Background. microRNAs (miRNAs) are small non-coding RNAs able to regulate protein levels by binding mRNAs. In multiple myeloma (MM), miRNAs play a critical role in deregulating several pathways involved in MM pathogenesis. Since miRNAs are present in many body fluids with high stability, they hold great potential of being used as biomarkers. However, a comprehensive profile of circulating miRNA in MM patients and a comparison with healthy subjects is still lacking. **Aims.** To identify circulating miRNAs specific to MM patients and evaluate their association with biological characteristics. **Methods.** On 164 samples (104 from newly diagnosed MM patients and 60 from age-matched healthy subjects), a screening analysis of 654 miRNAs was performed to identify those consistently expressed using nCounter technology (nanoString, Seattle, USA). Expression of miRNAs present in at least 20% of samples has been confirmed by quantitative PCR (qPCR) performed on ABI7900HT with 2-ΔCt approach, using synthetic spiked-in miR-759 as endogenous control. miRNA marker levels were log2 transformed and linear regression model was used for comparison employing two-sample t-tests and Spearman rank correlation coefficients. **Results.** Median age of MM patients was 71 yrs (range 56-86) compared to 73 yrs (range 55-88) of healthy subjects. Within MM patients, beta2-microglobulin median value was 4,66 mg/l (range 1,2-12,96) and, according to ISS, 16 patients were in stage 1, 39 in stage 2 and 28 in stage 3. Median bone marrow infiltration by malignant plasma cells (%BMPC) was 60% (range 12-95). According to FISH status, 70 patients had standard and 29 high risk. Twenty-five miRNAs were expressed in at least 20% of the 164 analyzed samples. After qPCR analyses, 11 out of 25 miRNAs were expressed with a median Ct value lower than 35 cycles. A general reduction of these 11 circulat-

ing miRNA has been found in MM samples in comparison with healthy subjects: in particular six miRNAs (miR-92a, miR-451, miR-16, miR-19b, miR-25 and miR-30a) were statistically lower in MM as detailed in Table 1A. Focus on MM patients, univariate analysis showed correlation between specific miRNAs and predictors of poor prognosis. In particular, the expression of miR-92a, miR-19b, miR-21, miR-126 and miR-223 was inversely correlated with ISS stage, while miR-21 and miR-126 were correlated with high beta2-microglobulin values. An inverse trend was also observed between levels of some miRNAs and FISH risk, but without reaching statistical significance (model p-value in Table 1B). A clear correlation between low hemoglobin (Hb) levels and low expression of several miRNAs was also observed. Interestingly, no correlation was found between miRNA levels and %BMPC suggesting a correlation with organ damage but not with tumor load. **Conclusions.** This is the largest analysis of miRNA expression in serum of MM patients. A diffuse reduction in miRNAs levels was observed in MM patients compared with healthy subjects and a low expression of specific miRNAs correlates with adverse prognostic factors in MM patients. These observations strongly demonstrate a specific profile of circulating miRNAs in MM, opening the discussion on their role in the pathogenesis of the disease and their possible use as a biomarker.

Table 1.

A

miRNA	Healthy (n=60) median (range)	Myeloma (n=104) median (range)	P-value
miR-92a	0.05 (0.005 – 0.49)	0.02 (0.0005 – 0.28)	<0.00001

[2]Center for Regenerative Medicine and Cancer Center, Massachusetts General Hospit, Boston, United States of America

Background. Bone marrow (BM)-derived mesenchymal stromal cells (MSCs) support multiple myeloma (MM) cell growth, but little is know about the putative mechanisms that may regulate the interaction between clonal MM plasma cells and the surrounding BM milieu. We characterized the role BM-MSC-derived exosomes as key regulators of MM pathogenesis. **Aims.** 1) To determine the ability of BM-MSCs to release and transfer exosomes to MM cells. 2) To determine the role of BM-MSC-derived exosomes in inducing MM tumor growth and MM cell dissemination. **Methods.** MSCs were collected from BM of healthy subjects and MM patients, showing a multipotent MSC phenotype (CD34-/14-/45-/19-/138-;CD73+/90+/105+/106+). Exosomes were collected from conditioned-medium of normal-BM-MSCs and MM-BM-MSCs, or HS-5 cells; and studied using electron microscopy, immunogold-labeling, and western-blot for CD63 and CD81 detection. Transfer of PKH67-fluorescently-labeled-exosomes to MM cells was evaluated by time-lapse confocal microscopy. Transfer of murine-derived miRNA-containing exosomes into human MM cells was evaluated by qRT-PCR (exosomes were collected from BM-MSCs of C57BL/6 miRNA-15a/16-1-/- or C57BL/6 mice). miRNA expression profiling was obtained from normal (n=4) and MM (n=9) BM-MSCs-derived exosomes (TaqMan-human-miRNA-profiling). Normal and MM BM-MSCs-derived exosomes were loaded into tissue-engineered bones (TEB) with MM.1S-GFP+/Luc+cells: MM cell homing and MM tumor growth have been tested *in vivo* by using confocal-microscopy and bioluminescence-imaging (BLI), respectively. Loss- and gain-of-function studies were performed using normal-BM-MSCs, MM-BM-MSCs and HS-5 cells transfected with either pre- or anti-miRNA-15a. **Results.** Normal-BM-MSCs and MM-BM-MSCs released CD63+/CD81+ exosomes, as confirmed by electron microscopy, immunogold labeling, and western blot. BM-MSCs exosomes are transferred into MM cells, as shown by confocal microscopy; and further validated by qRT-PCR in human MM cell lines incubated with murine (C57BL/6 miRNA-15a/16-1-/- and wild-type) BM-MSCs-derived exosomes. The impact of normal-BM-MSC- and MM-BM-MSC-derived exosomes on MM cell behavior *in vivo* was next evaluated. MM cells co-cultured with MM BM-MSC-derived exosomes induced rapid tumor growth at the site of the TEB scaffold, as well as rapid dissemination to distant BM niches, as compared to MM cells co-cultured with exosomes derived from normal BM-MSCs. We next performed miRNA expression profiling on exosomes isolated from MSCs, and found increased expression of 24 miRNAs and reduced expression of 3 miRNAs in MM-BM-MSCs-derived exosomes versus normal (1.5 fold-change; P<0.05). Specifically, miRNA15a was significantly lower in MM-BM-MSC-derived exosomes, similarly to primary MM cells that present with reduced miRNA-15a expression. We therefore sought to examine whether lack of transfer of the tumor suppressor miRNA15a can lead to significant change in tumor growth and dissemination in MM, and found that by over-expressing miRNA-15a in normal BM-MSCs and HS-5 cells inhibited MM cell proliferation and adhesion to fibronectin. Next MM cells were cultured in presence of BM-MSCs isolated from either C57BL/6 mice or C57BL/6 miRNA15a/16-/: miRNA15a-deficient BM-MSCs significantly induced MM cell proliferation (P<0.05). Moreover, exosomes isolated from HS-5 pre-miRNA15a-transfected cells both inhibited MM cell proliferation and reduced their adhesion properties. **Conclusions.** These findings demonstrate the existence of exosome-driven interactions between the BM milieu and MM cells, suggesting that exosomes might constitute a novel mechanism for intercellular transfer of miRNAs to MM cells.

[3]Universidad de Barcelona, Barcelona, Spain

Background. A group of genetic normal variations in DNA, mainly single nucleotide polymorphisms (SNPs), have been described in association with prevalence, response to treatment, progression-free and overall survival (OS) in multiple myeloma (MM). A distinctive and relative new group of polymorphisms is constituted by SNPs in microRNAs (miRNA) processing machinery in miRNA precursor molecules and in miRNA binding sites, known as miRSNPs. The aim of this study was to ascertain the prognostic impact of 9 miRSNPs located either in MM related miRNAs target genes or in miRNA biogenesis pathway proteins, in order to correlate our findings with response, toxicities and OS to bortezomib in patients with relapsed myeloma. **Patients and Methods.** Seventy-five patients (37M/38F; median age 65 years, range 29 to 80) with relapsed MM were treated from December 2002 to March 2010 with bortezomib-based regimens. Median follow-up for patients alive was 31 months. Genomic DNA was isolated from bone marrow slides using a commercial kit (Qiagen). The genes and SNPs evaluated in genomic DNA by allelic discrimination (TaqMan assays) were *KRT81* (rs3660), *FAM179b* (rs1053667), *MIR146A* (rs2910164), *MIR196A2* (rs11614913), *MIR149* (rs2292832) and *MIR423* (rs6505162) for miRNA target genes, and *RAN* (rs14035), *TRBP* (rs784567) and XPO5 (rs11077) for miRNA biogenesis pathway. These genes were selected based on their potential impact on prognosis in solid tumors in previous reports.

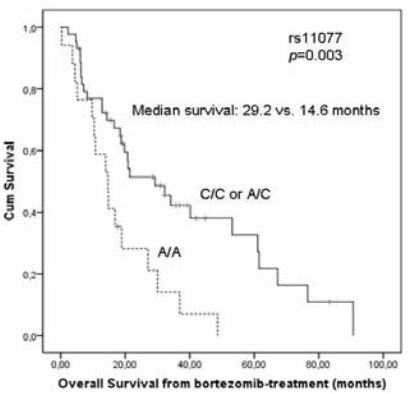

Figure 1. Overall survival according to the presence of polymorphism rs 11077 in XP05 (C/C=SNPs, A/C=herefozygous SNP, A/A=wild type).

Results. Overall response (OR) was achieved in 62% of the patients (complete remission 6.7%, partial response 44% and minor response 10.7%), while 9 (12%) and 20 (26.7%) showed no response (NR) or progressive disease (PD), respective-

ly. The median OS after bortezomib therapy was 19.6 months. OS was significantly longer in patients with SNP in *XPO5* (rs; *p*=0.003) (Figure 1) and *MIR146A* (0.037), with a trend for *TRBP* (0.086). *XPO5* rs11007 retained its prognostic impact on OS when a Cox multivariate regression analysis, including age (>65 years-old) and bone marrow plasma cell infiltration (≥50%), was performed (*p*=0.011). A vector containing the SNP *XPO5* rs11007 or the wild-type genotype in the 3'UTR region of *Renilla* luciferase gene was transfected in two myeloma cell lines. A reduction by 18% and 25% in the the *Renilla* luciferase activity analysis 24 hours after transfection suggests that the presence of the polymorphisms allows the binding of new miRNAs to this sequence, resulting in a significant reduction of XPO5 protein levels.Progressive disease under bortezomib treatment was more frequently observed in the case of polymorphisms in *MIR149* (p=0.033). The development of peripheral neuropathy bortezomib-related was more frequently observed in patients with polymorphism rs3360 in *KRT81* (p=0.03). **Conclusions.** A SNP in *XPO5* was significantly associated with longer OS after bortezomib treatment in patients with relapsed MM. This gene, exportin 5, mediates pre-miRNA nuclear export. This SNP could modify the miRNA biogenesis pathway through XPO5 protein levels, with a miRNA-target disturbance due to a global impairment of mature miRNAs. Concerning to the miRNA network, a polymorphism in a keratin gene (KRT81), target of diverse miRNA clusters and relevant in the structural cytoplasm framework, has been associated with clinically significant toxic neuropathy.

[4]Universita degli studi di Genova/Department of Internal Medicine, Genoa, Italy

Background. Multiple myeloma (MM) is a clonal malignancy of plasma cells with a striking genetic instability. This represents a very harmful disease process fundamental to the invasion and progression of MM cells. Consequently, inhibition of DNA repair mechanisms leads to significant reduction in acquisition of new genetic changes as well as progression of MM. Mammalian sirtuins are class III NAD^+-dependent histone deacetylase emerging as innovative proteins involved in multiple pathways, including genome maintenance. **Methods.** A panel of 18 different MM cell lines, both sensitive and resistant to conventional and novel anti-myeloma drugs, was used in the study. The antitumor effect of Nicotinamide combined with chemotherapic agents was investigated by CTG assay and Annexin-V/propidium iodide staining. Mechanistic studies were performed with thymidine incorporation, Western-blotting, lentivirus-mediated shRNAs and immunofluorescence. Finally, analysis of DNA DSB repair by chromosomally integrated reporter constructs followed by cytometer analysis was carried out. **Results.** We analyzed an Affymetrix GeneChip (GSE6477) for MM primary tumors (n=162) and normal plasma cells founding that transcript levels of two nuclear sirtuins (SIRT6 and SIRT7) were significantly higher in MGUS, smoldering myeloma, MM and relapsed cases when compared to normal donors. Importantly, a protein analysis assay confirmed increased levels of both sirtuins in 18 different MM established cell lines, including those resistant to novel (ANBL6-BR) and conventional (MM.1R, LR-5, Dox40) therapeutic agents, compared to PBMCs of healthy donors. Next we evaluated the functional role of Sirt6 and 7 in MM cells by using loss of function approaches with RNAi. As SIRT6 and SIRT7 silencing reduced MM cell proliferation compared with control scrambled cells but did show only a slight induction of cytotoxicity. We also examined the effects of Nicotinamide (Nam), a pan-sirtuins inhibitor, on DNA damage response signaling triggered by conventional anti-MM agents (Melphalan, Doxorubicin and 5-AZA). Nam treatment did not appreciably affect MM cell viability, conversely Nam pretreatment impaired DNA double-strand breaks (DSBs) as well as DNA repair mechanisms triggered by conventional DNA damage agents, as documented by γH2AX and RPA phosphorylation, respectively. Consistent with these findings, Nam-pretreated cells not only were impaired in forming RAD51 foci in response to Doxorubicin and Melphalan, but also caused their hypersensitivity. Importantly, this sensitizing effect was observed also in MM cells selected for resistance to Doxorubicin (RPMI-Doxo40) or Melphalan (LR5), indicating that Nam increases chemosensitivity in both drug-sensitive and -resistant MM cells. Similarly, lentivirus-mediated shRNA interference SIRT6 and 7 depletion sensitized cells to Melphalan and Doxorubicin. Finally, by using MM cell lines containing chromosomally integrated green fluorescent protein-based reporter constructs, chemical as well as genetic approaches improved the efficiency of both HR and NHEJ. Ongoing *in vivo* experiments are assessing how the chemical susceptibility of SIRT6 and/or 7-deficient cells can be exploited therapeutically. **Conclusions.** Our study strongly points towards the existence of a link between nuclear sirtuins and DNA instability of MM cells, providing the basis for further and innovative anti-MM therapeutic approach.

Allogeneic stem cell transplantation

DIFFERENT PREDICTOR ROLES OF NATURAL KILLER CELL RECEPTOR GENES AND THE MISSING SELF MODEL OR LIGAND-LIGAND MODEL ON SURVIVAL AFTER HAPLOIDENTICAL TRANSPLANTATION WITHOUT T CELLS DEPLETION IN VITRO

XY Zhao, YJ Chang, LL Xu, MR Huo, DH Liu, LP Xu, KY Liu, D Li, XJ Huang
Peking University Institute of Hematology, Beijing, China

Backgroud. HLA-haploidentical stem cell transplantation (SCT) is a feasible therapeutic option for advanced hematologic malignancies who lack an HLA-matched related or unrelated donor. Conflicting results have been reported about the impact of alloreactivity of natural killer (NK) cells on the outcome of haploidentical SCT to leukemia patients. **Aims.** The goal of this study was to explore the predictive roles of donor Killer-cell immunoglobulin-like receptor (KIR) genotype and the missing self model or ligand-ligand model in our myeloablative HLA-haploidentical SCT without T-cell-depletion *in vitro*. **Methods.** We studied 251 patients who received haploidentical SCT. Among of which, we have 251 data of donors' and 235 data of recipients' HLA-C and Bw4, as well as 209 data of donor's KIR genes. To apply the missing ligand model, the first step was to divide the donor-recipient pairs into 2 groups according to the number of KIR ligand in donors, ie, 3 KIR ligands ("without missing self") versus fewer than 3 ("with missing self"). Meanwhile, to apply the KIR ligand-ligand model, donors who were classified as NK alloreactive against their recipients termed KIR ligand mismatched donors throughout, possessed HLA class I KIR ligand(s) which were missing in the recipients. Furthermore, genotypes for the centromeric (Cen) and telomeric (Tel) parts of the KIR locus were assigned according to the presence or absence of one or more B haplotype defining KIR genes. Donors were assigned into with or without Tel BB or Cen BB genotype as defined previously. **Results.** Among the 251 pairs of donor-recipients, 181 and 70 recipients received SCT from "with missing self"and "without missing self"donors. Using Ligand-ligand model, 183 and 52 recipients received SCT from "KIR ligand matched"and "KIR ligand mismatched"donors. The cumulative incidence of 9-year relapse rate were higher in patients received transplantation from "with missing self"or "with KIR ligand mismatched"donors compared with those from "without missing self"(p=0.014) or "without KIR ligand mismatched"(p=0.040) donors. When combined the above predictive models together, patients were subgrouped as receiving graft from "without missing self"(best, n=70), "with missing self and without KIR ligand mismatch"(better, n=113), and "with KIR ligand mismatch"(neutral, n=52), respectively. The 9-year disease-free survival (DFS) was best predicted by the combination of missing self and KIR ligand mismatch between recipients and donors pairs (RR 1.428, p=0.028 for DFS). However, donors KIR genotype with Tel BB or Cen BB (n=28) were associated with superior survival (p=0.030). **Conclusions.** These data indicate that poor prognosis after transplantation is associated with the missing self and KIR ligand mismatch in recipients and T cell alloreaction may play the predominant role in this model. However, donor selection for Tel BB or Cen BB KIR genotype, which might associate with the NK cells alloreactivity, would lead to the superior survival in patient underwent haploidentical SCT without T cells depletion *in vitro*. Therefore, the best HLA-haploidentical donors for patients underwent T-cells-replete SCT would be with favorable Tel BB or Cen BB KIR genotype and without missing self between donor and recipients

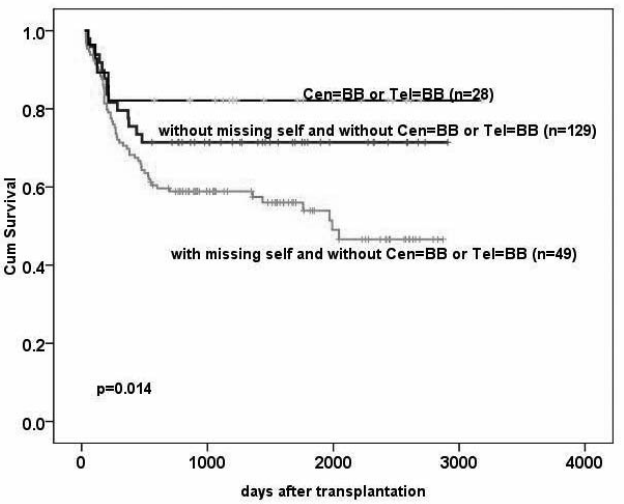

Figure 1. Disease free survival.

ALLOGENEIC STEM CELL TRANSPLANTATION (ALLO-SCT) FOR CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML): A REPORT FROM THE SOCIETE FRANCAISE DE GREFFE DE MOELLE ET DE THERAPIE CELLULAIRE (SFGM-TC)

S Park[1], M Labopin[2], I Yakoubagha[2], J Delaunay[2], N Dhedin[2], E Deconink[2], M Michallet[2], M Robin[2], T De Revel[2], T Lamy[2], B Lioure[2], S Lapusan[2], A Sirvent[2], R Tabrizi[2], JH Bourhis[2], C Recher[2], Y Beguin[2], F Dreyfus[1], P Fenaux[3], M Mohty[2]
[1]Hopital Cochin, Paris, France
[2]SFGM-TC, Paris, France
[3]GFM, Paris, France

Background. CMML is a heterogeneous disease with overall survival (OS) ranging from 12 mo to several years, where few series of allo-SCT have been published. This retrospective study aimed at determining prognostic factors for OS after allo-SCT in a group of consecutive 73 CMML patients reported to the SFGM-TC registry between 1992 and 2009. **Methods.** For this analysis, in addition to classical demographic and transplant characteristics, other characteristics at diagnosis and at transplant, including WHO classification in CMML 1 and 2, IPSS in patients with WBC <13G/L, and prognostic factors published by the GFM in CMML with WBC >13G/l, interval between diagnosis and allo-SCT, and prior treatments were analyzed. **Results.** at diagnosis M/F was 49/24, median age 53 yrs (range, 27-66). 36% patients had palpable SPM, 70% WBC>13X10^9/L. 48/13/9 patients had good/int/poor risk karyotype according to IPSS, 61% patients had CMML1, and 39% CMML-2. Of the 22 patients with WBC<13G/l, six had int-2 and 1 had high risk IPSS, while of the 45 patients with WBC>13G/l, 37 had at least 2 of our published poor prognostic factors. Before allo-SCT, 26 patients had received intensive anthracycline-cytarabine chemotherapy (CT), 21 low dose CT (18 HY, 3 VP16) and, 6 hypomethylating agents. 32 patients (44%) developed infection (bacterial or fungal) between diagnosis and allo-SCT.Median interval from diagnosis to allo-SCT was 10.6 mo (range 2.8-80). At time of allo-SCT, 15 patients had responded to AML like therapy, while 42 patients were treatment failure or in relapse, or had not been treated, including5 AML progressions. Nineteen patients still had palpable SPM before allo-SCT. The donor was an HLA-identical, unrelated and haploidentical sibling in 41/31/1 cases respectively. 43 patients (59%) received reduced-intensity conditioning (RIC), while the other received MAC. With a median follow-up of 23 mo (1-145), grade 0-1 acute GVHD and grade 2-4 developed in 23 and 21 patients respectively. Chronic GVHD was present in 25 patients (35%) (limited:15, extensive: 10; cum incidence: 37%at 3yrs).The 2- and 3-yr OS were 42% and 32%, respectively. The 3-yr cum incidence of NRM was 36%. The 3-yr relapse-free survival was 30%. OS was not influenced by the disease status at allo-SCT, including CMML1 vs CMML2, IPSS score (WBC<13G/l) and GFM score (WBC>13G/L), the number of prior treatments, HLA matching and cGVHD. However, palpable SPM at transplantation was a negative prognostic factor for OS (2-yr OS: 52% vs.28%, p=0.03). Presence of palpable SPM was correlated with thrombocytopenia, presence of peripheral blasts and myelemia. 2-yr DFS was better after 2004, year of transplantation (57% vs 19%, p=0,016). In multivariate analysis, the strongest prognostic factor for OS was palpable SPM at transplantation (HR=0,48 95%CI:0.24-0.98; p=0.042). **Conclusions.** Allo-SCT is a valid treatment option for CMML patients eligible to this treatment and is improving. Palpable SPM at transplantation was the only independent negative prognostic factor. Most patients were however treated before the advent of hypomethylating agents. The use of RIC regimens combined to those agents (and possibly to other novel agents) prior and after allo-SCT may further improve outcome.

Background. The role of allografting in multiple myeloma is controversial **Aims.** To evaluate clinical outcomes of allografting from unrelated donors in the treatment of myeloma **Methods.** We conducted a retrospective study from 2000 through 2009 through the Italian Bone Marrow Donor Registry.

Table 1.

Conditioning	Myeloablative	Reduced-intensity	Non-myeloablative
Patient number (%)	52/185 (28)	69/185 (37)	64/185 (35)
Median Age	45	53	55
Previous therapy lines < 2 (%)	23 (27)	33 (38)	30 (35)
Previous therapy lines ≥ 2 (%)	29 (29)	36 (37)	34 (34)
Stem Cell Source BM (%)	24 (57)	18 (43)	0 (0)
Stem Cell Source PBSC (%)	28 (19)	51 (36)	64 (45)

Results. Overall, 196 myeloma patients, median age 51 years (32-67), were transplanted at 34 Centers. Fifty-two (28.1%), 69 (37.3%), and 64 (34.6%) patients were treated with myeloablative, reduced-intensity and non-myeloablative conditioning respectively.Incidence of acute grade II-IV graft-versus-host-disease (GVHD) was 46.4% whereas chronic GVHD was 45.1%. There was no difference in GVHD incidence among the 3 cohorts. Complete and partial remissions in patients who survived at least 3 months post-transplant were 27% and 28%. At a median follow up of 32 (0-118) months post-transplant, in the entire study population, median OS from diagnosis was 70.6 months while OS and EFS from the allograft were 18.9 and 14.9 months. Overall, the cumulative incidence of transplant related mortality (TRM) was 29.6% at 1 year and 32.4% at 5 years. OS from diagnosis and EFS from transplant were 70.6 and 28.2 months; 66.8 and 9.1 months; 111.9 and 22.4 months in patients who respectively underwent a myeloablative, a reduced-intensity and a non-myeloablative transplant. One-year and 5-year TRM was 33.3% and 35.7%, 32.2% and 34.4%, and 22.1% and 26.5% respectively. By univariate analysis, lower number of chemotherapy lines before the allograft, disease status at transplant, a fully HLA-identical donor, the use of peripheral hematopoietic cells

rather than bone marrow were statistically significant variables for better OS whereas disease status at transplant, a fully HLA-identical donor, chronic GVHD (either limited or extensive) were statistically significant for better EFS. However, by multivariate analysis, only the development of chronic GVHD (HR 0.50; p<0.001) and a better response post-transplant (HR 2.11; p<0.03) were significantly associated with longer OS whereas chronic GVHD was the only variable associated with better EFS (HR 0.32; p<0.001). Acute GVHD was associated with both poorer OS (HR 2.35; p<0.001)) and EFS (HR 3.19; p<0.001). **Conclusions.** There appears to be a strong association between chronic GVHD and graft-vs.-myeloma effects. However, long term disease control remains an issue regardless of the conditioning employed. Prospective trials may allow to define which patient category may most benefit from an unrelated donor allograft.

DISTINCT RECEPTOR PROFILE DEFINES ALLOREACTIVE T CELLS BEFORE GVHD ONSET

A Bäuerlein[1], S Riedel[1], C Brede[1], AL Jordán Garrote[1], M Ritz[1], M Chopra[1], R Negrin[2], H Einsele[1], A Beilhack[1]
[1]University Hospital Würzburg, Würzburg, Germany
[2]Stanford University, Stanford, United States of America

Background. Acute graft-versus-host disease (aGVHD) poses a major complication after allogeneic hematopoietic cell transplantation (allo-HCT). This immune syndrome is mediated by alloreactive donor T cells that attack the gastrointestinal tract, liver and skin. Previously, we and others demonstrated that alloreactive T cells are primed in secondary lymphoid organs. Therefore, we reasoned that in order to cause aGVHD alloreactive T cells require to express appropriate homing receptors to efficiently migrate from their priming sites to the gastrointestinal tract, liver and skin. **Aims.** To identify alloreactive T cells in the peripheral blood (PB) by a panel of homing receptors before clinical aGVHD manifestation. **Methods.** In a preclinical minor antigen mismatch (miHAg) allo-HCT mouse model we transplanted luciferase-expressing C57Bl/6 (H-2b, Thy1.1) T cells plus C57Bl/6 wild type bone marrow (Thy1.2) into conditioned (8Gy) Balb/B (H-2b, Thy1.2) recipients. MHC major mismatched Balb/C (H-2d, Thy1.2, 8Gy) and syngeneic C57Bl/6 WT (H-2b, Thy1.2, 9Gy) recipients served as controls. PB donor T cells were characterized by FACS at previously identified peak time points of T cell migration (days+4, +11, +15). Histopathological scorings confirmed GVHD. **Results.** Clinically apparent aGVHD developed by day+21 after miHAg mismatched allo-HCT. When we analyzed the peripheral blood of miHAg allo-HCT recipients we found CC chemokine receptors CCR5 and CCR9 highly upregulated (47% and 70% on day+4) in comparison to untreated C57Bl/6 control mice (<10% of PB CD8+ T cells). Mean fluorescence intensity (MFI) of CCR5 on day+15 of CD8+ donor T cells in the allogeneic setting exceeded that of syngeneic controls by 2-fold.Importantly, alloreactive donor T cells highly upregulated α4β7 integrin after miHAg mismatch allo-HCT. Relative expression values (26% CD4+α4β7+; 60% CD8+α4β7+) and absolute cell numbers (3.4x10^4 CD4+α4β7+ cells/ml; 15.8x10^4 CD8+α4β7+ cells/ml) exceeded α4β7-expressing T cells in syngeneic controls (20% CD4+α4β7+; 5% CD8+α4β7+; 0.9x10^4 CD4+α4β7+ cells/ml; 0.3x10^4 CD8+α4β7+ cells/ml) on day+11. Interestingly, most allogeneic T cells were α4β7+αEβ7- in contrast to double positive α4β7+αEβ7+ syngeneic T cells. Furthermore, CD8+ donor T cells highly upregulated P-selectin-ligand (35% CD8+P-selectin-ligand+; 9.1x10^4 cells/ml) and E-selectin-ligand (21% CD8+E-selectin-ligand+; 2.7x10^4 cells/ml) in contrast to syngeneic controls (10%, 0.7x10^4 and 9%, 0.2x10^4 cells/ml, respectively). Activation markers such as CD44 were expressed on 80-100% PB T cells in either syngeneic or allogeneic recipients.Conclusion:Our data indicates that alloreactive T cells can be identified early in the peripheral blood upon their homing receptor expression profile before the onset of aGVHD. Relative and absolute expression levels of α4β7 integrin, αEβ7 integrin, P- and E-selectin-ligand homing receptors and MFI values of CCR5 but not CCR9 on CD4+ and CD8+ T cells identified alloreactive T cells 6 to 10 days before the onset of clinically apparent aGVHD symptoms. Our data suggests these markers as potential predictors for aGVHD.

T-CELLS SPECIFIC FOR THE ASPERGILLUS PROTEINS CRF1 AND CATALASE1 DEVELOP IN PATIENTS RECOVERING FROM INVASIVE ASPERGILLOSIS

H Jolink, R Hagedoorn, J van Dissel, J Falkenburg, M Heemskerk
LUMC, Leiden, Netherlands

Background. Invasive aspergillosis is a common and life-threatening complication in recipients of allogeneic stem cell transplantation (SCT). Patients are most severely at risk in the neutropenic phase, but there is increasing evidence that impaired T-cell mediated immunity also increases the risk of invasive aspergillosis. In healthy individuals we identified *Aspergillus*-specific T-cells by measuring CD154 expression and IFNγ production in response to stimulation with overlapping peptides of the *A. fumigatus* proteins Crf1 and Catalase1. Antigen specific CD4+ T-cells were single cell sorted to identify the recognized epitopes and *Aspergillus* specificity was confirmed, based on reactivity of the different T cell clones to dendritic cells loaded with *Aspergillus* crude extract or *Aspergillus* recombinant protein. **Aims.** To allow development of new therapeutic strategies including adoptive transfer of antigen specific T-cells, we investigated the role of *Aspergillus*-specific T-cells in the clearance of aspergillus infection, and characterized the T-cell mediated immune responses against *A. fumigatus* in patients with invasive aspergillosis. **Methods.** We analyzed the T-cell response against *A. fumigatus* in 7 patients after allogeneic SCT who were diagnosed with probable or proven invasive aspergillosis. All patients had received an allogeneic SCT because of a hematological malignancy and aspergillus infection was diagnosed 1 to 10 months after SCT. Peripheral blood mononuclear cells (PBMC) were stimulated with the overlapping peptides of Crf1 and Catalase1 at several time points before and after the diagnosis of invasive aspergillosis and analyzed by flowcytometry using intracellular staining for IFNγ and CD154. **Results.** Directly ex vivo no *Aspergillus*-specific T-cells could be detected by intracellular staining for IFNγ and CD154. However, when PBMC were stimulated with the peptide mixtures of Crf1 and Catalase1, cultured for 7 days in the presence of IL-2 and restimulated with Crf1 and Catalase1 we detected clear populations of *Aspergillus*-specific T-cells in 6 out of 6 patients with regression of aspergillus lesions or stable disease.In these 6 patients a peak of Crf1- and Catalase1-specific CD154 expressing CD4+ T-cells was present around the time of regression of aspergillus lesions. The peak frequency of Crf1- and Catalase1-specific CD154 expressing T-cells varied between 0.5 and 3% of CD4+ T-cells. In most patients both Crf1- and Catalase1-specific T-cells were present. After clearance of the aspergillus infection the frequency of *Aspergillus*-specific CD4+ T-cells decreased to low or undetectable levels. In one patient no Crf1- or Catalase1-specific T-cells could be identified. This patient had progressive aspergillus infection while suffering from severe GvHD of the skin, liver and colon and died shortly after the diagnosis of invasive aspergillosis. **Conclusions.** Using only 2 *A. fumigatus* proteins as target antigens, we demonstrated the induction of *Aspergillus*-specific T-cells in 6 patients, coinciding with the decline of aspergillus lesions. These data indicate that an immune response directed against *A. fumigatus* proteins helps to clear an aspergillus infection. Therefore, *Aspergillus*-specific T cells generated *in vitro* by stimulating with *A. fumigatus* proteins like Crf1 and Catalase1, may be used for adoptive T-cell therapy for invasive aspergillosis.

Bleeding disorders

STOP CODON READTHROUGH WITH PTC-124 AND GENTAMYCIN IN HEMOPHILIA A CAUSED BY NONSENSE MUTATIONS

JF Chen[1], LH Yang[1], RJ Zhang[1], YF Zhang[1], BF Cai[2]
[1]The Second Hospital of Shanxi Medical University, Taiyuan, China
[2]Institute of Biotechnology, Shanxi University, Taiyuan, China

Background. The hemophilia A is caused by the mutations in the factor Ⅷ gene. One of the most important molecular mechanisms of hemophilia A is nonsense mutation,which lead to the production of nonfunctional truncated, nonfunctional or deleterious protein. Aminoglycoside antibiotics, such as Gentamycin, could induce readthrough of premature termination codon (PTC) and increase the production of the protein with nonsense mutation. However, repeated use of high doses of aminoglycosides for the readthrough therapy, has significant adverse effects including the nephrotoxicity and ototoxicity. PTC-124, a novel and non-toxic chemical compound, could be able to accomplish the task. **Aims.** At present, due to lacking of the eradicative therapy, the hemophilia A patients should infusion the expensive blood coagulation factor in their lifetime. So searching for the new drugs has significant social effects. Through our study, we want to compare the readthrough ability of different concentrations of PTC-124 and Gentamycin in hemophilia A caused by different PTC and provide the basis for the further researches of readthrough therapy. **Methods.** The international hemophilia mutation database was analyzed for finding the hot spots of nonsense mutation sites in FⅧ gene. The nonsense mutants were constructed by site-directed mutagenesis. Detecting the HEK-293 cells viability after treated with different concentrations of PTC-124 and Gentamycin for 48h, using CCK-8(Cell Counting Kit-8). Then, HEK-293 cells were transfected with either the wild-type or mutated constructs by liposome-mediated gene transfer method, then treated with different concentrations of PTC-124 and Gentamycin for 48h. The mRNA expression levels of FⅧ gene were detected by real-time PCR. The procoagulant activity (FⅧ：C) and antigen (FⅧ：Ag) of FⅧ in the cell lysate were detected using one stage method and ELISA, respectively. **Results.** The hot spots of nonsense mutation sites and our objects in FⅧ gene were W14X R1696X K1827X and R2307X. Except the designed sites,there was no other nucleotide mutations in the sequences of four mutants. The IC50 of PTC124 and Gentamycin in HEK-293 cells were 111.585±9.597μM and 4.23±0.32mM respectively, then select different concentrations of PTC124 and Gentamycin for the readthrough study. Compared with the untreated controls ,the mRNA expression levels of FⅧ gene and the procoagulant activity (FⅧ：C) and antigen (FⅧ：Ag) of FⅧ in the cell lysate treated with different concentration of PTC124 and Gentamycin were significantly elevated (P□0.05) in those four mutants.**Conclusion** From our data, PTC-124 had the similar readthrough activity for those four mutants in FⅧ gene compared with Gentamycin, while with less concentration and toxicity. In hemohilia A, even a small increase in FⅧ expression level can dramatically ameliorate the clinical phenotype, so the readtrhough approach can be a good therapeutic strategy. Although the aminoglycoside antibiotics, such as Gentamycin, could increase the functional protein prodution, however, these drugs have serious side effects at therapeutically relevant concentrations. PTC124, which is not structurally related to aminoglycosides, could be able to provide a better treatment for hemophilia A caused by nonsense mutation.

INTRACRANIAL HEMORRHAGE IN PATIENTS WITH A HEMATOLOGICAL DISORDER REQUIRING INTENSIVE CHEMOTHERAPY AND/OR A STEM CELL TRANSPLANT: A SYSTEMATIC REVIEW

J Estcourt[1], S Brunskill[1], C Doree[1], M Trivella[2], S Stanworth[1], M Murphy[1]
[1]NHS Blood and Transplant, Oxford, United Kingdom
[2]Cochrane Collaboration, Oxford, United Kingdom

Background. To advance the quality of care for hematology patients receiving intensive chemotherapy it is important to gain a greater understanding of the risk factors for life-threatening haemorrhage. This systematic review concentrates on intra-cranial hemorrhage (ICH) because it is the most serious type of bleed caused by significant thrombocytopenia. If an ICH does not cause death it may lead to significant long-term morbidity. However, this complication is rare, its exact incidence is uncertain, and predisposing risk factors are currently unknown. **Aims.** A systematic review of cases published in the literature during the last decade to determine its incidence and possible risk factors. **Methods**. We searched MEDLINE, EMBASE, CENTRAL, NLH CINAHL, and the SRI RCT Handsearch(www.transfusionevidencelibrary.com) electronic bibliographic databases for studies published between January 2001 and December 2010. There were no language restrictions. We included studies of patients, of any age, with hematological disorders, who required intensive chemotherapy or a stem cell transplant, and were expected to develop a significant thrombocytopenia. If trials consisted of mixed populations of patients, with diagnoses of solid tumours, only data from the haematological sub-groups were used. We excluded studies if fewer than 80% of participants had a hematological disorder and sub-group data was not provided. We also excluded studies if the participants were receiving palliative treatment; fewer than 33% of participants were expected to become significantly thrombocytopenic, or participants had immune thrombocytopenia. Data were collected on baseline characteristics of the cases (age, diagnosis, treatment and presumed risk-factors for ICH(e.g sepsis, anticoagulants, coagulopathy)) as well as any data on the same characteristics that were reported for the entire study population. **Results.** 6852 studies were initially identified, 6002 studies were excluded on the basis of the abstract. 850 full text articles were reviewed and of these, 254 studies were included in the review (183 cohort studies, 22 case series, and 49 case studies). 1099 cases of ICH were described within the included studies. Over half(55%) died due to ICH. The majority of cases were poorly described, for example, only 26.7%(294/1099) reported whether the patient was thrombocytopenic, 18.1% whether patient had a coagulopathy and only 4.9% described the presence or absence of anticoagulants. The majority of patients (93.4%;511/547) whose disease status was known had active disease at the time of the ICH. Data on incidence ratios will be presented at the meeting. Studies which included patients with acute promyelocytic leukemia (APL), which is well known to have a high incidence of hemorrhage, were more likely to report the presence or absence of ICH. Overall, approximately a third of acute leukemia patients within the included studies had APL, whereas the actual incidence of APL is approximately 10%. **Summary and Conclusions.** Cases of ICH are poorly reported in the literature, and the literature is biased in favor of APL. To provide a more unbiased picture of the incidence and risk-factors for ICH in hematology patients we have set up a UK-wide prospective reporting system (Haematology Active Surveillance System (HASS)) with a case-control study (InCiTe study) embedded within it.

GLA-DOMAINLESS ACTIVATED FACTOR X: A MOLECULAR BAIT TO BYPASS A BLOCKED TENASE COMPLEX

B Polack, R Marlu
CHU de Grenoble, Grenoble cdx 9, France

Background. Hemophilia is caused by deficiencies in coagulation factor VIII or IX, resulting in a direct blockade of the intrinsic tenase complex and an indirect one of the extrinsic tenase complex that is rapidly inhibited upon binding of factor Xa to Tissue Factor Pathway Inhibitor. Therefore, we evaluated the ability of a truncated form of factor Xa devoid of procoagulant properties, Gla-domainless factor Xa, to bind to Tissue Factor Pathway Inhibitor and to alleviate the physiological inhibition of the extrinsic tenase. **Materials and Methods.** Using thrombin generation assay triggered by a low concentration of tissue factor, we evaluated the ability of Gla-domainless factor Xa to restore blood coagulation in plasma from hemophilia A and B patients without and with inhibitors. We then compared its efficacy to generate thrombin to depletion of antithrombin or Tissue Factor Pathway Inhibitor by specific antibodies. Finally, we compared the kinetics of neutralization of factor Xa and Gla-domainless factor Xa by antithrombin and Tissue Factor Pathway Inhibitor.Results. Gla-domainless factor Xa was able to restore thrombin generation in hemophilia plasmas. This effect was observed for plasmas from hemophilia A, without or with inhibitors, and hemophilia B donors. Gla-domainless factor Xa had a lower affinity for Tissue Factor Pathway Inhibitor than factor Xa whereas the affinities of both proteins to antithrombin were similar. Finaly, despite a short half-life in plasma, the effect of Gla-domainless factor Xa on thrombin generation was sustained for at least one hour.Conclusion. As Gla-domainless factor Xa was able to restore thrombin generation in plasma from hemophilia patients, our results suggest that it may be an effective alternative to current treatments for hemophilia with or without an inhibitor.

SYNOVIORTHESIS BY RIFAMPICIN IN PEDIATRIC PATIENTS WITH CHRONIC HAEMOPHILIC SYNOVITIS : A SINGLE PROSPECTIVE CENTER STUDY

S El-Alfy[1], S Elbarbary[1], A Eldesouky[2]
[1]Ain Shams University, Cairo, Egypt
[2]Orthopedic surgery,Shabrawishi Hospital, Cairo, Egypt

Background. Intra-articular bleeding (haemarthrosis) is the most common manifestation of haemophilia A (HA) and haemophilia B (HB) producing hypertrophic synovitis and, in the long term, progressive cartilage degradation leading to irreversible arthropathy. Rifampicin has demonstrated proteolytic and antifibrinolytic actions, producing fibrosis and sclerosis of the hypertrophic synovium when injected into the joints. **Objective**. The aim of the study is to assess clinical outcomes and standard scores in 23 patients with hemophilic arthropathy undergoing chemical synovectomy with rifampicin. **Methods.** Twenty-three Hemophiliacs with target joints were enrolled and followed-up prospectively; all were inhibitor negative; 13 severe HA, 8 moderate HA and two severe HB in the period between January 2011 and January 2012. The indication for synoviorthesis was chronic synovitis characterized by recurrent haemarthrosis, persistent pain and limited range of motion (ROM). All patients were on-demand replacement therapy. Their median age was 12 years (range 5- 18 years) .A schedule was adopted to treat each joint with 5 doses of intra-articular rifampicin once a week . The dose used for knees was rifampicin(500 mg) injected intra-articularly with 4 mL lidocaine 2% and for elbows and ankles, the dose was 250 mg, with 2 mL lidocaine 2% once a week. Patients were covered with 3 doses of factor FVIII 25 U/Kg; first dose one hour before injection with good FVIII recovery followed by two same doses every12 hours . Oral analgesia was offered as required because of acute but transient painful inflammatory reaction and compression bandage was applied. World Federation of Hemophilia score was assessed 24 hours before intra-articular injection and one month later; score improvement was considered from excellent to fair according to evaluation. Physiotherapy was initiated as early as could be tolerated. **Results**. The procedures were performed on twenty nine joints(17 knees, 8ankles, 4 elbows) with a total of 145 injections . After the procedures were done : 19 (82%) were considered effective injections (as excellent or good), while four(18%) were considered insufficient (fair or poor). Pain was reduced in 79% of cases and bleeding episodes were reduced from 2.8 to 1.4 per joint / month before and after the chemical treatment respectively . The mean (WFH) score was 11.5 (range 5-21) before synoviorthesis and 6 (range 3- 12) after treatment. Non had hypersensitivity reaction to rifampicin. **Conclusions.** Intra-articular injection with rifampicin appears to be effective in reducing joint pain and in improving the ROM that can be given to many patients simultaneously on an outpatient basis. This simple procedure presents a low risk of bleeding and a low cost of therapy by reducing haemarthrosis effectively . Its especially practical in developing countries where radioactive isotopes are not easily available.

0566

UPREGULATION OF ANNEXIN II BY PML/RARALPHA FUSION PROTEIN ENHANCES FIBRINOLYSIS AND CELL INVASION IN U937 CELLS

JS Yan[1], J Shao[2], D Huang[2], L Li[1], XR Dong[1], XB Wang[1]
[1]The Second Affiliated Hospital of Dalian Medical University, Dalian City, China
[2]School of Public Health, Dalian Medical University, China, Dalian City, China

Background. Life-threatening coagulopathy usually occurs in acute promyelocytic leukemia (APL), mainly due to hyperfibrinolysis, which is triggered by annexin II, a cofactor for plasminogen and t-PA to accelerate plasmin generation. High level of annexin II in APL blast cells leads to excessive production of plasmin, resulting in massive degradation of fibrinogen and fibrin, and destroying extracellular matrix. While APL have achieved high rate of complete remission, 5%-13.3% patients experience early death and 5% relapse with central nervous system leukemia. This indicates that coagulopathy and infiltration have emerged as challenges for further improving treatment efficacy. PML/RARalpha fusion protein is specific for APL and serves as the target of differentiation therapy, therefore we hypothesize aberrant expression of annexin II may be associated with PML/RARalpha fusion protein. **Aims.** To verify the hypothesis on regulatory expression of annexin II by PML/RARalpha fusion protein, and to investigate the role of aberrant expression of annexin II in fibrinolysis and cell invasion. **Methods.** U937/PR9 cells, stably expressing PML/RARalpha fusion protein in the presence of 100 μmol $ZnSO_4$, were used to explore the association between annexin II and PML/RARalpha protein at both transcriptional and translational levels by RT-PCR and western blot. U937/MT cells contain only eukaryotic vector as control. The effects of annexin II on fibrinolysis and leukemic cell invasion were studied using plasminogen generation assay and matrix invasion assay. **Results.** PML/RARalpha fusion protein was detected 1 hour after the addition of 100 μmol $ZnSO_4$, followed by marked increase of annexin II protein at 2 hours with lagging time of 1 hour (Figure A). In addition, RT-PCR assay showed that increased mRNA expression of annexin II after addition of zinc as against without zinc (Figure B). Expression of annexin II remained stable in U937/MT cells with addition of 100 μmol $ZnSO_4$, indicating $ZnSO_4$ had no effect on expression of annexin II (Figure C). To investigate the functional significance of increased annexin II expression, we examined fibrinolysis and cell invasion in U937/PR9 cells in presence or absence of zinc. The data demonstrated that the initial rate of plasmin generation speeded up to 4.2 times with addition of zinc, and was abolished to constitutive capacity when the cells were preincubated with monoclonal anti-annexin II antibody. In matrix invasion assay, high level of annexin II promoted cell invasion rate to 80% (with zinc) versus 43% (without zinc), and this elevated invasion rate was also diminished by preincubation with monoclonal anti-annexin II antibody (Figure D). **Conclusions.** The current finding raveled that PML/RARalpha fusion protein facilitates annexin II expression, which in turn mediates fibrinolysis and cell invasion in U937/PR9 cells. Annexin II may be a potential target for the optimization of APL treatment.

[7]VU Medical Center, Amsterdam, Netherlands
[8]University Hospitals Leuven, Leuven, Belgium
[9]The university of Texas at Austin, Austin, United States of America

Background. T-cell acute lymphoblastic leukemia (T-ALL) is caused by accumulation of somatic mutations in developing T-cells. Major driver mutations in T-ALL include hyperactivity of the NOTCH1 pathway, activation of JAK/STAT signaling, overexpression of a set of transcription factors, and loss of cell cycle control. Although pediatric T-ALL patients respond well to the current chemotherapeutic regiments, the treatment is very toxic and the survival of older patients is still below 40%.**Aims.** To gain insight in the spectrum of mutations present in T-ALL and to identify potential new targets for therapy, we performed exome sequencing in both pediatric and adult patients. **Methods.** Whole exome sequencing was performed on 36 paired diagnosis-remission T-ALL samples, 18 diagnosis only samples and on 17 T-ALL cell lines. **Results.** We initially limited our analysis to the 36 paired sample sets for discovery of novel somatic mutations. On average, we identified 13 somatic protein-altering mutations (single nucleotide variations and small insertions and deletions) per sample. 389 genes were mutated in this samples set, of which 35 genes were selected as candidate drivers because they showed a significantly higher mutation rate compared to the local background mutation rate (24/389 genes) or because they were recurrently mutated in at least 2 of the 36 samples (31/389 genes). Interestingly, the 35 selected genes contained an overrepresentation (8/35 genes) of genes on the X-chromosome, which may be linked to the male predominance in T-ALL. Ten of the selected genes (*PHF6*, *FBXW7, PTEN, WT1, NOTCH1, DNM2, JAK3, BCL11B, MYB*, and *EZH2)* are known oncogenes or tumor suppressors in T-ALL. The remaining 25 genes are potential novel oncogenic drivers in T-ALL, with functions in signal transduction (*TLR1, LPHN2, USP9X*), transcriptional regulation (*CNOT3, ZNF711, TBP*) and epigenetic regulation (*TET1, KDM6A, TDRD6*). Strikingly, 7 of 54 T-ALL cases (13%) harbored mutations in RPL5 or RPL10, two proteins that are part of the ribosome, the multi-protein complex that translates mRNA into proteins in the cell. Mutation of Arginine 98 in the X-linked *RPL10* gene was identified in 8.4% of pediatric T-ALL cases. By performing functional studies in yeast, we could document a clear ribosome biogenesis defect in cells expressing the Rpl10 R98S mutant. While more experiments are needed to determine the exact consequences of the ribosomal protein mutations in T-ALL, the yeast results suggest that ribosome mutations may cripple the ribosome in T-ALL. **Summary and Conclusions.** Our data provide insights in the landscape of mutations in T-ALL and identify the ribosome as a novel oncogenic factor and potential target for therapy in T-ALL.

MULTIPLE INHIBITORY LIGANDS INDUCE T CELL IMMUNOLOGICAL SYNAPSE DYSFUNCTION IN HEMATOLOGIC MALIGNANCY THAT CAN BE BLOCKED WITH LENALIDOMIDE - DEFINING A REVERSIBLE IMMUNE EVASION MECHANISM IN CANCER

G Ramsay, A Clear, R Fatah, J Gribben
Barts Cancer Institute, Queen Mary University of London, London, United Kingdom

Background. Cancer cell immune evasion is an emerging hallmark of disease progression. We have previously demonstrated that impaired actin polymerization at the T cell immunological synapse is a global immunosuppressive mechanism in chronic lymphocytic leukemia (CLL). Direct contact with tumor cells induces defective actin polarization at the immune synapse in previously healthy T cells. **Aims.** Identify the molecules mediating T cell immune synapse dysfunction in CLL. **Methods.** We designed a small interfering RNA (siRNA) functional synapse bioassay. This used the B cell leukemia cell line MEC1 (that induces the same T cell immune synapse defect as primary CLL cells) and customized siRNA libraries that included soluble and membrane immunosuppressive molecules.siRNA treated MEC1 cells were co-cultured with healthy donor T cells which were subsequently negatively selected and used in conjugation assays with superantigen (sAg)-pulsed third-party B cells as antigen-presenting cells (APCs). T cell F-actin polymerization was quantified using confocal image analysis software (Axiovision and Cellomics, Zeiss). In this bioassay, knockdown of tumor inhibitory molecules should lead to gain in T cell synapse function. **Results.** We identified three B7-related molecules CD200, CD274 (PD-L1), and CD276 (B7-H3), and one TNF-receptor superfamily member CD270 (TNFRSF14 or HVEM), for which siRNA treatment of MEC1 cells significantly enhanced immune synapse formation. We confirmed these results using primary CLL cells pre-treated with neutralizing antibodies and show that the combined action of these molecules are co-opted by CLL cells to induce potent immunosuppressive effects on both autologous and allogeneic T cell actin dynamics and effector function. In contrast, no effect on T cell synapse function was seen using healthy B cells treated with or without neutralizing antibody. Next, *in situ* immunohistochemistry analysis showed that all four inhibitory ligands were up-regulated in CLL compared to reactive lymph node tissue and linked to poor prognosis. We further show that impairment of actin dynamics in T cells is a common immunosuppressive strategy used by both hematologic (including follicular lymphoma and diffuse large B cell lymphoma) and solid carcinoma cells (including ovarian cancer and squamous cell carcinoma) and mediated by the activity of these inhibitory ligands. We demonstrate that this immunosuppressive signaling targets T cell Rho GTPase activation. Co-culture with CLL cells, compared with healthy B cell control cells, significantly decreased activated RhoA, Rac1 and Cdc42 levels in T cell receptor-stimulated cells. Of clinical relevance, the immunomodulatory drug lenalidomide prevented induction of these defects *in vitro* and *in vivo* (clinical trial samples) and mimicked the effect of antibody blockade by down-regulating tumor cell inhibitory ligands and inhibitory receptors on T cells during immunosuppressive co-culture interactions. **Conclusions.** These results using human CLL as a model cancer establish a novel evasion mechanism whereby malignant cells exploit multiple inhibitory ligand signaling to down-regulate small GTPases and lytic synapse function in global T cell populations. These findings should contribute to the design of immunotherapeutic strategies to reverse T cell tolerance in cancer.

Background and Aims. In over 10% of patients with acute myeloid leukaemia (AML) the translocation t(8;21) is present. This translocation results in the formation of an AML1-ETO oncofusion protein. AML1 is a subunit of the transcription factor CBF and ETO is a transcriptional co-repressor. The oncofusion protein contains the DNA binding domain of AML1 and almost the entire coding region of ETO. AML1-ETO contributes to leukaemia development through altered gene expression. Despite this knowledge, the exact molecular function of AML1-ETO is still poorly understood. Also genes directly deregulated by AML1-ETO implicated in disease development remain largely unknown. **Methods and results.** To gain insight into the molecular function of AML1-ETO, we performed genome-wide ChIP-seq experiments to identify genes directly bound

by AML1-ETO. We observed that AML1-ETO interacts with DNA sequences of the core promoter of the oncogene *GFI1* in primary leukemic cells. GFI1 is a transcription factor that represses gene expression. One of the genes normally silenced by GFI1 is the *GFI* gene itself. The fact that AML1-ETO binds to the *GFI1* gene is important because we reported recently that AML1-ETO also directly interacts with the GFI1 protein through the ETO moiety. In addition, we showed that AML1-ETO inhibited the auto-repressive function of GFI in reporter assays. Here we studied the relevance of this finding by analyzing *GFI1* RNA expression in a cohort of over 500 AML cases. This revealed that *GFI1* gene expression was significantly higher in AML1-ETO-positive leukaemia compared to other leukaemia subtypes (including the inv(16)/CBFB-MYH11) and to normal bone marrow stem cells (p<0.001). In AML1-ETO positive leukaemia, the *GFI1* paralogue *GFI1B* was not highly expressed and AML1-ETO did not interact with the *GFI1B* gene. Thus, *GFI1* is specifically induced in AML1-ETO positive leukaemia. Subsequent biological studies using lentivirally-mediated gene silencing showed that GFI1 is required for growth of AML1-ETO positive Kasumi1 cells. We also studied the role of GFI1 in leukaemia development *in vivo* by crossing conditional *AML1-ETO* knockin mice with *GFI1* null mice. Poly-IC induced CRE expression resulting in AML1-ETO expression followed by G-CSF and ENU treatment resulted in leukaemia development in over 80% of *AML1-ETO/GFI1* wild type mice within one year. In sharp contrast, none of the *AML1-ETO/GFI1* null mice developed leukaemia (n = 21 for both conditions, p<0.02). This indicates that GFI1 is required for AML1-ETO induced leukemia in mice.**Summary and Conclusions.** AML1-ETO binds the *GFI1* gene and inhibits the auto-repressive function of the GFI1 protein. This results in high *GFI1* expression in AML1-ETO positive leukemia. AML1-ETO also interacts with and needs the GFI1 protein for malignant transformation. Because GFI1 interacts with ETO, genes normally regulated by GFI1 could be de-regulated through the interaction with AML1-ETO. Vice versa, AML1-ETO may deregulate AML1 target genes through recruitment of the repressor GFI1. GFI1 may represent an important therapeutic target in AML1-ETO positive leukaemia.

Background. Fanconi anemia (FA) is due to inherited mutations of one of the 15 *FANC* genes involved in the FA/BRCA DNA repair pathway. In addition to congenital abnormalities, FA patients undergo progressive bone marrow failure (BMF) during childhood and they have a strong susceptibility to MDS/AML. **Aims.** The mechanisms underlying BMF have been elusive to date, largely because of practical difficulties in a disorder with poor bone marrow (BM) cells, and because murine Fanc$^{-/-}$ models do not fully recapitulate the BMF phenotype. In order to investigate BMF pathogenesis in FA, we conducted a study based on a large cohort of FA patients, and modeled the findings in mouse systems.**Methods.** Fresh BM cells from 91 FA patients were collected during BM aspirate and proceeded for CD34$^+$ purification and CFU-GM assays. Two *in vivo* models of hematopoietic transplant of FA cells were developed using *Fancg-/-* mice and human CD34$^+$ cells. Moreover, we generated double knockout *Fancd2-/-p53-/-* mice and analyzed hematopoietic stem and progenitor cells (HSPCs). **Results.** CD34$^+$ cell counts and *in vitro* clonogenic activity were lower in FA patients compared to 40 healthy BM donors (P<10^{-15}). Interestingly, even the youngest FA patients investigated before the onset of BMF had lower values, suggesting that the HSPCs impairment began before birth.As FA cells have a constitutional DNA repair defect, we investigated the cellular response to DNA damage. FA HSPCs had a strong activation of p53 and p21, leading to a delayed G0/G1 cell-cycle arrest after resolution of an early G2 checkpoint. Moreover, shRNA-mediated knockdown of p53 or p21 in HSPCs from FA patients dramatically rescued their *in vitro* clonogenic ability (P<10^{-4}). These data suggest this p53/p21 response restricts the cell cycle in HSPCs, and that this mechanism could be central in BMF pathogenesis in FA patients.Although *Fancd2-/-* mice do not develop spontaneous BMF, they exhibit HSPCs defects. This defect was rescued in *Fancd2-/-p53-/-* mice (P<10^{-3}). Moreover, in *Fancg-/-* mice, shRNA-mediated p53 inhibition improved the Lin$^-$ cells engraftment in competitive experiments (P<10^{-4}). To study human cells, we lentivirally knocked-down *FANCD2* in CD34$^+$ cells from normal cord blood and xeno-transplanted the resulting FA-like cells into immunodeficient NSG mice. Strikingly, simultaneous knock-down of *p53* and *FANCD2* using tandem shRNA dramatically improved the engraftment capacities when compared to *FANCD2* shRNA (P=10^{-2}). Finally, gene expression analysis of fresh cells from FA patients and healthy donors showed that FA HSPCs strongly expressed the *p21/CDKN1A* gene (P<10^{-2}) and a signature of G0/G1 cell cycle arrest. **Summary and Conclusions.** Altogether, these results identify an exacerbated p53/p21-mediated G0/G1 cell cycle arrest in response to cellular stress as a central mechanism of BMF in FA patients. Noteworthy, a p53 response has also been involved in Diamond-Blackfan anemia and Dyskeratosis Congenita, related to ribosomal and telomeres abnormalities, respectively. Our findings in FA point to p53 activation as a unifying downstream signaling mechanism for inherited BMF syndromes.

Multiple myeloma (MM) is an incurable malignancy of post-germinal centre B-cells whose pathogenesis is only partially understood. Chromosomal abnormalities, such as hyperdiploidy and recurrent immunoglobulin gene locus rearrangements are frequent, but are thought to be insufficient for malignant transformation because they are also observed in the pre-malignant syndrome called monoclonal gammopathy of uncertain significance (MGUS), while malignant progression is often associated with additional events, like MYC activation. This implies that the genetic landscape of MM changes over time as result of additional events that define its emergence and progression.To investigate genomic event underlying MM pathogenesis and evolution, we used targeted capture and massively parallel sequencing of exomes of CD138 purified plasma cells from 68 patients with MM. For 17 patients, serial samples (range 5-18 months apart) were available. Exome reads were used to call substitutions and insertions/deletions. We used single nucleotide polymorphisms (SNPs) to infer chromosomal copy number and allelic ratio of the tumor. Lastly, mutation burden was used to estimate the clonal architecture of each sample and its evolution over time (where available). All data were produced by in-house algorithms developed at the Wellcome Trust Sanger Institute.Our analysis confirmed mutation recurrence in some of the genes previously identified (Chapman et al, Nature 2011): KRAS 25%, BRAF 13%, NRAS 13%, FAM46C 9%, TP53 9%, CCND1 1%. Interestingly, 3/9 BRAF mutations co-occurred with activating KRAS mutations in the same patient, raising important therapeutic implications. We also described several genes previously unreported in MM. So far, 1803 variants have been validated in the cohort (range 0-140 per patient). 292 genes are recurrent, suggesting a role in MM pathogenesis, and among these are genes involved in the NF-kB pathway, histone-modifying enzymes, cyclins and cyclin-dependent kinases. We also report mutations in deubiquitinating enzymes, protein tyrosine phosphatases, cytoplasmic proteins involved in Golgi, endoplasmic reticulum and vesicle protein trafficking, and known tumor suppressors such as PTEN and APC.Analysis of the clonal structure showed at least two subclones in 66/68 (97%) patients at diagnosis, suggesting that myeloma is a heterogeneous disease at presentation. The burden of at least some of the mutations changed over time in 12/15 patients (80%) with serial samples, highlighting ongoing clonal evolution. Interestingly, 2/2 NRAS mutations only appeared in the late sample, and 3/6 KRAS mutations increased their burden over time. Furthermore, copy number analysis showed that 9/15 (60%) patients also acquired additional chromosomal gain/deletions, with loss of 17p in 4/9 (44%). This suggests a role for RAS activation and TP53 loss in disease progression.In conclusion, in our cohort of MM samples we show: 1) a comprehensive list of previously unreported variants, many of which are recurrent; 2) evidence of tumor heterogeneity at the time of diagnosis; 3) discernable genetic changes and shifts in the clonal structure of disease at the time of progression. Our study provides new insights into the molecular pathogenesis of MM, and will help identify molecular alterations associated with progression of disease and development of drug resistance.

[3]University of the Free State, Bloemfontein, South Africa

Background. Acquired thrombotic thrombocytopenic purpura (TTP) is a rare and life-threatening disorder. The disease is characterized by the deficient processing of ultra-large von Willebrand Factor (ULvWF) due to neutralization of ADAMTS13-activity. This leads to spontaneous platelet aggregation in the microvasculature responsible for the severe clinical symptoms of TTP. ALX-0681 is a therapeutic Nanobody that targets the A1-domain of vWF and inhibits the interaction between ULvWF and the platelet receptor GPIb-IX-V. Given the crucial role of ULvWF in the pathophysiology of TTP, inhibition of microthrombi formation by ALX-0681 offers an attractive new therapeutic concept for the treatment of acquired TTP. **Aims.** This study evaluated the efficacy and safety of ALX-0681 in a preclinical baboon model of acquired TTP, as described earlier (Feys *et al.*, Blood 2010, 116(12):2005-2010). **Methods.** ALX-0681 was evaluated for its potential to prevent or treat acute episodes of TTP induced by administration of an ADAMTS13-inhibiting monoclonal antibody (3H9). Onset of disease was demonstrated as rapid decreases of platelet counts and haptoglobin, and increases in LDH and schistocytes as major hallmarks of TTP. In the preventive setting, animals were treated with daily ALX-0681 injections starting on the day of the first 3H9 administration. In the therapeutic setting, animals received ALX-0681 only after confirmed onset of disease starting on day 5, after which daily dosing with the drug was ensued for the remainder of the study until day 11. **Results.** ALX-0681 completely prevented the rapid onset of thrombocytopenia after 3H9 injection when given before the onset of disease. Also intravascular hemolysis (indicated as decreasing haptoglobin levels), red blood cell fragmentation (increasing schistocyte count) and increasing LDH levels (tissue damage) were fully prevented. ALX-0681 also effectively treated the major hallmarks of acquired TTP. ALX-0681 completely reversed platelet counts to baseline levels. Schistocytic hemolytic anemia was halted as shown by the (partial) recovery of haptoglobin concentrations and stabilizing schistocyte counts, which showed a tendency towards normalization to baseline values. Another marker showing ALX-0681-induced normalization included LDH. Therapeutic efficacy of ALX-0681 fully correlated with complete neutralization of vWF activity as measured by ristocetin-induced cofactor activity. Importantly, brain CT scans during in-life phase and post mortem analysis of the organs did not reveal any sign of bleeding, irrespective of the observed reversible decreases of factor VIII clotting activity and vWF antigen concentrations.*Summary/* **Conclusions.** This study in the baboon model of acquired TTP convincingly demonstrated that ALX-0681 can prevent and treat the major hallmarks of acquired TTP by targeting the vWF-platelet interaction. Treatment was found to be safe in terms of bleeding risk even in the context of low platelet counts and full neutralization of vWF activity. Therefore, these preclinical data further strengthen the promising novel concept of inhibiting ULvWF-mediated platelet aggregation as adjunctive treatment for TTP in the clinic. ALX-0681 currently is undergoing Ph II clinical trials in TTP.

Novel technologies in acute lymphoblastic leukemia

Infant acute lymphoblastic leukemia (ALL) is characterized by rearrangements of the *MLL* gene (*MLL*-R) and a poor prognosis. We performed whole genome sequencing (WGS) on diagnostic leukemia and matched germ line samples from 22 infants with *MLL*-R ALL.Analysis of the structure of the *MLL*-R revealed that over half had complex rearrangements that involved either three or more chromosomes, carried cryptic rearrangements, or contained at the breakpoints deletions, amplifications, insertions, or inversion of sequences. In two of the complex cases, chromosomal rearrangements generated in addition to the *MLL-partner* gene fusion, novel in-frame fusions including *KRAS-MLL* and *AFF1-RAD51B-MLL*.An analysis of the non-silent variants (SNVs) revealed infant ALL to have the lowest frequency of somatic mutations of any cancer sequenced to date. After removal of structural variations (SVs) and copy number alterations associated with the *MLL*-R, and mutations present in minor subclones, the major clone in infant ALL contained a mean of only 3.5 SVs and 1.3 SNVs affecting the coding region of annotated genes or regulatory RNAs. Despite the paucity of mutations, several pathways were recurrently targeted including the PI3K/RAS pathway in 45% (*KRAS,* n=4, *NRAS,* n=2), and non-recurrent mutations in *NF1*, *PTPN11*, *PIK3R1*, and *ARHGAP32*,cell differentiation in 23% of cases as a result of mono-allelic deletion or gains of *PAX5*, 14% with deletions of *CDKN*, and 2 cases with focal deletions of the non-coding RNA genes *DLEU1/2*.WGS of two infant ALL relapse samples and comparison with their matched diagnostic samples revealed a marked increase in the number of mutations at relapse. Moreover, an analysis of the allelic ratios of mutated genes revealed clonal heterogeneity at diagnosis with relapse appearing to arise from a minor diagnostic clone.Because of the exceedingly low frequency of mutations detected in infant ALL, we determined the frequency of non-silent SNVs in *MLL*-R leukemia in older children (7-19 yrs). Exome sequencing on 20 *MLL*-R leukemias (9 ALLs, 10 AMLs, 1 AUL), revealed that non-infant pediatric *MLL* leukemias harbor a significantly higher number of non-silent somatic SNVs than infant ALL (mean 6.3/case in older patients versus 1.3/case in infants, $p<0.001$). In addition, genes involved in histone modification were mutated in 35% of non-infant leukemia. Although the increased frequency of mutations may be a reflection of the older age, the low number of cooperating mutations in infants raises the possibility that the target cell of transformation differs between infants and older children, with the cells present during early development requiring fewer cooperating mutations to induce leukemia.In summary, our data demonstrated an exceedingly small number of mutations in infant leukemia. The number of detected somatic mutations may represent the lower limit required to transform a normal human cell into a cancer. The lack of mutations in chromatin modifier genes in infant ALL raises the possibility that the target cell of transformation may differ between infants and older children, with the target cell in infants having a chromatin state that is more permissible to transformation by the *MLL* gene rearrangement.

[6]Pediatric Oncology/Hematology and Hematology, VU Medical Center, Amsterdam, Netherlands

Background. T-cell acute lymphoblastic leukemia (T-ALL) is a malignancy of T-cell precursors that occurs predominantly in children and adolescents. Chromosomal rearrangements resulting in the overexpression of transcription factors such as TLX1, TLX3, TAL1, LMO1, LMO2 or HOXA are frequently observed in T-ALL, but gene fusions have been less commonly described. **Aims.** To discover new oncogenic lesions in T-ALL, we used whole transcriptome sequencing (RNA-seq) in T-ALL samples and T-ALL cell lines. **Methods.** Total RNA from twenty-one T-ALL cases (7 children and 14 adults), 16 T-ALL cell lines and normal thymus cells was analyzed by whole transcriptome sequencing. Next generation sequencing libraries were constructed from the mRNA fraction, followed by paired-end sequencing on a HiSeq2000 (Illumina). Sequence reads were aligned to the reference genome, and were processed to identify gene fusion transcripts and gene expression levels. Novel candidate fusion transcripts were confirmed by RT-PCR and Sanger sequencing. **Results.** Whole transcriptome sequencing identified an average of 38 fusion transcripts in each primary T-ALL case (range: 4-73) and 56 in each T-ALL cell line (range: 15-98).As expected, we identified a variety of fusion transcripts already reported in T-ALL, including NUP214-ABL1 (n=3), TRBC2-NOTCH1 (n=1), MLL-FOXO4 (n=1), PICALM-MLL10 (n=1) and SIL-TAL (n=4), or fusions known in other malignancies such as the NUP98-SPSI fusion (n=1). Interestingly, we also detected fusion transcripts between the T-cell receptor gene (TCR) and the TLX1 gene in 1 T-ALL cell-line, which also showed TLX1 overexpression in our RNA-seq gene expression analysis. Moreover, we detected and confirmed the presence of novel fusion transcripts. Several novel in-frame fusion transcripts involving transcriptional regulators were identified, including the CLINT1-MEF2C, HNRP-ZNF219 (n=2), FUS-SET and DDX3X-AF10 fusions, and we detected 2 novel fusion transcripts involving the kinase domains of FER and JAK2. Furthermore, new translocations involving the TCR genes were discovered. These translocations resulted in the generation of fusion transcripts between the TCR genes and genes on the partner chromosome, and were accompanied by the clear overexpression of one or more genes on the partner chromosome. In this way, we identified chromosomal rearrangements between the IL7R gene and TRBC2, between RIC3 and TRBC2 (also causing LMO1 overexpression), and between SFT3 and TCRD (also causing NKX2-1 overexpression).Out-of-frame fusion transcripts were detected involving TP53, IKFZ1 and CDKN2A, which could be a mechanism to inactivate these tumor suppressor genes. **Conclusions.** Our study demonstrates the power of whole transcriptome analysis for the detection of fusion transcripts and overexpressed genes in T-ALL. Using a combined analysis of fusion transcript detection and gene expression levels, we were able to detect translocations involving the TCR genes, in-frame-fusion transcripts and out-of frame fusion transcripts that may cause inactivation of tumor suppressor genes.

[2]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands
[3]Department of Pediatric Hematology and Oncology, Medical University of Silesia, Zabrze, Poland

Background. Second hematologic malignancies in non-syndromic children without family history for cancer may be mistaken for relapses or therapy-related malignancies. Recently, we identified eight T-cell acute lymphoblastic leukemia (T-ALL) patients with two consecutive leukemias fully discordant for TCR-rearrangements and DNA copy number aberrations, strongly suggesting a predisposition to leukemia (J.Clin.Oncol.2011). **Aims and method**Here, we performed exome sequencing on leukemic and complete remission samples from four of these patients in order to assess clonal relationship at the sequence level, and to search for predisposing mutations. **Results.** We found an average of 25,000 variants/exome. All variants that were present in public (dbSNPv32) and in-house (672 exomes) databases were excluded for further analysis, as well as all synonymous variants or intronic variants, and those called in <20% of the reads. These filter steps resulted in an average of 430 private variants per exome.All candidate somatic variants shared between two consecutive leukemic samples were re-sequenced by Sanger sequencing and were shown to be either present in all three samples, and thus originally missed in the remission sample, or falsely detected in one or more leukemic samples. Therefore, we conclude that no somatic variants were shared between the first and second leukemic presentations, which confirms that these patients suffered from clonally unrelated second T-ALLs. From all somatic variants present in only one of the leukemic samples, we focused on variants in exons or splice junction sites. We identified and validated between one and six somatic variants per leukemic sample, the majority of which affected known T-ALL genes, such as *PTEN, FBXW7* and *PHF6*. In order to identify candidate predisposing constitutional variants, we focused on recurrently affected genes and known T-ALL associated genes. We identified highly conserved missense variants in *TYK2, RANBP17,* and *TIAL1*. *TYK2* was also affected by somatic mutations and belongs to the family of Janus kinases, which play a role in the pathogenesis of several hematologic malignancies. The germline *TYK2* variant G761V is located in a highly conserved region of the pseudokinase-like domain, which is frequently affected in the homologous *JAK2* kinase in precursor B-cell leukemias. **Conclusions.** We confirmed second leukemia in four patients with late T-ALL recurrences, and identified the tyrosine kinase *TYK2* as a candidate predisposing gene.

UNRAVELING A NOTCH1-LNCRNA-MIRNA REGULATORY NETWORK IN ACUTE T-CELL LYMPHOBLASTIC LEUKEMIA AND NORMAL T-CELL DEVELOPMENT

K Durinck[1], P Mestdagh[1], T Taghon[2], J van der Meulen[1], I van de Walle[2], P Volders[1], M Ongenaert[1], N van Roy[1], Y Benoit[1], B Poppe[1], P Van Vlierberghe[1], B Menten[1], J Vandesompele[1], P Rondou[1], F Speleman[1]
[1]Center for Medical Genetics, Ghent University, Ghent, Belgium
[2]Department of Clinical Chemistry,Microbiology and Immunology,University Hospital, Ghent, Belgium

Background. NOTCH1 signaling is of central importance in normal development and differentiation. NOTCH1 acts as a central player in oncogenesis of several cancer entities, in particular T-cell acute lymphoblastic leukemia (T-ALL). T-ALL is a hematological malignancy, characterized by uncontrolled proliferation and arrested differentiation of precursor T-cells. Activating *NOTCH1* mutations are present in more than 50% of all T-ALL patients. Although the protein coding regulatory network governed by NOTCH1 is extensively characterized, its function in non-coding networks remains largely unexplored. **Aims.** In this study, we aim to identify long non-coding RNAs (lncRNAs) and microRNAs (miRNAs) whose activities are controlled by NOTCH1 in normal and malignant T-cell development and functionally validate relevant candidate lncRNAs and miRNAs both *in vitro* and *in vivo*. **Methods.** Using a γ-secretase inhibitor (compound E) interfering with NOTCH1 signaling in four T-ALL cell lines (JURKAT, HPB-ALL, DND-41 and T-ALL1), transcriptional response of all protein coding genes and 8000 lncRNAs was assessed using gene expression microarrays (Agilent). In parallel, lncRNA expression profiles were also established for two sorted normal T-cell progenitor populations derived from either CD34+ cord blood or thymus cells cultured either with or without NOTCH1 stimulation using OP9-DL1 or OP9-GFP feeder layers. Finally, a top-50 ranked list of highest expressed lncRNAs in eight different T-ALL cell lines was generated upon RT-qPCR profiling of 1250 lncRNAs (Biogazelle). In addition to lncRNAs, the miRNAome (756 miRNAs) for all experimental conditions as well as nine distinct sorted subsets of normal developing T-cell populations and 20 T-ALL cell lines were profiled using high-throughput stem-loop qPCR (Applied Biosystems). Expression of known NOTCH1 protein coding target genes were in keeping with the expected response validating our procedure. **Results.** Using a unique integrated experimental approach, we were able for the first time to identify a subset of lncRNAs and miRNAs acting downstream of the NOTCH1 signaling cascade with a presumed function in both normal and malignant T-cell development. Differentially expressed lncRNAs and miRNAs between untreated (DMSO) and treated (compound E) conditions for each GSI-sensitive cell line (DND-41, HPB-ALL and T-ALL1) were scored in a time course experiment against the GSI-resistant cell line (Jurkat). In total, we identified 5 NOTCH1 neg-

atively regulated lncRNAs and 24 NOTCH1 positively regulated lncRNAs shared amongst the three GSI-sensitive cell lines. Publicly available NOTCH1 ChIP-seq data were used to search for direct NOTCH1 binding to the promoters of regulated lncRNAs (Aster et al., PNAS, 2011). A subset of these candidate lncRNAs will be further evaluated for their physiological role *in vitro* by means of overexpression or siRNA-mediated knockdown. **Conclusions.** We applied a unique experimental approach that enabled the first landscaping of a comprehensive integrated network of lncRNAs and miRNAs acting downstream of the NOTCH1 signaling pathway in T-ALL and normal T-cells. Given the central role of NOTCH1 in T-ALL oncogenesis, these data pave the way towards development of novel therapeutic strategies impacting on hyperactive NOTCH1 signaling.E-mail address: franki.speleman@ugent.be

PROTEOMIC EXPLORATION OF CELL SURFACE LANDSCAPE REVEALS NEW LEUKEMIA ASSOCIATED FEATURES

P Mirkowska[1], A Hofmann[2], B Bornhauser[1], M Schmitz[1], G Cario[3], JP Bourquin[1], B Wollscheid[2]
[1]University Children's Hospital Zurich, Zürich, Switzerland
[2]Institute of Molecular Systems Biology, ETH Zurich, Zürich, Switzerland
[3]University Hospital Schleswig Holstein, Kiel, Germany

Background. Proteins present on the cell surface constitute a gateway through which the cell can communicate with the environment. In leukemia, such surface proteins play a role in a wide range of events including cell homing and protective interactions with the microenvironment, which might lead to chemoresistance. Thus, describing the leukemia cell surface landscape will provide a resource to study the biology of this disease and to identify new leukemia-associated proteins as potential diagnostic markers and treatment targets. **Aims.** Here we combined a leukemia xenograft model with mass spectrometry based techniques in order to identify new leukemia associated cell surface proteins. **Methods**. Amplification of primary human material by xenotransplantation allowed generating highly viable samples of sufficient size to apply the mass spectrometry-based Cell Surface Capturing (CSC) technology that enables specific detection of glycoproteins exposed at the cell surface. We have analyzed 19 samples of precursor B-cell acute lymphoblastic leukemia (ALL), including cases with a very high risk of relapse and cases with very good prognosis, based on the levels of minimal residual disease (MRD) during treatment. This cohort composition enabled us to detect surface proteins that are expressed in most of ALL cases, but also to look for markers associated with *in vivo* resistance to treatment. **Results.** As a proof of concept, the immunophenotype established at diagnosis by flow cytometry was readily recapitulated in our proteomic dataset. In total, almost 1000 membrane-associated proteins were identified on the surface of ALL cells. Among these, we identified 234 proteins being consistently present on more than 60% of the samples. Taking advantage of recent comprehensive gene expression data from sorted cell populations of the normal human hematopoietic tree (DMAP, Novershtern et al, 2011, Cell, 144, 296-309), we filtered our candidate list for proteins which are not expected to be detectable at early stages of B-cell ontogeny. For 38 of these proteins, mRNA levels were very low also in sorted populations from other normal B lineage cells. Among those, we found surface proteins that have been detected by other approaches as useful markers for the distinction of leukemic blasts from their normal counterparts, such as CD99, IL3RA, CD300A and CD58. We are currently evaluating 15 new promising leukemia associated proteins by flow cytometry in ALL samples at diagnosis and during induction chemotherapy.Additionally we filtered our proteomic dataset for proteins that are detected preferentially in cases with very high-risk leukemia. Interestingly, this approach generated a limited list of 37 candidates, including two members of the vanin family (VNN), with proposed functions in hematopoietic cell trafficking. Validation studies showed that high expression of VNN2 identifies a small subgroup with positive MRD in a cohort of 600 patients, indicating that this protein may recognize a subset of ALL cases with more unfavorable biology. **Conclusions.** Taken together, our data provide an unprecedented view at the cell surface landscape of leukemia cells and identify subsets of cell surface proteins that could be amenable for diagnostic and prognostic use or therapeutic intervention in this deadly disease.

Chronic lymphocytic leukemia - Translation research

DEEP SEQUENCING IDENTIFIES TP53 MUTATIONS BEFORE THEIR CLONAL SELECTION BY THERAPY IN CHRONIC LYMPHOCYTIC LEUKEMIA

M Trbusek[1], K Stano-Kozubik[1], J Malcikova[1], J Smardova[2], L Sebejova[1], M Doubek[1], Y Brychtova[2], M Svitakova[2], S Pavlova[1], M Mraz[1], K Plevova[2], V Vranova[2], N Tom[2], J Mayer[2], S Pospisilova[1], B Tichy[1]

Background. Defects in the *TP53* gene are associated with a particularly adverse prognosis in chronic lymphocytic leukemia (CLL). The p53 mutation and/or 17p deletion effect a poor chemotherapy response and shorter clinical responses to chemoimmunotherapy or alemtuzumab. The frequency of p53 inactivation is substantially higher in pretreated cohorts compared to those investigated before first-line therapy. This raises questions on the role of treatment in *TP53* mutagenesis and specifically whether therapy only selects mutations or induces them *de novo*. **Aims.** The aims were to analyze i) frequency of new clonal *TP53* mutations in untreated and treated CLL patients ii) in cases with new clonal *TP53* mutation emerging after therapy, to analyze its presence before therapy using the ultra-sensitive deep sequencing. **Methods.** Clonal p53 mutations were identified by the yeast functional analysis (FASAY) and/or by direct Sanger sequencing. Presence of 17p- was assessed by I-FISH using probe from Abott-Vysis. The pyrosequencing on the GS Junior 454 platform (Roche) was performed to identify low-proportion (yet unselected) *TP53* mutations. For the positions of the studied mutations, we achieved a median coverage of 6 657 reads (range 5 212-16 427). Mutations were reliably detected with the sensitivity reaching 0.2%. **Results.** We have repeatedly analyzed p53 status in 248 CLL patients which had an intact *TP53* gene (no mutation and no 17p-) at first investigation; the median follow up was 33 months during which 60% of patients received therapy. The repeated investigations identified 31 patients with new p53 mutation (12.5%). All these mutations have emerged exclusively in patients that received treatment prior to detection of the p53-mutated clone; approximately each fifth treated patient acquired a new p53 mutation. Remarkably, missense mutations located in the p53 DNA-binding motifs (DBMs) - well defined and structurally important parts of the DNA-binding domain - were preferentially selected by therapy. Deep sequencing of pre-therapy samples from 9 patients that subsequently developed p53 mutation has revealed that all mutations were present as minor clones undetectable by standard techniques (range 0.24% -13.03% of mutated reads) ($P < 0.001$); all mutations were identified from both the forward and reverse primers. After the therapy, all analyzed mutations were clearly detectable by deep-sequencing in a much larger proportion of cells. Our data shows that therapy selects "ready-to-use" mutations; by other words, there is probably none or negligible *de novo* induction of new *TP53* mutations by therapy in CLL. **Summary and Conclusions.** We demonstrate that selection of very minor clones of CLL cells harboring *TP53* mutations is likely connected to the relapse of the disease and is a key event in evolution of certain refractory CLL cases. The detection of minor clones of CLL cells with p53 mutation prior to therapy could be of potential relevance for therapy selection and subsequent management of the disease relapse. INCREASED DISEASE SPREADING THROUGH CD49D/ALPHA4 INTEGRIN AND APOPTOSIS BLOCK MEDIATED BY CD69 REPRESENT TWO KEY PROGNOSTIC PARAMETERS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

G Del Poeta[1], M Del Principe[1], A Zucchetto[2], F Buccisano[1], D Ragusa[1], F Rossi[2], B Neri[1], G D'Arena[3], L Maurillo[1], L Pupo[1], P Bulian[2], A Venditti[1], P De Fabritiis[1], S Amadori[1], V Gattei[2]

[3]Dept of Onco-Hematology, IRCCS, CROB, Rionero in Vulture (PZ), Italy

CD49d-over-expressing CLL cells demonstrate enhanced migration properties spreading in peripheral lymphoid organs, thus characterizing patients with a more advanced disease (Gattei, 2008). On the other hand, CD69 overexpression reflects ongoing *in vivo* stimulation and increased intracellular sig-

nalling, thereby explaining a more aggressive disease (Del Poeta, 2012). Moreover, up-regulation of CD69 in CLL B-cells was associated with reduced spontaneous apoptosis and drug-induced apoptosis (Ding, 2009). On this line, the actual therapeutic availability both of a humanized anti-CD49d monoclonal antibody (natalizumab) and of small pro-apoptotic molecules prompted us to evaluate CD49d and CD69 expressions in a large number of CLL cases accrued at our Institution. The primary endpoints of our study were: 1) to test the associations between CD69 or CD49d and clinical/biological features; 1) to determine time to first treatment (TTFT) and overall survival (OS) upon CD69 and CD49d; 2) to assess the additive prognostic value of CD69 and CD49d and finally 3) to confirm CD69 and CD49d as independent prognostic factors. We investigated 528 pts, median age 65 years, 294 males and 234 females. The informed consent was obtained in accordance with the declaration of Helsinki. With regard to modified Rai stages, 171 had a low stage, 338 an intermediate stage and 19 a high stage. CD49d and CD69 antigens were determined by multicolor flow cytometry (FACSCalibur, BDIS), fixing the cut-off of positivity at 30%. CD69+ and CD49d+ pts were 129/484 (27%) and 186/425 (44%), respectively. CD69 and CD49d were significantly correlated with Rai stages (P<0.0001), beta-2 microglobulin (P=0.00003 and P=0.00002) and soluble CD23 (P<0.0001 and P=0.0005). Lymphocyte doubling time > or <12 months was correlated only with CD69 (P<0.0001), while 22/26 cases (85%) with a bulky disease (>10cm) were CD49d+ (P=0.00002). Noteworthy, CLL patients with splenomegaly and/or thoracic/abdominal lymphadenopathies >3cm were more frequently CD49d+ (96/150; P<0.0001). With regard to biological findings, CD69 >30% was significantly associated with a low bax/bcl-2 ratio (P=0.0006), confirming that upregulation of CD69 means to block spontaneous apoptosis. Interestingly, CD49d >30% was significantly correlated with trisomy 12 (44/65) and del17p (10/15) [P=0.00005]. Both CD69+ and CD49d+ cases were associated with IgVH unmutated status (P=0.00004 and P=0.0007). With regard to clinical outcome, shorter TTFT (P<0.0001, Figure) and OS (P<0.0001 and P=0.001) were observed both in CD69+ and CD49d+ pts. Noteworthy, CD69 and CD49d showed additive prognostic properties, since CD49d >30% plus CD69 >30% identified a CLL subset at worst prognosis with regard to TTFT (Chi-square: 56.94; P<0.00001, Figure) and OS (Chi-square: 14.32; P=0.002). The two discordant subsets (CD69+CD49d- and CD69-CD49d+) showed an intermediate outcome. In multivariate analysis of TTFT, CD69 (P=0.0006) and CD49d (P=0.03) together with cytogenetics, ZAP-70 and IgVH status were confirmed to be independent prognostic factors. In conclusion, CD69 and CD49d over-expressions may identify two different subsets of progressive CLL patients, the first characterized by a high proliferation rate and block of apoptosis, the second mainly by a large volume of disease. Their combined flow cytometric determinations at diagnosis are useful to better characterize these progressive CLL patients, directing a more targeted therapy.

Stimulation through the B-cell receptor (BcR) is critically implicated in CLL ontogeny. However, mounting evidence suggests that other modes of stimulation, acting in concert with BcR-mediated signaling, can also be relevant. We have recently reported that different CLL subgroups defined by specific molecular characteristics of the clonotypic BcRs exhibit distinct expression profiles of the Toll like receptor (TLR) signaling pathway molecules as well as differential functional outcomes after TLR stimulation. Here, we investigated whether miRNAs could be implicated in the control of TLR and BcR signaling in CLL. Using customized cDNA arrays, we profiled negatively selected $CD19^+$ B cells from 79 CLL cases for the expression of 34 miRNAs, which were selected through bioinformatics analysis on the basis of the following criteria: (i) deregulated in CLL compared to normal B-cells; (ii) differentially expressed in CLL subgroups with distinct clinical and biological features; and, (iii) if meeting (i)+(ii), having potential targets in the BCR and TLR pathways. miR-150 displayed the higher expression level among all miRNAs studied; high expression was also recorded for 7 other miRNAs, including miR-16 and miR-29a; intermediate expression for 5 miRNAs, including miR-101; low expression for 21 miRNAs, including several members of the 17-92 cluster, miR15a and miR15b. For certain miRNAs, great variability was observed among different CLL cases, prompting us to compare miRNA profiles in subgroups of cases defined by (i) IGHV gene mutational status and (ii) BcR stereotypy. The analysis revealed significant upregulation of miR-150 and miR-223 and downregulation of miR-15a in mutated vs. unmutated CLL cases, with miR-15a showing the highest fold difference overall. Through bioinformatics search, we identified JNK as the highest scoring potential target of miR15a in the BcR and/or TLR pathways and further investigated its expression by RQ-PCR and Western Blotting. We noted a significant anti-correlation ($p<0.01$) between miR-15a levels and JNK mRNA expression levels. Furthermore, preliminary data show that mutated CLL cases express higher JNK protein levels compared to unmutated CLL cases. We next compared two different subsets with stereotyped BcRs, namely subset #1 (IGHV1/5/7-IGKV1(D)-39, unmutated) vs subset #4 (IGHV4-34/IGKV2-30, mutated). These subsets are prototypes of unmutated/adverse prognosis and mutated/good prognosis CLL, respectively, and have also been shown to exhibit distinct signalling signatures. The most pronounced difference concerned miR-101, which was found up-regulated in subset #4. miR-101 is considered as an «epi-miRNA» since it targets EZH2, which mediates transcriptional repression through histone methyltransferase activity. Interestingly, EZH2 mRNA and protein levels were found downregulated in subset #4 vs #1, indicating that miR101 is functionally competent in this setting. With this in mind, we next investigated whether it may also modulate immune signalling in these subsets. We focused on c-FOS, the highest scoring predicted target of miR101 in the BcR and/or TLR pathways, and obtained evidence for significant anti-correlation between miR101 levels and c-FOS mRNA levels, whereas no correlation existed at the protein level. In conclusion, certain miRNAs differentially expressed among CLL subgroups with distinct BcRs may modulate immune signaling, eventually affecting the biological behavior of the CLL clones.

CMV-SPECIFIC T CELL FUNCTION IS NOT IMPAIRED IN CLL

G Te Raa[1], E Remmerswaal[1], J GarciaVallejo[2], M Pascutti[1], R Van Lier[3], E Eldering[1], M Van Oers[1], A Kater[1]

[3]Sanquin Blood Supply Foundation, Division of Research, Amsterdam, Netherlands

Introduction. The interaction between CLL cells and T cells is a dynamic and reciprocal process in which the exact impact on T cell function is ill-defined. Although T cell numbers are expanded, several lines of evidence showed impaired T-cell function, reflected both in disturbed immunological synapse formation and defective cytotoxic capability. Paradoxically, clinically relevant reactivation of latent viruses such as CMV is uncommon, especially in untreated patients. Whether the general disturbed defects in T cell homeostasis and function also applies to the subset of virus-specific T cells is currently unknown. **Aims.** To study consequences of CLL tumor burden on CMV-specific T cells **Methods.** T-lymphocyte subsets; i.e. naive, memory and effector-(memory) of $CD4^+$ and $CD8^+$ cells of 32 MBL, 26 CLL and 7 age-matched healthy donors (HD) were assessed by FACS analysis. Whole blood CMV-PCR was performed on 22 untreated CLL patients (median lymphocyte count XX (range XX-XX). $CD8^+$ CMV specific cytokine production was determined by FACS analysis on intracellular IFNγ, TNFα and IL-2 production of CMV-specific T-cells, 6 hours after stimulation with EBV-positive lymphoblastoid cell line derived from normal B lymphocytes loaded with CMV-pp65 NLV peptides. Additionally, $CD8^+$ CMV specific cytotoxicity against loaded EBV-positive lymphoblastoid cells was determined by FACS. Immunological synapse formation is assessed by Image Stream analysis. **Results.** $CD4^+CD28^-CD45RA^+$/- (effector) and $CD8^+CD27^-CD45RA^+$/- (effector-memory) T cells were found to be significantly expanded only in CLL patients with a B-lymphocyte count over $10x10^9$/L. This expansion was mainly seen in patients with positive CMV+ serology. All of these patients appeared to have undetectable CMV viral loads. To study whether the intact T-cell mediated CMV responses are attributed to the reported increased quantity of functionally disturbed effector-memory type $CD8^+$ cells or that function is maintained in this subset of cells we performed cell-to-cell comparative analyses. CLL derived CMV-specific T cells were able to produce equal amounts of IFNγ, TNFα and IL2 compared to HD-derived CMV-specific T cells, provided that they were stimulated with adequate antigen-presenting cells (APC) like CMV-peptide EBV-positive lymphoblastoid cell line. Moreover, CMV-specific cytotoxicity of CLL CMV-specific T cells and HD CMV-specific T cells started to occur at E:T ratios of 1:16 in equal amounts and reached a maximum at an E:T ratio of 2:1 (specific lysis 71,8% (95%CI 61,5-82,0) and 74,0% (95%CI 66,4-81,6) respectively). Currently, both qualitative and quantitative comparison of immunological synapse formation is performed by Image Stream analysis and will be presented. **Conclusions.** In recent years, putative systemic T cell dysfunction inCLLpatients has received increasing attention. This study shows that CLL specific alterations in T-cell subsets do not follow the defined cut-off of MBL and CLL. Despite evidence for disturbed immunological synapse-formation and cytotoxicity in general in T cells, our study is the first to show that T cell mediated immunity against latent viruses remains intact in this disease.

CYTOGENETIC ABERRATIONS IN THE CD38 POSITIVE FRACTION OF CD38 NEGATIVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS: A MARKER OF AGGRESSIVENESS?

GM Rigolin[1], L Rizzotto[1], M Ferracin[2], E Saccenti[1], S Martinelli[1], L Formigaro[1], F Cavazzini[1], F Cibien[1], M Ciccone[1], G Daghia[1], C Ambrosio[1], O Sofritti[1], M Negrini[2], A Cuneo[1]
[1]Azienda Ospedaliero Universitaria Arcispedale S. Anna, Ferrara, Ferrara, Italy
[2]Dipartimento di Medicina Sperimentale e Diagnostica, Università di Ferrara, Ferr, Ferrara, Italy

Background. Chronic lymphocytic leukemia (CLL) is a disease with a high variability in clinical presentation and outcome. Even though many patients live for long periods with the disease, some cases may show a progression to a more aggressive leukemia which may be characterized by the acquisition of new genetic abnormalities either by clonal evolution or by an expansion of a clone with high risk aberrations. Prognostic parameters that correlate with worse clinical outcome include stage, the expression of CD38 and/or ZAP70, the unmutated configuration of the variable region of the immunoglobulin heavy chain gene (IGHV), the presence of specific chromosome aberrations and/or molecular mutations affecting TP53, NOTCH1, SF3B1 and BIRC3. However in patients with favourable prognostic features the biologic and molecular events leading to disease progression and the occurrence of new molecular cytogenetic lesions are largely unknown. **Aims**. We studied the biologic and clinical significance of minor cytogenetically abnormal clones in the CD38 positive fraction of untreated CLL patients with good prognostic parameters (CD38 negativity and normal karyotype or del(13)(q14) as single aberration). **Methods**. Twenty eight consecutive CD38 negative (Cd38 positive cells < 5%) CLL patients with normal karyotype or del(13)(q14) were evaluated in this study. CD38 positive and CD38 negative CLL cells were isolated by sequential immunomagnetic sorting (Dynabeads) following depletion of CD3, CD16, CD14 positive cells (purity > 99%). CD38 positive and negative cells were then analyzed by (i) FISH analysis using commercially available probes for the regions most frequently involved in CLL patients (13q14, 12q13, 11q22/ATM, 17p13/TP53, 14q32) and by (ii) micro-RNA expression. Data were then correlated with clinical parameters. **Results**. In 16/28 CD38 negative CLL patients, FISH analysis demonstrated the presence of minor (15-34% of the cells) cytogenetically abnormal clones within the CD38 positive fraction: 11q deletion in 7 cases, 17p deletion in 6, trisomy 12 in 5, 14q32 rearrangements in 1 case. According to FISH results patients were therefore classified as CLL with and without subclones in the CD38 positive fraction. By micro-RNA analysis we found that patients with subclones had a distinctive profile, when compared to patients without subclones, characterized by a downregulation of microRNA-125a-5p (a tumor suppressor in various malignancies) both in the CD38 negative and positive populations. With a median follow-up of 36 months, patients with subclones showed a higher need of treatment (9/16 cases vs 1/11 in patients with and without subclones respectively, p=0.0159). Among CLL patients with subclones, 2 cases showed the emergence of a major clone in the peripheral blood sample (45-67% of the cells) with the same genetic lesions previously observed in the CD38 positive subpopulations.ConclusionsOur data showed that genetic instability within the CD38 positive fraction of CLL patients with favourable prognostic features (CD38 negativity and normal karyotype or del13q14) may favour the growth of small clones with poor prognosis cytogenetic aberrations which may be associated with microRNA-125a-5p disregulation, clonal expansion and, in some cases, disease progression.

First line trials in chronic myeloid leukemia

Background. At 2 years of follow-up from the landmark ENESTnd study, nilotinib significantly reduced progression to accelerated phase/blast crisis (AP/BC) and demonstrated superior rates of major molecular response (MMR; ≤ 0.1% BCR-ABL^{IS}), molecular response with a 4-log (MR^4, ≤ 0.01%^{IS}) or 4.5-log (MR$^{4.5}$, ≤ 0.0032%^{IS}) reduction in BCR-ABL transcript levels vs imatinib. **Aims.** Here, we report results at a minimum follow-up of 3 years. **Methods.** A total of 846 patients with newly diagnosed Ph+ CML-CP were randomized to nilotinib 300 mg twice daily (BID) (n = 282), nilotinib 400 mg BID (n = 281), or imatinib 400 mg once daily (QD) (n = 283). MMR, MR^4, MR$^{4.5}$, time to progression to AP/BC on treatment and after discontinuation, overall survival (OS), and treatment-emergent mutation data are reported.

Table 1.

	Nilotinib 300 mg BID (n = 282)	Nilotinib 400 mg BID (n = 281)	Imatinib 400 mg QD (n = 283)
Rate of response by 3 years, %			
MMR	73 *P* < .0001	70 *P* < .0001	53
MR^4	50 *P* < .0001	44 *P* < .0001	26
MR$^{4.5}$	32 *P* < .0001	28 *P* = .0003	15
Estimated 3-year rate of freedom from progression to AP/BC, %			
On core treatment	99.3 *P* = .0059	98.7 *P* = .0185	95.2
Including events after discontinuation	98.7 *P* = .0496	98.1 *P* = .0076	93.5
Estimated 3-year rate of OS, %			
All deaths	95.1 *P* = .4413	97.0 *P* = .0639	94.0
Only CML-related deaths	98.1 *P* = .0356	98.5 *P* = .0159	95.2
Patients with BCR-ABL mutation, n			
Any mutation	11	11	21
Mutation category, n			
T315I	3	2	3
Less sensitive to nilotinib[a]	6	9	4
Other mutations[b]	2	0	14
Patients with new mutations by Sokal score, n			
Low (n = 103, 103, 104)	1	2	1
Intermediate (n = 101, 100, 101)	5	3	8
High (n = 78, 78, 78)	5	6	12
Response status, n			
Treatment failure[c]	4	6	16
Suboptimal response[c]	6	2	5
Confirmed loss of MMR[c,d]	0	2	0
Other[c,e]	1	1	0

[a] E255K/V, Y253H, and F359C/V.
[b] All mutations except E255K/V, Y253H, F359C/V, and T315I.
[c] Patients were only counted once under the worst-case response category.
[d] Loss of MMR was not considered a criterion for suboptimal response.
[e] The patient in the nilotinib 300 mg BID arm progressed after discontinuation of treatment, and the patient in the nilotinib 400 mg BID arm had an unconfirmed loss of MMR but regained MMR after that.
Confirmed cytogenetic response data were not collected after 2 years.

Results. Significantly higher rates of MMR, MR^4, and MR$^{4.5}$ were observed for both doses of nilotinib vs imatinib (Table 1). The difference in rates of MR^4 and MR$^{4.5}$ between nilotinib and imatinib increased over time. Rates of molecular response were superior for nilotinib, regardless of Sokal risk score. No new progressions occurred on treatment since the 2-year analysis. There was a significantly lower rate of progression to AP/BC on treatment for both nilotinib arms compared with the imatinib arm (n = 2, 3, and 12 in the nilotinib 300 BID, nilotinib 400 mg BID, and imatinib arms, respectively). When events that occurred both on treatment and after discontinuation were considered, the rate of progression to AP/BC remained significantly lower for both nilotinib arms compared with imatinib (n = 9, 6, and 19 in the nilotinib 300 BID, nilotinib 400 mg BID, and imatinib arms, respectively). At 3 years, OS was 95.1%, 97.0%, and 94.0% for nilotinib 300 mg BID, nilotinib 400 mg BID, and imatinib, respectively. There were significantly fewer CML-related deaths in the nilotinib 300 mg BID (n = 5) and nilotinib 400 mg BID arms (n = 4) vs imatinib (n = 14). Twice as many patients had emergent BCR-ABL mutations on imatinib (n = 21) vs nilotinib (n = 11 in each arm); 5 additional patients had emergent mutations since the 2-year analysis (1 on nilotinib 300 mg BID, 3 on nilotinib 400 mg BID , and 1 on imatinib). Mutations were more frequent in patients with high or intermediate Sokal risk, and most of these patients had suboptimal response or treatment failure. The incidence of T315I mutations was similar for the nilotinib (n = 3, nilotinib 300 mg BID; n = 2, nilotinib 400 mg BID) and imatinib (n = 3) arms. Both drugs were well tolerated. Since the 2-year follow-up, increases in hematologic/biochemical abnormalities and other adverse events have been minimal. **Conclusions.** With a minimum follow-up of 3 years, nilotinib continues to demonstrate a significantly lower rate of progression to AP/BC (both on treatment and including events after discontinuation), lower rates of mutations, and superior rates of MRs vs imatinib. These data continue to support nilotinib as a potential new standard of care in newly diagnosed patients with Ph+ CML-CP.

Background. In the ENESTnd study, nilotinib significantly reduced progression to accelerated phase/blast crisis (AP/BC) both on treatment and including events occurring after discontinuation, and demonstrated superior rates of molecular response vs imatinib. Several independent groups have conducted analyses suggesting that achievement of BCR-ABL transcript levels according to the international scale (IS) of <10% and <1% (considered as equivalent to a complete cytogenetic response) at 3 months were associated with improved outcomes. **Aims.** Based on a landmark analysis of the BCR-ABL transcript levels at 3 months, we predicted the rate of future major molecular response (MMR; ≤0.1% BCR-ABL^{IS}), and molecular response with a 4.5-log (MR$^{4.5}$, ≤0.0032%^{IS}) reduction in BCR-ABL transcript levels at later time points, and also long-term outcomes including progression to AP/BC, and overall survival (OS). **Methods.** The nilotinib 300 mg BID (n = 282) and imatinib (n = 283) arms from ENESTnd were used for this analysis. In each treatment arm, patients were grouped based on BCR-ABL transcript levels of ≤1%, >1% to 10%, or >10% at 3 months (n = 258 and n = 264 patients with available PCR samples at 3 months in the nilotinib and imatinib arms, respectively). Rates of MMR and MR$^{4.5}$ as well as rates of progression to AP/BC and OS were evaluated among patients grouped according to their BCR-ABL transcript levels at 3 months. Patients who achieved the target response within 3 months (for response outcomes) or who had events or were censored within 3 months (for time-to-event outcomes) were excluded from the respective analysis. **Results.** Among evaluable patients at 3 months, 91% of patients in the nilotinib arm vs 67% in the ima-

tinib arm achieved BCR-ABL transcript levels of ≤10%; 56% vs 16% of patients achieved BCR-ABL transcript levels of ≤1%. With either treatment, the rates of MMR by 1 and 2 years and rate of $MR^{4.5}$ by 2 and 3 years were higher in patients who achieved BCR-ABL transcript levels of ≤1% than in patients who had either >1% to 10% or >10% BCR-ABL at 3 months (Table). The initial molecular response also correlated with progression to AP/BC and with OS. Of the 187 patients who achieved ≤1% BCR-ABL at 3 months, only 1 progressed on treatment (on imatinib); 2 of 222 patients who achieved >1% to 10% progressed (both on imatinib) and 9 of 111 patients who achieved >10% at 3 months progressed (1 on nilotinib and 8 on imatinib). Patients who achieved ≤1% BCR-ABL transcript levels at 3 months had a higher OS rate than patients who achieved >10% BCR-ABL transcript levels at 3 months (3-year OS 97% and 87%, respectively, in the nilotinib arm and 95% and 85%, respectively, in the imatinib arm). **Conclusions.** More patients in the nilotinib arm vs the imatinib arm achieved BCR-ABL transcript levels ≤1% (56% vs 16%) and ≤10% (91% vs 67%) at 3 months. Early molecular response at 3 months correlated with future MMR and $MR^{4.5}$ as well as an increased probability of freedom from progression and OS.

Table 1.

Background. The golden therapeutic standard for Philadelphia positive (Ph+) chronic myeloid leukemia (CML) in early chronic phase (ECP) are tyrosine kinase inhibitors (TKIs) as single agents. Nilotinib (NIL) is a 2nd generation TKI with superior efficacy to imatinib (IM) approved as initial treatment of CML in many countries. A proportion of CML patients treated with single TKIs as monotherapy develops primary or secondary resistance. The use of more than one TKI may decrease the frequency of drug-resistance. **Aims.** To evaluate the response and the outcome of ECP Ph+ CML patients treated with the sequential administration of NIL and IM. **Methods.** A phase 2 study was conducted by the GIMEMA CML WP (ClinicalTrials.gov. NCT00769327). NIL was administered first because of faster therapeutic effect. Schedule: alternating administration every 3 months of NIL 400 mg twice daily and IM 400 mg daily; the 3-month rotation schedule was respected, irrespectively of temporary discontinuations. In case of toxicity, the patient remained in study, continuing the better tolerated drug alone. Definitions: complete cytogenetic response (CCgR) was defined as the absence of Ph+ metaphases over at least 20 metaphases examined by conventional banding analysis or <1% BCR-ABL+ nuclei over 200 nuclei examined by I-FISH; major molecular response (MMR) was defined as BCR-ABL <0,1%^{IS}; failures were defined according to 2009 ELN criteria; events included death, failure and permanent discontinuation of both drug for any reason, whichever came first. All the calculations were performed according to the intention-to-treat principle. **Results.** 123 patients have been enrolled. Median age was 56 years (range 18-84); 33% low, 45% intermediate and 22% high Sokal score; median follow-up was 27 months (minimum observation: 24 months). CCgR rates were: 72%, 79% and 75% at 3, 6 and 12 months, respectively; the cumulative CCgR rate by 12 months was 87%. MMR rates at 3, 6 and 12 months were 58%, 63% and 65%, respectively; the cumulative MMR rate by 12 months was 82%. The median time to CCgR and MMR was 3 months. At the last contact, 84% of patients were still on treatment with the study drugs, 61% with the alternating schedule, 9% on NIL alone and 13% on IM alone. The overall survival was 94%, the progression-free survival was 93%, the failure-free survival was 87% and the event-free survival 79%. The events leading to study discontinuation were: treatment failure 11%, adverse events 3%, death in chronic phase 2%, second neoplasia 1%, protocol violation 2%. Seven patients progressed to advanced phase: 3 cases with early transformation (within 6 months) developed BCR-ABL kinase domain (KD) mutations (T315 in 2 patients and Y253 in 1 patient). Four patients progressed later on (10 to 24 months) without mutations. **Conclusions.** The response rates and the short-term outcome with the sequential administration of NIL and IM are in the range of the results reported in studies of 2nd generation TKIs as single agents. A longer follow-up is required to assess the effect of this alternating schedule on the occurrence of BCR-ABL KD mutations.**Acknowledgements:** European LeukemiaNet, COFIN, Bologna University, BolognAIL

Background. The superiority of frontline nilotinib over imatinib in inducing deeper molecular responses in Ph+ chronic phase CML (CML-CP) has been demonstrated in the Evaluating Nilotinib Efficacy and Safety in Clinical Trials"'Newly Diagnosed Patients (ENESTnd) study. These deeper molecular responses observed with nilotinib may increase patients' access to tyrosine kinase inhibitor discontinuation studies in the near future. **Aims.** The ENESTcmr study is evaluating the potential benefit of switching patients with persistent residual disease on long-term imatinib therapy to nilotinib. We report herein the results with a minimum patient follow-up of 12 months. **Methods.** Patients with Ph+ CML-CP who achieved a complete cytogenetic response but had detectable BCR-ABL transcripts by real-time quantitative polymerase chain reaction (RQ-PCR) after ≥ 2 years on imatinib were eligible (N = 207). Patients were randomized 1:1 to receive nilotinib 400 mg BID (n = 104) or continue their imatinib dose (400 or 600 mg QD [n = 103]). The primary endpoint was confirmed complete molecular response (CMR; undetectable BCR-ABL by RQ-PCR with a sensitivity of ≥ 4.5 logs in 2 consecutive samples) by 12 months.

Table 1.

[b]Stratified log-rank test.

Results. Switch to nilotinib resulted in faster and higher rates of molecular response compared with remaining on imatinib. Rate of confirmed CMR by 12 months was higher in the nilotinib arm than in the imatinib arm (13% vs 6%), and CMR by 12 months was significantly higher on nilotinib vs imatinib (23% vs 11%; *P* = .02) (Table). Nilotinib induced superior rates of all levels of molecular response (MMR, MR^4, $MR^{4.5}$, and CMR) in patients without the response of interest at baseline and was associated with significantly shorter time to response than imatinib (Table 1). Among those not in MR^4 or better at baseline, significantly more patients in the nilotinib arm than in the imatinib arm achieved $MR^{4.5}$ by 12 months (23% vs 10%; *P* = .04). Furthermore, patients treated with nilotinib experienced a 0.5-log reduction in median BCR-ABL level by 12 months, whereas imatinib-treated patients had minimal evidence of improvement in molecular response (Table 1). With ≥ 12 months' follow-up, 84% of patients remained on nilotinib and 96% on imatinib. The most common reason for discontinuation was adverse events (AEs). More (9%) patients on the nilotinib arm discontinued because of AEs vs imatinib (1%), likely reflective of the fact that 80% of patients received prior imatinib for ≥ 3 yrs and patients on the imatinib arm remained on this drug. Nilotinib and imatinib were relatively well tolerated, with a safety profile consistent with prior studies. **Conclusions.** Patients with ongoing detectable BCR-ABL transcripts who were switched to nilotinib experienced faster, deeper molecular responses compared with those remaining on imatinib. These results suggest that patients with CML with residual disease on long-term imatinib therapy are likely to benefit from switching to nilotinib, especially those without an MMR on imatinib. Further follow-up is needed, and the study is ongoing.

Background. The BELA study compared the efficacy and safety of bosutinib, a dual Src/Abl kinase inhibitor, with imatinib in newly diagnosed chronic phase (CP) chronic myeloid leukemia (CML). **Aims.** The current analysis reports data after ≥24 months of follow-up; updated data including ≥30 months of follow-up will be presented. **Methods.** A total of 502 patients with newly diagnosed CP CML were randomized to bosutinib 500 mg/day or imatinib 400 mg/day and stratified by Sokal risk group and geographic region. Efficacy analyses included all randomized patients (ITT population: bosutinib, n = 250; imatinib, n = 252) or treated patients without major protocol violations who had adequate baseline and either ≥1 post-baseline assessment or disease progression/death prior to the first post-baseline assessment (evaluable population: bosutinib, n = 220; imatinib, n = 241); safety analyses included all treated patients (safety population: bosutinib, n = 248; imatinib, n = 251). **Results.** The median treatment duration was 27.5 months in both cohorts; 63% of bosutinib patients and 71% of imatinib patients were still receiving treatment at the time of this analysis. The primary reason for bosutinib discontinuation was a treatment-emergent adverse event (TEAE; 24% vs 7% with imatinib), while the primary reason for imatinib discontinuation was disease progression (13% vs 4% with bosutinib). Cumulative complete cytogenetic response rates by 24 months were 79% for bosutinib and 80% for imatinib in the ITT population, and 87% versus 81% in the evaluable population (*P* = 0.046). Cumulative major molecular response (MMR) rates by 24 months were 59% for bosutinib (16% complete molecular response [CMR], 4.0-log sensitivity) and 49% for imatinib (12% CMR) in the ITT population (*P* = 0.019). In the evaluable population, cumulative MMR rates by 24 months were 65% for bosutinib versus 51% for imatinib (*P* = 0.002). On-treatment transformation to accelerated/blast phase occurred in 4 (2%) bosutinib patients and 14 (6%) imatinib patients. Kaplan-Meier estimates of event-free survival at 24 months were 92% for bosutinib and 87% for imatinib. Deaths were reported for 7 bosutinib patients (6 due to CML progression) and 13 imatinib patients (10 due to CML progression); 24-month Kaplan-Meier overall survival estimates were 97% for bosutinib and 95% for imatinib. Bosutinib was associ-

ated with higher incidences of gastrointestinal events compared with imatinib (Table); gastrointestinal events were typically transient (eg, median duration of a diarrhea event: 3.0 days for bosutinib vs 5.5 days for imatinib). However, bosutinib was associated lower incidences versus imatinib of musculoskeletal events and edema. The most common grade ≥3 TEAEs with bosutinib were diarrhea, vomiting, and rash (Table 1). Common grade ≥3 laboratory abnormalities with bosutinib or imatinib were neutropenia (10% vs 24%), thrombocytopenia (14% vs 15%), elevated alanine aminotransferase (23% vs 4%), and hypophosphatemia (6% vs 20%). **Conclusions.** Bosutinib was effective for treatment of newly diagnosed CP CML, with higher rates of MMR and CMR than imatinib. With continued follow-up both on-treatment transformation to accelerated/blast phase and overall survival continue to favor bosutinib versus imatinib. Additionally, bosutinib and imatinib had distinct toxicity profiles.

[2]„Seràgnoli„ Institute of Hematology, Bologna, Italy
[3]GIMEMA Italian Myeloma Network, Udine, Italy

Background. The p53 tumor suppressor pathway is tightly kept in check, or completely silenced in cancer cells. A potent inhibitor of p53 is MDM4, which is critical for control of p53 activity during response to stress and is often amplified in several types of tumors. Both *TP53* mutations and del(17p) are infrequently detected in newly diagnosed MM; nevertheless they have been strongly related to patients (pts) survival. Recently, the adverse prognostic impact of chr.1q amplification has been reported in MM. **Aims.** To investigate the prognostic and biological role of del(17p) and/or amp(1q) in newly diagnosed MM pts treated with bortezomib-thalidomide-dexamethasone (VTD) as induction therapy prior to, and consolidation after, double autologous stem-cell transplantation (ASCT). **Methods.** Eighty-eight pts treated with VTD incorporated into double ASCT were analyzed by means of gene expression profile (Affymetrix U133 Plus2.0 array) and unpaired analysis of copy number alterations (CNA) (Affymetrix 6.0 SNP array). **Results.** Thirty out of 88 pts (34%) carried a minimal amplification region of 1,1 Mb on chr.1q, which harbors *MDM4*. Nine out of 88 pts (10,2%) carried a minimal deletion region of 482 Kb on chr.17, which harbors *TP53*. Pts were stratified into two subgroups according to the presence of amplified *MDM4* and/or deleted TP*53* (group A, 36 pts, or 41%) or the absence of both these abnormalities (group B, 52 pts, or 59%). Baseline clinical characteristics were homogeneous, except for a higher rate of IgA isotype in group A.Rates of best complete or near complete response were 81% and 63% in group A and B respectively, with time-to-best-response of 7.7 months (group A) vs. 12.7 months (group B) (p=0.04). Rates of relapse or progression were 58% and 27% for group A and B respectively (p=0.004), with a median progression-free survival of 39.6 months and not reached for pts of group A and B respectively (p=0.04).The average number of aberrations per group was higher in group A as compared with group B (191 vs. 117 CNAs, p =0.03). A comparison of expression profiles of the two groups of pts highlighted an overall deregulation of genes involved in response mechanisms to genotoxic stress, i.e damage sensor genes (*ATM, RAD21*), damage signal mediator genes (*CHK1, MSH2, MSH5*), genes involved in regulation of cell proliferation (*CDKN2A*, *CDC14a*) and anti-apoptotic genes (*CASP6*, *BCL6*, *TP63*) (one-way ANOVA, p <0,01). Finally, group A significantly over-express the transcription factor *YY1*, which is known to interact with p53, thus inhibiting its transcriptional activity. **Conclusions.** Pts carrying amplified *MDM4* and/or deleted *TP53* showed a significantly higher number of CNAs and the significant overexpression of genes involved in response mechanisms to genotoxic stress, as compared to pts lacking these chromosomal aberrations. This might account for the worse outcome of these group of pts. Amplification of *MDM4* locus and over-expression of *YY1* might contribute to maintain p53 in an OFF state by indirect mechanisms. Additional data on the prognostic role of both direct and indirect control of p53 will be presented during the meeting.*Supported by: Ateneo RFO grants (M.C.) BolognAIL*.

[3]Italian Multiple Myeloma Network, Gimema, Italy
[4]Division of Nuclear Medicine 2, University of Torino, AOU San Giovanni Battista, Torino, Italy

Background. Chromosome 1 abnormalities (1p deletion and 1q amplification) have been recently analyzed in MM by several Authors. However, no uniform consensus has been obtained, concerning the impact of these abnormalities on clinical outcome. Moreover, their prognostic impact have never been previously evaluated in a huge cohort of elderly newly diagnosed MM patients, but only either in relapsed/refractory or younger patients, eligible for autologous stem cell transplantation. **Aims.** To evaluate the prognostic impact of chromosome 1 abnormalities in 511 newly diagnosed MM patients, older than 65 years, randomly assigned to receive either Bortezomib-Melphalan-Prednisone-Thalidomide followed by maintenance with Bortezomib-Thalidomide (VMPT-VT, N=254) or Bortezomib-Melphalan-Prednisone (VMP, N=257). **Methods.** Samples were suitable for FISH analysis in 336/511 patients (66%). FISH was performed on bone marrow plasma cells (BMPC) purified using anti-CD138-coated magnetic beads. Nuclei from fixed PC were prepared for interphase FISH using standard **Methods.** DNA probes were used to detect 13q14, 1p36, and 17p13.1 deletions, 1qter amplification; t(4;14)(p16;q32), t(14;16)(q32;q23), t(11;14)(q13;q32). **Results.** Frequency of deletion of chromosome 13q14 and 17p13.1 and IgH translocations, and the absence of significant prognostic relevance on PFS have been previously reported by Palumbo et al (JCO 2010; 28 (34): 5101-09). Chromosome 1 abnormalities were evaluated in 278 unselected patients. In the whole cohort of patients, 1q amplification (amp1q) (3 or more copies) was observed in 130 patients (47%) and 1p deletion (del1p) was present in 24 patients (8.6%). Median follow-up was 42 months (range 1-69). The overall median PFS was 32 months. Median PFS was 29.7 months in amp1q-positive and 34.1 in amp1q-negative (p=0.219), while it was 24.6 months in del1p-positive and 33.2 in del1p-negative group (p=0.03). In all the patients median OS was not reached: the 4-year OS was 74%. The 4-year OS was 68.5% in amp1q-positive vs 78.9% in amp1q-negative group, (p=0.04) and it was 58.3% in del1p-positive vs 75.5% in del1p-negative group (p=0.02). Interestingly, in patients carrying at least one aberration of chromosome 1 (amp1q and/or del1p), the shorter OS was even more significant (p=0.005) (Figure 1). In a multivariate Cox regression model, independent predictors of shorter OS were chromosome 1 aberrations (HR, 1.69; 95% CI, 1.00 to 2.85; p=0.05), ISS stage II vs I (HR, 2.37; 95% CI, 1.09 to 5.14; p=0.03) and ISS stage III vs I (HR, 2.72; 95% CI, 1.20 to 6.18; p=0.02), regardless of treatment.**Conclusions** Our results suggest that chromosome 1 abnormalities are an independent poor prognostic factor for OS in MM patients treated with novel Bortezomib-based regimens. A longer follow-up is needed to confirm the significant relevance of these results.

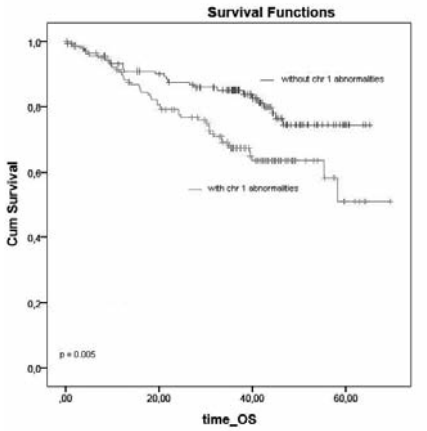

Figure 1. Kaplan-Meier curve for the OS according to chromosome 1 abnormalities.

[2]Masaryk University, Faculty of Science, Brno, Czech Republic

Background. Multiple myeloma (MM) is an incurable plasma cell malignancy, a heterogeneous disorder with incompletely understood molecular defects and variable clinical manifestations. Genome of malignant plasma cells (PC) is extremely unstable, characterized by a combination of complex structural and numerical abnormalities. Centrosome amplification (CA) is supposed to be one of mechanisms leading to chrosomal instability. Also, CA is associated with deregulation of cell cycle, mitosis, DNA repair and proliferation. As CA is common in all plasma cell stages including MGUS, it is therefore an early event in MM and can serve as a source of genomic instability. **Aims.** The objective of our study was to evaluate clinical impact of CA as well as its association with changes in expression of genes involved in centrosome structure/function in MM. **Methods.** A total of 216 patients were evaluated for this study. Patients' baseline characteristics were as follows: males/females (122/94), median age of 67.5 years (range 40-85 years). Newly diagnosed (123/216) and relapsed (93/216) patients were included in this study; most of them had advanced stage of MM (D-S II/III 84% [181/216]; ISS II/III 60% [129/216]). CD138+ cells were separated by MACS. Immunofluorescent labeling of centrin was used for evaluation of centrosome amplification (CA) in PCs. Interphase FISH with cytoplasmic immunoglobulin light chain staining (clg FISH) and qRT-PCR (113/216) were performed on PCs. **Results.** Based on immunofluorescent staining results, all newly diagnosed patients were divided to CA positive (40%) and CA negative (60%). MM related early death in two years after diagnosis was significantly higher in CA negative group 19% (6/32) vs 0% (0/29) in CA positive (*P*=0.032). Also, worse OS was indicated in CA negative patients (44/73) in comparison with CA positive patients (29/73) (*P*=0.029). Group of newly diagnosed MM patients showed significant differences in relative quantification coefficient R of the following genes: *AURKB*, *PLK4* and *TUBG1* between CA positive (n=13) and CA negative (n=18) groups of patients (p<0.05).Total of 85% of qRT-PCR samples (96/113) were available for further analyses. Gene expression in newly diagnosed (61/96) and relapsed (35/96) patients showed significant changes of the following (A*URKA, AURKB, CCNB1, CCNB2, CETN2, HMMR, PLK4, PCNT* and *TACC3.* All mentioned genes were upregulated in PC population of relapsed patients (p<0.05).Expression of genes connected with centrosome formation and function was significantly different between HY (25/54) and non-HY (29/54) myeloma patients. *AURKA* was upregulated in non-HY group, while *AURKB* and *PLK4* were upregulated in HY. **Conclusions.** Considering revealed clinical and gene expression heterogeneity between CA negative and CA positive patients, there is a possibility to characterize them as notable event in multiple myeloma pathogenesis. Centrosome abnormality as well as aneuploidy is spatially and timely tightly linked to the cell cycle disruption; CA triggers spindle checkpoints, leading to mitotic catastrophe and accumulation of genomic abnormalities during disease progression in MM. **Acknowledgments.** This work was supported by grants: NT11154, NT12130, MSM0021622434 and by project GAP304/10/1395.

Background. The International Staging System (ISS) and the cytogenetic profile are the most relevant disease-related prognostic factors. The benefit of complete response (CR) in patients with standard or high-risk disease is still a matter of debate. **Aims.** The primary objective of our study was to compare overall survival (OS) and progression-free survival (PFS) of newly diagnosed elderly myeloma patients who achieved CR with those who achieved very good partial response (VGPR) or partial response (PR) after a bortezomib-based regimen. We tested the hypothesis that benefit of CR could vary in different subsets of patients defined according to ISS stage and cytogenetic profile. **Methods.** Newly diagnosed patients included in the GIMEMA-MM-03-05 and the GEM05MAS65 trials were analysed. Details on treatment regimens and results of these studies have previously been reported. Data were pooled together and stratified according to best response achieved. Univariate and multivariate analyses of OS and PFS were performed. Response was treated as time-dependent variable. Landmark analysis with landmark point at 12 months was performed. **Results.** A total of 771 patients were retrospectively analysed. Best response was available in 751 patients: CR was reported in 267 (36%), VGPR in 141 (19%), PR in 242 (32%). Baseline demographics and disease characteristics, including median age, ISS and FISH abnormalities [presence of t(4;14) or t(14;16) or del17p] were similar in patients who obtained CR, VGPR, PR.After a median follow-up of 3 years, the 3-year OS and PFS for all patients were 75% and 30%, respectively. The 3-year OS was 94% in CR patients compared to 86% in VGPR patients (HR 0.30, 95%CI 0.16-0.52, P<0.001). The 3-year PFS was 68% in CR patients compared to 28% in VGPR patients (HR 0.18, 95%CI 0.12-0.28, P<0.001). Subgroup analyses showed that 3-year OS was 86% in patients with ISS stage I, 77% in patients with stage II (HR 0.68, 95%CI 0.46-1.02, P=0.064) and 67% in patients with stage III (HR 0.49, 95%CI 0.32-0.75, P=0.001). In CR patients, 3-year OS was 98% in patients with ISS stage I, 94% in patients with stage II (HR 0.66, 95%CI 0.23-1.89, P=0.434) and 93% in patients with stage III (HR 0.47, 95%CI 0.47-1.39, P=0.171). Similarly, 3-year OS was 76% in patients with standard-risk compared to 65% in patients with high-risk cytogenetic profile (HR 0.65, 95%CI 0.47-0.91, P=0.013), but in CR patients 3-year OS was 94% and 90% in the standard and high-risk group, respectively (HR 0.66, 95%CI 0.29-1.50, P=0.317). In multivariate analyses the achievement of CR was the dominant factor associated with significantly longer OS as compared with VGPR (HR 0.24, 95%CI 0.10-0.55, P<0.001). **Conclusions.** Achievement of CR is a stronger predictor of survival than ISS and cytogenetic profile in patients treated with bortezomib.

ARE WE MAKING PROGRESS? SURVIVAL IN PLASMA CELL MALIGNANCIES IN THE ERA OF NOVEL TREATMENTS A POPULATION BASED STUDY OF 17.790 PATIENTS IN THE NETHERLANDS

S Verelst[1], H Karim-Kos[2], H Blommestein[3], P Sonneveld[4]

[1]Erasmus Medical Center, Rotterdam, Netherlands

[2]Comprehensive Cancer South, Eindhoven Cancer Registry, Eindhoven, Netherlands

[3]Erasmus University, institute for Medical Technology Assesment, Rotterdam, Netherlands

[4]Erasmus Medical Center, department hematology, Rotterdam, Netherlands

Background. Over the last two decades, the use of High-dose Melphalan (HDM) and the development of novel agents like thalidomide, lenalidomide and bortezomib has changed the management of patients with plasma cell malignancies (PCM) dramatically and extended overall survival.Most results on survival improvement have been generated in randomized clinical trials. However, data from trials refer to a selected subgroup of patients that does not necessarily correspond to the general patient population.AimWe retracted data available from the Dutch Cancer Registry from 1989-2009 in order to get insight into recent and long term trends in survival in unselected patients treated with conventional and novel agents.MethodWe included all adult patients with plasma cell malignancies (i.e. multiple myeloma (MM), plasma cell leukaemia (PCL) and Plasmacytomas; both solitary bone (SP) and extramedullary (EP)), newly diagnosed during 1989-2009 in the Netherlands (n=17.790) We categorized patients into 4 treatment cohorts: 1989-1993:pre-HDM and autologous stem cell transplantation (AutoSCT), 1994-1998:routine use of HDM and ASCT, 1999-2003:thalidomide use for relapsed/refractory patients and 2004-2009: thalidomide use first line. Follow up was completed up to January 1st, 2010. Annual incidence rates were calculated per 100.000 person-year.. Relative survival, which can be interpreted as disease-specific survival within a cancer patient population was derived as the ratio of observed survival of the patients and the expected survival of a comparable age- and sex matched group of the underlying general population. **Results.** 16.822 patients with MM, 111 with PCL, 522 with SP and 335 with EP were diagnosed during 1989-2009. The incidence of PCM increased from 4.3 per100,000 in1989 to4.8 in2009 (estimated annual percentage change (EAPC) 0.4%). Among the subgroups MM and EP there was a trend of increasing incidence, but only for SP and PCL it rose significantly (Table 1). Five-year relative survival significantly improved for all patients with PCM from 30% in 1989-1993 to 39% in 2004-2009(p<0.001). Among the subgroups, significant survival improvement was observed for MM and SP patients(MM: from 28% in 1989-1993 to 37% in 2004-2009; SP: from 59% to 75%, respectively). Most substantial increase in MM survival was observed in patients up to 59 years of age, less pronounced for patient up to 70, while survival did not improve for patients above 70 and even decreased for patients 80+ years. Five-year relative survival decreased slightly for all EP patients from 84% to 70%, although not significant(p=0.44). For PCL patients, survival remains very poor with 1-year relative survival about 40%. However, patients below 65 had a better survival than patients aged 65 and over (in 1989-2009 59% versus 24%).ConclusionAccording to our population based study the incidence of PCM increased during the last two decades. Survival decreased for all patients with EP, remained stable for Patients with PCL but improved significantly for patients with SP and patients with MM up to 70 years. Survival improvement is observed after high-dose therapy and AutoSCT became treatment of choice for younger patients and thalidomide use for the elderly.

Table: age-standardized incidence rates of plasma cell malignancies by subgroup and calander period of diagnosis and estimated annual percentage changes (EAPC)

	age standardized incidence rates

GENETIC ANALYSIS OF PATIENTS WITH LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS REVEALS RECURRENT SRSF2 MUTATIONS WHICH ARE ASSOCIATED WITH ADVERSE OUTCOME

S Zhang[1], R Rampal[2], T Manshouri[3], J Patel[2], N Mensah[2], A Kayserian[2], T Hricik[2], A Heguy[2], C Hedvat[2], H Kantarjian[3], M Gönen[2], R Levine[2], O Abdel-Wahab[2], S Verstovsek[3]
[1]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China
[2]Memorial Sloan-Kettering Cancer Center, New York, United States of America
[3]MD Anderson Cancer Center, Houston, United States of America

Background. Myeloproliferative neoplasms (MPNs) are chronic, clonal hematopoietic stem cell disorders, individually carrying a risk of morbidity and mortality, including thrombosis,bleeding, and progressive bone marrow fibrosis.Importantly, a substantial proportion of patients with polycythemia vera (PV), essential thrombocytosis (ET) or primary myelofibrosis (PMF) transform to acute myeloid leukemia (AML).Leukemic transformation (LT) from a pre-existing MPN carries a dismal prognosis.Recently, a series of novel genetic alterations in multiple genes encoding members of the spliceosome including SRSF2 was identified. **Aims**. To determine the frequency of somatic alterations in known myeloid disease alleles in MPN patients with LT, and to identify recurrent somatic mutations in the SRSF2 gene in LT after MPN.

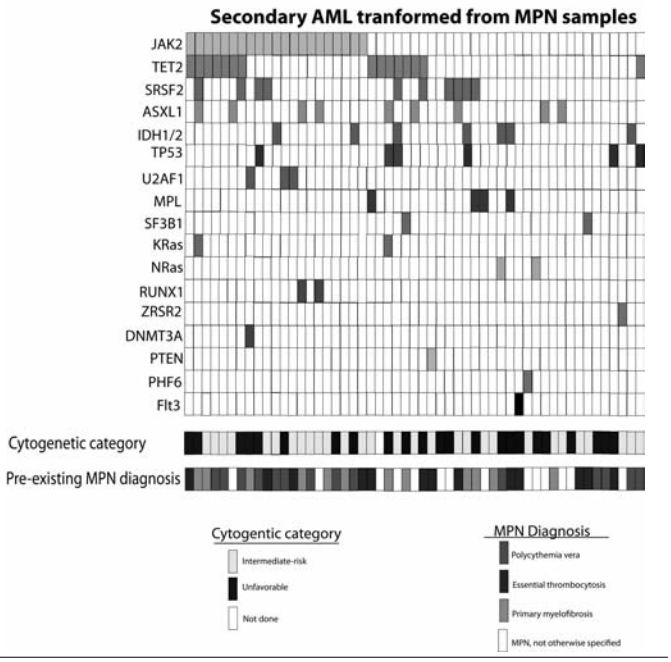

Figure 1. Distribution of mutations amongst patients with acute myeloid leukemia (AML) derived from a myeloproliferative neoplasm (MPN).

Methods. DNA was acquired from 53 patients with AML transformed from an antecendent MPN, 54 patients with *de novo* AML, and 42 patients with AML transformed from MDS.Of the 53 patients with LT of an MPN, 17 samples from the paired chronic phase MPN state were also available for analysis. DNA resequencing of all coding exons of known mutations in JAK2, MPL, IDH1, IDH2, FLT3, c-KIT, K/N/H-Ras, U2AF1, SF3B1, and SRSF2 and full length sequencing of GATA2, RUNX1, EZH2, WT-1, DNMT3a, TP53, TET2, ASXL1, PTEN, and ZRSR2 were performed in all secondary AML and paired MPN samples. Standard statistical methods were used for parameter comparison and survival curves were prepared by the Kaplan-Meier method and compared by the log-rank test. **Results.** Mutations in *JAK2, TET2, SRSF2,* and *ASXL1* are the most commonly mutated genes in this subset of disease. Furthermore, mutations in *SRSF2* are specifically enriched in patients with LT of MPNs compared with patients with *de novo* AML, chronic MPNs, or LT of MDS (p=0.05, two-tailed, Fisher's exact test). In addition, our analysis identified previously unreported somatic mutations in *U2AF1, SRSF2,* and *ZRSR2 in patients with MPN, MDS, and sAML/AML*. Mutational analysis of paired samples from 17 patients with chronic phase MPN who subsequently transformed to AML revealed that mutations in genes outside of the *JAK-STAT* pathway (not in *JAK2* or *MPL*) were significantly enriched in patients at the time of LT compared with the chronic MPN state (average of 1.2 mutations in LT versus 0.6 mutations/sample in chronic phase; p<0.02, Mann-Whitney U test). Correlative univariate analysis of the four most commonly mutated genes revealed that mutations in *SRSF2,* but not in *JAK2, TET2, or ASXL1,* were associated with worsened overall survival in patients with AML derived from MPNs (p=0.0309, HR 2.77 (95% CI 1.10-7.00). The adverse association of *SRSF2* mutations to overall survival was independent of age and cytogenetic risk classification in multivariate analysis (p=0.049, HR 2.11 (95% CI 1.01-4.42). **Summary and Conclusions.** *SRSF2* mutations are associated with adverse outcome in AML after MPN and can be detected in the chronic phase of MPN patients who transform to AML suggests that *SRSF2* mutations may predict for disease progression in MPNs and represent an important event leading to subsequent acute leukemic transformation.

PERTURBATION OF FETAL HEMATOPOIESIS IN A MOUSE MODEL OF DOWN SYNDROME TRANSIENT MYELOPROLIFERATIVE DISORDER

Y Birger[1], L Goldberg[1], J Jacob-Hirsch[1], S Izraeli[2]
[1]Sheba Medical Center, Ramat Gan, Israel
[2]Sheba Medical Center, Tel Aviv University, Tel Hashomer, Israel

Background. Fetal and adult hematopoiesis differ by unique gene expression profiles, transcription factor interactions and the presence of specific hematopoietic progenitors. In Down Syndrome (DS), fetal liver hematopoiesis is impaired and characterized by hyper-proliferation of megakaryocytic-erythroid progenitors (MEPs). The ETS transcription factor ERG coded by a gene on chromosome 21 has been one of the candidate oncogenes driving this abnormal proliferation. ERG regulates fetal hematopoietic stem cell maintenance and definitive hematopoiesis. It is expressed in megakaryocyte and erythroid progenitors and is down-regulated upon their differentiation. Its involvement in the DS hematological disorders is supported by a recent study showing that reversing ERG trisomy to functional disomy in the Ts65Dn mouse model corrected the hematological abnormalities in these mice. In About 5% of DS fetuses acquired mutations in *GATA1,* an x-chromosome gene, causing the formation of a shorter protein (GATA1s) lacking GATA1 amino terminal, lead to a congenital transient myeloproliferative disorder (TMD). GATA1s knock-in mice display transient proliferation of immature fetal megakaryocytic progenitors. We previously showed that ERG collaborates with GATA1s to immortalize fetal liver progenitors to generate AMKL. Developmental cooperation between ERG and GATA1 has been also suggested by demonstrating their co-binding to regulatory elements of key hematopoietic transcription factors such as Scl/Tal1. **Aims.** Our goal is to model DS TMD by studying the role of two key regulatory transcription factors, ERG and mutated GATA1, in fetal hematopoiesis and their involvement in generating the hematological abnormalities of DS. **Methods.** To test the hypothesis that ERG and GATA1s cooperate in initiating events of DS TMD, we created transgenic mice expressing the human ERG3 isoform under the Vav promoter, and crossed them with GATA1s Knock-in mice. **Results.** Similar to DS fetuses, ERG Tg mice displayed marked expansion of fetal liver MEPs. This phenotype was enhanced by GATA1s. Both proteins cooperated in enhancement of transient fetal megakarypoiesis. Gene Set Enrichment Analysis (GSEA) demonstrated that the expression profile of fetal liver hematopoietic cells expressing both ERG and GATA1s is significantly enriched with DS-TMD signature genes, suggesting that the biological events occuring in the double transgenic mice are similar to those in the human TMD state.The most profound observation was the almost complete block in primitive erythropoiesis causing the embryonic death of most ERG/GATA1s males. Detailed analysis of primitive erythropoiesis in GATA1s knock-in male embryos (lacking the normal GATA1), revealed markedly decreased formation of BFU-E colonies, dramatic drop in TER119 positive erythroid cells, arrest in erythroid differentiation and increased apoptosis of erythroid cells. These phenotypes were markedly enhanced in double transgenic ERG/GATA1s embryos. The cellular phenotypes were accompanied by decreased expression of erythroid and pro-survival genes such as EPOR, LMO2, KLF1 and Mcl1. **Summary and Conclusions.** We show here that interactions between ERG and GATA1s cause expansion and proliferation of fetal megakaryocytic - erythroid progenitors establishing a fetal TMD like disorder. We further demonstrate a critical role for the amino-terminal domain of GATA1 in primitive erythropoiesis and show that decreased ERG expression is required for terminal erythroid differentiation.

[10]Unité INSERM U940, Hôpital Saint-Louis, Paris, France

Background. Noonan syndrome (NS) is an autosomal dominant developmental disorder characterized by the hyperactivation of the RAS-MAPK signaling pathway. In about 40% of cases, a germline mutation in the *PTPN11* gene, encoding the protein tyrosine phosphatase SHP-2, is found. These patients are predisposed to develop a childhood myeloproliferative-myelodysplastic syndrome, the juvenile myelo-monocytic leukemia (JMML). Whereas sporadic JMML is known to be aggressive and to have a poor prognosis, JMML occurring in patients with NS is often considered as a benign and spontaneously resolutive "JMML-like"condition. However, few data are available. **Aims.** We investigated the incidence, genetics and clinical course of myeloproliferative disorders in a large cohort of patients centrally diagnosed with NS in our national reference center. **Patients and Methods.** A cohort of 562 patients carrying a germline mutation of *PTPN11* has been studied. JMML was diagnosed in 21/562 (3.7%) of them (NS-JMML). In 11 other patients (2.0%), hematologic anomalies suggestive of a myeloproliferative-myelodysplastic syndrome have been noted. Cytologic, genetic and clinical features of these 2 groups of patients have been compared with data of 24 patients presenting a *PTPN11*-associated sporadic JMML. **Results.** Hematologic anomalies are found in 32/562 (5.7%) of NS patients and encompass a broad phenotypic spectrum ranging from transient myeloproliferative-myelodysplastic syndrome to JMML. Cytological characteristics of the NS-MPD, NS-JMML and sporadic JMML are similar and *in vitro* endogenous growth of myeloid progenitors is observed in all patients. Conversely, clinical presentation differs between the 3 groups. Median age of onset is earlier in NS patients (neonatal versus 34 months in sporadic JMML). Clinical course of the NS-JMML group may be as aggressive as the sporadic JMML or may resolve progressively, whereas NS-MPD patients have a spontaneously favorable outcome. Among NS patients, 3 have recovered a normal peripheral monocyte count but remain thrombocytopenic throughout follow-up. The one-year overall survival is 100% in NS-MPD group versus only 48% in NS-JMML and 60% in sporadic JMML patients. Notably, boys seem to have a more unfavorable evolution than girls. The D61H mutation of *PTPN11*, never reported in NS, is found in 2 patients with a particularly severe neonatal course. More generally, the spectrum of *PTPN11* mutations is narrower in NS-MPD and NS-JMML patients than in the whole cohort of NS patients, with an increased incidence of mutations in codons 61, 139 and 506. Karyotype and SNP array analysis on 12 NS-JMML patients reveal fewer additional genetic alterations than in sporadic JMML patients. **Conclusions.** Some *PTPN11* mutations are associated with an increased risk of JMML. This genotype-phenotype correlation is confirmed by functional studies on iPS cells derived from 2 of our NS-JMML patients (B Gelb, unpublished). However, the risk of developing MPD or JMML cannot be fully predicted by the underlying *PTPN11* mutation since only a fraction of patients with a given mutation will develop an hematological disease. This suggests that additional factors, possibly gender-related, cooperate with the germline mutation to drive leukemogenesis.

0596

A NOVEL GERMLINE JAK2 MUTATION IN FAMILIAL THROMBOCYTOSIS

E Rumi[1], A Ashot Harutyunyan[2], D Daniela Pietra[1], C Chiara Elena[1], I Ilaria Casetti[1], T Thorsten Klampfl[2], T Tiina Berg[2], F Francesco Passamonti[3], R Robert Kralovics[2], M Mario Cazzola[1]
[1]Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy
[2]Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria
[3]Division of Hematology, A.O. Ospedale di Circolo e Fondazione Macchi, Varese, Italy

Background. Myeloproliferative neoplasms (MPN), including polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF) have in most instances a sporadic occurrence. However, familial clustering of MPN has been reported. Common mutations involved in the pathogenesis of MPN such as *JAK2* V617F, *MPL*, *CBL*, and *TET2* mutations are not inherited, but somatically acquired also in familial cases. Germline mutations underlying familial syndromes resembling MPN have been reported. In particular, germline mutations in thrombopoietin (*THPO*) and thrombopoietin receptor (*MPL*) gene have been shown to be responsible for hereditary thrombocytosis.Recently two cases of isolated thrombocytosis associated with novel *JAK2* germline mutations (R564Q and V617I) were reported. **Aims.** In an attempt to identify the germline genetic factors that underlie familial clustering of MPN we applied next generation sequencing to our MPN families. **Methods.** Our cohort of 61 MPN families was analyzed with two strategies. First we applied whole exome sequencing (Illumina instrument) in a subgroup of 16 families with MPN. As this approach resulted in the identification of a novel germline *JAK2* mutation other than V617F in one family, next we sequenced all exons of *JAK2* gene by PCR-based next generation sequencing in the remaining 45 families. Variants were validated by Sanger sequencing. All samples were collected after subjects gave their written informed consent. We used as control population 197 Italian subjects with normal hemogram or a hematological reactive condition. *Results* Exome sequencing resulted in the identification of a novel germline *JAK2* mutation in a pedigree with assumed diagnosis of familial ET. The proband (grandmother, MPC07-116) carried a heterozygous missense mutation (CAT>AAT, chr 9:5073743) of *JAK2* gene, causing a substitution of histidine with asparagine at position 608 (H608N) in granulocytes and T lymphocytes (Figure 1). The mutation was found also in the mother (58), both in granulocytes and in T lymphocytes, thus confirming segregation of the *JAK2* H608N germline mutation with the disease phenotype. The grandson (MPC07-115), a 17-years old male, was a carrier of the *JAK2* H608N germline mutation, as his mother and his grandmother, but he had not yet an overt thrombocytosis. The PCR-based next generation sequencing of the *JAK2* gene in the remaining 45 MPN families did not identify the *JAK2* H608N in any affected member. We did not find H608N in any of the public databases (dbSNP135, 1000 Genomes Project, Exome Variant Server) nor in the Italian control population, thus excluding the suspect of a polymorphism. The novel H608N mutation mapped in exon 14, as the classic V617F mutation. Histidine 608 belongs to the JH2 domain of JAK2 protein, involved in the inhibition of the JH1 kinase activity. **Conclusions.** *JAK2* germline mutations like H608N might account for some cases of familial ET that are indeed cases of hereditary thrombocytosis.

Background. Dysregulation of the JAK-STAT pathway is a central component in the pathogenesis of myelofibrosis, a myeloproliferative neoplasm characterized by splenomegaly, debilitating symptoms, cytopenias, and shortened survival. Ruxolitinib, a JAK1/JAK2 inhibitor, has demonstrated clinical benefit as therapy for patients with myelofibrosis. **Aims.** To explore the safety and efficacy of ruxolitinib in patients with myelofibrosis and low platelet counts, where clinical data are limited. **Methods.** In this phase II study (NCT01348490), patients with intermediate-1 to high risk myelofibrosis and platelet counts of 50-100x10^9/L started ruxolitinib at 5 mg twice daily (BID). Doses could be increased in 5 mg once daily increments every 4 weeks beginning at week 4. Doses were decreased or held for platelet counts <35x10^9/L or <25x10^9/L, respectively. Assessments included Total Symptom Score (TSS, using the modified Myelofibrosis Symptom Assessment Form v2.0, and comprised of scores from 0=absent to 10=worst imaginable for night sweats, itching, bone/muscle pain, early satiety, abdominal discomfort and pain under left ribs); Patient Global Impression of Change (PGIC, a 7-point scale ranging from "very much improved"to "very much worse"); spleen size by palpation and by MRI (data not yet available); and safety. All patients provided written informed consent. **Results.** At the time of analysis, 23 patients had completed ≥4 weeks on study. At baseline, median platelet count was 65x10^9/L, median spleen length was 16.0 cm, and median TSS was 24.5. According to the Dynamic International Prognostic Scoring System classification, 4% were high risk, 52% intermediate-2 risk, and 44% intermediate-1 risk. At the time of analysis, 40%, 26%, 26%, and 4% of patients were receiving ruxolitinib 5 mg BID, 5 mg AM/10 mg PM, 10 mg BID, and 10 mg AM/15 mg PM, respectively. At week 7, one patient (4%) was decreased to ruxolitinib 5 mg once daily for platelet count <35x10^9/L. At week 4 (all patients on ruxolitinib 5 mg BID), mean TSS improved 14%, and 13% of patients had ≥50% improvement. At week 8 (52% on ruxolitinib 5 mg AM/10 mg PM), mean TSS improved 23%, and 30% of patients had ≥50% improvement. Mean spleen length reductions of 22% (week 4) and 27% (week 8) were observed, and PGIC scores of "much improved"or "very much improved"were reported in 35% (week 4) and 39% (week 8) of patients. There were no Grade 4 thrombocytopenia events, no dose holds for adverse events, and no discontinuations from the study; one packed red blood cell transfusion-dependent patient had Grade 4 anemia. Three patients experienced a total of 4 serious adverse events (fever; hypnagogic dreams; spleen pain, pneumonitis) which resolved while on treatment. **Summary and Conclusions.** Effects on spleen size, PGIC, and TSS, even over the first weeks of ruxolitinib treatment when doses were low, are superior to those observed in the placebo group from the COMFORT-I study. These preliminary findings suggest that a dosing strategy starting with ruxolitinib 5 mg BID with subsequent dose optimization may be efficacious and well tolerated in patients with myelofibrosis who have low platelet counts. *Supported by Incyte Corporation.*

SELECTIVITY OF ANTIGEN RECEPTORS IN SPLENIC MARGINAL-ZONE LYMPHOMA: FURTHER EVIDENCE FROM THE IMMUNOGLOBULIN LIGHT CHAIN GENE REPERTOIRE

V Bikos[1], E Stalika[1], P Baliakas[2], N Darzentas[3], Z Davis[4], A Traverse-Glehen[5], A Dagklis[6], G Kanellis[7], A Anagnostopoulos[2], A Tsaftaris[1], M Ponzoni[8], F Berger[5], P Felman[5], P Ghia[6], T Papadaki[7], D Oscier[4], C Belessi[9], K Stamatopoulos[2]

We recently demonstrated that over 30% of cases with splenic marginal-zone lymphoma (SMZL) express B cell receptors (BcRs) that utilize a single polymorphic variant of the IGHV1-2 gene (IGHV1-2*04). These IGHV1-2*04 receptors carry distinctive antigen-binding sites and also exhibit a low impact of somatic hypermutation (SHM), albeit with preferential targeting of certain positions of the VH domain. These molecular features argue for selection by (super)antigenic element(s) in the pathogenesis of at least a subset of SMZL; in addition, they indicate heavy chain dominance in the clonogenic IG receptors of SMZL. That notwithstanding, the possibility that immunoglobulin (IG) light chains might also play an important role in SMZL ontogeny needs to be investigated, in view of their relevant role in normal, autoreactive and malignant B-cell clones. In order to address this issue, we systematically explored the IG light chain gene repertoire in 114 productive VJ rearrangements from 108 SMZL cases.Seventeen functional IGKV genes were identified in 83 IGKV-J rearrangements; IGKV3-20 was the most frequent gene (20/83 cases, 24%), followed by IGKV4-1 (13/83, 15.7%) and IGKV1-39, IGKV1-5, IGKV1-8/1D-8 (10 cases each, 12%). Collectively, the aforementioned IGKV genes accounted for 76% of all IGKV-J rearrangements. Fourteen functional IGLV genes were identified in 31 IGLV-J rearrangements; IGLV2-14 predominated by far (10/31, 32%). Accordingly, the IG light chain gene repertoire of SMZL is remarkably biased, in analogy to the corresponding IG heavy chain gene repertoire.Based on the percentage of IGKV/IGLV gene identity to the germline (GI), 21/114 sequences (18.5%) were assigned to a truly unmutated subgroup (100% GI), whereas the remaining sequences (93/114, 81.5%) exhibited some impact of SHM activity, ranging from minimal to pronounced. Sequences with 97-99.9% GI were classified as borderline/minimally mutated (n=61, 53.5%), whereas those with <97% GI as significantly mutated (n=32, 28%). Overall, the distribution of IG light chain sequences with regards to SHM status recapitulated what we observed in SMZL heavy chains, implicating a similar impact of SHM on both heavy and light chains.Focusing on the subgroup of 17 IGHV1-2*04 cases with available IG light chain sequence information (19 productive rearrangements), we obtained clear evidence for biased usage of two light chain genes, namely IGKV3-20*01 (6/19 cases, 32%) and IGKV1-8*01 (5/19, 26%). In these pairs, as for the heavy chain (IGHV1-2*04), also the light chain genes (IGKV3-20*01 or IGKV1-8*01) were borderline/minimally mutated. Interestingly, in the case of IGKV3-20*01 sequences, shared (stereotyped) somatic mutations were identified, with IMGT codons CDR1-37 and FR3-66 emerging as hotspots for recurrent, conservative amino acid changes.In conclusion, the present study indicates a complementary role of light chains in shaping BcR specificity and provides further evidence for the highly selective nature of the IG repertoire in SMZL. The restricted molecular features of the IG light chains in the IGHV1-2*04 subgroup may reflect an antigen-driven immune pathway to lymphoma development and further support our recent claims for the existence of distinct subtypes of SMZL defined by immunogenetic analysis.

ONCOGENETIC PATHWAYS IN FOLLICULAR LYMPHOMA REVEALED BY INTEGRATIVE GENETIC ANALYSES IN SEQUENTIAL BIOPSIES

M Eide[1], O Lingjærde[2], K Huse[1], M Hystad[3], G Trøen[4], H Holte[5], J Delabie[4], E Smeland[1]
[1]Oslo University Hospital, Institute for Cancer Research, Oslo, Norway
[2]University of Oslo, Department of Informatics, Oslo, Norway
[3]Statens Legemiddelverk, Oslo, Norway
[4]Oslo University Hospital, Department of Pathology, Oslo, Norway
[5]Oslo University Hospital, Department of Oncology, Oslo, Norway

Background. Genomic imbalances occurring secondary to the translocation t(14,18) are common in follicular lymphomas (FLs), and some are associated with prognosis. Unveiling of transcriptional programs that are affected by gene dosage may provide new insight to the pathogenesis of FL and clues to new treatment approaches. **Aims.** To identify genes and signaling pathways involved in FL pathogenesis and disease progression.

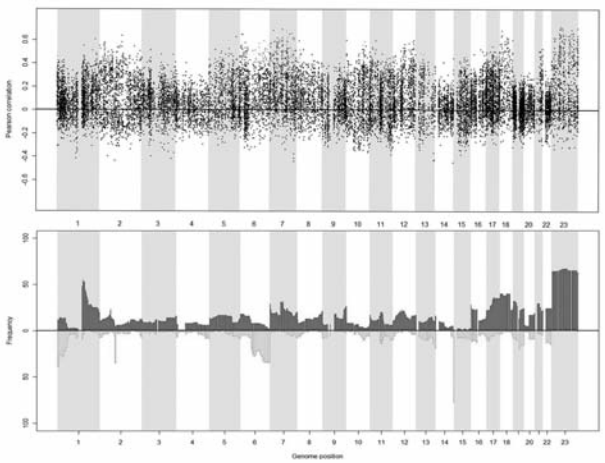

Figure 1 Upper panel: For each of the 21k genes the correlation coeffecients (r) for the relationship between DNA copy number and gene expression levels are plotted according to the respective genomic positions. The 699 genes with r > 0,4 and p < 0.05 are colored red and green according to their location within regions of genomic gains and losses, respectively. **Lower panel:** The frequency of genomic gains (red) and losses (green) in the 100 serial biopsies of FL are plotted according to genomic position. Comparison of the upper and lower panel clearly shows the predominance of positive correlations within frequently aberrant regions.

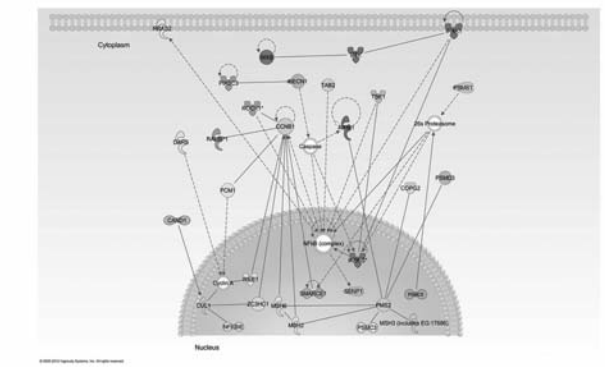

Figure 2: The top interaction network identified by Ingenuity Pathway Analysis (IPA) of the 699 genes showing a highly significant realtionship between DNA copy number and gene expression levels. Thirty-one of the 699 genes participate in the network. Genes colored red and green are located within regions of genomic gains and losses, respectively. The color shading indicates the frequencies of the respective genomic aberrations, with stronger color representing more frequent aberrations.

Methods. The study material consisted of 100 sequential biopsies from 44 patients, including 74 FL grade 1-2, 17 FL grade 3a and 9 FL with various proportions of DLBCL. Twenty-seven cases transformed to DLBCL during the disease course (median observation time 84 months). Seventeen cases never transformed (median observation time 97 months).Whole-genome gene expression profiles were obtained using Affymetrix HG U133 Plus 2.0 Gene Chip in 81 of the sequential biopsies, originating from 41 of the patients. Probes associated with the same gene identifier were averaged to obtain a unique expression value for each gene. The original 51013 probe values were thus reduced to 21485 gene expression values and these were mapped to their respective genomic positions. Whole-genome copy number profiles were obtained for all 100 sequential biopsies using a custom-made BAC/PAC array with a resolution of ~1Mb, and 3091 good-quality probes were used for analysis. The piecewise constant fit (PCF) method was used to segment the raw copy number data and to obtain fitted copy number values (PCF values) for the 3091 probes as well as for the 21k expression probes described above. PCF values above 0.05 were called as gains, and PCF values below 0.05 were called as losses.To robustly assess the effect of copy number on gene expression, two methods were applied. First, the Pearson correlation coefficient between copy number and gene expression in the 81 sequential biopsies was calculated. Second, we grouped the samples for each gene into gain vs. wild type (resp. loss vs. wild type) and used the Student's t-test to compare the expression in the two groups. **Results.** Gene dosage affects the expression level of a large number of genes within aberrant genomic regions in FL (Figure 1). A set of 699 genes (cis-genes) whose expression is profoundly affected by DNA copy number were identified by combining results from the Pearson correlation and the Student's test, applying thresholds of r > 0,4 and a z-score corresponding to p-value < 0.05, respectively. We used Ingenuity Pathway Analyses (IPA) to evaluate the functional associations of these genes. The 699 cis-genes are enriched for genes involved in regulation of cell death, cell cycle control, DNA replication, recombination and repair as well as regulation of cell growth and proliferation. The top interaction network identified by IPA includes genes in the NF-κB pathway, apoptosis signaling, IL-8 signaling and B-cell receptor signaling (Figure 2). **Conclusions and Summary.** We show that genes involved in the NF-κB pathway, apoptosis signaling, IL-8 signaling and B-cell receptor signaling are targeted by genomic imbalances in FL. The relationship of cis-genes to survival and transformation risk will also be discussed.

[5]Department of Hematology, Rigshospitalet, Copenhagen, Denmark
[6]Department of Pathology, Rigshospitalet, Copenhagen, Denmark

Introduction. The discovery of the functional role of the TET (Ten-Eleven Translocation) family of hydroxylases is a major break through for our understanding of how DNA methylation is deregulated in hematopoietic cancer. DNA demethylation may occur when the TETs convert methylated cytosine to hydroxymethylcytosine. The *TET2* gene is the most commonly mutated gene in myeloid malignancies. Clonal analysis of the hematopoetic stem cell compartment suggests that *TET2* mutations can be early events, and recent investigations showed that the lymphoid lineage was also affected in *Tet2* deficient mice. **Aims.** In the present study we aim to determine the frequency and clinical impact of *TET2* mutations in diffuse large B cell lymphoma (DLBCL) and to evaluate the role of *TET2* mutations on the methylation pattern in DLBCL. **Methods.** Fresh frozen lymphoma biopsies were obtained from 100 newly diagnosed cases of DLBCL and peripheral blood B-lymphocytes were isolated from random, anonymous donors. Clinical data was obtained from the patient files and from the Danish lymphoma registry LYFO. The entire coding sequence and all splice sites of the *TET2* gene (exons 3-11) were scanned for mutations by PCR in combination with denaturing gradient gel electrophoresis (DGGE) and automated sequencing. Global methylation profiling was performed using 450K Infinium arrays (Illumina) and gene expression analysis by Affymetrix arrays. Verification of promoter hypermethylation was done by Methylation-Specific Melting Curve Analysis. **Results.** Here, we show that TET2 is frequently involved in the pathogenesis of DLBCL with 17% carrying missense, nonsense, splice site, and frame shift mutations or deletions. Interestingly, most *TET2* loss-of-function mutations are associated with a hypermethylation signature. Using a stringent statistical analysis, we identified 111 differentially methylated probes in 70 genes all of which were significantly hypermethylated in *TET2*mut/del compared to *TET2*wt cases (p<0.01; t-test). Ingenuity pathway analysis of these differentially methylated genes showed that the majority act in a network involving hematopoietic system development and function, cellular development, cell cycle regulation and cancer. We observed a significant enrichment of the *TET2* signature probes being located at the promoter regions (TSS, 5'UTR and first exons) (73%) and gene bodies (26%). The correlation of methylation patterns with gene expression data is currently being analyzed and will be presented at the meeting. No difference in overall survival and in other clinical parameters were observed between *TET2*mut and *TET2*wt cases. **Summary**. We suggest that *TET2* loss-of-function mutations may lead to disruption of normal TET2 demethylase activity in hematopioetic progenitors and give rise to DNA hypermethylation in a set of genes involved in hematopoietic development and cell cycling. Depending on the secondary molecular changes this may give rise to either myeloid or lymphoid malignancies.

TRANSCRIPTIONAL REGULATION OF CD20 LEVELS IN LYMPHOMA CELLS IS REGULATED BY SRC FAMILY KINASES

K Bojarczuk, J Bil, D Nowis, M Wanczyk, M Dwojak, A Syta, G Basak, J Golab, M Winiarska
Medical University of Warsaw, Warsaw, Poland

Background. Anti-CD20 monoclonal antibodies have made a breakthrough in the treatment of non-Hodgkin's lymphoma and chronic lymphocytic leukemia. They trigger indirect effector mechanisms of the immune system, namely complement-dependent cytotoxicity (CDC), antibody-dependent cellular cytotoxicity (ADCC), and immunophagocytosis. Although for many years CD20 has been described as a stable antigen, accumulating evidence indicates that CD20 can be modulated at both transcriptional and posttranscriptional levels.

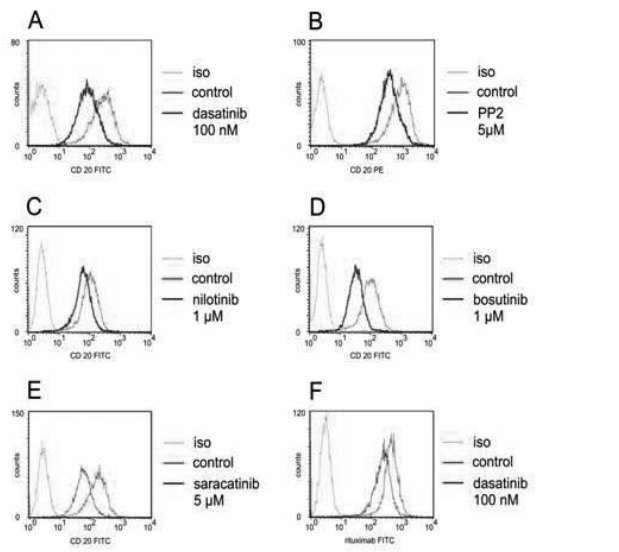

Fig.1 Raji cells, pretreated for 48 hours with various Src family tyrosine kinases inhibitors,were incubated with saturating amount of FITC-conjugated anti-CD20 mAb (**A-E**) or rituximab and secondary FITC- conjugated anti-IgG1 antibody **(F)** for 30 min at room temperature in the dark. Binding of mAb was determined with flow cytometry

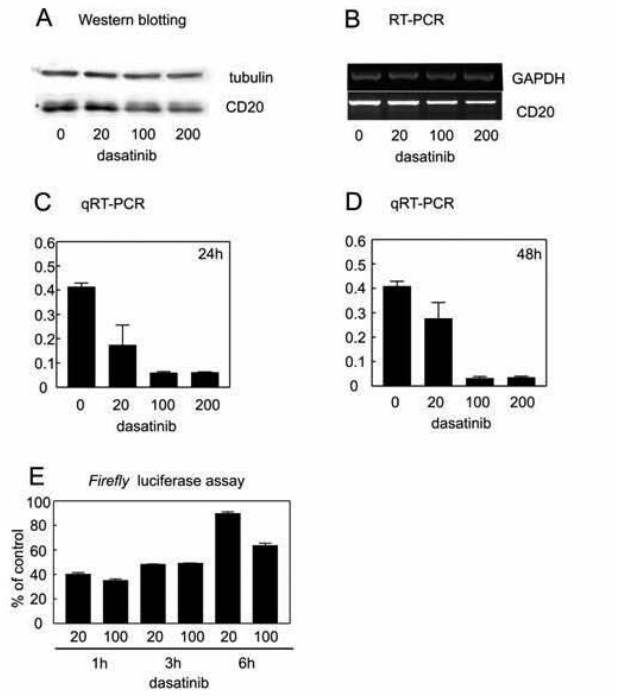

Fig.2 Raji cells were incubated with dasatinib for 48 hours, lysed with RIPA buffer and assayed by Western blotting for total CD 20 and tubulin levels **(A)**.CD20 mRNA levels in Raji cells incubated with increasing doses of dasatinib were assayed by RT-PCR **(B)** or qRT-PCR with specific hydrolysis oligonucleotide probes (**C-D**). Raji cells were stably transduced with CD 20 promoter-luciferase reporter gene construct (pCD20-Luc), incubated for indicated time with dasatinib and assayed for luminescence normalized to protein concentration **(E)**.

It seems that down-regulation of CD20 levels is one of the reasons of tumor resistance to rituximab. Src family kinases (SFKs) including Lyn, Fyn and Lck have been already reported to associate with CD20. However, to the best of our knowledge, the role of SFKs in the regulation of CD20 expression has not been studied so far. **Aims.** The aim of this study was to explore the molecular basis for Src family kinases-dependent regulation of CD20 levels in lymphoma cells. **Methods.** CD20 surface levels and rituximab-mediated CDC (R-CDC) in CD20-positive lymphoma cell lines and primary cells from patients were determined with flow cytometry. Total CD20 protein levels were assayed with Western blotting, the expression of CD20 gene was determined with both RT-PCR and qRT-PCR. The CD20 promoter activity was measured with reporter *Firefly* luciferase assay. Binding of transcription factors to the promoter of *cd20* gene was assayed using chromatin immunoprecipitation. **Results.** Initial experiments showed upon treatment with SFKs inhibitors a significantly reduced binding of anti-CD20 mAb to lymphoma cell lines as well as primary cells isolated from patients. All tested SFKs inhibitors, namely dasatinib, PP2, saracatinib, bosutinib, nilotinib, Btk-, Lck-, Src- and two Syk- inhibitors, as well as shRNA targeting Lyn kinase impaired R-CDC over a dose range of rituximab concentrations (1-100 ug/mL) in Raji cells. Interestingly, in Raji cells incubated for 48h with dasatinib we also observed a dose-dependent reduction of total CD20 protein levels, when assayed by Western blotting. Moreover, a 48-h incubation with dasatinib significantly reduced the transcription of *cd20* gene, as assessed with RT-PCR. To further elucidate the mechanism of transcriptional regulation of CD20 we performed qRT-PCR. A strongly reduced transcription of *cd20* gene was observed in Raji cells over a dose range of dasatinib (20-200 nM) after 24- and 48h- incubation. Additionally, the CD20 promoter activity measured with reporter *Firefly* luciferase assay has been reduced as early as 1 hour after dasatinib treatment. This effect was not observed for truncated CD20 promoter. To elucidate in more detail binding of transcription factors to the promoter of *cd20* gene, a chromatin immunoprecipitation assay was performed. Our early results indicate that dasatinib impairs binding of PU.1 transcription factor to its consensus site within *cd20* promoter in Raji cells. **Summary and Conclusions.** Our studies indicate for the first time that SFKs are involved in the transcriptional regulation of CD20 levels in lymphoma cells. Elucidation of the exact mechanism of this phenomena needs further studies. Results of these experiments will help to understand the biology and regulation of CD20 levels in lymphoma cells.

HIGH THROUGHPUT ANALYSIS OF ANTIGEN RECOGNITION BY THE B CELL RECEPTORS OF MALIGNANT LYMPHOMAS WITH HIGH DENSITY PROTEIN MICROARRAYS

M Navarrete[1], M Frick[2], K Heining-Mikesch[2], A Hafkemeyer[2], K Zirlik[2], H Veelken[1]
[1]Leiden University Medical Center, Leiden, Netherlands
[2]University Medical Center Freiburg, Freiburg, Germany

Background. Shared structural features of the B-cell receptor (BCR) suggest some role of antigen recognition in B-cell non-Hodgkin lymphomas (B-NHL) etiology. The BCRs expressed by CLL and marginal zone lymphoma (MZL) may recognize common autoantigens. Systemic autoimmune diseases are associated with certain B-NHL. Organ-restricted chronic inflammation plays an etiological role in extranodal MZL of MALT type (i.e. H. pylori-associated gastritis, Sjogren's syndrome). Despite this evidence, there has been no systematic and comprehensive assessment of autoantigen recognition by BCR expressed by B-NHL. **Methods.** BCR from 45 B-NHL (13 mantle cell lymphomas, 10 CLL, 5 nodal MZL, 5 diffuse large B-cell lymphomas, 4 follicular lymphomas, 3 myelomas, 2 splenic MZL, 2 lymphoplasmacytic lymphoma) were expressed as recombinant Fab fragments. Binding of lymphoma-derived BCR was tested simultaneously to 8000 human proteins displayed on high-density microarrays. Bound BCR were detected by AlexaFluor labeled antibodies. Z-scores and Z-factors were calculated for each Fab-protein interaction. Positive binding was defined as either Z-score >1.65 and Z-factor >0, or Z-score >1 and Z-factor >0.5 (Zhang et al., 1999). 27 BCR-protein interactions were validated by indirect ELISA. **Results.** 108 BCR-protein interactions involving 48 different proteins were identified. 21 BCR did not bind any protein; 12 BCR recognized one protein. 9 BCR were polyreactive as defined by binding to ≥5 proteins. MZL were classified as polyreactive with very similar recognition patterns, including the autoantigens cardiolipin and Ro-60/SS-A. Unexpectedly, 8 of 9 polyreactive BCR showed evidence of somatic hypermutation (mean: 7.1% range: 3.0-18.6%). The arrays showed a sensitivity and specificity of 99% and 95% respectively with positive correlation between ELISA OD and z-scores ($r=0.74$, $p<0.001$). Although the arrays used here carried the most comprehensive assembly of proteins available, they represent only a fraction of the human proteome. Therefore, homologues to recognized proteins were identified by BLAST and included, among others, the paraneoplastic neuronal autoantigen

Ma1 as being potentially recognized by 4 lymphomas, including a primary CNS lymphoma, and 2 cell wall proteins of pathogenic bacteria. **Conclusions.** This pilot study employing a broad selection of lymphoma types establishes protein microarrays as a novel and valuable platform to study antigen recognition by lymphoma in an unbiased and quantitative fashion, and to deduct a comprehensive pattern of putative antigen stimulation in NHL development. This platform permits definition of recurrent oligo- and polyreactivity patterns of antigen recognition by lymphoma BCR. Unlike in physiological B-cell affinity maturation, somatic hypermutation in B-NHL appears not to result in loss of polyreactivity, which may then continue to provide stimulation of the malignant cells via their BCR. These reactivity patterns appear to operate across various lymphoma entities, suggesting two different components in lymphoma development: A common requirement for BCR-mediated stimulation in the majority of cases, which may occur during various scenarios and may be either specific or follow definable patterns of cross-reactivity, and subsequent malignant transformation of the stimulated cell by genetic alterations. The latter step would be expected to define the lymphoma type through the developmental stage of the cell of origin and the nature of the oncogenic mutation.

INTERNATIONAL SURVEY OF T2* CARDIOVASCULAR MAGNETIC RESONANCE IN THALASSEMIA

JP Carpenter, M Roughton, D Pennell
Royal Brompton Hospital, London, United Kingdom

Background. Beta thalassaemia major (TM) is a substantial global health issue, with over 25,000 affected children born each year. Accumulation of cardiac iron is the cause of heart failure and early death in many TM patients who depend on regular blood transfusions. Cardiovascular magnetic resonance (CMR) T2* measurement has been shown to provide an accurate, reproducible measurement of cardiac iron and this technique has now been adopted as part of routine management in many countries. A dramatic 71% decrease in deaths has been observed in the UK thalassaemia cohort since the introduction of improved chelation and the routine use of CMR T2*. Whilst cardiac T2* has a strong prognostic value in the UK cohort, little is known about the burden of cardiac iron loading, its effects or the application of CMR T2* across different geographical regions. **Aims.** To gain an understanding of the worldwide use of CMR T2* via an international survey of centres that regularly use T2* to assess its clinical application, the degree of iron loading and relation to clinical outcomes.

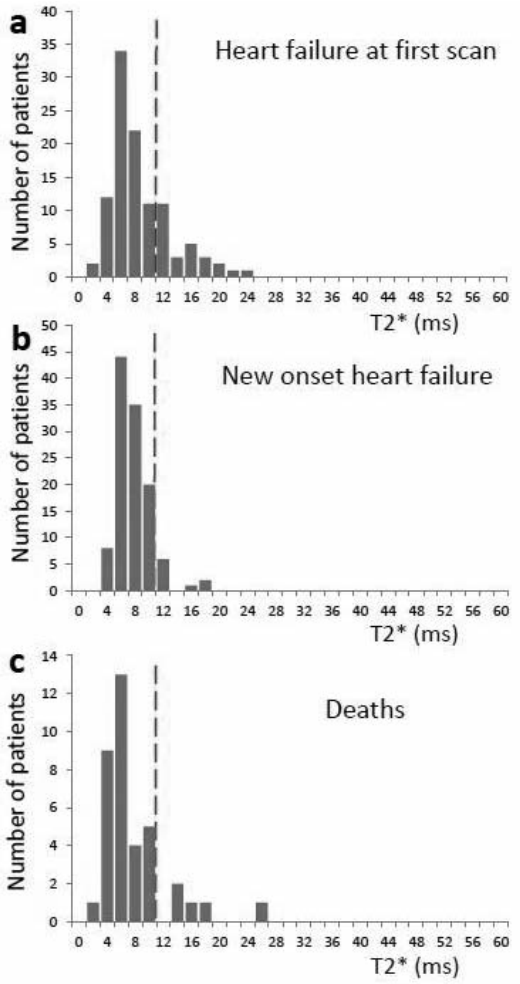

Figure 1. Distribution of T2* values. A: Patients in heart failure at first scan; B: New onset heart failure; C: Deaths.

Methods. A survey was undertaken in 35 worldwide centres of 3,445 patients from Europe, the Middle East, North America, South America, North Africa, Australia and Asia. Anonymised data on myocardial T2* values were analysed in conjunction with clinical outcomes (heart failure and death). For the purposes of this study, cardiac failure was defined as symptoms or signs of cardiac failure associated with objective evidence of ventricular dysfunction at rest (defined as reduced left ventricular ejection fraction <56% measured by CMR). **Results.** Of the total of 3,445 patients, overall 57.7% had no significant iron loading (T2*

>20ms), 22.5% had moderate cardiac iron (10ms < T2* ≤ 20ms) and 19.8% had severe cardiac iron (T2* ≤10ms) at baseline. The prevalence of moderate (T2* <20ms) and severe (T2* <10ms) myocardial iron loading varied significantly between regions with the lowest level being found in patients from Egypt and the highest in South-East Asia (P <0.001). At the time of the first scan, 107 patients (3.5%) had confirmed heart failure, the majority of whom (75.7%) had myocardial T2* <10ms, with 98.1% having T2* <20ms. During follow-up, 116 patients subsequently developed heart failure, and of these, 92.2% had T2* <10ms and 100% had a T2* of <20ms at the time of the first T2* CMR scan. There were 38 deaths during follow-up: at baseline scan, 86.4% had myocardial T2* <10ms, and 97.2% had myocardial T2* <20ms. **Conclusions.** In this well-treated cohort of TM patients from centres across the world who had access to regular transfusion, chelation and T2* CMR, a large proportion (42.3%) had moderate to severe cardiac iron loading. Cardiac T2* values <10ms were strongly associated with the development of cardiac failure and death. There were marked regional differences in the prevalence of cardiac siderosis which may reflect differences in predisposition to cardiac iron loading.

0604

HBA2 LEVELS IN ADULTS ARE INFLUENCED BY TWO DISTINCT GENETIC MECHANISMS

SL Thein[1], C Garner[2], H Rooks[1], T Spector[3], S Menzel[1]
[1]King's College London School of Medicine, London, United Kingdom
[2]University of California at Irvine, Irvine California, United States of America
[3]King's College London School of Medicine, Twin Research and Genetic Epidemiology, London, United Kingdom

Background. The switch from embryonic to fetal hemoglobin (HbF, α2γ2) in utero, and from fetal to adult hemoglobin at birth is well documented and achieved by the sequential activation of ε, γ and δ/β genes at the β globin gene (*HBB*) cluster. A change in the expression of hemoglobin genes also takes place in adult erythropoiesis: earlier erythroid progenitors have been shown to produce significant amounts of fetal hemoglobin, while the more mature progenitors contain essentially none. In keeping with the sequential activation of β-like globin genes, δ globin chain synthesis also declines as maturation in erythroid progenitors progresses. Understanding the developmental changes of gene expression at the beta globin locus is not purely of academic interest, since a therapeutic induction of HbF or HbA_2 (α2δ2) production would be of significant clinical benefit for patients with a defect of HbA (α2β2) function or abundance, such as sickle cell disease or β thalassemia. We have previously studied the genetic regulation of fetal hemoglobin persistence in a genome-wide association study (GWAS) in healthy volunteers, and are now extending this approach to the study of HbA_2. **Aims.** To assess the relationship between SNPs and the HbA_2 trait using a quantitative trait GWAS analysis. **Methods.** Our study population is the 'Twins UK' twin registry of healthy Europeans, mostly female adult individuals, with genome-wide single polymorphisms (SNP) data and hemoglobin phenotypes for a primary study group (n=2,322) and a second replication group (n=1,716).

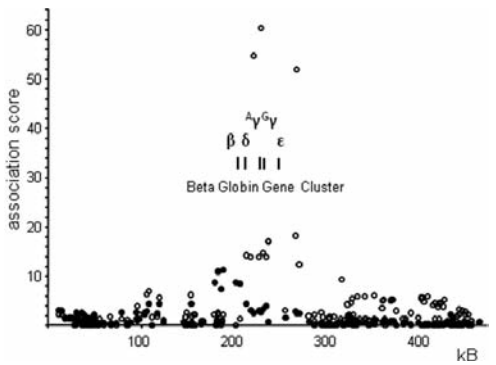

Figure 1. Association with single-nucleotide polymorphisms (SNP) near the beta globin gene cluster on chromosome 11p15.4 with abundance of HbA2.

Results. We found that HbA_2 (as a percentage of total hemoglobin) correlated weakly, but significantly, with the amount of fetal hemoglobin carrying cells (F cells) ($r = 0.14$, $p < 0.01$). This suggests the existence of some common biological process that influences both hemoglobin species. We also found that the same SNP alleles at chromosome 6q23.3 (*HBS1L-MYB*, peak signal rs7775698, $p = 2.51\times10^{-9}$) that are associated with F cells and and red blood cell volume (denoted by the mean cell volume or MCV) also promote HbA_2 levels, again pointing to some common biological factor connected with the erythropoietic maturation process. Interestingly, neither of the other two major HbF loci, *BCL11A* on chromosome 2p, or the HbF-promoting regions within the *HBB* cluster (at the β LCR and the γ globin genes) on chromosome 11p, showed association with HbA_2 levels. Instead, SNPs around the β globin gene itself (clearly separate also from the delta gene) exert a significant influence on HbA_2 levels (peak association rs12793110, $p=5.11\times10^{-12}$) (see Figure 1). In contrast to the *HBS1L-MYB* region on chromosome 6, the HbA_2-boosting alleles at these SNPs do not increase red blood cell MCV. **Conclusions.** Our results suggest that HbA_2 levels in adults are influenced by two distinct genetic mechanisms; one via the kinetics of erythropoiesis, and the other via a competitive process between *HBB* and *HBD* gene activity, mimicking a mild thalassemic effect. The systematic genetic study of specialized hematological traits in healthy volunteers can help to understand the biology of hematopoiesis.

BIOSIMILARS IN THE MANAGEMENT OF ANAEMIA SECONDARY TO CHEMOTHERAPY IN SOLID TUMOURS, LYMPHOMA AND MYELOMA: THE ORHEO STUDY

M Michaellet[1], E Luporsi[2], P Soubeyran[3], H Albrand[4]
[1]Pavillon Marcel Bérard 1G, Centre Hospitalier Lyon Sud, Lyon-Pierre Bénite, France
[2]Centre Alexis Vautrin, Vandoeuvre-les-Nancy, France
[3]Institut Bergonié and Université Bordeaux Segalen, Bordeaux, France
[4]Hospira France SAS, Meudon La Forêt, France

Background. Approval of epoetin biosimilars in the EU requires extensive scientific evaluation and stringent regulatory procedures. These range from preclinical and clinical studies to tightly controlled manufacturing processes. Post-marketing pharmacovigilance forms an integral part of the regulatory requirements for biosimilar products. The ORHEO (place of biOsimilaRs in the therapeutic management of anaemia secondary to chemotherapy in HaEmatology and Oncology) study examined the post-marketing efficacy and safety of biosimilar epoetins for the treatment of chemotherapy-induced anaemia in the clinical setting. **Aims.** To evaluate the efficacy and safety of biosimilars of epoetin alfa (EA) for the treatment of chemotherapy-induced anaemia in oncology and haematology in the clinical setting. **Methods.** ORHEO is an observational, non-interventional, longitudinal study performed in multiple centres in France. Patients >18 years with anaemia (haemoglobin [Hb] <11g/dL) secondary to chemotherapy for solid tumours, lymphoma or myeloma and eligible for treatment with EA biosimilar were included. Baseline demographic and disease-related characteristics were recorded at baseline along with anaemia-related data including Hb level, target Hb chosen by the treating clinician, brand and dose of EA biosimilar prescribed, and details of any other concomitant treatments (eg iron). Patients were followed up at 3 and 6 months. Analyses included achievement of target Hb, and Hb response defined as achievement of target Hb without blood transfusions in the preceding 3 weeks and during treatment *or* Hb ≥10 g/dL *or* Hb increase ≥1 g/dL since inclusion. The rate and type of adverse events were also evaluated. **Results.** In this study 2311 patients (mean age 66.5 years) from 232 centres were included. The majority of patients (79.6%) had solid tumours, 13.0% had lymphoma and 7.4% had myeloma. All but one patient received the biosimilar Retacrit (epoetin zeta, median dose 30 000 UI/week). The mean baseline Hb level was 9.6 g/dL, with target levels of 12-13 g/dL for 51% of patients. A total of 2056 and 1664 patients had at least one Hb value at 3 and 6 months, respectively, and Hb response was achieved in 81.6% and 86.5% of patients at these respective timepoints. Of these patients, 35.2% and 28.5% of patients achieved target Hb levels at 3 and 6 months, respectively. Where transfusion data were available, transfusion rates were 9.4% and 5.8% at 3 and 6 months, respectively. Of those patients who discontinued the treatment early, 53.7% at 3 months and 53.7% at 6 months did so due to early achievement of target Hb. Mean time to achievement of target Hb was 80.1 days for the responder population. The rate of thromboembolic events was 2.4% and 1.5% at 3 and 6 months, respectively. **Summary and Conclusions.** Retacrit was effective and well-tolerated in the management of chemotherapy-induced anaemia in patients with solid tumours, lymphoma and myeloma. The vast majority of patients achieved Hb response at 3 and 6 months.

[8]Children's Hospital Boston, Boston, United States of America
[9]Children's Hospital Los Angeles, Los Angeles, United States of America
[10]FerroKin BioSciences, Inc, San Carlos, United States of America

Background. FBS0701 is a novel, orally available iron chelator in clinical development for transfusional iron-overloaded patients. The primary outcome measure of protocol FBS0701-CTP-04 was the effect of a 24 week course of once-daily FBS0701 at two dose levels, 14.5 and 29 mg/kg/d (mpk), on liver iron content assessed by R2 (Ferriscan®) MRI. There was a clear dose response with no safety signals (Neufeld *et al* Blood, 2012. [Epub ahead of print]). Here we present 48 week data from an extension of CTP-04. **Aims.** To assess the safety and efficacy of FBS0701 in adults with transfusional iron overload after treatment for 48 weeks with dose modifications allowed at or after Week 24. **Methods.** Patients who had completed the first 24 weeks of CTP-04, had an LIC ≥2 mg/g dry weight, cardiac T2* ≥10 ms and LVEF ≥55% were eligible to participate. Patients, all with hemoglobinopathies, were dose-adjusted at or after week 24 if there was evidence of iron accumulation: patients randomized to receive 14.5 mpk were increased to 29 mpk; patients randomized to 29 were increased to 36 mpk, the highest permitted dose at that time. Patients were evaluated monthly including history, physical exam, clinical pathology, adverse events (AEs), ECG and LIC by MRI at Week 24 and 48. **Results.** Of 42 patients enrolled in the extension, thirty-nine (93%) completed 48 weeks of treatment; three withdrew for concerns about efficacy. Mean LIC at Baseline was 12.5 (N=42; SEM±1.1) and 13.2 mg/g (N=42; SEM±1) at Week 24. Seventeen (40%) patients had abnormal baseline transaminases and 18 patients (43%) had a history of viral hepatitis. At Week 24, 19 (95%;N=20) patients randomized to 14.5 mpk were dose-adjusted upward, the majority (N=16) to 29 mpk while 14 (64%; N=22) patients randomized to 29 mpk were increased to 36 mpk. FBS0701 was generally well tolerated at all doses. There were no treatment-related SAEs. No AEs showed dose-dependency in frequency or severity. Fewer than 5% had treatment-related nausea, vomiting, abdominal pain, or diarrhea. The most common treatment-related AE was an increase in transaminases (14%, N=6). No patient had a clinically significant increase in serum creatinine (Cr). The average change in LIC from Week 24 to 48 was -0.7 mg/g (N=39; SEM±0.5). **Conclusions.** FBS0701 was well tolerated up to 36 mpk; a maximum tolerated dose was not identified. No safety signals were noted at the higher doses. Treatment-related GI AEs were infrequent and Cr was stable. Transaminases increased in six patients, two of whom acquired HCV simultaneously from a single source as previously reported. Transaminase increases were <2-fold baseline, reversible and restricted to patients with a history of viral hepatitis. FBS0701 was effective at clearing hepatic iron in a majority (67%) of patients dosed at 36 mpk. Higher doses of FBS0701 might be expected to safely induce negative iron balance in a greater proportion of iron overloaded patients.

A NOVEL KLF1 GENE PROMOTER VARIANT (G.-148 G>A) IS ASSOCIATED WITH HEREDITARY PERSISTENCE OF FETAL HEMOGLOBIN

M Radmilovic[1], B Zukic[1], M Stojiljkovic Petrovic[1], N Kotur[1], B Stankovic[1], K Klaassen[1], L Dokmanovic[2], M Bartsakoulia[3], M Georgitsi[3], E Hatzimichael[4], F Koutsouka[4], E Briasoulis[4], G Patrinos[3], S Pavlovic[1]
[1]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia
[2]University Children's Hospital, School of Medicine, University of Belgrade, Belgrade, Serbia
[3]University of Patras, School of Health Sciences, Department of Pharmacy, Patras, Greece
[4]Academic Dep of Hematology, Thalassemia Unit, Ioannina University Hospital, Ioannina, Greece

Background. Hereditary persistence of fetal hemoglobin (HPFH) is characterized by persistent high levels of fetal hemoglobin (HbF) in adults. Several genetic factors that control HbF levels in adults have already been identified (*HBB*, *HBS1L-MYB*, *BCL11A* genes), while others remain elusive. Recent studies have reported variants within the *KLF1* gene, leading to high levels of HbF in adults. Elevated HbF levels may ameliorate the clinical phenotype of β-thalassemia. **Aims.** The aim of this study was to investigate the properties of a novel g.-148G>A *KLF1* gene promoter variant that was identified in individuals with elevated levels of fetal hemoglobin of Serbian and Greek origin. **Methods.** Mutation screening in the *KLF1*, *HBB, HBG1* and *HBG2* genes was done using PCR and direct resequencing. For the functional analysis, constructs containing the wild type *KLF1* promoter fragment and a *KLF1* promoter fragment bearing the g.-148G>A variant, were transfected into K562 cells and the promoter activity was measured as chloramphenicol acetyltransferase (CAT) activity. For electrophoretic mobility shift assays (EMSA), nuclear extracts from K562 cells and radiolabelled probes corresponding to the wild type (WT) and mutated (MT) *KLF1* sequences were used. In addition, "supershift"assay was performed using Sp1 antibody. **Results.** Three adult patients, presented with high level of HbF and with no mutations in the *HBB*, *HBG1* and *HBG2* genes, were analyzed for the presence of mutations in the *KLF1* gene. Sequencing analysis revealed that the patients were heterozygous for the g.-148G>A variant in the *KLF1* gene promoter. The results of the functional analysis showed the presence of significantly decreased activity (p=0.009) of the *KLF1* promoter bearing the g.-148A variant, compared to the wild type promoter. These results are in concordance with the results of *in silico* analysis, which showed that *KLF1* g.-148G>A promoter variant abolishes binding site of the Sp1 transcription factor. EMSA and "supershift"assays confirmed these data. Namely, addition of Sp1 antibody leads to the formation of a protein complex only in the case of nuclear proteins-KLF1 WT probe interaction, while no effect was observed in the reaction with KLF1 MT probe. **Conclusions.** Our study showed the presence of -148G>A variant within the *KLF1* gene promoter in three patients with elevated HbF level. We propose that this mutation influence *KLF1* gene expression by decreasing *KLF1* promoter activity, which, in turn, affects transcription of the γ-globin genes and, hence, HbF production.

MICRORNA REGULATE IMMUNOLOGICAL PATHWAYS IN T-CELLS IN IMMUNE THROMBOCYTOPENIA (ITP)

I Jernas[1], I Nookaew[2], H Wadenvik[1], B Olsson[1]
[1]University of Gothenburg, Gothenburg, Sweden
[2]Chalmers University of Technology, Gothenburg, Sweden

Background. ITP is an organ specific autoimmune disease in which T-cells play an important pathophysiologic role. MicroRNA are small non-coding RNA molecules that regulate gene expression. MicroRNA have been implicated in other autoimmune diseases but so far not studied in ITP. **Aims.** To investigate microRNA as a potential regulator of gene expression in T-cells from adult patients with chronic ITP. **Methods.** Blood was obtained from patients with chronic ITP and healthy controls followed by T-cell isolation and RNA preparation. For the genome-wide expression analyses RNA from 9 chronic ITP patients and 10 healthy controls was amplified using the Ovation amplification system V2 (NuGEN Technologies Inc) and hybridized to U133plus2.0 DNA microarrays (Affymetrix). MicroRNA from 9 ITP patients and 9 controls was labeled using the FlashTag Biotin HSR kit (Genisphere) and subsequently hybridized to the microRNA 2.0 microarrays (Affymetrix). Genes with different expression between ITP and controls were classified according to Gene Ontology. The target genes of the differently expressed microRNA were identified using the algorithms TargetScan and Miranda. The impact of the microRNA on gene expression was evaluated using the Kolmogorov-Smirnov test and the target genes from these microRNA were cross referenced against the list of significantly regulated mRNA between ITP patients and controls, identified in the T-cell gene expression analysis. Plasma levels of CXCL13 were analyzed by ELISA. **Results.** We identified 1915 regulated genes and 22 regulated microRNAs with different expression in ITP patients and controls. Seventeen of the 22 regulated microRNA had target genes with an affected expression; 57 of these target genes were associated with the immune system, e.g. T-cell activation and regulation of immunoglobulin production. Two microRNA target genes significantly increased in ITP were CXCL13 and IL-21. CXCL13 has been demonstrated to be central in the development of B-cell follicles and clonal B-cell expansion. IL-21 is the cytokine responsible for Th17 cell differentiation and cytotoxic T-cell responses in chronic infections, as well as B-cell proliferation and immunoglobulin class switch recombination. In line with the mRNA data we could demonstrate increased plasma levels of CXCL13 in ITP compared with controls. In addition, other investigators have previously reported increased plasma levels of IL-21 in ITP. **Conclusions.** Regulated microRNA were significantly associated with both gene and protein expression of molecules in immunological pathways suggesting that microRNA may be important regulatory molecules involved in the loss of tolerance in ITP.

ELTROMBOPAG RAISES PLATELET COUNTS PRIOR TO ANTIVIRAL THERAPY IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION ASSOCIATED WITH THROMBOCYTOPENIA

E Giannini[1], G Dusheiko[2], N Afdhal[3], P Chen[4], K Han[5], Y Mostafa Kamel[6], A Brainsky[6], J Geib[6], S Vasey[6], R Patwardhan[6], F Campbell[6], D Theodore[6]
[1]University of Genoa, Genoa, Italy
[2]University College London Medical School, London, United Kingdom
[3]Harvard Medical School, Boston, United States of America
[4]National Taiwan University Hospital, Taipei, Taiwan
[5]Severance Hospital, Seoul, South-Korea
[6]GlaxoSmithKline, Stockley Park, Uxbridge, United Kingdom

Background. Thrombocytopenia (TCP) is common in cirrhotic patients with hepatitis C virus (HCV) infection and is correlated with disease severity (Louie 2011). TCP may impair or prevent initiation of peginterferon alfa (PEG) therapy and necessitate PEG dose reduction or discontinuation, reducing or denying potentially curative treatment options for these patients. Eltrombopag, an oral, nonpeptide, thrombopoietin receptor agonist, increases platelets in patients with TCP due to HCV-related cirrhosis (McHutchison 2007). ENABLE 2 was a phase 3, multicenter, two-part study of eltrombopag for patients with HCV who are ineligible or poor candidates for antiviral therapy due to TCP. **Aims.** To assess safety and efficacy of eltrombopag during the open-label treatment phase (Part 1) of ENABLE 2 and the ability of eltrombopag to enable initiation of antiviral therapy (Part 2). **Methods.** Patients with chronic HCV and a baseline platelet count <75,000/μL received oral eltrombopag (25 mg daily with dose escalations every 2 weeks to a maximum of 100 mg) for up to 9 weeks until platelets reached ≥100,000/μL. Patients achieving these counts were eligible for randomization (2:1) to eltrombopag or placebo at the final dose received in Part 1, in combination with antiviral therapy (PEG-2b plus ribavirin) for up to 48 weeks (Part 2). Patients who failed to achieve platelets ≥100,000/μL following 3 weeks of eltrombopag 100 mg daily did not enter Part 2 and attended scheduled follow-up visits. **Results.** 805 patients were enrolled and entered Part 1. At study entry, most patients were male (63%) and Caucasian (75%); 16% were of Japanese/East Asian/Southeast Asian heritage. The median age was 52 years (range, 22-83). Most patients (79%) had advanced fibrosis or cirrhosis (FibroSURE® score equivalent to METAVIR F3/F4). The median duration of eltrombopag treatment during Part 1 was 21 days. Median platelets at baseline were 59,000/μL (range, 47,000-95,000/μL); these increased to a median of 93,000/μL (range, 9,000-489,000/μL) by week 2 of eltrombopag treatment and remained consistently elevated throughout Part 1 (Figure). Following a median of 2.8 weeks of treatment (range, 0.1-14.9 weeks), 773 patients (96%) achieved platelet counts ≥100,000/μL. Eltrombopag treatment was discontinued during Part 1 for 48 (6%) patients due to: platelets <100,000/μL (n=13); lost to follow-up (n=12); investigator discretion (n=10); adverse events (AEs, n=5); protocol deviation (n=5); or patient decision (n=3). During Part 2, 758 patients (94%) initiated antiviral treatment, the majority with eltrombopag doses of 25 mg/day (55%) or 50 mg/day (26%). The most common AEs observed during open-label treatment were headache (4%), diarrhea (3%), nausea (3%), and fatigue (2%). Two AEs (neither reported as related to eltrombopag treatment) resulted in fatal outcome (hepatorenal syndrome, malignant hepatic neoplasm). **Summary and Conclusions.** Eltrombopag treatment resulted in sustained platelet increases during the open-label, pre-antiviral treatment phase (Part 1) and was generally well-tolerated. Platelet increases were seen as early as 2 weeks following initiation of treatment. The vast majority of patients (96%) achieved platelet increases to ≥100,000/μL, the threshold for initiating PEG-2b plus ribavirin therapy, enabling a significant increase in SVR for eltrombopag- versus placebo-treated patients during Part 2 (Dusheiko 2011).

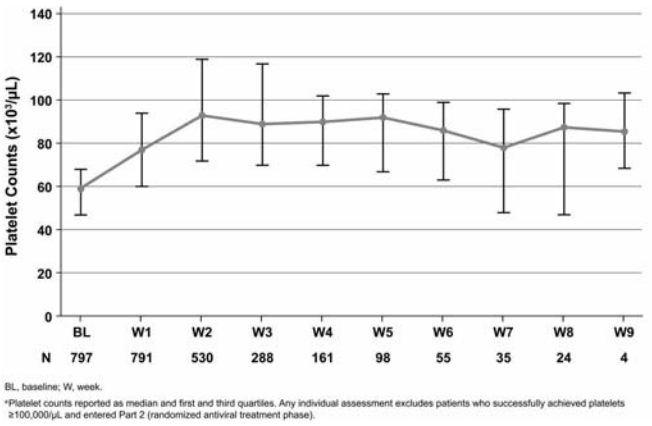

Figure 1. Platelet Counts During the Eltrombopag Open-Label Treatment Phase of ENABLE 2

0610

RITUXIMAB FOR THE TREATMENT OF THROMBOTIC THROMBOCYTOPENIC PURPURA: THE UCLH EXPERIENCE

J Westwood[1], H Webster[1], S McGuckin[2], S Machin[1], M Scully[2]
[1]University College London, London, United Kingdom
[2]University College London Hospital, London, United Kingdom

Background. Rituximab therapy represents an important advance in the treatment of antibody-mediated Thrombotic Thrombocytopenic Purpura (TTP), and is effective in a variety of settings, including acute *de novo*, refractory and relapsing disease. More recently it has been used to treat electively patients at high risk of relapse, identified by a drop in ADAMTS13 activity and/or rise in IgG anti-ADAMTS13 antibody level. **Aims.** To describe and evaluate the use of rituximab in a tertiary referral unit for TTP: for patients treated for acute TTP, and elective rituximab to prevent TTP relapse. **Methods.** Review of patients referred for TTP treatment, given rituximab between 2004-2011, and determination of the timing and frequency of rituximab administration, response to treatment and rates of relapse.ResultsBetween 2004-2011, 95 patients received rituximab at our centre, as part of treatment for acute TTP; none had previously received rituximab. 74 received rituximab for acute *de novo* TTP (78%) and 21 for relapsed TTP (22%). Median age was 43 (range 12-81), female/male ratio was 2:1 (65F, 30M). 62 were Caucasian, 17 Afro-Caribbean and 16

Indian/Asian.61 patients received their first rituximab dose within 3 days of diagnosis of TTP, and 34 (with refractory TTP) received rituximab after 3 days. 71 received 4 infusions (375 mg/m^2), 15 received 6-8. The median number of Plasma Exchange (PEX) to remission was 17 (3.5-40) with a median time to sustained platelet recovery of 14 days (4-52). 5 patients died during acute admission. 13 of the remaining 90 patients relapsed (14%), with a median time to relapse of 24 months (3-49).In patients receiving rituximab within 3 days of admission/diagnosis (n=61), there was a significant reduction in number of PEX (16 vs. 21, p=0.037) and length of admission (15 vs. 21 days, p=0.011), compared to patients given rituximab after 3 days (n=34). There was a significant reduction in median time to platelet recovery (12.5 vs. 19.5 days, p=0.005) but no difference in time to relapse (22 vs. 24 months, p=0.435). Eight patients who had relapsed following previous treatment with rituximab received further rituximab: of these, 2 had a 3RD relapse (at 22 and 29 months), 1 died during relapse, and the remaining 5 remain in remission (median follow-up 28 months).14 patients, with previous acute TTP relapses and normal ADAMTS 13 in remission, received rituximab electively when ADAMTS13 activity dropped to <5%. Rituximab was given weekly at a dose of 375mg/m^2 for 4 doses in all but one patient, who received 100mg/m^2. All patients responded, with recovery of ADAMTS13 activity into the normal range in all but one case. Although 2 patients have subsequently required 2 further courses of rituximab each, none have had an acute TTP relapse. **Summary and Conclusions.** In our extensive cohort of patients with acute TTP, rituximab given within 3 days of admission is associated with reduced PEX procedures, shorter admission and a shorter time to platelet recovery. Relapse following Rituximab was 14%, median 2 years. Elective rituximab appears effective in preventing florid relapse in patients with very low ADAMTS13 levels.

[9]Amgen Limited, Cambridge, United Kingdom
[10]Amgen (Europe) GmbH, Zug, Switzerland

Background. The thrombopoietin-receptor agonist romiplostim is recommended for second-line treatment of adult ITP, where the treatment goal is sustained increases in platelet counts to safe levels (Provan et al, 2010). Registrational studies of romiplostim in this setting were conducted in selected patient populations, and may not reflect routine clinical practice. **Aims.** Describe the use of romiplostim for the treatment of adult ITP in clinical practice. **Methods.** This ongoing, European, observational study enrolls ITP patients ≥18 years old, who have received romiplostim in clinical practice. Patients participating in another study, or who initiated romiplostim prior to commercial launch or have received other thrombopoietin-receptor agonists or related products are excluded. Data recorded as per clinical practice is collected for up to 2 years following romiplostim initiation, including any concomitant medications prescribed. Study outcomes include patient characteristics (at romiplostim initiation), romiplostim dose and adverse drug reactions (ADRs), summarized for patients meeting the study inclusion criteria (Full Analysis Set; FAS). We report data from an interim analysis conducted in September 2011. **Results.** 217 patients had enrolled, with 209 included in the FAS. Of these, 85% (178/209) remained on study, 9% (18/209) had completed the observation period and 6% (13/209) had withdrawn, with death the most common reason (11/209 [5%]). Median (Q1, Q3) age was 62.0 (47.0, 74.0) years, median weight 74.00 (64.00, 85.00) kg, and median baseline platelet count 18.0 (8.0, 33.0) x 10^9/L. One-third (70/209) of patients were splenectomised, 56% (116/209) female, and 76% (158/209) had received ≥3 prior ITP therapies. Median (Q1, Q3) time from ITP diagnosis was longer for splenectomised than non-splenectomised patients (9.75 [4.66, 22.18] *versus* 1.66 [0.22, 6.00] years). Median (Q1, Q3) duration of romiplostim exposure was 48.6 (20.1, 74.0) weeks (maximum 106 weeks), with romiplostim initiated at 1 and ≥3 µg/kg/week in 72% (150/209) and 16% (33/209) of patients. Taking the average weekly dose of all patients, the median (Q1, Q3) was 2.9 (1.5, 4.1) µg/kg/week. Platelet counts rose rapidly during the first 4 weeks of romiplostim treatment and remained >50 x 10^9/L thereafter (approximately 2 years). The most commonly reported ADRs were headache, thrombocytosis, arthralgia, asthenia, flushing and myalgia (2.6-7.3 events per 100 subject-years of exposure). Seven serious ADRs were reported: myelofibrosis (2 events, where the initial disease diagnosis was inconsistent with ITP and myelofibrosis more likely due to the underlying disease [MDS, metastases to bone marrow]); pulmonary embolism (2 events); drug ineffective (1 event); platelet count decreased (1 event, platelets <20 x 10^9/L); (reversible) thrombocytosis (1 event, platelets 477 x 10^9/L). No fatal ADRs were reported. **Summary and Conclusions.** At the time of this analysis, patients receiving romiplostim in clinical practice tended to be older and more heavily pre-treated than those enrolled in previous registrational studies. With similar doses as previously reported (Kuter et al, 2008), and no new safety signals, splenectomised and non-splenectomised patients with ITP of varying duration achieved sustained increases in platelet counts to safe levels. With the implementation of treatment guidelines, clinical practice will likely evolve to include younger, less heavily pre-treated patients.

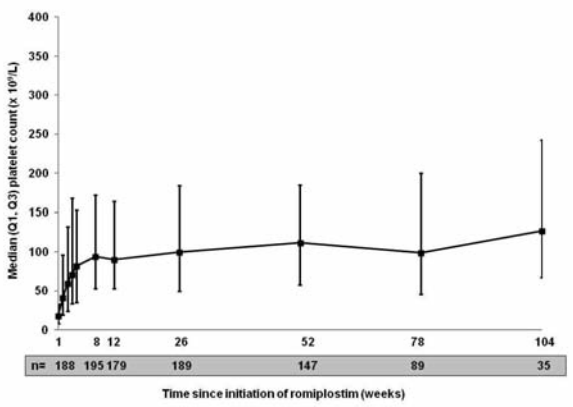

Figure 1. Platelet counts over time.

Background. In its report on standardization of terminology, definitions and outcome criteria in ITP (Rodeghiero et al, Blood 2009), the IWG deferred the def-

inition of the bleeding phenotype and the grading of its severity to a subsequent report. The IWG acknowledged that treatment response should ideally reflect clinical endpoints, including bleeding and quality of life, rather than rely exclusively on surrogate endpoints (platelet count) with arbitrary thresholds. **Aims.** To provide a consensus-based bleeding assessment tool inclusive of standardized definitions of bleeding, a symptom-specific and domain-specific grading and a harmonized standardized questionnaire for adults and children. **Methods.** The main issues were agreed-on and a final consensus was reached after several rounds of Delphi-like questionnaire and three face-to-face meetings. **Results.** *1. Definitions and terminology.* Definitions are consistent with those adopted for other bleeding disorders and are relevant for the purpose of developing an ITP-specific bleeding assessment. *2. Classification of bleeding symptoms*. Bleeding signs/symptoms are grouped according to three major domains: Skin (S), visible Mucosae (M) and Organs (O). Skin (epidermis, dermis and subcutaneous tissues) includes Petechiae, Ecchymosis (purpuric macula, bruise or contusion), Subcutaneous hematomas, Bleeding from minor wounds. Visible Mucosae include Epistaxis, Oral cavity (gum bleeding, hemorrhagic bullae/blisters, bleeding from bites to lips & tongue or after deciduous teeth loss/extraction), Subconjunctival hemorrhage. Organs include GI bleeding (hematemesis, melena, hematochezia, rectorrhagia), Lung bleeding (hemoptysis), Hematuria, Menorrhagia, Muscle hematoma, Hemarthrosis, Ocular bleeding, Intracranial (intracerebral, intraventricular, subarachnoidal, subdural, extradural). 3. *Gradation of bleeding severity (SMOG system)*. Each bleeding manifestation should be assessed at the time of examination. Its severity is graded from 0 to 4 (see example in table). Appreciation of bleeding based on history only, without supporting medical documentation, will be given a grade 1 designation. Within each domain, the same grading is assigned to the symptoms judged to have similar clinical relevance. For each symptom, the worst ever episode during the observation period is graded and then the worst episode within the domain is recorded. For example if the highest grade is 2 for skin, 3 for mucosae and 2 for organs, SMOG is S2M3O2. The index produced by summing the worst ever grade in the 3 domains represents the final score for that particular patient. In the example shown, the final score is 7. However, it is immediately appreciated that O2 has a much higher clinical impact than S2, so that a different weight (to be determined by ad hoc prospective studies) should be attributed to the different domains. *4. Questionnaire,* harmonized to the different bleeding manifestations and their grading, to facilitate the allocation of each symptom and its severity. **Conclusions.** The strength of this SMOG system lies in the agreement of a worldwide group of experts and should fill the existing gap in having a reliable and clinically relevant description of the bleeding phenotype of patients with ITP and its modifications by the various available treatments. The use of this tool for the purpose of decision making is discouraged until its value has been validated by appropriately designed prospective studies.

Type of bleeding	GRADES BASED ON THE WORST EVER EPISODE DURING THE OBSERVATION PERIOD				
	0	1	2	3	4
MUCOSAL					
Epistaxis	□ No/ unchanged/lasting < 5 min	□ Lasting > 5 min. or interfering with daily activities □ Any episode if based on patient history only	□ Antifibrinolytics or procedures by a physician not requiring packing or cauterization	□ Packing or cauterization or requiring in-hospital evaluation	□ RBC transf.
Oral cavity – gum bleeding	□ No/ unchanged/lasting < 10 min	□ Lasting > 10 min. or interfering with daily activities □ Any episode if based on patient history only	□ Antifibrinolytics or procedures by a physician not requiring hospitalization	□ Requiring in-hospital evaluation	□ RBC transf.

[2]Hematology and BMT unit, University of Brescia, Brescia, Italy
[3]GIMEMA Data Center, Rome, Italy

Background. During the last five years, *IKZF1* has been established as one of the most clinically relevant tumor suppressors in ALL. Deletion of a single *IKZF1* allele or mutations of a single copy of IKZF1 were firstly detected in 15% of all cases of pediatric B-cell ALL and in more than 80% of Ph+ lymphoid leukemia cases, either *de novo* Ph+ ALL or chronic myeloid leukemia at progression to lymphoid blast crisis. The deletions either involve the entire *IKZF1* locus, resulting in loss of function, or delete an internal subset of exons, resulting in the expression of dominant negative isoforms. The detection of *IKZF1* alterations at diagnosis might be useful in identifying patients with a high risk of treatment failure. *To better* stratify ALL patients according to *IKZF1* status, we set-up, validated and assessed the routine applicability of a *IKZF1* deletion screening strategy based on a multiplex-PCR. **Patients and Methods.** We studied 136 adult BCR-ABL1-positive and negative ALL patients. For each type of common *IKZF1* deletion (Δ4-7, Δ2-7, Δ4-8) an appropriate pair of primers will be designed using Primer 3 (http://frodo.wi.mit.edu/primer3/). Their ability to efficiently amplify the deletion was tested. PCR amplifications was performed using 50 ng genomic DNA as template for each reaction and a FastStart Taq DNA Polymerase (Roche Diagnostics). For each patient, 3 amplicons were generated and sequenced (amplicon A for Δ4-7, amplicon B for Δ2-7 and amplicon C for Δ4-8). Moreover, a multiplex amplification strategy was assessed and a forth amplicon was generated and sequenced (forward primers were localized on intron 1 and 3, the reverse ones in the intron 7 and at the end of the gene, after the exon 8). The size of amplicons depends on the positions of the breakpoints in the *IKZF1* gene and on the number of nucleotides added at the conjunction. It was in the range of 450-600 nucleotides. Positive controls were used for each run. **Results.** On 136 patients previously analyzed by SNPs array, we identified *IKZF1* deletions in 108/136 (79.4%) samples. Deletions were: 54 Δ4-7, 31 Δ2-7 and 4 Δ4-8; in 16 cases the deletion was extended to all gene, and 10 patients presented two breakpoints simultaneously. Multiplex PCR and subsequent sequencing were performed for most common deletions in 40 patients confirming previous results and indentifying the precise genomic positions of breakpoints and the nucleotides added at the conjunction. This rearrangement has been used to strictly monitor Minimal Residual Disease (MDR) during the follow-up and at relapse to confirm the clonal fidelity. **Conclusions.** We set-up a rapid and sensitive method using less amount of DNA sample, to screen ALL patients at diagnosis and to monitor MRD during the treatment. **Supported by**: European LeukemiaNet, AIL, AIRC, FIRB 2006, PRIN 2008, Fondazione del Monte di Bologna e Ravenna, Strategico di Ateneo, GIMEMA Onlus.

Background. Minimal residual disease is well established as an important prognostic parameter and is used for stratification and treatment decisions in acute lymphoblastic leukaemia (ALL). DNA- based PCR analysis of Ig-/TCR-rearrangements have been well standardised during the last decade, resulting in robust systems for MRD analysis with an intra- and inter-assay variability of less than half a log. In Ph+ALL, MRD analysis relies on RNA-based RT-PCR techniques that are highly sensitive but as yet lack standardisation between laboratories. Since laboratories differ substantially in both their methodology and analysis strategy, interpretation and meaningful comparison of results between laboratories and from different studies is difficult or impossible. Moreover, and in contrast to CML, there are no generally accepted definitions of molecular response that could identify thresholds on which to base therapeutic decisions. **Aims.** To assess *i)* the variability of BCR-ABL quantification between laboratories with recognized expertise in bcr-abl analysis, *ii)* identify optimal laboratory methods and iii) to standardize analysis and interpretation of RT-PCR results for Ph+ALL, the EWALL and ESG-MRD-ALL consortia initiated a multinational project for quality assurance involving more than 30 laboratories from 14 countries worldwide. We here report the results of the first seven m-BCR-ABL laboratory control rounds, performed between march 2008 and march 2012, that focussed on inter-intraassay variability of rt-PR techniques, comparison of housekeeping genes, plasmids, platforms and reagents. **Methods.** Serial dilutions of the BCR-ABL positive cell line Sup B15 with the BCR-ABL negative cell line Nalm 6 covering 5 logs were produced. In the 7 lab rounds, 1355 aliquots, each generated with a total amount of 5 x 10E+06 cells in a final volume of 1 ml were produced, stabilized in TRIZOL or buffer RLT and frozen at -20°C until shipment or centralized isolation of RNA and reverse transcribed. Participants were asked to process the material using predefined procedures. **Results.** In the first QC round a major finding was the high variability in RNA-yield between laboratories despite using the same extraction method, with an up to 3 log difference in ABL copy numbers. In addition, there was rare false-positivity and false negativity (specifity 94.8%). With centrally produced cDNA the variability improved and there was a lower frequency of false-positivity reaching 100% specifity in QC 2. By using standardized assays, in 12 of 33 laboratories no conversion factor is needed, 20 of 33 laboratories are at the moment within one log difference when comparing the BCR-ABL/ABL ratios. Comparison of housekeeping genes (ABL/GUS) revealed non-linearity at high transcript levels resulting in an underestimation of intraindividual log reductions and may be relevant when assessing disease prognosis. The quantitative range was generally above 10E-04. **Conclusions.** Initiation of laboratory control rounds and implementation of standardized methodology improved the variability and reduced the frequency of false-positive results. Sensitivity of current techniques is still unsatisfactory for diseases with aggressive growth kinetics such as Ph*ALL. Further standardisation of technical and analytical methodology

FREQUENCY AND CLINICAL PRESENTATION OF EZH2 MUTATIONS IN CHILDHOOD ACUTE LEUKEMIA

T Ernst[1], A Pflug[1], V Schäfer[1], J Rinke[1], A Waldau[1], J Ernst[1], U Bierbach[2], J Beck[1], A Hochhaus[1], B Gruhn[1]
[1]Universitätsklinikum Jena, Jena, Germany
[2]Universitätsklinikum Leipzig, Leipzig, Germany

Background. There is growing evidence that epigenetic deregulation plays an important role in the pathogenesis of both childhood and adult leukemia. Somatic mutations of the histone methyltransferase gene *EZH2* have recently been described in myeloid and lymphoid malignancies in adults and seem to be associated with poor prognosis. EZH2 catalyses trimethylation of histone 3 lysine 27 (H3K27) resulting in transcriptional repression of genes involved in development, stem cell maintenance and differentiation. **Aims.** We sought to determine the frequency and prognostic impact of *EZH2* mutations in a clinical well-defined cohort of 200 randomly selected childhood acute leukemia patients: acute myeloid leukemia (AML), n=75; B-lineage acute lymphoblastic leukemia (B-lineage ALL), n= 85; T-cell acute lymphoblastic leukemia (T-ALL), n=40. **Methods.** Genomic DNA was isolated from bone marrow cells at diagnosis. PCRs were performed using standard conditions with primers covering all 20 exons of the *EZH2* gene, including its intron-exon boundaries to detect potential splice mutations. Mutation analysis was performed by Sanger sequencing. **Results.** All 75 childhood AML and 48 B-lineage ALL cases have been analyzed so far. *EZH2* mutation status of the entire cohort will be presented at the meeting. To date, we identified two *EZH2* mutations, one each in AML and B-lineage ALL children. The AML patient was a 16-year-old girl (FAB type M2) without Auer rods and central nervous system involvement but confirmation of leukemic blasts in bilateral pleural effusions. Cytogenetic analysis showed the karyotype 45,X,t(8;21)(q22;q22). The patient was treated within the high-risk group of the German AML-BFM 93 trial, showed continuous complete remission but suffered from repetitive *Aspergillus fumigatus* infections and died due to a severe *Aspergillus* sepsis. The mutation is a homozygous in-frame insertion of 6 bp within *EZH2* exon 20. On protein level, the mutation inserts the two amino acids lysine and threonine at position 743 and 744 (SET domain), respectively, resulting in an abnormal EZH2 protein with a length of 753 amino acids. Analysis of a subsequent remission sample showed an absence of the mutation indicating that the *EZH2* mutation is somatically acquired. The patient with B-lineage ALL was a 10-year-old girl classified as a pro-B-ALL by immunophenotyping and treated within the German ALL-VII/81 trial. She initially achieved complete remission but relapsed and died 6 months after start of treatment. The underlying mutation is a heterozygous frameshift deletion of 3 bp within *EZH2* exon 6 that causes a change of the protein sequence starting from amino acid D184 and thus affects function of three major EZH2 domains (D2, CXC, SET). **Summary and Conclusions.** To our knowledge, this is the first report to describe *EZH2* mutations in pediatric acute leukemia patients. Although *EZH2* mutations seem to be rare in childhood leukemia our findings indicate that *EZH2* mutations might contribute to the disease in specific cases. The incidence of *EZH2* mutations in childhood acute leukemia needs to be assessed in a larger cohort of patients.

0616

DISTINCT GENETICS OF TEENAGE AND YOUNG ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA

F van Delft[1], C Furness[1], L Minto[2], J Irving[2], S Colman[1], M Greaves[1]
[1]Institute of Cancer Research, Sutton, United Kingdom
[2]Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom

Background. The outcome for Teenagers and Young Adults (TYA) with T-cell Acute Lymphoblastic Leukaemia (T-ALL) has improved significantly using paediatric based chemotherapy protocols, although it remains inferior to the outcome for children aged 1-9 years at diagnosis. This difference in outcome remains poorly understood. The genetic make-up of T-ALL is currently under investigation to establish the full repertoire of oncogenic events required to develop this aggressive disease. Comparison of genetic drivers identified in Teenagers and Young Adults with those in younger children would establish whether age related differences in leukaemia genetics could in part explain the observed difference in outcome. This genetic characterisation will at the same time identify drivers in those patients with an apparently normal karyotype. Current risk stratification in T-ALL is based on age and white cell count at presentation only. Thus these molecular studies have the potential to identify high risk patients to improve risk stratification. **Aims.** (1) To genetically characterise TYA T-ALL and establish whether T-ALL in Teenagers and Young Adults is a distinct disease entity; (2) Catalogue the comprehensive repertoire of collaborating genetic events required to lead to TYA T-ALL; (3) Correlate the genetic abnormalities with outcome. **Methods.** We accessed viable cells stored at diagnosis of TYA T-ALL (10-25 years) and extracted RNA and DNA. The patient DNA was examined at high resolution for Copy Number Alterations (CNAs) and Loss of Heterozygosity (LOH) using the Affymetrix SNP6.0 platform. The array data was analysed using CNAG 3.3.0.1 and Partek GS 6.6. The most frequent CNAs were confirmed by MLPA (P-383-T-ALL). In addition the DNA was screened for mutations in *NRAS, KRAS, CBL, FLT3* and *SHP2* using denaturing high performance liquid chromatography (dHPLC) on a Transgenomic WAVE machine using (whole genome amplified) genomic DNA. The RNA was transcribed to cDNA and will be subjected to real-time PCR for *CDKN2A* gene expression. Promoter methylation was performed by SABiosciences EpiTect Methyl qPCR Arrays and Methylation Specific PCR (MSP). **Results.** The most frequent CNA identified was deletion of *CDKN2A* in 72.7% of patient samples (91.6% homozygous deletions). Other frequent CNAs were loss of *MLLT3* (31%), *STIL* (27%), *PTEN* (19%), *LEF1* (15%) and gain of *MYB* (12%). These CNAs were confirmed by MLPA analysis. The only recurrent region of Copy Number Neutral LOH encompassed 9p24.3-p13.3, including the gene *CDKN2A* (27%). 2 Mutations have been identified; 1 *NRAS* and 1 *CBL* mutation (known variants). We demonstrated *CDKN2A* promoter methylation in cases without gene deletion by Methylation Specific PCR, but not Epitect Methyl Arrays, which indicates *CDKN2A* gene alteration in the majority of patient samples.Summary: Genomic analysis to date has not shown significant differences between T-ALL in children versus Teenagers and Young Adults. We are in the process of analysing additional cases for CNAs, LOH, including *NOTCH1/FBXW7/PTEN* gene mutations. To be able to appreciate potential cooperation between genetic abnormalities, we are complementing the DNA analysis with the measurement of gene expression of the oncogenes *TAL1, LYL1, LMO1, LMO2, TLX1, TLX3, NKX2, ERG* and *MEF2C*.

0617

CAMP-INDUCED P53 DEGRADATION IS INDEPENDENT OF EXCHANGE PROTEIN ACTIVATED BY CAMP IN PRE-B ALL CELLS

M Safa, A Kazemi
Tehran University of Medical Sciences, Tehran, Iran

cAMP-induced p53 degradation is independent of exchange protein activated by cAMP in pre-B ALL cells. **Background.** The p53 tumor suppressor protein is a potent roadblock to tumor development. Cells that are insulted by chemotherapeutic DNA-damaging agents or other forms of stress stabilize the p53 protein by phosphorylation or other modifications. Stabilized p53 accumulates in the nucleus to regulate the expression of numerous pro-apoptotic genes. **Aims.** The aim of this study was to investigate the inhibitory role of cyclic adenosine monophosphate (cAMP) levels on p53 protein in acute lymphoblastic leukemia (ALL) cells. More importantly, we were interested to show through which receptor cAMP acts to promote p53 degradation. **Methods.** In cell cultures, we investigated the effects of cAMP-increasing agents forskolin/IBMX on stimulated p53 of ALL cell lines. Western blotting analysis was performed to detect phosphorylation and acetylation state of p53 protein, total p53, phospho-cAMP response element-binding protein (CREB), and the levels of other proteins which were involved in doxorubicin-induced apoptosis. Flow cytometry was applied to analyze apoptosis. The gene expression of p53 and its target genes was examined by real-time polymerase chain reaction. **Results.** These results indicate that elevation of cAMP levels in ALL cells exposed to DNA damage attenuates p53 accumulation. We further demonstrate that elevated cAMP levels repressed DNA damage-induced p53 protein phosphorylation and acetylation in NALM-6 cells. Increased cAMP levels also shifted the ratio of the death promoter to death repressor genes via alteration of Bcl-2 and Bax proteins expression. Inhibition of proteosome function with MG-132 reversed the inhibitory effect of cAMP on p53. However, targeting the p53-Mdm2 interaction did not rescue accumulated p53 from the destabilizing signal of cAMP. The specific agonist of the cAMP receptor exchange protein activated by cAMP had no effect on p53 expression in doxorubicin-treated NALM-6 cells, whereas PKA activators decreased p53 accumulation. **Summary and Conclusions.** In conclusion, our studies demonstrate that cAMP-PKA pathway regulates the sensitivity toward DNA-damaging agents via inhibition of a p53-dependent pathway in B-cell precursor ALL (BCP-ALL) cells.

[2]Ludwig Boltzmann Cluster Oncology, Vienna, Austria
[3]Medical University of Vienna, Vienna, Austria
[4]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna,, Vienna, Austria

Acute lymphoblastic leukemia (ALL) is a life-threatening hematopoietic neoplasm characterized by abnormal growth and accumulation of lymphoblasts in various hematopoietic tissues. In a substantial number of patients, the Philadelphia (Ph) chromosome and the related oncoprotein BCR/ABL, are detectable. Despite recent improvements in therapy and use of BCR/ABL tyrosine kinase inhibitors (TKI), the prognosis is still poor. During the past few years, several attempts have been made to improve targeted treatment approaches in ALL. One strategy is to define markers and targets expressed on leukemic stem cells (LSC) in these patients. At least in Ph+ ALL, the leukemia-initiating cells are considered to reside within a CD34+/CD38- fraction of the clone. In the present study, we examined the expression of various stem cell markers and target antigens in CD34+/CD38-/CD123+ stem cells in patients with Ph+ ALL (n=4), Ph- ALL (n=8), Ph+ CML (n=20), and in control bone marrow (BM) samples (unexplained cytopenia, n=10). Surface expression of target antigens was analyzed by multicolor flow cytometry, and mRNA expression levels by qPCR. As assessed by flow cytometry, CD34+/CD38-/CD123+ cells were found to co-express CD19, CD44, CD52, CD133, CD135, and CXCR4 in all ALL patients examined. In most ALL patients tested (9/12), LSC also expressed CD33. In CML, LSC were found to express a similar profile of antigens, including CD33, CD44, CD52, CD133, CD135, and CXCR4, but not CD19. In control BM samples, CD34+/CD38- cells expressed the same antigens, however, the levels of CD33 and CD52 were lower compared to LSC in ALL and CML. The IL-1RAP was found to be expressed on LSC in Ph+ CML and in Ph+ ALL, but not on LSC in Ph- ALL or in normal BM stem cells. By contrast, the SCF receptor KIT (CD117) was expressed on LSC in Ph+ CML and in Ph- ALL, but was hardly detectable on LSC in Ph+ ALL. The IL-2RA (CD25) and the SDF-1-degrading surface enzyme dipeptidyl-peptidase IV (DPPIV=CD26) were found to be expressed on LSC in all patients with Ph+ CML and in a subset of patients with Ph+ ALL, namely those in whom BCR/ABL-p210 was detectable, whereas in patients with Ph+ ALL with BCR/ABL-p190 as well in Ph- ALL or normal BM samples, CD34+/CD38- cells did not co-express CD25 or CD26. The target receptor CD20 was not detectable on LSC in any of the patients´ cohorts analyzed, including Ph+ and Ph- ALL. In most instances, surface expression of target antigens could be confirmed by qPCR. Together, our data show that LSC in Ph+ ALL and Ph- ALL express a unique phenotype, including major surface targets. In Ph+ ALL with BCR/ABL-p210, the phenotype of ALL LSC closely resembles the phenotype of LSC in Ph+ CML, confirming the close relationship and similar pathogenesis of these two leukemic conditions.

0619

TRANSMEMBRANE ADAPTOR PROTEIN NTAL ENHANCES PROXIMAL SIGNALING AND POTENTIATES CORTICOSTEROID INDUCED APOPTOSIS IN T-ALL

K Svojgr[1], T Kalina[1], V Kanderova[1], T Brdicka[2], T Kacerova[2], J Stary[1], J Zuna[1]
[1]2nd Faculty of Medicine, Charles University Prague / University Hospital Motol, Prague, Czech Republic
[2]Institute of Molecular Genetics, Academy of Sciences, Prague, Czech Republic

Background. The biology of T-lineage acute lymphoblastic leukaemia (T-ALL) is characterized by the pre T-cell receptor (TCR) signaling. Transmembrane adaptor proteins could play an important role in the development of T- ALL. LAT is the adaptor protein essential for signal transmission from TCR. NTAL is an analogue of LAT except for a binding site for PCKgamma. **Aims.** We analysed the impact of NTAL and LAT expression on biology and treatment response in T-ALL. **Methods**. NTAL and LAT expression was analysed in diagnostic bone marrow samples of 39 pediatric patients with T-ALL using qRT-PCR and flow cytometry. Jurkat cell line (T-ALL cell line expressing no NTAL) (Jurkat/wt) and derived Jurkat cell line with stable NTAL expression (Jurkat/NTAL+) were used for in-vitro experiments. Cell signalling and cell death after TCR stimulation and after methylprednisolone treatment were analysed using flow cytometry, Western blot and qRT-PCR. **Results.** Leukemic blasts of T-ALL patients responding favourably to initial prednisone treatment had higher levels of NTAL than patients responding unfavourably (p=0.028) whereas LAT expression was stable (p>0.9). This observation was confirmed in in-vitro experiment - after 48 hours of methylprednisolone treatment the percentage of surviving Jurkat/NTAL+ vs. Jurkat/wt cells was 11% vs. 31% (p<0.05). Moreover, Jurkat/NTAL+ cells were more sensitive to TCR induced cell death than Jurkat/wt cells (40.7% vs. 61.0% surviving cells at 24 hours after TCR stimulation, p<0.05). Jurkat/NTAL+ cells showed significantly higher levels of ERK phosphorylation after TCR stimulation (median 1.5 fold, p<0.05) and of CD69 activation marker (90.5% vs. 77.4%, p<0.05) compared to Jurkat/wt, whereas phosphorylation of JNK showed an inverse pattern and phosphorylation of p38 MAPK was stable. The ERK inhibitor U0126 almost completely abrogated TCR induced cell death and reversed sensitizing effect of the NTAL protein to methylprednisolone induced cell death - percentage of surviving Jurkat/NTAL+ and Jurkat/wt cells after 48 hours of coincubation with methylprednisolone and U0126 is 29.3% and 29.9% respectively (p=0.49). **Conslusions**. We conclude that in our experiment NTAL is a tumor suppressor enhancing ERK phosphorylation of leukemic blasts. ERK molecule is the key protein responsible for increasing cell sensitivity to methylprednisolone induced cell death.This study was supported by grants NS/10473-3, MSM 0021620813 and MSMT NPV 2B06064.

CHANGES OF HEMATOPOIETIC MICROENVIRNMENT AND LYMPHOCYTES IN HEMATOPOIETIC STEM CELL TRANSPLANTATION OF ACUTE LYMPHOBLASTIC LEUKEMIA: COMPARISION BETWEEN RELAPSE AND NON-RELAPSE GROUPS

CJ Park, JW Chung, SS Jang, HS Chi, DY Kim, JH Lee, JH Lee, KH Lee
Asan Medical Center, Seoul, South-Korea

Background. Hematopoietic microenvirnment is essential for the recovery of the hematopoiesis after chemotherapy or hematopoietic stem cell (HSC) transplantation (HSCT). However, the exact interaction between HSCs and their microenvironment is not fully understood. The reconstitution of lymphocytes after chemotherapy or HSCT is also associated with hemopoietic engraftment. The delayed reconstitution of lymphocytes is related with relapse of malignancy. We analyzed markers of HSCs, hematopoietic microenvirnment and lymphocytes at regular intervals and evaluated the changes of them before and after HSCT to know the differences between engraftment and relapse groups. **Methods.** The immunohistochemistry for HSCs (CD34 and CD117), HSC microenvironment (osteonectin, CXCL12 and CXCR4), and lymphocytes (CD3, CD4, CD8, CD20 and CD56) was performed on bone marrow (BM) biopsies or clot sections, from the control group (8 lymphoma patients without BM involvement), non-relapse group (8 ALL patients with engraftment after HSCT) and relapse group (9 ALL patients with relapse after HSCT), at initial diagnosis (Dx), 1st complete remission (CR) after induction chemotherapy, before HSCT (pre-HSCT), and 1-3 months (after 1-3m) or 6-12 months after HSCT (after 6-12m). The positive cells for each marker were counted on 10 high power fields (x400) by microscopy, and then the average number of 10 fields was corrected with BM cellularity. **Results.** CD34 at Dx was more highly expressed in the patient groups (p<0.001), and CD117, osteonectin and CXCL12 expression was lower in the patient groups than in the control group (p=0.016, p<0.001, and p<0.001, respectively). Osteonectin from Dx to pre-HSCT in both non-relapse and relapse group were lower than in control group. At CR, pre-HSCT, and HSCT 1-3, CXCL12 expression was higher in the non-relapse group than in the relapse group (p=0.015, p=0.046, and p=0.015, respectively). With the exception of $CD56^+$ NK cells, the numbers of all lymphocytes (CD3+, CD4+, CD8+, and CD20+ cells) decreased in patient groups at Dx (p<0.001, p<0.001, p=0.001, and p=0.002, respectively). CD3, CD4, and CD8 expression were significantly higher in the non-relapse group than in the relapse group at pre-HSCT (p<0.001, p=0.001, and p<0.001, respectively). CD3 showed significantly higher expression in the non-relapse group at HSCT 1-3 and HSCT 6-12 (p=0.006 and p=0.033, respectively). At HSCT 6-12, CD4 expression also increased in the non-relapse group (p=0.017). **Conclusions.** We confirmed that BM T cells and T cell subsets in patients with ALL were reduced in the both periods of pre- and post-HSCT, and T lymphocytes in relapse group were less than those in non-relapse group. It was suggested that T lymphocytes played major roles to prevent from relapsing ALL, however, roles of NK cells in BM seemed to be insignificant. We thought that CD34 in ALL might be helpful in predicting the relapse of ALL following HSCT, and osteonectin might play a role as tumor suppressor in ALL. We also confirmed that CXCL12 had an important role to regenerate BM and a reduction of it might be a predictor as a relapse of ALL.

SHRNA-MEDIATED BAALC KNOCKDOWN AFFECTS PROLIFERATION AND APOPTOSIS IN HUMAN ACUTE MYELOID LEUKEMIA CELLS

B Xu[1], G Chen[2], X Song[2], P Shi[2], X Guo[2], S Zhou[2]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China
[2]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China

Background. Brain and acute leukemia, cytoplasmic (BAALC) gene, encodes a protein with no homology to known proteins or functional domains, is a novel molecular marker indicating the inferior outcome in acute myeloid leukemia (AML) with normal cytogenetics. But the biological function of BAALC is largely unknown. The functional studies investigating the impact of BAALC-expression in leukemia cell lines could not demonstrate a mechanistic role of BAALC on proliferation and apoptosis. **Aims.** To investigate the effect of small hair RNA (shRNA) -mediated BAALC gene knockdown on proliferation and apoptosis in human acute myeloid leukemia cells KG1a. **Methods.** The BAALC shRNA-expressing plasmid was constructed using the pGPU6/GFP/Neo vector, shRNA-NC and shRNA-GAPDH plasmid were also constructed to act as a negative and positive control separately. The shRNA expressing plasmid was transfected into KG1a cells using Nucleofector system. Total RNA and protein of transfected KG1a cells were extracted to verify the silence efficacy by RT-PCR and western blot. Silence of BAALC on proliferation of KG1a cells was detected by CCK-8 assays; the apoptotic nuclear changes after stained with DAPI was visualized by fluorescence microscopy and the population of apoptotic cells was determined by flow cytometric analysis. **Results.** RT-PCR showed that BAALC mRNA expression was markedly decreased in the pGPU6/GFP/Neo-BAALC-shRNA transfected KG1a cells. Consistently, the GAPDH mRNA levels in KG1a cells transfected with the positive control plasmid of shRNA-GAPDH were also decreased, whereas no change was observed in the pGPU6/GFP/Neo-shRNA-NC mock transfected cells. In line with the mRNA expression changes, the levels of BAALC protein were also remarkably inhibited in different pools of cells transfected with BAALC shRNA-expressing plasmid compared with those transfected with shRNA-NC-expressing plasmid. This suggested the BAALC gene expression in KG1a cells was stably silenced. Furthermore we investigated the impact of BAALC silence on proliferation and apoptosis. The growth curves of CCK8 assay showed proliferation of KG1a-BAALC shRNA cells was suppressed at different time point (48h, 72h, and 96h) when compared with the control groups. The apoptotic cellular nuclear changes (i.e., punctuated or granular and bright nuclei) were observed predominantly in the BAALC-shRNAs transfected but not shRNA-NC transfected cells. Annexin-V/PI flow cytometric analysis results showed that the apoptotic population of cells tranfected with BAALC-shRNA was significantly higher than those transfected with shRNA-NC (85.33% vs 12.67%, P<0.05). **Conclusions.** Our results showed that shRNA-mediated silence of BAALC inhibited proliferation and induced apoptosis of KG1a cells. Targeting BAALC may be a novel and effective approach for leukemia treatment. BAALC may act as an inferior prognostic factor through prompting proliferation and inhibiting apoptosis in leukemia cells.

FORCED RIZ1 EXPRESSION INDUCED TUMOR GROWTH SUPPRESSION, CELL CYCLE ARREST AND INCREASE IN GATA3 EXPRESSION IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA OF T CELL PHENOTYPE

H Shimura, N Mori, M Ohwashi, YH Wang, M Okada, T Motoji
Tokyo Women's Medical University, Tokyo, Japan

Background. Retinoblastoma protein-interacting zinc finger gene (*RIZ1)* has characteristics of a negative regulator of tumorigenesis. We recently reported that *RIZ1* expression is decreased in adult acute lymphoblastic leukemia (ALL). Moreover, *RIZ1* methylation of the promoter was more frequent and decrease in *RIZ1* expression was more significant in T-ALL than in B-ALL. RIZ1 was isolated as a GATA3-binding protein G3B. GATA3 is a transcription factor known to be expressed very specifically in the T-cell lineage. **Aims.** (1) To elucidate the relevance of *GATA3* in adult ALL. (2) To examine the association between *RIZ1* and *GATA3* expressions in T-ALL cells. (3) To investigate whether forced *RIZ1* expression in T-ALL cell lines induce growth suppression and affect *GATA3* expression. **Methods.** We examined the *GATA3* expression by quantitative real-time reverse transcription-polymerase chain reaction (PCR) analysis in 70 newly diagnosed adult ALL patients (60 B-ALL and 10 T-ALL). Normal T lymphocytes (n = 3) and leukemic cell lines (n = 9) were also examined. Patient characteristics (age, sex, WBC count, LDH at diagnosis and karyotype) were investigated. Correlations between *RIZ1* expression and *GATA3* or clinical characteristics were analyzed with t tests. The human RIZ1 protein expression vector p3RIZRH1 was transfected into T-ALL cell lines (MOLT-4 and Jurkat) with the Nucleofector system (Amaxa, Gaithersburg, MD, USA). The transfected cells were cultured for 96 hours, and cell growth, cell cycle, apoptosis and *GATA3* expressions were analyzed. **Results.** The mean *GATA3* expression in T-ALL patients was 4.84 (n = 10) and 1.27 in B-ALL patients (n = 60). Similar to *RIZ1* in T-ALL, the mean *GATA3* expression in T-ALL patients (mean 4.84) was lower than that in T lymphocytes from healthy individuals (mean 19.28). In addition, the association between *RIZ1* (mean 0.61) and *GATA3* (mean 4.84) expressions in T-ALL patients was statistically significant ($P = 0.004$). We found no statistical differences between the *GATA3* expression and other clinical characteristics. *GATA3* expressions in 6 T-ALL cell lines (mean 1.40) were also decreased, compared with those of normal T lymphocytes (mean 19.28). The *GATA3* was not expressed in B lymphoid (Raji) or myeloid (K562 and KG1) cell lines. Forced *RIZ1* expression in T-ALL cell lines resulted in inhibition of cell growth, G2/M arrest and increase of apoptotic cells. *GATA3* expressions in these cells were increased in accordance with *RIZ1* re-expression in a time-dependent manner. **Summary and Conclusions.** Decreased expressions of the *RIZ1* gene are frequent in T-ALL. Growth suppression accompanied with G2/M arrest and apoptosis were found by *RIZ1* re-expression in T-ALL cell lines. These results suggest that *RIZ1* inactivation is involved in T-ALL pathogenesis. Moreover, as *GATA3* expression of all T-ALL patients was decreased and it was increased by *RIZ1* re-expression in the cell lines, decreased *RIZ1* expression may be associated with *GATA3* suppression. Although leukemogenesis of T-ALL is heterogeneous and it originated from various T lineage cells, *RIZ1* might be involved in the development of T-ALL through *GATA3* repression.

GENETIC POLYMORPHISMS IN DNA REPAIR GENES AS MODULATORS OF ACUTE LEUKEMIA RISK

J Ouyang[1], F Tang[2], M Chen[1], Y Xu[1], M Zhou[1], R Zhou[1], Q Zhang[1], J Xu[1], B Chen[1]
[1]The Affiliated Drum Tower Hospital of Nanjing University, Nanjing, China
[2]Jiangsu province Hospital on Integration of Chinese and Western medicine, Nanjing, China

Background Although the pathogenesis of Acute leukemia (AL) remains unknown, the results of epidemiologic studies suggest that heritable factors are important in terms of susceptibility. Polymorphisms in DNA repair genes may modify the individual's risk for genomic damage, and, as a consequence, the risk of developing malignant diseases. **Aims.** To investigate the relavent of single nucleotide polymorphism in DNA repair gene(XPA XPC XPD XRCC1 and Rad51)and genetic susceptility of acute leukemia. **Methods.** The authors evaluated the relation between polymorphisms in 3 nucleotide excisionrepair pathway genes (XPA [A23G], XPC [Ala499Val and Lys939Gln], and XPD [Lys751Gln]), the base excision repair XRCC1 (Arg194Trp and Arg399Gln), and homologous recombination repair Rad51 (G135C) in a chinese population of 554ALcases and 651 matched controls using matrix-assisted laser desorption/ionization time-of-flight mass spectrometry . Variants were investigated independently and in combination; odd ratios (OR) and 95% confidence intervals (95% CIs) were calculated by logistic regression analysis and adjusted for the effect of sex and age. **Results.** There were no association between variation in the XPC Lys939Gln, XPD Lys751Gln, and XRCC1 Arg194Trp, Arg399Gln polymorphisms and acute leukemia. However there were significantly higher prevalence of the polymorphic variants RAD51G135C gene in acute promyelocytic leukemia (APL) cases and XPA-A23G gene in acute lymphoblastic leukemia (ALL) cases, when compared with controls, increasing the risk of APL 1.47-folds (95% CI: 1.04-2.07) and ALL 1.73-fold (95% CI: 1.01-2.97), respectively. The combined analysis demonstrated that Rad51/XPC and Rad51/XPD polymorphisms were associated with a significant increase in APL risk. The Rad51 135GC/CC and XPC 499CT/TT, or Rad51 135GC/CC and XPD 751GT/GG variant genotypes had ORs of 1.86 (95% CI, 1.2□'3.02) and 3.26 (95% CI, 1.49□'7.13), respectively. Similarly, Carriers of both the XPA-A23G and XPC-C499T variants were at highest ALL risk (OR:2.93; 95% CI: 1.11- 7.73). **Conclusions.** These findings indicate that XPA A23G and Rad51 G135C polymorphisms may be risk factors for ALL and APL in the Chinese population, respectively, and suggest that interactions between the polymorphisms in XPA/XPC Rad1/XPC and Rad51/XPD may occur.

***IN VIVO* IMAGING ALLOWS DISTINCT EVALUATION OF TREATMENT RESPONSES AND DISEASE STAGES OF PATIENTS` LEUKEMIA CELLS GROWING IN MICE**

I Jeremias[1], C Castro de Alves[1], U Zur Stadt[2], M Horstmann[2], L Quintanilla Fend[3], N Terziyska[1]
[1]Helmholtz Zentrum München, Munich, Germany
[2]Universitätklinikum, Hamburg-Eppendorf, Germany
[3]Universität, Tübingen, Germany

BackgroundDistinct animal models are required to preclinically evaluate novel therapeutic approaches for treatment of acute leukemia. As a timely vision, personalized strategies might be tested using primary patients´ samples. Unfortunately, precise disease monitoring is challenging in the individualized orthotopic xenotransplantation model of acute leukemia. **Aims.** The aim was to establish bioluminescence *in vivo* imaging as novel readout technique for sensitive and reliable follow up of leukemia in mice. **Methods**Patient-derived acute lymphoblastic leukemia cells were lentivirally transduced to express the membrane-bound form of Gaussia luciferase before engraftment into mice and bioluminescence *in vivo* imaging. **Results.** Bioluminescence *in vivo* imaging enabled reliable and continuous follow-up of single mice over time. Upon detecting a single leukemia cell within more than 10,000 bone marrow cells, imaging enabled monitoring minimal residual disease, time to tumor re-growth and relapse. Imaging quantified therapy effects precisely and with low variances discriminating treatment failure from partial and complete response. As an additional advantage, imaging conveniently quantified stem cell frequencies in limiting dilution assays and visualized that vincristine impaired leukemia stem cells. **Summary and Conclusion**Taken together, the most demanding challenges in anti-cancer treatment are precisely and individually modeled in mice using Gaussia luciferase-based imaging. The model will enable translating future individualized treatment strategies from bench to bedside.

CYTOGENETIC COMPLEXITY AND SUB-CLONAL ARCHITECTURE IN HIGH HYPERDIPLOID ACUTE LYMPHOBLASTIC LEUKEMIA

L Pajor[1], K Szuhai[2], G Pajor[1], M Kneif[1], L Poto[1], A Vojcek[1], G Ottoffy[1], D Alpar[1]
[1]University of Pecs, Pecs, Hungary
[2]Leiden University Medical Center, Leiden, Netherlands

Background. High-hyperdiploidy (HHD), characterized cytogenetically by 57-61 chromosomes, is the most common recurrent abnormality in pediatric acute lymphoblastic leukemia (pALL). Controversial assumptions are available regarding the exact mechanisms underlying the formation of HHD pattern and about the sequence of various cytogenetic events (aneusomies). **Aims.** In this study, we have investigated the cytogenetic complexity of HHD pALL using multicolor interphase fluorescence in situ hybridization (MI-FISH). Clonal evolution routes and sub-clonal architecture of leukemic cell population have been revealed. **Methods.** 80 bone marrow samples withdrawn from 76 patients at the time of diagnosis or relapse (72 and 8 samples, respectively) were selected based on DNA index and/or conventional cytogenetic results. Investigating copy number alteration of eight different chromosomes (chromosomes X, 4, 6, 10, 14, 17, 18 and 21) at the single cell level using MI-FISH and automated digital microscopy, we doubled the number of targets having been previously used for this purpose. Peripheral blood cells from 19 healthy individuals served as negative controls. The study was approved by the Regional and National Ethical Committees and it was conducted in accordance with the Basic Principles of the Declaration of Helsinki. **Results.** Gains of chromosomes 6 and 14 were presented in almost all samples and a decreasing incidence of gain was observed in the following order: chromosomes X, 4, 21, 18, 10 and 17. Considering the ratio of various individual abnormalities within the abnormal cell population of each patient, gains of chromosomes X and

21 were presented at the highest level referring to their early occurrence during the formation of HHD pattern, while aneusomy of chromosome 17 proved to be the latest event. Scrutinizing the combined (eight-target) signal pattern at single cell level, a high heterogeneity has been found. The most dominant clone was presented in a range of 28 to 85 percent. The count of non-dominant, but unambiguously abnormal signal patterns varied between 25-159 and the totalized rate of cells harboring these patterns proved to be 13-70%. Comparing paired samples withdrawn from the same patient at diagnosis and relapse, it has been found that not only the appearance of new aneusomies but also an increased rate of clonal heterogeneity is associated with disease progression. **Conclusions.** In HHD pALL, extra copies of chromosomes X, 4, 6, 10, 14, 17, 18, and 21 are acquired in the vast majority of cases. While a certain level of subclonal aneuploid heterogeneity has been previously revealed by other groups, it was only assumed so far that a real cell-to-cell variation characterizes the genetic profile of HHD pALL. Comparing our cell-based results to clinical outcome of patients, we found that clonal heterogeneity may have significant prognostic value providing further stratification regarding this genetic subgroup of pALL.laszlo.pajor@kk.pte.hu

T(14;18) TRANSLOCATION IN ADOLESCENTS WITH B ACUTE LYMPHOBLASTIC LEUKAEMIA/LYMPHOMA

P Kumar[1], S Samarasinghe[2], A Vora[3], C Harrison[4], S Daw[5], V Grandage[5], R Hough[5]
[1]Lister Hospital, Stevenage, United Kingdom
[2]Great North Children's Hospital, Newcastle, United Kingdom
[3]Sheffield Children's Hospital, UK, Sheffield, United Kingdom
[4]Northern Institute for Cancer Research, Newcastle, United Kingdom
[5]UCL Hospital NHS Foundation Trust, London, United Kingdom

Background. The t(14;18)(q32;q21) translocation is a common translocation described in B cell lymphoid neoplasms It is found in 80% of follicular lymphomas and 20% of diffuse large B cell lymphomas but rarely presents in acute lymphoblastic leukaemia/lymphoma It is an independent poor prognostic predictor in adults and has not been previously described in adolescents. **Aims**. To review the progress and outcome of all paediatric cases of acute lymphoblastic leukaemia/lymphoma with t(14;18) translocation enrolled in the national MRC UKALL 2003 trial3. **Methods.** The cytogenetics coordinator was contacted to get details of all patients enrolled in the trial with t(14;18) translocation; 1 patient was identified, treated at the adolescent unit at University College London Hospital. The unit treated another patient with acute lymphoblastic lymphoma, trial-ineligible. Their notes were retrieved and reviewed in detail.4 **Results.** Patient 1 was a 14 year old male presenting with a 2 month history of increasing lethargy, muscle aches and high white cell count. Bone marrow aspirate was consistent with precursor B ALL on morphology (90% blasts) and immunophenotyping. Cytogenetic analysis showed t(14;18)(q32;q21) in 96% of interphase cells by FISH. He was commenced on UKALL 2003 Regimen B. Day 8 marrow showed 33% blasts and treatment was changed to Regimen C. At Week 15 he was found to have CNS relapse during routine lumbar puncture for intrathecal chemotherapy. He achieved a complete response with salvage chemotherapy (fludarabine, cytarabine and idarubicin - FLA-Ida) and proceeded to an etoposide/TBI/T replete sibling allograft. He was admitted 2 months post transplant with respiratory failure due to pneumonia. Despite aggressive antimicrobial therapy, intubation and ventilatory support he died at 9 months from diagnosis.Patient 2 was a 13 year old female presenting with a 2 month history of migratory polyarthritis. Whole body MRI scan showed extensive bone marrow infiltration with a large soft tissue mass in the right wrist associated with pain and swelling. Bone marrow aspirate suggested ALL/lymphoblastic lymphoma on morphology (11% blasts) but immunophenotyping did not show clonality. CT-guided biopsyof the wrist lesion confirmed precursor B acute lymphoblastic lymphoma. Cytogenetic karyotype was complex and included t(14;18)(q32;q21) in 24% of metaphases analysed by G-banding. She was also found to have CNS disease. She began treatment according to UKALL 2003 Regimen B with progressive disease; Day 8 and Day 28 bone marrow aspirates showed increase in t(14;18) initially to 33% then 44%. Repeat MRI showed persistent abnormal bone marrow signal throughout the skeleton. Salvagechemotherapy with cytarabine and etoposide (CYVE) with Rituximab was started. A complete remission was achieved with 2 cycles of chemotherapy and she underwent a Cyclophosphamide/TBI/Campath matched unrelated donor allograft. Within 6 weeks her white cell count increased, and peripheral blood immunophenotyping confirmed relapsed disease. She died at home within 6 months of diagnosis. **Summary and Conclusions.** Precursor B acute lymphoblastic leukaemia/lymphoma with t(14;18)(q32;31) translocation is a poor prognostic indicator with an aggressive and fatal course in adult patients Both patients described here suggest that this disease in the adolescent population has a similarly poor outcome

TRIB2 GENE DYSREGULATION IS ASSOCIATED WITH ADULT MINIMALLY DIFFERENTIATED ACUTE MYELOID LEUKEMIA

C Minervini[1], V Buttiglione[2], N Coccaro[2], L Impera[2], L Anelli[2], A Zagaria[2], P Casieri[2], A Minervini[2], G Tota[2], M Delia[2], D Pastore[2], F Albano[2], G Specchia[2]
[1]Hematology - University of Bari, Bari, Italy
[2]Hematology - University of Bari, Bari, Italy

Background. Tribbles homolog gene 2 (TRIB2) is a pseudokinase gene belonging to a three member gene family. Tribbles gene was first identified in Drosophila melanogaster where is involved in the regulation of morphogenesis and mitosis. Likewise, mammalian homologous genes of Tribbles (TRIB1, TRIB2, TRIB3) promote the degradation of specific transcription factors and interact with several cell signaling mediators and modulators. Recently it has been demonstrated that TRIB2 was able to induce AML in bone marrow transplanted mice by inducing the proteasome-dependent degradation of C/EBPα. Moreover, gene expression profiles data from AML patients revealed that patients carrying C/EBPα mutations clustered with those patients with TRIB2 up-regulated. **Aims.** To test the hypothesis that the TRIB2 expression was associated to the differentiation degree in AML, we evaluated several cases based on FAB cytotype. **Patients and Methods.** We performed quantitative Real Time-PCR (qRT-PCR) analysis on bone marrow aspirate samples of AML patients (15 AML-M0, 14 AML-M2, 5 AML-M3 and 3 M5b) to measure the expression level of TRIB2. Healthy bone marrows were used as reference samples. The qRT-PCR was conduct using SYBR green chemistry, specific primers for TRIB2 transcript and two housekeeping genes (B2M and IPO8) previously tested. Each AML sample was tested by conventional cytogenetic analysis and by FISH using a TRIB2 specific probe. We performed, also, the mutational analysis of the TRIB2 coding sequence and the methylation analysis of a CpG island located in the TRIB2 promoter region through the methylation sensitive restriction enzymes (MSRE) and qPCR. **Results.** qRT-PCR experiments revealed that TRIB2 expression was higher (from 3 to 20 fold) in AML-M0 respect to the AML-M2 (p= 0.02), AML-M3 (p=0.01), AML-M5 (p=0.006) FAB subtypes, and references (p=0.003), respectively. Therefore qRT-PCR displayed a progressive decreasing TRIB2 expression across FAB subtypes. To disclose the reasons of such misregulation we performed further analysis. Conventional cytogenetic and FISH analysis did not show any kind of rearrangement involving TRIB2 gene as found in other cancers with TRIB2 up-regulated, and mutational analysis excluded the occurrence of activating mutations. MSRE experiments showed an higher methylation degree in a CpG island, located in the TRIB2 promoter region in AML-M0 cases when compared to the others FAB subtypes; moreover, methylation degree was significantly correlated to the TRIB2 expression (r = 0.9; p = 0.0002). **Conclusions.** Here we show that the TRIB2 expression correlate with the differentiation degree of leukemic cells in AML, and it is epigenetically regulated. In our cases the TRIB2 misregulation was not due neither to gene amplification nor to activating mutations. Our data reveal that TRIB2 gene promoter is differentially methylated according to the FAB subtypes. Usually, the methylation causes gene silencing but we have found that the methylation of TRIB2 promoter region was associated to the overexpression of the gene.Our hypothesis is that the methylation could inhibit binding of some unknown transcriptional repressor as already seen for hTERT gene in others tumors cells.

0628

THERAPY RESISTANT AML STEM CELLS CHARACTERIZED BY IMMUNOPHENOTYPE (CD34/CD38) AND FUNCTION (DRUG EFFLUX)

F Wouters[1], J Cloos[1], B Moshaver[2], A Snel[1], G Ossenkoppele[1], S Zweegman[1], G Schuurhuis[1]
[1]VUmc, Amsterdam, Netherlands
[2]UMC Radboud, Nijmegen, Netherlands

Background. Despite intensive therapy 40% of acute myeloid leukemia (AML) patients relapse after remission. Relapse is thought to originate from leukemia initiating cells/stem cells (LSC) most often described as CD34+CD38-. However, the side population (SP), which is based on activity of drug efflux pump activity, and thereby possibly linked with therapy resistance, is also enriched in LSC. **Aims.** To determine the relationship between the CD34+CD38- defined LSC and those based on SP analysis. **Methods.** We analysed CD34 and CD38 expression within SP and non-SP (NSP) compartments of 6 CD34 positive AML samples and 7 CD34 negative samples (only molecularly normal CD34 cells) Populations were defined as putative AML or normal based on

immunophenotypic aberrancies (van Rhenen, Leukemia 2007, Blood 2007; Moshaver Stem Cells 2008). In 2 CD34- and 5 CD34+ samples, molecular aberrancies were determined (after cell sorting) to distinguish between AML and normal. In 2 CD34- and 3 CD34+ samples SP/NSP fractions were tested for stem cell activity in the liquid culture colony assay. **Results.** As expected, the CD34+CD38- and CD34+CD38+ defined populations of the 7 CD34 negative cases, were immunophenotypically normal (lack of the markers CLL-1, CD56, CD7). In 2 cases (NPM1-mut and FLT3-ITD), all CD34+CD38- and CD34+CD38+ SP and NSP sub-populations were molecularly normal. CD34-CD38+ made up almost all (> 90%) CD34- cells, both in SP and NSP, and were largely (52.0- 99.5%) leukemic.For CD34 negative AML, both leukemic and normal clonogenic output (colonies per million input cells) was highest for the SP fraction (SP AML vs NSP AML: 16,000 vs 20; SP normal vs NSP normal: 8,000 vs 0).In the 3 CD34 positive AML with low CD34 percentages (0.1%, 8.7%, 10.3%) that were molecularly characterized (2 FLT3-ITD, 1 NPM1-mut) the CD34+CD38- within the SP population were molecularly normal. With higher CD34 percentages (17%, 55%, 93%) a larger part (16%, 43%, 85%) of the SP CD34+CD38- cells were leukemic: 2 both molecularly (1 NPM1-mut, 1FLT3-ITD) and immunophenotypically aberrant; 1 immunophenotypically aberrant) In the NSP fraction of all 6 CD34+ patients, the CD34+CD38- cells were largely (60-100% leukemic (3 FLT3-ITD, 2 NPM1-mut and in addition all 6 were immunophenotypically aberrant). Also for CD34+CD38+ cells, with increasing CD34 percentage, the contribution of leukemic cells within SP increased (23%, 93%, 100%). In the NSP fraction the CD34+CD38+ were largely (41-100%) leukemic. CD34-CD38+ cells were largely (50-100%) leukemic in both SP and NSP. Again, for CD34 positive AML, the clonogenic output was highest for the SP fraction (SP AML vs NSP AML: 4,900 vs 7; SP normal vs NSP normal: 2,300 vs 0). **Conclusions.** These results indicate that SP analysis can help to define small fractions of LSC that are highly clonogenic in both CD34 positive and negative AML. Since the frequency of CD34+CD38- LSC has strong prognostic impact *(Terwijn, ASH 2010;759)*, and the SP population is defined by high drug efflux ability, it must be considered that it may well be the CD34+CD38- SP fraction that preferentially survives therapy.

0629

WILMS' TUMOR 1 PROTEIN EXPRESSION IS DOWNREGULATED BY MICRORNA-132

M Luesink[1], J Nigten[2], R Knops[2], B van der Reijden[2], J Jansen[2]
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands
[2]Laboratory of Hematology - Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background. Apart from mutations in specific genes, aberrant expression of crucial genes is thought to contribute to leukemogenesis. Apart from transcription factors, microRNAs are important regulators of gene expression, both at the mRNA as well as the protein level. MicroRNAs contribute to the regulation of hematopoiesis via targeting of transcription factors or genes involved in cell cycle regulation and proliferation. Several microRNAs were shown to be associated with hematological malignancies, but information on the relevant target genes that are regulated by these microRNAs is sparce. **Aims.** We performed microRNA expression profiling to identify specific microRNAs which target genes involved in myeloid differentiation. **Methods.** The expression of 157 mature microRNAs was studied during granulocytic differentiation (induced by all-*trans* retinoic acid (ATRA)) in the acute promyelocytic leukemia cell line NB4 using stem-loop RT-PCR Taqman® microRNA assays (Applied Biosystems). Identification of candidate target genes of specific miRNAs was performed using four microRNA target prediction programs (DIANA-microT, miRanda, PicTar, TargetScanS). **Results**. We identified miR-132 as the most strongly induced microRNA during ATRA-induced differentiation in NB4 cells (491-fold). Induction of miR-132 during granulocytic differentiation was also observed in the non-APL cell line HL60 (31-fold), as well as in leukemic primary cells (9-fold, N=8) and normal primary cells (15 fold, N=5) which were obtained after informed consent in accordance with the Declaration of Helsinki and institutional review board approval. These data indicate that granulocytic differentiation is associated with induction of miR-132.We identified Wilms' Tumor 1 (*WT1*) as a putative target of miR-132 based on the presence of a conserved potential miR-132 recognition element (MRE) in the 3'UTR of *WT1*. The *WT1* gene encodes for a zinc-finger transcription factor which plays an important role in normal as well as malignant hematopoiesis. In myeloid malignancies, deregulation of WT1 is frequently observed. So far, the regulation of *WT1* expression has mainly been studied at the transcriptional level. The mechanisms of post-transcriptional regulation of *WT1* expression are largely unknown. We studied whether miR-132 can regulate *WT1* expression.To confirm the predicted interaction of miR-132 with the 3'UTR of *WT1*, luciferase reporter assays were performed. If the wild-type 3'UTR of *WT1* was present downstream of the firefly luciferase gene, co-expression of miR-132 resulted in a significant reduction of the firefly luciferase signal (mean reduction: 33±3%, N=3). Repression of the luciferase expression by miR-132 was lost if complementarity between the *WT1* 3'UTR and miR-132 was disturbed by mutations. To determine whether endogenous *WT1* expression is indeed regulated by miR-132, the effect of ectopic miR-132 expression on *WT1* mRNA and protein expression was studied. Endogenous *WT1* mRNA expression was not affected by ectopic expression of miR-132. However, endogeneous *WT1* protein levels were significantly lower in miR-132 transduced NB4 cells compared to empty vector transduced NB4 cells. **Summary and Conclusions.** We show that protein translation of *WT1* is repressed by miR-132 via a specific miR-132 recognition element located in the 3'UTR of *WT1*. We conclude that miR-132 functions as a translational repressor of *WT1*.

THE NOVEL TYROSINE KINASE INHIBITOR PONATINIB (AP24534) MAY OVERCOME RESISTANCE OF FLT3-ITD HARBOURING THE PREVIOUSLY REFRACTORY F691I MUTATION IN VITRO

S Scholl
Klinik für innere Medizin II, Jena, Germany

Elisabeth Zirm[1], Bärbel Spies-Weisshart[1], Florian Heidel[2], Ulf Schnetzke[1], Frank-D. Böhmer[3], Andreas Hochhaus[1], Thomas Fischer[2], Sebastian Scholl[11]Department of Hematology/Oncology, Clinic for Internal Medicine II, Jena University Hospital, Jena, Germany, [2]Department of Hematology/Oncology, Otto-von-Guericke-University, Magdeburg, Germany and [3]Center for Molecular Biomedicine, Jena University Hospital, Jena, Germany

Background. Molecular aberrations of the *fms*-like tyrosine kinase 3 (FLT3) represent the most frequent mutations that confer an unfavourable prognosis in acute myeloid leukemia (AML). Particularly, a ligand-independent autophosphorylation of FLT3 by internal tandem duplications (ITD) defines a promising target for therapeutic approaches using FLT3 tyrosine kinase inhibitors (TKI). However, distinct additional point mutations within the FLT3 tyrosine kinase domain (TKD) have been identified as one major mechanism to mediate secondary resistance towards FLT3 inhibitors. Recently, pharmacological research revealed ponatinib (AP24534) as an orally active TKI with inhibitory activity against tyrosine kinases including FLT3. **Aims and Methods.** In this study, we intended to evaluate the efficacy of the recently characterized FLT3-TKI ponatinib to overcome TKI resistance in murine Ba/F3 cells transfected with FLT3-ITD containing additional point mutations of the FLT3-TKD, notably the multi-resistant F691I mutation. **Results.** We can demonstrate that ponatinib potently induces apoptosis not only in the parental FLT3-ITD cell line but also in all stably transfected mutants harbouring the additional FLT3-TKD point mutations N676D, F691I, or G697R. Importantly, these observations correlate with a strong inhibition of FLT3-ITD and its downstream signalling pathways (STAT5, AKT, and ERK1/2) upon ponatinib treatment as determined by phospho-specific immunoblot analysis.Furthermore, ponatinib mediates a dose-dependent down-regulation of the important anti-apoptotic protein Mcl-1 in the FLT3-ITD harbouring cell line while a significant lower expression and an impaired regulation of Mcl-1 was detectable in Ba/F3-ITD-F691I cells by cytometry and Western blot analysis. **Conclusions.** Taken together, these results approve that ponatinib represents a promising FLT3-TKI *in vitro*. Therefore, clinical trials are warranted to further improve the therapeutic options for FLT3-ITD-positive AML patients. Moreover, the targeted therapy of FLT3-ITD-positive AML with ponatinib might be associated with a lower frequency of secondary resistance caused by acquired FLT3-TKD mutations.

0631

NOVEL SMALL MOLECULE INHIBITORS OF THE P53- MDM2 /MDM4 INTERACTION FOR INDUCTION OF APOPTOSIS IN AML

LM Köhler[1], B Beck[1], H Huang[2], T Holak[3], A Dömling[4], M Subklewe[1]
[1]Medizinische Klinik und Poliklinik III, Campus Groβhadern, Munich, Germany
[2]Department of Pharmaceutical Science, University of Pittsburgh, Pittsburgh, United States of America
[3]Max Planck Institute for Biochemistry, Munich, Germany
[4]Department for Drug Design, University of Groningen, Groningen, Netherlands

A promising new approach in cancer treatment is the inhibition of murine double minute 2 and 4 (MDM2/MDM4) which is a negative regulator of p53. In neoplasia with unmutated p53 the inactivation of MDM2/4 promotes apoptosis and growth arrest. A derivative of the first described p53/MDM2 antagonist Nutlin-3 has already entered clinical phase I / II studies, although recent *ex vivo* data also indicate that Nutlin-3 is able to induce DNA damage and promotes tumor cell resistance. We investigated a novel set of substances and their ability to

antagonize the protein-protein interaction between p53 and MDM2/4.The compounds described here, belonging to the YH-compound family, were synthesized according to the proposed structure by ANCHOR.QUERY based design and modelling in the p53/MDM2 protein structure. This YH-compound family consists of an acyclic Ugi four component reaction scaffold. The reaction yielded a mixture of enantiomers that could be easily separated by chiral HPLC. The initial screening by nuclear magnetic resonance (NMR) and fluorescence polarisation (FP) revealed several p53/MMDM2 antagonists. Further structure based optimisation led to potent and selective drug-like lead structures which were confirmed by co-crystal structures.To evaluate the biological effects of our compounds we analyzed four AML cell lines in which in general p53 mutations are rare events. The initial experiments were performed in OCI-AML-3 and MOLM-13 which were both confirmed to be wt-p53 and HL-60 and NB4 with deleted or mutated p53 (mt-p53). We determined the EC_{50} values of our substances by measuring the turnover of WST-1 to Formazan, depending on the cell metabolism. We investigated the influence on the metabolic activity of the wt-p53 and mt-p53 cells caused by treatment with our substances in different concentrations for 48 h. Notably, the compound YH239 showed an EC_{50} of 14 µM in MOLM-13 cells. To get further evidence of efficacy of the lead compound YH239 we analysed the influence on the cell cycle after 24 h treatment. A relative increase of 23% compared to untreated cells in the subG1 phase was observed. Furthermore, we measured the cell numbers and cell viability up to 72 h of treatment. In the wt-p53 MOLM-13 cell line a growth reduction of 65% was measured compared to no effect in the p53 deleted HL-60 cell line. Induction of apoptosis was analyzed after 72 h treatment with 20 µM YH239 by Annexin-V and propidium iodide (PI) staining. We noticed 86% of specific apoptotic cells in wt-p53 MOLM-13 cell line compared to 2 % in p53 deleted HL-60 cell line relative to the untreated control. A measurement of caspase 3/7 activity upon treatment (6 h and 12 h) with our substances indeed revealed an increased signal. Comparing both enantiomers YH239 A and B we found that YH239B is the more active one. In conclusion YH239 shows high efficacy for induction of apoptosis and cell growth arrest in wt-p53 cells. Further investigations in primary AML cells are under way.

MICRORNA EXPRESSION PROFILING OF HEMATOPOIETIC AND LEUKEMIC STEM CELLS IN ACUTE MYELOID LEUKEMIA

D de Leeuw, F Denkers, G Schuurhuis, G Ossenkoppele, L Smit
VU University Medical Center, Amsterdam, Netherlands

Background. Only a minority of cells in acute myeloid leukemia (AML) is responsible for leukemia growth and maintenance. These leukemia-initiating cells share cell surface markers with normal hematopoietic stem cells (HSCs) and have features of both self-renewal and differentiation which have given them the name "leukemic stem cells" (LSCs). Although 60-80% of AML patients achieve complete remission after chemotherapy, many patients experience a relapse which is thought to be caused by the survival of LSCs after chemotherapy. Eradication of LSCs is therefore necessary to cure AML patients.Both normal HSCs and LSCs co-exist in the bone marrow (BM) of AML patients and success of anti-LSC therapy relies on eradication of LSCs while sparing HSCs. For the development of these LSC-specific therapies the identification of molecules that are differentially expressed between normal and malignant stem cells is important. MicroRNAs (miRNA) are small non-coding RNAs which regulate gene expression at the post-transcriptional level by targeting mRNAs. These small RNAs are promising therapeutic targets since modulation of a single miRNA may affect many pathways simultaneously. **Aims.** Our aim is the development of novel LSC specific miRNA-based therapeutic strategies by identification of miRNAs differentially expressed and functioning in LSCs and HSCs. **Methods.** We have identified several phenotypic differences between LSCs and HSCs that reside within the CD34+CD38- compartment of the AML BM. These include aberrant expression of CD34, CD45, CLL-1, lineage markers, scatter properties, and recently the activity of aldehyde dehydrogenases. Stem cells with high aldehyde dehydrogenase activity have no molecular and immunophenotypical aberrancies suggesting a normal phenotype whereas stem cells with low aldehyde dehydrogenase activity harbor leukemia associated aberrancies. This allowed the identification and purification of both LSCs and HSCs from AML patients and gave us the opportunity to identify miRNAs differentially expressed between LSCs and HSCs and between LSCs and leukemic progenitors all derived from the same AML BM (n=6). **Results.** Microarray analyses revealed the differential expression of miR-21, miR-181a/b, miR-551b, miR-29b and miR-125b in LSCs compared to HSCs. MiRNAs with differential expression between LSCs and leukemic progenitors were miR-126/miR-126*, miR-335, miR-146a and miR-1260. We have confirmed the expression patterns of several of the identified miRNAs by qRT-PCR. **Conclusions.** In conclusion, we have identified several miRNAs that are differentially expressed between LSCs and HSCs and LSCs and leukemic progenitors. These miRNAs might characterize and potentially maintain AML LSCs through their effects on proliferation, apoptosis and differentiation. In the future these miRNAs may be used as valuable anti-leukemic miRNA-based therapeutics.

MUTATIONS OF THE SPLICEOSOME MACHINERY AND OF EPIGENETIC ENZYMES ARE RARE IN THERAPY-RELATED MYELOID NEOPLASMS

MT Voso, E Fabiani, L Fianchi, P Chiusolo, G Falconi, M Criscuolo, R Santangelo, S Giammarco, T Za, F Guidi, F D'Alò, S Hohaus, G Leone
Universita' Cattolica Sacro Cuore, Rome, Italy

Background Therapy-related neoplasms (t-MN), including myelodysplastic syndromes and acute myeloid leukemia (AML), are an increasingly recognized complication in patients previously treated with radiotherapy and/or chemotherapy for a cancer or autoimmune disease. t-MN display a high incidence of monosomal and complex karyotypes, *p53* mutations, and gene-specific promoter methylation, but some other mutations that are common in AML, are usually rare, as mutations in the genes FLT3, NPM1, CEBPA, and TET2. **Aims.** We studied the incidence of the recently described mutations in genes coding enzymes involved in epigenetic pathways (IDH1 R132, IDH2 R140 and R172, DNMT3A R882), and of genes of the spliceosome machinery (U2AF1, SF3B1 exons 13-14 and 15-16) in 101 patients with a therapy-related MN. We also analyzed the prevalence of methylene-tetrahydrofolate reductase (MTHFR) C677T and A1298C polymorphisms (SNP), compared to age and sex-matched controls. **Methods.** MTHFR SNP were studied using PCR-RFLP, while analysis of all other genes was performed on genomic DNA by Sanger sequencing (ABI PRISM 3130 Genetic Analyzer; Applied Biosystems). **Results.** There were 56 females and 55 males, with a median age of 66 years (range 16-88 years).The homozygous 1298A>C MTHFR variant was more frequent in t-MN (7/49 patients versus 5/110 controls, p=0.03). In this line, aplotype frequency of the CC vs CA and TA vs CA was significantly higher in t-MN compared to controls (p<0.005 for both). There were 4 mutations in the IDH1 gene at position R132 (4/96 patients, 4.2%, 3 R132C, 1 R132H),6 inthe IDH2 gene, (2 R172K and 4 R140, 6/94 patients, 6.4%). IDH1 and IDH2 mutations were mutually exclusive. DNMT3A was mutated at R882 in 5 of 95 patients (5.3%, 4 R882H and 1 R882C).The recurring K700 alteration in exons 15-16 of the SF3B1 gene was detected in 3 of 94 t-MN patients (K700E, 3.2%), so far we did not find any Exon 13-14 mutations. A concurrent R140Q IDH2 mutation and R882H DNMT3A mutation was observed in 2 patients.Looking at patient characteristics, there were no associations between the incidence of mutations and the proportion of bone marrow blasts or type of t-MN. IDH1 and IDH2 mutations were significantly more frequent in t-MN secondary to a myeloproliferative neoplasm (MPL) (5 of 14, versus 5 of 49 with a previous solid tumor, versus none of the 24 patients with a previous lymphoproliferative disease, p: 0.002). Two of two patients with available DNA from the MPL and the subsequent t-MN had the same pattern of mutations before and after evolution (1 mutated, 1 Wild Type). The pattern of mutations was similar in peripheral blood -mononuclear cells and CD34+ cells selected at the time of leukemic evolution in 3 patients.IDH mutations confirm that disease evolution plays a fundamental role in AML secondary to MPL. **Conclusions.** IDH 1/2, DNMT3A and SF3B1 mutations are rare in MDS/AML secondary to chemo- or radiotherapy for solid tumors or other hematological malignancies. In these diseases mutations of other pathways and aberrant karyotype may play a dominant role.

0634

THE EXPRESSION OF THE EGF-TM7 RECEPTOR CD97 IS HIGHER IN CD34-NEGATIVE AND NPM1/FLT3-ITD MUTATED AML

M Wobus, M Bornhäuser, C Klotsche, C Rüger, C Ortlepp, G Ehninger, C Thiede, U Oelschlägel
University Hospital Dresden, Dresden, Germany

Background. With an incidence of 25% the internal tandem duplication (ITD) of the receptor tyrosine kinase FLT3 represents one of the most common mutations in patients with AML which results in constitutive aberrant activation of FLT3 and increased proliferation of leukemic progenitors.CD97 is a member of the EGF-TM7 family of adhesion receptors and is broadly expressed in hematopoietic cells. In carcinomas of epithelial origin CD97 showed increased expression which correlated in some cases with a higher tumor grade and poor prognosis. **Aims.** So far, nothing is known about the expression of CD97 in AML bone marrow (BM) which was investigated in the present study. **Methods.** We studied 116 samples from patients with *de novo* acute leukemia, comprising AML M0-2 (n=73), AML M3 (n=7), AML M4/5 (n=31) and c-ALL (n=5). A 4-color immunophenotypic measurement was performed on a FACS Canto II using the following antibodies: CD14, CD2 and CD7 FITC, CD13 PE, CD34 Per-

Cp5.5, CD117 and CD56 PE-cy7, CD97 and CD33 APC, HLA DR APC-H7, CD45 V500. FLT3-ITD mutations and NPM1-mutations were detected as reported in detail previously (Thiede C et al. Blood 2002; Thiede C et al. Blood 2006).The human AML cell line MV4-11 which carries a homozygous FLT3-ITD mutation and normal CD34+ hematopoietic stem cells (HSC) were exposed to different concentrations of the protein kinase inhibitor PKC412 (Midostaurin). After 24 hours the CD97 expression was analyzed by flow cytometry and the migration capacity was tested in a transwell chamber assay. **Results.** Compared to BM blasts of healthy donors (n=10), we detected significant higher CD97 expression levels (mean fluorescence intensity, MFI) in 50 AML samples (42%), which is 31.5% of M0-2, 100% of M3 and 45% of M4/5, and 80% of the c-ALL, respectively. Patients with a CD97 expression above the mean on leukemic blasts showed also increased expression of the molecule within the residual granulo- and monopoiesis. Of note, higher CD97 expression was accompanied by a significantly higher BM blast count (75% vs. 53%, p<0.001). Interestingly, elevated CD97 expression was associated with mutations in NPM1 (46% vs. 18%, p=0.003) and FLT3 genes (39% vs. 7%, p<0001) as well as lower CD34 expression (46% vs. 81%, p<0.001). Furthermore, no AML1/ETO or CBFb/MYH11 fusion genes were detectable in CD97+ AML vs. 6% in CD97- AML. *In vitro*, we detected higher CD97 expression levels in MV4-11 AML cells in comparison to CD34+ HSC (MFI: 138 vs. 45.7). Treatment with PKC412 resulted in a decrease to 40.4% of CD97 expression in MV4-11 cells whereas it had no influence in CD34+ HSC. The lower CD97 expression levels correlated with inhibition of the spontaneous migratory capacity of the AML cell line. **Conclusions.** We present first evidence of higher CD97 expression in mFLT3/mNPM1 AML cells which might provide a new diagnostic and perhaps therapeutic target. The possible impact of CD97 expression on AML biology and clinical outcome should be evaluated in a larger patient cohort.

0635

COSTIMULATORY MOLECULE B7-H3 IN ACUTE LEUKEMIA: EXPRESSION CHARACTERISTICS AND PROGNOSTIC SIGNIFICANCE

H Qiu, Y Hu, X Lv, Y Wu, L Wang, W Cheng, W Zhang, J Li
The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

Background. B7-H3 is a recently identified costimulatorymolecule belonging to B7 family that has been implicated as a novel modulator of antitumor response. Many researches on B7-H3 expression and clinical significance of various human cancers were studied but not in hematopoietic malignancies.2. **Aims.** To contribute to an understanding of its role in acute leukemia (AL), we analyzed B7-H3 at protein levels by flow cytometry (FCM) and mRNA by RT-PCR in 134 patients with AL and 12 age- and sex- matched healthy controls. **Methods.** Positive expression was defined as ≥10% leukemia cells co-expressing B7-H3 molecule comparing with IgG mAb isotype control. Correlations between B7-H3 expression and clinico-biological characteristics were calculated for prognostic-prediction. Among all the patients, 101 acute myeloid leukemia (AML) and 33 acute lymphocytic leukemia (ALL) were included, with male/female ratio of 1.2:1 and median age of 43 years. B7-H3 was detected on surface of blast cells of ALs by FCM. RT-PCR confirmed the products at mRNA level within same samples. **Results.** According to our definition, 44.8% AL cases were B7-H3 positive expression and none was in healthy controls. Heterogeneously, positive rate and expression range of B7-H3 in AL subtypes were as follows: M1 42% (1.3~43.0%), M2 50% (0.5~74.8%), M3 22% (2.1~32.3%), M4 44% (1.2~43.1%), M5 36% (1.1~54.3%), B-ALL 54% (1.1~66.5%), T-ALL 20% (1.9~23.9%). No statistical special distribution was found in any subtype. From a clinico-biological standpoint, no significant relationship was observed between B7-H3 expression and sex, age, percentage of blast cells or white blood cell counts (WBC). However, B7-H3 had a significant higher expression in $CD34^+$ cases versus $CD34^-$ cases (P=0.018) and poor- versus good- or intermediate- risk karyotypes whether in AML or ALL patients (P=0.000). Likewise, the expression of B7-H3 was statistically relevant in predicting disease progression (P=0.001) and a shorter life survival (P=0.005). **Summary and Conclusions.** In summary, this study observed for the first time that B7-H3 also expressed on membranes of leukemia cells in ALs. B7-H3 expression correlated with progenitor marker CD34 and poor risk karyotype but not with other prognostic factors. Furthermore, in AL patients, B7-H3 expression predicted a shorter PFS and OS. Our results suggest that B7-H3 expression has prognostic significance.

0636

DIFFERENTIAL EFFECT OF CYTOTOXIC MAINTENANCE THERAPY ON T CELLS, TREGS AND NK CELLS IN AML PATIENTS

R Lorenz[1], F Lichtenegger[2], P Palluch[2], U Hoffmueller[3], J Braess[2], W Hiddemann[2], B Beck[2], M Subklewe[2]
[1]Ludwig-Maximilians-Universität, München, Germany
[2]Medizinische Klinik und Poliklinik III, Ludwig-Maximilians-Universität, München, Germany
[3]Epiontis GmbH, Berlin, Germany

The success of immunotherapies is hampered by negative regulatory mechanisms that inhibit anti-leukemic T and NK cell function. A promising approach to overcome immune evasion is the combination of immunotherapy with cytotoxic chemotherapy. Within the AML-CG study group, we regularly apply cytarabine in an alternating combination with daunorubicin, 6-thioguanine and cyclophosphamide every 28 days as a maintenance postremission therapy in AML patients not eligible for stem cell transplantation.Assessing the immune status of patients prior to and during maintenance therapy, we aimed at defining a potentially beneficial point of time for active immunotherapies, e.g. dendritic cell vaccination.We analyzed PBMC subpopulations ($CD3^+CD8^+$ cytotoxic T cells, $CD3^+CD4^+$ T helper (Th) cells, $CD4^+CD25^{hi}CD127^{lo}FoxP3^+$ regulatory T cells (Tregs), and $CD3^-CD16^+CD56^+$ natural killer (NK) cells) in 10 AML patients throughout early maintenance therapy cycles by flow cytometry. In addition, Tregs were quantified by a DNA methylation assay in 3 AML patients. In order to test the proliferative capacity of Th cells, CFSE assays with PHA as stimulus were performed in 3 patients. T cell polarization was analyzed by determination of secreted cytokines using a cytometric bead array after IL-2 stimulation. NK cell functionality was assessed in 4 patients using CD69 upregulation after stimulation with IL-2. The resulting data was compared to a total of 15 healthy donors.The absolute Th cell counts, absolute numbers of Tregs and absolute NK cell counts were significantly lower in AML patients prior to the start of maintenance therapy compared to healthy donors. In the course of maintenance therapy, several dynamics were observed: Total leukocyte numbers decreased, with the nadir around 1 G/l on day 21. The proportion of Th cells temporarily increased throughout the course of therapy. So did the fraction of Tregs, which more than doubled throughout therapy, explaining part of the relative increase in $CD4^+$ T cells. In contrast, relative numbers of NK cells declined in the course of maintenance therapy. Functionally, proliferative response of Th cells from AML patients was substantially reduced two weeks after the start of therapy. When comparing cytokine secretion after stimulation with PHA, we found that the Th cells isolated from AML patients tended to secrete higher concentrations of IL-4 and IL-17, but lesser amounts of IFN-γ. The activation capacity of NK cells was generally reduced in AML patients pretherapy relative to healthy donors.In our ongoing study of AML patients, we found that T and NK cell subsets after intense polychemotherapy significantly differed from those of healthy donors. Prior to the start of maintenance chemotherapy, we prominently saw a diminished number and function of NK cells. This is in accordance with previous reports on NK cell dysfunction in AML patients. In the course of maintenance therapy, we observed a significant relative increase in Tregs and a decrease in the functional response of Th cells. These results urge to intensively monitor T cell populations and functionality during chemotherapy and immunotherapy to be able to establish synergistic combinations of chemotherapy and immunotherapy.

THE ROLE OF AUTOPHAGY IN ACUTE MYELOID LEUKAEMIC CELL DIFFERENTIATION

N Orfali[1], T O'Donovan[1], M Nyhan[1], M Cahill[2], S McKenna[1]
[1]Cork Cancer Research Centre, Cork, Ireland
[2]Haematology Department, Cork University Hospital, Cork, Ireland

Background and Aims. Autophagy is a degradative cellular process in which aged, damaged or redundant proteins and organelles are engulfed within membrane-bound structures known as autophagosomes and metabolised by lysosomes. As well as being activated in times of cellular stress, autophagy has recently been proposed as a key player in cellular remodelling and differentiation. As differentiation block is a hallmark of Acute Myeloid Leukaemia (AML), we set out to characterize the involvement of autophagy in myeloid leukaemic cells undergoing pharmacologically induced differentiation. Morphologically autophagy is characterized by the accumulation of vesicles within the cell cytoplasm. Gabba-aminobutyric-acid-receptor-associated-protein (GABARAP) is a cytoplasmic protein that is conjugated on autophagy activation and recruited to these vesicles. **Methods and Results.** We treated NB4 cells - a model for Acute Promyelocytic Leukaemia (APL) carrying the PML-RARA translocation, with all-*trans*-retinoic acid (ATRA) (1uM) for 6 days. As expected, differentia-

tion along a granulocytic lineage was observed morphologically on Prodiff staining of cytospun cells. This was corroborated by a proliferation arrest as measured by daily viable cell counts (Chemometec Nucleocounter system) and confirmed by flow cytometric detection of the surface markers of early differentiation - CD11b and CD14.Microscopically, we observed a significantly increased number of cytoplasmic vesicles in ATRA-treated cells after 48 hours as compared with untreated controls. The presence of these vesicles preceded the characteristic cellular changes seen with granulocytic differentiation and we enumerated a progressive increase in vesicle quantity as differentiation advanced. We carried out immunoflourescence analysis of GABARAP in NB4 cells undergoing differentiation and observed a shift from diffuse cytoplasmic staining on Day 1 to a definite punctate pattern on Day 6 consistent with incorporation into autophagic vesicles. GABARAP was also seen to surround ring-shaped structures suggesting the formation of larger autophagic vacuoles. Western Blotting performed on protein lysates prepared from treated and control cell populations to detect Beclin-1 - a well-characterized protein involved in the initiation of autophagosome formation, revealed an increase in protein level from Day 3 of ATRA treatment as compared to untreated controls, suggestive of BECN1 gene up-regulation during the differentiation process. **Conclusions.** Autophagy plays a significant role in the myeloid differentiation of APL cells. Pharmacological induction of autophagy may have the potential to induce differentiation in other forms of AML. We are currently testing this hypothesis on AML patient samples.

0638

REDUCED RISK OF THERAPY-RELATED ACUTE MYELOID LEUKEMIA IN CARRIERS OF THE BCL2-LIKE-10-LEU21ARG VARIANT

E Fabiani, G Falconi, R Boncompagni, L Fianchi, M Criscuolo, F D'Alò, G Leone, MT Voso
Università Cattolica Sacro Cuore, Rome, Italy

Background. Proteins belonging to the Bcl-2 family are key regulators of apoptosis and have been shown to mediate survival and cell death processes. Bcl2L10 (also named Diva, Boo or Bcl-B) is a member of the Bcl-2 family characterized by an ambiguous function. Specifically, previous independent reports indicated that Bcl2L10 can have both pro- or antiapoptotic functions and it can influence the transit between quiescence and proliferation. The aberrant regulation of apoptosis and cell cycle have been directly linked to many diseases and is one of the hallmarks of cancer.We have previously demonstrated that Bcl2L10 is transcriptionally repressed by promoter hypermethylation and that its overexpression correlates with apoptosis and growth inhibition of the HL60 cell line. Moreover, patients affected by *de novo* and therapy-related acute myeloid leukemia (AML) were more frequently methylated at Bcl2L10 compared to controls. High levels of Bcl2l10 methylation were a negative prognostic factor for 5-azacytidine treatment in patients affected by a higher-risk myelodisplastic syndrome (MDS). **Aims.** We performed a case-control study to test the prevalence of the polymorphic variant of the Bcl2L10 gene (Bcl2L10 Leu21Arg; rs2231292) as risk factor for *de novo* and therapy-related AML/MDS.

Genotype	Controls	MDS	AML	t-MDS/AML	Statistical Analysis*	
	n (%)	n (%)	n (%)	n (%)	OD (95% CI)*	p-Value*
Bcl2L10-Leu21Arg	162	92	75	84		
Leu/Leu	57 (35.19)	39 (42.39)	24 (32.00)	43 (51.19)	1.00 (Ref)	
Leu/Arg	85 (52.47)	39 (42.39)	41 (54.67)	33 (39.29)	**0.51 (0.28-0.94)**	**0.029**
Arg/Arg	20 (12.34)	14 (15.22)	10 (13.33)	8 (9.52)	0.53 (0.19-1.43)	0.246
Leu/Arg and Arg/Arg	105 (64.81)	53 (57.61)	51 (68.00)	41 (48.81)	**0.52 (0.29-0.92)**	**0.022**

**The statistical analysis refers to t-MDS/AML patients vs controls. Significant differences between t-MDS/AML and controls are in bold.*

Figure 1.

Methods. Bone marrow or peripheral blood samples were obtained from 75 *de novo* AML, 92 *de novo* MDS and 84 therapy-related MDS/AML patients, diagnosed according to the WHO classification. Control peripheral blood samples were obtained from 162 Caucasians with a negative history for previous malignancies. Informed consent was obtained according to institutional guidelines. We established a PCR-RFLP technique to detect the Bcl2L10 Leu21Arg polymorphic variant. Hardy-Weinberg equilibrium was calculated for each population and Yates corrected test was used to calculate differences in genotypes population. Odds ratios with 95% confidence intervals were also calculated. **Results.** This is the first report on the frequency of the Bcl2L10 Leu21Arg SNP in myeloid malignancies. Frequencies of the polymorphic variant Leu21Arg of Bcl2L10 enzyme were similar in *de novo* AML, MDS patients and controls. On the other hand, the Bcl2L10 variant was less frequent in therapy-related MDS/AML patients compared to controls (O.R., 0.52; 95% C.I., 0.29-0.92; p=0.022), resulting in a reduced risk for therapy-related AML/MDS (table 1). The same was true when comparing therapy-related MDS/AML to *de novo* AML (O.R., 0.45; 95% C.I., 0.22-0.90; p=0.022), but not comparing to *de novo* MDS. Moreover, stratifying the analysis, the frequency of Bcl2L10 variant was lower in therapy-related AML than in *de novo* AML (O.R., 0.36; 95% C.I., 0.16-0.83; p=0.013), whereas no differences were found between *de novo* and therapy-related MDS.No significant associations were found between enzymatic polymorphisms and other patients' characteristics, including sex, age, cytogenetics, and therapy of the primary tumor. **Summary and Conclusions.** Bcl2L10 Leu21Arg variant is less frequent in therapy-related AML, compared to *de novo* AML and controls, probably playing a protective role against the development of secondary myeloid neoplasms.

ASSOCIATION OF CYP2B6 G516T POLYMORPHISM WITH THE SUSCEPTIBILITY OF *de novo* ACUTE MYELOGENOUS LEUKEMIA

A Daraki[1], S Zachaki[1], T Koromila[2], M Karakosta[1], G Pantelias[1], V Aleporou[2], C Sambani[1], P Kollia[2], K Manola[1]
[1]NCSR „Demokritos„, Athens, Greece
[2]Faculty of Biology, National & Kapodistrian University, Athens, Greece

Background. Acute myeloid leukemia (AML) is a heterogeneous disease with well-known clinical and pathological aspects. Nevertheless, the genetic etiology of AML which include gene mutations and chromosomal aberrations is largely unknown. Altered forms of genes that differ by a single nucleotide base-pair polymorphisms (SNPs) have been shown to predispose individuals to AML development. Interindividual differences based on detoxification genes polymorphisms may contribute to the AML susceptibility. Cytochrome P450 (CYP) enzymes are involved in the metabolism of many endogen and exogenous xenobiotics that act as precarcinogens. *CYP2B6, a* phase I metabolic enzyme, blocks the transformation of precarcinogens to their biologically active forms that provoke chromosomal instability and cancer. *CYP2B6* $G^{516}T$ SNP change the aminoacid sequence (Gln172His), resulting in enzymatic inactivation. Thus, individuals homozygous for the mutant allele (T/T) completely lack *CYP2B6* activity, whereas heterozygotes (G/T) present decreased enzymatic activity. **Aims.** We performed a case-control study in a series of AML patients to investigate the potential relation between the *CYP2B6* G/T and T/T variant genotypes and the risk of *de novo* AML. We also compared the genotypic frequencies in AML patients in respect to chromosome abnormalities, FAB classification and clinical characteristics. **Methods.** The *CYP2B6* $G^{516}T$ genotyping was performed on 132 *de novo* AML patients at diagnosis and 168 sex and age matched healthy controls using a PCR-RFLP assay. Unstimulated bone marrow cells were used for karyotypic analysis and karyotypes were described according to ISCN. Statistical analysis was performed using Chi-square test and $P<0.05$ was considered to be statistically significant. **Results.** Karyotypic analysis and *CYP2B6* genotyping were successfully performed in all 132 AML patients at diagnosis. Among them, 91 (68.9%) showed clonal karyotypic abnormalities. The genotypic distribution in patients and healthy controls groups showed: homozygous wild type G/G 56.8% *vs* 69%, heterozygotes G/T 37.8% *vs* 27.9% and homozygous mutant T/T 5.3% *vs* 2.9% respectively. The increased frequency of G/T+T/T variant genotypes in AML patients was statistically significant compared to controls ($p<0.05$). Stratification of patients according to gender revealed no differences in genotypic distribution of *CYP2B6* genotype between male and female AML patients. Among females, the frequency of the mutant variant T was significantly increased in AML patients comparing to the healthy controls (homozygous mutant T/T 5.2% vs 0%, $p<0.05$). No homozygous mutant T/T genotype was observed in patients with favorable prognosis chromosome abnormalities[inv(16), t(8;21), t(15;17)]. Interestingly, patients with aberrations of chromosomes 5 and/or 7 showed a statistically increased frequency of the homozygous mutant T/T genotype. Stratification of patients according to FAB classification and age groups revealed no differences in the mutant (G/T and T/T) genotypic frequencies. **Summary and Conclusions.** The increased frequency of G/T+T/T variant genotypes in AML patients indicates a possible implication of CYP2B6 G516T polymorphism in the pathogenesis of AML. The statistically increased frequency of the homozygous mutant T/T genotype in AML patients with aberrations of chromosomes 5 and/or 7 indicates that completely lack of CYP2B6 enzymatic activity may be associated with the formation of these aberrations which confer an unfavorable prognosis in AML patients.

FURTHER DELINEATION OF GENETIC LESIONS IN CORE BINDING FACTOR-ACUTE MYELOID LEUKEMIA BY ASSOCIATION OF G BANDING AND GENOMIC KARYOTYPES

AR Costa[1], M Rodrigues[1], A Krepischi[2], C Rosenberg[3], M Chauffaille[1]
[1]UNIFESP, São Paulo, Brazil
[2]CIPE - Hospital AC Camargo, São Paulo, Brazil
[3]Departamento de Genética e Biologia Evolutiva - IBUSP, São Paulo, Brazil

Background and Aims. Acute myeloid leukemia (AML) is a group of clonal diseases, resulting from two classes of mutation. We performed a SNP array (SNPa) in a set of core-binding factor acute myeloid leukemia (CBF-AML) patients to identify cooperating lesions, check the agreement between array and G banding analysis and detect the presence of *KIT* mutations, analyzing them in the context of arrays results**. Methods.** SNPa 6.0 experiments were carried out as recommended by the manufacturer and validated by comparative genomic hybridization array (aCGH), 180K as well as interphase FISH (iFISH) with probes for: *BCR* gene and *CBFB/MYH11* genes. Specific analysis programs were applied to each platform: Genotyping Console (SNPa) and DNA Analytics (aCGH); in addition, a thirdpart software was also used (Nexus 6.0). Analysis was performed using an effective resolution of 100Kb. Regions reported in the general population as copy number variations (CNV) were considered germline alterations and disregarded as relevant to cancer phenotype. *KIT* mutations (exons 8 and 17) were investigated by direct sequencing. Statistical comparisons by Nexus (Fisher's-exact test) were performed to determine the association between abnormalities by arrays and presence of *KIT* mutation. G-banding karyotype (KT) was performed as usual, and abnormalities described according to ISCN (2009). **Results.** Fifteen CBF-AMLs were analyzed. Many submicroscopic acquired somatic chromosomal alterations were detected by SNPa, most of them non-recurrent. Unbalanced inv(16) was detected by arrays in one case (nr 3): iFISH with CBFB/MYH11 probes confirms the presence of two breakpoint deletions. *KIT* mutations were detected in three cases. *KIT* mutation-positive cases were associated (p <0.05) either to high level gain of a 412kb region at 4q28 and a 2.2Mb segment at 16q22.1 exhibiting copy-number neutral loss of heterozygosity (CNN-LOH). Telomeric and long CNN-LOH regions (>25Mb) were detected in four out of fifteen cases. Microscopic alterations only detected by arrays were: nulisomy Y (cases 1 and 9); additional material at 1q25q44 region (case 6); interstitial 9q22 deletion (not terminal, case 13) and trisomy 8, not 9 (case 7). In one case, SNPa was not able to detect trisomy 22 in a low frequency mosaic. iFISH for 22q11.2 region (*BCR* gene) confirms this abnormality, as showed by KT. **Conclusions.** SNPa added valuable information to KT, but clinical significance of all these abnormalities still deserves validation. Analyzed cases are genomically heterogeneous by arrays. CNN-LOH regions were frequent in these CBF-AML cases. Regions found altered by arrays could be sites harboring new disease-related genes. Submicroscopical alterations in *KIT* mutation-negative cases could be the cooperating lesions required for clonal evolution.

0641

NEW QUANTITATIVE METHOD TO IDENTIFY NPM1 MUTATIONS IN ACUTE MYELOID LEUKAEMIA

S Huet, L Jallades, C Charlot, K Chabane, JP Magaud, S Hayette
Hospices Civils de Lyon et UMR5239, Pierre Benite, France

Background. Somatic mutations in the NPM1 gene, which encodes for nucleophosmin, have been reported to be the most frequent genetic abnormalities found in acute myeloid leukaemia (AML). Their identification and quantification remains crucial for the patients' residual disease monitoring. **Aims.** We investigated a new method that could represent a novel reliable alternative to sequencing for its identification. **Methods.** This method was based on high-resolution melting analysis in order to detect mutated patients and second, on an allele-specific-oligonucleotide real-time quantitative polymerase chain reaction (ASO-RQ-PCR) for the identification and quantification of NPM1 mutations (NPM1m) transcripts (Figure 1). Few patients carrying known NPM1m enabled us to set up a table with the different primers' ΔCT values. We then analysed a series of 337 AML patients' samples for NPM1 mutational status characterization, and confirmed the ASO-RQ-PCR results by direct sequencing. Analysis was performed by comparative cycle threshold (CT) method of relative quantification giving the amount of target, normalized to the ABL gene. A few patients (1-3 depending on mutation types) carrying known NPM1m were analysed in parallel in order to build an accurate and reliable table as follows: the ΔCT = CT(NPM1m) - CT(ABL) were calculated from each known mutated sample. **Results.** We identified NPM1 mutations in 86 samples (69 carried type A, 10 type B, 1 type C, 5 type D and 1 type P). Mutation types obtained by using ΔCT method were confirmed by direct sequencing for 36 samples (30 with mutation type A, 2 type B, 1 type C, 2 type D, and 1 type P) and none of them revealed any other mutation other than the one we identified with our ΔCT method. Two samples identified by HRM screening step showed ΔCT values which did not correspond to any of these mutation profiles and direct sequencing revealed rare type M and Q *NPM1* mutations. **Conclusions.** The results were fully correlated in 100% of the 36 sequenced samples. We also detected other rare NPM1m in two samples, that we confirmed by direct sequencing.This highly specific method provides a novel quick, useful and costless tool, easy to use in routine practice

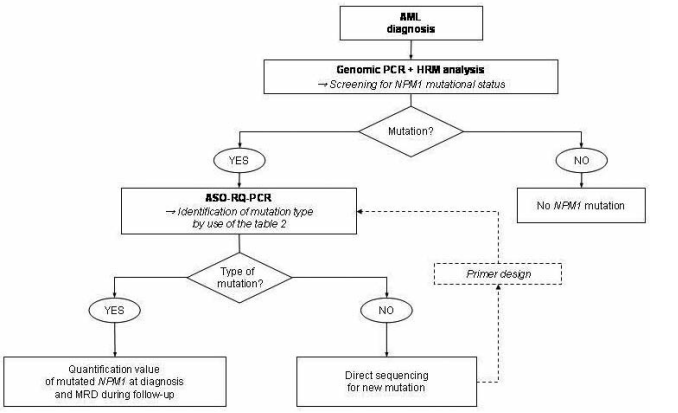

Figure 1. Strategy to identify NPM1 mutations.

CEBPA DOUBLE-MUTATED ACUTE MYELOID LEUKEMIA DISPLAYS A DISTINCTIVE IMMUNOPHENOTYPIC PROFILE

F Mannelli, F Pancani, Ponziani, S Bencini, I Cutini, G Gianfaldoni, Scappini, C Biagiotti, M Benelli, A Magi, A Bosi
University of Florence, Florence, Italy

Background. CEBPA double-mutated (CEBPA-dm) acute myeloid leukemia (AML) has been well established as a separate entity, as stated by WHO, due to distinctive gene expression profile, microRNA profile and a relatively favorable outcome. However, no specific immunophenotypic features have been described so far in this subset. A tendency to expression of CD15 and CD7 has been reported (Lin *et al*, Clin Cancer Res 2005) but these antigens are quite commonly expressed by AML blasts. Of note, given the high variability of type and site of mutations, the identification of CEBPA-dm cases requires whole gene sequencing. CEBPA mutational analysis is thus generally focused on normal karyotype AML, in the absence of NPM1 and FLT3-ITD mutations, since they appear mutually exclusive with a CEBPA double-mutated status. **Aims.** Our aim was to analyze systematically the phenotypic profile of whole BM at AML diagnosis, in order to highlight a CEBPA-dm specific profile, that could be used as a reliable screening method for gene mutations. **Methods.** Flow cytometry: A comprehensive immunophenotypic assessment of bone marrow (BM) cells was carried out on 100 AML cases. Data acquisition was performed using FACSCalibur (Becton Dickinson); for data analysis, Infinicyt (Cytognos) software was used. Some major BM compartments (immature, neutrophil, monocytic, erythroid, basophil) were identified on the basis of FSC/SSC properties and reactivity for CD45/CD34. Overall, 82 phenotypic parameters were defined and expressed as percentage of positive cells for a given antigen within a cell compartment and/or its mean fluorescence intensity. Twenty-one normal marrows were studied by the same approach to set the reference frame. Each individual value was normalized to the mean value obtained for each parameter in normal BM and a log2 transformation was applied to normalized values. Ward's hierarchical clustering analysis of the normalized log2 ratios was performed.CEBPA mutational analysis: Total cellular DNA was extracted using the QIAmp DNA Blood Mini Kit (Qiagen, Chatsworth, CA). The entire CEBPA coding region of the gene was amplified using three overlapping PCR primer pairs as previously described (Pabst *et al*, Nat Genet 2001). PCR products were verified on agarose gel electrophoresis, and sequenced in both directions. **Results.** The results of the analysis are showed in figure 1. AML cases were categorized according to WHO; among genotypic subgroups, those with complex karyotype were gathered separately; unclassifiable cases were grouped upon morphology from M0 to M7. The analysis confirmed clustering of well-defined genotypic forms, such as t(15;17) (n=4), t(8;21) (n=5) and inv(16) (n=8). Six cases carried bi-allelic mutations of CEBPA. No single phenotypic abnormality did result specifically associated with CEBPA-dm disease group. Clustering of CEBPA-dm cases was essentially provided by the simultaneous

assessment of all phenotypic parameters within all BM cell compartments. **Summary and Conclusions.** The systematic evaluation of phenotypic parameters, routinely used in the diagnostic workout of AML, provides clustering of CEBPA-dm cases. Beyond confirming the biological homogeneity of this subset, our approach might provide a reliable and relatively straightforward tool for screening CEBPA-dm cases, thus leading to prompt availability of a crucial prognostic information since the outset.

METNASE (SETMAR) AND HPSO4 (HPRPF19) EXPRESSION IN HEMATOLOGICAL CANCERS

D Jeyaratnam, B Baduin, L Ebbesen, J Jørgensen, C Nyvold
Aarhus University Hospital, Aarhus C, Denmark

Background. Balanced chromosomal translocation is a major event in both leukemia and malignant lymphomas, which characterize the molecular phenotype of the disease. The transposase domain protein Metnase promotes DNA double strand repair via non-homologous end-joining pathway and has previously been shown to suppress the development of chromosomal translocations. The human protein Pso4 (hPso4) has been shown to interact with *Metnase* thereby enhancing the DNA double strand breaks repair mechanism. **Aims.** We wished to establish a sensitive and specific qPCR assay for quantification of the expression of *Metnase* and *hPso4* with the intent to measure and compare the transcription levels of *Metnase* and *hPso4* in patients within acute myeloid leukemia (AML), chronic myeloid leukemia (CML), mantle cell lymphoma (MCL) and in a cohort of healthy individuals as control.*Methods*: Peripheral blood (PB) and bone marrow (BM) samples were collected from the time of diagnosis. Primer and probes were designed to span exon-exon junctions for mRNA specificity. All samples were normalized to the cell line Granta-519, thereby defining the *Metnase and hPso4* levels in Granta-519 as 1. *Beta-2-microglobulin* and *beta-glucuronidase* were used as reference genes. The qPCR results were analyzed using a Wilcoxon Rank system (Mann Whitney test) in order to find any differently expressed subgroups of patients. **Results.** We detected a significantly higher expression of *Metnase* in AML compared to healthy individuals. There was no difference in the expression of *Metnase* in the cohort of AML patients harboring a chromosomal translocation compared to the group of AML patients without a translocation.

Table 1. Expression of Metnase and hPso4.

	Patients groups	N	Median expression/range Normalized to Granta-519	Compared to healthy individuals p-value
Metnase	Healthy individuals, PB	19	0.127 (0.075-0.26)	-
	Healthy individuals, BM	18	0.314 (0.18-0.48)	-
	AML, translocation neg, PB	27	0.98 (0.08-11.29)	<0.0001
	AML, translocation neg, BM	21	1.26 (0.34-11.78)	<0.0001
	AML, translocation pos, PB	16	0.58 (0.14-1.29)	<0.0001
	AML, translocation pos, BM	12	0.92 (0.60-1.39)	<0.0001
	CML, PB	24	0.13 (0.04-0.73)	0.8641
	CML, BM	12	0.34 (0.11-0.96)	0.6115
	MCL, PB	19	0.31 (0.06-1.76)	0.0019
	MCL, BM	11	0.45 (0.1-0.63)	0.3687
hPso4	Healthy individuals, PB	19	0.286 (0.17-0.73)	-
	Healthy individuals, BM	18	0.396 (0.06-2.01)	-
	AML, translocation neg, PB	27	0.58 (0.08-2.17)	0.0022
	AML, translocation neg, BM	21	0.787 (0.004-3.29)	0.4639
	AML, translocation pos, PB	16	0.33 (0.21-0.89)	0.1361
	AML, translocation pos, BM	12	0.55 (0.26-0.75)	0.6597
	CML, PB	24	0.09 (0.031-0.26)	<0.0001
	CML, BM	12	0.11 (0.02-0.27)	<0.0001
	MCL, PB	19	0.55 (0.046-2.86)	0.0007
	MCL, BM	11	0.50 (0.26-2.8)	0.5896

Table 1 shows the expression levels of *Metnase* in healthy individuals, AML, CML, and MCL. The expression of *hPso4* (Table 1) was significantly decreased in CML compared to the cohort of healthy individuals. The contrary situation was found in PB MCL where both the expression levels of *Metnase* and *hPso4* were significantly increased. The expression ratio of *hPSo4*/*Metnase* was >1 in MCL and healthy individuals while the ratio of *hPSo4*/*Metnase* was <1 in the group of AML with and without translocation and CML patients.*Summary:* We designed a qPCR assay to detect the expression of *Metnase* and *hPsO4* in hematological cancers. Initially, we hypothesized that there was a higher *Metnase* expression in AML patients without translocation compared to those with a translocation, but interestingly, we found no significant difference between those groups but a significant increased expression in both AML subgroups compared to the cohort of healthy individuals. Moreover, we found a significantly reduced expression of *hPso4* and no differences of *Metnase* expression in the cohort of CML patients compared to healthy individuals. Finally, there was a significant higher expression of both *Metnase* and *hPso4* in MCL PB samples. This study elucidates the expression patterns of two of the co players in the non-homologous end-joining pathway with impact on the chromosomal events in subgroups of hematological cancers.

CLONAL MUTATIONS IN MATURE MONOCYTIC CELLS IN ACUTE MYELOID LEUKAEMIA

K Tawana[1], S Akiki[1], K Wall[1], M Griffiths[1], S Freeman[2]
[1]West Midlands Regional Genetics Laboratory, Birmingham, United Kingdom
[2]School of Immunity and Infection, University of Birmingham, Birmingham, United Kingdom

Background. In AML, genetic anomalies are sequentially acquired causing leukemogenesis. The ontogenic stage at which these changes occur and their impact on differentiation to mature myeloid cells such as monocytes, remains unclear. Leukemic mutations in monocytes, which are long-lived cells, could have implications for the interpretation of molecular minimal residual disease (MRD) monitoring. Furthermore, clonal monocytes might conceivably acquire additional leukemic genetic anomalies. **Aims.** To investigate the presence of recurrent AML-specific mutations in the mature monocytic (CD14+) component of AML with and without morphological evidence of maturation. **Methods**. The AutoMACS technique was used to separate CD14+ cells from whole blood or bone marrow in diagnostic and follow up samples from patients with AML/MDS. Purity of separation was confirmed by flow cytometry (=/>95%) and DNA was extracted from both the CD14+ fraction and the whole cell sample. Both fractions were routinely screened for mutations in *FLT3*, *NPM1, IDH1* and *IDH2.* Biallelic *CEBPA* mutations were identified in one case.

Table 1. Comparison of FLT3-itd allelic ratios in monoblastic/monocytic versus non-monocytic subtypes of AML

Non-monocytic AML (Allelic ratio whole/CD14)	Monocytic/Monoblastic AML (Allelic ratio whole/CD14)
0.70/0.05 (myelomonocytic)	0.72/0.73 (monocytic)
0.22/0.08 (with maturation)	0.61/0.90 (monocytic)
0.69/0.15 (minimal maturation)	0.63/0.67 (monocytic)
2.50/1.08 (without maturation)	0.50/0.32 (monoblastic)

Results. Cases of AML (n=29) and MDS (n=6) were analysed, with the majority of patients >60years (n=23). All were classified as per WHO criteria and AML cases morphologically grouped as follows; AML with dysplasia (n=8), AML with minimal/no maturation (n=3), AML with maturation (including core-binding factor and myelomonocytic AML) (n=9) and monoblastic/monocytic AML (n=6). *FLT3*-internal tandem duplication (itd) (n=9) and *NPM1* (n=7) mutations occurred most frequently and were predominantly seen in monoblastic/monocytic AML subtypes (56%, n=5 and 43%, n=3, respectively). *IDH1* and *IDH2* mutations were seen in 10% of AML cases. All mutations in the whole cell population were present in the CD14+ fraction. In addition, FISH studies demonstrated trisomy 8 in CD14+ cells from monoblastic AML with trisomy 8. These

findings suggest that monocytic maturation of leukaemia initiating cells can occur following the acquisition of clonal genetic aberrations in AML. Fragment analysis of DNA for *FLT3*-itd was used to calculate mutated to wild-type allelic ratios (ARs) in the whole cell and CD14+ fraction, providing a semi-quantitative measure of leukaemia burden in each. ARs in monoblastic/monocytic AML were highly comparable between the whole and CD14+fraction. In non-monocytic AML, the CD14+ AR was considerably lower than in the whole cell population, Table 1. It can be inferred that clonal monocytic maturation occurs to a greater degree in monoblastic/monocytic subtypes of AML but may also be seen in limited cell populations in AML with minimal or no evidence of maturation.Pre and post treatment CD14+ fractions were obtained in 6 cases with mutations in *FLT3, NPM1* or *CEBPA*. All mutations in the CD14+ fraction correlated with the whole cell population post treatment, suggesting that clonal mature monocytic cells show similar treatment susceptibility to the whole blast population. **Conclusions.** We have identified genetic abnormalities in CD14+ cells from various AML subtypes (excluding APML), suggesting that monocytic differentiation of the leukemic clone can occur even in non-monoblastic/monocytic AML. The pathogenic relevance of these differentiated subclones is unclear but further functional and quantitative assays will help to ascertain their significance.

THE ROLE OF CBL IN RELATION TO RAS-PATHWAY ACTIVATION IN PEDIATRIC AML

E Coenen[1], E Driessen[1], M Zwaan[1], J Stary[2], A Baruchel[3], V de Haas[4], E de Bont[5], D Reinhardt[6], G Kaspers[7], T Arentsen-Peters[1], C Meyer[8], R Marschalek[8], R Pieters[1], R Stam[1], M van den Heuvel-Eibrink[1]
[1]ErasmusMC/ Sophia Children's Hospital, Rotterdam, Netherlands
[2]2nd Medical School, Charles University, Prague, Czech Republic
[3]St. Louis Hospital, Paris, France
[4]Dutch Childhood Oncology Group, Den Haag, Netherlands
[5]UMC Groningen, Groningen, Netherlands
[6]AML-BFM study group, Hannover, Germany
[7]VUmc, Amsterdam, Netherlands
[8]Institute of Pharmaceutical Biology, ZAFES, Diagnostic Center of Acute Leukemias, Frankfurt, Germany

Background. Leukemogenesis in acute myeloid leukemia(AML) is hypothesized to evolve from mutations disrupting proliferation and differentiation. Several mutations resulting in activation of the RAS-pathway have been described in AML and *MLL*-rearranged ALL. Recently, mutations in the *Casitas B lineage lymphoma(CBL)* gene were reported to be involved in RAS-pathway activation in various myeloid malignancies. So far, the role of *CBL* in pediatric AML is unknown. **Aims.** We aimed to study the role of *CBL* mutations and CBL expression in pediatric AML and *MLL*-rearranged ALL. **Methods.** We performed mutation analysis in 277 initial and 33 relapse pediatric AML samples, and 18 *MLL*-rearranged infant acute lymphoblastic leukemia(ALL) samples. To further evaluate the functional role of CBL in pediatric AML, and RAS-pathway activation, we studied *CBL* mRNA and protein expression and performed *CBL* RNA interference knock-down experiments. **Results.** We identified only two mutant cases(0.7%) in newly diagnosed pediatric AML, and none in relapsed cases. One mutant case was *MLL*-rearranged; the other had a normal karyotype. No *CBL* mutations were present in infant ALL cases. *CBL* mRNA expression in mutated cases did not differ from non-mutated AML cases nor between any of the cytogenetic groups. Western blotting of patient samples showed no significant difference in protein expression of the two *CBL* mutants versus nine non-mutant AML cases(p=0.8)., and protein expression had a poor correlation with mutation status or *CBL* mRNA expression as determined by gene expression profiling and confirmed by RT-qPCR(Spearman r=0.17). Also, phosphorylated extracellular signal-regulated kinase(pERK) and CBL protein expression did not correlate. Nevertheless, *CBL* RNA interference knock-down experiments resulted in an upregulation of pERK protein expression in the Kasumi-1 cell line, with a maximum of 3-fold at t=48 hours. **Summary and Conclusions.** In conclusion, we report a very low *CBL* mutation frequency(0.7%) in pediatric AML and *MLL*-rearranged infant ALL and poor correlation with expression of *CBL* mRNA, CBL protein and pERK protein. However, enforced decreased CBL protein expression led to RAS-pathway activation in a pediatric AML cell line.

Acute myeloid leukemia - Clinical 3

THE PHARMACOKINETICS OF ELACYTARABINE IN AML PATIENTS

S Knapper[1], M Johansen[2], M Smith[3], T Chevassut[4], P Colucci[5], M Johansen[2], S Hagen[2], PA Hals[2], Flem Jacobsen[2], H Dirven[2], M Ducharme[6]
[1]University Hospitales of Wales, Cardiff, United Kingdom
[2]Clavis Pharma, Oslo, Norway
[3]St Bartholomew's Hospital, London, United Kingdom
[4]Royal Sussex County Hospital, Brighton, United Kingdom
[5]Cetero Research, Mississauga, Canada
[6]Université de Montréal, Montréal, Canada

Background. Elacytarabine is an elaidic acid ester derivative of cytarabine. Like cytarabine, elacytarabine is metabolized to the active ara-CTP and to ara-U. Elacytarabine has reached phase III of clinical development for treatment of relapsed or refractory Acute Myeloid Leukaemia (AML). The current study is using the same dose, schedule and formulation as in the ongoing pivotal CLAVELA study. **Aims.** To characterize the pharmacokinetics (PK) of elacytarabine and its metabolites ara-C and ara-U after a 120-h continuous i.v. infusion (CIV) of the recommended dose of elacytarabine to patients with relapsed or refractory AML. The study is also assessing the efficacy, safety and tolerability of elacytarabine in this patient population. **Methods.** Elacytarabine for infusion 7.5 mg/mL was administered at 2000 mg/m^2/d as a CIV for 120-h to adult patients with relapsed or refractory AML. Blood samples for PK analysis were collected at 12 predefined time points prior to, during and after administration. The plasma concentrations of elacytarabine, ara-C and ara-U were determined by a validated LC-MS/MS method. PK parameters like C_{max}, T_{max}, AUC, CL, V_{ss} and $T_{1/2}$ were calculated using both compartmental and non-compartmental analyses. **Results.** Thirteen patients [10 males, 3 females, median age 63 years (range 48-77), ECOG PS 0-1] were treated with elacytarabine. All patients had previously been treated with cytarabine, and received elacytarabine as either first or second salvage treatment.Elacytarabine and ara-C were detected in plasma up to 24 h after end of infusion. The plasma concentrations of elacytarabine and ara-C declined rapidly once the infusion was stopped. Using non-compartmental analysis, the median half-life and CL for elacytarabine were 9.9 h and 4.31 L/h/m^2. For ara-C and ara-U the half-lives were 3.2 and 9.7 h, respectively.Five patients achieved a CR/CRi and one patient had partial remission. The most frequently reported related non-hematologic adverse events (CTCAE grade ≥ 3) were febrile neutropenia, infections, hypokalemia and increased cholesterol. **Summary and Conclusions.** Elacytarabine is a novel anti-leukemic agent for treatment of patients with advanced AML. The PK of the drug and its metabolites as well as its toxicity and efficacy were characterized after CIV for 120 h in this patient population and showed that the drug has features making it a promising therapeutic for this disease.

0647

OUTCOME OF HIGH-RISK AND REFRACTORY AML/MDS PATIENTS AFTER FLAMSA SEQUENTIAL CHEMOTHERAPY REGIMEN FOLLOWED BY REDUCED-INTENSITY CONDITIONING AND ALLOGENEIC HEMATOPOEITIC STEM CELL TRANSPLANTATION

M Michallet[1], M Detrait[1], P Chevalier[2], M Sobh[1], T Guillaume[2], X Thomas[1], S Morisset[1], N Tedone[1], J Delaunay[2], F Nicolini[1], H Labussière[1], S Ducastelle[1], J Fatoum[1], F Barraco[1], Y Chelghoum[1], M Mohty[2]
[1]Centre Hospitalier Lyon Sud, Pierre Bénite, France
[2]CHU de Nantes - Hôtel Dieu - Hematology, Nantes, France

Aims. This retrospective analysis aimed to assess the outcome of 40 patients with refractory or high risk AML/MDS who received FLAMSA sequential chemotherapy. **Methods.** There were 30 males and 10 females with a median age of 52 years (32-66). Diseases characteristics were: progressive or refractory disease after rescue treatment for first relapse (n=21), early relapse without any further salvage therapy (n=4), and primary induction failure (n=4). The series also included 7 patients with high risk MDS and 4 patients in first CR but having a very poor prognosis. The FLAMSA regimen included Fludarabine (30 mg/m²/d), cytarabine (2 g/m²/d) and amsacrine (100mg/m²/d) from day -12 to day -9. After 3 days of rest, a RIC regimen was administered. In 28 patients, the RIC regimen included 4 Gy. TBI, ATG 5mg/kg total dose, and cyclophosphamide 40mg/kg in case of matched related donors, and 60 mg/kg for unrelated or mismatched donors. In the remaining 12 patients, TBI was replaced by I.V. Busulfan 3.2 mg/kg/d for 4 days. Eighteen patients were transplanted using an HLA identical sibling donor, and 22 received transplant from an unrelated donor. **Results.** After allo-HSCT, 39 patients (97.5%) engrafted. In the CR

group (n=4), after a median follow-up of 5 months (range, 3-31) all patients were still alive in CR at last follow-up. In the remaining 36 patients, 9 patients developed acute GVHD ≥2 with a cumulative incidenceat 3months of 18% (95%CI, 10-26). At day 90 post HSCT, 23 (64%) patients achieved hematological CR, and 14 of the 23 remained in CR at last follow-up. After a median follow-up of 6 months (range, 1-60), the 2-years probability of OS was 30% (95%CI, 17-52), and the 2-years probability of PFS was 29% (95%CI, 17-50). The cumulative incidence of relapseat 1year was 25% (95%CI, 18-33). Interestingly, none of the patients who received Busulfan instead of TBI, relapsed. The cumulative incidence of TRMat 3months and 1 year were 14% (95%CI, 8-20) and 22% (95%CI, 15-29), respectively.In the multivariate analysis there was a significantly worsened PFS in patients who received transplant from a mismatched donor (HR=3.6; [95%CI, 1.3-10] p=0.01). Also, when considering disease relapse, there was a highly significant impact of the type of RIC regimen (in favour of a FLAMSA regimen without TBI (HR=0; [95%CI, 0-0] p<0.0001). **Conclusions.** A modified FLAMSA regimen incorporating I.V. Busulfan instead of TBI is likely to allow better long-term disease control, warranting prospective evaluation.

TREATMENT OUTCOME OF BRAZILIAN PATIENTS WITH ACUTE MYELOID LEUKEMIA: AN ANALYSIS BASED ON THE EUROPEAN LEUKEMIANET CLASSIFICATION SYSTEM

M Benicio[1], A Ribeiro[2], A Lucena-Araujo[1], A Glória[2], F Oliveira[1], E Fagundes[2], E Rego[1]
[1]University of Sao Paulo, Ribeirao Preto, Brazil
[2]Clinics Hospital, Federal University of Minas Gerais, Belo Horizonte, Brazil

Background. It has been increasingly acknowledged that assumptions drawn from classical clinical trials are not always trustworthy clues for therapy decision-making. In particular in developing countries, where the result of the treatment of hematologic malignancies is poor, it is unknown whether European LeukemiaNet (ELN) recommendations for Acute Myeloid Leukemia (AML) risk stratification would be applicable in a real-life setting. **Aims.** To assess how to improve the risk stratification of Brazilian patients with AML, taking better advantage of the new ELN recommendations in addition to well recognized prognostic markers. **Methods.** Two hundred and seventeen consecutive patients treated at two University Hospitals between 2001-2010 with age between 15 and 65 years were studied. Age, gender, WBC count, karyotype, *NPM1*, FLT3-ITD, *CEBPA* and MLL-PTD mutations, and the *BAALC* gene expression levels were analyzed. Patients were treated with conventional chemotherapy: daunorubicin (60 mg/m^2/d for 3 days) and cytarabin (200 mg/m^2/d for 7 days) as induction, followed by two or three courses of consolidation therapy with high-dose cytarabin (above 1 g/m^2/d). Median follow-up time for surviving patients was 22 months. The median age was 42 years and 98 (45%) were male. Patients were assigned to the genetic groups proposed by the ELN as follows: favorable (n=83), intermediate I (n=61), intermediate II (31) and adverse (n=20). Direct sequencing of PCR products was performed to detect *NPM1* mutations (*NPM1*mut). *CEBPA* mutations were identified by DHPLC or direct sequencing. FLT3-ITD detection was performed by PCR. MLL-PTD was detected by RQ-PCR. The relative expression levels of *BAALC* gene were measured by RQ-PCR, and patients were dichotomized at *BAALC*'s median expression into low and high expressers. **Results.** The estimated five-year overall survival (OS) for all patients was 19%. Univariate analyses determined that age, genetic risk group, FLT3-ITD, MLL-PTD and WBC count were significant prognostic factors. Patients older than 45 years presented shorter OS in comparison to those ≤ 45 years (P=0.008). The mean OS for favorable, intermediate I, intermediate II, and adverse groups were 43, 13, 16 and 13 months, respectively (P=0.03), while the disease-free survival (DFS) was 61, 34, 42 and 5 months, correspondingly (P=0.001). Patients harboring either FLT3-ITD or MLL-PTD presented shorter OS in comparison to patients with wild-type genes (P=0.03 and P=0.002, respectively). WBC count above 50x10^9/L also predicted shorter OS (P=0.01). *CEBPA* mutations were associated to complete remission (CR) achievement (P=0.01) and longer OS (P=0.08). Multivariate analysis detected age, MLL-PTD and WBC count as independent prognostic factors for OS. Further stratification of intermediate risk group identified patients with distinguishable outcomes. The DFS was favorably impacted by *NPM1*mut (P=0.07) and *CEBPA* biallelic mutations (*CEBPA*bm) (P=0.08), or the absence of FLT3-ITD (P=0.06). *CEBPA*bm were also associated to longer OS (P=0.01), and *NPM1*mut to CR achievement (P=0.01). **Conclusions.** Brazilian patients indeed presented poorer outcome than those enrolled in the US and Europe clinical trials. Patients classified into intermediate I, intermediate II, and adverse groups presented similar outcome. The assessment of additional prognostic factors would help to guide patients' management when ELN recommendations fail to translate into clinical outcome.

0649

PROGNOSTIC IMPACT OF MONOSOMAL KARYOTYPE IN ADULT ACUTE MYELOID LEUKEMIA

C Moreira, D Pereira, M Nunes, M Dantas-Brito, S Chacim, C Leite, I Ferreira, M Marques, L Viterbo, A Martins, I Oliveira, N Domingues, I Moreira, M Teixeira, A Espírito-Santo, J Mariz
Instituto Português de Oncologia do Porto, Porto, Portugal

Background. Acute Myeloid Leukemia (AML) is a heterogeneous entity and comprises a group of hematologic neoplasms with distinct clinical and genetic features. Age and karyotype at diagnosis remain the most important independent prognostic factors in adults with AML. Recently, a new cytogenetic category was introduced, Monosomal Karyotype (MK), defined by the presence of 2 or more monosomies, or a single monosomy in the presence of structural abnormalities. This category has been described as having an adverse prognosis and as adding prognostic information even in patients with complex karyotype (CK). **Aims.** To evaluate the prognostic impact of MK in adults diagnosed with AML. **Methods.** From January 1998 to December 2010, 313 patients were diagnosed with AML at our Institution. For the purpose of this study, we excluded patients with Acute Promyelocytic Leukemia (45 patients) and patients with unknown karyotype at diagnosis (55 patients; not requested or not performed due to insufficient metaphasis). The remaining patients were divided according to karyotype into 3 prognostic groups: favorable (16.0%), intermediate (51.6%) and adverse (32.4%). Considering only the patients from the adverse prognostic group, 26 patients fulfilled criteria for MK and therefore this group was further divided into MK(+) and MK(-). Statistical analysis was performed with SPSS®Statistics v19. **Results.** Comparing both groups, MK(+) and MK(-), patients with monossomal karyotype were slightly older (median age of 64 years vs. 56 years, p=0.059), were predominantly of the female gender (75.0% vs. 32.6%, p=0.003) and presented a more elevated peripheral blast count (40.0% vs. 9.0%, p=0.065). No other differences were found regarding presentation symptoms, performance status, leukocyte count, marrow blast count or LDH at diagnosis. Induction therapy was equally distributed between both groups.Complete remission rate (CR) was similar between the groups analyzed (55% in MK(+) vs. 63.2% in MK(-), p=0.343). The incidence of disease recurrence was slightly more elevated in the MK(+) group (63.6% vs. 50%, p=0.352) with a median time to relapse of 3.2 months in MK(+) and 8.4 months in MK(-), p=0.196.MK(+) group had a worse overall survival (OS, median of 2.1 months vs. 10.0 months, p= 0.002; Figure 1a) and a worse disease-free survival (DFS, 4.0 months vs. 11.5 months, p=0.032; Figure 1b).On multivariate analysis of pretreatment characteristics only age (p=0.014) and presence of MK (p=0.004) were identified as independent prognostic factors.Analyzing further the patients with CK, we divided them in 2 groups: patients with both CK and MK (CK+MK+, 20 patients) and patients with CK without MK criteria (CK+MK-, 18 patients). No differences were found between the 2 groups in terms of CR and relapse rate. However, patients with CK+MK+ had a worse OS (median OS of 2.4 months vs. 10.0 months, p=0.008) and a worse DFS (median DFS of 3.2 months vs. 13.2 months, p=0.006). **Conclusions.** Our study reveals that the presence of MK is associated with an adverse outcome in AML and also suggests that the worse prognosis associated with the presence of CK might be related to the inclusion of MK patients in that group.

REDUCING DOSAGE OF IDARUBICIN AND FLAG FOR PATIENTS YOUNGER THAN 65 YEARS WITH RESISTANT ACUTE MYELOID LEUKEMIA: A PROSPECTIVE, MULTICENTER PHASE II STUDY

H Kim[1], JH Lee[2], YD Joo[3], S Bae[4], JH Lee[2], DY Kim[2], WS Lee[5], HM Ryoo[4], JH Park[1], KH Lee[2]

[3]Haeundae Paik Hospital, Inje University College of Medicine, Busan, South-Korea
[4]Daegu Catholic University Medical Center, Daegu, South-Korea
[5]Busan Paik Hospital, Inje University College of Medicine, Busan, South-Korea

Background and Methods. We previously assessed continuous infusion (CI) of fludarabine and cytarabine plus idarubicin (CI-FLAG ver. 1) for patients under 65-years old with resistant acute myeloid leukemia (AML). Induction chemotherapy consisted of idarubicin (IDA,12 mg/m^2 on Days 1-3), plus fludarabine (FLU, 30 mg/m^2/day) and cytarabine (ARAC, 1,000 mg/m^2/day) on Days 1-5 as a 24-hr CI. G-CSF was added on Days 1-5. In response to induction, 31.6% patients achieved CR and 68.4% failed treatment; of the latter, 42.1% had aplasia. We concluded that although CI-FLAG ver. 1 was effective for eradicating blasts, it carried a high risk of toxicity and reduced doses were recommended for CI-FLAG. Therefore we revised the protocol (CI-FLAG ver. 2) by reducing the dose of IDA (6 mg/m^2/d for 3 days) and ARAC (1000 mg/m^2/d on days 1 through 2, and then 200 mg/m^2/d on day 3 through 5 as CI). The schedule and dose of FLU and G-CSF were same as the original protocol. Here we present the result of CI-FLAG ver. 2 and the comparison with CI-FLAG ver. 1. **Results.** Total 39 patients were enrolled in CI-FLAG ver. 2. Patients were of median age 42 years (range, 16-62 years); of these, primary refractory disease in 26 (66.7%), early relapse in 12 (30.8%), and relapse after hematopoietic cell transplantation (HCT) in 1 (2.6%). Risk groups were favorable in 17.9%, intermediate in 61.5% and poor in 15.4%. Overall CR rate was 41%. CR, CRi, CRp and PR were achieved in 33.3%, 5.1%, 2.6% and 7.7% patients, respectively. A median day to CR was 36 (24-71). The main reasons of treatment failure were resistance in 12 (30.8%), intermediate course in 4 (10.3%), morphologic relapse in 2 (5.1%) and aplasia in 2 (5.1%). Three patients tried re-induction but all failed achieving CR. 25.6% patients received salvage chemotherapy after failure of CI-FLAG ver. 2. Twenty seven patients received SCT (13 after remission, 7 after salvage chemotherapy, 6 as salvage HCT). When comparing outcomes between ver. 1 and ver. 2, there were no difference in terms of CR rate (18.4 vs. 33.3%, p=0.136), all CR rate (31.6 vs. 41%, p=0.389) and objective response rate (ORR, 31.6 vs. 46.2%, p=0.190). Cumulative incidence of relapse among patients who had achieved CR were not different (37.7 vs. 63.2%, p=0.277). The median overall survivals showed only the trend of longer survival in ver. 2 (2.47; 95% CI, 0.073-4.861 vs. 6.32; 95% CI, 2.452-10.180 months; p=0.103; Figure 1). Among intermediate risk patients, there were significantly high response rate favoring ver. 2 in terms of CR rate (6.7 vs. 41.7%, p=0.028), all CR rate (20 vs. 50%, p=0.061), ORR (20 vs. 54.2%, p=0.035) and overall survival (2.6 vs. 7.2 months, p=0.093). **Conclusions.** Our prospective study for highly refractory AML showed substantially improved rate of response compared with our previous study. However there was high rate of resistance by reducing dosage at expense of decreasing aplasia. The reduced dose of CI-FLAG might be most beneficial for intermediate risk group.

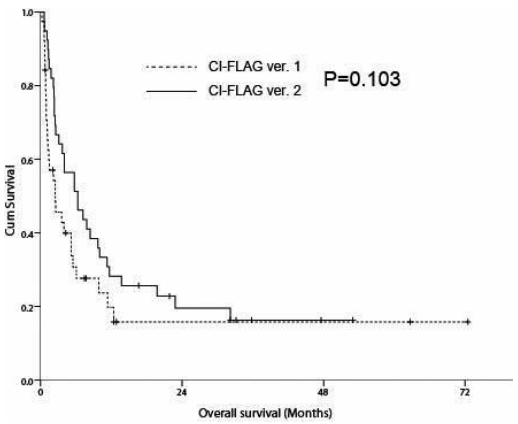

Figure 1. Overall survival.

CLINICAL AND LABORATORY CHARACTERISTICS OF ACUTE MYELOID LEUKEMIA PATIENTS WITH PARTIAL TANDEM DUPLICATION OF THE MLL GENE

G Balatzenko[1], B Spassov[1], P Ganeva[1], N Stoyanov[1], S Konstantinov[2], S Toshkov[1], M Guenova[1]
[1]National Specialized Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria
[2]Medical University, Faculty of Pharmacy Dept. of Pharmacology, Pharmacotherapy a, Sofia, Bulgaria

Background. Partial tandem duplications of the MLL gene (PTD-MLL) are one of common molecular abnormalities in acute myeloid leukemia (AML) and its detection is considered as a marker of unfavorable prognosis. **Aims.** To establish the incidence of MLL-PTD-positive [MLL-PTD(+)] AML in Bulgarian population and to search for an association with biological, clinical, morphological, immunophenotypic, and molecular characteristics of patients **Patients and Methods.** Peripheral blood and/or bone marrow samples of 246 (120 female; 146 males) adult AML patients, with mean age of 54.7±16.8 years were studied. Diagnosis and classification of AML were established using the standard criteria by means of routine hematological tests, morphology, cytochemistry, immunophenotyping by flow cytometry, conventional cytogenetics and reverse transcription polymerase chain reaction (RT-PCR). MLL-PTD status was determined using RT-PCR. **Results.** In total, MLL-PTD mRNA was found in 14 AML patients (5.7%). The MLL-PTD(+) group was characterized by a distinct predominance of male compared to female gender (11/126; 8.7% vs. 3/120; 2.5%; p=0.051); a clear tendency for higher frequency of therapy-related AML compared to *de novo* AML [4/27 (14.8%) vs. 10/219 (4.6%); p=0.054], and absence of fusion transcripts associated with recurrent genetic abnormalities, such as BCR-ABL; AML1-ETO; CBFb-MYH11; PML-RARA; MLL-AF6; MLL-AF9; and DEC-CAN. The remaining characteristics were heterogeneous and unspecific: the median age was 58.5 years (range 24 - 83 years); the median white blood cells count - 23.0x10^9/l (range 1.2x10^9/l -130x10^9/l); median platelets count - 41.1x10^9/l (range 19x10^9/l - 336x109/l), median hemoglobin concentration - 71.5 g/L (range 45 g/L - 105 g/L) and median bone marrow blasts/blast equivalents - 57.5% (range 31% - 98%). Among *de novo* AML cases, 2 were classified as AML with myelodysplasia-related changes, and 8 as AML, not otherwise specified, including: AML without maturation (n=1); AML with maturation (n=1); acute myelomonocytic leukemia (n=4); acute monoblastic and monocytic leukemia (n=1) and acute erythroid leukemia (n=1). By flow cytometry, 8 patients were CD34 and/or CD117-positive, and co-expression of lymphoid markers was seen in 9 (64.3%) cases, however, no one fulfilled the criteria for biphenotypic leukemia. Co-expression of FLT-ITD was detected in 3 cases (21.4%). Complete remission was achieved in only two cases (20.0% of patients in whom standard therapy was applied), and the median overall survival was 5 months. **Conclusions.** The estimated prevalence of MLL-PTD in our study does not differ from the generally reported values. As a whole, the main clinical and laboratory characteristics of MLL-PTD(+) varied in a significant degree, however poor response to therapy seems to be a common feature. **Acknowledgements:** This work was supported by the National Science Found grant No. CVP/01-0119 - DO-02-35/09

° POSTMORTEM EPIDEMIOLOGY OF INVASIVE FUNGAL INFECTION (IFI) IN HEMATOLOGIC MALIGNANCIES: A STUDY OVER A 10 -YEAR PERIOD (2002-2011) AT A HEMATOLOGIC TERTIARY CARE DEPARTMENT

A Chierichini[1], F Monardo[1], B Anaclerico[1], P Anticoli[1], V Bongarzoni[1], M Cedrone[1], S Fenu[1], B Ronci[1], F Francesca[2], L Annino[1]
[1]Azienda Ospedaliera S.Giovanni Addolorata Rome, Rome, Italy
[2]Gimema data center, Rome, Italy

Background. The lack of sensitive and specific diagnostic tools make difficult the IFI diagnosis in hematologic malignancies. Recent several reports outlined the increased incidence of moulds and yeast, which are difficult to identify early. Postmortem data may be useful: a) to monitor the frequency and the disease patterns , b) to better understand local epidemiology , c) to improve antifungal treatment strategy. **Aims**.The aim of this retrospective review is to show the local epidemiology and the prevalence at autopsy of proven IFI occurring in hematologic malignancies ,at a single center over a ten -year period. **Methods.** We retrospectively evaluated 148 patients- median age 64 y, range 22-81 - with hematologic malignancies, who underwent autopsy between 2002 - 2011. Of these pts, 69 were Acute Myeloid Leukemia (AML), 11 Acute Lymphoid Leukemia (ALL), 53 Lymphoprolipherative Disorders (LPD) ,and 9 other disorders. Acute leukemia pts received systemic antifungal prophylaxis ,whereas the others pts not absorbable prophylaxis. None patient underwent transplant . An experienced pathologist

evaluated the major organ involvement and the IFI pathologic patterns . Fisher's Exact test was used to recognize either the IFI prevalence ,the main occurring pathogen and the more involved site ; a p- value of < 0.05 was considered statistically significant. **Results.** The analysis of 148 consecutive autopsies identified 34 (23 %) pts resulting to have IFI; of these, 18 (12%) were AML, 7 (4 %) ALL, 8 (5%) LPD ,and 1 other. Aspergillus spp infection occurred in 17 (50%) cases , Mucor spp in 7 (21%), and Candida spp in the remaining 10 (29 %). In acute leukemia pts invasive mould infections were prevalent, and Aspergillus spp. proved to be the leading pathogen with respect to Candida and Mucor spp. (p 0.0091), with a statistically significant prevalence in ALL (p 0.0140). In all cases, lung resulted the site more significant involved (p 0.0011). Whereas the standardized EORTC/MSG criteria applied *in vita* were conclusive for IFI in 5 (14%) pts only ,postmortem findings revealed fungal infection in 29 (86%) pts. **Conclusions.** This analysis confirms that in hematologic malignancies the IFI diagnosis *in vita* is a still unresolved issue. Despite a larger availability of antifungal treatment , acute leukemias remain the subset with higher prevalence of mould infections. Like other larger previous studies ,also in our experience, Aspergillus Spp and lung proved to be the most recurrent pathogen and site involved. The epidemiology pattern is complex and present diagnostic methods are not still completely able to identify the underlying IFI, thus autopsy rate should be increased to achieve a better knowledge of epidemiology and to critically review previous misdiagnosis.

0653

HIGH CURE RATES CAN BE EXPECTED IN PATIENTS WITH THERAPY-RELATED ACUTE PROMYELOCYTIC LEUKEMIA (T-APL), BUT VIGILANCE FOR THERAPY-RELATED MYELODYSPLASTIC SYNDROME OR ACUTE MYELOID LEUKEMIA IS WARRANTED

J Park, D Douer, E Berman, J Jurcic, M Heaney, P Maslak, E Stein, T Rosenblat, M Frattini, M Tallman
Memorial Sloan-Kettering Cancer Center, New York, NY, United States of America

Background. An increasing number of patients with therapy-related acute promyelocytic leukemia (t-APL) has been reported. However, little is known about long-term outcomes and treatment-related complications of these patients as many APL clinical trials restrict eligibility to those patients with *de novo* disease. **Aims.** We conducted a single institution retrospective survey to examine the early death rate, long-term outcomes, and the rate of secondary malignancies in patients with t-APL. **Methods.** APL cases occurring after chemotherapy and/or radiotherapy for a previous malignancy were defined as t-APL. All t-APL patients, diagnosed between 1992 and 2007 at Memorial Sloan-Kettering Cancer Center, were identified. Analysis included primary malignancy, prior chemotherapy, interval from diagnosis of primary malignancy to t-APL, treatment-related complications and long-term outcomes. **Results.** A total of 122 patients with APL were identified; of these, 11 patients (9.0%) were classified as t-APL. Compared to patients with *de novo* APL, patients with t-APL were older (median age 60 vs. 46 years; p=0.012) and were women (9/11 vs. 53/111 patients). The primary malignancies were breast (n=4), cervical (n=2), colorectal (n=2), ovarian (n=1), endometrial cancer (n=1), Hodgkin's (n=1) and non-Hodgkin's lymphoma (n=1). Therapy for primary malignancies included radiation alone in 3 patients, chemotherapy alone in 7 patients, and both in 1 patient. The median interval from the diagnosis of primary malignancy to the diagnosis of t-APL was 28 months (range, 10-120 months). All patients received induction therapy with ATRA +/- anthracyclines. Ten patients (90.9%) achieved complete remission, and one patient with metastatic ovarian cancer died within 7 days of starting ATRA due to multi-organ failure from her primary malignancy. At a median follow-up of 7 years (range, 5 - 14 years), 7 of the 11 patients (64%) remain alive in continuous remission; 2 patients died from the primary malignancy; and the other 2 patients developed therapy-related MDS/AML (t-MDS/AML) and died at 51 and 71 months from their initial diagnosis of t-APL, and 3 and 11 months from the diagnosis of t-MDS/AML, respectively. t-MDS/AML was observed in one out of 111 (0.9%) *de novo* APL patients. **Summary and Conclusions.** High cure rates can be expected in patients with t-APL with no increase in the early death rate. However, there appears to be an additional risk of t-MDS/AML in patients following treatment for t-APL. Although the small number of patients precludes assessment of risk factors for t-MDS/AML, the risk appears higher than 1.1% reported in patients with *de novo* APL in large clinical trials, and warrants further studies in a larger patient cohort. Furthermore, molecular studies in the future may identify unique genetic abnormalities, which may distinguish t-APL from *de novo* APL and predict for those patients destined to develop t-MDS/AML.

0654

PREDICTORS OF MORTALITY DURING INDUCTION TREATMENT IN APL PATIENTS TREATED WITH AIDA BASED REGIMEN

R Jeddi[1], H Ghédira[1], R Ben Amor[1], Y Ben Abdennebi[1], H Ben Neji[1], M Zarrouk[1], K Kacem[1], S Mnif[2], L Aissaoui[1], R Ben Lakhal[1], H Ben Abid[1], Z Ben Hadjali[1], B Meddeb[1]
[1]Aziza Othmana University Hospital, Tunis, Tunisia
[2]Institut Pasteur, Tunis, Tunisia

Background. Early death during APL induction treatment remains a major concern in this highly curable disease. We aimed at identifying factors that could predict early mortality in 51 APL patients treated with the Spanish PETHEMA LPA99 trial. **Results.** Fifty one consecutive genetically confirmed APL (with t (15, 17) and /or PML-RARA) were treated in a single center (University Hospital of Tunis) between 2004 and 2010. Median age was 30 years (range 4-71). M/F was 0.64. Two (4%), 31(61%) and 18 (35%) patients were Sanz low, intermediate and high risk respectively. Median time between first symptom and diagnosis was 15 days (range 2-90).Complete remission (CR) was achieved in 43 (86%) of 50 evaluable patients (one patient died from severe bleeding before treatment onset). Eight (16%) patients developed severe bleeding and 16 (32%) differentiation syndrome (DS), severe in 11. Seven patients (14%) had early death (ED): 4 from DS and 3 from CNS bleeding. Median time from ATRA onset to ED was 8 days (range 2-22). In patients with ED and CR, respectively, median age was 40 years (range 15-71) and 30 years (range 4-64) (P=0.251) , 6/7(85%) and 24/43(55%) patients were females (P=0.134) ,71.5% and 28% were Sanz high risk (P=0.024), median time from first symptom to diagnosis was 11 days (range 3-30) and 15 days (range 2-90) (P=0.4), median baseline WBC was $17.9x10^9$/l and $3.6x10^9$/L (P=0.11) and renal failure was observed in 5 (71.5%) and 12 (27.9%) (P=0.024). By multivariate analysis, female gender (P=0.045), renal failure (P=0.021) and high WBC $>10^9$/l (P=0.041) were independent predictive factors of ED. Baseline WBC > 30 $x10^9$/l were associated with increased risk of ED by bleeding (P=0.049) and Body Mass Index (BMI) > 35 kg/m^2 of ED by DS (P=0.05).With a median follow up of 50 months, 4 year EFS and OS were 74 and 78% respectively. **Conclusions.** Female gender, renal failure and high WBC were associated with an increased rate of early death during induction therapy of APL. Despite a delay in hospital admission in many cases, interval to onset of treatment had no significant impact on ED. However, this delay may have contributed to increase WBC and impaired renal function, which in turn contributed to ED.

0655

TRANSFUSION INDEPENDENCE AND SURVIVAL IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA TREATED WITH 5-AZACYTIDINE

M Gavillet, J Noetzli, S Blum, O Spertini, M Duchosal, JF Lambert
Lausanne University Hospital, Lausane, Switzerland

Allogeneic stem cell transplantation is the only curative option for high-risk AML and MDS patients. Practically, a minority will reach such treatment. Few studies have addressed the difficult yet pertinent issue of alternative therapies for older patients deemed unfit for standard chemotherapies. Preliminary data suggest that AZA might be effective in the subgroup of advanced MDS and AML patients, resulting in 35 to 48% hematologic improvement (HI) or better response and prolonged overall survival (Silvermann 2006). In high risk MDS patients, AZA could prolong survival and delay AML transformation compared to conventional care regimen (CCR: best supportive care (BSC), low dose cytarabine or intensive chemotherapy) (Fenaux 2009). AZA therapy also increased the rate of, and prolonged, transfusion-independency (Fenaux 2010).We identified 52 consecutive AML patients (median age 68 [25-86]), treated with 5-azacytine (AZA) between January 1st 2007 and December 31st 2011 at our institution. They were not suitable for intensive chemotherapy because of high age (n=33) or comorbidities (n=9) or were refractory to initial intensive chemotherapy (n=10). AZA was administered at 100mg/m^2 sc d1-5, over 28-day cycles. Transfusion-independent (TI) patients were defined as 8 weeks without red blood cell (RBC) respectively platelet (PLT) transfusion.Our collective included 83% patients presenting with marrow blasts over 30%, thus clearly different from AZA-001 high risk MDS and RAEB-t subgroup study (Seymour 2010). At baseline, 15% (n=9) of our collective were RBC-TI, whereas 85% (43) were transfusion-dependent (TD). A similar proportion was PLT-TI, 25% (n=13) versus 75% (n=39) PLT-TD. Median overall survival of the 52 enrolled patients was 8.6 months, and twelve-month survival rate was 28% [95CI 15-43%].To evaluate TI acquisition, we selected 38 patients having received more than 2 cycles of AZA in order to achieve a minimum observation period of 8 weeks implied by TI definition. Half of RBC-TD patients (50%; 16) acquired TI on AZA treatment. Of the 28 PLT-TD patients at baseline, 50% (14) became TI. Overall, 50% (19) of the patients remained or turned out to be

both RBC and PLT-TI and 21% (8) RBC or PLT-TI.Interestingly, RBC-TI patients under therapy (16) or at baseline (6) had prolonged survival compared to RBC-TD patients (median OS 11.1 vs 5.0 months, 12-month OS 40% [95CI 19-60%] vs 13% [95CI 2-32%], P=0.0006). No difference in OS was observed whether TI was present at baseline or acquired under treatment (median OS 10.7 vs. 11.9, 12-month OS 40% [95CI 17-63%] vs. 45% [95CI 5-75%], P=NS). In multivariate analysis, baseline or acquired RBC-TI was the only significant parameter predicting survival (HR 0.36 [95CI 0.16-0.77], P=0.009) (Figure 1).We report for the first time that, despite not being curative for AML, AZA can induce transfusion independency in 50% of previously TD patients. Transfusion independence correlates to increased overall survival, regardless if present at baseline or acquired under AZA. These results suggest that transfusion independence is a strong prognostic factor in AML patients undergoing AZA therapy. This may allow extending previous observations made with MDS-WPSS risk score (Itzykson 2011), to acute leukemia.

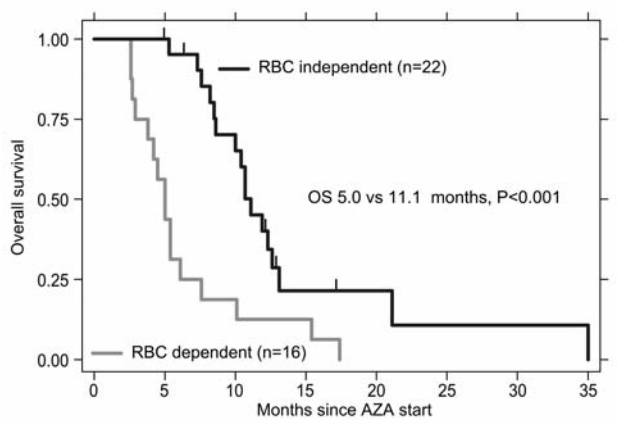

Figure 1. Survival according to RBC-transfusion independency.

CONSECUTIVE INTENSIFICATION OF ACUTE LEUKEMIA TREATMENT DURING PREGNANCY - TWO DECADES STUDY

V Troitskaya[1], E Parovichnikova[1], A Kokhno[1], M Vinogradova[2], S Makhinya[1], M Kurtser[3], V Savchenko[1]
[1]National Research Center for Hematology, Moscow, Russian Federation
[2]National Research Center for Obstetrics, Gynecology and Perinatology, Moscow, Russian Federation
[3]Centre of Family Planning and Reproduction, Moscow, Russian Federation

Background. Acute leukemia (AL) in pregnant women is a rare event and it's just impossible to conduct any large prospective study. **Aims.** Since 1990NationalResearchCenter for Hematology (NRCH) has been developing the optimal treatment approaches aiming to save two lives - both a mother and a child. **Methods.** From 1990 to 2012 yy 34 pregnant women with *de novo* and 3 with relapsed AL were treated in the NRCH. The median age was 26 (19-35 years). AML was diagnosed in 16 (43,25%), APL - in 5 (13,5%) and ALL - in 16 (43,25%). In the 1st trimester the abortion was performed before the treatment (1st group n=6). In the II/III trimesters (<36 weeks) the chemotherapy was started (2nd group n=24), and delivery was planned at 36-37 weeks of gestation. If AL was diagnosed at > 36 weeks, women were delivered before the chemotherapy (3rd group n=7). At the beginning of our study in AML 7+3 was applied with 135 mg/m^2 of daunorubicin (Dauno) (n=4), than - 36 mg/m^2 of idarubicin (IDA) (n=5), and later - 180 mg/m^2 of Dauno (n=4). APL was treated with either 7+3 (Dauno 60 mg/m^2) or AIDA protocol. ALL pts received 8 weeks induction, consolidation, reinduction and 2 years maintenance. **Results.** In the 1st group the interval between abortion at 7 weeks (3-14 w) of pregnancy and treatment constituted 3 days (1-5 d); in the 3rd group between the delivery at 38 weeks (36-39 w) and treatment - 7 days (1-35).24 (AML-13, APL-3, ALL-8) underwent chemotherapy during pregnancy at 24 weeks (14-34 w). 1 ALL pt is undergoing induction chemotherapy at time of analysis. So in 10 of 23 (43,5%) CR was achieved before the delivery; 13/23 pts (56,5%) delivered without achieving CR. It's worth to note that there were no CRs in AML pts after the 1st 7+3 with 135 mg/m^2 of Dauno, so for 10 years we use IDA and Dauno 180 mg/m^2.Totally CR rate in AML and APL pts was high - 81,3% and 80%, with ED 6,2% and 20%, resistant leukemia - 12,5% and 0%, correspondingly. On the contrary CR in ALL pts was achieved only in 60%, due high resistance 20% and induction mortality 20%. It possibly is attributed to prolonged steroids (5 weeks). 12/37 pts (32,4%) are alive (2 weeks - 13 years). Antenatal fetal mortality was registered in2 pts.12 ptsdelivered by their own and17 pts- by Cesar section. One child (4%) died due to pneumonia at the 1st week of life. Other children are alive (6 mo-22 y) and healthy. It's a curious fact but in AML the majority of newborns were boys (83%) and in ALL - girls (63%) (p=0,01). **Conclusions.** Our data demonstrate that chemotherapy in pregnant women with AL should be intensive in order to achieve CR after the 1st course; induction results in AML are better than in ALL; long-term results are comparable with usualAL outcome.

0657

TREATMENT FOR ELDERLY PAIENTS WITH ACUTE MYELOID LEUKEMIA WITH AZACITIDINE RESULTS IN FEWER HOSPITALIZATION DAYS AND INFECTIVE COMPLICATIONS BUT SIMILAR SURVIVAL COMPARED WITH INTENSIVE CHEMOTHERAPY

ZT Lao, R Yiu, C Diong, YS Lee, GC Wong, A Ho
Singapore General Hospital, Singapore, Singapore

Background. Intensive chemotherapy administered to elderly patients with acute myeloid leukemia (AML) is associated with high treatment related complications, mortality rates and low rates of long term survival. Azacitidine has been shown to prolong overall survival compared with best supportive care in elderly AML patients with low blast counts. **Aims.** Our study looks at the differences between the mortality and morbidity outcomes of elderly AML patients who received intensive chemotherapy, azacitidine based therapy or best supportive care. **Methods.** Patients 60 years or older diagnosed with AML between January 2009 and June 2011 were included in our retrospective review. Those who passed away within less than 2 weeks of diagnosis were excluded.Intensive chemotherapy regimen comprised intravenous idarubicin 12mg/m2 for 3 days and cytarabine 100mg/m2 infusion for 7 days as induction followed by consolidation with intraveous cytarabine 1.5 gram/m2 twice daily on days 1,3 and5. Azacitidine based regimen comprised subcutaneous azacitidine 75mg/m2 daily for 7 days with or without oral valproic acid and/or all-trans-retinoic acid. Best supportive care consisted of transfusion support and antibiotic therapy for infections. Overall survival (OS) curves were estimated by the Kaplan-Meier Method, differences between other patient characteristics were analyzed with the ANOVA test. **Results.** Of the 60 patients included in our analysis, 29 received best supportive care, 20 received azacitidine based therapy and 11 received intensive chemotherapy with curative intent. At a median follow up of 7.2 months (range: 0.5 to 26.4 months), estimated median OS for patients who received azacitidine based therapy was 10.9 months (range: 2.4 to 22.5 months), compared with 8.9 months (range: 0.9 to 26.4 months) for patients who received intensive chemotherapy (p = 0.89) and 2.4 months (range: 0.5 to 9.5 months) for patients who received best supportive care (p<0.005). Compared with azacitidine based therapy, intensive chemotherapy is associated with more inpatient days (median 99.5 (range: 27 to 150 days) vs 46 (range: 7 to 142 days) days; p=0.017) and higher number of episodes of febrile illness requiring inpatient stay or intravenous antibiotics (median 3 vs 2; p=0.019). Amongst patients who received azacitidine, those with bone marrow blast counts of less than 30% achieved a longer median survival compared with those with bone marrow blast counts of 30% or more (14.6 vs 9.8 months), however the difference was not statistically significant (p=0.31). Standard and favorable risk cytogenetics is associated with better survival compared with high risk cytogenetics in patients receiving azacitidine (14.6 vs 8months; p = 0.028). **Conclusions.** Compared with intensive chemotherapy in elderly patients with AML, azacitidine based therapy is associated with statistically similar median survival but lower number of hospitalization days and infective episodes, potentially maximizing time in the community while possibly maintaining a relatively good quality of life.

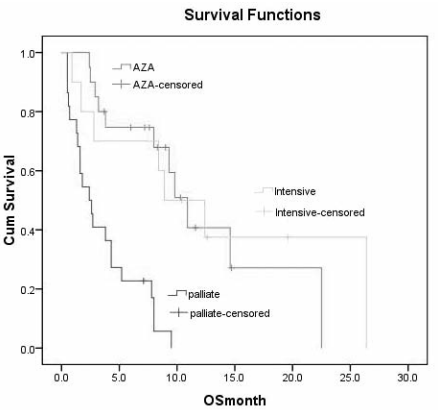

Figure 1. Kaplan Meier survival curve.

PRE-CLINICAL CHARACTERIZATION OF ANTI-CXCR4 ANTIBODY, BMS-936564/MDX-1338, AND PHASE 1 CLINICAL EXPERIENCE IN PATIENTS WITH RELAPSED/REFRACTORY AML

P Cardarelli, S Shelat, H Yoshitsugu, L Schweizer, M Kuhne, C Pan, P Sabbatini, L Alland, L Cohen
Bristol-Myers Squibb, Sunnyvale, United States of America

BMS-936564/MDX-1338 is an IgG4, fully human monoclonal antibody that specifically recognizes human CXCR4 and is currently in Phase 1 studies in patients with relapsed/refractory acute myeloid leukemia (AML) and multiple myeloma (MM). CXCR4 is a seven-transmembrane, G-protein-coupled receptor in the CXC chemokine receptor family. Expression of CXCR4 is elevated in a variety of cancers and the interaction of CXCR4 on tumor cells with CXCL12 in the bone marrow promotes tumor cell survival and growth. We have developed an antibody targeting CXCR4 which is predicted to be efficacious in a number of hematopoietic malignancies. Here we describe the pre-clinical *in vitro* and *in vivo* characterization of BMS-936564 and the preliminary clinical experience with BMS-936564 in a Phase 1 first-in human study in patients with relapsed or refractory AML.In vitro studies demonstrate that BMS-936564 binds to CXCR4 expressing cells with low nanomolar affinity. The antibody blocks CXCL12 binding to CXCR4 expressing cells and inhibits CXCL12 induced migration and calcium flux with low nanomolar EC50 values. In addition to these activities, BMS-936564 induces apoptosis on a large number of hematopoietic cell lines. Investigations into the pathway of apoptosis identified changes in mitochondrial membrane permeability and caspase 9 activation suggesting that the antibody is mediating apoptosis through the intrinsic pathway. Interestingly, the apoptotic activities associated with the CXCR4 antibody are CXCL12 independent. When given as monotherapy on established tumors, the antibody exhibits anti-tumor activity in multiple AML, NHL and MM xenograft models.In the Phase 1, first-in-human, multiple ascending dose clinical study in patients with relapsed or refractory AML, BMS-936564 is initially given as monotherapy during a lead-in period, followed by its administration with chemotherapy. The primary objectives are to assess safety and tolerability and to determine maximum tolerated dose. The data presented will include preliminary safety, pharmacokinetics, pharmacodynamics, and clinical efficacy. Informed consent has been obtained for all study subjects.

ANALYSIS OF PROGNOSTIC FACTORS FOR SURVIVAL OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

I Djunic[1], M Virijevic[1], A Novkovic[2], V Djurasinovic[1], N Colovic[1], A Vidovic[1], D Tomin[1], N Suvajdzic-Vukovic[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinical Hospital Center „Zemun„, Belgrade, Serbia

Background. Acute myeloid leukaemia (AML) occurring in people aged 60 years and older is a distinct disease with an unfavourable prognosis owing to particular biological and clinical features. **Aims.** Through the application of different risk factor scores, we aimed to identify a subset of elderly patients who might benefit from intensive chemotherapy and for whom it could be possible to assess prognosis. We also wished to determine our own prognostic score system. **Methods.** This single-center study involved 102 patients aged ≥ 60 years with nonpromyelocytic AML and a follow-up period of 65 months. We classified the patients into risk groups for overall survival (OS) using the following prognostic models (named from the authors of the cited references): 1) Malfuson et al.; 2) Rollig et al.; and 3) Wheatley et al.. We compared the outcome of our patients after stratification into risk groups using the named prognostic models in order to determine which model is most applicable for assessment of our patients. The following parameters were evaluated as risk factors: age, leukocytosis (≥3010^9/L), lactate dehydrogenase (LDH) more than 1.5 x upper limit of normal, CD34 expression (≥10%), ECOG performance status (<1 vs ≥2), cytogenetic risk group according to the Europian LeukemiaNet (ELN) and comorbidity score (<3 vs ≥3) obtained from the hematopoetic cell transplantation-specific comorbidity index (HCT-CI). Kaplan-Meier curves and log rank test were used to estimate OS and to compare differences between survival curves. For multivariate analysis a Cox proportional hazards model was constructed for OS adjusting for six variables. A backwards elimination procedure was employed to exclude redundant or unnecessary variables. Integer weights for the risk score were derived from Cox proportional hazards modeling. The prognostic score was validated via 10-fold cross validation. **Results.** The mean age of the patients was 67 years (range 60-89). For our group of patients the most significant coincidence with outcome was with Wheatley's scoring system, which stratified patients into three risk groups: favorable, standard and poor. Our results showed that the most significant factors for OS in univariate analysis were: age ≥65 years (p = 0.016), ECOG PS ≥2 (p = 0.004), leukocytosis (p = 0.046), elevated LDH (p <0.001), adverse cytogenetic (p <0.001) and HCT-CI ≥3 (p <0.001). Our prognostic scoring system was developed after analysis of the prognostic risk factors: age <65 years, normal LDH and HCT-CI <3 = 0 points, where age ≥65 years = 1 point, and elevated LDH and HCT-CI ≥3 = 2 points. According to this prognostic model, patients were classified into three risk groups: favorable = 0-2 points, intermediate = 3-4 points, and poor = >4 points. The OS between these groups was highly significant (p <0.001). Moreover, in comparison with other prognostic models by Cox analysis, our prognostic model had the greatest statistical significance: p<0.001, HR 2.013 (95% CI 1.464 - 2.768). **Conclusions.** The prognostic model developed in this study can distinguish between elderly AML patients in different risk groups regarding prediction of OS and can indicate a subset of patients suitable for intensive chemotherapy.

USE OF HIGH DOSE CYTARABINE INDUCTION IN ADULT *de novo* AML IS NOT ASSOCIATED WITH IMPROVED SURVIVAL

G Kennedy[1], K Jackson[1], S Durrant[1], D Gill[2], P Mollee[2], P Marlton[2], K Morris[1]
[1]Royal Brisbane and Women's Hospital, Brisbane, Australia
[2]Princess Alexandra Hospital, Brisbane, Australia

Background. High dose cytarabine (HiDAC) in treatment of adult AML is associated with improved disease free survival (DFS). However, data on the relative benefits of incorporating HiDAC into induction *versus* consolidation chemotherapy cycles is limited. **Aims.** We aimed to determine the outcome of adult patients with *de novo* AML treated with standard dose cytarabine *versus* HIDAC-based induction strategies at our institutions. **Methods.** All patients with *de dovo* AML aged 15-59yrs treated with induction chemotherapy at our institutions between February 1999 and July 2011 were retrospectively identified from institutional data bases. Information on cytogenetic risk (using Intergroup criteria), chemotherapy protocols, response to therapy, OS, and DFS were then determined retrospectively by review of individual medical records. Survival analyses were calculated by the Kaplan-Meier method and compared using the log-rank test. **Results.** In total 211 patients with *de novo* AML had been treated, including 105 patients (50%) treated with "standard"cytarabine at 100mg/m2 days 1-7, with 103 patients receiving standard 7+3 with idarubicin 12mg/m2 days 1-3 and 2 patients receiving standard 7+3+7 with etoposide; and 106 patients (50%) treated with HiDAC-based induction, including 76 patients treated with "Big ICE"(Blood 2005; 105: 481), 21 treated with "HiDAC 7+3"(HiDAC 3gm/m2 BD days 1, 3, 5 + 7 plus idarubucin 12mg/m2 days 1-3), 4 treated with FLAG and 5 with other HiDAC-based regimens. Median age of the entire cohort was 45yrs (range 15-59yrs). Based on cytogenetic profile, 36 patients (17%) had good-risk AML, 142 (67%) intermediate-risk and 33 (16%) poor-risk disease. Overall CR rate was similar between the 2 induction strategies (93% *vs.* 92% for standard *vs*. HiDAC based induction groups respectively; p=0.8). A majority of patients receiving standard-dose cytarabine induction subsequently received HiDAC-based consolidation (67%); conversely the majority of patients induced with HiDAC received standard-dose cytarabine in consolidation (81%). A similar proportion of patients in each group underwent allogeneic transplantation in 1st remission (34% *vs.* 25% for standard *vs.* HiDAC based induction groups respectively; p=0.17). At a median FU of survivors of 47mths (range 1-152mths), no difference in either OS or DFS was apparent between the standard and HIDAC-based induction groups (median OS 81 *vs*. 78mths respectively; p=0.9; median DFS not reached *vs.* 59mths respectively; p=0.9). Even when stratified into specific cytogenetic risk groups, no improvement in either OS or DFS was demonstrable with HiDAC-based induction. **Conclusions.** HiDAC-based induction for *de novo* AML in adults <60yrs of age is not associated with improvement in either OS or DFS in comparison with use of standard-dose cytarabine induction +/-y HiDAC based consolidation.

Acute myeloid leukemia - Clinical 4

LIPOSOMAL DAUNORUBICIN, FLUDARABINE AND CYTARABINE (FLAD), A WELL TOLERATED AND EFFECTIVE TREATMENT BRIDGING TO STEM CELL TRANSPLANT IN 66 PATIENTS WITH RELAPSED-REFRACTORY ACUTE LEUKEMIA

M Clavio[1], E De Astis[2], F Guolo[2], F Ballerini[2], L Mitscheunig[2], C Marani[2], G Pastori[2], P Minetto[2], M Bergamaschi[2], M Miglino[2], C Ghiggi[2], F Galaverna[2], S Aquino[2], F Cruciani[2], I Pierri[2], L Canepa[2], M Gobbi[2]
[1]Hematology and Oncology, IRCCS Ospedale S Martino IST, Genova, Italy
[2]IRCCS Ospedale S Martino IST, Genova, Italy

Background and Aims. Patients with relapsed or refractory acute lymphoblastic leukaemia (ALL), lymphoid blast crisis of CML (CML-LBC) and acute myeloid leukaemia (AML) experience a very poor outcome and only a small proportion of them can be rescued by allogeneic stem cell transplant (BMT). In these patients the use of Daunorubicin is usually limited by drug-induced cardiotoxicity depending on the cumulative dose administered. Compared to the unencapsulated antracycline, liposomal daunorubicin (DNX) is characterized by a higher tumor cell delivery and a reduced toxicity profile. We previously showed that the combination of fludarabine plus Ara-C and DNX (FLAD) had clinical activity in patients with poor risk AML and relapsed ALL (Clavio et al 2004). Herein we present our experience with FLAD as salvage and bridging therapy to BMT. **Patients and Methods.** The regimen consisted of three-days treatment with a 30-minute infusion of Fludarabine 30 mg/sqm followed 4 hours later by a 4 hour infusion of Ara-C 2 g /sqm and a 60 minute infusion of DNX 100 mg/sqm. All patients achieveing CR received at least an additional course of FLAD and, when possible, were scheduled for BMT. We have treated until now 34 pts with ALL, refractory (n. 12) or in relapse (n. 22, 4 after allogeneic BMT), 3 pts with relapsed CML-LBC, and 29 patients with relapsed (n. 20, 4 after BMT) or refractory (n. 9) AML. Median age was 34 years (range 13-76) for ALL patients and 53 years (range 13-70) for AML patients. Patients had received a median of 3 prior regimens (range 1-7). Seventeen ALL/CML-LBC patients (45%) and 7 AML patients (24%) had unfavourable cytogenetic alterations. **Results.** In ALL/CML-LBC group 4 pts died of infection during therapy (10%) and 23 patients out of 37 (62%) obtained complete remission (60% of those treated for relapse and 67% of refractory patients). In the AML group one patient died of infection during therapy (3%) and 14 patients out 29 (48%) achieved CR (70% and 0% among relapsed and refractory patients, respectively). CR rate was significantly affected by disease status (relapsed vs refractory) and karyotype in AML and by age in ALL patients. Fourteen ALL/CML-LBC patients (38%) and 8 AML patients (27%) underwent BMT. Projected DFS and OS for ALL patients is 9,1% and 13% respectively, both at 36 and 60 months. For AML patients DFS and OS is 10,3% and 10,7%, respectively, at 36 months and 60 months. DFS and OS were affected by age only in ALL (p 0.019) and by disease status (p 0.0001) and karyotype (p 0.03) in AML group.FLAD was well tolerated. Few severe infectious and no cardiac complications were recorded. **Conclusions.** Our experience in a series of patients with very severe prognosis shows that FLAD is a feasible and effective salvage treatment for patients with relapsed and refractory ALL and CML-LBC and relapsed AML. Furthermore, the low toxicity of the regimen and the fast haematological recovery allowed a significant proportion of patients (33% overall) to benefit of BMT.

0662

ROLE OF PERIPHERAL BLAST CLEARANCE IN SURVIVAL OF PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

K Naqvi, A Quintas-Cardama
UTMD Anderson Cancer Center, Houston, United States of America

Background. A combination of cytarabine and an anthracycline is the standard therapy for patients with AML and is associated with a complete remission (CR) rate of 60-70%. Early clearance of peripheral blood (PB) blasts has been established as an important prognostic factor in acute lymphoblastic leukemia. **Aims.** We evaluated the dynamics of PB blasts and white cell count (WBC) clearance in patients with AML undergoing induction chemotherapy with AI (ara-C 1.5g/m2x3d and idarubicin 12mg/m2x3d) at our institution and their impact on long-term outcomes.Patients & **Methods.** We reviewed the dynamics of PB blasts (PB blasts=0%) and WBC (WBC≤0.1x109/dL) clearance in patients with AML receiving AI (n=149). Patients with acute promyelocytic leukemia were excluded. Besides PB blasts and WBC, patient characteristics studied include age, hemoglobin, platelet count, bone marrow blasts and cytogenetics. **Results.** Of the 149 patients included in the study, 105 (70%) were <60 years of age, median age at treatment was 55 years (range, 19-73), median WBC 4.9 (range, 0.3-97.4), platelets 39 (range, 2-581), hemoglobin 8.4g/dL (range, 3.3-13.2), PB blasts 15% (range, 0-95), BM blasts 45% (range, 1-96), diploid cytogenetics (n=54, 36%) and poor cytogenetics (n=57, 38%). The overall response rate (ORR=CR+CRp) was 65% (58%+7%). Forty-four (30%) pts were resistant to induction therapy. To evaluate the dynamics of PB WBC and PB blast clearance, we divided all pts in 5 groups depending on the day they cleared their WBC or blasts from PB: group 1 (0-1 days), 2 (2-3 days), 3 (4-5 days), 4 (6-8 days), and 5 (beyond day 8). No differences in CR rates were observed across all 5 groups according to the time of clearance of PB WBC (p=0.65). Likewise, similar median overall survival (OS) rates were observed in all 5 groups regardless of the timing of PB WBC clearance (p=0.25). When groups 1, 2 and 3 were merged and compared to the merger of groups 4 and 5, the OS remained similar (p=0.30). However, the timing of PB blast clearance was associated with a distinct probability of achieving CR in all 5 groups (p=0.003). When groups 1, 2, and 3 were merged and compared with the merge of groups 4 and 5, the ORR for the resulting two new groups was 93% and 7% (p<0.001) and the corresponding median OS was 40 weeks and 75 weeks (p=0.038) suggesting that early PB clearance predicts long-term outcomes. In the Cox regression model,in addition to cytogenetics and platelet count, PB blasts clearance was also noted to be significantly associated with event free survival (p=0.03). However when controlling the association between PB blast clearance and response and PB blast clearance and survival, the association disappeared (p=0.19).Conclusion:We have shown in a large cohort of uniformly treated pts with AML that early clearance of PB blasts (but not WBC) is an important risk factor for achievement of CR and for OS. Clearance of PB blasts should be considered in prognostication schemas for pts with AML.

0663

CYCLIC AMP PROTECTS MYELOCYTIC LEUKEMIA BLASTS AND THE APL NB4 CELL LINE AGAINST ANTHRACYCLINE-INDUCED APOPTOSIS VIA ACTIVATION OF PKA TYPE I

G Gausdal[1], A Wergeland[1], J Skavland[2], E Nguyen[3], Ø Bruserud[2], B Gjertsen[2], E Ségal-Bendirdjian[3], S Døskeland[1]
[1]University of Bergen, Bergen, Norway
[2]2Institute of Medicine, University of Bergen, Bergen, Norway
[3]INSERM, UM1007 and Université Paris Descartes, UMR-S1007, Paris, France

Background. Cyclic AMP is the second messenger for a number of extracellular signals, including endogenous and exogenous beta-adrenergic stimulators and members of the prostaglandin family. While cAMP protects mature neutrophils against death, its effects on hematopoetic cell growth and survival are pleiotropic (1). A striking effect of cAMP is to enhance the ATRA-induced maturation of acute promyelocytic leukemia (APL) cells, like the NB4 cell line (2). ATRA-induced maturation is a cornerstone in APL therapy, and its combination with cAMP signaling stimulators has been advocated to improve current APL therapy. **Aims.** We wanted to study how the cAMP level modulates the response to current therapy for AML and APL. **Methods.** Blasts from AML and APL patients and several cell lines (NB4, HL60, MOLM13) were tested for death induction by DNR in the absence and presence of cAMP elevating agents (PGE2 + PDE inhibitor or cAMP analogs). cAMP analog pairs specifically activating cAMP-dependent protein kinase I (PKA-I) or cAMP-dependent protein kinase I (PKA-II) were used to elucidate the major mediator of the protection. **Results.** We have recently reported that cAMP synergizes with the first line drug daunorubicin (DNR) to induce apoptosis in the AML cell line IPC-81 (3). In patient blasts, we found no instance of cAMP enhanced DNR-induced apoptosis. Rather, we noted that cAMP protected the majority of the patient blast isolates against DNR-induced death. While no such protection was noted in HL60 or MOLM13 cells, protection by cAMP elevation was pronounce also for the NB4 APL cells. We found that cAMP protected NB4 cells against DNR (and Idarubicin) both in the absence and presence of ATRA and that the uptake and nuclear accumulation of anthracycline was unaffected by cAMP. The major mediator of the protection was PKA-I: Protection was achieved by PKA-I activating, but not PKA-II directed cAMP analog pairs. It was nearly abolished by the PKA-I directed inhibitor Rp-8-Br-cAMPS, but not by stable RNAi-induced downregulation of PKA-RII. cAMP mediated protection was independent of p53 status and mTOR pathway activity. The protection was associated with inactivating phosphorylation of the pro-apoptotic protein Bad and activating phosphorylation of the AML proto-oncogene CREB, both on known PKA targeted residues. **Conclusions.** The antagonism between cAMP and anthracyclines represents a therapeutic dilemma. In current APL therapy an anthracycline is combined with the maturation-inducing agent ATRA. ATRA depends on cAMP to achieve optimal differentiation, and stimulation of cAMP signaling has been advocated to improve the ATRA effect in APL patients. The present findings suggest that cAMP stimulation could be counter-therapeutic together with anthracyclines, and that cAMP elevating drugs like phosphodi-

esterase inhibitors should be used with caution during anthracycline treatment.

HIGH RESPONSE RATE TO COMBINED THERAPY OF LOW DOSE GEMTUZUMAB OZOGAMICIN AND CYTARABINE IN ELDERLY ACUTE MYELOID LEUKEMIA PATIENTS WITH FAVORABLE AND INTERMEDIATE I RISK CYTOGENETICS

S Tavor[1], E Rahamim[2], N Sarid[2], O Rozovski[2], E Naparstek[2]
[1]Hadassah Hebrew University Hospital, Jerusalem, Israel
[2]Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel

Introduction. The management of older patients with acute myeloid leukemia (AML), where the median age of presentation is approximately 70 years, remains a major challenge. The gemtuzumab ozogamicin (GO), a humanized anti-CD33 monoclonal antibody conjugated with an antitumor antibiotic, has been shown to be effective agent in the treatment of relapse AML in elderly. Two years ago, the FDA recommended the removal of GO from the US market due to product's safety issue and limited benefit in induction therapy of young (< 60 years) newly diagnosed AML patients. However, recently two prospective randomized trials showed a significant improvement in overall survival to the addition of GO to induction therapy in elderly patients with AML. The GO dose and the time of administration as well as the chemotherapy protocol were different. The aim of this study was to evaluate the safety and the efficacy of low dose GO with cytarabine in elderly patients with newly diagnosed AML. **Results.** Over the past five years, we have treated 16 elderly AML patients [median age 72 years (range 64-82)] with GO (3 mg/m^2) followed by continuous infusion of cytarabine (100 mg/m^2) for 7 days. Consolidation therapy was not predefined. The cytogenetic risk groups were defined using the new Genetic Risk Classification of the European LeukemiaNet Recommendations.Complete remission (CR) was achieved in 68.8% of patients however, only in patients with favorable or intermediate I cytogenetic risk groups. Of the 12 patients with favorable and intermediate I genetic group AML, 11 (91.7%) achieved CR. By comparison, of all 4 patients with intermediate II or adverse genetic groups, none of the patients achieved CR (p=0.003). The median disease-free survival and overall survival was 10.9 months and 18.8 months, respectively, for patients who achieved CR. The estimated median survival was 15 months in the favorable and intermediate I cytogenetic groups and only 4.4 months in the intermediate II and unfavorable risk groups (p=0.008). The toxicity profile was also manageable in AML patients mainly older than 70 years in a good performance status. The eight-week mortality was 6.25% (1/16), which is relatively low in this high risk group of patients. **Conclusions.** These data are in line with results from two randomized trials showing that the addition of low dose GO should be considered as first line induction therapy in selected elderly patients and raises the question regarding the optimal combined chemotherapy.

0665

CAN MDR1 GENE POLYMORPHISMS IMPROVE THE PROGNOSTIC IMPACT OF WHO ACUTE MYELOID LEUKEMIA CLASSIFICATION?

A Espirito Santo, M Gomes, J Bessa, J Mariz, R Medeiros
IPO-Porto, Porto, Portugal

Backgroud. Acute leukemias are clonal malignant disorders characterized by aberrant proliferation, differentiation and maturation of leukemic progenitors and precursor cells. Classification of these diseases, previously based only on morphological and cytochemistry findings (FAB classification), now also includes phenotypic aspects as well as cytogenetic and molecular characteristics, known to be valuable prognostic factors (WHO classification). Primary drug resistance in acute leukemia is probably the major cause of treatment failure and death. Many mechanisms have been thought to be related with this event, being the expression of P glycoprotein, the product of MDR1 gene, one of them. This protein functions as an efflux ATP-dependent pump, clearing drugs (such as antracyclines, vinca alkaloides, taxanes) out of cancer cells. **Aims.** to define the prevalence of MDR1 genes polymorphisms in Portuguese patients with acute myeloid leukemia (AML) and to evaluate the relevance of these polymorphisms in disease outcome (Overall Survival - OS). **Materials and Methods.** from 315 patients diagnosed and treated in our institution with AML we studied 25. DNA was extracted from peripheral blood samples. The polymorphism C3435T and C1236T was genotyped by Real Time PCR (RT-PCR) with Taqman®SNP Assay genotyping C___7586857_20 and C___7586662_10, respectively, from Applied Biosystems. Statistical analysis was performed with SPSS®Statistics v17. **Results.** Nineteen patients were males, median age 54 years old with good performance status (ECOG 0-1 in 84% patients). According to WHO classification 8 patients (32%) had AML with recurrent genetic abnormalities, 7 patients had AML with myelodysplasia-related changes and AML nos (28% each) and 12 % (n=3) had therapy related AML. Nine patients were treated according to SWOG9126, 8 patients according to "7+3"regimen, 4 patients were treated with mitoxantrone and arac and 2 patients were treated with acute promyelocytic protocols.In polymorphism C3435T the presence of C in both alleles was found in 9 cases (36%) and the presence of one allele T was observed in 16 cases (64%). In the other polymorphism (C1236T) 10 cases (52%) had two alleles C and 10 cases (40%) had one allele T. In none of the studied polymorphisms the presence of both alleles T was identified.The OS at 3 years for all patients was 40%. No significant difference was found in cytogenetic or age subgroup analyses of OS. The studied polymorphisms did not interfere in OS.A statistically significant difference (p=0,012) was found in the OS at 3 years, according to WHO subgroups in the presence of allele T cariers, which could not be reached when all patients were analyzed. Once again no significant difference was found when other subgroups analyses were performed (therapeutic, cytogenetic or age). **Discussion and Conclusions.** according to our results the WHO risk stratification is improved when adding to the subgroup analyses the evaluation of MDR1 polymorphisms. The relevance of WHO subgroups achieve more impact when allele T is present in C1236T. The treatment with SWOG 9126 regimen, which includes cyclosporine, did not improve outcome.Inclusion of more patients is a goal to reach in a near future aiming to ameliorate results.

A SINGLE INSTITUTION EXPERIENCE OF INDUCTION WITH HIGH DOSE CYTARABINE AND MITOXANTRONE FOR HIGH RISK ELDERLY ACUTE MYELOID LEUKEMIA (AML) PATIENTS INCLUDING AGE > 70

M Ramanathan, J Cerny, G Raffel, W Walsh, J Bednarik, N Fortier, A Kroll-Desrosiers, B Woda, P Miron, R Nath
UMASS Medical School and Medical Center, Worcester, United States of America

Background. Patients with high risk AML, defined as age>60 or presence of high risk cytogenetics carry a poor prognosis and inferior outcomes after standard 7+3 induction chemotherapy. Reported CR rates have been as low as 6% and induction death rates as high as 48%. **Aims.** We present here our experience on treating high risk AML patients with an induction regimen consisting of high dose mitoxantrone and cytarabine. **Methods.** We performed a retrospective analysis of all patients with AML who received this induction regimen from January 2009 to December 2011 at our institution. Patients treated with this regimen included patients who were age > 60 and age <60 if they had received prior treatment with daunorubicin, or treatment during daunorubicin shortage. Each patient received high dose cytarabine at 3gm/m2 over three hours on days 1 to 5 and mitoxantrone 60-80mg/m2 once on day 2. The primary endpoints of the study were response (CR + CRp) at day 30, treatment related mortality (TRM) within 30 days of initiation of treatment, overall and progression free survival (OS & PFS), ability to proceed to transplant and outcomes after transplant. Impact of high risk cytogenetics and non-denovo AML on the outcomes was analyzed and a subset analysis of patients age >70 was performed. **Results.** 50 AML patients received this induction regimen. The median age was 66.5 years (28 - 83), 20 patients (40%) were age ≥ 70. Median age adjusted Charlson comorbidity index (CCI) was 6 (2-12). Other high risk features included high risk cytogenetics in 27 (54%) and non-denovo AML in 24 (48%). 70+ subset were less likely to be denovo (p=0.0481). Response (CR+CRp) rate was 88% (44 of 50) including 11 who had CR with incomplete platelet recovery (CRp). Six (12%) patients were refractory to induction. There was no treatment related mortality. The median OS was 31.9 months (7.4 -*) Median PFS was *not reached (9.4 -*). Twenty five (50%) patients were able to proceed to autologous (6) or allogeneic (17) or autologous followed by allogeneic (2) stem cell transplantation. The median time to transplant was 105 days (32 to 195). Median OS and PFS of the patients who underwent SCT was *not reached (Figure 1). Median time to neutrophil and platelet recovery was 26 days (19-43) and 27 days (9-44) respectively. Echocardiography was performed either for cardiac symptoms or as pre transplant work up. Cardiac toxicity was noted in 14 (28%) patients, at a median of 63 days (22 -139) after induction chemotherapy. Anthracycline induced cardio toxicity was not reported to be the cause of death in any of these 14 patients. **Conclusions.** In this high risk AML population, high dose mitoxantrone and cytarabine induction was well tolerated and demonstrated a response (CR+CRp) rate of 88% and no induction deaths. Half (50%) were able to proceed to SCT. Advanced age

or high risk cytogenetics or non denovo AML did not adversely affect response rate or PFS, thus highlighting the utility of this regimen in high risk newly diagnosed elderly patients with AML.

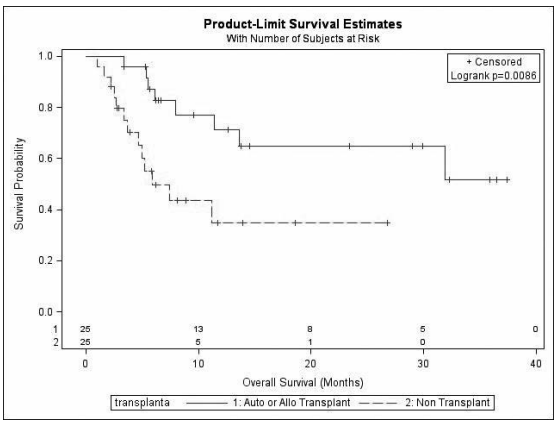

Figure 1 Overall Survival of Transplant versus Non transplant patients.

Introduction. Clofarabine is a second generation purine nucleoside analog approved by FDA and EMA in refractory paediatric ALL patients. Phase I and II studies have reported Clofarabine activity in AML and has emerged as a potential alternative for relapsed and refractory patients with AML as well as unfit patients. **Aims.** The aim of this study is to evaluate the experience in Spain with Clofarabine in the treatment of adult AML patients, analyzing effectiveness and toxicity profile. **Methods.** Twenty Spanish sites participated in this retrospective study of adult patients with AML treated with Clofarabine by compassionate use. Clinical records were reviewed collecting demographic date and the use of Clofarabine. Main points were complete remission as IWRv2003 criteria and toxicity as CTCAE v3.0 of NCI scale. **Results.** Between July 2007 and August 2011 a total of 78 AML adult patients were treated with Clofarabine based chemotherapy in Spain. We obtained clinical data from 73 cases. Median age at Clofarabine treatment 52.3 years (18-77). Male/Female: 36/37. Previous Myelodisplastic syndrome 13 (17.8%). Cytogenetic data was available in 67 patients (91.7%), and 31 of them had high-risk cytogenetic. Twelve of these patients had had a previous ALO transplant.Clofarabine treatment: 65 patients received CLF as salvage therapy (untreated AML relapsed in 27 cases and refractory disease in the rest 38), median previous lines 3 (1-7). The remaining 8 patients received Clofarabine as front-line treatment. Clofarabine was administered in combination with AraC in 95% patients and 93% received a five days schedule. The most frequent Clofarabine dose/day were: 40 mg/m^2/day (47 patients), 30 mg/m^2/day (11 patients), and 20 mg/m^2/day (10 patients).Response and outcome: Twenty three (31.5%) patients achieved complete remission and 38 (52%) had resistant disease.The statistical analysis shows a significant difference in the CR rate between first line therapy (CR 62.5%) and savage therapy in relapsed (CR 44%) and salvage therapy in refractory (CR 18%), (p0.012). Neither adverse cytogenetics nor previous MDS and previous Alo transplant did influence CR rate (p0.56, p0.54 and p0.53 respectively). Toxicity: All patients presented grade IV hematological toxicity with grade IV neuthopenia, grade IV trombopenia and transfusion depend anemia. The incidence of extra hematological toxic effects were low, creatinine >3 mg/dL: 5 cases (6.5%); bilirrubine > 3 mg/dL: 11 cases (14%). Twelve (16.4%) patients died during induction. **Conclusions.** In this study Clofarabine showed clinical activity in adult AML patients and confirms the effectiveness of Clofarabine as a salvage regimen. Of note was that Clofarabine could potentially overcome some adverse known factors as cytogenetics.

0668

THE CLINICAL SIGNIFICANCE OF THE EXPRESSION OF MDR-1, MRP-1. BCRP AND LRP MRNA IN ADULT ACUTE MYELOID LEUKEMIA

B Nasilowska-Adamska[1], I Solarska[2], M Paluszewska[3], W Jedrzejczak[3], B Marianska[2], K Warzocha[2]
[1]Institute of Hematology and Transfusuin Medicine, Warsaw, Poland
[2]Institute of Hematology and Transfusion Medicine, Warsaw, Poland
[3]Medical University, Warsaw, Poland

Background. Multidrug resistance (MDR) is a clinically relevant problemin the treatment of acute myeloid leukemia (AML). Whilesome mechanisms of drug resistance have been well characterized,this phenomenon still remains incompletely understood. One mechanism behind drug resistance is altered drug transport, which could be due to over-expression of the transport proteins that function as a membrane pump responsible for the efflux of a range of chemotherapeutic drugs: p-glycoprotein (Pgp)-product of *MDR1* gene and multidrug resistant protein-1 (MRP-1), breastcancer resistance protein (BCRP), lung resistance-related protein (LRP) encoded by the relevant genes. **Aims.** The aim of this study was to analyze the expression of the *MDR-1, MRP-1, BCRP, LRP* messenger RNA (mRNA) in relation to the response to induction chemotherapy and relapse and with pretreatment laboratory and clinical characteristics and prognostic factors. Moreover, the influence of MDR genes on disease free survival (DFS) and overall survival (OS) were estimated in presented patients. **Methods** A total of 185 adult consequent patients (88 females and 97 males) at a median age of 53,1 years (range18,5-86,6 years) with newly diagnosed, previously untreated AML, as well as 40 healthy donors were included in this study. DNA and RNA were extracted from mononuclear cells of bone marrow (147 patients) or peripheral blood (38 patients) samples collected after approval from the ethics committee and informed consent from the patients. *FLT3*-ITD was detected with PCR method in 53 patients (29%). The RQ-PCR method was performed for the assessment of expression ofthe *MDR-1, MRP-1, BCRP* and *LRP* mRNA and the results were presentedas coefficients calculated with an intermediate method accordingto Pfaffl's rule.The relative expression ratio of a target gene was calculated based on efficiency and the Ct deviation of the healthy donor´s sample versus the patient´s sample, and expressed in comparison to a reference gene: **Results.** The high expression of MDR genes correlates with worse treatment outcome of patients with AML. In univariate analysis, the high expression of *MDR-1* mRNA (>0,131) was associated with outcome of induction therapy (p=0,06) and of *BCRP* mRNA (> 1,148) with high relapse rate (RR) (p=0,013). We found that high expression of *MDR-1* (>0,131), *MRP-1* mRNA (> 0,84) and *BCRP* mRNA (> 1,148) significantly influence DFS (p=0,059, 0,032 and 0,009, respectively) and OS (0,048, 0,014 and 0,059, respectively). The *LRP* mRNA expression had no impact on treatment outcome in AML. Interestingly, high *BCRP* mRNA expression (>1,148) proved to be an independent prognostic factor for RR (p=0,011) and DFS (p=0,002) in the multivariate analysis.**Conclusions** The combined analysis of MDR genes allowed different classes of AML to be identified, with distinct clinico-biological features. Our study shows that MDR genes expression should also be considered for risk-adapted treatment strategies in AML in the future. It seems that especially BCRP is associated with clinical resistant disease in AML and influence the RR and DFS.This project was sponsored by grant of The Ministry of Science (NN402208935).

0669

THE DIFFERENCES IN PROGNOSTIC OUTCOME BETWEEN AML1/ETO AND CBFβ/MYH11 POSITIVE AML PATIENTS

J Marková, P Michková, J Soukupová Maaloufová, P Soukup, P Cetkovsky, J Schwarz
Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background. CBF-AML is considered to be a good-risk subtype of AML. However, there might be differences within this subgroup according to the respective fusion gene as well as due to various secondary aberrations. The results published so far are quite inconsistent. **Aims.** To search for possible differences in clinical outcome between patients with *AML1/ETO* and *CBFβ/MYH11* fusion genes. **Patients and Methods.** CBF-AML was diagnosed in 49 patients, their median age being 38.7 (18.5-70.6) years. The male/female ratio was 34/15, median follow-up was 38 months. RNA from 46 of them was available for searching of secondary aberrations. Minimal residual disease (MRD) was prospectively followed up in 39 patients.Presence of *AML1/ETO* and *CBFβ/MYH11* was detected by RT-PCR; MRD was monitored using real time RT-PCR. Direct sequencing was used to identify patients carrying secondary alterations such as *FLT3*/ITD, *FLT3* D835, *C-KIT* or *K-RAS* mutations. **Results.** 27 patients had *AML1/ETO,* 9/26 (34.6%) harboured secondary aberration (2 had *FLT3*/ITD, 2 *FLT3* D835, 4 carried *C-KIT* and 1 *K-RAS* mutations). 22

patients were *CBFβ/MYH11* positive, 13/20 (65.0%) had another molecular lesion (2 had *FLT3*/ITD, 5 *FLT3*/TKD, 7 *C-KIT* and 2 *K-RAS* mutations), 2 patients carried more than one of these changes. Secondary aberrations were more frequent among *CBFβ/MYH11* patients (P=0.020).The initial median WBC count was 15.8 x 10^9/L (1.3-256.1 x 10^9/L) and it differed between the *AML1/ETO* and *CBFβ/MYH11* cases (12.8 vs. 52.5 x 10^9/L; P=0.004). *CBFβ/MYH11*-positive patients harbouring any of secondary molecular aberrations had higher WBC (105.3 vs. 30.5 x 10^9/L; P=0.081).All but 3 patients (all of them having *AML1/ETO*) reached complete remission (CR). 12 of 20 (60.0%) patients carrying *AML1/ETO* achieved molecular remission (MR; defined as MRD negativity in at least two following bone marrow samples, with a minimal interval of 2 months), while only 7/16 (43.8%; P=0.166) *CBFβ/MYH11*-positive patients reached MR. Reaching MR was unfavourably influenced by the presence of any of the secondary aberrations monitored (P=0.023). Relapse free survival (RFS) was longer in cases reaching MR (P<0.0001) and there was no difference between *AML1/ETO* and *CBFβ/MYH11* cases. Only 1/19 (5.3%) patients reaching MR relapsed, while 9 relapses among 15 patients (60.0%) without MR were observed (P<0.0001). Patients achieving MR had also significantly longer overall survival (OS; P=0.025).*CBFβ/MYH11*-positive patients more often relapsed than those with *AML1/ETO* fusion (63.6% vs. 20.8%; P=0.002) and their RFS was shorter (P=0.014). The incidence of relapse as well as RFS was influenced by the presence of the secondary aberration only within the *CBFβ/MYH11*-positive subgroup (P=0.055 and P=0.033, respectively), not in the *AML1/ETO* patients (P=0.300 for relapse rate and P=0.603 for RFS). Although OS was not affected by the particular fusion gene within the whole group (P=0.878), when patients not reaching CR were excluded, there was a trend to shorter post-remission survival in *CBFβ/MYH11* cases (P=0.129). **Conclusions.** In our CBF-AML patient cohort, *CBFβ/MYH11*-positive cases had shorter RFS and higher incidence of relapse than those carrying *AML1/ETO* fusion. This might result from lower MR rate caused probably by higher incidence of the secondary molecular aberrations.

0670

PROGNOSTIC FACTORS OF ATRA RELATED COMPLICATIONS DURING INDUCTION TREATMENT OF APL

H Ghédira[1], R Jeddi[1], R Ben Amor[1], Y Ben Abdennebi[1], M Zarrouk[1], H Ben Neji[1], K Kacem[1], S Menif[2], R Ben Lakhal[1], H Ben Abid[1], Z Ben Hadjali[1], B Meddeb[1]
[1]Aziza Othmana University Hospital, Tunis, Tunisia
[2]Institut de Pasteur, Tunis, Tunisia

Background. The combination of all-trans-retinoic acid (ATRA) and chemotherapy has made acute promyelocytic leukemia (APL) a highly curable leukemia. However, several complications are reported with this treatment the most serious and life threatening being the differentiation syndrome (DS). We aimed at identifying factors that could predict complications caused by ATRA during induction treatment of APL. **Results.** Fifty one patients with confirmed APL (by t (15,17) and/or PML/RARA) treated in our institution (University hospital of Tunis) between 2004 and 2010 using the Spanish PETHEMA LPA99 trial. Induction regimen consisted of ATRA 45 mg/m^2/d until CR combined to Idarubicin 12 mg/m^2 d2, 4, 6, 8 IV. Prednisone (0.5 mg/kg d1-d15) was added if WBC >10x 10^9/L to prevent DS. Median age was 30 yr (range 4-71), M/F was 0.64 , median WBC was 4.4x10^9/L(range 0.6 - 123). Additional cytogenetic abnormalities were seen in 17 patients (39.5%). Median body mass index (BMI) was 23.5 kg/m^2 (range 13- 40), BMI >35 was noted in 5 patients (3 F and 2 M). 43 patients achieved CR (86%). Seven patients (14%) had early death: 3 from CNS bleeding and 4 from DS.Complications due to ATRA were: DS (16 patients), scrotal ulcerations (4 patients), Sweet syndrome (1 patient), headache (12 patients), skin dryness (22 patients) and arthralgia (8 patients). Prognostic factors for complications of ATRA excluding DS were: BMI >35 (P=0.045), Platelet count > 40x10^9/l (P=0.045) and age > 20 y (P<0.001), whereas sex, WBC and morphology were not predictive. For DS, BMI >30 (P=0.029), renal failure (P=0.021) and WBC > 10x10^9/l (P=0.047) were independent predictor factors. With median follow up of 50 months EFS and OS were 74% and 78%, respectively. ATRA related complications had no significant impact on CR, EFS and OS. **Conclusions.** We found very high BMI (>35) and age over 20 years to be significantly associated with ATRA related complications (DS excluded) during induction treatment for APL.

0671

CD56 ANTIGEN EXPRESSION IN ACUTE MYELOID LEUKEMIA

E Aguiar, M Badior, F Trigo, MP Gomes, JE Guimarães
Centro Hospitalar de São João, Porto, Portugal

Background. The expression of CD56 antigen has been reported in several hematologic malignancies, including acute myeloid leukemia (AML). Evidence suggested that CD56 positivity could be associated with extramedullary leukemic infiltration and an unfavorable prognosis in AML patients, in particular in AML with t(8;21) and acute promyelocytic leukemia (APL). In other AML subtypes its role is less clear. **Aims.** To investigate the frequency, clinical and biologic characteristics and prognostic impact of CD56 expression in AML patients. **Methods.** Two hundred and five patients with AML (53 with APL) received intensive chemotherapy in our center between January 2005 and March 2011. Immunophenotypic analysis was available for all patients and CD56 positivity was considered when at least 20% of blasts expressed this antigen. Patients were treated with EORTC Protocols AML12/AML17, ATRA-IDA or AIDA GIMEMA protocol for APL and 2 patients with ELAM-02 pediatric protocol, followed by consolidation chemotherapy and allogeneic or autologous transplantation. **Results.** Median age was 54 years (range, 16-78) and 56.1% (n=115) of patients were females. Thirty eight (18.5%) patients were CD56 positive. Its frequency was significantly higher in FAB subtype M5 (p=0.05) and in patients with t(8;21) (p=0.000). CD56+ patients had a significantly higher median leukocyte count (17.5x10^9/L vs. 5.6x10^9/L, p=0.03), higher median *lactate dehydrogenase* (LDH) (p=0.05) and extramedullary infiltration (50% vs. 28.7%, p=0.01). CD56 positivity did not correlate with age, sex and blast count. To assess the prognostic significance of CD56 positivity, we excluded patients with more than 60 years (n=55) and patients with favorable cytogenetic - t(8;21) (n=4), inv(16)/t(16;16) (n=5) and t(15,17) or PML-RARA+ (n=53). We analyzed 88 patients (54.5% female), with a median age of 46 years (range, 16-60 years). Seventeen patients were CD56 positive (19.3%). The median follow-up after beginning of treatment was 16 months (range, 0.36-72 months). CD56 positivity did not influence complete remission (CR) rate. The 5-year Overall Survival (OS) was 27% (95% CI, 25.72-28.28) for CD56+ patients and 42.9% (95% CI, 42.15-43.65) for CD56- patients (p=0.19). The 5-year Disease Free Survival (DFS) was 21% (95% CI, 19.73-22.27) for CD56+ patients and 41.2% (95% CI, 40.47-41.93) for CD56- patients (p=0.34). In multivariate analysis, only older age and chemotherapy resistance were independent prognostic adverse factors in OS. **Summary and Conclusions.** Our data confirm that CD56 positivity is associated with FAB subtype M5, AML with t(8;21), higher median leukocyte count and LDH and extramedullary disease. However, no statistically significant results were found in CR, OS and DFS rates, despite our CD56+ patients showed a trend to have lower DFS and OS. These results may allow to hypothesize that stronger prognostic factors abolish the prognostic value of CD56.

0672

PROGNOSTIC FACTORS AND OUTCOME OF CORE BINDING FACTOR ACUTE MYELOID LEUKEMIA PATIENTS

N Suvajdzic[1], A Novkovic[2], I Djunic[1], M Virijevic[1], N Colovic[1], A Vidovic[1], N Kraguljac-Kurtovic[1], V Djordjevic[1], I Elezovic[1], D Tomin[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinical Hospital Center Zemun, Belgrade, Serbia

Background. Translocation t(8;21) and inversion (inv)(16)/t(16;16) disrupt core binding factor (CBF) in acute myeloid leukemia (AML) and occur in approximately 7% and 8% of adults with *de novo* AML, respectively. CBF-AML has been associated with a favorable prognosis, but it seems that these two cytogenetic subgroups have different biological and clinical standpoints. **Aims.** The aim of this study was to assess prognostic risk factors for rate of complete remission (CR), overall survival (OS) and disease-free survival (DFS) in patients with CBF-AML. **Methods.** Fifty two patients with CBF-AML, 28 with t(8;21) and 24 with inv(16), diagnosed and treated during a 10-year follow-up period (2001-2011), were retrospectivelly assessed. The following parameters were estimated as risk factors for CR, OS and DFS: age, leukocytosis ≥50x10^9/L, CD117 expression ≥20% on leukemic cells assessed by flowcytometry, dysplastic features in bone marrow cells, hepatomegaly (>14 cm) and splenomegaly (>12cm). Patients were treated with the Medical Research Council (MRC) 10 regimen. C-kit assessment by PCR and treatment with MUD alogenous transplantation were not available. Risk factors were identified using univariate and multivariate analysis. **Results.** The mean age of the patients was 46 years (range 18-73). Median OS was 8 months, CR rate was 69.6%, relapse rate was 32,2% while DFS was 18 months. Significant risk factors for a lower CR rate in univariate analysis were: hepatomegaly (p=0.034), splenomegaly (p=0.015) and leukocytosis (p=0.001), while multivariate analysis indicated leukocytosis as the most significant risk factor (p=0.035). Significant risk factors for poor OS by univariate analysis were: age >50 years (p=0.012), leukocytosis (p=0.035) and CD117 antigen expression (p=0.022). Multivariate analysis identified leukocytosis as the most important risk factor for OS (p=0.006). Univariate analysis showed that significant risk factors for shorter DFS were: age >50 years (p=0.026), splenomegaly (p=0.011) and bone marrow dysplastic features(p=0.015). Moreover, the most important risk factor for DFS in multi-

variate analysis was bone marrow dysplasia (p=0.034). In the subgroup of patients with t(8;21), the overall CR rate was 80.8%, while in the subgroup with inv(16), it was 55%. In patients with t(8;21), the most important risk factor for CR rate (p=0.050) and OS (p=0.042) was age >50 years, while splenomegaly was the most important risk factor for DFS (p=0.050). In patients with inv(16), the most important risk factor for CR rate was leukocytosis (p=0.045), for OS it was age >50 years (p=0.040), and for DFS bone marrow dysplastic features (p=0.040). **Conclusions.** This study identified leukocytosis, age and bone marrow dysplastic features as the most important factors affecting CR rate, OS and DFS in patients with CBF-AML. These factors differ in importance between the two cytogenetic subgroups of CBF-AML, which indicates that patients with t(8;21) and inv(16) constitute two separate clinical entities.

0673

CLOFARABINE AS A SALVAGE THERAPY AND A BRIDGE TO TRANSPLANTATION IN PATIENTS WITH HIGH RISK ACUTE LEUKEMIA AND RELEVANT COMORBIDITY. A SINGLE CENTRE EXPERICENCE

S Imbergamo, G Binotto, C Gurrieri, T Berno, F Piazza, M Ermani, R Zambello, G Semenzato
University of Padua, Padova, Italy

Backgroud. Acute myeloid leukemia (AML) is an aggressive hematological malignancy and the outcome of patients with relapsed/refractory disease still remains unsatisfactory. Clofarabine is a second generation nucleoside analog with efficacy in acute leukemia. Combination therapies of Clofarabine either with cytarabine arabinoside (ARA-C) in AML or with cyclophosfamide in acute lymphoblastic leukemia (ALL) are feasible and effective as induction therapy or salvage treatment. **Aims.** To determine the efficacy and safety of clofarabine as a salvage therapy and as a bridge to transplantation in frail patients with unfavourable cytogenetics relapsed/refractory acute leukemia. **Methods.** A retrospective analysis was conducted on 21 patients with acute leukemias treated in our Department. The diagnosis was made according to 2008 WHO criteria. Median age at diagnosis was 52 years (range 19-76); 12 (57%) patients with relapsed and 9 (43%) with refractory acute leukemias; AML (n: 19)/ALL (n: 2); patients were treated with a median of 2 prior regimens (range 1-5). Fifteen patients (71.4%) were considered at high, one intermediate and five (23.8%) low cytogenetic risk. Eighteen patients (86%) had significant comorbidity (48% had high risk Charlson score index). AML patients received salvage therapy with ARA-C 1 g/m^2 for 5 day and Clofarabine, 40 mg/m^2 for 5 days, from day 2 to day 6, whereas in ALL patients Clofarabine was combined with Cyclophosfamide 400 mg/m^2, given for 5 days. **Results.** Seven patients (33%) achieved complete remission (CR); among these, 3 (14%) were classified as high risk cytogenetic at the start of therapy. The median DFS was 110.5±179 days (median: 30; range: 3 - 740), while the EFS was 36.8±39.8 (median: 21; range: 3-150). Neither the DFS nor EFS were significantly associated to cytogenetic risk profile (p=0.96 e p=0.33, respectively). The DFS was correlated with EFS (Rho=0.61, p=0.003). Eight patients (38%), three in complete remission and three with persistence of disease, underwent transplantation. Two cases relapsed after allogeneic bone marrow transplantation (allo-BMT) and were treated with clofarabine as salvage therapy; the median survival from the beginning of therapy was 100 days (95% CI: 35-165). The median survival was significantly correlated with transplantation (log rank, p=0.03), resulting 157 days (95% CI: 86-228) in transplanted patients versus 58 days (95% CI: 0-134) in non transplanted patients. Side effects with clofarabine included nausea (49%), transient liver dysfunction (71%), skin rashes (43%), mucositis (31%). Patients were treated with antibiotic prophylaxis with fluoroquinolones. We documented 13 (61%) febrile neutropenia, 8 (38%) septic shock, 5 (23%) cardiac abnormalities (3 atrial fibrillation and 2 heart failure). **Conclusion**. Clofarabine in combination with ARA-C or Cyclophosphamide represents a promising combination in the treatment of acute leukemias both as a salvage therapy to induce remission and as a bridge to transplant.

0674

NK CELL AS THE THIRD LINEAGE OF MIXED PHENOTYPIC ACUTE LEUKEMIA: BOTH CD56 AND CD16 EXPRESSION IN ACUTE MYELOID LEUKEMIA IS SIGNIFICANTLY ASSOCIATED WITH THE HIGH NUMBER OF PLATELET

HR Lee[1], SY Kim[2], SM Hwang[2], M Kim[2], CJ Park[3], HS Chi[3], S Jang[3], HK Kim[2], MH Park[2], DS Lee[2]
[1]Gyeongsang National University Hospital, Jinju, South-Korea
[2]Seoul National University Hospital, Seoul, South-Korea
[3]University of Ulsan College of Medicine and Asan Medical Center, Seoul, South-Korea

Background. There is no consideration of natural killer (NK) cell lineage in defining of mixed phenotype acute leukemia (MPAL) according to the WHO 2008 classification as well as bilineal acute leukemia or biphenotypic acute leukemia (BAL) according to the European Group for the Immunologic Classification of Leukemia (EGIL) scoring system of previous WHO 2001 classification. CD56, one of the antigens expressed on NK cells, is commonly used for immunophenotyping of acute leukemia. CD56 expression in acute myeloid leukemia (AML) has been reported to be associated with poor prognosis, comparing of AML without CD56 expression. **Aims.** We hypothesized that CD56 expression of AML is not aberrant expression of AML but NK lineage expression as the 3rd lineage of MPAL. Immunophenotype analysis for CD16, granzyme B, and perforin together with CD56 as NK lineage markers were performed in AML, and the hematologic, immunophenotypic, and cytogenetic features were investigated according to the expression of NK lineage markers. **Methods.** Patients, who were diagnosed with AML and BAL according to EGIL scoring system from September 2007 through July 2009 and whose BM cells were available for immunophenotyping by flow cytometry, were reclassified according to the WHO 2008 classification. In addition of immunophenotyping analysis, we analyzed several clinical and biological characteristics: age, sex, complete blood cell count and blast count in peripheral blood, cytogenetic features, and AML risk status based on cytogenetics of National Comprehensive Cancer network (NCCN) guidelines. **Results.** A total of 117 patients diagnosed with AML and MPAL, were enrolled according to the WHO classification of 2008. One hundred three out of 117 patients were classified as AML, 14 patients were classified as MPAL, 11 as MPAL, B/myeloid and three as MPAL, T/myeloid. To compare the hematologic, immunophenotypic, and cytogenetic features according to the presence of the NK markers in AML, we categorized the 103 patients (91 AML and 12 MPAL, NK/myeloid) into three groups according to the expression of CD56 and CD16: patients with the expression of both CD56 and CD16 (12 patients, 11.6%), patients with the expression of CD56 or CD16 (42 patients, 40.8%), and patients without the expression of CD56 and CD16 (49 patients, 47.6%). The number of platelet was significant higher in the patients with the expression of both CD56 and CD16 than in the patients with the expression of CD56 or CD16 and the patients without the expression of CD56 and CD16 (P=0.011). The immunophenotypic features were similar, except for the expression of CD5 and CD117 (P=0.005 and P=0.034, respectively). No significant differences in other characteristics were observed between three groups. **Conclusions.** We showed the unique hematologic feature of AML with expression of NK markers, CD56 and CD16. Therefore, we suggest NK cell lineage as the 3rd lineage of MPAL and propose the additional MPAL subtype, namely, MPAL, NK/myeloid. Further studies will be required to ascertain the prognosis of MPAL, NK/myeloid and NK marker expression in AML should be considered in the treatment strategy.

0675

AZACITIDINE FOR TREATMENT OF MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIAS: A SINGLE CENTER EXPERIENCE

M Michallet, C Champigneulle, M Sobh, S Morisset, M Detrait, F Nicolini, H Labussière, S Ducastelle, F Barraco, Y Chelghoum, X Thomas, E Wattel, F Ranchon, C Rioufol
Centre Hospitalier Lyon Sud, Pierre Bénite, France

Introduction. The efficacy of azacitidine in the treatment of high risk myelodysplastic syndromes (MDS), chronic myelomonocytic leukemias (CMML) and acute myeloid leukemias (AML) has been demonstrated. **Aims.** To investigate the outcome of patients receiving azacitidine in a daily clinical practice at our institution and its impact on disease response, overall survival (OS) and transfusions. **Materials and Methods.** We conducted this retrospective analysis on patients who received azacitidine between August 2005 and November 2011 at our institution for MDS or AML. The total number of treatment cycles, response rate, number of transfusions and overall survival were evaluated. **Results.** There were 96 patients, 59 (61%) males and 36 (39%) females with a median age of 70 years (25-91). The indication of azacitidine was the first line

treatment for MDS, mainly refractory anemias with excess of blasts,(n=68 (71%) patients: group1) and treatment following chemotherapy for AML patients (27 (29%) patients: group2). Prognostic factors according to FAB classification, ISPP risk and cytogenetics were assessed and will be further communicated. After a median follow-up of 9 months (1-75), the median number of azacitidine cycles in groups 1 and 2 was 8 (1-30) and 4 (1-16) respectively. There were 38 (40%) of responders (30 ingroup 1 and8 ingroup 2) while the rest of patients have progressed. There was a significant correlation between the number of treatment cycles and response rate; patients in response were statistically correlated with a number of cycles ≥ 6 (32 patients received ≥ 6 cycles:24 ingroup1 and8 ingroup 2). Accordingly, patients receiving ≥ 6 cycles of azacitidine had a significantly better survival comparing to those receiving less than 6 cycles. Beyond the number of 6 cycles, a higher treatment cycles did not show a significant difference in terms of OS. The median OS for the group 1 and 2 was 19.3 months (16-39) and 5.9 months (4.9-11.9) respectively, p<0.001. The median OS of responding patients was 24.5 months (24.5-not reached) while in the non-responders, it was 11.5 months (7-18.4). In terms of transfusion need, there was a significant decrease of red blood cells and platelets transfusions only in group 2, p=0.008. **Conclusions.** We showed a good response rate after azacitidine use especially when used for more than 6 cycles; its use in first line has significantly a better outcome on overall survival, while a transfusion benefit was demonstrated only in AML patients.

0676

PROGNOSTIC FACTORS IN ACUTE PROMYELOCYTIC LEUKEMIA

E Aguiar, M Badior, F Trigo, MP Gomes, JE Guimarães
Centro Hospitalar de São João, Porto, Portugal

Background. Acute Promyelocytic Leukemia (APL) is nowadays considered the most frequently curable acute leukemia of adults. It is known that some prognostic factors can affect the outcome of APL patients. Recently, an increased body mass index (BMI) was associated with a higher risk of developing differentiation syndrome and disease relapse (Breccia et al, *Blood*. 2012) **Aims.** To investigate the clinical and biologic characteristics and prognostic factors in APL. **Methods.** Fifty-three patients with APL received intensive chemotherapy in our center between January 2005 and June 2011. Patients were treated with regimens based in All-*trans* retinoic acid and anthracyclins. The following prognostic factors were evaluated in the overall survival (OS) and disease free survival (DFS) analysis: sex, age, French-American-British (FAB) subtype, breakpoint PML, CD34 antigen expression, BMI, hemoglobin, leukocyte and platelet count at diagnosis. **Results.** Median age was 44 years (range, 18-78) and 62.3% (n=33) of patients were females. The breakpoint PML analysis results were known in 49 patients: 31 (63.3%) with BCR1-2 and 18 (36.7%) with BCR3. Ten patients (18.9%) were classified as microgranular variant of M3. These patients showed a significant association with BCR3 breakpoint mutation (p=0.05) and higher median D-Dimers (54.83 vs. 23.34, p= 0.003). Twenty-six patients (49.1%) were under/normal weight (BMI < 25 Kg/m^2) and 27 (50.9%) were overweight/obese (BMI ≥ 25 Kg/m^2). An increased BMI was associated with older age (p=0.000), but not with sex, FAB subtype, leukocyte count or breakpoint PML. With a median follow-up after beginning of treatment of 36 months (range, 0.07 - 78.9 months), the 5-year DFS was 54.4% (95% CI, 53.03-55.77) in overweight/obese and 80.3% (95% CI, 80.21-80.38) in underweight/normal weight patients (p=0.04). The 5-year DFS was significantly lower in patients with older age (44.2% for ≥44 years vs. 85.4% for <44 years, p=0.002), isoform BCR3 (43.8% for BCR3 vs. 87.6% for BCR1-2, p=0.01) and CD34 antigen expression (50% for CD34+ vs. 71% for CD34- patients, p=0.02). In OS analysis, only older age showed to significantly affect the outcome (p=0.001). In multivariate analysis, the independent prognostic factors with negative impact on DFS were: BMI ≥ 25 Kg/m^2 (hazard ratio = 8.18, p= 0.04) and isoform BCR3 (hazard ratio = 9.06, p=0.04). **Summary and Conclusions.** Despite the high curable rates in APL, some factors can adversely influence the outcome of these patients. In univariate analysis, increased BMI, BCR3, older age and CD34 antigen expression had a significant negative impact on DFS, but only BCR3 and increased BMI showed an independent prognostic impact in multivariate analysis. Our data support the recent interest of increased BMI as a strong outcome predictor in APL.

0677

VALIDATION OF THE EUROPEAN PROGNOSTIC INDEX FOR ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA IN THE FIRST RELAPSE

M Virijevic[1], I Djunic[1], A Novkovic[2], A Vidovic[1], N Colovic[1], V Djurasinovic[1], N Suvajdzic-Vukovic[1], D Tomin[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinical Hospital Center „Zemun„, Belgrade, Serbia

Background. The outcome of patients with acute myeloid leukemia (AML) in the first relapse is poor. Predictive score for these patients could be generally applicable if they would furnish a simple and statistically valid prognostic score. **Aims.** The aim of this study was to assess the reproducibility of the European Prognostic Index (EPI) for stratification of patients with AML in first relapse into prognostic risk subgroups, as well as to evaluate various therapeutic options for treatment of these individuals. **Methods.** The single-center study involved 54 patients with nonpromyelocytic AML in the first relapse, with a 5-year follow up period. The patients were stratified into three prognostic groups: favorable, intermediate and poor, according the EPI. Four parameters were included in this index: length of relapse-free interval after first complete remission (CR), cytogenetics at diagnosis, age at relapse and whether prior stem cell transplantation had been performed. Patients were treated with three different therapeutic regimens: 1) Flagida - 45% of cases (Fludarabin 30mg/m^2 days 1-5; Cytarabin 2000 mg/m^2 days 1-5; Idarubicin 8 mg/m^2 days 1-3); 2) HiDAC - 35% of cases (Ara-C 3 gr/m^2 days 1,3,5) and 3) Mitoxantrone + Etoposide - 20% of cases (Mitoxantrone 10 mg/m^2 days 1-5; Etoposide 100 mg/m^2 days 1-5). Patients aged over 65 years were given palliative therapy (Hydroxyurea). The rate of second CR and OS were determined. **Results.** The mean age of the patients was 47 years (range 26-78). The overall rate of second CR was 40.9%. When patients were stratified into prognostic risk groups according to the EPI, the rates were as follows: favorable group - 100%, intermediate group - 41.7%, and poor group - 34.5%, which were significantly different (p = 0.05). Also, according the EPI stratification, OS (in months) was as follows: favorable group - 46, intermediate group - 17, and poor group - 13. Again, the differences were significant (p = 0.026). Differences in CR rate and OS between patients treated with Flagida, HiDAC and Mitoxantrone + Etoposide were not statistically significant (patients treated palliatively were excluded). **Conclusions.** The EPI is useful for stratification of patients with AML in first relapse into different prognostic groups, which provide important information about probable outcome and for therapeutic decision-making.

0678

PLASMA CYTOKINE AND ADHESION MOLECULE PROFILE IN PATIENTS TREATED FOR ACUTE MYELOID LEUKEMIA

J Horacek[1], L Jebavy[1], M Vasatova[2], P Zak[2], T Kupsa[1], M Jakl[1], J Maly[3]
[1]FMHS, Hradec Kralove, Czech Republic
[2]University Hospital, Hradec Kralove, Czech Republic
[3]Charles University, Faculty of Medicine, Hradec Kralove, Czech Republic

Background. Cytokines and adhesion molecules have been studied as markers of immune system activation in various diseases including hematological malignancies. Alterations in this network may have direct effect on the malignant cells or have indirect effect on leukemogenesis through altered functions of bone marrow stromal elements. The knowledge gained from multiple cytokine and adhesion molecule analysis should allow better diagnosis and disease management. **Aims.** The aim of our study was to evaluate plasma cytokine and adhesion molecule profile by biochip array technology in patients treated for acute myeloid leukemia (AML). **Methods.** A total of 15 AML patients (mean age 48.7 ± 12.1 years, median 51, 8 males and 7 females) treated with cyclic chemotherapy (3+7, 2+5, HiDAC) alone or in combination with high-dose chemotherapy (preparative regimen Bu/Cy2 or Cy/TBI) followed by autologous hematopoietic stem cell transplantation were studied. We evaluated plasma levels of the following 22 cytokines and adhesion molecules: interleukins (IL-1 alpha, IL-1 beta, IL-2, IL-3, IL-4, IL-6, IL-7, IL-8, IL-10, IL-12p70, IL-13, IL-23), vascular endothelial growth factor (VEGF), tumor necrosis factor-alpha (TNF-alpha), interferon-gamma (IFN-gamma), epidermal growth factor (EGF), monocyte chemotactic protein-1 (MCP-1), E-Selectin, L-Selectin, P-Selectin, Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1). All biomarkers were measured by biochip array technology on Evidence Investigator analyzer (Randox) at the diagnosis of AML (active leukemia) and at 6 months after completion of chemotherapy (durable complete remission /CR/ in all patients). Probability values (p) < 0.01 and lower were considered statistically significant. **Results.** Comparing plasma cytokine and adhesion molecule levels in active leukemia and in durable CR, we found significant increase in plasma IL-7 (5.34 ± 4.32 ng/L vs. 19.62 ± 12.05 ng/L; p < 0.001), EGF (16.48 ± 33.50 ng/L vs. 64.42 ± 35.33 ng/L; p < 0.001) and VEGF (63.93

± 67.85 ng/L vs. 114.39 ± 54.90 ng/L; p < 0.01). On the other hand, we found significant decrease in plasma E-Selectin (30.19 ± 20.46 mcg/L vs. 12.99 ± 8.00 mcg/L; p<0.01). Plasma levels of other evaluated cytokines and adhesion molecules were without significant differences. **Conclusions.** Our results indicate that plasma levels of some cytokines and adhesion molecules (IL-7, EGF, VEGF, E-Selectin) are significantly altered in patients treated for AML, showing activity of the disease. Whether these alterations could serve as a prognostic marker for AML is not known. Further studies in a larger number of patients and comparing cytokine and adhesion molecule levels with established prognostic markers (cytogenetics, molecular genetics) will be needed to define the potential role of these and additional markers in the risk stratification of AML patients.The work was supported by research projects MO 0FVZ0000503 and MZO 00179906.

0679

FRACTIONATED DOSES OF GEMTUZUMAB OZOGAMICIN COMBINED WITH STANDARD CHEMOTHERAPY AS SALVAGE TREATMENT FOR YOUNGER PATIENTS WITH RELAPSED ACUTE MYELOID LEUKEMIA.

JV Malfuson, J Konopacki, A Ségot, C Thepenier, V Foissaud, B Souleau, T De Revel
HIA Percy, Clamart, France

Background. Patients with relapsed acute myeloid leukemia (AML) usually have a poor outcome. Chemotherapeutic salvage regimens can yield complete remission (CR) in less than 50% of patients, with a 3-year overall survival (OS) rate of less than 30%.Used as single agent therapy for relapsing AML, gemtuzumab ozogamicin (GO) allows 25-35% CR, and some studies combining GO and chemotherapy are showing promising results. **Aims.** Retrospective evaluation of efficacy and toxicity of the association of fractionated doses of GO and standard intensive chemotherapy as salvage treatment for younger patients with relapsed AML. **Methods.** Included patients were aged less than 60 years, with a CD33+ AML in first relapse and an allogeneic transplantation planned in CR2. Salvage regimen consisted of GO 3mg/m^2 intravenously over 2 hours on days 1-4-7, cytarabine 200 mg/m^2 in continuous intravenous infusion over 24 hours on days 1 to 7 and daunorubicine 60mg/m^2 or idarubicine 12mg/m^2 intravenously over 30 minutes on days 1 to 3. **Results.** Fourteen patients were treated between April 2008 and April 2011. There were 6 male and 8 female, median age was 46 years (29-58), and median white blood cell count was 3.4 10^9/L (0.9-19). At diagnosis, according to the European Leukemia Net classification, there were 7, 2, 3 and 2 patients in the favourable, intermediate I, intermediate II and adverse groups, respectively. All the patients have been treated with standard AML practices and had received high or intermediate doses of cytarabine as consolidation therapy. Median CR1 duration was 11 months (1-42), with CR1 duration lesser than one year in 8 patients.Salvage therapy was performed as scheduled for the 14 patients, using daunorubicine in 12 patients and idarubicine in 2 patients. Six CR and 5 CR with delayed platelet recovery (CRp) were observed, allowing a 79% overall response rate. Median times to neutrophil (>0.5 10^9/L) and platelet (>20 10^9/L) recovery were 29 days (23-32) and 36 days (28-48), respectively. Treatment was complicated by three mild and one moderate veno-occlusive disease (VOD).Transplantations were performed in the 11 CR/CRp patients' within a median delay of 4 months (3-10). Ten patients were still in remission whereas one relapsed before transplant and was transplanted with refractory AML. Two mild VOD were observed after transplantation.Median follow-up of all the population is 10 months (2-45), and 6 patients are still alive and in CR with a median follow-up of 25 months (10-45), corresponding to a median overall survival (OS) rate of 10 months and an estimated 2-year OS of 42%. Five of the 11 transplanted patients died within a 5 months (1-10) median post transplant delay, corresponding to an estimated 2-year OS of 53% (median OS non reached). Death causes after transplantation were GVHD in three patients and AML relapse in two patients. **Conclusions.** In this limited size retrospective study on younger patients with AML in first relapse, fractionated doses of GO combined with 3+7 chemotherapy showed high anti leukemic activity and good safety profile, enabling to perform transplantation in most patients.

0680

COGNITIVE FUNCTIONS AND QUALITY OF LIFE IN ACUTE LEUKEMIA PATIENTS

S Verleden, K Audenaert, L Noens
Ghent University Hospital, Ghent, Belgium

Background. Chemotherapy for acute leukemia can have an effect on cognition and quality of life. Cognitive impairment and fatigue have been described in patients with AML/MDS, even before initiation of treatment.**Objective:** To assess cognitive evolution, and to measure both depression and quality of life in adult acute leukemia patients, before and after induction treatment. **Methods.** Current longitudinal-prospective study of adult acute leukemia patients treated with aggressive chemotherapy. Eligible patients are enrolled and are administered a comprehensive cognitive test battery, within five days after admission (T0) and after completion of induction treatment (T1). Cognitive functions assessed are attention, executive functions, motor dexterity, and verbal memory (tested with AVLT, COWA, PPT, SCWT, and TMT). Both depression and quality of life were assessed with two self-report questionnaires (assessed with CES-D and EORTC-QLQ-C30). **Results.** Thirty-five (n=35) adult acute leukemia patients were included between 01/2009 and 12/2011. The median age was 46 years, 53% were female. The median duration of education was 13 years. 88% had AML and 12% had ALL. Baseline mean hematological values were: WBC count (7,2 10E3/uL), RBC count (3,1 10E6/uL), and HgB (9,8 g/dL). Induction treatment used in AML patients was either the AML 2/95 protocol or the HOVON 102 AML protocol, in ALL patients the GMALL 7/03 protocol was used. Baseline cognitive functions were normal in different cognitive domains. Short-term evolution of cognitive functions was observed in executive functions (SCWT IV-III and TMT B), and in verbal learning (AVLT A1-5), both showed a significant improvement (all p<.005). Baseline levels of distress and depression were statistically significant, and adult leukemia patients had problems on all functional scales, except for cognitive function (CF=70), and on the symptom scale fatigue (F). Short-term changes in quality of life were observed in depression, global health score (QoL), functional scale emotional function (EF), and symptom scale fatigue (F) and pain (P). **Conclusions.** At baseline, adult acute leukemia patients had normal cognitive functions, except for verbal learning and especially motor dexterity. Depression and problems on quality of life were observed at baseline, whereas at follow-up only role and social function, and also fatigue were still impaired.

Table 1. Changes in cognition and quality of life (n=25-27/28).

WHICH IS MORE IMPORTANT: DURATION OR QUALITY OF LIFE IN PATIENTS WITH LEUKAEMIA AND LYMPHOMA?

RG Mihaila[1], I Lisan[2], R Dancu[2], D Lienerth[2], D Radu[2], D Stanciu[2]
[1]Lucian Blaga University Sibiu, Sibiu, Romania
[2]Emergency County Clinical Hospital, Sibiu, Romania

Background. It is usefull to regularly test the patients opinion according to the various issues raised by medical practice. Duration and quality of life are among them. Their responses are influenced by the hospital management and can provide starting points for improving it. **Aims.** We aimed to study the patients opinion from southern Transylvania on the relationship between duration and quality of life of patients with hematologic malignancies.**Material and Methods.** transversal study was performed on a sample of 250 consecutive hospitalized patients, who agreed to respond with 'yes', 'no' or ' don't know' to a questionnaire on the management of life quality of patients with leukemia and malignant lymphoma. The results were analyzed and they allowed conclusions with implications for clinical practice. **Results.** The mean age of patients surveyed was 55.64+/-16.01 years. Distribution by gender: women 44.39%, 55.61% men. About 75.61% of respondents felt that finding the diagnosis of leukemia or lymphoma is traumatic for patients and 16.59% of them said, surprisingly, not. 72.26% of the first measured depression between 8 and 10 notes on a scale of 1-10. 54.63% of them thought that it will be less traumatic for the patient if the doctor would not say the diagnosis of malignant hemopathy, but 69.27% of them considered depression caused by finding the diagnosis preferable to ignoring it for a long time. About half of respondents (49.27%) considered quality of life more important, and the other half - the duration of life of patients with malignant hemopathies. Most responders (72.68%) felt that it is more important how you live and only 25.37% - how much you live. Most (61.95%) agreed with aggressive chemotherapy, and only 31.22% opted for palliative treatment for these patients. Almost half (54.15%) agreed with the recommendation of herbal medicine. Almost all (93.17%) agreed to the idea that the family can contribute to the quality of life of patients. 91.71% felt that psychotherapy can improve the quality of life and 82.93% considered that psychotherapy should be done by the hematologist, in the absence of a psychologist since psychological balance can positively influence the course of disease (87.80% of respondents). 78.05% of them agreed to the idea of correcting anemia with erythropoietins, which could increase the quality of life of patients, even if they have adverse effects (60% of respondents). 77.07% agreed the idea of participation in multicenter studies with new drugs. 96.59% of them, would agree to donate blood for these patients, even if they were Romani (gypsy ethnic group) (95.12%), and even peripheral stem cells for allogeneic transplantation (87.32%).**Summary**: Most people put in the spotlight the quality of life and sustain all therapeutic means that improve it. In this respect they support the benefits of chemotherapy with curative intent and erythropoietin. They are concerned about depression in patients with malignant hemopathies and agree to any measure that might reduce it. They agree, as donors, to participate voluntarily in helping them.

Cytogenetics

Background. Cytogenetics provides the most powerful independent prognostic factor in AML presenting in children and younger adults, providing the framework for risk-stratified treatment approaches. However, approximately half the cases presenting in this age group fall into the intermediate cytogenetic risk category, within which patients have vastly different outcomes. The cytogenetically cryptic t(5;11)(q35;p15) leading to the *NUP98-NSD1* fusion, is a rare but recurrent gene rearrangement, recently reported to identify a previously unrecognised group of young AML patients with a poor prognosis for whom new treatment strategies are needed (Hollink et al, Blood 2011). **Aims.** The aim of this study was to determine the frequency of the *NUP98-NSD1* fusion in a series of 54 unselected *de novo* paediatric AMLs (median age 9yrs, range 0-18yrs) and to develop an RT-qPCR assay to track individual patient response to treatment. **Method.** Screening for the *NUP98-NSD1* fusions was performed using reverse-transcription PCR (RT-PCR) together with FISH confirmation of all positive cases. A reverse transcription-quantitative PCR (RT-qPCR) assay was designed to allow sensitive sequential analysis of post treatment material, where available. The sensitivity routinely achieved was sufficient to detect normalised *NUP98-NSD1* transcripts levels 4 logs below those seen at diagnosis. **Results.** Four positive cases (7%) were identified; three *de novo* AML and one t-AML following chemotherapy for osteosarcoma two years prior to presentation with AML. All were older children (median age 16yrs, range 13-18yrs) with very high white blood counts (WBC) at presentation, without favourable cytogenetic markers. All had a concurrent *FLT3*-itd and all lacked NPM1 and CEBPa mutations.All four patients received an allograft at 3,4,4 and 13 months post diagnosis respectively. One patient died of transplant related complications, but was shown to have low level MRD immediately prior to transplant by retrospective RT-qPCR analysis. Two patients remain alive and in molecular remission more than two years post-diagnosis, despite demonstrating a high tumour burden prior to transplant, suggesting a potential survival benefit from transplant. The fourth case failed to achieve molecular remission for the *NUP98-NSD1* gene fusion at any of the time points measured pre-or post-transplant and died 11 months post diagnosis of metastases from a pre-existing osteosarcoma. **Conclusions.** Our data suggests a non-random association of *NUP98-NSD1* with *FLT3*-itd in a group of older children with high WBC's with a poor prognosis who may benefit from transplant. The incidence of *NUP98-NSD1* rearrangement, potentially as high as 7% of *de novo* paediatric AML, is sufficient to recommend routine screening of *NUP98-NSD1* in combination with *FLT3*-itd for all new diagnostic cases, particularly in the absence of otherwise favourable cytogenetic markers, to accurately determine risk and allow for consideration of early transplant.

GENE MUTATIONS IN CHILDHOOD ACUTE MYELOID LEUKEMIA WITH SPECIAL REFERENCE ON THE MUTATIONS OF EPIGENETIC REGULATORS INCLUDING ASXL1, IDH1/2, AND DNMT3A

DC Liang[1], LY Shih[2], HC Liu[1], CP Yang[3], TH Jaing[3], IJ Hung[3], TC Yeh[1], SH Chen[3], JY Hou[1], YS Shih[4], TH Lin[4], YH Huang[4]
[1]Mackay Memorial Hospital, Taipei, Taiwan
[2]Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan
[3]Chang Gung Children's Hospital, Taoyuan, Taiwan
[4]Chang Gung University, Taoyuan, Taiwan

Background and Purpose. Four genes involving the epigenetic regulators, i.e. *ASXL1, DNMT3A, IDH1* and *IDH2*, have recently been described in adult acute myeloid leukemia (AML) and were associated with poor outcomes. In childhood AML, the reports on these gene mutations have been very rare, especially there has been no report on *ASXL1* gene mutations. In addition, comprehensive analyses of gene mutations in *de novo* childhood AML have been limited. We aimed to determine the genetic alterations in pediatric AML patients with special reference on the mutations of epigenetic regulators. **Materials and Methods.** We analyzed 18 gene mutations in 206 children with *de novo* AML

aged from 1 month to 18 years diagnosed between December 1995 and May 2011. The mutated genes examined included class I gene involving signaling and RAS pathways *(FLT3*-ITD, *FLT3*-TKD, *C-FMS*, *C-KIT, NRAS, KRAS, PTPN11, JAK2*V617F), class II affecting transcription and differentiation (*CEBPα*, *RUNX1*, *MLL*-PTD, and *NPM1*), class III of tumor suppressor genes (*WT-1* and *P53)*, and class IV of epigenetic regulators (*ASXL1*, *DNMT3A*, *IDH1* and *IDH2*). Mutational analysis was performed with PCR-based assays followed by direct sequencing. **Results.** One hundred and twenty of 206 patients (58%) were found to have at least one mutation; 51% had class I, 14% had class II, 6% had class III and 4% had class IV mutations. The most frequent gene mutations were *FLT*3 (21.6%; *FLT3*-ITD 14.9% and *FLT3*-TKD 7.4%), *RAS* (15.6%; *N-RAS* 8.3% and *K-RAS* 7.4%), and *C-KIT* 11.5%. Together, 15.5% had more than one mutation. Of the 7 patients with mutated genes of epigenetic regulators, *ASXL1* mutations were detected in 2 of 175 patients (E635fsX649 and P835fsX841), *DNMT3A* mutations in 2 of 168 (W795S and R882H), *IDH1* mutations in 2 of 177 (R132C and R132H), and *IDH2* mutation in 1 of 177 (R140Q). The 2 patients with *ASXL1* mutations were both of t(8;21), without cooperating mutation with other 17 genes analyzed. In the present series, 4 patients had *MLL*-PTD; two of them, both of FAB M0 subtype, harbored *IDH1* gene mutations compared with none of the 173 patients with non-*MLL*-PTD AML ($P < 0.0001$). One of the two *IDH1* mutated patients had *FLT3*-ITD, the other patient had trisomy 21and *RUNX1* mutation. The only one patient harboring *IDH2* mutation had normal karyotype and also had *FLT3*-ITD and *NPM1* mutations. Of the 2 patients with *DNMT3A* mutations, one cooperated with *PTPN11* and *CEBPα* mutations; the other patient had *MLL* translocation, *FLT3*-TKD and *WT1* mutations. All patients were treated with Taiwan Pediatric Oncology Group-AML 97 protocols. Since the numbers of patients with the 4 gene mutations were very small, it precluded the meaningful analysis of the prognostic impact. **Conclusions.** The present study on 18 gene mutations in a relatively large cohort of children with *de novo* AML in Taiwan showed 58% of patients had at least one gene mutation. The frequencies of mutations of epigenetic regulators were very rare, *ASXL1* mutations were associated with t(8;21) and *IDH1* mutations were significantly associated with *MLL*-PTD. FROM CYTOGENETICS TO MOLECULAR BIOLOGY: MAPPING OF UNIQUE CHROMOSOMAL ABNORMALITIES AT THE NUCLEOTIDE LEVEL

S Pekova[1], T Jancuskova[1], R Plachy[1], D Hardekopf[1], T Liehr[2], A Weise[2], N Kosyakova[2], J Stika[1], L Zejskova[1], L Sedlackova[1], L Krutilkova[1], R Cmejla[1]
[1]Chambon Laboratories, Prague, Czech Republic
[2]Universitätsklinikum Jena, Jena, Germany

Background. Acute myeloid leukemias (AML) in adulthood represent a heterogeneous entity, characterized by a recurrent chromosomal/genetic abnormality in only 50% of cases. In the remaining individuals, no common molecular abnormality can be identified using standard diagnostic screening (AcutePlexX[1], mutations in NPM1, WT1, CEBPa and others), though unique cytogenetic abnormalities can often be detected. As many AML patients are eligible for curative treatment, techniques allowing specific and sensitive minimal residual disease (MRD) monitoring are highly needed. **Aims.** To develop a technique that would allow mapping of cytogenetically identified unique clone-specific abnormalities from the chromosome level to the nucleotide level, enabling us to develop clone-specific quantitative Real-Time PCR assays for sensitive and specific MRD monitoring. **Methods.** Molecular-cytogenetic techniques (mFISH, mBAND, BAC-FISH), chromosome microdissection, next generation sequencing, long-range PCR and direct Sanger sequencing were used to map the chromosomal translocation in the der(10)t(3;10)(p21.3;q23) characteristic for the cell line K562. This model cell line was chosen to show the feasibility and reproducibility of the technique as a proof of principle, with prospective continuation to authentic patient samples. After cytogenetic identification of the chromosomal translocation (Figure 1A), the derivative chromosome was microdissected using a fine needle (Figure 1B). The microdissected fragments were directly subjected to whole genome amplification (WGA; Figure 1C) and then sequenced on the GS Junior platform for next generation sequencing (Figure 1D). Obtained reads were aligned to reference sequences of chromosomes 3 and 10, using in-house developed software (Figure 1E). The last mapped reads from both chromosomes were used as docking sites for primers for long-range PCR to amplify the putative breakpoint (Figure 1F). The long-range PCR products were directly sequenced using Sanger sequencing to reveal the precise nucleotide sequence of the breakpoint (Figure 1G). **Results.** Using a combination of cytogenetic and molecular approaches, we mapped the K562-unique translocation in der(10)t(3;10)(p21.3;q23) from the chromosomal level to the nucleotide level (Figure 1). Direct sequencing of this breakpoint revealed a head-to-head fusion of genes CDC25A and GRID1. The time demand of the whole procedure, starting from mFISH and ending with the actual sequence of the breakpoint was approximately 6 weeks. This is optimal timing for a standard clinical setting, when the laboratory receives the first follow-up samples one month after diagnosis. **Summary and Conclusions.** Current technologies of molecular cytogenetics and molecular biology open new vistas in the detection and identification of unique, clone-specific genetic abnormalities in patients with AML. As only half of the individuals with AML can be molecularly MRD followed-up using recurrent genetic abnormalities, there is still a sizeable proportion of patients who might benefit from the identification of the "finger prints"of their malignant cells for the design of clone-specific MRD Real-Time PCR assays. Our work clearly shows that "walking"from the chromosomal level to the nucleotide level is feasible and readily applicable for eligible AML patients. **Acknowledgements.** The work was supported by the Grant Agency of Ministry of Industry and Trade of the Czech Republic and in part by the Monika-Kutzner Foundation.

RUNX1 DISRUPTED BY A COMPLEX REARRANGEMENT OF CHROMOSOME 21 CAUSES FAMILIAL PREDISPOSITION TO HEMATOLOGICAL MALIGNANCIES

S Snijder[1], T Os[1], A Polstra[1], K Huijsdens-van Amsterdam[1], C Mellink[1], O Mook[1], W Kloosterman[2], C Huisman[1]
[1]Academic Medical Center, Amsterdam, Netherlands
[2]University Medical Center, Utrecht, Netherlands

Background. Clinicians are increasingly aware of familial predisposition to myelodysplastic syndromes (MDS) and acute myeloid leukemias (AML). In a substantial part of these families there is a mutation in the RUNX1 gene on chromosome 21q22. Chromosomal rearrangements, like deletions, involving the RUNX1 locus are less frequently described. *Aims and* **Methods.** In our hospital, a male patient (age 28) presented with mild thrombocytopenia and abnormal platelet aggregation. Family history revealed five relatives with leukemia (3 AML, 1 ALL and 1 of unknown origin). Our patient and his mother were not affected with leukemia. To elucidate the underlying genetic aberration in this family, blood and bone marrow samples of the index patient and his mother were examined by conventional karyotyping, fluorescence in situ hybridization (FISH), Agilent 180k microarray (AMADID 023363), Nimblegen capture array (custom made) and mutation analysis. **Results.** Although karyotyping and mutation analysis of both the index patient and his mother showed normal results, interphase FISH revealed 3 signals for the RUNX1 locus. Array CGH demonstrated 3 minor aberrations (2 gains and 1 loss) of distinct regions of chromosome 21q22, but could not explain the extra FISH signal. Therefore, it was speculated that an intra-chromosomal rearrangement with a breakpoint through RUNX1 had resulted in a split signal. This was confirmed by capture array data, which demonstrated a fusion of the 5' RUNX1 breakpoint to a chromosome 21 sequence 11 Mb upstream (same orientation). **Summary and Conclusions.** Based on the results so far, it was concluded that a complex rearrangement with several breakpoints on chromosome 21 resulted in the disruption of the RUNX1 gene. Currently, further investigations by using a novel next-generation sequencing technique are ongoing. We will perform genome-wide long mate-pair sequencing in order to delineate an exact map of the affect-

ed chromosome 21 in this family. By using this map, a diagnostic test for carriership analysis will be made available for screening family members at risk of developing MDS/AML themselves or as potential transplantation donors. Affected family members, especially the patient diagnosed with ALL, will also be examined. It is important to realize that adequate screening of families for predisposition to MDS/AML not only involves mutation analysis, but that other methods (e.g. aCGH, FISH) and genetic counseling should also be considered.

HIGH RESOLUTION MICROARRAY-BASED GENOMIC PROFILING FOR THE IDENTIFICATION OF SMALL GENETIC LESIONS AND SUBSEQUENT DESIGN OF MINIMAL RESIDUAL DISEASE TARGETS IN ACUTE LYMPHOBLASTIC LEUKEMIA

A Simons, M Stevens-Kroef, S van Reijmersdal, R Pfundt, E Waanders, R Kuiper, A Geurts van Kessel
Radboud University Medical Center Nijmegen, Nijmegen, Netherlands

Background. In acute lymphoblastic leukemia (ALL) specific genomic abnormalities provide important clinical information. We previously demonstrated that microarray-based genomic profiling allows the detection of focal genomic losses, frequently harboring clinically relevant ALL-related genes, such as *EBF1*, *CDKN2A/B*, *PAX5*, *ETV6*, *BTG1* and *IKZF1*. The latter gene was recently shown to be associated with a high relapse rate in patients with ALL (Kuiper et al., 2010, Leukemia). The ability to detect focal lesions, however, largely depends on the resolution of the platform used.The analysis of minimal residual disease (MRD) at early time points during therapy has been widely implemented as an accurate prognostic parameter to determine treatment strategy. MRD targets usually include immunoglobulin and/or T-cell receptor rearrangements detected in the major clone at diagnosis. Accurate array-based mapping of recurrent abnormalities on ALL may facilitate the development of ALL-specific MRD targets, as we recently described for *IKZF1* (Venn et al., 2012 Leukemia). **Aims.** We evaluated the performance of a novel high resolution genome-wide microarray platform (Cytoscan HD, Affymetrix) for the detection of ALL-specific genomic abnormalities. Due to the high coverage of probes on this platform, we also evaluated its suitability for accurate identification of breakpoints covering deletions of leukemia-specific genes, which could subsequently serve as markers in sensitive PCR-based MRD tests. **Methods.** The Cytocan HD platform (2.7 million probes) was used for genomic profiling of 8 patients with ALL. Genomic lesions affecting recurrent gene loci (see above) were evaluated and the positions of the breakpoints were accurately mapped. To confirm the focal genomic losses identified by the CytoScan HD, the samples were also evaluated with a commercially available multiplex ligation-dependent probe amplification (MLPA) test (MRC Holland) and breakpoint-spanning PCR. **Results.** In 8 ALL-patients tested we identified 21 deletions (sizes down to 10 kb) encompassing genes commonly affected in ALL, which were all validated by MLPA. Eleven of these deletions were smaller than 100 kb, which is below the detection level of most commonly used micro-array platforms. Next, we analyzed the resolution with which the breakpoints in the 21 deletions could be mapped by using the Cytoscan HD microarray data. In 8 of the 21 deletions covering leukemia genes both breakpoints were located in a region less than 1 kb. These data can be very helpful in designing leukemia-specific PCR primer sets in individual patients. By applying this approach we were able to identify such primer sets in 7 of the 8 patients and for which 5 deletion-specific PCR products were validated, so far. This demonstrates the additive value of the Cytoscan HD platform in designing PCR-based targets which can be used for MRD analysis. **Summary and Conclusions.** We conclude that the Cytoscan HD microarray platform has improved detection rate of small focal genomic losses, including *IKZF1*, as compared to other platforms. Additionally, we demonstrated the power of this platform for accurately identifying breakpoints of genomic losses for development of patient-specific targets for MRD analysis.

NUCLEOPORIN GENES INVOLVEMENT IN HAEMATOPOIETIC DISORDERS

V Nofrini[1], R La Starza[2], V Pierini[2], B Crescenzi[2], D Beacci[2], G Barba[2], C Harrison[3], C Mecucci[2]
[1]University of Perugia, Perugia, Italy
[2]Hematology and Bone Marrow Transplantation Unit, University of Perugia, Perugia, Italy
[3]Northern Institute for Cancer Research, Newcastle University, Newcastle, United Kingdom

Background. Nucleoporins (NUPs), a group of ~30 proteins, constitute the Nuclear Pore Complex, a large multi-protein channel which perforates the nuclear envelope and mediates macromolecular import and export between nucleus and cytoplasm. *NUP98*/11p15 and *NUP214*/9q34 are involved in the pathogenesis of haematopoietic disorders. In chromosomal translocations or inversions with different partner genes both produce abnormal fusion proteins with oncogenic properties. Although rearrangements are frequently cryptic, conventional cytogenetics may be predictive of *NUP98* involvement in around 20-30% of cases of Acute Myeloid Leukemias/Myelodysplastyc Syndromes with an 11p15 chromosome change. NUP98 maintains its 5'-end in all fusions while partners always contribute with the 3'-end. **Aims.** To investigate the involvement of 30 NUP genes in patients with diverse haematological disorders and abnormal karyotypes involving chromosomal regions/arms containing one or more NUP genes. **Methods.** The study included 194 cases (145 myeloid and 49 lymphoid neoplasms) collected from files of the Laboratory of Cytogenetics and Molecular Genetics of the University of Perugia (Prof. Cristina Mecucci). An additional series of 25 cases with myeloid neoplasms with 11p15 changes was provided by Prof. Christine Harrison (Leukemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University). Genomic clones were selected to test each NUP with a double colour break apart test. The following NUPs were investigated: *TMEM48*/1p32, 25 cases; *TPR*/1q31, 21 cases; *NUP133*/1q42, 20 cases; *NUP358*/2q13, 16 cases ; *NUP35*/2q32, 17 cases; *NUP210*/3p25, 14 cases; *SEC13*/3p25 14 cases*; NUP54/4q21,* 3 cases*; NUP155*/5p13 3 cases; *NUP153*/6p22, 13 cases; *NUP43*/6q24, 23 cases; *NUPL2*/7p22, 18 cases; *POM121*/7q11.2 18 cases; *NUP205*/7q33 22 cases; *GLE1*/9q34, 11 cases; *NUP188*/9q34, RP11-98H23 (5'), RP11-167N5 (3') 11 cases; *NUP214*/9q34, 11 cases; *NUP160*/11p11.5, RP11-346F1 (5'), RP11-112L21 (3') 10 cases; *NUP98*/11p15.5 35 cases; *AAAS*/12q13, 7 cases; *NUP107*/12q15 8 cases; *NUP37*/12q23 8 cases; *NUPL1*/13q12, 13 cases; *NUP93*/16q13, 4 cases; *NUP88*/17p13, 27 cases; *NUP85*/17q25, 9 cases; *SEH1L*/18p11.2 9 cases; *NUP62*/19q13.33, 1 case; *RAE1*/20q13 11 cases; *NUP50*/22q13, 10 cases. **Results.** *NUP98* was the only NUP gene shown to be directly involved in structural chromosomal rearrangements. Other NUPs underwent deletions or gains, most of them as expected were according to chromosome losses or gains as described in the karyotypes. Our *NUP98* break apart FISH test showed 5/35 (14%) positive cases among myeloid malignancies with a breakpoint at 11p (between p11 and pter). Additional FISH studies confirmed a *NUP98* fusion and characterized the partner gene as: *HOXA*/7p15 in 2 cases, *NSD1*/5q35.1 and *HOXC*/12q13, one case each. In the fifth case the *NUP98* 3' probe was deleted, suggesting rearrangement/fusion of the retained 5'-end. Unfortunately the study could not be finalized due to lack of biologic material. **Summary and Conclusions.** According to our results *NUP98* in karyotypes from myeloid malignancies with visible 11p15 abnormalities was the only NUP gene found to be directly involved in chromosomal rearrangements. Therefore, due to multiple known fusion partners of *NUP98*, FISH screening is recommended for precise diagnosis of these patients and for fusion partners characterization.

DETECTION OF LYMPHOBLASTIC TRANSFORMATION IN CHRONIC MYELOID LEUKEMIA AND REVEALING THE CLONAL ORIGIN OF RELAPSE IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA USING MLPA

D Alpar[1], D de Jonge[2], S Savola[3], H Yigittop[3], B Kajtar[4], L Kereskai[4], L Pajor[4], K Szuhai[2]
[1]University of Pecs, Pecs, Hungary
[2]Department of Molecular Cell Biology, Leiden University Medical Center, Leiden, Netherlands
[3]MRC-Holland, Amsterdam, Netherlands
[4]Department of Pathology, Faculty of Medicine, University of Pecs, Pecs, Hungary

Background. Multiplex ligation-dependent probe amplification (MLPA) is a robust technique to simultaneously detect copy number abnormalities (CNAs) at several loci. CNA profile provides valuable information for risk assessment of various hematological malignancies. **Aims.** We used MLPA to stratify samples from CML patients in chronic phase (CP) or in lymphoblastic transformation (lyBC) and to discriminate CML-CP cases responding or resistant to imatinib therapy. Furthermore, a large number of prognostically relevant CNAs were screened in pediatric acute lymphoblastic leukemia (pALL) using matched samples of diagnosis and relapse. **Methods.** We investigated bone marrow samples from 30 patients with CML-CP without evidence of blastic crisis (15 responder and 15 resistant to imatinib therapy), from 9 patients with CML undergone lymphoblastic transformation and from 49 patients diagnosed with pALL. Ethical Committee approval and written informed consent have been obtained for the study. Two different MLPA kits were applied allowing to detect gene locus centered CNAs at 58 different loci. Tumor cell ratio measured by flow cytometry and cytogenetic data were also considered at the calculation and

interpretation of copy number gains and losses. **Results.** CNAs were detected in a low proportion (2/30) of patients with CML-CP thus subclassification of cases being resistant or responding to imatinib therapy proved to be impossible. Investigating patients with CML having lyBC at diagnosis or at any follow-up time points, we did not find CNAs in their samples acquired during CP; however, in all but one samples withdrawn during lyBC, we observed several CNAs; an average of 22 probes per sample showed abnormal patterns. *IKZF1* was the most frequently affected gene followed by *PAX5*, *CDKN2*, *MIR31*, *MIR24-2*, *ETV6* and *EBF1*. CNAs were detected in 73% of patients with pALL; *CDKN* was the most frequently affected gene followed by *ETV6*, *PAX5*, *MIR31*, *IKZF1*, *RB1*, *BTG1*, *EBF1*, *IKZF3* and *MIR23A*. Comparing the CNA profile of diagnostic and relapsed samples of patients with pALL, in one-third of cases we found patterns referring to clonal evolution process (i.e. cells harbouring both original and newly acquired abnormalities recurred). In two-thirds of cases, cell populations dominating at different time points were not clonally related but independently arisen suggesting the presence of a preleukemic cell pool. **Conclusions.** MLPA has been used for investigating patients with CML for the first time and it proved to be an efficient tool for detecting transition not only from chronic phase to lymphoblastic crisis but vice versa as well. Evaluating samples from children with ALL, combined application of various MLPA probe mixes allowed us to detect a panel of CNAs broader than ever before. Identification of the origin of the malignant clone at relapse will have great impact on future treatment strategies in pALL. In this study, if the original leukemic clone recurred at relapse the patient died within a short period of time while the occurrence of a clonally independent cell population (i.e. a 'new disease') was associated with optimal response to the administered ALL-REZ BFM 2002 protocol.

A CONTRIBUTION TO THE CYTOGENETIC INVESTIGATION OF MONOCLONAL B-CELL LYMPHOCYTOSIS

I Kostopoulos[1], G Paterakis[2], G Androutsos[3], D Pavlidis[3], S Papadhimitriou[3], O Tsitsilonis[4]
[1]G.Gennimatas Athens Regional General Hospital, Athens, Greece
[2]G.Gennimatas Athens Regional General Hospital (Flow Cytometry Laboratory), Athens, Greece
[3]G.Gennimatas Athens Regional General Hospital (Haematology Laboratory), Athens, Greece
[4]Department of Animal and Human Physiology, Faculty of Biology, University of Ath, Athens, Greece

Background. Monoclonal B-cell lymphocytosis (MBL) has recently attracted a significant research interest as the prelude of chronic lymphoproliferations. However, despite the advances and wide application of flow cytometry which allow for the identification of the disorder in an increasing number of patients, the cytogenetic investigation of MBL remains a technical challenge and the relevant data is scarce. **Aims.** In this study, we have applied interphase FISH (i-FISH) for the investigation of chromosomal aberration frequently found in chronic lymphoproliferations in patients with documented MBL. **Methods.** 39 men and 21 women with MBL, according to the currenty established diagnostic criteria, were included in this study. Flow cytometry and i-FISH were performed on a peripheral blood sample. In cases with a B-cell count <15% of WBC, the i-FISH study was performed on purified B-cells after immunomagnetic separation targeting CD19. The presence of 13q-,+12, -11/11q-, 17/17p-,-6/6q- , t(11;14) and rearrangement of the BCL2 and IGH genes, was investigated in all cases, regardless of the morphological features or the phenotype. **Results.** High-sensitivity flow cytometry showed a chronic lymphocytic leukemia (CLL)-like (CD5+CD23+), a mantle cell lymphoma (MCL)-like (CD5+CD23-) and an "atypical"phenotype in 44, 5, and 11 cases, respectively. i-FISH was positive for t(11;14) in 3 cases (all with a MCL phenotype), +12 in 3 cases (all with CLL phenotype) and 13q-, involving 13q14, in 23 cases (19 with CLL and 3 with "atypical"phenotype. In one case, +12 was concurrent with hemizygous 13q-. Of the rest 22 cases with 13q-, the deletion was hemizygous in 16 (15 of which with CD5+CD23+, 1 with CD5-CD23- B-cell population), homozygous in 4 (all CD5+CD23+) and hemizygous coexisting with homozygous in 2 cases (CD5+CD23+). During the follow-up period (at least 24 months), evolution into "clinical"CLL (RAI stage 0) was observed in only one case (CD5+CD23+, with 13q deletion and no other aberrations upon diagnosis of the CLL). **Conclusions.** i. The most frequent finding in this series of MBL cases was 13q14 deletion. It was observed mainly - but not exclusively - in CD5+CD23+ phenotype, at a rate comparable to that in clinical CLL. On the other hand, the absence of aberrations denoting an adverse prognosis in overt lymphoproliferations - such as deletion of the ATM or p53 genes - implies that CD5+CD23+ MBL correspond to the low risk CLL. ii. Evidence for clonal evolution (namely homozygous and concurrent hemizygous/homozygous 13q14 deletion or the coexistence of 13q14 deletion with +12) indicates genetic instability in MBL already at the preclinical stage, but the biological and clinical significance of this phenomenon requires further investigation. iii. The presence of t(11;14) among cases with consistent phenotype is perhaps equivalent to the diagnosis of the recently described "indolent"MCL. The follow-up of these cases at the clinical and genetic level may provide important clues on the mechanisms of oncogenesis in human lymphomas.

[4]Dept. of Internal and Experimental Medicine, Second University of Naples, Naples, Italy
[5]Haematology Department, Azienda Ospedaliero Universitaria Careggi, Florence, Italy
[6]IRCCS A.O.U. San Martino-IST, Genoa, Italy

Background. Familial Hemophagocytic lymphohistiocytosis (FHL) is a rare immune deficiency with defective cytotoxic function. The age at onset is usually young and the natural course is rapidly fatal if untreated. A later onset of the disease has been sporadically reported even in adolescents and adults. **Aims.** To report all patients diagnosed with FHL at an age of 18 year or older and enrolled in the Italian Registry of HLH. **Methods.** A retrospective data collection was performed. FHL was defined according to the diagnostic criteria established by the Histiocyte Society. Patient information were collected on specific forms. Biological samples were collected for immunological studies (flowcytometry analysis of perforin expression and degranulation assay, cellular cytotoxicity) and direct sequencing of currently known FHL-related genes. Data were pooled in a common database and analysed. **Results.** A total of nine patients were diagnosed with FHL based on the finding of biallelic mutations in one FHL-related gene. They included 6 males and 3 females, from eight unrelated families; their age ranged between 18 years and 43 years (median, 25.1 years). Seven families were of Italian origin and one was from Colombia. Family history was unremarkable in six families at the time of the diagnosis. Their genetic diagnoses were: FHL2 (n=6), FHL3 (n=1), FHL5 (n=1), XLP1 (n=1). Isolated asymptomatic hypertransaminasemia followed by neurologic symptoms, lymphoproliferative-like manifestations, fulminant mononucleosis, mono-like episodes were the first manifestations of the disease in four patients; a clinical onset with full-blown rapidly progressive FHL was detected in only three patients. Outcome, molecular and functional data are reported in the Table 1.

Table 1.

UPN	Gender/ Age (years)	Diagnosis	Gene/ Protein	Genotype	Fever	Splenome galy	Platelet (count/mm³)	Fibrinogen (mg/dl)	Ferritin (ng/ml)	Hemophagocytosis	Functional study	Course and outcome

Conclusions. the concept that later onset of FHL is possible has been repeatedly brought to the attention of adult haematologists.Nevertheless adult patients are at most considered as potentially affected by the so-called "secondary"form of HLH rather than by genetic FHL with several implications.These data confirm that FHL may present beyond the paediatric age. The clinical criteria may be not completely fulfilled and unusual or not specific manifestations are common. Based on our experience we suggest adult specialists to consider FHL in the differential diagnosis of patients with cytopenia and liver or central nervous system disorders, especially when a clonal lymphoproliferative disease is sus-

pected but not confirmed. Anyway all patients with fever, splenomegaly, thrombocytopenia and high levels of ferritin, in whom bone marrow aspirate does not document leukemia, should be rapidly screened on peripheral blood lymphocytes by flow-cytometry for the expression of perforin and the ability to degranulate. The combination of these two assays, widely accessible to many haematology or immunology laboratories, can predict the presence of mutations in the *PRF1* or in the UNC13D, STX11, STXBP2 genes providing a robust support to the diagnosis and justification for high-risk chemo-immunotherapy including indication to allogeneic SCT. The question about indication to SCT for patients with milder clinical picture or even in a pre-symptomatic phase remains open.

0691

HIGHLY SENSITIVE MONITORING OF MINIMAL RESIDUAL DISEASE IN FLT3-ITD-POSITIVE ACUTE MYELOID LEUKEMIA PATIENTS WITH A MUTATION SPECIFIC QUANTITATIVE PCR METHOD

J Schiller, I Praulich, M Hallek, KA Kreuzer
University at Cologne, Cologne, Germany

Background. Minimal residual disease (MRD) monitoring in patients with acute myeloid leukemia (AML) can predict relapse clearly in advance and therefore allows early therapeutic intervention. Moreover, recent studies have highlighted the significance of personalized treatment on the basis of MRD status for improving outcome in AML. The *FLT3* internal tandem duplication (*FLT3*-ITD) occurs in 13-35% of all AML. Clinically, *FLT3*-ITDs have been strongly associated with poor outcome. However, due to the high sequence variability of individual *FLT3*-ITD commonly a universal PCR approach is applied which has a low sensitivity (approx. 1: $5x10^2$). **Aims** The aim of this study was to investigate individual *FLT3*-ITD in detail with respect to prognosis. As well as, to develop a novel cDNA-based, highly sensitive quantitative real-time reverse transcription polymerase chain reaction (qRT-PCR) assays for the detection of the *FLT3*-ITD mutation level. **Methods.** We investigated *FLT3*-ITD length and position in 39 AML cases. On the basis of individual *FLT3*-ITD, mutation-specific forward or reverse primers were designed. The expression of *FLT3*-ITD was determined using complementary DNA samples at different points in time diagnosis and subsequent treatment. **Results.** From a total of 409 newly diagnosed AML patients 54 (13%) were *FLT3*-ITD positive. Retrospectively we analyzed ITD mutation of *FLT3* in 39 available cases. Eleven patients had extra insertions of 2-38 base pairs between two repeats. The length of ITD ranged from 3 to 144 base pairs (median 45). Within our cohort patients with *FLT3*-ITD ≥45 base pairs had significantly higher relapse rates (*P*=0.03) and a worse overall survival (*P*=0.03). For the *FLT3*-ITD quantification we developed patient-specific qRT-PCR for 31 individuals with mutation-specific forward or reverse primers. Our method could be applied to 97% of *FLT3*-ITD positive patients and yielded similar results when compared to other high sensitive assays for molecular markers like *MLL*-PTD, *NPM1* mutations or *PML-RARA* (correlation: r=0.99; 0.99 and 0.63, respectively). In one cases a co-amplification of the wild-type could not be avoided resulting in lower sensitivity ($1:10^3$). MRD negativity predicted lasting remission independent of allo-SCT (*N*=7) or non-allo-SCT (*N*=9). All paired diagnostic/relapsed samples showed *FLT3*-ITD positivity. Compared with bone marrow samples *FLT3*-ITD analyses appeared to be equivalently sensitive in peripheral blood. **Conclusions.** We conclude that highly sensitive detection of individual *FLT3*-ITD posses equal prognostic power in AML like established molecular MRD markers. Using this approach MRD guided treatment decisions appear to be justified and should be incorporated in future studies.

0692

CLONAL EVOLUTION OF PROGNOSTICALLY ADVERSE MOLECULAR AND CYTOGENETIC FEATURES DURING THE DISEASE COURSE IN CHRONIC LYMPHOCYTIC LEUKEMIA

I Praulich, C Krings Rocha, J Schiller, M Hallek, KA Kreuzer
University at Cologne, Cologne, Germany

Background. It has been shown that chronic lymphocytic leukemia (CLL) patients displaying a mutation within the tumor suppressor gene *TP53* or a chromosomal deletion 17p (del(17p)) have an adverse prognosis when compared to CLL patients who do not exhibit these anomalies. Furthermore, there is growing evidence that complex chromosomal aberrations, and especially transclocations detected in the neoplastic clone are associated with a similar inferior outcome even if the patients otherwise exhibit prognostically favourable factors. **Aims.** The aim of this study was to investigate clonal evolution in CLL patients with prognostically adverse molecular and cytogenetic features during the course of the disease. **Methods.** Cytogenetic analysis and molecular genetic analysis of *TP53* and immunoglobulin heavy chain variable (IgHV) mutational status were applied to a cohort of 100 CLL patients. **Results.** In our cohort, we identified a total of 23 patients (23%) with progressive disease. Of these, 8 patients showing either a *TP53* mutation and a del(17p) (35%) or a sole *TP53* mutation (n=7, 30%) or a sole del(17p) (n=1, 4%) or complex chromosomal abnormalities (≥ three structural or numerical anomalies) without del(17p) (n=7, 30%). Eighteen patients of the population with progressive CLL (78%) exhibited an unmutated IgHV. In 6 cases, the observed lesion could not be detected in a previous investigation. Out of these cases in 3 patients adel(17p) evolved together with a *TP53* mutation, in one case a *TP53* mutation evolved without a del(17p) and in two cases complex chromosomal aberrations developed. The mean duration for the development of adverse parameters was 21 months. In most cases (n=4) those occurred after treatments with either fludarabine and/or cyclophosphamide and/or rituximab or bendamustine and/or rituximab. However, in two patients clonal evolution was detectable without any causative therapy for CLL. **Summary and Conclusions.** We conclude that clonal evolution of prognostically adverse molecular or cytogenetic lesions can occur in patients with initially favourable risk profile. It appears that this helds true not only for established parameters such as del(17p) and *TP53* mutations but also for newer prognostic factors such as a complex karyotype. Biologically, an overall genetic instability may account for this phenomenon as well as a mitogenic or mutagenic effect caused by cytostatic drugs. It can therefore be discussed, whether assessment of adverse risk factors including conventional karyotyping should be generally performed at an earlier point of the disease course and might be repeated if clinical signs of progression are evident.

REAL-TIME MONITORING OF THE JAK2V617F MUTATION BY ULTRA-RAPID, HIGH SENSITIVE FLUORESCENT AS-LAMP

G Minnucci[1], G Amicarelli[1], E D'Agostini[1], R Mesturini[1], S Salmoiraghi[2], O Spinelli[2], F Bonelli[1], F Colotta[1], A Rambaldi[3]
[1]DiaSorin SpA, Gerenzano (VA), Italy
[2]Ospedali Riuniti di Bergamo, Bergamo, Italy
[3]USC Ematologia, Ospedali Riuniti, Bergamo, Italy

Background. The molecular detection of the JAK2V617F mutation is part of the diagnostic work-up of Chronic Myeloproliferative Neoplasms (MPNs), as recommended by the 2008 WHO classification criteria. We recently described an innovative, non PCR method based on an Allele Specific-Loop mediated isothermal AMPlification (AS-LAMP) that specifically amplifies JAK2V617F mutated DNA with a high sensitivity under isothermal conditions (Minnucci G et al Haematologica 2012, *Epub ahead of print*). **Aims.** To improve the reliability of the JAK2V617F detection by implementing an internal control reaction to the AS-LAMP and to allow Real-Time monitoring.

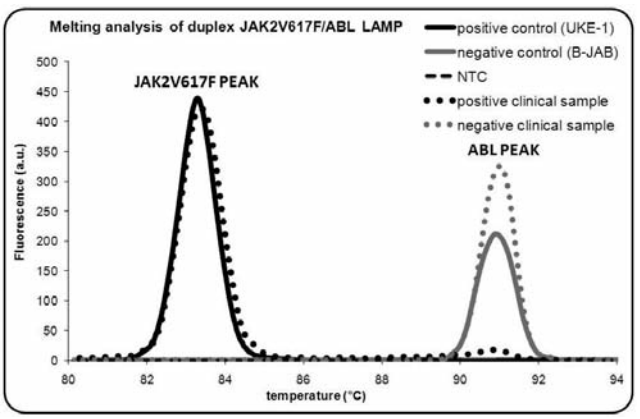

Figure 1. Melting analysis of duplex JAK2V617F/ABL LAMP.

Methods. The isothermal AS-LAMP reaction has been further optimized by the addition of an intercalating dye (Yo-Pro-1, Invitrogen) for fluorescent Real-Time monitoring. Moreover, an internal control reaction has been implemented for simultaneous amplification of the endogenous Abelson gene (ABL) DNA in the same tube. Target and internal control amplified products are characterized by different melting temperatures and can be therefore distinguished by a melting analysis. **Results.** The duplex JAK2V617F/ABL AS-LAMP assay detects in only 30 minutes the JAK2V617F mutation down to 0.05% (mutant DNA from UKE-1 into wild type DNA from B-JAB, 25 ng total). The analytical specificity is 100%, since 315 DNA replicates from wild type cell lines resulted JAK2V617F

negative. This novel JAK2V617F/ABL AS-LAMP assay was validated on DNA extracted from granulocytes of patients affected by PV (n=6), ET (n=7), other hematological malignancies (n=7) and demonstrated 100% concordance with conventional Allele Specific PCR (ASO-PCR). Furthermore, the high sensitivity level of the assay allowed to correctly detect the JAK2V617F mutation on 17 DNA samples extracted directly from peripheral blood, avoiding the step of granulocytes isolation. Interestingly, a direct relationship between the amount of mutant target tested and the height of peaks obtained after melting analysis has been consistently observed. Moreover, all the negative controls, (ET=5), (MF-Pos-ET=3), (healthy donors=10), proved negative for JAK2V617F mutation but showed a correct amplification of the ABL gene. This feature allows to ensure that the absence of JAK2V617F amplification does not depend on a low quality DNA or the presence of wrong reaction conditions or inhibitors.*Conclusions* This Real-Time AS-LAMP assay is a new robust and rapid test to detect the JAK2V617F mutation that can lead to a further development of a fully quantitative assay.

DOUBLE HIT B-CELL LYMPHOMAS

T Obukhova[1], E Baryakh[1], Y Lorie[1], G Alimova[1], I Kleina[1], S Chernysh[2], G Petrova[3], T Kolosheinova[1], A Magomedova[1], E Parovichnikova[1], A Kovrigina[1], E Domracheva[1]
[1]National Center for Hematology, Moscow, Russian Federation
[2]Botkin Hospital, Moscow, Russian Federation
[3]Russian Cancer Research Center, Moscow, Russian Federation

Background. Double-hit lymphomas are defined by a chromosomal breakpoint affecting C-MYC/8q24 locus (cytogenetic marker of Burkitt lymphoma) in combination with another recurrent breakpoint such as BCL2/18q21, BCL6/3q27 and CCND1/11q13. These tumors are known to behave aggressively with poor prognosis.AIM. In order to evaluate the cytogenetic, morphologic and immunologic peculiarities of these cases, clinical course of the disease and response to treatment we analyzed retrospective data in our cytogenetic database. **Patients and Methods.** For 12-years period in the National Center for Hematology double hits were revealed in 13 cases of B-cell lymphomas, 8 woman and 5 men, mean age 59 years (37-79). In 10 patient conventional cytogenetic analysis and FISH were performed, in 3 cases only paraffin-embedded tissues were available for FISH-assay. FISH studies were performed using a commercially available probes: LSI C-MYC/IGH, cep 8 DF TP, LSI C-MYC BAP, LSI BCL-2/IGH DF TP, LSI BCL-2 BAP, LSI BCL-6 BAP, LSI CCND1/IGH DF TP and LSI CCND1 BAP (Abbott), XL IGL BAProbe and XL IGK BAP (MetaSystems).

Table 1. Characteristics of 13 patients with Double-hit lymphomas.

Pt	Sex/ Age	Diagnosis	Karyotype	FISH	Time of C-MYC+ revelation	Survival, month

13	58/M	MM/ Extramedullar plasmacytoma	48,XY,+der(1)del(1)(p32),t(8;11)(q24;q13),t(15;21)(q21;q21),+mar [20]	t(11;14)+, C-MYC+, t(8;14)+	Progression	7, DOD

Results. 7 primary cases were diagnosed as DLBCL in 6 pts, FL in 1 and ALL in 1. Secondary C-MYC rearrangements were observed in 2 relapsed patients, 1 with FL and 1 MCL, after 9 years and 8 months of response, respectively. Two patients with MGUS and MM progressed to C-MYC+ plasmablastic lymphoma after 2 and 5 years after initial diagnosis. In one patient with DLBCL C-MYC rearrangement was not revealed by FISH at the diagnosis and was detected after 8 months in the disease progression. In 7 cases C-MYC translocations were found in coexistence with BCL-2 rearrangements (ALL - 2, FL - 1, DLBCL - 4), in 3 DLBCL patients - with BCL-6, in 3 patients (MCL -1, MM -2) with CCND1 translocations. The most common types of C-MYC alterations were translocations with non-Ig-partners (7 patients), translocations with IGH in 3 cases including one complex translocation t(8;11;14)(q24;q13;q32) and translocations with IGL in 3 patients. Double hits involving two IGH loci were observed in one untreated DLBCL patient within tetraploid clone. High proliferation rate (Ki-67~100%) was observed in all cases except the patient with MCL (~40%). Morphological and immunological features of 9 cases were those of Burkitt lymphoma. All relapsed and progressive patients have died of disease with a median survival after C-MYC revelation of 4,5 months. Among primary patients 5 died of disease in 1,4, 7, 8 and 12 months after diagnosis, one died in induction and two are alive on treatment (1 pt) or disease free (1 pt) with median OS of 7 months. **Conclusions.** Double-hit lymphomas are highly aggressive tumors with poor prognosis affecting, in our selection, predominantly woman and could be diagnosed in both primary and relapsed/progressive patients with acute lymphoblastic leukemia, follicular, mantle cell, diffuse large B-cell lymphomas and multiply myeloma. Diagnosis of these tumors is only possible on the basis of cytogenetic analysis. C-MYC translocations with IGH or IGL that are typical for Burkitt lymphoma are rare, and rearrangements with non-Ig chromosomal partners are predominated.

0695

ATYPICAL BCR-ABL1 REARRANGEMENTS DETECTED BY DNA SEQUENCING

L Chauffaille, K Miyashiro, R Sacramento, W Keller, D Cantagalli, G Santos, H Silva
Fleury, São Paulo, Brazil

Background. BCR-ABL1 quimeric gene is detected in 90-95% of chronic myeloid leukemia cases (CML), in 20% of adult acute lymphoblastic leukemia (ALL), 5% of child ALL and 2% of acute myeloid leukemia (AML). During treatment, the quantification of BCR-ABL1 transcripts is important for disease monitoring. However, some cases show atypical rearrangements that are not detected by the primers usually used for the most frequent subtypes as: e13a2 (b2a2)/e14a2 (b3a2) that code 210kDa protein and e1a2, for the 190 kDa protein. **Aims.** The objective of this study is to relate the result of DNA sequencing to detect the variant cases. **Methods.** Cases in which Ph chromosome was detected by karyotype but no BCR-ABL1 rearrangement was found by real time PCR (RqPCR) were selected for the present study. Direct DNA sequencing was performed with primers for exons 1 (5'- CGG TTG TCG TGT CCG AGG -3') and 13 (5'- TTC AGA AGC TTC TCC CTG ACA T -3') in BCR gene and in exons 10 and 11 (5'- TCA TGG TCC AGA GGA TCG CTC -3') in ABL1 gene. After the RNA extraction from peripheral blood or marrow samples, reverse transcription and amplification by nested PCR of BCR-ABL1 transcript was performed, followed by direct sequencing using ABI PRISM 3130 (*Applied Biosystems*). **Results.** Five rare rearrangements were detected: e1a3 (58yr, male, AML), e13a3 (b2a3) (52yr, female, CML), e19a2 (46yr, female, ALL); while in a patient with CML (female, 29yr) another rare subtype, e13a4 (b2a4), was detected simultaneously to a frequent one, e13a2; and a deletion of exon 7of ABL (41yr, male, CML). **Summary and Conclusions.** BCR-ABL1 rearrangements in which BCR gene is juxtaposed to ABL1 exon 3 and not to exon 2 are rare. Apparently, only five cases of CML with subtype e1a3 and ten with e13a3 have been described so far. We add more five cases to these described. In summary, the association of different methods (RqPCR, karyotype and sequencing) was of fundamental importance to detect the rearrangement and plan the disease monitoring.

0696

IDENTIFICATION OF CHROMOSOMAL ABNORMALITIES BY MICROARRAY-BASED GENOMIC PROFILING AS COMPARED TO KARYOTYPING IN PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS)

M Stevens-Kroef[1], A Simons[2], N Elldrissi-Zaynoun[2], M Linssen-Wiersma[2], A Siepman[2], P Muus[2], M MacKenzie[2], J Jansen[2], R Kuiper[2], A Geurts van Kessel[2]
[1]Radboud University Medical Centre, Nijmegen, Netherlands
[2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background. Cytogenetic anomalies are routinely used as diagnostic, prognostic and therapeutic markers in the clinical management of myelodysplastic syndrome (MDS) (Greenberg *et al*. Blood 89:2079,1997). Although karyotyping is generally considered as the gold standard in the genetic diagnosis of MDS, 40-60% of the patients exhibit a normal karyotype. Intrinsically, the resolution of karyotyping is limited by its capacity to detect only those copy number changes that are microscopically visible (5-10 Mb in size). In contrast, microarray-based genomic profiling analyses allow a genome-wide detection of copy number alterations (CNAs), down to 100 kb in size, and regions of acquired uniparental disomy (UPD). Such analyses also overcome some of the other major limitations of karyotyping such as low success rate due to inadequate metaphase yield and/or poor banding quality. **Aims.** We have compared karyotyping and SNP-based microarray analyses with respect to the detection yield for genetic abnormalities in bone marrow samples of 87 MDS patients. **Methods.** For

microarray-based genomic profiling we used the 250k SNP array platform of Affymetrix. In order to rule out false positive results we used the following interpretation criteria: (i) the threshold for copy number aberrations was set at >5 Mb, (ii) smaller gains or losses were interpreted as aberrant in case they coincided with known (recurrent) aberrations as reported in the literature or in "Atlas of Genetics and Cytogenetics in Oncology and Haematology"(http://atlasgeneticsoncology.org/) and (iii) the threshold for aUPD was set at >10 Mb and to telomeric. Karyotyping and interphase FISH were performed using standard cytogenetic methods. **Results.** 47 of the 87 MDS patients had a normal karyotype. Of interest, in 7 of these 47 (15%) patients with a normal karyotype, acquired UPD and/or focal abnormalities (< 5 Mb) encompassing genes known to be involved in MDS tumorgenesis were observed. Through microarray-based genomic profiling, almost all numerical abnormalities as observed by karyotyping were detected. In addition, acquired UPD and focal (<5 Mb) CNAs were observed in the karyotypically abnormal group. Microarray-based genomic profiling also allows the identification of unbalanced translocations and a recently described phenomenon of genomic instability, fulfilling the definition of chromothripsis. As expected, balanced chromosomal abnormalities such as t(3;3)(q21;q26) and t(6;9)(p24;q34), which are present in a minority of MDS patients, were not identified. **Summary and Conclusions.** We demonstrate that microarray-based genomic profiling allows the identification of almost all copy number abnormalities also observed by karyotyping. In addition, we show that microarray-based genomic profiling allows the detection of novel focal CNAs and acquired UPDs in patients with both normal and abnormal karyotypes. The prognostic value of novel CNAs and acquired UPDs has to be evaluated in prospective clinical trials.

[3]Greencross Reference Laboratory, Yongin-city, South-Korea
[4]Kyungpook National University, Daegu, South-Korea
[5]Hanyang University Kuri Hospital, Kuri, South-Korea
[6]University of Munich Hospital, Munich, Germany
[7]Service de Biologie/Hématologie, CHU, Nantes, France
[8]Goethe-University of Frankfurt, Frankfurt/Main, Germany

Background. Recently, rapid developments in new technology such as the whole genome/exome sequencing have revealed that some novel gene mutations such as *DNMT3A*, *IDH1*, *IDH2* and *TET2* contribute to the main process of leukemogenesis. Among these, *TET2*, one of the *TET* family gene located on 4q24, is becoming more important through its highly frequent mutation in various myeloid neoplasms such as myeloproliferative neoplasm (MPN), myelodysplastic syndromes (MDS), MDS/MPN and acute myeloid leukemia (AML). On the other hand, the *TET1* gene, located on 10q22, has been rarely reported as a partner gene for *MLL* rearrangement in AML and acute lymphoblastic leukemia (ALL) patients since its first report in 2002. **Aims.** There has been a total of nine documented instances of t(10;11)(q22;q23), where all except in two cases were detected in AML patients. Nonetheless, so far there has been little research with respect to the common features of the *MLL-TET1* rearrangement itself. Therefore the authors sought to provide a molecular, laboratory, and clinical characterization of the *MLL-TET1* rearrangement through literature review and three new AML patients. **Methods and Results.** Including three new cases, this study analyzes a total of 12 acute leukemia cases of t(10;11)(q22;q23) that are known so far, detected in 10 AML and 2 ALL patients. Six out of 10 AML patients (60%) have shown association with FAB-M4/M5 subtypes. There were seven male and five female patients and the median age was 38.0 (age range: 1 month ~ 67 years). Among nine patients with available chromosome study results, three patients have shown sole chromosomal abnormality of t(10;11), and the remaining six patients had accompanied various additional chromosomal abnormalities. *MLL-TET1* rearrangement was confirmed in eight out of 12 cases through molecular methods including Southern blot (1 case), long distance inverse-polymerase chain reaction (LDI-PCR) (6 cases), and reverse transcriptase-PCR (6 cases). The various genomic breakpoints of *TET1* gene in *MLL-TET1* rearrangement would be also described. **Conclusions.** As there were only six out of 12 patients with available clinical outcomes, this study may certainly lack sufficient amount of data. Nevertheless, the results show that four of them reached complete remission (CR). Meanwhile, three patients including one who did not reach CR died at an average of 18 months after initial diagnosis, showing little difference with the generally known poor prognosis of *MLL* rearrangements. Further clinical and molecular researches on acute leukemias with *MLL-TET1* rearrangement would be necessary. In the near future, the authors plan to conduct a functional study of the *MLL-TET1* fusion gene to know the role of the rare *MLL*-related fusion genes in leukemogenesis.

THE WHOLE BLOOD MULTIPLEX DETECTION OF THE HERITABLE THROMBOPHILIA MUTATIONS F5-LEIDEN (F5G1691A) AND PROTHROMBIN (F2G20210A) USING A SIMULTANEOUS APPLICATION OF FLUOROMETRIC PRIMERS AND REAL-TIME PCR

C Blessing, P Bignell, P Wright
John Radcliffe, Oxford, United Kingdom

A full thrombophilia screen includes direct testing of *F*5G1691A and *F*2G20210A mutations, which increase a patient's risk to developing deep-vein thrombosis. The Molecular Hematology Laboratory, at the John Radcliffe Hospital, analyzes 2,000 thrombophilia samples per-year. These mutations are routinely detected via a multi-stage process of: DNA extraction, PCR amplification, over-night restriction and interpretation by gel-electrophoresis. This method is robust, reliable and cost-effective for weekly, batched assays. However, the nature of batched assays causes a two-day method to generate turnaround times of up to two weeks. DNA extraction and long-term storage is costly.The 3M™ Integrated Cycler was evaluated to determine if this new technology could provide service improvement. The simultaneous application of real-time PCR and fluorescently labelled primers, produces a method which offers the possibility of detecting these mutations from whole-blood, within two hours. This rapid processing time is due, in-part, to the removal of a lengthy DNA extraction process.The 3M™ Integrated Cycler utilizes the Focus Simplexa™ direct chemistry to monitor PCR amplified fluorescence levels of four independent primer pairs. These primers are specific to *F*5 and *F*2 wild-type and mutant genotypes. The intensity of the fluorescence is quantified by four dedicated lazer-channels, over the course of 45 PCR cycles and is then compared to established thresholds; C_T values are based on a panel of control samples.This Simplexa™ kit contains four sets of primer pairs and a master-mix, which must be combined specifically for each run. This system also requires a one-part patient sample and three-parts PBS buffer dilution to be made before use. The primer-mix and samples are pipetted into the universal-disk, as indicated by the program software. Once the disk is loaded, it is sealed and placed onto the 3M™ Cycler for analysis using pre-programmed cycling conditions.Thirty-three samples of known genotypes were used to establish the initial whole blood C_T values. To audit the strength of these reference thresholds against the gel-electrophoresis method, a whole-blood, blind panel of 46 patient samples, 6 known positive controls and 2 negative controls were used; totalling 78 individual results for each SNP, over four separate runs.Two separate samples were run five times in the same assay and a further six samples were run four times in different assays, to determine the intra and inter-assay variation of C_T. The C_T values showed maximum results of 4.0% and 4.4% respectively; both in the *F*2 wild-type detection channel. There is a positive correlation of 97% between the 3M™ Cycler and the gel-electrophoresis method.Once the threshold limits were established, the 3M® Cycler was capable of identifying the *F*5G1691A and *F*2G20210A in wild-type, heterozygous and homozygous states. In this setting, where DNA samples are not needed for further investigation, family studies or archive, the assay may be useful for the rapid, simultaneous detection of the two SNP's. Further examination is required to establish sample acceptance criteria, including: white-cell-count, sample-condition and anticoagulant-status, and their corresponding effect on C_T levels.

FANCONI ANEMIA FOUNDER MUTATION IN MACEDONIAN PATIENTS

S Madzunkova[1], S Kocheva[2], D Plasevska-Karanfilska[1]
[1]Research Center for Genetic Engineering and Biotechnolgy MASA, Skopje, Macedonia
[2]University Children's Hospital, Skopje, Macedonia

Fanconi anemia (FA) is a rare autosomal recessive disorder (1-5/1 000 000 live births) genetically and phenotypically heterogeneous, defined by cellular hypersensitivity to DNA cross-linking agents. Clinically FA is characterized by variable developmental abnormalities that may affect skeletal morphogenesis as well as any of the major organ systems, stem cell loss, causing progressive bone marrow failure (BMF) and sterility, and profound predisposition to neoplasia mostly leukemia and solid tumors. FA is the most frequent inherited cause of BMF.The FA complementation system consists of 15 FANC genes. There are evidences that all 15 gene products operate in a common molecular pathway

to preserve genomic integrity. Biallelic disruption of any one of these genes results in this clinically defined syndrome. The most prevalent ones are FANCA, FANCC, FANCG, and FANCD2. At the molecular level, a fundamental defect in DNA repair underlies this complex phenotype. FA-A is the most common group, accounting for approximately 65% of all affected individuals. The mutation spectrum of the FANCA gene, located on chromosome 16q24.3, is highly heterogeneous, including point mutations, small insertions/deletions, splicing mutations, and large intragenic deletions. FA-A is usually associated with private *FANCA* mutations in individual families. Thus, the number of different pathogenic variants described for the *FANCA* gene is very high considering the relatively low number of patients. Here we describe three patients (2 females, 11 and 17 years old and 1 male, 23 years old) with Fanconi anemia with similar clinical presentation: BMF, ren arquatus and renal ectopy and abnormal skin pigmentation *(café-au-lait)* without skeletal abnormality. In one of the female patients the persistent Ductus arterious, vesico-ureteral reflux and ptosis were also present. The molecular analysis of FANCA gene using the MLPA kit Fanconi anemia P-031, showed homozygous deletion of exon 3 in all three patients. Molecular analysis of the flanking regions of exon 3 precisely defines unique deletion of 2040 bp and insertion of C (1788_3824insC). The breakpoints are in intron 3 and 4 in the Alu repetitive sequence. We conducted a familial analysis and proved that the mutation was inherited from the parents. These are the first three patients homozygous for deletion of ex3 described to date. The patients are not related but they came from the same region from Macedonia. Determination of family pathogenic variants is the ultimate confirmation of diagnosis and is necessary for molecular prenatal or preimplantation tests and mutation carrier detection. The homozygous deletion of exon 3 of *FANCA* gene is a founder mutation of Fanconi anemia patients inMacedonia. Our finding has very strong implication in diagnostic and carrier screening strategy for BMF and Fanconi anemia in Macedonian patients and in comprehensive genetic counseling.

IDENTIFICATION OF THE FIRST MUTATION IN BRE MOTIF OF β-GLOBIN GENE AND ITS POLYGENIC INHERITANCE WITH TWO OTHER β-GLOBIN MUTATIONS IN PATIENTS OF THE SAME FAMILY

A Inati[1], H Abbas[1], M Souaid[2], S Koussa[2], A Taher[2], T Abi Nasr[2], D Chui[3]
[1]Lebanese American University, Byblos, Lebanon
[2]Chronic Care Center, Beirut, Lebanon
[3]Boston University School of Medicine, Boston, United States of America

Background. Thalassemia is one of the most common inherited genetic diseases in the Mediterranean region. Patients with heterozygous mutations in beta thalassemia, and to a lesser extent alpha-thalassemia, suffer from mild microcytic anemia. While the anemia is mild and confers no clinical threat in carriers, homozygosity of the mutation often leads to major thalassemic disease. Mutations and variants of α-globin and β-globin chains usually segregate independently, and there are rare reports of co-inheritance. Clinical outcomes of β and α-globin homozygous mutations vary significantly. **Aims.** A 7 year-old boy presented to our clinic with persistent mild microcytic anemia and recurrent infections, but with repeatedly normal iron profile and with normal HPLC . This prompted further genetic investigation of underlying β-and α-globin gene mutations. **Methods.** Upon receiving IRB approval and parents' consent, DNA samples were extracted from blood withdrawn from proband, parents and sibling. Genetic analysis with multiplex gap-PCR tests were conducted in the Chronic Care Center, Lebanon and reconfirmed in Boston University, USA for single a-globin gene deletions of rightward ($-a^{3.7}$) and leftward ($-a^{4.2}$) types, deletion of two a-globin genes in cis of the($—^{MED}$) and $-(\alpha)^{20.5}$, as well as for β-globin gene single point mutations and single nucleotide polymorphisms . **Results.** The father's a-globin genotype was (aa^{Hph}/ aa), while the mother's a-globin genotype showed another mutation which was ($-a^{3.7}$/aa). The a^{Hph} mutation is a deletion in the IVSI donor splice site which is a 5-base pair deletion of (-GTGAG) in a2-globin genes. The $a^{3.7}$ deletion is a single a-globin deletion and is the most common form of a-thalassemia mutation in the US and the Asia. The proband and his sibling inherited both a-globin mutations from each parent, concomitantly, and their a-globin genotypes were ($-a^{3.7}$ / a^{Hph}a). While the father's β-globin genotype was normal, the mother had a novel mutation (G>C) at nucleotide (-39) in BRE motif. Notably, genetic analysis showed that the proband and his sibling also inherited the β-globinmutation (G>C) from the mother. A list of mutations in all four members of the family is found in Table 1. **Conclusions.** This is the first report to show a mutation in BRE motif, where TFIIB binds to the β-globin gene promoter. Moreover, the ($-a^{3.7}$/ aa) genotype segregated with the BRE-motif mutation of β-globin in the mother and both siblings. The polygenic segregation, although rare in beta and alpha thalassemias, led to a mild microcytic anemia without iron deficiency and normal HPLC. Moreover, carrying two different a-globin mutations in proband and sibling conferred no fulminant a-thalassmia disease, despite a concomitant β-globin mutation. Further studies to decipher the clinical significance of this novel mutation in BRE motif of β-globin gene are warranted.

Table 1. Distribution of mutations in a- and -globin genes among family members.

	Father	Mother	Brother	Proband
β-Globin genotype	Normal	Hetero Nt –39 G>C mutation	Hetero Nt –39 G>C mutation	Hetero Nt –39 G>C mutation
α-Globin genotype	$\alpha\alpha$ / $\alpha^{Hph}\alpha$	$-\alpha^{3.7}$ / $\alpha\alpha$	$-\alpha^{3.7}$ / $\alpha^{Hph}\alpha$	$-\alpha^{3.7}$ / $\alpha^{Hph}\alpha$

[10]Haematology Research Laboratory, Foundation of Biomedical Research, Academy of A, Athens, Greece

Background. Serial quantification of *BCR-ABL1* mRNA is an important therapeutic indicator for patients with CML and Philadelphia-positive ALL, but there is substantial variation in the qRT-PCR protocols employed by testing laboratories. The principal difference is the use of different internal control genes (CG) to normalise results . For positive specimens, raw results are expressed as a ratio of *BCR-ABL1/CG* transcripts whereas for negative specimens the number of CG transcripts indicates the sensitivity with which *BCR-ABL1* can be excluded for that sample. Determination of the number of *BCR-ABL1* and *CG* transcripts is typically performed by reference to a plasmid calibrator, however different calibrators are in use worldwide and currently no standard exists to which they can be aligned. Comparative studies have demonstrated that the use of different plasmid calibrators and different batches of the same calibrator give rise to significant variation in assay results. **Aims.** To help standardise the reporting of copy numbers of *BCR-ABL1 (e14a2)* and CG (*ABL1*, *BCR* and *GUSB*) transcripts we sought to develop an internationally accepted plasmid certified reference material (CRM). **Methods.** Fragments specific for the fusion transcript *BCR-ABL1 e14a2* and control genes *BCR* and *GUSB* were amplified and cloned into pUC18 in a 1:1:1 ratio. For the CRM production according to ISO Guide 34:2009 by the IRMM, the plasmid was linearised, diluted to six different concentrations and copy numbers were assigned following 18 independent digital (Fluidigm) PCR measurements results for each dilution. For confirmation of the identity the entire plasmid was sequenced. The material was characterised for inter unit-heterogeneity, stability during dispatch and storage in accordance with ISO Guide 35:2006. A commutability study to assess the utility of the six CRMs was performed by nine *BCR-ABL1* testing laboratories using the six plasmid dilutions, two common cDNAs and their own local methods. **Results.** The copy numbers of the 6 calibrants were assigned as $1.08 \pm 0.12\times10^6$, $1.08 \pm 0.11\times10^5$, $1.03 \pm 0.10\times10^4$, $1.02 \pm 0.09\times10^3$, $1.04 \pm 0.10\times10^2$ and 10.0 ± 1.5 copies/µl (with a coverage factor $k = 2$ used for the expanded uncertainty . Data from the commutability study assessing the utility of the CRM were collated and the calibration standard curves were evaluated for their gradient and coefficient of determination ($r2$). In total, 171/174 (98.3%) calibration curves showed acceptable gradients (range -3.0 to -3.6); *BCR-ABL1* (n= 84), *ABL1* (n=*36*), *BCR* (n=*23*) and *GUSB* (n=*28*). 3/174 (1.7%) calibration curves were rejected because their gradient was less than -3.60 (-3.61 (n=1), -3.62 (n=1). All calibration curves had an $r2$ above 0.99. The CRMs proved to be commutable for all methods employed. **Summary.** We conclude that this set of 6 plasmid CRMs with defined DNA copy numbers can be used to standardise the reporting of transcript numbers of *BCR-ABL1* and three control genes; *ABL1, BCR* and *GUSB* in *e14a2* RQ-PCR monitoring tests. The plasmid dilutions with the CRM code ERM-AD623a-f, can be obtained from the IRMM or its authorised distributors (http://irmm.jrc.ec.europa.eu).

COMPARISON OF THE BCR-ABL GENE EXPRESSION BY THE GENEXPERT SYSTEM AND STANDARDIZED RQ-PCR METHOD IN THREE POLISH MOLECULAR LABORATORIES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH TKIS

T Sacha[1], M Zawada[1], A Leszczynska[2], I Solarska[3], I Florek[1], S Czekalska[1], D Cwynar[1], W Prejzner[2], M Szalajko[2], K Borg[3], K Warzocha[3], A Skotnicki[1]
[1]Jagiellonian University Hospital, Kraków, Poland
[2]Medical University of Gdansk, Department of Hematology, Gdansk, Poland
[3]Institute of Haematology and Transfusion Medicine, Warszawa, Poland

Background. The GeneXpert System was introduced to facilitate the molecular monitoring of therapy with tyrosine kinase inhibitors (TKI) of patients suffering from chronic myeloid leukemia. **Aims.** The aim of the study was to evaluate the novel rapid PCR GeneXpert System with internationally standardized *BCR-ABL1/ABL1* RQ-PCR methodology **Methods.** The comparison of the *BCR-ABL1* gene expression consisted of paired *BCR-ABL1/ABL1* expression analysis performed in three Polish Molecular Laboratories by RQ-PCR TaqMan methodologies aligned to International Standard (IS) and by the GeneXpert *BCR-ABL* System. 90 patients with chronic phase chronic myeloid leukemia expressing e13a2 or e14a2 *BCR-ABL1* transcripts and treated with tyrosine kinase inhibitors were evaluated. Patients were subdivided into three groups according to BCR-ABL1 transcript level estimated by standardized RQ-PCR method. Group 1 consisted of patients with *BCR-ABL1/ABL1* ratio below 0,1% [IS], group 2 with *BCR-ABL1/ABL1* ratio between 0,1% and 1,0% [IS], and group 3 with *BCR-ABL1/ABL1* ratio between 1,0% and 10,0% [IS]. **Results.** The comparable results of two evaluable techniques were observed in 32% of all samples. The Wilcoxon test revealed statistically significant differences between the results of GeneXpert System and standardized RQ-PCR *BCR-ABL1/ABL1* method (p< 0,0001) (Figure 1). The mean *BCR-ABL1/ABL1* gene expression evaluated by the GeneXpert System was 1 log lower than in the RQ-PCR method. The comparable results of both techniques in group 1, 2 and 3 were noted in 35%, 15% and 17% respectively. The differences were statistically significant in each evaluated group. **Conclusions.** The GeneXpert system provides very easy to use and rapid diagnostic platform, which could be very useful in evaluating CML patients' response to TKI therapy. Improvement of system sensitivity and the development of proposed already a reagent lot-specific conversion factor to the international standard could further enhance the reliability of results obtained by the use of GeneXpert in patients with CML monitored for the response to TKI therapy.

THE PHENOTYPE OF EARLY ERYTHROID CELLS PARALLELS WITH THEIR GENE EXPRESSION PROFILE

S Machherndl-Spandl[1], S Suessner[2], M Danzer[2], J Proell[2], C Gabriel[2], J Lauf[3], R Sylie[4], A Weltermann[5], P Bettelheim[5]
[1]Elisabethinen hospital, Linz, Austria
[2]Blutzentrale Linz, Linz, Austria
[3]Labor Europaplatz, Linz, Austria
[4]Wagner Jauregg Hospital, Linz, Austria
[5]I.Interne Abteilung Elisabethinen Hospital, Linz, Austria

Background. Our current knowledge about the regulation of erythropoiesis is based on cell culture techniques using various cytokines, immunological methods such as flow cytometry, recent molecular techniques like gene expression profiling and animal models. However, the different stages of the early erythropoietic cells cannot be clearly delineated so far by flow cytometry nor by molecular analyses. **Aims.** The aim of our recent study was to investigate the gene expression profile of distinct stages of the erythroid differentiation separated by high-sensitive flow cytometry. **Material and Methods.** Bone marrow MNC from twenty patients without marrow involvement of an underlying disease and from six healthy volunteers were obtained after signing an informed consent. A backbone consisting of CD34, CD117, CD45, CD105 and CD71 was established for a ten colour FCM (Aria III cell sorter, Becton Dickinson) and used in combination with additional markers (CD13, CD33, HLA-DR, CD235a, CD238, CD239, CD36, CD19, CD14, CD 11b, CD38, CD173) to distinguish the different early erythroid precursor cells. FACSDiva software Version 6.1.3 (BD Biosciences) was used for the evaluation of the multicolour analysis. Pure (> 95%) subsets were obtained by flow cytometric sorting with specific marker combinations.RNA from 40.000 to 1.000.000 cells of each subset were extracted using the miRNAeasy kit (Qiagen) for the gene expression analysis, afterwards cDNA and double strand biotin labeled cRNA production samples were purified, fragmented and hybridized to the GeneChip U-133 Array (Affymetrix). After scanning, the normalization of raw data was performed in Partek software. **Results.** Using the ten colour FCM, four different stages of the early erythropoiesis could be delineated. The earliest compartment is the common progenitor stage (CD34+, CD117+, HLA-DR+, CD105-, CD71-, CD36-). The stage 2 can be defined by the occurrence of the CD71 (transferrin receptor) expression. At this stage of differentiation CD 34 and CD117 remain detectable, whereas all myeloid associated structures are no more present. Within stage 3 erythroid-specific antigens appear (CD105, CD173, CD238) while some antigens of the progenitor stage decrease (CD34 and HLA-DR). In stage 4 most blood group antigens are expressed whereas CD117 is lost.Gene expression analysis revealed a strong correlation for the expression level of most relevant markers and blood group antigens. A significant (p-value <0,01; fold change >2,0) up-regulation was found for 519 genes in CD105 positive erythroid precursor cells (stage 3 and 4) in comparison to the common progenitor level, whereas the expression level of 1520 genes was significantly reduced. Furthermore, significant differences between the erythroid stages 1 to 4 were detectable in all pathways studied (erythropoietin-receptor, BMP/Wnt, TGF, TNF) including almost all transcription factors responsible for the erythroid differentiation and functional relevant genes for hem-synthesis and iron metabolism. **Conclusions.** Using highly sensitive FCM different compartments of the erythroid development can be delineated, which enables further characterization of these populations by gene expression analysis. The results of this approach represent the basis for a systematic comparison with pathological conditions involving the early erythroid differentiation.

CYTOMEGALOVIRUS INFECTION IMPAIRS IMMUNOSUPPRESSIVE AND ANTIMICROBIAL EFFECTOR FUNCTIONS OF HUMAN MULTIPOTENT MESENCHYMAL STROMAL CELLS - IMPLICATIONS FOR THEIR CLINICAL USE

R Meisel[1], K Heseler[2], Ö Degistirici[1], W Däubener[2]
[1]Clinic for Pediatric Oncology, Hematology & Clinical Immunology, HHU Düsseldorf, Duesseldorf, Germany
[2]Institute for Medical Microbiology & Hospital Hygiene, HHU Düsseldorf, Düsseldorf, Germany

Background. In addition to their multilineage differentiation potential human multipotent mesenchymal stromal cells (MSC) provide pleiotropic immunosuppressive functions that are partly mediated by expression of the tryptophan-

catabolizing enzyme indoleamine-2,3-dioxygenase (IDO). Moreover, upon stimulation with inflammatory cytokines MSC exhibit broad-spectrum antimicrobial effector function directed against various clinically relevant pathogens and these effects are also IDO-dependent. This dual immunosuppressive and antimicrobial properties render MSC a promising novel cellular immunosuppressant which is currently under intensive clinical investigation in various auto- and alloimmune diseases such as steroid-refractory graft-versus-host-disease (GvHD) after allogeneic hematopoietic stem cell transplantation, Crohn's disease and multiple sclerosis. However, recent data indicate that signals from the microenvironment including those derived from microbes may modulate MSC effector functions e.g. via activation of toll-like receptors. **Aims.** As human cytomegalovirus (HCMV) represents a prominent pathogen in immunocompromised hosts, in particular in patients with GvHD, we here investigated the impact of HCMV infection on immunosuppressive and antimicrobial activity of human MSCs. **Methods and Results.** Human bone marrow-derived MSCs were infected with HCMV and their T lymphocyte inhibitory capacity was assessed in co-culture with anti-CD3-stimulated human peripheral blood lymphocytes. While uninfected MSCs substantially impaired T cell proliferation, HCMV infection significantly reversed this T cell inhibitory effect of human MSCs ($p<0.05$). In additional experiments we found that the inhibitory effect of MSC on T cell proliferation required a minimum amount of MSC present in the co-culture system. While the addition of HCMV to cultures with high numbers of MSCs antagonizes their T cell inhibitory effect, the same amount of HCMV added to low number of MSCs did not alter T cell proliferation, thus ruling out an unspecific T cell stimulatory effect of HCMV. In subsequent analyses, we observed a substantial negative impact of HCMV infection on cytokine-induced antimicrobial effects of MSCs which are directed against bacteria such as *Staphylococcus aureus* and intracellular parasites such as *Toxoplasma gondii*. We then went on to analyse the potential impact of HCMV infection on IFNγ-induced IDO expression as one of the key mechanism of MSC-mediated T cell suppression and antimicrobial effects. In these experiment we found a substantial impairment of IDO expression after HCMV infection of MSCs in western blot analysis as well as enzyme activity assays. Moreover, this interaction between HCMV and IDO-mediated effects critically depended on intact virus, the time point of CMV infection as well as the numbers of MSCs and virus employed. **Summary and Conclusions.** Our results provide first evidence that HCMV infection critically impairs immunosuppressive and antimicrobial effector functions of human MSCs via interaction with the IFNγ-induced IDO pathway. As a consequence, overt HCMV infection of MSC recipients might undermine the clinical efficacy of MSC treatment. Thus, antiviral treatment should seriously be considered in patients with active HCMV infection prior to MSC administration.

0705

ALTERATIONS IN BONE MARROW STROMAL PRECURSOR CELLS IN PATIENTS BEFORE AND AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

N Petinati, L Kuzmina, L Lubimova, I Shipounova, N Sats, A Bigildeev, E Parovichnikova, N Drize, V Savchenko
National Research Hematological Center, Moscow, Russian Federation

Background. Stromal damage and recovery in allogeneic hematopoietic stem cells transplant (alloHSCT) recipients is obscure. **Aims.** The aim of the study was to investigate the dynamics of stromal precursor cells - multipotent mesenchymal stromal cells (MSC) and colony forming unit fibroblasts (CFU-F) - in the bone marrow of patients during one year after alloHSCT. **Methods**. AlloHSCT was performed to 12 patients (6 male and 6 female): 3 patients with CML, 5 with AML, 3 with ALL and 1 with B-CLL. Conditioning was myeloblative in 8 patients and reduced intensity in 4. After informed consent bone marrow was aspirated: before conditioning, and 30, 60, 90, 120, 180-240 and 360 days after transplantation at the moment of control clinical observations. MSC were cultured in alfaMEM media supplemented with 10% fetal calf serum. Cumulative MSC production was counted after 5 passages. CFU-F concentration in bone marrow samples was analyzed in 14 days.*Results* The growth parameters of patients' and donors' MSC are significantly different. Even before alloHSCT average time to passage is 1.5 fold longer in patients' MSC (9.0 ± 0.8 days) than in donors' ones (6.6 ± 0.4 days). In 30 days after alloHSCT average time to passage increased 3 fold in comparison with donors' (20.6 ± 5.0 days), than it gradually decreased remaining longer than before alloHSCT up to one year. Before transplantation cumulative cell production of MSC is more than ten times lower than in donors' MSC. In 30 days after alloHSCT cumulative cell production decreased 1000 fold, than increased slowly, but at the day 120 it was 10 fold lower than at the day 90. Only in one year it attends basic level.Concentration of CFU-F in the bone marrow of patients before transplantation was 1.3 fold lower than in the bone marrow of donors. In 30 days after alloHSCT concentration of CFU-F in bone marrow of patients decreased more than 4 fold (29.6 ± 7.9 per 10^6 bone marrow cells before alloHSCT and 7.2 ± 3.1 per 10^6 - 30 days after). Further it gradually increased and one year after alloHSCT mount to 75% (22.4 ± 14.8) of value before transplantation. No differences were revealed between patients after myeloablative or reduced intensity conditioning regimen. **Conclusions**. The results demonstrate that stromal precursor cells - MSC and CFU-F are altered in patients after alloHSCT. MSC from patients have reduced proliferative potential in comparison with MSC from donors which does not restored even in one year after alloHSCT. So the data suggest that stromal cells are violently damaged by alloHSCT procedure and do not regenerate completely even in one year. The status of hematopoietic microenvironment could influence the hematopoiesis in patients after alloHSCT. Further investigations of stromal precursor cells are needed.

0706

CDK6 IN HSC HOMEOSTASIS

K Kollmann[1], V Sexl[2]
[1]Veterinary University of Vienna, Vienna, Austria
[2]Institute of Pharmacology and Toxicology, Vienna, Austria

Background. Cell cycle deregulation is a common feature of cancer (Cordon-Cardo 1995; Malumbres and Barbacid 2001; Deshpande, Sicinski et al. 2005; Kim and Diehl 2009). The G1-kinase, CDK6, is frequently expressed at high levels in human lymphoma and lymphoid leukemia (Chilosi, Doglioni et al. 1998; Lien, Lin et al. 2000; Schwartz, Engel et al. 2006; Nagel, Leich et al. 2008). Additional roles - apart from promoting cell cycle progression - have been postulated for CDK6; it has been for instance posited that CDK6 regulates differentiation in several cell types (Grossel and Hinds 2006). CDK6 deregulation in mice results in an altered composition of lymphoid cell subsets as well as hematopoietic stem and progenitor cells (Hu, Deshpande et al. 2009; Kollmann et al. 2011; Hu et al. 2011). **Aims.** With this study we want to analyze the impact of CDK6 on lineage differentiation as well as haematopoietic stem cell (HSC) homeostasis and if the efficacy of bone marrow transplantation depends on CDK6 kinase activity. A disturbed HSC homeostasis may play an important role in leukemia/lymphoma formation. Accordingly, CDK6 represents a potential target for the development of therapeutic drugs. **Methods and Results.** When we analyzed cell lineages in haematopoietic organs (bone marrow, spleen and blood) by FACS, we found one supplemental consistent alteration in *Cdk6-/-* mice. In mice lacking CDK6 the granulocytic population was significantly reduced in bone marrow and blood compared to control mice. To test if the lack of CDK6 influences HSC populations we analysed the HSC-fractions in 4- to 5-week-old *Cdk6-/-* mice by FACS. We found a significant increase of lineage negative cells as well as a higher percentage of HSCs, detectable in the bone marrow of *Cdk6-/-* mice. In contrast the percentage of myeloid progenitors (MPs) was decreased. To determine the reconstitution ability of *Cdk6-/-* bone marrow, we transplanted isolated *Cdk6-/-* and *Cdk6+/+* bone marrow cells into lethally irradiated mice. Successful engraftment was detected in both groups, albeit significantly less Lin^- cells were found in mice reconstituted with *Cdk6-/-* BM compared to the *Cdk6+/+* mice. **Summary.** These results indicate that CDK6 is involved in hematopoiesis at multiple levels including alterations of HSCs.

PPARG INHIBITOR PROMOTES HEMATOPOIETIC RECOVERY AFTER CHEMOTHERAPY

R Zhu[1], M Wu[2], K Liu[1]
[1]Peking University People's Hospital Peking University Institute of Hematology, Beijing, China
[2]Beijing Jishuitan Hospital, 4th Medical College of Peking University, Beijing, China

Background. Increased fat fraction within bone marrow microenvironment induced by high-dose HD chemotherapy used to be observed though its role in hematopoietic recovery was unclear. PPARγ has been considered as a vital transcriptin regulator of adipogenensis *in vitro* and *in vivo* in models of diabetes. BADGE, as an inhibitor of PPARγ, has been showed to successfully prevent bone marrow adipocytes formation after lethally irradiated, resulting a faster hematopoietic engraftment. Whether adipocytes play a negative role in hematopoietic recovery after high-dose chemotherapy remains unknown. **Aims.** We wonder if PPARγ inhibitor can prevent the adipogenesis induced by HD chemotherapy and then improves hematopoietic recovery. **Methods.** 6~8 week-old C57BL/J mice were treated with Arac in order to induce bone-marrow adipocytes formation. BADGE was administrated daily since the day Arac treated while DMSO was used as the control. Mice were bled every week for peripheral blood analysis and femurs and tibias as well as tail vertebraes were detached for pathological HE sections. BM cells were flushed out for further

experiments including RT-PCR ,colony forming unit (CFUs), flow cytometer (FACs) and magnetic active cell sorting (MACS). **Results.** Fat hyperplasia appeared in the control group since one week after HD chemotherapy which can be restrained in the BADGE-treated group. After 2 weeks BADGE treatment, peripheral white blood cells increase 30%~40% over the control group while the neutrophils were 1.5~2 times higher. CFUs of BM cells increased by 25%~30%. Meanwhile, compared with the control group, though HSCs (ckit+Lin-Sca1+) seemed no obvious difference between the two groups, percentage of hematopoietic progenitor cells (HPCs, ckit+Lin-Sca1-)sorted by MACs were 2 times higher. Further more, the proportion of Ki67 (+) CD45 (+)BM cells and Ki67 (+) LSK HSCs analyzed by FACs were significantly increased by 1.5~2 times. **Conclusions.** Fat hyperplasia within BM induced by HD chemotherapy can be restrained by PPAR γ inhibitors, resulting an improvement of hematopoietic recovery after the hematopoietic stress.

[5]Etablissement Français du Sang Aquitaine-Limousin,, Bordeaux, France
[6]Etablissement Français du Sang Aquitaine-Limousin, Bordeaux, France

Background. The short-term conservation of hematopoietic stem and progenitors cells is actually performed in hypothermia (+4°C). In nature, long-term survival of some animals in hypothermia is enabled by regulated metabolic depression which can be induced by their exposure to low O_2 (hypoxia) and increased CO_2 (hypercapnia) environment. Similarly, in physiological conditions, the primitive hematopoietic cells are maintained in a hypometabolic state in the poorly oxygenated bone marrow niche. Recently, we demonstrated that the same protective mechanism is operational in mobilized peripheral blood primitive hematopoietic progenitors and stem cells during their storage at4°C (Jeanne et al, Transfusion 2009). **Aims.** The aim of this study was to test if exposure to hypoxic/hypercapnic gas mixture could be also beneficial for the preservation of functional cord blood $CD34^+$ hematopoetic progenitors in hypothermia and, if so, to analyse physiological and proteomic aspects of this phenomenon. **Methods.** Cord blood $CD34^+$ cells were incubated in conservation medium Stem-α S3 for 10 days at +4°C under hypoxic (1 and 5% O2) and hypercapnic (2,5 and 9% CO2) concentration or air (20% O_2 and 0,05% CO_2). The functional maintenance of committed hematopoietic progenitors (CFC assay) and stem cells (Scid-Repopulating Cells (SRCs) assay estimated by the presence of human markers [CD45, CD19, CD33] and human CFC in NOG/Scid mice femur 6 weeks after transplantation) in parallel with a flow-cytometry analysis of phenotype and vital functions (Aldefluor, AnnexinV/PI, ATP bioluminescent assay, DiBAC4, TMRM, H2DCFDA staining). Proteomic analysis was performed using iTRAQ labelling followed by peptide fractionation (SXC chromatography) and mass spectrometry (LC/MS/MS). **Results.** Incubation in hypoxia and hypercapnia doubled the survival $CD34^+$ cells (60%) comparing to air (30%). Similar ratio is obtained for CFC (34±9% vs 18±6% in air). $5\%O_2/9\%CO_2$ ratio appeared to be the optimal hypoxic/hypercapnic combination. Better cell maintenance in this condition was associated with a higher frequency of primitive a*ldehyde dehydrogenase* (ALDH) expressing cells and SRCs. These cell-protective effects seem to concern a better preservation of the plasma and mitochondrial membrane potential. Hypoxia/hypercapnia also ensures maintenance of viable cells and induces less apoptosis, in spite of a production of deleterious ROS and a drop of ATP amount/per viable cell which were equivalent to that obtained in air. These effects seem to be principally mediated via hypercapnia. Proteomic study revealed that overall protein's content was better preserved in hypoxia/hypercapnia. In addition, this analysis enabled to identify and to distinguish proteins sensitive and insensitive to hypothermia irrespective to the gas phase, as well as the proteins contributing specifically to the hypoxia/hypercapnia cell protective effect. Among them are some protein families known to be implicated in the long time survival of hibernating animals in hypothermia. **Conclusions.** Present work demonstrates the critical physiological effects and indicates protein candidates implicated in hypoxia/hypercapnia-mediated functional maintenance of hematopoietic progenitors in hypothermia. These results suggest a way to optimise cell conservation without freezing and to design a new generation of conservation media.

0709

CYTOKINE PROFILE AND EFFECT OF ALLOGENIC BONE MARROW MESENCHYMAL STEM CELLS ON PROLIFERATION OF NORMAL HEMATOPOIETIC PROGENITORS AND LEUKEMIC CELLS

T Shamanskaya[1], E Osipova[1], O Tatarinova[1], S Plyasynova[1], O Kozlitina[1], Z Dishlevaya[2], E Skorobogatova[2], S Roumiantsev[1]
[1]Federal Clinical Research Centre of Pediatric Hematology, Oncology, Immunology, Moscow, Russian Federation
[2]Russian Children's Clinical Hospital, Moscow, Russian Federation

Background. Currently, immunological properties of MSCs have found a greater therapeutic use in transplantation to improve engraftment, treatment of GVHD and in regenerative medicine. MSCs have the capacity to maintain hematopoiesis (through the production of G-CSF, GM-CSF), immunomodulation properties (through the production of IFN-γ, IL-2, IL-6, IL-1β, TNF-α and chemokines - IL-8, MCP-1, MIP-1β) and stimulation of reparative processes (through the production of VEGF, FGF-basic, IGF-1, IL-6, TIMP-1/MMP-9). MSC has impact to leukemic cells present in bone marrow of the recipient in the form of minimal residual disease. **Aims.** to investigate the mechanism of the effect of allogeneic bone marrow MSCs on the ability of tumor cells to spontaneous and induced apoptosis. We also assessed the cytokine profile of MSCs according to the time of cultivation. **Methods.** Leukemic cells from bone marrow samples of patients (age 6 months - 17 years) with newly diagnosed acute leukemia (AL): B-ALL-45, T-ALL-13, AML-19. MSC (from 54 healthy donors) were cultured in DMEM with 20% FCS. Clonogenic study of granulocyte-macrophage bone marrow progenitors (from 15healthy donors) were performed in semisolid agar medium. The sensitivity of blast cells to cytotoxic drugs was studied by the MTT-assay. To determine the levels of spontaneous and induced apoptosis in leukemia cells we use Apoptosis Detection Kit II (BD). Cytokines produced by MSCs from the bone marrow was determined by flow Cytofluorometer using reagents BD Cytometric Bead Array early and late passages. **Results.** MSCs stimulate colony formation of granulocyte-macrophage precursors, surpassing the effectiveness of phytohemagglutinin-leukocyte conditioned medium as a source of colony stimulating factors. Efficiency of cloning was 27.9 (SD 1.5) and 22.9 (SD 2.4), respectively. When leukemic cells were cultured on MSC for 4 days the proportion of viable cells was higher at 47.2% in ALL, and 63.1% in AML compared with controls. Incubation of leukemic cells with MSCs resulted in a decrease of sensitivity to cytarabine in 2 times in B-ALL, in 1.5 times in AML and 6 times in T-ALL. Under the influence of MSCs sensitivity of leukemic cells to daunorubicin decreased in all groups. MSC increased the sensitivity of blast cells from ALL patients to MP, but did not influence the sensitivity of AML blast cells to MP. MSCs inhibit apoptosis of leukemic cells induced by cytarabine. The study of MSCs cultures with CBA showed that MSCs produce a wide range of cytokines (IL-2, 4, 6, 10; FGF, VEGF), which may mediate the effect of MSCs on the viability of hematopoietic progenitors and leukemic cells. Some changes in production of various cytokins depending on time of cultivation have been observed. **Conclusions.** On the basis of the research is clear that the important aspect is the safety of MSCs in terms of their influence on the sensitivity of leukemic cells to chemotherapy in patients with hematologic malignancies. The functional capacity of MSCs, which is realized through the production of a wide variety of cytokines, may play an important role in the regulation of immunological, reparative and other processes.

THE NUCLEAR FACTOR NF-YA IN HUMAN BONE MARROW MESENCHYMAL STEM CELLS: AN EMERGING ROLE IN ADIPOGENESIS

A Anthi[1], K Pavlaki[1], M Kastrinaki[1], E Simantirakis[1], J Papamatheakis[2], C Pontikoglou[1], H Papadaki[1]
[1]University of Crete School of Medicine, Heraklion, Greece
[2]Institute of Molecular Biology and Biotechnology, FORTH, Heraklion, Greece

Background. The nuclear transcription factor Y (NF-Y) is a heterotrimeric CCAAT-binding transcription factor consisting of the subunits A, B, and C that appears to have a complex role in hematopoietic stem cell (HSC) self-renewal and differentiation along different hematopoietic cell lineages. No available data, however, exist on the role of NF-Y in cells of the non-hematopoietic bone marrow (BM) stroma, namely the mesenchymal stem cells (MSCs) and their progeny. **Aims.** To evaluate mRNA expression and protein levels of the main regulatory NF-Y subunit, namely the NF-YA, throughout long-term BM-MSC cultures and probe its possible involvement in BM-MSC differentiation process towards the adipogenic and osteogenic lineages *in vitro*. **Methods.** MSCs were isolated from BM aspirates of hematologically healthy subjects undergoing orthopedic surgeries after informed consent. MSCs were *in vitro* expanded until passage (P)-10. P3 BM-MSCs were *in vitro* induced to adipogenic or osteogenic differentiation according to standard protocols. Differentiation were

verified by the appropriate cytochemical stains (Oil-Red O and Von-Kossa, respectively) and by evaluating the relative gene expression of lineage-associated markers by real-time PCR, namely PPARG, CEBPA, LPL for adipogenesis and RUNX2, DLX5, ALP, OSX, OSC, BSP for osteogenesis. All PCR results were expressed as $2^{-\Delta Ct}$. To knock-down NF-YA expression, P3 BM-MSCs were transduced with NF-YA shRNA or control (irrelevant shRNA) lentiviral particles. Protein levels of NF-YA were immunodetected by Western blots. **Results.** A statistically significant reduction in mRNA levels of NF-YA was found in P10, as compared to P3 BM-MSC cultures (n=9) (0.002±0.0007, and 0.004±0.001, respectively, *P*=0.0296). During adipogenic differentiation (n=12) a significant increase in NF-YA transcription levels was observed at day6 (0.007±0.003, *P*=0.0452) and day12 (0.01±0.005, *P*=0.347) as compared to the onset of differentiation induction (0.004±0.002). Moreover NF-YA expression levels strongly correlated to CEBPA (*r*=0.751, *P*=0.001), PPARG (*r*=0.705, *P*=0.003), and LPL (*r*=0.712, *P*=0.003) mRNA levels. In accordance to mRNA levels, protein levels of NF-YA also increased during adipogenesis. In contrast, during osteogenic differentiation (n=6) no statistically significant change was detected in NF-YA mRNA expression or protein levels. To evaluate whether NF-YA might be functionally related to adipogenesis, we lentivirally transduced BM-MSCs with NF-YA shRNA (shNF-YA) and subsequently induced differentiation. During adipogenesis (d14) NF-YA mRNA levels in shNF-YA BM-MSCs were constantly reduced to 51.9% of the respective levels in control cells. A 31.3%, 70.1% and 74.3% reduction was also observed in PPARG, CEBPA and LPL levels, respectively, in shRNA transduced cells compared to controls. Finally, cytochemical Oil-red O staining revealed a lack of lipid droplets in shRNA transduced cells. **Summary and Conclusions.** We have shown for the first time that NF-YA mRNA and protein levels increase during BM-MSC adipogenic differentiation and that NF-YA transcription levels strongly correlate with the adipocytic-related genes CEBPA, PPARG, and LPL. These findings are suggestive of a novel role of NF-YA in adipogenesis, a notion which is further corroborated by the decreased differentiation following NF-YA knock-down. We also observed a moderate decrease of NF-YA mRNA levels after long *in vitro* BM-MSC expansion. Whether this finding is related to BM-MSC loss of stemness and/or senescence is under investigation.

PATIENTS WITH GAUCHER DISEASE EXHIBIT INCREASED FREQUENCIES OF PERIPHERAL BLOOD ACTIVATED LYMPHOCYTES AND SEVERELY IMPAIRED REGULATORY T-CELLS

A Symeonidis[1], C Sotiropoulos[1], G Theodorou[1], C Repa[2], T Marinakis[3], P Karkaloussos[2], A Kouraklis-Symeonidis[1], E Solomou[1], M Karakantza[1], A Symeonidis[1]
[1]University of Patras, Patras, Greece
[2]3rd IKA Hospital of Athens, Athens, Greece
[3]G.Gennimatas General Hospital, Athens, Greece

Background. Gaucher disease (GD) is a Lysosomal Storage Disorder, characterized by splenomegaly, bone disease and peripheral blood cytopenias, resulting from the accumulation of undigested lipid-replete macrophages in the bone marrow and the reticuloendothelial system. Patients with GD commonly exhibit a chronic inflammatory response, as yet not completely understood. We have previously shown that these patients also exhibit constitutively deceased numbers of peripheral blood absolute lymphocyte count and of CD3+, CD4+ and CD4+/HLA-DR+ T-lymphocytes, as well as increased percentages and absolute numbers of CD8+/CD45RO+, CD8+/HLA-DR+ T-lymphocytes. **Aims.** To investigate the frequencies of regulatory T-cells (T-regs) and the polarization of T-helper cells in the same cohort of patients. **Patients and Methods.** A three color whole blood method of flow cytometry was used for evaluation of T-lymphocyte subpopulations, during the routine work-up of 17 patients with type I GD, after obtaining informed consent. T-regs were evaluated as the fraction of CD4+/CD25^{high}+/FOXP3+ cells. Cytoplasmic expression of IL-2, IL-4, IFN-gamma, IL-10 and IL-13 was evaluated after short activation with PMA, ionomycin and blockage of Golgi apparatus with BFA.Results were compared with those of 21 normal controls, sex-and age-matched. All estimations were performed in the absence of any infection or other inflammatory condition. **Results.** Compared to controls, we have again confirmed that patients with GD exhibited significantly decreased absolute lymphocyte count (x±SEM: 1738±235 versus 2053±157/μl, p=0.039), CD3+ lymphocytes (1197±128 versus 1403±139/μl, p=0.031) and CD3+/CD4+helper T-lymphocyte count (38.8±3.3% versus 44.7±3.6%, p=0.022, or 676±88 versus 931±101/μl, p=0.004). Conversely, they exhibited increased proportion of CD3+/CD8+ suppressor T-cells (26.5±2.4% versus 19.2±2.1%, p=0.007, or 446±52 versus 402±39/μl, p= 0.199) resulting in a significant reduction of the CD4/CD8 ratio (1.53±0.19 vs 2.26±0.22, p=0.0012). Patients with GD exhibited also increased proportions of activated CD4+/CD25+ lymphocytes (2.54±0.77, versus 2.04±0.94%, p=0.062), CD4+/HLA-DR+ lymphocytes (2.83±0.46 versus 1.47±0.27%, p=0.0021) and CD8+/HLA-DR+ lymphocytes (1.07±0.18 versus 0.47±0.06%, p<0.0001). Moreover, patients with GD had significantly lower percentage of CD4+CD25^{high}-FOXP3+ T-regs (1.27±0.22 versus 2.09±0.41%, p=0.017), and among CD4+/CD25^{high}+ cells, significantly lower percentage of FOXP3+ cells (76.1±5.5 versus 85.6±5.9%, p=0.004). Lymphocytes of patients with GD exhibited a clear TH1 polarization (CD4+IFNgamma$_{cy}$ unstimulated: 1.23±0.41 versus 0.58±0.14%, p=0.077 and following stimulation: 38.8±3.1 versus 23.6±2.3%, p=0.0003, CD4+IL2$_{cy}$ unstimulated: 0.30±0.06 versus 0.13±0.03, p=0.009 and following stimulation: 65.8±4.0 versus 62.5±3.1%, p=0.396, CD4+IL13$_{cy}$ unstimulated: 0.104±0.026 versus 0.072±0.020, p=0.170, and following stimulation: 0.549±0.085 versus 0.404±0.064, p=0.094, CD8+IFNgamma$_{cy}$ unstimulated: 0.51±0.34 versus 0.23±0.05%, p=0.211, and following stimulation: 62.1±7.3 versus 43.9±4.8%, p=0.025). Finally both, the percentage and the absolute number of CD5+/CD20+ autoreactive B-lymphocytes were not significantly different between patients and controls (2.45±0.58 versus 1.94±0.37%, and 60±18 versus 47±14/μl, p: n.s. for both comparisons).*Discussion and* **Conclusions.** Taken together, our results demonstrate that in patients with GD there is a significant numerical impairment of T-helper lymphocytes and a constitutive activation in both, the CD4+ and the CD8+ cell compartment, associated with a significant decrease of T-regs, although the autoreative B-lymphocytes are not always found increased. These findings may explain the chronic inflammatory reaction, as well as the increased incidence of lymphoid malignancies, which has been reported among patients suffering from GD.

CHARACTERIZATION OF HEMATOPOIETIC STEM AND PROGENITOR CELL ADHESION TO SURROGATE MICROENVIRONMENTS

V Giai[1], C Scharenberg[2], R Wallin[3], F Salomons[4], O Bergmann[4], S Conte[2], D Ferrero[5], E Hellström-Lindberg[2]
[1]Karolinska University Hospital, Stockholm, Sweden
[2]Center for Hematology and Regenerative Medicine, Karolinska University Hospital, Stockholm, Sweden
[3]Centre of Infectious Medicine, Karolinska Institutet, Stockholm, Sweden
[4]Department of Cell and Molecular Biology, Karolinska Institutet, Stockholm, Sweden
[5]Divisione Universitaria di Ematologia, Torino, Italy

Background. Hematopoietic stem cells reside in specialized microenvironments - stem cell niches - consisting of different cell types and extracellular matrices. Within these niches, a multitude of signals influence particular stem cell behaviours such as quiescence, self-renewal and differentiation. The dysregulation of these niches, either in structure or function, affects hematopoiesis and has been implicated in disease states of the bone marrow such as leukemia or myelodysplastic syndromes (MDS). Leukemic stem cells have been shown to co-opt cues from the microenvironment to further leukemic progression and mitigate the effects of cytotoxic therapies. Amongst the large number of signals in the niche, there are extracellular matrix components not only produced by the surrounding niche cells but also by the hematopoietic stem cells (HSCs) themselves. Understanding the complexity of stem cell-niche interactions could help to elucidate novel aspects that might lead to new targeted therapies. **Aims.** Given the requirements of leukemic cell interaction with the niche, our goal was to understand the interactions of healthy hematopoietic stem and progenitor cells (HSPCs) with defined extracellular matrix (ECM) components in an *in vitro* setting. We used cell lines as well as normal bone marrow CD34$^+$ cells to investigate adhesion to various substrates found in the bone marrow microenvironment. **Methods.** Using high-throughput microscopy, we developed a novel and robust adhesion assay to study the frequently limited cell numbers of HSPC obtained in certain diseases such as MDS. We combined this with multiparameter flow cytometry in order to study the various subsets of normal CD34$^+$ HSPCs. **Results.** Over 90% of healthy CD34$^+$ cells adhered to the well-studied substrates such as fibronectin and vascular cell-adhesion molecule 1 (VCAM-1); 37% of CD34$^+$ cells adhered to laminin and osteopontin and only 15% to collagen-I, suggesting heterogeneity within the adhesion of different HSPC-subsets. Overall, CD38$^-$ cells adhered more than CD38$^+$ to all the substrates studied, demonstrating the differential adhesion of primitive and mature progenitors. Regarding committed myeloid progenitors, megakaryocyte-erythroid progenitors (MEP) were the most adherent population, strongly attaching to all the substrates studied. Similar numbers of common myeloid progenitors (CMP) and granulocyte-macrophage progenitors (GMP) were recovered in the majority of the adherent vs. non-adherent fractions. Interestingly, both progenitor populations were enriched in the non-adherent fraction of VCAM-1 wells, suggesting that CMPs and GMPs do not bind to VCAM-1. Amongst the substrates studied, HSCs preferentially adhered to laminin and fibronectin; the number of adherent cells increased 5-fold and 2-fold in the laminin and in the fibronectin groups respectively. **Summary and Conclusions.** Herein, we

demonstrated the inherent adhesion heterogeneity of normal CD34+ progenitors towards defined ECM. These differences in adhesion are likely to play an important role in normal hematopoietic development as well as in malignant transformations. Further studies on HSC and their attachment towards the ECM could provide a sensitive tool for targeted therapy in hematological diseases.

0713

ROLE OF DNA DEMETHYLATION AGENT 5-AZA DEOXYCYTIDINE IN THE PRODUCTION OF VON WILLEBRAND FACTOR IN HUMAN BONE MARROW DERIVED CELLS CULTURED IN 3D PELLETS

A El-Serafi[1], H Roach[2], R Oreffo[2]
[1]Suez Canal University, Ismailia, Egypt
[2]University of Southampton, Southampton, United Kingdom

Epigenetic regulation of gene expression is recognized as a key mechanism governing cell determination, commitment, and differentiation as well as maintenance of cell state. An important component of epigenetic control is DNA methylation, which is associated with gene silencing. 5-aza deoxycytidine (5-aza-dC) is a cytidine analogue that traps the DNA methytransferase and consequently inhibits the methylation of the newly synthesized DNA strand in dividing cells. We have previously shown the potential to enhance human bone marrow stromal cell (HBMSC) differentiation along the osteogenic lineage with 5-Aza-dC in monolayer as well as in pellet culture. Pellets were formed with 5 X 10^5 cells and cultured in plastic tubes. When HBMSCs were seeded on glass tubes, the cells formed, initially, a monolayer that subsequently formed into a sphere and resided on migration at the air-media interface. These self assembled pellets were 16 times larger than their comparable pellets cultured in the classical plastic tubes. Untreated pellets displayed distinct collagen I matrix formation corresponding to osteogenic matrix. Pellets formed with HBMSCs pretreated with 5-Aza-dC displayed significantly less collagen matrix and extensive von-Willebrand factor (vWF) expression. Extensive vWF immunostaining was observed in the pellets in particular within the centre of the pellet with what appeared a loose capillary network. This study demonstrates the induction of vWF in HBMSCs by 5-Aza-dC although the exact cell phenotype remains unclear. These HBMSC 3D pellets expressing vWF protein offer an interesting model to examine tissue development and factor screen/analysis on the production of vWF and cell differentiation. Although the precise mechanism of 5-Aza-dC induction in this process is unclear, these studies emphasis the importance f DNA methylation in cell function and the potential to harness the activity of epigenetic modifier in cell lineage determination and function.

CONGENITAL MALFORMATIONS IN PATIENTS OF THE TUNISIAN FANCONI ANEMIA REGISTRY

L Kammoun[1], Y Ben Youssef[2], T Kammoun[1], Y Ben Abdennebi[3], M Ouederni[4], S Hammami[5], L Torjemane[4], M Hachicha[1], S Mseddi[1], Tunisian Fanconi Anemia Study[1]
[1]Hedi chaker hospital, Sfax, Tunisia
[2]Farhat Hached Hospital, Sousse, Tunisia
[3]Aziza Othmena Hospital, Tunis, Tunisia
[4]Centre National de Greffe de Moelle Osseuse, Tunis, Tunisia
[5]Fattouma Bourguiba Hospital, Monastir, Tunisia

Background. Fanconi anemia (FA) is an autosomal recessive disorder characterized by congenital malformations, bone marrow failure and increased risk of development of leukemia and other malignancies. Birth defects are heterogeneous, affecting diverse systems of the body and especially the skin, the bones and the urinary tract. Thus, the patients display a wide variety of phenotype. Here, we report the frequencies of congenital abnormalities in FA patients of the Tunisian Fanconi Anemia Registry (TFAR). **Aims.** To analyse different malformations in FA patients in Tunisia. **Methods.** This study concerns the 174 patients included in the TFAR, from January 1984 until November 2011. We report frequencies of different congenital malformations in our FA patients. **Results.** Growth retardation was seen in 109 patients (62%). Skin abnormalities were present in 139 patients (80%): café-au-lait spots (64.3%), hyperpigmentation (51.1%), hypopigmentation (12%). Head was affected (microcephaly, microphtalmy, fine lines, triangular facies) in 137 patients (78%). Explorations of the urogenital system were done in only 55% of our patients. They detected anomalies in 80% of explored cases: ectopic kidney (41patients), single kidney (9 patients), horseshoe kidney (6 patients), ectopic testicle (7 patients), urinary tract (10 patients). 47% of our patients had bone abnormalities, affecting the thumb (30%), the other fingers and toes (15%). Congenital dislocation of the hip was found in 5 patients and spina bifida in one patient. Neurologic system involvement was seen in 4%, with mental retardation in 3%, hearing loss in 1%, strabism in 1%. Gastrointestinal system anomalies were reported in 2.8%. Endocrinopathies have concerned 2.4% of our FA patients. **Conclusions.** This retrospective study is one of the largest series of FA patients in the literature. Globally, the frequency of different malformations, here, approach that described in several studies. However, some congenital anomalies, reported in other series but not in our one, such as cardiac defects, must be more carefully searched by systematic exams. Recent standardization of FA patient support in Tunisia may help better analysis of these findings.

GENOMIC COPY NUMBER ALTERATIONS IN HIGH-RISK CLL PATIENTS HARBORING TP53 DEFECTS: INSIGHTS FROM CONSECUTIVE INVESTIGATIONS

K Plevova[1], J Malcikova[2], N Darzentas[2], S Pavlova[2], N Tom[2], K Pal[2], L Jurackova[1], B Tichy[2], Y Brychtova[1], M Doubek[1], J Mayer[1], M Trbusek[2], S Pospisilova[2]
[1]University Hospital Brno, Brno, Czech Republic
[2]Central European Institute of Technology, Masaryk University, Brno, Czech Republic

Background. In chronic lymphocytic leukemia (CLL), recurrent copy number alterations (CNAs) have been described (deletions of 13q14, 17p13 and 11q22, and trisomy 12), that are typically present in variable proportions of leukemic cells. Significantly, genomic lesions can accumulate during the disease course, which is evident when pre-treatment and relapse samples are compared. Among them, *TP53* defects (mutations/deletions), that are in general associated with genomic instability, are selected in approximately one-fifth of treated CLL patients with an originally intact gene. Taken together, these phenomena likely contribute to the chronic relapsing course of CLL and the development of chemotherapy resistance. **Aims.** Our study aimed to describe specific CNAs accompanying selection of *TP53* defects by therapy in CLL patients, and compare them to those present in patients having either wild-type (wt) *TP53*, or mutant (mut) *TP53* in all subsequent samples. **Methods.** Consecutive peripheral blood samples from 22 well characterized CLL patients (unmutated IGHV in 18/22 cases) were collected. Since therapy administration can facilitate expansion of more aggressive subclones in the disease relapse, samples separated by therapy were preferentially selected for the study. *TP53* mutations were identified by FASAY and direct sequencing. Genomic DNA (gDNA) was isolated from separated CD19+ or mononuclear cells and analyzed using Cytogenetics 2.7M Array (Affymetrix). Further data parsing, filtering, and mining were performed with in-house computer programming. Array results were compared to results of I-FISH and metaphase cytogenetics with CpG/IL-2 stimulation. **Results.** In total, 46 gDNA samples were analyzed (two or three consecutive samples in 20/22 and 2/22 patients, respectively). Median interval between the samplings was 24 months (range 9-55 months). Altogether, 18 wt-*TP53* and 28 mut-*TP53* samples were analyzed. Concerning a simple number of CNAs, no significant differences between wt- and mut-*TP53* samples were observed. It might be explained by the fact that majority of patients belonged to the high-risk CLL and, more importantly, that accumulation, but also elimination of CNAs was observed during the disease course. The original and follow-up *TP53* status was used to divide the patients into three groups: group A with wt-*TP53* in consecutive samples (3/22 patients), group B with mut-*TP53* in consecutive samples (8/22), and group C with selection of new *TP53* mutations after CLL therapy (11/22). Group C exhibited the most dramatic genomic changes. Specifically, del(17p) leading to complete inactivation of *TP53*, as well as del(4p), del(4q), del(6q), and del(13q) (including *miR-15-1/16a* and *RB1* genes) occurred frequently in this group. Interestingly, in this group we also noted recurrent vanishing of del(11q); the subclone was likely replaced by the one harboring *TP53* defect. In group B, only del(15q) appeared recurrently. **Summary**. Our gradual analysis catalogues the appearance, but also disapperance of recurrent CNAs during the disease course of CLL. In particular, selection of *TP53* defects after therapy seems to be accompanied by accumulation of specific CNAs in our patients. We assume that these CNAs potentially drive disease aggressiveness, whereas CNAs which appear as well as diminish likely do not play role in disease progression. *Supported by CZ.1.05/1.1.00/02.0068, CZ.1.07/2.3.00/20.0045, CZ.1.07/2.4.00/17.0042, MSM0021622430, MUNI/A/0784/2011, GACR204/09/H058.*

EARLY DETECTION OF MINIMAL RESIDUAL DISEASE DETECTION TARGETING CD160 IN CHRONIC LYMPHOCYTIC LEUKAEMIA PREDICTS PROGRESSION FREE SURVIVAL AND CORRELATES WITH BIOLOGICAL PROGNOSTIC RISK GROUPS

W Farren[1], M Fanous[2], F Liu[2], M Macey[3], M Jenner[3], S Agrawal[2]
[1]Queen Mary University of London, London, United Kingdom
[2]Academic Haematology Unit - Blizard Institute, QMUL, London, United Kingdom
[3]Department of Haematology, Barts and The London NHS Trust, London, United Kingdom

Background. The prognosis of patients diagnosed with chronic lymphocytic leukaemia (CLL) is highly variable. Prognostication is currently based on a number of clinical and biological factors. Minimal residual disease (MRD) detection during and post-therapy is emerging as a powerful predictor of outcome. **Aims.** This study utilizes a multi-parameter flow cytometric assay to evaluate the time toMRD detection and correlate this with established prognostic markers and event free survival (EFS). **Methods.** Utilizing the anti-CD160 monoclonal antibody (BY55, Coulter Immunotech, Marseille, France), we have developed a single tube, highly sensitive flow cytometric assay (CD160FCA) incorporating a sequential gating strategy. 97 patients were investigated for MRD and response rates and EFS (time to next therapy, intervention or death) were determined. The time to MRD detection post therapy was correlated with the prognostic indicators, ZAP-70, CD38, beta-2 microglobulin (b_2M) and cytogenetic abnormalities. **Results.** CD160FCA could be used to monitor patients for MRD, including post-immunotherapy with Rituximab and Campath. 220 samples were analysed. Of patients achieving a complete remission (CR) by current NCI guidelines, those with residual disease by CD160FCA (CR-CD160+) had significantly shorter EFS compared with CR-CD160 negative patients (532 days *vs* 1825 days, P<0.0001). Interestingly, those patients who achieved a partial remission (PR), but were MRD positive, had a shorter EFS versus PR-CD160 negative patients (365 days *vs* 669 days, P=0.039).Patients with known adverse risk factors had a significantly shorter time to disease detection (TTD) by CD160FCA: high b_2M (184 days *vs* B_2M normal 852 days), CD38 positivity (185 days *vs* 638 days) and ZAP-70 positivity (276 days *vs* 760 days). Patients with poor risk cytogenetics (17pdel: 90 days, 11qdel: 122 days) had significantly shorter TTD over those with intermediate cytogenetics (+12: 244 days) and those with good risk (13qdel: 761 days). Of interest those patients with biallelic 13q- had a significantly shorter TTD (151.5 days). **Conclusions.** Detection ofMRD using CD160FCA, a single tube, tumour specific multi-parameter flow cytomteric assay, can independently predictEFS irrespective of therapy given and clinical outcome stratification (CR or PR). Patients with adverse prognostic markers had a significantly shorter TTD over those with favourable ones. Detection ofMRD by CD160FCA offers a simple biomarker endpoint as a surrogate for response assessment in clinical trials and the intriguing possibility of targeting CD160 forMRD eradication using therapeutic anti-CD160 chimaeric antibodies under development.

[4]University of Tor Vergata, Rome, Italy
[5]University of Salerno, Salerno, Italy

Background. Regulatory T cells (Tregs) are increased in chronic lymphocytic leukemia (CLL) and correlate with clinical and biological features of active/progressive disease. However, little is known about a possible relationship between Tregs and the time to first treatment (TFT) in patients with early stage CLL. **Aims.** To investigate this specific topic, we conducted a prospective multicenter study in patients with Rai stage 0 CLL, in whom the absolute number of Tregs was determined at the time of diagnosis and correlated to main clinical and biological prognostic factors, as well as to the need of receiving any specific therapy for CLL during the course of the disease. **Methods.** Seventy-five consecutive and previously untreated patients with Rai stage 0 CLL (mean age 68 years; range 44-90 years; M/F ratio 1.2) were evaluated. Circulating Tregs were determined at the time of diagnosis by means of multidimensional flow cytometry (CD4-PerCP/CD25-PE-Cy7/CD127-PE/CD45-APC-Cy7). Tregs

were defined by the expression of CD4, CD25 at high density and CD127 at low density or undetectable levels. The absolute Treg cell count was calculated by multiplying their percentage value (of all lymphocytes) by the absolute lymphocyte number as provided by the hematology analyzer (dual platform approach). **Results.** After a median follow-up of 30 months, twelve patients (16%) needed therapy at some time from the diagnosis, according to IWCLL criteria (median time: 16 months; range 1-34 months). At baseline, age, gender, and LDH serum levels, as well as ZAP-70 and CD38 expression, were not statistically different between untreated and treated patient groups. By contrast, treated patients showed a higher number of total peripheral white blood cells and B-lymphocytes (p <0.001), lower hemoglobin values (p 0.015), higher platelet count (p 0.012), a greater number of cases with unmutated IgVH status (p 0.025) and a higher frequency of high risk cytogenetic abnormalities (p 0.05) than patients who did not need therapy. Of interest, a greater median number of circulating Tregs (n. 79, range 35 - 112) was detected at diagnosis in treated patients, with respect to patients who did not receive therapy during the observation period (n. 30, range 5 - 54) (p<0.001). Multivariate analysis confirmed that the absolute number of Tregs was the only independent predictor of TFT in these patients (p<0.001), the best predictive cut-off (ROC analysis) being 41/µL. **Conclusions.** Our data show that an increased absolute number of Tregs found at diagnosis may be predictive for a shorter TFT in low risk, Rai stage 0 CLL patients.

[5]Department I of Internal Medicine and Center of Integrated Oncology Cologne Bonn, Bonn, Germany
[6]Klinik für Innere Medizin III, University hospital Ulm, Ulm, Germany

Background. Chemokines and cytokines are an integral part of the CLL specific tumor microenvironment. The exact biological role of cytokines and chemokines needs to be defined, especially in the light of distinct prognostic and biological subgroups of patients. **Aims.** To characterize chemokines and cytokines of the CLL microenvironment in more detail and to evaluate their impact on prognosis. **Methods.** Serum levels of chemokines and cytokines in a prospective cohort of 157 previously untreated Binet stage A patients (pts) from the CLL1 trial of the German CLL Study Group (GCLLSG) were measured. Serum samples had been centrally collected at study entry and stored at -80°C and were analyzed on a luminex-based multiplex platform, allowing simultaneous screening of 27 chemokines and cytokines. Median survival time was 83 months. For all serum parameters univariate and multivariate analyses were performed for progression-free and overall survival. Association with established risk parameters, like high leukocyte counts, FISH cytogenetics, IgHV status was evaluated. In addition, hierarchical clustering was used to identify sets of cytokines whose expression levels correlated among individual patients. **Results.** High CCL3 levels strongly correlated with high CCL4 levels (p<0.001) and tended to be associated with unmutated IgHV status (p=0.06), supporting the role of BCR triggering in biologically selected CLL pts. Serum levels of CCL2 and CCL17, both binding chemokine receptor CCR4, were concordantly elevated compared to healthy controls (p<0.001), suggesting a possible role of chemoattraction of CCR4+ T cells towards these chemokines in CLL. Pts with high serum levels of CCL21 had higher levels of CXCL10 (p<0.001) and CXCL12 (p=0.02). Elevated VEGF levels were strongly associated with elevated EGF level (p<0.001). High VEGF levels correlated with high white blood cell counts (p=0.008) and showed a trend towards association with del(11q) (p=0.07). Hierarchical clustering analysis divided the patient cohort into two distinct subgroups. Serum levels of EGF, TNFalpha, VEGF, CCL2, CCL3, CCL4, CCL21, and Il16 were significantly higher in Cluster 1 as compared to Cluster 2 (p<0.003, adapted for multiple testing). There was no difference in progression-free survival and overall survival between the two groups.High sIl2Ralpha levels were associated with decreased PFS and OS. These results could be confirmed by conventional ELISA. Mean estimated OS survival in pts within the highest quartile of sIl2Ralpha levels was 98 months compared to 111 months in the lower three quartiles (p=0.002). For PFS, but not for OS sIl2Ralpha could be identified as an independent prognostic factor. (HR 2.5, 95% CI 1.4-4.8, p=0.004). **Summary and Conclusions.** Patients in Binet stage A CLL can be classified into two subgroups with distinct chemokine and cytokine expression profiles. Median serum levels of different chemokines correlated with distinct biological characteristics of CLL patients, like genetic abnormalities or clinical parameters. sIl2Ralpha could be identified as an independent prognostic variable for PFS in early CLL.

CLONAL DIVERSITY OF THE T CELL REPERTOIRE IN CHRONIC LYMPHOCYTIC LEUKAEMIA ASSOCIATES WITH STEREOTYPY PREDICTS DISEASE PROGRESSION

A Egle, C Holler, N Zaborsky, J Pinon-Hofbauer, T Kocher, D Trapin, D Asslaber, R Greil
University Hospital Salzburg, Salzburg, Austria

Introduction. Antigenic selection in chronic lymphocytic leukaemia (CLL) is evidenced by a skewed BCR repertoire and continuing BCR signaling detected in subgroups of CLL. Evidence for a possible T cell involvement in maintaining the clone includes severe skewing of T cell subsets and the involvement of CD4 cells in so-called “proliferation centers”in lymph nodes. However, to date clonal or immunologic identities of these T cells are unclear. In Tcl1 transgenic mice we recently showed that CLL clones can drive changes in the T cell repertoire. Significant changes in subset distribution and clonal selection of T cells was apparent in murine CLL. **Methods.** We aimed to establish evidence for clonal T cell skewing in peripheral blood from human CLL. In 53 previously-untreated patients were characterized regarding BCR V gene usage, mutation status and clinical parameters. TCR V beta clonality in sorted CD4 cells was analysed by CDR3 length polymorphism in 20 TCR genes and by TCR V gene-specific flow cytometry in a subset. **Results.** BCR analysis showed that 10 IgVH V-genes accounted for > 75% of the cases. Stereotyped CDR3 regions were present in 41% of cases and 25% of the patients showed unmutatetd VH gene sequence. TCR CDR3 size distribution patterns showed heterogeneity of monoclonal CD4 T cell patterns between patients. While about half of the patients showed polyclonal patterns in all their TCR CDR3 regions, the others showed single or multiple clonal TCR families. Corresponding flow cytometric analyses showed sizeable T cell clones between 5 and 48% of total CD4 cells. In patients with longitudinal samples relevant stability of TCR patterns could be observed over time. As a control, TCR clonalities were not significantly associated with CMV serostatus in patients.Next we compared the TCR clonality database with established BCR characteristics. No strong association between mutation stae and clonality was observed. Overall we found no strong association with any specific IgVH gene, but intriguingly, we found a significant difference in the clonal T cell frequencies between stereotyped and non-stereotyped CLL. This difference was very prominent looking at the unmutated cases only (p<0.001), with unmutated stereotyped CLL displaying practically no T cell clonalities. Since stereotyped CLL has been speculated to be a B1 cell equivalent and murine B1 cells are prototypically T cell independent, our finding may suggest a different immunologic network driving stereotyped and non-stereotyped CLL. Functional studies to test the effects this difference *in vitro* are under way. Finally, analysed the influence of T cell clonality on clinical behaviour of CLL disease. The presence of more than one clonal TCR family was a significant predictor of a short treatment-free interval (p=0.03). This was true for both, patients with mutated and unmutated IgVH receptors, although it remained a trend in the latter. **Conclusions.** Our results suggest that a restricted CD4 T cell diversity could be important for CLL progression and that there are differences in the recruitment of clonal T cells between CLL of stereotyped and non-stereotyped origin.

0720

IS THERE A ROLE FOR BONE MARROW BIOPSY EXAMINATION IN THE DIAGNOSTIC WORK-UP OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? A REAPPRAISAL IN THE ERA OF BIOLOGICAL PROGNOSTIC MARKERS

P Baliakas[1], G Kanellis[2], N Stavroyianni[1], E Stalika[1], M Fameli[2], A Athanasiadou[1], C Vadikolia[1], C Lalayanni[1], R Saloum[1], C Belessi[1], K Stamatopoulos[1], A Anagnostopoulos[1], T Papadaki[2]
[1]G. Papanicolaou Hospital, Thessaloniki, Greece
[2]Evangelismos Hospital, Athens, Greece

According to the iwCLL/NIH guidelines for the diagnosis and treatment of CLL, bone marrow biopsy (BMB) is no longer considered as mandatory at

diagnosis and only recommended for the evaluation of cytopenias of unknown cause, before the initiation of treatment and for assessing response after treatment for patients enrolled in clinical trials. Though practical, this approach hinders the understanding of tumor dynamics within the compartment where the clonal B cell population may arise. Herein, we present the results from the multidisciplinary examination of diagnostic BMB samples from a series of 159 unselected CLL cases. The patient group included 96 males and 63 females with a median age of 64 years (range, 26-84). Most CLL patients were at early clinical stages (only 36/159 cases in Binet stages B/C). Our analysis confirms and significantly extends previous observations regarding the favorable impact of the nodular pattern of neoplastic lymphocytic infiltration (NLI) of the BM. In particular, it indicates a biological sub-context by showing that a nodular infiltrative component is significantly associated with mutated IGHV genes. In the vast majority of cases, the neoplastic population consisted almost exclusively of small, "well-differentiated"lymphocytes. Medium- or large-sized cells were admixed in 4 and 1 cases, respectively. Finally, 8 and 3 cases exhibited lymphoplasmocytoid and plasmacytic differentiation, respectively, as confirmed immunohistochemically by cytoplasmic monoclonal immunoglobulin of the same isotype as the bulk of the NLI. Interestingly, 34/159 cases (21%) showed a NLI of less than 30%. Though the possibility of sampling-related issues cannot be a priory discredited, this finding might reflect a focal pattern of BM infiltration or, alternatively, a distinctive compartmentalization of the neoplastic clone. In keeping with previous reports, the extent of BM involvement was also found to be prognostically relevant, since cases with less than 30% NLI of the BM exhibited longer time-to-first treatment, independently of IGHV gene mutational status. Regarding the hematopoietic marrow, 82 cases showed hyperplastic granulocytic series with a shift to the left and, occasionally, concomitant dysplastic changes of the mature forms. Hyperplasia of the erythroid and megakaryocytic series largely in a context of normal or decreased hemoglobin levels and platelet counts was observed in 97/157 and 121/158 cases, respectively. Most cases with erythroid and/or megakaryocytic hyperplasia exhibited dyserythropoiesis and dysmegakaryopoiesis. In such cases, CD34+ cell counts were always below 2%. In conclusion, we confirm that BMB examination permits identification of the rare CLL subtypes with lymphoplasmocytoid or plasmacytic differentiation. More importantly, on the evidence presented here, BMB examination offers important information not only for diagnostic purposes but also for elucidating CLL pathobiology, e.g. by pointing to CLL-associated hematopoietic autoimmunity even in patients with no cytopenias at diagnosis. By logical extension, it is expected to contribute to unraveling the mode of action of novel therapies which target the interaction of CLL cells and their (micro)environment.

0721

THE CLINICALLY ACTIVE BTK INHIBITOR PCI-32765 TARGETS B-CELL RECEPTOR- AND CHEMOKINE-CONTROLLED ADHESION AND MIGRATION IN CHRONIC LYMPHOCYTIC LEUKEMIA

M de Rooij
AMC/UvA, Amsterdam, Netherlands

Background. Several novel small molecule drugs targeting the B-cell antigen receptor (BCR) signalosome have recently demonstrated promising efficacy in the treatment of B-cell non-Hodgkin lymphoma. Most of these agents, including the BTK inhibitor PCI-32765, display an unexpected clinical response in chronic lymphocytic leukaemia (CLL): a rapid and sustained reduction of lymphadenopathy accompanied by transient lymphocytosis, which is reversible upon temporary deprivation of the drug. We have previously demonstrated that the B-cell antigen receptor (BCR) controls integrin $\alpha_4\beta_1$-mediated adhesion of B cells to fibronectin and VCAM1, which is mediated by Bruton's tyrosine kinase (BTK). More recently, we have shown that also chemokines induce activation of BTK and that integrin-mediated adhesion and migration in response to CXCL12 or CXCL13, as well as *in vivo* homing to lymphoid organs, is impaired in BTK-deficient B cells. **Aims.** We hypothesized that the clinical response observed upon PCI-32765 treatment reflects attenuated lymph node and bone marrow homing and retention of the CLL cells, due to impaired BCR- or chemokine-controlled integrin-mediated adhesion or migration. **Methods.** The Burkitt lymphoma cell line Namalwa or primary patient CLL cells, pretreated with PCI-32765, were allowed to adhere to either fibronectin- or VCAM-1-coated surfaces in the presence of anti-IgM, PMA, or chemokines (CXCL12, CXCL13 or CCL19), or were allowed to migrate towards these chemokines in VCAM-1-coated Transwells, **Results.** We found that PCI-32765 strongly inhibits BCR-controlled signaling and integrin $\alpha_4\beta_1$-mediated adhesion to fibronectin and VCAM-1, both in Namalwa and primary CLL cells. Furthermore, PCI-32765 also inhibits CXCL12-induced signaling and CXCL12-, CXCL13- and CCL19-induced adhesion and migration of primary CLL cells. **Conclusions.** Our data indicate that inhibition of BTK by PCI-32765 overcomes BCR- and chemokine-controlled homing and retention of the malignant B cells in their growth- and survival-supporting microenvironment, resulting in clinically evident CLL regression (Figure 1).

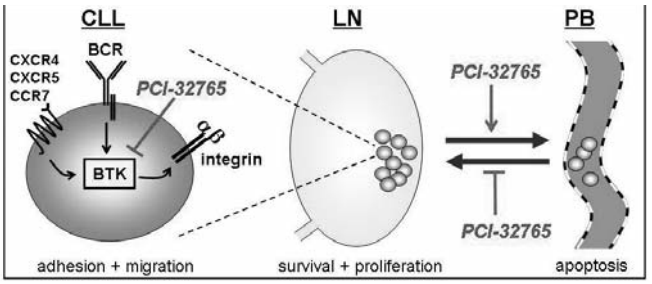

Figure 1. Inhibition of BTK impairs BCR-controlled integrin-mediated adhesion and chemokine-induced adhesion and migration of CLL cells.

0722

MAPPING THE TARGETS OF DASATINIB IN CHRONIC LYMPHOCYTIC LEUKEMIA; DISTINCT ROLES FOR ABL AND BTK IN DRUG RESISTANCE AND ADHESION/MIGRATION

E Eldering[1], C Geest[1], M de Rooij[1], N Liu[2], B Florea[2], H Overkleeft[2], M Spaargaren[1], A Kater[1]
[1]Academic Medical Center, Amsterdam, Netherlands
[2]Leiden University, Leiden, Netherlands

Background and Aims. Chronic lymphocytic leukemia cells in the protective lymph node (LN) microenvironment are chemoresistant due to upregulation of Bcl-XL, Mcl-1 and Bfl-1. In vitro, this can be mimicked via CD40-stimulation of CLL cells, which affords resistance to various chemotherapeutics. Novel drugs that target kinases involved in B cell signaling are currently in clinical development for CLL. We showed previously that Dasatinib, a broad spectrum inhibitor that targets Abl- and Src-family kinases, prevented CD40-mediated anti-apoptotic changes in CLL, and restored drug sensitivity. Here, we coupled Dasatinib to an affinity matrix and characterized its spectrum of targets in CLL. **Methods and Results.** Using pull-down, Abl and Btk were identified as specific targets of Dasatinib upon CD40 triggering. Functionally, Abl was mainly responsible for conferring drug resistance, while Btk mediated adhesion/migration to attach CLL cells in the LN. Additional kinases were identified by mass spectrometry and included 8 known targets of Dasatinib (e.g. Lyn, Fyn, Yes) and 7 CLL-specific kinases. These will be studied further for their contribution to drug resistance, apoptosis and adhesion/migration. **Conclusions.** By mapping the contribution of all kinases targeted by Dasatinib, this study highlights the crosstalk between BCR and CD40 pathways in CLL and may result in new therapeutic strategies.

0723

COMPARATIVE GENE EXPRESSION ANALYSIS PROVIDES NOVEL THERAPEUTIC TARGETS IN CLL

R Cordoba[1], B Herreros[2], E Domenech[2], M Rodriguez[2], C Blanco[2], C Gomez-Abad[2], J Delgado[3], J Garcia-Marco[4], J Garcia[5], J Martinez-Lopez[6], A Rodriguez[6], J Bischoff[2], M Sanchez-Beato[2], M Piris[2]

[4]Hospital Puerta de Hierro Majadahonda, Madrid, Spain
[5]MD Anderson International, Madrid, Spain
[6]Hospital Doce de Octubre, Madrid, Spain

Background. The different clinical and biological prognostic markers validated are not capable of explaining the pathogenesis of the CLL and the implication in the development of the disease is still under investigation. The identification at the molecular level of new variables thanks to massive analysis of gene expression profiles can contribute to a better knowledge of the pathogenesis of the disease, to the development of new prognostic factors, fit the treatment on the basis of the specific risk and the identification of new therapeutic targets. **Aims.** Identify a molecular signature which lead to find new therapeutic targets in CLL. **Methods.** Thirty-eight CLL lymph node samples were analysed and compared with normal lymph nodes in order to find differential gene expression profiles signatures. cRNA hybridization was performed in Agilent 44K microarrays. The arrays were scanned with a G2565BA microarray scanner system. After data normalization and preprocessing, data were

analysed with bioinformatic tools provided by Babelomics. Self-organising tree algorithm (SOTA) was use for hieralchical clustering. Clinical and biological markers were obtained from patients enrolled in the study. **Results.** Two molecular subtypes were identified, with 1092 genes with differential expression between both groups, with a fdr<0,05. After Gene Set Enrichment Analysis (GSEA), 4 molecular parhways were enriched in group A and 1 molecular pathway in group B, with a FDR q value <0,25. Group A pathways were IL12, ILR1, IL5, TALL1 and Group B pathways were CDK5. No difference in Treatment-Free, Progression or Overall Survival were observed between both group of patients. When compared CLL samples with reactive lymph nodes, 1178 genes showed differential expression pattern with a fdr<0,05. After Gene Set Enrichment Analysis, BCR molecular parhways was the only pathway with enrichment in CLL samples, whereas Germinal Genter and Stromal Germinal Center were enriched in normal lymph nodes, with a FDR q value <0,25. **Conclusions.** Despite molecular heterogeneity of CLL, we have not found a prognostic molecular signature. However, we have observed different molecular profiles which may lead to find therapeutic target in subgroups of patients and receive a personalised medicine.

0724

HDAC ISOENZYME EXPRESSION IS DEREGULATED IN CHRONIC LYMPHOCYTIC LEUKEMIA B-CELLS AND HAS A PROGNOSTIC SIGNIFICANCE

M Van Damme[1], N Meuleman[1], P Mineur[2], D Bron[1], L Lagneaux[1], B Stamatopoulos[1]
[1]Jules Bordet Institute (ULB), Brussels, Belgium
[2]Grand Hôpital de Charleroi, Gilly, Belgium

Background. Increasing evidences have highlighted the role of epigenetic modifications such as histone acetylation in the development of human cancer. Indeed, histone deacetylases (HDACs) including Sirtuins (SIRT) play an important role in transcriptional regulation by changing the chromatin structure and their deregulation has been reported in various cancers including hematological malignancies. **Aims**. In this context, we performed a complete and comprehensive study of the 18 HDACs (HDAC1 to 11 and SIRT 1 to 7) isoenzyme expression in Chronic Lymphocytic Leukemia (CLL) B-cells. **Methods.** In the present study, HDAC expression was quantified by real-time PCR on RNA extracted from purified CD19+ cells in a cohort of 200 CLL patients with a median follow up of 74 months and compared to that of peripheral blood B cells obtained from 20 age-matched healthy volunteers. The expression of the 18 HDACs was thereafter correlated to various classical prognostic factors and to treatment and survival data. **Results.** Comparison with peripheral normal B cells showed that HDAC2 (fold: -1.75) and SIRT4 (-2.78) were statistically downregulated while HDAC6 (+1.83), HDAC7 (+2.80), HDAC11 (+2.18), SIRT3 (+1.54), SIRT6 (+1.31), and SIRT7 (+1.43) were upregulated in CLL samples (P<0.05). When we compared the expression of all HDACs in different prognostic subgroups based on well-known prognostic factors (IgVH status, ZAP70, LPL, CDC38), no differential expression was found. Taken individually HDAC6 was significantly correlated with treatment-free survival (TFS) and HDAC3, SIRT2, 3 and 6 with overall survival (OS) but the P_{value} has a borderline significance. However, a multivariate Cox regression stepwise analysis indicated that HDAC6, 7, 10 and SIRT3 were independent prognostic factors (hazard ratio - HR - ranging from 0.39 to 1.95). Therefore, these factors were combined in a HDAC score (from 1 to 4 poor prognostic markers) that allows best treatment risk stratification: patients with a score of 1-2, 3 and 4 had a median TFS of 107, 57 and 26 months respectively (HR=4.23, P<0.0001). For OS, only SIRT2 is an independent predictor dividing patient in 2 groups with median OS of >360 and 237 (HR=0.39, P=0.0110).

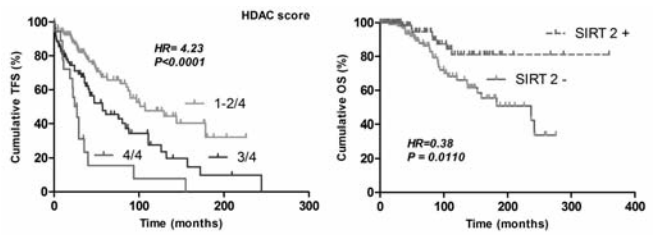

Figure 1. Prognostic significance of HDACs.

Conclusions. HDAC expression is clearly deregulated in CLL cells when compared to normal controls but no correlation between HDAC expression and classical prognostic factors was observed. However, a score combining HDAC6, 7, 10 and SIRT3 is a strong TFS predictor indicating that more than one HDAC had influence on the need of treatment while only SIRT2 is a significant predictor of OS. Interestingly, poor prognosis could be associated to an overexpression (HDAC7 and 10) or an underexpression (HDAC6, SIRT2 and SIRT3) of these isoenzymes.

0725

THE CDK INHIBITOR CR8 DIMINISHES NFβB ACTIVITY IN PRIMARY CLL CELLS

E Cosimo[1], A McCaig[1], O Middleton[1], H Wheadon[1], M Leach[2], A MMichie[1]
[1]University of Glasgow, Glasgow, United Kingdom
[2]Department of Haematology, West of Scotland Cancer Centre, Glasgow, United Kingdom

Background. Chronic lymphocytic leukaemia (CLL), often diagnosed in the elderly, is incurable with current therapeutic regimes. Recent studies have demonstrated that the microenvironment within lymphoid organs has a pro-survival effect on CLL cells, resulting in chemotherapy resistance. Novel therapies capable of overcoming such cytoprotective signals are therefore crucial. CLL cells exhibit constitutively active NFκB signalling, particularly in the lymph nodes (LN) microenvironment. Furthermore, the activation of Rel A (an NFκB transcription factor family member) acts as an independent poor prognostic marker for CLL. Therefore, inhibitors that target this pathway will greatly assist in the eradication of chemoresistant CLL cells. Recent findings indicate that cyclin-dependent kinase (CDK) inhibitors, which downregulate the levels of the anti-apoptotic Mcl-1 (a protein that plays a significant role in promoting the chemoresistance of CLL cells), can also inhibit NFκB signalling in T cells and myeloid leukaemia cell lines. **Aims.** This study was conducted to determine the mechanisms and the levels of inhibition of NFκB signalling by the Roscovitine analogue CR8 in primary CLL cells**. Methods.** Primary CLL cells were cultured in an *in vitro* co-culture system that closely replicates the LN microenvironment, and activates NFκB-mediated signalling pathways. Gene expression analysis was conducted by quantitative RT-PCR. Protein analysis was performed by western blotting. Nuclear Rel A activity levels in CLL cells were measured utilising an ELISA-based technique. **Results.** Our data establish that CR8 reduces transcriptional levels of NFκB family members (*REL*, *RELA*, *RELB*, *NFκB1* and *NFκB2)*, as a result of an inhibition of CDK9-dependent RNA polymerase II activity. CR8 treatment of CLL cells also stabilised the expression of IκBα, the cytoplasmic NFκB repressor, resulting in an inhibition of nuclear Rel A activity. These events resulted in the downregulation of the NFκB target gene cFLIP in CLL cells. **Conclusions.** Collectively, our study establishes that CDK inhibitors have the capacity to target key pro-survival microenvironmental signals that are generated in patient LNs both at a transcriptional level and by inhibiting NFκB DNA binding activity. This highlights the central role that these inhibitors could play as novel therapies to overcome CLL chemoresistance.

AMONG VEGF RECEPTORS, THE NEUROPILIN-1 (NRP-1) REPRESENTS PROMISING, NOVEL TARGET FOR CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

A Piechnik[1], M Zajac[1], P Wlasiuk[1], A Dmoszynska[2], L Bullinger[3], K Giannopoulos[1]
[1]Department of Experimental Hematooncology,Medical University of Lublin, Lublin, Poland
[2]Department of Hematooncology Medical University of Lublin, Lublin, Poland,, Lublin, Poland
[3]Department of Internal Medicine III, University of Ulm, Ulm, Germany

Background. Angiogenesis might substantially contribute in the progression of chronic lymphocytic leukemia (CLL).VEGF bounds 3 types of ligands VEGFR1(Flt-1), VEGFR2(Flk-1/KDR), VEGFR3(Flt-4), exerting tyrosine kinase activity and two non-enzymatic receptors (neuropilin-1 and -2). Neuropilin - 1 (NRP-1) represents a receptor for VEGF, which has been reported to be overexpressed in several malignancies. NRP-1 expression was also found on plasmacytoid dendritic cells (PDC) as well as on regulatory T cells (Tregs). Both, PDC and Tregs represent cells that are involved in tolerance mechanisms. Thus, in addition to its role in angiogenesis, NRP-1 might be involved in tumor escape mechanisms, and expression of NRP-1 on tumor cells, Tregs and PDC might point to a promising target for therapy. **Aims.** In our study, we characterized mRNA levels of VEGF receptors including NRP-1 in a large cohort of CLL patients. Next the detailed characterization of NRP-1 on the surface level was performed. In functional studies the regulation of NRP-1 by VEGF was assessed. **Methods.** qRT-PCR was performed for the Flt-1, KDR, NRP-1 and FOXP3 (forkhead box P3) in 114 CLL patients. For characterization of the sur-

face expression of NRP-1 on leukemic B-cells, PDCs and Tregs in a group of 38 CLL patients and 7 healthy volunteers (HVs) by five parameter flow cytometric analysis was used. In functional studies, magnetically separated leukemic cells from 8 CLL patients were cultured with different VEGF concentrations and analyzed with flow cytometric afterwards. **Results.** The expression of NRP-1 on leukemic lymphocytes was significantly higher compared to NRP-1 expression on lymphocytes derived from HVs, with median of 22.72% vs 0.2%, p=0.0003. The median expression of NRP-1 on Tregs was 42.6 %. NRP-1 was expressed on almost all PDC with median expression 100%. While VEGF levels of 0.1 - 0.5ng/ml, which are in the range of VEGF concentration observed in CLL patient samples, effectively induced expression of NRP-1, higher VEGF concentrations inhibited NRP-1 expression. In a greater cohort of 114 patients, we observed correlation between Flt-1, NRP-1 and FOXP3 expression (r^2=0.53, p<0.0001 and r^2=0.49, p<0.0001, respectively). In the group with unmutated *IGHV* status the median expression of NRP-1 was 0.074 (p=0.02), in the group with mutated *IGHV* status we observed higher expression of NRP-1 (median 0.081). In patients without KDR expression we found higher level of FOXP3 compared to patients with expression of KDR (p=0.008). **Conclusions.** In conclusion, we found NRP-1 expression on CLL cells, and for the first time demonstrated that CLL derived Tregs as well as PDC also express NRP-1. Furthermore, our data provide evidence that NRP-1 expression might be regulated by VEGF levels in CLL. Thus, NRP-1 might represent an interesting link between angiogenesis and tolerance mechanisms. This functional link was confirmed by the correlations between expression levels of certain VEGF receptors and FOXP3 in a greater cohort of CLL patients. Therefore NRP-1 might represent an interesting molecule for therapy of CLL since it could target both leukemic cells as well as Treg and PDC cells responsible for escape of tumor cells from the immunosurveillance.

CD200 EXPRESSION BY FLOW CYTOMETRY ACCURATELY DISCRIMINATES BETWEEN MANTLE CELL LYMPHOMA AND CHRONIC LYMPHOCYTIC LEUKAEMIA

A Catherwood[1], S Treacy[2], R Beattie[1], B Lundy[1], E Arnold[1], R Cuthbert[1]
[1]Belfast City Hospital, Belfast, United Kingdom
[2]University Of Ulster, Coleraine, United Kingdom

Chronic Lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL) are CD5+ chronic lymphoproliferative disorders (CLPDs) that share many features. A differential diagnosis between CLL and MCL is vital due to their divergent clinical courses. The differential diagnosis is aided by immunophenotyping using markers such as CD23, FMC-7 and CD79b. A transmembrane protein, CD200, belonging to the immunoglobulin superfamily is expressed on resting and activated T and B cells, but not on NK cells, monocytes, granulocytes or platelets. It has been suggested to play a role in the differential diagnosis of these two diseases, although its expression in cases of monoclonal B cell lymphocytosis (MBL) and small lymphocytic lymphoma (SLL) has yet to be ascertained.The aim of this present study was to assess both the gene and protein expression of CD200 in a series of CLPDs. **Methods.** We assessed the expression of CD200 by RQ-PCR and flow cytometry. CD19+ lymphocytes were purified from peripheral blood (PB) of CLL patients (Miltenyi-autoMACS). Gene expression of CD200 was assessed using RQ-PCR. The expression of CD200 was assessed using MRC OX-104 (BD) on neoplastic cells from CLPD cases using flow cytometry. **Results.** There were 116 patients included in the study which consisted of: CD5 negative CLPD (HCL, MZL, FL), (n=22), MCL (n=23), CLL (n=58), MBL (n=10) and SLL (n=3).Relative quantification of CD200 mRNA expression was also carried out by RQ-PCR. Gene expression, reported as a fold change from CD19 positive normal donors showed no significant differences between CLL and MCL cases. CD200 was expressed on all CLL patients (CD200 mean=89%), MBL (63%), SLL (95%) and in all 23 MCL patients (3%) CD200 was negative. Twenty-two patients had CD5 negative CLPD (CD5- CLPD) with variable expression of CD200, with positivity observed in cases of HCL and MZL. The positive predictive value of CD200 for CLL was 97.5% with a sensitivity of 100% and a Pearson's correlation coefficient of 1. **Conclusions.** Our results confirm CD200 expression in the neoplastic cells of CLL patients but not in MCL. This expression is controlled at the translational level as no significant differences existed when CD200 gene expression was compared between MCL and CLL cases normalized to CD19 positive controls.Our results also demonstrate that the antigen was expressed in the neoplastic cells of MBL and SLL patients. Our findings also confirm previous reports of CD200 positivity in CD5- CLPD such as HCL and MZL.We suggest that CD200 should be included in routine flow panels to differentiate between MCL and CLL cases

TELOMERES SHORTEN DURING CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) EVOLUTION: AN ANALYSIS ON 88 CASES

E Genuardi[1], E Bernocco[1], D Rossi[2], C Lobetti-Bodoni[1], P Ghione[1], R Bruna[1], D Drandi[1], M Coscia[1], M Ruggeri[1], M Fangazio[2], L Monitillo[1], D Barbero[1], B Mantoan[1], S Barbiero[1], M Zanni[1], V Gattei[3], L Bergui[1], P Omedè[1], M Massaia[1], M Boccadoro[1], G Gaidano[2], M Ladetto[1]
[1]Division of Hematology, A.O.U. San Giovanni Battista, University of Torino, Torino, Italy
[2]Division of Hematology, BRMA-Amedeo Avogadro University of Eastern Piedmont, Novara, Italy
[3]Division of Hematology CRO, Aviano, Italy

Background. Telomere length (TL) at diagnosis has been established as an independent outcome predictor in CLL (Rossi, Leukemia 2009). However data on TL dynamics over time are scant and anedoctal. **Aims.** Aim of this study was to evaluate telomere dynamics in the natural history of CLL. This issue has been here addressed on a series of 88 CLL patients (pts).**Methods:** 25 pts were assessed for TL at diagnosis and at relapse and 63 pts had two determinations during the 'watch and wait' (WW) phase. The series was characterized in terms of Binet stage, ALC, CD38, ZAP-70, IGHV mutational status (IGHV-MS), stereotyped receptors, cytogenetics and clinical history. LDH, B2-microglobulin, p53 mutations and CD49d were available in more than 70% of pts. TL was analyzed as previously described (Rossi, Leukemia 2009; Ladetto, Blood 2004). Median time between TL determinations was 44 months (range 12-231). Telomere loss was calculated in terms of absolute loss (AL) and yearly loss (YL). Continuous variables were compared by the Mann-Whitney test, while TFS by the stratified Kaplan-Meyer method. **Results.** Telomeres were shorter at follow-up compared to baseline (median loss of 651bp, range +493bp, -5874bp; p<0.001) (Fig 1A). AL and YL were greater in cases with higher baseline TL, while those with short telomeres at diagnosis had only modest additional erosion (p=ns for pts in the 25th lowest percentile) (Figure 1B). Telomere loss over time was noticeable both in pts assessed at diagnosis and at relapse as well as in those assessed during the WW phase, but clearly inferior in the former subgroup (YL of -61bp, p<0.05 and -210bp, p<0.01), possibly due to the higher number of patients with short telomeres. AL and YL did not correlate with any available clinical or biological parameter, with the exception of a positive association with IGHV-MS (p<0.05). Considering the sole WW population, with a clinical follow up of 78 months and a median TFS of 43 months, pts with baseline TL shorter than the validated cut-off value of 5000bp (Rossi, Leukemia 2009) had an inferior TFS (median TFS 41 vs 182 months; p<0.0001) as expected. Binet status and IGVH-MS were also predictive for TFS in this series. Surprisingly, also an YL above the median value (-210bp) appeared to be predictive for an inferior TFS (median TFS 82 vs 182 months; p<0.05) (Figure 1C). Following stratification of pts according to baseline TL (< or > 5000bp), YL was predictive for TFS in patients with long and stable telomeres (Figure 1D). **Conclusions.** The results of the first systematic analysis on TL dynamics in CLL indicate the following: i) progressive telomere erosion occurs as part of the natural history of CLL; ii) telomere loss is more pronounced when baseline TL is higher; iii) accelerated telomeric loss associates to an inferior TFS. The results described in the present analysis corroborate basic studies suggesting that telomere disruption represents a critical step associated to CLL progression.

CD80 AS A TARGET OF MIR-146 IN CHRONIC LYMPHOCYTIC LEUKEMIA ASSOCIATED WITH AUTOIMMUNE HEMOLYTIC ANEMIA

G Ferrer[1], A Navarro[2], R Tejero[2], T Baumman[1], M Monzo[2], C Moreno[3], E Montserrat[1]
[1]Hospital Clinic, Barcelona, Spain
[2]University of Barcelona, Barcelona, Spain
[3]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background. CD80 is a protein found on activated B cells and monocytes that provides a costimulatory signal necessary for T cell activation and survival. CD80 is the ligand for two different proteins on the T cell surface: CD28 (for autoregulation and intercellular association) and CTLA-4 (for attenuation of regulation and cellular disassociation). MicroRNAs (miRNAs) are small non-coding RNAs that negatively regulate mRNA translation and play an important regulatory role in most biological processes. We have previously shown that chronic lymphocytic leukemia (CLL) associated with autoimmune hemolytic anemia (AIHA) presents a distinctive miRNA signature, including a downregulation of miR-146b, which has been related to CLL and autoimmunity. **Aims.** The main objective of this study was to determine targets of miR-146 that can play a role in the the development of AIHA in CLL patients. **Methods.** Using Tarbase, a bioinformatic tool, we identified the putative targets of miR-146, including CD80. Two cell lines (HDMYZ and Ramos) were transfected with 1µg of modified psiCHECK-2 vector, which contains a fragment where miR-146 binds of the 3'UTR region of CD80, plus 200nM of pre-miR-146 or a pre-miR-negative control. Renila/luciferase luminescence was evaluated with the Dual Luciferase Promega kit. In order to examine the effect of miR-146 on protein levels, cells were transfected with 200nM pre-miR-146 or negative control, and CD80 levels on cell surface were evaluated by flow cytometry. CD80 was also evaluated on cryopreserved cells from five patients with CLL associated with AIHA and twelve with CLL not associated with autoimmunity. **Results.** Renila/luciferase levels were lower in both the HDMYZ and Ramos cell lines after transfection with pre-miR-146 than in cell lines transfected with the negative control (72.3 % and 80.4%, respectively) (Figure 1A). Although HDMYZ cells normally express low levels of CD80, we observed a 3.7% reduction of positive cells in HDMYZ cells transfected with pre-miR-146 compared to those transfected with the negative control (14.0% vs. 17.7%, respectively; p=0.015). After transfection with pre-miR-146, Ramos cells also showed a reduction of CD80+ cells (28.7% vs. 41.3%; p=0.020) (Figure 1B). Finally, patients with CLL associated with AIHA had higher levels of CD80 than those without autoimmunity (13.4% *vs.* 9.3% respectively; p=0.027). **Conclusions.** CD80 is a target of miR-146, which may account for the increased levels of CD80 in CLL associated with AIHA. Further analyses are warranted to ascertain the role of CD80 and miR-146 in B-/T-cell synapse in CLL associated with AIHA.

Background. CD200 is an immunoglobulin superfamily membrane glycoprotein widely expressed in multiple cell types. Its expression has been reported in non-hematological malignancies and also in some hematological diseases. Recent studies have demonstrated that CD200 expression may be helpful in the differential diagnosis of chronic lymphocytic leukemia (CLL) and mantle cell lymphoma (MCL). **Aims.** To analyze the expression of CD200 by flow cytometry (FC) on neoplastic cells in a series of patients consecutively diagnosed with mature B-cell neoplasms with peripheral blood (PB) involvement. **Methods.** PB samples of 150 patients diagnosed from October 2009 until June 2011 were evaluated by four-color FC with a panel of monoclonal antibodies (moAb) currently used in our center to study mature B-cell neoplasms. This panel included CD200-PE (BD Pharmingen, clone MRC OX-104) in combination with CD19-PerCP-Cy5.5 and CD5-APC. At least 30,000 events were acquired in a FACSCanto II flow cytometer (BD) and analyzed with the FACSDiva software. The expression of CD200 was assessed with respect to the mean fluorescence intensity observed in cells labeled with a matched isotypic moAb. The diagnoses were established according to the WHO 2008 classification (Table 1). In nine cases a definitive diagnosis was impossible to be established (SMZL-v vs HCL-variant, 1 case; CLL vs LPL, 2; CLL vs SMZL CD5+, 4; mature B-cell neoplasm different to CLL, 2).

Table 1.

DIAGNOSIS (N=161)*	N (%)	CD200 (median, range)	CD200≥20%, N (%)
CLL/SLL	61 (37.9)	100 (23-100)	61 (100)

Without definitive diagnosis	9 (5.6)	74 (0-100)	7 (78)

*10/150 patients (6.7%) with two (N=9) or more (N=1) B-cell populations.
CLL, chronic lymphocytic leukemia; SLL, small lymphocytic lymphoma; MBL, monoclonal B-cell lymphocytosis; MCL, mantle cell lymphoma; SMZL, splenic B-cell marginal zone lymphoma; HCL, hairy cell leukemia; FL, follicular lymphoma; LPL, lymphoplasmacytic lymphoma; MALT, mucosa-associated lymphoid tissue.

Results. In ten out of the 150 patients (6.7%) two (N=9) or three (N=1) B-cell populations with an abnormal phenotype were identified. The percentage of neoplastic cells with CD200 expression observed in the different diseases and the number of cases with CD200 expression ≥20% is shown in the table. An expression of CD200≥90% was observed in 59/61 (97%) CLL/SLL cases, 20/22 (91%) CLL-like MBL, 5/6 (83%) atypical CLL MBL, 0/2 (0%) CD5-negative MBL, 6/7 HCL (86%) and 0/16 (0%) MCL. In the remaining pathologies CD200 expression was highly heterogeneous. CD200 expression was similar in CLL and CLL-like MBL but significantly different between these and MCL (CD200≥ vs <20%, *P*=0.011). In addition, the expression of CD200 in MCL patients with conventional clinical behavior (N=7) was significantly lower than that observed in cases displaying an indolent clinical course (N=9, median survival without

treatment, 82 months; range, 15-167) (CD200≥ vs <5%, *P*=0.011). In the majority of HCL patients the expression of CD200 was ≥90%. CD200 expression in SMZL was variable and in some cases (7/28, 25%) similar to that observed in CLL. **Conclusions.** In our series, an expression of CD200≥90% was observed in nearly all cases of CLL, CLL-like MBL and HCL, being this expression significantly different from that observed in MCL. The expression of CD200 in MCL patients with an aggressive clinical course was significantly lower than that observed in MCL cases with an indolent behavior, data that need to be confirmed in longer series. Patients diagnosed with SMZL displayed a highly variable CD200 expression, in agreement with the clinical and biological heterogeneity of this entity.On behalf of Grupo Español de Citología Hematológica (GECH).This study has been funded in part by FIS PI10/00366.

[7]Attikon General Hospital, Athens, Greece

Background. Recent data suggest that PC play an important role in the biology of CLL, as they constitute its proliferative compartment. However, the complexity of the microenvironment as well as the molecular events that take place in PC and their clinical significance are not completely elucidated. **Aims.** To identify the presence of PC in lymph node and other tissues; to analyze their proliferative status; to evaluate the expression of molecules implicated in the apoptotic process in PC, compared to their expression in the nonPC areas; and to correlate the aforementioned findings with the clinical and laboratory features in a series of CLL patients. **Patients and Methods.**Fifty patients, fulfilling the diagnostic criteria of CLL/SLL were enrolled in this study. All necessary clinical and biological data were recorded on each patient. In all tissue sections(44 lymph nodes,5 spleens, 1skin), in the PC and the nonPC areas, the following molecules participating in the proliferative/apoptotic process were studied and evaluated by immunohistochemistry: Ki-67, Bcl-2, Fas, FasL, c-FLIP, survivin and cleaved caspase3 that was evaluated in the entire tumor area.RESULTS-Median patients' age was 55 years (36-77). Twenty-nine (58%) had disease stage A, 16(32%) B and 5(10%) C.PCs were easily identified after staining with H+E both in lymph node and splenic sections. In 17 cases the major diameter of PCs exceeded the diameter of a x20 power field and therefore were considered to be expanded. Median Ki67 proliferation index per proliferation center was 10% (1-20%), while median Ki67 in the whole tissue section was 3% (1-8%) (p<0,0001).Median Fas, Fasl and c-FLIP expression in the PCs was 50%, 30% and 50% respectively, whereas the respective values in the nonPC areas were 40%, 10% and 40%.Only the difference noted in the FaSL expression between PCs and nonPC areas was statistically significant(p= 0.0107) Moreover, FasL expression in the PCs was positively correlated with Fas and c-Flip expression in the same areas (p=0.018 for Fas and FasL, p=0.0154 for FasL and c-Flip). Survivin expression was detected in all cases with the percentage of positive neoplastic cells ranging from 1% to 80%. In half of the cases survivin expression in the PCs was higher than that of the rest tumour compartment. Those cases displayed also increased overall survivin expression (p=0.0266) and higher c-FLIP expression in the PC areas when compared to the nonPC areas (p=0.017).Strong homogenous Bcl-2 expression was observed both in PC and in the nonPC areas.In multivariate survival analysis concurrent overexpression of Fas/Fasl and c-FLIP in the PCs emerged to be an independent predictor of worse outcome for OS (p=0.042) as well as for DFS (p=0.008)CONCLUSIONSPC in lymph nodes and spleen of CLL pts present particular proliferative and apoptotic features.The correlation of Fas, FasL and cFlip in PCs implicates cFlip as an inhibitor of Fas induced death pathway in CLL patientsConcurrent overexpression of Fas,FasL and cFlip in PCs was correlated with patients' survival.

[2]Grupo Fleury, Sao Paulo, Brazil

Background. Multiparameter flow cytometry is a useful tool to the diagnostic evaluation of mature B-cell neoplasms (MBN). The combination of CD5 and CD10 restricts the diagnostic possibilities, assisting in the selection of subsequent. **Methods.** The most frequent association is CD5+/CD10-, whose main hypotheses are: chronic lymphocytic leukemia (CLL), mantle cell lymphoma (MCL) and atypical CLL. In this subgroup, CD23+ cases are usually classified as CLL; and CD23- cases, as MCL. However, the immunophenotype of CLL and MCL cases frequently overlaps, and the pattern of CD23 expression is not helpful for the diagnosis of most cases of atypical CLL . In addition, other MBN may have atypical expression of CD5, further complicating the differential diagnosis in this subgroup. Recently, it has been shown that CD200 may improve the distinction between CLL (CD200+) and MCL (CD200-), but the role of CD200 expression in atypical CLL and other MBN remains to be established. **Aims.** Investigate the expression of CD200 in 159 consecutive cases of MBN diagnosed over a period of 11 months. **Methods**: Expression of CD200 (clone OX104) was evaluated on PB, BM and lymph node samples in a FACSCalibur flow cytometer using a large panel of MAbs. Cases were classified as CD5+ MBN: 81 cases [typical LLC, 45; atypical CLL, 11; MCL, 14; CD5+ B-cell lymphoma, 11]; CD10+ MBN: 16 cases [follicular lymphoma (FL), 11; diffuse large cell lymphoma (DLCL), 5]; CD5-/CD10- MBN: 31 cases; lymphomas with hairy/villous lymphocytes, 20 [hairy cell (HCL), 13; splenic marginal zone lymphoma (SMZL), 6; unclassifiable, 1]; prolymphocytic leukemia (PL), 7; and lymphoplasmacytic lymphoma (LPL), 4. **Results.** In the CD5+ group, CD200 was expressed with high intensity in all cases of typical CLL (IMF= 284.1), but was absent in all MCL cases (p <0.0001). All cases of atypical CLL also expressed CD200, but with lower intensity than typical CLL (IMF = 153.3, p = 0.002). Among the CD5+ B-cell lymphomas, 9/11 cases expressed CD200 (IMF = 112.7). In the CD10+ group, CD200 was expressed with dim intensity in 8/11 FL (IMF = 39.8), and in 5/5 cases of DLCL (IMF = 40). All cases of HCL expressed CD200 with high intensity (IMF = 464.4), while SMZL cases had a lower intensity (IMF = 68.6, p <0.0001), with one negative case. The expression of CD200 was heterogeneous in CD5-/CD10- lymphomas, and expressed in 21/31 cases (IMF = 78.6). In PL, 2/7 patients were positive (IMF = 98.7); and in LPL, 2/4 cases (IMF = 46.6). **Summary and Conclusions.** CD200 is strongly expressed in CLL and is an excellent marker for the differential diagnosis with MCL, even in cases with atypical phenotype. Furthermore, CD200 is highly expressed in HCL, being useful in the differential diagnosis with SMZL. However, lack of CD200 is not an exclusive finding of MCL, being also observed in other MBNs, including PL and CD5+ B lymphomas. These results expand the understanding of the CD200 expression in MBNs, giving further support for the inclusion of this marker in the flow cytometric panels for the differential diagnosis of MBNs.

0733

CD200 IN DIAGNOSIS OF CHRONIC LYMPHOPROLIFERATIVE DISORDERS- A STUDY OF 122 PATIENTS

A Iova[1], H Bumbea[1], V Roman[2], AM Vladareanu[1], O Cazaceanu[1], C Enache[1], M Begu[1]
[1]„Carol Davila„ University of Medicine and Pharmacy, Bucharest, Romania
[2]Stefan Nicolau National Institute of Virusology, Bucharest, Romania

Background. The diagnosis and management of patients with chronic limphoproliferative diseases has become dependent on immunological criteria. Flow cytometry immunophenotyping is used for rapid and specific diagnoses. But, there are cases when we are not facing a typical immunophenotype and for that, there is a constant need for finding new markers and new combinations of markers that allow us to improve and develop our diagnoses. Mature B-cell lymphoproliferative disorders have specific phenotype and in the presence presence of a CD5 positive B-cell lymphocytosis, it is important to differentiate Chronic Lymphocytic Leukemia (CLL) from mantle cell lymphoma (MCL). **Aims.** Our aim was to evaluate CD 200 expression in different B-cell chronic lymphoproliferative disorders. CD200 is a membrane glycoprotein belonging to the immunoglobulin superfamily and overexpression of CD200 has been reported in a number of malignancies, including CLL, as well as on cancer stem cells. **Methods.** We analyzed CD200 expression in 122 patients diagnosed with chronic lymphoproliferative disorders(100 patients with CLL, 10 patients with splenic marginal zone lymphoma (SMZL), 10 patients with MCL and 2 patients with hairy cell leukemia), in the Hematology Department of Emergency University Hospital Bucharest.We performed immunophenotypical analysis of peripheral blood and bone marrow aspirate on BD FACS Calibur flowcytometer .Our diagnose panel included the following markers: CD19, CD20, CD5, CD23 , CD79B , CD103, CD11c, CD25, CD10, FMC7. **Results.** CD200 was brightly expressed in all 100 CLL patients (100%). In SMZL patients, CD200 was dim positive (40%-60%), in patients with HCL. CD200 was also bright positive (96% and 97%) and in patients with MCL CD200 was negative (1-10%); CD 200 was significantly higher in CLL patients compared with other B-cell chronic lymphoproliferative disorders. We found 14 patients with CD19, CD5 positive population and CD23-, but with high expression of CD 200. Cyclin D1 was negative on bone marrow biopsy in 13/14 of these patients. (1/14patients was without bone marrow involvement). **Conclusions.** CD200 has a great impact in diagnoses of B-chronic lymphoproliferative disorders, especially when we want to determine the origine of a CD19, CD5 positive population and differentiate CLL from MCL. CD 23 is a reliable marker in those cases, but, as we showed, CD23 might have a lower specificity than CD200 for CLL. The diagnosis of MCL has to be confirmed by detection of cyclin D1 positivity or by the presence of the t(11;14)(q13;q32) chromosomal translocation detected by cytogenetics, Western blot, Polymerase Chain Reaction (PCR) analysis, fluorescence in situ hybridization (FISH). But, these methods are expensive, time-consuming and not quite available.We added CD200 in our panels for diagnoses of chronic lymphoproliferative disorders, not to replace CD23, but to improve our diagnoses.

0734

EXPRESSION OF BCL2L12 GENE IN CHRONIC LYMPHOCYTIC LEUKEMIA: ASSOCIATION WITH CLINICAL AND MOLECULAR PROGNOSTIC MARKERS

T Karan-Djurasevic[1], V Palibrk[2], N Tosic[1], T Kostic[1], V Spasovski[1], G Nikcevic[1], S Srzentic[1], I Glumac[1], M Colovic[2], N Colovic[3], D Antic[3], B Mihaljevic[3], A Scorilas[4], C Kontos[4], S Pavlovic[1]

[3]Clin for Hematology,Clin Center of Serbia,Med Faculty,University of Belgrade, Belgrade, Serbia
[4]Dep of Biochem and Mol Biology,Faculty of BiologyUniversityof Athens, Athens, Greece

Background. Chronic lymphocytic leukemia (CLL) manifests as clonal expansion of mature $CD5^+$ $CD19^+$ $CD23^+$ $sIgM^{low}$ B lymphocytes, whose gradual accumulation in blood, bone marrow and lymphoid organs is attributed primarily to impaired apoptosis. Resistance to apoptosis results from microenvironmental survival signals, as well as from inherent dysregulation of apoptotic machinery in malignant B lymphocytes. Genetic alterations and aberrant expression of Bcl2 family proteins have been described in CLL, such as overexpression of Bcl2, $BclX_L$ and Mcl1, and increased Bcl2/Bax ratio. Bcl2L12 is a novel member of Bcl2 family of apoptosis regulators, whose pro- or anti-apoptotic role has not been fully elucidated yet. Nevertheless, its altered expression relative to normal tissue has been reported in several types of cancers. **Aims.** The aim of this study was to analyze the expression of Bcl2L12 in CLL, and to assess the association of Bcl2L12 mRNA levels with clinical features of patients. Furthermore, the association with molecular markers which exert the greatest prognostic value was studied, namely the mutational status of rearranged immunoglobulin heavy variable (IGHV) genes, CD38 and lipoprotein lipase (LPL) gene expression. **Methods.** This study enrolled 58 unselected CLL patients and 10 healthy controls. The expression of Bcl2L12 gene was analyzed in peripheral blood mononuclear cells by RQ-PCR methodology, using SYBR Green chemistry. LPL expression levels were also measured by RQ-PCR, using TaqMan chemistry. In all RQ-PCR experiments, Abl was used as endogenous control gene. Quantification of target gene expression was made by comparative ddCt method, using HL-60 cell line as the calibrator. CD38 status was determined by flow cytometry, and IGHV mutational status by sequencing of clonal IGHV rearrangements and sequence analysis by ImMunoGeneTics database and tools. **Results.** RQ-PCR expression analysis of Bcl2L12 revealed significantly higher levels of Bcl2L12 mRNA in CLL samples in comparison to normal blood samples (p=<0.001). ROC curve analysis showed that Bcl2L12 expression efficiently discriminates CLL cases from healthy controls (ROC curve area = 0.8733; 95% confidence interval = 0.7781-0.9685; p=0.0002) . Bcl2L12 mRNA levels showed no association with either gender, age at diagnosis, Binet stage or outcome of the disease (progressive vs. non-progressive). Although Bcl2L12 expression was negatively correlated to lymphocyte doubling time (LDT) and positively to β2-microglobulin levels, in both cases this correlation did not reach statistical significance. On the other hand, Bcl2L12 levels were significantly elevated in patients with abnormal vs. normal LDH values (p=0.038). Regarding molecular prognostic markers, no association was found between Bcl2L12 mRNA levels and either IGHV mutational status, CD38 status or LPL expression. **Conclusions.** Our results demonstrated a significant overexpression of Bcl2L12 gene in CLL patiens in comparison to healthy controls, implying its role in the pathogenesis of the disease. However, relatively homogenous Bcl2L12 mRNA levels among patients did not reflect their clinical characteristics (with the exception of LDH status), and failed to show association with molecular markers predictive of prognosis in CLL.

Chronic lymphocytic leukemia - Clinical 2

0735

AN INNOVATIVE BIOMEDICAL SCIENTIST LED REMOTE MONITORING PROGRAMME FOR STABLE EARLY CHRONIC LYMPHOCYTIC LEUKAEMIA

N Parry-Jones, S Wetherell, A Hunt, H Osman, J Chilcott, S Lewis
Aneurin Bevan Health Board, Abergavenny, United Kingdom

Background. Early Chronic Lymphocytic Leukaemia (CLL) is, with increasing frequency, diagnosed after 'routine' blood tests reveal lymphocytosis, predominantly in the elderly. CLL is frequently indolent, requiring no treatment. Patients can be frail with co-morbidities. We practise in a rural area where patients travel up to 25 miles to clinics. Increasing demand for our services are making clinics more congested. **Aims.** We have, with dual aims of avoiding unnecessary travel for patients and over-booking of clinics, piloted a biomedical scientist (BMS) led remote monitoring service for patients with stable early CLL. The extended role of the BMS fits in well with the modernising scientific careers pathway recently implemented in the UK. We report here results of our first 3 years of the programme. **Methods**. Patients with stage A CLL were identified from haematology clinic registers. Entry criteria included confirmed CLL stage A by clinical examination, morphology and immunophenotyping with CLL score of at least 4/5, minimum 1 year follow up from diagnosis, lymphocyte doubling time of >12 months and written informed consent. CD38 status was available in some cases, but CD38+ patients were not excluded. Information sheets were provided to patient and GP. Six monthly FBC and 12 monthly DCT, LFT and immunoglobulins were requested by posting blood forms for patients to have samples taken locally. The BMS conducted a 6 monthly telephone interview with the patient using a proforma which enquired about frequency of infection, weight loss, sweats or obvious lymphadenopathy as well as whether there was any issue they wished to discuss with their Haematologist.Results of questionnaires and corresponding blood tests were reviewed by the Consultant Haematologists. Patients with satisfactory results were re-tested as per protocol. Patient and clinician could request out-patient clinic review if deemed necessary by either party. A longer testing interval (12 months) was introduced in selected patients with long duration of stable disease.Hard copies of completed questionnaires were filed in the department. Blood test results were available electronically. After each interaction patients received a letter, copied to their GP, advising the outcome. A patient satisfaction survey of the service was recently undertaken. **Results**. Sixty three patients have been enrolled to date; 4 have died (none from CLL), 7 have been recalled for clinic review; 5/7 were subsequently returned to the monitoring programme. Two patients have requested annual clinic review with remote monitoring in-between. We estimate that at least 140 out-patient appointments per year have been saved. Forty patients responded to our satisfaction survey; all were happy with the programme. **Conclusions.** We have shown that a BMS led remote monitoring programme for early CLL is feasible and safe, with benefits for patient and clinician and a high level of patient satisfaction. We now plan to extend the programme to other areas of our Health Board, and with the implementation of the All-Wales Laboratory Information System (LIMS) in late 2012, there may be scope to extend further.

0736

NEW PROGNOSTIC SCORE BASED ON COMORBID CONDITIONS AND BETA-2 MICROGLOBULIN FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

D Antic, B Andjelic, M Dencic Fekete, M Smiljanic, V Vukovic, B Mihaljevic
Clinic for Hematology, Clinical Center Serbia, Belgrade, Serbia

Background. The clinical outcome of patients with chronic lymphocytic leukemia (CLL) is variable. The ability to predict the clinical course in patients with early stage CLL has been markedly improved by the use of molecular prognostic markers. Most of these data come from patients participating in clinical trials. Such trials typically have strict eligibility criteria based on performance status and organ function. Little is known about the organ function of unselected patients (i.e., regardless of whether they are eligible for trials). Adult comorbidity evaluation-27 (ACE-27), Cumulative Illness Rating Scale (CIRS) and hematopoietic cell transplantation comorbidity index (HCT-CI) are comorbidity indexes that take concurrent presence of nonmalignant diseases into account when explaining survival. They differ in both the number and categorization of comorbidities. **Aims.** We investigated the prognostic significance of three comorbidity indexes in adition to standard prognostic tools in a large sample of patients with CLL.Methods: We retrospectively evaluated the impact of ACE-27, CIRS and HCT-CI in a cohort of 115 adult patients with chronic lymphocytic leukemia (HLL). Also we tested impact od standard prognostic tool available in daily practice as age, gender, Rai/Binet clinical stage, LDH level, type of bone marrow infiltration and CD38 expression. Patient and survival data were acquired from inpatient hospital records. Cox hazard regression model was used to analyze overall survival according to standard prognostic factors and comorbidities classified by the ACE-27, CIRS and HCT-CI. **Results.** Median follow up of our group was was 39 months while median overall and progression free survival was 80 and 37 months, respectively . We found a significant association between ACE-27 and beta-2 microglobulin (b2M) and overall survival (p=0,011; RR=2,215; 95%CI for RR 1,203-4,076 and p= 0,014; RR= 2,971; 95%CI for RR 1,247 - 7,075, respectively). Other two comorbidity indexes - CIRS and HCT-CI and standard prognostic factors did not outperform the survival model, while in multivariate analysis ACE-27 remained the most important predictor of overall survival (p=0,009). Median overall survival time between ACE groups (none/mild *vs.* moderate/severe) was 94 *vs.* 56 months, respectively (Log rank=6,973; p=0,008). Also, patients with b2M < 3mg/ml had significantly longer overall survival (Log rank=6,721; p=0,010). We developed a new scoring system based on the ACE-27 score value and serum levels b2M. Patients with a score of 0 (low values of ACE and b2M) did not reach median overall survival while patients with a score of 2 (increased levels of ACE-27and b2M) had a significantly shorter overall survival of 34 months (p<0,0001). **Conclusions.** In our group of adult CLL patients the overall survival is associated with the presence of comorbidities defined by the ACE-27 index. ACE-27 and b2M present a superior comorbidity risk-adjustment model for HLL survival prediction.

0737

CYTOXAN AS FIRST-LINE THERAPY IN LGL LEUKEMIA : REPORT OF A SERIES OF 21 PATIENTS

A Moignet[1], R Zambello[2], L Pavan[2], B Bareau[3], O Tournilhac[3], M Roussel[4], R Houot[4], T Lamy[4]
[1]Rennes university hospital, Rennes cedex 09, France
[2]Department of Clinical and Experimental Medicine, Padova, Italy
[3]Hematology Department, Cesson Sévigné, France
[4]Rennes University Hospital, Rennes cedex 09, France

Background. Treatment of large granular lymphocytes (LGL) leukemia is based on immunosuppressive agents like methotrexate, ciclosporine or cytoxan. Given the lack of prospective studies, no standard regimen has been defined. Empirically, low dose oral methotrexate (MTX) is mainly used as first line therapy, except in LGL leukemia associated with pure red cell aplasia in which cytoxan has shown encouraging response rate. Among the few available retrospectival studies, continuous oral administration of low dose cytoxan appears to be efficient in LGL leukemia regardless of the treatment indication (neutropenia or anemia). Moreover, it has been reported that patients can respond to cytoxan after MTX therapy failure. **Aims.** We analysed retrospectively the results of cytoxan used as first-line therapy in LGL leukemia.**Methods:** Diagnosis criteria of LGL leukemia were those previously published (Lamy T, Blood 2011). Cytoxan was delivered at 100 mg/day except for one patient (200 mg/week), during 4 to 6 months. Five patients received concomitantly steroid during the first weeks. Response was evaluated after month 4. Complete response (CR) was defined as the complete normalization of blood counts and circulating LGL lower than $0.3x10^9$/L. Partial response (PR) was defined as an improvement in blood counts which do not meet criteria for CR (neutrophil increasing more than 50% and reaching more than 0.5 but less than $1.5x10^9$/L with non-recurrence of infections, or hemoglobin level increasing more than 2 g/dL from baseline and transfusion requirements stopping without normalization of the hemoglobin level. **Results.** Twenty one patients suffering from LGL leukemia (T cell n=18 and NK subtype n=3) were included in this study. There were 14 females and 7 males with a median age of 72 years. Diseases related to LGL leukemia were as follows: rheumatoid arthritis (n=2), chronic inflammatory bowel disease (n=1), dysthyroidism (n=3), pulmonary hypertension (n=2). Hemoglobin, neutrophil, and LGL median level counts were 12 g/dl, 0.5 G/L and 3.8 G/L respectively. Reasons for starting therapy were: isolated severe neutropenia (n=12) including two patients with severe infection, anemia (n=5), pulmonary hypertension and neutropenia (n=2), and two for other reasons (thrombocytopenia and auto-immune disease related to LGL leukemia). The overall response rate (ORR) was 71% (15/21) with 12 CR (57%) including 2 molecular CR,3 PR (14%), stable disease 4/21 (19%) and 2 failures/21 (10%). The ORR for neutropenic and anemic patients were 75% (9/12) and 60% (3/5), respectively. Median time to best response was 9 months. With a median follow-up of 27 months (4-98), only one out of the 15 responders has relapsed. PFS is 83% at 24 months. **Conclusions.** This largest series of cytoxan used as a first-line therapy in LGL leukemia shows encouraging results with an ORR of 71%. In comparison, ORR obtained with methotrexate and ciclosporine are

55% and 56%, respectively. Interestingly, cytoxan showed promising results in both neutropenic and anemic patients. Furthermore, compared to methotrexate, cytoxan treatment time is shorter, with longer response duration and less toxicity. These results support a prospective randomized study comparing cytoxan and methotrexate which is currently ongoing.

[9]Assaf Harofeh Medical Center, Tel-Aviv, Israel
[10]Hadassah University Hospital, Jerusalem, Israel

Background. Lymphocytes have been implicated in the development of marrow fibrosis. An increased reticulin network is seen in a variety of lymphoproliferative disorders, most prominently in hairy cell leukemia. Bone marrow (BM) biopsies from patients with chronic lymphocytic leukemia (CLL) may show different patterns of reticulin fibrosis but its incidence and prognostic significance have not been extensively studied and remain unclear. **Aims.** To assess the presence and possible significance of BM reticulin fibrosis in patients with treatment "naive "CLL and to attempt to correlate the degree of fibrosis with some of the well recognized clinical and laboratory prognostic parameters forCLL , as well as overall survival (OS) and eventual outcome in this patient cohort.Methods: We retrospectively reviewed data of untreated patients withCLL seen and followed at 9 medical centers inIsrael between1987-2012. BM trephine biopsies of all patients were evaluated for the presence and pattern of reticulin fibrosis before anti-leukemic therapy was started. Grading of fibrosis was established using a scoring system comprising four grades (0-3), based on the 2005 European consensus report. Prognostic and predictive factors forCLL outcome including: age, gender, Binet and Rai stages, CD38%, CD23%, Zap70 positivity determined by flow cytometry, serum beta 2 microglobulin levels, pattern of BM infiltration and spleen size were compared with grade of reticulin fibrosis, as well as OS and eventual outcome . **Results.** Our final cohort included 170 patients (150 males and 20 females). Median age at diagnosis was 63 years (range 32-86) and 5 years OS was 77.1%. The Binet staging system easily separated the cohort into 3 prognostic groups. Grading and the extent of reticulin fibrosis correlated with overall survival and mortality (p=0.003) readily dividing the patient cohort into four categories of survival curves according to the patterns defined (grade 0-3).Patients with reticulin fibrosis grade 2 had higher risk of mortality compared to grade 0 (H*azard Ratio* of *4.25)* and this trend was even more evident for patients with grade 3 fibrosis *(*H*azard Ratio* of *5.718)*.Advanced fibrosis (grade 3) was associated with thrombocytopenia (platelet<100.000mm^3)(p=0.025), anemia (hemoglobin<12.1 gr/L)(p=0.016), B2mg levels of > 4000 µg/mL (p=0.0031) , low expression of CD23 (p=0.0054) and CD38 positivity onCLL cells (p=0.03). There was no correlation between the extent of fibrosis and spleen size, pattern of BM infiltration (non diffuse versus diffuse), proportion of infiltrating CLL cells on bone marrow aspiration, level of lymphocyte count in the peripheral blood or Zap70 positivity in the leukemic cells . **Conclusions.** We identified a correlation between the grade of BM reticulin-fibrosis and poor survival in patients withCLL. This also correlated with the presence of very high levels of serum beta2 microglobulin and increased CD38 expression onCLL cells. Increased reticulin -fibrosis in the bone marrow appears to have significant prognostic implications for these patients. The simple histo-chemical staining procedure for detecting reticulin can easily be added routinely when examining BM biopsies of patients withCLL and can provide useful information relating to prognosis in these patients

0739

COMPARATIVE ANALYSIS OF JAPANESE AND EUROPEAN CLL PATIENTS

M Gruber[1], D Neuberg[2], S Aoki[3], U Jaeger[1], J Suzumiya[4]
[1]Medical University of Vienna, Vienna, Austria
[2]Dana Farber Cancer Institute, Boston, MA, United States of America
[3]Niigata University of Pharmacy and Applied Life Sciences, Niigata, Japan
[4]Shimane University Hospital Cancer Center, Izumo, Japan

Background. Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in Western countries but very rare in Eastern Asia. In studies among migrants this low incidence is maintained speaking in favor of a relevant hereditary predisposition. Such genetic factors could also account for significant differences in the biology of the disease. However, to date the impact of prognostic markers and drug therapy have been mainly studied among Caucasians. **Aims.** The aim of this retrospective study was to establish a framework for comparative studies between Japanese and European patient cohorts and to identify relevant factors, which need to be considered for prospective investigations. **Material and Methods.** CLL patient databases comprising clinical and molecular data from 316 Austrian patients diagnosed between 1973 and 2011 at the Medical University of Vienna and from 96 Japanese patients diagnosed between 1988 and 2007 at centers of the CLLRSG were analyzed. Patients with incomplete data were included in the analysis only for any data items that were available. An additional analysis, adjusted for Binet stage, was performed. **Results.** Several significant differences between the two patient populations were observed (Table 1). Japanese patients were older at diagnosis and the disease was more advanced. The latter was reflected in a significantly higher proportion of Binet B and C stages, more patients with elevated lactic dehydrogenase (above the institutional upper limit of normal) as well as lower mean platelet counts and hemoglobin concentration in the Asian cohort. The male to female ratio was 1.5:1 in both CLL populations. Interestingly, we found a notably higher proportion of atypical, surface CD23 negative, cases among Japanese CLL patients (33.8% of cases, compared to 2.3% in the European cohort, p<0.001). In contrast, the proportion of CD38 positive cases was almost twice as high among the Caucasians (30.6% vs. 17.6%, p=0.059). In unadjusted comparison, median treatment free (TFS) and overall survival (OS) were also shorter among Japanese patients, especially in the subset of typical CLL patients only.In Binet adjusted analysis among all patients, impact of ethnicity on TFS and OS lost significance. Differences in other markers remained, albeit less pronounced in most cases. In analysis of typical CLL patients only, Japanese origin was associated with shorter OS independently from Binet stage.**Summary.** Our analysis indicates the presence of relevant disparities between Japanese and European CLL patients. However, inter-observer variability and diverse techniques used for diagnostics could mimic differences which are not biologically or clinically reflected. These points require special attention. The presented data will serve as a basis to establish harmonized assessment by an independent panel. A prospective comparative study including cytogenetic and molecular analysis has already been initiated.

Table 1. Unadjusted and adjusted (according to Binet stage) comparison of Japanese and European CLL patients at diagnosis

Marker	Japanese (n analyzed)	European (n analyzed)	P-value unadj.	P-value adj.
Advanced Binet stage (B or C) (% patients)	33.3 (n=96)	18.8 (n=313)	**0.003**	-
Follow up (median, years)	5.1 (n=96)	6.2 (n=316)	**0.008**	**0.023**
Age at diagnosis (mean, years)	65.3 (n=96)	62.3 (n=316)	**0.020**	**0.017**
Male sex (% patients)	59.4 (n=96)	60.1 (n=316)	**0.895**	**0.904**
Hemoglobin (mean g/dl)	12.9 (n=96)	13.9 (n=284)	**<0.001**	**<0.001**
Platelets (mean number *10^4/µl)	16.9 (n=96)	20.1 (n=281)	**<0.001**	**<0.001**
Lymphocytes (mean number *10^3/µl)	26.3 (n=96)	24.6 (n=281)	**0.701**	**0.602**
High lactic dehydrogenase (% patients)	25.5 (n=94)	12.5 (n=306)	**0.001**	**<0.001**
CD23- (% patients)	33.8 (n=80)	2.3 (n=291)	**<0.001**	**<0.001**
CD38+ (% patients)	17.6 (n=51)	30.6 (n=291)	**0.059**	**0.056***
Treatment free survival				
All patients (median, years)	5.6 (n=95)	7.2 (n=314)	**0.100**	**0.466**
Typical CLL only (median, years)	5.6 (n=61)	7.2 (n=307)	**0.023**	**0.859**
Overall survival				
All patients (median, years)	21.5 (n=95)	22.9 (n=316)	**0.193**	**0.793**
Typical CLL only (median, years)	9.6 (n=61)	23.0 (n=308)	**0.003**	**0.023**

* Binet stage lost significance in the multivariable model

THE EXPERIENCE OF ALLELE-SPECIFIC POLYMERASE CHAIN REACTION AND MULTICOLOR FLOW CYTOMETRY USE IN MINIMAL RESIDUAL DISEASE ASSESSMENT IN B-CELL CHRONIC LYMPHOCYTIC LEUKEMIA

E Naumova
Russian Medical Academy of Postgraduat Educatione, Kraskovo, Russian Federation

The minimal residual disease (MRD) assessment was produced by means of multicolor flow cytometry and allele-specific polymerase chain reaction (PCR) in parallel for 45 peripheral blood specimens taken from 37 patients with B-cell chronic lymphocytic leukemia (B-CLL). Both methods results were similar in 93.3% (42 investigations of 45) with Spearman's rank correlation coefficient of 0.87 ($p < 0.0001$). 3 investigations of 45 (6.7%) have revealed malignant B-cells by one of the methods only: in first case by 6-color flow cytometry and in two others by real-time PCR.153 patients with B-CLL who have received combined FCR chemotherapy have undergone MRD assessment during the treatment period. The patients differed by gender - 56 female patients and 97 male ones, and by age: from 27 to 82 years. 290 investigations were produced in total: 222 of them were the analysis of peripheral blood specimens (98 investigations for interim evaluation of tumor clone, 98 - after 3 cycles of FCR chemotherapy and 124 investigations for final evaluation 6 cycles of chemotherapy after). The residual B-CLL population was performed using international standardized approach (Rawstron AC et. al, 2007; 21 (5): 956-64) which was modified for 5-color flow cytometry (Cytomics FC500, BC) and 6-color flow cytometry (FACS Canto II BD). 73 patients were undergone final MRD assessment with peripheral blood and bone marrow investigations. Of 124 B-CLL patients 65 (52.4%) went in immunophenotypical remission. In 16 (21.9%) cases the malignant B-CLL clone was determined in bone marrow only.In summary, the MRD assessment in B-CLL by means of multicolor flow cytometry has sufficient sensitivity and specificity and high correlation with real-time PCR results of MRD assessment using *patient-specific primers*. If MRD is not determined in peripheral blood, it is rational to investigate bone marrow for more exact evaluation of malignant cells elimination.

0741

CONTRADICTORY IMPACT OF SERUM BLYS LEVELS IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL), WALDESTRÖM'S MACROGLOBULINEMIA (WM) AND MULTIPLE MYELOMA (MM)

[3]University of Athens, 1st Department of Internal Medicine, Athens, Greece

Background. B-Lymphocyte-Stimulator (BLyS) is a member of the TNF-superfamily mainly produced by myeloid cells, monocytes, dendritic cells and osteoclasts in the bone marrow; it is involved in normal or malignant B cells' and plasmablasts' differentiation, proliferation, survival and in immunoglobulin production. It may be proteolytically cleaved from the cell membrane and circulate as a soluble protein. Few studies reported increased serum soluble BLyS in B-non Hodgkin lymphoma (B-NHL) and MM, especially in familial cases, but decreased in CLL while the clinical repercussions of BLyS levels remain unclear. **Aims.** To study the impact of serum BlyS levels on time to first treatment (TFT) and overall survival (OS) in patients with CLL, WM and MM. **Patients and Methods.** 203 patients were studied, of whom 73 had CLL, 33 WM and 97 MM. In the CLL cohort, 61% were males and 39% females and patients' median age was 60 years; 55% were in Binet stage A, 35% B and 10% C. CLL patients' median TFT was 34 months and median OS 79 months. Of WM patients, 76% were males and 24% females, median TFT was 6 months and median OS 103 months. In the MM series, 51% were males and 49% females; 24%, 33% and 43% of patients were in Durie and Salmon stage I, II and III respectively while 26%, 26% and 48% were in ISS stage 1, 2 and 3 respectively. Median TFT was 1 month and median OS 49.5 months. Sera drawn from patients at diagnosis were frozen and then, retrospectively, tested. Serum BLyS levels were determined by ELISA (R&D, Quantiquine) and assessed by Kaplan-Meier analysis, while survival curves were plotted and compared with the log-rank test. **Results.** Median serum BLys value was 65 pg/ml (range: undetectable - 680) in CLL, 218 pg/ml (range: 88 - 13200) in WM and 122 pg/mL (range: undetectable-921)in MM while it was 183 pg/mL (range: undetectable-381) in 14 healthy individuals. In CLL patients, serum BLys values below median were related to a significantly shorter TFT compared to values above median (p=0.0002) (Figure 1A) but no correlation was found with overall survival. In WM, there was not any correlation between BLyS levels and TFT or OS. In MM, serum BLyS levels above median correlated with a shorter OS (p=0.04, Figure 1B) but had no impact on TFT. **Conclusions.** The highest serum BLyS levels were observed in WM but did not affect TFT or OS. Low serum levels correlated with shorter TFT in CLL while, on the contrary, increased levels correlated with a shorter OS in MM. In view of the recent development of anti-BLyS agents, careful evaluation of its diverging effects in lymphoproliferative disorders is needed.

COMBINED ACTION OF NOVEL CD37 ANTIBODIES AND FLUDARABINE ON CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

G Krause[1], I Baki[1], S Kerwien[1], M Kuckertz[1], V Vondey[1], M Wigger[1], KH Heider[2], M Hallek[1]
[1]University of Cologne, Cologne, Germany
[2]Boehringer Ingelheim RCV GmbH & Co KG, Vienna, Austria

Background. Chemo-immunotherapy involving the monoclonal antibody (mAb) rituximab represents the standard treatment for chronic lymphocytic leukemia (CLL). Due to known limitations of the CD20 and CD52 antibodies in current clinical use for treating CLL, we conducted an assessment on CLL lymphocytes *ex vivo* of the purine analog fludarabine in combination with two newly developed mouse-human chimeric and humanized antibodies to the tetraspanin CD37, mAb 37.1 and mAb 37.2, which had shown promising *in vitro* anti-CLL activity as single agents (Krause *et al.*, 2011, Leukemia). **Methods.** Treatment-induced phosphatidylserine exposure was examined in freshly isolated CLL cells after treatment with 10 µg/ml of mAbs and 3 or 10 µM of fludarabine. At these fixed concentrations CD37 antibodies were compared to rituximab and alemtuzumab as single agents and in combination with chemotherapeutic agents. The expected additive effects of binary combinations were calculated as fractional products of the separate single agent effects. **Results.** The previously observed high direct cell death induction by the CD37 antibodies was reproduced in an independent set of eight freshly isolated CLL samples with the highest induction of phosphatidylserine exposure by mAb37.1, followed by mAb37.2 and alemtuzumab, which in turn clearly surpassed that by rituximab. While treatment with mAbs led to similar induction of phosphatidylserine exposure after 24 or 48 hours, apoptosis induction by chemotherapeutic agents was much more pronounced after the longer treatment period. The mean apoptosis induction after 48 hours by mAb 37.1 and 10 µM fludarabine was ~ 50 % for both single agents, but reached ~ 90 % in combination. This indicated strong mutual enhancement and clearly surpassed the apoptosis induction by combi-

nations of the other antibodies with fludarabine at this concentration. Relative to untreated samples, the combination of 10 μM fludarabine with all antibodies tested led to significantly increased phosphatidylserine exposure according to paired Student's t-test. For all mAbs tested, the apoptosis induction by combinations with fludarabine significantly surpassed that by the antibodies alone. In contrast, only the combination with mAb37.1 induced apoptosis significantly more efficiently than fludarabine alone. **Conclusions.** In line with its remarkable capacity of inducing apoptosis in CLL cells, combinations of mAb 37.1 with fludarabine consistently resulted in higher percentages of apoptotic cells than correspondent combinations including the mAbs in current clinical use.

THE ROLE OF IMAGING METHODS IN CHRONIC LYMPHOCYTIC LEUKEMIA: SIGNIFICANT INTERNAL LYMPHADENOPATHY IS FREQUENT AND ASSOCIATED WITH SHORTER OVERALL SURVIVAL

L Smolej, A Bachh, P Vodarek, M Motyckova, M Simkovic
University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic

Background. Chronic lymphocytic leukemia (CLL) is historically regarded as "liquid" malignancy but a significant subgroup of patients (pts) also presents with lymphadenopathy. With regard to extent of organomegaly, clinical staging systems by Rai and Binet rely solely on physical examination; the current version of NCI-WG guidelines for diagnosis and treatment of CLL does not recommend routine use of imaging methods in the management of CLL. However, several recent studies suggested that detection of internal lymphadenopathy may be associated with unfavourable prognosis. **Aims.** to evaluate the impact of internal lymphadenopathy on clinical course of pts with CLL. **Patients and Methods.** We performed a retrospective assessment of medical records from pts with CLL followed up at our institution between 2000-2010 who underwent a computer tomography (CT) of chest/abdomen or abdominal ultrasonography. A total of 301 pts were included (198 males, 103 females, median age, 63 years [range, 31-88]). Low/intermediate/high risk according to Rai modified staging was present in 38/50/12%. **Results.** During the course of CLL, internal lymphadenopathy was detected in 142 pts (48%): abdominal, 37%, mediastinal, 0.3%, abdominal and mediastinal, 11%. Bulky lymphadenopathy (defined as lymph nodes ≥ 5cm) developed during the course of the disease in 84 pts (28%). Interestingly, internal lymph nodes were frequently larger than palpable lymphadenopathy (45%; same size, 41%; external lymph nodes larger, 14%; n=117). Importantly, overall survival (OS) was significantly shorter in patients with internal lymphadenopathy (median 87 vs 124 months, p=0.024); there was also a trend towards shorter OS in pts with bulky lymph nodes (median 88 vs 112 months, p=n.s.). **Conclusions.** Our data strongly suggests that imaging methods should be incorporated into routine diagnostic workup of CLL as more than 51 % of pts had detectable internal lymphadenopathy during the course of the disease and 28% developed massive lymphadenopathy; in addition, patients with internal lymphadenopathy had shorter overall survival. These findings appear to have principal impact on the clinical management (decisions regarding therapy, adequate staging and assessment of therapeutic response, monitoring for relapse/progression). Updated results will be presented. Supported by Research Project MZO 00179906 from Ministry of Health, Czech Republic.

A RETROSPECTIVE, SINGLE CENTRE, STUDY COMPARING CLINICAL AND LABORATORY FEATURES IN PATIENTS WITH ATYPICAL CD5 -VE CLL WITH THOSE FROM PATIENTS WITH STANDARD (CD5 +VE) CLL.

F Olaiya, R McGilvray, W Wilson, P Batstone, R Herriot, D Culligan
Aberdeen Royal Infirmary, Aberdeen, United Kingdom

Background. Chronic lymphocytic leukaemia (CLL) is the most common leukaemia in developed countries. 7- 20% of cases do not show B cell expression of CD5 and are included in the atypical CLL group. CD5 is used in routine clinical practice to distinguish CLL and mantle cell lymphoma (MCL) from other types of lymphoproliferative disorders (LPDs). Confidently distinguishing CD5-ve CLL from other forms of LPDs can be challenging.DesignA retrospective analysis (2006-2010) was undertaken of patients diagnosed with CD5 -ve CLL with collection of clinical information and laboratory data including characterization of morphological, immunophenotypic and cytogenetic features and comparison with CD5 +ve cases diagnosed in the same five year period.Results239 cases of CLL were diagnosed during the study period from a catchment population of approximately 600,000. All cases fulfilled diagnostic criteria for CLL with peripheral blood lymphocyte counts of > 5x10^9/L. Biological prognostic factors including FISH analysis were available for 120 patients using probes specific to TP53 (17p13.1), ATM(11q22.3), centrometric region of chromosome 12 (12p11.1-q11) and d13S319(13q14.3). 55% of cases were male (median age 69.9 years, range 31-85), median age for females was 72.1 years (range 43-89). A total of 25.5% of cases were CD5 -ve (defined as <20% antigen expression on peripheral blood B cells) which is a slightly higher proportion than in other published series.57 % of patients with CD5 -ve CLL had CT scan at diagnosis to look for lymphoma.13 % had other diagnostic procedures performed, including bone marrow and/or lymph node biopsies. Baseline lymphocyte counts ranged between 5.3-174.8 x10^9/L with a similar distribution between CD5 +ve and CD5 -ve cases. With the exception of CD5 expression, flow cytometry cell profiles were identical in both groups. Bone marrow immunophenotyping, where available, showed identical profiles with peripheral blood in both CD5 +ve and CD5 -ve groups. Most of CD5 -ve cases were noted to have atypical cell morphology (larger cells or cleft nuclei on a background of otherwise typical CLL cells). Cytogenetics analysis was performed on 79 patients. 16.4% were CD5 -ve of which 56% had a poor prognostic karyotype, (45% 11q-, 0% 17p- and 11% both 11q- and 17p-). Of CD5 +ve CLL cases, 24% had poor prognosis karyotypes (13% 11q-, 9% 17p- and 2% both 11q- and 17p-). Median time from diagnosis to treatment was 12 months for CD5 -ve cases and 15.5 months for CD5 +ve cases.Conclusions This study demonstrated that CD5 -ve CLL is a relatively common occurrence in unselected haematology practice. CD5 +ve and CD5 -ve CLL were similar in terms of age, sex distribution and presenting lymphocyte counts. Cell phenotypes were similar in both groups except for levels of CD5 expression. Poor prognosis karyotypes were more prevalent in CD5 -ve CLL with a shorter time to first treatment.

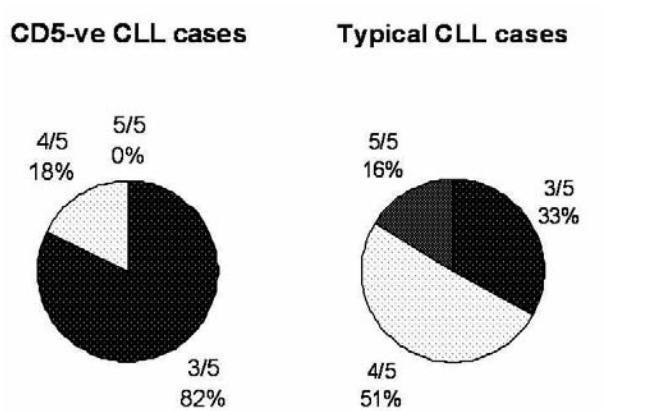

Figure 1. Patient groups stratified according to scoring criteria for CLL.

THE PROGNOSTIC EVALUATION OF TCL-1, MCL-1, BCL-2, AND BAX EXPRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

N Gozcu, M Yilmaz, M Pehlivan, V Okan, I Sari
Medical School, Gaziantep, Turkey

Background. Chronic lymphocytic leukemia is characterized with the accumulation of small mature-appearing CD5+, CD19+ and CD23+ lymphocytes in the bone marrow, blood, lymphoid tissues and very heterogeneous clinical course. Many adverse prognostic factors including the expression CD38, ZAP-70, Ig VH genes mutational status, lymphocyte doubling time have been described. **Aims.** In this study we aimed to investigate TCL-1, MCL-1, BCL-2 and BAX expression immuno histochemically in CLL patients and analyzed the prognostic value in the relationship between some other CLL prognostic markers such as clinical stage, ZAP-70, CD38, chromosomal abnormalities and infiltration of bone marrow pattern. **Methods.** 100 CLL patients, having undergone cytogenetic evaluation by FISH and 60 patients who showed normal bone marrow as a control group were included in this study. TCL-1,MCL-1,BCL-2,BAX were stained by automated methods (VENTANA,Benchmark XT). In the evaluation of TCL-1 and BAX staining , diffuse cytoplasmic staining of more than 20% of neoplastic B cells was accepted as positive. In the evaluation of MCL-1 and BCL-2 staining, diffuse cytoplasmic and nuclear staining of more than 20% of neoplastic B cells were accepted as positive. **Results.** In the immunohistochemistry section staining TCL-1 was detected in 70 patients (70%), BCL-2 was detected in 58 patients (58%), positive BAX was detected in 61 patients (61%). Positive MCL-1 was not observed in any patients. and control group showed no positive TCL-1, MCL-1, BCL-2, BAX expressiin. Cytogenetic abnormalities were observed in 41 patients group (41%). 15-year- event free survival of 42 patients with Rai stage 0-1 was found to be 184,4 months. 15-year- event free survival of 37 patients with Rai stage 2 was found to be 81,1 months (p=0.003). 15-year- event free survival of 62 patients with positive. TCL-1 was 124,3 months while 15-year- event free survival of 17 patients with negative TCL-1 was 74% (p=0.0043). In the univariate analysis age, stage (RAI 0-I-II-III) ,type of bone marrow stiffness, CD 38, TCL-1 remained significant while in the multivariable analysis (Cox proportional hazard model backward) stage (RAI 0-I-II-III), type of bone marrow stiffness and nodular diffuse (p=0.019, RR=3.055) CD38 (p=0.001, RR=0.228) remained significant. **Conclusions.** As a result , TCL-1 is accepted as a prognostic marker and may show progression of the disease follow up in CLL patients.. Inhibition of TCl-1 and especially in B-cell receptor inhibitiory mechanisms and the drugs may change clinical progression of CLL patients showing expression of TCL-1.

0746

LOW DOSE ALEMTUZUMAB-ASSOCIATED IMMUNE THROMBOCYTOPENIA IN CHRONIC LYMPHOCYTIC LEUKEMIA

G Reda
Fondazione Ca' Granda IRCCS Ospedale Maggiore Policlinico, Milano, Italy

The occurrence of alemtuzumab-associated immune thrombocytopenia (ITP) have been previously anecdotally reported in chronic lymphocytic leukemia (CLL) patients. Despite ITP is a common autoimmune complication in CLL, occurring in up to 5% of patients, it has never been reported as a significant event complicating alemtuzumab treatment in clinical trials. Recently, it has been reported a new distinctive form of secondary ITP occurring in 6 out of 215 patients with relapsing-remitting multiple sclerosis treated with alemtuzumab at very low-dose within the context of a randomized, controlled phase II trial (Cuker *et al*, Blood 2011).We investigated the incidence of ITP in a cohort of 64 consecutive patients treated at our center for relapsed/refractory CLL from 2003 to 2010 with low-dose alemtuzumab (Cortelezzi *et al*, Leukemia 2009). Alemtuzumab was administered at a dose that is one third weekly (30 vs 90 mg) and half cumulative (540 vs 1080 mg) with respect to the conventional schedule. ITP was diagnosed in 3 patients (4.7%) before alemtuzumab treatment during a median observation time of 76 months (range 6-280) and in 9 patients (14.8%) after alemtuzumab, during a median observation time of 30 months (range 2-93). ITP developed after a median time from alemtuzumab exposure of 12 months (range 1-42). Concomitant hemolytic anemia (Evans syndrome) was observed in one patient. At ITP diagnosis, median platelet count was $11x10^9$/L (range 3-70). Anti-platelet antibodies (Capture P® Method, ImmucorGamma, Norcross GA, USA) were found in 7 of the 8 patients tested. Only two patients showed a clinically significant bleeding and no patient suffered of severe bleeding events. Of the nine patients developing ITP after alemtuzumab, three progressed to a generalized disease after 3, 4 and 13 months respectively, and were treated with chemo-immunotherapy - one patient achieved a partial remission with ITP resolution, while the other two were treatment refractory and died in progression. In the remaining six patients, ITP was not associated to disease progression and they were treated with corticosteroids with or without intravenous immunoglobulins. Five patients achieved a complete remission, while one patient did not respond. Table 1 summarizes the clinical characteristics of the patients.In our cohort of CLL patients treated with alemtuzumab, the incidence of ITP was striking with 5.7 events/100 patient-year, that is almost three times higher than previously reported in CLLIn conclusion, we report for the first time the association between low-dose alemtuzumab treatment and ITP in a prospective cohort of CLL patients. This data suggested an important role of alemtuzumab induced disregulation of T-lymphocytes in the pathogenesis of ITP. As low-dose alemtuzumab have been advocated by our group to be an effective and less toxic treatment for CLL, and a retrospective practice-based study recently supported this notion, we would suggest to maintain a high level of vigilance and to consider routine monitoring for ITP in patients treated with this agent at low-dose.

0747

HAIRY-CELL LEUKEMIA: CHARACTERISTICS AND LONG TERM FOLLOW UP OF 57 PATIENTS

A Ségot[1], E Roméo[2], J Konopacki[3], J Bladé[2], B Souleau[3], O Gisserot[2], J De Jaureguiberry[2], T De Revel[3], J Malfuson[3]
[1]Hôpital Percy, Clamart, France
[2]Hôpital d'Instruction des Armées Sainte-Anne, Toulon, France
[3]Hôpital d'Instruction des Armées Percy, Clamart, France

Background. Hairy cell leukemia (HCL) is an uncommon, indolent, chronic B-cell lymphoproliferative disorder involving mainly bone marrow and spleen. Despite an usually indolent course, most patients require treatment for cytopenia or massive splenomegaly. Treatment has been revolutionized by the advent of interferon (IFN) and purine analogs. **Aims.** Few large series are described in the literature. In this long follow-up study, we describe presentation and evolution of HCL, particularly response to treatment and survival. **Methods.** All consecutive patients diagnosed with HCL between 1978 and 2011 in two Hospitals were included in this retrospective study. The criteria for response were those of the Consensus Resolution. Complete Response (CR) was defined as a morphological absence of Hairy Cells (HC) in the blood and bone marrow, without organomegaly, and normalization of cytopenias. A partial response (PR) required normalization of peripheral counts, together with at least 50% reduction in organomegaly and bone marrow HC, and <5% circulating HC. All other responses were considered as non responses. **Results.** Fifty seven patients were included with a median follow-up of 69.5 months (1-329). Two patients were diagnosed with HCL variant. Median age at diagnosis was 57 years (25-92). There was 44 male and 13 female (sex ratio M/F: 3.4).HCL was revealed by systematic blood count in 33 patients, by general symptoms, splenomegaly or infectious complications in 8, 4, and 9 patients, respectively.At diagnosis, 35 patients were symptomatic, with splenomegaly (n=33), hepatomegaly (n=10), and peripheral lymphadenopathies (n=7). Anemia (<10g/dL), thrombocytopenia (<100G/L), neutropenia (<1G/L) and monocytopenia (<0.1G/L) were present in 10, 48, 21 and 17 patients, respectively.Treatment was begun at diagnosis for 46 patients and delayed for 9 patients with a median time without treatment of 8 months (2-48).First line treatment choice were cladribine, pentostatin, IFN, rituximab and splenectomy in 19, 15, 15, 4 and 4 patients, respectively. Complete response (CR) rate, relapse rate and median relapse free survival (RFS) were respectively: cladribine (100%, 19%, 41.5 months), pentostatin (100%, 20%, 32 months), IFN (80%, 80%, 22 months), Rituximab (80%, 56%, 45.5 months) and splenectomy (50%, 75%, 8 months)Second line treatment were pentostatin (n=11), cladribine (n=8), IFN (n=8) and rituximab (n=3), with respective CR rates of 63%, 75%, 25% and 100%, relapse rate of 9%, 12,5%,85% and 33%, and median RFS of 28,19,20 and 35 months.13 patients received third line treatments and 4 a fourth one.26 patients had infectious diseases after treatment, and 7 developed secondary cancer.At the end of the study, 52 patients were alive, none died because of the disease. 39 were in CR, 6 in PR, and 7 with relapsed disease. 10 years estimated EFS and OS rates were 82% and 90%, respectively. **Conclusions.** This study confirms the good prognosis of this disease and previous observations that purine analogues induce long-term CR, included in second or more line of treatment. Outcomes for patients with recurrent disease have improved with the addition of rituximab to either purine analog with moderate infectious complications due to the immunosuppressive effects.

0748

CLINICAL FATE OF HIGH RISK CHRONIC LYMPHOCYTIC LEUKAEMIA (HR-CLL) PATIENTS TREATED WITH ALEMTUZUMAB BASED THERAPY

S Hewamana, P Kalkur, C Rajapakse, K Mohammed, L Whiteman, R Morilla, A Morilla, J Swansbury, I Chau, D Cunningham, C Dearden
Royal Marsden Hospital, London, United Kingdom

Background. Treatment options for HR-CLL are limited. Alemtuzumab based treatment has been shown to be effective with variable response rates in clinical trials. However, the clinical fate of this group of patients is not studied before. Furthermore delivering this treatment poses a challenge in the day-to-day clinical setting outside trials due to 'unselected' patient cohorts with other co-morbidities. **Aims.** To determine the clinical course of HR-CLL treated with Alemtuzumab based therapy. **Methods.** A retrospective analysis of 51 HR-CLL patients treated at the Royal Marsden Hospital (London, UK) from January 2005 to December 2011. **Results.** Median age at the time of therapy was 60 (range 35-78; > 25% age >65), Charlson co-morbidity index range 0-6, and ECOG PS range 0-2. Indications for Alemtuzumab based therapy included *TP53* deletion at diagnosis (17%) or at relapse (33%) or Fludarabine-refractory or relapsed disease without *TP53* deletion (50%) or a combination of the above. 16 patients received Alemtuzumab alone; 35 received Alemtuzumab in combination with methyl prednisolone. Response was assessed according to NCI-WG criteria.OR 82% with CR rate 37% in the whole cohort. There was no significant difference in OR or CR according to the age groups (<>65 years), the line of treatment, *TP53* status or Alemtuzumab alone compared to Alemtuzumab and Methyl Prednisolone group (P = 0.25 and 0.32; 0.56 and 0.24; 0.14 and 0.38; 1 and 1 respectively). There was a difference in CR but not OR for patients treated within clinical trials compared to patients treated outside clinical trials (P = 0. 01 and 0.7).Common complications included bacterial infections (31%), and CMV reactivation (19%). Two patients had invasive fungal infections; one case each had EBV and adenovirus infections. Treatment was interrupted before the planned end date in 13% of patients. There were 2 treatment related deaths. There was no difference in tolerability observed or treatment discontinuation in patients <> 65 years.On the interim analysis of survival data with median follow-up of 3.6 years since therapy, 32 patients are alive; 14 had allogeneic HSCT and 19 had another line of treatment but did not receive HSCT. Ten had Alemtuzumab as subsequent treatment at relapse and had an OR of 77%. The median OS of the whole cohort was 47 months; the median OS for patients who had transplants was 26 months. Sub group survival data analysis is in progress. **Summary and Conclusions.** Alemtuzumab based therapy is highly effective in relapsed high risk CLL irrespective of *TP53* deletional status. However duration of therapy is relatively short lived with majority of patients needing another line of therapy. Alemtuzumab can be used repeatedly with good OR. Alemtuzumab based therapy is deliverable in routine clinical practice even to older patients with co-morbidities with comparable response rates and response durations as reported in clinical trials. There is a high risk for infections but this is comparable to other regimens used in relapsed refractory setting.

0749

DASATINIB PLUS FLUDARABINE IN PATIENTS WITH REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS OF A MULTICENTER PHASE II STUDY

A Kater[1], M Spiering[1], R Lui[1], M Beckers[2], S Tonino[1], J Doorduijn[3], S Daenen[2], D Luijks[1], E Eldering[1], M van Oers[1]
[1]Academic Medical Center, Amsterdam, Netherlands
[2]University Medical Center Groningen, Groningen, Netherlands
[3]Erasmus Medical Center, Rotterdam, Netherlands

Patients with chemorefractory chronic lymphocytic leukemia (CLL) have an extremely poor prognosis. Development of chemoresistance in CLL is at least partly mediated by protective stimuli within the lymph node (LN) microenvironment. Dasatinib has activity against multiple kinases reported to be activated by the microenvironment including SRC, c-Abl and BTK. We recently showed by *in vitro* studies that dasatinib effectively inhibited the anti-apoptotic program and as a consequence, restored fludarabine sensitivity (Blood 2008;112:5141). These data indicate that CLL cells in chemoresistant niches may be sensitive to therapeutic strategies that include both dasatinib and purine-analogues.**Methods and Objectives:** We conducted an open-label phase 2 trial of Dasatinib/fludarabine combination in fludarabine-refractory CLL patients. Patients were treated with dasatinib 100mg once daily for 28 days. In patients that did not reach at least a PR, dasatinib was combined with oral fludarabine (40 mg/m^2 for 3 consecutive days q28) for at least 2 and maximally 6 cycles. The primary endpoints were response (IWCLL'08 criteria) and toxicity. CT-scans were performed at baseline, following dasatinib monotherapy, after 2 cycles of combination therapy and at end of protocol. At multiple time points peripheral blood-derived CLL samples and in a limited number LN biopsies were obtained. **Results.** The study was open at 3 sites in theNetherlands (Academic Medical Center Amsterdam, University Medical Center Groningen and Erasmus Medical Center Rotterdam). At time of analysis, 20 patients had been registered of which 18 patients received at least 1 treatment cycle. The median age was 69,5 years (range 29-82 years). Six patients (33%) had del (11q;22-23) and 2 patients (11%) haddel (17p;13). Patients had received a median of 5 prior treatment regimens (range 2-9). Eleven patients (61%) had bulky lymphadenopathy. PR was not observed following one cycle of dasatinib monotherapy. All but two patients (one Richter transformation and one patient refusal) continued for dasatinib/fludarabine combination treatment. At time of analysis, 3 patients completed all 6 cycles. Reasons for early discontinuation were: progressive disease (n=9), dasatinib related toxicity (n=2; both pleural effusion grade IV) and patient refusal (n=2). Fifteen patients had reductions in lymph node size. The mean maximal reduction in lymph node size was 30% (range 5%-79%; figure1). Three patients (17%) reached a PR. Twelve patients (67%) had stable disease as best response and 3 patients had progressive disease after 2 cycles of dasatinib+fludarabine. At time of analysis PFS following combination treatment was 11 months and OS was 17 months. Two patients proceeded to allogeneic stem cell transplantation. Numbers of SAE were 19; fever with/without proven infections being the most frequently reported (68%). Only 1 patient developed treatment related pleural effusion. There were no treatment related deaths.Currently, correlative ex vivo biological studies focussing on apoptosis regulation are being performed. **Conclusions.** In heavily pretreated fludarabine refractory CLL patients dasatinib/fludarabine combination treatment showed modest activity, notably as to LN size. As expected, infections were the most common toxicity. Dasatinib was relatively well tolerated. Future studies involving combinations of dasatinib at earlier phases of the disease should be con

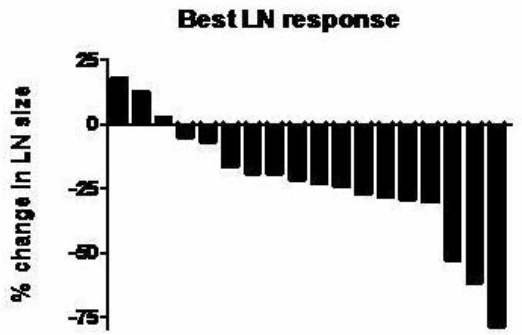

Figure 1.

sidered.

ALEMTUZUMAB FOR PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA - UPDATE OF A SYSTEMATIC REVIEW AND META-ANALYSIS

N Skoetz[1], K Bauer[1], T Elter[1], I Monsef[1], V Roloff[2], M Hallek[1], A Engert[1]
[1]University Hospital of Cologne, Cologne, Germany
[2]MRC Biostatistics Unit, Cambridge, United Kingdom

Background. Chronic lymphocytic leukaemia (CLL) accounts for 25% of all leukemias and is the most common lymphoid malignancy in Western countries. Comparatively new therapeutic options are monoclonal antibodies like alemtuzumab and rituximab administered alone or added to chemotherapy. However, the impact of these agents remains unclear, as there are hints of an increased risk of severe infections.**Aims**To assess the efficacy and safety of alemtuzumab compared to no further therapy or to other anti-leukaemic therapy in patients with CLL. **Methods.** We performed a systematic review with meta-analyses of randomized controlled trials (RCTs). We searched CENTRAL, MEDLINE, and EMBASE as well as conference proceedings from 01.1985 to 01.2012. Two review authors independently screened search results, extracted data and assessed quality of trials. **Results.** Of 1589 potentially relevant references, we included six RCTs involving 845 patients. Overall, we judged the quality of the trials to be moderate.Three trials (N=618) assessed the efficacy of alemtuzumab compared with no further therapy. Only one trial (N=335) reported overall survival (OS) with a statistically significant advantage for those patients receiving alemtuzumab (HR=0.65 (95% confi-

dence interval (CI) 0.45 to 0.94; P=0.021). The complete response rate (CRR; 3 trials) (RR=1.45; 95% CI 1.15 to 1.83; P=0.002) and progression-free survival (PFS; 2 trials) (HR=0.58; 95% CI 0.44 to 0.76; P<0.0001) were statistically significantly increased under therapy with alemtuzumab. However, a statistically significant 10-fold higher rate of cytomegalovirus (CMV) reactivation (RR=10.52; 95% CI 1.42 to 77.68; P=0.02) and infections (RR=1.32; 95% CI 1.01 to 1.74; P=0.04) occurred in patients receiving alemtuzumab.Two trials (N=177), evaluated alemtuzumab versus rituximab. Both studies did not report OS or PFS. We could not detect a statistically significant difference for CRR (RR=0.85; 95% CI 0.67 to 1.08; P=0.18) or treatment-related mortality (RR=3.20; 95% CI 0.66 to 15.50; P=0.15) between both arms, but a trend favouring the rituximab arm. One trial was stopped early due to an increase in mortality in the alemtuzumab arm. More serious adverse events occurred in this arm (43% versus 22% (rituximab), P=0.006).One trial (N=297), assessed the efficacy of alemtuzumab compared with chemotherapy (chlorambucil). Median survival has not yet been reached, 84% of patients were alive in each arm at the last follow-up date (24.6 months). Alemtuzumab statistically significantly improves PFS (HR=0.58; 95% CI 0.43 to 0.77; P=0.0001) compared with chlorambucil. Statistically significantly more asymptomatic (51.7% versus 7.4%) and symptomatic CMV infections (15.4% versus 0%) occurred in the patients treated with alemtuzumab. **Summary and Conclusions.** In summary, five of six trials reported an increased risk for infections in general and CMV reactivations.The currently available evidence suggests an OS, CRR and PFS benefit for alemtuzumab compared with no further therapy.The role of alemtuzumab versus rituximab still remains unclear. Further trials with longer follow-up are needed to evaluate the effects of both agents compared with each other.In comparison with chlorambucil, alemtuzumab seems to be favourable in terms of PFS, but a longer follow-up period is needed to determine whether this effect will translate into a survival advantage.

RITUXIMAB FOR CHRONIC LYMPHOCYTIC LEUKEMIA: A SYSTEMATIC REVIEW WITH META-ANALYSIS

K Bauer[1], M Rancea[2], T Elter[3], V Roloff[4], M Hallek[3], A Engert[3], N Skoetz[2]

[1]Cochrane Haematological Malignancies Group, Department I of Internal Medicine, Cologne, Germany

[2]Cochrane Haematological Malignancies Group, University Hospital of Cologne, Cologne, Germany

[3]Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

[4]MRC Biostatistics Unit, Cambridge, United Kingdom

Background. Chronic lymphocytic leukemia (CLL) is the most common lymphoid malignancy in Western countries. The administration of rituximab in addition to chemotherapy in the treatment of CLL patients showed promising results, but the effects differ between studies. Therefore, the impact of this monoclonal antibody remains uncertain. **Aims.** This systematic review with meta-analysis assessed the efficacy and safety of chemotherapy plus rituximab compared to chemotherapy alone in patients with CLL. **Methods.** We performed a systematic review with meta-analysis of randomized controlled trials (RCTs). Therefore we searched CENTRAL, MEDLINE, and EMBASE as well as conference proceedings from January 1985 to January 2012 for RCTs. Two review authors independently screened search results, extracted data and assessed quality of trials. **Results.** A total of 1150 potentially relevant references were screened. We included three RCTs (N=1421 patients). The quality of these three trials ranged from moderate to high. The meta-analyses showed a statistically significant OS and PFS advantage for patients receiving rituximab (OS: HR 0.78 95% confidence interval (CI) 0.62 to 0.98, P=0.03; PFS: HR 0.64 (95% CI 0.55 to 0.74, P < 0.00001). Rituximab caused more AEs, WHO grade 3 or 4 (RR 1.15, 95% CI 1.08 to 1.23, P < 0.0001). There was no statistically significant difference regarding treatment-related mortality (RR 1.19, 95% CI 0.70 to 2.01, P = 0.52). **Summary and Conclusions.** The available evidence showed that patients receiving additional rituximab benefit in terms of OS and PFS compared to those with chemotherapy alone. On the other hand, additional treatment with rituximab increased the amount of occurring severe acute adverse events, but this did not lead to a statistically significant difference in the treatment-related mortality.

0752

EFFICACY OF COMBINATION FLUDARABINE AND ALEMTUZUMAB IN PATIENTS WITH RELAPSED AND REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

T Zagoskina, E Zotina, O Malykh

Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background. It is known that refractory to the fludarabine-containing regimens and their combination with rituximab is observed in some patients with chronic lymphocytic leukemia (CLL). The possibility of use of alemtuzumab in clinical practice has become a new milestone therapy relapse and refractory CLL. **Aims**. To study the efficiency and toxicity of the combination of fludarabine and alemtuzumab (FluCam) in patients with relapsed and refractory CLL. *Methods.* Twenty-four CLL patients aged 36 to 69 years (median 56 years) were included in the study. Fourteen patients were in Binet stage B, and 10 in stage C. The refractory to prior therapy was registered in 9 (38%) patients, 15 (62%) patients had relapsed CLL. The prior therapy included alkylating agents and fludarabine-containing regimens (FC, FCM, and FCR). ZAP-70 and CD38 expression was positive by flow cytometry in 92% and 67% of cases, respectively. Deletion 17p was determined by FISH analysis in 38% of patients, complex chromosomal aberrations were detected in 29%. The program FluCam consisted of fludarabine (25 mg/m^2 intravenously, days 1-3), and alemtuzumab (30 mg subcutaneously, days 1-3, after a standard dose escalation). Courses repeated every 28 days, their numbers ranged from 4 to 6. Throughout the period of treatment and 2 months after it pneumocystis pneumonia prophylaxis with trimethoprim/sulfamethoxazole 960 mg orally once daily, 3 times a week was carried out, as well as reactivation of cytomegalovirus infection valganciclovir 900 mg (two 450mg tablets) orally once daily was accomplished. Pegfilgrastim 6 mg subcutaneously was administered on day 6 of each course of therapy as primary prophylaxis for neutropenia. DNA of cytomegalovirus, Epstein-Barr virus, herpes types 1 and 2, hepatitis B and HCV RNA were monitored in all patients before treatment and every 2 weeks during therapy with polymerase chain reaction. **Results**. By using combination FluCam as a 2-4 line therapy an overall response was obtained in 18 (75%) patients, complete remission (CR) was achieved in 6 (25%) patients, and partial remission (PR) - in 12 (50%) of cases. Disease progression was observed in 2 (8%), stabilization of the process - in 4 (17%) patients. Among 6 patients with CR minimal residual disease was not revealed in 4 patients. Median follow-up was 23 months. The median overall survival was not reached. The median progression free survival (PFS) was 11 months (95% CI: 8.2-17.6) in the overall group of patients. The median PFS was 21 months in patients with CR, among patients with PR - 8 months. A direct correlation between PFS was determined in patients with the presence of complex chromosomal aberrations and deletion 17p (R=0.624; p=0.017). The most common manifestations of hematologic toxicity were neutropenia (58%), thrombocytopenia (21%) and anemia (17%). Infectious complications were occurred in 54% of patients, including severe ones - in 17%, in the form of pneumonia. Asymptomatic CMV reactivation was revealed in 42% of cases. All side effects were curable. **Conclusions**. The combination FluCam is highly effective, characterized by acceptable toxicity in patients with relapsed and refractory CLL.

0753

SEVERE INFUSION-RELATED REACTIONS ARE UNCOMMON IN RITUXIMAB-TREATED CLL PATIENTS: RESULTS FROM A NATIONAL OBSERVATIONAL STUDY

N Norin[1], B Björkstrand[2], F Rommel[3], L Timberg[4], P Andersson[5], J Häggström[6], A Aldrin[7], L Hansson[8]

[7]Department of Medicine, Visby Hospital, Visby, Sweden

[8]Hematology Center, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

Since the approval of rituximab (R), there have been concerns about infusion-related adverse reactions, especially in patients with a large number of circulating tumor cells as in chronic lymphocytic leukemia (CLL). In the randomized CLL8 trial by the German CLL study group, comparing R-FC with FC, relatively few serious infusion-related adverse events were noted, but this has not been studied in a general population. We therefore conducted a multi-center observational trial to study the incidence and management of infusion-related adverse events.Patients with CLL requiring therapy were eligible for this study after informed consent if the planned therapy contained rituximab. Therapeutic regimen, premedication and management of adverse events were up to the physician and not stated in the protocol.Totally 96 (70 males, 26 females) patients from 19 centers were enrolled. Median age was 67 years (range 41-89). Median time from diagnosis to study inclusion was 3.4 years (range 0-17). Previous therapy for CLL had been given to 46 patients. Five patients had previously received rituximab. Median leukocyte count before therapy was $70*10^9$/L (range 2-422).The most used regimens were standard (n=66) or reduced (n=12) R-FC. Other regimens were R-bendamustine (n=8), R-CHOP (n=2), R-COP (n=3), R-chlorambucil (n=1), R-cyclophosphamide (n=1), R-fludarabine (n=1) and rituximab monotherapy (n=2). Of the 96 patients 81 received rituximab from the first course of therapy, nine from cycle 2, two from cycle 3, three from cycle 4 and one from cycle 5. The rituximab infusion was split over two days with 100 mg given the first day and the remaining dose at day 2 during the first course in seven patients and during the second in two patients. Almost all patients (98%) received antihistamine. and most of them also paracetamol (88%) and corticosteroids (86%) as premedication before the first rituximab infusion.Six courses of therapy were completed in 46 (48%) patients. Reasons for premature discontinuation include therapy-related toxicity (n=23), good clinical response after fewer courses (n=14), decision of the patient (n=4), refractory disease (n=4), secondary malignancy (n=1), death (n=1), stem cell transplantation (n=1), change of hospital (n=1) or not stated (n=1).Adverse reactions (AR) during rituximab infusion were seen in 56 patients (58%). However, grade 3 (n=5) or 4 (n=1) reactions occurred in only five patients on six occasions and in all but one case only during the first course. The reactions consisted of rigors (n=2), nausea (n=1), hypotension (n=1), dyspnea (n=1) or flushing (n=1). Only two of these patients had a leukocyte count > $50*10^9$/L. The AR was treated with steroids in 29 patients and pethidine was used in 7 cases. The patient with grade 4 hypotension was also given atropine. No cases of tumor lysis syndrome were recorded despite that the median reduction of leukocyte count between the first and second course was 91%.In this study the number of severe rituximab-related infusion reactions was low despite a high number of circulating tumor cells. Thus, R-FC or other rituximab-containing regimens can be considered safe in the general population of CLL patients.

0754

EFFICACY AND TOLERANCE OF FLUDARABINE AND CYCLOPHOSPHAMIDE(FC) COMBINATION REGIMEN IN ADVANCE STAGE CHRONIC LYMPHOCYTIC LEUKEMIA

F Alwan[1], F Matti[2], S Naji[2], F Majid[2], F Sabir[1]

[1]The National Center of Hematology, Baghdad, Iraq

[2]Baghdad Teaching Hospital, Baghdad, Iraq

Background. Chronic lymphocytic leukemia (CLL) is the classical leukemia of the elderly and the treatment often must be tailored to the patient's fitness level and ability to tolerate more toxic combination therapies.Many randomized trials have shown that the addition of cyclophasphamide to fludrabine clearly improves the CR and OR rate and PFS as compared with fludarabine monotherapy. An additional important result of these trials was that FC did not increase the rate of severe infections despite inducing more grade 3 and 4 neutropenias.aimsto assess the efficacy and tolerability of FC combination chemotherapy in Iraqi adult patients with advanced chronic lymphocytic leukemia, reflected by response rate, treatment free survival and overall survival.methodsA prospective study carried out in Baghdad teaching hospital and national hematology center in Baghdad between February 2005 and fabruary 2009 included 64 Iraqi patients aged between 39-77years old with advanced stage CLL. A written informed consent was obtained from all patient prior to start of therapy.they received FC combination therapy (fludarabine 25 mg/m^2 plus cyclophosphamide250mg/m^2 for 3 days intravenously, repeated every 28 days). Treatment was administered for 6 courses.ResultsOut of 64 CLL patients with Binet stage B&C who were included in this study, 41(64.1%)patients were male and 23(35.9%)patients were females (M:F ratio1.7:1) with median time of follow up 26 months. median age was 59.9years. forty- eight (75%)patients were previously untreated, of them 22(45.8%)patients were stage B and 26(45.1%)patients were stage C while the other 16(25%)patients with CLL were previously treated with an alkylating agents, of them7(43.7%) of stage B and 9(56.2%) with stage C.This combination chemotherapy resulted in 39.1% complete remission and 39.1% partial remission.The 2 years median treatment-free survival was 90% with the median duration of response was 18 months. there was a significant difference ($p<0.005$) between the different Binet stage group(C&B) and degree of response, with better response rate in those with stage C than those with stage B. the overall response rate was 88.3%, 65.5% for stage C and B respectively.The major toxicity(grade 3-4) were nausea and vomiting while the myelosupression of grade 1&2 for leucopenia and neutropenia occur in 19%, 14% respectively conclusion Fludarabine and cyclophosphamide combination regimen is an effective therapy for patients with advanced CLL with high response and complete remission rate in both untreated and previously treated CLL patients, with good tolerability to this combination

0755

EPHB4/ RAC1/CDC42/RHOA PATHWAY CONTRIBUTES TO IMATINIB RESISTANCE IN CHRONIC MYELOID LEUKEMIA

L Liu, H Huang, D Du, Z Zhang, X Xu
Nanfang Hospital, Guangzhou, China

Background. Although the mechanism of imatinib (IM) resistance in chronic myelogenous leukemia (CML) has been intensively investigated, few studies have investigated the role of Eph receptors in IM resistance. In 2003, Ohmine et al suggested the disturbance of RhoA protein kinase signaling, was involved in imatinib resistance. In 2010, Suzuki et al reported that there existed a new mechanism of IM resistance mediated by the activation of Ras/MAPK pathway and EphB4 in Philadelphia chromosome-positive acute lymphocytic leukemia (ALL). **Aims.** Our purpose was to address the role of EphB4 in IM resistance. Then, in order to further determine the mechanism of EphB4 receptor contributing to IM resistance, we detected a serious of phosphorylation of Ras/MAPK and RhoA related signaling proteins. **Methods.** K562 IM-resistant cell lines (K562-R) were supplemented with 5.45 mg/L IM. The stable underexpressing EphB4 cells (K562-R-EphB4-sh) were obtained (Oligonucleotides for shRNA were designed using ABI online software, Lentiviruses were generated and were cotransfected in 293T cells, then directly infected K562-R cells). Semi-quantitative PCR (SQ-PCR) was performed on ABI 9700 system. Phosphorylation of molecules was analyzed by Western Blot method. BALB/C female nude mice (4-5 weeks of age) were used in xenograft experiments. **Results**. Western Blot analysis showed that the EphB4 receptor was overexpressed in the IM-resistant K562-R cell line (P<0.001). We established the stable underexpressing EphB4 cell line K562-R-EphB4-sh. MTT analysis suggested that K562-R-EphB4-sh cell was sensitive to IM (IC50 0.93 mg/L) and K562-R showed IM resistance (IC50 5.45 mg/L, P<0.001). In a xenograft model, K562-R tumor volumes significantly increased in the setting of IM treatment (2301.25 mm^3 versus 1733.82 mm^3, P=0.001). In contrast, the K562-R-EphB4-sh xenograft volumes had no definite change (1630.16 ± 412.01 mm^3 versus 1720.06 ± 290.54 mm^3, P=0.40) after receiving IM treatment. Overall survival after 30-treatment-days was 66.7%, 0% and 33.3% in the K562-W, K562-R and K562-R-EphB4-sh xenograft groups, respectively (P=0.001). Meanwhile, there were no differences of the phosphorylation of MEK/ERK between K562-R and K562-R-EphB4-sh cells or xenograft tissue. Nevertheless, phosphorylations of RhoA and rac1+cdc42 were significantly decreased in K562-R-EphB4-sh cells and xenograft tissue compared with K562-R cells and xenograft tissue (P<0.001). **Conclusions**. We confirmed that EphB4 expression was increased in IM resistant cells and decreased in K562-R-EphB4-sh cells conferred sensitivity to IM. Similarly, low-expression of EphB4 also became sensitivity to IM in K562 xenograft model. MEK/ERK activity was not change with down-regulated EphB4. The phosphorylations of RhoA and Rac1+cdc42 were simultaneously decreased in K562-R-EphB4-sh cell line and xenograft tissue comparing with K562-R cell line and xenograft tissue. These data supported a new marker of IM resistance mediated by the activation of EphB4/Rac1/cdc42/RhoA pathway in CML.

SMALL CLONES OF BONE MARROW CELLS WITH BCR-ABL GENE AMPLIFICATION PREDICT UNFAVORABLE OUTCOME OF IMATINIB CML TREATMENT

S Kutsev[1], S Mordanov[2], O Ustaeva[2], E Grankina[2], Y Shatokhin[2], O Serdjuk[3], E Polevichenko[4], A Turkina[5]
[1]Research Center of Medical Genetics of RAMS, Moscow, Russian Federation
[2]Rostov State Medical University, Rostov-on-Don, Russian Federation
[3]Krasnodar Regional Oncology Hospital, Krasnodar, Russian Federation
[4]Research and Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation
[5]Research Hematologic Center, Moscow, Russian Federation

Background. The therapy of CML by TKI have shown impressive results last decade. However 24% of patients (pts) on imatinib therapy have failed to achieve optimal response in 18 months (O'Brien et al. , 2003) and 10% pts have lost the achieved response in 5 years (Druker BJ et al. , 2008). The amplification of BCR-ABL gene have postulated in a lot of review papers as one of the important mechanism of resistance to TKI therapy. Nevertheless there is no any large cohort of CML patients (pts) data according to the role of BCR-ABL gene amplification as well as the significance of clone size of BM cells with amplification in resistance to TKI. **The purpose** of this study was to elucidate the predictive significanse of BCR-ABL gene amplification and the role of small clones of BM cells with BCR-ABL gene amplification in large cohort of CML patients in resistance to imatinib. **Materials and Methods.** 174 CML patients (130 -CP, 44 -AP) on imatinib 400 or 600 mg QD therapy more than 12 months duration were included in study**.** According to the ELN criteria (2009) 51 pts have achieved optimal or suboptimal response, 86 pts have failure and 37 pts have loss of response. BM samples were analyzed by cytogenetic and D-FISH analysis with dual color/dual fusion BCR-ABL gene probe ("Vysis") with cutoff <1%. **Results.** In our study BCR-ABL gene amplification was revealed in 44/174 patients (25%). From 44 pts with amplification 28(63,6%) pts were in CP and 16(36,4%) - in AP (p<0.05). FISH did not revealed BCR-ABL amplifications in pts with optimal and suboptimal responses. Additional copies of BCR-ABL gene (from 1 to 7) were found in 32 (37,2%) pts with failure and in 12 (32,4%) pts with loss of response (p>0,5). The probability of complete cytogenetic response (CCyR) achievement in pts with BCR-ABL amplification was significantly lower than in pts without it (31,6% vs. 63,8%, p<0,0001). The probability of CCyR achievements in pts of Q1-Q2 (1-6% BM cells with BCR-ABL amplification) did not differ from pts of Q3-Q4 (7-72% BM cells with BCR-ABL amplification) (p>0,5). **In conclusion**, BCR-ABL gene amplification is not rare in resistant patients in chronic and accelerated phases of CML. The pts with low level clones with BCR-ABL amplification have the same unfavorable prognosis as well as pts with high level clones.

0757

EFFICACY AND SAFETY OF BOSUTINIB FOR PHILADELPHIA CHROMOSOME-POSITIVE LEUKEMIA IN OLDER VERSUS YOUNGER PATIENTS

C Gambacorti-Passerini[1], T Brümmendorf[2], J Cortes[3], P Schafhausen[4], A Hochhaus[5], T Kindler[6], T Fischer[7], N Besson[8], E Leip[9], V Kelly[9], HJ Khoury[3]

Background. Bosutinib is an oral dual Src/Abl kinase inhibitor with potent activity in Bcr-Abl-positive leukemia. **Aims.** To evaluate the efficacy and safety of bosutinib in older (≥65 years; n=119) and younger (<65 years; n=451) patients. **Methods.** Bosutinib 500 mg/day was administered to patients in 3 cohorts: chronic phase chronic myeloid leukemia (CP CML) after imatinib (CP2L cohort; n=287); CP CML after imatinib + dasatinib and/or nilotinib (CP3L cohort; n=119); and accelerated/blast phase (AP/BP) CML or acute lymphoblastic leukemia after imatinib ± dasatinib and/or nilotinib (ADV cohort; n=164).

	CP2L cohort		CP3L cohort		ADV cohort

MHR, major hematologic response; CHR, complete hematologic response; MCyR, major cytogenetic response; CCyR, complete cytogenetic response.
[a]Evaluable patients had ≥1 bosutinib dose and a valid baseline assessment.
[b]Kaplan-Meier estimate. [c]Treated population.
[d]Patients with AP CML (≥65 y, n=1/8; <65 y, n=3/56) who transformed to BP.

Results. Notable baseline medical events (≥65 vs <65 years) included respiratory disorders (35% vs 13%), cardiac disorders (29% vs 9%), and diabetes (4% vs 4%). Median numbers of baseline medications were 5 (≥65 years) and 3 (<65 years). The median duration of bosutinib treatment was 11 months and the median follow-up was 31 months among both patient groups. Common on-study concomitant medications (≥65 vs <65 years) included anti-diarrheals (64% vs 57%), antacids (69% vs 41%), analgesics (60% vs 50%), systemic antibacterials (56% vs 51%), and diuretics (48% vs 20%). Bosutinib was dis-

continued by 80% of patients ≥65 years and 67% of patients <65 years; 32% and 18% of patients, respectively, discontinued due to an adverse event (AE; most commonly thrombocytopenia [6% vs 3%]), while 19% and 25% of patients discontinued due to disease progression. Rates of response were similar or numerically lower in older versus younger patients (Table). On-treatment transformation to AP or BP CML was generally similar between age groups (Table). Rates of on-treatment progression-free survival (PFS) and on-study overall survival at 2 years were numerically lower among older versus younger patients in the CP2L and CP3L cohorts, but similar in the ADV cohort (Table). Eleven (9%) older patients and 32 (7%) younger patients died within 30 days of their last bosutinib dose. Incidences of non-hematologic treatment-emergent AEs were generally similar between older and younger patients, notably (all grades/grade ≥3 for ≥65 vs <65 years): diarrhea (85%/9% vs 81%/8%), infection (56%/15% vs 49%/10%), nausea (50%/1% vs 46%/2%), vomiting (43%/3% vs 38%/3%), rash (39%/8% vs 31%/6%), fatigue (34%/3% vs 20%/2%), and edema (8%/0% vs 4%/<1%). Cardiac AEs were reported for 29% of older (atrial fibrillation [6%], congestive cardiac failure [5%], cardiac failure [5%]) and 10% of younger patients, including 15% and 4% of patients with grade ≥3 events. Of patients with cardiac events, 44% and 33% received concomitant medication, and 53% and 67% had their event resolve (median event duration, 6 vs 11 days). Dose reductions and delays, respectively, due to AEs were required by 54% and 77% of patients ≥65 years versus 41% and 60% of patients <65 years. Common grade ≥3 laboratory abnormalities (≥65 vs <65 years) included thrombocytopenia (35% vs 35%), neutropenia (21% vs 25%), anemia (19% vs 19%), hypermagnesemia (8% vs 11%), and elevated lipase (10% vs 6%). **Conclusion:** In general, bosutinib demonstrated similar efficacy and acceptable safety in older and younger patients with Philadelphia chromosome-positive leukemia and resistance/intolerance to prior imatinib and possibly dasatinib and/or nilotinib.

0758

RESULTS FROM THE ENESTND EXTENSION STUDY: EFFICACY AND SAFETY OF NILOTINIB 400 MG BID IN PATIENTS WITH PH+ CML-CP AFTER SUBOPTIMAL RESPONSE OR TREATMENT FAILURE TO IMATINIB OR NILOTINIB 300 MG BID

In the ENESTnd study, nilotinib demonstrated superior response rates and lower rates of progression to accelerated phase/blast crisis (AP/BC) and CML-related death vs imatinib in patients with newly diagnosed Ph+ CML. Patients in ENESTnd who experienced suboptimal response or treatment failure (per European LeukemiaNet 2009 recommendations) on nilotinib 300 mg BID or imatinib could discontinue the core study and enter an extension study to be treated with nilotinib 400 mg BID; entrance was not allowed for intolerance alone. **Aims.** The purpose of the extension study was to evaluate the efficacy and safety of nilotinib 400 mg BID in patients after suboptimal response or treatment failure on imatinib (including patients on imatinib escalated to 400 mg BID) or on nilotinib 300 mg BID. Here, we report the results of the ENESTnd extension study with a median follow-up of 15-18 months. **Methods.** Patients entering the extension study were evaluated for complete cytogenetic response (CCyR) and major molecular response (MMR) on extension treatment with nilotinib 400 mg BID. Patients were also evaluated for progression to AP/BC and overall survival (OS). **Results.** Overall, 54 patients entered the extension study and received nilotinib 400 mg BID; 19 initially randomized to nilotinib 300 mg BID in ENESTnd (nilotinib dose-optimization group) and 35 initially randomized to imatinib (nilotinib second-line group). In the nilotinib dose-optimization group, 26% of patients had mutations at extension-study entry. In the nilotinib dose-optimization group, 33% of patients not in CCyR at extension-study entry and 39% not in MMR at extension-study entry achieved these responses on extension treatment with nilotinib 400 mg BID; 1 patient in the dose-optimization group progressed to AP/BC (after discontinuation from extension treatment). The estimated 18-month rate of OS was 94% in the nilotinib dose-optimization group. In the nilotinib second-line group, 69% of patients had prior imatinib dose escalation to 400 mg BID, and 31% of patients had mutations at extension-study entry. In the nilotinib second-line group, 58% of patients not in CCyR at extension-study entry and 32% of patients not in MMR at extension-study entry achieved these responses on extension treatment with nilotinib 400 mg BID. Of the 24 patients who had prior imatinib dose escalation, 15 and 23 patients, respectively, were not in CCyR and MMR at extension-study entry; 9/15 (60%) achieved CCyR and 7/23 (30%) achieved MMR on extension treatment with nilotinib 400 mg BID. Five patients in the second-line group progressed to AP/BC (2 while on extension treatment). The estimated 18-month rate of OS was 87% with second-line nilotinib. The safety profile of nilotinib 400 mg BID was consistent with previous studies, and nilotinib dose escalation appeared safe with minimal additional safety signals. **Conclusions.** These data demonstrate that nilotinib is an effective therapeutic option for patients after imatinib failure and that nilotinib dose escalation may benefit some patients with suboptimal response and treatment failure on nilotinib 300 mg BID. Additional follow-up will provide more information on this strategy.

The international, collaborative effort to standardize BCR-ABL qRT-PCR testing for CML has focused largely on determining whether a patient has or has not achieved MMR (≤0.1% BCR-ABL on the International Scale; equivalent to ≥3-log reduction in BCR-ABL transcript levels from the IRIS standard baseline). Many patients on imatinib achieve MMR, but only a minority progress to what has been termed complete molecular response (CMR), defined by the European LeukemiaNet (ELN) as undetectable BCR-ABL transcripts by qRT-PCR and/or nested PCR in 2 consecutive samples with a sensitivity >10^4. This def-

inition, however, is difficult to implement in a standardised fashion across multiple centres and does not adequately take into account variations in assay sensitivity within and between centres. Improved definition of molecular milestones is a pressing issue since second-generation TKIs result in deeper molecular responses compared to imatinib. Furthermore, there is considerable interest in conducting studies (e.g. EURO-SKI) to assess the possibility of stopping TKI therapy once significant and sustained molecular responses are achieved. There is a general consensus that it is not possible to have a single workable definition of CMR, but rather the level of response needs to be defined by an upper boundary. So, just as MMR corresponds to ≤0.1% BCR-ABL^{IS}, the terms CMR^4, CMR$^{4.5}$ and CMR^5 have started to be used to indicate levels of disease ≤0.01% BCR-ABL^{IS} (4-log reduction from IRIS baseline), ≤0.0032% BCR-ABL^{IS} (4.5-log reduction) and ≤0.001% BCR-ABL^{IS} (5-log reduction), respectively. However there are two immediate problems. The first is semantic: the fact that cut offs are defined by an upper boundary means that disease may still be detectable at a lower level, which does not fit well with the term 'complete'. We therefore propose that the terms for low level disease are modified to 'molecular response', i.e. MR^4, MR$^{4.5}$ etc. The second problem concerns laboratory standardisation: how is MR^4, MR$^{4.5}$ etc. actually determined in the testing laboratory and how comparable are results across different laboratories? ENEST1st is a phase IIIb, open-label study of nilotinib in adult patients with newly diagnosed CML (ClinicalTrials.gov NCT01061177). The primary study aim is to establish the rate of MR^4 at 18 months and to work with EUTOS (European Treatment and Outcome Study) laboratories to improve the sensitivity and standardisation of qRT-PCR for low level BCR-ABL detection. Preliminary analysis of data from the 12 ENEST1st molecular monitoring laboratories shows substantial variation in scoring of low level disease results caused principally by technical differences but exacerbated by differences in laboratory definitions. Since conversion factors are of questionable value when disease is undetectable, we suggest the following working criteria should be used to define molecular response: MR^4 = either (i) detectable disease ≤0.01% BCR-ABL^{IS} or (ii) undetectable disease in cDNA with ≥10,000 ABL or ≥24,000 GUSB transcripts MR$^{4.5}$ = either (i) detectable disease ≤0.0032% BCR-ABL^{IS} or (ii) undetectable disease in cDNA with ≥32,000 ABL or ≥77,000 GUSB transcripts . Details of these definitions, their implementation in the testing laboratory and what further work needs to be performed will be discussed.

Background. Research confirming the significance of achieving a complete molecular response (CMR) during treatment of the chronic phase of chronic myeloid leukemia (CML-CP) is going to be of importance. According to the Stop Imatinib (STIM) study reported by Mahon et al., 41% of patients who achieved a CMR for at least 2 years during treatment with imatinib had sustained the CMR for at least 12 months after cessation of the drug. **Aims.** The ratio of CML-CP patients achieving CMR (BCR-ABL^{IS}≦0.0032%) among those who achieved MMR was evaluated using international standard real-time quantitative PCR (IS-PCR). In addition, the correlation between the molecular response and the clinical parameters and immunological or pharmacokinetic background. was studied. **Methods.** Patients with a confirmed diagnosis of CML-CP, who were 16 years old or older, treated with ongoing imatinib at any dose, and in MMR confirmed within 3 months before enrollment, were eligible for inclusion at 21 participating institutions in Japan. The molecular response was assessed using IS-PCR at a central laboratory (BML, Inc., Kawagoe, Japan). CMR was confirmed by analysis of blood samples collected from each patient twice on different days after getting informed consent. Flow cytometry-based analysis (FCM) of peripheral blood T-cell subsets was performed using a whole blood lysis technique. Imatinib trough concentrations were determined using high-performance liquid chromatography (HPLC) equipped with a mass spectrometric detector. *ABCG2* 421C>A (rs2231142), ABCB1 3435C>T (rs1045642), *SLC22A1* 156T>C (rs1867351), *SLC22A1* 480G>C (rs683369), and *SLC22A1* 1022C>T (rs2282143) genotyping were performed using PCR-RFLP. **Results.** Of the 157 patients registered, data from 130 were evaluated by the deadline for this abstract. Imatinib was administered for a median of 70.0 months (range: 9.7-118.5 months), and the median actual daily dose was 396 mg (range: 159-528 mg). From the results of double IS-PCR tests performed on different days, 60 patients (46%) were classified into the CMR group. Comparison of patients who did and did not achieve CMR revealed several significant differences (Table 1). First, the median time to MMR from the onset of imatinib administration was significantly shorter in patients with CMR than in those without CMR. Second, although the median trough concentration of imatinib did not significantly differ between patients with and without CMR, the frequency of *ABCG2* 421C/A or 421A/A among patients with CMR was significantly greater than among those without CMR. Third, T cell profiles in peripheral blood evaluated by FCM were related to achievement of CMR. CD4+/CD25$^{high-int}$/CD127^{low} Treg cells were significantly less frequent in patients with CMR than in those without CMR. **Conclusions**. Among CML-CP patients confirmed to have achieved MMR, about half could have achieved CMR. The correlation between the molecular response and the clinical parameters and characteristics of patients achieving a confirmed CMR are discussed.

BONE MARROW ANGIOGENESIS AND ITS CLINICOPATHOLOGICAL CORRELATION IN CHRONIC MYELOID LEUKEMIA: A MORPHOMETRIC STUDY

S Sharma, S Raj, V Agrawal

SGPGIMS, Lucknow, India

Background. Angiogenesis is classically associated with growth, dissemination and metastases of solid tumors**.** Increased microvessel density has been documented in bone marrows of various hematological malignancies including chronic myeloid leukemia (CML). **Aims.** The aim was to study multiple morphometric microvessel characteristics in CML patients and evaluate their relationship to clinicopathological parameters of proposed prognostic significance. **Methods.** Bone marrow paraffin -embedded biopsies obtained at diagnosis from 50 patients with CML in chronic phase and 10 patients in blast transformation, diagnosed at our institute during 2005-2009, were studied. Ten age and sex matched patients in which marrow biopsies were performed as part of staging procedure for non-Hodgkin's lymphoma and had no evidence of marrow disease were taken as controls. Immunohistochemically stained slides using anti CD34 antibody were examined for microvessel density (MVD) using light microscopy and computerized Image analysis system for following morphometric parameters: MVD, total vascular area (TVA), perimeter, major and minor axis length. SPSS 15 was used for statistical analysis. The data is presented as mean ±SD. ANOVA was used to compare the morphometric variables among the three groups of CML chronic phase, blast transformation and controls. **Results.** The mean MVD on image analysis was 228.7± 63.2 / mm^2 in chronic phase CML patients and 275.1± 93.8 in blast transformation patients which was significantly higher (p<0.001) than in control group 58.4±12.9. A significant difference was also observed between size related parameters i.e. TVA, perimeter, major and minor axis lengths in the chronic phase group and controls. Total vascular area in CML chronic phase 2.0±0.7% and blast phase 1.6±0.7 % was significantly higher (p<0.001) than in controls 0.3 ±0.2 %. The mean perimeter

34.4 ±7.4µm and major axis length 11.9±2.9µm in blast transformation group were lower and differed significantly from the chronic phase group perimeter 47.8±9.6 µm and major axis length 16.8±4.0µm indicating a predominance of smaller vessels with less branching in the former group. MVD correlated significantly ($p<0.01$) with TVA. A positive correlation was found between MVD and blast percentage in bone marrow of patients in blast transformation. A negative correlation existed between vessel number and vessel size parameters (though not significant). None of the morphometric variables was related to patient's age, spleen size, hemoglobin level, total leukocyte count, platelet, eosinophil or basophil counts. **Conclusion.** Our data suggests that vascularity is increased in CML in both chronic and blast phase and supports the hypothesis that changes in angiogenic parameters may participate in conversion of normal marrow to CML.

THE NEW EUTOS SCORE HAS PROGNOSTIC VALUE IN THE TREATMENT OF CHRONIC MYELOID LEUKEMIA (CML) OUTSIDE CLINICAL TRIALS

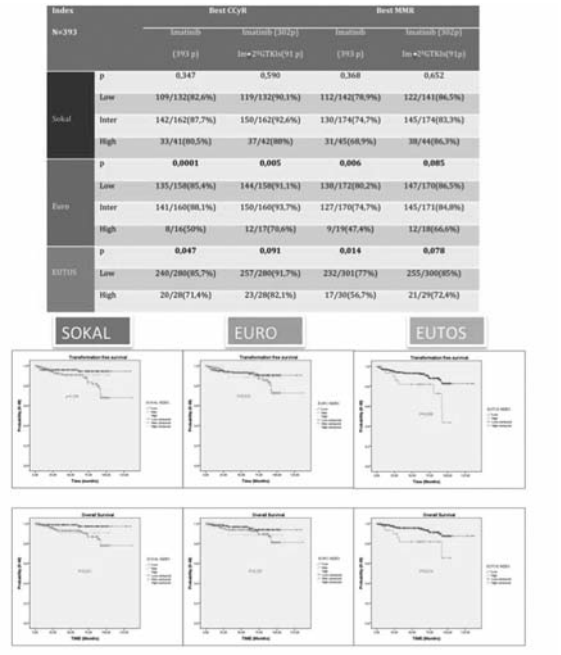
LF Casado Montero[1], V García-Gutierrez[2], B Maestro[2], I Massagué[2], P Giraldo[2], M Pérez-Encinas[2], R De Paz[2], J Martínez-López[2], G Bautista[2], S Osorio[2], MJ Requena[2], L Palomera[2], MJ Peñarrubia[2], MH Dumas[2], N García-Ormeña[2], C Calle[2], JA Hernández-Rivas[2], JL Steegmann[3]

[1]Hospital Virgen de la Salud, Toledo, Spain

[2]RELMC, Madrid, Spain

[3]Registro Español de Investigación y Tratamiento de Leucemia Mieloide Crónica, Madrid, Spain

Background. Hasford et al have published a new scoring system, which was developed by the EUTOS project of the European Leukemia Net. This study of 2060 patients includes only CML patients treated with imatinib-based regimes in clinical trials.This new EUTOS score identified only two variables with independent prognostic significance, the spleen size, and percentage of basophils, variables included in the Sokal and Euro score[3], respectively. As the EUTOS score has been developed from clinical trials, there is a need of validating it outside this specific settingThe RELMC Registry is a continuous, 17-hospitals-based CML registry including patients not included in clinical trials, and whose aim is to describe the treatments received by patients with CML in Spain, their outcomes, and the variables that influence treatment choices and results.



Aims. 393 newly-diagnosed CML-CP patients have been treated upfront with imatinib, with a median age of 54,3 years, 236(60%) were men, 157 (40%) women. At diagnosis, the score distribution was as follows: Sokal L-I-H (39%-49%-12%), EURO L-I-H (47%-48%-6%); and EUTOS: L-H (91%-9%). Out of the 393 patients, 302 remained in Imatinib as sole therapy. (252 imatinib 400, 27 with high dose upfront , and 23 patients switching from Im400 to 600 or 800 mg. Ninety patients were switched to a second generation TKI (2GTKI) (20 because of intolerance, and the others 71 because of failure, suboptimal response or lost of response). Out of them, 43 received dasatinib as second line, 25 nilotinib as second line, 16 dasatinib and then nilotinib, and 7 nilotinib and then dasatinib)The responses have been analysed considering the best response obtained during the initial treatment with Imatinib, or irrespective of the scheme in which they were obtained. **Results.** Response to treatment: Our results show that EUTOS score has substantial discriminating power, as far as CCyR and MMR is concerned, specially when analysing the best response obtained with Imatinib as first scheme of therapy. Euro score discriminates only between low intermediate versus high-risk groups.Survival and progression-free survival: Out of 393 patients, 13 patients have suffered transformation (6 AP, 7 BC). In total, 25 patients have dead (6,3%).The probability of transformation was statistically significant higher in high-risk EUTOS patients, but neither Hasford nor Sokal were discriminant in this aspect. The same applies for progression-free survival and overall survival. **Conclusions.** Our results validate the EUTOS score, within the setting of TKI based therapies, away from clinical trials. In fact, EUTOS score appears more discriminant than the other prognostic systems. While waiting the definitive results of the EUTOS project to see if this scoring system has significant predictive power in larger series of patients, we feel that the EUTOS score warrants application in every single CML patient, along with the Sokal and Euro scores.

0763

LONG-TERM CLINICAL SIGNIFICANCE OF CYTOGENETIC CLONAL EVOLUTION IN NEWLY DIAGNOSED CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH IMATINIB

SE Lee[1], SY Choi[2], JH Bang[2], SH Kim[2], EJ Jang[2], JY Byeun[2], JE Park[2], HR Jeon[2], M Kim[3], DW Kim[1]

[1]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea

[2]Cancer Research Institute, The Catholic University of Korea, Seoul, South-Korea

[3]Department of Laboratory Medicine, Seoul St. Mary's Hospital, The Catholic Unive, Seoul, South-Korea

Background. Cytogenetic clonal evolution in chronic myeloid leukemia (CML) is considered as a step to progression to accelerated phase and blast phase (BP). However, it has been described in approximately less than 10% of chronic phase (CP) CML already at diagnosis. Long-term clinical significance of the new other chromosome abnormalities (OCA) on therapy as well as additional chromosome abnormality (ACA)/variant Philadelphia translocation (vPh) found at diagnosis in newly diagnosed CP CML patients treated with imatinib mesylate (IM) is not yet fully clarified. **Aims.** The aim of this study was to investigate long-term clinical significance of the OCA on therapy as well as ACA and vPh at diagnosis in newly diagnosed CP CML patients treated with IM. **Methods.** 281 consecutive patients newly diagnosed as CP CML at Seoul St. Mary Hospital between January 2001 and May 2009, and started IM (400 mg/day) therapy without prior treatment except hydroxyurea or anagrelide were analyzed. The median number of cytogenetic examination for each patient was 4 (range, 1-28). There were 161 males (57%) and 120 females (43%). Median age was 41 years (range, 18-77). **Results.** At newly diagnosis, 259 patients (92%) of the 281 patients had only standard Ph translocation, 13 (5%) patients had ACA(s), and 9 (3%) patients had a vPh chromosome. Of the 22 patients with CCA, 17 (77.3%) 11 (50%), and 3 (13.6%) patients have achieved CCyR, 2 consecutive MMR and $MR^{4.5}$ after a median 6.0, 12.3 and 25.7 months of IM treatment, respectively. In contrast, of the 259 patients without CCA, 227 (87.6%), 164 (63.3%), and 50 (19.3%) patients have achieved CCyR, 2 consecutive MMR, and $MR^{4.5}$ after a median 6.3, 19.8, and 24.8 months, respectively. With a median follow-up of 78.6 months (range, 1.4-126.1 months), the-5-year OS, PFS and EFS were 77.8%, 77.8% and 75%, respectively for the patients with vPh; 100%, 100% and 66.3%, respectively for the patients with ACA; 96%, 94.3% and 92.1%, respectively for the patients without CCA. The patients with vPh had the lower OS, PFS and EFS compared to the patients without CCA. Whereas the patients with ACA had no difference in OS, PFS and EFS, compared to the patients without CCA.In our study, 19 patients developed new OCA in Ph- cells (n = 16) and Ph+ cells (n = 3) on therapy. The occurrence of OCA in Ph+ cells can lead to significantly decreased OS, PFS and EFS with a RR of 20.59 ($P <0.001$), 43.32 ($P <0.001$), and 38.02 ($P <0.001$), respectively compared with the patients who had no CCA at diagnosis and no OCA on therapy (no CA group). Whereas, OCA in Ph- cells had no impact on survival outcomes compared with no CA group. **Conclusions.** This study showed that vPh at diagnosis was associated with poor survival outcomes, whereas ACA did not affect long-term survival outcomes. In addition, the distinctive difference of prognostic impact of OCA in Ph+ cells or OCA in Ph- cells on therapy may identify a group of patients requiring a change of treatment strategy.

SPLICE VARIANT, ABL EXON 7 DELETION DOES NOT CONFER IMATINIB RESISTANCE IN CHRONIC MYELOID LEUKEMIA

N Meggyesi[1], L Kalmár[2], S Fekete[3], T Masszi[3], A Tordai[1], H Andrikovics[1]
[1]Hungarian National Blood Transfusion Service, Budapest, Hungary
[2]Institute of Enzymology, Hungarian Academy of Science, Budapest, Hungary
[3]St. István-St. László Hospital, Budapest, Hungary

Background. In chronic myeloid leukemia (CML), the best characterized imatinib resistance mechanisms are BCR-ABL tyrosine kinase domain (TKD) mutations and clonal evolution, but recently alternative splicing (AS) of BCR-ABL was also proposed as a mechanism for imatinib resistance. Most of the studies focused on three splice isoforms: deletions of exons 4 or 7 (Δexon4 or Δexon7) and a 35-basepair-long insertion between exons 8 and 9. Although several groups reported the presence of Δexon7 in patients with imatinib-resistant CML on BCR-ABL (BCR-ABL$^{\Delta exon7}$) and even in healthy controls on ABL (ABL$^{\Delta exon7}$), detailed structural analysis has not been performed yet.**Aims.** The aim of this study was the characterization of Δexon7 by systematic screening of the frequency of BCR-ABL$^{\Delta exon7}$ andABL$^{\Delta exon7}$ during the disease course and in healthy individuals as well as by bioinformatic modeling. **Methods.** The frequency of Δexon7 was investigated in 30 healthy controls and in 76 CML patients by four different molecular genetic methods (Sanger-sequencing, fragment analysis, allele-specific and quantitative PCR). The functionality and viability of the variant protein was tested by bioinformatic prediction.*Results*. By sequencing, BCR-ABL$^{\Delta exon7}$ was present in 17% (12/71) of imatinib resistant patients. Higher frequency of BCR-ABL$^{\Delta exon7}$ was found in patients at the time of imatinib resistance by fragment analysis and allele-specific PCR (70% [7/10]; 100% [10/10], respectively) compared to sequencing. In serial samples from imatinib-treated CML patients, using fragment analysis and allele-specific PCR, BCR-ABL$^{\Delta exon7}$ was more frequent at diagnosis (80% [12/15] and 87% [13/15]) and at the time of resistance (70% [7/10] and 100% [10/10]), than at the time of therapeutic response (0% [0/9] and 57% [8/14]). The BCR-ABL$^{\Delta exon7}$ negative samples exhibited lower BCR-ABL expression compared to positive samples. In contrast to BCR-ABL, the frequency of ABL$^{\Delta exon7}$ was similar comparing samples collected at different time points. ABL$^{\Delta exon7}$ was detectable in 77% (23/30) of healthy control samples by fragment analysis and in 100% (30/30) by allele-specific PCR. According to secondary structure prediction by bioinformatic methods, exon 7 deleted mRNA is a target for nonsense-mediated decay (NMD) which mediates mRNA degradation. Bioinformatic analyses also suggest that a large hydrophobic surface of the protein is exposed as a result of exon 7 deletion, which triggers the unfolded protein response mechanism eliminating the truncated protein as a misfolded protein. Furthermore, ABL$^{\Delta exon7}$ protein lacks the activation loop that prevents the truncated protein to function as a tyrosine kinase. **Summary**. We concluded that Δexon7 is not associated with imatinib resistance since it is abundantly present in imatinib naive CML patients on BCR-ABL. As Δexon7 also occurs on the non-translocated (normal) ABL, the AS process is likely to be independent from BCR-ABL translocation. The detection rate of Δexon7 is highly dependent on expression levels of BCR-ABL or ABL and the sensitivity of the detection method. The low translational efficiency due to NMD degradation of the variant mRNA, together with the significant structural changes in the truncated protein and its TKD are not in favour of the possibility, that the Δexon7 isoform is associated with drug resistance in CML.

PROGNOSTIC IMPACT OF ABCG2 AND HOCT1 TRANSCRIPT LEVELS IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB

YK Kim[1], NY Kim[2], L Yu[2], I Lee[2], SH Chung[1], JS Ahn[1], DH Yang[1], JJ Lee[1], HJ Kim[1]
[1]Chonnam National University Medical School, Gwangju, South-Korea
[2]Genome Research Center for Hematopoietic Ds, Chonnam Nat'l Uni. Hwasun Hospital, Hwasun, South-Korea

Background. Imatinib mesylate is a substrate for both drug efflux transporter ATP-binding cassette transporters (ABCG2; BCRP) and influx transporter human Organic Cation Transporter 1 (hOCT1; SLCA22). The clinical impact of these two transporters on imatinib-treated chronic myeloid leukemia (CML) patients remains clarified. **Aims.** The present study was performed to examine the correlation between the expression of ABCG2/hOCT1 and the clinical outcome in newly diagnosed chronic-phase CML patients treated with imatinib. **Methods.** All enrolled patients were diagnosed as chronic-phase CML and started imatinib treatment at a dose of 400 mg/day. ABCG2 and hOCT1 mRNA levels were determined by performing real-time polymerase chain reaction assays on bone marrow samples obtained at initial diagnosis from the patients. **Results.** Median age of 137 enrolled patients was 53 years (16-75 years) and median follow-up time from the start of imatinib treatment was 38 months (3-97.2 months). Of total 137 patients, 64.2%, 48.2%, and 8.0% could achieve complete cytogenetic response (CCR), major molecular response (MMR) and complete molecular response (CMR) during the whole period of imatinib treatment, respectively. The achievement of CCR or MMR during the treatment of imatinib was highly associated with progression-free survival (PFS) and overall survival (OS). Patients achieving CCR showed higher rate of 3-year PFS (92.8% vs. 46.0%, P=0.00) and OS (98.2% vs. 58.5%, P=0.00) than those without CCR. Patients achieving MMR also showed higher rate of 3-year PFS (94.6% vs. 57.6%, P=0.00) and OS (100% vs. 68.4%, P=0.00) than those without MMR. Patients with low ABCG2 expression (< 14.9 a.u.) could achieve higher rates of CCR (71.2% vs. 56.5%, P=0.04) and MMR (59.1% vs. 39.1%, P=0.02) than those with high ABCG2 expression (≥ 14.9 a.u.). The time to MMR achievement was significantly shorter in patients with low ABCG2 expression than those with high ABCG2 expression (18.1 months vs. 30.3 months, P=0.03). Patients with high hOCT1 expression (≥ 13.8 a.u.) showed significantly higher rate of intolerance with imatinib treatment than low hOCT1 expression (< 13.8 a.u.) (7.2% vs. 0%, P=0.02). There was no statistical significance in response and resistance rates to imatinib according to the hOCT1 expression levels. Although the patients with high hOCT1 expression showed a trend of shorter time to achieving CCR or MMR, there was no statistical significance. Low hOCT1 level showed the higher rate of imatinib failure (27.9% vs. 18.8%, P=0.21) than high hOCT1 expression, however, there was no statistical significance. **Conclusions.** This study revealed high expression of ABCG2 at diagnosis is related to the inferior treatment outcome in CML patients treated with imatinib. More stratified treatment plans such as the early use of newly developed tyrosine kinase inhibitors as a first line therapy may be warranted for those patients.

0766

PREGNANCY OUTCOMES AND TREATMENT REGIMENS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

E Chelysheva[1], A Turkina[1], T Kolosheinova[1], G Gusarova[1], M Sokolova[1], M Vakhrusheva[1], S Goryacheva[1], M Galaiko[1], N Khoroshko[1], Z Yasakova[2], G Kuchma[3], M Liubchenko[3], M Golubeva[4], I Grebenschikova[5], O Serdyuk[6], V Chertkova[3], S Volkova[3], A Lyamkina[7], S Menshakova[3], E Polushkina[8], R Shmakov[8]

[8]Federal State Research Center for Obsterics, Gynecology & Perinatology, Moscow, Russian Federation

Background. Knowledge about safe pregnancy management in chronic myeloid leukemia (CML) patients is an important issue due to the achieved high survival rates and improved life quality on tyrosine kinase inhibitors (TKI) therapy. **Aims.** To analyze the proper data of Pregnancy Registry in CML females and partners of males patients receiving TKI therapy in Russian Federation. To develop the tactics of pregnancy management in CML females in connection with cytogenetic and molecular monitoring data. **Results**. There were 33 pregnancy cases from 28 CML females on TKI therapy. 5 females had 2 subsequent pregnancies each, with different outcomes. Among 33 cases 6 artificial abortions were performed by decision of patient and physician, 1 on dasatinib, 5 on imatinib therapy. The outcomes of 27 cases when women intended to prolong pregnancy are listed below:- 19 healthy children: 16 from mothers on imatinib therapy, 2 from the same woman on 1st trimester of dasatinib therapy, 1 from woman on imatinib+hydroxyurea in 1st trimester and nilotinib from 10th week;- 3 spontaneous abortions (imatinib, 1st trimester);- 1 neonatal death (on imatinib);- 4 pregnancies ongoing now (3 on imatinib, 1 after bosutinib therapy)Only 4 of 27 females interrupted TKI uptake at conception. 23 of 27 pregnancies occurred during TKI treatment. Drug uptake was stopped from 4th-8th week, therapeutic decisions were based on the grade of existing remission.From 16 cases of childbirth on imatinib: 6 females were observed without treatment, 5 with complete molecular response (CMR) and 1 with major molecular response (MMR) at the start point. Molecular response was gradually lost during pregnancy but only one female lost complete hematologic response

(CHR). All 6 women had a good restoration of response after restarting imatinib.1 female with MMR used imatinib during the whole pregnancy period. 1 female with MMR had a cytogenetic relapse without treatment and continued on interferon alpha (IFNα).For other 8 females without MMR and different grades of cytogenetic and hematologic response a supportive treatment was used: IFNα (5 cases), IFNα plus hydroxyurea (1 case) and imatinib (2 cases). The IFNα therapy allowed to maintain CHR in 3 of 6 females; for 1 of them MMR on IFNα was achieved during pregnancy. Imatinib was used irregularly by 1 of 2 females (no proper dosage), and was effective for another one - a newly diagnosed patient who started imatinib 400 mg from 17th week of gestation.Also 14 favourable outcomes were observed in partners of CML males with a long period of TKI exposure and no treatment interruption at conception: 13 healthy infants from the CML males on imatinib, 1 child on nilotinib. **Conclusions.** Women planning the pregnancy have to achieve stable CMR or MMR, then can be observed without treatment using close molecular monitoring. The sufficient treatment regimens in case of response loss are discussable. For the known pregnancy cases of CML males partners on TKI the favourable outcomes are reported. Further data accumulation in CML Pregnancy Registry can help to develop more precise recommendations.

0767

CLINICAL AND BIOLOGICAL FEATURES OF PH+ CHRONIC MYELOID LEUKEMIA (CML) LONG SURVIVOR PATIENTS (MORE THAN 15 YEARS)

A Russo Rossi[1], N Sgherza[1], M Breccia[2], P Pinto[1], A Franco[1], M Mattia[1], A Scorca[1], A Salaroli[2], M Mancini[2], G Alimena[2], G Specchia[1]
[1]Hematology-University of Bari, Bari, Italy
[2]Department of Biotechnologies and Hematology, University of Rome „La Sapienza„, Rome, Italy

Background. Despite the positive results achieved by Interferon (IFN) and Tyrosine Kinase Inhibitors (TKIs) in the treatment of CML, there are limited data on the follow-up of CML long-survivor patients. **Aims**. We analyze the outcome of 65 (26M,39F) patients with Ph+ CML, with a follow-up of fifteen years or longer (median follow-up 214 months; range 180-312). **Methods.** All patients were diagnosed between the years 1986 and 1997; in 19 patients (29%) follow-up was > 20 years (group A), median 272 months, and in 46 patients (71%) follow-up was between 15 and 20 years (group B), median 204 months. Sokal's risk evaluation at baseline showed that 45 (69%) patients were low risk, 12 (19%) intermediate and 8 (12%) high risk. Sixty-three patients (97%) were low risk by the EUTOS revised risk score and 2 patients (3%) were high risk. The b2a2 fusion transcript was found in 26 patients (40%), and the b3a2 transcript in 39 (60%). All patients were treated with IFN-α + Cytarabine as first line treatment for a median time of 93 months (range 8-264). Some of these patients were enrolled in the GIMEMA CML0509 trial(ASH2011-Abstract 632). **Results**. Fifty patients (77%) started Imatinib as second line therapy after a median time of 100 months from the initial diagnosis. Median time on imatinib therapy was 96 months. Thirty-six patients continued Imatinib therapy while 14 patients were switched to second line TKIs for primary resistance or loss of response (n=11) or intolerance (n=3). One patient developed a Myeloid Blast Crisis (BC) and one Lymphoid BC, after 239 months and 161 months from the diagnosis, respectively. Five of sixty-five patients were transplanted : one patient died 15 years after HSCT of disease relapse (lymphoid BC); four are alive: one (receiving Imatinib) is in Complete Molecular Response (CMR), three patients (one on Imatinib, two off therapy) are in Major Molecular Response (MMR). In our patients cohort, overall survival after a median follow-up of 214 months is 97%. Twenty-nine patients (45%) are in CMR (17 receiving imatinib, 1 dasatinib, 1 nilotinib, 4 IFN-α, 6 off therapy); 25 (39%) patients are in MMR (16 receiving imatinib, 3 dasatinib, 1 nilotinib, 2 IFN-α, 3 off therapy); 4 (6%) patients are in CCgR (2 receiving dasatinib, 1 nilotinib, 1 off therapy); 1 (1%) patient receiving imatinib is in miCyR, 4 (6%) patients receiving dasatinib are in CHR. Two patients (3%) died due to disease progression, one after 172 months (transplanted patient) and one after 272 months. In group A, 5 patients (26%) are off therapy, while in group B 8 patients (9%) are off therapy. **Conclusions**. CML management changed dramatically with TKIs but the biological role of IFN-α remains crucial; our data from this subset of long-survival patients show that 15 of them (23%) never took TKIs : 6 are in MMR after receiving IFN-α therapy and 9 are off therapy (only one transplanted) after IFN. Longer follow-up in a larger series of patients is warranted to determine peculiar biological clinical features of this subset of patients.

[3]Klaipeda Seamen's Hospital, Klaipeda, Lithuania
[4]Panevezys Hospital, Panevezys, Lithuania
[5]Siauliai Hospital, Siauliai, Lithuania
[6]Affiliate of Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania

Background. The prognosis of individual CML patients has improved with tyrosine kinase inhibitor (TKI) treatment. Imatinib became partly available in Lithuania in 2005 with complete availability in 2011. The population based outcome of CML in the TKI era is only rarely analyzed and is the subject of this report. **Aims.** To evaluate relative survival trends of CML patients in Lithuania over 2000-2009 period. **Methods.** All cases with the ICD-10 code C92.1 (CML) registered within population based Hematology Monitoring System of Lithuania (average annual population 3.422 million[1]) in 2000-2009 were identified. Incidence and mortality crude rates were represented as number of cases per 100.000 inhabitants per year. Relative survival was defined as observed survival in CML group divided by the expected survival of a comparable group from a general population. **Results.** 474 patients were diagnosed with CML in 2000-2009 (263 cases from 2000 to 2004 and 211 cases from 2005 to 2009). The median age was 64 years (range 5-94). 246 (52%) patients were male. The incidence crude rate was 1.52 in 2000-2004 and 1.25 in 2005-2009 year periods, and the mortality crude rate was 0.82 during both time periods. One- and five-year relative survival ratios (RSRs) (95% CI) increased from 0.61 (0.55 - 0.67) and 0.33 (0.27 - 0.40) to 0.81 (0.74 - 0.86) and 0.53 (0.45 - 0.62) in 2000-2004 and 2005-2009 year periods, respectively (p = 0.031, Figure 1a). RSRs were also compared between Lithuanian and Swedish[2] CML patients. One- and five-year RSRs were found to be lower among Lithuanian than Swedish patients (0.69 and 0.44 vs. 0.94 and 0.80 for patients diagnosed from 2001 to 2008). The additional calendar period of 1995-1999 was included for better characterization of overall survival (OS) trends. By Kaplan-Meier analysis, OS improved with each time period with median OS (95% CI) of 19 (14 - 28), 21 (16 - 29) and 57 (41 - 72) months in 1995-1999, 2000-2004 and 2005-2009, respectively (1995-1999 vs. 2000-2004: p = 0.096, 2000-2004 vs. 2005-2009: p < 0.001, Figure 1b).

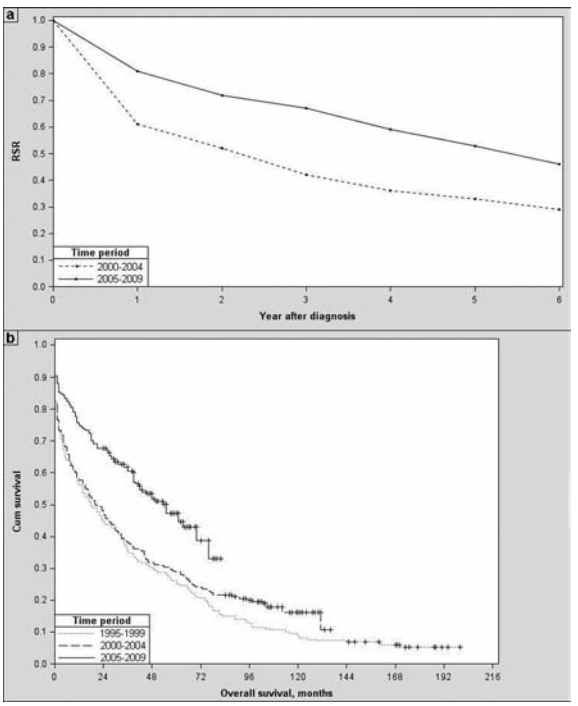

Figure 1. Relative (a) and overall survival (b) of chronic myeloid leukemia in Lithuania.

Conclusions. This population based study shows a significant improvement in outcome of CML patients in Lithuania. The most remarkable improvement in survival was observed in the last calendar period probably due to TKI treatment. However, RSRs were much lower in Lithuania as compared to Sweden which may be explained by deferred reimbursement of TKIs in Lithuania.

[4]Dipartimento di Scienze Biomediche, Università degli studi di Catania, Catania, Italy

Background. CML is diagnosed and monitored by cytogenetics, FISH and qRT-PCR to detect the BCR-ABL fusion gene at the chromosomal or transcript level; however, the fusion protein (FP) product of BCR-ABL is ultimately responsible for the transition to CML. Facilitating the detection of these BCR-ABL FPs may potentially complement the traditional genetic methods in CML follow-up. **Aims.** A Flow Cytometry (FC)-bead immunoassay [(BCR-ABL Protein Kit, BD Biosciences)] was evaluated to detect BCR-ABL FPs in CML in a prospective multicentre study belonging to the SCREEN group involving Hematology Centers from Sicily and Calabria, Italy. **Methods.** BCR-ABL^{POS} (p210^{+}:K562, BV173; p190^{+}:SD1) and BCR-ABL^{NEG} (HEL, HL60) cell lines, 127 peripheral blood (PB) or bone marrow (BM) samples from CML patients (n=26), ALL (n=7) and other disorders (n=5) were analyzed. PB from 32 healthy volunteers were used as controls to obtain the negative MFI cut-off values. FC-assay results were compared with those obtained by qRT-PCR normalized to BCR-ABL^{IS} and to FISH analysis. **Results.** FC-assay results using BCR-ABL^{NEG} and BCR-ABL^{POS} cell lines were concordant with qRT-PCR. Serial dilution of K562 cells in HEL cells showed the detection limit of the FC assay was >0.1%. Notably, we observed protein instability in frozen lysates and DMSO-cryopreserved patient samples with FC signals reduced by 0.05-46.9% compared to fresh samples. Time-course experiments using samples stored at 24°C (0-108h) showed comparable and progressive decline of FC signal within 48h. The presence of the BCR-ABL protein was investigated on fresh BM and/or PB from 99 samples of CML and 22 patients suspected of CML or Ph1^{+}-ALL. The FC-assay was positive in 15/15 newly diagnosed CML and in 4/4 accelerated phase CML cases (including one p230^{+}-patient). Evaluation of MRD, continued to show MFI-positive signals in 31 follow-up samples; detectable FP corresponded to 1-100% BCR-ABL^{IS}. For the remaining CML patients with undetectable FP (24), BCR-ABL^{IS} was <1%. Patients with other hematological disorders (ET, IMF, AML) tested negative both in FC and qRT-PCR. Of the Ph1^{+}-ALL cases, 2/5 pediatric patients were both FC and qRT-PCR positive, 2/2 adult ALL tested positive. We compared FISH and FC-assay; all cases testing FC-negative also tested negative for FISH, however 3/14 FC-positive cases were negative in FISH analysis although BCR-ABL^{IS} was >1%. Specifically, ROC analysis (n=89; 59 FC-positive and 30 negative) showed that a positive FC-assay could detect BCR/ABL transcripts up to BCR-ABL^{IS}=1.37% (AUC=0.97, *P*<.0001). Subdividing MFI into quartiles showed a strong proportional increase in relative %MFI corresponding to BCR-ABL^{IS} transcripts (*P*<.0001), indicating MFI values could be used as a semi-quantitative scale. **Conclusions.** The BCR-ABL FC-assay is a rapid and easy technique able to detect BCR-ABL proteins with high specificity and sensitivity. The FC-assay may thus circumvent more elaborate techniques for the initial follow-up phase of the disease, where preliminary data show that the it may be more sensitive than FISH in detecting positive samples. The SCREEN multicenter study will establish the validity of these assumptions and the relationship, if any, with cytogenetic FISH and molecular analysis using a larger cohort of CML patients.

0770

PROGNOSTIC IMPACT OF BASELINE QUALITY OF LIFE VALUES IN CML-CHRONIC PHASE PATIENTS TREATED WITH IMATINIB - 10-YEARS FOLLOW UP RESULTS

V Shuvaev[1], K Abdulkadyrov[1], O Vinogradova[2], E Zakharova[2], G Gusarova[2], E Chelysheva[2], M Sokolova[2], T Kolosheinova[2], L Kolosova[2], S Goryacheva[2], M Vakhrusheva[2], I Tischenko[2], N Liseeva[3], S Voloshin[1], A Shmidt[1], A Kuvshinov[1], M Fominykh[1], A Turkina[2], N Khoroshko[2]

[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

[2]Hematological Research Centre, Moscow, Russian Federation

[3]Clinics of The Samara State Medical University, Samara, Russian Federation

Background. At present CML in chronic phase is not lifetime-limiting disorder. Not quantity but quality of life (QoI) becomes the major endpoint of CML management. Few efforts have been made to assess and improve QoI in CML patients. No specific intervention is included in modern CML guidelines to improve QoI. The aim of the study was to investigate prognostic significance of baseline QoI values in CML patients treated with imatinib. **Methods.** . QoI data was obtained from validation study of FACT-BRM questionnaire that was carry out in 2001-2003. Analysis was conducted on data from 93 patients with chronic phase CML treated with imatinib. Patient population consisted of 45 men and 48 women with median age 43,7 years (18,8-65,5 years) on imatinib start time. All the patients were pretreated with hydroxyurea, busulfan, interferon and various chemotherapy regimens. QoI was assessed by self-completion of Russian version of Fact-BRM at several time points: within a month before, on days 1, 8, 28, months 3, 6, 9, 12, 24 after start of imatinib. Median time between CML diagnosis was made and start of imatinib was 32 months (0-157.3 months). Stratification of patients was performed in dependence of baseline QoI values.Statistical methods included cluster analyses by Ward's method, non-parametric Kruskall-Wallis ANOVA and Median test, repeated measures ANOVA in Statistica 7.0. Missing items in questionnaires were processed with mean substitution. **Results.** The numbers of completed QoI questionnaires was declined in time - 93, 89, 86, 82, 82, 78, 78, 76 and 62 patients according to study points. All the patients were divided on two groups (38 and 55 patients) with similar linkage distances according to cluster analysis of baseline QoI values. These groups were not statistically different according age and gender of patients. QoI profiles of all datasets were very similar to IRIS results. QoI changes according to strata groups demonstrated statistically significant differences from baseline to final point in all scales with exception of Social/family wellbeing scale. The QoI parameters in group 2 was stable over time whereas in group 1 QoI had gradually increased. The composition scale - TOI profiles presented in fig.1. Results of treatment in strata groups did not reach statistical significance, but there were strong tendencies in respect to Overall Survival (p=0.19) and Event-free Survival (p=0.27). Overall 10-years survival in all patients was 80.6% with difference between groups: 86.8% (group 1) and 76.3% (group 2). A significant (p=0.047) difference was revealed concerning the probability of switching to second-generation-TKI: 42.1% (group 1) and 21.8% (group 2). These findings could be influenced by small population of patients in both groups and censored data. **Conclusions.** QoI is important characteristic of CML patients. Existing standards of care did not pay any attention to QoI measurement and management. Results of our QoI monitoring are similar to those obtained from other studies. Baseline QoI values are determine profile of subsequent QoI and can influence patients' outcome. There is a need for more active incorporation of QoI assessment into future clinical trials and routine practice.

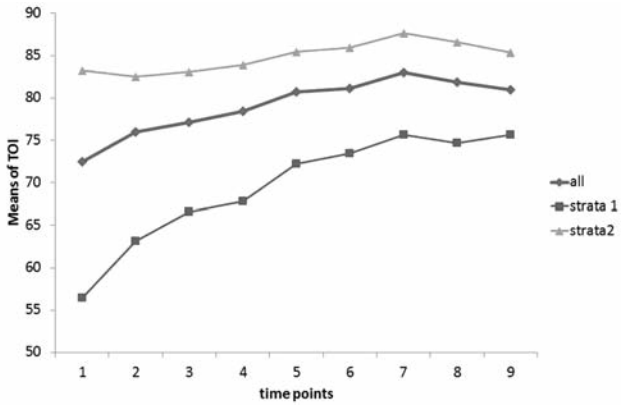

Figure 1. FACT-TOI means profile over time in stratification groups.

[3]Botkin Clinical City Hospital, Moscow, Russian Federation

[4]Orenburg State Medical Academy, Orenburg, Russian Federation

[5]Pirogov National Medical Surgical Center, Moscow, Russian Federation

Introduction of imatinib into chronic myeloid leukemia (CML) therapy marked a major advance in CML treatment. Despite remarkable responses with imatinib in chronic phase CML (CML-CP), there remains a proportion of patients who are resistant or intolerant to imatinib treatment. Importantly, without effective therapeutic intervention, these patients inevitably progress to advanced phases of disease, have a short survival and declined health outcomes. This emphasizes the importance of patient-reported outcomes in this patient population. Information about quality of life (QoL) and symptom profile in imatinib-resistant or -intolerant CML-CP patients is lacking**.** We aimed to study QoL parameters and symptom profile in imatinib-resistant or -intolerant CML-CP patients.33 CML-CP patients resistant or -intolerant to imatinib before second-line therapy were enrolled in the study (mean age - 47 years old, range - 22-71 years; male/female - 15/18). The median of disease duration was 6 years (2-13 years). Half of patients received imatinib 600 or 800 mg daily; the median duration of imatinib treatment - 42 months (4-101 months). 30 patients had resistance to imatinib treatment; 3 patients were intolerant to imatinib. The patients filled in the SF-36 for QoL assessment and Comprehensive Symptom Profile in Chronic Myeloid Leukemia Patients (CSP Leuk-CML) for symptom assessment. The CSP Leuk-CML is developed to assess profile of 47 symptoms specific for patients with CML. To compare patient population with normative data the sample from population norm (PN) data base adjusted to age and gender was used. For comparisons Mann-Whitney test was used. Symptom severity and percentages of patients with symptoms at moderate-to-severe (ratings ³ 5) levels was evaluated.Imatinib-resistant or -intolerant CML-CP patients experienced impaired QoL as compared to population norms: the values for the majority of SF-36 scales were significantly lower than in control group ($p<0.05$). No QoL impairment was observed in 32% of patients. 26% of patients had either mild (Integral QoL index <25% decrease from a PN) or moderate (25-50% decrease from a PN) QoL impairment; other 26% of patients - severe QoL impairment (50-75% decrease from a PN, and 16% of patients - critical QoL impairment (>75% decrease from a PN).The majority of patients (96%) experienced fatigue; a half of them suffered from moderate-to-severe fatigue. 75% of patients experienced at least one moderate-to-severe symptom; 13 patients (41%) had more than 7 moderate-to-severe symptoms. Almost half of patients experienced moderate-to-severe excessive sweat at rest and during mild physical activity; about one third of patients experienced moderate-to-severe fatigue (n=12), edema (n=12) and decreased work energy (n=10). Four patients experienced more than 20 (22-33) moderate-to-severe symptoms and had critical QoL impairment.Thus, QoL in imatinib-resistant or -intolerant CML-CP patients is significantly deteriorated. Fatigue is the leading symptom in this patient population. The majority of patients experience moderate-to-severe symptoms. Information about QoL and symptom profile in this patient population should be used should be used for comprehensive assessment of risks and benefits of second-line treatment of CML-CP.

0772

COST-EFFECTIVENESS ANALYSIS OF NILOTINIB VERSES IMATINIB FOR THE TREATMENT OF CHRONIC PHASE PHILADELPHIA CHROMOSOME POSITIVE CHRONIC MYELOID LEUKAEMIA

M Mildred[1], S Ward[1], H Squires[1], E Gray[2]

[1]University of Sheffield, Sheffield, United Kingdom

[2]Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom

Background. Nilotinib is a tyrosine kinase inhibitor (TKI) for the treatment of adult patients with newly diagnosed Philadelphia chromosome positive (Ph+) chronic myeloid leukaemia (CML) in chronic phase. The ENESTnd phase III trial demonstrated that nilotinib has clinical superiority over current standard treatment of first-line imatinib in patients with chronic phase Ph+ CML, on the basis that fewer patients progressed to accelerated phase/blast crisis. Whilst the clinical benefits of nilotinib have been demonstrated, the cost-effectiveness of first-line nilotinib has not been explored. **Aims**. To evaluate the cost-effectiveness of first-line nilotinib followed by second-line dasatinib compared to first-line imatinib followed by second-line dasatinib for patients newly diagnosed with chronic phase Ph+ CML. **Methods.** A Markov state-transition model based on the 24 month follow-up from the ENESTnd randomised controlled trial was developed to simulate the transitions of a hypothetical cohort of patients over a lifetime. The model estimates when one treatment will fail and hence the patient is switched to an alternative treatment. Patients who discontinue first-line treatment go on to second-line dasatinib. Patients who fail on second-line dasatinib receive stem cell transplantation or HU therapy. Patients transition from chronic phase, to accelerated phase, to blast crisis, to CML-related mortality. Patients may die from other causes at any time. EQ-5D utilities were applied to patients in each health state and utility decrements were estimated for patients experiencing severe (grade 3 and 4) adverse events (AEs) on TKI therapy. Costs (2010/11 Sterling) were estimated from the perspective of the UK National Health Service (NHS) and Personal Social Services (PSS). These include the costs associated with the different drug therapies, stem cell transplantation, routine hospital appointments for administration and monitoring, and treatment for severe AEs. A patient access scheme is available for first-line nilotinib therapy and is included in the analysis. All costs and QALYs were discounted by 3.5% as recommended by NICE. Probabilistic sensitivity analysis (PSA) was conducted to explore the impact of the joint uncertainty of all model parameters on the cost-effectiveness results. Cost-effectiveness was expressed in terms of incremental cost per quality-adjusted life-years (QALYs) gained. Cost-effectiveness acceptability curves (CEACs) were also generated. **Results**. The mean undiscounted survival in the nilotinib arm was estimated to be 13.96 years compared to 13.32 years in the imatinib arm. Over a lifetime horizon patients are estimated to gain an additional 0.64 life-years (LYs) and 0.49 quality-adjusted life-years (QALYs) in the nilotinib arm compared to the imatinib arm. Using a discount rate of 3.5% patients are estimated to accrue an additional 0.35 LYs and 0.28 QALYs in the nilotinib arm compared to the imatinib arm. Expected lifetime (discounted) costs in the nilotinib arm were £220,416 compared to £232,941 in the imatinib arm. The nilotinib arm dominates the imatinib arm as it is more effective and less costly. **Conclusions**. The results suggest that nilotinib produces improvements in survival and QALYs compared to standard treatment of first-line imatinib and it is likely to offer a cost-effective use of NHS resources.

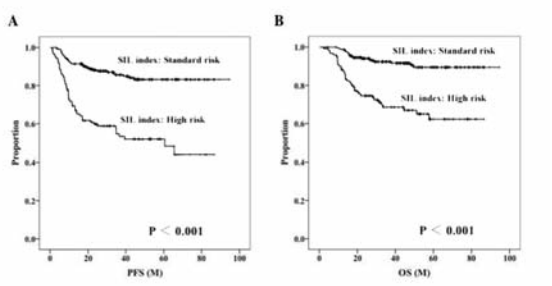
SIL INDEX AS A NEW PROGNOSTIC PREDICTOR IN DIFFUSE LARGE B-CELL LYMPHOMA

N Tomita[1], R Sakai[2], S Fujisawa[3], K Fujimaki[4], J Taguchi[5], C Hashimoto[6], K Ogawa[7], E Yamazaki[1], Y Ishigatsubo[1]
[1]Yokohama City University Graduate School of Medicine, Yokohama, Japan
[2]Kanagawa Cancer Center, Yokohama, Japan
[3]Yokohama City University Medical Center, Yokohama, Japan
[4]Fujisawa City Hospital, Fujisawa, Japan
[5]Shizuoka Red Cross Hospital, Shizuoka, Japan
[6]Yamato City Hospital, Yamato, Japan
[7]Yokosuka City Hospital, Yokosuka, Japan

Background. Rituximab (R) plus CHOP chemotherapy (R-CHOP) is the widely standard treatment for diffuse large B-cell lymphoma (DLBCL). The revised International Prognostic Index (R-IPI) was established in 2007 as a prognostic indicator for R-CHOP therapy. **Aims.** To reassess the utility of R-IPI and evaluate soluble interleukin-2 receptor (sIL-2R) level as a prognostic factor.
Methods. The Yokohama City University Hematology Group in Japan has uniformly and curatively treated DLBCL patients since 2003. Between 2003 and 2009, 554 consecutive patients with DLBCL were registered and treated. All DLBCL patients scheduled to undergo primary therapy with 6 cycles of full-dose R-CHOP were included in this study. From among them, patients over 70 years old with an Eastern Cooperative Oncology Group performance status greater than 1 who were treated with a reduced dose were excluded; however, according to the decision of the attending physician, if they were treated with full-dose R-CHOP, they were included. Patients for whom the initial therapy dose was reduced by □20% due to any major comorbidity were excluded. Those with human immunodeficiency virus infection were also excluded. Finally, 366 of the initial 554 patients were retrospectively analyzed. Patients who had partial remission (PR) after the 4 initial cycles were administered 8 R-CHOP cycles in total, while patients who did not achieve PR after the 4 initial R-CHOP cycles or those who exhibited disease progression at any given time received salvage therapy. Additional local irradiation was also performed in patients with PR or complete remission (CR), if deemed necessary by the attending physician. No patient received maintenance therapy with R. Patients with DLBCL who achieved CR but were initially at risk of central nervous system (CNS) involvement also received intrathecal CNS prophylaxis



Results The median age at diagnosis was 64 years (range, 18 -80 years). The median number of therapy cycles was 6 (range, 2 -8), and 91% of the patients received 6 cycles or more. Forty patients (11%) received radiation therapy as primary treatment, usually to treat sites of residual masses at the end of the chemotherapy. CNS prophylaxis was conducted in 45 patients (12%). Progression-free survival (PFS) curves in "very good"and "good"risk groups, as defined by the R-IPI showed no statistical difference. We added sIL-2R level to the factors comprising the R-IPI. Five levels of sIL-2R (1000, 1500, 2000, 2500, and 3000 U/ml) were weighed with respect to their impact on PFS, and an sIL-2R level of □2,500 U/mL was determined as the most appropriate threshold. We developed a new prognostic indicator, SIL index, which involves 3 independent prognostic risk factors: clinical stage (S), sIL-2R level over 2,500 U/mL (I), and elevated LDH level (L). This index indicates standard risk (0 or 1 risk factor: 5-year PFS, 83%; 5-year overall survival (OS), 89%) and high- risk (2 or 3 risk factors: 5-year PFS, 52%; 5-year OS, 62%) outcomes (Figure 1). **Conclusions** The SIL index is a simple and objective prognostic index for DLBCL patients to identify candidates for experimental therapy other than R-CHOP.

CAUSES OF DEATH AFTER COMPLETE REMISSION OF AIDS-RELATED NON-HODGKIN'S LYMPHOMA

JT Navarro[1], MJ Baptista[1], M Morgades[1], C Tural[2], J Juncà[1], E Feliu[1], F Millá[1], JM Ribera[1]
[1]Catalan Institute of Oncology, Badalona, Spain
[2]Hospital Germans Trias i Pujol, Badalona, Spain

Background. The use of highly active antiretroviral therapy (HAART) has dramatically improved the prognosis of AIDS-related Non-Hodgkin lymphoma (NHL), causing a remarkable increase in patients' long-term survival. With the introduction of HAART, the longer survival of HIV-patients after lymphoma treatment put them at risk of death due to causes different from lymphoma progression, such as second neoplasms and infections. There is scarce information regarding causes of death in HIV-infected patients who have responded to NHL treatment. **Aims.** We sought for causes of death among patients treated of AIDS-related NHL who achieve complete remission (CR), comparing those treated with HAART with those who did not receive it. **Methods.** We conducted a retrospective study of patient data on AIDS-related NHL individuals diagnosed between 1989 and2010 in our institution. Demographic, HIV infection, and lymphoma data on each case were collected. Two groups were considered: patients who did not take HAART at all, and those who started HAART at any stage of their HIV infection. Continuous and categorical variables are presented using descriptive statistics. Survival analyses were performed using the Kaplan-Meier method, and compared using the log-rank test. P-valuesof lessthan 0.05 were considered statistically significant.

Table 1a. Causes of death of patients after CR of NHL.

	Lymphoma progression	Second neoplasm	Infection	Other/Unknown
No-HAART	5 (50%)	0 (0%)	4 (40%)	1 (10%)
HAART	1 (8%)	4 (33%)	4 (33%)	3 (25%)

Table 1b. Comparison of CD4 lymphocyte counts and HIV load in patients from the HAART group who died versus those alive.

	Dead	Alive	P
Undetectable HIV load	4/9	22/25	0.020
median CD4 lymphocyte count/µl (range)	108 (9-199)	398 (82-1064)	<0.001

Results. Out of a series of 146 patients diagnosed with AIDS-related NHL, 139 patients were eligible for the study with a median (range) follow-up of 8.24 years (0.68-15.78): 70 patients belonged to the no-HAART group, and 69 to the HAART group. Patients in the HAART group were older at the time of lymphoma diagnosis than in the no-HAART group with a median (range) of 40 (26-68) and 34.5 years (19-66), respectively (p=0.002). There were more female patients in the HAART group: 29% versus 11% (p=0.01). A higher number of CR was observed in the HAART group: 62% versus 25%, (p<0.001). The 5-year overall survival and disease free survival were significantly longer for patients receiving HAART: 49% (95%CI: 37-61%) versus 3% (95%CI: 0-7%); and 92% (95%CI: 83-100%) versus 17% (95% CI: 0-46%), respectively. The causes of death were significantly different comparing both groups (p=0.049) (Table 1a). Four patients died of second malignancy in the HAART group (hepatocarcinoma, anal carcinoma, carcinoma of vagina and Kaposi's sarcoma), and none in the no-HAART one. However, similar percentages of deaths of infection were seen in both groups. In the HAART group, patients who died had lower CD4 counts and higher HIV loads than those patients kept alive (table 1b). Median time from CR to death of lymphoma progression was14.20 months (7-25.90) and to death of second neoplasm 112.27 (11.17-149.17). Patients who died from infection had similar median time from CR to death in both groups:9.23 months (1.47-57.77) in the non-HAART, and 6.85 (4-17.07) in the HAART. **Conclusions**. Causes of death among HIV-patients on HAART after CR of NHL are second neoplasms and infections rather than lymphoma progression. HIV-infected patients on HAART who die after treatment of NHL have poor control of HIV infection.Grants: RD06/0020/1056 from RTICC and EC11-041 from Ministerio de Sanidad.

FACTORS ASSOCIATED WITH FEBRILE NEUTROPENIA IN A PROSPECTIVE COHORT OF DIFFUSE LARGE B CELL LYMPHOMA

S Park, SJ Kim, WS Kim
Samsung Medical Center, Seoul, South-Korea

Background. Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of lymphoma, and rituximab-CHOP (RCHOP) is currently the standard chemotherapy in patients DLBCL. Chemotherapy-induced neutropenia and its complications are one of the major concerns in cancer chemotherapy. Especially, lymphoma belongs to the type of cancers which designated as risk factors for febrile neutropenia (FN), and R-CHOP is one of the common chemotherapy regimens associated with FN with a 19% of FN risk. However, it has been rarely studied in a homogenous group with regard to their pathologic diagnosis of DLBCL and received the current gold standard R-CHOP regimen. **Aims.** In this study, we attempt to evaluate the factors associated with FN in our prospective cohort with DLBCL who were treated with R-CHOP regimen. **Methods.** From September 2008 to June 2011, a total of 829 lymphoma patients were registered in the prospective cohort of Samsung Medical Center (Samsung Medical Center Lymphoma Cohort Study, SMCLCS, NCT#00822731). At diagnosis, their comprehensive baseline characteristics including disease-related factors and host-related factors were evaluated. Furthermore, data regarding treatment for lymphoma, treatment response and survival were regularly updated by primary physician and physician assistant nurse. From these prospective cohorts registered, 378 patients diagnosed with DLBCL were exclusively selected. Prophylactic G-CSF was not routinely administered because it was not reimbursed by insurance in Korea. **Results.** After excluding patients with CNS DLBCL, and patients who received anti-cancer treatment more than R-CHOP as first line treatment, 262 DLBCL patients who had completed R-CHOP cycles as first line treatment were analyzed in this study. The median age was 55 years (range, 16-86), and 116 patients (44.3%) presented with advanced stage disease. The distribution of patients according to IPI was 131 (50%, low), 47 (17.9%, low intermediate), 41 (15.6%, high intermediate) and 43 (16.4%, high), and the median number of R-CHOP cycle was 6. Of the total 262 patients, 118 patients (45%) had ever experienced FN during R-CHOP treatment. The initial episode of FN was more commonly observed in earlier courses of treatment with more than half (60.1%) of hospital visit for FN occurred during the first two chemotherapy cycles. To determine the risk factors associated with development of FN, both univariate and multivariate analyses were performed. In univariate analysis, there was no difference in the development of FN based on extralymphonodal involve, B symptoms, sex, nutritional status measured by skin fold or MAMC, smoking and/or alcoholic behavior, whereas stage, BM involvement, IPI score, LDH, Hb, age (≥60), prealbumin, transferrin level, and ECOG performance status showed significance for the development of FN. In multivariate analysis using clinically significant variables identified by univariate analysis, however, age (≥60) was the only significant factor which affects development of FN. **Conclusions**. Among the various clinical variables, old age (≥60) was the most significant risk factor associated with development of FN in R-CHOP treated DLBCL patients.

EVIDENCE FOR RITUXIMAB UNDERDOSING IN SUBPOPULATIONS OF ELDERLY PATIENTS WITH DLBC: RESULTS OF THE RICOVER-60 STUDY OF THE DSHNHL

C Zwick, C Mueller, S Zeynalova, G Held, V Poeschel, M Reiser, E Lengfelder, H Steinhauer, C Limmroth, N Schmitz, N Murawski, M Pfreundschuh
DSHNHL, Homburg/Saar, Germany

Background. Gender and weight independently influence rituximab clearance and serum elimination half-life. **Aims.** Therefore, we investigated the impact of rituximab pharmacokinetics on outcome of elderly DLBCL patients. **Methods.** The outcome of subpopulations of the 1222 patients treated in the RICOVER-60 trial with shorter rituximab half-lives was analyzed: elderly male vs. female patients and elderly weighty (upper quartile: >77kg) vs. slim (lower quartile: ≤60 kg) female patients. **Results.** The calculated rituximab half-life was 24.7 days in males and 33.4 days in females. Male gender was associated with a slightly increased risk for progression (relative risk: EFS: 1.0; PFS: 1.27; OS 1.3; p>0.05) after CHOP-14 without rituximab, but evolved as a significant risk factor when rituximab was added (relative risk EFS: 1.4 [p=0.016]: PFS: 1.692 [p=0.004], OS: 1.6 [p=0.063]). Addition of rituximab resulted in a significantly improved 3-year PFS (74% vs. 49%; p=0.002) in female patients with a body weight within the lower quartile (rituximab half-life: 41.1 days), while there was no improvement by the addition of rituximab (71% vs. 72%; p=0.816) in female patients with a body weight in the upper quartile (rituximab half-life: 26.1 days). **Conclusions.** The reduced benefit of adding rituximab to CHOP in elderly DLBCL patients with a shorter rituximab half-life (and consequently lower rituximab serum levels) strongly suggests that the respective subpopulations (males and weighty females) are underdosed when the rituximab dose is based on body surface area at 375 mg/m^2. Novel CD20 antibodies which are usually higher dosed should be compared with an optimized rather than the currently used suboptimal dose and/or schedule of rituximab. *Supported by deutsche Krebshilfe.*

FIRST-LINE TREATMENT OF DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) DRIVEN BY EARLY PETSCAN: EVALUATION AT 5 YEARS OF A SINGLE CENTER PROSPECTIVE STUDY

C Mariette, B Fabre, S Carras, JC Bourre, L Molina, C Lefebvre, JY Cahn, R Gressin
CHU Grenoble, Grenoble, France

Background. In 2006, the R-CHOP regimen (Rituximab, Adriamycine, Cyclophosphamide, Vincristine and Prednisolone) was considered as the standard first-line treatment of DLBCL for fit patients. Fourteen days interval between two cycles, with a total of 6 cycles (+ 2 rituximab) was considered at that time the best approach according to Ricover and Mint's trials (respectively for elderly patients and good prognosis young patients). Subsequently, interim Petscan , ABC/GCB type and R-IPI appeared of interest as new prognostic factors. **Aims.** Validate the most recent literature data concerning the first-line treatment for fit DLBCL patients in a prospective cohort of patients from a single institutionMethods:From July 2005 to January 2011, new DLBCL patients, with negative Petscan after 3cycles were treated with 6 R-CHOP14 combined with G-CSF(D6-12). If the 14 days intervals could not be applied for any reasons, or if early Petscan remained positive, eight courses were distributed. Exclusion criteria were: transformed indolent lymphoma, age > 80 years, PS-ECOG >3, left ventricular systolic function < 50% or severe renal or hepatic dysfunction unrelated to lymphoma. Responses were evaluated using Cheson criteria (1999). Early Petscan after 3 courses and at the end of the treatment was evaluated by the visual method. Hans's algorithm was applied to determine the ABC/GCB types and all patients were classified with the R-IPI score.Results60 patients were included, 57 were centroblastic, 40% (24/57) GCB and 60% ABC. There were 41(68%) patients > 60 years old, 40 (67%) with AAstage III-IV, 11 (18%) with a PS>1, 10 (17%) with more than one extranodal site and 19 (32%) with elevated LDH level. Hence R-IPI was 0 for 9 patients (15%), 1-2 for 27 (45%) and 3-5 for 24 (40%). After a median follow up of 29.5 months, 13 died (10 for lymphoma, 1 for digestive hemorraghe and 2 for relapse of previous other cancer). At the end of treatment 51 (85%) were in CR. Fifty two patients (91 %, 52/57) had an early negative Petscan, and 5 (9%) a positive Petscan.Three years OS is 84% and is statistically affected by R-IPI [0-2 = 100% vs 3-5=60% (p<.0001)] and early Petscan [negative=95% vs positive=30% (p<.0001)] but not ABC/GCB (p=0.6). Moreover the 3 years OS of R-IPI 3-5 and negative early Petscan population is only 65%.Three years PFS is 70% and was affected by R-IPI [0-2 = 96% vs 3-5=30% (p<.0001)] and early Petscan [negative=77% vs positive=53% (p<.006)] but not by ABC/GCB status (p=.54). Moreover the 3-years PFS for negative Petscan in R-IPI 3-5 population is only 40%.ConclusionWe confirm the good results of 6 R-CHOP14 for newly diagnosed DLBCL especially for R-IPI 0-2 having a negative early Petscan despite 6 Rituximab instead of 8. (asking the question of the necessity of 8 rituximab injections for those patients). The OS of R-IPI 3-5 remains very poor regardless ABC/GCB subtypes even for early negative Petscan. New approaches will be appropriate to overcome this very bad prognosis group.

0778

HIGH DOSE ETOPOSIDE AS AN EFFECTIVE PBSC MOBILIZATION REGIMEN IN PATIENTS WITH NHL PREVIOUSLY TREATED WITH RITUXIMAB-CHOP OR CHOP CHEMOTHERAPY

SY Hyun, J Ji Eun, JS Kim, YD Kim, DY Whang, SJ Kim, JW Cheong, YH Min
Yonsei University College of Medicine, Seoul, South-Korea

Background. Etoposide is one of the effective mobilizing agents in non-Hodgkin's lymphoma (NHL), but efficacy and toxicity of high dose etoposide followed by G-CSF compared with other mobilization regimens are not well defined. **Aims.** We conducted a retrospective study to evaluate the efficacy of high dose etoposide plus G-CSF compared with other mobilization regimens in peripheral blood stem cell (PBSC) mobilization. **Methods.** A total of 51 patients with NHL who were treated only with Rituximab -CHOP (cyclophosphamide, doxorubicin, vincristine, prednisolone) or CHOP chemotherapy and sequentially underwent PBSC mobilization between 2006 and 2011 were analyzed. Twenty nine patients received etoposide 500mg/m² at day 1,2,3 (VP16

group). Total 22 of other patients received ICE (ifosfamide, carboplatin, etoposide) or DHAP (cisplatin, cytarabine, dexamethasone) or R-CHOP and 2 patients received G-CSF only (others group). All patients administered G-CSF 10μ/kg/day until apheresis completed. Efficacy of PBSC mobilization and chemotherapy related toxicities were compared between the groups.

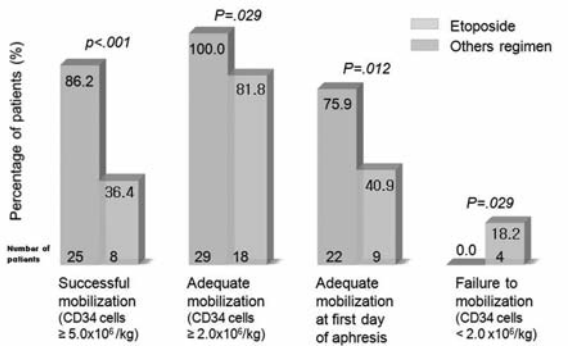

Figure 1. The results of PBSC mobilization in high-dose etoposide regimen group (left bar) and others regimen group (right bar).

Results. Both groups were comparable in age, gender, diagnosis, stage, the presence of bone marrow involvement at diagnosis, the number of previous chemotherapy, a disease status prior to mobilization and the number of days from last chemotherapy to start of mobilization chemotherapy. In the VP16 group, a median total $CD34^+$cells collected was 16.22 x 10^6 cells/kg, 75.9% of all patients having adequate (>2.0 x 10^6 cells/kg) $CD34^+$ collections after first day of apheresis compared with a median in the others group of 4.1 x 10^6 cells/kg (P<0.001), with 40.9% having adequate collection after first day (P=0.012) (Figure 1). A median total $CD34^+$cells collected per aphresis was 16.22 x 10^6 cells/kg in VP16 group and 1.97 x 10^6 cells/kg in others group (P<0.001). None of 29 patients in VP16 group and 4 of 22 (19%) in others group failed to collect sufficient $CD34^+$ cells (<2.0 x 10^6 cells/kg) (P=0.029) (Figure 1). In multivariate analysis, successful stem cell mobilization was independently influenced by high-dose etoposide regimen (P=0.044) and $CD34^+$ cells in peripheral blood at the day of apheresis (≥ 20x10^6/L) (P=0.002). Neutropenic fever developed in 20 patients (69%) in the VP16 groups, none of which were fatal, and 3 patients (14%) in the others group (P=0.003). **Conclusions**. High dose etoposide improves the effectiveness of mobilization with more than threefolds higher stem cell yield compared with other mobilization regimens. Considering no mortalities and grade IV infections in patients with neutropenic fever, high dose etoposide plus G-CSF is a highly effective mobilization regimen with acceptable toxicity in patients with NHL.

0779

RITUXIMAB COMBINATION WITH CHOP MAY NOT OVERCOME THE POOR PROGNOSIS IN PATIENTS WITH EPSTEIN-BARR VIRUS POSITIVE DIFFUSE LARGE B CELL LYMPHOMA OF THE ELDERLY

SH Jung[1], JS Ahn[1], DH Yang[1], YD Choi[1], HY Yhim[2], JY Kwak[2], YK Kim[1], HJ Kim[1], JJ Lee[1]
[1]Chonnam National University Hwasun Hospital, Jeollanam-do, South-Korea
[2]Chonbuk National University Medical School, Jeollabuk-do, South-Korea

Background. Epstein-Barr virus (EBV)-positive diffuse large B-cell lymphoma (DLBCL) of the elderly was included as a provisional entity in the 2008 WHO lymphoma classification. In patients with DLBCL, the incidence of EBV among patients of Asian ranges from 9% to 15%. Few published studies support a possible prognostic relationship between EBV tumoral status and DLBCL especially in rituximab era. **Purpose**. To evaluate the prognostic value of the EBV positive DLBCL of elderly in patients with treated by rituximab, cyclophosphamide, adriamycin, vincristine and presnisone (R-CHOP). **Patients and Methods.** Among the 228 patients included on the trial, histological material was available for a total of 179 patients at diagnosis. All 179 tissues were available for analysis by EBV-encoded RNA-1 (EBER) in situ hybridization. **Results.** Sixteen cases (8.9%) were identified as EBER-positive. Interestingly, all patients with EBV positive DLBCL of elderly was diagnosed as non-germinal center B (GCB)-like DLBCL that was based on the algorithm by Hans. The EBV negative DLBCL group showed 68.8% of non-GCB like DLBCL (p=0.009). There was no clinical difference between EBV positive and EBV negative DLBCL in terms of age, Ann Arbor stage, LDH level, B symptom, number of extranodal involvement and Eastern Cooperative Oncology Group performance status at diagnosis (p>0.05). After median 6th R-CHOP chemotherapy, the clinical response rate (≥PR) was 75% (12/16) in EBV positive and 89% (145/163) in EBV negative DLBCL of elderly (p=0.27). At a median follow-up of 19.2 months, EBV positive DLBCL of elderly demonstrated the poorer median progression free survival (EBV+ vs EBV- 25.7 months [95% confidence interval 5.8-45.6 months] vs not reached, p=0.047), but it could not showed the statistical difference in overall survival (p=0.292). We could not find the difference of progression free or overall survival between GCB or non-GCB like DLBCL. **Conclusions**. R-CHOP chemotherapy may not overcome the adverse prognostic influence of EBV-positive DLBCL of the elderly and this needs confirmation by long term follow-up and prospective study.

[12]Chung-ang University Hospital, Seoul, South-Korea
[13]NHIC Ilsan Hospital, Ilsan, South-Korea
[14]Konkuk University School of Medicine, Seoul, South-Korea

Background. Rituximab (Mabthera®) is a chimeric anti-CD20 monoclonal antibody indicated for the treatment of non-Hodgkin's lymphoma (NHL) and rheumatoid arthritis. SAIT101 is a biosimilar to rituximab. **Aims.** The purpose of this study is to assess safety, pharmacokinetic/pharmacodynamic (PK/PD) profiles and preliminary efficacy after intravenous infusion of Mabthera® and SAIT101 in patients with diffuse large B-cell lymphoma (DLBCL). **Methods.** This is a randomized, multi-center, open-label, parallel group study in 24 Korean patients with histologically proven DLBCL randomly assigned to receive CHOP (cyclophosphamide, doxorubicin, vincristine, and prednisolone) chemotherapy plus either SAIT101 or Mabthera® (375mg/m2) up to cycle 2. Then all patients received Mabthera® and CHOP up to total cycle 6 to 8. The primary objectives were to compare safety and PK and secondary objectives were to compare PK and primary efficacy of SAIT101 and MabThera®. For PK analysis, blood samples were collected at 0 (pre-dose), 2, 6 (end of infusion), 7, 8, 12 (Day 1) and 24 hours (Day 2), and on Days 4, 8, 11, 15, and 22 (before the cycle 2 infusion) after first dosing. The data was analyzed by a non-compartment method using WinNonlin. For PD analysis, change from baseline CD19 positive B-cell count (%) in peripheral blood was calculated up to 72 hours post-infusion in first cycle. For efficacy analysis, tumour response evaluation was done based on revised IWG criteria after completion of cycle 2 treat-

ment. **Results.** At the time of interim analysis, 24 patients were enrolled and no subject has withdrawn from the study. PK parameters were determined in 22 patients. The geometric least square (LS) means of area under the concentration-time curve (AUClast) and maximum concentration (Cmax) in first cycle were 26377 and 28657 hr*µg/ml and 201 and 215 µg/ml for SAIT101 and MabThera®, respectively (Figure 1). The ratio of geometric LS means (90% confidence interval, CI) of SAIT101 versus Mabthera® were 0.92 (0.78~1.09) for AUClast and 0.93 (0.78~1.13) for Cmax(Table 1). The LS means of change from baseline (72hr - 0hr) of B-cell(%) in SAIT101 and MabThera® group were -7.7 and -8.0, respectively and the difference between two groups was 0.3% (90% CI, -0.9 - 1.4). Tumor response assessment was performed in 13 patients (n = 6 for SAIT101, 7 for Mabthera®) at the time of interim analysis. The number of patients showing complete or partial responses was 2 and 4 in SAIT101 group and 3 and 4 in Mabthera® group. Safety population included all 24 patients who received at least one cycle of treatment with SAIT101 or of SAIT101 and MabThera® and CHOP. A total of 39 SAEs from 12 patients were reported. Most frequently reported adverse events were neutropenia, fatigue, nausea, dyspepsia, and decreased appetite and there was no safety signal of difference between two groups. There was one mortality case with drug-induced pneumonitis in SAIT101 group and no suspected unexpected serious adverse reaction (SUSAR) case. **Conclusions.** The study results show high probability of PK and PD equivalence of SAIT101 to MabThera® and preliminary safety and efficacy profiles of SAIT101 comparable to those of MabThera®.

TREATMENT INTENSIFICATION FOR HIV-POSITIVE PATIENTS WITH HIGH-RISK DIFFUSE LARGE B-CELL LYMPHOMA DOES NOT IMPROVE OUTCOME: A RETROSPECTIVE, MULTI-CENTRE STUDY

S Kassam[1], M Bower[2], SM Lee[3], J DeVos[4], P Fields[5], S Gandhi[6], M Nelson[7], S Montoto[4], M Tenant-Flowers[6], F Burns[1], R Marcus[6], S Edwards[8], K Cwynarski[1]

[3]UCL Hospitals and Cancer Institite, London, United Kingdom
[4]Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom
[5]Guy's and St Thomas' Hospital, London, United Kingdom
[6]Kings Collge Hospital, London, United Kingdom
[7]Chelsea and Westminster Hospital, London, United Kingdom
[8]Univesity College Hospital , The Mortimer Market Centre, London, United Kingdom

Background. Since the introduction of combination antiretroviral therapy (cART), the outcome for patients with diffuse large B-cell lymphoma (DLBCL) and HIV infection is similar to that of HIV-negative patients. However, in both groups, the outcome for those with an international prognostic index (IPI) score of 3-5, treated with the standard rituximab (R)-CHOP regimen, remains disappointing. Thus, in HIV-negative patients, studies are ongoing to determine whether chemotherapy intensification can improve prognosis. These more intensive chemotherapy regimens, such as CODOXM/IVAC, appear to be well tolerated in HIV-positive patients with Burkitt lymphoma, but their use in HIV-positive DLBCL has not been reported. **Aims.**To retrospectively review the response rate (RR), treatment toxicity and overall survival (OS) for HIV-positive patients with DLBCL, IPI score 3-5, and the role of treatment intensification. **Patients and Methods.** 50 patients from 5 UK centres treated with either R-CHOP (n=35) or CODOXM/IVAC+/-R (n=15) between 2004 and 2011 were included. The median age at diagnosis was 43 years (range 19-71; 38 male, 12 female).

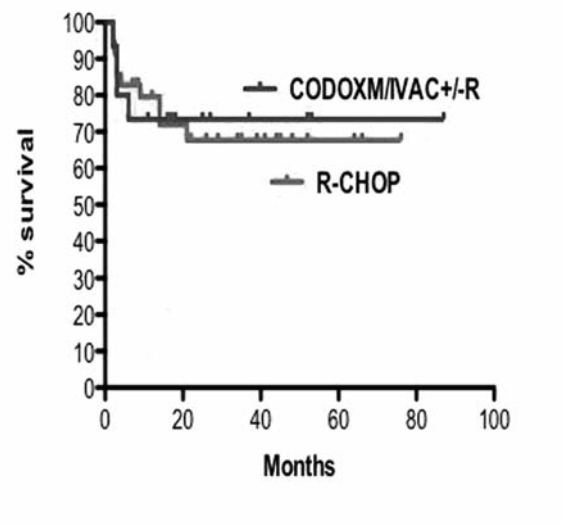

Figure 1. Kaplan Meier plot of survival for HIV-positive patients and high-risk DLBCL treated with R-CHOP vs CODOXM/IVAC+/-R.

Results. There were no significant differences in baseline characteristics of patients treated with the 2 different regimens. Nine patients were concomitantly diagnosed with HIV infection and DLBCL, and 21 (42%) were receiving cART at diagnosis. Seven patients (14%) had central nervous system (CNS) involvement. The median CD4 count and viral load at diagnosis was 91 cells/µl (range 0-740) and 40,633 copies/ml, respectively.Forty-seven patients (94%) received R with chemotherapy: median 6 doses (range 2-8). In those treated with R-CHOP and CODOXM/IVAC+/-R, the median number of cycles was 6 (range 2-8) and 4 (range 2-4), respectively. Additionally, 23 patients treated with R-CHOP received intrathecal methotrexate to prevent CNS recurrence. Seven patients with CNS disease received more intensive CNS-directed therapies. During treatment, 6 patients (17%) receiving R-CHOP and 7 (47%) receiving

CODOXM/IVAC+/-R required dose modifications. In conjunction with chemotherapy, 48 patients (96%) received cART. Additional, 48 (96%), 41 (82%) and 36 (72%) patients received prophylaxis against *pneumocystis jirovecii*, fungal infection and herpes viruses, respectively. Pre-emptive GCSF was administered to 100% of patients treated with CODOXM/IVAC+/-R and to 74% for R-CHOP.The RR and treatment-related mortality was not significantly different between the two groups. Overall, 34 patients (68%) achieved a complete remission, 4 (8%) a partial remission, 6 (12%) had no response and 6 (12%) died during treatment. There were more infections (p<0.0001) and grade 3/4 non-haematological (p=0.0004) toxicities in the CODOXM/IVAC+/-R treated group, and these patients required longer hospital admissions (p<0.0001).With a median follow-up of 28 months (range 7-87), the median remission duration and OS have not been reached, but these do not differ significantly between the 2 treatment groups (Figure 1). Two of 34 patients (6%) in whom CR was achieved have relapsed and 14 have died (8 lymphoma, 5 treatment-related infection).**Conclusions.** In our cohort, the outcome for HIV-positive patients with high-risk DLBCL is favourable (OS ~70% at 2 years). Treatment intensification with CODOXM/IVAC+/- R is feasible, but demonstrated no advantage over R-CHOP, instead resulting in increased morbidity and hospital stay.

[3]Kantonsspital Baden, Baden, Switzerland

[4]Coordinating Center, Swiss Group for Clinical Cancer Research (SAKK),, Bern, Switzerland

[5]IOSI (Istituto Oncologico della Svizzera Italiana), Bellinzona, Switzerland

[6]Kantonsspital Chur, Chur, Switzerland

Background. The majority of patients (pts) with aggressive B-cell lymphoma can be cured with R-CHOP-like standard first-line therapy. No standard therapy is established for pts who relapsed and are not eligible for intensive salvage regimens including high dose chemotherapy (HDT). In addition, frail pts are often not eligible for first-line anthracycline-based regimens. The combination of rituximab and bendamustine (RB) has demonstrated promising activity and tolerability anti-lymphoma treatment regimen. The immunomodulatory agent lenalidomide has also been shown to be active in the treatment of aggressive B-cell lymphoma. **Aims.** Based on the rationale of a hypothesised synergistic effect of lenalidomide in combination with the RB-regimen, this trial aims to develop a new effective and well tolerated regimen for pts with aggressive B-cell lymphoma not eligible for anthracycline-based chemotherapy or HDT. **Methods.** The phase I part was designed to identify the recommended dose (RD). The tentative RD was defined as one level below the dose level (DL) identifying ≥2/6 pts with a dose-limiting toxicity (DLT) during the first cycle. Lenalidomide was given at 10, 15 or 20 mg (dose level 1 to 3) on days 1-21 in combination with bendamustine 70 mg/m^2 days 1&2 and rituximab 375 mg/m^2 on day 1. Courses were repeated every 4 weeks. DLT was defined as one of the following events occurring within the first cycle: therapy related death, ≥ 6 missed doses of lenalidomide or delay of >2 weeks of cycle 2 due to trial drug-related adverse event (AE) toxicity, any grade 3 or 4 non-haematological AE related to trial treatment, neutrophils ≤0.5 x 10^9 G/L for ≥ 6 days, platelets ≤ 20 x 10^9 G/L or 21-50 x 10^9 G/L with major bleedings. Informed consent was obtained. **Results.** In the phase I part, 7 pts were enrolled between March 2010 and August 2011. Median age was 77 years (range 67- 79). WHO performance status 0 in 4 pts and 1 in 3 pts; disease stage I: 1 pt, stage II: 2 pts, stage III: 3 pts, stage IV: 1pt; B-symptoms: 2 pts; IPI 1 (2 pts); IPI 2 (4 pts); IPI 3 (1 pt). Two DLTs occurred at DL 2 within the first cycle: 1 pt had a delay of cycle 2 for > 2 weeks due to neutropenia grade 3, 1 pt experienced a grade 4 non-hematologic AE (myocardial infarction).Further non-dose-limiting grade 3/ 4 AE occurred during subsequent cycles: neutropenia grade 3 /4 (2 pts; DL 1), thrombocytopenia grade 3 (1pt; DL 2), febrile neutropenia grade 3 (1pt; DL 2), cardiac arrhythmia grade 3 (1pt; DL 2), gastrointestinal grade 4 (1pt; DL 2), neurologic-sensory grade 3 (1 pt; DL 1), dermatologic/skin grade 3 (1 pt; DL 2). **Conclusions.** The RD for the phase II part has been established at lenalidomide 10 mg/day for day 1-21 in combination with rituximab 375 mg/m^2 day 1 and bendamustine 70 mg/m^2 on day 1&2. Patient accrual is currently ongoing for the phase II part to evaluate the efficacy and safety of this regimen.

0783

FAVORABLE OUTCOME OF PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA: A SINGLE CENTER ANALYSIS

J Salvador, F Costa, A Botelho Sousa

Hospital Capuchos, Lisboa, Portugal

Background. Among diffuse large B-cell lymphomas, primary mediastinal large B-cell lymphoma (PMBCL) represents a distinct entity to which a poor prognosis is frequently assigned. The optimal treatment is controversial, with an ongoing debate over the role of radiotherapy (RT) and of upfront autologous stem cell transplantation (ASCT). This retrospective study aimed at comparing the outcomes in PMBCL with CHOP +/- rituximab[R] + involved-field mediastinal RT in the pre- and post-rituximab era in a single center. **Methods.** Between October 1993 and April 2010, 60 consecutive patients (pts) with a diagnosis of PMBCL were registered. Median age was 28 years (range 19-70) and the majority of pts were female (65%) and had stage I/II (83%) bulky disease (88%); 42% had a high or intermediate-high International Prognostic Index. These characteristics did not differ significantly between the 44 pts who received first-line therapy with CHOP + RT (group A) and the 16 pts who received (since 2006) R-CHOP + RT (group B). **Results**. The complete remission (CR) rate with the first-line regimen was 70% (68% in group A *vs* 75% in group B); 7 further pts achieved CR with 2nd-line regimens, for a total CR rate of 82% (80 *vs* 87%, ns). Four relapses occurred (all in group A). Of 10 pts who received an ASCT for refractory or relapsed disease, only 4 achieved long-term disease-free survival (DFS). Late toxicity consisted of 2 cases of cardiomyopathy (1 death), 3 cases of pulmonary fibrosis and 1 thyroid carcinoma. In group A, with a median follow up of alive pts of 120 months, overall survival (OS) and DFS at 12 years were 58% and 70%, respectively. In group B (median follow up 52 months) OS and DFS were 87% and 100% at 6 years (ns for both between the 2 groups). **Conclusions**. In this single institution study, survival rates appear excellent since the addition of rituximab, with a trend to superior results in both DFS and OS. These encouraging results could be used to justify withdrawal of upfront RT, with the aim of reducing late side effects. In our view, given the relative inefficacy of ASCT salvage in PMBCL (in our series and others), consolidation RT is to be maintained until randomized studies prove otherwise.

0784

CLINICAL STUDY OF AUTOLOGOUS NATURAL KILLER CELLS COMBINED WITH RITUXIMAB FOR THE TREATMENT OF ELDERLY PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA

JW Cui, W Li, O Bai, CS Liu, D Li, HF Jin

The First Hospital of Jilin University, Changchun, China

Background. Antibody-dependent cellular cytotoxicity (ADCC) by natural killer (NK) cells is a major effector mechanism of the monoclonal anti-CD20 antibody rituximab in eliminating B-cell lymphomas. It is indicated that the combination of NK cells will enhance the efficiency of rituximab. And the combined regimen with low toxicity would be an option for the patients who cannot tolerate chemotherapy, especially for the elderly patients. **Aims.** In this study, the combination of NK cells with rituximab was applied to the elderly patients with diffuse large B-cell lymphoma (DLBCL) who cannot tolerate aggressive therapy with its associated toxicity, in order to evaluate the effectiveness and safety of the combined regimen in the elderly patients with DLBCL. **Methods.** 13 patients with DLBCL were enrolled, and the median age was 70 years old (range: 64-87). All of them have received 1 to 3 cycle chemotherapy of CHOP or RCHOP (rituximab on day 1 plus cyclophosphamide, doxorubicin, and vincristine on day 2, and prednisolone on day 2 through 6.). Seven patients were in partial remission (PR), four patients with stable disease (SD), and two patients with progression disease (PD) prior to study entry. The majority had an ECOG performance status at baseline of 1 or 2, and could not tolerate further aggressive chemotherapy. Written informed consent was obtained from each patient before therapy. Peripheral blood mononuclear cells (PBMC) were isolated by apheresis from the patients and used for expansion of NK cells in the medium containing IL-2, IL-12, IL-15 and monoclonal antibody against CD16 ex vivo in the GMP facility. Autologous NK cells (5.5-9.0 ×10^7/kg· d) were then infused back to individual patients on day 1 to 3 and rituximab 375 mg/m^2 on day 1 of each 21-day cycle for three to six cycles. Patients were assessed for the condition of remission, quality of life (QOL), and side effects every 3 months until progression. Clinical response and tolerability were examined according to international criteria. **Results.** The purity of NK cells (CD3-CD16+CD56+ cells) expanded ex vivo ranged from 78-97%. The lymphoma symptoms were reduced and QOL was improved in all patients. Overall response rate was 100% with 9 complete responders (69.2%), 4 partial responders (30.8%) after three to six cycles treatment. Seven patients had improved response from PR to CR and the two patients with PD after 1-2 cycles of RCHOP prior to study, got PR after three cycles of NK combined with Rituximab. Currently, one patient got CR, another stayed in PR after six cycles of treatment. Adverse events were

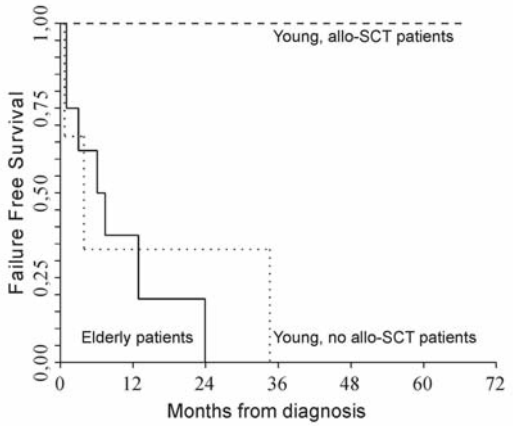
rare and mild. Two of the patients had fever. **Conclusions.** The regimen of autologous NK cell combined with rituximab is safe and efficacious for the treatment of elderly patients with DLBCL who cannot tolerate aggressive treatment. In our study, it is also implicated that NK cells potentially enhance the efficacy of rituximab against DLBCL and reverse the rituximab resistance. Thus this study encourages and warrants further evaluation of this immunotherapy for survival benefit.

0785

ALLOGENEIC STEM CELL TRANSPLANTATION AS CONSOLIDATION THERAPY AFTER CHOP-ALEMTUZUMAB CHEMOIMMUNOTHERAPY IN YOUNG UNTREATED PTCL PATIENTS

D Rapezzi, C Castellino, R Sorasio, A Borra, L Bertolotti, N Mordini, D Mattei, F Giordano, A Gallamini
Ospedale Santa Croce e Carle, Cuneo, Italy

Background. Peripheral T-cell lymphoma (PTCL) is a group of disease characterized by widespread presentation, aggressive course, very poor response to chemotherapy and a 5-year OS ranging between 25% and 40%. Front-line autologous stem cell transplantation (ASCT) has been shown to produce only a modest increase in disease control with a 5-y OS not exceeding 50%. Allogeneic Stem cell transplantation (AlloSCT) proved to be useful mainly in relapsing or refractory PTCL lymphoma, and only anecdotic reports have addressed its role in first-line treatment. **Aims.** To explore the role of AlloSCT as consolidation therapy after induction chemoimmunotherapy with CHOP supplemented by Alemtuzumab (CHOP-C) in untreated PTCL. **Methods.** Sixteen PTCL patients (p) were consecutively admitted to our department from December 2005 to May 2011 with the following histology: 6 PTCL NOS, 3 Enteropathy associated T cell lymphoma (EATL), 5 Anaplastic Large-Cell lymphoma (ALCL) ALK-negative, 2 Angioimmunoblastic T cell lymphoma (AITL). P aged <60 were defined "young"and suitable for CHOP-C ± high-dose chemotherapy Cyclophosphamide, ARA-and Methotrexate (Hyper-C-HiDAM) and AlloSCT; p aged >60, defined "elderly"were treated with CHOP-C for 6 courses when fit for treatment, and with palliation if unfit.



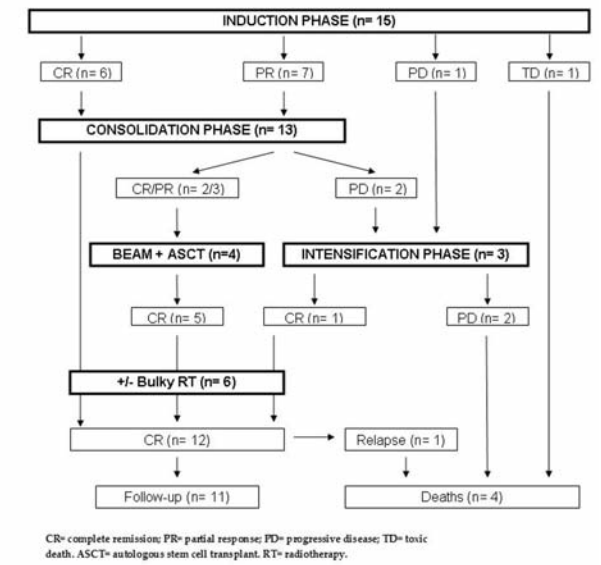
Results Half of the p (8/16) were young (median age 46 range 23-60) with IPI 0 in 1p, 2 in 1p, 3 in 5p, 4 in 1p. After induction 5 (3 in CR 2 in PR) underwent AlloSCT from sibling (2) and unrelated (3) donor, after a thiotepa containing regimen. After a median follow-up of 23 months (11-67) all p are in continuous CR. Four patients had CMV reactivation, 1 had pneumonia from Enterococcus Faecium and Invasive Aspergillosis. Two EATL p. died +1, +5 months after diagnosis for progressing lymphoma. One p refused AlloSCT, treated after induction with ASCT relapsed +34 months after diagnosis. Half (8/16) classified as "elderly"(median age 72; range 66-83) had IPI 0 in 1p, 1 in 3p, 2 in 3p, 3 in 1p. Three completed 6 C-CHOP courses. One is in CR +9 month after diagnosis, 2 experienced early progression and died (+ 42 m + 19 m from diagnosis). Two progressed after the 2nd course and died (+2 m and +5m from d). One died for septic shock after the first C-CHOP; two aged 77 and 83 were treated with palliation and died (+4m and +9 after d). Two CMV reactivations and one sepsis were observed. After a median follow-up of 20 months (9-67), the median EFS and OS for the Allo-SCT p was not reached (EFS and OS 100%). For non-transplanted young p. and elderly p median EFS and OS were: 3.9, 4.6 and 6, 9 months, respectively (Median EFS shown figure 1). **Conclusions.** These data seem to support that although feasible, CHOP-C do not improve the disease outcome in elderly patients but is able to achieve response in a high percentage of young patients, bridging chemosensitive p straight to AlloSCT, with an higher disease control. These data, though very preliminary, need to be confirmed in a larger prospective cohort of patients.

0786

SAFETY AND ACTIVITY OF INTENSIVE SHORT-TERM CHEMOIMMUNOTHERAPY IN HIV-POSITIVE PATIENTS WITH BURKITT LYMPHOMA

G Donadoni[1], M Bruno Ventre[1], A Re[2], M Spina[3], C Cattaneo[2], L Fumagalli[1], M Foppoli[1], S Mappa[1], S Govi[1], G Rossi[2], U Tirelli[1], F Caligaris-Cappio[1], AJM Ferreri[1]
[1]San Raffaele Scientific Institute, Milan, Italy
[2]Spedali Civili, Brescia, Italy
[3]CRO, Aviano, Italy

Background. Worldwide experience with intensive chemotherapy in HIV-positive patients with Burkitt lymphoma in post-HAART era is still limited, with complete remission (CR) rates of 70-80% and 2-year overall survival (OS) rates of 45-70%, but with a treatment-related mortality of 15-20%, mostly due to septic complications. Thus, we adapted an intensive, short-term chemoimmunotherapy program formerly used for HIV-negative patients to treat HIV-positive patients with Burkitt lymphoma with maintained efficacy and lower toxicity. **Aims.** To evaluate feasibility and activity of a new intensive, short-term chemoimmunotherapy program in HIV-positive patients with Burkitt lymphoma. **Methods.** Consecutive HIV-positive patients with Burkitt lymphoma, age ≤65 yrs and ECOG-PS ≤3 were treated with an intensified program at three Institutions. The program included a 40-day Induction Phase (*IP*) of sequential doses of methylprednisolone, cyclophosphamide, vincristine, rituximab, methotrexate, etoposide, and doxorubicin, with intrathecal prophylaxis/treatment. After *IP*, patients in CR received consolidation phase (*CP*; cytarabine + cisplatin or cytarabine + rituximab); patients in PR received *CP* followed by BEAM + ASCT; patients with SD/PD received intensification phase (R-ICEx2 => high-dose cyclophosphamide => high-dose cytarabine => BEAM + ASCT). Leukaphereses were performed after *CP*. Patients with residual or bulky disease at diagnosis were referred to involved-field radiotherapy. **Results.** Fifteen patients (median age 42 yrs, range 27-63; all males; ECOG-PS >1 in five cases) were considered. Most patients had advanced stage, increased LDH, B symptoms, bulky lesions, and extranodal disease (meningeal in two). Eight patients received HAART before lymphoma diagnosis; median CD4+ cells at lymphoma diagnosis was 248 (range 17-858).All patients but one completed *IP* (median duration 49 days; range 38-108), with >1 week delay in 7 patients. During *IP,* all patients experienced G3-G4 haematological toxicity, but it was manageable without drug dose reductions; only one patient showed G4 non-haematological toxicity (transient diarrhea). Response after *IP* was CR in six patients and PR in seven (ORR= 87%; 95%CI: 70-100%); one patient experienced meningeal PD and one died of septic complications (Figure).



CR= complete remission; PR= partial response; PD= progressive disease; TD= toxic death. ASCT= autologous stem cell transplant. RT= radiotherapy.

Thirteen patients were referred to *CP*; the first four patients received cytarabine+cisplatin combination and experienced prolonged G4 neutropenia, bacterial infections and viral reactivations (CMV); the following 9 patients were

treated with cytarabine+rituximab combination; none of them experienced infectious events. Leukaphereses were successful in 9 of the 11 referred patients. Four patients required BEAM treatment and six were referred to radiation therapy.Response after the whole treatment was CR in 12 patients (CRR= 80%; CI: 60-100%). At a median follow-up of 22 months (range 6-30), 11 responsive patients remain disease-free, whereas the remaining responder experienced relapse at 8 months, with a 2-year PFS of 71%. Eleven patients are alive, three patients died of lymphoma and one of sepsis, with a 2-year OS of 70%. **Conclusions.** This intensive, short-term chemoimmunotherapy is feasible in HIV-positive patients with Burkitt lymphoma and shows a better tolerability profile and a similar activity if compared to other more demanding and resource-consuming regimens. The addition of rituximab seems to not increase the risk of septic complications. A multicenter prospective phase II trial is ongoing.

0787

A RUXOLITINIB INDIVIDUAL SUPPLY PROGRAM FOR PATIENTS WITH PRIMARY MYELOFIBROSIS (PMF), POST-POLYCYTHEMIA VERA MYELOFIBROSIS (PPV-MF), OR POST-ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS (PET-MF)

[10]Medical University of Innsbruck, Innsbruck, Austria
[11]Medical University of Vienna, Vienna, Austria

Background. Ruxolitinib is a potent and selective JAK1/2 inhibitor approved in the United States based on results of the phase 3 COMFORT trials. Ruxolitinib demonstrated rapid and durable reductions in splenomegaly and improved MF-related symptoms and quality of life for patients with MF. Because of the unmet medical need, ruxolitinib has been made available through an individual patient supply program (IPSP) outside the United States.

Table. Demographics and Patient Characteristics by Request Status[a]

Characteristic	Approved Patients (n=746)
Sex, n (%)	
Male	433 (58)
Female	310 (42)

[a] Numbers may not add up to 100% because of missing data

Methods. Patients with PMF, PPV-MF, or PET-MF, who are in need of treatment as determined by their physicians, are evaluated for eligibility, irrespective of JAK2 mutation status. The starting dose of ruxolitinib is determined on the basis of baseline platelet count (15 or 20mg twice daily for patients with platelet counts of 100-200x10^9/L and >200x10^9/L, respectively) and can be adjusted for efficacy and safety. Dose changes during treatment are registered, and significant AEs and serious AEs (SAEs) are monitored.To date, 811 requests have been received from >530 physicians in 38 countries, including Canada, Australia, and locations in Europe, Latin America, the Middle East, and Asia. Baseline characteristics for patients whose requests for access were approved/enrolled (n=746) are shown in Table. Drug resupply requests are generally received every 3 months; follow-up data are available for 213 (54.6%) of the 390 patients with sufficient time on the program. Of these, 164 (77%) remain on ruxolitinib therapy, 19 (9%) have discontinued, 6 (3%) died, and 24 (11%) did not initiate therapy. Spleen response (change from enrollment to resupply) was available for 95 patients in whom spleen length increased, decreased, or was unchanged in 3, 80, and 12 patients, respectively. Changes in constitutional symptoms were available for 60 patients. Symptoms were reported to decrease in 43 patients and increase or remain unchanged for 1 and 16 patients, respectively. Safety information was available for 108 patients, of whom 34 were noted as having a significant AE or SAE by the investigators at the time of resupply.To date, the proportion of patients with the *JAK2*V617F mutation enrolled in this IPSP (74%) is higher than that for the general MF population (50%-60%) and may reflect the preference of physicians to treat more *JAK2*V617F-positive patients with ruxolitinib, even though ruxolitinib has demonstrated efficacy in both patient types (Verstovsek S, et al. *N Engl J Med*. 2010;363(12):1117-1127). **Conclusions**. Ruxolitinib, the only drug to have completed phase 3 studies, has garnered substantial requests for access through the IPSP underscoring the need for an effective medical treatment in patients over a range of IPSS risk-assessment scores. With the exception of a higher number of *JAK2*V617F mutation-positive patients, characteristics of the IPSP patients are generally similar to those expected in the overall MF patient population. Response and safety patterns seen in the IPSP appear to be similar to those from the COMFORT trials.

0788

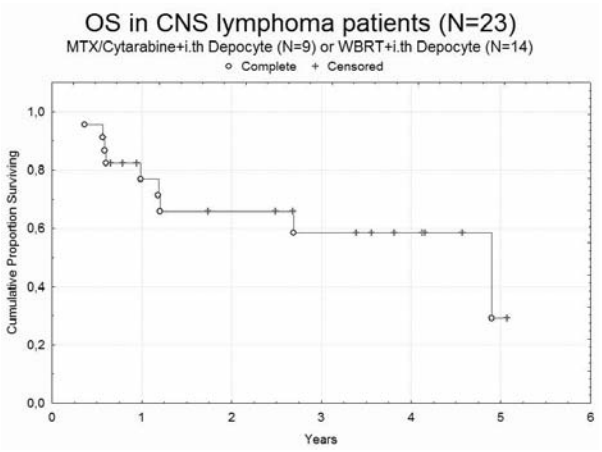
LYPOSOMAL CYTARABINE IN THE TREATMENT AND PROPHYLAXIS OF CNS LYMPHOMA - LONG TERM RESULTS OF RESULTS OF 120 PATIENTS TREATED IN PLRG CENTERS

W Jurczak[1], A Giza[2], S Fornagiel[2], T Ogorka[2], J Dzietczenia[3], T Wrobel[2], A Skotnicki[2]

[1]Dpt of Hematology, Krakow, Poland
[2]Dpt of Hematology UJ CM, Krakow, Poland
[3]Dpt of Hematology, Medical University, Wroclaw, Poland

Background. Treatment and prophylaxis of Central Nervous System (CNS) lymphoma remains a therapeutic challenge. Liposomal Cytarabine (DepoCyte) is a sustained release formulation of Ara-C for intrathecal administration that maintains cytotoxic concentrations in the CSF for more than 14 days.This is a retrospective analysis of 120 patients treated according to the PLRG protocols including DepoCyte. **Methods.** The efficacy and safety of Liposomal Cytarabine (DepoCyte) was assessed in three cohorts of patients: one in prophylaxis (N=88) and two in treatment (N=32). In our series prophylaxis was regarded necessary in lymphoblastic or Burkitt lymphoma (N=13) and high risk cases of other aggressive lymphomas (DLBCL, PMBCL, PTCL) defined as involvement of specific sites (infiltration of vertebral column, orbits, sinuses or testis; N=17) or at least 2 of recognized risk factors (IPI 3-5, elevated LDH, 2 or more extranodal sites; N=75). None of those patients had neurological symptoms at diagnosis, and the average pleocytosis was 2,4 (range 0-10). The patients received 3, 1 (range 1-6) DepoCyte injections every 2-4 weeks at the time of systemic chemotherapy or after its completion. In the treatment cohort we identified 9 patients with an increased pleocytosis (39, range 15-174) due to lymphoma in cytological analysis without neurological symptoms or typical radiologic findings. Those patients received systemic chemotherapy in doses not penetrating to CNS and the 3, 9 (range 2-7) DepoCyte injections with curative attempt. The third cohort consisted of 23 patients with a measurable CNS disease in imaging studies and/or important neurological signs (14 cases of PCNS lymphoma and 9 cases systemic lymphoma with CNS infiltrations. Those patients were treated with standard chemotherapy (whole brain radiotherapy -14 cases or high doses of cytarabine/methothrexate-9 cases) and additional Depocyte injection (4,3 doses, range 2-8). Both adverse reaction and survival data (PFS, CNS PFS, OS) were monitored during the average observation time of 3 years. **Results.** Liposomal Cytarabine was well tolerated (56% patients had no side effects, 37% experienced transient grade 1-2 adverse events: headache, nausea and vomiting, dizziness or fever, 7% developed grade 3 headaches or fever). At the average observation time of 3 years, none of 88 high risk lym-

phoma patients relapsed in CNS after Lyposomal Cytarabine prophylaxis. In patients with cerebrospinal fluid infiltration without neurological symptoms or radiologic findings Depocyte as the only CNS directed treatment was efficient in preventing relapse in 8/9 cases. The addition of Liposomal Cytarabine to standard radiotherapy or high dose cytarabine/metothrexate based chemotherapy in 23 lymphoma cases with neurological symptoms and infiltrates visualized in imaging studies possibly increased OS (median OS - 4,8 years, Figure 1). **Conclusions.** Liposomal Cytarabine administered nntrathecaly has good toxicity profile. Its pharmacokinetics allows using it at the time of routine chemotherapy without the necessity of additional hospital admissions.1) It is effective in CNS prophylaxis of high risk aggressive lymphoma patients,2) It may be considered adequate as the only CNS treatment in asymptomatic cases with increased pleocytosis,3) It possibly increases the efficacy of radiotherapy/systemic chemotherapy in cases with brain infiltrations.



Indolent lymphomas

BRAFV600E NEGATIVE HAIRY CELL LEUKEMIA IS RARE AND NOT ASSOCIATED WITH SPECIFIC IGHV REARRANGEMENTS OR A SPECIFIC IGHV MUTATION STATUS

F Dicker, C Eder, S Jeromin, T Alpermann, C Haferlach, T Haferlach, W Kern, S Schnittger
MLL, Munich, Germany

Background. The BRAFV600E mutation has initially been discovered in all cases of hairy cell leukemia (HCL), but not in cases of variant HCL (HCLv). Recently, this perfect correlation has been challenged by studies reporting HCL cases without BRAFV600E. Interestingly, the immunoglobulin heavy chain variable region gene IGHV4-34, which has been associated with poor prognosis in HCL, appeared exclusively and to a high percentage in these BRAFV600E-negative cases of classic HCL and also in HCLv (Xi et al., Blood, 2011). **Aims.** We wanted to characterize our cohorts of HCL and HCLv for the presence of BRAFV600E and correlate the results with IGHV gene usage. **Methods.** We analyzed the bone marrow or peripheral blood of 52 cases with HCL and 12 cases with HCLv at diagnosis as confirmed by multiparameter flow cytometry (MFC). The BRAFV600E mutation was detected by an mRNA-based reverse transcription allele-specific real-time quantification (RQ-PCR) assay. Results are given as %BRAFV600E/BRAFwt. IGHV genes and mutation status were analyzed by the use of Biomed-2 primers. An identity of >= 98% of the analyzed IGHV sequence compared to published germline sequences was considered an unmutated IGHV status. **Results.** In our cohort the median percent leukemic cells was 16% (range 0.2 - 74%) for HCL and 33% (range 5 - 59%) for HCLv as determined by MFC. The BRAFV600E mutation was detected in 51/55 (92%) of HCL cases, whereas 0/12 of HCLv were positive. The median BRAFV600E expression ratio of positive cases was 32.9 (range 3.9 - 280.3) and that of all negative cases was 0.005 (range 0.000 - 0.009). In detail, the percent leukemic cells in the four HCL BRAFV600E negative cases were 0.2%, 8%, 28% and 66% by MFC and within the clone size that can be detected with the BRAFV600E-specific RQ-PCR. Next, the IGHV genes and the IGHV mutation status of all samples were analyzed. We detected an unmutated IGHV status in 10/55 (18%) of HCL, which was less frequent compared to 5/12 (42%) of HCLv ($p = 0.087$). We could not find the usage of the IGHV4-34 gene, which has been associated with poor prognosis and BRAFV600E negativity in HCL, in any of our classic HCL cases, but in 5/12 (42%) of the HCLv cases. The IGHV mutation status was unmutated in 4/5 (80%) IGHV4-34 cases (100% identity to germline each). The four cases of classic HCL, which lacked BRAFV600E expression, expressed the IGHV genes IGHV1-3*01 (96.5% identity), IGHV1-69*02 (94.0% identity), IGHV3-9*01 (96.9% identity) and IGHV6-1*01 (99.0% identity), which were also expressed by BRAFV600E positive HCL cases in our cohort. **Conclusions.** We confirm the use of BRAFV600E as a marker for HCL, which helps to delineate classic HCL from the variant, prognostically poor form. We do, however, find rare HCL cases that lack the BRAF mutation, a finding that has been only appreciated by few of the recent studies. In our cohort, the BRAFV600E negative cases were not associated with a specific IGHV gene or IGHV mutation status and IGHV4-34 was only detected in HCLv but not in classic HCL.

[10]BC Cancer Agency, Vancouver, Canada

Background. GA101 (obinutuzumab) is a unique glycoengineered type II anti-

CD20 monoclonal antibody in phase II/III clinical trials for chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphoma (NHL). In preclinical models, GA101 enhanced direct cell death and increased antibody-dependent cell-mediated cytotoxicity compared with other anti-CD20 antibodies. GA101 clinical studies have demonstrated responses in patients with relapsed/refractory NHL and CLL however, this is the first head-to-head study to directly compare clinical responses of GA101 with rituximab. **Aims.** This randomized Phase II trial compares the safety and efficacy of monotherapy with GA101 vs. rituximab in patients with relapsed indolent NHL. **Methods.** Patients with relapsed CD20+ indolent NHL requiring therapy who had demonstrated a prior response to a rituximab-containing regimen lasting ≥6 months were eligible. A total of 175 patients (149 follicular lymphoma [FL] and 26 non-follicular indolent NHL) stratified by histology and country were randomized 1:1 to receive 4 weekly infusions of either GA101 (1000 mg, n=88) or rituximab (375 mg/m^2, n=87). End-of-treatment response was assessed 28-42 days after the last induction dose. Patients without evidence of progression following induction therapy received maintenance GA101 or rituximab q2m for up to 2 years at the same dose. The primary endpoint was the overall response rate (ORR) at the end of induction in the FL population as assessed by investigators and was designed to detect a 15% difference between GA101 and rituximab with ~80% power for a 1-sided chi-square test at a significance level of 0.2.

Table 1. ORR at end of induction and best ORR by investigator and IRF assessment in FL patients.

	Investigator-assessed		IRF-assessed	
Response, n (%)	rituximab (n=75)	obinutuzumab (n=74)	rituximab (n=75)	obinutuzumab (n=74)
Overall response rate (ORR)	25 (33.3)	33 (44.6)	20 (26.7)	33 (44.6)
CR/CRu	4 (5.3)	9 (12.2)	3 (4.0)	4 (5.4)
PR	21 (28.0)	24 (32.4)	17 (22.7)	29 (39.2)
Difference in ORR, % [95% CI]	11.3 [–5.1, 27.6]		17.9 [2.0, 33.8]	
p-value*	0.08		0.01	
Best ORR (BORR)	48 (64.0)	49 (66.2)	35 (46.7)	45 (60.8)
CR/CRu	14 (18.7)	26 (35.1)	15 (20.0)	20 (27.0)
PR	34 (45.3)	23 (31.1)	20 (26.7)	25 (33.8)
Difference in BORR, % [95% CI]	2.2 [–13.9, 18.3]		14.1 [–2.5, 30.8]	
p-value*	0.39		0.04	

* One-sided, chi-squared test with a significance level=0.2
CR = complete response, CRu = unconfirmed complete response, PR = partial response

Results. The clinical cutoff date was September 1, 2011, with a median observation time of 15 months for both arms. Overall, patients in the two treatment groups were balanced for baseline characteristics. Investigator-assessed ORR for patients in the GA101 arm was higher (44.6% [33/74]) than for the rituximab arm (33.3% [25/75]) in the FL population (difference 11.3% 95% CI: -5.1-27.6; *p*=0.08) (Table 1). A blinded independent review facility (IRF) also assessed responses (Table 1): ORR for GA101 was higher (44.6% [33/74]) compared with rituximab (26.7% [20/75]) constituting a difference of 17.9% (95% CI: 2.0-33.8; *p* = 0.01). The median PFS is not different between the treatment arms at this point in time.No new safety signals were observed in either arm. The most common adverse events (occurring in ≥5 patients) were infusion-related reactions (IRRs) (GA101 vs. rituximab: any grade, 74% vs. 51%), fatigue (25% vs. 20%), cough (21% vs. 6%) and upper respiratory tract infection (8% vs.10%). The majority of grade 3/4 adverse events reported over the entire treatment period occurred as a result of IRRs (GA101 vs. rituximab: 11% vs. 6%). **Conclusions.** This is the first head-to-head trial of GA101 against rituximab and has demonstrated higher responses rates without appreciable differences in safety. Although a higher rate of IRRs and cough was noted with GA101, the majority were grade 1/2 in severity and did not result in significant differences in treatment discontinuation. GA101 is under study in Phase III trials in combination with chemotherapy.

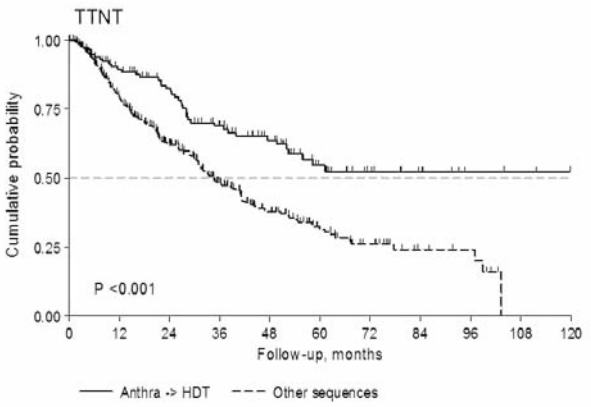
Background. The disease course of follicular lymphoma has been usually characterized by frequent remissions and subsequent relapses, with progressively shorter treatment-free intervals. During the course of the disease, patients often receive multiple lines of active treatments ranging from single-agent chemotherapy (CHT) or monoclonal antibodies, to high-dose therapy with stem cell transplantation (HSCT). In relapsed patients the efficacy of subsequent treatments may be affected by the type and the intensity of the previous treatments. However it is currently not known whether a definite sequence of active treatments exists which optimizes the outcome of patients and randomized trials can hardly be designed to answer this question. **Aims**. The REFOLL study is an observational, multicenter, retrospective study launched by the Fondazione Italiana Linfomi (FIL) to analyze the impact of different combinations of first- and second-line treatments on patient's outcome. **Methods.** Of 582 patients with follicular lymphoma at first relapse between 2000 and 2008 registered from 25 Institutions, 546 were analyzable. They had received either alkylating- (AA) (22%), or anthracyclin- (AC)(61%) or nucleoside analogues-based (NA)(17%) therapy as first-line treatment, with rituximab (R) in 52%. AA patients were older (P<.001) but had less stage III-IV (P=.011), FLIPI high-risk disease (P=.02), and had received maintenance R more often (P<.001) compared to other groups. Second-line treatment options included the same first-line options w/wo R (AA: 20%; AC 18%; NA: 14%), autologous HSCT (29%), or monoclonal antibody only (19%). The primary endpoint was time to next treatment (TTNT) after first relapse.



Results. The median follow-up from first relapse was 40 months (range 1-125). TTNT ranged between 1 and 120 months (median 23 months). AC+/-R as first-line treatment was associated with a better TTNT (HR: 0.71, P=0.007) than

AA+/-R and NAI+/-R. Among second-line treatments, auto-HSCT performed better when compared to any other second-line treatment with or without R (HR ranging from 1.79 to 2.40). Interestingly, using multiple Cox regression, the TTNT after auto-HSCT was significantly better in patients receiving AC as first line treatment (HR ranging from 1.88 to 3.3 compared to any other sequence with or without R) (Figure 1). Other factors independently influencing TTNT after HSCT were R maintenance (HR: 0.66), duration of first remission > 12 months (HR: 0.8), and stage III-IV at diagnosis (HR: 1.89). Overall survival from diagnosis was 89% at 5-yr (CI95% 85-91%) and the sequences CHT->HSCT and CHT->CHT with R showed a better outcome than CHT ->CHT without R (HR:0.55, P=0.015). Adjusted by age and stage at diagnosis the superiority becomes marginal (HR 0.61, P=0.047). **Conclusions.** Auto-HSCT at relapse obtained the best TTNT compared to standard CHT or chemoimmunotherapy. The results of auto-HSCT were optimized by the use of anthracyclin-containing CHT as first line treatment rather than of other types of CHT whereas the use of rituximab in first-line did not impact on the efficacy of auto-HSCT. This study supports the concept that sequences of similarly active treatments do not necessarily obtain similar results, which is important in the management of indolent diseases like follicular lymphoma and requires further, possibly prospective, studies.

LONG-TERM FOLLOW-UP ANALYSIS OF A SERIES OF 97 PATIENTS WITH SPLENIC MARGINAL ZONE LYMPHOMA TREATED WITH SPLENECTOMY AS A FIRST LINE TREATMENT

J Lenglet[1], C Traullé[2], N Mounier[3], C Benet[1], M Venon[1], N Munoz-Bongrand[1], P Brice[1], M Noguera[1], A Traverse-Glehen[2], M Ffrench[2], L Baseggio[2], P Felman[2], F Berger[2], G Salles[2], J Briere[1], B Coiffier[2], C Thieblemont[1]

[1]Hopital Saint Louis, Paris, France

[2]Centre Hospitalier Lyon Sud, Pierre-Bénite, France

[3]Groupe Hospitalier de L'Archet, Nice, France

Background. Splenic marginal zone lymphoma (SMZL) is an indolent B-cell lymphoma involving the spleen.SMZL spreads to the bone marrow and the blood where circulating villous lymphocytes are usually found. When required, several therapeutic options may be proposed as first line without consensus, except for HCV-positive patients. **Aims.** To perform a large retrospective analysis of 97 patients treated by splenectomy as a first line treatment. **Methods.** We collected patients with SMZL treated in two centers from June 1997 to February 2011. All of them were HCV negative. At diagnosis, median age was 63 years (range, 29-87). Sex ratio M/F was 0.78. Most of the patients (77%) had a good performance status. Involvement of bone marrow and blood was found in 88% and in 73% of the patients, respectively. High LDH level was seen in 46% of the patients. High aaIPI (> 2) was found in 48% (n=27) patients. The Intergruppo Italiano Linfomi (IIL) score was 0 for 30% (9), 1 for 40% (12), and 2 for 30% (n=9) of the patients. Anemia less than 12 and thrombocytopenia less than 100 occurred in 33% (n=32) and in 12% (n=12) of the patients, respectively. A monoclonal component was found for 33 patients. The most common associated immunological event was an autoimmune haemolytic anemia and / or a positive coombs' test. **Results.** Median follow-up after splenectomy was 6.3 years. Complications after splenectomy occurred in 5% of the patients, and included 2 splenic vein thrombosis, 1 pancreatitis, 1 nosocomial pneumopathy, 1 post-operative ARDS. Adjuvant therapy (clb, fludarabine, CHOP, R-CHOP, or rituximab alone).was proposed to 20% (20) of the patients.One year after splenectomy, only 4% of the patients had anemia (range 8.9 to 11.7 g/dL). None of the patients had thrombocytopenia. The 5- and 10-year overall survival (OS) rates were of 84% and of 67%, respectively. The respective 5- and 10- year progression free survival (PFS) rates were of 62% and 47%. Half of the dead patients (11%, n=11) died because of a non illness-related event (pulmonary infections, stroke, myocardial infarction, other non-related malignancies, accident). Histological transformation to high grade lymphoma occurred in 11% (11) of the patients.Significant prognostic factors for OS were age at diagnosis more than 60 years (p= .0382) and a histological transformation after splenectomy (p= .0328). Significant prognostic factors for PFS were an initial bone marrow involvement (p= .0436) and a histological transformation (p= .0001). None of the prognostic scores, neither aaIPI nor IIL score, discriminated significantly the outcome of the patients. **Conclusions.** Splenectomy proposed as first line therapy in patients with SMZL is an appropriate and safe treatment. It allowed to normalize cytopenias during the first year and is associated with a good PFS.

Background. Inotuzumab ozogamicin (INO) is a humanized anti-CD22 antibody conjugated with calicheamicin, a potent cytotoxic antitumor antibiotic. **Aims.** This phase 2 study evaluated the safety and efficacy of INO in indolent B-cell non-Hodgkin lymphoma (B-NHL) refractory to rituximab and chemotherapy, or radioimmunotherapy. **Methods.** Patients with follicular (FL), marginal zone (MZL), or small lymphocytic lymphoma (SLL) received INO 1.8 mg/m^2 every 28 days for 4 to 8 cycles, with dose and/or frequency adjusted based on toxicities. Patients must have ≥2 prior systemic therapies and no response/progression within 6 months of completion of rituximab-containing therapy or within 12 months of radioimmunotherapy. **Results.** Eighty-one patients have been enrolled and dosed with INO: 72 with FL, 4 with MZL, and 5 with SLL. Median age was 63 years (range, 29-84 years). Patients were heavily pretreated: median of 3 prior anticancer regimens (range, 1-14; 35% had ≥4), 5/81 [6%] patients had prior autologous stem cell transplant, and 29/79 [37%] were refractory to their most recent prior chemotherapy. Based on FLIPI scores, 24%, 28%, and 49% of FL patients were low, intermediate, and high risk, respectively. Median follow-up was 10.1 months. Patients received a median of 3 INO doses (range, 1-8 doses), with dose adjustments due to adverse events (AEs) allowed: 17% had reductions, and 15% had delays. The most common grade 3/4 AEs were thrombocytopenia (57%) and neutropenia (32%). Among 39 patients with grade 3/4 thrombocytopenia and complete laboratory data, mean time to grade 1/0 recovery was 35.9 days (range, 3.0-176.0 days). The most common non-hematologic grade 3/4 AEs were nausea (5%), elevated gamma-glutamyltransferase (5%; 2/5 resolved), elevated aspartate aminotransferase (4%; all resolved), and pneumonia (4%). In total, 41% patients discontinued treatment due to AEs, including 28% due to persistent thrombocytopenia that failed to recover to grade 1/0 within the 28-day dose delay allowed per protocol. Among 75 evaluable patients, the objective response rate (ORR) was 61% (FL, 67%) and complete response rate was 28% (FL, 32%); median duration of objective response was 24.8 months. Based on FLIPI scores, ORRs in FL patients were 75% in low-risk patients, 58% in intermediate-risk patients, and 56% in high-risk FL patients. ORR was 19% (5% complete response) for patients with bulky disease (≥7.5 cm) and 58% (35% complete response) for patients refractory to their most recent chemotherapy. Median progression-free survival (PFS) was 12.0 months (FL, 26.9 months; MZL, 8.8 months; SLL, 2.4 months). Among FL patients, median PFS has not been reached in low-risk patients, with a 1-year PFS rate of 76%; median PFS for intermediate- and high-risk patients were 11.1 and 12.6 months, respectively. Median overall survival has not been reached for all patients or FL patients; 1-year overall survival rate in FL patients was 84%. Median overall survival for MZL and SLL patients was 11.3 and 9.9 months, respectively. **Conclusions.** In patients with indolent B-NHL refractory to rituximab plus chemotherapy or radioimmunotherapy, INO demonstrated notable clinical activity with durable responses, especially in FL patients. Hematologic, gastrointestinal, and hepatic AEs were the most common toxicities.

0794

FINAL RESULTS OF STAGE 1 OF A PHASE IB STUDY TO INVESTIGATE THE PHARMACOKINETICS (PK), SAFETY, AND TOLERABILITY OF SUBCUTANEOUS RITUXIMAB IN FOLLICULAR LYMPHOMA (FL) AS PART OF MAINTENANCE TREATMENT

[7]Roche Products Ltd, Welwyn Garden City, United Kingdom
[8]F. Hoffmann-La Roche Ltd, Basel, Switzerland

Background. Rituximab is currently administered by intravenous (IV) infusion. Subcutaneous (SC) administration could significantly simplify treatment and reduce administration time. To determine a rituximab SC dose that yields a non-inferior serum trough concentration (C_{trough}) compared with rituximab IV (375 mg/m^2), a two-stage, adaptive Phase Ib study was conducted. In Stage 1, FL patients with a response to R-based induction therapy and at least one IV rituximab dose in maintenance were randomized to receive a single dose of rituximab at 375 mg/m^2 IV, 375 mg/m^2 SC, 625 mg/m^2 SC, or 800 mg/m^2 SC. Patients then continued with IV treatment (375 mg/m^2) on a 2-monthly (q2m) or 3-monthly (q3m) schedule until completion of 2 years of maintenance. However, once a final SC dose had been elucidated, patients randomized to an SC cohort who had completed 1 year of maintenance therapy were given the option to receive remaining maintenance doses with rituximab SC. In Stage 1 of this dose-finding study, IV and SC PK data were integrated into a PK model, and model-based simulations were then used to predict serum C_{trough} and AUC for various rituximab SC fixed doses (1100-1400 mg). **Aims.** To describe the model-based simulations used to determine a dose of rituximab SC that yields a non-inferior serum C_{trough} to that of the standard dose of rituximab IV given q2m or q3m. To provide an update on previously reported (ASH 2010) data on safety and tolerability of rituximab SC in the maintenance setting for FL.

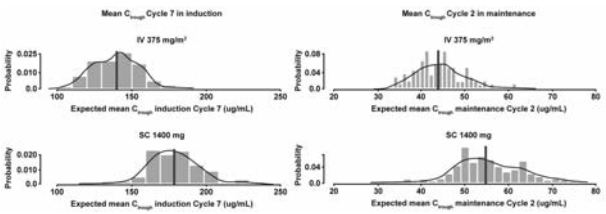

Figure 1. Distribution of simulated mean Ctrough levels comparing IV (375 mg/m^2) and SC (1400 mg) at Cycle 7 of induction and Cycle 2 of maintenance.

Methods. Population PK analysis was conducted using non-linear mixed-effect modeling with NONMEM VI. The first-order conditional estimation method with interaction was used. The structural model was a two-compartment model comprising a time-varying clearance component. SC injection was characterized by the SC absolute bioavailability and the rate of absorption from the SC compartment. After model qualification, simulations were used to compare SC C_{trough} and AUC values with those of IV for various rituximab SC doses during the maintenance and induction period. **Results.** Model-based simulations were performed for a virtual population of at least 50 patients in each arm for both maintenance and induction periods and were repeated 100 times. The outcome suggested that a dose of 1400 mg rituximab SC would potentially maintain patients at a level of efficacious concentrations independent of the regimen.Figure 1 illustrates the distribution of predicted mean C_{trough} at Cycle 7 in induction and Cycle 2 in maintenance, comparing the IV dose of 375 mg/m^2 with the fixed SC dose of 1400 mg. At the selected dose of 1400 mg, mean C_{trough} values are predicted to be non-inferior to those achieved with the IV dose. Similar simulations were performed for the 3-monthly maintenance regimen as well as for AUC_{tau} in both induction and maintenance. **Conclusions.** A fixed dose of 1400 mg has been selected for formal C_{trough} non-inferiority testing in Stage 2 of the trial. Treatment with SC doses of rituximab was well tolerated, with an AE profile comparable to that of rituximab IV. These data support further testing of rituximab SC.

0795

CLINICOPATHOLOGICAL FEATURES OF EXTRANODAL MARGINAL ZONE B-CELL LYMPHOMA OF THE MUCOSA ASSOCIATED LYMHOID TISSUE (MALT LYMPHOMA)

M Raderer[1], B Kiesewetter[2], M Troch[1], S Wöhrer[1]
[1]Medical University Vienna, Vienna, Austria
[2]Medical University vienna, Vienna, Austria

Background. Extranodal marginal zone B-cell lymphoma of the mucosa associated lymphoid tissue (MALT lymphoma) is among the more common types of lymphoma and is thought to follow a clinically indolent course. Recently, it has been suggested that the rate of dissemination might be substantial, and that systemic therapies are beneficial also in patients with localized disease. **Aims.** To retrospectively assess clinicopathological features and outcome of different types of therapy along with defining potential prognostic parameters in all patients with MALT lymphoma staged and treated at a single institution (University referral center). **Methods.** Between 1999 - 2011, a total of 245 patients with MALT lymphoma were diagnosed and treated at our institution, who constitute the collective analysed. Interestingly, only 35% of patients had gastric lymphoma, while 65% had extragastric lymphomas. All patients had undergone uniform staging, and the following parameters had been assessed: age, gender, localisation and stage, infection with Helicobacter pylori (HP), Hepatitis A, B and C, presence of an autoimmune disease, plasmacytic differentiation, monoclonal gammopathy, factors included in the IPI including LDH, beta-2-microglobulin, MALT-lymphoma specific translocations including t(11;18)(q21;q21), type of treatment, response to therapy, relapse/progression, time to relapse/progression and survival. **Results.** After an interim analysis of 180 patients (76 male/104 female), there was no difference in terms of survival between gastric versus extragastric MALT lymphomas, while a lower IPI-score (0,1 versus higher) was significantly associated with better survival (p= 0.014). after a median follow-up of 52 months (IQR 20 - 93), 16% have died. Curiously, low IPI-scores had a significantly shorter time to progression (141 vs 155 months, p=0.017) and a significantly higher rate of relapse as compared to higher IPI. Patients with gastric MALT lymphoma had similar rates of disseminated disease as extragastric MALT lymphomas (p=0.289, but stage was neither associated with survival nor relapse or time to progression. In total, 38% had only antibiotic therapy, 35% chemo/immunotherapy, 12% radiation and 9% surgery as initial treatment, while 5% had only wait and see after initial diagnosis. There was no influence of extragastric disease versus gastric lymphoma, LDH, B2MCG, plasmacytic differentiation and monoclonal gammopathy on relapse/progression and time to relapse. In addition, an underlying autoimmune disease (seen in 33% of patients) did not influence clinical outcome. Patients with gastric lymphoma, however, had a significantly higher likelihood to require further therapy than patients with extragastric lymphoma, most probably reflecting a selection bias of HP-refractory patients in our referral center. Patients undergoing systemic therapy (immuno/chemotherapy) had a signifcantly longer time to progression/relapse than patients after radiotherapy (117 vs 71 months, p = 0.006), further underscoring the potential of systemic therapy even in localised stages. However, there was no difference in survival according to initial therapy, suggesting a high rate of successful salvage in relapsing patients. **Conclusions.** MALT lymphoma has an excellent prognosis irrespective of initial therapy, localisation and stage, suggesting that patients should be initially managed with non-toxic therapies. However, early application of systemic therapies appears to be associated with a longer time to relapse also in localized disease.

[10]Division of Hematology, S. Giovanni B. Hospital and University of, Torino, Italy

Background. Radiotherapy (RT) is considered the standard treatment for stage I-II, non bulky, Follicular Lymphoma (FL). Despite initial therapy, most patients relapse especially outside the radiation field. To reduce the risk of disease recurrence, many authors have suggested to extend the irradiation field or to combine systemic chemotherapy to RT. However, both these approaches are associated with increased risk of early and late toxicity. Thus, the use of involved-field (IF) RT remain widely employed in stage I-II FL. The anti-CD20 monoclonal antibody rituximab (RIT) is extensively used in FL, with proven efficacy and excellent tolerability, either alone or in combination with chemotherapy. It should be effectively combined with RT, as well. **Aims.** To evaluate retrospectively the safety and efficacy of rituximab, administered in combination with RT as initial treatment for localized FL. **Methods.** From July 1999 to June 2011, 43 consecutive patients were treated for grade I-II FL, with stage I-II non-bulky at five Italian Hematologic centers. The treatment included 4 weekly infusions of rituximab at a dose of 375 mg/m^2, followed by IF-RT. Main patient characteristics were: median age = 50 years (range: 34-82); M/F ratio=26/17; FLIPI 0/1 = 35/8; Bulky = 0; stage I / II = 37/6. The median dose of RT was 30.6 Gray (Gy) (range 20-40). Bone marrow PCR to detect molecular disease was performed in 32 patients: 10 (31%) were PCR positive.

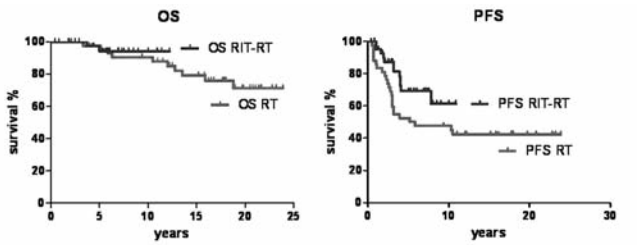

Figure 1. Overall survival (OS) and progression free survival (PFS) of patients treated with Rituximab and involved-field radiotherapy (RIT-RT) and patients receiving only radiotherapy (RT). OS p=NS; PFS p=0.032.

Results. the treatment was generally well tolerated, the addition of rituximab did not result in significant side effects except for some mild allergic reactions at the first infusion. All patients responded to therapy, with 42 (98%) complete remissions (CR) and 1 (2%) partial remission (PR). At a median follow up of 6.4 years (range: 0.4 to 12.2), the PFS was 69%, and overall survival (OS) 95%. As of December 2011, 41 of 43 patients (95%) were alive and 30 (70%) are in continuous CR; there were two deaths at 3 and 4 years for lung cancer in two smoker patients; 12 patients (30%) recurred (6 were PCR+ at diagnosis, 4 PCR- and 2 had no probe). These results were compared with a matched historical group of 46 patients with similar clinical characteristics and treated with IF-RT alone. The median PFS of RT alone vs RIT-RT was 5.2 years versus not yet reached. As shown in Figure 1, the 5-years PFS of RT alone vs RIT-RT was 52% and 69% respectively(p=0.032); the 5-years OS was similar 92% and 94%. **Conclusions**. Rituximab followed by RT-IF is a well tolerated treatment for patients with stage I-II FL; this approach offers prolonged PFS, higher than that observed in subjects treated with RT alone. The long-term results with RIT-RT are similar to those reported with the combination of RT to chemotherapy, but with significantly reduced side effects. The results suggest the usefulness of randomized phase III study designed to compare prospectively RIT-RT vs. RT alone in limited-stage FL.

0797

A PHASE II STUDY OF LENALIDOMIDE IN PATIENTS WITH EXTRANODAL MARGINAL ZONE B-CELL LYMPHOMA OF THE MUCOSA ASSOCIATED LYMPHOID TISSUE (MALT-LYMPHOMA)

B Kiesewetter[1], M Troch[2], W Dolak[3], L Muellauer[4], J Lukas[5], C Zielinski[2], M Raderer[2]

[1]Medical University Vienna, Vienna, Austria
[2]Medical University Vienna, Dept. of Internal Medicine I / Oncology, Vienna, Austria
[3]Medical University Vienna, Dept. of Internal Medicine III / Gastroenterology, Vienna, Austria
[4]Medical University Vienna, Dept. of Pathology, Vienna, Austria
[5]Medical University Vienna, Dept. of Ophthalmology, Vienna, Austria

Background. MALT lymphoma ranks among the more common lymphoma entities, and shares certain features with multiple myeloma. In view of this and the activity of lenalidomide in various B-cell lymphomas we have initiated a phase II study of lenalidomide in patients with MALT-lymphoma. **Aims.** To evaluate the efficacy of lenalidomide in patients with MALT lymphoma. **Patients and Methods.** Patients with histologically verified advanced MALT lymphoma (in case of gastric MALT lymphoma with demonstrated refractoriness to HP-eradication, i.e. at least a 12 months follow up after successful HP-eradication) were included in the study. Treatment consisted of lenalidomide 25 mg p.o. days 1 - 21, with a 7 day-break after each cycle. Restaging was scheduled after 3 and 6 courses, respectively. Response was assessed by radiological criteria or in case of gastric MALT by applying the GELA criteria for histological response.The study had been approved by the Ethical Board of the Medical University of Vienna and before opening the trial, it had been registered at www.clinicaltrial.gov. Informed consent was obtained of all patients. **Results** A total of 18 patients were included in the trial (10 female/8 male); 5 had gastric and 13 had extragastric MALT lymphoma (7 orbital, 3 pulmonary, 1 parotid, 1 intestinal and 1 subcutaneous); 4 patients had an underlying autoimmune disease (2 had Sjögren's disease, 2 a chronic autoimmune thyroiditis). In eleven of these patients lenalidomide was applied as the first line therapy.Sixteen patients were evaluable, showing an overall response rate of 62% (10/16; 6 complete and 4 partial remissions). Four patients had stable disease, while two progressed, including one case of transformation to diffuse large B-cell lymphoma. Side effects were manageable and included neutropenia (WHO grade III in 3 patients) as the leading hematotoxicity and pruritus/exanthema of the skin as the leading non-hematologic side effect (8 patients, 7 grade I/II). One patient each had to be hospitalized for pneumonia and pruritus/exanthema, respectively, but both recovered after consecutive dose reduction of lenalidomide to 15 mg. After a median follow-up of 18 months, one patient has died from lymphoma, while the remaining are alive and relapse-free. **Conclusions.** These data suggest activity of lenalidomide monotherapy in MALT lymphoma with an overall response rate of 62% and manageable toxicity in this study.

[3]Division of Hematology, Ospedali Civili, Brescia, Brescia, Italy
[4]Division of Hematology, Niguarda Ca'Granda Hospital, Milano, Italy

Background. High dose chemotherapy and autologous stem cell transplantation (ASCT) has been shown effective in the long-term control of relapsed/refractory follicular lymphoma. It has also been reported that the achievement of bcl-2 negative status is associated with a lower risk of recurrence. **Aims.** To evaluate the clinical outcome of patients with relapsed or refractory FL treated with immunochemotherapy, *in vivo* purging and high-dose therapy with ASCT. **Methods.** We updated a prospective multicenter phase 2 trial (*Arcaini et al. Annals of Oncology, 2008*) and herein we report data on 124 relapsed/refractory FL pts treated from 1999 to 2010 with a program of anthracycline-based debulking chemotherapy , immunochemotherapy (2-4 R-COP),

in vivo purging and SC mobilization with HD-AraC and rituximab followed by ASCT conditioned with BEAM. In selected pts 2 rituximab doses were administered on days +14 and +21 post infusion. Response was assessed according to the International Working Group Response criteria (Cheson et al. JCO 1999). **Results.** Median age was 52 yrs; grade 3 FL histology was detected in 15% of pts. Median number of previous chemotherapy lines was 1 (range 1-4). Prior radiotherapy was administered in 23 pts. Ann Arbor stage was III-IV in 77% and BM was involved in 49% pts. FLIPI was low in 48%, intermediate in 32%, high in 20%; FLIPI2 was low in 10%, intermediate in 70% and high in 20%. PB bcl-2 was positive in 32/67 pts and BM bcl-2 was positive in 51/106. Debulking chemotherapy allowed to obtain CR in 11% and PR in 79%, and molecular remission in 54% (28/52) of informative patients for bcl-2. After R-COP, CR was obtained in 58% and PR in 35%. 3 pts did not proceed to mobilization for progression. Before mobilization, 40 out of 45 informative pts for bcl-2 in BM (89%) became negative and 29/33 (88%) in PB. Two pts were poor mobilizers and 1 did not proceed for infection; 118 pts successfully mobilized (median number of CD34+ cells collected 14.6 x 10^6/Kg) and 117 proceeded to ASCT (1 was diagnosed with lung cancer before ASCT). All harvests in molecularly informative pts were bcl-2 negative. The median number of infused CD34+ was 7.86 x 10^6/Kg and the median take was on day +12 from BEAM. TRM was 0%. For the whole series the 5-yr PFS is 54% (median 7.2 yrs) and the 5-yr OS is 85% (median not reached) (Figure 1). After a median follow-up of 5.2 yrs (range 0.5-12.6 yrs), 81 pts are still in CR. Absence of the bcl-2 rearrangement in PB and BM after ASCT is associated with persistent clinical remission. In 3 pts an histologic shift was documented after ASCT and 4 pts developed a myelodisplastic syndrome; 16 pts died (3 in CR). **Conclusions**: these updated data confirm that prolonged PFS is achievable in relapsed/refractory pts with *in vivo* purging and ASCT. Persistent molecular response is associated with a better outcome.

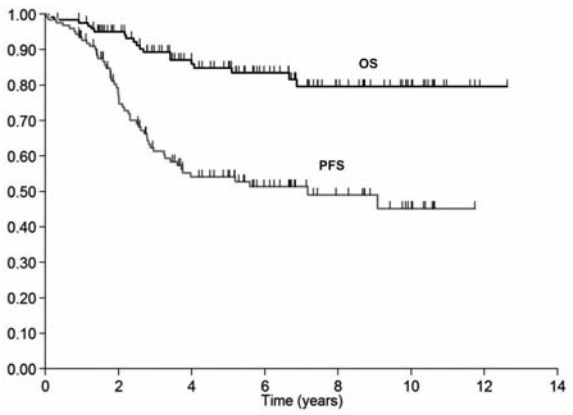

Figure 1. OS and PFS of entire series.

0799

INOTUZUMAB OZOGAMICIN PLUS RITUXIMAB VERSUS DEFINED INVESTIGATOR'S CHOICE IN CD20+/CD22+ FOLLICULAR NON-HODGKIN LYMPHOMA

D Gómez Almaguer[1], S Aung[2], R Kotb[3], A Ranade[4], JK Roh[5], E Vandendries[6], L Yang[6], J Clancy[6], M Tsai[7], J Leach[7]

[5]Yonsei Cancer Center, Seoul, South-Korea
[6]Pfizer Inc, Cambridge, MA and LaJolla, CA, United States of America
[7]Park Nicollet Frauenshuh Cancer Institute, St. Louis Park, MN, United States of America

Background. CD22 is expressed on the majority of B-cell non-Hodgkin lymphomas (NHL), including follicular NHL (FL). Inotuzumab ozogamicin (INO) is an anti-CD22 antibody conjugated to calicheamicin, a potent antitumor cytotoxic antibiotic. Rituximab (R), approved for FL treatment, can enhance the activity of chemotherapy. **Aims.** The primary objective was to evaluate progression-free survival (PFS) of R-INO versus a defined investigator's choice therapy. The study was terminated early due to poor recruitment, enrolling only 29 patients: 15, Arm 1 (all treated); 14, Arm 2 (13 treated). **Methods.** This open-label, phase 3 study was designed to enroll 978 patients with CD20+/CD22+ FL treated with 1-2 prior R-containing regimens. Patients were randomized 1:1"'Arm 1: R 375 mg/m^2 (Day 1) plus INO 1.8 mg/m^2 (Day 2), every 28 days; Arm 2: investigator's choice of R-CVP (R 375 mg/m^2, cyclophosphamide 750 mg/m^2, vincristine 1.4 mg/m^2 [Day 1], prednisone 40 mg/m^2 [Days 1-5]) or R-FND (R 375 mg/m^2 [Day 1], mitoxantrone 10 mg/m^2 [Day 2], fludarabine 25 mg/m^2 [Days 2-4], dexamethasone 20 mg/day [Days 1-5]). Patients were stratified by number of prior regimens, investigator's choice of therapy, and geographic region. Patients received up to 8 cycles.**Results.** For enrolled Arm 1 and Arm 2 patients, respectively: median ages, 66 years and 61.5 years; 60% and 43% male; 67% and 79% Caucasian. Median treatment durations were 143 days (range, 30-228 days) and 152 days (range, 111-203 days). Seven patients in each arm completed the treatment phase.Although a small sample size, the hazard of disease progression or death in Arm 1 appeared less than Arm 2 (hazard ratio=0.19; 95% CI, 0.04-1.02; *P*=0.036; Cox proportional hazard model, controlling for stratification factors). Arm 1 had higher PFS rates (12-month, 86% vs 55%; 24-month, 74% vs 27%); median PFS was not estimable in Arm 1 and 16.4 months in Arm 2. Objective response rate was 93% in Arm 1 versus 64% in Arm 2. The 24-month overall survival rates in Arms 1 and 2 were 87% versus 67%, respectively. Two (13%) patients in Arm 1 and 4 (29%) in Arm 2 died. Fewer patients in Arm 1 versus Arm 2 experienced grade 3/4 treatment-related adverse events (AEs) of neutropenia (20% vs 77%), leukopenia (7% vs 39%), febrile neutropenia (0% vs 23%), pneumonia (0% vs 8%), and anemia (0% vs 8%); other grade 3/4 AEs (³10% of patients) were thrombocytopenia (40% vs 23%) and lymphopenia (13% vs 8%). Treatment-related serious AEs were reported for 4 patients in Arm 1 (2 with hepatobiliary disorders) and 6 patients in Arm 2 (5 with hematologic disorders, 3 with pneumonia). Five patients in Arm 1 (none in Arm 2) discontinued treatment due to an AE (neutropenia, increased GGT, hyperbilirubinemia, pyrexia, venoocclusive disease). **Conclusions.** In this terminated study, R-INO showed longer PFS and a higher response rate than investigator's choice (R-CVP/R-FND) in these FL patients. Each arm had different, but acceptable, safety profiles. These interesting results need to be confirmed in a larger trial. Further clinical trials of R-INO for NHL treatment are ongoing.

[4]James P. Wilmot Cancer Center, University of Rochester, Rochester, United States of America
[5]University of Iowa, Holden Comprehensive Cancer Center, Iowa City, United States of America
[6]Department of Health Sciences Research, Mayo Clinic, Rochester, United States of America

Background. Our initial publication of the NLCS identified that rituximab (R) with chemotherapy constitutes more than half (51.9%) of strategies used in newly diagnosed FL patients (pts) in theUS. Given the lack of data comparing the effectiveness of front-line R-chemotherapy regimens in clinical practice, we examined outcomes for pts with stage III/IV FL receiving R with cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP), R with cyclophosphamide, vincristine, and prednisone (R-CVP), or R with a fludarabine-based regimen (R-Flu), as first-line therapy **Aims.** Assess the progression-free survival (PFS), time to next treatment (TTNT), and overall survival (OS). Determine the effect of each treatment regimen on these outcomes stratified by FL grade and FLIPI risk.

Table 1. Two-year Kaplan-Meier estimates, PFS, TTNT and OS for stage III/IV patients and selected subgroups.

Two-Year Survival Probability									
	2-Year PFS Rate			2-Year TTNT Rate			2-Year OS Rate		
	R-CHOP	R-CVP	R-Flu	R-CHOP	R-CVP	R-Flu	R-CHOP	R-CVP	R-Flu
Overall	0.77	0.71	0.76	0.77	0.72	0.78	0.94	0.88	0.91
All Stage III/IV Patients, HR (95% CI)									
	R-Flu vs R-CVP			R-CHOP vs R-CVP					
	PFS	TTNT	OS	PFS	TTNT	OS

Stage III/IV Patient Subgroups, HR (95% CI)[2]									
	PFS	TTNT	OS	PFS	TTNT	OS			
FLIPI high risk[3]	**0.54 (0.31-0.95)**	**0.37 (0.18-0.77)**	0.52 (0.26-1.06)	**0.66 (0.45-0.96)**	0.86 (0.57-1.32)	**0.38 (0.23-0.63)**			
Grade 1-2[4]	**0.55 (0.32-0.94)**	**0.36 (0.20-0.63)**	0.60 (0.25-1.43)	0.94 (0.65-1.36)	0.99 (0.68-1.44)	0.75 (0.42-1.33)			

[1]Adjusted for FLIPI components, histology, use of R-maintenance, practice setting, bone marrow involvement, sex, and geographic region.
[2]G3 patient subgroup was not evaluated due to small sample size.
[3]Adjusted for use of R-maintenance, practice setting, bone marrow involvement, sex, and geographic region.
[4]Adjusted for FLIPI components, use of R-maintenance, practice setting, bone marrow involvement, sex, and geographic region.

Methods. The NLCS is a prospective, multicenter, observational study collecting data on previously untreated pts with FL diagnosed from 2004 to 2007 at 265 sites in theUS. Initial management decisions were made by the treating physician. Two-year Kaplan-Meier estimation was used to evaluate PFS, TTNT, and OS. To compare the impact of treatment regimen on PFS, TTNT, and OS, Cox proportional hazards models were used controlling for FLIPI components, community or academic practice setting, R-maintenance or observation following treatment, and additional factors that were significantly correlated with induction regimen (bone marrow involvement, sex, and geographic region). **Results.** Of 2727 evaluable pts, 901 had stage III/IV FL and went on to receive the aforementioned regimens of interest (575 grade 1-2 [G1-2] FL; 206 grade 3 [G3] FL, 120 mixed or unknown grade). 51% of G1-2 pts received R-CHOP (n=296), 32% received R-CVP (n=186), and 16% received R-Flu (n=93). Among G1-2 pts, 241 had high-risk FLIPI scores (49% R-CHOP, 39% R-CVP, and 12% R-Flu). In comparison with G1-2 pts, more G3 pts received R-CHOP (82%, n=169), with R-CVP and R-Flu treatments given to 13% (n=27) and 5% (n=10) pts, respectively. Among G3 pts, 91 had high-risk FLIPI scores (79% R-CHOP, 17% R-CVP, 3% R-Flu).With a median follow-up of 62 months, median PFS, TTNT, and OS were not reached in most cases. Results of the Kaplan-Meier estimation and adjusted Cox proportional hazards models for PFS, TTNT, and OS are presented in the table. Two-year response rates for PFS, TTNT and OS were comparable across regimens. PFS and TTNT increased in pts treated with R-Flu vs. R-CVP overall (HR=0.61 and HR=0.42, respectively), and in G1-2 pts and pts with high-risk FLIPI. The benefit of R-Flu could not be evaluated in G3 pts due to small sample size. Although patients receiving R-CHOP tended to have slightly better outcomes than those receiving R-CVP, the only significant difference was seen in the high-risk FLIPI group (HR=0.66 and HR=0.38 for PFS and OS respectively). **Conclusions.** First-line R-chemotherapy regimens in clinical practice in the US provide robust PFS, TTNT, and OS. R-Flu is associated with significantly longer PFS and TTNT overall and for patients in selected sub-groups when compared with R-CVP. For high-risk FLIPI patients, R-CHOP was associated with improved PFS and OS compared with R-CVP.

0801

IRON CONTRIBUTES TO BORTEZOMIB SENSITIVITY IN MULTIPLE MYELOMA CELLS

A Campanella, P Santambrogio, F Fontana, M Frenquelli, S Cenci, M Marcatti, R Sitia, G Tonon, C Camaschella
San Raffaele Scientific Institute, Milan, Italy

Background. Multiple Myeloma (MM) is a malignant still incurable plasma cell disorder. Pharmacological treatment with the proteasome inhibitor bortezomib has improved patient outcome. However, bortezomib-resistance remains a major clinical problem. In the attempt to improve bortezomib efficacy, we explored whether cellular iron status may contribute to resistance. Proteasome plays an important role in iron homeostasis that might be altered by proteasome inhibition inducing iron excess. Excess iron is potentially toxic through generation of reactive oxygen species (ROS) that may cause cell death. To avoid ROS generation, cellular iron homeostasis is tightly regulated by the coordinated expression of iron import (Transferrin Receptor 1, TfR1), export (ferroportin) and storage (ferritins) proteins. **Aims.** To identify novel approaches to sensitize bortezomib-resistant cells. **Methods.** We analyzed iron and oxidative status together with cell viability in 7 MM cell lines (MMc) and in plasma cells from 4 patients. Cells were treated with increasing bortezomib concentrations with or without iron supplementation. Manipulation of ferritin levels was obtained by two approaches: by drug- (deferoxamine, DFO) induced iron reduction and by silencing with shRNA technology. **Results.** MMc showed a range of responsiveness to bortezomib. By plotting sensitivity versus iron parameters and ROS scavenger proteins we found that bortezomib resistance directly correlates only with ferritin levels and thus with iron storage capacity. In MMc with low ferritin, bortezomib enhanced ROS generation and iron supplementation increased bortezomib sensitivity by increasing ROS levels. In contrast, iron toxicity was less evident in bortezomib-resistant cells with high ferritin levels. In the absence of bortezomib, all MMc showed the expected coordinated regulation of iron proteins in response to iron. They were able to reduce iron import protein TfR1 while increasing ferritin levels and iron storage capacity after iron supplementation. Bortezomib deregulated the coordinated expression of iron proteins. In particular, it caused a two-fold increase of TfR1 through protein stabilization and inhibited iron storage by blocking translation of new ferritin molecules, without affecting iron export. In this way bortezomib increased iron toxicity. We concluded that basal ferritin levels mediate the sensitivity to iron toxicity in bortezomib-treated cells.To further prove this conclusion we manipulated ferritin levels in resistant cells. DFO treatment strongly abolished ferritin expression, while silencing by shRNA reduced ferritin of about 75%. In both cases the reduction of basal ferritin levels before bortezomib treatment sensitized resistant MMc.On patient derived CD138+ cells, we confirmed that iron supplementation sensitizes cells to bortezomib, that bortezomib prevents ferritin increase and that DFO pre-treatment overcomes bortezomib resistance. **Conclusions.** Bortezomib increases iron toxicity by deregulating the coordinated expression of iron proteins and by increasing cell iron entry in the presence of defective iron storage. Thus iron supplementation enhances bortezomib sensitivity in both MMc and patient primary cells. Ferritin reduction is a mechanism to increase iron toxicity overcoming bortezomib resistance worth to be explored *in vivo*.

[2]Cancer Research Center by N.N.Blochina, Moscow, Russian Federation
[3]MAPGE MHR, Moscow, Russian Federation
[4]Hematology Scientific Center, Moscow, Russian Federation

In a number of researches it is shown that the virus of a hepatitis C is one of etiopathogenic factors of NHL. Last time a number of lymphoproliferative diseases has been also related to the virus associated with tumors. According the data of WHO classification in 2008 HCV infection takes part in etiopathogenesis of several indolent lymphoms and those tumors may be virus associated.

Hematological response after antiviral therapy (AT) is the strongest argument in favourof an oncogenic role of hepatitis C virus (HCV) in non-Hodgkin's B-cell lymphoma (NHL)Method: In Cancer Research Center named by N.N Blokhina in the period 2000-2011 we observed 556 patients with NHL, who along with diagnosed of tumor were also analysed for chronic viral hepatitis C infection. In our research we analysed hematological and virological response of 87 pts with IBCNHL who had markers of HCL infection. Patients with IBCNHL were distributed in 2 groups: 1 group included 54 pts whose tumoral cells was positive of immunochemistry by proteins of hepatitis C (IGH+), and 2 group -33pts with negative immunochemistry tumoral cells (IGH-). Of those 87 patients in 24 patients the disease was diagnosed in I-II stage, in 63 - в III-IV stage Age of the patients varied from 27y.o. to 70 y.o. 65 patients had ALT and AST to be over normal. Mediana was 2,5 normal. Level of increasing of ALT achieved 10 normal. In IGH+ group level of HCV RNA was from $3x10^3$ to $7x10^7$ c/ml, in IGH- group level RNA was from negative to $5x10^5$ c/ml. All pts were characterized by an indolent course of disease not needing immediate conventional anti-lymphoma therapy. 74 pts received interferon (IFN) every days 3 m.U with ribavirin and 13 received only INF Results. 7 pts discontinued AT for toxicity, all pts IGH- group No pts interrupted AT for IBCNHL progression. Pts treated with AT in IGH+ group achieved a CR 37(69%) and 13 (24%) a PR while 4 had stable disease. Median F-UP of 3.3 yrs. Pts treated with AT in Igh- group achieved only PR in 13 (39%) a while 20 had stable disease. Virological response (VR) was achieved in 68 pts (78%). Considering the IGH+ group treated with AT , hematologic response (CR + PR) was highly significantly associated to the achievement of a VR (p <0.001)Conclusions: These data in a large series of pts confirm high rates of lymphoma regression in group of pts with indolent NHL IGH+ with AT. For this pts antiviral therapy may be defining as a first line therapy Lower response rate in second group suggested as a first line therapy anti-lymphoma treatment.

PHARMACOECONOMIC EVALUATION OF RITUXIMAB AS MAINTENANCE TREATMENT FOR FOLLICULAR LYMPHOMA: RESULTS OF A REAL WORLD POPULATION BASED STUDY

H Blommestein[1], D Issa[2], M Pompen[3], P Huijgens[2], C Révil[4], C Uyl-de Groot[1]
[1]Erasmus University, Rotterdam, Netherlands
[2]VU University Medical Center, Amsterdam, Netherlands
[3]Roche Netherlands, Woerden, Netherlands
[4]F. Hoffmann - La Roche Ltd., Basel, Switzerland

Background. Follicular lymphoma (FL) is the largest subtype of indolent non-Hodgkin lymphoma. FL is incurable and median overall survival ranges from six to ten years. The EORTC 20981 trial revealed longer progression-free survival (median 3.7 versus 1.3 years) after treatment with rituximab maintenance compared to observation. While randomised controlled trials (RCTs) are the golden standard for establishing effectiveness, the generalizability in daily clinical practice is limited. Therefore, health policy makers and clinicians increasingly require information on outcomes in unselected patient populations which are not treated under the idealised circumstances created in RCTs. **Aims.** Using real world data, we evaluate cost-effectiveness of rituximab maintenance compared to observation in FL patients responding to second line chemotherapy. **Methods.** A population based registry was created including patients with non-Hodgkin lymphoma diagnosed in the Netherlands since 2004. We selected patients with follicular lymphoma who responded to second line chemotherapy. Data was collected from medical patient records on patient characteristics, resource utilisation, treatment information (e.g. regimens, dosages and number of cycles) and treatment outcomes (e.g. response and survival). A cost-effectiveness model was applied to calculate cost per life year gained (LYG) and quality adjusted life year (QALY). **Results.** Our database contained 1457 patients with non-Hodgkin lymphoma including 545 patients diagnosed with FL. The observation group consisted of 46 patients responding to second line chemotherapy. The maintenance group included 33 patients receiving rituximab maintenance after second induction treatment. Median age was 60 [Range 34-82] and 62 years [Range 30-92] in the observation and maintenance group and not significantly different. Differences between the two groups were found for response to prior treatment (p=0.032) and prior treatment with rituximab in the second line (p=0.004). Besides, non-significant differences for B-symptoms and distribution of the FLIPI score were found. Compared to the EORTC 20981 trial, patients in the registry were older (p=0.0006) and although substantial variation across patients was observed, dosage, number of cycles and duration of treatment were comparable to the trial. We investigated overall survival (OS) and this was significantly better in the maintenance group (p = 0.021) compared to the observation group, although median OS was not reached. Incremental cost per LYG and QALY were low with € 5,156 per QALY and € 5,246 per LYG. Extensive sensitivity analyses did not change the results. While the results in our study are based on real world data and will be more generalizable to daily clinical practice, both OS and costs should be interpreted with caution since observed dissimilarities between the observation and maintenance groups suggested that the groups represent different types of patients. **Conclusions**. FL patients in daily practice are not identical to the patients in the EORTC 20981 trial emphasising the importance of studying real world data. However, analysing non-randomised patient groups is challenging because of the differences between the observation and maintenance group and therefore results should be interpreted carefully. However, we do find that in this real world setting, cost-effectiveness ratios for maintenance treatment with rituximab are low compared to other haematological treatments.

[2]Hematology Division, Mauriziano-Umberto I Hospital, University of Torino, Torino, Italy
[3]Department of Onco-Hematology, IRCCS, CROB Basilicata, Rionero in Vulture (PZ), Italy, Italy

Background. Achievement of maximal cytoreduction is a major goal of anti-lymphoma therapy: several studies indicate that follicular (FL) and mantle-cell lymphoma (MCL) patients entering molecular remission (MR) detected by PCR-based minimal residual disease (MRD) methods benefit of superior outcome independently from age and treatment received [Ladetto, Blood 2008; Pott, Blood 2010]. Conversely, the occurrence of molecular relapse (M-rel) often anticipates subsequent clinical relapse. Andersen et al. [JClinOncol2009] reported successful MR reinduction following rituximab administration in MCL patients, but no similar experience has ever been reported in FL. **Aims.** We here collected retrospective cases receiving at our Institutions pre-emptive treatment for M-rel with rituximab (pRTX) to evaluate feasibility and efficacy of this approach in FL and MCL. **Methods.** Between 2000-2008, FL and MCL patients in complete clinical response experiencing M-rel underwent pRTX. MRD was assessed on bone marrow using Bcl-2/IGH (FL) and Bcl-1/IGH translocation or IGH rearrangement (MCL), as described [Ladetto,BiolBloodMarrowTransplant2006;Ladetto,Blood2008]. According to the Nordic group approach, treatment decision was based on nested-PCR results; real-time quantitative (RQ)-PCR analysis was performed in all cases with available DNA leftovers. M-rel was defined as recurrence after MR of PCR-positivity on two consecutive samples (confirmed by direct sequencing), in absence of clinical relapse; molecular persistence (M-per) as persistent PCR-positivity after chemoimmunotherapy; MR reinduction as the occurrence of two consecutive PCR-negative samples within one year after pRTX; pRTX consisted of four weekly rituximab infusions: a double course was given within six months to patients still PCR-positive after the first course. Additional pRTX courses were offered, at the discretion of the treating physician, to patients experiencing subsequent M-rels. **Results.** Eighteen patients received at least one pRTX course (nine FL, nine MCL; median age 52 years; range 32-68; 16 males). These patients were previously treated with rituximab-supplemented autologous transplantation (13 patients) or R-CHOP and experienced either M-per (six patients) or M-rel (twelve patients, median time from treatment 40 months, range 10-103). Overall, 24 pRTX procedures (14 in MCL and ten in FL patients) were performed (17 single, seven double), with no grade 3-4 toxicities recorded; eighteen for first M-rel or M-per and six for second or third M-rel. In 18 cases MR reinduction was successful while in six failed (four failures in MCL, two in FL; five as first pRTX, one as second pRTX). None of the 14 patients reentering MR relapsed within two years from pRTX while two relapses were observed within six months among the six pRTX failures. Four second M-rels (occurring in FL patients) did not receive pRTX retreatment and relapsed within one year. RQ-PCR was performed on 80% of samples, basically confirming nested-PCR results; the majority of M-rels showed low MRD levels (median: 3x10^-4, range: 10^-6 to 8x10^-2). In this small series we failed to find associations between tumor burden at M-rel and pRTX efficacy. **Conclusions.** pRTX was safe and effectively reinduced MR in 75% of procedures in both FL and MCL, including cases of repeated delivery. Prospective MRD-tailored trials are needed to verify the clinical benefit of this approach, particularly in the context of maintenance regimens.

LONG TERM RESULTS OF THE LNH- PRO TRIAL FOR PATIENTS WITH INDOLENT NON HODGKIN´S LYMPHOMA TREATED WITH CVP PLUS INTERFERON ALFA 2B (IFN)

J Cannata-Ortiz[1], C Nicolás[2], A Garcia-Noblejas[1], J García-Laraña[3], P Sabin[4], P Zamora[5], J Requena[6], R Arranz[1]
[1]Hospital Universitario de la Princesa, Madrid, Spain
[2]Hospital Universitario Central de Asturias, Oviedo, Spain
[3]Hospital Universitario Ramón y Cajal, Madrid, Spain
[4]Hospital Universitario Gregorio Marañón, Madrid, Spain
[5]Hospital Universitario La Paz, Madrid, Spain
[6]Hospital Universitario Severo Ochoa de Leganés, Madrid, Spain

Background. Indolent non-Hodgkin B-cell lymphomas are clonal mature B-cell proliferations for which a curative treatment has not been defined to date. Nevertheless, survival has significantly improved since the incorporation of agents with immunomodulatory activity, such as recombinant alpha2 interferon (IFNα2b) first and anti CD-20 antibody (rituximab) in the last decade. Currently, there is not a consensus about the best chemotherapy to be associated with and treatment strategies under study use progression free survival as a surrogate marker for survival, but updated long term results are frequently lacking. Since 1990 our group introduced, for naïve low-grade NHL, the use of IFN in the induction treatment in association with CVP, using the Bagley regimen which includes 2 gr/m^2 of Cyclophosphamide per cycle. Herein, we report the long term results of our trial. **Aims.** . To evaluate the long term outcome of 170 patients treated with CVP plus IFN, 71 patients included in the LNH- PRO multicenter trial(Arranz et al, JCO 1998) and 99 patients in the subsequent trial that evaluated the role of maintenance IFN (Cannata el al, ASH 2004). **Methods.** From 1990 to 2000, 170 patients received CVP plus IFN. Doses were Cyclofosfamide 2g/m^2 po, Prednisone 500mg/m^2 po, Vincristine 1.4mg/m^2 (max 2mg) and IFN 3 MU/m^2 sc, 3 times a week for 12 weeks. Patients received the number of cycles necessary to achieve maximum response. Radiotherapy to bulky areas was admitted. Efficacy analysis has been performed on an intention to treat basis and data were updated in March 2011.

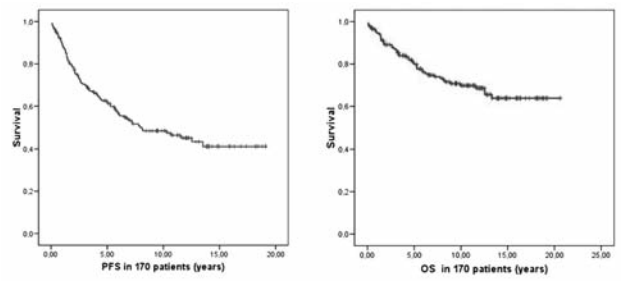

Figure 1. PFS and OS in the series.

Results. Included entities were grade 1-2 FL 65%, SLL 21% and MZL 13%. Patient's characteristics were median age 56 years-old (22-78 years-old), stage III-IV 80%, bone marrow involvement 58%, and 31% of high-risk FLIPI among FL patients. Median number of cycles administered was 6 (range 1-15). Overall response rate was 87%, with 68% achieving CR (116 patients). After a median follow-up of 10 years for surviving patients (range 0.3-19.6 years), median PFS for the whole series was 7.9 years (95% CI: 3.7-12.09 years, Fig 1) and 10 years for FL patients (95% CI: 4.5-15.9 years). DFS is 54 % (± 0.5% SD). Actuarial OS at 20 years is 64 % (± 5% SD, Figure 2). A plateau in PFS, DFS and OS curves is observed after 13 years.Fifty one patients (30%) have died due to disease progression (31 patients), secondary neoplasms (7 patients), cardiopathy (4 patients) and unknown causes (9 patients). Secondary neoplasms have been diagnosed in 24 patients (13%). All were solid tumours, except for 1 myelodisplastic syndrome. **Conclusions.** CVP chemotherapy plus 12 weeks IFN is a very effective therapy that has changed the expected natural history of our indolent NHL. Median PFS of nearly 8 years and OS of 64 % at 20 years should be considered for future strategies in the treatment of indolent NHL. In order to improve these results, and outside clinical trials, new approaches must consider long term toxicity, mainly the risk of secondary neoplasm and cardiopathy, which were responsible of the 22 % of deaths in our series.

THE SDF-1 INHIBITING SPIEGELMER NOX-A12 DISRUPTS THE INTERACTION OF MULTIPLE MYELOMA CELLS WITH THE BONE MARROW MILIEU IN VIVO, LEADING TO ENHANCED SENSITIVITY TO BORTEZOMIB

M Roccaro[1], A Sacco[1], P Quang[1], AK Azab[1], P Maiso[1], Y Zhang[1], Y Liu[1], M Reagan[1], Y Zhang[1], H Ngo[1], D Dirk[2], A Kruschinski[2], I Ghobrial[1]
[1]Dana-Farber Cancer Institute, Boston, MA, United States of America
[2]Noxxon Pharma AG, Berlin, Germany

Background. SDF1/CXCR4 axis plays a major role in homing and trafficking of multiple myeloma (MM) cells to the bone marrow (BM). We hypothesized that de-adhesion of MM cells from the surrounding BM milieu through SDF-1 inhibition will enhance MM sensitivity to therapeutic agents. We therefore tested NOX-A12, a high affinity l-oligonucleotide binder (Spiegelmer) to SDF-1 in MM, looking at its ability to modulate MM cell tumor growth and MM cell homing to the BM *in vivo* and *in vitro*. **Aims. 1**) To determine the *in vivo* localization of MM cells and SDF-1 within the BM niches. 2) To evaluate the ability of NOX-A12 to induce BM de-adeshion of MM cells thus enhancing MM cell sensitivity to proteasome inhibition. **Methods.** BM co-localization of MM tumor cells (MM.1S-GFP+) with SDF-1 (AlexaFluor633-conjugated-anti-SDF-1-mAb) has been tested *in vivo* by immunoimaging, using *in vivo* confocal microscopy. Detection of mobilized MM-GFP+ cells *ex vivo* has been performed by flow cytometry. *In vivo* homing and *in vivo* tumor growth of MM cells (MM.1S-GFP+/luc+) were assessed by using *in vivo* confocal microscopy and *in vivo* bioluminescence imaging (BLI), in SCID mice treated with 1) vehicle; 2) NOX-A12; 3) bortezomib; 4) NOX-A12 followed by bortezomib. DNA synthesis and adhesion of MM cells in the context of NOX-A12 (50-100nM) treated primary MM BM stromal cells (BMSCs), in presence or absence of bortezomib (2.5-5nM), were tested by thymidine uptake and adhesion *in vitro* assay, respectively. Synergism was calculated by using CalcuSyn software (combination index: C.I. according to Chou-Talalay method). **Results.** We first showed that SDF-1 co-localizes in the same BM niches of growth of MM tumor cells *in vivo*. NOX-A12 induced a dose-dependent de-adhesion of MM cells from the BM stromal cells *in vitro*. These findings were corroborated and validated *in vivo*: NOX-A12 induced MM cell mobilization from the BM to the peripheral blood (PB) as shown *ex vivo*, by reduced percentage of MM cells in the BM and increased number of MM cells within the PB of mice treated with NOX-A12 vs. control (BM: 57% vs. 45%; PB: 2.7% vs. 15%). We next showed that NOX-A12-dependent de-adhesion of MM cells from BMSCs lead to enhanced MM cell sensitivity to bortezomib, as shown *in vitro*, where a synergistic effect between NOX-A12 (50-100nM) and bortezomib (2.5-5nM) was observed (C.I.: 0.570.76). These findings were validated *in vivo*: tumor burden detected by BLI was similar between NOX-A12- and control mice whereas bortezomib-treated mice showed significant reduction in tumor progression compared to the control (P<.05); importantly significant reduction of tumor burden in those mice treated with sequential administration of NOX-A12 followed by bortezomib was observed as compared to bortezomib alone treated mice (P <.05). Similarly, NOX-A12+bortezomib combination induced significant inhibition of MM cell homing *in vivo*, as shown by *in vivo* confocal microscopy, as compared to bortezomib used as single agent. **Conclusions.** Our data demonstrate that the SDF-1 inhibiting Spiegelmer NOX-A12 disrupts the interaction of MM cells with the BM milieu both *in vitro* and *in vivo*, thus resulting in enhanced sensitivity to bortezomib.

0807

GENE EXPRESSION OF OSTEOBLAST REGULATORS IN WHOLE BONE MARROW SAMPLES FROM MULTIPLE MYELOMA PATIENTS IN ASSOCIATION WITH OSTEOLYTIC BONE DISEASE

I Kristensen[1], J Haaber[1], M Petersen[2], H Ditzel[2], N Abildgaard[1]
[1]Odense University Hospital, Odense C, Denmark
[2]University of Southern Denmark, Odense, Denmark

Background. . The multiple myeloma (MM) plasma cell (PC) is dependent on the BM microenvironment. Most gene expression studies have been performed upon BM aspirates, which differ in cellular composition, or MACS isolated PCs. We used a new strategy with snap-frozen BM biopsies for gene expression of known osteoblast and osteoclast regulating genes to examine what is "actually going on in the BM of MM patients". **Aims**. Osteolytic bone disease (OBD) in MM is caused by a combination of inhibition of osteoblasts and hyperactivation of osteoclasts. We studied the expression of several genes related to the regulation of osteoblasts: Osteoblast (OB)-inhibitory factors in the HGF pathway: **HGF**, its receptor **cMET**, the co-receptor **Syndecan-1**, the partial cMET-

antagonist **Decorin** and **HGFActivator**, which are known to stimulate MM PC growth and inhibit OB. Also inhibitors of the OB-stimulating Wnt-pathway: **DKK1**, **SFRP-2**, **SFRP-3**, **Sclerostin** and **Wif-1** were measured, and the OB transcription factors **RunX2**, regulating early osteogenic differentiation, and **Osterix**, regulating OB maturation. **Methods.** During the diagnostic procedure we obtained an extra BM core biopsy which was snap-frozen. Biopsies were cut, homogenized and RNA was purified using the MagNa Pure Robot (Roche). cDNA was loaded for QPCR on 384-wells micro-fluidic cards (Applied Biosystems). Using 3 internal reference genes (ABL, GAPDH and GUS) the relative quantitative gene expression was calculated. OBD was evaluated using standard radiographs. All patients were untreated and did not receive bone-remodeling medicine. We examined 10 HV, 41 MGUS and 71 untreated MM patients, which according to radiographic findings were divided into NO/LOW and advanced OBD, i.e. OBD in ≥2 regions. **Results**. Gene expression of HGF, SDC1, DKK1, cMET and SFRP3 were significantly ($p<0.05$) associated with OBD with increasing gene-expression with increasing OBD, while Osterix were significantly associated with decreasing gene-expression with increasing OBD. DCN, SFRP2, SOST, Wif1, and RunX2 were not associated to OBD. HGFActivator was not expressed in any of our samples. When comparing only HV, MGUS and MM independent of OBD Sclerostin showed a tendency to be overexpressed in MM vs MGUs and HV ($p=0.08$). **Conclusions.** In our gene expression study reflecting the *in vivo* situation in MM, BM OB-regulators were significantly associated to OBD and/or disease status. The use of whole snap-frozen BM biopsies is a new method to evaluate gene expression in MM that makes it possible to investigate patients independent of degree of MM PC infiltration. Validation of some of the genes at protein levels will also be presented.

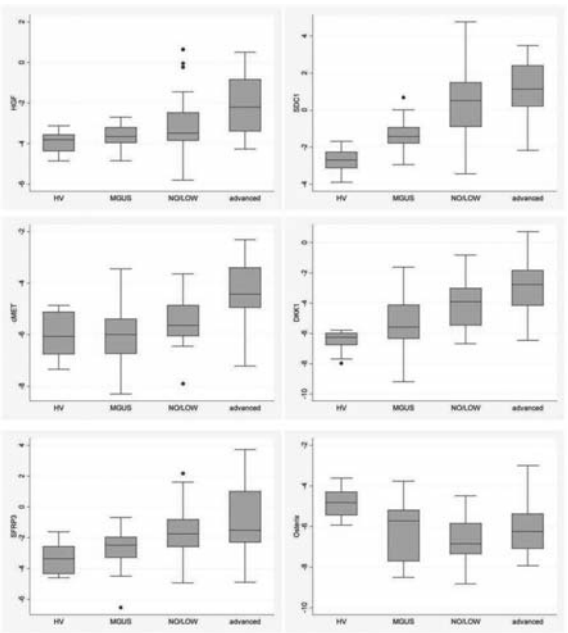

Figure 1. Delta Ct of significant genes.

0808

ASSOCIATION OF BASELINE CEREBLON (CRBN) EXPRESSION WITH CLINICAL RESPONSE, PROGNOSTIC PARAMETERS, AND β-CATENIN IN PATIENTS WITH MM TREATED WITH LENALIDOMIDE AND DEXAMETHASONE

D Heintel[1], A Rocci[2], S Caltagirone[2], A Bolomsky[3], M Schreder[3], N Zojer[3], U Jäger[4], A Palumbo[2], H Ludwig[3]

[1]Wilhelminenspital, Vienna, Austria

[2]Divisione di Ematologia dell'Università di Torino, Torino, Italy

[3]Wilhelminenhospital/Department of Medicine I/Center for Oncology and Hematology, Vienna, Austria

[4]Medical University Vienna / Center for Hematology and Haemostaseology, Vienna, Austria

Background. Cereblon (CRBN) recently has been identified as a target for IMiD therapy in multiple myeloma (MM) and downregulation has been reported at the time point of resistance to lenalidomide (Zhu et al, Blood 2011). Accumulation of ß-catenin during treatment with lenalidomide might be another cause for drug resistance (Bjorklund et al, 2010; Chang et al, 2011). **Aims.** (1) To correlate baseline CRBN expression levels with clinical response in an enlarged patient cohort from 2 different centers, (2) to analyze the association of CRBN with clinical and prognostic parameters, and (3) to evaluate the association of CRBN with ß-catenin.

Table 1. Response quality and CRBN expression in 56 patients treated with lenalidomide an dexamethasone.

Quality of response	*N*	*Median CRBN expression*	*Range*
CR	7	3.78	0.80-9.90
nCR	2	4.82	3.74-5.89
VGPR	6	3.65	0.60-28.74
PR	25	2.09	0-6.70
MR	3	6.74	3.65-462.08
SD	10	0.78	0-2.37
PD	3	0.90	0.30-1.087

Figure 1A. Clinical response according to CRBN expression in patients treated with lenalidomide and dexamethasone (N=56).

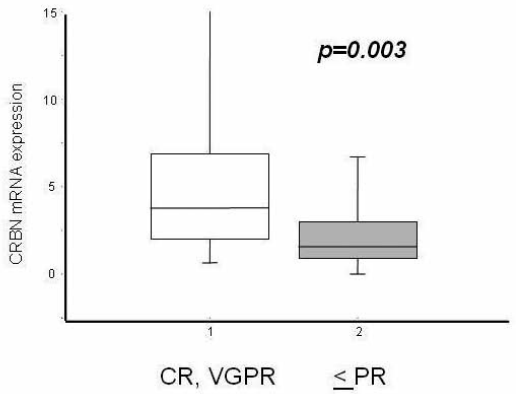

Figure 1B. Clinical response according to CRBN expression in patients treated with lenalidomide and dexamethasone (N=56).

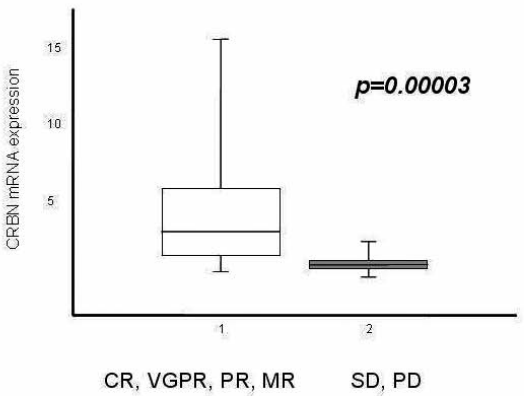

Methods. We measured CRBN and ß-catenin expression by real time PCR in 56 bone marrow (BM) samples of well characterized MM patients uniformly treated with lenalidomide and dexamethasone (len/dex). The median age was 62 years; 20 patients had ISS-stage I, 22 stage II, and 24 stage III. Twenty-seven patients from Vienna (learning series) and 29 from Torino (validation series) were included. **Results.** Len/dex treatment resulted in CR in 7 (12%), nCR in 2 (4%), VGPR in 6 (11%), PR in 25 (45%), MR in 3 (5%), SD in 10 (18%), and PD in 3 (5%) patients. Median CRBN expression was 3.78 in patients with CR, 4.82 in patients with nCR, 3.65 in patients with VGPR, 2.08 in patients with PR, 6.74 in patients with MR, 0.78 in patients with SD, and 0.90 in patients with PD (**Table 1**) compared to normal BM (=1; N=8). Of note, only patients with SD or PD had a median CRBN expression lower than normal BM. CRBN expression correlated with the quality of response: ≥VGPR vs. PR-PD ($r=0.36$; $p=0.003$); ≥MR vs. SD, PD ($r=0.51$; $p=0.00003$) **(Figure 1)**. Among established prognostic parameters including ISS stage, beta-2-microglobulin, albumin, hemoglobin, and FISH defined cytogenetic aberrations, only beta-2-microglobulin correlat-

ed highly significant with CRBN (r=0.52; p=0.00004). A trend for lower CRBN expression in patients with a normal karyotype (N=11) was found (r=-0.28; p=0.04). Among all parameters, only the presence of del(13) (N=14), and t(4;14) abnormalities (N=9) were associated with an inferior response (p=0.04; p=0.01 respectively).The analysis of a possible correlation between CRBN and ß-catenin expression revealed a significant correlation between both genes (r=0.7; p=0.0000001). In 3 available patients, ß-catenin could be measured before start of lenalidomide therapy and after continuous exposure. ß-catenin was found to be upregulated, unchanged, and downregulated in each one of the 3 patients. **Conclusions.** Our data show a significant association between baseline CRBN expression and myeloma response in MM patients treated with len/dex in an enlarged patient cohort confirming previous data and the role of CRBN as an essential requirement for IMiD therapy. CRBN was found to significantly correlate with beta-2-microglobulin and was identified (among the parameters studied) as the strongest predictor for response. In contrary to our expectations, a close correlation between baseline CRBN and baseline beta-catenin was noted. Exposure to len/dex resulted in increased ß-catenin expression in only 1/3 patients. Thus, baseline elevated ß-catenin levels are unlikely accountable for lenalidomide resistance.

0809

CIRCULATING ANGIOGENIC CYTOKINES IN PATIENTS WITH SMOLDERING MYELOMA; IMPLICATIONS INTO DISEASE BIOLOGY

M Gkotzamanidou[1], E Terpos[1], A Papatheodorou[2], E Eleutherakis-Papaiakovou[1], M Dimopoulos[1], E Kastritis[1]
[1]National & Kapodistrian University of Athens-School of Medicine, Athens, Greece
[2]251 General Air Force Hospital, Department of Medical Research, Athens, Greece

Background. Angiogenesis is a critical step in the evolution of carcinogenesis in solid tumors and hematologic malignancies and is considered to be an early event in tumorigenesis. Multiple myeloma (MM) is a hematologic malignancy in which a preceding monoclonal gammopathy (MGUS) is considered a precursor. Asymptomatic/smoldering MM (SMM) is associated with a substantial risk of progression to MM and according to current recommendations these patients should be followed without therapy. **Aims.** In order to study the role and evolution of circulating angiogenesis related cytokines, we studied their levels in patients with MGUS, asymptomatic MM and symptomatic MM, before the initiation of first line therapy and their possible role as markers of early evolution. **Methods.** We measured serum levels of vascular endothelial growth factor (VEGF), angiogenin, angiopoietin (angp)-1 and -2, using standard ELISA methodology (R&D Systems, Minneapolis, MN, USA). The definition of MGUS, SMM and symptomatic MM was based on the IMWG criteria. All above cytokines were measured in 21 individuals with MGUS, in 174 newly diagnosed, untreated MM patients (31 with SMM) and in 44 age- and gender-matched healthy controls.We focused our analysis on patients with SMM. The median age was 63.5 years (range 40-83 years) and 55% were males. The median bone marrow infiltration in trephine biopsy was 20% (range: 12%-75%). Sixty-one per cent had IgG, 29% had IgA isotype while 3% had light chain only myeloma and 6% had biclonal myeloma. **Results.** The median (range) serum levels for VEGF were 406.5 pg/ml (186.3-797.6 pg/ml), for angp-1 were 31064 pg/ml (18220-50856 pg/ml), for angp-2 were 1434 pg/ml (486.1-4004.5 pg/ml), for angp-1 to angp-2 ratio were 20.8 (6.5-78.1), for angiogenin were 262732.6 pg/ml (138670-1003040 pg/ml) and for bFGF were 12.082 pg/ml (non-detected to 123.37 pg/ml). Patients with extensive bone marrow infiltration (60%) had significantly higher levels of ang-2 (p=0.017) and significantly lower angp-1/angp-2 ratio (p=0.004) compared to all others. Compared to healthy controls, patients with SMM had higher levels of angp-1 (p=0.05) and angp-2 (p=0.03) but their respective ratio was not significantly different (p=0.272). Serum levels of VEGF were significantly higher in SMM patients than in controls (mean 429 pg/ml *vs*. 196 pg/ml, p<0.001). Similarly serum levels of angiogenin were significantly higher in SMM (mean 304028 pg/ml *vs.* 190245 pg/ml, p<0.001). When patients with SMM compared to MGUS patients, there were no significant differences for any of the studied angiogenesis related cytokines. Compared to patients with symptomatic MM, patients with SMM had higher levels of angp-1 (p<0.001) and lower level of angp-2 (p<0.001) resulting in a significantly lower angp-1/angp-2 ratio, indicating a switch to increased vessel-formation activity, while the levels of VEGF were similar. **Conclusions.** The above results indicate that early in the myelomagenesis there is an angiogenic switch which is manifested by an increase in the levels of angiogenic cytokines that promote neovasculogenesis (such as VEGF, angp-2 and angiogenin) and a gradual suppression of cytokines that balance their effects (such as angp-1).

LACK OF CORRELATION BETWEEN MCL-1 EXPRESSION AND SENSITIVITY TO ABT-737 DURING DISEASE PROGRESSION OF PLASMA CELL DISORDERS

R Licchetta[1], M Ricciardi[1], F Libotte[1], E Calabrese[1], S Santinelli[1], P Bergamo[2], A Levi[1], M Milella[2], R Foà[1], A Tafuri[1], MT Petrucci[1]
[1]„Sapienza„ University of Rome, Rome, Italy
[2]Medical Oncology A, Regina Elena National Cancer Institute, Rome, Italy

Background. Monoclonal plasma cells disorders (PCD) are clinically heterogeneous, including asymptomatic MGUS, smoldering multiple myeloma (SMM) and its progression to an overt disease represented by MM and plasma cell leukemia (PCL). Several molecular characteristics have been described in PCD, including the aberrant expression of the Bcl-2 family proteins, which prompt innovative therapeutic approaches based on the Bcl-2 targeted inhibition. However, neither potential differences in the expression of these protein members of the Bcl-2 family, nor differences in the activity of Bcl-2 inhibitors, have been associated with the clinical different status (SMM, MM and PCL), weakening the rationale of this novel therapeutic approach. **Aims**. We therefore examined the constitutive expression of the Bcl-2 family proteins (Bcl-2, Bcl-xL and Mcl-1) and the effects of the Bcl-2/Bcl-xL inhibitor, ABT-737 (kindly provided by Abbott Laboratories), on purified primary CD138+ cells from 11 SMM, 20 symptomatic MM (8 at diagnosis and 12 at relapse) and 4 PCL samples.METHODS: The cytotoxicity of ABT-737 on MM cells was established using the MTT assay. The drug concentration inducing 50% cell killing (IC-50) was calculated from the dose-response curve. Cell cycle inhibition and induction of apoptosis were analyzed by flow cytometry using the Acridine-Orange (AO) technique and by Annexin V binding assay. Cellular protein levels were evaluated by western blot analysis. **Results**. Our data indicate that the constitutive protein expression of Mcl-1 is significantly higher (p=0.059) in newly MM samples compared to SMM (mean ratio Mcl-1/GAPDH: 1.70±0.51 vs 0.95±0.27). Surprisingly MCL-1 expression decreases in the more aggressive PCD disorders (1.1±0.21 and 1.21±0.83 in relapsed MM and PCL, respectively). Bcl-2 and Bcl-xL did not differ between samples from these different groups of patients. A markedly ABT-737-induced pro-apoptotic activity was observed on purified CD138+ cells from primary samples. This effect was significantly (p=0.02) higher on CD138+ cells from SMM and on newly diagnosed MM compared to relapsed MM and PLC samples, which resulted progressively less sensitive to ABT-737. In particular, the pro-apoptotic activity of ABT-737 gradually decreased from SMM, newly diagnosed MM, relapsed MM and PCL, with a net apoptosis (sub-G0/1 peak) at 24 hours in the presence of 1000 nM ABT-737 of 55.9±15.2%, 49.3±21.3%, 37.6±10.6% and 33.3±17.9%, respectively. **Conclusions**. In summary, these data show that despite a Mcl-1 increase from SMM to MM, the sensitivity to ABT-737 is unchanged, supporting the recently reported hypothesis that the interaction between Mcl-1 and other pro-apoptotic members, such as Bim, is the major player in the response of MM cells to ABT-737. Moreover, the highest levels of sensitivity of SMM to ABT-737 associated with the lowest levels of Mcl-1 expression, prompt new investigational approaches for the management of patients with SMM

0811

TARGETING NAD+ SALVAGE PATHWAY INDUCES AUTOPHAGY IN MULTIPLE MYELOMA CELLS VIA MTORC1 AND EXTRACELLULAR SIGNAL-REGULATED KINASE (ERK1/2) INHIBITION

M Cea[1], A Cagnetta[2], M Fulciniti[2], YT Tai[2], D Chauhan[2], T Hideshima[2], R Roccaro[1], A Nencioni[3], M Gobbi[4], P Patrone[3], N Munshi[2], K Anderson[2]

[3]Universita degli studi di Genova/Department of Internal Medicine, Genoa, Italy
[4]Universita degli studi di genova/Department of Hematology and Oncology, Genoa, Italy

Background. Intracellular nicotinamide adenine nucleotide (NAD^+) is a coenzyme crucially involved in the regulation of several cellular processes. In mammals, NAD^+ stores are continuously replenished by a salvage pathway from Nicotinamide through the rate-limiting enzyme Nicotinamide phosphoribosyltransferase (Nampt). Indeed, tumor cells exhibit aberrant metabolic activity characterized by high levels of aerobic glycolysis and increased turnover of NAD^+ to support their rapid proliferation. In such scenario, promising results obtained in preclinical cancer models with Nampt inhibitors (such as FK866) suggest that Nampt activity represents an innovative therapeutic target for anticancer agents. **Methods.** a panel of 18 different MM cell lines, both sensitive and resistant to conventional and novel anti-myeloma drugs, and BM samples

from MM patients were used in the study. The antitumor effect of FK866 was investigated by Annexin-V/propidium iodide staining, thymidine incorporation, Western-blotting, lentivirus-mediated shRNAs and gene expression profiling analysis. Intracellular NAD^+ content was measured using a biochemical assay. Identification of autophagy was validated by 4 independent approaches: electron microscopy, proteolytic cleavage of endogenous LC3-I to LC3-II by Immunoblotting, formation of LC3 puncta pattern in GFP-LC3-transfected cells, as well as by gene expression profiling. Angiogenesis and osteoclastogenesis were measured in vitro using Matrigel capillary-like tube structure formation assay and osteoclast culture, respectively. In vivo study was performed using CB17-SCID mice xenografted subcutaneously with MM cells. **Results**. the chemical Nampt inhibitior FK866 triggered cytotoxicity in a panel of 18 MM cell lines and patient MM cells. Their viability was uniformly inhibited, with IC_{50} values at 96 hours ranging from 3-30nM. Additionally, Nampt inhibition killed, in a dose-dependent fashion, MM cells resistant to conventional and novel anti-MM therapies and overcome the protective effects of cytokines (IL-6, IGF-1), bone marrow stromal cells and primary osteoclasts. In contrast, FK866 treatment of PBMCs from 5 healthy volunteers did not affect cell viability. Nampt knockdown by RNAi confirmed its pivotal role in maintenance of both MM cell viability and intracellular NAD^+ stores. Interestingly, cytotoxicity of FK866 triggered autophagy but not apoptosis. A transcriptional-dependent (TFEB) and -independent (PI3K/mTORC1) activation of autophagy mediated FK866 MM cytotoxicity. Finally, FK866 synergized with conventional and novel anti-MM therapies and demonstrated significant anti-MM activity in a xenograft-murine MM model, associated with down regulation of ERK1/2 phosphorylation and proteolitic cleavage of LC3 in tumor cells. **Conclusions.** In conclusion, we identify for the first time a link between intracellular NAD^+ metabolism and autophagy in MM cells, providing the framework developing new targeted therapies in MM.

0812

DEPTOR EXPRESSION CHARACTERIZES GENETIC SUBGROUPS AND ASSOCIATES WITH MTOR SPECIFIC MICRORNAS IN MULTIPLE MYELOMA

C Langer[1], J Blöhdorn[1], M Kull[1], P Liebisch[2], S Knop[3], H Einsele[3], H Döhner[1], F Kuchenbauer[1]
[1]Universitiy of Ulm, Ulm, Germany
[2]Onkologische Praxis Moers, Moers, Germany
[3]University Hospital Würzburg, Würzburg, Germany

Background. Multiple myeloma (MM) is characterized by frequent and complex genomic abnormalities. In the majority of cases the PI3K/Akt/mTOR pathway is activated promoting growth, progression and resistance to therapy. This activation can be sustained by external factors, namely growth factors including insulin-like growth factor-1 (IGF-1) and Interleukin-6 (IL6). Recently, an mTOR interacting protein named *DEPTOR* was found to be highly expressed exclusively in MM (Peterson et al. *Cell* 2009). Importantly, knockdown of *DEPTOR* results in prevention of MM cell growth and apoptosis making it an attractive potential therapeutical target. **Aims.** Therefore, we aimed to determine if *DEPTOR* expression associates with clinically relevant subgroups. In addition, to investigate additional regulatory layers we determined key microRNAs (miRNAs) downstream of *DEPTOR* expression. **Methods.** *DEPTOR* expression was measured by quantitative real-time RT-PCR (TaqMan) using CD138 purified plasma cells from 175 patients with MM. *DEPTOR* copy numbers were measured and normalized to GUSB (internal control) copy numbers. In 38 patients miRNA expression levels were analyzed using Agilent mirRNA-Chips to measure miRNAs associated with *DEPTOR* expression. Additionally; all patients were characterized by a comprehensive set of FISH probes for the presence of recurring cytogenetic abnormalities. **Results.** *DEPTOR* expression was highly variable in the investigated MM samples (median: 0.33; range: 0.003 - 12.50). *DEPTOR* expression was significantly higher in patients presenting with translocations involving the immunoglobulin heavy-chain locus compared to patients with a hyperdiploid karyotype (p=0.0016). In particular, high *DEPTOR* expression was associated with the presence of a translocation t(14;16)(p<0.0001) and a deletion 13q14 (p=0.04), whereas low *DEPTOR* expression was associated with the presence of a gain at chromosomal band 9q34 (p=0.0006).Recently, activation of the mTOR pathway has been shown to be under the control of miRNAs, regulating tumor growth and differentiation. We detected twelve differentially expressed miRNAs (p<0.05), 8 miRNAs positively and 4 miRNAs negatively correlated with high *DEPTOR* expression. Of particular interest, miRNAs targeting the mTOR pathway (miR-99a, miR-193b, miR-365) or regulating IL6-Expression (miR-365) were found to be upregulated in high *DEPTOR* expressing patients, indicating a regulatory loop between mTOR activation and *DEPTOR* expression.**Summary.** High *DEPTOR* expression is associated with prognostic relevant genetic aberrations and specific miRNAs in MM, further dissecting the impact of *DEPTOR* expression on mTOR signaling.

NATURAL KILLER CELL ACTIVATION, CYTOKINE PRODUCTION, AND CYTOTOXICITY IN HUMAN PBMC / MYELOMA CELL CO-CULTURES EXPOSED TO ELOTUZUMAB ALONE OR IN COMBINATION WITH LENALIDOMIDE

A Rice, B Balasa, R Yun, N Belmar, G Starling
Abbott Biotherapeutics Corp., Redwood City, United States of America

Background. Elotuzumab (Elo) is a monoclonal IgG1 antibody targeting CS1, a cell surface glycoprotein highly expressed on >95% of myeloma cells. The primary mechanism of action of Elo is NK cell-mediated antibody-dependent cellular cytotoxicity (ADCC) of $CS1^+$ myeloma cells. Lenalidomide (Len) is an immunomodulatory agent reported to increase NK cell activity and may therefore provide additional therapeutic benefit in combination with Elo. The combination of Elo + Len synergistically enhanced anti-tumor activity in preclinical myeloma xenograft models. **Aims**. To investigate the mechanism of enhancing NK cell activation and myeloma cell killing with Elo in combination with Len. **Methods.** Human PBMC/OPM-2 myeloma cell co-cultures were treated for 24-72h with Elo (10-20 µg/mL), Len (1 µM), or Elo + Len. Activation markers and adhesion receptors were evaluated by flow cytometry. Cytokines were measured by Luminex and ELISpot assays. Cytotoxicity was assessed by absolute cell counting.

Treatment	IFN-γ (pg/mL) ave n=8	ICAM-1 on OPM-2 (MFI) n=4	CD25 on NK cells (MFI) n=8	IL-2 (pg/mL) (Luminex)		# IL-2 positive colonies (ELISpot) n=9	OPM-2 killing (%) n=4
				No blocking (control mAb) ave n=6	Anti-CD25 blocking mAb ave n=6		
*Control	48	427	155	21	-	30	1
**Lenalidomide	94	2040	131	50	-	71	15
Elotuzumab	65	3068	975	7.8	52	80	39
Elotuzumab + Lenalidomide	386	42,259	1546	14	134	191	67

*clgG1 (isotype); **plus clgG1.

Results. IFN-γ secretion increased significantly in Elo + Len treated cultures compared to Elo or Len alone. IFN-γ is known to elevate ICAM-1 expression and ICAM-1 surface expression on OPM-2 target cells increased synergistically with Elo + Len. Elo, Elo + Len, but not Len alone, increased the expression of CD25 (IL-2Rα) on NK cells. Len increased the level of soluble IL-2 but levels were decreased in the presence of Elo. The decrease in soluble IL-2 was likely due to increased consumption by CD25-expressing NK cells as blocking the uptake of IL-2 with anti-CD25 resulted in higher IL-2 levels than with Len alone. ELISpot assays confirmed that Elo + Len significantly increased the number of IL-2-producing cell colonies compared with cultures treated with Elo or Len alone. Elo alone induced NK-dependent myeloma cell killing and killing was significantly higher with the combination of Elo + Len. **Conclusions.** Elo alone activated NK cells and mediated the killing of myeloma cells in PBMC/OPM-2 co-cultures. The combination of Elo + Len synergistically increased IFN-γ secretion, ICAM-1 expression on myeloma cells, CD25 expression on NK cells, IL-2 production and consumption, and enhanced inhibition of myeloma cell growth.

0814

KDE AS AN ALTERNATIVE MOLECULAR TARGET FOR MINIMAL RESIDUAL DISEASE ASSESSMENT BY RQ-PCR IN PATIENTS WITH MULTIPLE MYELOMA

N Puig, M Sarasquete, M Alcoceba, A Balanzategui, M Chillón, E Sebastián, M González-Díaz, J San Miguel, R García-Sanz
University Hospital of Salamanca, Salamanca, Spain

Background. In multiple myeloma (MM) patients, the use of ASCT and novel agents is associated with high rates of complete response and thus, additional methods assessing higher degrees of disease eradication are required. Minimal residual disease (MRD) detection by immunoglobulin heavy-chain (IGH) real-time quantitative PCR (RQ-PCR) and multiparameter flow cytometry (MFC) has proved to be of prognostic value in MM patients, with the former showing higher sensitivity but lower applicability, in part due to the lack of a suitable target free of somatic hypermutation (SHM). *KDE* rearrangements occur in virtually all Ig-lambda B-cell malignancies and in 1/3 of Ig-kappa, are not affected by SHM and, as in ALL, could be used as PCR-targets. **Aims.** 1) To evaluate the incidence, gene segment usage and CDR3 composition of *IGK-KDE*

rearrangements in MM patients. 2) To test KDE as an alternative molecular target for MRD detection in patients with MM. **Methods.** A total of 96 untreated MM patients enrolled in GEM/PETHEMA protocols were included. The identification of the *IGK-KDE* rearrangements was performed according to the BIOMED-2 Concerted Action. IGH RQ-PCR was carried out using a germline reverse primer and a germline Taqman probe in combination with allele-specific oligonucleotides (ASO) as forward primers. Sensitivity and quantitative range were determined following EuroMRD recommendations (*Van der Velden, Leukemia 2007*). **Results.** Monoclonal *KDE* rearrangements were identified in 45% of the cases (29 monoallelic and 14 biallellic). Overall, 88% of cases (38/43) were successfully sequenced, *KDE* being equally frequently rearranged with *VK* and with intron-RSS. *VK* family usage was in line with normal B cells. Most cases (94%) were non-mutated (cut-off=2%). Median numbers of inserted and deleted nucleotides in the junctional region were one and five, respectively. Regarding the RQ-PCR analysis, sensitivity ≤5 x10^{-4} was reached in 44% of the ASO-primers designed to test *KDE* as a PCR target. **Conclusions.** *KDE* rearrangements can be found in approximately 50% of cases in MM, they can be quite easily sequenced and are essentially free of SHM. *KDE* rearrangements as alternative PCR targets for MRD assessment in MM improve the applicability of these studies in 9% of cases overall and in 20% of lambda cases. Due to the singular characteristics of *KDE* in MM frequent background. amplification could be observed, thus reducing the sensitivity of this marker as compared to ALL.noepuig@gmail.com

0815

QUANTITATIVE DETECTION OF FOUR CANCER-TESTIS ANTIGEN GENES IN MULTIPLE MYELOMA HAS CLINICAL VALUE

G Ruan, Y Zhang, L Bao, J Lu, KY Liu, JL Li, YZ Qin, H Chen, LD Li, Y Kong, HX Shi, YY Lai, YR Liu, B Jiang, SS Chen, XJ Huang
Peking University People's Hospital and Institute of Hematology, Beijing, China

Background. Cancer-testis (CT) antigen gene might promote the progression of multiple myeloma, and are considered as potential diagnostic and prognostic markers in myeloma. However, the expression levels and clinical implications of these genes are not fully understood in multiple myeloma. **Aims.** This study aimed to measure the expression levels of four CT antigen genes in Chinese MM patients and explore their clinical implications.

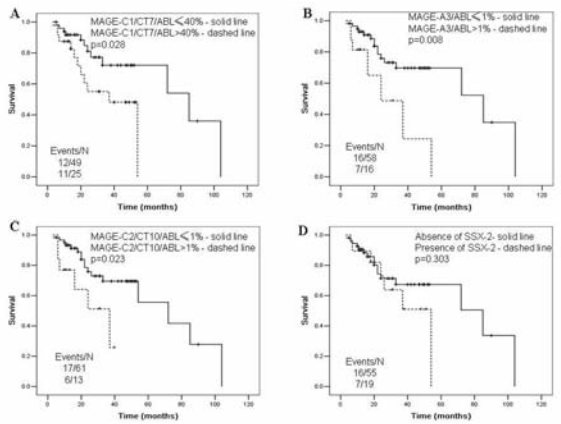

Figure 1. Overall survival (OS) analysis according to the qPCR expression levels of CT antigens: (A) MAGE-C1/CT7, (B) MAGE-A3, (C) MAGE-C2/CT10, (D) SSX-2

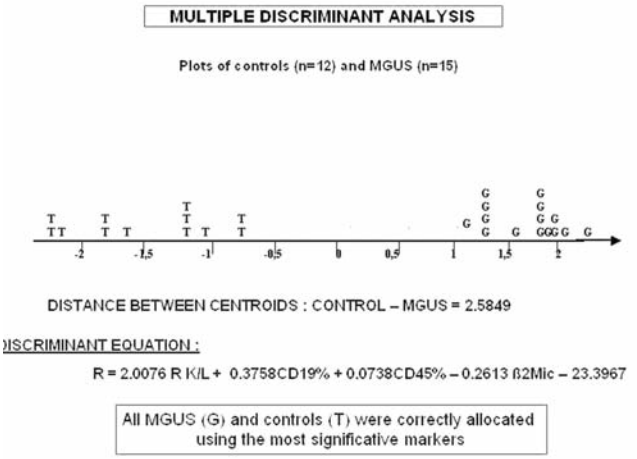
Methods. *Real-time quantitative polymerase chain reaction (qPCR) was used to quantify MAGE-C1/CT7, MAGE-A3, MAGE-C2/CT10 and SSX-2 mRNA expression in 238 bone marrow samples from 138 multiple myeloma patients.* The correlation between CT antigen expression and various clinical characteristics, and the clinical implications for molecular diagnosis, prognostic evaluation and treatment efficacy monitoring were determined. **Results.** *The qPCR method could sensitively quantify CT antigen expression. In the newly diagnosed, the positive expression rates were 90.0% for MAGE-C1/CT7, 84.3% for MAGE-A3, 84.3% for MAGE-C2/CT10 and 32.9% for SSX-2. MAGE-C1/CT7, MAGE-A3 and MAGE-C2/CT10 were frequently and persistently co-expressed in multiple myeloma patients. The expression levels and the number of co-expressed CT antigens correlated significantly with several clinical indicators, including the percentage of plasma cells infiltrating bone marrow as well as the clinical course of multiple myeloma and reduced overall survival.* **Conclusions.** *MAGE-C1/CT7, MAGE-A3 and MAGE-C2/CT10 expression leveles may provide potentially effective clinical indicators for auxiliary diagnosis, prognostic evaluation and monitoring of treatment efficacy in multiple myeloma.*

0816

QUANTITATIVE PHENOTYPING AND DISCRIMINANT ANALYSIS IMPROVE IDENTIFICATION IN MGUS DISORDERS

G Jung, B Nespola, S Sahbai, C Baralon, N Hirchy, A Debliquis, B Drenou
Laboratoire d'Hématologie Hôpital E.Muller, Mulhouse, France

Background. Monoclonal gammopathy of undetermined significance (MGUS) is a common plasma cell dyscrasia with controversial phenotype definition. **Aims**. The purpose of this study was to identify antigens that could be used to differentiate MGUS, myeloma and normal plasma cells. **Methods.** Multivariate analysis classification of these three populations is investigated in 115 patients by an extended panel of surface markers. Diagnosis was based on clinical features, bone marrow cytology and immunophenotyping. Results were obtained on directly labeled CD38 and CD138 plasma cells by six-color flow cytometry. We examined percentages and antigen fluorescence intensities for CD27, CD19, CD45, CD20, CD117, CD200, FGF-R3, CD56, CD191, β7 Integrin, kappa/lambda intracytoplasmic chains and serum β2-microglobulin level. Efficiency of this panel was assessed by Chi-Square test. Principal components analysis and discrimant multivariate approach were used with the selected best markers for predictive classification.



Results. For CD19%, CD45%, CD117%, kappa/lambda chains and β2-microglobulin level, χ^2 values indicated very high probability of correct classification for MGUS and normal plasma cells (varing from 3.882 to 2.022 ; $10^{-4} \leq p \leq 10^{-2}$). MGUS and myeloma χ^2 values were more significant for CD19%, CD45%, CD27%, kappa/lambda chains and β2-microglobulin (varing from 3,882 to 3,019 ; $p \leq 10^{-4}$). Percentages of CD20, CD117, β7 Integrin and fluorescence intensity of CD27 and CD56 gave low χ^2 values (varing from 2,104 to 2,000 ; $10^{-4} \leq p \leq 10^{-3}$). It should be noted that the effectiveness of percentages was much more significant than fluorescence intensities for all markers. Principal component analysis of CD19%, CD45% and kappa/lambda chain ratio showed separated points in the plot representing patients with MGUS and normal plasma cells. This representation confirmed the high predictive potential of our panel. In order to find the optimal combination of the selected best markers, a stepwise probit discrimination was performed. 100% of MGUS and normal plasma cells were correctly classified with kappa/lambda chains, CD45, CD19 and β2-microglobulin. It was 88.89% with three parameters (% of kappa/lambda chains, CD45 and CD19) and only 77.78% with two parameters (% of kappa/lambda chains and CD19). If myeloma were added, efficiency decreased to 50.0% correctly identified patients.5. **Conclusions.** Therefore, it is reasoned that phenotypic analysis of plasma cells with kappa/lambda chains, CD45, CD19 and assessment of serum β2-microglobulin could detect malignant plasma cells in MGUS with moderate plasmacytosis. Finally, our study may prove the utility of multivariate analysis, which correctly differentiates normal plasma cells and MGUS.

BENDAMUSTINE-INDUCED MYELOMA CELL APOPTOSIS DEPENDS ON REACTIVE OXYGEN SPECIES AND IS PARTLY P53 DEPENDENT

E Lemieux-Blanchard[1], S Surget[2], S Maiga[2], P Moreau[3], S Le Gouill[3], M Amiot[2], C Pellat-Deceunynck[2]
[1]INSERM UMR892, Univ Nantes, CNRS, UMR 6299, Nantes, France
[2]Inserm, UMR892, Univ Nantes,CNRS, UMR 6299, Nantes, France
[3]CHU de Nantes, Nantes, France

Background. Multiple Myeloma (MM) patients carrying del(17p13), which overlap the TP53 locus, are considered to have a high-risk disease. Treatment with alkylators does not overcome this poor prognostic factor. Bendamustine, an alkylator/purine analogue hybrid used as chemotherapeutic agent, has demonstrated clinical efficacy in lymphoproliferative disorders and MM. Although bendamustine has been used for more than 30 years, its precise mechanism of action is still poorly understood and no prognostic markers has been reported for patients. **Aims.** The aims of this study were 1) to define the efficiency of bendamustine to induce cell death of myeloma cells, 2) to define whether p53 impacts this efficiency and 3) to characterize the pathways controlling cell death. **Methods.** The cytotoxicity of bendamustine was assessed in 22 MM cell lines (8 $TP53^{WT}$ and 14 $TP53^{Abnormal}$) by measuring cell death using flow cytometry. Molecular cell death pathways were analyzed by western blot. Stable p53 silenced cell lines were used to directly address the involvement of p53. **Results**. Bendamustine induced cell death in all cell lines although with different LD50 values ranging from less than 25 µg/ml up to 200 µg/ml. $TP53^{wt}$ cell lines were significantly more sensitive to bendamustine than $TP53^{Abn}$ cell lines (p=0.01). Moreover, cell death was significantly decreased in shp53 NCI-H929 compared with shCont NCI-H929 (p=0.019). In $TP53^{wt}$ cells, but not in $TP53^{Abn}$ cells, bendamustine increased expression of 3 p53 target genes, p21, Puma and Bax in correlation with cell death. In contrast, bendamustine increased Noxa expression in both $TP53^{wt}$ and $TP53^{Abn}$ cells. Apoptosis was associated with cleavages of caspases 3 and 9 but cell death was only partly prevented by the pan-caspase inhibitor z-VAD-fmk, suggesting the involvement of another mechanism. Indeed, cell death was strongly inhibited by a reactive oxygen species (ROS) scavenger, N-Acetyl-Cysteine, pointing out that production of ROS was essential. **Conclusions**. Our results show that bendamustine induced myeloma cell death through both p53 dependent and p53 independent mechanisms, in which ROS production plays an important role. Further investigations are required to define this exact process.

0818

DETERMINING OF MOLECULAR SIGNATURE FOR CENTROSOME ABNORMALITIES IN MULTIPLE MYELOMA

F Kryukov[1], P Nemec[1], E Dementyeva[1], L Kubiczkova[1], I Ihnatova[1], E Budinska[1], J Jarkovsky[1], S Sevcikova[1], P Kuglik[2], R Hajek[1]
[1]Masaryk University, Faculty of Medicine, Brno, Czech Republic
[2]Masaryk University, Faculty of Science, Brno, Czech Republic

Background. In multiple myeloma (MM), biologic complexity originates from complex oncogenic processes involving somatic acquisition of myriad mutations coupled with genetic variability within the host. This pathogenically determined molecular heterogeneity predetermines clinical heterogeneity. **Aims.** In this study, we performed gene expression profiling (GEP) focusing on centrosome related genes to determine molecular signature characteristic for centrosome abnormalities in MM patients. **Methods.** In total, 73 patients were evaluated for current study. The patient baseline characteristics were as follows: males/females 37/36, median age of 69.5 years (range, 46-85 years). Newly diagnosed (38/73) and relapsed (35/73) patients were included in this study; most of them had advanced stage of MM (DS II/III n =52; ISS II/III n=68). CD138+ cells were separated by MACS. All patients were evaluated by GEP using Affymetrix GeneChip Human Gene ST 1.0 array. In total, 111 genes were selected for clustering. All of these genes are involved in regulation of centrosome duplication and have known function in oncogenesis. Interphase FISH with cytoplasmic immunoglobulin light chain staining and qRT-PCR were performed on the same PC samples. **Results**. We have found one distinct pattern of 35 genes belonging to following ontologies: cell-cycle genes (*CDK1*, *CDK2*, *E2F*, *Plk*, *AURKA*, *NEK2*); kinetochore and microtubule attachment genes (*AURKB*, *BIRC5*, *CENP*); mitotic checkpoint genes (*BUB1, MUD2)*; DNA damage checkpoint genes presented by CA suppressors, integrity and reduplicate regulators (*RAD51, XRCC2, MSH2, CHEK1*) and just one structural gene TUBG1. Based on expression of these genes, patients can be stratified into three groups - 'High-', 'Mediate-' and 'Low-expressed'. The expression levels of genes selected from revealed pattern (*AURKA, AURKB, CCNB1, CCNB2, HMMR, PLK4, TACC3*, *CDK2*) were validated by qRT-PCR. PCR-based results clearly corresponded with GEP-based findings in mentioned above three subgroups of MM patients. We have found significant differences in relative quantification coefficient R of all 8 analyzed genes (*P*<0.05).There were no significant differences between revealed subgroups of MM patients regarding the presence/absence of common for MM cytogenetic aberrations. Patients in "Low expressed' group showed significantly higher level of hemoglobin (P=0.008) and thrombocytes (P=0.018), otherwise patients in "Mediate-"and "High expressed"group had significantly higher b2m (P=0.004), LDH (p=0.019) and plasma cell infiltration in bone marrow (P=0.042). Although statistical significance was not reached as a result of the small numbers of patients (P=0.098), however, in newly diagnosed patients significant difference between subgroups was observed (*P*=0.005). There was worse OS of patients in "High"and "Medium"subgroups than in patients in 'Low' subgroup. **Conclusions**. We defined a gene pattern, which was used as a molecular signature of centrosome abnormalities. Defined associations with integral clinical parameters and OS allow us to suggest the impact of revealed functional gene set in MM genesis. Our findings still need to be confirmed and validated on a larger external cohort of patients. **Funding**. This work was supported by grants: NT11154, NT12130, MSM0021622434 and by project GAP304/10/1395.

EXPRESSION OF MCL1, GSTP1, AND CKS1B GENES IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND MULTIPLE MYELOMA

F Stella[1], D Fantl[2], J Arbelbide[2], N Schutz[2], I Slavutsky[1]
[1]Instituto de Medicina Experimental (IMEX) CONICET-Academia Nacional de Medicina, Buenos Aires, Argentina
[2]Hospital Italiano, Buenos Aires, Argentina

Background. Monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma (MM) comprise heterogeneous disorders with incompletely understood molecular defects and variable clinical features. Molecular studies have identified genes differentially expressed in MM but some of them have been scarcely explored in MGUS patients. **Aims.** The aim of this study was to evaluate mRNA expression of *MCL1, GSTP1* and *CKS1B* genes in patient with MGUS and MM in order to analyze their participation in the progression of disease. **Methods.** Bone marrow samples from 90 patients: 60 with MM (26 males; mean age: 66.4 years; range: 30-86 years; Durie & Salmon stage: I: 21%, II: 17%, III: 62%) and 30 with MGUS (9 males; mean age: 70.6 years; range: 41-84 years) and, mononuclear cells from 11 normal controls, were analyzed. Patients were studied at diagnosis. All individuals gave informed consent and the study was approved by the local Ethics Committee. Real-Time Quantitative PCR was used to quantify gene expression. For statistical analysis, Mann-Whitney test and Kendal coefficient were used. **Results.** Analysis of mRNA expression showed differences among evaluated genes. *MCL1* had overexpression only in MM patients (24.69±11.05) with significant differences with respect to controls (4.13±1.14) (p<0.0001). *GSTP1* and *CKS1B* genes showed abnormal expression in both MM and MGUS patients. Overexpression of *GSTP1* gene was observed in 32% of MM and 33% of MGUS patients. Although MGUS mRNA levels (0.05±0.01) were lower than those of MM patients (0.12±0.05), no significant differences between them were observed. The analysis of *CKS1B* also showed abnormal expression in a similar percentage of MM and MGUS patients (60% and 50%, respectively). Comparison of mRNA values showed higher *CKS1B* expression in MM (0.017±0.006) with respect to MGUS patients (0.004±0.001) (p<0.04) and in both entities compared to controls (0.002±0.0004) (p<0.04). The analysis of clinical characteristics in MM patients showed a positive association between β2microglobuline and *MCL1* mRNA levels (p=0.015). Expression of *CKS1B* was positively correlated with the percentage of bone marrow infiltration (p=0.0012; r^2=0.1942) and M protein levels (p=0.0005; r^2=0.2415). *GSTP1* gene expression did not show association with clinical parameters. **Conclusions.** To our knowledge, this is the first evaluation of *GSTP1* mRNA expression in MGUS patients. Our data showed deregulation of *GSTP1* and *CKS1B* genes in this disorder. Significant differences in *CKS1B* expression between MM and MGUS and a positive association with bone marrow infiltration suggest a role for this gene in the progression from MGUS to MM.

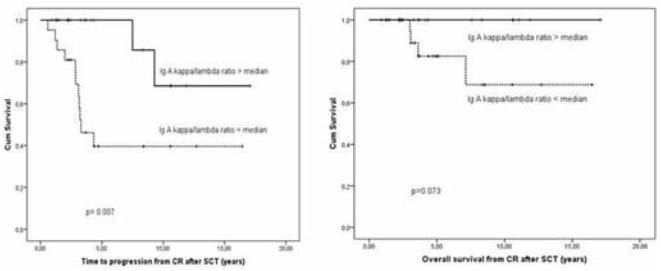
PROGNOSTIC IMPACT OF SERUM IMMUNOGLOBULIN HEAVY/LIGHT CHAINS RATIO IN PATIENTS WITH MULTIPLE MYELOMA IN COMPLETE REMISSION AFTER STEM-CELL TRANSPLANTATION

N Tovar[1], C Fernández de Larrea[2], M Elena[2], MT Cibeira[2], JI Aróstegui[2], L Rosiñol[2], X Filella[2], J Yagüe[2], J Bladé[2]
[1]Hospital Clinic de Barcelona, Barcelona, Spain
[2]Hospital Clinic, Barcelona, Spain

Background. Automatic assays for the measurement of serum free immunoglobulin chains have been available for a number of years and they have been useful for screening, diagnosis, prognosis and follow-up of monoclonal gammopathies. The recent development of antibodies against conjunction epitopes between the light and heavy chains has allowed for the first time to quantitate specific pairs of heavy/light chains (HLC) (IgGκ/IgGλ, IgAκ/IgAλ and IgMκ/IgMλ) in serum, which allows the determination of the quantity of tumoral immunoglobulin. In this context, the opportunity to determine HLC ratios provides a new tool to assess the response to treatment in MM. However, its prognostic contribution has not yet been determined. **Aims.** To establish the possible value of the serum HLC ratios in patients with MM in CR after stem-cell transplantation (SCT). **Methods.** Forty-two patients (19M/23F; median age 55 years) with MM in CR were studied. The patients were classified in two groups according to their previous treatments. The first one included patients who reached CR after melphalan-based autologous stem-cell transplantation (ASCT) (37, 88.1%), and the second one after allogeneic SCT (Allo-SCT) (5, 11.9%). Serum HLC measurement (Hevylite assay ®; kindly provided by Binding Site Ltd) was performed by immunonephelometry, and ratios were determined for each isotype (IgG, IgA, and IgM).



Results. On the overall series, an increased IgAκ/IgAλ ratio was associated with a longer PFS (p=0.007) and with a statistical trend for OS (p=0.073) (Figure 1). On the other hand, an increased IgMκ/IgMλ ratio was related to a longer PFS (p=0.006), with not significant impact on OS. Concerning the original isotype, neither PFS nor OS were modified in relation to the IgGκ/IgGλ ratio in those with an original monoclonal IgG isotype. However, a low IgAκ/IgAλ or a low IgMκ/IgMλ ratio was associated with a shorter PFS (p=0.075 and p=0.003, respectively). In the group of patients with an original monoclonal IgA isotype, a lower IgGκ/IgGλ ratio was also associated with shorter PFS (p=0.039) but no relationship with the IgA or IgM ratio was observed. **Conclusions.** We found that relative higher HLC ratio of the uninvolved immunoglobulin is predictor for a significantly longer PFS and even OS in patients with MM in CR. Since HLC ratios provide a measure of tumour immunoglobulinproduction plus immunoparesis rather than a marker of MRD, this parameter is more likely a surrogate marker of robust immune recovery. In MM, the achievement of a CR, with negative serum and urine IFEs, is the most significant prognostic factor. Furthermore, different CR categories are associated with different prognostic impact. In this context, the opportunity to determine HLC ratios provides a new tool to assess the response to treatment in MM. However, its prognostic contribution has not yet been determined.

PERIOSTIN IS ELEVATED IN THE BONE MARROW MICROENVIRONMENT AND IN THE SERUM OF PATIENTS WITH MULTIPLE MYELOMA; CORRELATIONS WITH ADVANCE DISEASE CHARACTERISTICS

E Terpos, D Christoulas, T Bagratuni, M Gkotzamanidou, E Eleutherakis-Papaiakovou, A Papatheodorou, C Liakou, N Kanellias, E Kastritis, M Dimopoulos
University of Athens School of Medicine, Athens, Greece

Background. Periostin is a disulfide-linked cell adhesion protein that belongs to the fasciclin family and is mainly produced by stromal cells. Periostin is highly expressed in early osteoblastic cells and in the periosteum, where it acts as a regulator of bone remodeling. In very recent reports, periostin seems to stimulate the metastatic growth of cancer cells regulating the interactions between cancer stem cells and their metastatic niche. However, there is no information on the role of periostin in multiple myeloma (MM). **Aims.** The aim of the study was to evaluate the production of periostin by myeloma cells in vitro, and to measure periostin in the bone marrow plasma and the serum of a large number of MM patients in order to explore possible correlations with disease features. **Methods.** We measured periostin in the supernatants of six myeloma cell lines (LR5, MR-20, L363, U261,H929ST and JJN3), in the bone marrow plasma of 41 newly diagnosed patients with MM and in the serum of 198 MM patients (106M/92F, median age 73 years) at different phases of their disease: 33 patients had smoldering myeloma (SMM) at diagnosis, 105 symptomatic MM at diagnosis, 30 patients were at a plateau phase and 30 patients had relapsed MM after previous response to therapy. Circulating periostin was also measured in 23 patients with MGUS and in 30, gender- and age-matched, healthy controls. Evidence of bone involvement in all patients was documented using plain radiographs, while a series of bone markers was also evaluated. **Results.** The mean periostin level in the supernatants of the myeloma cell lines was 18.4 ng/ml (±SD: 6.14 ng/ml), with no differences between the different cell lines. The mean periostin levels of the bone marrow plasma of the 41 patients were 638 ng/ml (±268 ng/ml). The circulating periostin concentrations of symptomatic MM patients at diagnosis (mean±SD: 911±694 ng/ml) were increased compared to controls (537±190 ng/ml; p<0.001), to SMM patients at diagnosis (601±351 ng/ml; p=0.001) and to MGUS patients (633±271 ng/ml; p =0.002). Patients with MM at plateau phase had a borderline reduction of serum periostin concentrations (729±360 ng/ml) compared to symptomatic MM patients at diagnosis (p=0.05) but they continued to have increased levels compared to controls (p=0.013). Patients with relapsed MM had increased circulating periostin (938±847 ng/ml) compared to controls (p=0.016), MGUS (p=0.04) and SMM patients (p=0.04) but no significant difference compared to symptomatic patients at diagnosis. In symptomatic MM patients at diagnosis, serum periostin strongly correlated with beta2-microglobulin, LDH, ISS stage, bone resorption and extensive lytic bone disease. In the 41 patients with measurements in both bone marrow plasma and serum, there was a strong correlation between the two values (r=0.445, p=0.01). **Conclusions.** Our results suggest that there is slight periostin concentrations in the supernatants of myeloma cell lines, but there are high periostin levels in both bone marrow plasma and serum of newly diagnosed, symptomatic myeloma patients. Circulating periostin correlates with advanced disease features and thus it seems that periostin is also implicated in the biology of multiple myeloma.

MONOCLONAL GAMMOPATHY: A GENE EXPRESSION STUDY

H Schiffhauer[1], H Steingrimsdóttir[2], J Guðbrandsson[3], H Ögmundsdóttir[4]
[1]University of Iceland, Reykjavík, Iceland
[2]Department of Clinical Haematology, Landspitali University Hospital, Reykjavík, Iceland
[3]Institute of Life and Environmental Sciences, University of Iceland, Reykjavík, Iceland
[4]Faculty of Medicine, University of Iceland, Rekjavík, Iceland

Background. Eight families in Iceland have been identified with multiple cases of monoclonal gammopathies (MG), including monoclonal gammopathy of undetermined significance (MGUS), multiple myeloma (MM) and Waldenström's macroglobulinemia (WM). It has also been shown that there is a multi-step transformation from MGUS to MM. An *in vitro* poke-weed mitogen (PWM) stimulation assay identified 12 disease-free relatives of patients within four of the eight families as having hyper-responding (HR) B-cells producing immunoglobulin at > 2 SD above controls. **Aims.** We established an *in vitro* model of the germinal centre (GC) reaction and performed gene expression analysis on unstimulated samples and those collected after 14 days in GC culture to investigate if the GC model faithfully mimics *in vivo* GC. We also screened for differences between controls (related and unrelated) and the HR group. **Methods.** B cells were isolated from peripheral blood (PB) samples from each HR (n=10), unrelated control (n=10), and related (n=9). mRNA was extracted immediately from B cells at day 0 and from B cells after 14 days of stimulation in the *in vitro* GC culture and used to synthesize cDNA. Cy-3 labeled, samples were loaded onto oligonucleotide microarrays. Gene expression data were normalized and appropriate ANOVA models were applied to prepared data for analysis between study groups and stimulation days. Maximum likelihood and likelihood ratio tests and Benjamini and Hochberg correction were applied. Analysis methods included unsupervised hierarchical cluster analysis and ontology group testing using bioinformatic software programs recommended by the Gene Ontology database. **Results.** Day 0 and day 14 gene expression results clustered separately on a heatmap. Approximately one-third (14,277) of gene transcripts were significantly different after 14 days in the GC

culture ($p_{adjusted}$ <0.001). The genes grouped into multiple ontology categories as expected. The largest fold change (FC) differences (FC > 2.5) yielded numerous genes and ontology categories, such as cell proliferation, DNA packaging and repair, apoptosis and cell survival, which mimicked those described by a previous study as being specific to the GC compartment *in vivo*. No significant differences were detected between the HR study group and the control groups when adjusted for multiple testing, but data which were unadjusted for multiple testing showed different expression of 44 gene transcripts on day 14 (p_{raw} < 0.001). **Conclusions.**The gene expression results suggest that the culture model faithfully mimics an *in vivo* GC response. The HR group as a whole does not display a significantly different gene expression pattern. Further analysis is in progress.

CHANGES IN PROTEIN PROFILES OF MULTIPLE MYELOMA CELLS IN RESPONSE TO BORTEZOMIB

Y Baran[1], T Turan[2], G Sanli-Mohamed[2]
[1]Izmir Institute of Technology, Izmir, Turkey
[2]Izmir Institute of Technology, Department of Chemistry, Izmir, Turkey

Background. Multiple Myeloma is a malignant B-cell neoplasm that is characterized by the accumulation of malignant plasma cells in the bone marrow. It is the second most common hematological disorder. Bortezomib is the first of a new class of anti-cancer agents known as proteasome inhibitor. Until now, the molecular mechanism of Bortezomib-induced apoptosis on Multiple Myeloma cells was explained but, to the best of our knowledge, there is not any study examining the changes in protein profiles of Bortezomib treated Multiple Myeloma cells in the literature. Protein profiling is a promising discovery tool to determine the protein-protein interactions, signaling pathways, and finding biomarkers for drug discovery. **Aims.** The objective of this study was to determine the changes in protein profiles of U-266 multiple myeloma cells in response to Bortezomib. **Methods.** At the first experiment part, the cytotoxic concentration of Bortezomib at 72 h was determined by XTT cell proliferation assay. Then, apoptosis was evaluated by measuring the changes in caspase-3 enzyme activity and loss of mitochondrial membrane potential (MMP). At the second part, total cellular proteins were isolated from U-266 cells (control group) and Bortezomib exposed U-266 cells and were visualized by running the proteins on Sodium Dodecyl Sulfate-Polyacrylamide Gel Electrophoresis (SDS-PAGE) and Two-Dimensional Polyacrylamide Gel Electrophoresis (2D PAGE) respectively. After that, differentiated proteins (increased and/or decreased or appear and/or disappear) were recovered from gel to be applied for Matrix-Assisted Laser Desorption/Ionization-Time of Flight-Time of Flight (MALDI-TOF-TOF) mass spectrometry for protein identification. **Results.** IC50 value (drug concentration that inhibits cell proliferation 50%) of Bortezomib on U-266 cells was found as 17 nM. Then, apoptosis was evaluated by measuring the changes in caspase-3 enzyme activity and loss of mitochondrial membrane potential (MMP). Treatment of U266 cells for 72 h with 20 nM Bortezomib caused a significant loss of MMP (about 2.14-fold) and also resulted in 1.17-fold increase in caspase-3 activity. In order to elucidate and compare protein profiles of bortezomib treated and untreated groups, two individual gel images were imported into gel analysis software DECODON Delta2D Version 4.3. Using the software, these 2D PAGE gels were superposed and comparative detailed analysis was performed. The analysis demonstrated 37 differentially expressed protein spots, 5 proteins were newly formed, 10 proteins were lost, 12 proteins were up-regulated and 10 proteins were down-regulated in Bortezomib treated group as compared to untreated control group. Some of the identified proteins after mass spectrometric analysis are as follows: Apoptosis Regulatory Protein Siva (newly formed), Caspase recruitment domain-containing protein 14 (lost), Ras-related protein Rab-25 (upregulated), Nuclear factor NF-κB p105 subunit (downregulated). **Conclusions.** We continue to analyse the differentially expressed proteins in response to Bortezomib. As we understand the changes in protein profiles in response to Bortezomib, we can explain the side effects of Bortezomib while we can also suggest potential use of Bortezomib for the treatment of various diseases. Additionally, the data obtained by this study can be helpful for medical schools and drug designers and may also provide new treatments.

INCREASED SERUM LEVELS OF MIP-1 ALPHA CORRELATE WITH BONE DISEASE AND ANGIOGENIC CYTOKINES IN MULTIPLE MYELOMA PATIENTS

G Tsirakis[1], A Boula[2], C Pappa[2], I Papadakis[1], P Samiotakis[1], M Tsigaridaki[1], D Stafylaki[1], K Sfiridaki[2], M Alexandrakis[1]
[1]University Hospital of Heraklion, Heraklion, Greece
[2]Venizelion Hospital, Heraklion, Greece

Background. Multiple myeloma (MM) is a malignancy with abnormal plasma cell growth within the bone marrow. Macrophage Inflammatory Protein-1 alpha (MIP-1 alpha), is a pro-inflammatory chemokine, crucial for immune responses towards infection and inflammation. It is produced by various cell types, particularly macrophages, dendritic cells and lymphocytes. It can activate human granulocytes, leading to acute neutrophilic inflammation, and also induce the synthesis and release of various pro-inflammatory cytokines, such as interleukin-1 (IL-1), IL-6 and tumor necrosis factor-alpha from fibroblasts and macrophages. MIP-1 alpha and its receptors, especially CCR1 and CCR5, play a major role in the pathogenesis of MM and MM-induced osteolytic bone disease. They can, directly and indirectly, stimulate tumor growth, being correlated with tumor burden, via upregulation of cell adhesion and cytokine secretion. In addition, they modulate the osteoclast/osteoblast balance, by inducing osteoclast differentiation and inhibiting osteoblast function. **Aims.** The aims of the present study was to determine if circulating MIP-1 alpha can be used as a marker of bone disease activity in patients with MM and if there is any relationship with indices of angiogenesis such as IL-18, basic fibroblast growth factor (b-FGF) and hepatocyte growth factor (HGF). **Methods.** We studied 60 newly diagnosed myeloma patients (34 male, 26 female, with mean age 58±13.4 years). According to Durie-Salmon staging system, 11 had stage I disease, 25 stage II and 24 stage III. Bone disease was graded according to skeletal involvement on x-ray (grade 0: no bone involvement, 1: one lytic lesion, 2: more than 1 lytic lesions, 3: bone fracture or vertebral collapse). Seventeen of them had grade 0, 11 grade 1, 11 grade 2 and 21 grade 3. Twenty-eight healthy persons were included in the study. MIP-1 alpha, IL-18, b-FGF and HGF serum levels were determined by ELISA, using commercially available kits. **Results.** All the above measured variables were significantly higher in MM patients compared to control group (p<0.001 in all cases). They were also higher with advancing disease stage (p<0.001 in all cases) and skeletal grade (p<0.04 for MIP-1 alpha and p<0.001 for the other cases). We also found significant correlations between MIP-1 alpha with IL-18 (r=0.596 p<0.001), b-FGF (r=0.509 p<0.001) and HGF (r=0.424 p<0.001).**Conclusions.** MIP-1 alpha seems to be a sensitive marker of bone disease activity in MM. The significant relationship with the measured angiogenic markers indicates the contribution of enhanced angiogenesis to the increased bone involvement seen in MM patients.

0825

RELATIONSHIP BETWEEN CIRCULATING BAFF LEVELS WITH PROLIFERATION MARKERS IN PATIENTS WITH MULTIPLE MYELOMA

G Tsirakis[1], M Fragioudaki[1], A Boula[2], M Spanoudakis[1], M Kaparou[1], P Kanellou[1], I Papadakis[1], A Alegakis[1], C Pappa[2], M Alexandrakis[1]
[1]University Hospital of Heraklion, Heraklion, Greece
[2]Venizelion Hospital, Heraklion, Greece

Background. Multiple myeloma (MM) is an incurable plasma cell malignancy, characterized by an unlimited proliferation and accumulation of malignant plasma cells in the bone marrow. The interactions between the various mediators, secreted from MM cells, with the microenvironment, in the bone marrow, seem to be critical in the pathogenesis and growth of MM. B-cell activating factor (BAFF) is a cytokine that belongs to the tumor necrosis factor superfamily with a significant role in the maintenance of normal B-cells development and homeostasis. Soluble form is secreted by various cell types, such as monocytes, macrophages, dendritic cells, activated T-cells and neutrophils. BAFF is a potent B-cell growth factor and co-stimulator of immunoglobulun production. **Aims.** The aim of the study was to measure serum BAFF levels in newly diagnosed MM patients, to estimate whether they were influenced by the disease stage and status and to correlate them with other proliferation indices of the disease, such as serum interleukin-6 (IL-6), IL-10, IL-15 and bone marrow plasma cell infiltration and Ki-67 proliferation index (Ki-67 PI). **Methods.** We studied 54 newly diagnosed MM patients (25 male, 29 female with mean age 66.2±10.0 years). Nine had stage I disease, 23 stage II and 22 stage III. We also studied 32 of them in plateau phase, as well as 25 healthy controls. BAFF, IL-6, IL-10 and IL-15 serum levels were measured by ELISA, whereas plasma cell infiltration and Ki-67 PI were estimated in bone marrow specimens by immunohistochemistry. **Results.** All the above markers were higher in patients compared to

control group (p<0.001 in all cases). All of them were also increasing with advancing disease stage (p<0.001 in all cases) and were significantly decreased in the plateau phase (p<0.002 for IL-10, p<0.001 for the other cases). We found significant correlations between serum BAFF levels with IL-6 (r=0.711 p<0.0001), IL-10 (r=0.634 p<0.0001), IL-15 (r=0.642 p<0.0001) serum levels, bone marrow plasma cell infiltration (r=0.369 p<0.006) and Ki-67 PI (r=0.693 p<0.0001). **Conclusions.** Our data confirmed that BAFF is secreted in MM as soluble factor. Additionally we found that serum levels were higher with advancing disease stage. Finally, our results showed that there is a strong correlation with other known proliferation indices of the disease, such as IL-6, IL-10, IL-15, bone marrow infiltration and Ki-67 PI. This finding could raise concerns about its use as a target for therapeutic interventions in myeloma patients.

0826

GENOME WIDE SNP ANALYSIS REVEALS UNIPARENTAL DISOMY (UPD) AS A NEW MECHANISM IN GENE DYSFUNCTION IN WALDENSTROM'S MACROGLOBULINEMIA (WM)

XL Leleu[1], S Poulain[2], C Roumier[3], S Galiègue-Zouitina[4], A Daudignon[2], C Herbaux[4], E Bertrand[4], S Manier[4], V Soenen[3], S Tricot[2], C Roche-Lestienne[3], P Morel[5]

[3]Centre de Biologie Pathologie, CHRU, Lille, France

[4]U837, IRCL, Lille, France

[5]Service d'Hématologie, CH, Lens, France

Background. SNP array was developed to combine the detection of CNV and LOH without copy number changes, also called UPD. Acquired UPD are not detectable by conventional cytogenetic or CGHa, and the regions with UPD might be important for the pathogenesis of cancer, and also lead to tumor suppressor gene inactivation or oncogene activation in cancer.Previous studies have demonstrated high frequency of chromosomal abnormalities in WM, a low grade B cell lymphoplasmacytic lymphoma type, using conventional cytogenetic, FISH and CGH analysis. We hypothesized that SNPa study would allow identification of novel genomic aberrations involved in WM, would permit a better understanding of WM pathogenesis, and favour the identification of novel targets for future drugs development. Our aim was to identify LOH/UPD involved in WM, and to characterize the clinical significance of these chromosomal defects. **Methods.** BM samples of 31 ptswith WM were analysed. DNA was extracted following B cells selection for tumoral cells. Genome-Wide Human SNP Array 6.0 (Affymetrix chips) was used. Paired samples (tumor/ normal T lymphocytes) were used as an intra-individual reference to identify germ line SNP. Size, position and location of genes were identified with UCSC Genome Browser HG18 assembly, LOH and CNA using genotyping console 3.02 software (Affymetrix) and Partek genomic suite. FISH analysis and conventional Karyotypes were available for all patients. **Results.** A total of 115 genetic aberrations (3.7 / patient) were observed, including 61 CNV (33 gains, 28 losses) in 58% of patients and 54 UPD (mean of 1.8 / genome). The area of CNV and UPD were widely distributed throughout the genome, and we have identified 12 recurrent regions of CNV and 7 of UPD. The UPD regions varied in size, from 0.8 to 114 mb, and the most frequent UPD were interstitial regions. We have identified 7 recurrent UPDs located in 17q, 4q, 3q and 13q. Several genes involved in cancer biology are located in these UPD regions. Only one patient had UPD detected on chromosome 6q, a hallmark of cytogenetic abnormalities observed in nearly half the WM, interestingly extending from 6q to the telomere. UPD regions did not cover known microRNA deregulated in WM. Although a higher frequency of more than 3 CNV was observed in patients with symptomatic WM, in our series, no difference in terms of UPD was observed in symptomatic and asymptomatic WM.In terestingly, large and telomeric UPD were only observed in symptomatic patients (14%). **Conclusions.** New cryptic clonal chromosomal lesions were observed and mapped in WM using genome wide SNP array in this study. We described a high frequency of UPD in WM, an important mechanism that might contribute to the inactivation of tumour suppressor genes and subsequently to the regulation of tumor progression in WM. This study revealed UPD as a new pathogenic mechanisms likely underlying WM pathogenesis, that might help deciphering the genome instability of patients with WM. The results of this study expand the view of the genomic complexity of WM with the identification of numerous and complex genetic aberration.

Myeloma - Clinical 2

[5]Winship Cancer Institute, Emory University, Atlanta, United States of America

[6]Duke University Medical Center, Durham, United States of America

[7]Novartis Pharmaceuticals Corporation, East Hanover, United States of America

Background. Patients with multiple myeloma (MM) refractory to bortezomib and an immunomodulatory drug have limited treatment options and a poor prognosis. In a phase I study of patients with relapsed or relapsed/refractory MM treated with panobinostat + bortezomib, durable clinical responses were observed overall and in patients with bortezomib-refractory disease. **Aims.** To evaluate the efficacy of the combination of panobinostat + bortezomib + dexamethasone, we conducted PANORAMA 2, a phase II trial in relapsed and bortezomib-refractory patients with MM. **Methods.** PANORAMA 2 is a single-arm, phase II study of panobinostat (20 mg, oral) + bortezomib (1.3 mg/m^2, intravenous) + dexamethasone (20 mg, oral) in patients with relapsed and bortezomib-refractory MM. Treatment phase 1 (TP1) consists of eight 3-week cycles of panobinostat (thrice weekly) and bortezomib (twice weekly) during weeks 1 and 2, with oral dexamethasone administered on the days of and after bortezomib dosing. Patients demonstrating clinical benefit enter treatment phase 2 (TP2), which consists of four 6-week cycles of panobinostat (thrice weekly) and bortezomib (once weekly) during weeks 1, 2, 4, and 5, with dexamethasone on the days of and after bortezomib. The primary endpoint is overall response (≥ partial response [PR]) in TP1. All patients provided informed consent, and patients who discontinued are followed for survival. **Results.** Fifty-five patients with bortezomib-refractory MM were enrolled with 6 patients ongoing and 30 in follow-up. The median age was 61 years (range 41-88 years). Patients were heavily pretreated: the median number of prior regimens was 4 (range 2-11), and most patients (64%) received prior autologous stem cell transplant. Twenty-seven (49%) and 36 (65%) patients had bortezomib and dexamethasone in their most recent prior line of therapy, respectively. Eighteen patients achieved ≥ PR for an overall response rate of 33% (1 near complete response and 17 PR), and 13 patients achieved minor response (MR) for a clinical benefit rate of 56%. Three patients achieved a very good partial response (VGPR). Eighteen patients completed TP1 and entered TP2, and 2 have completed ≥ 12 cycles. Common adverse events (AEs) of any grade included fatigue (72%), thrombocytopenia (64%), diarrhea (64%), nausea (58%), dyspnea (40%), anemia (40%), decreased appetite (40%), dizziness (38%), constipation (34%), peripheral edema (32%), and peripheral neuropathy (30%). Common grade 3/4 AEs included thrombocytopenia (60%), fatigue (17%), diarrhea (17%), anemia (15%), pneumonia (15%), and neutropenia (13%). Only 1 patient (2%) experienced grade 3/4 peripheral neuropathy.**Conclusions.** The addition of panobinostat restored bortezomib sensitivity in heavily pretreated bortezomib-refractory MM patients. The combination of panobinostat, bortezomib and dexamethasone may provide an important treatment option for patients with bortezomib-refractory MM. The combination is generally well tolerated with several patients continuing on therapy long term.

Background. SMM is an asymptomatic plasma-cell proliferative disorder associated with a high risk of progression to symptomatic multiple myeloma (sy-MM). Patients with SMM meet the diagnostic criteria of MM [serum monoclonal component (MC) higher than 3 g/l and a proportion of bone marrow plasma cells (BMPC) ≥10%] in the absence of clinical manifestations. Prognostic factors for the progression and outcome of this disease are unclear. **Aims**. In this retrospective study, we have analyzed some predictors of development in sy-MM in SMM. Moreover, In some of these SMM patients, we also had the opportunity to compare the risk of progression predicted by the % of bone marrow plasma cell (BMPC) involvement observed in the bone marrow biopsies (BMB) versus that observed in bone marrow aspirates (BMA). **Methods.** For this study, 397 patients with SMM observed in 12 centers of the Multiple Myeloma GIMEMA Latium Working Group between 01/1980 and 07/2010 were analyzed. At progression to sy-MM, the severity of clinical presentation was graded according to the need of intensive supportive care. **Results**. After a median follow-up of 135 months, the cumulative incidence of progression (CIP) rates to sy-MM were 45%, 55% and 75% at 10, 15 and 20 years, respectively. Hb ≤12.5 gr/dl, MC ³ 2.5 gr/dl and BMPC ³60% were the only parameters negatively affecting the CIP. In particular, 7/397 (1.7%) patients with BMPC ³60% had a 5.6-fold increased risk of fast progression (within 2 years) to sy-MM. This progression occurred with severe clinical manifestations in 62% of cases. BMB was more sensitive for the detection of BMPC involvement, even though BMA was a more reliable indicator of a rapid progression to sy-MM. **Conclusions**. These data show that SMM patients with ³60% BMPC rate at diagnosis present a very rapid progressions to sy-MM characterized, in the majority of cases, by more severe clinical manifestations and suggest that these patients should probably be candidate to standard treatment soon at diagnosis. Moreover, BMA is more sensitive than BMB in the identification of these very high risk SMM patients.

[3]McMaster University, Hamilton, Canada

Background. Patients with multiple myeloma are at an increased risk of venous thromboembolism (VTE) and arterial thrombosis, especially when treated with thalidomide and lenalidomide. In the general population, the occurrence of VTE is associated with a decreased survival. It remains unclear whether development of VTE and arterial thrombosis alters overall survival in patients with multiple myeloma. **Aims.** Aims of the study were to evaluate whether VTE and arterial thrombosis influence survival in multiple myeloma patients in a large population-based study. **Materials and Methods.** We assessed the impact of VTE and arterial thrombosis (using Swedish Patient-Registry) on survival in a population-based study on 9,399 multiple myeloma patients diagnosed in Sweden 1987 to 2005 using Cox proportional hazards models. We also performed landmark analyses that started follow-up time six months after diagnosis and assessed the impact of any thrombotic event during the first six months on overall survival. **Results.** We found multiple myeloma patients with (versus without) VTE to have a higher mortality at one-, five-, and ten-years of follow-up, with hazards ratio (HR)=2.9 (95% confidence interval (CI) 2.4-3.5), 1.6 (1.5-1.8), and 1.6 (1.4-1.7), respectively. The risk of dying was also increased among multiple myeloma patients with arterial thrombosis, HR=3.4 (3.0-3.8), 2.2 (2.0-2.3), and 2.1 (1.9-2.1) at one-, five-, and ten-years, respectively. Given that a multiple myeloma patient survived the first six months following diagnosis (landmark analyses), early VTE (within six months) was not associated with a higher risk of death at one year (HR=1.4; 95% CI 0.9-2.0), five years (1.1; 0.9-1.3), or ten years (1.0; 0.9-1.2) (Figure). In contrast, in landmark analysis, early arterial thrombosis was associated with a significantly higher risk of death at one year (1.5; 1.1-2.0), five years (1.4; 1.2-1.6), and ten years (1.4; 1.2-1.6). **Conclusions.** In this large population-based study including over 9,000 multiple myeloma patients, in contrast to prior smaller studies, we found the development of arterial and venous thrombosis to be associated with a significantly poorer survival. However, multiple myeloma patients with an early VTE that survived their first six months had similar survival as those without VTE. Our findings are important as they confirm that thrombosis in multiple myeloma is a serious complication, increasing morbidity and even mortality, also in the era of novel anti-tumor agents. The prevention of thrombosis in multiple myeloma is an important goal in the management of multiple myeloma.

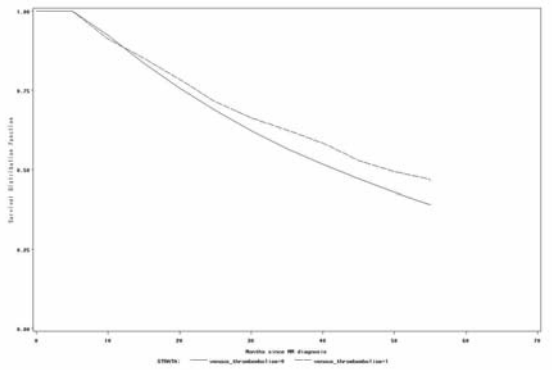

Figure 1. Survival among multiple myeloma patients with and without early venous thrombembolism (landmark analysis).

DELETION 17P IN UNSELECTED NEWLY DIAGNOSED SYMPTOMATIC PATIENTS WITH MULTIPLE MYELOMA TREATED WITH NOVEL AGENTS IS ASSOCIATED WITH POOR OUTCOME DUE TO POOR POST RELAPSE SURVIVAL

E Kastritis, E Terpos, M Gkotzamanidou, M Roussou, M Gavriatopoulou, M Migkou, E Eleutherakis-Papaiakovou, D Christoulas, D Gika, M Dimopoulos

University of Athens, Athens, Greece

Background. Multiple myeloma (MM) is characterized by significant genetic heterogeneity. Specific cytogenetic features may be associated with poor outcome. Deletion of the short arm of the chromosome 17 (del17p), involving the p53 locus, has been associated with poor outcome. The frequency of this abnormality increases in more advanced phases of the disease. Recent clinical trials indicate that novel drugs may overcome the poor prognosis associated with some cytogenetic abnormalities, but it seems that neither bortezomib nor thalidomide or lenalidomide may overcome the deleterious effect of del17p. **Aims**. To assess the prognostic importance of del17p in unselected patients with MM, most of which received upfront novel agents. **Methods.** We analyzed 195 consecutive previously untreated patients, who were treated in a single center (Department of Clinical Therapeutics, University of Athens, Greece) with available data for del17p. Some of these patients were included in clinical trials; however, several patients who were ineligible because of poor performance status, significant renal impairment or comorbidities were also included in the analysis, thus, being more representative of the general myeloma population. Presence of del17p was assessed by standard FISH methodology. IMWG criteria were used for the assessment of response, progression-free (PFS) and

overall survival (OS). **Results.** del17p was present in 27(14%) patients at initial diagnosis. The baseline clinical characteristics of patients with and without del17p were not significantly different, except ISS-3 which was more frequent in patients with del17p (p=0.046). Primary therapy was based on novel agents (thalidomide, bortezomib or lenalidomide) in 86% of patients and was similar for patients with or without del17p (p=0.887); response was also similar (93% for those with del17p versus 84% for those without, p=0.140) as was the quality of responses (CR, VGPR & PR). Sixty-seven percent of patients with a del17p and 50% of those without del17p have relapsed or progressed after initial therapy. The median PFS for patients with and without del17p was 18.5 *vs*. 21 months, respectively (p=0.2); however, the median survival was significantly shorter for patients with del17p (29.5 versus 75 months, p<0.001). When we adjusted for other prognostic factors, then the presence of del17 was the stronger prognostic variable associated with poor survival (HR:3, 95%CI:1.7-5.3, p<0.001). Other factors associated with shorter survival included age >65 years (p=0.006) and elevated serum LDH ≥300 IU/L (p=0.012). On further analysis, we found that median survival after first disease relapse for patients with del17p was 8 months *vs*. 42 months for patients without del17p (p=0.002), despite the fact that in almost all patients novel agents were used as salvage treatment**. Conclusions.** del17p remains an independent prognostic factor associated with poor survival in unselected patients with newly diagnosed MM, even when novel agents are used as initial therapy. Patients with del17p have very poor outcome after relapse, even with the use of novel agents as salvage therapy. Patients with del17p should be considered for participation in clinical trials of novel agents as soon as they relapse, since currently available treatment options offer limited benefit in these high risk patients.

0831

AN UPDATE ON THE OVERALL SAFETY AND INCIDENCE OF SPM IN LENALIDOMIDE-, THALIDOMIDE-, AND BORTEZOMIB-TREATED PATIENTS WITHIN THE EUROPEAN POST-APPROVAL SAFETY STUDY (EU PASS) OF RELAPSED/REFRACTORY MM

Background. The efficacy and tolerability of lenalidomide in patients with relapsed or refractory multiple myeloma (RRMM) has been demonstrated in 2 large, randomized, phase 3 studies (MM-009 and MM-010). Bortezomib and thalidomide are also proven to be effective for the treatment of RRMM. Post-approval observational studies provide additional information on the safety of novel medications in real-world clinical practice. **Aims.** To compare the incidence of adverse events (AEs) of special interest, such as neutropenia, thrombocytopenia, venous thromboembolism (VTE), peripheral neuropathy (PN), and second primary malignancies (SPM) in patients treated with lenalidomide and other antimyeloma therapies for RRMM in a real-world setting. **Methods.** In this observational, non-interventional, post-authorization safety study, patients with MM who had received at least one prior therapy were enrolled into the lenalidomide cohort (lenalidomide plus dexamethasone, the approved combination for the treatment of RRMM) or the background. cohort (all other treatments, including other novel agents) at the investigator's discretion. Thromboprophylaxis was allowed but not required. AEs were graded according to NCI-CTCAE (version 3) grading. Assessments for SPM were to be conducted up to 36 months after treatment discontinuation. **Results.** As of November 2011, 2,717 patients across 265 institutions, in 17 European countries were enrolled. Of those, 1,857 received lenalidomide, 670 received bortezomib, 101 received thalidomide, and 89 received other therapies or had missing data at time of analysis. Ninety-seven patients from the background. cohort crossed over following the physician's decision to initiate lenalidomide treatment. Median follow-up for all groups was 24 weeks (range, 0.6-157.3). Median age was 69 years (range, 29-95) and 54% were male. Most patients (66%) had good performance status (ECOG score 0-1); 17% had an ECOG score of 2-4. Median number of prior therapies was 2 (range, 0-6): 52% had 2 prior therapies and 22% had ≥3 prior therapies. Baseline characteristics were similar between groups. Overall, 1,189 (45%) had an AE of grade 3-4. Grade 3-4 neutropenia occurred in 19%, 7%, and 15% of patients in the lenalidomide, bortezomib, and thalidomide groups, respectively. Grade 3-4 thrombocytopenia developed in 16%, 14%, and 9% of patients, respectively. The overall incidence of peripheral neuropathy was 27% (4% grade 3-4) in the bortezomib group compared with 7% (1%) in the lenalidomide and 13% (1%) thalidomide groups. Grade 3-4 VTE developed in 2% of patients in the lenalidomide group and none in the other two treatment groups. The overall treatment discontinuation rate was 63%, 79%, and 78% in the lenalidomide, bortezomib, and thalidomide groups, respectively, with a similar discontinuation rate due to AEs in each group. The incidence of SPM was ≤1% overall (Table). Incidence of death during the study was similar with all treatments (lenalidomide 6%, bortezomib 5%, and thalidomide 5%). **Conclusions.** Lenalidomide has been shown to improve disease outcomes in RRMM patients. AEs, including SPM, were similar with all treatments except for higher rates of neutropenia and lower rates of PN with lenalidomide, compared with patients receiving bortezomib or thalidomide.

Table. Summary of SPM (*indicates same patient).

SPM	Len (n=1,875)	Bort (n=670)	Thal (n=101)	Total (N=2,628)

ALLOGENEIC STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA - A LONG-TERM FOLLOW-UP

A Weipert[1], R Reibke[2], J Braess[2], J Tischer[2], H Kolb[3]

[1]Klinikum Groβhadern Munich, Munich, Germany

[2]Ludwig-Maximilians-University - Groβhadern, Munich, Germany

[3]Technical University, Munich, Germany

The treatment of multiple myeloma is still unsatisfactory. Although in recent years survival improvement was seen, disease progression just seems to be deferred. Even after high dose chemotherapy and autologous stem cell transplantation (ASCT), most patients relapse. Treatment options fo those patients are, despite promising newer drug, still limited. In contrast, allogeneic human stem cell transplantation (HSCT) bears the potential of definite cure, however, being hampered by inacceptable high Treatment Related Mortality (TRM) rates. Reduced intensity conditioning (RIC) regimens lead to a drop in TRM, but this benefit is offset by higher relapse rates. Hence, in three recently published prospective studies no consistent superiority in Overall Survival (OS)/Progression Free Survival (PFS) was seen for RIC HSCT when compared to ASCT. We provide the result of a retrospective, long-term follow-up (median 6,75 years), single center analysis of 78 patients receiving allo-HSCT for multiple myeloma from 1994 to 2009. Median age was 49 years, 25 Patiens had received more than one prior ASCT, 32 patiens had stable disease (SD) (n=5) or even progressive disease (PD) (n=27) at time of HSCT. Matched related donors were available on only 30 cases. Preparative regimen consisted of either Melphalan (once 140 mg/m^2 or twice 100 mg/m^2), TBI (8-12 Gy) based or reduced intensity regimen (TBI </=4 Gy, n=26) in combination with Cyclophosphamide, Fludarabin and ATG in virtually all cases. After HSCT a complete remission (CR) or very good partial remission (VGPR) was reached in 87% of all evaluable patients (five patients died prior to staging). The 2-year Non-Relapse Mortality (NRM) was 19,3% (total 24,4%). Chronic GvHD was seen in ca. 25% of patients. Risk factors being associated with diminished PFS and OS (given data) were >1 prior ASCT (OS:HR=2,80, p=0,00;PFS:HR=2,76;

p=0,00), allo-HSCT more than 10 months after last ASCT (OS:HR=2,09, p=0,012;PFS:HR=2,47, p=0,001), no partial remission (PR) at time of HSCT (OS:HR=2,41, p=0,002;PFS:HR=2,31, p=0,002), application of a 'reduced intensity conditioning' (OS:HR=2,11, p=0,009;PFS:HR=1,93, p=0,015) and a lower CD 34/MNC count (OS:HR=1,89, p=0,047;PFS:HR=1,82, p=0,040) in univariate analysis. In multivariate analysis >1 prior ASCT (OS:HR=2,81, p=0,001;PFS:HR=2,89, p=0,000) and 'RIC' (OS:HR=2,00, p=0,022; PFS:HR=2,09, p= 0,010) could be confirmed as independent risk factors. Patients reaching at least a PR prior to HSCT and lacking the latter two risk factor reached an OS of 60% and PFS of 50% with a follow-up till 17,5 years. Summarizing the results, we established >1 prior ASCT as an independent risk factor for subsequent HSCT, contradictory to the use of double ASCT as standard therapy, especially in younger patients. Furthermore we saw moderate TRM rates after 'myeloablative' HSCT, resulting in a significant better outcome compared to the RIC regimen. This observations raise the question if early and myelablative HSCT might be the key to cure multiple myeloma.

Background. Multiple myeloma remains incurable with current approaches and the disease invariably relapses after responding to initial therapy. There is no uniform approach to the management of relapsed disease and is dictated by the response to initial therapy, types of initial therapy and availability of new drugs. The outcomes associated with current approaches in this group of patients have not been systematically examined. **Patients and Methods.** We enrolled 383 patients with myeloma who had the first relapse of their disease between Jan 1, 2007 and June 30, 2010. Of the 383 patients, 26 were from North America, 220 were from Europe, 106 were from Asia, and 31 were from South America. Clinical data was collected using detailed case report forms for uniformity. Time Zero (T_0)was defined as the date of the first anti-myeloma treatment after first relapse. The Institutional Review Board at the respective institutions approved the study. **Results.** Across the study, 61% were male and 49% were over 65 years at T_0. ISS stage distribution at diagnosis included 26, 40 and 33% of patients in stages 1, 2 and 3, respectively. A variety of regimens were used at first relapse; bortezomib containing regimens were used most commonly (54%), followed by lenalidomide (25%) and cyclophosphamide (21%) containing regimens. The overall response rate (>=PR) to the first regimen after relapse was 58% including 14% with a complete response. The response rates were higher for the US and European centers (62 and 64% respectively). In a multivariate analysis, ISS stage 3, ISS stage 3 at relapse and Asian center were predictive of a lower response rate. There was a progressive decrease in the response rates with successive regimens; 45%, 30% and 15% for regimens 2, 3 and 4 respectively. Of the 109 patients considered eligible for stem cell transplant, 39% received an SCT as salvage therapy. Lenalidomide use was considerably lower in the Asian cohort, while bortezomib use was comparable across the regions. The median progression free survival (PFS) from T_0 was 13 mos and overall survival (OS) was 35 mos, for the entire cohort. In a univariate analysis, ISS stage 3, presence of cytogenetic abnormalities, history of plasma cell leukemia or extramedullary disease, bone marrow PC% > 33% and presence of renal insufficiency were all associated with a shorter PFS as well as shorter OS (P<=0.01). In a multivariate analysis including the maximum number of variables, ISS stage 3 and presence of EMD were most associated with short OS. **Conclusions**: Median progression free survival for current second line regimens, which typically contain bortezomib or lenalidomide in combinations appear to be around 1 year with an OS from first relapse of about 3 years. The OS from first relapse is nearly double that seen in a cohort of patients in first relapse prior to introduction of new drugs. Clear-cut regional differences can be seen in terms of patterns of drug use and health care resource utilization and likely reflect drug availability and healthcare costs.

CONTINUOUS LENALIDOMIDE TREATMENT FOR TRANSPLANT-INELIGIBLE NEWLY DIAGNOSED MULTIPLE MYELOMA: UPDATE ON PATIENTS AGED 65-75 YEARS ENROLLED IN MM-015

A Palumbo[1], R Hajek[2], M Kropff[3], MT Petrucci[4], J Catalano[5], M Delforge[6], Z Adam[2], R Foà[4], Z Yu[7], L Herbein[7], C Jacques[7], M Dimopoulos[8]

[6]University Hospital Leuven, Leuven, Belgium
[7]Celgene Corporation, Summit, United States of America
[8]University of Athens School of Medicine, Alexandra Hospital, Athens, Greece

Background. MM-015 is a pivotal phase 3 randomized, double-blind, placebo-controlled trial designed to compare melphalan-prednisone-lenalidomide (MPR) induction followed by lenalidomide maintenance (MPR-R) with fixed cycle MPR and melphalan-prednisone (MP) induction in transplant-ineligible newly diagnosed multiple myeloma (NDMM) patients. Interim results demonstrated unprecedented progression-free survival (PFS) improvement (Palumbo A, et al. *Blood* 2011). **Aims.** Examine efficacy and safety in patients 65-75 years as a protocol-specified age group. **Methods.** Dosing and schedule have been described. Efficacy and PFS data are provided through the last adjudicated assessment (median follow-up of 27 months). The median follow-up for safety and overall survival (OS) is 41 months. **Results.** A total of 152, 153, and 154 patients were randomized to MPR-R, MPR, and MP, respectively. Median PFS was significantly improved with MPR-R (31 months) vs. MPR (14 months; *P*<.001) and MP (13 months; *P*<.001). A landmark analysis calculating PFS from the time of maintenance entry demonstrated that lenalidomide maintenance significantly prolonged median PFS (26 months from maintenance entry) vs. placebo (7 months) (HR=0.34; *P*<.001). Lenalidomide maintenance extended PFS independent of induction response (partial response vs. very good partial response or better), ISS stage (I/II vs. III) and age (65-75 years vs. >75 years). Patients aged 65-75 years were evenly distributed: 76% MPR-R patients (116/152), 76% MPR (116/153), and 75% MP (116/154). In these, MPR-R significantly prolonged median PFS vs. MPR and MP (Figure). Importantly, MPR induction alone improved PFS vs. MP (Figure). Lenalidomide maintenance reduced the progression rate by 65% (*P*<.001). PFS improvements were not-

ed in all patient subgroups (renal function, induction response, and ISS stage), and an OS trend has been observed (Figure). MPR induction had a manageable safety profile, allowing 67% of patients to reach maintenance. The most frequent adverse events (AEs) were hematologic. For patients aged 65-75 years, grade 4 neutropenia occurred in 31% (MPR) and 7% (MP); grade 4 thrombocytopenia was reported in 11% (MPR) and 4% (MP). Grade 4 febrile neutropenia was not reported. The most common grade 3/4 non-hematologic AE was infection (8% vs. 6%). Discontinuation from MPR and MP induction for AEs occurred in 12% and 4%, respectively. During lenalidomide maintenance, the most common AEs were grade 3/4 infections and bone pain (5% each). Eight percent discontinued lenalidomide maintenance due to AEs. Secondary primary malignancy (SPM) were uncommon corresponding to low incidence rates per 100 patient-years of 3.04, 2.57, and 0.98, respectively, which represent a total of 12 (MPR-R), 10 (MPR), and 4 (MP) SPM. Similarly, the risk of progression/death was higher than the SPM risk. **Conclusions.** Continuous lenalidomide treatment with MPR-R significantly extended PFS vs. MP and MPR. MPR induction significantly extended PFS vs. MP in patients aged 65-75 years. The manageable safety profile of MPR induction allowed 67% of patients to reach maintenance. Lenalidomide maintenance extended PFS in all patient subgroups analyzed. SPM were uncommon, although imbalanced across treatments. Overall, the risk of progression/death clearly outweighs the SPM risk. MPR-R should be considered a standard of care in transplant-ineligible NDMM patients aged 65-75 years.

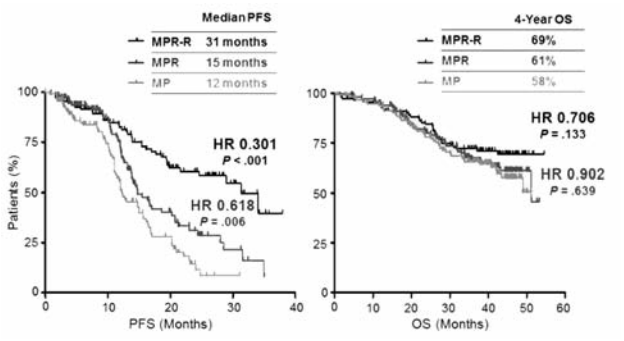

Figure 1. PFS and OS for Patients Aged 65-75 Years.

[9]Institut Curie, Paris, France

Bortezomib (V) plus Dexamethasone (D) is a treatment of choice of relapsed/refractory multiple myeloma. In small series, the addition of an alkylator was beneficial. Bendamustine (B) showed a high activity in advanced MM. The IFM 2009-01 trial evaluates the combination of B, V and D in elderly pts with MM progressive on or after 1st line therapy. We conducted a phase 2 trial combining B 70 mg/m^2 D1-8, V 1.3 mg/m^2 D1-8-15-22 and D 20 mg D1-8-15-22 every 28 days. 4 cycles were administered. In responders (PR or better), 2 additional cycles were provided followed by a maintenance phase with 6 cycles given every 2 months. Inclusion criteria were progression on or after 1 prior line of therapy, measurable disease, PS ECOG <3, ANC > 1.5x10^9/l, platelets > 100x10^9/l, creatinine < 250 mcmol/l, AST and ALT < 3xULN, provision of informed consent. Pts with prior exposure to bortezomib were excluded. Response was evaluated according to IMWG criteria. Primary end point was response at end of cycle 4, secondary objectives overall response rate (ORR), progression-free survival (PFS), overall survival (OS) and toxicity. The present analysis was restricted to the first 4 cycles. From 03/2010 to 07/2011, 73 pts were included, median age 75.8 years (range 66-86). Median time from diagnosis to inclusion was 29 months. All pts received only 1 prior therapy: MP in 12, MP-Thalidomide in 44, Lenalidomide-Dexamethasone (LD) in 14, other in 3. 42 pts (57.5%) were responders at end of cycle 4 [CR: 8 (10.9%), VGPR: 9 (12.3%), PR: 25 (34.2%), SD: 10 (13.6%), progression: 11 (15%), early discontinuation: 10 (13.6%)]. 6pts/10 were in PR and 1pt/10 in VGPR at time of discontinuation. ORR was 67.1% (49/73 pts). 11 pts died (MM: 6, sepsis: 4, renal failure: 1). Follow-up PFS and OS were 77.2% and 85%, respectively. Adverse events grade 3-4 were neutropenia: 16 pts, thrombocytopenia: 7 pts, sepsis: 12 pts, gastro-intestinal: 8 pts, anaphylaxis: 1 pt. 2 pts had DVT. Peripheral neuropathy grade>1 occurred in 9 pts, all grade 2. Treatment was stopped in 20 pts (lack of efficacy: 11, toxicity: 9). These results compare favorably with those achieved with VD or LD. The triplet BVD combination is very effective and tolerable in elderly pts with MM in 1st progression.

0836

RESPONSE RATES TO SINGLE-AGENT CARFILZOMIB IN PATIENTS DOUBLE REFRACTORY OR INTOLERANT TO BORTEZOMIB AND IMMUNOMODULATORS IN TRIAL PX-171-003-A1

Background. Patients with relapsed and refractory multiple myeloma (MM) (1) whose disease is refractory to bortezomib or are intolerant of bortezomib and (2) whose disease is refractory to at least 1 immunomodulatory drug (ie, thalidomide or lenalidomide) or are intolerant of at least 1 immunomodulatory drug (ie, "double-refractory/intolerant patients"), have few therapeutic options and a poor prognosis. Carfilzomib, a next-generation proteasome inhibitor, has shown durable single-agent activity in clinical studies including 003-A1, an open-label, single-arm phase 2b trial in relapsed and refractory MM. **Aims**. The present analysis from study 003-A1 describes clinical activity of carfilzomib in double-refractory/intolerant patients and in other groups of clinical interest, including patients with disease refractory to all 5 approved classes of anti-MM treatments (alkylating agents, anthracyclines, corticosteroids, immunomodulatory drugs, and proteasome inhibitors) in clinical use ("refractory to all approved treatments"). **Methods.** Responses in double-refractory/intolerant patients from 003-A1 were analyzed, as were responses in patients with disease refractory to all 5 approved classes of anti-MM treatments. Carfilzomib was given on days 1, 2, 8, 9, 15, and 16 of each 28-day cycle (C), (20 mg/m^2 in C1; 27 mg/m^2 in C2-12). The primary endpoint was overall response rate (ORR; ≥ partial response [PR]). Secondary endpoints included clinical benefit response rate (≥ minimal response), duration of response (DOR), overall survival, and safety. **Results**. The ORR for all patients (N=266) was 22.9% with a median DOR of 7.8 months. In the 228 (86%) double-refractory/intolerant patients the ORR was 20.6% with a median DOR of 7.4 months. **Conclusions**. Patients with double-refractory/intolerant MM or disease refractory to all 5 approved classes of anti-MM treatment achieved clinically meaningful, durable responses with single-agent carfilzomib. The response rates across groups of clinical interest were generally consistent with the results for the entire study population. These results are notable for a next-generation proteasome inhibitor and

demonstrate the activity of single-agent carfilzomib in patients with advanced stage MM and its potential for meeting the unmet medical need in these patients.

Background. The incidence of multiple myeloma (MM) is known to be variable according to ethnicity. However the difference of clinical characteristics between ethnic groups is not well-defined. In Asian countries the incidence of MM has been lower compared with Western countries. However, there are growing evidences that MM is increasing very rapidly in this region. Until now, only few data of Asian patients has been reported. Asian myeloma network (AMN) decided to analyze the first multinational project to explore clinical characteristics of Asian MM patients and clinical practice performed in Asian countries. **Aims.** We analysed the clinical characterics of Asian myeloma to characerize the differences with western data.

Table 1 Summary of clinical characteristics of AMN project

		n	%	median OS	p value
Total		2969	100.0	54.0

	no	2292	76.9	64.0	

Methods. Data were collected from 21 centers from 7 countries and regions were collected retrospectively. Clinical characteristics of 2969 symptomatic MM patients at diagnosis were described. Overall survival (OS) and prognostic factors were analyzed for 2273 patients who have survival data. **Results.** Clinical and genetic characteristics were summarized at table 1. Median OS was 54 months (95% CI 48.0-60.0). Patients who were diagnosed before 2000 were shorter survival. Transplantation was performed to 513 patients with better survival (84 vs. 45 months, p<0.001). First line treatment of 2339 evaluable patients was analyzed. Overall response rate was 71% with 30%, VGPR or better. New drugs including bortezomib, thalidomide or lenalidomide were combined for 32.5% of all 2339 patients without difference in response rate or OS according to combination. **Conclusions.** We successfully described clinical characteristics of Asian MM patients and this project will be the base for future studies or clinical trials for Asian MM patients. Updated analyses and comparison with Western data will be presented. AMN, supported by the International Myeloma Foundation (IMF) IMWG initiative.

AN INTERNATIONAL SURVEY INTO THE MANAGEMENT OF MYELOMA KIDNEY

R Allchin[1], A Bevins[2], M Cook[1], C Hutchison[1]
[1]University Hospital Birmingham, Birmingham, United Kingdom
[2]The Binding Site Group Ltd, Birmingham, United Kingdom

Introduction: A rapid diagnosis and reduction of serum free light chains (FLC) is essential for improving outcomes in patients with acute kidney injury secondary to multiple myeloma. The development of new generation high cut-off (HCO) haemodialysers with increased pore sizes has improved the ability to remove FLC in these patients. This study assesses how new high cut-off (HCO) dialysers are being used internationally to complement chemotherapy and the outcomes associated with their use. **Methods.** All clinicians that have treated patients with HCO dialysers were invited to take part in an international chart audit, using an electronic web-based data collection system.Results. To date, data from 60 patients, in 22 centres across 11 countries, has been included. All patients were Caucasian with a median age of 65 years (range 42-81). 79.3% of the population received renal biopsies at presentation, with 88.9% having myeloma kidney as their primary diagnosis. Baseline serum biochemistry was: creatinine 642.0umol (range 168-2263); eGFR 8 (1-27); calcium 2.32mmol (0.91-3.83); albumin 34g/L (14-46) and B2M 8.8mg/L (0-55.7). All patients had serum FLC measurements, 57.4% had lambda (median baseline concentration 4165mg/L (300-38000mg/L)) and 42.6% had kappa monoclonal proteins (median baseline concentration 5130mg/L (2250-63200mg/L)). In total 670 dialysis sessions have been recorded, with a median of 13 sessions per patient. The majority of patients (68.6%) were treated with the Theralite® dialyser, 25.7% were treated with the smaller HCO1100 dialyser and only 5.7% with 2xHCO1100 in series. 62.5% of patients received a bortezomib-based chemotherapy regimen, with only 10.4% receiving Thalidomide-based. The median reduction in serum FLCs per treatment was 92.4% (range 4.31-99.9). By day 12 the median reduction in FLCs was 76.0%. Patients treated with Theralite® had a significantly greater FLC reduction by day 12 (median 86.57%) compared to patients treated with HCO1100 (54.45%, Mann Whitney U p=0.019). Independence of dialysis was achieved in 58.3% of patients, at median time of 26 days (range 8-249). More patients treated with Theralite® became independent of dialysis (73.9%, median 24.5days) than those treated with the HCO1100 (50%, median 66.5days). Independence of dialysis was greater in those patients in whom there was a reduction in serum FLCs by day 12 (Mann Whitney U p=0.016).Discussion: Early reductions in serum FLC was associated with an increased likelihood of achieving dialysis independence. To achieve this rapid diagnosis and effective treatment is essential. In patients with AKI secondary to multiple myeloma, the extracorporeal removal of FLC by HCO dialysis complements effective chemotherapy treatment to improve patient outcomes.

Background. Monoclonal gammopathy of unknown significance (MGUS) is a potentially malignant condition associated with a cumulative probability of progression into one of the malignant forms of monoclonal gammopathy approximately 1% per year (Kyle et al., New Engl J Med 2002). **Aims.** The aims of this study were to verify the validity of already known risk factors separating benign and malignant MGUS using Register of Monoclonal Gammopathy (RMG) of Czech Myeloma Group. **Methods.** Before inclusion to RMG all persons signed informed consent. Total of, 1448 persons with MGUS were enrolled to the RMG in the Czech Republic retrospectively and prospectively, from May 2007 to November 2011. A total of 99,3% (1439/1448) persons were analyzed. The median follow up was 5 years (range 1.0 to 18.0). **Results**. Total of 7,1% (96/1356) persons with MGUS progressed into malignant form; 75% (72/96) into multiple myeloma; 10,4% (10/96) into Waldenström macroglobulinemia; 5,2% (5/96) into malignant lymphoma; 2,1% (2/96) into primary amyloidosis; 7,3% (7/96) into other types of malignancy with the median time to transformation 3 years (range 0-15 years). Variables associated with significantly higher risk of transformation were as follows: serum paraprotein levels >15 g/l (25,8% vs. 4,48%; p< 0.001), bone marrow plasma cells infiltration >5% levels (22,3% vs. 5,4%; p< 0.001), abnormal κ/λ index < 0,26 or > 1,65 (75,6% vs. 42,7%; p< 0.001), serum baseline lactate dehydrogenase levels >3,75 ukat/l, (7,82% vs. 4,62%; p= 0.016) and serum baseline hemoglobin levels <120 g/l (7,82% vs. 4,62%; p= 0.007). In contrast to stratification system published by Rajkumar et al.(Blood 2005), we did not find any correlation between Ig isotypes (non IgG vs. IgG) (32,6% vs. 29,5%; p= 0.523), however high-risk subgroup (presence of all three abnormal risk factors) belonged to a group with a relative risk (Hazard Ratio; HR) almost 18 times higher than normal (17.54; CI (5.78; 53.22); p<0,001) when Cox model was used to identify possible predictors of malignant transformation. High HR (4.18, CI (2.59, 6.74), p <0.001) also had a number of plasma cells greater than 5% levels, serum paraprotein levels >15g /l (HR 3.64, CI (2.39, 5.54) p <0, 001) and pathological values of the κ/λ index HR was 2.9 (2.90 (1.47, 5.75), p = 0.002). Persons in the lowest risk group had 5-year survival without malignant transformation in 96,7% of cases with an annual risk of transformation under 1%, while the highest risk group in 55,6% of cases with and annual risk of transformation about 8-9%. **Conclusions.** Our results confirm the validity of the known risk factors, except type of Ig for prediction of MGUS transformation into malignancy. Currently, we can well define the group with the lowest risk with an annual risk of transformation < 1%. Further optimization of the currently used model of stratification is required mainly for other than low risk groups. At this point, our data form one of the largest set of analyzed subjects with MGUS in the world; however, a certain limitation is a short median follow-up.

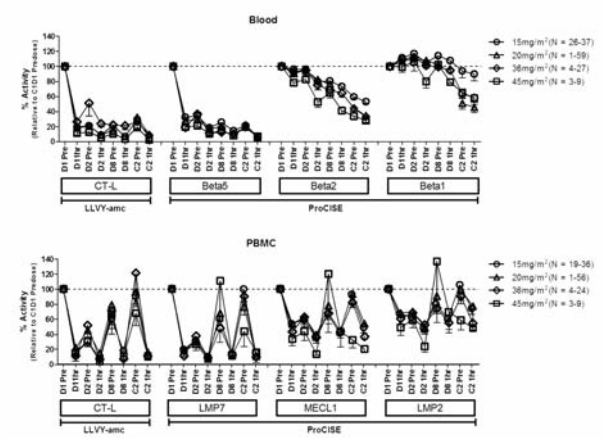
Background. Carfilzomib is a next-generation proteasome inhibitor with demonstrated anti-tumor activity in multiple myeloma (MM). MM tumor cells express both the constitutive proteasome (c20S) and immunoproteasome (i20S), but inhibition of individual active-site subunits has not been determined due to the lack of effective tools. Current assays have been limited to the chymotrypsin-like (CT-L) subunits and do not differentiate between the two proteasome types. In MM cells, both proteasome types are necessary for tumor cell survival. We analyzed proteasome inhibition by carfilzomib in patient samples using a recently validated assay that differentiates between inhibition of the two proteasome types as well as individual active sites. **Aims.** To 1) measure the inhibition of all 6 proteasome active sites in whole blood and peripheral blood mononuclear cells (PBMC) from patients treated with carfilzomib in clinical trials, 2) demonstrate proteasome inhibition in CD138+ tumor cells isolated from carfilzomib-treated patients, and 3) determine if a relationship exists between patient response and proteasome inhibition. **Methods.** ProCISE (Proteasome Constitutive Immuno Subunit ELISA) is an ELISA-based assay that accurately and reproducibly measures proteasome subunit levels and inhibition by clinically applied inhibitors. Whole blood and isolated PBMC were obtained from patients enrolled in one Phase 1b, 1 Phase 1b/2 and 3 Phase 2 trials utilizing carfilzomib by 2- to 10-minute or 30-minute infusion (single agent or in combination with lenalidomide and dexamethasone). Whole blood and isolated PBMC were obtained from 41 solid tumor (ST) and 73 MM patients enrolled in clinical trials. Blood samples were taken on multiple days during the first cycle and on day 1 of the second cycle. Bone marrow aspirates were obtained at screening and after the second dose of carfilzomib and enriched for $CD138^+$ tumor cells. Proteasome inhibition was measured by ProCISE across multiple time points and compared to best overall response rate (ORR).



Results. Carfilzomib administration induced consistent and potent inhibition of CT-L subunits of both the c20S (b5) and i20S (LMP7) and inhibited all subunits of the i20S (LMP7, LMP2 & MECL1). Across all tested doses, CT-L inhibition reached >80% (Figure). In CD138+ tumor cells, we measured CT-L and MECL1 activity and found that inhibition levels corresponded to that in PBMC. Proteasome inhibition was not affected by concomitant medication (high-dose lenalidomide) or renal function. Significantly greater inhibition was observed on cycle 1 day 8 for all i20S subunits 1hr post-dose in patients receiving 56 mg/m^2 carfilzomib compared to patients receiving lower doses (15 or 20 mg/m^2). A

64% ORR was observed in patients receiving 56 mg/m^2 carfilzomib, achieving >80% total i20S inhibition while the lower doses were associated with an 11% ORR and <50% total i20S inhibition. **Summary and Conclusions.** ProCISE represents the only known assay capable of measuring the activity of all 6 proteasome active sites in complex biologic samples. Carfilzomib administration results in potent and prolonged inhibition of multiple proteasome active-sites in patients with MM. By using ProCISE, we have demonstrated that higher doses of carfilzomib are associated with greater levels of immunoproteasome inhibition as well as improved clinical response.

Introduction: Mutltiple myeloma (MM) biochemical relapses after prior responses are usually not treated in the absence of symptoms. Such patients are an ideal group to explore the antitumor benefit of Zoledronic Acid (ZOL) in the absence of any other cytotoxic therapy.**Aims.** To evaluate the potential antitumor effect of ZOL treatment in MM patients under asymptomatic biochemical relapse. Primary end-point was Symptomatic Progression Free Survival (sPFS). Secondary evaluation variables were response rate, skeletal related events and time to next chemotherapy.**Patients and methods**: 192 patients are calculated to be recruited in a randomized, prospective, open label phase IV trial in which a group of patients receive ZOL (4 mg iv./4 wk, 12 doses) and Best Supportive Care (BSC) and the rest only BSC. All patients are monitorized every 4 wk.**Results.** This is an interim analysis corresponding to the first 75 patients included in the trial: 37 treated with ZOL and 38 without ZOL. All patients were in Asymptomatic Biochemical Relapse, with a median age of 70 yr (37-85) and a male female distribution of 39/36. M-component distribution was IgG (70%), IgA (26%) and only light chain (4%). Relapse had presented after 1, 2 or ³3 lines of therapy in 67%, 23% and 10% of cases, respectively. Prior treatment had included transplant (59%), bortezomib (59%) or IMiDs (38%), or a combination of them. One or two skeletal related events (SRE) were detected in 32% of cases. FISH/cytogenetics was abnormal in 52% of cases: t(11;14) 19%, Rb deletion (alone) 17%, del(p53) 8%, t(4;14) 4% and t(14;x) 4%. After randomization, both groups of patients were well balanced in terms of prognostic features, prior response, and time from diagnosis and relapse to the inclusion in the trial. 12 patients have completed the program and four terminated before completion due to patient refusal (n=2) and development of other diseases (n=2). 30 patients are still ongoing and 29 have progressed before 12 mo of treatment, rendering median sPFS of 307 days (10.1 months) with no statistically significant differences between the two arms, although the 12-month projected sPFS was slightly better in patients treated with ZOL vs. patients not treated with ZOL (55% vs. 42%, p>0.1). Interestingly, the patients not treated with ZOL progressed with more advanced bone disease (6 cases of new bone lesions or re-growth of prior lesions, 1 spinal cord compression, and 2 cases of hypercalcemia) vs. patients treated with ZOL (two cases regrowth of bone lesions, p<0.01). By contrast, patients treated with ZOL progressed more frequently with decrease of Hb level below 10 g/dL (11 vs. 7 cases). There were 7 SRE that occurred only in the group of patients treated without ZOL (p=0.006)**Conclusions**: Zoledronic Acid therapy in MM with asymptomatic relapse seems to reduce the risk of progression with symptomatic bone disease and SREs. The possible antitumor effect of Zoledronic Acid alone in biochemical relapses cannot be elucidated yet. This interim analysis supports the continuation of the trial in order to include a highernumber of patients and longer follow-up.

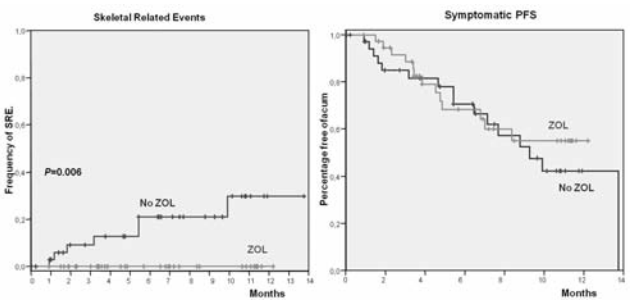

Figure 1. SRE and PFS according to the therapeutic arm.

IS MULTIPLE MYELOMA A CHRONIC DISEASE?

J Liwing[1], K Uttervall[2], P Näsman[3], J Andreasson[2], P Johansson[4], J Aschan[1], H Nahi[2]
[1]Janssen AB, Sollentuna, Sweden
[2]Karolinska Institute, Huddinge, Sweden
[3]Center for Saftey Research, KTH, Stockholm, Sweden
[4]Department of Internal Medicine, NU Hospital Organization, Uddevalla, Sweden

Background. The introduction of novel agents (Bortezomib, Thalidomide, Lenalidomide) in Multiple Myeloma (MM) has been shown to increase overall survival (OS). In clinical studies the effect of those drugs are always compared to a MM population and not an age and gender matched normal population. A question that has been asked is if MM could be regarded as a chronic disease after the introduction of the novel agents. We define a chronic disease to have a similar survival curve as a matched population without the disease under investigation. **Aims.** Evaluate OS outside clinical studies in non-HDT patients with MM. Comparing the effects of novel agents in 1st line vs. standard chemotherapy. Compare novel agents in 1st line vs. a gender and age at the time for diagnosis matched Swedish normal population to investigate if MM could be regarded as a chronic disease. **Methods.** All diagnosed patients with MM between January 2000 and July 2010 at Karolinska University Hospital Huddinge and Södersjukhuset and between January 2005 and July 2010 at Karolinska University Hospital Solna were included. Standard statistical methods were used. The entire Swedish population was included to select a gender and age at diagnosis matched cohort in 5-years age strata. All individuals matching the criteria were included. Actual observed death rates were used.

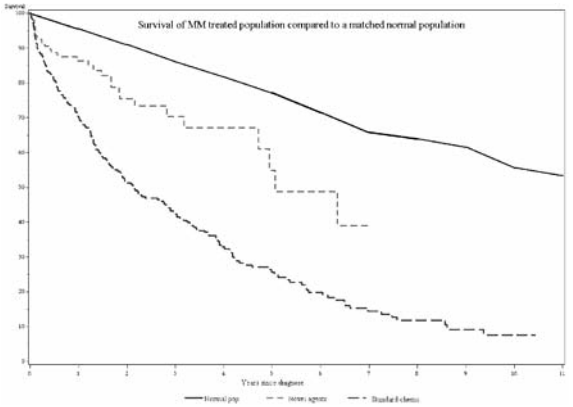

Figure 1. Survival of MM treated population in 1st line with standard cheomtherapy, novel agents and an age at diagnosis and gender matched normal population.

Results. Our MM study population consisted of 674 patients of which 89 patients (13%) were excluded due to non treatment demanding disease or plasmacytoma without MM diagnosis and 214 patients (32%) receiving high

dose treatment, setting the MM study population to n=371. The median age was 75 years and 51% male. The median follow up of the study population was 54.3 month. The most common type of MM was IgG (56%) followed by IgA (25%) and Bence Jones (15%). At diagnosis 59% of the patients had one or more skeleton destruction and 18% had a creatinine higher than 177 µmol/l. Patients treated with novel agents in the first line had a statistically significant lower creatinie 130 µmol/l vs.188 µmol/l compared to patients treated with standard chemotherapy. The use of novel agents in the 1st line predicted a longer OS, median 61.2 month vs. 26.4 month (p<0.001) compared to standard chemotherapy. In the matched normal population the median survival was not reached. When comparing patients treated with novel agents in 1st line to the matched normal population the 1-year survival was 86% vs. 96%, 3-year survival 69% vs. 86% and 5-year survival 52% vs. 77%. **Summary.** The patient cohort treated with novel agents in 1st line has a superior survival compared to the group treated with standard chemotherapy. In comparison to a gender and age at diagnosis matched normal population, the survival is still shorter. However, if novel agents were used in an optimal treatment sequence the survival could potentially be higher but there is still a need for further development in MM treatment before we can call it a chronic disease.

[5]Hospital La Princesa, Madrid, Spain
[6]Hospital Clinic I Provincial de Barcelona, Barcelona, Spain
[7]University of Frankfurt, Frankfurt, Germany
[8]Novartis Pharma AG, Basel, Switzerland
[9]Novartis Healthcare Pvt. Ltd., Madhapur/Hydrabad, India
[10]The Methodist Cancer Center, Houston, TX, United States of America

Background. The molecular chaperone HSP90 plays a pivotal role in the folding and maturation of proteins important in myeloma cell survival and hence multiple myeloma (MM) pathogenesis. AUY922 is a non-geldanamycin HSP90 inhibitor with potent preclinical activity against MM cell lines (IC_{50} <12.5 nM) (McMillin *et al.* ASH 2007). **Aims.** This open-label Phase I/Ib study assessed AUY922 as single agent or in combination with bortezomib (BTZ) in patients with relapsed or refractory MM. **Methods.** In the Phase I dose-escalation part, an adaptive Bayesian logistic regression model (BLRM) was employed to guide dose escalation. AUY922 was administered intravenously once-weekly in patients with MM who progressed following 2"'4 prior lines of therapy. In the Phase Ib part, AUY922 was administered in combination with BTZ in patients with MM who progressed following ≤2 prior lines of therapy. The primary objective was to determine the maximum tolerated dose (MTD) of AUY922 alone and in combination with BTZ in patients with previously treated MM. Secondary objectives included preliminary efficacy, safety, and pharmacokinetics (PK). Informed consent was obtained from all patients. **Results.** Phase I: 24 patients (median age 63.5 years; 63% male; 96% ECOG PS 0"'1) received AUY922 at doses of 8"'70 mg/m^2. Most patients were heavily pretreated: 79% had received >2 prior lines of antineoplastic therapy. One dose-limiting toxicity (DLT) was observed (Grade 3 blurred vision at 70 mg/m^2) and no MTD was reached. The recommended Phase II dose was 70 mg/m^2, which was identical to that declared in solid tumor studies (Samuel, *et al.* ASCO 2010). A best response of stable disease (SD) was achieved in 16/24 (67%) patients. There were no partial responses or complete responses.Phase Ib: 5 patients (median age 68 years; 40% male; 100% ECOG PS 0"'1) were treated with AUY922 50 mg/m^2 + BTZ 1.3 mg/m^2. All patients had received 1 line of previous antineoplastic therapy. Three patients experienced DLT (Grade 3 musculoskeletal pain, Grade 3 diarrhea, and Grade 3 non-cardiac chest and musculoskeletal pain [1 patient each]). No further dose escalation was performed and the study was discontinued; MTD was not established.The most frequent Phase I drug-related adverse events (AEs) of any Grade were diarrhea (46%), visual AEs (37.5%; most frequently night blindness [17%], photopsia [17%] and visual impairment [17%]), and nausea (17%). Grade 3/4 AEs were rare (all <10%). The safety profile was similar to that observed in solid tumor studies. PK profiles were also similar to those reported in previous studies, and drug disposition of AUY922 was unaffected by combination with BTZ. **Conclusions**. AUY922 administered as single agent had an acceptable safety profile. Limited activity was observed: SD was achieved by 67% of heavily pretreated patients with relapsed/refractory MM. Combination with BTZ was not tolerated at the standard recommended dose.

0844

CARFILZOMIB DOSE AND SCHEDULE NEED NOT BE ADJUSTED FOR BASELINE RENAL DYSFUNCTION, INCLUDING PATIENTS ON HEMODIALYSIS

D Harvey[1], S Lonial[1], P Patel[2], L McCulloch[2], R Niesvizky[3], J Kaufman[1]
[1]Winship Cancer Institute of Emory University, Atlanta, Georgia
[2]Onyx Pharmaceuticals, South San Francisco, United States of America
[3]Weill Cornell Medical College, New York, United States of America

Background. Patients with multiple myeloma (MM) are vulnerable to renal injury and impairment both from their disease and from treatments for the disease. Carfilzomib is a selective proteasome inhibitor with proven efficacy in MM. Safety data have been compiled from over 700 patients with relapsed and/or refractory MM who have received single-agent carfilzomib.**Aims.** Herein we present an analysis of the incidence and severity of carfilzomib treatment-emergent renal adverse events (AEs) from 526 patients in four phase 2 trials, including a study focused on individuals with varying degrees of renal function, which includes patients on hemodialysis. **Methods.** Patients from the PX-171-003-A0, PX-171-003-A1, PX-171-004, and PX-171-005 trials were included in this analysis. In all studies, carfilzomib was dosed on Days 1, 2, 8, 9, 15, and 16 of a 28-day cycle (C). Doses were 20 mg/m^2 in C1 for all studies escalating to 27 mg/m^2 in C2 per individual protocol, except 005 (15 mg/m^2 in C1, 20 mg/m^2 in C2, and 27 mg/m^2 in C3). Renal AEs"'the incidence, frequency, and resolution of episodes of worsening renal function, defined minimally as a doubling of serum creatinine from baseline"'and shifts in other laboratory parameters were tabulated and summarized based on NCI CTCAE v.3 criteria. **Results**. The majority of patients (71%) had renal dysfunction (CrCl <50 mL/min) at baseline. Overall, 87% experienced no significant worsening of renal function during the course of treatment. Transient worsening was reported in 31 patients (6%) with a median duration of 1.4 weeks and a median of 1.0 episode per patient; non-transient worsening was reported in 37 patients (7%) with 8 (2%) of those permanently discontinuing treatment due to renal dysfunction. 38 patients (7%) experienced Grade 3/4 acute renal failure AEs, of which 31 were Grade 3; 50% of patients with acute renal failure AEs required no change in carfilzomib therapy. The percentage of patients in 003-A0, 003-A1, and 004 whose creatinine levels shifted to Grade 3 or 4 from any lower grade was <5%. Results from 005 showed no major pharmacokinetic differences in patients with a wide range of renal function. **Conclusions**. Treatment-emergent renal AEs resulting in carfilzomib discontinuation were uncommon. Based on the findings from this cross-trial analysis, carfilzomib dose and schedule need not be adjusted in patients with baseline renal dysfunction, including patients on hemodialysis, allowing these patients to receive the benefits of standard carfilzomib treatment.

0845

UPFRONT USE OF NOVEL AGENTS IS BETTER ABLE TO OVERCOME THE ADVERSE IMPACT OF HIGH-RISK MYELOMA: A JOINT ANALYSIS OF THE SINGAPORE MM STUDY GROUP AND THE KOREAN MM WORKING PARTY

D TAN[1], K Kim[2], J Kim[2], G Teoh[3], H Eom[4], K Ong[5], W Chng[6], J Lee[7]
[1]Singapore General Hospital, Singapore, Singapore
[2]Sungkyunkwan University School of Medicine, Seoul, South-Korea
[3]Gleneagles Hospital, Singapore, Singapore
[4]National Cancer Center, Goyang, South-Korea
[5]Tan Tock Seng Hospital, Singapore, Singapore
[6]National University Health System, Singapore, Singapore
[7]Gachon University Gil Medical Center, Incheon, South-Korea

Introduction. Multiple myeloma (MM) is clinically heterogeneous and risk stratification is vital for prognostication and informing treatment decisions. We evaluate the survivaldata of MM patients managed at tertiary referral centers in Singapore (SG) and South Korea (SK) in the current era, where various novel agents were introduced at the same time, but the sequencing of their use in treatment algorithms of MM differs significantly due to differing healthcare reimbursement systems. We sought to determine the impact of an upfront risk-adapted vs a sequential approach to bortezomib (Btz) on the overall survival (OS) of patients. We aim to study the optimal sequencing of novel agents in treatment of MM. **Methods.** From the comprehensive MM registries of the SG and SK MM study groups, we study the survival data of 432 unselected and

previously untreated MM patients diagnosed from 2006 to 2009. Thalidomide (Th), bortezomib (Btz) and lenalidomide became available for treatment of relapsed MM in both countries from 2001, 2005 and 2009 respectively. From 2006 however, pts with high-risk MM (ISS III associated with renal impairment, del (13q) or hypodiploidy on metaphase cytogenetics, or presence of del (17p), t(4;14) or t(14;16) on interphase FISH) in SG could receive frontline Btz-based induction regimens, while Btz could only be approved for second or subsequent line usage in SK. All patients < 65 years were eligible for HDT/ASCT. Baseline pt, disease and treatment characteristics, and survival data were evaluated overall, and with respect to country of treatment. Disease response was assessed by the IMWG criteria after induction treatment and after HDT/ASCT for transplant ineligible and eligible pts respectively. We applied multivariate Cox's regression modeling to determine what baseline parameters, along with the eventual induction response, significantly affected the OS in the respective countries. **Results.** Median age of all patients was 61 years. Although baseline demographic features were comparable between the 2 countries, there were more pts presenting with ISS III disease in SK. Proportion of pts receiving novel agents (Th or Btz) in the frontline were 90% vs 26% in SG and SK respectively. At a median follow-up of 19 months, 47% vs 60% of pts had received Btz in SG and SK respectively. More pts in SG received Btz in the frontline while all pts in SK received Btz at relapse. Proportions of pts receiving HDT/ASCT were comparable. Significantly more pts had no response to induction treatment in SK. The median OS of pts in SG and SK were not reached and 4.83 years respectively (p=0.37). On multivariate analysis stratified by country of treatment, the attainment of ≥VGPR emerged as only significant prognostic factor in SG (p=0.006) while the presence of high-risk ISS and adverse cytogenetics still retains their prognostic significance in SK (p=0.003). **Conclusions**. Our study suggests that in the era of novel therapy, novel agents used upfront rather than sequentially may be better able to overcome the adverse impact of high-risk ISS and adverse cytogenetics. These findings have implications in healthcare resource planning.

0846

VELCADE CYTOXAN DEXAMETHASOE (VCD) OR VELCADE THALIDOMIDE DEXAMETHASONE (VTD) INDUCTION REGIMENS FOR NEWLY DIAGNOSED MULTIPLE MYELOMA - WHICH REGIMEN SHOULD WE PREFER?

M Leiba[1], T Freidman[1], R Leiba[2], M Kedmi[3], A Nagler[3], A Avigdor[3]
[1]The Chaim Sheba Medical Center and Tel-Aviv University, Ramat-Gan, Israel, Ramat-Gan, Israel
[2]Biostatistics, Haifa, Israel
[3]Hematology Division, The Chaim Sheba Medical Center and Tel-Aviv University, Ramat-Gan, Israel

Background. Three drug induction regimens have become the standard of care in patients with multiple myeloma (MM). Two of the most frequently used protocols are Velcade-Cytoxan-Dexamethasone (VCD) and Velcade-Thalidomide-Dexamethasone (VTD). These regimens differ in their response rate, toxicity profile and cost. However, prospective "head to head"comparisons between the two are lacking. **Aims.** In this study we attempted to identify the differences in response and toxicity between the VCD and VTD regimens by reviewing the relevant literature and conducting meta-analysis of the eligible studies. **Methods.** We thoroughly searched MEDLINE, Cochrane library, and the web sites of the American Society of Hematology, the American Society of Clinical Oncology and the European Hematology Association for clinical trials in which VTD or VCD were used as first line induction regimens for newly diagnosed MM patients. A meta-analysis using the Chi square for testing homogeny and odds-ration (OR) with 95% confidence interval to estimate adverse events, overall response rate (ORR), complete remission (CR) rate and near complete remission (nCR) rate, was performed. **Results.** Twelve clinical trials were proved eligible. Overall 807 patients were treated with either VCD (n=170) or VTD (n=637) as induction therapy. After a median of 4 induction cycles the ORR didn't differ between the groups: 85.3% in the VTD and 86.5 % in the VCD group (OR =0.90, CI= 0.52-1.56). VCD protocol was found to be slightly superior in terms of CR/nCR rate: 45% vs. 34% in the VTD arm (p= 0.05). Grade 3-4 adverse events of any type were documented in 68% of patients treated with VCD, compared with only 51% in the VTD group (p=0.01). Interestingly, there was no statistically significant difference in the incidence of grade 3-4 neuropathy (5.4% vs. 5.9%) between the two groups. **Conclusions**. Both VCD and VTD induction regimens in patients with MM are efficacious in term of ORR. VCD regimen may be superior in its ability to achieve CR/nCR; however, grade 3-4 adverse events are more frequently observed with this regimen. Surprisingly, the incidence of grade 3-4 neuropathy was comparable between the two groups. Due to the limited number of trials and their heterogeneity, randomized controlled trials are needed to confirm these results.

0847

BORTEZOMIB-BENDAMUSTINE-DEXAMETHASONE (BBD) IN PATIENTS WITH RELAPSED/REFRACTORY MYELOMA AND DIFFERENT RISK PROFILES NAMELY, CYTOGENETICS, PREVIOUS EXPOSURE TO BORTEZOMIB OR TO LENALIDOMIDE

H Ludwig[1], L Pour[2], H Kasparu[3], R Greil[4], W Linkesch[5], J Thaler[6], C Leitgeb[7], E Rauch[7], D Heintel[7], N Zojer[7], A Weissmann[7], Z Adam[2]

[3]Hospital Elisabethinen / Department of Internal Medicine, Linz, Austria
[4]Hospital Salzburg / Department of Internal Medicine III, Salzburg, Austria
[5]Medical University / Department of Hematology, Graz, Austria
[6]Hospital Wels-Grieskirchen / Department of Internal Medicine IV, Wels, Austria
[7]Wilhelminenspital/Department of Medicine I / Center for Oncology and Hematology, Vienna, Austria

Background. To evaluate the efficacy of Bortezomib-Bendamustine-Dexamethasone in relapsed/refractory myeloma in relation to FISH defined cytogenetics, and pre-exposure to Lenalidomide- and Bortezomib-based treatments**.** Outcome of treatment in patients of relapsed/refractory myeloma depends on the efficacy of the rescue regimen, on patient and tumour characteristics and on previous treatments. Bendamustine, an alkylating drug with purine like activities may exert synergistic activity in combination with bortezomib and may render patients previously exposed to bortezomib sensitive to anew treatment with the proteasome inhibitor. **Methods.** 71 patients with relapsed/refractory MM have been enrolled. Median age: 65 years, range 40-86 years, male/female: 32/39, ISS stage*I//III: 22, 29, and 20 patients, respectively. ECOG status* II: 37, 31, and 3 respectively. Previous treatment lines: 1-2: 44, 3-4: 22, and ≥ 5: 5, respectively. Full data documentation for response (>1 cycle) is available for 65 patients. Treatment regimen: Bendamustine 70 mg/m^2 day 1+4, Bortezomib 1.3 mg/m^2 days 1, 4, 8 and 11, Dexamethasone 20 mg on days 1, 4, 8 and 11, repeated every 4 weeks. Treatment was scheduled for 8 cycles, but should be discontinued in case of no response after 4 cycles at latest. Survival curves were calculated using SPSS software (version 17); comparisons were made using the log rank test. All survival data are provided for the intent-to-treat population.

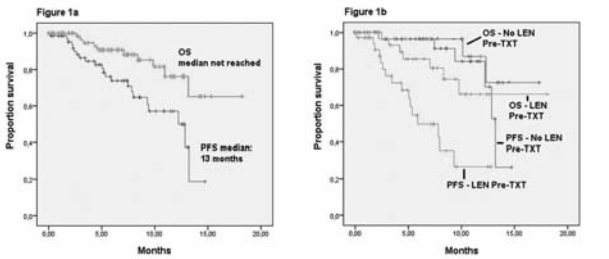

Figure 1a: PFS and OS in all patients; Figure 1b: PFS and OS in Lenalidomide naive and pre-treated patients; (p<0.0001; p=0.074, respectively)

Results. At the time of analysis the median follow up is 7,1 months. 6 of the 71 patients enrolled had less than 1 cycle, while in the entire group the median number of cycles is 4. Overall response rate (CR-PR) was 58.5% and 75.4%, respectively when MR was included (CR-MR) in the patients who completed ≥ 1 cycle. Eleven patients (16.9%) had CR/nCR, 10 (15.4%) VGPR, 17 (26.2%) PR, and 11 (16.9%) MR, respectively. Overall response rate (CR-PR) in patients previously exposed to bortezomib was 56% (CR-MR: 73%) and was 47% (CR-MR: 68%) in those pre-treated with lenalidomide-based regimens.Median progression-free survival (PFS) was 13 months, while for overall survival (OS) the median has not been reached as yet (figure 1a). Interestingly, no difference in PFS (p=0.733) and in OS (p=0.377) was found between patients with and without FISH defined adverse cytogenetics (t(4; 14), del17p, ampl 1q21). In patients pre-exposed to bortezomib, no difference in PFS (p=0.219) and in OS (p=0.378) was noted in comparison to bortezomib-naïve patients. In contrast, pre-treatment with lenalidomide was found to be significantly associated with shortened PFS (p=0.0001), while for OS (figure 1B) no difference was noted (p=0.074).Toxicities: Grade 3/4 anaemia was found in 13%, leucopenia in 14%, thrombopenia in 36%, infections in 15% (plus 3% G5) and PNP in 5% of patients. **Summary.** In conclusion, the BBD regimen showed significant activity in relapsed/refractory myeloma. PFS and OS were similar in patients with and without adverse cytogenetics as well as in those pre-exposed to bortezomib or bortezomib naïve. Lenalidomide pre-treatment, however was associated with significantly shorter PFS. The regimen was well tolerated with mainly haematological side effects and only 5% grade 3/4 PNP.

0848

COMBINED BENDAMUSTINE, PREDNISOLONE AND LENALIDOMIDE (RBP) IN PATIENTS WITH REFRACTORY OR RELAPSED MULTIPLE MYELOMA. FINAL RESULTS OF A PHASE I CLINICAL TRIAL - OSHO - #077

W Pönisch[1], S Heyn[1], I Wagner[1], M Mohren[2], FA Hoffmann[3], T Lange[1], M Schmalfeld[4], T Zehrfeld[5], A Schwarzer[6], C Winkelmann[7], T Edelmann[3], R Röhrborn[1], H Al-Ali[1], J Jäkel[1], D Niederwieser[1]

[6]Gemeinschaftspraxis für Haematologie/Onkologie, Leipzig, Germany
[7]Paul-Gerhardt-Stift, Wittenberg, Germany

Background. While the role of lenalidomide monotherapy in the treatment of relapsed/refractory patients with multiple myeloma (MM) is established, combination therapies with lenalinomide are still under investigation. Bendamustine is a bi-functional alkylating agent with a purine-like benzimidazole ring effective in combination with steroids, thalidomide and bortezomib for the treatment of patients with MM. In the current trial, combination therapy of bendamustine, lenalinomide and prednisolone (RBP) was tested for feasibility and safety in patients with relapsed or refractory MM. **Methods.** In this phase I part of the trial the dosing of lenalidomide in combination with bendamustine and prednisolone was examined. The first cohort of patients received a starting dose of 10 mg/d d1-21 lenalidomide, 60mg/m²/d d1-2 bendamustine and 100mg/d d1-4 prednisolone. Escalation steps in the next cohorts included 15, 20 and 25mg of lenalidomide followed by an escalation step of 75 mg/m² bendamustine. 3 (to -6) patients were enrolled at each dose level and the first two cycles were evaluated for maximum tolerable dose (MTD). Patients received RBP in 4-week cycles for a maximum of 8 cycles in order to evaluate efficacy. Patients with stable or responding disease following 8 cycles of RBP received single-agent oral lenalidomide 10 mg once daily on days 1-21 of each 28-day cycle as maintenance. **Results**. 21 patients (3 at the first three dose levels and 6 at the last two dose levels) have been enrolled in this phase I study and all patients have completed at least 2 cycles. Response was assessed using modified EBMT criteria to include near complete remission (nCR) and very good partial remission (VGPR). 16 patients (76%) responded after at least two cycles of RBP with 1 sCR, 1 nCR, 4 VGPR and 10 PR. Three patients experienced a MR and two a SD/PD.Two of the 21 patients developed dose-limiting hematoxicity as defined by an ANC < 1,0 x 10^9/l with fever for > 3 days or an ANC < 0,5 x 10^9/l for > 7 days or platelet count < 25 x 10^9/l for > 3 days: One patient in the dose level with 60 mg/m² bendamustine and 25 mg lenalidomide and one patient in the last dose level with 75 mg/m² bendamustine and 25 mg lenalidomide. The study finished with 75 mg/m^2 for bendamustine and 25 mg for lenalidomide without reaching MTD. **Conclusions.** RBP with a dose of 25 mg lenalidomide d 1-21 and 75 mg/m² bendamustine d 1-2 is well tolerated in patients with relapsed or refractory MM. The study is ongoing and 29 additional patients will be enrolled in the phase II study at the last dose level to better evaluate toxicity and clinical activity.

0849

COMPARISON OF THE CKD-EPI, MDRD AND A FORMULA BASED ON CYSTATIN-C AND SERUM CREATININE FOR THE ESTIMATION OF GFR IN PATIENTS WITH MULTIPLE MYELOMA; IS IT TIME TO CHANGE FROM MDRD TO CKD-EPI EQUATION?

E Terpos[1], E Kastritis[1], E Katodritou[2], A Pouli[3], E Michalis[4], D Christoulas[1], M Gkotzamanidou[1], I Papassotiriou[5], K Zervas[2], M Dimopoulos[1]
[1]University of Athens School of Medicine, Athens, Greece
[2]Theagenion Cancer Center, Thessaloniki, Greece
[3]St Savvas Oncology Hospital, Athens, Greece
[4]Georgios Gennimatas General Hospital, Athens, Greece
[5]Aghia Sophia Children's Hospital, Athens, Greece

Background. Renal impairment (RI) is a frequent complication of multiple myeloma (MM). The IMWG has recommended the use of the MDRD formula for the estimation of glomerular filtration rate (GFR) in MM patients with stabilized serum creatinine (sCr). Because MDRD equation has limitations, other prediction equations based on serum cystatin-C (cys-C), a very sensitive GFR surrogate marker, have been suggested for use in patients with chronic kidney disease (CKD). Furthermore, the CKD Epidemiology Collaboration (CKD-EPI) has proposed a new formula for the estimation of GFR, which is based on age, race and sCr, and is more accurate than the MDRD in the estimation of GFR in CKD and in kidney transplant patients. **Aims**. The aim of this study was to evaluate the renal function of newly diagnosed patients with symptomatic MM using the MDRD, the CKD-EPI equations and an equation based on Cys-C/age/sCr (Stevens et al, Am J Kidney Dis 2008;51:395-406) and explore their prognostic value on survival. **Methods.** We studied 204 newly-diagnosed, previously untreated, symptomatic MM patients. Their median age was 69 years (range: 36-94 years); 16% of patients had sCr ≥2 mg/dl, while 59% had elevated Cys-C. **Results**. The median values for eGFR calculated by the MDRD, the Cys-C/age/sCr and the CKD-EPI equations were 63.95 ml/min/1.73m^2, 68.08 ml/min/1.73m^2 and 56.5 ml/min/1.73 m^2, respectively (p<0.01 for all comparisons between equations). Patients were divided in the 5 CKD stages of the KDIGO classification. For each studied equation, the number of patients with RI stage 3-5 (i.e. eGFR <60 ml/min/1.73^2) was 42%, 41% and 52% for MDRD, Cys-C/age/sCr and CKD-EPI, respectively (p<0.001; see also the table).

Table. Evaluation of Renal Function Stage by Different Equations

CKD stage	MDRD equation	Equation based on Cys-C/age/sCr	CKD-EPI equation	p-value
1	47 (23%)	51 (25%)	30 (15%)	
2	70 (34%)	68 (33%)	66 (32%)	Friedman-test
3	54 (26%)	54 (26%)	68 (33%)	p<0.001
4	22 (11%)	23 (11%)	23 (11)	
5	11 (5%)	8 (4%)	17 (8%)	

Concordance for CKD stage allocation for the three equations was 68% for MDRD *vs.* CKD-EPI and Cys-C/age/creatinine and 61% for CKD-EPI *vs.* Cys-C/age/sCr. A significant correlation was found between ISS stage and each of the three equations (p<0.001). The median survival for all patients was 49 months. By using the eGFR of 60 ml/min/1.73 m^2 as a cut-off, patients with eGFR <60 ml/min/1.73 m^2, assessed by each of the 3 studied equations, had a significantly shorter median overall survival: 24 months *vs.* 98 months (χ^2=9.8, p=0.002) for MDRD equation, 27 months vs. 98 months (χ^2=12.8, p<0.001) for Cys-C/age/sCr equation and 38 months *vs.* not reached (χ^2=13.3, p<0.001) for CKD-EPI equation. When we adjusted for ISS stage, the allocation to RI of stage 3-5, using the CKD-EPI equation was significantly associated with survival (p=0.041); this was not observed for the allocation to stage 3-5 RI using the other formulas (p=0.357 for MDRD equation and p=0.235 for Cys-C/age/sCr equation). **Conclusions.** Our data suggest that CKD-EPI equation for the estimation of GFR detects more MM patients with stage 3-5 RI than MDRD or Cys-C/age/sCr equations. Furthermore, CKD-EPI was the only equation that could predict for overall survival adjusted for ISS stage. The confirmation of these data may lead to the broader use of CKD-EPI formula for the evaluation of RI in patients with MM, as it has been suggested for patients with several renal disorders.

Myeloma - Clinical 3

IMPACT OF NEUROPATHY ON STEM CELL MOBILIZATION IN PATIENTS WITH PLASMA CELL DISORDERS

V Rana, G Srivastava, M Gertz, M Lacy, A Dispenzieri, F Buadi, S Hayman, D Dingli, W Hogan, S Kumar
Mayo Clinic, Rochester, Minnesota, United States of America

Background. Number of autologous stem cell transplants (ASCT) being done for treatment of Multiple Myeloma (MM) and Amyloidosis has increased in the past decade. Nearly 10% of patients fail to mobilize adequate number of cells to proceed to SCT. Multiple factors contribute to poor mobilization including previous therapy, age, degree of disease control and type of mobilization regimen. Sympathetic nervous system plays critical role in the control of stem cell niche as has been described in mouse models. Patients with MM and amyloidosis may have neurological involvement either due to the plasma cell disorder or as a side effect of the treatment for their disease. We hypothesized that patients who have peripheral neuropathy at time of stem cell collection may have a poorer stem cell collection as compared to those without. **Methods.** Study included a cohort of consecutive 906 patients with MM or/and Amyloidosis seen at Mayo Clinic Rochester from December 1999 to October of 2008 who underwent stem cell collection. All patients were mobilized using G-CSF. Data was abstracted using chart review. We analyzed the difference in number of stem cells collected (CD34cells/kg) between patients with neuropathy at the time of collection versus those without. **Results.** Median age was 58 years (range 20-77). Of a cohort of 906 patients; 567 (62%) had MM, 340 (38%) had amyloidosis and 277 (31%) had a diagnosis of neuropathy at the time of stem cell collection. This was either a previous diagnosis, related to their disease or a side effect of treatment. There was no difference in rates of neuropathy based on time from diagnosis. Among patients with amyloidosis there was no difference in stem cell collection based on presence of neuropathy (Days 1-3 collection 5.59×10^6 vs 5.81×10^6; p=0.31). However, among patients with MM with neuropathy, stem cell collection on Day 1 was significantly lower as compared to those without (2.10×10^6 vs 2.56×10^6; p=0.027). Combined total stem cell collection (Days 1-3) was also significantly lower in patients with neuropathy (3.0×10^6 vs 3.7×10^6 p=0.016). Previous studies have shown that lenalidomide significantly lowers stem cell collection. Our data confirmed the same with significantly lower stem cell collection in the cohort treated with lenalidomide (2.24×10^6 vs 3.79×10^6, p<0.0001 for Days 1-3). After excluding patients who received lenalidomide, the impact of neuropathy on stem cell collection in MM patients was more pronounced: Day 1 collection was 2.12×10^6 vs 2.72×10^6, (p=0.009); and collection for Days 1-3 was 5.74×10^6 vs 7.23×10^6 (p=0.003) for those with and without neuropathy. **Conclusions.** Peripheral neuropathy in patients with plasma cell disorders is associated with poor stem cell collection. The impact of peripheral neuropathy may reflect disruption of autonomic nervous system, which may interfere with stem cell mobilization form the marrow niche. Studying role of adrenergic agonists in patients with neuropathy may be worth investigating to see if that enhances the stem cell collection.

BONE MARROW BIOPSY SHOULD BE CONSIDERED FOR THE INITIAL EVALUATION OF INDIVIDUALS WITH ASYMPTOMATIC MONOCLONAL GAMMOPATHY AND IMMUNOPARESIS OR MONOCLONAL COMPONENT =1GR/DL

E Kastritis, E Terpos, E Eleutherakis-Papaiakovou, M Migkou, M Gavriatopoulou, D Christoulas, M Gkotzamanidou, M Roussou, M Dimopoulos
University of Athens, Athens, Greece

Background. The incidental finding of a monoclonal gammopathy is increasingly common. It has been proposed that a bone marrow (BM) aspirate and biopsy is indicated when the monoclonal protein (M-protein) is ≥1.5 g/dL, when abnormalities are noted in the FBC and in serum creatinine, serum calcium, or radiographic bone survey, in individuals with non-IgG monoclonal gammopathy and in those with an abnormal serum free light chain ratio. **Aims.** To identify factors that could aid in the evaluation of individuals presenting with asymptomatic monoclonal gammopathy and in whom invasive diagnostic testing with a BMbiopsy is considered. **Methods.** We analyzed the database of patients who were referred to our department (University of Athens, Greece) for evaluation of asymptomatic monoclonal gammopathy. A BM trephine biopsy, a serum and urine protein electrophoresis with immunofixation and quantitative immunoglobulins are routinely performed in all patients with monoclonal gammopathy. Patients with a monoclonal M-protein ≥3 g/dl (30 g/L), i.e. those diagnosed with asymptomatic myeloma or Waldenstrom's macorglobulinemia based on the standard criteria, were not included in the analysis. BM plasma cells or lymphoplasmacytic cells clonality was assessed by immunohistochemistry. Patients who eventually were diagnosed with plasma cell related conditions (i.e. amyloidosis, peripheral neuropathy, etc.) were also excluded from the analysis. **Results**. Our analysis included 162 patients (females 53%, median age 64 years, range 33-89 years); 53% had a monoclonal IgG, 15.5% IgA, and 24% IgM, while 4% had a biclonal paraprotein; 63% of patients had a kappa light chain. The median serum M-protein was 0.95 g/dl (range 0.1-2.99 g/dl) and was higher in those with IgG or IgA *vs.* those with IgM (p=0.009). Fifty-two percent had an M-protein <1 g/dl and 21% had ≥2 g/dl. Immunoparesis of at least one of the uninvolved immunoglobulins was present in 38% and of both of the uninvolved immunoglobulins in 6% of patients. Median infiltration by monoclonal cells in BM biopsy was 7% for those with an IgM-gammopathy and 15% for those with monoclonal IgG or IgA (p=0.047). There was a significant correlation of the size of M-protein and of the infiltration of the BM (R=0.592, p<0.001). Among those with M-protein<0.5 g/dl, 11% had≥10% clonal cells in their BM biopsies while the respective rates were 88% for those with M-protein ≥1 g/dl and 97% for M-protein ≥2 g/dl. Immunoparesis of at least one of the uninvolved immunoglobulins was associated with ≥10% BM clonal cells in 90% of patients. Light chain isotype, age and gender were not predictive of BM infiltration. In regression analysis, immunoparesis of at least one of the uninvolved immunoglobulins (OR:6.45, 95%CI:2.32-18, p<0.001), an IgG or IgA monoclonal protein (OR:2.67, 95%CI:1.1-6.4, p=0.028) and an M-protein ≥1 g/dl (OR:5.4, 95%CI:2.23-13) were independently associated with ≥10% clonal infiltration in BM biopsy. **Conclusions**. Our data, from a large number of individuals with asymptomatic monoclonal gammopathy who underwent a BM biopsy, indicate that BM biopsy can reveal asymptomatic myeloma or WM who may escape identification with standard criteria and should be included in the standard initial workup of individuals with asymptomatic monoclonal gammopathy.

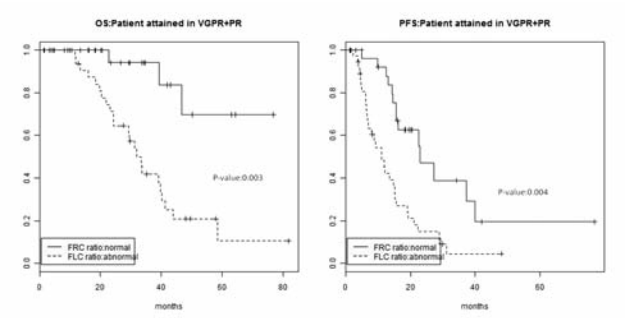
0852

NORMALIZATION OF SERUM FREE LIGHT CHAIN KAPPA/LAMBDA RATIO IS STRONGLY ASSOCIATED WITH FAVORABLE OUTCOME IN PATIENTS WITH MULTIPLE MYELOMA

K Iwama
Kameda Medical Center, Kamogawa City, Japan

Background. Although serum free light chain kappa/lambda ratio (sFLCk/l) has been incorporated into the IMWG response criteria of myeloma, its attainment in prognosis remains controversial. **Aims.** We investigated the prognostic impacts of normalization of sFLCk/l on progression-free survival (PFS) and overall survival (OS) among patients with MM treated with novel agents. **Patients and Methods.** A total of 104 consecutive patients (58 male and 46 female, median age 71) treated at Kameda General Hospital, Kamogawa-shi, Japan, between April 2005 and January 2012 were analyzed. All patients received chemotherapy containing at least one novel agent, including thalidomide, bortezomib, and lenalidomide. Treatment response was analyzed by bone marrow aspiration and/or biopsy, serum immunofixation, sFLC test, and assessed by IMWG criteria. PFS and OS were calculated from time of diagnosis until date of relapse or death from any cause/date on which the patient was last known to be alive, respectively. **Results.** At a median follow-up of 24 months, 3- and 5-year PFS and OS rates of all patients were 35%, 28% and 61%, 45%, respectively. CR was obtained in 22% of patients (23/104), very good partial response (VGPR) in 31% (32/105), partial response (PR) in 34% (33/104), and stable disease (SD) or less in 13% (14/104). Kaplan-Meier estimated 3-year PFS and OS were 78% and 100 % in patients with CR, which were significantly superior to those in patients with VGPR (PFS 23%, OS 65%), PR (PFS 0%, OS 44%), and SD or less (PFS 0%, OS 0%). Normalization of sFLCk/l was attained in 45 patients (43%) who showed significantly longer survival than 59 patients who did not (3-year OS, 94% vs. 48%; $P < 0.001$). Normal sFLCk/l was attained among patients with 80% of CR, 51% of VGPR, and 6.6% of PR, and 0% of SD or less. Although CR patients who attained normal sFLCk/l did not show significant survival advantage in PFS and OS, patients with VGPR or less with normal sFLCk/l showed significantly longer PFS and OS than those without normal sFLCk/l ($P < 0.001$). Univariate analysis showed that patients age > 70 and abnormal LDH showed negative prognostic impacts on attaining normal sFLCk/l. On multivariate analysis, none of these factors remained significant. Proportional hazard Cox models showed achievement of immunofixation-negative CR and normalization of sFLCk/l ratio were emerged as positive prognostic predictors for longer PFS and OS in patients with MM. **Conclusions.** This study confirmed the importance of immunofixation-negative CR for longer PFS and OS. We also demonstrated the significance of obtaining normal sFLCk/l ratio not only in patients with CR but also in those with

VGPR or PR. The data presented here indicated that analysis of sFLCk/l could identify the favorable group of patients independent of immunofixation results, and support the inclusion of sFLCk/l test as part of the response criteria for MM.



0853

EFFICACY AND SAFETY OF LENALIDOMIDE 25 MG IN ELDERLY PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA AND NORMAL RENAL FUNCTION

A Chanan-Khan[1], S Lonial[2], R Foà[3], A Swern[4], J Shiansong Li[4], P Lewis[5], M Dimopoulos[6]

[1]Mayo Clinic, Jacksonville, United States of America
[2]Emory Winship Cancer Institute, Atlanta, GA, United States of America
[3]Sapienza University of Rome, Rome, Italy
[4]Celgene Corporation, Summit, NJ, United States of America
[5]Celgene International, Boudry, Switzerland
[6]The University of Athens School of Medicine, Athens, Greece

Background. Lower doses of some multiple myeloma (MM) treatments, including lenalidomide, have been suggested when treating elderly patients. However, lenalidomide 25mg plus dexamethasone is shown to be effective in elderly patients with MM when closely monitoring renal function (Touzeau, Leukemia & Lymphoma 2012). Evidence suggests that any dose reduction after ≥12 months of lenalidomide 25mg in patients of all ages significantly reduces the risk of myeloma disease progression (Dimopoulos, Leukemia 2011). **Aims.** To investigate the efficacy and safety of a 25mg starting dose of lenalidomide in elderly relapsed or refractory MM patients with normal renal function. **Methods.** Pooled analysis of patients treated with lenalidomide (25mg on days 1-21 of a 28-day cycle) plus dexamethasone (40mg on days 1-4, 9-12, and 17-20 for the first 4 cycles; thereafter on days 1-4 only) was conducted from two pivotal phase III trials (MM-009 and MM-010). Patients with a creatinine clearance (CrCl) ≥60mL/min (based on the Cockroft-Gault equation) were categorized into those aged <65, 65-75, and >75 years. Efficacy outcomes were overall response rate (defined as partial response or better), time-to-progression (TTP), progression-free survival (PFS), and overall survival (OS). TTP, PFS, and OS were evaluated using Kaplan-Meier survival curves and a log rank test. Age was evaluated as a predictor of PFS in both univariate and multivariate Cox proportional hazards models adjusted for other baseline covariates. Safety outcomes included grade 3-4 adverse events (AEs) and discontinuations due to AEs. Dose intensity (calculated as total dose received/expected total dose) and dose reductions were assessed. **Results.** A total of 239 patients were included: 158 were aged <65 years, 70 were aged 65-75 years, and 11 were aged >75 years. Baseline characteristics were balanced across the groups, with the exception that older patients were more likely to have an ECOG performance score ≥1 (43% aged <65 years, 69% aged 65-75, and 82% aged >75), and younger patients were more likely to have received prior stem cell transplantation (67%, 44%, and 9%, respectively). Despite this, efficacy outcomes were similar across the 3 age groups (p=0.40, 0.38, and 0.81 for TTP, PFS, and OS, respectively). Age as a continuous variable was not a significant predictor of PFS in Cox regression analyses (p=0.53 for the univariate model and p=0.43 for the multivariate model). The incidence of grade 3-4 neutropenia, infection, fatigue, anemia, thrombocytopenia, and neuropathy was similar across all age groups. The rates of dose reduction and discontinuation due to AEs were also comparable across groups (Table). Dose intensity across the age subgroups was: 64%, 59%, and 59% in patients aged <65, 65-75, and >75 years, respectively (Table 1). **Conclusions.** Despite the small number of patients aged >75 years, these results suggest that a lenalidomide starting dose of 25mg (days 1-21 of a 28-day cycle) is effective and adequately tolerated in elderly MM patients with normal renal function, regardless of age. However, careful monitoring and dose adjustments are warranted at the physician's discretion, especially for patients >75 years.

Table 1. Outcomes in elderly patients with relapsed or refractory multiple myeloma and normal renal function (creatinine clearance ≥60mL/min).

	<65yr (n=158)	65-75yr (n=70)	>75yr (n=11)

A STATISTICAL COMPARISON OF THE EFFICACY AND SAFETY OF LOW-DOSE LENALIDOMIDE + LOW-DOSE DEXAMETHASONE WITH FULL-DOSE LENALIDOMIDE + DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA (RRMM)

H Quach[1], L Fernyhough[2], R Henderson[3], G Corbett[4], D Honemann[5], H Blacklock[6], P Browett[7], E Link[8], L Cowan[8], J Li[5], A Swern[5], M Hussein[5], K Lynch[5], M Dimopoulos[9], M Prince[8]

[8]Peter MacCallum Medical Centre, Melbourne, Australia
[9]University of Athens School of Medicine, Alexandra Hospital, Athens, Greece

Background. Two pivotal phase 3 trials, MM-009 and MM-010 established lenalidomide + dexamethasone (RD) as a standard of care for RRMM patients. However, elderly patients or those at high risk of myelosuppression may be susceptible to toxicities necessitating dose reductions/disruptions and treatment cessation. Interim results from the phase 2 RevLite study suggested that low-dose lenalidomide and low-dose dexamethasone (rd) may achieve similar efficacy with improved tolerability vs RD in patients at high risk of myelosuppression. An initial retrospective comparison with a subset of MM-009/010 patients who met RevLite entry criteria was performed. **Aims**. Compare results from an updated interim analysis of RevLite with those from a subset of MM-009/010 patients who met RevLite enrollment criteria. **Methods.** In RevLite (N = 150), patients received 15 mg lenalidomide for 21 days of a 28-day cycle plus 20 mg dexamethasone on days 1-4, 9-12, and 17-20 for cycles 1-4 and days 1-4 in subsequent cycles until disease progression or unacceptable adverse events (AEs). In the active arm of MM-009/010, patients received a similar schedule, except lenalidomide was given at 25 mg and dexamethasone at 40 mg. A total of 255 RD-treated patients from MM-009/010 were included in this analysis that met ≥ 1 of the following RevLite eligibility criteria: age ≥ 60 years, creatinine clearance (CrCl) ≤ 60 mL/min, platelets ≤ 75 × 10^9/L. Progression-free survival (PFS), time to progression (TTP), and OS were evaluated using Kaplan-Meier methods and the log-rank test. OS was adjusted for baseline covariates using

Cox regression analyses. **Results**. Patient characteristics were similar other than prior thalidomide (rd 65% vs RD 36%). After median follow-up of 18.7 (rd) and 30.0 (RD) months, overall response rates (rd 69% vs RD 60%), median PFS (rd 10.4 vs RD 11 months), and TTP (rd 12.5 vs RD 13.1 months) were similar. Median OS was 30.6 months for rd and 34.8 months for RD, *P* = .02 (log-rank, Kaplan-Meier); adjusting for baseline covariates, HR = 0.59 (0.42, 0.82) for RD vs rd, *P* = .002 (Cox regression). Patients receiving rd had a lower incidence of grade 3/4 AEs vs RD, including neutropenia (27% vs 41%), thrombocytopenia (7% vs 16%), and thrombotic events (3% vs 13%). Lenalidomide dose reductions were 34% vs 46% and dexamethasone dose reductions were 41% vs 31% for rd and RD, respectively. Duration of treatment was shorter with rd vs RD (7.3 vs 9.2 months). Similar efficacy and safety outcomes were observed for patients with CrCl ≤ 60 mL/min. **Conclusions**. In patients who are elderly and/or have renal impairment or thrombocytopenia, rd is a reasonable option with improved tolerability. In view of the potential survival advantage associated with the full dose regimen, risk-benefit should be considered when choosing the dose of lenalidomide and steroids. Standard-risk patients should receive the approved RD dosing demonstrated to improve PFS and OS in two large randomized studies.

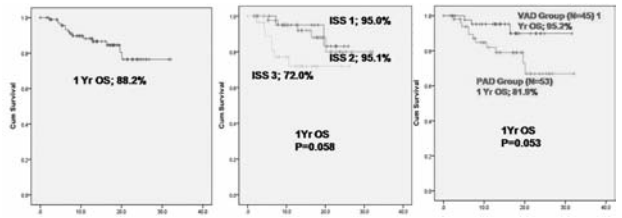
Background. Induction treatment followed by ASCT is the standard therapy for the newly diagnosed younger patients with MM. Although new drugs such as lenalidomide or bortezomib have been shown the promising results as induction treatment, many different type of induction treatment regimens still have been used. We evaluate the efficacy and safety of the short course of high dose dexamethasone (HD dexa) and the response adapted PAD (Bortezomib, Adriamycin, Dexamethasone) or VAD induction chemotherapy in the newly diagnosed younger patients with MM. **Methods.** 125 newly diagnosed patients with MM from 21 institutions received 2nd cycles of HD dexa followed by PAD or VAD chemotherapy according to the response to the initial high dose dexamethasone. The primary endpoint was complete response (CR) + near CR rate after ASCT. Among 125 patents enrolled this study from November 2009, 27 patients (22%) have been dropped out. This trial will be continued until total 210 patients will be enrolled. The trial is registered on National Cancer Institute website, number NCT01255514. **Results**. 125 patients (67 male, 58 female) were enrolled (median age; 56). 30 (24%) light chain disease were included. 34 (27%) patients were D-S stage II and 82 (66%) were stage III. According to the ISS, 27 (22%) patients had stage I, 59 (47%) had stage II and 39 (31%) had stage III. 26% patients had abnormal cytogenetics. There were 29% del13, 7% del17, 19% t(4;14), 14% t(14;16) and 25% t(11;14) in FISH analysis. Among the 98 evaluable patients, CR + PR rate was 46% (45/98) after 2nd cycles of HD dexa therapy. 45 patients (46%) received subsequent VAD chemotherapy and 53 patients (54%) received PAD chemotherapy. Among the 85 patients finished VAD or PAD chemotherapy, CR + PR rate was 80% (79%, 32/41 in VAD group vs. 80%, 36/44 in PAD group). 75 patients were finished ASCT until now. CR + near CR rate after ASCT were 75% (71% in VAD group vs. 80% in PAD group). Mortality rate during the treatment was 7% (7/98). The cause of death was disease progression (n=1), bleeding (n=1) and infections (n=5). Among 98 patients in whom VAD or PAD chemotherapy was actually performed, 1 year overall survival (OS) rate was 89.2%. 1 year survival rate was 95.2% vs. 81.9% (P=0.052) with VAD vs. PAD (median follow-up; 13.7 months). **Conclusions**. Risk adapted approach using initial steroid response showed good response results after ASCT compared with previous trial (CR + near CR rate of IFM 2005-01 trial-Bortezomib+dexa induction & ASCT was 35%, J Clin Oncol. 2010;28:4621-9) The MM patients who had poor response to HD dexa also showed similar good response rate after ASCT compared with the patients

who had good response to HD dexa treatment in this trial. PAD re-induction therapy after failure of initial steroid induction treatment might overcome the inferior results in the high risk MM patients. Therefore, initial steroid response adapted strategy might be the more cost-effective and might reduce the burden of induction therapy for lower-risk newly diagnosed ASCT eligible MM patients.



0856

BOTH HEMATOLOGIC AND RENAL RESPONSE AFFECT OVERALL SURVIVAL OF MYELOMA PATIENTS WITH ACUTE KIDNEY INJURY

R Allchin[1], F Bridoux[2], S Kumar[3], M Cook[1], S Rajkumar[3], L Ecotiere[2], H Ludwig[4], C Hutchison[1], N Leung[3]
[1]University Hospital Birmingham, Birmingham, United Kingdom
[2]University Hospital Poitiers, Poitiers, France
[3]Mayo Clinic, Rochester MN, United States of America
[4]Wilhelminen Hospital, Vienna, Austria

Background. Acute kidney injury (AKI) is a common but serious sequela of multiple myeloma. Recently, the International Myeloma Working Group (IMWG) introduced a new renal response criteria with complete (CRenal), partial (PRenal) and minimal (MRenal) responses. This study compares the IMWG criteria with other models to determine their correlation with overall survival (OS). **Methods.** Patients with AKI (serum creatinine (Scr) ≥2.0 mg/dl) complicating multiple myeloma were identified from international centers. OS was calculated from the day of AKI. Renal function was assessed by eGFR using the MDRD method. Hematologic response was the best achieved as assessed by International Uniform Response Criteria for Multiple Myeloma. Separate analyses were performed on the newly diagnosed (ND) patients versus previously treated (PT) patients.

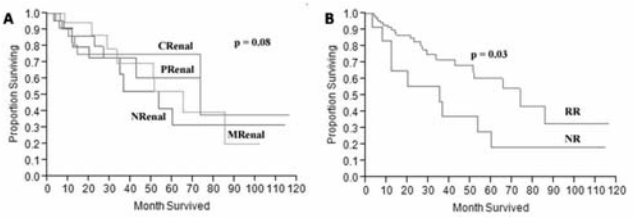


Figure 1. (A) Overall survival (OS) of 115 patients evaluated by the IMWG renal response criteria. OS was not significantly different by Log-Rank test between patients with CRenal and NRenal, p = 0.08. (B) In a separate model, 85 newly diagnosed patients with hematologic response of PR or better were evaluated. Patients who were dialysis independent achieved a renal response (RR) and those who remained on dialysis had no response (NR). Patients with RR had a superior overall survival than patients with NR. Renal response was independent of a hematologic response of PR or better.

Results. A total of 143 patients were collected of these 115 were ND, median age was 64 (34-87) years and 58.7% were male. Median Scr was 5.1 (2.0 to 18.6) mg/dl and eGFR was 10.6 (2.8-36.5) ml/min/1.72m^2. Dialysis was required in 49.3%, and 72.9% were dialysis independent at the end of the study. By IMWG criteria, median OS ranged between 6.0 months (m) in PT patients with no renal response (NRenal) to 23.7m in patients with CRenal, p=0.34. In ND patients, OS was 31.4m in NRenal vs 73.8m in CRenal (p=0.08). However, the difference in OS between PRenal and CRenal was not significant, p=0.70 (Figure 1A). If only patients with a hematologic PR or better were analyzed, the OS range was 6.0m in NRenal to 23.7m in CRenal in PT patients (p=0.85) and 36.6m in NRenal to 73.8m in CRenal in ND patients, p=0.73.The best model tested was one that defines renal response (RR) as regaining or maintaining dialysis independence and no response (NR) as dialysis dependence. Patients who achieved RR had a superior survival than NR for both PT patients (13.5m vs 6.0m respectively, p=0.03) and ND patients (73.8m vs 20.1m respectively, p <0.001). RR increased with the depth of hematologic response, p = 0.04. RR occurred in 75% of the PT patients with hematologic PR or better and 66.7% in those with less than PR, p=0.64. In ND patients, RR occurred in 85.7% of those with PR or better and 54.6% of those with PR or less, p=0.003. This may explain the differences in OS when hematologic response was considered. In PT patients with hematologic PR or better, renal response did not improve OS (21m vs 6m, p=0.28) but it remained beneficial in the ND patients (73.8m vs 35.1m, p=0.04, Figure 1B). Renal response was no longer significantly associated with OS for any patient with hematologic response that was VGPR or better. In a multivariate analysis, RR (p=0.001), ND (p <0.001) and PR or better hematologic response (p=0.046) were associated with OS. **Conclusions.** The results of our study suggest renal response is important to OS but the depth of response was not as important. Based on our results, reducing the number of response categories and simplifying the current consensus criteria seems justified.

0857

CARFILZOMIB IS ASSOCIATED WITH A LOW RATE OF TYPICALLY MILD TO MODERATE, NON-DOSE LIMITING TREATMENT-EMERGENT PERIPHERAL NEUROPATHY

T Martin[1], R Vij[2], A Badros[3], P Patel[4], L McCulloch[4], S Jagannath[5]
[1]University of California San Francisco, San Francisco, United States of America
[2]Washington University School of Medicine, St. Louis, United States of America

[5]Mount Sinai Medical Center, New York, United States of America

Background. Patients with multiple myeloma (MM) often experience debilitating peripheral neuropathy (PN) as part of their disease progression, and many drugs used to treat MM can worsen or cause painful, treatment-limiting PN. Identifying next-generation agents that demonstrate minimal treatment-emergent PN is critical. Carfilzomib, a proteasome inhibitor being evaluated for the treatment of relapsed and/or refractory MM, has demonstrated less neurodegeneration than bortezomib in pre-clinical models, and early clinical studies of carfilzomib suggest a favorable PN profile. **Aims**. To further assess treatment-emergent PN following therapy with single-agent carfilzomib, a cross-trial analysis of 526 patients from 4 phase 2 studies, many of whom had baseline PN or a history of PN, has been performed and the results provided herein. **Methods.** Patients receiving carfilzomib in the following trials are included in this analysis: PX-171-003-A0, PX-171-003-A1, PX-171-004, and PX-171-005. In all studies, carfilzomib was dosed on Days (D) 1, 2, 8, 9, 15, and 16 of a 28-day cycle (C). Doses were 20 mg/m^2 in C1, escalating to 27 mg/m^2 in C2 as defined per individual protocol for all studies except 005 (C1, C2, C3 were 15, 20, 27 mg/m^2 respectively). Assessments for these patients included neuropathy history and baseline neuropathy status, along with directed neurologic physical exams and FACT/GOG-Ntx v 4.0 questionnaires at screening and on D1 of Cycles 3, 5, 7, 9, and 11, and at the end of the study. Assessment of PN was based on an aggregate of PN terms, including peripheral neuropathy, neuropathy, peripheral sensory neuropathy, and peripheral motor neuropathy. **Results**. The majority of patients (84.8%) in these studies had medical histories significant for PN in prior treatments (42.6% due to bortezomib and 43.3% due to thalidomide, which resulted in discontinuation of those treatments in 25.9% and 21.1% of patients, respectively). During treatment with carfilzomib, PN occurred infrequently (13.9% overall) across all studies. Of 526 patients, 41 (7.8 %) experienced Grade 1 PN, 25 (4.8 %) Grade 2 PN, and 7 (1.3%) Grade 3 PN. Notably, no ≥Grade 4 PN was reported. In response to a PN-related AE, 1 (0.2%) patient discontinued treatment and 4 (0.8%) required a dose modification. Although 378 (71.9%) patients had active PN at baseline (all Grade 1 or Grade 2), the majority (87.3% [330/378]) did not report AEs related to PN at any time on treatment or within 30 days of last dose. **Conclusions**. In contrast to currently approved MM therapies,carfilzomib is associated with a low rate of mild to moderate, non-dose-limiting PN, causes a low rate of treatment-emergent PN in patients with a history of PN, and does not exacerbate PN in patients with pre-existing neuropathy. Dose modifications and discontinuations due to PN are extremely low, allowing for longer duration of treatment for MM.

[8]Sezione di Ematologia e Immunologia Clinica, Perugia, Italy
[9]Ematologia, Pisa, Italy
[10]Ematologia Binaghi, Cagliari, Italy

Background. Bendamustine is a bifunctional purine analog/alkilator hybrid compound having no-cross resistance to other alkylating agents and that proved to be effective either in relapsed/refractory and in naïve MM as single agent or combined with steroids. In vitro, Bendamustine showed additive/synergistic activity with bortezomib which in turn synergizes with dexamethasone. **Aims.** The primary objective of this phase II, multicenter study was to assess the activity (response rate ≥ PR after 4 cycles) and the toxicity of the BVD combination. Secondary end-points were best response at the end of therapy, PFS and OS. **Methods.** Patients pre-treated with no more than 4 regimens, not refractory to bortezomib and with adequate laboratory tests, received Bendamustine 70 mg/m^2 on days 1 and 8, Bortezomib 1.3 mg/m^2 on days 1, 4, 8, 11 in the first 2 cycles and 1.3 mg/m^2 on day 1, 8, 15, 22 thereafter, Dexamethasone 20 mg the same day and the day after bortezomib every 28 days for 4 cycles of induction. Patients who obtained less than PR went off-study whereas those achieving at least PR after induction received 2 additional cycles every 28 days and thereafter other 6 cycles every 56 days as consolidation. Antimicrobial prophylaxis with acyclovir and thrimethoprim-sulfamethossazole was mandatory while G-CSF and EPO could be administered on demand. Response and toxicity were assessed according to IMWG and CTCAE version 3 criteria, respectively. According to Fleming method, 70 patients would have to be recruited to demonstrate a PR rate of 60% with 80% of power and 5% of type 1 error. This is a not pre-planned interim analysis. **Results.** As February 25, 2012, a total of 44 patients were enrolled in 11 Italian Centres. Thirty patients completed at least one cycles and are evaluable for response and toxicity. Median age was 69.5 years (range 53-83) and 11 patients (36%) had PS (WHO) = 2. Twenty-two patients had ISS stage ≥ 2, 8 (27%) had renal insufficiency and 10 (33%) had received ≥ 2 prior regimens. All patients had been just treated with regimens containing new-drugs (50% thalidomide, 57% lenalidomide, 40% bortezomib, 40% two new-drugs) and 50% had received alkylators. Seven patients underwent one cycle, 4 two cycles, 3 three cycles and 16 four cycles. At least PR was obtained in 23 patients (77%). Five patients (17%) achieved CR, 6 (20%) VGPR and 12 (40%) PR and 3 (10%) SD whereas 4 (13%) progressed. Grade 3-4 adverse events comprised 30% thrombocytopenia, 17% anemia, 10% neutropenia, 13% infections. Only 1 patient developed grade 3 peripheral neuropathy; another 2 had severe cardiac and liver toxicity, respectively. There were 2 early deaths due to pneumonia with septic shock and 1 sudden death during 2nd cycle. Only one patient discontinued therapy because of toxicity and 4 patients (13%) reduced therapy mainly due to hematologic toxicity. **Conclusions.** BVD combination shows a remarkable anti-myeloma activity in patients previously treated with any new-drugs with manageable hematological and non-hematological toxicity. Pneumonia represented the main, sometimes fatal, complication warranted adequate prophylaxis.

Background. Outcomes of patients in clinical trials often differ from those of patients in daily clinical practice. The safety and tolerability of novel treatments for multiple myeloma (MM) in the "real-world"setting are important considerations, but have been insufficiently investigated. **Aims.** To evaluate the tolerability of lenalidomide, bortezomib, and thalidomide as salvage therapy for patients with relapsed or refractory MM (RRMM). **Methods.** This multicenter, observational, non-interventional post-authorization safety study included patients with RRMM who had received at least one prior therapy and were commencing a new treatment. Patients were enrolled into the lenalidomide cohort (lenalidomide plus dexamethasone, the approved combination for the treatment of RRMM) or background. cohort (all other treatments, including other novel agents) at the investigator's discretion. Thromboprophylaxis was allowed, but not mandated. Assessments for second primary malignancies (SPM) were to be conducted up to 36 months after treatment discontinuation. **Results.** As of November 2011, 768 RRMM patients were enrolled at 54 institutions in Italy. Of these, 510 received lenalidomide, 219 bortezomib, 13 thalidomide, and 26 other therapies. In the background. cohort, 26 patients crossed over to lenalidomide. The median follow-up was 25 weeks (range, 0.6-117.4), the median age was 70years (range, 40-95), and 53% of patients were male. Most patients had a good performance status (ECOG 0-1), while 22.1% had an ECOG score of 2-4. All patients were heavily pre-treated; overall, the median number of prior treatments was 2 (range, 0-6), 33% had received 2 prior treatments and 19% had received ³3; 35% had undergone autologous stem cell transplantation. In the lenalidomide group, 59% of patients received ³2 prior treatments, while 35% of bortezomib-treated patients and 31% of thalidomide-treated patients had ³2 prior regimens. Baseline characteristics were similar across groups. The incidence of grade 3-4 and serious AEs is reported in the Table. Notably, the incidence of end-stage renal disease (ESRD) was similar in the lenalidomide and bortezomib groups (5.1% and 4.1%, respectively); 2 thalidomide-treated patients had ESRD. Venous thromboembolism (VTE) occurred in 5% of lenalidomide-treated patients (2% grade 3-4) and 1% of bortezomib-treated patients. Peripheral neuropathy (PN; all grades) was observed in 28% of bortezomib-treated patients and 10% of lenalidomide-treated patients; 4% and 2% grade 3-4, respectively. In total, 61% of patients discontinued lenalidomide therapy, while 80% and 77% of patients discontinued bortezomib and thalidomide, respectively. Primary reasons for treatment discontinuation were overall AEs and disease progression. Incidence of SPM was very low (0.1%), with 1 case of leukemia in the lenalidomide group. Overall, patients had favourable prognoses; only 1% of deaths due to AEs were thought to be treatment-related (lenalidomide, 1%; bortezomib, 1%; thalidomide, 0%). **Conclusions.** Lenalidomide plus dexamethasone is associated with survival benefit in clinical trials of RRMM. In this "real-world"study, ESRD did not impact ini-

tial treatment choice. Incidence of AEs was similar across treatment groups, with the exception of higher rates of PN and VTE in bortezomib and lenalidomide-treated patients respectively. Only one SPM has been observed to date.

Table. Incidence of adverse events (%).

AEs, (%)	Lenalidomide (n = 510)	Bortezomib (n = 219)	Thalidomide (n = 13)
Any grade 3–4 AE	44	32	23
Drug-related grade 3–4 AE	30	23	8
Drug-related serious AE	10	3	8
AE leading to death	7	5	0
All-grade VTE	5	1	0
Grade 3–4	2	0	0
All-grade PN	10	28	0
Grade 3–4	2	4	0
Discontinuation	61	80	77
Due to AEs	10	12	15
Due to progressive disease	18	12	31

AE, adverse event; PN, peripheral neuropathy; VTE, venous thromboembolism.

FLOW CYTOMETRY AS A PREDICTIVE TOOL FOR TRANSFORMATION OF MGUS INTO MM

L Rihova[1], V Sandecka[1], T Varmuzova[2], M Klincova[1], P Zarbochova[1], A Mikulasova[2], M Almasi[2], R Suska[1], M Penka[1], R Hajek[2]
[1]University Hospital Brno, Brno, Czech Republic
[2]Babak Myeloma Group, Dept. of Pathological Physiology, Masaryk University, Brno, Czech Republic

Background. Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant state with possibility of the transformation into multiple myeloma (MM). Traditional prognostic parameters have limited sensitivity and specificity to predict transformation within 3 years from time of diagnosis. MGUS is characterised by presence of mixture of normal $CD19^+$ and abnormal $CD19^-$ plasma cells (PCs). Disappearance of $CD19^+$ PCs should correlate with transformation, but there are other markers exist which could be useful in prediction of transformation MGUS into MM. **Aims.** Flow cytometry analysis of surface antigens and their comparison with standard prognostic factors to predict possibility of transformation MGUS into MM. **Methods.** Analysis of 150 untreated MGUS cases in time of diagnosis was done. Number of $CD19^+$ B cells and $CD38^+CD138^+$ PCs was analysed in whole bone marrow. Expression of CD19, CD56, CD20, CD27, CD28 and CD117 on PCs was analysed by flow cytometry. Parameter $CD19^-$ PCs is equivalent to abnormal PCs. Flow cytometry results were compared with standard prognostic factors. **Results.** Transformation of MGUS into MM was found only in 9 subjects. These have statistically decreased number of B cell [7.0% (0.0-23.7) vs. 13.3% (1.2-68.4); p<0.02], increased number of PCs [1.0% (0.2-8.8) vs. 0.4% (0.0-4.2); p<0.01] and decreased number of normal $CD19^+$ PC [3.8% (0.9-33.4) vs. 25.9% (0.2-87.2); p<0.002] when compared to subjects without transformation. There were found non-significant decrease of CD27 and increase of CD56 expression on PCs in transformed group. Surprisingly, there was found almost IgG isotype of clonal immunoglobulin (MIG) in 93.5% (29/32) subjects with $CD28^+$ PCs. Significantly higher MIG concentration (>15g/l) was found only in cases with $CD19^+$ PC ≤5% (p=0.001), but abnormal FLC index was found already when $CD19^+$ PC <20% (p=0,017). Subjects with $CD19^+$ PC ≤5% were more frequently presented in high medium risk group when compared to subjects with $CD19^+$ PC >5% presented more frequently in low medium risk group (p=0.009). When analysed connection between parameter "$CD19^+$ PC ≤5%" and progression into MM, this parameter was able to predict progression with 55.6% sensitivity and 91.2% specificity (p=0.019). **Conclusions.** Flow cytometry in analysis of MGUS cases seems to be helpful approach. The most powerful factor is presence and/or loss of CD19 on PCs. Decrease of relative count of $CD19^+$ PC under 5% (from whole PC population) can predict possibility of transformation into MM what is in concordance with previously published results.

BORTEZOMIB-BASED THERAPY INCREASES THE INCIDENCE OF POST-TRANSPLANT VIRAL INFECTIONS IN MULTIPLE MYELOMA PATIENTS UNDERGOING AUTO-SCT: A RETROSPECTIVE ANALYSIS FROM THE ROME TRANSPLANT NETWORK

F Marchesi[1], A Mengarelli[2], S Angelini[3], F Giannotti[3], R Porrini[4], A Picardi[3], A Chierichini[5], E Cerchiara[1], T Dentamaro[6], L Cudillo[3], B Anaclerico[5], A Tendas[6], E Montefusco[4], A Romano[2], M Tirindelli[1], P De Fabritiis[6], L Annino[5], M Petti[2], B Monarca[4], G Avvisati[1], W Arcese[3]

[4]Hematology Unit, S. Andrea Hospital, Rome, Italy
[5]Hematology Unit, S. Giovanni-Addolorata Hospital, Rome, Italy
[6]Hematology Unit, S. Eugenio Hospital, Rome, Italy

Background. The recent large use of proteasome inhibitors (i.e. Bortezomib) and immunomodulator agents (i.e. Thalidomide and Lenalidomide) in pre-transplant treatment has determined an increase in the global incidence of viral infections in MM patients. On the contrary, multiple myeloma (MM) patients undergoing conventional chemotherapy with VAD (Vincristine, Doxorubicin and Dexamethasone) followed by autologous hematopoietic stem cell transplantation (AutoSCT) have a relatively low risk of post-engraftment viral infection by herpesviridae family viruses (Cytomegalovirus, CMV; Varicella-Zoster Virus, VZV; Herpes Simplex Virus 1 and 2, HSV1-2). **Aims**. The aims of the present study were: 1) to establish the post-engraftment incidence of viral infection in MM patients undergoing AutoSCT after treatment with proteasome inhibitors and immunomodulator agents; 2) to perform a retrospective comparison with patients treated with only VAD regimen before AutoSCT. **Methods.** We performed a retrospective analysis on 80 consecutive adult patients (median age 54 years, range 38-69) with a diagnosis of MM who underwent AutoSCT following treatment with proteasome inhibitors and/or immunomodulator agents in the Hematology Institutions participating in the Rome Transplant Network (RTN) from January 2008 to July 2010 (Group A). Eighty-nine MM patients with similar characteristics who underwent AutoSCT in the RTN after treatment with conventional chemotherapy from January 2004 to January 2008 represented the control group (Group B). **Results.** In group A, 53/80 patients (66.2%) were treated with Bortezomib (with or without immunomodulator agents) and 27/80 (33.8%) with only immunomodulators agents. Overall, in this group, 9 patients received a specific antiviral therapy for a viral infection after AutoSCT (CMV n=6, VZV n=2, HSV n=1) with a global incidence of 11.3%. Of these 9 patients, 6 were treated with a specific antiviral therapy for a symptomatic CMV infection. No cases of end-organ disease according to published criteria were observed. The global incidence of viral infections and CMV symptomatic infections was significantly higher in group A than in group B. In particular, viral infections incidence was 11.3% vs 2.2% (P=0.026) and CMV symptomatic infection incidence was 7.5% vs 1.1% (P=0.05) in group A and B respectively. Transplant-related mortality (TRM), neutrophils and platelets engraftment and clinical outcome were similar in the two groups. Considering separately the 53 patients who received a Bortezomib-based regimen prior to AutoSCT, the incidence of viral infections and CMV symptomatic infections was significantly higher when compared with that of patients not given Bortezomib before AutoSCT. In particular, viral infection incidence was 13.2% in the Bortezomib group vs 3.4% in the remaining patients (P=0.037) and CMV symptomatic infection incidence was 9.4% in the Bortezomib group vs 1.7% in the remaining patients (P=0.032). **Conclusions.** From our retrospective analysis, MM patients treated with novel agents and in particular with Bortezomib-based therapy seem to be at higher risk to develop clinically relevant herpesviridae family infections, in particular from CMV, after AutoSCT compared with patients treated with conventional pre-transplant chemotherapy. A post-AutoSCT monitoring for viral infection could be recommended in these patients in order to start promptly a specific antiviral therapy.

HIGH DOSE THERAPY AND ASCT AS CONSOLIDATION AFTER SECOND LINE TREATMENT OF MULTIPLE MYELOMA RELAPSED AFTER FIRST LINE ASCT: ANALYSIS OF PROGNOSTIC FACTORS

C Crippa, S Ferrari, F Antoniazzi, F Schieppati, C Pagani, A Peli, G Rossi
Spedali Civili Brescia, Brescia, Italy

Background. Baseline clinical and laboratory findings have been identified as prognostic factors and for risk stratification of newly diagnosed pts. Few studies have been performed exploring this aspects at relapse. **Aims**. To analyse impact of characteristics at first relapse on PFS after second line therapy of a consecutive series of relapsed MM pts receiving up-front ASCT. **Methods** .In 217 MM pts treated at our Institution between 1997 and 2009 with first-line HD-Mel and ASCT, relapse occurred in 160 pts (74%).As induction therapy before ASCT, 177 (82%) had received VAD and 40 (18%) thalidomide (T)/bortezomib **-based regimens. Ninetyfive (44%) had received double ASCT. Second-line therapy was given to 137 (86%) pts: in 94 (69%) with** based regimens only, in 43 (31%) with ASCT as consolidation after TB-regimens (n 28) or chemotherapy (n 15). Median follow-up from diagnosis was 60 mo (12-168). CR/VGPR and ORR after first line therapy was 59% and 94%.The following characteristics at relapse were considered potential prognostic factors: gender, age (>65 vs <65), serum and urine monoclonal component, bone marrow plasmocytosis, ISS (I vs II-III), bone progression, haemoglobin (>10 g/dl vs < 10 g/dl) and creatinine (> 2 mg/dl vs < 2 mg/dl) level, hypercalcemia, response after second-line therapy (>VGPR), type of second line therapy (ASCT as consolidation vs TB-regimens only), time of relapse after first line therapy (> 12mo vs < 12mo). **Results**. CR/VGPR and ORR (CR+VGPR+PR) after second line therapy were 27% and 64% respectively. After a median follow-up from second line therapy of 51 months (11-168 mo), 2 yrs PFS was 20% (median 15 mo) and 2 yrs OS 69% (median 37 mo).CR/VGPR rate and PFS was significantly better after ASCT consolidation than after TB regimens only (CR/VGPR 47% vs 18%, median PFS 16 vs 11 mo- p 0.036).At univariate analysis female sex, low haemoglobin level, hypercalcemia, high ISS, relapse < 12mo after first line therapy, < VGPR after second line therapy and TB regimens adversely affected the duration of PFS. At multivariate analysis high ISS and < VGPR after salvage therapy retained independent adverse prognostic value (p 0.002). **Conclusions**. Our study confirm ISS at relapse and the quality of response to therapy as important prognostic factors also in the relapse setting. ASCT after second-line treatment increased CR/VGPR rates and significantly impacts on PFS. It should be considered a valid therapeutic adjunct in patients who do not achieve a VGPR after second-line TB regimens.

0863

AMONG MICROENVIRONMENTAL CYTOKINES WITH BIOLOGIC ACTIVITY IN MULTIPLE MYELOMA (MM), ONLY SERUM SOLUBLE SYNDECAN-1 CORRELATES WITH FLCR; SUGGESTED ROLE IN FLC SECRETION CONTROL

[5]Metaxa Anticancer Hospital, Department of Hematology, Athens, Greece
[6]Agios Savvas Anticancer Hospital, Department of Hematology, Athens, Greece

Background. The mechanisms of FLC inappropriate over-secretion by malignant plasma cells are unknown and probably relate to genetic and/or microenvironmental factors. **Aims.** To study any possible correlation between multiple myeloma (MM) patients' serum FLC and FLCR levels and serum cytokines with a well-known involvement in MM biology, namely soluble syndecan-1 (s-synd-1), IL-6R, VEGF, bFGF, TGF-beta, IGF, MIP-1alpha, OPG, RANKL, MMP-2, MMP-9, and BLyS. **Patients and Methods.** In 181 MM patients with available frozen serum aliquot collected at diagnosis, serum cytokine levels were retrospectively determined by ELISA KITs according to the manufacturers' instructions; resulted values were correlated with baseline serum FLC and FLCR. Serum FLCs were measured by nephelometry (FREELITE, The Binding Site Ltd. Birmingham, UK). The light chain ratio (sFLCR) κ/λ or λ/κ was built with the uninvolved LC as denominator. Statistical analysis was performed by standard **Methods.** Differences were considered of statistical significance when p values were below 0.05. **Results.** Serum s-synd-1 levels, determined in 155/181 ranged from 7 to 5070 ng/ml (median, 85 ng/ml), IL-6R (in 91) from undetectable to 43301 pg/ml (median, 5949 pg/ml), VEGF (in 100) from undetectable to 4000 pg/ml (median, 210 pg/ml), bFGF (in 66) from 3 to 60 pg/ml (median, 10 pg/ml), TGF-beta (in 42) from 1350 to 99000 pg/ml (median, 61500 pg/ml), IGF (in 61) from 13 to 260 pg/ml (median, 84 pg/ml), MIP-1alpha (in 97) from 14 to 100 pg/ml (median, 32 pg/ml), OPG (in 87) from 820 to 25000 pg/ml (median, 3100 pg/ml), RANKL (in 59) from 0.08 to 10 pmol/L (median, 0.19 pmol/L), MMP-2 (in 57) from 84 to 700 pg/ml (median,250 pg/ml), MMP-9 (in 69) from 53 to 1000 pg/ml (median, 230 pg/ml), and BLyS (in 102) from undetectable to 3482 pg/ml (median, 155,5 pg/ml). Involved serum FLC and FLCR values strongly correlated with s-synd-1 (p=0.008 and <0.0001 respectively) while no statistical significant correlation was found for all other cytokines studied although some of them shared with FLC, FLCR and s-synd-1, prognostic information. Likewise an inferior overall survival was observed in patients with FLC (p=0.001), FLCR (p<0001), s-synd-1 (p<0001), sIL-6R (p=0.02), BLyS (p=0.04), IGF-1 (p=0.04, inversed), RANKL (p=0.006, inversed), MMP-2 (p=0.001) serum levels above median. **Conclusions**. The strong relationship between s-synd-1 and FLC or FLCR, that was not observed with the other cytokines studied, suggest a biological involvement of syndecan-1 in FLC secretion's modulation.

0864

IN PATIENTS WITH MYELOMA AND RENAL FAILURE FREE LIGHT CHAIN LEVELS (SFLC) CAN BE REDUCED GREATLY WITHIN 2 WEEKS AND LOWER SFLC LEVELS ARE ASSOCIATED WITH A BETTER CHANCE OF RENAL RECOVERY

M Drayson[1], J Behrens[2], D Cohen[3], N Iggo[4], S Bell[3], G Jackson[5], W Gregory[3], G Gaskin[6]

[5]Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom
[6]Imperial College Faculty of Medicine, London, United Kingdom

Background. In patients presenting with myeloma and renal failure the aetiology of renal damage is multi-factorial but serum immunoglobulin free light chains (sflc) from the malignant clone are the predominant cause. Particularly in patients on dialysis sflc measurements are superior to urine flc measurements in determining the flc load that the kidney is exposed to. Since 2002 it has been possible to quantitate the levels of sflc in routine clinical practice. **Aims.** In a prospective study we measured levels of sflc at diagnosis and serially thereafter to determine if lower sflc levels are associated with a higher chance of renal recovery. Accordingly we attempted to maximise rapid reduction of sflc and to measure that reduction. All patients received dexamethasone alone for two weeks from entry to the trial. Additionally they were randomised to receive 7 plasma exchanges or not. **Methods.** The UK MERIT trial recruited 78 newly diagnosed myeloma patients with acute renal failure unresponsive to treatment with fluid and/or treatment of hypercalcaemia with bisphosphonate (creatinine >500mmol/l, urine output <400 ml/d or requiring dialysis). 40 patients were randomised to no plasma exchange (PE) and 38 to PE; 7 plasma exchange treatments by cytocentrifugation or plasma filtration (days 1-14; 4 in days 1-7). All patients received dexamethasone 40 mg days 1-4 and 9-12 and from day 17-100 chemotherapy as specified at randomisation by the treating clinician. The primary end point was the proportion of patients alive and dialysis-independent at 100 days. Serum flc levels (mg/l) were measured centrally on days 0, 5, 10, and 17 and these levels compared between the 22 patients who were alive and dialysis free at day 100 and the 56 patients who were not. **Results.** In the PE group at 100 days 11 (28.9%) patients were alive and dialysis Independent, 17 (44.7%) were alive and dialysis dependent, 7 (18.4%) were dead and 3 (7.9%) missing data.In the No PE group at 100 days 11 (27.5%) patients were alive and dialysis Independent, 21 (52.5%) were alive and dialysis dependent, 5 (12.5%) were dead and 3 (7.5%) missing data.There is no evidence of a difference between these two treatment groups (p=0.876).At entry median sflc levels were 6,319 (range 800-57,695) and the median for lowest sflc level in the first 2 weeks was 1655 (191-32767) with no difference between treatment arms. Results show that for every percentage reduction in log-FLC from baseline, the odds of being alive and dialysis independent are 6.6% greater (p-value=0.015). **Conclusions.** Lower levels of serum flc at diagnosis and greater percentage reductions in those levels are associated with improved chance of renal recovery. PE removes large quantities of sflc but across the trial this was insignificant compared to the reduction achieved by dexamethasone. Dexamethasone can achieve rapid hundred fold reductions of flc levels but response is very variable between patients and should be monitored at early intervals to allow consideration of a change of therapy.

0865

HIGH LEVELS OF NEURAL STEM CELL MARKER NESTIN ARE ASSOCIATED WITH 1Q21 GAIN AND PREDICT WORSE RESPONSE TO CONVENTIONAL AND NOVEL THERAPY IN MULTIPLE MYELOMA

H Svachova[1], F Kryukov[2], E Dementyeva[2], L Kubiczkova[2], S Sevcikova[2], P Nemec[2], H Greslikova[2], L Kovarova[3], L Zahradova[4], R Hajek[4]

Backround. Nestin, an intermediate filament protein, is detected in undifferentiated multipotent cells of some embryonic and fetal tissues. During terminal differentiation, nestin expression is diminished but may be reexpressed under certain pathological conditions, such as injury or cancer. Nestin is a suitable diagnostic and prognostic indicator of malignancy and potential cancer stem cells marker in solid tumors. Our recent work confirmed nestin protein as a tumor-specific marker for $CD138^+38^+$ plasma cells (PC) and proved significant higher nestin levels in multiple myeloma (MM) compared with controls without any hematological malignancy. **Aims.** The aim of this study was i) to analyze relationship between nestin expression and cytogenetic aberrations in $CD138^+$PC, ii) to analyze relationship between nestin and standard prognostic parameters and iii) evaluate whether pretreatment levels of nestin predict response to therapy. **Methods.** A total number of 93 newly diagnosed MM patients (36M/47F; median age 70 years) were enrolled in this study. Gene expression of nestin was analyzed by quantitative real-time PCR in 70.9% (66/93) of MM patients and quantified by the comparative ddCt method. Nestin was detected in $CD138^+38^+$PC of 50.5% (47/93) of MM patients and 10 individuals without hematological malignancy by flow cytometry. Nestin levels were assessed as the percentage of nestin-positive PC (%Nes^+PC) and ratio of median fluorescence intensity of nestin (MFI) and isotypic control. $CD138^+$PC of MM patients were analyzed for del(13q14), del(17p53), IgH rearrangement, 1q21 gain and hyperdiploidy by FISH. Pretreatment levels of nestin mRNA and protein were evaluated in MM patients treated with conventional therapy or novel agents without autologous stem cell transplantation. Differences among groups were analyzed by non-parametric Mann-Whitney U test or Kruskall Wallis H test. Correlation was analyzed by Spearman correlation coefficient. **Results.** Significant differences between MM patients and the control group were demonstrated based on %Nes^+PC (98.5 vs. 0.1; $p<0.00001$) and MFI ratio (3.5 vs. 2.0; $p<0.0001$). High %Nes^+PC ($p=0.007$) and MFI ratio ($p=0.012$) were significantly associated with 1q21 gain-positive patients. No correlation between gene or protein expression of nestin and standard prognostic parametres was confirmed. Differences of MFI ratio between patients who achieved at least VGPR and patients with worse response reached only borderline significance ($p=0.053$). Patients who achieved ≥VGPR had lower nestin expression compared with patients who achieved ≤PR [median RQ 1.3(0.6-3.9) vs median RQ 4.6(1.7-152.0); $p=0.001$]. **Conclusions**. MM patients have significantly higher levels of nestin protein and percentage of Nes^+PC compared with the control group. The association with 1q21 gain may be explained by the fact that nestin gene is located at 1q23.1 and gain of whole q-arm of chromosome 1 is found in most MM patients. Relationship between nestin and other prognostic parameters was not proved. High levels of nestin mRNA appear to be a potential predictor of worse response in patients treated with conventional therapy or novel agents. This pilot study needs to be further validated on a larger cohort of patients.

Background. Lenalidomide is an effective antimyeloma therapy that is currently approved in combination with dexamethasone by the US Food and Drug Administration and the European Medicines Agency, as well as in other countries for the treatment of multiple myeloma (MM) patients who have received at least one prior therapy. Although many studies have described the safety of antimyeloma drugs in clinical trials, few have evaluated the tolerability of these agents in daily clinical practice. **Aims.** To characterize the safety profile of lenalidomide and compare the incidence of adverse events (AEs) in patients treated with lenalidomide versus other antimyeloma therapies in daily clinical practice in Spain. **Methods.** This multicenter, observational, non-interventional, post-authorization safety study included patients with relapsed or refractory MM (RRMM) who had received at least one prior therapy and were commencing a new treatment. Patients were enrolled into the lenalidomide cohort (lenalidomide plus dexamethasone, the approved combination for treatment of RRMM) or the background. cohort (all other treatments, including novel agents) at the investigator's discretion. Thromboprophylaxis was allowed but not required.

Table. Incidence of adverse events (AEs) according to NCI-CTCAE (version 3) grading (%).

AEs, (%)	Lenalidomide (n = 323)	Bortezomib (n = 107)	Other, including thalidomide (n = 27)
Any grade 3–4 AE	55	48	44
Drug-related grade 3–4 AE	39	22	19
Drug-related serious AE	16	11	0
All-grade hematologic AE	51	40	44
Grade 3–4			
Neutropenia	24	5	11
Thrombo-cytopenia	14	13	7
Anemia	12	11	4
Drug-related AE leading to death	3	2	0
All-grade VTE	2	0	0
Grade 3–4	1	0	0
All-grade PN	3	23	0
Grade 3–4	1	3	0

Results. As of November 2011, 457 RRMM patients were enrolled in Spain. Of those, 323 received lenalidomide, 107 bortezomib, and 27 other therapies, including 5 patients who received thalidomide or had missing data. Twenty-two patients from the background. cohort crossed over to receive lenalidomide. Baseline characteristics were similar across cohorts. The median age was 71 years (range, 34-90); 53% were female. The median number of prior therapies was 2 (range, 0-6); 70% had received 2 prior therapies and 20% had received 3 or more. Overall, 22% had received prior stem cell transplantation. The median follow-up for all groups was 5.4 months (range, 0.3-28.1). Prior to treatment initiation, baseline neuropathy was reported in 24% of patients who later initiated treatment with lenalidomide and 16% who initiated treatment with bortezomib. The incidence of grade 3-4 and serious AEs is reported in the Table. More lenalidomide-treated patients experienced grade 3-4 neutropenia (24% lenalidomide, 5% bortezomib, 11% other). Peripheral neuropathy (PN; all grades) was observed in 3% of patients treated with lenalidomide and 23% treated with bortezomib; 1% and 3%, respectively, were grade 3-4. VTE was low in both groups. Treatment discontinuations were 65% with lenalidomide, 81% with bortezomib, 82% with other treatments. Primary reasons for discontinuation were AEs (17% lenalidomide, 12% bortezomib, 22% other) and disease progression (16% lenalidomide, 14% bortezomib, 32% other). Incidence of death was similar with all treatments (6% lenalidomide, 8% bortezomib, 5% other). Assessments for second primary malignancies (SPM) were to be conducted up to 36 months after treatment discontinuation; no patient has developed SPM so far. **Conclusions.** In this post-authorization study, AEs observed in patients treated in daily clinical practice in Spain were similar with all treatments, with the exception that PN and neutropenia were higher in patients treated with bortezomib and lenalidomide, respectively.

Myelodysplastic syndromes - Clinical 2

0867

THE CLINICAL IMPLICATION OF SRSF2 MUTATION IN PATIENTS WITH MYELODYSPLASTIC SYNDROME AND ITS STABILITY DURING DISEASE EVOLUTION

SJ Wu[1], YY Kuo[2], HA Hou[3], HF Tien[1]
[1]National Taiwan University Hospital, Taipei, Taiwan
[2]National Taiwan University, Taiepi, Taiwan
[3]National Taiwan Univeristy Hospital, Taipei, Taiwan

Background. Recurrent somatic mutation of *SRSF2*, one of the RNA splicing machinery genes, has been identified in a substantial proportion of patients with myelodysplastic syndrome (MDS). However, its clinical implication and prognostic impact remain to be clarified. **Aims** This study aimed to define the clinical correlations of *SRSF2* mutation in patients with MDS and examine the interactions of this mutation with other genetic alternations. In addition, sequential analysis of *SRSF2* mutation during the clinical follow-ups was performed to evaluate the stability of this mutation in disease progression. **Methods.** In total, 233 MDS patients, comprised 161 males and 72 females with the median age of 66 years, were included for *SRSF2* mutation analysis. Mutations of *SRSF2* and other genes were analysed by polymerase chain reaction (PCR) with direct sequencing. The results were correlated with the patients' clinical characteristics and outcomes. **Results**. *SRSF2* mutation was detected in 34 (14.6%) of the 233 patients. Twenty-five patients had missense mutations including P95H in 13 patients, P95L in nine, P95R in two, and P95A in one. Eight patients had P95_R102del(c.284_307del), a 24 base pair deletion resulting in a 8 amino acid deletion starting from P95. One patient had a novel mutation: P95_D97del (c.283_291del), a 9 base pair deletion that resulted in a 3 amino acid deletion starting from P95. *SRSF2* mutation was closely associated with male gender (19.9% in males vs. 2.8% in females, p=0.001) and older age (median, 74.5 years for *SRSF2*-mutated patients vs. 63.0 years for *SRSF2*-wild patients, p<0.001). It occurred concurrently with at least one additional mutation in 29 patients (85.3%). *SRSF2*-mutated patients had higher incidences of *RUNX1*, *IDH2*, and *ASXL1* mutations (29.4% vs. 10.1%, p=0.004; 20.6% vs. 2.5%, p<0.001; and 47.1% vs. 19.6%, <0.001, respectively). Patients with *SRSF2* mutation had an inferior overall survival (OS) (33.9 months vs. 19.0 months, p=0.010), especially in the lower risk patients defined either by IPSS (low and intermediate-1, 69.3 months vs. 32.0 months, p=0.002), by WHO classification (RA, RARS, RCMD, and RCUD, with/without RS, 93.0 months vs. 28.7 months, p=0.001), or by FAB classification (RA and RARS, 87.4 months vs. 28.7 months, p=0.001). Further exploration showed that the prognostic impact of *SRSF2* mutation might be attributed to its close association with old age. Sequential analyses of *SRSF2* mutation was performed in 173 samples from 66 patients, 37 of whom showed disease progression to higher risk subtypes during follow-ups, including 28 with transformation to AML. The analyses showed that all eight *SRSF2*-mutated patients retained their original mutations, while none of the other 58 *SRSF2*-wild patients acquired a novel mutation during disease evolution. **Conclusions**. *RSF2* mutation occurs more frequently in male and older MDS patients. There is a close association of *SRSF2* mutation with *RUNX1*, *IDH2*, and *ASXL1* mutations. The mutation is stable during the clinical follow-ups; the stability during the clinical course in MDS suggests that *SRSF2* mutation may play little role in disease progression.

0868

INVESTIGATION OF THE IMPACT OF MDS FROM THE PATIENTS' PERSPECTIVE

S McKenna[1], J Twiss[1], J Wilburn[1], S Crawford[1], K Loth[2]
[1]Galen Research Ltd, Manchester, United Kingdom
[2]Celgene, London, United Kingdom

Background. Little research is currently available on the impact of MDS from the patients' perspective. Where research has been conducted it has predominantly used generic cancer outcome measures. Such measures do not provide an accurate assessment of MDS patients as they miss important aspects of the condition.**Aims.** To conduct a qualitative study with MDS patients to investigate how their lives are affected by the condition. **Methods.** Qualitative, unstructured interviews were conducted with patients. Verbatim transcripts of the interviews were analysed thematically to assess the impact of MDS in terms of symptoms experienced, activity limitations and quality of life (QoL). Emergent themes were identified, clustered and harmonised. Investigation of issues related to

impairments and activity limitations were guided by the World Health Organizations (WHO) classification of outcomes related to health and injury. Investigation of QoL issues was guided by the needs-based model of QoL (Hunt SM, McKenna SP. The QLDS: A scale for the measurement of quality of life in depression. (1992). *Health Policy* 22; 307-319).This model identifies several core fundamental needs that are important to an individual's QoL and adjustment to society. Illness affects QoL by preventing the satisfaction of these needs. *Results.* The sample included 30 participants (male 17 (56.7%); mean (SD) age 65.5 (11.3) years; mean (SD) time since diagnosis 5.0 (4.5) years with low to intermediate-1 risk MDS. 30% of the sample were receiving transfusions and 33.3% were not receiving any treatment. The analyses identified several symptoms. The most frequently reported symptoms were; fatigue (97%), breathlessness (60%), increased infections (60%), sleep problems (53%), cognitive problems (50%), temperature fluctuations (47%), increased bruising (40%) and bleeding (10%), pain (30%), depression (23%) and anxiety (10%). Several common functions were affected by MDS, including; standing, walking, bending, lifting, carrying and rising from sitting. Various more complex functions were also affected such as the ability to socialise, shop and do jobs around the house. A total 33 QoL issues were identified. Quality of life issues affected six fundamental needs; physiological, safety and security, social, affection, esteem, cognitive. The QoL impact of the condition is shown in figure 1. **Conclusions.** The study was successful in developing outcome models describing the symptoms, activity limitations and QoL issues associated with MDS. Following this study a large bank of potential items has been created that will aid the development of MDS-specific outcome scales for these three different kinds of outcome.

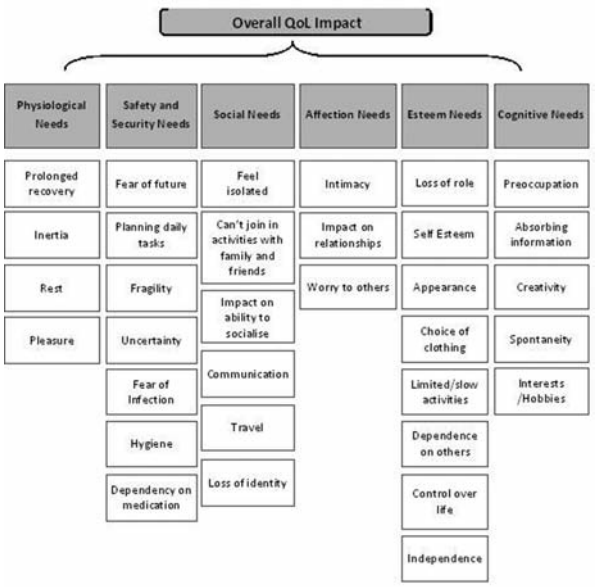

Figure 1. Needs-based QoL impact.

CMML201: A PHASE 2 TRIAL OF AZACITIDINE IN CHRONIC MYELOMONOCYTIC LEUKAEMIA

W Drummond[1], M Boissinot[2], P Cauchy[3], N Cross[4], S Hartley[2], J Kell[5], C Pocock[6], A Szubert[2], J Brown[2], P Cockerill[3], D Bowen[7]
[1]Beatson Oncology Centre, Glasgow, United Kingdom
[2]University of Leeds, Leeds, United Kingdom
[3]Institute of Biomedical Research, Birmingham, United Kingdom
[4]University of Southampton, Southampton, United Kingdom
[5]University Hospital of Wales, Cardiff, United Kingdom
[6]East Kent Hospitals NHS Trust, Canterbury, United Kingdom
[7]St Jame's Institute of Oncology, Leeds, United Kingdom

Background. Chronic myelomonocytic leukemia (CMML) has a poor prognosis and effective therapeutic strategies are lacking. Azacitidine (AZA) is licensed for non-proliferative CMML-2 (in the EU) on the basis of 11 patients randomised in the pivotal AZA-001 study *(Vidaza SmPC, Fenaux et al. Lancet Oncol 2009; 10:223-32)*. We designed a two-stage Phase 2 single-arm, multi-centre study of safety, tolerability and efficacy of AZA in CMML. **Aims and Methods.** 32 patients with CMML-1 (IPSS Int-2 / High Risk, intermediate / high Dusseldorf score, plus marrow failure / myeloproliferation or systemic symptoms) or CMML-2 (new or previously treated, PS≤2), were enrolled after informed consent was obtained. Primary endpoints were safety, tolerability and overall response rate (ORR, according to Wattel *et al,* Blood 1996) at day 28 of the 6th or last cycle of AZA (whichever came first). Secondary endpoints included incidence of complete (CR) or partial remission (PR) and haematological improvement (HI) as per the modified IWG response criteria (Cheson *et al*, Blood 2006). Responses were determined by central review. AZA was administered at a dose of 75mg/m^2 sc for 7 days (days 1-5 and 8-9) every 28 days, up to a minimum of 6 cycles. Responders and patients with stable disease were allowed to continue therapy until loss of response / progressive disease. Mutations were analysed in TET2, ASXL1, EZH2, Cbl and NRAS genes by high resolution melt and/or direct sequence analysis (n=21 evaluable patients). Bone marrow mononuclear cells from 9 patients were analysed at baseline and post course 6 for global methylation using Illumina 454K oligo arrays.

Table. Results of Phase 2 Study of Azacitidine in CMML.

Wattel Response Criteria n(%)		IWG Response Criteria n(%)	
		n=30	
CR	1 (3%)	CR	2 (7%)
GR	2 (7%)	Marrow CR	2 (7%)
MR	10 (33%)	Marrow CR, HI-P	1 (3%)
Stable Disease	2 (7%)	Stable Disease	5 (17%)
Progression	11 (37%)	Progression	9 (30%)
ORR (CR+GR +MR)	*13 (43%)*	Failure	8 (27%)
Died before last cycle (<6)	2 (7%)	HI-E, HI-P	1 (3%)
Not evaluable (<1 cycle)			2 (7%)

CR, Complete remission; GR, Good response; MR, Minor Response; ORR, Overall Response Rate; HI, Haematological Improvement

Results. 30/32 patients received AZA therapy and were suitable for analysis. Median age was 70 years (range 57 to 85); 67% were male. 13 patients (43%) had received prior treatment with hydroxycarbamide. Median number of AZA cycles was 7 (range 1-16). 2 patients (7%) received <1 cycle and were not evaluable. 14 patients (47%) received ≤ 6 cycles. Reasons for stopping were disease progression (7), toxicities, side effects, complications (2), death during treatment (2), AML transformation (1) and other (2). 16 patients (53%) continued therapy beyond 6 cycles. No AZA related deaths were observed; 1 patient (3%) had a grade 3/4 non-haematological adverse event. ORR was 43% (13 patients, see Table). 5/7 patients were able to stop hydroxycarbamide. Of 20 transfusion dependent patients at study entry (blood and / or platelets) 6 became transfusion independent (30%). Of evaluable patients, 15 had TET2 and 6 ASXL1 mutations. 10/15 patients with TET2 mutation responded as compared to 2/6 WT. 6/9 ASXL1 WT patients responded as compared to 3/6 mutated. Several patients displayed decreases in global DNA methylation to varying degrees. Cluster analysis of patients according to DNA methylation status before and after treatment did not reveal any correlations with TET2 mutation status. **Conclusions.** AZA was well tolerated. Clinically meaningful responses (including CR, GR and PR) were limited (10-17% depending on response criteria). These results do not support a Phase 3 study with this agent in CMML.(EUDRACT NUMBER: 2008-006349-23; ISRCTN: 21428905)

0870

UPDATE ON SAFETY AND LONG-TERM OUTCOMES IN LENALIDOMIDE (LEN)-TREATED PATIENTS WITH RED BLOOD CELL (RBC) TRANSFUSION-DEPENDENT LOW-/INT-1-RISK MYELODYSPLASTIC SYNDROMES (MDS) AND DEL(5Q)

E Hellström-Lindberg[1], A Giagounidis[2], D Selleslag[3], M Mittelman[4], P Muus[5], B Benettaib[6], T Fu[6], P Fenaux[7]
[1]Karolinska University Hospital, Stockholm, Sweden
[2]St Johannes Hospital, Duisburg, Germany
[3]AZ St Jan AV, Brugge, Belgium
[4]Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel
[5]Radboud University Medical Centre, Nijmegen, Netherlands
[6]Celgene Corporation, Summit, NJ, United States of America
[7]Hopital Avicenne, Bobigny, France

Background. In a multicenter, phase 3 study (MDS-004), LEN (5 and 10 mg)

resulted in RBC transfusion-independence for ≥ 26 weeks (43% and 56%, respectively) in patients with RBC transfusion-dependent Low-/Int-1-risk MDS and del(5q) (Fenaux, et al. Blood. 2011;118:3765-76). The most common grade 3-4 adverse events (AEs) were: neutropenia in 73.9% (with rates 46.4% and 46.4% in cycles 1 and 2, respectively) and 75.4% of patients (46.4% and 43.5%); and thrombocytopenia in 33.3% (18.8% and 18.8%) and 40.6% of patients (27.5% and 26.1%) in LEN 5 and 10 mg, respectively. Median overall survival (OS) was ≥ 35.5 and 44.5 months. For combined LEN doses, the 3-year OS rate was 56.5% and the 3-year acute myeloid leukemia (AML) progression rate 25.1%. Further evaluation of AEs of clinical interest is needed.**Aims.** To evaluate AEs of clinical interest (neutropenia, thrombocytopenia, gastrointestinal disorders, rash, pruritus and hypothyroidism) and long-term outcomes (AML progression and OS) in LEN-treated patients enrolled in MDS-004, with 1-year additional follow-up (maximum follow-up duration 70.8 months) at data cut-off in June 2011. **Methods.** Patients received either LEN 5 mg on days 1-28 or 10 mg on days 1-21 of 28-day cycles. AEs of clinical interest were evaluated using NCI-CTCAE version 3. Dose reductions were required for grade 4 neutropenia or thrombocytopenia by protocol.

Table. Grade 3-4 AEs and treatment modifications.

	Neutropenia		Thrombocytopenia		Diarrhea and abdominal pain	
Lenalidomide dose	5 mg	10 mg	5 mg	10 mg	5 mg	10 mg
Grade 3–4 events, n	154	184	70	97	3	1
Median time to onset, months (range)	1.59 (0.16–11.96)	1.64 (0.26–12.25)	1.64 (0.16–11.73)	1.51 (0.26–11.07)	5.12 (1.41–7.03)	0.30
Recovery (resolution of AE), %	97.4	98.9	97.1	93.8	66.7	100
Median time from onset to recovery, months (range)	0.33 (0.03–5.03)	0.26 (0.03–3.75)	0.26 (0.03–2.99)	0.30 (0.03–4.17)	0.85 (0.36–1.35)	0.16
Dose interruption, %	7.8	11.4	14.3	13.4	33.3	100
Dose reduction, %	17.5	17.4	10.0	22.7	33.3	0
Discontinuation, %	0.6	0.5	0	0	0	0
Bleeding (all grades), %	NA	NA	15.7	17.5	NA	NA
Infection (all grades), %	24.7	11.4	NA	NA	NA	NA
NA, not applicable						

Results. All 138 patients randomized to LEN (5 mg, n=69; 10 mg, n=69) were included in the safety population. In the double-blind phase, grade 3-4 hematologic AEs in LEN 5 and 10 mg groups were reported previously and are described above. Gastrointestinal disorders (all grades) in LEN 5 and 10 mg groups occurred in 59.4% and 65.2%, with grade 3-4 diarrhea and abdominal pain in 4.3% and 1.4% patients. Other AEs (all grades) of interest in LEN 5 and 10 mg groups included: rash, 23.2% and 13.0%; pruritus, 23.2% and 27.5%; and hypothyroidism, 0% and 1.4% patients. Per-event based analysis of grade 3-4 AEs of interest and the resulting treatment modifications are shown in the Table. No grade 5 AEs of interest were reported. G-CSF was used in events of neutropenia: 46.8% and 62.5% in LEN 5 and 10 mg groups, for a median duration of 10 (range 1-847) and 6 days (range 1-534), respectively. Median follow-up duration for AML progression in LEN 5 and 10 mg groups was 31.8 (range, 0.8-70.8) and 36.9 months (range, 0.4-69.6), with 4-year AML progression rates of 32.52% and 28.97%. Median follow-up duration for OS in LEN 5 and 10 mg groups was 35.8 (range, 1.9 -70.8) and 40.7 months (range, 0.4-69.6), with 4-year OS rates of 46.73% and 49.85%; median OS was 41.9 and 44.5 months (*P*=0.1731). **Summary and Conclusions.** In patients with Low-/Int-1-risk del(5q) MDS treated with LEN, AEs of clinical interest (neutropenia, thrombocytopenia, gastrointestinal disorders, rash, pruritus, and hypothyroidism) were manageable and rarely led to treatment discontinuation. In contrast to neutropenia and thrombocytopenia events, diarrhea and abdominal pain events were rare. AML progression and OS rates corroborate published findings.

0871

PREDICTORS OF OUTCOMES AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR MYELODYSPLASTIC SYNDROMES

S Sirop, D Gastineau, M Litzow, W Hogan, M Patnaik
Mayo Clinic, Rochester, United States of America

Background. Allogeneic stem cell transplantation (allo-SCT) for myelodysplastic syndromes (MDS) remains the only potentially curative option. This process however, is frequently associated with significant morbidity and mortality and is typically offered to a highly selected group of patients. **Aims.** We wished to identify prognosticators predicting survival in patients with MDS following allo-SCT. **Methods.** This is a retrospective analysis of the Mayo Clinic MDS transplant database (1995-2011). The study was approved by the Institutional Review Board. Outcomes analyzed included overall survival calculated from the time of diagnosis, relapse following transplant, and non-relapse mortality (NRM). Variables included: age, Revised International Prognostic Scoring (IPSS-R), cytogenetics (according to IPSS-R categories), World Health Organization (WHO) categories, therapy related MDS, presence of monosomal karyotype, conditioning regimen, HLA disparity, incidence of acute and chronic graft versus host disease (GVHD), presenting hemoglobin, platelet count, bone marrow blasts, circulating blasts and serum ferritin levels. Multivariate analysis was performed using the Cox Regression Model. Results. From 1995 through 2011, a total of 80 consecutive patients with MDS underwent allo-SCT at the Mayo Clinic. Of these, 55 were male (68.75%) with a median age of 54 years (range, 24-68 years). Twenty one patients (26.3%) had therapy related MDS. A myeloablative conditioning was used in 47 (58.7%) patient (23 - cyclophosphamide/total body irradiation and 24- busulfan/cyclophosphamide). Reduced intensity conditioning was used in 33 (41.3%) patients (30 - fludarabine/melphalan, 1- busulfan/fludarabine and 2- pentostatin/total body irradiation). Monosomal karyotype was found in 32 (40%) patients. IPSS-R risk stratification identified 48 (60%) patients in the very poor, 13 (16.3%) poor and 19 (23.7%) in the intermediate/good risk categories. In 67 (83.7%) patients, allo-SCT utilized cells from HLA-matched donors. NRM was noted in 25 (31.3%) patients. The median survival was 29 months (range, 4-333 months) with a four-year survival of 36.3%. Twenty patients (25%) relapsed following allo-SCT (15 - with very poor IPSS-R risk category, 4 with poor, and 1 with intermediate). Acute (grade 2 to 4) and chronic graft versus host disease (limited or extensive) were noted in 44 (55%) and 45 (56.3%) patients respectively. On a univariate analysis, the presence of monosomal karyotype, poor or very poor IPSS-R categories, high risk cytogenetics (poor/ very poor per IPSS-R), and therapy related MDS were associated with an inferior survival while the presence of chronic GVHD was associated with better outcomes. On a multivariate model, good/intermediate IPSS-R risk categories and the presence of chronic GVHD were independent predictors for better survival (table 1).

Table 1. Prognostic variables affecting survival in 80 patients with MDS following allogeneic stem cell transplantation.

Variable	P-Value (univariate analysis)	P-Value (multivariate analysis)
Age	0.38	
WHO classification	0.33	
Hemoglobin at diagnosis	0.43	
Platelet count at diagnosis	0.07	
Bone marrow blasts at diagnosis	0.08	
ANC at diagnosis	0.5	
Peripheral blood blasts at diagnosis	0.28	
Conditioning regimen	0.7	
HLA disparity	0.1	
Ferritin at diagnosis	0.7	
Presence of MK	**0.007**	
Cytogenetics per IPSS-R Categories	**0.0003**	
Therapy related MDS	**0.03**	
IPSS-R	**0.02**	**0.04**
Acute GVHD	0.42	
Chronic GVHD	**<0.0001**	**0.001**

* Using Cox regression Model, MDS = myelodysplastic syndromes, WHO=world health organization, ANC=absolute neutrophile count, MK=monosomal karyotype, IPSS-R=revised international prognostic scoring system, GVHD=graft versus host disease.

Conclusions. Of all established prognostic factors in MDS; IPSS-R risk categories, high risk cytogenetics (monosomal karyotype and poor/very poor IPSS-R cytogenetic groups), therapy related MDS and chronic GVHD were found to be prognostic in patients who had undergone allo-SCT. However, only good/intermediate IPSS-R risk categories and chronic GVHD were independent predictors for better outcome.

Background. Transfusion dependency has been proposed as a key prognostic variable for Myelodysplastic Syndrome (MDS) patients by Malcovati et al in the WHO classification-based Prognostic Scoring System (WPSS). More recently, the use of severe anemia with a defined hemoglobin (Hb) level cut off as a surrogate for transfusion dependency has been proposed in a new version of the WPSS score (rWPSS). **Aims**. aim of our study was to investigate rWPSS reproducibility and accuracy in defining OS and risk of leukemic evolution (LE) in a cohort of MDS patients enrolled in the MDS Piedmont Registry. **Methods.** 946 patients with all available data out of 1558 patients enrolled in the Registry from 1999 to 2011 were analysed. We evaluated overall survival (OS) and time to LE according to IPSS and rWPSS risk scores. Results. Median age was 75 years (range 26 - 106). 577 out of 946 patients were male. WHO classification was as follows: 212 RCMD; 188 RAEB-1; 138 RAEB-2; 408 RA, RARS, isolated 5q deletion or RCUD. We included 63 secondary MDS in the analysis. According to IPSS score, 40% of the patients were low risk, 39% Int-1, 16% Int-2 and 5% high risk. rWPSS stratification was as follows: 269 out of 946 patients were very low (VL) risk, 258 low (L), 160 intermediate (I), 208 high (H) and 51 very high (VH).OS by Kaplan-Meyer method was analysed according to rWPSS and IPSS scores. In our cohort rWPSS can very well define five prognostic risk groups (median OS of 106 months in VL, 71 in L, 44 in I, 22 in H and 14 in VH respectively). Our data are in agreement with the work published by Malcovati et al. In 2011. Conversely IPSS, even if useful to define four prognostic groups, cannot separate very well the slopes of Int-2 and high risk curves.Considering time to LE, VL and L curves according to rWPSS show similar trends without a statistically significant difference in OS, otherwise I, H and VH risk groups show well differentiated survival curves (time to 25% LE: not reached in VL; 134 months in L; 41 months in I; 16 months in H; 6 months in VH). Conversely, the differentiation of the unfavourable Int-2 and high risk groups according to IPSS score is not so evident (time to 25 % LE: 10 months in Int-2 and 5 in high risk group patients respectively; p value >0,05). **Conclusions.** Both IPSS and rWPSS are very well reproducible prognostic scores. However, in our hands, rWPSS score (including the degree of anaemia and WHO classification) can better stratify higher risk patients in comparison to IPSS considering both OS and time to LE. Our results confirm the usefulness of the degree of anaemia and WHO evaluation in defining MDS patients prognosis.

Background. Chromosomal aberrations play an important role in pathogenesis, diagnosis, prognosis and treatment allocations of patients (pts) with myelodysplastic syndromes (MDS). The gold standard of cytogenetic diagnostics in MDS are conventional chromosome banding (CCB) analyses of bone marrow (bm) metaphases. Most abnormalities can also be detected by fluorescence in situ hybridisation (FISH), but a frequent cytogenetic monitoring based on CCB analyses is not possible due to patients intolerance of repeated bm biopsies. In the present prospective multicenter German diagnostic study "Screening and genetic monitoring of patients with MDS under different treatment modalities by cytogenetic analyses of circulating CD34+cells"(ClinicalTrails.gov: NCT01355913) we followed MDS pts by sequential FISH analyses of peripheral blood samples. **Methods.** CD34+ progenitor pb cells were enriched by immunomagnetic cell sorting (MACS®) and analysed by FISH using a "Superpanel"(D7/CEP7, EGR1/D5, CEP8, CEP X/Y, D20, TP53, IGH/BCL2, TEL/AML1, RB1, MLL, 1p36/1q25, CSF1R, all Abbott® Products) at initial screening, every 12 months during follow-up and in case of suspected disease progression and a "standardpanel"(EGR1/D5, D7/CEP7, CEP8, TP53, D20, TEL/AML1, CEP X/Y, plus if necessary an informative probe from the superpanel) every 2 months in the 1st and every 3 months in the 2nd and 3rd year. If bm aspirate was available, additional CCB and FISH analysis on enriched CD34+ and non-enriched bm cells were performed. Blood counts were performed monthly and full blood counts to all FISH analyses. Cut-off values for each FISH probe were evaluated at our lab. All cytogenetic informations and bm morphology, clinical course and therapies were documented in a central database. All pts gave their written informed consent. The study was approved by all local ethic committees. **Results**. After 40 months study duration 364 pts (160 m, 204 f) with suspected or cytomorphologically proven MDS from 18 German centres of haematology were included in the study: With regard to age, gender distribution and MDS subtypes the study cohort was representative of the disease. Median follow-up at the time of analysis was 8.2 months (1-36 months).In 72.3% of pts chromosomal aberrations were detected by FISH of circulating CD34+ cells. The median number of anomalies was 2 (range 1-10). The most common aberrations in order of frequency were del(5q), del(7q)/-7, +8, del(12p), del(17p), aberrations of chromosome 21 and 11, followed by rare aberrations of chromosomes Y, 13, 18, 1, X and 14. Out of 250 pts with at least 2 sequential analyses, 37 (14.8%) showed a karyotype evolution by FISH. **Conclusions**. Our first results show that FISH analyses of enriched circulating CD34+ pb cells is a reliable method for screening and cytogenetic monitoring of MDS pts. It is an easy tool for frequent follow-up analyses. With a large FISH probe panel even rare abnormalities can be detected. Small deletions such as del(12p) and del(11q) seem to be not that rare in MDS as it is known from CCB analyses. Karyotype evolution can be observed from pb, so we expect to learn more about chromosomal instability and the course of cytogenetic progression in MDS.

RESULTS OF A PHASE II TRIAL OF AZACITIDINE (AZA)+/- EPOETIN BETA (EPO) IN LOWER RISK MDS

C Gardin[1], S Thepot[2], O Beyne-Rauzy[2], T Prebet[2], S Park[2], A Stamatoullas[2], A Guerci[2], S Cheze[2], G Tertian[2], B Choufi[2], L Legros[2], J Bastie[2], J Delaunay[2], E Wattel[2], F Dreyfus[2], N Vey[2], S Boehrer[2], P Fenaux[2]
[1]Hôpital avicenne, Bobigny, France
[2]Groupe francophone des myelodysplasies, Bobigny, France

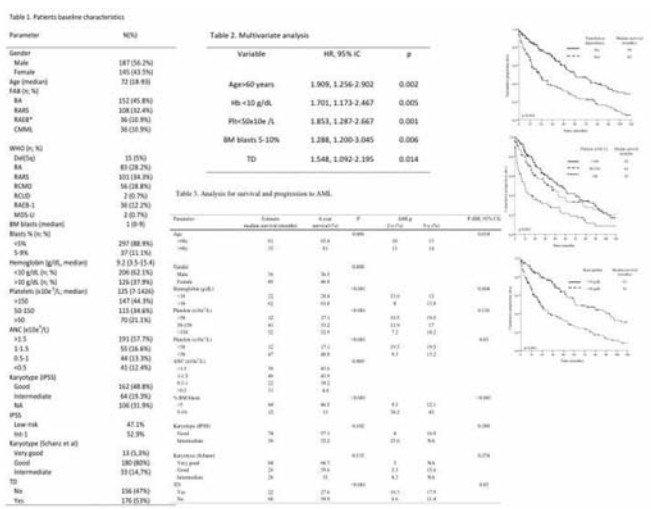
Background. Although anemia of IPSS low and int-1 (LR) MDS initially responds to erythroid stimulating agents (ESA) in 40-50% of patients (pts), response is generally transient. Anemia recurrence with RBC cell transfusion dependency (RBC-TD) is an indicator of poor prognosis, even in absence of progression to higher risk MDS. AZA leads to RBC transfusion independence (RBC-TI) in 30-40% of LR-MDS (Lyons, JCO, 2009), but it has not been prospectively tested in LR-MDS patients resistant to ESA. It also remains unknown if the addition of ESA to AZA would be useful in such pts. **Methods.** In this randomized phase-II trial (GFMAzaEpo-2008-1 trial, NCT01015352), the Groupe Francophone des Myélodysplasies (GFM) compared AZA 75mg/m2/d for 5 days every 28 days for 6 cycles (AZA arm) to the same treatment plus EPO 60000U/week (AZA+EPO arm). Inclusion criteria were LR-MDS resistant to at least 12 weeks of ESA, with RBC-TD ≥ 4 RBC units in the previous 8 weeks. Responders in both arms were eligible for maintenance up to 12 monthly cycles, unless progression or loss of erythroid response occurred. The primary endpoint was RBC-TI (HI-E major using IWG 2000 criteria) after 6 courses.**Results.** Between 2009 and 2010, the 98 planned pts were included: M/F 65/28; median age 71y (41-84); 5 pts were excluded (one consent withdrawal, 2 early unrelated events and 2 with exclusion criteria). In the remaining 93 pts, IPSS risk was low in 69 and int-1 in 23 pts, with no imbalance between arms. Five pts received < 4 cycles and 16 received only 4 or 5 cycles, mainly due to toxicity or progression. RBC-TI after 6 courses was observed in 16.7% (8/48) in the AZA arm and 18 % (8/45) in the AZA+EPO arm (P=1), and in 19.5% (8/41) and 26 % (8/31) respectively, in the 72 pts who received ≥ 6 cycles (P=.57). Overall best response rate (at least HI-E minor using IWG 2000 criteria) was 35 and 33% in the AZA and AZA+EPO arms, respectively (P=0.99).The 26 patients in response received further AZA maintenance courses (median; 18, range; 6-18). Response duration was 18 months in AZA+EPO arm *vs* 15,2 in AZA arm (P=0.229). Of note, only 9 pts in the AZA+EPO arm required at least one hospitalization for a SAE, compared to 22 pts in the AZA arm (P=0.015).**Conclusion:** Erythroid response to AZA, in LR MDS with demonstrated ESA resistance, appears lower than expected, with no improved outcome when combined with an ESA. The latter may however improve tolerance of AZA in LR MDS.

0875

CLINICAL PROGNOSTIC FACTORS FOR MYELODYSPLASTIC SYNDROMES PRESENTING NON-UNFAVOURABLE CYTOGENETIC CATEGORIES ACCORDING TO IPSS AND THE NEW CYTOGENETIC PROGNOSTIC SCORING SYSTEM

J Falantes, C Calderón, F Márquez-Malaver, D Alonso, A Martín-Noya, I Montero, J González, ML Martino, R Parody, I Espigado, JA Pérez-Simón
Hospital Virgen del Rocío, Seville, Spain

Background. Prognosis of patients with myelodysplastic syndromes (MDS) and particularly those categorized as lower risk (<10% blasts or Low/Int-1 IPSS) is very heterogeneous, as different clinical or biological factors may impact on survival[1,2]. Recently, a new cytogenetic prognostic scoring system[3] has been proposed for the upcoming revised-IPSS, which also includes the degree of cytopenias in predicting, globally, the outcome for MDS patients. However, the role of these clinical parameters is not validated for the new groups of very good, good and intermediate (except del7q) cytogenetic categories. **Aims.** To evaluate prognostic significance of clinical factors for survival and risk for progression to acute myeloid leukemia (AML) in lower risk MDS patients defined as <10% bone marrow blasts or lower risk cytogenetic categories as defined by Schanz et al[3]. **Methods.** A total of 332 MDS patients from a single institution (period: 1990-2011) were analysed for survival and risk for progression to AML. Median age was 71y (18-93). Patients baseline characteristics are shown in table 1. Demographics, peripheral blood count, transfusion dependency (TD), cytogenetic subgroups (good and intermediate by IPSS and very good, good and intermediate by Schanz) and bone marrow (BM) blasts were evaluated. Almost 90% of patients received either best supportive care with blood transfusion as clinically required and/or just observation until symptomatic cytopenia occurred. Patients treated with 5-azacitidine, lenalidomide, intensive chemotherapy or alloSCT receptors were censored at the time of initiation of such therapies. Altogether, no patients receiving treatment with potential survival advantage was included. Survival was analyzed from diagnosis until death from any cause and estimated by the Kaplan and Meier method and log rank test. Cox proportional hazards regression model was used to analyze OS as end point. Risk for AML progression was analyzed using the Gray test. The cumulative incidence was computed with the cmprsk package for R 2.6.2 software. The competing event was death without AML progression. **Results**. After 41 months mean follow up (1-238 months), 232 patients had died (69.8%). In multivariate analysis, severity of cytopenias (anemia and thrombocytopenia), age >60y, BM blasts 5-9% and TD, significantly influenced on survival (all p<0.05. Table 2). Forty-eight patients progressed to AML (14.4%). Transfusion dependency (p=0.05), platelet<50x10e^9/L (p=0.05) and BM blasts 5-10% (p<0.001) were the only factors associated with increased risk of progression to AML (Table 3). Interestingly, neither IPSS cytogenetic category (good vs intermediate) or the very good, good or intermediate categories by the new cytogenetic scoring system influenced on OS or AML progression in this set of MDS patients with <10% BM blasts. **Conclusions**. Although cytogenetics remain the main prognostic factor in MDS, the current study identifies clinical parameters predicting outcome among patients with the better cytogenetic profile. Degree of cytopenias, blasts 5-9% and TD may identify a subset of patients within the non adverse karyotype, in which aggressive approaches could possibly be required to improve survival or prevent disease progressionReferences1-Garcia-Manero et al. Leukemia 20082- Falantes et al. ASH Annual Meeting Abstracts, Nov 2011; 118: 17303-Schanz et al. J Clin Oncol 2012.



0876

THE STUDY OF CELL CHIMERISM AFTER ALLOGENEIC TRANSPLANTATION CAN IMPROVE THE MANAGEMENT OF PATIENTS WITH HEMATOPOIETIC MYELOID MALIGNANCIES.

M Díez Campelo[1], T Bernal[2], V Godoy[1], M Alcoceba[1], E Colado[2], S Rojas[1], M Gonzalez[1], M Cañizo[1]
[1]University Hospital of Salamanca, Salamanca, Spain
[2]Hospital Central de Asturias, Oviedo, Spain

Background. delayed full donor cell quimerism may be associated with relapse in myeloid malignancies. The kinetics and the impact of chimerism on outcome of these patients could be relevant for adequate patients management.**Objectives**. To describe the kinetics of the cell chimerism and to analyze its impact on MDS/AML outcome patients after hematopoietic trasplant. **Patients and methos** 124 patients with MDS (n=56)/AML (n=68), allotransplanted in two different units from January 2005 to December 2012, were studied. Chimerism was performed in whole bone marrow as well as CD3+ and CD15+ selected peripheral blood cells. MRD was analysed by flow cytometry. Univariant comparisons between patients were done using T or Chi-square tests as appropriate. Variables with a significance level below 0.1 were included in a logistic regression analysis. Survival was studied using the Kaplan-Meier method. **Results.** Median age at trasplant was 55 years and median CD34+ cell dose was 5.5 x 10^6/Kg. At day + 56, complete BM chimerism was present in 70% of patients while complete CD15 PB chimerism was 89% and complete CD3 PB chimerism was only 30%. At day +100 percentage of chimerism results was as follows: 74%, 92% and 40% of complete chimerism for BM, PB CD15 and PB CD3, respectively.All patients engrafted and at day +100, all alive patients but one (n=102) were in CR. MRD monitoring at day +100 was positive in 21% of patients.After a median follow up of 2 years, overall and relapse free survival

were 57 and 60%, respectively.Regarding overall survival the presence of complete chimerism in BM at day +56 and +100 improves outcome (OS of 62% vs 51% and 64% vs 49% respectively at day +100 for patients with complete vs mixed chimerism, p=0.017 and p=0.02). When patients with mixed chimerism in BM at day +100 were analyzed for cGVHD development overall survival was improved for patients in which it was present (OS of 66% vs 28% for patients with and without cGVHD, p=0.02).Regarding relapse free survival (RFS) the presence of complete chimerism in BM at day +56 and +100 was associated with better evolution (RFS of 63% vs 60% at day +56 and 73% vs 60% at day +100 for patients with complete vs mixed chimerism, p=0.04 and p=0.004, respectively). Development of cGVHD in patients who showed mixed chimerism in BM at day +56 improved RFS in this subgroup of patients (RFS of 80% vs 33% for patients with and without cGVHD, p=0.03).Multivariate analysis for OS showed that the presence of MRD+ [HR 1.3 (0.08-0.8), p=0.02] and mixed BM chimerism at day +100 [HR 1.2 (0.09-0.9), p=0.04] were the two variables retaining statistical significanceFor RFS the same variables as well as PB CD3 mixed chimerism at day +56[HR 1.8 (0.01-1.3), p=0.08], significantly influenced relapses. **Conclusions**. Early evaluation of chimerism may help to identify patients at high risk for relapse in AML/MDS. Due to the graft anti-tumor effect the development f cGVHD could improve evolution and strategies modifying the immunosuppressive status could benefit patient´s outcome.

Background. acquired aplastic anemia has a peak incidence in adolescence and treatment algorithms are often cut below the age of 18 years without further subdivision. we analyzed the OS and EFS in 642 consecutive adolescents included in the database of the SAAWP of the EBMT from 2000 to 2009, after the following treatments: first line immunosuppression (IS), first line matched family (MFD) or alternative (ALT) donor HSCT, HSCT after failed IS. Death, relapse, MDS/AML, PNH clone, late tumours from diagnosis to death/last follow-up were considered as the events. **Aims**. to evaluate the impact of different treatments on the outcome of the disease, including the occurrence of post-therapy late tumors; to identify the best treatment strategy in this group of age. Data base anaslysis. **Results**. Three 3 year probability OS and EFS were 82% and 77%, respectively. Interval diagnosis-treatment >0.21 years negatively affected OS and EFS. OS after IS (90%) was higher than after both MFD (86%) and ALT HSCT (72%); OS for HSCT post IS was 78% (P= 0.005). In post-hoc analysis differences were significant only for IS over ALT HSCT (p=0.01) and for MFD over ALT HSCT (P=0.001). EFS was 64% after IS, 83% after MFD HSCT, 70% after ALT HSCT and 71% after HSCT post failed IS (P=0.004). In post-hoc analysis differences were significant only for MFD over both ALT HSCT (P= 0.004) and IS (P=0.003). A trend for significantly better EFS was seen for ALT HSCT over HSCT after failed IS. AcGVHD III-IV occurred in 23% of MFD, 30% of ALT HSCTs and 23% of HSCT after failed IS. Chronic GVHD occurred in 7% of MFD, 18% of ALT HSCTs and 27% of HSCT after failed IS. BM as source of cells provided a significant advantage in OS and EFS over PB and CB. OS, but not EFS, was significantly superior in adolescents transplanted in adult centres than in mixed and pediatric centres. Twelve late tumors (2%) occurred at a follow-up of 3 years in 7% of patients after IS, 5.3% after transplant in failed IS and 0.9% after front line transplants (MDF plus ALT). IS either alone or before HSCT induced a significant increased risk of late tumors (7.1, P = 0.001). In the whole cohort, the only factor negatively affecting OS and EFS in univariate and multivariate analysis was interval diagnosis-treatment > 0.21 years. IS negatively impacted on EFS in univariate and multivariate analysis. In the transplanted patients, interval diagnosis-treatment ≤ 0.21 years, BM as source of cells and MFD were favourable prognostic factor for OS and EFS in univariate analysis. Only interval diagnosis-treatment and BM cells were confirmed in multivariate analysis. **Conclusions**. aplastic anemia in adolescents has a very good outcome. If a MFD is available, HSCT performed in an adult Centre using BM cells is the first choice treatment. If there is no MFD, first option is IS that provides a survival of 90% although an inferior EFS. If IS fails, ALT HSCT is a good rescue option.

Background. Immunophenotyping by flow cytometry (FCM) reveals a variety of abnormalities in hematopoietic cells in myelodysplastic syndromes (MDS). Such aberrations may help elucidate the disease pathophysiology. In our previous FCM studies, we reported that: 1) The immunophenotype of myeloblasts becomes more immature as the disease progresses, in particular when transformed into acute myeloid leukemia (AML), as exemplified by the increase in the fraction of $CD7^+$ and $CD15^-$ myeloblasts. 2) Expression of the B7-H1 protein (CD274), a B7 family molecule associated with evasion of the antitumor immune response in some neoplasia, is observed on MDS myeloblasts in some patients. Furthermore, our in vitro studies suggested that the expression of either the CD7 or B7-H1 molecule on MDS myeloblasts is associated with their increased proliferative potential. **Aims.** We conducted a multicenter FCM study to explore whether our previous immunophenotypic data from patients with MDS and AML transformed from MDS (AL-MDS) were reproducible, in particular whether CD7 and B7-H1 molecule expression on myeloblasts was associated with advanced disease. **Methods.** Bone marrow cells from 115 patients (93 MDS and 22 AL-MDS) were stained with three antibodies conjugated with fluorescein isothiocyanate (FITC), phycoerythrin (PE), or peridin chlorophyll (PerCP). Combinations of the three antibodies were CD7/CD34/CD45 (FITC/PE/PerCP), CD10/CD34/CD45, CD15/CD34/CD45, CD34/CD11b/CD45, CD34/CD56/CD45, and CD34/B7-H1/CD45. Data were acquired using a FACSCalibur flow cytometer (Becton Dickinson, BD) and analyzed with CellQuest software (BD). Analysis of FCM parameters was performed according to previous reports (Ogata et al., Haematologica 2009, 94, 1066-1074; Della Porta et al, Haematologica, in press).**Results.** With progression of disease stage, the immunophenotypes of $CD34^+$ myeloblasts became more immature, acquiring CD7 and losing CD15 expression, and the percentages of $CD34^+$ B-progenitors among total $CD34^+$ cells and the granularity of granulocytes decreased. There was a strong negative correlation between the percentages of $CD34^+$ myeloblasts in all nucleated cells and percentages of B-progenitors in all $CD34^+$ cells in all patients. In multivariate logistic regression analysis, three parameters alone, percentages of $CD34^+$ myeloblasts in all nucleated cells, CD7 expression on $CD34^+$ myeloblasts, and B7-H1 expression on $CD34^+$ myeloblasts, were independently associated with AL-MDS patients. **Conclusions.** The present data consolidate the concept that CD7 and B7-H1 mole-

cules are associated with the disease progression mechanism in MDS. We conclude that further studies and targeting of the pathophysiology mediated by these molecules in MDS would be worthwhile.

TP53 MUTATIONS ARE ASSOCIATED WITH COMPLEX CYTOGENETICS IN HIGHER-RISK MYELODYSPLASTIC SYNDROMES AND IMPACT RESPONSE TO AZACITIDINE

C Müller-Thomas[1], M Rudelius[2], B Schmidt[3], C Peschel[1], U Platzbecker[4], K Götze[1]

[1]Klinikum rechts der Isar, München, Germany
[2]Institut für Allgemeine Pathologie und Pathologische Anatomie der TU München, München, Germany

[4]Universitätsklinikum Carl Gustav Carus, Dresden, Germany

Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of bone marrow disorders characterized by ineffective hematopoiesis leading to peripheral cytopenias. Higher-risk MDS progress to acute myeloid leukemia within months. Treatment with azacitidine has been shown to prolong overall survival and delay progression to acute leukemia. Azacitidine also shows encouraging results in elderly patients with secondary acute myeloid leukemia (sAML) not suitable for intensive chemotherapy. TP53 mutations have been described mainly in MDS with del(5q) and shown to be associated with disease progression, poorer prognosis and poor response to therapy. **Aims.** We retrospectively analyzed the prevalence of TP53 mutations by immunostaining of bone marrow biopsies in patients with higher-risk MDS (IPSS intermediate-2, high) and sAML treated with azacitidine and correlated this to outcome. **Methods.** Patients with higher-risk MDS and sAML who received at least one complete cycle of azacitidine (75 mg/m^2 d1-7) were screened for evaluation. Paraffin-embedded bone marrow slices were stained for p53. Staining was defined as positive if more than 5% of cells showed strong nuclear staining. Sequencing of TP53 revealed mutations in 7/7 positively stained bone marrow slices so that positive staining correlated well with TP53 mutation status. **Results.** Until now 61 patients were successfully screened. Currently, immunostaining for p53 has been performed on bone marrow slices of 46 patients; it was positive in 24% (n=11) and negative in 76% (n=35). Regarding the cohort of p53 negative patients the median age was 71.5 years; 3 (9%) patients had RAEB-1, 15 (43%) RAEB-2, 1 (3%) CMML-1/-2 respectively, 15 (43%) sAML; within these patients 7 (20%) had therapy-related MDS and AML. IPSS was intermediate-2 and high in 29% (n=10) respectively, not evaluable in 43% (n=15). Complex karyotype was present in 17% with chromosome 5 abnormalities in 50%. The median number of cycles of azacitidine was 5.4 (range 1-23), responses were 3% (n=1) CR (with CCR), 6% (n=2) bone marrow CR, 46% (n=16) SD, 40% (n=40) failure, HI (excl. CR) was seen in 17% (n=6). The subgroup of p53 positive patients consisted of 2 (18%) RCMD, 4 (36%) RAEB-2, 4 (36%) sAML and 1 (9%) MDS/MPN overlap; 4 (36%) patients had therapy-related MDS and sAML. The median age was 72.6 years. IPSS was intermediate-2 in 18%, high in 36% and not evaluable in 45%. Complex karyotype was found in 91% with chromosome 5 abnormalities in 70%. The median number of cycles of azacitidine was 3.2 (range 1-6), responses were 9% (n=1) CR (with CCR), 9% (n=1) bone marrow CR, 36% (n=36) SD, 45% (n=5) failure, 27% (n=3) HI (excl. CR). **Summary and Conclusions.** Positive immunostaining of p53 as a correlate for TP53 mutations was seen in 24% of patients with higher-risk MDS and sAML. TP53 mutations were predominantly associated with complex karyotype with chromosome 5 abnormalities. Patients with TP53 mutations received fewer cycles of azacitidine due to shorter time to progression, revealing a trend towards poorer response to azacitidine. Currently, we are increasing the patient cohort (aim: 90-100 patients) to consolidate the data. An update will be presented at the meeting.

[5]Novartis, Nürnberg, Germany
[6]St. Johns Hospital, Duisburg, Germany

Background. Epigenetic mechanisms have been identified to play an important role in the pathophysiology of myelodysplastic syndromes (MDS). Recently, they have received much attention as therapeutic targets in this disease. In fact, inhibition of histone deacetylation (HDAC) with single agent valproic acid (VPA) has been demonstrated to result in substantial erythroid improvement in up to 50 % of patients with IPSS low/Int-1 disease. With the development of more potent HDAC-inhibitors this therapeutic approach might become an interesting option especially for patients with less-advanced MDS. A promising new compound is panobinostat (LBH589), a class I/II-DAC inhibitor that has shown anti-tumor activity in pre-clinical models and leukemia patients. **Aims.** The primary objective of the trial CLBH589BDE04 (GEPARD, NCT01034657) was to evaluate the erythroid hematological improvement using modified IWG criteria in patients treated for 4 months with LBH589 as a single agent. The secondary objectives included the evaluation of the objective response rate as well as the safety and tolerability profile of LBH589. **Methods.** We prospectively investigated the single agent activity of LBH589 in red blood cell (RBC) transfusion-dependent low or int-1 risk MDS patients after providing informed consent. Main inclusion criteria were RBC transfusion dependency of at least 4 units of blood within an 8 week period and being either refractory to ESA or with a low likelihood to respond to ESA. LBH589 treatment was performed orally at a starting dose of 40 mg on Monday, Wednesday and Friday every week for a period of at least 4 months. **Results.** Of 34 pts enrolled, median age was 66 years (range 51 to 81 years), IPSS categories were low (n=11) or int-1 (n=23). The majority of patients (n=20) displayed no cytogenetic abnormalities, while del(5q) was the most common abnormality and observed in 8 patients.The patient population received LBH589 treatment for a median of 26 days (range 2 - 126 days). 31 patients began treatment with 40 mg/d, only these patients will be reported hereafter because the subsequent patients started with a lower dose within the 1st amendment.18 of the 31 patients completed the 4 months' treatment period, 15 patients had dose reductions and 13 patients stopped LBH589 prematurely due to adverse events. These included infectious complications (n=2), asthenia/fatigue (n=5) or hematologic abnormalities (n=3). Therapy-induced grade 3-4 neutropenia or thrombocytopenia occurred in 7 (22.6 %) and 8 (25.8 %) pts, respectively. Of the 18 pts evaluable for response at month 4, 1 pt (5.6 %) achieved an erythroid response. No CR or PR was reported, 1 pt (5.6 %) with a del(5q) had a cytogenetic response while 12 pts (66.7 %) had stable disease. Interestingly, the patient with erythroid response had previously responded to VPA, suggesting HDAC-inhibition as the main mechanism for response. **Summary/conclusions.** We conclude that in low/int-1 MDS patients, LBH589 at a starting dose of 40 mg q3w is poorly tolerated and has very limited clinical activity. We recommend a dose of 20 mg q3w for further exploration of this compound in combination with other drugs in older patients with MDS.

MYELODYSPLASTIC SYNDROMES WITH =15% RING SIDEROBLASTS: EVALUATION OF PROGNOSTIC VALUE OF HISTOLOGIC SUBCATEGORIES FOR OVERALL AND LEUKEMIA FREE SURVIVAL

M Patnaik, C Hanson, N Sulai, J Hodnefield, R Knudson, R Ketterling, A Tefferi
Mayo Clinic, Rochester, United States of America

Background. Ring sideroblasts (RS) represent abnormal mitochondrial iron deposits in myelodysplastic syndromes (MDS). RS ≥15% defines refractory anemia with ring sideroblasts (RARS). In addition, other WHO-defined MDS sub-categories can also display ≥15% RS. For this study, we have referred to these as refractory cytopenias with multilineage dysplasia with RS (RCMD-RS), MDS-unclassifiable with RS (MDS-U-RS) and refractory anemia with excess blasts and RS (RAEB-1/2-RS). Amongst these categories, RARS is believed to have the best survival rate with the lowest risk of leukemic transformation, largely due to the absence of associated dysplasia in more than one lineage. **Results**. We wished to evaluate the prognostic role of WHO based histological sub-categorization in patients with MDS-RS, especially in the context of risk stratification by karyotype and the revised IPSS (IPSS-R). **Methods.** 130 consecutive patients with primary MDS and ≥15% RS were seen at the Mayo Clinic from 1997 through 2007. All patients underwent bone marrow examination and cytogenetic evaluation at diagnosis and the pathology slides, including iron stains, were centrally re-reviewed to accurately quantify bone marrow (BM) RS percentage and to confirm WHO histologic sub-categories. In addition, each patient was assigned IPSS and IPSS-R prognostic scores at diagnosis and risk stratified by karyotype according to the IPSS-R. Cox proportional regression method was used for multivariable analysis. **Results**. Of the overall 130 study patients, 87 (67%) were male and median age was 72 years (range, 21-90 years). Fifty-three (40%) patients had RARS, 54 (41%) RCMD-RS, 5 (4%) MDS-U-RS and 18 (14%) RAEB-1/2-RS. At presentation, 32 (25%) patients were red cell transfusion-dependent and 51 (39%) displayed an abnormal karyotype including 24 very poor/poor risk karyotype per IPSS-R (1 RARS, 15 RCMD-RS, 8 RAEB-1/2-RS); monosomal karyotype was noted in 16 patients (1 RARS, 8 RCMD-RS, 7 RAEB-1/2-RS). At a median follow-up of 35 months, 100 (77%) deaths and 15 (12%) leukemic transformations were documented. Median survivals were 67 months for RARS, 29 months for RCMD-RS (HR 2.0; 95% CI 1.3-3.2), 43 months for MDS-U-RS (HR 0.8; 95% CI 0.2-2.5) and 16 months for RAEB-1/2-RS (HR 4.5; 95% CI 2.4-8.4) (p<0.0001). In univariate analysis, risk factors included anemia, thrombocytopenia, increased BM blasts, red cell transfusion need, IPSS-R and cytogenetic risk categories per IPSS-R. Significance attached to hemoglobin level, platelet count, BM blasts, and specific histologic subcategory was lost during multivariable analysis that accounted for either IPSS-R or cytogenetic categories per IPSS-R, whereas red cell transfusion need retained prognostic significance. Univariate analysis disclosed significantly inferior leukemia-free survival (LFS) in patients with RAEB-1/2-RS (HR 40.0; 95% CI 4.4-364.0) and RCMD-RS (HR 12.7; 95% CI 1.6-101), compared to RARS (p<0.0001). This was confirmed by multivariable analysis that took cytogenetic risk groups into consideration. **Summary and Conclusions:** Histologic subcategories in MDS with ≥15% RS might not be prognostically relevant for overall survival, in the context of IPSS-R or cytogenetic risk stratification. However, they retained independent prognostic value in predicting leukemic transformation. The current study also showed that red cell transfusion need is an IPSS-R-independent predictor of inferior survival in MDS-RS

Background. Prognostic factors for response and survival in patients with myelodysplastic syndromes (MDS) treated with azacitidine (AZA) remain largely unknown. RBC transfusion dependence, independently predicted shortened OS (Itzykson R et al Blood. 2011 J13;117). Transfusion dependency seems to have a major prognostic impact in patients with MDS (Malcovati L et al. J Clin Oncol 2007; 25:3503). Sanz et al in 2008 demonstrated the independent prognostic value of development of iron overload on OS and AML risk in MDS and Sorror et al in 2010 demonstrated that serum ferritin (F) concentration can indicate iron overload and is thought to predict morbidity and mortality after hematopoietic cell transplantation (HCT) but little is known about this parameter in relation to other treatments such as azacitidine.

Key: BOR: Best Overall Response (mRC+ CR+ PR+ HI+ RCit) ; TD: Transfusion dependence ;F: ferritin levels; OS: Overall Survival

B)

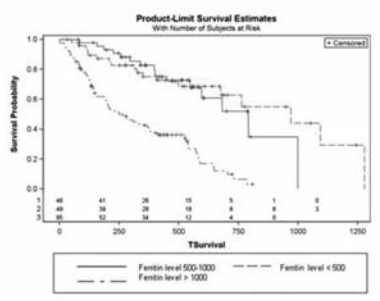

Figure 1. Overall Survival.

Aims. To assess the influence of pre-AZA ferritin levels(F) on response and survival in patients with World Health Organization (WHO) defined MDS or acute myeloid leukemia (AML) with 20-30% bone marrow blasts. **Methods.** We report a retrospective analysis of 240 patients from a Spanish compassionate use registry. **Results.** The median pre-aza serum F was 1001 ng/ml, (range: 21,

5548).The patients were divided into 3 groups according to pre-AZA levels of F (<500, 500-1000 and >1000). There was no significant difference between the low and high F groups for pre-AZA factors such as IPSS, time from diagnosis and hemoglobin levels. There was a strong correlation between a higher pre-AZA serum F (>1000 ng/ml) and a significantly inferior OS (p<0.0001). Best Overall response (BOR: mRC+ CR+ PR+ HI+ RCit) and BOR at 4 and 6 months (p<0.0001) were noted in patients with F levels < 1000. **Conclusions.** Prospective studies incorporating alternative biomarkers of iron metabolism alongside serum F levels are needed to improve our understanding of the significance of iron overload in MDS patients treated with AZA. Our results also suggest that avoiding or reducing iron overload with an appropriatechelation therapy could improve OS and response in patients with MDS treated with azacitidine. However, prospective controlled clinical trials are needed to confirm our hypothesis.

STAT5 ACTIVATION IN MDS PRIMARY BONE MARROW CELLS

A Sanna[1], E Spinelli[1], R Caporale[2], F Buchi[1], E Masala[1], F Sassolini[1], A Valencia[1], A Gozzini[3], A Bosi[1], V Santini[1]
[1]Hematology, AOU Careggi, University of Florence, Florence, Italy
[2]AOU Careggi, Florence, Italy
[3]Hematology, AOU Careggi, Florence, Italy

Myelodysplastic syndrome (MDS) patients may respond to erythropoietin (EPO) treatment, but they often loose response or are refractory to the stimulating factor. This may be due to signal transduction abnormalities. Signal transducer and activator of trascription (STAT5) activation has been shown to be critical in hemopoiesis.We evaluated basal STAT5 phosphorylation in different marrow subpopulation and subtypes of MDS and analyzed its correlation with outcome. We have recently shown that EPO response in vivo is strongly predicted by STAT5 phosphorylation in CD71+CD45 following in vitro EPO stimulation. We analysed by a multiparameter flow-cytometry method STAT5 activation in specific cellular subpopulations of MDS bone marrow cells. Cells were stained with APC anti-human CD34, PE anti-human CD71, PerCP anti-human CD45 and Alexa-Fluor488 anti-STAT5 (pY694). Samples were analysed on a flowcytometer with 6 color laser (FACScanto). Activation of STAT5 were determined by calculating the ratio of the specific Median Fluorescence Intensity (MFI) of stimulated *versus* unstimulated cell populations. EPO response was considered positive when >1.3.We analysed in bone marrow mononuclear CD34+ cell, CD45+ and CD71+CD45- of 112 MDS cases phosphorylation of STAT5 and compared it with that of normal bone marrow cells. At the time of our study median age of patients was 72 years, 45/112 was female and the patients' diagnosis was: RA 33(29%), RARS 6(5%), RCMD 31(27%), RAEB1 17(15%), RAEB2 12(11%), 5q-syndrome 5(4%), MDS-U 1(1%), CMML 6(5%) and 1(1%) MDS/MPL. IPSS risk calculated as follow for 41 patients: Low 17(42%), INT-1 15(36%), INT-2 7(17%) and high 2(5%). The relation between STAT5 activation and overall survival was calculated for all MDS cases.Basal STAT5 phosphorylation in CD34+, CD71+ and CD45+ cells was not significantly different within WHO classification classes (p>0.05) and IPSS (p>0.05) and did not correlate with survival. EPO stimulation induced STAT5 activation in CD71+CD45- cells subpopulation of 27/90 MDS cases and in normal bone marrow cells. Non-parametric Mann Withney test showed that level of EPO-induced STAT5 activation in CD71+CD45- MDS cells was significantly lower than in normal cells (p<0.001). Evaluation of EPO response in vivo (Hb increase > 2 g/dl without transfusions after 8 weeks of EPO treatment) has shown that in 43/47 cases it correlated with in vitro EPO dependent STAT5 activation (Spearman's rho=0.401 and *p*<0.009).Although STAT5 represent an important marker of cell activity, basal STAT5 phosphorylation in CD34 + MDS cells and in other cell subpopulations did not correlate with clinical outcome and no significant clustering within WHO MDS subtypes was evident. We confirm here that evaluation of EPO response in vitro by STAT5 activation is the strongest predictor of EPO response in vivo.

[19]Hematology, Basel, Switzerland

Background. In the last decade, several studies have reported an improved outcome after hematopoietic stem cell transplantation (HSCT) from a voluntary unrelated donor (VUD) in patients with acquired severe aplastic anemia (SAA). This has led to a marked increase in the utilization of unrelated donor transplantation for patients with marrow failure. However, despite these recent results, the decision to transplant patients who are refractory to immunosuppressive therapy (IST) with VUD remains difficult, the alternative being repeated courses of IST that may be beneficial. In this study, we aimed to shed light on the question of the utility of unrelated HSCT by comparing the outcome of patients with or without a VUD identified. **Methods.** We conducted a multicenter donor versus no-donor comparison in 249 pediatric and adult patients with acquired SAA qualifying for a VUD search through the French and Italian donor registries over the 1994-2005 period. In median, the recipient age at diagnosis of SAA was 16 years (range=0-61) and the time interval between diagnosis and donor search initiation was 6 months (range=0-190). HLA matching was defined on low-resolution typing for HLA-A and B class I antigens and high-resolution DNA testing for HLA-DRB1. **Results**. Comparing 161 patients in whom a HLA-A, -B and -DR matched donor was identified with 88 patients without such a donor, we show no difference in survival with a median follow-up of 4.3 years from donor search initiation. However, among 179 patients who received IST using anti-thymocyte globulin (ATG), those who were 17 year-old or younger at the time of VUD search initiation had a survival benefit when belonging to the donor group (4-year probability of survival from donor search initiation = 79% ± 6% vs 53% ± 10% for the no-donor group, p=0.01). In the same ATG-treated patients (pediatric and adult), the donor group also showed a survival advantage when donor search was initiated within the more recent 2000-2005 study period (4-year survival = 74% ± 6% vs 47% ± 10%, p<0.05). **Conclusions.** HSCT from an HLA-matched VUD offers a better survival than alternative options in several subgroups of ATG-treated SAA patients. This first confirms, in an intent-to-treat manner, the conclusion of a previous prospective study conducted in children with ATG-refractory SAA. It also suggests that, in the more recent period, unrelated donor HSCT would be the best option in ATG-treated patients independently of their age.

MYELODYSPLASTIC SYNDROMES WITH MONOSOMAL KARYOTYPE TREATED WITH OR WITHOUT ALLOGENEIC STEM CELL TRANSPLANTATION: THE MAYO CLINIC EXPERIENCE

S Sirop, D Gastineau, M Litzow, W Hogan, M Patnaik
Mayo Clinic, Rochester, United States of America

Background. Patients with myelodysplastic syndrome (MDS) and a monosomal karyotype (MK) have inferior outcomes in comparison to other karyotypic risk categories, including complex karyotypes. The median survival of this group is reported to be ≈ 7 months. In acute myeloid leukemia, MK adversely affect-

ed survival, even after allogeneic stem cell transplantation (allo-SCT). However, outcomes of patients with MDS and MK following allo-SCT have not been well studied. **Aims.** We aimed to evaluate outcomes of MDS patients with MK treated with allo-SCT and compare that to patients treated without allo-SCT at a single institution. **Methods.** A retrospective review of the Mayo Clinic MDS database was undertaken. Patients with MK were identified. MK was defined as either having two or more autosomal monosomies or one autosomal monosomy and one additional structural abnormality. The primary outcome was overall survival calculated from the time of diagnosis. Revised International Prognostic Scoring System (IPSS-R) risk categories were calculated for the group. Categorical and continuous variables were compared using chi-square and student t-tests respectively. Survival was analyzed using Kaplan-Meier plots and compared using log-rank test. The study was approved by the Institutional Review Board. **Results**. A total of 123 consecutive patients with MDS and MK were identified. Of these, 32 underwent allo-SCT and 91 were treated with supportive care or hypomethylating agents The median age at diagnosis in the two groups was 52 (range, 28-61) years and 71 (range, 40-81) years respectively. There was no statistically significant difference in the IPSS-R, frequency of therapy related MDS, or the 2008 World Health Organization (WHO) categories between the two groups (table 1). Of the 32 patients treated with allo-SCT, myeloablative regimens were used in 19 (59.4%) patients (11-busulfan/cyclophosphamide and 8 - cyclophosphamide/total body irradiation), with 19 patients received reduced intensity conditioning (11-fludarabine/melphalan and 2- pentostatin/total body irradiation). Acute (grades 2-4) and chronic graft versus host disease developed in 18 (56.3%) and 14 (43.8%) patients respectively. Non-relapse mortality occurred in 10 (31.3%) patients. Twelve (37.5%) patients relapsed with a median time to relapse of 4 months after transplantation. The median survival of patients treated with allo-SCT was 17 months compared to 4 months when allo-SCT was not utilized. The four-year overall survival was 34.4% after allo-SCT.

Conclusions. While MK in patients with MDS is associated with poor prognosis, Allo-SCT is associated with improved survival outcomes in a select group of patients with MDS and MK that are transplant eligible.

Table 1. Characteristics and outcomes of patients with MDS-MK treated with or without allogeneic stem cell transplantation

		Allo-SCT (32 patients)	No allo-SCT (91 patients)	P Value
Median Age (years)		52 (28-61)	71 (40-81)	<0.0001
WHO Classification	RCMD	9/32 (28%)	24 (26.4%)	0.8
	RAEB-1	6/32 (18.7%)	21 (23%)	
	RAEB-2	10/32 (31.3%)	17 (18.7%)

INCIDENCE OF PNH CLONES BY DIAGNOSTIC CODE UTILIZING HIGH SENSITIVITY FLOW CYTOMETRY

M Movalia[1], I Weitz[2], S Lim[3], A Illingworth[4]

[1]Dahl-Chase Diagnostic Services, Bangor, United States of America

[2]Medicine, University of Southern California, Los Angeles, United States of America

[3]Hematologic Malignancy Program, Texas Oncology-Amarillo Cancer Center, Amarillo, United States of America

[4]Flow Cytometry, Dahl-Chase Diagnostic Services, Bangor, United States of America

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a chronic complement-mediated and life-threatening hematopoietic stem cell disorder characterized by deficiency of the glycocosylphosphatidylinositol (GPI)-anchored complement inhibitory proteins CD55 and CD59. Chronic hemolysis arising from this deficiency leads to serious clinical morbidities, including thromboembolism, chronic kidney disease, and increased mortality. The International Clinical Cytometry Society (ICCS) recommends multiparameter, high-sensitivity flow cytometry (HSFC) as the standard for diagnosing PNH and suggests screening for PNH in patients with bone marrow failure (BMF), unexplained cytopenias, unexplained thrombosis (arterial and venous), hemoglobinuria, Coombs' negative hemolytic anemia, and hemolysis.**Aims.** To determine the prevalence of PNH clones using multiparameter HSFC (maximum sensitivity: 0.01%) in a population of 7109 patients with unexplained cytopenias, anemia, hemolysis, and BMF by ICD-9 diagnostic category. **Methods.** HSFC was conducted using a combination of gating antibodies and GPI-linked antibodies/reagents resulting in a sensitivity of at least 0.01% in red blood cells and neutrophils. CD59 deficiency is determined in CD235a+ RBCs, FLAER/CD24 deficiency in CD15+/CD45+ neutrophils, and FLAER/CD14 deficiency in CD64+/CD45+ monocytes. Validation of this assay was based on the ICCS guidelines for PNH testing. Patients were grouped by ICD-9 diagnostic code (Table 1) and were screened for the presence of PNH clones. The change in PNH clone sizes in patients who had follow-up in studies 3-12 months after initial screening were also investigated. **Results.** A total of 7109 patients were screened for PNH clones. Of these patients, 5653 had a diagnosis aligning to one of the ICD-9 diagnostic categories identified in Table 1. Of these patients, 426 (7.5%) had PNH clones. The incidence of PNH clones categorized by ICD-9 diagnostic code are presented in Table 1.

Table 1. Incidence of PNH Clones in Patients with ICD-9 Diagnostic Code at Dahl-Chase Diagnostic Services

ICD-9 Diagnostic Code	General Description	Incidence of PNH Clone
284, 284.01, 284.8, 284.81, 284.89, 284.9	Aplastic Anemia	26.1% (94/360)
238.7, 238.72, 238.73, 238.74, 238.75, 238.76	Myelodysplastic Syndrome	5.5% (32/584)
287.5	Unexplained Cytopenia	5.3% (14/263)
284.1	Pancytopenia	6.0% (61/1011)
285.2, 285.21, 285.29, 285.9	Anemia Unspecified	3.1% (37/1176)
283, 283.1, 283.10, 283.11, 283.19, 283.9	Hemolytic Anemia[a]	22.0% (143/651)
791, 791.2	Hemoglobinuria	11.3% (7/62)
790.6, 790.99, 790.4	Hemolysis	6.5% (15/231)
325, 415.1, 415.11, 434, 434.01, 444.22, 451.11, 451.19, 452, 453, 453.0, 453.2, 453.4, 453.41, 453.89, 453.9, 557, 557.1	Thrombosis	1.7% (17/1020)
280.9	Unspecified Iron Deficiency	2.0% (6/295)

[a]*Includes patients who were known to be PNH positive.*

Anemia unspecified and thrombosis comprised the most common reasons for testing. In BMF syndromes, patients with aplastic anemia had the highest incidence of PNH-positive clones (26.1%), followed by patients with pancytopenia (6.0%), myelodysplastic syndrome (5.5%), unexplained cytopenia (5.3%), and unspecified anemia (3.1%) (Table 1). The incidence of PNH clones for other symptoms was 22.0% for hemolytic anemia, 11.3% for hemoglobinuria, and 6.5% for unspecified hemolysis. **Conclusions.** In this single-laboratory retrospective study, when analyzing patients by ICD-9 diagnostic code, PNH-positive clones were detected in 7.5% of patients (426/5653). The high prevalence of positive PNH clones supports the ICCS guideline recommendations to screen for PNH in patients with hemolytic anemia, hemoglobinuria, and bone marrow dysfunction. Thrombosis was one of the most common ICD-9 codes tested in our study, with approximately 2% of patients positive for a PNH clone. The ICCS guidelines recommend testing patients with thrombosis and elevated hemolysis or unexplained cytopenia, or prior thromboembolism in unusual sites. Combining these clinical risk factors should increase PNH prevalence in patients with thromboembolism. This study confirms the need to consistently test high-risk populations for PNH to ensure early, accurate diagnosis and intervention.

COMPARISON OF MULTIPLE PROGNOSTIC MODELS IN PATIENTS WITH MYELODYSPLASTIC SYNDROME: THE IMPACT OF COMORBIDITIES

KW Chen, YC Huang, C Liu, Y Yu, CY Liu, L Hsiao, JP Gau, JH Liu, TJ Chiou, PM Chen, Tzeng, YC Hong

Taipei Veterans General Hospital, Taipei, Taiwan

Background. Several prognostic models have been developed for patients with myelodysplastic syndrome (MDS), a heterogeneous and complex hematologic clonal disorder primarily in elderly population. Growing evidence suggests that baseline comorbidities at diagnosis influence outcome negatively.

Aims. We investigated the optimal prognostic model in these patients in a tertiary medical center. **Methods.** The study enrolled 263 consecutive patients diagnosed of myelodysplastic syndrome between 1996 and 2010. International prognostic scoring system (IPSS), WHO classification-based prognostic scoring system (WPSS), MD Anderson Cancer Center (MDACC) total MDS scores were calculated. Overall survival (OS) was compared for different risk groups in each model. The efficacy of these models was compared by the value of Akaike information criterion (AIC). Other clinical and laboratory variables associated with survival were assessed by Kaplan-Meier method, and then validated by Cox regression. A new prognostic model incorporating age, baseline comorbidities, bone marrow blast percentage and karyotype was proposed to predict survival in this cohort. **Results.** Total MDACC MDS prognostic model was more informative to categorize these patients into different risk groups than IPSS and WPSS according to the analysis of AIC value. Univariate analysis of this cohort revealed multiple prognostic factors, including age, performance status, lactate dehydrogenase (LDH), presence of blast in peripheral blood, blast percentage in bone marrow, high risk karyotype, Hematopoietic cell transplantation-comorbidity index. In multivariate analysis, more than 70 years [hazard ratio(HR), 4.02], complex karyotype or chromosome 7 anomalies [hazard ratio(HR), 6.22], bone marrow blast ≥ 10% [hazard ratio(HR), 10.47], and HCT-CI ≥ 3 [hazard ratio(HR), 5.27] were significant prognostic factors. We proposed a new prognostic scoring system using the four factors mentioned above to categorize patients into five risk groups with the median OS of not reached, 33.7 months, 12.9 months, 8.1 months, and 3.2 months, respectively. Conclusions. Adding HCT-CI in the new model incorporating other well-established factors in the prediction of outcome could better determine the prognosis in these patients and warrant further validation of this strategy in prospective large scale trials.

CLINICAL EVALUATION OF ARRY-614, A DUAL P38/TIE2 INHIBITOR FOR PATIENTS WITH MYELODYSPLASTIC SYNDROMES, IDENTIFIES UNIQUE DISEASE-RELATED AND DRUG-RELATED BIOMARKERS

G Garcia-Manero[1], R Komrokji[2], S Winski[3], J Garrus[3], L Cable[3], D Kilz[3], D Chantry[3], G Hogeland[3], S Bell[3], S Rush[3], M Ptaszynski[3], A List[2], H Khoury[4]

[2]H. Lee Moffitt Cancer Center and Reseach Institute, Tampa, United States of America
[3]Array BioPharma Inc., Boulder, United States of America
[4]Winship Cancer Institute of Emory University, Atlanta, United States of America

Myelodysplastic syndromes (MDS) are diseases of defective hematopoiesis associated with apoptosis of hematopoietic progenitor cells. A number of signal transduction pathways have been implicated in these processes, including p38 mitogen-activated protein kinase (MAPK) and Tie2. ARRY-614 is a low-nanomolar, small-molecule dual inhibitor of p38 MAPK and Tie2 that has been studied in a Phase 1 clinical trial in patients (pts) with MDS and has demonstrated encouraging clinical activity. Forty-five pts with IPSS Low (n = 11) or Int-1 (n = 34) Risk MDS were studied. All but 2 pts had disease that was refractory/relapsed from prior therapy (median 3 prior regimens); 80% received prior hypomethylating agents (HMA). Hematological improvement (HI) was assessed by International Working Group 2006 criteria and responses were observed in all lineages (erythroid, neutrophils, platelets), including 5 bi-lineage responses (duration 8-80 weeks). All responders (n=13 of 44 evaluable pts, 30%) received at least one prior HMA. At the highest dose (1200 mg QD), 6 of 16 evaluable pts (38%) achieved HI in one or more lineage (67% bilineage).To identify possible biomarkers of disease or response, plasma from patients in the Phase 1 trial and age-defined healthy subjects was submitted for multi-analyte profiling using quantitative multiplex immunoassays. Differences in baseline levels between patients, age-matched subjects (60-75 years old) and younger subjects (≤ 60 years old) were considered significant by the Kruskal-Wallis test if $p<0.01$. Numerous analytes in patient baseline samples were different from younger healthy subjects but many changes were found to be related to age rather than disease, including eotaxin, eotaxin-3, IL-13, MMP-3 and others. This reflects the need for utilizing age-matched controls in this population. Some differences in baseline analyte concentrations were found to be related to MDS compared to age-matched subjects, including EPO, Ferritin, B2M, VCAM-1, CD40 and the Tie2 ligand, Angiopoietin-2.A subset of analytes was evaluated for change from baseline during ARRY-614 treatment. Of interest were analytes bearing AU-rich sequences in the 3'-untranslated region (e.g. IP-10, TARC, MIP1beta, IL-8 and EPO); known targets for p38-dependent regulation by mRNA stabilization and surrogate markers for p38 inhibition. Decreases in MIP1beta over 24 hours correlated with increasing ARRY-614 administered dose, suggesting this analyte to be a useful biomarker of drug exposure. The decrease in MIP1beta, while likely related to acute drug exposure, was not sustained and returned to baseline within 30 days. Other analytes had a similar pattern of regulation (e.g. IL-8, IP-10, etc.), suggesting that these may be associated with acute p38 inhibition but are not associated with improvements in disease. Importantly, some analytes remained suppressed for 90+ days (e.g. EPO, MCP-4), and thus may be associated with improvements in disease. This possible association between long-term cytokine modification and disease status or response is being further explored.In summary, ARRY-614 is a dual p38/Tie2 inhibitor, actively in development in MDS, that has demonstrated clinical activity and on-target PD effects in pts with MDS. The identification of unique biomarkers that are associated with disease improvement could greatly aid the understanding of the pathophysiology of MDS.

[9]Medical University of Bialystok, Bialystok, Poland
[10]Pomeranian Medical University, Szczecin, Szczecin, Poland
[11]Medical University of Gdansk, Gdansk, Poland

Background. Severe form of acquired aplastic anemia (SAA) in children is treated with the bone marrow transplantation from the family donor as the method of choice. The combinated therapy with antithymoglobulin (ATG) with cyclosporine is used in the absence of a matched related donor. The horse globulin (hATG) has been the first choice treatment recently, but already is almost unavailable in Europe. That is why the rabbit ATG (rATG) started to be used, which was applicable in the second course of immunosuppressive therapy (IST) with good results in cases of failure after hATG **Aims.** The aim of this study was a retrospective analysis of treatment effects in children with SAA with hATG and rATG. **Methods.** The study included 123 children with SAA in the period from 1995 to 2011, who were treated in 11 centers of pediatric hematology and oncology inPoland. (Age from 2 to 17 years). 60 of them received hATG (15mg ATG/kg/5 days and cyclosporine-CSA 5 mg / kg for 12-24 months) and 63 were given rATG (3.75 mg/kg/5 days and CSA 5mg/kg for 6-12 months). Response rate was assessed on 112, 180 and 360 day and defined as complete remission (CR), partial remission (PR), no response (NR).Results The response to the treatment (complete and partial remission in total) at the 84th day was 69% in hATG group versus 45%in rATG group ($p = 0.0070$) respectively, 69% versus 50% in the 112th day ($p = 0.03$) and 75% versus 57% in the

180th day (p = 0.04). There was no difference in the response in the 360th day-86% versus 77% (p = 0.25). The registered deaths in both groups were 10 in hATG group versus 15 in rATG group respectively. The estimated probability of overall survival did not differ between groups of patients treated with hATG and rATG (p = 0.09) for 11 years of observation period. The estimated event-free survival was 0.73 (95% CI 0.60, 0.83) for hATG and 0.57 (95% CI 0.35, 0.74) for rATG (p = 0.18) in the same period of time. In graph we perform EFS in groups treated with hATG and rATG according to response at 360th day of therapyThe estimated value of the probability of absence of the relapse (PFS) after 9 years of follow-up were 0.87 (95% CI 0.74, 0.93) in the hATG group and 0.81 (95% CI 0.44, 0.95) in the rATG group respectively. Relapses occurred in 13% patients after hATG treatment and in 19% patients treated with rATG approximately (p = 0.31).. The bleeding complications occured significantly more often after rATG in relation to hATG (p = 0.021).Summary Although this was not a randomized study, but it proved that the use of hATG as first-line treatment gives better results in children with SAA. OS in both groups was not significant, but at the border for the benefit of hATG. The bleeding complications were observed more often after rATGEtiology, age and sex have no influence on the survival.

[5]Service d'Onco-hématologie, Centre Hospitalier Avignon, Avignon, France
[6]Novartis Pharma, SAS, Rueil-Malmaison, France
[7]Service d'Hématologie, Centre hospitalier Annecy, Annecy, France
[8]Service d'Hématologie, CH Lyon sud, Pierre Bénite, France
[9]Service d'Hématologie Clinique, Centre Hospitalier Hôtel Dieu, Nantes, France

Background. Controlling iron overload during MDSs is of critical importance for patients dependent on frequent and/or regular transfusions. **Aims.** To describe how iron overload is managed in real conditions as part of this disease. **Methods.** An observational, prospective study was carried out in France, involving 50 physicians. MDS patients were included when they presented with an iron overload defined by, at least, serum ferritin ≥ 800 ng/ml or transfusion of > 15 PRBC. **Results**. 270 patients were included between October 2010 and January 2011. Results for 247 patients were included in the final analysis. Median age was 75 years (33-92), and 57% of patients were male. The distribution according to WHO classification was: 9.7% RA, 16.6% RCMD, 22.9% RARS, 7.4% RCMD-RS, 15.4% RAEB-1, 16.6% RAEB-2, 4.6% MDS 5q-, and 6.9% unclassifiable MDS. MDS was of low risk in 78% of patients, and high risk in 22% of patients. Patients' IPSS score was 0 for 38.8%; 0.5 for 24.9%; 1 for 14.4%; and greater than 1 for 22%. Median hemoglobin before the first transfusion was 7.8 g/dl. 73% of patients had received more than 2 PRBC/month over the last six months. 74% of patients were/are treated with ESAs, 27% with hypomethylating agents, and 13% with IMids. At inclusion, 73.5% of patients had serum ferritin levels at >1000 ng/ml; median serum ferritin was 1571 ng/ml. For low-risk MDS, median serum ferritin was 1473 ng/ml, compared to 1900 ng/ml for high-risk cases. At inclusion, 53.3% of patients were treated with iron chelation therapy; median serum ferritin for this group was 1742 ng/ml (670-9549). In the 46.6% not receiving chelation therapy, median serum ferritin was 1556 ng/ml (263-9500). Chelation therapy was initiated in the 12% of patients with a median serum ferritin of 1643 ng/ml. The main reasons for initiating this treatment were: serum ferritin level (93%), number of PRBC transfused (58%) with PRBC transfusions >20 (38%), age (25%), and, finally, IPSS score (23.5%). Hepatic and cardiac MRI were performed in 12% and 18% of patients, respectively. At six months, compliance was good, with only 2% of treatment discontinuations. In 125 patients* receiving chelation therapy at six months, a reduction in median serum ferritin from 1493 ng/ml (66-8443) to 1274 ng/ml (9-7524) was observed. A reduction of transfusion requirements was observed in 51 patients, of which 29 were under chelation therapy, and 14 were not receiving any treatment with a potential effect on hematopoiesis. **Summary and Conclusions.** Recommendations suggest starting chelation therapy when serum ferritin exceeds >1,000-1,500 ng/ml. In this study, therapy was more likely to be initiated above 1,600 ng/ml, probably due to the fact that patients were at high-risk (22%), and older (23% over 80 years).This large cohort is representative of iron overload management in MDS patients in France in real conditions, including management of high-risk MDS.

0891

THERAPY-RELATED MYELODYSPLASTIC SYNDROME: AN ANALYSIS OF 5 RISK MODELS IN PATIENTS TREATED WITH AZACITIDINE

V Duong, J Lancet, N Al-Ali, A List, R Komrokji
H. Lee Moffitt Cancer Center, Tampa, FL, United States of America

Background. Therapy-related myelodysplastic syndrome (t-MDS) arises as a complication of prior chemotherapy and/or radiation, and outcomes are generally poor. Several risk models for MDS have been developed but only the Global MD Anderson Risk Model and the recently reported therapy-related MDS risk model have been validated in patients with t-MDS, and none have specifically evaluated patients treated with azacitidine. **Aims.** The primary objective of the study was to compare the performance of 5 current MDS risk models (International Prognostic Scoring System (IPSS), revised International Prognostic Scoring System (rIPSS), WHO Classification-based Prognostic Scoring System (WPSS), Global MD Anderson Risk Model, and the therapy-related MDS risk model) in predicting overall survival in t-MDS patients treated with azacitidine. **Methods.** Outcomes of patients with t-MDS treated with azacitidine at the Moffitt Cancer Center were analyzed retrospectively. Each patient was assigned the appropriate score based on each risk model. The Kaplan-Meier method and log-rank test were used to evaluate survival according to each risk model and descriptive statistics were used for baseline characteristics. All statistical analyses were conducted using SPSS software, version 20.0. **Results.** We identified 84 patients (88% Caucasian, 56% male, median age 65 years) with t-MDS treated with azacitidine. Chemotherapy was previously administered in 51% of patients, radiation in 12%, and both chemotherapy and radiation in 37%. The median overall survival of the cohort was 14.7 months. When the five risk models were applied, only the Global MD Anderson risk model predicted overall survival with statistical significance. Using this model, patients with either low or int-1 risk (n=8) had a median survival of 28.3 months, compared to 17.0 months in patients with int-2 risk (n=23) and 11.5 months in patients with high risk (n=53), *p*=0.04 **(FIGURE 1)**.

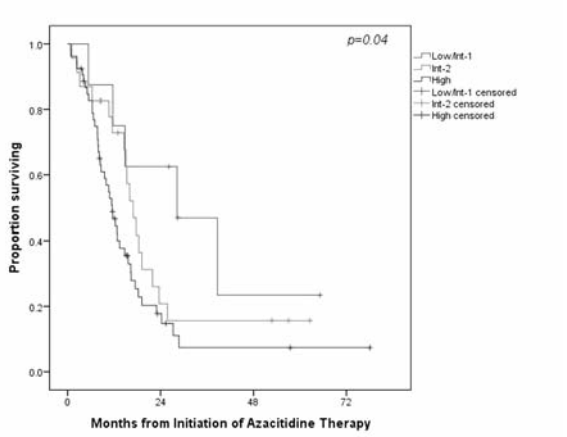

Figure 1. Survival according to Global MD Anderson Risk Model.

Using the therapy-related MDS risk model, the respective median overall survival for patients with low (n=6), intermediate (n=41), and high (n=28) risk scores were 14.8 months, 16.4 months, and 11.6 months, respectively (*p*=0.08). The IPSS, rIPSS, and WPSS did not predict overall survival with statistical sig-

nificance. With every risk model, patients in the highest risk category had a median overall survival between 11.4-11.7 months. **Summary and Conclusions.** In our cohort of patients with t-MDS treated with azaciditine, the Global MD Anderson risk model appeared to be the best predictor of overall survival, followed by the therapy-related MDS risk model, although the latter did not reach statistical significance. As expected, the IPSS, rIPSS, and WPSS were not useful in predicting survival. Our analysis is limited by the retrospective nature and the relatively small number of patients, but supports previous studies reporting poor outcomes in this patient population.

P53 AND PUMA EXPRESSIONS IN BONE MARROW BIOPSIES OF PATIENTS WITH MYELODYSPLASTIC SYNDROME (MDS)

O Bektas, A Uner, Y Buyukasik, B Uz, E Eliacik, A Isik, I Haznedaroglu, H Goker, H Demiroglu, S Aksu, O Ozcebe, N Sayinalp
Hacettepe University, Ankara, Turkey

Background. p53 is a tumor suppressor gene and a key regulator of apoptosis. P53 mutations confer a poor prognosis in several hematologic malignancies. PUMA (p53 upregulated modulator of apoptosis) is also extremely effective in inducing apoptosis. PUMA is a critical mediator of p53-dependent and independent apoptosis. **Aims.** The objectives of this study were i) To compare the expressions of p53 and PUMA in bone marrow hematopoetic cells of MDS patients with those of healthy subjects ii) to evaluate the prognostic effect of these apoptosis regulators (p53 and PUMA) on overall and event free survival of MDS patients, iii) to evaluate the relationship between p53 and PUMA. **Methods.** The expression of p53 and PUMA was evaluated using immunohistochemistry The procedure was carried out using specific antibodies against p53 and PUMA. Bone marrow biopsies of MDS patients at the time of diagnosis (n=103) as well as at the time of transformation (n= 20) were included in the study group. Bone marrow biopsies from individuals who had no hematologic disorder (n=12) were included as control. After staining a total of 500 bone marrow precursors were counted to calculate the percentage of positively staining cells. **Results.** The percentage of cells showing p53 and PUMA expressions were significantly higher in bone marrows of MDS patients as compared to normal bone marrow samples (p= 0,012, p=0,000, respectively). In MDS samples, there was a moderate positive correlation between p53 and PUMA expressions (R= 0.478). Although there was a mild correlation between PUMA expression and high scores in IPSS, WPSS and MPSS clinical scoring systems (R= 0.326, 0,236, 0,208 respectively), such association was not identified for p53. Additionally, there was no association between p53 or PUMA expression levels and bone marrow cellularity, cytogenetic risk assessment, MDS subgroups, overall survival and event free survival. There was however, a significant increase in PUMA expression in cases which showed transformation (p=0,038) as compared to the initial diagnostic bone marrows. No such association was observed for p53 expression (p=0,601). **Summary.** Our results showed that p53 and PUMA expressions are significantly higher in bone marrow cells of MDS patients compared to healthy controls. This finding may be especially helpful in the diagnosis of hypocellular and normocellular MDS cases. The observation that PUMA expression increases during transformation while the expression of p53 is not significantly altered suggests that PUMA alterations might be a late event during the development of MDS. However, studies with higher number of cases comparing bone marrow samples from before and after transformation are needed for a more conclusive statement. **Acknowledgments.** Supported by a grant from Hacettepe University Research Foundation

RUNX1 MUTATIONS IN LEUKEMIAS DEVELOPED IN PATIENTS WITH CONGENITAL NEUTROPENIAS

J Steinemann, J Skokowa, C Zeidler, G Göhring, B Schlegelberger, K Welte
Medical School Hannover, Hannover, Germany

Background. Most bone marrow failure syndromes (bmfs) are associated with a marked propensity to transform into myelodysplastic syndrome (MDS) or acute leukemia, with a cumulative rate of transformation that may exceed 20% (e.g., in the case of severe congenital neutropenia). **Aims**. The genetic (and epigenetic) changes that contribute to malignant transformation in bmfs patients are largely unknown and have to be resolved. **Methods.** To elucidate the underlying molecular mechanisms of cancer susceptibility and progression in secondary MDS or acute leukemia in bmfs patients we conducted a comprehensive genome-wide characterization of genetic aberrations in the malignant cells at high-resolution level. We used high density DNA microarray (Agilent 400k/180 k) and direct sequencing of putative cancer genes to analyze a series of 31 bmfs patients at different time points during the progression into MDS and AML (51 samples in total). **Results**. Large genomic alterations, namely monosomy 7/-7q, +21q or +3q were associated with leukemic progression. Beside common copy number variants like *UGT2B*, *GSTT1*, *HEATR4*, no microdeletions or microduplications were detected in the primary or secondary diseases. However, we found recurrent somatic missense and frameshift mutations in the transcription factor *RUNX1/AML1* in 12% of all bmfs patients. Of the 31 bmfs patients, 26 were diagnosed as congenital neutropenia, one as cyclic neutropenia, two with Fanconi-anemia (FA), one with Shwachman-Diamnond syndrome (SDS), one with MDS. Eight of the 26 patients with congenital neutropenia developed secondary AML, four of the 8 (50 %) revealed somatic mutations within the *RUNX1* gene. The mutations were missense mutations of the conserved Arginine residues R139G, R174L or truncating frameshift mutations. None of the FA, SDS, or MDS patients revealed *RUNX1* mutations.**Summary**. Notably, *RUNX1/AML1* mutations have recently been described in Fanconi anemia during leukemic progression. *RUNX1/AML1* may have a more general role in the malignant transformation of patients with bone marrow failure syndromes, especially in patients suffering from congenital neutropenia.

A RANDOMIZED STUDY OF DECITABINE ALTERNATING WITH CLOFARABINE VERSUS DECITABINE ALONE IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROME (MDS)

S Faderl, G Garcia-Manero, T Kadia, G Borthakur, E Jabbour, F Ravandi, Z Estrov, J Cortes, J Autry, H Kantarjian
MD Anderson Cancer Center, Houston, United States of America

Background. Patients (pts) with higher-risk MDS continue to have a poor prognosis even in the era of hypomethylating agents such as decitabine (DAC) or azacitidine (AZA). Clofarabine (CLO) is a second generation deoxyadenosine nucleoside analog with activity in pts with MDS as previously reported by us and other groups. **Aims.** In this study we aim to compare the efficacy and safety of using DAC alternating with CLO compared with a standard approach of DAC alone. **Methods.** Eligible pts were older than 18 years (yrs) with a diagnosis of higher-risk MDS (intermediate-2 and high risk groups based on the International Prognostic Scoring System [IPSS] and/or ≥ 10% marrow blasts). Prior intensive chemotherapy was not permitted but patients could have been exposed to biological or targeted therapies (not more than 1 cycle of DAC or AZA). Patients were randomized to DAC 20 mg/m^2 IV daily x 5 for up to a total of 24 cycles or DAC 20 mg/m^2 IV daily x 5 for 3 cycles each alternating with CLO 10 mg/m^2 IV daily x 5 for 3 cycles each for a total of 24 cycles. Concomitant use of hematopoietic growth factors was permitted as per the treating physicians' discretion. **Results.** Twenty pts were enrolled of whom 15 are evaluable. Among the 5 inevaluable pts 2 were too early and 3 did not start treatment because of insurance denial. None of the pts received prior therapy for the MDS. The median age was 66 yrs (50-85). Based on IPSS, 9 pts were intermediate-2 and 6 high-risk. Based on WHO 5 pts had RAEB-2, 3 RAEB-1, 3 therapy-related MDS (marrow blasts 5%, 6%, 12%), 2 CMML-2, and 1 MDS-unclassifiable. One pt had 20% marrow blasts consistent with RAEB-T. Six pts were randomized to DAC alternating with CLO and 9 to receive DAC only. Overall, 11 pts (80%) responded (7 CR [47%], 2 PR, 2 hematologic improvement [HI]). Responses were comparable in both arms (DAC alternating with CLO: ORR 67%, CR 50%; DAC single agent: ORR 78%, CR 44%). Four pts (2 in each arm) proceeded to an allogeneic stem cell transplant (2 in CR, 1 PR, 1 stable disease). Three patients were taken off study because of progression to AML (2 pts on DAC single agent). The median number of cycles administered was 6 (2-15). Treatment was tolerated well in both arms. Most toxicities were < grade 2. Only one grade 3 toxicity (infection) occurred (DAC single agent). **Summary and Conclusions.** Both treatment arms are equally effective and well tolerated. The substitution of DAC with CLO in half of the cycles has not resulted in higher toxicities. The study is ongoing. With ongoing accrual, updated results and time-to-event parameters will be presented.

[6]Di Cristina Hospital, Pediatric Hematooncology, Palermo, Italy

Fanconi Anemia (FA) is a chromosomal instability syndrome with hypersensitivity to alkylating agents. Many laboratories have demonstrated involvement of FA proteins in DNA-repair mechanisms. Recent work has also demonstrated other functions of some FA proteins suggesting alternative roles in other regulatory pathways, particularly those influencing hematopoiesis. Eighty percent of FA patients develop bone marrow failure with high incidence of evolution in myelodysplasia and/or acute leukemia. These abnormalities have been related to TNF-alpha hypersensitivity in the stem and progenitor-cell pools and to toll-like receptor (TLR)-dependent overproduction of TNF-alpha by FA macrophages. The TNF-hypersensitive phenotype involves two kinases, PKR and ASK1, hyperactivated in FA cells inducing apoptotic responses both in ground state and after TNF-alpha stimulation. Recent evidence showed that TNF-alpha gene expression in *Fancc*-deficient mononuclear phagocytes induced by TLR8-ligand R848 and TLR4-ligand LPS, is inhibited by kinase-inhibitors dasatinib and BIRB796. We sought to evaluate the activity of these agents in primary monocytes and colony assays from children with FA-A. **Aims.** (i) To determine whether primary monocytes from FANCA-deficient patients: (a) exhibit TNF-overproduction phenotype in response to LPS and R848, and (b) respond to dasatinib and BIRB796 by suppressing TNF-production. (ii) Evaluate the effect of dasatinib and BIRB796 on colony growth of marrow mononuclear cells (MNCs) and CD34+ cells from FANCA-deficient patients. **Methods.** Eight FA patients with mild to severe marrow failure were included. Healthy subjects were recruited as normal controls that were run in parallel in each case. CD14+ monocytes freshly isolated from peripheral blood were cultured for 24 hours with LPS and R848 with or without dasatinib and BIRB796. Supernatant media were collected and frozen at -80 degrees. After thawing samples, TNF-alpha content was quantified by ELISA. Marrow mononuclear and CD34+ cells, freshly isolated by magnetic beads from marrow MNCs, were cultured in semi-solid culture medium supplemented with grow factors and with BIRB, dasatinib and anti-TNFalpha. Colonies were counted after 14 days.Results. Baseline TNF-alpha concentration (without TLR-stimulation) was higher in FA-A patients' monocytes than controls. After LPS and R848 stimulation FA-A monocytes produced substantially more TNF-alpha than control samples. Both dasatinib and BIRB796 suppressed spontaneous and TLR-induced (both LPS and R848) TNF-alpha production in FA monocytes. In MNC colony assay BIRB alone and BIRB in association with antiTNF-alpha increased erythroid and myeloid colony numbers and in CD34+ colony assay increased erythroid colony growth. Dasatinib alone and in combination with antiTNF-alpha consistently suppressed colony growth.Conclusions: These findings demonstrate that in primary FANCA-deficient monocytes TLR-induced TNF-alpha gene expression is aberrantly regulated and TNF-alpha overproduction can be controlled by therapeutically achievable doses of BIRB796 and dasatinib. Colony growth from MNCs and CD34+ is increased by BIRB but suppressed by dasatinib. Thus, given that in FA patients TNF-alpha hypersensitive stem-cells are over-exposed to TNF-alpha, particularly during inflammatory events, and that exposure to TNF-alpha was shown not only to suppress hematopoiesis in FA but also to favour the emergence of neoplastic clones, these results point to BIRB796 as a potential candidate for preclinical trials seeking to enhance hematopoiesis and suppress clonal evolution.

PLATELET RESPONSE AT SECOND CYCLE OF DECITABINE CAN PREDICT RESPONSE AND SURVIVAL FOR MYELODYSPLASTIC SYNDROMES (MDS) PATIENTS

HA Jung, J Jang, S Kim, C Maeng, K Kim, C Jung
Samsung Medical Center, Seoul, South-Korea

Background. Decitabine treatment is effective in patients with MDS. However, there is wide range of response rate of decitabine as 30-54%. However there was no predictive marker for overall response rate and overall survival. **Aims.** We aimed to describe the efficacy and safety of decitabine and to investigate predictors for response and survival. **Methods.** We analyzed clinical data including treatment outcome in MDS patients who received 5-day regimen of decitabine in Samsung Medical Center between August 2008 and August 2011 retrospectively. **Results.** We analyzed 100 MDS patients (total 708 cycles). Patients received decitabine for a median of six cycles (range 1-25). The overall response rate (complete/partial/hematologic improvement) was 58%. Median time to any response was 1 (range 1-6). With a median follow-up duration of 380 days (range 110-1320), median overall survival was 17.7 months. Patients who showed hematologic improvements (HI) had significantly longer survival than those who did not (16.7 vs 22.5 months, P=0.002). The difference in OS was evident in the Intermediate-2/High risk group but not in the Intermediate-1 risk group. The OS in patients with marrow complete remission (m-CR) was not different to those without m-CR. Among 708 treatment courses, there were 128 fever episodes requiring intravenous antimicrobials. Multivariate analysis confirmed platelet response at second cycle [Hazard Ratio (HR) 0.339, 95% confidence interval (CI) 0.125-0.917; P=0.033] as a independent predictor for response and OS. 91.4% of patients that demonstrated improvement (CR/m-CR/PR/HI) by cycle 2. **Conclusions.** In conclusion, response of decitabine is fast and effective, and the OS was significantly longer in patients showing HI.

EFFICACY AND SAFETY OF ECULIZUMAB IN CHILDREN AND ADOLESCENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

U Reiss[1], J Schwartz[2], G Puthenveetil[3], M Ogawa[4], R Ware[5]
[1]St. Jude Children's Research Hospital, Memphis, United States of America
[2]Nemour's Children's Clinic, Pensacola, United States of America
[3]Department of Pediatrics, Children's Hospital of Orange County, Orange, United States of America
[4]Alexion Pharmaceuticals, Inc., Cheshire, United States of America
[5]Texas Children's Hematology Center, Houston, United States of America

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a progressive, life-threatening disease characterized by chronic intravascular hemolysis caused by uncontrolled complement activation. The cellular abnormality in PNH originates from a somatic mutation in the *PIG-A* gene that results in a deficiency of the glycosylphosphatidylinositol (GPI)-anchored complement regulatory proteins CD55 and CD59. Clinical manifestations of PNH include hemolysis, cytopenia, thromboembolism, multiorgan damage, bone marrow failure, and death. Patients with PNH also experience a range of debilitating symptoms, including fatigue, shortness of breath, and abdominal pain, that significantly reduce quality of life. Systematic research in pediatric PNH patients has been limited, largely due to small patient numbers. However, pediatric PNH patients experience many of the same clinical features and life-threatening complications as adult patients. **Aims.** Assess the safety, pharmacokinetics, and efficacy of eculizumab treatment in children and adolescents with PNH. **Methods.** This 12-week, open-label, multicenter Phase I/II study included children and adolescents (aged 2-17 years) with a diagnosis of PNH. Inclusion criteria: ≥5% GPI-deficient red blood cells or granulocytes and either serum lactate dehydrogenase (LDH) levels greater than the upper limit of normal (ULN; 275 U/L) or to have received ≥1 transfusion during the previous 2 years for anemia or anemia-related symptoms. Eculizumab was administered using weight-based dosing (300-900 mg IV) at protocol-specified regular 7-14-day intervals throughout the treatment period.**Results.** Seven pediatric patients with PNH (aged 11-17 years; 4 females) participated in this study. At baseline, patients had elevated LDH, thrombocytopenia, and anemia. Peak and trough eculizumab plasma levels increased gradually and appeared to reach a plateau between 3 and 4 weeks. Mean (standard deviation) trough plasma eculizumab concentration at week 12 was 214.5 µg/mL (68.3 µg/mL), with a range of 124.2-321.1 µg/mL. Eculizumab treatment led to a rapid and sustained reduction in LDH levels from a mean of 1020 U/L at baseline to 257 U/L already at 2 weeks. When compared with baseline values, LDH decreased by 90% in all patients, indicating full inhibition of hemolytic activity. None of the patients experienced breakthrough hemolysis. Eculizumab was well-tolerated; the most common adverse

events, reported by 2 or more patients, included headache, upper abdominal pain, cough, and pyrexia, and were all mild to moderate in severity. The pharmacodynamic and safety profile of eculizumab was consistent with that previously reported in adult patients with PNH. **Conclusions.** Consistent with results in adults, eculizumab was well tolerated in pediatric patients and successfully inhibited uncontrolled complement activation and intravascular hemolysis. These results highlight the potential of eculizumab for the treatment of children and adolescents with PNH.

Background. Transfusion-dependent (TD) MDS patients have a significantly shortened survival as compared to patients who are not dependent on transfusions. This effect might be propagated or exacerbated by cumulative systemic iron deposition following repeated RBC transfusions. While appropriate iron chelation can prolong survival in patients with thalassemia major, this is still a highly debated topic in MDS. **Aims**. To investigate the effect of iron chelation treatment (ICT) on overall survival and leukemia-free survival and to collect information on treatment modalities, transfusion needs and chelation practices in transfusion dependent MDS patients in Belgium. **Methods.** A Belgian cross-sectional analysis, performed in Oct-Dec 2008, identified a cohort of 193 TD MDS patients (Delforge *et al.*, Ann Hemat, 2011). Two years later, this non interventional, retrospective study allowed us to collect and analyze follow-up data from 186 patients of the original cohort, providing longer term information on patterns of disease management in TD MDS patients, including ICT and its potential impact on survival. **Results**. Of 186 patients included in this study, 38% were still alive and 4% were lost to follow-up 2 years after the first cross-sectional study. At the time of diagnosis, 127 patients (68%) were classified as low-intermediate1 IPSS score, 17 (9%) with intermediate2-high IPSS score, while for 42 patients no IPSS score was available. At diagnosis mean serum ferritin was 524 µg/L. Iron chelation therapy was started on average 3.6 yrs after diagnosis and 1.4 years after the first RBC transfusion. At initiation of ICT, the mean serum ferritin was 2302 ± 2607 µg/L. 74 patients (40%) never received any chelation therapy. For 18% of patients progression to AML was reported after a median of 24 months.MDS patients with low-intermediate1 IPSS scores at diagnosis had a median survival of 87 months. Patients from this group who received ICT for at least 6 months had a significantly longer median survival than non-chelated patients (126 *vs.* 37 months; *p<0.001*). This survival difference remained significant when looking only at low IPSS patients (171 *vs.* 37 months; *p<0.001*) or only at intermediate1 patients (126 *vs.* 37 months; *p=0.002*). AML-free survival was similarly different between the two groups. In Cox Proportional Hazard models the use of iron chelation therapy appeared to be the most prominent factor impacting survival, followed by calculated "transfusion intensity". **Conclusions**. Although we cannot exclude a patient selection bias, this study confirms in an independent way the previous findings of the Groupe Francophone des Myelodysplasies (Rose *et al.*, Leuk Res, 2010) and of the Dusseldorf registry (Fox *et al.*, Blood abstr 1747, 2010): patients who received iron chelation treatment have a better outcome. Prospective randomized trials remain necessary to confirm the benefit of ICT and to identify the reason for the survival advantage.

MECHANISMS DRIVING THROMBOPOIETIN RECEPTOR DOWN MODULATION IN JAK2 V617F-POSITIVE MYELOPROLIFERATIVE NEOPLASMS

S Constantinescu[1], C Pecquet[1], C Diaconu[2], J Staerk[3], M Girardot[4], Y Royer[5], JP Defour[1], A Dusa[1], L Knoops[1], S Giraudier[6], JL Villeval[6], P Courtoy[1], W Vainchenker[6]

[6]Institut Gustave Roussy, Paris, France

Beyond the role of JAK2 in the induction of signaling pathways, JAK2 has been shown to play a crucial role in the receptor traffic by increasing the cell surface expression and by stabilizing the mature Endoglycosidase-H resistant form of TpoR. The constitutively active JAK2 V617F mutant is the major determinant of human myeloproliferative neoplasms (MPNs). One hallmark of MPNs consists in the post-translational down-regulation and impaired maturation of TpoR (c-MPL) in megakaryocytes and platelets of patients.We are showing that co-expression of JAK2 V617F and TpoR in hematopoietic cell lines or heterozygous knock-in of JAK2 V617F in mice leads to down-modulation of TpoR levels. The mechanisms behind this effect is represented by enhanced TpoR ubiquitinylation at cytosolic lysine residues, proteasomal degradation, along with reduced recycling and maturation.TpoR down-regulation required the presence of the two lysine residues, K40 (544) and K60 (564), in the intracellular domain as well as Y626 residue necessary for MAP-kinase and STAT3 signaling pathways. Restoration of TpoR levels by inhibitors could be detected in platelets from JAK2 inhibitor treated myelofibrosis patients that express the JAK2 V617F mutant, and in platelets from JAK2 V617F knock-in mice that were treated with JAK2 or proteasome inhibitors.In addition, we show that Tpo can induce both proliferative and antiproliferative effects via Y626 of TpoR at low and high JAK2 activation levels, respectively, or upon expression of JAK2 V617F suggesting that selection against TpoR antiproliferative signaling occurs by Tpo down-modulation. Furthermore, a microarray analysis performed on Ba/F3 cells expressing TpoR and JAK2 wild-type stimulated with high Tpo concentration shows down-regulation of 70 cell cycle related genes, which coincides with the antiproliferative role of Tpo in cells that express high JAK2 levels.Finally, we have explored the ubiquitome and the profiles of ISGylated and SUMOylated proteins upon Tpo activation based on the Ubiscan® Ubiquitinylation proteomics method to detect with a specific monoclonal antibody a diglycine (KGG) tag that is the remnant after trypsin digestion of ubiquitin/ISG15/SUMO on protein substrates. We were able to identify 145 proteins that were modified in a Tpo-dependent manner either by enhancing (88) or diminishing (57) proteins with such post-translational modifications. The identity of the proteins informs about the signaling events induced by Tpo, and again, proliferative and antiproliferative signaling appear to associate with different profiles of ubiquitinylated/ISGylated and SUMOylated proteins.

0900

LNK PH DOMAIN POINT MUTATIONS WHICH OCCUR IN MPN PATIENTS ARE PARTIAL LOSS OF FUNCTION MUTATIONS

M Koren-Michowitz[1], S Gery[2], T Tabayashi[2], A Nagler[3], P Koeffler[2]
[1]Sheba Medical Center, Cedars Sinai Medical Center, Los Angeles, CA USA, Ramat Gan, Israel
[2]Cedars Sinai Medical Center, Los Angeles, United States of America
[3]Sheba Medical Center, Ramat Gan, Israel

Background. Somatic point mutations in the PH domain of Lnk, an adaptor protein that is highly expressed in hematopoietic cells, were recently described in patients with myeloproliferative neoplasms (MPN). Lnk inhibits signaling through the thrombopoietin, as well as the erythropoietin receptors (cMPL and EPOR, respectively). It directly binds to the WT JAK2 and the activated JAK2 V617F mutant, decreasing their autophosphorylation and downstream signaling through STAT5, ERK and the PI3K/AKT pathways. Knockout (KO) of Lnk cooperates with JAK2 activating variants in the formation of myeloproliferative disease in a murine bone marrow transplantation model. This further supports the importance of Lnk in the inhibition of the JAK2 STAT pathway (Bersenev A et al. J Clin Invest;120(6):2058-2069). Most of Lnk activity is thought to occur through direct binding to phosphorylated tyrosine residues on target proteins via Lnk SH domain, and a synthetic point mutation in Lnk SH2 domain (R392E) greatly abolishes Lnk inhibitory activity. Interestingly, most of the Lnk point mutations found in MPN patients occur in the Lnk PH and not the SH2 domain. In order to delineate the mechanism by which the Lnk PH domain mutations contribute to the pathogenesis of MPN, we studied the effect of these mutations on JAK2 signaling pathways in cells with WT JAK2 (BaF3 with stable EPOR expression [BaF3-E] and murine BM), as well as in JAK2V617F harboring (HEL) cells. **Results.** Overexpression of WT Lnk inhibited cell growth in WT and JAK2 mutated cells. In contrast, the PH domain mutants E208Q and G220V partially lost the ability to inhibit cell growth. In order to study if the PH domain mutants have a dominant negative effect on WT Lnk function, we reintroduced WT Lnk and Lnk mutants into Lnk KO and WT murine BM cells and assessed their colony formation potential. We found that WT Lnk inhibited colony formation to a greater extent in WT compared to KO Lnk cells. The number of BM colonies in all the Lnk mutants was either equal to or less than colony numbers in the vector control, thereby not supporting a dominant negative effect of the Lnk mutants on WT Lnk. We also examined the effect of Lnk mutants on downstream signaling of JAK2. Overexpression of WT Lnk resulted in decreased STAT5 phosphorylation in BaF3-E stimulated with Epo, in murine BM cells stimulated with IL-3 and in serum starved, unstimulated HEL cells compared to a vector control. Lnk mutants inhibited STAT5 phosphorylation less than WT Lnk in all the cells studied, further supporting the loss of Lnk inhibitory effect conferred by mutations in the PH domain. Lnk mutants retained binding capacity for JAK2, an established Lnk target, as well as for the adaptor proteins 14-3-3 and c-Cbl. **Conclusions:** Our data suggest that the loss of Lnk inhibitory function conferred by the PH domain mutations may collaborate with JAK2V617F and c-Cbl mutations in order to promote the development or progression of MPN. Studying Lnk status in MPN patients may have prognostic and therapeutic implication.

THE 46/1 HAPLOTYPE IS INVOLVED IN TRANSCRIPTIONAL REGULATION OF JANUS KINASE 2 GENE

V Spasovski[1], N Tosic[1], G Nikcevic[1], M Stojiljkovic-Petrovic[1], B Zukic[1], M Radmilovic[1], T Karan-Djurasevic[1], S Srzentic[1], N Colovic[2], M Colovic[2], S Pavlovic[1]
[1]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia
[2]Clinic for Hematology, CCS, School of Medicine, University of Belgrade, Belgrade, Serbia

Background. The role of *JAK2* gene and its genetic variant, *JAKV617F* mutation, in biology of myeloproliferative neoplasms (MPN) is well studied. It was shown that *JAK2* gene acts both as somatic as well as germline susceptibility locus for this specific type of diseases. Association of the *JAK2* SNP rs12343867 T>C, a part of 46/1 haplotype, with a predisposition to develop MPN and to acquire *JAKV617F* mutation, has been demonstrated. How this specific haplotype influences susceptibility to develop MPN is not clarified yet, but regulation of *JAK2* gene expression could be one of possible mechanisms. The expression of the *JAK2* gene is elevated in MPN patients regardless the presence of the V617F mutation, and this elevated level of the mRNA is one of the potential mechanisms of action of 46/1 haplotype. **Aims.** In this study, we genotyped 46/1 haplotype in our cohort of 35 MPN patients and 14 healthy controls in order to determine the C/T allelic frequency. Also, we functionally analyzed polymorphic site T>C within the intron 14 of the *JAK2* gene in order to shed light on its transcriptional activity. Our goal was to discover weather this intronic region possesses transcriptional regulation capability that could contribute to the pathogenesis of MPN and explain some specific issues, such as predisposition to develop MPN in families, or the presence of disease in the absence of *JAK2* and other oncogenic mutations. **Methods.** Screening of the JAK2 46/1 haplotype was performed using direct sequencing. PCR products containing T or C allele at the polymorphic site were subcloned into pBLCAT5 reporter vector. Functional analysis was performed in K562 cells and enhancer activity was compared to pBLCAT5 vector activity. For electrophoretic mobility shift assays (EMSA), nuclear extracts from K562 cells and radiolabelled probes corresponding to the T or C allele were used. In addition, "supershift"assay was performed using MEIS1/2 antibody. **Results.** In patients, the rs12343867 CC genotype frequency was significantly higher than that observed in controls (37% vs. 7%). Functional analyses of *JAK2* intron 14 polymorphism showed that it acts as a transcriptional repressor *in vitro*. A decrease of repressor activity was detected for C allelic variant compared to T allelic variant, potentially leading to an increase of *JAK2* mRNA level. EMSA experiments showed an involvement of activating transcriptional factor Meis1 in this process. **Conclusions:** This is the first evidence of a transcriptional regulatory element within an intron of *JAK2* gene. Our results implies the role of the SNP

rs12343867 T>C in the regulation of *JAK2* gene expression and points out that transcriptional regulation of *JAK2* gene should be taken into consideration regarding pathogenesis of MPN and heterogeneity of clinical presentation of MPN.

ONCOSTATIN M (OSM) IS A FIP1L1/PDGFRA-DEPENDENT CYTOKINE AND MODULATOR OF THE MICROENVIRONMENT IN CHRONIC EOSINOPHILIC LEUKEMIA

G Hoerman[1], S Cerny-Reiterer[2], I Sadovnik[1], M Bilban[1], M Gröger[1], L Müllauer[1], C Mannhalter[1], P Valent[2], M Mayerhofer[3]
[1]Medical University of Vienna, Vienna, Austria
[2]Medical University of Vienna and Ludwig Boltzmann Cluster Oncology, Vienna, Austria
[3]Hanusch-Hospital, Vienna, Austria

Background. Chronic eosinophilic leukemia (CEL) is a myeloproliferative neoplasm characterized by expansion of neoplastic eosinophils, tissue infiltration, and organ damage. In a subset of CEL patients, the FIP1L1/PDGFRA (F/P) oncoprotein is detectable. F/P exhibits constitutive tyrosine kinase activity and has been described to activate a number of signaling pathways. So far, however, little is known about F/P-dependent expression of proteins in leukemic cells and their potential role in the pathogenesis of CEL.**Aims**The aim of our study was to identify F/P-dependent cytokines and to investigate their potential functional role in the pathogenesis of CEL.**Methods**To screen for F/P-dependent cytokines, F/P was lentivirally expressed in growth factor-dependent TF-1 and Mo7e cells. In addition, Ba/F3 cells with doxycycline-inducible expression of F/P were generated. The human F/P+ cell line EOL-1 was used to study F/P-dependent signaling in neoplastic eosinophils. Expression of OSM in the bone marrow of CEL patients was investigated by immunohistochemistry and real time PCR.**Results**We found that F/P upregulates expression of oncostatin M (OSM), an IL-6 family cytokine, in various cell line models including F/P+ EOL-1 cells via activation of STAT5. Immunohistochemistry revealed that EMBP+ neoplastic eosinophils in the bone marrow of patients with CEL express substantial amounts of the OSM protein. Correspondingly, OSM mRNA levels were increased in the bone marrow of CEL patients compared to non-leukemic control samples. OSM secreted by F/P+ cells stimulated growth of fibroblasts and microvascular endothelial cells and upregulated production of angiogenic and profibrogenic cytokines in fibroblasts. Importantly, OSM derived from F/P+ neoplastic cells was found to stimulate production of SDF-1 in human fibroblasts. SDF-1 itself induced migration of EOL-1 cells in a dose-dependent manner.**Conclusion**Our data show that neoplastic cells in CEL express OSM in a F/P- and STAT5-dependent manner. F/P-mediated upregulation of OSM may contribute to microenvironment alterations as well as to taxis of neoplastic eosinophils into tissues suggesting that OSM might represent a new potential target in CEL.

THE HDACI GIVINOSTAT MODULATES HEMATOPOIETIC TRANSCRIPTION FACTORS IN JAK2V617F CELLS FROM MYELOPROLIFERATIVE NEOPLASM PATIENTS

A Amaru Calzada
OORR Bergamo, Bergamo, Italy

Background. The HDAC inhibitor Givinostat (GVS) is a hydroxamate pan-HDAC inhibitor, and recently has been discovered to inhibit colony formation of cells from myeloproliferativeneoplasms (MPN) patients at doses at least 2-3 times lower than those required to affect cells bearing wild type JAK2. The mutant protein, confers to hematopoietic progenitors cells growth factor independent proliferation and colony formation.**Aims.** Analyse the biological effects of low and high doses of GVS on $JAK2^{V617F}$ mutated cells in long and short terms assays. Study the mechanism of action of GVS in $JAK2^{V617F}$ cells using gene expression profiling (GEP). **Methods.** Clonogenic assay, cytotoxicity, proliferation, cell death and erythroid differentiation was used for evaluate the biological effects of GVS in cell lines and CD34+ cell of patients with MPN. GEP was performed to obtain a global picture of the effect to GVS in HEL and UKE1 cell lines. Western Blot, Real-Time PCR (RTQ-PCR) and Chromatin Immunoprecipitation (ChIP) were performed to evaluate the molecular effects of GVS in cell lines.**Results.** Our study confirmed the higher sensitivity of mutated $JAK2^{V617F}$ with respect to unmutated MPN cell lines in colony and alamar blue assays. Furthermore we have confirmed that GVS inhibits JAK2 and STAT5 phosphorylation in mutated but not unmutated cell lines. By global gene expression analysis, we observed that GVS modulated 293 common genes in the $JAK2^{V617F}$ cell lines HEL and UKE1, of which 19 are implicated in cell cycle regulation and 33 in hematopoiesis. In particular the hematopoietic transcription factors NFE2 and C-MYB were downmodulated by the drug specifically in $JAK2^{V617F}$ cells at both the RNA and protein level. GVS also inhibited JAK2-STAT5-ERK1/2 phosphorylation, but modulation of NFE2 and C-MYB was JAK2-independent, as shown using the JAK2 inhibitor TG101209. Indeed GVS had a direct effect on the NFE2 promoters, as demonstrated by specific enrichment of their associated histone H3 acetylated at Lysine 9. Modulation by GVS of NFE2 was also observed in freshly isolated $CD34^+$ cells from MPN patients, and was accompanied by inhibition of their proliferation and differentiation towards the erythroid lineage.**Conclusions:** GVS inhibits the JAK2/STAT5/ERK1/2 pathway and independently expression of crucial hematopoietic TF, most importantly NFE2. These effects offer an explanation for the response of $JAK2^{V617F}$ cells to the drug, making this compound of particular interest in the context of MPN treatment.**Keywords:** Givinostat, $JAK2^{V617F}$, NFE2, C-MYB

IN VITRO AND IN VIVO DATA CONFIRMED JAK1 GENE EXPRESSION AS PREDICTOR MARKER OF RESPONSE TO IFN IN ESSENTIAL THROMBOCYTHEMIA (ET)

N Pugliese, C Quintarelli, B De Angelis, S Errichiello, L Marano, N Esposito, M Raia, L Del Vecchio, V Martinelli, F Pane
University of Naples Federico II, Napoli, Italy

Background. Interferon-alpha (IFN) has shown antitumor and immunomodulatory activity in ET and has been associated with normalization of peripheral blood count and suppression of abnormal hematopoietic clone. Although about 80% of patients respond to this therapy, some patients could be defined as bad responders.IFN-α receptor lack tyrosine-kinase activity and rely on Janus-kinase, Tyk2 and Jak1, for their phosphorylation, on signal transducing proteins, such as STATs, for the transmission of intracellular messages. The STATs activated in response to IFNs include STAT1, STAT2, STAT3 and STAT5.STATs proteins induce the transcription of SOCSs, whose role is to extinguish cytokine signaling by inhibition of JAK kinase-activity directly through the KIR-domain, and indirectly promoting the proteasomal degradation of Jak2, by SOCS-box-motif.IFN, inducing SOCSs expression, inhibits TPO mediated signaling through Jak2 inhibition.In vitro studies suggest that clonal MPN progenitors may be more sensitive to IFN than their normal counterparts.**Aims.** This study aimed to identify molecular markers to predict IFN treatment responsiveness in ET patients. We evaluated the mRNA expression of JAK1, TYK2, STAT1, STAT3, SOCS1 and SOCS3, which signal cross-talks with the JAK-STAT pathway under IFN and TPO. **Methods.** We analyzed 46 ET patients treated with 3 million units of IFN-α-2b 5 times a week as induction (3 months), and 3 times a week as maintenance.Two groups of response were identified: *Responders(R)* (n=31), who achieved a reduction of platelet count below $400x10^9$/L, and *No-Responders(NR)* (n=15) who failed.For in vitro study, HEL and SET2 cell lines, carrying respectively homo and hemizygous $JAK2^{V617F}$ mutations, were treated with dose escalation of IFN (10-10000 IU/mL). Proliferation rate and apoptosis were evaluated after 24-48-72-96-168 hrs. The expression of target mRNA was explored in bone marrow samples of ET patients by RTq-PCR. Data were normalized as following: [mRNA normalized copy number (NCN)=mRNA target gene/mRNA GUSB*104]. **Results.** We detected JAK2 V617F mutation in 40% of R and 66% of NR. Patients showed a median spleen volume of 500 ml in R and 300 ml in NR group (p=0.04). No other clinical characteristics were different between the two patient categories.Among all six investigated target mRNA, we detected a significant higher JAK1 mRNA expression in NR than R (141638 vs 55116, respectively;p=0.000016). This enforces our previous data. Also, NR showed a higher expression of SOCS3 mRNA than R (15214 vs 10828, respectively;p=0.02). Thus, we confirmed our in vivo data also in an in vitro model of MPN.Indeed, SET2 cell line shows a significant inhibition of cell growth (p=0.007) and apoptosis induction (p=0.005) upon IFN treatment compared with HEL cell line. Molecular analysis revealed that JAK1 and SOCS3 mRNA expression was higher in HEL cell line than in the IFN sensible SET cell line (p=0.009, p=0.01 respectively). **Conclusions.** In vitro and in vivo data confirmed JAK1 gene expression as predictor marker of response to IFN in ET patients. Patients with low levels of JAK1 and SOCS3 mRNA may be eligible for IFN therapy. Moreover, patients with IFN-unresponsiveness molecular signature may be considered for JAK1/JAK2 inhibitor treatment.

[4]Centre Hospitalier d'Annecy, service d'hématologie, Pringy, France

[5]Centre Hospitalier, Service d'hématologie, Chambery, France

Background. Spontaneous hematopoietic colony formation from bone marrow or peripheral blood was shown to be a functional hallmark of deregulated signalling pathway in myeloproliferative neoplasms (MPNs). Consequently, it is used as a diagnostic criteria according to the 2008 World Health Organization (WHO) classification but is limited to the study of erythroid colony in polycythemia vera. Endogenous megakaryocytic colony (EMC) growth, even if not included in WHO criteria, has also proven to be a good diagnostic tool in MPNs especially in essential thrombocythemia (ET). Considering involvement of megakaryocyte lineage in MPNs, EMC obtained from bone marrow with standardized and reproducible method, gives phenotypic argument for MPNs clonality and information complementary to *JAK2V617F* status. **Aims**. The current place of *in vitro* EMC in ET and primary myelofibrosis (PMF) diagnosis needs to be evaluated in particular in comparison to genetic abnormalities (*JAK2V617F*, *MPL* mutations). **Methods.** In this four-centre retrospective study, we compared endogenous erythroid colony (EEC) and EMC formation with *JAK2V617F* status in 190 ET and 15 PMF, diagnosed between January 1st, 2007 and December 31th, 2010. EEC and EMC were assessed in peripheral blood and/or bone marrow using a standardized method. *JAK2V617F* and *MPL* mutations were detected using ARMS-PCR (Amplification Refractory Mutation System) and HRM (High Resolution Melt) respectively. Results. In PMF, 53% of patients (8/15) had *JAK2V617F* mutation and 60% (9/15) led to spontaneous hematopoietic colony formation (EEC and/or EMC). In ET, 82% of patients (155/190) displayed EEC and/or EMC growth. Compared with *JAK2V617F* status (68% of ET (129/190)), the study of spontaneous colony formation significantly improves the sensitivity for diagnosis of ET (Mac Nemar's test, $p<0.05$). Moreover, we used the presence of EMC to select a subgroup of 43 patients among JAK2-negative ET/PMF. Surprisingly, somatic mutations of MPL (thrombopoietin receptor) were detected in 16 out of 43 (37%). This result contrasts dramatically with the 3% and 10% *MPL* mutations frequencies usually described in ET and PMF respectively. **Conclusions**. Our study shows that EMC associated with EEC assays improved sensitivity of clonogenic cultures for the diagnosis of ET and PMF. Moreover, EMC might serves as a predictive tool for the selection of potent *MPL* mutants among JAK2-negative ET and PMF. Altogether, these data suggest that EMC formation should be consider as a useful parameter for the phenotypic and genotypic characterizations of MPNs.

0906

EASY AND RAPID QUANTIFICATION OF JAK2 V617F MUTATION BY NEXT GENERATION SEQUENCING

M Figeac[1], E Abdelhamid[2], A Renneville[2], C Villenet[1], S Quief[3], T Boyer[2], O Nibourel[2], V Coiteux[2], B Cassinat[4], E Lippert[5], C Preudhomme[2]

[4]AP-HP, Unite de Biologie Cellulaire, Hopital Saint-Louis, Paris, France

[5]Laboratoire d'Hematologie, CHU de Bordeaux, U1035, Universite Bordeaux, Bordeaux, France

Background. Since the discovery of JAK2 V617F mutation, the quantification of mutant allele has been widely studied especially in order to predict clinical outcome but also to better understand the role of V617F in myeloproliferative neoplasms. Some laboratories have developed JAK2 V617F quantification technique based on real time quantitative PCR with variable sensitivities and specificities. In order to compare these techniques, some groups including the European Leukemia Net have organized Quality Control rounds evaluations. The recent conclusions are very promising but require very stable standards and cooperation with manufacturers. NGS is a very sensitive technique that allows absolute quantification without standard curve and is applicable for many targets. **Aims**.To evaluate the feasibility and the performance of JAK2 V617F quantification by NGS.MethodsQuantification was performed on genomic DNA using the Ion Torrent platform. Primers were designed in order to produce a short PCR product (81bp) including the V617F mutation in the median part. The standard barcoded amplicon libraries with ligation of adapter and template preparation were used. The sequencing was performed on 314 chips.Samples used were UKE1 cell line, 4 negative controls collected from healthy subject, 11 patients quantified by the Mutaquant kit from Ipsogen (mutated allele percentage ranging from 94% to 1.3%), and a two-fold dilution. The dilution (100% to 0.024%) of the UKE1 cell line was performed in negative control sample B. Each diluted sample was further processed with multiple barcodes to assess reliability of libraries construction.The allelic ratio was computed as the number of reads with V617F mutation versus the total number of reads. Only reads with at least 80% of bases with Q17 qualities were taken into account. The probability that allelic ratio was positive was computed with Fisher exact test. **Results**. The normal samples showed only one read with V617F mutation. Combining the 4 samples, the computed allelic ratio was about 0.0045%. The computed allelic ratios from the diluted UKE1 show a straight linear correlation with theoretical dilution (r=0.983 pearson correlation, p-value=1.100e-08). All diluted samples but one are below the theoretical values. Last but not least, all diluted samples showed positive allelic ratio values with p-value < 2.5^{-5}. Patient samples with mutaquant allelic ratio ranging from 94% to 1.3% showed linear correlation (r=0.974 pearson correlation, p-value=4.003e-07).Summary/conclusionsWe report detection values below 10^{-4} with p-value under 2.5^{-5}. There is no absolute limitation in low allelic ratio detection as we can always sequence more reads. The detection limit is determined by the false positive in normal samples. The cost is increasingly low as our data show that we can reliably compute allelic ratio from 20000 reads to reach 5.10^{-4}. The 314 chip allows to multiplex from 10 to 15 samples by run. We are planning to cross check more patient blind-quantified from others centers and to enable detection reaching 10^{-5} on diluted samples. The use of Ion Torrent technologies is a very easy and simple way to quantify JAK2 V617F mutation.

A N,N'-DIARYLUREA INHIBITOR OF PROTEIN TRANSLATION INITIATION SELECTIVELY SUPPRESSES THE PROLIFERATION OF CD34+ CELLS ISOLATED FROM POLYCYTHEMIA VERA PATIENTS VIA ACTIVATION OF THE HRI-EIF2α PATHWAY

J Jeong[1], M Levine[2], B Aktas[3], M Chorev[3], N Abayasekara[2], M Silver[2], N Berliner[1], J Halperin[1], G Vanasse[1]

[1]Harvard Medical School, Brigham and Women's Hospital, Boston, United States of America

[2]Brigham and Women's Hospital, Boston, United States of America

[3]Harvard Medical School, Boston, United States of America

Background. Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Primary Myelofibrosis (PMF) comprise the subgroup of BCR-ABL negative myeloproliferative neoplasms (MPN). Identification of the gain-of-function $JAK2^{V617F}$ mutation in over 95% of PV and approximately 50-60% of ET and PMF patients has greatly advanced our understanding of MPNs. MPNs are associated with significant morbidity, reduced quality of life, and premature death. In addition to phlebotomy, treatment with hydroxyurea or interferon-alpha remains standard of care in PV patients. Although these interventions help control symptomatic disease, they have little if any effect on JAK2 allelic burden and do not alter disease natural history. Although JAK2-inhibitors are approved for PMF, their role in PV remains to be defined, and novel therapies are desperately needed for patients. **Aims.** We investigated the efficacy of *N,N'*-diarylurea compounds, previously shown to inhibit solid tumor cell growth by reducing the eIF2-GTP-$tRNA_i^{Met}$ translation initiation complex, in decreasing the proliferative capacity of $JAK2^{V617F}$ mutant cells. We demonstrate that a specific compound, #1781, selectively reduces the proliferation of both human cell lines (HEL and SET-2) and primary CD34+ cells isolated from PV patients without altering growth characteristics of normal CD34+ cells. **Methods.** Cell growth and apoptosis were measured by CellTiter Blue cell proliferation assay and Annexin V staining, respectively. Protein phosphorylation and expression levels were determined by immunoblotting, and mRNA expression determined by quantitative real-time PCR. FACS was used to sort transfected cells and to detect cell surface marker expression. Semisolid methylcellulose culture was used to evaluate BFU-E formation in human CD34+ cells.**Results.** We examined the effects of several protein translational inhibitors on proliferation of human $JAK2^{V617F}$-mutant cell lines [HEL (homozygous), and SET-2 (heterozygous)], and normal human CD34+ cells. We found that a novel *N,N'*-diarylurea compound (#1781) potently decreased HEL and SET-2 cell proliferation at doses non-toxic to normal human CD34+ cells, exhibiting significantly lower IC_{50}

values in both HEL (4 μM)] and SET-2 (3 μM)] cells compared to normal CD34+ cells (> 10 μM)]. #1781 treatment increased eIF2α phosphorylation, while replacement of endogenous eIF2α with non-phosphorylated eIF2α^{S51A} rendered HEL cells less sensitive to #1781. Furthermore, knock-down of heme-regulated inhibitor kinase (HRI), which phosphorylates eIF2α, made cells less sensitive to #1781, indicating that #1781 mediates cell growth inhibitory effects by activating the HRI-eIF2α pathway, thereby inhibiting protein translation initiation. #1781 treatment significantly reduced phospho-JAK2, phospho-STAT5, phospho-ERK1/2 and c-Myc expression within 24 hours. Finally, #1781 treatment reduced BFU-E colony numbers in CD34+ cells isolated from four PV patients by 49% to near baseline, without adversely affecting BFU-E formation in normal CD34+ cells ($p<0.02$, t-test), indicating that #1781 selectively suppresses PV-associated erythropoiesis. In contrast, an inactive analog (#1527) of #1781 exhibited no effects on cell growth or signaling. **Summar and Conclusions**. Our study demonstrates that a novel *N,N'*-diarylurea small-molecule protein translational inhibitor suppresses proliferation of human PV hematopoietic progenitors via selective inhibition of protein translation and signal transduction pathways required for PV cell growth and survival. Our results provide important pre-clinical data supporting further study of this class of compounds as therapy for MPN patients.

0908

INCREASING THE SENSITIVITY OF JAK2V617F DETECTION MUST BE CONSIDERED CAUTIOUSLY FOR ACCURATE DIAGNOSIS

E Kouroupi[1], JJ Kiladjian[1], ML Menot[1], N Bonnin[1], L Ades[2], C Chomienne[1], B Cassinat[1]

[1]Hopital Saint Louis, Paris, France

[2]Hopital Avicenne, Bobigny, France

Background. According to the WHO classification, the detection of the JAK2V617F mutation in Myeloproliferative neoplasms (MPN) diagnosis is one major criteria for Polycythemia Vera (PV), Essential Thrombocytemia (ET) or Myelofibrosis (MF) diagnosis. Stretching down the lower limit of detectability of a molecular marker is of utmost importance for accurate diagnosis but also for its potential use as minimal residual disease marker.. However, using methods with higher sensitivity at the time of diagnosis may lead to the identification of patients bearing very low mutant allele burden with questionable clinical relevance. **Aims**. To explore whether changing for a more sensitive method may improve the diagnosis in Myeloproliferative Neoplasms (MPN) and identify potential pitfalls. **Methods.** Results of JAK2V617F screening from our lab were analyzed 6 months after changing from the JAK2 Mutascreen® (Ipsogen) method (sensitivity: 2%) for the JAK2 Mutaquant® (Ipsogen) method (sensitivity: 0.1%). Absence of false positive results was confirmed on 49 samples taken from blood donors and the level of sensitivity was established on serial dilutions of mutated patient's DNA. **Results.** We re-tested with the Mutaquant (MQ) method 191 patients previously analyzed using the Mutascreen (MS) method. 98 patients had been found positive and 93 negative with MS. In 98/98 cases the MQ assay confirmed the positivity found previously using the MS assay. In contrast, 7 patients among the 93 (7.5%) previously found negative by the MS assay were found positive with MQ. The allele burden for these 7 patients was always lower than 1% (median 0.49%, range 0.1% to 1%). In 3/7 patients, additional sample (taken 1 to 5 years before) were reanalyzed using MQ method: all these samples were confirmed positive with a similar JAK2V617F allele burden. In 5 patients the diagnosis of MPN could be made according to the WHO criteria including JAK2V617F mutation as a major criterion: 3 with ET, 1 with PV, 1 with MF. One patient had unclassifiable MPN with hyperleucocytosis, myelemia and trisomy 8. Finally 1 patient presented with repeated pulmonary embolisms with normal blood counts (Hct: 47.4%; Hgb: 17.1 g/dl; Red Cell Mass: +20% of the expected value; WBC: 7.7 G/L; Plt: 335 G/L). In this latter case, the mutation was already present at the same level 5 years before. The presence of an additional *MPL* or *JAK2*-exon 12 mutation was excluded in these patients. **Summary and Comments.** This study argues for the choice of a *JAK2V617F*detection method characterized by a detection limit under 1% as no indication is given regarding the allele burden according to the recent WHO classification's major criteria. In this regard, patients detected with a mutant allele burden of 0.5% should be considered equally to those with 5% or 50%. However as shown for 1 out of 7 patients, the correlation between the presence of the mutation and a possible MPN may be questionable. The decision for any potential therapeutic intervention must be made very cautiously in these cases until prospective clinical studies are available.

0909

SPECIFIC INHIBITION OF CHOLESTEROL SYNTHESIS INDUCES CYTOPROTECTIVE AUTOPHAGY IN HUMAN LEUKEMIC CELLS BUT NOT NORMAL HUMAN LYMPHOCYTES

U Urosh[1], M Bosnjak[1], A Bogdanovic[2], I Markovic[3], A Isakovic[3], V Trajkovic[4], V Bumbasirevic[1]

[1]University of Belgrade School of Medicine Institute for Histology and Embryology, Belgrade, Serbia

[2]University of Belgrade School of Medicine Hematology Clinic, Belgrade, Serbia

[3]University of Belgrade School of Medicine Institute for Medical Biochemistry, Belgrade, Serbia

[4]University of Belgrade School of Medicine Institute for Microbiology Immunology, Belgrade, Serbia

Background. In addition to cholesterol lowering effects, high dose statin treatments exhibit anti-leukemic properties *in vitro.* These effects are due to suppression of the mevalonate pathway by the inhibition of 3-hydroxy-3-methylglutaryl coenzyme A. Apart from being involved in cholesterol synthesis, the mevalonate pathway is also involved in the synthesis of farnesylated and geranylgeranylated proteins which are critical to key cellular functions such as cell survival, proliferation, and growth. Furthermore, inhibition of cholesterol synthesis, protein farnesylation and geranylgeranylation have all been shown to have independent antileukemic effects. **Aims**. Our aims was to discern the effects of low dose statin treatments on leukemias as well as to determine whether these effects were due to the inhibition of cholesterol synthesis, or the inhibition of protein farnesylation or geranylgeranylation. **Methods.** The human leukemic cell lines HL-60, REH, JVM-2 and JVM13, as well as PBMCs isolated by density centrifugation from 6 leukemic patients and 3 healthy volunteers were used. Cell viability was determined by acid phosphatase assay. Apoptotic responses were analyzed by Western blotting for active caspase-3, and by flow cytometry using annexin V-FITC and propidium iodide for phosphatidylserine externalization and DNA fragmentation. Autophagy was determined by electron and fluorescence microscopy as well as by Western blotting for the appearance of the LC3II variant of the LC3 protein. Inhibition of autophagy was performed by use of bafilomycin A1 and by knockdown of the beclin-1 protein using siRNA techniques.

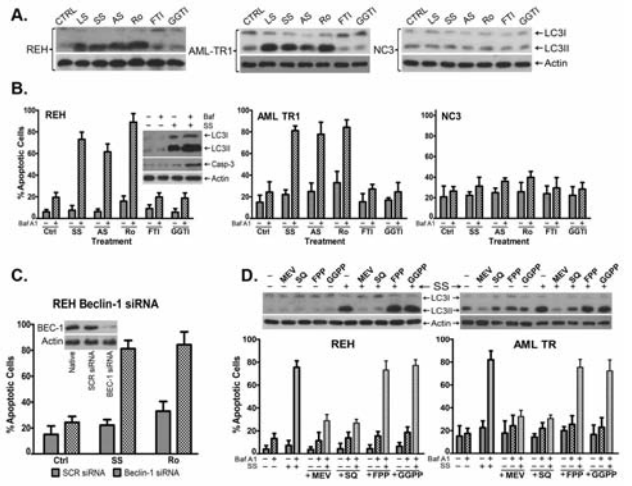

Figure 1. Specific Inhibition of Cholesterol Synthesis Induces Cytoprotective Autophagy In Human Leukemic Cells But Not Normal Human Lymphocytes.

Results. Lovastatin, simvastatin and atorvastatin treatment, as well as specific inhibition of cholesterol synthesis, farnesylation or geranylgeranylation all resulted in dose-dependent decreases in the viabilities of leukemic cell lines and leukemic patients' PBMCs. Flow cytometric analysis of cell cycle phase distributions and apoptosis suggested that the statin-induced decrease in cell viability was due to inhibition of cell cycle progression as well as apoptosis. These effects were dramatically muted in normal human lymphocytes. Significantly, we have shown that the inhibition of the mevalonate pathway by statins, as well as specific inhibition of cholesterol synthesis Ro-48-8071, but not the inhibition of protein farnesylation or geranylgeranylation, induces a strong autophagic response in leukemic cells but not normal human lymphocytes. Furthermore, inhibition of autophagy by treatment with the vacuolar acidification inhibitor bafilomycin A1, or siRNA-mediated knockdown of the autophagy regulating

protein beclin-1, dramatically increases apoptosis in leukemic cells, an effect that is attenuated by the addition of mevalonate pathway product squalene, but not by the addition of farnesylpyrophosphate or geranylgeranylpyrophosphate. **Conclusions.** Our study shows that inhibition of the mevalonate pathway by low dose statin treatment induces cytoprotective autophagy that is dependent specifically on inhibition of cholesterol synthesis. The effect seems to be specific to leukemic cells, as it was not observed in normal human lymphocytes. Furthermore, we have shown that inhibition of autophagy uncovers a potent apoptosis-inducing effect of cholesterol synthesis inhibition in leukemic cells. These results suggest that selective cholesterol reducing therapies in combination with autophagic inhibition warrant further exploration as potential candidates for selective anti-leukemic therapy.

PHOSPHATIDYLINOSITOL-3 KINASE AND NF-κB AS POTENTIAL THERAPEUTIC TARGETS IN MYELOID MALIGNANCIES ASSOCIATED WITH HYPEREOSINOPHILIA AND PDGF RECEPTOR REARRANGEMENTS

C Montano-Almendras[1], A Essaghir[1], H Schoemans[2], L Noël[1], A Velghe[1], I Varis[1], D Latinne[1], L Knoops[1], JB Demoulin[1]
[1]University of Louvain, Brussels, Belgium
[2]UZ Leuven, Leuven, Belgium

Background. ETV6-PDGFRB and FIP1L1-PDGFRA are receptor-tyrosine kinase fusion genes causing chronic myeloid malignancies associated with hypereosinophilia. Imatinib is the standard treatment of this disease but resistance has been reported.The **aim** of this work was to set up a human model for this disease and analyze the mechanisms whereby PDGF receptor fusions induce hypereosinophilia in order to identify new therapeutic targets. **Methods.** We introduced ETV6-PDGFRB and FIP1L1-PDGFRA using lentiviral particles in human CD34$^+$ hematopoietic progenitors and stem cells isolated from umbilical cord blood. Signal transduction and gene regulation were explored by flow cytometry and Affymetrix microarrays. **Results.** We first analyzed the expression of PDGFRA in CD34+ cells. By contrast to previous reports, no PDGFRA expression (protein of mRNA) could be detected on these cells. CD34+ cells were then transduced with ETV6-PDGFRB and FIP1L1-PDGFRA. These cells formed hematopoietic colonies even in the absence of cytokine. Both oncogenes also stimulated the proliferation of cells in liquid culture and their differentiation into eosinophils. This model thus recapitulated key features of the myeloid neoplasms induced by ETV6-PDGFRB and FIP1L1-PDGFRA. Microarrays were used to identify genes regulated by these oncogenes. A bioinformatics analysis based on TFactS revealed the regulation of a number of transcription factors. By flow cytometry, we confirmed that both fusion genes activated the transcription factors STAT1, STAT3, STAT5 and NF-κB. The importance of STAT5 downstream both oncogenes is well established. We focused on NF-κB activation, whose importance in PDGF signal transduction has been debated. Phosphatidylinositol-3 kinase inhibition blocked NF-κB activation in transduced progenitors and patient cells. NF-κB was also activated in the human FIP1L1-PDGFRA-positive leukemia cell line EOL1, the proliferation of which was blocked by the proteasome inhibitor bortezomib and the IkB kinase inhibitor BMS-345541. A mutant IκB that prevents NF-κB nuclear translocation inhibited cell growth and the expression of eosinophil markers, such as the interleukin-5 receptor and eosinophil peroxidase, in progenitors transduced with ETV6-PDGFRB. **Conclusions.** We show that human CD34$^+$ cells expressing PDGF receptor fusion oncogenes proliferate autonomously and differentiate towards the eosinophil lineage in a process that requires a phosphatidylinositol-3 kinase - IKK - NF-κB pathway. These results suggest new treatment possibilities for imatinib-resistant myeloid neoplasms associated with PDGF receptor mutations.

AP-1 IMPACTS ON ANGIOGENESIS IN BCR/ABL DRIVEN DISEASE

R Scheicher[1], K Kollmann[2], V Sexl[1]
[1]Institute of Pharmacology and Toxicolcogy, Vienna, Austria
[2]Veterinary University of Vienna, Vienna, Austria

Background. Several forms of leukemia are caused by chromosomal translocation resulting in the Philadelphia chromosome. The resulting fusion product is the constitutively active BCR/ABL tyrosine kinase that activates several signalling pathways. One endpoint of these signalling cascades is the AP-1 transcription-factor family which contains important modulators of transformation and tumorigenesis. Our laboratory has investigated the effects of JUNB and c-JUN for BCR/ABL driven leukemogenesis. Whereas JUNB suppresses BCR/ABL driven leukemia and is considered a tumor suppressor for this disease entity c-JUN is promoting tumor formation and accelerates leukemogenesis. Accordingly, JUNB is lost in BCR/ABL transformed cells in people. **Aims.** In this project we aim to elucidate the mechanism how c-JUN contributes to leukemia formation. We intend to characterize the effects of c-JUN on angiogenesis and its relevance in BCR/ABL driven malignancies. Several AP-1 target genes have been identified, that are key players in angiogenesis. We intend to characterize their expression and role for BCR/ABL driven disease. **Methods.** We use transgenic mouse models to elucidate the role of c-JUN in BCR/ABL driven disease. Moreover we have established several cell lines lacking components of the AP-1 family to analyse gene expression. **Results**. We have recently delineated a novel mechanism how the AP-1 transcription factor c-JUN regulates lymphoma formation in Bcr/Abl+ cells. During the course of these experiments we learnt that c-JUN is involved in the regulation of de novo blood vessel formation in BCR/ABL driven disease. Angiogenesis was severely impaired if the tumor cells lack the expression of c-JUN (c-JUNΔ/Δ). In accordance, the expression of VEGF-A and VEGF-C was significantly decreased in c-JUNΔ/Δ lymphoma cells. According to the opposing roles of c-JUN and JUNB we also found that JUNB deficient cells show an increased VEGF-A expression. An angiogenesis array revealed a consistent pattern of differentially expressed pro- and anti-angiogenetic genes in Bcr/Abl+ cells lacking c-JUN compared to wt. Among these genes, we have already confirmed the upregulation of TGFβ3 in c-JUNΔ/Δ cells. TGFβ3 is considered to be an important suppressor of tumor angiogenesis. **Conclusions.** We here propose that c-JUN not only regulates cell proliferation but also angiogenesis in Bcr/Abl+ cells by regulating a number of different genes. We propose that this regulation impacts on leukemogenesis.Our study has human relevance as alterations in the AP-1 transcription factor c-JUN are common in human cancer patients. It is thus essential to understand the molecular mechanisms driven and maintained by the AP-1 transcription factor family.

IRON-DEPENDENT REGULATION OF HEPATIC HEPCIDIN EXPRESSION IN HJV-/- MICE

K Gkouvatsos, K Pantopoulos
McGill University, Montreal, Canada

Hemojuvelin (HJV) is a bone morphogenetic protein (BMP) co-receptor that plays a pivotal role in systemic iron homeostasis. Mutations in HJV are causatively linked to juvenile hemochromatosis, an early onset and severe form of hereditary iron overload. The marked suppression of hepcidin expression observed in juvenile hemochromatosis patients and in HJV-/- mice, suggests a function of hemojuvelin, as an upstream regulator of this liver-derived iron-regulatory peptide hormone. To elucidate the role of HJV in iron-sensing pathways, we employed HJV-/- mice and analyzed their responses to dietary or other iron manipulations.8-weeks old HJV-/- and wild type (HJV+/+) control mice were placed in diets of varying iron content (low, normal and high) for 4 weeks. Serum iron parameters, liver iron deposition and hepatic hepcidin, pSmad1/5/8, pErk1/2, BMP6, Smad7 and Id1 expression were assessed.Serum iron levels were significantly increased in HJV-/- mice in comparison to wild type controls in all diet regimens. Interestingly, transferrin was highly saturated (97%) in HJV-/- mice regardless the iron content of the diet. Massive liver iron deposition in HJV-/- mice was assessed with both a qualitative (Prussian blue stain) and quantitative (ferrozine assay) technique. As expected, hepatic levels of hepcidin mRNA correlated to dietary iron intake in wild type mice. Surprisingly, hepcidin mRNA expression was likewiseresponsive to dietary iron intake in HJV-/- mice, despite the marked overall suppression of hepcidin mRNA levels as compared to wild type controls. HJV-/- mice placed in low and normal iron diets exhibited significantly higher levels of BMP6 mRNA compared to wild type controls.Our data are consistent with earlier observations that the disruption of HJV leads to suppression of hepcidin expression and severe iron overload. Furthermore, our data suggest that HJV is not essential for iron sensing and rather acts as an enhancer for hepcidin expression. Importantly, our findings uncouple the iron-dependent regulation of hepcidin expression from alterations in transferrin saturation, at least in HJV-/- mice.

REPROGRAMMING OF THE STAT SIGNALING NETWORK IN CD4+ CELLS: A NOVEL IMMUNOMODULATORY ROLE OF 5-AZACITIDINE

I Kotsianidis[1], P Miltiades[1], E Labrianidou[1], S Papageorgiou[2], A Galanopoulos[3], T Vassilakopoulos[4], E Nakou[1], E Spanoudakis[1], D Margaritis[1], C Tsatalas[1]

[1]Democritus University of Thrace, Alexandroupolis, Greece
[2]Hematology Unit, University General Hospital Attikon, Athens, Greece
[3]Department of Hematology, Athens Regional General Hospital „G. Gennimatas„„ Athens, Greece
[4]National and Kapodistrian University of Athens, Laikon General Hospital, Athens, Greece

Background and Aims. Signal transducer and activator of transcription (STAT) proteins have essential roles in the epigenetic control of TH cell differentiation and defective STAT signaling can compromise tumor immunity. 5-azacytidine has immunomodulatory properties which may contribute to its antitumor activity. Though the exact mechanism is unknown, it has been shown that the demethylation of regulatory elements of transcription factors involved in T helper (TH) cell polarization may enhance tumor immunity by restoring the deficient cytokine signaling. Myelodysplastic syndromes (MDS) have a strong immunopathogenetic component, but the CD4+ cell signaling via STATs has not yet been intensively investigated.

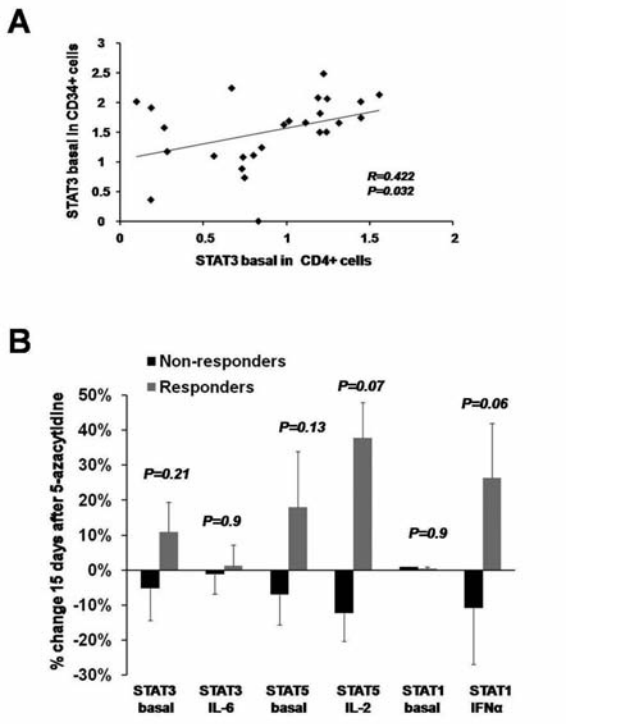

Figure 1. Correlation of basal STAT3 levels in CD4+ and CD34+ cells (A). Alterations of signaling nodes 15 days after 5-azacitidine initiation (B).

We applied phospho-specific flow cytometry to explore the alterations of STAT signaling in CD4+ cells during 5-azacitidine treatment and addressed their association with clinical and biological parameters.METHODSPeripheral blood (PB) and bone marrow (BM) mononuclear cells of 31 high risk MDS patients were obtained before and 15 days after 5-azacitidine initiation. According to WHO classification, 15.5% of the patients had RAEB-I, 40.5% RAEB-II, 19% CMML-II and 25% AML/MDS. Cytogenetics according to IPSS were good in 39% of the patients, intermediate in 39% and poor in 22%. Based on the IWG response criteria patients were divided into responders (CR and PR, n=9) and non-responders (stable disease and failure, n=22). Cells were either left untreated (basal levels) or stimulated with IL-6, IL2 and IFNα for 15' (potentiated response) and then stained for surface CD4, CD3, CD34 and intracellularly with phospho-STAT1, 3 and 5. The following potentiated signaling nodes, i.e. target/stimuli combinations, were studied: STAT3/IL-6, STAT5/IL-2 and STAT1/IFNα. Basal levels were expressed as log2 [Median fluorescence intensity (MFI) (unmodulated)/MFI (isotype)] and potentiated nodes as log2 [MFI (modulated)/MFI (unmodulated)]. Statistical comparisons were performed by unpaired Student's t test or one-way ANOVA as appropriate. Correlations were assessed by Spearman's rank test. **Results.** No differences were observed in both basal and potentiated nodes between the various MDS subtypes or in relation to the cytogenetic status. By contrast, non-responders had significantly higher basal STAT3 levels in both PB (p=0.04) and BM (p=0.02) CD4+ cells, whereas the other nodes were similar among the two groups. Interestingly, basal STAT3 levels were also higher in CD34+ blasts of the same patients and correlated positively with constitutive STAT3 expression of CD4+ cells (R=0.422, p=0.032) Figure 1A), indicating an underlying mechanism of global upregulation of STAT3 in patients refractory to 5-azacitidine. More important, all nodes, except basal STAT1, were upregulated 15 days after treatment initiation in responders, in contrast to non-responders where the same nodes were slightly dowregulated. However, the differences were marginally significant only in STAT5/IL-2 (p=0.07) and STAT1/IFNα (p=0.06) nodes (Figure 1B).**Conclusions**. STAT3 is constitutively overexpressed in both CD4+ and CD34+ cells in MDS patients resistant to 5-azacitidine, illustrating the multiple roles of STAT3 in tumorigenesis. Also, the upregulation of signaling nodes after 5-azacitidine treatment only in responding patients indicates enhancement of CD4+ cell cytokine responsiveness by epigenetic reprogramming of STAT signaling network, which may potentially favor the antitumor response.

CHARACTERIZATION OF CYCLIN E EXPRESSION IN MULTIPLE MYELOMA AND ITS FUNCTIONAL ROLE IN SELICICLIB-INDUCED APOPTOTIC CELL DEATH

K Beider, L Josefsberg Ben-Yehoshua, O Ostrovsky, A Shimoni, A Nagler
Sheba Medical Center, Ramat Gan, Israel

Background. Multiple Myeloma (MM) is a lymphatic neoplasm characterized by clonal proliferation of malignant plasma cell that eventually develops resistance to chemotherapy. Drug resistance, differentiation block and increased survival of the MM tumor cells result from high genomic instability. Chromosomal translocations, the most common genomic alterations in MM, lead to dysregulation of cyclin D, a regulatory protein that governs the activation of key cell cycle regulator - cyclin dependent kinase (CDK). Genomic instability was reported to be affected by over expression of another CDK regulator - cyclin E (CCNE). This occurs early in tumorgenesis in various lymphatic malignancies includingCLL,NHL and HL. We therefore, sought to investigate the role of cyclin E in MM. **Results.** CCNE1 expression was found to be heterogeneous in various MM cell lines. Incubation of MM cell lines with seliciclib, a selective CDK-inhibitor, results in apoptosis which is accompanied by down regulation of MCL1 and p27 protein levels. In addition, seliciclib treatment significantly inhibited the phosphorylation of MCL1 and CCNE1 in MM cells. Ectopic over expression ofCCNE1 resulted in reduced sensitivity of the MM tumor cells in comparison to the paternal cell line, whereas CCNE1 silencing with siRNA increased the cell sensitivity to seliciclib. Adhesion to FN of MM cells was prevented by seliciclib, eliminating adhesion-mediated drug resistance (CAM-DR) of MM cells. Furthermore, combination of seliciclib with doxorubicin, a known drug that displays CAM-DR, significantly enhanced anti-MM effect. To achieve more prominent CDK inhibition, we evaluated the effect of seliciclib in combination with another CDK inhibitor, flavopiridol. Combined treatment with seliciclib and flavopiridol demonstrated enhanced anti-myeloma activity, effectively reduced CCNE1 and CCND1 protein levels, increased subG1 apoptotic fraction and promoted MM cell death in BMSCs co-culture conditions, therefore over-coming stroma-mediated protection. **Conclusions**. We suggest that CDK combined inhibition with seliciclib effectively targets MM and overcomes microenvironment-produced resistance. CCNE1 is involved in seliciclib-induced apoptosis and may affect the sensitivity of MM cells to the treatment. All together, our data provide the rationale for CDK inhibition as part of therapeutic strategy in myeloma patients.

TARGETING NEUROPILIN-1 IN CLL AND MULTIPLE MYELOMA

S Napoletano[1], J Harmey[1], J Quinn[2], P Murphy[2]
[1]Royal College of Surgeons in Ireland, Dublin, Ireland
[2]Hematology Department, Beaumont Hospital, Dublin, Ireland

B-cell chronic lymphocytic leukemia (CLL) is the most common leukemia in the Western world with an incidence of 2-6 cases per 100,000 people per year. It is characterized by a clonal growth of long lived, slowly proliferating mature CD19+, CD5+, CD23+ B lymphoid cells in the bone marrow (BM), peripheral blood (PB) and lymphoid tissues. Multiple myeloma (MM) is a bone marrow-based, multifocal plasma cell neoplasm associated with a paraprotein in serum and/or urine. It comprises about 1% of malignant tumours, 10-15% of haematopoietic neo-

plasms and causes 20% of deaths from haematological malignancies. Standard therapies result in long durations of remission in most patients, while newer treatment regimens, which include the anti-angiogenic agents thalidomide and lenalidomide as well as the proteasome inhibitor, bortezomib, have improved outcomes. However, both diseases remain incurable and are associated with multiple disease relapses and death. Increased angiogenesis appears to play an important role in CLL and MM progression, VEGF emerging as the most clinically relevant of the known angiogenic factors. The transmembrane VEGF co-receptor Neuropilin-1 (NRP-1) plays an important role in angiogenesis and progression of many diseases, and it is expressed on endothelial and some tumour cells, including breast, lung and prostate. Previous studies have also shown NRP-1 acting through VEGFR-dependent and independent mechanisms. NRP-1 has been detected in CLL cells of approximately 65% of patients and elevated NRP-1 levels have also been found in bone marrow of acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL) patients compared to healthy controls. However, the importance of NRP-1 in hematological malignancies remains to be established.The aim of this study is to elucidate NRP-1 role in CLL and MM using primary cells isolated from CLL patients and a panel of MM cell lines. Western blot analysis show that NRP-1 and VEGF receptors are expressed in primary CLL cells and MM cell lines. CLL serum samples also express considerable levels of NRP-1. CLL cells treated with the NRP-1 specific ligand $VEGF_{165}$ increase expression of NRP-1 and the anti apoptotic protein Mcl-1 in a dose dependent manner, suggesting that NRP-1 signaling may play a role in CLL cell survival. NRP-1 knockdown using siRNA specific nucleotides results in decreased p42/p44 ERK activation, while Akt phosphorylation is unaffected. This suggests that NRP-1 signals predominantly through ERK in this system. Additionally, NRP-1 signaling blockade using a peptide corresponding to the NRP1 binding site on $VEGF_{165}$ in NRP-1-expressing MM cell lines decrease cell viability.These results suggest that targeting NRP-1 signaling may be valuable for CLL and MM treatment.

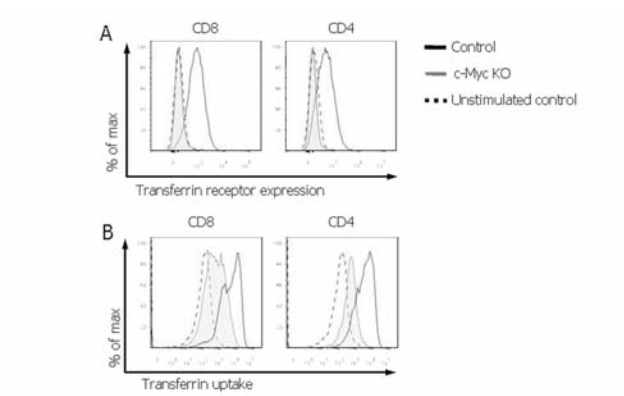
C-MYC CONTROLS T CELL TRANSFERRIN RECEPTOR EXPRESSION DOWNSTREAM OF JAK AND GSK3 MEDIATED SIGNALLING PATHWAYS

G Preston, D Cantrell
University of Dundee, Dundee, United Kingdom

Background. Previous studies have shown that the proto-oncogene c-Myc is essential for cell growth and proliferation of both normal and transformed lymphocytes. It has also been recently been demonstrated that the expression of c-Myc in T cells is required for the metabolic reprogramming that accompanies T cell activation and in particular is necessary for glucose metabolism and glycolysis. What controls the expression of c-Myc in T cells and whether c-Myc expression is sufficient for metabolic reprogramming of T cells is unknown. **Aims.** We set out to identify signalling pathways that physiologically regulate c-Myc expression and to further identify important downstream c-Myc biological functions.



c-Myc is required for the increased transferrin receptor surface expression and transferrin uptake triggered by naïve T cell activation. Flow cytometric analysis of transferrin receptor expression (A) and transferrin uptake (B). Splenocytes from CD4-Cre/c-$Myc^{fl/fl}$ and litter mate control mice (Cre neg/c-$Myc^{fl/fl}$) were unstimulated or activated with CD3 (5µg/ml) and CD28 (3µg/ml) antibodies for 24 hours. All data are representative of 3 independent experiments.

Figure. c-Myc is required for the increased transferrin receptor surface expression and transferrin uptake triggered by naïve T cell activation.

Methods. We used specific inhibitors to probe the signalling pathways responsible for c-Myc regulation downstream of the T cell antigen receptor and the interleukin-2 receptor in primary T cells. To investigate c-Myc function we used both gene knockout and retroviral expression strategies. This allows us to probe the consequences of both failure to upregulate c-Myc on T cell activation and sustained c-Myc expression in the absence of cytokine signals. **Results.** We show that c-Myc expression in CD8 T cells is initiated in response to antigen receptor signals and then sustained by common gamma chain cytokine mediated activation of Janus kinase 3 (JAK3). Moreover, c-Myc protein levels in CD8 T cells are tightly controlled by GSK3 mediated signalling pathways that ensure c-Myc protein has a very short half life. Immune activated T cells thus cannot autonomously sustain c-Myc protein levels although they can sustain high levels of c-Myc mRNA; to maintain c-Myc protein expression there is a requirement for sustained common gamma chain cytokine mediated activation of JAK3. Analysis of c-Myc function revealed that c-Myc is required and sufficient to sustain transferrin receptor expression and transferrin uptake by T cells. This effect was selective as c-Myc expression was not sufficient to maintain glycolysis or amino acid uptake in T cells. Moreover, c-Myc expression also was insufficient to drive cell survival or protein synthesis and cell growth in primary non-transformed T cells. **Summary and Conclusions.** Herein we demonstrate that c-Myc expression in T cells is controlled by cytokine signals mediated through JAK3 and GSK3. Furthermore c-Myc expression is both necessary and required for the expression of the transferrin receptor and transferrin uptake. This ability of c-Myc to control transferrin uptake is important because iron is a critical co-factor for many key metabolic enzymes that control ATP generation. Work from other groups has suggested that targeting the transferrin receptor with monoclonal antibodies or using iron chelators may be a useful strategy in haematological malignancies. The current study provides a rationale for investigating this further in T cell malignancies.

0917

FLT3 MUTATION STATUS IN AML ALTERS THE TRANSCRIPTIONAL AND FUNCTIONAL ROLE OF CREB

J Skavland[1], L Wergeland[1], P Hallenborg[2], Ø Bruserud[1], B Gjertsen[1]
[1]Institute of Medicine, Bergen, Norway
[2]University of Southern Denmark, Odense, Denmark

Background. In acute myeloid leukemia (AML) frequent mutations in signaling pathways are found. Some of these altered proteins are used to determine disease prognosis and treatment regime. An example is the receptor tyrosine kinase Flt3. Internal tandem duplications in Flt3 (Flt3-ITDs) changes its functionality and also changes downstream signaling and transcriptional activities. Moreover, Flt3-ITD is known as a high risk prognostic factor in AML. Additionally, activation or up-regulation of cAMP response element-binding protein (CREB) is found to be a bad prognostic factor in AML. Currently there is no evidence of a direct interaction between these two interesting members of important signaling pathways in AML.**Aims.** We aim to elucidate the potential connection between Flt3 and activation of CREB in AML. **Methods.** We stimulate Flt3 with its ligand (FL) and investigate the phospho-signaling cascade from Flt3 to CREB using phospho-specific flow cytometry. We have a panel of leukemia cell lines defined statuses of Flt3 or transduced cell lines overexpressing different forms of Flt3. Inhibitors of signaling pathways are used to verify the results. In order to elucidate the mechanisms behind FL regulation of CREB, we utilized a CREB promoter assay to enlighten the transcriptional differences between Flt3-wt and Flt3-ITD. The data obtained were verified by qPCR. In addition, we aim to verify the most important findings in a panel of primary AML cells with defined Flt3 mutational status. **Results.** Using AML cell lines with distinct amounts and mutational status of Flt3 we see an increased phosphorylation of CREB upon FL stimulation only in cells with Flt3-wt. These results was verified to be Flt3 specific by using the Flt3-inhibitor PKC412 (Figure 1). Incubation of the cells with PKC412 before FL stimulation totally abolishes the phosphorylation of CREB while the Bcr-Abl specific kinase inhibitor Imatinib had no effects on CREB phosphorylation. As activated receptor tyrosine kinases are known to activate CREB through Erk1/2, we tried to inhibit Erk1/2 using the specific inhibitor U0126. However, we still see CREB activation upon FL stimulation without Erk1/2, but in Flt3-wt cells only. Our data suggest that this FL-mediated activation of CREB occurs via PI3K/Akt in Flt3-wt cells. To verify that activated CREB transcribe mRNA and translates it further into protein we used a CREB promoter assay. After 24 hours we found a significantly increased FL-mediated translation in Flt3-wt cells compared to Flt3-ITD cells. Measured by pPCR, CREB target genes like TNFalpha and SNF1LK was significantly up regulated only in Flt3-wt after 2h FL stimulation. ITDs in Flt3 are known to give a constitutive active receptor, our results suggest that this active signaling response differs from the FL-induced signaling seen in Flt3-wt cells. **Conclusions.** Stimulation of Flt3 with its ligand FL leads to activation of CREB in Flt3-

wt cells independent of Erk1/2. This activation leads to both transcription and translation of Flt3 target genes. However, in Flt3-ITD cells, the constitutive active receptor seems not to transcriptionally activate CREB. These differences need to be further explored in order to evaluate the potential prognostic impact.

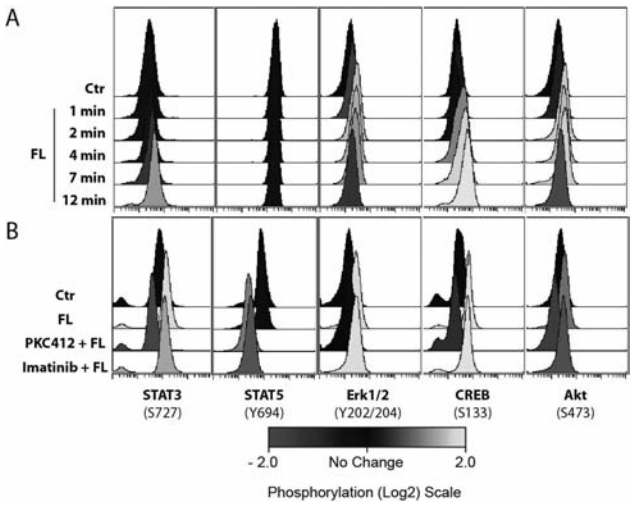


Figure 1. Flt3-Lignad(FL) respond in leukemic EOL-1 cell line. (A) FL stimulation (50 ng/ml). (B) Inhibitors were given 1 hour before FL.

OXIDATIVE STRESS AND C-JUN-AMINO-TERMINAL KINASE ACTIVATION INVOLVED IN APOPTOSIS OF MOLT4 CELLS INDUCED BY DISULFIRAM/COPPER COMPLEX

B Xu[1], YY Zhang[1], P Shi[2], Z Zha[1], X Guo[2], L Yu[2], S Zhou[2]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China
[2]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China

Background. Disulfiram (DS), an old drug clinically used for alcoholism, was reported to have antitumor effects and copper (Cu) could significantly enhance the DS-induced cell death. We have recently demonstrated disulfiram/copper (DS/Cu) resensitized doxorubicin resistant leukemia cells to doxorubicin through activation of stress related signaling pathway (c-Jun-amino-terminal kinase, JNK), but the messengers responsible for its activation remain unidentified. In many instances, stress-activated protein kinases (SAPK)/JNK signaling mediates the link between oxidative stress and cell death. **Aims.** To determine the killing effect of DS/Cu complex on human acute lymphoblastic leukemia cells Molt4 and investigate whether oxidative stress and JNK signaling pathway were involved. **Methods.** The cytotoxity of DS/Cu complex on Molt4 cells was detected using MTT assay. Annexin-V/PI and DCFH-DA were employed for apoptosis and intracellular ROS level analysis by flow cytometric analysis. Morphological observation of Molt4 cell stained with Hoechst 33342 was underOLYMPUS fluorescence microscope. The anti-oxidative transcription factor NF-E2-related factor 2 (Nrf2) mRNA and protein expression levels were detected by QT-PCR and western blot respectively. The DS/Cu-induced JNK and p-JNK activation was also examined by western blot. Statistical analysis was carried out with a one-way ANOVA followed by Dunnett's test to assess statistical significance (*$p < 0.05$). **Results.** A serial concentrations of DS in combination with a low concentration (1μM) of Cu^{2+} induced cytotoxicity in Molt4 cells with IC_{50} of 0.435±0.109 μM at 24h. The cell morphology (nuclear condensation and apoptotic body formation) and Annexin-V/PI flow cytometric analysis indicated that DSF/Cu induced Molt4 cell death into apoptosis. With the increasing concentrations of DS (0.125, 0.25, 0.5, 1μM), the apoptotic proportion of Molt4 cells increased from 17.75% to 79.5% at 24h. Nrf2 plays a central role in the protection of cells against oxidative. Results of QT-PCT showed that DS/Cu down-regulation Nrf2 gene expression in a concentration dependent manner, consistently, western blot indicated Nrf2 nuclear translocation was also inhibited. As ROS levels are predominantly regulated by the transcription factor Nrf2, We also detected the ROS levels in Molt4 cells and flow cytometric analysis showed DS/Cu induced ROS generation. ROS-mediated signals have been demonstrated to be strong promoters of JNK activation. Western blot in this study also showed DS/Cu complex induced phosphorylation of JNK expression in Molt4 cells, the total JNK was not changed. To further explored the potential role of oxidative stress in DS/Cu complex-mediated apoptosis, Molt4 cells were exposed to indicated concentration of DS/Cu complex in the presence or absence of an antioxidant N-acetyl-L-cysteine (NAC). Results showed that NAC attenuated DS/Cu complex-induced apoptosis, restore Nrf2 nuclear translocation and block JNK activation. **Conclusions.** DS/Cu complex potentiated cytotoxitiy to Molt4 cells through apoptosis induction. Oxidative damage including Nrf2 inhibition and ROS generation, followed by activation of JNK, play a functional role in DS/Cu mediated antileukemic effects.

THE ACUTE MYELOID LEUKEMIA-DERIVED CELL LINE OCI-AML1 IS A MODEL FOR VEGF-C SIGNAL TRANSDUCTION STUDIES

H Quentmeier[1], R Geffers[2], J Romani[1], M Zaborski[1], H Drexler[1]
[1]DSMZ, Braunschweig, Germany
[2]Helmholtz Zentrum für Infektionsforschung, Braunschweig, Germany

Background. Vascular endothelial growth factors (VEGFs) and their receptors (VEGF-Rs) are important regulators of angiogenesis and lymphangiogenesis. VEGF-A triggers the activation of the tyrosine kinases VEGF-R1 (FLT1) and VEGF-R2 (KDR) on blood vessel endothelial cells. VEGF-R3 (FLT4), primarily expressed on lymphendothelial cells, is stimulated by VEGF-C and VEGF-D. VEGF-Rs can also be expressed in solid tumors and on leukemic cells. The interaction of receptors with their ligands mediates survival and can lead to proliferation of the malignant cells. Results of our study of 95 leukemia-lymphoma cell lines show that not only *FLT1* and *KDR*, but also *FLT4* is regulated by DNA methylation. **Aims.** To find models for VEGF-C/FLT4 signalling, we tested the FLT4 protein expression on cell lines with unmethylated *FLT4* promoters. OCI-AML1 was the only FLT4-positive cell line which was cytokine-dependent. Cytokine-dependent cell lines are particularly useful models for signalling studies, as cytokine starvation silences receptors and the receptor-downstream enzymes. Addition of a cytokine then activates its receptor and relevant signalling cascades. Here, we set out to test whether cell line OCI-AML1 can be used as model system for VEGF-C/FLT4 signalling. **Methods.** Cell signalling was tested by Western bloting using antibodies against the phosphorylated and unphosphorylated forms of canonical signal transduction kinase targets. RNAs of unstimulated and VEGF-C-stimulated OCI-AML1 cells were reverse-transcribed. Expression array analysis (Affymetrix Gene Chip HG-U133 Plus 2) was performed to detect genes differentially expressed in unstimulated and VEGF-C-stimulated cells. Expression levels of VEGF-C-regulated genes were reanalysed by quantitative real time PCR. Results were confirmed in experiments studying time course and dose dependence of the VEGF-C effect.**Results.** Of the 95 leukemia-lymphoma cell lines tested, 6 strongly expressed *FLT4* mRNA and protein (BV-173, HEL, MEG-01, MHH-CALL2, OCI-AML1, SUP-B15). Among these six cell lines only OCI-AML1 was cytokine-dependent. Stimulation with VEGF-C (125 ng/ml) induced phosphorylation of ERK1/2 (after 5 min) and induced expression of a set of genes, e.g. *Angiopoietin-1* (1.6x after 4h, 3.2x after 48h), ETV5 (2.5x after 4 h; 2.1x after 48h), and FAM101B (2.3x after 4h, 3.7x after 48h). **Summary and Conclusions.** Bisulfite sequencing and methylation-specific PCR of the *FLT4* promoter performed for 95 leukemia-lymphoma cell lines revealed the inverse correlation between promoter methylation and gene expression that is typical for epigenetically regulated genes. Confirming epigenetic regulation of *FLT4*, DNA demethylating agents induced gene expression in *FLT4* methylated cell lines. Cell line OCI-AML1 was the only FLT4 protein expressing cell line that requires cytokines for cell growth. VEGF-C induced phosphorylation of ERK1/2 in starved OCI-AML1 cells and induced expression of specific genes, *Angiopoiein-1* being the most interesting one. Like VEGF-A and the VEGF-Rs *FLT-1* and *KDR*, *Angiopoietin-1* and its receptor Tie2 are important mediators of angiogenesis. These results suggest that VEGF-C may induce expression of Angiopoietin-1 in tumor cells which, in turn might lead to vascularization of the tumor. These results show that OCI-AML1 is a promising new model for VEGF-C/FLT4 signalling studies.

MOLECULAR INTERACTION OF THE SMALL GTPASE RAC1 WITH THE HEMATOPOIETIC PROTEIN DOCK10. EXPRESSION STUDIES OF THE ZIZIMIN SUBFAMILY OF DOCK PROTEINS.

N Ruiz-Lafuente, M Alcaraz-Garcia, S Sebastian-Ruiz, A Parrado
Hospital Virgen Arrixaca, Murcia, Spain

Background. Dedicator of cytokinesis (DOCK) proteins are a family of guanosine nucleotide exchange factor (GEF) for small Rho GTPases. The Zizimin subfamily includes DOCK9, DOCK10, and DOCK11. Recently, our group described tissue expression of the alternative first coding exon DOCK10 isoforms, designated DOCK10.1 and DOCK10.2 (Alcaraz-Garcia *et al*. Hum Immunol 2011; 72: 531-537). There is evidence that DOCK9 and DOCK11 are

specific activators of Cdc42. Specificity of DOCK10 for Rho GTPases remains to be elucidated. **Aims.** 1) To identify the isoforms of DOCK9 and DOCK11, and their tissue expression; 2) to study the cytosolic/nuclear distribution of the three Zizimin proteins; and 3) to define the specificity of DOCK10 for Rho GTPases. **Methods.** RT-PCR and qPCR methods were designed to identify the suspected isoforms of DOCK9 and DOCK11. Cytoplasmic and nuclear protein extracts were obtained from primary cells and cell lines and assayed by western blot analysis. GST fusions with "classical"Rho GTPases were used to pulldown protein extracts from 293T transfected with Zizimin proteins, in nucleotide-free (nf) conditions or loaded with GTP or GDP. **Results.** Four DOCK9 isoforms result from the combination of two alternative starts and two alternative ends. The usage of two alternative first exons gives rise to the components designated DOCK9.1 and DOCK9.2. The alternative splicing of exon 33 gives rise to long (L) and short (S) isoforms, i.e., the components designated DOCK9.L and DOCK9.S. Thus, the isoforms were designated DOCK9.1.L, DOCK9.2.L, DOCK9.1.S, and DOCK9.2.S. One single form of DOCK11 was described. Total DOCK9 was expressed in diverse tissues, being the highest levels found in T cells. DOCK11 expression was more restricted to hematopoietic tissues, being expressed with the highest levels also in T cells. DOCK9, in contrast to DOCK10 and DOCK11, was not expressed in B cells. In the majority of tissues, DOCK9.l.L and DOCK9.1.S were the predominant isoforms and were expressed with similar levels. DOCK10 and DOCK11 located in the cytoplasmic fraction of PBMC. Consistent with previous reports, DOCK9 and DOCK11 interacted with nf Cdc42 but not with GDP- or GTP-loaded Cdc42, nor with Rac1 or RhoA, supporting their role as Cdc42-specific GEFs. Both DOCK10 isoforms interacted with nf Rac1but not with GDP- or GTP-loaded Rac1. With less intensity, DOCK10 isoforms interacted with nf Cdc42 but not with GDP or GTP-loaded Cdc42. They did not interact with RhoA. In addition, the DOCK10 isoforms interacted weakly with nf Rho F, Rac2, RhoG, and RhoD, and did not interact with Rac3, RhoJ, or RhoQ. **Conclusions.** The Zizimin subfamily is a group of 3 proteins mainly expressed in lymphoid tissues. Four DOCK9 isoforms have been described, being DOCK9.1.L and DOCK9.1.S the ones expressed with the highest levels in most tissues. A single isoform of DOCK11 was found. The Zizimin proteins located to the cytoplasm in PBMC. In contrast to DOCK9 and DOCK11 that specifically interacted with Cdc42, DOCK10 interacted with more intensity with Rac1, suggesting that DOCK10 could be a specific GEF for

[5]National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Bethesda, United States of America

The S100 family represents small acidic proteins with common EF-hand calcium-binding motifs. S100 proteins mainly exhibit a diverse cell- and tissue-specific expression pattern with intra- and extracellular functions. Furthermore, several S100 proteins have also been reported to play important roles in cancer progression and suppression, as well as cell proliferation and differentiation. S100 proteins activate some intracellular transduction pathways including JAK/STAT signaling pathway constitutively activated in myeloproliferative neoplasm (MPN) with JAK2V617F mutation. Using microarray analysis, we studied the cancer related S100 genes expression profile of hematopoietic $CD34^+$ progenitor cells and granulocytes from peripheral blood of patients with essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). The proteomic studies of S100 proteins in granulocytes have been performed in 4 groups: PV, ET, and PMF with JAK2 mutations and ET/PMF with no JAK2 mutation. Cancer promoters S100A4 and S100A6 genes expression have statistically significant increases in hematopoietic progenitor cells of ET and PV patients compared to healthy controls, with decreased expression in granulocytes of MPN patients. S100A4 protein expression is decreased in PV patients in contrast to other MPNs regardless of JAK2 mutation. In addition, S100A4 and S100A6 protein expression is increased in PMF patients versus ET/PMF patients without JAK2 mutation and PV patients, respectively. S100A8/A9 expression in cancer cells has also been linked with tumor development and cancer invasion. S100A8 has largely increased gene expression in hematopoietic progenitor cells of MPN patients, while S100A8 protein expression is increased in PV and PMF patients with JAK2 mutation in comparison to MPN patients with no mutation. S100A9 protein expression is increased in ET and PMF, opposed to counterpart with no JAK2 mutation and PV, and more prominent in ET patients. S100A9 has mostly increased gene expression in hematopoietic progenitor cells and granulocytes of MPN patients, significantly reduced only in ET granulocytes. Tumor suppressor and cell growth inhibitor S100A11 gene expression is decreased both in hematopoietic progenitor cells and granulocytes of MPN patients, whereas the protein expression is significantly increased only in PMF patients with JAK2 mutation versus mutation negative MPN patients. In contrary, proinflamatory S100A12 protein expression is increased in mutation negative MPNs compared to MPN patients with JAK2 mutation, where PMF patients demonstrated the most increased protein expression. S100A12 gene expression, absent in controls, is increased in hematopoietic progenitor cells of PV patients, and occasionally present in ET and PMF patients. In conclusion, our results show that s100 gene expression balance is significantly altered in MPN hematopoietic progenitors, together with modification of protein expression in granulocytes. These results propose a novel role for S100 proteins in phenotypic and genotypic characteristics of MPNs.

TRANSCRIPTOME-WIDE MRNA TARGETS OF THE RNA-BINDING PROTEIN MSI2 INVOLVED IN MYELOID MALIGNANCIES

K Hezaveh[1], S Duggimpudi[2], E Larsson[3], A Borkhardt[2], J Hoell[2]

[1]Heinrich Heine University, Duesseldorf, Germany

[2]1Department of Pediatric Oncology, Hematology and Clinical Immunology, Duesseldorf, Germany

[3]Institute of Biomedicine, University of Gothenburg, Gothenburg, Sweden

Background. Musashi homolog 2 (MSI2) is an RNA-binding protein (RBP) with an RNA-binding domain located in its N-terminus. It was first associated with myeloid malignancies when it was shown to form a fusion protein with HOXA9 in chronic myeloid leukemia (CML). Moreover, expression of wild-type MSI2 is highly up-regulated during CML progression. Additionally, the depletion of MSI2 in human myeloid leukemia cell lines leads to decreased proliferation and increased apoptosis. Expression of MSI2 expression predicts unfavorable outcome in AML patients. MSI2 was suggested as a new prognostic marker and a new therapeutical target in AML. **Aims.** Gene expression in eukaryotes is extensively controlled at the post-transcriptional level by RBPs modulating the maturation, stability, transport, editing and translation of the RNA transcripts they are bound to.Neither the mechanism by which the overexpression of MSI2 contributes to leukemogenesis nor the physiological function of this protein are understood. It is therefore crucial to gain insight into its transcriptome-wide mRNA targets.We aim to establish the physiological role of MSI2 to then better understand the impact of its overexpression in myeloid malignancies. **Methods.** PAR-CLIP (photoactivatable ribonucleoside-enhanced crosslinking and immunoprecipitation) was developed to identify the transcriptome-wide RBP binding sites by incorporation of the photoreactive nucleoside 4-thiouridine into nascent mRNAs of cultured cells. Using next-generation sequencing, this allows mapping of the exact crosslink sites thus shedding light on the RNA-recognition elements (RREs), bound mRNA and ultimately the function of the studied RBP. **Results.** PAR-CLIP was employed for MSI2. The roughly 200 million generated mRNA reads gave rise to around 20000 clusters meeting stringent quality criteria. We found that cytoplasmically localized MSI2 predominantly binds intronic and 3'UTR mRNAs at roughly equal distribution.We have performed an siRNA knockdown of MSI2 and will correlate the data of genes whose expression is altered to those bound by MSI2 as defined by PAR-CLIP paying special attention to such genes previously published to be dysregulated in myeloid malignancies.We have also bioinformatically defined the RRE of MSI2 and are now in the process of validating it biochemically. **Summary and Conclusions.** We have successfully applied PAR-CLIP to the RBP MSI2, which was previously shown to play a role in myeloid malignancies. For the first time, the direct mRNA targets of MSI2 have been elucidated and the RRE was defined. This serves as the starting point to further investigate the physiological role of this RBP to then analyze the impact of its overexpression in myeloid malignancies.MSI2 has already been proposed as a new target for therapy in AML and our data, especially the newly described RRE, provides the starting point for the design of inhibitors such as RNA decoys containing a high affinity ligand for MSI2.

PHOSPHOPROTEOM ANALYSIS OF CHRONIC MYELOID LEUKEMIA CELLS USING PROTEIN ARRAYS

M Zackova[1], T Lopotova[2], S Nadvornikova[1], H Klamova[2], J Moravcova[1]
[1]Institute of Hematology and Blood Transfusion, Prague, Czech Republic
[2]Institute of Hematology and Blood Trasnfusion, Prague, Czech Republic

Backround. There are probably a number of mechanisms of resistance to tyrosine kinase inhibitors. It has been suggested that in many cases over time from chronic myeloid leukemia (CML) diagnosis, the disease may become partially or totally BCR-ABL independent, driven by other proteins, especially kinases. List of those proteins is probably still incomplete and is increasing rapidly. Knowledge of the other players in CML pathogenesis is of high importance as it might improve both CML patients monitoring and therapy. **Aims**. In our current study, we aim to select proteins differentially activated in CML patients with different responses to kinase inhibitor therapies (imatinib, nilotinib, dasatinib). These proteins might serve as novel biomarkers and therapy targets. We look at the changes in CML cell lines and primary patients´ leukocytes treated with tyrosine kinase inhibitors in vitro. As many proteins are activated/deactivated by phosphorylation at different sites, we aim to study phoshoproteom of CML cells. **Methods.** We have applied commercially available protein arrays to see phosphorylation profiles. Antibody array analyses were optimized and data for selected proteins were checked by Western blot analyses.4.ResultsPreliminary data showed differences in activated pathways in samples of patients with different response to therapy and CML aggressiveness. In our study, we found differences in phosphorylation status of different kinases including Src family (Src, Yes) and others (BTK, ZAP-70). Interestingly, we also found differences in proteins which regulate cellular kinases (CSK) or interact with them (GRB2, GRAP) and influence their effects. Differences in expression and/or activation of such regulators might explain different CML aggressiveness in patients with comparable levels of BCR-ABL. Differences were found upon treating CML cell lines and primary patients´ leukocytes with tyrosine kinase in vitro.**Summary and conclusions.** Protein antibody arrays are novel promising tool to provide complex insights into disease pathogenesis. Complex coverage of the proteome by todays´ available protein arrays allow to reveal important pathways in disease pathogenesis and to find novel markers and targets for therapy.Grant support: NT/12392-4 IGA MZ-CR.

[11]Universitá di Milano, Ca Granda Foundation IRCCS, Milan, Italy

Background. Non-transfusion-dependent thalassemia (NTDT) patients, including β-thalassemia intermedia (β-TI), mild/moderate forms of HbE/β-thalassemia and α-thalassemia (HbH disease) require occasional/no blood transfusions, but are at risk of clinically relevant iron overload as they age. This is mainly due to increased intestinal iron absorption driven by ineffective erythropoiesis, leading to increased risk of vascular, endocrine and bone disease. The 1-year, randomized, double-blind, placebo-controlled THALASSA study assessed efficacy and safety of the iron chelator deferasirox for investigational use in iron-overloaded NTDT patients. **Aims.** To assess the consistency of deferasirox efficacy on liver iron concentration (LIC) in various subgroups of NTDT patients. **Methods.** Study design and inclusion/exclusion criteria for THALASSA have been described previously (Taher *et al. Blood* 2011;118:abst902). Patients (or parents/guardians) provided written, informed consent. Deferasirox dose could be doubled at Week 24 in patients with insufficient response (LIC >7mg Fe/g dw and reduction <15% compared to baseline). Primary efficacy endpoint was the absolute change from baseline in LIC at Week 52 (last-observation-carried-forward); analyzed here by subgroups: age, gender, race, baseline LIC/baseline SF, splenectomy, underlying thalassemia syndrome and requirement for dose increase. Estimates were also obtained from an ANCOVA model with treatment as factor and baseline LIC as covariate. **Results.** 166 patients with β-TI (n=95), HbE/β-thalassemia (n=49) or α-thalassemia (n=22) were randomized to starting deferasirox doses 5 mg/kg/day (n=55)/matching placebo (n=28) or 10 mg/kg/day (n=55)/matching placebo (n=28). At Week 24, dose was doubled in 26 (47.3%) and 25 (45.5%) patients receiving starting deferasirox doses 5 or 10 mg/kg/day, respectively; mean±SD actual deferasirox doses were 5.7±1.4 and 11.5±2.9 mg/kg/day, respectively. At Week 52, LIC significantly decreased from baseline by least-squares mean -1.95 and -3.80mg Fe/g dw in the deferasirox 5 and 10 mg/kg/day groups, and increased by 0.38mg Fe/g dw in the placebo.Patients receiving deferasirox 10 mg/kg/day throughout the study achieved mean LIC reduction of -3.57mg Fe/g dw; those escalated from 10 to 20 mg/kg/day achieved -4.02mg Fe/g dw. LIC reduction for patients receiving deferasirox 5 mg/kg/day with/without escalation to 10 mg/kg/day was similar (-1.82mg Fe/g dw with escalation; -1.88mg Fe/g dw without escalation; Figure A). Mean LIC decreased in both deferasirox dose groups irrespective of analyzed subgroups. In general, the direction of the estimated differences by subgroup was consistent with the primary efficacy analysis (Figure B).No relevant differences were observed in the deferasirox adverse event profile across the analyzed subgroups. Laboratory evaluations (shifts in aspartate aminotransferase, alanine aminotransferase, serum creatinine, creatinine clearance, urinary protein/creatinine ratios, or change in hematology variables from baseline) also did not show relevant differences across subgroups. **Summary and Conclusions.** Based on this subgroup analysis, larger reductions in LIC were achieved in NTDT patients receiving starting deferasirox 10 mg/kg/day, with greatest reductions in those escalated to 20 mg/kg/day. Although not powered to determine differences between subgroups and low patient numbers in several subgroups precluded clinically relevant conclusions, LIC decreased from baseline in all subgroups and there

were no observed differences in safety between subgroups. Thus, deferasirox efficacy and safety is consistent across this diverse group of NTDT patients.

Figure. (A) Changes in LIC by requirement for dose escalation during the study; and (B) least squares mean with 95% confidence interval for differences in absolute change in LIC from baseline to Week 52 between deferasirox 10 mg/kg/day and all placebo combined by subgroups

[8]Genova Hospital, Genova, Italy

Background. Heart failure related to cardiac siderosis is a major cause of death in transfusion dependent anemias, and in particular beta-thalassaemia major. Replacement fibrosis been reported as causative of heart failure in siderotic cardiomyopathy in historical reports, but the relevance of these is now controversial as they do not accord with the reversible nature of heart failure in cardiac siderosis achievable with intensive iron chelation. **Aims.** We aimed to assess the prevalence of fibrosis in cardiac siderosis in the modern era. **Methods.**Ten whole hearts (9 beta-thalassaemia major, 1 sideroblastic anaemia) were examined for iron loading and tissue fibrosis. Of these patients, 5 died from heart failure, 4had cardiac transplantation for heart failure, and 1 died from a stroke with no heart failure. Heart samples were quantified for iron content using inductively coupled plasma atomic emission spectroscopy. Fibrosis was quantified by computer using picrosirius red (PSR) staining and expressed as collagen volume fraction (CVF) with normal value <3%. **Results**. There was no significant macroscopic replacement fibrosis in any heart. In only 2 hearts was fibrosis identifiable, and this was predominantly interstitial but with low CVF: in one patient who died from a stroke with no cardiac siderosis, CVF was 5.9%; in the second patient who had heart failure, the CVF was 2%. In the remaining 8 patients, no fibrosis was seen despite all having severe cardiac siderosis and heart failure (mean CVF 1.86% ±0.87%). **Conclusions.** This study shows that in the modern era, cardiac fibrosis is not responsible either for heart failure, or death from heart failure in patients with transfusion dependent anaemia, including beta-thalassaemia major patients. Replacement fibrosis was not seen and the minor interstitial fibrosis identified in 2 patients was not contributory to heart failure. The absence of cardiac fibrosis accords with the reversible heart failure seen in iron overload cardiomyopathy These findings are in marked contrast to the major historical pathological series in transfusion dependent patients by Engle (1964) and Buja (1971). The explanation for the change in prevalence of cardiac fibrosis over 40 years can only be subject to speculation. The likely possibilities include improved blood transfusion preventing damage from excessive cardiac output, and the introduction of the iron chelator deferoxamine which came into widespread clinical use in the 1970's. Our data therefore suggests that modern management prevents cardiac fibrosis, despite cardiac siderosis ultimately being a common cause of cardiac death.

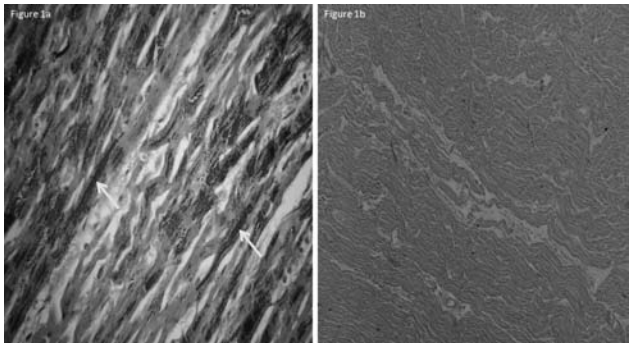

Figure 1a: Heavily iron loaded myocardium (Perl's stain). Nearly all myocytes showed homogenous positive purple/blue iron granules (arrows) within the cytoplasm.b: Picrosirius red staining of myocardium from a patient with severe cardiac siderosis. No significant fibrosis is sen

IRON OVERLOAD LOWERS THE GLOMERULAR FILTRATION RATE ESTIMATED BY CYSTATIN C IN PATIENTS WITH THALASSEMIA MAJOR

K Al-Khabori[1], S Bandhari[2], H Al Rasadi[1], T Mevada[1], H Al-Dhuhli[1], A Khan[1], F Daar[1]

[1]Sultan Qaboos University Hospital, Muscat, Oman

[2]University Hospitals of Hull & East Yorkshire and Hull York Medical School, Kingston upon Hull, United Kingdom

Background. Thalassemia major is an inherited hemoglobinopathy requiring frequent lifelong blood transfusions. Patients suffer from complications related to necessary regular blood transfusions including iron overload. The renal complications have not been well studied. **Aims.** In the current study, we analyzed the impact of iron overload on the glomerular filtration rate (GFR) in children and adults with thalassemia major. **Methods.** One hundred and fifty five adults and children with thalassemia major treated at our center were eligible for the cross sectional study. None had known abnormal renal function. We used Cystatin C to estimate the GFR given the previous reports of improved accuracy and correlation with measured GFR using this method. Univariable and multivariable linear regression modeling was used to study the impact and adjust for the multiple baseline characteristics on the GFR as estimated by serum Cystatin C. These included age, gender, diabetes mellitus and type of chelation therapy.Results. Of the 155 patients approached, 6 patients were excluded (5 declined consent, 1 was pregnant). The mean age was 17.3 years (standard deviation [SD] 9, range 2.5-38.5) with 78 males and 71 females. The mean body mass index was 19.2 (SD 4.7, range 10.6-35.8). The mean systolic and diastolic blood pressures were 106 mmHg (SD 10, range 81-138) and 64 (SD 10, range 42-8) respectively. Eight and 9 patients had non-insulin dependent and insulin dependent diabetes mellitus respectively. Twenty-six patients were on combined chelation therapy (deferiprone and deferoxamine), 58 on deferiprone (mean dose 92mg/kg/day), 62 on deferasirox (mean dose 37mg/kg/day) and 1 on deferoxamine (dose 29mg/kg/day). The mean ferritin level was 1913 ng/ml (SD 1972, range 70-11927). The mean serum creatinine and urea concentrations were 39 micmol/l (SD 14, range 3.6-83) and 5 mmol/l (SD 4, range 1.4-46) respectively. The mean GFR estimated using Cystatin C was 105 ml/min (SD 28, range 44-224). In the univariable analyses, ferritin (coefficient = -0.003; p=0.004), diabetes status (coefficient = 22.8; p<0.001) and chelation type (coefficient = -13.23, p<0.001) were statistically significant. After adjusting for the baseline differences using multivariable modeling, ferritin (coefficient = -0.002; p=0.018) and diabetes status (coefficient = 23.9, p<0.001) remained statistically significant. **Conclusions.** In patients with thalassemia major, iron overload is associated with lower GFR. This is likely a direct effect of iron on glomerular function. Diabetes mellitus status is associated with higher GFR which is likely related to hyperfiltration seen typically in early diabetes. Further studies are needed to confirm these findings.

0927

ESTIMATION OF LIVER IRON CONCENTRATION BY SERUM FERRITIN MEASUREMENT IN NON-TRANSFUSION-DEPENDENT THALASSEMIA PATIENTS: ANALYSIS FROM THE 1-YEAR THALASSA STUDY

Background. Many non-transfusion-dependent thalassemia (NTDT) patients develop elevated liver iron concentration (LIC) over time, increasing the risk of clinical complications. In NTDT patients, data suggest that serum ferritin (SF) levels underestimate iron load. Although non-invasive magnetic resonance imaging (MRI) assessment to determine LIC and guide chelation therapy is more robust clinically, due to limited access in many parts of the world, it would be practical to also use SF levels to manage iron overload. The randomized, double-blind, placebo-controlled THALASSA pivotal study assessed the efficacy and safety of deferasirox for investigational use in iron-overloaded NTDT patients and provided a large dataset to allow exploration of the relationship between LIC and SF. **Aims.** To evaluate using Receiver Operating Characteristic (ROC) analysis whether SF can be used to estimate LIC and determine SF cut-offs with high positive predictive value (PPV) and low negative predictive value (NPV) in predicting clinically relevant LIC thresholds in NTDT patients. **Methods.** THALASSA enrolled iron-overloaded NTDT patients (LIC ≥5mg Fe/g dw and SF >300ng/mL) aged ≥10 years. After obtaining written, informed consent from patients (or parents/guardians), NTDT patients underwent eligibility screening prior to enrollment. Using data from all screened patients with available SF (measured at a central laboratory) and LIC (measured using validated R2 MRI and read centrally), a ROC analysis was performed using LIC ≥5 and ≥7mg Fe/g dw, the levels used to initiate and dose increase deferasirox therapy, respectively during THALASSA. PPV was calculated as the percentage of true positives (based on LIC) among all positives (based on SF) and NPV was calculated as the percentage of true negatives (based on LIC) among all negatives (based on SF). **Results.** 282 patients with β-thalassemia intermedia, HbE/β-thalassemia or α-thalassemia had LIC and SF determined at screening. Patients with SF >800ng/mL had a high probability (91.7%) of LIC ≥5mg Fe/g dw and SF >2000ng/mL was highly predictive (92.9%) of LIC ≥7mg Fe/g dw. Among patients with SF ≤800ng/mL, 46.4% had LIC ≥5mg Fe/g dw. To assess SF thresholds for potential clinical guidance of chelation therapy, percentages of patients with LIC <3 (iron chelation stopping criterion), <5 and <7mg Fe/g dw at SF cut-off of 100 (used in THALASSA as a SF-based treatment stopping criterion) and 300ng/mL were calculated. Three patients had SF ≤100ng/mL and all had LIC <3mg Fe/g dw. At the SF 300ng/mL cut-off, 12/15 (80.0%) patients had LIC <3mg Fe/g dw, 13/15 (86.7%) had LIC <5mg Fe/g dw, and 15/15 (100%) had LIC <7mg Fe/g dw. **Summary and Conclusions.** Although underlying factors may affect the SF/LIC correlation, this ROC analysis suggests that SF could be useful in some NTDT patients to guide iron chelation. Patients with SF >800ng/mL had a high probability of LIC ≥5mg Fe/g dw, at which level deferasirox was initiated in THALASSA; in patients with SF ≤800ng/mL, LIC confirmation of iron overload is desirable. SF >2000ng/mL was highly predictive of LIC ≥7mg, at which level deferasirox dose increase was allowed in THALASSA. SF ≤300ng/mL appears adequate and safe to interrupt deferasirox therapy.

Figure. ROC curve for using serum ferritin to predict LIC ≥5 mg Fe/g dw based on all screened patients with screening serum ferritin and LIC

Background. As heart failure related to cardiac iron is a major cause of death in patients with β-thalassemia major and Diamond-Blackfan-anemia (DBA), it is important to understand the prevalence of cardiac siderosis in this population. Cardiac T2*<20ms indicates cardiac iron outside the normal range, with T2*<10ms being associated with highest risk of heart failure and arrhythmia. No studies have had sufficient sample size to examine the distribution of cardiac siderosis across geographic regions. **Aims.** To examine the prevalence and distribution of cardiac iron overload by geographic regions in a large cohort of patients with transfusion-dependent anemias. The relationships between T2* and other iron parameters are also examined. **Methods.** Enrollment is complete for the multicenter, open-label, randomized, Phase II 1year clinical trial evaluating deferasirox versus deferoxamine for the treatment of cardiac siderosis in patients aged ≥10 years with β-thalassemia major, DBA, sideroblastic anemia or Low/Int-1 risk myelodysplastic syndromes (MDS) and history of ≥50 transfusions (CORDELIA; NCT00600938). Data received by Jan 9, 2012 are reported for screened patients. Patient characteristics were summarized by T2* categories and by geographic regions (West: Canada, Cyprus, Italy, Turkey, UK; Middle East: Egypt, UAE, Lebanon; Far East: Taiwan, Thailand, China). Correlations were evaluated using Pearson's correlation coefficient (r). Left ventricular ejection fraction (LVEF) below the lower limit of normal (LLN) was identified using Westwood criteria (males <59%; females <63%). **Results.** 923 patients were screened (99.1% β-thalassemia major, 0.1% DBA, 0.4% MDS 0.3% other; 54.5% male; mean age, 19.2 ± 7.8 years). 83.3% of patients had received >100 transfusions and the majority (98.4%) had received previous chelation therapy. 49.7% of patients had undergone splenectomy.Overall, 20.1% of patients had T2*10-≤20ms; 16.8% had T2*<10ms (West 20.6%, Middle East 12.4%; Far East 20.5%. Furthermore, 64.6% of patients had LIC≥15mg Fe/g dw, and LIC varied between regions (Table).

Table: Prevalence of iron overload in patients with transfusion-dependent anemias, by geographic region.

	Overall (n=923)	Western (n=258)	Middle East (n=462)	Far East (n=203)
T2*	n=755	n=233	n=346	n=176
Geometric mean (95% CI), ms	21.7 (20.7, 22.8)	19.4 (17.8, 21.2)	24.4 (22.8, 26.1)	20.0 (18.0, 22.2)
Cardiac T2* categories, n (%)				
<6ms	41 (5.4)	13 (5.6)	16 (4.6)	12 (6.8)
6–<10ms	86 (11.4)	35 (15.0)	27 (7.8)	24 (13.6)
10–≤20ms	152 (20.1)	59 (25.3)	57 (16.5)	36 (20.5)
>20ms	476 (63.0)	126 (54.1)	246 (71.1)	104 (59.1)
LIC	n=757	n=242	n=326	n=189
Mean (SD), mg Fe/g dw	25.9 (17.0)	19.4 (14.7)	25.4 (16.3)	35.1 (16.9)
LIC categories, n (%)				
≥15 mg Fe/g dw	489 (64.6)	124 (51.2)	210 (64.4)	155 (82.0)
7–<15 mg Fe/g dw	148 (19.6)	53 (21.9)	75 (23.0)	20 (10.6)
<7 mg Fe/g dw	120 (15.9)	65 (26.9)	41 (12.6)	14 (7.4)

Median serum ferritin was 3739ng/mL (West 2272, Middle East 3804, Far East 5261ng/mL).LIC was highest in patients with T2*<6ms (36.0 [15.0]mg Fe/g dw), and was also elevated in patients with T2*>20ms (LIC 23.5 [16.1]mg Fe/g dw). Mean LVEF was 63.8, 63.8, 66.4 and 67.8% in patients with T2*<6, 6-<10, 10-≤20 and >20ms, respectively. Overall, 12.1% of patients had LVEF below LLN. The proportion of patients with LVEF below LLN was higher in low T2* categories (24.4, 22.4, 15.1 and 8.1% in T2*<6, 6-<10, 10-≤20 and >20ms, respectively).There was no clinically useful correlation between T2* and age (r=-0.054), LIC (r=-0.213), serum ferritin (r=-0.250) or LVEF (r=0.179). **Summary/Conclusions.** Data from this large cohort of patients with transfusion-dependent anemias allowed examination of cardiac siderosis by geographical region. Overall, the prevalence of cardiac siderosis was slightly lower but similar to previous reports (T2*10-≤20ms, 20.1% vs 22.2%; T2*<10ms, 16.8% vs. 23.5% [Daar *et al*. 2008]). Lower levels of cardiac siderosis in Middle Eastern patients (also observed by El-Beshlawy *et al*. 2010) may have influenced overall T2* values in screened patients. Differences in cardiac siderosis between regions may reflect transfusion and chelation practices, as well as genetic population differences.

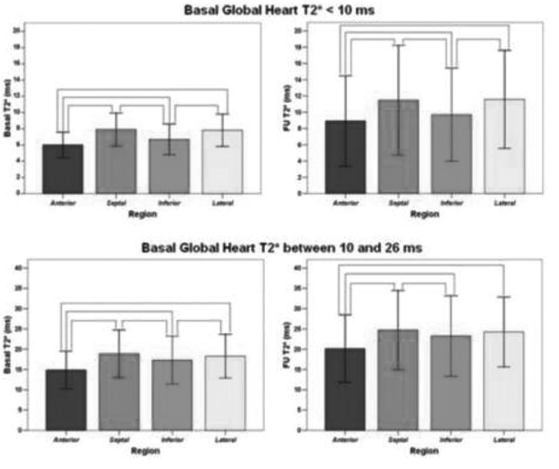
[8]Departement of Radiology, □'□'John Paul II'' Catholic University, Campobasso, Italy

Background. T2* multislice multiecho cardiac magnetic resonance (CMR) allows quantification of the segmental distribution of myocardial iron overload (MIO). **Aims.** This study aimed to determine if a preferential pattern of MIO was preserved between two CMR scans in thalassemia major (TM) patients. **Methods.** Among the 812 TM patients with a CMR follow-up (FU) study at 18±3 months, we selected 259 patients with significant MIO at baseline (global heart T2* <26 ms). Three short-axis views of the left ventricle were acquired and analyzed using a 16-segment standardized model. The T2* value on each segment was calculated, as well as the global value. Four main circumferential regions (anterior, septal, inferior and lateral) were defined.



Results The selected patient population was divided into two groups: severe (N=80, global T2* < 10 ms) and mild-moderate MIO (N=179, global T2* 10-26 ms). During the FU all patients were regularly chelated with excellent/good compliance in the 90 % of the cases. For each group, there was a significant improvement in the global heart as well as in regional T2* values (P<0.0001 for all the pairwise comparisons). For the whole patient population as well as for both two groups, at basal the mean T2* value over the anterior region was significantly lower than the mean T2* values over the other regions and the mean T2* over the inferior region was significantly lower than the T2* values over the septal and the lateral regions. The same pattern was present at the FU, with a little difference for patients with mild-moderate MIO (see figure). **Conclusions**. A preferential pattern of iron store in anterior and inferior regions was present at both basal and FU CMRs, with an increment of T2* values at FU due to a basal CMR-guided chelation therapy. The anterior region seems to be the region in which the iron accumulates first and is removed later. Our data confirm the segmental T2* cardiac MR approach useful for identifying early iron deposit and for tailoring chelation therapy.

IMPROVED IRON CHELATION WITH DEFERASIROX AND ZINC COMBINATIONAL THREAPY IN PATIENTS WITH BETA THALASSEMIA MAJOR: IS IT ADDITIVE OR SYNERGISTIC?

S Unal[1], T Celik[2], C Ozer[2], G Ilhan[1], G Oktay[1]
[1]Antakya State Hospital, Hatay, Turkey
[2]Mustafa Kemal University, Hatay, Turkey

Background. In this study, we aimed to determine whether administration of zinc had any effect on iron chelation of patients with beta-thalassemia major who were under regular erythrocyte transfusions and chelated with oral deferasirox regularly. **Methods.** Eighty-five cases in a single center who were under regular deferasirox chelation for an average of 3 years (1 to 5) were included.Out of these patients, 46 (45.9%) who have received zinc treatment for at least 1 year and 39 who did not receive zinc treatment were evaluated. The height and weight percentile of the patients and their serum ferritin values have been compared. **Results.** Of the 85 patients with beta thalassemia major who were compliant to medications and follow-up, the mean age was 14.5±7.6 years (3 to 40). 53 patients (62.4%) were male and 32 (37.6%) were female. All of the patients were on deferasirox treatment. The mean dose of deferasirox was 31.15±4.26 (21.4-41.6) mg/kg/day in the all study group. The patients received deferasirox early in the morning. 46 patients (54.1%) used zinc while 39 (45.9%) not. The dose of zinc sulfate was 1x15 mg for 2-10 years of age and 2x15 mg for patients above 10 years of age. The patients received zinc sulfate before going to bed. All of the patients were on zinc treament by the age of 2; however some patients were unable to continue the drug for gastrointestinal problems including abdominal pain and/or vomiting and the drug was ceased by the physician. The deferasirox dose of zinc-users and non-users were mean: 30.82±4.78 and 31.53±3.56 mg/kg/day, respectively. The difference between deferasirox doses among zinc users and non-users were statistically insignificant (p=0.45). The mean duration of deferasirox use was 39.1±10.8 months for zinc users and 36.1±11.6 for non-zinc users, the difference between deferasirox using time was statisticaly insignificant between two groups (p=0.22). At the end of the study, the serum ferritin values of the patients who were zinc-receivers and non-zinc-receivers were found to be 1456±214 and 2019±327 ng/ml, respectively and this value was statistically significantly lower in the patients who received oral zinc supplementation (p=0.01). 26.1% of the zinc-treated patients were 3 percentiles and below in terms of height, while 46.2% of the non-zinc-treated patients are 3 percentiles and below. Though this difference was outstanding, it was statistically insignificant (p=0.054). **Conclusions.** In addition to increasing patient compliance in enhancing iron chelation activity, increasing the dosage in monotherapies or applying combined treatment; supporting the treatment in deferasirox-receiving patients with orally given zinc may decrease the growth delay, and also might enhance the activity of the chelation significantly.

INTERIM RESULTS FROM THE MULTICENTER COMPACT STUDY OF COMPLICATIONS IN PATIENTS WITH SICKLE CELL DISEASE AND UTILIZATION OF IRON CHELATION THERAPY: A RETROSPECTIVE MEDICAL RECORDS REVIEW

L Jordan[1], P Adams-Graves[2], J Kanter-Washko[3], H Lau[4], F Vekeman[5], C Bieri[5], M Sasane[4], A Marcellari[4], M Magestro[4], V Steele[2], G Bluett-Mills[3], Z Gorn[5], M Duh[5]
[1]Sickle Cell Disease Association of America, Baltimore, United States of America
[2]University of Tennessee, College of Medicine, Memphis, TN, United States of America
[3]Tulane University, School of Medicine, New Orleans, LA, United States of America
[4]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States of America
[5]Analysis Group, Inc., Washington, DC, United States of America

Background. Sickle cell disease (SCD) patients are living longer and face multiple complications. While early detection and treatment may lead to prevention or delayed onset of complications, evidence-based standards for screening and treatment of SCD complications in adults are lacking. A retrospective chart review may help to identify intervention strategies to minimize or prevent SCD complications and understand transfusion and iron overload management in adult SCD patients. **Aims.** Examine the number and type of SCD complications, blood transfusion patterns, iron chelation therapy (ICT) use, and associated resource utilization in SCD patients ≥16. **Methods.** Medical records of SCD patients ≥16 were retrospectively reviewed at two US tertiary care centers. Patient data were collected from their first visit after age 16 (index date) until the earliest indication of a patient's death, loss to follow-up, or last patient record on file prior to the centers' IRB submission date. Patients were classified into one of three cohorts based on lifetime units of blood received and whether or not they received ICT: <15 units of blood and no ICT (minimally transfused, Cohort 1), ≥15 units of blood and no ICT (Cohort 2), and ≥15 units of blood and ICT (Cohort 3). SCD complication rates were expressed as the number of complications per patient per year (PPPY) and compared among cohorts using rate ratios (RRs). **Results.** A full sample size of over 200 patients is expected. Interim results from 73 patient records reviewed between 08/2011 and 01/2012 (Cohort 1: 15, Cohort 2: 20, Cohort 3: 38) are presented. Mean (range) age at index date was similar across cohorts (23 yrs [16-50]). Mean length of observation was 9.8 years. Patients in Cohort 1 received an average of 1 unit of blood PPPY (p<0.05 vs. Cohort 2 and Cohort 3), whereas patients in Cohort 2 and Cohort 3 received an average of 14 and 11 units per year (p=0.717), respectively. Overall, acute pain crisis (62.6%), priapism (6.4%), infection (6.0%), leg ulcers (3.0%), and acute chest syndrome (1.9%) were the most frequently reported SCD complications. The rate (95% CI) of any SCD complications was the highest in Cohort 1 at 1.23 (1.03-1.42) PPPY, followed by 0.99 PPPY (0.85-1.12) in Cohort 2, and 0.45 PPPY (0.39-0.52) in Cohort 3 (Table 1). Patients in Cohort 1 were more likely to experience SCD complications than those receiving more frequent transfusions (RR [95% CI] Cohort 1 vs. (Cohort 2 + Cohort 3): 1.89 [1.56-2.29]). Among patients receiving more regular transfusions, those receiving ICT were less likely to experience SCD complications than those not receiving ICT (RR [95% CI] Cohort 2 vs. Cohort 3: 2.17 [1.78-2.65]). Similar trends in the rates of SCD complications were observed in outpatient, hospital, and emergency room (ER) visits with the greatest contrast observed in the reduction of ER visits among patients who received ICT (RR [95% CI] Cohort 2 vs. Cohort 3: 5.89 [3.70-9.37]). **Conclusion:** Results from this interim analysis show that the rate of SCD complications is lower in patients receiving more regular transfusions and ICT treatment.

RATE AND RATE RATIO OF SCD COMPLICATIONS BY TYPE OF SETTING

	Cohort 1 n = 15	Cohort 2 n = 20	Cohort 3 n = 38	Cohort 2 + Cohort 3 n = 58	Rate Ratio (RR) Cohort 1 vs. Cohort 2 + Cohort 3	Rate Ratio (RR) Cohort 2 vs. Cohort 3

MYOCARDIAL IRON LOAD AND LEFT VENTRICULAR SYSTOLIC FUNCTION IN CURRENTLY TREATED THALASSEMIA MAJOR PATIENTS

D Farmakis[1], E Polymeropoulos[1], S Delicou[1], E Gotsis[2], A Aessopos[1]
[1]University of Athens Medical School, Athens, Greece
[2]Encephalos/Euromedica Laboratories, Athens, Greece

Background. Iron-induced left ventricular (LV) dysfunction is traditionally considered to be the leading cause of heart failure and thus mortality in regularly transfused thalassemia major (TM) patients. Cardiac siderosis can now be accurately quantified by cardiac magnetic resonance (CMR) T2* relaxation time and its functional impact needs to be reassessed in large cohorts of TM patients on modern CMR-guided therapy. **Aims**. To investigate the relationship between myocardial iron load and LV systolic function in a large cohort of consecutive TM patients on modern therapy using CMR T2* imaging. **Methods.** We studied 610 consecutive thalassemia major patients, aged 29±8 years, on regular blood transfusions (pre-transfusion hemoglobin level ≥9.5 g/dL) and standard iron chelation regimens (deferoxamine, deferiprone or both). Patients underwent CMR for the assessment of myocardial T2* and LV ejection fraction (LVEF).
Results. Myocardial T2* was 23±12 ms; 60% of patients had no evidence of cardiac siderosis (T2* ≥20 ms), 21% had mild to moderate iron load (T2* 10-19 ms) and 19% had severe iron load (T2* <10 ms). LVEF was 66±7%; 86% of patients had preserved LVEF (≥60%), 12% had borderline or mildly reduced LVEF (50-59%) and 2% had clearly reduced LVEF (<50%). LVEF was significantly correlated with T2* (Spearman's rho=0.189, p<0.001, Figure, left panel). The prevalence of reduced LVEF differed significantly according to cardiac iron (30% in patients with severe siderosis, 17% in those with mild to moderate siderosis) and interestingly was present even in the absence of cardiac

siderosis (8%, p among the 3 groups <0.001, Figure, right panel). **Conclusions.** The majority of TM patients on modern CMR-guided therapy have no evidence of myocardial siderosis. Systolic LV function is still crucially dependent upon cardiac iron, but LVEF may also be reduced in the absence of cardiac siderosis.

[7]Pediatria, Adolescentologia e Talassemia, Arcispedale „S.Anna„, Ferrara, Italy

Background. The relationship between diabetes mellitus (DM) and cardiac complications has never been systematically studied in thalassemia major (TM).
Aims. The aim of this study was to evaluate in a large retrospective historical cohort of TM in the cardiovascular magnetic resonance (CMR) era if DM was associated with an higher risk of heart complications. **Methods.** We compared 86 TM patients affected by DM with 709 TM patients without DM consecutively included in the Myocardial Iron Overload in Thalassemia (MIOT) data base where the clinical history is recorded from the birth to the first CMR (years 2006-2010). Myocardial iron overload (MIO) was evaluated by T2* multislice technique. Biventricular function parameters were quantitatively evaluated by cine images. Myocardial fibrosis was evaluated by late gadolinium enhacement CMR technique. All considered cardiac events were developed after DM diagnosis.

Table 1. Logistic regression analysis.

	Adjusted for no-MIO		Adjusted for no-MIO and covariates	
	OR (95% CI)	P-value	OR (95% CI)	P-value
Cardiac complications	4.2 (2.7-6.8)	<0.0001	2.8 (1.7-4.67) #	<0.0001
Heart failure	3.1 (1.9-5.3)	<0.0001	2.3 (1.3-4.1) #	0.003
Hyperkinetic arrhythmias	4.1 (2.2-7.7)	<0.0001	2.2 (1.1-4.4) #	0.023
Myocardial fibrosis	2.1 (1.2-3.6)	0.006	1.9 (1.1-3.3) §	0.021
Heart dysfunction (LV and/or RV)	1.5 (0.4-2.3)	0.093		
Biventricular dysfunction	1.5 (0.8-2.7)	0.235		
LV dysfunction	0.8 (0.4-1.6)	0.487	1.6 (0.4-5.9) *	0.470
RV dysfunction	1.8 (1.0-3.3)	0.048	1.3 (0.7-2.5 *	0.366

Covariates: * age; § endocrine co-morbidity; # age and endocrine co-morbidity

Results. DM patients were significantly older than no-DM patients (37.4 ± 6.2 years vs 32.0 ± 6.7 years, P<0.0001) and showed an higher frequency of endocrine co-morbidity (hypogonadism, hypothyroidism and hypoparathyroidism) (76.7% vs 49.2%, P<0.0001). In DM patients versus no-DM patients we found a significantly higher frequency of cardiac complications (46.5% vs 16.9%, P<0.0001), heart failure (HF) (30.2% vs 11.7%, P<0.0001), hyperkinetic arrhythmias (18.6% vs 5.5%, P<0.0001), and myocardial fibrosis (29.9% vs 18.4%, P=0.008).Table 1 shows odds ratios (OR) and 95% confidence intervals (CI) estimating the relationship between DM and cardiac involvement. Patients with DM had a significant higher risk of cardiac complications, HF, hyperkinetic arrhythmias and myocardial fibrosis, also adjusting for the absence of MIO assessed by T2* CMR (all cardiac segments with T2* ≥ 20 ms) and for the covariates significantly different between groups and significantly associated to the dependent variable. **Summary.** DM increases the risk for cardiac complications, HF, hyperkinetic arrhythmias and myocardial fibrosis irrespective of MIO.

Background. Cardiac Magnetic Resonance (CMR) and Echocardiography (US) are applied in parallel to thalassemia major (TM) patients for cardiac evaluation and ongoing monitoring. A comparison study between the two techniques involving 135 TM patients demonstrated a mild discrepancy of values in the net volume (diastolic and systolic) but not significantly different ejection fractions (EF). **Aims**. The aim of this study was to compare the agreement of left ventricular (LV) volumes and ejection fraction (EF) by CMR and US in a larger cohort of TM patients.

EDVI= end diastolic volume index; ESVI= end systolic volume index; SVI= stroke volume index; EF= ejection fraction

Methods. 307 TM patients (145 M and 162 F; mean age 31.8 ± 8.5 yrs) patients were studied by both echo and CMR (1.5T) within 3 months of each other. All TM patients were enrolled within the MIOT (Myocardial Iron Overload in Thalassemia) network where CMR exams were performed in 8 sites using homogeneous and validated procedures. Steady-state free procession cine images were acquired during 8-second breath-holds in sequential 8-mm short-axis slices from the atrio-ventricular ring to the apex to assess biventricular function parameters quantitatively in a standard way, using MASS® software. Previously demonstrated inter-center variability for the quantification of cardiac function was 6.3%. Echocardiographic studies were carried out in 10 echo labs linked to the thalassemia centers. LV volumes and LVEF were measured by two-dimensional echocardiography using the biplane Simpson's formula. Paired-samples t-test or Wilcoxon test, correlation coefficient, intraclass correlation (ICC), and Bland & Altman plot were used to compare CMR and US parameters. The Cohen's kappa coefficient (k) was used to evaluate the agreement between CMR and echo in identifying borderline EF, mild EF reduction and abnormal EF. **Results**. Table 1 shows the CMR and US parameters, quoted as mean ± SD with 95% CI in round brackets, and the results of the compari-

son between the two techniques. All US volumes were significantly underestimated, especially the end-diastolic volume index, while the US EF was significantly higher than the CMR EF. The correlation between US and CMR volume indexes and EF was significant, but with a low coefficient; especially for the EF. The ICC was good for all the parameters, but never excellent. The Bland Altman plot ranges were wide, with the widest value found for the end-diastolic volume index. In all EF categorizations, k was <0.2, indicating slight agreement. **Conclusions**. In a large CMR versus echocardiographic comparative study in TM patients, metrics of LV volume index and function showed significant systematic inter modality differences. Conversely to the previous findings, CMR and US resulted not interchangeable for LV EF assessment. Of clinical relevance, this study suggests that serial measurements of volumes and function in TM should be performed using the same method and if it is available the more reproducible CMR technique.

THE USE OF APPROPRIATE CALIBRATION CURVES CAN CORRECT THE SYSTEMATIC DIFFERENCES BETWEEN SOFTWARES IN HEPATIC R2* ESTIMATION

A Meloni[1], H Rienhoff[2], A Jones[2], A Pepe[1], M Lombardi[1], J Wood[3]
[1]Fond. G.Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy
[2]FerroKin BioSciences, Inc, San Carlo, California, United States of America
[3]Dept. of Pediatrics, Division of Cardiology, Children's Hospital Los Angele, Los Angeles, United States of America

Background. Liver R2* can be used as a surrogate for liver iron concentration (LIC) in iron overloaded subjects. Two different signal decay models, truncated exponential and exponential plus constant, have been validated for R2* estimation and calibrated to liver biopsy. However, reported calibration curves for these two analysis methods differ by 15%. **Aims.** Our aim was to evaluate if the different fitting models yielded significantly different R2* estimates and if these differences disappeared once R2* estimates were converted to LIC units using method-appropriate calibration curves. **Methods.** A single-center (N=45) and a multi-center cohort (N=47) of patients were used. Gradient echo images optimized for R2* estimation were collected at each site according to local clinical practice. R2* values were generated using the CMRTools (truncated exponential model) and custom Matlab code (exponential plus constant model). R2* values were converted to dry weight liver iron concentration using calibrations published by Garbowski and Wood, respectively. Bland Altman analysis was performed with respect to both R2* and LIC estimates. **Results.** Figure 1a shows the Bland-Altman plot of R2* values for the single-center cohort. Results were unbiased for R2* < 300 Hz, but R2* values obtained using exponential plus constant were systematically larger at higher R2* and the difference increased with increasing values. The mean difference was 54.7 ± 85.7 Hz (95% confidence intervals of the difference: lower 28.9 and upper: 80.5 Hz), corresponding to a percentage difference in R2* values of 9.1 ± 11.8%. The bias was eliminated following conversion to LIC units (Figure 1b). The mean difference was -0.8 ± 1.5 mg/g dry (95% confidence intervals of the mean difference: lower -1.3 and upper: -0.3 mg/g dry).Similar differences in R2* estimation were found in the multi-center cohort and the conversion of R2* values to LIC units again removed the disparity.

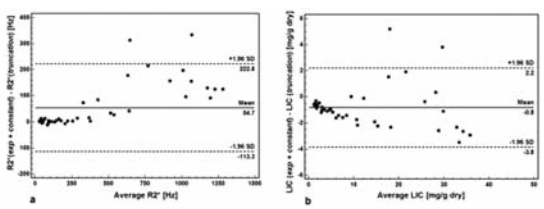

Figure 1. Bland-Altman plot of R2* values (a) and LIC values (b) for the singe-center cohort.

Conclusions. R2* values varied with post-processing method but yielded statistically identical LIC values when technique-appropriate calibration curves were used. LIC, rather than R2* values, should be reported and compared across studies.

LIFETIME COST-UTILITY ANALYSES OF DEFERASIROX IN BETA THALASSAEMIA PATIENTS WITH CHRONIC IRON OVERLOAD: A UK PERSPECTIVE

J Karnon[1], K Tolley[2], D Chandiwana[3], J Vieira[3]
[1]University of Adelaide, Adelaide, Australia
[2]Tolley Health Economics Ltd, Buxton, United Kingdom
[3]Novartis Pharmaceuticals, East Hanover, United States of America

Background. Regular blood transfusions for beta thalassaemic patients lead to the accumulation of iron deposits in the body. In order to remove such deposits, iron chelation therapy (ICT) is required. Desferrioxamine (DFO) is administered subcutaneously and has been the gold standard ICT for over 40 years. Deferasirox (DFX) is a newer ICT that is taken orally once daily.**Aims.** In this study, a cost-effectiveness model was developed to estimate the long-term costs and quality-adjusted life-years (QALYs) associated with DFO and DFX treatment in a cohort of beta thalassaemic patients from a UK health service perspective. **Methods.** A 50-year annual cycle state transition cohort model comprised three core health states: alive without cardiac complications, alive with cardiac complications and dead. Within the defined states, patients may experience one or more of the following chronic complications of iron overload: diabetes, hypogonadism, hypoparathyroidism and hypothyroidism. Costs associated with iron chelation and treatment of the listed complications were summed over patients' lifetimes, and utility weights applied to the different health states to inform the estimation of QALYs. The main assumption was that each ICT was equally effective at lowering iron given equal levels of compliance to specified treatment regimens. The model was calibrated to identify sets of convergent input parameter values that best predicted observed data reporting overall survival by lifetime ICT compliance.**Results.** Average lifetime treatment costs for patients receiving DFO were £70,000 higher than DFX: DFX drug costs were £100,000 higher, but DFO equipment costs resulted in overall administration costs that were £170,000 higher. Higher compliance associated with oral DFX administration led to fewer complications. Combined with the quality-of-life effects of an oral mode of administration, an average gain of 4.85 QALYs for DFX was estimated. Thus, in the reference case, DFX dominates DFO, ie, DFX costs less and patients gain more QALYs. The key parameter is the proportion of DFO patients using balloon infusers (the more expensive method - annual cost £13,000 vs £1,400 for pump-based infusion). Sensitivity analyses showed that even when the proportion of patients using balloon infusers is decreased from 79% to 25%, the incremental cost per QALY gained remains well under £20,000. **Summary and Conclusions.** Higher drug costs for DFX are offset by the avoidance of infusion-related equipment costs. Combined with health benefits derived from an oral mode of administration and improved compliance, DFX has a high probability of being an extremely cost-effective intervention compared to DFO.

QUALITY OF LIFE OF CHILDREN WITH SICKLE CELL ANAEMIA: ASSESSING SELF-, PARENT AND HEALTHCARE PROFESSIONAL REPORTS

P Inusa[1], C Constantinou[2], N Payne[2]
[1]Guy's and St Thomas NHS Foundation Trust, London, United Kingdom
[2]Middlesex University, London, United Kingdom, London, United Kingdom

Background. Sickle Cell Anaemia (SCA) would be expected to adversely affect the Quality of Life (QoL) of children. There has been extensive research in the QoL of children with SCA; however, the majority of research uses the Paediatric Quality of Life Questionnaire (PedsQL). There have been some inconsistencies with prevalent paediatric QoL measures such as the PedsQL. Furthermore, there have also been reservations with regards to the theory, method and development of current paediatric QoL psychological measures. Therefore, innovative discrepancy measures such as the Generic Children's Quality of Life Measure (GCQ) should be validated using multiple informants such as children with SCA and also adult proxy-reports. Adult proxy-reports may be used when some groups of children with SCA are unable to provide useful QoL self-reports because of age, physically illness, emotionally distressed or too fatigued. **Aims.** The primary objective was to determine whether there was a relationship between the QoL of paediatric patients measured by children with SCA, their parents or carers and healthcare professionals. Secondary objectives were to examine the extent to which demographic indicators and measures of symptom severity predicted child self-reported, parent proxy-reported and healthcare proxy-reported QoL. Moreover, to ascertain whether there was a difference between the QoL of children with SCA compared to their healthy peers. **Methods.** The study adopted an inter-dependent groups, correlational design using a cross-sectional questionnaire, the GCQ. There was a convenience sample of three groups of participants attending a London hospital; chil-

dren with SCA (n = 74) aged between six to sixteen years old (M = 10.61, SD = 3.10), their parents or carers (n = 74) and four members of the healthcare team (n = 74). The three independent groups completed the GCQ as if they were the child. **Results.** Parents or carers and healthcare professionals were able to gauge the QoL of children with SCA. Additionally, child self-reports were not affected by demographic indicators or measures of symptom severity. However, in multivariate analyses, parents or carers who were single reported a lower proxy QoL compared to those who were married or in a relationship, and high parent proxy-reports were also associated with some high stroke risk measurements (Transcranial Doppler examinations) in univariate analyses. Also, higher healthcare proxy-reported QoL were related to fewer days missed from school due to SCA, as well as to less number of crises in univariate analyses. Finally, a comparison between children with SCA and the general child population showed no difference in QoL. **Conclusions.** Adult proxy-reports are valid and may be utilised when children with SCA are unable to provide valuable QoL self-reports. Moreover, parents or carers and healthcare professionals often choose their child's treatment and care in paediatric SCA populations. Their choices are based on an accurate assessment of child's needs. Further research should examine other variables that may affect the QoL of children with SCA such as psychological factors. However, it seems as though children with SCA have adapted to their condition. Moreover, contrary to previous evidence, it appears as though SCA does not impair their QoL.

Table 1. Measures of symptom severity included the total number of crises, days missed from school due to SCA, A&E admissions, or attendance (via parent report and hospital records) and stroke risk measure (TCD).

	Child-self reported QoL	Parent proxy-reported QoL	Healthcare proxy-reported QoL
Total number of crises	-.19	.14	-.36**
Days missed from school due to SCA	-.16	.06	-.40**
A&E admissions, or attendance (parent report)	-.17	.07	-.24
A&E admissions, or attendance (hospital records)	-.14	-.15	-.09
Right ICA	.07	.13	-.04
Left ICA	.07	.26*	-.03

HAEMOGLOBINOPATHY PATIENT ACCESS TO MODERN COMMUNICATION TECHNOLOGY: THE FEASIBILITY OF ALTERNATIVE COMMUNICATION STRATEGIES TO MANAGE CLINIC APPOINTMENTS

F Nawaz, A Gilmore, S Naorose-Abidi, G Cho
Central Middlesex Hospital London, London, United Kingdom

Background. Attendance at our Haemoglobinopathy outpatient clinics often falls to less than 70%, leading to inefficient use of staff time and resources and hindering optimal care. It reduces hospital income, making services less financially viable. Some patients misplace their hospital correspondence or forget appointments because of the 6-12 months between routine visits. **Aims.** In an attempt to improve attendance rates, thereby optimising the use of hospital resources and improving patient care, we explored patient access to electronic modes of communication. **Methods.** We collected data from 51 patients attending Adult Haemoglobinopathy clinics at Central Middlesex Hospital (London,England) between August 2011 and January 2012 (approximately 20% of our patient cohort). Patients were asked about mobile phone ownership, phone access to the Internet, access to a personal computer (P.C), and whether the P.C had Internet access. **Results.** Of these 51 patients, 73% had Sickle Cell Disease, with the remaining 27% having Thalassaemia.28/51 patients (54.9%) were male. The mean age was 39 years, the highest age being 72 years and the lowest being 18 years. 28 patients (54.9%) were in the 31-50 age group.All 51 patients owned mobile phones and 39 (76.5%) had Internet access on their phone. 47/51 patients (92.1%) had access to a P.C and 45/51 (88.2%) had Internet access on these computers.48/51 patients (94.1%) were able to access the Internet in some form. Of those patients who had Internet access on their phones, 87.2% had smartphones with applications. **Summary and Conclusions.** This survey illustrates:1. Ubiquitous access to mobile phones. Hospital communication by phone calls or text messaging would reach almost everyone.2. High levels of access to the Internet (94.1%), allowing communication options such as reminder emails or a dedicated website for patients to manage appointments. The hospital could offer vacated appointments to others, leading to improved use of resources.76.5% had phone Internet, allowing convenient checking of emails (perhaps in preference to using the P.C). A minority of patients (5.9%) had no Internet access at all, meaning our current method of clinic notification (sending letters) may still be required.3. The high level of smartphone ownership. Phone applications ("apps") are another potential form of communication. However, such an app would need to work across different platforms (with cost implications) given that patients own phones from several manufacturers.Using technology such as smartphones and the Internet could be an efficient alternative to printed letters to manage clinic appointments. This survey has demonstrated the widespread, but not universal, access to such technologies within our patient group. Using a range of communication channels may be the best strategy. Possible benefits include improved resource management, optimisation of patient care, empowering patients to manage their healthcare and reducing the use of paper; in accordance with the QIPP (Quality, Innovation, Productivity and Prevention) agenda and their vision of a "paperlight"health service.(QIPP is a UK National Health Service initiative seeking to improve quality of care whilst making efficiency savings to be invested in frontline care).

CHARACTERIZATION OF THE SEC23B PROMOTER: IMPLICATIONS FOR THE DIAGNOSIS OF CDA II

R Russo, I Andolfo, A Gambale, R Asci, MR Esposito, C Langella, A Iolascon
CEINGE - Biotecnologie Avanzate, Naples, Italy

Background. *SEC23B* gene is distributed on 53.86 kb of the chromosome 20p11.23. Multiple alternatively spliced transcript variants encoding the same protein (767 aa) have been found for this gene. The SEC23B encoded protein has similarity (66.4%) to yeast Sec23p component of the coat protein complex (COP)II, involved in the anterograde protein trafficking from the endoplasmic reticulum to the Golgi apparatus. Mutations in the *SEC23B* gene cause the vast majority of the cases of Congenital Dyserythropoietic Anemia type II (CDA II), an autosomal recessive disorder characterized by ineffective erythropoiesis, with a reticulocytosis not corresponding to the degree of anemia. To date, more than 50 different causative mutations have been described, localized along the entire coding sequence of the gene (Iolascon, 2011; Russo, 2011; Punzo, 2011). The vast majority of patients had two mutations (in the homozygous or compound heterozygous state), in accordance with the pattern of autosomal recessive inheritance. However, in our cohort approximately the 10% of cases showed only one coding/splicing mutation in heterozygous state. So, we postulate the occurrence of another allelic mutation in the regulatory regions of the gene. **Aims.** To identify and characterize the minimal promoter region of *SEC23B* gene. **Methods.** In order to identify the minimal promoter region of *SEC23B* gene, we established deletion mutants: a 3500 bp upstream region of the gene has been divided into 10 overlapping fragments, amplified from genomic DNA. Each deletion mutant construct has been cloned upstream the luciferase gene into PGL3 vector in the HindIII and XhoI sites. A prediction analysis of transcription factor binding site (TFBS) has been performed by bioinformatic tool MatInspector, from Genomatix web server. Thirteen CDA II independent cases from the International Registry were enrolled for the mutational analysis of the *SEC23B* promoter.Results. By luciferase assay of the deletion mutants we identified the minimal promoter region of the *SEC23B* gene. *In silico* analysis of *SEC23B* upstream region showed the presence of putative binding sites of the main transcription factors involved in the erythroid differentiation, such as GATA1 and KLF1. Finally, we performed a sequencing analysis of *SEC23B* regulatory regions in 13 CDA II independent cases from the International Registry. We found only one patient with an heterozygous mutation in 5'UTR of the gene, which could impair a potential TFBS.Summary/conclusions. Promoter analysis is an essential step on the way to identify regulatory networks. Here, we characterized the minimal active transcriptional region of the *SEC23B* gene. We also predicted the putative GATA1 and KLF1 binding sites: both are involved in peculiar type of inherited dyserythropoietic anemias. The effective binding of these TFBS to *SEC23B* promoter region will be proven by chromatin immuno-precipitation (ChIP) assay, in erythroid cellular models induced to erythroid differentiation. The identification of TFBS could allow the definitive diagnosis of CDA II patients with peculiar clinical phenotypes or those with incomplete pattern of mutations in *SEC23B* coding region.

GLUCOCORTICOID RECEPTOR SELECTIVELY MEDIATES THE EXPANSION OF ERYTHROID PROGENITOR CELLS DURING CHRONIC RESTRAINT STRESS

S Vignjevic, M Budec, D Djikic, G Jovcic, D Markovic, O Mitrovic, M Diklic, T Brekovic, V Cokic
University of Belgrade, Institute for Medical Research, Belgrade, Serbia

Background. The stress-induced erythropoiesis is critical for survival and recovery during various pathophysiological conditions, and its inappropriate activation may predispose to leukemic transformation. The spleen provides a special microenvironment favorable for rapid expansion of erythroid progenitors in response to stressful stimuli. Stress erythropoiesis has been studied primarily in murine models of anemia, but the erythropoietic effects of chronic restraint, that is both physical and psychological stressor, remain largely unknown. Furthermore, the target cell and the physiological effects of glucocorticoids in stress-induced erythropoiesis have been elusive. **Aims.** The purpose of the present study was to investigate the effects of chronic restraint stress on committed erythroid progenitor cells in mouse spleen and to examine the role of glucocorticoid receptor (GR) in restraint-induced changes. **Methods.** Adult male CBA mice were subjected to 2 h daily restraint stress for 7 or 14 consecutive days, and changes within erythroid progenitor cells were analysed in the spleen. The role of GR was assessed by pretreatment of mice with GR antagonist mifepristone (RU486) dissolved in DMSO. To this end, the mice were randomly assigned to five weight-matched groups: 1) R-restraint group exposed to 2 h daily restraint stress during 7 consecutive days; 2) RU486+R group, treated with mifepristone (50 mg/kg) 60 min prior to daily restraint; 3) RU486 group, received only the daily dose of mifepristone; 4) DMSO+R, vehicle injected restraint group; and 5) control group, simply handled daily. *Results.* Chronic exposure to 2 h daily restraint stress resulted in markedly increased number of erythroid progenitors in mouse spleen. Compared to untreated control, there was a significant increase in both early and late committed erythroid progenitors, the erythroid burst (BFU-E) and colony forming (CFU-E) units, after 7 and 14 days of restraint stress. In addition, plasma erythropoietin (Epo) levels were significantly elevated in chronically stressed animals. Pretreatment with RU486 completely abolished the stimulatory effect of chronic restraint stress on CFU-E formation in mouse spleen. In contrast, blockade of GR had no influence on restraint-induced stimulation of BFU-E growth. **Conclusions.** These findings indicate that GR is required for increased expansion of splenic Epo-dependent CFU-E progenitors during chronic restraint stress, suggesting the involvement of GR/Epo-receptor crosstalk mechanism in stress-induced erythropoietic response.

HEREDITARY SPHEROCYTOSIS WITH NORMAL RED CELL SPECTRIN AND REDUCED EMA BINDING IS PREDOMINANTLY CAUSED BY MUTATIONS IN BAND 3

R van Zwieten[1], J François[2], K Leeuwen[3], A van Wesel[2], P Bianchi[4], W van Sollinge[2], R van Bruggen[3], D Roos[3], A Verhoeven[5], R van Wijk[2]
[1], Dept of Blood Cell Research, Sanquin Blood Supply Foundation, Amsterdam, Netherlands
[2]Lab. for Red Blood Cell Research, Dept of Clinical Chemistry and Haematology, Utrecht, Netherlands
[3]Dept of Blood Cell Research, Sanquin Blood Supply Foundation, Amsterdam, Netherlands
[4]University Medical Center, Hematology 2 Unit,Cà Granda Ospedale Maggiore, Milan, Italy
[5]Dept of Medical Biochemistry, Academic Medical Centre University of Amsterdam, Amsterdam, Netherlands

Background. Hereditary spherocytosis (HS), one of the major red blood cell (RBC) membrane disorders, has heterogenic molecular causes but is in general characterized by low binding of eosino-5'-maleimide (EMA) to the outer surface and decreased osmotic resistance (OR) of the cells. Because RBC spectrin, a main cytoskeletal protein, is often decreased as a primary or secondary cause of disease, we investigated its presence in relation to EMA binding.**Aims.** EMA binds predominantly to band 3 and because all HS patients show low EMA binding, we were interested in the incidence of band 3 mutations being the primary cause of HS in subgroups of patients with and without spectrin deficiency. **Methods.** We examined 677 patients suspected for RBC membrane disorders by RBC morphology, osmotic resistance, EMA binding and spectrin content. Diagnosis of hereditairy spherocytosis (HS) was based on low EMA binding accompanied by the presence of spherocytes and/or low OR. Two groups of HS patients, with and without spectrin deficiency, were screened for mutations in *SLC4A1*, the gene encoding band 3, and for band 3 content.*Results.* A majority of HS patients showed low spectrin levels and reduced EMA binding. Quantification of RBC spectrin, binding of eosino-5'-maleimide (EMA) to the RBC surface, and measurement of the OR revealed a subgroup (36%) of spherocytosis patients with low EMA-binding but without spectrin deficiency. In this subgroup, HS was caused mainly (60%) by mutations in *SLC4A1*. Twenty-four different mutations associated with low levels of band 3 protein were detected, the majority of which were novel. In HS patients without spectrin deficiency the band 3 levels were not significantly decreased, and only 11% carried a mutation in *SLC4A1.* Detected mutations were correlated to band 3 protein levels by Western blotting. The overall incidence for *SLC4A1* mutations in patients with HS is 30%.**Conclusions.** Our results reveal the discriminative value of measuring both spectrin content and EMA binding for the identification of HS due to aberrant band 3. This enables a subdivision of HS. We conclude that aberrant band 3 can cause spherocytosis without affecting red cell spectrin levels, whereas the decreased EMA binding seen in HS patients with decreased spectrin content is likely caused by cytoskeletal rearrangements.

0942

CONSEQUENCES OF DMT1 MUTATION ON ERYTHROPOIESIS

M Horvathova[1], Z Zidova[2], K Kapralova[2], D Dolezal[2], D Pospisilova[3], V Divoky[3]
[1]Faculty of Medicine, Palacky University, Olomouc, Czech Republic
[2]Faculty of Medicine and Dentistry Palacky University, Olomouc, Czech Republic
[3]Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic

Background. Deficiency of the divalent metal transporter 1 (DMT1) leads to the development of hypochromic microcytic anemia associated with ineffective erythropoiesis. In contrast to *mk/mk* mice (strain MK/ReJ), a mouse model with DMT1 mutation, majority of DMT1-mutant patients presented with hypersideremia and hepatic iron overload. **Aims.** The aim of this study was to characterize erythropoiesis in *mk/mk* mice propagated on novel 129S6/SvEvTac background. (Gunshin et al, J Clin Invest 2005;115(5):1258-66; provided by Dr. Fleming, Boston). **Methods.** The iron status parameters and tissue non-heme iron content in 129S6/SvEvTac- *mk/mk* mice were evaluated. Colony forming assays were used to analyze the *in vitro* growth of DMT1- mutant erythroid progenitors. Differentiation of erythroid precursors was assessed by flow cytometry analysis. The extent of apoptosis of erythroid precursors and erythrocytes was determined by analysis of Annexin V binding. The expression of key factors of the bone marrow-hepcidin axis was evaluated.Results. The 129S6/SvEvTac-*mk/mk* mice showed significantly increased plasma iron levels when compared to wild-type littermates (48.6±11.7 μM/L *vs.* 33.7±3.7 μM/L) but reduced non-heme iron content in the spleen (49.9±11.9 μg/g *vs.* 535.8±125.4 μg/g) and liver (14.2±3.3 μg/g *vs.* 67.3±18.6 μg/g). Colony forming assay revealed abnormal morphology of *mk/mk* erythroid colonies, reduced number of *mk/mk* CFU-E (164±25 *vs.* 283±50) and BFU-E (9±4 *vs*. 22±5) colonies, and twofold reduction in cellularity of *mk/mk* BFU-Es in comparison to colonies of wild-type mice. Flow cytometry analysis of viable Ter119/CD71 double-stained cells showed that immature erythroblasts predominate in the bone marrow and spleen of *mk/mk* mice when compared to wild-type mice; the difference is more profound in the spleen, reflecting the dramatic expansion of splenic erythropoiesis in *mk/mk* mice. The *in vivo* apoptotic rate of Ter119+ erythroblasts in the bone marrow and spleen was 4.4-fold and 6.6-fold higher in *mk/mk* mice than in the wild-type littermates. A markedly increased susceptibility of *mk/mk* erythrocytes to undergo apoptosis after exposure to stress conditions *in vitro* was observed when compared to wild-type erythrocytes. Low to undetectable expression of hepcidin in *mk/mk* liver correlated with increased expression of growth differentiation factor 15 (GDF15) in the bone marrow and spleen.Conclusions: The phenotype of iron restricted erythropoiesis in spite of increased plasma iron present in 129S6/SvEvTac-*mk/mk* mice is reminiscent of that of DMT1-mutant patients but differs from originally described *mk/mk* mice strain MK/ReJ. In this regard, 129S6/SvEvTac-*mk/mk* mice seem to be more accurate model for comparison with patients' samples. The lack of tissue iron deposits in 129S6/SvEvTac-*mk/mk* is in contrast to hepatic iron overload of DMT1-mutant patients and likely reflects increased intestinal iron (heme or non-heme) absorption and redistribution of iron from erythroid tissues to the liver in the human subjects. Our results also show that impaired DMT1 function negatively affects all stages in the erythroid lineage.Grant support:Czech GrantAgency, grants No. P305/10/P210 and P305/11/1745; Internal Grant of PalackyUniversityOlomouc(LF_2012_016).

SHORTER CAROTID ARTERY OCCLUSION TIME IN A THALASSEMIC MOUSE MODEL: A POTENTIAL ROLE FOR OXIDATIVE STRESS AFFECTING BOTH RBC AND PLATELETS

E Rachmilewitz[1], Z Malyutin[2], E Shai[2], D Mutaz[2], E Fibach[2], D Varon[2]
[1]Edith Wolfson Medical Center, Holon, Israel
[2]Hadassah Ein Kerem, Jerusalem, Israel

Background. Beta-thalassemia is a common hereditary hemolytic anemia which is due to mutations in the alpha or beta-globin genes, resulting in partial or complete synthesis of HbA. Increased life expectancy due to improved therapy resulted in the appearance of complications in adult patients which were not recognized earlier due to hypercoagulable state. Among them were deep venous thrombosis pulmonary embolism as well as arterial thrombosis and stroke. **Aims.** Recently, we reported an increased platelet adhesion in patients with β thalassemia intermedia (Thromb Haemost. 2008 Nov;100(5):864-70) which may contribute to their thrombophilic state. The present study was carried out to elucidate the effect of thalassemic blood cells on the development of arterial thrombosis in carotid arteries in thalassemic mice. **Methods.** We used a model of transgenic heterozygous thalassemic mice (C57B1/6 Th3/+ , obtained from S. Rivella, Weill Medical College, NY,), that have targeted mutations in both murine beta globin genes (major and minor) on one chromosome. The mice exhibited enlarged spleens with average weight of 420 mg compared to 130 mg in the controls, associated with anemia and aberrant RBC morphology comparable with that found in patients with beta-thalassemia intermedia. Platelet counts were normal. There mice and their wild-type littermates were subjected to photochemical injury, and blood flow was monitored. **Results** :Mean time to occlusive thrombus formation of the carotid arteries in wild-type mice was 64.6±8 minutes compared with 49.1±9 minutes in thalassemic mice (n=10 per group; P<0.05). Flow cytometry measurement of oxidative stress markers revealed higher reactive oxygen species generation (mean fluorescence index (MFI) of 315 vs. 193 in controls, lower content of reduced glutathione (MFI of 34 vs. 128 in controls) and higher expression of phosphatidylserine (10.2% vs 7.6%), known to be associated with platelet activation, in platelets of thalassemic mice compared to wild type mice. Comparable results were obtained with RBC. These differences were unaffected by the application of either the photosensitizer or the laser beam in the injury model. Aspirin treatment (100mg/kg) delayed the time to occlusion in thalassemic mice, bringing it to a value close to wild type mice (57.8±8 minutes).**Conclusion**: The present study contributes to the identification of mechanisms and consequences of RBC pathology and platelet hyper- reactivity in thalassemic mice associated with increased parameters of oxidative stress. It is suggested that anti-platelet aggregants as well as anti-oxidants could be used for prevention of thrombosis in patients with β thalassemia intermedia.

REFERENCE INTERVALS FOR HEMOGLOBIN IN SUBJECTIVELY HEALTHY ELDERLY INDIVIDUALS - HOW VALID ARE THE WHO CUT-OFFS? INSIGHTS FROM THE WWW.SENIORLABOR.CH STUDY

U Nydegger, P Medina Escobar, M Risch, L Risch
Labormedizinisches zentrum Dr. Risch, Liebefeld bei Bern, Switzerland

Background. Anemia is a frequently encountered disorder in the elderly. The defining cut-offs are provided by the WHO and are 120 g/L for women and 130 g/L for men. Although older age is associated with lower hemoglobin levels, these cut-offs do not account for age. **Aims.** To characterize reference intervals in subjectively healthy individuals and to gain insights on factors being associated with hemoglobin levels. **Methods.** TheSeniorlabor study has so far recruited over 1600 subjectively healthy Caucasian inhabitants>60 yrs of age.Venous blood samples were drawn after an overnight fasting period. Hemoglobin was assessed using an XE-5000 hematology analyzer (Sysmex-Digitana, Switzerland). Reference intervals were assessed according to the CLSI-guideline C28-A3.*Results.* Here we report on the results from 557 men and 722 women. Men had significantly higher median hemoglobin levels than women(149 vs. 137 g/L; p<0.001), and there was a significant Spearman rank correlation between age and hemoglobin level (r=-0.113; p<0.001). Thus reference ranges were stratified according to age and gender. Double-sided 95% reference intervals for men were: 129-168 g/L (age 60-69), 125 - 168 g/L (age 70-79), 118-169 g/L (age >80). The respective reference intervals for females were: 120-157 g/L (age 60-69), 116 - 156 g/L (age 70-79), 115-164 g/L (age >80). A linear regression model incorporatingage, female gender, testosterone,ferritin, CRP, low ALAT, cholinesterase, and total bilirubin as significant predictors (all p<0.01) of hemoglobin concentrations accounted for 37.4% of hemoglobin concentration variance. Interestingly, in this model , we could not observe a significant association between hemoglobin and kidney function (CKD-EPI eGFR), folate concentrations, Holo-Transcobalamin concentrations, and fT4 concentrations.**Conclusions.** With progressive age, there is a considerable decline of the lower limits of hemoglobin concentrations., which is more pronounced in men than in women and seems to converge above age 80. In both sexes, the upper limit remains more or less constant over the whole age range. The WHO cut-offs seem to be valid at age 60, but tend to get too restrictive at older age. This may cause overdiagnosis of anemia, and consequently, may perturbate an elderly persons wellbeing and lead to unnecessary and costly follow-up investigations.

CREB1 IS REQUIRED FOR HYDROXYUREA-MEDIATED INDUCTION OFGAMMA-GLOBIN EXPRESSION IN K562 CELLS

M Banan[1], E Esmaeilzadeh[1], M Nezami[1], Z Deilami[2]
[1]University of Social Welfare and Rehabilitation Sciences, Tehran, Iran
[2]Azad University, Zanjan, Iran

Background. Hydroxyurea (HU) is a drug used for the treatment of hemoglobinopathies. HU functions by up-regulating γ-globin transcription and fetal

hemoglobin (HbF) production in erythroid cells. The K562 erythroleukemia cell line is widely used as a model system to study the mechanism of γ-globin induction by HU. However, transcription factors required for the up-regulation of γ-globin expression by HU in K562 cells have not been identified. Similarities between the HU and sodium butyrate (SB) pathways suggested CREB1 as a potential candidate. **Aims.** The aim of this study was to investigate the possible role of CREB1 in the HU / γ-globin induction pathway in K562 cells. **Methods.** We performed transient and stable RNAi experiments to show that CREB1 is necessary for HU-mediated induction of γ-globin expression and hemoglobin production in K562 cells. Furthermore, Western blot analyses demonstrated that CREB1 becomes phosphorylated in a dose-dependent manner after HU treatment of K562 cells. We also investigated role of a Gγ promoter CREB1 response element (G-CRE) in this pathway. First, quantitative ARMS-PCR (Amplification Refractory Mutation System) experiments were performed to demonstrate that HU induces both Gγ and Aγ expression in this cell line. In addition, electrophoretic mobility shift assays (EMSAs) were used to show that levels of CREB1 complexes binding to the G-CRE site are increased upon HU treatment and are decreased in the CREB1 knockdown cells. Conclusions. Our results suggest that CREB1 is necessary for γ-globin induction by HU in K562 cells"'a role which may, in part, be mediated through the G-CRE element.

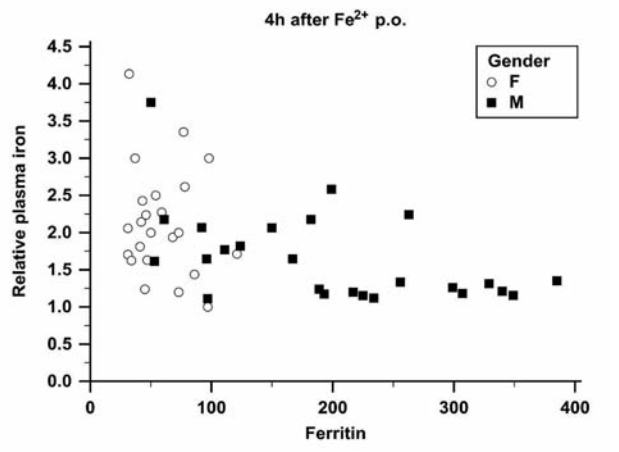
REFERENCE VALUES FOR ORAL IRON ABSORPTION OF BIVALENT IRON IN HEALTHY VOLUNTEERS

A Rüfer[1], K Klöpfer[2], P Schmid[2], W Wuillemin[2]
[1]Division of Haematology, Luzern, Switzerland
[2]Luzerner Kantonsspital, Luzern, Switzerland

Background. Iron deficiency anaemia is the most frequent cause of anaemia in the western world. Despite progress in diagnosis and treatment there is a challenge in establishing the cause of iron deficiency in the absence of obvious reasons such as blood loss or deficient dietary intake. There are no prospectively validated iron absorption tests that could confidentially confirm or exclude iron malabsorption. **Aims**. To establish an oral iron absorption test and to define reference values of plasma iron in healthy volunteers after oral iron intake. **Methods.** Healthy volunteers were included into this study that was approved by ethics committee. Relevant comorbidities (inflammation, preexisting malabsorption or liver disease) were excluded by medical history and laboratory tests (haematogram, ferritin, CRP, ASAT). Each of the 49 volunteers received 200 mg of the bivalent ferrous fumarate in fasting condition at 8 AM after blood samples were drawn for plasma iron, ferritin, soluble transferrin receptor, haemoglobin, reticulocytes and reticulocyte haemoglobin. Two and 4 hours later as well as on days 3 and 5 plasma iron, haemoglobin, reticulocytes and reticulocyte-haemoglobin were measured, all of those in fasting condition. After a wash-out phase of two weeks 23 healthy volunteers proceeded to receive trivalent iron hydroxide polymaltose and 11 healthy volunteers did not receive any iron. In these latter two groups the identical laboratory analyses were performed as described above. Data are shown as mean ± standard deviation. Two sided t-test was used for comparison.



Results. Forty-nine healthy volunteers (24 females, 25 males; age 36±10 years) were studied. Haemoglobin was 136±7 g/L in females and 157±8 g/L in males; ferritin was lower in females (59±24 µg/L) compared to males (199±99 µg/L; p<0.0001); and fasting plasma iron was 17±4 µmol/L in females and 21±7 µmol/L in males. Plasma iron increased to 27±7 µmol/L in females and 28±9 µmol/L in males after 2 hours and to 34±12 µmol/L in females and 32±11 µmol/L in males after 4 hours (both p<0.0001 compared to iron values prior iron ingestion). All other parameters did not change relevantly. Relative increase of plasma iron after 4 h was higher in females (2.1±0.7) compared to males (1.7±0.6; p=0.02). While a negative correlation between ferritin and relative iron increase could be detected in males (r= -0.51, p=0.008), females had lower ferritin values in general and a wider variation of iron increase (see Figure). On days 3 and 5, we found values for all tested parameters comparable to initial values. There was no relevant increase of plasma iron after ingestion of trivalent iron in fasting condition or in volunteers not receiving iron. **Conclusions**. Reference values of absolute and relative iron increase after oral iron ingestion could be established. There was a significant increase of plasma iron after bivalent iron intake within 4 hours after ingestion. Relative iron increase correlates to iron storage. Females had in general lower ferritin levels and thus higher increase of plasma iron. These results lead the way to a prospective validation of an oral iron absorption test using bivalent iron among patients.

ASSOCIATION OF CD40L IN PLATELET-MEDIATED INFLAMMATION IN SICKLE CELL DISEASE

V Tonin Garrido[1], V Dominical[1], F Marconi Roversi[1], R Proença-Ferreira[1], M Cavalcanti Bezerra[2], A Araújo[3], F Ferreira Costa[1], N Conran[1]
[1]University of Campinas, Campinas, Brazil
[2]Centre for Biological Sciences, Federal University of Pernambuco, Recife, Brazil
[3]Hematology and Hemotherapy Foundation of Pernambuco (HEMOPE), Recife, Brazil

Background. The interaction between inflammatory cytokines, activated blood cells and endothelial cells is a critical step in vaso-occlusive processes in sickle cell disease (SCD), leading to vascular dysfunction, inflammation and additional recruitment of inflammatory cells to the vessel wall. It is now recognized that platelets (PLTs) modulate immuno-inflammatory reactions through cytokine secretion and subsequent interaction with leukocytes and endothelium. Platelet-associated CD40 ligand (CD40L), when bound to the CD40 receptor, plays an important role in this inflammatory response between platelets and other cells. **Aims.** Since the involvement of platelets in the vaso-occlusive process is not well understood, we hypothesized that CD40L may contribute to platelet-mediated inflammatory responses in SCD. This study evaluated the production of platelet-derived CD40L and the expression of its receptor on platelets and neutrophils of SCD individuals. **Methods.** IL-8, soluble ICAM-1, VCAM-1 and CD40L (sCD40L) were determined in PLT-free plasma/supernatant of stimulated (ADP or Collagen) and unstimulated PLTs ($2x10^8$/ml in Kreb's buffer) from healthy individuals (CON) and SCD patients by ELISA. Quantitative Real Time PCR was performed to analyze the CD40 gene expression in neutrophils from the peripheral blood of SCD and CON individuals. The expression of CD40 and P-selectin, and PAC-1 binding (anti-activated αIIbß3 integrin) on the PLT surface was determined by flow cytometry. **Results.** sCD40L was elevated in the plasma of SCD individuals (724.4±55.7pg/ml; n=90), compared to CON (241.5±34.6pg/ml, P<0.0001; n=41). Plasma sCD40L presented correlation with PLT counts in SCD individuals (r_s=0.255, P=0.015). No correlation was found between plasma sCD40L and IL-8, ICAM-1 or VCAM-1. PLT sCD40L release from SCD and CON (90min, 37ºC, 5% CO_2) were evaluated and PLTs of SCD patients released higher amount of CD40L (8347.0±1464.0pg/10^8 PLTs; n=10) than PLTs of CON individuals (3652.0±568.3pg/10^8 PLTs; n=5, P=0.019). sCD40L release from SCD PLT was augmented by incubation with collagen (P<0.001), but not ADP, indicating that collagen stimulation may be an important activator of CD40L release from platelets in SCD. Expression of CD40 receptor on the platelet surface was elevated in the SCD group, compared to the CON, and this expression presented a correlation with PAC-1 (r_s=0.498, P=0.018), a marker of PLT activation. Gene expression of CD40 protein (0.021±0.003U.A., n=14), was increased in SCD neutrophils, compared to CON (0.007±0.002U.A., n=9; P=0.005). **Conclusions.** The pro-inflammatory protein CD40L is elevated in the plasma of SCD patients and its release from SCD PLTs is higher when compared to CON PLTs. Several studies have reported that CD40L is a potent inductor of adhesion molecules and pro-inflammatory cytokines in endothelial cells and leukocytes, however no correlation was found between plasma levels of CD40L, IL-8, ICAM-1 and VCAM-1. We found an increase of CD40 expression in SCD PLT and this expression was correlated with PLT activation. Interestingly, the expressions of both CD40/CD40L on platelets could allow crosstalk between platelets, vascular cells and leucocytes. Gene expression of CD40 was also increased in SCD neutrophils, suggesting a possible participation of platelet-derived cytokines in activation of these cells. These results suggest that CD40L may play an important role in platelet-mediated inflammatory responses in SCD.

GROWTH DIFFERENTIATION FACTOR 15 EXPRESSION AND REGULATION DURING ERYTHROID DIFFERENTIATION IN NON-TRANSFUSION DEPENDENT THALASSEMIA SYNDROMES

L Ronzoni, L Sonzogni, L Duca, A Colancecco, G Graziadei, K Musallam, MD Cappellini
Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy

Background. Growth differentiation factor 15 (GDF-15), a cytokine member of the TGF-beta superfamily that is released by mature erythroblasts, was shown to regulate hepatic expression and release of the iron regulatory protein hepcidin probably in response to increased iron demand from the bone marrow. However, the exact mechanisms regulating GDF-15 expression remain unknown. GDF-15 serum levels in non-transfusion dependent thalassemia (NTDT) patients are considerably elevated; however, little is known about its expression and regulation during thalassemic erythropoiesis. NTDT represents an ideal model to study thalassemic erythropoiesis and its relationship with iron metabolism. **Aims.** To determine the GDF-15 expression and regulation during normal and thalassemic erythroid differentiation in vitro. **Methods.** After informed consent, $CD34^+$ cells were obtained from peripheral blood of healthy volunteers (control group) and NTDT patients and cultured for 14 days with a medium stimulating erythroid differentiation. GDF-15 expression was evaluated at day 0 (erythroid progenitors), 7 (proerythroblasts) and 14 (mature erythroblasts) of culture by real-time PCR (2^-dCt). GDF-15 levels in culture supernatants were evaluated by ELISA assay (R&D Systems, Minneapolis, MN). Intracellular iron concentrations were estimated by colorimetric assay (BioVision, Milpitas, CA).

Table 1

	GDF-15 expression (2^-dCt)			GDF-15 levels (pg/mL)		Iron concentrations (µM)	
	Day 0	Day 7	Day 14	Day 7	Day 14	Day 7	Day 14
Control	0,005 ± 0,004	0,04 ± 0,03	5,66 ± 2,64*	198 ± 49	5595 ± 4245*	28 ± 2,8	9,5 ± 4,5*
NTDT	0,18 ± 0,04°	0,67 ± 0,66°	4,5 ± 3,6*	636 ± 415°	8427 ± 5136*	13,5 ± 3,6°	5,8 ± 3,4*

* day 14 vs day 7: p<0.05; * NTDT vs control: p<0.05

Results. GDF-15 expression and secretion increased significantly during erythroid differentiation (from day 7 to day 14 of cultures) both in control and NTDT cultures. However, GDF-15 levels at the early phase of differentiation (day 0 and day 7) were significantly higher in NTDT cultures compared to controls. Intracellular iron concentrations significantly decreased during erythropoiesis in both control and NTDT cultures; however, at day 7 iron levels were significantly lower in NTDT cultures compared with controls (Table 1).**Conclusions.** GDF-15 expression and levels in erythroid cultures are related to the erythropoietic stage of differentiation, being higher in mature erythroblasts. However, at the early phase of erythropoiesis, GDF-15 expression and secretion in NTDT cultures is higher than controls, reflecting the higher erythropoietic activity of thalassemic cells. There is an association between GDF-15 levels and intracellular iron concentrations, with lower concentration being associated with higher GDF-15 production. These findings suggest that GDF-15 can be considered a marker of erythropoietic activity and that intracellular iron concentrations could be a major contributor to GDF-15 regulation, although other factors, such as oxidative stress, can still be involved in this process.

EVALUATION OF FERRIC CARBOXYMALTOSE FOR REDUCTION OF DOXORUBICIN-INDUCED CARDIOTOXICITY IN IRON DEFICIENT SPONTANEOUSLY HYPERTENSIVE STROKE PRONE RATS

J Toblli, G Cao, J Giani, F Dominici, M Angerosa
Hospital Alemán and School of Pharmacy, University of Buenos Aires, Buenos Aires, Argentina

Background. Iron deficiency anemia (IDA) and hypertension are frequent complications and cardiac risk factors in patients with neoplasms and cytotoxic therapies. IDA can induce oxidative, nitrosative and inflammatory stress. Furthermore, previous studies demonstrated that IDA can aggravate doxorubicin (DOX)-induced cardiotoxicity in spontaneously hypertensive stroke prone (SHRSP) rats. **Aims.** This study evaluated whether ferric carboxymaltose (FCM) treatment can prevent IDA- and DOX-associated decrease of cardiac performance and induction of oxidative and nitrosative stress as well as inflammatory reactions in SHRSP rats. **Methods.** SHRSP rats were randomized into five groups (G1-G5; n=8 each). IDA was induced in groups G2-G5 by a 12-week low iron diet; G1 had normal diet (control). G3-G5 received DOX (4 mg/kg body weight/week) for 6 weeks. G4 and G5 received one dose of FCM (15 mg iron/kg body weight) either concomitantly with or 3 days after the second DOX administration. In G1-G3, active treatments not applicable to the group were replaced with saline solution. Fractional shortening (FS; difference between the end-systolic and end-diastolic dimension normalized by the end-diastolic dimension) was assessed by echocardiography before initiation of DOX treatment (baseline [BL]) and at the end of the study (EOS). Further analyses at the end of the study assessed hemoglobin (Hb) levels and transferrin saturation (TSAT) in blood samples and markers of oxidative, nitrosative and inflammatory stress (thiobarbituric acid reactive substances [TBARs], reduced/oxidized glutathione ratio [GSH/GSSG]; nitrotyrosine; tumor necrosis factor-alpha [TNF-α], interleukin-6 [IL-6]) in homogenates and tissue sections from heart samples.

Table	G1 control	G2 IDA	G3 IDA/DOX	G4 +FCM (c)	G5 +FCM (d)
Hb (g/dL)	17.2±0.7	11.0±0.3*	10.3±0.3†	15.6±0.4‡	15.5±0.6‡
TSAT (%)	41.3±2.2	20.0±3.2*	19.2±3.1*	36.2±2.0‡	36.4±2.1‡
FS (%, BL)	45.4±1.3	40.6±1.2*	41.0±0.9*	41.1±1.0*	41.3±1.1*
FS (%, EOS)	44.8±1.1	35.7±0.6*	32.2±1.0†	38.7±0.6‡	39.2±0.9‡
TBARs (nmol/mg)	1.8±0.2	2.5±0.2*	4.3±0.2†	2.9±0.1‡	2.7±0.2§
GSH/GSSG (ratio)	4.8±0.2	3.9±0.1*	2.4±0.2†	3.6±0.2‡	3.8±0.2§
Nitrotyrosine (%/area)	11.6±1.3	16.8±3.8*	29.1±3.4†	16.9±3.1§	16.1±2.2§
TNF-α (%/area)	11.9±1.1	15.0±1.5*	19.6±1.4†	14.2±1.2§	14.1±1.3§
IL-6 (%/area)	3.6±1.0	20.3±1.6*	28.4±2.5†	15.2±1.4‡	14.4±1.6‡

mean±SD, (c) concomitant with DOX, (d) delayed 3 days after DOX
*p<0.01 vs. G1; †p<0.01 vs. G1,G2; ‡p<0.01 vs. G1-G3; §p<0.01 vs. G1,G3

Results. Iron deficient rats treated with a single dose of FCM in addition to a 6-week DOX regimen (G4-G5) maintained significantly better cardiac performance (FS) compared to saline-treated iron deficient rats with or without DOX (G2, G3) (Table 1). In fact, FCM maintained FS close to baseline levels. Addition of FCM to the DOX treatment also lead to significantly less oxidative, nitrosative and inflammatory stress compared to saline-treated, DOX-exposed, iron deficient rats (G3), thus reducing the synergistic effects of IDA and DOX (G2 and G3 vs. G1). Notably, the treatment benefit was independent whether FCM was given together with DOX or 3 days afterwards. **Conclusions.** A single dose of FCM in the early phase of a 6-week DOX treatment schedule prevented cardiac dysfunction and alleviated DOX- and IDA-associated oxidative, nitrosative and inflammatory stress in the heart of SHRSP rats. Concomitant or delayed administration of FCM showed the same benefit in reduction of DOX-induced cardiotoxicity and evaluated stress parameters.

0950

DECREASED AQUAPORIN 1 (AQP1) EXPRESSION AND LOW SERUM OSMOLALITY IN HEREDITARY SPHEROCYTOSIS (HS)

R Crisp[1], L Solari[1], D Vittori[2], D Gammella[1], G Schvartzman[3], E García[1], C Rapetti[4], G Alfonso[1], H Donato[4]
[1]Hospital Nacional Profesor Alejandro Posadas, Buenos Aires, Argentina
[2]Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Buenos Aires, Argentina
[3]Consultorios de Hematología Infantil, Buenos Aires, Argentina
[4]Hospital del Niño de San Justo, San Justo, Buenos Aires, Argentina

Background. AQP1 is the membrane water channel responsible for fast changes of red cells volume as response to tonicity of medium. The red blood cell membrane is extensively remodeled during erythropoiesis, conditioning the expression of membrane proteins. Throughout the process of enucleation, proteins are distributed between the extruded nuclei and the remaining reticulocyte. As the aberrant distribution of proteins in HS generates deficiencies of proteins other than those codified by the mutated gen, we postulated that AQP1expression might be impaired in HS erythrocytes. Moreover, since AQP1 expression in the mature red cell is modulated by serum osmolality, we also measured serum osmolality of HS patients. **Aims**. To evaluate AQP1 expression and impact of serum osmolality on AQP1 expression in patients with HS **Methods.** AQP1 expression was evaluated through flow cytometry in 6 nor-

mal controls (NC), 1 autoimmune hemolytic anemia, 10 HS (2 mild, 3 moderate, 2 severe, and 3 splenectomized), and 3 silent carriers (SC). Fixed and permeabilized red cells were stained with rabbit anti-AQP1 antibody followed by FITC or Phycoerythrin conjugated anti-rabbit IgG. The number of AQP1 molecules per erythrocyte was cuantified. The effect of AQP1 inhibitors (Cl2Hg 0.1-40 □M and Cl2Cu 400 □M) was evaluated through water flow-based tests: osmotic fragility (OF) and hypertonic cryohemolysis (CH). Serum osmolality was measured using a pressure vapor osmometer in 20 NC and 13 HS (4 mild, 4 moderate, 2 severe, and 3 splenectomized). HS and SC individuals presented single or combined deficiencies of ankyrin, spectrin, protein 4.1, and protein 4.2 **Results.** AQP1 expression was decreased, compared to simultaneously performed NC, in all of the HS patients and SC. The decrease was greater as HS was more severe: significant correlation between AQP1 expression and hemoglobin level was found (rho Spearman: 0.6510; p; 0.0086). Negative correlationship between AQP1 expression and CH was observed (n=16; r2=-0,607; p:0,006). AQP1 inhibitors increased CH but did not modify OF. The CH increase induced by Hg++ showed a direct positive relationship with the level of AQP1 expression (n=4, r2= 0,916). Osmolality was significantly lower in HS patients compared to NC (270.5±1.58 vs. 275.9±1.50, respectively; p: 0.015) **Conclusions**. Decreased AQP1 expression reveals a deficiency common to all patients with HS, a disorder based on alterations of membrane proteins and cytoskeleton. It is likely that an abnormal AQP1 secretion occurs during the enucleation process. As reticulocytes of HS patients are immersed within plasma with lower osmolality than normal, the loss of AQP1 might be increased during the subsequent reticulocyte maturation process. We suggest that these two mechanisms could help to explain these observations. Results of assays with inhibitors suggest that AQP1 decrease influences processes involving water efflux rather than water influx. No study concerning these findings has been published in the literature up to date.

0951

RED BLOOD CELL PYRUVATE KINASE (PK) HYPERACTIVITY UNLINKED TO THE PKLR OR PKM2 GENE - PREDICTION OF A NOVEL ELEMENT REGULATING PKLR EXPRESSION

B van Oirschot, A van Wesel, W van Solinge, R van Wijk
University Medical Center Utrecht, Utrecht, Netherlands

Background. Red blood cell (RBC) pyruvate kinase (PK-R) is an important enzyme of RBC energy metabolism, yielding ATP in the final step of glycolysis. Hereditary deficiency of PK-R is a autosomal recessive disorder associated with chronic nonspherocytic hemolytic anemia. It is due to mutations in *PKLR*.PK hyperactivity is a very rare autosomal dominant abnormality of RBC metabolism associated with high ATP levels and mild erythrocytosis. In the few families examined the hyperactivity has been attributed to either persistent expression of the PK-M2 isozyme (Max-Audit et al. Blood 1980;56:902) or a Gly37Glu missense mutation in *PKLR* (Beutler et al. Hum Mutat 1997;9:282). **Aims.** To identify the nature and origin of a novel case of PK hyperactivity. **Methods.** *PKLR* analysis was performed by DNA sequence analysis and Multiplex Ligation-dependent Probe Amplification (MLPA). Enzymatic characterization of PK-R was performed by standard **Methods.** RBC PK expression was studied by western blot using antibodies against PK-L and PK-M2. PK-R antigen levels were determined by ELISA. **Results.** We identified PK hyperactivity (34.3 U/gHb; reference range: 6.1-12.3 U/gHb) in a 2-year-old female child who was also heterozygous for glucose-6-phosphate dehydrogenase (G6PD) deficiency. The mutant G6PD (G6PD Vanua Lava) was inherited from the child's mother whereas the child's father, paternal grandfather, paternal aunt and younger sister all showed elevated PK activity (range 20.5-30.4 U/gHb) in absence of reticulocytosis. The mother and paternal grandmother showed normal PK activity. All family members were clinically unaffected.DNA sequence analysis failed to detect any mutation in the coding region of *PKLR*, including splice sites, or 1000 bp of its upstream regulatory region. Furthermore, MLPA analysis showed no variations in *PKLR* copy number. In agreement with these results PK-R displayed no abnormal kinetic properties: K_m for phosphoenolpyruvate and ADP, as well as inhibition by ATP were all normal. Western blot analysis of PK-M2 expression showed very low but similar amounts of the fetal isozyme in all family members. PK-R expression, in contrast, was markedly elevated in all family members displaying PK hyperactivity. Further quantification of PK-R expression by ELISA demonstrated antigen levels that varied between 998-1601 arbitrary units (au)/gHb in affected individuals (mean: 1324 au/gHb), whereas the 494 and 789 au/gHb as detected in the 2 unaffected individuals was comparable to the normal range: 171-711 (mean 441) au/gHb. Hence, the 2-3 times elevated PK activity was accompanied by a concomittant increase in protein levels. **Summary and Conclusions.** We have identified a family with a novel type of inherited PK hyperactivity. The autosomal dominant abnormality was not due to an altered property of PK-R or persistent expression of the PK-M2 isozyme but, rather, was caused by isolated overexpression of the PK-R isozyme. We therefore postulate the existence of a novel, yet-unidentified, DNA region regulating *PKLR* gene expression. We expect that mutations of this region may be involved in patients with PK deficiency without mutations in *PKLR*. In addition, this region may represent one of the putative phenotypic modifiers involved in the highly variable expression of PK deficiency

0952

IRON BURDEN, LOW GRADE INFLAMMATION, ENDOTHELIAL DYSFUNCTION AND ANGIOGENESIS IN PATIENTS WITH THALASSEMIA INTERMEDIA

I Papassotiriou[1], A Kattamis[2]
[1]Aghia Sophia Children's Hospital, Athens, Greece
[2]Athens University Medical School, Athens, Greece

Background. Placental growth factor (PlGF) is a member of the VEGF family of angiogenic proteins which binds to its receptor, the fms-like tyrosine kinase receptor 1 (Flt-1 or VEGF-R1). These growth factors exert pleiotropic effects, potentially beneficial, such as the promotion of angiogenesis, and/or potentially harmful pro-inflammatory effects, such as the promotion of endothelial dysfunction and pulmonary hypertension. von Willebrand factor (vWF) has been proposed as a biomarker of endothelial damage/dysfunction because increased plasma levels have been found in inflammatory and atherosclerotic vascular diseases and is defined as a novel link between hemostasis and angiogenesis. **Patients and Methods.** Using peripheral biomarkers, we investigated whether alterations in inflammation, endothelial dysfunction and angiogenesis relate to iron overload in patients with thalassemia intermedia (TI). Thirty-four adult patients with TI were included in the study, while 20 healthy individuals served as controls. We measured by means of immunoenzymatic techniques automated and/or manual, serum levels of high-sensitivity C-reactive protein (hs-CRP), von Willebrand factor, nitric oxide (NO) along with PlGF and soluble Flt-1, and ferritin in patients and controls. **Results.** The main results of the study showed that: a) plasma levels of vWF, NO, PlGF, sFlt-1 and ferritin were significantly higher in patients with TI compared to controls (88.0±21.8 vs 71.1±21.5 IU/dL, 101.5±34.7 vs 52.1±8.2 mmol/L, 52.2±20.0 vs 17.2±4.0 pg/mL and 96.5±25.2 vs 76.8±11.5 pg/mL, 740.5±505.2 vs 72.0±34.5, respectively ($p<0.01$), while angiogenic balance expressed as sFlt-1/PlGF was significantly lower in patients with TI compared to controls ($p<0.0001$), b) ferritin levels showed significant correlation with hs-CRP ($r=0.485$, $p<0.01$), vWF ($r=0.510$, $p<0.008$), NO ($r=0.535$, $p<0.005$), PlGF($r=0.495$, $p<0.01$) and sFlt-1($r=0.385$, $p<0.05$). **Conclusions**. Our findings demonstrate that patients with TI have a significant degree of low grade inflammation, endothelial dysfunction and active angiogenesis. The severity of these events seems to be related to the degree of ferritinemia, suggesting a possible pathogenetic role for iron load.

SETTING UP SERUM HEPCIDIN ASSAY IN PEDIATRICS

G Cangemi, A Pistorio, M Miano, M Gattorno, M Acquila, P Bicocchi, R Gastaldi, C Gatti, F Fioredda, M Calvillo, G Melioli, A Martini, C Dufour
Giannina Gaslini Pediatric Institute, Genova, Italy

Background. The measurement of circulating hepcidin is considered a promising biomarker for evaluating the iron status in various diseases. Very few commercial tests are available and assay harmonization for hepcidin has not been reached as yet, making reference intervals and consequent clinical decisions still elusive for each assay and specific population. In addition very rare studies have been conducted in children so far both on reference values and on correlation with age, sex and iron status in different clinical subsets. **Aims.** The aim of this study was to set up hepcidin testing in children by using a commercially available kit with automated and high throughput procedures. In addition we aimed to clinically validate the test for use in paediatric age. **Methods.** One hundred and thirty four subjects were included in the study. Control group included 86 healthy children while the patients' group comprised 52 patients (19 with anemia in systemic Juvenile Idiopathic Arthritis (JIA), 14 with b-thalassemia major in chronic transfusion and chelation regimen, 19 with iron deficiency anemia (IDA) mostòy on iron supply. A subset of 8 patients with systemic JIA were considered before or after treatment with anakinra. All the patients were tested for hematologic (Hb, MCV, hematocrit, serum iron, ferritin, transferring) and inflammatory (CRP, ERS and IL-6) parameters by using routinary laboratory techniques. Hepcidin-25 was measured by using a commercially available ELISA kit with automated procedures. **Results.** In control subjects, hepcidin levels showed a normal distribution (mean =40.8 ng/mL , SD=13.9) and were significantly higher in males (median: 43.6; 1^{st}-3^{rd} q: 32-52.7) than in females (median: 36.4; 1^{st}-3^{rd} q: 28.5-45.7) (P=0.039). In anemia of systemic JIA, hepcidin concentrations were significantly higher than in controls. After treatment with anakinra, an anti IL-1 agent hepcidin levels decreased significantly, and so

did inflammatory markers. Hepcidin in b-thalassemic and IDA patients was comparable to normal subjects. Correlations between hepcidin concentration and other iron parameters was investigated in both control and in the patient groups. No significant correlations were observed in controls while in the whole group of patients a significant inverse correlation could be found between hepcidin serum levels and age (r_S= -0.40), MCV (r_S= -0.40), serum iron (r_S= -0.55) and plasma transferrin saturation (r_S= -0.54). In thalassemic patients an inverse correlation between hepcidin and age (r_S= -0.51), most of red cells parameters, serum iron (r_S= -0.53) and tranferrin levels (r_S= -0.42) was observed. In systemic JIA patients only a moderate positive (R= 0.48) correlation could be seen between hepcidin and transferrin (r_S= 0.48). In iron deficiency anemia (IDA) none of the correlations reached the level of 0.40. **Summary and Conclusions.** Our study provides a reliable technical evaluation of the normal range values of serum hepcidn in childhood. In addition it shows that hepcidin serum level may discriminate microcitic inflammatory anemia of JIA from IDA and may be investigated as a potential marker of good chelation in thalassemic patients. Overall it may a helpful tool for addressing future studies aiming to further understand the role of hepcidin in managing iron disorders in children.

0954

FINE-MAPPING OF TELOMERIC BREAKPOINTS OF CHROMOSOME 16P DELETIONS IN ALPHA-THALASSEMIA OR ATR-16 PATIENTS

M Phylipsen, M van der Kraan, A Schaap, P van Delft, S Arkesteijn, M Geerts, F Kok, M Bakker-Verweij, P Giordano, C Harteveld
Leiden University Medical Center, Leiden, Netherlands

Background. Alpha-thalassemia is a genetic disorder of hemoglobin, which is a protein in the erythrocytes responsible for oxygen and carbon dioxide transport. Approximately 80% of all alpha-thalassemias is caused by deletions in the alpha-globin gene cluster located on chromosome 16p13.3. The majority of the deletions involves one or both alpha-globin genes and can be detected by gap-PCR for the 7 most common deletions during routine diagnostics. However, larger deletions also occur in this region causing alpha-thalassemia. When the deletion length is more than 1.5 Mb, they may be associated with a variable clinical picture, including alpha-thalassemia, dysmorphic features and mental retardation, which is known as the alpha-thalassemia-mental retardation syndrome (ATR-16). Most of these deletions extend a considerable end into the 3' direction, either involving the complete telomeric end of chromosome 16p, or leaving the telomeric region intact. **Aims.** The aim of this study was to investigate different types of telomeric deletions on chromosome 16p, leading to alpha-thalassemia or ATR-16. By determining the breakpoints of the deletions more exactly, it is possible to study the molecular mechanisms underlying these rearrangements. Furthermore, when breakpoints are determined at sequence level, relatively simple gap-PCR assays can be designed for diagnostic purposes. **Methods.** A group of 25 patients carrying a deletion on chromosome 16p, extending into the telomeric region, was investigated. These deletions were detected by MLPA during routine diagnostics for hemoglobinopathy. Fine-tiling array CGH was applied to fine-map the deletion breakpoint more precisely. In cases with an intact telomeric region, primers were designed to perform gap-PCR and sequence analysis to determine the exact breakpoints. **Results.** From the 25 cases studied, the fine-tiling array CGH showed an intact telomeric region in 13 cases. The other 12 patients carried deletions involving the whole telomeric end of chromosome 16p. Gap-PCR and sequence analysis to determine the exact breakpoint was successful in two cases. **Conclusions.** The fine-tiling array CGH technology is a valuable tool to fine-map deletion breakpoints. In this study, the array showed to be able to discriminate between interstitial deletions with an intact telomeric region (telomere capture) and deletions involving the complete telomeric end (telomere healing). Furthermore, array CGH results enabled the design of gap-PCR assays for 2 deletions. Due to the repetitive nature of the telomeric sequence, it is very difficult to design unique primers in this region. However, determination of the 3' end breakpoint by aCGH also provides valuable information.Because many genes are located at chromosome 16p13.3, loss of this region may have significant clinical consequences such as the ATR-16 syndrome. It is yet unknown which genes are responsible for the mental retardation phenotype in these patients. Therefore, it is important to study this kind of deletions to gain more insight in the genotype-phenotype correlations.

A NOVEL 506 KB DELETION CAUSING εγδβ THALASSEMIA

SL Thein[1], H Rooks[1], B Clark[2], S Best[1], P Rushton[2], M Oakley[2], O Thein[3], A Britland[4], A Ruj[4], A Cuthbert[4]
[1]King's College London School of Medicine, London, United Kingdom
[2]King's College Hospital NHS Foundation Trust, London, United Kingdom
[3]University of Oxford, Oxford, United Kingdom
[4]Airedale General Hospital, Keighley, West Yorkshire, United Kingdom

Background. εγδβ-thalassemias are rare and found only in the heterozygous form. They are caused by large deletions in the β globin cluster and are divided into two groups: Type I deletes the β globin gene and all or most of the β globin cluster, and Type II deletes the upstream regulatory region (β LCR) but leaves the β globin gene itself intact. The εγδβ-thalassemia heterozygous adult phenotype is like that of β thalassemia trait but with normal HbF and HbA_2 levels. However, newborns can present with severe hemolytic anemia that require blood transfusions. **Aims and Methods.** Here we describe a novel εγδβ-thalassemia deletion in a Pakistani family, named Pakistani I. The characterization of the deletion has encompassed a multitude of methodologies, mirroring changing DNA analysis technology; Southern blot hybridization, quantitative PCR, MLPA and CGH array mapping, gap PCR and sequence analysis. The Pakistani I deletion is 506 kb in size and the second largest reported so far. The deletion removes the entire β globin cluster and a large region upstream. The 5′ breakpoint is located 431 kb upstream of the ε gene, and the 3′ breakpoint, 75 kb downstream of the ε gene. The regions flanking the deletion are both LINE/LTR repeats but there was no homology between the 5′ breakpoint region and the 3′ breakpoint region. The 3′ breakpoint junction includes a duplication and inversion of a 250 bp region within an LTR repeat. This is adjacent to a 160 bp palindrome, of which one half has been deleted. The 250 bp repeat and the palindrome share a short 9 bp common junction sequence at their ends which may have led to a recombination event. The region flanking the 3′ breakpoint also includes seven known SNPs and a novel 24 bp deletion. The 5′ breakpoint junction is a simple break point within a LINE repeat. **Conclusions.** To date, 25 εγδβ-thalassaemia deletions have been reported: 15 are type I and 10, type II. Deletions over 0.5 Mb causing εγδβ-thal are extremely rare, this deletion being only one of two, and the second largest reported so far. Whilst detection of deletions is becoming easier and quicker with the use of MLPA and array CGH, full characterization has only been achieved in a few of the deletions reported so far. This case illustrates the technical challenges of defining the exact breakpoints of deletions which occur within repetitive regions. For comprehensive prenatal genetic counseling, the importance of fully characterizing these deletions is as relevant today, as it was two decades ago, when characterization of this deletion first began. Since εγδβ-thalassaemia deletions tend to be unique, there is a need for a comprehensive single methodology, such as next generation sequencing, that can fully characterize breakpoints and recombination events in a single analytical process. By comparing breakpoints among different deletions we may gain further insight into the biological processes that create them.

0956

IMPROVEMENT OF GENETIC DIAGNOSIS IN α-THALASSEMIA PATIENTS: MLPA DETECTION OF ELEVEN ALTERATIONS IN THE αα GLOBIN CLUSTER (INCLUDING THREE NOVEL DELETIONS)

J Martinez-Nieto, L Vinuesa, F de la Fuente-Gonzalo, P Ropero, F Gonzalez, E Anguita, B Pérez, E Fontanés, A Villegas, J Díaz-Mediavilla
Hospital Clínico San Carlos, Madrid, Spain

Background. Copy number variations (CNVs) are very common events in the α globin cluster. In this cluster there are two functionally α gene copies (four copies per diploid genome, denoted as αα/αα). Ninety percent of α-thalassemia patients carry a large deletion in this genetic region. There are two kinds of deletions: α+ deletions eliminates only one α gene copy (-α/αα), and α0 eliminates both copies in the cluster (—/αα).α0 carriers are usually healthy individuals with mild microcytic anemia, however, since α-thalassemia is one of the most prevalent monogenic disorders around the world, their offspring are in risk of developing: 1) a thalassemia intermedia condition named HbH dissease (—/-α) or 2) Hb Bart's dissease (—/—), a lethal condition for the fetus (in the late fetal stage of development), with the consecuent pregnancy complications for the mother. Thus, screening for deletions in patients suspected to have thalassemia is mandatory in order to prevent these events, and there are PCR methods designed to detect specifically a few of the most common deletions in the cluster. Nevertheless, rare and novel deletions can not be detected with

such methods, and the molecular diagnosis becomes difficult in a considerable proportion of the cases.The recent development of CNV searching tools allow to detect both previosly known and novel deletions, helping to improve the genetic diagnosis in α-thalassemia patients.AIM:This is a descriptive work showing the results of the analysis by Multiplex Ligation-dependent Probe Amplification (MLPA) of cases suspected to carry a rare alteration in the α globin cluster.METHODS:Screening for most common deletions was carried out with Alpha Globin StripAssay method in α-thalassemia patients (microcytic hipocromic anemia and normal HbA2 levels). MLPA was performed in those patients with normal or inconsistent genetic results after the initial screening.The MLPA is a quantitative technique based on the amplification and a subsequently fragment analysis of multiple probes hybridized across a region of interest. This method allows for a genetic profile showing the copy number variation of those targets. Here we used a commercial kit (P140-B3 HBA, MRC-Holland) that contains 25 probes designed to detect copy number changes in the α cluster, from POLR3K gene to 4Kb downstream of α1 globin gene, spanning more than 130Kb.RESULTS:Eleven different genetic alterations have been detected in this study (detailed view in figure 1); three of them have not been previously described in scientific publications and are novel alterations.CONCLUSIONS:In some cases, StripAssay method leads to interpretation mistakes in genetic diagnosis. The reason for this is that the method is designed to detect just the eight commonest deletions worldwide. Thus, in carriers of a combination of a common α+ deletion (ie α3.7Kb) together with a rare α0 deletion (that can not be detected with this method), the former technique indicates a (-α/-α) condition while the real condition is a (-α/—) genotype.Within this scenario, MLPA analysis improves the molecular diagnosis and the genetic counseling in this group of diseases.

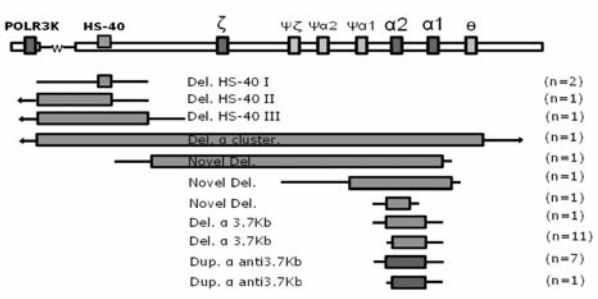

Figure 1. Alterations detected in this study. Bars denote the minimal lenght of the deletion/duplication, while lines show the theoretical maximun lenght. Arrows indicate that rearrangement can not be delimited at that point. Finally, the number of cromosomes (n) affected for each alteration is indicated in column at the right.

A THREE BASE PAIR DELETION IN 3'UTR OF G6PD GENE : [3'UTR +66 DEL (-GGA)]

I Benmansour[1], I Moumni[1], K Moradkhani[2], C Prehu[2], S Abbes[1]
[1]Pasteur Institut of Tunisia, Tunis Belvedere, Tunisia
[2]AP-HP, Groupe Henri-Mondor Albert-Chenevier, Créteil, France

Background. Glucose-6-phosphate dehydrogenase (G6PD, MIM 305900) catalyzes the first step in the pentose phosphate pathway and plays a critical role for protecting cells against oxidative stress. Molecular characterisation of the G6PD gene, showed that G6PD deficiency is mainly caused by: over 160 missense mutations leading to amino acid substitutions, eight base pair deletions (6 three, 1 six and 1 twenty four bases) that do not produce frame shifts and two splicing mutations Up to now, there is no documented mutation in the 5' or 3' untranslated region (UTR) of this gene. **Aims.** We aimed to check whether this deletion is causing G6PD deficiency or it is simply a polymorphism. **Methods.** Deletion was detected by PCR amplification followed by sequencing. Apart the two probands (unrelated females) in whom we found the deletion of 3 bp, we sequenced 150 chromosomes bearing different variants responsible for G6PD deficiency and 150 B chromosomes.Results. The deletion [3'UTR +66 del (-GGA)] was detected in two unrelated females in a heterozygous state. The two proband showed acute haemolysis, palpable spleen and history of neonatal jaundice.Exploration for hemoglobinopathies and pyruvate kinase were negative.The chromosomes B and those bearing deficient variants were negative for the deletion. We suspect that this deletion is the causative of G6PD deficiency, especially that ARN secondary structure changes when deletion occurs.Summary:In the herein study we report, for the first time, a 3-base pair deletion in the 3'UTR of the G6PD gene [3'UTR +66 del (-GGA)]. This deletion is in a heterozygote state. We suspect it is causative of G6PD deficiency.

[4]Royal Manchester Children's Hospital, Manchester, United Kingdom
[5]Kings College Hospital, London, United Kingdom

Background. Recently we have described two cases of heterozygosity for the common β°-thalassemia mutation β39 (C>T) presenting with a thalassemia intermedia phenotype. Multiplex Ligation dependent Probe Amplification (MLPA) analysis of the α-globin gene cluster revealed two new rearrangements, consisting of a full duplication of the α-globin genes locus including the upstream regulatory elements. Here, we present three other cases. **Aims.** Study the molecular background. of carriers of a single beta-thal mutation expressing a beta-thalassemia intermedia phenotype. **Methods.** Multiplex Ligation-dependent Probe Amplification (MLPA), direct sequencing and haematological/biochemical analysis.**Results.** The first is a 2 year-old girl of mixed Sephardic Ashkenazi Jewish origin living in Canada, who presented with a pronounced microcytic hypochromic anemia. She was found to have borderline HbA_2 levels and heterozygosity for a β polyA mutation inherited from the parent who had mild microcytic hypochromic anemia due to heterozygosity for the same β-mutation. The second case, a 6 year old girl of middle-eastern origin living in the UK, has severe anemia and splenomegaly, while the mother from whom she has inherited the β^0-thalassemia mutation is clinically asymptomatic. The third case is an Albanese adolescent living in Rome with pronounced microcytic hypochromic anemia, borderline HbA_2 levels and heterozygosity for the β IVS1-110 g>a mutation. She showed modest hepatomegaly and marked splenomegaly, elevated bilirubin (~3mg%), normal ferritin (~160 ng/ml) and reticulocytosis (>4%). MLPA analysis of the α-globin gene cluster in the 3 cases revealed three new rearrangements, consisting of a full duplication of the α-globin gene cluster and the upstream regulatory elements, arranged head-to-tail in the patient's genome. **Summary and Conclusions.** We report the clinical and hematological data and the molecular characterization. We conclude that α-globin gene duplication is more common than previously thought and should be investigated as a contributing cause in all unexplained unusually severe anaemia in carriers for β thalassemia.

HOMOZYGOUS ABSENCE OF THE TMPRSS6 GENE IN AN 11 YEARS OLD CHILD RESULTING IN SEVERE IRON DEFICIENCY IRON REFRACTORY ANEMIA

A Donker[1], M Raphael[2], G Visser[2], J van der Smagt[2], D Swinkels[1]
[1]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands
[2]University Medical Centre Utrecht, Utrecht, the Netherlands, Utrecht, Netherlands

Background. Iron Refractory Iron Deficiency Anemia (IRIDA) is a rare hereditary disease characterized by microcytic hypochromic anemia with low transferrin saturation (TSAT), not responsive to oral iron. The genetic substrate of IRIDA is the *TMPRSS6* gene (transmembrane protease serine 6) encoding the protein matriptase-2.*TMPRSS6* defects lead to increased levels of hepcidin, inappropriate for the low body iron status, resulting in decreased intestinal iron absorption and iron release by macrophages by degradation of the cellular iron exporter ferroportin.Hitherto reported human *TMPRSS6* defects cause impaired function of matriptase-2. Here we describe an 11 years old girl with a severe phenotype of IRIDA due to a homozygous "knockout"of *TMPRSS6.* **Aims.** Description of phenotype and genotype of homozygous absence TMPRSS6 mutations. **Methods. Case report. Results.** An 11 years old girl born to healthy consanguineous Northern African parents presented with severe microcytic anemia with low TSAT at the age of 3 years (Hb 7.9 g/dl, MCV 53 fl , TSAT 4%, ferritin 29 µg/l).Oral iron was not effective, in contrast to intravenous iron (Hb 12 g/dl, MCV 64 fl, TSAT 7%, ferritin 304 µg/l). There was no evidence of malabsorption , gastrointestinal blood loss or hemoglobinopathy.In addition to the anemia, the patient suffered from unclassified mental retardation (IQ around 50) and auditory hallucinations.Serum hepcidin, analysed by time-of-flight mass spectrometry, was 25.4 nmol/L, which is inappropiately high relative to the low TSAT (TSAT/hepcidin ratio 0.16 %/nM, local reference values for premenopausal women 2.0-330 %/nM, for children unknown) and suspicious of the IRIDA-phenotype.SNP analysis (2.7M cyto array Affymetrix) of the *TMPRSS6* gene showed a homozygous deletion of 120 kb at the distal breaking point in

intron 2, arr22q12.3 (35,704,120-35,827,974)x0, confirming the IRIDA-genotype. In addition to the matriptase-2 encoding region, 4 other not previously reported genes were deleted. Two of them might affect mitochondrial function. However, serum lactate, amino-acids and organic acids were within reference ranges.It is well possible that the retardation is the result of the severe lack of iron, as iron deficiency in childhood may have severe effects on neurodevelopment. An alternative explanation can be the absent genes.Screening of the family showed that both the parents and the brother were heterozygous for the relevant deletion. The mother and brother of the patient are asymptomatic with Hb, MCV and TSAT/hepcidin ratio within reference ranges. The father's phenotype is unknown. **Conclusions.** We conclude that a homozygous absence of the *TMPRSS6*-gene is compatible with life and results in severe IRIDA. We hypothesize that the iron deficiency in severe IRIDA may lead to mental retardation.Our observations support the idea that IRIDA is an autosomal recessive disease. However, anecdotal reports of symptomatic heterozygous IRIDA patients suggest a co-dominant disease, indicating that the inheritance of IRIDA still needs elucidation.Intravenous iron is effective in IRIDA. A dose limiting side effect is toxic macrophage iron loading. Recent reports suggest a positive influence of erythropoetin by creating a better iron utilization. The optimal treatment of IRIDA remains to be investigated.

0960

LYN DEPENDENT PHOSPHORYLATION OF BAND 3 REGULATES ERYTHROCYTE FUNCTIONALITY

E van den Akker, E Ovchynnikova, N Yagci, D Philips, M von Lindern
Sanquin Research, Amsterdam, Netherlands

Background. Optimal *ex vivo* or *in vitro* expansion of erythrocytes is important if red cell production is to be realized on a grand scale for transfusions. The flexibility and rigidness of the erythrocytes is in part dictated through associations of the spectrin based cytoskeleton with the plasma membrane. Within the abundant band 3 macro-complexes within the erythrocyte membrane, the interaction of tetrameric band 3 with ankyrin and protein 4.2 is of pivotal importance to function as a spectrin cytoskeleton-membrane anchoring point. This interaction, in part, dictates the shape of erythrocytes. The strength of this cytoskeleton-membrane association may thus regulate membrane flexibility and shape of erythrocytes. This could be important to withstand shear stress in the capillaries and during band 3-spectrin complex formation throughout reticulocyte maturation to biconcace erythrocyte. Band 3, ankyrin, protein 4.2 as well as spectrins have been shown to be tyrosine and serine phosphorylated and this phosphorylation could potentially regulate the strength of cytoskeleton-membrane association. **Aims.** How does tyrosine phosphorylation of band 3 influence the functionality of erythrocytesMethods:To understand the role of phosphorylation in erythrocyte flexibility, phosphorylation is induced by different concentration of ortho-vanadate treatment (OV). The effect of this treatment on morphology (microscopy), osmotic tolerance (NaCl concentration curve), deformability (ARCA) and cytoskeleton-membrane linkage (detergent extractability assays) is assayed. We use immune-precipitations to asses how phosphorylation affects the associations with the band 3 macrocomplex.Results. We found that 0.1mM ortho-vanadate (OV) treatment causes increased fragility of erythrocytes and an echinocyte morphological appearance. Furthermore, orthovanadate treatment results in band 3 tyrosine and serine phosphorylation. This phosphorylated form of band 3 is extractable by detergents indicating a weakened cytoskeleton link (C12E8), whilst spectrins remain inextricable. These effects were reversible upon removing the OV from the medium, indicating the presence of active phosphatases in erythrocytes. Interestingly, no reduction of the interaction between protein 4.2 and band 3 after OV treatment was observed indicating that band 3 phosphorylation does not affect this interaction. Inhibition of Src kinases (PP2) during OV treatment rescued the echinocytes appearance and fragility of erythrocytes. Furthermore, it decreased the tyrosine and serine phosphorylation of band 3. We identify LYN is the SRC-kinase family members that is activated after OV treatment. PKC inhibitors (Gö6967) also rescued the increased fragility after OV treatment, however, erythrocytes were spherocytes and tyrosine or serine phosphorylation of band 3 induced by OV treatment was not affected. This suggests that PKC elicits its effects independent from band3 and that serine phosphorylation of band 3 is independent from calcium dependent PKCs. Summary and Conclusions.These data show that LYN-induced band 3 phosphorylation weaken the interaction of the membrane with the underlying spectrin cytoskeleton thus regulating the flexibility of erythrocytes without inhibiting protein 4.2-band 3 interactions.

THE CLINICAL SIGNIFICANCE OF RESPIRATORY VIRUSES AND COINFECTIONS IN HEMATOLOGICAL PATIENTS

AC Ostby[1], M Arpi[2], H Birgens[3]
[1]State Serum Institute, Copenhagen S, Denmark
[2]Department of Clinical Microbiology, Herlev, Denmark
[3]Department of Hematology, Herlev, Denmark

Background. The extent of respiratory virus infections in immunocompromised hematological patients is only partially elucidated. **Aims.** To determine the incidence of 12 common respiratory viruses detected in adult hematological patients admitted to hospital with respiratory symptoms, to evaluate the clinical presentations and outcome, and finally to relate and compare the findings with that obtained from current practice microbiological diagnostics. **Methods.** Throat swabs were collected and analyzed by a polymerase chain multiplex technique from 329 patients with 450 episodes of acute respiratory symptoms at two hematological departments from January 2007 through December 2007, and from December 2008 through November 2009. The following viruses were detected: influenza A, influenza B, respiratory syncytial virus, human metapneumovirus, adenovirus, rhinovirus, coronaviruses 229E, NL-63 and OC43, and parainfluenza viruses type 1, 2 and 3. Clinical data and results of laboratory and microbiological analyses were collected simultaneously. **Results.** Respiratory viruses were detected in 138 (31%) of the 450 episodes of respiratory symptoms. The most frequent viruses were rhinovirus (n=44, 32%) and influenza A (n=30, 22%). In ten of the episodes (2%), the patients had two or three viruses detected in the same sample.The most frequent diagnoses in viral-positive patients were AML (32 %) and malignant lymphoma (17 %). The number of virus-positive patients was not higher in patients with neutrophil counts below 0.5 x 10^9/l than in patients with neutrophil counts above 0.5 x 10^9/l. The frequency of viral infections was higher in patients undergoing hematological stem cell transplantation (85 of 215 patients), than in other patients (53 of 235 patients, p<0.001). There was no difference in the frequency of viral infections between autologous or allogeneic stem cell transplant patients, but significantly more viruses were detected in patients who had undergone a myeloablative allogeneic stem cell transplantation (47 of 95 patients, 49%), compared to a non-myeloablative allogeneic stem cell transplantation (29 of 88 patients, 33%, p=0.023).Coincident bacteria or fungi were detected in 49 of the 138 viral infections (36%). Bacteria considered clinically significant were detected in 19 viral infections (14%). The most frequent combinations of virus and clinically relevant bacteria were rhinovirus and H. influenzae (n=4) and rhinovirus and S. aureus (n=2).Death within 30 days of the viral sample was seen in 18 (4%) of the respiratory episodes, but the mortality frequencies did not differ between the virus-positive and virus-negative patients. Likewise, the mortality frequencies did not differ between patients with a virus-only-infection, and patients with coinfections of a virus and bacteria.**Summary.** Respiratory viruses are frequently diagnosed in hematological patients. Only in few cases was a mix of viral and bacterial etiology found. The presence of respiratory virus was not related to the degree of neutropenia and did not have an impact on the mortality. Patients who have undergone hematological stem cell transplantation were more prone to viral infections. This highlights the importance of using comprehensive diagnostic methods, including viral diagnostics, when managing acute respiratory infections in these patients.

0962

CHRONIC/RELAPSING LYMPHADENOPATHY ASSOCIATED WITH HHV-6B INFECTION: A NEW BENIGN CLINICO-PATHOLOGIC ENTITY OCCURRING IN IMMUNOCOMPETENT INDIVIDUALS

F Forghieri, L Potenza, P Barozzi, D Vallerini, G Riva, E Zanetti, C Quadrelli, M Morselli, G Leonardi, M Maccaferri, A Paolini, V Coluccio, E Colaci, L Pedrazzi, V Fantuzzi, S Bigliardi, F Soci, G Bonarcorsi, P Zaldini, G Rossi, M Milani, F Rivasi, W Gennari, M Pecorari, A Grottola, S Tagliazucchi, F Rumpianesi, F Mattioli, L Presutti, C Franzoni, R Gelmini , M Saviano , C Cermelli , R Marasca , F Narni , M Luppi
University of Modena and Reggio Emilia, Modena, Italy

Background. HHV-6 DNA sequences were disclosed in lymph node (LN) tissues of several patients with lymphoid malignancies, but a direct major role of HHV-6 in lymphoid malignant transformation has so far not been confirmed. In contrast, active HHV-6 infection has been associated to either infectious mononucleosis-like syndrome or acute lymphadenitis occurring in febrile

patients with systemic symptoms, or to Rosai-Dorfman disease in which viral antigens have been detected by immunohistochimical (IHC) analyses in both histiocytes and follicular dendritic cells (FDCs). **Methods.** We have retrospectively analyzed clinical and pathological data of 365 adult patients, consecutively observed at our Institution over a period of 5 years (2006-2010), because of enlarged superficial lymph nodes and subsequently undergoing lymphadenectomy. In the benign/reactive cases in which well-recognized etiologies have been excluded, an involvement of HHV-6 active infection or reactivation was investigated by molecular and immunohistochemical examinations. *Results.* Malignant disorders, namely malignant lymphoproliferative disorders or solid cancer metastases, were found in 227 cases (62%), whereas in 138 cases (38%) benign/reactive pictures were documented on lymph node examination. Among these latter cases, a well-recognized etiology was demonstrated in 84 patients (61%), while in 54 cases (39%), a well-defined non-malignant reactive/infectious cause could not be documented. Immunohistochemical analyses resulted negative for both HHV-6A and HHV-6B in 38 of these latter lymph nodes (70%). In 7 patients (13%), a scattered, scanty and aspecific positivity for HHV-6B late protein was documented in rare interfollicular plasma cells and histiocytes. Surprisingly, in 9 patients (17%), immunohistochemical analyses showed HHV-6B positive staining of FDCs, together with scattered positivity of interfollicular cells. These 9 HIV-negative adult patients (median age 42 years, range 18-76 years), with either localized or generalized LAP, were observed for a median follow-up of 38 months (range 28-166). Of note, six of them presented with recurrent LAP (one to 3 recurrences), without evolving into lymphoma. A common LN histological pattern at presentation showed florid follicular hyperplasia with concurrent mild paracortical expansion. Three cases also showed features consistent with PTGC. Constitutional symptoms were absent in all patients. The IHC reactions for both HHV-6A and HHV-6B, performed on further control cases, represented by 131 LN tissues from patients with either benign LAP induced by other known etiologies or lymphoma, were invariably negative. Serology was positive for both IgM and IgG with high avidity suggesting viral reactivation/reinfection. However, the molecular analyses failed to detect HHV-6 viremias in cell-free-serum samples of all the 9 patients with positive HHV-6B IHC staining, while positivity for HHV-6B DNA was disclosed by PCR analyses in 7 out of the 7 LN tissues studied. *Conclusions*. We show for the first time that local reactivation/infection of HHV-6B should be considered among the possible causes of chronic/relapsing benign LAP in immunocompetent individuals. IHC is the method of choice for investigating the presence of HHV-6 infection in such cases. HHV-6B may indirectly modulate and trigger the proliferation of lymphocytes, by locally affecting FDCs and LN microenvironment. FDCs may indeed be involved in presenting HHV-6B antigens to other immune cells, mainly cortical B lymphocytes.

0963

HUMAN HERPESVIRUS 6 IS A FREQUENT INFECTION IN MYELOMA PATIENTS UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION IN THE ERA OF NOVEL ANTI- MYELOMA AGENTS

N Horowitz, N Lavi, T Zuckerman, N Benyamini, I Oren, Z Kra-Oz, V Held, I Avivi
Rambam Health Care Campus, Haifa, Israel

Background. Human herpesvirus 6 (HHV-6) disease, evoked by viral reactivation in the presence of immune suppression, presents with fever, skin eruption, encephalitis and pneumonia. The incidence of HHV-6 disease has not yet been studied in a large homogenous cohort of autografted patients with multiple myeloma (MM) in the era of novel agents, which are known to alter the immune system function.**Aims.** The aim of the current study was to evaluate the frequency and importance of the HHV-6 disease in consecutive patients undergoing autologous stem cell transplantation (ASCT) for MM after treatment with novel agents. **Methods.** Data on 62 consecutive MM patients treated with bortezomib-dexamethasone (VD) or thalidomide-dexamethasone (TD) induction therapy in conjunction with melphalan 200mg/m^2, who underwent ASCT between 01.2005 and 09.2010, were reviewed. According to the department protocol, during the study period, patients with an unexplained post-engraftment fever of 3 days underwent a polymerase chain reaction (PCR) screen for viral infection. Diagnosis of HHV-6 disease required a positive PCR test for this virus, with no evidence for a bacterial or fungal pathogen in blood cultures or in a chest computerized tomography scan.**Results.** Twenty one patients (34%) received TD and 41 (66%) VD. There were no statistically significant differences in patient characteristics between the 2 groups, apart from the dexamethasone dosage, which was significantly higher in patients receiving TD (640 vs 1000 mg, p=0.024). Eight patients in the TD cohort and 18 in the VD cohort experienced a post-engraftment unexplained fever, hence, underwent viral screening. Ten patients of the whole series (16%), accounting for 35% of those who had been screened, were diagnosed with HHV-6 disease. The incidence of this disease in patients treated with VD approached 19.5% (n=8) versus 9.5% (n=2) in those treated with TD. All patients recovered without sequels. **Conclusions**. HHV-6 disease is relatively common after ASCT, accounting for at least third of post-engraftment episodes of unexplained fever, with a presumably higher incidence following VD induction. Timely identification of this infection might eliminate the need for further diagnostic evaluations and contribute to the efficient management of these patients.

ROMIPLOSTIM AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION: RESULTS OF A PILOT STUDY

M Fominykh, S Voloshin, A Schmidt, V Shuvaev, A Kuzyaeva, I Zapreeva, K Abdulkadyrov
Russian Research Institute of Heamatology and Transfusiology, Saint-Petersburg, Russian Federation

Background. A number of studies have demonstrated that G-CSF can fasten neutrophil recovery in patients undergoing high-dose chemotherapy (HDCT) and hematopoietic stem cells transplantation (HSCT). Unfortunately, the only measure available to correct post-transplant thrombocytopenia is platelets transfusions. Recently immune thrombocytopenic purpura management has changed with introduction of thrombopoietin receptor agonists (TRA), which were highly effective and safe in such patients. To date the only two TRA are available - romiplostim and eltrombopag. It is possible that administration of TRA can significantly alter clinical course of patients undergoing HDCT. To address this question we have initiated a pilot study to assess the efficacy of TRA after HDCT with HSCT. **Patients and Methods.** Seven patients (median age, 45 years; range 21-56; 6 male and 1 female): 2 patients with non-Hodgkin's lymphoma (NHL), 2 patients Hodgkin's lymphoma (HL) and 3 patients with multiple myeloma (MM) were treated with HDCT/autologous HSCT and romiplostim support [autoHSCT+romiplostim group]. Two patients: 1 patient (20 years, male) with aplastic anemia (AA) and 1 (50 years, male) with chronic myelogenous leukemia (CML) were treated with allogeneic HDCT/HSCT and romiplostim support [alloHSCT+romiplostim group]. Romiplostim was given subcutaneously at a dose of 250 μg on day of HSC infusion. Twelve patients (median age, 39 years; range 19-64; 6 male and 6 female) with NHL (n=6), HL (n=5) and MM (n=1) were assessed as a control group (without romiplostim support). The endpoints of the study were time of platelets recovery (TPR), duration of thrombocytopenia (DT), and length of hospital stay (LHS). Statistical analysis was conducted with nonparametric statistical methods (Mann-WhitheyU test for continuous variables and Fisher exact and Chi-square tests for categorical variables).**Results.** The DT grade 3 was 10.7 days in the autoHSCT+romiplostim group in comparison with 19.0 days in the control group (*p=0.044*). DT grade 3 in alloHSCT+romiplostim group was 57 days for AA patient and 29 days for CML patient. DT grade 4 was 6.9 and 13.8 days in average groups, respectively *(p=0.259)*. DT grade 4 was 54 days for AA and 3 days for CML patients. TPR grade 3 was 13.9 days for autoHSCT+romiplostim group and 22.2 days for the control group (*p=0.044*). TPR grade 3 was 48 days for AA patient and 35 days for CML patient (alloHSCT+romiplostim group). TPR grade 4 was 13.0 and 18.7 days according to study groups (*p=0.035*). TPR grade 4 was 45 days for AA patient and 11 days for CML patient (alloHSCT+romiplostim group). LHS was 27.9 in the autoHSCT+romiplostim group in comparison with 36.7 days in the control group (*p=0.021*). LHS was 60 for AA patient and 45 days for CML patient (alloHSCT+romiplostim group). **Discussion.** The duration of thrombocytopenia, times of platelet recovery and the length of hospital stay are shortened when romiplostim is administered after HDCT. This tendency confirms the rationale for use of romiplostim which can improve patients' outcome in setting of HDCT and HSCT. Further studies are needed to evaluate the efficacy and safety of romiplostim support as a part of post-transplant care for auto- and allograft recipients.

0965

CAN JC VIRUS BE PREEMPTIVELY DETECTED PRIOR TO THE DEVELOPMENT OF MULTIFOCAL LEUKOENCEPHALOPATHY IN PATIENTS UNDERGOING ALLOGNEIC STEM CELL TRANSPLANTATION?

N Benyamini, N Horowitz, T Zuckerman, Z Kra-Oz, T Wittman, I Avivi
Rambam Health Care Campus, Haifa, Israel

Background. Recent studies demonstrated an increased incidence of JC virus (JCV)-related progressive multifocal leukoencephalopathy (PML) in immunocompromised patients. PML, mostly fatal, has been reported in transplanted patients, including those undergoing allogeneic stem cell transplantation (alloSCT). The expanding application of alloSCTs nowadays, reflecting the growing availability of matched unrelated donors, is expected to increase the incidence of this complication.Therapeutic options in PML are extremely limited and usually unsuccessful, resulting in a rapid neurological progression and

death. However, immune restoration, whenever possible, is claimed to be highly important for PML treatment.**Aims.** The aims of the current study were to determine the natural course of JCV reactivation and the correlation between serum JCV levels and immunosuppression and to explore the possibility for preemptive detection of JC reactivation prior to PML clinical development. **Methods.** The study was approved by the Rambam IRB (approval # RMB 0097-12). Two patients (out of 116 allografted at the Rambam Medical Center over the last 2 years), were diagnosed with PML based on positive PCR test for JCV in blood and cerebrospinal fluid (CSF), in the presence of a typical brain MRI scan. Data, focusing on immunosuppressive therapy administered, clinical presentation and course of PML, were recorded. DNA samples of both patients, originally taken for quantitative CMV-PCR analysis, were evaluated by JCV-PCR during the transplant period. JCV was detected by quantitative RT0-PCR of whole blood. **Results.** The two patients were diagnosed with PML 188 days or 195 days after alloSCT (Table 1). Reassessment of stored blood samples revealed JCV reactivation in both patients, which occurred 126 or 111 days prior to appearance of neurological symptoms and PML diagnosis. These two patients were heavily pretreated before alloSCT. Moreover, their post-alloSCT period was complicated with chronic relapsing GvHD and repeated severe infections. They received immunosuppressive drugs, including steroids. The patients were JCV-negative during and early after the alloSCT, but became persistently positive (on days 62 or 84 post-transplant) long before developing PML (table 1). Remarkably, their JCV blood levels tended to correlate with steroid dosage.

Days from SCT	Patient 1		Patient 2	
	JC virus#	Steroid dosage†	JC virus#	Steroid dosage†
62	8000	0	0	0
84	8750	0	2200	0
97	912,000	40	5000	0
132	110,000	20	NA	40
153	620,000	40	8000	40
173	500,000	40	3500	20
188	**2600000* PML**	40	3700	20
195	2,200,000	20-10	**4500*PML**	20
209	1,350,000	60	7000	10
219	25,000,000	60	NA	10
226	19,000,000	60	3000	20
246	>100,000,000	60	NA	20

Quantitative PCR in copies/ml; † Steroids dosage in mg adjusted to GvHD severity;
* Clinical PML with JC in CSF and MRI findings

Conclusions. The findings of the current study suggest that preemptive JCV monitoring and management should be considered in heavily pretreated alloSCT patients. The revealed correlation between steroid doses and JCV may imply that early detection of the virus reactivation and reduction in immunosuppression could ultimately lead to prevention of clinical PML. Prospective studies are warranted for the elucidation of these issues.

EFFECT OF A SINGLE DOSE OF ANTI D (WIN RHO*) IN REDUCING HEMORRHAGIC COMPLICATIONS IN PATIENTS HAVING SEVERE THROMBOCYTOPENIA SECONDARY TO DENGUE VIRUS INFECTION

A Bhalla, D Thakur, V Suri, S Varma, R Ratho, R Sharma
Post Graduate Institute of Medical Education and Research., Mohali, Punjab, India

Background. Dengue is an important cause of acquired thrombocytopenia in tropical counties. Although self limiting, it may result in life threatening hemorrhagic complications. **Aims.** In this study our aim was to evaluate the efficacy of a single dose of Anti -D in reducing hemorrhagic complications due to severe thrombocytopenia (<20,000) in dengue virus infection. **Methods.** An open label, investigator initiated , randomized interventional study was conducted at our centre. Patients presenting with fever and thrombocytopenia were screened and evaluated for enrolment. 30 patients with diagnosed dengue haemorrhagic fever with severe thrombocytopenia (platelet count ≤20,000/m^m3) were enrolled. They were divided into two groups. The intervention group received injection Anti - D , 50 µg/kg (250IU/kg) along with the standard care while the control group received standard care only. Both the groups reeived platelet transfusions when indicated. The base line parameters were recorded Platelet count at presentation, the grade of bleeding , improvement in the bleeding grades, the volume of the platelet transfused and the duration of hospital stay were compared in both the groups. Any serious adverse event was noted and reported Continuous data was expressed as Mean (S.D.) and / or Median (range). Categorical data was expressed as % 95% Confidence interval was calculated for all the parameters For intergroup comparisons Paired T-test was used and for intragroup comparison Wilcoxon sum rank test was used. For categorical data, Chi Square test or Fischer Exact test was used p value of < 0.05 was considered significant. **Results**. A total of 30 patients were included in the study. Baseline parameters were comparable. 73.3% patients were in the age group of 20 - 50 years, with a male predominance; (93.3%) The mean duration of symptoms was 4.2(±1.14) days (intervention group) as compared to 5.53 (±1.92) days (control group). The baseline platelet count of the intervention group 12,266 (±3614.78) was low as compared to the control group platelet count 14,333(±3579.04). 6 (40 %) patients in the control group and 5 (33.3 %) in the intervention group who had grade 1 bleed at presentation whereas 7 (46.7%) patients in the control group and 5 (33.3 %) in intervention group had grade 2 bleeding at presentation Although there was no deterioration in the bleeding grades in either group but the improvement in the bleeding grades was rapid in the intervention group of the patients as compared to the control group. The requirement of the platelet concentrate infusion in the control group was significantly higher 342.3 ml (±192.61) as compared to the intervention group requiring only 187.3 ml (±79.16) The mean duration of hospital stay was comparable in both groups, 5.8 days (control) vs 5.78(intervention group). There were no serious adverse events noted. **Conclusions**. Bleeding in patients having severe thrombocytopenia (20,000/mm3) secondary to Dengue Virus Infection was rapidly and safely reversed by administration of a single dose of 50 µg/kg (250IU/kg) Anti D intravenously.

HIGH DOSE PROPHYLACTIC ACICLOVIR IMPROVES OUTCOMES IN ADULT UNRELATED DONOR STEM CELL TRANSPLANTATION

L George[1], N Duncan[1], S Nagra[1], J Khan[2], R Malladi[1], C Craddock[1]
[1]Queen Elizabeth Hospital, Birmingham, United Kingdom
[2]Cancer Research UK Clinical Trials Unit, School of Cancer Sciences, Birmingham, United Kingdom

BACKGROUND. Cytomegalovirus (CMV) disease remains an important cause of morbidity and mortality following allogeneic stem cell transplantation (SCT) particularly in recipients of unrelated donor transplants. Pre-emptive ganciclovir (GCV) treatment, although effective, is associated with significant toxicity. The role of prophylactic strategies remains unclear and considerable uncertainty still surrounds the benefit of high dose aciclovir (ACV) in reducing the risk of CMV infection and death after allogeneic SCT.AIMSWe wished to compare the impact of two different ACV prophylaxis strategies on CMV-related mortality and transplant outcome in adult unrelated donor stem cell transplant recipients.METHODSDemographic and clinical data were collected on all patients undergoing matched unrelated SCT between January 2002 and December 2010 at risk of reactivating CMV (defined as CMV seropositive patient or donor prior to SCT). 144 adults with a haematological malignancy underwent transplantation from a matched (7/8 or 8/8 match at HLA-A,B, C or DRb1) donor. 53 (37%) patients were transplanted using a myeloablative conditioning regimen (Cy/TBI) and 91 (63%) using a fludarabine-based reduced-intensity regimen. Alemtuzumab (10mg/day x 5 days) was administered to all patients on days -5 to -1. Between January 2002 and July 2004, 24 patients at risk of CMV infection received "low dose ACV"(LDACV) (200mg PO q.d.s) until day +35. Between August 2004 and December 2010, 120 patients received a "high dose ACV"(HDACV) schedule (500 mg/m^2 IV t.d.s followed by 800 mg qds po until day+100). CMV viral loads were measured at weekly intervals until day +100 and patients who developed CMV viraemia immediately commenced therapeutic doses of GCV. The method of Kaplan and Meier was used for comparison between treatment groups. Survival rates are reported with 95% confidence intervals at 100 days and 6 months post transplant with no patients lost to follow up.RESULTSAn improvement in overall survival (OS) was observed at 100 days with 87% OS in the HDACV group (95% CI: 79% to 92%) compared with 71% OS in LDACV (95% CI: 48% to 85%) (Figure 1). CMV-specific mortality at 100 days was reduced in the HDACV group (CMV survival rate: 0.99, 95% CI: 0.94 to 1.00) compared with the LDACV group (CMV survival rate: 0.82, 95% CI: 0.59 to 0.93). The reduction in CMV-specific mortality was still apparent at six months; HDACV CMV survival rate of 83% (95% CI: 0.75 to 0.89) vs LDACV CMV survival rate of 74% (95% CI: 0.51 to 0.87). The incidence of CMV disease was also lower at day 100 post transplant (OR=0.24, 95% CI: 0.07 to 0.95) and at 6 months (OR=0.27, 95% CI: 0.08 to 1.04). Overall survival rate at 2 years was 58% in the HDACV group (95% CI: 49% to 67%) compared with 38% in the LDACV group (95% CI: 19% to 56%).CONCLUSIONSOur data indicate that high dose ACV may have the capacity to reduce early CMV-related mortality in recipients of unrelated donor transplants. The

optimal dose of prophylactic ACV in patients undergoing alternative donor SCT requires examination in prospective randomized trials.

SERUM FREE LIGHT CHAINS IN PATIENTS WITH HIV: THEIR ASSOCIATION WITH MARKERS OF DISEASE STAGE AND SEVERITY, AND THE EFFECT OF ANTIRETROVIRAL THERAPY

A Zemlin[1], H Ipp[1], J Germishuys[1], M Rensburg[1], M Esser[1], M Janse van Vuuren[2], R Erasmus[1]

[1]National Health Laboratory Services and University of Stellenbosch, Cape Town, South Africa

[2]Pathcare Private Laboratory, Bloemfontein, South Africa

Background. Monoclonal serum free light chain (FLC) measurements are used to follow up and manage patients with monoclonal gammopathies, and abnormal serum free light chain (FLC) ratios have been associated with risk of progression in certain diseases. B-cell dysfunction has been well-described in HIV infection and B-cell abnormalities are associated with disorders leading to monoclonal gammopathies and abnormal FLC levels in other studies. However, to date, only one publication describes FLC levels in HIV infection. **Aims.** To determine whether the B-cell dysfunction in HIV leads to abnormal FLC levels and to correlate these levels with recognized markers of disease in HIV. **Methods.** We determined serum albumin, IgG, $CD4^+$ counts, viral loads and kappa (k) and lambda (λ) FLC levels on 369 HIV positive subjects. The k and λ FLC results were used to calculate a FLC ratio. These results were then correlated with $CD4^+$ counts, viral loads, IgG, albumin, stage of disease and the use of antiretroviral treatment (ART).Results. Our study population consisted of 66% females with a mean age for the whole population of 37.7 years (95%CI = 36.8 - 38.6). Most were black Africans (66%) followed by 26% of mixed ethnicity, with the remaining 8% being either Caucasian, of unknown race or another race. Eighty-nine percent were on ART. The k FLC values ranged from 5.59-387.0 mg/l (median 19.6 mg/l) and the λ FLC ranged from 9.28-286 mg/l (median 22.3 mg/l). Both k and λ FLC concentrations positively correlated with viral load ($p<0.05$) and IgG ($p<0.05$) and negatively correlated with $CD4^+$ counts ($p<0.05$) and albumin levels ($p<0.05$). Lambda FLC levels significantly correlated with stage of disease ($p<0.01$). Of all disease markers evaluated, the FLC ratio only correlated with IgG levels ($p<0.05$). A significant correlation was found between k and λ FLC and patients taking ART ($p<0.01$), with those on ART having lower FLC levels. However, the FLC ratio was not significantly affected by ART use ($p=0.98$). **Conclusions.** We demonstrated that FLC levels were significantly correlated with markers of HIV disease severity in our population. The fact that individual FLC levels but not the FLC ratio correlated with these markers may be due to the well-described polyclonal hypergammaglobulinemia that is associated with B cell dysfunction in HIV-infection. We postulate that individual FLC measurements may be of value in the follow up and monitoring of response to therapies in HIV positive patients.Acknowledgement: The Binding Site for supplying the FLC kits to perform this study and for providing ongoing scientific support.

ANTHRACYCLINES THERAPY INDUCES CHANGES IN ECG IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML).

J Dzietczenia, T Wrobel, A Butrym, O Dobrzynska, G Mazur, K Kuliczkowski
Wroclaw Medical University, Wroclaw, Poland

Background. Anthracyclines are widely used in AML therapy. Cardiotoxicity is a serious complication of anthracyclines treatment especially in patients with cardiovascular comorbidities.Variety methods have been used for evaluation of early cardiotoxicity in patients during and after anthracyclines administration. The R wave in lead aVL reflects left ventricle (LV) mass. The R wave changes may be associated with higher risk of cardiovascular disease.AimThe aim of this study was to evaluate the voltage of wave R and QRS in lead aVL and its significance as an indicator of early cardiotoxicity in patients with AML after anthracyclines-based chemotherapy.Materials and methods50 patients with newly diagnosed AML were included in the study (20 females and 30 males). The median age of patients was 47 years (range:18-65 years). 12 (24%) patients had hypertension (WHO 1 and 2) and 4 patients (8%) had type II diabetes mellitus.All patients were treated following the standard chemotherapy protocol based on daunorubicin in dose 60 mg/m^2 and conventional dose of cytarabine arabinoside (Ara-C). 12-lead ECG records with a paper speed of 50 mm/s were performed in all patients before chemotherapy and after first cycle with anthracyclines. ECG voltages were measured manually. In patients with hypertension and diabetes mellitus ECHO was performed. We evaluated ECG parameters as follows: R-wave voltage and total QRS duration, PQ interval and presence of repolarization changes in lead aVL.Statistical analysis was performed by means of Mann-Whitney's U-test using 'STATISTICA 8,0 software 'and $p<0,05$ indicated a significant difference.ResultsThe voltage of wave R in lead aVL after anthracyclines-based chemotherapy was significantly higher in comparison with values before treatment (0,6±0,13 mV vs 0,4±0,11 mV; $p<0,01$). The difference was even higher in patients with hypertension and diabetes mellitus. The total QRS voltage decreased significantly after chemotherapy (4,15±1,12 mV vs 4,59±1,56; $p<0,01$). Repolarization changes were observed in 5 patients (10%). We found no significant correlation between PQ interval at baseline and after chemotherapy. The results are shown in table 1.ConclusionOur results show that the value of voltage of the wave R in lead aVL could be the early indicator of anthracyclines-based cardiotoxicity before other changes in ECG and ECHO especially in patients with cardiovascular diseases .This observation should be validated by larger study.

Table 1: ECG measurements before and after anthracyclines chemotherapy in AML patients.

aVL mV	Before chemotherapy N=50	After chemotherapy N=50	P-value
R	0,4±0,11	0,6±0,13	<0,01
QRS	4,59±1,56	4,15±1,12	<0,01
PQ	0,15±1,23	0,16±1,54	0,08

N=number of patients

INTERFERON-GAMMA MRNA EXPRESSION CAN PREDICT VIROLOGIC RESPONSE TO HEPATITIS C VIRUS THERAPY IN PATIENTS WITH HCV GENOTYPE 4

F Attia, A Abel Rasol, G Eldin Rabie, F Attia
Faculty of Medicine, Ismailia, Egypt

Background and Aims. Ribavirin & peginterferon is the most effective treatment of chronic hepatitis C but has unpleasant side effects and high costs. A large proportion of patients do not respond to therapy for reasons that are unclear. We hypothesized that pretreatment gamma interferon gene expression level could be used to predict treatment outcome (responders and non-responders) in Egyptian HCV patients. **Subjects.** This study involved 29 HCV subjects; they were classified after the 24 weeks of a treatment regime (Ribavirin & peginterferon) into two groups (16 patients with non-detectable HCV classified as responders & 13 patients who had detectable HCV classified as non-responders). **Methods**. Baseline gamma interferon (IFN gamma) gene expression was measured by real time-polymerase chain reaction (RT-PCR) methods using glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as a housekeeping gene. **Results**. Levels of IFN-gamma expression were higher in the non-responder group compared with the responder group ($p<0.05$). There was no correlation between IFN-gamma expression levels, stage of fibrosis or viral

load level. **Conclusions.** An interferon gamma gene expression cutoff level of 0.54 at baseline (before starting the treatment regime) can discriminate patients with response from patients with failure of response. These data may be of use in predicting clinical responses to treatment

0971

LARGE UNSTAINED CELLS ON ROUTINE HEMATOLOGY ANALYZER CORRELATE WITH IMMUNE ACTIVATION LEVELS IN ASYMPTOMATIC TREATMENT-NAÏVE HIV INFECTION

H Ipp, N Vanker, A Abayomi
University of Stellenbosch and NHLS, Cape Town, South Africa

Background. HIV infection is characterized by ongoing immune activation and inflammation which drive the loss of CD4 T cells and progression to AIDS. Furthermore, despite adequate control of viral loads, patients are at increased risk of inflammatory-associated complications such as cardiovascular disease and cancer. The expression of the activation marker CD38 on CD8 T cells is a valuable measurement of immune activation levels in HIV-infection and has been shown to predict for poor prognosis in untreated patients and for reduced recovery of CD4 counts on antiretroviral therapy (ART). However, CD38 expression on CD8 T cells is measured by Flow Cytometry which may not be readily available in resource-limited areas. HIV continues to devastate Sub-Saharan Africa where the disease burden remains highest. Cost-effective screening measures to determine levels of immune activation may impact on management strategies in resource-limited settings. A full blood count is regularly requested in the work-up of these patients and may add value where Flow Cytometry is not readily available.aim:Our aim was to develop a method to assess immune activation and HIV disease progression, in resource-limited settings. The proposed method would have to be cost-effective and easy to perform on the equipment available in these settings.methods:Patients were recruited from a primary health clinic inCape Town,South Africa. The 80 cases were HIV-infected adults who were ART-naïve and clinically well, with 50 uninfected age- and sex- matched controls. Blood from these patients was used to measure: the CD38 expression on CD8 cells (%CD38onCD8), the percentage of large unstained cells (%LUCs), the CD4 count, the viral load and the total lymphocyte count. The %CD38onCD8 and CD4 counts were analyzed using Flow Cytometry; the viral load was quantified using Polymerase Chain Reaction (PCR)); and the total lymphocyte count and %LUCs were performed on a standard Hematology laboratory analyzer, the Siemens ADVIA 2120 system. The %LUCs usually include: virally activated lymphocytes, plasma cells, hairy cells, pediatric lymphocytes and peroxidase negative blasts. The %LUCs, %CD38onCD8, CD4 count, total lymphocyte count, and viral load were tested for statistical significance, and were then correlated against %LUCs. results:There were a statistically significant differences between the case and control groups, for the %LUCs (mean 2.5±0.9 vs 2.0±0.9; p=0.001); %CD38onCD8 (mean 57.8±19.7 vs 40.3±16.4; p=0.000) total lymphocyte counts (mean 1.7±0.5 vs 2.1±0.8; p=0.01); and CD4 counts (mean 405±177 vs 952±332; p=0.000). There was also a statistically significant positive correlation between %LUCs and %CD38onCD8 (r=0.3241; p=0.000) and a significant inverse correlation between %LUCs and CD4 counts (r= -0.248; p=0.006). There was no correlation observed between the %LUCs and the total lymphocyte count (p=0.570) or the viral load (p=0.208).conclusion:Our study found statistically significant correlations between %LUCs and both %CD38on8 and the CD4 count. The %LUC test is relatively cost-effective and easy to perform as part of the differential count, which is often requested with a full blood count. This suggests that large unstained cells may serve as a useful prognostic marker for HIV disease progression, in a resource-limited setting.

0972

SAFETY AND EFFICACY OF AN EDUCATIONAL PROGRAM IN REDUCING THROMBOTIC AND INFECTIVE COMPLICATIONS OF PERIPHERALLY INSERTED CENTRAL CATHETERS (PICCS) IN HAEMATOLOGICAL PATIENTS

A Malato, A Luppino, R Pipitone, MG Donà, F Acquaviva, F Fabbiano
Ospedali Riuniti Villa Sofia-Cervello, U.O. di Ematologia e UTMO, Palermo, Italy

Purpose. Patients with haematological disorders frequently require the insertion of medium or long-term central venous catheters (CVCs) for stem-cell transplantation, the administration of chemotherapy, or transfusion of blood products. Although peripherally inserted central catheters (PICCs) have been in use for many years, little data exist on their use in patients receiving intensive chemotherapy. **Methods.** Evidence-based interventions were implemented in our department in December 2010, and include:1.An high level nurse education program for correct practices and prevention of catheter-associated complications. was developed for PICC nursing team;2) The use of ultrasound guide for the insertion of the tip of PICCs, thanks to a special operator training; 3) Bedside placement and confirmed PICC tip placement by chest radiography after removal of the guidewire and before the securing of the catheter; 4) Maintenance of maximum sterile barrier precautions during PICC insertion and aftercare; 5) chlorhexidine preparation, replace 10% povidone iodine for skin antisepsis; 6) adoption of PICC patient nurse archive, including the information of weekly PICC line review at our department for each patient.Here, we carried out a clinical investigation to determine the efficacy of these interventions in reducing the rate of PICC-related complications (thrombotic events, exit site infection and other complications requiring early removal of PICCs) and to compare PICCs-specific complications (CR-BSI) with a cohort population defined as each consecutive CVC non tunneled inserted over a 6-month period (May-November 2009), and before these evidence-based interventions. **Results.** Ninety-fivePICCs were in place for a total of 7,295 PICC days (range, 1-331 days; mean, 76,7 days), and fifty-one CVCs were inserted before these interventions (range, 3-577 days; mean, 176,2 days). Sixty-six PICCs were inserted during severe thrombocytopenia (platelets < 50 x 10(9)/L), and 70 during severe neutropenia (neutrophils < 0.5 x 10(9)/L). The majority of the patients were affected by leukaemia, and PICCs were inserted to ensure adequate access throughout chemotherapy. Other mechanical complications occurred in 11 catheters, and were accidental dislodgement (4), catheter break (3), catheter inadequate (4). Compared with CVCs group, the PICCs group was associated with a lower incidence of CRBSI complication rate during neutropenia (1,05% vs 41,17%, 0,14 vs 3,67 per 1,000 CVC days) [odds ratio (OR) 0,051; relative odds reduction (ROR) 0,98]. The rate of thrombotic complications was lower in PICCs group (0,27 per 1,000 CVC days, vs 0,70 per 1,000 CVC days) [odds ratio (OR) 0,252; relative odds reduction (ROR) 0,747]. **Conclusions.** Our results indicate that a training and competence assessment program is effective in reducing the main complications PICCs-related in haematological setting.

MINIMAL RESIDUAL DISEASE AS A PREDICTIVE FACTOR FOR ADVERSE OUTCOME AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA

R Grubovikj, G Schiller
Stem Cell Transplant Program, David Geffen School of Medicine at UCLA, Los Angeles, United States of America

Background. Allogeneic hematopoietic stem cell transplantation (allo-SCT) is potentially curative for patients with high-risk leukemia, but disease recurrence remains the leading cause of treatment failure. Our **aim** was to determine the impact of minimal residual disease (MRD) by any technique in adult patients with acute myeloid leukemia (AML) in morphologic first (CR1) and second complete remission (CR2) undergoing allo-SCT in predicting adverse outcome. **Materials and methods.** Our study group consisted of AML patients in first and second complete remission treated in the Hematologic Malignancies/Stem Cell Transplant Unit at the UCLA, from January 2000 through January 2010 using allogeneic bone marrow, blood-derived and cord blood stem cells from histocompatibile related and unrelated donors. For the MRD assessment we used multiparametric flow cytometry, cytogenetics and fluorescent in situ hybridization. Any level of residual disease was considered MRD positive. **Results.** 59 patients were eligible for the study of 160 patients transplanted over ten years; 19 patients (32.2%) were identified as MRD positive. Patients with MRD had a consistently worse outcome over those without MRD, with 3-years leukemia-free survival (LFS) of 15.8% vs. 62.4 % and overall survival (OS) of 17.5% vs. 62.3%. Relapse rate was significantly higher in MRD-positive patients; 3 years relapse rate in MRD-positive patients was 57.9% vs. 15.1% in MRD-negative patients. Detection of MRD in complete remission was associated with increased overall mortality (HR=3.3; 95% CI: 1.45-7.57; p=0.0044) and relapse (HR=5.26; 95%CI: 2.0-14.0; p=0.001), even after controlling for other risk factors. There was no statistically significant difference in the MRD techniques employed in predicting adverse outcomes. **Conclusions.** Our study showed that for patients in morphologic complete remission the presence of MRD predicts for significantly increased risk of relapse and reduced LFS and OS. Presence of MRD in pre allo-SCT AML patients defines a high risk group of patients. Further therapeutic possibilities in these patients, such as post-transplant donor lymphocyte infusions (DLI), alternative high dose conditioning regimens, adjuvant treatments, or other early therapeutic intervention should be considered.

COINFUSION OF HAPLO-IDENTICAL DONOR STEM CELLS WITH AN (UN)RELATED CORD TRANSPLANT PROVED TO BE SUCCESSFUL IN A VERY HIGH RISK GROUP OF PATIENTS

C Lindemans, J Kuball, L te Boome, A Versluys, M Bierings, J Boelens
UMC Utrecht, Utrecht, Netherlands

Background. Combining haplodonor stem cells with a full graft cord blood unit has been proposed as a cell support mechanism which can make single cord blood available as a donor source for allogenic HSCT to a larger proportion of patients: e.g. patients with only CB donors available with low NC counts or active infection.MethodsSince 2009 we have a CB + haplo protocol for this groups of patients, with either active ongoing infection or a high probability of graft failure. Patients (with any indication) with active infection (e.g. fungal) as well as patients with only one CB-unit available below the lower acceptable NC number cut-off were offered CB + Haplo grafts. Conditioning: 1st HSCT myeloablative busulfan with therapeutic drug monitoring + fludarabine and ATG; 2nd HSCT reduced intensity with Treosulfan, fludarabine and campath The haplografts were CD34+ selected (except 1: CD3/CD19 depleted). After infusion of the CB, 5 milj/kg Cd34+ haplo-cells were infused. G-CSF was given from day +7. All patients received GvHD profylaxis with CsA and pred 1 mg/kg.Results.11 patients (10 children, 1 adult; 10 with active infection, 1 low cell count CBU) were transplanted with haplo-cord transplantation. Median age was 12,4 yr (0.25-42,2 yr). 8 of them had non-malignant disease (6 immunodeficiencies, 1 Osteopetrosis, 1 AA), 3 had a malignant indication. For 2 patients it was their second transplant. All patients but one engrafted at a median time of 12 days post HSCT (9-15). Median thrombocyte engraftment (TBC50) was 29 days (14-300). EFS was 27 % after a median follow-up of 324 days (14-1387). Incidence of GVHD gr. 2-4 was 18%. The non-relapse mortality was 2/11 (day 14 and day 24 respectively) The initial chimerism at 1 month post SCT showed > 80% haplo chimerism in most patients. However, all reach full donor *cord blood* chimerism (>95%) by a median of 121 days (28-925 days) post SCT.ConclusionCoinfusion of a CD34 selected haplo graft with (unrelated) CB transplantation is a safe and effective option for a group of very high risk patients (including patients with higher non-engraftment risks) Haplo-support leads to early haplo-engraftment, switching to full CB donor chimerism within 4 months, allowing a normal immune recovery and repertoire. A remarkably low incidence of GVHD was observed for this high risk population

IS THE USE OF 9/10 HLA UNRELATED DONORS STILL ACCEPTABLE IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR HEMATOLOGICAL MALIGNANCIES?

M Michallet, M Sobh, S Morisset, M Detrait, H Labussière, N Tedone, S Ducastelle, F Barraco, Y Chelghoum, X Thomas, F Nicolini
Centre Hospitalier Lyon Sud, Pierre Bénite, France

Introduction. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) represents the only potential to cure wide types of hematological diseases. The use of 10/10 HLA matched unrelated transplants has been used as a main alternative and with its unavailability, when available, a 9/10 HLA mismatched unrelated transplant has been used. **Aims.** To evaluate the outcomes of allo-HSCT from 9/10 HLA mismatched unrelated donors compared to those from 10/10 HLA identical unrelated donors and siblings; and to define which category of patients can benefit the more in each alternative. **Methods.** We have retrospectively studied the outcome of 213 patients who received allo-HSCT for different hematological malignancies, 121 (57%) from HLA identical siblings, 63 (29%) from 10/10 HLA identical unrelated donors and 29 (14%) from 9/10 HLA mismatched unrelated donors treated during the same period of time between 2006 and 2011 at our institution. The different characteristics are detailed in Table 1.

CI TRM at 12m.	12% (9-15)	33% (27-39)	45% (35-55)	<0,0001

Results. After HSCT, engraftment was significantly lower in the 9/10 HLA group (90%) than in the 10/10 HLA group (95%) than in the sibling group (99%), (p=0.03); the cumulative incidence of acute GVHD≥2at 3months was 32% (23-41), 20% (15-26) and 27% (23-32) respectively; the cumulative incidence of extensive chronic GVHD at one year was 21% (13-30), 9% (5-13) and 17% (14-21) for the 3 groups respectively. After a median follow-up of 8 months (0-54) in the 9/10 HLA group, 10 months (0-60) in the 10/10 HLA group and 18 months in the siblings group, the median overall survival (OS) was 10 months (5-21), 18 months (11-NR) and 60 months (31-NR) respectively with a 2-years probability of 19% (8-44), 43% (31-59) and 63% (54-74) respectively (Figure). There

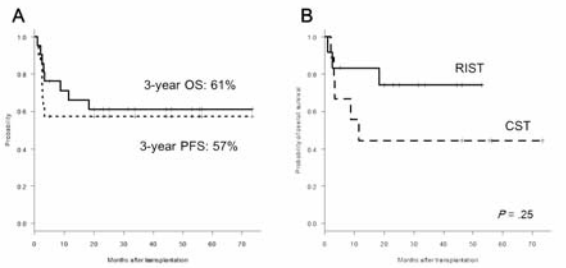
was a higher but not significant relapse incidence at one year in the 9/10 HLA group compared to other groups while the transplant related mortality was significantly higher with a cumulative incidenceat 1year of 45% (35-55), (p<0.001) (Table1-results). In multivariate analysis, OS was negatively affected by unrelated donors [9/10 HR=5 (2.7-10), p=0.0001; 10/10 HR=2 (1.2-4), p=0.01], female donors [HR=2 (1.4-4), p=0.03] and disease status < CR1 or <0.001; 10/10 HR=4 (1.2-10), p=0.03], female donors [HR=3 (1.2-7); p=0.01] and ABO minor incompatibility [HR=2.5 (1.2-5), p=0.01]. The funnel plot showing the adjusted TRM according to all covariates and comparing to the global population death rate, shows that the 9/10 HLA group has the worse TRM independently of any other factor.**Conclusion**We showed that allo-HSCT from 9/10 HLA mismatched unrelated donors have a significantly worse OS than those from matched unrelated donors and siblings; this was mainly due to an increased TRM in this group. Patients in first CR or CP could benefit the more from matched or 9/10 unrelated allo-HSCT while the use of transplants from 9/10 HLA unrelated donors in patients not in CR should be limited to clinical trials.

0976

FAVORABLE OUTCOME OF REDUCED-INTENSITY STEM CELL TRANSPLANTATION FOR ADULT T-CELL LEUKEMIA

F Iwai[1], H Kaneko[1], G Tatsumi[1], T Matsumoto[1], S Inada[1], Y Sueki[1], N Toyooka[1], S Fujii[1], C Nakamura[1], M Watanabe[1], H Hirata[1], Y Miura[2], M Tsudo[1]
[1]Osaka Red Cross Hospital, Osaka, Japan
[2]Kyoto University Hospital, Kyoto, Japan

Background. Adult T-cell leukemia (ATL) endemic in southwestern Japan is an HTLV-I-induced mature T-cell neoplasm. It has a dismal prognosis when treated with conventional chemotherapy, mainly because ATL cells overexpress multidrug-resistance genes. Allogeneic hematopoietic stem cell transplantation (allo-SCT) has been reported to improve the prognosis. However, it is also known that allo-SCT shows high treatment-related mortality (TRM) because of disease characteristics of severely deteriorated cellular immunity. **Aims**. We evaluated the outcome of reduced-intensity stem cell transplantation (RIST), compared to conventional stem cell transplantation (CST) for ATL patients.



Methods. We retrospectively analyzed consecutive 21 patients with aggressive ATL (acute type, 17; lymphoma type, 4) who underwent allo-SCT between 2001 and 2011 in our institute. The median age at transplantation was 55 years (43-65). All patients received induction chemotherapy with Japan Clinical Oncology Group regimen (VCAP-AMP-VECP) or biweekly CHOP and disease status at transplantation was 3 CR, 11 PR, 4 SD and 3 PD. The median time from diagnosis to transplantation was 7 months (4-14). Nine patients received a conventional myeloablative conditioning with CY/TBI-based (n=8) or BU/CY-based (n=1) regimen and 12 patients received a reduced-intensity regimen (fludarabine 25 mg/m^2 on days -6 to -2 + melphalan 40 mg/m^2 on days -4 and -3 ± TBI 4 Gy on day -1). The age of patients who received RIST was significantly older than that of CST (median 59 vs 49, P < .001). The other parameters were balanced between the two groups. Stem cell source was bone marrow (n=17) and peripheral blood (n=4). Graft-versus-host-disease (GVHD) prophylaxis consisted of cyclosporine plus short-term methotrexate (sMTX) for HLA-matched sibling donor recipients and tacrolimus plus sMTX for the others. *Results.* The estimated 3-year overall survival (OS) and progression-free survival (PFS) rates for all patients were 61% and 57%, respectively (Figure 1A). At the median follow-up duration of 27 months (1-73), 13 patients were alive. The cumulative incidences of disease-associated mortality and TRM at 3 years were 20% and 19%, respectively. Importantly, after 1 year post-transplantation, the curve of PFS reached plateau phase. Therefore, allo-SCT could be a curable therapy for ATL. It is notable that RIST showed excellent OS. Although not significant, 3-year OS for RIST and CST were 74% and 44% (P = .25), respectively (Figure 1B). TRM of RIST trended to be low compared with that of CST (17% vs 22%, P = .80). In addition, chronic GVHD was observed in 83% of the evaluable 12 patients. It is suggested that both improvement of TRM and the induction of graft-versus-leukemia effects may contribute to the favorable outcome in RIST for ATL. Furthermore, it should be stressed that older patients who preferentially received RIST rather than CST achieved favorable survival comparable to younger patients (≥ 50 years: 61% vs < 50 years: 60%, P = .86). *Conclusion:* Allo-SCT for aggressive ATL remarkably improved the poor prognosis. Especially, RIST is a promising procedure for excellent outcome. We would suggest that RIST should be applied to all aggressive ATL patients eligible for allo-SCT, regardless of the age.

0977

LONGITUDINAL FOLLOW UP OF MINIMAL RESIDUAL DISEASE IN AML AFTER SCT WITH QUANTITATIVE EVALUATION OF WT1 GENE EXPRESSION

A Candoni, E Simeone, R Gallina, E Toffoletti, C D'Odorico, F Zanini, R Fanin
Hematology and BMT unit, Udine, Italy

Introduction. Wilms Tumor gene (WT1) overexpression is described in several oncological diseases including acute myeloid (AML)leukemias. The majority of AML patients don't have a suitable specific molecular marker for monitoring minimal residual disease(MRD). Quantification of WT1 in bone marrow samples can be useful as a marker of MRD after allogeneic stem cell transplantation (SCT) and can predict AML relapse.METHODS and RESULTS. We have evaluated, sequentially and using a quantitative RT-PCR technique (LeukemiaNET method), WT1 expression in 50 consecutive AML patients that overexpressed WT1 at diagnosis and that underwent allogeneic SCT at our centre. The cDNA level of WT-1 was detected in bone marrow samples at diagnosis at the time of transplant and after the allogeneic SCT. Samples of diagnosis showed high WT1 expression levels in all cases with a mean of 5570 (SD 4055) copies of WT1/10000 Abl, median 4600 (range 658-23913) copies WT1/10000 Abl. At transplant 34 pts (68%) were in complete cytologic remission (CcR) and 16 (32%) had refractory or relapsed AML. Bone marrow samples from pts in CcR at BMT showed significantly lower WT1 expression levels (mean 88±130), compared to the samples from pts with relapsed or refractory disease (mean 5727±4265) (P < 0,001). After BMT a rapid decline of WT1 expression levels was observed in all pts that achieved and/or maintained a condition of CcR, especially in those that were in CcR at SCT. After a median follow up of 11 mths from transplant, 10 out 50 pts relapsed (20 %) and all of them had high expression levels of WT1 before the cytological relapse. Three of these pts were successfully reinduced with DLI ± chemotherapy with a rapid reduction of WT1 levels.CONCLUSIONS. 1)In our experience there is a complete concordance between WT1 expression levels (measured by quantitative RT-PCR) and status of AML before and after SCT. 2)Our study confirms that longitudinal quantitative evaluation of WT1 after SCT may be useful as a non-specific leukemia marker (NSLM) for monitoring MRD and as a predictor of AML relapse. 3) Based on these results cases with an increase of WT1 levels after SCT and without GVHD should be candidate to DLI and/or discontinuation of immunosuppressive therapy.

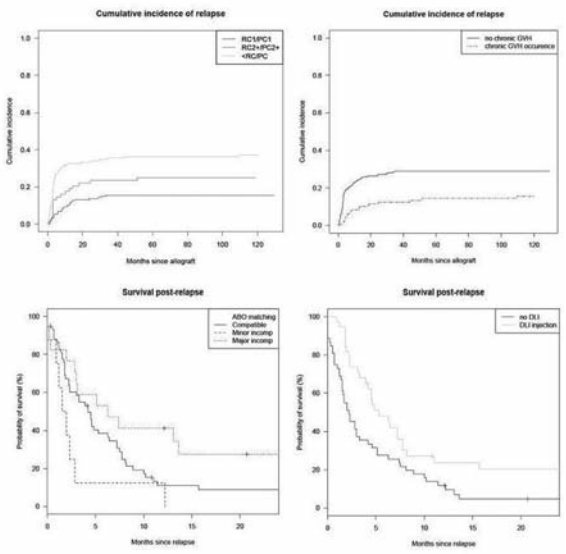
0978

RELAPSE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN HEMATOLOGICAL MALIGNANCIES: FACTORS IMPACTING ITS OCCURRENCE AND TREATMENT OPTIONS FOR A BETTER MANAGEMENT

M Michallet, M Sobh, S Morisset, M Detrait, H Labussière, S Ducastelle, F Barraco, Y Chelghoum, X Thomas, F Nicolini
Centre Hospitalier Lyon Sud, Pierre Bénite, France

Introduction. Relapse remains a major cause of mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in patients with hematological malignancies. **Aims.** To evaluate at a first time the different pre- and post-transplantation factors impacting the relapse occurrence after allo-HSCT, and at a second time, to evaluate factors impacting the survival post-relapse including the different treatment options. **Methods.** We have retrospectively studied the occurrence of relapse in 345 patients, 198 (57%) males and 147 (43%) females with a median age of 43 years (range17-66) who received allo-HSCT at our institution for hematological malignancies between years 2000 and 2011; 205 (59%) from siblings donors and 140 (41%) form unrelated donors. At transplantation, there were 148 (43%) patients in first complete response or first chronic phase (CR1/CP1), 66 (19%) in CR2/CP2 and 131 (38%) < CR2/CP2. Two hundred and six (60%) patients received a full intensity condi-

tioning and 139 (40%) a reduced intensity one. The different patients and transplantations characteristics will be communicated during the meeting. **Results.** After HSCT, 336 (97%) patients engrafted. The cumulative incidence of acute GVHD≥2at 3months was 35% (95%CI 32-37); the cumulative incidence of extensive and limited chronic GVHD at one year was the same 15% (95%CI 13-17). After a median follow-up of 11.4 months (range 4-129), the median overall survival (OS) for the whole population was 19 months (range 12-33) with a 2-years probability of 47% (95%CI 42-53). Eighty eight (25.5%) patients relapsed with a cumulative incidence at one and two years of 19% (95%CI 17-21) and 22% (95%CI 20-24) respectively. After relapse, 65 (74%) patients were treated [21 (32%) received donor lymphocyte infusion (DLI) alone, 21 (32%) chemotherapy alone, 14 (22%) DLI + chemotherapy and 9 (14%) received other treatment] and 23 (26%) were not treated due to deadly relapse. The median OS from relapse was 4 months (range 3-5) and the one year probability of OS in patients who relapsed was 21% (95%CI 14-31).The multivariate analysis studying the pre- and post-relapse variables on the survival after relapse showed a positive impact of ABO incompatibility [Major ABO incompatibility: HR=0.39 (0.16-0.9), p=0.03], a negative impact of disease status [HR=2.4 (1.3-4.4), p=0.003] and a positive survival outcome in patients receiving DLI [HR=0.5 (0.3-0.8), p=0.005].



Conclusions. Survival after relapse post-allo-HSCT is still very low reflecting the difficulty to find an optimal treatment, disease status at transplantation seem to have a long term effect while the use of DLI with or without chemotherapy can offer better results. In addition to the new chemotherapy molecules, immunotherapy should be used in order to enhance the graft-versus-leukemia effect not only after relapse, but also early in presence of a minimal residual disease.

0979

REDUCED INTENSITY CONDITIONING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH AGGRESSIVE CHRONIC LYMPHOCYTIC LEUKEMIA

H Kaur[1], C Anthias[2], J Baddeley[1], J Byrne[1], E Dasgupta[1], M Ethell[2], M Potter[2], B Shaw[2], N Russell[1]

[1]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

[2]Royal Marsden Hospital, London, United Kingdom

Background. Allo-HSCT remains the only curative option in patients with CLL. With the median age at presentation of 72 years, and the high TRM associated with myeloablative conditioning regimens, several groups have opted for a reduced-intensity conditioning (RIC) approach which appears to provide long-term disease control in a subset of patients with aggressive disease **Aims.** There have been recent reports suggesting that the use of pre-transplant alemtuzumab and/or T-cell depleted conditioning regimens may increase the risk of early relapse/progression. We therefore assessed the outcomes of CLL patients undergoing RIC allo-HSCT with a T-cell replete conditioning regimen in terms of TRM, acute and chronic GVHD, OS and relapse/progression post-transplant.**Methods**A retrospective analysis was performed on 19 consecutive patients with biologically aggressive CLL who underwent RIC allo-HSCT from NottinghamUniversityHospitalsand the RoyalMarsdenHospitalbetween 2008 and 2011. All patients received Fludarabine 90mg/m^2 and 2Gy TBI conditioning, with mycophenolate mofetil and cyclosporine for GVHD prophylaxis. Biologically aggressive disease was characterized by del(17p13) or del(11q23) cytogenetic abnormalities and/or purine analogue refractoriness and/or high-grade transformation.

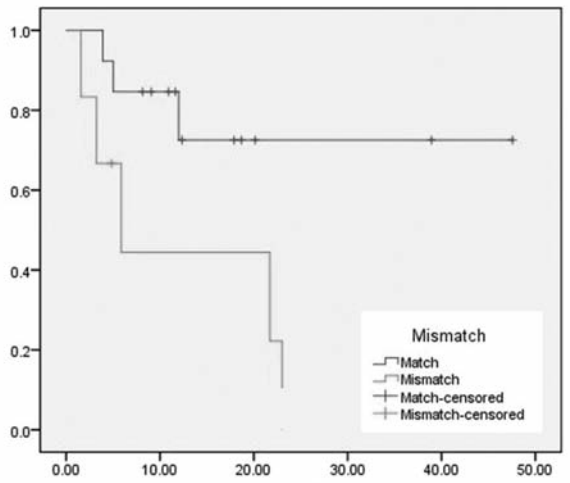


Figure 1. Overall survival comparing matched (sibling and unrelated donor) vs. mismatched donor allografts.

Results. Median age at the time of allo-HSCT was 59 years (range 48-69). Only 2 patients were female. Median duration from CLL diagnosis to allo-HSCT was 5.8 years (range 1-15). Patients received a median of 3 lines of chemotherapy pre-transplant (range 1-7). 13/19 patients had received purine analog-based chemotherapy of whom 12/13 were refractory, 15/19 had alkylating agents and 14/19 had alemtuzumab. Two patients had high-grade transformation during the course of their disease. On evaluation by FISH, 9 patients haddel(17p13), 5 haddel(11q23) and 2 haddel(13q14).At the time of allo-HSCT, 5 patients were in CR, 11 in PR and 3 had SD. 16/19 patients received unrelated donor allografts (10 matched by high-resolution typing at HLA-A, B, C, DRB1 and DQB1; 6 mismatched) and 3/19 received HLA-identical sibling grafts; 18/19 patients received PBSC.Patients were followed up for a median of 1 year (range 0.1-3.9). 11/19 patients remain alive, of whom 10/11 are in CR, and 1/11 in stable PR. OS at 1 year is 72% and 32% at 2 years, with a marked difference in survival between the HLA-matched (sibling and UD) vs. mismatched transplants (85% vs. 44% at 1 year, 72% vs. 16% at 2 years). This was due to a higher TRM in mismatched transplants. Acute GHVD occurred in 11/19 patients with 4/11 patients developing Grade 3-4 GVHD. 11/19 patients developed chronic GVHD, which was extensive in 6/11 patients. Viral reactivation occurred in 8/19 patients (5/8 CMV with one causing CMV disease, 2/8 HHV6 and 1/8 EBV). The use of alemtuzumab pre-HSCT, number of prior treatments, patient age or donor source were not predictive of outcome. **Conclusions.** In this cohort of patients with high risk CLL, degree of HLA matching was found to be the greatest predictor of OS following RIC allo-HSCT. Excellent results can be achieved with matched sibling and unrelated donors. Our results would suggest avoiding the use of mismatched donors in this setting.

[7]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Plerixafor has been recently approved to enhance mobilization of peripheral blood stem cells (PBSC) in combination with G-CSF in patients with lymphoma and multiple myeloma. Prospective monitoring of CD34 levels on day 4 of G-CSF could allow identifying patients for whom the benefit derived from the enhanced mobilization capacity of plerixafor can be maximized. To uniformly manage these patients who appear to mobilize poorly, we present our preemptive algorithm of plerixafor use based on PB CD34 cell counts on day 4 of G-CSF as a target. Forty one patients (7 myeloma, 34 lymphoma; 24 men; median age 58 [27-69]; 68% failed prior mobilization attempts [1-4]) with suboptimal PB CD34 cell levels on day 4 of G-CSF steady-state mobilization and receiving plerixafor rescue treatment (CD34/µL <5, n=25; 5-10, n=13; 10-20, n=3) were compared with 130 coetaneous controls from the same institutions (53 myeloma, 77 lymphoma; 73 men; median age 56 [22-71]; 11% with prior failed mobilization attempts [1-2]) with day 4 CD34 level monitoring who did not receive plerixafor (CD34/µL <5, n=47; 5-10, n=20; 10-20, n=63). Plerixafor administration on day 4 significantly increased the PB CD34 level 4.7-fold±2.8, even for the subgroups with <10 CD34/µL (4.7-fold ±2.9) and <5 CD34/µL (5.3-fold ±3.2) compared to G-CSF alone (2±1.1 for all subgroups, p<0.001). In particular, patients with <10 CD34+ cells/µL on day 4, who are more likely to mobilize poorly, collected higher numbers of PBSC with plerixafor compared to G-CSF alone in the first apheresis (2.3 vs 0.6 CD34 x10^6/kg; p<0.001) and overall (2.9 vs 1.02 CD34x10^6/kg; p<0.001). Moreover, the preemptive use of plerixafor provided >=2x10^6/Kg CD34 cells in 74% of these patients compared to 27% with G-CSF alone (p<0.001). Even in patients with baseline PB CD34 levels <5/µL, plerixafor provided a CD34+ yield of 1.8±1.5 x10^6/kg in the first apheresis, and 2.4±1.5 x10^6/kg overall, successfully collecting >=2x10^6/kg CD34 cells in 68% of these patients vs 15% with G-CSF alone (p<0.001). In first mobilizations attempts, the addition of plerixafor in the evening before the first apheresis, significantly increased up to 92% (vs 28%, p<0.001) and 86% (vs 16%, p<0.001) the number of patients collecting overall >=2x10^6/kg CD34 cells when the PB CD34 on day 4 were <10/µL and <5/µL, respectively. There were no adverse drug-related events. Up to now, 29 plerixafor patients (71%) have received an autologous HSCT with a median CD34+ cell dose infused of 3.4 (1.6-7.2) x10^6/kg. Of note, all patients engrafted and reached >0.5x10^9/L neutrophils after a median of 12 (10-21) days and achieved a self-sustained platelet count >20 x10^9/L after a median of 15 (11-28) days. No cases of secondary graft failure were observed. Based on these data, it seems possible to establish an algorithm for preemptive plerixafor use based on day 4 PB CD34+ cell counts. This strategy may identify potential poor mobilizers (<10 CD34+ cells/µL on day 4) for whom the incremental benefit of plerixafor is maximized. This approach may translate into a reduction of remobilization attempts, preventing from treatment delays and improving cost-effectiveness and resources utilization.

RECONSTITUTION OF THE T CELL COMPARTMENT AND THE THYMIC FUNCTION AFTER REDUCED-INTENSITY ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

B Bruno[1], P Omedè[1], S Cena[1], V Boccasavia[1], M Gilestro[1], L Cimolin[1], S Mattia[1], C Sfiligoi[1], L Giaccone[1], M Festuccia[1], F Ferrando[1], R Passera[2], M Boccadoro[1]

[1]Division of Hematology, University of Torino, Torino, Italy

[2]Division of Nuclear Medicine 2, A.O.U. San Giovanni Battista, Torino, Italy

Background. The thymus plays a pivotal role in generating naive T cells from hematopoietic precursors and long-term immune reconstitution after allografting. **Aims.** To asses the short- and long-term reconstitution of the CD4+ T cell compartment and the residual thymic activity in elderly patients undergoing allogeneic hematopoietic cell transplantation. **Methods.** The study population consisted of 63 consecutive recipients, median age 56 (r 23-67), of a T cell repleted allograft from siblings or unrelated donors after thiotepa/cyclophosphamide-based reduced-intensity or low-dose total body irradiation-based non-myeloablative conditionings. One patient underwent thymectomy 10 years before the allograft. The reconstitution of the CD4+ T cell compartment was evaluated by flow cytometry. Naïve, central memory, effector memory, and "revertant"CD4+ T cells were identified by co-expression of CD45RA and CD27, CD45RO and CD27, expression of CD45RO (CD27 negative), and co-expression of CD45RA and CDRO, respectively. Blood samples were drawn at baseline, and at 3, 6, 12, 18 and 24 months post-transplant. To quantify residual thymic function and to differ true naïve CD4+ from "revertant"CD4+ T cells, T-cell receptor excision circles (sjTRECs) were assessed by real time PCR at the same time points on DNA extracted from sorted CD4+ T cells. sjTRECs are episomal excision products of the T cell receptor gene rearrangements that occur in maturing thymocytes; do not replicate during mitosis and are diluted during cell division providing an excellent measure of thymic function during periods of immune reconstitution. Primary endpoint was the trend over time of sjTRECs copy number/ 100 ng DNA; secondary endpoints were trends over time of naïve, central memory, effector memory, and revertant CD4+ T cell numbers after transplant, and their potential modifications by patient- and transplant-related independent variables. Univariate and multivariate analyses included: age at transplant (>56 vs. ≤56 years), gender (female vs. male), conditioning regimen (reduced-intensity vs. non-myeloablative), donor type (unrelated donor vs. sibling donor), disease status at transplant (less than CR vs. CR), occurrence of acute graft-vs.-host disease (GVHD) and chronic GVHD, number of CD3+ and CD34+ cells/ kg recipient body weight infused.*Results.* Naïve, central memory, effector memory, and, to a far lesser extent, "revertant"CD4+ T cell values showed a gradual significant increase throughout the study period. However these values were lower than those observed in healthy donors. A gradual statistically significant increase in sjTRECs from baseline up to 2 years post-transplant was also observed (p<0,001). Importantly, siTRECs levels were undetectable in the patient who had undergo thymectomy prior to transplant. By multivariate analysis, a significantly lower sjTRECs increase was seen in patients conditioned with a reduced-intensity rather than a non-myeloablative regimen (p=0,008), transplanted from an unrelated donor (p=0,002), and in those who developed chronic GVHD (p=0,029). By contrast, no differences were seen in patients who developed acute GVHD from those who did not. **Conclusions.**Effective residual thymic activity contributing to long-term immune reconstitution was seen in this elderly patient cohort. The thymus remains sensitive to chemotherapy-induced damage and is the target of chronic GVHD but not acute GVHD.

0982

ETANERCEPT FOR STEROID REFRACTORY ACUTE GRAFT VERSUS HOST DISEASE: THE SCOTTISH EXPERIENCE

D Clark, A Copland, I McQuaker, N Parker, A Nicholson

Beatson Oncology Centre, Glasgow, United Kingdom

Background. Etanercept is a recombinant human tumour necrosis factor alpha (TNF-α) receptor fusion protein that inhibits the action of TNF-α, a cytokine crucial in the pathogenesis of acute GvHD. Etanercept has shown potential benefit in treating steroid refractory acute GvHD. **Aims.** We report the experience of using Etanercept for the treatment of acute GvHD in the Scottish alternative donor HSCT unit. **Methods.** This study is a retrospective analysis of patients who received Etanercept for acute GvHD between May 2008- August 2011. Transplant demographics, prior treatment for GvHD, Etanercept treatment, complications and outcomes were assessed. Etanercept was administered as 25mg subcutaneously twice weekly for 4 weeks, followed by 25mg weekly for 4 weeks. **Results.** 19 patients with acute GvHD were identified; 7 classical acute GvHD (2 post DLI), 9 late onset acute GvHD, 3 acute pulmonary GvHD/Idiopathic pneumonia syndrome. Patients with classical acute GvHD all had grade III/IV disease and were refractory to corticosteroids, while late onset patients had grade II disease and had had partial response to previous therapies. Diseases were AML (n=6), ALL (n=3), CLL/Lymphoma (n=6),CML (n=2),MF (n=1), Fanconi Anaemia (n=1). Stem cell source was PBSC in all cases. Conditioning was myeloablative in ten cases and reduced intensity (RIC) in nine. GvHD prophylaxis was with Ciclosporin and short course methotrexate in the myeloablative patients and ciclosporin alone in the RIC patients. Donor was a sibling in eight patients, a volunteer unrelated donor in nine (10/10 (1 second transplant) (n=6), 9/10 (n=2), 8/10 (n=1)), and double umbilical cord blood in two patients (4/6 x 4). The average cell dose was 6.1x10^6/kg. All had evidence of GvHD at multiple sites; gastrointestinal disease was most common n=15, liver n=12, skin n=12, lung n=3. The median number of prior therapies

was four (1-6). The median days from transplant to Etanercept treatment was 139 (47-4316) and from onset of GvHD was 68 (10-3986). The median number of doses of etanercept was eight (4-12) and concominant therapies was three (2-5). Concomitant therapies included corticosteroids ,ciclosporin, tacrolimus, MMF,photopheresis and BudesonideResponses were seen in 6/9 (66%) late onset patients (1CR, 5PR); 3/7 (43%) classical acute (3PR), and 0/3 acute lung damage. All patients who responded were able to reduce or stop steroids and had improvement of the gastrointestinal component of their disease. There were 4 long term responders in the late acute GvHD group (3 alive, 1 died MI). Unfortunately, in the classical acute GvHD patients, all responders died of infection, with recurrence of GvHD in 2/3. **Conclusions.** n our hands, Etanercept was ineffective in treating acute pulmonary injury < 100 days post transplant and there was limited durable efficacy in those patients with severe grade III/IV classical acute GvHD with true steroid refractoriness. However, valuable, durable responses were seen in patients with late onset acute GvHD, especially affecting GI tract, where steroid doses were able to be reduced or stopped.

AUTOLOGOUS STEM CELL TRANSPLANTATION AS SALVAGE TREATMENT FOR PRIMARY REFRACTORY/RELAPSED HODGKIN AND NON HODGKIN LYMPHOMA: LONG-TERM OUTCOME IN OVER 300 PATIENTS

D Donnini, L Rigacci, B Puccini, S Guidi, C Nozzoli, G Benelli, A Gozzini, A Bosi
Careggi, Florence, Italy

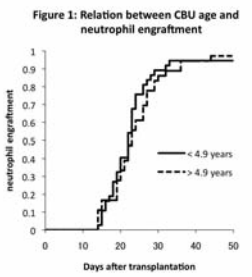
Aims. To analyze clinical outcome and significant prognostic factors for overall survival (OS) and progression free survival (PFS) in patients(pts) with Hodgkin (HD) and non Hodgkin lymphoma (NHL) undergoing autologous stem-cell transplantation (ASCT). **Methods.** Between October, 1987 and November, 2010 330 pts with HL and NHL that were not controlled by conventional chemotherapy underwent high-dose chemotherapy and ASCT by our transplant centre.Results. 216 pts were NHL and 114 HD, 183 were male, median age was 39 years (range, 15 to 67 years). At the time of ASCT 161 (125 NHL, 36 HDG) were in complete remission (CR), 72 (55 NHL, 17 HDG) were in partial remission (PR) and 97 (36 NHL, 61 HDG) presented a resistant disease (RD). All pts received chemotherapy with high-dose regimens: 126 were treated with BEAM, 119 with ICE, 67 with Mitoxantrone-Melphalan and 18 were treated with other type of therapy. To proceed to ASCT, pts had to have adequate cardiac, pulmonary, hepatic, and renal function. The median time to engrafment was 11 (range 7-20) days for absolute neutrophil count (>500), 11 (range 5-40) days for platelets (20.000). After ASCT 204 pts were in CR, 44 were in PR and 82 presented a RD. With a median period of observation of 61 months (CI 95% 54-67) 221 pts are alive and 109 are death, the overall survival (OS) calculated with the Kaplan Mayer method is 59%. With a median period of observation of 49 months (CI 95% 40-52) 162 pts are free from progression and the progression free survival (PFS) is 49%. No differences in OS or PFS were observed between NHL and HD (respectively 67% vs 55% and 51% vs 46%). In NHL OS was significantly superior in pts arrived at transplant in CR (p:.003), and in pts treated with no more than two previous chemotherapy (p:.002); in HD, OS was affected only by the CR status at transplant (p:.01). Similarly, in NHL PFS was significantly affected by CR status at transplant (p:.0000) and to have received less than three previous therapy (p:.001); in HD only CR status at transplant affected significantly the PFS (p:.0004). **Conclusions.** this monocentric data confirm the importance of ASCT as salvage treatment either in NHL or in HD, in NHL it seems better to use this strategy earlier in the history of the disease while in HD even ptstreated with several therapy, reaching a response before transplant, obtain excellent results. Finally chemo-sensibility remains the most important factor for prognosis.

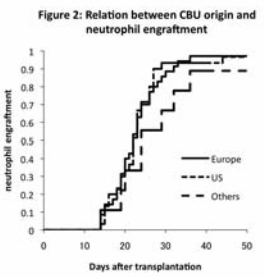
0984

HEMATOLOGICAL RECOVERY AFTER INTRA-BONE CORD-BLOOD TRANSPLANTATION IS INFLUENCED BY NUMBER OF TOTAL NUCLEATED CELLS AND CD34 CELLS, BUT NOT INFLUENCED BY ORIGIN OF BANKS OR TIME OF CRYOPRESERVATION

N Kurita[1], F Frassoni[2], N Sacchi[3], C Cossu[2], A Serio[2], D Cilloni[4], M Podestà[2]
[1]University of Tsukuba, Tsukuba, Ibaraki, Japan
[2]Ospedale San Martino, Centro Cellule Staminali e Terapie Cellulari, Genoa, Italy
[3]Ospedale Galliera, IBMDR, Genoa, Italy
[4]University of Turin, Dept. of Clinical and Biological Sciences, Orbassano, Italy

Background. Cord-blood transplantation (CBT) is an effective option for both malignant and non-malignant hematological diseases and its increasing number in the last years has enlarged opportunities to use cord-blood units (CBUs) trough international borders in order to maximize chances of identifying optimal CBUs. Since not all banks are accreditated by a global standard regarding CB quality control, the quality of CBUs can be affected by the origin of banks. In addition, little information is available on cord blood engraftment capacity after long-term cryopreservation. In this study, we evaluated whether the origin and the age of CBUs may influence the quality of CBUs and post-transplant hematological recovery. **Methods.** CBTs with single unit were performed at San Martino Hospital in Genoa for hematological malignancies using an intra-bone CBT technique. Just before infusion, a small sample of the CBU was obtained and post-thawing number of total nucleated cells (TNCs), CD34-positive cells, and colony-forming cells (CFCs) were characterized. Median pre-freezing number of TNCs and CD34-positive cells were 2.32 (1.15 - 4.52) x 10^9 and 9.3 (2.4 - 27.24) x 10^6, respectively. Recovery of neutrophil and platelet were compared according to the origin and the age of each CBU.Results. 95 CBUs were tested. The origin of CBUs was Europe (n = 45), the United States (n = 40), and other regions (n = 10). Median age of CBUs was 4.9 (0.4 - 11.8) years; CBUs originated from European banks were significantly older than CBUs from other regions (5.9 years vs 3.8 years, p value of unpaired t-test < 0.001). Median post-thawing number of TNCs, CD34-positive cells, and CFCs did not differ considering older (> 4.9 years) or younger CBUs (< 4.9 years) or the origin of the banks. Median time of neutrophil and platelet engraftment was as follows: younger CBUs: 24 and 34 days, older CBUs: 25 and 35 days, respectively (Fig.1). Hematological recovery was not influenced by the bank origin of CBUs as well, namely, rate and time of neutrophil and platelet engraftment was, 22 and 34.5 days (Europe), 22 and 35 days (the United States), 24 and 42 days (the other region), respectively (Fig.2). In contrast, days of neutrophil and platelet recovery were strongly correlated with the number of TNCs and CD34-positive cells per recipient's body weight.Conclusions: Although time of cryopreservation depends on origin of banks, the origin and the age of CBUs have little impact on post-thawing values of TNCs, CD34-positive cells, and CFCs. In addition, hematological recovery after CBT was influenced by number of TNCs and CD34-positive cells per recipient's body weight, but not influenced by the origin or the age of CBUs. These data suggest that quality control of CBU is working well regardless of the bank origin.





0985

COMPARISON OF VARIOUS HEMATOPOIETIC STEM CELL MOBILIZATION REGIMENS IN PATIENTS WITH LYMPHOMA AND MYELOMA

U Yilmaz, O Salim, L Undar
Akdeniz University, Antalya, Turkey

Background. A little-known mobilization regimen, IEV (Ifosfamide, epirubicin, and etoposide), has been used for hematopoietic stem cell mobilization recently as well as standard mobilization protocols. But retrospective and prospective studies that compare the efficacy and toxicity of hematopoietic stem cell mobilization regimens are needed to determine the least toxic and most effective regimen. **Aims.** The aim of this study was to compare the stem cell mobilization success, the factors affecting the stem cell sufficiency, and the toxicities of well-known and effective cyclophosphamide or platin-based regimens and IEV regimen in MM, HL, NHL patients who were planned to undergo autologous hematopoietic stem cell transplantation. **Methods.** A total of 203 (119 male and 84 females) patients who underwent peripheral stem cell mobilization before autologous hematopoietic stem cell transplantation (SCT) between January 2000 and April 2010, with the diagnosis of multiple myeloma (MM, n= 94), Hodgkin lymphoma (HL, n= 37) and non-Hodgkin lymphoma (NHL, n= 72) were retrospectively analyzed. G-CSF (filgrastim, lenograstim) 10 mcg/kg/day was administered to all patients in addition to mobilization protocol. Successful mobilization was defined as collection of ≥3x10^6 CD34 (+) cells/kg after apheresis for single autologous transplantation and ≥5x10^6 CD34 (+) cells/kg for double autologous transplantation. **Results.** There were no significant differences between platinum- or cyclophosphamide-based mobilization regimens and IEV

chemotherapy schema in terms of success of peripheral stem cell harvest. Peripheral blood stem cell yield was significantly higher in ESHAP group than that of DHAP and ICE groups (median 12.7 vs 6.6 vs 6.9 x10^6 CD34 (+) cells/kg, respectively, p=0.01). There were no significant differences between cyclophosphamide-based regimens and IEV regimen in patients tandem transplantation planned. Low and high dose cyclophosphamide provided comparable amount of stem cells collected. Grade 3-4 toxicity profiles were similar between mobilization groups. Regression analysis did not reveal any significant independent predictor for stem cell mobilization success or yield of collected stem cells. **Conclusions.** Although there was not any significant differences between the mobilization procedures, use of ESHAP may be preferable for peripheral stem cell mobilization in lymphoma patients whom unsuccessful mobilization expected or back-up stem cell collection needed. Because of comparable efficiency and toxicity, IEV may be an alternative regimen for stem cell mobilization.

0986

ALLOGENEIC STEM CELL TRANSPLANTATION FOR RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA: A SINGLE CENTER EXPERIENCE

M Tiribelli, D Damiani, A Geromin, M Cerno, A Sperotto, E Toffoletti, E Simeone, A Candoni, S Buttignol, R Fanin
Division of Hematology and Bone Marrow Transplantation, Udine, Italy

Background. Patients with acute myeloid leukemia (AML) who are refractory to induction therapy or relapse after remission have a 1 year survival probability lower than 30%. Because of this dismal prognosis, in these patients allogeneic HSCT is considered the recommended therapy.AimsWe retrospectively analyzed 78 patients with relapsed (n=38), primary refractory (n=34) or untreated (n=6) AML who underwent allogeneic HSCT at our Institution between 2002 and 2011, to verify outcome and to identify factors that can affect long term outcome. MethodsMedian age at HSCT was 48 (range: 18-72) years, with 21 patients (27%) who received transplant when aged over than 60 years. For the 38 relapsed patients, median duration of CR was 6.5 months. Allogeneic HSCT was performed at a median of 8 (range: 1-179) months from diagnosis; in relapsed patients, median time from relapse to transplant was 3 months. Forty-two patients (54%) received grafts from a sibling donor and 36 (46%) from a matched unrelated donors (MUD). In 53 patients (68%) stem cells source was peripheral blood (PB), while bone marrow (BM) stem cells were used in 25 cases. Myeloablative conditioning regimens were used in 48 patients (24 siblings, 24 MUD): BuCy in 43 cases, TBI-based regimens in 5. Thirty patients (18 siblings, 12 MUD) received reduced-intensity conditioning.ResultsAcute GVHD developed in 37/78 patients (47%), with a similar incidence in sibling (43%) or MUD (53%) transplants and in recipients of BM (56%) or PB (43%) stem cells. Chronic GVHD occurred in 19 of the 65 evaluable patients (29%), with an almost identical incidence in MUD (30%) and sibling recipients (29%) and according to stem cell source (BM=30%, PB=29%). With a median follow-up time of 5 years, 13 of the 78 transplanted patients (17%) are alive and in CR, while 64 patients have died. The mortality rate was similar in the MUD (31/36, 86%) and sibling (33/42, 79%) transplant. Main causes of death were disease recurrence (37 patients, 58%), infections (10 patients, 16%) and GVHD (6 patients, 9%). Cumulative 1-year non-relapse mortality (NRM) was 27%, with infections (10 cases, 37%) and GVHD (6 cases, 22%) being the two most common causes of NRM. Analyzing clinical factors before transplantation, a Karnovsky performance status (PS) ≥ 80% and a full matched donor were associated with a better outcome of HSCT. Considering the post-transplant variables, full donor myeloid chimerism at recovery and development of chronic GVHD were associated with a longer overall survival. Grouping patients according to the two pre-transplant factors (PS and HLA compatibility), we identified three cohorts with significant differences in death probability: 5-years survival probability was 75%, 24% and 0% in patients with no, one or two risk factors (P = 0.0001).Summary / conclusionsOur data confirm the capacity of allogeneic transplant to prolong survival in a significant proportion of extremely high-risk AML patients. Further studies are warranted to establish the best conditioning regimen and identify strategies improving graft versus leukemia effect.

0987

PREDICTORS OF PROLONGED SURVIVAL AND LONG-TERM OUTCOME AFTER ALLOGENEIC STEM-CELL TRANSPLANTATION WITH RIC IN PATIENTS WITH MULTIPLE MYELOMA.

J Elcheikh, R Crocchiolo, S Furst, C Faucher, AM Stoppa, A Granata, R Devillier, C Oudin, P Ladaique, D Coso, B Calmels, C Lemarie, R Bouabdallah, C Chabannon, D Balise
Institut Paoli Calmettes, Marseille, France

Allogeneic stem cell transplantation (allo-SCT) has been used in the hope of harnessing the curative potential of the graft-versus-myeloma effect. This study examines the long-term outcomes of a cohort of patients with myeloma who were treated with reduced-intensity conditioning (RIC) regimens after a minimum follow-up of 5 years at the INSTITUT PAOLI CALMETTES Cancer Centre.A total of 53 patients with multiple myeloma (MM) who received allo-SCT between January 2000 and January 2007 were identified. Use of ATG, patient age, number of prior auto-SCT, delay between auto and allo-SCT, disease status at allo-SCT, occurrence of grade II-IV acute or chronic GVHD were included as predictive factors for OS, PFS and TRM. Variables with p<0.10 were included in multivariate analysis. The median follow-up of alive patients was 82 months (48-137). Median age of MM patients was 50 (28-70) years. 51 patients (96%) received transplant from a sibling donor. The median time between diagnosis and allo-SCT was 34 months (6-161), 51 patients (96%) received at least one auto-SCT; 24 patients (45%) received a tandem auto-allo-SCT. and the median time between auto-SCT and allo-SCT was 10 months (1-89). Conditioning regimens were Melphalan-based for all Auto-SCT patients, whereas the allo-SCT patients received Fludarabine, busulfan and Anti thymoglobulin (ATG)-based (58%), or Fludarabine and Total body irradiation (TBI) based (38%) or other (4%).At last follow-up, there are 21 patients (40%) who are alive >5 years post RIC allo-SCT; of those 14 (26%) are in first complete remission (CR), and 4 patients (8%) in second CR after donor lymphocytes injection or re-induction with the new drugs (bortezomib or lenalidomide) after allo-SCT. Only 4 patients (19%) of these long survivors received one of the new antimyeloma drugs as induction or relapse treatment before allo-SCT.Cumulative incidence of grade II-IV acute graft-versus-host disease (aGVHD) was 36% and the cumulative incidence of chronic GVHD (cGVHD) was 55% at 2 years. Acute GVHD had not influence on overall survival (OS) or progression-free survival (PFS), while cGVHD had significant protective effect on PFS: HR=0.42 (0.22-0.78, p=0.007). OS was 52% (39-65) at 5 years and 32% (16-48) at 10 years. The PFS was 26% (14-38) at 5 years and 24% (12-36) at 10 years. Treatment-related mortality (TRM) at 1 year was 20% (9-31).Only disease status and occurrence of cGVHD were significantly associated with PFS; acute GVHD was correlated with higher TRM. No variables were associated with OS.In conclusion, we observe that long-term disease control can be expected in a subset of MM patients undergoing RIC allo-SCT. With OS and PFS after 10 years of 32% and 24 % respectively, and the survival curves after RIC allo-SCT stabilizes with time.

0988

RABBIT-DERIVED ATG BUT NOT HORSE-DERIVED ATG IN THE CONDITIONING INDUCES A POST TRANSPLANT IN VIVO IMBALANCE BETWEEN B AND T-CELL RECOVERY RESULTING IN HIGH RISK OF EBV ASSOCIATED PTLD

C Halkes[1], J Falkenburg[1], H van Egmond[1], J Olde Wolbers[2], P von dem Borne[1], W Marijt[1], J Veelken[1], I Jedema[1]
[1]Leiden University Medical Center, Leiden, Netherlands
[2]Medisch Spectrum Twente, Enschede, Netherlands

After reduced intensity conditioning with fludarabin, busulphan and Lymphoglobulin (horse-derived ATG, hATG) followed by alemtuzumab-based T-cell depleted (TCD) allogeneic stem cell transplantation (alloSCT), CMV reactivations were frequently observed in our patient cohort, but no EBV-associated post-transplant lymphoproliferative disease (PTLD). After the enforced replacement of hATG by Thymoglobulin (rabbit-derived ATG, rATG) CMV complications remained similar but an unacceptable incidence of 26% of early EBV-PTLD was observed.In this study, we analyzed the cause of this immune escape of EBV-infected B-cells by measuring antibody levels and specificity in relation to B and T-cell recovery early after transplantation.During conditioning 16 patients received rATG (total 8 or 14 mg/kg) for in vivo TCD. This cohort was compared to 16 patients conditioned with hATG for in vivo TCD (total 20 or 40 mg/kg).Total serum ATG levels after alloSCT as measured with species-specific ELISA at 3 and 6 weeks after alloSCT were similar for the hATG (43 and 15 ug/mL) and the rATG cohort (41 and 21 ug/mL). Next, specific ex-vivo reactivity of the circulating ATG with human B and T-cells was measured by a flow-

cytometry-based method. In serum from hATG treated patients, a high and sustained specific anti-B-cell reactivity was detected, which was dominant over anti-T-cell reactivity, resulting in expansion of memory T-cells which include EBV-specific T-cells prior to B-cell recovery. In contrast, serum of rATG treated patients contained only marginal levels of antibodies showing anti-B-cell reactivity, but dominant anti-T-cell reactivity resulting in early B-cell expansion in the absence of T-cell recovery. Interestingly, when tested directly out of the vial both ATG products showed similar dominant functional anti-T-cell reactivity over anti-B-cell reactivity as demonstrated using cell lineage-specific flow-cytometry and in vitro CDC assays. Interestingly, when in-vivo absorption of lineage-specific reactivity by circulating cells was mimicked in-vitro by co-incubation of a fixed amount of ATG to increasing amounts of peripheral blood mononuclear cells (PBMC) from healthy donors a similar difference was observed between rATG and hATG. Whereas the anti-B-cell reactivity was easily absorbed from the rATG already by low numbers of PBMC (<50x10^6), sustained anti-B-cell reactivity was present in hATG even after absorption with up to 300x10^6 PBMC. Absorption experiments with purified T and B-cells suggest a higher component of B-cell-reactive antibodies with no cross-reactivity for T-cells in hATG compared to rATG, explaining their longer persistence.In conclusion, after treatment with rATG, high levels of specific anti-T-cell reactivity was found up to 9 weeks after alloSCT, whereas anti-B-cell reactivity was only detectable early after transplant, allowing B-cell outgrowth and EBV-associated PTLD in the absence of EBV-specific T-cell control. In contrast, in vivo TCD with hATG resulted in dominant persistence of anti-B-cell reactivity up to 9 weeks after transplant. In-vitro absorption experiments suggest that the differential persistence of anti-B-cell reactivity after conditioning with hATG versus rATG is caused by differences in cell lineage specificity between the polyclonal ATG products.

0989

MIPI SCORE AND DAY-15 POST TRANSPLANT LYMPHOCYTE COUNT PREDICT SURVIVAL IN PATIENTS WITH MANTLE CELL LYMPHOMA TREATED WITH RITUXIMAB AND HYPERCVAD FOLLOWED BY BUSULPHAN AND MELPHALAN ASCT

A George, M Dickinson, R Howman, J Seymour, M Prince, S Lade, D Ritchie
Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia

Background. Improved complete remission (CR) and overall survival (OS) rates have been reported in MCL (Mantle cell lymphoma) patients treated with Rituximab-HyperCVAD regimen (Romaguera JE et al. J clin Oncol 2005; 23: 7013-7023). ASCT (autologous stem cell transplantation) provides a further incremental improvement (Ritchie DS et al. Ann Hematol 2006; 86:101-105). MIPI (MCL international prognostic index) predicts outcome in non-ASCT treatment of MCL, but was reported to be not prognostic in patients treated with R-HyperCVAD (Shah, J J et al. Blood 2008; 112:2583-2583). ALC (absolute lymphocyte count) recovery after ASCT predict OS and PFS (progression free survival) in MCL patients treated predominantly with CHOP/CHOP-like regimens (Joao C, et al. BMT 2006; 37:865-871), but has not been assessed in those treated with R-HyperCVAD and ASCT.**Aims.** To analyse the impact of MIPI and ALC on day +15 after ASCT (ALC15) on patient outcome after treatment with Rituximab-HyperCVAD followed by ASCT with Busulphan(Bu) and Melphalan(Mel) conditioning as the initial therapy in patients with MCL. **Methods.** We analysed on an intention to treat basis, the outcome of 28 patients with MCL under the age of 65 enrolled in our treatment protocol with R-HyperCVAD followed by BuMel ASCT. One patient in CR post R-HyperCVAD refused ASCT. MIPI was calculated from pre-treatment variables. ALC15 was obtained from serial blood counts after ASCT. Informed written consent was taken from all patients.

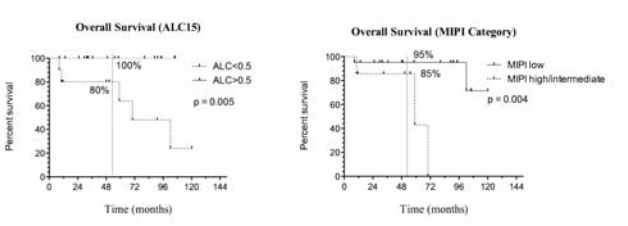


Figure 1. Overall Survival by ALC 15 and MIPI Category.

Results. CR was achieved after R-HyperCVAD in 92.6% of the patients. 100% of pts were in CR after ASCT. At a median follow up of 53months, estimated EFS (Event Free Survival) and OS were 68 % and 92.7% respectively. Because of low numbers patients with intermediate and high MIPI were analysed as a single group. Median ALC15 for the whole group was 0. 5x10^9/L. There were no significant differences between the two groups (ALC15>0.5 and ALC15 <0.5). EFS and OS rates at 53months in patients with ALC15 >0.5x10^9/L (n=17) were 94% and 100% compared to 34% and 80% in those with ALC15 <0.5x10^9/L (p=0.02 and 0.005 respectively). These rates in the patients with low MIPI (n=21) were 81% and 95% compared to 34% and 85% in those with intermediate/high MIPI (p=0.03 and 0.004 respectively). Transplant related mortality occurred in one patient by day 100. There have been no therapy-related MDS or AML in these patients. **Conclusions**. Treatment with Rituximab+Hyper-CVAD followed by ASCT with Busulphan-Melphalan conditioning achieves high CR rates and durable remissions in patients with MCL, in particular those with low MIPI and early ALC recovery. Patients with high MIPI or poor ALC recovery justify consideration of post-ASCT maintenance therapty.

0990

LONG-TERM FOLLOW-UP ON THE EFFECT OF THIOTEPA DOSE-INTENSITY IN THE CONDITIONING FOR ALLOGENEIC TRANSPLANTATION IN HEMATOLOGIC MALIGNANCIES

F Spina, M Morelli, L Farina, A Dodero, V Montefusco, P Corradini
Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy

Background. Thiotepa-fludarabine-cyclophosphamide (Thio-Flu-Cy) is an effective and reliable conditioning regimen for allogeneic transplantation (alloSCT). The intensity of Thio-Flu-Cy can be modulated varying Thiotepa dose based on patient age and comorbidities. **Aims.** This study was aimed at assessing whether varying the dose-intensity of Thiotepa in the conditioning has an effect on engraftment, survival, and graft-versus-host disease (GVHD). **Methods.** Eighty-seven patients with hematologic malignancies received peripheral blood stem cells (PBSC) at our centre between 2001-2011 from HLA identical siblings (77%), mismatched siblings (14%), or matched unrelated donors (9%) after Thio-Flu-Cy conditioning. Thio-Flu-Cy consisted of Thiotepa 5-15mg/kg (total dose) at days -6 and -5, Fludarabine 30mg/m^2/day and Cyclophosphamide 30mg/kg/day at days -4 and -3. The dose of Thiotepa was 5, 10, 12, and 15mg/kg for 13%, 39%, 15%, and 33% of patients, respectively. MUD or mismatched sibling recipients received rabbit anti-thymocyte globulin (rATG) 5-7.5mg/kg (total dose) at days -3 and -2, or alemtuzumab 7.5-15mg/m^2 at day -2. All patients received short-course methotrexate and cyclosporine for GVHD prophylaxis. Patients had non-Hodgkin (51%) or Hodgkin lymphoma (26%), multiple myeloma (16%), or AML (7%). At alloSCT, 47% of patients had >50 years, 51% were in CR, 34% in PR, 5% in SD, and 10% in PD. Thiotepa >10mg/kg was most frequently given to patients aged <=50 years and to those with residual disease at alloSCT (test for trend, p<0.001 and p=0.002). **Results**. Myeloablation occurred at day +2 (range, -3 to +7). Neutrophil and platelet engraftment (>500/mcl and >20000/mcl) occurred at day +12 (range, 5-21) and +13 (range, 9-33), and were not significantly affected by Thiotepa dose. All patients had full-donor chimerism by day +60. Median follow-up was 6.4 years (range, 0.2-10.4). Non-relapse mortality (NRM) was 7% at 100 days, 11% at 1 and 13% at 3 years. Relapse incidence was 44% at 3 and 47% at 5 years. Thiotepa dose did not affect NRM and relapse. Relapse was increased by disease burden at alloSCT (p=0.009). PFS was 43% at 3 and 39% at 5 years, OS was 63% at 3 and 60% at 5 years of follow-up. Multivariate analysis of PFS and OS included Thiotepa dose, disease status at alloSCT, rATG or alemtuzumab, and donor type (HLA identical sibling, mismatched sibling, or MUD). Disease status at alloSCT impacted PFS and OS (p<0.001 and p=0.01). Thiotepa dose and the other factors analyzed did not affect PFS and OS. The cumulative incidence of aGVHD was 35%. Thiotepa >10mg/kg increased the incidence of aGVHD compared to lower doses (48% vs 22%, p=0.01). The cumulative incidence of cGVHD was 28% at 1 and 40% at 3 years (extensive cGVHD, 11% and 14%). cGVHD was not affected by Thiotepa dose. Donor type did not impact aGVHD (p=0.39) and cGVHD (p=0.24). **Conclusions.** Thiotepa doses >10mg/kg in Thio-Flu-Cy conditioning are associated with an increased risk of aGVHD without improving relapse incidence, PFS and OS. Survival and relapse are independently affected only by disease status at alloSCT. Thus, Thiotepa at doses <=10mg/kg should be preferred even in case of residual disease when using Thio-Flu-Cy.

0991

RISK-BASED STRATIFIED GVHD PROPHYLAXIS IN ALLOGENEIC PERIPHERAL BLOOD STEM CELL TRANSPLANTATION OF ACUTE MYELOID LEUKEMIA PATIENTS

SY Kim, MH Lee
KonKuk University Medical Center, Seoul, South-Korea

The general perception is that an unrelated donor HSCT, especially an HLA-mismatched unrelated donor HSCT presents greater risks in terms of graft-versus-host disease (GVHD) and non-relapse mortality (NRM) than matched sibling donor (MSD) HSCT. However, differences in post-transplant outcomes between MSD and unrelated donor PBSCT should be analyzed independently from the BMT setting in single-disease entity patients. Our center has adapted risk-based stratified GVHD prophylaxis according to the donor type and HLA matching degree in allo-PBSCT setting. In MSD transplants, patients received a short course of methotrexate in combination with cyclosporine, while tacrolimus and methotrexated were used in HLA-matched unrelated donor (MUD) transplants. In HLA-mismatched unrelated donor (MMUD) transplants, 1.25 mg/kg/day of anti-thymocyte globulin (ATG; Thymoglobulin, Genzyme Transplant) was infused for 2 days (D-2 and D-1) in addition to tacrolimus and methotrexate for GVHD prophylaxis. One hundred four consecutive AML patients who underwent allo-PBSCT were included in this analytic study. Fifty four patients (51%) received PBSCT from MSD, while 29 patients (28%) received PBSCT from MUD and 21 patients (20 %) received PBSCT from MMUD. The median follow-up duration after transplant was 19.4 months (range, 0.3-71.3). The median follow-up for living patients was 34.7 months (range, 6.5-71.3). Cumulative incidence of grade 2-4 acute graft-versus-host-disease (aGVHD) at 100 days was 22.6% in MSD transplant, 44.8% in MUD transplant, and 25.3% in MMUD transplant. MUD transplant showed the higher risk of grade 2-4 aGVHD compared to MSD transplant (P=0.028), while there was no difference between MMUD that used ATG and MSD transplant in terms of grade 2-4 aGVHD risk (P=0.932). Cumulative incidence of chronic GVHD (cGVHD) at 3 years was 70.5% in MSD, 63.4% in MUD, and 42.1% in MMUD. There was a trend towards lower risk of cGVHD in MMUD transplant compared to MSD transplant (P=0.092). Relapse incidence at 3 years was 16.7% in MSD transplant, 23.4% in MUD transplant, and 19.1% in MMUD transplant (P=0.562). Relapse risk did not differ between the each group. NRM at 3 years was 29.9% in MSD transplant, 21.1% in MUD transplant, and 30.2% in MMUD transplant (P=0.666). Disease free survival (DFS) and overall survival (OS) were 53.4% and 61.1% in MSD transplant, 61.7% and 65.1% in MUD transplant, 50.8% and 52.8% in MMUD transplant, respectively. DFS and OS also did not differ significantly between the each group. The analyses showed that ATG was able to overcome the high risk of acute and chronic GVHD in MMUD transplant and make comparable transplant outcomes between MSD and MMUD transplants. This present study demonstrates outcomes of MSD transplant and unrelated donor transplant for AML can be comparable in a allogeneic PBSCT setting if an adequate GVHD prophylaxis strategy is applied in unrelated donor PBSCT and the degree of HLA mismatch is not significant at the level of high resolution HLA typing.

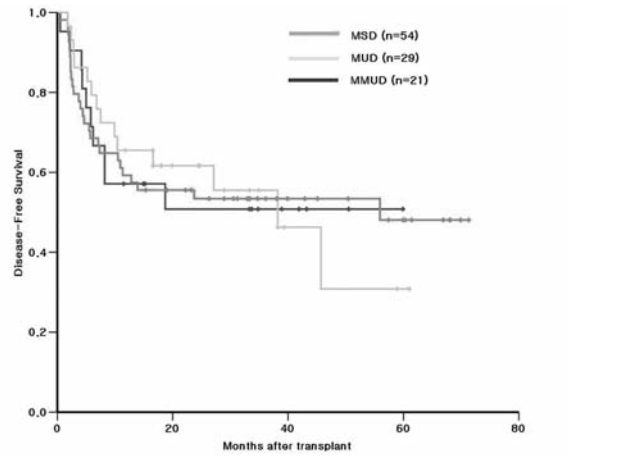

Figure 1. Disease-Free Survival in AML patients who adapted risk-based stratified GVHD prophylaxis in allogeneic peripheral stem cell transplantation.

COMPLETE RESPONSE AFTER HIGH-DOSE THERAPY WITH AUTOLOGOUS STEM CELL SUPPORT IS THE ONLY IMPORTANT PREDICTIVE FACTOR FOR SURVIVAL

B Lee[1], SH Shin[2], CK Min[2], HY Yhim[3], JY Kwak[3], JA Kim[1]
[1]St. Vincent Hospital The Catholic University of Korea Colleage of Medicine, Suwon, South-Korea
[2]St. Mary's Hospital The Catholic University of Korea Colleage of Medicine, Seoul, South-Korea
[3]Chonbuk National University Medical School, Jeonju, South-Korea

Background. High-dose chemotherapy with autologous stem cell support (HD/ASCT) is the standard treatment for young patients with multiple myeloma (MM). **Aims.** In this study, we evaluated the relationship between the depth of HD/ASCT response and survival rates and examined whether the primary therapy with bortezomib-containing regimen was a factor for survival. **Methods.** We analyzed the clinical data of 129 patients treated with HD/ASCT in three institutions from 2000 to 2011. Every patient received two cycles of high dose dexamethasone. Then we treated the patients who showed response ≥PR with VAD (vincristine, adriamycin, dexamethasone) and treated those who had responses. **Results.** Clinical data of 129 patients were evaluated for their treatment responses based on previous their medical records. Their median age was 54 years old (range: 35-65 years) and 69 patients (53.5%) were male. Among these patients, 71 % of them (92 of 129 pts) were treated with bortezomib-containing regimen and 29% of them (37 of 129 pts) were treated with VAD before HD/ASCT. The response rates after PT were 27% CR, 17% VGPR, 43% PR. And post-HD/ASCT response rates were 64% CR, 17% VGPR, 10% PR. Median follow-up durations were 36.28 months (range, 5.52~145.33 months). Five-year overall survival (OS) rates and 5-year progression-free survival (PFS) rates were 58% and 25%. ß2-microglobulin and post-HD/ASCT CR are the strong predictive factors for OS (5-year OS rate; 79.3% and 41.2% in ß2-microglobulin <3.5 and≥3.5, respectively; p=0.01), (5-year OS rate; 73.5% and 31.6% in CR andWe evaluated the response rates and survival rates between bortezomib-containing regimen and VAD treated-group. The response rates after VAD were 27% CR, 16% VGPR, 49% PR and the response rates after bortezomib-containing treatment were 27% CR, 17% VGPR, 40% PR. In two groups, the response rates were similar (p=0.86). After HD/ASCT, the rates of OS were not significantly different in two groups (5-year OS rate; 48% in VAD group vs 65% in bortezomib-containing group respectively; p=0.26) The percentage of ≥ grade III peripheral neuropathy was 25% in bortezomib-containing regimen group but was not observed in VAD group (p= 0.01). And the number of collected CD34+ cells was not inferior in VAD group when compared to bortezomib-containing group (median CD34+cell counts/one harvest; 5.4 (10^6/kg) in VAD group vs 6.1(10^6/kg) in bortezomib-containing regimen respectively; p=0.52). **Conclusions**. We concluded that CR after HD/ASCT is the primary factor which impacts the survival rates of the patients. And when the patients show good responses to dexamethasone, VAD is still a feasible primary therapy in MM before HD/ASCT.

[5]Department of Hematology,Zhujiang Hospital,Southern Medical University, Guangzhou, China

Background. Bone marrow failure is a kind of refractory complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT). **Aims.** In this study ,we evaluated prospectively the efficiency and safety of expanded mesenchymal stem cells (MSCs) from bone marrow of a third party donor to patients with bone marrow failure after allo- HSCT. **Methods.** Twenty patients with bone marrow failure including primary failure in 7 and secondary failure in 13 received MSCs at a dose of 1×10^6/kg for 1 to 3 cycles, with an interval of 28 to 30 days. **Results** Seventeen patients were responsive to MSCs and 3 were not after 1 to 3 cycles of treatment. Within the first 100 days after MSCs treatment, 13 patients developed 20 episodes of infection. Moreover, 5 patients occurred cytomegalovirus-DNA viremia and 7 occurred Epstein-Barr virus (EBV)-DNA viremia within the first 100 days after MSCs treatment, 3 of whom developed into EBV-associated posttransplant lymphoproliferative disorders (PTLD) in the follow-up period. One patient occurred grade Ⅱ acute graft-versus-host disease (GVHD) and 2 occurred chronic GVHD after receiving the MSCs treatment, including 2 occurred acute GVHD and local chronic GVHD, respectively, after they accepted donor lymphocyte infusion because of PTLD. Following up of 508 (range, 166 to 904) days post-transplants, 9 patients were alive and 11 died. Short-term toxic side effect were not obsvered and 2 patients experienced leukemic relapse after MSCs treatment. Except for 3 episodes of PTLD, other secondary tumor did not occur. **Conclusions** MSCs from bone marrow of a third party donor is effective to patients with bone marrow failure after allo-HSCT, whether it might increase the risk of EBV reactivation and EBV-associated PTLD need further study.

0994

LOW COUNTS OF PLASMACYTOID DENDRITIC CELLS AFTER ENGRAFTMENT ARE ASSOCIATED WITH HIGHER EARLY TRANSPLANTATION-RELATED MORTALITY IN PATIENTS RECEIVING UNRELATED HEMATOPOIETIC STEM CELL TRANSPLANTATION

M Gonçalves[1], M Yamamoto[1], V Colturato[2], M de Souza[2], M Mauad[2], M Ikoma[2], E Kimura[1], F Guirao[1], N Hamerschlak[3], F Kerbauy[3], L Morelli[3], Y Novis[4], V Ginani[5], A Seber[5], V Rocha[4], A Orfao[6], CA Rodrigues[1]

[6]Universidad de Salamanca, Salamanca, Spain

Background. The heterogeneous status of host immune defenses may influence the risk of infection and graft-versus-host disease (GVHD) after hematopoietic stem cell transplantation (HSCT). In such defense, dendritic cells (DC), which act as specialized antigen-presenting cells that bridge the innate and adaptive immune systems, are essential cell components. **Aims.** To monitor the recovery of different subsets of DC after unrelated umbilical cord blood (UCB), bone marrow (BM) and peripheral blood (PBSC) HSCT, and to evaluate the impact of the distribution of these cell subsets on the outcome of the transplant. **Methods.** DC [lineage negative, HLA-DR+ and CD123+ plasmacytoid(p)DC, CD11c+ myeloid(m)DC, and CD16+ monocytoid(mo)DC] were quantified by multiparametric flow cytometry at 6 sequential time points (at engraftment, and at days 3, 7, 14, 21 and 60 after engraftment). Overall, 34 patients (19 male; median age 13y, range 1-63y) receiving a UCB (n=15), BM (n=14) or PBSC (n=5)unrelated HSCT were studied. The most common diagnosis was acute leukemia (ALL, 12 cases; AML, 10; CML, 5; aplastic anemia/MDS, 6; Hodgkin lymphoma, 1; SCID, 1). Most patients received myeloablative conditioning (MAC) regimens (73%). Antithymocyte globulin (ATG) was used in 38% and total body irradiation (TBI) in 41% of cases. Median time to neutrophil engraftment was 18 days (range: 12-45). Median follow up time was 6 months. **Results.** Patients who died from early transplantation-related causes (TRM) had significantly lower counts of pDC and mDC during the first 3 weeks after HSCT. At day 21 after engraftment, the median number of pDC and mDC was 0.9 and 2.0/uL among patients who died from TRM vs. 7.1 (p=.006) and 8.4/uL (p=.01) in the remainder, respectively. Patients presenting grade II-IV acute GVHD also had significantly lower pDC counts at days 14 and 21. There was no significant association of both the hematopoietic stem cell source and the conditioning regimen on the risk of TRM or acute GVHD. **Conclusions:** Low pDC counts in the first weeks after unrelated HSCT are associated with an increased incidence of GVHD and mortality. The precise mechanisms that might explain the role of pDC on immunity early after HSCT deserve further investigations.

0995

PROGNOSTIC IMPACT OF MIXED CHIMERISM AND MINIMAL RESIDUAL DISEASE IN MDS/AML AFTER ALLOGENEIC STEM CELL TRANSPLANT

T Bernal[1], M Díez Campelo[2], V Godoy[2], M Alcoceba[3], S Rojas[3], M GonzaLez Díaz[3], E Colado[1], E Luño[1], F Sanchez-Guijo[3], L Lopez Corral[3], M Del Cañizo[3]

[1]Hospital Universitario Central de Asturias, Oviedo, Spain

[2]Hospital Clínico Universitario Salamanca, Salamanca, Spain

[3]Hospital Clínico Universitario Salmanca, Salamanca, Spain

Background. delayed full donor T cell quimerism may be associated with a high incidence of relapse in the context of reduced intensity conditioning (RIC) and T-cell depletion (TCD) in myeloid malignancies. The impact of T cell mixed chimerism (MC) has not been studied in myeloablative conditioning, T-cell repleted transplants, nor the relationship with minimal residual disease (MRD).**Aims.** To identify factors associated with (MC) and its impact MDS/AML evolution after transplant. **Methods.** 99 patients (40/59 female/male, 52±12 years) with MDS (n=47)/AML (n=52), allotransplanted (84% RIC) in two different units from Jan-2005 to Dec-2011, were studied. Demographic, clinical and analytical data (including chimerism and minimal residual disease at day 100) were collected. Univariant comparisons between patients with and without MC were done using T or Chi-square tests as appropriate. Variables with a p<0.1 were included in a logistic regression analysis, and odds ratios (OR [95% confidence interval]) were calculated. Patients with and without relapse were also compared using the same methodology. Survival was studied using the Kaplan-Meier method and the log rank test. A p<0.05 was considered significant in multivariate analysis.**Results.** Status at transplant was complete remission in 64%, refractory/progressive disease in 6% and others in 30%. TCD was part of the GVHD prophylaxis in 16%, Tacrolimus-Rapamicin in 14%, all others were CyclosporinA based. Mixed T cell chimerism was present in 57 patients at day +100. Factors associated with MC at day 100 in univariate análisis were sex (MC in male 69% vs 45% in females, p=0.015), infused CD34 cells (5.6±2.16 vs 4.7±2.2 $x10^6$ cells/Kg in those with or without mc respectively, p=0.049) and acute GVHD (43% vs 68% of MC in patients with and without acute GVHD respectively, p=0.014). In multivariate analysis, male sex (OR 2.97 [1.21-7.3]) and aGVHD (OR 0.29 [0.12-0.74]) were significantly related to development of MC. After a median follow up of 2 years overall and relapse free survival were 57 and 60%,. Factors related to relapse in univariant analysis were age (47±13 vs 53±11 years for patients with and without relapse, p=0.021), chronic GVHD (15% vs 41% of relapse in those with or without chronic GVHD, p=0.004), MC at day 100 (32% of relapse vs 10% in patients with complete chimerism, p=0.01), positive MRD at day 100 (50% of relapse vs 14% in cases of negative MRD, p=0.003) and mieloablative conditioning (44% of relapse vs 19% in cases of RIC, p=0.03). In logistic regression analysis, only presence of MC (OR 10.1 [1.6-64]) and positive MRD at day 100 (OR 5.7 [1.1-29.9] remained significant. Based on these results, the sample was stratified into four groups according to chimerism and MRD. Relapse rates (RR) among these groups were significantly different (log-rank p<0.01): Group 1 (MRD neg, CQ: RR 4%), group 2 (MRD neg, MC: RR 23%), group 3 (MRD pos, CQ: RR 25%), group 4 (MRD pos, MC: RR 60%).**Conclusions**: Evaluation of MRD plus T-cell chimerism at day 100 may help to identify patients at high risk for relapse in AML/MDS after allotransplantation.

0996

FLUDARABINE + EXPOSURE-TARGETED BUSULFAN IN CHILDREN WITH MALIGNANT AND NON-MALIGNANT DISEASES: AN EFFECTIVE AND LOW TOXIC REGIMEN

J Boelens, I Bartelink, C Lindemans, A Versluys, M Bierings
UMC Utrecht, Utrecht, Netherlands

Background. Busulfan (Bu) as myeloablative agent is used in conditioning regimens prior to HSCT. We recently found a clear association between Bu-exposure and outcomes. Comparison studies in adults showed a favourable toxicity profile for fludarabine+busulfan (FludBu) compared to the conventional BuCy regimen.**Aims.** We recently initiated a prospective study analysing the effectively of FluBu in myeloid malignancies and all non-malignant indications in pediatrics. We compared the outcomes with our Bu(-exposure targeted)/Cy/(Mel) from a previous cohort (2005-2008). **Methods.** Fludarabine 40mg/m2 was given in 1 hour prior to a 3 hour infusion of once daily busulfan. The target area under the curve (AUC) for Bu was 75-95 mg*h/L (in total) in both groups. Bu dose targeting, based on therapeutic drug monitoring was performed before the second dose. Primary endpoint was event free survival (EFS) and survival. Secondary endpoints were acute graft-versus-host disease (aGvHD), VOD, IPS, neutropenic period and the number of erythrocytes and thrombocytes transfusions. A risk factor analysis was performed using univariable and multivariable COX regression.**Results.** 103 patients were included: 65 unrelated-CBT, 21 MSD and 17 MUD. 55 patients were included in the FludBu group (median follow up 11 mths; range 1.1 - 36) and 48 in the BuCy(Mel) group (44 mths; range 0.2 - 81). The median exposure of Bu was 88 (81-100) mg*h/L in FluBu and 82 (74-104) mg*h/L in BuCy(Mel). The groups were comparable regarding age, cell source, gender, indication for BMT and match-grade. The probability on EFS in FludBu and BuCy(Mel) was 76+/-6% and. 65+/-7% (NS), resp. No difference in aGvHD (≥grade 2: 27 vs.26%) was found. Less IPS was seen after FluBu 3 +/-3% vs. 31+/-7% (p=0,001) and less VOD was seen in BuFlu 3% vs. 22% (p=0.01).A trend to a lower "non-relapse mortality"was found in the FluBu group 7+/-4% vs. 19+/-6% (p=0.08). The period of neutropenia was median 11 in the FludBu compared to 20.5 in BuCy(Mel) (HR 0.38, p=0.05, CI95% 0.20-0.75). The median number of erythrocytes transfusion was 1 (range 1-13) in the FludBu group and 5 (0-22) in the BuCy(Mel) group (p=0.02) and thrombocyte transfusions 4 (range 0-33) vs 10 (range 2-44; p=0,02).**Conclusion:** Bu with a total target AUC of 75-95mg*h/l in combination with Flud showed to be an effective and lower toxic regimen in comparison to BuCy(Mel). A shorter neutropenic period and a lower number of transfusions were needed in FludBu. FludBu as reduced toxicity regimen showed promising results.

0997

DISPARATE CD52 EXPRESSION RESULTS IN DIFFERENTIAL OUTGROWTH OF LYMPHOCYTE SUBSETS EARLY AFTER LOW DOSE ALEMTUZUMAB-BASED T CELL DEPLETION EXPLAINING LOW INCIDENCE OF EARLY VIRAL COMPLICATIONS

Leiden University Medical Center, Leiden, Netherlands

Despite profound T-cell depletion by in vitro (20 mg) and low dose in vivo (30 mg) Alemtuzumab (ALT, anti-CD52) for acute GvHD prevention, no early CMV disease and a low incidence (2%) of EBV-associated PTLD was seen in a cohort of 60 patients receiving allogeneic stem cell transplantation (alloSCT) after reduced intensity, fludarabin and busulphan-based conditioning.We hypothesized that antiviral protection in the presence of circulating Alemtuzumab early after alloSCT is based on survival of protective memory and effector cells and preferential deletion of naïve T-cells capable of inducing acute GVHD.Since significant Alemtuzumab levels are detected up to 9 weeks after alloSCT, we analyzed the recovery and CD52 expression of NK-cells and CD4 and CD8-positive T-cell subsets (including CMV- and EBV-specific T-cells) during the first 9 weeks after alloSCT.Three weeks after alloSCT, already 70% of the patients had normal levels of circulating NK-cells (median 71x10^6/L, range 0-441x10^6/L). This percentage increased to 89% after 9 weeks (median 217x10^6/L, range 1-1424x10^6/L). After 9 weeks, 30% of the patients had normal numbers of circulating CD8 positive T-cells (median 108x10^6/L, range 1-1539x10^6/L) and only 6% had normal numbers of circulating CD4 positive T-cells (median 88x10^6/L, range 2-612x10^6/L). Interestingly, naive (CD27+CD45RA+) T-cells were virtually absent in the first three months after alloSCT, explaining the low incidence of acute GvHD. A significant proportion of T-cells showed loss of CD52 expression due to GPI-anchor protein deficiency. Using tetramer staining and flowcytometric cell sorting, CD52 positive and CD52 negative CMV and EBV-specific CD8 T-cells were isolated and cytotoxicity and cytokine production assays revealed proper functionality of both the CD52 positive and CD52 negative cells, demonstrating their anti-viral protective capacity. Since NK-cells and a significant proportion of the CD8 positive T-cells surviving in the presence of detectable levels of circulating ALT (median levels 0.39, 0.05 and 0.02 ug/ml, after 3, 6 and 9 weeks, respectively) were CD52 positive,,we examined CD52 expression levels and in-vitro sensitivity to ALT-mediated complement-dependent cytotoxicity (CDC) of NK-cells and CD4 and CD8 positive T-cells in healthy control individuals. CD52 expression was highest on CD4 positive T-cells. Compared to CD4 positive T-cells, the relative CD52 expression on CD8 positive T-cells and NK-cells was only 58% (range 51-70% , n=5) and 27% (range 14-39%, n=5), respectively, resulting in relative protection of NK-cells and CD8 positive T-cells against ALT-mediated CDC, explaining their early outgrowth directly after transplantation. Within CD8 positive T-cells, CD52 expression was highest in the naïve compartment, whereas the relative CD52 expression in antigen-experienced CD8 positive T-cells was 80% (range 76-86%) compared to naïve cells.In conclusion, after ALT-based T-cell depletion, early outgrowth of NK-cells and CD8 positive T-cells in the presence of circulating Alemtuzumab levels is enabled by their low membrane expression of CD52 compared to CD4 positive T-cells and B-cells. Naïve CD8 positive T-cells show a relatively high CD52 expression explaining their prolonged absence after allo-SCT. This resulted in a low incidence of viral complications in spite of T-cell depletion for GVHD prevention.

RETROSPECTIVE ANALYSIS OF STEM CELL TRANSPLANTATION FROM AN HLA-MISMATCHED DONOR AND IMPACT OF PROPHYLAXIS FOR GRAFT-VERSUS-HOST DISEASE

A Shigematsu[1], K Ikumi[1], S Ota[2], S Hashino[1], T Endo[1], T Kondo[1], J Tanaka[1], N Kobayashi[2], I Imamura[1]
[1]Hokkaido University Hospital, Sapporo, Japan
[2]Department of Hematology, Sapporo Hokuyuu Hospital, Sapporo, Japan

Background. GVHD is a major morbidity in patients who have received allogeneic stem cell transplantation (allo-SCT). Although it has been established that the incidence and the severity of acute GVHD (AGVHD) are increased in patients receiving allo-SCT from an HLA-mismatched donor, the impact of GVHD prophylaxis on severity of GVHD in patients who have undergone HLA-mismatched SCT is not known. **Aims.** To evaluate the clinical impact of HLA-mismatched SCT and prophylaxis for GVHD on the incidence and severity of GVHD, transplantation-related mortality (TRM) and survival, we conducted a retrospective analysis in Hokkaido, Japan. **Methods.** Clinical data were obtained for 393 patients who met the following criteria: diagnosed between 2000 and 2009, first time for allo-SCT, bone marrow (BM) or peripheral blood stem cells (PBSC) as a stem cell source, and aged more than 15 years.Results. The median age of the patients was 44 years (range: 15-73 years). The diagnoses were AML (n=131), ALL (n=69), Lymphoma (n=68), MDS (n=48), CML (n=43) and other diseases (n=34), with 38% of the patients being at high risk and 62% of the patients being at standard risk. Thirty-four percent of the patients underwent SCT from a genotypically HLA-matched related donor (MRD), 34% of the patients underwent SCT from a genotypically HLA-matched unrelated donor (MUD) and 32% of the patients underwent SCT from a genotypically HLA-mismatched donor (MMD). Sixty-one percent of the patients received myeloablative conditioning and 39% of the patients received reduced-intensity conditioning. Seventy-eight percent of the patients received BM and 22% of the patients received PBSC. Forty-six percent of the patients received cyclosporine A and short-term methotrexete (CSP+sMTX), and 51% of the patients received tacrolimus (TK) +sMTX as a GVHD prophylaxis. CSP and TK were continuously administered from day -1 at starting doses of 2-3 mg/kg and 0.02-0.03 mg/kg, respectively. MTX was administered intravenously on days 1, 3 and 6, and the doses were 15 mg/m2, 10 mg/m2 and 10 mg/m2, respectively. TK+sMTX was administered more frequently in the patients who underwent SCT from MUD or MMD (P<0.001). AGVHD, grade II-IV AGVHD and grade III-IV AGVHD occurred in 60%, 40% and 17% evaluable patients, respectively, at median onset day of 26. Chronic GVHD occurred in 51.4% evaluable patients. After a median follow-up period of 41 months, 5-year overall survival rate (OS) was 50.8% and there was no difference between the donor groups (P=0.70). TRM was significantly increased in patients who underwent SCT from an MMD (P=0.03), and grade III-IV AGVHD was marginally significant (P=0.06). In patients who developed grade III-IV AGVHD, OS was significantly decreased (5y-OS: 57.4% vs. 25.6%, P<0.001). Among patients who received HLA-mismatched SCT, incidence of grade III-IV AGVHD was significantly lower in patients who received TK+sMTX than in patients who received CSP+sMTX (P=0.02). OS and TRM were not different between the GVHD prophylaxis groups of the patients who underwent HLA-mismatched SCT (P=0.59 for OS and P=0.24 for TRM).Conclusions: TK+sMTX as a GVHD prophylaxis decreased severe AGVHD in patients who underwent HLA-mismatched SCTs.

EPSTEIN-BARR VIRUS ASSOCIATED CENTRAL NERVOUS SYSTEM DISEASES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Q Liu, MQ Wu, F Huang, Z Fan, HS Zhou, X Zhang, G Yu, J Sun
Nanfang Hospital, Southern Medical University, GuangZhou, China

Background. Central nervous system(CNS) viral infections, especially Epstein-Barr virus(EBV) infection, are not rare in recipients of transplants.**Aims.** To evaluate CNS infection of EBV in the recipients of allogeneic hematopoietic stem cell transplantation(allo-HSCT). **Methods.** Fifty-three patients were enrolled in this prospective study, including 34 patients with EBV-associated diseases, 11 with asymptomatic EBV-DNA-emia and 8 with CNS manifestations but without EBV-DNA-emia. The levels of EBV-DNA in cerebrospinal fluid(CSF) were detected by real-time polymerase chain reaction assay(RQ-PCR). Otherwise, cytomegalovirus (CMV) - and BK virus (BKV)-DNA were detected by RQ-PCR, and herpes simplex virus (HSV) types 1 and 2-, varicella zoster virus (VZV)- and human herpes virus types 6-8 (HHV6-8)- DNA were detected by qualitative PCR in blood and CSF. **Results** Of the 45 patients with EBV-DNA-emia, 12 patients were EBV-DNA positive, 1 was CMV-DNA positive and 1 HSV-1-DNA positive, respectively, in CSF. In 8 patients with CNS manifestations but without EBV-DNA-emia, EBV-, HSV-1- and VZV-DNA were detectable in 1, 2 and 1 case, respectively, in CSF. All patients who were virus-DNA positive in CSF had CNS manifestations. These patients all were simultaneous corresponding viremia except 1 patient, who had EBV-DNA-emia at 19 days after the onset of EBV-DNA positivity in CSF. Magnetic resonance imaging (MRI) revealed that 10 cases were abnormal and 8 normal in the 18 patients who were virus-DNA positive in CSF. Thirteen patients were diagnosed as EBV-associated CNS diseases, 3 as HSV-1 encephalitis, 1 as CMV encephalitis and 1 VZV encephalitis according to the results of CSF, MRI and so on. Of the 13 patients with EBV-associated CNS diseases, 7 cases were diagnosed as EBV-associated encephalitis/myelitis and 6 as post transplant lymphoproliferative disorder(PTLD) at the time of disease onset. With the development of disease, 1 case who was diagnosed as encephalitis initially had space-occupying lesions in CNS, and diagnosed as PTLD finally. The time of EBV-associated CNS diseases onset was from +22 days to +184 days (median time, +46 days) post-transplantation. The patient with CMV encephalitis occurred on days +41, 1 VZV on days +308, and 3 HSV-1 on days +29, +938 and +1245 post-transplantation, respectively. The EBV-DNA levels of CSF were higher than that of blood in patients with EBV-associated CNS diseases. The EBV-DNA levels of blood and CSF declined with control of the diseases. On the contrary, the EBV-DNA levels of CSF increased, and blood increased or remained unchanged with the development of the diseases in those who were unresponsive to the treatment. To now, 9 patients were alive (EBV-associated CNS diseases in 6, HSV-1 encephalitis in 2 and VZV encephalitis in 1, respectively) and 9 death.**Conclusions** EBV infection in CNS is common, as well as more frequently than other opportunistic viral infections in the early times of allo-HSCT. Both encephalitis/myelitis and PTLD may act as the initial presenting manifestation, and encephalitis/myelitis can progress to CNS PTLD with the development of disease. A few EBV-associated CNS diseases might be EBV-DNA negative of blood at the time of disease onset.

EPSTEIN-BARR VIRUS LOAD IN CEREBROSPINAL FLUID AND PERIPHERAL BLOOD OF PATIENTS WITH EBV-ASSOCIATED CENTRAL NERVOUS SYSTEM DISEASES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Q Liu[1], YW Ling[1], Z Fan[1], QL Jiang[1], J Sun[1], XL Wu[2], J Zhao[1], Q Wei[1], Y Zhang[1], G Yu[1], MQ Wu[1], R Feng[1]
[1]Nanfang Hospital, Southern Medical University, GuangZhou, China
[2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background. The EBV-DNA loads of blood could act as an indicator for development and therapeutic evaluation of EBV-associated diseases other than central nervous system (CNS), but whether it also could act as an indicator for development and therapeutic evaluation of EBV-associated CNS diseases need to be defined. **Aims.** To evaluate the diagnostic and prognostic utility of monitoring the Epstein-Barr virus (EBV) load in the cerebrospinal fluid (CSF) and peripheral blood for the patients with EBV-associated central nervous system (CNS) diseases after allogeneic hematopoietic stem cell transplantation (allo-HSCT). **Methods.** 172 patients undergoing allo-HSCT were enrolled in the prospective study.The EBV-DNA levels of blood were monitored regularly with RQ-PCR in recipients of transplants for 3 years post-transplantation. The EBV-DNA levels of CSF were monitored in patients with EBV-associated CNS diseases before the treatment and at different points following the treatment. **Results** Twenty-seven patients occurred post-transplant EBV-associated diseases, including 12 patients with EBV-associated CNS diseases. The 3-year cumulative incidences of EBV-associated diseases and EBV-associated CNS diseases were 19.5 ± 3.5% and 8.6 ± 2.4%, respectively. Patients with EBV-associated diseases showed higher loads of EBV-DNA in their blood than that of patients with EBV-DNA-emia. There was no difference between the EBV-DNA levels of blood in patients with CNS involvement and patients without CNS involvement. The EBV-DNA loads of blood increased 3 to 14 days before the clinical manifestations of EBV-associated diseases emerged. The EBV-DNA loads of CSF were higher than that of blood in patients with EBV-associated CNS diseases. In 12 patients with EBV-associated CNS diseases, EBV-DNA levels were declining both in blood and CSF with the control of diseases and the EBV-DNA loads of CSF decreased faster than that of blood in 5 patients who responded to treatment, and the EBV-DNA levels of CSF increased in 5 patients who were unresponsive to treatment. Otherwise, in 2 patients, their EBV-DNA levels in blood decreased and lymphadenectasis became smaller after the use of intravenous rituximab-based treatment, but their EBV-DNA levels in CSF increased and CNS manifestations did not have improvement or worsened. And their EBV-DNA levels in CSF quickly decreased and CNS manifestations were improved after they treated with intrathecal rituximab. On multivariate analysis, the use of antithymocyte globulin and intensified conditioning regimens were independent risk factors for EBV-associated diseases and EBV-associated CNS diseases. **Conclusions.** EBV-associated CNS diseases are not rare after allo-HSCT. The EBV-DNA loads of CSF could act as an important indicator, but the EBV-DNA loads of blood could not, for the diagnosis, prognosis and therapeutic evaluation of EBV-associated CNS diseases.

THE SUCCESSFUL TRANSPLANTATION OF SEVERE APLASTIC ANEMIA WITH AUTOLOGOUS CORD BLOOD

SK Park
Ulsan University Hospital, Ulsan, South-Korea

Background. Cord blood transplantation may be curative for patients with acquired and genetic disorders of hematopoiesis and use of cord blood as an alternative hematopoietic stem cell source has increased substantially. At present, cord blood transplantation has been limited to patients who do not have a matched family or unrelated donor. We report the successful autologous cord blood transplantation in the treatment of two children with severe aplastic anemia. **Methods.** Two patients with severe aplastic anemia whose cord blood units had been collected at birth and stored for years prior to onset of pancytopenia were treated with autologous cord blood transplantation: one in a 6-year old boy and the other in a 3-year boy. The preparative regimen consisted of cyclophosphamide 50mg/kg/d on days -7 through -4, rabbit antithymocyte globulin(Thymoglobulin) 2.5mg/kg/d on days-6 through -3, followed by infusion of 1.8×10^7 , 6.0×10^7 total nucleated cells per kilogram containing 1.28×10^5 ,0.9×10^5 $CD34^+$ cells per kilogram.Results. White blood cell engraftment (ANC $>0.5 \times 10^9$/L) occurred by day 18, 29 and platelet engraftment ($> 20 \times 10^9$/L) by day 31, 46. The patient's recovery was unremarkable. At 1 year and 6 years of follow-up, the patients are in complete hematologic remission with a normal complete blood count. **Summary**. We report the two cases of successful autologous cord bloodtransplantation for the treatment of severe aplastic anemia.

A WEB-BASED STEPPED CARE INTERVENTION FOR PSYCHOLOGICAL DISTRESS AND QUALITY OF LIFE AFTER AUTO-SCT FOR HEMATOLOGICAL MALIGNANCIES: A RANDOMIZED CLINICAL TRIAL

AMJ Braamse[1], B van Meijel[2], O Visser[1], P van Oppen[1], A Boenink[1], C Eeltink[1], P Cuijpers[3], P Huijgens[1], A Beekman[1], J Dekker[1]
[1]VU University Medical Center, Amsterdam, Netherlands
[2]Inholland University for Applied Sciences, Amsterdam, Netherlands
[3]VU University, Amsterdam, Netherlands

Background. In the first year after treatment with auto-SCT, anxiety and depressive symptoms are being reported by approximately 18% and 26-36% of the patients, respectively. Psychological distress has shown to be a strong predictor of health-related quality of life in cancer patients following stem cell transplantation. Psychological treatment is hypothesized to improve psychological distress, functional status and other aspects of quality of life in these patients. We offer patients a stepped care intervention, including internet self-help therapy, in a randomized clinical trial.**Aim.** The aim is to evaluate the outcome of a stepped care intervention for psychological distress on functional status and other aspects of quality of life in patients with hematological malignan-

cies treated with auto-SCT. **Methods.** The study is designed as a randomized clinical trial with 2 treatment arms: stepped care versus care as usual. Stepped care consists of (1) watchful waiting; (2) internet self-management program; (3) face-to-face counseling, medication, or referral. **Results.** The study started in August 2009 and is still ongoing. Preliminary analyses show that just before transplantation, 51% of the patients are psychologically distressed. At 13, 30 and 42 post-transplant, this percentage rises from 30 to 43%, with female patients being more likely to be distressed. Up to now, 29 patients were offered treatment with the online self-help intervention 'Stress under control', and no patients were referred to step 3 of the stepped care program. Of the 21 patients who chose to start with online self-management therapy, 12 quit after lesson 1 or 2. The other 9 patients completed the intervention successfully; preliminary evaluation showed a reduction of psychological distress in this group.**Summary and Conclusions.** This study has several innovative characteristics. First, the outcome of the intervention for psychological distress in auto-SCT patients is evaluated in a randomized clinical study. Furthermore, the intervention concerns an web-based treatment in the first step. Finally, the intervention is characterized by an emphasis on self-management, efficiency, and a multi-disciplinary approach. In the treatment of psychological distress, internet therapy seems to be a valuable option for hematological cancer patients undergoing auto-SCT. However, not all patients judge this treatment type to be helpful. Detailed assessment of the need for psychological treatment, in a face-to-face contact, seems to be important in this intensively treated patient group. Patients' need for treatment should be assessed, and intensity of treatment should be tailored to the specific needs of the individual patient.

1003

QUALITY OF LIFE IN BLOOD CANCER PATIENTS IN COMPLETE REMISSION AT LONG-TERM FOLLOW-UP AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION (AHSCT)

I Ionova[1], V Melnichenko[2], D Fedorenko[2], N Mochkin[2], K Kurbatova[1], G Gorodokin[3], A Novik[2]

[1]Multinational Center for Quality of Life Research, St. Petersburg, Russian Federation

[2]Pirogov National Medical Surgical Center, Moscow, Russian Federation

[3]New Jersey Center for Quality of Life and Health Outcome Research, New Jersey, United States of America

It is now clearly established that cure or control of the underlying malignancy is not necessarily accompanied by full restoration of health or quality of life (QoL) in long-term survivors. At the same time, there is lack of information about QoL profile in blood cancer patients in complete remission at long-term follow-up after ASCT. We aimed to examine QoL in patients with hematological malignancies in complete remission at long-term follow-up after AHSCT as compared with population norms.A totalof 72 patients with hematological malignances (non-Hodgkin lymphomas - 24 patients, Hodgkin lymphoma - 24, multiple myeloma - 20, others - 4) in complete remission with the follow-up period of at least 12 months were enrolled in the study (mean age 40.3, SD-12.7; male/female -33/39). All patients were treated by AHSCT. Mean follow-up was 24 months. QoL was assessed using generic questionnaire SF-36. To compare patient population with normative data the sample from population norm (PN) data base adjusted to age and gender (n=72) was used. For comparisons t-test for independent samples or Mann-Whitney test was used. Distribution of patients according to the grades of QoL impairment was analyzed: no QoL impairment (Integral QoL index similar to the one in normative population sample), mild (25% decrease from a PN), moderate (25-50% decrease), severe (50-75% decrease), and critical(>75% decrease).QoL parameters in patients in long-term remission were similar to the ones in general population for the majority of scales: role-physical functioning - 75.0 vs 78.6, bodily pain - 85.9 vs 79.7, general health - 60.5 vs 66.1, vitality - 66.9 vs 68.9, social functioning - 84.6 vs 77.4, role-emotional functioning - 79.5 vs 74.1, and mental health - 72.0 vs 66.4. The value of physicalfunctioning scale was significantly lower in patients as compared to PN: 77.1 vs 92.4 ($p<0.001$). The majority of patients had no QoL impairment (55 patients); 5 patients - mild QoL impairment, 7 - moderate QoL impairment; 4 - severe QoL impairment, and 1 - critical QoL impairment.In conclusion, patients with hematological malignances in complete remission with follow-up of at least 1 year after ASHT had QoL parameters similar to normative data except physical functioning. The vast majority of patients exhibited either no or mild to moderate QoL impairment. At the same time, 7% of patients had either severe or critical QoL impairment. Further studies are needed to examine QoL profile in this patient population to better define treatment outcomes after AHSCT.

1004

A DEDICATED GVHD CLINIC CAN IMPROVE THE QUALITY OF LIFE FOR CANCER SURVIVORS

L Dignan, R Manwani, M Potter, M Ethell, H Leonard, J Brennan, B Shaw
The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom

Background. Graft versus host disease (GVHD) remains a major cause of morbidity and mortality following haematopoietic stem cell transplantation (SCT). These cancer survivors can have complex medical, psychological, physical and social issues which may not be fully addressed in standard transplant follow-up clinics due to time restraints or lack of resources. A specialist GVHD clinic was established at the Royal Marsden NHS Foundation Trust,UKto try and improve the quality of care for these patients.AimsTo evaluate the impact of the new GVHD clinic on quality of life, morbidity and mortality and referral patterns. **Methods.** All patients who attended the clinic from 1/9/2010 to 1/9/2011 were included in the study. Data were collected from the electronic patient record. A proforma was completed for each new patient and patients were asked to complete FACT-BMT and chronic GVHD symptom scale questionnaires as a measure of health related quality of life. The study was approved by the Royal Marsden NHS Foundation Trust audit committee. **Results**. Thirty patients attended the clinic (24 had chronic GVHD and 6 had acute GVHD). 20 patients were male and the median age was 48 years (range 22-68 years).Ten patients had severe chronic GVHD and 14 had moderate GVHD according to NIH criteria. All patients with acute GVHD had grade III/IV disease. 26/30 (87%) were within one year of transplant. 24/30 (80%) were on two immunosuppressive agents. 17/30 (57%) had single organ involvement, 13% had two organs involved and 30% had 3 or more organs involved. 42 referrals to other specialists were made. The most frequent referrals were made to dermatology (13/30) and ophthalmology (8/30). Patients frequently required input from the dietician (12/30), physiotherapist (8/30), occupational therapist (5/30) or psychological medicine (8/30). Ten patients stopped immunosuppression and 13 remained on immunosuppression at last follow up. Seven patients died (2 GVHD alone, 5 GVHD plus infection). A subset of patients completed the chronic GVHD symptom scale and FACT BMT questionnaires as a measure of quality of life. The patients with more severe GVHD according to NIH criteria had lower chronic GVHD symptom scores and higher FACT BMT scores indicating poorer quality of life. Nine patients completed the cGVHD symptom scale at different time points. All patients showed an improvement in scores and, in five patients, this improvement was large enough to suggest a significant change in quality of life. **Conclusions.** This pilot study evaluated the first year of a new dedicated GVHD clinic. This report shows that the clinic led to active involvement of the multidisciplinary team, referrals to specialists with an interest in GVHD and preliminary data suggest an improvement in patients' quality of life.

1005

BIOCHEMICAL MARKERS FOR EARLY DETECTION AND PREDICTION OF CARDIOTOXICITY IN PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

L Roziakova[1], M Mistrik[1], E Bojtarova[1], J Dubrava[2], J Gergel[3], N Lenkova[3], B Mladosievicova[4]

[1]University Hospital, Bratislava, Slovakia

[2]Non-invasive Cardiology Department, Bratislava, Slovakia

[3]Department of Clinical Biochemistry, Bratislava, Slovakia

[4]Institute of Pathological Physiology, School of Medicine, Comenius University, Bratislava, Slovakia

Background. Cardiac events are emerging life-threatening complications after allogeneic hematopoietic stem cell transplantation (HSCT). **Aims.** We aimed to *assess the predictive* value of high sensitive cardiac troponin T (hs-cTnT) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) testing and early identification of patients at high risk of a cardiac event after HSCT. **Methods.** Sixty-three patients with the median age of 37 years at the time of allogeneic HSCT for hematologic diseases were studied. Fifty patients were conditioned with myeloablative regimens and the remaining 13 patients with nonmyeloablative regimens. Forty-four patients (69,8%) were previously treated with anthracyclines. Cardiac biomarkers were serially measured before conditioning regimen and at days 1, 14 and 30 after HSCT. Cardiac systolic and diastolic functions were assessed before conditioning regimen and 1 month after HSCT by echocardiography. Written informed consent was obtained from all patients. **Results.** The differences in plasma NT-proBNP and hs-cTnT concentrations during the 30 days following the HSCT were statistically significant ($P < 0,01$ v.s. $P<0,01$). Thirty days after HSCT, we found a statistically significant decrease in systolic and diastolic parameters performed by echocardiography ($P<0,01$ v.s. $P<0,01$). Seven of 63 patients (11%) developed a cardiac event defined as cardiac dysrhythmias, pericarditis with cardiac tampon-

ade and heart failure. In two patients, the cardiotoxicity was severe and resulting in death. By multivariate analysis, the strongest predictor of cardiac event was an increased level of hs-cTnT and NT-proBNP persisted for a period 14 days after HSCT (P < 0,01). The use of hs-cTnT at day 14 after HSCT (with the diagnostic cutoff value of 0,014 µg/L) had a sensitivity of 100% and a specificity of 83.9%. The use of NT-proBNP (with the diagnostic cutoff value of 1411 pg/mL) at day 14 after HSCT had also a sensitivity of 100% and a specificity of 83.9%. Results of hs-cTnT testing were better than those of NT-proBNP testing, with significantly greater area under the curve (0.93 vs 0.91, P < 0,01). The area under the curve from hs-cTnT testing plus NT-proBNP testing (0.95) was superior to each diagnostic modality alone. **Conclusions**. Receiver-operating characteristic analyses demonstrated hs-cTnT and NT-proBNP to be highly sensitive and specific for the diagnosis of cardiotoxicity after HSCT. Measurements of plasma NT-proBNP and hs-cTnT concentrations might be a useful tool for identification of high-risk patients requiring further cardiological follow up. Measurement of hs-cTnT plus NT-proBNP was superior to hs-cTnT and NT-proBNP measurements alone. Further studies are needed to clarify whether combination of both biomarkers improve detection of cardiotoxicity.This work was supported by a grant from the Scientific Grant Agency of the Ministry of Health, Slovak Republic 2007/42-UK-18.

[10]CancerCare Manitoba, University of Manitoba, Winnipeg, Canada
[11]UBC, Manitowoc, USA, United States of America

Background. In order to prevent some of the high mortality associated with invasive fungal infections (IFI), antifungal prophylaxis (AFP) may be indicated for allogeneic hematopoietic cell transplant (alloHCT) recipients at high risk for IFI, in particular for invasive mould infections. **Aims.** To evaluate the cost-effectiveness of voriconazole compared with other oral azoles (fluconazole, itraconazole, posaconazole) as primary AFP in patients undergoing alloHCT in Spain. **Methods.** A decision analytic model was used to simulate prophylactic treatment in a hypothetical cohort of 1000 patients undergoing alloHCT. Costs and outcomes for a 180-day period post-transplant were estimated. A previously presented, mixed treatment comparison (MTC) of randomized clinical trials (RCTs) was used to derive the probability of developing invasive aspergillosis (IA), invasive candidiasis (IC), or other IFI, as well as the proportions of patients requiring other licensed antifungal treatment (OLAT). Duration of AFP was derived from the clinical trial data included in the MTC (posaconazole prophylaxis was assumed to have the same duration as voriconazole prophylaxis) and confirmed by expert opinion. Costs of treating breakthrough IFI and IFI case fatality rates were based on published literature. The model considered direct costs associated with drug acquisition (separately for AFP and OLAT), IFI monitoring, and IFI treatment from the perspective of the Spanish national health system in 2011. **Results.** Costs and outcomes based on the hypothetical 1000-patient cohort are summarized in the table. Itraconazole was associated with the lowest total cost (€15,210,908) followed by fluconazole (€17,636,100), voriconazole (€19,443,320), and posaconazole (€23,615,334). Voriconazole was associated with the lowest number of breakthrough IFI cases (n=30), fewest deaths from breakthrough IFI (n=21), and fewest deaths from any cause (n=217). Voriconazole was also associated with the most life-years gained. Compared with estimates for posaconazole, voriconazole resulted in cost savings of €4,172,014, along with 20 fewer IFIs, 8 fewer deaths from IFI, and 6 fewer total deaths. Compared with fluconazole as control, the number of patients needed-to-treat to prevent one IFI was 20 for voriconazole and 33 for both itraconazole and posaconazole; the number of patients needed-to-treat to prevent one additional death was 36 (voriconazole), 59 (itraconazole) and 47 patients (posaconazole). Results of the base-case analysis showed that posaconazole was "dominated"(ie, more costly and resulted in fewer life years and more IFIs) by voriconazole. Similarly, fluconazole was "dominated"by itraconazole. Compared with itraconazole, voriconazole was associated with higher costs but also resulted in more life years and fewer IFIs. **Conclusions**. Among the second-generation azoles, voriconazole was less costly and more effective (reduced mortality, IFI avoided, and life years gained) than posaconazole as primary AFP in alloHCT recipients 180 days post-transplant. In this model, itraconazole appeared to be more cost-effective than second-generation azoles; this result is not surprising, given that itraconazole is available as an inexpensive generic. However, there are important clinical limitations with itraconazole as AFP, such as relatively poor long-term tolerability and lack of an alternative intravenous formulation in some countries.[Note: AFP currently constitutes off-label use for voriconazole.

USE OF PERIPHERAL VENOUS ACCESS IN PERIPHERAL BLOOD STEM CELL COLLECTION: A COST ANALYSIS

JM Garcia Gala, MJ Garcia de la Fuente, E Martinez Revuelta, R Fueyo, C Buesa Garcia, C Alarcon Gil, A Fonseca Mourelle, O Alvarez Garcia, A Estrada Rodriguez, F García Menendez-Tevar
Hospital Universitario Central de Asturias, Oviedo, Spain

Aims. The cost of a stem cell harvest procedure from peripheral blood is high. It is usual practice to place a central venous catheter to perform the aphaeresis, specially when large volumes of blood are processed. However, this technique is not free of complications and requires hospital admission, which incises in the global cost of the aphaeresis procedure. Obtaining stem cells by peripheral venous access (PVA) is feasible and it is performed in an out-patient basis which could minimize the expense without affecting the outcome of the procedure. Our centre has developed a protocol aiming to use PVA. We present the results of this protocol and a cost analysis. **Methods.** In order to assess the efficacy and cost of a PVA, we obtained the records of the aphaeresis procedure performed during the years 2010 to 2011 in our unit. Inclusion criteria were: weight >50 kg and stem cell mobilization with G-CSF alone or G-CSF and plerixafor for autologous stem cell transplantation. Healthy donors were excluded. Expert nurses assessed whether PVA or central line was to be used for the procedure in the baseline visit in the aphaeresis unit. Stem cells were collected by aphaeresis using a COBE-Spectra (Cobe BTC, Lakewood, CO, USA) to obtain a number of CD34+ cells which was considered enough to perform the transplantation depending on the pathology of the patient. The Economics Evaluation Unit of our hospital calculated the global cost of each aphaeresis procedure. **Results.** A total of 105 aphaeresis procedures from the 78 patients were performed (Median±SD 1.36±0.61). PVA was used in 45 (57.7%) patients. All of the patients had received previous chemotherapy. Median age was 58 (range 7 - 78). Diagnosis was Multiple Myeloma (42.3% patients), Non-Hodgkin Lymphoma (32.1%) and others, including acute leukaemia and Hodgkin lymphoma (25.6%). 51 patients (65.4%) underwent a single aphaeresis procedure, whereas 2 patients required 3. The target CD34+ cells dose was obtained in 72 (92.3%). There was no difference in the number of aphaeresis procedures needed. (1.45 in the PVA vs 1.3 in the central line group. p=NS). 2 patients in the PVA group needed a central line placement due to hematoma in the puncture site before a second procedure due to insufficient stem cells collected in the first day of aphaeresis. Global cost for patient with Central line was 2.402,86 € (Personnel cost 236,90 €, Material 1.325,96 €, Admission 840 €). Global cost in the case of use PVA was 1.418,70 € (Personnel cost: 196,70 €, Material: 1.222,90 €). **Conclusions.** Peripheral venous access can be successfully used for stem cell collection in peripheral blood aphaeresis procedures in previously chemotherapy-treated patients. A throughout assessment by expert nurses in the aphaeresis area is fundamental to increase the use of PVA in aphaeresis procedures. The use of PVA allows a median save of 984.16€ per patient

Stem cell transplantation - Experimental

IMPACT OF MYELOID DERIVED SUPPRESSOR CELLS FREQUENCIES IN G-CSF MOBILIZED UNRELATED DONOR GRAFTS ON THE INCIDENCE OF ACUTE GVHD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

C Carniti[1], A Vendramin[1], A Bermema[1], S Gimondi[1], P Longoni[1], M Morelli[1], P Corradini[2]

[1]Fondazione IRCCS Istituto Nazionale Tumori, Milano, Italy

[2]Fondazione IRCCS Istituto Nazionale Tumori, University School of Medicine, Milano, Italy

Background. Myeloid-derived suppressor cells (MDSCs) comprise a heterogeneous population of immature myeloid cells with immunosuppressive capabilities. Recent evidence suggests that in mice graft-versus-host disease (GvHD) can be abrogated by *ex-vivo* expanded, bone marrow derived, MDSCs generated in the presence of GM-CSF, G-CSF and IL-13 (Highfill et al. Blood 2010). Whether MDSCs play a role in human allogeneic hematopoietic stem cell transplantation (allo-HSCT) is still unclear. In this scenario, we hypothesized that G-CSF stem cell mobilization may be protective from acute GvHD (aGvHD) in unrelated donor HSCT by increasing MDSC frequencies. **Methods.** G-CSF-mobilized peripheral blood (PB) samples were collected from 40 healthy unrelated donors (median age 34, range 20-43, male/female 31/9) who received G-CSF (Filgrastim) at 10 µg/kg/day for 5 days. Donor selection had been performed according to standard criteria, including molecular typing for HLA-A, -B, -C, DRB1, and DQB1. Donors were 10/10 HLA-matched (MUD) in 20 cases, 9/10 in 13 cases and the remaining 7 cases were mismatched in 2 or more HLA loci (MMUD). Patients (median age 46, range 18-67) received reduced intensity conditioning based on low-dose total body irradiation (TBI 2Gy) (8), Fludarabine-Rabbit Antithymocyte Globulin (rATG) (9) or Thiotepa-rATG (23) followed by unmanipulated allo-HSCT. Diagnosis were lymphomas (29), myelomas (8), acute myeloid leukemia (3). Patients received cyclosporine plus either methotrexate (36) or mycophenolate mofetil (4) for GvHD prophylaxis. As controls, PB samples were collected from 10 healthy adults (median age 30, range 23-40). Informed consent was obtained from all subjects. Cells were characterized using flow cytometry (MACSQuant Analyzer, Miltenyi Biotec, Germany) with Abs against CD3, CD14, CD16, CD19, CD20, CD56, CD11b (Biolegend, San Diego, CA), HLA-DR, CD33 (Miltenyi Biotec, Germany) after Ficoll separation. The frequencies of MDSCs present in the graft were correlated with the clinical characteristics and outcome of the 40 patients. *Results.* A population of MDSCs defined as CD3/CD19/CD56/CD14$^{-/Lo}$ or Lin$^{-/Lo}$, HLA-DR^{-} CD33^{+}CD11b^{+} was easily detected in G-CSF mobilized PB samples. Expansion of MDSCs in the PB of G-CSF-treated unrelated donors was found with respect to steady state control individuals ($p< 0.03$, Mann Whitney-U). Acute GvHD occurred in 16 of 40 patients (40%). There was no significant correlation between the incidence of aGvHD and the degree of HLA incompatibility or the presence of donor-recipient sex mismatches. Neither the conditioning regimens nor the GvHD prophylaxis had effect on risk of aGvHD. Conversely, aGvHD patients received grafts containing significantly lower number of MDSCs when compared to non-aGvHD patients ($p < 0.006$, Mann Whitney-U). The ability of MDSC levels in the graft to predict the occurrence of aGVHD was determined by the receiver operating characteristic (ROC) curve: sensitivity was 100%, specificity was 60%, area under the curve, AUC=0.768.**Conclusions.** G-CSF mobilization significantly increases circulating MDSCs in Matched Unrelated Donors relative to healthy volunteers. A significant correlation between the frequencies of MDSCs present in the graft and the incidence of aGvHD was found. Although these findings should be confirmed in prospective studies, modulating MDSCs in the graft might represent a promising strategy for GVHD prophylaxis.

1009

MYELOID-DERIVED SUPPRESSOR CELLS CONTRIBUTED TO CONTROL ACUTE GRAFT-VERSUS-HOST DISEASE IN PATIENTS UNDERGOING UNMANIPULATED ALLOGENEIC BLOOD AND MARROW TRANSPLANTATION

M Lv, XJ Huang, XY Zhao, XS Zhao

Peking University People's Hospital, Beijing, China

Background. The regulatory role of myeloid-derived suppressor cells (MDSCs) is emerging in immune tolerance induction of animal transplantation models. Previously our team found MDSCs mobilized by G-CSF in allografts positively correlate with low risk of acute graft-versus host disease (aGvHD) in patients undergoing unmanipulated allogeneic blood and marrow transplantation.**Aims.** The aim of this study was to further investigate :(1) the immune reconstitution of MDSCs after allogeneic transplantation ;(2)their roles during the onset and recovery of aGvHD, as well as the potential regulatory network with alloreactive and regulatory lymphocytes. **Methods.** After unmanipulated allogeneic blood and marrow transplantation, patients were monitored for MDSCs in peripheral blood at +7, +15, +30days. Patients with aGvHD were prospectively analyzed for the subsets and cytokine secretion of MDSCs: monocytic MDSCs (CD33^{+}CD11b^{+}CD14^{+}lin^{-}HLA-DR^{-}), granulocytic MDSCs (CD33^{int}CD11b^{+}CD15^{+}lin^{-}HLA-DR^{-}), as well as Th1/Th17, regulatory T cells (Treg), etc. in peripheral blood at the onset of aGvHD, during therapy and post-therapy evaluation. Prophylaxis for aGvHD post transplantation included cyclosporine A(CsA) and short-term methotrexate (MTX) with mycophenolate mofetil (MMF) The first-line therapy for aGvHD mainly included methylprednisolone, FK506; second-line therapy included anti-CD25 monoclonal antibodies.**Results.** MDSCs were undetectable at+7days, gradually increased from +15days, and nearly recovered to the level of healthy donor around +30days in the absence of aGvHD or poor neutrophils engraftment. There are no significant differences between the immune reconstitution of two subgroups. 10 of 18 patients got I-II degree of aGvHD only involving with skin; other 8 patients got II-III degree of aGvHD with mild to moderate gut involvement. In those patients (n=12) responding well to steroid and adjusting CsA/FK506, monocytic MDSCs are found lower (0.05%-0.64% of nucleated cells)at the onset of aGvHD, rapidly increased to the peak(1.81%-6.79%) as the rash spread or diarrhea become severe, then decreased gradually after partial recovery(PR). The sustaining low level of monocytic MDSCs predicted poor response to the first-line therapy, and those patients (n=6) got partial or complete recovery with anti-CD25 antibodies. Granulocytic MDSCs showed similar pattern yet more obviously in patients involved with gut. The secretion of IL-10 and TGF-beta increased corresponding to the number of MDSCs. The percentage of INF-gamma and/or IL-17 producing CD4+ T cells (Th1/17, etc.) negatively correlated with the variation of MDSCs; while MDSCs slightly increased after the application of anti-CD25 antibodies.**Conclusions**: These data indicate that besides MDSCs in allografts, the immune reconstitution of MDSCs after allogeneic transplantation may also contribute to the control of aGvHD; the expansion of MDSCs in vivo seems to be kind of negative feedback to the alloreactive lymphocytes and aGvHD. Such a regulatory phenomenon may be important to interpret the roles of MDSCs in allogeneic hematopoietic stem cell transplantation and provide base for clinical practice, such as infusion of MDSCs or application of M-CSF/G-CSF post transplantation for prophylaxis and treatment of aGvHD.

HLA CLASS II RESTRICTED ANTIGENS WHICH PRESENTATION IS ABOLISHED BY HLA-DM AND RESTORED BY HLA-DO ARE APPROPRIATE TARGETS FOR SELECTIVE GRAFT-VERSUS-LEUKEMIA REACTIVITY

A Kremer, E Van der Meijden, M Honders, M Pont, J Falkenburg, M Griffioen

Leiden University Medical Center, Leiden, Netherlands

Background. In contrast to the majority of solid organs, hematological malignancies often express HLA class II at their cell surface. HLA class II restricted antigens may therefore be attractive targets for CD4+ T-cells in allogeneic hematopoietic stem cell transplantation (alloSCT) to induce beneficial Graft-versus-Leukemia (GvL) reactivity without Graft-versus-Host Disease (GvHD). In the presence of pro-inflammatory cytokines, however, non-hematopoietic tissues may express HLA class II and become targets for CD4+ T-cells in GvHD. We previously identified various HLA class II restricted antigens as targets for CD4+ T-cells in alloSCT, and demonstrated that these antigens can be divided into DM-resistant and DM-sensitive antigens based on their behavior towards HLA-DM and its natural inhibitor DO. In a human cell line model, pres-

entation of DM-sensitive antigens was shown to be abolished by HLA-DM and could only be restored by HLA-DO. As expression of HLA-DO in its full heterodimer configuration is hardly induced by pro-inflammatory cytokines in non-hematopoietic cells, DM-sensitive antigens are not efficiently presented on non-hematopoietic tissues. DM-sensitive antigens may therefore be ideal targets for CD4+ T-cell based therapies with the aim to induce a selective GvL effect.**Aims**Aim of this study is to investigate whether DM-sensitive antigens are appropriate targets for CD4+ T-cells in GvL reactivity.**Methods**Gene expression of HLA-DRA, invariant chain, HLA-DMA and DMB, HLA-DOA and DOB was measured in primary leukemic cells of different origins by microarray gene expression analysis. T-cell recognition of primary leukemic cells was measured by IFN-g ELISA. HLA-DO expression levels were modified in acute leukemia cell lines by gene introduction and silencing by specific short hairpin RNA.**Results**All HLA class II positive primary leukemic samples were shown to express similar mRNA levels of invariant chain, HLA-DMA and DMB. Also HLA-DOA was highly expressed by all HLA class II positive primary leukemic samples, with exception of a small subgroup of AML samples. HLA-DOB expression was low but present in all AML samples and high in all CLL and some ALL samples. HLA-DOB gene expression in these CLL and ALL samples was comparable to mature DC and B-cells. In the AML subgroup, we could show that lack of T-cell recognition of DM-sensitive antigens correlated with low expression of HLA-DOA. The relevance of HLA-DOA expression was confirmed in ALL cell lines showing that T-cell recognition of DM-sensitive antigens was inhibited upon introduction of HLA-DO specific short hairpin RNA. The experiments furthermore demonstrated and confirmed that T-cell recognition of DM-sensitive antigens was significantly enhanced by HLA-DOB gene overexpression.**Summary/Conclusions**This study shows that the majority of primary leukemic cells express sufficient amounts of HLA-DO to present DM-sensitive antigens, and that expression levels of both components of the HLA-DO dimer are critical for T-cell recognition. The experiments furthermore demonstrate that HLA-DOA and DOB expression in CLL and some ALL cells was comparable to professional antigen presenting cells, suggesting that DM-sensitive antigens may be particularly relevant targets for CD4+ T-cell therapy of leukemic cells of B-cell origin.

[5]Pediatric Clinic, University of Milano-Bicocca, San Gerardo Hospital, Monza, Italy

[6]Adult Haematology Dept., San Gerardo Hospital, Monza, Italy

Background. Graft-versus-Host Disease (GvHD) is a major obstacle to safe allogeneic haematopoietic stem cell transplantation (HSCT). GvHD pathophysiology is still poorly understood and its diagnosis depends on clinical manifestations and invasive biopsies. Specific biomarkers would facilitate the early and accurate recognition and the monitoring of this invalidating disease. The long pentraxin-3 (PTX-3) is locally produced at sites of inflammation. Its rapid increase in different human inflammatory diseases and the correlation between PTX-3 levels and disease severity suggest the potential usage of this molecule as GvHD diagnostic marker.**Aims.** Our aim was to correlate PTX-3 plasma levels with GvHD occurrence in HSCT patients, to define its potential use as early marker of pathology. **Methods.** Having obtained an informed consent, we collected plasma samples from 92 adults and pediatric patients, who received HSCT, and from 17 healthy donors (HD) volunteers. After HSCT, 56/92 patients developed acute GvHD, while 36/46 never experienced it. Concerning GvHD patients, blood samples were collected at the day of GvHD onset, before the beginning of GvHD-specific drug therapy. PTX-3 plasma levels were monitored by ELISA assays.**Results.** Patients who did not develop GvHD after HSCT showed augmented PTX-3 plasma levels (mean=5.57 ng/ml, range=1.1-22.3 ng/ml) if compared to HD (mean=2 ng/ml, range=0.3-5.4 ng/ml, p<0.01). Interestingly, we observed a strong increase of PTX-3 plasma levels in patients with acute GvHD in correspondence to the disease onset (mean=63 ng/ml, range=6-847 ng/ml, p<0.01 vs no GvHD patients). Since PTX-3 values could be influenced by the occurrence of opportunistic infections, we refined our analysis. In particular, we compared PTX-3 plasma levels measured at the onset of GvHD before day 28 after HSCT, time-frame that in our cohort of patients always resulted free from infectious events, with PTX-3 plasma levels measured at the same time point (day 28) in patients who did not develop GvHD within day 28 (no GvHD group). This refined analysis confirmed our previous findings: the median PTX-3 level in 29 patients who developed GvHD within day 28 after HSCT was 35.80 ng/ml (range=11.21-847.44 ng/ml) and was significantly higher than the no GvHD group (PTX-3 plasma level=14.22, range=4.23-58.49 ng/ml, n=30). The difference between the two groups was statistically significant, Wilcoxon p-value<0.001.**Conclusions:** These preliminary results show that PTX-3 plasma levels increase very rapidly in patients experiencing acute GvHD, candidating this molecule as an easily measurable soluble factor useful to corroborate the clinical monitoring of the pathology. *Further studies* are needed to elucidate the role of PTX-3 in GvHD pathophysiology and to confirm its potential usage as GvHD biomarker in a larger cohort of patients.

1012

ADULT MOUSE HAEMATOPOIETIC STEM CELLS DO NOT GIVE RISE TO MESENCHYMAL STEM CELLS OR TUMOR ENDOTHELIAL CELLS

S Wohrer[1], A Patenaude[2], D Knapp[2], K Rowe[2], A Karsan[2], C Eaves[2]

[1]Medical University of Vienna, Vienna, Austria

[2]Terry Fox Laboratory, Vancouver, Canada

Background. Hematopoietic Stem Cells (HSCs) are multi-potent cells that give rise to all hematopoietic cells over extended periods of time. It has been reported that HSCs could also generate non-hematopoietic cells, including mesenchymal cells and endothelial cells. This differentiation capacity could give rise to new and exciting therapeutic opportunities for HSC treatments. However, some research groups could not find the suggested differentiation capacity in their experiments and questioned the methodological exactness of the previously reported results. These incongruous findings led to an ongoing confusion and unabated debates about the differentiation potential of HSCs.**Aims**The aim of this study was, therefore, to investigate the potential of single HSCs to give rise to non-hematopoietic cells in vivo.**Methods**Highly purified HSCs isolated from mouse adult bone marrow (i.e. $EPCR^+$, $CD150^+$, $CD48^-$, $CD45^+$ (ESLAM) cells, 40% with long-term hematopoietic repopulating ability) were transfected overnight with a lenti-GFP virus and a single cell was then injected into each of 28 sub-lethally irradiated congenic *W41/W41* mice. Five mice, that showed a robust contribution (>1%) to all WBC for at least 16 weeks, then received a subcutaneous injection of Lewis lung carcinoma cells. After 10 days the resulting tumor was harvested and the tumor endothelial cells (TEC = $CD45^-Lin^-CD31^+$) were analyzed for GFP expression with fluorescence microscopy and fluorescence activated cell sorting (FACS). GFP^+ cells were further analyzed for viral integration sites and for X/Y chromosomes in mice where the ESLAM donor-host combination was sex-mismatched. Concurrently, bone marrow was harvested from the sacrificed mice and cultured using a protocol to selectively promote mesenchymal stem cell/fibroblast growth and differentiation. The MSCs were further differentiated into osteoblasts, adipocytes, and chondroblasts, which were then analysed for GFP expression with fluorescence microscopy.**Results**Between 2 and 32% of all TECs expressed GFP when analysed by FACS. Tumor sections analysed with fluorescence microscopy showed focal areas of GFP^+ endothelial cells that also expressed CD144. However, viral integration sites could not be detected on sorted GFP^+ TECs. Additionally, TECs from mice that received a sex mismatched cell, showed a triple-X pattern, which was also found in the Lewis lung carcinoma line. Bone marrow MSCs were entirely GFP^-, and so were the MSC-derived adipocytes and osteoblasts. Chondroblasts could not be analyzed definitively. Interestingly, $CD45^-Lin^-CD31^-GFP^+$ cells could be found in the bone marrow of positively engrafted animals but their exact relationship to other hematopoietic cells and their biological function remains to be determined.**Summary/Conclusions**Evidence of tumor endothelial cells or bone marrow mesenchymal stem cells could not be obtained from rigorously analyzed recipients of single HSCs in spite of FACS and fluorescence microscopy evidence of HSC progeny in tumors at sites suggestive of endothelial contributions. On the other hand, our data clearly demonstrate an ability of HSCs to generate $CD45^-Lin^-CD31^-$ bone marrow cells of unknown biological function and significance.

1013

OUTPATIENT AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MALIGNANT HEMATOLOGIC DISORDERS

A Ghavamzadeh, K Alimoghaddam, A Karimi, R Maheriazar, AR Shamshiri, A Jalali
Hematology-Oncology and Stem Cell Transplantation Research Center, Tehran, Iran

Background. High-dose chemotherapy with autologous stem cell support is utilized for the treatment of a variety of malignancies including Multiple myeloma, Hodgkin/non-Hodgkin's lymphoma and AML. The purpose of this study was to describe the time of engraftment, event-free and overall survival rates in outpatient cases treated with autologous stem cell transplantation in our center. **Methods.** From December 2005 to October 2011, medical records of 137 outpatients (97 MM, 24 HL, 10 NHL and 6 AML) were reviewed. Median age was 47 years (15-65). Complete remission was achieved in all patients and no significant evidence of organ failure was observed. They received conditioning regimen (melphalan for MM, CEAM for NHL and HL, busulfan and etoposide for AML) and stem cell infusion in the hospital. The first day after SCT, patients were discharged and then followed-up by outpatient SCT team. If the patients developed febrile neutropenia, rehospitalization was required. After sepsis workup and chest x-ray performance, they received the first dose of antibiotic in the hospital and then the therapy continued at home.**Results.** With a median follow-up of 20.5 months (1-68), the 2-year overall and disease-free survivals were 85.2% and 58.5%, respectively. Median time to ANC and PLT engraftments were 11.3 (rang: 8-26) and15 days (rang: 8-78), respectively. 118 patients are still alive while 4 patients due to transplant-related complications died during the first month following SCT. Relapses occurred in 48 patients. **Conclusions.** The results of the study show that autologous SCT in outpatient cases with malignant hematologic disorders is feasible. Further studies with longer follow-up are required to achieve reasonable results.

OVER EXPRESSION OF PML CAN INHIBIT PROLIFERATION AND PROMOTE OSTEOGENIC DIFFERENTIATION IN HUMAN MESENCHYMAL STEM CELLS

J Sun, S Fu, N Zhu, W Zhong, H Huang
Zhejiang University, Hangzhou, China

Background. With highly potential clinical application of human Mesenchymal Stem Cells (hMSCs), how to get more exogenous MSCs comes to be a new challenge. PML is an important regulator on many fundamental processes, such as apoptosis, cellular proliferation, senescence, cell cycle regulation. In our previous studies, we found PML is highly expressed in MSCs, but very low in tumor cells. We were interesting if PML has some special role on regulating proliferation and/or differentiation of MSCs. In this study, we explored the role of PML in MSCs.**Aims.** Our aim is to investigate the expression and localization of PML in MSCs and how PML regulates the proliferation and differentiation of MSCs. **Methods.** After approval by institutional review board, MSCs were isolated from the**bone** marrow of volunteers Ficoll-paque and its phenotype was confirmed by flow cytometry. Experiments were duplicated in 3 different and randomized samples. QRT-PCR and western blot was used to detect PML mRNA and protein expression. MTT assay and flow cytometry was used to analyse the proliferation of MSCs. PML expression plasmid plenti-6.3/PML and control vector (Invitrogen) were transfected into MSCs. MSCs were cultured with osteoinductive medium (Sigma-Aldrich) for two weeks and cells were collected on day 7 and day 14. Differentiated cells were identified with vonkossa staining and ALP activity analysis (KeyGEN). Ostoblast-specific genes were examined by QRT-PCR and Western blot after PML over expression in MSCs on day 7 and day 14. The location of PML protein during cell proliferation and differentiation was detected by immunofluorescence.**Results.** Isolated MSC cells were uniformly positive for CD29,CD44, CD166 and CD105, while negative for CD34, CD45 and HLA-DR. Compared to 293T cells, PML gene was highly expressed in MSCs, and increased time-dependently along with cell proliferation. The size of PML-NBs in MSCs was also increased during cell proliferation. After over expression of PML, the proliferation of MSCs was inhibited by more than 70% ($P<0.05$). However P27 was significantly lower and cyclin-D1 had an obvious increase in the plenti6.3-PML transfected cells compared with control. Also we found caspase-3, caspase-9 and PARP were not obviously increased with PML over expression. These indicate that over expression of PML can inhibit the proliferation of MSC cells, which is not mediated by cell cycle arrest or cell apoptosis. On day 14, MSCs of osteogenic differentiation were positive for vonkossa staining, and the expression of PML increased time-dependently. During cell osteogenic differentiation, PML-NBs were bigger but unequal in size compared with control. After over expressed with transfected PML, the relative mRNA expression of osteoblastic differentiation-related genes (SPP1□IBSP□BMP2) were up-regulated in MSCs, while the activity of ALP increased, which implied that the capacity of cell osteogenic differentiation was enhanced by PML.**Conclusion:**Our data suggests that PML regulate in MSCs as an inhibitor of cell proliferation but a promoter of cell differentiation. Our findings might give a new sight on better clinical application of MSCs..

1015

IMPACT OF REGULATORY T CELLS (TREG) ON EFFICACY OF AUTOLOGOUS AND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: PRELIMINARY STUDY

J Debski, L Usnarska-Zubkiewicz, D Urbaniak-Kujda, K Kuliczkowski
Medical University of Wroclaw, Wroclaw, Poland

Background. CD4+CD25+Treg are largely responsible for suppressing GvH reactions in patients undergoing alloHSCT, thereby preventing the development of GvHD, facilitate engraftment and determine the effect of GvT. In the autologous setting and cancer evolution model Treg are supposed to actively participate in counteracting of antitumor immunity, contributing to the accelerated growth kinetics and tumor promotion. **Aims.** To assess reconstitution of hematopoiesis, CMV reactivation, aGvHD occurrence and overall survival in patients who underwent autoHSCT or alloHSCT according to the percentage of Treg during the peritransplant period. **Methods.** The study was conducted in 25 patients (M/F=13/12) aged from 20 to 59 years (median 37.7), including 9 with a diagnosis of AML, 1 - ALL, 7 - CML, 4 - HD, 2 - MM, 2 - NHL. AutoHSCT and AlloHSCT were performed in 11/25 and 14/25 patients, respectively. Treg cells CD4+CD25+ were determined by flow cytometry in all patients before transplantation and at +5, +10, +15 and +20 day post-transplant. *Results.* In patients undergoing autoHSCT neutrophil engraftment (ANC> $1.5x10^9$/L) was observed from 11 to 17 days post-transplant (median 12.8), platelet engraftment (PLT> $50x10^9$/L) - from 13 to 35 days (median 21,7). CMV reactivation was not confirmed in any patient of this group. The median percentage of Treg cells was as follows: before autoHSCT - 4.5%, in 5 days after the transplantation - 8.4%, at day +10 - 10.2%, at day +15 - 10.8%, at day +20 - 5,4%. The 5-year OS was 77%, median survival time (MST) was 57.6 months in median follow-up of 74.4 months. In 3/11 (33%) patients who had a relapse after autoHSCT (median TTP 3.6 months) Treg tended to increase in +5, +10 and +15 day (median 13%, 27.5 % and 15.5%), MST reached 18.3 months.In patients after alloHSCT neutrophil engraftment time extended from 14 to 26 days post-transplant (median 17.3) and platelet engraftment - from 19 to 39 days (median 28.5), respectively. The percentage of Treg was: before alloHSCT - 4.8%, at day +5 - 8.7%, at day +10 - 9.1%, at day +15 - 13.1%, at day +20 - 6%. 5-year OS was 7.1%, MST - 36 months in median follow-up of 67.5 months. In 4/14 (28.5%) patients who developed CMV reactivation, a higher values of Treg were observed, successively - 5%, 7%, 11.6%, 19%, 7.5%, MST - 45,7 months. aGvHD occurred in 6/14 (42.8%) patients, the Treg percentage presented levels - 4.6%, 9.8%, 10.8%, 12%, 5.3% and at day +15 and +20 reached values lower than reported in patients without aGvHD, while the MST was 27.6 months. Relapse of disease was observed in 5/14 (35.7%) - TTP = 23.4 months, MST 34 months - in this group analysis revealed a bias that Treg percentage were lower before alloSCT, at day +5 and +10, and higher at day +15, +20, comparing to the patients without relapse. *Summary.* Labelling of Treg cells percentage might be useful in the assessment of post-transplant course, especially in the risk of disease recurrence, but it requires further investigations in a larger group of patients.

Thrombosis and vascular biology 2

MANAGEMENT OF HEMANGIOMAS: A SINGLE CENTER EXPERIENCE

T Celkan, G Tuysuz, B Kutlubay, G Ozdemir
Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background. Hemangiomas are benign neoplasms of the vasculature characterized by abnormal growth of endothelial cells.**Aims.** To share our experience of 185 (F/M: 2.4) patients with hemangiomas followed between 2003-2011 at Cerrahpasa Medical Faculty, Pediatric Hematology Unit in Istanbul Turkey.**Results.** Of the 185 patients, 40% presented at birth. Onehundredtwenty eight (69%) had a single lesion whereas 31% had multiple lesions. In patients with a single lesion; 87 (68%) had a cutaneous hemangioma in the head and neck region (44 at eyelid and/or around eye). In 57 patients with multiple hemangiomas; 46 had a lesion in the head and neck region, 21 had a visceral lesion (4 liver, 1 spleen, 3 larnyx, 2 oropharynx, 4 parotid gland, 3 vertebrae, 2 internal jugular vein, 2 common carotid artery). Most of the patients (n:94) were followed by a "watch and wait"policy and 40 of them did not require any medical or surgical intervention as the lesion convoluted on follow-up. Only 6 (3%) patients required surgery to prevent the life-threatening complications and complications interfering normal physiology. Nine patients with lesion around eye required intralesional steroids to prevent visual disturbance. In 7 patients with an open, bleeding lesion local imiquimod was used with a successful result in 7-10 days. Bleomycin was used as a sclerosing treatment in 2 patients with a giant hemangioma in the tongue. In 21 patients with multiple diffuse lesions causing cosmetic problems, interferon was given. Medical treatment was given in other patients on follow-up due to growth, ulceration, bleeding or persistance of the lesions at older ages; 14 were treated by systemic steroids, 73 by propranolol and 39 by combination therapy due to insuffient response. Propranolol was the first choice of treatment in patients diagnosed after 2008 regarding the new literature. All patients treated by propranolol were evaluated by echocardiography and electrocardiograpy before and during therapy, no cardiac side effects were noted. One patient under treatment presented with increased sweating and was found to have hypoglycemic attacks associated with propranolol during periods of restricted oral intake. The drug was restarted increasing the frequency of breastfeeding with no further hypoglycemia attacks.**Conclusion:** The excellent clinical outcome and apparent lack of side effects of propranolol makes it a good choice as a first-line treatment for hemangiomas especially in young patients who may have interferance in vaccination with steroid treatment. We would like to call the attention that hypoglycemia may be noted in infants under propranolol in restricted periods of feeding.

1017

CLINICAL FACTORS AND THROMBOPHILIA AS RETHROMBOSIS RISK FACTORS

AC Godoy Molias[1], C Aguilar Franco[2], F Sevil Puras[2], J Lao Romera[1], JF Lucía Cuesta[1], R Pazo Cid[1], D Rubio Félix[1]
[1]Hospital Universitario Miguel Servet, Zaragoza, Spain
[2]Hospital Santa Bárbara, Soria, Spain

Background. predictive factors of rethrombosis can help to stratify patients with venous thromboembolism and to apply for the best available treatment. **Aims.** to determine the relationship between rethrombosis and various clinical and thrombophilic factors. **Methods.** this is a nested case-control retrospective cohort study including 242 patients from the spanishprovince of Soria, with a history of venous thrombosis recruited between January 1998 and December 2010. Inclusion criteria: diagnosis of venous thromboembolism by objective methods three months before entering the study; spontaneous thrombosis (defined as that ocurred in patients not exposed in the 60 days prior to trauma, immobilization, surgery, pregnancy / puerperium or oral contraceptive use); less than 80 years of age; no previous history of chronic liver disease or kidney failure; no active neoplasia at the time of thrombosis; no oral anticoagulation within 30 days before entering the study.Determinations by STA-R coagulometer: antithrombin, protein C levels and clotting protein S, free protein S, resistance to activated protein C, factor VIII levels and lupus anticoagulant. Mutations in factor V Leiden, and prothrombin gene were determined by PCR. Levels of fasting plasma homocysteine were also tested. Positive samples, except the mutant ones, were confirmed by a new determination at 3 months. **Results.** 212 patients were included: 119 (56.1%) males and 93 (43.9%) female. Median age at diagnosis of the first event was 41 years (9-79). Median number of episodes was 1. First thrombotic event: 112 (52.8%) deep vein thrombosis (DVT), 59 (27.8%) proximal deep vein thrombosis, 26 (12.3%) pulmonary embolism, 10 (4.7%) cerebral venous thrombosis, 4 (1.9%) mesenteric venous thrombosis and 1 (0.5%) renal vein thrombosis. 119 (56.1%) were spontaneous thrombosis and 93 (43.9%) secondary. Re-thrombosis risk was 2.7 times higher in the group aged ≥ 55 years. Patients who developed DVT, proximal or distal had high risk of recurrence, with an OR of 5.8 (1.7 to 19.7, p = 0.002). The presence of a genetic or acquired thrombophilic factor was associated with an increased risk of rethrombosis with an OR of 2.5 (1.3 to 4.8, P = 0.004). A higher risk of re-thrombosis was observed in patients with positive lupus anticoagulant OR of 5.3 (1.3 to 22.2-, p = 0.01), elevated homocysteine levels (> 12 mcmol / L) OR 3.7 (1.1 to 12.4-, p = 0.02) and high Factor VIII levels (> 150 IU / dL) OR 2.6 (1.2 to 5. 3, p = 0.008). **Summary and Conclusions.** our study shows a statistically significant relationship between certain thrombophilic disorders (factor VIII, presence of lupus anticoagulant, elevated homocysteine levels) and risk of rethrombosis. The age and type of initial thrombosis was also statistically significant correlated with the risk of thrombosis recurrence.

1018

FREQUENCY, CLINICAL PATTERN AND OUTCOME OF THROMBOSIS IN CANCER PATIENTS

A Aleem, A Al Diab, K Alsaleh, F Algahtani, E Alsaeed, Z Iqbal, S El sherkawi
King Khalid University Hospital, King Saud University, Riyadh, Saudi Arabia

Background. Thrombotic risk is increased in patients with cancer and there are important implications for cancer patients who develop VTE.**Aims.** We undertook this study to determine the frequency, clinical patterns, and outcome of thrombosis in Saudi patients with cancer. **Methods.** Cancer (solid tumors and lymphoma) patients who developed thrombosis from January 2004 to December 2008 were studied retrospectively. Demographics and characteristics related to thrombosis and cancer along with the outcome were evaluated.**Results.** A total of 701 patients with cancer were seen during the study period. VTE was diagnosed in 47 (6.7%) patients (median age 52, range 18-80 years). Lower limbs DVT was the most common type of thrombosis seen in 47% patients, followed by PE in 19% patients and 19% patients had both DVT & PE. Thrombosis was symptomatic in 70% patients while it was an incidental finding on routine workup in 30% patients. 38% patients were diagnosed to have cancer and VTE at the same time, and 47% developed VTE during the course of disease after the cancer diagnosis. Majority of the VTE post cancer diagnosis occurred during the first year (median 4 months, range 1-14 months). Additional risk factors for VTE were present in 22 patients and 14 of these patients were receiving chemotherapy at the time of thrombosis. Only 5 (10.6%) patients were receiving thrombo-prophylaxis at the time of VTE diagnosis. Most common type of cancers associated with thrombosis were breast cancer, non-Hodgkin's lymphoma and lung cancer. Majority of the patients (33, 70%) with VTE diagnosis had advanced stage of cancer. After a median follow-up of 13 (range 0.5-60) months, 37 (79%) patients have died. Almost all the patients with stage 3 or 4 cancer and thrombosis died except for 2 patients with non-Hodgkin's lymphoma.**Conclusions:** Thrombotic complications can develop in a significant number of Saudi patients with cancer and almost half of the patients have additional risk factors for VTE. Thrombosis is usually associated with advanced disease and can be asymptomatic in almost one-third of patients. Thrombo-prophylaxis in cancer patients is under-utilized. Community based studies are needed to accurately define the extent of this problem and to develop effective prophylactic strategies.

1019

RECURRENT CEREBRAL AND ABDOMINAL THROMBOSES AND PULMONARY EMBOLISM (PE) IN A NON-TRANFUSION DEPENDENT PATIENT WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA. EFFECTIVENESS OF ECULIZUMAB TREATMENT

M Carbone[1], L Luzzatto[2], G Rossi[1]
[1]Spedali Civili, Brescia, Italy
[2]Istituto Toscano Tumori, Firenze, Italy

Background. Paroxysmal nocturnal hemoglobulinuria (PNH) is a rare, genetic, hematopoietic stem cell disorder characterized by chronic uncontrolled terminal complement activation, causing hemolysis, platelet activation, and inflammation, and ultimately leading to serious morbidities. Thromboembolism (TE) is among the most dangerous complications of PNH. **Aims.** To present a case highlighting severe recurrent TE occurring in a non-transfusion dependent PNH patient, despite prophylactic warfarin anticoagulation. *Results.* In July 2004, a 36-year-old woman in her second pregnancy presented with isolated low platelet count ($37x10^9$/L). Routine diagnostic work-up was unremarkable includ-

ing tests recommended to detect causes of secondary thrombocytopenia. LDH level was between 1 and 1.5 ULN, a potential clue to an early diagnostic workup to exclude PNH Bone marrow aspiration was normal and idiopathic thrombocytopenic purpura was diagnosed. Despite treatment with high-dose steroids, intravenous immunoglobulin and cyclosporin A her platelet count did not improve. At term, a Caesarean section was performed along with a splenectomy. Following a massive post-partum hemorrhage requiring packed RBC transfusions the patient was discharged in September 2004 with Hb 11.6 g/dL, but still low platelets ($35x10^9$/L). Two years later the patient was hospitalized in the department of neurology of another hospital after experiencing drowsiness, headache and transient aphasia. Cerebral CT scan revealed thrombosis of the sagittal sinus, moreover hepatic enlargement, ascites, due to Budd Chiari syndrome ,along with asymptomatic PE were detected and warfarin treatment initiated. The patient was diagnosed with thrombophilia of unknown origin. Platelet count ranged between 50 and $100x10^9$/L. During follow-up, a series of diagnostic tests, including bone marrow biopsy (cellularity 15%), tumor markers and markers of congenital and acquired thrombophilia were performed. PNH was diagnosed by flow cytometry (99% GPI-linked CD14 and CD55 defect). The patient developed hepatic vein thrombosis in 2007 and was hospitalized again in January 2009 with persistent abdominal pain while on warfarin and with INR within the therapeutic range. D-dimer level was 5290 ng/ml and LDH 2N , Abdominal Doppler US revealed massive portal vein thrombosis with cavernoma of the liver. Eculizumab therapy was started in June 2009, as recommended in patients with recurrent abdominal and cerebral thromboses (Brodsky, Blood 2011), and because oral warfarin had proven ineffective. The subsequent clinical course was unremarkable with no further reports of abdominal pain, or TE and normalization of all hematological values (LDH: 159-364 IU/L; Hb: 12.6 g/dL; platelets: 231,000/mm^3). D-dimer level range between N and 2N.*Conclusions*: We suggest that in patients who have a history of potentially devastating recurrent venous thrombosis eculizumab treatment must be considered, even when haemolysis is not serious enough to require blood transfusion. In this particular patient, who had experienced at least 3 major thrombotic events over a 5 year period, there has been no recurrence since eculizumab was started over 2 years ago. (Medical writing support was provided by Åsa Lommelé.)

THROMBOPHILIA IN CHRONIC HEMOLYTIC ANEMIA PATIENTS: ANALYSIS OF GENETIC PREDISPOSING FACTORS

M Sherif, S El Sayed, A Adly
Pediatric Department, Ain Shams University, Cairo, Egypt

Background. Genetic thrombophilia as a contributing factor for hypercoagulability among patients suffering from hemogloinopathies has been Recently studied. Thromboembolic events as transient ischemic cerebral attacks, strokes, pulmonary embolism, deep venous thrombosis, and portal vein thrombosis, have been observed in thalassmia patients.The hypercoagulable state has been attributed to a wide variety of hemostatic alterations including platelet hyperaggregability, protein C and antithrombin deficiency and procoagulant alterations of red cells. Few studies have evaluated the impact of prothrombotic polymorphisms in thalassemia patients. **Aims.** to determine the frequency of selected prothrombotic gene polymorphism (FV, FII, MTHFR) in a cohort of beta-thalassemia and sickle cell disease patients and to assess their impact on the precoagulant state, clinical and laboratory parameters. **Methods.** Study included 80 patients with chronic hemolytic anemia divided into:Group A: Thalassemia major patients (n=30) with age ranging from 11- 33 years with a median age of 20 years.Group B: Thalassemia intermedia patients (n=20) with age ranging from 5 - 18 years with a median age of 10 years.Group C: Sickle cell disease patients (n=30) with age ranging from 8 - 19years with a median age of 9 years. One-hundreds healthy age and sex matched subjects were served as controls.*Patients were subjected to history taking, laying stressing on:*demographic data,consanguinity,history of splenectomy.Symptoms suggestive of previous attack of thromboemolic manifestation,family history of thrombotic disorders,blood transfusion details and history of vasooclusive crises. L*aboratory Investigations included* :Complete blood count,PT, PTT and mean serum ferritin level.Polymerase chain reaction analysis of a sample of DNA for factor V Leiden G1691 A, factor II G20210A, and MTHFR C677T .Results. heterozygous Factor V leiden mutations were present in 28.7% of the studied patients with the highest frequency in thalassemia intermedia compared to thalassemia major and SCD patients(16%,9%,3.7%,p=0.02). Heterozygous Factor II 20210 mutation was present in 4.8%, all of them in SCD patients. Heterozygous MTHFR C677T mutation in 33.3% with the highest frequency in thalassemia intermedia patients compared to thalassemia major and SCD (20%,11%,2,3% respectively,p=0.01). MTHFR C677T homozygous mutation were found in 4.8% and all were thalassemia major patients. While factor V lieden, MTHFR mutations were present together in 9.5% of cases (7% in thalassemia intermedia and 2.5% were SCD patients).Patients with β-thalassemia major and SCD with positive mutations had higher higher incidence of past history of thrombotic events (p=0.02).Cases with β-thalassemia major showed significantly higher rate of heterozygous (G/A) when compared to SCD and TI(p=0.04).Patients with β-thalassemia intermedia showed significantly higher rate of inherited thrombophilia mutation than those with thalassemia major (P=0.01) with an odds ratio of 2.7 (95%CI 0.84-8.5). TM patients with positive mutations showed significant higher level of mean total leucocytic count and short values of PT when compared to cases with no mutation(P<0.05). All TI patients with positive mutations had past history of venous thrombosis. SCD patients with positive thrombophilic mutations had higher frequency of vasco-occlusive crisis(p<0.05). Conclusions:thrombophilia work up is necessary in patients with chronic haemolytic anemia especially thalassemia and sickle thalassemia patients presenting with past history of thromboembolic events.Thrombophilic mutations is related to vasoocclusive crisis risk in SCD patients .

CANCER PATIENTS REQUIRING INTERRUPTION OF LONG-TERM WARFARIN BECAUSE OF SURGERY OR CHEMOTHERAPY INDUCED THROMBOCYTOPENIA: THE USE OF FIXED SUB-THERAPEUTIC DOSES OF LOW-MOLECULAR WEIGHT HEPARIN

G Saccullo, A Malato, S Raso, M Santoro, V Zammit, A Casuccio, S Mancuso, S Siragusa
Policlinico P. Giaccone, Palermo, Italy

[1]Giorgia Saccullo, [1]Alessandra Malato, [1]Simona Raso, [1]Marco Santoro,[1]Valentina Zammit, [2]Alessandra Casuccio, [1]Salvatrice Mancuso and [1]Sergio Siragusa[1]Cattedra ed U.O. di Ematologia con trapianto, Dipartimento di Medicina Interna e specialistica (DIMIS), Azienda Ospedaliera Universitaria Policlinico "P. Giaccone", Università di Palermo, Italy[2]Dipartimento di Neuroscienze Cliniche, Università di Palermo, Italy

No data is present regarding the management of cancer patients requiring interruption of long-term vitamin-K antagonist (VKA) therapy. For this purpose, we tested the efficacy and safety of fixed doses of low-molecular weight heparin (LMWH) in substitution of VKA because of invasive procedures or chemotherapy-induced thrombocytopenia. In cancer patients on VKA, therapy was discontinued 5 + 1 days before surgery or chemotherapy. Heparin was given at prophylactic dosage in patients at low risk and at fixed sub-therapeutic doses (3,800 or 4,000 UI anti-FXa, b.i.d.) in those at high-risk for thrombosis. LMWH was reinitiated 12 hours after surgery and VKA the day after. In patients receiving chemotherapy, LMWH was reinitiated 12/24 h after obtaining a stable platelet count > 30,000 mmc^3, and VKA after a stable platelet count > 50,000 mmc^3.

Table 1. Baseline characteristics.

Patients characteristics (n=156)	
Mean age (range, y)	66.6 (32/89)
M/F (%)	84/72
Weight, mean ± SD (Kg)	75.4 ± 16.5
Solid cancer, n (%)	98 (62.8)
Haematological cancer, n (%)	58 (37.2)
Advanced/metastatic cancer, n (%)	101 (64.7)
Bridging therapy with nadroparin, n (%)	71 (45.5)
Bridging therapy with enoxaparin, n (%)	79 (50.6)
Bridging therapy with others heparin compounds, n (%)	6 (3.8)
Low-risk for TE	88 (56.4)
- Patients on chemotherapy-induced thrombocytopenia	22*
High-risk for TE	68 (43.5)
- Patients on chemotherapy-induced thrombocytopenia	17**
Venous thromboembolism, n (%)	52 (33.3)
- Events lasting < 3 months, n (%)	28
- Events lasting > 3 months, n (%)	24
Atrial fibrillation without previous stroke (AF-NoAT), n (%)	48 (30.7)
Atrial fibrillation with previous stroke (AF-AT), n (%)	21 (13.4)
Prosthetic aortic/mitral valves (PAV), n (%)	19 (12.1)
Others (arterial hypertension, dilatative myocardiopathy, valvulopathy, myocardial infarction, coronary artery by-pass graft), n (%)	16 (10.2)

*16 (72.7%) had haematological malignancies

**11 (64.7%) had haematological malignancies

Thromboembolism and major bleeding events were recorded from the time of VKA suspension to 30 + 2 days post-procedure, or until the next chemotherapy. Overall,156 patients (56.4% at low risk and 43.5% at high risk for thrombosis) were enrolled; 34.6% underwent major surgery, 40.4% non-major surgery, and 25% chemotherapy. Thrombotic events occurred in 5 patients (3.2%, 95% CI 1.41-7.27), 4 belonging to the high-risk and 1 to the low-risk group. Major bleeding occurred in 5 patients (3.2%, 95 CI 1.41-7.27), all belonging to the high-risk group (3 during major surgery and 2 during chemotherapy). In conclusion, LMWH given at fixed sub-therapeutic is a feasible and relatively safe approach for bridging therapy in cancer patients on long-term VKA.

1022

EFFECTS OF DIAGNOSTIC ULTRASOUND-MEDIATED MICROBUBBLE CONTRAST AND UROKINASE ON AUGMENTATION OF THROMBOLYSIS AND OPTIMIZATION OF THE MAJOR PARAMETERS: AN IN VITRO STUDY

T Niu, QM Yu, X Zhou
West China Hospital, Chengdu,Sichuan, China

Objective To investigate the efficacy of diagnostic ultrasound and microbubble contrast (MB) on enhancing thrombolysis combined with urokinase(UK) and explore the major parameters to confirm the optimal combination for thrombolysis *in vitro*. **Methods.** Four types of standardized red thrombus were prepared *in vitro* for the present study, including 3-hour-old (3h), 6-hour-old(6h), 12-hour-old(12h), 24-hour-old(24h), respectively. The major parameters for the designed experiments included transmit powers of ultrasound (factor A, 5%, 25%, 50%, 100%), MB volumes (factor B, 50μL, 100μL, 200μL, 400μL), UK concentrations (factor C, 100U/ml, 200U/ml, 400U/ml, 800U/ml), and lysis time (factor D,10min, 20min, 30min, 40min), respectively. Then an orthogonal array experimental design (OAD) based on four parameters above and four levels[$L_{16}(4^5)$]was employed to optimize the thrombolysis conditions in our study. The blood clots were weighed before(W_0) and after(W_1) experiments to determine lysis efficiency(LE) based on the following formula, LE=[(W_0 − W_1)/W_0]×100%. Sixteen thrombolysis experiments were performed based on the $L_{16}(4^5)$matrix, and for each level, three experiments were repeated per protocols. During the procedure of thrombolysis, the diagnostic ultrasound frequency was fixed at 1.82MHz. The histopathological changes measured by HE staining and scanning electron microscope (SEM) were carried out to observe the clots before and after thrombolysis. The direct observation analysis was used to optimize and the analysis of variance (ANOVA) was used to assess the results according to the $L_{16}(4^5)$ matrix. **Results** The HE staining and SEM observation of thrombolysis under the following experimental condition of 5% ultrasound transmit power, 400μL MB volume, 800U/ml UK concentration, 40min lysis time showed remarkable disaggregation of fibrin nets. Four factors above were shown to be statistically significant in each type of thrombus at different levels (all conditions, P<0.01). Among them, UK concentrations (factor C) was one of the most significant parameters for four types of clots. The optimal scheme was determined as the C_4-D_4-A_1-B_4 mode, UK concentration 800U/ml, lysis time 40min, transmit power 5%, MB volume 400μL, respectively. The LE curves of each factor for 3h clots were superior to the other LE curves for 6h, 12h and 24h clots in turn. **Conclusions** 1.82MHz diagnostic ultrasound and microbubble contrast may be applied to augment thrombolysis *in vitro* even transmit power was lowest to 5%. Under the condition of fixed ultrasound frequency, the LE of thrombus increased with increasing UK concentrations, lysis time and MB volumes, while decreased with increasing thrombus ages. Therefore, the older aged thrombi may not obtain better thrombolytic rates.

1023

MEAN PLATELET VOLUME AND PLATELET COUNT: OVERSEEN MARKERS OF HIGH ON-TREATMENT PLATELET REACTIVITY AND WORSE OUTCOME IN PATIENTS WITH ACUTE CORONARY SYNDROME

M Jakl[1], R Sevcik[2], J Ceral[2], J Vojacek[2], I Fatorova[3], J Horacek[1], R Pudil[2]
[1]University of Defense, Faculty of Military Health Sciences, Hradec Kralove, Czech Republic
[2]Charles University Prague, Faculty of Medicine in Hradec Kralove, 1st Department, Hradec Králové, Czech Republic
[3]Charles University Prague, Faculty of Medicine in Hradec Kralove, Dept Clinical, Hradec Králové, Czech Republic

Background. Mean platelet volume (MPV) is a marker of platelet activation and turnover. Platelet count (PC) and platelet hematocrit (PCT) correlate with total volume of platelet cytoplasm rich of proaggregatory substances. It can be expected that increase in these values leads to worse response to antiplatelet treatment and worse outcomes.Objectives: The primary aim of the study was to assess the relationship between MPV, PC, PCT and responsiveness to the antiplatelet treatment. The secondary aim was to assess the relationship between MPV, PC, PCT and mortality in patients with acute coronary syndrome.Patients/methods: We performed a cohort study of 190 patients with acute coronary syndrome. In these patients the MPV, PC and PCT were measured. The response to aspirin and clopidogrel was simultaneously assessed by the impedance aggregometry-based assay.Results. Patients with high MPV were in higher risk of dual poor responsiveness (HR 2.53, 95 % CI 1.15-5.37, p<0.05) and poor responsiveness to aspirin (HR 2.38, 95 % CI 1.37-3.92, p<0.01). Patients with high PC were in higher risk of poor responsiveness to clopidogrel (HR 2.60, 95 % CI 1.07-4.33, p<0.05). The three-year mortality was increased in patients with high MPV (25.7% vs. 13.5%, p<0.05). **Conclusions.** MPV and PC are useful tools in prediction of response to antiplatelet treatment. Increased MPV is a predictor of increased long-term mortality in patients with acute coronary syndrome.

1024

SOME HEMOSTATIC BIOMARKERS IN PATIENTS UNDERGOING LASER INTERVENTION OF LEG VARICES

J Stasko, S Zelnik, J Buchancova, P Kubisz
Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia

Background. The thermal effect of endovenous laser ablation (EVLA) induces endothelium damage and intraluminal thrombus formation in leg varicose veins. In the case of thrombus extension from superficial to the deep venous system this can bear a risk of pulmonary embolism.**Aims.** The study was aimed to verify the changes of molecular hemostatic biomarkers in patients undergoing laser intervention of leg varices. **Methods.** Twenty patients (age 43,8 ± 11,6 years; 14 female, 6 male) undergoing EVLA due to incompetence of great saphenous vein were enrolled in the study. All patients gave their informed consent with participation in the study. Plasma levels of D-dimers (DD), prothrombin fragments 1+2 (F1+2), soluble P-selectin (sP-selectin), soluble thrombomodulin (sTM), von Willebrand factor (vWF), factor VIII (FVIII) and plasminogen activator inhibitor (PAI-1) were measured from the venous blood before EVLA as well as on 1st day, 9th day and 1 month after EVLA.**Results.** DD plasma levels were significantly increased on the 9th day after EVLA compared to the DD levels before EVLA and on the 1st day after EVLA (1,36±1,36 vs. 0,25±0,14 mg/l; p<0,05 and 1,36±1,36 vs. 0,61±0,44 mg/l; p<0,05, respectively). Moreover, the DD plasma levels taken 1 month after EVLA were significantly decreased in comparison with DD levels on the 9th day after EVLA (0,48±0,29 vs. 1,36±1,36; p<0,05). F1+2 plasma levels increased on the 1st and 9th day after EVLA but without significance. vWF plasma levels on the 1st day after EVLA were significantly increased compared to the vWF levels 1 month after EVLA (1,17±0,25 vs. 0,99±0,21 U/ml; p<0,05). FVIII plasma levels on the 9th day after EVLA was also significantly increased in comparison to the FVIII levels before EVLA (1,10±0,33 vs. 0,92±0,20 U/ml; p<0,05). The sP-selectin, sTM and PAI-1 plasma levels did not change significantly. **Summary and Conclusions.** Our preliminary results suppose that EVLA did not lead to the platelet activation in systemic circulation and the endothelial dysfunction after EVLA seems to be expressed in systemic blood only as an endothelial activation (increased vWF but not sTM). The limited increase of DD levels can reflect that surgical trauma caused by EVLA is modest.*Acknowledgement: This study was supported by the grant Vega 1/0016/12, project CEVYPET (ITMS 2622012053) and project CEPV II (ITMS 26220120036).*

LONG-LASTING OBSERVATION OF A GROUP OF PATIENTS WITH RARE (HOMOZYGOUS OR COMBINED) TYPE OF THROMBOPHILIA

A Skubiszak, J Kurosz, A Regdos, J Jaworski, K Zawilska
J.Strus Hospital, Poznan, Poland

Summary. The aim of the study was a long-lasting observation of a group of patients with rare (homozygous or combined) thrombophilias, selected from a group of 350 patients with all types of thrombophilia.The study group consisted of 29 patients (18 women and 11 men) of the mean age of 38 years (22 - 71 years), who experienced at least one venous thromboembolic (VTE) episode in the past and were diagnosed to have a rare type of thrombophilia (8,3% of all thrombophilias).20 patients were on long-term secondary antithrombotic prophylaxis with vitamin K antagonists (INR 2,0 - 3,0); 5 patients were treated with enoxaparin for one year after the acute VTE episode, and with vitamin K antagonists afterwards; 4 patients were without secondary prophylaxis. Patients treated with oral anticoagulants received enoxaparin (50% of therapeutic dose)

for a week before blood drawing.Type of thrombophilia: 8 patients were carrying the homozygous factor V Leiden mutation (*G1691A*, FVL), 6 patients - the heterozygous factor V Leiden mutation along with heterozygous prothrombin gene mutation (*G20210A*), 7 patients had hereditary thrombophilia and coexisting antiphospholipid antibodies, 6 patients other combined thrombophilias (4 patients - Factor V Leiden or prothrombin gene mutation, along with protein C deficiency or increased activity (>150%) of factor VIII; 2 patients - protein S deficiency along with an increased activity of factor VIII).7 out of 8 patients (87,5%) with homozygous FVL mutation experienced their first thrombotic event before the age of 40. Family history of VTE has been noticed in 35% of patients with hereditary thrombophilia.During the observation time, which lasted for 1 to 14 years (mean 5 years) in 7 patients (24%) the recurrence of VTE has been diagnosed, in three of them during secondary prophylaxis. We observed atypical localization of thrombosis in five patients (17%), in two of them it was coexisting with proximal deep vein thrombosis of lower extremities. None of the patients had splanchnic venous thrombosis. Our most severe case was a 49 - year old patient with homozygous FVL mutation and coexisting antiphospholipid antibodies. She experienced three spontaneous cerebral ischemic strokes (first at the age of 36 years) and thrombosis of common jugular vein, left axillary vein and left subclavian vein after hysterectomy. **Conclusion**s. Homozygous or combined thrombophilias, diagnosed in about 8% of patients with all types of thrombophilias, are characterized by an early onset of VTE, and in a long-lasting observation by a tendency to recurrence, in some of patients even during secondary antithrombotic prophylaxis, as well as by atypical localization of thrombosis.**Keywords**:thrombophilia, venous thromboembolism, recurrent venous thrombosis

HEMOSTATIC PARAMETERS AND LIPID PROFILE IN PATIENTS WITH PRIMARY HYPERPARATHYROIDISM: ASSOCIATIONS WITH PARATHYROID HORMONE

M Dalamaga[1], M Triantafilli[2], K Karmaniolas[2], K Daskalopoulou[3], M Pantelaki[3], G Sotiropoulos[2], A Lekka[2]
[1]Attikon General University Hospital, Athens, Greece
[2]NIMTS General Hospital, Athens, Greece
[3]ELPIS General Hospital, Athens, Greece

Background. Primary hyperparathyroidism (P-HPT) represents a generalized disorder of calcium, phosphate and bone metabolism characterized by the increased secretion of parathyroid hormone (PTH) resulting in hypophosphatemia and hypercalcemia which represents the most common cause of hypercalcemia in the outpatient setting, in patients without an underlying malignancy. The diagnosis is frequently made in patients who are asymptomatic and present hypercalcemia and elevated levels of PTH. Patients with P-HPT present an increased risk for hypertension and cardiovascular disease. The influence of P-HPT and PTH in hemostasis and platelet function is not fully elucidated.**Aims.** The aim of the present study was to assess hemostatic parameters in patients with P-HPT in comparison to age-, gender and body mass index (BMI)-matched healthy controls and to explore the associations between these parameters with serum PTH, calcium and serum lipid profile. **Methods.** In a cross-sectional study between 2007 and 2011, we have evaluated eighteen patients with P-HPT due to a parathyroid adenoma, prior to any therapeutic intervention (parathyroid surgery) (15 women and 3 men) with a mean age: 49.05 ± 8.1 years (range: 33-64 years) and a double number of healthy subjects (30 women and 6 men) with a mean age: 51.02 ± 9.3 years (range: 32-66 years). Healthy subjects were matched (2 controls to one patient) on gender, age (±5 years), body mass index (± 1.5 kg/m^2) and year/month of diagnosis (±1 month). None of the subjects (patients and controls) presented any infectious and neoplastic conditions, diabetes mellitus, hypertension and dyslipidemia. Prothrombin time (PT), activated partial thromboplastin time (aPTT), fibrinogen, vWF, antithrombin III (ATIII), plasminogen, protein C and S, and D-Dimer were evaluated using immunonephelometry (Dade Behring). Lipid variables such as triglycerides, total cholesterol (C), LDL-C and HDL-C were also assessed. To evaluate thrombopoiesis, we have determined platelet indices (mean platelet volume, MPV; platelet distribution width, PDW; platelet count) using the Sysmex 9000 analyzer. PTH was determined using an electro-chemiluminescence immunoassay intended for use on Elecsys 2010 analyzer (Roche Diagnostics, Indianapolis, USA). Statistical analysis of data was performed with IBM-SPSS® statistical package version 20 for Windowssoftware.Results. Cases with P-HPT presented significantly higher mean fibrinogen levels (p=0.032), D-Dimer (p=0.042), MPV (<0.001), PDW (<0.001) and platelet count (p=0.002) than healthy controls. Moreover, cases exhibited statistically significant decreased levels of HDL-C (p=0.03) and significant increased levels of triglycerides (p=0.028), total cholesterol (p=0.047) and LDL-C levels (p=0.039). Moreover, PTH levels were positively associated with MPV (Spearman r=0.58, p=0.013) and D-dimer (Spearman r=0.41; p=0.024) in patients with P-HPT. We did not find any significant association between PTH and serum calcium with the other studied hemostatic and metabolic parameters. **Conclusions.** In conclusion, we have found that subjects with P-HPT present increased platelet parameters, platelet count, fibrinogen and D-Dimer which represent a potential hypercoagulable state. Elevated platelet activation and hypercalcemia in conjunction with coagulation and lipid perturbations may contribute to an increased risk of atherosclerotic complications observed in P-HPT. Serum PTH may account for the platelet morphologic changes observed in patients with P-HPT.

CLINICO-DEMOGRAPHIC ANALYSIS AND OUTCOME OF CHILDHOOD THROMBOSIS IN PEDIATRIC HEMATOLOGY AND ONCOLOGY UNIT

M Mokhtar, M Matter, A Ragab, M Salah-Eldeen
Pediatric Department, Ain Shams University, Cairo, Egypt

Background. Although thrombosis is rare in childhood, children with certain disorders may be at a higher risk.**Aims.** Our retrospective study was designed to evaluate patients with documented thrombotic events registered in Hematology -Oncology Unit over the last 3 years as regards clinical features, etiology, management and outcomes. **Methods.** The study included 30 patients (16 female and 14 male, age ranged from 1 month to 15 years; median 4.5 years) with clinical and radiological evidence of thrombosis. Data collection included clinical presentation, any identifiable risk factors for thrombosis including pre-existing hematological disorder as sickle cell anemia(SCA)/thalassemia, pre-identified cancer disorder and other risk factors including sepsis, immune disorders, catheter insertion, basic thrombophilia screening if done , chosen radiologic investigations, details of drug therapy and patients outcome.**Results.** Age at first thrombotic event was higher for occurrence of secondary thrombosis (median 6 years) than primary cases (median 8 months) (p=0.018). In 66.7% of patients, there was at least one identified risk for thrombosis, with cancer chemotherapy being the most frequent risk factors in 33.3% of patients(23.3% ALL-Pre B)then the presence of a pre-existing hematological disorder in 20% (10% sickle cell disease). In 33.3% of patients, inherited thrombophilic conditions were suggested (proven in 13.3% and undefined in 20%).Secondary thrombophilia presented with neurological symptoms (convulsions/decreased conscious level) related to central thrombosis in 70% of cases while inherited thrombophilias presented by gangrenous lesions (in 80%), especially small vessel disease presenting as purpura fulminans (P=0.001). No difference in the management between primary and secondary cases (56% of primary cases and 58% of secondary cases received a combination of low-molecular-weight heparin (LMWH) and oral anticoagulation) (p=0.063). A fixed dose was adopted for LMWH: 150 IU/kg/day for neonates and 100 IU/kg/day for older children. Fresh frozen plasma (FFP) was used mostly in primary thrombophilias (30%), and once in a patient with purpura fulminans secondary to sepsis. Two SCA patients with thrombosis were managed by exchange transfusion. Two studied patients with inherited thrombophilia were initially presented by neonatal stroke, their management included FFP followed by oral anticoagulation, and both experienced recurrence despite oral anticoagulant therapy. Recurrence occurred in 80% of patients despite oral anticoagulation. However, the recurrence was higher with primary thrombophilias (30%) compared to secondary cases(10%); yet no significant difference was found regarding residual effects with neurological deficit being the most common residual effect in both primary (20%) and secondary (31.6%) thrombophilias(p=0.139). Outcome of patients included normal (37%), neurological deficits (29.6%), recurrence (16.6%), amputation (7.4%) and death (16.6%). Out of the 16 patients who experienced central thrombosis, neurological sequelae included residual hemiparesis (33%), pschycosocial problems (33%), recurrent seizures (22%) and recurrent headache(11%) **Conclusion:** Compared to inherited thrombophilias; thrombosis secondary to an acquired risk factor tend to occur at an older age, commonly presented by central thrombosis with no significant difference between primary and secondary thrombosis as regards residual effects and recurrence rate. Further studies are warranted to determine proper duration of anticoagulant therapy to prevent possible recurrence.

STUDY OF PLASMA FIBRINOGEN IN PREGNANT WOMEN WITH SEVERE PREECLAMPSIA

F Alwan[1], M Zubair[2], W Salman[3]
[1]The National Center of Hematology, Baghdad, Iraq
[2]Almustansiriya medical college, Baghdad, Iraq
[3]Alyarmouk Teaching Hospital, Baghdad, Iraq

Background. Preeclampsia is a complication of pregnancy constituting a major cause of maternal and fetal morbidity and mortality. Pregnancy is a hypercoagulable state with changes in procoagulant, anticoagulant, and fibrinolytic systems.In preeclampsia, there is a shift in the haemostatic balance towards a pro-thrombotic state, together with changes in endothelial function. It is a state of enhanced coagulation as evidenced by an increased amount of clotting factors in maternal circulation. **Aims.** To study the changes in plasma fibrinogen, in pregnant women suffering from severe preeclampsia, and compared with healthy normotensive pregnant women. To correlate its level with the severity of preeclampsia **Methods.** This study conducted at Alyarmouk teaching hospital / obstetric and gynecology department in cooperation with the national center of hematology.before start of the study a written informed consent was obtained from all patients and healthy controls.It included thirty five pregnant women in the third trimester of pregnancy with severe preeclampsia .Their age range between 18-41 years. A total of thirty five healthy pregnant women who were not in labour, their age and gestational age matched with the patients and normotensive throughout gestation were included as a control group.The patients who had any confounding conditions that could altered coagulation tests e.g placental abruption or previa, sepsis, stillborn or heavy vaginal bleeding, history of diabetes, renal disease, chronic hypertension, cardiovascular diseases, symptomatic infectious diseases , and use of anticoagulant drugs were excluded from the study. Blood samples were taken from both groups for measurement of Fibrinogen [by parallel line bioassay of coagulation factors].The student T-test and correlation coefficient study were used for statistical tests. **Results.** There was significant difference in mean plasma fibrinogen between patients with severe preeclampsia (5.10±0.83) and control group (4.24±0.61). (P value < 0.0001). characteristics of patients and healthy controls groups with statistical significance shown in Table 3. **Conclusions.** Plasma fibrinogen was significantly increased in patients with severe preeclampsia than control group and show significant direct linear correlation with the severity of preeclampsia.

Table 3: showing mean, standard deviation, range and P value of different parameters in pregnant women with severe preeclampsia and control subjects.

	Preeclampsia		Control		P value
	Mean±SD	Range	Mean±SD	Range	<
Age (years)	29.40±6.60	18-41	30.80±6.54	19-41	0.376
Gestational age (weeks)	35.97±2.79	30-40	35.74±2.90	30-40	0.738
Systolic blood pressure (mmHg)	174.42±15.84	160-210	112.00±9.0	100-130	0.0001*
Diastolic blood pressure (mmHg)	114.57±5.19	110-125	66.71±7.56	60-80	0.0001*
Mean arterial pressure (mmHg)	134.80±6.65	127-150	81.80±6.12	73-93	0.0001*
Fibrinogen (g/l)	5.10±0.83	3.5-6.5	4.24±0.61	3.3-5.3	0.0001*

*:Statistically significant difference ($p < 0.05$) from the controls

ALGORITHM FOR ASSESSING THROMBOTIC RISK IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

RG Mihaila[1], I Lisan[2], R Dancu[2], A Olteanu[2], G Cocisiu[2], A Catana[2], O Flucus[2], C Bus[2]
[1]Lucian Blaga University Sibiu, Sibiu, Romania
[2]Emergency County Clinical Hospital, Sibiu, Romania

Background. If assessing the presence of thrombophilia markers is not a common determination, the risk of thrombotic events can be estimated by evaluating the history, clinical examination, blood count (including platelet count and mean platelet volume), blood lipids and the presence of metabolic syndrome components. **Aims.** We aimed to develop an algorithm to estimate the risk of thrombotic accidents in patients with CLL. **Methods.** We studied all 64 patients with CLL from their first hospitalisation in 2011, who were in the electronic filing system of the Hematology Department of Sibiu. We noted: gender, age, disease stage, platelet count, mean platelet volume, serum cholesterol, the possible presence of the metabolic syndrome components and a history of thrombotic events. We analyzed the correlations between the data obtained and the risk of thrombosis. **Results.** The mean age of the group was 66.93+/-10.70 years. Distribution by gender: women - 37 (57.81%), male - 27 (42.19%). The average number of platelets in peripheral blood was 192,837.21+/-83,277.20/mm^3. There was a moderate direct correlation between platelet count and thrombotic stroke in the history of patients (r=0.319). Those who have had thrombotic events have higher risk for new ones. There is a small but inverse correlation between the number of history of thrombotic events and the stage of CLL (r=-0.230). There was no correlation between thrombotic history and other analyzed data. It follows that the main thrombotic risk factor in our group is the increased number of platelets. Platelets are slightly, directly correlated with the number of components of metabolic syndrome (r=0.237). So, in early stages of disease, the presence of metabolic syndrome components could be an additional thrombotic risk factor. But, while the infiltration of bone marrow by leukemic cells grows, platelet count decreases, as reflected by moderate inverse correlation between platelet count and stage of disease (r=-0.343), and cholesterol decreases (average cholesterol 195.65+/-49.72mg/dl). There is a slight, direct correlation between platelet count and cholesterol (r=0.260). Disease stage correlates, also moderate and inversely, with cholesterol (r=-0.321), which in turn, correlates inversely, moderately, with the mean platelet volume, which was 10.59+/-0.84fl (r=-0.360). As a result, patients with advanced disease have a tendency to decrease in cholesterol (cholesterol is captured by leukemic cells and used for their proliferation), which correlates with increased mean platelet volume - a thrombotic risk factor. Between cholesterol and triglyceride there is a moderate direct correlation (r=0.407) and serum triglyceride correlates slightly and inversely with mean platelet volume (r=-0.140). Age, cholesterol and triglyceride correlates directly, slightly, with the number of components of the metabolic syndrome. In advanced disease, in addition to increased mean platelet volume, chemotherapy may contribute to increased thrombotic risk. **Conclusions**. In the early stages of CLL, increased number of platelets is an important prothrombotic factor, to which the presence of metabolic syndrome components adds. In advanced stages, increased mean platelet volume and chemotherapy are the main thrombotic risk factors, to which one can add the decrease in cholesterol and triglyceride levels, which is associated with an increased mean platelet volume.

1030

COAGULATION FATOR XIII TYR204PHE GENE POLYMORPHISM AND ISCHEMIC STROKE

M Landau, G Castro, M Zalis, T Gadelha
University Hospital Clementino Fraga Filho, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil

Background. A gene variant in the subunit A1 of the coagulation factor XIII (factor XIII A1 Tyr204Phe) was previously described and was strongly associated with ischemic stroke, with a 9-fold increased risk of ischemic stroke. The risk was further increased in carriers of Phe allele who were using oral contraceptives (20-fold). These results, however, have not been confirmed in other studies.**Aims.** To investigate the prevalence of the factor XIII A1 Tyr204Phe variant in a sample of Brazilian patients with ischemic stroke. **Methods.** 160 patients with a diagnosis of ischemic stroke referred to our service were included. All cases were tested for factor XIII A1 Tyr204Phe variant by polymerase chain reactions with fluorescent allele-specific oligonucleotide probes. Risk factors for ischemic stroke as obesity, hypertension, diabetes mellitus, current smoking, dyslipidemia and contraceptive use were also recorded. Exclusion criteria were cardioembolic events, malignancy or chronic inflammatory diseases. **Results.** The median age of the 160 patients was 37 years (range 15 - 72) and

105 (66%) were females. The frequency of acquired risk factors was: 4% obesity; 31% hypertension; 5% diabetes; 29% current smoking; 33% dyslipidemia; 25% (of females) contraceptive use. The factor XIII A1 Tyr204Phe variant was found in three patients (2%). **Conclusions.** This study shows a low prevalence of factor XIII A1 Tyr204Phe variant among Brazilian patients with ischemic stroke. A prevalence of this gene variant of 3.5% in Brazilian population had been previous described. Given its low prevalence, factor XIII A1 Tyr204Phe variant does not seem to be a major risk factor for ischemic stroke in this population.

1031

PROSPECTIVE EVALUATION OF THE PATIENT/NORMAL RATIO OF THE ACTIVATED PARTIAL THROMBOPLASTIN TIME AND DILUTED RUSSELL VIPER VENOM TIME IN LABORATORY DIAGNOSIS OF LUPUS ANTICOAGULANT (LA)

B Grand[1], G Mainetti[2], E Pagliaro[2], C Naymark[2], L Voto[3], R Hermes[2]
[1]Hospital Juan A Fernandez, Buenos Aires, Argentina
[2]Haemostasis and Thrombosis Laboratory, Buenos Aires, Argentina
[3]Department of Maternal and Fetal Medicine, Buenos Aires, Argentina

Background. Lupus anticoagulant (LA) is clinically the most relevant among all antiphospholipid antibody tests. We recently reported a retrospective evaluation of the value of activated thromboplastin time and diluted russell viper venom time ratios (APTTr and dRVVTr) in a subgroup of samples negative for LA and with borderline mixing tests (8TH Meeting of the European Forum on Antiphospohilipid Antibodies). We suggest performing in these samples the neutralization tests. **Aims.** 1- To calculate the APTTr and dRVVTr in samples received to determine the LA. 2- To perform the neutralization test in selected samples negative for LA but with borderline mixing studies and high APTTr and dRVVTr.Design: Prospective observational. **Methods.** Patients n= 190; Samples: 195 (September 2011-January 2012). LA was done according to the recommendations of the Subcommittee on Lupus Anticoagulant/Anthiphospholipid Antibodies of the International Society on Thrombosis and Haemostasis.1) Screening tests: APTT using PTT-LA (STAGO) and dRVVT using Lac Screen (Instrumentation Laboratory)2) Mixing tests: pooled normal plasma homemade (1:1) proportion. Rosner Index (RI) and % of correction (%C) as criterion of mixing and confirmatory tests interpretation. Our cut off values: RI<0.12 and %C< 75 for APTT and dRVVT respectively.3) Ratios: cut-off value for APTTr >1.21 and dRVVTr >1.24.4) Confirmatory tests: homemade reagent for platelet neutralization procedure (PNP-APTT) and Lac confirm for dRVVT.Results. 24/195 (12.31%) were positive for LA .There were 5 samples with borderline correction in mixing tests and abnormal ratios for APTT (1) or dRVVT (4). We performed confirmatory tests to these samples and 3 of 5 samples were positive for LA increasing the final number of LA to 27.Conclusions: 1- The APTTr and dRVVTr as part of screening tests for LA can improve the diagnosis of LA in patients with negative LA, borderline mixing studies and positive neutralization tests. 2- This results must be confirmed with a larger number of samples.

1032

THE D DIMER TEST IN THE DIAGNOSIS OF VENOUS THROMBOEMBOLISM - AN AUDIT OF IT'S UTILIZATION IN AN IRISH TEACHING HOSPITAL AND A SURVEY OF JUNIOR DOCTOR KNOWLEDGE OF IT'S USES AND LIMITATIONS

M Crowley[1], B Kevane[2]
[1]University Hospital Galway, Galway, Ireland
[2]Mercy University Hospital Cork, Cork, Ireland

Background. The use of D-dimer measurement in the clinical setting has been most extensively studied and validated for the exclusion of venous thromboembolism (VTE) in low risk populations and the diagnosis and monitoring of DIC. In our laboratory, the Innovance® assay is used. It is a particle-enhanced immunoturbidimetric assay for the quantitative determination of cross-linked fibrin degradation products. D Dimer assays are widely used in Irish hospitals. There are many reasons for D Dimers to be elevated and if this test is not judiciously used, patients may undergo unnecessary radiological procedures. **Aims.** D-Dimer tests were reviewed prospectively to ascertain: 1. Appropriateness of the test 2. Accuracy of the test. Junior doctors were surveyed to see if there were any obvious knowledge gaps that could be filled by a teaching session to improve the institutions use of the test. **Methods.** The audit was carried out between February 15th and march 14th 2011. Consecutive D Dimer tests were reviewed by obtaining the specimen numbers from the analyzer and reviewing the medical notes of those tested. Junior doctors were also given a survey to fill out to ascertain their knowledge of the indications for performing a D-Dimer test, how to interpret the results and the cost of the test. **Results.** 345 cases were reviewed. The average age of those tested was 58.91 years (Range 14-95). 156 (45%) of those tested were men. Most tests were requested in the emergency department. The main reasons for requesting the test were dyspnoea, chest pain, general decline and limb swelling but it was requested for a wide variety of reasons, many of which were inappropriate. 193 patients had positive D dimer results and 12 of these had a proven thrombus. The high level of positive tests did not lead to a correspondingly high level of radiological procedures. 31% of the junior doctors in our institution responded to the survey, and their overall knowledge of the use of the test was good. 60% recognized that the D Dimer test is useful to out rule VTE when there is a low suspicion and 76% agreed that the test was most useful for patients with a low probability of VTE where a negative result makes it unlikely that they have VTE. 92% felt that a risk assessment score e.g. Wells score was required in most situations. Only 2 respondents felt that it was a good screening test if it was unclear what was wrong with the patient. Only 4 respondents had read the emergency medicine handbook D Dimer section. **Conclusions.** The D Dimer test is a useful test for out-ruling VTE. The limitations of the test, specifically those of the assay used by the institution must be fully understood by those ordering it. The greatest yield is obtained when the test is used in accordance with guidelines.

1033

IMPACT OF THROMBOPHILIA ON RISK OF PERINATAL STROKE IN NEONATES: A RETROSPECTIVE STUDY IN 54 CASES

M Luciani[1], M Balestri[1], K Girardi[2], L Altomare[2], M Soldati[1], S Pancotti[1], A Minozzi[1], G Avvisati[2], F Locatelli[1]
[1]Children Hospital Bambino Gesù IRCCS, Roma, Italy
[2]Campus Biomedico University, Rome, Italy

Background. Perinatal stroke (PS) may be defined as an acute neurologic syndrome with chronic sequelae due to cerebral injury of vascular origin occurring between 20 weeks gestation and 28 days postnatal life. There is increasing evidence of role of inherited thrombophilic factors in pathogenesis and clinical outcome of PS. **Aims.** The aim of this study is to value the role of inherited thrombophilia observed in neonates with stroke. **Methods.** 141 patients with diagnosis of PS or presumed PS were admitted to the Pediatric Hospital Bambino Gesù of Rome from 2001 to 2010. Assesment of thrombophilia was available only in 54 patients (26 females and 28 males), so the our analysis was performed only in this cohort. The mean age at presentation was 8 months (range birth-7 year); 9 patients (16.6%) were diagnosed at birth, 43 children (79.6%) were diagnosed as presumed PS. The mean follow-up was 64 months. In the patients with presumed PS, focal neurological signs (hemiparesis, epilepsy, psychomotor delay) were the most common presentation. In all patients arterial infarction was documented by MRI, performed at the admission to the hospital. In 7 patients familiar history for thrombophilia (1), cerebrovascular event (2) or epilepsy (4) were observed. At the last follow-up, 6 patients did not presented disabilities; 29 patients had only emisyndrome, 9 had cognitive and motor impairment, 10 had motor deficits and epilepsy, that in 3 patients was uncontrolled by pharmacological therapy. Nobody showed recurrence of the stroke, or died. Of 48 patients with persistent neurological disabilities, 22 (45.8%) had inherited thrombophilia: 9 had factor V Leiden, 3 prothrombin II and 10 MTHFR; when we limited the observation to children with PS at the birth, 5/9 patient had a mutation, that was in 3 children factor V Leiden and in a patient it was observed the presence of Factor V Leiden and prothrombin II G20210A. The other child had MTHFR. In the patients without disabilities inherited thrombophilia was observed in 3 children. There was not significative correlation between thrombophilia and the occurrence of stroke or clinical outcome*(p 0.12)*.However when we considered only patients with PS at the birth, the presence of inherited thrombophilia resulted significative*(p 0.039)*, but it did not influence clinical outcome*(p 0.16)*. **Results.** Thrombophilia was documented in 45.8% of the children. In our study we did not find a significative correlation between the thrombophilia and the stroke in patients with presumed PS. **Conclusions.** The datas observed in patients with PS need to be confirmed, because of the limited number of patients and the retrospective analysis. Prospective observational study could be useful to assess the role of inherited thrombophilia in PS and the safety of eventual anticoagulant prophilaxys in neonates with high risk of PS or recurrence of thromboembolism. For that we believe that thrombophilia testing should be performed on any child with PS and their parents. to reduce the risk of PS in future life of children and in eventual pregnancies of mothers.

1034

HYPERCOAGULABLE STATE; PARADIGM SHIFT IN CLINICAL STATUS OF THALASSEMIA MAJOR PATIENTS

I Mohammad[1], S Sultan[1], H Maheen[2], J Kakar[1]
[1]Liaquat National Hospital, Karachi, Karachi, Pakistan
[2]Agha Khan Hospital, Karachi, Pakistan

Background. Customary blood transfusion programs and iron chelation remedies have dramatically extended the life expectancy of thalassemia major cases into fourth decade of life. Morbidity due to the diverse siderotic and non siderotic complications significantly obliterates the worth of life. Hypercoagulopathy and thromboembolic manifestations are being increasingly acknowledged in transfusion dependent thalassemics. Preliminary studies in last two decades have shown that hemostatic amendment obligate thalassemic at the verge of thromboembolism. We accomplished this study to determine if this might be owing to the deficiency of naturally occurring anticoagulants; protein C, protein S and antithrombin III. **Aims.** The aim of this study is to evaluate the deficiency of coagulation inhibitors in Pakistani thalassemic individuals, so that timely intervention could be done to secure the life of high risk patients. **Methods.** This is a prospective cross sectional study, started from August 2011 to Jan 2012. Thirty patients with beta thalassemia major were enrolled in this study. Complete blood counts, liver function test, serum ferritin and hepatitis B and hepatitis C were analyzed by standard laboratory methodology. Hemostatic markers includes prothrombin time, activated partial thromboplastin time, protein C, protein S and antithrombin III which were analyzed by CA 1500 (Sysmex Japan). We computed frequencies for isolated and grouped deficiencies, and percentages for the prevalence of Hepatitis B and C. We also computed spearman correlation at 5% level of significance to identify relationship between the deficiency of protein C, protein S and antithrombin III with hemostatic markers and maternal characteristics. **Results.** 30 patients incorporated in our study having mean age 13.1±5.4 years. Male to female ratio is 1:1. None of the patient was splenectomized. The mean pre-transfusion hemoglobin was 7.84±1.42 g/dl. Prolonged prothrombin time was accredited in 17% patients while prolongation of activated partial thromboplastin time was endorsed in 13%. Serum ferritin was considerably high with the mean of 4300.3±2435.8 ng/ml. The prevalence of hepatitis C is substantially higher (33%) as compared to hepatitis B (3%), however, its relationship with prothrombotic markers could not be established statistically. Protein C was predominantly deficient in 60% patients whereas protein S in 37% and antithrombin III in 27%. Protein C deficiency was exceedingly distinctive and divulges positive correlation with anemia, thrombocytopenia, prolonged PT and high ferritin. The proportions of all these deficiencies were higher in cases above 10 years of age. **Conclusions**. Our study revealed substantial decrement of the prothrombotic markers predominantly protein C, which may be implicated for elevated incidence of thrombotic events in thalassemia patients. These outcome raise the concern either it will be cost beneficial to suggests prophylactic anticoagulation, particularly for those who are at high risk and should all the individuals with thalassemia needs screening for the prothrombotic markers. Large scale prospective studies will be required to delineate specific recommendations for screening and the circumstance when to start prophylactic therapy and upon which point of deficiency.

MEDIUM PLATELET VOLUME - AN IMPORTANT PREDICTIVE FACTOR FOR AGGRESSIVE EVOLUTION IN ACUTE MYOCARDIAL INFARCTION PATIENTS

V Popov, G Tase, S Marinescu, M Stancu, D Blajan, C Stocheci, V Petri, M Popescu
County Emergency Hospital, Pitesti, Romania

Background. Larger platelet are hyperreactive and represent a risk factor for thrombotic complications, like acute myocardial infarction (AMI) or stroke. A**im** of the present study was to determine the importance of platelet indices in risk stratification of AMI patients. **Methods.** We performed the medium platelet volume (MPV), platelet distribution width (PDW), and plateletcrit (PCT) in 55 consecutive AMI patients (30 STEMI and 25 non-STEMI) admitted in our clinic during 1 Oct. - 31 Dec. 2011, splitted in groups using variables like heart failure (HF) presence, association of diabetes mellitus or hypertension (HTA), iterative thrombosis in medical history. **Results.** MPV is increased in female patients with history of thrombosis vs. female patients without thrombosis with history of thrombosis as follows: 7.4 (7.13-11.17) vs. 6.98 (6.152-7.323), p=0.01, patients with HF and HTA, vs. patients with HF without HTA 8.07 (6.82-13.35) vs. 6.85 (6.09-7.32), p=0.02 or HF and age over 65 7.27 (6.80-7.67) vs. age below 65 7.52 (7.12-8.65), p=0.01. Inside the STEMI = 65 years group of patients, MPV was higher than non-STEMI group patients = 65 years, p=0.03. We did not find any significant differences for MPV in diabetes mellitus group. PDW is also increased in HF and = 65 years group vs. HF and <65 years group, median: 18.3 (16.98-19.61) vs 17.2 (16.72-17.4), p=0.01. There are not any differences for PDW or PCT between STEMI and non-STEMI groups. The analysis of risk factors in = 65 years patients showed 75% for non-STEMI group and 40% for STEMI group; actually, non-STEMI was more frequent in elderly patients, OR 0.22. p=0.02. The incidence of either non-STEMI or STEMI was not influenced by diabetes, hypertension, thrombosis history, cardiac failure. **Conclusions**. MPV=7.4 is the most important risk factor in elderly STEMI patients, and also in heart failure and hypertension patients, or female patients with recurrent thrombosis, either AMI or stroke.

1036

METABOLIC SYNDROME, MEAN PLATELET VOLUME AND RISK OF THROMBOSIS IN PATIENTS WITH PHILADELPHIA NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASIAS

RG Mihaila[1], A Olteanu[2], R Dancu[2], I Lisan[2], A Catana[2], O Flucus[2], C Bus[2]
[1]Lucian Blaga University Sibiu, Sibiu, Romania
[2]Emergency County Clinical Hospital, Sibiu, Romania

Background. Philadelphia negative chronic myeloproliferative neoplasias predispose to thrombosis. Metabolic syndrome is involved in the activation / hyperreactivity of platelet. An increased mean platelet volume is known as an index of platelet activation and thrombotic risk. Hypertriglyceridemia - a component of metabolic syndrome - is associated with increased plasma levels of protrombotic markers (plasminogen activator inhibitor-1 and tissue plasminogen activator). **Aims.** We aimed to analyze the relationship between metabolic syndrome, mean platelet volume and thrombotic history of patients with chronic myeloproliferation. **Methods.** In the study were included all the 50 patients with Ph negative chronic myeloproliferative neoplasias who were hospitalized in 2011 in the Hematology Department of Emergency Clinical County Hospital of Sibiu and appear in the electronic filing system ATLAS. We studied: age, gender, diagnosis, platelet count, mean platelet volume, cholesterol, triglycerides, number of components of metabolic syndrome, treatment, thrombotic accidents. We note that blood samples were analyzed in the laboratory within 2 hours after withdrawing. We compared the data of patient with and without one or two components of the metabolic syndrome and those with and without a history of thrombotic accidents. Statistical analysis was performed with the arithmetic mean, standard deviation, Student t test and Pearson test. **Results.** The number of components of metabolic syndrome is directly correlated with serum triglyceride (r=0.454) and, slightly, with mean platelet volume (r=0.253). Of the 50 patients, 35 had at least one component of metabolic syndrome (group A) and 15 - none (group B). Patients in group A had an older age ($p<0.01$), higher number of platelets ($p=0.01$), higher cholesterol and triglycerides ($p<0.05$, respectively, $p=0.01$). From the entire group, 15 patients had at least two components of the metabolic syndrome (group C) and 15 - none (group B). Patients in group C had significantly higher cholesterol and triglycerides than those in group B ($p<0.05$, respectively, $p<0.005$). Among patients who had at least one component of metabolic syndrome, those with a history of thrombotic accidents had higher triglycerides values ($p <0.005$) and mean platelet volume ($p<0.0005$) than in those without thrombosis in the past. Among patients who had at least two components of the metabolic syndrome, those with a history of thrombotic events had higher triglycerides values ($p <0.05$) and mean platelet volume ($p <0.05$) than in those without thrombosis in the past. In the entire group the total number of antecedents of thrombotic events is directly associated with higher values of average platelet volume (r=0.470) and triglycerides (r=0.263). **Conclusions**. Among the components of metabolic syndrome, hypertriglyceridemia is mostly associated with the presence of thrombotic accidents in history. The fact that patients who had thrombotic stroke continues to have an increased platelet volume and that this is associated with the number of components of metabolic syndrome, means that they continue to be prone to produce thrombosis.

1037

EXPERIENCE WITH ENOXAPARIN IN PEDIATRIC DEEP VEIN THROMBOSIS: MONITORING OF TREATMENT

M Andrade-Campos, M Limon, F Mosteirín, M Torres, F Lucia, R Felix
Miguel Servet University Hospital, Zaragoza, Spain

Introduccion. The diagnosis of Deep Vein Thrombosis (DVT) in children has an estimated incidence of 0.7/10,000. It´s related with high hospitalization rates and central venous catheter (CVC) carriers. Early diagnosis and treatment are important because it is a serious disease that, if untreated, can lead to a postthrombotic sequel or a pulmonary thromboembolism (PTE). There is a little data on clinical outcomes following therapeutic low-molecular-weight heparin revealing problems in anti-Xa monitorization levels in children current recommendations for anticoagulant and therapy are based in the adult setting. **Aims.** To describe demographic and clinic characteristics of pediatric patients with DVT in our institution. To evaluate fluctuations in enoxaparine doses and anti-Xa concentration in patients until they achieve therapeutic levels. **Methods.** A retrospective chart review was performed using anti-Xa test laboratory data base in patients under 16 years old with diagnosis of DVT, treated with enoxaparin in our institution since January 2005 to February 2012. Data on enoxaparin doses, anti-Xa concentrations, clinical characteristics and outcomes were obtained. **Results.** In our cohort (n=14), thrombosis was diagnosed at a median age of 3.5 months (0.5-168),male/female ratio 8/4. Cerebral venous sinus thrombosis (CVST) was the most common indication (5), followed by DVT with/without PTE (4), thrombosis related to CVC (3), thrombosis related to vascular prosthesis (1) and purpura fulminans secondary to acquired protein S deficit (1). Systemic sepsis (9), CVC carriers (9), malignancies and cardiovascular interventions (2) were the most frequent risk factors. Genetic thrombophilia pattern was detected in 2 cases; one with FV Leiden who develop DVT with PTE associated to obesity and oral contraceptives use; one patient with thrombin mutation (G20210A) developed CVST related to asparaginase for ALL therapy. Enoxaparin was initiated at mean dose of 1.5 mg/kg/every 12 hours. Therapeutic anti-Xa concentrations (0.5-1 U/mL) were achieved in 12 patients (85%); 4 patients with doses of 1.3-1.5mg/kg/12 h, 6 patients with 2 mg/kg/12 h, one 14 days patient need 2.4 mg/kg/12 h and one 2 year patient need 2.7 mg/kg/12 h. The Mean of number controls were 3 (1-5), with a median of 11 (3-63) days to achieved therapeutic anti-Xa concentration. During maintenance therapy 2 patients lost therapeutic concentrations with secondary therapeutic levels after increasing dose. Early discontinuation of enoxaparin occurred in 1 patient secondary to cerebral hematoma by tumoral hemorrhage, 2 patients are still on therapy; in the rest of cases complete resolution were achieved. No mortality related to anticoagulant therapy was observed. **Conclusions**. It seems that current adult dose recommendation may not be appropriate for children; age based enoxaparin dose should be adapted in early pediatric patients. Anti-Xa concentrations fluctuate during maintenance therapy being necessary periodic anti-Xa controls. Despite this, enoxaparin seems efficacious in thrombosis resolution. Further studies to determine the role of anti-Xa concentrations for control on outcomes in this population are needed.

[3]Klinikum der Justus-Liebig-Universität, Giessen, Germany
[4]Dalhousie University, Halifax, Nova Scotia, Canada
[5]St. George Hospital, Sydney, Australia
[6]University of Debrecen Medical and Health Science Center, Debrecen, Hungary
[7]Uniwersyteckie Centrum Kliniczne, Gdansk, Poland
[8]Amgen Inc, Thousand Oaks, United States of America

1. **Background.** Patients with ITP may have evidence of reticulin fibers in the bone marrow without apparent clinical sequelae. In clinical trials with the thrombopoietin mimetic romiplostim, 10 of 271 patients were reported to have increased reticulin fibers of various grades (1-4, grade 4 includes minimal collagen) in the bone marrow that often decreased in grade after romiplostim discontinuation (documented in 3 cases). However, bone marrow biopsies were not systematically performed in these trials.2. **Aims.** This study of adult ITP patients treated with romiplostim was designed to prospectively evaluate bone marrow biopsies for collagen and reticulin levels. Changes in cytokine levels (TGF-β, PDGF, bFGF, and osteoprotegerin) relative to bone marrow changes were also assessed.3. **Methods.** Eligible ITP patients had platelet counts <50x10^9/L, received ≥1 prior ITP therapies, and had no collagen fibrosis in baseline bone marrow biopsies (i.e., before romiplostim). Three cohorts of patients were scheduled to have biopsies after 1, 2, or 3 years of romiplostim, respectively, with romiplostim dosed to maintain platelet counts at 50-200x10^9/L. Bone marrow biopsies were also performed when patients discontinued early or failed to achieve or maintain a response to romiplostim, with lack of response defined as having platelet counts ≤20x10^9/L for 4 consecutive weeks at the maximum romiplostim dose of 10 µg/kg. An independent expert bone marrow panel reviewed bone marrow data provided by a central pathology laboratory.

Table 1-Year Romiplostim Cohort Results

Patients	Number
Enrolled	50
Had 1 year of romiplostim and biopsy	35
Missing 1 year biopsy	15
- Due to serious adverse event	1
- Withdrew consent	5[1]
- Nonresponders	4[2]
- Died	3
- Severe joint pain	1
- Discontinued due to investigator decision	1
Bone marrow biopsies	38[2]
Biopsies evaluable for collagen (trichrome stain)[3]	33
- Positive for collagen	0
Biopsies evaluable for reticulin (silver stain)[3]	32
- Increase in reticulin grade from grade 0 to 2	2

[1] One of the 5 were nonresponders
[2] Bone marrow biopsies were obtained from 3 of the nonresponding patients prior to the one year assessment.
[3] Trichrome and silver staining could not be performed on all 38 biopsies due to inadequate samples.

Fibrosis was measured using the modified Bauermeister scale (0 no reticulin, 1 occasional fine fibers/foci fine fiber network, 2 fine fiber network, 3 diffuse fiber network, scattered coarse fibers, 4 diffuse coarse fiber network with areas of collagenization). Collagen was detected by trichrome staining and reticulin by silver staining.4. Results. Of the 50 patients enrolled in the 1-year romiplostim cohort (54% female, mean age 55.5 years, range 20-86 years), 37 (74%) had grade 0 reticulin, 13 (26%) had grade 1 reticulin, and none had collagen in baseline biopsies (i.e., before romiplostim). Thirty-five patients completed one year of romiplostim; of the 15 discontinuing (details in Table), 3 (all nonresponders) also had bone marrow biopsies performed. Examination of the 38 available biopsies from the 1-year cohort showed that none had collagen and 2 had an increase in reticulin grade from 0 to 2. The safety profile was similar to that seen in previous trials. Overall, cytokine levels remained within normal levels. As there were few bone marrow findings, no correlation between cytokine levels and changes in bone marrow morphology were evident. There were no neutralizing antibodies to romiplostim or thrombopoietin. Three patients died (not attributed to romiplostim); causes were fungal sepsis in a patient with long-standing corticosteroid use, cerebral hemorrhage (platelet count 4 days prior was 8x10^9/L), and pulmonary hemorrhage (platelet count one day before death was 59.8x10^9/L).5. Summary/ **Conclusions.** There was a low incidence of increased reticulin and no cases of collagen formation in the 1-year romiplostim cohort, consistent with findings from previous romiplostim studies. This ongoing study will provide additional data regarding bone marrow changes with up to 3 years of romiplostim.

1039

STICKY PLATELET SYNDROME AND THE GENETIC VARIABILITY IN THE PLATELET GLYCOPROTEIN 6 GENE IN WOMEN WITH FETAL LOSSES

P Kubisz, J Sokol, K Biringer, P Holly, P Chudy, J Danko, J Stasko
Jessenius Faculty of Medicine, Comenius University, Martin, Slovakia

Background. Sticky platelet syndrome (SPS) is the second most common hereditary thrombophilia after resistance to activated protein C (APC-R) and the most common thrombophilia associated with arterial thrombosis. Either after antiphospholipid syndrome is SPS the second most common thrombophilia that causes recurrent spontaneous abortions or fetal loss syndrome.**Aims.** The aim of the study was to evaluate the genetic variability of the GP6 gene in women with sticky platelet syndrome (SPS) type I or II and fetal losses. **Methods.** 27 women with SPS type I or II, clinically manifested as fetal loss, and 42 healthy women (blood donors) without SPS and with no previous history of fetal loss and venous or arterial thrombosis were enrolled. All subjects gave their informed consent with participation in the study. SPS was diagnosed by platelet aggregometry (PACKS-4 aggregometer, Helena Laboratories) according to the method and criteria described by Mammen and Bick. Seven single nucleotide polymorphisms (SNP) of the GP6 gene (rs1654410, rs1671153, rs1654419, rs11669150, rs1613662, rs12610286, rs1654431) were evaluated with the use of restriction fragment length polymorphism analysis.**Results.** We found a higher occurrence of three SNPs of GP6 gene in SPS group compared to controls (rs1671153, 0,204 vs. 0,048; OR 5,116; CI 1,536-17,03; rs1654419 0,204 vs. 0,071; OR 3,326; CI 1,149-9,619; rs1613662 0,204 vs. 0,071; OR 3,326; CI 1,149-9,619). The haplotype analysis showed a significantly higher occurrence (p<0,05) of two haplotypes in SPS women (CGATAG, 0,204 vs. 0,048; OR 4,961; CI 1,488-16,53 and CTGAG, 0,185 vs. 0,059; OR 3,568; CI 1,142-11,14, respectively). **Summary and Conclusions.** Our results, especially the higher occurrence of two GP6 haplotypes in SPS women with fetal losses, can support an idea that variability of the GP6 gene may be associated with the platelet hyperaggregability in these women.*Acknowledgement: This study was supported by the grant Vega 1/0029/11, project CEVYPET (ITMS 2622012053) and project CEPV II (ITMS 26220120036)*.

ROLE OF RETICULATED PLATELETS IN THROMBOCYTOPENIC CHILDREN

M Sherif[1], M Matter[1], M Ismail[2], H Ibrahim[1]
[1]Pediatric Department, Ain Shams University, Cairo, Egypt
[2]Clinical Pathology Department, Ain Shams University, Cairo, Egypt

Background. Thrombocytopenia can result from production insufficiency of the bone marrow or increased peripheral destruction. Reticulated platelets (RP) are the youngest circulating platelets recently released from marrow megakaryocytes and contain abundant mRNA which can be quantified by flowcytometry. **Aims.** We aimed to evaluate RP % by flowcytometry in different types of thrombocytopenia, to find out their clinical significance and to correlate RP% with response to therapy. **Methods.** RP% was estimated by flowcytometry on peripheral blood of eighty patients suffering from thrombocytopenia(their ages ranged from1.3to15years) recruited from Hematology/Oncology Clinic, Children Hospital, Ain Shams University. They were twenty patients with acute immune thrombocytopenic purpura (ITP) (mean age 6.15 + 2.32 years), twenty chronic ITP patients (mean age 7.92 + 3.27 years), twenty patients with bone marrow failure (mean age 6.61 + 4.37 years) and twenty patients with thrombocytopenia secondary to chemotherapy (mean age 8.4 + 2.7 years). Twenty healthy age and sex matched subjects (mean age 6.75 + 2.84 years) were included as control group. **Results.** The study revealed significant increase in percentage of reticulated platelets in acute and chronic ITP patients when compared to control group, (P<0.0001, 0.04 respectively). In bone marrow failure group, the percentage of reticulated platelets was significantly higher than the control group (P <0.0001). In group of thrombocytopenia secondary to chemotherapy, there was no significant difference in percentage of reticulated platelets compared to control group (P>0.05). When chronic ITP patients were followed up six months after therapy they revealed significantly higher mean RP% in

patients with platelet count>100 x 10^9/L than those with platelet count<100x 10^9/L with positive correlation between RP% and platelet count (P<0.05). In patients with bone marrow failure, RP% was higher in patients whose platelets increment >30x10^9/L than those with platelets increment <30 x 10^9after therapy. **Conclusions.** Measurement of reticulated platelet percentage by flowcytometry is useful in classifying the origin of thrombocytopenia into peripheral or central. High RP% can predict patients with good response to therapy especially in patients with chronic ITP and bone marrow failure

1041

RITUXIMAB BEFORE SPLENECTOMY IN ADULTS WITH PRIMARY IDIOPATHIC THROMBOCYTOPENIC PURPURA: A META-ANALYSIS

S Auger[1], Y Duny[2], JF Rossi[1], JP Daures[2], P Quittet[1]
[1]University Hospital Saint Eloi, Montpellier, France
[2]Biostatistical and Epidemiology, Montpellier, France

Primary immune thrombocytopenia (ITP) is an acquired immune-mediated disorder with absence of any underlying cause. Corticosteroids are the standard initial treatment. Splenectomy is the main second-line treatment. A trend to delay or avoid splenectomy has developed thanks to new agents like Rituximab. Few studies have assessed the response rate to Rituximab in chronic ITP. We performed the first meta-analysis of randomized clinical trials and observational studies on rituximab as an effective splenectomy-avoiding option in adult chronic ITP. Overall methods were adapted from MOOS and PRISMA guidelines for meta-analysis. Two hematologist investigators carried out study selection and data extraction independently, recording ORR and CR as primary assessment criteria. 364 records were identified through electronic databases. 19 retrospective or prospective observational studies were retained after removing duplicate studies and full-text analyses. For 368 non-splenectomized patients after rituximab ORR was 57 % (IC95: 48-65), CR was 41 % (IC95: 0.33-0.51) for 346 patients. Results were stable for ORR and CR in all subanalyses. In univariate or multivariate mixed-effect meta-regression, age was the most relevant effect. According to our results, rituximab should be used in second line in non-splenectomized patients.

1042

GAUCHER DISEASE: LONG-TERM FOLLOW UP AND COMPLICATIONS IN PATIENTS TREATED WITH ENZYME REPLACEMENT THERAPY (ERT) IN A SINGLE CENTRE

F Brevi, E Cassinerio, L Zanaboni, M Mazzoleni, E Poggiali, M Cappellini
„Ca' Granda„ Foundation Ospedale Maggiore Policlinico IRCCS, University of Milan, Milan, Italy

Background. Gaucher disease (GD) is a common inherited lysosomal storage disorder due to an autosomal recessive defect of the gene encoding glucocerebrosidase enzyme, responsible for accumulation of glucosylceramide into reticuloendothelial cells. GD is a clinically heterogeneous disorder and it is classically classified in type 1 (non-neuronopathic disease), types 2 and 3 (acute and chronic neuronopathic disease, respectively). Actually, the standard therapy for GD is ERT with imiglucerase, but alternative therapies became available. **Aims.** To study the improvement of the haematological, visceral, biochemical and bone parameters during ERT in patients with GD in a long period of time. **Methods.** Twelve patients (pts) (9 males and 3 females) are followed for a mean of 8 ± 3 years at Hereditary Anemia Centre in Milan. In all patients GD type 1 was diagnosed by the enzymatic activity dosage and the molecular analysis. A yearly follow up was performed, evaluating biochemical parameters (liver and kidney function tests, coagulation tests, count of blood cells (CBC), chitotriosidase levels, vitamine B12 and folic acid dosage, iron balance tests), liver and spleen diameters (US of the abdomen), cardiac and pulmonary function (ECG, echocardiographic examination, chest x-ray, functional respiratory tests) and bone involvement (dual-energy X-ray absorptiometry-DEXA-, magnetic resonance-MRI- of pelvic track and femurs). GAUSSI-I scores were calculated to describe the burden of GD. Each parameter was evaluated before starting ERT and in 2011. The mean actual dose of ERT was 31 ± 9 UI/kg every two weeks. The mean period of treatment was 10 ± 6 years. **Results.** The mean age of our patients was 43 ± 13 years. The genotypes represented were N370S/N370S homozygous (3 pts), N370S/L444P (3 pts), N370S/P401L (1 pts), N370S/IVS2+1 (1 pts), N370S/delta55 (1 pts), N370S/RecNcil (1 pts), N370S/unknown (1 pts), unknown (1 pts). Thrombocytopenia and splenomegaly were the most frequent presenting symptoms and all patients had skeletal involvement at diagnosis. During the follow up a significant improvement of platelets (PLT) (p = 0,0461) and a significant decrease of spleen diameter (p = 0,086) were detected; a good improvement of haemoglobin (Hb) and a good reduction of GAUSSI-I were observed also if they were not statistically significant (Figure 1). During the first year of ERT there is an improvement of levels of Hb and PLT and a decrease of spleen diameter. Vertebral and femoral Z score improvement (p = 0,0002 and 0,0024) appeared later in time. During the period of follow up one patient developed a myelodisplastic/myeloproliferative syndrome and a femoral necrosis. **Conclusions.** GD is a multiorgan and a multidisciplinary disease. Its early diagnosis is necessary to start as soon as possible the treatment, reducing the invalidating complications. This study showed that the administration of an adeguate and personalized ERT improves not only the haematological and visceral parameters in a short period of time but also the bone mineral density in a longer period. A disease severity score is useful to quantify the response of the disease to the treatment. Long term complications of GD, such as haematological malignant diseases, has to be considered.

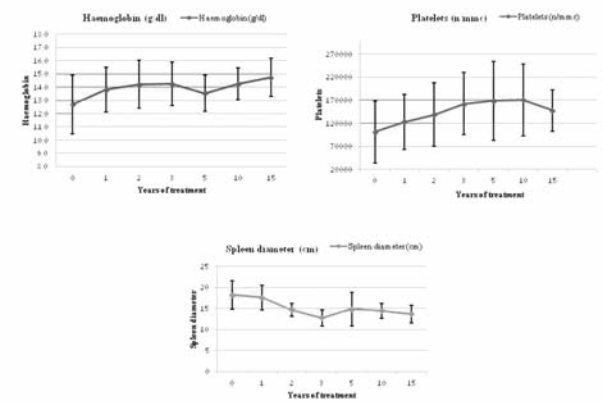

Figure 1: Haemoglobin levels, platelets count and spleen diameter during ERT treatment

1043

INTERACTION BETWEEN T AND B LYMPHOCYTES AND THE IMPACT OF PROLIFERATION OF B LYMPHOCYTES ON THE PATHOGENESIS OF IMMUN THROMBOCYTOPENIA IN CHILDHOOD

S Gozmen[1], T Karapinar[1], O Tufekci[1], C Vergin[2], F Yuksel[1], G Irken[1], H Oren[1]
[1]Dokuz Eylul University Hospital, Izmir, Turkey
[2]Behcet Uz Children's Hospital, Izmir, Turkey

Immune thrombocytopenia (ITP) is a disease characterized by forming autoantibodies against antigens on platelets and the clearance of these antibody coated platelets by reticuloendothelial system. The aim of this study is to determine the levels of B cell activating factor (BAFF) and a proliferation inducing ligand (APRIL), the interaction between T and B lymphocytes, the impact of proliferation of B lymphocytes in the pathogenesis, and other cellular interactions probably having influence on this proliferation (T lymphocyte, activating B lymphocyte with complement, relationship between the levels of BAFF and APRIL, and the expressions of CD 21, CD40, CD154) in ITP of childhood.Twenty acute ITP patients, 20 chronic ITP patients, and 20 healthy subjects as a control group were enrolled in this study. BAFF, APRIL, IL-4, and IFN- γ in sera by ELISA, expressions of CD19, CD 3, CD21, CD40, CD154 inleucocytes and lymphocytes by flow cytometry were measured in both patient and healthy groups. We also measured these parameters again after the therapy between the day seven and fourteen.Informed consent from all participants was obtained for this study.There was no difference between groups for gender. Median age was 86,5 ± 50,3 months (range: 16-204 months) within whole study group without any significant difference among groups. Platelet levels were lower in acute and chronic ITP groups before therapy compared with controls. But there was no difference between groups for any other hemogram parameters. Sixteen patients in acute ITP group were treated with IV immunglobulin and four with high dose methylprednisolone. In chronic ITP group, nine patients were treated with IV immunglobulin and three were treated with high dose methylprednisolone. Twenty one patients (fourteen acute and seven chronic) were studied again after therapy between the day seven and fourteen.Serum BAFF levels, evaluated for the impact on the pathogenesis of ITP in childhood, were significantly higher in acute ITP group than that of both chronic ITP and healthy controls and were significantly decreased compared with pretherapy. APRIL, second molecule evaluated for the impact on the pathogenesis of İTP in childhood, which is homologue to BAFF, were not correlated with BAFF levels and similar in groups before and after therapy. IL-4 and IFN- γ levels, determining the Th1 and Th2 response, were similar in groups before and after therapy.

Expressions of CD3, CD19, CD21, CD40, and CD 154, evaluated for the interaction between T and B lymphocytes, were also similar in groups before and after therapy. Although the number of patients in this study is limited, this study shows that BAFF plays role in the pathogenesis of acute ITP, and data from adult ITP studies are not similar to data from childhood ITP. More comprehensive prospective studies are required for childhood ITP.

1044

CHILDHOOD IMMUNE THROMBOCYTOPENIC PURPURA: LONG-TERM FOLLOW-UP DATA EVALUATED BY THE CRITERIA OF INTERNATIONAL WORKING GROUP OF IMMUNE THROMBOCYTOPENIC PURPURA

A Meral Günes
Uludag University, Bursa, Turkey

Background. Immune thrombocytopenic purpura (ITP) is a common bleeding disorder in childhood, characterized by isolated thrombocytopenia. The definitions, and clinical criteria used in the diagnosis and management of ITP are widely heterogeneous in different studies. International Working Group (IWG) of ITP has recently published a consensus report about standardization of terminology, definitions and outcome criteria in ITP to overcome these difficulties. The aim and procedure: The records of patients were retrospectively collected from January 2000 to December 2009. Our aim was to evaluate the data of children with ITP by using the new definition of IWG. **Results.** Thrombocytopenia less than 100x109/L were found in 201 children. The median follow-up period was 22 months (12-131 months). The median age and platelet count at presentation were 69 months (6 months-208 months) and 19x109/L (1-93x109/L), respectively. The female and male ratio was 1.16. We found two risk factors for chronic course of ITP; female gender (OR=2.55, CI=1.31-4.95) and age being more than 10 years (OR=3.0, CI=1.5-5.98). Life-threating bleeding occurred in 5% (n=9) of the patients. Splenectomy was required in 7 (3%) cases. Two of them was splenectomized within one year and the rest (n=5) had splenectomy after one year. When we excude splenectomized cases, CR was achieved in 139 out of 199 (70%) children at one year. The disease was also resolved in 9 (5%; n=9/194) more children from 12 to 90 months, achieving 76% (n=148/194) CR rate. **Conclusions**. In total, CR rates at 12 and 90 months has reached to 70% and 76% (n:148/194), respectively. Therefore, long-term follow-up is necessary in these children. Female gender and being more than 10 years old significantly influenced the chronicity.

1045

COST-CONSEQUENCE ANALYSIS COMPARING ROMIPLOSTIM TO RITUXIMAB IN THE TREATMENT OF ADULT PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN GERMANY

M von Depka[1], A Salama[2], A Perrin[3], I Oelze[3], M Chulikavit[3], E Kunz[4], L Kutikova[4], M Thalheimer[5]
[1]Werlhof Institute, Hannover, Germany
[2]Charité, Universitätsmedizin Berlin, Institut für Transfusionsmedizin, Berlin, Germany
[3]Analytica LA-SER International, Inc., New York, United States of America
[4]Amgen GmbH, Munich, Germany
[5]Universitätsklinikum Heidelberg, Heidelberg, Germany

Background. ITP is an autoimmune disorder characterized by isolated thrombocytopenia. Patients can experience a range of bleeding symptoms, some of which may require hospitalization and emergency treatment. Romiplostim stimulates platelet production via the thrombopoetin-receptor and is used for pretreated patients with chronic ITP. Other treatment options in this setting include off-label use of the immunosuppressant rituximab.**Aims.** This analysis assessed the cost per responder of romiplostim compared to that of rituximab in adult ITP patients in Germany. **Methods.** A decision analytic model was developed to estimate the 6-month cost per patient responding to treatment (achieving a platelet count ≥50x10^9/L). Romiplostim patients received weekly administrations; rituximab patients received a course of 4 weekly intravenous infusions. Resource utilization was based on international treatment guidelines and validated by clinical expert opinion. Unit costs were derived from German reimbursement lists, and included the costs of routine physician visits, treatment administration, and emergency care. Non-responders incurred the additional cost of rescue therapy (IVIg and prednisone) and hospitalizations/physician visits associated with bleeding-related events.**Results.** Response rates were 83% and 62.5%, as per most robust evidence, the romiplostim pivotal trials and systematic review on rituximab, respectively (Kuter et al, Lancet, 2008; Arnold et al, Ann Intern Med, 2007). Romiplostim and rituximab were associated with comparable treatment costs; mean overall 6-month cost per patient was €21,650 for romiplostim and €21,493 for rituximab. Dividing mean cost per patient by response rates yielded a cost per response of €26,084 for romiplostim and €34,389 for rituximab. The 32% increase in cost per platelet response observed for rituximab was mainly driven by the higher rate of rituximab non-responders, which increased the incidence of bleeding, and subsequently rescue medication use. Sensitivity analyses based on resource use, rescue medication use, and rituximab schedule were performed. **Conclusions**. In adult ITP patients in Germany, romiplostim was associated with lower cost per response over 6 months compared to rituximab. As romiplostim has a higher response rate, thereby lowering the incidence of rescue treatment usage, it represents a more efficient use of resources in the German healthcare system compared to rituximab. Although this analysis was not based on a head-to-head comparison of the two treatments, findings closely reflect the cost of treating ITP in clinical practice.

BONE MARROW CD20 AND MORPHOLOGY IN CHILDREN WITH CHRONIC ITP

S El-Alfy, A Abdelmaksoud, W Darwish, N Shehata
Ain Shams University, Cairo, Egypt

Background. The presence of excess CD20B- lymphocytes in the bone marrow is related to an unfavorable outcome and anti-$CD20^+$ monoclonal antibodies therapy has been reported to be useful in patients with refractory ITP. **Aims.** To assess the bone marrow (BM) CD20 B-lymphocytes and BM morphology in relation to various clinical parameters and response to treatment in patients with chronic ITP. **Methods.** This prospective study was conducted on 30 patients with persistent thrombocytopenia >12 months after diagnosis of ITP. They were either non-responder or failed to maintain response to at least two treatment modalities before enrollment. All patients discontinued any medication 2 weeks prior to study entry. Any patient with life-threatening bleedings was excluded. Data collected included; age, sex, duration of illness, bleeding score and response to treatment. Laboratory investigations included; CBC, BM biopsy stained with reticulin to detect fibrosis and BM aspirate stained according to Leishman to assess plasma cells (%) , eosinophils (%), megakaryocytes (form and number/LPF). The number of megakaryocytes was rated as either normal (1 megakaryocyte per 1 to 3 low-power fields), increased (more than 2 megakaryocytes per low-power field), or decreased (1 megakaryocyte per 5 to 10 low-power fields). Assessment of CD20 B-lymphocytes was done by EPICS XL Coulter flowcytometer. Patients were considered positive for CD20 when >20% of total marrow lymphocytes expressed it. Informed consent was signed by parents, patients signed either ascent or consent forms. **Results.** Patients were 20 males (66.7%) and 10 (33.3%) females, their ages ranged from 2 -18 years old with mean age of 9.2 ± 4.1 years. The duration of illness ranged from 1- 9 years with mean duration of 3.5 ± 2.1 years. Mean platelet count at the study entry was 47.8 ± 31.5(x 10^3/ µl). Seventeen patients (56.7%) had normal level of CD20 B-lymphocytes (<20%), while 13 patients (43.3%) had positive CD20B-lymphocytes (>20%) with significantly higher bleeding score (p=0.025), lower mean platelets (p=0.026), a significant inverse correlation with platelet count (r=-0.48, p=0.008) and NR to steroids and Anti-D (p=0.035 and 0.04 respectively). $CD20^-$ patients showed significantly higher CR and PR to steroids (p<0.05). CD 20 B-lymphocytes level was not significantly related to age, gender or disease duration (p>0.05). All patients had normal bone marrow plasma cells (%), while bone marrow eosinophils were increased in all patients (4-13% with a mean of 6.4 ± 2.1%).There was an increased megakaryocytes number (3-8/LPF). No significant difference in CD20 B-lymphocytes level in relation to megakaryocytes (number or form) or eosinophils(%) (p>0.05). Fibrosis grade 1 to 2 was reported in two patients. Small sample size and unavailable BM samples at diagnosis were the 2 main limitations of this study. **Conclusions.** Increased bone marrow CD20B-lymphocytes is independent of bone marrow morphology and is related to lower platelet count, increased bleeding score and poorer response to steroids and Anti-D.

1047

NEW INSIGHTS INTO THROMBOPOIESIS IN NEONATAL SEPSIS

D Mohamed, R El-Farrash
Ain Shams University, Cairo, Egypt

Background. Thrombocytopenia is one of the most frequent hematologic abnormalities in the neonatal period, affecting about 18-35% of all patients admitted to the Neonatal Intensive Care Unit (NICU), with sepsis being among the most common causes of severe neonatal thrombocytopenia. It is unclear whether increased platelet consumption or decreased platelet production contributes to thrombocytopenia of septic neonates. **Aims.** To answer a question

whether thrombocytopenia in neonates with infection is a result of increased platelet destruction, or rather reflects decreased megakaryocytes due to sepsis-mediated suppression of megakaryocytopoiesis, we evaluated the effects of sepsis on neonatal thrombopoiesis, using a panel of tests. **Methods.** This prospective case-control study was conducted on 50 neonates with confirmed sepsis admitted to NICU at Pediatrics Department, Ain Shams University Hospitals. Thirty healthy newborns were included as controls. The enrolled neonates were subjected to detailed history taking, thorough clinical examination and laboratory investigations including complete blood count, C-reactive protein, blood cultures, and tests of thrombopoiesis; namely serum thrombopoietin (TPO) assay, flow cytometric analysis of reticulated platelets percentage (RP%) and calculation of absolute RP counts. **Results.** Septic neonates comprised 24 males and 26 females with mean gestational age of 36.0±3.1 weeks. Twenty-eight (56%) of the septic neonates were thrombocytopenic (platelets <150,000/μL). While platelets and RP counts were decreased, TPO and RP% were increased in septic neonates compared to healthy controls. Neonates with Gram-negative sepsis had the lowest platelet and RP counts and the highest TPO and RP% followed by those with fungal septicemia. Platelet counts showed inverse correlations with TPO and RP% and direct correlation with RP count. **Conclusions.** Neonates respond to sepsis by upregulating thrombopoiesis, where thrombocytopenia ensues when the rate of platelet consumption exceeds the rate of platelet production. Simultaneous measurements of serum TPO levels and RP% are helpful in discriminating hyperdestructive from hypoplastic thrombocytopenia among septic neonates.

ASSESSMENT OF THE ANTIPLATELET ANTIBODIES(USING MACE 1: MODIFIED ANTIGEN CAPTURE) IN THROMBOCYTOPENIC HEPATITIS C VIRUS (HCV) CHRONICALLY INFECTED PATIENTS

A Abd Elhamid, K Khalil, A Abd el Hai, E Bakr, A Hassan, M Abdo, G ElGhazalawy
Suez Canal University, Faculty of Medicine, Ismailia, Egypt

Background. Chronic HCV infection commonly manifest circulating autoantibodies and deposits of immune-complexes in various tissues outside the liver which may represent a major pathological pathway of extrahepatic manifestation development in the course of HCV infection. Several different mechanisms are reported to be related with thrombocytopenia in HCV positive patients: Portal hypertension and hypersplenism in end stage liver disease. Auto-immune reaction to platelets. Direct infection of platelets and megakaryocytes by HCV. In HCV-associated immune thrombocytopenia, the most common target reported was glycoprotein IIb/IIIa, but all other glycoproteins were also targets. **Design of the study.** Case control study. **Objectives of the study.** Assessment of serum level of Anti-platelet antibodies using **MACE 1** (Modified Antigen Capture)in HCV chronically infected thrombocytopenic patients. Detection of the presence of a correlation between the levels of the serum anti-platelet antibodies, platelet count and the viral load. **The study Population:** Case control study. *The study group:* 20 HCV positive thrombocytopenic patients. *Control Group*: 20 HCV positive non-thrombocytopenic patients. **Methods.** Medical histories, clinical examination, HCV- RT-PCR assay, liver functions, Anti-nuclear antibody, Rheumatoid factor. Anti-platelet antibodies using **MACE 1** (Modified Antigen Capture) is a qualitative solid phase ELISA designed to detect IgG antibodies to platelet GPIIb/IIIa. **Results.** There was statistically significant difference between the two group regarding the platelet count (101.5 ± 27.4 ×103 cell/ μl) in the patient group versus the control group (207 ± 49.5 ×103 cell/μl), (p< 0.05). Regarding the prevalence of anti-platelet antibodies a statistical significant increase among the thrombocytopenic patients 60%, compared to 10% in the control group (p< 0.05) with odds ratio. ALT, total and direct bilirubin and viral load are higher in the patient group compared to the control group. There was statistically significant correlation in the following: positive correlation between albumin (r= 0.5, p<0.05), and platelet count. There was a negative correlation between HCV-RT-PCR (r= - 0.4, p< 0.05) and platelet count. There were no statistically significant correlation for anti-platelet antibodies (r= -0.2, P= 0.4). reaching 13.5%. **Conclusions.** From the previously mentioned data, we concluded that HCV infection play an important role in the development of thrombocytopenia through production of PAIgG leading to platelet destruction together with the other contributing factors as it's an integrated process consisting of several factors which lead in the end to thrombocytopenia.

1049

PERSISTENT RESPONSE AFTER ROMIPLOSTIM DISCONTINUATION IN PATIENTS AFFECTED BY PRIMARY THROMBOCYTOPENIA

F Biondo, C Santoro, E Baldacci, A Leporace, R Foa', MG Mazzucconi
Hematology, Rome, Italy

Background. The efficacy of thrombopoietin mimetics (TPO-mimetics) in the treatment of chronic-refractory primary thrombocytopenia (pITP) patients (pts) has been demonstrated. The two available TPO-mimetics for the treatment of pITP are Romiplostim and Eltrombopag. These drugs have been approved by EMA for the treatment of chronic and refractory (post-splenectomy) pITP pts.It is well known that these drugs have to be chronically administered to maintain a platelet response.AIMS: To report our experience with Romiplostim treatment and discontinuation in chronic/refractory pITP patients. **Methods.** Twenty-three adult pITP pts [12 M, 11 F; median age, 59.3 yrs (31.9-79.8)] were treated with Romiplostim (initial dose 1μg/Kg/week). The dosage was adjusted in order to maintain the platelet count between 50-250x10^9/L. The median time between diagnosis and Romiplostim start was 14.4 yrs (0.08-38.75). All pts had already received ≥2 lines of therapy [median 2.5 (2-6)], which included prednisone, pulsed high-dose dexamethasone, immunoglobulins, rituximab, interferon, azathioprine and splenectomy in 8 pts. At the start of Romiplostim, the median platelet count was 11x10^9/L (2-32).RESULTS: Seventeen/23 (73%) pts reached a persistent response and 6/23 (27%) were non-responders. Four/17 (24%) responder pts maintained a persistent response after Romiplostim discontinuation. The characteristics of these latter 4 ptswere: median follow-up from therapy start, 20.5 months (12-34); median platelet count during therapy, maximum 382.5x10^9/L (406-1649), minimum 14x10^9/L^{-1} (1-79); median Romiplostim dose to achieve a response, 3.5 μg/Kg/week (1-4); median maintenance dose, 2.5 μg/Kg/week (1-3); median time to response, 3.5 weeks (1-5). Two out of these 4 pts started Romiplostim after 36.9 and 0.25 yrs from splenectomy, respectively; the first one started therapy after 38.75 yrs from the diagnosis of pITP and after 7 therapy lines; the second one started therapy after 2.3 yrs from pITP diagnosis and after 4 therapy lines. In an other pt, splenectomy was contraindicated because of a concomitant cardiovascular disease and age; she started Romiplostim after 14 yrs from pITP diagnosis and after 2 therapy lines; the 4th pt started Romiplostim after only 1 month from pITP diagnosis and prednisone treatment, because of the need to quickly increase the platelet count during a severe GI bleeding refractory to standard emergency therapy (high-dose immunoglobulins, platelet transfusions). All pts were receiving prednisone at the start of Romiplostim; all of them discontinued it at a median time of 14 weeks after response (5-21). They are persistent responders after 17, 9, 10 and 21 months after stopping Romiplostim, respectively. No serious adverse events were observed during and after therapy discontinuation. **Conclusions.** Four/23 (17%) pITP pts treated with Romiplostim maintained a persistent response after therapy discontinuation. So far, few literature data are available on the persistent response after TPO-mimetics discontinuation in pITP pts. Our experience could open new modalities in the use of these drugs, although randomized/controlled clinical trials are necessary to conclusively confirm these results.

1050

ACTIVATION AND FUNCTION OF ELTROMBOPAG-INDUCED PLATELETS COMPARED TO PLATELET FUNCTION IN CORTICOSTEROID- TREATED AND UNTREATED ITP PATIENTS

J Haselboeck, C Ay, A Kaider, I Pabinger, S Panzer
Medical University Vienna, Vienna, Austria

Background. Eltrombopag is approved for the treatment of chronic immune thrombocytopenia (ITP). So far, no systematical analysis of platelet function in eltrombopag-treated ITP patients in comparison to corticosteroid-treated or untreated ITP patients has been performed.**Aims.** We aimed to assess a possible influence of eltrombopag on platelet function *in vivo. Patients/* **Methods.** Platelet function in chronic ITP patients after eltrombopag-induced platelet rise (group 1; n=10) was compared to a control group (group 2; n=12) of patients on continuous therapy with corticosteroids and untreated ITP patients in a non-randomized prospective single-center study. All patients gave written informed consent.Platelet function was assessed both, naive and after in vitro addition of agonists at 2 different time points and averaged. Platelet adhesion under high shear conditions (surface coverage, SC), P-selectin expression, and formation of platelet-monocyte aggregates (PMA) served as parameters of platelet function.Data are given as median [1st-3rd quartile]. Group 1 is listed first. In case of normally distributed data, the Student's t- tests and in case of non-normally distributed parameters the nonparametric Mann-Whitney U test were used to compare the groups. **Results.** Eleven patients (female=9) were included in the treatment group with eltrombopag (group 1). The control group (group 2) con-

sisted of 6 (female=4) patients on ongoing corticosteroid treatment and 6 untreated (female=5) patients. One eltrombopag-treated patient was not included in the final comparative platelet function analysis, because he had no treatment induced platelet rise. None of the included patients developed severe bleeding during the study period, and none received rescue medication. Two patients developed venous thromboses during eltrombopag treatment.Platelet counts [10^9/L] were 49.5 [45.00-59.00] in group 1 after eltrombopag-induced platelet rise, and 70.0 [64.0-80.0] in the control group. Naïve SC showed no difference between eltrombopag-treated patients and the control group with median levels of 5.80 [1.80-9.00] and 6.23 [5.03-11.75], respectively (p=0.488). Neither did activation with ADP (1.55 [1.05-2.70] and 1.80 [1.25-2.35]; p=0.692) or collagen (2.15 [1.90-2.30] and 2.75 [1.30-3.70]; p=0.339) reveal any difference in platelet activatability. Still, SC after addition of TRAP was decreased in the eltrombopag treatment group (1.00 [0.60-2.95] and 2.63 [1.90-4.48]; p=0.032).There were no differences in P-selectin expression [GeoMFI], neither without nor with addition of ADP, TRAP or collagen. The formation of PMA with and without agonistic stimulation was comparable in both groups, in the naïve measurement. Median levels after addition of ADP were 18.01 [10.15-53.13] and 27.23 [15.64-34.05] (p=0.489), and 47.24 [32.24-58.57] and 29.18 [21.84-44.09] (p=0.070) after addition of TRAP. **Conclusions.** We proofed a good functional competence of eltrombopag-induced platelets. No substantial hyperreactivity or increased activatability of eltrombopag-induced platelets was identified in comparison to platelets of untreated or corticosteroid-treated chronic ITP patients.
(*Funded by GlaxoSmithKline, ClinicalTrials.gov number NCT00888901*).

LONG TERM FOLLOW UP ANALYSIS FOLLOWING RITUXIMAB SALVAGE THERAPY IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIA (ITP)

F Zaja[1], S Volpetti[1], M Chiozzotto[1], S Puglisi[1], M Isola[2], R Fanin[1]
[1]DISM, Azienda Ospedaliero Universitaria S. M. Misericordia, Udine, Italy
[2]Cattedra di Statistica, Università degli Studi, Udine, Italy

Background. Several studies previously indicated the short to mid-term therapeutic activity of Rituximab in adults with relapsed-refractory ITP.**Aims.** In order to investigate the long term outcome, we retrospectively analyzed patients with ITP who were treated with Rituximab in our institution from October 1999 to March 2011. **Methods.** According to the different period of therapy, patients received either standard dose (SD) Rituximab (<i*e.* 375 mg/m^2 weekly for 4 weeks) or low dose (LD) Rituximab (<i*e.* 100 mg total dose weekly for 4 weeks). Primary objective was to evaluate EFS which included, as negative events, the absence of response within 2 months from Rituximab start and the lost of response. **Results.** 57 consecutive adult patients, median age 47 years (range 14-80), median platelet count 23 x 10^9/L were evaluated. All patients had active disease that had relapsed or was refractory to at least one full course of steroid therapy or was steroid dependent. Other treatments before Rituximab included splenectomy (3 patients), intravenous immunoglobulin (25 patients), azathioprine or cyclosporin-A (7 patients). The median time from diagnosis to Rituximab was 24 months (range 2-324). Rituximab was administered at SD in 32 patients and at LD in 25. Patients who received SD *vs.* LD Rituximab had better outcome as far as short term response (OR 66% *vs.* 52%, CR 50% *vs.* 28%), relapse rate (38% *vs.* 54%), 4 years EFS (40% *vs.* 24%). The only factor which correlated with EFS was the duration of the interval from diagnosis to Rituximab treatment. Three patients developed short term adverse events, 2 serum syndromes and 1 interstitial pneumonia. Six patients developed delayed adverse events including 4 neoplasms and 2 herpes zoster reactivation; 1 patient died for cerebral bleeding. During this period of observation no cases of opportunistic infections, progressive multifocal leukoencephalopathy or other severe infectious complications were observed.**Conclusions:** Rituximab SD appears a safe and active agent allowing in nearly 40% of cases to achieve long-term response. This effect seems to be superior when treatment is anticipated, thus suggesting a possible advantage of Rituximab treatment in an earlier phase of the disease.

1052

FACTORS ASSOCIATED WITH RESPONSE TO RITUXIMAB; ANALYSIS OF AN IRISH MULTI-CENTER STUDY OF RELAPSED OR REFRACTORY IMMUNE THROMBOCYTOPENIA (ITP)

N Appleby[1], A Burke[2], S Mc Pherson[3], M Khan[4], Y Suliman[5], J Lewis[6], J Mackarel[7], M Gleeson[8], J Krawczyk[9], S Khan[10], K Murphy[6], B Hennessy[3], C Flynn[8], P Murphy[9], P Thornton[11], P O'Gorman[10], O Gilligan[4], M O'Dwyer[5], M Murray[5], H Enright[2], G Crotty[7], D O'Keeffe[1]

[7]Tullamore General Hospital, Tullamore, Ireland
[8]St James's Hospital, Dublin, Ireland
[9]Beaumont Hospital, Dublin, Ireland
[10]Mater Misecordiae Hospital, Dublin, Ireland
[11]James Connolly Memorial Hospital, Dublin, Ireland

Background. In the treatment of relapsed or refractory ITP, rituximab is associated with response rates of 60%. The response is transient and 85% of patients will require salvage therapy within two years. Factors predicting a sustained response to rituximab are unknown. **Aims.** This retrospective multi-center study aimed to identify factors associated with a sustained response to rituximab. **Methods.** Patients who received rituximab for the treatment of relapsed or refractory ITP were identified from hospital records at 11 Irish haematology centers.Data were collected from patient notes and laboratory records.Response was graded as follows:1 Complete response. Platelet count > 1002 Good response. Platelet count 50-80 and > 50% increase from baseline platelet count3 Intermediate response. Platelet count 30-50 and > 50% increase from baseline4 No response. Platelet count stable or rise not meeting criteria for intermediate response5 Loss of response. Platelet count < 30 in a patient previously meeting criteria for response or need for salvage therapy.Overall response rate included Grade 1, 2 and 3 responses. **Results.** 117 patients with relapsed or refractory ITP were identified. No data on response were available for 12 patients and they were excluded from analysis.Of the 105 patients for analysis, 41.1 % were male and 58.9 % were female. The median age at rituximab treatment was 55 years. 85.7 % had primary ITP. Patients received a median of two prior treatment modalities, with 9.5 % having four or more treatments modalities. 20 % had undergone splenectomy.The median platelet count commencing treatment was 19x10^9/L. 97.8% of patients received rituximab at a dose of 375mg/m^2 weekly for four weeks.The overall response rate was 57.3% at one month with responses sustained for up to 36 months. There was no statistically significant difference in response rates when groups were compared for gender, age, number of prior treatments or use of steroid with rituximab.A difference in overall response was observed between splenectomised and non-splenectomised patients (42.1% versus 59.5% p=0.2) at one month and at six months (50% versus 64.9% p=0.38). The difference in response rate achieved statistical significance at 12 months (30.8% versus 58.6% p=0.05), at 24 months (11.1% versus 58.6% p=0.02) and at 36 months (16.6% versus 76.5% p=0.018). **Conclusions.** Rituximab offers an efficacious therapeutic option for treatment of relapsed or refractory ITP. Our study found older adults are as likely to respond to rituximab as younger patients.Non-splenectomised patients respond to rituximab and the response is sustained for up to three years. Randomised data are needed to determine the optimal treatment for young surgically fit patients with ITP.In patients who relapse following splenectomy, the response rate is lower and responses are not sustained. Thrombopoeitin receptor agonists may be more appropriate therapy for splenectomised patients requiring further ITP treatment.

1053

INVESTIGATION OF IL1B, IL1RN, IL4, IL6 AND IL10 GENE POLYMORPHISM IN ADULT PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA

J Vilela[1], E De Paula[2], J Annichino-Bizzacchi[3], M Addas-Carvalho[2]
[1]State University of Campinas, Campinas, Brazil
[2]State University of Campinas- UNICAMP, Campinas, Brazil
[3]State University of Campinas - UNICAMP, Campinas, Brazil

Background. The immune thrombocytopenic purpura (ITP) is an autoimmune disease characterized by the presence of autoantibodies against the platelet membrane glicoproteins. The inflammatory reaction is regulated by a balance

between pro and anti-inflammatory cytokines and it was reported that there was an association between the cytokine gene polymorphisms affecting the cytokine production and its secretion in autoimmune and malignant diseases both at the stage of formation, in the course of disease and their responses to treatment. **Aims.** In this study, the aim was to investigate whether there were any differences between the ITP patient group and the healthy control group in a population of the southwestern state of São Paulo, Brazil in cytokines gene polymorphisms *IL1B, IL1RN, IL4, IL6, IL10* known to be related to autoimmunity inflammation and to investigate the association between the identified genotypes and their responses to treatment. **Methods.** We investigated polymorphisms in genes using polymerase chain reaction, real-time PCR and polymerase chain reaction-restriction fragment length polymorphism **Methods.** Associations were evaluated using Fisher exact test. In total, 216 adult patients with ITP were matched with 118 controls and clinical data were obtained from medical records. **Results.** Analysis of allele and genotype frequencies of *IL1B*-511C/T, *IL1B*+3953C/T, *IL4* VNTR, *IL6*-174G/C, *IL10*-1082G/A, *IL10*-819C/T and *IL10*-592A/C polymorphisms showed no significant differences between the two groups. However, for the IL1RN VNTR polymorphism there was a significant difference between allele 2 frequencies, with genotypes non carriers of allele 2 significantly increased in ITP as compared to the controls (p <0.001; OR = 4.15, CI = 2.31 to 7.58). The same goes for the *IL4* -590C/T polymorphism in which there is an increase statistically significant of the C allele in ITP group. (p <0.001, OR = 0.42, CI = 0.29 to 0.6). Also, studying *IL10* haplotypes, the comparison between High Producer (GCC/GCC) and Middle (GCC/ACC, GCC/ATA) Lower (ACC/ACC, ACC/ATA, ATA/ATA) showed that patients with genotype High Producer are much more frequent in ITP (p=0,001; OD=0.008; CI =0 to 0,49). Analyzing the polymorphisms associated with clinical parameters, this study showed that *IL1B*-511CC were present in individuals with good response to splenectomy (p =0.05, OR = inf, CI = 0.94 to inf). **Conclusions.** With these findings it is proposed that the non carriers of allele 2 of the *IL1RN* VNTR polymorphism, confers risk for patients in the study as well as observed for *IL4* -590C/T polymorphism that could be a protective factor against development of disease. Also, patients with High Producer *IL10* haplotypes could have a greater chance of developing the disease. *IL1B*-511C/T polymorphism may be an important factor and that there is a tendency of those who are CC respond well to splenectomy.

1054

PLATELET SURFACE HIGH MOBILITY GROUP BOX PROTEIN-1 BINDS RECEPTOR FOR ADVANCED GLYCATION END-PRODUCTS IN PLASMA OR ON MONOCYTES IN SEPTIC PATIENTS

V Thachil, V Barrera, B Djebari, S Abrams, G Wang, C Toh
University of Liverpool, Liverpool, United Kingdom

Background. High mobility group box protein-1 is a cytokine mediator of inflammation in septic patients. Receptor for advanced glycation endproducts (RAGE) is a pattern recognition receptor, which has one of its ligands, HMGB1. Soluble form of RAGE levels increase several-fold in patients with sepsis. Since platelets play an important role in sepsis, it was hypothesised that platelet surface HMGB1 may bind to soluble RAGE. **Methods.** Flow cytometry (FACS) and Western blotting experiments were performed to identify RAGE on the surface of platelets in septic platelet-rich plasma and washed platelets. Soluble RAGE levels were analysed in septic plasma by ELISA and correlated with clinical scores including platelet count. Surface HMGB1 was measured on the septic platelets to identify the ligand for soluble RAGE on platelets. Different stimuli were used to activate platelets to identify the surface expression. Blocking experiments were done to see if platelet-surface HMGB1 was involved binding to RAGE on activated monocytes (U937 cell line). **Results.** RAGE was not expressed by platelets but was noted to be increased on platelets in septic platelet-rich plasma. Platelet-associated RAGE was the soluble form and not the receptor. Levels of soluble RAGE was increased in septic plasma and correlated with platelet counts. Surface HMGB1 was increased on septic platelets and binds to soluble RAGE in septic plasma. Blocking experiments suggested platelet HMGB1may be involved in binding to RAGE expressed by activated monocytes. **Conclusions**. Platelet-surface HMGB1 binds to soluble RAGE in the plasma of septic patients. This ligand may be important in platelet-monocyte aggregation in sepsis through HMGB1-RAGE interaction.

[3]Medical Science, Antakya/Hatay, Turkey

Background. - Sickle cell anemia (SCA) is characterized by intermittent vaso-obstructive events and chronic hemolytic anemia.**Aim** - The purpose of this study is to determine the impact of mean platelet volume (MPV) on the incidence and severity of vaso-occlusive and cerebrovascular events in patients with SCA. **Methods. -** The 238 cases diagnosed with SCA were evaluated retrospectively with respect to the occurrence of painful crisis for the previous year. The severities of vaso-occlusive crisis were determined by the need of hospitalization and site of vaso-occlusive crisis. **Results.** Of the SCA patients, 104 (43.7%) had 1-3 attacks (Group 1), 34 (14.3%) had 4-5 attacks (Group 2) and 100 (42%) had more than 6 attacks (Group 3). In accordance with the results obtained during the evaluation of the cases diagnosed with sickle-cell anemia, MPV value was found to be significantly higher in patients with cerebrovascular events. Also MPV values increased with increasing incidence of the crises (r=0.297) (p=0.001). **Conclusions.** One of the contributing factors for this clinical heterogeneity may be related to the MPV values in patients with sickle cell anemia. The higher MPV values may be an early predictor of future cerebrovascular events in patients with sickle cell anemia and may require close follow-up and additional measures.

Table 1: Some characteristics of patients in relation with the hematological parameters (CVE: Cerebrovascular event; MPV: mean platelet volume)

ROMIPLOSTIM ALLOWS CHEMOTHERAPY ADMINISTRATION IN A PATIENT WITH HEPATOPATHY-ASSOCIATED THROMBOCYTOPENIA

JM Arguiñano, M Lasa, T Pamplona, J Coll, MC Mateos, MA Ardaiz, MA Goñi, M Noceda, Y Burguete, M Perez, AM Redondo, MJ Paloma, I Ezpeleta, F Oyarzabal
Complejo Hospitalario de Navarra, Pamplona, Spain

Background. Thrombocytopenia is a frequent complication of chronic liver disease and is considered an indicator of advanced disease. Among other factors, this low platelet count is due partly to decreased thrombopoietin production. Romiplostim is a protein that acts as a thrombopoietin receptor agonist, thus increasing platelet counts. Romiplostim and other orally administrated drug, eltrombopag have been approved by FDA and EMEA for use in immune thrombocytopenia. Use of thrombopoietin receptor agonists in liver disease is troublesome because of the risk of portal vein thrombosis, but has been safely administrated in cirrhosis associated with hepatitis C.Case Report: We report the case of a 63-year-old female with alcoholic cirrhosis in a Child-Pugh stage A6, abstinent for the last 4 years. She had been diagnosed of ductal carcinoma of breast 12 years before and remained in remission after surgery and tamoxifen therapy. When relapse occurred, it was found to be positive for estrogen receptor and c-erbB-2. Therapy with trastuzumab and paclitaxel was planned, but thrombocytopenia precluded paclitaxel use since platelet counts were 50,000/µL. Then romiplostim was started in a named patient basis in order to increase platelet counts. Eltrombopag has extensive experience in hepatopathy associated thrombocytopenia, but was discarded because of pharmacologic interaction with paclitaxel. On the other hand, according to product information, romiplostim is allowed for use in patients with Child-Pugh score below 7, but eltrombopag cannot be used with scores over 5.Dose schedule of romiplostim was the same as in immune thrombocytopenia, starting with 1 µg/kg and increasing 1µg/kg per week as to reach a target of 100,000/µL (higher than in immune thrombocytopenia). This was accomplished at 6 µg/kg and allowed paclitaxel therapy to be administered as scheduled except for a febrile neutropenia episode that delayed one dose. Platelet counts were maintained between 100,000 and 150,000/µL throughout the whole course of chemotherapy without any change in dose requirements.As well as physical examination, D-dimer was determined with every platelet count in order to screen for thrombosis. Moreover, a Doppler ultrasound scan has been performed every other month in order to rule out asymptomatic portal vein thrombosis. Despite increasing D dimer measurements, no thrombotic complications have been detected. **Conclusions.** Thrombopoietin receptor agonists can make possible chemotherapy administration when low platelet counts are the main limitation, although in an off-label use. Agent selection must carefully consider comorbidities, side effects and drug interactions. Surveillance of side effects must also be tailored to the individual patient

1057

ACTIVATION AND FUNCTION OF ELTROMBOPAG-INDUCED PLATELETS COMPARED TO PLATELET FUNCTION IN CORTICOID- TREATED AND UNTREATED ITP PATIENTS

J Haselboeck, I Pabinger, C Ay, S Koder, S Panzer
Medical University Vienna, Vienna, Austria

Background. Eltrombopag is approved for treatment of chronic immune thrombocytopenia (ITP). So far, no systematical analysis of platelet function in eltrombopag-treated ITP patients in comparison to steroid-treated or untreated ITP patients has been performed.**Aims.** We aimed to assess a possible influence of eltrombopag on platelet function *in vivo*. *Patients/* **Methods.** Platelet function in chronic ITP patients after eltrombopag-induced platelet rise (group 1; n=10) was compared to a control group (group 2; n=12) of patients on continuous therapy with corticoids and untreated ITP patients in a non-randomized prospective single-center study. All patients gave written informed consent.Platelet function was assessed both, naive and after in vitro addition of agonists at 2 different time points and averaged. Platelet adhesion under high shear conditions (surface coverage, SC), P-selectin expression, and formation of platelet-monocyte aggregates (PMA) served as parameters of platelet function.Data are given as median [1st-3rd quartile]. Group 1 is listed first. In case of normally distributed data, the Student´s t- tests, and in case of non-normally distributed parameters the nonparametric Mann-Whitney U test were used to compare the groups.*Results.* Eleven patients (female=9) were included in the treatment group with eltrombopag (group 1). The control group (group 2) consisted of 6 (female=4) patients on ongoing steroid treatment and 6 untreated (female=5) patients. One eltrombopag-treated patient was not included in the final comparative platelet function analysis, because he had no treatment induced platelet rise. None of the included patients developed severe bleeding during the study period, and none received rescue medication. Two patients developed venous thrombosis during eltrombopag treatment.Platelet counts [10^9/L] were 49.5 [45.00-59.00] in group 1 after eltrombopag-induced platelet rise, and 70.0 [64.0-80.0] in the control group. Naïve SC showed no difference between eltrombopag-treated patients and the control group with median levels of 5.80 [1.80-9.00] and 6.23 [5.03-11.75], respectively (p=0.488). Neither did activation with ADP (1.55 [1.05-2.70] and 1.80 [1.25-2.35]; p=0.692) or collagen (2.15 [1.90-2.30] and 2.75 [1.30-3.70]; p=0.339) reveal any difference in platelet activatability. Still, SC after addition of TRAP was decreased in the eltrombopag treatment group (1.00 [0.60-2.95] and 2.63 [1.90-4.48]; p=0.032).There were no differences in P-selectin expression [GeoMFI], neither without nor with addition of ADP, TRAP or collagen. The formation of PMA with and without agonistic stimulation was comparable in both groups. Median levels after addition of ADP were 18.01 [10.15-53.13] and 27.23 [15.64-34.05] (p=0.489), and 47.24 [32.24-58.57] and 29.18 [21.84-44.09] (p=0.070) after addition of TRAP.*Conclusion:* We proofed a good functional competence of eltrombopag-induced platelets. No substantial hyperreactivity or increased activatability of eltrombopag-induced platelets were identified in comparison to platelets of untreated or steroid-treated ITP patients.(Funded by GlaxoSmithKline, ClinicalTrials.gov number NCT00888901).

WAIT AND SEE IS IT THE BEST THERAPY FOR IMMUNE THROMBOCYTOPENIC PURPURA IN CHILDREN?

M Anicic[1], J Konja[1], B Konja Glavas[2]
[1]University Hospital Center, University Department of pediatrics, Zagreb, Croatia
[2]Universitiy Hospital Center, Zagreb, Croatia

Background. Immune thrombocytopenic purpura (ITP) occurs in acute form in 75%-85% of affected children, with complete recovery within 6 months with or without therapy. Optimal therapy for ITP remains unknown. The need of treatment is based on the low but definitive risk of intracranial hemorrhage. The opinions about the need and type of therapy are contradictory. **Aims.** The aim of the present study was to assess the efficacy of different methods oftreatment ITP in children. **Methods.** During the 1980-2010 period, 74 male and 68 female aged 0-16 years with ITP were treated withcorticosteroids or IVIG or their combination, or were only observed. The use of therapy was primarily indicated by clinical picture rather than platelet count. Of 142 patients,101(71%) received no therapy, whereas 41(29%) patients with pronounced hemorrhagic diathesis and very low platelet count administered therapy as follows: steroids in 24(16.9%), IVIG in 14(9.8%), and a combination of steroids and IVIG in three (2.1% patients) for intracranial hemorrhage in two patients, and for emergency operativeprocedure for appendicitis in one patient).Results. All patients are alive to the present. Platelet count normalized within 6 months in 98(69%)patients, i.e.78 (54.9%) without therapy and 28(19.7%) with therapy, in 9(6.3%) within 5 years. Recurrent ITP developed in 11 (7.7%) and chronic ITP in the remaining 24(16.9%) patients.Conclusions: Accordingly, we believe that most children with ITP require no therapy.

PLATELET MORPHOLOGY IN PATIENTS WITH SUBCLINICAL HYPOTHYROIDISM: RESULTS FROM A CROSS-SECTIONAL STUDY

M Dalamaga[1], K Daskalopoulou[2], M Triantafilli[3], G Sotiropoulos[3], K Karmaniolas[3], M Pantelaki[2], A Lekka[3]
[1]Attikon General University Hospital, Athens, Greece
[2]ELPIS General Hospital, Athens, Greece
[3]NIMTS General Hospital, Athens, Greece

Background. Subclinical hypothyroidism (SH) is often seen in the general population. Patients may be asymptomatic or may present non-specific symptoms. They are often diagnosed via routine screening and they have normal serum values of thyroxine (T4), triiodothyronine (T3) and mildly elevated serum concentrations of thyroid stimulating hormone (TSH). On the other hand, platelet parameters and especially mean platelet volume, an important determinant of platelet function, morphology and activation, constitutes a novel emerging risk factor for atherosclerosis and its complications such as coronary heart disease. Increased mean platelet volume (MPV) reflects active and large platelets that could release more thromboxane than smaller ones. It has been suggested that SH could represent a risk factor for cardiovascular disease, especially coronary heart disease. MPV, platelet distribution width (PDW), platelet count (PLT) have not been studied in depth in subclinical hypothyroidism.**Aims.** The aim of the present study was to compare the platelet count as well as the platelet indices MPV and PDW in SH and in euthyroidic healthy subjects and to investigate whether SH may possess a predictive significance in the determination of platelet morphology and function. **Methods.** In a cross-sectional study between 2009 and 2011, we have evaluated forty three patients with SH prior to any therapeutic intervention with levothyroxine (33 women and 10 men) with a mean age: 34.8 ± 8.3 years (range: 18-50 years) and an equal number of euthyroidic healthy subjects (33 women and 10 men) with a mean age: 33.9 ± 8 years (range: 20-48 years). Healthy subjects were matched on gender, age (±5 years), body mass index (± 1.5 kg/m^2) and year/month of diagnosis (±1 month). None of the subjects (patients and controls) presented any infectious and neoplastic conditions, diabetes mellitus, hypertension and dyslipidemia. To assess thrombopoiesis, we have determined platelet indices using the Sysmex 9000 analyzer. TSH, T3, free-T3, T4 and free-T4 were determined using an electro-chemiluminescence immunoassay intended for use on Elecsys 2010 analyzer (Roche Diagnostics). Statistical analysis of data was performed with IBM-SPSS® statistical package version 20 for Windowssoftware.Results. Cases presented significantly higher MPV (mean ± SD: 12.31 fL ± 0.45) and PDW (mean ± SD: 15.3 % ± 1.1) than controls (mean MPV ± SD: 10.7 fL ± 0.82, p<0.001 and mean PDW ± SD: 13.4 % ± 1.42, p<0.001). On the contrary, patients with SH exhibited similar number of platelets per mm^3 than healthy euthyroidic controls (mean PLT in patients: 250 x 10^3/mm^3 ± 37 versus mean PLT in controls 262 x 10^3/mm^3 ± 37, p=0.24). In a linear regression model, adjusting for age, gender, body mass index and smoking status, the diagnosis of SH was the most significant predictor of MPV and PDW levels (p<0.001). **Conclusions.** These results may suggest that subjects with SH tend to present an augmented platelet size. Elevated platelet activation could contribute to an increased risk of cardiovascular complications observed in SH. Finally, these findings suggest that platelet morphologic changes observed in SH, such as higher MPV and PDW, could be attributed to metabolic parameters.

Targeted therapies

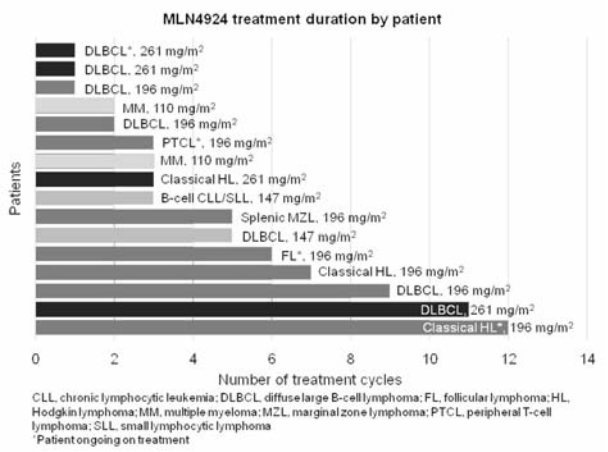
MLN4924, AN INVESTIGATIONAL NEDD8-ACTIVATING ENZYME (NAE) INHIBITOR, IN PATIENTS WITH RELAPSED AND/OR REFRACTORY LYMPHOMA OR MULTIPLE MYELOMA (MM): PHASE 1 DOSE-ESCALATION STUDY OF TWICE-WEEKLY DOSING

R Harvey[1], D Lebovic[2], S Lonial[1], A Jakubowiak[3], M Pickard[4], A McDonald[4], G Mulligan[4], S Blakemore[4], S Kuan[4], B Dezube[4], O O'Connor[5]
[1]Winship Cancer Institute of Emory University, Atlanta, United States of America
[2]University of Michigan Comprehensive Cancer Center, Ann Arbor, United States of America
[3]University of Chicago Medical Center, Chicago, United States of America
[4]Millennium Pharmaceuticals, Inc., Cambridge, United States of America
[5]Center for Lymphoid Malignancies, Columbia University Medical Center, New York, United States of America

Background. MLN4924 is an investigational, first-in-class, small-molecule NAE inhibitor that prevents neddylation of cullin-RING ligases (CRLs) and consequently inhibits proteasomal degradation of CRL substrate proteins. MLN4924 induced apoptosis in lymphoma cell line studies and, *in vivo,* resulted in tumor growth inhibition/regressions in lymphoma xenograft models. Using a dosing schedule of days 1, 2, 8, and 9, 21-day cycles, the MLN4924 maximum tolerated dose (MTD) in patients with relapsed and/or refractory lymphoma or MM was 110 mg/m^2 (Shah *et al*, EHA 2010; dose-limiting toxicities [DLTs]: muscle cramps, febrile neutropenia, AST elevation, myalgia). Here we report an alternative twice-weekly MLN4924 dosing schedule. **Aims.** Objectives included: determining the MTD and safety of MLN4924; describing pharmacokinetics and pharmacodynamics; and evaluating response. **Methods.** Patients aged ≥18 years with relapsed and/or refractory B-/T-cell non-Hodgkin's lymphoma, Hodgkin lymphoma (HL), or MM following ≥2 prior lines of therapy received MLN4924 via 60-minute intravenous infusion on days 1, 4, 8, and 11 of 21-day cycles. Dose escalation proceeded from 110 mg/m^2 in 1.33-fold increments using a Bayesian continual reassessment method based on cycle 1 DLTs. For MLN4924 plasma pharmacokinetics analysis, serial blood samples were obtained during cycle 1. For pharmacodynamic analyses, peripheral blood mononuclear cells (PBMCs) and whole blood were isolated at baseline and following MLN4924 administration; skin biopsies were performed at baseline and after the second dose.



Results. Sixteen patients (12 male) were enrolled, including 2, 2, 8, and 4 to dose levels of 110, 147, 196, and 261 mg/m^2, respectively. Median age was 59.5 years (range, 26-68). Median time since primary diagnosis was 35.5 months (range, 2-101). Primary diagnoses were diffuse large B-cell lymphoma (DLBCL; n=7), classical HL (n=3), B-cell chronic lymphocytic leukemia, follicular lymphoma (FL), splenic marginal-zone lymphoma, peripheral T-cell lymphoma (PTCL; each n=1), and MM (n=2). One DLT was reported: grade 3 MLN4924-related thrombocytopenia (110 mg/m^2). Based on observed toxicities in all enrolled patients, the MTD was determined as 196 mg/m^2 using this twice-weekly schedule. Patients received a median of 3 treatment cycles (range, 1-12); at data cut-off (January 24), 4 were ongoing (Figure). The most common adverse events were fatigue (75%), nausea (69%), vomiting (63%), and decreased appetite (56%). Twelve (75%) patients experienced grade ≥3

events; only neutropenia and pneumonia (each n=2) were reported in >1 patient. In 11 evaluable patients, MLN4924 plasma exposure did not accumulate following multiple dosing, but maximum observed concentration increased more than dose-proportionally over the range studied. MLN4924 induced increased levels of Nrf-2-regulated gene transcripts/pIκBα in PBMCs and Cdt-1/Nrf-2 in skin biopsies. Two patients (DLBCL, PTCL; 196 mg/m^2) had a partial response, and 11 patients had stable disease, with disease control for up to 11 cycles. **Conclusions.** The MLN4924 MTD was 196 mg/m^2 using the twice-weekly schedule studied. Only neutropenia and pneumonia were reported as grade ≥3 toxicity in >1 patient. MLN4924 resulted in increased levels of the CRL substrates pIκBα, Cdt-1, and Nrf-2, the expected pharmacodynamic effects of NAE inhibition. Clinically meaningful responses (DLBCL, PTCL) and durable disease control (FL, HL, DLBCL) were seen in heavily pretreated patients.

1061

SMALL MOLECULES TARGETING ROR1 INDUCE SPECIFIC KILLING OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) CELLS

A Moshfegh[1], S Khan[1], J Vågberg[2], S Byström[2], M Hojat-Farsangi[1], L Mansouri[1], Å Sandin[1], A Danesh Manesh[1], A Österborg[3], H Mellstedt[1]
[1]Karolinska Institutet, Stockholm, Sweden
[2]Kancera AB, Stockholm, Sweden
[3]Karolinska University Hospital, Stockholm, Sweden

Background. There is a great interest to develop targeting drugs for CLL to improve the outcome for the disease. ROR1 is a receptor tyrosine kinase, overexpressed on CLL cells but not on normal cells. ROR1 is constitutively phosphorylated and siRNA transfection induces leukemic cell death. **Aims.** Produce small molecules inhibiting the cytoplasmic tyrosine kinase activity of ROR1 and subsequent specific killing of leukemic cells. **Methods.** A high-throughput screening assay in 384-format has been developed measuring phosphorylation of a substrate peptide by a human recombinant intracellular ROR1 kinase domain. A collection of 80.000 small molecules has been screened generating two chemical series. Novel leads have been synthesized and structure-activity-relationship has been developed using the assay. **Results.** Five compounds were selected (KAN0173631, KAN0438063, KAN0438175T, KAN0438427T, KAN0438434). Freshly isolated leukemic CLL cells were used as targets as well as PBMC from healthy donors. The five compounds induced specific apoptosis of CLL cells (Annexin V/PI and MTT)(24h). Efficacy index (EI), i.e. killing of leukemic cells in relation to normal PBMC was favourable. The most promising drug KAN0438063 (IC_{50} 10μM) had an EI of 40 i.e. killed 40 times more CLL cells than PBMC at a conc. of 10μM. The compounds induced down regulation of PARP and caspases 8 and 9 as well as down regulation of Mcl-1 and Bcl-xl. ROR1 was dephosphorylated as PKC and ERK (Western Blot). The selective apoptotic effect was compared to other small molecules targeting non-ROR1 structures in CLL (PCI-32765, CAL-101, R406, R788, STK-156485, STK-156133) and our compounds were significantly more effective (EI)($p<0.001$). **Conclusions:** We have developed effective and selective series of compounds targeting ROR1 with promising ADMET properties. ROR1 targeting small molecules might also be effective for other tumor cells expressing ROR1 as other lymphoid and myeloid malignancies. Our model molecules will be further optimized and tested in animal tumor models. These molecules represent the first small molecules targeting ROR1 - a “survival factor”in CLL.

1062

GS-1101 (CAL-101), A SELECTIVE PHOSPHATIDYLINOSITOL 3-KINASE-DELTA INHIBITOR, IN COMBINATION WITH OFATUMUMAB FOR THE TREATMENT OF RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

J Barrientos[1], J Sharman[2], S De Vos[3], J Leonard[4], S Coutre[5], M Schreeder[6], N Wagner-Johnston[7], T Boyd[8], N Fowler[9], I Flinn[10], R Boccia[11], R Furman[4], L Holes[12], B Lannutti[12], D Johnson[12], T Jahn[12], L Miller[12]

[12]Gilead Sciences, Inc., Seattle, WA, United States of America

Introduction. PI3Kδ is predominantly expressed in cells of hematopoietic origin where it regulates the survival and proliferation of malignant B-cells. GS-1101 is an orally bioavailable, small-molecule inhibitor that selectively targets PI3Kδ and is highly active in patients with hematologic B-cell malignancies. **Methods. and Patients.** This Phase 1/2 study evaluated repeated 28-day cycles of GS-1101 (CAL-101) in combination with ofatumumab for the treatment of relapsed or refractory chronic lymphocytic leukemia (CLL). GS-1101 (150mg BID) was co-administered with a total of 12 infusions of ofatumumab over 24 weeks (300mg initial dose either on Day 1 or Day 2 (relative to the first dose of GS-1101), followed 1 week later by 1000mg weekly for 7 doses, followed 4 weeks later by 1000mg every 4 weeks for 4 doses). Start of ofatumumab treatment either on Day 1 or on Day 2 allows for evaluating an additional beneficial effect of GS-1101 on ofatumumab-related infusion reactions. After finalizing the ofatumumab treatment, each subjects received single-agent GS-1101 as long as the subject was benefiting. **Results.** At the time of abstract submission, accrual was complete with 21 subjects enrolled and 11 evaluable. Median [range] age was 63 [54-76] years. The majority (9/11; 82%) of patients had bulky adenopathy. The median [range] number of prior therapies was 3 [1-6], including prior exposure to alkylating agents (10/11; 90%), rituximab (9/11; 82%), purine analogs (8/11; 72%), alemtuzumab (3/11; 28%) and/or ofatumumab (2/11;18%). At the data cutoff, the median [range] treatment duration was 5 [0-7] cycles. Almost all subjects (9/11;82%) experienced marked and rapid reductions in lymphadenopathy within the first 2 cycles**.** The lymphocyte mobilization that is expected with PI3Kδ inhibition was significantly reduced in magnitude and duration and persisted past Cycle 1 in only 1 patient. Early follow up data support a favorable safety profile and confirm a lack of clinically significant myelosuppression. Elevated baseline levels of CCL3, CCL4, CXCL13, and TNFα were significantly reduced after 28 days of treatment.**Conclusions.** The combination of GS-1101 (CAL-101) and ofatumumab offers a well-tolerated non-cytotoxic regimen with substantial activity in patients with previously treated CLL. Updated data on the complete cohort of 21 subjects will be presented.

1063

ONCE-WEEKLY MLN9708, AN INVESTIGATIONAL PROTEASOME INHIBITOR, IN PATIENTS WITH RELAPSED/REFRACTORY LYMPHOMA: RESULTS OF A PHASE 1 DOSE-ESCALATION STUDY

S Assouline[1], J Chang[2], R Rifkin[3], A-M Hui[4], N Gupta[4], J Yu[4], A Di Bacco[4], Y Shou[4], P Martin[5]

[1]Jewish General Hospital, McGill University, Montreal, Canada
[2]University of Wisconsin, Carbone Comprehensive Cancer Center, Madison, United States of America
[3]Rocky Mountain Cancer Center, Denver, United States of America
[4]Millennium Pharmaceuticals, Inc., Cambridge, United States of America
[5]Weill Cornell Medical College, New York, United States of America

Background. MLN9708 is a reversible, orally bioavailable, specific 20S proteasome inhibitor. This is the first study of IV MLN9708 in patients with relapsed/refractory lymphoma (NCT00893464).**Aims.** To determine the safety, maximum tolerated dose (MTD), pharmacokinetics (PK), and pharmacodynamics (PD) of once-weekly IV MLN9708 in patients with relapsed/refractory lymphoma. **Methods.** Patients aged ≥18 years with confirmed lymphoma who had failed ≥2 chemotherapeutic regimens received IV MLN9708 on days 1, 8, and 15 of 28-day cycles until disease progression or unacceptable toxicity. One patient was enrolled at a starting dose of 0.125 mg/m^2; dose doubling proceeded with 1 patient per dose up to 1.0 mg/m^2. Dose escalation occurred in 30-40% increments using a standard 3+3 scheme based on occurrence of dose-limiting toxicites (DLTs) in cycle 1. Toxicity was evaluated using NCI CTCAE v3.0. Blood samples were collected at multiple time points after dosing on days 1 and 15 of cycle 1 for PK/PD analyses. Response was assessed using IWG criteria. **Results.** At data cut-off (Feb 10, 2012), 22 patients had been enrolled: 1 each at 0.125 and 0.25 mg/m^2, 2 at 0.5 mg/m^2, 1 at 1 mg/m^2, 4 at 1.4 mg/m^2, 7 at 1.76 mg/m^2, and 6 at 2.34 mg/m^2. Twenty-one patients were included in the safety population. Median age was 57 years (range 23-78); 57% were male. Median number of prior therapies was 5; 32% had received prior radiation and 23% prior stem cell transplant. Median time from last dose of prior therapy to first dose of MLN9708 was 5 months (range 0.6-17.2). Histologies included follicular lymphoma (FL; n=7), T-cell lymphoma (TCL; n=5), DLBCL (n=4), Hodgkin lymphoma (n=3), and other (n=2). Patients received a median of 2 cycles (range 1-22). Two DLTs were seen (grade 4 neutropenia at 1.76 and grade 3 neutropenia at 2.34 mg/m^2); MTD has not yet been reached. All patients experienced adverse events (AEs); the most common all-cause AEs included fatigue (n=13), cough, diarrhea, headache, nausea, and pyrexia (each n=7). The most common drug-related AEs included fatigue (n=10), nausea (n=6), diarrhea (n=6), pyrexia, thrombocytopenia, and vomiting (each n=5). Nine patients had drug-related grade ≥3 AEs. One patient receiving 2.34 mg/m^2 discontinued due to drug-related grade 3 neutropenia. Three patients had drug-related peripheral neuropathy (1 grade 1, 2 grade 2). One on-study death occurred, due to respiratory failure unrelated to MLN9708. Of 20 response-evaluable patients, 3 achieved partial response (including 2 with FL and 1 with TCL) and 4 had stable disease. The 2 FL patients remain in response: 1 achieved PR after cycle 8 (now in cycle 23) and the other achieved PR after cycle 4 (now in cycle 16). PK analyses showed linear PK (0.5-2.34 mg/m^2) and a terminal half-life of ~6-9 days. There was a dose-dependent increase in maximal whole blood 20S proteasome inhibition.**Conclusions:**These phase 1 data suggest that once-weekly IV MLN9708 is generally well tolerated, with infrequent PN, and signs of clinical activity in heavily pretreated lymphoma patients. The trial is ongoing and updated data will be presented.

1064

THE IMPACT OF ENTERAL GRANULOCYTE COLONY STIMULATING FACTOR AND ERYTHROPOIETIN ON FEEDING TOLERANCE IN PRETERM INFANTS

M El-Ganzoury, H Awad, T El-Gammasy, R El-Farrash, E Ismail, H Mohamed
Ain Shams University, Cairo, Egypt

Background. Feeding intolerance in premature neonates and prolonged times of nothing per os (NPO) result in intestinal villous atrophy and subsequent increase in the incidence of necrotizing enterocolitis (NEC). Intestinal growth factors could help prevent villous atrophy. **Aims.** This study aimed at evaluating the benefit of granulocyte colony stimulating factor (G-CSF) and erythropoietin (EPO) in preventing feeding intolerance when given enterally to achieve maximum effects on neonatal bowel and to minimize systemic side effects. **Methods.** The present study is a double-blind randomized case-control study carried out on 90 preterm infants less than 33 weeks gestational age. The study protocol was reviewed and approved by the Research Ethical Committee of Ain Shams University under ID number FMASU 548/2010. This trial is registered at ClinicalTrials.gov; identifier: NCT01441427. The infants who met study criteria were identified and informed consents were obtained from parents. Newborns with congenital anomalies of gastrointestinal tract or major congenital anomalies were excluded. Neonates were assigned to 4 groups; 20 received rhG-CSF, 20 received rhEPO, 20 received both and 30 received plain distilled water (control). Treatment was started with the start of enteral feeding. The test solution (or placebo) was discontinued if enteral intake >80 ml/kg of milk any time even before 7 complete days of treatment. Feeding tolerance and adverse effects of treatment (if any) were assessed by clinical follow up. **Results.** All the studied neonates tolerated the received treatment well without side effects that could be attributed to drug intake. The study group showed better feeding tolerance as reflected by earlier achievement of full feeds, earlier weight gain and lesser hospital stays. The incidence of NEC was significantly decreased among treatment groups. The best feeding tolerance was found among neonates receiving both G-CSF and EPO. No significant difference was found between serum G-CSF or EPO levels in days 0 and 7 among the three treatment groups. **Conclusions:** This study provides further insights on the improvement of neonatal outcomes and help decrease morbidities from malnutrition and feeding intolerance in premature babies. Enteral administration of rhG-CSF and rhEPO may play a critical role in preventing villous atrophy, thereby, reducing feeding intolerance and NEC. Serum levels of the studied intestinal growth factors were stable with no difference before initiation and after cessation of treatment. Larger prospective multicenter studies are required to further assess the safety and side effects of these factors before their clinical application on a wider scale.

PRE-CLINICAL ACTIVITY OF A NOVEL CRM1 INHIBITOR IN ACUTE MYELOID LEUKEMIA

P Ranganathan[1], X Yu[1], C Na[1], S Ramasamy[1], S Shacham[2], M Kauffman[2], G Marcucci[1], R Garzon[1]

[1]Ohio State University, Columbus, United States of America
[2]Karyopharm Therapeutics, Natick, United States of America

Background. CRM1 is a nuclear export receptor involved in the active transport of numerous cargo proteins, including transcription factors, tumor suppressors and cell-cycle regulators such as p53, p21/27, and nucleophosmin (NPM1). The mislocalization of a nuclear protein in the cytoplasm can render it ineffective as a tumor suppressor. Therefore, blocking CRM1 mediated export of proteins using CRM1 inhibitors is a novel and attractive anti-neoplastic therapeutic modality. Karyopharm Therapeutics has developed small molecule Selective Inhibitors of Nuclear Export (KPT-SINEs) that specifically and irreversibly bind to CRM1 and block the function of this protein. **Aims.** To investigate the anti-leukemic activity of KPT-185 and KPT-276 in AML cell lines and patient samples and to establish in-vivo efficacy using a murine xenograft AML model. **Methods.** Cell proliferation (MTS assay), apoptosis (Annexin V), cell-cycle (PI) and differentiation (FACS and Morphology) were assessed in AML cell lines and primary samples after KPT administration. To investigate the in-vivo anti-leukemic activity of the KPT-SINEs, we use an established xenograft mouse model of AML, where human MV4;11 leukemic cells were injected into NOD/SCID/IL-2Rgamma deficient mice. **Results.** KPT-185 displays potent anti-proliferative properties in AML cell lines (MV4;11, Kasumi-1, OCI-AML3, THP-1, KG1a, MOLM-13) as well as in 6 primary AML samples (including CN-AML with NPM1 mutated, FLT3-ITD+, t(8;21) and inv16). The IC50 values ranged from 100nM to 500nM. KPT-185 induces cell-cycle arrest in cell lines at G1 (82.64±0.42% vs. 61.4±8.87%, p=0.008) with a concomitant decrease in the percentage of cells in S (5.34±1.07% vs. 21.51±5.08%, p=0.003) and G2/M phase (4.55±0.25% vs. 12.46±3.33%, p=0.008) at 24 hrs. Apoptosis was induced (average 50%) by KPT-185 in all cell lines and primary AML samples compared with controls (DMSO). Remarkably, granulocytic differentiation was observed in MV4;11 and Kasumi-1 cells after KPT-185 treatment as measured by CD11b (CD11b MFI, DMSO vs. KPT, 264±1.41 vs. 513±16.97, p=0.002 and 617.66±40.77 vs. 2084.5±396.68, p=0.003, respectively) and morphology. Treatment with KPT-185 in AML cell lines results in significant nuclear accumulation of CRM1 cargo proteins such as p53 and NPM1. Interestingly, we also found strong downregulation of FLT3 and c-KIT protein expression, while CEBPA protein and mRNA expression were up-regulated. Due to the critical role of CEBPA in myeloid differentiation and our findings that KPT-185 induces blast differentiation, we further investigated the mechanisms by which KPT-185 up-regulates CEBPA. We found that CEBPA upregulation is mediated through p53, since blocking p53 using siRNA in MV4;11 and OCI-AML3 abrogates CEBPA upregulation induced by KPT-185. Finally, using our xenograft tumor mouse model, we show that in vivo treatment of mice with oral KPT-276 (ana-

log of KPT-185 for in vivo studies) significantly prolongs survival of leukemic mice (median survival, vehicle vs. drug treated, 27 vs. 39.5 days, p=0.0002, log-rank test, n=12 per group). **Conclusions.** KPT-SINE CRM1 inhibitors are highly potent in AML and prolong survival in a mouse model of AML. Mechanistically, we show that blast differentiation after KPT-SINE treatment is mediated through P53-CEBPA and identified FLT3 as a novel pharmacodynamic endpoint for testing in Phase 1 clinical trials.

1066

SYNERGISTIC COMBINATION OF MLN4924, AN INVESTIGATIONAL SMALL MOLECULE INHIBITOR OF NEDD8-ACTIVATING ENZYME (NAE), WITH AZACITIDINE, A HYPOMETHYLATING AGENT, IN PRE-CLINICAL AML CANCER MODELS

T Traore, M Milhollen, S Grossman, M Thomas, U Narayanan, J Garnsey
Millennium Pharmaceutical INC, Cambridge, United States of America

Background. MLN4924 is an investigational small molecule inhibitor of NEDD8-activating enzyme (NAE). NAE regulates cullin-dependent ubiquitin E3 ligases (CDLs) which target a subset of cellular proteins for ubiquitination and degradation by the proteasome. MLN4924 treatment of cultured cells causes accumulation of these proteins and can cause DNA re-replication, DNA damage and apoptosis. MLN4924 has shown some limited signs of clinical activity in a Phase I trial of acute myelogenous leukemia (AML). **Aims.** To evaluate the effects of MLN4924 on cell cycle and viability in a variety of AML cell lines, as a single agent and in combination with other drugs, and to further characterize a synergistic combination in xenograft models of AML grown in immunocompromised mice. **Methods.** HL60, OCI-M2, THP-1 and NB4 cells were treated with MLN4924 in vitro. Cell cycle distribution was measured by flow cytometry. Apoptosis was measured by Western blot for cleaved caspase-3 and flow cytometry for annexin V. A high-throughput combination screen was performed with the Cell Titer Glo® viability assay in a 384 well format using AML cell lines treated with MLN4924 and approximately 40 compounds covering a wide variety of mechanisms of action. Synergy was determined by combination index. For in vivo combination studies, HL60, THP-1 and OCI-M2 xenograft-bearing mice were dosed subcutaneously with MLN4924 and azacitidine as single agents or in combination on Days 1, 4, 8, 11, 15 and 18.Results. In vitro characterization of AML cell lines revealed that all 4 lines were sensitive to MLN4924 with EC50 <500 nM, but there were two distinct cell cycle phenotypes following MLN4924 treatment. OCIM2 and THP1 demonstrated moderate S-phase accumulation with greater than 4N DNA content, consistent with DNA re-replication. In contrast, HL60 and NB4 demonstrated rapid accumulation of subG1 cells without S-phase accumulation or DNA re-replication, suggesting faster progression to apoptosis. The combination screen identified 2 hypomethylating agents (azacitidine and decitabine) as synergistic with MLN4924 in multiple AML cell lines. The combinations significantly increased apoptotic cell death compared to single agent alone. In vivo studies in the HL-60 xenograft model demonstrated marginal single-agent activity of MLN4924 and azacitidine, whereas co-dosing of MLN4924 and azacitidine led to complete and sustained tumor regressions in a subcutaneous xenograft model and significantly prolonged survival in a disseminated model. In the THP-1 xenograft model, single agent azacitidine showed limited anti-tumor activity whereas MLN4924 inhibited tumor growth, but only co-administration of both MLN4924 and azacitidine led to tumor regressions. Additionally, the combination treatment group showed a statistically significant delay in tumor regrowth after the end of the treatment period compared to the MLN4924 group. In the OCI-M2 xenograft model, MLN4924 and azacitidine as single agents significantly inhibited tumor growth, while the combination produced complete tumor regressions. The mechanism of in vivo synergy is currently under evaluation; initial studies have shown a dramatic elevation in cleaved-caspase 3 in the tumors treated with the combination as compared to the single agent. Thus MLN4924 and azacitidine can combine to produce synergistic antitumor activity in pre-clinical models of AML.

1067

PONATINIB AS TARGETED THERAPY FOR THE 8P11 MYELOPROLIFERATIVE SYNDROME

A Chase, C Bryant, J Score, N Cross
Wessex Regional Genetics Laboratory and University of Southampton, Salisbury, United Kingdom

The 8p11 myeloproliferative syndrome (EMS) is a rare, poor prognosis stem cell disorder that typically presents as an MPN with eosinophila and T- or B-cell lymphoma. EMS is characterised by chromosome rearrangements involving 8p11-12 that fuse several different partner genes to *FGFR1*, resulting in constitutively active tyrosine kinase fusion proteins. Although a number of FGFR1 inhibitors have shown in vitro activity against these disorders, none are in use clinically and there is a need to assess additional compounds as potential agents for the treatment of EMS patients. Ponatinib (AP24534) is a small molecule tyrosine kinase inhibitor with activity against ABL, SRC, FGFR, VEGFR and PDGFR family kinases currently in trials for chronic myeloid leukemia patients with resistance to currently available TKIs. We have examined its activity in in-vitro assays using cell line models and primary patient material from patients with *FGFR1* translocations. Activity was assessed in the KG1A cell line, which carries an *FGFR1OP2-FGFR1* fusion gene, and Ba/F3 cells transformed to IL3 independence by *BCR-FGFR1* (Ba/F3-BF) or *ZNF198-FGFR1* (Ba/F3-ZF). Non-transformed Ba/F3 cells and HL60 were used as negative controls. Cells were grown in a range of ponatinib concentrations for two days with proliferation and survival assessed by MTS assay. Ba/F3-BF, Ba/F3-ZF and KG1A showed reduced proliferation and survival (IC_{50} = 22 nM, 29 nM and 55 nM respectively) compared with untransformed Ba/F3 cells and HL60 (IC_{50} =8,690 nM and 585 nM respectively). Western blotting showed a dose-dependent reduction in phosphorylation of the FGFR1 fusion protein, STAT5 and ERK. Primary cells from patients with *FGFR1* fusion genes and from healthy controls were grown in methylcellulose for two weeks and colonies counted on days 7 and 14. An index of response was measured as the mean relative colony number at all inhibitor concentrations compared to untreated cultures. Median index values for patients (N=5) and controls (N=8) were 0.29 and 0.71 respectively indicating a greater reduction in colony growth in FGFR1 translocation patients compared with controls. Overall, reduced numbers of colonies were seen in patient cultures compared to controls at all ponatinib concentrations used. Fluorescence in situ hybridization on plucked colonies from one patient demonstrated a reduction in the proportion of *FGFR1* fusion gene positive colonies in ponatinib-treated versus untreated cultures. In summary we have shown that ponatinib has in-vitro activity against cells with *FGFR1* fusion genes and therefore shows promise for the treatment of patients with EMS.

AKT INHIBITION - A NOVEL THERAPEUTIC AGENT IN REFRACTORY LANGERHANS CELL HISTIOCYTOSIS

D Lee[1], P Walker[1], A Grigg[2], A Spencer[1]
[1]Alfred Hospital, Melbourne, Australia
[2]Austin Health, Melbourne, Australia

Background. Langerhans cell histiocytosis (LCH) is a rare clonal disorder of Langerhans cells with a broad disease spectrum. Trialled therapies include steroids, chemotherapy, radiotherapy and stem cell transplantation, but for patients with disease refractory to these modalities there are few options available.AKT (a serine/threonine) is a protein kinase involved in oncogenesis with key roles in cellular survival and proliferation. AKT inhibition is a novel therapeutic approach under evaluation in a variety of haematological malignancies. We present the case of an adult with heavily pretreated, refractory mediastinal and pulmonary LCH who achieved a sustained response after treatment with an oral AKT-inhibitor (GSK2110183) as part of a phase I, open-label study.**Case.** A 44 year old woman presented with cough, weight loss and sweats. CT & whole-body PET imaging revealed a large pulmonary and hilar mass accompanied by extensive mediastinal lymphadenopathy. Tissue biopsy confirmed LCH. Six cycles of conventional therapy consisting of 2-chlorodeoxyadenosine (0.14mg/kg/day for 5 days) and subsequent adjuvant local radiotherapy resulted in a partial response based on PET criteria. Within 12 months there was disease progression with additional mediastinal lymphadenopathy and pulmonary involvement confirmed by rebiopsy. Treatment with multi-agent conventional chemotherapy ("Third International Study for Langerhans Cell Histiocytosis protocol") for 6 months resulted in a partial PET response, but within 6 months, disease progression was evident with dysphagia secondary to external compression of the gastro-oesophageal junction. At this stage GSK2110183 was commenced (150mg daily, in 21-day cycles) with a rapid resolution of her dysphagia and cough after 2 cycles. CT and PET demonstrated reduction in size and activity of known lesions. No significant adverse events were experienced. She has now completed 25 cycles of therapy and remains asymptomatic with a sustained near complete response. **Results & Discussion.** Mutation analysis of the patient's cervical lymph node and mediastinal mass biopsy was performed by PCR using Sequenons OncoCarta™ Assay Panel v1.0. Dysregulation of the BRAF pathway has been suggested as a mechanism in the pathogenesis of LCH. The most common mutation, BRAF600VE causes constitutive activation of the BRAF protein and hence increased expression of its downstream molecules, pMEK and pERK. No mutations were found (including BRAF and AKT1, AKT2) in our patient's biopsy specimens. Immunohistochemistry revealed over-expression of phospho-AKT and moderate expression of pMEK, pERK and SK6. Cyclin D1, p53 and NFKB (all downstream molecules of AKT)

expression was low.Low expression of pMERK and pERK combined with absent BRAF mutations suggest the pathogenesis of LCH is due to an alternative pathway. Given the over-expression of phospho-AKT in out patient's sample and the response to AKT inhibition, we propose the AKT pathway is involved in the pathogenesis of LCH. **Conclusions.** The dramatic and sustained response to AKT inhibition in this case of refractory LCH provides a rationale for the re-evaluation of the pathogenesis of LCH and the mechanisms underlying the response.No conflicts of interest to disclose.

SINGLE UK CENTRE EXPERIENCE OF BRENTUXIMAB VEDOTIN MONOTHERAPY IN REFRACTORY CD30+ LYMPHOMAS

A Gibb, C Jones, A Bloor, S Kulkarni, K Linton, T Illidge, J Radford
The Christie NHS Foundation Trust, Manchester, United Kingdom

Background. The CD30-targeted agent brentuximab vedotin (BV) has shown impressive activity in relapsed/refractory Hodgkin lymphoma (HL) and Anaplastic Large Cell Lymphoma (ALCL) in two pivotal phase 2 studies. We present our single centre experience of BV in a population of patients with relapsed/refractory CD30+ lymphomas treated on a Named Patient Programme. **Aims**To describe objective response rates, adverse events, subsequent allotransplant rate, progression-free and overall survival. **Methods.** 24 patients with HL, ALCL or CD30+ T cell lymphoma refractory to at least 2 lines of chemotherapy or autotransplant, and fit for systemic therapy, were enrolled December 2010 - August 2011. BV was administered at a dose of 1.8mg/kg once every 3 weeks. Response was assessed by FDG-PET/CT using IWG criteria after cycles 4 and 8 (PET4, PET8) and additionally as clinically indicated. Eligibility for allotransplant was assessed per institutional guidelines (including age ≤65). Toxicity was graded by CTCAE v3.0.

Table 1. Results of the brentuximab vedotin NPP.

Median age (range)	41.5 (21,78) years
Female	13
Histology	18 HL, 5 ALCL, 1 CD30+ TCL
Median number of prior regimens (range)	3 (2,8)
Prior auto-HSCT	8/24 (33%)
Previous radiotherapy	10/24 (42%)
No response to most recent treatment	17/24 (71%)
Number eligible for allo-HSCT at baseline	22/24 (92%)
IWG Response after 4 cycles BV	ORR 67% (6 CR (25%), 10 PR (42%)). 4 PD
Best response to BV	6 CR, 10 PR
Median number of cycles of BV (range)	5.5 (1,13)
Disease status at end of BV	5 CR, 1 PR, 17 PD
Median PFS	156 days
Median OS	Not reached
Median Follow Up (from C1d1)	363 days
CTC AE > Grade 2 during BV treatment	9/24 (38%)
Proceeded to allo-HSCT	5/22 (23%) 3 CR (2 ALCL,1HL), 1 PR (HL), 1 PD*(HL)
Type of allo-HSCT	5 RIC (1 Sibling, 4 MUD)
Disease status after allo-HSCT	3 CR, 1 awaits assessment, 1 deceased
CTC AE > Grade 2 post allo-HSCT (inc. GvHD)	2 (Fatal CMV reactivation, colitis)

Results. Best responses were seen at PET4 with 6 CR, 10 PR and 4 PD at this time (Table). 4 patients experienced clinical progression or death before PET4. One PR patient discontinued therapy for personal reasons and has been excluded from PFS analysis.Most toxicity was mild to moderate: 9 patients experienced grade 3/4 events including sub-acute bowel obstruction (n=1), neuropathy (n=3) and sepsis (n=5, three of which fatal, including a case of EBV reactivation). 3 patients with neurotoxicity and 1 with neutropaenic sepsis at the time of CR were dose-reduced to 1.2mg/kg.At a median follow-up of 363 days, 16/24 patients are alive (67%) and median PFS in 23 patients is 156 days. 5/22 (23%) eligible patients (HL 3, ALCL 2) have undergone allotransplant and a further 2 await this procedure (HL 1, ALCL 1). One patient* in PD with a single new lymph node site following BV proceeded to allotransplant but subsequently died of CMV reactivation; all other patients were in CR (n=3) or PR (n=1) at allo-transplant. 12 patients potentially eligible for allotransplant at baseline did not proceed due to PD at PET4 (n=2) or PET8 (n=10). So far in early post-transplant follow-up, one patient converted from PR to CR and 1 patient has had treatment for severe colitis. There have been no other unexpected toxicity events. **Summary and Conclusions.**BV was well tolerated and effective in a population of heavily pretreated patients including a majority refractory to their most recent therapy. Response and survival rates were comparable to phase 2 data and 23% of our cohort (5/22 eligible on an intention-to-treat basis) proceeded to allogeneic transplantation following BV. The best response was observed at PET4 in all patients.For those deemed eligible for allotransplant, our data suggest that BV is an effective induction regimen in approximately 25% of patients with CD30+ lymphomas refractory to conventional salvage chemotherapy. Our observation that best response occurred at PET4 also supports the view that consideration of allogeneic transplantation should be made early in therapy and, if appropriate scheduled following the first assessment indicating response.

1070

RUXOLITINIB AS POTENTIAL TARGETED THERAPY FOR MYELOPROLIFERATIVE NEOPLASMS WITH JAK2 FUSION PROTEINS

A Chase[1], C Bryant[1], J Score[1], C Haferlach[2], J Schwaab[3], WK Hofmann[3], A Reiter[3], N Cross[1]
[1]Wessex Regional Genetics Laboratory and University of Southampton, Salisbury, United Kingdom
[2]MLL Münchner Leukämielabor GmbH, München, Germany
[3]Universitätsmedizin Mannheim, Mannheim, Germany

Chromosome translocations that target JAK2 are rare but recurrent abnormalities observed in myeloproliferative neoplasms (MPN), acute leukemia and lymphoma. Three fusion variants, *PCM1-JAK2*, *BCR-JAK2* and *ETV6-JAK2* have been described in MPN that give rise to constitutively active fusion proteins that are believed to drive the disease process in a manner analogous to *BCR-ABL* in chronic myeloid leukaemia. To date, however, no compound with activity against JAK2 has been investigated for this indication or approved for clinical use. Ruxolitinib (also known as INC424; Novartis/Incyte) is an orally available JAK1/2 inhibitor which has been approved by the US FDA for the treatment of intermediate or high-risk myelofibrosis and is being investigated for the treatment of other MPN. We have examined the activity of ruxolitinib against *JAK2* fusions using in vitro assays, cell line models and primary material from patients with *JAK2* rearrangements. Response was assessed in Ba/F3 cells transformed to IL3 independence by ectopic expression of *ETV6-JAK*. KG1A and Ba/F3 cells transformed by *BCR-ABL*, *ZNF198-FGFR1* or *SPTBN1-FLT3* were used as negative controls. Cell lines were grown in a range of ruxolitinib concentrations for two days and then assessed for proliferation and survival by MTS assay. *ETV6-JAK2* cell lines showed reduced proliferation and survival (mean IC_{50} = 697 nM) compared with all negative control cell lines (IC_{50} not reached at 10 μM for all). Western blotting demonstrated a dose-dependent reduction in phosphorylation of the JAK2 fusion protein, ERK and STAT5. Colonies from cryopreserved primary cells from two patients with MPN and *JAK2* rearrangements and from healthy controls were grown in methylcellulose containing 0, 20, 100 or 500 nM ruxolitinib and colonies were counted on day 7. An index of response was measured as the mean reduction in colony number compared to untreated cultures. Median index values for controls (N=7) and patients (N=2) were 0.48 and 0.23 respectively, i.e. a clear reduction in colonies grown from MPN patients with *JAK2*-rearrangements compared with controls ($p<0.05$). Overall, reduced numbers of colonies were seen in patient cultures compared to controls at all ruxolitinib concentrations used. Colonies were plucked into fixative for fluorescence in-situ hybridisation analysis using *JAK2* split-apart probes. Both patients showed a significant reduction in the proportion of *JAK2*-rearrangement positive colonies in treated compared to untreated cultures ($p<0.05$). One patient showed complete eradication of *JAK2*-rearrangement positive colonies at 500 nM ruxolitinib. Our in vitro assays therefore demonstrate that ruxolitinib has significant activity against cells containing *JAK2* rearrangements and shows promise for the treatment of patients with *JAK2* fusion gene positive MPN

1071

INDUCTION OF CELL DEATH BY APOPTOSIS SENSITIZING SMAC MIMETICS IN PRIMARY ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

M Schirmer, M Queudeville, L Trentin, F Seyfried, SM Eckhoff, LH Meyer, KM Debatin
University Medical Center Ulm, Ulm, Germany

Acute lymphoblastic leukemia (ALL) is the most frequent malignant disease in childhood and adolescence. Although intensification of multiagent chemotherapy regimens have led to improvement of remission induction and long-term survival, patients with high risk ALL or relapse do not respond well to current treatments and still have a poor prognosis. Because this failure is, in part, due to defects in apoptosis programs, new strategies are required that counter apoptosis resistance in order to sensitize for cell death and improve prognosis. Since "Inhibitor of Apoptosis"(IAP) proteins are expressed at high levels in acute leukemia and block apoptosis at a central point of the apoptosis machin-

ery, they present a suitable molecular target for therapeutic intervention.We previously showed that the principle to neutralize IAP proteins by small molecule IAP inhibitors is an effective approach to sensitize childhood acute leukemia cells for death receptor- or chemotherapy-induced apoptosis. In this study we further extended our analyses and investigated the effect and mechanisms of new small molecules mimicking the IAP inhibiting molecule SMAC (second mitochondria derived activator of caspases), so called SMAC mimetics, on ALL cell lines and a panel of primary (patient or patient derived xenograft ALL).First, we used ALL cell lines and observed apoptosis induction upon SMAC mimetic treatment in a majority of cell lines at nanomolar concentrations. Interestingly, SMAC mimetic induced apoptosis by was dependent on a TNF-alpha feed forward loop in sensitive cell lines indicated by inhibited apoptosis induction by soluble TNF-alpha receptor (Etanercept).Moreover, the small molecule SMAC mimetic was tested on a variety of 30 primary ALL samples either directly obtained from patients at diagnosis (n=3) or isolated from ALL bearing mice of established patient derived NOD/SCID/huALL xenograft leukemia samples (n=27). Treatment with the SMAC mimetic at nanomolar concentrations showed a clear induction of cell death in the vast majority of primary ALL samples tested. In most of these SMAC mimetic induced cases cell death was inhibited by the soluble TNF-alpha receptor Etanercept indicating TNF-alpha dependency also in primary ALL.Intact apoptosome formation, a key downstream apoptogenic event, was functionally analyzed assessing mitochondrial cytochrome c release and activation of the effector caspase-3 in a subset of primary xenograft samples (Cytochrome c-related caspase-3 activation, CRAC). Interestingly, upon treatment with small molecule SMAC mimetics induction of cell death was also observed in primary xenograft ALL samples showing constitutive deficient apoptosome function. Furthermore, we previously described that rapid engraftment of ALL cells transplanted onto NOD/SCID mice analyzed as weeks from transplantation to onset of leukemia related morbidity in the recipients (short Time To Leukemia, TTL^{short}) is indicative for early patient relapse. Importantly, primary xenograft ALL samples with a TTL^{short}/early relapse phenotype showed increased cell death upon treatment with SMAC mimetic small molecules.Thus, induction of apoptosis by the new generation of small molecule SMAC mimetics provides a promising novel strategy for targeted therapy of high risk acute lymphoblastic leukemia.

1072

EFFECTS OF PONATINIB ON GROWTH AND SURVIVAL OF OF NEOPLASTIC HUMAN MAST CELLS

K Gleixner[1], K Blatt[1], B Peter[2], V Suppan[1], E Hadzijusufovic[1], P Valent[1]
[1]Medical university of Vienna, Vienna, Austria
[2]Ludwig Boltzmann Cluster Oncology, Vienna, Austria

Background. In patients with advanced systemic mastocytosis (SM) including aggressive SM (ASM) and mast cell leukemia (MCL), neoplastic cells usually harbor the D816V-mutated variant of KIT, that mediates resistance against several tyrosine kinase inhibitors (TKI). The response to conventional or targeted therapy in advanced SM is poor and the prognosis is grave. Recently, novel TKI, such as midostaurin (PKC412), have been described to block KIT D816V and to inhibit the proliferation of neoplastic MC. However, in clinical trials, midostaurin failed to induce long-lasting complete remissions in most patients with ASM or MCL. A possible reason for non-response/relapse may be the activation of KIT D816V-independent oncogenic pathways contributing to abnormal survival of neoplastic MC. Therefore, combinations of TKI covering a large spectrum of targets may represent an interesting approach in advanced SM. Ponatinib is a novel multikinase-inhibitor applied in TKI-resistant CML. **Aims.** We explored the effects of ponatinib as single agent or in combination with midostaurin on neoplastic MC. **Methods.** Primary neoplastic mast cells and the MCL cell line HMC-1 were used. Effects on kinase phosphorylation were evaluated by Western blotting. Cell proliferation was measured by ^{3}H-thymidine uptake. Apoptosis was determined by light microscopy, flow cytometry and by a TUNEL assay. **Results** Ponatinib was found to inhibit the phosphorylation of a number of pro-oncogenic molecules in HMC-1 cells, including KIT D816V, Lyn, and STAT5. In addition, ponatinib induced growth inhibition and apoptosis in HMC-1.1 cells (KIT G560V+) and HMC-1.2 cells (KIT G560V+ and D816V+). These effects were dose-dependent, with 100-fold higher IC_{50}-values in HMC-1 cells harbouring KIT D816V compared to cells lacking KIT D816V. Furthermore, ponatinib was found to inhibit the proliferation of primary neoplastic MC isolated from patients with indolent SM (ISM, n=4), ASM (n=2), and MCL (n=1), with IC_{50}-values ranging between 50 nM and 500 nM. Growth inhibition was accompanied by induction of apoptosis as assessed by light microscopy, flow cytometry, and TUNEL assay. Finally, we were able to demonstrate that ponatinib synergizes with midostaurin in producing growth-arrest and apoptosis in HMC-1.1 cells, HMC-1.2 cells, and in primary neoplastic MC isolated from a patient suffering from MCL. Synergistic TKI effects obtained with suboptimal concentrations of single agents were accompanied by complete blockage of important signaling molecules including KIT, Lyn, and STAT5. **Conclusions:** Ponatinib exerts major growth-inhibitory effects on neoplastic MC. Moreover, ponatinib synergizes with midostaurin in inducing growth inhibition and apoptosis in HMC-1 cells and primary neoplastic MC. Whether this drug-combination also exerts major antineoplastic effects *in vivo* in patients with ASM and MCL remains to be determined.

1073

IMPROVED EFFICACY OF MAB 37.1, A NOVEL FC-ENGINEERED CD37 ANTIBODY, IN COMBINATION WITH CHEMOTHERAPY AND RITUXIMAB IN MODELS OF B-CELL LYMPHOMA

KH Heider, A Baum, I Schweiger, N Rodi, R Ruzicka, G Adolf, E Borges
Boehringer Ingelheim RCV, Vienna, Austria

Background. MAb 37.1 is a CD37-specific antibody engineered for high-affinity binding to Fc-receptors with potent pro-apoptotic and enhanced ADCC activity against lymphoma cell lines and primary CLL cells. MAb 37.1 has substantially greater B-cell depleting activity in several *in vitro* systems than rituximab, and displays profound pharmacodynamic and anti-tumor effects in animal models. The antibody is currently in phase I clinical development for patients with B-cell malignancies. **Aims.** In clinical practice, the combination of B-cell depleting monoclonal antibodies (e.g. the CD20 mAb rituximab) with chemotherapy (e.g. CHOP, ICE) results in substantial benefit for patients with B-cell malignancies. To assess the potential of mAb 37.1 for combination with established chemotherapy regimens or rituximab, *in vitro* and *in vivo* studies were performed using the B-cell lymphoma lines Ramos and Raji. **Methods.** The effect of a combination of mAb 37.1 with CHOP or ICE was assessed in a nude mouse model with established Ramos tumors. MAb 37.1 was administered twice weekly at suboptimal doses (1 mg/kg). For CHOP chemotherapy a mixture of cyclophosphamide, doxorubicin and vincristine was injected i.v. once weekly, prednisolone was administered p.o. 5-times weekly. For ICE chemotherapy, a mixture of ifosfamide, carboplatin and etoposide was injected i.p. three times weekly on consecutive days. The pro-apoptotic effect of a combination of mAb 37.1 with chlorambucil and bendamustine was assessed *in vitro* on Ramos and Raji cells. Cells were incubated for 24 hours with different concentrations of chlorambucil (0 µM to 300 µM), bendamustine (100 µM to 400 µM), mAb 37.1 (10 µg/ml), or a combination thereof. Apoptosis was determined by FACS analysis of AnnV/PI positive cells. The combination of mAb 37.1 and rituximab was tested on Ramos cells. One antibody at a fixed concentration (mAb 37.1: 10 µg/ml; rituximab: 30 µg/ml) was combined with the other antibody titrated in a concentration range from 0.1 ng/ml to 10 µg/ml. **Results** In two independent experiments, mAb therapy as well as chemotherapy resulted in significant lymphoma growth delay *in vivo* (TGI mAb 37.1: 63%, CHOP: 74%; mAb 37.1: 70%, ICE: 65 %). The combination of mAb 37.1 and chemotherapy resulted in slower tumor growth (TGI mAb 37.1 + CHOP: 86%; mAb 37.1 + ICE 84%) indicating superior antitumor efficacy of the combination treatment. Treatment of Ramos or Raji cells with mAb 37.1, chlorambucil, or bendamustine *in vitro* resulted in induction of apoptosis. Combination of mAb 37.1 with chlorambucil or bendamustine resulted in a significant increase of apoptotic cells compared with single agent treatment, indicating a synergistic effect. Likewise, apoptosis induction by the combination of mAb 37.1 with rituximab exceeded that of single agent treatment, indicating an additive pro-apoptotic effect. **Conclusions.** Combination of the novel, Fc-engineered CD37 antibody mAb 37.1 with chemotherapy or rituximab resulted in improved efficacy against lymphoma cells *in vitro* as well as in a xenograft model of human lymphoma in mice. These data support further clinical evaluation of mAb 37.1 in combination with established treatment regimens in patients with B-cell malignancies.

1074

GAS1 AND KIF27 GENES ARE STRONGLY UP-REGULATED BIOMARKERS OF HEDGEHOG INHIBITION (PF-04449913) ON LEUKEMIA STEM CELLS IN PHASE I ACUTE MYELOID LEUKEMIA AND CHRONIC MYELOID LEUKEMIA TREATED PATIENTS

Hedgehog (Hh) pathway activation contributes to leukemia development and growth, and that targeted pathway inhibition is likely to offer an efficient therapeutic opportunity. PF-04449913, a Hh pathway inhibitor, is a new selective and potent inhibitor of leukemia self-renewal and is currently being evaluated in phase I clinical trials. In order to identify new potential clinical biomarkers for the PF-04449913, we studied CD34+ leukemia stem cell population (LSC) collected before and after 28 days treatment in a phase I dose escalation protocol (Clinical Trial Gov. NTC00953758) enrolling selected hematological malignancies. This experimental clinical trial enrolled Myelofibrosis (MF), MDS, blastic phases CML, chronic myelomonocytic leukemia (CMML) and AML patients (pts). We were able to collect and separate highly purified (98%) bone marrow CD34+ cells from 5 AML, 1 MF and 2 CML pts by immunomagnetic separation, and analysed them for gene expression profile using Affimetrix HG-U133 Plus 2.0 platform. 1197 genes were differentially expressed between CD34+ cells collected before and after 28 days of PF-04449913 dose finding oral therapy. Clustering of their expression profiles showed that mostly genes differentially expressed are mainly related to Hh signaling,this providing further evidences that PF-04449913 really therapeutically targets the Hh pathway. Regarding genes involved in Hh signaling pathway, Gas1 and Kif27 were strongly upregulated (fold change 1.0947 and 1.12757 respectively; p-value 0.01 and 0.02 respectively) in CD34+ LSC after 28 days exposure to PF-04449913 as compared to baseline, suggesting these two genes have potential as new biomarkers of activity. GAS-1 is a Sonic Hedgehog (Shh)-binding protein; it acts to sequester Shh and inhibit the Shh signalling pathway. Kif27 mainly acts as a negative regulator in the Hh signaling pathway, and inhibits the transcriptional activator activity of Gli1 by inhibiting its nuclear translocation. Other genes were differentially expressed after 'ex- vivo' treatment with PF-04449913 as compared to baseline: we observed a down regulation of Bcl2 (fold change -1.03004), ABCA2 (fold change -1.08966), LEF1 (fold change -1.28457), Gli1 (fold change -1.0775), Smo (fold change -1.07702), and an upregulation of Gli2 (fold change 1.08191). Conclusions: This data demonstrates that PF-04449913 specifically targets the Hh Pathway in CD34+ cells, suggesting that Hh inhibition may impair leukemia stem cell maintenance. In addition, we identify several new potential biomarkers (e.g. Gas1 and KIF27). Taken together, these data may be useful for pts selection strategies and subsequent eradication of the LSC. Multiple myeloma (MM), one of the most common hematological malignancies in adults, is a neoplasm of terminally differentiated B cells, i.e. plasma cells. The transition of a plasma cell to a fully transformed, aggressive myeloma is a multistep process, which requires subsequent acquisition of mutations in multiple genes. Most of this evolution takes place in the bone marrow (BM). Studying the pathogenesis of MM is seriously hampered by the lack of appropriate conditions for the engraftment of patient-derived MM (pMM) cells which, unlike MM cell lines, strongly depend on a human microenvironment to engraft, survive and expand. This indicates that the interaction of MM cells with the cellular and extracellular components of the human BM microenvironment plays a crucial role in the growth behavior of MM cells.Previously, we presented a unique mouse model to study the pathobiology of MM by implementing a technology for creating a natural human bone environment in the immune deficient $RAG2^{-/-}gc^{-/-}$ mouse. This humanized environment was found to act as a 3-D hematopoietic "niche"and to facilitate pMM cell growth, which was accompanied by bone resorption, being one of the most important clinical sequelae of MM. By gene-marking of pMM cells with luciferase and using bioluminescent imaging, we were able to follow myeloma outgrowth in time, and to visualize the effect of treatment. Using this novel model, we now have evaluated treatment responses of mice inoculated with pMM cells, by applying similar treatment as the MM patients received. Interestingly, the pMM-bearing mice showed identical responses as patients to the various treatments given. Indeed, mice receiving cells from heavily treated and refractory patients did not respond to treatment, while mice receiving cells from newly diagnosed patients did respond. In addition, pMM-bearing mice were used to further investigate the killing of MM cells by daratumumab (DARA).DARA is a human CD38 antibody with broad-spectrum killing activity. DARA effectively kills target cellsby CDC, ADCC and by induction of apoptosis, which is considered to be highlyrelevant for the treatment of hematological malignancies,including MM and chronic lymphocytic leukemia. Our data show that DARA was well able to kill MM cells from newly diagnosed patients in this model. More important, DARA was also effective on cells growing in the humanized ossicles and that were obtained from patients that were refractory to dexamethasone and bortezomib. Hence, our novel humanized mouse model can be utilized for preclinical testing, accurately visualizing treatment responses and resistance to therapy, and it confirms that DARA is an effective new treatment option for multiple myeloma patients.

PRECLINICAL ACTIVITY OF THE JAK1/2 INHIBITOR RUXOLITINIB ON MALIGNANT PLASMA CELL GROWTH AND SURVIVAL

R Burger, T Bugdahn, M Staudinger, M Peipp, A Günther, M Gramatzki
Division of Stem Cell Transplantation and Immunotherapy, Kiel, Germany

Background. In multiple myeloma, cytokines in the tumor environment, in particular interleukin-6 (IL-6), support the growth and survival of malignant plasma cells. Binding of IL-6 to its receptor leads to gp130 dimerization and activation of Janus kinases (JAK) and STAT3 transcription factors. Ruxolitinib (INCB018424/INC424) is the first small molecule JAK inhibitor approved for the treatment of patients with myelofibrosis.**Aims.** The aim of our study was to evaluate the effects of ruxolitinib on malignant plasma cells. **Methods.** Cell growth was studied in seven human plasma cell lines including the IL-6 dependent INA-6. The JAK inhibitor was tested in a concentration range of 0.0625 µmol/L to 8 µmol/L. Proliferation of plasma cell enriched patient samples was measured by [3]H-thymidine uptake. IC50 concentrations and combination index were calculated with CalcuSyn. Apoptosis was evaluated by flow cytometry upon annexin(Ax)V-FITC/7-AAD staining. Levels of STAT3 and ERK1/2 phosphorylation were determined by Westernblot analysis. IL-6 levels were determined by ELISA.**Results.** Ruxolitinib induced a significant and dose-dependent inhibition of plasma cell growth in IL-6 dependent INA-6 cells with an IC50 of 0.22 µmol/L. Complete growth inhibition was achieved at 1 µmol/L in the absence and presence of bone marrow stromal cells. Importantly, stromal cell viability and IL-6 production were not affected. Treatment of INA-6

cells with 1 µmol/L ruxolitinib increased the number of apoptotic, AxV-positive cells from approx. 10% in cultures with medium alone to 39% and 63% after 48 and 72 hours, respectively. The induction of cell death is consistent with the inhibition of IL-6 induced STAT3 phosphorylation. A similar strong inhibitory activity of ruxolitinib (IC50 0.16 µmol/L) was observed in tumor cells of a patient with plasma cell leukemia which proliferated in response to IL-6. In addition, IL-6 dependent growth of B9 hybridoma cells was equally inhibited with an IC50 of 0.6 µmol/L of the drug. In contrast, none of the myeloma cell lines that grow autonomously were sensitive, pointing to the kinase specificity of the drug. Using INA-6 as a model, combinations with other signaling inhibitors revealed additive to synergistic effects with PI3K, mToR and IGF-1R inhibitors.**Conclusions:** In multiple myeloma, ruxolitinib has a strong cytotoxic activity against malignant plasma cells that require IL-6 for growth and survival. This warrants further clinical testing but also points to the need of identifying molecular markers to predict benefit from JAK inhibitor treatment.

Introduction. There is a clear need for new effective drugs in the treatment of acute myeloid leukemia (AML). Alkylphosphocholines are promising antitumor agents, which affect multiple signal transduction networks, inducing apoptosis and cell cycle block. Erufosine (erucylphospho-N,N,N-trimethylpropylammonium, ErPC3) is without significant toxicity to normal haematopoietic progenitors, therefore being very promising in leukemia treatment. The exact mechanisms underlying the antitumor activity of ErPC3 have not been completely elucidated. **Aims.** To evaluate the antileukemic potential of ErPC3 in AML cell lines and to estimate the impact on the expression of miRNAs. **Methods.** In vitro experiments were performed using AML cell lines: EOL-1 (ACC 386), Nomo-1 (ACC 542) and U-937 (ACC 5) [DSMZ]. For each cell line the cytotoxicity of ErPC3 was measured by the colorimetric MTT-assay and IC_{50} values after 24-48-72h incubation were calculated. In addition, a bead-based liquid assay for single-tube detection of 50 pre-selected on the basis of a known relation to AML miRNAs was conducted with total RNAs extracted from the studied cell lines before and after 48h incubation with erufosine at IC_{50} concentrations [Flexmir v.2, Luminex Corp.]. All samples were run in duplicates. The mean expression value for each microRNA in each sample was background. corrected and normalized to the untreated control. In addition, Western blot analysis was performed to investigate phosphorylated Akt (pAKT), JNK and Lamin B.**Results.** To assess whether ErPC3 affects the viability of AML cell lines, cells were treated with various doses (0,39-100 µM) for 24, 48 and 72h, harvested, and analyzed by MTT assay. Erufosine was found to have dose-dependent cytotoxicity in all studied cell lines with the lowest IC_{50} value of 2,2 µM after 72h of treatment in EOL-1, followed by Nomo-1 (IC_{50}=2,9 µM), while the relatively least sensitive cell line was U-937 (IC_{50}=4,76 µM). The multiplex analysis of the responses of miRNAs to ErPC3 treatment showed that mir-126, known for its tumor suppressor characteristics, was the only significantly up-regulated miRNA in all studied samples. On the other hand, the number of down-regulated miRNAs was related to the differences in the treatment efficacy, as the least sensitive U-937 cell line did not show any down-regulated miRNA, while the number of down-regulated miRNAs increased with the increase of chemosensitivity to ErPC3. The following six microRNAs were down-regulated in both of the remaining cell lines: mir-181a-5p, mir-17-5p, mir-92a-3p, mir-221-3p, mir-222-3p, mir-191-5p. On analyzing next the predicted targets and affected pathways of these altered miRNAs, MAPK, JNK, Akt were important molecular signaling pathways related to their expression patterns, which have also been previously shown to play central role in the mechanisms of alkylphosophocholines antitumor effects. This was confirmed by Western blot analysis showing down-regulation of pAkt, JNK alteration and lamin B fragmentation.**Conclusions:** These observations suggest that modulation of miRNA expression may be an important mechanism underlying the biological effects of erufosine and warrants further investigation of the targeted genes and signaling pathways.**Acknowledgements:** This work was supported by the National Science Fund and the Alexander von Humboldt Foundation.

BOTANICAL ALKYL HYDROQUINONE HQ17(3) INDUCES REACTIVE OXYGEN SPECIES AND EXHIBITS CYTOTOXIC EFFECT ON RS4;11 ALL CELLS HARBORING T(4;11) CHROMOSOME TRANSLOCATION

CY Hu, YW Kao, YJ Chang, SB Lin, LI Lin, DT Lin

College of Medicine, National Taiwan University, Taipei, Taiwan

Background. Acute lymphoblastic leukemia (ALL) is the most prevalent childhood cancer. Although the rate of success in the treatment of childhood ALL has been increased to more than 80 percent for children and approximately 40 percent for adults with ALL, patients succumbing very-high- risk (VHR) ALLs (those harboring t(9;22) or MLL rearrangements chromosomal abnormalities) display poor clinical outcomes even with intensive combined chemotherapies. HQ17(3) (10'(Z), 13'(E), 15'(E)-heptadecatrienyl-hydroquinone), is a natural product isolated from the sap of *Rhus succedanea*. HQ17(3) has been reported to have cytotoxic activity on tumor cell lines (cervical, colon cancers and hepatoma cells) and HL-60 myeloid leukemia cells. We found HQ17(3) exhibited very effective cytotoxic effect on four tested ALL cell lines (RS4;11, REH, SUP-B15, and JURKAT) with the IC_{50} of 0.5 to 5 µM, but spared normal peripheral blood mononuclear cells. Thus, investigation of the molecule mechanisms involved in the selective cytotoxic effects on leukemic cells will be beneficial for finding new anti-leukemic therapeutics. **Aims.** To investigate the molecular pathways involved in the HQ17(3)-induced cytotoxicity in acute lymphoblastic leukemia cells RS4;11 (VHR ALL harboring t(4;11)). **Methods.** HQ17(3)-treated and control RS4;11 cells were subjected to the following tests to study the cytotoxic effects of HQ17(3) on lymphoblastic leukemic cells. The membrane lipid disturbance in apoptotic cell death was analyzed by Annexin V/PI stain. DNA fragmentation was defined as sub-G1 fraction of cellular DNA content after the PI staining. ROS production and mitochondrial membrane potential loss were stained by DCFDA and DiOC6(3), respectively. The stained cells were subjected to flow cytometric analysis. Western blot analysis was applied to study the activation of caspases 3, 7, 9 and cleavage of poly (ADP-ribose) polymerase (PARP) after HQ17(3) treatment. **Results.** RS4;11 cells treated with HQ17(3) showed features of apoptotic cell death (Annexin V^+ and DNA fragmentation) in 24 hours. HQ17(3) induced reactive oxygen species (ROS) production and disrupted the mitochondrial membrane potential. Activated caspase-3, and cleaved PARP were confirmed. Pan-caspase inhibitor, zVAD-fmk, effectively inhibited HQ17(3)-induced caspase-3 activation, however, could not rescue cells from death. Thus, HQ17(3) induced caspase-independent cell death of RS4;11 cells. Addition of antioxidants or ROS scavengers (GSH or vitamin C) attenuated HQ17(3)-induced ROS production, mitochondrial membrane potential lost, and cell death. These results indicate that oxidative stress associated with ROS production be the major mechanisms implicated in HQ17(3)-induced RS4;11 cell death.**Summary/conclusion:** Naturally-derived HQ17(3) displayed significant anti-leukemic activity in RS4;11 ALL cells by inducing ROS production and apoptotic cell death. It is interesting to further investigate molecules implicated in HQ17(3)-induced, caspase-independent DNA fragmentation and cell death. These results further indicated that agents selectively induce or sustain ROS in leukemic cells would potentially augment the treatment for VHR ALL with t(4;11) translocation.

1079

FOCUS ON INTRACELLULAR SIGNALING - NEW TARGETED THERAPEUTIC APPROACHES IN DIFFUSE LARGE B-CELLS LYMPHOMA

J Mendes, A Ribeiro, A Gonçalves, R Alves, V Alves, A Sarmento-Ribeiro

Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Diffuse large B-cell lymphoma (DLBCL) is a common type of non-Hodgkin lymphoma, accounting for about 25-30% of all cases in the western countries. It is a clinically aggressive lymphoma in which the patients have a five-year survival rate of 50%. Several intracellular pathways are related to lymphomagenesis and of the most frequently involved are the BCR/PI3K/AKT/mTOR pathway (B-Cell-Receptor/Phosphatidylinositol-3-kinase/AKT protein kinase B/Mammalian Target of Rapamicin), NF-kB pathway (Nuclear factor kB) and RAS/MAPK pathway (MAPK, Mitogen Activated Protein Kinase, associated with the RAS-RAF proteins). RAS proteins are activated by farnesylation, a process mediated by the farnesyltranferase enzyme. On the other hand, several proteins involved in these pathways are degraded in the ubiquitin-proteasome pathway.In this context, the aim of this study is to evaluate the potential therapeutic of the mTOR inhibitor (Everolimus), the proteasome inhibitors (MG262), the IkB inhibitior (Parthenolide) and the farnesiltransferase inhibitor (L-744832) in DLBCL.For this purpose we used the a DLCL cell line, the Farage cells, cultured in the absence and presence of several concentrations of Everolimus, MG262, Parthenolide and of L-744832, in monotherapy and in association with each other and with conventional chemotherapy drugs (Vincristine, VCR). Cell growth and viability were evaluated

by the rezasurin assay. The effectiveness of the drugs was determined by dose-response curve with determination of IC_{50}. Cell death was analyzed by optical microscopy using the May-Grunwald staining and by flow cytometry, through the annexin-V and propidium iodide double staining. We also analyzed, by flow cytometry, cell cycle using Propidium Iodide incorporation and the expression levels of KI-67, Lamin A/C, Ubiquitin conjugates, NF-kB and Caspase 3.Our results show that all of the tested compounds induced cell death in a time- and dose-dependent manner, with IC_{50} values of 25 μM for Everolimus, 25 nM for MG262, less than 10 μM for Parthenolide and ranging from 50 μM to 75 μM for L-744832, after 24h of treatment. These compounds induced cell dead mainly by apoptosis, which may be mediated by caspase 3. These drugs also induce cell cycle arrest in G0/G1 phase, mainly Everolimus, which may be related with a reduction of KI-67 and Lamin A/C levels and with an increased in ubiquitin conjugates levels. The association of lower doses of these inhibitors shows an additive/synergist cytotoxic effect.In summary, this study suggests that Everolimus, MG262, Parthenolide and L-744832 alone or in combination with VCR, may constitute new promising therapeutic approach in DLCL treatment.*Frist and second authors contribute equally to the study.*

THE ANTI-KAPPA MONOCLONAL ANTIBODY MDX-1097 COOPERATES WITH IMMUNOMODULATORY DRUGS TO ENHANCE ANTIBODY-DEPENDENT CELL CYTOTOXICITY OF MULTIPLE MYELOMA CELLS

R Cuddihy[1], T Khong[1], P Asvadi[2], R Dunn[2], A Spencer[3]
[1]Monash University, Melbourne, Australia
[2]Immune System Therapeutics Ltd., Sydney, Australia
[3]The Alfred Hospital, Melbourne, Australia

Background. Multiple Myeloma (MM) is a malignancy of clonal plasma cells in the bone marrow with median overall survival duration of 3-5 years. Despite recent advances in the treatment and management of MM, which have improved progression free survival (PFS) and overall survival (OS), the majority of patients will ultimately relapse and die from their disease. The anti-kappa monoclonal antibody, MDX-1097, is one of many novel therapeutic approaches in development for the treatment of MM. MDX-1097 currently is being assessed as a single agent in a Phase 2 clinical trial for the treatment of kappa light-chain restricted (κ-type) MM. MDX-1097 binds to kappa myeloma antigen (KMA), a tumor-specific membrane-associated protein expressed on malignant plasma cells in patients with κ-type MM and exerts its anti-tumour effects via a number of mechanisms including antibody-dependent cell cytotoxicity (ADCC) in the presence of human immune effectors such as natural killer (NK) cells. Immunomodulatory drugs (IMiDs) such as lenalidomide, are currently in use for the treatment of MM and have been shown to exert anti-tumor effects both directly, via apoptotic mechanisms, and indirectly via a number of different mechanisms including the augmentation of NK-dependent cellular cytotoxicity. **Aims.**To determine whether IMiD-treated PBMCs more effectively kill MDX-1097-bound MM cells via ADCC compared to untreated PBMCs, and whether IMiD-treated MM cells are more sensitive to MDX-1097 mediated immune effector cell cytotoxicity compared to untreated MM cells. **Methods.** For ADCC assays, a FACs-based method was used. Briefly, untreated or IMiD-treated JJN3 cells (a κ-type MM cell line) were first labeled with carboxyfluorescein succinimidyl ester (CFSE) and then incubated with MDX-1097 or human IgG. These JJN3 cells were mixed with untreated or *in vitro* IMiD-treated PBMCs from normal donors, or with PBMCs from MM patients pre- and post-IMiD treatment. 12 hours later, the viability dye 7-AAD was added to the cells and analyzed by FACS. Percentage cell death was calculated as the proportion of CFSE+/7-AAD+ cells to the total number of CFSE+ cells. **Results***In vitro* pre-incubation of normal PBMCs with IMiDs prior to incubating with MDX-1097 treated JJN3 cells caused 1.5 fold more cell death, compared to untreated PBMCs. Pre-incubation of JJN3 cells with IMiDs resulted in a 2-fold increase in KMA expression (and MDX-1097 binding) and enhanced ADCC by 1.7 fold in the presence of untreated PBMCs when compared to non IMiD-treated JJN3 cells. A further modest increment in cell killing was observed when IMiD-treated PBMCs were mixed with IMiD-treated JJN3 cells. Finally, use of *in vivo* IMiD exposed PBMCs isolated from a MM patient treated with IMiD demonstrated that these PBMCs were, on average, 1.8 fold more effective in killing MDX-1097 bound JJN3 cells compared to PBMCs obtained from the same patient prior to IMiD treatment. **Summary/Conclusions**Our *in vitro* results suggest that treatment of PBMCs and MM cells with IMiDs can enhance MDX-1097-mediated ADCC of MM cells. This provides a strong rationale for the clinical evaluation of MDX-1097 in combination with IMiDs for the treatment of multiple myeloma.

1081

OCARATUZUMAB, A FAB-ENGINEERED ANTI-CD20 ANTIBODY, DEMONSTRATES GREATER AFFINITY TO CD20 AND ABILITY TO BIND TO RITUXIMAB-COATED B-CELLS

A O'Reilly, T Davis, J Wayne, S Marulappa, V Jain
Mentrik Biotech, Dallas, United States of America

Background. Ocaratzumab, previously known as AME-133v, is a humanized, Fab-engineered anti-CD20 antibody optimized for superior binding. Using single-point codon-substitutions, thousands of variations of the antibody complementary determining regions were screened. Ocaratuzumab was selected from the variants because of its improvement in K_{off} rate, which prolongs binding of the antibody. Compared to the K_d constant of rituximab, ocaratuzumab has 13- to 20-fold greater binding affinity for CD20 (Figure 1). Ocaratuzumab and rituximab bind to the same epitope, potentially allowing competition and displacement between the two antibodies.**Aims.** Experiments were performed to assess the ability of ocaratuzumab's increased affinity to improve binding to lymphoma B-cells pre-coated with rituximab. **Methods.** 50 μg/mL of biotinylated rituximab was added to fixed SKW.4 lymphoma B-cells and incubated overnight at 37°C. Ocaratuzumab was added to each plate at half the concentration of rituximab (25 μg/mL) for 3, 6, and 24 hours. The amount of rituximab still bound to the B-lymphocytes was assessed by detecting biotinylated antibody using neutraAvidin alkaline phosphatase conjugate and a colorimetric substrate (optical density was measured at 560 nm in a spectrophotometer).**Results.** Even at half the concentration of rituximab, ocaratuzumab reduced the amount of rituximab bound to the lymphoma B-cells. The reduction in pre-bound rituximab was 8.44% at 3 hours, 16.32% at 6 hours, and peaked at 31.12% at 24 hours from baseline. Additional experiments were performed, and higher concentrations of ocaratuzumab (75, 150 μg/mL) showed no additional displacement of rituximab, suggesting that low concentrations of the antibody are effective in maximally displacing rituximab bound to B-cells. Under controlled conditions, no spontaneous reduction in rituximab binding occurred, demonstrating the ability of ocaratuzumab to preferentially replace rituximab due to its faster K_{on} rate and its ability to remain bound longer due to its slower K_{off} rate. Furthermore, independent experiments have shown pre-incubation of ocaratuzumab in primary chronic lymphocytic leukemia cells can significantly inhibit the binding of rituximab. This suggests that the improved affinity of ocaratuzumab to CD20 and its low K_{off} rate prevent binding of a second antibody to these B-cells.**Conclusions:** Ocaratuzumab (AME-133v) has the ability to bind to rituximab pre-exposed B-lymphocytes even at concentrations 50% lower than that of rituximab. Combined with Fc-engineering to improve antibody dependent cellular cytotoxicity, ocaratuzumab may improve clinical benefit in rituximab pre-treated patients with B-cell neoplasia.

Table 1. Ocaratuzumab and Rituximab Binding Kinetics on Lymphoma Cells.

	Ocaratuzumab	Rituximab
K_d (pM)	97	2097
K_{on} (10^5/M/s)	7.8	4.7
K_{off} (10^{-5}/s)	7.6	98.6

1082

LASRT (LARGE-SCALE REAL-TIME TITRATION): A RECOMBINED VIRUS TITRATION METHOD SIMPLE, SAFE AND EFFICIENT FOR PRE-CLINIC GENE TRANSFER RESEARCH

QL Jiang[1], LQ Zhu[2], S Jiang[1], LZ Yuan[2], FL Chen[3], CX Yin[3], KF Shen[3], FY Meng[3]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, China
[2]Southern Medical University, Guangzhou, China
[3]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background. Titer of recombinant virus (RV) on cells is the most accurate and important index, however, classic titration method need to be improved. If RV can infect human cells, titration should be carried out in S2 lab, but method used for titering such as flow cytometry (FCM) is normally not carried in S2 condition in most labs. Exposure to the environment means either much more works to exclude any infective virus in the samples or to detect at high risks. Is it possible to simply detect the titers under S2 condition? **Aims.** To establish and evaluate a simple, safe and efficient titration method (LaSRT) for pre-clinic gene transfer research **Methods.** :(1)Virus: Lentivirus with GFP maker was produced by pWPXLd, pMD2.G, pCMVR8.74 3-vector-system (Addgene Co.) and 293T/17 cell (ATCC). Retrovirus with puromycin resistant gene was produced by pMSCVpuro vector (Clontech Co.) and Plat-E cell (Cellbiolabs Co.). 293 cells (ATCC) are used as titration target cell. Virus supernatants from 48h to 72h were used. (2) Classic titration: For lentivirus with GFP, FCM titration was used as control. 2 × 10e5 293 cells were transfected with serial dilutions of supernatant as 1mL, 100μl and 10μl (n=3). Titer (TU/mL)=(2×10e5 target cells)×(positive cells%)/volume of supernatant (mL). For pMSCVpuro retrovirus, 2-week-clone-forming method were used as control.(3) LaSRT titration (see Fig.1): ① -1d, plate 10 000 293 cells/well in a 96 well-plate, each well with 180ul IMDM, 10% FCS and 4 μg/mL Protamine sulfate (Elkins-Sinn, Inc.); ② 0d, add 20ul virus supernatant to the first well then to limited dilute at 1:10 in the following wells (n=3), ③+2d, observe GFP$^+$ cells under inverted fluorescence microscope, the positive cell numbers (M) would only be counted in the "counting well"(the last well where the M≤10, and no positive cells in the next well), the serial number (N) of the counting well is used for titer calculation.④ Titer Transfection Units (TU/mL) = M×10^{N+1}.⑤ For pMSCVpuro retrovirus, the only difference is to count survival cells in the counting well on +4d.4. Results. No significant difference was seen between the results of pWPXLd GFP-lentivirus got by FCM vs LaSRT, (5.3±1.5)×10e5vs(5.1±1.3)×10e5,P>0.05; as well as between those of pMSCVpuroR retrovirus got by CF vs LaSRT, (7.0±4.4)×10e5vs(5.8±3.7)×10e5,P>0.05. 5 Summary / ConclusionsLaSRT is a better titration method for pre-clinic gene transfer reasearch for the following reasons: ①Simple and accurate, regardless big difference of original titers of RVs; ② Safe□closed system till detection; ③Efficient and economic, large scale samples can be tested with only a drop of virus; ④Valid for different RV with a suitable maker, such as AV, AAV and LV with GFP. In near future, it can be easily developed to be automatic or semi-automatic detection as RQ-PCR and FISH.

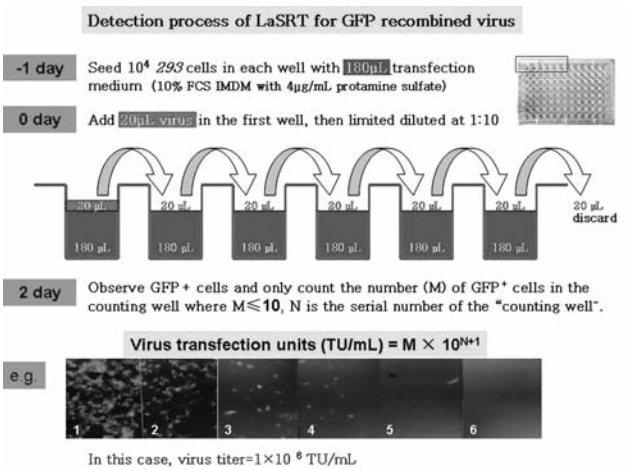

Figure 1 Detection process of LaSRT for GFP recombined virus.

Quality of life and health economics - Multiple Myeloma

THE IMPACT OF TREATMENT PERSISTENCE WITH LENALIDOMIDE FOR THE TREATMENT OF MULTIPLE MYELOMA (MM) ON DISEASE CONTROL

J Henk[1], S Kaura[2], Z Khan[2], T Burton[1], A Teitelbaum[1]
[1]OPTUMInsight, Eden Prairie, United States of America
[2]Celgene Corporation, Summit, United States of America

Background. While persistence to drug therapy is essential to achieve optimal patient benefits, poorly controlled MM results in more rapid disease progression, disease-related complications, impact on quality of life, and ultimately death.**Aims.** To evaluate the real-world persistence with lenalidomide treatment and to assess the relationship between treatment persistence and indicators of lack of disease control and disease-related complications for MM patients. **Methods.** Claims database from aUS health plan were assessed between 1 July 2007 and 30 June 2011 to identify commercial enrollees and Medicare Advantage enrollees with Part D (MAPD), initiating lenalidomide for treatment of MM. MM was identified by at least 2 medical claims at least 7 days apart with a MM diagnosis code (ICD-9: 203.0x). Eligible patients were required to have continuous pharmacy and medical benefits in the 6 months prior and 1 year following initiation of lenalidomide. Treatment discontinuation was defined as the first appearance of a gap greater than 30 days between runout date (prescription fill date + days supply) and next lenalidomide prescription fill. Persistence was defined as the number of days from the first date of treatment with lenalidomide to the earlier of the date of discontinuation or end of the 12-month follow-up period. Indicators of disease control included in this study were an inpatient hospitalization and number of ER visits. Disease-related complications included in this study was evidence of skeletal-related events (SREs) defined as fracture, spinal cord compression, or radiation to the bone; and sepsis after initiation of lenalidomide. Logistic and negative binomial regression models were used to examine the relationship between persistence and measures of disease control and complications, controlling for age, sex, comorbidity score, prior stem cell transplant, prior SREs, and insurance type (commercial or MAPD).

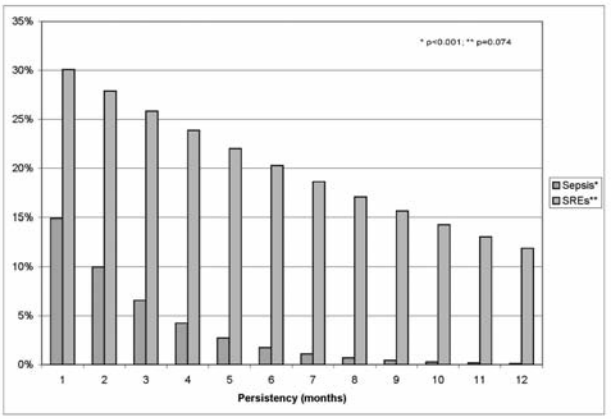

Figure 1. Predicted Risk of Sepsis and SREs as a function of lenalidomide persistence.

Results. 1,524 lenalidomide-treated MM patients were identified; 605 had at least 12 months of continuous eligibility following lenalidomide treatment initiation, 690 disenrolled from the health plan prior to 12 months, and 229 died prior to 12 months. Among the 605 patients enrolled for 12 months, persistency with lenalidomide averaged 6.0 months (median = 4.9) with 350 (57.9%) persistent for the entire year. Sixty-six (10%) of patients developed sepsis and 167 (28%) developed SREs. Controlling for the variables listed above, a one-month increase in persistence/treatment duration was found to be associated with, on average, a lower probability of developing SREs (OR=0.88; p-value=0.074) as well as sepsis (OR=0.63; p-value<0.001) [Figure 1]. Additionally, the probability of an inpatient hospitalization (OR=0.68; p-value<0.001) and additional ER visits (OR=0.83; p-value=0.002) were both lower with better persistence. **Conclusions.** Greater persistence with lenalidomide therapy is associated with improved patient outcomes as demonstrated by fewer SREs and

lower likelihood of developing sepsis, consequently leading to fewer hospitalizations and ER visits. This analysis demonstrates that continuous treatment with lenalidomide may not only improve disease control in MM patients , but in addition also reduces health care utilization and related costs as indicated by the lower risk of a hospitalization and number of ER visits.

[7]University Hospitals Bristol, Bristol, United Kingdom
[8]Ovatech Solutions, London, United Kingdom
[9]Amgen Inc., Thousand Oaks, United States of America
[10]Forschungszentrum Ruhr, Witten, Germany

Background. Skeletal-related events (SREs; pathologic fracture, radiation to bone, spinal cord compression or surgery to bone) are common in patients with bone disease related to multiple myeloma and are associated with increased patient morbidity and mortality. Limited prospective data on the related economic burden are available in the literature.**Aims**To evaluate health resource utilisation (HRU) associated with SREs in patients with bone lesions secondary to multiple myeloma. **Methods.** Patients with bone lesions secondary to multiple myeloma; at least one SRE within 97 days prior to enrollment; life expectancy ≥6 months; ECOG 0, 1 or 2 were enrolled from Germany, Italy, Spain and the UK. Data on HRU associated with SREs were collected retrospectively for 90 days prior to enrollment and prospectively for up to 18-21 months. HRU type included number and length of inpatient hospitalisations, outpatient visits, emergency room visits and procedures. Attribution of HRU to each SRE was determined by the investigators. **Results.** A total of 153 eligible European (Germany n=51; Italy n=39; Spain n=38; UK n=25) patients with MM entered the study; mean age (SD) ranged from 63.7 (9.9) to 67.9 (10.0) years. Percentage of female patients ranged from 12.0% (UK) to 56.4% (Italy), Germany and Spain reported 41.2% and 44.7%, respectively. A total of 103 of 281 SREs (36.7%) were associated with in-patient stays with a mean (SD) duration of 18.1 (19.8) days per stay for the 114 stays (a SRE could contribute multiple hospitalisations). The length of inpatient stays varied by facility (i.e., oncology, radiation, surgical) and SRE type. The most common SRE requiring hospitalisation was surgery to bone: 34 of 47 events (72.3%) with 39 in-patient stays requiring a mean (SD) length of stay of 12.7 (14.4) days. The least common SRE requiring hospitalisation, radiation to bone (15 of 107 events [14.0%]), was still associated with 13 in-patient stays with an average (SD) of 18.3 (10.2) days per stay. Overall, 179 (63.7%) SREs required at least one outpatient visit and 88 (31.3%) required >5 visits. As expected, radiation to bone was associated with the highest number of outpatient visits: of the 107 SREs, 80 (74.8%) were associated with an outpatient visit. Surgery to bone and spinal cord compression were associated with the least number of outpatient visits, with 24 (51.1%) of 47 SREs and 16 (53.3%) of 30 SREs requiring a visit, respectively. Seven (2.5%) of 281 SREs (5 pathologic fractures and 2 spinal cord compressions) were associated with an emergency room visit. **Summary/Conclusions**SREs are associated with lengthy hospitalisations and numerous outpatient visits. Thus, preventing SREs may substantially reduce the burden of HRU across European healthcare systems.

1085

THE IMPACT OF NEW TECHNOLOGIES ON MULTIPLE MYELOMA MANAGEMENT: A COST-EFFECTIVENESS ANALYSIS

A Corso, C Pascutto, S Mangiacavalli, F Cocito, A Pompa, L Pochintesta, M Cazzola
Fondazione IRCCS Policlinico san Matteo, Pavia, Italy

Background. Although the introduction of high-dose therapy and novel agents has improved the outcome of MM in terms of response, progression free and overall survival (PFS, OS), it is still not clear if this amelioration has also produced a significant improvement in cost/effectiveness. **Aim**This study aimed to evaluate the economic impact of new technologies in Multiple Myeloma frontline treatment.**Methods**Two groups of patients were compared: Group A included 78 patients receiving MP between January 1th 1986 and December 31st 1994; Group B included 73 patients receiving an autologous transplant between January 1th 1995 and December 31st 2003. Patients were considered eligible for the study when having baseline characteristics suitable for transplantation whether or not high-dose therapy was an available treatment option at time of therapy starting.**Results**The characteristics of patients at presentation were similar in the two groups. After a median follow-up of 36.7 months and 50.7 months, 3% and 24% patients were alive in group A and B respectively. The median overall survival (OS) was 3.2 years and 5.4 years respectively (p=0.0002). Analysis of costs was done by computing resource utilization: number and cause of hospital admissions split by type of admission (outpatient visit, day-hospital, long-term hospitalization), type of administered therapies, concomitant treatments particularly focusing on supportive therapies (transfusions, growth factors, antibiotics, bisphosphonates). The resource costs were computed in accordance to the current "Sistema Sanitario Regionale (SSR)"regional tariffs.A total number of 1756 hospital admissions were distributed as follows: 778 in group A and 978 in group B. Hospital admission distribution was different between the two groups (p<0.001): 407/778, 52% long-term hospitalizations in group A vs 607/978, 62% in group B; 231 (29%) outpatient visits and 140 (19%) day-hospital admissions in group A vs 243 (25%) and 128 (13%) in group B.A cost utility analysis was carried out based on quality-adjusted life years (QALY). QALYs were computed by applying utilities to follow-up periods: 0.8 during off-treatment periods, 0.58 during therapy, and 0.63 during maintenance (values based on the literature). The incremental cost-effectiveness ratio (ICER) was calculated for a single patient.In order to make the two groups comparable in terms of length of observation, cases in group A were censored when exceeding the maximum observation time in group B.Mean cost per patient was significantly different between groups 9343 € in group A vs 103948 € in group B (p<0.001). The total person-years were 336,4 and 478.2 respectively in group A and B, while the cost per person-year was 5134.4 € and 9161.9 € in group A and B respectively. The final quality adjusted life-year gain in group B patients as compared to group A was 1.79 QALY, with an ICER of 52767€.**Conclusions**Basing on the significant prolongation of OS obtained with first-line autologous transplant with respect to conventional oral therapy (2,2 years P=0,0002) in a still poor prognosis disease, and keeping into account the low prevalence of multiple myeloma, our conclusion is that the calculated ICER is within an acceptable threshold.

1086

COST EFFECTIVENESS OF CHEMOTHERAPY REGIMENS IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: A SYSTEMATIC REVIEW

S Dhanasiri[1], L Heron[2], G Medic[2], M Goodall[2]
[1]Celgene Ltd, Uxbridge, United Kingdom
[2]Mapi Values, Macclesfield, United Kingdom

Background. An important treatment goal for patients with newly diagnosed multiple myeloma (ndMM) is maintaining the level of response achieved through successful induction therapy. Results from clinical studies demonstrate that maintenance treatment may provide favorable quality of response, progression-free survival and overall survival. However, to facilitate successful market access, all new treatments require economic assessment to determine their cost-effectiveness to healthcare services.**Aims.** To conduct a systematic literature review of health economic evidence for maintenance therapy in patients with ndMM. **Methods.** A broad search strategy was devised to identify all cost-effectiveness data for multiple myeloma (MM) treatments both in ndMM and in patients with relapsed or refractory MM (rrMM), and in patients eligible for autologous stem cell transplantation (ASCT) and ineligible for ASCT. Searches were performed in Medline, MEIP, EMBASE and BIOSIS via OVID and in the NHS Economic Evaluation Database. Screening was performed in two steps. One reviewer screened and extracted the data, a second checked the screening and extracted data, and a third independent reviewer checked the report for accuracy. **Results.** Four manuscripts and six abstracts were identified, each of which reported the results for distinct studies.[1-10] Five of these studies were cost-effectiveness analyses (CEAs) of treatments in patients with ndMM, one was a cost-consequence analysis in patients with ndMM, and four were CEAs of treatments for patients with rrMM. No studies investigating the cost-effectiveness of maintenance therapy were identified. **Conclusions.** To date no studies have been published on the cost-effectiveness of maintenance therapy in ndMM, either following ASCT or following induction therapy in patients ineligible for ASCT. Currently there are no treatments approved for maintenance therapy in MM which may offer a reason for the absence of cost-effectiveness studies in this area. For treatments currently under regulatory review, cost-effectiveness evidence may be required for reimbursement. However, the accu-

racy of such assessments will be contingent upon the quality and extent of data available. [1]De Abreu Lourenco et al. ISPOR Oct 2009; [2]Green et al. HTA 2009;13(1):29-33; [3]Hornberger et al. 1087

COST-EFFECTIVENESS OF LENALIDOMIDE/DEXAMETHASONE IN MULTIPLE MYELOMA PATIENTS WITH A PRIOR THALIMODMIDE THERAPY

S Schey[1], S Stern[2], S Dhanasiri[3], R Brown[2]
[1]King's College Hospital, London, United Kingdom
[2]United BioSource Corporation, Bethesda, United States of America
[3]Celgene Ltd, Uxbridge, United Kingdom

Background. NICE guidance recommends thalidomide or bortezomib for first-line treatment of multiple myeloma (MM), two agents associated with a risk of peripheral neuropathy (PN). PN can interfere with daily activities leading to treatment discontinuation (5-10% of patients) and dose reduction (approximately 15% of patients). For patients developing PN following first-line treatment, lenalidomide/dexamethasone (Len/Dex), approved by the EMA for patients with MM who have received ≥1 prior therapy, may be an appropriate option for second-line treatment. **Aims.** Economic modelling evaluated the cost-effectiveness of Len/Dex vs dexamethasone (Dex) from the perspective of the National Health Service (NHS) in England and Wales in patients previously treated with thalidomide. **Methods.** An Excel-based individual simulation model was developed for relapse refractory MM patients in the MM-009/10 trials who had prior thalidomide therapy to determine time-to-progression (TTP) and overall survival (OS) after being treated with Len/Dex or Dex. OS within the model was calculated from the sum of TTP and post progression survival (PPS) for each patient. The effect of treatment on TTP was derived from a subgroup analysis of patients from the MM-009/010 pivotal trials (Len/Dex vs Dex) who had received one prior therapy. PPS was also derived from the MM-009/010 trials; however, as 47% of patients on Dex switched to Len/Dex at progression, there was a significant crossover effect in the Dex group. This was adjusted for using data from the UK Medical Research Council myeloma trials. Resource use for monitoring and managing adverse events (AEs) was obtained via a survey of expert haematologists in the UK. Drug costs and costs for managing AEs were taken from NHS sources. A patient access scheme whereby patients received Len free of charge beyond 26 cycles was included. Utility values were taken from published literature and applied to the period prior to progression (based on best response achieved) and after progression. The robustness of model results was assessed by sensitivity analyses whereby individual model parameters were varied across 95% confidence intervals. Cost-effectiveness was determined over a lifetime horizon; a discount rate of 3.5% was applied for future benefits and costs. **Results.** Compared to Dex, Len/Dex was associated with a substantial increase in life years (LYs, 4.42) and quality-adjusted life-years (QALYs, 2.97) in patients who have received prior thalidomide therapy. Total costs were greater for Len/Dex than Dex (£79,549 vs £3,134), but were off-set by the gains in LYs and QALYs, resulting in a cost of £17,290 per LY gained and £25,713 per QALY gained. Model results remained robust to sen sitivity analyses conducted on most parameters. **Conclusions.** These results indicate that Len/Dex is a cost-effective option when compared to Dex as second-line treatment for relapsed/refractory MM patients who have received thalidomide as a prior therapy (<£30,000 per QALY gained). Len/Dex is currently recommended by NICE for MM patients with ≥2 prior therapies. However, recent guidance recommending thalidomide and bortezomib as first-line treatments suggest that Len/Dex may be an option for patients who relapse, or develop PN following first-line treatment.

1088

ECONOMIC IMPACT OF BENDAMUSTINE IN THE PHARMACEUTICAL EXPENDITURE IN THE TREATMENT OF MULTIPLE MYELOMA IN SPAIN

MV Mateos[1], JM Collar[2]
[1]University Hospital of Salamanca, Salamanca, Spain
[2]Mundipharma Pharmaceuticals, S.L., Madrid, Spain

Background. Due to the development of novel cytostatic agents such as proteasome inhibitors and immunomodulators, the standards of care for the Multiple Myeloma (MM) patient has changed. The costs associated with current and emerging therapies are significant and pose a tremendous financial burden to the Public Health Systems, specifically at the hospital setting. Bendamustine is a novel bifunctional alkylating agent recently available in Spain, approved for treatment of non-candidates for transplantation MM patients, which is under investigation to be combined with the other cytostatic drugs in relapsing-remitting MM patients. **Aims.** To calculate the economic impact of MM treatment in Spain, and to develop a Budget Impact Analysis (BIA) to estimate the potential savings bendamustine availability would introduce as a treatment option for MM patients, non-candidates for transplantation, who are likely to be treated with other cytostatic combinations. **Methods.** A Budget Impact model was developed, assuming a prevalent treatable population of 1,380 patients in 1st line and 2,317 patients in 2nd onwards lines in 2011, with a patient estimated increase at a 3% yearly rate. The time horizon considered was 3 years and the analysis was made from the perspective of the Spanish Health System. Pharmaceutical expenditure on cytostatic agents was analyzed, excluding other medical costs. The drug costs were based on the official ex-factory prices (EFP), discounting the price reduction established in 2010 by the Spanish Government. The base case scenario (without bendamustine) was based on prevalent epidemiological and market survey data available, enriched with the expert opinion input. The bendamustine scenario considered different drug combinations and different dosages (90-120mg/m^2), depending on the treatment line to analyze. No combinations bendamustine+lenalidomide were considered in the model due to the hematological toxicity profile of both drugs. A deterministic sensitivity analysis (SA) was performed, switching the most relevant variables included in the model, to confirm the BIA results robustness. **Results.** The drug expenditure for MM treatment is slightly under €130 Mio/year in Spain. There is a wide variety of drug acquisition costs, the single cycle costs are ranging from €3 (melphalan+prednisone) to €5,969 (lenalidomide+dexamethasone). Bendamustine based treatments would reach from 7% (1st year) to 21%(3rd year) of the treated patients analyzed. Fifty-four percent of the bendamustine treatments considered were combinations with other high-price drugs (bortezomib or thalidomide), where the bendamustine cost would be only 17% or 21% respectively of the whole treatment regimen. The introduction of bendamustine would reduce drug expenditure in €5.4 Mio/year on average. The SA confirmed the data analyzed, with savings ranging from €14.3 to €18.2 Mio in the 3-year cost projections. **Conclusions.** The economic impact of MM treatment in Spain poses a high financial burden to the hospital drug budgets. The introduction of bendamustine would produce drug cost savings in the MM patients, mainly from the 2nd treatment lines onwards. Considering only the drug acquisition costs, the savings observed in the model were mainly due to the substitution of high cost combinations like those based on bortezomib, thalidomide or lenalidomide therapies.

1089

MODELLING THE 10-YEAR COST EFFECTIVENESS OF BENDAMUSTINE AS FIRST LINE TREATMENT FOR CHRONIC LYMPHOCYTIC LEUKAEMIA IN THE NETHERLANDS

K Holtzer-Goor[1], S Vandekerckhove[2], D van den Steen[2], Y van Megen[3], P Huijgens[4], M Lamotte[2], C Uyl-de Groot[1]
[1]Erasmus University Rotterdam, Rotterdam, Netherlands
[2]IMS HEOR, Brussels, Belgium
[3]Mundipharma Pharmaceuticals B.V., Hoevelaken, Netherlands
[4]VU University Medical Center, Amsterdam, Netherlands

Background. Although promising treatment combinations for chronic lymphocytic leukemia (CLL) like fludarabine, cyclophosphamide and rituximab (FCR) became available in the last decade, a significant proportion of patients is not suitable or eligible for such intensive chemotherapy. In those patients chlorambucil remains a widely used first-line therapy. However, overall and complete response rates with chlorambucil are relatively modest and therefore more effective treatment options are required for this patient group. Bendamustine is a promising drug in this setting, but by being more expensive compared to chlorambucil, it will increase pressure on health care budgets. In this situation, healthcare authorities will require information on cost-effectiveness for regulating reimbursement. **Aims.** The objective of this study was to assess the cost-effectiveness of bendamustine compared to chlorambucil, the current first line treatment for CLL patients with Binet stage B or C disease not eligible for fludarabine combination therapy, from a health care payer perspective in the Netherlands. **Methods.** A Markov model was designed representing the normal evolution of patients with CLL over different treatment lines (Figure 1). Transition probabilities were derived from clinical trials. Healthcare resource utilisation was estimated for each CLL state using clinical guidelines and a Dutch CLL expert panel. Outcomes were life years (LY), quality-adjusted life years (QALYs), progression free life years (PFLY), and CLL related health care costs (e.g. in- and outpatient visits, diagnosis tests, chemotherapy and immunotherapy, costs of best supportive care). The model time horizon was 10 years. **Results**. The mean number of QALYs was 3.77 for bendamustine and 2.21 for

chlorambucil. The total average costs amounted to €79,328 for bendamustine, and €67,172 for chlorambucil (2011 values). Compared with chlorambucil, the cost-effectiveness of bendamustine was €7,809 per QALY gained. The costs per LY gained were €7,374 and the costs per PFLY gained were €6,908. The probability is around 95% that bendamustine costs less than €20,000 per QALY when compared with chlorambucil.Conclusions. Bendamustine compared to chlorambucil, in previously untreated CLL patients with Binet stage B or C disease not eligible for fludarabine combination therapy, generated an ICER of €7,809 per QALY gained, indicating that bendamustine is 10-year cost-effective as first line treatment for CLL in the Netherlands.

IMPACT OF MULTIPLE MYELOMA AND ITS TREATMENT ON QUALITY OF LIFE: DEVELOPMENT OF A CONCEPTUAL MODEL

R Baz[1], H Lin[2], A-M Hui[2], R Harvey[3], K Colson[4], K Gallop[5], P Swinburn[5], K Breheny[5], S Acaster[6], D Berg[2], H Huang[2], P Richardson[4]

[1]H. Lee Moffitt Cancer Center & Research Institute, Tampa, United States of America

[2]Millennium Pharmaceuticals, Inc., Cambridge, United States of America

[3]Winship Cancer Institute of Emory University, Atlanta, United States of America

[4]Dana-Farber Cancer Institute, Boston, United States of America

[5]Oxford Outcomes (An ICON plc Company), Oxford, United Kingdom

[6]Oxford Outcomes Inc., San Francisco, United States of America

Background. There is a paucity of published qualitative research exploring the impact of multiple myeloma (MM) and its treatment on patients' health-related quality of life (HRQL).**Aims.** To explore patient perspectives on signs/symptoms associated with MM, the burden of undergoing treatment for the disease, and the subsequent impact of these experiences on HRQL. Further, the study aimed to develop a conceptual model to illustrate the key concepts identified and the nature of their inter-relationships. **Methods.** Patients with MM were recruited into this cross-sectional qualitative study through a patient panel in the United States. An interview discussion guide was developed using information obtained from a review of published literature and through interviews with experienced MM professionals (three clinicians, one oncology nurse). The study protocol received independent ethical approval, and patients provided informed consent prior to participation. In-depth, semi-structured interviews were conducted via telephone with MM patients to explore their experiences of both the disease and its treatment. Data were analyzed using a thematic analysis approach. **Results.** To date, 15 MM patients have participated in open-ended, semi-structured interviews. The sample was diverse in terms of age (mean: 60.07 years; SD: 6.65; range: 47-72), and included 8 male and 7 female patients. The patients were at various stages of treatment (10 receiving second-line treatment or beyond; 4 receiving first-line treatment; 1 newly diagnosed who had not received any treatment). Patients reported signs/symptoms they currently or previously experienced from MM. Almost all had experienced fatigue (93.3%) and pain (86.7%); other commonly reported burdens were bone damage or fractures (40.0%), anemia (33.3%), and nausea, neuropathy, shortness of breath, aches, and infections (each 20%). Qualitative data analyses revealed that undergoing therapy for MM can have a profound impact on patients' HRQL. MM signs/symptoms were a major cause of distress, with most patients experiencing difficulties as a result of bone pain and/or severe fatigue. Interventions aimed at controlling MM signs/symptoms could themselves pose challenges for patients' HRQL. A wide range of treatment-related adverse events were reported including fatigue, neuropathy, insomnia, and gastrointestinal symptoms. Undergoing treatment for MM placed a substantial psychological and physical burden on patients; in addition, it could result in significant disruption of social and leisure activities, as well as loss of independence, and impact on relationships. A conceptual model was subsequently developed to illustrate the relationship between the different concepts and their moderating factors.**Conclusions:** The conceptual model developed in this study graphically depicts influences on HRQL for those undergoing MM therapy. To our knowledge this is the first formal attempt to create a comprehensive model of HRQL in MM that explores the inter-relationships between signs/symptoms, treatment burden and HRQL concepts. Using an open-ended qualitative approach allows important issues to be reported by patients that may not be highlighted in standard HRQL questionnaires. The model demonstrates that the determination of HRQL is complex and extends beyond either simple disease progression or treatment response. This model may prove useful in informing measurement strategies, developing new instruments, or selecting endpoints for future trials in MM.

1091

LIVING WITH MYELOMA-RELATED PAIN: PERCEPTIONS OF UK PATIENTS, CARERS AND CONSULTANTS

R Lobban, Myeloma UK, S Schey

Myeloma UK, Edinburgh, United Kingdom

Background. Pain is the most common symptom of myeloma and will affect up to 80% of patients at some point. It can have a huge impact on the patient's quality of life, particularly if it is untreated or poorly managed. For many myeloma patients, pain can be frustrating and debilitating, affecting them physically, emotionally and socially. It can also have a significant impact on their carers and family members. **Aims.** To ask patients, their carers and consultants about the impact of living with myeloma-related pain, to establish if there are differences in perceptions between those who are directly impacted by pain and those who treat and manage it. **Methods.** Patients and carers were invited to complete a questionnaire that was available as a paper copy and online. Consultant haematologists were asked to complete an online survey. Further qualitative data was collected through ten one-to-one interviews with patients and carers. The survey was devised and conducted by Myeloma UK and supported by a grant from Napp Pharmaceuticals Limited. **Results.** 87 patients, 56 carers and 10 consultants participated in the survey. 68% of patients reported that they lived with pain every day or most days. Most (76%) said that on average, their pain was mild or moderate in intensity. Patients reported that pain interfered with day-to-day activities (84% of patients), ability to work (82%), mobility (86%), sleep (74%), mood (74%), and social life/relationships (81%). 81% of carers said they thought that the patient they care for lived with pain every day or most days and 60% of consultants thought they got a better understanding of the patient's pain from the carer. Compared with patients, carers perceived that pain impacted more on mood, mobility and day-to-day activities. Most patients (85%) and carers (77%) thought that the consultant had a good understanding of the patient's pain; 80% of consultants were confident about their management of myeloma-related pain, 70% said they often initiated discussions with patients about their pain. However, 50% of consultants said that managing side-effects of pain treatment was a challenge and 40% said they didn't have enough time in clinic to accurately assess the patient's pain. Perceptions of compliance with medication differed: 10% of consultants, 90% of patients and 82% of carers thought the patient always took the pain-killers prescribed to them. **Summary and Conclusions.** The survey results confirm that pain is a common and debilitating symptom of myeloma. It is difficult to ascertain if the difference between the proportions of patients and carers reporting myeloma-related pain reflect over-reporting by carers (to protect the patient and ensure pain is treated) or under-reporting by patients (to avoid being a burden on the carer). Communication between patients, carers and consultants does not seem to be an issue, suggesting that where pain is undertreated, it is due to practical issues such as limited clinic time, lack of pain specialist support and a need for better short-acting, myeloma-specific agents.

SIMULTANEOUS SESSION II

Acute myeloid leukemia - Trial design and novel agents

1091A

EVALUATION OF THE CLINICAL IMPACT OF DIFFERENT CATEGORIES IN AML WITH MDS-RELATED CHANGES DEFINED ACCORDING TO THE WHO CLASSIFICATION IN A LARGE COHORT OF 2392 NEWLY DIAGNOSED ADULT AML PATIENTS

Background. The current WHO classification defines acute myeloid leukemia (AML) with a prior history of myelodysplastic/myeloproliferative neoplasm (MDS/MPS), AML with multilineage dysplasia and AML with specific cytogenetic abnormalities as AML with MDS-related changes (MRC-AML). These patients are considered to have an inferior outcome compared with *de novo* AML. Whether this is due to an adverse genetic risk profile or by the fact of MRC-AML per se remains open. In addition, the prognostic impact of the different subcategories has not been evaluated. The minimal time period between diagnosis of preceding MDS/MPN and subsequent AML is defined differently (≥one month by Cheson et al. JCO 2003 versus ≥six months according to WHO 2001). **Aims.** To study the clinical impact of MRC-AML in a large cohort of newly diagnosed AML patients in the context of clinical and genetic characteristics. **Methods.** The study included 3177 adult patients (median age, 54.5 years; range, 16-85 years), entered on five protocols of the German-Austrian AML Study Group between 1993 and 2008, using intensive induction and consolidation therapy. Information on type of AML, karyotype and molecular marker status of *NPM1*, *FLT3* and *CEBPA* was available in 96%, 91%, 90%, 85% and 74% of the patients, respectively. Patients with therapy-related AML (n=200), those with recurrent cytogenetic abnormalities according to the WHO classification (n=452) and those lacking information on type of AML (n=133) were excluded. **Results.** Of 2392 patients, 210 (9%) had a history of preceding MDS/MPN (n=69, one to six months; n=141, >six months) and 197 (8%) had evidence of multilineage dysplasia. MDS-related cytogenetic abnormalities were present in 468 of 2099 (22%) patients with available cytogenetics, in 51 of 201 (25%) with prior MDS/MPN and in 56 of 197 (28%) patients with multilineage dysplasia. MRC-AML patients were significantly older compared with *de novo* AML (median age, 58 versus 53 years, p<0.0001) with highest median age in the subgroup defined by a history of preceding MDS/MPN of at least six months (median age, 62 years). White blood counts were significantly and consistently lower (p<0.0001) in MRC-AML (median 5.0/nl) compared with *de novo* AML (median, 17.4/nl), whereas percentage of blast cells in bone marrow and peripheral blood were equally high in *de novo* AML and AML with MDS-related cytogenetics, but substantially lower in all other subcategories of MRC-AML. Notably, the incidence of *NPM1*-wildtype/*FLT3*-ITDnegative/*CEBPA*negative (triple negative) normal karyotype AML was more than twice as high in MRC-AML compared with *de novo* AML (62% versus 24%; p<0.0001). In uni- as well as multivariable analyses MRC-AML was associated with an inferior outcome for all clinical endpoints compared with *de novo* AML. Within the group of MRC-AML, the subcategory defined by multilineage dysplasia was associated with a superior outcome compared with the other MRC-AML subcategories. Of note, in the genetically defined subset of triple-negative normal karyotype AML MRC-AML lost its prognostic impact. **Conclusions.** In this large cohort of adult AML patients, MRC-AML was an adverse prognostic factor. However, in genetically well defined subgroups this prognostic impact gets lost.

[14]Depart. of Med. Inform., Biometry, a. Epidemiology, Ludwig Maximilian University, Munich, Germany

Background. Patients with acute myeloid leukemia (AML) used to participate in different clinical trials launched by five German study groups. Each study group pursued its own treatment strategy with respect to dosage of chemotherapy during induction and consolidation therapy as well as to the use of allogeneic hematopoietic stem cell transplantation (HSCT) and maintenance therapy. **Aims.** To possibly identify a treatment strategy superior to the others, adjusted clinical outcome was compared between the study groups. **Methods.** The five groups agreed on upfront randomization of 10% of their patients into a common standard treatment arm. Standard induction treatment consisted of two courses of cytarabine 100 mg/m²/d for one week plus daunorubicin 60 mg/m²/d on three days. Consolidation therapy consisted of either three cycles of standard high-dose cytarabine or, based on cytogenetic risk, an allogeneic HSCT. The remaining 90% of the patients of each study group were allocated / randomized to treatments according to each study groups' own trial design. Inclusion criteria were primary AML or AML secondary to cytotoxic treatment or to myelodysplastic syndrome, diagnosed at 16-60 years. Patients with acute promyelocytic leukemia were excluded. Endpoints for the intention-to-treat comparisons of each study-internal treatment strategy with the common standard treatment were percentage of complete remission (CR) and CR with incomplete recovery (CRi) after induction therapy, overall survival (OS), relapse-free survival (RFS), and event-free survival (EFS). To adjust for variations in baseline characteristics, differences in survival probabilities were assessed through multiple Cox regression. Direct adjusted survival curves based on the Cox model were estimated. Regarding CR / CRi, adjustment for prognostic variables was performed through multiple logistic regression. **Results.** Of 3171 patients eligible for analysis, 305 were randomized to the standard treatment and 828, 373, 235, 808, and 622 to the five study group-specific treatment arms, respectively. CR/CRi rate after induction therapy was 70% (95% confidence interval (CI): 65-76%) in the common standard arm and ranged from 74% to 82% in the study group-internal treatment strategies. Also when adjusted for prognostically significant baseline variables, with 82%, one study group presented a significantly better result than the standard treatment arm. With the standard treat-

ment, the adjusted five-year OS probability was 44% [95% CI: 37-50%]. The five-year OS probabilities of the studies' internal treatment strategies ranged from 42-48%. Adjusted five-year RFS probabilities were 46% [95% CI: 38-53%] in the standard arm and 36-48% in the studies' internal treatment groups. The adjusted five-year EFS probability of the standard arm was 33% [95% CI: 27-39%] and 29-39% in the studies' internal groups. Adjusting for influential baseline variables, no significant difference with regard to OS, RFS, or EFS was observed between the standard treatment arm and any of the five internal treatment strategies. **Conclusions.** Due to the lacking differences with regard to all survival endpoints, we conclude that the overall treatment strategies of the five study groups were neither worse nor better than the concept of the standard treatment arm. However, in further detailed analysis, AML subgroups may profit from specific regimen used within the study groups.

1091C

EPIGENETIC THERAPY IS ASSOCIATED WITH SIMILAR SURVIVAL COMPARED WITH INTENSIVE CHEMOTHERAPY IN ELDERLY PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA

A Quintas-Cardama, J Cortes, T Liu-Dumlao, F Ravandi, M Brandt, S Faderl, S Pierce, G Borthakur, G Garcia-Manero, H Kantarjian
M.D. Anderson Cancer Center, Houston, United States of America

Background. The prognosis of pts with acute myeloid leukemia (AML) aged 60 and above (AML>60) is very poor. The complete remission (CR) rates among older patients with AML treated with a standard combination of cytarabine and an anthracycline (e.g. 7+3) are 35%-60% but the early (4-8 weeks) mortality is high (20-50%), which result in median survival of 4-7 months. Epigenetic therapy (decitabine, azacitabine, histone deacetylase inhibitors) is standard in MDS. We compared the outcomes of elderly patients with AML treated with standard chemotherapy vs epigenetic therapy.**Methods**. We examined 909 pts with newly diagnosed AML>60 treated either with epigenetic therapy (n=130, 78 decitabine-based, 52 azacitidine-based) or with intensive chemotherapy (n=779) between 2000 and 2010. Of the 779 pts receiving chemotherapy, 34% received AI (ara-C 1.5g/m^{2}x3d and idarubicin 12mg/m^{2}x3d) and 22% high dose araC-based chemotherapy. No differences were observed regarding cytogenetic grouping (p=0.44), including the proportion of patients with poor karyotypes (25% vs 32%; p=0.13), or regarding performance status 0-2 (740 [95%] vs 124 [95%], p=0.8).

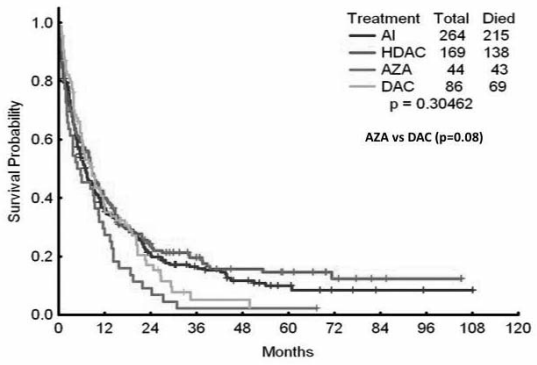

Figure 1. Overall survival of patients with AML>60 according to therapeutic modality

Results. The CR rates for patients treated with chemotherapy and epigenetic therapy were 47% and 28%, respectively (p=0.0001) while the overall response rate (ORR=CR+CR with incomplete platelet recovery) was 53% and 29% (p=0.0001). Early mortality rates (8 weeks) for both groups were 16% and 11%, respectively (p=0.13). The 2-year relapse free survival (RFS) and OS for the chemotherapy and epigenetic therapy groups were similar at 37% vs 37% mos (p=0.9) and 7.6 vs 6.9 mos (p=0.13), respectively. When the analysis was limited to the 325 pts with poor risk cytogenetics (e.g. -5 and/or -7, complex), the CR rates for pts receiving chemotherapy (n=271) or epigenetic therapy (n=54) were 31% and 33% (p=0.06) while median OS was 4.2 vs 6.2 weeks (p=0.3), respectively. The corresponding CR rates for patients with diploid karyotype were 58% vs 31% (p=0.0001). However, median OS was 12.7 vs 9.5 mos, p=0.088. Similarly, CR rates for patients carrying the *FLT3*-ITD mutation were 56% vs 42% (p=0.469) with median OS of 7.6 vs 9.2 months (p=0.73). The CR rate (25% vs 29%, p=0.6) and OS (4.8 vs 8.5 mos, p=0.08) for pts treated with azacitidine/azacitidine-based or decitabine/decitabine-based therapy showed a trend towards improved outcomes with decitabine. A multivariate analysis of these prognostic factors for survival identified the following to be independently adverse: older age (p=0.002), adverse cytogenetics (p=0.004), poor performance (p<0.0001), elevated creatinine (p<0.0001), leukocytosis (p=0.002), and prior chemotherapy for other cancers (p=0.2). Repeating the multivariate analysis for pts ≥70 years identified the same first 4 prognostic factors. The median OS of pts who failed (but not died after) initial AML therapy (114 chemotherapy, 33 azacitidine, 60 decitabine) after first salvage therapy was 1.2 mos with intensive chemotherapy, 1.1 mos with azacitidine and 3.1 mos with decitabine (p=0.036). **Conclusions**. This retrospective analysis in a large cohort of pts with AML>60 treated at our institution over the last decade showed similar long-term outcomes with epigenetic therapy versus intensive chemotherapy

[15]Hopital St. Antoine, Paris, France

Background. Gemtuzumab ozogamicin (GO), a calicheamicin-linked anti-CD33 monoclonal antibody, has clinical activity in relapsed AML and has recently been shown to significantly improve survival in older patients when administered in combination with frontline standard chemotherapy (Burnett et al, Blood 2011: a582; Castaigne et al, Blood 2011: a6). **Aims.** Study AML-17 is an open-label randomized phase III trial to evaluate the benefit and toxicity of adding upfront GO to standard induction and consolidation therapy in older patients with untreated AML. **Methods.** Eligible patients (age 61-75 years; WHO PS 0-2; maximum allowed WBC pre-therapy 30x10^9/L [a short course of HU permitted]) with newly diagnosed non-M3 AML were randomized (stratified by age, initial WBC,% CD33 expression, and Institution) to receive, or not, two upfront infusions of GO (6 mg/m^2 on day 1 and 15) prior to a course of MICE (mitoxantrone, cytarabine, etoposide), to be started within 10 days from response assessment to GO (day +43) or sooner whenever disease progression was documented. Patients achieving CR or CRp received consolidation therapy with 2 courses of ICE (idarubicin, cytarabine, etoposide) with or without a single infusion of GO (3 mg/m^2 on day -1 of each course), according to their initial assignment. The primary endpoint was OS; secondary endpoints included CR+CRp rate after induction, RFS, and toxicity. A total of 378 deaths were required in order to detect an increase in OS at 2.5 years from 20% (No GO) to 30% (GO): HR=0.75 (alpha=5%, power=80%). For efficacy endpoints, all analyses were performed according to the intent-to-treat principle. **Results.** Between 09/2002 and 08/2007, 472 patients (median age 67 years) were randomized in the study by 60 centers. After induction CR/CRp was achieved in 223 pts (47%), and at a median follow-up of 5.2 years 414 deaths were reported. As shown in the Table, induction response was comparable in the two arms, but GO treatment was associated with a higher 60-day mortality (mostly due to adverse events) and a shorter OS. Importantly, age emerged as a significant predictor of outcome: while treatment results were comparable in the younger age cohort (61-69 years), pts older than 70 years of age who received GO, as compared with those in the same age group treated with standard chemotherapy only, fared significantly worse in terms of both induction response (P=0.01) and OS (P=0.002), and had a higher 60-day mortality rate. The most common grade

3 or higher adverse events were febrile neutropenia and infection in each treatment arm. Severe liver toxicity occurred in 10% of pts during GO induction resulting in two fatalities. **Conclusions.** In this study, the sequential addition of GO to frontline intensive chemotherapy in older pts with AML was not beneficial overall, and even detrimental in those aged 70 years or more due to a higher risk of early mortality.

Table.

	All patients		Age 61-69 yr		Age 70-75 yr	
	No GO	GO	No GO	GO	No GO	GO
N. Patients	236	236	152	153	84	83
CR+CRp	116 (49%)	107 (45%)	72 (47%)	80 (52%)	44 (52%)	27 (32%)
OR (CI) p-value	0.86 (95%; 0.60-1.23) 0.46		1.22 (99%; 0.67-2.20) 0.42		0.44 (99%; 0.19-1.00) 0.01	
60d mortality (all causes)	17.8%	22.5%	15.8%	17.1%	21.4%	32.5%
2.5y OS (median, mos)	21.7% (10.0)	16.0% (7.1)	21.8% (10.1)	20.4% (8.8)	21.4% (9.1)	7.8% (4.0)
HR (CI) p-value	1.20 (95%; 0.99-1.45) 0.07		1.05 (99%; 0.76-1.45) 0.69		1.64 (99%; 1.08-2.51) 0.002	
2.5y RFS (median, mos)	18% (9.1)	17.4% (9.5)	22.1% (10.1)	17.5% (10.7)	11.4% (7.8)	18.5% (6.2)
HR (CI)	1.08 (95%; 0.81-1.44)		1.14 (99%; 0.71-1.81)		1.11 (99%; 0.57-2.20)

F14512 A NOVEL POLYAMINE-VECTORIZED ANTI-CANCER DRUG TARGETING TOPOISOMERASE II IN ADULTS PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): RESULTS FROM A PHASE 1 STUDY

S De Botton[1], C Berthon[2], CE Bulabois[3], T Prebet[4], N Vey[4], P Chevallier[5], X Thomas[6], F Lefresne[7], S Favrel[7], B Quesnel[2]
[1]Institut Gustave Roussy, Villejuif Cedex, France
[2]Hospital Claude Huriez, Lille, France
[3]CHU Grenoble, Grenoble, France
[4]Institut Paoli-Calmettes, Marseille, France
[5]CHU Nantes, Hôtel Dieu, Nantes, France
[6]Hospital Edouard Herriot, Lyon, France
[7]Institut de Recherche Pierre Fabre, Boulogne Cedex, France

Background. F14512 is a novel class of targeted cytotoxic agent that exploits the polyamine transport system (PTS) to deliver a drug selectively into cancer cells. This polyamine (spermine)-conjugated epipodophyllotoxin is 10-fold more potent than etoposide *in vitro*. This is most likely a consequence of an increased affinity for DNA and a stabilisation of the DNA/Topoisomerase II complex mediated by the polyamine moiety. **Aims.** This first-in man multicenter phase I study was designed to determine the maximal tolerated dose (MTD) of F14512 single agent in patients (pts) with relapsed or refractory AML by determining the incidence of dose-limiting toxicities (DLT) during the first cycle. Secondary objectives include safety, pharmacokinetics (PK) and anti-leukemic activity. **Methods.** Eligible pts were adults aged 18-75 years with *de novo* or secondary AML and previously treated with a maximum of 3 prior induction regimens. Pts received i.v. administration of F14512 from day 1 to day 5 of each cycle. Cycles were repeated every 2 to 6 weeks depending on dose levels, leukaemia response, recovery to sufficient haematopoiesis and resolution of toxicities. Dose escalation was based initially on an accelerated titration design with 50% increment and one pt by dose level until 1 DLT was observed. The activity of the PTS was assessed for each patient on blasts cells and lymphocytes at baseline and blood samples for PK analysis were taken on days 1 and 5 of cycle 1. **Results.** From January 2010 to November 2011, 39 pts (24 males) were treated in 6 participating sites through 12 dose levels ranging from 1 to 44 mg/m^2/day. Median age was 68 years (range: 22-75 years). 27 pts had *de novo* AML, 12 had secondary AML. 14 pts had unfavourable and 18 had intermediate cytogenetics. Drug related adverse events (AE) were reported in 36 pts (92 %). The most frequent grade 3-4 drug-related AEs (≥ 5%) included reversible hypomagnesemia (23%), neutropenia (18%), sepsis (13%), febrile neutropenia (10%), asthenia (5%), hypokaliemia (5%) and thrombocytopenia (5%). Three DLT were reported: second degree atrioventricular block in 1 pt at 15.2 mg/m^2/day, non-blastic aplasia during more than 6 weeks in 1 pt and early life-threatening sepsis in 1 pt at 44 mg/m^2/day. Therefore, MTD was reached at 44 mg/m^2/day, dose at which 2 pts out of 4 experienced a DLT. Anti-leukemic activity was shown at different dose levels: 4 complete responses (CR, 10%) at 1, 15.2, 34 and 39 mg/m^2/day, 3 complete responses with incomplete recovery (CRi, 8%) at 6.8, 34 and 44 mg/m^2/day. Of note, 3 pts experienced haematological improvements respectively at 10.1, 15.2 and 26 mg/m^2/day. The PTS activity results are presented separately. The preliminary PK results illustrated an increase of drug exposure proportional to the dose, and reproducible PK behaviour between days. **Conclusions.** This phase I determined the MTD of F14512 single agent to be 44 mg/m^2/day. Accrual is still ongoing at the recommended dose at 39 mg/m^2/day. Clinical outcome in this heavily pre treated population seems promising and updated results will be presented at the meeting.

Pediatric acute lymphoblastic leukemia

Background. Children with Down syndrome (DS) have an increased risk of developing B-cell precursor acute lymphoblastic leukemia (BCP-ALL) characterized by a low frequency of the common genetic aberrations, and a high frequency of *CRLF2* and *JAK* aberrations.**Aims.** Because DS ALL is relatively rare (only 2% of ALL patients), the clinical outcome, treatment-related mortality (TRM) and prognostic factors of DS-ALL patients treated in contemporary protocols are uncertain. Hence, we performed a retrospective study within the International ALL ("Ponte di Legno") Working Group to investigate clinical outcome and to identify prognostic factors in DS ALL patients. The further aim of the study was to translate new insights of the biology of DS ALL into improved risk stratification and hence more accurate tailoring of therapy. **Methods.** We retrospectively analysed 653 DS children with BCP-ALL treated in clinical trials of 16 collaborative study groups between 1995 and 2005. A predefined set of data was collected for each patient, consisting of clinical data obtained at diagnosis, treatment, cytogenetic and molecular data. All genotypes obtained from conventional karyotyping, FISH or RT-PCR were centrally reviewed and assigned to specific cytogenetic groups. A Dutch Childhood Oncology Group (DCOG) non-DS BCP-ALL cohort (n=827) from the same treatment era served as a reference cohort.**Results.** DS ALL patients had a higher 8-year cumulative incidence of relapse (CIR) (26±2% vs. 18±1%; p=0.001) and higher 2-year TRM (7±1% vs. 1.0±<0.1%; p<0.0001) than non-DS BCP patients, resulting in lower 8-year event free survival (EFS) (64±2% vs. 78±1%; p<0.0001) and overall survival (74±2% vs. 86±1%; p<0.0001). Children age <6 years with WBC <10x109/L had the best outcome (EFS 78±3%, TRM 3±1%, CIR 17±3%), confirmed by multivariate Cox regression analyses (EFS: age < 6 years hazard ratio (HR) =0.58, p=0.002, WBC <10x109/L HR =0.58, p=0.002). The 8-year EFS of subjects with ETV6-RUNX1 (8.3%) was 95±4%, similar to non-DS ALL patients. Within high hyperdiploid (HeH, modal number >50) DS ALL, 45% of the patients had trisomies 4&10 with EFS of 88±8%, which was explained by reduced TRM rate. Neither *JAK2* R683 nor genomic *CRLF2* aberrations were associated with outcome (n= 30 and n=93 respectively). TRM was not restricted to a specific treatment-phase or treatment-regimen. Specifically, inclusion of anthracyclines in induction had no impact on TRM (1.5±1% vs. 1.7±1%; p=0.46) or EFS (64±6% vs. 69±5%; p=0.39).**Summary / Conclusion:** This large international study showed that age <6 year, WBC <10x10^9/L and the presence of *ETV6-RUNX1* or trisomies 4&10 are favourable prognostic factors within DS ALL which may be used to guide future risk-adapted treatment. DS ALL patients have a relatively poor survival compared to non-DS ALL patients, primarily due to a higher relapse rate, but also to a higher TRM. The occurrence of TRM throughout the entire treatment period and the lack of association with specific treatment elements suggest the need for improved supportive care strategies. Furthermore, there is a need for caution in treatment reduction for the majority of DS ALL patients that lack the good prognostic features, as relapse is a major problem.

THE TIMING AND SUB-CLONAL GENETIC ARCHITECTURE OF CRLF2 REARRANGEMENTS IN DOWN'S SYNDROME ACUTE LYMPHOBLASTIC LEUKAEMIA

E Potter[1], J Wiemels[2], L Ermini[1], I Titley[1], A Ford[1], M Greaves[1], L Kearney[1]

[1]Institute of Cancer Research, Sutton, Surrey, United Kingdom
[2]University of California, San Francisco, United States of America

Children with Down's syndrome (DS) have a 40 fold increased risk of acute leukaemia with approximately half developing acute lymphoblastic leukaemia (ALL). These leukaemias are a cytogenetically distinctive group, with a lower incidence of the common chromosomal translocations in childhood ALL. 60% of DS-ALLs show overexpression of *CRLF2* due to rearrangements including translocations, t(X;14) or t(Y;14), juxtaposing *CRLF2* to the *IGH* enhancer or deletions resulting in a *P2RY8-CRLF2* fusion-gene. *CRLF2* overexpression has been associated with activation of the JAK/STAT pathway in transduced primary B- cell progenitors. It has been proposed that *CRLF2* overexpression is an early event in the evolution of DS-ALL, with activating mutations or copy number alterations (CNAs) occurring as secondary events driving leukaemogenesis. Our aim was to determine whether *CRLF2* rearrangements are a prenatal event in the pathogenesis of DS-ALL and to investigate the sub-clonal genetic architecture at a single cell level.We have been able to collect and "backtrack"six neonatal blood spots from *P2RY8-CRLF2* positive DS-ALLs, each with a unique fusion-gene break point. Blood spot screening for the fusion-gene identified two positive and four negative cards. This suggests that *CRLF2* rearrangements can occur before birth but may not necessarily always do so (negative blood spots are uninterpretable).To define the genetic architecture of six *CRLF2* rearranged DS-ALLs (including one case which relapsed) we characterized patient specific genomic alterations using SNP6 arrays and mutation screening and interrogated mononuclear cell cytospins from each case using four-colour FISH. Two samples harbored *IGH-CRLF2* translocations and four were positive for the *P2RY8-CRLF2* fusion. Loss of *CDKN2A* or a small region at 6p22.22 were the most frequent CNAs, occurring in two cases. *IL7R*α mutations were found in two cases and the relapse sample was positive for the R683G *JAK2* mutation, but this was not found at diagnosis. FISH analysis revealed a branching subclonal genetic architecture similar to that identified in *ETV6-RUNX1* positive ALL (Anderson K et al; 2011). Moreover, in the relapse case, the major clone present at relapse could be found as a minor clone at diagnosis.As FISH is limited by the number of CNAs that can be analysed and cannot be used for simultaneous CNA and mutation analysis we have developed a novel multiplex Q-PCR approach using the BioMark HD (Fluidigm) to interrogate CNAs, fusion-genes and mutations simultaneously in a single cell. We have investigated a *P2RY8-CRLF2* positive DS-ALL case, which harbored an *IL7R*α mutation and loss of *CDKN2A* by standard approaches. Single cell analysis confirmed that the fusion-gene was present in 98% of cells and that 96% of these harbored a heterozygous *IL7Rα* mutation, 2% were homozygous and 2% carried the wildtype gene. Loss of both *CDKN2A* copies occurred in 11% of *P2RY8-CRLF2* positive cells, loss of one copy in 76% of cells but retention of *CDKN2A* was found in 9%. These data suggest a sequence of genetic events and sub-clonal structure with *CRLF2* close to or at the apex. This is compatible with *CRLF2* rearrangements being an early and possibly initiating event in DS-ALL.

[2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands
[3]COALL study group - Hamburg University, Hamburg, Germany
[4]Dutch Childhood Oncology Group (DCOG), The Hague, Netherlands

Background. The prognosis of childhood precursor B-ALL has improved tremendously during the past decades. This improvement is largely due to risk-adapted therapies including e.g. the *BCRABL1*-translocation and *MLL*-rearrangement as high-risk factors. Recently, *IKZF1*-deletions and the *BCRABL1-like* signature were introduced as new unfavorable prognostic markers in pediatric ALL. The *BCRABL1-like* group is characterized by a high frequency of *IKZF1*-deletions, indicating that the (in)dependency of both prognostic factors needs to be established.**Aims**We aimed to determine the prognostic value of *IKZF1*-deletions and *BCRABL1-like* signatures in newly diagnosed children with precursor B-ALL who were treated according to 3 recent treatment protocols. In addition, we aimed to study the prognostic interaction/independence of *IKZF1*-deletions and *BCRABL1*-like signature.**Methods**Leukemic cell samples of pediatric precursor B-ALL patients enrolled in DCOG ALL-9, DCOG ALL-10, and COALL-97/03 were studied. *BCRABL1*-positive and *MLL*-rearranged cases, characterized by inferior outcome, were excluded. *BCRABL1-like* cases were identified by an established 110 probe sets classifier using Affymetrix U133 plus2.0 gene expression arrays (Den Boer et al, Lancet Oncology 2009). *IKZF1* deletions were detected by multiplex-ligation dependent probe amplification (MLPA) p335-assay (MRC Holland) and validated by an MLPA p202-assay (MRC Holland) or array-comparative genomic hybridization (Agilent, 180k array-CGH). Mutations in *IKZF1* were determined by genomic DNA- sequencing. The cumulative incidence of relapse (CIR) curves were calculated using death as competing event.**Results**Gene expression profiling of 447 pediatric precursor B-ALL cases revealed 78 (17.4%) *BCRABL1-like* cases. *IKZF1*-deletions were detected in 15% of precursor B-ALL cases with the highest frequency of 37% found in *BCRABL1-like* ALL (28/76). In 3 independent patient cohorts, as well as for all cohorts together, the 5-year cumulative incidence of relapse (CIR) of *BCRABL1-like* cases was 3-fold higher than of remaining precursor B-ALL cases (31% vs 10%, p=0.001 for all cohorts together). The 5-year CIR of *IKZF1*-deleted cases was 2.8-fold higher compared to *IKZF1*-wildtype cases (36% vs 13%, p<0.001 for all cohorts together). Strikingly, an *IKZF1*-deletion did not further impair clinical outcome within *BCRABL1*-like cases (p=ns) whereas it remained poor prognostic within non-*BCRABL1-like* cases (p<0.001). Vice versa, *BCRABL1-like* cases did not have a poorer outcome than remaining precursor B-ALL cases within the group of *IKZF1*-deleted cases (p=ns) whereas this signature was predictive for a poorer outcome within the *IKZF1*-wildtype group (p<0.001). The absence of additional prognostic value was not explained by inactivating mutations in *IKZF1*-wildtype cases and suggests that both factors are complementary but not mutually exclusive. Multivariate analysis stratified for treatment cohort revealed that the unfavorable outcome predicted by *IKZF1*-deletions (hazard ratio 2.9, p<0.001) and *BCRABL1-like* signature (hazard ratio 2.3, p=0.003) are independent of each other and of other prognostic markers including age and white blood cell count.**Conclusions**The *BCRABL1-like* signature and *IKZF1*-deletion are independent poor prognostic markers in children with precursor B-ALL. Co-presence of both factors does not further impair prognosis. These data imply that *BCRABL1-like* ALL and *IKZF1*-deleted ALL represent partially overlapping subsets of patients which may have different biology of disease. Therefore, both prognostic markers remain relevant for patient risk stratification.

CLINICAL SIGNIFICANCE OF OCCULT CEREBROSPINAL FLUID INVOLVEMENT ASSESSED BY FLOW CYTOMETRY IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M Ramírez, C Martínez-Laperche, A Gómez-García, A Lassaletta, L Madero
Hospital Universitario Niño Jesús, Madrid, Spain

Background. The contemporary use of risk-directed systemic chemotherapy and CNS-directed treatment (intrathecal chemotherapy) has increased the 5-year relapse free survival (RFS) rates for childhood acute lymphoblastic leukemia (ALL) to 80% or more in some studies, with 90% 5-year overall survival (OS). The levels of residual disease in the bone marrow at discrete time points during therapy, has become an important prognostic factor in the management of these patients. Relapses continue to be the main cause of treatment failure, so new approaches are needed in order to identify children who relapse in the absence of known risk factors. **Aims**To assess the clinical significance of the levels of residual ALL cells in samples of cerebrospinal fluid (CSF) during therapy.**Methods**We studied 990 CSF samples from 108 patients with ALL, under an approved protocol. Samples were drawn at the time of diagnosis (108) and at each time of intrathecal therapy (882). The proportions of cells with the same immunophenotype as that of the ALL at diagnosis were assessed by multiparametric flow cytometry. Clinical data were collected from each patient for statistical analysis. **Results**Patients with CNS involvement at diagnosis (FCM+) showed a trend towards known negative prognostic factors: high risk group (36,6% vs 24%, p=0,15), higher WBC counts ($40x10^9$ vs $27x10^9$, p=0,09), T inmunophenotype (20% vs 6,4%, p=0,06), normal karyotype (23,4% vs 14%, p=0,1), and BCR-ABL fusion gene (6,7% vs 1,3%, p=0,18). The TEL-AML1 fusion gene was less represented among this cohort (10% vs 24,4%, p=0,07). No differences in RFS and OS were observed between FCM+ vs FCM- at diagnosis. Patients with CNS involvement during therapy showed significantly older age (7,1 years vs. 4,9 years, p=0,017), and higher frequencies of T-cell leukemia (30% vs 3,8%, p<0,001). Involvement of the CNS during therapy before relapse was detected in 63/882 samples. We found a significantly higher RFS and a trend to a lower OS in patients with FCM+ during therapy, especially in maintenance: 3-years RFS (72% vs. 98%, p<0,001) and 3-years OS (88% vs. 100%, p=0,2). Applying the same analysis to the 4 periods that compose therapy independently (i.e., induction, consolidation, reinduction, and maintenance), the detection of subclinical CNS disease by FCM during maintenance was associated with significantly lower 3-years RFS (61% vs. 94% p<0,001) and 3-years OS (88% vs. 98%, p=0,045).**Summary/conclusions**We show here that a sensitive methodology like flow cytometry can be applied for a close follow-up of the levels of ALL in CFS samples during therapy. The detection of residual leukemic cells at the CNS during the treatment period may identify a group of patients at high risk for relapse

[4]Ural State Medical Academy, Ekaterinburg, Russian Federation

Background. *MLL* rearrangements are found in the vast majority of infant acute lymphoblastic leukemia (ALL) cases, so in this cohort of patients minimal residual disease (MRD) monitoring by detection of fusion gene transcripts(FGt) can be a reliable tool for prediction of outcome. In MLL-Baby protocol for infant ALL conventional chemotherapy is augmented by administration of all-trans retinoic acid(ATRA). **Aim**. To investigate the prognostic significance of MRD monitoring by detection of FGt in infants with *MLL*-rearranged ALL treated by MLL-Baby protocol. **Methods.** 39 infants (12 boys, 27 girls) with defined *MLL* rearrangements were included in the current study. Median age was 4.37 months (range 0.03-11.80). MRD detection was performed by nested RT-PCR and real-time quantitative PCR (RQ-PCR) in bone marrow samples, obtained at the time of diagnosis, on the day 15 and at the end of remission induction (time point (TP) 1 and TP2) and then after each course of ATRA administration (TP3-TP9).

Median of follow-up period was 32 months (range 5-99). **Results**. All patients were MRD-positive at TP1. Proportion of MRD-negative patients increased from 8% at TP2 to 67% at TP5. At later TPs number of MRD-negative patients remained stable. TP4 was the earliest TP when discriminative data was obtained. Event-free survival (EFS) in MRD-negative patients was higher while cumulative incidence of relapse (CIR) was lower in comparison with MRD-positive ones (0.79±0.09 vs 0.13±0.11, 0.20±0.01 vs 0.85±0.03, respectively, p=0.001 in both cases). MRD-positivity at TP5 also led to unfavorable outcome (EFS 0.14±0.12 vs 0.80±0.08, CIR 0.86±0.02 vs 0.19±0.0 p=0.006 and p=0.005, correspondingly). MRD data obtained at TP5 did not bring any advantages as compared with TP4. Among initial patients characteristics (age, sex, WBC count, immunophenotype, CNS-status, type of *MLL* partner gene) and treatment response parameters (day 8 blast cell count, bone marrow status on day 15, day 36 remission achievement, TP4 MRD-status) age less than 6 months and MRD-positivity at TP4 revealed prognostic significance on risk of relapse in the univariate analysis (p=0.001 and p=0.003, respectively). In Cox regression model only MRD-positivity was associated with poor outcome (hazard ratio 3.771, 95% confidential interval 1.033-13.674, p=0.044). MRD-positivity at TP4 remained significant parameter for high risk group patients(n=18). Based on receiver operator characteristic curves analysis of RQ-PCR TP3 data the threshold level for the best discrimination between patients with various outcomes was defined as 0.1%. 7 patients with MRD higher than 0.1% at TP3 had lower EFS and higher CIR compared to 21 patients with MRD at TP3 lower than 0.1% (p=0,011 and p=0,017, relatively). In the multivariate analysis MRD value at TP3 higher than 0.1% was the single independent prognostic factor(hazard ratio 4.250, 95% confidential interval 1.159-15.585, p=0.029). Comparison between presence of MRD-positivity at TP4 and MRD level higher than 0.1% at TP3 did not allow us to determine the best discriminative factor (p=0.099 and p=0.332, correspondingly). **Conclusions**. In our series level of MRD higher than 0.1% at TP3 and any MRD-positivity at TP4 were associated with unfavorable outcome. MRD data obtained at later TPs did not bring extra advantages.

EPIGENETIC UPREGULATION OF LNCRNAS AT 13Q14.3 IN LEUKEMIA CORRELATES WITH DOWNREGULATION IN CIS OF A GENE CLUSTER REGULATING NF-KB

D Mertens[1], N Bhattacharya[1], A Garding[1], R Claus[2], M Zucknick[2], K Filarsky[2], I Keklikoglou[2], I Idler[1], A Benner[2], C Plass[2], H Döhner[1], P Lichter[2], S Stilgenbauer[1]

[1]University Ulm, Ulm, Germany
[2]DKFZ, Heidelberg, Germany

Background. NcRNA genes are central players in the regulation of target gene function. The mode of action varies from posttranscriptional regulation (i.e. miRNA genes) to regulation *in cis* or *in trans,* either via competition or blockage (e.g. lincRNA genes), by acting as organization complexes or as targeting factors of chromatin modifying factors (e.g. *HOTAIR, KCNLQT1* and *XIST*). NcRNA genes can even act as enhancers themselves. However, for the vast majority of ncRNAs, the cellular function remains enigmatic. In chromosomal band 13q14.3 near the retinoblastoma gene (*RB1*), two miRNA genes *miR15a* and *miR16-1* and two long non-coding RNA (lncRNA) genes *DLEU1* and *DLEU2* have been identified.AimsTo characterized the epigenetic tumor suppressor mechanism in 13q14.3 and its role in the pathogenesis of CLL. **Methods.** We used aPRIMES, MCIp (n=25 CLL, n=7 B-cells from healthy donors), bisulfite sequencing (CLL, n=7; sorted B-cells from healthy donors n=4), ChIP of macroH2A and H3K4me2 (CLL, n=7; and PBMC from healthy donors, n=5) and BioCOBRA/MassARRAY (CLL, n=82; sorted B-cells from healthy probands, n=19) to characterize the epigenetic makeup of the critical region in 13q14.3. Gene expression analysis of candidate genes in the critical region was performed by qRT-PCR in patients with normal karyotype (n=34) and sorted B-cells from healthy donors (n=20).

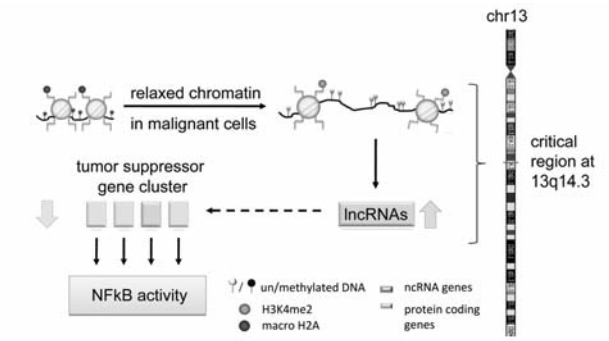

Figure 1. Model of the tumorsuppressormechanism in 13q14.3

The functional impact on the expression of candidate genes was adressed by modulation of DNA-methylation in cell lines (n=16) and luciferase reporter assays. In order to assess the functional role of the 13q14.3 candidate genes, we performed a screen of the human miRome (n=810 miR-mimics) and overexpressed and knocked down 13q14.3 candidate genes in timecourse experiments in cell lines and in primary CLL cells and quantitated the effect on NFkB signaling. Results.The critical region displays a relaxed chromatin status in CLL cells: It is enriched for activating histone modifications. The transcriptional start sites of the lncRNA genes are DNA-hypomethylated in 95% of CLL samples and is independent of cytogenetic aberrations, IGHV status and overall survival. Intriguingly, it correlates with upregulation of the lncRNA transcripts and downregulation of the protein-coding genes. This points to a regulation *in cis* of the candidate tumor suppressor genes by the lncRNA genes. 13q14.3 genes are also functionally related. *RFP2, DLEU7, KPNA3* and *KCNRG* modulate NF-kB signaling, both in cell lines and *RFP2* also in primary leukemia cells. Kinetics of NFkB induction exclude an indirect effect. Induction of NFkB by *RFP2* can be abrogated by mutation of the ubiquitin ligase activity of RFP2, coexpression of dominant negative IkB or IKK or knockdown of RelA. This points towards involvement of the canonical NFkB pathway. Moreover, a miRome-wide screen showed the *miR15/16* family localized at 13q14.3 to be the strongest inducers of NF-kB. **Conclusions.** In summary, the tumor suppressor mechanism in 13q14.3 involves long non-coding RNAgenes that are transcriptionally deregulated by DNA-demethylation in leukemic cells and arepart of a colocalized cluster of functionally related genes that modulate NF-kB signaling.

TCL1A AND ATM ARE COEXPRESSED IN CLL

D Mertens[1], I Idler[1], N Bhattacharya[1], F Mueller[2], K Ickstadt[2], S Stilgenbauer[1], H Döhner[1]
[1]University Ulm, Ulm, Germany
[2]Technical University, Dortmund, Germany

Background. Chronic lymphocytic leukemia (CLL) is characterized by the accumulation of B cells that are resistant to apoptosis. This resistance is induced by pro-survival stimuli of the microenvironment. *TCL1* and *ATM* are central to the pathogenesis of CLL and associated with more aggressive disease. Their protein products have recently been shown to physically interact in CLL cells and to impact on NF-kB signaling, which is a key regulator of apoptosis. **Aims.** To characterize the functional interrelation of *TCL1A* and *ATM* in CLL.MethodsWe used methyl-immunoprecipitation (MCIp) of CLL patient samples (n=13) and sorted B-cells from healthy probands (n=6) to assess DNA-methylation of *TCL1A* and *ATM* promoters in primary CLL cells. To quantitate expression of *TCL1A* and *ATM* upon complex external stimuli, CLL cells from n=6 patients were cocultured on human stromal cells (HS-5), conditioned medium from HS-5 cells and on murine stromal fibroblasts. Results from gene expression profiling of these cells at 7 different timepoints and quantitative RT-PCR were modeled for Bayesian networks of transcriptional interdependencies of candidate genes. Finally, in order to assess its role in the pathomechanism of CLL, *TCL1A* gene expression was knocked down in primary CLL cells and the impact on apoptosis was measured by FACS and staining with 7AAD, Annexin V/PI and CD19 APC. **Results.** In peripheral CD19 positive B-cells from healthy donors (n=9) and CLL patients (n=15), *TCL1A* and *ATM* show a significant coregulation (r=0.82, p=0.00005). Expression levels of *TCL1A* are partially deregulated in CLL cells by aberrant DNA methylation at the centromeric end of the promoter-associated CgP island (r=-0.42, p=0.037), while no aberrant DNA-methylation could be detected at the ATM promoter. *TCL1A* and *ATM* have recently shown to synergize in the activation of anti-apoptotic NFkB signaling. We therefore tested whether the observed coregulation of *ATM* and *TCL1A* also occurs upon complex external stimuli, e.g. by microenvironmantal anti-apoptotic support. To this end we cocultured primary CLL cells with different stimuli mimicking the microenvironmental support. Intriguingly, all external stimuli induced similar *TCL1* and *ATM* time-course kinetics. This was supported by Bayesian modeling using Markov-chains of the 8 most deregulated genes that included *TCL1A* and *ATM,* and these two genes showed the most significant coregulation. In line with a coordinative regulation of NF-kB signaling by *TCL1*, its knockdown induced apoptosis in primary CLL cells (p<0.001). These findings suggest that both genes functionally cooperate and modulate similar cellular pathways such as NF-kB. **Conclusions**. In the present study we show that *TCL1* and *ATM* are significantly coexpressed in malignant as well as non malignant B cells upon different microenvironmental stimuli, underlining their functional cooperation in the pathomechanism of CLL.

1099

IDENTIFICATION OF AN EXPANDED POPULATION OF TERMINALLY DIFFERENTIATED CD8+ T CELLS WITH A NOVEL PHENOTYPIC AND FUNCTIONAL PROFILE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

J Riches, J Davies, F McClanahan, S Iqbal, R Fatah, S Agrawal, A Ramsay, J Gribben
Barts Cancer Institute, London, United Kingdom

Background. Chronic lymphocytic leukemia (CLL) is associated with a profound defect in T-cell function. We have previously demonstrated global alterations in gene expression and functional defects in T cells from CLL patients, which had similarities with those described in exhausted T cells seen after persistent antigenic stimulation in chronic viral infections. **Methods.** We used multiparameter flow cytometry and functional assays to determine if peripheral blood T cell populations from previously untreated CLL patients exhibited features of exhaustion. As both advanced patient age and expansion of CMV-specific T cells in CMV seropositive patients were potential confounding factors, we matched CLL patients (n=32) and healthy controls (n=12) for both age and CMV-serostatus. **Results**. We found increased expression of CD279 (PD-1), CD160, and CD244 on both CLL CD8+ and CD4+ T cell populations from CLL when compared with healthy donor T cells, *independent* of CMV-serostatus. CD160 and CD244 were co-expressed, and were preferentially upregulated on T cells lacking expression of CD28. The expression of these molecules was dependent on the stage of T-cell development, with the highest expression on the terminally differentiated T_{EMRA} subset. Of note, we did not observe CLL-induced downregulation of the IL-7 receptor (IL-7R), which is usually seen on exhausted T-cells. We identified a subset of CD8+ T cells expressing PD-1 with high intranuclear staining of Blimp-1, a transcriptional repressor implicated in T-cell exhaustion. We examined cytokine production, proliferative capacity, and cytotoxicity to characterize T cell function. In contrast to what has been described in many chronic viral infections, T cells from CLL patients showed *increased* production of interferon-γ, and normal production of IL-2, on a background. of increased expression of the Th1/Tc1 transcription factor T-bet. Compared with T cells from healthy donors, CLL T cells showed a proliferative defect, and while they retained the ability to degranulate, they exhibited severely impaired ability to lyse idiotype-pulsed dendritic cells. Confocal microscopy identified failure of granzyme B trafficking to the immunological synapse, reflecting profound cytoskeletal dysfunction. Of clinical relevance, treatment of CLL T cells with the immunomodulatory agent lenalidomide repaired granzyme localization and enhanced lytic synapse function. **Conclusions**. We have identified a novel phenotype of expanded terminally differentiated CD8+ T cells in patients with CLL, independent of CMV serostatus. While these cells show phenotypic characteristics consistent with chronic antigen stimulation and some similarities to “exhausted”T cells, they show *increased* production of interferon-γ, and do not downregulate IL-7R. This phenotypic and functional profile closely resembles lymphocytes found in the healthy intestinal epithelium, a site of chronic antigenic stimulation, which occur at low frequencies in the peripheral blood of normal donors. These T-cells exhibit significant cytotoxic activity in healthy individuals, but CD8+ T cells from CLL patients have defective cytolytic activity due to tumor cell-induced cytoskeletal defects. These observations suggest that the expansion of CD8+ T cells seen in CLL results from an aberrant response to chronic antigen stimulation. Furthermore, the defective cytolytic activity exhibited by these cells represents a potential therapeutic target.
