year and 5 year relapse rates were 23% (17-29%) and 39% (30-48%) respectively. 25 patients (11%) developed Grade III-IV acute GvHD and 16 (7%) patients developed chronic extensive GvHD. OS was influenced by status at transplant (CR/stable disease 47% v 31% at 2 years p=0.045) and co-morbidity score (score 0/1 59% at 2 years versus 7% for higher score p=0.0001). In multivariate analysis NRM was influenced by co-morbidity score (p=0.001) and a dose of CD34+ cells >5.5x10^6 CD34/kg (p=0.028). OS was influenced by disease status at transplant (p=0.003) and co-morbidity score (p=0.001) but not patient age. **Conclusions.** Alemtuzumab based RIC allografts can be delivered safely in patients above the age of 60. The most important determinants of outcome are disease status at transplant and co-morbidity score. This is the first study to examine the impact of patient co-morbidities on outcome after a T cell depleted RIC allograft. Whilst our data require confirmation in a larger cohort of patients they suggest that meticulous co-morbidity scoring is mandatory in older patients who can benefit from a RIC allograft

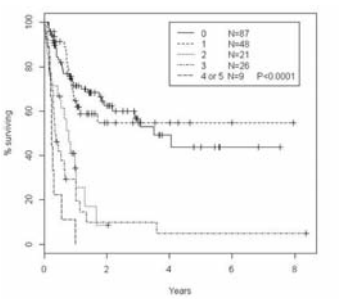

Figure 1. Overall survival by seattle comorbidiy score.

0440

FLUDARABINE AND TREOSULFAN CONDITIONING FOR ALLOGENEIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH AML AND MDS NOT ELIGIBLE FOR STANDARD MYELOABLATIVE CONDITIONING

A Shimoni[1], A Crotta[2], N Shem-Tov[1], J Peccatori[2], R Yerushalmi[1], M Bernardi[2], A Nagler[1], F Ciceri[2]
[1]Chaim Sheba Medical Center, Tel-Hashomer, Israel
[2]San Raffaele Scientific Institute, Milano, Italy

Background. Allogeneic stem-cell transplantation (SCT) is curative approach in AML and MDS. However, standard myeloablative conditioning (MAC) is limited to younger, medically fit patients. Reduced-intensity conditioning (RIC) is feasible in patients not eligible for MAC, however relapse rates are increased, especially in patients not in remission at SCT. Novel approaches are needed to deliver dose-intense conditioning, yet with RIC type toxicity, to these patients. Treosulfan is a bifunctional alkylating agent with cytotoxic and immunosuppressive effects. Prior studies demonstrated the feasibility of fludarabine-treosulfan(FT) conditioning, suggesting it is effective with limited toxicity.*Aims* & **Methods.** To better define the role of FT, we analyzed outcomes of a relatively large cohort of 202 patients with AML (n=128) or MDS (n=74) treated in two institutions. Patients were eligible for FT only if considered non-eligible for MAC. FT included fludarabine 30 mg/m^2 x5 days and treosulfan 12 gr/m^2 x3 days in one institution (FT12, n=109) or 14 gr/m^2 x3 in the second institution (FT14, n=93). **Results.** The median age was 58 years (21-76). The donor was an HLA-matched sibling (n=96), matched unrelated (n=96) or alternative donor (n=10); 35 patients (17%) had an HLA-mismatched donor. Disease status was CR1 (n=62), CR2/later CR (n=31), no CR (n=40) or previously untreated MDS (n=69). 55 patients had comorbidity score>2 (27%). 194 patients engrafted in a median of 15 days (9-28), 8 died prior to engraftment (4%) and 3 had primary non-engraftment (1.5%). With median follow-up of 34 months (1-93), 100 patients are alive and 102 have died. The cumulative incidence of acute GVHD grade II-IV and III-IV was 30% and 20%, respectively. The cumulative incidence of chronic GVHD was 41%. The 3-year non-relapse (NRM) and relapse mortality was 28% (95%CI, 22-36) and 27% (95%CI,21-35), respectively. The 3-year overall survival rate (OS) was 45% (95%CI, 37-52). OS was 63% (95%CI, 50-76), 39%(95%CI, 20-58), 20% (95%CI, 7-33) and 46% (95%CI, 32-60) in patients in CR1, CR2/later CR, no CR or previously untreated, respectively (p<0.001). Disease status at SCT was the only prognostic factor in multivariate analysis. Patients not in CR had hazard-ratio of 4.2 (p<0.001) for shortened OS, 4.9 (p=0.001) for relapse, and 2.6 (p=0.04) for NRM. There was no significant difference in any of these outcomes between FT12 and FT14. However, there was a trend for better OS with FT12 compared to FT14 in patients in CR1, 85% Vs. 56%, respectively (p=0.1) due to lower NRM in this subgroup. Among intermediate-risk patients (CR2/ previously untreated) OS was 40% and 49%, respectively, due to less relapses with FT14 in this subgroup, but not reaching statistical significance. There was no difference in the poor-risk subgroup (no CR). **Conclusions.** This relatively large cohort defines the expected outcomes with treosulfan-based conditioning. This is a promising approach in MAC- ineligible patients with outcomes that are similar to MAC. Favorable results were observed in patients in CR or untreated MDS at SCT. The role of different treosulfan doses should be further defined in prospective studies.

INDUCTION THERAPY WITH BORTEZOMIB-THALIDOMIDE-DEXAMETHASONE (VTD) DOES NOT IMPAIRE AUTOLOGOUS PERIPHERAL BLOOD STEM-CELL (PBSC) COLLECTION IN NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

A Brioli[1], G Perrone[1], M Galli[2], F Di Raimondo[2], S Bringhen[2], MR Motta[1], V Montefusco[2], T Spadano[2], N Pescosta[2], A Ledda[2], A Falcone[2], A Pezzi[1], R Zambello[2], F Gherlinzoni[2], B Zannetti[1], S Ballanti[2], M Petti[2], M Marcatti[2], S Rizzi[1], A Nozza[2], C Califano[2], M Baccarani[1], M Cavo[1]
[1]Seragnoli Institute of Hematology, Bologna, Italy
[2]GIMEMA Italian Myeloma Network, Bergamo, Italy

Background. The novel agents bortezomib, thalidomide and lenalidomide have been successfully incorporated into autologous stem-cell transplantation (ASCT) for MM. However, several concerns have been raised about the impact of novel agent-based induction therapies on PBSC collection. **Aims.** The GIMEMA Italian Myeloma Network designed a phase III study to compare VTD with thalidomide-dexamethasone (TD) as induction therapy prior to double ASCT. We compared the effect of VTD versus TD induction regimens on CD34+ cell collection. **Methods.** After three 21-day cycles of VTD or TD induction therapy, patients received cyclophosphamide (CTX, 4 g/m^2) followed by G-CSF (10 mcg/Kg/die). The target threshold to safely perform double ASCT was 4 x 10^6 CD34+ cells/Kg. **Results.** Of 474 patients who received induction therapy, 435 (223 in VTD and

212 in TD) were evaluable for PBSC collection. The median number of collected CD34+ cells was 9.7 x 10^6/Kg in VTD arm and 10.7 x 10^6/Kg in TD arm (p= 0.220). The planned yield of 4 x 10^6 CD34+ cells/Kg was achieved with a single harvest in 91% of patients in both treatment arms (p= 0.867). Collected CD34+ cells >10 x 10^6/Kg (50% in VTD and 58% in TD) and collection failure (2% each) did not differ between treatment groups (p= 0.228). Most of patients (86% in VTD and 82% in TD, p=0.320) received CTX as an in-patient procedure (median hospitalization: 4 days); less than 5% of patients developed grade 3-4 infectious complications. Following ASCT, no significant difference was observed between VTD and TD in terms of hematologic recovery and non hematological toxicity. Kaplan-Meier curves of TTP and PFS were almost superimposable for patients with a CD34+ yield in the range between 4 and 10^6/kg and >10 x 10^6/Kg or (group 1), as well as for those who collected between 2 and 4 x 10^6/Kg and <2 x 10^6/Kg (group 2). The 3-year estimates of TTP and PFS were 70% for group 1 vs 39% for group 2 (p= 0.0000) and 69% vs 35% (p= 0.0000), respectively. OS rate at 3 years was 90% in group 1 vs 69% in group 2 (p= 0.0002). In a multivariate Cox regression analysis, a yield of CD34+ cells >4 x 10^6/Kg was independently associated with prolonged PFS (p=0.000), and extended OS (p=0.000). Absence of t(4;14) and/or del(17q) and beta2-microglobulin <3.5 mg/L were favorable prognostic factors for both PFS and OS; randomization to VTD independently predicted for longer PFS. **Summary and Conclusions.** Both VTD and TD regimens did not adversely affect PBSC collection and the engraftment potential of collected PBSCs. As a result of early PBSC collection and use of CTX plus G-CSF, the target of >4 x 10^6/Kg CD34+ cells was achieved with a single harvest in more than 90% of patients, and collection failure was seen in only 2%. Notably, the collection of >4 x 10^6 CD34+ cells/Kg was independently associated with extended PFS and OS.

0442

TREOSULFAN-BASED CONDITIONING FOR CORD BLOOD TRANSPLANTATION IS SAFE AND EFFECTIVE: RESULTS FROM AN ONGOING PHASE-II STUDY

F Milano[1], J Deeg[1], J Gutman[2], E Nemecek[3], C Delaney[1]
[1]Fred Hutchinson Cancer Research Center, Seattle, United States of America
[2]University of Colorado, Denver, United States of America
[3]Oregon Health & Science University, Portland, United States of America

Backgrounds. Treosulfan (is an immunosuppressive and myeloablative alkylating agent recently introduced as a conditioning agent for hematopoietic cell transplantation (HCT). While previous studies have investigated the role of treosulfan-based conditioning regimens for conventional donor HCT, the experience in cord blood transplantation (CBT) is limited. **Methods.** Between March 2009 and November 2011, 33 consecutive CBT recipients were enrolled in this prospective non-randomized Phase II study at Fred Hutchinson Cancer Research Center. The conditioning regimen consisted of Treo (14 gm/m^2/day) from day -6 to day -4, Fludarabine (30 mg/m^2/day) from day -6 to day -2, and a single fraction of 200cGy TBI on day -1. Two patients deemed at high risk of graft failure received a total dose of Flu equal to 35 mg/m^2/day. Graft versus host disease (GVHD) prophylaxis consisted of cyclosporine and mycophenolate mofetil. All CBT grafts were 4-6/6 HLA-matched (A and B antigen level, DRB1 allele level) to the patients. Engraftment, non-relapse mortality (NRM), relapse and GVHD were calculated using cumulative incidence rates to accommodate competing risks. Disease-free survival (DFS) and overall survival (OS) were analyzed using Kaplan-Meier estimates. **Results.** All but 2 patients received a double CBT, with a median dose of total nucleated and CD34+ cells of 3.6 x 10^7/kg (range, 2.2-10.2) and 0.19 x 10^6/kg (range, 0.04-0.66), respectively. The median age was 52 years (range, 5-63) and weight 76 kg (range, 17-114). The median follow-up of the survivors was 300 days (range, 105-1085). Disease status pre-transplant included acute myeloid leukemia in 1st complete remission (CR1) (n=9) and in CR2 (n=5), acute lymphoblastic leukemia in CR1 (n=3) and in CR2 (n=8), myelodysplastic syndrome (n=6) and myeloproliferative disorder (n=2). Fifteen patients (47%) had minimal residual disease at the time of transplant. Five patients (15%) had failed a prior myeloablative allogeneic HCT. Median time of neutrophil recovery was 23 days (range, 13-89 days) with a cumulative incidence of engraftment of 93% (95% CI, 76-98%). Two patients (6%) experienced primary graft failure. The median time to platelet recovery (>20 x 10^9/L) was 34 days (range, 24 - 62) with a cumulative incidence at day 100 of 73% (CI 95%: 56 - 81). The probability of 2-year OS and DFS was 66% (95% CI, 44-81%) and 60% (95% CI, 37-78), respectively. The cumulative incidence of NRM at 2 years was 22% (95% CI, 8-40%) and relapse 17% (5-36%). Ten (30%) patients died, with relapse/multiorgan failure as the most common causes (n=7). The cumulative incidence of grade II-IV acute GVHD was 66% (95% CI, 47-80) and grade III-IV 23% (95% CI, 10-39%), whereas chronic GVHD at 1 year was 28% (95% CI, 10-45%). **Conclusions.** The preliminary results presented herein from this first prospective CBT trial utilizing treosulfan-based conditioning demonstrates that this approach is well-tolerated and sufficiently immunosuppressive to promote sustained CB donor engraftment. Importantly, this regimen extends donor options for patients in need of myeloablative HCT without conventional donors who are ineligible for other myeloablative regimens, especially those containing high dose TBI. A large randomized study is now needed to confirm these favorable outcome results.

THE PROGNOSTIC SIGNIFICANCE OF PET SCAN BEFORE AND AFTER HIGH-DOSE THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN RELAPSED/REFRACTORY HODGKIN LYMPHOMA (HL) PATIENTS

M Angelopoulou[1], M Moschogiannis[2], P Rondogianni[3], V Pappis[4], P Tsirkinidis[2], O Tsopra[4], Z Galani[4], S Sachanas[2], X Yiakoumis[2], S Masouridi[4], G Boutsikas[4], C Kalpadakis[4], E Dimitriadou[4], M Dimopoulou[1], V Telonis[4], P Flevari[4], G Gainarou[4], T Ntalagiorgos[1], D Exarchos[3], I Datseris[3], A Gouliamos[5], MC Kyrtsonis[1], P Panayiotidis[1], G Pangalis[2], I Meletis[1], T Vassilakopoulos[1]

[2]Athens Medical Center, Athens, Greece
[3]Department of Nuclear Medicine «EVANGELISMOS» Hospital, Athens, Greece
[4]Laikon General Hospital, Athens, Greece
[5]University of Athens, Athens, Greece

Background. ASCT is the standard approach for relapsed/refractory HL patients. Chemosensitivity prior to ASCT is a powerful prognostic factor for outcome; the predictive significance of PET scan in the ASCT setting has not been firmly established yet. **Aims.** To further update our previous results (presented in EBMT 2010) with respect to the prognostic significance of PET scan before and after HDT/ASCT in a series of 68 patients with relapsed/refractory HL from a single Transplant Unit. **Methods.** Computed tomography and PET scan were performed just prior to ASCT and at 3 months post transplant. Findings were correlated with failure free survival (FFS). PET scan was considered negative, when no uptake was present, positive, when any lesion was FDG-avid with SUV ≥4 and minimal residual uptake positive (MRUp), when any lesion showed abnormal uptake with SUV<4. MRUp cases were analyzed as positive pre-ASCT and as negative post-ASCT. Patients achieving a complete or partial remission prior to ASCT as assessed by conventional methods were considered chemosensitive.

Table 1. Relapses according to pre- and post ASCT PET scan, N=53.

Pre-ASCT PET-scan	Post-ASCT PET-scan	Relapses/patients	2-year FFS (%)	p
negative →	negative	2/16	86±7	P<0.0001
positive →	negative	1/17	93±7	
negative →	positive	1/2	50±35	
positive →	positive	15/16	6±6	

Results. Among 68 patients included in the study, 47% were treated for primary refractory disease, 41% at first relapse and 12% beyond first relapse. All patients received salvage chemotherapy and 75% had chemosensitive disease prior to ASCT. A PET-scan was available pre-ASCT in 55 patients, post ASCT in 62 and at both time points in 53. Pre-ASCT PET scan was positive or MRUp in 24/45 chemosensitive patients vs 10/10 chemoresistant ones (p=0.02). There was no chemoresistant patient with a negative PET-scan. Pre-ASCT PET-scan was of prognostic significance for outcome: 3/21 patients with a negative pre-ASCT scan relapsed vs 17/34 with a positive or MRUp one, resulting in a 2-year FFS of 85% and 48% respectively (p=0.005), Thus almost

50% of pre-ASCT PET(+) patients did not relapse at a median follow-up of 30 months (4-93), while a plateau was reached at 15 months post-transplant. Chemosensitivity remained significant as expected: 2-year FFS was 71% and 24% for chemosensitive and chemoresistant patients respectively (p=0.0001) Chemosensitivity could further stratify pre-ASCT PET(+) patients: Chemosensitive PET(-) patients had a 2-year FFS of 85%, vs 56% for chemosensitive PET(+) and 30% for chemoresistant PET(+) ones (p=0.002). Post-ASCT PET scan had the strongest predictive value for outcome: 2-y FFS was 87% for post ASCT PET(-) or MRUp cases vs 19% for PET(+) ones (p< 0.0001). When we further compared the results for the 53 patients who had a PET-scan available both pre- and post-ASCT, we found that patients who became PET(-) post ASCT had an excellent outcome irrespectively of pre-ASCT PET-scan findings, whereas almost all PET(+) ones relapsed, as shown in the Table 1. **Conclusions.** Pre-ASCT PET scan positivity does not preclude a favorable outcome for patients with relapsed/refractory HL undergoing HDT/ASCT, since half of them remain relapse free. Chemosensitivity prior to ASCT can further discriminate the outcome of PET(+) patients. Patients who become PET(-) after ASCT have an excellent outcome in contrast to PET(+) ones whose prognosis is dismal.

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE LEUKEMIA OF AMBIGUOUS LINEAGE IN ADULTS: THE COMPARISON BETWEEN STANDARD CONDITIONING AND INTENSIFIED CONDITIONING REGIMENS

Q Liu[1], Z Fan[1], MQ Wu[1], J Sun[1], XL Wu[2], D Xu[1], QL Jiang[1], Y Zhang[1], F Huang[1], YQ Wei[1], J Zhao[1], G Yu[1], FY Meng[1]
[1]Nanfang Hospital, Southern Medical University, GuangZhou, China
[2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background. Acute leukemia of ambiguous lineage (ALAL) are a rare disorders. Knowledge concerning the clinical and biological characteristics of ALAL is limited. Until now, there has been a lack of uniformity in the optimal therapeutic strategy to these cases. **Aims.** To evaluate the efficacy of two intension conditioning regimens for allogeneic hematopoietic stem cell transplantation (allo-HSCT) in adults with ALAL. **Methods.** Fifty-three adult ALAL were enrolled in the study. Twenty-four patients received the standard conditioning (Total body irradiation (TBI) + cyclophosphamide (CY) or busulfan + CY protocol) and 29 the intensified conditioning (TBI + CY+ etoposide or fludarabine, cytarabine and TBI + CY + etoposide protocol). Thirty-four patients received related donor and 19 received unrelated donor transplantation. Cyclosporine A (CsA) was withdrawn rapidly in a stepwise fashion to avoid overwhelming Graft-versus-host disease (GVHD) reactions if acute GVHD did not develop at day +30 post-transplantation. **Results.** Of the 53 patients, 18, 19 and 16 cases received the initial induction chemotherapy protocol for acute lymphoid leukemia (ALL), acute myeloid leukemia (AML), and both lymphoid and myeloid lineages, respectively. The rate of complete remission (CR) was 83.3%, 47.4% and 75.0%, respectively, in the three protocols (*P*=0.049). All patients obtained hematopoietic reconstitution after transplantation. 3-year transplant-related mortality was 18.3±10.0% and 32.6±10.0%, respectively, in the standard conditioning and intensified conditioning groups (*P*=0.224). 3-year overall survival (OS) was 17.1±8.7% and 60.9±10.0%, and disease-free survival (DFS) was 16.2±8.2% and 57.8±10.9%, respectively, in the standard conditioning and the intensified conditioning groups (*P*=0.049 and *P*=0.009, respectively). The 3-year cumulative rate of relapse was 84.4±9.2% and 23.3±11.2%, respectively, in the standard conditioning and the intensified conditioning groups (*P*=0.000). Both univariate and multivariate analysis indicated that the patients with CR at the time of transplantation, the intensified conditioning regimen and acute GVHD all were the favorable factors to reduce the relapse. The patients with CR at the time of transplantation (*P*= 0.002 for OS; *P*= 0.011 for DFS), the intensified conditioning regimen (*P*=0.000 for OS; *P*= 0.002 for DFS) were also favorable factors to elevate the survival. **Conclusions.** CR rate of ALAL patients received initial induction chemotherapies for ALL or both myeloid and lymphoid lineages was higher than those received AML- based treatment. Intensified conditioning regimens followed by allo-HSCT might improve long-term survival and decrease relapse of leukemia in adult ALAL compared to the standard conditioning regimens.

0445

UPDATED EXPERIENCE WITH INOLIMOMAB AS TREATMENT FOR CORTICOSTEROID-REFRACTORY ACUTE GRAFT VERSUS HOST DISEASE

I García-Cadenas[1], D Valcárcel [2], JL Piñana[3], S Novelli[1], A Garrido[1], M Granell[1], ME Moreno[1], J Briones[1], S Brunet[1], R Martino[1], J Sierra[1]
[1]Hospital de Sant Pau, Barcelona, Spain
[2]Hospital Vall d'Hebron, Barcelona, Spain
[3]Hospital de Manises, Valencia, Spain

Background. Acute graft versus host disease (aGVHD) is the most important cause of non-relapse mortality after allogeneic stem cell transplantation. Response to first-line steroid therapy is obtained in 50% of the patients. Multiple second line options have been investigated with initial encouraging results; however, until now the best option, if any, in terms of improved survival remains unclear. In 2006, our group published a series of 40 patients who received inolimomab as salvage therapy for refractory aGVHD.[1] Overall response rate was 58% (CR 38%), leading to an OS of 30% at 1 year (59% for responders). Given these results, inolimomab was the standard second line treatment for aGVHD in our center. **Aims.** To analyze whether the prior promising experience was reproduced in a much larger group of patients with prolonged follow-up treated at our institution. **Methods.** We retrospectively analyzed the clinical data of 92 consecutive patients who received inolimomab as salvage treatment for refractory aGVHD between April 1999 and December 2011. All patients gave their informed consent, and the drug was administered as compassionate use. Twenty-seven (29%) had received myeloablative conditioning and 65 (71%) reduced intensity preparative regimen. Thirty-three (36%) patients had been transplanted for early disease and 59 (64%) for intermediate or advanced stage hematologic disorders. **Results.** There were 65 (71%) men. Median age was 50 years (range: 17-68). Acute GVHD developed at a median of 34 days (range: 5-170) after transplantation. Ninety-four percent of the patients presented an overall aGVHD grade III or IV at the time of starting inolimomab. The drug was initiated at a median of 17 days (range: 2-204) after diagnosis. Forty-six patients (50%) had received a prior second line immunosuppression without response. Median follow-up for survivors was 1307 days (95-4121).Overall response rate was 42% (CR 14%) on day 28. Predictors of day-28 failure to respond were: EMBT risk score >4, grade III-IV gastrointestinal involvement, female-to-male sex mismatch and lymphocyte count <$0.3x10^9$/L at starting inolimomab (p<0.01). Despite the acceptable initial response rate, results in terms of mid and long-term survival were unfavourable; during the follow-up period 79 patients (86%) died after a median of 34 (0-3068) days and 13 remained alive, for a 3-year OS of 13.2% (95% CI 5.6-20.8%), being 7% (95% CI 0-14%) and 24% (95% CI 10-38%) for day-28 non-responders and responders respectively (P<0.001). Acute GVHD was the main cause of death (42%) followed by infectious complications (26%). **Commentaries.** Our results in this update are worse than in the former report[1], highlighting the need of reporting long-term outcomes in GVHD studies. The use of inolimomab, which seems an active drug with 42% of short-term response, is associated with prolonged OS only in one fourth of responding patients. This reflects that investigating new rescue treatments with sustained effect is mandatory.

ROLE OF DONOR SPECIFIC ANTI-HLA ANTIBODIES ON GRAFT FAILURE ON CORD BLOOD TRANSPLANTATION AFTER REDUCED INTENSITY CONDITIONING REGIMEN. AN EUROCORD, SFGM-TC AND SFHI ANALYSIS

A Ruggeri[1], V Rocha[1], E Masson[2], R Cunha[1], L Absi[3], A Boudifa[4], B Coeffic[5], D Charron[2], A Devys[5], M De Mattei[5], V Dubois[5], D Hanau[5], F Hau[5], I Jollet[5], D Masson[5], B Pedron[5], P Perrier[5], E Gluckman[1], P Loiseau[5]

[3]St Etienne, St Etienne, France
[4]Hôpital La Pitié, Paris, France
[5]EFS, Angers, France

Backgound. Delayed hematopoietic recovery and graft failure (GF) are critical complications of cord blood transplantation (CBT) and are associated with TNC or CD34 cell dose and HLA disparities. Other factors such as patients's HLA-antibodies (Ab) may impact neutrophil recovery. **Methods.** To analyze the effect of anti-HLA-Ab on CBT outcomes we analyzed 206 patients (pts) who underwent CBT after reduced intensity conditioning (RIC) from 2000-2010, in France. Median follow-up was 36 months. Eighty-two percent of pts were transplanted for malignancies, median age was 43 years. Graft composition: 82 pts (40%)

received a single CBT and 124 (60%) had a double CBT. Thirty percent of CBU had 0-1 HLA mismatch (A, B, DRB1), 67% received CyFluTBI2Gy and median infused TNC was $3.7x10^7$/Kg. Pre-transplant serum was tested for HLA-Ab with a panel of fluorescent beads coated with single HLA-antigen using Luminex™ platform. Results were interpreted as fluorescence intensity (MFI) against donor-specific mismatch (>1000 MFI was the threshold for positivity). Overall 48 pts (23%) had anti-HLA-Ab before CBT and those were donor specific anti-HLA-Ab (DSA) in 16 pts. Among the 16 pts with DSA (11 females, 5 males), 9 had single and 7 double-CBT (none had DSA directed to both CB units). Seven pts had DSA vs to HLA-Class-I, 5 vs to HLA-Class-II and 4 to both HLA-Class-I and-II. DSA threshold ranged from 1620-17629 MFI. **Results.** Cumulative incidence (CI) of day-60 neutrophil engraftment was 76%. It was 44% for recipients with DSA and 81% in pts without DSA (p=0.006). There was no difference for pts with anti-HLA-Ab non donor-specific (77% vs 69%). Multivariate model showed DSA (RR 2.7, p=0.01) and CBT before 2008 (RR 1.49, p=0.03) independently associated with GF.Seven pts with DSA engrafted, 4 after double CBT and chimerism analysis showed the engraftment of the CBU with DSA in 1 case.Among 50 pts who failed engraftment,· 9 (20%) pts had DSA specific for donor HLA-Class-I(n=4) or Class-II(n=2) or both Class-I and Class-II (n=3).CI of platelet recovery at day-180 was 62%, 12 of 16 patients with DSA did not achieve platelet recovery. CI of 1-year TRM was 35%. DSA was associated with higher TRM (p=0.002). Overall survival at 3-years was 44%, it was 41% and 45% for pts with non-malignant and malignant disease respectively. OS was 47% for recipients without DSA and 25% for those with DSA, p=0.006. In multivariate analysis, the absence of DSA was the only factor associated with better survival (RR 2.41, p=0.005). **Conclusions**. Donor-specific anti-HLA-Ab in recipients of CBT is associated with failed engraftment and lower survival. Screening for DSA may be included in the algorithm of donor choice for cord blood transplantation.

ENDOTHELIAL STRESS IN STEROID-REFRACTORY GVHD: A BURDEN STATINS CANNOT LIFT

S Dietrich[1], C Falk[2], A Benner[3], S Karamustafa[4], E Hahn[4], M Andrulis[5], U Hegenbart[4], A Ho[4], P Dreger[4], T Luft[4]
[1]University of Heidelberg, Heidelberg, Germany
[2]Institut für Transplantationsimmunologie, Medizinische Hochschule Hannover, Hannover, Germany
[3]German Cancer Research Center, Heidelberg, Germany
[4]Medizinische Klinik V, University of Heidelberg, Heidelberg, Germany
[5]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany

Graft-versus-host disease (GvHD) is the major complication of allogeneic stem cell transplantation (alloSCT) and its therapy-resistant form causes significant morbidity and mortality. The pathomechanism of steroid resistance is currently not completely understood; however, we have recently suggested that endothelial dysfunction seems to play an important role (Luft et al., Blood 2011). The aim of this study was to validate in a large cohort of patients that steroid refractory acute GvHD is associated with endothelial stress. Secondly we assessed if this endothelial stress can be overcome by statins, which are known to have endothelial protective effects. **Patients and Methods.** For this retrospective study, 393 patients were eligible who had undergone alloSCT between 09/2001 and 08/2010 at our institution. Serum levels of endothelial stress markers (Angiopoietin-2: Ang-2, soluble Thrombomodulin: sTM, Interleukin-8: IL-8 and Vascular endothelial growth factor: VEGF) were compared between patients with no GvHD (n=221), grade1-2 (n=103), steroid sensitive grade 3-4 (n=27) and steroid refractory grade 3-4 (n=41) GvHD, and correlated with outcome. Serum levels of these markers were also compared between patients with and without concomitant statin treatment. **Results.** Landmark analyses at days +50 and +100 after alloSCT showed that NRM was dramatically high in the steroid refractory group but was equivalently low in the no GvHD-, sensitive grade 1-2 - and grade 3-4 - groups (p<0.0001, Figure 1). Steroid-refractory patients showed higher serum levels of Ang-2 (p=0.03) prior alloSCT and significantly stronger rises in IL-8 (day 50: p=0.006; day 100: p=0.003) and sTM (day 50: p=0.04; day 100: P=0.006) levels post alloSCT than sensitive grade 3-4 GvHD patients. High levels of sTM, IL-8, Ang-2 were significantly associated with increased NRM rates (day +50: IL8 p=0.06, sTM p=0.0008, Ang-2 p=0.0001; day +100: IL8 p=0.0007, day +100 sTM p<0.0001, Ang-2: p=0.05); even after multivariate adjustment for donor, conditioning intensity, disease status at alloSCT, and sex mismatch. In contrast, VEGF was elevated in steroid sensitive grade 3-4 GvHD patients at day 100 but did impact on NRM rates.When comparing these markers in patients who had (n=84) or had not (n=309) received concomitant therapy with statins, no difference was seen for any endothelial cell stress markers neither in the whole cohort nor in patients with grade 3-4 GvHD. Patients with or without statins had similar NRM, relapse rates and overall survival. **Conclusions.** This study supports the hypothesis that steroid-refractory GvHD is associated with progressive microangiopathy. Statins, although reported to have protective effects on endothelial cells, were inefficient to alleviate endothelial stress in this context and accordingly, did not change the outcome of acute GvHD patients.

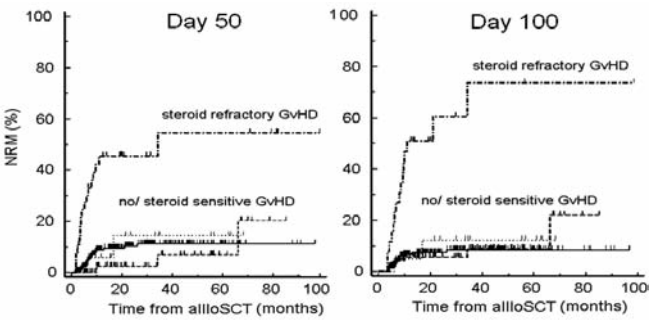

Figure 1. NRM rate by GvHD.

[2]CHU Mont-Godinne, Mont-Godinne, Belgium
[3]KUL, Leuven, Belgium
[4]UZ Gent, Gent, Belgium
[5]Virga Iesse Hospital, Hasselt, Belgium

Background. The impact of the type of reduced intensity conditioning regimen used on immune recovery after allogeneic hematopoietic cell transplantation (allo-HCT) is poorly determined. **Aims.** We analyzed immune reconstitution in patients enrolled in a BHS-HCT sponsorised randomized study comparing two non-myeloablative conditioning regimens for allo-HCT for which cell samples were prospectively collected. **Patients and Methods.** The conditioning regimen consisted of either 2 Gy TBI with 90 mg/m² fludarabine (=TBI arm, n=21), or 8 Gy TLI plus thymoglobulin (ATG) 7.5 mg/kg (=TLI arm, n=19). Median ages at HCT were 59 yrs and 61 yrs in the TBI and TLI arms, respectively. Immune reconstitution was assessed by flow-cytometry phenotyping, signal joint T-cell Receptor Excision Circle (sjTREC) quantification, and T-cell spectratyping. Written informed consent has been obtained for each patient included. **Results.** Absolute T cell counts were lower in the TLI arm than in the TBI arm on day 28 after HSCT (P=0.04) but not thereafter. Further, B cells, as well as CD4+, CD4+CD45RA+ and CD4+CD45RO+ T cell reconstitution lagged behind in the TLI arm compared to the TBI arm the first year after HCT (B cells: p=0.0295 and others: p>0.0001). In contrast, reconstitution of CD8+ T cells, NK cells, Tregs and iNKT cells were similar in the 2 groups. For the thymic function, while sjTREC levels were higher in the TBI arm than in the TLI arm on day 100 (P=0.002) and on day 365 (not significant) after HCT, the increase in sjTREC levels from day 100 to day 365 was similar in the 2 groups of patients. The diversity of the TCR repertoire was similar in the 2 groups of patients on day 100 after HCT. Finally, we found that ATG persists in patients up to 17 days after allo-HCT in TLI patients (median of [ATG] at day 17=0.62 mg/l and for one patient at day 20=0.53). **Conclusions.** These preliminary results suggest that ATG may be responsible for the delay of immune reconstitution of CD4+ T cells in the TLI arm. Furthermore, ATG probably destroyed grafted sjTREC+ T cells, explaining the difference of sjTRECs level at days 100 and 365 between the two groups while sjTREC increment from day 100 to day 365 was similar in the 2 groups. Finally, TLI conditioning has no impact on immune regulatory populations (Treg and iNKT) after the transplantation.

[3]Dept. of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic
[4]Dept of Pathology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

Background. Intensive frontline therapy of follicular lymphoma remains controversial. But in the era of conventional chemoimmunotherapy, long-term progression-free survival of high-risk patients is poor and drops to only 30% in 5 years. **Aims.** A retrospective analysis of FL patients with unfavorable prognostic features receiving up-front autologous stem cell transplantation and comparison with anthracycline-based regimens. **Methods.** We studied 164 patients with newly diagnosed FL who met the GELF criteria. Forty (24%) were treated with ASCT (conditioning BEAM 200) due to high-risk disease (FLIPI, B2M, s-TK, bulky). Frontline therapy with chemotherapy only (CHT) was administered to 124 (76%) patients: CHOP/CHOP-like regimen to those with low-risk FL (n=95) and intensive protocol (Promace-Cyta-BOM/adequate intensity protocol) to intermediate-risk patients. Rituximab was added to frontline therapy in 60% and 56% of cases in ASCT and CHT group, respectively (p=ns). Maintenance immunotherapy was applied in 30% (ASCT) and 41% (CHT), p=0.22. ASCT patients shared more unfavorable prognostic features than CHT group: H-FLIPI (66% vs 34%, p=0.001), bulky disease >7cm (81% vs 51%, p=0.001), advanced clinical stage (95% vs 80%, p=0.02), elevated B2M (64% vs 39%, p=0.007). ASCT patients were significantly younger (median age 46 vs 57 years, p<0.01). **Results.** Complete remission rates were 93% and 81% in ASCT and CHT group, respectively (p=ns). Molecular CR was achieved in 89% of ASCT patients and 81% of CHT group (p=ns). After a median follow-up of 87 months (7.3 yrs), 29/40 (73%) ASCT patients are alive in the 1st CR as compared with only 68/124 (55%) in CHT group. Five-year PFS was 76% (95% CI 0.62-0.90) and 56% (95% CI 0.47-0.66, p=0.018) in ASCT and CHT group, respectively. Five-year overall survival of 95% (95% CI 0.88-1.00) in ASCT group was superior to that of 84% (95% CI 0.77-0.91, p=0.024) in CHT arm. Subanalysis of 93 patients treated with rituximab showed higher proportions of relapses and deaths in CHT group (22 events in 69 patients) than in ASCT group (4 events in 24 patients, p=0.048). Five-year PFS was higher in ASCT (86%, 95% CI 0.71-1.00) than CHT group (63%, 95% CI 0.51-0.76). Despite 23% difference in 5-year PFS in favor of ASCT, statistical significance was not achieved (p=0.08). There was no difference in OS in rituximab treated patients; only 2 (8%) ASCT patients died as compared to 10 (14%) deaths in CHT group (p=0.13).Long-term toxicity in ASCT arm is acceptable. So far, no secondary MDS or AML have been observed; during the follow-up (median 100 months), only 4 patients died (2 lymphoma, 1 prostate cancer, 1 pneumonia). **Conclusions.** Frontline ASCT is very effective in high-risk FL patients. This approach overcomes multiple negative prognostic features of the disease and leads to superior survival compared to lower-risk patients treated with chemotherapy only.Supported by grants from Czech Ministry of Education (MSM 6198959205) and Faculty of Medicine and Dentistry, Palacky University Olomouc (LF-2011-006).

SINGLE-INSTITUTION LONG-TERM OUTCOMES FOR PATIENTS RECEIVING NONMYELOABLATIVE CONDITIONING HEMATOPOEITIC CELL TRANSPLANTATION FOR CHRONIC LYMPHOCYTIC LEUKEMIA AND FOLLICULAR LYMPHOMA

B Mortensen[1], P Andersen[2], P Brændstrup[3], B Kornblit[3], H Sengeløv[4], N Andersen[4], S Petersen[4], L Vindeløv[3]
[1]Rigshospitalet, Copenhagen, Denmark
[2]Department of Biostatistics, University of Copenhagen, Copenhagen, Denmark
[3]Allogeneic Hematopoietic Cell Transplantation Laboratory, Rigshospitalet, Copenhagen, Denmark
[4]Department of Hematology, Rigshospitalet, Copenhagen, Denmark

Background. Chronic lymphocytic leukemia (CLL) and follicular lymphoma (FL) are indolent lymphoproliferative malignancies that can transform into more aggressive high-grade non-Hodgkin lymphomas. In this group of often elderly and heavily pretreated patients, the introdution of nonmyeloablative conditioning (NMC) has made allogeneic hematopoietic cell transplantation (HCT) an efficacious and safe treatment option. The results for NMC-HCT in FL have been encouraging with long term overall survival up to 85% and low relapse rates. For patients with transformed FL, a worse prognosis than in non-transformed patients has been reported. Patients with CLL generally have a lower overall survival and a higher relapse rate after NMC-HCT. **Aims and Methods.** The aim of this study was a retrospective analysis of treatment outcome after NMC-HCT in patients with FL and with CLL. Data from all patients treated in our instutition with NMC-HCT for CLL and FL from 2000 to 2011 were identified. Patient pre-HCT characteristics and outcome were analysed. **Results.** In a cohort of 85 patients (45 with CLL and 40 with FL) we observed five years overall survival (OS) and progression free survival (PFS) of 53% and 38% in the CLL group and 81% and 76% in the FL group. In the CLL group the estimated four years OS and PFS were both 86% for patients in CR at HCT and five years OS and PFS were 50% and 33% for patients not in CR at HCT. In the FL group the five years OS and PFS were 96% and 91% for patients in CR at HCT and 67% and 62% for patients not in CR at HCT. Within the FL group sixteen patients had at one or more time points in their disease history had transformed FL. The five years OS was almost identical in patients with transformed and non-transformed FL, 83% and 78% respectively (figure). **Conclusions.** Our study supports that NMC-HCT is a safe and efficacious treatment in elderly, heavily pretreated patients with FL and CLL. Especially patients with FL, and also transformed FL, seem to have a great benefit of NMC-HCT. CR at the time of HCT is an important prognostic factor.

THROMBOTIC AND HEMORRHAGIC EVENTS AFTER ALLOGENEIC HEMATOLOGIC STEM CELL TRANSPLANTATION: ANALYSIS OF 443 CONSECUTIVE PATIENTS IN A SINGLE INSTITUTION

J Labrador, E Pérez-López, L López-Anglada, L Vázquez, F Lozano, I Alberca, L López-Corral, M Sánchez-Barba, F Sánchez-Guijo, D Caballero, J San Miguel, JR González-Porras
Hospital Universitario de Salamanca, Salamanca, Spain

Background and Aims. In recent years, it has been recognized that the incidence of thromboembolic events (TEEs) in patients undergoing allogeneic stem cell transplantation (HSCT) is similar to that of patients with solid tumours. In this setting, a thromboprophylaxis strategy could be effective in preventing

TEEs in selected allogeneic HSCT recipients. However, TEEs events have been separately analyzed without taking into consideration the increasing risk of bleeding in allogeneic HSCT recipients. Here, we report the largest study for competing risk of thrombosis and bleeding in allogeneic HSCT performed to date. **Methods.** We conducted a retrospective analysis of 443 consecutive patients (age > 18 years-old) who had undergone allogeneic HSCT between 1995 and 2011 at the Hospital Universitario de Salamanca. Twelve patients who received prophylaxis or therapeutic anticoagulation at the time of HSCT admission were excluded. The primary end-points of the study were the incidence, risk factors and clinical impact of post allogeneic HSCT TEEs and hemorrhages. **Results.** Median follow-up was 20 months. The incidence of venous TEEs, arterial TEEs and bleeding episodes were 6.03%, 1.9% and 32.5 % respectively. The probability of post allogeneic HSCT venous TEEs, arterial TEEs and bleeding at 14 years were 20.7%, 6.6% and 36.6 %. The median time from allogeneic HSCT day 0 to diagnosis of venous TEEs and first bleeding episode were 211 days (range, 9 to 4080 days) and 60 days (range, 2 - 3660 days). The development of extensive chronic graft versus host disease (GVHD) was the only risk factor for the occurrence of venous TEEs post allogeneic HSCT [OR = 2.85, 95% CI (1.20 - 6.80)]. Only a trend to higher rate of arterial events was observed for patient with a BMI > 25 [OR = 2.85, 95% CI (0.81 - 12.34, p = 0.098)]. Advanced disease, ablative conditioning regimen, umbilical cord stem cell transplantation, anticoagulation after HSCT, grade acute III - IV GVHD and thrombotic microangiopathy (TMA) retained their association with bleeding events in the multivariate analyses. The median OS of patients with bleeding episodes was only 15 months, as compared to patients without bleeding episodes (122 months) (p<0.001) (Figure 1A). In the multivariate analysis, bleeding events after allogeneic HSCT retained their independent prognostic value (HR: 3.18 95% CI: 2.2). However, there was no significant difference in OS between allogeneic HSCT recipients with TEEs and allogeneic HSCT recipients without TEEs (p = 0.856) (Figure 1B). **Conclusions.** This study evaluates the incidence, risk factor and mortality of thrombosis and hemorrhage of patients undergoing allogeneic HSCT with the longest follow-up to date. The incidence of VTE was relatively high, during both early and late phase of HSCT but did not influence survival. The most important risk factor for developing this complication was the presence of extensive chronic HSCT. In contrast, bleeding which was more frequent is associated with increased mortality. The principal risk factors for bleeding were myeloablative conditioning, umbilical cord transplantation, severe thrombocytopenia after day +28 and development of grade III-IV acute GVHD or TMA.

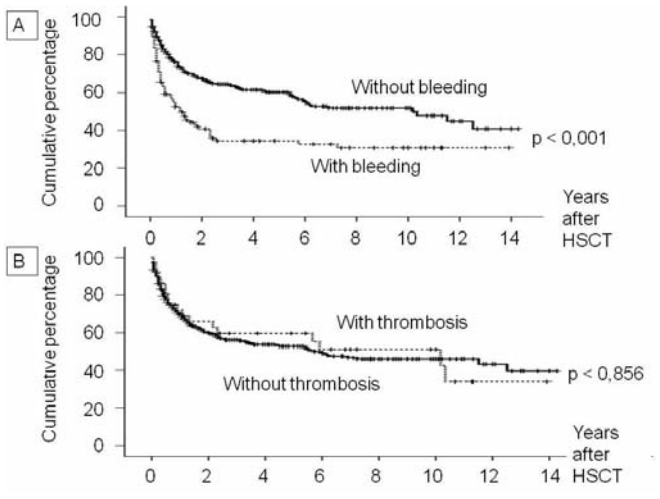

Figure 1. Overall survival of patients with and without bleeding (A), and patients with and without thrombosis (B) after allogeneic HSCT.

USE OF A BIOSIMILAR GRANULOCYTE COLONY STIMULATING FACTOR (GCSF) FOR PERIPHERAL BLOOD STEM CELL MOBILISATION PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION: AN ANALYSIS OF MOBILISATION AND ENGRAFTMENT

F Publicover, D Richardson, K Hill, M Jenner, A Davies, J Lamb, D Hutchins, H Launders, K Orchard
University Hospital Southampton, Southampton, United Kingdom

Background. Mobilisation of peripheral blood haematopoietic progenitor cells (PBPCs) has become a standard procedure for patients prior to an autologous stem cell transplant (ASCT). In September 2008 a biosimilar GCSF (Ratiograstim) was granted an EU licence for use in mobilisation of PBPCs. Ratiograstim was incorporated into clinical use for PBPC mobilisation in the Wessex Blood and Marrow Transplantation Programme from November 2008, replacing the previous form of GCSF. **Aims.** An audit of stem cell harvests was performed for the periods Jan 2007- Sept 2008 (standard GCSF) and Jan 2009-Dec 2011 with the biosimilar GCSF (Ratiograstim), comparing the CD34+ maximum predictor, total yield and number of days required for collection. In addition, we have compared engraftment data for the two groups following high dose chemotherapy and ASCT using the harvested stem cells. **Methods.** Data were retrospectively collected for 154 patients undergoing PBPC harvest at University Hospital Southampton (UHS) from Jan 2009-Dec 2011 using the biosimilar GCSF; 92 patients who underwent the procedure Jan 2007-Sept 2008 were used as a comparator group mobilised with a standard GCSF. The protocols for stem cell priming were essentially the same throughout. The p values were calculated using two tailed t tests. **Results.** Of the patients in the period Jan 2007-Sept 2008 (standard GCSF) 42 patients had myeloma, 49 lymphoproliferative diseases (LPDs) and one non-haematological malignancy. Of the patients in the period Jan 2009-Dec 2011 (biosimilar GCSF) 76 patients had myeloma, 71 LPDs, six non-haematological malignancies and one non-malignant condition. With one exception, all the patients with myeloma were primed with cyclophosphamide and GCSF. The LPD and non-haematological patients received a variety of regimens. The mean age of patients was 53.1 (±26.5, two standard deviations) years for the Ratiograstim group and 54.1 (±.23) years for the standard GCSF group.The mean number of sessions required for harvest was 1.4 (±1.2) for the Ratiograstim group and 1.4 (±1) for the standard GCSF group, with 66% of both groups completing their harvest in one session. The mean CD34x10^6/kg count per complete collection was 6.6x10^6 (±13.8) for the Ratiograstim group and 6.5x10^6 (±14.6) for the comparator group (p=0.9).Of those patients audited, 111 patients in the biosimilar GCSF group, and 57 in the standard GCSF group proceeded to high dose therapy and ASCT. Engraftment data were compared for the two groups until day of discharge. The mean number of days to a neutrophil count of 0.5x10^9/L was 13 (±6) in the Ratiograstim group and 13 (±4.8) in the standard group (n=107 and n=57, p=0.6). The mean number of days to a platelet count of >20x10^9/L was 13 (±8) in the Ratiograstim group (n=90) and 14 (±8) in the standard group (n=55)(p=0.4). **Conclusions.** This is the largest comparison of a biosimilar GCSF and standard GCSF used to mobilise PBSCs and shows no statistically significant difference between standard and biosimilar GCSF for the key parameters measured for PBPC harvest. In addition this study has not found a significant difference in time to engraftment between the two groups.

CD3/T REGS RATIO IN DONOR GRAFT DOES NOT IMPACT ON RELAPSE FREE SURVIVAL WHILE PROTECTING AGAINST AGVHD

M Delia[1], D Pastore[2], A Mestice[1], P Carluccio[1], T Perrone[1], F Gaudio[1], P Curci[1], R Angarano[1], C Germano[1], C Bitetti[1], L Perona[1], G Specchia[1]
[1]Hematology - University of Bari, Bari, Italy
[2]Hematology - Univeristy of Bari, Bari, Italy

Introduction. The therapeutic efficacy of allogeneic stem cell transplantation (alloSCT) for hematological malignancies relies largely on the graft versus leukemia (GVL) effect exerted by the donor CD3 cells, but an uncontrolled graft-versus-host-disease (GVHD) bears a risk of complications. On the other hand, T regs cells (CD4+CD25^{high} Foxp3+) are believed to maintain tolerance and to inhibit GVHD after alloSCT; also, the Foxp3 gene encodes a transcription factor that is a key for thymic development, so T regs cells could also preserve an optimal microenviroment for the reconstitution of functional immunity after alloSCT. **Patients and methods.** In this study we analyzed the graft CD3+/Tregs ratio (gCD3/Tregs R) and determined its impact on acute GVHD (aGVHD), immunological recovery and survival rates (OS and RFS) after myeloablative alloPBSCT. We analyzed 75 consecutive patients transplanted with unmanipulated peripheral blood stem cells from an HLA identical related donor (n=50) or an HLA identical unrelated donor (n=25); diagnoses were acute

myeloid leukaemia (n=62), acute lymphoblastic leukaemia (n=13).The median CD3+ and Tregs dose administered was 238 (range (r): 67-550) and 12,5x10^6/Kg (r: 2-21), respectively; the median gCD3/Tregs R was 19 (r: 8-250). Patients were subdivided into a high gCD3/Tregs R (>=36) group (n= 31) and a low gCD3/Tregs R (<36) group (n=44). **Results.** The incidence of aGVHD (grade II-IV) in the low gCD3/Tregs R (LR) group was lower than in the high gCD3/Tregs R (HR) group (9/44 or 20% vs 24/31 or 77%, p<.001). At multivariate logistic regression, gCD3/Tregs R was correlated both with aGVHD (Odds Ratio (OR): 2.60, 95% CI (1.35,4.90), p=.05) and with CMV infection/disease (OR: 2.45, 95% CI (0.8,5.50), p=.05). The mean OS time was significantly affected by gCD3/Tregs R (32 vs 67 months in the H and LR group, respectively, p<.001); on the contrary, there was no difference with regard to RFS (mean RFS time: 64 vs 65 months; p=.90). **Conclusions.** Taken together, our data may suggest that Tregs content is able to mediate protective effects against aGVHD, while maintaning GVL effect, as suggested by RFS median time equality between H and LR group.Larger studies are needed in order to understand the real contribution of gCD3/Tregs R on control of both GVHD and leukemia. HIGH 7 YEAR-SURVIVAL RATES IN ADULT LYMPHOBLASTIC LYMPHOMA AFTER TREATMENT WITH A NORWEGIAN INTENSIFIED ALL INDUCTION, HIGH-DOSE BEAM, AUTOLOGOUS STEM CELL SUPPORT AND MEDIASTINAL RADIATION THERAPY

G Lauritzsen[1], H Bersvendsen[2], A Kolstad[1], A Fossså[1], E Aurlien[1], G Lehne[1], AK Blystad[1], J Delabie[1], S Kvaløy[1], G Kvalheim[1], H Holte[1]
[1]The Norwegian Radium Hospital, Oslo University Hospital, Oslo, Norway
[2]University Hospital of Nothern Norway, Tromsø, Norway

Lymphoblastic lymphoma is a highly aggressive disease with reported overall (OS) and event free (EFS) survival of 46-72%. Many achieve CR by acute lymphoblastic leukaemia (ALL) -like regimens, but often progress or rapidly relapse.Since 1999 we have treated adult patients with T- (T-LL) or B- (B-LL) lymphoblastic lymphoma with 4 months of the Norwegian intensified ALL regimen adapted from the MRC Leukaemia Unit , London, as induction and first consolidation, and if in CR/CRu, followed by high-dose BEAM with autologous stem cell support (ASCT). Patients with mediastinal tumour at diagnosis, received radiotherapy 23.4 - 30 Gy at end of treatment.During 1999-2010 twenty five patients were admitted with lymphoblastic lymphoma to The Norwegian Radium Hospital: median age 32.5 years (15-65), male/female 60/40%, T-LL/B-LL 76/24%, stage I-II/III-IV 24/76%, B-symptoms 32%, high LDH 68%, bulky tumour (≥10 cm) 48%, minimal (≤25%) bone marrow involvement 20%, significant bone marrow involvement (>25%) 4%, CNS involvement 12%.Induction therapy included prednisone, vincristine and L-asparaginase, with doxorubicine weekly for three weeks and cyclophosphamide weekly for three weeks. Consolidation was daunorubicin, cytarabine and 6-thioguanine (RAT), followed by 2 doses of high-dose methotrexate (MTX) and continuous 6-mercaptopurine orally for 7 weeks. Intrathecal MTX was administered x 7. Stem cells were harvested after RAT.Four patients received other drugs for one course prior to inclusion. One patient was treated with enforced consolidation with MTX and Ara-C due to cranial nerve involvement and young age (15yrs). Another young (15yrs) patient was treated according to the BFM-95 regimen prior to BEAM and ASCT due to solely involvement of the central nervous system.23 of 25 patients completed ASCT. 16 of 17 patients with mediastinal involvement received radiotherapy. One patient with t(9;22) (BCR-ABL translocation) and bone marrow involvement, who was considered too fragile for allogeneic transplantation, received imatinib as maintenance treatment post-ASCT.At median follow up of 7 years (1-153 months) of the whole cohort, OS and EFS survival are 84% and 76%, respectively. 19 of 25 are alive in first CR. Two patients died due to toxicity (veno-occlusive disease and cerebral sinus venous thrombosis), one due to progressive disease (T-LL) prior to ASCT and one from relapse (T-LL) two years after treatment. Two patients (B-LL), who relapsed at 5 and 25 months of follow up, respectively, are in second CR after reinduction with hyperCVAD and myeloablative allogeneic stem cell transplantation. In 2 of 4 relapsing patients the disease returned as lymphoblastic leukaemia.No secondary cancers are reported. None has developed heart failure or permanent clinically reduced lung function. Disabling polyneuropathy is seen in two patients, both highly overweight at diagnosis. Surgical treatment due to osteonecrosis in large joints is done in three patients, all males. Three females got pregnant after treatment, one by egg donation and four males have become fathers, either by cryopreserved sperm or fresh samples. **Conclusions.** We report 84% OS and 76% EFS in lymphoblastic lymphoma 7 years after the Norwegian intensified ALL induction, high-dose BEAM with ASCT and radiotherapy consolidation to the mediastinum in a population-based cohort.

0455

HIGHER INCIDENCE OF SEVERE PNEUMONIA AFTER CONDITIONING WITH BUSULFAN-FLUDARABINE COMPARED TO BUSULFAN-CYCLOPHOSPHAMIDE IN A PERSPECTIVE, RANDOMIZED STUDY

DH Liu[1], XJ Huang[2], LP Xu[2]
[1]Intitute of Hematology, Beijing, Cocos Islands
[2]Institute of Hematology, Peking University, Beijng, China

Background. Cytarabine-busulfan-phosphomide (CBuCy) regimen has been the most frequent types of myeloablative conditioning used in allogeneic hematopoietic stem cell transplantation (HSCT) in our center. However, its non-hematologic toxicities and related mortality were still concerned. Fludarabine showed its safety and efficacy in non- myeloablative conditioning regimens. However, whether cyclophosphomide in CBuCy could be substituted with fludarabine is unknown. Therefore, we designed the perspective, randomized, comparative study. **Aims.** To investigate whether CBuCy could be substituted with Cytarabine - busulfan - fludarubine (CBuF) in HSCT from identical siblings. **Methods.** The elements of conditioning CBuF and CBuCy were described in Table 1. 105 patients were enrolled,52 in CBuF group and53 in CBuCy group. At baseline both groups were matched for characteristics demographics and disease. Surviving patients were followed up to 20 February, 2012. The primary study endpoints were overall survival (OS), engraftment, and acute GVHD. The secondary endpoints were leukemia-free survival (LFS), relapse, non-relapse mortality (NRM), conditioning toxicity and chronic GVHD. **Results.** All patients in CBuF achieved neutrophils and platelets engraftment. Fifty-two (98.1%) patient from the CBuCy group achieved neutrophils engraftment and 51 platelets engraftment (96.2%). There were 43 and 46 patients from the two groups did not develop acute GVHD. The incidences of acute GVHD grade 1-4 (P = 0.577) or 3-4 (P = 0.189) were not significantly different. Ninety-eight patients (49 in each group) were evaluated for occurrence of chronic GVHD. No difference in the incidence of chronic GVHD (P = 0.590), extensive GVHD (P = 0.241) was found. Up to 20th of February, 2012, 37 patients from CBuF group and 36 from CBuCy survived. Thirty-two patients died, 19 died of non-relapse (NRM) causes and 13 died of recurrence of disease. The 2 yr probability of OS was 70.5% and 69.1% (P = 0.912), and LFS was 61.4% and 64.5% (P = 0.714), respectively. No difference of NRM (P = 0.192) or relapse (P = 0.415) between the two groups was found.Within the first 2 weeks after transplantation, there was no difference in occurrence of hematological toxicities, diarrhea, liver or renal dysfunction. In CBuF group, lower incidence of nausea and vomiting (9.6% vs 28.3%, P = 0.024) and higher incidence of mucosal damage (65.4% vs 32.7%, P = 0.002) was found compared to CBuCy group.Thirty patients developed pneumonia, 18 of these were severe and accompanied with respiratory failure. Ten patients died of severe pneumonia. The cumulative incidence of severe pneumonia in CBuF group was higher than that in CBuCy group (30.6% vs 13.1%, P = 0.05), however, no difference in pneumonia related mortality was found (P = 0.057). The study started from March of 2009, and was closed on 20th, August of 2010 due to this severe side effect. **Conclusions.** This is the first randomized, perspective study to compare CBuF and CBuCy for allogeneic HSCT. It should be cautious to substitute cyclophosphomide with Fludarabine in the context of cytarabine/busulfan/phosphomide based conditioning due to the pulmonary morbidity.

Table 1. Conditioning regimens for allo-HSCT from identical siblings.

HSCT(d)	Modified BUCY	Bu-Fludarabincin

THE OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN KOREAN CHILDREN WITH HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

KN Koh[1], HJ Im[2], JJ Seo[2]
[1]Asan Medical Center, University of Ulsan, College of Medicine, Seoul, South-Korea
[2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

Background. Although chemoimmunotherapy-based treatments have improved the survival of patients with hemophagocytic lymphohistiocytosis (HLH), outcomes of the patients with familial hemophagocytic lymphohistiocytosis (FHL), or refractory or reactivated HLH are still unsatisfactory. **Aims.** This study was conducted to evaluate the prognostic factor and treatment outcome of Korean children with HLH who underwent allogeneic hematopoietic stem cell transplantation (HSCT). **Methods.** We analyzed the data of Korean nationwide HLH registry. Retrospective nationwide data recruitment for the pediatric HLH patients diagnosed between 1996 and 2011 was carried out by the Korea Histiocytosis Working Party. **Results** Thirty patients who received allogeneic HSCT among the total of 279 enrolled children with HLH were analyzed. Conditioning regimen included busulfan/cyclophosphamide/etoposide with or without antithymocyte globulin (ATG) (n = 20), busulfan/fludarabine/ATG (n = 3), fludaraibe/melphalan with ATG or alemtuzumab (n = 4), and others (n = 3). The probability of 5-year overall survival (OS) after HSCT was 75.4% with a median follow-up of 72 months. The reasons for HSCT were active disease after 8 weeks of initial treatment (n = 10), reactivated disease (n = 10), and FHL (n = 10). Eight of the 10 patients with FHL were shown to have mutations of the *UNC13D*. Twenty-three patients are currently alive without disease after HSCT, whereas 6 patients died of treatment-related events at early post-transplant period, and 1 patient died of reactivation at 1 year post transplantation. The survival of patients who were transplanted because of active disease after 8 weeks of initial treatment was inferior compared to those patients who had inactive state at that time (62.2% vs. 100%, respectively, P = 0.031). Patients who received cord blood graft (n = 6) showed significantly inferior OS than those who received bone marrow (n = 15) or peripheral blood graft (n = 9) (33.3% vs. 80.0% vs. 100%, P = 0.025). The 5-year OS rate after HSCT according to the donor type was 75.0% for the matched related donors (n = 8) and 74.8% for the unrelated donors (n = 22) (P = 0.813). Other variables such as age, CNS involvement at the time of diagnosis, the etiology of HLH (familial or secondary), and the conditioning regimens had no influence on the survival outcome of the HLH patients who underwent HSCT.5. **Conclusions.** HSCT improved the survival of the patients who had familial, reactivated, or severe and persistent secondary HLH in the Korean nationwide HLH registry. The disease state after initial treatment and the stem cell source were the important prognostic factors. The impact of the intensity of the condition regimen and the graft source on the outcome is required to be evaluated in the prospective trial.

NINE NOVEL ADAMTS13 MUTATIONS IN CONGENITAL PREGNANCY ASSOCIATED ADULT ONSET TTP

K Langley, E Heelas, M Underwood, J Iseppi, I Mackie, S Machin, M Scully
UCL, UK, United Kingdom

ADAMTS13 (a disintegrin and metalloprotease with thrombospondin type I domains 13) deficiency is associated with thrombotic thrombocytopoenia pupura (TTP), a rare, life threatening thrombotic microangiopathic anaemia. TTP may be acquired, usually due to the presence of autoantibodies, or congenital. The congenital form can present in childhood, adolescence or adulthood, but in adults usually occurs secondary to haemostatic challenge. The differences in age of onset are likely to result from the individual repertoire of mutations in the ADAMTS13 gene, located on Chromosome 9.DNA sequencing was performed on nine patients with pregnancy associated, adult onset TTP, two of whom were sisters. Eight of the patients were Caucasian and one of Asian origin. All the patients presented with a markedly reduced ADAMTS13 activity of < 5% (FRETs NR 60-123%) and negative for anti-ADAMTS13 IgG autoantibody. Using population data from the 1000 Genomes Project and Hapmap we confirmed the presence of 3 single nucleotide polymorphisms (SNPs), 10 synonymous SNPs, 5 missense mutations, 4 frame shift mutations and 4 intronic mutations.Six novel exonic mutations and 3 novel intronic mutations were identified. These included two exonic missense mutations: R497C and R1219Q. Four frame shift mutations were found: p.A111QfsX18, p.N667TfsX31, p.M486VfsX47 and p.I1339SfsX21, one of which occurred in both of the two siblings. The intronic mutations detected were c.L987+11, c.L1786+90 and c.Q1245+81. Some SNPs had a higher prevalence in our patients than anticipated from normal population frequencies, for example R7W is present in 7% and A1033T is present in 3% of the general Caucasian population, but were found in 7 of the 8 Caucasian patients studied. Exons 4,6,13,15 and 24, exclusively in our cohort, demonstrated several differences from wild type, whereas exons 2,3,7,9,10,14,20,22,25,27 showed no variation from wild type in any of the patients investigated. Notably, seven of the nine patients had both the R7W and A1033T SNPs in conjunction with the R1060W mutation. The patients' full mutational profile (including synonymous mutations) was examined in the context of their clinical features. One patient with a moderate clinical profile; only one heterozygous missense mutation (R1060W) and relatively few exonic differences from wild type (R7W, A900V, A1033T, V970V) however had three intronic mutations. It is not yet understood how these may interact to influence the clinical picture, or how their position on the allele may contribute. In conclusions in conjunction with further novel mutations in our cohort, we have also documented a higher frequency of SNPs and intronic mutations in association with synonymous SNPS, further work will focus on how these new findings result in changes in expression and function of ADAMTS13 in relation to TTP.

PLASMA CONCENTRATION OF PROTEIN Z AND PROTEIN Z-DEPENDENT PROTEASE INHIBITOR IN PATIENTS WITH HAEMOPHILIA A

L Bolkun[1], M Galar[2], D Lemancewicz[2], K Mazgajska-Barczyk[2], E Cichocka[2], J Kloczko[2], J Piszcz[2]
[1]University Hospital, Bialystok, Poland
[2]Haematology Department, Bialystok, Poland

Background. The potential role of alterations in protein Z concentrations in the pathogenesis of coagulation has been investigated in several studies which, however, yielded conflicting results. Protein Z deficiency may induce bleeding as well as prothrombotic tendencies and it might occur as an inherited disorder. **Aims.** The purpose of the present study was to explore the concentration of protein Z and protein Z-dependent protease inhibitor in patients with haemophilia A. Additionally; it examined the correlation between PZ/ZPI plasma concentration and bleeding rate and joint bleeding per year. **Materials and Methods.** The study was based on fifty male patients: 25 with severe, 15 with moderate and 10 with a mild form of haemophilia A. Median age at the time of samples taking was 29 (range 19-55 years). None of these patients had undergone prophylaxis of bleeding with FVIII (factor VIII) before the study. All studied subjects received FVIII on demand, doses depending on the kind of bleeding. Haemophilia A patients with confirmed hepatitis B or C and with inhibitor of factor VIII had been excluded from the study. The control group consisted of 90 healthy male blood donors at median age of 30 (range 19-52). The yearly bleeding rate and joint bleeding rate were calculated on the basis of data from medical records and home-treatment reports from 2005 to 2011.Quantitative assessment of protein Z and ZPI in the plasma was performed using commercial test (Asserachrom Protein Z Elisa Kits, Diagnostica Stago, France) with expected mean value (±SD), 1.56±0.61µg/mL) and Enzyme-linked Immunosorbent Assay Kit for Protein Z Dependent Protease Inhibitor (ZPI) (USCN Life Science Inc, China). Quantitative determination of FIX in the plasma was done using Stago® Deficient IX (Stago,France), with expected normal range of factor IX between 60-150%. Active form of FVIII was tested by means of standard methods. **Results.** In haemophilia A patients mean plasma concentrations of PZ and ZPI were significantly higher than in healthy individuals: PZ (1.87±0.68 µg/mL vs 1.49±0.54 µg/mL) and ZPI (5.02±1.11 µg/mL vs 4.22±0.55 µg/mL), with p=0.02 and p=0.03, respectively. In the subgroup with severe haemophilia A, an in-depth analysis revealed a tendency to modulating effect of the PZ (r=-0.53; p=0.072) and a statistically significant one in the case of ZPI (rho=-0.79, p=0.002) on the bleeding rate. It simultaneously disclosed a statistically significant correlation between the number of bleeds to the joints (20.18±14.1), PZ (r=-0.72; p=0.04) and ZPI (rho=-0.88, p=0.001). With reference to this particular group of patients, the study also showed some other statistically meaningful correspondences: between PZ and ZPI (rho=0.65, p=0.02), PZ and FIX (r=-0.61, p=0.04), as well as ZPI and FVIII (rho=0.78, p=0.002).No such link in patients with mild and moderate haemophilia A was established. **Conclusions.** Despite the fact that FVIII deficiency is undoubtedly the main mechanism of bleeding in haemophilia A patients, the activity of PZ/PZI complex may play some modulating role in the matter. Further research is required to fully elucidate the haemostatic role of ZP/ZPI complexes in haemophilia A patients.

LOCAL EXPERIENCE IN REVERSAL DABIGATRAN USING ACTIVATED PROTHROMBIN COMPLEX CONCENTRATES (FEIBA)

KC Cheung, S Rodgers, S Mcrae
IMVS, Adelaide, Australia

Background. Dabigatran etexilate (Pradaxa, Boehringer Inhgelheim) is a prodrug of dabigatran, a reversible direct inhibitor of thrombin that exhibits its effect by binding directly to the active site of thrombin. The major advantage of dabigatran over warfarin is that it produces a predictable pharmaco-dynamic effect which renders routine laboratory monitoring unnecessary. Several studies demonstrated that the efficacy of dabigatran is at least comparable to that of current therapies in preventing stroke related to atrial fibrillation and venous thrombosis following hip and knee replacement surgeries.Like other anticoagulants, Dabigatran is associated with a risk of major bleeding with an expected rate of 1-2% per annum receiving therapeutic anticoagulation. The optimal management of a major bleeding complication occurring in patients receiving Dabigatran remains uncertain, and current recommendations regarding the use of reversal agents are based on a combination of pre-clinical data, anecdotal case reports and the absence of effective alternatives. **Aims.** To determine the usefulness of the CAT in determining the effect of dabigatran at therapeutic concentrations, and to measure the effect of activated prothrombin complex concentrate (FEIBA®, Baxter AG, Vienna, Austria) in reversing the haemostatic defect induced by dabigatran. **Methods.** The thrombin generation assay was performed in platelet poor plasma (PPP) using the Calibrated Automated Thrombogram (CAT) (Thrombinoscope). Commercial plasmas containing a range of concentrations of dabigatran (30 to 500 µg/L) were tested. Different therapeutic concentrations of FEIBA (0.2 - 3 U/ml) were added to a test plasma containing approximately 200 µg/L dabigatran. Commercial PPPLOW reagent (1 pM Tissue factor with 4 µM phospholipids) and Fluorogenic substrate (FluCa) were used (Thrombinoscope) according to manufacturer's manual. **Results.** Dabigatran induced a concentration-dependent increase in lag time and time-to-peak, as well as a decrease in peak height and ETP at higher concentrations (>130 µg/L). Addition of FEIBA to the test sample decreased the lag-time and time-to-peak in a concentration-dependent manner between 0.2 and 1U/ml FEIBA, with no further decrease with 2 and 3 U/ml FEIBA. At all concentrations both times remained prolonged in comparison to normal. Peak height and ETP was increased to normal values by 0.2 U/ml FEIBA, with further increases above normal up to 1 U/ml, and no further increase with higher concentrations of FEIBA. **Conclusions.** Our results demonstrated that FEIBA partially reversed dabigatran mediated inhibition of thrombin generation (i.e. shortening of delay in lag time and increasing peak response). Future experiments should be conducted to determine the in-vivo effect of FEIBA in reversing dabigatran in overdosed patients, correlated with clinical outcomes.

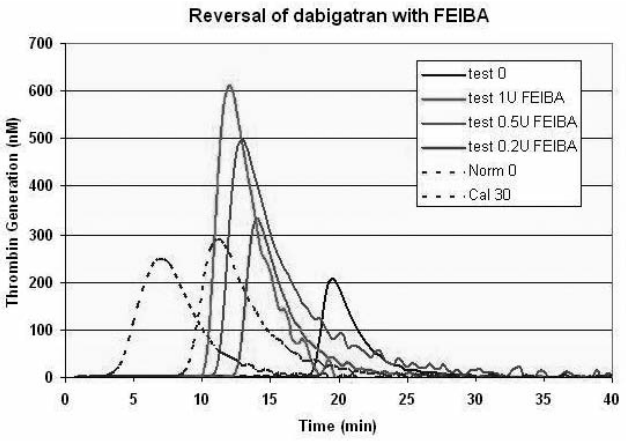

Figure 1. Partial reversal of delay in lag time in Thrombinoscope by Feiba in test sample.

A NOVEL FLOW CYTOMETRY-BASED PLATELET AGGREGATION ASSAY THAT DISCRIMINATES BETWEEN GLANZMANN THROMBASTENIA AND LAD-III SYNDROME.

L Gutiérrez[1], I De Cuyper[1], M Meinders[1], E Van de Vijver[1], A Gerrits[1], D De Korte[1], L Porcelijn[2], M De Haas[2], K Seeger[3], A Verhoeven[4], T Kuijpers[5], T van den Berg[1]
[1]Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands
[2]Sanquin Diagnostics, Amsterdam, Netherlands
[3]Otto-Heubner-Center for Pediatric and Adolescent Medicine, Charité-Universitätsm, Berlin, Germany
[4]AMC, Amsterdam, Netherlands
[5]Emma Children's Hospital, AMC, Amsterdam, Netherlands

Background. The main function of platelets is to maintain normal hemostasis. Several platelet function tests have been developed to date to be used in the clinic and in experimental animal models. In particular, platelet aggregation is routinely measured in an aggregometer, which requires normal platelet counts and significant blood sample volumes, making difficult analyses in thrombocytopenic patients or infants. For the same reason, analysis of platelet aggregation in small rodents can be tedious. Patients with Glanzmann thrombasthenia or Leukocyte Adhesion Deficiency-III syndrome (LAD-III or LAD-1/variant) present with increased bleeding tendency because of the lack or dysfunction of the fibrinogen receptor GPIIb/IIIa (integrin αIIbβ3), respectively. Although the bleeding disorder is more severe in LAD-III patients, classic aggregometry or perfusion of Glanzmann or LAD-III platelets over collagen-coated slides under physiologic shear rate does not discriminate between these 2 conditions because it requires functional integrin αIIbβ3 as a readout. **Aims.** To develop a novel test of platelet aggregation, in which lower platelet counts or volumes can be used, and that would allow dissection of single receptor contribution to the platelet aggregation process. **Methods.** Platelet labeling with fluorescent dyes or conjugated antibodies, flow cytometry. **Results.** We have developed a novel flow cytometry test of platelet aggregation, in which 10-25-fold lower platelet counts or volumes can be used, either from platelet-rich plasma or whole blood (including murine embryonic blood) from human subjects or mice. Furthermore, this novel test is able to discriminate between Glanzmann thrombasthenia and LAD-III aggregopaties. We were able to measure collagen-dependent aggregate formation in Glanzmann platelets, whereas LAD-III platelets were not able to form aggregates upon this stimuli. These aggregates required functional GPIa/IIa (integrin α2β1) instead of integrin αIIbβ3, thus explaining the clinically more severe bleeding manifestations in LAD-III patients, in which all platelet integrins are functionally defective. These findings provide genetic evidence for the differential requirements of platelet integrins in thrombus formation and demonstrate that correct integrin function assessment can be achieved with a combination of diagnostic methods**. Summary and Conclusions.** This set-up can be applied to test in small assay volumes the influence of a variety of stimuli, drugs and plasma factors, such as antibodies, on platelet aggregation. The presented principle stands as a promising user-friendly tool, which allows analysis of platelet aggregation in thrombocytopenic patients or infants, and facilitates studies in platelets obtained from experimental animal models without the need of special devises but a flow cytometer.

NOVEL VON WILLEBRAND GENETIC MUTATION (C.4097T>G) ASSOCIATED WITH VON WILLEBRAND DISEASE TYPE 2M

A Danaee, D Bevan, J Cutler, M Mitchell
Guys and St Thomas' Hospital, London, United Kingdom

We report a previously unreported von Willebrand Factor (vWF) gene mutation associated with an unusual phenotype of von Willebrand Disease (probable vWD Type 2M) characterised by markedly reduced vWF Ristocetin co-factor activity (vWF:RCo) in the presence of normal or high von Willebrand Factor antigen (vWF:Ag), von Willebrand Factor Collagen Binding Acitivity (vWF:CBA), and FVIII:C activity.The proband C (female, 55yrs) and both her daughters (J, 26yrs; L, 28yrs) were referred for investigation of a bleeding disorder. The father of J and L was already known to have mild haemophilia A. C was found to have normal plasma vWF:Ag (120iu/dL; nr 45-160iu/dL) and vWF:CBA (95u/dl; nr 35-140u/dL) but reduced vWF: RCo of 25 iu/dl (nr 54-202iu/dL). Her blood displayed delayed closure times in both collagen/ADP and collagen/epinephrine cartridges in the PFA-100® system. Low resolution Von Willebrand Factor multimeric analysis (Phast system) showed a normal distribution with no deficit in HMW multimers. Her factor VIII:C was 140iu/dl (nr 50-150iu/dL).DNA analysis of the von Willebrand Factor (VWF) gene detected a heterozyogus substitution in exon 28 of her VWF gene (c.4097T>G). This mutation corresponds to the replacement of native phenylalanine at codon 1366 with a cysteine (p.Phe1366Cys). This mutation has not previously been reported but *in silico* analysis strongly supports its being pathogenic and it is in the same region as several other mutations associated with a Type 2M phenotype (E1359K, V1360A, K1362T and F1369I). The associated phenotype suggests that this mutation results in a highly selective effect on vWF binding to its platelet receptor, demonstrated by low ristocetin cofactor activity in the washed-platelet ristocetin co-factor assay without evidence of reduced vWF function in other modalities.Both daughters inherited this mutation, and the associated Type 2M von Willebrand Disease phenotype, from their mother, in addition to inheriting their father's factor FVIII mutation (p.Tyr551Cys). This resulted in J manifesting a mild bleeding disorder with the combined phenotype of Type 2M vWD (vWF:RCo 12.5iu/dL; vWF:Ag 61iu/dL) and mildly-affected carrier of Haemophilia A (FVIII:C 40iu/dL).L. had a FVIII:C level of 64iu/dl (indicating non-affected carrier status for Haemophilia A), vWF:RCo of 19iu/dl, vWF:Ag 79iu/dl. Both sisters also had normal vWF:CBA assays, normal vWF mulimer composition and prolonged closure times in both cartridges of the PFA-100® system.

CONGENITAL FXI DEFICIENCY: EVALUATION OF POST-SURGERY BLEEDING PHENOTYPE AND CORRELATION WITH FXI ACTIVITY (FXI:ACT)

C Santoro, R Di Mauro, E Baldacci, F Biondo, R Abbruzzese, P Pignoloni, R Foà, MG Mazzucconi
Hematology, Rome, Italy

Background. The bleeding phenotype in FXI deficiency is variable and generally related to surgery/trauma. Moreover, there is a poor correlation between bleeding and baseline FXI:Act. **Aims.** To describe the post-surgery hemorrhagic phenotype of our FXI deficient population and to relate the phenotype with FXI:Act. **Patients and Methods.** Since 1973, we have been following 50 FXI deficient patients: 26 F, 24 M; median age at diagnosis: 34 years, range 1.7-79.6; median follow-up: 1.9 years, range 0.1-36.2; positive family history: 18; median FXI:Act of all patients: 37% (range 0.25-60%; normal values: 70-140); FXI:Act ≤1% in 4 patients, >1≤5% in 10, >5 ≤10 in 2, >10 ≤20 in 3, >20 in 31. **Results.** Eighteen patients experienced bleeding episodes not surgery-related: ecchimoses in 14, hematomas in 7, epistaxes in 11, gastrointestinal hemorrhages in 7, meno-methrorrhagia in 1.Prior to diagnosis, 15 patients underwent 69 major/minor surgeries without prophylaxis: 21 hemorrhages were reported. The median FXI:Act in the bleeders was: 28%, range 0.25-53%. Ten spontaneous deliveries (SD) and 5 caesarian sections (CS) were performed: 1 post-partum hemorrhage occurred (patient FXI:Act 27%). Twenty-eight patients underwent dental surgeries, 7 experienced hemorrhages (bleeders median FXI:Act: 6.9%, range 1-43%). Post-diagnosis, 13 minor/major surgeries were performed, 8/13 with anti-hemorrhagic prophylaxis: plasma in 3 cases, plasma and tranexamic acid in 2 cases, tranexamic acid in 2 cases, desmopressin in 1: no bleedings were reported. Three dental exctractions were performed, 1 prophylactically treated with plasma and tranexamic acid: one bleeding was reported in a patient who self-administered anti-inflammatory drugs (FXI:Act 45%). One CS and 1 SD were performed: desmopressin was used as prophylaxis in 1 case: no bleedings reported. **Conclusions.** We confirm the wide variability in post-surgery bleeding events in FXI deficient patients, not related to the FXI:Act levels. Because of the low correlation between FXI:Act and the phenotype, we highlight the need of laboratory-based prognostic factors for a better management of these patients.

0464

INDIVIDUALIZED REPLACEMENT OF FACTOR VIII ACCORDING TO THE *IN VIVO* RECOVERY IN HEMOPHILIA A PATIENTS DURING SURGERY

KS Lee[1], YJ Shim[2], JK Suh[1]
[1]Kyungpook National University Hospital and School of Medicine, Daegu, South-Korea
[2]Kyungpook National University Medical Center and School of Medicine, Daegu, South-Korea

Backgroud and Aims. Although patients' individual pharmacokinetics is considered very important in hemophilia, there have been few reports about the practical result after direct application of individual *in vivo* recovery (IVR) to the surgery. Thus we investigated the correlation between individual IVR and the outcome of each operation. **Methods.** The hemophilia A patients who had blood tests for IVR just before each operations from January 2000 to January 2012 were reviewed. The patients with inhibitor (anti-FVIII) were excluded. The respective surgery cases were divided into 3 groups; A (IVR > 80% of expected), B (IVR < 80% of expected, but they were managed by immediate additional replacement of FVIII), and C (IVR < 80% of expected and the extra supplementations of FVIII were delayed over 3 days). Their each consumption of FVIII and hospitalization periods was analyzed. The Mann-Whitney U test (SPSS ver. 19) with bonferroni adjustment was used to compare inter-group differences.4. ResultsTwenty hemophilia A patients underwent total 27 various operations. Twelve patients were severe (FVIII:C < 1 IU dL^{-1}), 4 patients were moderate (FVIII:C 1-5 IU dL^{-1}), and the remainder were mild (FVIII:C > 5 IU dL^{-1}) hemophilia A. They were all males. Their mean age at the time of surgery was 32 (range from 0 to 69) years old, and mean number of surgery they received was 1.4 (range 1 to 3) times. The total dose of FVIII was respectively 31,693 ± 22,858 (mean ± SD) IU in group A, 53,389 ± 48,778 IU in B, and 166,596 ± 149,327 IU in C. There was no statistical difference between them. The FVIII dose per patient's body weight was respectively 481 ± 195 IU kg^{-1} in group A, 1,311 ± 283 IU kg^{-1} in B, and 3,502 ± 1,529 IU kg^{-1} in C. The mean value was lower in group A than B ($p < 0.001$), and in group B than C ($p = 0.006$). The hospitalization period was respectively 14.5 ± 12.1 days in group A, 13.9 ± 4.0 days in B, and 45.8 ± 15.7 days in C. There was no extension of hospitalization in group B in comparison with A ($p = 1.000$). The mean duration was longer in group C than A and B (respectively, $p = 0.015$ and $p = 0.006$). **Summary and Conclusions**. The medical costs were much more expensive in low IVR groups (B and C) than high IVR group (A) according to our expectation. However, the immediate extra supplementation of FVIII reduced the hospitalization period as well as economized the FVIII consumption per body weight in low IVR group (B). It is very important to check IVR on all occasions just before surgery and supply the FVIII according to the result to minimize the medical cost.

0465

CASE STUDY OF THE USE OF INTRANASAL BEVACIZUMAB TO TREAT RECURRENT EPISTAXIS DUE TO HEREDITARY HAEMORRHAGIC TELANGECTASIA

C Alderman, J Corlett, J Cullis
Salisbury District Hospital, Salisbury, United Kingdom

Background. Hereditary Haemorrhagic Telangectasia (HHT) is an autosomal dominant condition with a prevalence of approximately 1:10,000 of the population. Severe cases present with recurrent bleeding and may require regular blood transfusions or intravenous iron. Several genetic mutations have been associated with HHT and many of these encode proteins that are involved in the vascular endothelial growth factor (VEGF) and transforming growth factor-β (TGF-ß) signalling cascades. Furthermore, plasma levels of VEGF and TGF-ß are increased in patients with HHT. Limited published data suggest that interruption of VEGF signalling by Bevacizumab (a humanised monoclonal VEGF inhibitor) may represent a potential therapy for patients with HHT. **Aims.** Our aim was to assess the potential off label use of topical Bevacizumab to treat patients with severe epistaxis due to HHT. **Methods.** We treated a 65 year old male patient with a life-long history of severe epistaxis due to HHT. He was dependent upon regular iron infusions and had also required frequent blood transfusions as well as pulsed dye laser therapy given monthly for over 20 years. A history of pulmonary embolism and intracoronary stents precluded use of antifibrinolytic drugs or intravenous Bevacizumab.After informed consent was obtained, we injected a total dose of 100 mg of undiluted Bevacizumab via an intranasal atomization device given in 100 µL volumes to each nostril every five minutes until completion of the 4 mL ampoule. This was repeated on a monthly basis for three months. The severity of his symptoms were assessed using a normalised Epistaxis Severity Score (ESS) to give a value out of 10. **Results.** After three months, subjectively, his quality of life had improved remarkably. His average daily duration of epistaxis reduced from 17 to less than 2 minutes. Objectively, his ESS has reduced from 10 to 3, and his need for pulsed dye laser therapy has diminished. **Summary and Conclusions.** Bevacizumab can be sprayed intranasally to treat severe recurrent epistaxis due to HHT. We are planning to investigate further the potential of this therapeutic approach in further patients with severe epistaxis due to HHT. We anticipate that, in addition to the above therapeutic benefits, patients will require fewer blood transfusions and less intravenous iron support. It is, therefore, likely that there will also be a significant economic advantage to this novel treatment.

0466

PLATELET FUNCTION DIAGNOSTIC LABORATORY INVESTIGATION IN THALASSAEMIC PATIENTS

S Theodoridou[1], M Economou[2], A Teli[1], E Vlachaki[1], D Kleta[1], A Karioti[1], A Agapidou[1], N Kouri[1], S Vakalopoulou[2], V Garypidou[2], N Gompakis[2], F Papachristou[2]
[1]Hippokration Hospital, Thessaloniki, Greece
[2]Aristotle University, Thessaloniki, Greece

Platelet function disorders constitute a rare cause of symptomatic bleeding. Haemostatic disorders are reported in thalassaemic patients. The aim of this study was the platelet function investigation in thalassaemics and the detection of any relation with the chelation treatment. The platelet function investigation consisted of the aggregation testing in platelet rich plasma with light transmission aggregometry (LTG) by the use of 5 agonists (arachidonic acid, ADP, adrenaline, collagen, ristocetin), and the global test of haemostasis by PFA-100 (Dade Behring) whose principle is the *in vitro* platelet plug formation under sheer stress with either collagen and epinephrine or collagen and ADP as agonists. The P2Y12 receptor was also tested.39 thalassaemic patients (24 males, 15 females, aged 5 to 45 years) were included. Patients were on chelation treatment with either deferasirox (18 patients), or deferiprone, desferioxamine or both (21 patients). Eight were splenectomised and six received aspirin as prophylactic treatment, seven patients had a liver biopsy. No haemostatic cover was used and no untoward bleeding was reported. One patient had experienced a peptic ulcer bleeding. Four cases with chronic viral hepatitis were included.RESULTS66% (26) of the patients showed reduced LTG with adrenaline and 20% (8) showed reduced LTG to two or more of the agonists used. 34 patients were tested with PFA-100 and was prolonged in 73% (25) of them. 43,5% (17 patients) had both a defect in platelet aggregation and a prolonged PFA-100 test, while 10,2% (4) had abnormal LTG and normal PFA-100 time. 20,5% (8) patients had normal aggregation and abnormal PFA-100 test, while 10,2% (4) had both normal aggregation and PFA-100 time. Three patients with chronic hepatitis had reduced LTG and one was found normal. The patients that had undergone liver biopsies had abnormal LTGs and 4 had prolonged PFA-100. Among the patients that had undergone a splenectomy, we found five of them to have abnormal LTG and prolonged PFA-100, while two of them had normal tests. The patient with GI hemorrhage had abnormal LTG and PFA-100. We found no correlation with either chelation regimen and LTG or PFA-100.Our patients' results are indicative of a platelet defect similar to disorders of platelet secretion and signal transduction. The clinical manifestations though were few. The defective LTG can be explained by the release of ADP from the haemolysed red blood cells, which leads to defective platelet aggregation and secondly the presence of two platelet populations in the circulation of the patients. The more active platelets present as circulating aggregates and are not detected by *in vitro* study and the less active are poorly aggregable. An alternative explanation is the *in vitro* effect.In literature and clinical practice there is a lack of consensus about the best diagnostic tests concerning platelet function. In thalassaemics the reduced LTG and the prolonged PFA-100 closure time must not be overestimated due to the limited clinical manifestations. The administration of salicylates in splenectomised thalassaemics should not be ignored. Nevertheless, bleeding can occur in patients with platelet defects of the above type.

0467

ACQUIRED HAEMOPHILIA A-RETROSPECTIVE ANALYSIS OF 46 CASES FROM A SINGLE CHINESE HAEMOPHILIA CENTER

Y Yang, F Xue, H Shi, H Wang, L Ji, R Yang
Institute of Hematology and Blood Diseases Hospital, Tianjin, China

Background. Acquired hemophilia A (AHA) is a rare disorder caused by the autoantibody directed against factor VIII in patients without previous history of a bleeding disorder. Severe bleeding occurs in a majority of patients with a high rate of mortality. The patients of AHA usually present to clinicians without experience of this disease. As a result, the diagnosis and proper treatment is often delayed. **Aims and Methods.** We retrospectively analyzed the characteristics and outcomes of 46 patients with AHA from 1994 to2011 in our center. **Results.** The median age was 53 years ranging from 14 to 78 years.The major peak of age was 60-70 years 16 of 46, 35%, the second frequency peak was 20-30 years 9 of 46, 20%. The associated disease was observed in 7 (16%) patients. Nine patients had medical conditions that were unlikely to be related to acquired inhibitors. The symptoms included ecchymosis (44 of 46, 96%), muscle or soft tissue haematoma(33 of 46,77%), hematuria (12 of 46,28%), mucous bleeding (10 of 46, 21%), hemarthrosis (7 of 46, 16%), intracranial bleeding (2 of 46, 5%). Twenty-four patients with acute bleeding episode were treated with prothrombin complex concentrate (PCC) at a relative low dose of 30-50U/kg· d and achieved good outcomes without adverse reaction. Corticosteroids alone or combined with cyclophosphamide were used as first-line therapy to eradicate the inhibitors. In 37 evaluable patients, 33 (89%) cases achieved complete remission (CR). Four cases died of hemorrhage and 2 of them had neutropenia-associated infections which conversely aggravated haemorrhage. The response time was not related to FVIII:C and inhibitor titre. Two patients relapsed after 4.5 months and 1 year respectively, but they achieved second CR after the second cycle of therapy. **Conclusions.** This study summarizes the experience about AHA from a single Chinese hemophilia center where expensive bypassing agents such as recombinant activated factor Ⅶ and activated prothrombin complex concentrate are not available . We find that PCC is effective and safe to control acute bleeding. Corticosteroids alone or combined with cyclophosphamide used as first-line therapy achieved good outcomes with CR rate of 89%. The comorbidities and side-effect of immunosuppressant in patients probablely have adverse impact on the prognosis.

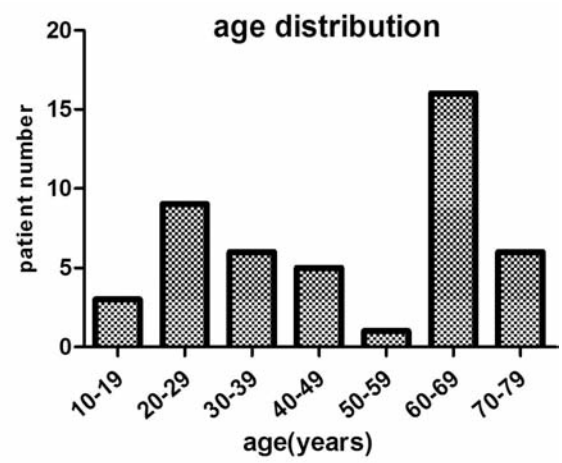

Figure 1. Age distribution.

A SINGLE CENTRE EXPERIENCE OF INHIBITOR ERADICATION THERAPY IN SEVERE HAEMOPHILIA A

G Ooi, C Owoeye, L O'Connell, E McLaughlin, M Kavanagh, J Smith, B Philbin, I Regan, O Smith, B Nolan
Our Lady's Children's Hospital, Crumlin, Dublin, Ireland

Background. One of the most serious complications of haemophilia A is the development of factor VIII (FVIII) inhibitors. Immune tolerance induction (ITI) protocols use FVIII at varying doses with the addition of other immunomodulatory therapies in non-responders. This is a 20 year single centre experience of inhibitor eradication therapy in severe haemophilia A. **Methods.** We reviewed the heath care records of all patients with severe haemophilia A (FVIII: C <0.01 iu/ml) who had developed a factor VIII inhibitor between 1990 and 2011. We identified 22 patients. Patients were excluded from the study if clinical details were inadequate or if the inhibitor was transient. All patients underwent ITI with recombinant FVIII (rFVIII) ± immunomodulatory therapy. Immune tolerance was defined as 3 consecutive negative monthly inhibitor screens with FVIII recovery greater than 66%.ResultsWe report on 14 children (ten unrelated and two brother pairs) with severe haemophilia A and FVIII inhibitor. Age at inhibitor detection ranged from 0.9 months to 79 months and number of exposure days varied from 5 to 182 (Table 1). Circumstance of inhibitor development is shown in Table 1. Time from first exposure to inhibitor diagnosis was 0.5 to 79.1 months. 50% had high responding inhibitors [>10 Bethesda units (BU)] with peak inhibitor titre ranging from 10 to 712 BU. All patients had received rFVIII. ITI was started when the inhibitor titre was <10 BU in 11 patients. Three patients started ITI at inhibitor titres of 17, 26 and 256 BU respectively. ITI rFVIII schedules varied from low dose (50 IU/kg 3 times weekly) to high dose (100 IU/ kg twice daily). Three patients with high inhibitor levels (141, 276 and 712 BU) also received immunosuppressive therapies; Rituximab, vincristine, prednisolone and mycophenolate mofetil. All 14 patients had a central venous device (CVC) inserted. Eight had CVC related infection(s), necessitating CVC removal and subsequent replacement in seven of the eight patients. Breakthrough bleeding was treated with rFVIIa. Immune tolerance was achieved in all patients. Time to elimination of inhibitors ranged from 1.2-48.3 months (median of 9 months). All patients are now on rFVIII prophylaxis.ConclusionDespite the variability of the patient characteristics and the ITI schedules, all patients were successfully tolerised with rVIII.

Table 1. Summary of inhibitor development. Patients 1, 4 and 9 received other immunomodulatory therapies. Patient 4 had 2 relapse needing further ITI.

Patient	Age (months)	Highest inhibitor (BU)	Inhibitor at ITI start (BU)	Total exposure days	Circumstance of inhibitor formation	ITI duration (months)
1*	22.7	141	N/A	13	Joint bleed	32.4
2	23.6	6	6	12	GI bleed	11.0

MANAGEMENT OF PATIENTS WITH HHT DURING PREGNANCY

J Byrne, K Murphy
The National Maternity Hospital, Dublin, Ireland

Background. Hereditary Hemorrhagic Telangiectasia (HHT) is a genetic disorder of the blood vessels, which affects approximately 1 in 5000 people. Pregnant women with HHT should be considered 'high risk'. They should regularly attend multidisciplinary (Consultant Haematologist, Consultant Obstetrician, Consultant Anesthetist and midwives) high risk clinics. At these clinics the women will be advised on the pregnancy-associated risks. The women should highlight if and when they experience any haemoptysis or sudden severe dyspnoea, which can lead to immediate hospital admission. The outcome for any high-risk pregnancy is better when the high-risk multidisciplinary team is informed and have a plan of care in place. **Aims.** We highlight the management of 3 women (five pregnancies) with significant issues pertaining to the management of HHT in pregnancy. **Methods.** PAVMsIdeally women planning a pregnancy should have pre-pregnancy screening of PAVMs and treated accordingly. If there was no recent screening of PAVMs prior to conception then regular screening of PAVMs at the high-risk clinic and treatment of same during the pregnancy.MRIsA spinal MRI must be carried out during pregnancy ideally ear ly in the pregnancy to ensure there are no spinal AVMs and also to allow for regional anesthesia.A cerebral MRI must be carried out on women experiencing cerebral symptoms or a strong family history of cerebral hemorrhage, or cerebral symptoms. Delivery. All women must receive prophylactic antibiotics during her labour. Prolonged second stage of labour should be avoided especially in women where cerebral AVMs have not been excludedIf general anesthesia is required, a modified induction regimen using opiates should be administered. Postnatal. Refer women and baby back to the nearest HHT centre and ensure family screening where not previously not done. **Summary and Conclusions.** Most cases where HHT is known in pregnancy the outcome is favorable as the pregnancy proceeds normally. Due to the complications associated with HHT these pregnancies should be considered high risk**.**

FREQUENCY OF BLEEDING DISORDERS IN WOMEN PRESENTING WITH MENORRHAGIA IN THE NORTH OF IRAN

G Janbabai[1], S Borhani[1], M Rashidi[1], T Farazmandfar[1], R Shekarriz[1], M Khademloo[2]
[1]Cancer Research Center, Sari, Iran
[2]Departement of Social Medicine,Sari,Iran, Sari, Iran

Background. Menorrhagia is a common presentation of bleeding disorders, especially VWD in women. **Aims.** We decided to determine the frequency of these disorders in women with menstruation problems. **Methods.** 208 patients in reproductive age with menorrhagia were investigated for bleeding disorders in two steps. Step one includes CBC, PT, PTT and BT tests which were performed for all patients; patients who had an abnormality in step one, the second step tests including VWF: A;VWF: RCo, factors level, RIPA and platelet aggregometry were performed. **Results.** Of 208 patients who were investigated for bleeding disorders, 53 patients (25%) had abnormalities in coagulation tests or platelet counts. Frequencies of bleeding were as follows: VWD, 14(6.73%); thrombocytopenia,13(6.25%); factor II deficiency , 2(0.96%); factor V,1(0.48%); factor VII,3(1.44%); factor VIII,2(0.96%); Factor XI,4(1.92%); factor XII,4(1.92%); Bernard Soulier,2(0.96%). Furthermore, we found that 18 patients (8.65%) had abnormal PT, PTT or BT with no definite diagnosis. **Conclusions.** In this study, the most common bleeding disorder was VWD followed by thrombocytopenia. Although other bleeding disorders are rare, in our study a number of them were found. We recommend that, every woman with menorrhagia should be offered the above coagulation tests.

0471

SCREENING BLEEDING DISORDERS IN ADOLESCENTS AND YOUNG WOMEN WITH MENORRHAGIA

N Sarper, S Caki Kilic, E Zengin, S Aylan Gelen
Kocaeli University, Kocaeli, Turkey

Background. Chronic menorrhagia causes anemia and impairment of life quality. **Aims.** To screen bleeding disorders in adolescents and young women with menorrhagia. **Methods.** The study was performed prospectively by the pediatric hematologists. A form including demographic characteristics of the patients, bleedings other than menorrhagia, familial bleeding history and characteristics of the menorrhagia and impairment of the life quality due to menorrhagia was filled by the researcher during face-to- face interview with the patient. Pictorial blood assessment chart was also delivered for evaluation of blood loss. All the patients underwent pelvic examination and pelvic USG by the gynecologists. Whole blood count, peripheral blood smear, blood group, serum transaminases, urea, creatinine, ferritin, PFA-100, PT, aPTT, INR, TT, fibrinogen, VWF:Ag, VWF:RCo, FVIII, platelet aggregation assays were performed. Platelet aggregations were studied by lumiaggregometer. **Results.** Sixty patients completed the study. Mean age was 20.68±10.34 (10-48) years and 65% (n=39) of the patients were younger than 18 years. In 18 (46%) of the adolescents menorrhagia subsided spontaneously. In 20% (n=12) of the patients, a bleeding disorder was detected (4 Von Willebrand disease, 3 Bernard-Soulier syndrome, 2 Glanzmann thrombastenia, 2 immune thrombocytopenic purpura, 1 congenital factor VII deficiency). **Summary and Conclusions.** In patients with menorrhagia at least complete blood count, peripheral smear, aPTT, PT, VWF:Ag, VWF:RCo, and fibrinogen assays must be performed. When there is history of nose and gum bleeding, platelet function assay by lumiagregometer must also be performed. In nearly half of the adolescents, menorrhagia is dysfunctional and transient. Detailed coagulation assays can be postponed in adolescents if bleeding history other than menorrhagia and/or family history of bleeding and/or parental consanguinity is absent. All subjects with menorrhagia must be consulted with gynecologists and hematologists.

THROMBIN GENERATION AND MICROPARTICLE-ASSOCIATED PROCOAGULANT ACTIVITY AS NEW TOOLS TO EVALUATE THE HEMOSTATIC PROPERTIES OF PLATELET CONCENTRATES

L Russo, M Marchetti, C Tartari, A Vignoli, E Diani, C Giaccherini, C Verzeroli, S Marziali, A Falanga
Ospedali Riuniti di Bergamo, Bergamo, Italy

Introduction. Thrombin generation (TG) and platelet microparticles procoagulant activity (MP-PCA) are two emerging assays utilized to characterize the hemostatic profile of plasma samples. **Aims of the study.** In this study we evaluate: 1) the applicability of TG and MP-PCA assays in assessing the procoagulant properties of platelet concentrates (PC) prepared for transfusion therapy; and 2. whether these assays are sensitive to the methodology used for PC preparation. **Methods.** PC were prepared from pooled buffy-coat of overnight-stored whole blood from healthy donors at the Immunohematology and Transfusion Medicine Dept of Bergamo (Italy). 10 PC were prepared with the Fenwal System (FS) and 4 with Terumo TACSI System (TTS). PC samples were collected the day of preparation (D0) and after 3 days of storage (D3) at 22°C, and then processed to isolate supernatants of PC (S-PC) by two serial centrifugations. S-PC were tested for their TG potential by the calibrated automated thrombogram (CAT) assay employing 1 and 5 pM TF concentrations (both with 4 uM phospholipids), and for MP-PCA by the P-PPL/1 kit (all reagent by Stago). Results of TG are expressed as lag-time, peak, area under the curve (ETP), and time-to-peak (ttPeak). Results of MP-PCA are expressed in seconds (sec). **Results.** At D0, TG of S-PC was directly proportional to the concentration of TF used as trigger, and similar to that generated in normal pool plasma (NPP). Lag-time of S-PC derived from PC prepared with TTS was significantly shorter compared to those prepared with FS ($p<0.05$), being the other TG parameters not different. Lag-time (+43%) and ttpeak (+24%) of S-PC collected after 3 days of storage were significantly ($p<0.05$) increased compared to D0, independently of the type of PC preparation. Differently, we could observe a significant decrease of ETP in S-PC prepared with TTS (1478±238 *vs* 1058±216 nM*min; $p<0.05$), but not in S-PC prepared with FS (1501±240 *vs* 1440±216 nM*min). At baseline, MP-PCA in S-PC (80.34±9.21 sec) was similar to that found in NPP (82.5±10.01 sec; p=ns). The analysis according to method of PC preparation did not show any significant difference in MP-PCA at baseline. The MP-PCA of S-PC collected at D3 was significantly higher compared to D0 ($p<0.05$), as this time point the S-PC prepared with TTS (TTS: 84±6.5; FS: 78±10.01 sec) showed the highest procoagulant potential. **Conclusions.** Our data support the validity of CAT and P-PPL1 assays in the assessment of procoagulant activity of PC. The increased MP-PCA observed in samples collected after 3 days of storage reveals the occurrence of platelet activation/apoptosis, particularly in S-PC prepared with TTS. These results provide background for further evaluation of the usefulness of these new tests to assess the quality of PC.

THE EGFP-EGF1-PLGA NANOPARTICLE MEDIATED THE TARGETED DILEVERY OF SIRNA FOR THE CEREBRAL THROMBUS THERAPY IN VITRO.

C Chen[1], Y Hu[2], W Shi[1], H Mei[2], J Deng[2], B Zhang[1], F Wang[2], T Guo[2]
[1]Institute of Hematology, Union Hospital, Tongji Medical College, Wuhan, China
[2]Institute of Hematology, Union Hospital, Tongji Medical College,, Wuhan, China

Background. It was reported that the fusion protein EGFP-EGF1 ,which had the specific TF binding capacity,could improve the cerebral thrombus targeting property of PEG-PLA nanoparticles. **Aims.** The main objective of our study was to developed the EGFP-EGF1-conjunated PLGA nanoparticles(ENP) as a new targeted dilevery of the TF-specific siRNA for the gene therapy of cerebral thrombosis *in vitro*. **Methods.** Firstly,we established a cerebral thrombus model *in vitro*,which the brain capillary endothelial cells (BCECs)were treated with TNFα.Then the treated cells were transfected with the siRNA/ENP complex.The gene silencing of tissue factor(TF) and the TF activity were measured.And the cytotoxicity of the nanocarrier was also determined. **Results.** After transfection,the total RNA were isolated from the cells for real-time PCR and the efficiency of the TF mRNA downregulation was 1.64 folds compared with siRNA/NP.The TF protein expression,determined by the western-blotting and flow cytometry ,decreased 58.5% and 80.41% of the treated BCECs respectively,while the efficiency of downregulation were 1.41 folds and 1.34 folds than siRNA/NP.Moreover,the relative TF activity in siRNA/ENP group was lowest and was 1.5 folds than the siRNA/NP group.With the dose of the nanocarrier increasing,there were almost nontoxity to BCECs.The TF expression could be inhibited by siRNA/ENP complex in both quantity and quality in treated BCECs and the gene silencing efficiency was better than siRNA/NP complex. Conclusion:The EGFP-EGF1-PLGA nanoparticle provided a targeted delivery of TF-specific siRNA and the siRNA/ENP complex was effective for the gene therapy of cerebral thrombosis *in vitro*.

EFFICACY OF LOW MOLECULAR WEIGHT HEPARIN IN PREVENTING PREGNANCY-RELATED RECURRENT VENOUS THROMBOEMBOLISM.

V De Stefano[1], S Betti[2], T Za[2], A Ciminello[2], E Rossi[2], G Leone[2]
[1]Institute of Hematology, Rome, Italy
[2]Institute of Hematology, Catholic University, Rome, Italy

Background: Women with a history of venous thromboembolism (VTE) have an increased risk of recurrence in subsequent pregnancies, so that prophylaxis with low molecular weight heparin (LMWH) is warranted in most of them during pregnancy and puerperium. However, efficacy of LMWH has been debated, suggesting to be dose-dependent. **Aims.** To assess the efficacy of LMWH among pregnant women with a history of VTE. **Patients and Methods.** We analyzed a cohort of 627 women who had had deep vein thrombosis and/or pulmonary embolism before 45 years of age and were referred to our Center; 84 of them had been pregnant at least once after VTE and were considered suitable for the study. The presence of inherited thrombophilia and/or antiphospholipids was not a criterion of exclusion. We stratified women according to use of prophylaxis with LMWH during pregnancy and puerperium (defined as 6 weeks after delivery at >16 weeks' gestation). During the first pregnancy after VTE, 40 women (18 with thrombophilia) received LMWH and 44 (19 with thrombophilia) did not. Six women were at highest risk (two VTE events before pregnancy) and received LMWH in 5 cases. All the unprophylaxed pregnancies and 6 prophylaxed pregnancies occurred before referral to our Center, whereas 85% of the prophylaxed pregnancies occurred after referral and were prospectively followed. LMWH was b.w.-adjusted (nadroparin 3800 or 5700 IU o.d. and enoxaparin 4000 or 6000 IU o.d. for b.w. < 70 kg or > 70 kg, respectively). Only 2 women received nadroparin 2850 IU o.d. To assess the ante-partum efficacy of LMWH we compared the cumulative probability of recurrence according to the period of pregnancy between treated and untreated women by the Kaplan-Meier method. In order to ensure the independence of the observations, we avoided multiple correlated outcome events in women with multiple pregnancies after VTE considering only the first pregnancy after VTE. The rate of VTE during puerperium was also recorded. **Results.** During pregnancy there were 6 DVTs (13.6%, 95%CI 6.4-26.7) among the untreated women and 1 DVT (2.5%, 95%CI 0.4-12.8) among the treated women. The hazard ratio of recurrent DVT during pregnancy was 0.14 (95%CI 0.04-0.91, p=0.03) among the women receiving LMWH in respect to those without treatment (Figure). Fetal loss before the 16th week of gestation occurred in 10 women without LMWH and in 1 woman receiving LMWH (p=0.007); there were 3 DVTs during 34 puerperium periods without LMWH (8.8%, 95%CI 3.0-22.9) and 2 DVTs during 39 puerperium periods with LMWH (5.1%, 95%CI 1.4-16.8, p=0.65). None of women at highest risk or receiving nadroparin 2850 IU o.d. had DVT. Among the untreated women, heterozygous factor V Leiden was present in 2 with ante-partum DVT and in 2 with post-partum DVT (odds ratio for overall pregnancy-related recurrent DVT associated with thrombophilia 1.06, 95% 0.24-4.66). **Conclusions.** In women with a history of DVT the use of b.w.-adjusted LMWH significantly reduces the rate of ante-partum recurrent DVT by 86%. The rate of puerperium-related recurrent DVT does not seem to be significantly reduced by prophylactic doses of LMWH.

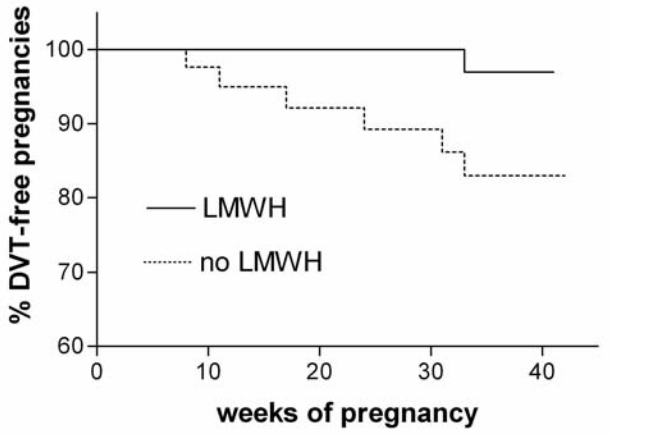

Figure 1.

0475

THE RISK OF FETAL LOSS IS INCREASED IN WOMEN WITH INHERITED THROMBOPHILIA AND FAMILY HISTORY OF OBSTETRIC COMPLICATIONS.

E Rossi[1], A Ciminello[2], T Za[2], S Betti[2], G Leone[2], V De Stefano[2]
[1]Institute of Hematology, Rome, Italy
[2]Institute of Hematology, Catholic University, Rome, Italy

Background. Several studies have demonstrated an association between inherited thrombophilia and obstetric complications (OC), in particular recurrent fetal loss (greater than 2) and unexplained intrauterine fetal death after the 20th gestational week. However, the strength of association is weak and it is uncertain whether women with inherited thrombophilia are more prone to OC than non-carriers. **Aims.** To assess the risk of OC among the carrier women with inherited thrombophilia. **Methods.** We carried out a family study and we analyzed the clinical history of 415 women recruited from a large family cohort

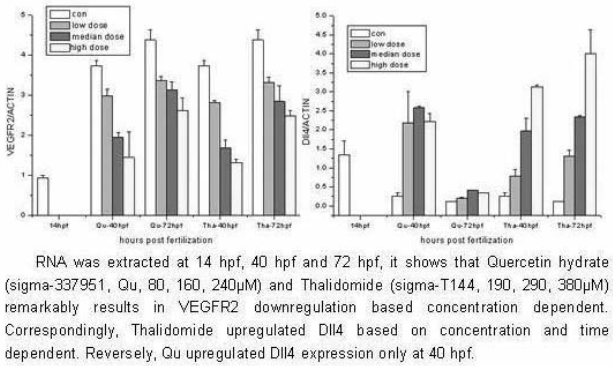
of 1,720 relatives of 563 probands with inherited thrombophilia. The inclusion criteria were a) to be a relative of a proband diagnosed as carrier of inherited thrombophilia after venous thromboembolism (VTE) or OC; b) to have been genotyped for inherited thrombophilia; c) to have been pregnant at least once. The presence of antiphospholipids was a criterion of exclusion. **Results.** The two study groups consisted of 93 relatives (54 carriers) of a proband with OC, and 322 relatives (187 carriers) of a proband with VTE. Out of 241 carriers, 13 had antithrombin, protein C or S deficiency, and the remaining ones had factor V Leiden and/or prothrombin G20210A. Overall, we recorded 1,038 pregnancies. If the proband had OC, the rate of fetal loss was 21.4% among carriers (32 of 149 pregnancies) and 15.3% among non-carriers (15 of 98 pregnancies); if the proband had VTE, the rate of fetal loss was 14.2% among carriers (64 of 450 pregnancies) and 12.6% among non-carriers (43 of 341 pregnancies). The carriers with a history of fetal loss were 22 among the relatives of a proband with OC (40.7% of the carriers), and 47 among the relatives of a proband with VTE (25.1%); the non-carriers with a history of fetal loss were 9 and 34, respectively. In women with thrombophilia in comparison with non-carrier women, the odds ratio (OR) of having at least one fetal loss was 2.29 (95%CI 0.91-5.76) among the relatives of a proband with OC and 0.99 (95%CI 0.59-1.66) among the relatives of a proband with VTE. The risk for fetal loss was double in the carriers identified because a history of OC in the proband in respect to the carriers identified because a history of VTE in the proband (OR 2.04, 95%CI 1.08-3.86). Moreover, the risk of VTE was 3.78-fold increased (95%CI 1.40-10.23) among carriers who were relatives of a proband with VTE (12.2%) in respect to non-carriers (3.7%); on the opposite, the rate of VTE was not different between carriers who were relatives of a proband with OC and non-carriers (3.7% versus no events, p=0.51). **Conclusions.** In women with inherited thrombophilia and family history of OC the risk of fetal loss is increased. Whether this information could be applied in tailoring pharmacological prophylaxis in their pregnacies should be investigated in proper studies. Finally, we confirmed that the risk of VTE among family members with inherited thrombophilia is dependent on the clinical phenotype of the proband (VTE or OC).

0476

INHIBITING ANGIOGENESIS ACTIVITIES OF QUERCETIN HYDRATE IN ZEBRAFISH

LJ Shen[1], FY Chen[1], WJ Lin[1], Y Kuang[2]
[1]RenJi Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China
[2]Shanghai Research Center for Biomodel Organisms, Shanghai, China

Background. Several molecules isolated from Chinese herb can inhibit the growth of cancer cells with an ability of antiangiogenic. Angiogenic homeostasis is maintained by a balance between vascular endothelial growth factor (VEGF) and Notch signalling in endothelial cells (ECs), which are closely related to tumor diameter, clinical stage, histological grade and lymph node metastasis. Quercetin (Qu) is considered an excellent “chemopreventer”, but the underlying mechanism still is unclear. **Aims.** To investigate the antiangiogenic effects of Quercetin hydrate (sigma-337951, Qu) *in vivo*. **Methods.** Tg(fli1:EGFP) transgenic zebrafish embryos were treated with different concentrations of Qu (80, 160, 240μM), 0.1% DMSO as vehicle control and different concentrations of Thalidomide(sigma-T144, 190, 290, 380 μM) as positive control from 14 hours post fertilization (hpf) to 72 hpf. Thalidomide has a significant antiangiogenic effect against VEGF-induced neovasclar growth. Taking the advantage of the transparent characteristics of the zebrafish, we dynamically observed green intersegmental vessels (ISVs) real time by laser confocal microscope imaging technology. Kinds of transcription factors in Dll4/Notch (Delta-like 4 is the only ligand of Notch expressing in endothelium) and VEGF(R) signaling pathway were evaluated using quantitative real-time PCR (qRT-PCR) and Western blotting. **Results.** When zebrafish were analyzed at 72 hpf, a time point where all ISVs in the vehicle control group have fully extended to form the dorsal longitudinal anastomotic vessels (DLAVs), Qu-treated and Thalidomide-treated groups were found to result in significant reductions in the number of complete ISVs and angiogenic sprouts compared with the vehicle control group, with a greatest reduction in embryos treated with high concentration. These results demonstrate that Qu serves as an inhibitor of ISVs angiogenesis in zebrafish embryos. We extracted RNA and protein from these embryos at 14 hpf, 40 hpf and 72 hpf, respectively, found that Qu and Thalidomide remarkably results in VEGFR2 (VEGF Receptor 2) downregulation based on concentration dependent. Correspondingly, Thalidomide upregulated Dll4 based on concentration and time dependent. Reversely, Qu upregulated Dll4 expression only at 40 hpf VEGF. And there were no significant change of VEGF, VEGFR1, Notch1, Delta like I□3(ligand of Notch) detection.**Summary.** Zebrafish represents a powerful model system for chemical discovery and gene targeting in tumor angiogenesis. Our results indicate that significant inhibition of zebrafish embryos’ angiogenesis was caused by doses under the minimum lethal concentration of Quercetin treatment at 14 hpf (when the ISVs begin to bud) and mainly via inhibition of VEGFR2-mediated signaling. It has an instantaneous effection on Dll4/ Notch signaling pathway. No obvious side effects were recorded. We present a comprehensive framework of study using fluorescence microscopy, transcriptomics and qPCR to demonstrate the proangiogenic effects of Quercetin *in vivo*. The data have elucidated the connection between morphological observations and genomic evidence, indicating the potential roles of several key signaling pathways in angiogenesis.



RNA was extracted at 14 hpf, 40 hpf and 72 hpf, it shows that Quercetin hydrate (sigma-337951, Qu, 80, 160, 240μM) and Thalidomide (sigma-T144, 190, 290, 380μM) remarkably results in VEGFR2 downregulation based concentration dependent. Correspondingly, Thalidomide upregulated Dll4 based on concentration and time dependent. Reversely, Qu upregulated Dll4 expression only at 40 hpf.

Figure 1. The outcome of qRT-PCR.

HIGH ON-TREATMENT PLATELET REACTIVITY: RISK FACTORS AND 3-YEARS OUTCOMES IN PATIENTS WITH ACUTE CORONARY SYNDROME

M Jakl[1], R Sevcik[2], J Vojacek[2], I Fatorova[3], J Horacek[1], R Pudil[2]
[1]University of Defense, Faculty of Military Health Sciences, Hradec Kralove, Czech Republic
[2]Charles University Prague, Faculty of Medicine in Hradec Kralove, 1st Department, Hradec Králové, Czech Republic
[3]Charles University Prague, Faculty of Medicine in Hradec Kralove, Dept Clinical, Hradec Králové, Czech Republic

Background. High on-treatment platelet reactivity (HTPR) is expected to be a negative prognostic factor in patients with stable coronary artery disease. But in patients with acute coronary syndrome the data about prognostic value and association with risk factors are lacking.Objectives: The aim of the study was to assess the relationship between HTPR, potential risk factors and with three-year mortality in patients with acute coronary syndromes. **Patients and Methods.** We performed a prospective cohort study of 198 patients with acute coronary syndrome. In these patients the response to aspirin and clopidogrel was assessed by the impedance aggregometry. According to the response to antiplatelet treatment patients were divided in groups with sufficient response, dual poor responsiveness (DPR), poor responsiveness to aspirin (PRA) and poor responsiveness to clopidogrel (PRC). Simultaneously the age, gender, left ventricle ejection fraction, presence of heart failure, diabetes mellitus and smoking habit was recorded. After three years, the myocardial reinfarction incidence and overall mortality were assessed. **Results.** Poor response to antiplatelet treatment was significantly more frequent in patients in NYHA III and IV class (HR 8.35, 95 % CI 3.7-18.8, p<0.0001 for DPR, HR 3.47 95 % CI 1.95-5.57, p<0.0001 for PRA, HR 4.34, 95 % CI 2.58 - 6.51, p<0.0001 for PRC) and in patients with left ventricle systolic dysfunction (HR 1.86, 95 % CI 3.29-1.34, p<0.05 for PRA). Three-year mortality was significantly higher in all groups of patients with HTPR compared with patients with sufficient response to antiplatelet treatment: in patients with poor responsiveness to aspirin 31.7 % vs. 11.5 %, p <0.01, with poor responsiveness to clopidogrel 33.3 % vs. 10.9 %, p<0.001 and with poor response to both aspirin and clopidogrel 40.9 % vs. 12.5 %, p<0.001. Risk of repeated myocardial infarction was increased as well (HR 4.0, 95 % CI 1.25-11.5, p<0.05 for DPR, HR 4.37, 95 % CI 1.51-12.77, p<0.01 for PRA, HR 3.25, 95 % CI 1.11-9.36, p<0.05 for PRC). **Conclusions.** Poor response to aspirin, clopidogrel or both aspirin and clopidogrel are strong negative risk factors of death and repeated myocardial infarction in patients with acute coronary syndrome. We found a heart failure and left ventricle systolic dysfunction to be risk factors of HTPR development.

AUTOPSY PROVEN FATAL PULMONARY EMBOLISM CAUSED BY HOSPITAL ACQUIRED THROMBOSIS: AN EXEMPLAR CENTRE EXPERIENCE

T Nokes, Y Thi, J Copplestone
Derriford Hospital, Plymouth, United Kingdom

Background. Pulmonary Embolism (PE) is an important cause of death in hospitalised patients but significantly under-reported due to non-specific presentations and falling autopsy rates. An estimated 250,000 deaths are reported to be caused by preventable Hospital Acquired Thrombosis (HAT) in England. HAT includes venous thromboembolism (VTE) which occurs during inpatient stay of more than 3 days and within 90 days of discharge.AimTo determine the number of fatal PE associated with HAT and to use this data to help inform outcome metrics associated with venous thromboembolism (VTE) prevention initiatives within the a teaching hospital and DoH Exemplar centre.MethodA retrospective review of the autopsy reports was carried out over a 12 month period in 2011. The case notes were identified where PE was the cause of death and there had been an in-patient stay within 90 days prior to death. The latter detail was obtained from the PM reports and patients notes. Three notes from the HAT group were unobtainable.Results1009 autopsies were performed over 12 months (autopsy rate = 44%). Fatal PE was identified in 61 cases (6.1%). Of these deaths, 20 (33%) were associated with HAT according to detail from PM reports and the notes were reviewed: Five deaths (8.2%) occurred as in-patient, 6 (9.8%) within 30 days of discharge and 6 (9.8%) within 90 days of discharge. Median Age was 78 years (range 52-98) with a male to female ratio of 1:3. Median duration of hospital stay was 15 days (range 5-120). Five patients had advanced cancer, 4 patients underwent major operations, 3 patients had sepsis and 2 had significant dehydration. VTE risk assessment according to NICE guideline was carried out in 12/17cases where notes were available (71%). Thromboprophylaxis (TP) was given in the form of low molecular weight heparin (enoxaparin®) to 15/17 (88%). However of the 15 patients who received enoxaparin®, 3 (20%) had unexplained missed doses, making a total of 5 patients who experienced potentially preventable fatal PE. SummaryWhen this data is compared to the autopsy analysis of the previous year (2010) where 19 deaths (26%) were identified as being HAT events, there is a 7% increase. Whereas in 2009, 35 deaths (41%) were recorded as HAT events. In 2010, there were no cases of preventable death from fatal PE and one from 2009. However, the previous data did not include missed doses and therefore the comparison is not accurate. Since the introduction of NICE VTE Clinical Guideline 92, in January 2010, there has been an emphasis on thorough VTE risk assessment and appropriate TP on admission to hospital, regular auditing by a designated VTE prevention team and real-time feedback to clinicians may have played a role in a reduction of fatal PE due to HAT over the last 24 months. There has also been a focus on other measures to reduce VTE events such as early mobilisation, adequate hydration, regional anaesthesia and advances in surgical technique.

RECURRENT PEDIATRIC THROMBOSIS: INFLUENCE AND UNDERLYING OR COEXISTING FACTORS

M Gokce[1], I Altan[2], S Unal[3], B Kuskonmaz[2], S Aytac[2], M Cetin[3], M Tuncer[3], F Gumruk[2], A Gurgey[3]
[1]Hacettepe Medical Faculty, Ankara, Turkey
[2]Hacettepe Medical Faculty, Pediatric Hematology Division, Ankara, Turkey
[3]Hacettepe Medical Faculty, Pediatric Hematology, Ankara, Turkey

Background. Despite advances in our understanding of the pathogenesis and risk factors of pediatric thrombosis, the experience of recurrent venous thrombosis (rVTE) in children is still limited. It is a well-identified issue that after a first episode of thrombosis, one has the risk of recurrence lifelong. Some factors may constitute the risks of rVTE such as multiple prothrombotic mutations, persistently elevated factor VIII and/or d-dimer levels, positive family history of rVTE. **Aims.** To evaluate the underlying diseases, thrombus localizations and other risk factors of the pediatric patients with recurrent thrombosis in order to obtain a sense of early awareness. **Materials and Methods.** We retrospectively evaluated both inherited & acquired thrombophilic risk factors in children with recurrent thrombosis who were diagnosed and treated at Pediatric Hematology Division, Hacettepe Medical Faculty, Ankara, Turkey. The confirmation of a newly developed thrombosis by classic imaging modalities seven days after the first episode was defined as recurrence. Both congenital & acquired risk factors responsible for the recurrence and treatment modalities were analyzed in detail. **Results.** Of 569 children with thrombosis, 32 (5.6%) presented with rVTE. The median age at the first presentation (11 females, 34.4%) was 132 months. Twenty-nine (90.6 %) had an underlying chronic disorder of which the most common one was congenital heart diseases (n=11, 34.4%). At presentation, intracardiac localization including inferior and superior vena cavae entrance was observed in almost one third of the patients (n=10, 31.2%). The thrombosis recurred at the same location in fifteen (47%) but at a different location in seventeen (53%). The median time interval between first and second episodes of thrombosis was 6.5 months (range; 1-180 months). Considering both acquired and congenital thrombophilic factors; three (9.3%), four (12.5%) and fourteen (43.8%) patients had 5 , 4 and 3 risk factors, respectively. More than half of the patients have higher plasma FVIII (> 150 IU/dl) & d-dimer (> 0.5mg/ml) levels. As a treatment option, thrombectomy was performed in three patients with organized, chronic intracardiac thrombus. Tissue plasminogen activator (t-PA) had been used more commonly at the recurrence (15.6% vs 28.1%) and the ratio of complete resolution was higher (40% vs 77.7%). The thrombus was partially resolved in eleven of the patients at initial episode and in ten at recurrence (34% vs 32%). Twenty-nine (87.5%) patients were on prophylaxis -by warfarin (n=16) and LMWH (n=12)- at the time of recurrence. Four patients (12.5%) died of their underlying disorders and six (18.7%) developed postthrombotic syndrome during follow up. **Conclusions.** The recurrent thrombosis should be predicted particularly in cases with congenital heart diseases or ongoing inflammatory processes such as malignancies and collagen vascular disorders. On the other hand; incomplete thrombus resolution and elevated plasma FVIII/d-dimer levels are also well known risk factors for rVTE. In the light of this knowledge; we suggest treating the patients with high recurrence risk aggresively.

0480

ROLE OF THROMBOSPONDIN IN THE INCREASED INCIDENCE OF VASOOCCLUSIVE CRISIS IN BLOOD GROUP 'O' SCD PATIENTS

M Al-Hunieni, S Alkindi, C Ho, K Al-Falahi, D Gravell, V Panjwani, H Khan, F Wasim, A Pathare
Sultan Qaboos University, Muscat, Oman

Background. Abnormal adhesive interactions between sickle erythrocytes and vascular endothelial cells (EC) and/or subendothelial matrix are known to play a dominant role in initiation of vasoocclusive events (VOC). Thrombospondin-1 (TSP) and von Willebrand factor (vWF) are the two most important mediators of the adhesive interactions between sickle erythrocytes and the blood vessel wall. Furthermore, TSP was also found more important than vWF to promote sickle cell adhesion to EC, but vWF was found to inhibit the effect of TSP. **Aims.** The aim of this study was to find if there is an increased incidence of VOC's in Blood Group "O"SCD patients, and if so, was it related to an upregulation of TSP along with a the relative reduction in the circulating vWF as compared to non-"O"blood group SCD patients. **Methods.** 89 consecutive SCD patients were enrolled in this study after an informed consent and institutional ethical clearance. Blood samples were obtained for vWF antigen, collagen binding activity, blood group typing, C-reactive protein, variant hemoglobin analysis (HPLC), Serum TSP levels, complete blood counts, liver function tests, LDH and renal function tests during VOC episodes and in steady state conditions. Disease severity was assessed by the annual frequency of inpatient admissions and disease complications. **Results.** Of the evaluable 71 patients, in the "O"blood group SCD subjects [n=36] the mean serum TSP$\pm$SD [Interquartile range] was significantly higher than the non-"O"blood group SCD subjects [n=35], namely, 38.8$\pm$28[22.4-38.4] v/s 25.5$\pm$12[17.5-27.6][p <0.05, Mann-Whitney test]. Furthermore, the serum TSP levels of 34.5$\pm$23 [22.6-36.6] in steady state conditions [n=72] were significantly reduced to 22.4$\pm$11[13.6-26.7] in patients presenting with acute vasoocclusive crisis [n=17] [p,<0.05, Mann-Whitney test]. **Summary and Conclusions.** It was observed that there was an inverse relation between TSP and vWF levels, in Blood group "O"SCD patients with an upregulation of the TSP levels leading to an increased propensity for vasoocclusion. However, during active VOC crisis, the TSP levels were significantly depressed.

0481

INPATIENT ENOXAPARIN FOLLOWED BY OUTPATIENT RIVAROXABAN USE IN ELECTIVE HIP AND KNEE ARTHROPLASTY: A SUCCESSFUL STRATEGY FOR EXTENDED THROMBOPROPHYLAXIS

N Ahmad, P Madahar, L Nancarrow, R Heatherley, V Venugopal, F Egbuonu, F Amjad, N Ford, M Wallace
Burton Hospitals NHS FT, Burton on Trent, United Kingdom

Background. Venous thromboembolism (VTE) is a serious complication after total hip or knee replacement surgery and studies have shown that this risk persists for many weeks. Extended thromboprophylaxis (TP) is now well recognised but parenteral administration of heparins pose a significant challenge. Treatment with vitamin k antagonists is also fraught with difficulties. Therefore

the recent availability and licensing of Rivaroxaban, a once-daily, fixed dose, oral anticoagulant for extended TP following elective orthopaedic surgery holds considerable promise. But, whilst clinical trials have demonstrated Rivaroxaban's safety and efficacy profile, experience from clinical practice is still limited. Additionally, concerns about higher bleeding rates and a lack of specific antidote to reverse its anticoagulant effect in the post operative period may hamper its widespread implementation amongst orthopaedic surgeons. **Aims.** We devised a thromboprophylaxis strategy using a combination of TP with Enoxaparin and Rivaroxaban at our orthopaedic department which would navigate these concerns. Enoxaparin has well established safety and efficacy profile and has been widely used for TP in orthopaedic and other settings. We administered Enoxaparin once daily in prophylactic doses during the inpatient phase, and on discharge from the hospital, Rivaroxaban was prescribed at a dose of 10mg once daily for 35 days after hip and 14 days after knee arthroplasty. **Methods.** Using our fully integrated electronic patient record system, we performed a 7 month retrospective audit for all elective THA and TKA performed at our centre with an aim to evaluate the incidence of VTE and bleedings rates in this cohort of patients. Each patient's records were evaluated for any evidence of VTE and or bleeding for up to 90 days post operatively. The primary end points were the incident of VTE and major and minor bleeding events. **Results.** Over a period of 7 months, 330 patients were evaluated. 167 were knee and 163 hip arthroplasty patients. Overall, mean age was 69.8 (age range 45-100), with 75.6% >65 years old, sex ratio was 184 female/145 male, and average duration of inpatient stay 5.18 days. After follow up of 90 days, only 2 VTE events were identified (0.60%). Both case were proximal DVT and occurred in patients after hip arthroplasty. Root cause analysis showed that the standard TP protocol was followed in both cases. Only one minor bleeding event was identified (0.30%) in the knee arthroplasty group with the development of a calf hematoma 25 days after discharge which was about 10 days after completing Rivaroxaban. None of the patient suffered from a major bleeding event, PE or mortality. **Summary and Conclusions.** Our data is a reflection of practical experience with this new oral anticoagulant and it indicates a low incidence of thrombotic and bleeding events which is no worse than primary endpoints reported in clinical trials of Rivaroxaban. Despite its limitations, our study suggests that the combination of Enoxaparin during in-patient phase followed by Rivaroxaban for extended prophylaxis can be an effective and safe strategy for TP after elective hip or knee arthroplasty and may allow better adherence to appropriate extended TP.

PLASMINOGEN ACTIVATOR INHIBITOR-1 G4/G5 POLYMORPHISM AND RISK OF VENOUS THROMBOEMBOLISM: A DANISH FOLLOW-UP STUDY

MT Severinsen[1], V Andersen[2], K Overvad[3], R Steffensen[4], T El-Galaly[5], A Tjønneland[6], S Kristensen[7]
[1]Aalborg Hospital, Aalborg, Denmark
[2]Department of Cardiology, Center for Cardiovascular Research, Aalborg, Denmark
[3]Department of Epidemiology, School of Public Health, Aarhus, Denmark
[4]Department of Clinical Immunology, Aalborg Hospital, Aalborg, Denmark
[5]Department of Haematology, Aalborg Hospital, Aalborg, Denmark
[6]Diet, Genes and Environment,Danish Cancer Society Research Center, Copenhagen, Denmark
[7]Department of Clinical Biochemistry, Aalborg Hospital, Aalborg, Denmark

Background. Plasminogen activator inhibitor-1 (PAI-1) exerts a role in blood coagulation through inhibition of fibrinolysis and raised plasma levels of PAI-1 has been proposed as a risk factor for venous thromboembolism (VTE). Evidence suggests that the insertion/deletion polymorphism 4G/5G located in the promoter region of the PAI-1 gene locus affects PAI-1 plasma levels and the 4G/4G variant has been associated with a higher risk of VTE in some studies. Given the fact that obesity and smoking habits also modulate PAI-1 levels potential interaction between obesity, smoking and the PAI-1 polymorphism was explored. **Aims.** To investigate the association between the 4G/5G polymorphism and VTE as well as the interaction with obesity and smoking in a Danish follow-up study. **Methods.** From 1993 to 1997, 57.053 participants age 50 to 64 years and free from a prior diagnosis of cancer joined the Danish "Diet, Cancer and Health"cohort. The primary outcome of this study was a first-time verified VTE episode defined as deep venous thrombosis or pulmonary embolism, and participants with a diagnosis of VTE before enrolment were excluded. Detailed data on body mass index (BMI) and smoking habits as well as blood samples from each participant were obtained at baseline. G4/G5 genotypes were determined by allele specific real-time polymerase chain reactions (predesigned Taqman SNP genotyping assay from Applied Biosystems). A case-cohort design including all incident VTE cases and a randomly selected subcohort of 1841 participants from the whole cohort was applied. Cox proportional hazard model with age as time-axis were used for statistical analyses and adjustments were performed for smoking, BMI, sex, age and hormone therapy. **Results.** A total of 641 incident VTE cases were verified. Sufficient DNA was available for SNP genotyping in the majority of VTE cases and subcohort members. The 4G/4G variant was found in 25.8 % of participants in the subcohort, the 5G/5G variant was found in 24.2 % and the 4G/5G was found in 48.0%. The incidence rates (IR) of VTE and Hazard rate (HR) according to PAI-1 polymorphisms are shown in the Table. We found no association between VTE and PAI-1 genotype. There were no significant interactions between lifestyle factors and 4G/5G polymorphism and adjustments did not change the estimates. **Conclusions.** The present study could not confirm the previously reported association between the 4G/5G polymorphism and VTE and there was no apparent interaction between the 4G/5G polymorphism and common thrombogenic lifestyle factors.

Table 1. PAI-1 polymorphism and risk of VTE. Adjustment for BMI, smoking, sex, and use of hormones (women).

RELEVANCE OF CEREBRAL VEIN THROMBOSIS IN ADULTS TREATED FOR ACUTE LYMPHOBLASTIC LEUKEMIA

M Lauw[1], S Zuurbier[1], J Coutinho[1], C Majoie[1], B van der Holt[2], J Cornelissen[3], S Middeldorp[1], B Biemond[1], J Stam[1]
[1]Academic Medical Center, Amsterdam, Netherlands
[2]Hovon Data Center, Erasmus MC-Daniel den Hoed, Rotterdam, Netherlands
[3]Erasmus MC-Daniel den Hoed, Rotterdam, Netherlands

Background. Venous thromboembolism (VTE) frequently complicates the treatment of acute lymphoblastic leukemia (ALL). The reported incidence varies from 1.7% to 36.7% and seems higher in adult than pediatric patients. Occurrence is associated with disease, host and treatment modalities. A large proportion of VTE is located in the cerebral veins (CVT), however the reason for this preference is unknown. **Aims.** To determine etiological and clinical associations of CVT, we analyzed incidence, relationships with treatment elements, and clinical characteristics and outcome in a large cohort of adults treated for ALL. **Methods.** A post-hoc analysis was performed in patients treated for newly diagnosed ALL in a multicenter study (HOVON-37 ALL). 240 patients aged 16-59 years were included between April 1999 and November 2005. All symptomatic objectified VTE was prospectively recorded. For patients with CVT, clinical parameters were extracted from hospital records. **Results.** Nine patients experienced CVT (3.8%; 95% confidence interval (CI) 1.4-6.2). One of nine patients had a central nervous system localisation of ALL, while four of nine had a poor ALL prognostic risk classification, based on presence of cytogenetic abnormalities (t(9;22), t(4;11), or t(1;19)), pro-B-cell immunophenotype, and high WBC (i.e. > 30 x 10^9/L in case of B-cell ALL; > 100 x 10^9/L in case of T-cell ALL). All CVT occurred during cycle 1 of remission induction treatment and CVT was located in the superior sagittal sinus in eight of nine patients. Eight

patients presented with seizures and six had focal neurological defects upon presentation. Seven patients had parenchymal brain lesions and two had significant mass effect due to hemorrhagic infarction. Median time between inclusion and CVT was 21 days (range 13-33), 0 days (range 0-2) between last L-asparaginase administration and 6 days (range 1-13) between last intrathecal methotrexate administration and CVT. L-asparaginase was discontinued if CVT occurred during L-asparaginase therapy, and withheld in one patient due to CVT. All patients but one were treated with anticoagulation after CVT. Two patients also received endovascular thrombolysis preceding anticoagulation. However, both died in the acute phase due to transtentorial herniation as a result of increase in hemorrhagic infarction. Patients with CVT were less likely to obtain complete remission than patients without CVT after cycle 1 (odds ratio (OR) 0.17; 95% CI 0.03-0.82; $p = 0.01$) and on protocol overall (OR 0.13; 95% CI 0.03-0.72; $p < 0.01$). **Conclusions.** CVT is a relative frequent complication during ALL treatment in adults. The clinical presentation of CVT in ALL seems more severe than in other CVT events, with a high mortality rate, and common seizures, hemorrhagic infarctions and localisation in the superior sagittal sinus. Our study suggests etiological relationships with L-asparaginase and intrathecal methotrexate therapy in the first remission induction cycle. Future studies are necessary to confirm these results and to clarify underlying mechanisms.

0484

DEALING WITH THE GREY AREA: BORDERLINE RESULTS IN PROTEIN C, PROTEIN S AND ANTITHROMBIN TESTING

M Pereira, G Marques, M Lourenço, G Ribeiro
Coimbra University Hospitals, Coimbra, Portugal

Background. Protein C (PC), Protein S (PS) and Antithrombin (AT) deficiencies carry an increased risk of thrombosis, and levels are tested during thrombophilia workup; however, there are marked inter and intra-individual biological variations in measurements, even in the absence of disease.Normality is a continuum. However, “normal”values are determined statistically for lab tests, with artificial boundaries separating “normal”from “altered”results. In tests with high intra-individual variation, the patient can fall on either side of the boundary between “normal”and “not-normal”on sequential determinations.Assuming adequate quality-control, results with a severe deviation from normal are of easy interpretation; however, altered results can fall into a grey area between “normal”and “low”that requires further investigation. We aim to characterize the difficulties these results raise for the clinician, by analyzing the occurrence of falsely positive values in borderline-low results. **Methods.** We reviewed all requests for free PS, PC and AT received in our lab between 01-Jan-1999 and 26-Feb-2012, defining a Normal interval of 60-130% for PS, 70-140% for PC and 80-120% of AT. “Borderline”was within a 10-percentual-unit range of the lower limit of normal. **Results.** Reviewing 5938 results for PS, 5900 for PC and 5568 for AT, we found that 82.9%, 80.7% and 82.2% were Normal, respectively, while 2.8%, 8.3% and 6.3% were above Normal. Values below 20% accounted for 0.51%, 0.44% and 0.07%, while 5.6% of samples were Borderline (6.2% PS, 3.5% PC and 7.1% AT).A total of 682 patients were repeatedly tested for PS and PC, and 616 for AT; the average intra-individual variation-coefficients were 11.7%, 9.7% and 6.3%.Considering Borderline results for PC, 56 patients had repeated testing: 46.4% were previously Normal, 7.1% were previously low and 44.6% had no prior assays; 32.1% had no follow-up assay, 42.9% were Normal, 14.3% remained Borderline and 10.7% were low. For PS, of 95 repeatedly tested patients, 32.7% were previously Normal and 17.9% previously low; at follow-up 48.4% were Normal, 11.6% remained Borderline and 11.6% were low. For AT, 36.1% of 97 repeat patients were previously Normal, 8.2% previously low; 52.6% Normal at follow-up, 11.3% Borderline and 4.1% low. **Discussion.** We observed that 86-89% of results (85.7% PS, 88.9% PC and 88.4% AT) obtained were either Normal or above Normal, carrying no thrombotic risk and being, therefore, of easy interpretation, while under 0.5% of results were also of easy interpretation, falling below 20%.However, 4-7% of results (6.2% PS, 3.5% PC and 7.1% AT) fell into a grey area below the boundary of normal, requiring further investigation. The uncertainty of results within this borderline-low area was demonstrated by the fact that 33-47% of patients were previously normal and 7-18% were previously low, and that 43-53% had subsequent normal assays, while 15-25% were low-to-borderline-low, findings compatible with the high intra-individual variation-coefficients obtained (6%-12%).Our results reinforce the notions that when interpreting isolated thrombophilia test results, an adequate patient history is fundamental, and that confirmatory assays should be obtained before establishing a diagnosis, moreover when results fall into borderline values.

0485

TISSUE FACTOR EXPRESSION PREDICTS OUTCOME IN CHILDREN WITH NEUROBLASTOMA

T Hassan[1], L Sherief[2], E Eshak[3], M Bebars[4]
[1]Zagazig University, Zagazig, Egypt
[2]Zagazig university, Zagazig, Egypt
[3]Pathology Department-Cairo University, Cairo, Egypt
[4]Pediatrics department, Zagazig university, Zagazig, Egypt

Background. It has recently been proposed that oncogenic changes may impact the level of tissue factor (TF) and thereby affect cancer coagulopathy, angiogenesis and other vascular effects associated with cancer. For this notion, there is already a growing body of experimental and early clinical evidence. For instance, TF upregulation parallels the expression of several mutant oncogenes and this was documented in cancer cells of colorectal, mammary gland, cutaneous, astrocytic and hematologic origin. **Aims.** To the best of our knowledge we report for the first time the detection of tissue factor expression by immunohistochemistry in neuroblastoma in pediatrics and its correlation with tumor pathology, stage and clinical outcome. **Methods.** Twenty children registered in Pediatric Oncology Unit of Zagazig University Hospital with biopsy proven neuroblastoma were studied retrospectively. The patients were enrolled and treated on COG risk- based protocol during the period from January 2006 to February 2011. We collected full clinical, laboratory, imaging and tumor data. Data regarding response to treatment and outcome were also collected. TF expression level was detected on formalin-fixed, paraffin -embedded tissue sections. **Results.** Increased tissue factor expression by immunohistochemistry was detected in 75% of our patients. 75% of patients with stage IV neuroblastoma were expressing TF and 67% of patients with stage III had TF expression by immunohistochemistry. There was no significant relationship between TF expression and each of age, gender, clinical and laboratory findings. Although higher percentage of unfavorable Shimada pathology was noted in patients with positive tissue factor expression than those with negative TF expression (60% versus 20%), still the difference was insignificant. None of patients with negative TF expression had MYCN amplified while 62% of those with positive TF expression and known MYCN status had MYCN amplification.TF expression was significantly related to patient outcome where all patients with negative tissue factor expression cured while 81.8% of those with positive tissue factor expression and known outcome, died. There was no significant correlation between intensity of staining of TF and pathology, stage nor age. **Summary and Conclusions.** Tissue factor is a promising research subject as a prognostic factor for neuroblastoma tumor. More studies are needed to clarify the mechanisms by which tissue factor affects cancer progression and outcome, and its potential role as a therapeutic target.

COAGULATION PROFILE OF ET PATIENTS PRESENTING THROMBOTIC COMPLICATIONS

B Sokolowska[1], M Kowalska[2], K Bykowska[3], A Nowaczynska[1], A Walter-Croneck[1], S Chocholska[1], E Mendek-Czajkowska[3], T Gromek[1], K Wejksza[4], M Kandefer-Szerszen[4], J Windyga[3], K Warzocha[3]
[1]Medical University , Lublin, Poland, Lublin, Poland
[2]The Children’s Hospital of Philadelphia, Philadelphia, United States of America
[3]Institute of Hematology and Blood Transfusion, Warszawa, Poland
[4]Virology and Immunology ,University of Marie-Curie -Sklodowska, Lublin, Poland

Background. ET is a relatively indolent disease but a reduction of survival has been observed. The relative survival ratio at 10 years is 0.68 (0.64-0.71) for ET patients. The main risk factors for reduced survival are advanced age and the history of thrombotic complications. Therefore, it is essential to search for main risk factors of thrombosis. **Aims.** The study was designed to identify a characteristic coagulation profile of ET patients presenting thrombotic complications. **Methods.** We have examined 106 patients with ET, 80 females and 26 males, mean age 54 (23-82) yrs. The control group (CG) consisted of 20 healthy persons: 6 males and 14 females, mean age 41 (31-54) yrs. Thrombotic complications (TC) occurred in 21 ET patients, bleeding episodes (BE) were noticed in 22 ET patients. Thrombosis is caused by a variety of reasons. We put them into several main groups to find which the most common ones are:1. Gene mutations: JAK-2 V617F; factor V Leiden, G20210A prothrombin, MTHFR C667T and PAI-1 polimorphism.2. Coexistence of at least one of cardiovascular risk factors: diabetes, hypertension, smoking.3. Proteins level below normal range: C, free S, AT and F XII.4. F I, F VIII, vWF and homocysteine levels above normal range as well as abnormal lipid profile.5. Additional factors: age >60, BMI >30, WBC (at diag.)>8.4G/l, Ht >45%.Additionally,

besides evaluating PF4 concentration in patient's serum we assessed its concentration in platelet lysates. **Results.** The median age of TC patients was over 60 and higher than the median age of BE patients: 61yrs; 48-67 vs 48.5yrs; 36-60; p<0.05 (all results are expressed by median and P25-75%). They also present more thrombotic risk factors (TC:7; 5-9 vs BE: 4; 3-5; p<0.001). vWF activity and antigen concentration as well as factor VIII level were higher in TC than in BE patients (87.4%; 67-134 vs 66.5% 48.9-87.4 and 127% 99-153.5 vs 94.6%; 72-128.97, and 85%; 81.3-122.5 vs 79.5%; 61.05-92.8; p<0.05). As much as 14 (32.56%) patients with TC were JAK-2 positive as compared to only 5 (11.63%) BE patients. Moreover, JAK2 positive patients with TC had lower free protein S levels as compared to JAK2 negative patients. The median level of fibrinogen in TC patients was over 350mg/dL and higher, as compared to ET patients without any complications (353mg/dL; 290-409 vs 281mg/dl; 240-340 mg% p<0.05).The median PF4 conc. in platelet lysates was 12.78 IU/l; 10.07-17.35 for the whole ET group, 15.25 IU/L; 11.37-15.567 for CG , 15.6 IU/L; 10.41-17.68 for TC patients , 11.34 IU/L; 9.93-13.56 for BE patients and 14.17 IU/L; 9.99-17.13 for patients without any vascular complications. **Conclusions.** *1.*Patients with TC are older, more often JAK-2 positive and present more thrombotic risk factors as well as higher FVIII, and vWF levels compared to patients with BE.2. Although BE patients have lower PF4/1mln platelets ratio than TC patients (our previous results), the concentration of PF4 in platelets lysates was the same in all ET patients groups irrespective of presence or type of vascular complications.

PROTHROMBIN G20210A AND ORAL CONTRACEPTIVES AS RISK FACTORS FOR CEREBRAL VENOUS THROMBOSIS

M Landau, A Eugênio, N Rossato, G Castro, T Gadelha
University Hospital Clementino Fraga Filho, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background. Prothrombin variant G20210A (PT G20210A) and the use of oral contraceptives (OC) are major risk factors for cerebral venous thrombosis (CVT). A synergism between these factors has also been reported. However, the role of factor V Leiden (FV Leiden) and PT G20210A as independent risk factors for CVT according to gender and the intensity of the synergism with OC remain controversial. **Aims.** This study evaluated the association between FV Leiden and PT G20210A with CVT in each gender and the interaction with oral contraceptives. The results were also compared with those observed in patients with venous thromboembolism (VTE).**Methods.** 91 patients (73 women and 18 men) diagnosed with CVT were studied. A control group of 284 individuals with no history of thrombosis (matched by age and sex) and a group of 343 patients (218 women and 125 men) with VTE were also studied. Cases and controls were tested for the presence of FV Leiden and PT G20210A. **Results.** The frequencies of FV Leiden, PT G20210A by gender and the interaction with oral contraceptive use are showed in Table 1. **Conclusions.** Our results confirm that PT G20210A is an independent risk factor for CVT, with a higher risk than in patients with VTE. The risk was similar in men and women, and was higher than that of OC use alone. The association of PT G20210A with OC use had a strong synergistic effect. In contrast with the observed for VTE FV Leiden was not a risk factor for CVT.

Table 1. Frequencies of prothrombin G20210A, factor V Leiden and oral contraceptive use in patients and controls.

Variables	CVT patients	Controls	OR 95% CI	VTE patients	Controls	OR 95% CI
			MEN			
N	18	110		125	110	
FV	1	2	3,2(0,3-37)	21	2	10 (2,5-47)
PT	2	1	14 (1-162)	12	1	11 (1,5-90)
			WOMEN			
N	75	176		218	176	
FV	3	3	2,4 (0,5-12)	33	3	10 (3-34)
PT	12	3	12 (3-43)	19	3	5,5 (1,6-19)
OC	49	70	3 (1,5-4,8)	143	70	2,8 (2-4)
PT + OC	10	1	43 (5–346)	10	1	14 (2-115)

CVT - cerebral venous thrombosis; VTE - venous thromboembolism; FV - factor V Leiden; PT - prothrombin G20210A; OC - oral contraceptives; OR – odds ratio; CI - confidence interval.

0489

HEMOSTATIC AND METABOLIC PARAMETERS IN PATIENTS WITH SUBCLINICAL HYPOTHYROIDISM: IS THERE A RELATIONSHIP WITH THYROID STIMULATING HORMONE?

M Dalamaga[1], K Daskalopoulou[2], G Sotiropoulos[3], M Pantelaki[2], K Karmaniolas[3], M Triantafilli[3], A Lekka[3]
[1]Attikon General University Hospital, Athens, Greece
[2]ELPIS General Hospital, Athens, Greece
[3]NIMTS General Hospital, Athens, Greece

Background. Previous data regarding abnormalities of blood coagulation during hypothyroidism and hyperthyroidism have been published. Nevertheless, a controversy exists concerning the presence of a hypercoagulable status in these disease states. Subclinical hypothyroidism (SH) is often encountered in the general population. Patients may be asymptomatic or may present non-specific symptoms. It has been suggested that SH could represent a risk factor for cardiovascular disease, especially coronary heart disease. Hemostatic and metabolic parameters as well as their relationship with thyroid stimulating hormone (TSH) have not been studied in depth in subclinical hypothyroidism. **Aims.** The aim of the present study was to evaluate hemostatic and metabolic perturbations in patients with SH in comparison to euthyroidic healthy subjects, and to investigate whether serum TSH and thyroid hormones may contribute to the variation of hemostatic parameters. **Methods.** In a cross-sectional study that we conducted between 2009 and 2011, we have evaluated forty three patients with subclinical hypothyroidism prior to any therapeutic intervention with levothyroxine (33 women and 10 men) with a mean age: 34.8 ± 8.3 years (range: 18-50 years) and an equal number of euthyroidic healthy subjects (33 women and 10 men) with a mean age: 33.9 ± 8 years (range: 20-48 years). Healthy subjects were matched on gender, age (±5 years), body mass index (± 1.5 kg/m^2) and year/month of diagnosis (±1 month). None of the subjects (patients and controls) presented any infectious and neoplastic conditions, diabetes mellitus, hypertension and dyslipidemia. Prothrombin time (PT), activated partial thromboplastin time (aPTT), fibrinogen, vWF, plasminogen, antithrombin III (ATIII), protein C and S were evaluated using immunonephelometry (Dade-Behring). Lipid variables such as triglycerides, total cholesterol (C), LDL-C and HDL-C were also assessed. To evaluate thrombopoiesis, we have determined platelet indices (mean platelet volume, MPV; platelet distribution width, PDW; platelet count) using the Sysmex 9000 analyzer. TSH, T3, free-T3, T4 and free-T4 were determined using an electro-chemiluminescence immunoassay intended for use on Elecsys 2010 analyzer (Roche Diagnostics, Indianapolis, USA). Statistical analysis of data was performed with IBM-SPSS® statistical package version 20. **Results.** Cases with SH presented significantly higher MPV (mean ± SD: 12.31 fL ± 0.45) and PDW (mean ± SD: 15.3 % ± 1.1) than controls (mean MPV ± SD: 10.7 fL ± 0.82, p<0.001 and mean PDW ± SD: 13.4 % ± 1.42, p<0.001). Also, cases exhibited a significantly decrease in PT (p=0.043) and HDL-C (p=0.045) and significant increases in fibrinogen (p=0.05), triglycerides (p=0.023) and total cholesterol levels (p=0.045). Moreover, serum TSH levels were correlated with MPV (Spearman r=0.63, p<0.001) and PDW (Spearman r=0.42; p=0.024) in patients with SH but not euthyroidic healthy controls. No other significant correlations were found between thyroid hormones and hemostatic variables (p>0.05). **Conclusions.** This study suggest that subjects with SH tend to present minor coagulation abnormalities. Elevated platelet activation in conjunction with minor coagulation and lipid perturbations could contribute to an increased risk of cardiovascular complications observed in SH. Finally, the findings of this study suggest that platelet morphologic changes observed in SH may be attributed to hormonal parameters.

0490

SYSTEMIC MULTI-ORGAN COMPLICATIONS IN ATYPICAL HEMOLYTIC UREMIC SYNDROME (AHUS): RETROSPECTIVE STUDY IN A MEDICAL PRACTICE SETTING

C Langman
Feinberg School of Medicine, Northwestern University and Children's Memorial Hos, Chicago, United States of America

Background. Atypical hemolytic uremic syndrome (aHUS) is a genetic and life-threatening disease, in which permanently uncontrolled complement activation leads to platelet activation, endothelial damage, and multiple thrombotic occlusions in small vessels throughout the body (a process called systemic thrombotic microangiopathy, or TMA). Historically, the prognosis for aHUS patients is very poor and despite plasma exchange/infusion (PE/PI), 33%-40% of patients progress to end-stage renal disease or death with the first clinical aHUS manifestation and 65% of patients require dialysis, have permanent kidney damage, or die within 1 year of diagnosis. Though kidney impairment and end-stage renal disease are recognized as severe complications of aHUS, pre-

vious reports of cardiovascular (43%) and neurologic (48%) complications in the medical literature highlight the significant extra-renal morbidity that results from ongoing TMA in other vital organs. **Aims.** To identify and describe evidence of systemic multi-organ aHUS complications in a cohort of patients in the medical-practice setting. **Methods.** Medical record data were retrospectively collected for 30 pediatric, adolescent, and adult aHUS patients who received eculizumab treatment between 2007 and 2009 outside of a controlled clinical trial setting. Data corresponding to the time period prior to first eculizumab dose are described. **Results.** aHUS disease characteristics for patients at study baseline (prior to administration of first dose of eculizumab) are shown in Table 1. Medical records of all 30 aHUS patients (100%) showed evidence of kidney impairment during the time period prior to eculizumab treatment. Extra-renal, systemic organ complications were reported in 19 patients (63%; Table 2). Eleven patients (37%) experienced extra-renal thrombi, including deep vein thrombosis (n=5 patients [distal lower extremity, upper arm, shoulder, right iliac vein, nonspecified location]), myocardial infarction and pulmonary embolism (n=1), transient ischemic attacks (n=1), stroke (n=1), splenic vein occlusion (n=1), central retinal vein occlusion (n=1), and multiple thromboses (n=1). Four of these 11 patients experienced thrombotic events with no history of dialysis. In addition to extra-renal thromboses, cardiac morbidities included cardiac arrest (n=2) and cardiomyopathy (n=2). Gastrointestinal signs/symptoms were associated with aHUS presentation in 11 patients (37%) and included diarrhea (n=8), vomiting (n=5), and pancreatitis (n=2) together with the splenic vein occlusion (n=1) described above. Neurologic complications were found in this cohort, including seizures (n=2, including 1 patient with acute disseminated encephalomyelitis), headache (n=2), and facial paralysis (n=1), as well as the extra-renal thromboses of stroke and transient ischemic attacks (n=1 each) above. **Conclusions.** aHUS is a devastating and progressive disease in which TMA can be associated with sudden and potentially fatal systemic aHUS morbidities. These data are consistent with previous reports of multi-organ aHUS complications due to systemic TMAs, and suggest that evidence of TMA or progressive systemic organ involvement (including cardiac, gastrointestinal, and neurologic complications, as well as peripheral thrombi) should prompt high suspicion of aHUS as a clinical diagnosis, even in the absence of kidney failure.Craig Langman: c-langman@northwestern.edu

Table 1. Baseline[a] aHUS Disease Characteristics

Characteristic	All Patients (N=30)
Duration from aHUS diagnosis to 1st eculizumab dose, months, median (range)	11 (<1–176)
Platelet count <150×10⁹/L, n (%)	13 (43)
Serum LDH >ULN, n (%)	20 (67)
eGFR mL/min/1.73 m², n (%)	
≥90	4 (13)
60 to <90	2 (7)
30 to <60	11 (37)
15 to <30	5 (17)
<15	8 (27)
Received dialysis in 4 weeks prior to baseline, n (%)	11 (37)
Previous kidney transplantation, n (%)	11 (37)
Identified genetic complement mutation, n (%)	14 (47)

[a]Prior to initiation of eculizumab treatment. aHUS=atypical hemolytic uremic syndrome; eGFR=estimated glomerular filtration rate; LDH=lactate dehydrogenase; ULN=upper limit of normal.

Table 2. Incidence of aHUS Complications by System

System	Signs/Symptoms	No. (%) Patients
Renal	Kidney impairment	30 (100)
Cardiovascular	Thrombi (various locations), cardiac arrest, cardiomyopathy	11 (37)
Gastrointestinal	Diarrhea, vomiting, pancreatitis, splenic vein occlusion	11 (37)

PLATELET-ASSOCIATED ANTI-GPIIB/IIIA AUTOANTIBODIES IN PRIMARY IMMUNE THROMBOCYTOPENIA RECOGNIZE HIGHLY RESTRICTED REGIONS IN THE BETA-PROPELLER DOMAIN OF GPIIB WITH CLONALITY

K Kiyomizu[1], H Kashiwagi[1], T Nakazawa[1], S Tadokoro[1], S Honda[2], Y Kanakura[1], Y Tomiyama[3]
[1]Osaka University Graduate School of Medicine, Osaka, Japan
[2]National Cerebral and Cardiovascular Center, Osaka, Japan
[3]Department of Blood Transfusion, Osaka University Hospital, Osaka, Japan

Background. Primary immune thrombocytopenia (ITP) is an autoimmune disorder characterized by thrombocytopenia that results from immune-mediated platelet destruction and reduced platelet production. Platelet-associated (PA) anti-GPIIb/IIIa autoantibodies (Abs) play a key role in its pathogenesis. We and others have reported that epitopes of PA anti-GPIIb/IIIa Abs are mainly localized on GPIIb. However, the details of the epitopes have not been elucidated. **Aims.** To characterize epitopes of PA anti-GPIIb/IIIa Abs. [Methods] Platelet eluates from 76 patients with primary ITP (21 males, 55 females) were obtained by diethylether elution method. (We obtained written, informed consent for blood sampling from all patients.) We explored PA anti-GPIIb/IIIa Abs reactivity to human-mouse chimeric GPIIb/IIIa, since we noticed that the PA anti-GPIIb/IIIa Abs had markedly impaired reactivity to mouse GPIIb/IIIa. Human-mouse chimeric GPIIb/IIIa was transiently expressed in 293T cells and IgG binding was detected by flow cytometry. We also examined the light chain usage of the PA anti-GPIIb/IIIa Abs by flow cytometry. **Results.** PA anti-GPIIb/IIIa Abs were detected in 26 patients (34%) out of 76 patients, and we further analyzed 15 patients. We first found that the epitopes of PA anti-GPIIb/IIIa Abs were mainly localized in the N-terminal half of the β-propeller domain (L1-W235) of GPIIb. Next, using chimeric GPIIb in which surface residues of the N-terminal half of the β-propeller domain were serially exchanged with the corresponding mouse sequences, we could identify three major epitopes of PA anti-GPIIb/IIIa Abs; 1) Group A: The PA anti-GPIIb/IIIa Abs in 2 patients recognized W1:1-2 and W2:3-4 loops. W1:1-2 loop was very close to the W2:3-4 loop on the lower face of the β-propeller domain. Interestingly, the PA Abs reactivity was abolished by the following single amino acid substitution in GPIIb from human to mouse; S29K and R32S in W1:1-2 and E136Q and R139G in W2:3-4. 2) Group B: The PA anti-GPIIb/IIIa Abs in 5 patients recognized W1:2-3 loop. The PA Ab of one patient exclusively recognized the W1:2-3 loop and the PA Ab reactivity was markedly impaired by G44N and P45A substitutions in the loop. The PA Abs of other two patients mainly recognized W1:2-3, W2:3-4, and W3:3-4 loops, and the PA Abs from the remaining two patients recognized W1:2-3 and W2:3-4 loops. The PA Abs reactivity of these four patients was markedly impaired by R139G substitution in W2:3-4 like Group A patients. 3) Group C: The PA anti-GPIIb/IIIa Abs in 4 patients recognized W3:4-1 loop, which is near the ligand binding site, and furthermore 3 patients of them also recognized W4:4-1 loop which was immediately adjacent to the W3:4-1 loop. The PA anti-GPIIb-IIIa Abs in the remaining 4 patients also mainly recognized the N-terminal half in the β-propeller domain of GPIIb, but they could not be classified in the three groups described. Moreover we observed that many of the PA anti-GPIIb/IIIa Abs exhibited restricted usage of κ/λ light chain. **Summary**. We have demonstrated that many PA anti-GPIIb/IIIa Abs recognized highly restricted regions in the N-terminal half of the β-propeller domain of GPIIb with clonality.

SPECIFIC BINDING OF PARAPROTEIN TO PLATELET RECEPTORS AS A CAUSE OF PLATELET DISFUNCTION IN MONOCLONAL GAMMOPATHIES

I Djunic[1], I Elezovic[1], M Vucic[2], T Srdic-Rajic[3], A Konic-Ristic[4], V Ilic[4], N Milic[5], J Bila[1], N Suvajdzic-Vukovic[1], M Virijevic[1], D Antic[1], A Vidovic[1], D Tomin[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinic for Haematology, Clinical Center Nis, University Nis, Nis, Serbia
[3]Institute for Oncology and Radiology, Belgrade, Serbia
[4]Institute for Medical Research, Belgrade, Serbia
[5]Institute for Medical Statistics and Informatics, Belgrade, Serbia

Background. About 10% of patients with monoclonal gammopathies (MG) have hemostatic disorders at presentation, while the results of platelet function tests are abnormal in 30-55% of cases. The arising mechanism is believed to be connected with paraprotein. **Aims.** Our objectives were to examine the role of paraprotein in the appearance of abnormalities in platelet aggregation, and

to determine specific mechanisms whereby paraprotein inhibits normal platelet function in patients with MG. **Methods.** The study included 48 untreated patients with MG. Platelet aggregation was initially, induced with collagen (COL) and ristocetine (RIS). Paraprotein was isolated from the serum of ten patients with poor platelet aggregation. Platelet aggregation was measured before and after addition of the isolated paraprotein to platelet rich plasma (PRP) from ten healthy donors, *in vitro*. Expression of platelet vWF receptor-glycoprotein (GP) Ib and platelet collagen receptor GPVI was determined by flow cytometry in PRP of healthy donors before and after addition of isolated paraprotein using the monoclonal antibodies, CD42b (for GPIb), and CD36 (for GPVI). To evaluate surface changes on platelets, blood samples were mixed with the following mouse monoclonal antibodies: fluorescein isothiocyanate (FITC)-conjugated anti-CD36 and phycoerythrein (PE)-conjugated anti-CD42b. Peridinin Chlorophyll Protein Complex (PerCP)-conjugated anti-CD61 (specific for GPIIIa) was used to identify the platelet population. Appropriate isotype-matched controls were run in parallel to all monoclonal antibodies. The proportion of positive (%Pos) cells and the mean fluorescence intensity (MFI) were obtained for each sample as an index of receptor expression. The results were then expressed as total fluorescence intensity (TFI), where TFI = (%Pos/100) x MFI. As previously described, TFI takes into account both the %Pos cells and MFI.The same tests were repeated before and after addition of human immunoglobulins for intravenous use to PRP of healthy donors. **Results.** Platelet aggregation with COL (p = 0.008) and RIS (p = 0.001) in PRP of healthy donors was significantly decreased after addition of paraprotein. Flowcytometry showed that expression of CD42b and CD36 positive cells was significantly lower after addition of isolated paraproteins to PRP from healthy donors (p<0.001), while expression of CD61 positive cells was not changed. Also, MFI and TFI for both antibodies (CD42b and CD36) declined significantly after addition of paraprotein to PRP of healthy donors. In comparison, when human immunoglobulin was added to PRP of healthy donors, neither platelet aggregation nor expression of CD42b and CD36 positive cells nor MFI and TFI were altered. **Conclusions.** These investigations demonstrated that paraprotein causes platelet disfunction in patients with MG due to specific binding to the platelet vWF receptor GPIb and platelet collagen receptor GPVI. Specific binding of paraprotein to these platelet receptors was confirmed by the markedly decreased expression of CD42b and CD36 positive cells without changes in expression of CD61 positivity. By this mechanism paraprotein disables the normal function of platelets.

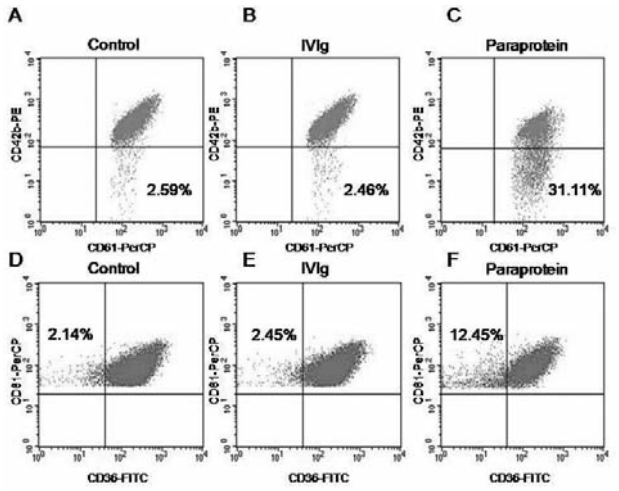

Figure 1. Decreased expression of CD42b and CD36 positive cells after addition of paraprotein in platelet rich plasma of healthy donors by flowcytometry.

ANALYSIS OF BASELINE BONE MARROW CHARACTERISTICS IN A LONGITUDINAL 2-YEAR BONE MARROW STUDY OF ELTROMBOPAG IN PREVIOUSLY TREATED PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA

R Brynes[1], A Orazi[2], K Bakshi[3], C Bailey[3], A Brainsky[3]
[1]University of Southern California, Los Angeles, United States of America
[2]Weill Cornell Medical College, New York, United States of America
[3]GlaxoSmithKline, Collegeville, United States of America

Background. Bone marrow biopsies are not routinely performed in the management of chronic immune thrombocytopenia (cITP). Although some studies have retrospectively reviewed biopsy specimens, prospectively collected data in cITP are limited. Reticulin grades 0, 1, and 2 (Bauermeister scale) have been reported in healthy volunteers in 7%, 73%, and 20%, respectively [Sundström 2002]. A Danish study of 187 cITP patients never treated with thrombopoietin receptor agonists (TPO-RAs) showed that 60% had MF-0, 38% MF-1, and ~2% MF-2 or MF-3 (European Consensus scale) [Ettrup 2010]. TPO-RAs have been associated with varying degrees of increases in reticulin fibers [Brynes 2011, Ghanima 2011], but the lack of prospectively collected and consistently stained and analyzed pre-treatment bone marrow specimens has limited the robustness of the conclusion. This study was designed to prospectively investigate potential effects of eltrombopag on the bone marrow. **Aims.** To assess the degree of baseline bone marrow reticulin and collagen in adults with cITP. **Methods.** Adults with cITP who failed first-line therapy were enrolled in this open-label, 2-year study (NCT01098487). Bone marrow biopsies were collected at baseline and after 1 and 2 years of eltrombopag treatment. Specimens were centrally processed and underwent a central pathology review. They were assessed for cellularity; megakaryocyte, erythroid, and myeloid quantity and appearance; trabecular bone quality; reticulin grade; and collagen deposition (European Consensus scale) [Thiele 2005]. Baseline findings of the bone marrow biopsies are reported. **Results.** One hundred fifty-five patients were analyzed. Median age was 41 years (18-80); 100 (65%) were female. Median time since cITP diagnosis was 3.9 years (0.5-45.7). 143 (92%) patients were TPO-RA-naive and 12 (8%) had received prior TPO-RA treatment (eltrombopag or romiplostim), the last dose at least 6 months prior to enrollment. 34 (22%) patients were splenectomized. Median platelet count prior to bone marrow biopsy was 21,000/μL (0-222,000/μL).Cellularity was normal (40-60%) in 130 (85%) patients (Table 1). 139 (91%) patients demonstrated megakaryocytic hyperplasia. Megakaryocyte morphology was normal in 144 (94%) patients. Erythroid hyperplasia was observed in 27 (18%) patients and granulocytic maturation was hyperplastic in 7 (5%) patients.Trabecular bone thinning was found in 60 (43%) patients, the majority with prior exposure to corticosteroids. Reticulin fibers were graded as MF-0 in 139 (90%) and MF-1 in 16 (10%) patients. Reticulin fibers were graded as MF-0 for all 12 patients who had received prior TPO-RA treatment. No patients demonstrated collagen deposition. **Summary and Conclusions.** Analysis of this prospectively collected database indicates that approximately 10% of cITP patients may have MF-1 reticulin in their bone marrow. It has been hypothesized that TPO-RAs may increase reticulin and collagen deposition in the bone marrow. Data from the EXTEND study presented in 2011 [Brynes 2011] do not indicate a clinically relevant increase in reticulin; however, the analysis was limited by lack of baseline bone marrow data. Prospective data from the current study will allow a better understanding of the potential effect of eltrombopag on the bone marrow.

[7]Queensland Institute of Medical Research, Brisbane, Australia
[8]Frankston Haematology & Oncology, Frankston, Australia

Background. Idiopathic thrombocytopenic purpura (ITP) is an auto-immune disorder characterized by low platelet count and mucocutaneous bleeding. Post-acute presentation, 25-30% adult patients develop chronic ITP, up to 30% of whom become refractory to corticosteroids and require additional therapy. B-cells play an important pathophysiological role in auto-immune disease. Rituximab depletes CD20+ B-cells and an exploratory dosing regimen based on lymphoma therapy (375 mg/m^2 weekly intravenous x4) has shown promising efficacy (~38% overall response rate-ORR) in adults with chronic and relapsing ITP. We explored the effectiveness of an abbreviated fixed dose rituximab schedule that has been approved in rheumatoid arthritis. Rituximab is not currently approved for the treatment of ITP. **Aims.** The primary objective was to determine the ORR at week 8 in adults (≥18 years), with chronic or relapsing ITP (platelet count >10x10^9/L and ≤50x10^9/L) according to the ASH guidelines, who received rituximab 1000mg on days 1 and 15. Secondary objectives included time to, duration of and incidence of therapeutic response (defined below). **Methods.** After obtaining informed consent, patients received scheduled rituximab and were followed-up for at least 12 weeks. Evaluations were at mandatory follow-up visits on weeks 8, 12, 26, 39 and 52. ORR was defined as the proportion of patients achieving complete response (CR, platelet count >150x10^9/L) or partial response (PR, >50x10^9/L) at week 8 with 2 consecutive measurements, confirmed at least 2 weeks apart. Minor response (MR) was defined as platelet count >30x10^9/L. Simon's 2-stage design was used to determine if the ORR was more likely to be ≤38% or ≥50%. At least 50 out of 108 responders (46%) were required to conclude, with 95% confidence and 80% power, that the ORR was more likely to be ≥50%. Duration of response was determined for patients with a response (MR/PR/CR) at week 8. Time to response was defined as time from first rituximab infusion to time of onset of MR/PR/CR, at any time throughout the study. Therapeutic response was defined as achieving a week 8 response, with at least minor response sustained through to weeks 26 and 52, and reduction in ITP medication.

Table 1. Incidence of response at week 8, duration of response, time to response and time to initiation of new ITP therapy.

Incidence of Response at Week 8 (N = 108)		Patients with relapse n (%)	Patients without relapse n (%)	Median duration of response (days)	95% CI
CR	N = 10	1 (10)	9 (90)	ND	(ND, ND)
CR+PR	N = 47	25 (53)	22 (47)	247	(219, ND)
CR+PR+MR	N = 66	33 (50)	33 (50)	256	(168, ND)
Time to Response at any visit		**Patients with response n (%)**	**Patients without response n (%)**	**Median time to response (days)**	**95% CI**
CR		30 (28)	78 (72)	ND	(305, ND)
CR+PR		61 (57)	47 (44)	53	(36, 152)
CR+PR+MR		77 (71)	31 (29)	22	(8, 30)
Time to New ITP Therapy*		**Patients with new therapy n (%)**	**Patients without new therapy n (%)**	**Median time to new therapy (days)**	**95% CI**
Any New ITP Therapy		54 (50)	54 (50)	314	(215, ND)

ND= not determined due to insufficient events. *Including patients who did not respond at week 8.

Results. Of 124 recruited patients, 2 did not receive study medication and 14 did not have platelet count ≤50x10^9/L within 7 days of first rituximab dose and were excluded from analysis. At week 8, the ORR was 44% (47/108 patients). Median duration of response, time to response and time to initiation of new ITP therapy results are presented in Table 1. Therapeutic response at weeks 26 and 52 was achieved in 47(44%) and 38(35%) patients, respectively. Treatment was well tolerated with no new safety signals reported. **Conclusions.** The observed response rate and durability of response in this study compare favorably with rituximab given weekly for 4 weeks, and offers relapsing/chronic ITP patients an alternative to ongoing thrombopoietin receptor agonists. Further investigations are warranted to determine whether the same response can be achieved with single/lower dosing rituximab or whether longer/more intense dosing, as well as maintenance dosing, might improve ORR and durability of responses.

Background. Eltrombopag is an oral, nonpeptide, thrombopoietin receptor agonist approved for treatment of chronic immune thrombocytopenia (cITP). EXTEND is an ongoing, open-label extension study of long-term cITP treatment with eltrombopag in patients completing a prior eltrombopag study (including 6-month follow-up). Interim EXTEND data describing effects of eltrombopag on health-related quality of life (HRQoL) from June 2006-December 2008 have been reported (Bussel 2009); effects of longer treatment on HRQoL have not been reported. **Aims.** To assess longer-term effects of eltrombopag on HRQoL among cITP patients in EXTEND from June 2006 to February 2011, following a median treatment duration >2 years. **Methods.** HRQoL (7-day recall) was self-reported at baseline (BL) and upon progression toward establishing an effective dose, using the SF-36v2, FACIT-Fatigue subscale, MEI-SF, and 6 items from FACT-Thrombocytopenia (FACT-Th6), focusing on bruising and bleeding concerns and limitations in daily physical and social activities. Generalized estimating equations were used to account for multiple assessments of the same patient. Clinical meaningfulness was expressed using developer specifications or minimally important differences (MIDs) using a distribution-based method (0.5 standard deviations of BL scores). **Results.** As of this analysis, 287-291/300-301 patients in EXTEND (depending on the assessment tool) had both BL and on-therapy HRQoL assessments. BL SF-36v2 and FACIT-Fatigue scores were consistent with shorter-term eltrombopag studies, reflecting impaired HRQoL in chronic ITP patients compared with the general US population (Ware 2000; Cella 2002). Improvements from BL in HRQoL were observed throughout EXTEND while remaining lower than US general population norms.Patients experienced statistically significant (*P*<0.05) and modest clinically meaningful improvements from BL at every stage of EXTEND for the FACIT-Fatigue and FACT-Th6, and during Stages 2-4 for the MEI-SF, corresponding to reductions in fatigue and bleeding/bruising concerns and improved motivation and energy (Table 1).

Table. Adjusted HRQoL Score Changes From BL During EXTEND. Covariates included time since BL visit; stage; prior splenectomy; BL platelet count «15x10^9/µL; age; ethnicity; body mass index; region; sex; country; prior exposure to eltrombopag; and treatment termination status. Significant values (*P*<0.05) are highlighted.

HRQoL Measure	BL Score (95% CI)	Dosing Identification (Stage 1)[a]	Minimizing ITP Medications (Stage 2)[b]	Optimizing Dosing (Stage 3)[c]	Maintenance Dosing (Stage 4)[d]
		Estimated Change From BL (95% CI)

[a]Identification of an eltrombopag dose that increases platelets ≥100,000/µL.
[b]Reduction or elimination of any concomitant ITP medication use while maintaining platelets ≥50,000/µL.
[c]Identification of minimal eltrombopag dose to maintain platelets ≥50,000/µL in conjunction with the minimal dose of any concomitant ITP medication use.
[d]Long-term treatment and monitoring using doses identified in Stage 3.
BL, baseline; CI, confidence interval; ITP, immune thrombocytopenia; MCS, mental component summary; PCS, physical component summary.

Statistically significant improvements from BL for the SF-36v2 physical component summary (PCS) were reported during eltrombopag dose identification (Stage 1), optimization (Stage 3), and maintenance (Stage 4; Table 1). No such improvements from BL were reported for the SF-36v2 mental component summary (MCS). Statistically significant improvements from BL occurred for several SF-36v2 domains, notably when patients reached maintenance dosing. Improvements in bodily pain and mental health domains were limited to the maintenance dosing stage.Patients withdrawing from or completing study reported mean HRQoL scores at their last on treatment visit that were at or slightly lower than BL, a decrease driven by withdrawals (41%); in contrast, HRQoL remained higher than BL for patients remaining on treatment. **Summary and Conclusions.** EXTEND study results suggest that treatment with eltrombopag is associated with improvement in HRQoL across multiple measures and domains related to fatigue and physical dimensions of HRQoL. Improvements were seen across multiple stages while on therapy, especially during the maintenance stage, while consistently remaining lower than general population norms. Emotional role, mental health, and bodily pain improvements were limited, suggesting difficult domains to modify even with extended therapy. These results support interim findings reported previously, suggesting durable improvements in HRQoL domains, especially fatigue and physical functioning, in cITP patients with long-term eltrombopag treatment.

Background. TPO-RAs increase platelet counts in patients with ITP by promoting magakaryocyte proliferation and differentiation. One potential adverse effect of TPO-RA is the stimulation of bone marrow fibrosis (BMF). The relation between megakaryocyte stimulation and BMF has been demonstrated in animal models by showing that high doses of TPO-RA result in dose-dependent BMF - a process that may be mediated by transforming growth factor-β (TGF-β). However, in humans the knowledge regarding the extent of BMF with prolonged exposure to TPO-RA is limited.The N- and C-terminal propeptides of collagen I and III are removed in a 1:1 ratio before fibril formation occurs- the basis for their use as biomarkers for collagen production in fibroproliferative conditions. Hyaluronan is abundantly present in the extracellular matrix, particularly at sites of tissue inflammation. Altered concentration of these substances has been reported in patients with primary myelofibrosis.**Aims**The aims of the study were to determine blood levels of connective tissue metabolites and fibrosis-related growth factors and their significance in consecutive samples collected from ITP patients treated with TPO-RA. **Methods.** Forty-eight TPO-RA treated ITP patients in whom BM biopsies were performed during treatment were identified. Pre-treatment (<2 months) and sequential on-treatment frozen blood samples were retrieved at 6 months intervals, whenever available. Myelofibrosis (MF) was graded according to the European Consensus Grading System. Connective tissue metabolites were analyzed in serum by radioimmunoassay; TGF-β was analyzed in plasma by ELISA and Hepatocyte GF (HGF) by immuno-bead-based multiplex assay (R&D systems). **Results.** Median age (28 females 58%) was 50 years. Median duration of treatment with TPO-RA to the time of last available BM Biopsy (BMB) was 1.8 years (range 0.15-6.7). In 46 evaluable biopsies, reticulin was graded MF-0 in 8 (17%), MF-1 in 31 (67%), MF-2 in 7 (15%). Median duration of exposure was 1.8 years in MF0/1 and 1.5 years in MF-2. Median values of collagen metabolites and GFs are shown in the Table. **Discussion and Conclusions**85% of the patients treated with TPO-RA had no or low-grade (MF-1) reticulin deposition in the BM. No difference in duration of treatment was noted between those with less than MF-2 and those with MF-2. Sequential measurements of connective tissue metabolites revealed decreasing levels of PINP and PIIINP over time, confirming our previous findings, and suggesting decelerated collagen synthesis despite sustained platelet response, and unchanged dosage. TGF-β increased initially after treatment, but then declined gradually along with PIIINP. HGF, an antifibrotic and angiogenesis-related GF, seemed to decrease after initiation of TPO-RA and remained low.The number of samples limits subgroup analysis, however, levels of HA, ICTP and HGF at 24 months appeared higher in MF-2 than MF-0/1.In conclusion, persistent low-grade reticulin fibrosis was observed in most patients; MF-2 was seen in several, but none had MF-3. Biomarkers of collagen synthesis and fibrosis-related-GFs tended to decrease while collagen degradation remained steadily elevated. These findings suggest that ITP is associated with an abnormal bone marrow stromal reaction, which is partially corrected during TPO-RA treatment.

EFFECT OF THROMBOPOIETIN-RECEPTOR AGONISTS ON CIRCULATING CYTOKINE AND CHEMOKINE LEVELS IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)

S Gudbrandsdottir[1], W Ghanima[2], X Feng[3], S Lee[4], C Nielsen[1], H Hasselbalch[5], J Bussel[4]
[1]Copenhagen University Hosp Rigshospitalet, Copenhagen, Denmark

[4]Dep of Pediatric Hematology/Oncology, Weill Cornell Medical College, New York, United States of America
[5]Dep. of Hematology, Copenhagen University Hospital Roskilde, Roskilde, Denmark

Background. Thrombopoietin receptor agonists (TPO-RA) are new treatment modalities for chronic ITP, exerting their effect by stimulating platelet production. It is well established that platelets are associated with inflammatory processes involving both the innate and the adaptive immune compartment, and preliminary studies show that treatment with TPO-RA increase suppressive activity of regulatory T-cells. The effect of TPO-RA on inflammatory cytokine production in ITP patients before and during treatment has not been investigated previously. **Aims.** To determine the influence of TPO-RA on the production of a panel of inflammatory cytokines and chemokines in chronic ITP patients before and during treatment with TPO-RA compared to healthy controls. **Methods.** Cytokines and chemokines in EDTA-plasma samples from 48 ITP patients treated with TPO-RA (28 females, median age 50 years [IQR 20-69 years], median platelet counts 24 x 10^9/L [IQR 15-47x 10^9/L]) and 16 healthy controls (9 females, median age 37 years [IQR 22-51 years]) were analysed by enzyme-linked immunosorbent assay and immuno-bead-based multiplex assay. **Results.** Compared to healthy controls, elevated levels of the pro-inflammatory immunomodulating molecules TNF-a ($p < 0.001$) and IP-10 ($p < 0.001$) were observed in pre-treatment samples from ITP patients, as were levels of the anti-inflammatory anti-osteolytic molecule osteoprotegerin (OPG) ($p < 0.05$). During treatment with TPO-RA, levels of IP-10 (after 18 months, $p < 0.05$) and OPG (after 12 and 18 months, $p < 0.05$) decreased compared to pre-treatment values, while TNF-a remained elevated. The IL-1ra/IL-1b ratio decreased after 6 months of treatment ($p < 0.05$), although at no point were levels statistically

different from those of healthy controls. Levels of CD40L increased after 6 months of treatment ($p < 0.05$) but then decreased to pre-treatment values that were comparable to those of healthy controls. IFN-g and IL-10 did not differ significantly from healthy controls or change during treatment. **Summary and Conclusions.** It is well established that platelets possess immunomodulatory properties. Since TPO-RA increase platelet counts by stimulating platelet production in the bone marrow, the question arises of whether this treatment also exerts some effects on the immune system. In this study we report, for the first time, the influence of TPO-RA on a panel of immunolmodulatory cytokines and chemokines, compared to both pre-treatment values and healthy controls. We found a decrease in concentrations of the pro-inflammatory mediators IP-10 and CD40L, accompanied by a decrease in the anti-inflammatory osteoprotegerin as well as an initial decrease in the IL-1ra/IL-1b ratio during treatment. However, levels of TNF-a remained elevated indicating that autoreactive T-helper cells stay activated at least to some extent during treatment. Levels of IL-10 and IFN-g did not differ from healthy controls or change during treatment. Our findings suggest that TPO treatment influences the expression of immunomodulatory signalling molecules associated with the bone marrow micro-environment. The underlying effector mechanisms and clinical implications of these findings need to be further investigated.

EFFECT OF ACTIVATED PLATELETS ON INTERLEUKIN-10 PRODUCTION BY MONOCYTES IN VITRO

S Gudbrandsdottir[1], HC Hasselbalch[1], CH Nielsen[2]
[1]Copenhagen University Hospital Roskilde, Roskilde, Denmark
[2]Institute for Inflammation Research, Copenhagen University Hosp Rigshospitalet, Copenhagen, Denmark

Background. Platelets are associated with inflammatory processes involving both the innate and the adaptive immune compartment. Recent studies have indicated that activated platelets may stimulate maturation of monocyte-derived dendritic cells and regulate T- and B-cell activity, but little is known about the direct effects of platelets on monocytes. **Aims.** To investigate the effect of activated autologous platelets on cytokine production and $CD4^+$ T-cell proliferation in cultured mononuclear cells. **Methods.** Mononuclear cells (MNCs) from 11 healthy donors were stimulated with the self-antigen thyreoglobulin (TG) and the foreign antigens tetanus toxoid (TT) and lipopolysaccharide (LPS) and cultured in the absence or presence of activated autologous platelets. Supernatants were harvested after 24 hours and analysed for Th1/Th2 cytokine production, $CD4^+$ T-cell proliferation was determined by flowcytometry as dilution of carboxyfluorescein succinimidyl ester (CFSE). MNCs from an additional 10 healthy donors were stimulated with TT or TG and cultured correspondingly. After 18 hours of culture monocytes were analysed for IL-10 and TNF-a secretion by flow cytometry. **Results.** Addition of activated platelets caused an increased production of IL-10 in MNC cultures stimulated with LPS ($p < 0.001$) and TG ($p < 0.05$). Moreover, activated platelets reduced the production of TNF-α in cultures stimulated with LPS ($p < 0.001$) and TG ($p < 0.05$) and inhibited the production of IL-6 in LPS-stimulated cultures ($p < 0.01$). Correspondingly, addition of activated platelets increased the proportion of monocytes secreting high amounts of IL-10 following stimulation with TG ($p < 0.05$. Platelet/monocyte aggregates were detected flow cytometrically as events double-positive for the monocyte marker CD14 and the platelet marker CD61. Platelet/monocyte aggregates were found in the cultures irrespective of platelets had been added *in vitro*, but their proportion was increased after addition of activated platelets to cultures stimulated with TG (3.9 vs 8.0 %, $p < 0.01$). Interestingly, platelet-bearing monocytes showed significantly higher IL-10 secretion than monocytes without adherent plateles in MNC cultures stimulated with TG ($p < 0.05$). Moreover, the presence of activated platelets inhibited the proliferation of $CD4^+$ T cells elicited by TT ($p < 0.05$) or TG ($p < 0.01$). **Summary and Conclusions.** The data suggest that activated platelets exert an immunoregulatory function by enhancing IL-10 production by monocytes and that this, at least in part, depends on direct platelet-monocyte adhesion. Platelets inhibit proliferative T helper-cell responses to self- and non-self antigens, probably via their induction of monocyte IL-10 production.

PLATELET FLOW CYTOMETRY AND MARKERS OF IMMUNE ACTIVATION IN ASYMPTOMATIC, TREATMENT- NAÏVE HIV INFECTION

B Nkambule[1], H Ipp[2], R Glashoff[3]
[1]Stellenbosch University, Cape Town, South Africa
[2]Divisions of Haematology, Stellenboch University and Tygerberg Hospital, Cape Town, South Africa
[3]Division of Virology, Stellenbosch University and Tygerberg Hospital, Cape Town, South Africa

Background. In the era of antiretroviral therapy (ART), the risk of acquired immune deficiency syndrome (AIDS)-related deaths has decreased and people living with Human Immunodeficiency Virus (HIV) have prolonged life spans. HIV-infected patients are now at a higher risk of developing cardiovascular disease (CVD) and other inflammatory-associated complications. Activated platelets play a key role during infection and the inflammatory process, by mediating interactions between cells of innate immunity and the endothelium. Soluble markers of platelet activation are increased during HIV-infection. P-selectin (CD62P) is expressed on the platelet surface only upon platelet activation. Activated platelets play a role in HIV-induced atherosclerosis through the expression and release of mediators that induce endothelial activation and support leukocyte adhesion to the inflamed vessel wall. **Aims.** To determine the levels of platelet activation and function by Flow Cytometry in HIV-infected individuals as compared with uninfected controls; and further, to correlate these levels with full blood count, coagulation and other inflammatory parameters. **Methods.** In this study, a total of 57 adult South Africans were recruited from a clinic in the Western Cape. These included 32 HIV positive, ART- naïve patients and 25 HIV negative individuals. Platelet activation and platelet function were investigated using a novel whole blood Flow Cytometry assay: Platelet-specific markers CD41a and CD42b were used to ensure platelet-specific gating. CD62P expression was used to evaluate platelet activation. Platelet function was evaluated by investigating the response of platelets to endogenous agonists; adenosine diphosphate(ADP) and arachidonic acid (AA) at varying concentrations. A full blood count and differential as well as fibrinogen levels were determined using routine hematology laboratory analyzers. **Results.** Baseline levels of CD62P expression were significantly higher in treatment-naïve HIV positive patients compared with uninfected controls (mean %CD62P 71.74 + 2.18 vs control 54.52+ 2.42; p=<0.0001). CD62P expression correlated directly with platelet counts (r=0.374, p=0.042) whereas platelet counts showed an inverse correlation with viral loads (r=-0.65, p=0.0061). Fibrinogen levels correlated with absolute WCCs (r=0.659, p=0.0021); absolute neutrophil count (r=0.619, p=0.0105); absolute monocyte count (0.562, p=0.0235) and hsCRP (r=0.688 p=0.0011). Importantly, fibrinogen showed a negative correlation with CD4 counts (r=-0.594, p=0.0014) and may be a valuable marker of prognosis in treatment- naïve, HIV positive patients. HsCRP levels correlated with absolute neutrophil counts (r=0.392, p=0.0005).The HIV Group showed an overall hyper-response to ADP at a concentration 0.025 μM as compared to uninfected controls (62.34 + 9.7 vs control 36.90 + 5.7, p=0.0433). **Conclusions.** We describe a novel Flow Cytometry technique that may be used to evaluate the levels of platelet activation and function in HIV-infected patients. In addition we report a cost-effective panel in the form of fibrinogen, WCC and platelets that may be valuable in predicting the progression to AIDS or other inflammatory- associated complications in treatment-naïve HIV-infected patients. This may impact on patient management prior to initiation of ART and provide a tool for monitoring responses to treatment. Longitudinal studies will be required to assess risk of thrombosis based on these assays and the potential for application in other chronic inflammatory conditions.

[3]Department of Haematology, St George's Hospital, Blackshaw Road, London, United Kingdom
[4]Department of Cell Therapy and Hematology, San Bortolo Hospital, Vicenza, Italy
[5]Clinica Ematologica, Centro Trapianti e Terapie Cellulari „Carlo Melzi„ DISM, Udine, Italy
[6]Department of Hematology, Niguarda Ca'Granda Hospital, Milan, Italy

Background. Splenectomy is still regarded as the best second line treatment of immune thrombocytopenia (ITP). Recently, new medical therapies (anti-CD20 monoclonal antibodies and thrombopoietin mimetics) have entered into clinical practice, encouraging a general tendency to delay splenectomy. Consequently, the importance to define the efficacy and safety of splenectomy in the long-term is substantial. **Patients and Methods.** We retrospectively analyzed clinical data of 214 ITP patients who underwent splenectomy between 1962 and2001, in 6 different European hematological Institutions and have now a minimum follow-up of 10 years from surgery (median, 20.4 years; range 10-43 years). **Results.** Overall, 140/214 (65%) ITP patients were women. Median time from diagnosis to splenectomy was 13 months (range 0-254 months) and median age at splenectomy was 33 years (range 6-74 years). All patients but 3 underwent splenectomy after one or more steroid-based treatments. Overall, 187 patients (87%) achieved a response (R, platelet count >30x10^9/L), which was complete (CR, platelet count >100x10^9/L) in 162 patients (76%). In 123 cases (66%), the response was stable at last contact. Sixty-four patients (34%) lost the response during the follow-up. Sixteen of these patients (25%) experienced an early relapse (within 6 months from splenectomy), while in the remaining 48 patients, relapse occurred after a median time of 25 months (range, 6-256), for a relapse-free survival of 65% at 20 years of all responding patients (Figure 1). Median time to relapse was significantly shorter in R-patients compared to CR-patients (12 vs 21 months, p<0.01). Overall, 90 patients of 214 patients (42%) needed further treatment after surgery, that induced at least a R in 77 patients (86%). Fifty-five patients (26%) experienced 204 hemorrhagic events (14 of which grade 3-4 WHO), after a median time of 15 months. Twenty-six thrombotic events (4 fatal) have been observed in 18 patients (8%), after a median time of 200 months (range 0-392 months). Seventy patients (33%) experienced one or more infectious episodes after surgery, which were severe (pulmonary) in 33 cases and were observed after a median follow-up of 36 months (range 0-355 months). Forty-one of them (59%) were vaccinated against encapsulated bacteria and 38 (54%) received one or more treatments because of refractory or relapsed disease after splenectomy. Thirty-five patients died during follow-up (median age 73 years at death, range 43-88 years). The causes of death were related to ITP or ITP-treatment in 3 cases (2 patients had fatal hemorrhages, 1 patient sepsis). **Conclusions.** Splenectomy induced a stable remission in 66% of ITP patients with a minimum and median follow-up after splenectomy of 10 and 20.4 years respectively. Relapses were mainly observed during the first months following surgery, reaching a plateau after about 12 years (Figure 1). The incidence of late severe infectious complications was not negligible, probably due to the fact that about 40% of these patients did not receive prophylactic vaccinations and half of them have needed further medical therapy. A detailed analysis concerning prognostic factors for response after splenectomy is also planned.

[7]Hospital Infantil Universitario Nino Jesus, Madrid, Spain
[8]Hospital La Paz, Madrid, Spain
[9]University of New Mexico, Albuquerque, United States of America
[10]GlaxoSmithKline, Collegeville, United States of America

Background. Most therapies for chronic immune thrombocytopenia (cITP) have side effects that reduce their tolerability in children. PETIT is an ongoing open-label and randomized, placebo-controlled trial to investigate efficacy and safety of eltrombopag in children with cITP who failed initial therapy and have platelets <30,000/μL. **Aims.** To report open-label data from PETIT. **Methods.** Five patients were enrolled in Cohort 1 (12-17 years) and received open-label eltrombopag. After 12 weeks, safety, pharmacokinetics, and platelet counts were reviewed and 18 patients (not part of this abstract) were randomized 2:1 to eltrombopag or placebo. All patients received 24 weeks of eltrombopag therapy. In Cohort 1, the 12-week review identified no safety issues, so dosing began for 5 open-label patients in Cohort 2 (6-11 years), with identical procedures followed for safety review and randomization of 18 patients. Cohort 3 (1-5 years) opened once data from the completed randomized periods of Cohorts 1 and 2 were evaluated by an independent data safety monitoring board.Conservative starting doses were used (Cohort 1, 25 mg daily; Cohort 2, 25 mg [weight ≥27 kg] or 12.5 mg [<27 kg]; Cohort 3, 0.7 mg/kg) and adjusted as needed to a maximum of 75 mg daily, to maintain platelet count ≥50,000-<400,000/μL. Starting doses were reduced 50% for East Asian patients. Assessments were weekly until a stable dose was achieved and monthly thereafter. Response was platelets ≥50,000/μL at any time in the absence of rescue treatment. **Results.** Data from the 15 open-label patients, 5 from each cohort, are presented (Table 1). At baseline, 9 (60%) patients had platelets ≤15,000/μL, 1 was splenectomized, and 1 was receiving a stable dose of methylprednisolone.Median doses during 24 weeks were 75 mg for both Cohorts 1 and 2, and 70 mg for Cohort 3. All patients completed 24 weeks of treatment.Response was achieved at least once by 80% of patients (4/5 in each cohort). Between weeks 17-24, 8/15 (53%) patients had platelets ≥50,000/μL in ≥50% assessments and 11/15 (73%) had ≥30,000/μL in 80% of assessments, without rescue treatment. The patient receiving methylprednisolone discontinued it after 71 days. Seven (47%) patients received rescue treatment.Incidence of WHO bleeding grades 1-4 and 2-4 was 87% (13/15) and 33% (5/15) at baseline, decreasing to 50% (7/14) and 7% (1/14) by Week 24.All patients reported adverse events (AEs). 88% were grades 1-2, 9% were not graded, and there was 1 grade 4 AE (neutropenia). Serious AEs were reported for 2 patients (neutropenia, epistaxis). The most common AEs were headache (8 patients, 53%), vomiting (7, 47%) and diarrhea (5, 33%). No patient had AEs of liver enzyme elevation or thrombosis, and none were withdrawn due to AEs.**Summary and Conclusions.** Preliminary data suggest that eltrombopag is safe and potentially effective for children with cITP failing first-line therapy. No safety issues prevented enrollment into subsequent cohorts or the double-blind phase. Efficacy conclusions are limited by small patient numbers, lack of comparator arm, and low starting doses. The ongoing randomized study will further characterize safety and efficacy of eltrombopag in childhood cITP.

MEASUREMENT OF SERUM B-CELL ACTIVATING FACTOR OF TUMOR NECROSIS FACTOR FAMILY (BAFF) IN PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA AND ITS CORRELATION WITH IMMUNOSUPPRESSIVE THERAPY

M Ayoub, A Abdel-Hamid, M Al- Feky, G Tawfick, G Kamal, H Abd El Bary
Ainshams University, Cairo, Egypt

Background. B-cell activating factor of the tumor necrosis factor family (BAFF) is a homotrimeric type 2 transmembrane protein that also exists in a soluble form. It belongs to the family of tumor necrosis factor (TNF) ligands. BAFF is expressed at the surfaces of myeloid cells and antigen- presenting cells (APCs) and induces B-lymphocyte proliferation and immunoglobulin secretion. **Aims.** to assess serum BAFF level in patients with idiopathic thrombocytopenic purpura and correlate its level with response to immunosuppressive therapy (corticosteroids). **Methods.** The study included 60 subjects; 40 patients with newly diagnosed idiopathic thrombocytopenic purpura (ITP) who were followed for 3 months after immunosuppressive therapy (steroids) then divided into responders and non responders and 20 healthy control subjects. **Results.** Serum BAFF level was lowest among controls (mean ± SD 3.4+2.2 ng/mL) ITP patients (responders and non-responders) before treatment (mean ± SD19.8+2.9 ng/ml and 20.5+8.8 ng/ml respectively) with statistically highly significant difference (P value is highly significant <0.001), But no significant difference between responders and non responders. On the other hand BAFF level after treatment was still high among non responder group (mean ± SD 18+7.6 ng/ml) with statistically highly significant difference in comparison to responders and controls (mean ± 3.6+1.9 and 3.4+2.2 ng/mL respectively), with highly significant P value (<0.001). **Conclusions.** It was found that BAFF decreased markedly among total cases and among responder group with statistically highly significant difference. Percentage of change was 84% among responders compared to 10% only among non responders.Therefore,it is possible that transcriptional down regulation of BAFF represents a novel target in therapy of ITP.

COST-EFFECTIVENESS OF ROMIPLOSTIM FOR THE TREATMENT OF ADULT IMMUNE THROMBOCYTOPENIA IN IRELAND

P Thornton[1], D Lee[2], A Hirst[2], R Deuson[3], L Kutikova[4], N Brereton[2]
[1]Connolly Hospital, Dublin, Ireland
[2]BresMed Health Solutions, Sheffield, United Kingdom
[3]Amgen, Thousand Oaks, United States of America
[4]Amgen Europe, Zug, Switzerland

Background. Immune thrombocytopenia (ITP) is an autoimmune disorder that results in accelerated platelet destruction as well as reduced platelet production. The use of thrombopoietin-receptor agonists romiplostim and eltrombopag are recommended for second-line use in adult ITP patients[1]. **Aims.** To assess the cost-effectiveness of treatment of ITP in Irish patients by firstly introducing romiplostim versus eltrombopag after rituximab treatment into current standard of care (SC; including rituximab) for adult ITP in Ireland, and secondly placing romiplostim in different positions in the treatment pathway. **Methods.** A lifetime treatment-sequence cost-utility model was built from an Irish healthcare payer perspective. The model was driven by platelet response (platelet count ≥50×10^9/L), which determined treatment progression, need for rescue therapy and risk of experiencing bleeds. Clinical inputs, patient characteristics and utilities were derived from indirect comparison of efficacy between romiplostim and eltrombopag[2], clinical trials, International Consensus Guidelines[1] and other published evidence. Treatment of bleed-related events consisted of rescue therapy (intravenous immunoglobulin IVIg and intravenous steroids), physician visits and hospitalizations associated with bleeds. Treatment sequences and health care utilization practice was validated by clinical experts. Costs were derived from published Irish reimbursement lists and other relevant sources. For different treatment sequences, which included romiplostim, eltrombopag and rituximab, total treatment costs and Quality Adjusted Life Years (QALYs, One QALY = one year in full health) over a patient's lifetime were calculated. **Results.** In the treatment sequence after rituximab, compared to eltrombopag, romiplostim was associated with cost savings of €25,386 and increased QALYs by 0.96 over a patient's lifetime. Cost savings are due to a reduction in the costs of rescue therapies (IVIg and steroids) and a reduction in the cost of treating bleeds. In the same sequence, compared to SC including rituximab, romiplostim was associated with cost savings of €27,022 with an increase of 1.14 QALYs over a patient's lifetime (Table 1). When romiplostim and eltrombopag were placed before rituximab in the treatment sequence, use of romiplostim remained the more efficacious treatment pathway, at a lower cost compared to both eltrombopag and SC. **Summary.** Romiplostim not only improves clinical outcomes for patients with ITP in Ireland but, by reducing bleeding-related events and the use of rescue therapies, also results in cost savings and improved quality of life when compared to current treatment practices. **References**1. ALPS AND ALPS- RELATED DISORDERS. WHAT THE HAEMATOLOGISTS HAVE TO FACE WITH : SINGLE CENTER EXPERIENCE

F Fioredda[1], A Lucarelli[2], C Micalizzi[3], J Svahn[3], M Miano[3], M Calvillo[3], L Banov[3], U Ramenghi[4], S Pagliano[4], E Boggio[5], U Dianzani[5], M Caso[3], C Dufour[3]
[1]Giannina Gaslini Children's Hospital, Genova, Italy
[2]Pediatric Oncology and Haematology Department, Vito Fazzi Hospital, Lecce, Italy
[3]Unit of Haematology, Giannina Gaslini Children's Hospital, Genova, Italy
[4]Hematology Unit, Regina Margherita Hospital, Torino, Italy
[5]Department of Medical Sciences, University of Eastern Piedmont, Novara, Italy

Background. Autoimmune lymphoprolipherative syndrome (ALPS) is a disease characterized by lymphadenopathy, hepatosplenomegaly, and autoimmune cytopenias, such as haemolytic anemia, neutropenia and thrombocytopenia. According to current diagnostic criteria (table I), "ALPS related disorders"shares the lymphoproliferation and the apoptotic defects characteristic of ALPS , but do not fullfill at all the above citated criteria. **Aims.** to describe a cohort of patients referred to our center from 1981 to 2011 for recurrent/refractory cytopenias and/or lymphoproliferation who were subsequently defined and treated as ALPS and ALPS related-disorders. **Methods.** patients with refractory autoimmune haemolytic anemia, chronic thrombocytopenia, persistent neutropenia and/or lymphoproliferation entered the analysis. ALPS and "ALPS related disorders"as from literature (table I) .Patients data were obtained throught medical records. Anagraphic, clinical and imaging data, biochemical tests, double-negative T (DNT) cells test (pathological if > 1.5% of total lymphocytes), FAS mediated apoptosis test and molecular analysis when available, autoimmunity markers (DAT , IAT, ANA, indirect antibodies against neutrophils and platelets) were collected. **Results.** 38 patients, 20 males and 18 females entered the study, median age at presentation was 6.9 years (0.1-15years). ALPS criteria were fully matched in 9pts/38 (24%), the remaining 29pts (76%) were classified as ALPS-related disorders. Recurrent/refractory thrombocytopenia in 15/38 (40%), acute refractory haemolytic anemia in 10/38 (26%), lymphoproliferation in 9 pts/38 (24 %) and neutropenia in 4/38 (10 %) was the leading symptom. In 5 patients cytopenia was bilinear and 1 trilinear. At least one autoimmunity marker was positive in two third of the cohort and. DAT was the most frequent althoughnot necessarily associated to anemia. Mutations of TNFR6 gene, studied in 13/38 patients, were found in 2 (ongoing in 5). In 27/38 pts (71%) treatment was necessary. The 11 patients who did not require treat-

ment were affected by "non sintomatic lymphoproliferation", mild throrombocytopenia and two patients with neutropenia were managed with G-CSF only. First line treatment was steroids providing complete response in 11/27 (37%) of cases (in all but one it was stopped). One patient died because of hyperacute haemolytic process in a time when "new drugs"were not available yet. In the remaining 15 patient a second (7/15, 50%), third (5/15, 33%), fourth line regimen (3/15-17%) was needed. "Second line drugs"were mainly cyclosporin in combination with steroids (4 pts: transient response), mycophenolate mofetil (9 pts: 4 pts transient and 5complete response) and sirolimus alone (5 pts: 4 complete response and 1 in progress). **Summary and Conclusions.** Diagnosis of ALPS andALPS related diseases has to be considered in patients affected with chronic thrombocytopenia, refractory autoimmune haemolytic anemia and chronic neutropenia associated with lymphoproliferation and autoimmunity markers. Double negative T cells , a required criteria of ALPS, was detectable only in one fourth of the population. Treatment was necessary in more than 2/3 of patients and in nearly half of them more than "one line regimen" was needed. In our experience, mycophenolate mofetil and sirolimus are efficacious to control the diseases sparing long term steroids use with their well-known side effects.

Table 1. Revised classification of ALPS and related disorders. Oliveira JB *et al*. Blood 2010.

ALPS		
Revised nomenclature	**Gene**	**Definition**
ALPS-FAS	*FAS*	Germ-line homozygous or heterozygous *FAS* mutations. Previously ALPS type 0 and type Ia.
ALPS-sFAS	*FAS*	Somatic mutations in *FAS*. Previously ALPS type Im.
ALPS-FASLG	*FASLG*	Germ-line mutations in *FASLG*. Previously ALPS type Ib.
ALPS-CASP10	*CASP10*	Germ-line mutations in *CASP10*. Previously ALPS type IIa.
ALPS-U	Unknown	Meets ALPS criteria but with undetermined genetic defect. Previously ALPS type III.
ALPS related disorders		
Revised nomenclature	**Gene**	**Definition**
CEDS: Caspase-8 deficiency state	*CASP8*	Germ-line mutations in *CASP8*. Lymphadenopathy and/or splenomegaly, marginal elevation of DNT cells, recurrent infections. Previously ALPS type IIb.
RALD: Ras-associated autoimmune leukoproliferative disease	*NRAS*	Somatic mutations in *NRAS*. Autoimmunity, lymphadenopathy, and/or splenomegaly, normal to elevated DNT cells, defective in vitro Fas-mediated apoptosis. Previously ALPS type IV.
DALD: Dianzani autoimmune lymphoproliferative disease	Unknown	ALPS-like signs but with normal DNT cells and defective in vitro FAS-mediated apoptosis
XLP1: X-linked lymphoproliferative disease	*SH2D1A*	*SAP* Germ-line mutations in *SH2D1A* or *SAP*. Fulminant Epstein-Barr virus infections, hypogammaglobulinemia, or lymphoma. Defective apoptosis in response to TCR restimulation

0505

ROMIPLOSTIM INCREASES AND MAINTAINS PLATELET COUNTS IN ADULTS WITH NEWLY DIAGNOSED OR PERSISTENT PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) WHO HAVE NOT UNDERGONE SPLENECTOMY

F Rodeghiero[1], I Pabinger[2], D Selleslag[3], D Valcarcel[4], H Wei[5], G Kreuzbauer[6]
[1]San Bortolo Hospital, Vicenza, Italy
[2]Medical University of Vienna, Vienna, Austria
[3]A-Z Sint-Jan, Bruges-Oostende, Belgium
[4]Hospital de la Santa Creu i Sant Pau, Autonomous University of Barcelona, Barcelona, Spain
[5]Amgen Inc, Thousand Oaks, United States of America
[6]Amgen (Europe) GmbH, Zug, Switzerland

Background. Deferral of splenectomy is recommended for at least 6-12 months following diagnosis of adult ITP to allow for spontaneous remission (Provan, *Blood* 2010). Traditional ITP therapies which are used in the interim have efficacy and tolerability limitations, with some used off-label, e.g. rituximab, which renders vaccines to prevent post-splenectomy infection ineffective for up to 6 months. Romiplostim is recommended for second-line treatment of adult ITP. **Aims.** To investigate the use of romiplostim in adults with newly diagnosed or persistent ITP who have not undergone splenectomy. **Methods.** This retrospective, pooled analysis included non-splenectomised patients, ≥18 years old, diagnosed with ITP for ≤1 year, who had received romiplostim in a randomized, standard of care study (Kuter, *N Engl J Med* 2011), or a single-arm study of patients with ITP of varying duration and severity (Janssens, *ASH* 2011). The analysis was descriptive, included data from patients' first 52 weeks on study, and summarized the following: platelet response, romiplostim dose, serious adverse events (AEs), and bleeding events. As per the original studies, platelet response was defined as a platelet count ≥ 50 x 10^9/L, with no rescue medications in the preceding 8 weeks. The proportion of time during which patients achieved a platelet response was calculated as: number of weeks with response/number of weeks with non-missing platelet counts. **Results.** Of the 92 patients analysed, 55% (51/92) had completed 52 weeks of treatment, and 23% (21/92) were continuing in their respective study (with less than 52 weeks of treatment). Median (Q1, Q3) age was 59 (36.0, 72.0) years, median time since ITP diagnosis 2.94 (1.20, 6.60) months, and mean (SD) baseline platelet count 22.6 (14.1) x 10^9/L. Median (Q1, Q3) duration of exposure to romiplostim was 51.86 (14.43, 52.00) weeks. Platelet counts rose rapidly during the first 3 weeks of romiplostim treatment, with median platelet count consistently above 100 x 10^9/L thereafter. Overall, 88% (81/92) of patients achieved a platelet response. On average, these patients had a response during three-quarters of the 52-week time period analysed (median [Q1, Q3], 78.9% [47.1%, 94.4%]). Romiplostim dose over time was similar to that reported previously (Kuter, *Lancet* 2008). Taking the average weekly dose of all patients, the median (Q1, Q3) was 3.00 (2.00, 5.06) µg/kg/week. Serious AEs occurred in 20% (18/91) of patients, with thrombocytopenia the most common non-bleeding event (2 [2%] patients). Fewer than half (43/91 [47%]) of all patients experienced bleeding events. Serious bleeds were rare (5 [6%] patients), with rectal hemorrhage and epistaxis the most common events (2 [2%] patients each). Thromboembolic events occurred in 2 (2%) patients (pulmonary embolism and thrombophlebitis [right arm], 1 patient [1%] each). **Summary and Conclusions.** With similar doses as reported previously, and no new safety signals, romiplostim maintained increased platelet counts in patients with newly diagnosed or persistent ITP who had not undergone splenectomy. Romiplostim may be an important treatment option when splenectomy is deferred in such patients, potentially reducing the risk of serious bleeding in those subsequently proceeding to splenectomy without impacting vaccinations administered to prevent post-splenectomy infection.

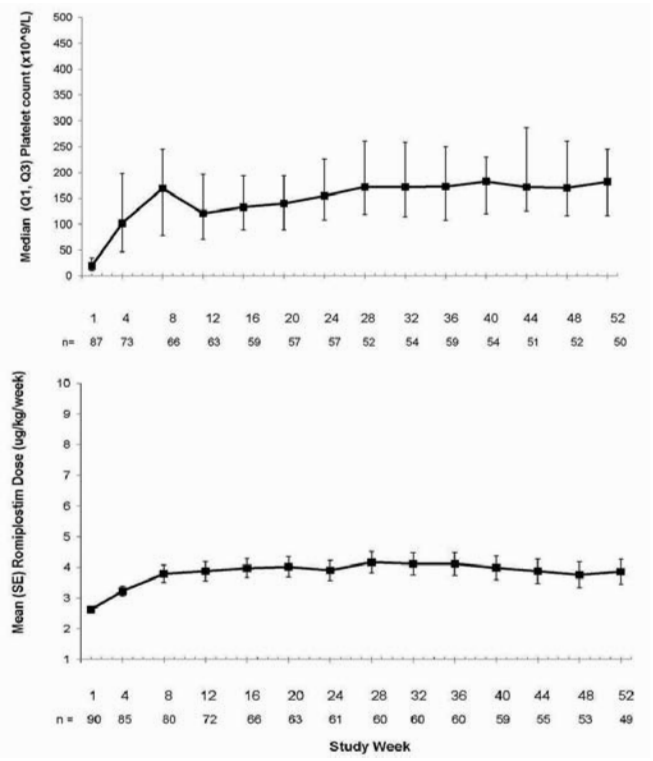

Figure 1. Platelet counts and romiplostim dose over time.

0506

BEYOND STANDARD PLATELET MEASURES, PREDICTORS OF BLEEDING SEVERITY IN IMMUNE THROMBOCYTOPENIC PURPURA

L Greene[1], S Chen[2], C Seery[2], J Bussel[2]
[1]Weill Cornell Medical College, New York, United States of America
[2]Division of Pediatric Hematology/Oncology, Weill Cornell Medical College, New York, United States of America

Background. Immune thrombocytopenic purpura (ITP) comprises a heterogeneous group of disorders characterized by autoimmune mediated platelet destruction and impaired thrombopoiesis. Platelet count is frequently used to define bleeding risk with a platelet count of ≥30x 10^9/L generally considered haemostatic. Clinical bleeding heterogeneity exists in patients despite similar

platelet counts. This may provide false reassurance or, conversely, exposure to unnecessary treatment complications. A global assay, thromboelastometry, provides measures of haemostasis and fibrinolysis (Table 1). Measuring newly-formed platelets, immature platelet fraction (%IPF) and absolute immature platelet fraction (A-IPF), may also contribute insights to ITP bleeding severity. **Aims.** We hypothesized measures of thromboelastometry and IPF may better predict bleeding severity in ITP than platelet count and mean platelet volume (MPV). **Methods.** A prospective institutional-review-board-approved study enrolled 117 consenting patients with known ITP at a single center. Thromboelastometry whole blood clot formation profiles in patients were recorded by ROTEM® (Luddington, Clin Lab Haematol 2005). Four ROTEM assays were performed: INTEM and EXTEM representing initiation of intrinsic and extrinsic pathways respectively; APTEM to confirm possible hyperfibrinolysis; and FIBTEM measuring fibrin clot formation after blocking platelets. Blood counts were analyzed using Bayer-ADVIA 120 (Giacomini, Clin Lab Haemotol 2001). A-IPF and %IPF were determined by Sysmex XE2100 (Barsam, Blood 2011). Acute and chronic bleeding histories were evaluated per the ITP bleeding score (Page, BJ Haem 2007). **Results.** The platelet count, but not MPV, significantly correlated with acute bleeding score (ABS) (r=-0.32, P=0.0005). None of the FIBTEM parameters significantly correlated with ABS. INTEM, EXTEM and APTEM parameters correlated significantly (P=<0.0001) with ABS almost always demonstrating a greater correlation with ABS than observed with platelet count (Table 1). Mann-Whitney U subgroup analysis of subjects with platelet <60x10^9/L (n=53) compared subjects with ABS 0-2 (asymptomatic or ≤2 cutaneous symptoms) to those with ABS ≥3 and demonstrated that the INTEM, EXTEM and APTEM parameters (except CT) outlined in table 1 differed significantly (P≤0.0002). Among subjects with IPF data (n=86), significant correlations were observed with ABS versus %IPF (r=0.30, P=0.006) and ABS versus A-IPF (r=-0.30, P=0.006); however, ABS correlated more strongly with platelet count (r=-0.35, P=0.001). **Conclusions.** Measures of clot formation, clot firmness, and both clotting and fibrinolysis more strongly correlated with ABS than platelet count. Analyzing only subjects with platelets <60x10^9/L, the outlined (Table 1) significant assay parameters differed significantly among subjects with ABS 0-2 versus those with ABS ≥3. These findings suggest thromboelastometry may improve identification of patients at risk of bleeding and thereby guide management decisions as well or better than standard platelet counting. The same parameters being significant across INTEM, EXTEM and APTEM assays, but not FIBTEM, support the global role of platelets in haemostasis and suggest the need to define platelet function in ITP to appropriately predict bleeding. The lesser significance of %IPF and A-IPF with ABS suggests younger platelets may not be the dominant factor influencing bleeding. Further work will study additional patients at lower counts, explore these parameters in children with ITP, and better characterize factors underlying platelet function and bleeding in ITP patients.

Table 1. Correlation of acute bleeding score with ROTEM assay parameters.

		INTEM		EXTEM		APTEM		FIBTEM

ISOLATION AND EXPANSION OF DIFFERENT MEGAKARYOCYTE PROGENITORS AND THEIR SUBSETS IN NORMAL AND DISEASE STATES

V Deutsch, S Kay, M Cipok, S Baron, E Naparstek
Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background. Platelet production is regulated by physiological demand and entails several developmental steps beginning with hematopoietic stem cell (HSC) commitment to megakaryocyte progenitor progenitors (Mk-p), proliferation of Mk-p, terminal Mk maturation, and proplatelet production. While each step in this complex pathway is crucial for platelet production, the megakaryocyte progenitor pool provides the platform for platelet development. **Aims.** The aim of this study was to assess the quantity and properties of HSC and MK-p and their subpopulations in normal and myeloproliferative disease states **Methods.** Using high definition flow cytometry (HDFC) we resolved, characterized and isolated these populations. The recently described CD41^{high/ SSC low /CD45 dim/neg} Mk-p (1) were sorted and colony forming capacity tested. The populations studied were from normal bone marrow-BM, cord blood-CB, mobilized peripheral blood, and BM from Immune Thrombocytopenia Purpura. Results. We demonstrate for the first time that the relative proportion of early Mk-p including CD41^{high/ SSC low /CD45 dim/neg} that still retain CD34 and CD34+ HSPC that acquired high levels of CD41 vary under different physiological conditions. $CD34^+$ and $CD34^+/CD41^+$ cells were increased in PBSC and decreased in CB, correlating with the known shorter platelet nadir in patients transplanted with PBSC and the protracted thrombocytopenia following CB transplant. Further analysis of normal BM and PBSC resolved that 1-2% of the CD41^{high/ SSC low /CD45 dim/neg} MK-p remained early progenitors expressing CD34. The same MK-p population in CB contained no detectable CD34+ cells, once again pointing to reduced numbers of transplantable early Mk-p in CB. In CML and ET, where platelet counts are high $CD34^+/CD41^+$ cells were reduced, implying forced maturation of MK-p and facilitated thrombopoiesis. We further resolved the subpopulations of Mk-p that maintained CD34 in ITP, CML and ET and found a higher proportion of these early Mk-p in ITP and CML. In ET which is characterized by MK maturation and increase platelet production, the proportion of CD41^{high/ SSC low /CD45 dim/neg} Mk-p was increased 10X over normalBM, yet few CD34+ cells were noted, again implying accelerated maturation and loss of CD34. The CD41^{high/ SSC low /CD45 dim/neg} MK-p population from normal and disease states was sorted by HDFC and multiple gating and CFU-MK assays performed with the addition of thrombopoietin. The sorted cells have a uniform stem cell like morphology with a 5-10 fold enrichment in CFU-MK over the unsorted fraction. Sorted Mk-p from JAK mutations+ ET patients displayed a 10 fold increase in CFU-MK formation over all other samples tested. This increment was independent of TPO confirming the original FC analysis data. Sorted Mk-p were expanded 3 fold over one week in culture. Studying Mk-p under normal and disease states has now provided new information about these rare populations that are key contributors to platelet production and indicate that these progenitors may be appropriate for developing cellularexpansion strategies to treat thrombocytopenia. Further investigation of purified Mk-p may provide us with new insights into the molecular and cellular mechanisms that regulate normal and aberrant thrombopoiesis

INCREASE IN PLATELET COUNT AFTER FIRST DOSE OF ROMIPLOSTIM PREDICTS DIFFERENT DOSING REQUIREMENTS DURING THE FIRST SIX MONTHS OF TREATMENT IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA (ITP)

S Baldini, R Fjerza, V Carrai, L Rigacci, R Alterini, A Bosi
University of Florence, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background. Patients treated with romiplostim for immune thrombocytopenic purpura (ITP) are more susceptible to variations in dosage during the first 6 months of treatment[1]. Splenectomized patients require higher dosages during this period[2]. Other predictors of different dosing requirements among patients throughout this period may contribute to easily achieve a stable dosage. **Aims.** To determine whether increase in platelet count after first dose of romiplostim is able to predict different dosing requirements among ITP patients during the first six months of treatment. **Methods.** 14 adult ITP patients with previous treatment failure started romiplostim in our Day Hospital between May 2010 and April 2011. Median age was 68 years (range 59-91), median weight was 77 kg (range 58-110). 5/14 (35,7%) of patients were splenectomized. Romiplostim was administered every 7±1 days starting from 1 mcg/kg. Dose was adjusted weekly on the basis of platelet response (PLT < 50 x 10^9/l: dose increased by 1 mcg/kg; PLT 50-400 x 10^9/l: dose maintained; PLT > 400 x 10^9/l: dose withheld and restarted reduced by 1 mcg/kg when PLT < 200 x 10^9/l). Concomitant steroid therapy remained unchanged until platelet count was ≥ 50 x 10^9/l, then was tapered up to termination. Weekly platelet counts and dosages were recorded during the first 24 weeks. Patients were divided in two groups on the basis of an increase in platelet count ≥ 30 x 10^9/l or smaller after first dose of romiplostim. Median dosages of romiplostim during the first 24 weeks were calculated and compared between the two groups using the two tailed Mann-Whitney U test at a significance level of 0,05. **Results.** 7 patients (2 splenectomized, 28,6%) had an increase in platelet count ≥ 30 x 10^9/l after first dose of romiplostim (median 83 x 10^9/l, range 12-414) and 7 (3 splenectomized, 42,9%) had a smaller one (median 11 x 10^9/l, range 1-100). Median weight was77 kg (range 58-56) and75 kg (range 58-110) respectively. Median dosage of romiplostim throughout the first 24 weeks of treatment was 2 mcg/kg (range 0-7) and 3 mcg/kg (range 0-10) respectively and the difference was statistically significant (p < 0,001). Figure 1 summarizes weekly median dosages of both groups. **Conclusions**. Patients achieving an increase in platelet count ≥ 30 x 10^9/l after first dose of romiplostim required a lower median dosage and had a more narrow range of dose during the first six months of treatment. However, an influence of the higher proportion of splenectomized patients in the group with a smaller increase cannot be excluded. Thus, in our experience increase in platelet count after first dose of romiplostim was predictive of different dosing requirements during the first six months of treatment but these data need to be confirmed in larger perspective studies

IMPAIRED PLATELET PHOSPHATIDYLSERINE EXTERNALIZATION AND CIRCULATING PLATELET-DERIVED MICROPARTICLES AFTER STRENUOUS EXERCISE IN GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENT INDIVIDUALS

A Palasuwan, M Chanda, D Suksom, D Nantakomol
Chulalongkorn University, Bangkok, Thailand

Background. It was previously reported that glucose-6-phosphate dehydrogenase (G6PD)-deficient mice suffered from an increase in oxidative stress, as manifested by a decrease in NADPH and intracellular glutathione levels, and an increase in lipid peroxidation marker. These oxidation-induced changes in the membrane contribute to phosphatidylserine externalization, the accelerated senescence and random destruction of blood cells. **Aims.** This study aimed to determine whether decreased G6PD activity after a strenuous exercise can cause deleterious changes in membrane phospholipid asymmetry and an increase production of cell-derived microparticles (MPs). **Methods.** Eighteen individuals with G6PD Viangchan variance (871G>A) and matched healthy subjects were allowed to perform running on a treadmill at their maximal oxygen uptake. We quantified and identified the cellular origin of circulating MPs (red blood cells, platelets, and endothelial cells) in G6PD deficient individuals using flow cytometry. We also investigated the association between the level of MPs and several blood redox status markers including the total antioxidant capacity, the level of lipid peroxidation, the antioxidant enzyme activities, such as glutathione peroxidase (GPx), and superoxide dismutase, and G6PD. **Results.** The results showed that the concentration of platelet-derives MPs (PMPs) and the amount of the phosphatidylserine externalization on outer leaflet of platelets were decreased in G6PD deficient individuals after the strenuous exercise as compared to healthy subjects (P<0.05). After 45 min of recovery, the concentration of PMPs returned to basal values in both groups. The G6PD activity was decreased during exercise and continue to low in recovery period in G6PD deficient individuals (P<0.05), while healthy subjects had no change of G6PD activity during exercise. This study demonstrated that the amount of platelet-phosphatidylserine externalization was related to the activities of G6PD (r = -0.342, P<0.05) and GPx (r = 0.300, P<0.05), and the concentration of malondialdehyde - lipid peroxidation marker (r = 0.404, P<0.05). **Conclusions.** This study suggested that the amount of PMPs was increased in patients with Viangchan (871G>A) G6PD deficiency induced by an acute strenuous exercise and may correlate with the impairment of antioxidant status. The knowledge from this study may help the G6PD patient in prevention toward severe hemolysis inducing by strenuous exercise.

THE ROLE OF DNA METHYLTRANSFERASE 3A MRNA EXPRESSION IN EGYPTIAN PATIENTS WITH IDIOPATHIC THROMBOCYTOPENIC PURPURA

S Bessa, E El-Shiekh, S Abdou, W El-Refaey
Faculty of Medicine-Tanta University, Tanta, Egypt

Background. Idiopathic thrombocytopenic purpura (ITP) is an organ specific autoimmune hemorrhagic disease characterized by breakdown of self tolerance and triggering auto-reactive lymphocytes' response against platelets. The underlying etiology of ITP remains largely unknown. DNA methylation plays an essential role in maintaining T-cell function, and impaired methylation can lead to inappropriate gene expression and contribute to T-cell auto-reactivity and autoimmunity. **Aims.** This study aimed to evaluate the role of DNA methyltransferase 3A gene expression in the pathogenesis of ITP. **Methods.** This study included 60 subjects; 20 healthy volunteers as a control group, 20 patients with acute ITP and 20 patients with chronic ITP. DNA methyltransferase 3A (DNMT3A) mRNA expression in peripheral blood mononuclear cells was measured by real-time quantitative polymerase chain reaction. Plasma S-adenosylhomocysteine (SAH) levels were assayed with reversed-phase high performance liquid chromatography. All cases gave informed consent to participate in this study. **Results.** DNMT3A mRNA expression was significantly decreased in ITP patients as compared with the control group. Plasma SAH level was significantly elevated in ITP patients than in healthy controls. However, no significant difference was found in DNMT3A mRNA expression or plasma SAH level between acute and chronic ITP patients. **Summary and Conclusions.** Aberrant DNA methylation status reflected by decreased mRNA expression of DNMT3A and increased plasma SAH level may play an important role in the pathogenesis of ITP, although the precise underlying mechanisms still await further investigations and extensive work in this field is clearly needed to provide novel therapeutic targets for ITP.

EFFICACY AND SAFETY OF SPLENECTOMY IN ADULTS WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA:SINGLE INSTITUTION STUDY

M Colovic, R Colovic, D Tomin, N Colovic, N Suvajdzic, A Vidovic
Medical Faculty, University Belgrade, Belgrade, Serbia

Background. The spleen in immune thrombocytopenic purpura (ITP) patients is an important source of anti-platelet antibodies and the major site of platelet destruction. Splenectomy is the only treatment known to have curative effects in a susbstantial fraction of ITP patients. However in modern era of new thrombopoietic agents the place of splenectomy is somewhat uncertain. This study included patients with ITP who underwent splenectomy between 2004.-2009 at single medical center in Serbia. **Material and Methods.** We analyzed data of 116 patients (female 81, male 35) who underwent splenectomy for the treatment of ITP between December 2004 to January 2009 in Clinical Center of Serbia with a postoperative follow up between 16 and 64 months, median). The median age of the patients was 37 year (range 18-80), with median platelet counts before splenectomy 23x10^9/L (range 1-87x10^9/L). All patients before splenectomy were treated with prednison and 35 patients with other therapeutic procedures as: 18 patients with IVIg, 5 with danazol, 8 with azathioprin, 2 with vincristin loaded platelets and 2 with cyclophosphamide. In this cohort of 35 patients the number of platelets before splenectomy was below 20x10^9/L. All 18 patients who got IVIg at a doses of 0.400 mg/kg body weight for 5 days achieved a platelet counts >100 x10^9/L. All 116 patients received preoperative pneumococcal vaccination as well as steroid preparation. The spleens were removed with classical surgery and in 17 patients an accessory spleen was found and removed. The average weight of the spleen was 151 g (range 90-500g) and there was no major alterations in histology of the spleens. **Results.** After splenectomy 73 patients had a excellent platelet response over a mean follow up of 11 months (range 12/64). Their steroid therapy was tapered within the first week after operation. In 24 patients there were an increase of platelet count above 500 x109/l so they were under aspirin and 5 of them even under LMW heparin until the normalization of platelet count. Another 9 patients had partial response. Ten patients were considered nonresponders to primary splenectomy and continued to require immunosuppressive therapy to maintain the platelet count above dangerous level or at the time of bleeding even IVIg. There was no operative mortality. The operative morbidity was subphrenic abscesses 1(he required drainage) and 4 patients had a small collection of liquid in the place of removed spleen, 3 patients had postoperative bleeding, 2 patient were operated the same day and one patient the day after splenectomy, one patient (heavily and long treated with corticosteroids) had tuberculosis miliaris, one patient cardiac arrest (but recovered), one thrombosis of v.portae and gangrene of small intestine (she had normal platelet count and recovered after resection), one patient pancreatic fistula. All patients recovered completely. **Conclusions**. This study shows that splenectomy is a safe procedure and effective in approximately two thirds of patients with chronic ITP. This therapeutic procedure still remains first line treatment for the majority of patients with ITP.

0512

SUDDEN FLUCTUATIONS OF WEEKLY PLATELET COUNT (SFPC) ARE RARELY INDICATIVE OF CHANGES IN THE EFFECTIVENESS OF ROMIPLOSTIM IN PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA (ITP)

S Baldini, R Fjerza, V Carrai, L Rigacci, R Alterini, A Bosi
University of Florence, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background. Romiplostim is an effective treatment for chronic immune thrombocytopenic purpura (ITP). Recently it has been pointed out that frequent changes in dose may create great fluctuations in platelet count, and therefore should be avoided whenever possible[1]. However, most of patients require up to six months before achieving a stable dosage[2]. Sudden Fluctuations of weekly Platelet Count (SFPC) within the range 50-400 x 10^9/l are common during this period leading sometimes to pre-emptive dose changes. **Aims** To determine whether SFPC are indicative of changes in the effectiveness of romiplostim and predict the necessity of changing dosage. **Methods.** 14 adult ITP patients with previous treatment failure started romiplostim in our Day Hospital between May 2010 and April 2011. Median age was 68 years (range 59-91), median weight was 77 kg (range 58-110). 5/14 (35,7%) of patients were splenectomized. Romiplostim was administered every 7±1 days starting from 1 mcg/kg. Dose was adjusted weekly on the basis of platelet response (PLT < 50x10^9/L: dose increased by 1 mcg/kg; PLT 50-400x10^9/L: dose maintained; PLT > 400x10^9/l: dose withheld and restarted reduced by 1 mcg/kg when PLT <200x10^9/L). Weekly platelet count was assessed in all patients during the first 24 weeks, for a total of 327 evaluable counts (9 counts were excluded because assessed in a different laboratory). SFPC were defined as increases or reductions ≥ 50x10^9/L platelets within the range 50-400x10^9/L without changes in two weeks previous neither in dose of romiplostim nor in concomitant therapy. SFPC were considered indicative of changes in the effectiveness of romiplostim if in 2 weeks a variation in dose of romiplostim congruous with the type of oscillation was needed (e.g.: for increases in platelets a congruous variation was a reduction in dose). **Results.** Incidence of SFPC on total counts was 11,6% (38/327). Among SFPC, 21,1% (8/38) was indicative of changes in effectiveness of romiplostim and 78,9% (30/38) was not. 92,8% (13/14) of patients had at least 1 not indicative SFPC (range events per patient: 0-4), while only 57,1% (8/14) experienced an indicative event (range events per patient: 0-1). Table 1 summarizes differences between indicative and not indicative SFPC. Incidence of indicative SFPC on total counts of splenectomized and not splenectomized patients was 2,5% (3/118) and 2,3% (5/209) respectively. **Conclusions** SFPC were common during the first six months of treatment, but only a minority of them was indicative of changes in effectiveness of romiplostim with similar incidence between splenectomized and not splenectomized patients. Besides, quite all the patients experienced one or more not indicative SFPC while indicative ones regarded few more than half patients and never twice the same subject. Therefore, pre-emptive changes of dose when SFPC occur should be avoided and an observation period of 1 week may be considered also for SFPC slightly out of range

DUAL GSTT1 AND GSTM1 GENE DELETIONS INCREASE THE RISK OF IMATINIB FAILURE IN CHRONIC MYELOID LEUKAEMIA (CML)

A Davies[1], A Giannoudis[1], LH Wang[1], G Austin[1], T Holyoake[2], M Mueller[3], L Foroni[4], M Pirmohamed[1], R Clark[1]
[1]University of Liverpool, Liverpool, United Kingdom
[2]University of Glasgow, Glasgow, United Kingdom
[3]University of Heidelberg, Mannheim, Germany
[4]Imperial College London, London, United Kingdom

Background. GSTs are highly abundant phase II metabolising enzymes that are responsible for the conjugation of glutathione onto reactive drug intermediates. Deficiencies in enzyme activity may increase the risk of malignancies by allowing unconjugated intermediates to cause DNA damage. Alternatively, high enzyme activity may contribute to cancer drug resistance by increasing drug metabolism. The most commonly reported GST defects are whole gene deletions of GSTT1 and GSTM1, carried by 20% and 50% of the Caucasian population respectively.In CML, a meta-analysis of 9 studies combining 757 CML cases versus 1959 healthy controls of mixed ethnic groups associated deletions of GSTT1 with an increased risk of developing CML. A further recent study demonstrated that GSTT1del, either alone or with GSTM1del, increased the risk of CML. However, the effect of GSTT1 and GSTM1 gene deletions on imatinib response in CML has not been investigated. **Aims.** To study the effect that GSTM1 and/or GSTT1 deletions, or gene copy number, have on response to imatinib treatment in CML patients. **Methods.** 193 chronic-phase CML patients treated from original diagnosis with imatinib (400mg daily) were included, from Liverpool, Glasgow, London (Hammersmith) and Mannheim. Imatinib failure was defined as a change of treatment from imatinib due to either intolerance or disease resistance in line with ELN recommendations. Time to imatinib failure was assessed by Kaplan-Meier survival plots using the Mantel-Cox log-rank statistical test (SPSS® software). GSTM1 and GSTT1 gene copy number analysis was performed on the ABI Prism 7900HT Sequence Detection System using pre-tested Taqman® assays with RNase P as an internal calibrator (Applied Biosystems®). Data were collected using the SDS software and copy number was determined by the ΔCt method using the CopyCaller® software. **Results.** Gene copy number amplification was frequently observed with the GSTT1 gene (44% with 3-11 copies), whereas copy number reduction/deletion was common with GSTM1 (88% with 1 or no copies). GSTM1 copy number was unrelated to time to imatinib failure (p = 0.936), however a statistically significant copy number concentration-dependent trend was seen with GSTT1 (p = 0.015). However, once data was stratified according to absence or presence of each gene, regardless of copy number, those patients with both gene deletions were at greater risk of imatinib failure (p = 0.007) (Figure 1): in addition, this appeared more likely to occur within 2 years of treatment. **Summary and Conclusions.** CML patients carrying both GSTT1 and GSTM1 gene deletions are more likely to fail imatinib treatment. Screening patients for these gene deletions at diagnosis may be useful in guiding personalised TKI treatment, and merits prospective investigation.

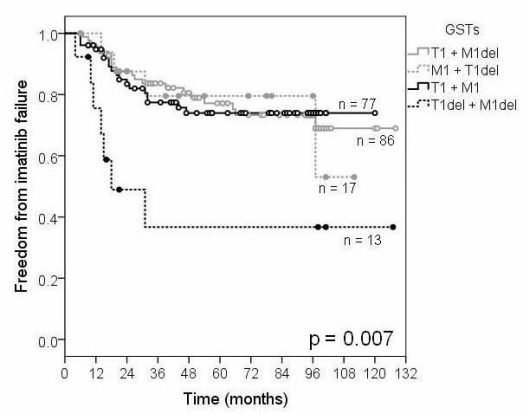

Figure 1. Kaplan-Meier log-rank survival curve of GSTT1 and GSTM1 gene deletions. Grey solid line/open grey circle = only the GSTT1 gene is present; grey dashe.

TARGETING THE HEDGEHOG SIGNALING PATHWAY IN THERAPY-RESISTANT BCR-ABL1 POSITIVE LEUKEMIA

T Tauchi[1], S Katagiri[1], S Kimura[2], T Maekawa[3], K Ohyashiki[1]
[1]Tokyo Medical University, Tokyo, Japan
[2]Saga University, Saga, Japan
[3]Kyoto University, Kyoto, Japan

An emerging concept in concept in cancer biology is that a rare population of cancer stem cells exists in the heterogeneous cell mass that constitutes a tumor. This concept also applies to BCR-ABL1 positive leukemia. Major advances also have been made in understanding the interactions between Hedgehog signaling and other pathways during carcinogenesis. Therefore, we examined the expression of Gli1 and BCR-ABL signaling pathways. Gli1 is regulated by BCR-ABL signaling, especially, mTOR/PI3K signaling pathways. Vismodegib is a selective Hedgehog pathway inhibitor that blocks hedgehog signaling by binding to Smo and inhibiting activation of downstream Hedgehog target genes. In the present study, we investigated the combined effects of vismodegib and ponatinib, a pan-ABL1 kinase inhibitor, in mutant forms of BCR-ABL1-expressing BaF3 cells and T315I-expressing human leukemia cell line, SK-9. To assess the *in vivo* efficacy of ponatinib and vismodegib, athymic nude mice were injected s.c. with BaF3 cells expressing wild-type (WT)-BCR-ABL1 and BCR-ABL1 mutants (M244V, G250E, Q252H, Y253F, E255K, T315A, T315I, F317L, F317V, M351T, H396P). 5 days after injection (average tumor volume, 100 mm^3), the mice were randomized into four groups (5 mice per group), with each group receiving either vehicle, ponatinib (30 mg/kg; q.d.), vismodegib (10 mg/kg; q.d.), ponatinib (30 mg/kg; q.d.) + vismodegib (10 mg/kg; q.d.). The ponatinib and vismodegib combination more effectively inhibited tumor growth in mice compared to either vehicle- or ponatinib- or vismodegib-treated mice. To investigate combined effects of vismodegib and ponatinib on T315I-expressing human leukemia cells, NOD/SCID mice were injected intravenously with SK-9 cells. Treatment with vismodegib and ponatinib demonstrated a marked segregation of apoptotic cells in both the central bone-marrow cavity, the endosteal surface, spleen and liver. The residual leukemia cells assayed by BCR-ABL mRNA were lowest in the vismodegib + ponatinib -treated mice, compared with the vehicle or ponatinib alone. To further investigate the effects of Hedgehog inhibition of self renewal and the relevance of the Hedgehog pathway as a therapeutic target in BCR-ABL1 positive leukemia, we examined the activity of vismodegib against SK-9 cells *in vivo*. NOD/SCID mice were injected with SK-9 cells then treated with vismodegib for 28 days. All mice demonstrated engaraftment of leukemia. We isolated human CD45+ cells from the spleen of mice from each treatment group and injected equivalent numbers of leukemia cells into secondary recipients, subsequently treated with vismodegib for 28 days. Following 60 days, all mice receiving SK-9 cells from vehicle treated mice engrafted with leukemia. In contrast, leukemia engraftment was detected in only 2/5 recipient mice receiving SK-9 cells from vismodegib treated donors. These results demonstrate persistent effects of Hedgehog inhibition on the long term self-renewing BCR-ABL1-positive leukemia cells. These results suggest that the combination with a Smo inhibitor and ABL1 tyrosine kinase inhibitors (TKIs) may help to eliminate the therapy-resistant T315I BCR-ABL1 positive leukemia cells.

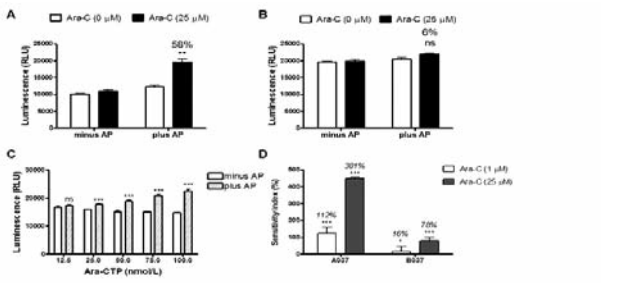
Background. Acute Myeloid Leukaemia (AML) is treated routinely (except for Acute Promyelocytic Leukaemia) with Cytarabine (Ara-C) at varying dose (20 mg/M^2/d to 3G/M^2/d) in combination with other cytotoxics. Regrettably, this fails to achieve CR in approximately 40% of cases, with resistance to chemotherapy, including cytarabine, being a major reason for failure. **Aims.** To correlate biosensor assay findings of Ara-C sensitivity of mononuclear cells from presentation blood/bone marrow of AML patients with clinical outcomes (CR or NR) after first course of cytarabine containing induction chemotherapy. **Methods.** We have previously validated a 8 hour *in vitro* bioluminescent bacterial biosensor assay which measures Ara-CTP (active metabolite of Ara-C) generation inside AML cells exposed to 1microM and 25 μM Ara-C (equivalent to 20 mg/M^2

and 200 mg/M2 respectively) for 30 minutes, in leukemic cell lines (Alloush *et al*. Clin. Chem. 56: 1862-70, 2010). Briefly, after AML cell incubation with Ara-C, Ara-CTP levels in cell lysates are deduced by increase in light generated by the reporter MG1655 *E.coli* strain (which has been genetically modified to permit this function: Dcdd +dCK +lux). Bioluminescent light emission is compared with internal controls and any increase above 13% is deemed a positive result indicating AML cell capability to produce Ara-CTP and hence Ara-C sensitivity. Biosensor data was validated against results obtained from a 3 day commercial cytotox assay, flow cytometric viability studies and HPLC assessment of Ara-CTP production (data not shown). This paper extends our experience of this assay using diagnostic blood/bone marrow samples in 71 AML patients and for the first time attempts to correlate the assay with known clinical outcome in 53 of these patients. Examples of assay findings in patient samples with low and standard dose Ara-C are described in Figure 1. **Results.** In the 53 patients with known outcome (median age 64.5 years) the assay correctly predicted outcome in 44 (22 CR and 22 NR). The sensitivity range (SI%) for CR was 14 to 128% (median 36%) and for NR -9 to 7% (median 3.5%). Typical profiles are shown for a clinically responsive (Figure 1A) and non-responsive individuals (Figure 1B). ROC curve analysis again determined a cut-off sensitivity index of 13% (AUC=0.81, p<0.0001) which produced 5 false positives and 4 false negatives for the 53 patients. Sample quantity limited the investigation into the source of this error. Testing for response to Ara-C in the 53 presenting patient samples gave 83% efficiency (sensitivity 85%, specificity 82%) when correlated with remission status following actual treatment with Ara-C containing induction chemotherapy. **Conclusions.** By predicting chemosensitivity to varying doses of Ara-C, this assay could potentially offer a tailored treatment approach in AML. Selection of an optimal dose of cytarabine upfront could reduce the risk of induction failures and may also help prevent overtreatment of elderly patients whose AML is sensitive to lower doses of Ara-C. Prospective clinical correlation in a larger cohort of AML patients in the context of national clinical trials is planned with funding from the Medical Research Council in the UK.



Patient profiles using the biosensor assay (A and B), the limit of detection of the biosensor for Ara-CTP(C) and in vitro low dose (1 µM) and standard dose (25 µM) Ara-C testing in AML patients (D).
Effect of 30-minutetreatment with Ara-C (25 µM) on cells from a clinically Ara-C sensitive patient (A) and a clinically Ara-C resistant patient (B) analysed using the Ara-C biosensor assay.
(C) Peak light emission from the biosensor treated with Ara-CTP at 0 to 100 nM (n=3, error bars show range). Correlation between Ara-CTP and light emission ±AP produced an R2=0.9953.1 Reproducibility studies using calibrators with defined Ara-CTP levels have shown CV<10% (n=16) and using cell lines CV<5% (n=9).
(D) Cells from patients considered unfit for intensive chemotherapy were treated with in vivo equivalents to low and standard dose Ara-C (patient ages: A037=78 years and B037=63 years). The elderly patient (A037) shows a high SI% and could benefit from low dose Ara-C treatment, determinable due to the wide detection range of the biosensor (0.025 to 100 µM). Error bars represent standard deviation (n=3), statistical significance relative to control (*p<0.05, **p<0.01, ***p<0.001).

SMAC MIMETIC OVERCOMES APOPTOSIS RESISTANCE OF FADD- OR CASPASE-8-DEFICIENT ACUTE LYMPHOBLASTIC LEUKEMIA CELLS BY TRIGGERING NECROPTOSIS TOGETHER WITH TNF?

S Fulda[1], B Schenk[1], B Laukens[1], C Jennewein[1], N Vanlangenakker[2], S Cristofanon[1], I Jeremias[3], M Bertrand[2], P Vandenabeele[2]

Evasion of apoptosis contributes to treatment resistance, one of the major, yet unresolved obstacles in oncology. Searching for new strategies to bypass apoptosis resistance we investigated the potential of Smac mimetic in acute lymphoblastic leukemia (ALL) cells, which are deficient in FADD or caspase-8, two key signaling molecules in the extrinisic apoptosis pathway. Smac mimetic antagonizes Inhibitor of Apoptosis (IAP) proteins that are expressed at high levels in ALL. Here, we demonstrate for the first time that Smac mimetic primes apoptosis-resistant leukemia cells for TNFα-induced necroptosis as an alternative mode of cell death. The interaction of Smac mimetic and TNFα is highly synergistic as calculated by combination index (CI <0.1). Kinetic analysis reveals that Smac mimetic and TNFα cause cell death rapidly within few hours. Interestingly, Smac mimetic- and TNFα-mediated cell death in FADD-deficient cells occurs without characteristic features of apoptosis, namely without caspase activation or DNA fragmentation, pointing to non-apoptotic cell death. In sharp contrast, Smac mimetic and TNFα trigger activation of caspase-8, -9 and -3 and DNA fragmentation in apoptosis-proficient wildtype cells that express FADD and caspase-8. Consistently, the caspase inhibitor zVAD.fmk protects wildtype cells against Smac mimetic- and TNFα-triggered cell death, whereas zVAD.fmk fails to block cell death in FADD-deficient cells. Furthermore, production of reactive oxygen species (ROS) precedes Smac mimetic- and TNFα-induced cell death in FADD-deficient cells. In line with the notion that ROS contributes to cell death induction, the addition of ROS scavengers (i.e. butylated hydroxyanisole (BHA) and trolox) or the addition of the NADPH oxidase inhibitor diphenyliodonium (DPI) significantly reduce cell death upon combination treatment. Moreover, Smac mimetic- and TNFα-triggered cell death is accompanied by enhanced RIP1 kinase activity in FADD-deficient cells. Of note, Smac mimetic and TNFα cooperate to trigger the formation of the necrosome complex. Necrostatin-1, a RIP1 kinase inhibitor, reduces Smac mimetic- and TNFα-induced ROS generation and completely abolishes cell death in FADD-deficient cells, in accordance with necroptotic cell death. Importantly, Smac mimetic also sensitizes apoptosis-resistant, primary leukemic blasts derived from patients with ALL to TNFα-induced necroptosis, underscoring the clinical relevance of these findings.In conclusion, Smac mimetic primes leukemia cells to TNFα-induced apoptosis or necroptosis in a context-dependent manner. In apoptosis-proficient cells which express both FADD and caspase-8, Smac mimetic enhances TNFα-induced, caspase-dependent apoptosis. However in apoptosis-resistant cells lacking either FADD or caspase-8, Smac mimetic sensitizes ALL cells for TNFα-initiated necroptosis that critically depends on RIP1 and ROS production. These findings have important implications for the therapeutic exploitation of necroptosis as an alternative cell death program to overcome apoptosis resistance of cancers.

FOLYLPOLYGLUTAMATE SYNTHETASE SPLICING ALTERATIONS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: IMPLICATIONS FOR MTX-THERAPY EFFICACY

A Wojtuszkiewicz[1], G Jansen[1], Y Assaraf[2], M Stark[2], G Peters[1], GJ Kaspers[1], J Cloos[1]
[1]VUmc, Amsterdam, Netherlands
[2]Technion-Israel Institute of Technology, Haifa, Israel

Background. Methotrexate (MTX) is one of the key antifolate drugs, commonly used in treatment of acute lymphoblastic leukemia (ALL) as well as other malignancies. In order for MTX to exert its full pharmacological activity, it must first undergo a unique intracellular metabolism known as polyglutamylation, catalyzed by the enzyme folylpoly-g-glutamate synthetase (FPGS). FPGS-dependent polyglutamylation of MTX results in intracellular retention and thus enhanced cytotoxicity. Hence, loss of FPGS function results in lower intracellular levels of MTX and as a consequence drug resistance. The mechanism underlying this phenomenon however remains elusive. Recent studies suggest FPGS mRNA splicing alterations as a possible contributor to MTX resistance (Stark et al, Blood 2009). Analysis of FPGS transcripts in specimens from adult ALL patients revealed exon 12 skipping, both at diagnosis and at relapse after high dose MTX-containing chemotherapy. Until now there are no reports available on this phenomenon in childhood ALL, therefore pediatric studies are warranted. **Aims.** The aim of the study is to evaluate FPGS mRNA splicing alteration patterns as a contributing factor to MTX treatment failure in childhood ALL patients. **Methods.** A PCR-based assay was devised that allows accurate screening of the entire FPGS mRNA sequence for aberrations in splicing. This method was subsequently used to screen childhood ALL patient samples and selected MTX-sensitive and MTX-resistant human leukemic cell lines. The identity of the most frequently appearing alterations was confirmed by sequencing. **Results.** The initial scan performed on a set of 14 childhood ALL patient specimens showed 7 different aberrations in FPGS mRNA splicing, including both exon skipping and intron retention. The detected alterations appeared with variable frequencies (ranging from 50% - 100%) among the samples. Most of these aberrations were either absent in specimens obtained from healthy individuals or present only at a very low abundance (Figure 1.). In addition, some of the alterations were found at an elevated level in several antifolate resistant cell lines (including MTX-resistant cells showing marked loss of FPGS activity with no substantial alterations in mRNA level) in comparison to their parental MTX-sensitive cell lines with proficient FPGS activity. **Conclusions.** Aberrancies in FPGS mRNA splicing seem to be a frequently occurring phenomenon in childhood ALL and may potentially be responsible for loss of FPGS activity. To which extent the identified FPGS splicing alterations contribute to MTX resistance and MTX treatment failure in childhood ALL in a clinical setting needs further investigation. Together these findings may assist in designing accurate and targeted tools that will be able to identify antifolate resistance

of leukemic cells. Ultimately these results may guide pediatric oncologists in efficacy assessments of MTX-containing anticancer treatment in individual patients (i.e. personalized medicine).

CHARACTERISATION OF MINOR CML BLAST SUBSET THAT ARE SIGNIFICANTLY RESISTANT TO BOTH GROWTH INHIBITION AND APOPTOSIS MEDIATED BY IMATINIB AND NILOTINIB IN VITRO

H Galski, M Simanovsky, A Nagler
Chaim Sheba Medical Center, Ramat Gan, Israel

Background. Although very effective in chronic phase CML, imatinib (IM) usually less effective in advanced CML since drug-resistant clones inevitably shortly emerge. While nilotinib (NL) is more effective than IM, appearance of drug resistance to NL might be also relevant in advanced CML. We have previously found that in blast crisis CML, blasts of the same CML clone are heterogeneous, containing a small subset (1-3%) of blasts that are significantly more aggressive than the major malignant population (Differentiation. 76: 908-922, 2008). These minor subsets (MS) of blasts (both from patients and human, drug naive CML-BC cell lines) display higher clonogenicity than the common subsets (CS) and preferentially overexpress seven genes including BCR-ABL, transcription factors and extracellular matrix adhesion molecules. **Aims.** To evaluate whether the MS blasts also exhibit differential sensitivity toward IM and NL, we compared the two blast subsets for the effects of IM and NL on both proliferation and apoptosis. **Methods.** Various CS and MS blasts of CML-BC were evaluated before and after short exposure (24-48 h) to IM or NL *in vitro*. The anti-proliferative effects of IM and NL at various concentrations were measured by MTT proliferation assay. The apoptotic effects of IM and NL at various concentrations were measured by annexin-V assay and caspase-3 assay. **Results**. In the absence of drugs neither significant differences in the proliferation and apoptosis rates could be detected between the CS and the MS blasts. While IM (50-500 nM) and NL (10-50 nM) efficiently inhibited the proliferation of the CS blasts in a dose-dependent manner, the proliferation rate of the MS blasts was essentially not affected in all the tested concentrations. Similarly, IM at 500 nM and NL at 50 nM induced apoptosis of 60% and 90% of the CS blasts, respectively. However, the MS blasts were highly resistant to the apoptotic effects of IM and NL (Figure1). **Conclusions.** The existence of a minor 'pool' of CML blasts of both greater clonogenicity and aggressiveness, apparently signify clonal evolution toward both increased tumoreginicity and lower therapeutic sensitivity to both IM and NL. Specifically this study indicates that MS blasts are highly resistant to both the anti-proliferative and apoptotic effects of IM and NL. Future novel therapies should try targeting this minor aggressive blast cell population most probably by drug combinations, in order to improve outcome in advance CML.

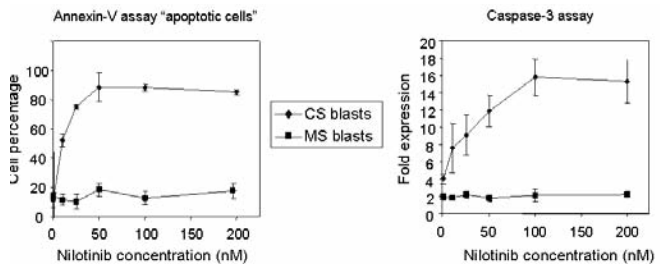

Figure 1. Apoptosis rate of MS versus CS blasts in the presence of nilotinib (NL) at various concentrations.

THE HSP90-INHIBITOR AUY922 POTENTLY INHIBITS THE MOST FREQUENT BCR-ABL KINASE MUTATIONS EXCEPT T315I IN CHRONIC MYELOID LEUKEMIA CELLS

N Härtel, B Hanfstein, J Schwaab, R Hehlmann, WK Hofmann, MC Müller
Universitätsmedizin Mannheim, Mannheim, Germany

Background. BCR-ABL kinase mutations are the most frequent reason for primary as well as secondary imatinib resistance in chronic myeloid leukemia. Recently differential antiproliferative activity against BCR-ABL mutations has been reported for the HSP90-inhibitor AUY922. Thus we asked whether AUY922 alone or in combination with imatinib would be able to overcome BCR-ABL dependent resistance. Recently Tauchi et al. showed a prevention of BCR-ABL mutation emergence when non-mutant BCR-ABL transformed cells were incubated with AUY922. Furthermore they demonstrated a significant inhibition of complete imatinib resistant T315I-BCR-ABL expressing cells. However we generated some controversial data. **Aims.** In vitro experiments were performed in order to characterize the activity of AUY922 alone and in combination with imatinib in BCR-ABL transformed cells. We further sought to analyze the potency of AUY922 to prevent the emergence of BCR-ABL kinase mutations. **Methods.** The murine hematopoietic cell line Ba/F3 and its derivative Ba/F3p210, as well as their mutant BCR-ABL expressing derivatives (Ba/F3p210^{M351T}, Ba/F3p210^{E255K}, Ba/F3p210^{Y253F}, Ba/F3p210^{T315I}) were used for MTS-based proliferation assays. Synergistic effects were calculated using a mathematical approach. Dose response experiments and subsequent Western blot analyses were performed to semiquantitatively determine BCR-ABL activity using pTyr as well as BCR-ABL specific antibodies. An N-Ethyl-N-Nitrosourea-(ENU)-based mutation screen was performed in non-mutant BCR-ABL transformed cells exposed to escalating doses of imatinib (0-16µM) +/- AUY922 (doses: 0.625 and 1.25nM ensured not to be antiproliferatively active). Primary cells of imatinib naïve patients as well as those of healthy donors were exposed to AUY922 (2.5 and 5nM) alone and in combination with imatinib (0.5 and 1 µM) to reveal differential antileukemic activity in colony forming assays. **Results.** Treatment of mutant BCR-ABL expressing cells using AUY922 as single agent revealed antileukemic activity in the nanomolar dose range. Although no significant difference was observed when IC50 values of mutant and non-mutant BCR-ABL expressing cells were compared. A synergistic activity was observed for both, mutant (Ba/F3p210^{M351T}, Ba/F3p210^{E255K}, Ba/F3p210^{Y253F}) and non-mutant (Ba/F3p210) BCR-ABL expressing cells, when AUY922 was combined with imatinib. Colony forming assays revealed the synergistic activity of AUY922 and imatinib for non-mutant BCR-ABL expressing primary cells.Furthermore protein analysis in non-mutant BCR-ABL transformed cells (Ba/F3p210) showed for AUY922 in combination with imatinib even at low doses (2.5nM) a significant BCR-ABL suppressive effect after 24 hrs. In contrast, T315I mutant cells (Ba/F3p210^{T315I}) on combined imatinib/AUY922 treatment were associated with unaffected cell growth and T315I-BCR-ABL protein expression levels.The hypothesis that addition of AUY922 might prevent imatinib treated BCR-ABL positive cells (Ba/F3p210) from emergence of BCR-ABL mutations was disproved in ENU-based mutation screens. In most cultures BCR-ABL kinase mutations were detected. Interestingly the occurrence of BCR-ABL mutation T315I was slightly enhanced (p=ns) in the presence of AUY922. **Summary and Conclusions.** In conclusion, our data provides further experimental evidence that AUY922 is a promising candidate to optimize ABL-inhibitor based CML therapy. AUY922 in combination with imatinib overcomes BCR-ABL dependent resistance in most frequent BCR-ABL mutations except T315I.

POSSIBLE ROLE OF UGT2B17 GENE IN HAEMATOPOIETIC STEM CELL TRANSPLANTATION AS PHARMACOGENE

M Guarene[1], C Badulli[1], F Romano[1], C Pascutto[1], G Giorgiani[1], A Colombo[1], D Caldera[1], EP Alessandrino[1], M Zecca[1], F Locatelli[2], M Martinetti[1], L Salvaneschi[1]
[1]IRCCS San Matteo University Hospital Foundation, Pavia, Italy
[2]IRCCS Children Hospital Bambino Gesu', Roma, Italy

In the hematopoietic stem cell transplant (HSCT) setting, the UDP-Glucuronil-trasferase 2B17, UGT2B17, is considered as a minor histocompatibility antigens (mHAg). Functionally, it belongs to a group of enzymes that catalyze the coniugation of glucuronic acid to a variety of substrates including steroid hormones, carcinogens, pollutants and chemotherapeutic drugs. Glucuronidation is implicated in the liver detoxification from noxious endogenous and exogenous compounds. The homozygous UGT2B17 gene deletion exists, is compatible with life, and is not rare, representing about the 15% in our population. People lacking this enzyme are constitutively poor metabolizers of steroid drugs and we questioned if this condition could represent an intrinsic risk of HSCT failure, for

a recipient, due to the inefficient metabolism of immune-suppression treatment and liver accumulation of toxic catabolites. To this, we analyzed retrospectively 156 Italian patients, 74 pediatric and 82 adult, 105 transplanted with an HLA-identical related donor and 51 unrelated. The frequency of the gene deletion, defined by PCR-SSP molecular technique, was 13.5% in the recipients and 14.1% in their donors. Ten years of follow up revealed that this condition associated significantly with death and relapse. In fact, 12/21 (57.14%) homozygous deleted patients died vs 38/135 (28.14%) (OR=3.409, p=0.008) and 11/16 (68.75%) relapsed vs 30/102 (29.4%) (OR=5.28, p=0.002) (see Kaplan-Meier curves in the Figure below). Pepe and Mori statistical test revealed that the constitutive absence of UGT2B17 influenced the relapse much more than the overall survival (p=0.0039). We also observed that, among the UGT2B17 homozygous deleted patients, the death rate was significantly higher in males (72.7%) than in females (40%) and in female to male couples, compared to all the other gender combinations (p=0.0013).In summary, we might suppose that the recipient's lack of UGT2B17 enzyme could be itself a risk factor for relapse and death independently from the mismatch. Beyond its documented role as a mHAg, UGT2B17 seems to have an important function in HSCT as a pharmacogene. The deleterious effect of UGT2B17 gene deletion seems to be even more prominent in deleted males receiving a transplant from a female donor. Our findings suggest that the UGTB217 molecular definition might be appropriate to identify the patients prone to the relapse and that sex matching should be preferred in UGT2B17 deleted male patients.

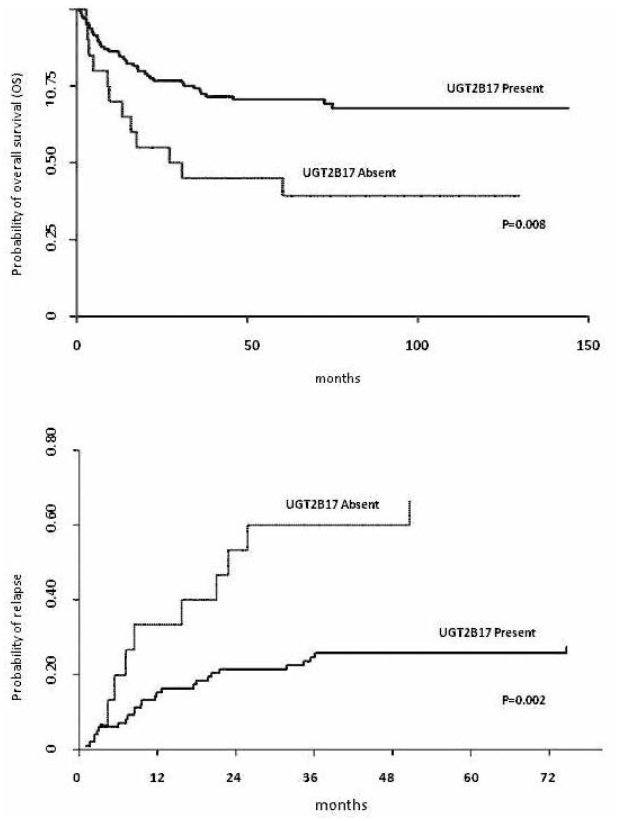

Figure 1. Influence of UGT2B17 deletion on overall survival and relapse.

0521

SUCCESSFUL CO-TREATMENT OF BCR-ABL LEUKEMIC CELLS WITH PONATINIB, AN ABL KINASE INHIBITOR, AND VORINOSTAT, A HISTONE DEACETYLASE INHIBITOR: A POTENTIAL TREATMENT FOR BCR-ABL POSITIVE LEUKEMIA CELLS

S Okabe[1], T Tauchi[1], S Kimura[2], T Maekawa[3], K Ohyashiki[1]
[1]Tokyo Medical University, Tokyo, Japan
[2]Saga University, Saga, Japan
[3]Kyoto University Hospital, Kyoto, Japan

Background. Resistance to imatinib is most commonly explained by acquired point mutations in the kinase domain of BCR-ABL, which impair drug binding. Ponatinib, also known as AP24534, is an oral, the multi-targeted tyrosine kinase inhibitor (TKI) and highly activity against ABL kinase point mutation included T315I. Ponatinib is currently being investigated in a pivotal phase 2 clinical trial (PACE trial). However, ABL1 inhibitor-resistant patients already harboring mutations have a higher likelihood of developing further mutations under the selective pressure of ABL1 TKIs. The challenge for development of an effective Philadelphia chromosome (Ph) positive leukemia therapy is therefore to develop an alternative treatment strategy that does not rely solely on kinase domain inhibition but rather results in degradation of the offending BCR-ABL1 protein regardless of its mutation status. Histone acetyltransferases (HAT) and histone deacetylases (HDAC) control the acetylation of histones and intracellular proteins, and regulate the transcription and function of the proteins. **Aims.** Combination therapy using a ponatinib and an HDAC inhibitor, vorinostat may help prevent development of Abl TKI resistance and may improve their long-term outcome. **Methods.** We analyzed the ponatininb and vorinostat efficacy by using the BCR-ABL positive cell line, K562 and murine Ba/F3 cell line which was transfected with imatinib resistant BCR-ABL random mutagenesis and T315I and E255K mutant cells and BCR-ABL positive primary samples. **Results.** 72 hours treatment of ponatinib exhibits cell growth inhibition and induced apoptosis against K562 cells. We also found that ponatinib potently induced cell growth inhibition of Ba/F3 T315I mutant cells. We found that phosphorylation of BCR-ABL, Crk-L was decreased and poly (ADP-ribose) polymerase (PARP) was activated. We also analyzed by mouse xenograft model. Combined treatment of Ba/F3 T315I mutant cells with vorinostat and ponatinib caused significantly more cytotoxicity than each drug alone. Although phosphorylation of BCR-ABL, Crk-L was not reduced after vorinostat treatment, acetylation of histone H4 was increased and BCR-ABL degradation was induced in the point mutant cells. Protein degradation of BCR-ABL was inhibited by co-treatment with lactacystin. Caspase 3 and PARP activation were increased after combination of ponatinib and vorinostat. Moreover, an increase in phosphorylation levels of γ-H2A.X was observed suggests that combination of ponatinib and vorinostat induced DNA damage against T315I mutant cells. We next established ponatinib resistant cells by using Ba/F3 BCR-ABL with resistant random mutants. In the ponatinib resistant cell lines, IC50 of ponatinib was 200 nM. BCR-ABL triple point mutations (T315I, E255K and Y253H) were detected by direct sequence and invader analysis. Ponatinib resistant Ba/F3 cells were also resistant to imatinib (IC50: more than 10μM) or nilotinib (IC50: 7.5 μM) and also resistant to dasatinib (IC50: more than 100nM). We investigated the efficacy between ponatinib and vorinostat by using these cell lines. Combined treatment of Ba/F3 ponatinib resistant cells with ponatinib and vorinostat caused significantly more cytotoxicity. **Summary**. Data from this study suggested that administration of the ponatinib and HDAC inhibitor, vorinostat may be a powerful strategy against BCR-ABL mutant cells and enhance cytotoxic effects of ponatinib in those BCR-ABL mutant cells.

0522

IMATINIB, BUT NOT NILOTINIB, IS ACTIVELY TRANSPORTED BY SLCO1A2 IN CHRONIC MYELOID LEUKAEMIA CELLS

S Francis[1], A Giannoudis[1], A Davies[1], G Austin[1], J Konig[2], M Pirmohammed[1], R Clark[1]
[1]University of Liverpool, Liverpool, United Kingdom
[2]Institute of Experimental and Clinical Pharmacology and Toxicology, Erlangen, Germany

Background. We showed in 2004 that imatinib is actively transported into chronic myeloid leukaemia (CML) cells by human organic cation transporter 1 (hOCT1; SLC22A1). We and others have subsequently shown that a) CML patients with high levels/functional activity of hOCT1 have superior responses to imatinib; and b) hOCT1 does not transport the second generation tyrosine kinase inhibitors (2G TKI) dasatinib and nilotinib. However, there are many patients with low hOCT1 activity who respond well to imatinib. This suggests that other transporters may also transport imatinib and maybe 2G TKI.Hu et al showed that transfection of either SLCO1A2 (OATP1A2), SLC22A4 (OCTN1) or SLC22A5 (OCTN2) into *Xenopus* oocytes (which do not express any mammalian transporters) increased imatinib uptake, suggesting these transporters may be relevant to TKI transport in Man. **Aims.** To assess the role of SLCO1A2, SLC22A4 and SLC22A5 in TKI transport in CML cells and on treatment outcome. **Methods.** For transfection work, the CML cell line KCL22 was selected since it has low basal levels of transporter expression. KCL22 cells were transfected with pcDNA3-SLCO1A2 (kind gift of Prof M Fromm, Germany), the pcDNA-SLC22A4 and pcDNA-SLC22A5 plasmids (kind gift of Profs A Tsuji and Y Kato, Japan) and stable lines with high expression were selected. The time course of uptake of 5 μM radiolabelled imatinib or nilotinib into each of these lines was assessed, with and without the inhibitors naringin (for SLCO1A2 transfected) and verapamil (for SLC22A4 and A5 transfected) at 100 μM. Sixty-six newly diagnosed chronic phase CML cases receiving either imatinib (60) or nilotinib (6) as first line treatment were assessed for mRNA expression of SLCO1A2, SLC22A4 and SLC22A5 using TaqMan gene expression assays. Relative expression levels were normalised to GAPDH and compared to four normal controls. **Results.** Functional assays showed that uptake of imatinib into SLCO1A2 high expressing cells was significantly greater than into control cells ($p = 0.001$), and that this excess was blocked by the SLCO1A2 inhibitor naringin ($p=0.035$). In sharp contrast, uptake of nilotinib by SLCO1A2 high expressing cells did not differ from control cells. Neither imatinib nor nilotinib showed any enhanced uptake into CML cells over-expressing SLC22A4 or SLC22A5. There was no significant difference in diagnostic mRNA expression levels of SLCO1A2 between responders (defined as achieving complete cytogenetic remission (CCR) after 12 months treatment), non-responders (no CCR by 18 months) or patients who subsequently progressed to blast crisis. mRNA expression levels for SLC22A4 and SLC22A5 also showed no correlation to outcome. **Conclusions.** *In vitro*, imatinib is a substrate for SLCO1A2 but not for SLC22A4 and SLC22A5. The clinical significance of this is not clear and requires further assessment. Functional studies in clinical samples for patients with high expressing SLCO1A2 are in progress. Nilotinib is not transported by SLCO1A2, SLC22A4 or A5, and to date there is no evidence that it is transported actively into CML cells.

0523

POLYMORPHISMS IN ABC TRANSPORTER GENES ARE ASSOCIATED WITH COMPLETE MOLECULAR RESPONSE TO IMATINIB IN CHRONIC MYELOID LEUKEMIA PATIENTS

D Vivona[1], L Lima[1], C Bueno[1], R Hirata[1], M Hirata[1], A Luchessi[2], M Zanichelli[3], C Chiattone[4], E Guerra-Shinohara[5]
[1]Universidade de São Paulo, São Paulo, Brazil
[2]Universidade Federal do Rio Grande do Norte, Natal, Brazil

[4]Departmento de Hematologia e Hemoterapia, Santa Casa de São Paulo, São Paulo, Brazil
[5]Clinical Chemistry and Toxicologic,University of São Paulo, São Paulo, Brazil

Background. The resistance to the imatinib mesylate (IM) is the main cause of failure in the treatment of patients with chronic myeloid leukemia (CML). The efflux and influx membrane transporters are crucial elements in IM pharmacokinetics. Single nucleotides polymorphisms (SNPs) in membrane transporter genes could be related to resistance of this drug. **Aims.** To investigate the relationship between *ABCG2* (rs2231142 and rs1564481)*, SLCO1A2* (rs11568563), *SLCO1B3* (rs4149117, rs7311358 and rs17674290) and *ABCA3* (rs323043 and rs150929) SNPs and IM response in CML patients. **Methods.** One hundred and eighteen patients in the chronic phase of CML, both genders with an age range of 18 to 80 were studied. All patients were initially treated with a standard dose of IM (400 mg/day) and divided into two groups according to their response. The responder group comprised 70 patients who had a complete cytogenetic response within 18 months of treatment. The non-responder group comprised 48 patients who did not have a complete cytogenetic response with the initial dose (400 mg/day) of IM or who relapsed during treatment and were submitted to higher doses of 600 or 800 mg/day. Criteria of failed response to treatment were established by European LeukemiaNet. Patients with cytogenetic patterns other than the Philadelphia chromosome and/or with mutations in the BCR-ABL1 gene were excluded from this study. Major molecular response (MMR) was defined as a reduction of BCR-ABL1 transcript levels to ≤ 0.1% in the peripheral blood standardized on the International scale. Complete molecular response (CMR) was defined as a reduction ≤ 0.0032% BCR-ABL1 transcript levels. DNA from one hundred and twenty blood donors was also evaluated. The genotyping for ABCG2, SLCO1A2, SLCO1B3 and ABCA3 SNPs was performed by Real Time PCR. **Results.** None of the studied SNPs was related with increased risk of having CML. The distribution of genotypes for *ABCG2*, *SLCO1A2* and *ABCA3* SNPs was similar between responder and non-responder groups. There was a trend of higher frequency of GG (*SLCO1B3* rs7311358, p=0.055) and TT genotypes (*SLCO1B3* rs4149117, p=0.055) carriers in responder group. High frequency of *ABCA3* rs150929 GG+GT (N=51) genotype was found in group of poor CMR when compared with TT carriers (N=5, p= 0.014) in responder group. There was high frequency of CC genotype for ABCG2 rs2231142 in patients with CMR (p= 0.025). Furthermore, carriers of haplotype CC/GG (*ABCG2* rs2231142/rs1564481) had higher probability to achieve the CMR compared with the non-carriers (OR: 5.29; 95%CI: 1.06-26.28, p=0.042). None of the studied SNPs was associated with MMR. **Conclusions.** The haplotype CC/GG (*ABCG2* rs2231142/rs1564481) is associated with CMR, while *ABCA3* rs150929 GG+GT genotypes are related with poor CMR.

DIMINISHED ASPARAGINASE CLEARANCE DUE TO A GERMLINE MUTATION IN CATHEPSIN B

L van der Meer, M Levers, E Waanders, H Venselaar, P Hoogerbrugge, F van Leeuwen, M te Loo
Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background. Asparaginase (ASNase) is a key component of multi-agent chemotherapy protocols used in the treatment of pediatric as well as adult acute lymphoblastic leukemia (ALL). Patients who are treated according to fixed administration schemes show a strong inter individual variation in serum ASNase levels. While underexposure may compromise therapeutic benefits, strongly elevated serum levels may lead to serious adverse effects including encephalopathy as a result of increased ammonia levels. Although ASNase levels and activity can be accurately monitored, in at least 10% of the patients the desired ASNase levels are either not reached or exceeded. **Aims**. Our understanding of ASNase dynamics *in vivo* needs to be improved. Here we report a link between a mutation in the gene encoding Cathepsin B and diminished ASNase clearance in a pediatric patient with ALL, suggesting a role for this protease in ASNase turnover. **Methods**. We have used cell biological and biochemical experiments to study the effect of a mutation in Cathepsin B that was found in a pediatric patient who experienced serious toxicity in reaction to ASNase treatment. **Results.** A 3-year-old girl diagnosed with ALL experienced serious toxicity in the form of hyperammonemic encephalopathy during treatment with ASNase derived from *Erwinia chrysantemi*. Pharmacokinetic data showed a strongly delayed clearance of the ASNase, which with the standard treatment protocol resulted in extremely high serum ASNase levels. Plasmapheresis was performed and administration frequencies were adjusted to improve the clinical status of the patient. No underlying metabolic disorder could be diagnosed.Based on a previous report describing the role of proteases in degradation of ASNase *in vitro*, we hypothesized that the cysteine protease Cathepsin B might be implicated in the strongly reduced clearance of ASNase in this patient. Sequencing of the open reading frame of the Cathepsin B gene (*CTSB*) revealed a single codon deletion in the germline of the patient, affecting a lysine residue in the carboxy terminus of the protein. Immunofluorescence and biochemical experiments show that this single amino acid deletion leads to a protein product that is retained in the endoplasmic reticulum and is inefficiently processed. ASNase degradation assays show that the mutant Cathepsin B has lost its ability to efficiently degrade ASNase which can explain the high levels of ASNase as observed in our patient. **Conclusions**. Together, these findings suggest that variation in Cathepsin B expression or activity may contribute to the large variation in serum ASNase levels in patients. Monitoring or therapeutically altering Cathepsin B activity could therefore improve ASNase administration regimens and therapy responses.

TARGETING THE RAS/MAPK AND PI3K/MTOR SIGNALING PATHWAYS: A NEW APPROACH IN SENSITIVE AND RESISTANT CML CELL LINES?

R Alves, R Fonseca, A Gonçalves, V Alves, A Sarmento-Ribeiro
Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the presence of the *BCR-ABL* fusion gene that encodes an oncoprotein, with a deregulated tyrosine kinase activity. The first-line treatment is Imatinib, a tyrosine kinase inhibitor that blocks BCR-ABL activity. This oncoprotein activates multiples signaling pathways responsible for tumor cells characteristic, namely the high cellular proliferation and resistance to apoptosis. One of these pathways is the RAS/MAPK that controls the cell proliferation and survival. The activation of RAS proteins requires the attachment of a farnesyl group, mediated by the farnesyltranferase. Other pathways include de activation of the PI3K/AKT/mTOR pathway. So, the knowledge of cell signaling pathways involved in CML may contribute to the development of new therapeutic approaches and also became an alternative in cases of resistance to standard therapies.The aim of this study was to evaluate the therapeutic potential of the farnesiltransferase and mTOR inhibitors (respectively, L-744832 and Everolimus) alone and in combination with Imatinib in sensitive and resistant CML cell lines.For this purpose, we used a CML cell line sensitive to Imatinib, the K562 cells, and established two sub-cell lines resistant to Imatinib, the K562-RC and K562-RD cells. To obtain these resistant cells, K562 cells were exposed to Imatinib following two strategies: continuous exposure of increasing concentrations of Imatinib (K562-RC cells) and discontinuous exposure, with interchanged mediums with and without Imatinib (K562-RD cells). To evaluate the effect of Imatinib, L-744832 and Everolimus in cell viability, all cell lines were treated in the absence and presence of different drug's concentrations and analyzed by the resazurin assay. Cell death was determined by optical microscopy (May-Grünwald staining) and by flow cytometry (FC) using the Annexin V/Propidium Iodide staining and by caspases expression levels. The effect of the drugs in cell cycle was accessed using Propidium Iodide incorporation by FC.Our results show that the half maximal inhibitory concentration (IC_{50}) of Imatinib in K562 sensitive cells was 75nM, whereas in K562-RC cells this value is increased eight times (605nM) and in K562-RD cells is around eighteen times higher (1389nM). The L-744832 shows a cytotoxic effect in sensitive and resistant cell lines, but the last one requires a higher dose (35mM vs 50mM, respectively). The same pattern was observed in presence of Everolimus, but this drug has also the ability of interfering with the cell cycle. The both compounds induced cell dead by apoptosis in a time- and dose-dependent manner. The association of lower doses of Imatinib (10nM) with 5uM of L-744832 or/and Everolimus shows a synergist cytotoxic effect in sensitive and in resistant cells. Combined therapy reveals to be a more effective strategy since the effects are greater with the use of smaller doses, even in cases of resistance.In conclusion, our results suggest that discontinuous drug exposure induces higher resistance levels. The inhibition of others pathways besides BCR-ABL oncoprotein could be used as a new potential approach in the treatment of CML and in overcoming resistance to standard therapies.Frist and second authors contribute equally to the study.

EFFECTS OF AUTOPHAGY ON CYTOSINE ARABINOSIDE-HL60 INDUCED CELL DEATH

C Bincoletto[1], C Santos[1], G Pereira[2], H Hirata[3], S Smaili[3]

[3]Pharmacology, São Paulo, Brazil

Macroautophagy (autophagy) is a cellular process for degradation of proteins and defective organelles in eukaryotic cells, by their sequestration by double-layered membranes which form autophagosomes, which fuses with lysosomes where the sequestered contents are degraded. Studies have demonstrated that autophagy inhibition accelerates the demise of tumor cells that are subjected to chemo or radiotherapy, constituting an important target for the anticancer new strategies development. Cytosine arabinoside (AraC) is an important drug that has been used in the treatment of acute myeloid leukemia (AML) for more than three decades. However, only a few studies have demonstrated the signaling pathways involved in AraC-induced leukemia cell death and there are no reports involving the role of autophagy in the response of leukemia cells to AraC. In this work, we have evaluated the modalities of cell death induced by this drug alone and in association to the autophagy inhibitors 3-Methyladenine (3-MA) and Chloroquine (CQ) on human myeloid leukemia cell line (HL60). Cytotoxicity of AraC in association to 3-MA (10 mM) or CQ (25 μM) in HL60, assessed by trypan blue exclusion assay, demonstrated that 3-MA increased significantly the AraC effects to HL60 cells. AraC HL60-induced cell death, analyzed by flow cytometer in cells labeled with FITC Annexin V and PI, demonstrated an increase in the percentage of apoptosis and secondary necrosis in AraC/3-MA treated HL60 cells in relation to AraC alone. Interestingly, CQ, another autophagy inhibitor, when used in association to AraC, although it has also decreased the viability of HL60 cells and increased the percentage of cell death in relation to AraC alone, these data were not statistical different. The involvement of autophagy process in our results was evaluated by Western blot, which demonstrated an increase of p62 and decreased of LC3II/LC3I ratio in HL60 AraC treated cells in relation to control non-treated HL60 cells. No additional increase and decrease in these parameters (p62 and ratio LC3II/LC3I), respectively was observed in our results when HL60 cells were treated with 3-MA and CQ in association to AraC. Beclin-1 expression in HL60 cells was not modified by AraC alone or in association to autophagy inhibitors for 24 hours. Our results suggest that autophagy plays a complex role in the AraC-induced death of HL60 cells since it amplifies the AraC-mediated cell death programs. Thus, autophagy might be a mechanism of AraC resistance, since the pharmacological inhibition of this process sensitized HL60 cells to AraC death stimulus.**Financial Support:** FAPESP and CNPq.

Background. The incidence of childhood acute lymphoblastic leukemia (ALL) is higher by 20% in males relative to females. Male sex is also associated with a worse response to treatment and an inferior prognosis. The mechanism behind the phenomenon of gender-specific differences is presently not understood. **Patients, Methods and Results.** We have initially identified a previously described deletion of the 5' region of *C20orf94* - a gene coding for an uncharacterized DNA repair-associated protein - by SNP array and high-resolution CGH array in 5 of 20 ALL samples. As the breakpoints within *C20orf94* were defined to recurrent positions, we performed sequence analysis and revealed specific breakpoint junctions with typical characteristics of illegitimate V(D)J recombination. We next screened diagnostic leukemic specimens of a representative cohort of 512 patients enrolled into trial ALL-BFM 2000 by PCR. Here, *C20orf94* deletions were detected in 32.0%. The deletions were significantly associated with male gender ($P < 0.001$) and *ETV6/RUNX1*-rearranged ALL ($P < 0.001$). Additional screening of an independent cohort of 232 *ETV6/RUNX1*-rearranged ALLs identified 145 positive samples and not only confirmed the high incidence of *C20orf94* deletion in this subgroup, but also allowed validation of its specific association with male gender ($P = 0.049$). By analyzing additional 249 *ETV6/RUNX1* negative patients diagnosed in 2001 and 2002 the association with male gender was also confirmed in this subgroup ($P=0.029$). Breakpoint sequencing analysis in additional 38 patients confirmed illegitimate V(D)J recombination in all samples. In 21 of 22 paired initial and relapse leukemic samples, *C20orf94* deletions were maintained at relapse. Breakpoint analysis showed the same monoclonal sequences in nine patients indicating stability of *C20orf94* deletions during disease progression. The remaining samples either developed heterogeneity of *C20orf94* breakpoints at relapse subsequent to monoclonal sequences or already showed an oligoclonal pattern at initial diagnosis. We next collected information on *TAL1* deletion status - a second marker associated with illegitimate V(D)J-mediated recombination in childhood ALL. It occurs in approximately 5 to 15% of T-cell ALL. Employing the ALL-BFM 2000 trial and additional national trials conducted in Austria, Czech Republic, Israel and Italy, 128 (11.1%) *TAL1*-deleted patients were identified from an entire *TAL1* deletion-screened T-ALL population of 1149 patients. *TAL1* deletions were significantly more frequent in male patients ($P = 0.002$). **Conclusions.** As we found a clear association of *C20orf94* deletion with *ETV6/RUNX1*-rearranged ALL and male sex, our results not only suggest a potential role for *C20orf94* deletion and illegitimate V(D)J recombination in the pathogenesis of childhood ALL, but point towards gender-specific differences in illegitimate V(D)J-mediated recombination as one potential explanation for the observed and currently only poorly understood gender bias in childhood ALL.

THE ORIGIN AND NATURE OF TIGHTLY CLUSTERED BTG1 DELETIONS IN PRECURSOR B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA SUPPORT A MODEL OF MULTICLONAL EVOLUTION

B Scheijen[1], E Waanders[1], L van der Meer[1], S van Reijmersdal[1], L van Emst[1], Y Kroeze[1], E Sonneveld[2], P Hoogerbrugge[1], A Geurts van Kessel[1], F van Leeuwen[1], R Kuiper[1]
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands
[2]Dutch Childhood Oncology Group (DCOG), The Hague, Netherlands

Background. B-cell precursor acute lymphoblastic leukemia (BCP-ALL) is the most common form of cancer in children and comprises genetically distinct subtypes. These ALL subtypes are characterized by specific genetic abnormalities, including aneuploidies (hyperdiploidy and hypodiploidy) and chromosomal translocations leading to *ETV6-RUNX1*, *TCF3-PBX1*, *BCR-ABL1*, and *MLL* gene fusions. An additional layer of complexity was recently revealed by the identification of recurrent copy number alterations, including single gene deletions, which may act as 'drivers' in the development of BCP-ALL. One of the newly identified players in BCP-ALL is the *B cell translocation gene-1* (*BTG1*), which belongs to the *BTG/TOB* family of anti-proliferative genes and expression of their gene products is altered in a variety of different cancers. **Aims.** Recurrent deletions in genes affecting key cellular pathways are a hallmark of pediatric BCP-ALL. To gain more insight into the mechanism underlying these deletions, we have studied the occurrence and nature of abnormalities in *BTG1* in a large cohort of pediatric BCP- and T-lineage ALL cases. **Methods.** By performing SNP-based CGH analyses (n=24) and MLPA (n=831) clonal *BTG1* deletion breakpoint clusters were identified. Using a sensitive deletion-spanning PCR the deletion breakpoints were subcloned and further examined in detail for RAG recombination signal sequences and the presence of multiple subclonal *BTG1* deletions. Genomic sequencing of the open reading frame (n=293) and bisulphite sequencing of the *BTG1* promoter region (n=25) provided information about the presence of *BTG1* point mutations and promoter methylation, respectively. Finally, by chromatin immunoprecipitation (ChIP) the level of H3K4me3 and H3K9/14Ac within the *BTG1* gene locus was assessed to determine their role in the *BTG1* deletion mechanism. **Results.** *BTG1* was found to be exclusively affected by genomic deletions, which were detected in 65 out of 722 BCP-ALL patient samples (9%), but not in 109 T-ALL cases. There was no evidence for the presence of *BTG1* point mutations or promoter methylation. Eight different deletion sizes were identified, which all clustered at the telomeric site in a hotspot region within the second (and last) exon of the *BTG1* gene, resulting in the expression of truncated *BTG1* read-through transcripts. The presence of V(D)J recombination signal sequences at both sites of virtually all deletions strongly suggests illegitimate RAG1/RAG2-mediated recombination as the responsible mechanism. Moreover, high levels of H3K4me3, which is known to tether the RAG enzyme complex to DNA, were found within the *BTG1* gene body in BCP-ALL cells, but not T-ALL cells. *BTG1* deletions were rarely found in hyperdiploid BCP-ALLs, but were predominant in other cytogenetic subgroups, including the *ETV6-RUNX1* (19%) and *BCR-ABL1* (26%) positive BCP-ALL subgroups. Through sensitive PCR-based screening, we identified multiple additional *BTG1* deletions at the subclonal level in BCP-ALL, with equal cytogenetic distribution and which, in several cases, grew out into the major clone at relapse. **Conclusions.** Taken together, our results indicate that *BTG1* deletions may act as 'drivers' of leukemogenesis in specific BCP-ALL subgroups, in which they can arise independently in multiple subclones at sites that are prone to aberrant RAG1/RAG2-mediated recombination events.

Background. Acute leukemias are characterized by a multi-step oncogenic process leading to maturation arrest and malignant transformation of a hematopoietic precursor. TCR chromosomal translocations represent a recurrent oncogenic hallmark of T-ALL, amongst which over-expression of the homeobox proteins TLX1 and TLX3 are the most frequent. This oncogene deregulation is classically considered to be driven by the TCR enhancer. Almost all TLX1/3 T-ALLs are arrested at the cortical thymic stage, with expression of cytoplasmic TCRb but no surface TCRab. **Aims.** To determine whether TLX oncoproteins are linked to the cortical thymic maturation arrest and whether they impact on initiation, development and maintenance of TLX+ T-ALLs. **Methods.** An Ea-CAT gene reporter assay was used to analyse the role of TLX protein on Ea, including protein/protein interaction by CoIP and GST pull down followed by protein/DNA interaction by Chip and EMSA. The effect of TLX down-modulation was evaluated using ShRNA TLX1/3 in TLX+ cell lines. The effect of TCRab expression on differentiation and survival was also assessed. TCR-TLX1 translocations were analysed by FISH and LM-PCR. **Results.** The Ea-dependent reporter assay showed repression of Ea transcriptional activity by TLX1/3 proteins via ETS1. TLX1/3 and ETS1 proteins interact in the TLX1$^+$ ALL-SIL and TLX3$^+$ DND41 cell lines. The ETS1 protein led to a shift of the labelled Ea probe by EMSA, and addition of TLX1/3 produced a super-shifted complex. ChIP analysis demonstrated that knockdown of ETS1 reduced Ea-binding of both ETS1 and TLX1/3 in TLX$^+$ cell lines, in keeping with recruitment of TLX1/3 to Ea through ETS1 in TLX$^+$ T-ALL. These results suggested that inhibition of Ea activity by TLX1/3 in T-ALL blocks ab rearrangement and, consequently, T-cell maturation. Knock-down of TLX1/3 in TLX$^+$ cell lines induced sTCRab expression and massive apoptosis. ALL-SIL cells were transduced using lentiviral vectors enabling expression of TCRb and TCRa. sTCRab$^+$ ALL-SIL cells exhibited reduced viability and cell growth and increased apoptosis, when grown on OP9-DL1. These data demonstrate the key role of TCR expression and signalling in mediating cell death in TLX$^+$ T-ALLs, and strongly suggest that the apoptosis observed upon TLX inhibition is a consequence of re-differentiation.Mapping of the translocations breakpoints in *TCRb-TLX1* and *TCRd-TLX1* T-ALLs showed that whereas *TLX1* activation in *TCRb-TLX1* was consistent with classical TCR enhancer-mediated activation, the *TCRd-TLX1* translocations separated the *TLX1* gene and Ea on the two derivative chromosomes, indicating Ea-independent activation. TCRd-TLX1 translocations with breakpoints downstream to *TLX1* could however be found by PCR in normal thymus. This suggest that deregulation of *TLX1*, when driven in-*cis* by Ea, will not lead to oncogenic selection but rather to autonomous counter-selection of the chromosomal translocation due to feed-forward repression **Summary and Conclusions.** TLX1 expression in T-ALLs prevents TCRa rearrangement by ETS1 mediated inhibition of the TCR Ea, with consequent maturation arrest. Abrogation of this maturation arrest by loss of TLX expression or, more surprisingly, TCRab expression in an appropriate cellular context leads to cell death, providing evidence in favor of an oncogenic role for the failure to express a TCRab in TLX1 T-ALLs.

LEUKEMIA INITIATING CELL: A NOVEL PROGNOSTIC MARKER IN B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

Y Kong, YR Liu, H Le, YZ Wang, J Qian, KY Liu, XJ Huang
Peking University People's Hospital, Beijing, China

Background. Minimal residual disease (MRD) is currently the most powerful prognostic indicator in ALL. Using neonatal NOD/SCID/IL2rγ^{null}(NOG) mouse model, we previously reported that CD34$^+$CD38$^+$CD19$^+$ cells as well as CD34$^+$CD38$^-$CD19$^+$ cells have the capacities to initiate B-ALL *in vivo* and to self-renew, that is, CD34$^+$CD19$^+$ cells are candidate leukemia initiating cells(LICs) in human B-precursor ALL (B-ALL)(Kong Y et al. Leukemia 2008;22:1207-1213). Preliminary study demonstrated that mean fluorescence intensity of CD58 and CD123 were significantly higher on LICs from newly diagnosed B-ALL and relapsed B-ALL than that of normal B-cell progenitors (Kong Y et al. Blood 2011;118(21):1084a). Nevertheless, the delivery of the LICs identified in xenotransplantation assay to the clinics still remains controversial. **Aims.** To evaluate prognostic significance of the candidate LICs as a novel MRD biomarker in B-ALL patients. **Methods.** Using a cohort of 140 patients (including pediatric and adult patients) with CD34$^+$ B-ALL, candidate LICs were examined by seven-color flow cytometry (FCM) at different time points during treatment. A total of 1,050,000 events were routinely collected. More than 0.001% of LICs with aberrant overexpression of CD123 and/or CD58 in bone marrow samples after complete remission(CR) were defined as LIC positive (LIC+), all other cases were defined as LIC negative (LIC+). Real-time quantitative polymerase chain reaction (RQ-PCR) was applied concurrently to evaluate MRD in Ph$^+$ ALL, MLL$^+$ and TEL-AML1$^+$ patients. The value of the above specific genes equal to 0 was defined as RQ-PCR negative (RQ-PCR). The study was approved by the Ethics Committee of Peking University People's Hospital and written informed consent was obtained from all subjects. **Results.** The candidate LICs population with aberrant overexpression of CD123 and/or CD58 was identified in 100% of CD34$^+$ B-ALL patients at diagnosis. In the sequential MRD monitoring, sixty-four patients were detected as LIC+. Among them, LICs from 75% cases with CD58 overexpression, 97% with CD123 overexpression, and 100% with CD123 or CD58 overexpression. Thirty cases relapsed during follow up, of them 25 cases were detected as LIC+ at a median time of 57 days (13-90days) before the recurrence. In addition, a good correlation was found between the MRD results of LICs detected by seven-color FCM and RQ-PCR (n=313 pairs, Spearman r=0.889, p<0.001). Importantly, patients who were LIC+ after CR had a lower event-free survival (EFS) of 0.41 and a higher cumulative incidence of relapse (CIR) of 0.51 compared to an EFS of 0.90 and a CIR of 0.13 in LIC$^-$ patients (EFS, p<0.001; CIR, p<0.001). Similar results were obtained in high-risk patients and Ph$^+$ ALL patients. Multivariate analysis for EFS, overall survival (OS) and CIR showed that LIC+ after CR was an independent prognostic factor (p=0.000, p=0.000, and p=0.000, respectively). **Summary and Conclusions.** Detection of the B-ALL initiating cells with aberrant overexpression of CD123 and/or CD58 by seven-color FCM promises to be an efficient tool for MRD assessment and risk stratification in human B-ALL. **Acknowledgments.** This work was supported by grants from National Natural Science Foundation of China (30800483) and Beijing Municipal Science and Technology Program (Z111107067311070).

AN AUTOMATED MICROSCOPY-BASED PLATFORM FOR FUNCTIONAL INVESTIGATION OF PROTECTIVE INTERACTIONS BETWEEN BONE MARROW STROMAL AND PRIMARY ALL CELLS

J Boutter[1], B Bornhauser[1], G Csúcs[2], P Horvath[2], JP Bourquin[1]
[1]Kinderspital Zürich, Zürich, Switzerland
[2]ETH Zurich, RISC, Zürich, Switzerland

Background. Leukemia cells are critically dependent upon interactions with the microenvironment in the bone marrow and extramedullary sanctuary sites, which is likely to provide a protective mechanism to escape the effect of chemotherapy. *In vitro*, co-culture of primary ALL cells on human mesenchymal bone marrow derived stromal cells (MSC) provides survival cues enabling long-term cultures. In contrast, primary ALL cells rapidly undergo cell death when cultured without stromal support. **Aim.** We developed an automated microscopy-based platform to identify pro-survival signals by RNA interference of candidate genes in MSC cells and subsequent evaluation on leukemia cell survival, enabling us to functionally profile primary leukemia cells. **Methods.** We took advantage of our leukemia xenograft system as a renewable source of well characterized samples derived from cases with very high risk ALL. Based on gene expression data and on cell surface proteomic data obtained from both cellular compartments, we generated a customized siRNA library for 110 candidate genes with a potential function in stromal support. Primary ALL cells were seeded on reversely transfected MSC cells in a 384 well format, and ALL cell viability was assessed with a fluorescent vital dye after 6 days. A machine learning algorithm was developed for quantification of surviving ALL cells on top of MSC. This readout correlated well with the standard method using 7-AAD by flow cytometry. **Results.** In this pilot study we evaluated three cases with VHR-ALL. We observed a consistent decrease of viability when interfering with the expression of 16 candidate genes. Interestingly the response patterns were different among the individual cases. As a proof of concept, we could show that down-regulation of VCAM1 and VEGFC had an effect on ALL survival as suggested by earlier studies. Down-regulation of VCAM-1 showed a decrease of ALL cell viability down to 58% compared to control on average for 3 different patients, whereas down-regulation of VEGFC decreased ALL cell viability down to 63%. One of the strongest effect on ALL survival by knockdown of a single gene was achieved for the membrane protein CD147 (Basigin). Down-regulation of CD147 decreased ALL cell viability in 12 of 17 patients tested. This protein exerts important chaperone function for monocarboxylate transporters, which have been shown to be important for tumor cell survival, and induces matrix metalloproteinases, which potentiate important microenvironmental signals. **Conclusions.** We have established a robust platform for systematic functional investigation of primary ALL cells in a 2-D model of the microenvironment. Critical interactions between ALL cells and bone marrow stromal cells can be identified with this approach, which can be extended for unbiased higher throughput screening and combinatorial testing. This platform will be of great interest for preclinical drug profiling on clinically relevant patients samples in the context of protective bone marrow signals. Finally, our data indicate that important differences will be found between leukemias derived from different patients, which underscores the need for a comprehensive study to better define functional subgroups and their potential clinical implications with respect to a more personalized approach to treatment.

Background. *NPM1* gene mutations are frequently identified in AML. They have been reported as suitable molecular markers for minimal residual disease (MRD) monitoring. Recently, gemtuzumab ozogamicin (GO) has been shown to improve event-free and overall survival in patients with AML. **Aims.** To follow MRD in patients with *NPM1* mutated (*NPM1*mut) AML treated in the randomized ALFA-0701 GO trial conducted by the Acute Leukemia French Association (Castaigne et al, ASH meeting 2011), in order to evaluate its prognostic significance and the effect of GO on MRD level. **Methods.** The ALFA-0701 trial included 278 patients aged 50-70 years with newly-diagnosed *de novo* AML, randomized to receive or not five doses of 3 mg/m^2 GO, on day 1, 4 and 7 of standard induction chemotherapy and on day 1 of two consolidation chemotherapy courses, respectively. A total of 93 *NPM1*mut AML patients were studied (45 GO arm, 48 control arm). Peripheral blood and bone marrow samples were collected at diagnosis, after induction and after each consolidation course. MRD levels were assessed using cDNA-based real-time quantitative PCR (RQ-PCR) assays specific for the detection of the 3 most common types of *NPM1* mutations, A (n=72), B (n=10) and D (n=5) and reported as the ratio *NPM1*mut transcript/100 *ABL* transcript, with a threshold for MRD quantification at 0.1%. Occurrence of a MRD level below this threshold was defined here as a good MRD response. The prognostic value of MRD was assessed by comparing the outcome of good *versus* poor MRD responders after induction and after second consolidation, in terms of cumulative incidence of relapse (CIR). Effect of GO was then evaluated by comparing MRD levels in both treatment arms.

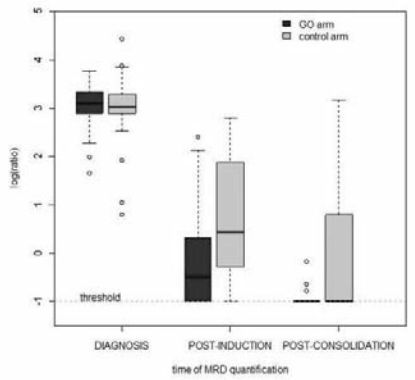

Figure 1. MRD levels according to treatment arm (GO or control).

Results. *NPM1*mut transcript levels at diagnosis were available for 77/93 patients (42 GO, 35 control) and had no prognostic impact on complete remission (CR) rate or CIR. In the 67 CR patients, post-induction MRD level was predictive of relapse: one-year CIR was 50% [95% CI: 36%-64%] in the 51 poor *versus* 27% [95% CI: 3%-52%] in the 16 good MRD responders (p=0.03). This prognostic impact on CIR was also observed for post-consolidation MRD level (SHR=0.3, 95%CI: 0.1 - 0.6; p= 0.002). Post-induction and post-consolida-

tion MRD levels were lower in the GO as compared to the control arm (Figure 1). The rate of good MRD response was 14/37 (38%) *versus* 2/30 (6%) after induction (p=0.004) and 24/27 (89%) *versus* 11/20 (55%) after consolidation (p=0.02), in GO and control arm patients respectively. Separate analysis in each treatment arm was limited by low patient numbers. **Conclusions.** Our data confirm the already reported predictive value of *NPM1* MRD and show that treatment with GO had a sustained effect on MRD reduction after induction and after consolidation.

Background. Acute myeloid leukemia (AML) with translocation t(8;21)(q22;q22) is a clinicopathologic genetic entity that is recognized in the WHO category of AML with recurrent genetic abnormalities. At the molecular level t(8;21) results in the *RUNX1-RUNX1T1* fusion gene which can be used as a molecular marker for monitoring minimal residual disease (MRD). In contrast to AML with *CBFB-MYH11*, *MLLT3-MLL* and *NPM1* mutation for which the prognostic impact of MRD monitoring could be demonstrated, the value of MRD in *RUNX1-RUNX1T1* positive AML is still undefined. **Aims.** To evaluate the prognostic impact of MRD in a large cohort of *RUNX1-RUNX1T1* positive AML patients by quantitative reverse transcriptase polymerase chain reaction (RQ-PCR) during and after treatment. **Methods.** A total of 68 patients (age 18-60 years) were treated within one of the AMLSG treatment trials (AMLHD93 n=2, AMLHD98A n=12, AMLSG 07-04 n=54). Treatment consisted of double induction therapy with ICE (idarubicin, cytarabine, etoposide); postremission therapy comprised high-dose cytarabine-based regimens(n=59) as well as autologous (n=2) or allogeneic (n=4) stem cell transplantation (SCT) in first CR. Median follow up for survival was 43.5 months. Patient samples (bone marrow [BM] and/or peripheral blood [PB]) were collected at diagnosis (n=124), during treatment (n=354), and during follow up (n=305). RQ-PCR was performed using TaqMan technology. MRD levels were reported as the normalized values of *RUNX1-RUNX1T1* transcripts per 10^6 *beta-2-microglobulin* (*B2M*) transcripts (*RUNX1-RUNX1T1*/10^6 *B2M*), hereafter designated as *RUNX1-RUNX1T1* transcript levels. The maximum sensitivity of the assay was 10^{-6}. **Results.** At diagnosis transcript levels in BM samples ranged from $2{,}9x10^4$ to $14.4x10^6$ (median $3.0x10^5$) without correlation to presenting clinical features; in PB samples transcript levels ranged from $6.3x10^3$ to $10.3x10^6$ (median $2.3x10^5$) and were associated with white blood cell count (p=0.06) and peripheral blood blast percentage (p=0.02). There was no prognostic impact of pretreatment transcript levels in BM (HR, 1.07; p=0.86) and PB (HR, 1.02; p=0.96) on relapse free survival (RFS). After induction therapy the $\log_{10}$ reduction of transcript levels ranged from 1.4 to 6.6; three patients became MRD negative in BM and remained in sustained CR. During consolidation therapy 20 and 21 patients became at least at one time point MRD negative in BM or PB samples, respectively. This resulted in a significantly better RFS (p=0.02) of 85% (95%-CI, 70-100%), 65% (95%-CI, 47-90%) and 46% (95%-CI, 26-83%) in BM-negative, PB-negative and never-RQ-PCR negative (n=13) patients, respectively. The beneficial effect of RQ-PCR negativity translated into a better overall survival (p=0.008). After consolidation therapy, 21 of the 41 BM- and/or PB-negative patients became positive at least in one sample during follow up. Ten patients developed increasing transcript levels and all relapsed, whereas in the remaining 11 patients only single samples became positive with a maximum value of 881. **Conclusions.** In our study, achievement of RQ-PCR negativity after induction and consolidation therapy was significantly associated with favorable outcome in *RUNX1-RUNX1T1*-positive AML. MRD monitoring should be incorporated in future clinical trials to evaluate whether early intervention will improve outcome of the patients.

GATA2 MUTATIONS ARE FREQUENT IN INTERMEDIATE RISK KARYOTYPE AML WITH BIALLELIC CEBPA MUTATIONS AND ARE ASSOCIATED WITH FAVORABLE PROGNOSIS

A Fasan, C Eder, C Haferlach, A Kohlmann, V Grossmann, F Dicker, W Kern, T Haferlach, S Schnittger
MLL Munich Leukemia Laboratory, Munich, Germany

Background. *GATA2* belongs to the *GATA* family of zinc finger transcription factors with importance in gene regulation in hematopoiesis. Recently, *GATA2* mutations have been described in families with predisposition to AML/MDS and in cytogenetically normal AML (CN-AML) with biallelic *CEBPA* mutations (*CEBPA*mut). **Aims.** The evaluation of *GATA2*mut in AML with intermediate-risk karyotype for frequency, association with other mutations and impact on outcome. **Methods.** We analyzed 212 cases with intermediate risk *de novo* AML for *GATA2*mut by direct Sanger Sequencing of exon 4 and 5, which contain the two highly conserved zinc finger domains of *GATA2.* Mutation status of other genes were available as follows: *NPM1*: n=212, *FLT3*-ITD: n=212, *CEBPA*: n=212, *MLL*-PTD: n=211, *RUNX1*: n=207, *ASXL1*: n=138, *FLT3*TKD: n=209, *WT1*: n=108. 156 cases (73.6%) were CN-AML and 56 (26.4%) had intermediate-risk aberrant cytogenetics according to MRC criteria. Female/male ratio was 107/105 and age ranged from 15.7-84.9 y (median: 59.7). **Results.** Overall, in 21/212 patients (9.9%) *GATA2*mut were detected. All mutations were point mutations. In detail, most mutations (n=14) were located in the first zinc finger domain (ZFD) (aa 294-344). Five patients harbored a mutation in the second ZFD (aa 349-398). One patient had two mutations in the first ZFD and one patient had each one mutation in each of the two ZFDs, respectively. In 10/21 *GATA2*mut cases remission samples were available and in all these cases the *GATA2*mut were not detectable in remission and thus were somatic and not germline. *GATA2*mut tended to be more frequent in females than in males (n=15/107, 14.0% vs 6/105, 5.7%, p=0.064). There was no association with age, leukocyte count, hemoglobin level, platelet count or cytogenetics. In 103 cases immunophenotyping data was available and cases with *GATA2*mut (n=10) had a higher expression of CD133 (52±29% vs 29±27%, p=0.015), CD34 (67±30% vs. 42±31%, p=0.018) and HLA-DR (59±28% vs. 38±24%, p=0.017) as well as lower expression of CD11b (19±14% vs 37±24%, p=0.003) and CD36 (10±5% vs. 23±15%, p<0.001) and thus had a more immature phenotype as compared to *GATA2*wt. With regard to cytomorphology we observed a preponderance of AML M1 (n=12/21) and AML M2 (n=8/21) subtypes in *GATA2*mut cases. In addition, *GAT*A2mut were strongly associated with *CEBPA* biallelic mutations (n=18/120, 15.0% vs 3/92, 3.3% in *CEBPA* wt, p=0.005), whereas *GATA2*mut were mutually exclusive of *CEBPA* monoallelic mutations (0/22) and of *FLT3*-ITD (0/45). Patients with *GATA2*mut had significantly better 2-year overall survival (2y-OS) (100% vs. 53.1%, p=0.001) and 2y event-free survival (63.8% vs. 35.7%, p=0.025) compared to *GATA2*wt cases. Because of the high coincidence of the two mutations the prognostic impact of *GATA2*mut in dependence of biallelic *CEBPA*mut was analyzed. Patients with biallelic *CEBPA*mut and additional *GATA2*mut (n=18) had a better 2ys-OS compared to patients with biallelic *CEBPA*mut and *GATA2*wt (n=80) (100% vs: 76.1% p=0.058). **Summary.** *GATA2* mutations are frequent in intermediate risk AML and are associated with female sex, biallelic *CEBPA*mut and favorable impact on survival. *GATA2* thus seems to be a promising new marker to identify patients with even more favorable prognosis in biallelic *CEBPA*mut AML.

Background. We and others have previously shown that cytogenetically normal acute myeloid leukemia (CN-AML) with biallelic *CEBPA* gene mutations (bi*CEPBA*) represents a distinct disease entity with a homogeneous gene expression profile and an independent favourable clinical outcome. Patients with bi*CEBPA* mutations are rarely associated with prognostic mutations commonly occurring in CN-AML, like mutated *NPM1*, *FLT3*-ITD, mutated *DNMT3A* or *IDH1/2*.So far, it is not known if other unknown genetic alterations cooperate with bi*CEBPA* mutations during leukemogenesis.**Aims**Therefore, we aimed to discover collaborating mutations in bi*CEBPA* mutant AML and to study their frequency as well as prognostic and functional relevance. **Methods.** We performed whole exome sequencing of five bi*CEBPA* patients at diagnosis and at remission. Leukemia-specific variants were verified by Sanger sequencing and their incidence evaluated in a larger cohort by scanning all coding exons using high resolution melting analysis. Mutation data were correlated to important clinical and molecular markers and to overall and event-free survival. The *in vitro* functional relevance of the most interesting mutations was tested using Dual Luciferase Reporter gene assays. **Results.** Somatic *GATA2* mutations were recurrently found in two out of 5 sequenced exomes. Further mutational screening uncovered *GATA2* mutations in 13 of 33 bi*CEBPA* positive CN-AML patients (39.4%). Interestingly, *FLT3*-ITD (6/33) was negatively associated with *GATA2* mutations in bi*CEBPA* mutant AML (p=0.027, Fisher's Exact Test).Strikingly, no *GATA2* mutations were found in 38 CN-AML patients with a monoallelic *CEBPA* mutation and in 89 CN-AML patients with wild-type *CEBPA* status. All *GATA2* mutations were exclusively located in the highly conserved N-terminal zinc finger domain (ZF1). The *GATA2* missense mutations A318T and G320D surrounding the C319 which coordinates the zinc atom were recurrently detected in 6 out of 13 bi*CEBPA* patients. *GATA2* mutations were lost during disease remission.Both GATA2 and CEBPA are transcription factors crucial for hematopoietic development. Inherited or acquired mutations in both genes have been associated with leukemogenesis. Interestingly, GATA2 is a direct protein interactor of CEBPA (Tong *et al*, MCB, 2005).In reporter gene assays using a CEBPA responsive promoter, all tested GATA2 ZF1 mutants showed reduced capacity to enhance CEBPA-mediated activation of transcription suggesting that the GATA2 ZF1 mutations may collaborate with biCEPBA mutations to deregulate target genes during malignant transformation. The presence of *GATA2* mutations did not negatively impact on the favourable overall and event-free survival of bi*CEBPA* patients. **Summary and Conclusions.** In summary, we describe for the first time the specific association of recurrent *GATA2* ZF1 mutations with bi*CEBPA* mutations. Our data suggest that GATA2 ZF1 and biCEBPA mutations functionally collaborate in interfering with the transcriptional activation of CEBPA.

0541

THE INCIDENCE AND PROGNOSTIC SIGNIFICANCE OF GATA2 MUTATIONS IN AML PATIENTS WITH CEBPA MUTATIONS

C Green[1], R Hills[2], A Burnett[2], D Linch[1], R Gale[1]
[1]UCL Cancer Institute, London, United Kingdom
[2]Cardiff University School of Medicine, Cardiff, United Kingdom

GATA2 is a transcription factor that is important for megakaryocytic differentiation and the proliferation and maintenance of haematopoietic stem/progenitor cells. A number of recent studies have revealed germ-line mutations in the GATA2 gene in a range of phenotypically diverse disorders including familial MDS/AML (Hahn *et al*, Nat Genetics 43:1012, 2011), although studies of sporadic AML cases have reported either no acquired mutations (Zhang *et al*, PNAS 105:2076, 2008; Hahn *et al*, Nat Genetics 43:1012, 2011) or occurrence at low frequency (3.6%; Yan *et al*, Nat Genetics 43:309, 2011). However, a recent exome analysis of 5 AML cases with a normal karyotype (NK) and biallelic CEBPA mutations (CEBPA-double) detected recurrent acquired GATA2 mutations in these patients (Dufour *et al*, Blood 118:35, 2011). Strikingly, they found mutations in 41% of 32 CEBPA-double patients, all located in the N-terminal zinc finger domain of GATA2, but no mutations in 38 cases with one CEBPA mutation (CEBPA-single) or 90 NK patients with wild-type CEBPA (NK/CEBPA-WT). CEBPA-double patients have a favourable outcome compared to CEBPA-WT or CEBPA-single cases, although this benefit is lost in the presence of a FLT3/ITD (Green *et al*, JCO 28:2739, 2010). Given that the particular combination of mutations present in the same patient can influence outcome, we investigated the incidence of GATA2 mutations in CEBPA-mutated cases and analysed the impact on outcome in CEBPA-double patients. Exons 4, 5 and 6 of GATA2, encoding both zinc finger domains, were analysed by dHPLC using samples from 150 young adult AML patients treated on the UK MRC AML 10 or 12 trials. GATA2 mutations were detected in 14 of 53 (26%) CEBPA-double patients and also in 6 of 42 (14%) CEBPA-single cases, this difference not being significant (P = .15). No GATA2 mutations were found in 55 NK/CEBPA-WT patients. All mutations detected were located in one of the two zinc finger domains and they were predominantly missense mutations. The same mutations were detected in both CEBPA-single and CEBPA-double cases and recurrently affected A318 (n=6), L321 and R330 (both n=4). One CEBPA-double patient had two GATA2 mutations. There was a negative association between a GATA2 mutation and a FLT3/ITD in CEBPA-mutated cases, 0 of 20 (0%) GATA2-mutated cases were FLT3/ITD-positive vs. 16 of 75 (21%) GATA2-WT (P=.004), suggesting that these mutant genes have overlapping roles in the leukaemogenic process. Outcome analyses were performed for the CEBPA-double patients excluding the 6 FLT3/ITD-positive cases. GATA2-WT cases had a better remission rate than GATA2-mutant cases (97% vs. 79%, OR=10.1, 95% CI=1.10-92.7, P=.04). However, overall survival at 5 years was similar for the two groups (67% vs. 71% for GATA2-WT and GATA2-mutant, respectively; HR=0.71, CI=0.26-1.96, P =.5,) probably due to the lower, although not significantly different, relapse rate in the GATA2-mutant group (38% vs. 19%, HR=0.44, CI=0.15-1.30, P = .14). Therefore, although GATA2 and CEBPA mutations commonly occur together, there is no evidence that identification of the former provides additional prognostic information.

Chronic lymphocytic leukemia - Clinical

Background. BTK is an essential mediator of B-cell receptor signaling and a critical kinase for lymphoma cell survival. Ibrutinib (PCI-32765), an oral, selective, irreversible inhibitor of BTK, inhibits proliferation, migration and adhesion in CLL cells. The combination of fludarabine, cyclophosphamide and rituximab have markedly improved outcomes of younger-fit patients in the first and second-line setting. However, effective salvage regimens for patients who develop treatment resistance are lacking. Fludarabine-based therapy, while effective is toxic and carries significant risk of morbidity and mortality in elderly pts. Patients who relapse following fludarabine-based regimens and older CLL patients represent a high priority for new therapeutic approaches. A multicohort Phase Ib/II trial evaluated 2 doses of single-agent ibrutinib in TN and R/R CLL/SLL patients**. Aims.** The primary objective was to determine the safety of 2 dose regimens. Secondary objectives were to assess the preliminary efficacy, PK, and long-term safety. **Methods.** Patients with R/R CLL who had failed at least 2 lines of therapy (including a purine analog) and TN CLL patients >65 years old were treated with oral ibrutinib at doses of 420mg or 840 mg administered daily for 28-day cycles until disease progression (PD).

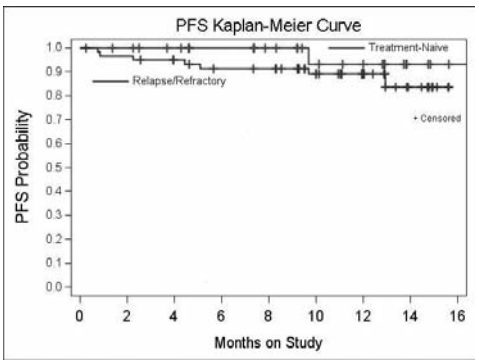

Figure 1.

Results. The data cut-off for R/R patients was 10/25/11 and 12/10/11 for TN patients. 61 patients were enrolled to the R/R cohorts- 27 patients (420mg) and 34 patients (840 mg). 31 patients were enrolled to the TN cohorts- 26 patients (420 mg) and 5 patients (840 mg). The 840mg TN cohort was terminated after comparable activity and safety between doses was shown in R/R patients. Median age was 64 and 71 years for R/R and TN patients respectively. 59% of R/R and 61% of TN patients had baseline cytopenias consistent with advanced stage disease. Unmutated IgVH was present in 79% of R/R and 43% of TN patients. Del17p was present 36% (R/R) and 6% (TN) of patients. The majority of AEs have been Gr<=2 in severity, most commonly diarrhea, nausea, and fatigue. Hematologic toxicity >= G3 was infrequent. Response (ORR; PR + CR) by IWCLL criteria in the 420 mg R/R cohort was 67% with 12.6 months median follow-up. In the 840 mg R/R cohort ORR is 68% at 9.3 months median follow-up. An additional 22%, and 24% of patients in these R/R cohorts, respectively, achieved a nodal response with residual lymphocytosis (NodR). With 10.7 months median follow-up the ORR in the 420mg TN cohort is 73% including 8% CRs with morphologically normal marrows. With only 4.6 mo median follow-up, ORR in the 840 mg TN cohort is 40%. An additional 12%, and 20% of patients in these TN cohorts, respectively, achieved a NodR. ORR was independent of high-risk factors. Estimated 12 month median PFS for those pts treated at 420 mg dose is 88% for R/R patients and 93.3% for TN patients. **Conclusions.** PCI-32765 is highly active and well tolerated in R/R and elderly TN CLL patients. No differences in activity or toxicity were noted between the two dose levels. The high ORR and very low PD rate indicate that ibrutinib warrants further study in CLL.

Background. Bruton's Tyrosine Kinase (BTK) is an essential mediator of B cell receptor signaling and a critical kinase for lymphoma cell survival. Ibrutinib (PCI-32765), is an oral, selective, irreversible inhibitor of BTK, that inhibits proliferation, migration and adhesion in CLL cells. Single agent ibrutinib administered to relapsed/refractory CLL patients was highly active as evidenced by an IWCLL overall response rate (ORR) of 67% and estimated 12 month PFS of 86% (O'Brien ASH 2011). Bendamustine (B) and rituximab (R) (BR) is also active in relapsed/refractory CLL patients with an ORR of 59% and median PFS of 15 months (Fischer JCO 2011). We report interim data on the combination of ibrutinib with BR. **Aims.** The primary objective of the study is to evaluate the safety of ibrutinib in combination with BR administered to relapsed or refractory CLL patients. The secondary objective is to estimate the efficacy of the combination. **Methods.** Relapsed/refractory CLL patients received ibrutinib 420 mg orally daily for 28-day (D) cycles (C) until disease progression (PD). B was administered 70 mg/m^2 on D1 and D2 combined with R 375 mg/m^2 on D0 for C1 and 500 mg/m^2 on D1 for subsequent courses for a maximum of 6 cycles. Response was evaluated according to IWCLL criteria. **Results.** 30 patients were enrolled. The median age of patients was 62 yrs (range 41-82). 46% of patients were Rai stage III/IV and the median # of prior therapies was 2 (range 1-4). 37% and 13% were considered refractory (treatment free interval <12 mo) to a purine analog containing regimen or BR, respectively. Bulky disease (lymph nodes >= 5 cm) was present in 52% of patients. Adverse events (AE) have been generally consistent with that expected with BR. Gr 3/4 neutropenia and thrombocytopenia have been noted in 47% and 10% of patients, respectively. Grade >=3 non-hematologic AEs potentially related to ibrutinib included rash (3 pts) and fatigue and tumor lysis reported in 2 pts each. There were no Gr 3/4 infusion reactions. SAEs occurred in 10% of patients including one aforementioned case of TLS, one cellulitis, and one neutropenic fever. There have been no discontinuations due to AEs and no deaths on study. At a median follow-up of 4.9 mos (range 2.7-8.3 mo) 16 patients have completed BR (median 6 cycles, range 2-6) and 14 patients are still receiving BR. The ORR is 90% (27/30 patients) (CR 10%, PR 80%). 2 additional patients achieved a nodal response with residual lymphocytosis. Responses appear independent of high-risk features. 90% of patients remain on study; reasons for discontinuation include PD (n=2) and 1 pt pursuing SCT. **Conclusions.** Ibrutinib, administered in combination with BR, is safe and highly active. The high ORR, low rate of PD, and good tolerability compare very favorably with historical controls, warranting additional investigation of this combination.

0544

PHASE I STUDY OF THE CYCLIN-DEPENDENT KINASE (CDK) INHIBITOR DINACICLIB (SCH 727965) IN PATIENTS (PTS) WITH RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

J Jones[1], J Flynn[2], L Andritsos[2], A Johnson[2], K Blum[2], E Wiley[2], K Small[3], M Grever[2], T Graef[3], R Bannerji[4], J Byrd[2]
[1]The Ohio State University, Columbus, United States of America

[3]Merck & Co. Inc, Kenilworth, New Jersey, USA, Kenilworth, United States of America
[4]Division of Hematologic Malignancies, The Cancer Institute of New Jersey, Robert, New Brunswick, United States of America

Background. Dinaciclib (MK-7965/SCH 727965) is a novel, potent, small molecule inhibitor of CDKs 1, 2, 5, and 9 (IC_{50} values between 1-4 nM) with anti-leukemic activity against CLL. **Aims.** A Phase 1 trial was initiated to characterize the dose-limiting toxicity (DLT) and determine the recommended phase 2 dose (RPTD) of dinaciclib administered as a 2-hour IV infusion to patients with relapsed or refractory CLL. **Methods.** Patients received treatment on days 1, 8 and 15 of a 28-day cycle. Based on preclinical data, 5 mg/m^2 was selected as the initial starting dose. Once the RPTD was determined, additional patients were accrued utilizing an intrapatient dose escalation schedule to mitigate tumor lysis toxicity (7, 10 and 14 mg/m^2 on days 1, 8, and 15 during cycle 1 and 14 mg/m^2/dose for each cycle thereafter). Response was assessed according to 1996 NCI Working Group (NCI-WG) criteria for CLL. Patients were followed until disease progression, death, or dropout. **Results.** To date 39 pts have been treated in 5 dose-escalation cohorts (5, 7, 10, 14 and 17 mg/m^2). Median age is 62 (range 43-79) years, with 40% ≥65 years, 71% Rai stage 3 or 4, 63% with bulky disease, and 43% with del 17p. The median number of prior therapies is 3 (range 1-12) with 89% having received prior fludarabine. In the dose determination phase, the RPTD was established as 14 mg/m^2. Dose limiting toxicities (DLT) of bacterial pneumonia and tumor lysis syndrome were observed at the maximum administered dose of 17 mg/m^2. TLS was observed in 7 of the first 39 subjects with CLL, 2 of the 7 TLS events resulted in temporary hemodialysis. Both subjects recovered rapidly and continued dinaciclib after dose reduction. Other common treatment related adverse events included leukopenia, neutropenia, anemia, thrombocytopenia, hyperglycemia, and diarrhea. Clinical response as assessed by the 1996 NCI-WG CLL criteria indicated an overall partial response rate of 54%. Response rates in patients withdel 17p was 53% (9/17), and 58% (7/12) withdel 11. Overall clinical response rates on the RPTD were 69% (11/16), with 6 responders out of 8 patients with del 17. An additional 13 patients have been enrolled in the intrapatient dose escalation expansion cohort, of which 7 are currently evaluable for response. Five patients have achieved a PR, 1 stable disease and 1 with progressive disease. **Conclusions.** Dinaciclib demonstrates single-agent activity in heavily pre-treated CLL patients, including those with deletion 17p and other high-risk genomic features. Compared to first-generation CDK inhibitors, the drug demonstrates a broader therapeutic index, but investigation of alternative dosing schemes to further mitigate risk for tumor lysis are warranted and ongoing. This study supports further study of dinaciclib in CLL, both alone and in combination.

[6]Fox Chase Cancer Center, Philadelphia, United States of America
[7]Abbott Laboratories, Abbott Park, United States of America

Background. Orally bioavailable navitoclax binds with high affinity (Ki ≤1nM) to Bcl-2, Bcl-xL, and Bcl-w, promoting apoptosis. Preclinically, N enhances rituximab (R) efficacy in B-cell lymphoma, alone or combined with chemotherapy. Phase 1 data showed that N monotherapy was well-tolerated and had anti-tumor activity in CLL patients. **Methods.** We treated relapsed/refractory CLL patients in a phase 1 study to evaluate the safety and pharmacokinetics (PK) of escalating doses of navitoclax combined with standard-dose bendamustine (B)-rituximab (R) or a fixed dose of navitoclax (110 mg) with standard-dose fludarabine (F)-cyclophosphamide (C)-R. Secondary objectives were to assess efficacy endpoints (PFS, ORR, TTP, OS, duration of response). Patients required therapy as per iwCLL criteria and had ECOG ≤1. For patients treated with navitoclax-BR, navitoclax was administered once daily (starting dose, 110 mg) on D3-5 of C1 and D1-3 of subsequent cycles, with 6 patients per dose cohort. Dose escalations were via continuous reassessment to identify a dose combined with chemotherapy in which <33% of patients experienced dose-limiting toxicity (DLTs). We assessed tumor response (NCI-WG 1996 criteria; updated 2008) and adverse events (AE; NCI CTCAE V4). Patients received navitoclax for 1 year or until progressive disease (PD) or intolerable toxicity. **Results.** 26 patients (median age 58 yr [39-80]) enrolled in the BR navitoclax-dose escalation study and 5 patients in the fixed-dose navitoclax-FCR cohort. Median number of prior therapies was 2 (range 1-13). For patients treated with navitoclax-BR 5 had DLTs; 1 elevated liver enzymes (110 mg), 1 grade 4 febrile neutropenia (200 mg), and 3 grade 4 thrombocytopenia (250 mg). 1 patient had a DLT of febrile neutropenia in the navitoclax-FCR cohort. Frequent (>20%; any grade) AEs were nausea (77%), neutropenia (46%), fatigue (42%), vomiting (31%), pyrexia (31%), headache (31%) and diarrhea (27%). For patients treated with N-FCR, 2 had partial responses (PR) (including 1 with del[11q] CLL), 2 had stable disease (SD) and 1 had incomplete data. Among patients treated with navitoclax-BR, there were 6 complete responses (1 confirmed; 2 with del[17p] and del [11q] CLL), 7 PR (2 confirmed; 2 with del[17p] and del [11q] CLL and 1 with del[17p] CLL), 4 SD, 1 PD, and 8 with incomplete data.The overall response rate of patients treated with navitoclax-BR was 72% (13/18). Preliminary PK results suggest no apparent PK interaction between navitoclax and bendamustine. **Conclusions.** Navitoclax combined with BR appears well-tolerated and shows anti-tumor activity. The maximum tolerated dose (MTD) and recommended phase 2 dose of navitoclax is 250 mg. Navitoclax at 110 mg dose also appears well tolerated when combined with FCR. To date, unacceptable myelotoxicity has not been observed when navitoclax was combined with standard chemo-immunotherapy regimens for treatment of patients with CLL.

0546

SELECTIVE INHIBITION OF BCL-2 IS ACTIVE AGAINST CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): FIRST CLINICAL EXPERIENCE WITH THE BH3-MIMETIC ABT-199

A Roberts[1], M Davids[2], D Mahadevan[3], M Anderson[4], T Kipps[5], J Pagel[6], B Kahl[7], W Wierda[8], D Darden[9], C Nolan[9], H Xiong[9], D Huang[4], B Chyla[9], T Busman[9], E Cerri[9], S Enschede[9], R Humerickhouse[9], J Seymour[10]

Background. New treatments are needed for patients with relapsed CLL, especially fludarabine-refractory disease. Targeted therapy with the BH3-mimetic navitoclax inhibits BCL-2, induces apoptosis and achieves partial remissions (PRs) in patients with CLL (Seymour EHA 2011). However, concomitant inhibition of BCL-x_L by navitoclax results in dose-limiting thrombocytopenia, highlighting the need for a more BCL-2-selective inhibitor. ABT-199 is a potent, orally bioavailable BCL-2 inhibitor (K_i<0.10 nM) with 500-fold less activity against BCL-x_L (K_i=48 nM). ABT-199 induces apoptosis of primary CLL cells *in vitro.* **Methods.** This first-in-human study of ABT-199 is a phase-I dose-escalation trial using a modified Fibonacci design in patients with relapsed/refractory CLL or non-Hodgkin lymphoma (NHL) with the objectives: evaluate safety, pharmacokinetics (PK), maximum tolerated dose, efficacy, and recommend a phase-2 dose. Patients with measurable disease, ECOG ≤1, and adequate marrow function were enrolled to Arm-A (CLL/SLL) or Arm-B (NHL). Data from Arm-A are reported. Patients received a single dose of ABT-199 on Week1 Day -7 (W1D-7), followed by continuous once-daily dosing from W1D1, until progressive disease (PD) or unacceptable toxicity. Evaluations included: adverse events (AE; NCI CTCAE V4), tumor response (NCI-WG 1996 criteria; updated 2008), and mechanism-of-action studies (Annexin-V and caspase-3 activation assays). **Results.** To date, 15 patients (median age 65 yr [36-84]) have enrolled. They had received a median of 3 (range 1-8) prior therapies; 8 had bulky adenopathy (≥5 cm), 8 were fludarabine-refractory, and 5 had del(17p) on FISH. The first three patients (cohort 1) experienced dose-limiting, clinically significant Gr3 tumour-lysis syndrome (TLS) following the W1D-7 single dose (200mg, 200

mg, 100 mg) of ABT-199, associated with a rapid reduction in palpable lymphadenopathy, and >95% reduction in lymphocytosis in the two subjects with pretreatment lymphocytosis. In the subsequent two cohorts, the W1D-7 dose was reduced to 50 mg, and the continuous dosing from W1D1 escalated weekly in step-wise fashion to the target cohort daily dose (150 mg [n=6], 200mg [n=6]). Gr3/4 ABT-199-related AEs observed include neutropenia (27%), TLS (27%) and febrile neutropenia (20%). Thrombocytopenia has not been dose-limiting. Preliminary PK was consistent with dose-proportional exposure. ABT-199 reached C_{max} approximately 6hrs after a low-fat meal, with a $t_{1/2}$ of ~21hrs. With a median follow-up of 4Mo, 11 patients are active; 4 have discontinued; 3 due to PD and 1 due to incidentally-detected adenocarcinoma. >50% reductions were observed in PB lymphocytes (11/11 patients with pretreatment lymphocytosis; median 86% [range 59-99%]), and lymphadenopathy (9/15 patients). In early formal response evaluations (W6 and W12), 8 (53%) patients had achieved PR (2 with marrow clearance); 4 confirmed, 4 awaiting re-assessment, including 4/8 F-refractory disease and 3/5 with del(17p). CLL cells collected 6-8hrs after initial dosing of ABT-199 show increased Annexin-V staining and caspase-3 activation. **Conclusions.** A single dose of ABT-199 can achieve a rapid reduction in CLL burden in patients with refractory disease. ABT-199 induces apoptosis of CLL cells *in vivo*, consistent with a mechanism-of-action based on BCL-2 inhibition. TLS can be mitigated with initial 50mg/day dosing and step-wise escalation. Patient accrual and identification of optimal dose and schedule for future studies continue.

Molecular advances in myelodysplastic syndromes

Background. Mutations in genes encoding multiple components of the RNA splicing machinery in myeloid malignancies with myelodysplasia have been identified by next-generation sequencing approaches. The most frequently documented mutations affect splice genes *U2AF35*, Z*RSR2*, *SRSF2* and *SF3B1*. The high prevalence of these mutations suggests an important contribution of genetic alterations involving splice components to the pathophysiology of MDS. **Aims.** In the present study we investigated the clinical phenotype, the genetic characteristics and prognostic impact of *U2AF35*, Z*RSR2*, *SRSF2* and *SF3B1* mutations 221 MDS patients. **Methods.** DNA was extracted from diagnostic bone marrow cells. *SF3B1* (exons 12-16), *SRSF2* (exon2), *ZRSR2* (exons 1-11), and *U2AF35* (exons 2 and 6) were amplified using intron-flanking primers tagged with M13 universal primers at the 3' or 5' prime ends. PCR fragments were directly sequenced in both directions, and were analyzed using the Mutation surveyor version 3.97 software. Non-tumoral tissue was analyzed when available (DNA from buccal swab or CD3+ T-cells; n=20). In order to identify molecular interactions, the genomic regions that span exon 12 of *ASXL1,* exons 8 and 9 of *CBL*, exons 15-23 of *DNMT3A*, the entire coding regions of *ETV6* and *EZH2,* exons 4 of *IDH1* and *IDH2,* exon 14 of *JAK2*, exons 1 and 2 of *NRAS,* exons 3 to 8 of *RUNX1*, the entire coding region of *TET2,* and exons 5 to 8 of *TP53* were analyzed. Statistical analyses were performed using SPSS. **Results.** Among the 221 patients with MDS, 37 had *SF3B1* mutations (16.4%), 25 had *ZRSR2* mutations (11.1 %), 25 had *SRSF2* mutations (11.1%), and 12 patients harbored mutations affecting *U2AF35* (5.4%). In total, 99 mutations affecting one of the four genes were detected in 95 patients (42.2%). These mutations were mostly mutually exclusive and less likely to occur in patients with complex cytogenetics or *TP53* mutations. *SF3B1mut* patients presented with lower hemoglobin levels, increased WBC and platelet counts and were more likely to have *DNMT3A* mutations. *SRSF2*^{mut} patients clustered in RAEB-1 and RAEB-2 subtypes and exhibited pronounced thrombocytopenia. *ZRSR2*^{mut} patients clustered in IPSS int-1 and int-2 risk-groups, had higher percentages of bone marrow blasts and more often displayed isolated neutropenia. *SRSF2* and *ZRSR2* mutations were more common in *TET2*^{mut} patients. *U2AF35mut* patients had an increased prevalence of chromosome 20 deletions and *ASXL1* mutations. Multivariate analysis revealed an inferior overall-survival (OS) and a higher AML transformation rate for the genotype *ZRSR2*^{mut}/*TET2*^{wt} (OS: HR 3.3; 95%CI 1.4 - 7.7; *P*=.006; transformation: HR 3.6; 95%CI 2 - 4.2; *P*=.026). **Conclusions.** Our results demonstrate that splice gene mutations are amongst the most frequent molecular aberrations in MDS, they define distinct clinical phenotypes and show preferential associations with mutations targeting transcriptional regulation. Integration of molecular analysis of splice genes at diagnosis may improve the classification of MDS patients in the future.

[8]Chang Gung University, Taipei, Taiwan

Background. Myelodysplastic syndromes (MDS) are a group of myeloid neoplasms characterized by deregulated blood cell production and a high propensity to AML. To date, a number of gene mutations, which are largely common to many myeloid neoplasms, have been identified and implicated in the pathogenesis of MDS, including *RAS*, *TP53*, *RUNX1*, *c-CBL*, *TET2*, *ASXL1*, *EZH2*, *IDH1/2* and *DNMT3A*. Recently we reported comprehensive mutation analysis in 29 cases with myelodysplasia using whole-exome sequencing, which unmasked frequent mutations of the splicing machinery that is largely specific to MDS and other myeloid neoplasms with features of myelodysplasia. However, MDS are highly heterogeneous diseases and our knowledge about the spectrum of gene mutations with their intratumoral structure is still incomplete. **Aims.** The purpose of this study is to reveal the heterogeneity of MDS in terms of gene mutations and also characterize the intratumoral structure of those gene mutations in MDS and related myeloid neoplasms, using high-throughput deep sequencing in a larger set of MDS cases. **Methods.** To this aim, we performed whole-exome sequencing of additional 21 cases with MDS and related myeloid neoplasm and analyzed spectrum of gene mutations within a total of 50 myelodysplasia cases. We further analyzed a panel of 164 cases for recurrent mutations by target deep sequencing to accurately estimate frequency of each mutant allele within tumors. Whole genome sequencing was also performed in 5 cases to evaluate intratumoral structure of gene mutations. **Results.** Whole-exome analysis of 50 myelodysplasia cases disclosed a comprehensive registry of gene mutations in myelodysplasia, leading to the identification of a number of novel gene targets in myelodysplasia. Among these are *BCOR*, *STAG2* and other cohesine components. *BCOR* encodes an ubiquitously expressed nuclear protein which acts as a co-repressor of BCL6 and is recently reported to be mutated in acute myeloid leukemia. Cohesine is a multimeric protein complex, which regulates the separation of sister chromatids during cell division, post replicative DNA repair and regulation of gene expression. Subsequent mutation screening of these recurrently mutated genes for a panel of 164 MDS samples demonstrated these mutations were frequently mutated in MDS and other myeloid neoplasms. Mutation of cohesion complex occurred in an almost mutually exclusive manner among mutated cases. We also analyzed the allele frequencies of mutations in each tumor. Intratumoral heterogeneities of gene mutations seemed to exist in almost all cases, suggesting multiple clonal evolution events during the development of MDS.**Summary / Conclusions.** Whole exome analysis of 50 cases with MDS and related myeloid neoplasms revealed a full spectrum of common gene mutations in MDS including a number of previously unreported gene targets. MDS commonly shows intratumoral substructures, which may be implicated in the disease progression and evolutions.

BackgroundRecent genetic studies have revealed a number of novel gene mutations in myeloid malignancies. Many of these mutations, implicated in deregulated histone modification (*ASXL1* and *EZH2*) or DNA methylation (*TET2*, *IDH1/2* and *DNMT3A*), affected both acute and chronic myeloid neoplasms, indicating their general roles in myeloid leukemogenesis. However, our knowledge about the spectrum of gene mutations in myeloid neoplasms is likely to be still incomplete.**Aims**In the previous study, to obtain comprehensive complements of gene mutations in myelodysplasia, we analyzed 29 paired tumor-normal samples with chronic myeloid neoplasms with myelodysplastic features using whole exome sequencing. Although the major finding was the discovery of frequent spliceosome mutations uniquely associated with myelodysplasia phenotypes, a closer inspection of a revised list of mutations disclosed four candidate driver changes commonly affecting the cohesin complex, including *STAG2*, *STAG1*, and *PDS5B*. In this study, we aimed to confirm the finding from the discovery set and explore further the cohesin mutations in different myeloid malignancies.**Methods**We examined an additional 440 primary specimens of various myeloid neoplasms for gene mutations in major cohesin components, including *STAG1, STAG2, RAD21, SMC1A, SMC3* and *PDS5B*, using high throughput sequencing enhanced by DNA pooling. Copy number alterations in cohesin loci were also interrogated by SNP array karyotyping. **Results.** We identified a total of 38 Sanger-validated non-synonymous mutations and 16 deletions affecting 6 components of the cohesin complex in 52 out of the 469 primary cases with myeloid neoplasms (11%), including AML (17/115), CMML (13/84) and MDS (20/197), and also in 7 out of the 34 myeloid leukemia cell lines. 19 out of the 20 *STAG2*, 6 out of the 8 *RAD21* and one of the 5 *PDS5B* mutations were either nonsense, frameshift or splice site changes, which were predicted to cause a premature truncation of the protein. On the other hand, almost all the mutations found in *SMC1A, SMC*3 and *STAG1* were missense changes without showing apparent mutational hot spots. Most of the mutations and deletions were heterozygous and occurred in a mutually exclusive manner, suggesting that mutations in multiple cohesin components at a time may be catastrophic to cell viability.Unexpectedly, all 41 informative cases with cohesin mutations/deletions in our cohort showed diploid or near diploid karyotypes, of which 20 retained completely normal karyotypes, clearly arguing against the previous view that aneuploidy caused by these mutations would be responsible for their oncogenic action in glioblastoma and colorectal cancers. Alternatively, a growing body of evidence suggests that cohesin regulate gene expression, arguing for the possibility that cohesin mutations might participate in leukemogenesis through deregulated gene expression. Of additional note is that 6 cohesin-mutated cases accompanied significantly increased numbers of non-silent mutations in whole exome analysis, compared to non-mutated cases, raising the possibility that compromised cohesin function could induce DNA hypermutability associated with increased double strand break and contribute to leukemogenesis. **Summary and Conclusions.** In conclusion, massively paralleled sequencing of myeloid neoplasms revealed frequent mutations/deletions in cohesin complex. Our findings highlight a possible role of compromised cohesin functions in myeloid leukemogenesis.

Background. The vast majority of patients with myelodysplastic syndrome (MDS) present with anemia, and most of them become transfusion dependent in the long term.The redistribution of transfusion iron from reticuloendothelial to parenchymal cells is modulated by hepcidin. In beta-thalassemia syndromes, ineffective erythropoiesis is associated with a downregulation of hepcidin, resulting in increased iron absorption and parenchymal iron loading.Different pathogenetic mechanisms are responsible for anemia in MDS. Recently, somatically acquired mutations in *SF3B1*, a gene encoding a core component of RNA splicing machinery, were identified in diverse WHO categories but predominantly in MDS patients with ring sideroblasts. The available evidence supports a causal relationship between *SF3B1* mutations and mitochondrial iron overload, and establish a link between these mutations and ineffective erythropoiesis. **Aims.** We studied *SF3B1* mutations, erythroid marrow activity, transfusion iron overload and hepcidin levels in patients with MDS in order to investigate the relationship between *SF3B1* mutation, ineffective erythropoiesis and parenchymal iron loading in these disorders. **Methods.** We evaluated 76 patients with MDS or myelodysplastic/myeloproliferative neoplasms (MDS/MPN) according to WHO criteria, followed at the Department of Hematology Oncology, University of Pavia & Fondazione IRCCS Policlinico San Matteo,Pavia,Italy.The coding exons of *SF3B1* were screened using massively parallel pyrosequencing. Erythroid activity was evaluated through soluble transferrin receptor (sTfR) and growth differentiation factor 15 (GDF15). Serum hepcidin-25 measurements were performed by combination of weak cation exchange chromatography and time-of-flight mass spectrometry.*Results*. Overall, 21 of 76 patients (28%) had a somatic mutation of *SF3B1,* with a median value for mutant allele burden of 44.7%. Significant associations were found between *SF3B1* mutation and proportion of bone marrow erythroblasts (*P*=.009), and sTfR levels (*P*=.039). Significant positive correlations were also found between these parameters and *SF3B1* mutant allele burden (*P*=.003, and *P*=.02, respectively). A significant effect of *SF3B1* mutation on GDF15 levels was noticed, mutant patients having higher values than wild-type ones (*P*=.023).Serum hepcidin ranged from 0.18 to 92.05 nM, and higher levels were found in transfusion-dependent versus transfusion-independent patients (*P*<.001). Multivariable analyses showed that hepcidin levels were independently determined by sTfR (the higher sTfR, the lower hepcidin; *P*=.015), serum ferritin (the higher serum ferritin, the higher hepcidin; *P*<.001), and *SF3B1* mutation (the higher allele burden, the lower hepcidin; *P*=.029). **Conclusions.** These findings provide evidence that *SF3B1* mutations are strongly connected with an expanded but ineffective erythropoiesis, resulting in inappropriately low hepcidin levels that may favor the internal redistribution of transfusion iron from macrophages to parenchymal cells.

0551

RAP-536 ATTENUATES INEFFECTIVE ERYTHROID DIFFERENTIATION AND REDUCES ANEMIA IN A MURINE MODEL OF MYELODYSPLASTIC SYNDROMES

R Suragani, R Li, SP Pearsall, R Kumar

Acceleron Pharma Inc, Cambridge, United States of America

Myelodysplastic syndromes (MDS) are a complex group of hematopoietic stem cell disorders. Patients develop peripheral blood cytopenias such as anemia, neutropenia or thrombocytopenia and a significant proportion of patient progress to acute myeloid leukemia (AML). The erythroid hyperplasia, with increased rates of apoptosis and abortive maturation of erythroid precursors, leads to ineffective erythropoiesis and severe anemia. Despite high physiological levels of endogenous erythropoietin (EPO), patients with MDS are given recombinant erythropoietin therapy to stimulate erythropoiesis. Consequently, only 20%-25% of MDS patients respond to EPO therapy for their anemia. Therefore, alternative therapies to EPO that promote effective erythroid differentiation are necessary to treat anemia in MDS patients. Members of the TGFβ superfamily of signaling molecules have been implicated in erythropoiesis. ACE-536 is a soluble receptor fusion protein consisting of a modified activin receptor Type IIB extracellular domain linked to a human Fc domain. ACE-536 acts as a ligand trap to modulate the activity of TGFβ ligands and promote erythroid differentiation. While it is known that EPO treatment increases proliferation of erythroid progenitors, differentiation analysis of bone marrow and splenic erythroblasts after treatment with RAP-536 (murine version of ACE-536) demonstrated that ACE-536 promotes maturation of terminally differentiating erythroblasts.In this study we investigated the effect of ACE-536 on anemia during various stages of disease using a murine model of MDS. The NUP98-HOXD13 (NHD13) transgenic mouse carries a common translocation found in MDS patients. NHD13 mice develop anemia, neutropenia and lymphopenia starting at 4 months of age, with normal or hyper cellular bone marrow and majority (60%) of the mice progresses to AML over time. Over 90% of the mice die by 14 months due to severe pancytopenia or acute leukemia. In this study, mice were divided into three groups based on age. Early (~4 months old), mid (~8 months old) and late stage (~10 months) groups were randomized and dosed subcutaneously with either RAP-536 at 10 mg/kg or vehicle control twice per week for 8 weeks. Wild-type littermate controls were also dosed on the same schedule.All NHD13 mice in each group had severe anemia characterized by reduced RBC, Hemoglobin and HCT and compared to wild-type littermates at baseline prior to treatment. Treatment of RAP-536 for 8 weeks significantly increased RBC parameters and reversed anemia at all stages. Peripheral blood smear analysis revealed no indication of increased leukemic progression due to RAP-536 treatment. Cell differential and flow cytometric evaluation of erythroid precursors from bone marrow demonstrated decreased erythroid precursors and hyperplasia consistent with RAP-536 treatment compared to vehicle treated control.Our data demonstrate that RAP-536 can increase hematology parameters by enhancing maturation of terminally differentiated red blood cells. We have also shown RAP-536 corrects ineffective erythropoiesis, decreases erythroid hyperplasia and normalizes myeloid: erythroid ratios without enhanced progression to AML. Therefore ACE-536 may represent a novel treatment for anemia associated with MDS, particularly in patients that are refractory to EPO therapy. ACE-536 is currently being evaluated in Phase I clinical trials in healthy human volunteers.

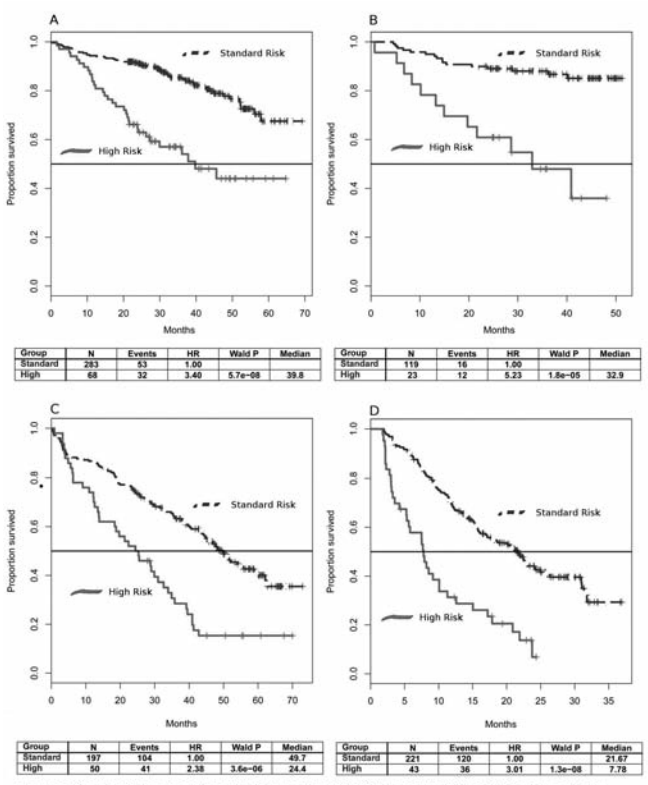
Background. Survival of patients with newly diagnosed multiple myeloma is highly variable and there is a strong need to improve current prognostic markers. Gene expression profiles reflect the biology of MM in individual patients and have potential to be of prognostic value.**Aims.**We aimed to establish and evaluate a prognostic signature based on gene expression profiling. **Methods.**The HOVON65/GMMG-HD4 trial compared the efficacy of bortezomib induction and maintenance treatment with standard induction and maintenance regimes.[1] For 290 patients, both gene expression and survival data were available. These were selected for training. Supervised principal components analysis was applied to generate a signature of 92 probe sets. High-risk disease within the training set was defined to be the proportion of patients with an overall survival of less than two years. Four independent datasets were available for validation, including newly diagnosed patients (TT2, n=351; TT3, n=142; MRC-IX, n=247) and relapsed patients (APEX, n=264).[1-5] **Results.** In all validation sets, patients defined as high-risk by the EMC-92-gene signature show a clearly reduced overall survival. A hazard-ratio (HR) of 3.4 (95%CI:2.19-5.29) was found for the TT2 study, HR:5.23 (2.46-11.13) for the TT3, HR:2.38 (1.65-3.43) for the MRC-IX and HR:3.01 (2.06-4.39) for the APEX (p<0.0001 in all studies; Figure 1).



Group	N	Events	HR	Wald P	Median
Standard	283	53	1.00		
High	68	32	3.40	5.7e−08	39.8

In multivariate analyses, the EMC-92-gene signature proved an independent and superior predictor compared with clinical variables such as the International Staging System and cytogenetic aberrations including del(17p). Furthermore, in standard-risk classified patients in the MRC-IX validation set, no survival difference was found between patients with or without at least one poor risk FISH marker, confirming the strength of the EMC-92 gene signature in relation to cytogenetics. In addition the performance of the EMC-92 is independent of existing signatures like the UAMS-17,70 and 80. Likelihood-ratio tests for pair-wise comparison showed that the increase in likelihood on addition of the EMC-92 was consistently higher than when another signature was added to EMC-92. For instance, the adjusted p-value for the addition of the EMC-92 to UAMS-80 and vice versa were $7.6x10^{-7}$and $2.2x10^{-3}$ respectively. The genes in the EMC-92 signature had little overlap to other signatures and was limited to genes such as *BIRC5* and *ITM2B*. Within the HOVON-65/GMMG-HD4 high-risk patients, bortezomib treated patients survived longer than patients treated with vincristine based chemotherapy (30 months compared to 19 months, respectively), albeit not significant (p=0.06). **Summary and Conclusions.** The EMC-92-gene signature has a strong and highly significant predicting ability in multiple myeloma patients irrespective of age and setting, newly diagnosed or relapse. Use of this signature will contribute to risk assessment in clinical trials and could ultimately provide a tool for treatment choices in high-risk multiple myeloma patients.This work was supported by the European Hematology Association, the Center for Translational Molecular Medicine, Skyline Diagnostics, Erasmus MC Translational Research Grant, Janssen and the FW6 program MSCNET.
