The tumor microenvironment is postulated as the prime source for proliferation and survival of chronic lymphocytic leukemia (CLL) cells. Although many different signals can protect CLL cells in vitro, direct evidence for lymph node (LN)-specific pro-survival signals in vivo is sparse. Recent in vitro studies point to TNF-receptor ligand family members BAFF and APRIL mediated signaling as key events in CLL survival through activation of NF-κB. CLL patients have increased serum levels of APRIL which correlates with prognosis. Despite these correlative studies, a clear role for APRIL in CLL leukemogenesis and progression is lacking. Moreover, formal proof of APRIL expression within the LN microenvironment is absent.In this study we address the role of APRIL in CLL leukemogenesis and progression in the EμTcl-1-transgenic (Tg) mouse model.Measurement of expression levels of the APRIL receptors TACI and BCMA revealed high expression levels of TACI on $CD5^+CD19^+B220^{dull}$ aged Tcl-1 derived leukemia cells as compared to residual normal B-cells, indicating susceptibility of these cells to APRIL-induced signaling. Indeed, ex vivo culturing of Tcl-1 derived leukemia cells with rhAPRIL-conditioned medium resulted in significant increased survival as compared to inactive APRIL-mutant medium.Next, we crossed Tcl-1-Tg mice with mice overexpressing APRIL (lck-hAPRIL transgenic (tg) mice) and measured development of leukemia over time. Already at 4 months of age both a relative and an absolute increase in $CD5^+CD19^+B220^{dull}$ cell population was observed in double-Tg mice as compared to both single-Tg strains. In contrast, increased relative and absolute leukemia cells Tcl-1-Tg mice started to occur at 8 months of age. Moreover, at 4 months of age double-Tg mice showed enhanced leukemia infiltration in bone marrow, spleen and peritoneal cavity. The average lifespan of double-Tg animals was only 303 days differing significant (p=0,0011) from 408 days in the single-Tg group.Although proliferation was enhanced in leukemia cells of both double-Tg and Tcl-1-Tg mice as compared to normal B cells, no clear difference was observed between the 2 strains. In contrast, apoptosis levels in spleen fragments of APRILxTcl-1 Tg mice appeared lower than that of Tcl-1-Tg mice. In order to study whether APRIL affected leukemogenesis or progression we compared development of clonality in the CDR3 region of sorted leukemia cells. In both mouse strains sorted $CD5^+CD3^-$ revealed to be oligoclonal at 4 months of age. This indicates that although Tcl-1 induced leukemogenesis develops early in life, it remains in an ‘MBL-like’ state in single-Tg mice while presence of APRIL results in rapid outgrowth of clonal cells. This was proven by adoptive transfer studies showing enhanced development of leukemia of transferred Tcl-1-tg splenocytes in APRIL-tg versus wild-type recipient mice. In vivo relevance of APRIL was corroborated by immunohistochemistry on humanCLL LN biopsies, which showed large APRIL positive cells throughout leukemic infiltrated

lymph nodes.This study shows that APRIL, which is present in the human CLL LN microenvironment, significantly enhances leukemia development in a mouse model. These findings suggest a rationale for pharmaceutical targeting of this pathway in CLL.

THE EXPRESSION AND PHOSPHORYLATION OF HS1 ARE FINELY TUNED IN CLL PATIENTS

C Scielzo[1], E Ten Hacken[1], MT Bertilaccio[1], L Scarfò[1], M Ponzoni[1], U Restuccia[1], A Bachi[1], K Stamatopoulos[2], P Ghia[1], F Caligaris-Cappio[1]
[1]San Raffaele Scientific institute, Milano, Italy
[2]Papanicolau Hospital, Thessaloniki, Greece

Background. We previously demonstrated *i)* that HS1 expression has a profound effect on the development and progression of murine CLL, *ii)* that both leukemic cells lacking HS1 and leukemic cells carrying hyper-phosphorylated HS1 have a preferential homing to the bone marrow (BM) suggesting that the hyper-phosphorylation of HS1 leads to its inactivation rather that activation, and *iii)* that the phosphorylation status of HS1 is a potential prognostic marker in CLL, the hyper-phosphorylated form being an adverse prognostic factor.**Aims.** Our aim was twofold. First to elucidate the sites of HS1 phosphorylation and next to analyze the expression of HS1 in different tissue compartments. **Methods.** .We utilized both human and mouse samples. Primary human CLL cells were used to perform WB analyses and to identify HS1 phosphorylation sites by mass spectrometry. CLL cells were isolated from the BM and peripheral blood (PB) of the same patients and HS1 expression was comparatively analyzed. Finally we sorted different B cell populations from different lymphoid compartments in 8-week old C57BL6 mice to analyze HS1 expression.**Results.** We found that in CLL cells HS1 is differentially phosphorylated at Tyr397, where HS1 gets rapidly phosphorylated by Syk and Lyn kinases following B cell receptor stimulation. Tyr397 is not the only site of phosphorylation in hyperphosphorylated CLL cells. Preliminary data show that the total amount of Serine and Threonine is also different among different patients and we found new phosphorylation sites of HS1 in Serine and Threonine.We also investigated the expression pattern of HS1 in BM and PB of CLL patients either lacking or carrying the hyperphosphorylated form of the molecule. We observed that in the same patient HS1 is differentially expressed in the BM as compared to the PB; specifically that BM CLL cells lack HS1 expression when the protein is hyperphosphorylated in PB cells. These data suggest that HS1expression is tuned in different compartments and that cells that preferentially accumulate in the BM are the ones that have switched off the protein expression.We previously demonstrated that HS1 phosphorylation in modulated also in human normal B cells depending on the activation status of the cell. We asked whether this can occur also for HS1 expression: to this aim we analyzed the expression of HS1 in murine B cells. We isolated cells from spleen, peritoneal cavity and BM of wild type mice (C57BL6) and we sorted the distinct B cells populations based on differential surface marker expression. We observed that HS1 is differentially expressed in the lymphoid compartments, especially in the BM were HS1 is expressed at very low level in Pre and Pro-B cell lineages while it is expressed at a higher level in mature B cells.**Conclusions.** These findings strengthen our previous observation that HS1 phosphorylation has an important role in CLL. The fact that HS1 expression appears to be finely modulated in CLL patients suggests its functional role in the behaviour of leukemic cells. In addition the modulation of HS1 in normal B cells can help understanding its function in B-cell ontogeny

Chronic myeloid leukemia - Biology and prediction of response

1102

REGULATION OF CHRONIC MYELOID LEUKEMIA STEM CELLS BY LEUKEMIA ONCOGENE EVI1

T Sato[1], S Goyama[2], K Kataoka[2], T Tsuruta[2], R Nasu[2], M Nakagawa[2], K Kumano[2], M Kurokawa[2]
[1]Tokyo University Hospital, Tokyo, Japan
[2]Dept of Hematology & Oncology, Grad. Sch. of Medicine, Tokyo University, Tokyo, Japan

Background. Chronic myeloid leukemia (CML) is a hematopoietic stem cell (HSC) disease caused by BCR-ABL oncogene, and now newly targeted therapies toward CML stem cells are warranted because of the minimal effect of BCR-ABL-targeted tyrosine kinase inhibitors. Due to its similarity to HSCs, CML stem cells is worth being analyzed with a guide of HSC-specific factors, one of which is Evi1, a transcription factor highly expressed in HSCs and activated in myeloid malignancies including CML blast crisis (CML-BC). Our newly generated Evi1-GFP knock-in mice, the Evi1-reporter mouse line, proved to be HSC-reporter mice, and enabled us to dig into behavior monitoring of Evi1-high leukemia cells in vivo. **Methods.** We developed murine Evi1-reporter models of CML in a chronic phase (CML-CP) and CML-BC, the former by intercrossing Evi1-GFP knock-in mice with p210 BCR/ABL transgenic mice or retroviral induction of BCR/ABL into Evi1-GFP knock-in bone marrow cells, the latter by retroviral induction of BCR/ABL and NUP98/HOXA9. We also performed quantitative RT-PCR to evaluate EVI1 expression in the stem/progenitor fraction of bone marrow cells of healthy donors and CML-CP patients. **Results.** In CML-CP model, we found that Evi1 positive CML cells as a minor population, about 0.1-0.5% of total bone marrow cells, predominantly reside in the CML stem cell fraction (Lin- Sca-1+ c-kit+ (LSK)), but Evi1 expression is sharply downregulated even in myeloid progenitor (Lin- Sca1- c-kit+ (MP)) cells or more differentiated cells. Evi1-high CML LSKs showed an enhanced colony-forming capacity and were more quiescent than the other CML cells, which was correlated with its gene expression profile. The characteristic features of Evi1-high CML LSKs by GSEA analysis were hyper metabolism, activated TGF-beta signaling and activation of ABC transporters. Strikingly, Evi1-high CML LSKs were more resistant to in vivo nilotinib administration than Evi1-low CML LSKs. In concert with our data of Evi1-trafficking CML mouse, in CML patients, we have also recently found that CD34+ 38- CML stem cells showed higher EVI1 expression than CD34+ 38+ CML progenitor cells or total CML cells, which implies that EVI1 could mark CML stem cells as well as normal HSCs. In CML-BC model, which more differentiated MPs have a high leukemia initiating potential, a sizable fraction of MPs show distinct Evi1 expression. Evi1-high MP cells showed a colony-replating ability with active cycling status, and remarkably, in vivo transplantation assay revealed CML-BC stem cells that can recapitulate the disease are exclusively enriched in Evi1-high MPs. **Conclusions**. Our data of CML-CP model showed that high Evi1 expression could enrich CML stem cells and mark nilotinib-resistant cells, and those of CML-BC model were the first report to show that a limited fraction with high Evi1 expression within stem/progenitor cells possesses enhanced proliferative and leukemia-initiating capacities. The Evi1-trafficking leukemia model provides us with a new tool for dissecting pathogenesis and exploiting novel targeted therapies to eradicate CML stem cells, and would ensure an establishment of Evi1-related therapy for CML stem cells, which could be applied to EVI1-high malignancies.

Background and Aims. point mutations within the Bcr-Abl kinase domain (KD) have been implicated in resistance to tyrosine kinase inhibitors (TKI) in chronic myeloid leukemia (CML) and Ph+ acute lymphoblastic leukemia (ALL) patients. Sanger sequencing (SS) is the recommended method for mutation screening, but it cannot identify mutant subpopulations <20%, nor can it discriminate polyclonal from compound mutations, unless it is preceded by cloning. The majority of patients positive by SS have a single mutant clone detectable, more rarely two or more; multiple mutations are thought to accumulate mainly after multiple lines of therapy. The recent development of ultra-deep amplicon sequencing protocols based on the Roche 454 next-generation-sequencing (NGS) technology has opened the way to a more accurate qualitative and quantitative characterization of the mutant clones that survive TKI therapy. **Methods.** longitudinal analysis of 92 samples collected at regular timepoints during treatment was retrospectively performed in 25 patients with TKI-resistant and 5 patients with TKI-sensitive CML or Ph+ ALL. NGS allowed to screen the Bcr-Abl KD with a lower detection limit of 0.1% and to reconstruct the clonal architecture of the mutated subpopulations, following quantitatively their evolution over time. SS was performed in parallel. **Results.** NGS revealed an unexpected complexity in the Bcr-Abl mutation status. In 94% of the samples, the higher sensitivity allowed to identify a variety of minor subclones (n=2-12 per sample; abundance,1%-18.8%) harbouring point mutations and more rarely insertions or deletions, alone or in addition to the dominant mutations detectable by SS. In all the cases, complexity was found to be high since diagnosis. The analysis of patients who later showed evidence of a single TKI-resistant mutation by SS (n=12) showed that, in all cases, additional low-level mutations were present - either in a small subfraction of the dominant mutated clone, or in an independent one, or both. The analysis of patients who accumulated multiple TKI-resistant mutations as assessed by SS showed that the newly acquired mutations could arise in the pre-existing mutated subclone(s) (2/13 patients), or in a previously wild-type subclone (2/13 patients), but they more often arose in parallel in both wild-type and mutated subclones (9/13 patients) - generating a complex jigsaw of multiple, competing populations harbouring different combinations of mutations. However, quantitative follow-up of these subclones showed that only one or a few take over, and some specific compound mutants (T315I+F359V; F317L+M351T..) were found to have greater 'fitness' over individual mutants, while others (T315I+E355G; Y253H+E255V..) have lower. **Conclusions.** mutation(s) detectable by SS are often the 'tip of the iceberg'. A mosaic of small mutated subclones are present since diagnosis. Depending on their absolute and relative 'fitness', some may survive TKI therapy, although only one or a few will be capable to achieve dominance; acquisition of additional mutations dictates further dynamics of shrinkage/expansion. The level of heterogeneity is reduced only transiently when a highly-resistant subclone takes over. Reasoning on the basis of mutation(s) detectable by SS may not always be sufficient to predict responsiveness to a TKI or substantiate clinical decisions.

Background. Ponatinib is a potent, oral, pan-BCR-ABL inhibitor active against the native enzyme and all tested resistant mutants, including the uniformly resistant T315I mutation. **Methods.** The PACE (Ponatinib Ph+ALL and CML Evaluation) trial started in Sept 2010. Patients with refractory CML (CP, AP or BP) or Ph+ALL resistant or intolerant (R/I) to dasatinib or nilotinib or with T315I received 45 mg ponatinib orally once daily. The trial is ongoing; enrollment completed in Sept 2011. Data as of 17 Jan 2012 are reported. Median follow-up was 6.6 months. **Results**. In total, 449 patients were enrolled, 5 of whom were ineligible (post-imatinib, non-T315I) but treated. Median age was 59 (18-94) years; 53% were male. Diagnoses were: 271 CP-CML (R/I=207; T315I=64); 79 AP-CML (R*60; T315I=19); 94 BP/ALL (*48; T315I=46). Median time from diagnosis to ponatinib was 6 years. Prior TKIs included imatinib (96%), dasatinib (85%), nilotinib (66%), bosutinib (7%); 94% failed >2 prior TKIs, 59% failed >3 prior TKIs. A total of 83% had a history of resistance to dasatinib or nilotinib; 12% were purely intolerant. In CP, best response to most recent dasatinib or nilotinib was MCyR 25%. Frequent mutations confirmed at entry included 29% T315I, 8% F317L, 4% E255K, 4 % F359V, and 3% G250E. Response rates are presented in Table 1. Overall, 64% remained on therapy (77% CP) at the time of reporting. Most frequent reasons for discontinuation were progression (12%) and AE (10%). Most common drug- related AEs were thrombocytopenia (33%), rash (33%), and dry skin (26%). **Conclusions**. Ponatinib has substantial activity in heavily pretreated patients and those with refractory T315I. Response rates continue to improve with longer follow-up. Multivariate analyses of predictors of outcome will be presented.

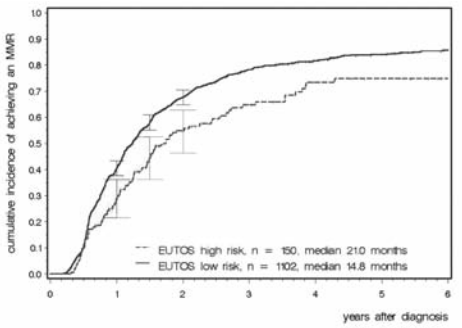
Background. The EUTOS Score was validated as a prognostic tool for the achievement of complete cytogenetic response at 18 months for chronic-phase (CP) CML patients under imatinib therapy. Using only two variables at diagnosis (basophils and spleen size), the score identifies high-risk patients with a better positive predictive value than the Sokal and EURO scores (Hasford et al. Blood 2011). **Aims**. We sought to evaluate the clinical impact of the EUTOS score to predict molecular response and to analyze the composition of the risk groups compared to the EURO score. We analyzed patients from the German CML-Study IV, a randomized 5-arm trial (imatinib 400 mg vs. imatinib 800 mg vs. imatinib in combination with interferon-alpha vs. imatinib in combination with araC vs. imatinib after interferon failure). **Results**. From July 2002 to December 2011, 1,541 patients with CP CML were randomized. 1,337 patients were evaluable for overall and progression-free survival (OS and PFS), 1,252 for molecular responses. 749 of these patients were part of the score development project. Therefore cytogenetic analyses were not described here. According to the EURO score, 36% of patients (n=475) were classified as low-risk, 51% (n=681) as intermediate-risk, and 12% (n=167) as high-risk. Applying the EUTOS score, 88% belonged to low-risk (n=1163) and 12% to the high-risk group (n=160). 12% of the high-risk patients using EUTOS score would have been classified as low-risk (n=19) according to EURO score, 45% as intermediate- (n=68) and in 43% as high-risk (n=73). Vice versa, 94 high-risk patients according to EURO (56%) were classified as low-risk using EUTOS score. Patients with high-, intermediate-, and low-risk EURO score achieved MMR after a median of 22, 16, and 13 months (p-values: 0.03 for low- vs. intermediate-risk groups and <0.001 for high- vs. low/intermediate-risk groups) and MR[4] (BCR-ABL <=0.01%) in 59, 41, and 34 months (p-values: 0.04 for low- vs. intermediate-risk groups and <0.001 for high- vs. low/intermediate-risk groups). At 12 months, the proportion of patients in MMR was 38%, 46%, 54% for high-, intermediate-, and low-risk patients, respectively. Patients with high-risk EUTOS score achieved molecular responses (MMR and MR[4]) significantly later than patients with low-risk EUTOS score (time to MMR: median 21.0 vs. 14.8 months, p<0.001, Fig. 1; time to MR[4]: median 60.6 vs. 37.2 months, p<0.001). Significantly less EUTOS high-risk patients achieved MMR at 12 months than EUTOS low-risk patients (31% vs. 51%, p<0.001). OS after 5 years was 85% for high- and 91% for low-risk patients (p=n.s.), PFS was 85% and 90%, respectively (p=n.s.). **Conclusions**. The EUTOS high-risk population differs substantially from the EURO high-risk population. Therefore the results of clinical trials using different scores have to be interpreted with utmost caution. The EUTOS score clearly separates CML patients according to MMR and MR[4] and should be used in future trials with tyrosine kinase inhibitors in CML.



1106

AN EXPLORATORY ANALYSIS FROM 3-YEAR DASISION FOLLOW-UP EXAMINING THE IMPACT ON PATIENT OUTCOMES OF EARLY COMPLETE CYTOGENETIC RESPONSE AT 3 MONTHS AND MAJOR MOLECULAR RESPONSE AT 12 MONTHS

[6]Bristol-Myers Squibb, Wallingford, CT, United States of America

[7]Universitätsklinikum Jena, Jena, Germany

[8]University of Turin, Orbassano, Italy

Background. In the phase 3 DASISION trial of dasatinib v imatinib in patients with newly diagnosed chronic myeloid leukemia-chronic phase (CML-CP), dasatinib showed superior efficacy over imatinib with higher rates of complete cytogenetic response (CCyR) and major molecular response (MMR) at 12 months, lower rates of transformation and acceptable tolerability (Kantarjian et al. Blood 2012;119:1123). The value of earlier and deeper response in outcome prediction has emerged in CML-CP patients receiving first-line imatinib. A recent analysis of patients treated with dasatinib or nilotinib as initial therapy for CML has shown that patients who achieve a CCyR at 3 months have significantly higher probability of event-free survival at 3 years than those without CCyR (Jabbour et al. JCO 2011;29:4260). **Aims.** Explore landmark analyses of CCyR at 3 months and MMR at 12 months on PFS. **Methods.** Patients with CML-CP diagnosed within 3 months were randomized to receive dasatinib 100 mg QD (n=259) or 400 mg imatinib QD (n=260). MMR was defined as a BCR-ABL/ABL transcript level of ≤ 0.1% on the international scale (3-log reduction compared to the standardized baseline). PFS events considered were increasing WBC; loss of complete hematologic response or major cytogenetic response; progression to AP/BP; or death from all causes. Kaplan Meier curves of progression in patients achieving or not achieving CCyR at 3 months were generated. **Results.** Patients receiving dasatinib v imatinib had faster responses; median time to CCyR and MMR was 3.2 v 6.0 months and 15 v 36 months, respectively. Higher rates of CCyR at 3 months were achieved in patients receiving dasatinib v imatinib (54% v 31%). The rates of MMR at 12 months were also higher for patients receiving dasatinib v imatinib (47% v 28%). Of those patients who achieved MMR at 12 months, 97% and 92% of patients receiving dasatinib v imatinib, respectively, maintained their MMR at 24 months. In a landmark analysis, CCyR at 3 months was associated with higher PFS rates (p-value 0.0372). Similarly, achieving an MMR at 12 months was also associated with higher PFS (p-value 0.0380). Given the low number of events and exploratory nature of this analysis these data should be interpreted cautiously. Additional analyses will be reported exploring measures potentially predictive of improved outcome. Updated analyses will be presented with minimum 36-month follow-up. **Conclusions.** In patients with newly diagnosed CML-CP, first-line dasatinib resulted in faster and deeper responses compared with imatinib. The achievement of an early deep response at 3 and 12 months appear predictive of improved PFS in patients with early CML-CP treated with tyrosine kinase inhibitors.

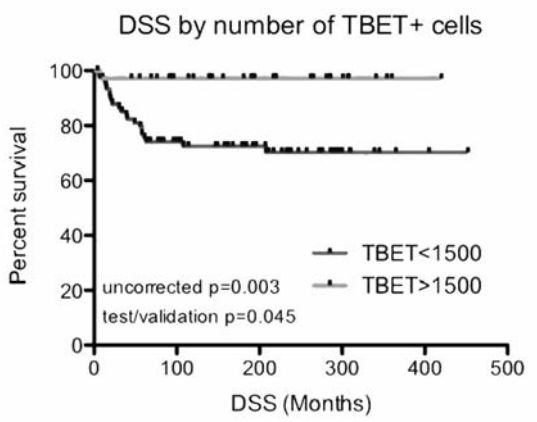
Hodgkin's lymphoma

1107

THE MICROENVIRONMENT IN CLASSICAL HODGKIN LYMPHOMA SHOWS EVIDENCE OF A TH1 AND NOT TH2 RESPONSE WITH TBET EXPRESSION BEING ASSOCIATED WITH IMPROVED SURVIVAL AND EBV STATUS

P Greaves, A Clear, A Owen, A Wilson, J Matthews, M Calaminici, J Gribben
Barts Cancer Institute, London, United Kingdom

Background. The microenvironment in classical Hodgkin lymphoma (CHL) is dominated by CD4+ T cells with EBV detected in 20-30% of cases. The microenvironment has been described as TH2-dominated and suppressive although functional evidence is sparse. High FOXP3/Treg infiltration is associated with favourable prognosis but the mechanism for this is uncertain. The significance of TH1 cells remains unclear although some literature suggests this may be associated with EBV. **Aims.** Using tissue microarray (TMA) immunohistochemistry with automated image analysis we assessed expression of transcription factors (TF) including TBET (TH1) and CMAF/GATA3 (TH2), validated with single-cell cytokine profiling of frozen single-cell-suspensions (SCSs) from patient-derived tissue and determined prognostic associations. **Methods.** Formalin-fixed paraffin-embedded tissue was available for 110 patients: median age 30, 65% male, 71% advanced stage, median follow-up 16.5 years (2-40). Triplicate TMA cores were stained for TBET, GATA3, CMAF and EBER-in-situ-hybridization. Cells were counted using an automated system, expressed as total numbers per 1mm^2 and patient groups discriminated using cutpoints based on numbers of cells expressing each marker using a test/validation set methodology. Survival was analysed using the Kaplan-Meier method for overall survival (OS), disease-specific survival (DSS) and freedom from first-line treatment failure (FFTF). The significance of survival differences were assessed using the logrank method. Five diagnostic CHL biopsies, two tonsils and three reactive nodes SCSs were then assessed for cytokine profile. Thawed suspensions were stimulated with PMA/inomycin and stained for CD3, CD4 and either TH1-specific IL2, TNF-alpha and Ifn-g, or TH2-specific IL4, IL10, IL13 and IL21, and analysed by flow cytometry.



Results. TBET was variably expressed in the microenvironment and HRS nuclei in most patients ranging from 14-5406 cells/mm^2 (median 879). Analysis revealed that using a cutpoint of 1500 cells/mm^2 patients with higher infiltrate of TBET positive cells had superior DSS (5 year DSS 97% vs 77%; p=0.045; Figure 1) but no significant difference in OS (92%vs76%; p=0.13). Although TBET was expressed in the malignant cell in the majority of cases (>80%), with strong expression in 25%, the level of expression had no impact on outcome. TBET expression in the microenvironment was significantly higher (p=0.0033) in EBV+ cases (35%; median expression = 1448 cells/mm^2) than EBV- (median expression = 669 cells/mm^2); TH1 cytokines were expressed at high levels in CHL SCS-derived CD3+CD4+ lymphocytes in all cases: IFN-G (median=31%; range 18-66%) and TNF-A (median=26%; range 8-20%) but no detectable IL2 expression. Median TH1-cytokine expression was lower in benign samples: IFN-G=19.7% (p=ns); TNF-alpha=4.6% (p=0.03). Nuclear expression of GATA3 or CMAF was minimal in the CHL microenvironment of all cases while there was no expression of IL4, IL13 or IL21 in any CHL SCS-derived CD3+CD4+ lymphocytes despite expression in reactive nodes. **Conclusions**. We find no evidence for over-representation of TH2 in the CHL microenvironment with clear evidence for a TH1 presence, more notable in EBV-associated cases, which may have prognostic significance. This challenges the assumption of a TH2 bias being responsible for the failed immune response in CHL. Interactions between CD4+ T cells, EBV, other immune and HRS cells remains to be demonstrated functionally.

COMPARING INTENSITY OF CHEMOTHERAPY FOLLOWED PET-GUIDED RADIOTHERAPY IN PATIENTS WITH ADVANCED STAGE HODGKIN LYMPHOMA: FINAL RESULTS OF THE GHSG HD15 TRIAL

M Engert[1], H Haverkamp[1], C Kobe[1], J Markova[2], C Renner[3], A Ho[4], J Zijlstra[5], Z Král[6], H Stein[7], H Eich[1], RP Müller[1], M Dietlein[1], P Borchmann[1], V Diehl[1]

[6]University Hospital of Brno, Brno, Czech Republic
[7]Berlin Reference Center for Lymphoma and Hematopathology, Berlin, Germany

Background. Intensified chemotherapy with eight cycles of BEACOPP$_{escalated}$ in advanced stage Hodgkin lymphoma (HL) is highly effective but also associated with relevant treatment related toxicity. In addition, the need for radiotherapy in this setting is unclear. To reduce toxicity without losing efficacy the GHSG thus conducted the prospective randomized clinical HD15 trial investigating two less intensive chemotherapy variants, followed by PET guided radiotherapy. **Methods.** Between January 2003 and April 2008, 2182 patients with newly diagnosed, histology-proven HL aged 18-60 years were included. Patients in Ann-Arbor stage IIB with large mediastinal mass or extranodal lesions, or those in stage III or IV were randomly assigned to receive either eight cycles of BEACOPP$_{escalated}$ (8B$_{esc}$), six cycles of BEACOPP$_{escalated}$ (6B$_{esc}$), or eight cycles of BEACOPP$_{14}$ (8B$_{14}$). After completion of chemotherapy, patients in partial response (PR) with a persistent mass measuring 2.5 cm or more were assessed by PET. Only patients who were positive on centrally-reviewed PET scan received additional radiotherapy (RT) with 30Gy. The study was designed to show non-inferiority for the primary endpoint, freedom from treatment failure (FFTF).Results. The full analysis set comprised 2126 patients. Baseline characteristics were well balanced between groups. Hematological toxicities occurred in 92.4% (8B$_{esc}$), 91.7% (6B$_{esc}$), and 79.7% (8B$_{14}$) ofcases. After a median follow-up of 48 months, there were 53 deaths (7.5%) in the 8B$_{esc}$ group, 33 (4.6%) in the 6B$_{esc}$ group and 37 (5.2%) in the 8B$_{14}$ group. There were 72 secondary cancers including 29 secondary AML/MDS, 19 (2.7%) after 8B$_{esc}$, 2 (0.3%) after 6B$_{esc}$ and 8 (1.1%) after 8B$_{14}$. Complete response (CR) was achieved in 90.1% of patients after 8B$_{esc}$, in 94.2% after 6B$_{esc}$ and in 92.4% after8B$_{14}$ (p=0.01). FFTF at 5 years was 84.4% in the 8B$_{esc}$ group, 89.3% in the 6B$_{esc}$ group (97.5% confidence interval (CI) for difference 0.5% to 9.3%), and 85.4% in the 8B$_{14}$ group (97.5 CI -3.7% to 5.8%), respectively (see figure). Overall survival at five years was 91.9%, 95.3%, and 94.5%, and was also better with 6B$_{esc}$ compared to 8B$_{esc}$ (97.5% CI 0.2% to 6.5%). PFS results were similar to FFTF. PET scans performed after chemotherapy were centrally reviewed in 822 patients of whom 739 were in PR with residual mass ≥ 2.5 cm having no other exclusion criteria. 548 patients were PET-negative (74.2%) and 191 were PET-positive (25.8%). Importantly, PFS was comparable between patients in CR or those in PET-negative PR after chemotherapy with 4-year PFS rates of 92.6% and 92.1%, respectively. Only 11% of all patients in HD15 received additional RT as compared to 71% in the prior HD9 study. **Conclusions**. Six cycles of BEACOPP$_{escalated}$ followed by PET-guided RT are more effective and less toxic compared to 8 cycles in patients with advanced stage HL. In particular, critical toxicities observed with 8 cycles whereredуced with 6 cycles of BEACOPP$_{escalated}$. PET performed after chemotherapy can guide the need of additional RT in this setting and reduces the number of patients requiring RT.

1109

LONG-TERM FOLLOW-UP RESULTS OF AN ONGOING PIVOTAL STUDY OF BRENTUXIMAB VEDOTIN IN PATIENTS WITH RELAPSED OR REFRACTORY HODGKIN LYMPHOMA (HL)

S Smith[1], R Chen[2], A Gopal[3], S Ansell[4], J Rosenblatt[5], K Savage[6], J Connors[6], A Engert[7], E Larsen[8], E Sievers[8], A Younes[9]

[7]University Hospital of Cologne, Cologne, Germany
[8]Seattle Genetics, Inc., Bothell, United States of America
[9]University of Texas MD Anderson Cancer Center, Houston, United States of America

Background. CD30 expression by Reed-Sternberg cells is a defining feature of HL. Brentuximab vedotin comprises an anti-CD30 antibody conjugated by a protease-cleavable linker to MMAE, a microtubule-disrupting agent. Brentuximab vedotin selectively induces apoptotic death of CD30+ cells by binding, internalizing, and releasing MMAE. **Aims.** A pivotal phase 2 study was conducted to determine the efficacy and safety of brentuximab vedotin in patients (pts) with relapsed or refractory HL after autologous stem cell transplant (auto-SCT) (ClinicalTrials.gov #NCT00848926); long-term follow-up data from this ongoing trial are presented.

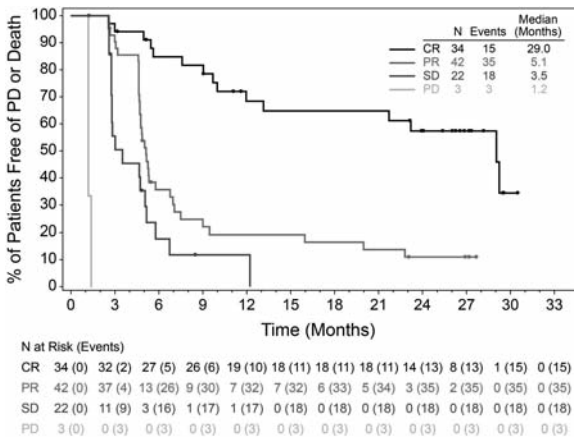

Figure 1. Progression-free Survival by Best Clinical Response.

Methods. The primary endpoint was the objective response rate (ORR) per independent review according to the Revised Response Criteria for Malignant Lymphoma (Cheson 2007). Pts received 1.8 mg/kg brentuximab vedotin every 3 weeks as a 30-minute outpatient IV infusion for up to 16 cycles. Informed consent was obtained for all patients. **Results.** 102 pts were enrolled; 53% were female and the median age was 31 yrs (range, 15-77 yrs). Pts had received a median of 3.5 (range 1-13) prior cancer-related systemic therapies excluding auto-SCT. 71% of pts had primary refractory disease and 42% had not responded to their most recent prior therapy. As previously reported, the ORR was 75% (76 of 102 pts) with complete remissions (CRs) in 33% of pts (n=34). At the time of this analysis (January 2012), the median observation time from first dose was 26.5 months (mths; range, 1.8 to 30.9 mths). 38 of 102 pts have died and the median overall survival has not yet been reached. The estimated 24-mth survival rate was 65% (95% CI: 55%, 74%). The median progression-free survival (PFS) for all pts was 5.6 mths (range, 1.2 to 30.5+ mths). 34 pts obtained a CR with brentuximab vedotin; 13 remain in CR and have not started a new anti-cancer therapy since discontinuing study treatment other than 3 who received prophylactic allo-SCT following brentuximab vedotin while in CR. The PFS for these 13 pts ranged from 23.1+ to 30.5+ mths. The median PFS for pts who obtained a CR was 29.0 mths, which was notably longer than the median PFS for patients who obtained a partial remission (PR; 5.1 mths) or stable disease (SD; 3.5 mths). As previously reported, the most common (≥15%) treatment-related adverse events (AEs) of any grade were peripheral sensory neuropathy, nausea, fatigue, neutropenia, and diarrhea. AEs ≥ Grade 3 occurring in ≥5% of pts were neutropenia, peripheral sensory neuropathy, thrombocytopenia, and anemia. **Conclusions.** 34 of 102 heavily pretreated pts (33%) with relapsed or refractory HL obtained a durable CR with brentuximab vedotin treatment. More than a third of the pts who obtained a CR remain in CR at the time of this long-term follow-up analysis. The median PFS for pts who obtained a CR was 29.0 mths, which was notably longer than the median PFS for patients who obtained a PR or SD (5.1 mths and 3.5 mths, respectively).

1110

OUTCOME OF PATIENTS WITH EARLY STAGE HODGKIN LYMPHOMA ACCORDING TO GHSG AND NCIC-CTG RISK CLASSIFICATION: THE PRINCESS MARGARET HOSPITAL EXPERIENCE

L Davison[1], A Albert-Green[1], R Tsang[1], D Hodgson[1], V Kukreti[1], J Kuruvilla[1], A Sun[1], W Wells[2], K Tybinkowski[1], M Gospodarowicz[1], M Crump[1]
[1]Princess Margaret Hospital, Toronto, Canada
[2]Southlake Regional Health Centre, Newmarket, Canada

Background. Early stage Hodgkin lymphoma (HL) carries a very favourable prognosis; nevertheless, a subset of patients progress after first-line therapy, and others achieve cure at the expense of considerable treatment-related toxicity. Risk-adapted therapy has been tested, aimed at minimizing toxicity for those with favourable HL. Criteria used to identify high risk patients were developed at a time when sub-total nodal irradiation was standard for early stage HL, questioning their relevance in the modern era of combined modality therapy (CMT). **Aims.** We wished to determine whether the German Hodgkin Study Group (GHSG) or National Cancer Institute of Canada Clinical Trials Group (NCIC-CTG) stratification criteria for early stage HL could discriminate between low and high-risk patients treated with doxorubicin-based CMT, in terms of overall (OS) and progression-free survival (PFS). **Methods.** We performed a retrospective review of 495 stage I-II HL patients diagnosed and treated at PMH from 1997 to 2009. Patients were stratified into early favourable, early unfavourable or advanced groups using GHSG and NCIC-CTG risk factors, and their OS and PFS assessed by group.

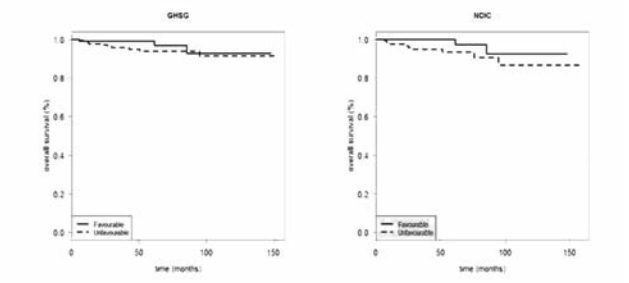

Figure 1. Kaplan-Meier estimates of overall survival probabilities by GHSG and NCIC-CTG classification schemes.

Results. Before multiple imputation to complete missing data, 21%, 44.6% and 10.3% of patients were classified as early favourable, early unfavourable and advanced, respectively, according to GHSG criteria (24% unclassifiable due to missing data); similarly 18.6%, 32.3%, 38.6% and 10.5% had early favourable, early unfavourable, advanced or unclassifiable HL, respectively, by NCIC-CTG criteria. After a median follow up of 37.4 months, OS was 94.4% and PFS 88.1%. After controlling for treatment intensity, there was no statistically significant difference in OS or PFS between early favourable and early unfavourable groups as defined by either criteria set. Hazard ratios (HR) for death and progression were 1.779 (95% CI -0.422, 1.573; p=0.256) and 1.327 (-0.396, 0.961; p=0.410), respectively, for unfavourable compared with favourable patients by GHSG stratification, while HRs by NCIC-CTG criteria for death and progression were 3.556 (-0.286, 2.823; p = 0.110) and 1.451 (-0.560, 1.304; p = 0.426). Estimated 10-year OS for early favourable and early unfavourable patients by GHSG criteria was 92.8% (95% CI 0.762, 0.979) and 91.3% (0.827, 0.958), respectively, while PFS was 87.8% (0.739, 0.945) and 77.7% (0.637, 0.868). Similar estimates were seen for patients categorized by NCIC-CTG criteria: OS for favourable patients was 92.4% (0.714, 0.981) vs 86.5% (0.719, 0.938) for unfavourable, and PFS was 85.9% (0.693, 0.939) and 71.8% (0.499, 0.854), respectively. Patients with advanced disease by both criteria had significantly inferior OS relative to favourable patients, while PFS, although inferior, was only marginally significant. Exploration of individual prognostic factors defined by GHSG and NCIC-CTG criteria revealed extranodal disease and age > 40 predicted OS, while extranodal disease, elevated ESR and bulky mediastinal disease were predictive of PFS. **Conclusions**. Although individual risk factors carry prognostic relevance, previously proposed

criteria may not identify patients at increased risk of treatment failure or death. As these criteria are increasingly used to deliver risk-adapted therapy, further studies are needed to identify additional, biologically meaningful prognostic factors for early stage HL.

TREATMENT-RELATED MORTALITY IN PATIENTS UNDERGOING THERAPY FOR ADVANCED HODGKIN'S LYMPHOMA: ANALYSIS OF THE GERMAN HODGKIN STUDY GROUP (GHSG)

D Wongso, A Plütschow, M Fuchs, H Haverkamp, B Klimm, S Sasse, V Diehl, A Engert, P Borchmann
University Hospital of Cologne, Cologne, Germany

Background. The outcome of patients with Hodgkin's Lymphoma (HL) has improved over the past decades. Even patients with advanced-stage HL show a 10 year freedom from treatment failure (FFTF) of 82% and an overall survival (OS) of 86% when treated with eight cycles of $BEACOPP_{escalated}$ (Bleomycin, Etoposid, Adriamycin, Cyclophosphamide, Vincristine, Procarbacine, Prednisone). However, $BEACOPP_{escalated}$ has been associated with some acute and long-term toxicity, including a concern for treatment related mortality (TRM). **Aims.** The objectives of this study were to identify possible risk factors for TRM and help improve supportive-care strategies in advanced stage HL patients undergoing $BEACOPP_{escalated}$, thus reducing TRM and improving overall survival in these patients. **Methods.** We investigated the incidence of TRM and possible risk factors in a retrospective analysis of 3402 patients with advanced HL who were treated with $BEACOPP_{escalated}$ within the GHSG HD9, HD12 and HD15 multicenter clinical trials between 1993 and 2008. **Results.** The overall TRM rate was 1· 9% (HD9 = 6/439, HD12 = 38/1569, HD15 = 20/1394). TRM occurred during the first course of $BEACOPP_{escalated}$ in 20 cases (31· 3%). The median age of patients who died from TRM was 50 years (17 to 64), as compared to 33 years (16 to 65) in the whole group of analyzed patients. Most common causes of TRM were neutropenic infections, either bacterial or (n=56, 87· 5%). Univariate analyses of possible risk factors revealed that TRM was six times increased in patients older than 40 years, four times increased in patients with a poor performance status (ECOG=2 or Karnofsky<80) and three times increased in patients with an International Prognostic Score (IPS) of ≥3 compared with patients without these risk factors, respectively. Gender, stage of disease, B-symptoms, and well-known risk factors such as 3 or more involved lymph node areas, extranodal involvement, large mediastinal tumor or elevated ESR were not associated with an increased risk of TRM. In a multivariate analysis of TRM and all mentioned risk factors, age and poor performance status were the only significant prognostic factors of TRM. A particularly higher risk of TRM is seen in patients between 40 and 50 years of age with poor performance status as well as in patients who are 50 years and older. According to the identified risk factors age and performance status, it is possible to define a risk score for TRM ranging from zero to three. Patients with a TRM-Score of ≥2 have an increased risk for TRM. **Conclusions.** Since important risk factors for TRM could be identified in our study, possible measures should be taken to reduce toxicity with $BEACOPP_{escalated}$ in patients with these risk factors. Such measures include a pre-phase treatment of patients over 40 years of age, inpatient treatment of patients with risk factors at least for the first course of $BEACOPP_{escalated}$, an earlier administration of G-CSF starting from day 4 of every cycle instead of day 8 as was previously the case, as well as the prophylactic use of antibiotics during the whole chemotherapy period. These measures have currently been implemented in the GHSG ongoing trial HD18 for advanced stage HL.

Non-Hodgkin's lymphoma - Clinical

[12]University Hospital Großhadren, Ludwig Maximilians University, Munich, Germany

Background. CNS involvement in Mantle Cell Lymphoma (MCL) is an uncommon but devastating event. Limited data exist to define true incidence or clinical features. **Aims**. To describe the clinical characteristics and outcomes of patients with CNS involvement in Mantle Cell Lymphoma. **Methods.** The study design was a multicentre retrospective case series. 12 participating institutions provided 1) total number of patients in their MCL database, 2) number with CNS involvement and 3) detailed information including demographics, baseline characteristics, presentation, prior treatments, investigations, subsequent therapies and outcomes. **Results.** 1314 patients with MCL were included in this analysis. 53 patients with CNS involvement were identified between 1988 and 2011. The crude cumulative incidence of CNS involvement was 4.0%. Of those with CNS disease, 71% were male, median age 61 years (38 - 82). At diagnosis, 36 (68%) had classical MCL, 15(28%) blastoid histology. Among 26 patients with data, Ki67 value by immunohistochemistry was 60% or higher in 12 cases (46%). 91% of patients were stage IV, 52% had B symptoms at presentation, and the median white cell and lymphocyte counts were 17.5 x 10^9/L and 12.2 x10^9/L respectively. Among 24 patients with data, high MIPI score (6 or more) was seen in a striking 18(75%). 9 patients had CNS involvement at diagnosis. The commonest neurological symptoms were weakness (26%), altered mental state (25%), ocular/diplopia (21%) and headache (19%). Sensory disturbances were less common. 5% were asymptomatic. Lumbar puncture was performed in 46 patients, with 85% positive by cytology. Flow cytometry improved the yield to 91% in the 33 patients tested. Radiographic changes suggestive of CNS disease were seen in 36/44 (82%) cases performed, with leptomeningeal changes was present in 15/36 (42%) and cortical lesions in 11/36 (31%).Prior therapies were heterogeneous with a median of 2 prior treatments (0 - 6), the commonest regimen being (R)-CHOP like in 26 (49%) with 16 (30%) receiving CNS penetrating doses of methotrexate and cytarabine ie (R)-Hyper CVAD, R-maxiCHOP/high dose cytarabine). 18/45 (40%) patients with data received prior intrathecal prophylaxis. 36 (68%) of patients had concurrent systemic relapse at the time of their CNS relapse, with 15 (28%) having isolated CNS relapse. The median time to CNS relapse from diagnosis was 11.5 months, with 67% occurring within 2 years of diagnosis. 38 (72%) received chemotherapy alone as treatment for their CNS relapse, with 5 (9%) receiving combined modality incoroporating chemotherapy with radiotherapy. A further 5% were not offered active treatment. There was a predictably poor outlook once diagnosed (median OS 3.3 months) although 9 patients remain alive at the time of reporting (median survival from CNS diagnosis 3.9 months, range 0.9 to 63.2 months). **Conclusions**. This is the largest dataset describing CNS involvement in Mantle Cell Lymphoma with an estimated cumulative incidence of 4%. In particular, high MIPI score and high Ki67 were notable features. Most CNS relapse occurred within the first two years., suggesting that if high risk features can be targeted CNS prophylaxis as part of initial therapy may be effective in preventing CNS progression.

1113

RISK FACTORS FOR CNS RELAPSE/ PROGRESSION IN PATIENTS WITH AGGRESSIVE B-CELL LYMPHOMA: THE ROLE OF EXTRANODAL SITES

N Schmitz[1], S Zeynalova[2], L Trümper[3], B Glass[1], M Loeffler[2], M Pfreundschuh[4]
[1]Asklepios Klinik St. Georg, Hamburg, Germany
[2]Universität Leipzig, Leipzig, Germany
[3]Universitätsmedizin Göttingen, Göttingen, Germany
[4]Universitätsklinikum des Saarlands, Homburg, Germany

Background. We recently reported on frequencies and risk factors for CNS relapse or progression in elderly (Boehme et al., BLOOD 2009: 113, 3896f) and younger patients (Schmitz et al., Ann. Oncol. 2011: doi:10.1093) with aggressive B-cell lymphoma. **Aims.** With this study we wanted to address the question if involvement of distinct extranodal sites increased the risk for CNS relapse or progression. **Methods.** Four thousand four hundred seventy patients aged 18-80 years with newly diagnosed aggressive B-cell lymphoma were analyzed. All patients were treated on trials of the German High-Grade Lymphoma Study Group (DSHNHL) or the Mabthera International trial (MInT). Systemic first-line therapy consisted of 4 - 8 courses of CHOP+/-etoposide+/-rituximab. Cycle number and doses of cytotoxic agents varied according to patients` age and the individual risk factor profile defined by the International Prognostic Index (IPI).Results. 2494 patients (55.8%) were male, median age was 60 years, 2404 patients (53.8%) presented with stage I-II disease, IPI was 0, 1 in 2295 patients (51.4%) and 864 patients (19.3%) showed more than 1 E-lesion. 154 patients (3.4 %) developed meningeal and/ or parenchymal CNS relapse or progressed in the CNS during therapy. Uni- and multivariate analyses were performed in order to address the question if involvement of distinct organs or sites indicated an increased risk of CNS disease. In univariate analyses involvement of lungs, liver, bone, pleura, gastrointestinal tract, paranasal sinuses, breast, kidney, adrenals, peritoneum, bladder, ovary, soft tissue and skin was associated with an increased risk of CNS disease. Using multivariate analysis adjusted for the IPI factors (LDH>N, ECOG>1, advanced stage, age>60years, number of extranodal sites involved) involvement of the following organs/ sites remained significant: skin (relative risk 3.7, p<0.001), paranasal sinuses (RR 3.0, p=0.001), breast (RR 2.9, p=0.011), kidney (RR 2.4, p=0.003), adrenals (RR 2.4, p=0.006), and testes (RR 2.2, p=0.039) whereas other organs/ sites (e.g. bone marrow, orbita, salivary glands) involvement of which is often considered as a risk factor for CNS relapse did not significantly increase the risk of CNS disease. **Conclusions**. Patients with elevated LDH, B-symptoms, and involvement of more than 1 extranodal site have been reported to carry an increased risk for CNS relapse or progression. Analysing > 4400 study patients we show that involvement of certain extranodal sites (paranasal sinuses, breast, kidney, adrenals and testes) significantly increased this risk while other sites traditionally considered to increase CNS disease were not found significant. These findings will have important clinical implications when considering future strategies which patients with aggressive B-cell lymphoma should be candidates for CNS prophylaxis.

1114

ROLE OF RADIOTHERAPY FOR ELDERLY DLBCL PATIENTS IN THE RITUXIMAB (R) ERA: FINAL RESULTS OF THE RICOVER-60-NO-RX STUDY OF THE DSHNHL

G Held, N Murawski, M Ziepert, V Poeschel, C Zwick, M Reiser, S Wilhelm, T Gaska, M Heike, J Schubert, N Schmitz, M Loeffler, C Ruebe, M Pfreundschuh DSHNHL, Homburg/Saar, Germany

Background. 117/306 (38%) of the total of 1222 elderly (61-80 y) DLBCL pts. treated in RICOVER-60 with 6xR-CHOP-14+2R were assigned to receive additional radiotherapy (Rx) to bulky disease (*Pfreundschuh et al., Lancet Oncol. 2008*). **Aims.** To study the relevance of Rx to bulky disease (Bx) in elderly DLBCL patients. **Methods.** 166 pts. were prospectively treated without Rx in the R-CHOP-14-noRx amendment of RICOVER-60. the outcome of these 166 R-CHOP-14-noRx patients was compared with the 306 patients who had received 6xR-CHOP-14+2R plus radiotherapy to Bx (³7.5 cm) in RICOVER-60. **Results.** 164/166 R-CHOP-noRx patients are evaluable (median observation: 39 mos). Patients in R-CHOP-noRx were older (71 vs. 69 y.; median; p=0.018), more frequently in advanced stages (60% vs. 50%; p=0.037), and with extranodal involvement (63% vs. 53%; p=0.024), while Bx was more frequent in R-CHOP-14-Rx (38% vs. 29%; p=0.038). Overall response to therapy, EFS and OS were similar in the two studies adjusting for the prognostic imbalances between the cohorts. Patients with Bx who received received additional radiotherapy to Bx in R-CHOP-14-Rx had a better 3-year EFS (80% vs. 54%; p=0.001), a better PFS (88% vs. 62%; p<0.001), and a better OS (90% vs. 65%; p=0.001) compared to R-CHOP-14-noRx. This was due the worse outcome of pts. with Bx in R-CHOP-14-noRx not achieving CR or CRu after 6xR-CHOP, since there was no difference in 3-year EFS in patients with Bx in CR or CRu after 6xR-CHOP-14 with and without additional radiotherapy (3-year EFS and PFS: 84% vs. 75%; p=0.430); OS 87% vs. 79%; p=0.839). **Conclusions.** In the R era, radiotherapy to bulky disease does not improve the outcome of elderly pts. in CR/CRu after completion of R-CHOP-14 immunochemotherapy, but appears to be beneficial for pts. with Bx not achieving CR/Cru. By restricting Bx radiotherapy to patients not achieving a CR/CRu, 43% of the patients with Bx could be spared radiotherapy. *Supported by Deutsche Krebshilfe.*

Background. Diffuse large B cell lymphoma (DLBCL) is the most common histotype of non-Hodgkin's lymphoma. R-CHOP21 (C21) is considered the standard therapy but a large number of studies tested the dose dense regimen R-CHOP14 (C14). **Aims.** The aim of our multicenter retrospective study was to evaluate the efficacy in terms of Overall Survival (OS) and Progression free survival (PFS) of the two regimens C21 and C14 in a large cohort of patients (pts) with a diagnosis of DLBCL or follicular grade IIIb lymphoma, treated with curative intent. **Methods.** We evaluated 712 pts treated in seven Italian Haematology Departments from January 2002 to December 2010, 478 treated with C21 and 234 treated with C14. The two cohorts of pts were balanced for all clinical characteristics excepted age higher than 65 years (54% in C21 vs 26% in C14 (p 0.000)), involvement of more than three nodal stations (37% C14 vs 27% C21 (p 0.005)), and bone marrow involvement (21% in C14 vs 15% C21 (p 0.05)). All pts in C14 used primary prophylaxis with G-CSF.

Overall Survival	CHOP21 p value	CHOP14 p value
Age > 64 years	.0000	.01
Stage III-IV	.001	.0001
Systemic symptoms	.0000	n.s.
Abnormal LDH value	.0000	.0002
Marrow positivity	.01	n.s.
> 3 stations involved	.0000	n.s.
> 1 extranodal site	.0000	n.s.
High IPI	.0000	.001
Progression Free Survival	**CHOP21 p value**	**CHOP14 p value**
Age > 64 years	.001	n.s.
Stage III-IV	.0000	.0000
Systemic symptoms	.0000	n.s.
Bulky disease	.009	n.s.
Abnormal LDH value	.0000	.0000
Marrow positivity	.0000	n.s.
> 3 stations involved	.0000	n.s.
> 1 extranodal site	.0000	n.s.
High IPI	.0000	.001

Results. After induction therapy 554 pts (78%) obtained a complete remission: 367/478 (77%) after C21 and 187/234 (80%) after C14. After a median period of observation of 36 months 72 pts out of 554 CR pts relapsed, 46 (46/367: 12,5%) in the C21 arm and 26 (26/187: 14%) in the C14 arm. OS was 80% in C21 and 83% in C14 (p:n.s.); PFS was 77% in C21 and 76% in C14 (p:n.s.). Univariate statistical analysis showed that OS was significantly superior in younger pts (<65 year), Ann Arbor stage I-II, absence of B-symptoms, no bulky disease, normal LDH value, negative bone marrow biopsy, low and low-intermediate risk IPI, less than four nodal stations involved and less than two extranodal site; PFS was significantly superior for the same characterstics except bulky disease. Multivariate analysis showed that OS was affected by age (p .002) and IPI (p .0000) and PFS by stage (p .002) and IPI (p .0000). The results of univariate analysis performed

stratifying for therapy are shown in table1.As expected, haematological grade III/IV toxicity was more frequently observed in pts treated with C14. No differences in extra-haematological toxicities were observed; three deaths for sepsis were observed (1 in C14 and 2 in C21). **Conclusions**. Our results confirm that C14 does not improve either OS or PFS in comparison with standard C21 in the whole lymphoma population analysed. However, we observed in univariate analysis that the intensified therapy reduced the prognostic impact on OS and PFS of important factors such as bone marrow involvement and high tumor burden in comparison with standard C21, suggesting that C14 should be useful in higher risk pts (e.g. marrow positivity or high tumor burden at diagnosis). Due to the retrospective nature of this study these results should be confirmed in prospective multicentric studies.

[7]H del Salvador, Santhiago, Chile

Background. The pathogenic association between *Chlamydophila psittaci (Cp*) infection and ocular adnexal marginal zone lymphoma (OAMZL) has been demonstrated in some geographical areas; with several complementary evidences; the efficacy of chlamydial eradication with doxycycline monotherapy has been associated with lymphoma regression in half of these patients. However, clinical and therapeutic knowledge on this association mainly result from retrospective series with variations in stage, management and follow-up duration. **Aims.** This is the first phase II trial aimed to elucidate *Cp* prevalence and activity of first-line doxycycline in lymphoma regression and *Cp* eradication in patients with stage-I OAMZL (ClinicalTrial.gov NCT01010295). **Methods.** Forty-seven patients with stage-IEA OAMZL were registered. Tumor tissue, conjunctival swabs and peripheral blood from 44 patients were assessed for seven Chlamydiaceae infections by three PCR protocols. Thirty-four patients with measurable/parametrable disease were treated with doxycycline 100 mg bid for 21 days and assessed for chlamydial eradication and lymphoma response (primary endpoint). Bacterial eradication was tested at basal time, at 3 and 12 months after antibiotics on swabs and PBMC. Response assessment was assessed at the same timepoints, and every six months afterward. **Results.** *Cp* DNA was detected in biopsies of 39 (89%) patients; no other chlamydiaceae were detected. *Cp* DNA was detected in 97% (n= 38) of baseline conjunctival swabs and in 69% (n= 27) of PBMC samples of the 39 *Cp*-positive OAMZL; no cases with *Cp*-negative biopsy disclosed *Cp* DNA in their swabs or PBMCs. Twenty-two (92%) of the 24 patients who reported history of prolonged contact with household animals had a *Cp*-positive lesion.Twenty-nine patients had *Cp* DNA in baseline swabs and/or blood samples and were evaluable for chlamydial eradication, which was achieved in 14 (48%) patients. Lymphoma regression after doxycycline treatment was complete in six patients and partial in 16 (ORR=65%, 95%CI:49-81%); 11 had SD and one PD. Nineteen of the 29 patients with *Cp*-positive OAMZL achieved an objective response (ORR: 66%; 95%CI: 50-82%). Lymphoma regression was achieved in 12 of the 14 *Cp*-eradicated patients and in seven of the 15 non-eradicated patients (86% vs. 47%; p=0.02).At a median follow-up of 37 months (range 15-62), 20 patients remain relapse-free (5-year PFS: 55±9%). Fifteen of the 22 patients with responsive lymphoma were relapse-free at the time of analysis, with a median TTP of 30+ months (range 8 - 62+). None of the patients who achieved CR experienced relapse after 36-60 months. Tumor failure occurred in four of the 14 *Cp*-eradicated patients and in eight of the 15 non-eradicated patients, with a 5-yr PFS of 68±13% and 47±13% (p=0.11), respectively. No patient died of lymphoma, two deaths due to stroke and unrelated sudden death were recorded. **Conclusions.** Upfront doxycycline is a rational and active treatment for patients with stage-I, *Cp*-positive OAMZL. Lymphoma regression is consequent to *Cp* eradication, which can easily be monitored on conjunctival and blood samples. The definition of mechanisms of resistance to doxycycline and the design of more effective administration schedules are warranted.

Autologous stem cell transplantation

STRONG PROGNOSTIC VALUE OF ETOPOSIDE PHARMACOKINETICS IN LYMPHOMA PATIENTS TREATED WITH BEAM REGIMEN AND ASCT: MULTICENTER STUDY OF GROUPE D'ETUDES DES LYMPHOMES DE L'ADULTE (GELA)

B You[1], O Bally[1], G Salles[1], AS Michallet[1], O Casasnovas[2], H Tilly[3], V Ribrag[4], C Sebban[5], C Falandry[1], G Freyer[1]
[1]Hospices Civils de Lyon; Université Claude Bernard Lyon 1, Pierre-Bénite (Lyon), France
[2]Centre Hospitalier Universitaire de Dijon, Dijon, France
[3]Centre Henri Becquerel, Rouen, France
[4]Institut Gustave Roussy, Villejuif, France
[5]Centre Léon Bérard, Lyon, France

Background. Relationships between pharmacokinetic (PK) parameters of etoposide and toxicity-survivals were reported in solid tumor patients treated at standard doses [1]. When given at high dose in lymphoma patients, etoposide PK may have a strong influence on outcomes. **Aims.** The prospective LYMPK study primary objective was to assess the impact of etoposide pharmacokinetic (PK) parameters on toxicity & efficacy in lymphoma patients receiving the BEAM regimen (carmustine, cytarabine, etoposide and melphalan) followed by autologous stem cell transplant (ASCT). We previously showed the high inter-individual variability in etoposide PKs, defined by area under the curve (AUC) and trough concentration (Cmin), among study patients treated with the same doses /m2 [2]. **Methods.** Ninety-six patients with malignant lymphoma [Non-Hodgkin lymphoma (NHL): 84; Hodgkin lymphoma (HL): 12] at 1st line (n=52) or relapse (n=44) were enrolled in 5 centers. All received BEAM regimen, including high dose etoposide (100 to 200 mg/m2 bid for 4 days), followed by ASCT. Individual etoposide AUC and Cmin were estimated by population PK approach using NONMEM® program. The impact of PK parameters on toxicity and survival was assessed using linear regression and univariate/multivariate analyses.

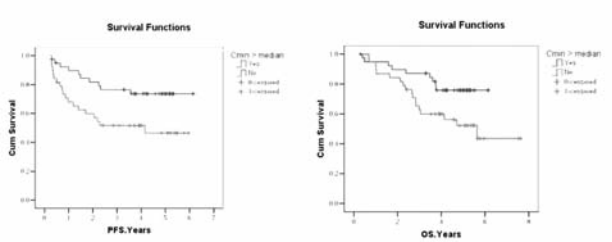

Figure 1. Impact of etoposide residual concetration (Cmin) on PFS and OS.

Results. Data from 90 patients (NHLs: 78; HLs: 12) were assessable after a 4.2 year median follow-up. The bi-compartment model previously reported was used to characterize PK parameters [2]. Etoposide AUC and Cmin correlated with mucositis duration, especially for grade 3-4 toxicity ($p< 0.05$), but not with other toxicities. In NHL patients, Cmin categorized by the median had significant prognostic value regarding 5 year progression free survival (PFS) (73.6% vs 46.5%, if Cmin > median, p=0.01) and 5 year overall survival (OS) (76% vs 52%, if Cmin > median, p=0.03). When assessed with available IPI prognostic factors (age; performance status; LDH & stage) using Cox analysis, Cmin was the only significant independent prognostic factor regarding PFS (HR = 0.39, 95% CI = 0.18-0.86); disease specific survival (HR = 0.35, 95% CI = 0.14 - 0.91) and OS (HR = 0.43, 95% CI = 0.19 - 0.96) in NHL patients. Etoposide AUC was also a significant independent factor against IPI prognostic factors using Cox analysis factor adjusted on lymphoma type (HL vs NHL) regarding disease specific survival (HR= 0.38, 95% CI = 0.16-0.93) and overall survival (HR = 0.46, 95% CI = 0.21-0.98). **Conclusions.** LYMPK study results suggest that individual etoposide pharmacokinetic parameters, especially systemic exposure and residual concentration, have strong impacts on survival in lymphoma patient receiving BEAM regimen and ASCT. Given the high variability in patient pharmacokinetics [2], plasma concentration-based adjustment of etoposide dose may be considered in future studies.

RANDOMIZED STUDY OF IBRITUMOMAB TIUXETAN (ZEVALIN) & HIGH-DOSE BEAM CHEMOTHERAPY (Z-BEAM) VS BEAM ALONE PRIOR TO AUTOLOGOUS TRANSPLANTAT IN AGGRESSIVE LYMPHOMA; LONG-TERM FOLLOW-UP AND SUBSET ANALYSIS

A Shimoni[1], I Avivi[2], J Rowe[2], M Yeshurun[3], I Levi[4], R Or[5], A Nagler[1]
[1]Chaim Sheba Medical Center, Tel-Hashomer, Israel
[2]Rambam Medical Center and Bruce Rappaport Faculty of Medicine, Technion, Haifa, Israel
[3]Davidoff Center, Rabin Medical Center, Petah-Tiqva, Israel
[4]Soroka University Medical Center, Beer Sheva, Israel
[5]Hadassah University Hospital, Jerusalem, Israel

Background. High-dose chemotherapy and autologous stem-cell transplantation (ASCT) is the standard therapy for patients with refractory/relapsed aggressive lymphoma. In the era of rituximab-containing front-line regimens, it is becoming more challenging to salvage patients in this setting and novel approaches are required. **Aims and Methods.** We have conducted a multi-center, prospective randomized study comparing the outcomes following ASCT with high-dose BEAM chemotherapy compared to BEAM combined with standard-dose Zevalin (0.4 mCi/kg) administered on day-14 prior to ASCT in patients with aggressive lymphoma. The primary end-point was 2-year overall survival (OS). Initial results showed the feasibility and safety of this approach and suggested a possible survival advantage. The current analysis is a long-term follow-up with all surviving patients reaching the primary end-point.*Results.* The study included 43 patients, median age 55 years (range, 23-67). Thirty-four patients had diffuse large B-cell lymphoma (DLBCL), refractory to first-line therapy (n=6) or recurrent (n=28). Nine patients had transformed follicular lymphoma. All patients responded to second-line therapy, however 16 had positive PET-CT prior to ASCT. Twenty-six patients were scored as high-risk disease if they had a short initial remission (<12 months) or high IPI score (3) at relapse, while 17 patients were scored as low-risk disease. In all, 22 patients were randomized to Z-BEAM and 21 to BEAM alone. Patient and disease characteristics were well matched between the groups and there was no difference in engraftment kinetics or toxicity profile. The median follow-up is 39 months (range, 24-60). The 2-year OS is 91% (95%CI, 79-100%) and 61% (95%CI, 39-82%) after Z-BEAM and BEAM, respectively (p=0.03). Similar results were observed when the analysis was limited to the 34 patients with DLBCL (94% Vs 54%, p=0.01). The 2-year progression-free survival (PFS) was 59% (95%CI, 39-80%) and 42% (95%CI, 20-63%), respectively (p=NS). Advanced age (55 years) was associated with worse outcome; 2-year OS been 90% and 64% in the younger and older subgroups, respectively (p=0.07). Z-BEAM was beneficial in both subgroups, but more so in the older subgroup. 2-year OS was 85% and 33% in the older group (p=0.02) compared to 100% and 83% in the younger subgroup (p=0.20), respectively. Similarly, Z-BEAM was beneficial in high-risk disease, 86% Vs 58% (p=0.11) and low-risk disease, 100% Vs 67% (p=0.08), and in patients with positive PET-CT prior to ASCT, 82% Vs. 50% (p=0.20) or negative PET-CT, 100% Vs. 71% (p=0.06). Multivariable analysis identified advanced age [HR 7.2 (p=0.02)], high-risk disease [HR 4.2 (p=0.08)] and conditioning with BEAM alone [HR 10.1 (p=0.006)] as poor prognostic factors for 2-year OS. The same factors were also prognostic for 2-year PFS with HR of 10.2 (p=0.002), 2.5 (p=0.07) and 2.7 (p=0.04), respectively. Positive PET-CT had borderline statistical significance, HR 2.3 (p=0.09).*Conclusions*: Standard-dose Zevalin combined with BEAM high-dose chemotherapy is safe and possibly more effective than BEAM alone as conditioning regimen for ASCT in the era of rituximab-containing chemotherapy regimens. Based on these data, a consortium of centers was formed to validate these conclusions in a larger international phase-3 randomized trial.

THIOTEPA-BASED HIGH-DOSE PREPARATION VS BEAM FOR AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION (AUTOHSCT) IN LYMPHOMA OTHER THAN PCNSL: A RETROSPECTIVE STUDY FROM THE EBMT

A Boumendil[1], H Finel[1], G Da Rosa[1], M Martelli[1], V Liso[1], J Vernant[1], R Scime[1], M Janvier[1], P Mazza[1], G Kobbe[1], D Bunjes[1], I Majolino[1], F Ferrara[1], A Rambaldi[1], A Delmer[1], A Sureda[1], P Dreger[2]
[1]EBMT Lymphoma Working Party, Paris, France
[2]EBMT, Paris Cedex 12, France

Background. Thiotepa is an alkylating agent approved for high-dose therapy for autologous HSCT. Because of its excellent capacity to cross the blood-brain barrier, it is regularly used for autoHSCT for primary CNS lymphoma (PCNSL). However, although thiotepa-based myeloablation might have benefits over traditional BEAM preparation because of better brain availability and less pulmonary toxicity, clinical level information about thiotepa-based autoHSCT outside of the PCNSL field is sparse. The purpose of the present retrospective study was to provide information on the potential risks and benefits of thiotepa-based preparative regimens in autoHSCT for distinct subtypes of lymphoma outside of the PCNSL setting. **PRIMARY OBJECTIVE** was to compare the outcome of thiotepa-based autoHSCT (TT) with that of BEAM autoHSCT (BEAM) separately for diffuse large B-cell lymphoma (DLBCL; excluding PCNSL), follicular lymphoma (FL), peripheral T Cell lymphoma (PTCL) and Hodgkin's lymphoma (HL). **PRIMARY ENDPOINT** was progression-free survival (PFS), secondary endpoints were overall survival (OS), non-relapse mortality (NRM), and incidence of relapse (IR). **ELIGIBLE** were patients >18 years from 12 European countries who were registered with the EBMT and had received TT-based myeloablation or BEAM for a first autoHSCT between 2003-2010 for FL, DLBCL, PTCL, or HL, and had Med A level information available. **STATISTICAL ANALYSIS** was based on a 1:2 matched pair comparison using stratified Cox and Fine & Gray regression models for comparison. Matching factors were age (+/- 10 years), sex, lymphoma subtype, time from diagnosis to autoHSCT, remission status at autoHSCT, and year of autoHSCT. **results.** 420 patients with TT fulfilled the inclusion criteria and were matched with 816 BEAM patients (24 patients had only one match). Of these 1236 patients, 67% had DLBCL, 8% FL, 3% PTCL, and 22% HL. Remission status at autoHSCT was CR/PR1 in 42%, CR/PR >1 in 28%, more advanced disease in 19%, and unknown in 11%. The TT group contained a significantly larger proportion of patients with poor performance status (12% vs 6%, p 0.0011). Because of the low numbers PTCL were excluded from endpoint analyses. The hazard ratio for PFS with TT vs BEAM inDLBCL,FL, and HL was 1.31 (0.91-1.89), 0.65 (0.19-2.2), and 0.86 (0.49-1.51). Similarly, no significant differences between TT and BEAM became evident in any lymphoma subset for OS, NRM, and IR. **Conclusions.** Despite the unfavourable imbalances in performance status, we found no evidence for inferiority of TT-based compared to BEAM autoHSCT forDLBCL,FL, and HL. Thus, in these lymphoma subtypes TT-based high-dose therapy might be a valuable alternative to BEAM in situations were BEAM is unavailable or contraindicated.*Supported by a restricted grant from Riemser AG, Greifswald, Germany.*

PLERIXAFOR FOR FIRST LINE STEM CELL MOBILIZATION PRODUCES GREATER STEM CELL YIELDS THAN CONVENTIONAL CHEMOTHERAPY: AN INTERIM ANALYSIS OF THE PHANTASTIC TRIAL

R Clark[1], J Bell[2], S Francis[2], J Clark[2], B McEvoy[2], N McGinnity[2], T Callaghan[2], G Brearton[2], E Jones[2], R Salim[2]
[1]University of Liverpool, Liverpool, United Kingdom
[2]Royal Liverpool University Hospital, Liverpool, United Kingdom

Background. Plerixafor is an effective and well tolerated agent for mobilising blood stem cells in patients who fail mobilisation with conventional chemotherapy schedules. It has a product license for second line use in myeloma and lymphoma patients. However, its place as a first line stem cell mobilisation agent is unclear. The PHANTASTIC study (ClinicalTrials.gov Identifier: NCT01186224) is examining first line plerixafor with G-CSF in 100 patients with underlying myeloma or lymphoma requiring autologous transplantation. **Aims.** In a planned interim analysis of the first 60 patients, to determine whether $CD34^+$ yields after first line plerixafor are superior to those attained with conventional chemotherapy + G-CSF in historical controls. **Methods.** All entrants received G-CSF at ~5ug/kg on days 1-4, and plerixafor on day 4, at a dose of 240 ug/kg if creatinine clearance >50 mls/min (59 cases) or 160 ug/kg if creatinine clearance 30-50 mls/min (1 case). Stem cell harvesting was performed on days 5-8 with additional daily G-CSF and plerixafor as needed, until the target yield of 4×10^6 $CD34^+$ cells /kg recipient weight was collected. Results were compared with 270 consecutive historical control patients mobilised by conventional chemotherapy (mostly cyclophosphamide 1.5gm/m2) + G-CSF. All entrants and controls were treated at our institution.**Results.** 26 patients had underlying myeloma, 26 Non-Hodgkin lymphoma and 8 Hodgkin's disease. No serious adverse events were seen during or in the 21 days following harvesting completion,. Ten patients developed mild transient gastrointestinal symptoms, insomnia and headaches which were possibly plerixafor-related.48 (80%) of the 60 plerixafor mobilised patients achieved the primary composite endpoint of BOTH an adequate stem cell harvest ($^3 4 \times 10^6$ $CD34^+$ cells/kg in ≤ 2 aphereses) AND no evidence of a neutrophil count < 1×10^9/ L over the 3 weeks after starting mobilisation. This is significantly greater than the 100 (37%) of 270 historical control patients who achieved this endpoint ($p < 0.0001$). Plerixafor also achieved a significantly greater median $CD34^+$ cell yield than in 235 assessable historical controls (median 5.49 vs. 3.89×10^6 /kg; $p < 0.001$). All plerixafor treated patients met the target $CD34^+$ cell dose within 4 harvests, whereas 135 of 270 assessable historical controls failed to meet this target, 18 of whom required either marrow harvesting or an additional round of stem cell mobilisation.To date, 49 of the 60 plerixafor mobilised patients have undergone transplantation and all these are assessable for engraftment. The median time to neutrophil engraftment of 0.5×10^9/L was 12 days, and for platelet engraftment to 50×10^9/L was 21 days. 23 cases are assessable at 12 months post transplant, of whom 1 has died and 3 have relapsed; the remaining 19 are alive and well. **Conclusions.** Plerixafor is safe and effective as a first line mobilisation agent and yields superior $CD34^+$ cell yields than historical chemotherapy based schedules. Patients mobilised by first line plerixafor have an excellent probability of proceeding uneventfully from harvest to transplantation, with acceptable engraftment time and 12-month outcome.

[12]University of Heidelberg, Heidelberg, Germany

Background. Despite the significant improvement in the outcome of patients with follicular lymphoma (FL) in recent years, FL is still incurable with conventional treatment. Defining the role of high-dose therapy with autologous stem cell rescue (HDT-ASCR) and of allogeneic transplantation in the therapeutic algorithm of FL is a major challenge, given the lack of informative prospective trials in the rituximab era. **Methods.** A panel of international experts on transplant/lymphoma were invited to join the project. The members of the panel decided in advance the statements to discuss and agreed the threshold to define consensus. Nineteen statements were subsequently scored individually and anonymously by each participant using a 9-point scale (1-3: disagree; 4-6: neither agree nor disagree; 7-9: agree). After discarding the highest and lowest ratings, consensus was reached if all the scores fell in the same group. No consensus was reached if there was >1 ratings in group 1-3 and >1 in group 7-9. Consensus was assessed after two rounds of rating, according to the threshold previously defined. Results. Consensus was reached on the following statements: 1) HDT-ASCR is not an appropriate treatment option to consolidate first remission in patients responding to immuno-chemotherapy, outside the setting of clinical trials; 2) In patients in first relapse with chemo-sensitive disease HDT-ASCR is an appropriate treatment option to consolidate remission; 3) Remission consolidation with HDT-ASCR is an appropriate treatment option in first relapse in patients with a short response duration (<3 years) after immuno-chemotherapy; 4) Remission consolidation with HDT-ASCR is an appropriate treatment option in first relapse in patients with high-risk FLIPI at relapse; 5) Remission consolidation with HDT-ASCR is an appropriate treatment option in patients in second or subsequent relapses with chemosensitive disease; 6) Allotransplant should be considered in patients with relapse after HDT-ASCR; 7) Reduced-intensity/non-myeloablative conditioning regimens are generally more appropriate in patients receiving an allotransplant; 8) In FL, the available biological and genetic risk factors are not sufficient to guide treatment decisions (including the indication for HDT-ASCR and allotransplant), but they are mainly guided by the clinical course. In addition, there was consensus to reject that HDT-ASCR is an appropriate treatment option to consolidate first remission in patients with high-risk FLIPI or grade 3a FL at diagnosis. However, no consensus could be reached about the role of HDT-ASCR in low-risk first relapse (low-risk FLIPI, long first remission or rituximab-naïve) or the criteria to select patients in whom allotransplant should be preferred over a first HDT-ASCR. Conclusions: Despite the undoubted impact of rituximab on the outcome of patients with FL, HDT-ASCR remains a strong treatment option at first relapse, especially in patients with high-risk features (i.e short response duration, high-risk FLIPI). In contrast, no specific indications for allotransplant (other than at relapse following HDT-ASCR) were agreed. This project demonstrates that, in the absence of evidence-based data, consensus methods may provide valuable tools to define indications for hematopoietic stem cell transplantation in FL.

Relapsed/refractory B-precursor ALL in adults has a dismal prognosis where only 35-40% of patients reach a hematological complete remission (CR) with a median overall survival of approximately 4.5 months. An exploratory phase II trial was conducted in this patient cohort with blinatumomab, a bispecific T-cell engaging (BiTE®) antibody that directs cytotoxic T-cells to CD19 expressing target cells.The primary endpoint was hematological CR or CR with partial hematological recovery (CRh*) within 2 cycles of blinatumomab. Secondary endpoints included overall survival and safety.Blinatumomab was administered by continuous intravenous infusion for 28 days followed by a 14-day treatment-free interval. Responding patients could receive 3 additional cycles of treatment or proceed to allogeneic hematopoietic stem cell transplantation (HSCT). Three dose levels were explored as shown in Table 1.In total, 36 patients were enrolled; data of 25 are currently available. Seventeen out of 25 treated patients (68%) achieved a hematological CR/CRh*. Five out of 17 responders (29%) had a CRh*.

Table 1. Summary of Dose Cohorts and Outcomes (Oct 2011).

Cohort	Patients Treated	Week 1, Cycle 1 µg/m²/day	Week 2, Cycle 1 µg/m²/day	Weeks 3-4, Cycle 1 and Subsequent Cycles µg/m²/day	CR/CRh*
1	7	15	15	15	5
2a (Final dose)	5	5	15	15	4
2b	6	5	15	30	3
3 (Final dose)	7	5	15	15	5
Total	25				17

All responders reached a minimal residual disease level below 10^{-4} within the first 2 cycles. Six patients proceeded to HSCT in CR/CRh* after blinatumomab treatment, and one of them developed a medullary $CD19^-$ relapse after HSCT. Eleven patients did not receive HSCT. Five of them relapsed: 2 relapses were $CD19^-$ (1 medullary and 1 extramedullary) and 3 were $CD19^+$ (1 medullary and 2 extramedullary).For the first 18 patients (cohort 1, 2a and 2b), median response duration is 7.1 months (218 days); median survival is not reached and the current median follow-up time for overall survival is 11.4 months.Cytokine release syndrome (CRS) and CNS events were reported as medically important events. In 2 patients with high tumor burden and no cytoreductive prephase, 3 CRS events were observed. Both patients received further blinatumomab therapy without CRS recurrence. Fully reversible adverse drug reactions of the CNS leading to treatment interruption were observed in 5 patients: 3 patients with seizures and 2 patients with disorientation. CNS symptoms fully resolved and all 5 patients were able to resume treatment at a lower dose.As final dose and schedule, 5 µg/m²/day in week 1 and 15 µg/m²/day for the remaining treatment (cohort 2a and 3) was selected for further investigation. In these cohorts (n=12), the most common treatment emergent adverse events (TEAEs, all grade 1-2) were pyrexia (67%), headache (33%) and tremor (33%). TEAEs of grade ≥3 (7 in 5 patients, no grade 4), irrespective of relationship, were infections, confusion, epilepsy, hypertension and thrombocytopenia.The final dosing regimen of blinatumomab produced an exceptionally high CR respectively MRD response rate and was well-tolerated. A global phase II study to confirm these data is underway.

Background. Front-line combination of imatinib with conventional chemotherapy has demonstrated an improved complete response (CR) rate, an increased transplantation proceeding rate, and a better survival in adults with Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph-positive ALL). However, in the light of disease aggressiveness and recurrence, mainly as a result of the outgrowth of leukemic subclones with imatinib-resistant mutations, an improved strategy to induce more effective leukemic cell clearance is clearly needed. Dasatinib has been shown to be effective in patients with imatinib-resistant Ph-positive ALL. **Aims.** Here, we present the interim results of the Korean prospective phase II study protocol designed to evaluate the clinical efficacy of first-line dasatinib plus conventional chemotherapy for adults with newly diagnosed Ph-positive ALL. **Methods.** This study is registered at www.ClinicalTrials.gov as NCT01004497. The protocol enrolls patients (15-65 years) who receive dasatinib (100 mg once daily for 4 weeks) as an alternative schedule after each conventional chemotherapy course (alternating modified hyper-CVAD and high-dose cytarabine/mitoxantrone). Patients who have a suitable donor undergo allogeneic transplantation as early as possible. Patients without a donor continue to receive dasatinib plus conventional chemotherapy (up to 4 courses; depending on the patient's tolerability) followed by dasatinib maintenance therapy (100 mg/d for up to 2 years). Minimal residual disease monitoring for BCR-ABL1 transcript is centrally evaluated by real-time quantitative PCR (4.5 log sensitivity) through handling of bone marrow samples from all patients (Research Institute of Molecular Genetics, The Catholic University of Korea,Seoul,Korea). All patients in the study provided written informed consent, and the study protocol was approved by the institutional review board of The Catholic University of Korea. **Results.** Recruitment started in March 2010 and was completed in February 2012 (n=51). Of these, 8 patients are receiving the first or second dasatinib cycles (too early); 4 patients died from infections before starting dasatinib administration. Thus, 39 patients are evaluable for assessment of response. Median age was 42 (19-64) years. Karyotype analysis revealed additional chromosomal changes in 26 patients (67%). Twenty-seven patients (69%) had m-BCR transcript. All patients (100%) have achieved CR by the first dasatinib cycle, and of these, 18 patients (46%) have achieved major molecular response [MMR; including 7 complete molecular response ($CMR^{4.5}$)]. By the second dasatinib cycle, 30 patients (77%) have achieved MMR (including 17 $CMR^{4.5}$). No dasatinib-related serious adverse events (≥grade 3 toxicity) have been observed. To date, 30 patients (77%) have undergone allogeneic transplantation in CR. With a median follow-up duration of 14 months, 34 patients are alive and 31 are in continuous CR; 5 patients died in CR (2 infections during consolidation chemotherapy, 3 transplant-related com-

plications). Three patients have relapsed (CR durations were 4, 6, and 9 months, respectively) with T315I mutations. The 1-year cumulative incidence of relapse was 10%, and the 1-year disease-free survival and overall survival rates were 75% and 84%, respectively. **Conclusions.** Our data indicates that first-line combination of dasatinib with conventional chemotherapy appears to be effective in achieving a good quality of molecular response (MMR or CMR[4.5]) in adults with Ph-positive ALL.

Background. Incorporation of imatinib in front-line treatment strategies for Ph+ALL results in complete remission rates exceeding 90%, but long-term outcome remains unsatisfactory in patients not undergoing allogeneic stem cell transplantation (SCT). In a previously reported randomized trial of imatinib-based induction and consolidation chemotherapy in elderly patients with Ph+ALL, overall survival (OS) and disease-free survival (DFS) of all 55 patients at 24 months was 42% ± 8% and 19.2% ± 6.4%, respectively (Ottmann OG et al., Cancer. 2007; 109:2068-76). Published data on long-term outcome of elderly Ph+ALL patients, most of whom are not considered candidates for SCT, are very limited.**Aims.** To determine the proportion of long-term surviving elderly Ph+ALL patients receiving imatinib combined with intensive consolidation, examine the characteristics of the subset of long-term survivors, and obtain preliminary results on the feasibility and efficacy of SCT in this patient population. **Study design and patients demographics:** Our current analysis includes a total of 122 patients (120 ALL, 2 CML in lymphoid blast crisis), with a median age of 66 years (range 54-80). Fifty-five patients were enrolled in a previously reported randomized clinical trial comparing single-agent imatinib and chemotherapy as induction therapy, followed by up to 6 cycles of consolidation chemotherapy; a further 67 patients were subsequently treated according to this protocol as per recommendation by the GMALL Study Group.**Results.** The overall CR rate was 87%, median remission duration and OS was 16.6 months (range 1-79.4) and 18.3 months (range 0.5-80), respectively. Probabilities of remission duration, survival and DFS at 5 years were 8%, 18% and 8%, respectively. The type of initial induction therapy had no significant impact on OS and DFS. In univariate analysis, pulmonary disease was the only comorbidity associated with inferior outcome (median OS 10 months vs. 20 months, evaluable 59 pts.). Allogeneic SCT was performed in CR1 in 11 patients and as salvage therapy in 6 patients. Median age of these 18 patients was 62y (range 54-69). The time from diagnosis to SCT in CR1 was 133 days (87 d - 509 d) and from relapse to SCT in >CR1 92 days (63 d - 185 d).The 5yr OS in patients transplanted in CR1 vs. non-transplanted patients was superior (48% vs 13%). Remarkably, OS of the 7 patients transplanted beyond CR1 as part of salvage therapy was 43% after 3 years. With a median follow-up of 18.7 months (range 1.3 - 50) after SCT, 7 patients are in ongoing CR with a median OS of 34.7 mo. (range 16 - 50), 4 pts. died in CR, 7 pts. relapsed.**Conclusions:** The combination of imatinib in conjunction with intensive chemotherapy is feasible in elderly patients, but is associated with extremely poor survival primarily due to high relapse rate. Despite the small patient number, allogeneic SCT in CR1 is superior and should be considered as front-line therapy in this elderly patient population. Moreover, SCT as part of salvage therapy beyond CR1 is a feasible treatment option.

[6]Eusapharma, Lyon, France
[7]CHU de Angers, Angers, France

L-asparaginase is a component of therapy for ALL. Asparagine depletion is considered as a surrogate marker for L-asparaginase activity (Wetzler, Blood 2007) but silent neutralizing anti-asparaginase Abs are associated with poor prognostic in children (Panosyan, J Pediatr Hematol Oncol 2004).We investigated asparagine depletion and Ab detection in adult patients treated in 5 GRAALL centers within the GRAALL-2005 study, derived from the published GRAALL-2003 protocol (Huguet, J Clin Oncol 2009). Asparagine level was evaluated by reversed-phase liquid chromatographic/tandem mass spectrometric method (Piraud, Rapid Commun Mass Spectrom 2005) while anti-asparaginase Abs were detected by ELISA (Wang, J Immunols **Methods.** 2000). After informed consent, 38 patients were included. Induction included administration of 6,000 IU/m² L-asparaginase (Kidrolase®) at d8, 10, 12 then at d20, 22, 24, 26 and 28, inorder to not interact with anthracycline, cyclophosphamide and vincristine. Before the first L-asparaginase infusion at d8, median asparagine basal level was 39 µmol/L (25-60), showing then full depletion (<2 µmol/L) at d13, 20 and 29 in97%, (28/29), 100% (30/30) and 100% (26/26) of patients who received the planned infusions, respectively. Anti-asparaginase Abs were detected (positive above 0.2) in 0% (26/26), 3% (1/29), 0% (29/29) and 4% (1/26) of patients at day 8, 13, 20 and 29, respectively. Two patients had low Ab levels (0.089 and 0.112) at d29, subsequently followed by a level increase in one patient and a clinical allergic reaction associated with depletion failure in the other, suggesting that Ab level as low as 0.1 may be clinically significant. At the onset of first consolidation block (d40 to d59), lack of depletion was observed in 32% (6/19) patients and Abs were detected in all of them, as well as in 2 patients still fully depleted but in whom consolidation was started before d35, leading to a 42% (8/19) Ab positivity at consolidation initiation. Interestingly, the first consolidation block was given earlier after d28 of induction in patients without Ab (median, 5 days) than patients with Ab (median, 12 days). L-asparaginase (10,000 UI/m²) was reintroduced during consolidation blocks 1, 2, 4 and 5. During these blocks, 48% of patients (11/23) demonstrated Ab positivity, 48% of patients (11/23) presented an anaphylactic reaction (10 with Ab, 1 without). Among the 4 patients with Ab tested for asparagine depletion at that time, 3 were not depleted (others pending). Conversely, among 6 patients without Ab tested, all were fully depleted. L-asparaginase was then reintroduced during late intensification and 8 patients were studied at that time (6 of them receiving 12,000 IU/m² Erwinase® instead of 6,000 IU/m² Kidrolase® due to earlier allergic reaction or CNS toxicity). All these 8 patients experienced full depletion.In conclusion, all patients were correctly depleted during induction, despite no L-asparaginase infusion between d12 and d20. During consolidation, 48% of patients had Ab and 48% anaphylactic reaction. Switch for Erwinase® allowed correct re-depletion during late intensification despite previous immunization. These results suggest that monitoring of asparagine depletion and anti-asparaginase Ab may be usefull to individualize L-asparaginase therapy in adults treated for ALL.

Background. Despite a widespread use in children and young adults, L-asparaginase has been limited in older patients with Philadelphia Chromosome-Negative (Ph-) ALL because of frequent and severe toxicities. With its improved efficacy/tolerability potential, L-asparaginase-loaded red blood cells (GRASPA®) could be a suitable option for combining L-asparaginase with standard chemotherapy in this population.**Aims.** The aim of GRASPALL/GRAALL-SA2-2008 study was to determine the optimal dose of GRASPA® that could be combined with the standard EWALL chemotherapy backbone in patients aged >55y with newly diagnosed Ph-ALL. Haematological, molecular Ig/TCR minimal residual disease (MRD) response and survival were the major secondary endpoints. **Methods.** It was an open label Phase II dose escalation study using a Bayesian experimental plan. Primary composite endpoint included tolerance and efficacy, the latter being defined as the achievement of target asparagine depletion for at least 7 days. Three doses of Graspa® (50, 100 and 150 IU/kg), infused at d3 and d6 of two successive induction cycles, were investigated. After each 3-pts cohort, an independent Data Safety Monitoring Board reviewed study drug tolerance before opening the next dose. EWALL backbone consisted of dexamethasone prephase followed by induction-1 (dexamethasone d1-2/8-11, vincristine d1,8, and idarubicine d1-2/8-9) and induction-2 (cyclophosphamide d15-17 and cytarabine d16-19/23-26). Consolidation consisted of 6 monthly alternating cycles with methotrexate (d1) / E.coli asparaginase (d2) and high-dose cytarabine (d1,3,5). Maintenance included mercaptopurine, methotrexate and vincristine/dexamethasone pulses for 2 years. Dose reductions were recommended for patients aged >70y.*Results.* Between March 2009 and October 2010, 30 patients were recruited in 20 centres in France. The 50, 100 and 150 dose levels included 3, 13 and 14 patients, respectively. Median age was 67 years (range 59-77). No differences in baseline characteristics were observed across the 3 dose level groups. Overall, 0 (0%), 2 (15%) and 5 (36%) patients presented limiting toxicities in the 50, 100 and 150 dose level, respectively. Because of insufficient serum asparagine depletion, only 3 patients received the lower dose. At the higher 100 and 150 dose levels, 85% and 71% patients reached target asparagine depletion, respectively. During induction, grade 3/4 infections were observed in 69% and 71% patients and invasive fungal infection in 23% and 43% patients, in the 100 and 150 IU/kg groups respectively. Anti L-asparaginase Abs were detected in 0/3, 2/13 and 1/14 patients after induction-1 and 1/2, 3/9 and 5/9 patients after induction-2, in the 50, 100 and 150 dose level group, respectively. Nevertheless, no clinical allergy was observed after the second drug infusion, but allergic reactions to native E-Coli L-asparaginase were observed in 5/19 pts after consolidation 1.Early response to therapy as well as event-free survival (EFS) and overall survival (OS) are presented in the table below according to the GRASPA dose.*Conclusion*: Two infusions of GRASPA® appears to be and active manner of introducing L-asparaginase during induction chemotherapy of older patients with Ph-ALL. The dose of 100 IU/kg showed the higher activity/safety profile so far but larger prospective evaluations of this new L-asparaginase formulation are warranted.

	Dose levels			
	50 IU/kg n=3	100 IU/kg n=13	150 IU/kg n=14	All
Induction failure	0/3 (0%)	1/13 (8%)	2/14 (14%)	3/30 (10%)

[3]Institute for Stem Cell Research, Edinburgh, United Kingdom

Background. A striking but poorly understood feature of many oncogenic mutations is their lineage fidelity. Whilst this might simply reflect that mutations target a specific cell lineage, more intriguingly, if a mutation targets a primitive multipotent cell, it might impact on lineage fate decisions.**Aims.** To understand how oncogenic mutations might influence lineage specification using Flt3-ITDs as an informative model as, although wild-type FLT3 strongly promotes early lymphoid development, FLT3-ITDs are paradoxically restricted to myeloid-lineage leukaemias. **Methods.** We explored the impact of ITDs on leukaemic transformation and lineage capability of primitive multipotent haematopoietic cells using a Flt3-ITD knock-in mouse model to better understand the cellular and molecular basis for this myeloid-bias.**Results.** To determine the impact of FLT3-ITDs on leukaemic transformation, we generated Flt3-ITDRunx1$^{fl/fl}$Mx1-Cre^{+} mice. Importantly, Runx1 loss-of-function mutations occur in patients with both myeloid and lymphoid lineage acute leukaemias. Unexpectedly, even without poly I:C induction, Flt3-ITDRunx1$^{fl/fl}$Mx1-Cre^{+} mice developed a Runx1-deleted, high-penetrance, short-latency acute leukaemia of universal myeloid phenotype. This model recapitulates a particularly poor prognostic form of AML by targeting two collaborating mutations to their endogenous genetic loci which individually induce a relatively mild phenotype. This also demonstrates a key role for Flt3-ITD signaling in introducing a myeloid transformation bias.Flt3-ITD mice showed a cell-extrinsic and marked suppression of hematopoietic stem cells. The most primitive population expanded by Flt3-ITDs were LSKCD48+150- multipotent progenitors (MPPs), comprising >90% of LSK cells. Nanofluidic and global gene-expression analysis demonstrated that Flt3-ITD MPPs were myeloid-primed with loss of megakaryocyte and erythroid (MkE) priming. Lymphoid transcriptional priming, present at high-level in wild-type MPPs, was downregulated in Flt3-ITD MPPs. These findings were confirmed in functional assays through absent MkE and reduced lymphoid potential of Flt3-ITD MPPs, and together demonstrate that primitive lympho-myeloid MPPs, a population recently implicated in human AML, are expanded and biased towards myeloid development by Flt3-ITDs.In agreement with reduced lymphoid-priming of Flt3-ITD MPPs, analysis of early thymic development demonstrated a 10-fold reduction of early thymic progenitors (DN1 Kit+) as well as suppression of later stages of thymic development in Flt3-ITD mice. Expression of the chemokine receptor Ccr9 was reduced in Flt3-ITD MPPs, suggesting a suppression of thymic seeding by Flt3-ITDs. Furthermore, pre-pro-B cells, which retain both B-cell and myeloid potential, were markedly expanded and myeloid-bias in Flt3-ITD mice, whereas subsequent stages of committed CD19+ B-cells were reduced.To explore the mechanistic basis for this ITD-induced myeloid-bias, we examined levels of Pu1, a master-regulator of myeloid commitment during early hematopoiesis, using a Pu1-YFP reporter. Expression of Pu1 was significantly increased in LSK cells (1.4 fold) and in pre-pro-B cells (2.6 fold) in Flt3-ITD mice. Moreover, gene-set enrichment analysis in MPPs demonstrated upregulation of Pu1 target genes in Flt3-ITD mice. Furthermore, the loss of mature B-cells in Flt3-ITD mice could be partially rescued by Pu1 haploinsufficiency.**Summary:** These findings demonstrate how activating growth factor receptor mutations might subvert lineage commitment pathways and decisively influence the lineage outcome of the resulting cancer already at the pre-commitment stage.

Background. Acute myeloid leukemia (AML) is hypothesized to be sustained by self-renewing leukemia stem cells (LSCs). Recently, Eppert et al (Nat.Med.2011;17:1086-93) studied functionally defined AML LSC populations, derived an LSC-specific gene expression signature (GES), and compared it with a normal hematopoietic stem cell (HSC) signature. Expression of a "core enriched"(CE) GES, which was based on the LSC signature and represents genes commonly activated in both normal and leukemic stem cells, was linked to worse survival in CN-AML. However, whether other molecular markers and microRNA (miR) expression associate with and contribute to the prognostic impact of the CE GES remains unknown.**Aims.** To study associations of the CE GES with known molecular prognosticators, miR expression, and outcomes in cytogenetically normal (CN-)AML. **Methods.** Gene/miR expression profiling was performed on pretreatment marrow/blood samples from 200 older (60-83 years[y]) patients with primary CN-AML enrolled on frontline Cancer and Leukemia Group B protocols, using Affymetrix HG-U133plus2.0 and OSU-CCCv4 microarrays. The CE score, a linear combination of CE GES expression values, was derived as described by Eppert et al. CE-high and CE-low groups were divided at the median CE score of all patients. Patients were also characterized for *NPM1,WT1,CEBPA,IDH1/IDH2,TET2,DNMT3A,ASXL1&RUNX1* mutations, *FLT3*-internal tandem duplications (ITD)&tyrosine kinase domain (TKD) mutations, *MLL*-partial tandem duplications, and *BAALC,ERG&MN1* expression. **Results.** Compared with CE-low patients, CE-high patients had higher marrow blast percentages (*P*=.004), were more likely to have *FLT3*-ITD (48% vs 15%, *P*<.001), mutated *RUNX1* (26% vs 7%, *P*<.001), high *BAALC* (67% vs 36%, *P*<.001) and high *ERG* expression (77% vs 30%, *P*<.001). On the other hand, CE-high patients were less likely to belong to the European LeukemiaNet Favorable Genetic Group (*P*<.001), have *FLT3*-TKD (*P*=.01) and mutated *TET2* (*P*=.01).Compared with CE-low patients, CE-high patients showed significant upregulation of 21 miRs, with no miRs being downregulated. Some of the upregulated miRs are known to be highly expressed in HSCs, including *miR-125a/b* (enhance proliferation/disturb differentiation of myeloid progenitors), *miR-126/miR-126** (increase survival/inhibit apoptosis of AML blasts, downregulated in *NPM1*-mutated CN-AML), *miR-130a/b*, *miR-146*, *miR-155* (upregulated in *FLT3*-ITD-positive AML), and *miR-196a*.Regarding treatment outcomes, CE-high patients had a lower CR rate (58% vs 75%; *P*=.02), shorter disease-free survival (DFS; *P*<.001; 3y rate, 5% vs 27%), and shorter overall survival (OS; *P*<.001; 3y rate, 11% vs 28%) than CE-low patients. In multivariable analyses, CE-high status remained associated with shorter DFS (*P*<.001) after adjustment for R882-*DNMT3A* mutation status (*P*<.001) and *BAALC* expression (*P*=.02), and shorter OS (*P*<.001) after adjustment for R882-*DNMT3A* mutation status (*P*=.03), *BAALC* expression (*P*<.001), and WBC (*P*=.01). **Summary.** Expression of the CE GES, representing genes highly expressed in LSCs and HSCs, associates with known unfavorable molecular markers (*FLT3*-ITD, mutated *RUNX1* and high *BAALC/ERG* expression) in older CN-AML, but remains independently associated with inferior outcomes after adjustment for known prognosticators. Strong expression of the CE signature was paralleled by a characteristic miR signature, including upregulation of miRs with known importance for stem cell function. Our results suggest these miRs may be functionally important in LSCs and might thus be targets for novel therapies.

Background. In acute myeloid leukemia with complex karyotype (CK-AML) *TP53* alterations are the most common known molecular lesions, and recently a link between p53 and miR-34a network has been identified to play an important role in the pathogenesis of many tumors. **Aims.** To further explore the p53-miR-34a axis in CK-AML we analyzed a large cohort with and without *TP53* alteration (n=57 *TP53*^{altered} and n=31 *TP53*^{unaltered} cases; alteration refers to either loss and/or mutation of *TP53*).Results. First, we profiled microRNA (miRNA) expression to delineate *TP53* alteration-associated miRNA profiles. This identified miR-34a and miR-100 as the most significantly down- and up-regulated miRNAs, respectively. Profiling gene expression we also found a distinct miR-34a expression-linked gene expression profile enriched for genes belonging to p53-associated pathways and implicated in cell cycle progression or apoptosis (such as the Biocarta pathways "Cell Cycle G2/M Checkpoint", "Cell Cycle G1/S Checkpoint", "Regulation of cell cycle progression by Plk3", or "Tumor Suppressor Arf pathway"). CK-AML with low miR-34a-expression (below median expression of the entire cohort, CK$^+$/miR-34a$^{low\ expression}$) were older (median age, 59 vs. 52 years, p=.006) and showed in trend higher LDH serum levels (median U/l, 591 vs. 415, p=.05). Subgroup analysis comparing cases with the lowest miR-34a expression (1st quartile, CK$^+$/miR-34a$^{1st\ quartile}$) with all other cases (2nd-4th quartiles, CK$^+$/miR-34a$^{2nd\text{-}4th\ quartiles}$) revealed higher WBC for CK$^+$/miR-34a$^{1st\ quartile}$ (p=.02). Furthermore, miR-34a-expression was associated with resistance to chemotherapy. Response to induction therapy for CK$^+$/miR-34a$^{1st\ quartile}$ and CK$^+$/miR-34a$^{2nd\text{-}4th\ quartiles}$ was as follows: complete remission (CR) 14% (3/21) vs. 42% (26/62) (p=.03), and refractory disease (RD) 57% (12/21) vs. 34% (21/62) (p=.07), respectively. Other variables predicting for poor response to induction therapy were age [CR 18% (6/34) vs. 47% (23/49) for CK-AML >60 years and CK-AML <60 years, respectively; p=.009] and *TP53* alteration [CR 25% (13/52) vs. 52% (16/31) for *TP53*^{altered} and *TP53*^{unaltered} CK-AML, respectively; p=.02]. MiR-34a-expression was associated with inferior survival, the 3-year estimated survival rates for CK$^+$/miR-34a$^{low\ expression}$ and CK$^+$/miR-34a$^{high\ expression}$ patients were as follows: overall survival (OS) 4% vs. 20% (p=.006), and event free survival (EFS) 0% vs. 7% (p=.003), respectively. Other variables predicting for inferior OS in univariable analysis were *TP53*^{altered} (p=.0007) and in trend age (>60 years; p=.05). Multivariable analysis revealed miR-34a-expression (HR, 1.47; 95%-CI, 1.06 to 2.03; p=.02), *TP53*^{altered} (HR, 2.93; 95%-CI, 1.43 to 6.02; p=.003), logarithm of WBC (HR, 1.71; 95%-CI 1.02 to 2.89; p=.04), and age (HR, 1.03; 95%-CI, 1.01 to 1.04, p=.008), but not LDH serum level or monosomy 7 as significant variables for OS. Of note, we also observed several cases with high miR-34a-expression despite a biallelic alteration of *TP53*. Explorative subgroup analysis revealed that among *TP53*$^{biallelic\ altered}$ CK-AML, those with high miR-34a-expression [4th quartile (n=11) compared to the other cases (n=30) of the *TP53*$^{biallelic\ altered}$ cohort] had a significantly better OS (p=.02). Summary and Conclusions. Detailed molecular profiling links impaired p53 to decreased miR-34a-expression but also suggests p53-independent mechanisms of miR-34a-induction. An improved understanding of this mechanism might provide novel therapeutic options to restore miR-34a-function and thereby induce cell cycle arrest and apoptosis in *TP53*^{altered} CK-AML.

Background. AML with balanced rearrangements of the *mixed-lineage leukemia* gene (*MLL*) on chromosome band 11q23 occur in ~5% of adult cases. Outcome of t(11q23) AML is reported to be poor, except for AMLs with t(9;11) (intermediate prognosis). Risk stratification still largely depends on clinical risk factors and the translocation type present. High expression of *ecotropic viral integration-1* (*EVI1+*) was shown to be associated with t(11q23) AML; furthermore, *EVI1+* appeared to confer inferior prognosis in this AML subset.**Aims.** We hypothesize that *EVI1+* may be one of the important genetic events underlying the clinical heterogeneity of t(11q23) AML and thus aimed to explore the prognostic impact of *EVI1+* in a large cohort of t(11q23) AMLs in the context of clinical features and genetic markers.*Patients and* **Methods.** 286 (3.6%) AMLs with t(11q23) were identified in a combined cohort of 7728 AML patients enrolled in German-Austrian AMLSG and Dutch-Belgian HOVON prospective treatment trials. Patients were enrolled in seven different trials of the AMLSG (HD93, HD98A, HD98B, 07-04, 06-04, SHG95, SHG99) and five trials of the HOVON/SAKK AML study groups (HO04/A, -29, -42/A, -43, -92). Material could be retrieved in 177 cases for *EVI1* expression analysis.*Results.* Most frequent t(11q23) AML subgroups were as follows: t(9;11)(p22;q23) (n=128, 44.8%), t(6;11)(q27;q23) (n=42, 14.7%), and t(*v*;11q23) (n=116, 40.5%). Most common translocation partners within t(*v*;11q23) were t(11;19)(q23;p13.1)/*MLL-ELL* (n=18, 15.5%) and t(10;11)(p13;q23)/*MLL-MLLT10* (n=14, 12.1%). *EVI1+* was found in 45.8% (81/177) of all t(11q23) cases, with t(6;11) showing the highest frequency (83.9%), followed by t(9;11) (40.0%), and t(*v*;11q23) (34.8%). Multivariable analysis among all available t(11q23) AMLs revealed *EVI1+* to be the sole prognostic factor, predicting for inferior overall (OS; *p*=.001, HR 2.30), relapse-free (RFS; *p*=.004, HR 2.19), and event-free survival (EFS; *p*=.004, HR 1.93). There was no difference in achievement of complete remission (CR) between *EVI1+* and *EVI1*$^-$ t(11q23) AMLs. Relapse probability of t(11q23) AMLs was significantly higher in the presence of simultaneous *EVI1* overexpression (cumulative incidence of relapse at 5 years 74.8% of *EVI1+ vs* 48.3% of *EVI1-*, *p*=.0002). *EVI1+* t(11q23) AMLs in first CR had a significantly better outcome after allogeneic transplantation compared with other consolidation therapies (5-year OS: 54.7% *vs* 0%; Mantel-Byar, *p*=.0006). Within the subgroup of t(9;11) AML, *EVI1*$^-$ AMLs had lower white blood cell counts (*p*=.01), higher platelet counts (*p*=.01), more commonly FAB M5 morphology, and frequently had additional trisomy 8 (39.6%; *p*<.001). Concurrent gene mutations were virtually absent in t(9;11) AMLs; only rare *FLT3*-ITDs were identified (5/89 cases; 5.6%), whereas no sequence variations were found for all other genes analyzed (*CEBPA*, *NPM1*, *RUNX1*, *IDH1/2*, *ASXL1*, *TET2*, *DNMT3A*). Following multivariable analyses among t(9;11) AMLs, *EVI1+* again was the sole independent adverse prognostic factor for OS (*p*=.004, HR 3.20), RFS (*p*=.002, HR 3.73), and EFS (*p*=.001, HR 3.27).*Summary:* High expression of *EVI1* is found in approximately 50% of all t(11q23) AMLs. *EVI1+* is the strongest adverse prognostic factor in all t(11q23) AMLs and in the subset of t(9;11) AMLs. Allogeneic SCT in first CR seems to be beneficial for patients with *EVI1+ MLL*-rearranged AML.

LEUKEMIC STEM CELL FREQUENCY WITHIN MINIMAL RESIDUAL DISEASE PROVIDES ADDITIONAL PROGNOSTIC INFORMATION IN ACUTE MYELOID LEUKEMIA PATIENTS

W Zeijlemaker, A Kelder, M Terwijn, A Snel, A Rutten, D Veldhuizen, Y Oussoren-Brockhoff, W Scholten, G Ossenkoppele, G Schuurhuis
VUmc, Amsterdam, Netherlands

Background. Relapses of acute myeloid leukemia (AML) after chemotherapy occur in about 40% of AML patients due to outgrowth of minimal residual disease (MRD) cells, which in turn originate from leukemic stem cells (LSC). Retrospective studies have shown that MRD frequency can predict clinical outcome. We have recently demonstrated the prognostic impact of MRD in a prospective study (*Terwijn, submitted),* emphasizing the importance of MRD assessment for future clinical decision making. However, relapses are still seen in patients with low MRD levels, indicating that these patients have remaining, but poorly detectable or undetectable disease. A possible explanation is that apart from the frequency of leukemic blast cells, also the much lower frequencies of LSC determine the chance for relapse. **Aims.** To assess whether in AML LSC frequencies offer prognostic information additional to MRD. **Methods.** LSCs, similar to normal hematopoietic stem cells (HSC), reside within the CD34+CD38- compartment. LSCs can be discriminated from HSC by aberrant expression of CLL-1 *(van Rhenen, Blood 2007)* and lineage markers *(van Rhenen, Leukemia 2007)*. However, these markers were often not, or only partly expressed on LSC, leaving marker negative LSC unidentified. In part of these cases secondary gating strategies like forward scatter (cell size) and sideward scatter (cell granularity) could be applied to discriminate LSCs from HSCs *(Terwijn, ASH 2010:759*). **Results.** LSC assessment using marker expression was possible in 179/250 (72%) CD34+ AML patients. Using a marker/secondary gating approach this percentage increased to 88% (219/250) and we have demonstrated for the first time the presumed importance of LSCs by showing that high LSC frequency in remission bone marrow predicts relapse in AML patients *(Terwijn, ASH 2010;759).*Since both MRD and LSC frequency have prognostic impact, we combined both in a series of 68 AML patients and found that LSC frequency assessment in remission bone marrow revealed a poor prognostic subgroup (n=12), with a median relapse-free survival of 12 months, within the patient group with low/undetectable MRD levels (n=49), thereby strongly improving the prognostic impact. Poor performing patients can now be defined as having high MRD, high LSC or both high MRD and LSC. To make LSC assessment possible in all CD34+ AML patients we are currently using a multiple marker approach, combined with the secondary parameters. Upon using multiple markers the number of patients potentially eligible for LSC assessment increased from 72% to 89%. Current efforts are also directed towards identification of LSCs in CD34 negative AML, with the ultimate aim to track LSC in all AML cases. In ongoing studies we will establish whether the prognostic impact of LSC frequency as well as the combination of LSC and MRD assessment holds in a prospective setting. If so, we think it will become important to include both MRD and LSC frequency assessment in clinical decision making. **Conclusions:** 1. LSC frequency together with MRD frequency best predicts adverse outcome in AML patients. 2. With a multiple marker/secondary parameter flow cytometry approach we are able to identify LSCs in almost 90% of the CD34+ AML patients.

Background. Acute myeloid leukemia (AML) is a biologically and clinically heterogeneous disease. Although karyotype remains the most powerful prognostic factor of AML, gene mutations have become increasingly important for prognostic assessment and therapeutic management of AML patients, especially in cytogenetically normal (CN) AML. Recently, we showed that the addition of fractionated doses of gemtuzumab ozogamicin (GO) to standard chemotherapy significantly improves outcome in older AML patients (Castaigne *et al.*, ASH meeting 2011).**Aims.** To evaluate the incidence of mutations in 8 genes, their associated characteristics and prognostic relevance in AML patients enrolled on the Acute Leukemia French Association (ALFA) 0701 trial. **Methods.** We studied a cohort of 278 patients (50-70 years) with primary AML treated in the ALFA-0701 trial. Patients were randomized to receive "3+7"induction without (arm A) or with (arm B) GO. Patients achieving CR/CRp received two "1+4"consolidation courses ± GO according to randomization arm. Diagnostic samples were analyzed by standard PCR-based methods and Sanger sequencing for the presence of *FLT3* internal tandem duplication (*FLT3*-ITD), *MLL* partial tandem duplication (*MLL*-PTD), *FLT3*-D835/I836, *NPM1, CEBPA, WT1 (*exons 7 and 9*), IDH1*R132*, IDH2*R140*, IDH2*R172*,* and *DNMT3A* (exons 8-9 and 11-23) mutations. The screening for *IDH1/2* and *DNMT3A* mutations was restricted to CN-AML.*Results.* In the whole patient cohort, incidence of *NPM1, FLT3*-ITD*, CEBPA, FLT3*-D835/I836, *WT1* and *MLL*-PTD mutations was 34%, 18%, 7%, 4%, 2.5% and 2%, respectively. Within the CN-AML subgroup (n=142), incidence of *NPM1, DNMT3A, FLT3*-ITD*, IDH1*R132, *CEBPA, IDH2*R140, *IDH2*R172, *MLL*-PTD, *WT1* and *FLT3*-D835/I836 mutations was 50%, 31%, 25%, 12%, 9%, 8%, 4.5%, 3%, 2.5% and 2%, respectively. *NPM1*, *FLT3*-ITD, *DNMT3A* and *CEBPA* mutations were associated with leukocytosis and *IDH2*R172 with leukopenia. *FLT3*-ITD, *IDH2*R140 and *DNMT3A* mutations were strongly associated with the presence of *NPM1* mutations. *FLT3*-ITD frequently co-occurred with *DNMT3A* but rarely with *IDH2*R140 mutations. Prognostic significance of mutations was investigated in the whole CN-AML cohort. In univariable analyses, *CEBPA* mutations predicted longer event-free survival (EFS) (P=0.039) but not overall survival (OS) (P=0.33). Longer but not significantly different EFS (P=0.089) and OS (P=0.092) were observed in case of *IDH2*R140 mutation. In contrast, *DNMT3A* mutations and, to a lesser extent *FLT3*-ITD, predicted shorter EFS (P=0.005 and 0.13, respectively) and OS (P=0.0010 and 0.035, respectively). Age, white blood cell count and other mutations studied, including *NPM1* mutations, did not significantly affect outcome. In multivariable analysis, *IDH2*R140 and *DNMT3A* mutations remained significantly predictive of EFS (P=0.05 and 0.01, respectively), while only *DNMT3A* mutational status was retained as significantly associated with OS (P=0.001). We next performed survival analysis in CN-AML considering each randomization arm separately. Notably, this analysis revealed that *FLT3*-ITD was associated with shorter EFS (P=0.023) and OS (P=0.0025) in arm A, but had no impact on EFS (P=0.90) and OS (P=0.71) in arm B.*Conclusions.* In this trial*,* the only prognostic factors identified in CN-AML were *IDH2*R140 and *DNMT3A* mutations, associated with favorable and adverse outcome, respectively. Importantly, our results suggest that the addition of fractionated doses of GO to standard chemotherapy could overcome the negative prognostic impact of *FLT3*-ITD.

[6]Dutch Childhood Oncology Group (DCOG), The Hague, Netherlands

Background. Due to optimization of induction treatment, approximately 90% of AML pediatric patients achieve a complete remission in high income countries. However, relapses still occur in 30-40% of patients and outcome in these patients is dismal. Prevention of relapse offers the best opportunity for improvement of outcome, however mechanisms involved in AML relapse development are largely unknown. **Aims.** By genome wide gene expression profiling, we aim to identify key molecules and signaling pathways that are involved in the development of relapses that may offer opportunities for targeted treatment. **Methods.** Total mRNA of primary and relapse bone marrow samples (>80% blasts, n=46) was obtained from 23 pediatric AML patients and used for Affymetrix HGU 133 plus 2.0 microarrays. Mutation analyses for relevant type I/II aberrations were performed in both primary and relapse samples. For statistical analyses we used BioConductor packages, Significance Analysis of Microarrays (SAM) and BRB Arraytools. Pathway analysis was performed using Ingenuity pathway analysis. **Results.** Analysis of paired diagnosis and relapse samples revealed large inter-patient differences in the number of genes that were differentially expressed. Unsupervised cluster analysis showed that for 61% of patients the primary leukemia and relapse sample cluster next to each other. The remaining paired samples clustered more distant and interestingly the majority of these pairs also showed changes in mutation status of *FLT3*, *RAS* and *WT1*. In concordance with previous results (Bachas *et al,* Blood, 2010), these events were associated with shorter time to relapse. Pathway analysis of matched primary AML and relapse samples of the differentially expressed genes (> 2 fold) revealed molecular pathways implicated in cancer, inflammatory disease, hematopoietic development and genetic disorders. Subset expression of previously published *FLT3/ITD*, *WT1* and *RAS* mutation specific signatures in individual patients, changed according to gain or loss of mutations. In patients without mutational shifts, the signatures retained their expression levels.By *in silico* class prediction, we found 31 genes to be differentially expressed and discriminative for diagnosis or relapse samples with an accuracy of 70%-83%, depending on the method. Of the 31 genes, 29 showed a lowered expression in the relapse sample when compared to the initial diagnosis sample (median intensity ratio diagnosis/relapse= 1.74, range=1.47-2.33, $P_{29th\ gene}$=0.032) and 7 of these 29 genes have functions in the maintenance of chromatin structure, among which a number of histone variants. Preliminary RT-PCR results on histone variants *HIST1H1C* and *HIST1H2BG* confirmed this for an independent set of patient samples. *In vitro* cytotoxicity experiments indicate that 4 AML cell lines show a strong sensitivity towards an experimental drug that specifically targets histone variant mediated apoptosis. Additional tests using primary patient material are currently performed.ConclusionsWe identified genes and pathways that were significantly differentially expressed between diagnosis and relapse samples. Mutational shifts contribute to changed gene expression. Depletion of specific histone variants may be an epigenetic phenomenon in relapse development and may be targetable via new experimental therapeutics. Our efforts are directed to determine if these findings will be instrumental to design therapies aimed at preventing relapses.

[3]Paris Cardiovascular Research Center, Paris, France

Background. Engagement of cell surface receptors coupled to the activation of the phospholipase C leads to an increase in intracellular calcium that results in the activation of calcineurin (Cn), a serine/threonine phosphatase composed of a catalytic (CnA) and a regulatory (CnB) subunit. Calcium-dependent activation of Cn leads to dephosphorylation of its substrates, including the NFAT family of transcription factors (NFATc1-c4). Cn/NFAT signaling plays critical role in a number of developmental processes, but is best characterized for its implication in controlling many aspects of T cell biology. We have previously reported the sustained activation of Cn in human lymphoma, acute lymphoblastic leukemia (ALL) and mouse models of lymphoid leukemias/lymphomas. Preclinical studies showed that pharmacological targeting of Cn with cyclosporine A (CsA) and FK506 has clear anti-leukemic effects in T-ALL mouse models. Besides its inhibitory activity towards leukemic cells, systemic delivery of these compounds is likely to inhibit Cn in cells of the tumor microenvironment, possibly contributing to their anti-leukemic activity. **Aims**. To investigate the intrinsic function of calcineurin in leukemic cells, we generated mouse T-ALL in which Cn can be specifically inactivated in tumor cells without affecting the tumor microenvironment. **Methods.** We generated mouse models of human T-ALL induced by either an activated *Notch1* allele (ICN1) or the TEL-JAK2 fusion oncoprotein in which Cn inactivation is specifically obtained in leukemic cells by Cre-mediated deletion of a conditional, floxed *CnB1* allele. We examined consequences of Cn inactivation on leukemia dissemination and reinitiation in these models. **Results.** We found that Cn activation in leukemic cells is under stromal control and that Cn inactivation alters physical and functional interactions that leukemic cells establish with their microenvironment, including their abnormal adhesion, migration and defective leukemic cells survival and proliferation. We show that Cn favors but is not required for *in vivo* expansion of leukemic blasts. In contrast, Cn is critical for leukemia-initiating cell activity as analyzed in transplantation studies. Importantly, Cn ablation in *de novo* homed leukemic cells also abolished disease re-initiation. **Conclusions.** These results demonstrate that calcineurin has an intrinsic pro-oncogenic function in leukemic cells that affects several phenotypic traits of tumor cells that ultimately control leukemia dissemination and expansion *in vivo*. Besides, these findings indicate that calcineurin is a promising target to prevent T-ALL relapse and call for clinical trials combining conventional debulking therapies with- or followed by Cn inhibitors during consolidation therapy.

[2]Department of Pediatrics and Adolescent Medicine, University of Ulm, Ulm, Germany

Intensification of chemotherapy regimens have improved the outcome of patients suffering from acute lymphoblastic leukemia (ALL) presently achieving cure rates of above 80%. Still 20% of the patients encounter relapse associated with inferior outcome, especially if occurring early. Importantly, despite the efforts achieved by stratification strategies including detection of molecular minimal residual disease, the majority of relapse patients are initially not identified by current markers and stratified into non-high risk groups. This clearly emphasizes the need for additional prognostic markers that reflect features of leukemia biology and thereby point to novel therapeutic targets.Previously, we have described a strong association of leukemia cell engraftment of primary patient B cell precursor (BCP) ALL samples transplanted in a NOD/SCID/huALL mouse model and patient outcome. Rapid engraftment (time to leukemia, TTL^{short}) is indicative for early patient relapse and associated with a gene expression profile pointing to pathways involved in cell growth and proliferation, most prominently mammalian target of rapamycin (mTOR).In this study we now functionally address mTOR activation in xenograft ALL samples and evaluate inhibition of this key survival pathway as novel treatment strategy for ALL *ex vivo* and *in vivo*. Previously characterized xenografts with respect to their engraftment phenotype (TTL^{short}/early relapse, n=5 or TTL^{long}/no or late relapse, n=8) were re-transplanted onto NOD/SCID mice and ALL cells were harvested at disease onset from leukemia bearing mice. We analyzed mTOR pathway activation by flow cytometry assessing phosphorylation of ribosomal protein S6 (P-S6), a molecule downstream of mTOR. Increased P-S6 levels were detected in TTL^{short} compared to TTL^{long} xenografts (U-test, P= .019) implying constitutive mTOR hyperactivation in TTL^{short}/early relapse leukemia. Moreover, the mTOR inhibitor rapamycin and the dual PI3K/mTOR inhibitor BEZ235 were analyzed. Most interestingly, both inhibitors showed a significant reduction in pathway activation in the TTL^{short} but not in most of the TTL^{long} xenografts indicating that the hyperactivated mTOR pathway of this high risk ALL subtype can be efficiently targeted.We then investigated the effect of mTOR inhibition on individual patient derived ALL *in vivo*. TTL^{short} (n=3) or TTL^{long} (n=2) leukemia samples were transplanted onto NOD/SCID mice. Upon appearance of leukemia in the peripheral blood, mice were treated with rapamycin or solvent and time to reoccurrence (TTR) of leukemia was analyzed as time from treatment until onset of leukemia related morbidity. Most interestingly, mTOR inhibition led to a significant delay of post-treatment ALL reoccurrence in all TTL^{short}/high risk ALL xenografts in contrast to similar leukemia free survival of TTL^{long}/low risk leukemias irrespective of rapamycin treatment. In a clinical setting high risk disease is unlikely to be treated by one compound alone. Therefore, we combined mTOR inhibition with multidrug chemotherapy resembling ALL induction treatment and observed a significantly prolonged TTR in 2 TTL^{short} leukemias compared to chemotherapy alone.In summary, we show that TTL^{short}/early relapse leukemia is functionally characterized by hyperactivated mTOR signaling and can effectively be targeted by mTOR inhibition *ex vivo* and *in vivo* thus providing a novel therapeutic strategy for the treatment of high risk ALL.

Background. MTORC1 signaling pathway is constitutively activated in most AML. The RAD001 (Everolimus) is a specific allosteric inhibitor of mTORC1 whose effectiveness has been demonstrated in solid tumors. We present here the results of a Phase Ib trial combining RAD001 and intensive chemotherapy in patients under 65 years with AML in first relapse (NCT 01074086).Materials and methods:Patients (pts) under 65 years in relapse more than one year following their first CR after chemotherapy + / - auto or allograft were enrolled between March 2008 and December 2011. The treatment consisted of increasing doses of RAD001 from 10mg to 70mg, with 10mg increments, administered orally on day 1 and day 7 of chemotherapy (Daunorubicin 60mg/m2/D1-D3+aracytine 200mg/m2/D1-D7). A second course of induction chemotherapy was re-administered without RAD001 if medullary blasts> 5% at D15. The plasma inhibitory activity (PIA) of the pts on the phosphorylation of p70S6K in MOLM14 cell line and the RAD001 AUC were determined.Results. Twenty five pts were enrolled in this trial. Their median age was 50.3 years (median: 20 to 65), sex ratio M / F: 1/1 (13/12); subtypes of AML: AML0 = 1, AML1 = 4, AML2 = 2, AML4 = 2, AML5 = 6, chemotherapy related AML = 4, with multilineage dysplasia = 2, CBF AML= 2. Cytogenetics: intermediate (n = 19) including 17 normal, good (n = 2), poor (n = 4). Treatment was well tolerated with less than 10% toxicity of all grade, mainly gastrointestinal liver and lung toxicity. The SAE were: appendicitis and mucormycosis at 10mg dose level (DL), a grade 4 skin toxicity with erythema and ulceration at 20mg DL, Fournier gangrene and Candida parapsilosis sepsis considered as DLT at 50mg DL which justified the inclusion of three additional patients at 50mg, one interstitial pneumonia with alveolar hemorrhage caused by infection at 70mg DL where there are currently 4 patients included. 17/25 pts were in CR (68%), of which 11 had a double induction. Eight pts have been allografted.The PIA was tested. We observed a strong inhibition of phosphorylation of p70S6K in all samples, 4 hours after administration of RAD001, regardless of the DL (mean decrease 93%). At 60 mg and 70 mg DL, significant inhibition was maintained through D3. On day 7 with 70 mg, the average inhibition was still around 40%.The median RAD001 AUC (1.82mg.h / l) was reached from 50mg DL. The CR rate of pts with AUC above the median was 90% vs 45% if AUC <1.82mg.h / l (p = 0.01) and this result remained significant after adjustment for karyotype, Flt3 status and age.Conclusion:In this Phase Ib trial testing the combination of RAD001 and chemotherapy, the DLT is not reached at 70mg/week. The overall CR rate is 68%. Above 50 mg DL, the CR rate is 90%. The PIA observed at 70 mg DL of RAD001 shows sustained inhibition of mTORC1 activity in vivo. An expansion cohort is underway at 70mg DL and the promising CR rates should be confirmed.

MDS and AML - Clinical & translational

[3]MD Anderson Cancer Center, Houston, United States of America

Background. Severe congenital neutropenia (SCN) is a bone marrow failure syndrome frequently associated with constitutional mutations in neutrophil elastase *(ELANE)* and a high risk to progress towards acute myeloid leukemia (AML). SCN patients are routinely treated with colony-stimulating factor 3 (CSF3). Acquisition of truncating mutations in the granulocyte-colony stimulating factor receptor (*CSF3R*) gene is a known phenomenon in SCN patients; these mutations are found in approximately 80% of SCN patient who have progressed towards AML, while they can be present in a minority of bone marrow cells already years before leukemic progression. Hence, alterations other than *CSF3R* truncating mutations are involved in SCN evolution to AML. So far, these underlying mechanisms remain largely unknown. **Aims.** We aimed to identify commonly affected pathways in SCN and its progression towards AML by next-generation sequencing of sequential hematopoietic samples of SCN and SCN/AML patients. **Methods.** A 27-year old male with SCN (index patient), with an *ELANE* and a *CSF3R* truncating mutation, developed AML after 17 years of CSF3 treatment. Serial blood/marrow samples of this patient representing evolutionary stages of the disease, the first obtained 15 years before the AML became overt, were analysed. Acquired mutations in the leukemic blasts of this patient were determined using whole exome sequencing, followed by amplicon-based sequencing to detect them in earlier disease stages. As a germ line control, bone marrow derived fibroblasts were used. Single myeloid colony analysis was done to investigate co-occurrence of mutations in single myeloid progenitors early during the disease. The functional consequences of a new *CSF3R* mutation were analyzed in myeloid colony assays. **Results.** In the leukemic blasts of the index patient, we identified 12 acquired non-synonymous mutations in 11 genes. Three of these, a *CSF3R* truncating mutation and mutations in *LLGL2* and *ZC3H18*, were present already 15 years before the AML became overt and co-occurred in single myeloid progenitors already in the early SCN phase. The progenitor population carrying these mutations expanded in time, whereas clones solely harboring *CSF3R* mutations disappeared from the bone marrow. The other 9 mutations were only apparent in the AML phase and affected known AML-associated genes *(RUNX1* and *ASXL1*) and chromatin remodelers (*SUZ12* and *EP300)*. We designed a custom capture library, covering the 11 genes identified in the index case, their interaction partners and close homologues (32 genes in total) to identify mutations in an additional cohort of SCN (n=21) and SCN/AML (n=5) patients. These experiments are currently ongoing. Furthermore, a new extracellular *CSF3R* mutation was found in the leukemic blasts of the index patient, which was located on the allele that already carried the *CSF3R* truncating mutation. Strikingly, this new mutation induced autonomous proliferation of myeloid progenitors. **Conclusions**. Progression from SCN towards AML is a multistep process with mutations arising early during the neutropenia and late mutations appearing in the AML phase. A novel *CSF3R* mutation, imposing CSF3 independence on an already functionally defective *CSF3R* mutant, supports the involvement of abnormal CSF3 signaling in leukemic transformation of SCN.

[7]Hematology Unit, Azienda Ospedaliera B-M-M, Reggio Calabria, Italy

Background. Patients with severe thrombocytopenia due to myelodysplastic syndromes (MDS) are at a risk of bleeding. Lower IPSS risk patients receive platelet (PLT) transfusions, mainly in the presence of bleeding. Short therapeutic effect and the development of refractoriness to PLT transfusions motivate research in novel treatments. Eltrombopag is an orally bioavailable thrombopoietin receptor (TPO-R) agonist indicated for the treatment of thrombocytopenia in chronic immune idiopathic thrombocytopenia with insufficient response to corticosteroids, immunoglobulins, or splenectomy. **Aims.** We present preliminary results of a multicenter, prospective, randomized, single blind placebo-controlled trial to evaluate the safety and efficacy of eltrombopag in low and intermediate-1 risk MDS with PLT count $<30\times10^9$/L. Patients are ineligible for or relapsed or refractory to other treatments and naive to TPO-R agonists. **Methods.** Eltrombopag vs placebo (2:1 ratio) will be administered to 69 patients at a 50 mg daily initial dose with 50 mg increases every 2 weeks to a target PLT count of $100x10^9$/L. Dose interruptions or reductions are required for PLT $>200x10^9$/L or adverse events. PLT response is defined as response (R) if either an increase of PLT$\geq30\times10^9$/L from $\geq20\times10^9$/L or an increase to $>20\times10^9$/L from $<20\times10^9$/L and by at least 100% not due to transfusion is observed in the absence of bleeding; complete response (CR) if PLT $\geq100\times10^9$/L. Quality of life (QoL) is assessed from baseline with the QOL-E and EORTC QLQ-C30 questionnaires. **Results.** 12/69 patients (8 on active drug - Arm A) of median age 68, interquartile range 49-78, are enrolled and 2 are in screening at the time of the present report. Baseline median PLT count was 16×10^9/L (IQR 11-22$\times10^9$/L). Two cases (Arm A) had a WHO bleeding score >1. Only 1 patient (Arm A) had a bone marrow (BM) blast count >5%. In Arm A, four cases obtained an R and one a CR after 7 days and 3 of 6 evaluable patients had a CR after 14 days at the initial 50 mg daily dose; an additional patient had a CR at 6 weeks at a 250 mg dose. In Arm A no bleeding events occurred; at week 8 there was an increase in median PLT count from 16×10^9 to 120×10^9/L (IQR 51.5-189 10^9/L), while no change was observed with placebo (arm B), in which 9 bleeding events occurred. Among the 5 patients in Arm A reaching day 22 in study, QoL scores improved in Treatment Outcome Index in 4 cases; Physical, Functional, Fatigue, and Cognitive Well-being in 3; Social, and MDS-Specific dimensions in 2; and Emotional functioning in 1 case. Adverse events occurred in 4 patients in Arm A: grades 2 (n=2), 3 (n=1) and 4 (n=1), all unrelated to eltrombopag. One patient experienced a second adverse event (asthenia, grade 1) with a possible association with eltrombopag. Neither peripheral nor BM blast counts increased in either arms at interim analysis. **Conclusions.** Preliminary data suggest that Eltrombopag is effective and safe in the prevention of bleeding and in raising PLT counts in lower risk MDS patients with severe thrombocytopenia.

CLINICAL FEATURES, TREATMENT AND PROGNOSIS IN PATIENTS WITH MONOSOMY 7-INTERIM RESULTS FROM A GERMAN MULTICENTER STUDY

J Schanz[1], F Braulke[1], K Shirneshan[1], K Nachtkamp[2], U Germing[2], R Weis[3], M Lübbert[3], U Platzbecker[4], D Haase[1]
[1]University Medicine of Goettingen, Goettingen, Germany
[2]University of Duesseldorf, Duesseldorf, Germany
[3]University of Freiburg, Freiburg, Germany
[4]University of Dresden, Dresden, Germany

Background. Monosomy 7 is observed in about 2% of patients with myelodysplastic syndromes (MDS). Recent publications demonstrated a different prognostic impact for partial (del7q) as compared to total (-7) monosomy 7 (Cordoba et al., 2012, Schanz et al., 2012) and a therapeutic benefit for demethylating agents (DMA) in this group of patients (Fenaux et al., 2009). It was our aim to analyze the clinical features, prognosis and therapeutic strategies in a large, multicentric cohort study. **Patients and Methods.** To date, 172 patients with monosomy 7 were collected and retrospectively analyzed. Patient data was coalesced from the Universities of Göttingen (n=15; 9%), Düsseldorf (n=114; 66%), Freiburg (n=32; 19%) and Dresden (n=11; 6%). The median age of patients was 65 years, 65% were males. Based on the IPSS, 14.7% were classified as intermediate-1, 42.1% as intermediate-2 and 43.2% as high-risk. Concerning treatment, patients were classified as followed: Best supportive care (BSC), low-dose Chemotherapy (LDC), high-dose chemotherapy (HDC), demethylating agents (DMA; either 5-azacytidine or decitabine) and others. Patients who received allogeneic stem cell transplantation (allo-Tx) as the first line therapy were excluded from survival analyses. Those who were transplanted at a later stage were censored at the time of transplantation. **Results.** Patients with a monosomy 7 showed a higher proportion of advanced MDS stages at the time of the first diagnosis. In a recently published (Schanz et al., 2012) MDS study, RAEB-1/2 stages were found in 13.1% of all patients while in the present cohort, it was observed in 42.6% (p<0.01). The median and range was 9.1 g/dl (2.5-14.5) for hemoglobin (Hb), $1.3*10^3$/ml (0-22.4) for ANC and $75.0*10^3$/ml (3.0-843.0) for platelets, respectively. As compared to the independent cohort mentioned above, the median Hb did not show a pronounced difference (9.6 g/dl in the independent versus 9.1 g/dl in the -7/7q- cohort), while the median ANC ($2.1*10^3$/ml versus $1.3*10^3$/ml) and platelet count ($124*10^3$/ml versus $75*10^3$/ml) was clearly lower. The median survival in untreated patients with isolated -7 (n=21) was 12.5 months and 33.9 months (n=19) in del 7q (p=0.068); the median time to AML transformation was not reached in del(7q), while in -7 it was 14.4 months (p=0.149). The majority of patients were treated with best supportive care (BSC; 62.2%). The remaining patients received 1-3 sequential therapies (1: 23.8%; 2: 7.6%; 3: 6.4%). As a first line therapy, 21 patients (12.2%) received an allo-Tx, 6 (3.5%) HDC, 4 (2.3%) LDC, 23 (13.4%) DMA and 11 (6.4%) were treated with other therapies. Patients who received DMA at any course of their disease showed a median survival of 23.6 months as compared to 10.0 months in patients treated with any other therapy (p=0.025). The AML-free survival was 22.8 months in DMA vs. 14.4 in others (p not significant). **Conclusions.** Patients with monosomy 7 show distinct clinical features, prognostic impact and response to therapy. Here, we present first interim results of the German monosomy 7 cohort. Further data of the ongoing study will be presented in detail.The study is supported by research funding from Celgene

1140

HIGH LEVELS OF GLOBAL DNA METHYLATION ARE AN INDEPENDENT ADVERSE PROGNOSTIC FACTOR IN A SERIES OF 90 PATIENTS WITH DE NOVO MYELODYSPLASTIC SYNDROME (MDS)

X Calvo[1], M Nomdedeu[1], D Costa[1], A Navarro[2], A Pereira[1], R Tejero[2], C Muñoz[1], F Cobo[3], J Rovira[1], M Díaz-Beyá[1], M Monzó[2], J Esteve[1], B Nomdedeu[1]
[1]Hospital Clínic, Barcelona, Spain
[2]Human anathomy and Embriology department, School of Medicine, UB, Barcelona, Spain
[3]Teknon Hospital, Hematology Department, Barcelona, Spain

Background. Since the introduction of hypomethylating agents, the pathogenic involvement of methylation in the progression and prognosis of MDS has become of great interest. The DNA methyltransferase inhibitors have been the only treatment capable of significantly prolonging survival in high-risk MDS by inducing direct citotoxicity and global hypomethylation. The hydroxymethylation, which consists in adding a hydroxyl group at the 5' end of the 5-methylcytosines (5-mC), has been described as a passive DNA demethylation process inducing gene reexpression. **Aims.** To test whether 1) higher levels of global methylation are associated with a worse prognosis, and 2) higher hydroxymethylation levels predict a better outcome. **Methods.** Ninety patients (49M/41F; median age 75 years, range 32-97) with de novo MDS diagnosed from 2002 to 2009 were classified according to WHO 2008 criteria as RA (n=2), RARS (n=3), isolated del(5q) (n=1), RCMD (n=63), RAEB-1 (n=9), RAEB-2 (n=11), MDS-U (n=1). At the study closing date, median follow-up for surviving patients was 4.8 years (range 1.3 - 9.3 years). According to IPSS 77 patients belonged to the low risk (low, Int-1) categories and 13 patients to the high risk (Int-2, high) categories. We also applied the WPSS (65 low vs. 25 high) and R-IPSS (77 low vs. 13 high). Genomic DNA was isolated from bone marrow samples obtained at diagnosis using a commercial kit (Qiagen®). Global methylation and hydroxymethylation were determined in all patients by ELISA (Epigentek®) using anti-5-mC and anti-5-hydroxymethylcytosine (anti-5-hmC) monoclonal antibodies obtaining the percentage of 5-mC and 5-hydroxymethylcytosine (5-hmC) in total DNA. **Results.** Using the R software version 2.9.0. (maxstat), we estimated a significant cutpoint of the percentage of 5-mC: 2.7269%, near the 75 percentile, selecting 15 patients with global 5-mC levels above the cutpoint. We could not obtain an optimal cutpoint for the 5-hmC percentage with statistical significance. 5-hmC levels had no impact in overall survival (OS) or leukemia-free survival (LFS), moreover, we could not correlate it with IPSS, WPSS or R-IPSS risk subgroups. In contrast, patients with 5-mC below 2.7269% had a better OS than those with more methylated DNA (median 59.2 vs. 14.4 months; p=0.018; Figure 1). On the other hand, we observed a positive trend in terms of LFS (p=0.084). Furthermore, we observed higher 5-mC percentage at the high risk groups (poor and very poor) of R-IPSS using the Student's t-test (mean 2.8% vs. 2.1%; p < 0.001; 95% CI 0.5-0.8). It is of note that patients with transfusion requirement had a worse OS (p=0.01) and a shorter LFS (p=0.048). Using the Cox regression analysis including age, sex, 5-mC above 2.7269%, transfusion requirement and IPSS (Int-2/High), all these variables were independently associated with worse outcome except sex.**Conclusions:** Degree of global DNA methylation appeared as an independent prognostic factor in MDS patients. These results, if validated in larger series of patients, would support using this assay as a new prognostic tool and might guide the use of hypomethylating agents in the treatment of MDS.

C/EBPg and C/EBPa are transcription factors that belong to the family of CCAAT/enhancer-binding proteins (C/EBPs). Proper C/EBP levels and activity are necessary during hematopoiesis, and defects in these proteins have been related to the development of AML. We recently demonstrated that C/EBPg is highly upregulated in a specific subset of AML samples characterized by silencing of C/EBPa. Similarly, C/EBPg was upregulated in C/EBPa knockout murine hematopoietic stem/progenitor cells (LSK). Downregulation of C/EBPg expression in murine C/EBPa deficient LKS cells or in human AML samples with C/EBPa silencing was sufficient to completely restore granulocytic differentiation, as demonstrated by in vitro experiments and transplantations assays. Given these observations, in the present study we investigate (1) whether and how C/EBPa regulates C/EBPg expression, (2) whether high C/EBPg levels are sufficient to induce a granulocytic differentiation arrest and (3) the mechanism by which C/EBPg overexpression results in a differentiation block. First, we performed C/EBPa chromatin immunoprecipitation (ChIP on Chip) in a C/EBPa expressing cell line, and showed that C/EBPa binds to the C/EBPg promoter. To determine whether C/EBPa could negatively regulate C/EBPg we generated a human C/EBPg promoter luciferase reporter construct and performed luciferase assays. Cotranfection of this reporter with increasing amounts of a C/EBPa expression plasmid showed that C/EBPa was able to repress C/EBPg promoter activity in a dose-dependent manner. Mutation and deletion reporter constructs demonstrated that the C/EBPa binding sites within the C/EBPg promoter were not required for the C/EBPa mediated repression and that C/EBPa reduced C/EBPg transactivation by affecting E2F1 activity. Next, to study the contribution of C/EBPg to the pathogenesis of AML we overexpressed C/EBPg in an *in vitro* differentiation model and in murine bone marrow cells, and observed that sustained expression of this transcription factor induced a block of neutrophilic differentiation. Using a C/EBPg-ER inducible system, we demonstrated that C/EBPg regulates crucial granulocytic differentiation factors, such as C/EBPa and G-CSF-R. Altogether our experiments indicate that C/EBPa binds and represses C/EBPg expression, that enforced C/EBPg expression results in a granulocytic differentiation block and that this block is mediated by the repression of myeloid differentiation drivers. In conclusion our study provides novel insights of the contribution of C/EBPg to the development of AML in a specific subset of AML.

Multiple myeloma - Clinical

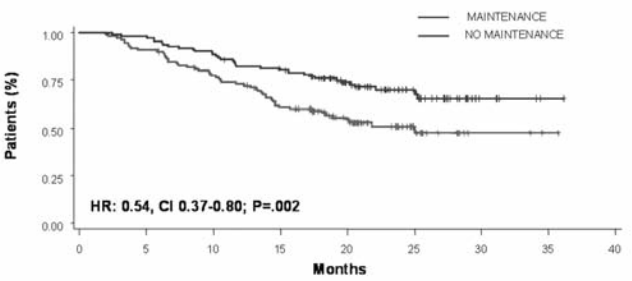
Background. High-dose therapy with autologous stem cell transplantation (ASCT) is considered the standard treatment for patients with multiple myeloma (MM) who are younger than 65 years. The incorporation of new drugs into induction, consolidation and maintenance therapy is changing the treatment paradigm of newly diagnosed MM.**Aims.** To compare in a prospective randomized trial (MM-RV-PI209) conventional chemotherapy plus novel agents [melphalan-prednisone plus lenalidomide (MPR)] with tandem high-dose melphalan (melphalan 200 mg/m2 with stem-cell support; MEL200), both followed by maintenance with lenalidomide or no maintenance.

Figure. Progression free-survival by maintenance



Methods. Four-hundred two patients were enrolled and received induction treatment with four 28-day cycles of lenalidomide (25 mg, days 1-21) in combination with low-dose dexamethasone (40 mg, days 1,8,15,22). After induction therapy, 202 patients were randomly allocated to MPR treatment [six 28-day cycles of melphalan (0.18 mg/kg days 1-4), prednisone (2 mg/kg days 1-4) and lenalidomide (10 mg days 1-21)] followed by maintenance with lenalidomide (10 mg, days 1-21; N=98) or no maintenance (N=104). The 200 other patients were assigned to receive MEL200, followed by maintenance with lenalidomide (10 mg, days 1-21; N=100) or no maintenance (N=100). Progression-free survival (PFS) was the primary endpoint of this study. Data were analyzed in intention-to-treat. **Results.** Patients characteristics were well balanced, including median age (58 years in both groups), ISS and FISH abnormalities [presence of t(4;14) or t(14;16) or del17p]. Response rates were similar after consolidation (MPR vs MEL200), with very good partial response (VGPR) or better of 60% vs. 58% (p=0.24) and complete response (CR) rate of 20% vs. 25% (p=0.49). After a median follow-up of 33 months (IQR 26-37), the 3-years PFS was 38% in MPR and 59% in MEL200 (HR=0.60, p=0.0009). The 3-year overall survival (OS) was similar: 82% with MPR and 85% with MEL200 (HR 0.87, p=0.57). The median duration of maintenance was 18.4 months (IQR 13-22). Lenalidomide maintenance did not significantly increase response rate: CR rate was 20% after MPR and 22% after maintenance, while it was 25% after MEL200 and 30% after maintenance. The 2-year PFS from the start of maintenance was 66% for patients randomized to maintenance and 47% for the no-maintenance arm, demonstrating that maintenance with lenalidomide reduced the risk of disease pro-

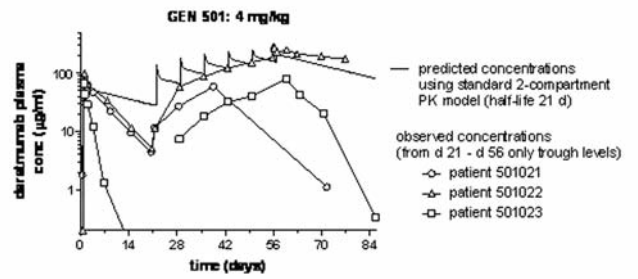
gression by 46% (HR 0.54, p=0.002, Figure). The 2-year OS survival was similar: 88% with lenalidomide maintenance and 85% without maintenance (HR 0.71, p=0.28). Patients who received MPR plus lenalidomide maintenance had a similar 2-year PFS compared with patients receiving MEL200 without maintenance (59% and 63%, respectively, p=NS). The rate of second primary malignancies was 2% in both maintenance arms. **Conclusions.** Lenalidomide maintenance significantly reduced the risk of progression in newly diagnosed young MM patients. PFS of patients receiving MPR plus maintenance is comparable to MEL200 without maintenance, at present no difference in survival is reported.

1143

DARATUMUMAB, A CD38 MONOCLONAL ANTIBODY IN PATIENTS WITH MULTIPLE MYELOMA - PRELIMINARY EFFICACY AND PHARMACOKINETICS DATA FROM A DOSE-ESCALATION PHASE I/II STUDY

H Lokhorst[1], P Gimsing[2], H Nahi[3], P Richardson[4], T Plesner[5], S Lisby[6]
[1]University Hospital Utrecht, Utrecht, Netherlands
[2]Copenhagen University Hospital, Copenhagen, Denmark
[3]Karolinska University Hospital, Huddinge, Sweden
[4]Dana-Farber Cancer Institute, Boston, United States of America
[5]Vejle Hospital, Vejle, Denmark
[6]Genmab A/S, Copenhagen, Denmark

Background. Daratumumab (HuMax®-CD38) is a human CD38 monoclonal antibody with broad-spectrum killing activity; it effectively kills CD38-expressing tumour cells via antibody-dependent cell-mediated cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC), and apoptosis. In this ongoing first-in-human (FIH) dose-escalation study of daratumumab in pts with multiple myeloma (MM) (ClinicalTrials.gov CT00574288), the safety profile has been accetable[1].AimThe purpose of this ongoing FIH study is to establish the safety profile and maximal tolerated dose. Furthermore, exploratory assessments of efficacy and pharmacokinetics (PK) will be performed.MethodsPts ≥18 years and previously diagnosed with MM requiring systemic therapy and considered relapsed or refractory to at least two different prior lines of therapy and not eligible for salvage ASCT were enrolled. The design of this study encompasses an accelerated dose-escalation based on a classical 3+3 design. Daratumumab is administrated over a 9 week period encompassing 2 pre-doses and 7 full-doses.



The doses range from 0.005 mg/kg to 24 mg/kg.Daratumumab plasma concentrations were measured by ELISA. Plasma levels were compared with those predicted using a standard 2-compartment PK model with V_{cen} = 40 ml/kg and elimination half life = 21 days.Evaluation of efficacy data was according to Rajkumar[2]. This abstract presents preliminary data on PK and efficacy, and the results presented are based on data analyzed before database lock.ResultsData from 23 pts including the 4 mg/kg cohort are collected.PK analysis showed plasma peak levels as expected, but relatively rapid and variable clearance at low dose levels. Clearance rate decreased with increasing dose, which suggests an effect of target binding on the PK. At 4 mg/kg, the impact of target-mediated clearance tended to become small and plasma concentrations went up towards the range expected for non-binding IgG (Figure).Preliminary efficacy evaluation in this abstract is based on best response to paraprotein as reflected by change in serum and/or urine M-component. For groups ≤ 1 mg/kg, 3/17 pts achieved a reduction in serum M-component (12%, 14%, 19%); in the 2 mg/kg group, 1/3 pts had a reduction in urine M-component (55%); and in the 4 mg/kg group, 3/3 pts had a reduction in the serum M-component of 49%, 55%, and 64%, respectively. Furthermore, a marked reduction to normal level in the percentage of bone marrow plasma cells was seen in the 4 mg/kg group in all patients, 80%, 89%, and 97%, respectively.The toxicity has been manageable.Conclusion-In pts with relapsed or refractory MM treated with daratumumab, a reduction in M-component and bone marrow plasma cells has been observed in the 4 mg/kg cohort. No unexpected accumulation of daratumumab has been seen in patients treated with 4mg/kg during 9 weeks of treatment. The toxicity has been manageable. Further data will be presented at the meeting.[1]Gimsing: ASH 2011 abstract 1873[2]Rajkumar: Blood 2011;117:4691-5

Background. MLN9708 is an oral, reversible, and specific 20S proteasome inhibitor under clinical evaluation in multiple tumor types, including previously untreated multiple myeloma (MM). The feasibility and efficacy of combining a proteasome inhibitor with an immunomodulatory drug and a steroid in previously untreated MM has been demonstrated with the bortezomib, lenalidomide, and dexamethasone (RVD) regimen.**Aims.** Two Phase 1/2 studies (NCT01217957, weekly MLN9708, and NCT01383928, twice-weekly MLN9708) are ongoing to determine the safety, maximum tolerated dose (MTD), recommended Phase 2 dose (RP2D), and anti-tumor activity of oral MLN9708 in combination with lenalidomide and dexamethasone.

	MLN9708 W (n=51)	MLN9708 TW (n=6)

Drug-related grade ≥3 AEs, n (%)	19 (37)	1 (17)
Most common related grade ≥3 AEs, n (%)		
Diarrhea	2 (4)	0
Erythematous rash	2 (4)	0
Syncope	2 (4)	0
Vomiting	2 (4)	0
Serious AEs, n (%)	16 (31)	1 (17)
Discontinuations due to AEs, n (%)	2 (4)	0
On-study deaths, n	0	0

Methods. Patients with previously untreated MM aged ≥18 years with measurable disease received weekly (W) or twice-weekly (TW) oral MLN9708: W dosing, MLN9708 days 1, 8, and 15, lenalidomide 25 mg days 1-21, and dexamethasone 40 mg days 1, 8, 15, and 22 of 28-day cycles; TW dosing, MLN9708 on days 1, 4, 8, and 11, lenalidomide 25 mg days 1-14, and dexamethasone 20/10 mg (cycles 1-8/cycles 9-16) days 1, 2, 4, 5, 8, 9, 11, and 12 of 21-day cycles. Dose escalation proceeded using a standard 3+3 schema based on the occurrence of dose-limiting toxicities in cycle 1. Adverse events (AEs) were graded by NCI-CTCAE v4. Response was assessed by IMWG criteria with nCR included. **Results.** At data cut-off (Jan 27, 2012), 51 patients (median age 65 years [range 38-86]; 82% ISS stage I/II) had received MLN9708 W (15 Phase 1, 1.68-3.95 mg/m^2; 36 Phase 2, 4.0 mg fixed dose), and 6 patients (median age 64 years [range 56-78]; all ISS stage I/II) had received MLN9708 TW (all Phase 1, 4 at 3.0 mg, 2 at 3.7 mg). To date, on the W schedule, Phase 1 and 2 patients have received a median of 6 (range 1-13) and 2 (range 1-4) cycles, respectively; TW patients have received a median of 2.5 cycles (range 1-3). 39 W and all 6 TW patients remain on treatment; 6 W patients discontinued to receive ASCT. Safety data are shown in the Table. Drug-related grade ≥3 toxicity was reversible and included diarrhea, erythematous rash, syncope, and vomiting (each n=2) on the W schedule, and hyperglycemia (n=1) on the TW schedule. Any-grade drug-related peripheral neuropathy (PN) was observed in 7 patients on the W schedule and 1 patient on the TW schedule; there was only 1 patient with grade ≥3 PN on the W schedule (at 3.95 mg/m^2, a dose above the MTD). Of 38 response-evaluable W patients, 34 (89%) have achieved ≥PR, including 7 CR (1 sCR), 5 VGPR, and 22 PR; all remain in response with duration of response of up to 13 cycles. All 3 response-evaluable TW patients have achieved ≥PR, including 2 VGPR and 1 nCR after cycle 2. Response evaluation is ongoing.**Conclusions:**Data suggest that both W and TW oral MLN9708 plus lenalidomide and dexamethasone are generally well tolerated with manageable toxicity and demonstrate encouraging signs of anti-tumor activity in patients with previously untreated MM.

Background. Elotuzumab is a humanized monoclonal IgG1 antibody targeting CS1, a cell surface glycoprotein. CS1 is highly expressed on >95% of multiple myeloma (MM) cells, with lower expression on natural killer cells and little to no expression on normal tissues. A phase 1 trial of elotuzumab plus lenalidomide and low-dose dexamethasone demonstrated an 82% objective response rate (ORR) in patients with relapsed/refractory (RR) MM (Lonial et al. J Clin Oncol, in press). **Aims.** To determine safety and efficacy of elotuzumab in combination with lenalidomide and low-dose dexamethasone in patients with RR MM including those with high-risk disease. **Methods.** In this phase 2 study, previously treated patients with MM were randomized to elotuzumab 10 or 20 mg/kg IV (days 1, 8, 15, and 22 every 28-days in first 2 cycles and days 1 and 15 of subsequent cycles), lenalidomide 25 mg PO (days 1-21) and dexamethasone 40 mg PO weekly. Prophylaxis for infusion-related reactions (IRs) was administered prior to each elotuzumab infusion. Treatment continued until disease progression or unacceptable toxicity. The primary objective was to assess efficacy (ORR ≥partial response [PR]) according to IMWG criteria.Results. Among 73 patients (median age 63 years; range, 39-82), 55% had received ≥2 prior therapies, 60% had received prior bortezomib, and 62% prior thalidomide. ORR was 82% for all patients including 48% ≥ very good PR (VGPR). The ORRs were 92% in the 10 mg/kg group (n=36) and 73% in the 20 mg/kg group (n=37). Median time to objective response was 1.0 months (range, 0.7-5.8). After a median follow-up of 14.1 months, median progression-free survival (PFS) has not been reached, with PFS rates of 75% (10 mg/kg) and 65% (20 mg/kg). ORRs of 80% and 81% were shown in patients with high-risk cytogenetics and/or Stage 2-3 MM, respectively. The most common grade 3/4 toxicities were neutropenia (16%), lymphopenia (16%), and thrombocytopenia (16%). Investigator-designated IRs were reported in 12% of patients (all grades); 1 patient (1.4%) had grade 3 IR (rash). Summary and Conclusions. Elotuzumab in combination with lenalidomide and low-dose dexamethasone was generally well tolerated and resulted in a high ORR, and PFS not reached after 14.1 months of median follow-up in patients with RR MM. The combination also showed encouraging activity in patients with high-risk cytogenetics and/or Stage 2-3 MM. Updated results will be presented at the meeting. Two phase 3 trials of 10 mg/kg elotuzumab in this combination are ongoing in newly diagnosed MM (ELOQUENT1; CA204-006; NCT01335399) and RR MM (ELOQUENT2; CA204-004; NCT01239797).

A MUTLI-INSTITUTIONAL EXPERIENCE WITH UPFRONT CYCLOPHOSPHAMIDE, BORTEZOMIB AND DEXAMETHASONE (CVD) IN THE TREATMENT OF AL AMYLOIDOSIS

P Venner[1], A Jaccard[2], P Hawkins[1], M Roussel[3], S Gibbs[1], J Gillmore[1], H Lachman[1], C Whelan[1], L Maramattom[4], H Parameswaran[4], R Comenzo[5], A Wechalekar[1]

[3]Hématologie Clinique, CHU Purpan,, Toulouse, France

[4]Medical College of Wisconsin, Milwaukee, United States of America

[5]Tufts Medical Center, Boston, United States of America

Background. Bortezomib combinations have shown great promise in the treatment of AL amyloidosis. Here we present the largest multi-centre experience to date using the cyclophosphamide, bortezomib and dexamethasone (CVD) regimen as upfront therapy. The series is representative of patients from France, the USA, and the UK.**Objective.** Characterise the response to CVD when used in the upfront treatment of AL amyloidosis. **Patients and Methods.** The primary cohort was comprised of 75 patients treated between 2006-2011. Bortezomib (1.0-1.3 mg/m^2) was administered on either the a weekly (days 1, 8, 15 and 22 in a 5 week schedule) or twice weekly (days 1, 4, 8 and 11 in a 3 week schedulte) with oral dexamethasone (10 or 20 mg, 4 to 8 doses) and cyclophosphamide (300 mg/m^2 (max 500 mg) on days 1, 8 and 15). Complete information for staging by the Mayo clinic criteria was available in 73 patients, and 73% were stage III based on biomarkers obtained prior to the initiation of CVD. Haematologic and dFLC responses were measured and analyzed on an intention-to-treat (ITT) basis. Deaths during therapy were deemed non-responders. Overall survival (OS) was estimated from the start of treatment and measured in months (m). BNP response were also assessed as previously described. Data use was approved by the institutional review boards at each site. Written consent was obtained from all patients. **Results.** Median follow-up was 7.9m (0.0-37.3). Average number of cycles given was 4 (1-8). By ITT 74 patients were assessable for response based on conventional hematologic response criteria. Seventy one patients were assessable for a dFLC response. By ITT the overall hematologic response rate (RR) was 78% (CR = 42% and dFLC-VGPR = 54%). Eighteen patients (24%) died within 6 m of therapy all with stage III disease. Analyzing the patients assessable for response at 6 m of treatment the RR was 92%, CR rate was 51% and dFLC-VGPR rate was 63%. Mayo cardiac staging succesfully identified high risk patients (figure 1A). Thirty one patients were assessable for a NT-proBNP response which was acheived in 10 patients (35%). Median OS has not been reached. The estimated 1-year OS was 74%. Attaining both a CR and dFLC-VGPR correlated with a significant improvement in OS (figure 1B). Neuropathy was seen in 19% of patients but contributed to discontinuation of treatment in only 8%. **Conclusion:** This retrospective series lends further support to the use of bortezomib containing regimens in the treatment of AL amyloidosis, especially in the upfront setting. It is the largest series of patients treated with CVD reported to date. Despite a large proportion of patients with advanced Mayo stage disease high rates of CRs and dFLC-VGPRs are attained. In

addition, it emphasizes the importance of attaining deep clonal responses to maximize outcome. Overall, these response rates compare favorably to previously published treatment options for this disease and corroborate recently published single-institution experience with the CVD combination. Larger prospective phase III studies are warranted and are underway.

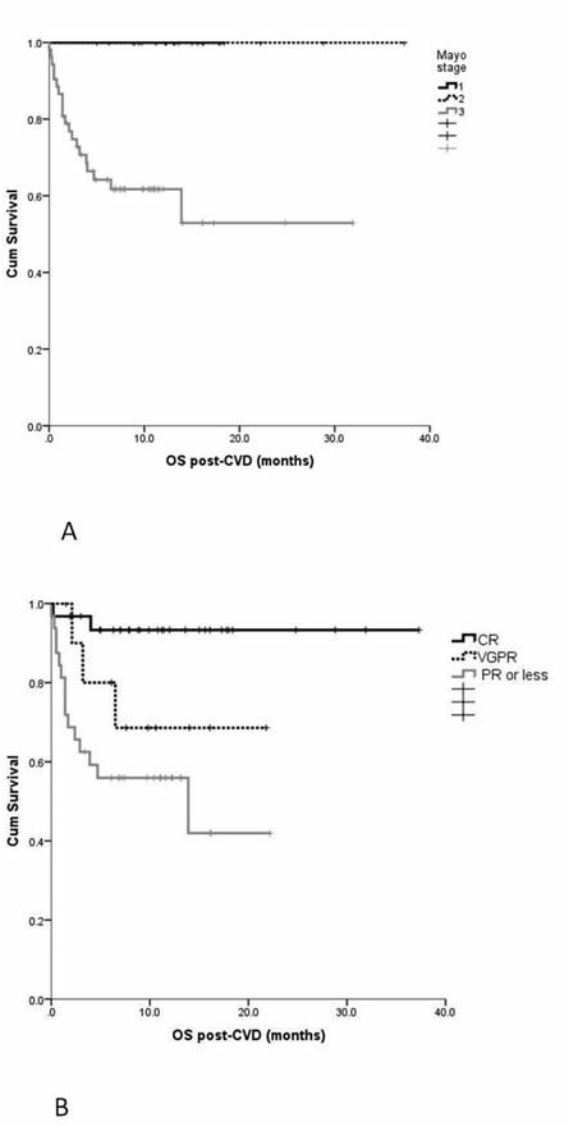

Figure 1. Overall survival in based on (A) Mayo cardiac stage (P=0.03) and (B) depth of hematologic response (P=0.001).

VON WILLEBRAND FACTOR EXPRESSION IDENTIFIES A SUBPOPULATION OF THROMBOPOIETIN-DEPENDENT MEGAKARYOCYTIC-BIASED HEMATOPOIETIC STEM CELLS

A Sanjuan Pla[1], I Macaulay[2], C Jensen[2], S Moore[1], C Nerlov[1], S Jacobsen[1]
[1]MRC Centre for Regenerative Medicine, Edinburgh, United Kingdom
[2]The Weatherall Institute of Molecular Medicine, Oxford, United Kingdom

Primitive multipotent stem and progenitor cells express at low level lineage-specific genes otherwise restricted to mature blood cell types, an event known as lineage priming. Although, the concept of multi-lineage transcriptional priming is well established, its importance in lineage commitment is less understood. We observed that the megakaryocyte and endothelium restricted gene encoding von Willebrand factor (*Vwf*) is expressed at relatively high levels in phenotypically defined hematopoietic stem cells (HSCs). To determine if *Vwf* expression and megakaryocytic lineage priming identifies a novel subset of potentially megakaryocytic biased HSCs, we generated a bacterial artificial chromosome (BAC) transgenic reporter mouse line expressing enhanced green fluorescent protein (EGFP) under control of murine *Vwf* regulatory elements. Flow cytometry phenotyping of this reporter line showed that *Vwf*-EGFP transgene is selectively expressed in a fraction of phenotypic HSCs, in megakaryocyte progenitors and platelets. We fractionated the adult long term hematopoietic stem cell (LT-HSC: LSKCD150^{+}CD48^{-}CD34^{-}) compartment using *Vwf*-EGFP transgene, isolated and characterized molecular and functionally both subpopulations. Global gene profiling and gene set enrichment analysis demonstrated that *Vwf*-EGFP^{+} HSCs are megakaryocyte transcriptionally primed, expressing genes present in a megakaryocyte-specific molecular signature as determined by Q-PCR. When transplanted at low numbers, *Vwf*-EGFP^{+} HSCs are more efficient in producing platelets/myeloid cells than *Vwf*-EGFP^{-} HSCs whereas the latter, although fulfilling the HSC definition, give rise to more B and T cell progenitors. A hierarchy can be established between these two subpopulations, with *Vwf*-EGFP^{+} HSCs preceding *Vwf*-EGFP^{-} HSCs. To get insight into *Vwf*-EGFP^{+} HSCs regulation, we generated *Vwf*-EGFP$^{tg/+}$; *Thpo*$^{-/-}$ mice and observed that no *Vwf*-EGFP^{+} HSCs are present in these mice. Furthermore, thrombopoietin-deficient LSKCD34^{-}Flt3^{-} HSCs down-regulate megakaryocytic genes and up-regulate erythroid and myeloid genes in comparison to wild-type HSCs. These results suggest a role of thrombopoietin as a driver of the megakaryocytic bias observed in *Vwf*-EGFP^{+} HSCs. In summary, our work expand current knowledge on HSCs heterogeneity and reveal, to our knowledge, not previously described megakaryocytic-biased HSCs.

STAT1-DEFICIENT MICE DEVELOP A MYELOPROLIFERATIVE SYNDROME RESEMBLING HUMAN CML

C Christine[1], A Hölbl[1], M Müller[1], T Kolbe[1], T Decker[2], V Sexl[1]
[1]University of Veterinary Medicine Vienna, Vienna, Austria
[2]MFPL, University of Vienna, Vienna, Austria

Background. The transcription factor STAT1 (signal transducer and activator of transcription) is a member of the JAK-STAT signaling pathway and is activated by a wide range of cytokines and growth factors. Gene deletions in mice revealed the essential role for STAT1 in immunity and tumor surveillance. This can be attributed to an impaired Interferon (IFN) signaling, as well as to defective *Stat1-/-*cytotoxic T-cells (CTLs) and NK cells which are incapable of lysing tumor cells. Interestingly, several patients have been reported to suffer from germline STAT1 mutations or even from complete STAT1-deficiency, which is reflected by severe immunodeficiencies, especially with susceptibility to mycobacterial or viral diseases.Besides being a key factor in immune regulation, STAT1 is also considered an important tumor suppressor. We have recently shown that mice deficient for STAT1 develop mammary cancer, which can be attributed on the one hand to impaired CTL activity, on the other hand to enhanced proliferation of *Stat1-/-*mammary epithelial cells and their tendency to uncontrolled growth.Now we show for the first time that *Stat1-/-* mice spontaneously develop a myeloproliferative syndrome during age. **Aims.** The aim of the project is to characterize *Stat1-/-*leukemia and to understand the molecular mechanisms driving the disease. We further intend to investigate which cell is the origin of the disease and whether this cell also maintains leukemia. **Methods.** *& Results.* Analysis of *Stat1-/-*mice at different time points revealed, that increased amounts of Gr1^{+}Mac1^{+} myeloid cells can already be detected at an

early age in bone marrow and blood of *Stat1-/-*mice, compared to wild-type controls. In the course of time, these cells start to manifest as well in peripheral lymphoid organs like spleen and lymph nodes. Beginning at the age of 8 months *Stat1-/-*mice succumb to the disease - the animals suffer from severe hepatospleenomegaly and blood leukocyte counts reach numbers up to 300 000 per microliter. Bone marrow transplantation experiments revealed that the disease can be transferred into recipient animals.*Conclusion:Stat1-/-*mice develop a myeloproliferative syndrome, which can be transplanted into secondary recipient mice. The exact mechanism how the disease develops is still unclear and requires further investigation.

1149

ROLE OF JAM-B/JAM-C INTERACTION IN THE CIRCULATION OF HEMATOPOIETIC STEM CELLS AND THEIR RETENTION IN THE BONE MARROW

ML Arcangeli[1], F Bardin[1], R Adams[2], C Chabannon[1], M Aurrand-Lions[1]
[1]CRCM UMR Inserm 1068, Marseille cedex 09, France
[2]Max Planck Institute for Molecular Biomedicine, Muenster, Germany

Background. The junctional adhesion molecules JAM-B and JAM-C belong to the Ig superfamily and interact together. We have previously shown that JAM-C is involved in the regulation of the immune response and controls chemokine secretion by stromal cells in secondary lymphoid organs (Frontera, Arcangeli et al 2011). In adult mammals, cells from the blood system are continually generated by hematopoietic stem cells (HSC) that reside in the bone marrow (BM). HSC are maintained in a quiescent and undifferentiated state through adhesive interactions with specialized microenvironmental niches. We have recently demonstrated that JAM-B, expressed by BM stroma microenvironment, controls HSC maintenance and retention in the BM and delivers stemness signals to HSCs (Arcangeli et al Blood 2011). Indeed, *jam-b* deficient mice are characterized by increased BM cellularity and frequency of cycling HSCs, suggesting that HSC from *jam-b* deficient mice are more prone to exit the niche. This is consistent with our results showing, *jam-b* deficient mice exhibit an exacerbated response to mobilizing agents (Arcangeli et al Blood 2011).**Aims.** In the present study, we address the question whether JAM-B and JAM-C are involved in the circulation of hematopoietic progenitors in mouse as well as in human model of xenograft and whether targeting the JAM-B/JAM-C interaction can induce the mobilization of hematopoietic progenitors specifically.**Method:** Using flow cytometry, blocking antibodies, *jam-b* deficient mice and xenograft model in NGS mice, we show that the couple JAM-B/JAM-C controls the circulation of murine as well as human hematopoietic progenitors.**Results.** Targeting JAM-B/JAM-C interaction using anti-JAM-C blocking antibody induces specifically hematopoietic progenitor mobilization, but not mature cells. In addition, the anti-JAM-C blocking antibody does not mobilize progenitors of *jam-b* deficient mice showing that the anti-JAM-C dependent progenitor mobilization is dependent of JAM-B expression by BM stromal cells. Mobilized HSC have downregulated JAM-C expression at cell surface and have lost the ability to interact with its ligand, JAM-B. In addition, anti-JAM-C antibody prevents hematopoietic progenitor homing and engraftment in the BM suggesting that the couple JAM-B/JAM-C regulates the entrance as well as the adhesion of hematopoietic progenitors in specific niches (manuscript in preparation). In parallel, we show that human CD34+ hematopoietic progenitors express JAM-C and are able to use JAM-B to adhere *in vitro*. *In vitro*, the addition, in the culture medium, of JAM-B or JAM-C soluble proteins or anti-JAM-C blocking antibody alters the adhesion of CD34+ progenitor cells on MS5 stromal cell lines. Furthermore, *in vivo*, in xenograft models, we show that anti-JAM-C blocking antibody prevents CD34+ hematopoietic progenitor homing in murine BM suggesting that in humans, the couple JAM-B/JAM-C may also regulate the interaction between hematopoietic progenitor and their specific microenvironment (manuscript in preparation). **Summary:** Altogether, our data suggest that the interaction JAM-B/JAM-C participates to the crosstalk between the bone marrow microenvironment and the hematopoietic progenitors. Although the mechanism by which the couple JAM-B/JAM-C acts on this crosstalk remains unclear, evidences suggest that this couple acts in BM homeostasis by regulating chemokine secretion.

1150

THE TRANSCRIPTION FACTOR MEIS1 REGULATES COMMITMENT TOWARDS THE MEGAKARYOCYTE-ERYTHROCYTE LINEAGE BY REGULATING GATA1 EXPRESSION

S Zeddies, S Jansen, F Summa, M von Lindern, C van der Schoot, D Thijssen-Timmer
Sanquin Research, Amsterdam, Netherlands

Background. The expression of specific transcription factors in hematopoietic stem and progenitor cells has been associated with the commitment towards a certain lineage fate.The homeobox transcription factor MEIS1 is required for hematopoiesis. Mice deficient for MEIS1 die at mid-gestation due to internal hemorrhages caused by defective vascularization and a lack of megakaryocytes and platelets. **Aims.** The aim of our studies is to unravel the contribution of MEIS1 to human hematopoiesis. **Methods.** MEIS1 knockdown and overexpression was achieved using lentiviral transductions. Transduced CD34+ human stem and progenitor cells were employed to semisolid media for colony formation. Cells were also harvested for RNA isolation and expression profiling.**Results.** Expression analysis of human hematopoietic stem and progenitor cell subpopulations showed that MEIS1 is present in the most immature hematopoietic stem cells (HSC: CD34+/CD38-) whereas expression decreased in more committed common myeloid progenitors (CMP: CD34+/CD38+/CD110-/CD45RA-), granulocyte-monocyte progenitors (GMP: CD34+/CD38+/CD110-/ CD45RA+) and megakaryocyte-erythrocyte-progenitors (MEP: CD34+/CD38+/CD110+/ CD45RA-). Lentiviral MEIS1 overexpression in CD34+ cells resulted in a 3-fold increase in erythroid colonies and a decrease in granulocyte-monocyte colonies. As total colony numbers were unaffected, the number of erythroid colonies increased at the expense of granulocyte-monocyte colonies. Concordantly, silencing MEIS1 abrogated erythroid colony formation. We therefore hypothesized that MEIS1 expression is important for the lineage decision of hematopoietic stem and progenitor cells towards a MEP fate. To elucidate at which level MEIS1 influences lineage fate, MEIS1 expression vectors were expressed in sorted CD34+ HSC, CMP, GMP and MEP. Erythroid colony formation increased 2-fold in HSC and 3-fold in the CMP subset indicating that MEIS1 is involved in the lineage decisions in these subsets. Interestingly, we also observed erythroid colony formation upon MEIS1 expression in sorted GMP indicating that MEIS1 overexpression can reprogram granulocyte-monocyte restricted progenitors into MEPs. Elevated MEIS1 expression in MEP does not affect colony composition compared to empty vector indeed indicating that lineage decision in less committed progenitors towards MEP is affected. We further investigated how MEIS1 exerts its effects. For this purpose we focused on the transcription factors GATA1 and PU.1. GATA1 upregulation negatively regulates PU.1 expression thereby restricting hematopoietic progenitor cells towards an erythroid fate. Vice versa, when PU.1 is induced cells are committed towards the granulocytic-monocytic lineage. Expression profiling of CD34+ cells 48 hours after transduction with MEIS1 expression vector showed increased GATA1 expression whereas PU.1 expression was not significantly altered. The CD34+ population in which we analysed Gata1 and PU.1 expression consisted mainly of CMP and GMP. GATA1 upregulation may be a first step to restrict the cells towards a MEP fate, which will be followed by PU.1 downregulation, subsequently.**In conclusion**, we show that MEIS1 is a crucial transcription factor for the megakaryocyte/erythroid lineage fate in human hematopoiesis and we provide evidence that GATA1 is a downstream target of MEIS1.

NERVE GROWTH FACTOR AND COLLAGEN 1 PREVENT APOPTOSIS AND MAINTAIN DURABLE SELF-RENEWAL OF ADULT MOUSE HEMATOPOIETIC STEM CELLS STIMULATED WITH PROLIFERATIVE CYTOKINES

S Wohrer[1], D Knapp[2], K Rowe[2], H Mader[2], M Copley[2], C Benz[2], D Kent[2], R Oostendorp[3], C Eaves[2]
[1]Medical University of Vienna, Vienna, Austria
[2]Terry Fox Laboratory, Vancouver, Canada
[3]Klinikum rechts der Isar, Munich, Germany

Background. Self-renewal is a key property of hematopoietic stem cells (HSCs) and the hallmark of stem cells in general. However, despite decades of research, it is still unknown which extrinsic factors are necessary to optimize HSCs self-renewal *ex vivo*.**Aims.** The present experiments were designed to identify potential stromal-derived factors that promote mouse HSC self-renewal *ex vivo***. Methods.** Highly purified HSCs isolated from mouse adult bone marrow (i.e. $EPCR^+$, $CD150^+$, $CD48^-$, $CD45^+$ cells, 42% having longterm repopulating ability) were cultured for 7 days in vitro in serum-free medium (SFM) and various combinations of cytokines, stromal cells and factors they produce. HSCs numbers were determined by performing limiting dilution transplants in sub-lethally irradiated congenic *W41/W41* mice assessed for repopulation activity of the transplanted cells 4-6 months post-transplant. Culture conditions that supported the greatest expansion of HSCs were used to assess the HSC output of single input cells and to design comparative gene expression analyses on 6-hour-stimulated cells to identify potential stromal factors involved. These were then tested for their potential to replicate the effects of stroma cells and stromal cell conditioned medium.**Results.** Of the various conditions initially tested, the addition of stromal cells or stromal cell-conditioned medium (CM) to Steel factor and IL-11 gave maximal and equivalent HSC outputs after 7 days. (5- to 11-fold expansion of transplantable HSC numbers). This indicated a stromal cell contact-independent mechanism. Visual tracking of single-cell cultures revealed that stromal cell-derived factors prevented the apoptosis of ~50% of the input cells and transplant assays of the CM-containg cultures showed that 90% of the cells that produced at least one daughter HSC did so asymmetrically and only 10% did so symmetrically. Gene expression analysis showed that pathways activated by collagen 1 (Col1) and nerve growth factor (NGF) were significantly upregulated during the self-renewing process and a direct test of these two factors combined indicated they could replace the activity of CM in promoting HSC survival and expansion.**Conclusion:** NGF and Col1 are key stromal-derived factors that can positively regulate adult HSC expansion when these are stimulated with proliferative cytokines.

BONE MARROW DERIVED MESENCHYMAL STROMAL CELL THERAPY FOR TREATING BIOLOGIC-REFRACTORY CROHN'S DISEASE, A MULTI-CENTRE AUSTRALIAN PHASE II STUDY

R Herrmann[1], M Sturm[1], K Shaw[1], J Fogarty[1], J Pawlik[1], A Cummins[2], R Leong[3], G Forbes[1]
[1]Royal Perth Hospital, Perth, Australia
[2]The Queen Elizabeth Hospital, Adelaide, Australia
[3]Concord Hospital, Sydney, Australia

Background. Mesenchymal stromal cells (MSCs) have immunomodulatory properties at multiple levels, involving action on T cells, B cells, dendritic and NK cells..These qualities have resulted in application to steroid-refractory acute graft versus host disease (AGVHD). Following a successful phase 1 trial in refractory GVHD (Herrmann, R et al, Int. J. Hem, 2012, 95 (2),182-128) we have expanded their application to biologic-refractory Crohn's disease and shortly will start a phase 2b randomised trial in de novo AGVHD. The treatment of advanced Crohn's disease has improved in recent years with the advent of the biologic therapies but in one third there is either primary non-response or a loss of response, resulting in the need for surgical removal of bowel. **Aims.** . The purpose of this study is to undertake an Australian multicentre phase II randomised safety and efficacy trial of allogeneic MSCs in biologic-refractory Crohn's disease where surgical intervention is declined. Four of eight Australian centres have obtained ethics approval for the study. The primary endpoint is clinical response (Crohn's disease activity index (CDAI) fall >100) and secondary endpoints include clinical remission (CDAI fall to <150) and endoscopic improvement at day 42. **Methods.** . MSCs are isolated after bone marrow aspiration from third party volunteer donors after informed consent and expanded under GMP in CTTWA, cryopreserved and assessed for microbial contamination as well as viability, phenotypic and cytogenetic characterisation. After patient screening, including mucosal biopsy for flow cytometric analysis and storage of samples for cytokine and chemokine array, patients receive four intravenous infusions of 2 x 10^6 MSCs per kg bodyweight, at weekly intervals.Results. To date 9 patients have been treated after giving informed consent; six have completed therapy, five (83%) demonstrating a clinical response (p=0.02) and three (50%) clinical remission to CDAI<150. Endoscopic improvement has been seen in two. All patients have experienced dysgeusia from the cryopreserving agent dimethyl sulfoxide. No infusion reactions, infections or secondary tumours have been seen to date.Logistic issues included the difficult (and often new) concept for ethics committees of cell therapy, the funding issues of an investigator led vs an industry study, the need for multi-disciplinary and multicentre collaboration and the ethical issues of obtaining normal volunteer donors.Conclusions. The study has proven feasible and regulatory and transport issues between states and capital cities overcome. Preliminary results are encouraging.

[7]University of Innsbruck, Innsbruck, Austria
[8]University of Milano Bicocca and S. Gerardo Hospital, Monza, Italy
[9]University of Milano Bicocca, Monza, Italy

Background. The Anaplastic Lymphoma Kinase (ALK) gene is fused to several partner genes (mainly NMP) in the majority of Anaplastic Large Cell Lymphoma (ALCL) patients. This disease is characterized by deregulated ALK tyrosine kinase activity, through the phosphorylation of proteins involved in apoptosis, cellular proliferation and differentiation. Although ALK + ALCL are responsive to cytotoxic drugs, relapses occur and bear a poor prognosis.Crizotinib is an experimental, orally bio-available, ATP-competitive small-molecule inhibitor of c-Met/HGFR receptor tyrosine kinases with cellular IC50 values between 24 and 60 nM in NPM-ALK+ cells. The recommended dose in ALK + ALCL, previously established in Phase I study, is 250 mg BID.MethodsWe report the safety and efficacy results of crizotinib in 9 ALK+ lymphoma patients (age 20-56y), resistant to cytotoxic therapy who received crizotinib 250 mg BID as a part of compassionate use named patient protocol. Morphological diagnosis was ALCL in 7 cases and Diffuse Large Cell Lymphoma in 2 cases. All patients were resistant to at least 3 lines of treatment including autologous bone marrow transplant (ABMT) in 3 cases and allogenic bone marrow transplant (alloBMT) in one patient. All had involvment at multiple sites (nodal and extranodal) as well as B symptoms (fever and bone pain). No steroids or drugs with antineoplastic activity were permitted during crizotinib treatment. All ALK + diagnosis were confirmed by FISH analysis using an ALK break-apart probe. Disease status was also assessed by CT/PET scans following RECIST criteria.ResultsIn all cases of B symptoms disappeared (median time 5 days after start of crizotinib, range 2-10 days), and LDH levels normalized (median time 25 days, range 15-35 days).

Patient	Previous treatment	Age	ABMT y/n	Best response
1	CHOP DHAP HD-VP16 + ALL 2000 scheme	27	n	CR 20+
2	CHOP MAD	20	y	CR 2
3	BFM HD-CTX + ARA-C VD	23	y	PR 1
4	CHOP VCR-ARA C-Dx-PND HYPER-C-HYDAM	23	n	CR 15+
5	BEP CHOP ICE HD-MTX + HD ARAC HYPER-C_VAD RT	40	n	SD 1
6	CHOP DHAP	30	y	PR 1
7	IEV DHAP CHOP	66	n	CR 11+
8	CHOP DHAP Dexa-BEAM	28	n	PRO
9	CHOP, ESHAP, ESHAP	34	n (alloBMT)	CR 8+

BM aspirates were ALK-positive in 4 patients by FISH and became negative within the initial 2 months of treatment. The earliest sign of therapeutic activity detectable by CT or PET scan was observed on day + 12 of crizotinib. Seven patients achieved response to crizotinib (5 CR, 2 PR see table 1) for an ORR of 78% (95% C.I.: 44-93%), 1 patient achieved stable disease (SD). Disease status at the latest follow-up is as follows: 4 CR (months 8+-20+), 5 PRO (4 deaths due to progression). Three of the 5 patients who relapsed had previously undergone ABMT. One patient in CR1 stopped crizotinib and underwent a related alloBMT. The disease recurred on day + 76 after transplant. She restarted crizotinib and obtained CR2 in 14 days. Toxicities observed were mild and include grade I-II diarrhoea, rash and ocular flashes. **Conclusions**.Crizotinib exerted a potent antitumor activity in advanced ALK+ lymphoma and obtained durable response (4/9 patients or 44% 95% C.I.: 19-73%) even in this population of heavily pre-treated patients.

MILATUZUMAB-AS A SINGLE AGENT IN REFRACTORY CLL- INTERIM RESULTS OF A PHASE I-II STUDY

M Haran, A Berrebi
Kaplan Medical Center, Rehovot, Israel

On behalf of the Israeli CLL study groupBackground. : Our previous work showed that the MHCII related protein-CD74, is over expressed from the very early stages of the disease. Activation of CD74 with its ligand MIF leads to survival signals in all stages[1]. Further more it also leads to increased VLA-4 expression with resultant homing to the bone marrow in advanced stages of the disease. We also showed that blocking CD74 with the humanized MoAb-milatuzumab leads to increased apoptosis and decreased migration to the bone marrow[2]. **Aims.** Based on our pre-clinical results the aim of our study was to assess the efficacy and toxicity of milatuzumab in advanced refractory CLL patients. **Methods.** Milatuzumab (120mg/m2) was given twice weekly for two months. After a four week wash out period, this was followed by escalating doses up to 600mg/m^2 for another 3 months. (See figure for details). Patients were then allowed to continue treatment as long as there were no significant adverse events or no further response.Results. So far, 6 patients with advanced refractory CLL, all heavily pretreated, were recruited. 3/6 showed significant improvement in their cytopenias, with no need for blood transfusions in 2 patients who were transfusion dependent prior to enrolment. 5/6 patients had significant improvement in B symptoms and functional level. None of the patients died or suffered significant treatment related toxicity during the study period. Patient samples were also studied and showed a decrease in bcl-2 , mcl-1 and VLA-4 mirroring what we have seen in the xenograft mouse model.Conclusions: Our results so far, combined with data from other studies using this agent in the USA suggest that it is safe and improves the quality of life and functional ability of frail elderly advanced stage CLL patients. It also suggests that it should be given continuously, as in most patients the effects were diminished after a short period of discontinuation of the agent. This was seen both in clinical and laboratory parameters. One patient received milatuzumab for over a year with no significant adverse effects.1. Binsky I, Haran M, Starlets D, et al. IL-8 secreted in a macrophage migration-inhibitory factor- and CD74-dependent manner regulates B cell chronic lymphocytic leukemia survival.

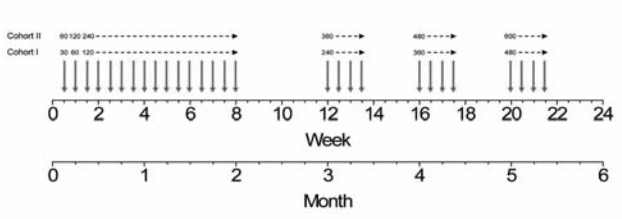

Figure 1. Milatuzumab treatment plan. The numbers to the left of top arrows are doses in mg per meter squared.

Background. Atypical hemolytic uremic syndrome (aHUS) is a rare, genetic, and life-threatening disease driven by chronic, uncontrolled complement activation that results in multi-organ damage caused by thrombotic microangiopathy (TMA). Despite plasma exchange/infusion (PE/PI), patients with aHUS have a poor prognosis, with a 33%-40% rate of progression to end-stage renal disease or death with the first clinical aHUS manifestation. Within a year of diagnosis, 65% of aHUS patients will require dialysis, have permanent renal damage, or die. Chronic treatment with eculizumab, a terminal complement inhibitor, has been demonstrated to be safe and effective in 2 prospective clinical trials of adult/adolescent aHUS patients and was recently approved in the United States and Europe for treatment of pediatric and adult aHUS patients.**Aims.** Assess the efficacy and safety of eculizumab treatment for aHUS in pediatric patients within a medical-practice setting. **Methods.** Medical record data were retrospectively collected for 19 aHUS patients aged <18 years (<2y [n=5]; 2-11y [n=10]; 12-17y [n=4]) who received eculizumab between 2007 and 2009 outside of a controlled clinical trial setting.

Baseline Characteristics	Aged <12 Years (n=15)	Aged <18 Years (N=19)
Platelet count <150×10^9/L, n (%)	7 (47)	8 (42)
eGFR <60 mL/min/1.73 m^2, n (%)	9 (60)	13 (68)
Received dialysis within 4 weeks of 1st eculizumab dose, n (%)	6 (40)	8 (42)
Previous kidney transplantation, n (%)	3 (20)	6 (32)
Identified genetic complement mutation, n (%)	7 (47)	10 (53)
Efficacy Outcomes During Eculizumab Treatment		
Platelet normalization (>150×10^9/L)		
All patients, n (%)	14 (93)	17 (89)
Patients with abnormal platelet count at baseline, n/N (%)	6/7 (86)	7/8 (88)
eGFR improvement ≥15 mL/min/1.73 m^2, n (%)	8 (53)	9 (47)
TMA event-free status attained, n (%)	11 (73)	13 (68)
Median (range) TMA intervention rate (PE/PI or dialysis events/patient/day)		
Pretreatment period	0.45 (0-2.38)	0.31 (0-2.38)
Treatment period	0 (0-0.08)	0 (0-0.08)

eGFR=estimated glomerular filtration rate; PE=plasma exchange; PI=plasma infusion; TMA=thrombotic microangiopathy.

Results. Baseline data and eculizumab efficacy outcomes for the 19 patients aged <18 years and a subgroup of 15 patients aged <12 years are presented in the Table. Median duration of eculizumab therapy was 28 weeks (range=1-70wks). Eculizumab inhibited terminal complement activation in all patients for whom evaluation was requested by the treating physician. Eculizumab also reduced TMA as demonstrated by platelet count normalization in 17 (89%) of all 19 patients and in 7/8 patients (88%) with platelet count levels <150×10^9/L at baseline. Nine patients (47%) demonstrated kidney function improvement (estimated glomerular filtration rate increase ≥15 mL/min/1.73 m^2) and 4/8 patients (50%) eliminated the need for dialysis during eculizumab treatment. Thirteen patients (68%) achieved TMA event-free status (no PE/PI, no new dialysis, and no decrease in platelet count >25% from baseline for ≥12 weeks). TMA intervention rate (PE/PI or new dialysis events/patient/day) was reduced in all patients receiving PE/PI or dialysis prior to eculizumab treatment (median [range] TMA intervention rate=0.31 [0-2.38] pretreatment vs 0 [0-0.08] during eculizumab therapy). The most common adverse event during eculizumab treatment was pyrexia (n=9; 47%). Efficacy and safety outcomes were similar in the subgroup of patients aged <12 years, with kidney function improvement in 8 patients (53%), achievement of TMA event-free status in 11 patients (73%), and a reduction in TMA intervention rate (median [range] rate=0.45 [0-2.38] pretreatment vs 0 [0-0.08] with eculizumab) during eculizumab treatment. **Conclusions:** In this pediatric population (aged <18y), chronic eculizumab treatment inhibited terminal complement activation, reduced TMA, and improved kidney function, including elimination of dialysis in 50% of patients (4/8). Eculizumab treatment also reduced need for PE/PI in all patients who previously required PE/PI. The efficacy of eculizumab treatment was similar in both pediatric age groups and treatment was well tolerated. These findings are consistent with prospective clinical trial results of adult/adolescent aHUS patients, thereby supporting the role of eculizumab as a new standard of care for aHUS patients of any age.

[4]Department of Paediatric Haematology, Justus-Liebig University, Giessen, Germany
[5]Department of Paediatric Haematology, Julius Maximilians University, Wuerzburg, Germany

Pediatric patients with B cell malignancies refractory to standard therapy have limited treatment options and display poor prognosis. Thus, novel treatment approaches are urgently required. Here we follow up ten children diseased with Non Hodgkin's Lymphoma (NHL) or acute leukemia being treated with FBTA05, a trifunctional anti-CD3 x anti-CD20 antibody in compassionate use. According to patient history, all children presented extensively pretreated and refractory to standard treatment (radiation, chemotherapy) including rituximab and allogeneic stem cell transplantation (five patients) before treatment with FBTA05.Within individual treatment schedules, two different treatment strategies were studied. Weekly applications of FBTA05 escalated up to 300µg after allogeneic transplantation were intended to provoke sustained remissions by FBTA05 induced cellular immune response. Daily applications, with escalated doses of FBTA05 up to maximal 1,000µg within one week were intended to harness the antibody´s cytotoxic potential to reduce tumour burden or to eradicate minimal residual disease before allogeneic transplantation.In two patients FBTA05 was combined with escalated doses of DLIs after allogeneic transplantation. In one child with NHL, FBTA05 and DLI were combined with lenalidomide within a second and third treatment cycle. All other children were treated stand alone with FBTA05 whereas in one case, subsequent to allogeneic transplantation additional weekly applications of FBTA05 were performed.Nine of the ten children displayed a clinical response: two stable diseases, two partial remissions and five complete responses (CR). Of note, in one of these patients a molecular CR was achieved after stand alone treatment with FBTA05. In follow up, overall survival (OS) is currently in the range of 25 up to 856 days and will be updated at time of presentation. Three out of these nine responders died, two children due to relapse or tumor progression (OS 59 and 129 days, respectively), one due to suspected pulmonary embolism (OS 829 days). The other patients still sustain in complete or partial remission.Within follow up analysis human anti-mouse antibodies (HAMAs) were detectable only in one case appearing four weeks after start of FBTA05 therapy. Interestingly, two additional applications of FBTA05 could be administered safely. Thereby HAMAs disappeared four months later. Graft-versus-host disease (grade III-IV) could be observed in two patients (in one case after DLI) and resolved by further immunosuppressive therapy.In general, FBTA05 applications were well tolerated by all children and adverse events were restricted to fever, chills and fatigue (one case). Combination of FBTA05 with lenalidomide was also well tolerated, but resulted in nausea and a transient aggravation of a preexistent leukocytopenia during the first cycle (10 and 15mg daily) which could be resolved by dose adjustment of lenalidomide to 5mg daily in the following cycles.Taken together, despite poor clinical prognosis of pediatric patients refractory to standard treatment, immunotherapy with FBTA05 resulted in a favorable clinical outcome including partial and complete remissions.

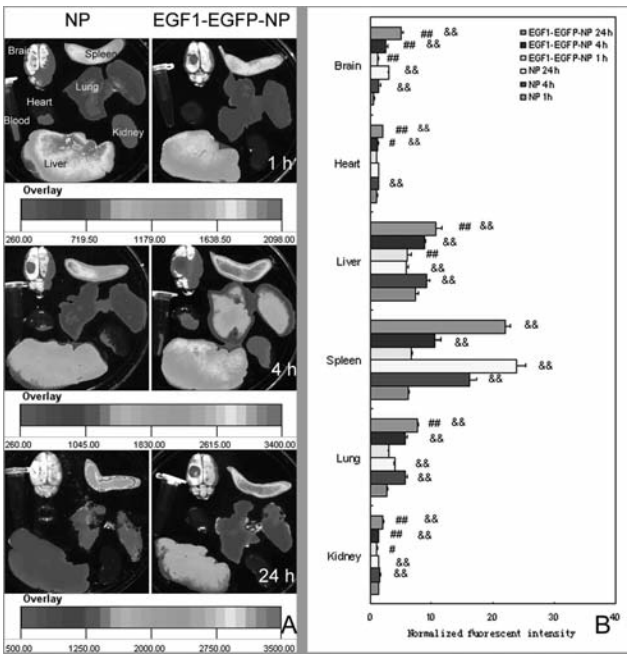
EGFP-EGF1 PROTEIN-CONJUGATED PEG-PLGA NANOPARTICLES ALLOW NF-κB DECOY DELIVERY INTO INJURED CEREBROVASCULAR ENDOTHELIUM TO PREVENT CEREBRAL THROMBOSIS

S Shi, H Hu
Institute of Hematology, Wuhan, China

Background. Tissue factor (TF) interacts with either plasma coagulation factor FVII or FVIIa, and the resulting fibrin serves as a trigger for thrombosis formation. The transcription factor nuclear factor-kappa B decoy oligonucleotides (ODNs), which can inhibit TF expression in stimulated vascular endothelial cells. Recently, we reported the synthesis of EGFP-EGF1 protein-conjugated PEG-PLA nanoparticles and showed their accumulation in the thrombi upon caudal vein administration.



Methods. EGFP-EGF1 protein-conjugated PEG-PLGA nanoparticle (EGF1-EGFP-NP) was employed as a new vector, and ODNs was incorporated into EGF1-EGFP-NP, and the resulting EGF1-EGFP-NP-ODNs was evaluated as a vector for gene therapy of cortex infarction. **Results.** At 2 hours after transfection of TF expressed rat brain capillary endothelial cell (BCECs), EGF1-EGFP-NP-ODNs was more efficiently internalized and located in the cytoplasm compared with NP-ODNs. At 4 hours and 6 hours after transfection, respectively, released ODNs were present in the nuclei and obviously inhibited the TF expression induced by TNF-α. At 6 hours after i.v. administration of NIR dye Dir loaded NPs to photchemical Cerebral thrombosis rats, the mean fluorescence intensity of the EGF1-EGFP-NP group was more than 4 times that of the NP group at the illuminated regions and most EGF1-EGFP-NPs were distributed in the vessel wall, via absorptive-mediated transcytosis, accumulated in endothelium cells and lowered the TF expression. At 24 hours after i.v. administration of EGF1-EGFP-NP-ODNs, MR imaging of cortex infarcted volumes were predominantly dwindled. **Conclusions.** EGF1-EGFP-NP-ODNs is a promising candidate for noninvasive gene therapy of cerebral infarction.

[5]Diet, Genes and Environment, Danish Cancer Society Research Center, Copenhagen, Denmark

Background. Various single nucleotide polymorphisms (SNP) located in genes with a role in coagulation have been associated with a higher risk of venous thromboembolism (VTE). However, reproducibility of these associations has not been entirely successful and replication studies are warranted. **Aims.** We investigated the VTE risk related to SNPs in the genes for Glycoprotein VI on platelets (GP6 rs1613662 A>G), Antithrombin (SERPINC1 rs2227589 G>A), Factor XI (F11 rs2036914 T>C and F11 rs2289252 C>T), Fibrinogen (FGG rs2066865 C>T) and Factor XII (F12 rs1801020 C>T) in a Danish follow-up study. **Methods.** From 1993 to 1997, 57.053 persons between the age of 50 and 64 years and free from a prior diagnosis of cancer joined the Danish "Diet, Cancer and Health"cohort. The primary outcome of this study was a first-time verified VTE episode defined as deep venous thrombosis or pulmonary embolism, and participants with a diagnosis of VTE before enrolment were excluded. Blood samples were drawn from each participant at baseline and SNP genotypes were determined by allele specific real-time polymerase chain reactions (predesigned Taqman SNP genotyping assay from Applied Biosystems). A case-cohort design including all incident VTE cases and a randomly selected subcohort of 1841 participants from the whole cohort was applied. Cox proportional hazard model with age as time-axis was used for statistical analyses and adjustments were performed for sex, age and hormone therapy. Persons homozygous for the allele reported to be protective for VTE in previous studies were chosen for reference group.

Table. Associations between examined SNPs and venous thrombosis. *Hazard ratios adjusted for age, sex and hormone therapy (women only).

Gene and SNP	VTE cases	subcohort members	Hazard ratio* (95% CI)

Results. A total of 641 incident VTE cases were verified. Sufficient DNA was available for SNP genotyping in the majority of VTE cases and subcohort members. The table shows the number of cases and subcohort members included in each SNP analysis as well as the hazard ratios (HR) for VTE. Genotypes TT and CT of rs2289252 and genotype CC of rs2036914 (both located in the *F11* gene) were significantly associated with a higher VTE risk when using their corresponding low-risk genotypes as reference. For the remaining four investigated SNPs a trend towards a higher VTE risk corresponding to the number of risk allele copies was observed. Among the subcohort members the risk allele was also the common allele for rs2036914 (*F11*), rs1801020 (*F12*) and rs1613662 (*GP6*). **Conclusions.** Genotype CC of rs2036914 and genotype TT of rs2289252, both located in introns of the *F11* gene, displayed statistically significant associations with VTE (HRs≥1.65). The mechanism by which they affect blood coagulation could be through increased plasma levels of FXI, which has been related to higher VTE risk. Although we included more than 600 VTE cases, our study lacks power to detect weak associations especially if allele frequencies are low. This may explain that the measures of association were not statistically significant for the remaining four included SNPs.

1159

PROSPECTIVE TWELVE MONTH STUDY COMPARING RISK FACTORS FOR HOSPITAL ACQUIRED THROMBOSIS WITH COMMUNITY ACQUIRED THROMBOSIS

J Nokes, H Rowswell
Derriford Hospital, Plymouth, United Kingdom

Background. Venous Thromboembolism (VTE) is estimated to be responsible for approximately 25,000 deaths in England annually. Since 2010, The Department of Health (DoH) has mandated hospitals in England to undertake VTE risk assessment of their inpatients using a national tool. Appropriate thromboprophylaxis (TP) should then be administered. Additionally, Hospital acquired thrombotic (HAT) events should be investigated to detect whether a risk assessment occurred or the event could have been prevented, using a root cause analysis (RCA) process. HAT is defined as a VTE event occurring as an inpatient or within 90 days following discharge. Identifying HAT events in a timely manner has been difficult. Coding is inaccurate and is a discharge process. The radiology reporting and record system has provided an effective mechanism for identifying HAT events to enable RCA to occur. **Aims.** This study was developed to assess the risk factors from the national tool that are most highly associated with VTE locally. Also to detect whether there is a significant difference in risk profile between HAT events compared with community acquired VTE (CAT). **Methods.** Over twelve months from January 2011, the hospital computerised radiological information system (CRIS) was reviewed on a daily basis, to record VTE events. Specifically computed tomography pulmonary artery scans, ventilation/perfusion scans and doppler ultrasound scans of the lower and upper limbs were reviewed for positive results. Incidental VTE events were also collected from the CRIS system. The patient information system was cross-checked to detect which VTE events satisfied the criteria for HAT. The hospital records of all patients with VTE were then interrogated to assess the presence of DoH VTE risk factors.

RISK FACTORS	CAT DVT (255)	CAT PE (305)	HAT DVT (76)	HAT PE (165)	ALL VTE (801)
AGE	126 (49%)	183 (60%)	46 (61%)	122 (74%)	477 (60%)
CANCER	44 (17%)	73 (24%)	21 (28%)	59 (36%)	197 (25%)
SMC	74 (17%)	143 (47%)	22 (29%)	78 (47%)	317 (40%)
OBESITY	49 (19%)	21 (7%)	16 (21%)	20 (12%)	106 (13%)
PREVIOUS VTE	79 (31%)	57 (19%)	13 (17%)	15 (9%)	164 (20%)
FAMILY HISTORY VTE	37 (15%)	16 (5%)	0	2 (1%)	55 (7%)
PREGNANCY	1 (0.4%)	5 (2%)	1 (1%)	3 (2%)	10 (1%)
DEHYDRATION	0	0	8 (11%)	16 (10%)	24 (3%)
IVDU	26 (10%)	5 (2%)	3 (4%)	0	34 (4%)
NO RISK FACTORS	37 (15%)	55 (18%)	1 (1%)	2 (1%)	95 (12%)

Results. Table shows the breakdown of HAT and CAT events, comparing risk factors defined by the national tool. SMH is a significant medical co-morbidity, as defined in the DoH tool and IVDU is Intravenous drug use which was additionally included as a prevalent group in this patient cohort. In 2011 there were 801 VTE events (331 DVT & 470 PE) of which 241 (30%) met the HAT criteria (165 PE & 76 DVT). There was also a significantly increased association of HAT with PE compared to DVT (Chi-squared statistic 8.57, p value 0.0034)Age is the most common risk factor showing a greater relationship with HAT compared to CAT events. Cancer is significantly more associated with PE than DVT in both HAT & CAT groups. Medical co-morbidity appears to carry an equivalent risk for HAT and CAT but again a greater association with PE. Personal and family history of VTE, are more associated with CAT than HAT events and finally, not surprisingly, intravenous drug users are more associated with CAT and DVT. **Summary.** Risk factor profiles are different between CAT and HAT events, as well as PE compared to DVT. Of some concern, the ratio of PE to DVT is significantly greater in HAT events (2.7 v 1.2).16% of CAT events had no risk factors whereas only 1% of HAT events fell in this category.

NOVEL ROLE OF OXYGEN SENSING MESENCHYMAL STEM/PROGENITOR CELLS AS INITIATORS OF NEO-VASCULOGENESIS *IN VIVO*

NA Hofmann[1], A Ortner[2], R Jacamo[3], A Reinisch[2], K Schallmoser[4], R Rohban[2], M Fruehwirth[2], C Beham-Schmid[5], W Linkesch[6], M Andreeff[3], D Strunk[2]

[5]Institute of Pathology, Medical University of Graz, Graz, Austria
[6]Department of Hematology, Medical University of Graz, Graz, Austria

Background. In response to hypoxic tissue damage endothelial colony-forming progenitor cells (ECFCs) are considered to perform new vessel formation and subsequently recruit mesenchymal stem/progenitor cells (MSPCs) to differentiate into stabilizing pericytes. Stem cell therapy to re-vascularize ischemic tissue has been a promising tool for various therapeutic targets including stroke, myocardial infarction and peripheral artery disease. Isolation and expansion of large quantities of stem/progenitor cells from different blood sources and bone marrow have set the first stone to meet this medical need. However, transplantation of endothelial without mesenchymal progenitors in a hypoxic environment failed to induce neo-vasculogenesis *in vivo*.**Aims.** We hypothesize that MSPCs have a primary role as oxygen sensors during vascular regeneration. Here we show for the first time that ECFCs in hypoxic conditions *in vivo* require the presence of MSPCs not only to stabilize but mainly to initiate neo-vasculogenesis. **Methods.** Adult human ECFCs were isolated from blood andMSPCs from bone marrow aspirates and expanded under humanized culture conditions. *In vitro* studies of progenitor cell phenotype, long-term proliferation, wound repair, migratory and vasculogenic functions were monitored at different oxygen conditions. ECFC and MSPC interaction *in vivo* were studied in immune-deficient NSG mice (NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl}/SzJ) after subcutaneous transplantation in various extracellular matrices (matrigel, collagen/fibronectin, human platelet lysate). To investigate the respective roles of MSPCs and ECFCs during vasculogenesis under hypoxia *in vivo,* chemical and genetic inhibitors of protein synthesis (cycloheximide) and HIF-1α (YC-1, shRNA) were employed. Immune histochemistry, immune fluorescence and an TUNEL assay were performed in time course after transplantation. **Results.** *In vitro* progenitor proliferation and function were reduced with declining oxygen levels. ECFCs stabilized hypoxia-inducible factor-1α (HIF-1α) only at 1% O_2, while MSPCs had already stabilized HIF-1α at 5% O_2 resembling venous oxygen conditions. In a immune-deficient mouse model, ECFCs transplanted into a hypoxic environment did not stabilize HIF-1α after 1 day and underwent apoptosis, while transplanted sole MSPCs showed strong nuclear HIF-1α stabilization. In co-transplanted ECFCs and MSPCs a subset of cells stabilized HIF-1α 1 day after transplantation and formed perfused human vessels within 7 days. Inhibition of HIF-1α stabilization in MSPCs significantly abrogated vessel formation *in vivo*, whereas HIF-1α inhibition in ECFCs could not circumvent vasculogenesis. Blocking the down-stream target of HIF-1α vascular endothelial growth factor (VEGF) resulted in an inhibition of neo-vasculogenesis.**Conclusions:** This data demonstrates that hypoxic ECFCs alone show reduced functionality *in vitro* and failed to form patent vessels *in vivo*. In contrast, MSPCs react to the low oxygen environment more sensitively than ECFCs and promote vessel formation at least in part by rescuing ECFCs from hypoxia-induced apoptosis. Surprisingly, this study shows that therapeutic vasculogenesis can occur independent of endothelial HIF stabilization. This data shows that MSPC and not ECFC

oxygen sensing is crucial to initiate vascular regeneration. This suggests a shift of focus from endothelial cells to perivascular cells as a therapeutic target in regenerative medicine and anti-angiogenic therapy.

RELATIONSHIP BETWEEN SERIAL ULTRASOUND, D-DIMER AND FACTOR VIII AND DEVELOPMENT OF POST-THROMBOTIC SYNDROME FOLLOWING A FIRST DEEP VEIN THROMBOSIS

N Roberts, R Patel, D Goss, L Bonner, R Arya
King's College Hospital NHS Foundation Trust, London, United Kingdom

Background. Post-thrombotic syndrome (PTS) is a common complication of deep vein thrombosis (DVT). Venous reflux and persistent obstruction are thought to contribute to the development of PTS. **Aims.** To evaluate the relationship between residual vein thrombosis (RVT), deep venous reflux, D-dimer and Factor VIII and development of PTS following a first DVT. **Methods.** 114 participants with confirmed DVT were recruited and followed for six months post completion of anticoagulation (or 12 months from diagnosis if anticoagulation continued). Ultrasound, D-dimer and Factor VIII were undertaken at six weeks following completion of anticoagulation (T1) and at end of follow up (T2). PTS was considered present in those with a score of ≥ 5 on Villalta scale at T2.Results. PTS was present in 40.4% of participants at end of follow-up. Those with PTS were significantly older (mean age 55.8 +/- 13.8 versus 42.4 +/-12.6 years, P<0.001) and had a higher body mass index (BMI: 30.7 compared 28.7, P=0.09). PTS was more common following proximal (47.4%) than distal DVT (33.3%, P=0.12). Median D-dimer in those with PTS was significantly higher at both time points (T1 480 IQR 300-750, T2 540 IQR 320 - 900) compared to those without (T1 310 IQR 240-490, P=0.008; T2 280 IQR 220-480, P<0.001). Similarly, Factor VIII measured at both time points was significantly higher in those with PTS (T1 176 IQR 145-238, T2 195 IQR 149 - 236) compared to those without (T1 150 IQR 130-200, P=0.032; T2 142 IQR 125-175, P<0.001). The presence of RVT was not significantly associated with PTS at either time point. PTS was more common in those with deep venous reflux at either time point (T1 73.7%, T2 70.6%) than those without (T1 32.3%, P=0.001; T2 33.0%, P=0.004). On univariable analysis of markers associated with PTS measured at T1, D-dimer >500ng/ml gave an odds ratio (OR) for PTS of 3.2 (95%CI 1.41- 7.35, P=0.005). Factor VIII >150u/dl was associated with an OR for PTS of 2.3 (95% CI 1.03- 5.02, P=0.04). The presence of deep venous reflux was associated with an OR of 5.88 (95% CI 1.94 - 17.84, P=0.002). Similar ORs were seen for these variables measured at T2. On multivariable analysis, after adjustment for age, BMI and location of DVT (proximal vs distal), only FVIII>150ng/ml and deep venous reflux at T2 were significantly associated with PTS. The OR for PTS associated with a high FVIII was 3.1 (95% CI 1.22 - 7.93, P=0.017) with the presence of deep venous reflux associated with an OR for PTS of 4.86 (95% CI 1.10 - 21.44, P=0.037). Summary and Conclusions. Factor VIII and deep venous reflux are independently associated with PTS at six months post end of anticoagulation but not earlier in the disease course. This supports the role of reflux in the pathophysiology of PTS. Increased FVIII activity suggests underlying activation of coagulation as a contributor to PTS.

PROGNOSTIC SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE IN PEDIATRIC PRECURSOR-B ACUTE LYMPHOBLASTIC LEUKEMIA

A Kamel, N El-Sharkawy, E Kandeel, HS Moussa, A El-Haddad
NCI, Cairo University, Cairo, Egypt

Background. Minimal residual disease (MRD) has emerged as the most powerful tool for assessing response to chemotherapy in pediatric precursor B ALL. **Aims.** This study aimed to assess the presence of MRD in relation to other prognostic parameters such as age, gender, CSF status and molecular genetic abnormalities in pediatric precursor-B ALL. In addition, we aimed to clarify the impact of MRD status on disease progression. **Methods.** Bone marrow samples were obtained from 70 newly diagnosed pediatric ALL patients diagnosed in 2008-2011. Immunophenotypic characterization was performed at diagnosis. Cases were followed up for MRD at day 15 (d15) and 42 (d42). Leukemia associated phenotype(s) were identified using the following panels: CD58/CD10/CD34/CD19, CD38/CD10/CD34/CD19 and CD45/NG2/CD19/CD22 as well as any aberrant myeloid (CD13 or CD33) or T markers (CD7, CD2)/CD19/CD34/CD45. The cut off value used for MRD detection was 0. 01%. Patients were treated according to the Egyptian NCI treatment protocol modified from the total therapy study XV. Disease free survival (DFS) was evaluated at 28 months. **Results.** At D15 post-induction MRD was evaluated in 61 patients; 31 had MRD <0. 01, 20 had ≥0. 01<0. 1, 4 had MRD level ≥0. 1<1. 0%, 4 had MRD level > 1% and 2 patients did not achieve complete remission (CR). Associations between MRD at d15 post induction and other clinical and biological risk factors including age, gender, TLC, lymphadenopathy, hepatosplenomegly, cytogenetic molecular studies and DNA index were of no statistical significance. We reported statistically significant association between MRD positivity at d15 post induction and CSF infiltration (P value = 0. 03). The association between MRD, OS, and DFS at 28 months did not reveal statistical significance using different cutoff values of 0. 01 or 0. 1%. A trend of association with poor outcome was demonstrated with 0. 1% cutoff value though not statistically significant. At d42 post-induction MRD was evaluated in 56 patients; 32 had MRD level <0. 01, 19 had ≥0. 01<0. 1 and 4 patients had MRD level ≥0. 1<1. 0% and one patient had a level of > 1%. As with d15, we reported statistically significant association between MRD positivity at d42 post induction and CSF infiltration (P value = 0. 01) Also, significant association was demonstrated between MRD at d42 and molecular genetics; t(12;21) was significantly associated with negative MRD while t(9;22) was significantly associated with positive MRD (p=0. 045). Patients with negative MRD at d42 had significantly better DFS than those with positive MRD (p<0. 0001). No statistically significant association between d42 MRD and other prognostic parameters was encountered. **Summary and Conclusions.** Positive MRD is associated with some other bad prognostic parameters namely CSF infiltration and t(9;22). At day 42, MRD detection by flow cytometric assay using 0. 01% cutoff level is useful in predicting treatment outcome. The proven clinical value of MRD in the plethora of studies would raise a need for changing the current definition of CR, which is still based on the morphologic appearance of BM. Investigation of MRD identifies patients who will experience relapse in spite of a standard morphologic.

1163

PROGNOSTIC ROLE OF BLOOD COAGULATION FACTOR XIIIA EXPRESSION IN ACUTE LYMPHOBLASTIC LEUKEMIA

I Szegedi, L Csáthy, Z Hevessy, J Kappelmayer, C Kiss
University of Debrecen, Debrecen, Hungary

Background. Previously we have identified B-cell progenitor (BCP) lymphoblasts as a new expression site of coagulation factor XIII subunite A (FXIIIA). Detection of FXIIIA in BCP ALL blasts by flow cytometry (FC) can be used for more accurate definition on the leukemia-associated immunophenotype (LAIO) and quantitation of minimal residual disease (MRD). **Aims.** Here we have examined, for the first time, the possible impact of factor XIIIA expression in childhood BCP ALL. **Patients and Methods.** MRD detection was performed using four color FC analysis with a FACSCalibur flow cytometer. Sixty-one leukemic children with a BCP ALL phenotype were treated according to the antileukemic protocol BFM95/BFM ALL-IC 2002 and studied retrospectively. **Results.** Multiparametric data analysis of prognostic factors pointed on the possible role of FXIIIA expression to influence disease outcome. Unfavorable genetic conditions were significantly more frequent among FXIIIA-negative vs positive cases. Distribution of other conventional prognostic factors was similar between the two groups. Three-years overall survival of patients with FXIIIA positive disease (64%) was significantly higher than that of FXIIIA-negative patients (36%). **Conclusions.** Retrospective analysis of a limited number of patients indicated an important prognostic role of FXIIIA expression in childhood BCP ALL. Preliminary data suggest that FXIIIA expression may define a new subgroup of childhood ALL. Granted by TÁMOP-4. 2. 1/B-09/1/KONV-2010-0007 project, supported by the European Union, co-funded by the European-Social Fund.

UTILITY OF A SINGLE MULTIPLEX REVERSE TRANSCRIPTASE POLYMERASE CHAIN REACTION (RT-PCR) ASSAY FOR DETECTION OF THE COMMON CHIMERIC FUSION TRANSCRIPTS IN ACUTE LEUKEMIA PATIENTS FROM NORTH INDIA

N Varma, P Bhatia, J Binota, D Bansal, A Trehan, P Malhotra, S Varma
PGIMER, Chandigarh, India

Background. Cytogenetic and molecular abnormalities identify prognostically relevant subgroups in B-cell acute lymphoblastic leukemia (ALL) and Acute Myeloid Leukemia (AML). Many western studies quote the incidence of these fusion transcripts to be 30-35% in B-ALL and around 40-45% in AML. However the data from Indian Sub-continent is limited. **Aims and Objectives.** The present pilot study was undertaken to detect the incidence of common chimeric fusion transcripts of t(12;21), t(9;22), t(1;19), t(4;11), t(8;21), t(15;17) and t(inv16) in adult and pediatric B-ALL and AML cases using a single Multiplex RT-PCR assay. **Methods.** This prospective study carried out over a period of one year included 95 B- ALL cases and 56 AML cases diagnosed on bone marrow (BM) examination and flowcytometric Immunophenotyping (FCM-IP) analysis. A single Multiplex RT-PCR assay was carried out using primers specific to the fusion transcripts. **Results.** Out of the 95 B-ALL cases enrolled in the study, 56 (59. 0%) were pediatric and 39 (41. 0%) adult cases. A total of 29/95 cases (30. 52%) showed positivity for the various fusion transcripts with 15/56 (26. 8%) pediatric and 14/39 (35. 9%) adult cases. Of the fifteen positive pediatric cases, 9/56 (16. 07%) were positive for TEL-AML1 transcript, 3/56 (5. 35%) for BCR-ABL transcript, 2/56 (3. 5%) for MLL-AF4 transcript and 1/56 (1. 79%) for E2A-PBX transcript. Out of the fourteen positive adult cases, 10/39 (25. 64%) were positive for BCR-ABL transcript, 2/39 (5. 12%) were positive for TEL-AML1 transcript and 1/39 (2. 56%) each for E2A-PBX transcript and MLL-AF4 transcript. Of the total 56 AML cases, 44 (78. 5%) were adult AML cases and 12 (21. 5%) pediatric cases. A total of 27/56 (48%) AML cases showed positivity for various fusion transcripts of which 18/44 (40%) were adult AML cases and 9/12 (75%) pediatric cases. Of the 18 positive adult cases, 8/44 (18%) each were positive for t (8;21) and t (15;17) and 2/44 (4. 5%) for t (inv 16). In the 9 positive pediatric cases, 5/12 (42%) were positive for t (8;21), 2/12 (16%) each for t (15;17) and t (inv 16). **Conclusions.** Our study results show that TEL-AML1 and AML1-ETO transcripts are the most common fusion transcripts seen in pediatric B-ALL & AML cases and BCR-ABL and AML1-ETO & PML-RARA in adult B-ALL & AML cases respectively. The incidence of the above common fusion transcripts in our pilot study is in accordance with that described in western studies. It is important to identify these transcripts as they provide useful prognostic information to the treating clinician.

1165

GERMLINE MUTATIONS IN MRE11/RAD50/NBN COMPLEX GENES IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M Mosor[1], I Ziólkowska-Suchanek[1], K Nowicka[2], D Januszkiewicz-Lewandowska[3], J Nowak[2]
[1]Institute of Human Genetics, Polish Academy of Sciences, Poznan, Poland
[2]Institute of Human Genetics Polish Academy of Sciences, Poznan, Poland
[3]University of Medical Sciences, Poznan, Poland

Background. The *MRE11*, *RAD50*, and *NBN* genes encode proteins of the MRE11-RAD50-NBN (MRN) complex involved in cellular response to DNA damage and the maintenance of genome stability. In our previous study we showed that the germline I171V mutation in *NBN,* may be considered as a risk factor in the development of childhood acute lymphoblastic leukemia (ALL) and some specific haplotypes of that gene may be associated with childhood leukemia. This finding raises important questions about the role of mutations in others genes of the MRN complex in childhood ALL. **Aims.** The aim of the study was to answer the question whether *MRE11* and *RAD50* alternations have a potential role in childhood acute lymphoblastic leukemia. **Methods.** The aim was carried out by determining the frequency of constitutional mutations and polymorphisms in selected regions of *MRE11*, *RAD50*, and *NBN* in the group of 200 children diagnosed with ALL and treated at the Department of Pediatric Hematology, Oncology and Transplantology Poznan University of Medical Sciences in Poland. We have for the first time made simultaneous

analysis of *MRE11, RAD50* and *NBN* genes in childhood ALL. Anonymous blood samples collected on Guthrie cards were used as controls The analysis was focused on exon 5, 10, 14, 15, 19 of *MRE11*, exon 3, 4, 5 and 7 of RAD50 and 2, 5, 6, 7, 10, 13 of the *NBN* gene and was performed by specific amplification of region of interest by PCR and followed by multi-temperature single-strand conformation polymorphism (PCR-MSSCP) technique. Each sample showing shifts in MSSCP analyses was sequenced. **Results.** In cohort of the 200 children diagnosed with ALL we didn't identified any mutation neither in the *RAD50* nor in the *MRE11*. We identified 2 alternations in 3 out of 506 controls in the *RAD50* gene. The V127I in exon 4 of the *RAD50* gene, detected twice, was predicted to be tolerated using the SIFT and PolyPhen analysis. The V315L in exon 7 occurring only one among 506 controls was predict to be benign. In addition we were able to detect c. 551+19 G>A single nucleotide polymorphisms in the intronic sequence of exon 4 with a different frequency in ALL patients and controls. The frequency of the AA genotype was higher in leukemia patients, as compared to controls (p= 0,0032). In the pooled group of ALL patients (135 cases from previous study) we still observed the higher incidence of the I171V mutation in ALL group (5/200) than among controls (12/2400) (p< 0,0007). **Conclusions.** Although we observed variant allele of the intronic SNP in the *RAD50* gene as more frequent in childhood ALL in comparison to controls, no clear association of mutations in *RAD50* and *MRE11* gene has been seen. Interpretation of these results is limited by the rather low number of patients studied and needs further investigation. Nevertheless the obtained results confirmed the participation of the I171V germline mutation of *NBN* gene in childhood ALL. This research was supported by the grant from the Ministry of Sciences and Higher Education (NN407 201 737)

AN ATYPICAL BCR-ABL TRANSCRIPT WITH AN INTRONIC SEQUENCE FROM THE BCR AND ABL GENES UNDETECTABLE BY EAC Q-RT-PCR IN A PATIENT ACUTE LYMPHOBLASTIC LEUKEMIA

L Elia[1], MC Puzzolo[1], M Matarazzo[1], S Grammatico[1], C Cavallari[1], MG Kropp[2], R La Starza[3], G Cimino[1], R Foa[1]
[1]Hematology, Rome, Italy
[2]Department of Hematology Pugliese-Ciaccio Hospital, Catanzaro, Italy
[3]University of Perugia, Perugia, Italy

Background and Aims. The Philadelphia(Ph) chromosome arises from the reciprocal translocation t(9;22) (q34;q11) which produced the *BCR-ABL* chimeric gene. Very rare cases have been described with *BCR-ABL* breakpoints outside the well defined cluster regions. At diagnosis, the classical and unusual *BCR-ABL* variants can be successfully detected through sensitive techniques such as reverse transcriptase-polymerase chain reaction (RT-PCR) and/or fluorescence in situ hybridization (FISH). For minimal residual disease (MRD) monitoring, the quantitative RT-PCR (Q-RT-PCR) is required and is necessary for the management of patients with ALL or with chronic myeloid leukemia (CML) treated with tyrosine kinase inhibitors (TKI). To our knowledge, this is the first report of a PH+ALL with a rare e13a2 fusion transcript undetectable by EAC Q-RT-PCR but successfully diagnosed with a multiplex RT-PCR and by FISH analysis. **Materials and Methods.** According to the Multicenter GIMEMA studies for ALL, the diagnostic molecular analysis was performed in the reference laboratory of the Department of Hematology, University "Sapienza"(Rome). Total RNA was extracted using the Qiaquick gel extraction kit (Qiagen-Germany), and the *BCR/ABL* positivity was detected using the multiplex RT-PCR assay. FISH analysis was performed with LSI *BCR/ABL* dual color dual fusion translocation probe (Vysis; Abbott Molecular). The number of *BCR/ABL* copies was determined according to the EAC program methods. All Q-RT-PCR reactions were performed on a 7500 ABI platform (Applied Biosystems). Nucleotide sequencing was performed using an ABI PRISM 3130 genetic analyzer (Applied Biosystems, Foster City, CA). Sequence analysis was carried out using the basic local alignment search tool BLAST. **Results.** At diagnosis, the multiplex RT-PCR assay detected a *BCR/ABL* p210 positivity in the bone marrow sample with a PCR product sizing 397 bp which represents the b2a2 transcript; FISH confirmed the *BCR-ABL1* fusion. In contrast, by Q-RT-PCR the *BCR/ABL* junction could not be detected suggesting the presence of an aberrant transcript. Direct sequencing analysis of the RT-PCR product revealed that this patient harbored a novel form of aberrant e13a2 transcript located at 22 bases upstream of the 5'-terminal of the BCR gene and fused to the truncated ABL1gene in-frame with a 16-base insertion (Figure 1). This aberrant transcript lacked the fragment which contain the sequence recognized by the ENF 501primer, explaining why the Q-RT-PCR assay failed to detect the *BCR/ABL* positivity. For this reason, we designed a new forward primer located 41 nucleotides upstream from the breakpoint and this strategy allowed to successfully monitor the MRD levels of the patient (Figure 2) treated with Imatinib 800mg total dose plus steroids, which allowed to obtain a clinical remission with a 2 log Q-RT-PCR reduction from diagnosis. **Conclusions.** Our data demonstrate that qualitative, rather than quantitative, methods are mandatory for the detection of the *BCR/ABL* gene in Ph+ ALL, being able to detect also very rare cases with aberrant fusion transcripts. This is the first case among about 280 *BCR/ABL*+ ALL tested by EAC Q-RT-PCR that nonetheless indicates-as in CML- the possible pitfall of this strategy, at a time when the management of Ph+ ALL has dramatically changed following the advent of TKI.

[2]Izmir Institute of Technology, Department of Molecular Biology and Genetics, Izmir, Turkey
[3]Baskent University, Adana Education and Research Hospital, Department of Bone Ma, Adana, Turkey

Background. Quercetin, a flavonoid derived from red wine, onion, and tea, has important functions such as anti-inflammatory, anti-viral, immune system enhancer, anti-oxidant, and anti-cancer. Quercetin has cytotoxic effects on several cancer cells including leukemic, prostate, and breast cancers via several mechanisms such as cell cycle arrest at G_1 phase, induction of apoptosis, and inhibition of tyrosine kinase activity. In addition, quercetin also inhibits important oncogenes including c-myc and ras, while it upregulates p53. Dexamethasone, a glucocorticoid, is a drug having anti-inflammatory and immune suppressive effects. It is used in the treatment of several diseases such as rheumatoid arthritis, allergy, and asthma. Dexamethasone is also used for the treatment of hematological malignancies such as multiple myeloma and acute lymphoblastic leukemia. **Aims.** In this study, we aimed to determine possible synergistic apoptotic effects of quercetin and dexamethasone combination on Jurkat T-cell acute lymphoblastic leukemia cells. **Methods.** Cytotoxicity effects of quercetin and dexamethasone alone and their combinations on Jurkat cells were determined by MTT cell proliferation assay. Apoptotic effects of quercetin and dexamethasone alone or combination of both were assessed by examining the changes in caspase-3 enzyme activity, loss of mitochondrial membrane potential, and the localization of phosphatidylserine on the plasma membrane. **Results.** MTT analyses showed that there were significant decreases in proliferation of Jurkat cells in response to quercetin and dexamethasone. IC50 values of quercetin and dexamethasone for 72 hours were calculated from cell proliferation plots and determined as 0. 7 and 9 μM, respectively. There were 1, 5, 6, 30 and 56% decreases in cell proliferation in response to 0. 1, 0. 5, 1, 5

and 10 μM dexamethasone, respectively, while combination of the same doses of dexamethasone with 0. 7 μM quercetin decreased proliferation of Jurkat cells 29, 36, 47, 63 and 72% respectively, as compared to untreated controls. In an attempt to confirm these data with apoptotic assays, the cells were treated with quercetin and dexamethasone alone or combination of both. The results revealed that there were significant apoptotic effects of combination of quercetin and dexamethasone compared to any agent alone or untreated control groups. There were 1. 0- and 1. 05- or 2. 88- and 3. 33-fold increases in loss of mitochondrial membrane potential in response to 0. 5- and 10 μM dexamethasone alone or the same doses of dexamethasone in combination with 0. 7 μM quercetin, respectively, while quercetin by itself induced loss of mitochondrial membrane potential 2. 12-fold. Furthermore, while apoptotic cell population treated with 0. 5 and 10 μM dexamethasone alone were increased 5 and 12%, combination of the same doses of dexamethasone with 0. 7 μM quercetin increased apoptotic cell population 85 and 228%, respectively, compared to untreated control group. Quercetin itself increased apoptotic cell population 27%. **Summary and Conclusions.** The results of this study demonstrated that there were synergistic cytotoxic and apoptotic effects of combination of dexamethasone and IC50 value of quercetin. Taking together these results showed that the use of quercetin in combination with dexamethasone may enhance the effectiveness of dexamethasone on Jurkat cells.

1168

GENE POLYMORPHISMS IN CRETAN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

N Karathanasis, E Stiakaki, G Goulielmos, M Kalmanti
Dept Pediatric Hematology-Oncology University of Crete, Heraklion, Greece

Background. Acute lymphoblastic leukemia (ALL) in children represents the most frequent form of malignancy. Several studies that have been conducted lately, have revealed an association between both the risk and the treatment outcome of ALL, with polymorphisms located in genes encoding for enzymes which are involved in various metabolic pathways. Such an example is the methylenetetrahydrofolate reductase (MTHFR), an enzyme which plays a role in the folic acid metabolism. Two common single nucleotide polymorphisms (SNPs) have been characterized in the *MTHFR* gene, at nucleotide positions 677 (C→T) and 1298 (A→C). Another case is the reduced folate carrier (RFC), an anion exchanger which transports both folate and methotraxate (MTX) into cells. The gene encoding RFC has been proved polymorphic at nucleotide position 80 (G→A). **Aims.** The presence of the *MTHFR* and *RFC* SNPs was examined in 35 children with ALL (14 females, 21 males-median age 6. 33 years) and in 48 healthy adults (control group), with Cretan origin. A comparison between the children's and the controls' genotype and allele frequency distributions was also performed. Moreover, the association between the *MTHFR* and *RFC* SNPs and the presence of MTX-related mucositis, hepatotoxicity and hematological toxicity, were also studied. **Methods.** The possible correlation between the SNPs in the genes examined and the susceptibility to ALL was examined using polymerase chain reaction/restriction fragment length polymorphism (PCR/RFLP) based approaches. The presence of hematological toxicity and hepatotoxicity was established from the average values of hemoglobin, platelets and white blood cells regarding the former and the average values of aspartate transaminase, alanine transaminase and gamma-glutamyltransferase regarding the latter. The laboratory values were each time calculated one week after the administration of IV MTX and the analysis was performed considering only higher grade toxicity. For statistical reasons and using the CTCAE(v4) from the NCI, children with normal laboratory values and no stomatitis, were labeled as having no presence of an adverse event, while children with toxicity grades 1-4, were labeled as having an adverse event. **Results.** The genotype and allele frequencies, regarding both SNPs in cases and controls, did not show any statistical differences. The results for the A1298C polymorphism, showed a statistically significant non-predisposing role of the A allele (A1298A+A1298C) regarding hepatotoxicity, as expressed by AST values (p=0. 039). The effect of the gene-gene interactions was also evaluated (*RFC/MTHFR* SNPs). The results revealed that the MTHFR A1298C / RFC G80A genotype, had a non-predisposing role regarding the susceptibility to ALL (p=0. 035), while the differences between the remaining haplotypes were not statistically significant. **Summary and Conclusions.** The results from our study of gene polymorphisms in children of Cretan origin with ALL may play a role in assessing the risk, both for the ALL susceptibility and the drug-induced toxicity, in our population. SNPs may be a tool in the ongoing effort of individualizing treatment, taking into account the genetic profile of each patient, the possible gene-gene interactions and the role of environmental factors and dietary habits.

1169

SIMULTANEOUS OCCURRENCE OF A ETV6-RUNX1 AND BCR-ABL (E1A2) TRANSCRIPTS IN A CHILD WITH A B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

G Balatzenko[1], M Guenova[1], I Kalinova[2], M Belcheva[2], H Hristozova[2], V Kaleva[2]
[1]National Specialized Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria
[2]Clinic of Pediatric Hematology and Oncology, St. Marina University Hospital, Varna, Bulgaria

Background. According to the WHO classification (2008), the category of B-cell acute lymphoblastic leukemia (B-ALL) with recurrent genetic abnormalities comprises subtypes in which the presence of specific genetic abnormalities is associated with distinctive clinical or phenotypic properties, and clearly demonstrates that they are biologically distinct with important prognostic implications. The simultaneous co-existence of two of these aberrations in one and the patient are rare and raises questions concerning mechanisms of pathogenesis, exact sub-classification, risk group assignment and treatment policy. **Aims.** We present a rare case of simultaneous occurrence of a *ETV6-RUNX1* and *BCR-ABL* transcripts in a child with a B-cell acute lymphoblastic leukemia. **Case Report.** A 3-years-old boy presented with fever up to 38^{o}C, diarrhea, anemia and thrombocytopenia. Previous medical history included chicken pox and flu, respectively 4 and 2 months ago. On physical examination the patient was pale without hemorrhages The liver was enlarged, there was cervical micro-lymphadenomegaly, however no splenomegaly was detected. At the time of admission, laboratory tests revealed normal white blood cell counts of 5,9x10^{9}/l without blasts; hemoglobin level of 56 g/l and platelet counts of 40x10^{9}/l. On aspirate smears bone marrow was markedly hypercellular with a total infiltration with lymphoblasts. Flow cytometry of the bone marrow revealed a blast cells population accounting for 57% of all cells with a low FSC, low SSC, dim to negative expression of CD45 and B-II (pre-B) lymphoblastic phenotype: cytoplasmic CD79α(+), CD19(+), sCD22(+), CD10(+), CD34(+), CD20(-), sIgM(-), with aberrant dim CD13(+) and CD33(+) expression. Conventional cytogenetic analysis was unsuccessful. Molecular analysis using qualitative reverse transcription polymerase chain reaction according to the BIOMED-1 protocol revealed: negative results for *BCR-ABL* (p210); *MLL-AF4* and *E2A-PBX1* transcripts; and positive results *for BCR-ABL* (p190) and *ETV6-RUNX1* (long type) transcripts, which was confirmed in a second independently taken bone marrow specimen. Taking into account all of the above, a diagnosis of *BCR-ABL*-(p190)-positive and *ETV6-RUNX1*-positive B-cell precursor acute lymphoblastic leukemia was made and treatment was initiated according to the Protocol AIEOP-BFM-ALL 2000 for high-risk patients in combination with Imatinib 300 mg/m2 (since the 15-th day of induction therapy). A complete remission was achieved after the first course of treatment and 9 months after the diagnosis the child is alive with levels of minimal residual disease of 0. 036% (3,6x10-4) leukemia cells estimated by flow cytometry, 0. 035% (3,5x10^{-4}) *ETV6-RUNX1*/*ABL*, and 0. 023% (2. 3x10^{-4}) *BCR-ABL* (e1a2)/*ABL* transcripts evaluated by real-time quantitative RT-PCR. **Conclusions.** Up to our knowledge this is the first case reported with the simultaneous presence of *BCR-ABL*-(p190) and *ETV6-RUNX1* in a child with a B-ALL, that contributes to the heterogeneity of precursor lymphoblastic neoplasms. It does not demonstate any specific clinical, morphological or immunophenotypic features. The applied combined imatinib-chemotherapy approach seems to be effective allowing for MRD cleara

Acute Undifferentiated Leukaemia (AUL) is a very rare type of leukaemia that shows no clear evidence of lymphoid or myeloid lineage specific antigen expression. It is classified within the Acute Leukaemias of Ambiguous Lineage in the WHO classification 2008. Little is known of the clinical features, genetics or prognosis associated with this type of leukaemia. The blast phenotype is defined as positive for CD45, HLA-DR, CD34 and/or CD38. TdT may be positive. Essentially the blasts do not express the T - or myeloid-lineage specific markers, cCD3 and MPO, and are negative for B-lineage specific markers such as cCD22 cCD79a or strong CD19. They lack specific features of other lineages such as megakaryocytic or antigens expressed by plasmacytoid dendritic cells. We diagnosed two

cases of Acute Undifferentiated Leukaemia with the above phenotype which were subsequently well characterised by cytogenetic and molecular studies. Peripheral blood and bone marrow was obtained from two elderly male patients, (83 and 84 years old). One of them had previous history of CLL and cutaneous DLBCL. The blasts were positive for CD45, HLA-DR, CD34, TdT, CD38 and CD123. Blasts from one of the patients were also positive for CD117 in the BM, but not in the blood. All T-, B- lymphoid and myeloid lineage markers were negative in both patients (cCD3, CD2, cCD22, cCD79a,CD19, MPO, CD13, CD33, glycophorin CD235a, CD41, and the plasmacytoid dendritic cell markers CD56 and CD4). Karyotype and FISH analyses showed 46XY +13, -21 in one of the patients; the karyotype of the second patient was normal. Molecular studies showed clonal rearrangement of the TCR beta chain and the Ig heavy chain gene DJH in both patients. One patient tested negative for NPMI/FLT3ITD. There is very little data in the literature on the genetic profile of these rare leukaemias. The molecular rearrangements suggest that they may arise from a very early lymphoid stem cell, although no myeloid-specific rearrangements have been tested. More cases need to be studied to attain a better understanding of the origin of AUL .

Conventional flow cytometry measures intensity of scattered light at two directions. Some advanced experimental devices, known as scanning (wide-angle) flow cytometers, measure angular dependences of intensity of scattered light ("cell fingerprints") over a wide interval of scattering angles. Such flow-cytometric light-scattering patterns give new opportunities for characterization of normal and pathological cells. Mononuclear cells of fresh peripheral blood were investigated in parallel for healthy donors, hepatitis B/C and acute lymphoblastic leukemia patients aged 26 to 48 y.o. The cells were isolated using Ficoll-Paque-TM PLUS separation solution. The purity of lymphocyte population isolated for analysis was approximately 94%. Computational modeling for single-lymphocyte light scattering was fulfilled. The findings showed that the scattering channels of flow cytometer provide opportunity of express assessment of cell optical pattern and allow to refer the cell to "normal", "viral" or "malignant" population without use monoclonal CD markers. Modeling data were validated by simultaneous flow-cytometry investigation. Both the experimental and modeling data demonstrated the utility of optical cell pattern ("cell fingerprint") in biomedical applications. Further investigations will show the potential value of light scattering approach in diagnosis and monitoring of acute blood malignancies.

1172

EXCELLENT OUTCOME AFTER T CELL DEPLETED ALLOGENEIC STEM CELL TRANSPLANTATION WITH PRE-EMPTIVE DONOR LYMPHOCYTE INFUSION FOR PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA IN FIRST REMISSION

M Eefting, C Halkes, S Kersting, C van Pelt, E Marijt, P von dem Borne, J Veelken, J Falkenburg
LUMC, Leiden, Netherlands

Background. Approximately 25% of adult acute lymphoblastic leukemia (ALL) are Philadelphia chromosome positive (Ph^+) and express the *BCR-ABL protein* resulting from the t(9;22) translocation. Despite polychemotherapy Ph^+ALL is associated with a poor overall prognosis, with a median survival of 8 months. Although tyrosine-kinase-inhibitors (TKI) can provide additional disease control, most patients eventually relapse. Allogeneic hematopoietic stem cell transplantation (HSCT) in ALL is being performed to provide a graft-versus-leukemia (GVL-) effect, but at the cost of acute and chronic graft-versus-host-disease GVHD). T-cell-depletion (TCD) can prevent GVHD, but is associated with higher relapse rates. Pre-emptive donor T-lymphocyte infusion (DLI) may reintroduce GVL-reactivity with limited GVHD. Since the alloreactive GVL effect appears to be independent of the molecular risk profile, we hypothesized that also in Ph^+ALL TCD-HSCT followed by pre-emptive DLI and additional disease control with temporary TKI treatment may be beneficial. **Aims.** In this study, we compared the results of TCD-HSCT followed by pre-emptive DLI in patients with Ph^+ and Ph^- ALL in first complete remission (CR1). **Methods.** Twenty-two patients underwent myelo-ablative TCD-HSCT for ALL in first complete remission at LUMC between September 2003 and June 2010. Patient with GVHD needing systemic immune-suppression (IS) did not receive pre-emptive DLI. Patients without GVHD were scheduled to receive DLI between 3 and 6 months after alloSCT. Dosing of DLI depended on time after HSCT. Patients with a related donor (RD) were scheduled to receive up to 3. $0x10^6$ $CD3^+$cells/kg and patients with an unrelated donor 1. $5x10^6$ $CD3^+$cells/kg. **Results.** Eight patients had Ph^+ALL (36%). Seven Ph^+ALL patients received additional imatinib before HSCT of whom 3 also received imatinib after HSCT. Another 8 patients were diagnosed with (Ph^-) B-precursor ALL and 6 with T-ALL. Median time from diagnosis to HSCT was 175 days for Ph^+ALL *vs* 190 days for Ph^-ALL patients (p=0. 393). Five Ph^+ALL patients and 8 Ph^-ALL had a RD, respectively (p=0. 810). Median follow-up after HSCT is 63 months. Three of 8 Ph^+ALL patients developed chronic GVHD. The remaining 5 patients received DLI (median time-to-DLI 180 days). Hereafter, one did not convert to full-donor chimerism (FD) and developed a molecular relapse, which was successfully treated with DLI, interferon-alpha and nilotinib. None died during follow-up. None of 14 Ph^-ALL patients developed chronic GVHD. Three patients relapsed and 2 died of NRM within 6 months, before DLI was installed. Two did not receive DLI due to physician's choice. The remaining 7 received DLI (median time-to-DLI 189 days). One patient died 4 days later due to NRM. Another did not convert to FD and relapsed. One-year OS for Ph^-ALL was 50% (95% CI: 23-77%). Overall, OS of Ph^+ALL was superior to Ph^-ALL (log-rank p=0. 022, see Figure 1). Only 2 patients (9%) developed grade 3-4 acute GVHD after HSCT. After DLI, none developed ≥grade 2 acute GVHD, but one patient developed extensive chronic GVHD requiring IS. **Conclusions.** This study with long follow-up shows that myelo-ablative TCD-HSCT with pre-emptive DLI in CR1 abolishes the increased mortality associated with Ph^+ALL compared to Ph^-ALL in the era of BCR-ABL inhibitors.

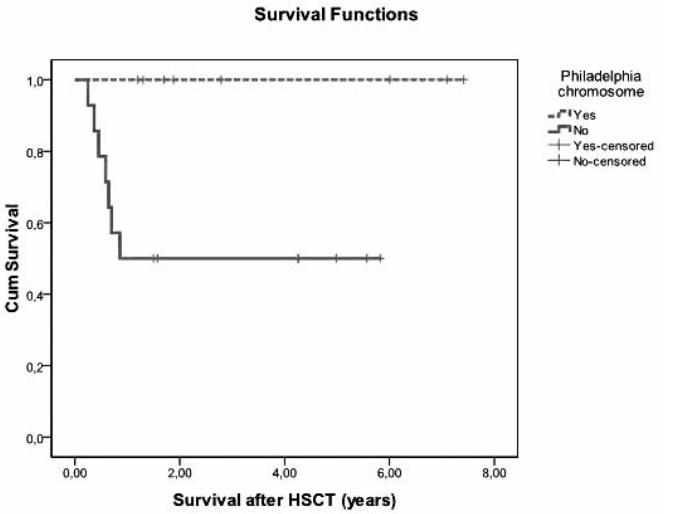

Figure 1. Overall survival Ph-positive ALL versus Ph-negative ALL.

1173

HIGH FREQUENCY OF BCR-ABL AND MLL-AF4 FUSION ONCOGENES IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS IS CORRELATED WITH DISEASE BIOLOGY AND POOR SURVIVAL

Z Iqbal[1], T Awan[2], N Sabir[2], M Iqbal[3], S Asad[4], M Tariq[5], S Sehar[2], A Akram[2], A Tahir[6], A Aleem[7], T Akhtar[2]

[6]Department of Internal Medicine, Montefiore Medical Centre, New York, United States of America
[7]Hematology/Oncology Unit,Department of Medicine,College of Medicine and KKUH,KSU, Riyadh, Saudi Arabia

Background. ALL is a complex genetic disease involving many prognostically important fusion oncogenes (FGs) [1], frequency of which can vary in different ethnic groups[2, 3] thus having implication in differential diagnosis, prognosis and

treatment. **Aims.** The objective of this study was to find out the frequencies of common fusion oncogenes in ALL and their correlation with disease biology and treatment outcome. **Methods.** We studied FGs in 101 pediatric ALL patients managed at Children Hospital, Jinnah Hospital and INMOL Hospital in Lahore, Pakistan. We used interphase-FISH and RT-PCR[1] at diagnosis (Day 0), and RT-PCR for follow up on Day 15 and Day 29, and studied the association of FGs with clinical features and treatment outcome. **Results.** Five most common FGs i. e. BCRABL (t; 9:22), TCF3-PBX1 (t; 1:19), ETV6-RUNX1 (t; 12:21), MLL-AF4 (t; 4:11) and SIL-TAL1 (Del 1p32) were found in 89/101 (88. 1%) patients. Survival of patients with >50,000 platelets count was significantly higher than patients with <50,000 platelets count (P=0. 013). Frequency of BCR-ABL gene was 44. 5% (45/101). Patients with BCR-ABL had significantly higher TLC count as compared to other patients and significantly lower survival (43. 7 ± 4. 24 weeks, p=0. 004) as compared to patients with other fusion genes, except MLL-AF4 (Figure 1). Overall survival for the whole group was 52. 2±3. 75 weeks. Survival of the patients harbouring ETV6-RUNX1fusion gene was better (65. 2± 9. 9 weeks, p=0. 009). The overall poor survival may be attributed to high frequency of poor prognostic fusion oncogenes (71%) and suboptimal supportive care.

Case Processing Summary

Oncogene	Total Number	Number of Events	Censored	
			N	Percent
BCR-ABL	45	30	15	33.3%
ETV6-RUN X 1	18	13	5	27.8%
MLL-AF 4	18	11	7	38.9%
SIL-TALL 1	6	5	1	16.7%
TCF3-PBX 1	2	1	1	50.0%
Overall	89	60	29	32.6%

Means and Medians for Survival Time according to oncogenes

Gene	Median			
			95% Confidence Interval	
	Estimate	Standard Error	Lower Bound	Upper Bound
BCR-ABL	40.000	2.683	34.741	45.259
ETV6-RUN X 1	56.000	5.392	45.431	66.569
MLL-AF 4	36.000	4.255	27.661	44.339
SIL-TALL 1	96.000	21.909	53.059	138.941
TCF3-PBX 1	72.000	.	.	.
Overall	48.000	5.110	37.985	58.015

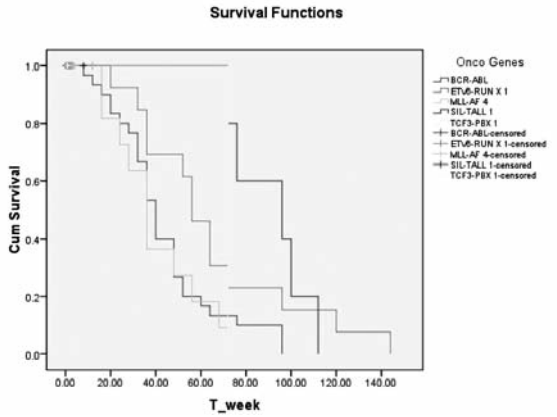

Figure 1. Frequency of different fusion oncogenes in pediatric acute lymphoblastic leukemia and their correlation with survival (Survival of patients with "ETV6-RUNX 1" is significantly higher than patients with other oncogenes. (p-value 0.009). BCR-ABL and MLL-AF4 genes have the lowest survival).

Summary and Conclusions. This is the first study from Pakistan correlating molecular genetic markers and disease biology to treatment response. It shows the highest frequency of BCR-ABL in pediatric ALL reported so far. Some authors have reported BCR-ABL frequency higher than Western populations[2, 4, and 5] while others reported 45% frequency of ETV6-RUNX1[6]. These and our data reflect strong interplay of genetic and environmental factors in the biology of pediatric ALL and its correlation with response to treatment [2, 3]. Our data also indicate an immediate need for large clinical trials to study the efficacy of tyrosine kinase inhibitors in paediatric ALL treatment in this ethnic group. This study will help unravel the role of BCR-ABL in leukemogenesis, and to find population-specific biomarkers and drug targets.

THYROID DYSFUNCTION IN LONG-TERM SURVIVORS OF ACUTE LYMPHOBLASTIC LEUKEMIA/LYMPHOMA: EXPERIENCE OF A SINGLE ITALIAN PEDIATRIC INSTITUTION

F Petruzziello[1], S Buffardi[1], A Mangione[1], R Parasole[1], L Marchese[1], G Menna[1], A Misuraca[1], S Di Maio[1], R Cuccurullo[1], M D'Amico[1], P Lubrano[2], V Poggi[1]
[1]Pausilipon Hospital, Naples, Italy
[2]Santobono Hospital, Naples, Italy

Background. The risk of thyroid dysfunction increases in long-term childhood survivors treated with radiotherapy (RT), due to disruption of the hypothalamic-pituitary axis during craniospinal RT or direct injury to the thyroid gland. There are few reports in the literature on the contribution of chemotherapy alone to the development of central hypothyroidism in childhood cancer survivors. **Aims.** We retrospectively evaluated the incidence of thyroid dysfunction in 397 long term survivors affected by lymphomas (97 patients) or acute lymphoblastic leukemia (ALL; 300 patients). Three hundred and six children were treated with chemotherapy alone and 91 received also cranial/craniospinal RT (43 ALL) or local RT (48 HD). All patients were treated in according with the protocols of the Italian Association of Pediatric Hemato-Oncology (AIEOP). **Methods.** From June 1986 to January 2012, 48 (30 M/18 F) Hodgkin lymphoma (HD), 49 (34 M/15 F) non-Hodgkin lymphoma (NHL) and three hundred (149 M/151 F) ALL long-term survivors were followed in a single pediatric Hemato-Oncology Institution. All patients annually underwent thyroid echography and blood measurement of free T4 and T3; TSH, anti-thyroperoxidase, and anti-thyroglobulin antibodies. All thyroid nodules exceeding 1,5 centimetres were aspirated and cytologically analyzed. **Results.** In our cohort of 397 long-term survivors, the average follow-up duration from completion of therapy to last follow-up was 7. 1 years (range, 1-26 years). Three out of 48 HD long-survivors (6,2%) developed thyreopathy (1 hypothyroidism, 1 nodules and hypothyroidism, 1 secondary neoplasm); all patients were treated with RT (respectively, 2 local RT followed by involved field after auto BMT and 1 total field). One out of 49 NHL (2,0%) survivors experienced thyroid nodules with normality of thyroid function; all patients were treated with chemotherapy alone. No ALL patients treated with cranial RT experienced thyreopathy; ten (2 males and 8 females) out of 257 ALL patients (3,9%), treated with chemotherapy alone, reported thyroid dysfunction. Six developed one or more thyroid nodules without lost of gland function (only one with thyroperoxidase and thyroglobulin antibodies). The fine needle aspirate cytology resulted negative for neoplasm. Subclinical hypothyroidism was observed in two patients. One patient developed autoimmune hypothyroidism and started thyroid replacement therapy while another reported autoimmune hyperthyroidism treated with methimazole. In two patient, familiar anamnesis was positive for thyreopathy. The mean time to thyroid dysfunction after stop-therapy was 3. 4 years (range, 1-12. 9 years); the mean age at the event was 13. 2 years (range, 6. 9-22 years). Table 1 resumes the clinical characteristics of survivors with thyreopathy.

Table 1. Clinical characteristics of patients.

14	F	ALL	7 yrs 7 mos	9 yrs 8 mos	No	Thyroid nodule	No	Normal	8 yrs	17 yrs 8 mos	No	Yes

Pts: patients
Dx: diagnosis
ST: stop therapy
RT: radiotherapy
TTEFST: time to event from stop therapy
*: papillary thyroid cancer
#: hypothyroidism after thyroidectomy
§: 4 months from stop therapy after second relapse

Conclusions. In our experience, the incidence of thyroid dysfunction in long-term pediatric survivals treated with RT was higher than in patients treated with chemotherapy alone. The more frequent thyroid abnormalities observed were thyroid nodules without gland failure. The short series of radiotherapy-treated survivors do not allow a correct evaluation of thyroid cancer incidence in these cohort of patients. We believe that childhood long-term survivors require lifelong surveillance after completion of therapy, for an early recognition and prompt treatment of late thyreopathy.

1175

BENDAMUSTINE PHARMACOKINETICS (PK) IN PEDIATRIC PATIENTS WITH RELAPSED/REFRACTORY ACUTE LEUKEMIA

M Darwish[1], G Megason[2], M Bond[1], E Hellriegel[1], P Robertson Jr. [1], R Clementi[1], L Phillips[3], T Grasela[3], C Fraser[4]
[1]Teva Pharmaceutical Industries Ltd., Frazer, United States of America
[2]University of Mississippi, Jackson, United States of America
[3]Cognigen Corporation, Buffalo, United States of America
[4]Royal Children's Hospital, Brisbane, Australia

Background. The PK profile of bendamustine in adult patients is well characterized. Bendamustine is an investigational drug in pediatric acute leukemia. **Aims.** The objective of this analysis was to describe the pediatric PK profile of bendamustine relative to the adult PK profile and correlate the systemic exposure of bendamustine to efficacy and safety parameters in pediatric patients. **Methods.** Samples were obtained after a single dose from patients aged 1-19 years with relapsed/refractory acute leukemia who were enrolled in an open-label, nonrandomized study of bendamustine (90-120 mg/m^2, infused over 60 minutes). Caregivers/patients provided informed consent. Samples were obtained prior to bendamustine infusion and at preselected time points through 24 hours after start of infusion on day 1. Because cytochrome P450 1A2 (CYP1A2) is the principal enzyme that forms the two active metabolites (γ-hydroxy-bendamustine [M3] and *N*-desmethyl-bendamustine [M4]) in the liver, the effect of concomitant administration of medications known to be CYP1A2 inhibitors/inducers on bendamustine exposure was assessed. Other known parameters influencing systemic exposure (eg, kidney and liver function) were also assessed. Population PK modeling was performed using plasma concentration data from the pediatric patients. PK data from adults were used for comparison.

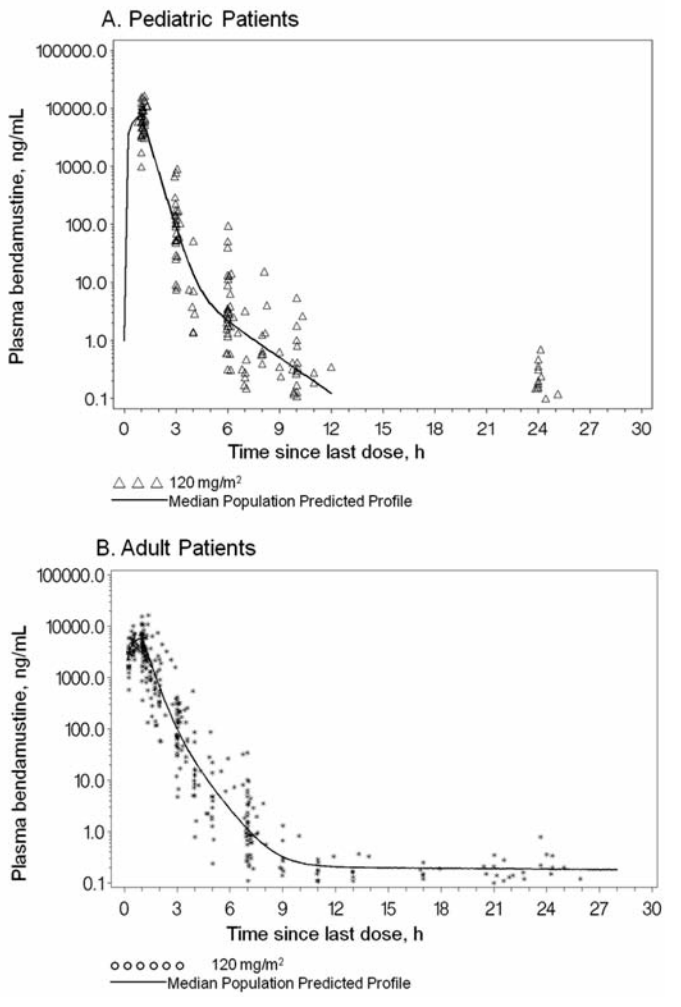

Figure 1. Bendamustine Systemic Exposur.

Results. Systemic exposure of pediatric patients to bendamustine was similar to that obtained previously in adult patients (see Figure 1, pediatric patients in panel A and adult patients in panel B). After a dose of 120 mg/m^2, mean maximum concentration (C_{max}) was 6806 ng/mL and mean area under the concentration-time curve from time 0 to 24 hours (AUC_{0-24})was 8240 ng-hr/mL in pediatric patients, compared with a mean C_{max} of 5746 ng/mL and AUC_{0-24} of 7121 ng-hr/mL in adults. The similarity in exposure despite the large range of body surface area across the pediatric and adult populations confirms the appropriateness of the body surface area-based dosing scheme. In pediatric patients, age, race, sex, or disease state had no statistically significant effect on systemic exposure to bendamustine. No changes in systemic exposure to bendamustine in the presence of a CYP1A2 inhibitor were observed. Differences in PK were not observed in pediatric patients with mild renal impairment, compared with patients with normal renal function; however, because only 3 patients had mild renal dysfunction, study data did not allow for a conclusive assessment of the effect of mild renal dysfunction on systemic exposure measures of bendamustine. Exposure in 2 pediatric patients with moderate hepatic dysfunction appeared to be higher. No clear exposure-response relationship was observed. Of fatigue, nausea, vomiting, and infection, infection was the only adverse event for which the probability of occurrence increased with increase in exposure to bendamustine. **Summary and Conclusions.** The PK profile of bendamustine in pediatric patients was similar to the known PK profile in adults, demonstrating that exposures reflective of the therapeutic range in adults were attained following administration of 120 mg/m^2 to pediatric patients. Support - Teva Pharmaceutical Industries Ltd.

TIME COURSE OF ADRENOCORTICAL RECOVERY AFTER GLUCOCORTICOID THERAPY IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA:COMPARISON BETWEEN TWO DIFFERENT PROTOCOLS

A Tantawy, M Salem, H El-Sedfy, M El-Laboudy, N Mahmoud, D Selim
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. Glucocorticoids are essential in protocols of therapy of acute lymphoblastic leukemia (ALL). Among the adverse effects of prolonged glucocorticoid therapy, adrenal insufficiency secondary to hypothalamic -pituitary - adrenal axis (HPA)suppression is a cause of concern. **Objectives of the study.** To assess the incidence, severity,morbid effects, and risk factors for HPA suppression in children with ALL, and the time course of recovery. **Study Design.** The study is a prospective study including 40 newly diagnosed patients with ALL diagnosed and followed in the Pediatric Hematology/Oncology Unit, Ain Shams University,Egypt. Prior to 2006, ALL patients were on modified BFM-1990 protocol; since 2006 treatment was changed to CCG based protocols . Accordingly, patients were classified according to the type of corticosteroid into: dexamethazone (DXM) group: 20 ALL patients on (CCG-1991) protocol, received DXM in induction I and II;and the prednisone (PDN) group: 20 ALL patients,received prednisone in induction I and II phases of modified BFM-1990 protocol. Patients were followed for glucocorticoid related complications especially life threatening adrenal decline, the steroid withdrawal syndrome, septic episodes, severe neutropenia, and associated drug therapy mainly fluconazole . The basal morning and the stimulated values of s. ACTH, cortisol, DHEAS were assessed, and the Low Dose Adrenocorticotropic hormone LD-ACTH (1mcg) stimulation test was done in all 40 patients at diagnosis, and, on weeks 0, 2 & 4 after steroid tapering. It was repeated every 2 weeks till adrenal recovery with additional testing during febrile and/or stress episodes. **Results.** Asymptomatic adrenal insufficiency was detected in 27. 5% of patients before treatment. Symptoms and signs of steroid withdrawal syndrome developed in 50% of PDN group and 75% of DEXA group after induction phases I and II; they occurred on days 1-3 and on days 4-9 following DXM and PDN tapering respectively . The HPA axis recovery assessed by serum cortisol and ACTH was earlier in PDN compared to DEX group($p<0.05$); 65% and 75% of patients on PDN recovered on week 2, while 45% and 50% of DXM group recovered in week 4 following tapering of steroids over 9 days in the induction phases I and II, respectively. Adrenal recovery was predicted 2 weeks earlier by normalized s. DHEAS levels. Gender did not affect the timing of recovery. Children below 5 years of age showed significant earlier recovery in induction phases I and II in PDN group compared to older age ($p=0.004$); there was no age effect in DEX group. Patients who had adrenal suppression prior to therapy had significantly late recovery ($p<0.001$). Increasing number of intercurrent infections were associated with late recovery in induction II in both groups. Fluconazole therapy ≥10mg/kg/day was significantly associated with longer duration to recovery in both groups in induction phases I and II. **Conclusions.** Prolonged adrenal suppression and related clinical morbidities is an inevitable consequence of high dose corticosteroid therapy in ALL children. Laboratory monitoring of cortisol levels, and, steroid coverage during periods of stress is recommended. A more gradual tapering of steroid therapy might be suggested.

1177

OUTCOME OF REINDUCTION TREATMENT USING MODIFIED DOSE OF IDARUBICIN FOR CHILDHOOD RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA

KN Koh[1], HJ Im[2], SH Lee[3], KH Yoo[3], HH Koo[3], H Kim[4], HJ Kang[4], KD Park[4], HY Shin[4], H Ahn[4], JJ Seo[2]

[1]Asan Medical Center, University of Ulsan, College of Medicine, Seoul, South-Korea

[2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

[3]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South-Korea

[4]Seoul National University College of Medicine, Seoul, South-Korea

Background. Treatment of marrow-relapsed childhood acute lymphoblastic leukemia (ALL) remains a great challenge. During reinduction treatment, induction failure and treatment-related toxicity are two major causes of treatment failure. Optimal intensity regimen is required to achieve the best remission induction rate and to minimize treatment-related mortality (TRM). **Aims.** This multi-center trial (CALL-0603) from Korea was conducted to develop an effective reinduction regimen with minimal toxicity by modifying the dose of idarubicin according to bone marrow suppression. **Methods.** Between 2006 and 2008, CALL-0603 trial accrued patients aged from 1 to 21 years with first isolated or combined marrow-relapsed ALL prospectively. Reinduction protocol consisted of oral prednisolone 60 mg/m^2/day for 28 days, weekly intravenous vincristine 1. 5 mg/m^2, intramuscular L-asparaginase 6000 IU/m^2 thrice weekly with a total of 9 doses and weekly intravenous idarubicin 10mg/m^2 on day 0, 7, 14, 21. If complete blood count on day 14 or day 21 showed absolute neutrophil count < 500/mm^3 or platelet count < 50,000/mm^3, administration of idarubicin was withdrawn. **Results.** A total of 38 patients were enrolled in the trial. The median ages at initial diagnosis and relapse were 8. 5 and 12. 0 years, respectively. Median duration from diagnosis to relapse was 23 months. Nineteen patients relapsed during initial treatment, 5 patients relapsed less than 6 months after the cessation of initial treatment, and 14 others relapsed more than 6 months. The second remission rate after 4 weeks of reinduction therapy was 74%, or 28 of 38 patients. Three patients achieved remission with extended or repeated reinduction treatment, resulting in the final remission rate of 82%. Median dose of idarubicin administered was 30 mg/m^2. Remission rate by idarubicin dose less or more than 20 mg/m^2 were not significantly different (69% vs. 77%, *P*=0. 713). Documented or suspected infection developed in 28 (74%), and 2 of them died of septic shock in refractory state during the reinduction attempt, resulting in the TRM rate of 5%. Length of initial complete remission less than 24 months was a marginally significant predictors of failure to enter second remission (*P*=0. 067). Twenty one patients received allogeneic hematopoietic stem cell transplantation (HSCT). Ten of them died of relapse after HSCT, and 5 of them died of transplant-related causes. The 3-year overall survival rate was 17. 5%. Duration of first remission and achievement of second remission after 4 weeks of reinduction treatment were significant predictors of long-term survival, while the total doses of idarubicin, and allogeneic hematopoietic stem cell transplantation were not. **Conclusions.** Four-drug reinduction treatment with a modified dose of idarubicin according to bone marrow suppression resulted in a favorable second remission rate in the treatment of relapsed ALL, which was due to lower TRM. However, despite a favorable remission rate, overall survival rate was unsatisfactory. More effective post-remission therapy should be investigated.

1178

THE INFLUENCE OF METHYLENETETRAHYDROFOLATE REDUCTASE (MTHFR) POLYMORPHISMS ON THE SEVERITY OF MEDIUM DOSE-METHOTREXATE INFUSION RELATED TOXICITY AND PROGNOSIS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M Karakukcu[1], E Unal[2], F Mutlu[3], M Ozdemir[3], T Patiroglu[3], Y Ozkul[4]

[1]Erciyes Univesity, Faculty of Medicine, Kayseri, Turkey

[2]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology, Kayseri, Turkey

[3]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology, Kayseri, Turkey

[4]Erciyes University, Faculty of Medicine, Department of Genetics, Kayseri, Turkey

Background. The over-all survival of acute lymphoblastic leukemia (ALL) of childhood reached to approximately 80% of the patients. Recent approaches focused to cure patient with minimal treatment associated morbidity and mortality. MTHFR, a fundamental enzyme that regulates folate metabolism, recently serves as a binoculer of a telescope to the pharmacogenetic world. Methotrexate (MTX), which interrupts folate metabolism, is widely used in the treatment of a variety of diseases including ALL, but causes some undesirable toxic effects especially on mucosal epithelia. **Aims.** We aimed to investigate the association of the MTHFR gene (C677T) polymorphisms with prognosis and toxicities after medium dose MTX (1000 mg/m^2/36h) infusion. **Methods.** We investigated the relationship between MTX related neutropenia and mucositis and MTHFR polymorphism. Toxicities were assessed using the Common Terminology Criteria for Adverse Events (CTCAE), Version 3. 0, published by the National Cancer Institute. The registration included nadir laboratory values [white blood cell count (WBC), absolute neutrophil count (ANC), hemoglobin level (Hb), platelet count (PLT), maximum plasma values of alanine aminotransferase (ALT)], occurrence of fever (hospitalization with temperature>38ºC), and delay in the chemotherapy regimen. **Results.** Of 85 enrolled children (54 boys and 31 girls; mean age 6. 3±3. 6, range 1-16 year) with newly diagnosed ALL treated to the Turkish national BFM ALL protocol at Erciyes University, Children's Hospital, Kayseri, Turkey, between January 2006 and January 2006, 196 courses of MTX infusion at medium dose of 1 gr/m^2/36 hours were evaluated. Subjects with wild type (CC), heterozygote, and homozygote MTHFR polymorphism was 47 (55. 3%), 29 (34. 1%), and 9 (10. 6%), respectively. The distribution of wild type (CC), heterozygote, and homozygote MTHFR polymorphism for the MTX infusion group was found to be 100 (51. 0%), 80 (40. 8%), and 16 (8. 2%), respectively. We did not found any effect of MTHFR polymorphism for the prognosis and outcome of the patients. However, there is a correlation between MTHFR polymorphism and MTX related neutropenia and mucositis. **Summary and Conclusions.** Our data suggest that MTHFR gene variants play a critical role in MTX related mucositis and neutropenia in ALL patients. Further studies about the genotyping of folate pathway gene variants might be useful to enable reduction of chemotherapy toxicity and/or to improve survival by individualized dose adjustments or alternative treatments.

1179

TELOMERASE GENE SCREENING AND TELOMERE OVERHANG DETECTION IN CHINESE PATIENTS WITH ACUTE MYELOID LEUKEMIA

S Yan, B Han, YJ Wu, YQ Zhao

Peking Union Medical Colleague Hospital, Beijing, China

Background. Telomeres are complex structures capping the ends of all eukaryotic cell chromosomes. Loss-of-function mutations in telomerase complex genes reduce telomerase activity and shorten overall telomere length in leucocytes, and they can clinically manifest as aplastic anaemia and dyskeratosis congenita, which predispose to acute myeloid leukemia. Telomeres are constituted of double-stranded tandem TTAGGG repeats followed by a 3' G-rich single-stranded overhang, a crucial telomeric structural component responsible for the t-loop formation. Loss of telomerase function also leads to short telometric overhangs, potentially resulting in chromosome instability. **Aims and Methods.** In this study, we screened bone marrow samples from 72 Chinese patients with acute myeloid leukemia (AML, excluding AML-M3) for variants in telomerase reverse transcriptase(TERT) and telomerase RNA component(TERC) gene. We also investigated the length of telomeric overhangs in those patients and 46 healthy individuals, using Southern blot analysis. Cytogenetic status, disease severity and short time survival rate in patients with AML were evaluated. **Results.** Our cohort included 2 M1,48 M2, 5 M4, 5 M5 and 12 secondary AML. Age was 48(13-77), medium follow-up time was 4 months (2-10 months). 3 TERT mutations (m896G>A□ m1079C>G and m1451G>A) but no TERC mutation was identified in patients with AML. Patients carrying TERT mutations had very short telomeres, critical short overhangs and poor response to the induction chemotherapy and died in their follow-up period. In contrast to overall telomere length, which shortened with ageing, telomeric overhang lengths were constant overtime and much shorter in patients with AML compared to those of normal controls(P<0. 001). In AML cohort, those who have shorter overhangs did worse than those with normal ones. Multivariant analysis showed telomeric overhang length, as well as unfavorable chromosome abnormalities, served as an independent prognostic marker for AML patients(P<0. 0001). **Conclusions.** We report 3 mutations in TERT gene patients with AML, which may cause short telomere and overhang and account for poor prognosis in those patients. Short overhang length may be an independent factor for poor response and shorter survival in patients with AML. These findings would have to be confirmed in large, prospective studies.

1180

CLOFARABINE FOLLOWED BY CYCLOPHOSPHAMIDE FOR TREATMENT OF RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA IN ADULT PATIENTS

A Malato, A Santoro, R Felice, D Turri, S Magrin, R Di Bella, R Scimè, D Salemi, F Acquaviva, F Fabbiano
Ospedali Riuniti Villa Sofia-Cervello, U. O. di Ematologia e UTMO, Palermo, Italy

Introduction. Relapsed or refractory adult acute lymphoblastic leukemias (ALL) have poor prognosis. The strategy for treating these patients is through reinduction chemotherapy followed by allogeneic stem cell transplantation, provided that the toxicity of the salvage regimen is acceptable. Clofarabine, a next-generation deoxyadenosine analog, has demonstrated significant activity in children and adults with refractory lymphoid and myeloid leukemia in early clinical trials and was granted approval for use in children with acute lymphoblastic leukemia in second or higher relapse. Promising activity of clofarabine in combination with cyclophosphamide, with DNA damage and apoptosis in both AML and ALL blasts, has been reported (Karp JE et al, Blood 2007). **Aims.** We present a series of ten cases in which clofarabine was combined with cyclophosphamidein adult patients with relapsed or refractory acute lymphoblastic leukemia. **Methods.** Patients aged 23-59 years with refractory/relapsedALL were treated at the dose of clofarabine 10mg/m2 + cyclophosphamide 400g/m2 on days 1-3 and 8-10. We evaluated the overall remission rate (ORR), duration of remission (DOR) and overall survival (OS). Minimal residual disease (MRD) by molecular targeting was considered in all patients. **Results.** Nine patients received clofarabine 10mg/m2 + cyclophosphamide400mg/m2, both on Days 1-5 and 8-10;one patient received only one cycle. All patients had relapsed/refractory lymphoblastic leukemia and had received multiple priors tharapies. Eight had pre-B cell ALL, 2 pts had T cell ALL; two pts had received a prior hematopoietic stem cell transplant (HSCT). Four patients achieved a complete remission (CR);two patients went on to receive allogeneic transplants after clofarabine/cyclophosphamide salvage. The median of Overal survival (OS) forall the patients was 103 days, the media was 172,70 days. The overall remission rate (ORR) was 44,4%, and we estimated a duration of remission (DOR) as 223,25 days in media (we calculated from the first day of remission). Treatment was complicated by neutropenic fever (n=4), grade III-IV mucositis (n=3), prolonged aplasia >30 days (n=3). One patient died of sepsis before completing the regimen. **Conclusions.** Combination treatment with clofarabine and cyclophosphamide in adults pts with refractory or relapsed ALL resulted inan ORR of 44%, two ptsproceeded to HSCT. The safety profile is acceptable in this relapsed/refractory population. The response rates and durability of remission observed with this regimen were encouraging given that these patients were highly refractory to prior therapies. However, more studies with this combination in adults are warranted.

Table 1.

N	Age	Diagnosis	Previous regimen (n.)	Response after Clofara-Cy	Toxicities	HSCT

1181

ASSESTMENT OF NEUROPSYCHIATRIC LATE EFFECTS AMONG SURVIVORS OF CHILDHOOD LEUKEMIA

A Kalafatçilar, O Tüfekçi, H Ören, S Hiz, H Çakmakçi, A Akay, E Orçim, Y Olgun, S Yilmaz, S Gözmen, T Karapinar, G Irken
Dokuz Eylul University, Izmir, Turkey

Background. The cure rate has improved significantly with advances in the treatment of acute leukemia. As numbers of childhood leukemia survivors increase the importance of monitoring late effects become more important. **Aims.** To identify the neurophyschiatric late effects and to provide an assesment about the degree and incidence of late effects of acute leukemia treatment in children. **Patients and Methods.** Patients who had been diagnosed as acute leukemia at least five years ago and treated between 1993-2009, in Dokuz Eylül University Hospital Department of Pediatric Hematology were included. All of the patients were treated with BFM protocols and none of them had relapsed. Demographic features, signs of neurological and ophtalmological examination, cranial MR imaging (MRI), auditory tests and neurocognitive tests were performed. The control group for neurocognitive tests were consisted of sibling of the patient. Informed consent was obtained. Questionnaires of quality of life were filled in by patients or parents. **Results.** There were 44 patients whom were 8-31 years old (mean age 16. 4±6. 4 years). Of 44 acute leukemia survivors, 48% were females and 52% were males. 11% of the patients were diagnosed as AML and 89% of them were diagnosed as ALL. Patients that had been off therapy for 2-18 years, were diagnosed at least 5 years ago. One or more late effects detected by physical examination, neurological tests or neurocognitive tests encountered in 80% patients, and 64% patients specified at least one complaint in the quality of life questionnaire. Cataracts and/or increased intraorbital pressure were found in 9% of patients and sensorineuronal hearing loss was found in 9% of patients. MRI revealed pathological findings in 18% of patients. EEG abnormalities were present in 9% of patients. Evaluation of total intelligence scores revealed that 30% of patients' IQ scores were less than 80 and 70% of patients' scores demonstrated neurocognitive dysfunctions. Comparison of the neurocognitive functions between patients and the control group revealed no statistically significant difference. Patients who had central nervous system involment at the time of diagnosis had significantly more pathological findings on neurological examination and tests. Based on the BFM protocol risk criterias the patients in the high risk group at the time of the diagnosis had higher incidence of cataract. The patients > 18 years during the study, or < 6 years at the time of diagnosis, or had AML, or had taken high dose (18 Gy) radiotherapy had lower IQ scores. Also neurocognitive disorders were more frequently detected in the patients > 18 years at the time of study. The patients > 6 years at the time of diagnosis were found to have more psychological problems and higher rates of smoking and alcohol consumption. The most frequent complaint was headache and the most common problem in school was denoted as diffuculty in concentration. **Conclusions.** In our study at least one neuropyschiatric late effect was detected in most of the cases. Survivors of chilhood leukemia are at risk of developing neurological and neurocognitive late effects as a result of exposure to chemotherapy and radiotherapy.

1182

EARLY RISK OF OBESITY AND THE METABOLIC SYNDROME IN EGYPTIAN CHILDREN SURVIVING ACUTE LYMPHOBLASTIC LEUKEMIA

A Tantawy, S Abdel Ghani, I Salama
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. The metabolic syndrome is increasingly recognized in adults surviving childhood cancer . **Objectives.** This study aimed to assess the early prevalence of obesity and the metabolic syndrome in children surviving acute lymphoblastic leukemia(ALL). **Methods.** 33 ALL survivors of mean age 13. 8 ±4. 9 years, who completed therapy for a mean of 5. 2±2. 1 years were compared to 33 healthy controls. All patients received chemotherapy, 13 received prophylactic cranial irradiation . All were subjected to clinical history, examination, anthropometric measures; assessment of lipid profile, fasting blood glucose, serum insulin, serum uric acid, serum leptin, growth hormone level (after provocation test), thyroid hormone assays. **Results.** HDL cholesterol, HDL/total cholesterol were lower in survivors compared to controls(P < 0. 001),with no significant difference between the two groups of leukemia survivors. Among survivors, 81. 8% had low HDL and 39. 4% had hyperinsulinemia, 12. 1% were overweight,and 9. 1% were obese. Systolic blood pressure above the 90th centile for age and sex was observed in 2 patients (6. 1 %),associated with obesity in one patient,combined with overweight and hyperinsulinemia in one patient . None had frank hypertension. Only one male survivor (3%) fulfilled the main criteria of the metabolic syndrome (hyperinsulinemia, obesity,low HDL cholesterol, in addition to raised blood pressure). Among the remaining survivors, 11 (33. 3%) had low

HDL with hyperinsulinemia, 1(3%) had hyperinsulinemia and raised systolic blood pressure, 15 (45. 5%) had only low HDL. Overall, 28 out of 33 studied survivors (84. 8%) had at least one main risk factor of the metabolic syndrome . Growth hormone deficiency (GHD) was found in 15 survivors of ALL (45. 4%), with a significantly higher percentage (76. 9%) among survivors who had cranial radiotherapy (RT),compared to 25% in survivors who received chemotherapy only (p<0. 05) . Among the survivors with GHD,20%, (3 out of 15) were overweight and 20% (3 out of 15) were obese . However, among the non- GHD survivors 1 out of 18 was overweight (5. 5%), and none of them was obese, the difference was statistically significant (p<0. 05) . Thyroid hormones and serum leptin were normal in all leukemia survivors while serum uric acid was significanltly elevated compared to controls (p<0. 001) . Multivariate analysis identified increased systolic blood pressure as significant predictor for low HDL(p=0. 04), female gender and increased systolic blood pressure as significant predictors for hyperinsulinemia (p=0. 04 and p=0. 05,respectively), and increased BMI was significant predictor for combined low HDL with hyperinsulinemia (p=0. 02). **Conclusions.** Childhood leukemia survivors have early increased prevalence of obesity, astherogenic dyslipidemia and hyperinsulinemia, denoting early risk of metabolic syndrome. They need follow up for early detection and preventive intervention.

1183

MAGNETIC RESONANCE IMAGING OF THE BRAIN IN SURVIVORS OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

T Hassan, M Badr, K El-Gerby, M Lamey
Zagazig University, Zagazig, Egypt

Background. Delayed treatment-related neurological damage is becoming increasingly important now that more and more children survive ALL treatments. After modification of the treatment protocols, severe symptomatic late effects are rare, and most adverse effects are detected by sensitive imaging methods such as MRI or by neuropsychological testing. **Aims.** We aimed to evaluate the incidence and characteristics of late CNS damage by MRI and clinical examination in children treated for ALL at the oncology unit of Pediatrics department of Zagazig university hospitals. **Methods.** Our study included 25 patients who were consecutively enrolled and treated according to modified Children Cancer Group (CCG) 1991 protocol for standard risk ALL and modified CCG 1961 protocol for high risk ALL and who had survived more than 5 years from the diagnosis. All relevant data were collected from patients' medical records specially those concerning the initial clinical presentation and initial brain imaging. All patients were subjected to thorough history and full physical examination with special emphasis on neurological system. MR Imaging of the brain was performed for all patients. This study was done according to the international and local ethical standards and informed consents were obtained from all patients.

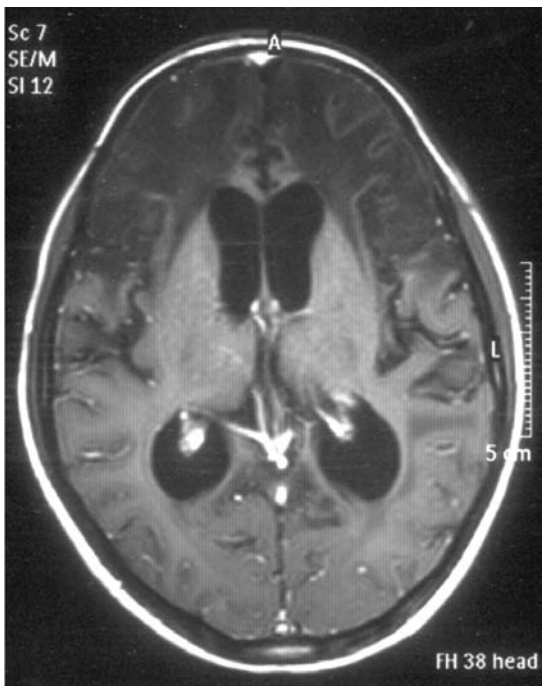

Figure 1. MRI brain of 13 year old boy previously treated with cranial irradiation displaying grade III leukoencephalopathy.

Results. Mean age of patients at diagnosis was 6. 9 ± 3. 04 and at study time was 12. 9 ± 3. 2. Patients were 14 males and 11 females. Abnormal MRI findings were detected in six patients (24%). They were in the form of leukoencephalopathy in two patients (8%), brain atrophy in two patients (8%), old infarct in one patient (4%) and old hemorrhage in one patient (4%). Abnormal MRI findings were significantly higher in high risk patients, patients who had CNS manifestations at diagnosis and patients who received cranial irradiation. **Summary and Conclusions.** We conclude that cranial irradiation is associated with higher incidence of MRI changes in children treated for ALL. Limitation of cranial irradiation to selected patients contributed to the lower incidence of neurological complications in our study. MRI is a sensitive radiological tool to detect structural changes in children treated for ALL even asymptomatic ones.

1185

THE INFLUENCE OF RANKL/OSTEOPROTEGERIN ON THE PROGNOSIS OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

E Unal, T Patiroglu, M Ozdemir, F Mutlu, M Karakukcu
Erciyes Uiversity, Faculty of Medicine, Kayseri, Turkey

Background. The discovery of the nuclear factor-kappa B (RANK)/RANK ligand (RANKL)/ osteoprotegerin (OPG) system and identification of their role in osteoclastogenesis provided a major advance in bone biology. RANKL directly induces osteoclast differentiation and proliferation by binding to its receptor RANK on the surface of osteoclast precursors. OPG is the soluble decoy receptor for RANKL thereby inhibiting bone resorption. **Aims.** We aimed to investigate the association of the OPG/ soluble(s) RANKL with the prognosis of children with acute lymphoblastic leukemia. **Methods.** We investigated the relationship between OPG/sRANKL at the diagnosis and remission (at continuation phase) with the prognosis of children with acute lymphoblastic leukemia. The registration included demographic features (sex, age, risk group), nadir laboratory values [white blood cell count (WBC), lactate dehydrogenase (LDH), erythrocyte sedimentation rate (ESR), immunphenotype, involvement of central nervous system, bone mineral density at presentation], and data of response to the treatment, relapse and out-come. **Results.** Forty five children (20 girls and 25 boys; median age 72 months, range 22 -216 months) with ALL treated according to the Turkish national BFM ALL (TRALL) protocol at Erciyes University, Children's Hospital, Kayseri, Turkey, between February 2008 and February 2010 were enrolled to this prospective study. The distribution of standard risk group, medium risk group, high risk group according to the TRALL was 14 (31. 1%), 20 (44. 4%), 11 (24. 4%) respectively. During the study 6 patients showed relapse, moreover 6 patients died because of progressive disease and 2 children died because of infection. The serum levels of OPG and RANKL at diagnosis were 58. 29±86 ng/ml, 0,29±0. 41 ng/ml, respectively; whereas their values at remission were 35. 5±40. 86 ng/ml, 0,03±0. 05 ng/ml, respectively. We detected a significant decrease for OPG (p=0. 000) but the decrease for sRANKL was not below the level of significance (p=0. 699). There was a correlation between initial levels of OPG, sRANKL and initial WBC, LDH. But we did not found any correlation with prognosis (response to treatment, relapse and out-come). **Summary and Conclusions.** Our data suggest that OPG and sRANKL is increased at diagnosis of childhood ALL. We speculate that, it may be related to the micro environment of the initial leukemic cell burden. Additionally we did not found any relation with prognosis. Further studies such as flow-cytometric expression with large numbers are necessary to highlight the clear effect of these molecules in children with ALL.

1186

BACTEREMIA AND PATTERNS OF BACTERIAL SUSCEPTIBILITY AMONG CHILDREN WITH HEMATOGICAL MALIGNANCIES

M Kourti[1], A Katragkou[2], V Sidi[3], E Papakonstantinou[3], E Siaka[4], A Orfanou[4], D Koliouskas[3], E Roilides[2]
[1]Hippokration General Hospital, Thessaloniki, Greece
[2]Infection Unit, 3rd Pediatric Department, AUTH, Thessaloniki, Greece
[3]Pediatric Oncology Department, Hippokration General Hospital, Thessaloniki, Greece
[4]Microbiology Department, Hippokration General Hospital, Thessaloniki, Greece

Background. Infections cause substantial morbidity and morbidity in children with hematological malignancies receiving chemotherapy. Epidemiology of bac-

teremia differs between institutions and constitutes the basis for selection of empiric antibiotic therapy for febrile neutropenia. **Aims.** To investigate the long-term epidemiology and resistance of pathogens isolated from blood cultures in children with hematological malignancies. **Patients and Methods.** We conducted a retrospective data collection on all positive blood cultures from children with hematological malignancies in a pediatric Oncology Department during 2002-2011. **Results.** A total of 225 bacteremic episodes and 2 candidemias were documented in 136 children with median age of 6 years old (range 1-16) and 42% boys. The majority of patients (69. 8%) was diagnosed with acute lymphoblastic leukemia, 20. 5% (28/136) with non-Hodgkin lymphoma, and 9. 5% (13/136) with acute myeloid leukemia. The leading pathogen was Coagulase-Negative-Staphylococci (CNS) (49. 3%), followed by *Klebsiella* spp. (10. 6%), *Pseudomonas* spp. (8. 9%), *Escherichia coli* (8. 4%), *Enterobacter cloacae* (3. 1%) and *Staphylococcus aureus* (2%). It is noteworthy that 48% of *Klebsiella* spp. and 50% of *E. coli* isolates were extended beta-lactamase producers (ESBL), while 8% of *Klebsiella pneumonia* but none of the *E. coli* isolates were resistant to imipenem. 20% of the *Pseudomonas aeruginosa* isolates were resistant to ceftazidime. Vancomycin resistance was noted in 1% of the CNS, but none of the *Staphylococcus aureus* isolates. CNS and *S. aureus* were 80% and 9% resistant to methicillin (MRSA), respectively. Since the beginning of the study Gram-negative episodes increased (from 3. 1 to 13. 7/1000 patients, chi-square for trend p<0. 01) and Gram-positive episodes decreased from 18. 14 to 8/1000 patients, chi-square for trend p<0. 01). The overall mortality was 22. 7% while infection related mortality was 8. 8%. **Conclusions.** Gram-positive bacteria are the more commonly isolated etiologic pathogens but the significant increase of Gram-negative episodes needs special attention in children with hematological malignancies. Infection epidemiology among patients with hematological malignancies should be monitored in order to guide prompt empiric antibiotic treatment.

1187

OUTCOME OF PATIENTS WITH PHILADELPHIA CHROMOSOME-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA- A SINGLE CENTRE EXPERIENCE

PK Liew[1], TC Ong[1], S Yegappan[1], YK Guan[1], Z Zakaria[1], TK Chew[2], SM Tan[1], AS Goh[2], KM Chang[1]
[1]Ampang Hospital, Selangor, Malaysia
[2]Penang Hospital, Penang, Malaysia

Background. Philadelphia chromosome-positive (Ph+) Acute Lymphoblastic Leukemia accounts for about a quarter of adult ALL. This group of patients is associated with dismal outcome with standard chemotherapy. In recent years, haematopoietic stem cell transplantation (SCT) has been an attractive curative option to improve survival in these patients. Patients in our centre are treated with combination chemotherapy with tyrosine kinase inhibitors as induction therapy prior to SCT. **Aims.** We evaluate the outcome of patients with Ph+ Acute Lymphoblastic Leukemia who had undergone combination chemotherapy versus haematopoietic stem cell transplantation. **Methods.** All records of the patients were analyzed in a non-randomized retrospective study on 1st February 2012. Overall survival was estimated using the Kaplan-Meier method. **Results.** There were 35 patients, diagnosed with Ph+ ALL out of 141 patients with B lineage ALL (24. 8%) from January 2007 to Dec 2011. The median age of patients at diagnosis was 36 years (range 22 to 62). Male to female ratio was almost 1:1 with an ethnic composition of Chinese 48. 6 %, Malays 34. 3 %, Indian 11. 4 % and others 5. 7 %. In our cohort, 21 patients were unable to undergo stem cell transplantation due to refractory disease, medically unfit or no HLA-matched donor. In this group of patients, only 18 patients were analyzed as 3 were lost to follow-up. A total of 14 patients (40%) underwent haematopoietic stem cell transplantation (9 HLA-identical sibling, 4 unrelated HLA-matched donor, 1 autologous). Four-year overall survival (OS) for patients who underwent haematopoietic transplantation versus patients without transplantation were 69. 6 % and 0 % (p= 0. 0001). Median follow-up for these two groups was 22. 5 months and 7 months respectively. Eleven out of 14 patients were in first complete remission (CR 1) prior to transplantation. Amongst the 9 HLA-identical siblings allo-SCT, three died due to disease progression and/or veno-occlusive disease. There was one mortality due to GVHD in the unrelated HLA-matched allo-SCT group. The patient with autologous transplantation is still in complete remission. All patients are monitored for minimal residual disease (MRD) by PCR real time quantitative. **Conclusions.** The analysis of a small cohort of our patients with Ph+ ALL suggests a trend towards a favorable outcome with HSCT. Statistical inferences are limited by small number of patients, short duration of follow-up and non-randomization. Longer duration of follow-up and a prospective randomized comparative trial is needed to conclusively confirm the finding.

1188

OUTCOME OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA TREATED BY THE EORTC 58951 PROTOCOL ABOUT 152 CASES

I Frikha, M Medhaffar, S Hdiji, N Ajmi, H Bellaaj, L Sfaihi, O Kassar, L Kammoun, M Hachicha, M Elloumi
Hedi Chaker Hospital, Sfax, Tunisia

Background. Acute lymphoblastic leukemia (ALL) is the most common malignancy diagnosed in children, representing nearly one third of all pediatric cancers. In this study we analysed the clinical, biological features and therapeutic results of patients treated for ALL and aged less than 19 years. **Patients and Methods.** From January 2000 to December 2010, 152 patients aged from 13 months to 19 years were treated for ALL by the pediatric EORTC 58951 protocol in the Hematologic department of Hedi Chaker Hospital. From these patients, we analysed the clinical and biological features (Age, sex, blood count, cytogenetics abnormalities and blasts phenotypes) and therapeutic results (remission, relapse, overall survival (OS), event free survival (EFS) and relapse free survival (RFS) at 5 years or follow up). **Results.** The median age of patients was 9 years. Sex ratio H/F= 1. 45. The median WBC count at diagnosis was 19500 cells per µL (ranged from 700 to 402000 cells per µL). The high leucocytosis more than 100000 cells per µL was observed in 17. 5% children. There were 66% with B-cell ALL and 34% with T-cell ALL. Among 152 children, 135 (89%) have a successful cytogenetic result: normal karyotype, hyperdiplopid >50 chromosomes, t (9, 22) and del 11q23 translocation were found respectively 49%, 33%, 7% and 6%. The Cortico-resistance at day 8 of corticosteroid (more than 1000 blasts/mm^3 on the blood smear) was observed in 17% of patients. Poor prednisone response was associated with high leucocytosis and T-cell ALL ($p<10^{-4}$). The children were stratified into low risk, average risk and high risk in respectively 4% (6 patients), 70% (106 patients) and 27% (40 patients). Seven children (4. 5%) were treatment failure after two courses of chemotherapy and 13 patients (8. 5%) died during induction. The complete remission was obtained in 133 children (95%), among them 29 relapsed (22%). The death of post induction was noted in 7% patients. At 5 years of follow-up, the OS, EFS and the RFS were respectively 60%, 57% and 71%. **Discussions.** Our study is characterized by higher rate of male gender and T phenotype of blasts than reported in the literature. Despite the acceptable results concerning remission rate and survival, we have a high rate of death related to chemotherapy. Therefore, the need to improve supportive treatment in the management of our patients

1189

HYPEREOSINOPHILIA AS FIRST CLINICAL PRESENTATION OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: REPORT OF TWO SUBSEQUENT CASES

R Parasole[1], F Petruzziello[1], N Marra[1], G Maisto[1], L Castelli[2], ME Errico[3], G Menna[1], V Poggi[1]
[1]Pausilipon Hospital, Naples, Italy
[2]Radiodiagnostic Unit, Pausilipon Hospital, Naples, Italy
[3]Anatomic-Pathology Unit, Pausilipon Hospital, Naples, Italy

Background. Hypereosinophilia as first clinical presentation has rarely been reported in pediatric acute lymphoblastic leukemia (ALL). This subtype of leukemia is frequently associated with specific cytogenetic abnormalities, even if eosinophilia seems to be a reactive, nonneoplastic epiphenomenon. Hypereosinophilia seems to affect negatively the prognosis of this unusual ALL. **Aims.** On a cohort of 340 ALL children, treated with a protocol in a single pediatric institution, we observed two consecutive patients with marked eosinophilia as the main clinical onset of ALL. The coincidence of two subsequent ALL with hypereosinophilia at presentation warranted a description of their case histories. **Case 1.** A 13-year-old-girl with history of evening feveret and fatigue. Blood examination: normal leukocyte count associated with hypereosinophilia (44. 3%), mild anemia and thrombocytopenia. Peripheral blood smears: morphologically mature eosinophils and absence of blasts. No parasitic or allergic conditions were found. Bone marrow aspirate: marked eosinophilia (30%) and partial infiltration of L2 lymphoblasts (52%). Immunophenotyping: B-lymphoid CD10 positive blasts, and the cytogenetic analysis showed a 46, XX karyotype; the main molecular leukemic rearrangements (bcr/abl, TEL/AML1, MLL/AF4, E2A-Pbx1) were negative, including Jak2 and 4q(12). Doppler ultrasound: left iliac-femoral deep venous thrombosis as thrombotic complication. Treatment: AIEOP-BFM ALL 2000 protocol, without L-Asparaginase, for its pro-thrombotic property. Outcome: complete hematological remission during maintenance treatment 8 months from diagnosis. **Case 2.** A 20 month-old-boy, fifteen days after the first patient,

experienced mild leukocytosis, hypereosinophilia (32. 1%), feveret, night sweat, pruritic erythroderma and left inferior limb arthralgia with claudication; all other hematological parameters were normal and no liver or spleen enlargement was observed (Table 1). Peripheral blood smears: eosinophils associated with lymphoblasts (11%). Bone marrow aspirate: diffuse infiltrates (60%) of L1 CALLA positive lymphoblasts and hypereosinophilia (36%). Skin biopsy of the erythroderma confirmed cutaneous infiltration by leukemic cells associated with eosinophilia. CT scan of the left inferior limb: tibial osteolytic area with interruption of cortical bone; the biopsy of this area showed leukemic and eosinophilic infiltration. Cytogenetic studies: hyperdiploid karyotype (52 chromosomes), with all leukemic rearrangements negative, including bcr/abl, and 4q(12). Treatment: AIEOP-BFM ALL 2000 protocol. Outcome: hematological complete remission during reinduction at 7 months from diagnosis. The short follow-up of both patients does not allow any prognostic evaluation. **Comments**. Although, in our experience, the incidence of hypereosinophila, as first clinical presentation of ALL, was very rare (0,6%), we emphasized the importance of a correct differential diagnosis in persistent, unexplained peripheral hypereosinophilia. Clinicians should keep in mind that eosinophilia can be caused by acute leukemia and needs to be explored with a bone marrow aspirate. The poor prognosis reported for these atypical ALL in children should prompt clinicians to carry out an accurate and prolonged follow-up. Besides, childhood ALL with hypereosinophilia requires careful surveillance, for an early recognition and prompt treatment of eosinophilia-related morbidities, such as cardiac failure, pulmonary pathology, peripheral neuropathy and thromboembolic phenomena.

Table 1. Patients' clinical characteristics.

Characteristics	Patient 1	Patient 2
Sex	Female	Male
Age at diagnosis	13 years	20 months
Peripheral blood:		
Hb(g/dL)	9,8	12
White blood cells count (mL)	7870	14390
Eosinophil count (mL)(%)	3490 (44.3%)	4620 (32.1%)
Platelet count (mL)	129.000	223.000
Blasts (%)	None	11
Bone marrow aspirate:		
Blasts (%)	52	60
Eosinophils (%)	30	36
FAB category	L2	L1
Immunophenotype	Common	Common
DNA index	1	1.01
Bone marrow biopsy	B cells lymphoproliferative syndrome; MF1 (WHO grading)	B cells lymphoproliferative syndrome; MF0 (WHO grading)
Karyotype	46,XX	Hyperdiploid (52,XXY,+6,+14,+17,+21,+21[5])
Molecular biology for ALL rearrangements	Negative	Negative
Molecular biology for thrombophilia	Positive (Homozygous for -455G/A of b-fibrinogen)	Positive (Eterozygous for P1b of HPA)
Clinical presentation	Hypereosinophilia Evening feveret Left iliac-femoral deep venous thrombosis	Hypereosinophilia Claudication Slight fever Night sweat Left inferior limb arthralgia Pruritic erythroderma
Other organ involvement	No	Skin Bone (tibial osteolysis)

FAB, French-American-British classification; MF, myelofibrosis; WHO, World Health Organization; HPA, human platelet antigen

1190

STUDY OF VON WILLEBRAND FACTOR AND FACTOR VIII LEVELS IN CHILDREN WITH NEWLY DIAGNOSED ACUTE LYMPHOBLASTIC LEUKEMIA IN RELATION TO PERIPHERAL BLAST CELLS AND STEROID THERAPY

S Elhabashy, N El Sherif, T Elkerdany, M Narouz
Ain Shams University, Cairo, Egypt

Background. The pathogenesis and the impact of therapy on thrombin activation in children with acute lymphoblastic leukemia (ALL) are unknown. Steroids may contribute to ALL-associated thrombosis. **Aims.** Of this study is to assess children with newly diagnosed ALL for Von Willebrand Factor antigen and Factor VIII relevant to peripheral blast cells and the effect of steroids therapy on their levels. **Methods.** This study was conducted on 32 newly diagnosed patients ALL patients; 24 patients with peripheral blasts, and 8 patients without. **Results.** The study showed that at diagnosis patients with peripheral blasts had a significantly higher levels of VWF antigen, FVIII, and total leucocytic count than those without. After 8 days of steroid therapy, patients with peripheral blasts had a significant reduction in both factors, while those without peripheral blasts showed a significant increase in VWF antigen, and FVIII. There was a significant positive correlation between total leucocytic count and VWF antigen, and between peripheral blasts and VWF antigen, FVIII at diagnosis among ALL patients with peripheral blasts. **Conclusions.** In presence of circulating blasts, steroids have two types of effects: a direct effect resulting in the increase in VWF antigen and FVIII levels and an indirect effect through reduction in circulating blasts which results in normalization of endothelium and resultant reduction in both factors levels. This reduction may be in excess of steroid-induced increment in VWF antigen and FVIII levels with a net effect of reduction in the levels of both.

1191

OUTCOME OF CORTICORESITANT PATIENTS TREATED WITH THE PEDIATRIC EORTC 58951 PROTOCOL FOR ACUTE LYMPHOBLASTIC LEUKEMIA

M Medhaffar[1], I Frikha[1], N Ajmi[1], S Hdiji[1], A Lakhal[2], H Bellaaj[1], O Kassar[1], L Kammoun[1], T Ben Othmen[2], M Elloumi[1]
[1]Hedi Chaker Hospital, Sfax, Tunisia
[2]CNGMO, Tunis, Tunisia

Background. Corticoresistance at day 8 has been described as one of high risk factor in acute lymphoblastic leukaemia (ALL). In this study we analysed the impact of corticoresistance on the prognosis of patients treated for ALL. **Patients and Methods.** Between January 2000 and December 2010,175 patients were treated for ALL with the pediatric EORTC protocol in the hematologic department of Hedi Chaker hospital. Risk group stratification was made according to White blood cells count, blasts phenotype, cytogenetics abnormalities, response to corticosteroids (Préphase) at day 8 and response to chemotherapy in the end of induction. High risk group is considered if one of these criteria was observed: Cyto-genetics abnormalities like t(9,22) or del11q23, Cortico-resistance at day 8 of Préphase (more than 1000 blasts/mm^3 on the blood smear) and chemo-resistance at the end of induction. We studied the remission rate, the 5 years relapse free survival (RFS) and the 5 years overall survival (OS) for cortico-resistant patients . Then we compared these results to those of corticosensitive patients. **Results.** Among 175 ALL patients aged from 1 to 28 years and treated by the pediatric EORTC 58951 protocol, 31were corticoresistant at day 8 of Préphase (18%). Corticoresistance was the only high risk factor in 22 patients (71%). The rate of death during induction and post induction therapy were respectively 18% and 10% for corticoresistant and corticosensitive ALL. The remission rate was 84% for corticoresistant ALL and 98% for corticosensitive ALL $P<10^{-4}$. Among 24 corticoresitant patients allograft was indicated for 22 and only six patients undergone allograft with a familial donor. At 5 years of follow up, the RFS and the OS were respectively 42% and 23% for corticoresistant compared to 78% and 68% for cortico-sensitive ALL ($P= 0.0006$ and $P<10^{-4}$) **Conclusions.** In this study, corticoresiatnce was more observed than described in the literature 18% vs 9%. And it has a negative impact alone or with the other high risk factors on the remission rate and in the outcome of the ALL (RFS and OS). Allograft should improve the outcome of majority of patients and we think that the minimal residual disease study recently introduced in the follow-up of our patients can distinct some cortico-resistant ALL with better prognosis.

1192

THE INFLUENCE OF CD40/CD40 LIGAND ON THE PROGNOSIS OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

T Patiroglu, E Unal, M Karakukcu, FT Mutlu, MA Ozdemir
Erciyes University, Faculty of Medicine, Kayseri, Turkey

Background. CD40 plays a critical role in immunoregulation, the levels of sCD40 in adult patients with hematologic malignancies were reported to be elevated, and associated with a poor prognosis at least in patients with MM and AML, suggesting that sCD40 may have a role in modulating antitumor responses and also may be a useful prognostic marker. Experience in children, however, is extremely limited. **Aims.** We aimed to investigate the association of the CD40/CD40 ligand with the prognosis of children with acute lymphoblastic leukemia (ALL). **Methods.** We investigated the relationship between CD40/CD40 ligand at the diagnosis and remission (at continuation phase) with the prognosis of children with acute lymphoblastic leukemia. The registration included demographic features (sex, age, risk group), nadir laboratory values [white blood cell count (WBC), lactate dehydrogenase (LDH), erythrocyte sedimentation rate (ESR), immunophenotype, involvement of central nervous system, bone mineral density at presentation], and data of response to the treatment, relapse and out-come. **Results.** Forty five children (36 B cell, 9 T cell; 20 girls and 25 boys; median age 72 months, range 22 -216 months) with ALL treated according to the Turkish national BFM ALL (TRALL) protocol at Erciyes University, Children's Hospital, Kayseri, Turkey, between February 2008 and February 2010 were enrolled to this prospective study. The distribution of standard risk group, medium risk group, high risk group according to the TRALL was 14 (31. 1 %), 20 (44. 4%), 11 (24. 4%) respectively. During the study 6 patients showed relapse, moreover 6 patients died because of progressive disease and 2 children died because of infection. The serum levels of CD40/CD40 ligand at diagnosis were 22. 41±9. 91 ng/ml, 0. 22±0. 38 ng/ml, respectively; whereas their values at remission were 15. 17±5. 49 ng/ml, 1. 04±0. 51 ng/ml, respectively. We detected a significant decrease for CD40/CD40 ligand (p=0. 008 and 0. 000 respectively). There was a correlation between initial levels of CD40 and initial WBC, LDH, immunophenotyping, CNS involvement, But we did not

found any correlation with prognosis (response to treatment, relapse and outcome). **Summary and Conclusions.** Our data suggest that CD40/CD40 ligand is increased at diagnosis of childhood ALL. On the bases of its physiological effect CD40 may have a role in modulating antitumor responses and also may be a useful prognostic marker. Additionally we did not found any relation with prognosis. Further studies such as flow-cytometric expression with large numbers are necessary to highlight the clear effect of these molecules in children with ALL.

1193

THE EFFECT OF MTHFR POLYMORPHISMS ON THE PROGNOSIS AND SEVERITY OF ORAL METHOTREXATE RELATED TOXICITY DURING CONTINUATION THERAPY IN CHILDREN WITH ALL

M Karakukcu[1], E Unal[2], F Mutlu[3], M Ozdemir[3], T Patiroglu[3], Y Ozkul[4]
[1]Erciyes Univesity, Faculty of Medicine, Kayseri, Turkey
[2]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology, Kayseri, Turkey
[3]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology, Kayseri, Turkey
[4]Erciyes University, Faculty of Medicine, Department of Genetics, Kayseri, Turkey

Background. Methotrexate (MTX), which interrupts folate metabolism, is the fundamental drug widely used in the treatment of childhood acute lymphoblastic leukemia (ALL). Methylenetetrahydrofolate reductase **(**MTHFR) is the most important enzyme in this pathway and has a wide polymorphism. **Aims.** We aimed to investigate the association of the MTHFR gene (C677T) polymorphisms with the prognosis and severity of oral methotrexate related toxicity during continuation therapy in children with acute lymphoblastic leukemia. **Methods.** We investigated the relationship between MTX related neutropenia and mucositis and MTHFR polymorphism. Toxicities were assessed using the Common Terminology Criteria for Adverse Events (CTCAE), Version 3. 0, published by the National Cancer Institute. The registration included nadir laboratory values [white blood cell count (WBC), absolute neutrophil count (ANC), hemoglobin level (Hb), platelet count (PLT), maximum plasma values of alanine aminotransferase (ALT)], and delay in the chemotherapy regimen. **Results.** Eighty five children (54 boys and 31 girls; mean age 6. 3±3. 6, range 1-16 year) with ALL treated with oral 6 mercaptopurine 40 mg/m2/day and methotrexate 25 mg/m2/week for the continuation therapy according to the Turkish national BFM ALL protocol at Erciyes University, Children's Hospital, Kayseri, Turkey, between January 2006 and January 2006 were enrolled to this retrospective study. Subjects with wild type (CC), heterozygote, and homozygote MTHFR polymorphism was 47 (55. 3%), 29 (34. 1%), and 9 (10. 6%), respectively. The distribution of wild type (CC), heterozygote, and homozygote MTHFR polymorphism for the MTX infusion group was found to be 100 (51. 0%), 80 (40. 8%), and 16 (8. 2%), respectively. We did not found any effect of MTHFR polymorphism for the prognosis and outcome of the patients. However, there is a correlation between MTHFR polymorphism and MTX related neutropenia and mucositis. **Summary and Conclusions.** Our data suggest that MTHFR gene variants play a critical role in MTX related mucositis and neutropenia in ALL patients at the continuation phase. Further studies about the pharmacogenetic area are necessary to enable reduction of chemotherapy toxicity with individualized dose adjustments.

1194

ACUTE METABOLIC SIDE EFFECTS OF REMISSION INDUCTION TREATMENT IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M Aydogan, F Atasoy, D Tugcu, F Akici, Z Salcioglu, A Akcay, H Sen, M Demirkaya, N Ayaz
Istanbul Kanuni Sultan Suleyman Research and Education Hospital, Istanbul, Turkey

Background. Remission-induction treatment phase in children with ALL is critical due to the fact that severe complications like tumor-lysis syndrome might occur. It is important to know possible metabolic derangements and take the precautions for reducing additional morbidity and mortality. **Aims.** The aims of this study is to report the metabolic abnormalities during remission induction treatment, to evaluate the complications and define their effects on treatment process. **Methods.** 40 ALL patients (0-15 years old) in the remission-induction phase treatment were included to the study. TRALL BFM 2000 treatment protocol was used on the patients. In every patient alkaline hydration and allopurinol treatment for TLS prophylaxis were starting before ALL protocol. Baseline complete blood count, biochemical parameters, PT and aPTT were measured . On follow-up, deviations from normal parameters were recorded according to the protocol day. The frequencies of these deviations, possible aetiological causes, durations and clinical reflections were recorded. The patients, in whom the treatment was postponed due to metabolic abnormalities and their 33rd day responses were evaluated. **Results.** During the remission-induction phase, at least one metabolic disorder was detected 97. 5%. Increase in urea level was found to be the most common metabolic disorder (62. 5%). These were followed by hypophosphatemia and hypocalcemia (%52,5) hyponatremia (50%) hyperuricemia (27. 5%), hypochloremia (25%), hypopotassemia and hyperphosphatemia (22. 5%), hyperpotassemia (10%), hypomagnesemia and hypermagnesemia (7,5%). Transient hyperglycemia was detected 5%, hypertriglyceridemia 20%, hypertransaminasemia 52. 5% and hyperbilirubinemia 35%. LTLS rate was determined as 5% and KTLS was 2. 5%. In none of the cases indication for dialysis and mortality due to TLS were encountered. **Conclusions.** Remission-induction treatment in childhood ALL is critical due to the fact that severe complications like tumor lysis syndrome might occur. Allopurinol and alkaline hydration therapy were found to be succesfull in TLS prophylaxis due to the low mortality and morbidity rates.

1195

ALEUKEMIC LEUKEMIA CUTIS: AN UNUSUAL RASH IN A CHILD

D Atay, E Turkkan, K Boluk, F Karaaslan
Okmeydani Education and Research Hospital, Istanbul, Turkey

Background. Leukemia cutis is an infiltration of the skin by neoplastic leukocytes (myeloid or lymphoid), resulting in clinically identifiable cutaneous lesions. It is seen most commonly in congenital leukemia and acute myelogenous leukemia (approximately 10%). In the pediatric population, the frequency of leukemia cutis in acute lymphoblastic leukemia is rare (1%). **Aims.** Although leukemia cutis tends to present with other features of leukemia, it can occasionally precede the development of blast cells in the marrow and blood (aleukemic leukemia cutis). The aim of this case presentation is to illustrate how leukemia cutis can masquerade as a clinically benign-appearing cutaneous eruption without leukemic changes in blood or bone marrow. To confirm the diagnosis immunohistochemistry of the skin lesions as well as a complete staging procedure is necessary. **Case Report.** A previously healthy twenty two months old girl presented with a sudden onset rash consisting of erythematous macules on an abdomen. Over the next two week, the rash became papular and darker. The patient had no other symptoms or signs. Complete blood count showed no leukocytosis (WBC: 5. $95x10^9$/L) and thrombocytopenia (Plt: $215x10^9$/L) but anemia (Hb: 8. 46 g/dL). Biochemical analysis revealed high lactate dehydrogenase level (LDH: 873 U/L) and peripheral blood smear showed no blast cells. A skin biopsy performed four weeks after the onset of the rash showed leukemic blast cells (precursor B cell lymphoblastic lymphoma/leukemia). A bone marrow aspirate confirmed precursor B-cell lymphoblastic leukemia with 30% blast cells. **Conclusions.** Leukemia cutis can be the first sign of leukemia, preceding the diagnosis of systemic leukemia by months or even years. A sudden, persistent rash of unknown cause warrants full physical examination, hematologic investigation including complete blood count and dermatological evaluation. Remission can achieved with early recognition of leukemia cutis and prompt hematological treatment in aleukemic patients.

1196

EFFECTS OF RECOMBINANT URATE OXYDASE (RASBURICASE) AND ALLOPURINOL FOR PROPHYLAXIS AND TREATMENT OF HYPERURICEMIA IN PATIENTS WITH LEUKEMIA AND LYMPHOMA

K Arjmandi Rafsanjani[1], R Taghipoor[2]
[1]Tehran University of Medical Sciences, Tehran, Iran
[2]Semnan University of Medical Sciences, Semnan, Iran

Background. Efficacy of rasburicase in pediatric patients with leukemia and lymphoma is proved. This study aims to weigh efficacy and safety of rasburicase versus more conventional therapy, allopurinol, and to compare their safety and properties in tumor lysis syndrome (TLS) of leukemia and lymphoma patients. Materials and **Methods.** The study was done with a retrospective cohort design. Patients were selected from our hematology ward admitted from 2005 through 2008. Patients were put into two groups based on their blood levels of uric acid, before initiation of chemotherapy; treatment group (the Uric Acid level of 6. 5 mg/dl or more) and the prophylaxis group (the uric acid level below 6. 5 mg/dl). Evaluation of effectiveness of therapy was performed after 24, 48, 72-hour, and longer periods. **Results.** Of 184 patients; 69% had leukemia, and 31% lymphoma. Twenty patients were treated with rasburicase and 164 with allopurinol. Mean age of patients was 7. 93± 4. 247 years old. 60. 8% were male and 39. 2% were female. According to Chi-square test results, there was no significant difference between two agents regarding prophylaxis (chi-square =

4. 247, p-value = 0. 193) and treatment (chi-square = 0. 780, p-value = 0. 677). Most of the response to each agent was seen in the first 24 hours after drug administration. Mean level of uric acid reduced from 7. 4 to 3. 4 mg/dl in rasburicase, and from 5. 4 to 3. 9 mg/dl in allopurinol group. Mean duration of treatment for rasburicase was 2 days, and for allopurinol 6 days. Adverse effects were minimal in both groups (in rasburicase 1. 6% and in allopurinol 5. 4%). **Conclusions.** Rasburicase seems to be highly efficient in both prophylaxis and treatment of Hyperuricemia. Due to high costs in our practice, it was only administered to 20 patients with high levels of blood uric acid or leukocytosis. It prepares patients for chemotherapy faster and decreases cost of hospital stay indirectly by lowering cost of treatment. Allopurinol, alternatively showed equal efficiency and comparable results. Thus, it can be used safely and effectively until rasburicase becomes more widely available and more cost-effective.

1197

THE BONE MARROW AND THE BONE SURFACE CELLS IRRADIATION DOSES IN CHILDREN WITH ACUTE LEUKAEMIAS WHICH WERE EXPOSED TO IONIZING RADIATION DUE TO CHERNOBYL ACCIDENT

G Bebeshko, V Repin, S Nechaev, K Bruslova, N Tsvietkova, O Kuznetsova
SF "National Scientific Center of Radiation Medicine National AMS of Ukraine", Kiev, Ukraine

Background. Small doses of radiation can promote development of genetic and cancerogenic effects, in particular the development of acute leukemias in children's population which have suffered in result of Chernobyl accident (CA). **Aims.** To study the influence of small doses irradiation of the bone marrow (BM) and the bone surface cells (BSC) after Chernobyl accident on development of acute leukaemias (AL) in children and duration of their life. **Methods.** 19 children with AL are surveyed. Sex, age at the diagnosis, life expectancy of children (less than 60 months and more than 60 months), time passed from CA was considered. The accumulated irradiation doses for BM and the BCS resulting from internal acting of radionuclides are calculated, results of studying ^{137}Cs and ^{90}Sr dynamics of entering and radionuclides content in child organism are used and age features of consumption of local manufacture provisions are considered. **Results.** AL children age was in 2 -16 years limit. 13 children had ALL, 6 - AML. 13 children had life expectancy more than 60 months, 6 - less than 60 months. Equivalent BM irradiation doses of children fluctuated from 0,08 to 35,02 mZv, and BSC irradiation doses - from 0,11 to 35,41 mZv. The maximum doses had inhabitants of Chygyry village in Korostensky district of Zhitomir region that is caused by considerable levels of soils pollution (density of ^{137}Cs pollution is 492 kBq·м$^{-2}$, and ^{90}Sr - 9,25 kBq·м$^{-2}$) and permanent living in radioactive contaminated territory. The average irradiation dose for BM in this children group was 5,37 mZ, and for BSC - 5,58 mZv. **Conclusions.** There were no correlation between AL development, irradiation dose, age, sex and the life expectancy of children revealed. Direct correlation between children age and the accumulated doses from internal irradiation of BM and BSC is established (Ro-Spearm. = 0,46 and Ro-Spearm. = 0,49 accordingly).

SURVIVIN EXPRESSION IN ELDERLY AML PATIENTS AT DIAGNOSIS AND DURING HEMATOLOGICAL REMISSION AFTER CHEMOTHERAPY

A Tsiga, P Klonizakis, E Vlahaki, E Mandala, P Papagiannakis, I Klonizakis, E Ioannidou-Papagiannakis
Hippokration Hospital, AUTH, Thessaloniki, Greece

Background. AML is a complex disease with considerable phenotypical as well as genotypical heterogeneity, and more than 50% of AML patients are over 60 years of age. Increasing evidence indicates that the unique member of the inhibitors of apoptosis proteins (IAPs), survivin, is implicated in regulation of cell division, apoptosis inhibition and drug/radiation resistance in various cancer cells. Many observations also provide new perspectives on survivin, as a valid therapeutic target for treatment of cancer and suggest new research directions for therapies without toxicity to normal human tissues· a process that is very interesting for adult AML patients. **Aims.** The Aim of this study is to evaluate survivin expression in elderly AML patients at diagnosis and during hematological remission after chemotherapy and correlate it with the expression in control individuals. Furthermore, survivin expression -in both mRNA and serum protein level- will be correlated with well-established AML prognostic factors and patients' response to chemotherapy. **Methods** Total RNA was isolated from peripheral blood cells (PBCs) of 40 elderly patients with AML. All patients (24 males and 16 females) were above 60 years of age (range 60-86 years, median age 67,72±11,47 years) and had not been treated prior to the study. Diagnosis was based on standard clinical and laboratory criteria. All patients were treated on standard AML protocols, with Ara-C and Idarubicin and 18 of them (10 males and 8 females) succeeded hematological remission (bone marrow blasts <5%) and were investigated again, during remission. Twenty-five healthy individuals, with normal haematopoiesis, age and sex matched, consisted the control group. Real-Time PCR assay was performed for the quantification of survivin mRNA levels. All PCR reactions were carried out in an Opticon2 Real-Time PCR System. Relative quantification of survivin mRNA expression was performed by employing the relative Ct method. Data was analyzed using the REST-XL©-Version2 software. Serum survivin protein levels were measured in patients at presentation and during remission, as well as in control individuals, using the ELISA assay. Statistical analysis was performed using the SPSS11. 5 software. **Results.** The mean survivin mRNA levels of PBCs in patients at presentation were significantly higher by 2,562 times (p=0,038), related to mean mRNA levels of patients in remission and significantly higher by 5,672 times (p=0,042) compared to control group. Serum survivin protein concentration was detected in all patients (100%) at diagnosis and in 11 out of 18 patients (61,2%) in hematological remission. The mean serum survivin protein concentration was 33,19±24,89 pg/ml in patients at diagnosis, while during remission detectable levels were found, although very low (0,011±0,028 pg/ml) (p=0,005). Serum survivin protein was undetectable in control individuals. High survivin mRNA levels were significantly correlated with unfavourable karyotype (p=0,033) and failure to response to chemotherapy (p=0,037), while high survivin serum levels were correlated with patients' failure to achieve remission (p=0,036). **Conclusions.** In our study both mRNA and serum protein levels of survivin were down-regulated after chemotherapy and were significantly correlated with failure to achieve remission. Thus, survivin could be used as an unfavourable prognostic marker or a marker of resistance in chemotherapy.

1199

BAALC CAN PROMOTE THE SURVIVAL AND INHIBIT THE AS2O3-INDUCED APOPTOSIS IN HL60/DOX-BAALC THROUGH BCL-2 AND NF-κB P65 UP-REQULATION SIGNALING PATHWAYS BUT NOT IN MOLT4-BAALC

B Xu[1], P Xiao[2], P Shi[2], G Chen[2], X Guo[2], X Song[2], S Zhou[2]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China
[2]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China

Background. BAALC (brain and acute leukemia, cytoplasmic) located at chromosome 8q22. 3, normally is highly conserved in neuroectoderm-derived tissues among mammals and CD34-positive progenitor cells from bone marrow, but it can't be found in lower organisms and mature hematopoietic cells. Under pathological conditions, BAALC overexpression can be found in patients with AML, ALL, and chronic myelogenous leukemia in blast crisis, which leads to a poor prognosis. Although it is confirmed that BAALC is correlated with the occurrence of AL, the biological function of BAALC protein at the molecular level still largely unknown. **Aims.** This study aims to investigate the biological function and the molecular mechanism of BAALC in AL. **Methods.** Molt-4 (human T-cell lymphocytic leukemia cell) and HL60/Dox (human doxorubicin resistant promyelocytic leukemia cell) whose have no original BAALC expression were chosen as the representative cells of T-ALL and AML respectively. BAALC 1-6-8 isoform was introduced into the Molt-4 and HL60/Dox cells with retrovirus infection. The stable BAALC overexpression in the two cells after the infection was confirmed by both quantitative real time PCR and western blotting. Survival rate of HL60/Dox-BAALC, Molt-4-BAALC and negative control were Analysis by MTT assay. As_2O_3-induced apoptosis of HL60/Dox-BAALC, Molt-4-BAALC and negative control were assessment by using Annexin V-FITC/PI apoptosis kit. The expression level of MDR1 was detected by using quantitative real-time PCR amplification and the he expressions of BCL-2 and NF-κB p65 were detected by western blotting. **Results.** MTT and apoptosis assays showed that HL60/Dox-BAALC had a significantly higher survival rate (P<0. 001) and a much lower As_2O_3-induced apoptosis rate (P<0. 001) than those of HL60/Dox and HL60/Dox-Vector; BAALC overexpression had no such effects on Molt-4-BAALC (P>0. 05). RT-PCR showed that the expression level of MDR1 in HL60/Dox-BAALC has no statistical difference (P>0. 05) compared with that in HL60/Dox and HL60/Dox-Vector. Western blotting showed that both BCL-2 and Nuclear factor κB (NF-κB) p65 were activated in the As_2O_3-induced apoptosis of HL60/Dox-BAALC. **Conclusions.** BAALC can affect the survival rate and As_2O_3-induced apoptosis of HL60/Dox-BAALC through BCL-2 and NF-κB p65 up-regulation signaling pathways, but the effects did not occur in Molt-4-BAALC.

FLT3-ITD MUTATION DIFFERENTIALLY PRESENT IN AML BLASTS SUB-POPULATION SORTED BY ITS CD34 EXPRESSION

Y Ofran, D Sahar, M Hayun
Rambam health care campus, Haifa, Israel

Background. Mutations within the FMS-like tyrosine kinase 3 (FLT3) gene have been detected in 20-25% of acute myeloid leukemia (AML) patients, corresponding with poor prognosis. Intact FLT3 is associated with normal hematopoiesis and is over-expressed in CD34+ leukemic blasts. Internal tandem duplication (ITD) mutation increases FLT3 kinase activity and may play a role in leukemogenesis. Leukemia stem cells reside mainly in the CD34+ compartment. Therefore, interest is growing in comparing FLT3 status in specific CD34-/+ blasts sub-populations. **Aims.** To examine the presence of FLT3-ITD mutation in both CD34+/- blasts sub-populations of adults AML patients known to carry the mutation. **Methods.** Six AML patients diagnosed with FLT3-ITD mutation were evaluated. AML blasts were sorted by FACSAria flow cytometer into CD34+ and CD34- groups. DNA was extracted from each cell population and the presence of FLT3-ITD mutation was detected following PCR reaction (amplifying exons 11 and 12). **Results.** High quality DNA was extracted from blasts sub-populations in five patients. Flow cytometry analysis validated that both CD34+ and CD34- sorted cells express abnormal (leukemic) phenotype. In two patients, FLT3-ITD mutations were evident in both compartments (Figure 1. patients A and B). In the other three, FLT3-ITD mutation was selectively expressed in only one sub-population as shown in Figure 1 (patients C and D; patient E result is not shown). Patient C is a 37 year old male. On diagnosis 95% of his blasts were CD34 positive. Sorting revealed that the FLT3-ITD mutation was specific to the CD34 positive cells. Patient D is a 34 years old male. On diagnosis he presented with NPM1 positive, FLT3-ITD negative mutation and a CD34 negative phenotype. Unfortunately, he relapsed two months after concluding his treatment plan. On relapse, the NPM1 mutation was not detected and two distinctive CD34+/- blast populations were observed. A new FLT3-ITD mutation was detected solely in the CD34- sub-population. Patient E is a 67 year old male. On diagnosis 40% of his blasts were CD34 positive. His FLT3-ITD mutation signal was weak, corresponded with a low burden of mutated allele, but was apparent only in the CD34+ compartment. **Conclusions.** FLT3-ITD mutation is not considered the leukemia initiating event, and therefore occurs later in leukemogenesis. It is known as a poor prognostic factor but yet, the underlying mechanism is not clear. The ability to separate blast populations harboring FLT3-ITD mutation and compare them to blasts from the same patient expressing wt-FLT3 may help to understand FLT3-ITD mutation biological effect. In three out of five examined patients FLT3-ITD mutation reside only in blasts sub-population differentiated by CD34 expression. Our results indicate that leukemic blasts may be divided in some cases into distinct phenotypic and genetic properties populations. This may serve as an opportunity to better explore late events during leukemogenesis.

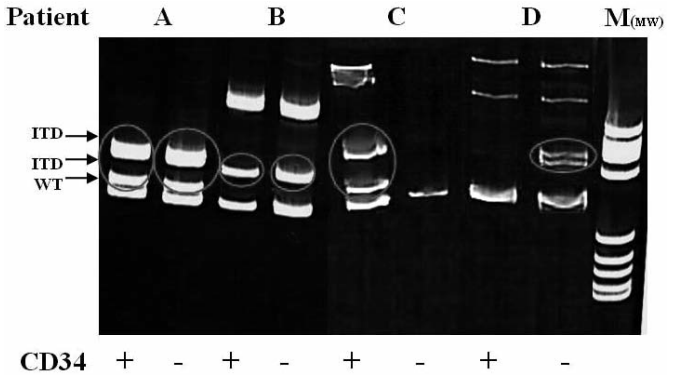

Figure. 1. PCR analysis of FLT-3-ITD mutation. Acrylamide gel electrophoresis of PCR products with (red circle) and without FLT3-ITDs.

DEVELOPMENT AND APPLICATION OF AN ASSAY FOR IDENTIFICATION OF PROGNOSTIC MUTATIONS IN AML PATIENTS

M Hansen, A Aggerholm, L Ebbesen, D Melsvik, P Hokland, C Nyvold
Aarhus University Hospital, Aarhus C, Denmark

Background. In acute myeloid leukemia (AML) with a normal karyotype, which constitutes approximately 50 % of all AMLs, the genetic basis for the disease seems to arise from somatic mutations. During the past years, numerous somatic mutations with prognostic implication have been identified and described for this subgroup of patients. **Aims.** To develop a convenient method for identification of prognostic mutations in the genes *FLT3 (ITD* and *D835*), *c-KIT (D816V)*, *IDH1* (*R132*), *CEBPA*, *NPM1*, and *WT1* (*exon 7*) and to apply the assay to a cohort of 73 AML patients diagnosed at our department. **Methods.** Fragment analysis using fluorescence labeled PCR products was developed for detection of indel mutations in *FLT (ITD)*, *CEBPA*, and *WT1* (*exon 7*) while restriction endonuclease-mediated selective PCR (REMS-PCR) in combination with fragment analysis was designed for detection of the point mutations *FLT3-D835*, *c-KIT-D816V*, and *IDH1-R132*. **Results.** In a pilot study of a cohort of 73 AML patients, we found one or more mutations in 45. 2% of all patients (one mutation: 26. 0 %; two mutations: 15. 1 %; three mutations: 4. 1 %). The distribution and frequency of mutations differed between patients in age groups <60 years and >60 years. The *IDH1-R132* and *FLT3-D835* mutations were not found in the patients < 60 years while it constituted 41. 9 % of all mutations in patients > 60 years. Furthermore the WT-1 mutation was found with a higher frequency in the younger group of patients. *Discussion:* This newly developed assay identified prognostic mutations in a high proportion of patients with AML. The assay is easily applicable in a clinical routine setting and enables upfront prognostication of the individual patient. In addition, the achievement of molecular phenotypes in the heterogeneous group of AML patients, not defined by chromosomal translocations, enable the clinician to follow minimal residual disease in more patients.

P45NF-E2 FUNCTIONS AS TUMOR SUPPRESSOR GENE IN F-MULV INDUCED ERYTHROLEUKEMIA BY INDUCTION OF G1 CELL CYCLE ARREST

YH Tan, C Wang, GJ Wang, JW Cui, C Yao, W LI
The First Hospital of Jilin University, Changchun, China

Background. Nuclear factor erythroid 2 (NF-E2) is one of the most important transcriptional factor to erythroid differentiation, its p45 subunit is critical for the normal globin and platelet production. Frequent proviral insertional inactivation of the p45NFE2 locus in Friend murine erythroleukemia virus (F-MuLV) induced erythroleukemia cells, combined with the evidence that p45NFE2 mutant mice succumb to the disease significantly faster than control mice and that the absence of p45NFE2 in erythroleukemic cells promotes tumor growth by accelerating the rate of cellular proliferation, has defined a pivotal role for NF-E2 in the progression of F-MuLV induced erythroleukemia. **Aims.** The aim of this study was to explore the mechanism of the anti-tumor effect of p45NF-E2 by reintroduced the gene into non-producing erythroleukemia cells produced by F-MuLV integrational inactivation. **Methods.** p45NF-E2 gene was transfected into non-producing erythroleukemia cell line HB22. 2 with constructed pEF-NFE2 plasmid and the expression of α-globin was detected with Northern blot to determine the gene activity. The cell proliferation was assayed by depicting the growth curve and the cell cycle was detected by flow cytometry. The expression of cell cycle relative protein was detected by Western blot. And the interaction between proteins was detected by Co-immunoprecipitation. **Results.** The reintroduction of p45NFE2 in HB22. 2 cells attenuated the growth of erythroleukemic cells in culture through G1 cell cycle arrest that associated with the marked increase of the expression of p27 Kip1 and decrease of CDK2. The interaction between p27 and CDK2 was decreased. Up-regulation of p27Kip1was regulated post-translationally, partially by reduced degradation by phospho-ERK which was shown marked reduction in the cells reintroduced with p45NFE2 compared to the control cells. **Conclusions.** By this study, initial evidence was provided that the erythroid transcription factor, p45NF-E2 can function as tumor suppressor by attenuating the growth rate of F-MuLV-induced erythroleukemia cells and inactivation of its expression contributes to the progression of F-MuLV-induced erythroleukemia.

1203

IMMUNOPHENOTYPIC AND MOLECULAR FEATURES OF 'CUPLIKE' AML

P Carluccio, A Mestice, D Pastore, M Delia, P Casieri, M Martelli, A Liso, M Longo, R Angarano, D D'Amore, C Pascazio, G Amoruso, G Specchia
Hematology, Bari, Italy

Background. Nuclear invaginations, also referred to as fishmouth or cuplike nuclei, are often identified in microgranular APL, myelomonocytic and monocytic AMLs. More recently, this typical morphological feature has been associated with NPM1 and Flt3 mutations, as well as with the lack of CD34 or HLA-DR expression, in non APL and non myelomonocytic or monocytic AMLs. **Aims.** In this study we retrospectively analyzed the morphologic, immunophenotypic, cytogenetic and molecular features of 68 AML patients admitted to our Institute since

January 2010. **Methods**. A cuplike morphology was defined by the presence of >10% of blasts showing nuclear incision spanning >25% of the nuclear diameter at May Grunwald-Giemsa staining, independently assessed by two hematologists. Four-color or 6-color flow cytometry immunophenotypic analysis was performed on bone marrow aspirate using a FACSCanto II with a large panel of monoclonal antibodies; blasts were gated for CD45 expression and light side scatter characteristics. PCR was used to screen for Flt3-ITDs. NPM mutations were detected by immunohistochemical analysis of abnormal localizations in the NPM protein cytoplasm. Conventional cytogenetics was performed on bone marrow aspirate using standard Giemsa trypsin G-banding procedures. **Results**. Sixty-eight patients were included in the study, 39 males and 29 females, with a median age of 64 years (26-84). According to FAB criteria, 9 cases were classified as M0, 15 as M1 and 44 as M2. A cuplike nuclear invagination was detected in 15 (22%) cases; the cuplike blasts showed a relatively scanty, pale basophilic cytoplasm with little granularity; there was a 38% median percentage of blast cells with nuclear invagination (range: 10-80). No difference was observed between cuplike and control cases as regards age, sex, FAB group, WBC and platelet counts, haemoglobin level, percentage of blasts and normal karyotype. Loss of CD34 expression was observed in 53% of cuplike cases vs. only 23% in the control group (p: 0. 03); the same significant difference was observed for the lack of HLA-DR expression (43% vs. 13%, p: 0. 03). In cases with a cuplike morphology, a higher incidence of internal tandem duplication of the Flt3 gene and abnormal cytoplasmic localization of NPM protein were observed (73% and 50% vs. 31% and 24%) but the difference was statistically significant only for Flt3-ITD (p: 0. 02). **Concluions**. Our data show that non promyelocytic-non monocytic AMLs with cuplike nuclear invagination are associated with Flt3-ITD positivity as well as loss of CD34 and HLA-DR expression. This relationship is not sufficient to suggest that they could represent a distinct AML subtype, but further molecular investigations could yield a better characterization of this AML subgroups.

Table 1.

	N	M/F	Lack of CD34	Lack of HLA-DR	FLT3-ITD+	NPM+	Normal Karyotype
Cuplike+	15	7/8	53%	43%	73%	50%	64%
Cuplike-	53	32/31	23%	13%	31%	24%	50%
p			0.03	0.03	0.02	ns	ns

1204

BCL2 ASSOCIATED ATHANOGENE-1 (BAG-1) IS OVEREXPRESSED IN CHILDHOOD AML

S Aveic, E Manara, B Accordi, M Pigazzi, G Basso
University of Padova, Padova, Italy

Background. BCL2 associated AthanoGene-1 (BAG-1) represents a pro-survival protein. In humans, it can be found as three, diverse in length, protein isoforms (BAG-1L; BAG-1M; BAG-1), characterized by BAG-domain, and Ubiquitin-like domain which mediates BAG-1 / proteasome interaction. Recently, we showed that BAG-1 was highly expressed in leukemic cell lines. We demonstrated that BAG-1 exerted a pro-survival role by disabling proteasome dependent degradation of anti-apoptotic protein BCL2. The same was observed for USP9X deubiquitinase, which was revealed to be a key BAG-1's target. In fact, USP9X kept the anti-apoptotic MCL1 protein away from degradation in our model. As a result, leukemic cells were well protected from apoptosis induction, and hence, had better surviving capacity. **Aims.** We aimed to confirm our in vitro studies about BAG-1, BCL2 and MCL1 in pediatric patients affected by acute leukemia. **Methods.** RQ-PCR and Western Blot (WB) study is performed to study BAG-1's expression in 10 patients affected by acute myeloid (AML) and lymphoid leukemia (ALL). Reverse-phase protein array (RPPA) analysis was conducted in large cohort of AML (n=66) patients at diagnosis. **Results.** The mRNA expression of BAG-1 showed to be heterogeneous in acute leukemia at diagnosis being not so informative. Its protein expression was higher with respect to healthy bone marrow (hbm) where it was undetectable by WB. We found the tendency of mitigating protein expression of either all three of BAG-1 isoforms in ALL, or in particular of BAG-1 in AML samples during remission phase suggesting a putative BAG-1's role in leukemia onset. By RPPA, we showed that BAG-1 protein was overexpressed in 56 AML patients (84. 8 %) with respect to hbm (mean AML intensity value (m. i. v): 113616 ± 66721; fold increase: 2. 36). We then studied the expression of direct or indirect BAG-1 interacting partners previously identified. We confirmed a significant ($p < 0.001$) correlation between BAG-1 elevated levels and high BCL2 protein levels (m. i. v = 110033 ± 89117), high BCL2S70 (m. i. v: 70387 ± 40864; $p < 0.001$), and high MCL1 (112309 ± 49254; $p < 0.001$). Then, we considered patients for the typical clinical biological features (karyotype, molecular genetics, FAB, age and WBC). We highlighted a relationship with the highest BAG-1 expression and normal karyotype group of patients, who are known for a poor prognosis. Whereas, the lowest BAG-1 protein expression, found in 15. 2 % of analyzed patients, is connected with t(8;21) AML-ETO translocation (found in 9/10 patients with low BAG-1 expression; $p < 0.001$), who are stratified in standard risk group and have a better prognosis. **Conclusions.** Our results revealed the tendencies of pediatric AML to express highly BAG-1 at diagnosis, as well as BCL2 and MCL1. We supported BAG-1 protein to be unraveled as a novel marker in AML, and to be considered for future therapeutical opportunities.

1205

THE EFFECT OF PROLIFERATION INHIBITION AND APOPTPSIS INDUCTION OF ICARIIN ON NB4 LEUKEMIA CELLS AND ITS MOLECULAR MECHANISMS

G Sujun, SF Song[1], SJ Gao[2], Y Yang[2], L Wei[2], YH Tan[2], XL Liu[2]
[1]First hospital jilin university, Changchun, China
[2]The First Hospital, Jilin University, Changchun, China

Background. Acute promyelocytic leukemia (APL) is a special type of acute myeloid leukemia, and bleeding symptoms are very prominent. Since the usage of all-trans retinoic acid (ATRA) and arsenic trioxide (ATO), prognosis of APL has been significantly improved. However, there are still 40% patients relapse after treatment with ATRA and ATO, and ATRA results in serious Retinoids Acid Syndrome in some cases. Hence, new regimens are necessary for patients of APL. Icariin (ICA) is traditional Chinese drug which is derived from several species of plants in the Epimedium family, commonly known as Horny Goat Weed or Yin Yang Huo. It has been reported that ICA can inhibit the proliferation of K562 and HL-60 cell lines, and induces apoptosis of HL-60 cell line. However, little is known about the effect of ICA on APL cell line. **Aims.** To investigate effects of ICA on proliferation, cell cycle and apoptosis of NB4 cells and its underlying anti-tumour mechanisms. **Methods.** The inhibitory effect of ICA on proliferation of NB4 cells was assayed by MTT. Cell cycle and apoptosis of NB4 cells treated with ICA were detected by flow cytometry (FCM), Western blotting was employed to access the role of BAX and BCL-2 family proteins in the apoptosis pathway of NB4 cells. . **Results.** ICA could produce a significant cytotoxicity on NB4 cells in a dose-dependent (0, 4, 8, 16, 32 and 64 μmol/L) and a time-dependent (24, 48 and 72 hours) manners, for 48hours, inhibition rate of NB4 cells increased from 22. 80%±0. 65% to 74. 29%±0. 89%($F=21.493$; $P<0.01$), ICA inhibited NB4 cells growth with IC50 of 18. 48 μmol/L. Compared with the vehicle-treated controls, the NB4 cells treated with ICA at a concentration of 8, 16, 32 and 64 μmol/L for24 hours, were arrestted in G1 phase. Meanwhile, ICA could induce a significant apoptosis effect at all the series of concentrations. After incubated with 4, 8, 16 and 32 μmol/L ICA for 24 hours, apoptosis rate of NB4 cells increased from 9. 73% ± 0. 85% to 28. 45% ± 0. 99% ($F=16.183$; P□0. 05). Further research found ICA treatment of NB4 cell resulted in a decrease the levels of antiapoptosis Bcl-2 protein, whereas a concomitant increase proapoptosis Bax protein, and the effect was in a dose-dependent manner. The Bax/Bcl-2 ratio of NB4 cells was significantly increased in a dose-dependent manner treated with ICA. **Conclusions.** The present study suggested that ICA could significantly inhibit the proliferation and promote apoptosis of NB4 cells in a s dose and time-dependent manner. Furthermore, the result also demonstrated that ICA could arrest cell cycle in G1 phase, and significantly down-regulate BCL-2 and up-regulate Bax proteins, by which the apoptosis of NB4 cells was initiated. Key words Icariin; NB4 cells; Acute promyelocytic leukemia; Proliferation;Apoptosis; Bax; Bcl-2.

[8]Ospedale "Arezzo", Ragusa, Italy
[9]Università degli Studi di Catania, Catania, Italy

Background. Acute myeloid leukaemia is a cytogenetically heterogeneous disorder with acquired recurrent chromosomal alterations detected in about 55% of patients. The remaining cases, 40-50% of AMLs, have normal karyotype and are characterized by an heterogeneous group of molecular abnormalities. In normal karyotype AML (NK-AML), molecular alterations with adverse prognostic impact include gene mutations of FLT3, WT1, IDH1, DNMT3A and high expression levels of the BAALC, ERG and MN1 genes, whereas favourable prognosis is associated with the presence of mutations in the CEBPA and NPM1 genes. **Aims.** We planned to perform a regional study to realize a bio-bank of molecular characterized leukemic blasts. All the Haematology Sicilian Centre are involved and the objectives are to valuated the incidence of the molecular aberration in our region and to offer to the clinicians useful information about the biologic risk-category of patients. Preliminary results on 147 consecutive AML patients enrolled in the study, during the year 2011, are reported. **Methods.** Nucleic acids and leukemic cells at diagnosis were collected and stored according to standard protocols. Cytogenetic studies were performed according to standard protocols. Molecular characterization included fusion gene (PML/RARalfa, BCR/ABL, AML1/ETO, CBFB/MYH11, MLL rearrangements); gene mutations (FLT3, NPM1, WT1, IDH1, IDH2 and DNMT3A); gene expression (WT1, BAALC and MN1). AML1/eto and CBFB/MYH11 (CBF leukaemias) were also characterized for KIT gene mutation. **Results.** We enrolled 147 AML cases from across the region: 68 cases from western sicily and 79 cases from eastern sicily . We identified 10 APL carrying PML/RARAalfa fusion gene, the remaining 137 AML cases were so distributed: 26 AML NPM1 mutated (19%), 31 FLT3 mut (23%) (29 with FLT3 ITD and 2 with D835), 2 AML cases showed WT1 mutations, 6 AML cases showed R132C IDH1 mutations, 4 AML cases showed R172 IDH2 mutations, 6 CBF AML cases 1 of them showing D816V KIT mutation, no one AML showed BCR/ABL fusion gene, 1 AML case showed MLL rearrangements, 6 AML cases showed R882H DNMT3A mutations. Cytogenetic studies available on 94 cases allow to identified 59 normal karyotype, 14 adverse, 14 intermediate karyotype, 7 favourable karyotype. Gene expression analysis of WT1 showed a median of 7304 copies/104 *ABL* copies (range from 2 to 26x10E6). 50 NK-AML patients were divided into quartiles by gene expression levels of BAALC and MN1 and into low and high expressers using the median expression level. Patients were scored as high risk when showed high expression of both genes and as low risk when showed low expression values of both genes. . Integrative analysis of a large molecular panel of markers and cytogenetic characteristics allow us to perform a prognostic stratification in high and low risk at disease onset in more than 80% of patients, only 10-20% of patients remained in the less informative "intermediate"category. **Conclusions.** Assessment of a exhaustive molecular and cytogenetic study at the presentation of the acute leukaemia may be very helpful to appropriately tailor the aggressiveness of therapy in the great majority of AML patients.

1207

HYPERDIPLOID KARYOTYPE IN ACUTE MYELOID LEUKEMIA WITH MDS-RELATED CHANGES PATIENTS

M Szostek, M Jakóbczyk, E Zdzilowska, M Zawada, A Skotnicki
Jagiellonian University, Kraków, Poland

Background. Acute myeloid leukemia with myelodysplasia-related changes is an acute leukemia presenting usually complex karyotype, various lineage myelodysplasia and generally poor prognosis. The group of AML with complex karyotypes is heterogenous and may include monosomal as well as hyperdiploid karyotypes. In hematological neoplasms several cytogenetic findings are associated with morphologic abnormalities. Except for usual trisomy 8 and rare gains of chromosomes 9,11 or 21, hyperdiploidy defined as >46 chromosomes has rarely been reported in MDS and AML. **Aims.** the aim of this study was to characterize the ploidy status of karyotype in accordance with bone marrow dysplasia. **Methods.** Over the last two years, 58 patients were referred to our institution for evaluation and treatment of *de novo* AML. These patients did not present with recurrent cytogenetic abnormalities. Conventional cytogenetic analysis was performed on G-banded metaphase cells prepared from bone marrow aspirate cultures using standard techniques. Bone marrow aspirate smears were assessed according to criteria for dysplasia stated in the 2008 WHO classification. **Results.** Twenty three patients under 60 years of age (22. 4%) were diagnosed as an AML with MDS-related changes according established criteria and 13 of this group had a complex karyotype with ploidy changes. According to combined FAB- immunologic classification the patients were diagnosed as: AML M1-5 pts, M2-1 pt, M4-4 pts, M5-2 pts, M6-1 pt. None of molecular markers including EVI1 by Q-PCR, FLT3-ITD by PCR and MLL-PTD by RT-PCR methods were detected. Based on the ploidy status, cases were stratified into two groups: presenting monosomal karyotype (7 pts, 53. 8%) and high hyperdiploid karyotype (6 pts, 46. 1%) with chromosomes number ranged from 49 to 96 Recurrent karyotype abnormalities presented gains of chromosomes 1, 8, 11, 13,15, 21, 20, 21, 22 and only one patient had structural changes: add(19)(q13),+mar. The most frequent dysplastic features of bone marrow in presenting monosomal karyotype patients group were megaloblastic changes and multinuclearity in erythroblasts, hypogranulation, hyposegmentation and gigantism in granulopoesis and presence giant forms of platelets and micromegakaryocytes in the megakaryocytic lineage. In all patients in the group with high hyperdiploid karyotypes marked dyserythropoesis characterized by presence of multinucleated cells especially poli-and ortochromatofil erythroblasts was observed. The overall outcome was extremely poor with early death in almost all patients. **Conclusions.** This finding has suggested that DNA content per se affects cellular functions and seems to be another poor prognostic factor in the AML patient group. This particular hyperdiploid pattern of karyotype remains associated with marked dyserythropoiesis in bone marrow and should be considered as a unique group with extremely poor prognosis.

1208

CD200 EXPRESSION IN MYELOID LEUKEMIC BLASTS

G Palumbo, S Colarossi, N Mangialetto, MG Franzese, G Spinosa, S Capalbo
Hematology Unit, Foggia, Italy

Background. CD200 is a membrane glycoprotein, belonging to the immunoglobulin superfamily, expressed on a subset of T and B lymphocytes, endothelial cells, dendritic cells and neurons. The overexpression of CD200 has been implicated in the pathogenesis of solid tumors and hematological malignancies including lymphoma, myeloma, chronic lymphocytic leukemia and acute myeloid leukemia (AML). Previous studies have shown that expression of CD200 on AML blasts is associated with a poor prognosis. **Aims.** Assess the frequency of expression of CD200 in myeloid leukemic blasts and the correlation with the expression of other antigens. **Methods.** The study included 24 patients, 13 male and 11 female, with a median age of 73 years (range 52-94); of these 20 with diagnosis of AML (5 M0, 1 M1, 5 M2, 2 M3, 5 M4, 2 M5 according to FAB criteria) and 4 with diagnosis of refractory anemia with excess blasts-2 (RAEB-2). Flow cytometry immunophenotype of bone marrow and peripheral blood were analyzed using a panel of monoclonal antibodies included CD200, CD13, CD33, CD34, CD14, CD15, CD2, CD3, CD7, CD19, CD20, CD56, CD117, HLA-DR. **Results.** CD200 was present on blast cells of 13/24 patients (54. 1%). In all 13 patients CD200 was co-expressed with CD34, CD117 and HLA-DR. CD13 and CD33 were co-expressed in 12/13 and 8/13 patients respectively. No patient co-expressed CD200 and CD14, CD15, B and T lymphoid antigens. Only one patient co-expressed CD200 and CD56 and one CD200 and CD7. On contrary of the 11 patients that did not express CD200 only 5 expressed CD34, while CD117 was expressed in 10/11 and HLA-DR in 9/11. CD13 and CD33 were expressed in 10/11 patients while CD14 and CD56 in 2/11 and 3/11 respectively. The expression of CD200 in the FAB subgroups was 5/5 in M0 (100%), 1/1 in M1 (100%), 2/5 in M2 (40%), 0/2 in M3, 4/5 in M4 (80%), 0/2 in M5. As regards the four RAEB-2, two expressed CD200. **Conclusions.** In our cohort of patients, the expression of CD200 was 54. 1%. In particular the expression of CD200 is associated with CD34+ AML blasts in all cases, while is not expressed on more differentiated myeloid cells (0/13 co-expressed with CD15) or on monocytes (0/13 co-expressed with CD14); moreover CD200 was not expressed in the two M3 and in the two M5 and was expressed only in 40% of M2 AML. In our series CD200 can be considered as a marker of myeloid blast cells less differentiated and introduced into the panel of immunophenotypic characterization of AML. Further studies are need to investigate the prognostic significance of CD200 expression in myeloid leukemic cells.

1209

HIGH EXPRESSION OF MIR-181A PREDICTS LONGER SURVIVAL OF PATIENTS WITH ACUTE LEUKEMIA - PRELIMINARY DATA

A Butrym, D Baczynska, J Dzietczenia, J Dybko, T Dobosz, K Kuliczkowski, G Mazur
Wroclaw Medical University, Wroclaw, Poland

Background. MicroRNAs (miRNAs) are small non-coding RNA molecules, that control gene expression by targeting messenger RNA (mRNA), via degradation or suppression of translation. miRNAs play important role in many cellular processes, including cell growth and proliferation, differentiation, metabolism and apoptosis. **Aims.** The aim of the study was to determine expression of miR-181a in acute leukemia patients and its influence on patient clinical outcome. **Methods.** miRNAs from isolated leukemic cells were extracted using mirVana™ miRNA Isolation kit (Ambion Inc., Carlsbad, CA, USA) following the manufacturer's protocol. Reverse transcriptase (RT) reactions were performed

for mature miRNA cDNA synthesis in separate tubes using specific stem-loop RT primers and TaqMan® MicroRNA™ Reverse Transcription kit (Applied Biosystems, Foster City, CA, USA). After microRNA isolation, reverse transcriptase reactions were performed, followed by cDNA amplification. The relative amount of microRNA-181a was normalized according to the reference RNU48 level. Results were considered statistically significant with p-value < 0. 05. **Results.** 30 patients (11 women and 19 men), median age 58 years (range 32-86) were included into the study. There were 26 patients with acute myeloid leukemia (FAB classification: M0 - 1, M1 - 7, M2 - 9, M3 - 1, M4 - 7, M5b - 1) and 4 patients with acute B-lymphoblastic leukemia. 9 patients had intermediate cytogenetic risk and 21 patients had high cytogenetic risk. The patient bone marrow samples were obtained pretreatment. Median expression of miR-181a was 0. 9203337 (range 0. 017784-224. 1603, SD 43. 9080). Higher expression of miR181a was positively correlated with lactate dehydrogenase level LDH (p=0. 038) and negatively correlated with anemia (p=0. 01). There was no correlation between expression of miR-181 and cytogenetic risk group, achieving complete remission and risk for disease relapse. Higher expression of miR-181a was positively correlated with longer survival of acute leukemia patients (p=0. 02). **Conclusions.** We proved that higher expression of miR-181a positively correlated with acute leukemia patients overall survival. As the study includes a small number of patients it needs confirmation on a bigger cohort.

1210

VEGF MRNA LEVELS, PROTEIN CONCENTRATION AND MICROVESSEL DENSITY IN AML PATIENTS, BEFORE AND AFTER TREATMENT IN NORTH-WEST OF IRAN

Z Sanaat[1], M Aliparasti[2], S Almasi[2], A Movasaghpoor[1], R Khalili[1]
[1]Hematology and Oncology Reaserch Center, Tabriz, Iran
[2]Tabriz University of Medical Sciences, Tabriz, Iran

Background. Angiogenesis, the formation of new blood vessels from pre-existing ones, plays a crucial role in the pathophysiology of solid tumors and hematologic malignancies. In AML, the increased micro vessel density (MVD) is the result of the action of several angiogenic growth factors secreted by leukemic blasts. Vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), acidic fibroblast growth factor (aFGF), transforming growth factor (TGF) and the angiopoietins (Ang) are recognized as angiogenic growth factors. Vascular endothelial growth factor plays an essential role in normal and pathologic angiogenesis but its clinical role in AML is unclear. **Aims.** As the prognosis of AML patients may be correlate with the degree of angiogenesis and VEGF, we investigated the expression of VEGF-C and VEGF-A, evaluate MVD in the bone marrow, levels of VEGF-C in the bloodstream of patients with newly diagnosed AML before and after treatment. **Methods.** A Interventional before and after study of 31 patients with newly diagnosed AML was conducted in Hematology-Oncology Research Center in Tabriz -Iran from 2009 to 2010. We investigated the mRNA expression of VEGF-A and VEGF-C from bone marrow of thirty-one patients with newly diagnosed AML before and after treatment. Real- time Quantitative RT-PCR assay was performed in order to detect the mRNA levels of VEGF. Bone marrow biopsy from all AML patients were assay for micro vessel density (MVD), using anti-CD 34 monoclonal antibody. Serum concentrations of VEGF in 31 AML patients were measured by ELISA assay. Allpatients, recovered combination chemotherapy with cytosine arabinoside[Ara-C] and an anthracyclin. **Results.** 20 (62%) patients were male while 11(38%) were female. The mean age was 36+1. 4. The mean amount of MVD was reduced from 10. 8±3. 6 to 7. 6±3. 3 after treatment (P=0. 008). VEGF levels were also reduced from 0. 59±0. 16 to 0. 24±0. 03 after treatment (P=0. 005). Gene expression differences for VEGF-A, mRNA was 4. 6±1. 4 while it was 120. 7±93. 2 for VEGF-C mRNA, which was significant only for VEGF- A mRNA (P=0. 02). **Summary and Conclusions.** According to these results, AML is associated with an increased expression of VEGF-A and VEGF-C mRNA after therapy. It seems that VEGF had a tumor inhibitory role and up-regulation of VEGF-A and VEGF-C inhibits the growth and progression of AML leukemic cells. We can conclude that anti-angiogenesis preparations can be effective in treatment course of AML in combination with chemotherapy regimen.

1211

ASPARAGINE SYNTHETASE AS A BIOMARKER OF ASPARAGINE DEPLETION EFFICACY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

Y Godfrin[1], W Berlier[1], K Aguera[1], F Gay[1], Y Godfrin[1], X Thomas[2]
[1]ERYTECH Pharma, Lyon, France
[2]Service of Hematology, Hospices Civils de Lyon, Lyon, France

Background. Asparagine synthetase (ASNS) is an enzyme converting aspartate to asparagine, which is the target of L-asparaginase. Thus, its low expression in tumor cells is susceptible to represent a marker of sensitivity to L-asparaginase. In clinics, several cases of successful asparaginase treatment in monotherapy have been reported in patients with acute myeloid leukemia (LAM). Capizzi *et al*. also demonstrated that, in adults patients with refractory or relapsing LAM, sequential administration of cytarabine and asparaginase (CLASP) was more efficient than cytarabine alone (40% vs. 24% of complete remission in refractory patients, p=0. 02). Moreover, several recent *in vitro* studies suggest that the efficacy of asparaginase to treat LAM is inversely correlated with ASNS expression in leukemic cells. Asparaginase encapsulated into red cells (GR-aspa) shows a tolerance profile that allows considering a secure treatment of LAM by asparaginase, particularly in elderly patients. **Aims.**To evaluate the *in vitro* sensitivity to asparagine depletion of myeloid tumor cells from AML patients and to determine if the expression of ASNS is correlated to this sensitivity. **Methods.** Total RNA will be immediately extracted (PAXgene® kit) from bone marrow cells of AML patients and ASNS mRNA expression will be evaluated by qRT-PCR. Blasts will be isolated by Ficoll separation and ASNS protein expression will be assessed by western-blot. Sensitivity to asparaginase of the isolated blasts will be evaluated *in vitro* by incubating the cells for 4 days with concentrations of asparaginase ranging from 0. 01 to 10 IU/mL and by measuring the cytotoxicity (IC50) with a cell counting CCK-8 kit. **Results.** ASNS protein and mRNA expressions of the leukemic cells will be compared to the IC50 for each patient to determine if a correlation is observed between those parameters. Our preliminary results obtained *in vitro* with lymphoid and myeloid cell lines (MOLT-4, HL-60) clearly show a correlation between a low expression of ASNS and a good sensitivity to asparaginase. In addition, these results will be compared to FAB/WHO classifications of LAM to evaluate the possible impact on asparaginase sensitivity. **Conclusions.** Selection of AML patients based on their level of ASNS expression may be necessary in further clinical trials evaluating the efficacy of asparaginase encapsulated into red blood cells.

1212

IDH1 MUTATIONS ASSOCIATES WITH UNFAVOURABLE PROGNOSIS IN YOUNGER ADULTS WITH NPM1 MUTATED ACUTE MYELOID LEUKAEMIA.

C Martinez-Laperche, M Kwon, P Balsalobre, M Gonzalez-Rivera, G Rodriguez-Macias, J Gayoso, J Diez-Martin, B Buño
Hospital Universitario Gregorio Marañón, Madrid, Spain

Background. During the last decade it has become clear that gene mutations add important prognosis information to the cytogenetic subtypes in acute myeloid leukemia (AML), mostly in patients with normal karyotype (NK). More recently, a novel mutation affecting the arginine residue at position 132 of the *IDH1* gene (NADPH dependent isocitrate dehydrogenase 1), an enzyme from the citric acid cycle, has been described in AML patients. Different studies suggested an association with NK and a probable unfavourable impact in AML in terms of progression free survival (PFS) and overall survival (OS). **Aims.** To analyze the influence of IDH1 mutations in NK-AML, particularly in patients without FLT3-ITD, classified as intermediate risk (IR) o low risk (LR) who could benefit with more intensive treatment. **Patients and Methods.** The study comprised 23 NK-AML patients diagnosed in our hospital during the last 5 years (2007-2011). Clinical characteristics, treatment administrated, FLT3/NPM1 mutations and outcomes are shown in Table 1.

Table 1.

N, negative; P, positive; L, low; I, intermediate; H, high; Ttreatment. induction IA(3x7) all cases except ICE in #16; Consolidation IA(3x7) all cases except IA(2x5) en #19. *Only SCT performed before relapse are considered. LFU: Last follow up (days from diagnosis)

Genomic DNA was purified, after written informed consent, from bone marrow (BM) samples at diagnosis. IDH1 mutations were determined by direct DNA sequencing as previously reported (Balss et al, Acta Neuropathol 116, 2008).

Results. The frequency of IDH1 mutation in the present series was in accordance with previous reports, being 21,8% (5/23) including 30% (3/10) FLT3neg/NPM1pos, 16,7% (1/6) FLT3neg/NPM1neg and 14,3% (1/7) FLT3pos patients (Table 1). Within the 10 LR patients according to FLT3/NPM1 mutations (neg/pos), 2/3 (67%) IDH1pos patients relapsed while only 2/7 (28,5%) IDH1neg did. Interestingly, one of these two relapsing IDHneg patients showed WT1 gene mutations, which has also been associated with poor prognosis. Moreover, from the 6 patients with IR according FLT3/NPM1 mutations (neg/neg), only one showed IDH1 mutations and progressed during treatment before stem cell transplantation (SCT; Table 1). **Conclusions.** IDH mutations are frequent in NK-AML patients, particularly in those with NPM1 mutation. IDH1 mutations are associated with an increased incidence of relapse in the subset of NK-AML with mutated *NPM1* without *FLT3*-ITD (patients LR). According to the IDH mutation status, such patients should not be assigned to the LR group and would probably benefit from more intensive therapies in the first complete remission, including stem cell transplantation

1213

PROGNOSTIC RELEVANCE OF WILMS' TUMOR 1 (WT1) GENE MUTATION IN-PATIENT WITH ACUTE MYELOID LEUKEMIA

S Aref
Mansoura University, M3011ansoura, Egypt

This study aimed to assess the prognostic impact of Wilms' tumor 1 (WT1) gene mutations in cytogenetically normal acute myeloid leukemia (CN-AML) among Egyptian patients. Exons 7 of WT1 was screened for mutations in samples from 82 CN-AML patients out of 203 newly diagnosed AML patients, age range from 21-74 years, using a high-resolution capillary electrophoresis. Seven patients out of 82 (8. 3%) harbored WT1 mutations. There was no statistically significant difference between the WT1 mutant and wild type as regard age, sex, French-American-British subtypes and the prevalence of success of induction remission therapy (P = 0. 966; 28. 6% vs 29. 3%). Patients with WT1 mutations had overall survival (OS) lower than the wild type one (*HR*= 1. 38; 95% CI, 4. 79 to 6. 86; *P* = 0. 004). *In conclusion,* CN-AML patients with WT1 gene mutation have poor clinical outcome. We recommend testing the WT1 mutations as part of molecularly based risk assessment and risk-adapted treatment stratification of patients with CN-AML.

1214

EXPRESSION OF LEUKEMIA-ASSOCIATED ANTIGEN GENES IN AML PATIENTS AT DIAGNOSIS AND DURING A COURSE OF THE DISEASE

R Petrboková, J Polák, H Hájková, C Šálek, C Haškovec
ÚHKT, Prague 2, Czech Republic

New molecular markers of residual disease are needed for monitoring of residual disease (MRD) in AML patients. MSLN, ST18, CSPG4 and XAGE1 genes, which belong to leukemia-associated antigen genes (LAA), are possible candidates for this purpose. These genes have high expression in cells of leukemia patients and the background expression found in cells of healthy persons is very low. The level of expression of these genes was estimated by quantitative RT-PCR in leukocytes of AML patients. An overexpression of XAGE1 and CSPG4 genes was found in 29/154 (23 %) patients, CSPG4 in 29/154 (19 %) patients and ST18 in 69/154 (45 %) patients at diagnosis. 8 patients, who neither had mutated NPM1 gene, nor they had overexpressed Wt-1 gene, were monitored by expression of the LAA genes. The results showed a good correlation between the expression of the LAA genes and a clinical course of the disease. Monitoring of MRD by the LAA genes seems to be a suitable marker particularly for AML patients, who do not have any other suitable molecular marker.

1215

PROGNOSTIC ROLE OF IMMUNOPHENOTYPING IN ACUTE MYELOID LEUKEMIA.

M Mitra, M Fadda, V Abbadessa, M Norata, R Bono, G Iovino, G Franco
University Palermo, Palermo, Italy

Immunophenotyping is a major tool to assign leukaemia blast cells to myeloid lineage while the prognostic value of immunophenotyping in Acute Myeloid Leukaemia (AML) is still unclear. The Cytogenetic alterations are the most important prognostic factors in AML and in Myelodisplastic Syndromes (MDS). However it's impossible to have information concerning chromosomal abnormalities from all patients. Therefore we analyzed the pattern of expression of selected antigens: CD13, CD15, CD34, CD33, CD117, DR, CD14, CD64, CD19, in bone marrow blasts of de novo AML by flow cytometry. The aim of the study was to verify the relationship between antigens expression, FAB subtype, karyotype, biomolecular study, and disease outcome (remission rate). We analyzed 72 patients, 51 males and 25 females, median age 58,5 years old (range 15-83) with de novo AML (4 FAB M0, 25 FAB M1, 28 FAB M2, 11 FAB M4 (1FAB M4eo), 7 FAB M5, 1 FAB M6) treated in our department from January 2003 to December 2011 with standard induction chemotherapy for AML. Biomolecular study showed FLT3 mutation in 8 patients and NMP1 mutation in 15 patients. Karyotype was favourable in 2 patients, intermediate in 32 patients and unfavourable in 12 patients. The analysis showed that patients with AML blasts negative for CD13, CD34 and positive for CD33, and CD64 had a higher complete remission rate, independently from FAB subtype risk. This antigen expression was confirmed generally in patients with normal karyotype, age <60 years and normal value of serum LDH . The AML CD13+, CD33+, CD34+, CD117+ blasts were related with poor outcome of disease (partial remission or resistance). HLA DRpositivity appears non specific. Expression of lymphoyd antigen (CD19) was seen in 19 patients. The high expression of CD19 antigen was associated with AML FAB M1 (9 patients) and biomolecular study positive for MLL (1 patient) and complex kariotype. Higher expression of CD13, CD33, CD64, CD14, CD15 was observed in M5b FAB subtype where was obtained complete remission. The low expression of CD34 was associated with NPM mutation and good prognosis. These preliminary data show the prognostic value of immunophenotyping in AML patients and may be useful for risk stratification in this patients. Nevertheless is necessary to analyse a large number of cases for statistical considerations. The AML immunophenotyping should be included as individual prognostic factor.

1216

NEUTROPENIC ENTEROCOLITIS IN ACUTE MYELOID LEUKEMIA

N Colovic[1], D Tomin[1], A Vidovic[1], N Suvajdžic[1], I Djunic[2], V Djurasinovic[2], M Virijevic[2], M Colovic[1]
[1]Medical Faculty, University Belgrade, Belgrade, Serbia
[2]Clinic of Hematology, Clinical Center Serbia, Belgrade, Serbia

Introduction. In this report we focus on the importance of an accurate diagnosis of gastrointestinal complications during chemotherapy for acute myeloid leukemia. The leukemic infiltrtion of the digestive system may cause mucosal ulcers which can lead to bleeding or perforation. The immune system deficiency in this cohort of patients may result in necrotic enterocolitis (leukemic typhlitis), perianal inflammation, abscesses, and peritonitis. **Patients and Results.** Retrospective review of medical documentation of 37 patients with acute leukemia and neutropenic enterocolitis recorded on Clinic of hematology during the four year period (2005-2009). AML M2 was diagnosed in 16 patients, 2 patients had hypoplastic type of AML, 15 patient AML M4, and 4 patient AML M5. All 37 patients with neutropenic enterocolitis received chemotherapy according to protocol MRC AML12 and one received protocol LALA85. 11 patients had unfavorable karyotype. Seven patients had a complex chromosomal abnormalities (more than 3 chromosomal aberrations in more than 2 mitoses), and in four cases monosomal karyotype was registered. At the time of gastrointestinal difficulties all patients were in neutropenic phase (WBC<0. 5x109/l >0. 1x109/l) after receiving induction chemotherapy. For the final diagnosis relevant finding was ileal, cecal or ascedent colon wall tickening larger than 5 mm, verified by utrasonography in all patients. Abnormal findings also included dilated bowel loops (19 patients), air fluid levels (9 patients), dumb - printing (7 patients) and pneumatosis intestinalis (5 patients). All patients were managed with conservative treatment with broad spectrum antibiotic coverage combined with bowel rest, nasogastric suction and total parenteral nutrition. The antibiotic regimens consisted of vancomycin in combination with carbapenem and metronidasole and in combination of cefepime with metronidazole. Twentyfive patients has recovered with just medical treatment after mean time period of 17. 5 days and returned to normal diet. But only 14 of these patients has achieved a complete remission of the acute leukemia. Only two patients were managed surgically. Nine patients died because of neutropenic enterocolitis. Lethal end was the consequence of paralytic ileus (4 patients), mechanical ileus (3 patients) and peritonitis with perforation (2 patient). **Conclusions.** We emphesize the importance of collaboration between the hematologist and the surgeon in monitoring gastrointestinal complications during and after chemotherapy for acute leukemias and diagnostic value of abdominal ultrasonography evaluation.

1217

IMMUNOPHENOTYPIC PROFILE AND MOLECULAR ANALYSIS OF ACUTE MYELOID LEUKEMIA WITH T(15;17) AND T(8;21)

S Varma, N Varma, P Bhatia, S Naseem, M Sachdeva, J Binota, P Malhotra, RK Marwaha
PGIMER, Chandigarh, India

Background. French-American-British (FAB) classified acute myeloid leukemia (AML) according to morphology and cytochemistry. FAB-M2 and M3 categories now correspond to World Health Organization (WHO) subcategory of AML with t(8;21) and t(15;17) respectively. WHO in its latest 2008 classification, includes a separate category of AML with balanced translocation/ inversion, which comprises of 7 categories characterized by characteristic genetic abnormalities [i) t(8;21); ii) t(15;17); iii) inv16; iv) t(9;11); v) t(6;9); vi) inv3; vii) t(1;22)] and 2 provisional entities [mutated NPM1 and mutated CEBPA]. It has increasingly been found that, many of these genetically distinct subgroups in AML possess distinctive immunophenotypic profiles, which can be correlated with underlying specific cytogenetic/molecular defects. **Aims.** to evaluate the usefulness of flowcytometric immunophenotyping (FCM-IP) profile in identifying the AML cases with t(8;21) and AML cases with t(15;17). **Methods.** Results of immunophenotypic profile and molecular analysis of AML cases with t(15;17) and t(8;21) were analyzed. In all cases, bone marrow morphologic examination along with cytochemical staining, immunophenotyping and molecular genetic testing was performed. FCM-IP was done using CD1a, CD2, CD3, CD4, CD5, CD7, CD8, cyCD3, TdT, CD34, HLA-DR, CD117, CD56, CD10, CD19, CD22, cyCD22, CD79a, CD13, CD33, MPO, CD11c, CD14 and CD64 on FACS Canto II (BD Biosciences, USA). Molecular testing was done by multiplex RT-PCR (Roche Thermal Cycler, USA). **Results.** From August 2010- December 2011, molecular analysis for t(15;17) and t(8;21) was done in 80 AML cases. Of these, 13 cases were positive for t(15;17) and 17 for t(8;21). Immunophenotyping results were available in 8 cases with t(15;17) and 15 cases with t(8;21). Cases in which immunophenotyping was done were included in this study and analyzed. *AML with t(15;17)*- All cases were strongly positive for MPO cytochemically. Immunophenotyping revealed CD33 and MPO-bright positive; CD34 and HLA-DR- negative; B-lymphoid and T-lymphoid markers- negative in all cases. CD13 and CD117 were also positive in all cases tested, however the intensity varied form dim to moderate. *AML with t(8;21)*- All cases showed moderate to strong positivity for MPO cytochemically. On immunophenotyping, positivity for CD13, CD117, CD33 and MPO were seen in all cases, however, the intensity varied from dim to bright. CD34 and HLA-DR were bright positive in all cases, except 1 where it was dim to moderate. Of the lymphoid markers, CD19 was positive in 6 cases (5- bright positive, 1- dim), CD7 and CD4 in 5 cases each (2- bright positive, 3- dim each) and CD56 bright positive in 2 cases. **Summary and Conclusions.** We found the FCM-IP profile of the two molecularly defined subgroups with t(15;17) and t(8;21), to be clearly distinctive. All cases with t(15;17) were negative for CD34 and HLA-DR, however, these were positive in all cases with t(8;21). Aberrant positivity for lymphoid markers (CD19, CD7, CD4 and CD56) was frequently seen in AML with t(8;21), however, it was not seen in any case with t(15;17). Therefore, cases with a morphologic diagnostic dilemma between FAB-M2 and M3, immunophenotyping can aid in differentiating between the two and also guide towards the underlying genetic defect.

1218

STUDY ON THE EXPRESSION OF TGF-?1 IN HYPERLEUKOCYTIC ACUTE MYELOID LEUKEMIA

L Wang
Fu Xing Hospital, Capital Medical University, Beijing, China

Background. Hyperleukocytic acute myeloid leukemia (AML) which has an extremely high white blood cell count in peripheral blood, is associated with a high early mortality. The mechanisms for Hyperleukocytic AML have not yet been fully elucidated. TGF-β1 is one of the most potent negative regulator of proliferation, its role in the occurrence of Hyperleukocytic AML is still unknown. **Aims.** To investigate the role of TGF-β1 in pathogenesis of Hyperleukocytic AML by detecting the mRNA transcription and protein expression of transforming growth factor-β1 (TGF-β1) in bone marrow cells and serum levels of TGF-β1 in hyperleukocytic and non-hyperleukocytic AML patients. **Methods.** Bone marrow aspirate samples from 17 hyperleukocytic AML, 21 non-hyperleukocytic AML patients, and 17 normal controls were collected. Informed consents were received from all the patients. The mRNA transcriptional levels of TGF-β1 were detected by real-time fluorescence quantitative polymerase chain reaction (RQ-PCR). The protein expression levels of intracellular TGF-β1 were analyzed by flow cytometry. TGF-β1 serum levels were measured by double-antibody sandwich enzyme-linked immunosorbent assay (DAS-ELISA). **Results.** (1) The transcriptional levels of TGF-β1: The median levels of TGF-β1 mRNA in hyperleukocytic AML, non-hyperleukocytic AML, and normal control group were 0. 0135, 0. 0259, and 0. 0155, respectively, no statistical difference was observed among these three groups (P>0. 05). (2) The protein expression of intracellular TGF-β1: The mean fluorescence intensity of TGF-β1 in hyperleukocytic AML, non-hyperleukocytic AML, and normal control group were 178±79, 160±54, and 98±18, respectively. TGF-β1 expression in both hyperleukocytic AML and non-hyperleukocytic AML group were significantly higher than that in normal control group (P<0. 05). However, there was no significant difference between the hyperleukocytic and non-hyperleukocytic AML group (P>0. 05). The mean fluorescence intensity of TGF-β1 in AML patients was 168±66, which was significantly higher than that of in normal controls (P<0. 05). (3) Serum levels of TGF-β1: The serum levels of TGF-β1 in hyperleukocytic, non-hyperleukocytic AML, and normal control group were 10. 70±6. 43, 8. 20±6. 34, and 27. 97±14. 55ng/ml, respectively. Serum levels of TGF-β1 in both hyperleukocytic and non-hyperleukocytic AML group were significantly lower than that in normal control group (P<0. 05). There was no difference between hyperleukocytic and non-hyperleukocytic AML patients (P>0. 05). **Conclusions.** (1) This study show that there exists a down-regulation of serum TGF-β1 level in hyperleukocytic and non-hyperleukocytic AML patients, suggesting that TGF-β1 secreted by leukemia cells in AML patients is reduced, so the negative regulation function of TGF-β1 on leukemia cells is diminished. (2) The transcriptional levels of TGF-β1 in hyperleukocytic and non-hyperleukocytic AML patients had no differences with normal controls. However, the expression levels of intracellular TGF-β1 in these patients were increased, with the levels of extracellular TGF-β1 reduced. The results indicate that there may exist abnormality in the process of TGF-β1 secreting outside of cells. (3) The intracellular and serum levels of TGF-β1 between hyperleukocytic and non-hyperleukocytic AML patients have no significant differences. The results show that TGF-β1 hasn't an important impact on pathogenesis of hyperleukocytic AML.

1219

DO AML PATIENTS WITH DNMT3A EXON 23 MUTATIONS BENEFIT FROM IDARUBICIN AS COMPARED TO DAUNORUBICIN? A SINGLE CENTER EXPERIENCE

S Bertoli[1], F Vergez[2], O Larochelle[2], JE Sarry[3], V De Mas[2], S Dobbelstein[2], A Kruczynski[4], C Demur[2], A Huynh[5], F Huguet[5], E Delabesse[2], C Récher[5]
[1]Toulouse University Hospital, Toulouse, France

[3]Inserm UMR 1037 CRCT, Toulouse, France
[4]Pierre Fabre Laboratory, Centre de Recherche et Développement, Toulouse, France
[5]Department of Hematology, Toulouse University Hospital, Toulouse, France

Background. Mutations in *DNMT3A* gene, encoding DNA methyltransferase 3A, were recently described in patients with acute myeloid leukemia (Ley TJ *et al*. NEJM 2010). In 60% of cases, mutations occur in the R882 aminoacid of the methyltransferase domain (exon 23). Most studies have suggested that these mutations confer a poor prognosis in the intermediate-risk AML subset, where this molecular abnormality, could help clinician stratify therapeutic strategy. **Aims.** Because we did not find any prognostic impact in our series (LaRochelle *et al*. EHA 2011), we analyzed the impact of treatments in patients with *DNMT3A* mutations. **Methods.** We determined the mutational status of *DNMT3A* exon 23 in 288 patients aged 18 to 65 years, with newly diagnosed AML in Toulouse University Hospital between 2000 and 2009, excluding promyelocytic leukemia. We focused on intermediate-risk AML and analyzed their outcome depending on the chemotherapy they received (*ie*. type of anthracycline at induction: daunorubicin 180 mg/m² or idarubicin 40 mg/m² total dose, associated to continuous cytarabine 200 mg/m²/d day 1-7). **Results.** A *DNMT3A* exon 23 mutation was detected in 39 patients (13. 5%): 23 R882H, 13 R882C, two R882P and one W893S. Mutations significantly correlated with a higher white blood cell count (median 52 *vs*. 14. 6 G/L, p<0. 001) and a monocytic differentiation (FAB M4/M5, p<0. 0001). All *DNMT3A* exon 23 + patients had intermediate-risk cytogenetics (39/194, 20%). They were associated with *NPM1* (p<0. 001) and *FLT3-ITD* mutations (p=0. 027). No difference in outcome between *DNMT3A* exon 23 + and *DNMT3A* exon 23 - patients was found (CR rate, 87% *vs*. 81%, p=0. 48; median DFS, not reached *vs*. 17. 6 months, p=0. 16 and median OS, not reached *vs*. 24. 7 months, p=0. 17), even after stratifying by *NPM1* or *FLT3-ITD* status. However, *DNMT3A* exon 23 + patients had better median DFS (not reached *vs*. 11. 6 months, p=0. 009) and OS (not reached vs. 14. 3 months, p=0. 005), as compared to DNMT3A exon 23 - patients when treated with idarubicin, whereas patients treated with daunorubicin had similar outcome regardless the *DNMT3A* exon 23 status. In multivariate analysis including age, white blood cell count, *FLT3*-ITD/*NPM1* genotype, anthracycline type and allograft, idarubicin treatment was the only prognostic factor significantly associated with longer OS (HR = 0. 27; 95% CI [0. 08-0. 97]; p=0. 046) in *DNMT3A* exon 23 + patients. **Conclusions.** *DNMT3A* exon 23 mutations have no impact on global outcome in this series, but could be a predictive factor

for response to idarubicin. Other studies testing different modalities of anthracycline administration, especially in the setting of randomized controlled trials (idarubicin *vs*. daunorubicin, high-dose daunorubicin *vs*. standard-dose daunorubicin) are warranted to confirm these preliminary results. If so, anthracycline scheme could modify *DNMT3A* exon 23 + patients outcome and could justify therapeutic stratification early at induction.

1220

ACUTE MYELOID LEUKEMIA IN PATIENTS AGED 70 OR OLDER. EXPERIENCE AT A SINGLE CENTRE

J Rodríguez, E Gil, MV Moreno, A Palma, G García-Donas, K Gómez, A García-Sola, S Ramírez, S Zamora, I Vázquez-Pastor, J Diéguez, A Amian, A Fernández-Jurado
Hospital "Juan Ramón Jiménez", Huelva, Spain

Background. The management of old patients with acute myeloid leukemia remains controversial, specially in those cases affecting very old patients (aged >=70) in which the dilemma therapeutic abstention versus treatment (with low or high intensity schemes) is a major subject. **Aims.** We present the experience in our centre with this group of patients in the period 1990-2011. **Methods.** During the period of study 95 cases were diagnosed (relapses, FAB M3 cases and patients initially treated with 5-AZA were excluded). Patients were divided into 3 groups according to the treatment: no treatment (supportive treatment), low intensity treatment (low doses Ara-C: 10 mg/m^2/12h s. c. days 1-21) and high intensity treatment (adapted ICE: Idarubicin 10 mg/m^2 days 1 and 3; Ara-C 100 mg/m^2/12h days 1-3; Etoposide 100 mg/m^2 days 1-3). **Results.** The mean age of patients was 76,6 years (70-97); sex distribution was 47 males and 48 females; mean Karnofsky index was 70 (median 80; 30-100); 57 patients received treatment and 38 only did not; overall survival was 6,9 months (median 2; 0,03-90+), significant differences were observed in the mean overall survival between the treated and no-treated groups (9,9 vs 2,3 months respectively; p=0,017). In the low intensity group (31 patients) an overall response of 32,2% (6 CR, 4 PR, 14 NR and 7 not evaluable) was observed while in the high intensity one (26 patients) overall response was 53,7% (12 CR, 2 PR, 6 NR and 6 not evaluable); no statistical differences were observed between both groups considering all subgroups of response (p=0,13), or when these subgroups were grouped into PR+CR versus NR+Not Evaluable (p=0,11). Considering overall survival, no statistical differences were observed between the low and high intensity groups 7,1 (0,25-90+) vs 13,4 (0,25-90+) months (p=0,21) respectively. **Conclusions.** 1. - Overall survival in the treated group is higher than in the non-treated one, differences reached statistical significance. 2. - Comparing both arms of treatment no statistical differences were observed in the quality of response, though a higher proportion of complete responses were observed in the high intensity group (46% vs 19,3%, respectively), however, up to now, this circumstance has not contributed to a longer survival. 3. - No statistical differences have been observed in the overall survival between both groups of treatment.

1221

EVALUATION OF IMMUNE STATUS AT DIAGNOSIS AND IMMUNE MONITORING AFTER CHEMOTHERAPY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

M Bae, CJ Park, S Jang, HS Chi, EJ Seo, DY Kim, JH Lee, JH Lee, KH Lee
Asan Medical Center, Seoul, South-Korea

Background. Lymphocyte subpopulation is known to be associated with prognosis in patient with certain malignancies. The role of immune cells in hematologic malignancies, however, are not well studied. This study prospectively investigated whether differences in proportion of lymphocyte subset affect the survival or treatment outcomes in patients with acute myeloid leukemia (AML). **Methods.** Fourty-one patients with AML (M0, 1 patient; M1, 9; M2, 15; M3, 6; M4, 8; M6, 1; M7, 1; by FAB classification) were enrolled. The diagnosis of AML is made based on bone marrow study, immunophenotyping and cytogenetic analysis. We also underwent molecular study by Hemavision and PCR for FLT3, NPM1 and kit mutation. We measured lymphocyte subsets (T cells, helper/inducer T cells, suppressor/cytotoxic T cells, naïve T cells, memory T cells, regulatory T cells, NK cells and B cells) by multi-color flow cytometry with the peripheral blood from the patients at diagnosis and during complete remission (CR). **Results.** Patients are divided into 2 groups: Complete remission group (CR group, 30 patients) and non-responder group (NR group, 9 patients) after induction chemotherapy. We compared the lymphocyte subsets determined at diagnosis between 2 groups. The proportion of suppressor/cytotoxic T cells in CR group was higher than that of in NR group (p=0. 007). Patients were also classified into 3 groups as good, intermediate and poor prognosis groups by risk status based on cytogenetic and molecular abnormalities. In poor prognosis group, proportion of effecter memory T cells showed low level (p=0. 047) at diagnosis than that in other prognosis groups, but did not during complete remission. When poor prognosis group was divided into 2 categories as CR and NR, the CR group showed tendency of higher proportion in suppressor/cytotoxic T cells than NR group (p=0. 093). **Conclusions.** The high proportion of suppressor/cytotoxic T cells at diagnosis might contribute CR after induction chemotherapy, and it would be a strong marker for prognosis determination. The low proportion of effecter memory T cells at diagnosis is also associated with the poor cytogenetic or molecular risks in AML patients, and it could be one of the mechanism in leukemogenesis.

1222

CLOFARABINE IN COMBINATION WITH CYTARABINE (ARA-C) FOR TREATMENT OF RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA IN ADULT PATIENTS

A Malato, A Santoro, S Magrin, R Felice, D Turri, R Di Bella, D Salemi, F Acquaviva, R Scimè, F Fabbiano
Ospedali Riuniti Villa Sofia-Cervello, U. O. di Ematologia e UTMO, Palermo, Italy

Introduction. Relapsed/refractory AML patients have a poor prognosis, with CR rates of 1%-30%, unless allogeneic hematopoietic stem cell transplantation (HSCT) is an available option. Although retrospective modeling studies have demonstrated the prognostic value of selected parameters, responses with salvage therapies remain still poor. It was previously established the activity of clofarabine plus cytarabine in AML relapse (clofarabine dosed once daily for 5 days with 40 mg/m2 followed 4 hours later by ara-C at 1 g/m2 per day). However, modifications of this combination in AML therapy of relapsed/refractory patients warrant further evaluation. **Aims.** To determine the efficacy and safety of clofarabine and cytarabine (Ara-C) in adult patients with relapsed or refractory acute myeloid leukemia (AML). **Methods.** Patients aged 35-66 years with refractory/relapsed AML were treated at the dose of clofarabine 30 mg/mq on days 1-5 + cytarabine 1000 mg/mq gg on days 1-5. We evaluated the complete remission rate (CRR), duration of remission (DOR) and overall survival (OS). Minimal residual disease (MRD) by molecular targeting was considered in all patients. **Results.** Seventeen patients received clofarabine 30 mg/mq on days 1-5 + cytarabine 1000 mg/mq gg on days 1-5 (their characteristics are summarized in Table 1), followed by gentuzumab therapy in only three patients. All patients had relapsed/refractory myeloid leukemia and had received multiple priors tharapies.

Table 1.

N	Age	Refractory/relapsed	Karyotype and molecular genetyc	Previous regimen (n.)	Response after Clofarabine/ARA-C	Toxicities	HSCT
1	55	refractory	47 XY,+8;	1	Refractory	Severe febrile neutropenia	n
2	41	refractory	48 XY, -21,+ 3 der(21)	1	Complete Remission	Severe febrile neutropenia	n
3	46	relapsed	46,XX/FLT3 ITD mutated	2	Refractory	Severe febrile neutropenia	n
4	55	relapsed	46, XY	2	Complete Remission	Severe febrile neutropenia	y
5	62	refractory	Complex karyotype, monosomy 7	1	Refractory	skin rash	n
6	66	refractory	47,XX,+8	1	Refractory	Severe febrile neutropenia	n
7	49	refractory	46 XX	2	Complete Remission	Severe febrile neutropenia	y
8	53	relapsed	46,XY	1	Died in induction	Skin rash	n
9	62	relapsed	46, XY	3	Complete Remission	Nausea, vomiting	n
10	48	relapsed	46,XY+8	3 + HSCT	Complete Remission	Nausea, vomiting	n
11	40	refractory	48,XY,+8	2	Died in induction	Nausea, vomiting	n
12	50	relapsed	46, XY	2	Refractory	Mucositis	n
13	42	refractory	46, XX/FLT3/ITD mutated	1	Complete Remission	Mucositis	n
14	61	relapsed	46, XY	1	Refractory	Severe febrile neutropenia	n
15	35	relapsed	46, XX	1	Complete Remission	Severe febrile neutropenia	y
16	40	relapsed	46, XY	1	Complete Remission	Severe febrile neutropenia	y
17	54	relapsed	46, XX/FLT3/ITD mutated	2 + HSCT	Complete Remission	hepatic transaminase elevations	n

Two pts had received a prior hematopoietic stem cell transplant (HSCT). Eight patients achieved a morphologic complete remission (CR);fourpatients went on

to receive allogeneic transplants after clofarabine/ARA-C salvage. The complete remission rate (CRR) was 52,94 %. The Median of Overall survival for all patients was 59 days (range 23-769), while the media of Overall survival (OS) was 158,41 days,and we estimated a duration of remission (DOR) as101,50 days in median (range 3-785), and 260 days in media (we calculated from the first day of remission). Treatment was complicated by neutropenic fever (n=9), grade III-IV mucositis (n=2), skin rush (n=2) grade II- III, hepatic transaminase elevations(n=1). Two patient died of sepsis during the induction. **Conclusions.** Combination treatment with clofarabine 30 mg/mq and ARA-C 1000 mg/mq in adults pts with refractory or relapsed AML resulted in an ORR of 52,94 %, and of the 8 patients who achieved a CR, four (50%) proceeded to HSCT (two are still alive and in complete remission). The safety profile is acceptable in this relapsed/refractory population, and our results are very similar to previous regimes using higher clofarabine dosages. More studies with this combination in adults are warranted.

1223

OVEREXPRESSION OF MN1 IS ASSOCIATED TO A LOWER RATE OF COMPLETE REMISSION AND AN INCREASE OF RELATIVE RISK OF RESISTANCE TO INDUCTION CHEMOTHERAPY IN AML OF INTERMEDIATE RISK

C Rodriguez Medina[1], MT Gomez-Casares[2], CE Lopez Jorge[2], J Lopez Brito[2], G Santana[2], M Gordillo Martinez[2], Y Ramos de Leon[2], B Sevillano Zamarreño[2], D Fiallo Suarez[2], H Luzardo Henriquez[2], A Suarez Cabrera[2], S Jimenez Bravo de Laguna[2], C Campo Adsuar[2], G Santana Lopez[3], T Molero Labarta[2]

[1]HUGC Dr Negrin, Las Palmas, Spain

[2]Hematología-HUGC Dr Negrin, Las Palmas, Spain

[3]Medicina Preventiva y Epidemiologia. HU GC Dr Negrín, Las Palmas, Spain

Background. The presence of certain genetic disorders in Acute Myeloblastic Leukemias (AML) provides relevant prognosis information and allows to take therapeutic decisions. However, currently, up to a 40-50% of AML, according to the reported series, show a normal cytogenetic (AML-NK). In this subgroup of patients, submicroscope techniques have been shown to be useful in order to identify alterations (mutations or genes overexpression), which may help to clarify the prognosis and take decisions with these patients. NPM1, FLT3 or CEBPA are examples of these kind of disorders. In the last years, two studies about retrospective analysis of MN1 gene oveexpression in AML-NK group have been reported. They have shown that this gene overexpression has a negative impact on Overall Survival (OS), Progression Free Survival (PFS) and less rate of Complete Remisions (CR). **Aims.** To study the impact of MN1 gene overexpression in a group of 48 intermediate-risk AML patients in Complete Remission, who have been treated with al least one cycle of intensive chemotherapy, according to 3+7 scheme (idarubicin three days and cytarabine seven days).

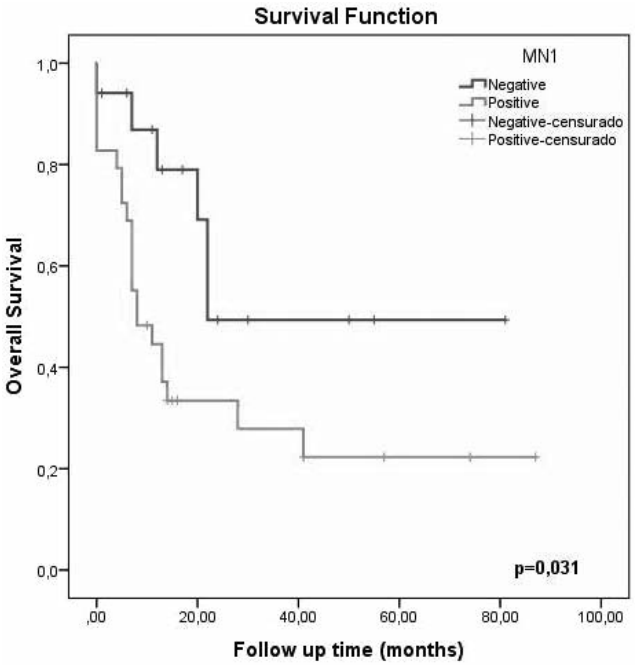

Figure 1.

Methods. We retrospectively study MN1 gene expression in bone marrow frozen samples of 48 AML patients, diagnosed between 2004-2011, with intermediate risk cytogenetic disorders according to MRC 1998 criteria. Median age was 54 years old and the range of age was from 15 to 75. Overexpression analysis was performed by Q-PCR. The cut-off was previously determined from the study of MN1 expression media in healthy bone marrow donors, determining overexpression from up to +2,5 SD. Normalization was performed using ABL as control gene. Relevant clinical data were reviewed in the clinical histories. Complete remission was studied after recovery from first chemotherapy cycle according to Cheson criteria. Statistical analysis was performed with the software SPSS 15. 0. **Results.** It was observed a rate of 48% of resistance to induction treatment in MN1 positive group against a 5. 9% in the MN1 negative group (P=0. 004 according to $\chi 2$ Test), with a Relative Risk (RR) of persistence of 8. 2 (95% CI 1. 2-57. 1). The survival study for the intermediate risk patients by Kaplan-Meier was of 27 months for the MN1 positive group and 42 months for the MN1 negative group (p=0. 031). However, we have to point out that there exist differences in the assignment of the consolidation therapy (32% Alo-BMT in the MN1 positive group against 21% in the MN1 negative group). **Conclusions.** 1. - In our serie, MN1 overexpression is associated with a higher rate of induction treatment resistance, with an increase resistance Relative Risk of 8. 2 (CI 1. 2-57. 1*).* Nonetheless, we believe that an increase in the sample size is necessary to define better the CI of the RR. 2. - We also observed a significative difference in overall survival (42 months vs 27 months p=0. 031), according to what has been published in the literature so far. Nevetheless, there exist differences in the consolidation treatment, and due to the small sample size, the age has not been taken into account as a risk factor.

1224

THERAPY-RELATED ACUTE MYELOID LEUKEMIA (T-AML) VERSUS AML WITH MYELODYSPLASIA-RELATED CHANGES AND DE NOVO AML: CLINICOBIOLOGICAL DIFFERENCES AND OUTCOME

C Lalayanni, A Antoniou, P Baliakas, M Iskas, E Georgiadou, A Marvaki, A Syrigou, A Athanasiadou, A Anagnostopoulos

Hematology Department and HCT Unit, G Papanicolaou Hospital, Thessaloniki, Greece

According to the WHO 2008 classification, t-AML is related to previous administration of chemotherapy and/or radiaton and comprises 10% of AML cases. Since it is considered a secondary leukemia, t-AML is often grouped along with AML evolving from myelodysplastic (MDS) or myelohyperplastic (MPD) syndrome, which is currently included in the AML with myelodysplasia-related changes (MDS/MPD-AML) entity. We retrospectively studied 359 patients who were diagnosed with AML (151 females, 208 males) with a median age of 50 (9-75) years. De novo (dn) AML was the initial diagnosis for 255 cases, while in 68 cases AML evolved after MDS or MPD (63 and 5 case respectively) and in 36 cases (14%) the disease was considered t-AML. Twenty five of these patients had received previous chemotherapy, 2 radiation and 9 cases were exposed to both cytotoxic therapies for various primary malignancies or autoimmune diseases; solid cancers: 9, NHL: 8, LH: 6, ALL: 2, AML: 3, myeloma: 3, aplastic anemia: 2, rheumatoid arthritis: 2, ITP: 1. The majority had received a combination of alkylating agents with topoisomerase II inhibitors and the median latent time for the t-AML diagnosis was 5 (1. 5-21) years. We investigated the clinocobiological characteristics and outcome of all patients, separating them in 3 groups: de novo AML, MDS/MPD-AML (sAML) and t-AML. Median age was 48 vs 62 vs 53 years respectively. White blood cell count (WBC) was higher in de novo AML group (median: 15600 vs 7000 vs 4900/µl respectively, p=0. 045) as well as MPO positivity in bone marrow blasts (median: 80% vs 39% vs 38% respectively, p=0. 038). Performance status and LDH were similar in all groups. Gytogenetic investigation revealed significant differences. The karyotypic prognosis was favorable in 15% vs 0% vs 6%, intermediate in 70% vs 65% vs 37% and poor in 15% vs 35% vs 57% of dnAML, sAML and tAML cases respectively. Achievement of complete remission (CR) along with overall survival (OS) was also different in the 3 groups. CR was achieved in 188/255 (74%) dnAML, 23/68 (34%) sAML and 12/36 (33%) tAML cases (p=0. 031). The 5-year disease-free-survival (DFS) was 31% vs 6% vs 24% (p=0. 046) and ten-year OS was 32% vs 3% vs 11% respectively (p=0. 004). In multivariate analysis WBC at diagnosis, dnAML and cytogenetic profile influenced DFS while significant factors for OS were dnAML, cytogenetic profile and age. In conclusion t-AML and MDS/MPD-AML seem to have similar response to treatment and OS. They differ in cytogenetic profile; the frequency of unfavorable cytogenetics is significantly higher in t-AML, yet favorable cytogenetics can be found. Both t-AML and MDS/MPD-AML share a different and worse outcome when compared to de novo AML.

1225

VALOR, AN ADAPTIVE DESIGN, PIVOTAL PHASE 3 TRIAL OF VOSAROXIN OR PLACEBO IN COMBINATION WITH CYTARABINE IN FIRST RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

Background. The promising phase 2 activity/tolerability profile of vosaroxin with cytarabine in first relapsed or refractory AML (N=69) with median overall survival (OS) 7. 1 mo, combined complete remission rate 28% [complete remission (CR) 25%], median leukemia-free survival (LFS) 25 months, and 30-day all-cause mortality 3%, supported a phase 3 trial. **Aims.** VALOR (NCT01191801), a phase 3, randomized, controlled, double-blind trial, evaluates vosaroxin and cytarabine versus placebo and cytarabine in patients with first relapsed or refractory AML and incorporates an adaptive design. Primary objective is OS; secondary/tertiary objectives include CR rates, safety, event-free survival, LFS, and transplantation rate. **Methods.** Key eligibility criteria: persistent AML or first relapsed AML after 1 or 2 induction cycles that include at least 1 regimen of cytarabine with an anthracycline/anthracenedione; adequate cardiac, hepatic, renal function; and adults with no upper age restriction. Informed consent is obtained from all patients. Adaptive design: Base case assumed 40% improvement in median OS (hazard ratio, HR=0. 71), 90% power, 2-sided alpha of 0. 05. At the interim analysis (50% events), the Data and Safety Monitoring Board (DSMB) may recommend a 50% sample size increase from 450 to 675 evaluable patients if results indicate a larger sample size is required to reduce the risk of failing to confirm a clinically meaningful OS benefit (Mehta, Pocock, Stat Med 2010). In consideration of FDA and EMA guidance on Data Monitoring Committees and adaptive design with respect to trial integrity, operational bias, firewalls, and data confidentiality and archival, VALOR uses the Access Control Execution System (ACES®) to store, share, and archive confidential DSMB reports in a secure environment with an audit trail, and to facilitate communication between the DSMB and trial sponsor. The DSMB periodically reviews a combination of blinded and unblinded analyses while the study team remains blinded as specified in the DSMB charter. **Results.** VALOR is recruiting patients at over 100 sites in 14 countries in North America, Europe, and Australia/NZ. Enrollment opened Dec 2010; 183 patients enrolled through Dec 2011. The DSMB recommended VALOR continue as planned after reviewing safety data in Dec 2011. **Summary and Conclusions.** The key advantage of VALOR's innovative adaptive design is that the 50% increase in patient numbers is only called for at the interim analysis, if it is clear that this increase can substantially reduce the risk of failing to detect a clinically meaningful survival benefit. This novel methodology thus optimizes the chances of demonstrating clinical utility in the context of a disease as complex and heterogeneous as AML. Enrollment opened Dec 2010; 183 patients enrolled through Dec 2011. The DSMB recommended VALOR continue as planned after reviewing safety data in Dec 2011. The outcome of the interim analysis is anticipated in the third quarter of 2012.

[9]Manises Hospital, Valencia, Spain
[10]Vinaroz Hospital, Castellón, Spain

Introduction. Acute myeloid leukemia (AML) is more frequent in elderly patients, and the prognosis is very poor. Currently, there is no established standard treatment since the survival of patients treated with intensive chemotherapy is 10% at 3 years. In addition, most patients are not candidates for intensive treatment due to age, comorbidity or other biological characteristics. **Methods.** We conducted a retrospective analysis of 167 consecutive patients 65 years of age or older, diagnosed for AML between January 2007 and December 2010, in several health departments in Spain, and without selection bias. This was done in order to analyze the biological characteristics of leukemia, and patient characteristics and responses to different treatments. Variables related to patient and disease characteristics were compared among groups using *t* Student test for categorical variables and Krukal-Wallis for continuous variables. Cox regression analysis was used to explore the relationship between survival and explanatory variables. Survival was calculated utilizing Kaplan-Meier and long-rank test. **Results.** Total subjects were 91 men and 74 women. Median patient age was 75 years (range, 65-92 years). Forty-eight patients (28. 7%) had a secondary AML and 35 (21%) a previous myelodysplastic syndrome. In 83 patients (50%) cytogenetics was not performed or not valuable. Cytogenetic groups according to MRC criteria were as follows: favourable 5 (6%), intermediate 35 (42%) and adverse 43 (52%) -see Table 1-. In multivariable analysis, PS <= 2, intensive chemotherapy and 5-AZA treatment were found to be statistically significant for survival.

Table 1. Clinical characteristics and outcomes according to type of treatment.

Variables	Palliative (n=87)	Ara-C (n=10)	AZA (n=19)	Chemotherapy (n=51)	*p*
Age (median)	80 [65-92]	75 [67-81]	74 [66-86]	70 [65-78]	0. 000
Sex (men/women)	47/40	6/4	11/8	29/22	ns
PS >2	44. 3%	22%	15. 8%	5. 9%	0. 000
Comorbidities	1 [0-6]	2 [0-4]	1 [0-5]	1 [0-5]	ns
I Sorror >= 2	59. 7%	60%	69%	31. 8%	0. 02
Hb at diagnosis (g/dL)	9 [4. 5-12. 4]	9. 1 [5. 7-14. 0]	8 [6. 6-13. 9]	8. 8 [4. 5-12. 4]	ns
Leucocytes (x10^9/L)	11. 5 [1-357]	16. 5 [2-168]	4. 0 [1-47]	5. 7 [0. 7-178]	ns
Platelets (x10^9/L)	57 [6-2463]	73. 5 [10-321]	72 [19-459]	50 [4-242]	ns
PB blasts (%)	18 [0-95]	26 [0-95]	6 [0-76]*	29 [0-97]	0. 006
BM blasts (%)	45. 5 [12-99]	52 [28-92]	30. 5 [3-90]	52 [20-99]	ns
Secondary AML	34. 5%	50%	31. 6%	13. 7%*	0. 025
Favorable cytogenetic	0%	0%	0%	9%	-
Intermediate cytogenetic	17. 2%	50%	10. 5%*	25. 5%	0. 000
Adverse cytogenetic	18. 4%	0%	47. 4%*	35. 2%	0. 000
Unknown cytogenetic	64. 4%	50%	42. 1%	29. 4%*	0. 000
CR (%) Cheson 2003	0%	0%	0%	57%	-
Survival (median in months)	1. 6 [1. 2-2]*	4. 1 [0-8. 3]*	7. 4 [1. 7-13. 1]	8. 2 [5. 6-10. 8]	0. 000

Conclusions. Patients aged over 65 years, diagnosed with AML are a group with a very poor prognosis. There is an increased prevalence of patients with secondary AML, poor cytogenetic profiles and high rates of comorbidities. Although the clinical and biological characteristics of the intensive chemotherapy group are more favourable, overall survival was not significantly better than that for the group treated with 5-AZA. Further research is needed to establish optimal management and improve outcomes of elderly patients with AML.

TWO STEPS FLOW-CYTOMETRIC DIAGNOSIS OF ACUTE LEUKEMIA: SINGLE CENTER EXPERIENCE

D Dukovski, L Cevreska, S Trajkova, M Ivanovski, M Popova, I Panovska-Stavridis
University Clinic for Haematology, Skopje, Macedonia

Background. Flow cytometry analyses are powerful diagnostic tool for acute leukemia and their classifications in different acute myeloid leukemia (AML) from acute lymphoblastic leukemia (ALL) entities. Inspired by a resent published paper concerning the distinct CD45/SSC panel associated with AML and ALL cases we analyzed our lab data-base in order to make cost-effective and more efficient our diagnostic work-up for acute leukemia. **Methods.** We retrospectively analyzed 140 consecutive cases of acute leukemia that were diagnosed in the last two years at the University Clinic of hematology-Skopje. We correlate the blast distribution patterns in the CD45/SSC panel with the morphology and the detailed immunophenotype. The diagnosis of acute leukemia was made by standard morphological examination and cyto-chemical analyses of bone marrow smears according to the criteria established by FAB Cooperative Study Group and confirmed by immunophenotyping of bone marrow aspirates and/or peripheral blood samples following the criteria of the European group for the immunological Classification of acute leukemias (EGIL). Flow-cytometric analyses were performed by using the FAXS Canto II BD flow cytometer analyzer. Acquired data were analyzed with the software FACSDiva version 6. 1. 2 by using CD45 gating strategy. Slightly modified panel of monoclonal antibodies (McAb) against myeloid- and lymphoid-associated antigens as suggested by the EGIL was utilized. The samples contained more than 20% of blast cells (most of which had more than 50%). Antigen expression was considered positive if 20% or more blats cells reacted with the particular antibody, except reactivity of blast cells with anti-MPO which is considered positive if 10% or more mononuclear cells are MPO positive **Results.** Our results showed that blast distribution patterns in the CD45/SSC panel in correlations with the morphology allows primary provisional distribution of acute leukemia cases in the three groups *AML, ALL,* and one *indeterminate group which* guides to implementation of specific immunological analyses in each group with *modified AML, ALL,* and *indeterminate* flow panels. Using this two step approach, we have efficiently and correctly diagnosed almost all acute leukemia cases. Our analysis also determined the minimal numbers of immunological markers needed for the lineage assignment of acute leukemia. **Conclusions.** Our two steps immunological analyses of acute leukemia cases maintained diagnostic accuracy while significantly improved the cost efficacy of acute leukemia diagnostic work up by reducing reagent use, labor, and time.

AGE SPECIFIC CYTOGENETICS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA IN CHINESE POPULATION

S Gao[2], L Su[1], W Li[2], Y Tan[2], X Liu[2], P Yu[2]
[1]The First Hospital, Jilin University, Changchun, China
[2]Jilin University, Changchun, China

Background. The clonal chromosomal abnormalities observed in the leukemia cells of patients diagnosed with acute myeloid leukemia (AML) are the hallmark of AML. Different mechanisms may lead to different types of genetic alternations. The mechanisms might occur at different frequencies over lifetime. Age is an important factor to be considered when investigating the etiology of a disease as it can provide clues to its pathogenesis. Both age and cytogenetics are critical for acute myeloid leukemia (AML), and the relationship between these two factors were reported in several previous studies. However, little is known about Chinese population, and there are also limited data on the cytogenetics of AML in children. **Aims.** To observe the distribution of cytogenetic subgroups in Chinese population with AML of both children and adults. **Methods.** In present study we analyzed 684 patients with *de novo* AML. The patients were divided into six age groups, group I (≤16 years), II (16-30 years), III (30-40 years), IV (40-50 years), V (50-60 years), VI (≥60 years) according to age factor. The cytogenetically grouping was performed as normal, balanced (including translocations and inversions), monosomal (two or more distinct autosomal chromosome monosomies or one single autosomal monosomy in the presence of structural abnormalities), complex (≥3 clonal aberrations) and unbalanced karyotype (get or loss in genetic quantity, excluding monosomal and complex karyotype). All participating patients gave informed consent prior to enrollment into the studies. **Results.** The frequency of normal, balanced, monosomal, complex and unbalanced karyotype were 39. 62%, 32. 89%, 2. 92%, 2. 34% and 22. 22%, respectively. The distribution of normal and balanced karyotype showed age specific characteristics. The frequency of normal karyotype was increasing from the group I (30. 2%) to the group VI (48. 7%) ($\chi 2$=15. 459, P=0. 009). The incidence rate of balanced karyotype decreased from the group I (37. 7%) to the group VI (17. 7%) ($\chi 2$=22. 801, P<0. 001). The incidence rate of unbalanced karyotype remained static across the different age groups. There was no evident age specific tendency was detected for both monosomal and complex karyotype groups because of the low incidence of these aberrations. No significant difference was observed in frequency of abnormal karyotype between children and adults (69. 8% versus 59. 6%) (χ^2=2. 136, P=0. 144), and the distribution of cytogenetic subgroups was not evidently different ($\chi 2$=8. 577, P=0. 073) as well. t(8;21) and t(15;17) occurred at the highest incidence in children and adults, respectively. **Conclusions.** The different age profiles of the cytogenetic subtypes may indicate the different mechanisms of the pathogenesis of AML, which may also offer beneficial information for etiological research and development of new treatment.

1229

PROGNOSTIC SIGNIFICANCE OF WT1 EXPRESSION AT DIAGNOSIS AND END OF INDUCTION IN EGYPTIAN ADULT ACUTE MYELOID LEUKEMIA PATIENTS

I Mossallam, M Abdel Hamid, K Mahmoud
National Cancer Institute, Cairo, Egypt

Background. Acute myeloid leukaemia (AML) is the most common leukaemia in adults, only about one-third of these patients remain free of disease for more than five years. Wilms' tumor (WT1) gene encodes a transcription factor important for normal and malignant haematopoiesis. Its overexpression has been reported in the majority of AML patients at diagnosis and has been evaluated as prognostic and minimal residual disease (MRD) marker. **Aims.** To assess the prognostic significance of WT1 overexpression at diagnosis and to evaluate its use as MRD marker at the end of induction. **Patients and Methods.** WT1 overexpression was evaluated in sixty eight adult AML patients at diagnosis using quantitative real time RT-PCR. The impact of WT1 transcript reduction at the end of induction was evaluated in eighteen patients in CR in whom the initial level of transcript at diagnosis was sufficient to follow-up using 2 log reduction. Patients received Doxorubicin and Cytosine arabinoside (3 and 7 regimen) for induction. **Results.** WT1 overexpression was detected in 51/68 (75%) of patients. No significant associations were encountered between WT1 overexpression at diagnosis and other prognostic factors. Complete remission was achieved in 74% of patients with WT1 overexpresssion compared to 80% of patients with normal levels (p=0. 5). No significant associations were encountered between WT1 overexpression at diagnosis and DFS or OS (p=0. 6 and 0. 3, respectively). At the end of induction, the median duration of DFS in patients achieving ≥2 log reduction was not reached compared to 5 months (range: 2. 1-7. 9m.) in those attaining <2log reduction (p=0. 2) (Figure 1).

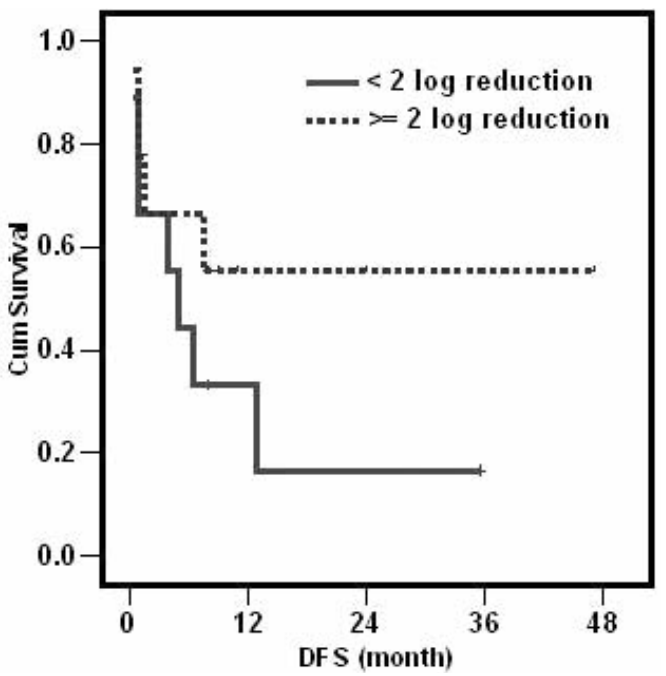

Figure 1. DFS in relation to ≥2log reduction at the end of induction (p=0.23).

The median duration of OS in patients achieving ≥2log reduction was 13 months (range: 0-33. 3m.) compared to 7. 5 months (5. 4-9. 6m.) in those attaining <2log reduction (p=0. 3). The survival at one year in patients achieving ≥2 log was

double the group with <2log reduction 66. 7% compared to 33. 3%. **Conclusions.** Our results, although not reaching the level of significance, which could be due to the small sample size, suggest that early assessment of the WT1 transcript level at the end of induction in patients in CR may have an impact on clinical outcome and may thus be a useful marker for risk stratification especially in patients lacking disease specific marker. Its applicability must be evaluated in a larger cohort of patients.

1230

INTERNAL TANDEM DUPLICATION (ITD) MUTATIONS OF THE FLT3 RECEPTOR AND CXCR4 EXPRESSION IN DE NOVO ADULT ACUTE MYELOID LEUKEMIAS (AML)

S Improta[1], A Gagliardi[1], A Quirino[1], C Tommasino[2], L Mastrullo[1]
[1]UOC Ematologia ASL Napoli 1 Centro, Naples, Italy, Naples, Italy
[2]U. O. C. di Patologia Clinica P. O. San Gennaro ASL NA1 Centro Napoli, Naples, Italy

Introduction. Internal tandem duplication (ITD) mutations of the FLT3 receptor are associated with a high incidence of relapse in acute myeloid leukemia (AML). It is also known that the complete immunophenotypic characterization contributes to define the prognosis of de novo adult AML. Stromal cell-derived factor-1 (SDF-1)is a homeostatic chemokine that is constitutively secreted by marrow stromal cells. SDF-1 signals through CXCR4, which plays an important role in hematopoiesis, development and organization of the immune system. Prognostic impact of CXCR4 expression levels on the neoplastic cells has been demonstrated in breast cancer, renal cell cancer and AML. **Aims.** We investigated the expression of the chemokine receptor CXCR4 on bone marrow blast cells in a group of adult de novo AML with FLT3-ITD. **Methods.** We have observed 45 young adult de novo AML patients (median age: 44 years, r: 22-62) in the last 4 years, who presented FLT3-ITD-positive AML blasts in bone marrow blood. On the basis of FAB classification the patients were considered LMA-M5 (17 pts.), LMA-M2 (12 pts.), LMA-M4 (6 pts.), LMA-M1 (7 pts.) and LMA-M0 (3 pt.). 12 patients showed complex chromosomal anomalies; 19 patients presented hyperleukocytosis (WBC> 40x10(e)9/L). The clinical outcome was that one of a "high risk"AML; at the present only two patients are still alive in CR (+40 months and +46 months). **Results.** We found at the diagnosis, in all cases, an high CXCR4 expression on leukemic blasts, as defined by CXCR4 mean fluorescence intensity ratio thresholds of more than 5. **Conclusions.** Several studies have shown the prognostic significance of the expression of differentiation myeloid markers at the diagnosis of adult de novo AML. However, specific immunophenotype expression patterns associated with internal tandem duplication (ITD) mutations of the FLT3 receptor are still unknown. Further studies are warranted to confirm the correlation between FLT3-ITD and "CXCR4 over-expression" immunophenotypic pattern.

1231

ADULT ACUTE MYELOID LEUKEMIA IN FIRST RELAPSE - SUPPORTIVE VS. SALVAGE THERAPY

C Moreira, D Pereira, M Nunes, M Dantas-Brito, S Chacim, C Leite, I Ferreira, M Marques, L Viterbo, A Martins, I Oliveira, N Domingues, I Moreira, A Espírito-Santo, J Mariz
Instituto Português de Oncologia do Porto, Porto, Portugal

Introduction. For adult patients diagnosed with Acute Myeloid Leukemia (AML) who achieve complete remission (CR), maintaining remission is the primary goal. However, the majority of patients will relapse. The probability of relapse depends of numerous factors including age and cytogenetics at diagnosis. Despite the progress in understanding the pathophysiology of this disease, the prognosis after AML relapse is still very poor. Frequently the clinician is faced with the decision to intensively treat a relapsed AML patient, with all the inherent complications' risk, or to provide the best supportive care in view of a quality-of-life benefit. **Aims.** To compare the survival after relapse between adult AML patients in first relapse who received therapy without achieving CR and patients given supportive care. **Methods.** Retrospective review of the clinical files of adult patients diagnosed with AML, excluding all cases of Acute Promyelocytic Leukemia, between January 1998 and December 2010 at our Institution (268 patients). Of the 246 patients submitted to induction therapy, 202 achieved CR with relapse occurring in 88 patients. At the time of 1st relapse, 27 patients were given only supportive care (group A) and 61 were submitted to intensive treatment; of those 28 achieved a 2nd CR and 33 didn't respond to therapy (group B). Survival was compared between groups A and B and was measured from the time of relapse. Statistical analysis was performed with SPSS®Statistics v19. **Results.** Comparing both groups, A and B, patients on the supportive group were older (median age: 61 years vs. 47. 5 years, p= 0. 03) and relapsed earlier (median time to relapse: 3. 95 months vs. 10. 65 months, p=0. 082). Distribution of gender, performance status and karyotype at diagnosis was similar in both groups; no patient presented favorable cytogenetic risk. The most frequent chemotherapy regimens used were SWOG-9126 (33. 3%), and VC (Etoposide+Carboplatin; 33. 3%). Overall, median survival after relapse was 1. 7 months in group A and 5. 9 months in group B (p=0. 003), which represented a survival benefit of 4. 2 months for patients who received chemotherapy. On multivariate analysis, age (p=0. 022) was the only independent prognostic factor identified. Subgroup analysis was performed in order to identify those patients who achieved the most benefit from salvage therapy. We identified age ≤60 years (median survival: 1. 6 months in group A vs. 6. 8 months in group B, p= 0. 014), time for relapse >12 months (median survival: 1. 5 months in group A vs. 7. 6 months in group B, p=0. 007) and intermediate risk cytogenetics (median survival: 1. 6 months in group A vs. 5. 9 months in group B, p=0. 01) as the groups with superior survival advantage. **Conclusions.** We conclude that there is a survival benefit associated with receiving salvage therapy in first relapse, in spite of failure to achieve CR, when compared to supportive treatment only. That advantage might be related to a reduction in the proliferation of malignant cells and/or an improvement in "functional"cell counts. However, this was a retrospective analysis and we admit the results may reflect a bias related to the selection of the more "fit"patients to receive treatment.

1232

EXPERIENCE OF A 5-DAY SCHEDULE OF AZACITIDINE IN A SINGLE-CENTRE ACUTE MYELOID LEUKEMIA POPULATION

D Fiallo[1], H Luzardo[2], A Suárez[2], S Jimenez[2], C Campo[2], J López[2], L Guerra[2], A Lemes[2], M Perera[2], D Navarro[3], M Gómez[2], T Molero[2]
[1]Hospital Universitario de G. C. Dr. Negrin, Las palmas de gran canaria, Spain
[2]Hospital Universitario de G. C. Dr. Negrín., Las Palmas G. C., Spain
[3]Statistics ULPGC, Las Palmas G. C., Spain

Background. Acute Myeloid Leukemia(AML) is the most common type of acute Leukemia occurring in adults. First line Intensive chemotherapy would be the best treatment option but for some population, as elderly patients, who have poor performance status and other recognized poor prognostic factors may not be the most suitable option. Similarly, AML refractory or patients with an early relapse after induction, have a poor prognosis and limited therapeutics options. For both cases, preliminary studies with 5-Azacitidine seems to be an active and well tolerated drug pending to be corroborated in further prospective studies. **Aims.** To describe our experience with 5-Azacitidine in unfit or no candidate for intensive chemotherapy and relapse/resistant AML patients and to compare it with previous data reports in the literature. **Methods.** We include in these study all AML patients (and 4 high-risk MDS) treated in our center with 5-Aza. The protocol used was 75 mg/m2/day intravenous for 5 consecutive days every 28 days. Data of responses were described according to IWG criteria. **Results.** 20 patients were included, 16male/4Female, with a median age of 73. 5 years (39-81) with 16 patients(80%) >65 years. According to WHO criteria, 16 were AML (4 unfit untreated, 12 relapse/resistance) and 4 MDS (all four with high risk IPSS and severe transfusion dependence, 3 unfit-untreated, 1 relapse/resistance). 3/20 patients are separately reported because they began 5-Aza as a consolidation/maintenance in Complete Remission(CR) after a cycle of chemotherapy induction. Median pre-treatment Bone Marrow blasts percentage in AML patients was 31%(6-90). Karyotype was evaluable in all patients, 11(74. 8%) adverse-risk, 6(35. 2%) intermediate-risk). A total of 83 treatment cycles were administered with a median of 3 cycles (1-18) (all patients included, at least completed 1 cycle). After a median follow up of 8. 3 month (1-21), 7/17(41. 1%) had some kind of response (CR/partial remission/hematology improvement(HI) and Stable disease(SD). With 3 CR(17. 64%) and 4 SD(23. 5%) We did not find any PR or HI. The median response duration of CR was 5 month (3-9). The median overall survival(OS) time of the whole cohort was 4. 9 month (0. 4-23,3). OS in the adverse and intermediate-risk Karyotype group was 4. 35 and 6,6 month respectively and in the unfit-untreated and relapse/resistance patients was 5. 03 and 4. 9 month. In the 3 patients who began 5-Aza in CR after induction therapy the median OS and EFS was 25. 3 and 10. 8 month respectively. **Conclusions.** As this is a retrospective study with a small simple size and heterogenety among the patients, it is not posible to stablish statistically significant results. Taking this facts into account, we can conclude that our OS, CR, DFS data and the difference by cytogenetic risk group, coincide with what have been published in the literature. In the same way, OS and DFS data obtained in our 3 patients on maintenance treatment are also similar to what have been described in similar AML patients after induction treatment. Therefore, these preliminary data encourage us to continue in this line of treatment, as well as to widen and improve our study in this poor prognosis patients with limited treatment options.

1233

PATTERN OF DISSEMINATED INTRAVASCULAR COAGULATION IN ACUTE PROMYELOCYTIC VS OTHER SUBTYPES OF ACUTE MYELOID LEUKEMIA

SG Park, HJ Park
Chosun University Hospital, GwangJu, South-Korea

Background. Acute promyelocytic leukemia (APL) is a specific subtype of acute myeloid leukemia (AML) with distinctive morphology, molecular presentation, clinical course, and treatment. Up to 90% of APL patients present with hemorrhagic complications due to disseminated intravascular coagulation (DIC), which constitutes one of the most serious and often lethal aspects of the disease. When APL is suspected, initiation of all-trans retinoic acid (ATRA) is recommended, without waiting for molecular confirmation. However, published criteria are lacking for differentiating unconfirmed APL from other AML subtypes in the setting of DIC. **Aim**Herein, we report our comparison of the DIC pattern in APL with that of other AML subtypes. **Methods.** From January, 2005 to November, 2011, a retrospective analysis of patients diagnosed with APL (n=10) and other subtypes of AML (n=14) was conducted to establish diagnostic criteria for DIC. **Results.** INR (1. 44 vs 1. 23, *p*=0. 044) and FDP (79. 42 μg/mL vs 21. 06 μg/mL, *p*=0. 033) levels were higher, as were neutrophil fractions (65. 23% vs 28. 07%, *p*<0. 001), and fibrinogen (134. 92 mg/dL vs 354. 86 mg/dL, *p*<0. 001) was lower in patients with APL compared with other AML subtypes. Accordingly, our threshold values were as follows: INR ≥1. 35, FDP ≥27 μg/mL, neutrophil fraction ≥50%, and fibrinogen ≤220 mg/dL. Given that at least three of these criteria are met, the diagnostic sensitivity and specificity for APL are 80. 0% and 92. 86%, respectively. These markers may thus be characteristic of APL and help support a presumptive diagnosis. **Conclusions.** APL may be differentiated from other subtypes of AML by core markers of DIC (INR, FDP, fibrinogen, and neutrophil fraction), for which we suggest new diagnostic thresholds. Despite its small scale, our study offers added support for early initiation of ATRA, prior to PML-RARA molecular confirmation.

1234

FLUDARABINE BASED CHEMOTHERAPY REGIMENS FOR HIGH RISK ACUTE MYELOID LEUKEMIA PATIENTS

B Veggia, F Saltarelli, E Conte, E Montefusco, G Antolino, R Porrini, V Naso, A Moscetti, MP Bianchi, A Ferrari
Azienda Ospedaliera Sant'Andrea, Rome, Italy

Background. Acute myeloid leukemia (AML) patients older than 60 years have a poor prognosis due to many unfavorable factors: comorbidities, poor tolerance and elegibility to intensive treatment, multiple chromosomal abnormalities, higher incidence of secondary diseases, low response rate to treatment. Secondary or refractory/recurrent AML as well, represents an high risk subset because of a particularly aggressive disease, multidrug resistance expression resulting in poor response to treatment. In that subset of patients, standard induction regimens based on cytarabine and daunorubicin association showed low remission rates and poor outcome. Moreover, many of these patients are not eligible for transplant procedures due to age or to toxicity. The association of fludarabine and cytarabine as induction therapy seems to offer an effective treatment in AML patients with high risk disease even if few data have been published until now. We describe thirty-one cases of patients affected by high risk AML treated with combined regimens with fludarabine and cytarabine. **Patients and Methods.** From November 2005 to December 2011 in our Clinical Hematology Unit we observed 31 patients with high risk AML eligible for aggressive induction chemotherapy (17 males, 14 female; median age 67 years, range 34-74); 14 patients aged > 60 years presented *de novo* AML, 7 patients were affected by AML secondary to myelodysplastic syndrome (MDS), 1 patient showed AML secondary to mitoxantrone treatment for multiple sclerosis, 9 patients showed refractory/recurrent disease. Patients were all treated with fludarabine based regimens: 8 with FLA regimen (Fludarabine 30 mg/m^2 day 1-5, Ara-c 2 g/m^{2}day 1-5), 19 with FLAN regimen (Fludarabine 30 mg/m^2 day 1-5, Ara-C 2 g/m^2 day 1-5, Mitoxantrone 10 mg/m^2 day 3-5), and 4 with FLAI regimen (Fludarabine 30 mg/ m^2 day 1-5, Ara-C 2 g/ m^2 day 1-5, Idarubicin 10 mg/ m^2 day 1,3,5). **Results.** After induction treatment, 21/31 patients obtained a complete remission (CR) (67. 6%), 5 (16%) were refractory and 5 (16%) died during treatment because of infection. 10 patients (47,6%) who achieved CR, relapsed after a median time of 8 months (range 2-17 months). 8 patients (38%) died in first CR: 6 during consolidation treatment (4 due to sepsis, 1 due to brain hemorrhage and 1 due to invasive candidiasis) and 2 before consolidation treatment because of infection. Currently, 3 patients are in continuous complete remission from respectively 69. 5, 64. 5 and 14 months and 1 patient is in second CR with a follow-up of 37 months from diagnosis. Median overall survival (OS) is 4 months (range 0. 1 - 66. 6+), with 24% of patients projected to be survivor at 24 months, while median disease free survival (DFS) is 8. 4 months (range 0. 9 - 70. 6+), with 19. 4% of patients at 24 months. **Conclusions.** In our experience combined regimens with fludarabine and citarabine represent an effective induction treatment for AML patients with high risk disease; unfortunately, infections still represent a primary cause of death especially in heavily pretreated patients.

1235

OUTCOME OF FLAG REGIMEN IN THE TREATMENT OF REFRACTORY OR RELAPSED ADULT ACUTE MYLOID LEUKEMIA

F Alwan[1], F Matti[2], S Naji[2], J Almudhaffar[2]
[1]The National Center of Hematology, Baghdad, Iraq
[2]Baghdad Teaching Hospital, Baghdad, Iraq

Background. A large proportion of adult patients with acute myeloid leukemia (AML) relapse after treatment, and some of them are resistant to primary induction chemotherapy. Over the past decade emphasis has been made in the development of regimens containing fludarabine, combined with cytosine arabinoside for the treatment of refractory/relapsed acute leukemias. **Aims.** The aim of this study was to evaluate the efficacy and toxicity of fludarabine, high dose cytarabine, and granulocyte colony stimulating factor in refractory or relapsed acute myloid leukaemia. **Methods.** Between January 2008 and February 20011, 23 adult patients older than 16 years, with primary refractory or relapsed AML, with exclusion of promyelocytic leukemia, were included in this study. Absence of heart, liver, or kidney damage, as well as no active infection, were required for inclusion in the trial. Adequate heart function was assessed by echocardiography(left ventricular ejection fraction ≥50%) and electrocardiogram. Written informed consent was obtained from all patients. Morphologic leukemia subtypes wereevaluated on bone-marrow smears according to standard procedures, using the revised FAB criteria. Treatment protocol consisted of Fludarabine 25 mg/m2/d (d1-5) i. v. as a 30-minute infusion, then 4 hours later Ara-C 2 g/m^2/d (d1-5) i. v. as a 4-hour infusion; G-CSF 300 microgram/day was given subcutaneously from day zero until absolute neutrophil count (ANC) >1x 10^9/L. **Results.** There were 14 men and 9 women with a median age of 32 (range 21-44) years. ten patients had primary refractory disease, and 13 were in first relapse. Twelve (52. 1%) patients achieved complete remission (CR) following salvage therapy, whereas 10 (43. 4. 5%) patients were refractory, and one patient died in aplasia due to infection. In patients achieving remission, the median time to reach absolute neutrophil count (ANC)more than 1×10^9/l was 24 (range 20-28) days from the start of chemotherapy, Platelet level of more than 20×10^9/l was achieved in a median time of 23 (range 19-25) . Nonhematological side effects, consisting mainly of mucositis (18/23 or 78. 2%) and transient liver toxicity increase (10/23 or 43. 4%), were generally tolerated. Of twelve patients who achieved CR 3 patients received a second course with FLAG, and 9 patients stayed without treatment (allogeneic stem cell transplantation was not available) while two did not reach that stage due to early relapse from CR. The median overall survival (OS) for all 23 patients was 4. 5 (range 1-38) months. **Conclusions.** FLAG is a good choice in cases with refractory or relapsing acute myeloidleukemia for salvage chemotherapy. High efficacy and a low-toxicity profile are preferable properties of this regimen, and this regimen has been found to be useful for cytoreduction, especially in candidates for allogeneic stem cell transplantation

1236

NPM1 AND FLT3 MUTATIONS IN ACUTE MYELOID LEUKEMIA (AML)

E Aguiar, M Amorim, MP Gomes, P Guimarães, F Trigo, JE Guimarães
Centro Hospitalar de São João, Porto, Portugal

Background. Acute Myeloid Leukemia (AML) is a disease with marked heterogeneity in both response to therapy and survival. The molecular analysis resulted in the emergence of new prognostic factors, including gene mutations in FLT3 (Fms-like tyrosine kinase 3) and NPM1 (nucleophosmin 1). The presence of these gene alterations may exert profound effects on outcome of disease. **Aims.** To investigate the clinical and biologic characteristics and the prognostic impact of NPM1 and FLT3 mutations in AML. **Materials and Methods.** One hundred and thirty patients with AML were consecutively admitted in our hospital between October 2008 and March 2011. Were included patients with de novo AML and secondary to myelodysplastic syndrome. Ninety one patients were candidates to intensive chemotherapy. Only 71 of 91 patients were analyzed for the presence of FLT3 and NPM1 mutations. Patients were treated with EORTC Protocols AML12/AML17, AIDA GIMEMA protocol for acute promyelocytic leukemia and 1 patient with ELAM-02 pediatric protocol, followed by consolidation chemotherapy and allogeneic or autologous transplantation. **Results.** Median age was 51 years (range,16-78) and 44 (62. 0%) were

females. FLT3 mutation was found in 18 (25. 4%) patients, 13 with FLT3 internal tandem duplication (FLT3ITD) mutation and 5 with FLT3 Tirosine Kinase Domain (FLT3TKD). NPM1 mutation was found in 14 (19. 7%) cases. Nine of these (64. 3%) were also FLT3+ (p=0. 001). Median leukocyte count was significantly higher in patients with NPM1 mutation (81. 04x10^9/L vs. 7. 30x10^9/L, p=0,003) and FLT3 mutation (64. 70x10^9/L vs. 5. 45x10^9/L, p=0. 000). Median *lactate dehydrogenase* (LDH) was higher in FLT3+ patients (p=0. 03) and NPM1+ patients (p=0. 05). FLT3+ patients had significantly higher blasts counts (81% vs. 60%, p= 0. 008), but not NPM1+ patients. We observed a trend of FLT3+ patients being classified with FAB subtype M1, M3v and M4/M5 (p=0. 07) and a significant association between NPM1 mutation and subtypes M1, M2 and M4/M5 (p=0. 02). FLT3 mutation presented more frequently in patients with normal karyotype and t(15;17) or PML-RARA (p=0. 92). Normal karyotype was observed in thirteen (92. 9%) of the NPM1+ patients (p=0. 01). To assess the prognostic impact, we analyzed the intermediate cytogenetic group of patients (n=38), with a median follow-up of 12 months (0-31). One patient died before start chemotherapy. Patients were divided in group 1 (NPM1+, FLT3ITD-), 2 (FLT3ITD-, NPM1-), 3 (FLT3ITD+, NPM1+) and 4 (FLT3ITD+, NPM1-). No statistical significance was found in Disease Free Survival (DFS) rates, with a 2-year DFS of 66. 7%, 27. 6% and 25. 0% in group 1, 2 and 3, respectively (p=0. 10). None of group 4 patients achieved complete remission. The 2-year Overall Survival (OS) was significantly higher in group 1 (83. 3%), than group 2 (34. 3%), 3 (28. 6%) and 4 (0%) (p=0. 002). **Summary and Conclusions.** Our data confirm that the presence of FLT3 and NPM1 mutations is associated with specific clinical characteristics in AML patients, like higher median leukocyte count and LDH. *FLT3ITD* mutation was associated with an unfavorable outcome and *NPM1* mutation, in the absence of FLT3ITD, may be a favorable prognostic factor for OS.

1237

CLINICAL CHARACTERISTICS AND ANALYSIS OF NONLEUKEMIC MYELOID SARCOMA: A REPORT OF 13 CASES

L Zhu[1], X Ye[2], J He[2], W Xie[2], L Li[2], J Zhu[2], H Huang[2], Z Cai[2]
[1]Sir Run Run Shaw Hospital,Medical School, Zhejiang University, Hangzhou, China
[2]First Affiliated Hospital, College of Medical Science, Zhejiang University, Hangzhou, China

Background. Myeloid sarcoma (MS) is an extramedullary mass composed of immature myeloid cells. The tumor may involve any part of the human body, especially the skin, bone and lymph nodes. On rare occasions, MS manifests before the onset of AML, in which case it is often misdiagnosed as malignant lymphoma. An accurate diagnosis of nonleukemic MS is important for effective therapies. **Aims.** To analyze the clinical characteristics, immunohistochemistry, cytogenetic findings, treatment approaches of myeloid sarcoma (MS), and assess the prognosis. **Methods.** Thirteen cases of nonleukemic MS were enrolled in this study. Histologic and immunohistochemical examinations were performed on biopsies or surgical specimens for MS diagnosis. All patients underwent a complete history, physical examination, and laboratory tests included peripheral blood cell count, bone marrow aspiration and biopsy. Clinical characteristics, pathological findings, treatment response and prognosis were analyzed. **Results.** The male-to-female ratio was 1:1. 6. Majority of patients (11/13, 84. 6%) received diagnosis between the ages of 20 and 42. The most sensitive immunohistochemical biomarkers were myeloperoxidase (12/13, 92. 3%). Chromosomal abnormalities were only observed in one cases with the t (8; 21) (q22; q22) translocation. All patients received systemic anti-AML chemotherapy. The median survival time was 20 months (range, 4-63 months), of which four cases (4/13, 30. 8%) progressed to AML within 16 months (range, 6-62 months). **Conclusions.** Accurate initial diagnosis and aggressive treatment play a key role on improving the prognosis of nonleukemic MS. Anti-AML chemotherapy is still the first line treatment. The treatment choice of refractory and relapsed MS is still difficult. The standardized and unified strategies are needed to develop for effective treatment, by expanding the case samples and designing prospective studies.

1238

ACUTE MYELOID LEUKEMIA-TYPE CHEMOTHERAPY REGIME INDUCES COMPLETE REMISSION OF BLASTIC PLASMACYTOID DENDTRITIC CELL NEOPLASM

R Eichner, N Alakel, S Parmentier, M Bornhaeuser, G Ehninger, M Schaich
University Hospital Dresden, Dresden, Germany

Background. Blastic plasmacytoid dendritic cell (BPDC) neoplasm is a rare and highly aggressive hematological malignancy. Formerly, it was known as blastic natural-killer cell lymphoma or CD4/CD56 hematodermic neoplasm because it almost always presents with skin lesions, and often involves lymph nodes and bone marrow. Although conventional chemotherapy leads initial to high response rates, relapse rates remain very high, then with chemotherapy-resistant disease. **Aims.** Several treatment protocols were suggested with controversial results. However, long-term remission and survival rates appear to be achieved only by hematopoetic stem cell transplantation. Herein we report three patients, which were treated in our hematologic department in 2011 with different clinical manifestations. **Case Report.**Two patients presented with painless reddish erythematous skin plaques. The patients denied fever, night sweats or weight loss. Complete blood count was normal. After several months of topical treatment with corticoids no improvement could be observed. Repeated skin biopsies were performed and revealed a diffuse lymphomatous infiltrate demonstrating a BPDCN. A computed tomography scan of the chest and abdomen as well as bone marrow biopsy revealed no further manifestations. Third patient presented initially with fever and pancytopenia. Bone marrow aspiration was performed. Immunophenotypic examination using FACS-analysis revealed the co-expression of CD4/CD56 and raised the suspicion of BPDCN. The immunohistochemical stains of bone marrow confirmed the diagnosis and showed an infiltration grade of 90%. The patient had cutaneous manifestation at back as well. Since this neoplasm is derived from the precursors of plasmacytoid dendritic cells a therapeutic trial using bortezomib was performed in one patient with isolated cutaneous manifestation, but without success. Reviewing the literature BPDC neoplasms were successfully treated using intensive acute leukemia polychemotherapy followed by allogenic stem cell transplantation. Due to high toxicity rates associated with acute lymphoblastic leukemia-like regimes we decided to treat with intensive chemotherapy according to AML-like protocol. All three patients received induction chemotherapy with cytarabine (100 mg/m^2 on day 1-7) and daunorubicin (60 mg/m^2 on day 3-5). The skin lesions regressed clearly after one cycle of chemotherapy, and after the second cycle the cutaneous lesions had resolved completely. Bone marrow transplantation was carried out in one patient with isolated cutaneous manifestations. One year after allogenic stem cell transplantation the patient is still in complete remission and good health. The other two patients are waiting for allogenic stem cell transplantation. The patient with bone marrow involvement developed severe prolonged pancytopenia after induction therapy, which may be a result of bone marrow infiltration. Unfortunately the patient developed an invasive pulmonary aspergillosis. **Conclusions.** Blastic plasmacytoid dendritic cell neoplasm is a rare malignancy with poor prognosis. In our case report, AML-like induction therapy followed by allogenic stem cell transplantation represents an accepted treatment option with lower toxicity. However bone marrow involvement may be accompanied with prolonged pancytopenia and therefore high susceptibility to infections.

1239

PROGNOSTIC IMPACT OF LEUKOCYTOSIS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MUTATED NPM1 AND FLT3-ITD

M Virijevic[1], I Djunic[1], A Novkovic[2], N Tosic[3], A Vidovic[1], N Colovic[1], V Djurasinovic[1], N Suvajdzic-Vukovic[1], D Tomin[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinical Hospital Center "Zemun", Belgrade, Serbia
[3]Institute for Molecular Genetic and Genetic Engineering, Belgrade, Serbia

Background. Mutation in nucleophosmin (NPM1) is the most frequently observed molecular abnormality, present in about 50% of acute myeloid leukemia (AML) cases, and is associated with a favorable outcome. Internal tandem duplication of the fms-related tyrosine kinase 3 gene (FLT3-ITD) is another frequent molecular abnormality and can be observed in about 25% of patients with AML. The presence of FLT3-ITD is generally considered as an unfavorable prognostic factor. **Aims.** The aim of this study was to investigate the prognostic impact of white blood cell (WBC) count at diagnosis on outcome within specific AML subgroups of patients with mutated NPM1 (as a favorable risk factor) and FLT3-ITD (as a poor risk factor). **Methods.** This single-center study involved 20 AML patients with mutated NPM1 and FLT3-ITD. The follow up period was 3 years. Patients with all other cytogenetic abnormalities and AML patients without cytogenetic abnormalities were excluded from this investigation. Patients were divided into three groups according to their WBC count: 1) a WBC count <20x10^9/L; 2) a WBC count 20-100x10^9/L and 3) a WBC count >100x10^9/L. Cox regression analysis was applied to determine the association of WBC and overall survival (OS) in months. **Results.** The mean age of the patients was 51 years (range 21-71). There was a strong correlation between the NPM1 mutation and a high WBC count, p = 0. 004. Also, differences in OS between the three groups of patients divided according to WBC count (<20x10^9/L vs 20-100x10^9/L vs >100x10^9/L) were statistically significant, p = 0. 003. **Conclusions.** This study demonstrated that leukocytosis

is an important unfavorable risk factor for OS in the subgroup of patients with AML and mutated NPM1 and FLT3-IDT.

1240

ARE WE CLOSE TO FIND CLEAR PROGNOSTIC FACTORS FOR SURVIVAL OF PATIENTS WITH ISOLATED MYELOID SARCOMA?

D Antic, I Elezovic, N Suvajdzic Vukovic, A Vidovic, M Perunicic-Jovanovic, M Sretenovic, I Djunic, M Mitrovic, V Vukovic, D Tomin
Clinic for Hematology, Clinical Center Serbia, Belgrade, Serbia

Background. Isolated myeloid sarcoma (MS) is a extramedullary tumor of immature myeloid cells defined by the absence of a history of leukemia, myelodisplastic syndrom (MDS) or myeloproliferative neoplasm with a negative bone marrow biopsy. MS is very rare condition and has been described in limited case reports. Therefore, knowledge about the exact incidence and treatment of isolated MS is not clear but untreated isolated MS will almost always progress to acute myeloid leukemia (AML). The median time to the development of AML in this setting is about 5 months. Aims. We reviewed a single centre one decade experience and assess multiple prognostic factors with intention to determine the possible prognostic factors of survival outcomes in patients with MS. **Methods.** Eleven patients who underwent treatment for MS at Clinic for Hematology, Clinical Center of Serbia in period of 10 years (2002. to 2012.) were identified. Using Kaplan-Meier and Cox regression survival analysis we evaluated different prognostic factors: gender, age, MS localisation, CD68 expression, treatment options (chemotherapy (CT), surgery as well as auto/alo hematopoetic stem cell transplantation (HCT)) as possible prognostic factors that determining survival in patients with MS. **Results.** In our group consisted predominantly of males (7m/4f) the mean patient age was 37. 3 years (range, 19-68). Affected sites were: lymphoid tissue (3 patients), female genital tract (2 patients), testicular tissue, spine, spleen, gastrointestinal tract, bone, hearth. Patients were treated with chemotherapy (n=6) or surgery (n=5) combined or not with adjuvant radiotherapy. In 3 patients HCT (2 alo, 1 auto) was performed. After CT a total of 3 patients (50%) achieved complete remission and one patient achieved partial remission. During follow up period 8 patients died. The Kaplan-Meier estimates of median overall survival was 14 months (range, 2-36) while event (AML development or extramedulary relapse) free survival was 8 months. The patients undergoing chemotherapy had a overall survival of 14 months while patients treated with surgery alone had a overall survival of 13 months (p>0,05). Also, patients on CT had significantly longer event free survival time compared to those who did not (18 months vs 4 months, respectively, Log Rank=7. 484, p = 0. 006). Cox regression analysis identified a significant association between chemotherapy treatment and event free survival (p=0,029; RR=0,089; 95%CI for RR=0,010-0,784). Other investigated prognostic factors did not outperform the survival model, while the age bellow 40 remained significant prognostic factors in combination with chemotherapy. **Conclusions.** Based on our study population, MS presence implies rather a systemic instead of a localized aproach with surgery or radiotherapy. Early diagnosis and start of chemotherapy as soon as diagnosis is established can help in disease control and may promote a longer progression free survival time in patients with MS. Given the rarity of MS, collaboration of multiple cooperative groups to create a registry, tissue bank, conduct uniform correlative laboratory studies, develop clinical trials, and generate treatment guidelines is required.

1241

ACUTE MYELOID LEUKEMIA (AML) IN ELDERLY PACIENTS. ANALYSIS OF 92 CASES

MS Infante[1], M Ballesteros[2], I Gonzalez-Gascón[3], P Font[4], F Carretero[5], G Rodriguez Macias[6], C Encinas[7], S Osorio[8], I Perez Sanchez[9], M Kwon[10], J Gayoso[11], A Escudero[12], J Diez Martin[13]
[1]Hospital Gregorio Marañon, Madrid, Spain
[2]Monica Ballesteros, Madrid, Spain

[4]Patricia Font, Madrid, Spain
[5]Fernando Carretero, Madrid, Spain
[6]Rodriguez Macias Gabriela, Madrid, Spain
[7]Cristina Encinas, Madrid, Spain
[8]Santiago Osorio, Madrid, Spain
[9]Isabel Perez Sanchez, Madrid, Spain
[10]Mi Kwon, Madrid, Spain
[11]Jorge Gayoso, Madrid, Spain
[12]Antonio Escudero, Madrid, Spain
[13]Jose Luis Diez Martin, Madrid, Spain

Introduction. Median age of patients with AML is 65 years and its incidence increases with age. Advanced age and associated morbidity hamper the selection of older patients to treat with intensive chemotherapy (QTi). Therefore, QTi is only offered to 30% of them. Results in terms of complete remission (CR), mortality and survival are worse than in younger patients. Poorer outcome and higher incidence of morbidities is associated with increased expression of the multidrug resistance gene, increased incidence of poor prognosis chromosome abnormalities and worse tolerance to QTi in this group. **Patients.** We describe 92 patients, 52 men and 40 women, all over 65 years, diagnosed with AML at our institution between June 2006 and Octuber 2011. M3 subtype was excluded. Median age was 76 years (63-95). 58. 6 % (54/92) were dismissed for QTi treatment due to advanced age and /or associated comorbidity. 41,3% (38/92) were selected for treatment with QTi. 17/38 (36%) had evolved from prior MDS. 8/38 (21%) had a complex karyotype at diagnosis. Induction chemotherapy was administered according to various regimens with the intention of completing 3 cycles in those who had achieved CR: IA (3X7): 5, attenuated IA (3x7): 20, IdaFLAG/FLAG: 9, Lenalidomide: 1 (with isolated 5q-), and 5-Azacitidine: 3. **Results.** Median overall survival (OS) of the total group was 5. 7 months. The OS of the patients treated with support therapy was 2. 5 months with a median hospital stay of 14 days, while the OS of the treated patients was 14. 9 months (4. 1- 25. 7), with a median hospital stay of 74 days. 55% (21/38) of patients undergoing QTi were resistant to treatment and all died. Of the remaining patients, 45% (17/38) achieved CR and all completed 3 cycles of treatment. Of these, 80% had been diagnosed of de novo AML and 20% had progressed from prior MDS. Only 1 of the 8 patients with complex karyotype achieved CR. The treatment-related mortality was 1/38 (3. 8%): one death in CR by aspergillosis. 13 of 16 patients (81%) relapsed and showed a median disease-free survival (DFS) of 18. 4 months (16- 20). 9 out of these 13 (58%) were rescued: 6 with QTi and 3 with 5-azacitidine. At the moment, 5/9 are still alive (all rescued with QTi). **Conclusions.** QTi induction treatment in elderly patients with AML prolongs survival in 11 months compared with supportive treatment and an acceptable median hospitalization stay. An adequate selection of patients for QTi treatment leads to a low mortality rate. The observed rate of resistance to QTi is similar to that described in the literature. Better responses are usually seen in patients with de novo AML and without poor prognosis cytogenetic.

1242

EVALUATION OF A PROSPECTIVE PROTOCOL OF THERAPY OF CHILDHOODACUTE MYELOID LEUKEMIA: A TUNISIAN MONOCENTRIC STUDY

O. Kassar[1], N. Ellouze[1], M. Mdhaffar[1], A. Lakhal[2], H. Bellaaj[1], N. Ajmi[1], S. Hdijji[1], L. Kammoun[1], A. Mahfoudh[3], M. Hachicha[3],T. Ben Othman[2], M. Elloumi[1]
[1]Department of haematology, CHU Sfax
[2]National Bone marrow transplantation center Tunisia
[3]Department of pediatrics, CHU Sfax

Background. Despite major achievements in the treatment of acute myeloid leukemia (AML) long term survival remains poor. About half of pediatric AML patients relapse and die. **Aims.** to study the outcome in children and adolescents treated with a local prospective protocol. **Methods.** Between January 2005 and December 2010, we analyze a prospective study, including patients, aged less than 20 years, diagnosed with AML, according to the WHO classification at department of hematology of Hedi Chaker hospital, Sfax. Secondary leukemia and FAB M3 were excluded. All patients treated with a protocol, contained an induction therapy: Ara-C (200mg/m^2/j on days 1-7) and Daunorubicine (60mg/m^2/j on days 1-3), if patients achieving complete remission (CR), consolidation therapy: 3 courses of consolidation chemotherapy (2courses with high dose cytarabine 18g/m^2/course+ Mitoxantrone or Asparaginase and 1 course withAraC200mg/m^2/j+Daunorubicine+Etoposide) or allogenic stem cell transplantation in presence of an HLA-identical family donor. We evaluated complete remission rate, toxic death induction, overall survival (OS) and event-free survival (EFS). The Kaplan-Meier method was used to estimate OS and EFS. **Results.** Twenty eight patients (15 girls and 13 boys) enrolled in our study. Mean age was 14. 3 years. WBC was >100000/mm^3 in 28%. According to the Medical Research Council's Trial (MRC): 5 patients were classified into favorable, 16 into intermediate group and 5 into unfavorable. Twenty patients (71%) achieved CR after one course. Five patients (18%) died during the induction therapy. Induction failure was observed in 3 patients (11%). Fifteen patients had a matched sibling donors but bone marrow transplantion was performed only in 4 patients. Relapse occurred in 6 patients (30%) in median of period 12 months. The overall survival and EFS are 44% and 40% at 5 years respectively. AML presenting with hyperleucocyosis than 100000/mm3 has been associated with high induction morality and had poor outcome. **Conclusions.** Despite significant improvement in outcome in pediatric acute myeloid leukemia in our

center, results of this protocol are still unsatisfactory. We need to improve them more by reducing induction mortality and more widely performed stem cell transplantation for patients achieving complete remission.

1243

DE NOVO ACUTE MYELOID LEUKEMIA (AML) IN ELDERLY AND EFFECTIVENESS OF INDUCTION THERAPY (IR)

S Gritsaev, I Martinkevitch, I Kostroma, M Ivanova, A Sergeev, L Martinenko, E Petrova, N Tsibakova, I Zapreeva, K Abdulkadirov
Russian Institute of Hematology, St. Petersburg, Russian Federation

Background. Complete remission (CR) is associated with prolong relapse free survival of AML patients. There are different ways to improve the results of IR therapy. The problem of the second IR is not solved till now. **Aims.** To evaluate the response to the first and the second IR therapy and reveal the predictors of treatment outcomes. **Methods.** A retrospective analysis of the outcomes of 93 patients with de novo AML (excluding APL) was performed. The first course of IR was "7+3"scheme with Ara-C 100 mg/m^2 1-7 days and daunorubicin 60 mg/m^2 1-3 days. If there was no CR the same IR course or course with Ara-C ≥1 g/m^2 per injection ± antraciclyne was started. **Results.** The median age of patients was 48 y. (17-76). The results of the first IR were next: 55 patients with CR (59. 1%), 31 patients with no response (33. 3%) and 7 patients were died during first 28 days (7. 5%). The median age of patients with CR, no response and who were died was 43, 52 and 56 y.; *p=0. 097*. The rate of CR of patients with good, intermediate and poor ELN karyotype was 94. 4%, 55. 0% and 33. 3%, respectively; *r=0. 377, p=0. 0001*. There was no response to the first IR in 38. 3% and 53. 3% patients with intermediate and poor karyotype, respectively; *r=0. 344, p=0007*. The early death was fixed in 5. 6%, 6. 7% and 13. 3%, respectively; *r=0. 083; p=NS*. Among 26 patients with normal karyotype the rate of CR was higher if there was no *FLT3-ITD* mutation in comparison with the presence of *FLT3-ITD* independently of NPM1 status: 73. 7% vs 42. 9%; *p=NS*. The results of the second IR were evaluated in 26/31 patients with no response to the first IR. There were 19 patients with intermediate karyotype and 7 patients with poor karyotype. 16 patients were treated with scheme "7+3"and 10 patients with high dose Ara-C. There were only 3 CR (11. 5%). All patients with CR after second IR have intermediate ELN karyotype. **Conclusions.** Second IR "7+3"is not advisable to de novo AML patients with intermediate karyotype in the absence of response to the 1 standard IR. The possible condition to improve the results of IR in AML patients with poor karyotype is adding new drugs, e.g. purine analogue.

1244

TREATMENT OUTCOME IN YOUNG PATIENTS WITH ACUTE MYELOID LEUKAEMIA

H Bellaaj[1], I Ben Amor[1], A Lakhal[2], L Kammoun[1], M Medhaffar[1], N Ajmi[1], C Kallel[3], O Kassar[1], S Mseddi[1], T Ben Othmen[2], M Elloumi[1]
[1]Hematology department, Hedi Chaker Hospital, Sfax, Tunisia
[2]Centre National de Greffe de Moelle Osseuse, Tunis, Tunisia
[3]Hematologic laboratory, Habib Bourguiba Hospital, Sfax, Tunisia

Background. Treatment of patients with acute myeloid leukaemia (AML) consists of an induction course followed by post remission consolidation. The post remission strategies for young patients are: intensive chemotherapy, autologeous stem cell transplantation, and allogenic haematopoietic cell transplantation. The choice of the optimal strategy is determined by a number of parameters including age, performance status, cytogenetic risk group and recently by molecular abnormalities. We report the results of a retrospective study in patients with AML treated in department of haematology of sfax (Tunisia). **Methods.** 60 patients are included from 2004 to 2009, aged between 20 and 55 years old. Patients with acute promyelocytic leukaemia or with histories of prior myelodysplasia are excluded. Cytologic diagnosis was performed according to the FAB classification. The chromosomal analysis was performed in all patients. The induction regimen was: Cytarabine 200mg/m2 continuous intravenous infusion for 7 days with Idarubicin 12mg/m2 (or Daunorubicin 45mg/m2 for 3 days). Consolidation strategy is based on cytogenetic classification, age and the obtaining of remission (CR) after one course, 3 groups are defined:Group1: favourable cytogenetic and CR after one induction (CR1)Group2: CR1 and intermediate cytogeneticGroup3: no CR1 and/or unfavourable cytogenetic* 3 cycles of high dose of cytarabine was proposed for patients included in group1* Patients bellow to group 2, 3 and patients bellow to group 1 and aged than 40 years old, received 3 courses of consolidation (ADE, MACE, and MIDAC)* An allogenic transplantation was proposed for patients < 40 years old with intermediate or unfavourable risk, when a HLA matched related donor is available. **Results.** The mean age was 36 years (20-55). FAB classification: M0 (4 %), M1 (20%), M2 (28%), M4 (18%), M5 (14%), M6 (3%), M7 (3%) and unclassified AML (10%) Karyotype: 16% low risk, 82% intermediate risk, 2 % high risk (MRC classification). The complete remission (CR) rate was 79 %, after one course it was 72 %. Death in induction was observed in 6 cases (10%). Primary failure was observed in 11 cases (18%). 36 patients received chemotherapy alone as consolidation. Only 11 patients undergo an allogenic transplantation in first remission. 4 deaths were noted in consolidation . The relapse rate was 33% (36% for patients treated with chemotherapy alone and 20% for who's received allogenic transplantation). Overall survival at 5 years was 44 %. **Conclusions.** We have better results than published in others local publications . However, it is required to improve the quality of hygiene and the supportive treatment to reduce mortality in CR, and performs allogenic hematopoietic cell transplantation to all AML patients with intermediate and unfavourable risk when possible.

1245

DEFERASIROX-ASSOCIATED SEVERE APLASTIC ANEMIA

T Zudaire, MC Mateos, JM Arguiñano, M Lasa, J Coll, M Aznar, MA Ardaiz, Y Burguete, M Perez-Salazar, M Redondo, MJ Paloma, I Ezpeleta
Complejo Hospitalario de Navarra B, Pamplona, Spain

Background. Deferasirox is an iron chelating agent approved for the treatment of trasfusional iron overload. Pancytopenia is a well-known side effect mostly reported during post-marketing surveillance. True incidence of this complication remains unknown but all reported cases are mild to moderate. There have been no published cases of bone marrow aplasia to date. **Case Report.** We report the case of a 53 year old male with a medical history of myocardial infarction and unstable angina, as well as a locally advanced prostatic adenocarcinoma, treated with radiotherapy and androgen blockade, in remission at the time of hematology unit admittance. In June 2010 he was diagnosed with acute promyelocytic leukemia, carrying typical t(15;17) translocation. Patient was allocated to low risk group in Spanish Pethema LPA-2005 protocol, and therapy started. During induction therapy, several blood units were transfused in order to maintain a safe hemoglobin level and to avoid ischaemic angina. After consolidation therapy complete remission was assessed through bone marrow morphology and cytogenetics, both found to be normal, as well as a negative PCR detection for PML-RARalpha mRNA. Maintenance therapy was started in November 2010 with daily mercaptopurine and weekly methotrexate as well as intermittent ATRA. Doses were adjusted to maintain an absolute neutrophil count above 1500/µL, and by September 2011 doses of mercaptopurine (50 mg daily) and methotrexate (15 mg weekly) had been stable for several months. Iron status assessment showed a serum ferritin level of 2092 ng/mL; then iron chelating therapy with deferasirox was started at a dose of 500 mg once a day, aiming to a slow raise. In December 2011 bone marrow was obtained through aspiration and molecular absence of PML-RARalpha confirmed. Bone marrow cellularity was judged to be normal for patient age and no morphologic abnormalities were found. Blood platelet count was slightly decreased to 79,000/µL, but no dose adjustements in maintenance therapy were required according to Pethema LPA-2005 protocol. Deferasirox dose had been escalated to 1250 mg daily in January 2012, when severe pancytopenia was detected. The patient complained of petecchiae and bruising as well as severe asthenia and fever. Hemoglobin was 7,7 g/dL, leucocytes 300 with neutrophils 100/µL and platelets 5,000/µL. The patient was admitted to hospital for antibiotic therapy; etiologic studies for pancytopenia showed absence of hematopoietic cells, resulting in a diagnosis of severe bone marrow aplasia. Deferasirox, mercaptopurine and methotrexate were stopped, and pegylated GCSF administered as well as erythropoietin. Seven days after deferasirox withdrawal blood counts returned to normal, fever disappeared and the patient was fully recovered. Aplastic anemia was thought to be caused by deferasirox since no dosage variations had been made to mercaptopurine and methotrexate. These were soon reintroduced at former dosage with no substantial decrease in blood counts. **Conclusions.** clinical scenarios in which deferasirox is being used are increasing. As any new drug, further side effects and drug interactions might appear in the future. Post marketing surveillance essential to know actual risk associated with new drugs

1246

ACTIVATION STATE OF PLATELET IN EXPERIMENTAL SEVERE HEMOPHILIA A

M Teyssandier[1], S Delignat[2], J Rayes[2], S Kaveri[2], S Lacroix-Desmazes[2]
[1]INSERM U872, Paris, France
[2]INSERM U 872, Paris, France

Hemophilia A (HA) is a rare X-linked hemorrhagic disorder consecutive to the absence of endogenous pro-coagulant FVIII. Abnormal FVIII levels are asso-

ciated with the development of crippling arthropathy and with elevated morbidity and risk of death. Depending on the residual activity of FVIII in plasma, HA is classified as severe, moderate or mild. Although this classification correlates with the bleeding phenotype, about 10% of severe HA patients rarely bleed spontaneously, indicating that FVIII activity is not the only parameter defining the phenotypic severity of the disease. Recently, van Bladel et al investigated the basal state of activation and responsiveness of circulating platelets as a potential parameter influencing the bleeding phenotype in patients with HA. They found that the state of activation of platelets is up-regulated in patients with severe HA, as compared to patients with mild/moderate HA and to healthy donors. An earlier report from Grünewald et al had however failed to find signs of enhanced platelet pre-activation in patients with severe HA. In order to address this question *in vivo* in a system that is not 'perturbed' by differences in genetic or environmental factors that are typical of the human population, we thus compared the states of activation and responsiveness of platelets from wild-type mice and from FVIII-deficient mice, an experimental model of severe HA. Our results indicate that the absence of pro-coagulant FVIII in un-manipulated adult animals is associated neither with alterations in the activation status of circulating platelets nor with their ability to be activated.

1247

HEMORRHAGIC DIATHESIS IN THREE PATIENTS WITH NORMAL HAEMOSTASIS TEST

I Parra Salinas, B De Rueda Ciller, N Fernandez-Mosteirin, M Torres Gomez, J Lucia Cuesta, D Rubio Felix
Miguel Servet Hospital, Zaragoza, Spain

Background. Deficiency of F XIII is very infrecuent, it can cause spontaneous CNS haemorrhage in 30% of patients. The acquired form is very aggresive and may cause haemorrhages with mild reduction in factor levels; it appears frecuently in physiological stress circumstances (surgery, traumatism and disseminated intravascular coagulation) or by a non-antibody mediated drug-induced (statin, valproate) reduction. Is being the most frecuent underdiagnosed coagulopathy because the fact of normal routine test. We describe a serie of 3 cases of acquired deficit in our center. **Case 1.** 33-months oldchild with LAL-B under induction chemotherapy that 72hours later develops lowered level of consciousness and cardiorespiratory arrest after mild craneoencephalic trauma. Cardiopulmonary ressucitation and tracheal intubation were needed. Cranial CT scan: left subdural haematoma with active bleeding and secondary uncal herniation. Bleeding was controled with neurosurgical drainage. Clotting studies were requested because of minor head trauma. Haemostasis test: Fibrinogen: 5,1 g/L, Von Clauss Fibrinogen: 2,3 g/L, D-dimer: 1083 µg/L, Antithrombin III: 145%, Thrombin time: 23,9", Reptilase time: 22,7", XIII factor: *42,8%* with negative qualitative inhibition study. Treatment: 4 days administration of fresh frozen plasma (FFP) (10 mL/kg) to achieve levels of factor around 60%. Levels were normalized on 21th day of hospitalization and patient developed residual spastic tetraparesis but reached medular complete remission of LAL. **Case 2.** 77-years old man with aortoiliac aneurysm and left hypogastric artery embolization, admited at the hospital to aneurysm endoprothesic surgery. Torpid postoperative period with endoleak and incoercible inguinal haemorrhage requiring transfusion of 26 U of red blood cells and 1 platelet pool. Haemostasis test: Fibrinogen: 2,8 g/L, Von Clauss Fibrinogen: 1,6 g/L, D-dimer: 3476 µg/L, Antithrombin III: 81%, Thrombin time: 27,5", Reptilase time: 21", XIII factor: *42%*. Treatment: infusion of 9 FFP units, suspensión of prophylactic anticoagulation and antiaggregation therapy until bleeding control, suspension of statin and local compression. On 20th day of postoperative period levels of factor become at normal values with subsequent good progress. He was discharged on 78th day with a normal bypass functioning. **Case 3.** 72-years old man with recently right femoral pseudoaneurysm surgery, admited at the hospital to study a 12 cm nonpulsatile mass localized on surgery zone. He needed surgical drainage of haemathoma and developed torpid postoperative period requiring transfusion of 6 U of red blood cells and various antibiotic treatments because of wound infection. Haemostasis test: Fibrinogen:2,4 g/L, XI factor: 84,8%, XIII factor: *38,2%*. Treatment: infusion of 10 FFP units, iron therapy, recombinant human erythropoietin and tranexamic acid**.** Levels of factor reached normalization on day 15 after FFP infusion. **Conclusions.** the diagnosis of F XIII deficiency requires a high clinical suspicion and it must be considered in patients with recurrent bleeding in postoperative period as well as in patients receiving statin or valproate therapy in spite of normal standard coagulation tests. To define if routine preoperative F XIII activity screening is a cost-effective policy remains at present undefined requiring further research in this setting.

1248

CUTANEOUS HYPERSENSITIVITY REACTION FOLLOWING THE USE OF TWO RECOMBINANT FACTOR VIII PREPARATIONS, KOGENANTE® BAYER AND ADVATE®: A THERAPEUTIC CHALLENGE SOLVED BY FACTANE®

B Polack, R Marlu, C Armari-Alla, P Pouzol, C Barro
CHU de Grenoble, Grenoble cdx 9, France

Backgroud. A severe hemophilia A boy was started prophylaxis when he was 9. 5 months old using 250 UI twice a week of Kogenate® Bayer for cutaneous bleedings. Dose was rapidly increased to 500 UI twice a week. However, at 9 CED and 3500 IU of Kogenate® Bayer an inhibitor was detected at a level of 104 BU. He was then shifted to NovoSeven® on demand for 316 days until inhibitor level was 2. 5 BU. Immune tolerance induction was then started with Kogenate® Bayer at a dose of 93 IU/kg twice a day. After the 2nd infusion, he developed an urticaria allergic reaction. Despite the use of antihistaminic and prednisone, urticaria reaction was higher for the subsequent infusion. Methods. After discussions with the French hemophilia reference center it was decided to replace Kogenate® Bayer with Recombinate® at the same dose. We took the precaution to maintain antihistaminic and prednisone for the first infusion of Recombinate®. However, despite this preventative measure a very similar urticaria reaction was observed. Since these two recombinant factor VIII were from different cell lines (BHK and CHO) but both purified with monoclonal antibody affinity column, it was then decided to try to pursue the immune tolerance induction using a highly purified plasma derived factor VIII that was not using monoclonal antibody in its process. Factane® was then used at the same dose. **Results.** No cutaneous reaction was observed, and immune tolerance induction was fulfilled in 351 days with Factane®. **Conclusions.** With a follow up of two years, he is still with a normal recovery, a half life > 8 h and an inhibitor < 0. 6 BU under a well tolerated prophylaxis using Factane®.

1249

PSYCHOSOCIAL IMPLICATIONS OF THE DIAGNOSIS OF HEREDITARY THROMBOPHILIA

G Mihaescu[1], R Stoian[2], M Gug[3], S Mozos[3], N Gruici[3], P Serban[3]
[1]University of Medicine of Timisoara, Timisoara, Romania
[2]Oncomed, Timisoara, Romania
[3]UMFT, Timisoara, Romania

Background. Thrombophilia is an inappropriate tendency to thrombus formation. Its causes are hereditary or acquired and often may be associated. In recent years numerous studies were conducted in the field of heritable and acquired thrombophilia, in an attempt to prevent the consequences of thrombotic disease. However, there are few studies to evaluate impact of diagnosis on quality of life and socio-economic implications of this situation. **Aims.** Our aim was to evaluate the psychological impact of the diagnosis of hereditary thrombophilia on the patients. **Methods.** Between 02. 2010-01. 2012 in Oncomed Timisoara we evaluated 104 patients with thrombophilia, 94 women and 10 men. A questionnaire was given to every patient, to assess the quality of life. **Results.** There was a major difference between men and women, all men had a normal life, without any thoughts about the disease. All of them were taking 75 mg of aspirin per day, without any other concomitant medication. Their emotional well-being score was the same with the score of general population. Between women, only 70 patients accepted to answer the questionnaire. This can be explained by the implication of thrombophilia diagnosis in women and the anxiety they felt about their disease and the failure to conceive. All non-pregnant women were taking 75 mg of aspirin (70) and all pregnant women were taking LMWH in different doses according to weight (24). Among pregnant women, emotional well-being score was not different than in general population, but was better than in women who did not achieve pregnancy. These women were having thoughts of hope- 70%, but 85% of them felt frustration and 27% - fatigue. Differences in QOL were observed by number of miscarriages, the patients with more than 2 miscarriages were more depressed than those with one miscarriage or none. Factors associated with lower quality of life included age, severity of co-morbid health conditions (other obstetrical conditions) and number of miscarriages and thrombophilia type (those with homozygous condition felt more depressed). None of them resigned or were expelled due to low quality of daily work**. Conclusions.** Thrombophilia has a profound impact on QOL of patients. This result shows that a close collaboration between hematologist, gynecologist and psychologist is the key to a good quality of life for these patients.

1250

DABIGATRAN INTERFERENCE IN FOLLOW-UP OF ANTI-THOMBIN EFFECT OF MONOCLONAL IMMUNOGLOBULIN

J Devignes[1], M Martin[1], M Toussaint-Hacquard[1], V Eschwege[1], C Hulin[2]
[1]Biological Haematology Service, University Hospital Center of Nancy, Vandoeuvre-les-Nancy, France
[2]Haematology service, University Hospital Center of Nancy, Vandoeuvre-les-Nancy, France

Introduction. In case of monoclonal anti-globulin, haemostatic disorders as anti-thrombin (anti-IIa) effect can be observed. Haemorrhagic syndrome can happen. In other hand, dabigatran, new oral anticoagulant treatment, with reversible direct anti-IIa effect, is administrated without biological follow-up, prolonges usual coagulation time. In this case is reported an interference of dabigatran on haemostasis tests for checking anti-thrombin effect of a monoclonal immunoglobulin. **Observations.** A 74 year-old female followed for a IgG Kappa (28. 9 g/L) myeloma benefits from a preoperative assessment of haemostasis before a total knee prosthesis (TKN). The activated partial thromboplastin time (APTT) Patient (P)/Control (T) (48/30 seconds), the prothrombin time (PT) P/T (20/13 seconds), and the thrombin time (TT) P/T à 163/20 are prolonged. The fibrinogen dosage (von Claus method) is low (1. 2 g/L; 2. 5-4. 5 g/L) . A normal reptilase time with prolonged TT without unfractionated heparin points out a anti-thrombin effect of the monoclonal immunoglobulin. The patient has no sign of haemorrhagic diathesis and considering these results, the surgery is reported. A first remission of myeloma is achieved after 12 months of chemotherapy with Alkeran®, Cortancyl® et Velcade®. The APTT is then P/T 38/30 s, the PT is 14 s, TT P/T 74/20 s and fibrinogen 2. 4 g/L, with a stable electrophoretic peak of 15 g/L. Two months later, haemostasis tests show again a prolonged APTT à P/T 74/30 s, a prolonged TT >180 s and a normal TR. Anti-Xa activity is lower than 0. 1 UI/mL without increase of the electrophoretic monoclonal peak (14. 5 g/L). The thrombin generation assay shows a profile compatible with a direct anticoagulant anti-IIa. After discussion with physician in charge of the patient about the discordance of prolonged APTT and lack of increase of the electrophoretic monoclonal peak, the information was given that the TKN has been done without any complication and that the patient undergoes a prophylactic treatment by dabigatran after the surgery. **Conclusions.** This case report is an example of the possible difficulties of the interpretation when a new oral anticoagulant treatment is given which, because of the lack of need for laboratory monitoring may not be filled by prescribers.

1251

DESMOPRESIN TEST IN A CASE OF SEVERAL BLEEDING DISORDERS IN NOONAN SYNDROME: LITERATURE REVIEW AND A CASE REPORT

F Lopez Jimenez
Virgen de las Nieves University Hospital, Granada, Spain

Background. Noonan Syndrome (NS) is a common genetic disease with multiple organ defects. Bleeding diathesis is considered part of the clinical findings with a prevalence of 1/1,000 to 1/2,500. The syndrome was first described in 1963 by Noonan and Ehmke. The hematologic disorders associated with this syndrome were last reviewed in 2011 by Benjamin J. Briggs, and Joseph D. Dickerman. Four etiologies are postulated to explain the NS bleeding disorders: thrombocytopenia, platelet dysfunction, VWD, and factors deficiencies. NS often combine several bleeding disorders, therefore, if a patient has one bleeding disorder is expected to have another. A large number of patients with NS require surgery for congenital heart disease, cryptorchidism, lymphatic vessel anomalies or cosmetic reason. Therefore is clinically important a knowledge of bleeding disorders in NS. **Aims.** Provide a case to make it available for both pediatricians and hematologists professionals in their clinical practice since there is little literature about. MethodsA four years old patient diagnosed of NS and mild pulmonary valve stenosis was derived to coagulation unit from pediatric surgery for active bleeding started 48h after surgery of right cryptorchidism. **Results.** Coagulation study revealed an elongated APTT ratio of 47. 20 sec, the rest of results are shown below:VWF:Ag:62. 90%, VWF:RiCof: 48. 20%, FII:120. 70%, FV:105. 30%,FVII:94. 80%, FVIII:103. 40%,FIX:106. 3%,FXI:106. 80%,FX:122. 10%,FXI:106. 80%, FXII:79. 70%, FXIII:65. 50%, circulating antibody negative. A slight deficiency of VWF and FXIII was detected and we performed an intranasal DDAVP test. The results are summarized in Table 1. **Conclusions.** NS often combine several bleeding disorders, therefore, if a patient has one bleeding disorder is expected to have another as shown in this case. There are no standard treatments for bleeding complications in patients with NS and recommendations regarding management are derived from case studies. The perform of desmopressin test may be useful in patients with Von Willebrand mild factor deficiency and Noonan Syndrome to show its effectiveness as antihemorrhagic treatment in case of surgery or spontaneous bleeding. A hematological investigation, especially prior to an invasive procedure, is required with some frequency in this disorder to avoid bleeding complications.

Table 1.

DESMOPRESIN TEST				
	Basal	One hour after	Four hours after	Normal Laboratory values
VWF:Ag	46.40 (57-170)	92.80	95.60	(57-170)
VWF:RICof	39.70 (50-150)	96.20	77.30	(50-150)
F VIII %	96.10 (70-150)	379.60	227.40	(70-150)
PT %	95.70 (70-130)	90.40	83.50	(70-130)
aPTT sec	36.70 (25-38)	27.60	30	(25-38)
aPTT ratio	1.20 (0.80-1.20)	1.10	1.00	(0.80-1.20)
PFA ADP	117 (71-118)	217	97	(71-118)
PFA Norepinephrine	166 (94-193)	72	99	(94-193)

1252

SUCCESSFUL USE OF RECOMBINANT ACTIVATED FACTOR VII FOR A MAJOR SURGERY IN A PATIENT WITH SEVERE FXI DEFICIENCY AND SEVERE ALLERGIC REACTION TO FRESH FROZEN PLASMA

A Unuvar[1], E Hocaoglu[2], A Ozguven[1], S Yazar[2], O Devecioglu[1]
[1]Istanbul University School of Medicine, Dep. of Pediatric Hematology&Oncology, Istanbul, Turkey
[2]Istanbul University School of Medicine,Dep. of Plastic and Reconstructive Surgery, Istanbul, Turkey

Severe congenital FXI deficiency is the commonest of the rare bleeding disorders. In contrast to hemophilia A or B, bleeding tendency in FXI deficiency do not correlate with FXI level. Therefore, optimal management of the patients with FXI deficiency is difficult. In addition, the bleeding risk for a surgery depends upon the type and the site of surgery and increases in high fibrinolytic areas such as the mouth, and nose. Several therapies such as fresh frozen plasma (FFP), FXI concentrate, fibrin glue, antifibrinolytic drugs are available for these patients. In the last years, the successful use of recombinant activated factor VII (rFVIIa) has been reported in a very limited number of cases, including those with inhibitors. This is an off-label use of this product. The dose of treatment and the duration has varied greatly between these case reports. In this case report, we present our successful experience with the use of rFVIIa for repairing the alveolar cleft and anterior palatal fistula in a 7-year-old boy with severe congenital FXI deficiency and severe allergic reaction to FFP. The patient was born to first degree consanguineous parents with the clefts of lip and palate. He was diagnosed as a severe congenital FXI deficiency (FXI:C level 0. 2%) after the bleeding from the cleft lip repair surgery when he was 6 months old. First successful cleft palate surgery was done with FFP concentrates and tranexamic acid, when he was 18 months old baby. He was followed-up in our unit. The repairing surgery of alveolar cleft and anterior palatinal fistula was planned when he was 6. 5 years old. However, severe allergic reaction developed during FFP infusion at the dental extraction before surgery. For this reason, we planned to use of rFVIIa for his surgery. Tranexamic acid was started orally every eight hours the day before surgery, and was given intravenously two hours before surgery, and rFVIIa was given 40 µg/kg one hour before surgery. Secondary alveolar bone grafting technique was performed under general anesthesia for the patient who was in his period of mixed dentition. Ilium was chosen as the donor site for obtaining autogenous cancellous bone grafts. The second dose of rFVIIa was given 4 hours later after the first dose, and the dose of rFVIIa was reduced to 20 µg/kg, and continued at 6 hourly intervals for the first day, 8 hourly for the second day, 12 hourly for the 3rd and 4th day, and once a day for 5th and 6th day at the same dosage. Tranexamic acid was given until to 10 days after the surgery. No excessive bleeding or thrombosis were observed. In conclusion, low-dose rFVIIa therapy was successfully used for a major surgery in our patient with severe FXI deficiency and severe allergic reaction to FFP. However, treatment safety is a major concern and the best dosing regimen of this off-label drug is still to be defined for the selected patients.

1253

SPONTANEOUS RUPTURE OF SPLEEN IN A CHILD WITH EWAN'S SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS

H Tokgoz, U Caliskan, B Atas, O Ozbek
Konya University Meram Faculty of Medicine, Konya, Turkey

Background. Spontaneous rupture of spleen is a rare but documented complication of hematologic, infectious and neoplastic diseases. Splenic involvement has been reported in collagen vascular diseases and vasculitis, but splenic rupture is extremely rare. Because of high mortality rate, early diagnosis and treatment are life-saving. In patients with systemic lupus erythematosus (SLE), the management of splenic rupture may be difficult because of thrombocytopenic conditions. Herein, we report a case of spontaneous splenic rupture which occurring background of SLE and Ewan's Syndrome. **Case Report.** A previously healthy 15 year-old boy was referred to our clinic because of pancytopenia. Physical examination revealed paleness, jaundice and mild splenomegaly, 1 cm below left costal margin. Laboratory results included white blood cell count of 2. 3x109/L, hemoglobin level of 6. 5g/dl, platelet count of 12x109/L. Normoblastemia, reticulocytosis, indirect hyperbilirubinemia and positive direct antiglobulin test which were showing autoimmune hemolytic anemia were detected. Urine analysis showed hematuria and proteinuria. Serum levels of kidney function tests (urea, creatinin) were in normal range. Bone marrow examination revealed that erythroid hyperplasia, increased number of early megakaryocytic cells, rare thrombocytes and no maling infiltration. Bilateral pleural effusion was seen on chest X-Ray. Antinuclear antibody and anti-double stranded DNA were positive. These findings were consistent with Ewan's syndrome which occurring background of SLE. Steroid treatment initiated to patient, but no clinic and hematologic response achieved. Cyclophosphamide was added to therapy on day 7. On the 10th day of hospitalization, he was clinically shocked with tachypnea, tachycardia and hypotension. Abdominal distension with tenderness of left upper quadrant was present on his abdominal examination. Spontaneous rupture of spleen and intraabdominal hemorrhage were detected by abdominal ultrasound and computerized tomography scan (Figure 1). There was no history of trauma. Simultaneously, complete blood count revealed that white blood cell count of 2. 6 x109/L, hemoglobin level of 5. 8g/dl, platelet count of 12x109/L. Prothrombin time (12 sec) and activated partial thromboplastin (28 sec) time were in normal range. Immediate fluid resuscitation was applied, he transfused with 2 units of packed red cells and 1 unit of platelet suspension prepared by method of apheresis because of life-threatening bleeding. Although the severe thrombocytopenia, intraabdominal hemorrhage were controlled successfully without any additional transfusion. The patient did not need to abdominal surgery, because the patient's hemoglobin levels did not decrease anymore. The patient's vital signs were gradually improved. In the following period, intraabdominal bleeding was resorbed at day14. Plasmapheresis was applied to patient when the patient's situation was convenient. The patient's cytopenias were improved at the end of one month of therapy. **Conclusions.** Our case indicates that splenic rupture may occur in the course of SLE even without massive splenomegaly. The control of bleeding may be difficult in the presence of Ewan's syndrome and thrombocytopenia. If a patient with non-traumatic splenic rupture, hemodinamically stable, conservative treatment may be preferred to avoid surgical complications. Serial ultrasound or computerized tomography scan are useful to monitoring of the resolution of the intraabdominal bleeding and the healing of the spleen.

Figure 1. Axial CT image showing splenic rupture.

1254

ESTABLISHMENT OF KOREAN STANDARD FOR BLOOD COAGULATION FACTOR IX CONCENTRATE

YK Lee, DH Ryu, SJ Ban
Korea Food and Drug administratoin, Chungbuk, South-Korea

Background. National Standard for Factor IX had not been established yet in Korea and the working standard plasma material was used as replacement for the reference standard to measure factor IX potency. It has different factor IX content on every batch and there are other coagulant factors besides IX. **Aims.** A collaborative study among four laboratories including three manufacturers and one national control laboratory was carried out to evaluate the suitability of a candidate to serve as the 1st Korean Standard for blood coagulation factor IX. **Methods.** The candidate material for national standard was manufactured according to the WHO guideline for biological standards and the Minimum Requirements for Biological Products in Korea, issued by KFDA. It was distributed to four laboratories and assayed using a one-stage clotting assay with two kinds of equipments against the 4th International Standard for FIX Concentrate (07/182) to determine the potency of this candidate. Accelerated thermal degradation at -20, 4, 20, 37, 45℃ and the real-time stabilityuntil 18 months for long-term storage were examined. The 3rd IS for Blood Coagulation Factors II, VII, IC and X, Plasma, Human (99/826) and Standard Human Plasma was also included to evaluate the relationship between the factor IX plasma and concentrate unitage. **Results.** One hundred thirty-one sets of clotting assay results were analysed. Based on the data collected from all participants, intra-laboratory variability was found to range from 2 -5. 55% and good inter-laboratory agreement with the majority of GCV around 5% was obtained. Stability studies indicated that the candidate was very stable. The way to measure the clotting time depends on the equipment showed little differences on the potency value. The estimated mean value obtained from the one-stage clotting assay was 12 international units (IU)/vial. **Summary and Conclusions.** As the result of this collaborative study, the candidate standard is adopted as the 1st Korean National Standard for Blood coagulation factor IX, concentrate. It is expected to contribute the globalization of quality control in factor IX product by establishing the national standard.

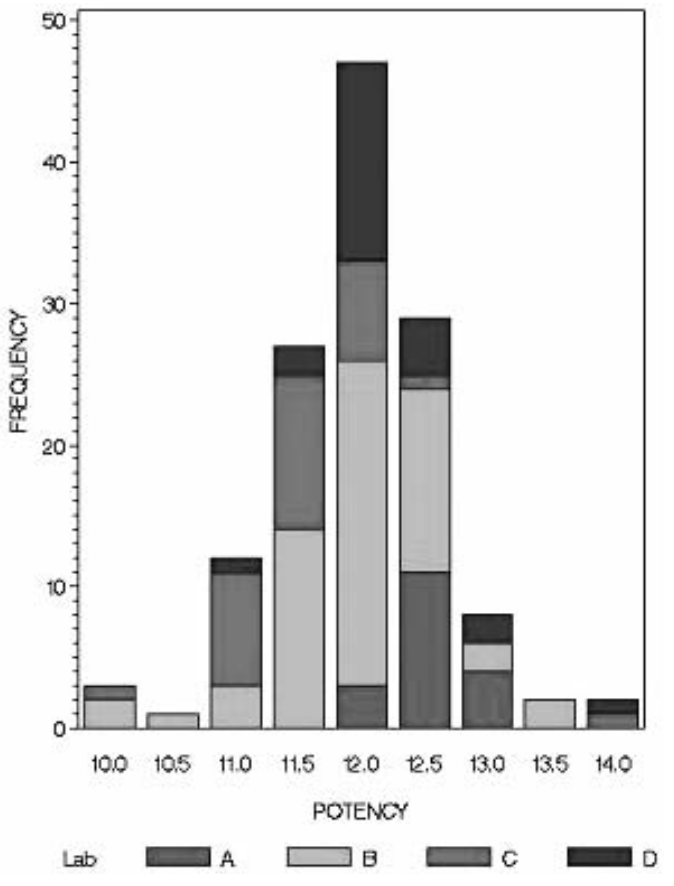

Figure 1. Histogram of potency estimates by laboratory.

1255

HEMATOLOGICAL MANIFESTATIONS OF NOONAN SYNDROME: A CLINICAL CASE

R Lopes[1], S Morais[1], S Alvares[2], E Costa[3], J Barbot[4]

[4]De Hematologia Pediátrica do CHP - Unidade Maria Pia, Porto, Portugal

Background. Noonan syndrome is a congenital disorder with multisystemic achievement that, in addition to cardiac involvement (congenital heart defects and heart disease), gastrointestinal, mental and growth retardation and dysmorphic facies, also affects platelets (number and function) and the coagulation system, with hemorrhagic manifestations described in the literature as easy bruising, epistaxis and menorragias. The bleeding can be significant during and after surgical procedures. **Aims.** Description and analysis of a clinical case, focusing on the clinical and hematological findings in a female teenager with Noonan syndrome waiting for cardiac surgery. **Methods.** Collection of clinical data contained in the medical record of the patient and review of recent literature. **Results.** The authors present the case of a 13 year-old teenager that had since newborn age a dismorfic syndrome associated to a left ventricular hypertrophic cardiomyopathy. Hematologically she presented a severe thrombocytopenia, moderate anemia without other cytopenias and slight increase of hemoglobin F. The diagnosis of Fanconi Anemia was excluded. The former diagnosis was Amegakaryocytic Thrombocytopenia face to the presence of no megakaryocytes in bone marrow. Paradoxically along the years the platelet count showed a progressive increase. At four years of age the diagnosis was reviewed to Hipomegakaryocytic Thrombocytopenia. The platelet count stabilized at 100000/mm^3, but with the presence of a moderated hemorrhagic syndrome. There is maintenance of a mild anemia, without leucopenia or neutropenia, and the levels of hemoglobin F became normal. At 12 years-old the diagnosis of Noonan Syndrome was considered and confirmed at molecular level. At this time hemostasis was reevaluated. This study showed an abnormal APF-100 test (Colagen/ADP>246,0 sec. and Colagen/Epinephrine>280,0 sec.) disproportionate to the value of thrombocytopenia, suggesting platelet dysfunction. This platelet dysfunction was confirmed by platelet aggregation studies. The assay of FVIII: C was normal. The von Willebrand factor (vWF) despite being quantitatively normal (vWF: Ag - 82. 5%) had impaired function (vWF: RCo - 43. 9%). This evaluation is currently of particular importance since the child is waiting for heart surgery. **Conclusions.** The authors highlight the need to evoke the Noonan Syndrome facing an unexplained thrombocytopenia, especially if associated with a dysmorphic syndrome and/or disproportionate hemorrhagic symptoms. They also emphasize the importance of a careful investigation in these patients, performing coagulation screening tests, especially before surgical procedures, often needed in this disorder. The hematologist can play a key role in appropiate evaluation and management

Table 1. Hemostasis tests results.

Test	Result	Reference values
Activated partial thromboplastin time (APTT)	34.2 sec.	27.9 sec.
	1.21 Ratio	
Prothrombin time (PT)	12.7 sec.	10.1 sec.
INR (International Normalized Ratio)	1.09	
FVIII: C	98.00 % of N	
FvW: Rco	43.9 % of N	
FvW: Ag	82.5 % of N	
Platelet Count	100000/µL	
APF100 Colagen/Adenosine Diphosphate (ADP)	> 246.0 sec.	56 a 120 sec.
APF100 Colagen/Epinephrine (Col/Epi)	> 280.0 sec.	106 a 146 sec.
Aggregation with colagen (2µg/mL)	Normal	
Aggregation with ADP (10µM)	Normal	
Aggregation with ADP (20µM)	Normal	
Aggregation with arachidonic acid (1mM)	Normal	
Liberation of ATP* (Agonist: Colagen)	Normal	
Liberation of ATP (Agonist: ADP)	Absent	
Liberation of ATP (Agonist: ADP 20µM)	Absent	
Liberation of ATP (Agonist: Arachidonic Acid)	Decreased	
Agglutination with ristocetin (1mg/mL)	Normal	
Agglutination with ristocetin (0.5mg/mL)	No Agglutination	

Note - Platelet count in platelet-rich plasma - 104000/µL
* Adenosine triphosphate

SURGICAL INTERVENTIONS IN OUR HEMOPHILIA PATIENTS

Z Salcioglu[1], A Akcay[1], H Sen[1], N Aktay Ayaz[1], D Tugcu[1], G Aydogan[1], F Akici[1], M Demirkaya[1], S Sander[2], G Aydin Tireli[2]
[1]Kanuni Sultan Süleyman Education and Research Hospital, Pediatric Hematology, Istanbul, Turkey
[2]Kanuni Sultan Süleyman Education and Research Hospital, Pediatric Surgery Clinic, Istanbul, Turkey

Surgical procedures in hemophilia patients may be performed safely as in healthy individuals by providing appropriate factor therapy and preperation. Abnormal tests of haemostasis prior to surgery may cause anxiety and hesitancy in surgical team. Inspiration of confidence to surgeons by hematologists may help overcoming this situation. 158 surgical prosedures performed in various surgical clinics, on 83 hemophilia patients followed up in our clinic between 1990-2011, were evaluated retrospectively. Of these patients 71 were hemophilia A (3 with inhibitor) and 12 were hemophilia B. The ages at the admission were between 2 months-18 years. Of these patients 51 had severe, 14 had moderate and 18 had mild hemophilia. Performed procedures include; r*adioisotope synovectomy (*54 patients), circumcision (50 patients), tooth extraction (23 patients), various orthopedic interventions (14 patients), drainage of in central nervous system hematomas (7 patients), appendectomy (3 patients) and other various procedures (7 patients). In 44 surgical procedures antifibrinolytic agents were also used in addition to factor replacement therapy. Six patients were diagnosed due to prolonged bleeding during or after surgical procedure. Postoperative late bleeding was encountered and treated in four patients. None of our patients died due to bleeding and antibody development was not observed in any patients. In our report, preparation for surgical procedures, factor replacement prior and after surgery, and postoperative complications in hemophilia patients are discussed.

1257

CONTINUOUS ACTIVE STATE OF COAGULATION SYSTEM IN PATIENTS WITH NONTHROMBOTIC INFLAMMATORY BOWEL DISEASE

S Ayaz[1], H Alkim[2], C Alkim[3], A Ulker[4], B Sahin[4]
[1]T Yuksek Ihtisas Hastanesi, Ankara, Turkey
[2]Bakirkoy Dr Sadi Konuk Training and Research Hospital,, Istanbul, Turkey
[3]Sisli Etfal Training and Research Hospital, Istanbul, Turkey
[4]Turkiye Yuksek Ihtisas Teaching and Research Hospital, Ankara, Turkey

Aims. This study was planned for searching possible changes of the total coagulation and fibrinolysis system in inflammatory bowel disease (IBD) in order to obtain some clues for explaining the relation between IBD and hypercoagulability. **Methods.** A total of 24 patients with ulcerative colitis, 12 patients with Crohn disease, and 20 healthy controls were studied. Platelets; prothrombin time (PT); partial thromboplastin time (PTT); fibrinozgen; D-dimer; fibrinogen degradation products; protein C; protein S; antithrombin; thrombin time; von Willebrand factor; coagulation factors V, VII, VIII, IX, XI, and XIII; plasminogen; antiplasmin; tissue plasminogen activator; plasminogen activator inhibitor 1; and prothrombin fragments 1 + 2 were studied. **Results.** Most of the procoagulants (platelets, fibrinogen, von Willebrand factor, coagulation factor IX, and plasminogen activator inhibitor 1) were found increased together with decreases in some anticoagulants (protein S and antithrombin) in IBD. Also the activation markers of coagulation D-dimer, fibrinogen degradation products, and prothrombin fragments 1 + 2) were all increased. **Conclusions.** The parameters of the total coagulation-fibrinolysis system were increased in IBD, regardless of the form and the activity of the disease.

1258

SUCCESSFUL PROPHYLACTIC USE OF RECOMBINANT ACTIVATED FACTOR VII (RFVIIA) IN A PATIENT WITH CONGENITAL FVII DEFICIENCY AND INHIBITORS TO FVII

H Tokgoz[1], U Caliskan[1], G Lavigne-Lissalde[2], M Giansily-Blaizot[3]
[1]Konya University Meram Faculty of Medicine, Konya, Turkey
[2]SysDiag CNRS/Bio-Rad, Parc Euromédecine, Montpellier, France
[3]Hôpital Saint-Eloi, Montpellier, France

Background. Congenital factor VII (FVII) deficiency is a rare, autosomal recessive bleeding disorder. The clinical phenotypes range from asymptomatic condition to severe disease characterized by life-threatening bleeds including intracranial hemorrhage (ICH) or gastrointestinal bleeds. **Case Report.** A 3-month-old boy presented with intracranial haemorrhage and was diagnosed

with severe congenital FVII deficiency. Genotyping identified a homozygous, nonsense mutation (p. Ser112Stop) in the FVII gene. Using x-MAP® technology, we showed that the patient developed inhibitors against rFVIIa with high antigenic reactivity, with a progressive switch to IgG4 subclass during the follow-up treatments. The bleeding episodes were successfully treated with classical doses of rFVIIa, suggesting that such treatment saturates the inhibitory activity of the antibody. Despite the persistence of inhibitors, rFVIIa prophylaxis was successful and the patient reported nearly no bleeds for 2 years. **Conclusions.** Prophylaxis using rFVIIa should be recommended even for patients with inhibitors to FVII.

1259

ACQUIRED HEMOPHILIA: REPORT OF FIVE CASES. A SINGLE CENTER EXPERIENCE

F Lopez Jimenez
Virgen de las Nieves University Hospital, Granada, Spain

Background. Acquired hemophilia A (AHA) is an autoimmune disease caused by an autoantibody to factor VIII (FVIII) and is associated with various underlying conditions such as pregnancy, malignancy, autoimmune diseases, and allergic reactions to medications (penicillin, chloramphenicol, phenytoin, etc.). However, in almost 50% of cases not determined a causal factor. It has a high morbidity and mortality and the incidence is estimated about 1 case per million populations per year. Mortality rate reported is between 10 - 22% and is due to severe bleeding complications or side effects of immunosuppressive therapy. Perhaps the ignorance of the disease by health professionals, contribute to this incidence has been underestimated. Prognosis of this disease depends of an early diagnosis and therapy. The literature available on this subject comes from case series and retrospective studies. The largest cohort reported to date is the European Acquired Hemophilia Registry (EACH2) with data of 501 patients prospectively reported. It was created with the objective of solving unknowns in the management of clinical bleeding and inhibitor eradication, but these data are only available in abstract. **Aims.** We describe a series of 5 patients with an AHA seen in a five years period in a university hospital in the south of Spain. **Methods.** We reviewed clinical data from patients who were classified with an AHA in the period from January 2007 to December 2011 at the Virgen de las Nieves Hospital, in Granada, in the south of Spain. **Results.** In this period 5 cases met the diagnosis of AHA, the average age was 33 years (range 29 to 80) with a male-female ratio of 1:4. Two of the 5 patients had an AHA in late postpartum, one patient was personal history of Evans syndrome, one of breast cancer and one of bilateral inguinal hernia. The symptoms were bruising and prolongation of APTT in all the patients, except in one of them, which presented active bleeding in the immediate postsurgical period. The average time until remission was 2,5 for months(range 1 to 7). The inhibitors were completely resolved in all patients only one of the five patients died due to opportunistic infection secondary to immunosuppressive therapy. Characteristics of the patients are shown in Table 1. **Conclusions.** Experience in our hospital with the usual treatment is satisfactory, with only a death due to infection secondary to immunosuppressive therapy in an older patient. The limited number of cases of AHA make difficult to establish their clinical course and to perform randomized trials. Therefore the management of patients with this disease is complicated because the literature available on this subject comes from case series and retrospective studies. Knowledge of the symptoms of this pathology by health professionals is critical because the prognosis depends on early diagnosis and treatment.

Table 1.

No	Sex	Age	Predisposing condition	Hemostatic treatment	Immuno-modulatory therapy	Time until complete remission	Outcome
1	F	33	Late Postpartum	Recombinant factor VIIa	Streroids+ cyclophosphamide+ Rituximab	One month	Favourable
2	F	29	Late Postpartum	Tranexamic acid	Steroids+Rituximab	Seven month	Favourable
3	F	30	Evans Syndrome	no	Steroids	One month	Favourable
4	F	80	Breast cancer	Recombinant factor VIIa	Streroids+ cyclophosphamide+ Rituximab	Four month	Favourable
5	M	74	Postsurgical	Recombinant factor VIIa	Steroids+ cyclophosphamide	No complete remission	Died

1260

IMPROVED CYTOTOXIC T CELL RESPONSES AGAINST A HETEROCLITIC HLA-A*0201 BINDING PEPTIDE DERIVED FROM THE 37/67 KDA LAMININ RECEPTOR PROTEIN

M Zeis, S Wirth, S Siegel, N Schmitz
Asklepios Clinic St. Georg, Hamburg, Germany

Background. The 37/67kDa laminin receptor protein (37/67 kDa LRP) is a target molecule for immunotherapeutic studies in several tumor entities including hematologic malignancies. **Aims.** To identify a new heteroclitic-modified HLA-A*0201-presented peptide epitope (iLR-2het) deduced from the 37/67 kDa LR protein capable of eliciting tumor-specific human cytotoxic T cell (CTL) responses. **Methods.** T2-binding assays were combined with ELISPOT- and cytotoxicity assays. **Results.** Spontaneous T cell reactivity against the iLR-2het peptide was detectable in a significant proportion of patients with chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) compared to the native peptide iLR-2. In addition, iLR-2het-specific CTLs recognized and killed LRP-expressing CLL cells in an MHC-restricted manner. **Conclusions.** The identification of a new LRP-derived peptide epitope with high capability of eliciting CTL responses independent of the low binding ability of the naturally processed peptide increases the number of potential targets for peptide vaccination strategy against LRP expressing tumors.

1261

DEVELOPMENT OF ANTIBODY RESPONSES AGAINST HISTOCOMPATIBILITY-Y ANTIGENS AND THEIR X-VARIANTS AFTER ALLOGENEIC HEMATOPOEIETIC STEM CELL TRANSPLANTATION AND DONOR LYMPHOCYTE INFUSION

J van der Griendt[1], E van der Meijden[1], M Eefting[1], B Ayoglu[2], J Schwenk[2], P Nilsson[2], J Falkenburg[1], M Griffioen[1]
[1]Leiden University Medical Center, Leiden, Netherlands
[2]Albanova University Center, Stockholm, Sweden

Background. Allogeneic hematopoietic stem cell transplantation (alloSCT) is an effective treatment for patients with hematological malignancies. The beneficial graft-versus-leukemia (GvL) effect, however, is often accompanied with undesired graft-versus-host disease (GvHD). To reduce the incidence and severity of GvHD, T-cells can be depleted from the graft and readministered later as donor lymphocyte infusions (DLI) to preserve GvL reactivity. Evidence is accumulating that not only T-cells but also antibody responses coincide with GvL and GvHD. Antigens encoded by the Y-chromosome (histocompatibility-Y or H-Y antigens) have been described as targets for T-cells and antibodies in male patients transplanted with female donors, and immune responses against H-Y antigens are reported to correlate with clinical outcome. **Aims.** The aim of the study is to investigate the occurrence, specificity and biological relevance of antibodies against H-Y antigens during GvL and GvHD after treatment with alloSCT and DLI. **Methods.** Overlapping protein fragments for H-Y antigens ZFY and DBY and their respective X-variants (ZFX and DBX) were produced in E. Coli and coupled to fluorescent beads. In a high throughput Luminex bead assay, 1300 serum/plasma samples collected from 93 patients with myelodysplastic syndrome (MDS) or acute myeloid leukemia (AML) before and during treatment with alloSCT and DLI were screened for antibody binding to the antigen-coupled beads. All sex-matched and mismatched patient-donor combinations were represented in the cohort (19 female-to-male, 17 female-to-female, 19 male-to-female and 31 male-to-male combinations). Mean fluorescence signals were normalized for background values as defined by reactivity against an irrelevant protein (HCV-core24). High titer antibodies were defined as $p<0.0001$ compared to the mean of all measurements for a given protein fragment. **Results.** Pre-existing H-Y reactive antibodies were measured in one male patient. Six of 93 patients developed H-Y antibodies after treatment with alloSCT and DLI. Five of these patients were male patients transplanted with female donors who developed antibodies against DBY (2x) or ZFY (3x) after treatment with DLI. In all 5 patients, antibodies against H-Y antigens were accompanied with reactivity against the respective X-variants, albeit in some cases with a lower fluorescence signal. Furthermore, in three of the five patients, detection of antibodies against H-Y antigens was associated with GvL reactivity and development of severe GvHD (grade II-IV, requiring systemic immunosuppressive treatment) . Of the remaining two patients, one patient displayed GvL reactivity without GvHD, whereas the other failed to develop any clinical response in spite of two administrations of DLI combined with intensive chemotherapy. **Summary and Conclusions.** We successfully used a Luminex bead assay for measurement of antibodies against multiple protein targets in a small sample volume and demonstrated that two ubiquitously expressed intracellular H-Y antigens are targets for antibodies in male patients transplanted with female donors. In these patients, humoral responses against H-Y anti-

gens and their X encoded variants were measured shortly after DLI and often coincided with development of GvL and severe GvHD. In conclusion, our data suggest that antibodies against H-Y antigens develop as a result of cellular debris induced by treatment with DLI, and that these antibodies display cross-reactivity towards X-encoded protein homologues.

1262

MATURE DENDRITIC CELLS CAN DIRECTLY INHIBIT THE GROWTH OF TUMOR CELLS IN VITRO

V Akhlynina[1], A Misiurin[1], N Lyzhko[1], Y Finashutina[1], E Aksenova[1], I Soldatova[1], A Shpakova[2], B Khasigova[2]
[1]Research Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation
[2]Research Centre for Hematology, Moscow, Russian Federation

Background. Dendritic cells (DC) are important antigen-presenting cells that involved in an induction of cellular and humoral immune response. This function is related to their ability to capture an antigen, express the immunostimulatory molecules and to migrate into lymph nodes. PRAME, cancer-testis antigen was chosen for DC pulsing because it is highly expressed in patients with hematogical malignancies and some solid tumors. Autologous dendritic cell vaccination is a promising strategy for adjuvant cancer therapies since DC are able to kill residual leukemic cells and/or prevent leukemia relapse. From recent studies we know that certain DC subsets have direct tumoricidal property by delivering cell death signals to malignant cells. **Aims.** To estimate the suppressing action of DC on the tumor cells by themselves in the culture in vitro. **Methods.** Immature leukemic dendritic cells have been cultured from mononuclear cells from bone marrow patient with acute myelogenous leukemia (AML) and from healthy donor blood, in the presence of GM-CSF, interleukin (IL)-4; mature DC were obtained in the presence of tumor necrosis factor (TNF)- and prostaglandin E. Part of DC was pulsed with recombinant PRAME antigen. DC and several human tumor cell lines (K562, THP-1, NOMO-1, U937) were co-incubated at different ratios. The viability of tumor cells was estimated by H3-thymidine incorporation assay as well as by trypan blue staining in the 3rd and 7th day of incubation. **Results.** We revealed that K562 cell line with high proliferation rate was more resistant to suppressive action of DC of healthy donor. Also we found that suppressive action of DC is reduced or disappear in condition of increasing of tumor cell growth rate. It is necessary that the number of DC considerably exceeds the number of tumor cells. In addition, specific loading DC with PRAME protein and consequent maturation significantly increases their initial tumor-suppressive activity. During co-incubation of mature DC from AML patient and K562 cells at a ratio of 1:1 the number of K562 cells decreased by 2,5 time; increasing the ratio of mature DC to 3:1 led to a reduction in the number of K562 cells to 7th day of incubation by 8 times. Thus the suppressive effect of DC from AML patient remains. **Summary.** It is shown that DC of donor directly cause the suppression of tumor cell growth and the effect of DC depends on the maturity of the DC as well as the rate of growth of tumor cells. So for developing of DC vaccine is necessary to control the conditions of maturing DCs, the number of input cells and load them to the appropriate antigen.

1263

HIGH EXPRESSION OF AURKA AND AURKB IS ASSOCIATED WITH HIGH WBC COUNTS AND COMPLEX KARYOTYPE IN CHRONIC LYMPHOCYTIC LEUKEMIA

R Lucena-Araujo, F De Oliveira, D Matos, F Careta, F Saldanha-Araujo, R Falcao, E Rego
Medical School of Ribeirao Preto, Ribeirao Preto, Brazil

Background. Aurora kinases are mitotic kinases especially important in the regulation of G2/M phase of the cell cycle and various mitotic events, including centrosomal duplication, mitotic spindle assembly, chromosome segregation and cytokinesis. The three major aurora kinases (*AURKA, AURKB* and *AURKC*) have been previously described and they are related to different stages of mitosis. Furthermore, aurora kinase overexpression leads to genetic instability and trigger the development of tumors. In fact, altered expression of aurora kinase proteins has been implicated in the pathogenesis of various cancers. **Aims.** In the present investigation, we have evaluated *AURKA* and *AURKB* gene expression in peripheral blood (PB) cells from chronic lymphocytic leukemia (CLL) patients and correlated these findings with hematological parameters and classical cytogenetics. **Methods.** Sixty two CLL patients (24 female and 35 male) and 10 age-matched healthy donors were selected. The comparative cycle threshold (Ct) method was used to evaluate expression of *AURKA* and *AURKB* genes in leukemic and normal samples. Metaphase induction in CLL was performed by using the immunostimulatory method that employs the combination of DSP30 and IL-2. Chromosome preparations were obtained by using standard procedures and the subsequent cytogenetic analysis and interpretation were made according to the ISCN (2009). All cytogenetic and gene expression data were validated by FISH analysis by using a specific set probes. According to median value of *AURKA* and *AURKB* gene expression, patients were divided into two groups (≥3. 4, considered as AURKA+ and >2. 3, considered as AURKB+) and their clinical and laboratorial characteristics were correlated. **Results.** Higher *AURKA* and *AURKB* expression were observed in CLL samples compared with normal samples (*AURKA* [mean value of ΔCt ± SD]: 9. 3 ± 3 *vs* 7. 1 ± 1, *p*=0. 02; *AURKB*: 16. 6 ± 1 *vs* 9 ± 2, *p*=0. 02). Moreover, *AURK*+ patients presented a significantly high leukocyte count compared with *AUR*- patients (*AURKA* [WBC count x 10^3 ± SD]: 37. 8 ± 5. 5 *vs* 68. 8 ± 5. 8, *p*<0. 001; *AURKB*: 40 ± 5. 5 *vs* 66. 6 ± 6. 2, *p*=0. 002, respectively). No significant differences were found regarding to Binet classification, gender or platelets count. Among the classical cytogenetic profile obtained, normal karyotype was found in 15 patients (24%) and metaphases with abnormal karyotype were seen in 47 subjects (76%). Interestingly, Pearson correlation showed a significant association between high expression of *AURKA* and *AURKB* and complex karyotype (relative risk: 2. 4 [95%CI: 1. 46-3. 93], *p*<0. 001). We demonstrated a significant correlation among high expression levels of *AURKA* and *AURKB* genes in CLL with chromosomal abnormalities and other hematological parameters. Overexpression of aurora kinase genes have been extensively studied in solid tumors. **Conclusions.** In CLL, our results may be associated to the genesis of chromosomal abnormalities and possible be used to predict the course of genomic instability in CLL patients.

1264

THE POTENTIAL ROLE OF UGT1A1*28 POLYMORPHISM IN THE PATHOGENESIS OF CHRONIC LYMPHOCYTIC LEUKEMIA

M Karakosta[1], V Kalotychou[2], S Zachaki[1], A Daraki[1], A Kostakis[3], G Kouraklis[4], K Manola[1]
[1]NCSR "Demokritos", Athens, Greece
[2]University of Athens School of Medicine, Laikon General Hospital, Athens, Greece
[3]Center of Experimental Surgery, Academy of Athens, Athens, Greece
[4]Second Department of Propedeutic Surgery, Medical School, University of Athens, Athens, Greece

Background. It is assumed that Chronic Lymphocytic Leukemia (CLL) may be caused by the interindividual differences in the disposal of toxic substances resulting from polymorphisms in detoxification genes. UDP-glucuronosyltransferases (UGTs), which are Phase II conjugating enzymes, are involved in the detoxification of certain environmental toxins and carcinogens related to CLL. Studies in UGT1A1, a highly polymorphic gene and one of the most important UGTs, shed light to a possible cytoprotective role in human lymphocytes. UGT1A1*28 genetic polymorphism is characterized by an additional TA repeat in the $A(TA)_nTAA$ box region of UGT1A1 gene promoter. The dominant allele contains 6 TA repeats [$A(TA)_6TAA$], whereas the variant has 7 [$A(TA)_7TAA$] resulting in significant down regulation of UGT1A1 activity. **Aims.** We present a case-control study to investigate the potential risk effect of UGT1A1*28, an inborn polymorphism which has never been associated with any types of leukemia before, in CLL or CLL specific abnormalities. **Methods.** UGT1A1*28 polymorphism was investigated in 109 Greek CLL patients and 108 matched healthy controls using Real Time PCR (RT-PCR) assay. Fluorescence in situ hybridization (FISH) studies were performed on 64 patients to identify the commonest aberrations of CLL; deletions of 13q14. 3, 13q34. 3, 17p13. 1(p53), 11q22. 3(ATM) and trisomy 12 (+12). Statistical analysis was performed using Chi-square test and *P*<0. 05 was considered to be statistically significant. **Results.** The distribution of UGT1A1*28 polymorphism in CLL patients vs controls was: homozygous wild type (TA_6/TA_6) 39. 5% vs 39. 8%, heterozygotes (TA_6/TA_7) 40. 4% vs 45. 4%, homozygous mutant (TA_7/TA_7) 20. 2% vs 14. 8%. FISH analysis was successful in all 64 patients and cytogenetic abnormalities were detected in 43/64 (67. 2%). The comparative study of genotype and allele frequencies between CLL samples and controls revealed a significant high frequency of UGT1A1*28 in patients carrying abnormal FISH patterns (*P*=0. 020). Moreover, the incidence of TA_7/TA_7 genotype was higher in patients carrying +12 (*P*=0. 000) and TA_7 allele was found more often in patients carrying del(11)(q22. 3) (*P*=0. 016). However, no differences were observed in patients with del(17)(p13. 1), del(13)(q34. 3) and del(13)(q14. 3) (*P*>0. 050). Interestingly, TA_7 allele frequency was extremely high in patients with del(13)(q14. 3) followed by ≥1 aberrations (*P*=0. 000). It is noteworthy that all patients with del(13)(q14. 3) and +12 (n=4) carried the variant allele (25% TA_6/TA_7, 75% TA_7/TA_7). **Summary and Conclusions.** To the best of our knowledge, this is

the first study to investigate the correlation between UGT1A1*28 polymorphism and CLL. The distribution of UGT1A1*28 polymorphism indicated an increasing tendency in CLL patients homozygous for the mutant TA_7 allele vs controls. The high incidence of mutant genotypes found in patients carrying the commonest aberrations of CLL[+12,del(11)(q22. 3),del(13)(q14. 3)] suggests that UGT-deficient individuals may be at a greater risk for developing CLL specific abnormalities. Therefore, UGT1A1*28 polymorphism might be a predisposing factor to the pathogenesis of CLL. The chronic accumulation of toxic substrates implicated in CLL aetiology, caused by the lower corresponding catalytic ability of UGT1A1*28, supports the idea of a complex CLL biology, reliant on the interplay of inherited, environmental and host factors.

1265

T-LGLL AND NK-CLPD: TWO DISORDERS WITH A COMMON ETIOPATHOGENETIC MECHANISM?

C Gattazzo, A Teramo, F Passeri, T Berno, G Semenzato, R Zambello
University of Padova, Padova, Italy

Background. The large granular lymphocytes (LGL) disorders are characterized by expansions of lymphocytes with cytotoxic activity. This expansion could be sustained by T or NK cells and WHO classification considers these disorders as separate entities, referred to T-LGL leukemia (T-LGLL) or NK-chronic lymphocyte proliferation disease (NK-CLPD). The marker of clonality is represented by the rearrangement of TCR in T-LGLL whereas a restricted pattern of Killer Immunoglobulin-like Receptor (KIR) expression is a characteristic figure in NK-CLPD. The etiology of LGL leukemia is largely unknown but several reports support the hypothesis of an antigenic stimulation as initial step, that would led to the expansion of LGLs which is not eliminated as a consequence of an impairment of apoptotic pathways and of a persistent inflammatory stimulation mediated by cytokines. Although these disorders are characterized by the expansion of different cells types, with specific genetic features and abnormalities, compelling evidences support the hypothesis that a common pathogenetic mechanism would be involved in both these disorders. **Aims.** We evaluated whether clonal T cell populations were detectable in patients with KIR restricted NK-CLPD, to corroborate the hypothesis that a persistent antigenic pressure takes place in these patients. **Methods.** We enrolled 50 therapy-free patients with NK-CLPD. All enrolled patients provided written informed consent in accordance with the Declaration of Helsinki. TCR gamma chain rearrangement was investigated by PCR in DNA purified from PBMC of NK-CLPD patients. KIR restriction was analyzed in all patients. **Results.** We found that in 27 out of 50 NK-CLPD patients (54%) a clearly detectable clonal T cell population was present, despite to the fact that all patients presented a NK disorder with a restricted pattern of KIR expression. The clonal T cell population ranged from a fairly detectable band to a strong signal. This surprisingly high percentage of T clones present in NK cell proliferation can not be explained by concomitant infections, since all patients were asymptomatic. Follow up analysis confirmed that TCR rearrangements were stable during time. Furthermore, in two patients we could demonstrate a switch between KIR restricted NK-CLPD to a monoclonal T-LGLL during a mean follow up of 5 years. **Conclusions.** Results of this study support the hypothesis that an antigenic pressure is taking place in patient with NK-CLPD. The demonstration of switch between NK-CLPD and T-LGLL further suggests that a common mechanism is involved in the pathogenesis of these disorders.

1266

CD38 GENE POLYMORPHISM AND RISK OF CHRONIC LYMPHOCYTIC LEUKEMIA

V Abramenko[1], I Bilous[1], V Pleskach[1], A Chumak[1], A Kryachok[2], V Martina[3], S Dyagil[1]
[1]Research Center for Radiation Medicine, Kiev, Ukraine
[2]National Cancer Institute, Kiev, Ukraine
[3]Resrach Center for Radiation Medicine, Kiev, Ukraine

Objectives. Recent studies suggested the importance of CD38 signaling in the pathogenesis of B-cell chronic lymphocytic leukemia (B-CLL) and impact of rs6449182 *CD38* polymorphism on clinical course of disease. An association between genotypes rs6449182 of *CD38* and susceptibility to CLL was found in Polish Caucasians (Jamroziak et al., 2009) but these data were not confirmed in group of Italian CLL patients (Aydin et al., 2008). The aim of this paper was to study a risk CLL depending on rs6449182 of *CD38* in Ukrainian CLL cohort. **Patients and Methods.** rs6449182 CD38 gene polymorphism was determined by polymerase chain reaction with restriction of reaction products in 328 CLL patients and 271 age- and sex-matched controls. Immunoglobulin heavy chain variable (*IGHV*) gene mutation status was determined in 321 CLL patients. **Results.** In the control group the study of polymorphisms' distribution showed an association with signs of dyslipidemia and the proportion of GG carriers among persons with elevated triglycerides (TG>2. 1 mmol/l), low-density lipoproteins (LDL>2. 2 mmol/l), or total cholesterol (TC>6. 5 mmol/l) level was higher than among persons with normal levels of these parameters (3. 8% vs 19. 1%, p=0. 001; 4. 2% vs 13. 8%, p=0. 013; and 3. 8% vs 17. 8%, p=0. 025, correspondingly). The distribution of rs6449182 *CD38* genotypes in CLL patients was as follow: CC - 168 cases (51. 2%), CG - 117 cases (35. 7%), GG - 43 cases (13. 1%), and G allele frequency of 0. 31. In comparison with controls who did not have abnormalities in TC, LDL, and TG level an associations between GG genotype and CLL risk in a whole group of CLL patients (OR=3. 92, 95% CI 1. 37-11. 19; p=0. 006), in patients with mutated *IGHV* genes (OR-3. 35, 95% CI 1. 04-10. 76, p=0. 03), and in patients with unmutated *IGHV* genes (OR=4. 03, 95% CI 1. 37-11. 78, p=0. 006) were significant. In contrast, the genotype distributions in CLL patients and controls with abnormalities in TC, LDL, and TG level were similar (p>0. 05). **Conclusions.** we hypothesize that rs6449182 of *CD38* may contribute to the increased CLL risk through generation in GG carriers of increased number and increased diversity of lipid neoantigens due to more frequent dyslipidemia. These neoantigens may be additional antigenic stimules for B-cells prior or after neoplastic transformation. AUTOCRINE IL-6 PRODUCTION CORRELATED WITH SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKAEMIA CELLS

F Liu[1], L Jia[2], T Farren[1], J Gribben[2], S Agrawal[1]
[1]Blizard Institute, QMUL, London, United Kingdom
[2]Barts Cancer Institute, QMUL, London, United Kingdom

Signal transducer and activator of transcription 3 (STAT3) proteins have been found to play an important role in cancer cell survival and proliferation. The activation of STAT3 signalling pathways require interleukin-6 (IL-6) and tyrosine kinase (JAK2) phosphorylation. Constitutive activation of the IL6/JAK2/STAT3 pathway is contributed to chemo-resistance in Chronic Lymphocytic Leukaemia (CLL). Previous studies have shown that in patients with CLL elevated levels of serum IL6 correlate with adverse disease features and shorter survival. We investigated the relationship of CLL cell autocrine IL-6 production, STAT3 activation and apoptosis resistance. 36 CLL patients with high count of lymphocyte have been investigated and western blot, flowcytometry, gene transfection, fluorescent microscopy techniques have been used for this study. The median autocrine IL6 production in cultured CLL cells was 9. 23pg/ml (range 0. 2-38pg/ml); the patients with higher autocrime IL-6 production (≥9. 23 pg/ml) exhibited a significant good survival in vitro compare with lower autocrine IL-6 production (< 9. 23pg/ml) patients (p < 0. 00001). as compared with stage A patients (6. 1pg/ml, range 0-23pg/ml) (p=0. 02). Patients with high autocrine IL6 production exhibited a high ratio of phosphorylated STAT3/ total STAT3, indicating a high level of STAT3 activation and apoptosis resistance. Activation of the IL6/JAK2/STAT3 pathway by exogenous IL6 led to increased expression of anti-apoptotic proteins Mcl-1 and Bcl-xl. STAT3 activation also protected mitochondrial function during apoptosis: inhibiting cytochrome C release (p=0. 004), mitochondrial membrane potential collapse (p=0. 0004) and ROS generation (p=0. 0007). Finally, STAT3 activation led to increased resistance of CLL cells to spontaneous apoptosis (15% range 2-36%) (p=0. 00008). This study demonstrates that higher CLL autocrine IL6 production correlates with STAT3 activation and apoptosis resistance in CLL. The IL6/JAK2/STAT3 signal pathway may reveal new therapeutic targets.

CLOPIDOGREL (PLAVIX) INDUCES IN VIVO REDUCTION OF NORMAL B CELLS AND IN VITRO APOPTOSIS OF B CLL CELLS. POSSIBLE ROLE OF AKT EXPRESSION.

A Berrebi, G Duek, L Bassous, M Shtalrid, L Shvidel
Kaplan Medical Center, Rehovot, Israel

Background. Clopidogrel, widely used in cardiology, is a drug which inhibits the ADP receptor on platelets. Very few patients using this drug suffer also from CLL.

We had the opportunity to follow 2 patients with this association and were surprised to observe a 50% reduction of their peripheral lymphocyte count. **Aims.** To search a possible effect of clopidogrel on B lymphocytes in vitro. **Methods.** We performed the following studies: 1. Determination of B cell count defined by expression of CD19, CD20 on flow cytometry, before and after 4 to 6 weeks use of *plavix*. Twenty patients were selected at the Cardiology Unit and blood was collected after informed consent. 2. Evaluation of apoptosis of B CLL cells induced by clopidogrel in vitro in twenty non-treated CLL patients. Blood was collected after informed consent; lymphocytes were separated on ficol then studied for apoptosis using the Annexin V assay by flow cytometry before and after addition of clopidogrel. The dosage of 20 mcg per 4 x10^6 cells represents approx. the concentration of treated patients by the drug. Higher dosages of 50 and 100 mcg were used for comparison. **Results.** 1. B lymphocyte counts were significantly reduced in non CLL patients treated by *plavix* for cardiac reasons. Mean CD19 was 15. 5% before *vs* 10% after (p=0. 015) and mean CD20 was 15% before *vs* 9% after 4 to 6 weeks of *plavix* treatment (p=0. 014). 2. Addition of *plavix* in CLL cells vitro induced an increased apoptosis: mean from 10 to 20% (p=0. 004) with 20 mcg and the higher dosage of 50 and 100 mcg induced a high level of necrosis. Since the mechanism of platelet activation is inhibited through the Akt promoter, we studied the expression of Akt on B CLL cells using anti-AktMoAb(ENCO) after cells permeabilization. We found a significant reduction of the expression of Akt from 63% to 22% after addition of 20 mcg clopidogrel. **Conclusions.** We demonstrated that non-CLL patients treated with clopidogrel (*plavix*) had a significant reduction of their B cells after 4-6 weeks of treatment. The addition of pharmaceutical dosage of clopidogrel induced a significant increase of in vitro apoptosis in CLL cells, possibly explaining the lymphocyte reduction count showed in our two B CLL patients who received *plavix* for cardiac reasons. Since we showed a reduction of the Akt expression in CLL cells after addition of clopidogrel in vitro, we suggest that inhibition of Akt is possibly involved in our findings.

Background. Deregulation of TCL1 oncogene has implicated in the pathogenesis of the aggressive form of B CLL with however unknown mechanism of action. Akt pathway has been proposed to be a possible target of TCL1 oncogene. AIMTo evaluate TCL1 expression in a series of CLL patients (pts), correlate its expression with the clinical and laboratory data as well as other prognostic factors, and investigate the possible involvement of Akt pathway in TCL1 mechanism of action. **Patients and Methods.** 69 pts diagnosed with CLL/SLL by using standard criteria included in this study. Baseline clinical and laboratory features were recordedTCL1 as well as ZAP70 and pAkt expression were evaluated by immunohistochemistry (IHC) with standard techniques in bone marrow paraffin embedded sections(61pts) and lymph node sections(8pts). TCL1 positive cases were confirmed by flow cytometry too. **Results.** 69 pts (42male) with median age of 61 years (35-85) included in the study. 53 pts(77%) had disease stage A, 11 (16%) B, and 5(7%) C, according to Binet staging system. IgVH mutational analysis was performed in 38 pts and 21/38 were unmutated. FISH analysis for 11q del and 17p del were evaluated in 33 και 36 pts respectively. In 3 pts 11q del was detected while one patient was positive for 17p del. CD38 detection was performed in 43 pts (19% were CD38 positive). Forty-five (65%) pts were TCL1 positive and 37 pts (54%) were ZAP70 (+). The majority of TCL1 positive CLL patients showed strong positivity whereas TCL1 localization was mainly in the cytoplasm. In addition, pAkt expression was observed only in TCL1 positive CLL pts and it was localized both in membrane and cytoplasm. Thirty-one out of 42(73%) male pts presented TCL1 positivity while 14 out of 27 females were TCL1(+) (p:0. 03). 32/37 ZAP70(+) pts were also TCL1(+) against 13/32 ZAP(-) (p:<0,001). Moreover 18 out of 21(86%) unmutated pts expressed TCL1 while 8 out of 17(47%) mutated pts were TCL1(+) (p:0. 03). TCL1 expression was more frequent in pts with non nodular pattern of bone marrow infiltration. Proliferation centers(PCs) were recognized in 20 bone marrow sections and in all lymph node sections. TCL1 was strongly expressed in the small cell compartment of the PCs but it was negative/weak in the mitotically active paraimmunoblasts in these areas. No differences in 7-year treatment free interval and 10 year overall survival were observed between TCL1(+) and TCL1(-) pts. **Conclusions.** TCL1 expression was strongly correlated with markers of the pre-germinal center subset of CLL (unmutated VH genes status and higher ZAP 70 expression levels), findings that were in accordance with previous published data. TCL1 expression was not correlated with any of the clinical predictive factors. TCL1 was correlated with male gender. No correlation was found between TCL1 expression and patients' survival. pAkt expression was observed exclusively inTCL1positive cases. pAkt coexpression with TCL1 may suggest a common mechanism of action.

1270

ASSOCIATION BETWEEN MBL2 GENE POLYMORPHISMS AND PREDISPOSITION TO THE DEVELOPMENT OF INFECTIOUS DISEASE ON CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

K Holanda
University of São Paulo, Ribeirão Preto, Brazil

Background. Chronic lymphocytic leukemia (CLL) is the most common adult leukemia in the western hemisphere. It is characterized by a progressive accumulation of small mature B lymphocytes on the peripheral blood and lymphoid tissues. Infectious disease represents the main cause of death on CLL patients. *MBL2* gene codes the mannose-binding lectin (MBL), an important constituent of human immune defense. The MBL protein act as initial factor of the lectin pathway of the complement system and its deficiency appears to predispose to serious infection. It was been reported that polymorphisms on *MBL2* gene could be associated to a higher risk to the development of infectious disease. **Aims.** We aimed to define how *MBL2* gene polymorphisms varied among CLL patients and clarify the relationship between these genetic alterations with infections and others clinical and laboratorial features. **Methods.** Patients diagnosed with CLL by immunophenotyping had their records analyzed for clinical and laboratorial data collection. Real-time PCR techniques were used to identify the polymorphisms G-550C and G-221C at promoter region and the presence of *O* allele, which result from polymorphisms at exon 1 region in *MBL2* gene. We also determined the *MBL2* secretor haplotypes. **Results.** A total of 116 patients with CLL were enrolled in our case-control study. Forty-four patients presented laboratorial and clinical signs or symptoms of infectious diseases after diagnosis. The control group consisted of 72 patients with absence of infectious events. Herpesvirus and respiratory tract infections represented the most common forms of infections on our cohort. The follow-up time was significantly lower (p=0. 034) in the control group. Binet stage (p=0. 001) and splenomegaly (p=0. 002) presented high association on the case group compared with the control group. However, the variant alleles and genotypes of *MBL2* gene promoter and exon 1 regions do not demonstrate influence as genetic modulator of infection risk on our cohorte. MBL levels correlate with *MBL2* haplotypes also showed no significant association with infection. **Summary and Conclusions.** From all parameters analyzed in our study, only follow-up time, Binet stage and splenomegaly showed significant influence as modulators for infectious diseases prevalence on patients with CLL. The genetic heterogeneity among different populations may explain the failure in reproducibility of previous gene association studies, and warrants further studies in worldwide collaboration to determine the actual relevance of findings involving genetic polymorphisms in *MBL2* gene and their influence on the susceptibility to infections in CLL.

ENDOGLIN MRNA EXPRESSION IS INCREASED IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA WITH POOR PROGNOSTIC MARKERS

F Vrbacky, J Nekvindova, V Vroblova, M Simkovic, Z Jiruchova, J Maly, L Smolej
Faculty of Medicine and University Hospital, Charles University, Hradec Kralove, Czech Republic

Background. Angiogenesis is considered to play an important role in pathogenesis and progression of chronic lymphocytic leukemia (CLL). Endoglin (CD105), a member of transforming growth beta receptor family, is one of key angiogenic molecules and its elevated expression has been reported in hematological malignancies as well as solid tumors. However, data regarding endoglin expression in CLL cells are very limited. **Aims.** To evaluate prognos-

tic significance of endoglin mRNA expression in malignant lymphocytes from CLL patients and its relationship to traditional and modern prognostic factors. **Methods.** Endoglin mRNA levels were analyzed in CD19+ cells of 49 untreated CLL patients by real-time quantitative PCR and normalized for differences in RNA concentration in each sample by quantitation of housekeeping gene hypoxanthine phosphoribosyltransferase 1 (HPRT1). ZAP-70 and CD38 expression were analyzed by flow cytometry; IgVH mutation status was assessed according to usual methodology using cDNA and IgBLAST database. **Results.** We found significant association between high endoglin mRNA levels and unmutated IgVH genes (n= 38, p < 0. 001), high CD38 expression (n = 46, p = 0. 005) and high ZAP-70 expression (n = 45, p = 0. 043). In addition, endoglin expression was significantly higher in patients with progressive disease (n = 49, p = 0. 011) and significantly lower in Rai stage 0 (n = 49, p = 0. 004). **Conclusions.** Our pilot data show that endoglin mRNA is differentially expressed in malignant lymphocytes of CLL patients and high endoglin expression is associated with unmutated IgVH and high expression of CD38 and ZAP-70; thus, it seems to be associated with poor prognosis of CLL. Moreover, expression of endoglin might play an important role in the biology of CLL progression, because it is elevated in patients with Rai stage I - IV and those with progressive disease. Supported by research project MZO 00179906 from Ministry of Health,Czech Republic.

ANTIPROLIFERATIVE AND APOPTOTIC EFFECTS OF RESVERATROL ON CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

Y Baran[1], A Gokbulut[2], MA Ozcan[3], O Piskin[3], M Unlu[2]
[1]Izmir Institute of Technology, Izmir, Turkey
[2]Izmir Institute of Technology, Department of Molecular Biology and Genetics, Izmir, Turkey
[3]Dokuz Eylul University, Faculty of Medicine, Department of Hematology, Izmir, Turkey

Background. Chronic lymphocytic leukemia (CLL), defined by accumulation of pathogenic B cells. CLL has a complex biology due to interplay of inherited, enviromental and host factors. Therefore, its complicated etiology makes treatment of CLL difficult. Recently, finding new treatment agents or development of novel treatment strategies have been paid attention. Resveratrol is a natural polyphenolic phytoalexin and found in a wide variety of plants like skin of red grapes, peanuts, and mulberries. It was previously shown that resveratrol has antioxidant, antiviral, chemopreventive and antitumoral activities. The anticarcinogenic effects of resveratrol were investigated on a variety of cancer types like colon, lung, breast, pancreas and chronic and acute myeloid leukemia. **Aims.** In this study, we aimed to investigate cytotoxic, cytostatic and apoptotic effects of resveratrol on 232B4 chronic lymphocytic leukemia cells. **Methods.** Antiproliferative effects of increasing concentrations of resveratrol on 232B4 cells were determined by MTT cell proliferation assay. Apoptotic effects of resveratrol were determined by changes in caspase-3 enzyme activity, loss of mitochondrial membrane potential, and Annexin-V staining by flow cytometry. Effects of resveratrol on cell-cycle progression of 232B4 cells were examined using DNase-free RNase and propidium iodine by flow cytometry. **Results.** There were significant decreases in proliferation of 232B4 CLL cells exposed to increasing concentrations of resveratrol (1-500 μM) for 72 hours and the IC50 value of resveratrol was found as 27 μM. Resveratrol increased caspase-3 enzyme activity, induced loss of MMP and triggered apoptosis in 232B4 cells in a dose-dependent manner. There were 2, 16, 38, 49 and 107% increases in caspase-3 enzyme activity; 3, 5, 99, 1792 and 3105% increases in loss of MMP; and 2, 8, 133, 350 and 382% increases in apoptotic cells in response to 0. 5, 1, 10, 50 and 100 μM resveratrol, respectively, compared to untreated 232B4 cells. Treatment of 232B4 cells with resveratrol (0. 5-100 uM) resulted in a significant increase in G0/G1 phase while decreased S phase cell population as compared to untreated controls. **Summary and Conclusions.** Taken together these results showed that resveratrol inhibits proliferation and cell cycle progression of 232B4 cells in addition to induction of apoptosis in a dose-dependent manner. Resveratrol triggers apoptosis by inducing caspase-3 enzyme activity and forming pores on the mitochondrial membrane.

1274

EVALUATION OF SERUM FREE LIGHT CHAINS (FLC) AS A NEW PROGNOSTIC FACTOR FOR CHRONIC LYMPHATIC LEUKEMIA B (CLL-B) PATIENTS

MJ Requena, E Anduaga, J Jimenez, M Peñalver, E Yebra, C Payamps, R Riaza, M Berberana, R Rodriguez, P Sanchez- Godoy
Hospital Severo Ochoa, Madrid, Spain

Background. Serum FLC quantitation has prognostic value in multiple myeloma, MGUS (monoclonal gammapathy of unknown significance) solitary plasmocytoma and primary amyloidosis; FLC has been included in response criteria for myeloma and amyloidosis. Several recent studies have described FLC abnormalities in 39-54% of CLL-B patients and their association with poor survival and fast progression. **Aims.** We intend to compare the clinical outcome of our CLL-B patients with or without abnormal serum FLC. **Patients and Methods.** We analyzed restrospectively 58 CLL-B patients diagnosed between 1995 and september 2011. They were 23 female and 35 male patients of a median age of 70 years (44-91). FLC were determined in serum samples stored at diagnosis; a nephelometry immunoassay was used. Monoclonal FLC elevation was defined as elevated FLC (kappa >19. 4mg/l or lambda>26. 3 mg/l) with an abnormal FLC ratio(0. 25-1. 65); polyclonal FLC elevation was defined as elevated FLC with a normal FLC ratio;patients with normal FLC but an abnormal FLC ratio were evaluated as abnormal FLC ratio. 81% of patients were classified as Binet stage A, 15. 6% as stage B and 3. 4% as stage C. Cytogenetic analysis was evaluable in 67. 2% of cases:10. 2% of them were hig risk (del17positive), 15. 3% had trisomy 12, 33. 3% were del13q positive and 41,3 % were normalCD38 was determined in 91. 3% of cases and was negative in 86. 8%ZAP70 had been performed in just 29. 3% of patients and was positive in 41. 2% of them. 77. 6% of patients had a normal LDH and 65% a normal B2 microglobulin. These clinical and laboratory measures were evenly distributed in both groups of patients, with normal or anomalous FLC, except for CD38 (more frequently positive in the abnormal FLC group). **Results.** With a median follow-up of 59. 5 months (6-216), 37. 9% of patients required treatment and overall mortality was 8. 6%. Abnormal FLC were found in 48. 2% of patients (18 monoclonal, 7 polyclonal and 3 abnormal FLC ratio)None of the patients diagnosed of Richter syndrome had abdnormal FLC. With a median follow-up of 65. 5 months (9-189), mortality was 10. 7% for the group of patients with abnormal FLC and 6. 7% for the normal FLC group with 57m of follow up; we did not find a statistical significant difference. The percentage of patients requiring treatment was 35. 7% for the abnormal FLC group and 40% for the normal FLC group; it was not significantly different . When analyzed separately, patients with monoclonal FLC elevation were not significantly associated with poor survival nor with early treatment requirement, compared with normal FLC patients. **Summary and Conclusions.** In our cohort of CLL-B patients, FLC elevation was neither associated with an inferior survival nor with a shorter time to treatment as had been previously published . So we cannot assess for certain the usefullness of this assay as a biomarker or prognostic factor in CLL-B. More studies with a higher number of patients and longer follow up may be needed

1275

CD38 GENE POLYMORPHISM IS NOT ASSOCIATED WITH CHRONIC LYMPHOCYTIC LEUKEMIA SUSCEPTIBILITY IN PERSONS EXPOSED TO IONIZING RADIATION DUE TO THE CHERNOBYL NPP ACCIDENT

N Bilous[1], I Abramenko[1], A Chumak[1], Z Martina[1], I Dyagil[1], I Kryachok[2], I Filonenko[3]
[1]Research Center for Radiation Medicine, Kyiv, Ukraine
[2]National Cancer Institute, Kyiv, Ukraine
[3]Poltava Regional Hospital, Poltava, Ukraine

Background. Chronic lymphocytic leukemia (CLL) is the most common leukemia among adults in Ukraine, as well as in Western Europe and USA. CLL also was shown to be the most common form of leukemia in the clean-up workers of the Chernobyl Nuclear Power Plant (NPP) accident, although impact of ionizing radiation (IR) in CLL development is not proven. Recent studies suggest the association of some genotypes with elevated risk of CLL. Particularly, CD38 rs6449182 (184 C>G) single nucleotide polymorphism (SNP) was reported may contribute to CLL predisposition, affecting CD38 expression. Association of variant CD38 rs6449182 G allele with more aggressive CLL phenotype also was shown. CD38 antigen is well-known negative prognostic marker in CLL, which is supposed to be also one of the key elements in the disease pathogenesis, ruling proliferation/survival signals in leukemic cells. **Aims.** The aim of the study was to evaluate whether CD38 rs6449182 polymorphism influence predisposition to CLL in persons exposed to ionizing radiation. **Methods.** The CD38 rs6449182 genotypes were detected by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method using primers

proposed by Aydin S. et al. (Blood, 2008). The 128-bp PCR product was digested with *Pvu*II (Fermentas), resolved on 4% agarose gel, and analyzed. **Results.** Genotyping of CD38 rs6449182 SNP was performed in 77 IR-exposed CLL patients and in the group of 136 IR-exposed controls. CLL patients and IR-exposed controls were comparable by gender and age (67 M/10 F, mean age 57. 5+8. 9, range 39-87 years vs. 120 M/16 F, mean age 61. 5+ 8. 3, range 37-86 years). CD38 rs6449182 genotypes distribution was in accordance with Hardy-Weinberg equilibrium in both groups. The frequency of variant CD38 rs6449182 G allele in CLL group was comparable to health controls (0. 33 vs. 0. 31, P=0. 79). The distribution of genotypes among CLL patients was found as CC - 42. 9%, CG - 48. 1%, GG - 9. 1%). It also did not differ significantly from that found in control group (CC - 44. 9%, CG - 48. 5%, GG - 6. 6%, P=0. 63). To evaluate possible clinical/biological associations of CD38 rs6449182 SNP, we analyzed range of prognostically important variables in CLL group depending on CD38 genotype. No correlation was found between the CD38 rs6449182 genotypes and age, sex, Binet stage at diagnosis, initial WBC count. Furthermore, there were more cases with mutated IGHV (immunoglobulin heavy-chain variable region) genes among variant rs6449182 G allele carriers in comparison with rs6449182 CC homozygotes (44. 2% vs. 21. 2%, P=0. 036). **Conclusions.** Our results suggest that CD38 rs6449182 SNP does not influence the risk of CLL in persons exposed to IR. Variant CD38 rs6449182 G allele is not associated with poor risk prognostic markers in IR-exposed CLL patients.

1276

SERUM LEVEL OF VASCULAR ENDOTHELIAL GROWTH FACTOR (VEGF), BUT NOT VEGF RECEPTOR EXPRESSION, IS ASSOCIATED WITH THE PROGNOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA

M de Faria, C Rodrigues, E Kimura, M Gonçalves, M Silva, M Silva, A Sandes, V Sthel, F Guirao, J Pesquero, M Yamamoto
Universidade Federal de São Paulo, São Paulo, Brazil

Background. VEGF, a potent pro-angiogenic factor, regulates vascular proliferation through its receptor (VEGFR) activation. Chronic lymphocytic leukemia (CLL) cells express VEGFR and synthesize and secrete VEGF (sVEGF) and might be involved in the pathophysiology of CLL. sVEGF levels have been associated with advanced clinical stage and disease progression but the prognostic value of VEGFR is still controversial. **Aims.** To determine in CLL patients, serum concentration of sVEGF and the expression of VEGF in leukemic cells, to correlate the results with the clinical and biological prognostic factors, and to evaluate their effect on disease progression. **Methods.** Seventy seven previously untreated CLL patients (61% male; median age 70 years, range 38-88 were studied). Most patients were Binet A (n=45, 58%). In addition, 14 healthy volunteers (6 males; median age = 54 years, range: 38-79) were evaluated as controls. VEGFR expression was evaluated in peripheral B lymphocytes by flow cytometry using the Fluorokine ® Biotinylated Human VEGF (R&D systems Inc., Minneapolis, MN, USA) kit. Results were expressed as mean fluorescence intensity (MFI). sVEGF was also determined, in 36 patients, by ELISA, using the Quantikine ® Human VEGF Immunoassay kit (R&D systems Inc., Minneapolis, MN, USA). Results were compared according to Binet clinical stage (A vs. B or C), absolute lymphocyte count (< vs. ≥30x10^9/L), LDH (< vs. ≥276UI/L), β2 microglobin (< vs. ≥2,7mg/L), expression of CD38 (< vs. ≥30%), *IgVH* mutational status (mutated vs. unmutated). Progression-free survival was determined by the Kaplan Meyer method. Median follow-up time was 40 months (range: 2 - 41). **Results.** Median MIF of VEGFR was lower in CLL patients (147, range: 8-1489) as compared to controls (373, range: 222 - 1072) (p<0,0001). Median sVEGF was similar between patients and controls. No significant differences regarding Binet stage, lymphocyte count, LDH, CD38 expression and *IgVH* mutational status were observed between patients with higher or lower VEGFR levels (IMF < or ≥141). There was also no difference in progression-free survival at 3 years between the groups. Patients with high sVEGF values (≥ 400pg/mL) had more frequently high LDH levels (63% vs. 37%, p=0,04), high lymphocyte count (65% vs. 35%, p=0,04) and a trend to present more advanced disease (66% vs. 33%, p=0,08), as compared to those with low sVEGF values. No correlation between sVEGF levels and*IgVH* mutational status, CD38 expression and β2 microglobin was observed. Patients with higher sVEGF levels had a worse progression-free survival at 3 years (68%) as compared to those with lower sVEGF levels (92%, p=0. 03). **Conclusions.** High levels of sVEGF are associated with unfavorable prognosis and worse progression free survival in CLL patients. Correlation between VEGFR expression and sVEGF deserves further investigations and may contribute to understand the pathophysiology of the disease.

[6]Department of Immunology, Tehran University of Medical Sciences, Tehran, Iran
[7]Departments of Oncology and Hematology, Karolinska University Hospital, Stockholm, Sweden

Background. ROR1, a receptor tyrosine kinase, is expressed in CLL and other subtypes of lymphoma. **Aims.** The aim of this study was to further characterize expression of ROR1 and the other member of the ROR family, ROR2, in lymphoid and myeloid malignancies using self-produced antibodies and commercial anti-ROR1 as well as anti -ROR2 antibodies. **Results.** Normal PBMC and reactive lymph nodes were negative for ROR1 and ROR2. A significantly higher and uniform surface expression of ROR1 was found in CLL compared to the other tumors (p=0. 02-<0. 001). Lymphoma subtypes (MCL, MZL, DLBCL, FL), myelomas, ALL and myeloid leukemias showed a variable staining and considerable inter-patient variability. The lowest proportion of ROR1+ cells was found in follicular lymphomas whereas CLL and CML had significantly higher numbers of ROR1+ cells. Longitudinal follow-up of individual CLL patients revealed that the fraction of ROR1+ cells remained stable over time in non-progressive patients but increased when the disease progressed (p<0. 05). ROR2 was not detected in hematological malignancies. Self-produced anti-ROR1 mAbs detected more ROR1+ cells than the commercial anti-ROR1 antibody (p<0. 05-<0. 01). **Conclusions.** In summary, ROR1 but not ROR2 is expressed in different hematological malignancies with a variable staining pattern ranging from very high (CLL) and high (CML), to intermediate (myeloma and DLBCL) or low (FL).

QUERCETIN INDUCED APOPTOSIS IN 232B4 CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

Y Baran[1], A Gokbulut[2], E Apohan[3], O Piskin[4], MA Ozcan[4]
[1]Izmir Institute of Technology, Izmir, Turkey
[2]Izmir Institute of Technology, Department of Molecular Biology and Genetics, Izmir, Turkey
[3]Inonu University, Department of Biology, Malatya, Turkey
[4]Dokuz Eylul University, Faculty of Medicine, Department of Hematology, Izmir, Turkey

Background. Chronic lymphocytic leukaemia (CLL) is the most frequent form of leukemia in adult population (22-30% of all leukaemia cases) in the Western world. Cell death evasion and progressive accumulation of B cells in the blood, bone marrow, lymph nodes, and spleen are the major events in CLL pathogenesis, At present, there is no curative therapy for CLL due to variable prognostic factors, course of disease and even advanced age of many patients. Quercetin is an important dietary flavonoid, present in different vegetables, fruits, seeds, nuts, tea and red wine. Quercetin is used as potential chemopreventers or chemotherapy reagents on a variety of cancer types like colon carcinoma, glioma and non-small cell lung cancer. The mechanisms of quercetin-induced apoptosis vary from one cancer type to other. **Aims.** In this study, we aimed to examine antiproliferative and apoptotic effects of quercetin on 232B4 CLL cells. **Methods.** Antiproliferative effects of step-wise increasing concentrations of quercetin on 232B4 cells were determined by MTT cell proliferation assay. Apoptotic effects of quercetin were determined by changes in caspase-3 enzyme activity and Annexin-V staining by flow cytometry. Cytostatic effects of quercetin on 232B4 cells were examined using DNase-free RNase and propidium iodine by flow cytometry. **Results.** There were significant decreases in proliferation of 232B4 CLL cells treated with increasing concentrations of quercetin (0. 1 to 100 μM) for 72 hours and the IC50 value of quercetin was calculated from cell proliferation plots and found as 24 μM. Increasing concentrations of quercetin increased caspase-3 enzyme activity and triggered apop-

tosis significantly. There were 3, 12, 38 and 47% increases in caspase-3 enzyme activity in response to 0. 1-, 5-, 10- ve 50 μM quercetin, respectively, as compared to untreated 232B4 control. The same concentrations of quercetin induced apoptotic cell death by 56, 133, 160 and 297% as compared to untreated control cells. Interestingly, treatment of 232B4 cells with quercetin (0,1 to 50uM) resulted in a significant increase in G0/G1 phase as compared to untreated controls showing that quercetin not only induces apoptosis but also arrest the cell cycle progression. **Summary and Conclusions.** Taken together, these data reveal that quercetin inhibits proliferation and cell cycle progression and induces apoptosis in a dose-dependent manner in a CLL cells.

1279

STROMAL MICROENVIRONMENT LYMPH NODES IN CLL

N Semenova, S Bessmeltsev, V Rugal
Russian Research Institute Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background. Role or the lymphoid microenvironment in regulation of development lymphoid precursors is known. However the state of lymphoid stromal cells when lymphocyte proliferation is impaired continues to be studied insufficiently. In the work presented structural changes stromal elements lymphoid nodes and impaired capability of stromal cells lymphoid tissue secrete IL-4, IL-6 and TNF- α in CLL. **Aims.** To study cellular and humoral factors of stromal microenvironment lymph nodes in patients with CLL before treatment. MethodsStromal cells of biopsy lymph nodes seventy-five patients with CLL was studied using morphology, immunohistochemistry method. Proliferative activity of stromal cells was evaluated in organ culture lymphoid tissue. Concentration IL-4, IL-6, TNF- α in culture medium has been studied. **Results.** Increase microvessels and reticular cells in lymph nodes were bound. Reticulin staining showed fibrosis in 53 patients. In vitro increased proliferative activity stromal cells lymphoid tissue was established in all patients. The production of humoral factors by lymphoid microenvironment changed. We found increase IL-4, IL-6, TNF- α in condition medium after two weeks of culture in the presence of stromal cells. The stromal cells of tissue section of lymph nodes contained lymphocytes in cytoplasm. The process emperipolesis in adherent cells of lymph nodes cultures was seen too. **Conclusions.** The changes stromal microenvironment of lymph nodes can be one of the main pathogenetic factors in the impairment of lymphoid cells development in CLL.

EVALUATION OF 6Q21 AND 8Q24 ABERRATIONS AS MARKERS FOR PROGRESSION AND EVOLUTION OF CLL

M Moussa, G Eissa, M Elgendi, A Fouad
Ain Shams University, Cairo, Egypt

Background. Deletion 6q21 and 8q24 amplification are associated with poor prognosis in lymphoproliferative disorders that should be discovered to identify patients with poor prognosis. **Aims.** to detect 6q21/c-Myc aberrations in addition to the common aberrations in CLL patients and correlate these chromosomal abnormalities to the standard prognostic markers and clinical outcome of the disease.

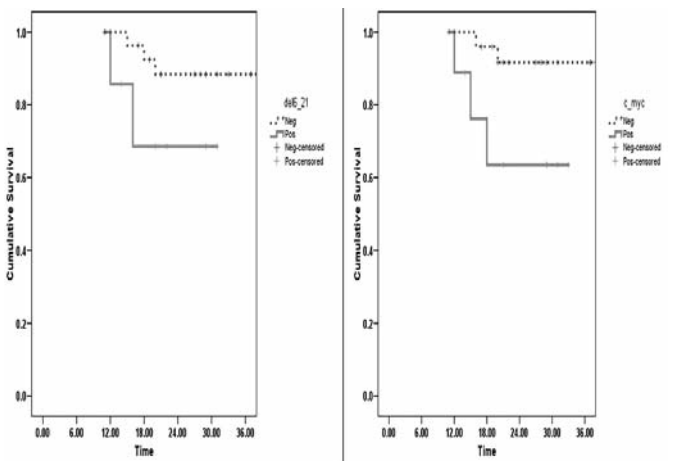

Figure 1. Kaplan Meier curves showing difference in event free survival of CLL patients having 6q21 deletion and c-Myc amplification (8q14) compared to negative ones.

Methods. Fluorescence in situ hybridization (FISH) technique using locus-specific identifier (LSI) 6q21 deletion /c-Myc (8q24), was applied on 75 B-CLL patients, in addition to the routine panel of probes (LSI 13q14,17p13 and centromeric 12) together with Immunophenotyping using the routine panel for lymphoproliferative disorder. **Results.** 6q21 deletion were detected in 14/75 (18. 7%) patients while c-Myc amplification were positive in 20/75 (26. 7%) patients. Each of these aberrations was associated with a shorter disease free survival. 6q21 deletion was significantly associated with low Hb level, high total leucocytic count, low platelets count, short LDT, advanced Rai clinical staging and higher expression of CD38. c-Myc amplification had statistically significant association, with lower Hb level, high TLC and shorter LDT. Deletions in 13q14 were 29/75 (38. 7%), trisomy 12 were in 18/75 (24%), and finally deletion 17 q (P53) were in 6/75 (8%). Higher incidence of 13q14 deletion was detected in patients with good outcome. On the contrary, trisomy 12 was significantly associated with a number of poor laboratory prognostic parameters and poor outcome. Disease outcome showed statistical significant association with some standard prognostic markers as old age, sex, advanced Rai staging, LDT, and CD38 expression. **Conclusions.** Deletion 6q21 and amplification c-Myc identify subgroup of CLL patients, associated with poor prognosis. These aberrations should be investigated before designing management protocols for patients presenting with advanced disease or poor prognosis early stage disease.

1281

EXPRESSION OF NATURAL KILLER CELL ACTIVATING RECEPTORS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

T Costello, B Knoblauch, C Sanchez, D Mercier, T Le Treut, G Sébahoun
Assistance Publique des Hôpitaux de Marseille, Marseille, France

Backgroud. Recent advances in chronic lymphocytic leukemia (CLL) treatment, more particularly *via* upfront use of anti-CD20 monoclonal antibodies, have prolonged patient progression-free survival. Nonetheless, apart from allogeneic stem cell transplantation, no curative treatment is available. One possible explanation for the lack of cure in CLL could be defective immune antitumor response. Due to abnormal human leukocyte antigen (HLA) class I molecule expression, CLL cells escape from specific T-lymphocyte immunity but thus should be the target for innate NK-mediated immune response. **Aims.** Defective NK cytotoxicity due to decreased expression of the Natural Cytotoxicity Receptors (NCR) NKp30/NCR3, NKp44/NCR2 and NKp46/NCR1 has been described in hematological malignancies such as acute myeloid leukemia (AML). This prompted us to focus our attention on NCR expression on NK from CLL patients. **Methods.** NK cell analysis as performed by flow cytometry using NK cells from CLL patient (obtained after informed consent) in comparison with age-matched donors. NK cells were defined as CD3-CD56+. **Results.** Although we failed to detect any difference between CLL patients and healthy age-matched controls, a precise analysis of clinical data showed a correlation between decreased NCR expression and poor prognosis factors such as low hemoglobin (Hb) level, high (>30 G/L) lymphocyte number or elevated C reactive protein (CRP). **Conclusions.** Together, these observations support the rationale for restoration of normal NK functions in CLL patients, putatively *via* the use of immune therapy protocols that already have demonstrated some benefit in AML such as IL-2 plus histamine dihydrochloride.

1282

T PERIPHERAL CD26 NEGATICE CELLS IN CD4 POSITIVE LONG TERM LYMPHOCYTOSIS

G Tagariello, R Di Gaetano, R Sartori, B Callegari, N Maschio, P Radossi, E Scarpa
Castelfranco Veneto Hospital, Castelfranco Veneto, Italy

Introductions. Flow cytometric (FC) immunophenotyping is a powerful modality in the characterization of lymphocytosis but it can be insufficient, in detecting the nature of T cell expansions. Seen that T neoplasms can often show aberrant phenotype, from 2009 we have analyzed in patients with persistent asintomatic T lymphocytosis, the expression of different antigens. **Methods.** 30 asymptomatic subjects (average age 62 years) with persistent peripheral lymphocytosis with T proliferations (>4560 mm^3 T cells) were followed up for three years; antigens such as CD3, CD4, CD7, CD8, and TCRV were tested. Over the pan-T-cell antigens, we have investigated the CD26 which represents a molecule expression with multiple biological functions and demonstrated utility in the diagnosis of T cell disorders (it is preferentially restricted to the CD4+ helper/memory population and many reports show its absence is characteristic of circulating Sézary cells). Cells from peripheral blood were stained with monoclonal antibodies and analyzed by FC to assess the expression of T cell antigen. In samples with phenotypic alterations we have studied the TCRV and

performed molecular analysis for TCR gamma gene clonal rearrangement. **Results.** over the antigen panel positive for the phenotype $CD3^+$ $CD4^+$ $CD8^-$ and $CD45R0^+$,the most commonly observed aberrancy was the lack or the very low expression of CD26 subset (100% of cases) while CD7 subset was variable as it was absent/low in 50% of samples. All, moreover, showed alterations variously in the TCRV repertoire and their clonal nature was confirmed by the demonstration of TCR rearrangement. After this 3 yrs follow up 2 out of 14 (14%) of the subjects have been diagnosed as Sezary syndrome. **Conclusions.** Asymptomatic persistent clonal lymphocytosis with immunophenotype $CD4^+$ $CD26^-$ defined as monoclonal T lymphocytosis (MTL) should be monitored carefully as the absence of CD26 expression may be suitable of the progression towards T malignant lymphoprolipherative syndromes such as SS

1283

C-KIT MUTATION DETECTION IN TUNISIAN PATIENTS WITH NEWLY DIAGNOSED MYELOGENOUS LEUKEMIA: PREVALENCE AND PROGNOSTIC SIGNIFICANCE

S Ouerhani, H Gharbi, S Menif, I Safra, S Abbes
Pasteur, Tunis, Tunisia

Background. *C-KIT* gene encodes a class III tyrosine kinase receptor. Specific somatic mutations in this gene were associated with many diseases. **Aims.** In this study we investigated the prevalence of *C-KIT* mutations in patients with chronic and acute myelogenous leukemia (CML and AML) and their prognostic significance. **Methods.** A total of 157 subjects was included in the present study (84 patients with CML, 33 with AML and 40 healthy controls). All patients were analyzed at the first diagnosis. The *C-KIT* mutations were screened by PCR and direct sequencing. **Results.** Our results have reported the presence of G/A transition at codon 796 which is associated with R796K protein variation. This mutation is described for the first time and detected at 21. 42 % in CML subgroup and it was absent for AML and healthy controls. However, we have not found any correlation between this mutation and clinical parameters such us molecular response to Gleevec. **Conclusions.** In conclusion we retain that *C-KIT* gene is highly mutated in CML but its role as a prognostic factor needs to be more elucidated.

1284

DISTRIBUTION OF CYTOGENETIC ABNORMALITIES IN CHRONIC LYMPHOCYTIC LEUKEMIA IN BLIDA

S Taoussi, S Oukid, M Abad
EHS CAC, Blida, Algeria

Background. To clarify the cytogenetic characteristics of chronic lymphoid leukemia (CLL) in our region, a prospective study by fluorescent in situ hybridization (FISH) was conducted. **Aims.** to identify patients with poor prognosis cytogenetic abnormalities. **Materials and Methods.** Over a period of 5 years, 95 cases of LLC have been studied by FISH; collection of peripheral blood on heparin lithium; a culture of 72 hours with PMA / PHA is carried out. The probes used: CEP12,13 q 14 / 13qter, P53 (17p13) / ATM (q 11, 22), 6 q 21 / SE 6. **Results.** The study involved 95 new cases of LLC; 69 men and 26 women with a median age of 61 years (37-80). Matutes score =3 in6 cases (6. 3%), the rest (93. 7%) at 4-5. Binet classification: stage A = 17, stage B = 33, stage C = 45. Recurrent anomalies found in 78 cases (82. 1%):del(13 q 14) in 48 cases (50. 5%), 25 times isolated. Trisomy12 in25 cases (26. 3%), isolated in 13 cases;del(P53) in 17 cases (17. 8%), isolated in 2 cases;del(ATM) in 16 cases (16. 8%), isolated in 3 cases;del(6 q 21) in 11 cases (11. 5%). No abnormalities in 17 cases (17. 9%). According to Binet stage: Stage A (17 cases): 12 present adel(13 q 14), isolated in 10 cases (58. 8%). Trisomy 12: 3 cases. del(P53) in 2 cases. No abnormalities: 2 cases. Stage B (33 cases): no abnormalities in 10 cases (30%); a del (13 q 14) in 14 cases, isolated in 5 cases (15%); a Trisomy12 in8 cases (24. 2%); an del (ATM) in 7 cases (21. 2%), a del (P53) in 2 cases (6%), a del (6q 21) in 5 cases (15%). In the stage C (45 cases): del (13 q 14) in 22 cases, 10 times isolated (22. 2%), in 7 cases associated with del (P53)and with 3 del (ATM) cases and in 2 cases with del (6 q 21); a del (P53) in 11 cases (24. 4%), isolated in one case; a Trisomy12 in 14 cases, isolated in 7 cases (15. 5%); an del (ATM) in 9 cases (20%) isolated in a case; No abnormalities in 5 cases (11%). **Conclusions.** Cytogenetic analysis by FISH is a useful prognostic tool. The frequency of recurrent abnormalities found by FISH in our work is similar to other published series. (82. 1% vs 80%); The del (13 q 14) is a little less common than which was previously reported by others (50. 5% vs. 55 to 63%, respectively); frequency of Trisomy 12 (26, 3 vs 13 to 25%), and the del (ATM) (16. 8% vs 11 to 18%) join those of literature; the frequencies of the del (P53) (17. 8% vs. 7%) and the del (q 6, 21) (11. 5 vs 7%) are higher than those observed in the literature. Thedel(ATM) is found only in the stages B and C; of the 17 cases ofdel(P53), 11 cas (64. 7%) are found at stage C. These data indicate the high frequency of del(P53) in our study, deemed very poor prognosis because of the resistance to therapeutic regimens fludarabine-based.

1285

CORRELATION BETWEEN ZAP-70 LEVEL AND OTHERS PROGNOSTICS MARKERS IN B- CLL PATIENTS

A Rivkina[1], M Murovska[2], G Vitols[2], S Lejniece[3]
[1]Chemoterary and Haematology Clinic, Riga, Latvia
[2]Riga Stradins University, A. Kirhensteins Institute of Microbiology and Virology, Riga, Latvia
[3]Riga Eastern Clinical University Hospital, Chemotherapeutic and Haematological C, Riga, Latvia

Background. ZAP-70 (zeta-associated protein-70kDa) is normally expressed in T cells and NK cells. Recent studies have shown its value as a surrogate marker for the IgVH mutation status in B-CLL. ZAP-70 is very useful for B-CLL prognosis. Using flow cytometry we investigated if there is any correlation between ZAP-70 expression and other prognostic markers in B-Cell chronic lymphocytic leukemia (B-CLL). B-CLL is the most frequent oncoheamatological diagnosis inLatvia within the past 10 years. **Aims.** The levels of ZAP-70, Thymidine kinase (TK), B-2 microglobulin (B2mg), Lactate dehydrogenase (LDH) and CD38 was determined in patients with B-CLL both pre treatment, 6 months and 12 months post initiation of chemo and glucocorticoid therapy. Patients were grouped using the Rai staging system and levels of markers assessed within each stage. B-CLL is the most common oncohaematological disease inLatvia and to be able to rapidly identify and utilize all markers as a prognostic factor in this disease will improve the appropriate selection of more effective treatment. **Methods.** The research group consisted of 120 newly diagnosed B-CLL patients during the period 2008 to 2010. The selection of patients was carried out at the Centre of Haematology inLatvia. ZAP-70 level was determined using the PN 772587 kit from Beckman Coulter, Inc. We had defined three levels of ZAP-70 expression: ZAP-70 interval 0-10 % positivity, reflects low degree of disease activity, 10-20 % positivity reflects medium degree of disease activity, greater than 20 % positivity corresponds to a high degree of disease activity. The level of CD38 was determined using CD38-FITC PN IM0775 from Beckman Coulter, Inc. The cut-off level was defined as 30 % positive. Serum TK levels was determined using an ELISA technique. Serum TK level in healthy donors is less then 50 ng/L. In this method a minimal detection level (sensitivity) of 50ng/L was attained. The parameters LDH, B2mg were determined by using of lumeniscent immunochemocal method Latvian Central Ethics Commission approved the research design and all patients enrolled in this investigation had given informed consent. **Results.** 120 patients were assessed in this study, consisting of 60 females and 60 males; the mean age of patients was 68. The patients were divided into three groups according to ZAP-70 expression: I- ZAP-70 0-10% +ve; II - ZAP-70 10-20% +ve and III - ZAP-70 greater then 20% +ve. **Conclusions.** The correlation between ZAP-70 and CD38 are in all period of control, in groups with 10-20% expression of ZAP-70. There are correlation between TK and LDH in different groups ZAP-70 expression in the period of after 12 month . The pair of prognostic markers ZAP-70/CD38 can use for control in the boundary group of patients, and the pair of prognostic markers TK/LDH can use for control after period of treatment.

Table 1. Correlation between ZAP-70 level and others prognostics markers in B-CLL patients.

1286

ANALYSIS OF BLOOD LYMPHOCYTOSIS MIMICKING OF ADULT CHRONIC LYMPHOCYTIC LEUKEMIA

S Belakehal, M Rahali, L Sahraoui, A Cherait, F Ardjoun
HCA, Algies, Algeria

Background. In most cases, the presence of an absolute lymphocytosis and lasting (more than 3 months) in adults is related to the existence of a B-chron-

ic lymphoproliferative disorder (B-CLD). It is important to characterize the exact type of CLD, because the therapeutic management varies with the blood disease. Lymphocytosis is a benign event frequently observed after conditions of stress or a viral infection. Sustainable lymphocytosis was also described in rheumatoid arthritis and Hodgkin's disease. The blood smear examination is the first step of diagnosis. Morphological analysis must be completed within a second time by the study of lymphoid cells by flow cytometry (FCM) to distinguish malignant proliferations B or T, and reactive lymphocytosis. **Methods.** 66 patients with blood lymphocytosis have been included in this study for two years [January 2010-December 2011]. We performed a systematic way a complete blood count, a very careful cytological analysis of blood smears stained with MGG, and immunophenotypic study of lymphoid cells in peripheral blood by CMF. In some cases the comparison with histology (bone marrow biopsy) was necessary. **Results.** The average age of the study population was 61. 45 years [20-90], with a male predominance (53 men 13 women) and a sex ratio = 4. 07. At the NFS, the average WBC = 55,711 élts/mm3 [1840-436 490], with an average rate of lymphocytes élts/mm3 = 47 642 [1380 to 405 935], a mean Hb = 11,04 g/ dl [5. 7 to 14. 9], and an average of 154 288 platelets élts/mm3 [13 000-446 000]. The myelogram was practiced in 13 cases (8%), and bone marrow biopsy was performed in 15 cases (10%). In CLL (n = 37 cases), there is a very interesting way to FS, a monomorphic appearance, with the constant presence of non-slotted small mature lymphocytes and shadows of Gumprecht. The score for Matutes (SM): = 3 (n = 7 cases), = 4 (n = 15 cases), and = 5 (n = 15 cases). During the B-CLD (n = 16): the cytological aspect depends on the type of lymphoma. Two cases of hairy cell leukemia, with a score of hairy cell (CD11c, CD25, CD103) = 3. One case of follicular NHL, with a SM = 3. Six cases of MCL, with SM <3. Four cases of MZL, with SM <3 (n = 3) = 3 (n = 1). A case of SLVL with SM = 1. Two cases of small cell B-NHL difficult to classify, with SM <3. The T-CLD (n = 3): 2 cases of leukaemia NHL-T and one case of Sézary syndrome. There 09 cases of benign reactive lymphocytosis, and 01 cases of CMML, with a Matutes score = 1 (CD5 +) and an aspect polyclonal B-cell CD19 + (expression of two light chains). **Conclusions.** The lymphocytosis is frequently encountered when reading in the blood. On a blood smear, the reactive nature of the lymphocytosis has not escaped the eye of a hematologist warned. A persistent lymphocytosis should be investigated, including immunophenotypic analysis by FCM. Admittedly, there is always a risk of missing a CLD B or T.

1287

VALUE OF SERUM THYMIDINE KINASE LEVEL, EXPRESSION OF ZAP-70 PROTEIN AND CD38 ANTIGEN IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA WITH STAGE A

T Zagoskina, E Zotina, O Malykh
Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background. The clinical course of chronic lymphocytic leukemia (CLL) is characterized by extreme heterogeneity. We know a lot of factors to evaluate its prognosis. The most significant of these is the mutation status of the heavy chain variable regions immunoglobulin genes (IgVH). However, using this method in clinical practice is very difficult. At the same time the expression of protein ZAP-70 and antigen CD38 is considered to be a reflection of mutation status IgVH. Along with surrogate markers in recent years, much attention is paid to the study of cell proliferative activity of CLL, for which the enzyme thymidine kinase (TK) may serve as an indicator. **Aims.** To determine the clinical course of CLL, depending on the content of TK, expression of ZAP-70 and CD38 at the time of diagnosis. **Methods.** Ninety-eight CLL patients aged 35 to 79 years (median 62) were included in the study. All patients were in Binet stage A. At the time of diagnosis the expression level of Zap-70 and CD38 by flow cytometry, has been investigated, the threshold of positive expression of ZAP-70 was 20%, CD38 - 30%. The content of serum TK was assessed by a radioenzyme method. The level of TK in healthy people (n=50) was equal to 5. 2 U/L (95% CI: 4. 3-6. 8). Patients were divided into 2 groups by the nature of the flow of CLL. The first group included 67 (68%) patients with indolent disease course, in which the median treatment free survival (TFS) was 36 months. The second group included 31 (32%) patients with progressive CLL, in which the median TFS was 8. 7 months. The formation of groups was performed retrospectively. The observation of the course of disease was three years or more in every patient from the moment of diagnosis. **Results.** A positive expression of ZAP-70 was observed in 21 (31%) patients with indolent CLL, CD38 in 16 (24%). In the group with progressive disease the expression of ZAP-70 was positive in 30 (97%) patients, CD38 in 27 (87%), so it is almost 3 times higher than in patients with the sluggish variant of CLL. The content of the TK was 22. 6 U/L (95% CI: 20. 5-26. 3) in the progressive form of the disease. Whereas in the indolent form of CLL TK level was equal to 12. 7 U/L (95% CI: 8. 3-14. 9). At the same time the correlation between the expression of ZAP-70, CD38, and TK levels in patients with indolent CLL was not found (R=0. 199; p=0. 137 and R=0. 163; p=0. 437, respectively). **Conclusions.** The positive expression of ZAP-70, CD38 correlates with progressive CLL, but this relationship is not absolute. Along with the expression of ZAP-70, CD38 the determination of serum TK at the time of diagnosis of CLL adds prognostic information. For a more precise stratification of the patients a complex of prognostic factors, including the ZAP-70, CD38, and TK should be used on the risk of disease progression at the same time, which allows to identify a subgroup with a poor prognosis among patients with indolent course of CLL.

1288

COMPLEMENTARY AND ALTERNATIVE MEDICINE USE IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A MULTICENTRIC ITALIAN SURVEY

Background. According to the National Institute of Health (NIH), Complementary and Alternative Medicine (CAM) is defined as a group of diverse medical and health care systems, practices, and products that are not generally considered part of conventional medicine and, generally, have limited scientific evidence. The use of CAM is common in cancer patients and is steadily increasing over time. **Aims.** This study reports the preliminary results of an ongoing Italian multicentric survey in which we would like to assess the use of CAM in patients with chronic lymphocytic leukemia (CLL) and to identify social and economical features related to its use. The protocol was approved by local Ethical Committees and informed consent was given by patients. **Methods.** Data were collected by means of a standardized questionnaire with several items assessing the use of CAM, reasons for CAM use, as well as demographic, disease status and treatment. The sample consisted of 309 patients with CLL followed at 13 Italian Hematologic Institutions. **Results.** One hundred seventy-seven (57%) patients were male and 132 (43%) female. Mean age was 69 years (range 37-94 years). The majority of patients came from Southern Italy (59%), the remaining patients came from Central (32%) and Northern Italy (9%), respectively. Of 309 participants, 42 (14%) were found to be CAM users. The majority of them started CAM after the diagnosis of CLL. The most commonly CAM therapies were green tea (18 patients), aloe (7 patients), and high dose vitamins (7 patients). Main sources of information about CAM were friends, family, media, physicians and Internet. Predictors for CAM use were a higher education level (p <0. 01) and internet availability (p <0. 001). No difference, however, were found among gender, age, occupation and urban or rural area of residence. **Conclusions.** CAM is frequently used in CLL patients. The reasons for CAM popularity among these patients are complex. Given the number of patients combining conventional therapy with CAM and the possible drug interactions, doctor interest as well as patient education about CAM should be improved.

1289

FRONT-LINE THERAPY WITH CHLORAMBUCIL PLUS RITUXIMAB IN ELDERLY AND/OR UNFIT PATIENTS AFFECTED BY CHRONIC LYMPHOCYTIC LEUKEMIA

I Innocenti, M Tarnani, B Vannata, L De Padua, F Santini, S Marietti, T Za, S Bellesi, F Autore, P Chiusolo, F Sorà, S Sica, G Leone, L Laurenti
Institute of Hematology UCSC, Rome, Italy

Background. Despite the increasing use of combination therapy with rituximab (R), fludarabine and cyclophosphamide for chronic lymphocytic leukemia

(CLL), a significant proportion of patients (pts) are not suitable for such intensive chemotherapy regimen because of co-morbidities and/or age. In those pts unfit for fludarabine based regimen, chlorambucil (CHL) remains a widely used first-line therapy. Its combination with monoclonal antibodies such as R seems to increase the overall responses rates (ORR) with good tolerability. Up to now two cooperative studies showed an ORR of 82% with a progression free survival (PFS) of 23,5 months after association of CHL-R as induction therapy for untreated elderly CLL patients. **Aims.** The purpose of this study was to evaluate the safety and efficacy of CHL-R as front-line therapy in elderly pts and /or unfit to Fludarabine regimens. Secondary endpoints included the adverse event profile, PFS, time to re-treatment and overall survival. **Methods.** At our institution, starting from February 2008, 22 pts(14 male, 8 female) received CHL (1 mg/kg p. o. at standard dose of 10 mg/day every 28 days for 8 cycles) plus R (day 1 375 mg/m^2 i. v. cycle 1, 500 mg/m^2 cycles 2-6) as front-line therapy. At study entry FISH analysis, IgVH mutational status, expression of Zap-70 and CD38 were evaluated. Fourteen pts were elderly and 8 unfit for CIRS; median age was 70 years (range 58-81). Four pts were in Binet stage A, 10 in stage B and 8 in stage C. Biological profile was characterized by good FISH profile (del13q, normal karyotype, trisomy 12 and del11q in 11, 6, 2,3 pts respectively). Moreover 7 pts were CD38+ and 6 pts were Zap-70+. Eighteen pts were informative for IgVH mutational status and 11 pts were unmutated. **Results.** The ORR was 73%; seven pts (32%) obtained CR and 9 pts PR (41%). A progressive disease (PD) was recorded in 1 patient and a stable disease in 3 pts. Two out of 22 did not complete therapy for progressive disease (one patient for autoimmune haemolitic anemia and one for increasing lymphoadenopathy). Median PFS and time to treatment was not reached at a median of 16 and 14,5 months respectively. Five pts showed PD and 6 pts required therapy; 3 pts died (2 for secondary solid neoplasia and 1 patient for PD) after 17, 31 and 23 months respectively. None of 22 enrolled patients required dose reduction of chemo-immunotherapy or needed hospitalization. Five patients (23%) experienced haematological toxicity (4 pts with grade IV neutropenia requiring G-CSF) and six patients extra-haematological toxicity consisting of tumor lysis syndrome in 5 pts and CMV reactivation in 1 patient. **Conclusions.** These data confirm that in elderly/unfit untreated CLL pts the combination of CHL-R is efficacy and well tolerated, resulting in a good ORR. Future multicentre study with a higher number of patients and with a longer follow-up will be planned to solve the question if this treatment could be useful for elderly and/or unfit patients and if a maintenance therapy could be recommended.

1290

CLINICAL SIGNIFICANS OF SERUM IGG SUBCLASS DEFICIENCY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

G Svensson, H Cherif, M Höglund
Department of Hematology, Uppsala, Sweden

Background. Hypogammaglobulinemia is a well known immune defect in patients with Chronic Lymphocytic Leukemia (CLL). Serum levels of immunoglobulins (Ig) are routinely measured and patients with hypogammaglobulinemia and recurrent infections are offered prophylactic intravenous Ig substitution. The occurrence of selective IgG-subclass deficiency (with normal total Ig levels) and its clinical significance in patients with CLL is not well defined. **Aims.** To assess the prevalence of IgG subclass deficiency and its correlation to increased risk of infectious complications in patients with CLL. To investigate the clinical value of routine measurement of serum IgG subclass levels. **Methods.** At a given point year 2011, patients with the diagnosis CLL at Uppsala University Hospital, diagnosed 1987-2011, were asked to participate in the study. Serum levels of Ig and IgG subclasses were determined. Hypogammaglobulinemia was defined as: IgG < 6,7 g/L, IgA < 0,88 g/L and IgM < 0,27 g/L. Subclass deficiency was defined as IgG1 < 2,8 g/L, IgG2 < 1,15 g/L, IgG3 < 0,24 g/L. Clinical data regarding patient and disease characteristics were collected through patient records and questionnaires. Possible risk factors for infections and Ig-defects were analyzed. **Results.** A total of 111 CLL patients, median age of 71 (range 49-90), were included. The median disease duration at inclusion was 48 months (range 4-286), and 33. 3% had previously received chemotherapy. The annual overall risk for simple (outpatient) infections, severe (inpatient) infections and sepsis were 79. 3%, 12. 6% and 2. 3% respectively. Hypogammaglobulinemia was common and occurred in 52. 3% of the patients. Those with hypogammaglobulinemia had longer disease duration (median 61. 5, range 5-286 vs. 35, range 4-222 months, P=0. 004) and had more frequently received treatment for CLL (44. 8 vs. 20. 8%, P=0. 009), than patients without hypogammaglobulinemia. However, patients with hypogammaglobulinemia did not have a higher annual risk of infections than patients without hypogammaglobulinemia (79. 5 vs. 79. 1%, P= 0,706 for all infections; 13. 4% vs. 11. 2%, P= 0. 394 for severe infections and 1. 7% vs. 3. 4%, P= 0. 083 for sepsis). Selective subclass deficiency was uncommon and occurred in six of 111 patients (5. 4%). Although the figures were small, the annual overall risk of infections, of severe infections or of sepsis for these patients did not differ from patients with no hypogammaglobulinemi and no subclass deficiency (70. 8 vs. 80. 7%, P=0. 334, 11. 8 vs. 11. 1%, P=0. 497 and 8. 9 vs. 2. 3%, P=0. 067, respectively). **Summary and Conclusions.** Selective IgG subclass deficiency is rare in patients with CLL. In this heterogeneous cohort of patients, neither hypogammaglobulinemia nor selective IgG subclass deficiency were significant risk factors for infectious complications. Measurement of serum levels of Ig may be motivated in selected patients with recurrent severe infections, but routine analysis of IgG subclass levels in patients with CLL is not warranted.

1291

DETECTION OF MINIMAL RESIDUAL DISEASE IN PATIENT WITH CHRONIC LYMPHOCYTIC LEUKEMIA USING BOTH FOUR-COLOR AND EIGHT-COLOR FLOW CYTOMETRY AND QUANTITATIVE REAL TIME PCR APPROACH

J Chovancova[1], O Stehlikova[2], V Hrabcakova[2], B Tichý[3], H Francova Skuhrova[2], K Burckova[2], M Krejci[2], Y Brychtova[2], M Borsky[2], J Mayer[4], S Pospisilova[2], M Doubek[2]
[1]Masaryk Univesity Brno, Brno, Czech Republic
[2]University Hospital Brno, Brno, Czech Republic
[3]Central European Institute of Technology, Brno, Czech Republic
[43]Central European Institute of Technology, Brno, Czech Republic

Background. Minimal residual disease (MRD) is a routinely used term for small population of pathologic cells that remain during or after treatment when the patient is in remission. Rawstron et al. (2007) published four-color flow cytometric method, which made possible to standardize MRD assessment in patients with chronic lymphocytic leukemia (CLL). Application of this method enables to determine the MRD level in peripheral blood or bone marrow down to less then 0. 01% of leucocytes. The results can be compared to RQ-ASO IgH PCR (real-time quantitative allele-specific oligonucleotide Immunoglobulin Heavy chain gene PCR). In ASO-PCR individual patient-specific oligonucleotide primer are designed to detect MRD, its sensitivity reaches to 1 cell in 10^6. **Aims.** The aim of our study was to compare multiparametric flow cytometry to molecular biology approaches with detection of IgVH specific clones in patients with CLL diagnosis. **Methods.** Cohort of 22 CLL patients who underwent allogeneic stem-cell transplantation (SCT) was included in the study. MRD were analyzed employing four-color flow cytometry protocol (Rawstron, 2007) together with eight-color flow cytometry protocol. Cell surface were stained with fluorescence labeled monoclonal antibodies (anti-CD3, 5, 14, 19, 20, 22, 38, 43, 45, 79b and 81). Flow cytometric acquisition was performed on a FACSCantoII flow cytometer (Becton Dickinson,NJ,USA). Detection of clonal IgVH was performed by RQ-PCR with LNA probe (Locked Nucleic Acid, TaqMan technology). **Results.** Since RQ-ASO IgH PCR shows sensitivity attaining 1 cell in 10^6, 8. 6% of samples were found positive using RQ-PCR but negative using flow cytometry. However, 10 patients were simultaneously observed using flow cytometry and RQ-PCR method with strong correlation (r=0. 94). In 17 patients both flow cytometric protocols (four- and eight-color) were employed to observe the correlation of these two methods. It was found out that the correlation coefficient is getting closed to one (r=0. 96). **Summary and Conclusions.** We compared multiparametric flow cytometry to molecular biology approaches with detection of IgVH specific clones in patients with CLL diagnosis. Despite lower sensitiveness, flow cytometry is adequate method to MRD detection. Concurrently, we demonstrate potential application of eight-color flow cytometric protocol. The advantage of this protocol lies in simultaneous detection of more than two markers compared to four-color cytometry. **Acknowledgement.**This work was supported by grant MUNI/A/0784/201.

CD-MORPHOLOGY MICROARRAY - A NEW DIAGNOSTIC METHOD IN ONCOHEMATOLOGY APPLIED TO HAIRY CELL LEUKEMIA

A Khvastunova[1], A Doronina[1], I Chernykh[1], L Al-Radi[2], F Ataullakhanov[3], S Kuznetsova[1]
[1]Centre for Children Hematology, Oncology and Immunology, Moscow, Russian Federation
[2]Research Centre for Hematology, Moscow, Russian Federation
[3]Centre for theoretical problems of Physico-Chemical Pharmacology, Moscow, Russian Federation

Background. Current diagnosis of oncohematological malignancies is based on a variety of methods. Most widely used are the blood or bone marrow smear examination for leukocyte morphology and immunophenotyping. The presence of leukocytes with atypical or pathological morphology in smears is

in many cases the first indication of hematological neoplasia. At the same time, in case of a suspected lymphoproliferative disorder the final diagnosis requires the differentiation between the lymphocyte subpopulations that cannot be done by morphology alone. The flow cytometry, currently used for immunophenotyping, allows to define the general amount of cells with a specific immunophenotype but gives no information about the cell morphology. **Aims.** The impossibility of applying both methods to the same cell can lead to controversies in diagnosis. We have developed a new diagnostic method for simultaneous determination of CD markers and complete cell morphology analysis based on a CD-Morphology microarray. **Methods.** CD-Morphology microarray is a set of monoclonal antibodies specific for 35 leukocyte surface antigens including isotype controls spotted on a transparent plastic slide. Upon incubation of leukocyte suspension with the microarray, cells with specific surface antigens are binding to corresponding immobilized antibodies. After the nonspecifically bound cells are washed away, areas of leukocytes positive for individual CD antigens stay bound with the microarray. The morphology of the bound cells can then be studied after standard cytological staining. Thus the CD-Morphology microarray allows to investigate the morphology of blood cells for which one of its surface CD antigens is known. **Results.** We have studied lymphocyte suspensions from peripheral blood of 10 patients with suspected hairy cell leukemia. Hairy cell leukemia (HCL) is a mature B-cell lymphoproliferative disorder characterised by distinct morphology and immunophenotype. HCL is diagnosed based on the presence of "hairy"or villous lymphocytes with strong expression of CD19, CD20, CD22, CD11c and moderate expression of CD103 and CD25 in blood or bone marrow smears. In all studied patients immunophenotype and lymphocyte morphology in smears corresponded to HCL. In 7 patients we have found lymphocytes with cytoplasm edge irregularities ranging from hairy projections through shaggy to serrated or festooned borders positive for CD11c, CD19, CD20, CD25 and CD103 that permitted us to suggest the presence of hairy cell leukemia. In two of those seven patients the hairy cells (HC) were also positive for CD2. For this patient group the HCL diagnosis was confirmed by histological and cytochemical examination. The peripheral blood of the remaining 3 patients contained small amount of CD11c+ lymphocytes, but no CD103-positive lymphocytes. In all of them various amounts of villous lymphocytes positive for CD19 (1-10% of total B-cells) but not for 11c were detected. We have also detected a group of CD19+, CD20+, CD22+ lymphocytes uncharacteristic for HCL and morphologically similar to neoplastic cells seen in patients with splenic marginal zone lymphoma (SMZL). These patients were diagnosed with SMZL based on immunophenotyping, histology and cytochemistry. **Conclusions.** The CD-Morphology microarray can be used in differential diagnostics of hairy cell leukemia vs splenic marginal zone lymphoma with villous lymphocytes.

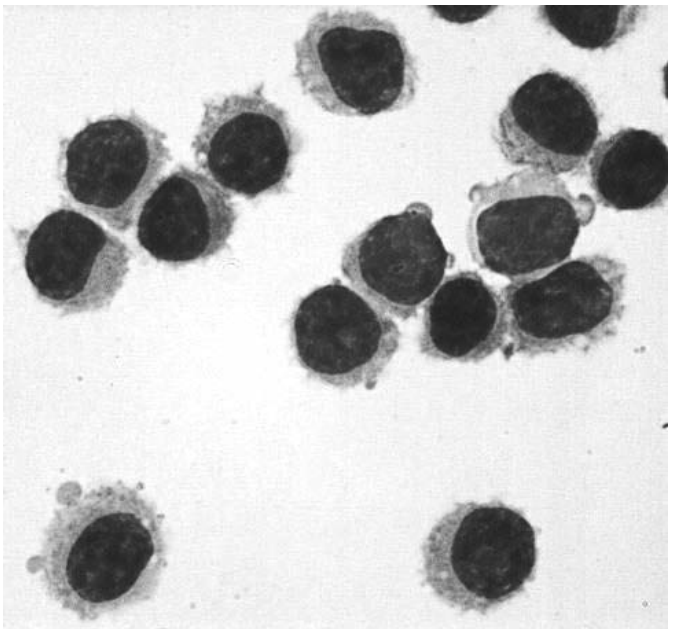

Figure 1. The morphology of CD11c+ lymphocytes isolated from peripheral blood of a patient with hairy cell leukemia.

1293

RITUXIMAB INFUSION-RELATED TOXICITY IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M Simkovic, M Motyckova, D Belada, J Maly, L Smolej
University Hospital and Faculty of Internal Medicine Hradec Kralove, Hradec Kralove, Czech Republic

Background and Aims. Rituximab in combination with chemotherapy is an effective treatment of patients (pts) with chronic lymphocytic leukemia (CLL). The most frequent adverse event of rituximab is infusion-related toxicity, e. g. cytokine-release syndrome that occurs usually during the first infusion. However, there is scarce data on feasibility and tolerability of rituximab infusions in CLL outside clinical trials. Therefore, we performed a single-center retrospective analysis of the frequency of rituximab infusion-related adverse events during the first- and the second line CLL treatment administered in the routine practice. We also analyzed its relation to parameters of tumor load and possible association with treatment efficacy. **Patients and Methods.** We analyzed 88 pts (62 males, median age, 62 years [range, 31-84]) with CLL treated between March 2005 and May 2011 at our institution. The most common first-line regimens were FCR (37 pts) and low-dose FCR (13 pts); 5 pts were treated by other protocols. Thirty-three pts underwent second line treatment: 7 pts FCR, 12 pts rituximab-dexamethasone, 6 pts low-dose FCR and 8 pts other regimens. Intravenous hydration (2000 ml on days 0 and 1 of cycle), allopurinol 300-600 mg p. o. and premedication with methylprednisolone 80 mg i. v., acetaminophen 1000 mg p. o. and bisulepine 1 mg i. v. were administered before rituximab infusion. Rituximab was given by fractionated infusion (100 mg for 2 hours, then if tolerated well, the rest of the dose with infusion rate escalation from 100mg/hour up to 400mg/hour) in a total dose 375 mg/m^2 in the first cycle and 500 mg/m^2 in subsequent cycles. **Results.** Rituximab infusion-related toxicity occurred in 35% pts (n=19) during the first line treatment and 21% pts (n=7) during the second line treatment. Adverse events were predominantly mild and NCI CTCAE grade III/IV occurred rarely (4% in the first line, 3% in the second line). Infusion toxicity manifested predominantly as rigors, chills, fever and/or hypotension and grade III/IV adverse events were syncope, respiratory distress and hypotension with collapse. All patients with adverse events could finish rituximab infusion at initially planned dose on the same day. Treatment response analysis did not demonstrate statistically significant differences between patients with and without rituximab infusion toxicity (fist line ORR 86 vs. 89%, second line 86 vs. 68%). Patients who developed rituximab infusion toxicity had higher initial absolute lymphocyte count (first line, 87 vs. 56 x 10^9/l, p=0. 21; second line, 101 vs. 14 x 10^9/l, p=0. 043). At the median time of follow up 27. 7 months, there were no statistically significant differences in PFS or OS in both cohorts. **Conclusions.** Rituximab infusion-related toxicity in pts with CLL is relatively frequent (35%). However, occurrence of infusion-related symptoms can be reduced by proper premedication and severe adverse events are uncommon. In our experience, all patients were able to receive the planned dose of rituximab. We did not find statistically significant association between rituximab infusion toxicity and effectiveness of treatment. Acknowledgements: Supported by research project MZO 00179906 from Ministry ofHealth,Czech Republic.

1294

DOSE DENSE HIGH DOSE METHYLPREDNISOLONE (HDMP) AND RITUXIMAB (RTX) ARE EFFECTIVE IN RELAPSED CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) WITH 17P DELETION (17P DEL) / TP53 MUTATION

R Pileckyte, V Valceckiene, T Zvirblis, L Griskevicius
Vilnius University Hospital Santariskiu Clinic, Vilnius, Lithuania

Background. Management of CLL patients with defective *TP53* pathway is a considerable challenge and the prognosis remains dismal. There are a few treatment options, including monoclonal antibody alemtuzumab as monotherapy or in combination, but response rates, progression free survival (PFS) and overall survival (OS) are still unsatisfactory. **Aims.** was to evaluate the efficacy and safety of dose dense HDMP and Rtx combination in relapsed CLL patients with 17pdel/*TP53* mutation in a frame of LT-CLL-001 study (described earlier[1]). **Methods.** Patients with 17p del/*TP53* mutation, who had relapsed or progressive disease after at least one line of chemotherapy were treated. HDMP was administered at 1 g/m^2 intravenously daily for five consecutive days of each treatment course. Rtx was administered at a dose of 375 mg/m^2 on day 1 and 500 mg/m^2 on day 5 of the first course, on days one and five of the second course, and on day one of courses three to six. Courses were repeated every 21 day for a total of 6. Response was evaluated according NCIWG-96 criteria. **Results.** 14 patients (13 enroled into a prospective study[1] and 1 on compassionate use grounds) were treated. Median age was 62 years (range

46 - 76), 11 (79%) patients had Rai III-IV stage, 8 (57%) had bulky (> 5 cm) lymphadenopathy. Five (36%) had 17p del only, one (7%) - *TP53* mutation only and 11q deletion, 8 (57%) patients had 17p del and *TP53* mutation, 4 (29%) patients were fludarabine refractory. Median number of HDMP-Rtx courses was 6 (1 - 6). Overall response rate (ORR) was 72%, all partial responses (PR), one patient (7%) had stable disease, 3 (21%) patients progressed. Two patients with PR underwent allogeneic bone marrow transplantation and are alive and free of disease to date. After the median follow-up of 30. 5 months, the median PFS is 12 months (range 9 - 15) and median OS is 31 month (26 - 36) (Figure 1). The most common toxicity was hyperglycemia not requiring intervention. 4 cases of III-IVº neutropenia and 2 cases of febrile neutropenia were observed. There were 3 (one treatment related) early deaths. **Conclusions** The dose dense HDMP and Rtx is effective and has acceptable safety profile in pretreated CLL patients with 17p del/*TP53* mutation. However it should be evaluated in a larger cohort as first or second line therapy, also before allogeneic bone marrow transplantation.

MATURE B-CELL NEOPLASMS AND RENAL CELL CARCINOMA OF CLEAR CELL TYPE - IS THERE A LINK?

Z Cvetkovic[1], N Suvajdzic[2], D Celeketic[3], B Cvetkovic[4]
[1]Clinical Hospital Centre Zemun, Belgrade, Serbia
[2]Clinic of Haematology Clinical Centre of Serbia, Belgrade, Serbia
[3]Department of Haematology Clinical Hospital Centre Zemunl, Belgrade, Serbia
[4]Department of Urology Clinical Hospital Centre Zemun, Belgrade, Serbia

Background. Mature B-cell malignancies (i. e. B -lymphoproliferative diseases, LPD) and renal cell carcinoma (RCC) account about 4% and 3% of all adult malignancies, respectively. Besides the trend of steady increase in incidence of both malignancies**,** several population-based epidemiological studies have also confirmed previously reported clinical observations of higher than expected occurrence of both malignancies in a same patient. It is shown that patients with RCC have 1. 51 and 1. 86 higher overall relative risk of multiple myeloma (MM) and non-Hodgkin lymphoma (NHL) than general population, respectively. On the other hand, the relative risk for developing RCC in patients with MM is 1. 89 and in NHL patients is 2. 67**.** Several reasons for that such as primary cytotoxic treatment, interactions of several environmental factors, genetic predisposition, viral infections or immunomodulatory effects of tumor itself are postulated, but the etiology is not jet clarified. **Aims.** To evaluate demographic, clinico- pathological characteristic and outcome of patients with LPD and RCC co-occurrence. **Methods.** Medical records of 680 consecutive patients with LPD and 570 consecutive patients with RCC diagnozed between January 1997 and December 2011 were retrospectively analyzed. **Results.** We found co-occurrence of both diseases in five patients (2. 5%; 3 males and 2 females) whose median age at LPD diagnosis was 58. 6 years (range 44-70). In two patients LPD were diagnosed synchronously with RCC. Indolent chronic lymphocytic leukemia (CLL) preceded RCC in one patent, while advanced-stage MM refractory to applied chemotherapy was diagnosed after RCC in two patients after a very short latent period. According to RCC type, all five patients had localized clear-cell RCC, predominantly of right kidney. None of these patient s have received any adjuvant therapy after nephrectomy and there was no sign of RCC recurrence during their last follow-up (Table 1). **Conclusions.** Although the number of patients in our study is small, our results suggest the significant association of LPD and clear-cell RCC. Extranodal presentation of NHL and poor outcome of patients with MM are in line with previously reported data. Synchronous occurrence of LPD and RCC or short latent period between the diagnoses of these two malignancies in the same patient, as well as no cytotoxic treatment for firstly occurring neoplasm indicate the common pathobiology of both diseases.

KIDNEY INVOLVEMENT IN CHRONIC B-CELL LYMPHOCYTIC LEUKEMIA

H Julhakyan[1], L Birjukova[2], I Kaplanskaya[2]
[1]Hematological Scientific Center, Moscow, Russian Federation
[2]Hematological Research Center, Moscow, Russian Federation

Background. Patients with non-Hodgkin lymphoma can develop renal failure in many ways: obstruction, infiltration of various parts of urinary tract. This can lead to renal failure. And finally, kidneys can be damaged as a result of treatment. Leukemic infiltration of the kidney has been found in over 60%-80% of the autopsies performed patients with chronic lymphocytic leukemia (CLL), but it is only rarely associated with renal failure. **Aims.** of this study To determine the incidence of kidney damage in patients with chronic lymphocytic leukemia and identify the morphological features of kidney damage in patients with CLL, complicated by the development of acute renal failure. **Materials and Methods.** Following retrospective analysis, 30 cases with CLL from the Department of Pathology of the Hematological Research Center(Moscow, Russia) were examined by light microscopy. All patients were treated with various regimens of chemotherapy and undergoing to autopsy between January 2000 and December 2010. We reviewed kidney specimens and assessed them for the presence of leukemic infiltrates. There were 24 male and 6 female. The median age was 61 years (from 43 to 71 years). Patients over 60 years were 13. Disease duration was from 3 to 64 months. All patients were died in the intensive care unit in connection with the development of complications during chemotherapy. Acute renal failure (ARF) was observed in 18 (60%) patients and in same patients hypertension were in 3 cases, diabetes mellitus - in 2 cases, hyperuricemia - in 4 cases, paraprotein secretion - in 5 cases, hyperleukocytosis (45 - 219 x 10^9/l) in peripheral blood - in 11 cases. Acute tubular necrosis in histological specimens was revealed in cases of CLL with acute renal failure. **Results.** Morphological study of histological specimens of autopsied kidney was detected leukemic infiltration in 26 (86. 7%) cases. Leukemic infiltration of the glomeruli was detected in 11 (42. 3%) cases, while in other cases infiltration only interstitial. Leukemic infiltration of the glomeruli was detected in cases where CLL was characterized with hyperleukocytosis. In cases with secretion of paraprotein there were morphological signs of glomerulitis. Sclerosis and fibrosis was apparent in cases with concomitant diseases (hypertension, diabetes mellitus). **Conclusions.** Thus, more than in 80% cases renal

damage was observed in CLL according to the autopsy. The development of acute renal failure not only related to the therapy or complications or concomitant disease, but also associated with clinical manifestations of the disease (hyperleukocytosis, M-component). The massive leukemic lesions of the glomerular apparatus were observed only in patients with hyperleukocytosis.

1297

COMBINATION OF THE DISTINCT CLINICAL AND BIOLOGICAL MARKERS OF CLL PATIENTS IN THEIR PROGNOSTIC STRATIFICATION: PRELIMINARY RESULTS FROM SINGLE CENTER EXPERIENCE

S Trajkova, L Cevreska, A Stojanovik, M Ivanovski, D Dukovski, I Panovska-Stavridis
University Clinic for Haematology, Skopje, Macedonia

Introduction. The clinical course for patients with chronic lymphocytic leukemia is extremely heterogeneous, some patients have indolent disease, never needing treatment, whereas others have aggressive disease requiring early treatment. One of the most important challenges in the clinical management of those patients is the decision of initiating their treatment because there is no available prognostic system that will resolve this issue. Usually, criteria for active disease are used to initiate therapy. Recently, some authors proposed prognostic models that combines a set of clinical risk factors and estimates individual patient survivals. Here, we report our initial results from a study designed to evaluate the statistical association of the distinct clinical and biological parameters with the prognosis and time to initiating treatment for patients with CLL. **Materials and Methods.** Our study incorporated 115consecutive, treatment naïve CLL patient. In each patient all traditional laboratory, clinical and biological prognostic factors were evaluated at their first visit to our Institution. Than we combined the following independent characteristics: age, β-2 microglobulin, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups, which are included in some of the already published CLL prognostics index, in association with the CD38 expression. Further, we correlate those factors by multivariable analysis with time to first treatment. This multivariable model was used to develop a nomogram-a weighted tool to calculate 5- and 10-year survival probability a 2- and 4-year probability of treatment and estimate median time to first treatment. **Results.** According to prognostic index a classification tree was built that identified three subsets of patients who scores were 1-3 (low risk- 20pts-17,3%), 4-7 (intermediate risk-80pts-69,5%) and >8 (high risk-15pts-13%). Estimated median survival at low risk subset of patients is 22,5years, 10,8 and 4years respectively at intermediate and high risk subsets of patients. Projected survival in respectively low, intermediate and high-risk groups was 70%, 92,5%, 100%, and 100%, 99%, 60% at 5-year and10-year, respectively. The following were independently associated with shorter time to first treatment: Also, statistical analyses showed that three involved lymph node sites and CD38 expression is associated with shorter time to first treatment. **Conclusions.** Our prognostic model that combines and correlates the distinct clinical and biological markers of CLL patients enables identification of the patients that are at high risk for progression. This prognostic model may facilitate clinical decision for initiating treatment. Reply to: Send

THE HISTORY OF CHRONIC LYMPHOCYTIC LEUKEMIA IN A SINGLE CENTRE OF HEMATOLOGY: CLINICAL AND BIOLOGICAL CHARACTERISTICS AND OUTCOME IN 315 PATIENTS AFFECTED BY CLL DIAGNOSED DURING THE LAST 11 YEARS

L Laurenti, F Autore, M Tarnani, B Vannata, I Innocenti, F Santini, S Marietti, T Za, S Bellesi, S Sica, G Leone
Institute of Hematology UCSC, Rome, Italy

Background. Chronic Lymphocytic Leukemia (CLL) is the most common lymphoproliferative disorder of the elderly population in Western countries. Clinicians collect many clinical and biological data useful for prognosis and management of the disease. No comprehensive data on epidemiological, clinical and biological characteristics and evolution of the B-CLL population are available in a single centre analysis. **Aims.** This retrospective study has the purpose to analyse demographic, clinical and biological characteristics of our B-CLL population, diagnosed and followed at Institute of Hematology of Catholic University of Rome. **Methods.** From our database consisting of 402 diagnoses during the last 11 years, we excluded 87 patients previously treated in other centre or referred to our centre for consultancy. Thus we selected 315 patients affected by CLL diagnosed from January 2000 to December 2010 and followed until May 2011. The diagnosis of CLL was made according to criteria from the National Cancer Institute. For each patient in the database we reported clinical and biological features at diagnosis, comorbidities, any relevant clinical condition developing during CLL history, progression free survival (PFS), time to treatment (TTT), overall survival and cause of death. **Results.** We recorded a mean of 29 B-CLL diagnosis per year (range 14-41). The median age at diagnosis was 67 years (range 35-89 years) with a ratio M:F of 1. 6:1 (195 males, 120 females). The Binet stage was A stage in 228 patients (72. 4%), B stage in 64 (20. 3%) and C stage in 23 (7. 3%). The median value of absolute lymphocyte count was 10. 025 lymphocytes/mmc (range 1000 to 240. 000), 45 patients (14. 3%) were diagnosed as Monoclonal B lymphocytosis because of clonal lymphocytes were less of 5000/mmc. Biological characteristics consisted of positivity of ZAP-70 in 108 pts (36. 9%; data available for 293 pts), CD38 in 71 pts (24. 1%; data available for 295 pts) and CD49d in 56 pts (42. 7%; data available for 131 pts). The analysis of chromosomal aberrations conducted in 279 patients by FISH demonstrated del(13q14) in 72 pts (25. 81% of the investigated pts), trisomy 12 in 44 pts (15. 77%), del(11q22) in 23 pts(8. 24%) and del(17p13) in 21 pts (7. 53%). The analysis of the IgVH mutational status in 246 available patients displayed 101 pts (41. 1%) unmutated and 145 pts (58. 9%) mutated. Analysing the outcomes the median PFS and TTT were not achieved after a median of 34. 5 and 36 months respectively. We noticed 153 progressions (48. 6% of the pts) after a median time of 25 months (range 1-132) and 132 pts (41. 9%) were treated after a median time of 24 months (range 1-109). After a median of 56 months (range 5-136 months), 15 patients were lost at follow-up and 56 patients died (17. 8%):26 pts (46. 5%) for causes related to CLL, 7 pts for neoplasia, 5 pts for heart diseases and 10 pts for unspecified extra-hematological diseases. In 8 cases, it was not possible to document the cause of death. **Conclusions.** Confronting our analysis to the literature data we found that the cohort of our patients is representative of the CLL population.

1299

EFFICACY, TOLERABILITY, COST-SAVING OF FRONTLINE ORAL FLUDARABINE AND CYCLOPHOSPHAMIDE COMBINATION THERAPY FOR CHRONIC B-CELL LYMPHATIC LEUKAEMIA AND LOW GRADE NON HODGKIN LYMPHOMA ELDERLY PATIENTS

M Bergamaschi, A Ghiso, M Miglino, M Clavio, F Ballerini, L Canepa, F Galaverna, R Grosso, M Gobbi, I Pierri
A. O. U. S. Martino ist IRCSS, Genoa, Italy

Background. Treatment decision of elderly patients has to be made individually considering, not only stage and risk factors of the disease, but also patients' physical condition and social environment. Fludarabine was the first purine analogue with an oral formulation available for clinical use. Oral formulation offers equivalent efficacy and an improved tolerability profile compared to the intravenous (IV) formulation. IV fludarabine requires several administrations that will expose patients to the risk of IV injection complications and cost for going to hospital. **Aims.** We would like to show that frontline oral fludarabine and cyclophosphamide combination therapy, for B-cell lymphatic leukaemia and low grade non Hodgkin lymphoma aged patients, is well tolerated, efficacy and cost-saving. **Methods.** Between April 2005 and December 2011, 10 elderly untreated patients (mean age 75, range 68-86) with treatment requiring B-cell lymphatic leukaemia (according to ESMO guidelines working group) and 13 elderly indolent stage ≥3 non Hodgkin lymphoma untreated patients (mean age 75, range 59-80) received therapy with low dose of oral fludarabine (25mg/mq/die) and cyclophosphamide (150mg/mq/die) (FC) both from days 1 to 3. Study design consisted of 6 cycles repeated at 4 weeks intervals in outpatient regimen. Patients received antibiotic prophylaxis with trimethoprim/sulphamethoxazole (160/800 mg twice a day, 3 times week) and allopurinole (300 mg once a day from days 0 to 4). Performance status was WHO £2 inall patients. Comorbidities, including diabetes, hypertension, chronic heart disease and chronic renal failure, were present in 13 patients. The mean of administered cycles was 3 with range 2-6. No patients reduced dose and number of cycles because of haematologic and extra-haematologic toxicities. Specifically only 2 patients experienced grade III neutropenia, treated with GCSF. **Results.** Definition of response was reviewed according to the updated IWCLL-NCI 2008 international general practice criteria. 20 of 23 patients (9 RC and 11 RP) obtained a response with overall response 87%. Only one responder patient died due to stroke and another patient lost response, but she didn't require therapy; mean overall survival was 28 months (range 3-56). We used Genzyme sponsored Excel program to compare direct hospital cost of oral and IV FC (both 3 days regimen). IV treatment required 18 day hospital accesses with total cost of € 7. 527, oral regimen required 6 ambulatory accesses with total cost of € 1. 642 (costs including: pharmacy, nurses and physicians resources). In this analysis we didn't consider social and psychological cost: transports, relatives' lost of working hours, disease consciousness, trauma of repeated venipunctures. **Conclusions.** These results suggest that this regimen could be effective and well tolerated for elderly patients unfit. Moreover this therapy compared to chlorambucil, the most used agent in these patients, is more effective and better tolerated. In fact although some patients relapsed or pro-

gressed, most of them do not experience severe toxic side effects or required hospitalisations, obtaining satisfactory quality of life and survival. In addition ambulatory regimen is preferred by our patients, who are treated in a friendly environment, with fewer complications and minor use of hospital resources.

THE STUDY OF DYSLIPIDEMIA AND MEAN PLATELET VOLUME IN RELATION WITH THE AGGRESSIVENESS OF DISEASE, RESPONSE TO TREATMENT AND THROMBOTIC RISK IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

RG Mihaila[1], A Olteanu[2], G Cocisiu[2], I Lisan[2], R Dancu[2], A Catana[2], O Flucus[2], C Bus[2]
[1]Lucian Blaga University Sibiu, Sibiu, Romania
[2]Emergency County Clinical Hospital, Sibiu, Romania

Background. Leukemic cells have increased cholesterol metabolism, which they capture intracellular and use it for their proliferation, which could be reflected by hypocholesterolemia. An increased mean platelet volume is an index of platelet activation and of thrombotic risk, as well as hypercholesterolemia. **Aims.** We aimed to analyze the changes induced by chemotherapy in patients with CLL on lipids and platelets. **Materials and Methods.** We studied all 64 patients with CLL in 2011, who were in the electronic filing system of the Department of Hematology of Sibiu. They were divided into 2 groups: A - who had chemotherapy during 2011 and B - without chemotherapy in 2011. We noted: gender, age, disease stage, platelet count and associated diseases. In group A patients, we have also studied the number and type of chemotherapy session and cholesterol, triglycerides and mean platelet volume before and after chemotherapy. We considered in those in group B the same biological data from their first hospitalisation in 2011. **Results.** In group A mean age was 65. 4+/-10. 4 years; the gender distribution: 8 women (42. 11%) and 11 men (57. 89%). Average disease stage: 2. 16+/-12. Cholesterol increased (p<0. 005), with an average of 30. 29+/-27. 59 mg/dl from a baseline average of 177. 44+/-49. 61 mg/dl to 186. 88+/-39. 04 mg/dl after an average of 3. 58+/-2. 04 chemo sessions. Initial cholesterol was directly correlated with the initial number of platelets (r=0. 712) and inversely correlated with disease stage before treatment (r=-0. 261), so the higher leukaemic cell mass, the lower cholesterol, which is in agreement with previous findings in literature that the leukaemic cell uses cholesterol for its proliferation. Final cholesterol was directly correlated with platelet count (r=0. 384) and inversely with patient age (r=-0. 300) and number of chemo sessions (r=0. 360). The variation of cholesterol was inversely correlated with age (r=-0. 491), with initial cholesterol (r=-0. 355) and number of chemo sessions (r=-0. 330). Triglycerides did not significantly vary, but there was a slight direct correlation between it and initial cholesterol (r=0. 264). Mean platelet volume after final chemo session was directly correlated with disease stage before chemotherapy (r=0. 626) and inversely with platelet count (r=-0. 380) and final cholesterol (r=-0. 290). In patients of group B mean age was 66. 9+/-10. 7 years; the distribution by gender: 28 women (62. 22%) and 17 men (37. 78%). Disease stage of patients in group B was significantly lower than those in group A (p<0. 00005) and correlated directly with age (r=0. 315) and inversely with cholesterol (r=-0. 255) and triglycerides (r=-0. 280). Cholesterol was not significantly different in the 2 groups, but in group B was directly correlated with serum triglycerides (r=0. 483), as in group A, but stronger. Mean platelet volume of group B was higher than that of group A post-therapy (p=0. 01) and correlated inversely with the cholesterol of group B (r=-0. 470). **Conclusions.** Cholesterol decreases as the disease stage increases and may be an indicator of mass growth of leukemia cells and of disease aggressiveness. Higher cholesterol and lower mean platelet volume after chemotherapy may be indicators to treatment response. Postchemotherapy, the decrease of mean platelet volume lowers thrombotic risk, while hypercholesterolemia rises it and requires therapeutic measures.

SUCCESSFUL MANAGEMENT WITH INTRAVENOUS IMMUNOGLOBULINS IN ALEMTUZUMAB-INDUCED ACUTE INFLAMMATORY DEMYELINATING NEUROPATHY: CLINICAL REPORT OF THREE PATIENTS

R Castelli, G Gritti, A Cannavò, G Grava, G Conti, A Cortelezzi
University of Milan, Milan, Italy

Several neurological complications have been associated with the use of monoclonal antibodies (mAbs), anddemyelinating disorders have been estimated to affect the 0. 02-0. 20% of treated patients. Alemtuzumab is ahumanized chimeric mAbthat targets the CD52 antigen, it is currently approved for relapsed/refractory and high-risk untreated chronic lymphocytic leukemia (CLL). The major complication of alemtuzumab therapy is the increased risk of opportunistic infections secondary to the profound immunosuppression. Autoimmune diseases as Graves disease, immune thrombocytopenic purpura and Good pasture syndrome, have been reported to be associated to the treatment. In the present report, we present three CLL patients developing acute inflammatory demyelinating neuropathy during treatment with alemtuzumab. Despite the severity of the complication, all the patients showed an univocal good clinical response after treatment with intravenous immunoglobulin (IVIG). As alemtuzumab represents, nowadays, a key therapeutic option for CLL, clinicians should be aware of this rare and disabling toxicity.

A CASE OF REFRACTORY IMMUNE THROMBOCYTOPENIA (ITP) SUCCESSFULLY TREATED WITH ROMIPLOSTIM IN A PATIENT AFFECTED BY CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

F Guidotti, F Maura, G Reda, A Gregorini, A Cortelezzi
Hematology-BMT Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background. Romiplostim is a TPO mimetic agent which has been shown to be a clinically effective treatment for idiopathic ITP. Recently its use is being extended to secondary ITP; as 2-5% of patients affected by CLL develops ITP, this agent is raising a lot of interest regarding its possible role in treatment-refractory forms. Even if some reports describe the development of bone marrow fibrosis and the tendency to venous thrombosis, adverse events are usually mild or moderate in severity; similarly there is currently no evidence to suggest that romiplostim affects the natural history of CLL. However, in both cases, more experience is required before final Conclusions can be drawn. **Aims.** We describe the case of a patient affected by CLL who develop a chronic, refractory ITP and has been successfully treated with romiplostim. **Case Report.** In August 2006, a 45-year-old man was diagnosed with CLL, stage II-Rai, A-Binet. His leukemic clone expressed unmutated IGHV and, analyzing VDJ recombination and HCDR3, he appeared to belong to stereotyped subset #7. Analyzing by FISH we reported an isolated deletion in the region 13q14. Two months from the diagnosis, the patient developed severe thrombocytopenia; a bone marrow biopsy showed normal megakaryocyte count with 60% B-lymphocyte infiltration. Diagnosis of ITP was made as all the other common causes of thrombocytopenia were ruled out. After treatment with oral prednisone (1 mg/Kg daily), platelets started increasing, so that we soon began slowly tapering the dose. However, while the patient was assuming 7. 5 mg/d of prednisone, we observed an ITP relapse; the autoimmune complication appeared to be refractory to treatment with IV immunoglobulin and with cyclophosphamide, therefore we started treatment with alemtuzumab at low doses: at the 9th week normal platelet values were reached and at the 18th also a complete response of CLL was achieved. After about two years, while the patient started again low-dose alemtuzumab because of CLL progression, platelets decreased to 9x10^9/l; bone marrow evaluation showed a scanty infiltration of B-cells and a number of megacaryocytes considerably increased. We firstly retreated the patient with prednisone and IV immunoglobulin without any efficacy; then we associated rituximab observing only a partial response on platelet values. In September 2010 ITP relapsed again and we started treatment with romiplostim 1 mcg/kg every week. Platelets soon started increasing and therapy was well tolerated. Treatment was then interrupted in February 2011 when the platelet count was permanently above 200x10^9/l. In the meantime a CT scan performed because of fever and asthenia showed pleural effusion and pleural thickening; a biopsy revealed the presence of a biphasic mesothelioma. In April 2011 the patient, still showing a normal platelet count, underwent chemotherapy without any other autoimmune complication and he is still alive on September 2011. **Summary and Conclusions.** Even if studies in a large number of patients are needed to draw definitive Conclusions, this case confirms that romiplostim could represent an useful therapeutic option for patients affected by CLL who develop chronic and refractory ITP, with prompt efficacy and few adverse events.

1303

CAN BENDAMUSTINE BE USED IN CLL PATIENTS WITH ACTIVE HEMOLYTIC ANEMIA? REPORT OF 2 CASES

V Strugov, E Stadnik, A Petrov, N Lazorko, Y Alexeeva, A Zaritskey
Almazov Federal Heart, Blood and Endocrinology centre, Saint-Petersburg, Russian Federation

Background. Although studies have shown low prevalence of AIHA in CLL patients treated with FCR as compared to fludarabine monotherapy, safety of FCR is not sufficiently tested in patients with clinically overt hemolysis and thus FCR is rarely used in such context. Activation of AIHA usually coincides with

CLL progression and pathophysiologic links between two conditions were proposed. Immunosuppressive therapy alone is not very effective in CLL. Hence there is a need of new safe and potent agents for patients presenting with disease progression combined with severe AIHA. Beside anecdotal reports of bendamustine-associated hemolysis there is still no evidence whether this drug can be safely used in this patient group. **Methods.** Clinical and key laboratory data were collected from medical documentation of 2 relevant patients. Diagnosis and response criteria were as per IWCLL (2008). **Results.** Patient 1 was 70 yo male whose medical history comprised 5 lines of treatment (cyclophosphamide for 2 years, 6 courses of FC with PR lasting 1. 5 years, chlorambucil±prednisone for 2 years, 2 courses of fludarabine) with subsequent development of severe AIHA after F mono for which he received rituximab, prednisone and cyclophosphamide in different combinations for 2 years with relative CLL and AIHA control. He was admitted 3 mos after last rituximab dose with overt CLL progression, Rai II stage disease, fast drop in Hb level to 91 g/l, positive DAT, increased levels of reticulocytes and indirect bilirubin. Treatment with BR was initiated. Because of insufficient control of hemolysis methylprednisone (500 mg x 3 d) was added from D15. In about a week reticulocyte counts dropped to normal and Hb levels increased. Patient developed grade 2 neutropenia. Subsequent courses were R (D1) + B (D2-3) + 40 mg dexamethasone (D2-3). B dose in this combination was 55 mg/m2 initially but had to be reduced to 30 mg/m2 from course 3 because of grade 4 neutropenia and pulmonary infection. This reduced dose was well tolerated with no hematological toxicity. After course 6 CR was documented and there were no signs of hemolytic anemia (Hb 143 g/l, Ret 6 prom.). AIHA-free CR lasted for 13 mos. He had been successfully retreated with 2 courses of BRD in relapse and is currently on cyclosporine maintenance. Patient 2 was 51 yo male with AIHA already present at CLL diagnosis. His anamnesis included chlorambucil, R-CHOP, R±prednisone. At admittance he had active progression, del11q, bulky disease, Hb 61 g/l, Ret 61 prom, positive DAT and increased indirect bilirubin. He was treated with BR after methylprednisone preface (750 mg x 3 d from D-3) with additional R given on D8 and D15. After course 1 active hemolysis was eliminated and Hb levels normalized. Courses 2-5 were standard BR with PR after 3 courses achieved at the cost of transient grade 4 neutropenia and some infectious complications. **Conclusions.** In our experience combination of bendamustine with corticosteroids and rituximab is effective both in disease control and active hemolysis elimination and thus can be used even in patients with severe CLL-associated steroid-refractory AIHA.

1304

COMPLETE REMISSION CHRONIC LYMPHOCYTIC LEUKAEMIA(B-CLL) AND HEPATITIS C CONSERVED AFTER ANTIVIRAL THERAPY.

S Lepkov[1], S Lepkov[1], I Subortseva[2], T Byalik[3], A Kovrigina[4], N Tupicin[3], N Kuprichina[3], S Kosura[1], A Gettueva[1], O Kolomeytsev[3], Y Ryabukhina[3], G Storozhakov[1]

[1]Moscow Medical University by N. I. Pirogov, Moscow, Russian Federation

[2]MAPGE MHR, Moscow, Russian Federation

[3]Cancer Research Center by N. N. Blochina, Moscow, Russian Federation

[4]Hematology Scientific Center, Moscow, Russian Federation

Background. In a number of studies have shown that patients with B-CLLwith hepatitis C virus (HCV) infection makes 2-3%. Patients with B-CLL now receive more often chemotherapy with rituximab. During chemotherapy with rituximab in patients with B-CLL and hepatitis C have often develop liver dysfunction. This required antiviral therapy. **Patients and Methods.** In this research was 12 pts with B-CLL HCV RNA-positive. All 12 pts have typical immunohistochemistry (IHC) type B-CLL- CD 5+,CD20+,CD19+,CD23+. Among those patients in 2 in immunohistochemistry (IHC) analysis a expression of markers of viral protein on the tumor cells (IHC «+») were found. Median age was 62 years. The median level HCV-RNA before chemotherapy was $2x10^4$ copy/ml. At diagnosis, ALT value was above UNL in 6 patients. All pts undergoing chemotherapy with rituximab. . Increased level of HCV-RNA during chemotherapy were observed in all 12 pts and median level after reactivation was 4. $6x10^6$ copy/ml. Increased level of transaminases(ALT, AST) during chemotherapy were observed in all 12 pts and was from 3 to 50 time. When increased level ALT all 12pts were treated by antiviral therapy α - interferon 3ME once and ribaverin 800 mg daily. Decreased level of ALT and HCV-RNA was reached in all pts. In 2 pts IHC «+» was achieved molecular complete remission B-CLL and hepatitis C infection. In 10 patients with B-CLL IHC «-» was achieved only stabilization B-CLL. **Conclusions.** IHC analysis of B-CLL in patients with HCV infection is a determining factor for defining antiviral therapy as ferste line therapy as key method of treatment.

1305

EFFICACY OF RECOMBINANT HUMAN ERYTHROPOIETIN IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH ANEMIA

N Romanenko, K Abdulkadyrov

Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Anemia in Chronic Lymphocytic Leukemia (CLL) is a frequent symptom and can influence the efficacy of chemotherapy, survival rate and overall quality of life (QoL). Red blood cell (RBC) transfusions are routinely used to treat anemia, while Recombinant Human Erythropoietin (rHuEPO) treatment has been shown to significantly increase hemoglobin (Hb) concentration, reduce the number of RBC transfusions and improve QoL in patients with chemotherapy induced anemia. **Aims.** To study the efficacy of rHuEPO in CLL patients with anemia: increasing Hb concentration and anemic symptoms. **Methods.** In this study were included 26 CLL patients (stage C by J. Binet) had been diagnosed between 2005-2011. The median age of patients was 66 years (48-80). All patients had anemia with initial Hb concentration <10. 0 g/dL. The RBC transfusion threshold were Hb <8. 0 g/dL. rHuEPO (erythpoietin beta) was administrated subcutaneously in dosage 30. 000 IU one times a week. The effectiveness of rHuEPO-therapy was estimated by Hb concentration, red blood cells count and hematocrit (Ht) concentration and so anemic symptoms. The target Hb level was 12. 0 g/dl and planned duration of rHuEPO-therapy within 16 weeks. Positive response was considered as 1) transfusion-independency in patients earlier needed RBC transfusions, 2) increase Hb concentration <2. 0 g/dL. All patients earlier received 3 cycles of chemotherapy or more. Patients who had deficiency of iron, vitamin B_{12}, severe hemolysis (bilirubin >30 μmol/L), uncontrolled arterial hypertension were excluded. **Results.** Mean baseline Hb concentration was 8. 24±1. 65 g/dL (4. 6-10. 0 g/dL), RBC count - 2. 78±0. $64×10^{12}$/L (1. 36-3. $40×10^{12}$/L) and Ht - 24. 6±7. 4% (15. 4-32. 6%). In whole group of CLL patients (n=26) positive response was observed in 15 patients (57. 7%) and their Hb concentration, RBC count and Ht significantly (p<0. 05) increased from baseline to 12. 25±1. 17 g/dL (10. 7-14. 1 g/dL), 4. 07±0. $60×10^{12}$/L (3. 11-4. $90×10^{12}$/L) and 37. 6±3. 4% (32. 3-43. 4%), respectively. 12 patients had severe anemia (Hb <8. 0 g/dL) therefore they received 1-12 RBC transfusions during latest 1-3 months. During the study period (within 16 weeks) out of 13 patients 8 (61. 5%) were keeping transfusion-dependency, Hb concentration of these patients was depended on RBC transfusions (7. 9-10. 0 g/dL). However 5 (38. 5%) anemic patients significant increased Hb and stop doing RBC transfusions. Besides most patients with positive response reduced such symptoms as feeling fatigue (from 73. 1% to 38. 5%), weakness all over (from 50. 0% to 38. 9%), having trouble starting things because of tiredness (from 46. 2% to 26. 9%), drowsiness (from 73. 1% to 26. 9%), giddiness (from 46. 2% to 23. 1%), headaches (from 50. 0% to 23. 1%), pain in thorax (from 65. 4% to 34. 6%). Two patients with positive response in 6 weeks needed in repeated of rHuEPO administration because of anemia relapsed (Hb concentration decreased to 10. 0 g/dL). Nevertheless this way of persistent treatment could prevent RBC transfusions. No one case of thrombosis were observed during the period above 6 months. But four patients (26. 7%) with positive response had arterial hypertension (increasing more 20 mm/Hg) and needed in administration of hypotensive remedies. **Summary.** rHuEPO-therapy is effective treatment to reduce RBC transfusion, increase Hb concentration and decrease anemic symptoms in CLL patients with anemia.

1306

THE CLINICAL FEATURES OF 105 CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS FOLLOWED UP AT A SINGLE CENTER IN TURKEY

G Pamuk, M Uyanik, M Akker, M Demir

Trakya University Medical Faculty, Edirne, Turkey

Background. Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in western countries. CLL is a disease characterized by the clonal proliferation and accumulation of neoplastic B cells in peripheral blood, bone marrow, lymph nodes and the spleen. **Aims.** We evaluated the clinical features, survival and factors affecting prognosis in CLL patients followed up at our center. **Methods.** We included 105 CLL patients diagnosed at Trakya University Medical Faculty, Division of Hematology, Edirne, Turkey. The diagnosis of CLL was based upon the criteria of International Workshop on CLL. The demographic data, clinical features, treatment modalities and response to treatment were recorded from hospital files. Rai staging system was used for clinical staging. The definitions of partial (PR) and complete response (CR) were the criteria of National Cancer Institute Working Group. **Results.** Of 105 CLL patients, 65 were males and 40 were females (M/F=1. 62). The median age of the patients was 64. 8±9. 1 years (range:37-88). According to Rai staging system, 22 patients (21%) were stage 0, 18 (17. 1%) were stage I, 19 (18. 1%) were stage

II, 25 (23. 8%) were stage III, and 21 (20%) were stage IV. Autoimmune haemolytic anemia was diagnosed in 8 (7. 6%) CLL patients. Six patients developed a secondary malignancy, and 4 had Richter's transformation. Eighteen (30. 5%) of early stage Rai patients and 46 (100%) of advanced stage patients were decided to be given chemotherapy. The initial treatment modality in 23 cases was chlorambucil, it was fludarabine plus cyclophosphamide in 15 cases, COP in 12 cases, CHOP in 9 cases, and fludarabine only in 5 cases. Of early stage patients at initial diagnosis, 6 (33. 3%) had CR and 5 (27. 8%) had PR to initial treatment modalities. Four (8. 9%) of advanced stage patients had CR and 17 (37. 8%) had PR to initial treatment modalities. Unresponsiveness to initial treatment modalities was significantly more frequent in advanced stage patients (24 cases, 53. 3%) than in early stage patients (6 cases, 33%) ($p<0.05$). The duration of median follow-up was 40 months (1-140 months). The median duration of overall survival according to disease stages at the time of initial diagnosis was 112 months in early stage disease (Rai 0,I,II) and 68 months in advanced stage disease (Rai III,IV). The 5-year survival in early stage CLL was 86. 5% and in advanced stage patients it was 54%. Patients younger than 60 years at the time of diagnosis had significantly longer survival than elder patients (120 and 76 months, $p=0.01$). Patients with initially high LDH levels tended to have shorter survival than others (106 and 42 months, $p=0.001$). According to Cox multivariable regression analysis, being older than 60 years at the time of initial diagnosis (OR:3. 2, $p=0.014$), high LDH level (OR:6. 25, $p=0.01$) and advanced stage Rai disease (OR:5. 9, $p=0.01$) were independent poor prognostic parameters. **Summary and Conclusions.** The analysis of 105 CLL patients followed up at our center revealed that older age and advanced stage at the time of initial diagnosis were independent poor prognostic parameters.

1307

FIRST LINE TREATMENT IN CLL PATIENTS. PROSPECTIVE STUDY ABOUT DECISION CRITERIA AND CLINICAL PRACTICE IN GALICIA

A Simiele
POVISA Hospital, Vigo, Spain

Introduction. Population in Galicia is estimated in 2. 795. 422 habitants with a median age of 45. 41 years. The prevalence of CLL is stimated in 2,2/100. 000 hab. (data of previous study). Data from were collected from 4 general hospitals during september 2009 to march 2011. **Patients.** 21. Median age: 66. 9 years old (46,0 - 86,0). Sex: Male: 66. 7 % - Female: 33. 3 %. All were Caucasian. None of them presented familial history of Non Hodgking Lymphoma no CLL. Criteria: B symptoms: 77% (fatigue: 33. 3 %; weight loss: 23. 8 %; night swears: 9. 5 %); Binet stage; Lymphocyte doubling time (100%); Lymphadenopathy: 84,6%. Splenomegaly: 47,6% Bulky disease: 16,7%; ECOG (100%); Bone marrow pattern: 61,1% (Diffuse: 18,2%; Interstitial: 36,4%; Nodular,diffuse: 18,2%); FISH: 61,1% (17 p:2 pts; 11q: 3 pts; 13q: 5 pts; +12: 5 pts. IGHV mutation status: not determined. Treatment: Median time from diagnosis to treatment was 19,4 months (0. 0- 90,1). FCR: 42,9 % (9 pts). Median time from diagnosis to treatment: 2,1 meses (0,0- 4,2). Median age: 60 years old (46,0- 72,0). Median lymphocyte doubling time: 3 months. Binet B: 44,4% . ECOG 0 (55,6%). No Bulky disease. Pattern Diffuse (40%). FISH: 13q (50%); +12 (50%). Estimated cycles: 5-6. Treatment completed in 100% of patients at full dose. FC: 4,8% (1 pt.). Characteristics were similar to patients included in FCR. Completed 6 cycles at a dose 100%. Chemotherapy with/without anthraciclins: 28,6% (6 pts). Median time from diagnosis to treatment: 30,5 months (12,2- 52,2). Median age: 70,3 years old (54,0- 82,0). Median lymphocyte doubling time: 23,2 months (4,0- 48,0). Binet A: 66,7%. ECOG 1 (50%). Generalized lymphadenopathy. Pattern Interstitial (100%). Estimated cycles: 5-6 Dose: 100% (3 pt); 75% (1pt); No data (2 pts). Completed in 90 % of patients. Alemtuzumab: 9,5% (2 pts). FISF: 17p. Treatment was not completed (adverse effects). The other schemes: Chlorambucil (1 pt); Chlorambucil + Prednisone (1 pt); Cyclofosfamide + Rituximab + Dexametasone (low dose) (1 pt) were considered in older patients with Unfit condition. **Conclusions.** Most criteria used B Symptoms; Binet stage; Median lymphocyte doubling time; Lymphadenopathy/splenomegaly; pattern of bone marrow infiltration and FISH analysis. Most frecuent scheme was FCR (included younger patients with rapid disease progression; Binet B and C; a diffuse pattern in B. M. and shorter lymphocyte doubling time). Median duration of treatment: 5. 1 months (median number of cycles 5,6). Chemotherapy was administer to older patients with longer lymphocyte doubling time; Binet A; generalized lymphadenopathy and an interstitial pattern of infiltration in B. M. Patients with 17p (2) were considered candidates to Alemtuzumab. Data showed that 85% of patients have completed the treatment with a Complete Response (CR- NCI WG criteria) of 52,4% (11 pts.) and Partial Response (PR) in 28,6% (6 pts.). Best responses were obtained in patients who finished all the programmed cycles at a dose of 100%. None of the patients underwent Bone Marrow Trasplantation nor Radiotherapy.

1308

LONG MAINTENANCE THERAPY OF INTERFERON IN HAIRY CELL LEUKEMIA

S Lepkov[1], S Lepkov[1], I Subortseva[2], Y Ryabukhina[3], O Kolomeytsev[3], T Byalik[3], A Kovrigina[4], S Kosura[1], G Storozhakov[1], O Ettinger[1], P Zeynalova[3]
[1]Moscow Medical University by N. I. Pirogov, Moscow, Russian Federation
[2]MMAPGEMHR, Moscow, Russian Federation
[3]Cancer Research Center by N. N. Blochina, Moscow, Russian Federation
[4]Hematology Scientific Center, Moscow, Russian Federation

Historically, the first treatment choices for hairy cell leukemia (HCL) were splenectomy and α -interferon. In this study we evaluate the efficacy of long-term maintenance therapy of α -interferon (IFN) in hairy cell leukaemia (HCL), a disease that remains incurable. **Methods.** 8 patients (5 male, 3 female, aged 45-62 yrs) with hairy cell leukaemia (HCL) from 1994 to 1996 beginning the therapy of IFN 3mU 3 times weekly. Complete remission has been reached at all pts. Therapy has been then continued as long-term maintenance therapy INF once time 3 mU weekly. **Results.** All 8 patients are in a state of complete response at 14-17 years (median 15 years). No incidence of second cancers of this 8 HCL pts has not been documented. **Conclusions.** We hope that these reports will lead to a multi-centre, phase III study of IFN maintenance therapy (including pegylated IFN, given less frequently) in HCL patients achieving optimal response to initial therapy, be it IFN or a purine analogue.

1309

CELL SURFACE PHENOTYPE OF CD34+ PROGENITORS IN CHRONIC MYELOID LEUKAEMIA: POTENTIAL FOR DIAGNOSIS AND FOLLOW-UP

S Van Der Meeren, F Trullemans, W Renmans, L Smet, K Jochmans, R Schots, M Bakkus, M De Waele
UZ Brussel, Brussels, Belgium

Background. Chronic myeloid leukaemia (CML) is characterized by the translocation t(9;22)(q32;q34) resulting in the BCR/ABL fusion gene. The diagnosis of CML is based on the detection of this translocation either by cytogenetic or molecular techniques. Only a few flow cytometric studies have examined the immunophenotype of CML progenitors, but some interesting aberrancies were seen. **Aims.** To assess the diagnostic potential of immunophenotyping $CD34^+$ cells in CML, considering this could be a useful tool to reduce the number of cytogenetic/molecular tests needed. In addition, we studied the changes in the phenotype that occurred during treatment of patients. **Methods.** All bone marrow (BM) aspirates, taken in our hospital between 2000 and 2009 for suspicion of a chronic myeloproliferative neoplasm and for which also an analysis for the presence of BCR/ABL was performed, have been included in this study. Samples from CML patients at diagnosis (n=17), BCR/ABL negative myeloproliferative neoplasms (n=42), myelodysplastic/myeloproliferative neoplasms (n=5) and from patients with non-neoplastic myeloproliferation (n=8) were examined. The results were compared with samples obtained in a control population, consisting of healthy BM donors and cardiosurgery patients (n=32). In addition, BM samples from CML patients treated with hydroxyurea (n=7) or imatinib (6 patients, 16 samples) were studied. $CD34^+$ cells were enumerated and their expression of cell surface antigens was determined with flow cytometry. The following antigens were analyzed: the B-cell lineage markers CD19 and CD10, the myeloid markers CD13 and CD33, the stem cell marker CD133, the stem cell factor receptor (CD117), the interleukin-3 receptor alpha (CD123), the chemokine receptor CXCR4 (CD184) and the common leukocyte antigen (CD45). Results were expressed as relative mean fluorescence intensity (RMFI). Reference values were defined for each parameter as the range of results obtained in the control population. **Results.** At diagnosis, the $CD34^+$ cells in all CML patients showed a CD133 RMFI below that of the normal population. This low CD133 expression identified CML patients within all patients with myeloproliferation with 100% sensitivity and 87. 3% specificity. Only 7 out of 55 patients with BCR/ABL negative myeloproliferation showed the above abnormality. Therefore, cytogenetic/molecular tests for t(9;22) were only needed to differentiate the latter patients from CML in the 'CD133 low' group (33% of all samples). In addition $CD34^+$ cells of CML patients at diagnosis showed high levels of CD33 and CD45, and a low positivity for CD19, CD10 and CD123. Treatment with hydroxyurea induced no changes in the phenotype. In CML patients treated with imatinib CD10, CD33 and CD45 levels normalized. CD133 levels increased compared to diagnosis but remained lower than normal. CD19 and CD117 RMFI were respectively higher and lower compared to normal controls. **Conclusions.** CML progenitor cells display distinct immunophenotypic abnormalities, predominantly characterized by low CD133 expression. These phenotypic characteristics could help to reduce the number of patient samples for which molecular techniques are required. With

a more extensive panel of antibodies, it might be possible to identify CML with higher specificity. The diagnostic immunophenotype of CML largely normalizes under imatinib treatment.

1310

ZOLEDRONATE INDUCES APOPTOSIS VIA EFFECTING ON STAT PATHWAY IN CHRONIC MYELOID LEUKEMIA CELLS

G Saydam[1], HD Kiper[1], B Tezcanli[2], N Selvi[2], CB Avci[2], Y Baran[3], B Kosova[2], F Sahin[4]
[1]Ege University Hospital, Bornova Izmir, Turkey
[2]Medical Biology, EUTF, Izmir, Turkey
[3]Molecular Biology, IYTE, Izmir, Turkey
[4]Hematology, Internal Medicine EUTF, Izmir, Turkey

Background. Although development of tyrosine kinase inhibitors has revolutionized the CML therapy, resistance to targeted drugs is a frequent clinical problem. To overcome this, targeting alternative downstream regulators of BCR-ABL is probably the best therapeutic strategy. **Aims.** In this study, we aimed to evaluate the cytotoxic and apoptotic effects of Zoledronate on K562 human chronic myeloid leukemia cells and to examine the roles of signal transducers and activator of transcription proteins (STATs) on Zoledronate-induced apoptosis. **Methods.** Cell viability and cytotoxicity tests were conducted by using Trypan blue dye exclusion and XTT assays, respectively. Apoptotic analyses were performed by using AnnexinV-EGFP staining method under fluorescence microscopy. Expression levels of STAT3, -5A and -5B genes were analysed in Zoledronate-treated K562 cells by qRT-PCR. To confirm the data, protein expressions of mentioned genes were evaluated by using Western Blotting. **Results.** The results showed that Zoledronate decreased viability and proliferation and induced apoptosis in K562 cells in a dose- and time-dependent manner as compared to untreated controls (Figure 1). The IC50 value of Zoledronate is found to be as 60 microM. Concurrently, the expressions of STAT3, STAT5A and STAT5B genes both in mRNA and protein levels have significantly been reduced in Zoledronate-treated K562 cells as compared to untreated controls. **Summary and Conclusions.** These data indicated that STAT inhibition by zoledronate is the underlying mechanism of Zoledronate-induced apoptosis of K562 cells. More importantly, we have shown for the first time that zoledronate triggers apoptosis through inhibiting the expression levels of STATs in a hematological malignancy. If it can be conveyed to clinical area, zoledronate may contribute to the treatment of CML as a promising therapeutic agent.

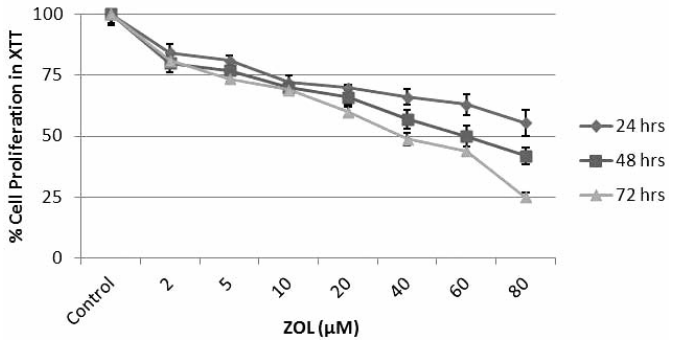

Figure 1. The cytotoxic effect of Zoledronate in K562 cells in dose and time dependent manner.

MUTATIONAL ANALYSIS OF THE FOCAL ADHESION ADAPTOR PROTEIN PAXILLIN IN CML

V Papadopoulou, E Polonyfi, M Sofotasiou, M Mantzourani, T Iliakis, F Kalala, P Diamantopoulos, E Papakostas, E Variami, NA Viniou
Laiko Hospital, University of Athens, Athens, Greece

Background. Pathogenesis of chronic myelogenous leukemia may not only involve increased proliferation of stem cells/myeloid progenitors but at the same time impaired homing/adhesion of myeloid progenitors to the bone marrow stroma. Altered focal adhesion to stroma could be associated not only with premature release to the periphery, but also with altered proliferation and/or differentiation procedures, since cell-matrix adhesions are specific types of macromolecular assemblies through which both mechanical force and regulatory signals are transmitted. One of various key molecules within focal adhesions is the adaptor protein paxillin, whose tyrosine phosphorylation from FAK (focal adhesion kinase) and Src participates in the actin polymerization/depolymerization procedure. Several reports have linked BCR-ABL kinase activity to FAK and Src phosphorylation, while somatic paxillin mutations have been found in lung cancer with a frequency of 10% in a reported series, the most frequent of them (A127T) residing between its LD1 and LD2 motifs and being absent in normal tissues of the same patient series. Paxillin A127T mutation was shown to enhance tumor growth and invasion in vivo (engraftment of a H522 cancer cell line harboring the mutation or not in nude mice). **Methods.** DNA samples from 41 CML patients prior to therapy with BCR-ABL kinase inhibitors were subjected to mutational analysis of the most frequently mutated region of the paxillin gene (between LD1 and LD2 motif) using PCR amplification and direct sequencing. **Results.** In the 41 samples tested, the A127T mutation was found in one sample. No other mutations were detected within this region, while mutations at different positions within the same region have been reported in other cancers. The sample carrying the A127T mutation corresponded to a patient who developed diphenotypic acute leukemia six years after diagnosis, having received no TKI therapy, as she died shortly before their introduction into clinical practice. **Summary and Conclusions.** Mutation of the paxillin gene, at least at a frequently mutated position in lung cancer, is a rare event in CML. Its significance for paxillin expression as well as the role of paxillin expression in the response to therapy with TKI inhibitors remains to be determined in our ongoing study. This is the first report of the A127T mutation in a haematological malignancy and further sample sequencing and comparison with non-relevant samples is under way.

1312

CHRONIC MYELOID LEUKEMIA WITH VARIANT PHILADELPHIA TRANSLOCATION AND CONSTITUTIONAL PERICENTRIC INVERSION BOTH OF HOMOLOGOUE CHROMOSOMES 9

A Djordjevic[1], D Bogdanovic[1], V Jovanovic[1], S Dencic-Fekete[1], D Pantic[2], D Gotic[1]
[1]Clinical Center of Serbia, Belgrade, Serbia
[2]3Genomics lab, Department of Haematology/Oncology, University Medical Center, Freiburg, Germany

Background. Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the presence of the Philadelphia (Ph) chromosome resulting from the reciprocal translocation t(9;22)(q34;q11). In 5-10% of patients with newly diagnosed CML, additional chromosome(s) combine to generate the composite, so-called variant translocations. Some previous studies have suggested that patients with variant Ph translocations may have inferior prognosis to those with classical traslocations. Other have reported the lack of prognostic impact of variant Ph translocation in imatinib mesylate (IM)-treated patients in the chronic phase (CP). In contrast to the Ph chomosome, constitutional pericentric inversion of chromosome 9 [inv(9)(p11-12q13)] has been considered as a normal familiar variant in human genome. The incidence varies with ethnicity and is approximately 0,8 to 2%. A thorough study of the heterochromatin organization in the pericentric region has revealed a homology between 9p11-12 and 9q13-21. Such homologous sequences may participate in the mechanism generating the inversion. Whether constitutional inv(9) predisposes to cancer remains controversial. Because inv(9) is not considered an important finding, a bias in reporting it may account for the paucity of references to on constitutional inv(9) in hematological disorders. **Aims.** Report of association of the variant Ph translocation and the constitutional bichromosomal inv(9) in a newly diagnosed CP CML patient. **Methods.** A 54-year-old female was diagnosed with CP-CML in October, 2008. Cytogenetic and FISH studies were done on the bone marrow cells prepared according to standard techniques and using DNA probes that hybridize at the BCR and ABL regions. Constitutional karyotype was confirmed in phytohemagglutinin-stimulated peripheral blood lymphocytes. Karyotypes were described according to the International System for Cytogenetic Nomenclature (ISCN 2009). Isolated RNA sample was transcribed into cDNA and tested for p210 transcript by Real Time PCR. **Results.** The diagnostic karyotype 46,XX,t(5;inv(9)c;22)(q13;q34;q11), inv(9)(p11q13)c was found in 20/20 analyzed metaphases. The banding confirmed that variant Ph chromosome resulted from a complex translocation including chromosomes 5q13, inv(9) and 22q11. Another homologue 9 also was inverted. The constitutional karyotype obtained from the peripheral blood lymphocytes was 46,XX,inv(9)(p11q13)c,inv(9)(p11q13)c[22]. This novel variant translocation incorporating chromosomes 5q13, inv(9), and 22q11 was confirmed by FISH. The patient was treated with IM as a first-line therapy (400 mg/d) and after 6 month obtained a complete cytogenetic response. She still remains in the CP-CML. **Conclusions.** In conclusion, diploid form of constitutional inv(9) is a truly random chromosomal aberration. As far as we know, the karyotype of our patient is unique because it contains inverted chromosome 9 on both homologues, and one of them is affected by a variant Ph translocation. Our patient treated with IM as a frontline therapy confirm that the clinical characteristics and outcome of patients with variant Ph

translocations are similar to those with classic Ph translocation. Therefore, our results suggest that patients with variant translocation do not constitute a 'warning' category in the imatinib era.

1313

STUDY OF THE RELATION BETWEEN CD34 AND CD7 EXPRESSION ON MARROW STEM CELLS OF CML PATIENTS AND THE BCR-ABL TRANSCRIPTS COPY NUMBER

H Al Lithy, M Mattar, M El Masry, N El Hossiny
Kasr Al Ainy, Cairo, Egypt

Background. Among CML patients who achieve BCR-ABL transcript-undetectable status; few remain transcript negative after molecular target therapy is stopped while others show re-appearance of transcripts. Quiescent leukemic stem cells are responsible for recurrence. This suggests the origin of malignant leukemic cells may be variable. **Aims.** To study the relation between the expression of early myeloid progenitor marker; CD7 on CD34 CML cells, the prognostic Sokal score and BCR-ABL transcripts level aiming to find out if the origin of stem cells is related to any prognostic factor or the BCR-ABL load. **Patients and Methods.** This study was conducted on a group of 34 Egyptian patients newly diagnosed to have Chronic myeloid leukemia in chronic phase from clinical hematology unit of Kasr El Einy teaching hospital. They did not receive TKIs or interferon prior to sampling. RT-PCR for BCR-ABL and Dual culture Epics XL Flucytometry; using dual color, FITC for CD34 and PE for CD7 on bone marrow aspirate samples. **Results.** Thirty one of 34 patients (91%) have CD34 +ve with mean expression 10. 5918%. Twenty two patients (65%) have dual CD7 and CD34 expression with mean 1. 6256%. Dual CD7 and CD34 expression didn't correlate with Sokal score or BCR-ABL transcripts copy number. CD34 expression correlated significantly with transcript copy number (P:0. 04). **Conclusions.** The CD34 expression in CML may bear a relation to the initial BCR-ABL transcripts number. This may impact the preponderance of recurrence of disease on stoppage of tyrosine kinase inhibitors treatment.

1314

MDR1 GENE EXPRESSION MONITORING BY RQ-PCR IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA RESISTANT TO IMATINIB THERAPY

S Czekalska, M Zawada, I Florek, D Cwynar, T Sacha, A Skotnicki
Jagiellonian University Hospital, Krakow, Poland

Background. Chronic myeloid leukemia (CML) is a clonal disorder of the hematopoietic stem cells, characterized by the presence of *BCR-ABL* fusion gene. Imatinib mesylate is now in widespread use for the initial treatment of chronic phase of CML. In most patients this therapy allows for achievement of cytogenetic, and deep molecular response, however, this is not possible in remaining patients. Several molecular mechanisms of resistance to imatinib has been described. The most important are mutations occurred within *ABL* kinase domain of *BCR-ABL* gene, the other could be low *hOCT1* and high *MDR1* genes expression responsible for low effective intracellular imatinib concentration . *MDR1* (multidrug resistance gene 1) gene is one of the several members of ABC transmembrane transporter family ABCB1. *MDR1* gene encodes P-glycoproteine (Pgp) which is responsible for imatinib efflux from the cell. **Aims.** The aim of the study was to develop the RQ-PCR-based method allowing for *MDR1* expression measurement using the TaqMan Technology. **Methods.** 11 CP-CML (chronic phase CML) patients resistant to imatinib were included in the study. White blood cells were collected by using lyses erythrocytes method. Total RNA was extracted using TRIzol method and then reverse transcription was performed (with use of SUPERSCRIPT II, Life technologies). *MDR1* gene expression was detected by Real Time PCR. RQ-PCR was performed using TaqMan Master Mix (Life technologies) and primers and probe as described by Galimberti S et al (MDR1 forward primer 5`-TGC AGC ATT GCT GAG AAC ATT, MDR1 reverse primer 5` TGC CCT CAC AAT CTC TTC CTG, MDR1 probe 6FAM-CCT ATG GAG ACA ACA GCC GGG TGG TT-TAMRA) on ViiA 7 Dx platform. *MDR1* gene expression levels were normalized with *ABL* gene (primers and probes as described in *EAC* protocol, Gabert et al.) expression levels in the same sample. CEM VBL 100 cell line (CEM vinblastine treated cell line was kindly provided by Dr Wiliam T. Beck) was adopted as a reference. 2^-ddCt method was used to calculate the results. *MDR1* expression level of CEM VBL was arbitrally defined as 100 AU (arbitrary units). *MDR1* expression in CML patients` results obtained in the study were compared. by relating them to CEM VBL cell line. **Results.** All CP-CML patients resistant to imatinib showed low level of normalized *MDR1* expression. The range was 1,23 - 11,03 AU, median was 3,67. The parallel analysis of mutational *ABL KD* gene status in this group of patients did not show the presence of any mutation. However, in 2 patients high level of *hOCT1* expression was observed. **Conclusions.** RQ-PCR based methodology developed within this study is feasible and allows for the *MDR1* gene expression analysis. The molecular mechanisms of resistance to imatinib in studied group of patients was not related to the alteration of *MDR1* gene expression. In 2 patients low level of *hOCT 1* expression is the most possible cause of imatinib resistance. In remaining 9 patients the resistance mechanisms were not recognized.

1315

EFFICACY OF NILOTINIB IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE WITH AND WITHOUT PH1 VARIANT TRANSLOCATION

C Gug
University of Medicine and Pharmacy Victor Babes, Timisoara, Romania, Timisoara, Romania

Background. Chronic myeloid leukemia (CML) is characterized by Philadelphia (Ph) chromosome with a chimeric gene BCR-ABL. Variant Ph chromosome translocations involving chromosomes other than 9 and 22 are found in 5-10% of CML cases. Nilotinib is a tyrosine kinase inhibitor with high target specificity approved for use in patients with newly diagnosed CML in chronic phase (CML-CP). **Aims.** In this study we evaluated the efficacy of Nilotinib in Ph1 positive chronic myeloid leukemia patients with classical or complex translocation. **Methods.** We here report a group of 7 patients (4 males, 3 females) with a median age of 44 that receive Nilotinib during a median follow up period of 12 months (range 6-21 months). The evolution of patients with CML-CP was evaluated to determine the efficacy and tolerability of Nilotinib. **Results.** Five patients (72,4%) presented classical Ph1 created by reciprocal t(9;22)(q34;q11) translocation and 2 patients (28,6%) have a complexe Ph1 translocation. One of the cases has mosaic translocation with 2 clones t(8;9;19;22) and t(9;19;22) and the other case has omogen translocation t(7;9;15;22). All patients achieved a hematologic response after 4 months of Nilotinib treatment. Complete cytogenetic response (CCyR) was achieved in 100% of the 7 patients, while for cases with classical Ph1 translocation after 4 months and for cases with variant Ph chromosome translocation after 10 months. Responses were durable, with 100% of patients maintaining CCyR in courses of follow-up. **Conclusions.** We found out that nilotinib was efficacious in chronic phase CML patients and it was also successful in CML patients with a variant of Ph chromosome translocations. These findings indicate CCyR rates higher for nilotinib. Administration of nilotinib offered an effective treatment in a CML patients with a variant of Ph chromosome translocations.

1316

P190 BCR-ABL IS ASSOCIATED WITH INFERIOR OUTCOME IN CHRONIC MYELOID LEUKEMIA

F Chaker[1], M Ben Said[1], R Jeddi[2], R Ben Amor[2], N Ben Romdhane[3], S Menif[1]
[1]Pasteur Institute of Tunis, Ariana, Tunisia
[2]Aziza Othmana Hospital of Tunis, Tunis, Tunisia
[3]Rabta hospital of Tunis, Tunis, Tunisia

The most common bcr-abl transcript in chronic myeloid leukemia(CML) are e13a2 and e14a2 which are transcribed in P210 protein. e1a2 transcript is reported in acute lymphoblastic leukemia (ALL) and rarely in CML. We analyzed 470 CML Tunisian patients for bcr-abl transcript isoform. Results showed that 45% of patients express the isoform e13a2, 51% express the isoform e14a2, and identified only 1%(3 patients) with e1a2 isoform patients . These 3 patients were in accelerated phase and never reached the major molecular response with tyrosine kinase inhibitors. These results confirm the data from the literature which agree on the pejorative prognosis of CML expressing the P190 isoform. CML with P190 rearrangement is rare and is associated with an inferior outcome. These patients need to be identified as high risk patients. In conclusion the identification of variant bcr-abl is a crucial step in the diagnosis of CML since it allows reliable monitoring of residual disease. Since the era of second generation ITK, patients with P190 should be considered as high-risk forms and benefit of increased therapeutic.

1317

INCIDENCE OF SECOND MALIGNANCIES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) IN CLINICAL PRACTICE ANALYSED IN THE FRAME OF INTERNATIONAL RESEARCH PROJECT EUTOS IN RUSSIAN FEDERATION (RUS)

O Lazareva[1], A Turkina[1], S Kulikov[1], I Tischenko[1], E Vasil'ev[2], E Martynova[2], E Vinogradova[2], T Olkhovik[3], N Karaseva[4], G Milutina[2], O Senderova[2], L

Background. Success of tyrosine kinase inhibitors (TKIs) in CML has given patients(pts) hope for a long disease free survival. With the increase in survival can be revealed, such long-term effects of TKI treatment as the development of other tumors. Some pts have a history of previous cancers by the time they are diagnosed with CML. According to the literature, the incidence of secondary tumors varied from 1,02% (Kim DW, et al. Blood 2009) up to 4,02% (Verma D, et al Blood2008); similar in terms of a cohort of pts analyzed by the research group GIMEMA (Gugliotta G, et al. Blood 2010). **Aims.** To evaluatethe incidence and variants of second malignancies(SM) in CML patients treatedwith imatinib(IM) frontline in clinical practice in RUS. **Methods.** Analyzed data from 29 administrative districts of RUS. The selection of regions based on the quality of the data from CML pts registry. 608 CML pts were included in this study with the criteria (EUTOS OSP-study): Ph'/bcr-abl-positive CML diagnosed in 2002-2006, age of pts ≥ 18 years (y), initiation of IM therapy ≤6 months (mo) from the date of diagnosis. Median (Me) age was 48(18- 82) y, sex ratio (M/F(%)) 288/320 (47/53) pts, Me time from diagnosis to IM therapy was 2. 4(0- 6) mo. Pretreatment: Hydrea 461 (76%) pts; Mielosan 4 (0. 6%) pts, chemotherapy 21(3. 5%) pts, IFN-α 37 (6%) pts. Me follow-up since the beginning of CML treatment was 55. 2 (1- 108) mo (*6 pts have not data on the date of analysis). Statistical analysis performed using a package SAS9. 1. 3. **Results.** The cumulative incidence of SM in our CML pts was 2. 9% (17 pts). It should be noted that the identified cases were divided into subgroups: tumors detected before the diagnosis CML (prior malignancies, (pM)) and after (SM). Three out of observed incidences- pM (lung cancer, thymoma, stomach tumor) were revealed and treated surgically in 11, 10 and 19y respectively, before diagnosis of CML; 2 pts are alive (observation time since diagnosis of CML- 83 and 78 mo), treated by IM as a first line with complete molecular response (CMR). In 14 patients were identified SM; sex ratio (M/F) 8/6pts. Me age at the diagnosis of CML was 58(extr. 44- 75)y; Me time detection of SM since diagnosis of CML was 31 (extr. 0- 57) mo. Me time of IM therapy 58 (14- 71) mo. The most common SM: breast cancer (4 of 17 cases) and tumors of the gastrointestinal tract (4 of 17 cases). Most of the pts (among 17 incidences) had good results of TKI therapy: 11 pts achieved major and complete molecular response (Me 37 (extr. 6- 67)mo). Six out of the 608 (1%) pts or 35% of 17 pts died due to second neoplasmprogression in stable CP CML (1pt- pM/5pts- SM). **Conclusions.** Identified cases of a combination of malignancies and CML are of interest. The study of this aspect of CML will allow a deeper understanding the relationship between the development of SM, leukemia and their therapy.

TYROSINE KINASE INHIBITORS FOR THE TREATMENT OF CHRONIC MYELOID LEUKAEMIA: A SYSTEMATIC REVIEW

R Ferdinand[1], S Mitchell[2], S Batson[2], I Tumur[1]
[1]Pfizer Ltd, Surrey, United Kingdom
[2]Abacus International, Oxfordshire, United Kingdom

Background. Chronic myeloid leukaemia (CML) is a myeloproliferative disorder of blood stem cells. The tyrosine kinase inhibitor (TKI) imatinib was the first targeted therapy licensed for patients with chronic phase (CP) CML and it's introduction was associated with substantial improvements in response and survival compared with previous therapies. Clinical trial data are now available for the second-generation TKIs (nilotinib, dasatinib, and bosutinib) in the first-, second-, and third-line settings. **Aims.** To systematically review and qualitatively compare the clinical effectiveness, safety and effect on quality of life (QoL) of TKIs for the management of chronic, accelerated or blast phase CML patients. **Methods.** Included studies were identified through a search of electronic databases (accessed March 2011), and relevant conference proceedings. Outcome data were extracted by two independent reviewers. Primary outcomes of interest included complete cytogenetic response (CCyR), major molecular response (MMR), complete molecular response (CMR), transformation rates, incidence of adverse events (AEs) and QoL. **Results.** Of 3,248 potentially relevant citations, 47 publications of 23 unique studies met the pre-defined inclusion criteria (11 randomised controlled trials (RCTs) and 12 single-arm studies). All RCTs enrolled CP CML patients: eight investigated first-line treatments (imatinib, n=4; dasatinib, n=2; nilotinib, n=1; bosutinib, n=1) and three second-line treatment with dasatinib. In the first-line setting, the long-term efficacy (up to eight years) of imatinib has been confirmed in a single RCT (IRIS). In contrast, 2-year follow-up data on the second-generation TKIs have recently been published from three imatinib-controlled Phase III RCTs (nilotinib [ENESTnd study, n=846 enrolled patients]; dasatinib [DASISION, n=519]; bosutinib [BELA, n=502]). All second-generation TKIs reported lower rates of transformation, and comparable or superior cumulative CCyR, MMR and CMR rates compared with imatinib by 2-years follow up. Each of the second-generation TKIs was associated with a distinct AE profile compared with imatinib: nilotinib with increased incidence of rash, dasatinib with certain haematological AEs and bosutinib-treated patients reporting increased gastrointestinal AEs. Bosutinib was the only second generation TKI to report QoL data (no statistically significant difference compared with imatinib). Of the 12 single-arm studies, eight investigated second-line treatments (dasatinib, six studies, n= 916 enrolled patients; nilotinib, n=280; bosutinib, n=288), three third-line (nilotinib, n=60; bosutinib, n=170; nilotinib/dasatinib, n=26) and one study enrolled both second- and third-line patients (nilotinib/dasatinib, n=48). Data in the second- and third-line setting confirmed the efficacy of the second-generation TKIs in either imatinib resistant or intolerant patients as measured by CCyR and MMR rates. **Summary and Conclusions.** Data from first-line RCTs reporting up to 2-year follow up indicate superior response rates of the second-generation TKIs compared with imatinib. However, whether this superior efficacy over imatinib is maintained over longer treatment periods and is associated with improved overall survival remains to be confirmed. There is currently a paucity of QoL data in the first-line setting, with bosutinib the only second-generation TKI to have published RCT evidence. Current evidence from single arm studies in the second-line setting confirm that nilotinib, dasatinib, and bosutinib are valuable treatment options for the significant subgroup of patients who are intolerant or resistant to imatinib treatment.

1319

THE DIFFERENCES AND CORRELATIONS OF BCR-ABL TRANSCRIPTS BETWEEN PERIPHERAL BLOOD AND BONE MARROW ASSAYS ARE ASSOCIATED WITH THE MOLECULAR RESPONSES IN THE BONE MARROW FOR CHRONIC MYELOGENOUS LEUKEMIA

Q Jiang, XJ Zhao, YZ Qin, YR Liu, YY Lai, B Jiang, XJ Huang
Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background. Previous studies concerning *BCR-ABL* mRNA monitoring by quantitative real-time RT-PCR (Q-PCR) for chronic myelogenous leukemia (CML) have shown a significant concordance between peripheral blood (PB) and bone marrow (BM) assays, confirming that it was not necessary to obtain BM aspirates for accurate molecular monitoring. **Aims.** To determine whether molecular monitoring by Q-PCR using PB is comparable to using BM during the treatment of CML. **Methods.** Between May 2006 and July 2011, a prospective comparative study was performed to analyze the Q-PCR results (*ABL* as a control gene) of 712 simultaneous paired PB and BM samples from 330 CML patients in the chronic phase or the accelerated phase before and during imatinib therapy. All patients provided written informed consent. The study protocol was registered in the Chinese Clinical Trial Registry (Registration Number: ChiCTR-ONC-11001697). **Results.** For the 78 paired pretreatment samples from 78 newly diagnosed CML patients, the level of *BCR-ABL* mRNA in the PB was lower than that in the BM (P=0. 007). Among the 634 paired on-treatment samples which were collected from 262 patients (10 patients were diagnosed and followed from before the treatment and to during the treatment) at a median follow-up of 18 months (range 3-120 months) from the initiation of imatinib therapy, although the overall amounts of *BCR-ABL* mRNA in the PB and BM samples were comparable (P=0. 072) and there was a strong correlation (r=0. 839, P<0. 001), the level of *BCR-ABL* mRNA in the PB was lower than that in the BM (P<0. 001) where BM *BCR-ABL* mRNA < 1 log-reduction from the baseline (n=78 pairs), comparable with that in the BM (P=0. 499) where BM *BCR-ABL* mRNA ≥1-<2 log-reductions (n=99 pairs), and higher than that in the BM (P<0. 001) where the BM *BCR-ABL* mRNA ≥2 log-reductions (n=457 pairs). A strong correlation (r=0. 811, P<0. 001) was only found where BM *BCR-ABL* mRNA <1 log-reduction. Overall, the depth of the molecular response (the log-reduction values for *BCR-ABL* mRNA: 2. 39 vs. 2. 71, P<0. 001) and the proportion of major molecular response (29. 3% vs. 38. 3% P=0. 001) in the PB were lower than those in the BM. A further analysis on the dynamics of the leukemia burden for the 55 patients revealed that the log-reduction values for *BCR-ABL* mRNA in the PB were com-

parable with those in the BM at 3 months (P=0. 975) and 6 months (P=0. 076), and lower than those in the BM after 12 months (all P values < 0. 05) of imatinib therapy. **Summary.** The differences and correlations of the levels of *BCR-ABL* mRNA between PB and BM assays were associated with the molecular response in the BM and Q-PCR monitoring using PB has a greater sensitivity than using BM, especially while monitoring the deeper molecular responses of CML patients during imatinib therapy. **Conflict of interest disclosure:** All authors declare no competing financial interests.

Background. The tyrosine kinase inhibitor (TKI) imatinib is used as first-line therapy for newly diagnosed chronic myeloid leukemia (CML). However, some patients fail to respond to imatinib or become intolerant to it. Nilotinib is a second-generation TKI with higher selectivity and more potent inhibitory effects on BCR-ABL than imatinib, and several studies have reported hematologic and cytogenetic responses with nilotinib in patients who cannot tolerate imatinib or whose CML is imatinib-resistant. **Aims.** The safety and efficacy of nilotinib at 400 mg bid was evaluated in imatinib-resistant and -intolerant patients with CML-chronic phase (CP) or -accelerated phase (AP) at The East Japan CML Study Group (EJCML). The response to nilotinib was evaluated based on the BCR-ABL mutation status and its plasma trough concentration. **Methods.** Nilotinib was administered orally at 400 mg bid for one year, and the molecular responses were monitored using the international standard method of quantitative PCR (IS-PCR). BCR-ABL mutation was analyzed by direct sequencing (DS) at baseline and after 12 months of nilotinib treatment or at the time of an event. Plasma trough concentrations of nilotinib were measured using HPLC after 3 months. **Results.** From March 2009 through February 2011, 51 patients were registered in the study, and CRFs were collected from 49 patients (33 imatinib-resistant and 16 intolerant; 46 CP and 3 AP) by February 2012. The median follow-up period was 11. 7 months (range: 0. 1-13. 3). Forty-nine patients were evaluated for a molecular response. The rates of MMR (≤0. 1% IS) were 30. 8% and 55. 0% at 6 and 12 months, respectively, and the CCyR equivalent (≤1. 0% IS) rates were 61. 5% and 85. 0% at 6 and 12 months, respectively. Using DS, 5 BCR-ABL mutations (M244V, F317L, N358D, F359V and E459K) were detected in 6 patients (12. 2%) at baseline, and the M244V, N358D, F359V and E459K mutations had disappeared after 12 months of nilotinib. On the other hand, acquired BCR-ABL mutations (Y253H, I418V and exon 8/9 35bp Insertion) were detected after 12 months in 3 patients (6. 1%) who did not achieve CCyR or MMR. No patients acquired a T315I mutation. In the safety evaluation, grade 3/4 hematological toxicity included anemia in 12. 2% of patients, neutropenia in 26. 5% and thrombocytopenia in 18. 4%. QTc prolongation at all grades was found in three patients (6. 4%). Thirty-nine (77. 6%) patients are still on treatment; reasons for discontinuation were progressive disease in one patient with F317L, insufficient effects in one patient with no mutations, and adverse events in 9 patients. Among those on treatment, the plasma trough concentration of nilotinib was significantly higher in patients with MMR than in those without it (mean: 1067. 4 ng/ml vs. 629. 8 ng/ml, *P*=0. 0328). And patients with MMR were significantly less in Q1 (<489. 7 ng/ml) than in Q2-4 (489. 7-2899. 9 ng/ml) (44. 4% vs. 80. 0%, *P*=0. 0447). **Summary.** Imatinib-resistant patients, even those with BCR-ABL M244V, N358D, F359V and E459K mutation, achieved MMR after nilotinib treatment. The plasma trough concentration of nilotinib was related to the response in this study. Nilotinib showed good efficacy and tolerability in Japanese imatinib-resistant and -intolerant CML-CP or -AP patients.

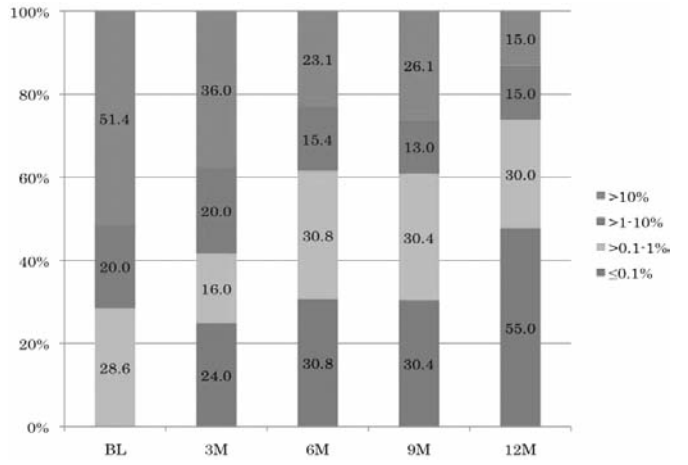

Figure 1.Complete Cytogenetic Response equivalent (≤1. 0% IS) and Major Molecular Response (≤0. 1% IS) to Nilotinib Over Time.

HOMOHARRINGTONINE BLOCKS THE EPHB4/RAC1/CDC42/RHOA PATHWAY CONTRIBUTING TO IMATINIB RESISTANCE

L Liu, H Huang, D Du, X Xu, Z Zhang
Nanfang Hospital, Guangzhou, China

Background. At present, the homoharringtonine (HHT) + imatinib (IM) therapy may overcome disease-poor response to conventional doses of imatinib. However it is not still determined the mechanism of overcome IM resistance. In our pre-experiment stage, it was determined that a new marker of IM resistance mediated by the activation of EphB4/Rac1/cdc42/RhoA pathway. **Aims.** Our purpose is to address whether HHT contributes to block the EphB4-mediated pathway. **Methods.** The apoptosis rate of K562 IM-resistant (K562-R) cell was detected with PE Annexin. The IM inhibition rates of K562-R or K562-R+HHT were analyzed by MTT assay. BALB/C female nude were used in xenograft experiments. Phosphorylation of related protein was analyzed by Western Blot. **Results.** The apoptosis detection showed the apoptosis rate of K562-R was only 2. 35 ± 0. 11% co-cultured with IM (1. 2 mg/L), but the apoptosis rate reached 58. 71 ± 2. 39% with K562-R incubated with HHT□20ug/L□+IM (P<0. 001). MTT assay showed that K562-R was IM resistance (IC50 5. 45 mg/L), but HHT made K562-R cell become sensitive to IM (IC50 1. 17 mg/L, P<0. 001). K562-R xenograft volumes significantly decreased with IM+HHT treatment comparing with before treatment (1692. 82 ± 317. 14 mm^3 versus 975. 56 ± 132. 42 mm^3, P<0. 001). On the contrary, K562-R tumor volumes significantly increased with simple IM treatment comparing with before treatment (1733. 82 ± 399. 22 mm^3 versus 2301. 25 ± 555. 76 mm^3, P=0. 001). Overall survival after treatment termination was 0, 16. 7% and 83. 3% in the IM, HHT, and HHT+IM therapy groups, respectively (P<0. 001). The EphB4, phosphorylation of Rac1+Cdc42 and RhoA was significantly decreased after HHT incubate in K562-R cells (P<0. 001). Analysis of xenograft tissue demonstrated that the parallel results. The expressions of EphB4/Rac1/cdc42/RhoA began to decreased after HHT treatment (P<0. 001). 5. **Conclusions.** We demonstrated HHT enhanced the sen-

sitivity to IM for K562-R cell and xenograft. There were no differences in the phosphorylation of MEK/ERK using HHT culture. The EphB4 and phosphorylations of RhoA and Rac1+cdc42 were simultaneously decreased after HHT intervention in K562-R cell and xenograft tissue. HHT, as a conventional anti-leukemia drug, locked the EphB4/Rac1/cdc42/RhoA pathway.

1322

SECOND-GENERATION TYROSINE KINASE INHIBITORS AS SECOND LINE TREATMENT IMPROVE OUTCOME OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA RESISTANT OR INTOLERANT TO IMATINIB

LF Casado Montero[1], V García-Gutierrez[2], B Maestro[2], I Massagué[2], P Giraldo[2], M Pérez-Encinas[2], R De Paz[2], J Martínez-López[2], G Bautista[2], S Osorio[2], MJ Requena[2], L Palomera[2], MJ Peñarrubia[2], MH Dumas[2], N García-Ormeña[2], C Calle[2], JA Hernández-Rivas[2], JL Steegmann[3]

[1]Hospital Virgen de la Salud, Toledo, Spain

[2]RELMC, Madrid, Spain

[3]Registro Español de Investigación y Tratamiento de Leucemia Mieloide Crónica, Madrid, Spain

Background. Imatinib has offered an outstanding improvement in the prognosis of chronic myeloid leukemia (CML) patients. Nevertheless, the IRIS trial has shown that, at eight years, 22% are off-therapy because of resistance (16%) or toxicity (6%) (Deininger M, et al. ASH 2009;114:1126). Clinical trials have shown that second-generation tyrosine kinase inhibitors (2GTKIs) using as salvage therapy, can induce long-term progression-free survival (PFS) in almost 60% of the patients (Shah NP et al Haematologica. 2010; 95:232-240.). However, data on this topic are scarce outside of clinical trials. As second-generation tirosin kinase Inhibitors (2G TKIs) are being evaluated as first line treatment with quite favourable outcomes so long, it is important to know what has happened when 2G TKIs have been used sequentially for patients with previous unfavourable responses to Imatinib, outside the controlled clinical trial setting.

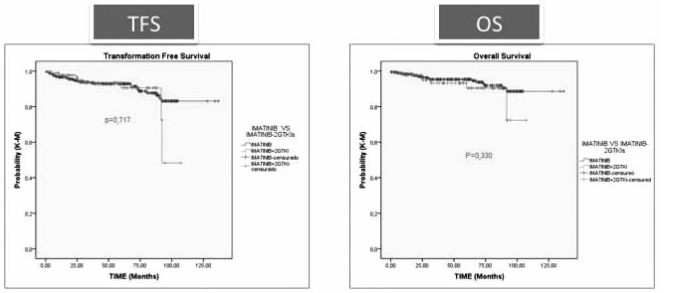

Figure 1.

Aims. Evaluate the actual benefit of 2G TKIs as salvage therapy for CML patients failing to Imatinib, regardless of the indication for its use, outside of clinical trials.**Study groups and Methods.** We have studied 393 CML patients, newly diagnosed, treated with imatinib as first TKI in our registry, which includes only patients outside clinical trials (compassionate uses are not excluded). These patients have been classified according whether second-generation TKIs were available or not. Group 1 includes 303 patients treated with imatinib or increased imatinib dose. Group 2 includes 91 patients (23%) that need treatment change (20 due to intolerance and 70 due to either failure, suboptimal response or loss of response to imatinib). 2G TKI prescribed were dasatinib in 43 patients, nilotinib in 25 patients and 23 patients received either dasatinib or nilotinib as third line after failure 2G TKI. **Results.** The use of second-generation TKIs as salvage therapy resulted in significant benefit to patients in terms of responses. Proportions of response (complete cytogenetic responses (CCR) at any time and major molecular responses (MMR)) only with imatinib and before 2GTKIs are included in Figure 1, according to Sokal, Euro and Eutos index risk groups. All groups of patients improve the rate of CCyR or MMR and the difference between groups of risk lost statistically significance. The outcome in terms of transformation free survival and overall survival was similar in patients with only imatinib (optimal response) and in patients that have to change to a 2GTKI (Figure1). **Conclusions.** The use of second-generation TKIs as salvage therapy has improved the responses of CML patients treated with TKIs. Outside clinical trials, the outcome of patients with 2GTKIs as salvage therapy seem to be similar that patients with good responses to imatinib. Although the use of 2GTKI frontline has shown benefit compared to imatinib, this therapeutic strategy merits, in our view, to be compared with the use of imatinib followed of 2GTKI for patients without optimal responses to imatinib.

EVALUATION OF REAGENTS FOR THE QUANTITATIVE MULTIPLEX MEASUREMENT OF BCR-ABL1 EXPRESSION ON THE INTERNATIONAL SCALE

J Brown[1], B Hanfstein[2], P Erben[2], K Ackermann[2], M Müller[2]

[1]Asuragen, Austin, United States of America

[2]Medizinische Fakultät Mannheim der Universität Heidelberg, Mannheim, Germany

Background. BCR-ABL1 e13a2 or e14a2 fusion transcripts corresponding to the major breakpoint M-BCR of t(9;22) are present in >95% of chronic myeloid leukemia (CML) patients. This molecular signature is useful to monitor tumor burden and TKI treatment response. Large studies have led to establishment of the International Scale (IS) for consistent interpretation between patients and laboratories. On this scale, baseline BCR-ABL1 (e13a2 or e14a2) to control gene ratio is defined as 100% IS with a 3-log reduction indicative of MMR (0. 1% IS or lower). **Aims.** The objective of this study was to evaluate the use of a multiplex assay (BCR/ABL1 Quant™ Test, CE-marked IVD) for the quantitative detection of e13a2 and e14a2 fusion transcripts. We investigated the Test's performance relative to a laboratory-developed test (LDT) reporting on the IS and the potential interference by rare fusion transcripts. **Methods.** A series of RNA specimens was generated by diluting cultured, immortalized cells in non-leukemic donor specimens. Purified total RNA, at an input optimized for the Test, was then reverse transcribed and amplified by multiplex, real-time quantitative PCR on the ABI 7500 Fast Dx (in "standard"mode) using target-specific primers for BCR-ABL1 (e13a2, e14a2, and e1a2) and ABL1 as an endogenous internal control. The variant e1a2 resulting from the minor breakpoint m-BCR was not evaluated in this study. Four-point standard curves were generated in each run using the included multiplex Armored RNA Quant® (ARQ) Calibrators. Each Calibrator, containing BCR-ABL1, ABL1, and BCR/ABL1 Quant Norm, an exogenous internal control, was prepared by heat lysis prior to reverse transcription. Data were analyzed using the 7500 Fast Dx instrument's software (SDS v1. 4). **Results.** Linearity of 5 logs was observed with the RNA specimens derived from a mixture of cultured leukemic cells in a background of non-leukemic cells (R2 > 0. 99). Known negative specimens did not generate a fluorescence signal. The breakpoints e13a2 and e14a2 were specifically detected. Inter-run reproducibility was excellent. An IS conversion factor of about 0. 2 was calculated using 37 residual clinical specimens tested in singleton across two runs. After conversion to the IS, 97% of the IS % ratios generated with the Test were within 3-fold of the LDT results and 81% within 2-fold. Specimens positive for the rare e19a2 fusion transcript (an exon e1-containing variant resulting from the micro breakpoint µ-BCR) yielded percent ratios on average 50-fold lower with the Test relative to the LDT. Specimens with the rare variants e13a3 and e14a3 were confirmed negative with the Test. **Conclusions.** The BCR/ABL1 Quant Test is compatible with reporting on the IS and provides results across a broad linear range. As expected, rare transcripts do not interfere with the Test. The Test does quantify e13a2 and e14a2 fusion transcripts in a single reaction and shows excellent correlation with the IS. Streamlined reagent formulation, multiplex assay format, and inclusion of ARQ calibrators improve the workflow and increase the number of specimens that can be tested per run.

METHYLATION STATUS ANALYSIS OF THE ZONULA OCCLUDENS-1 (ZO-1) GENE PROMOTER REGION OF CHRONIC AND BLASTIC PHASE CHRONIC MYELOID LEUKEMIA

C Wang[1], YH Tan[1], C Yao[1], YZ Wang[1], W LI[1], L Yu[2], GJ Wang[1]
[1]The First Hospital of Jilin University, Changchun, China
[2]Department of Hematology, Chinese PLA General Hospital, Beijing, China

Background. Despite encouraging treatment success has been obtained in chronic phase (CP) chronic myeloid leukemia (CML), the treatment in blastic phase (BP) remains a difficult problem. Exploring the markers of disease progression constitutes the important problem. Zonula occludens-1 (ZO-1) is one kind of membrane-associated guanylate kinases, previous study has showed the aberrant hypermethylation in ZO-1 gene promoter region may concern with leukemia pathogenesis and progression. **Aims.** The aim of this study was to compare the methylation status of ZO-1 gene promoter region between CP and BP CML patients and analyze the relationship between the methylation status and the disease progression. **Methods.** From March 2011 through December 2011, the methylation status of the ZO-1 gene promoter region of the bone marrow samples of 20 CML patients (10 CP patients and10 BP patients) was detect with Methylation-specific PCR (MS-PCR). The appropriate informed consent from each individual was obtained after explaining the nature and consequences of the research. **Results.** For the 10 CP-CML patients, there was no one showed hypermethylation in the ZO-1 ene promoter region, but for the 10 BP-CML patients, 7 patients showed hypermethylation. For one CP patient, the methylation status was changed from hypomethylation to hypermethylation when the disease advanced to BP, and was change back to hypomethylation when the diseases returned to CP after treatment. **Conclusions.** Our results showed that the methylation status of ZO-1gene promoter regions were significant difference between chronic and blastic phase of CML and its change may be closely related to disease progression.

Background. Chronic Myeloid Leukemia (CML) is a type of myeloproliferative disease characterized by the chromosomal translocation between the part of the BCR gene from chromosome 22 and ABL gene from chromosome 9. As a consequence of this reciprocal translocation is a novel BCR/ABL gene coding a constitutively active protein, tyrosine kinase that activates multiple downstream signaling pathways. Activity of this fusion BCR/ABL protein can be specifically inhibited by tyrosine kinase inhibitor (TKI) - imanitib mesylate. According to clinical trials, patients who had MMR or those who have at least 3 log reduction of BCR/ABL transcript level after 18 months of imanitib therapy had a significantly lower risk of disease progression and better event-free survival than patients without major molecular response (MMR) at this time point [M. Baccarani et al, 2006[1]]. First use of imatinib in CML patients was started in Russia in 2001 and it became widespread since 2005. To date Russian Federation registry of CML patients includes 5866 patients from all the 83 federal subjects of Russia. **Aims**. To analyze proportion of patients who have achieved an MMR after 18 months of imanitib therapy of CML patients in chronic phase (CP) in the Russian Federation. **Methods.** We analyzed peripheral blood samples of 2215 CML CP patients from all of 83 federal subjects of the Russian Federation. All patients were on imatinib therapy (400-600 mg/day) more than 18 months. Relative BCR/ABL gene expression was measured by quantitative real-time polymerase chain reaction (RQ-PCR) in comparing with expression of reference gene ABL. Quantity of reference gene was no less than 10000 copies per reaction, so the sensitivity of RQ-PCR was 0. 01%. Relative expression of BCR/ABL gene was multiplied to conversion factors in order to obtain results according to international scale (IS). **Results.** In November of 2011, eleven laboratories of the Russian Federation working in the field of CML diagnostics successfully passed the international standardization for RQ-PCR for BCR/ABL gene expression according to IS. Since that time, BCR/ABL gene expression has been analyzed for 2215 patients. We estimated that frequency of MMR was 57. 7% after 18 months of imanitib therapy in chronic phase (CP) of CML patients in the Russian Federation (from 38. 9% to 66. 7% in various federal subjects). **Conclusions.** Tyrosine kinase inhibitors (TKIs) efficiently decrease BCR/ABL gene expression and successfully induce high rate of MMR in CP of CML after 18 months of therapy. We showed that MMR could be achieved for about half of patients (38. 9-66. 7%) and in this group imanitib therapy is reasonable for further treatment. However, the remnant part of the patient has no MMR, thereby their therapy should be re-assessed to second-generation TKIs to induce durable remission and safety of progression. Reference: [1]M. IMPACT OF TREATMENT ADMINISTRATION ON SELECTION OF BCR-ABL1 KINASE DOMAIN MUTATIONS

F Razga[1], T Jurcek[1], D Zackova[1], D Dvorakova[2], M Toskova[1], I Jeziskova[1], J Mayer[2], Z Racil[2]
[1]University Hospital Brno, Brno, Czech Republic
[2]University Hospital Brno and CEITEC, Masaryk University Brno, Brno, Czech Republic

Background. Availability of different tyrosine kinase inhibitors (TKIs) with distinct anti-leukemic potency enables the optimization of current therapeutic regimens; however, some patients lose their therapy responses and acquire TKIs resistance. **Aims.** In this study, a single center experience with monitoring of *BCR-ABL1* kinase domain (KD) mutations is described and, particularly, the impact of the treatment administration on mutations selection is discussed. **Methods.** The CML patients treated with TKIs at our institution during the years 2003 - 2011 were included in this study. Peripheral blood and/or bone marrow samples were collected, processed and analyzed using the published procedures; detection of *BCR-ABL1* KD mutations was performed by direct sequencing. **Results.** First, we evaluated the impact of non-TKI pretreatment on: a) spectrum of *BCR-ABL1* KD mutations; b) their frequencies and c) time to mutation detection after the administration of a first-line TKI. Our data shows that pretreatment with non-specific non-TKI drugs does not preferentially select the *BCR-ABL1* KD mutations, as there was no difference between the frequency of T315I or p-loop mutations compared to mutations in other KD regions (52. 7% vs. 47. 3%). In contrast, the imatinib (IMA) as first-line therapy led to clear predominance of T315I or p-loop mutations (90. 9% vs. 18. 2% of mutations located in other KD regions). In addition, median time to the detected p-loop mutations was substantially shorter in patients treated with IMA first-line compared to patients who were pretreated (16 months (3 - 41) vs. 46 months (20 - 109), p = 0. 005). Second, we analyzed the impact of administered TKIs on appearance and selection of mutations in patients that were recurrently resistant to TKIs therapy. Among the patients with initial *BCR-ABL1* KD mutation, 32. 0% developed a second mutations after the change of TKIs treatment. The more potent second-line TKIs therapy caused the elimination of most of the initial IMA resistant mutations; however, several mutations resistant to second-line therapy subsequently emerged, with considerably shorter time compared to the initially detected ones (9 months (1 - 25) vs. 21 months (3 - 109), p = 0. 007). Moreover, after the therapeutic intervention with third-line TKIs, similar consequences were observed. Third, we confirm the previously described poor prognosis of CML patients with mutated *BCR-ABL1* KD, since 40. 0% of our CML patients that harbored *BCR-ABL1* KD mutation died during the treatment with TKIs. Moreover, 27. 8% of patients who are still on treatment have already progressed. Last, our data confirms the unique position of T315I mutation with respect to its strong resistance to the currently approved TKIs. **Conclusions.** Based on a "real-life"data described in this study, for some of the CML patients that harbor *BCR-ABL1* KD mutations, it may seem that therapy itself consecutively leads to its failure, selecting thus the most resistant mutations under the selective pressure of applied therapy regimen (Figure 1). Note that formation

and selection of mutations, that could reflect the genomic instability, is not a single process, thus all aspects must be taken into account. **Acknowledgements.** Supported by The *CzE*ch *L*eukemia Study Group for *L*ife (*CELL*) and grants MSM0021622430 and MUNI/A/0784/2011.

EARLY AND DEEP RESPONSES TO IMATINIB ARE STRONG PREDICTORS OF COMPLETE MOLECULAR RESPONSE

V Garcia-Gutierrez, L Abalo Perez, P Herrera Puente, M Calbacho Robles, J Alonso Dominguez, S Gomez Rojas, A Jimenez Martin, L Ramos Oliva, Lopez Jimenez
Hospital Universitario Ramón y Cajal, Madrid, Spain

Background. Imatinib has consistently proven a survival benefit in patients with chronic myeloid leukemia (CML). Second line tirosine kinase inhibitors (TKI) seem to bring deeper and earlier responses, but to asure that this means survival benefits requires longer follow up. TKI need to be taken for unlimited period of time in order to avoid the risk of accelerated phases. It has been described recently that patients with a continued, complete molecular response (CMR) for at least 2 years, could safely quit treatment. Less is known about the real rates of patients under TKI to achieve CMR and which factors may add to maintain the response. **Aims.** To analyze the probability of achieving CMR of patients treated with imatinib in the long term follow up and to identify factors predicting its achievement and maintainance. **Patients and Methods.** We have analyzed 108 patients treated with imatinib as first tirosine kinase inhibitor in a single institute. Median follow-up was 55 months (10-124). Sex ratio (M/F) was 54/46 with a median age of 53. 1 years (27. 4-78. 2). Sokal score distribution was 42%, 40% and 18% for low, intermediate and high values respectively. Eutos score distribution was 87% and 13% for low and high values. 48% of the pts received interferon therapy prior to imatinib. We used European Leukemia Net recomendations for the follow up. CMR was defined as $CMR^{4.5}$: *BCR-ABL/ABL IS ratio* <0. 0032% or UMRD (undetectable Bcr-Abl using standardized RTQ-PCR) under imatinib therapy in two consecutive determinations. **Results.** The probability of a CMR at any time during treatment was 38% (N=42). Only 22 of the 42 patients (20% in the entire cohort) that achieved CMR mantained it for a period of 2 years. We have indentified the cytogenetic responses at 6 months and the molecular responses at 12 months as strong predictor factors for CMR. Probability for CMR during follow up was 63% for patients with complete cytogenetic responses (CCyR) at 6 months vs 17% for patients that did not get a CCyR at that time (p=0. 00). Patients with mayor molecular response (MMR) (<0. $1\%^{IS}$) at 12 months showed more probabilities for achieving CMR (81% vs 24% p=0. 000). Neither Sokal or Eutos prognostic factors were identified as predictor factors for CMR. **Conclusions.** Complete molecular responses maintained for 24 months are not so frecuent in patients under imatinib. We have identified early and deep responses as strong predictor factors for this achievement. Strategies that improve cytogenetic and molecular responses, as the use of a second line TKI, could increase CMR rates, as well as the possibilities for a discontinuation of the treatment.

THE Results OF 10-YEAR TREATMENT PERIOD BY TYROSINE KINASE INHIBITORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN LATE CHRONIC PHASE

O Vinogradova, A Turkina, E Chelysheva, G Gusarova, O Lazareva, E Zakharova, M Sokolova, T Kolosheinova, L Kolosova, S Goryacheva, M Vakhrusheva, S Kulikov, I Tischenko, N Khoroshko
Hematology Research Center, Federal State Institution of Ministry of Health, Moscow, Russian Federation

Background. Imatinib (IM) therapy in chronic myeloid leukemia (CML) patients started in Russian Federation from 2000-2001. The first patients treated by IM had a late chronic phase (LCP) with IM therapy started in >6 months from diagnosis. **Aims and Methods.** To analyze the results of the IM treatment in the LCP CML patients within the durable follow-up period. 219 LCP CML patients (107 males and 112 females) who started IM from 2000 to 2004 were analyzed**.** Median age at diagnosis was 41 years (9-73years). Median period from diagnosis till the data assesement was 116 months (16-165 months). Median CML duration from diagnosis till IM treatment was 32 months (6,5 -57 months). Sokal risk groups ratio was 143(65%):32(15%):44(20%) for low, intermediate and high risk correspondently. 192(88%) of patients received interferon alpha (IFNά) before IM treatment, 29 (13%) received busulfan. Median duration of IM treatment was 79 months (0,9 - 118 months), median duration of the following treatment by 2nd generation of tyrosine kinase inhibitors (TKI2) in 60 patients was 40 months (2-61 months). **Results.** The nine years overall survival (OS) for LCP CML patients from IM treatment start was 78% and significantly differed in low, intermediate and high Sokal risk groups: 84%, 75% and 61% correspondently (p<0,002). At the moment of evaluation 171 (78%) patients were alive and on TKI treatment: IM in 121 (55%), mostly on standart dose 400 mg/day and TKI2 in 48(23%) of patients; 2 patients resistant to IM and TKI2 receive hydroxyurea. The stable complete cytogenetic response (CCyR) was achieved in 147(67%) of patients; in majority of cases during first 3 years of treatment, in some patients CCyR was achieved firstly on 4th-8th year of treatment. 93 (75%) of the evaluated patients achieved a major molecular response (MMR), 47 of them also got a complete molecular response (CMR), in 10 of patients MMR was not stable. 31 (25%) of the evaluated 124 patients did not get MMR. Progression to accelerated phase (AP) or blast crisis (BC) developed in 74(26%) of patients in median period of 71 months (7-86 months). 48 (22%) patients died: 41(85%) of them from disease progression, 5 (11%) from comorbidities, 2 (4%) from unknown reason. OS in patients with CML duration >60 months before IM treatment, 12-60 months and 6-12 months significally differed: 60%, 84% and 83% correspondently (p<0,02). Usage of busulfan before IM had a negative impact on OS: OS was 81% in patients without busulfan pretreatment vs 59% in those who received busulfan (p<0,001). The highest mortality in patients pretreated by busulfan was within the first 3 years of IM treatment, and they got CCyR in later terms. The group with IFNά pretreatment had significantly higher OS compared to the group without IFNά pretreatment: 80% vs 60%(p<0,001) correspondently. **Conclusions.** TKI therapy in LCP CML patients permitted to restore the Ph'-negative hemopoesis even on late terms of therapy and also allowed to achieve the high rates of OS and long-lasting response rates in group of CML patients with the durable pretreatment period.

CLONAL EVOLUTION IN PHILADELPHIA CHROMOSOME-NEGATIVE CELLS DURING IMATINIB MESYLATE THERAPY IN PHILADELPHIA CHROMOSOME POSITIVE CHRONIC MYELOID LEUKEMIA PATIENTS

V Novakovic[1], A Bogdanovic[2], V Djordjevic[1], J Jovanovic[1], D Lekovic[1], M Dencic Fekete[1], M Gotic[2]
[1]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinic of Hematology Clinical Ctr, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Background. Imatinib is current standard treatment for newly diagnosed patients (pts) with CML. Secondary chromosomal changes are known to develop in Philadelphia chromosome negative (Ph-) cells in chronic myeloid leukemia (CML) during treatment with imatinib. The most common abnormalities are trisomy 8 and monosomy 7 occuring in 3-4% patient with CML. **Aims.** The aim of our study was to investigate chromosomal changes in Philadelphia negative cells in large cohort of our CML pts. **Patients.** Between 2002 and 2011, 140 pts with CML were treated with imatinib in our institution (frontline in 102 and 38 pts as second line). Imatinib therapy was in standard dose 400 mg, with escalation to 800 mg/d in patients not achieving optimal response according to ELN and national guidelines. **Results.** In our group, 9 patients (6. 4%), 4 males and 5 females, mean age 38 years (27-79 yrs) developed clonal chromosomal abnormalities in Ph-negative cells. They were noted on 14 months in average (range, 6-26) after imatinib therapy was initiated. All pts were in chronic phase CML, 3 pts had low risk, 4 pts intermediate and 2 pts high risk Sokal score and all patients achieved complete cytogenetic response (CCgR) at six months. Six patients had trisomy 8 and three lost chromosome Y without myelodisplasia. The median interval of the first trisomy 8 observation was 12 months (range 6-24). Three of six patients with +8 lost cytogenic response after 24, 36 and 38 months from start of imatinib. They were subsequently treated with Nilotinib (2 pts) or escalated dose of Imatinib (1 pts) and all pts achieved again CCgR and also complete or major molecular response (MR3. 0/MR4. 0) without progression during further follow-up of 26 months (range 6-64 months). In all pts with the loss of chromosome Y, with median follow-up of 24 months (range 6-48), no progression of CML was observed. **Conclusions.** Imatinib may favor the emergence of additional clonal chromosomal abnormalities. Those abnormalities in Ph-negative clone were not associated with myelodisplasia. These

changes did not impair the cytogenetic response to IM but in some patients may lead to loss of prevoius treatment response. In general, imatinib therapy was not interrupted due to those aberrations. Futhermore, our current findings suggested that patients on imatinib should be regularly monitored by all means like cytology, and conventional karyotype besides regular molecular monitoring.

SUDDEN BLASTIC TRANSFORMATION AFTER A GOOD RESPONSE WITH IMATINIB IN CML PATIENTS, EXCEPTION RATHER THAN THE NORM

P Neelakantan, D Milojkovic, D Marin, K Rezvani
Imperial College, London, United Kingdom

The introduction of tyrosine kinase inhibitors (TKIs) has proved to be a major advancement in the management of patients with chronic myeloid leukemia in chronic phase (CML-CP)[1] although the clinical benefit seems to be limited to those patients who achieve CCyR. Patients who achieve CCyR are believed to have an excellent prognosis, however a very small proportion of those patients may loose the response and progress to blastic phase. In this work we study a cohort of 210 patients who achieved CCyR on imatinib first line therapy in order to identify the incidence of blastic transformation in this population. Between June 2000 and December 2010, 210 consecutive adult patients with CML-CP received imatinib 400 mg daily as first-line therapy (as described earlier[2]) at our institution. The median follow-up was 69 months. Of the 210 patients, 5(2. 3%) progressed to blastic phase (3 myeloid and 2 lymphoid). The median time to achievement of CCyR in these 5 patients was 18 months (range 9-20 months). Four patients achieved a major molecular response (MMR, one of them achieved a 4 log reduction in the transcript levels) and one patient had a CCyR with no MMR. None of the patients had a mutation prior to transformation to an advanced phase and subsequently two patients developed a new mutation at the time of transformation (M244b and T315I). The cumulative incidence (CI) of blastic transformation after attainment of CCyR was 2. 3% (Figure 1). The median time from achievement of CCyR to blastic transformation was 18 months (Range 12-40 months). In summary, sudden blastic transformation is a rare but devastating event in patients who have achieved CCyR on imatinib with an 8 year CI of 2. 3%.

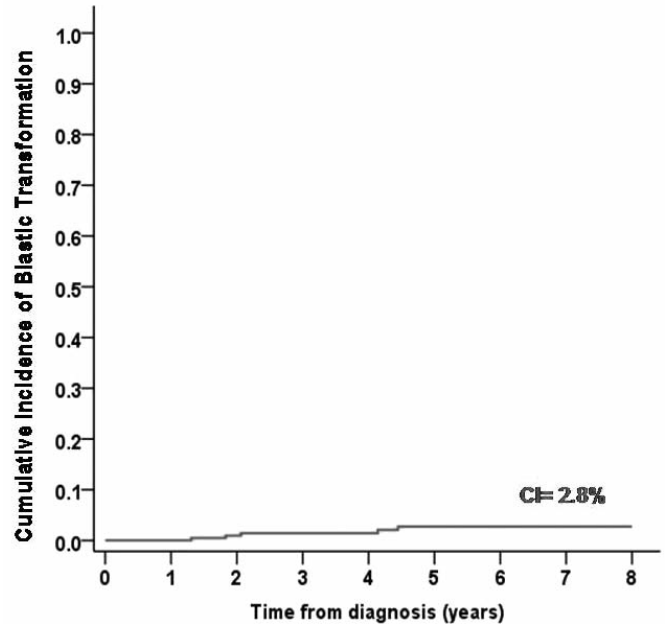

Figure 1. CI of progression to blast phase after attainment of CCyR, n=210.

CHRONIC MYELOGENOUS LEUKEMIA IN LEBANESE AND JORDANIAN CHILDREN AND ADOLESCENTS

L Samia[1], R Rihani[2], Z Otrock[1], S Muwakit[1], R Saab[1], R Mahfouz[1], M Abboud[1]
[1]American University of Beirut, Beirut, Lebanon
[2]King Hussein Cancer Center, Amman, Jordan

Background. Chronic myelogenous leukemia (CML) is rare in childhood. Allogeneic hematopoietic stem cell transplantation (AHSCT) remains the only proven cure. However, the excellent outcome induced with the advent of molecularly-directed therapy that inhibits the tyrosine kinase (tyrosine kinase inhibitors, TKI) in adults resulted in a radical change in the management of pediatric CML. **Aims.** We report our joint experience with pediatric CML at the Children's Cancer Center of Lebanon (CCCL) and King Hussein Cancer Center (KHCC) in Jordan and the associated challenges. Patients and **Methods.** We retrospectively reviewed data on children and adolescents younger than 20 years, who were diagnosed with CML for the period of April 2002 through May 2011. An informed consent was obtained from either the patients or their legal guardians. Medical records and laboratory data were reviewed for clinical presentations, disease course, response to treatment, adverse effects and tolerance. **Results.** A total of 17 children (7 from CCCL and 10 from KHCC) with CML were identified. There were 10 males (58. 8%) versus 7 females (41. 2%) with a median age at diagnosis of 10. 5 years (range, 1 to 20 years). The median follow-up time was 4. 5 years (range, 1 to 12 years). A complete hematologic response was achieved initially in all of patients on imatinib mesylate. An optimal response (complete molecular response after 18 months and complete cytogenetic response at 1 year) was achieved in 76. 4% (13/17 patients) of cases. The median time to achieve complete molecular response was 9 months (Figure 1). Two patients failed imatinib and were switched to second generation TKI (one achieved complete molecular and cytogenetic response while the other awaits AHSCT) and 4 underwent AHSCT. None of the patients died. There were no major adverse effects reported, particularly those related to delayed growth velocity in children. However, the major challenge with TKI therapy was compliance, especially in adolescents. **Conclusions.** Imatinib mesylate has become the first-line of treatment in children with CML with AHSCT reserved to those who have full-matched related donors or fail medical treatment. On the other hand, further studies are needed to assess the efficacy of second generation TKI in children. The major challenge to medical treatment in our series was the availability of the drug in developing countries and the adherence to therapy, especially in adolescents.

A RETROSPECTIVE REAL-LIFE ANALYSIS OF CHRONIC MYELOID LEUKEMIA PATIENTS IN SUBOPTIMAL RESPONSE TO IMATINIB: A SINGLE CENTRE EXPERIENCE

D Ferrero[1], E Crisà[1], M Cerrano[1], F Pirillo[2], P Riccomagno[2], M Nicolosi[2], M Boccadoro[1], U Vitolo[2], P Pregno[2]
[1]University of Study of Turin, Turin, Italy
[2]AOU S. Giovanni Battista, Hematology Division, Turin, Italy

Background. Life expectancy of CML patients has greatly improved in tyrosine-kynase inhibitor (TKI) era, but still some questions remain about the management of suboptimal responders (SR) to imatinib standard dose. European Leulemia Net (ELN) recommended to continue imatinib in case of optimal response and to move to second generation TKI in case of failure but there isn't a clear agreement on SR: maintaining imatinib at standard or higher dose or switching to another TKI are all considered acceptable options (Baccarani et al, JCO 2009). **Aims.** Outcome evaluation of 43 SR patients to imatinib 400 mg/d treated according to the 3 different ELN options. **Methods and Results.** We retrospectively analysed 43 CML patients, diagnosed in chronic phase between 1988 and 2011, SR to imatinib 400 mg/d. Forty patients received imatinib front line, 3 had been previously treated with interferon and cytarabine. Sokal score, evaluable in 27 patients, was high risk in 2, intermediate in 13 and low in 12, respectively. Seventeen patients were cytogenetic SR and 26 molecular SR according to 2009-ELN. The median follow-up from diagnosis was 72 months (range 10-288), only one patient died (gastric cancer). At suboptimal response detection 33 patients (77%) continued imatinib 400 mg/d, 9 increased imatinib dose to 600 mg/d (4) or 800mg/d (5), one switched to new TKI (response not yet evaluable). Among the patients who continued imatinib 400 mg/d (88% for at least 6 months), 9 (27%) major molecular responses (MMR) (7 long-lasting) and 13 failures (39%) were detected. Ten patients maintained a suboptimal response and eventually increased imatinib dose (9/10) or changed TKI (1/10). Eighteen SR patients increased imatinib dose, 50% at suboptimal response detection and 50% after further 12 months (median) of standard dose treatment (range 3-18). Thirteen patients (72%) obtained MMR, that was durable in 11 (61%). Four failures were observed (one after the achievement of MMR, one after intolerance to high dose imatinib). A total of 12 SR patients switched to a new TKI (8 dasatinib and 4 nilotinib), 10 after high dose imatinib, and 5 of 8 evaluables (62%) achieved MMR. At the end of the follow-up 32 patients (74%: 59% of the cytogenetic SR and 85% of the molecular SR) were in stable MMR; 6 more patients achieved complete cytogenetic response only. No patient progressed to accelerate/blastic phase. **Conclusions.** In our casistics no clear advantage in maintaining imatinib 400 mg/d after suboptimal response was observed (only 21% durable MMR, 39% failures). Imatinib dose increment led to a 61% of stable MMR and might represent a more reasonable option. The switch to 2nd generation TKI brought results comparable to those obtained with high dose imatinib (62% MMR) in patients mostly unresponsive to the last option. Therefore, an earlier switch to new TKI might further increase the proportion of optimal responders. However, the small number of patients treated with new TKI in our study prevents definitive Conclusions about the optimal management of SR.

1333

IS THERE A DIFFERENCE IN TREATMENT OUTCOMES OF ADOLESCENTS&YOUNG ADULTS OR ELDERLY PATIENTS WITH CHRONIC MYELOID LEUKEMIA?

A Bogdanovic[1], V Novakovic[2], D Lekovic[2], V Djordjevic[2], M Dencic Fekete[2], J Jovanovic[2], G Jankovic[1], M Gotic[1]
[1]Clinic of Hematology Clinical Ctr, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

In leukemia treatment, most of treatment efforts are directed towards improving outcomes in younger patients providing better long term survival. On the contrary, CML is disease of advanced age, and often in clinical practice certain number of patients >60y would not receive TKI treatment due to comorbidities, possible drug interactions or clinical judgment. Also, it is known that Sokal score is rising with patient's age and in general, elderly population had worse outcome in classical CML. **Aims.** We analyze outcomes of frontline imatinib treatment in large cohort of CML patients from database of Clinical Center of Serbia from 2005 to 2011. **Patients.** In last 7y, 102 patients with CML were treated by imatinib frontline. Outcome was assessed as optimal response on 6 and 12 months of treatment according to ELN proposals. **Results.** Patients were separated in 4 age groups (younger ones 15-29y, middle age 30-44y and 45-60y, and elderly patients with age >60y). Mean age in the whole group was 54y (16-85). Younger group had 13 pts, while other groups had 21, 38 and 30 pts respectively. At 6 months, in young group optimal response (majorCgR) was achieved in 11 of 13 patients (84%), but CCgR was achieved in 7 pts (53%). On the other side, in elderly group, majorCgR was achieved also in 82% of pts (23/28), but CCgR was achieved in 19/28 pts (67%) (Fisher p=0. 29). At 12 months, in young group optimal response (CCgR) was present in 7 of 11 patients (63%). On the other side, in elderly group, CCgR was achieved in 22 of 25 pts (88%) (Fisher p=0. 08). We have analyzed other variables that might influence obseved differences and we have found that younger patients have more often high WBC count (180 vs. 77. 6 G/L, t test p<0. 01), higher blast count in blood (2. 1% vs. 0. 8%, t test p<0. 05) and also larger spleens (6. 5 vs. 2. 4 cm below LCM, t test p<0. 05). Large splenomegaly (>5cm) was noted in half of younger patients 7/13 (54%) but only in 7 of 30 pts in elderly group (23%)(Chi sq p=0. 05, Fisher p=0. 055). We have not found differences in basophil, eosinophil or platelet count. We have found that there was a difference in Hasford score distribution between these two groups, younger ones were more low risk (8/13), and elderly were intermediate risk (22/30) (Chi square p<0. 05). There was no difference in EUTOS score between two groups. Two younger patients died (15%) one due to blastic transformation and other one during SCT, and 3 elderly patients died (10%), 2 in blastic transformation. Overall survival of those two distinct groups was similar, OS5y 92% for younger and 88% for elderly population of patients. **Conclusions.** Our results are in concordance with recently published data suggesting that young adults have less optimal outcome on long term, therefore they need different prognostic and therapeutic approach. Also, we have found that most of patients >60y can tolerate imatinib treatment well with achievement of excellent treatment goals like CCgR.

Background. Tyrosine kinase inhibitors(TKI) dramatically change the life of patients with chronic myeloid leukemia(CML) - drastic decrease of disease progression and increase of the overall survival of CML patients. Evaluation of incidence and prevalence is important for planning of therapeutic and financial strategies in the region. **Aims.** To evaluate the dynamics of CML incidence and prevalence in Saint-Petersburg and Leningrad region. **Methods.** CML patient (pts) databases were obtained from all hematological clinics and outpatient departments of Saint-Petersburg(SPB)and Leningrad region(LR). In 2005 the data of all alive or ever treated with Imatinib (IM) CML pts (Ph and/or bcr-abl positive) were collected. Afterwards all new CML cases were registered and updated at least annually. To evaluate the incidence and prevalence we used the data of the general census of the population of Russia in 2010(SPB population - 4848700 and LR -1712700). The data were analyzed using SPSS statistics 17. 0. **Results.** In the database there are data of 477 CML pts: 56, 170 and 251 pts of them were diagnosed before 2000, during 2000-2005 and 2006-2011 respectively. The most of them (347/477, 73%) are alive at the time of analysis. The mean incidence of CML during 2006-2011 was 0,64 (range 0,44-0,8) with median age of 53,2 years. The mean incidence of male/female CML ratio was 0,7:0,6. At the diagnosis the mean annual frequency of chronic phase (CP), accelerated phase (AP) and blastic phase (BP) was 93%, 5% and 2% respectively. In the whole group TKI therapy was ever given to 438/477(91,8%) pts (IM was ever given to 427 pts). The majority of pts (245/251, 97%) diagnosed during 2006-2011 was treated with TKIs as first line (IM in 234, other TKIs in 11pts), whereas the pts diagnosed before 2006 (151/193, 78%) mainly obtained IM in late CP. Second generation TKI were given to 90/427 (21%) IM resistant or intolerant pts. In the database there are only 16 pts after alloSCT (5 of them are alive, 10 - dead and 1 - lost to follow-up). At present the quantity of pts alive and the prevalence of CML nearly doubled as compared with the end of 2005 (Table 1). Estimated overall survival by 8 year for pts treated with

IM in early and late CP was 90% and 73% (p=0,028). Estimated overall survival was significantly lower in patients with high versus low Sokal score irrespective of IM start time (early or late CP, p=0,014 and 0,000). Whereas the estimated overall survival in low and intermediate risk score groups was equal only in pts who received IM in early (p=0,12), but not in late CP(p=0,009). **Summary.** In TKI era significant increase of CML prevalence is documented in our region. Overall survival of pts with low and even intermediate Sokal score is very impressive, meanwhile pts with high Sokal score are still at considerable risk of IM failure. Increasing number of pts with early start of IM and timely switch to new TKIs yield Results. overall survival during last years is notably increasing.

Table 1. The quantity of alive pts and CML prevalence in Saint-Petersburg and Leningrad region during 2005-2011 years.

Parameter	At the end of year						
	2005	2006	2007	2008	2009	2010	2011
Quantity of pts(n=)	187	207	247	255	292	310	347
CML prevalence	2,85	3,15	3,76	3,89	4,45	4,72	5,29

[5]Leningrad Regional Hospital, St-Petersburg, Russian Federation, Russian Federation

Background. In tyrosine-kinase inhibitors era chronic myeloid leukemia (CML) is potentially curable disease. Due to close monitoring of the treatment effectiveness clinicians can make appropriate decisions in time. Nowadays molecular monitoring became available in many countries and due to international standardization of RQ-PCR methods in different laboratories results can be compared and interpreted according to international recommendations. **Aims.** To evaluate the achievement and stability of major molecular response (MMR) in CML chronic phase (CP) patients with complete cytogenetic response (CCyR) while Imatinib therapy. **Materials and Methods.** In this study, 153 pts with CML CP with the different date of diagnosis, older than 18 years, treated with imatinib, CCyR and at least 1 molecular analysis by international scale (IS) were included. During 2011 325 samples were analyzed. The median age of patients at the moment of diagnosis was 49. 85 yrs (18. 6-81. 9). Male/female ratio was 72/81. The qPCR testing was performed in standardized by IS in 2011 local laboratories (Federal Almazov center, Russian Research Institute of Hematology and Transfusiology). **Results.** The achievement of MMR in this group was 78% (119/153). The rate of MMR increased in time (Figure 1).

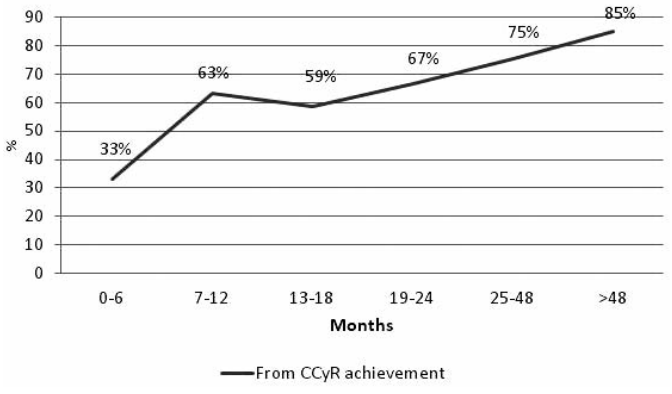

Figure 1. Dynamic of MMR rate according to the time from CCyR achievement.

During the evaluation we didn't reveal any significant factors, influencing on achievement of MMR (time to CCyR, MCyR, time from the diagnosis to imatinib start, Sokal score). The loss of MMR was 7,8% (8/103). In 3 cases MMR was reobtained without any treatment changes. No one patient with MMR subsequently lost CCyR, whereas 1 patient without MMR did. No one patient progressed to accelerated phase and blast crisis or dead during observational time. **Conclusions.** The probability of MMR achievement increases in time. Achievement of molecular response as well as CCyR gives high probability of progression-free and overall survival. Molecular monitoring provide early detection of response loss.

1336

EFFICACY OF NILOTINIB IN EARLY CHRONIC PHASE CML PATIENTS WHO HAVE SUBOPTIMAL CYTOGENETIC OR MOLECULAR RESPONSE TO IMATINIB. A MULTICENTRIC RETROSPECTIVE STUDY

Backgroud. The CML-CP suboptimal responders rappresent an eterogenous group of patients because they can either obtain an optimal renponse or experiment a failure. The Clinical trials at MDACC,HammersmithHospitaland GIMEMA observed that patients with suboptimal response at 6 and 12 months have worse long term outcomes than patients with optimal responses, particularly if the suboptimal response occurs early in the treatment, suggesting an advantage for pts with early major molecular response expecially for event free survival and progression free survival. Recently, the German group showed the benefit of early major molecular response on overall survival too. So these kind of patients deserve to be switched to other treatments even if ELN does not recommend automatic change of therapy for them. **Aims**. This study was designed to explore the efficacy of the early switch to Nilotinib in patients with suboptimal responses to imatinib (IM) according to ELN. **Methods.** In this multicentric retrospective study, 12 CML-CP patients with suboptimal response to IM within 24 months from diagnosys were evaluated: 4pts with a low, 3 with intermedied and 5 with high Sokal score. The best response to IM was CCyR for6 pts, PCyR for one pt and Complete Hematological Response for5 pts. As for suboptimal responses,5 pts were defined in suboptimal cytogenetic response:2 pts at 12 months and2 pts at 6 months; 6pts were 18 months suboptimal molecular responders and1 pt had a loss of CCyR at 12 months. All patients were switched to Nilotinib 400 mg twice daily. Bone marrow was done at baseline in all pts and at 3,6,12 and 18 months in cytogenetic suboptimal pts until CCyR, while the molecular analysis was performed on peripheral blood every three months as for molecular suboptimal pts. **Results.** 12 pts have been treated with Nilotinib for a median of 17,5 months (range 3-37), 9 patients for ≥ 12 months. Before switching to Nilotinib pts were treated with IM 400 mg once daily apart for 2 patients who needed an adjustment dose to 300 mg and 600 mg for toxicity and suboptimal response, respectively. Among6 ptswith suboptimal CyR, 4 obtained CCyR, 3 at 3 months and one at 6 months;2 ptshad any response at the milestones timepoints and they switched to another therapy. All pts with molecular suboptimal response obtained MMR at 3 months apart for one, who showed MMR at 12 months. Nilotinib was well tolerated in all12 pts; only one developed a moderate transaminase elevation. A brief drug intrerruption was sufficient to manage this adverse event. **Conclusions.** Nilotinib treatment results in high and relatively quick cytogenetic and molecular response rate in CML -CP- pts with suboptimal response to IM. These preliminary results demonstrate that early switching to Nilotinib couldbe raccomanded in suboptimal responders in order to improve the outcome of this kind of pts. A larger patient population and a longer period of observation could confirm these preliminary data.

1337

ASSESSMENT OF CARDIAC FUNCTION IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB AT THE NATIONAL CENTER OF HEMATOLOGY

F Alwan[1], A Alshami[1], A Alshammari[2]

[1]The National Center of Hematology, Baghdad, Iraq

[2]Alyarmouk Teaching Hospital, Baghdad, Iraq

Background. Imatinib has transformed the outlook for chronic myeloid leukaemia (CML) and gastrointestinal stromal tumour**.** Although rare, severe

CHF and left ventricular dysfunction have been reported during imatinib treatment, especially in patients with risk factors or comorbidities. The mechanism underlying imatinib induced cardiac failure is currently unclear. In an in vitro study, physiological concentrations of imatinib significantly and adversely affected mitochondrial membrane potential, apoptosis, cell viability, and cellular ultrastructure. **Aims.** To evaluate the effect of imatinib therapy on the cardiac function in patients with CML. **Methods.** This is a cohort prospective study conducted at the National Hematology center of Almustansiriya university between May 2008 and December 2009, fifty sequential patients with CML included in this study . All patients received Imatinib (Gleevec®;Novartis Pharmaceuticals Corporation, New Jersey, USA) 400 mg/day. All patients gave informed consent. The criterion for entry into the study was treatment for CML with imatinib at any dose for at least 12 months. ECG and Echocardiography were used to evaluate the cardiac function. **Results.** Of the 50 patients evaluated, 24 (41%) were men, and 26 (59%) were women. Their ages ranged from 18 to 74 years, with a median age of 36. 8 years. The mean duration of imatinib treatment prior to enrolment was 3. 4±1. 8 years. there were no differences in ejection fraction before and after imatinib therapy P value >0. 5. **Conclusions.** the study confirm that imatinib has no negative effect on cardiac function in CML patients.

Table 1. Shows the relationship of Ejection Fraction (EF) with patients subgroup according to gender, age and duration of imatinib treatment.

factors	subgroup	No.of patients	Mean EF ±SD at start	Mean EF ±SD after 1 yr	P value
Age(yrs)	15-25	8	57.13±6.221	56.00±6.908	
	26-35	18	60.28±4.824	59.78±4.918	
	36-45	11	60.18±8.589	57.64±6.439	NS

APPLICATION OF THE NEW MOLECULAR PROGNOSTIC RISK SCORE FOR MONITORING CML-CP PATIENTS IN ONE SINGLE INSTITUTION

M Andrade Campos[1], A Montes Limon[1], G Caballero[1], A Rubio-Martinez[1], P Giraldo[2]
[1]Miguel Servet University Hospital, Zaragoza, Spain
[2]Centro de Investigación Biomedica en Red Enfermedades Raras (CIBERER), Zaragoza, Spain

Background. The introduction of tirosin kinase inhibitors (TKIs) has proven to be a major advance in the therapeutic of Chronic Myeloid Leukemia in chronic phase (CML-CP). Development of molecular based assessment like R-PCR and RQ-PCR permitted a better diagnosis and control of therapy and defining a new disease level, molecular disease. Until now no prognostic factors in early-stage disease has been validated to predict poor response to TKIs; in January 2012 *Marin et al*. (JCO 2011 38. 6565) published a new prognostic score: molecular score (MS) based on molecular assessment (MA) during the first year of TKIs therapy. **Aims.** To describe demographic and clinic characteristics of CML patients who received TKIs as first-line therapy in our institution and applied the MS based in assessment of BCR-ABL1 transcript levels at 3, 6 or 12 months as *Marin et al* described. **Patients and Methods.** A review of clinical histories of patients treated with TKI as first-line therapy since December 1999 to February 2012 was performed. Data on clinical characteristics, date of first TKIs therapy, MA and outcomes were obtained. Molecular assays were made using RQ-PCR technology; results were expressed as percent ratios relative to a gen internal control. European Leukemianet criteria for response were applied. **Results.** A total of 37 adult patients have been diagnosed of CML-CP and received TKIs as first-line therapy in our department. Mean age 52. 4 years (28-72), M/F ratio 23/14. According to Sokal risk score: low: 20 (54. 05%), medium: 10 (27. 02%), high: 4 (10. 81%). For Hasford risk score: low: 27 (72. 97%), medium: 3 (8. 10), high: 4 (10. 81%), missing data occured in 3 patients. First-line therapy: 2 patients received nilotinib and 35 Imatinib. MA of BCR-ABL1transcripts level at 3 and/or 6 and/or 12 months were made in 33 (89. 2%) patients. According to *Marin et al.* molecular score: 4 patients (12. 12%) had poor molecular prognosis (≥ 9. 5% transcript levels at 3 months, and/or ≥ 1. 67% at 6 months, and/or ≥ 0. 53% at 12 months), one achieved good molecular response at 12 months; 29 patients (87. 88%) had good molecular prognosis. Actual status revealed: 5 patients (15. 15%) had a Suboptimal MR (soMR) (only one was classified as poor molecular responder); 28 (84. 65%) had MMR and 8 patients (24. 25%) achieved a CMR. CCyR was achieved in all cases before 12 months. One patient was classified into poor risk group at 3 months and lost response to Imatinib by T315I mutation 3 years later. One patient discontinues Imatinib therapy to start on fertility program. ITK change: 6 patients switched to dasatinib because of intolerance and 1 for soMR; 2 patient switched to nilotinib, one because of intolerance and one for soMR The rest of patients (27) continue with Imatinib, 96. 29% in MMR, 22. 22% in CMR and 3. 70% (1) in soMR. No progression neither deaths were registered. **Conclusions.** Despite our small experience, application of molecular response risk score could be useful for predicting response CML-CP patients; more studies are required to determine the correct management approach specially in the poor risk patient group.

1339

CLONAL EVOLUTION IN PHILADELPHIA CHROMOSOME NEGATIVE CLONE IN CHRONIC MYELOGENOUS LEUKEMIA PATIENTS TREATED WITH IMATINIB, CYTOGENETIC FINDING AND CLINICAL COURSE

A Ungkanont, S Jootar
Mahidol University, Bangkok, Thailand

Background. Imatinib has set a new standard of treatment outcome in patients with chronic myeloid leukemia (CML). However, not all of the patients get long term disease free status. Besides transformation led by additional mutation and clonal evolution (CE) in Philadelphia chromosome (Ph) positive leukemic clone, CE in Ph negative clone have been frequently observed. **Methods.** Data were collected from patients diagnosed with CML who had Ph chromosome as sole abnormality during 2001 through 2006. All of them were treated with 400 mg/day of imatinib. Cytogenetic study were performed intervally according to ELN guideline. Clinical finding, marrow finding and cytogenetic results were analyzed by descriptive basis. **Results.** CE in Ph negative clone has been found in 13 of 104 patients treated with imatinib (12. 5%). The median onset of CE was 12 months after initiation of imatinib (range 9 to 57 months). Additional chromsome 8 is the most frequent cytogenetic abnormality, followed by deletion of chromosome 7. Marrow examination from all of the patients did not display dysplastic feature. The finding of CE in Ph negative clone did not lead to treatment modification in our patients and no disease transformation was observed. **Conclusions.** CE in Ph negative clone in imatinib treated patients is not an infrequent finding. The significance of this type of CE is yet to be determined.

1340

NILOTINIB IN IMATINIB RESISTANT OR INTOLERANT PATIENTS WITH CHRONIC MYELOID LEUKEMIA - SINGLE CENTRE EXPERIENCE

Z Sninska, M Martisova, K Slezakova, A Hatalova, E Demeckova, M Mistrik
University Hospital Bratislava, Bratislava, Slovakia

Backround. In the last decade we can see great success of targeted molecular therapy of chronic myeloid leukemia. The greatest benefit is basically in better tolerance of signal transduction inhibitors in comparison with conventional chemotherapy. The identification of imatinib caused a revolution in the CML treatment. However a group of patients that does not respond to imatinib or loose initially achieved response still alarms. The second generation of targeted molecular therapy represented by nilotinib prooved its position in treatment of patients with imatinib failure or intolerance as well as in the front line therapy in newly diagnosed chronic phase CML patients. **Aims.** Analyse second line nilotinib treatment in imatinib resistant or intolerant patients. **Methods.** In the period ranging from January 2007 to December 2011 there were twenty-one patients (13 men) treated with second line nilotinib, due to imatinib resistance (18 patients) or intolerance (3 patients) at the Clinic of Hematology and Blood Transfusion in Bratislava, Slovakia. The age of patients was between 23-77 years (median 49). According to Socal risk score, ten of them were classified in low, five in median and six in high risk score. Twenty patients were in chronic phase, one was in accelerated phase. All patients were pre-treated by imatinib from 1 to 74 months (median 27). Eighteen imatinib resistant patients were treated from 9 to 74 months (median 32,5). Four of them achieved transient CMR, 5 CCR and 9 PCgR. Three imatinib intolerant patients were treated from 1 to 17 months (median 3). **Results.** Patients were treated with nilo-

tinib 400mg bid 3-59 (median 22) months. One patient, who started treatment in accelerated phase, didn't achieve hematologic response and died after 6 months in blastic phase. One patient progressed to blastic phase after 24 months of nilotinib treatment, with transient CCR. Both patients were in Sokal low risk at the time of diagnosis. Regarding cytogenetic response, after 3 months, five patients from twentyone (23,8%) achieved MMR or CMR, six (28,6%) CCR and ten (47,6%) partial or none cytogenetic response. After 12 months, from 12 patients proceeding nilotinib treatment, 4 (33,3%) achieved CMR, 3 (25%) CCR and 5 (41,7%) PCgR. After 48 months, 1 patient is in CMR, 2 in CCR and 1 in PCgR. From 21 patients, 14 (66,7%) continue on nilotinib, 11-59 (median 33,5) months. 2 patients died and 5 changed to dasatinib because of resistance or intolerance to nilotinib. Adverse events occured by 12 patients (57,1%): 3 had hematologic, 4 nonhematologic and 5 combined toxicity. Hematologic toxicity was present by anemia (7 patients), thrombocytopenia (6 patients) and leukopenia (2 pts). Due to anemia complications 5 patients received erythropoetin, in 2 of them also hemotherapy was needed, with transient dose reduction. Nonhematologic toxicity was present by hepatotoxicity (8 patients), skin rash (5 patients), dyspnoe, acute pancreatitis and GIT intolerance. **Summary.** The second line treatment with nilotinib is an optimal option for patients resistant or intolerant to imatinib. However the regular monitoring is necessary because of possible adeverse effects. Our experience is similar to other centers.

1341

LONG TERM MOLECULAR RESPONSE IN IMATINIB TREATED CHRONIC MYELOID LEUKEMIA PATIENTS

V Jovanovic, D Bogdanovic, A Djordjevic, S Dencic-Fekete, D Gotic
Clinical Center of Serbia, Belgrade, Serbia

Background. CML is characterized by t(9;22)(q34;q11) (Ph chromosome) and by expression of BCR-ABL fusion protein. Tyrosine kinase inhibition by imatinib opened a new era in the treatment of CML. In large number of CML patients complete cytogenetic response (CCgR) can be achieved with imatinib. European LeukemiaNet (ELN) recommendations made efforts in unifying follow up of patients throughout the Europe and recommended several scenarios concerning cytogenetic and molecular evaluation by real time reverse transcriptase PCR (RQ-PCR) as method of choice. In several countries, like Serbia, regular PCR follow up is not always available, and current national recommendations based on ELN proposals include regular cytogenetic and occasional molecular follow up. **Aims.** After establishment of molecular monitoring in Clinic of Hematology, Clinical Center of Serbia, based on "baseline"principle (EUTOS IS evaluation is pending), we evaluated depth of molecular response in cohort of CML patients on long lasting imatinib therapy and long lasting CCgR. **Patients and Methods.** Between July 2011 and February 2012, 40 CML patients on imatinib therapy in CCgR in our center were analyzed by RQ-PCR. Cytogenetic analysis was performed on unstimulated bone marrow cells applying HG-banding technique. Molecular response was assessed by RQ-PCR according to EAC protocol with primers and probes for TaqMan technology on ABI 7500 Real Time PCR System in peripheral blood samples. For absolute quantification were used standards for fusion BCR-ABL gene and control ABL gene (Ipsogene) and ratio BCR-ABL/ABL was compared with baseline (BCR-ABL/ABL ratio in 30 de novo CML patients). **Results.** Our group comprise of 40 CML patients in chronic phase, age 49. 5 yrs (20-74y), treated by imatinib for at least 3 years (36-363 months). 38 patients are on 400 mg/day and 2 patients are on 800 mg/day imatinib. All of them had normal karyotype (20 normal metaphases) on last cytogenetic evaluation. RQ-PCR analysis revealed complete molecular response (MR4. 0) in 30 patients (75%), major molecular response (MR3. 0) in 6 patients (15%). In this group, two patients were escalated to 800mg/d imatinib in second year of treatment because of no optimal cytogenetic response according to current proposals (ELN and national). Due to escalation, they achieved MR4. 0. In 4 patients (10%) optimal molecular response was not present (>0. 1% BCR-ABL/ABL) and during further follow up, we confirmed loss of previous complete cytogenetic response in 3 of them. Unsatisfactory molecular response by RQ-PCR suggested earlier evaluation and change in treatment (dose escalation or nilotinib). **Conclusions.** In our cohort of long term treated patients, molecular monitoring revealed good molecular response as almost 90% of patients achieved at least MR3. 0 after >3 years of treatment. Introduction of molecular monitoring will help us in further changes in treatment policy and further modification of national guidelines adopting international standards for molcular evaluation. As we have shown, regular molecular monitoring of CML patients would be useful for early prediction of undesirable events like loss of response.

1342

TYROSINE KINASE INHIBITORS IN CHRONIC MYELOID LEUKEMIA. HIPOGAMMAGLOBULINEMIA, ANOMALOUS PLASMATIC CELLS AND CLONALITY

J Groiss Buiza[1], MT Vazquez Godoy[1], E Delgado Casado[1], A Corbacho Hernandez[1], I Rangel Bravo[2], J Melero Ruiz[1], R Elduayen Izaguerri[1], R Fernández de Soria[2], R Bajo Gómez[1]
[1]Hospital Infanta Cristina, Badajoz, Spain
[2]Hospital de Mérida, Mérida, Spain

Background. The tyrosine kinase inhibitors (ITK): imatinib, dasatinib and nilotinib, when blocking specific tirosín-kinasas of the immune answer, interfere the T (inhibition TCR) and B (inhibition CD19) immune response. Certain publications show some coincidence between the imatinib administration and the development of multiple myeloma (MM). **Aims.** To determine if the use of ITK in patient of CML alters plasmatic cells and immunoglobulins. **Methods.** MLC patients in treatment with ITK in december 2010. Eighteen patients (mean age: 57 years (25-82)) in treatment (12 Imatinib, 3 Dasatinib, 3 Nilotinib) for a mean of 62 months (4-114). We quantified immunoglobulins (Igs) and the clonality is valued by Immunofijación (IF) and serum free light chains (sFLC) by Freelite-Turbidimetry. Immunofenotype (flow cytometry) of plasmatic cells in bone marrow (MO), looking of: CD38, CD138, CD19, CD56 and CD117 was made. **Results.** Mean level of Igs: 1191,94 mg/dl (634-3066). Hypogammaglobulinemia: 11 patients; hipergammaglobulinemia: 1 patient; normal level: 6 patients. Of the 18 cases, 15 MO were useful for valuation: 13 show plasmatic cells with aberrant fenotipo (CPa): CD19 (-) and CD56(+). only 2 of these 13 cases are CD56 (-). All they were CD117 (-). Percentage average of CPa in MO regarding total celularidad: 0,15% (0,002-0,47). percentage average of CPa regarding normal CP: 48% (3-100). There is not difference among the rate of Igs for age, time of treatment or immunofenotype. Less immunoglobulins level is observed in patients with imatinib regarding dasatinib and nilotinib (means of Igs: 983 mg/dl, 1382 mg/dl and 1835 mg/dl, respectively, Kruskal Wallis, tendency: p = 0,06). Two of the patients with hypogammaglobulinemia (women, 64 and 69 years) showed clonality IgG kappa; 0,11% and 0,34% of CPa on total medullary, and 70% and 50% have more than enough plasmatic normal, respectively. **Conclusions.** 1º. We suggest that the treatment with ITK is related with hypogammaglobulinemia, with the presence of aberrant populations of plasmatic cells in MO and, in smaller measure, with the existence of monoclonality. 2º. Although the presence of monoclonal gammopathy (general population: 0,7-1,7%; up to 3% in > 70 years; in our study: 11%) it doesn't condition the immediate progression to MM, the patients treaties with ITK should be watched over by means of sFLC, IF and screening of CPa

1343

EVALUATION OF THE SAFETY OF IMATINIB MESYLATE IN PATIENTS WITH CHRONIC MEYLOID LEUKEMIA

F Alwan[1], F Matti[2], A Alkassir[3], J Hussein[3]
[1]The National Center of Hematology, Baghdad, Iraq
[2]Baghdad Teaching Hospital, Baghdad, Iraq
[3]Alyarmouk Teaching Hospital, Baghdad, Iraq

Background. Imatinib Mesylate, a Tyrosine Kinase inhibitor, is presently the drug of choice for Chronic myeloid leukemia (CML). During therapy, a few patients develop myelosuppression and present with cytopenias. Adverse side-effects of the drug include edema, nausea,vomiting, diarrhea, cramps and cutaneous reactions. Adverse hematologic side-effects include anemia, neutropenia,and thrombocytopenia. **Aims.** The aim of this study was to evaluate the safety of imatinib therapy in patients with CML. **Methods.** Between December 2007 and October 2010. 200 patients with Ph+ CML-CP were included in the study. Eligibility criteria included-age 15 years and older, Eastern Cooperative Oncology Group-(ECOG) performance status of 0 to 2, adequate hepatic and renal functions, no prior imatinib therapy, non pregnant patients. CML-CP was defined as less than 10% blasts and less than 20% basophils in the peripheral blood and bone marrow and a platelet count of more than 100 x 10^9/L, but < 1000x10^9/L . Therapy was initiated with imatinib 400 mg orally daily and patients were monitored carefully for any adverse effects. Complete hemogram and liver function tests were done once in two weeks during the first month and there after monthly. Toxicities encountered were graded as per the National Cancer Institute common toxicity criteria version 2. Both hematologic and non-hematologic toxicities were managed with short interruptions of treatment and supportive measures, but the daily dose of imatinib was not reduced below 300 mg/ day. **Results.** Out of 200 cases included of CML in the study, all the cases were in chronic phase, male: female ratio was 0. 7:1 with median age 39. 06±13. 21(ranged from 15-81). The study showed that the commonest hematological side effects were grade 2 anemia 12. 5%, followed by leucopenia 8%, and thrombocytopenia 4%. While the most com-

mon non-hematological adverse effects were superficial edema and weight gain 51. 5%, followed by musculoskeletal pain 35. 5%, then gastro-intestinal(vomitting,diarrhea)19%. Fluid retention was the commonest side effect, which responded to low dose diuretics. Skin reactions were managed with corticosteroids and interruption of treatment, except in one case where the drug had to be discontinued permanently. Musculoskeletal pain responded to analgesics. The drug was safe and well tolerated. There were no deaths due to toxicity. **Concluions.** Imatinib mesylate is a well tolerated drug, and all undesirable effects could be ameliorated easily. The most common hematological side effect was anemia. while the non hematological side effects was fluid retention

1344

DELETION OF IKAROS GENE IS CONSIDERED AS AN ACQUIRED LESION IN THE BLAST CRISIS PHASE OF CHILDHOOD CHRONIC MYELOID LEUKEMIA: A CASE REPORT

M Moschovi[1], M Adamaki[1], A Athanasiadou[1], Y Ktena[1], V Papasavva[2], K Dioikitopoulou[2], A Divane[2]

[1]Hematology-Oncology Unit,First Department of Pediatrics,University of Athens, Athens, Greece

[2]"Life Code", Genetic Centre for Research and Diagnosis, Athens, Greece

Background. Structural rearrangements in the gene IKZF1 (Ikaros) are considered as a strong adverse risk factor in leukemia, whether alone or in conjunction with other adverse prognostic markers. The most common prognostic factor is thePhiladelphia chromosome (Ph), representing the main characteristic of chronic myeloid leukemia (CML) and of a subset of acute lymphoblastic leukemia (ALL). **Aims.** To present the case of a pediatric patient with BCR/ABL1 positive CML who was treated with imatinib mesylate and achieved remission, but transformed to lymphoid blast crisis (BC) within 205 days following the diagnosis of CML with detected deletion of Ikaros in the phase of blastic transformation. **Methods.** A previously healthy 13-year-old girl was admitted to our unit due to arthralgia and leukocytosis (WBC 145 x 10^9/L, HB 11,2g/dL, HCT 35%, PLTs 588 x 10^9/L). Physical examination revealed hepatomegaly, splenomegaly and lymphadenopathy. The diagnosis of CML in chronic phase (CP) was based on the peripheral blood findings, on the bone marrow biopsy and on the histopathologic findings in the bone marrow biopsy. The cytogenetic analysis demonstrated 46,XX,t(9;22)(q34;q11). The presence of the translocation was confirmed by quantitative RT-PCR. The patient was treated with imatinib (400mg/m^2/day) and achieved morphologic, cytogenetic and molecular remission. **Results.** On the 205th day, the blood test revealed WBC 100 x 10^9/L, HB 13,3g/dL, HCT 39,5%, PLTs 205 x 10^9/L and that 73% of peripheral blood white blood cells were peripheral blood blasts. From the findings of the bone marrow studies, an ALL B-cell diagnosis was considered. At this time, cytogenetic findings indicated 46,XX,der(3)t(1;3)(q12;p26),t(9;22) (q34;q11). FISH analysis confirmed t(9;22)(q34;q11) and quantitative RT-PCR confirmed BCR/ABL1 gene fusion. FISH analyses testing for ETV6/RUNX1, PBX1/TCF3 fusion genes and MLL rearrangement were negative, but three copies of PBX1 were detected. MLPA analysis of the bone marrow sample at the diagnosis of ALL revealed a deletion in the Ikaros gene including exons 4-8 and a deletion in the EBF1 gene in exon 1. No copy number variation was found in the bone marrow sample from the CML diagnosis. The patient received chemotherapy according to the ALL IC-BFM 2009 treatment protocol plus imatinib at 400mg/m²/day. The patient failed to achieve complete remission and the duration of survival from the onset of blast crisis was 75 days. **Summary and Conclusions.** Genetic abnormalities of Ikaros are strongly associated with a very poor outcome and a high rate of relapse in childhood leukemia, independent of Ph status. Deletion of Ikaros was not detected in CP-CML, but was identified as an acquired lesion in the BC-CML sample. This finding suggests that alterations in Ikaros directly contribute to the pathogenesis of BCR/ABL1 ALL, in a way that remains to be determined.

1345

DASATINIB ACHIEVED A CMR AND AN IMPORTANT IMPROVEMENT IN CHRONIC GVHD IN A RELAPSED CHRONIC MYELOID LEUKEMIA PATIENT AFTER HAPLOIDENTICAL HCT

M Andrade-Campos, A Montes-Limon, A Godoy Molias, A Rubio-Martinez, P Delgado, J Garcia-Zueco

Miguel Servet University Hospital, Zaragoza, Spain

Background. Dasatinib is widely used in postrasplant CML patients, reaching and maintaining molecular response. Its role in GVHD is not clear. Dasatinib is a potent inhibitor of TK Lck, implicated in the cascade of TCR activation and acts as a potent immunomodulator inhibiting T-cell activation, inflammation, leukocyte recruitment and host or allograft tissue destruction, the three steps involved in chronic GVHD (cGVHD). It's proved that dasatinib is able to inhibit PDGF-R, c-Kit and TGF-B receptors, implicated in cGVHD. **Aims.** To report outcomes with dasatinib therapy in a Ph+ CML patient who relapsed after haploidentical hematopoietic cell transplantation (HCT) with cGVHD. **Case Report**. A 40 years old man was admitted to our department in June 2009 with leukocytosis (WBC >103 x 10^9,blasts: 73%) and left leg deep vein thrombosis. Bone marrow aspiration (BMA) and immunophenotype revealed: ALL-B EGIL II suggestive of MPN; Cariotype: 23 X,Y; t(9;22); 9q-(100%). RT-PCR BCR/ABL Major: 67. 798% transcripts. He was diagnosed as Ph+ CML in Lymphoid Blast Crisis. He had normal physical examination, and no comorbidities. The patient received induction chemotherapy with PETHEMA ALL Ph+ 2002 regimen (vincristine, daunorubicin, Imatinib, prednisone and ITT), without response in day + 14 BMA. Intensification with IdAC, mitoxantrone was started, followed by two consolidation courses and submission to haploidentical HCT program. Complete remission was achieved. In September 2009 patient underwent haploidentical related donor HCT with ABO mismatch, and in day +100 post-HCT evaluation, he was in complete hematological and molecular response, complete chimerism and without Imatinib treatment. By March 2010 the patient was admitted to the hospital because of grade 3 hepatic cGVHD, skin and ophthalmic grade 2 cGVHD was also confirmed. Cyclosporine (CYA) immunosuppressive therapy after SCT was intensified with corticosteroids and mycophenolate mofetil (MFM); moderate improvement was achieved, liver enzymes were persistently elevated without symptoms. Patient remained in CCyR, CMR and complete chimerism. Immunosuppressive therapy with CYA and MFM was maintained with slow dose reduction and cGVHD was stable. By May 2011 Molecular relapse was confirmed and patient was admitted in our department. Immunosuppressive therapy was suspended gradually and the patient started treatment with Dasatinib 70mg/ day in May 30 2011. Mutational analysis was negative. No adverse effect was registered and it has not been discontinued because of toxicity; the dose was escalated to 70mg bid. CMV reactivation occurred on several times, starting preemptive treatment with valganciclovir each time and no CMV disease developed. In November 2011 the patient had MMR (BMA: BCR/ABL 0 transcripts in onetime), CCyR, CHR and complete chimerism. Moreover the patient has achieved cGVHD improvements, especially on skin affection, almost inappreciable at this time (Figure 1), liver enzymes decreased but have not normalized (360U/L to 220 U/L), and ocular involvement improved. It's remarkable that since molecular relapse, patient has been without immunosuppressive therapy. **Conclusions.** Dasatinib was well-tolerated and conduced to MMR, while achieving an improvement in liver dysfunction, skin lesions and ocular involvement of cGVHD. The role of dasatinib in cGVHD offers a window for investigation and future target therapy.

MGUS, MLUS, ICUS... AND NOW CML-US? REPORT OF TWO CASES

G Binotto[1], F Lessi[1], A Quinto[1], R Bertorelle[2], L Bonaldi[2], S Imbergamo[1], A Barzan[1], C Gurrieri[1], G Semenzato[1]
[1]University of Padua School of Medicine, Padova, Italy
[2]U. O. C. Immunologia e Diagnostica Molecolare Oncologica, Ist. Oncologico Veneto, Padova, Italy

Background. Detection of the Philadelphia (Ph) chromosome, a derivative of the reciprocal translocation t(9;22)(q34;q11. 2) is a recognized clinical hallmark for chronic myeloid leukemia (CML) diagnosis. CML is often suspected on the basis of pherypheral blood leukocytosis with "left shift", eosinophilia and basophilia. At the time of diagnosis, hematopoiesis results mostly from Ph+ clone, which is quickly debulked by target therapy with tyrosin kinase inhibitors (TKI). **Aims.** Here we report two interesting cases of patients incidentally diagnosed with CML, when cytogenetic analysis was performed without any clinical or laboratory data supporting an underlying Ph+ proliferative disorder. **Results.** A 65 years old woman was diagnosed with stage IVA Diffuse large B-cell lymphoma, from a biopsy of retroperitoneal mass in April 2011. Bone marrow staging was consistent with extended lymphoma infiltration (almost 70% of cellularity). Unexpectedly, bone marrow cytogenetic analysis showed 22% of 25 metaphases carrying the t(9;22) as sole alteration; RT-PCR identified b3a2 variant of BCR-ABL transcript. CBC count was normal, no splenomegaly was present. The patient underwent six courses of R-CHOP with achievement of complete remission confirmed by CT and PET scan. Bone marrow evaluation after the completion of chemotherapy did not show evidence of lymphoma or leukemia; cytogenetic was not evaluable but FISH analysis detected BCR-ABL fusion signal in 1,6% of 300 interphase nuclei; peripheral blood RT-PCR showed 1. 5% IS of BCR-ABL transcript . Normal CBC count, absence of splenomegaly and low disease burden prompted for careful molecular monitoring and TKI therapy was not commenced. The patient clinical status is currently good and there is no evidence of lymphoma recurrence. She is monitored every three months with RT-PCR analysis and the last evaluation of BCR-ABL transcript showed 5%IS. The second report concerns a 51-year-old man with type one diabetes mellitus who underwent kidney/pancreas transplantation in June 2005 and was subsequently treated with immunosuppressive therapy (prednisone, cyclosporine A, mycophenolate and tacrolimus). Shortly after transplant, he developed stable mild leukocytosis with neutrophilia, which was not furthly investigated as it was ascribed to steroid therapy. However, an unscheduled quantitative RT-PCR analysis performed in October 2011 revealed the presence of 1,01% IS BCR-ABL transcripts (both b3a2 and b2a2 variants). Bone marrow evaluation showed normal cellularity but cytogenetic s confirmed peripheral blood findings disclosing 12% of metaphases with t(9;22) translocation and 11%IS BCR-ABL transcript. As concomitant immunosuppression was considered a risk factor for disease progression, imatinib therapy was started but renal function worsened one month later. Creatinine clearance improved after TKI discontinuation. At present the patient is strictly monitored for TKIs resumption. **Summary.** These cases describe a peculiar presentation of CML (preclinical stage?) whose evolution is not clearly predictable and raise the issue of best treatment approach between watch and wait policy and TKI "pre-emptive" therapy. Molecular monitoring might help herapeutic decision making.

MICROARRAY COMPARATIVE GENOMIC HYBRIDIZATION REVEALS ACCURATE CYTOGENETIC DIAGNOSIS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

C Mellink[1], M Berens[1], S Snijder[1], M van Oers[2], A Kater[2], L Beks[1], A Polstra[1]
[1]Department of Clinical Genetics, Amsterdam, Netherlands
[2]) Department of Hematology, Academic Medical Center Amsterdam, The Netherlands, Amsterdam, Netherlands

Background. Chronic Lymphocytic Leukemia (CLL) is characterized by the presence of malignant mature monoclonal B-cells (co-expressing CD5, CD19, and CD23) in peripheral blood, bone marrow and secondary lymphoid organs. CLL exhibits a highly variable clinical course with life expectancies ranging from a few years to many decades. Cytogenetic evaluation is of major importance in CLL and has revealed recurrent genomic alterations which have proven to be highly significant prognostic markers for this disease. In particular, patients with deletions of the short arm of chromosome 17 or the long arm of chromosome 11 show advanced disease, significantly shorter treatment free intervals, and shorter overall survival times. **Aims, Materials and Methods.** Current cytogenetic analysis in many diagnostic laboratories for patients with CLL involves routine FISH assays using targeted probes. DNA microarray technology (aCGH) supplies an alternative robust tool for large scale analysis of genomic imbalances in B-CLL. The aim of this study was to compare the aCGH results to the data obtained with FISH. For this purpose, peripheral blood (n=23) or bone marrow (n=3) from 26 previously untreated CLL patients were investigated on the Agilent 180k array (Agilent Technologies, AMADID 023363). Formerly, these cases were screened with a FISH probe panel for recurrent aberrations involving chromosomes 11q, 13q, 17p, and whole chromosome 12. Interphase FISH was performed according to standard procedures with commercially available probes (Abbott Molecular). **Results.** Array CGH screening identified in all but one patient the clonal imbalances recognised by FISH. Additional novel information was provided for 75% of the cases. This included gain of 2p, loss of 6q, gain of 8q, loss of 22q, loss of 14q, gain of 22. Analytical sensitivity for the detection of aberrant cells with aCGH was 10%. **Conclusions.** Our data demonstrate that aCGH and FISH results are highly comparable and support the implementation of aCGH into a clinical setting. Furthermore, the identification of additional (sub-microscopic) genomic imbalances will most likely lead to the identification of new prognostic markers important in the risk-stratification of CLL patients. An overview of the array CGH results will be presented.

[2]UCL, Cancer Institute, London, United Kingdom

Background. Specific genome aberrations are recognised prognostic factors in haematological malignancies. FISH based genome risk stratification has been used in clinical decision-making for over a decade in particular for chronic progressive disorders such as chronic lymphocytic leukemia (CLL) and myeloid disorders (MDS and AML). Molecular karyotyping (array CGH) is gaining acceptance as an alternative that provides comprehensive whole genome scanning at high resolution. AIMTo assess the feasibility of molecular karyotyping for the routine diagnosis of haematological malignancies by comparing G banding, FISH and array CGH (aCGH). **Materials and Methods.** A total of 70 CLL and 50 MDS/AML samples were investigated. All had karyotyping and FISH tests done as part of the routine investigations. aCGH was performed using 8x60 oligonucleotide arrays (Agilent) with DNA from fresh p. blood/bone marrow samples and/or from fixed cells following manufacturer's protocols and bio-informatics routines (Z score and ADM1/2 algorithms). **Results.**The aCGH and G banding/FISH data were consistent for all presentation CLL and MDS/AML samples. Inconsistencies arose in 4 follow-up samples due to an aberrant cell population of less than 9%. Array data provide additional important novel information relevant to treatment and survival:In 40% of the 24 samples with 13q14 deletions detected by FISH, aCGH stratified the loss as class II/type 2 (>2Mb and the including RB1 gene), associated with high risk for disease progression. The total genome aberrations (TGA) at diagnosis varied between 3 and 17 with higher levels found in samples with p53 loss and/or high risk 13q14 deletions. Persistent disease was consistently associated with increased TGA count, while low TGA level coincided with clinical remission. In 21 out of 24 AML and 10 out of 16 MDS samples aCGH revealed novel, mostly multiple and recurrent hidden aberrations alone or in combination with other changes, indicating increased genome instability and hence offering a powerful novel clinical prognosticator. aCGH confirmed the preferential concomitant involvement of chromosomes 5 and 7 in MDS/AML as established by G banding and FISH but highlighted the role of cryptic losses as indicator for advanced disease irrespective of karyotypic features. Recurrent hidden loss of several gene regions, namely BUB1, TET2, TOP1, SYYK, TYK, NOTCH, ETV6 and RUNX1 were identified across all MDS/AML samples. **Conclusions.** aCGH is cost neutral when compared to currently used tests, so a strategy of array interrogation at presentation, followed by therapy response monitoring using FISH/molecular assays on a selected marker is a plausible alternative to routine practice. In cases where FISH has provided evidence for persistent disease, array screening on target cell isolates can assess genomic damage to assist risk stratification and treatment decisions. This preliminary study demonstrates that aCGH screening in routine settings offers a new powerful prognosticator for haematological malignancies

Background. qPCR analysis of BCR-ABL is a tool for decision making in CML patients treated by tyrosine kinase inhibitors (TKI). According to European guidelines all qPCR studies in reference laboratories have to be internationally standardized. There are more than 100 clinical centers supervising more than 5000 CML patients in Russia, but only 15 Russian laboratories can provide accurate qPCR BCR-ABL analysis. So majority of centers need to collect samples in tubes with RNA-stabilizer and to send tubes to different laboratories for a long distance, and usually there are more than 24 hours from samples collection to analysis. Thus routine European protocols are not applicable to the majority of Russian laboratories. International standardization of BCR-ABL analysis taking into account specific Russian conditions is the vital problem. **Aims.** To create standardization protocol and perform standardization procedure in Russia in order to implement European CML monitoring guidelines and provide molecular monitoring according to International Scale (IS) for all Russian CML patients. **Methods.** Fifteen Russian molecular laboratories participated in standardization process. Informed consent was obtained when we used patients' blood samples. Flowchart of our project is shown on the scheme. Standardization process consisted of two main steps: local standardization (relating to Russian Reference laboratory) and international standardization (relating to ELN). Two protocols were standardized: RNA-unpreserved approach and method based on RNA stabilization.

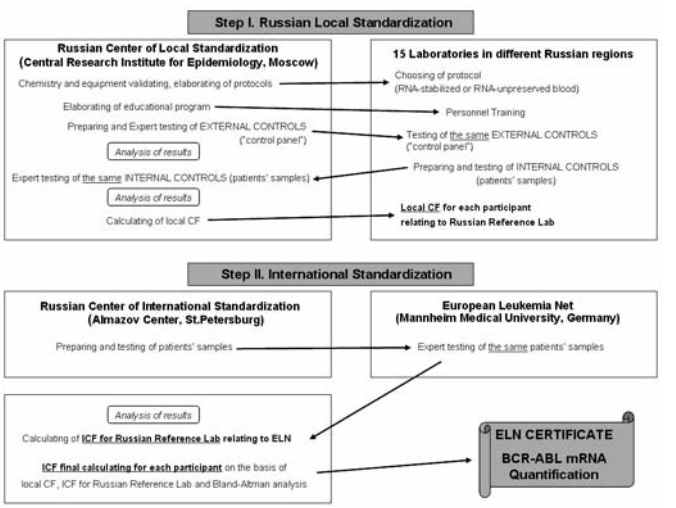

Figure 1. Flowchart of international standardization of quantitative studies of BCR-ABL in CML patients in Russia.

Results. 1. For the first time in the world quality assurance procedures for BCR-ABL molecular studies in the long-distance country are elaborated and implemented. 2. The reagents for both local BCR-ABL studies and for samples sent to distant laboratories are elaborated and certified. Reagents demonstrated high sensitivity (the majority of samples demonstrated 4. 0 log or 4. 5 log sensitivity). 3. Two universal protocols for processing of RNA-unpreserved and RNA-stabilized blood samples were approved. 4. Laboratory personnel were trained to work with reagents according protocols. 5. Twelve laboratories finalized standardization successfully and individual CFs were obtained. Individual iternational CFs (ICFs) ranged from 0. 48 to 1. 22 for the RNA-unpreserved protocol and from 0. 77 to 2. 05 for the RNA-stabilized samples. Three laboratories are still in process.

IDENTIFICATION OF PROGNOSTIC RELEVANT GENETIC ABNORMALITIES IN MULTIPLE MYELOMA USING MICROARRAY-BASED GENOMIC PROFILING: EVALUATION OF DETECTION YIELD, SENSITIVITY AND COST-EFFICIENCY

M Stevens-Kroef[1], A Simons[2], S Croockewit[2], L Derksen[2], J Hooijer[2], N ElIdrissi-Zaynoun[2], A Siepman[2], D Olde Weghuis[2], A Geurts van Kessel[2]

[1]Radboud University Medical Centre, Nijmegen, Netherlands

[2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands

Background. Multiple myeloma (MM) is a heterogeneous disease with a highly variable clinical course. Genetic abnormalities such as t(4;14)(p16;q32), t(11;14)(q13;q32), t(14;16)(q32;q23), 17p loss, 13q loss, 1q gain, 1p loss and hyperdiploidy have been shown to provide prognostic information (Fonseca et al. Leukemia, 2009). The most common molecular-cytogenetic technique currently used to detect these genetic abnormalities is interphase fluorescence in situ hybridization (FISH) on purified plasma cells. **Aims.** Although interphase FISH is a well established approach, it is relatively laborious. We, therefore, we aimed to evaluate the sensitivity, cost-efficiency and detection yield of numerical genetic abnormalities using microarray-based genomic profiling. **Methods.** CD138+ cells (plasma cells) were enriched by an immuno-magnetic cell selection procedure (Stem Cell Technologies) from bone marrow samples of 13 MM patients. Microarray-based genomic profiling and data interpretation were performed as recently reported (Simons et al. Genes Chrom & Cancer, 2011). Interphase FISH on enriched plasma cells was performed using commercially available probes according to the manufacturer's specifications (Abbott Molecular for 13q-, 17p- and hyperdiploidy, and Kreatech Diagnostics for 1q gain and 1p loss). **Results.** All copy number alterations (CNAs) present in at least 20% of the cells, as determined by FISH, were also detected by microarray-based genomic profiling. In only one patient a minor sub-clone with loss of 17p, as detected by FISH in 13% of tetraploid cells was not detected by microarray analysis. The microarray-based genomic profiles of all 13 samples disclosed highly rearranged genomes, harboring 3 to 22 distinct CNAs or regions exhibiting acquired uniparental disomy (UPD), both recurrent as well as novel in nature. When microarray data analysis was focused on the loci also covered by the FISH panel (1p, 1q, 13q, 17p and hyperdiploidy), it appeared that microarray-based genomic profiling was cost effective. The use of microarray-based approaches may also have implications for the prognostification of MM by avoiding misinterpretation of tetraploid cells as exhibiting hyperdiploidy. The additional identification of local genomic instability (chromothripsis) that we observed in one patient, may serve as a novel high-risk factor. Summary and **Conclusions.** Our results indicate that microarray-based genomic profiling exhibits a high sensitivity and specificity in identifying MM-associated numerical abnormalities. Although balanced translocations cannot be identified this way, the detection CNAs is cost-effective. In addition, we show that microarray-based genomic profiling allows the detection of novel focal CNAs and acquired UPDs in patients. The prognostic significance of these novel CNAs and acquired UPDs have to be evaluated in prospective clinical trials.

[3]Aghia Sophia Children's Hospital, Athens, Greece

[4]Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece

[5]Hematology-Lymphoma Department, Evangelismos Hospital, Athens, Greece

Background. Diagnostic cytogenetics is recognized as one of the most significant prognostic factors in childhood and adolescent acute myeloid leukemia

(AML). **Aims.** We reviewed the clinical and cytogenetic characteristics of 140 AML patients ≤21 years of age at the time of diagnosis in order to investigate the cytogenetic features and their correlations with clinical characteristics and outcome in children and adolescents with AML in Greece. **Methods.** Cytogenetic analyses were performed on diagnostic unstimulated bone marrow cells, derived from children and adolescents with AML, between 1998 and 2010. Chromosome studies were carried out on trypsin G-banded chromosome preparations and karyotypes were described according to the ISCN 2009. **Results.** The sex ratio showed a male predominance (M/F:1. 33), especially in secondary AML (s-AML) patients (M/F:2. 4). According to FAB classification, M0 was found in 5. 88% of patients, M1 in 8. 4%, M2 in 30. 25%, M3 in 17. 65%, M4 in 14. 29%, M5 in 12. 61%, M6 in 5. 88% and M7 in 5. 04 %. Cytogenetic results were available in 124 patients (88. 6%). A normal karyotype was found in 23. 4% and an abnormal in 76. 6% of them. Chromosome analyses showed t(15;17) in 15. 32% of the available karyotypes, t(8;21) in 13. 7%, +8 in 10. 5%, 11q23 rearrangements and -7 in 8. 1% each, -X in 6. 5%, abn7p in 4. 8%, del(7q), del(9q) and abn12p in 4% each, del(6q), abn3q, inv(16) and -Y in 3. 2% each, t(9;11) and acquired +21 in 2. 4% each, t(11;19)(q23;p13. 1), t(16;21)(p11;q22), del(20q) and del(5q)/-5 in 1,6% each. Other abnormalities were identified in small numbers. Patients with t(15;17) showed the most favorable outcome with a 4-year OS of 93. 33%, followed by t(8;21) (72. 22%) while patients with 11q23 rearrangements and -7 showed the worst outcome with a 4-year OS of 38. 9% and 37. 5% respectively. Striking differences in genetic abnormalities and FAB subtypes were found between infants, children and adolescents. Infants <2 year old, showed the highest incidence of abnormal karyotypes (81. 25%) and complex karyotypes (53. 9%). The most common FAB subtypes were M5 and M7, and the most common abnormality was 11q23 rearrangement, followed by abnormalities of 7p. In children (>2 years until the age of 14 years), the most frequent abnormality was t(8;21), followed by -7 and the most common FAB subtype was M2, followed by M5. In adolescents (>14 years until the age of 21 years), the most frequent abnormality was t(15;17) followed by t(8;21) and trisomy 8 and the most common FAB subtype was M2 followed by M3 and M4. **Summary and Conclusions.** This study confirmed the high incidence of cytogenetic changes in children and adolescents. The frequencies of most chromosome aberrations and most FAB subtypes were comparable to previous studies. Interestingly, a high frequency of AML-M3 and a high frequency of t(15;17), +8 and -7 was observed in this cohort. Complex karyotypes did not emerge as an adverse prognostic feature in this study. The frequency of specific chromosome aberrations and FAB subtypes was found to vary between the AML age groups. Striking differences concerning mostly chromosome abnormalities and survival were also observed between de novo and s-AML.

CHROMOSOME 1 ABNORMALITIES IN MULTIPLE MYELOMA

T Boneva[1], L Mitev[2]
[1]Military Medical Academy, Sofia, Bulgaria
[2]Lubomir, Sofia, Bulgaria

Summary. Chromosome 1 is frequently affected in multiple myeloma (MM) and is related with tumor progression of the disease. The aim of our study was to describe the chromosome 1 rearrangements in MM. Cytogenetic examinations with G-banding techniques and fluorescent in situ hybridization (Fish) were performed on 56 untreated patients. Conventional cytogenetic study was successful in 46 cases and revealed 21 cases with clonal changes. Structural abnormalities of chromosome 1 were seen in 13 (62%) cases. All of them had complex karyotype. The most frequent aberrations of chromosome 1 were deletions of the short or long arm and unbalanced derivative translocations. Isochromosomes, isodicentrics or jumping translocations of chromosome 1 were also observed. More often the additional copy of chromosome 1 was rearrangement (8 cases). The following chromosomal bands were involved: 1p34, 1p32, 1p22, 1p13, 1p10, 1q10, 1q12 and 1q23. Fish examination of 25 patients with 1p36 and 1q21 specific DNA probes found clonal anomalies in 19 (76%) cases: 1p36 deletion in 6 cases, 1q21 deletion in 5 cases and 1q21 duplication in 9 cases. The pathological clones was always accompanied with minor clones carrying variety of abnormal Fish signal patterns. In conclusion, our results suggest that multiple loci in chromosome 1 are related with nonrandom chromosome aberrations. This confirms that possible hemizygosity of tumor suppressor genes or activation of oncogenes in chromosome 1 could lead to progression of MM. **Key Words.** multiple myeloma, chromosomal abnormality.

1354

DETECTION DNMT3A MUTATION IN ACUTE MYELOID LEUKEMIA BY PCR FROM CDNA AND SEQUENCING

QL Jiang[1], CX Yin[2], A Annette[3], KF Shen[2], L Lisa[3], D Daniela[3], LZ Yuan[4], FL Chen[2], C Carsten[3], FY Meng[2]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, China
[2]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China
[3]Department of Medicine A, Hematology and Oncology, University of Münster, Münster, Germany
[4]Southern Medical University, Guangzhou, China

Background. DNMT3A mutation is one of the most common genetic mutations in AML patients, which related with poor clinical results; more than half of mutations located on R882 site. It's necessary to include detection of DNMT3A mutation into routine clinic diagnosis; however, the method should not be too expensive and complex. **Aims.** To establish a detection protocol simple and efficient for DNMT3A mutation in clinic. **Methods.** 1) Primers design: a pair of PCR and sequencing primers are designed from 2121-bp to 2782-bp of cDNA, (F: 5'-CAGTCCCTGCAATGACCTCT-3'; R: 5'-TTGTTTAACTTTGTGTCGCTACC-3'), which covering of most part of methyltransferase region (707aa-912aa), in the one PCR reaction production of 663-bp, including the highest mutation hotspots. 2) Patient samples: Bone marrow or peripheral blood samples were collected from 77 German patients in Department of Medicine A, Hematology and Oncology, University of Münster, Münster, Germany, the median age at diagnosis was 63 (range: 28-84) yrs; and 72 Chinese patients in Department of Hematology, Nanfang Hospital, Southern Medical University, China, the median age was 39 (range: 16-78) yrs, AML with PML-RARa and AML-ETO fusion gene were excluded. Samples collected after informed consent. (3) PCR and sequencing: The PCR reaction mixture consisted of 1ul sample cDNA, 250 nmol of both forward and reverse primers (Invitrogen), 200 umol dNTPs, 2. 5 ul 10×pfu PCR reaction buffer, 2 mmol MgCl2, 1 U Pfu DNA Polymerase (Fermentas), and sterile water up to the final volume of 25 uL. The first denaturation temperature was set at 94℃ for 5min, followed by 40 cycles of denaturation at 94℃ for 30s, annealing at 58℃ for 30s and extension at 72℃ for 90s, and ended with an extension at 72℃ for 7min. PCR production were then be sent to Invitrogen company (Shanghai, China) or by classical sequencing (using the Big Dye Terminator kit v. 3. 1). Each sample had at least 2 independent tests from both forward and reverse sequencing primers.

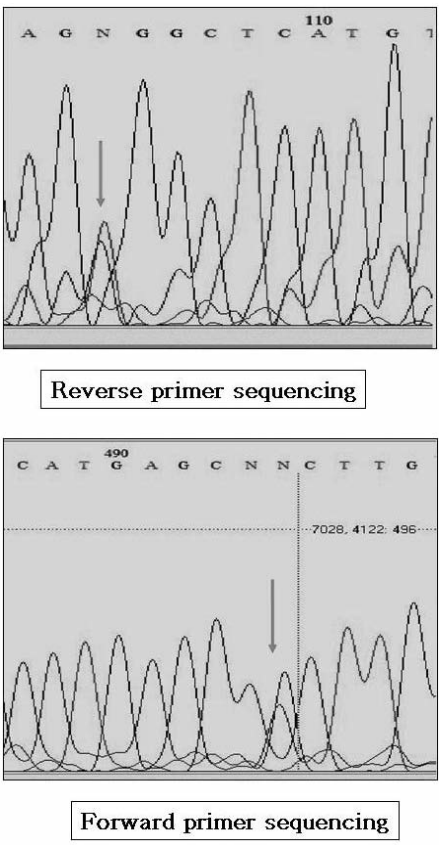

Figure 1. Double-peaks on R882 from one patient, with forward and reverse primers.

Results. 74 among 77 German samples have readable results, and 5 of them have potential DNMT3A R882 mutations (double-peaks on R882); while 69 among 72 Chinese patients have readable results, 2 of them have DNMT3A with R882C mutations and 5 have potential DNMT3A R882 mutations (double-peaks on R882). Double-peak single (Figure 1) at R882 position remained to be puzzled after sequencing repeated. Taken together, we have 12 positive or potential positive R882 mutations from 142 readable samples. **Summary and Conclusions.** We have detected DNMT3A mutations from both Chinese and German patients by our protocol, which can be use as a screening method at least, since the protocol is simple and economic. However, the puzzled results occurred in both Chinese and German, which may be improved by further detection with specific Taqman probe and primes, or new-generation sequencing.

1355

AMPLIFICATION OF 19P IS NONRANDOM EVENT IN ACUTE MEGAKARYOBLASTIC LEUKEMIA

E Matveeva[1], A Kazakova[1], L Bajdun[2], Y Olshanskaya[1], A Maschan[1]
[1]Research Center for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation
[2]Russian Republic Children Hospital, Moscow, Russian Federation

Acute megakaryoblastic leukemia (AML M7) is a very rare disease. Its exact genetic cause is under investigation, excluding t(1;22), which is found mostly in infants under 6 months. Hyperploid karyotype with complex aberrations is observed in the vast majority of cases. The most frequent abnormalities are 3q26 rearragements, -7, +8, +19 and +21. However the specific molecular markers in AML M7 are not found. Therefore our aim was to collect patients with successful karyotypes and search for recurrent cytogenetic abnormalities. We collected 11 cases of AML M7 (2009-2011). Cytogenetic analysis was performed on bone marrow cells, chromosomes were identified with G-banding technique. mFISH (Xcyte24, MetaSystems) and FISH (Vysis, Abbot Molecular) techniques were also used to evaluate chromosome aberrations. We had 7 patients with successful karyotypes. One patient had hypoploid karyotype with multiple rearrangements. One patient had Down syndrome and also exhibited complex hypoploid karyotype. Four patients had hyperploid karyotypes, three of them having additional chromosome 19. One patient had additional chromosome 3 as a sole abnormality. Using mFISH we elucidated karyotypes compared to those obtained by G-banding in all cases and identified the nature of marker chromosomes (see Table 1). We also had 4 patients without mithoses. Interphase FISH analysis was performed, but 3q26 rearragements, -7, +19 were not found in this group. In two patients amplification of 19p was found. In case 1 a marker chromosome was found in hyperploid karyotype. mFISH showed that it consists of the material of chromosome 19. Study with DNA probe LSI 19p13/19q13 (Vysis, Abbot Molecular) revealed that the derivative chromosome is composed of amplified 19p13 material. In case 5 mFISH showed hypoploid clone displaying jumping translocations involving chromosome 19 (t(2;5;19)(q12-14;q13;?), t(8;19)(q12;?), t(9;15;19)(q13;q11;?) etc). In this case we found that jumping material consists of amplified 19p13 region. So far, amplification of 19p is nonrandom event in AML M7 and usually correlates with complex karyotypes. The exact location and function of the amplified region in 19p is to be investigated, as well as clinical and biological aspects of this phenomenon.

EXPRESSION AND LOCALIZATION OF THE PRAME PROTEIN IN THE DIFFERENT CELL CULTURES

N Lyzhko, V Akhlynina, A Misiurin, YP Finashutina, E Aksenova, I Soldatova
Research Clinical Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background. PRAME protein is one of the cancer-testis antigens common for haematological malignancies. There is no significant PRAME expression in blood and tissues of healthy donors. PRAME gene expression is reported for different types of leukaemia as well as for a number of solid tumours. PRAME mRNA evaluation is useful for MRD monitoring to prevent molecular relapse long before some other tests made it possible. PRAME protein cell localization has not been yet clear. **Aims.** To detect PRAME protein expression and cell localization in a number of cell cultures with different levels of PRAME mRNA expression. **Methods.** All cells after ethanol fixation were stained by anti-PRAME moAB's following by the secondary fluorescent AB treatment (Invitrogen) giving green signal. Cell nuclei were blue stained by Hoeshst. Green and blue in-cell staining was detected by Karl Zeiss Axiovert 40CL. Images were analysed by AxioVision software. Gene cloning and transfection were performed using standard techniques. **Results.** Earlier we developed 2 hybridoma lines (5D3F2-Prm and 6H8F12-Prm) secreting anti-PRAME moAB. In this study we used K562 erythroblastoid cell culture, human melanoma MEL-Kor, human fibroblasts WI-38 and mouse melanoma B16F10. In preliminary experiments by means of RQ-PCR we have shown that WI-38 and B16F10 were PRAME-negative whereas K562 and MEL-Kor were strongly PRAME-positive. We found that both 5D3F2-Prm and 6H8F12-Prm moAB's specifically bind PRAME protein. In case of highly PRAME expressing MEL-Kor and K562 it has been found that moAB's have different binding sites within the cells. It turned out that 5D3F2-Prm moAB (at dilution 1 to 100) binds mostly inside the cells, namely, to the nuclei, to the peri-nucleus area and within the cytoplasm. 6H8F12-Prm moAB not only stained the same cell compartments as 5D3F2-Prm, but also the cell surface (Figure 1 A,B). WI-38 and B16F10 that shown to not express PRAME mRNA was also negative at staining by 5D3F2-Prm and 6H8F12-Prm moAB's. On the contrary, those cell lines after transfection by PRAME-expressing pCEP4-PRAME plasmid became RQ-PCR PRAME positive and shown PRAME positivity following the staining by moAB's. In transfected cells both moAB's mostly bind nuclei creating green bright clusters (Figure 1 C,D), but distinct signal was detected also on the cell surface, especially when 6H8F12-Prm moAB was used. Interestingly, when both moAB's were used at less dilutions, fluorescent signal was detected only on the cell surface (Figure 1 G,H). It suggests that the AB's binding sites on the cell surface may obtain at these conditions some advantage to compare with intracellular binding sites. Not transfected WI-38 and B16F10 cells were never stained even at low dilutions of anti-PRAME moAB's (Figure 1 E,F),. When K562, Mel-Kor and WI-38 and B16F10 were stained alive, the fluorescent signal was observed only on the cell surface in the form of distinct green dots. **Conclusions.** Our data suggest that PRAME protein has at least two main cell localization sites revealed by moAB'S: nuclei and cell surface. The PRAME signals prone to form clusters both within the nucleus as well as on the cell surface. We believe that moAB's against PRAME may be useful for diagnostic purposes.

CONCURRENT REARRANGEMENTS OF BCL2, BCL3 AND BCL11A GENES RESULTING FROM THREE BALANCED TRANSLOCATIONS INVOLVING IMMUNOGLOBULIN GENES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL)

H Podgornik[1], B Skopec[2], P Cernelc[2]
[1]University Medical Center Ljubljana, Ljubljana, Slovenia
[2]University Medical Centre, Ljubljana, Slovenia

Background. Chromosome translocations including *IGH* rearrangement were thought to be relatively infrequent in chronic lymphocytic leukemia (CLL). This is not supported by more recent studies which have shown a higher incidence of *IGH@* rearrangements. B-CLL with t(14;19)(q32;q13) or t(2;14)(p16;q32) commonly presents with atypical cytological features, trisomy 12, and a progressive course of disease. Hence some have suggested it represents a distinct clinicopathological entity. This far three cases with concomitant translocations t(14;19) and t(2;14) have been described in literature. The t(18;22)(p11;q21), a rare variant of another *IGH* translocation t(14;18)(q32;q21), has been never found in combination with t(14;19) or t(2;14), although alone it has been most commonly observed in CLL. **Aims.** To present a case of B-CLL with three concomitant balanced translocations involving immunoglobulin genes in CLL. **Case Report.** We report a case of a 45 year -old female patient who was diagnosed with lymphoproliferative disease in 2004. The immunophenotype was typical for B-CLL, but because of the atypical morphologic features, four consecutive bone marrow examinations could not differentiate between CLL and mantle cell lymphoma. Initially negative FMC7 and Igl have become partially or completely positive in later analysis. CD38 has also gradually increased over years. The disease progressed in spite of aggressive treatment which started in 2007 (Fludarabine, Fludarabine Cyclophosphamide, Alemtuzumab). In 2011 the patient underwent an allogeneic hematopoietic stem cell transplantation and is currently in remission. Due to an aggressive course of disease and uncertain diagnosis, conventional cytogenetics was repeated in 2010. **Methods.** Conventional GTG banding was done after short term cultivation of bone marrow cells. Interphase FISH analysis was performed by Abbott DNA probes LSI IGH CCND1 and LSI IGH/BCL2. Translocations were confirmed by metaphase FISH analysis using Kreatech WCP probes. **Results.** In 2006 conventional cytogenetics confirmed trisomy 12 as a sole anomaly. Besides a normal female clone two leukemic clones were found in 2010. A small one with the isolated trisomy 12 and the main clone with three balanced translocations and trisomy 12: 47,XX,+12[2]/47,idem,t(2;14)(p13;q32),t(14;19)(q32;q13),t(18;22)(q21;q11)[16]/46,XX[2]. By interphase FISH analysis a biallelic rearrangement of *IGH@* and a rearrangement of *BCL2* (18q21) were observed. All three balanced translocations were also confirmed by metaphase FISH. **Conclusions.** We report here a case of CLL patient with three concomitant balanced translocations involving biallelic rearrangement of *IGH@* (14q32) and monoallelic rearrangement of *IGL@* (22q21). Partner genes involved are *BCL3, BCL11A,* and *BCL2* in t(14;19), t(2;14), and t(18;22) respectively. Although deregulation of *BCL3* and *BCL11A* were considered to play a major and primary role in the pathogenesis of CLL, in our case they were found as a result of a clonal evolution. Whereas atypical cytological features were observed already at the onset of disease (2004) translocations have evolved only after 2006 when trisomy 12 was found as the sole anomaly. Our case is additionally interesting since a rare t(18;22) was concurrently found with both *IGH@* translocations for the first time. Concurrent translocations are a further challenging topic in elucidation of clinical significance of *IGH@* rearrangements in CLL.

1358

COMPLEX THREE-WAY CHROMOSOMAL TRANSLOCATION T(3;3;5)(Q21;Q26. 2;Q32) - A NOVEL VARIANT OF ACUTE MYELOID LEUKAEMIA WITH INV(3)/T(3;3) WITH A BETTER PROGNOSIS?

T Martín-Santos, JM Raya, S Afonso, B Esquivel, S Iraheta, B Soria, ML Brito, JL García-Miranda, L Hernández-Nieto
Hospital Universitario de Canarias, La Laguna - Tenerife, Spain

Background. AND AIM: Acute myeloid leukaemia (AML) with abnormalities of 3q represents 3. 5-4. 4% of all AML, but only that carrying inv(3)(q21q26. 2) or t(3;3)(q21;q26. 2) is recognized as a clinicopathological entity in the 2008 WHO classification. This type of AML shows typically an aggressive course and short survival. To date, other patients with AML carrying 3q abnormalities different to inv(3)/t(3;3) do not constitute a specific subgroup in this classification. We report a patient with a novel variant of AML with a t(3;3;5) (q21;q26. 2;q32), not previously described, with special attention to clinical and laboratory features. **Case Report.** A 62-year-old male without relevant antecedents attended to the emergency department referring dry cough, skin rash, fatigue and anorexia in the last two weeks. As remarkable data, the physical examination revealed a palpable hepatomegaly of 2-3 cm below the costal margin, and the analytical findings included pancytopenia (WBC 1. 3 x 10^9/L, neutrophils 0. 6 x 10^9/L, haemoglobin 68 g/L, MCV 108 fL, and platelet count 25 x 10^9/L). Peripheral blood smear examination revealed the presence of some isolated immature cell. Serology for hepatitis B, C, and HIV infection, and also autoimmunity screening, were negative, and a slight increase in serum lactic dehydrogenase (LDH) was observed. Bone marrow aspiration showed a very poor sample with a 7% of blasts, which were positive for CD34, CD13, CD38, CD61, CD36 and CD117. A marrow biopsy revealed hypercellularity with marked hyperplasia ("cobblestone"pattern) and dysplasia of megakaryocytic series, some "pockets"of blasts and red cell precursors clusters, and reticulin focal fibrosis (grade II). By immunohistochemistry, staining with CD31 showed a significant quantitative presence (>20%) of immature cells, also positive for CD34. Conventional cytogenetics evidenced the existence of a three-way translocation t(3;3;5)(q21;q26. 2;q32) in all metaphases analyzed, and *BCR-ABL1* was negative. Overexpressions of *EVI1, MN1* and *BAALC* were detected. The patient received intensive chemotherapy according to PETHEMA LAM/99 protocol with Idarubicin + Ara-C, but a marrow aspirate at +14 postinduction-day showed the persistence of blasts (5%). We decided to perform an allogeneic stem-cell transplant from a related donor (HLA-matched brother) in a reference center, which went off without significant adverse events. At present the patient has completed one year of post-transplant, always in complete remission and without complications. **Conclusions.** The disease in our patient shares some features with AML carrying inv(3) or t(3;3), mainly the histological appearance of marrow biopsy (increased small aberrant megakaryocytes, marrow fibrosis), but also the presence of hepatomegaly, an increased serum LDH and the overexpression of *EVI1*. However, the clinical course was much less aggressive. In a Spanish series of 35 patients with AML inv3/t(3;3) *(Raya et al,* EHA Congress 2011), median overall survival was only 7 months and median disease-free survival 3 months, even including those transplanted (29%). The evolution in our patient seems to be better, continuing in complete remission after 20 months from diagnosis.

[3]Department of Clinical Hematology-CHU Farhat Hached, Sousse, Tunisia
[4]Department of Clinical Hematology-CHU Hédi Cheker, Sfax, Tunisia

Background. Multiple myeloma (MM) is a malignant lymphoproliferative disease of B cells characterized by the accumulation of monoclonal plasma cells in bone marrow. Chromosomal abnormalities have played a major role in the disease progression of MM, among which we found by order of frequency: translocations involving 14q32 region (60%), especially t(11; 14)(q13, q32)(~20%), t(4; 14)(p16; q32)(~15%), t(14; 16)(q32; q23)(~5%), deletions of the long arm of chromosome 13(40-50%) and deletions of the short arm of chromosome 17(10%). **Aims.** We propose to study the chromosomal aberrations in 30 Tunisian patients with MM by conventional and molecular cytogenetic. **Methods.** The patients were prospectively analyzed by conventional karyotype, fluorescent in situ hybridization (FISH) and cIg-FISH which is a combination of cytoplasmic immunostaining of plasma cells and conventional FISH and compared the contribution of molecular cytogenetic techniques in the detection of chromosomal abnormalities. **Results.** Patients were firstly analyzed with conventional cytogenetic which detected four abnormal karyotypes (13. 4%). Molecular cytogenetic revealed at least one chromosomal abnormality in 16 patients (53. 4%), 14 of them didn't show any chromosomal abnormality by conventional karyotype. We detected by iFISH and cIg-FISH t(11;14) respectively in 23. 33% and 20%,t(4;14) in 3. 33% and 6. 67% and t(14;16) in 16, 67% and 20%. The same percentage of 6. 67% was found by the two techniques for deletion 13. We have not detected any 17p deletion. We also revealed association between t(14;16) and 13q deletion in 2 patients and a second association between t(4;14) and 13q deletion in 1 patient. The statistical study showed a sensitivity of 84. 6% with a confidence interval (CI_{95}%) of [53. 7% - 97. 3%] and a specificity of 82. 4% with a CI_{95}% equal to [55. 8% - 95. 3%] of cIg-FISH compared to iFISH. **Conclusions.** Our study indicates that cIg-FISH is the preferred method for the detection of chromosomal abnormalities involved in the MM. This will allow patients to be stratified into the new risk-adapted therapies based on cytogenetic and FISH.

A CASE OF APLASTIC ANEMIA WITH KLINEFELTER'S SYNDROME

G Ozgur, R Acar, D Torun, I Erturk, O Nevruz, F Avcu, K Kaptan, T Cetin
Gulhane School of Medicine, Ankara, Turkey, Ankara, Turkey

Abstract. Aplastic anemia is characterized by diminished or absent precursors in the bone marrow. Klinefelter syndrome is the most common congenital abnormality causing primary hypogonadism. To our knowledge, the occurence of aplastic anemia with Klinefelter's syndrome has been reported twice before. We described a 22- year-old man who had suffered epistaxis and had been detected aplastic anemia and Klinefelter's syndrome at the time of searching of the etiology of pancytopenia. **Introduction.** Aplastic anemia is characterized by diminished or absent precursors in the bone marrow, in which normal hematopoetic cells are replaced by fat cells. In most patients, bone marrow hypoplasia is caused by immunological destruction of stemcells. The disease is estimated to occur in two to four subjects per million population per year (1,2). Klinefelter's syndrome is a variation of sex chromosome disorder characterized by hypogonadism, gynecomastia and azospermia and the most common congenital abnormality causing primary hypogonadism, occuring in approximately 1 in 1000 live male births(3,4). A case of Klinefelter's Syndrome with leukemia have been reported (7). **Case Report.** A 22-year-old man, suffered lasting epistaxis five hours and pancytopenia was detected, in his blood count white cells 3,2 x 10 ^{9}/L, hemoglobin 4,2 g/dL, hematocrit 12,1%, platelet 13 x 10 ^{9}/L. For the etiology of pancytopenia further tests were needed. Bone marrow aspirate revealed a severe hypocellular marrow, consisting of 1,6% blasts. Markers were negative for Hepatitis A, B, C, HIV and TORCH. Serological markers were also negative such as serum anti nuclear antibodies (ANA), double stranded deoxy ribonucleic acid (ds DNA). Chromosome analysis was performed with shortterm cultures of bone marrow cells. The karyotype was 47,XXY. In semen analysis azoospermia was detected. Gonadal hormone (normal range shown in brackets) such as testosterone 20. 22 pg/ml (8. 6-54. 6), follicle stimulating hormone 38. 88 u/l (1. 4-18. 1), luteinizing hormone 19. 6 u/l (1. 7-8. 6), prolactin 28. 17 ng/ml (2. 1-17. 7). With these laboratory findings we confirmed that his diagnoses were severe aplastic anemia and Klinefelter's Syndrome. After that,we performed patient and patient's family histocompatibility testing. A-38-year old brother was fully HLA-matched with him. So, we performed allogenic hematopoetic stem cell transplantation from his brother. Patient is still alive and we follow up him for two months after transplantation, recovery of bone marrow is achieved. **Conclusions.** Klinefelter's Syndrome patients have high risk of autoimmun disease. Aplastic anemia is also systemic autoimmune disease that hyperfunction of T cell causes to injury to hematopoetic tissue resulting in pancytopenia. Androgens stimulate hematopoietic system by various mechanisms. In the case reported androgen level was normal but FSH and LH levels were increased. So that can also increase levels of CD3+,CD4+ and CD8+, inducing bone failure. The mechanism of aplastic anemia and hyperprolactinemia in Klinefelter's syndrome was presumed to be elevated FSH and LH, but a detailed mechanism remains to be elucidated. And also we see that aplastic anemia accompanied by Klinefelter's syndrome dont influence the treatment. The patient has been responded to treatment like the other aplastic anemia patients.

AN UNUSUAL CYTOGENETIC RESULT IN A PATIENT WITH ELLIPTOCYTOSIS, THROMBOCYTOPENIA AND A CONSTITUTIONAL MOSAIC 20Q DELETION

E van den Berg-de Ruiter, J Herkert, A Mulder, R Tamminga
UMCG, Groningen, Netherlands

We report on a 6-year old boy with a constitutional low-grade mosaic 20q11. 21q13. 32 deletion of 25. 6 Mb. He presented with a Robin anomaly, a short stature and a mild expressive speech delay. He was referred to us for cytogenetic examination of bone marrow because he also developed a mild anaemia, thrombocytopenia, elliptocytosis, a variable granulocytopenia and an increased HbF. Bone marrow examination showed no features of myelodysplasia, but nearly all bone marrow cells showed a 20q11q13 deletion; suggesting a relationship between the constitutional 20q deletion and the aberrant blood count. In several reported cases of myelodysplastic syndrome with marked elliptocytosis, an acquired del20q was observed. Congenital hereditary spherocytosis, irregular antibodies, folate and vitamin deficiency and growth hormone deficiency were excluded. To our knowledge this is the first patient with a constitutional 20q deletion of 25. 6 Mb and cytopenia with marked elliptocytosis and no myelodysplastic syndrome as yet.

A MINOR BETA THALASSEMIA MASKED BY A NEW MUTANT OF THE HEMOGLOBIN A2

S Ayari[1], S Omar[1], B Hammami. [1], M Feki[1], S Abbes[2], N Kaabachi[1]
[1]CHU Rabta, Tunis, Tunisia
[2]Institute Pasteur Tunis, Tunis, Tunisia

Abstract. The elevation of hemoglobin A_2 (HbA_2) is an essential criterion in the diagnosis of minor β thalassemia. We report a case of minor β thalassemia with normal rate of HbA_2. **Case Report.** We report the case of ten years old boy, native of hafouz (governorate of Kairouan) which consults for an hypochromic and microcytic anemia refractory to iron treatment with a rate of Hb at 10 g/dl, a TCMH= 17,8 pg/GR, a VGM=59 fl and a normal rate of ferritin= 35 µg/l. The study of the hemoglobin revealed besides the HbA (93%), the HbA_2 (2,5%) and the HbF (1,5%) an additional minor abnormal fraction of Hb estimated to 3% migrating at middle distance between the HbA and the HbA_2. The phenotypic family's study revealed at the mother's one a minor β thalassemia isolated (the father was died) and we noted in the siblings (one brother and four sisters) tow anomalies of the hemoglobin (the β thalassemic line and the additional fraction of Hb) transmitted in an isolating or associating way. The genotypic study revealed the presence of a β^0 thalassemia mutation and showed that this minor abnormal fraction of Hb is a new mutant delta (δ) of the globin, which was called "Hb A_2 Pasteur"(δ59:E_3 lys→Asn (AAG→AAC). **Conclusions.** The presence of a mutant δ has reduced the rate of HbA_2 masking the β thalassemic line. The rigorous and methodic interpretation of the phenotypic data is primordial for not underestimate a minor β thalassemia whose diagnosis is decisive for genetic counselling.

THE INVESTIGATION OF 621 PATIENTS SCREENED FOR THE JAK2 V617F MUTATION

A Toylu, O Salim, A Irfanoglu Timuragaoglu
Akdeniz University, Antalya, Turkey

Background. Janus kinase (JAK) family of proteins are cytoplasmic protein kinases which are activating transcription factors by phosphorylation. During hematopoietic cell differentiation pathway, JAK2 plays an essential role by interacting with the hematopoietic growth factor signaling. It has been reported that somatic mutations which activate JAK2 kinase, could be responsible for erythrocytosis by inducing the erythrocytic proliferation. JAK2 exon 14 V617F mutation has been reported in most of patients with sporadic polycytemia vera. Studies has also shown that JAK2 V617F mutation may also be found in different types of leukemia. **Aims.** Here we aimed to analyze the patients screened for the JAK2 V617F mutation in our laboratory for molecular hematology . Between 2007-2012 years, the patients evaluated for the JAK2 V617F mutation were included the study. **Methods.** Mutation analysis was performed with the melting curve analysis and the allele specific PCR methods from the samples of bone marrow and/or peripheral blood. **Results.** A total 621 patient sample were analyzed for somatic JAK2 V617F mutation. For each year, about 40 % of the patients screened for JAK2 were found to have a somatic mutation. **Conclusions.** The allele specific PCR method has displayed a higher sensitivity and also allowed us to diagnose even very low persantage of mutant JAK2 in bone marrow / blood sample.

TRANSLOCATION T(3;21)(Q26;Q22) IN PHILADELPHIA CHROMOSOME POSITIVE CHRONIC MYELOID LEUKEMIA PATIENT WITH BLAST CRISIS

A Bennour[1], M Zaier[2], I Ouahchi[1], Y Ben Youssef[2], A Khelif[2], A Saad[1], H Sennana[1]
[1]Cytogenetics, Molecular Genetics and Reproductive Biology-CHU Farhat Hached, Sousse, Tunisia
[2]Department of Clinical Hematology-CHU Farhat Hached, Sousse, Tunisia

Background. The acquisition of secondary chromosomal aberrations in chronic myeloid leukemia (CML) patients with Philadelphia chromosome-positive karyotype signifies clonal evolution associated with disease progression to accelerated/blastic phase. Therefore, these aberrations are of clinical and biological importance. AimsWe report herein, a patient with Philadelphia chromosome-positive CML in whom a rare translocation t(3;21)(q26;q22),developed during disease progression. **Case Report.** A 35 year- aged man was diagnosed with CML. Chromosome analysis of bone marrow aspirate identified a Philadelphia translocation t(9; 22)(q34; q11). The patient received imatinib

treatment during 22 months. He was then lost to follow up. 12 months later, he developed blastic crisis, conventional cytogenetic analysis at that time revealed a reciprocal translocation t(3;21)(q26;q22) in the Philadelphia positive clone. He received chemotherapy with second tyrosine kinase inhibitor (dasatinib). Despite intensive care and supportive chemotherapy, the patient died of pulmonary infection and sepsis. **Discussion.** The t(3;21)(q26;q22) is a recurrent chromosomal abnormality in some cases of CML blast phase and in treatment-related myelodysplastic syndrome and acute myeloid leukemia. This translocation may result in the AML1-MDS1, AML1-Evi1 or AML1-EAP fusion transcripts. These secondary aberrations are thought to play a causative role in leukemic transformation of hematopoietic cells and should be the molecular basis of CML patient with t (3;21) (q26;q22) in blastic crisis. **Conclusions.** Our study indicates that the coexistence of BCR/ABL and t(3;21)(q26;q22) might play a pivotal role in the CML blast transformation and indicates a poor prognosis.

1365

APPROACHES TO GUIDE LUCATUMUMAB DOSE AND DOSING SCHEDULE BASED ON PHARMACOKINETIC (PK), PHARMACODYNAMIC (PD), RECEPTOR OCCUPANCY, AND TUMOR LOAD DATA FROM CYNOMOLGUS MONKEYS AND PATIENTS

S Bilic[1], D Robinson[1], J Rediske[1], W Feng[1], J Baeck[1], J Bendiske[1], B Ewald[1], D Carreon[1], L Finke[1], H Schran[1], P Lowe[2]
[1]Novartis Pharmaceuticals Corporation, Florham Park, United States of America
[2]Novartis Pharma AG, Basel, Switzerland

Background. Lucatumumab is a fully antagonistic human anti-CD40 monoclonal antibody that has demonstrated activity in preclinical and clinical studies and is hypothesized to act through dual mechanisms of inhibiting CD40L-CD40 signaling and inducing antibody-dependent cell-mediated cytotoxicity. Lucatumumab is being evaluated in several B-cell malignancies, including chronic lymphocytic leukemia, multiple myeloma, non-Hodgkin lymphoma, and Hodgkin lymphoma. **Aims.** To guide dose selection and dosing frequency, PK and PD (measured by receptor occupancy) data from cynomolgus monkeys and patients and tumor volume data (measured by computed tomography and/or fluorodeoxyglucose positron emission tomography) from patients were analyzed using mixed-effect modeling. **Methods.** A NONMEM® dataset (ICON plc, Dublin, Ireland) was constructed with PK and PD data in 52 cynomolgus monkeys from 2 toxicology studies and 63 lymphoma patients from a phase 1a/2 open-label study. A target-mediated drug disposition (TMDD) model, which describes the nonlinear PK resulting from lucatumumab binding to CD40 on the cell surface, was adopted. Free lucatumumab concentrations in serum were described by a 2-compartment model. Population model-predicted target saturation profiles were used to estimate the percentage of patients that would maintain 90% target saturation over 18 weeks of lucatumumab treatment with various doses and dosing schedules. **Results.** Lucatumumab exhibited target-mediated disposition in cynomolgus monkeys and patients with chronic lymphocytic leukemia, multiple myeloma, and lymphoma, which was well described by the 2-compartment TMDD model. Earlier analysis demonstrated that the model-predicted target occupancy profiles closely mimic those of an independent ex vivo fluorescence-activated cell sorting-based lymphocyte occupancy assay in both cynomolgus monkeys and patients. The typical nonspecific linear clearance was 0. 251 L/day (coefficient of variation [CV]: 46%) and the nonlinear target-mediated clearance was 1. 18 L/day (CV: 170%) (clearance of target and complex [lymphoma patients]) and 0. 2 L/day (clearance of target and complex [cynomolgus monkeys]); the central volume of distribution was 2. 59 L (CV: 61%). The lucatumumab concentration required for 90% receptor occupancy was 1. 7 µg/mL. The projected percentage of patients (at a typical weight of 70 kg) who would maintain 90% target saturation at lucatumumab PK steady state (achieved after approximately week 7) is tabulated (Table 1). A consistent induction of soluble CD40 ligand upon dosing as well as an inverse relationship between free CD40 and PK concentration was observed, both of which support the receptor occupancy findings. **Summary and Conclusions.** The PK of lucatumumab exhibited target-mediated disposition, which was well described by the TMDD 2-compartment PK model. Lucatumumab administered on an every-2-weeks schedule provides the desired target receptor occupancy of ≥ 90% at a dose level of 4 to 6 mg/kg.

Table 1. Model-predicted percentage of patients showing 90% receptor occupancy.

	Lucatumumab Dose, %			
Lucatumumab schedule	1 mg/kg	3 mg/kg	4 mg/kg	6 mg/kg
q2wk	17.5	84.0	92.3	97.7
q3wk	2.5	53.0	68.3	85.8

q2wk, once every 2 weeks; q3wk, once every 3 weeks.

CHARACTERIZATION OF THE INTERACTIONS BETWEEN MDR PROTEINS AND ANTICANCER AND ANTIINFLAMMATORY DRUGS

B Vaskó, E Kis, K Tauber Jakab, J Márki-Zay, P Krajcsi
Solvo Biotechnology, Szeged, Hungary

Background. The multidrug resistance phenotype in hematological malignancies and other tumors can be associated with the overexpression of certain ABC transporters, termed MDR proteins. The P-glycoprotein -ABCB1/MDR1-mediated multidrug resistance was discovered first and probably still is the most widely observed mechanism in clinical multidrug resistance. Two other ABC transporters have been demonstrated to participate in the multidrug resistance: the multidrug resistance associated protein 1 (ABCC1/MRP1), and the breast cancer resistance protein (ABCG2/BCRP/MXR). Recently MDQ-kit™ was developed as an improved flow cytometric method to measure the functional activity of the three, clinically most relevant efflux transporters in the living cells. Following the successful multicenter performance evaluation of the kit, the SOLVO MDQ-kit has been approved for in vitro diagnostic use in the EU. The knowledge of the drug-transporter interactions is of pivotal importance because it may lead to treatment failures due to the efflux of chemotherapies from the target cells. **Aims**. The major goal of our study was to test several drugs used to treat diseases where the MDR phenomenon is common, such as chemotherapy of malignant diseases and immunosuppressive treatments in chronic inflammatory disorders. **Methods.** Drug - transporter interactions were characterized using relevant MDR transporter expressing in vitro test systems. The cytotoxicity assay is a widely used method to screen cytotoxic effects of the compounds. Cell lines overexpressing ABCB1/ABCC1/ABCG2 protein show resistance to drugs that are substrates of the given transporter. Calcein and Hoechst assay are useful whole cell based methods to detect interactions between the compound and the selected transporter. Molecules that are substrates or inhibitors of the transporter increase cellular fluorescence by inhibiting the ABC transporter mediated efflux of the dye. **Results.** We tested a panel of over 30 drugs (eg alkylating agents, nucleoside analogue, antimetabolites, etc). Overexpression of ABCB1/ABCC1/ABCG2 transporters resulted in increased resistance to 65%/52%/35% of compounds respectively. Some of these interactions have not been described previously. The inhibition of profile of the same set of drugs was tested using the same ABCB1/ABCC1/ABCG2 transporter expressing cell lines in Hoechst and Calcein assay. The correlation is limited between the two assays. Although, it should be taken into consideration that the cytotoxicity assay is a substrate assay and the dye efflux assay is an inhibition assay. **Conclusions.** The presented HT in vitro assays are well suited to predict interactions between molecules and MDR proteins. Passive permeability of the compound is a critical parameter. In general, high passive permeability compounds are good inhibitors. At the same time, high passive permeability may overcome resistance by MDR transporters. This may explain lack of correlations between the two assay types.

1367

ROLE OF CYTOKINES IN RESISTANCE TO ERYTHROPOIESIS STIMULATING AGENTS TREATMENT OF ANAEMIA IN PATIENTS WITH LYMPHOPROLIFERATIVE DISORDERS

N Romanenko, O Rozanova, T Glazanova, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Anaemia often develops in patients with lymphoproloferative disorders (LPD), decreases survival and worsens the quality of patients' life. Pathogenesis of the anaemia is based on the suppression of erythroid precursors by proinflammatory cytokines. Therefore erythropoiesis-stimulating agents (EPSA) are used as a pathogenetic therapy of anaemia in patients with LPD. However the resistance to EPSA develops in 30-40% of patients. **Aims.** To evaluate the influence of proinflammatory cytokines on the efficacy of anaemia correction with EPSA. **Methods.** We have examined the patients with multiple myeloma (n=10), chronic lymphocytic leukemia (n=5) and non-Hodgkin's lymphoma (n=6), age from 24 to 82 years (62. 7±12. 1). All patients have previously received not less than 3 cycles of programmed chemotherapy. Before the beginning of EPSA therapy we have evaluated the levels of proinflammatory cytokines: interleukin-6 (IL-6), interleukin-1β (IL-1β), tumor necrosis factor alpha (TNF-α), interferon-γ (INF-γ); also a hemogram was controlled every two weeks during the whole treatment period. Anaemia with hemoglobin level less than 100 g/L was considered an indication to prescription of EPSA treatment. EPSA (Epoetin alpha) was administrated subcutaneously in dosage 150 IU/kg of body weight 3 times a week. The duration of EPSA treatment was 9. 0±3. 7 weeks on average (from 6 to 16 weeks). Patients with haemorrhages, severe hemol-

ysis, iron and B_{12} deficiency were not included in this study. Target level of Hb was 120 g/L. A positive response to treatment was considered in increasing of Hb concentration ≥20 g/L. **Results.** We have established that the initial level of proinflammatory cytokines in examined patients with anaemia was increased and it varied broadly: IL-6 - 301-810 pg/ml (487±142 pg/ml), IL-1β - 14-998 pg/ml (423±358 pg/ml), TNF-α - 12-156 pg/ml (57. 9±50. 3 pg/ml), and INF-γ - 47-1000 pg/ml (556±314 pg/ml). Nevertheless, there have not been observed any significant correlation between the cytokine level and the severity of anaemia (Hb concentration). However, there were positive correlations between levels of IL-1β and TNF-α (r=+0. 76; p<0. 05), IL-1β and INF-γ (r=+0. 48; p<0. 05), TNF-α and INF-γ (r=+0. 63; p<0. 05), evidencing their participance in suppression of erythroid precursors. There have not been observed any correlations between IL-6 and TNF-α, INF-γ, IL-1β (p>0. 05). Having compared the levels of proinflammatory cytokines and the efficacy of EPSA therapy we have shown negative correlation with IL-1β (r=-0. 59; p<0. 05), TNF-α (r=-0. 72; p<0. 05), INF-γ (r=-0. 50; p<0. 05). Thus, high level of cytokines decreases the probability of development of response to EPSA treatment. In the whole group the positive response was stated in 13 of 21 patients (61. 9%), i. e. Hb level increased from 89. 8±11. 7 g/L to 113. 1±19. 3 g/L (p<0. 002), red blood cell count - from 2. 98±0. 49×10^{12}/L to 3. 64±0. 88×10^{12}/L (p=0. 004), and Hct - from 27. 2±3. 0% to 35. 3±4. 3% (p<0. 001). **Conclusions.** Cytokines Il-1β, TNF-α, and INF-γ play a role in development of anaemia being suppressors of erythropoiesis and thus can serve as the predictors of response to EPSA therapy in patients with lymphoproliferative disorders.

1368

ROLE OF SERUM ERYTHROPOIETIN LEVEL AS A PREDICTOR OF RESPONSE TO ANAEMIA TREATMENT WITH RECOMBINANT HUMAN ERYTHROPOIETIN IN LYMPHOPROLIFERATIVE DISORDERS (LPD) PATIENTS

N Romanenko, M Berkos, S Gritsaev, T Glazanova, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Anaemia in LPD patients often decreases the efficacy of antineoplastic therapy and survival of patients, also worsening their quality of life. Correction of anaemia is usually performed using RBC transfusions and administrated the Recombinant Human Erythropoietin (rHuEPO) which significantly reduce the need of transfusions and the risk of RBC transfusion-induced complications. Nevertheless, the efficacy of rHuEPO in LPD patients with anaemia is about 60-70%, while the cost this treatment is rather high. The use of prognostic factors predicting the efficacy of rHuEPO treatment will allow target administration of rHuEPO to patients who will probably respond to this therapy. **Aims.** To study the predictive value of level of serum erythropoietin (sEPO), measured in LPD patients with anaemia before the rHuEPO treatment. **Methods.** The studied group included patients with LPD (n=48): chronic lymphocytic leukemia (n=13), indolent non-Hodgkin's lymphoma and multiple myeloma (n=21). Patients' age varied from 24 to 82 years (62. 7±12. 1). rHuEPO were administrated in anaemia with Hb <10. 0 g/dL. All patients have previously received ≥3 cycles of programmed chemotherapy. 14 patients received RBC transfusions because of severe anaemia (Hb<8. 0 g/dL) before rHuEPO-therapy. We exncluded patients with haemorrhages, marked hemolysis, iron or B_{12} deficiency. rHuEPO were administrated at doses 150 IU/kg body weight 3 times a week subcutaneously. Before and during the rHuEPO treatment we controlled the haemogram. sEPO was evaluated before rHuEPO-therapy. The target Hb concentration was defined 12. 0 g/dL. Duration of treatment was withing 16 weeks. Positive response was defined as the increase of Hb ≥2. 0 g/dL. **Results.** Initial Hb level was found at 8. 30±1. 65 g/dL, erythrocytes - 2. 64±0. 64×10^{12}/L and hematocrit - 25. 9±5. 5%. Initial sEPO level in patients with anaemia varied broadly - from 3 to 1810 mIU/mL (in average 323±479 mIU/mL). Duration of rHuEPO-therapy was in average 9. 0±3. 7 weeks (from 4 to 16 weeks). In 30 of 48 patients (62. 5%; p<0. 05) positive response was stated. In the whole group of patients with positive response to rHuEPO treatment (n=30) there was observed a significant increase from baseline for the following parameters: Hb level - up to 12. 82±1. 03 g/dL (p<0. 01), erythrocytes - up to 3. 89±0. 67×10^{12}/L (p<0. 01) and Hct level - up to 38. 5±4. 2% (p<0. 01). Negative correlation between the initial sEPO level and efficacy of rHuEPO-therapy (r=-0. 36; n=48; p<0. 05) allowed us to conclude that a positive response was more commonly observed in patients with low sEPO at baseline. Having divided the patients to different groups depending on their baseline sEPO level we have revealed that in cases of initial sEPO level <130 mIU/mL (39±38 mIU/mL) positive response was observed in 20 of 25 patients (80%), with initial sEPo level 130-500 mIU/mL (265±107 mIU/mL) - in 7 of 11 (66. 7%), and with sEPO >500 mIU/mL (1016±561 mIU/mL) - in 3 of 12 (25%). In the former group of patients (with sEPO >500 mIU/mL) the efficacy of rHuEPO treatment was significantly lower than in first two groups (p<0. 05). **Summary.** Initial level of sEPO allows to predict the response to rHuEPO treatment and thus can be used in medical practice.

1369

IMPACT OF VKORC1 AND CYP2C9 POLYMORPHISMS ON INITIAL ANTICOAGULATION THERAPY WITH ACENOCOUMAROL

E Jimenez-Varo[1], M Aguilera Gomez[2], M Cañadas-Garre[2], M Calleja-Hernandez[2]
[1]Hospital Universitario Virgen de las Nieves, Granada, Spain
[2]Virgen de las Nieves University Hospital, Granada, Spain

Background. Although acenocoumarol has a narrow therapeutic range, it is the most prescribed drug in prevention and treatment of thromboembolism disorders inSpain. To reach the interindividual dose-requirement in the first weeks of anticoagulation is the main clinical goal, because of the high risk of bleeding or thrombosis during the first weeks. VKORC1 polymorphisms (rs9923231, rs9934438) are related to coumarin derivate sensitivity in the initial phase of therapy, and represent 20-25% of influence on interindividual dose-requirement. Pharmacogenetics can improve safety and effectiveness of acenocoumarol prior therapy has begun. **Aims.** Our goal was to evaluate the impact of CYP2C9, VKORC1, CYP2C19 and CYP4F2 variant genotypes on the required-dose, risk of overanticoagulation (bleeding) or underanticoagulation (thrombosis) and the time to achieve a therapeutic INR range. **Methods.** Hospitalized medical patients treated with acenocoumarol at the Virgen de las Nieves University Hospital (Granada, Spain) were genotyped by PCR Real-Time (CYP2C19*2 rs4244285), PCR-RFLP (VKORC1 rs9923231; CYP2C9*2 rs1799853 and CYP4F2 rs2108622) and direct sequencing (CYP2C9*3 rs1057910) and their clinical parameters were analyzed after starting anticoagulation therapy. All patients signed an informed consent. **Results.** Carriers AA for VKORC1 (rs9923231) were associated with a higher risk of INR>4 infirst days of anticoagulation. CYP2C9*2 (rs1799853) and CYP2C9*3 (rs1057910) were associated with delayed time to achieve therapeutic INR range. **Summary and Conclusions.** Patients carriers of described allelic variations for VKORC1, CYP2C9*2 and/or CYP2C9*3 needed lower doses at the beginning of anticoagulation than patients wild-type for these genes.

1370

DOES ANTI-PEG STATUS INFLUENCE THE EFFICACY OF PEG-CONJUGATED FILGRASTIM AS A TREATMENT?

M Downes, P Thornton, M Marren
Health Service Executive, Dublin, Ireland

Background. PEG-conjugated Filgrastim is widely used as primary prophylaxis for febrile neutropenia in patients on myelosuppressive chemotherapy, however the effects of anti-PEG on its efficacy have not been adequately investigated. Recent published research indicates that as many as 25% of the normal population have detectable anti-PEG in their circulation with evidence to suggest that there is a direct correlation between those with anti-PEG and those with a reduced response rate to PEG-conjugated drug treatment. These significant findings indicate that anti-PEG status could influence the efficacy of PEG-conjugated drug treatments and needs further investigation in patients undergoing myelosuppressive treatment. **Aims.** To establish a laboratory protocol for the serological detection of anti-PEG in human plasma. Three cohorts of patient samples were aimed to be tested for the presence of detectable anti-PEG in their plasma; normal healthy subjects, haematology patients with no known exposure to PEG-conjugated Filgrastim and haematology patients with known exposure to PEG conjugated Filgrastim. The prevalence of the antibody in the normal healthy population and in the haematology patients not on PEG-conjugated drug treatments were determined to see if its occurrence is similar to that found in the general population by previous research carried out by Armstrong et al i.e. ~25%. The prevalence of anti-PEG in patients exposed to PEG-conjugated Filgrastim was also determined and together with their Full Blood Count results at the time of PEG-conjugated Filgrastim administration, a statistical assessment was made to determine whether or not there is any direct correlation between patients with anti-PEG and those with a reduced response rate to PEG-conjugated Filgrastim. **Methods.** A serological tube technique involving the preparation of PEGylated red cells was set up and this technique was then used to investigate whether any of the collected patient samples had anti-PEG in their circulation. The protocol used for anti-PEG detection was established by Armstrong et al. in 2003 and to date there is no published evidence of this novel detection method being used elsewhere. The set up of this serological technique for the purpose of this research study is the first of its kind inIreland. **Results.** There is a statistically significant difference in the proportion of plasma samples from the subjects with no known exposure to PEG conjugated Filgrastim which tested positive, i. e. 20%, and the proportion of sub-

jects with known exposure to PEG conjugated Filgrastim which tested positive, i. e. 0% (χ^2 = 5. 8, p = 0. 016). **Conclusions.** Anti bodies to PEG are less prevalent in haematology patients, likely due to the immuno-incompetence associated with their disease or the immune suppression associated with their chemotherapy. This suggests that PEG conjugated Filgrastim is likely to be a successful drug treatment for the reduction of febrile neutropenia in haematology patients.

1371

EVALUATION OF THE ROLE OF THE NEW INNOVANCE PFA P2Y TEST CARTRIDGE IN DETECTION OF CLOPIDOGREL RESISTANCE

A Tsantes[1], I Ikonomidis[2], I Papadakis[2], C Kottaridi[3], A Tsante[4], E Kalamara[5], P Kopterides[4], A Kardoulaki[4], P Karakitsos[3], J Lekakis[6], A Travlou[4]
[1]"Attikon" University Hospital, School of Medicine, Athens, Athens, Greece
[2]Second Cardiology Department, "Attikon" University Hospital,, Athens, Greece
[3]Department of Diagnostic Cytopathology, "Attikon" University Hospital,, Athens, Greece
[4]Laboratory of Haematology and Blood Bank Unit, "Attikon" University Hospital, Athens, Greece
[5]Laboratory of Haematology and Blood Bank Unit, "Attikon" University Hospital, Athens, Greece
[6]Second Cardiology Department, "Attikon" University Hospital, School of Medicine, Athens, Greece

Background. Light transmittance aggregometry (LTA) has been extensively used in monitoring clopidogrel therapy. However, the availability of simple and rapid point-of-care platelet function assays is of great clinical importance. Thus, the manufacturer of the Platelet Function Analyzer (PFA)-100 System has recently provided the INNOVANCE PFA P2Y test cartridge. **Aims.** To assesss the capacity of the new test to detect reliably clopidogrel resistance. **Methods.** We enrolled 90 consecutive patients with coronary artery disease receiving chronic clopidogrel maintenance therapy in combination with aspirin. Twenty healthy volunteers served as controls. Clopidogrel resistance was simultaneously analyzed by the INNOVANCE PFA P2Y test cartridge, ADP-induced LTA, the flow-cytometric vasodilator-stimulated phosphoprotein (VASP)-phosphorylation assay and the multiple electrode aggregometry (Multiplate). In statistical calculations, for all platelet function assays we used both reference ranges as they are provided by the manufacturers and those derived from the 5th-95th percentiles of measurements in the group of healthy blood donors. Agreement among the 4 platelet function methods by two was assessed using Cohen's kappa coefficient. Spearman correlation coefficients were also used to test for associations between INNOVANCE PFA-100 P2Y CTs and ADP-induced LTA values. **Results.** According to the cut-off points for clopidogrel resistance proposed by the literature, agreement was fair between INNOVANCE PFA-100 P2Y and LTA (74. 4%) and Multiplate (75. 6%), while poor agreement was noticed with VASP assay (63. 3%). Based on cut-off points derived from the measurements from 20 healthy volunteers, agreement between the PFA-100 System and the other three methods improved compared to the previous cut-offs (76. 7%, 77. 8% and 67. 3%, respectively), but this improvement didn't reach statistical significance. There was also a statistically significant negative correlation of INNOVANCE PFA-100 P2Y CTs with peak (r=-0. 51, p<0. 001) and late aggregation (r=-0. 55, p<0. 001), Multiplate (r=-0. 47, p<0. 001) and VASP-assay values (r=-0. 41, p=0. 003) and a weak positive correlation with disaggregation values (r=0. 37, p=0. 003). **Conclusions.** The INNOVANCE PFA-100 P2Y seems to be comparable to other established platelet function assays in detecting clopidogrel resistance. However, the modest agreement among platelet function methods makes crucial the performance of platelet function testing with more than one technique in order to reliably identify poor responders to clopidogrel treatment.

1372

THE EXPRESSION OF RLIP76 AND MRP IN LEUKEMIA CELLS

A Toylu, O Altiok Clark, O Salim, A Irfanoglu Timuragaoglu
Akdeniz University, Antalya, Turkey

Background. RLIP76 is a membrane-located protein mediating the transport of multiple molecules, including both glutathione-conjugated and lipid-oxidized metabolites and drugs. Studies have shown that there is an increased expression of RLIP76 in several types of cancer cells, and that it plays a prominent role in drug resistance. While there are a large number of studies showing that leukemia cells can develop resistance to chemotherapeutic drugs due to the increased expression of multiple drug resistance (MDR) proteins, it isn't known if this resistance is also accompanied by a change in the expression of RLIP76. **Aims.** The aim of this study was to investigate RLIP76, MRP-1, and MRP-2 expression in leukemia cells. **Methods.** All of the investigations were performed at the mRNA level on the THP-1, REH, HEL, MV4-11, and U937 leukemia cell lines using quantitative PCR. **Results.** Each of the cell lines expressed comparable levels of RLIP76 and MRP-1, but the expression of MRP-2 was nearly 100 times lower than RLIP76 and MRP-1 in all cell lines. The REH cell line had the highest amount of RLIP76 and MRP-1 expression. While both the THP-1 and MV4-11 (AML M5) cell lines expressed more RLIP76 than MRP, the HEL (AML M6) cell line showed a greater amount of MRP expression. **Conclusions.** These results suggest that the RLIP76 gene could contribute to the development of chemotherapeutic drug resistance in leukemia cells.

POLYMORPHISMS IN COAGULATION-RELATED GENES AND COLORECTAL CANCER PROGRESSION

C Vossen[1], M Hoffmeister[2], J Chang-Claude[2], F Rosendaal[3], K Salzmann[2], C Ulrich[2], H Brenner[2]
[1]University Medical Center Utrecht, Utrecht, Netherlands
[2]German Cancer Research Center, Heidelberg, Germany
[3]Leiden University Medical Center, Leiden, Netherlands

Background. We recently reported an association between factor V Leiden, prothrombin G20210A and factor XIII Val34Leu and colorectal cancer (CRC) onset. Our results did not support an effect on CRC risk for the other tested polymorphisms: PAI-1 4G/5G, *FGG* 10034C>T and *MTHFR* 677C>T. Earlier data from other studies did show a reduced survival for PAI-1 4G carriers with Dukes' stage A or B disease, and for *MTHFR* 677-T carriers with Dukes' stage C disease, but these data come from small studies. **Aims.** To determine the association between the above six variants and cancer progression (vital status, recurrences, three-year progression-free survival) in 1322 German colorectal cancer cases with at least three years of follow-up after diagnosis. **Methods.** Patients were included in the DACHS study (Darmkrebs: Chancen der Verhütung durch Screening) between 2003 and 2007 and were at least 30 years old with a first diagnosis of primary invasive, histologically confirmed CRC. About three years after diagnosis, follow-up information was gathered on local recurrences, secondary tumors and distant metastases by sending a questionnaire to patients' treating physicians. Information on vital status was ascertained through population registries. Mortality and recurrence risk during follow-up associated with gene variants was determined by calculating hazard ratios (HRs) and their 95% confidence intervals (CIs). Adjustments were made for age, sex, body mass index, disease stage, cancer detection circumstances and cancer site. In addition, progression-free survival within three years after diagnosis was compared across genotypes using logistic regression with adjustment for the above confounders. All participants gave written informed consent. **Results.** Of the 1322 patients, 328(25%) patients died during follow-up (251(19%) due to CRC) and 289(22%) patients developed a recurrence. The median follow-up time until recurrence, death or the end of follow-up, whichever occurred first, was 3. 0 years (range 0-7 years). In total 883 (67%) patients survived progression-free within three years after diagnosis. In contrast to earlier studies, we found a reduced CRC-related mortality for 177 patients with UICC stage II who were heterozygous for PAI-1 4G/5G (CRC-deaths 6%; HR 0. 35; 95% CI 0. 15-0. 83) compared to 73 5G/5G carriers (CRC-deaths 16%), but no clear reduction in CRC-related deaths for 121 4G/4G carriers (CRC-deaths 8%; HR 0. 60; 95% CI 0. 25-1. 43). We also found a reduced CRC-related mortality for 147 *FGG* 10034-CT carriers with UICC stage II (CRC-deaths 8%; HR 0. 48; 95% CI 0. 23-0. 98) and no CRC-related deaths among 28 TT carriers with stage II disease compared to 194 CC carriers (CRC-deaths 12%). Also in contrast to earlier studies, we found an improved progression-free survival for patients with colon cancer stage III for 111 *MTHFR* CT carriers (progression-free survival 69%; RR 2. 00; 95% 1. 10-3. 65) and 29 TT carriers (progression-free survival 79%; RR 3. 26; 95% 1. 18-8. 90) compared to the 96 CC carriers (progression-free survival 56%). **Summary and Conclusions.** We found a beneficial effect on CRC survival for patients carrying PAI-1 4G/5G, *FGG* 10034-T and *MTHFR* 677-T. Further studies are needed to validate our findings and to determine the prognostic value of these three variants.

[2]VI Division of General Surgery, A. O. U. San Giovanni Battista, University of Tori, Torino, Italy
[3]Division of Hematology and Cell Therapy, A. O. Ordine Mauriziano, University of T, Torino, Italy
[4]Division of Nuclear Medicine, A. O. U. San Giovanni Battista, University of Torino, Torino, Italy
[5]Division of Hematology, A. O. U. San Giovanni Battista, University of Torino, Torino, Italy

Background. Stem cells, namely the easily accessible bone marrow-derived cells (BMC) are reportedly capable of tissue repair in different damaged organs and might favour wound healing. The present study was undertaken to evaluate the feasibility and safety of BMC mobilization induced by granulocyte-colony stimulating factor (G-CSF) in patients undergoing surgery for sacro-coccygeal pilonidal cyst (SPC). To evaluate the possible clinical benefit of G-CSF in reducing time to complete resolution, a comparison with a control group receiving surgery without G-CSF was performed. **Methods.** Eight patients with complex SPC were included in this prospective trial. Patients were treated with G-CSF (5 µg/ kg b. i. d) for 3 consecutive days, standard surgical exeresis of the pilonidal cyst was scheduled on day 2 of mobilization. Mobilization was assessed in terms of circulating CD34+ cells and CFU-GM progenitors. **Results.** Mobilization of CD34+ cells and CFU-GM occurred in all patients, along with a marked increase in white blood cells (median peak value: 28,435/µL, day 3). G-CSF was well tolerated, no adverse events occurred. All patients received the planned surgical treatment without any complications. Interestingly, as detailed in Figure 1, G-CSF group patients had a median time to resolution (117 days, range 110-130) significantly shorter than controls (145 days, range 118-168) (p =0. 034). **Conclusions.** G-CSF administration, along with BMC mobilization, is feasible and well tolerated in patients undergoing surgery for SPC; clinical results compare favourably with those observed in controls not receiving G-CSF; the results suggest the potential use of G-CSF as additional treatment to accelerate wound healing in patients undergoing surgery.

[4]Teva Ratiopharm, Ulm, Germany

Background. Cancer chemotherapy frequently causes neutropenia, leading to an increased risk of infections and delays in subsequent chemotherapy treatments. Pegfilgrastim is a pegylated recombinant form of granulocyte colony stimulating factor (G-CSF) that extends the half-life and requires less frequent dosing than nonpegylated G-CSF. Lipegfilgrastim is a glycosylated and pegylated G-CSF. **Aims.** The objective of this study was to compare the efficacy and safety of lipegfilgrastim and pegfilgrastim in chemotherapy-naïve patients with breast cancer who are candidates to receive docetaxel/doxorubicin. **Methods.** In this double-blind, randomized, active-controlled, noninferiority trial, patients with high-risk stage II, III, or IV breast cancer and an absolute neutrophil count ≥1. $5x10^9$ cells/L were randomly assigned to lipegfilgrastim 6 mg (n=101) or pegfilgrastim 6 mg (n=101). Study medication was injected subcutaneously on day 2 of the chemotherapy cycle (4 cycles maximum). Primary efficacy endpoint was the duration of severe neutropenia (days with an absolute neutropenia count <0. $5x10^9$ cells/L) during cycle 1. Secondary endpoints included the incidence of febrile neutropenia. The efficacy analysis population included patients who were randomized but did not have major protocol violations. **Results.** Overall, 37%, 46%, and 17% of patients had stage II, III, and IV breast cancer, respectively. The mean duration of severe neutropenia in cycle 1 was 0. 7 days in the lipegfilgrastim group and 0. 8 days in the pegfilgrastim group (poisson regression least squares mean [95% CI] -0. 218 [-0. 498 to 0. 062]). 56% and 49%, respectively, did not experience severe neutropenia in cycle 1. Three patients experienced febrile neutropenia; all were in the pegfilgrastim group during cycle 1. 28% of patients in the lipegfilgrastim group and 26% in the pegfilgrastim group had adverse events that the investigator considered to be related to study medication. Three and 7 patients, respectively had serious adverse events. **Conclusions.** The results of this study confirm that the efficacy of lipegfilgrastim is comparable with pegfilgrastim. No unexpected safety events were observed.

1376

ALTERATIONS IN LYMPHOCYTE SUBPOPULATIONS OF HEALTHY PRETERM AND TERM NEWBORNS

S Akarsu[1], S Akarsu[2], A Kurt[3], D Benzer[4], A Aygun[5]
[1]University of Firat, Faculty of Medicine, Elazig, Turkey
[2]University of Firat, Faculty of Medicine, Department of Pediatric Hematology, Elazig, Turkey
[3]University of Baskent, Faculty of Medicine, Department of Neonatology, Ankara, Turkey
[4]Zeynep Kamil State Hospital, Department of Neonatology,, Istanbul, Turkey
[5]University of Firat, Faculty of Medicine, Department of Neonatology, Elazig, Turkey

Background. Relative, and absolute numbers of blood elements in lymphocyte groups, and subgroups change with life. Their numbers in preterms in various gestational weeks of their intrauterine life are expected be different when compared with newborns with mature immune systems. **Aims.** Health states of preterm, and term newborns can be evaluated using immunophenotyping performed based on the gestational week of the newborn. The aim of this research was determine major lymphocyte populations and subpopulations between premature and term newborns. **Methods.** The lymphocyte subsets from the cord blood of 122 premature and 44 term newborns were analyzed using two-color monoclonal antibodies and flow cytometry. Informed consent was obtained. The premature newborns were divided into three groups and the immunophenotypes of premature newborns with different age groups were compared. Here, the findings of a study of normal preterm and term subjects divided into cohorts of newborns, preterms (26-31 weeks, 32-35 weeks, 36-37 weeks), and terms (³38 weeks) are presented. **Results.** WBC counts decreased towards 32-35. gestational week. They increased a little bit, but at term they dropped to the levels below those detected at 26-31 weeks (p<0. 05). Relative WBC counts demonstrated a declining trend at a period close to term, while levels of $CD19^+$, $CD8^+$, $CD16^+$ 56^+ started to rise. Although absolute values changed during the interim period, values detected at 26-31 weeks, and term were close to each other. **Summary and Conclusions.** Numerical values related to immunity can be meaningful if compared between age-matched infants. Difference in relative rates of change can provide more information for the evaluaton of maturity.

1377

A CASE REPORT OF AN ACUTE DISTRESS RESPIRATORY SYNDROME FOLLOWING BY SEVERE PULMONARY EDEMA AFTER ADMINISTRATION OF G-CSF IN AUTOLOGOUS TRANSPLANTATION

Y Yafour, F Attaf, H Tadj, A Fettouhi, M Bekadja
EHU 1st November, Oran, Algeria

Introduction. Granulocyte-colony stimulating factor (G-CSF), a hematopoietic growth factor, is widely used to mobilization of peripheral blood stem cell

(PBSC), and to accelerate recovery from neutropenia after severe chemotherapy to decreasing the risk of infection. Adverse effects occur with G-CSF use in approximately 30% of cases, comprised predominantly of bone pain, headache, and general fatigue. Pulmonary toxicity is rare. Here we describe our first experience case of acute respiratory distress syndrome (ARDS) and pulmonary edema, following G-CSF administration. **Case Report.** We report the case of a patient who received G-CSF to accelerate recovery from neutropenia in ASCT for a refractory Hodgkin's disease, who had developed an ADRS followed by severe pulmonary edema. In April2008, a19-year-old female patient was diagnosed with nodular sclerosing Hodgkin's disease, Cervical and mediastinal lymphadenopathies were identified, and the patient was staged as unfavorable IIA. A complete remission obtained after six cycles of ABVD and 36gy initial focus sites complementary radiotherapy. In June 2009 patient relapse, with a ventro-basal pulmonary nodules infiltrates in computed tomography (CT) scan, a second complete remission was obtained after 2 cycles of DHAP. This patient was found to be in good health after physical examination, lung function testing, ECG as well as a chest x-ray; she was mobilized with G-CSF (lenolgrastim) 10 µg/kg for five days, and had received high dose chemotherapy with CBV regime included: cyclophosphamide, carmustine and etoposide, following by non-cryopreserved autologous stem cell transplantation. Beginning at day 6 lenograstim 263 µg/d was administered, and the WBC count had 0, 3 x109/L. After a second infusion of G-CSF, patient developed suddenly dyspnea, sinus tachycardia 135 bpm then 220 bpm, despite oxygen administration via mask9 litersper minute, arterial hypoxemia (Pao2/fraction of inspired oxygen [Fio2]:175 mmHg), bilateral infiltrates on a frontal chest radiograph, there was not heart failure, and no signs of pulmonary arterial embolism with contrast medium, that were indicative of ARDS. Four hour after, patient developed cough, retrosternal discomfort, and hemoptysis, with pulmonary hemorrhage in a plain radiograph of the chest. She was treated in reanimation with corticoid, furosemide, and amiodarone, and with empirical antibacterial (piperacilline and vancomycine) because of concomitant fever 38,5. After 3 days, there was marked improvement of the radiographic and physical findings, and she is alive at present, and remission has been maintained. **Discussion.** The lung injury is caused by neutrophil-dependent damage to the endothelial and epithelial barriers of the lung. Human granulocyte colony-stimulating factor (G-CSF) is the most important regulatory cytokine capable of stimulating neutrophil production and induces leaking of potentiation of proinflammatory cytokines from committed hematopoietic progenitor cells expression. **Conclusions.** A careful and close clinical monitoring of respiratory symptoms must be proposed in patients with antecedents of pulmonary disorders.

1378

EFFICACY AND SAFETY OF LIPEGFILGRASTIM IN PATIENTS WITH LUNG CANCER WHO ARE RECEIVING CHEMOTHERAPY

M Udo[1], O Gladkov[2], C Volovat[3], I Bondarenko[4], R Elaesser[5], A Buchner[5], P Bias[5]

[4]Dnipropetrovisk State Medical Academy, Dnipropetrovisk, Ukraine
[5]Teva Ratiopharm, Ulm, Germany

Background. Cancer chemotherapy can cause neutropenia, leading to an increased risk of infections and delays in subsequent chemotherapy treatments. Recombinant granulocyte colony stimulating factors (G-CSFs) have been shown to promote the proliferation and differentiation of neutrophils in patients receiving chemotherapy. Lipegfilgrastim is a glycosylated and pegylated G-CSF. **Aims.** We evaluated the efficacy and safety of lipegfilgrastim in patients receiving cisplatin/etoposide for stage IIIb/IV non-small cell lung cancer. **Methods.** In this double-blind, randomized, placebo-controlled study, patients with ≥1. 5x10^9 neutrophils/L and ≥100x10^9 platelets/L were randomly assigned to lipegfilgrastim 6 mg (n=250) or placebo (n=125). Patients with high risk for febrile neutropenia were excluded. Study medication was injected subcutaneously on day 4 of the chemotherapy cycle (4 cycles maximum). The primary efficacy endpoint was the incidence of febrile neutropenia during cycle 1. Secondary endpoints included the duration of severe neutropenia (days with an absolute neutropenia count <0. 5x10^9 cells/L). **Results.** The population consisted of 87% men; the mean age was 58 years. Overall, 2. 4% of patients in the lipegfilgrastim group and 5. 6% of patients in the placebo group had febrile neutropenia during cycle 1 (odds ratio [95% CI]: 0. 390 [0. 121 to 1. 260], p=0. 1151). Mean duration of severe neutropenia in cycle 1 was 0. 6 and 2. 3 days, respectively (least squares mean difference [95% CI]: -1. 661 [-2. 089 to -1. 232], p<0. 0001). Thirty-two percent and 59%, respectively, experienced severe neutropenia in cycle 1 (odds ratio [95% CI]: 0. 325 [0. 206-0. 512], p <0. 0001). Fourteen percent and 10%, respectively, had adverse events that the investigator considered to be related to study medication. Twenty-three percent and 18%, respectively, had serious adverse events. **Conclusions.** The odds ratio for the incidence of febrile neutropenia in the lipegfilgrastim group is in line with published results for filgrastim and pegfilgrastim. The incidence and duration of severe neutropenia was significantly reduced in patients who received lipegfilgrastim. No unexpected safety events were observed.

IMPACT OF NUTRITIONAL STATE OF INFANTS ON LYMPHOCYTE GROUPS AND SUBGROUPS

S Akarsu[1], S Akarsu[2], A Kurt[3], D Benzer[4], A Aygun[5]
[1]University of Firat, Faculty of Medicine, Elazig, Turkey
[2]University of Firat, Faculty of Medicine, Department of Pediatric Hematology, Elazig, Turkey
[3]University of Baskent, Faculty of Medicine, Department of Neonatology, Ankara, Turkey
[4]Zeynep Kamil State Hospital, Department of Neonatology,, Istanbul, Turkey
[5]University of Firat, Faculty of Medicine, Department of Neonatology, Elazig, Turkey

Background. Advantages of breastfeeding with human milk containing immunologic components protective for the newborn are more prominent during the first 6 months of life. Extent of prophylaxis provided by breast milk *per se* is more comprehensive when compared with mixed feeding. Limited information is available on the effect of breastfeeding, and its duration on lymphocyte subgroups. **Aims.** In this study we wanted to reveal the potential effects of breastfeeding, and formula feeding within the first 6 months of life on immune system. **Methods.** Our study group consisted of 26-32-week-old 106 healthy infants who were breast (n=40) or formula-fed (n= 66). Formula-fed infants either received breast milk for the first 4 weeks their lives (n= 46) or only fed with milk substitutes (n=20). Informed consent was obtained. The lymphocyte subsets were analyzed using two-color monoclonal antibodies and flow cytometry. **Results.** Relative values of CD16 56, and CD8 increased in formula-fed infants, while relative values of other parametres declined. WBC, and absolute values of all other parametres were found to be higher in breast-fed infants. **Summary and Conclusions.** Breastfeeding, and its application for longer periods exert favourable effects on immune system.

1380

THE DIFFERENCE IN THE INCIDENCE AND THE TREND OF HEMATOLOGIC MALIGNANCIES IN JAPAN AND THE UNITED STATES.

D Chihara[1], H Ito[1], T Matsuda[2], K Katanoda[2], A Shibata[2], T Sobue[2], K Matsuo[1]
[1]Aichi Cancer Center Research Institute, Nagoya, Japan
[2]National Cancer Center, Tokyo, Japan

Background. Hematologic malignancies are heterogeneous with diverse etiology and prognosis. Therefore, evaluating the incidence and its trend according to subtype is very important. However, no detailed data from Asia is available. In addition, comprehensive comparison between Asian and Western is lacking. **Aims.** The aim of this study is to assess the incidence and its trend according to subtype of hematologic malignancy and to evaluate the difference between Japan and US. The diseases evaluated in this study were acute myeloid leukemia (AML), acute lymphoblastic leukemia (ALL), chronic myelogenous leukemia (CML), multiple myeloma (MM), Hodgkin lymphoma (HL), and non-Hodgkin lymphoma (NHL) with detailed subtypes. **Methods.** We used the data from a population-based cancer registry in Japan and from the Surveillance Epidemiology and End Results (SEER) program 9. Registry data of Japan included 100,637 cases and the data of US, SEER 9 included 172,925 cases. The period covered in this analysis was 1993 to 2006 in Japan and 1993 to 2008 in the US. Rates of sex-specific, age-standardized incidence were estimated and the trend of disease is evaluated by joinpoint regression analysis. **Results.** The overall age-standardized incidence rate of all hematologic malignancies per 100,000 in 2006 was 14. 9 for males and 10. 0 for females in Japan, 33. 4 for males and 24. 3 for females in the US. The incidence is higher in the US than in Japan with most of subtypes especially for the lymphoid malignancies. The total numbers of hematologic malignancies are constantly increasing in both male and female in Japan and female in the US (Figure 1). As for details, male with AML in Japan, female with ALL in the US, both male and female with HL in Japan, male with NHL in the US and both male and female with NHL in Japanare constantly increasing. Interestingly, CML are constantly decreasing in this period in both Japan and the US. No obvious change in trend was seen with MM. Several lymphoma subtypes such as follicular lym-

phoma, mantle cell lymphoma, Burkitt lymphoma and the total numbers of T-cell lymphomas are constantly increasing while Hodgkin lymphoma-mixed cellularity is constantly decreasing in this period. **Summary and Conclusions.** We showed the difference in the incidence of hematologic malignancies between Japan and the US. As expected, incidence was higher in the US than in Japan with most disease. But the magnitude of difference varies between subtypes, such that Hodgkin lymphoma-nodular sclerosis and chronic lymphoid leukemia showed largest difference. Results of this study could be possible clues for future studies especially about etiology.

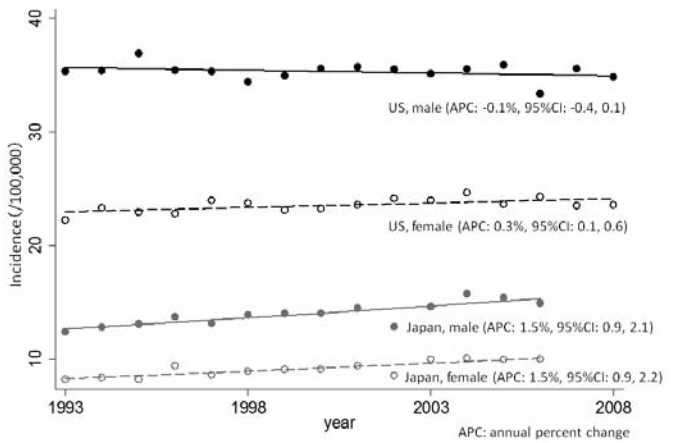

Figure 1.

1381

REDUCED CIRCULATING BLOOD LEVEL OF BDNF IS ASSOCIATED WITH CHEMOTHERAPY INDUCED PERIPHERAL NEUROPATHY IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

D Azoulay[1], D Lavie[2], M Gat[2], C Suriu[1], L Akria[1], A Braester[1], D Ben-Yehuda[2]
[1]Western Galilee Hospital, Nahariya, Israel
[2]Hadassah Hebrew University, Ein Karem Hospital, Jerusalem, Israel

Background. Chemotherapy Induced Peripheral Neuropathy (CIPN) is a major side effect and dose-limiting factor in cancer patients. Brain Derived Neurotrophic Factor (BDNF) is a neuronal growth factor that is responsible for the development, maintenance and repair of the peripheral nerve system. **Aims.** To identify alterations in the circulating blood levels of BDNF during CIPN development in patients with hematological malignancies. **Methods.** We used standard ELISA procedure to quantify the total level of BDNF in the blood plasma of patients with Multiple Myeloma (N=40), Hodgkin's (N=12) and Non-Hodgkin's lymphoma (N=25), prior to and during their treatment with the neurotoxic chemotherapies: Bortezomib, Vincristine and Vinblastine. CIPN development in these patients was assessed according to the cancer common toxicity criteria index. **Results.** We found that the plasma of patients who developed CIPN (SCORE≥2) during their treatment had lower BDNF level as compared to patients who did not develop CIPN (SCORE<2). (Mean±SEM in patients with CIPN vs. patients without CIPN 1. 71±0. 436ng/ml vs. 4. 62±0. 607ng/ml respectively P<0. 0001). No significant difference in the basal level of BDNF was observed between the different disease groups. **Conclusions.** These preliminary results indicate the involvement of loss of neuroprotective elements in the mechanism of CIPN and suggest the potential of blood circulating level of BDNF as a biomarker for CIPN development in patients with hematological malignancies.

1382

COST ANALYSIS OF SELF MANAGED VERSUS TRADITIONAL CARE ORAL ANTICOAGULATION THERAPY

K Palla[1], S Chisimellis[2], K Stini[2], N Pantieras[1], A Maragoudaki[1]
[1]Chania General Hospital, Chania, Greece
[2]Roche Diagnostics, Athens, Greece

Background. Requirements for anticoagulation therapy are increasing due to an expansion of clinical indications for therapy. It has been shown that the evaluation of the oral anticoagulant therapy (OAT) effect can be achieved through frequent monitoring of international normalized ratio (INR). Portable coagulometer for patient self managed (PSM) of long term OAT is a fast, accurate, safe option for suitable trained patients of all ages. **Aims.** To evaluate the incremental cost between standard care and PSM for patients receiving long term OAT in the case of Chania district (Crete island). **Methods.** The current clinical practice is monitoring the INR and managing OAT by a physician. The alternative strategy is PSM where the measurement of INR is done by the patient using a portable equipment. Limitations of PSM procedure are that may be applicable to patients with ability to receive adequate training, capacity to perform the test, acceptable level of collaboration, compliance with the treatment, telephone contacts for advice and direct intervention to the anticoagulation clinic. **Results.** A cost minimization analysis was applied. All unit costs were estimated at 2011 prices in Greece and amortized over a 5-year period (Table 1). The cost evaluation was based on the costs of diagnostic procedures. Staff costs (doctor, scientist, technicians) were calculated on the basis of salary scale mid-points. Equipment costs were based on purchase prices. Patients in the traditional strategy would require 4 medical visits annually and those in PSM would have 1 visit. Patients having moderate hemorrhagic event were expected to stay 1-3 days in hospital. The cost of training was not included in the total cost. Furthermore both transportation costs of the patient and time lost from work were not calculated. It should be pointed out, according to the Greek national health system (GNHS),that the portable coagulometer is available free of charge for patients with atrial fibrillation, thrombophilia and mechanical heart valve whose the INR monitoring is inconvenient by public or private laboratory. **Conclusions.** PSM appears to be economically attractive over a 5-year period. This method requires identification and education of selected patients. Under strictly certain conditions, it is a funded option, in a number of patients in GNHS. The social benefit by improving the quality of life in the case of residents of isolated and rural areas seems to be significant.

Table 1. Estimated anticoagulation costs.

	Variable	*Unit cost(€)*	*Cost /5years(€)*
		Routine care	
Direct cost	INR analysis	4.05	243
	Medical visit	5.0	100
Indirect cost	Doctor salary/test	17.48	1048.8
	Technician & scientist salary/test	3.01	180.6
	Hospitalization 1-3 days (moderate complications)		514
Total cost			**2086.4**
		Patient self-	**managed**
Direct cost	Machine	678	678
	Test strip	5.08	610
	Medical visit	5	25
	Hospitalization 1-3days (moderate complications)		514
Total cost			**1827**

1383

A NEW SCORE TO DETERMINE THE PROBABILITY OF FINDING AN HLA IDENTICAL UNRELATED DONOR: A PROMISING EFFICIENT TIME AND COST SAVING METHOD

M Michallet[1], M Balère[2], M Sobh[1], S Morisset[1], H Labussière[1], M Detrait[1], F Nicolini[1], S Rey[3], V Mialou[4], Y Bertrand[5], V Dubois[3]
[1]Centre Hospitalier Lyon Sud, Pierre Bénite, France
[2]Registre France greffe de Moelle Agence de la biomédecine, Saint Denis la Plaine, France
[3]EFS, Lyon, France
[4]Institut d'Hématologie et d'Oncologie Pédiatrique, Centre Léon Bérard, Lyon, France
[5]Ihop, University Hospital, Lyon, France

Introduction. We recently demonstrated that a delayed time to find a compatible donor and also to proceed to allogeneic-HSCT can worsen the disease outcome (Michallet et al. ASH 2010). When a patient is presenting at our hospital for unrelated allogeneic-HSCT a donor search on the Bone Marrow Donor Worldwide (BMDW) registry is done, this query is limited to only 2-digits HLA typing of -A, -B, -DRB1 or -DQB1 loci. The identification of a compatible unrelated donor can be very long and expensive because of the limited HLA typing information in the registries. Tiercy et al. developed a computerized software that predicts the chance to find a suitable donor and the French transplant registry has recently developed a software called "Easy Match" that predicts the number of compatible donors for a given patient. **Aims.** To refine and acceler-

ate the process of donor search by combining the results of Tiercy and Easy-Match programs and define a new score for donor finding probability, in order to be time- and cost-efficient. **Materials and Methods.** We retrospectively analyzed 104 adult and 34 pediatric patients transplanted between 2009 and 2011 after finding an unrelated donor or cord blood units. Firstly, we analyzed the HLA characteristics of each patient as previously described by Tiercy et al. to provide a HLA score with Low, intermediate or high probability to identify a suitable identical donor. Then, we used the EasyMatch software which realize a "qualitative"analysis that consist on checking that each HLA recipient phenotype was found among all possible pair wise combinations of 2 haplotypes of the different sets of haplotypes. The EasyMatch software gives for each patient a number of potential donors sharing the same phenotype as the patient. **Results.** Our 138 patients were classified in 5 different categories (A to E) according to the combined results of the HLA score (Tiercy) and the Easy-Match software (Table 1). The results of the combination of the two methods allowed the definition of a new scoring system applicable to each patient and an economic strategy for an active search of donor. Score 0 (group A): 0% of chances to identify a 10/10 identical donor for the recipient. The choice of the source will be defined considering the HLA characteristics of the recipient; in case of class I rare allele or rare HLA-BC linkage disequilibrium; a cord blood unit will be easier and more rapidly available. A complementary help should be given by an associated analysis with 4-digit haplotypes as defined by Maiers (*Human Immunology 2007, 68; 779-788*). Score 1 (groups B and C): 50% of chances to identify a suitable 10/10 identical donor. Score 2 (groups D and E): from 75 to 100% of chances to identify a suitable 10/10 identical donor. **Conclusions.** The use of this new scoring system allows time and cost spare. In case of low chance to find a donor, physicians can have a fast redirection to find another treatment alternative in order to keep an optimal results.

Table 1.

	Tiercy Score	EasyMatch Number of potential donors	Patients	% of patients who found a donor and received allo-HSCT	
A	Low	0 or < 1	59	No HLA identical donor or cord blood unit : 100%	p=0,0003
B	Low	> 1	5	Non HLA identical donor or cord blood unit: 60%	p=ns
C	Intermediate	< or = 5	23	No HLA identical donor or cord blood unit: 56%	p=0,0008
D	Intermediate	> 5	16	HLA identical donor: 87%	p=ns
E	High	> 1	35	HLA identical donor: 100%

Hospital Txagorritxu, Vitoria-Gasteiz, Spain

Background. Rituximab infusion according to the technical data sheet, generally requires 4 to 6 hours for de first infusion and 3-4 hrs for furthers. Several pilot studies have investigated the feasibility of faster infusion of Rituximab. We report a single center experience in fast infusion of Rituximab in second and subsequent administrations as routine practice. **Aims.** We analyze the security of patients receiving fast infusion of Rituximab and the rate of adverse events. **Methods.** We have retrospectively recorded data from patients treated with a fast rate infusion of Rituximab. To receive fast infusion, patients had to be treated with a first Rituximab infusion at an initial rate of 50 mg/hr, and in the absence of toxicity progressively increase by 50 mg/hr to a maximum of 400 mg/hr. Patients with infusion-related adverse effects were not suitable for fast infusion, as well as patients with significant cardiac disease. Patients received acetaminophen, dexchlorpheniramine and metylprednisolone before each rituximab infusion. In the absence of adverse event at maximum rate infusion, subsequent Rituximab cycles were administered at an initial rate of 400 mg/h. **Results.** Between 2006 and 2010, 882 rapid infusions were recorded in 102 patients with the following diagnostics: Folicular Lymphoma (49%), Diffuse Large Cell Lymphoma (18'6%), Chronic Lymphocytic Leukemia (15'7%), Marginal Lymphoma (11'8%), Lymphoplasmacytic Lymphoma (3'9%), Mantle Cell Lymphoma (11'8%) and Idiopathic Thrombocytopenic Purpura (1'2%). Administration of Rituximab was part of the following quimiotherapeutic regimens: R-CHOP in 395 infusions (44'78%), R-CNOP in 19 (2'15%), R-COP in 81 (9'18%), R-ESHAP in 16 (1'81%), R-FC in 6 (0'68%), R-MINE in 22 (2'49%), and R-Cisplatin in 6 (0'68%). Rituximab was administered as single agent in 286 infusions (32'43%). Among 882 rapid infusions, there were 2 adverse effect events (0'23%), consisting in hypotension and nausea and vomiting. The median infusion duration was 97'5 minutes (range 57-150 minutes). **Conclusions.** In our experience, fast infusion of Rituximab is a safe procedure that does not increase the rate of adverse events and results in a shorter hospitalization time, decreasing hospital's medical care load.

1385

NEW HAEMATOLOGY OUTREACH SERVICE PROVIDING TREATMENT AND SUPPORT FOR PATIENTS IN THE COMMUNITY: LOOKING AT FIRST 3 MONTHS OF DATA TO DETERMINE IF THE SERVICE CAN BE COST EFFECTIVE

N Jones, J Palmer
University Hospital Birmingham, Birmingham, United Kingdom

Background. The service was set up to provide a range of treatments and support for patients with haematological malignancies in the community. The service consists of two- haematology clinical nurses specialists funded by the Kay Kendall leukaemia foundation and offers a range of services in the patient's home such as; chemotherapy, IV infusions, platelet infusions, post high dose chemotherapy reviews and blood testing. All patients being treated within the service are under the care of University Hospital Birmingham. **Aims.** To reduce the number of hospital visits made by patients and where possible delivering treatment in the patients home. To provide support and information to patients undergoing treatment for haematological malignancies, identifying and managing complications and side effects of treatment as early as possible, whilst improving quality of life and the services for patients and being cost effective. **Methods.** 263 domiciliary visits made from December 2011 to February 2012. 90-chemotherapy deliveries. 8 platelet infusions. 14 intravenous infusions. 38 post high dose chemotherapy reviews and blood testing. 113 blood tests and x-matches for blood transfusions. Saving 67 return hospital transport journeys. 235 day unit visit. Prevention of 25 clinic visits. **Results.** Transport saving £6077, chemotherapy delivery saving £12000 Day unit time 130hours £25250 Clinic saving £3025. **Summary.** Our experience although in the early stages of a growing the service demonstrates that there are a number of savings to be made when delivering care and treatment in the community. Quality of life is also of huge importance when caring for haematology patient and the outreach service is not only saving on social costs for patients but is proving there are financial savings to be made on treatment delivery and time saved in hospital. Further audit and evaluation of the service is needed and expenses will need to be considered.

1386

MORTALITY MORBIDITY AND COST EFFECTIVENESS IN PATIENTS WITH FEBRILE NEUTROPENIA AN EXPERIENCE FROM QATAR

M Yassin, H El-AYoubi, R Kamzoul, H El-Ghazouani, M Hafeez, J Daghfal, M Al-Badri
Hamad Medical Corporation, Doha, Qatar

Background. Febrile neutropenia is a major complication of chemotherapy, costly in terms of morbidity, mortality and associated financial expenditure. **Aims.** The present study was conducted with the goal of highlighting Febrile Neutropenia as a serious problem in Qatar, with the longer term objective of improved cancer survival, reduction in, morbidity, mortality length of stay (LOS) in hospital and costs in our existing scenario. **Patients and Methods.** A cross-sectional descriptive study was conducted on patients, ≥14 years, admitted with Febrile Neutropenia as a consequence of chemotherapy at Al-Amal Hospital in Qatar cancer centre from 1st January 2007 to 31st of December 2011. **Results.** A total of 175 patients [128 (73%) males and 47 (27%) females] were selected. The mean age was 41. 6 years; age range (14- 99) years. One hundred fifty three patients (87. 4 %) were ≤ 60 years, and twenty two patients (12. 6 %) were ≤ 60 years old. Almost 45% of the patients (n = 79) were previously healthy (no co-morbidity), hypertension was the most common co-morbidity (n = 35; 20%) followed by diabetes (n=26; 15%). Overall hospital mortality was 14%; (4. 5% for patients on granulocyte colony stimulating factor (G-CSF) pro-

phylaxis as against 9. 5% for those without). Febrile Neutropenia average medications cost is 5,330 USD/ patient and lengthen the hospital stay. The main cause of death was septic shock due to line related infections. Hematological malignancies, pneumonia and culture positivity were significantly associated with LOS and death. Those below 60 years of age were more than six times more likely to die than the patients above 60 years old, which is explained partially by predominance of younger population in Qatar (majority of Qatar populations whether native or expatriates are young). Bacteremia and line related infection conferred a 3-fold increase in the risk of death. **Conclusions.** The results of this study indicate that vital instability, culture positivity and hematological malignancies are high risk factors in chemotherapy induced Febrile Neutropenia. Identification of Febrile Neutropenia risk factors with poor outcomes may help in developing the protocols. This may help reduce the cost of cancer care as well as mortality and morbidity.

1387

MEASURE AND IMPACT OF NON-ADHERENCE TO BCR-ABL INHIBITORS FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA: OVERVIEW OF THE CURRENT LITERATURE

L Noens[1], M Hensen[2], I Kucmin[2], C Lofgren[3], I Gilloteau[3]
[1]Ghent University Hospital, Ghent, Belgium
[2]Pharmerit BV, Rotterdam, Netherlands
[3]Bristol-Myers Squibb, Paris, France

Background. Recent studies have demonstrated that poor adherence to oral BCR-ABL inhibitors is an independent factor in the lack of success in treating patients with chronic myeloid leukemia (CML). **Aims.** The primary aim is to review the extent of non-adherence to BCR-ABL inhibitors and the resulting impact on clinical and economic outcomes. Secondary objectives include the evaluation of definitions and methods used to measure adherence and the identification of predictors of non-adherence to BCR-ABL inhibitors in patients with CML. **Methods.** A systematic literature review was completed using PubMed, Cochrane Library and EmBase, with no limits for time and language, including conference proceedings during the last three years (2009-2011). Search terms were related to CML, adherence/compliance, imatinib, dasatinib and nilotinib. The final studies included in the review reported adherence rates, adherence-related outcomes or proposed ways to improve adherence to BCR-ABL inhibitors. Because CML is a chronic disease, studies reporting persistence or discontinuation and subsequent reintroduction of medication were excluded from the review. **Results.** Out of a total of 342 studies, 38 met all the inclusion criteria and formed the basis of the literature review. Among the studies included in the review, adherence to BCR-ABL inhibitors in patients with CML varied from 25% to almost 100%. Additionally, multiple definitions and methods were used to measure adherence. Most of the studies (89%) examined the adherence to imatinib (first generation BCR-ABL inhibitor), with a few (8%) reporting on the adherence to dasatinib and nilotinib (second generation BCR-ABL inhibitors) only. The studies described that poor adherence can decrease event free survival, increase the risk of a suboptimal response, reduce the likelihood of achieving a complete cytogenetic response and molecular response and is associated with increased inpatient visits, length of stay in hospital, and healthcare costs. Adherence rates were found to be superior among patients receiving second generation BCR-ABL inhibitors compared to patients receiving imatinib. The number and severity of adverse events, duration of disease and duration of treatment, are key predictors for poor adherence. In addition, complexity of the treatment regimen has been identified as a significant factor increasing non-adherence in patients with CML. **Summary and Conclusions.** Adherence to BCR-ABL inhibitors is a critical component in ensuring long-term treatment efficacy. In addition, lower adherence has been associated with increased hospital resource utilization and healthcare costs. Among predictors for poor adherence to BCR-ABL inhibitors, adverse events and treatment regimen complexity require particular attention. Further research is needed to distinguish non-adherence across BCR-ABL inhibitors and to assess intervention initiatives that may enhance adherence to treatments for CML on a long-term basis.

1388

THE PRIMARY PRÉVENTION OF NEURAL TUBE DÉFECTS BY FOLIQUE ACID IN THE WILAYA OF BATNA

Y Ouarhlent[1], N Boudjerra[2], H Bounecer[3]
[1]CHUof Batn, Batna, Algeria
[2]Hematology Service, Algiers, Algeria
[3]Epidemiology service, Batna, Algeria

Background. The terme of Neural tube défect(NTD) denotes a set of birth defects resulting from abnormal neural tube closure of variable size at the fourth week of embryonic developmentEtiology of NTD linked to food;famine of Holland 1944, where the incidence of spina bifida had doubled . Folate related NTD reported in 1965 by Hibbard . The preventive effect of folate evoked the 1960s, demonstrated the 1990s Folic acid supplementation is problematic because unplanned pregnanciesIt's a real public health problem and their impact is serious **Aims.** This work was undertaken to estimate the prevalence of folates deficiency in pregnant women in the wilaya of Batna. **Methods.** This is a semi longitudinal study which involved 375 parturients, mean age was 30. 11 ± 6. 9 years, attending antenatal clinics. **Results.** The prevalence of anemia was 59. 7% with 1. 34% of severe anemia, 33. 63% moderate and 65. 02% light. The prevalence of deficiency is, folate37. 6%, iron 49. 3% and vitamin B12 5. 3%. The prevalence of folates deficiency is 34. 9% in prégnant not anemic and 39. 5% in pregnant with anemia those 8. 5%, 14. 3% and 16. 6% respectively for first, second and third trimester of pregnancy. The prévalence of folates deficiency in pregnant women is even higher than the age of pregnancy is advanced. As for the assessment of knowledge of folic acid for pregnant revealed that 19. 7% had heard of folic acid, 8. 3% are able to cite at least one food rich in folate and 7. 7% of pregnant may clarify the rôle of periconceptional folic acid. Their source of information was midwives followed by the media. **Summary and Conclusions.** The prevalence of folate deficiency in pregnant women in this study is high preventive measures are essential, especially health education Donc, en termes de prévention de la carence en économie de la santé folique chez les femmes enceintes est plus intéressante que la gestion des conséquences de cette carence comprennent les cas de spina-bifida.

1389

RECONSTRUCTION OF HEMATOPOIETIC INDUCTIVE MICROENVIRONMENT AFTER TRANSPLANTATION OF VCAM-1-MODIFIED HUMAN UMBILICAL CORD BLOOD STROMAL CELLS

Y Liu[1], X Zhang[2], X Chen[2]
[1]Xinqiao Hospital, The Third Military Medical University, Chongqing, China
[2]Xinqiao Hospital,The Third Military Medical University, Chongqing, China

The hematopoietic inductive microenvironment (HIM) is where hematopoietic stem/progenitor cells grow and develop. Hematopoietic stromal cells were the key components of the HIM. In our previous study, we had successfully cultured and isolated human cord blood-derived stromal cells (HUCBSCs) and demonstrated that they could secret hemopoietic growth factors such as GM-CSF, TPO, and SCF. However, it is still controversial whether HUCBSCs can be used for reconstruction of HIM. In this study, we first established a co-culture system of HUCBSCs and cord blood $CD34^+$ cells and then determined that using HUCBSCs as the adherent layer had significantly more newly formed colonies of each hematopoietic lineage than the control group, indicating that HUCBSCs had the ability to promote the proliferation of hematopoietic stem cells/progenitor cells. Furthermore, the number of colonies was significantly higher in vascular cell adhesion molecule-1 (VCAM-1)-modified HUCBSCs, suggesting that the ability of HUCBSCs in promoting the proliferation of hematopoietic stem cells/progenitor cells was further enhanced after having been modified with VCAM-1. Next, HUCBSCs were infused into a radiation-damaged animal model, in which the recovery of hematopoiesis was observed. The results demonstrate that the transplanted HUCBSCs were 'homed in' to bone marrow and played roles in promoting the recovery of irradiation-induced hematopoietic damage and repairing HIM. Compared with the control group, the HUCBSC group had significantly superior effectiveness in terms of the recovery time for hemogram and myelogram, CFU-F, CFU-GM, BFU-E, and CFU-Meg. Such differences were even more significant in VCAM-1-modified HUCBSCs group. We suggest that HUCBSCs are able to restore the functions of HIM and promote the recovery of radiation-induced hematopoietic damage. VCAM-1 plays an important role in supporting the repair of HIM damage.

1390

OXYGEN SENSING PATHWAY DEFECT DUE TO AN UNUSUAL COMPOUND HETEROZYGOTY FOR VHL GENES MUTATIONS: P. ASP126 (D126G) AND P. LEU188 VAL (L188V)

K Kalumba, P Monagle, C Barnes
Royal Children's Hospital, Melbourne, Australia

Background. Oxygen sensing pathway defects, known as Chuvash Polycythemia, are rare autosomal recessive conditions. The von Hippel - Lindau gene (VHL gene) protein product is the main negative regulator of the hypoxia sensing pathway through its rapid clearance of hypoxia inducible factor-1 (HIF-1 alpha) under normoxic condition. Some VHL mutations will cause derangement of the oxygen sensing pathway with resulting persistent increased secretion of erythropoietin. This condition, in majority of reported cases,

responds well to regular venesection and often has a benign course even if the increased risk of thrombo-embolic events and some tumours such as pheochromocytoma and vertebral hemangioma have been reported. Few cases of Chuvash Polycythemia have been reported worldwide and none in Australia until this case. **Case Report.** A 7 year old boy, with no significant past medical history, was referred to the Royal Children's Hospital, Melbourne with 6 months of intermittent frontal headache and 3 days of lethargy and drowsiness following a mild head injury. The clinical findings and investigations were consistent with polycythemia (Hb 224g/L). Serum erythropoietin level was markedly raised. Extensive investigations included imaging of brain and abdomen/ pelvis, echocardiography, overnight oximetry, 2,3 DPG level and activity, Hb electrophoresis, chromosome analysis and Hb oxygen affinity. All returned within normal limits. Bone marrow biopsy revealed erythroid hyperplasia with mildly reduced granulopoiesis. VHL mutation testing confirmed the diagnosis of Chuvash Polycythemia due to compound heterozygoty: p. Asp126 (D126G) and p. Leu188 Val (L188V). To the best of our knowledge, although the two mutations identified have been previously reported in isolation, no case of similar combined heterozygoty have been reported in patients with Chuvash Polycythemia. Whether this explains his poor response to regular venesection, hydroxyurea and digoxin therapy, and unusual clinical course remains to be determined. Regular venesection was complicated by iron deficiency and pica. Hydroxyurea and Digoxin therapy were unsuccessful. **Conclusions.** VHL mutation testing should be part of the investigation of a patient with unexplained polycythemia. It is important to establish this diagnosis to facilitate the medical follow up, rationalise surveillance and avoid unnecessary ongoing investigations. These abnormalities are not confined to Russia despite few cases reported elsewhere.

1391

REMARKABLE PROMOTERS: ACCOUNTING FOR SEQUENCE VARIATION IN THE CONTEXT OF THE REGULATION OF GENE EXPRESSION IN HAEMATOPOIESIS

M Dicato[1], G Mahon[2]
[1]Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg
[2]Fondation Recherche Cancer et Sang, Luxembourg, Luxembourg

Background. The DNA sequences of human promoters have a characteristic consensus sequence although variation about the consensus sequence has received little attention. In particular, we have found correlations between the bases at different positions amongst the sequences. **Aims.** We have sought to take account of the correlations using multivariate analysis to define groups of promoters with similar sequences. We have found a pattern amongst the eigenvalues, not previously described (we believe), and we examine which particular promoters have led to this pattern. **Methods.** The 60-base sequences of 1975 human promoters were extracted from the Eukaryotic Promoter Database. There were sequences for several factors involved in haematopoiesis and the differentiation of precursor cells, in particular, interleukins, CSF's, TNF-alpha and TGF-beta. Each base was coded by two binary digits and correlation coefficients were calculated between all pairs of the resulting 120 variables. A principal component analysis of the 120 variables was carried out and the eigenvectors were used to calculate principal components by which the promoters were classified. The principal components analysis was repeated using data which had been randomised to break down the correlations. **Results.** Notable correlations were found in the region of the transcription initiation site and the TATA site. After the principal component analysis of both the original and randomised data, the eigenvalues showed a downward trend. However, the first 5 eigenvalues were considerably larger for the original than the randomised data. The first eigenvalue was 0. 86 for the original data but only 0. 37 for the randomised, thus an excess variance of 0. 49 was observed. Certain promoters with a large first principal component (positive or negative) accounted for this excess variance and we term them *remarkable* promoters (positive: group 1a; negative: group 1b). Similarly, further remarkable promoters were identified for the next major principal components. Group 1a comprised 120 remarkable promoters, including TGFB1I1 (TGF-beta 1, induced transcript 1); group 1b, 202 promoters, including IL1A, IL1B, IL2, IL2RA 1 (Interleukin-2 receptor, IL2RA gene, alternative promoter 1), IL4, IL5, IL6 2; CSF2 (GM-CSF, gene) and TNFSF10 (TNF ligand superfamily, member 10). Group 2a comprised 90 promoters including CSF2RA (GM-CSF receptor alpha); group 2b, 139 promoters including TGFB1I1 (again). Group 3a contained 83 remarkable promotes and group 3b, 139 promoters of which TGFB1I1 (again); group 4a, 44 promoters including TNF and TNFSF10 (again); and group 4b, 65 remarkable promoters. **Conclusions.** The multivariate approach accounts in a systematic way for the variation of the promoter sequences. The major principal components sort promoters according to sequence features, and separate promoters of different functional groups including those involved in the regulation of gene expression in haematopoiesis, particularly the interleukins. The underlying sequence similarities could reflect a common origin for the various genes, i. e. gene duplication followed by divergence, or convergent evolution due to similarities of function. The finding that certain promoters (such as TGFB1I1) were remarkable on more than one dimension invites further study.

1392

INHIBITION OF THE JAGGED-1/NOTCH PATHWAY INCREASES THE HEMATOPOIESIS-SUPPORTIVE ACTIVITY OF MESENCHYMAL STEM CELLS

A Briquet, C Grégoire, Y Beguin, A Gothot
University of Liège, Liège, Belgium

Background and Aims. Mesenchymal stem cells (MSC) are able to support hematopoiesis ex vivo. The aim of this work consisted in determining the contribution of the Notch/Jagged-1 pathway in the ex vivo hematopoiesis-supportive activity of MSC. **Methods and Results.** It is well known that Notch is expressed in CD34+ hematopoietic precursors. By Western blot and flow cytometric analysis, we confirmed the expression of Jagged 1 by MSC. Next, Dexter-type long-term cultures were carried out with MSC and cord blood CD34+ cells in the presence of neutralizing anti-human Jagged-1 antibody (anti-Jagged-1). After 3 weeks, absolute numbers of CD34+, CD10+, CD19+, CD11b+ and CD33+ cells grown in culture were determined by flow cytometric analysis using TruCount tubes. Compared to culture with irrelevant IgG, outgrowth of lymphoid and myeloid cells, as well as expansion of CD34+ cells, were not affected by Jagged-1 inhibition. Repopulation assays in irradiated NOD/SCID mice were set with the expansion product of CD34+ cells co-cultured for one week in contact with MSC and in the presence of anti-Jagged-1 or non- specific IgG. Compared to infusion of CD34+ cells cultured in the presence of control IgG, repopulating activity was increased by Jagged-1 neutralisation. In further experiments, to determine whether this enhancement of repopulating activity was due to direct or indirect effects, the influence of anti-Jagged-1 on MSC was studied. The phenotype, adipogenic, chondrogenic and osteogenic differentiation capacity, as well as CFU-F content of MSC were not affected by Jagged-1 inhibition. However, we noted a 2-fold increase of IL-8 secretion ($p<0.001$) in the presence of anti-Jagged-1. **Conclusions.** These data suggest that, in our conditions, the Jagged-1/Notch pathway inhibits the supportive activity of MSC toward NOD/SCID-repopulating cells. This is not paralleled by changes in the phenotype, differentiation potential or CFU-F capacity of MSC but may be related to inhibition of IL-8 secretion.

1393

BONE MARROW MESENCHYMAL STEM CELLS IN CHILDHOOD AUTOIMMUNE DISEASES

M Pesmatzoglou, H Dimitriou, E Stiakaki, C Perdikogianni, M Kalmanti
Dept Pediatric Hematology-Oncology University of Crete, Heraklion, Greece

Background. Mesenchymal stem cells (MSCs) represent a promising source for cellular therapy due to their easy ex vivo expansion and their capability to differentiate into various cell types of mesenchymal origin. A unique property of these cells is their immunomodulatory and anti-inflammatory function *in vitro* and *in vivo*, making them attractive candidates for the treatment of inflammatory autoimmune diseases. Several clinical trials have been designed in order to study the use of MSCs in the treatment or prevention of acute graft versus host disease (GvHD) exploiting their immunomodulatory capacity. Recently, clinical trials have been conducted with the aim to investigate the therapeutic potential of MSCs in severe, refractory to standard therapy autoimmune diseases (AD). Although the characteristics and the role of MSC have been studied in adults with AD, there are no reports for childhood AD. **Aims.** To study the phenotypical and functional characteristics of bone marrow (BM)-derived MSCs from children with autoimmune diseases. **Patients and Methods.** BM mononuclear cells (MNC) from 11 children with AD, and a control group (CTL) of 9 children with solid tumours without BM involvement, were cultured under conditions that favor MSC growth for five consecutive passages (P1-P5). Cell doubling time (DT), surface antigen expression, CFU-F colony development and differentiation ability towards adipo-, osteo- and chondrocytes were evaluated. BM-MSCs from AD patients and from CTL group were also tested for their ability to suppress *in vitro* proliferation of autologous and allogeneic peripheral mononuclear cells (PBMCs) stimulated with PHA. **Results.** AD-MSCs seem to have similar fibroblast-like morphology, immunophenotypic characteristics and proliferation capacity, as expressed by DT, as those of CTL-MSCs. Their capacity to develop CFU-F colonies and their ability to differentiate into adipo-, osteo- and chondrocytes did not differ from those of the CTL ones. Comparing CTL-MSCs with MSCs from children with

rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), SLE-MSCs appeared to have impaired clonogenic potential. This finding was mainly due to the reduced number of the medium sized colonies (p=0. 006). Both AD-MSCs and CTL-MSCs reduced the proliferation of allogeneic PBMCs in a cell dose-dependent fashion. AD-MSCs inhibited both allogeneic and autologous PBMCs proliferation, after PHA stimulation, although the latter one to a lesser degree (80% vs 57. 5% respectively) without this difference to be statistically significant (p=0. 196). **Conclusions.** BM-derived MSC from children with autoimmune diseases exhibit the same phenotypical and functional characteristics compared with the control group with the exception of the impaired clonogenic potential of SLE-MSCs. Further characterization of the properties of MSC and assessment of their immunomodulatory properties are required before they could be introduced as a therapeutic approach to severe paediatric autoimmune diseases.

1394

GROWTH PROMOTING AND INHIBITING EFFECTS OF LENALIDOMIDE ON CD34+ STEM AND PROGENITOR CELLS IN VITRO: ROLE OF DOSE AND CYTOKINE SUPPLEMENTATION

R Möhle, A Drost, A Mazier, U Krauβ, L Kanz, K Weisel
University of Tübingen, Tübingen, Germany

Background. The immunmodulatory drug lenalidomide has emerged as a mainstay in multiple myeloma therapy, and in del(5q) MDS in some countries. However, hematotoxicity and suppression of stem cell mobilization are observed during lenalidomide treatment. It is still a controversial issue to which extent direct effects on hematopoietic stem and progenitor cells (HPC) or indirect modulation of the hematopoietic microenvironment contribute to these side effects. **Aims.** We analyzed the effect of lenalidomide on apoptosis and cytokine-driven proliferation *in vitro* using isolated CD34+ HPC to assess dose dependency, and to distinguish direct from indirect effects. **Methods.** Human mobilized CD34+ HPC were isolated from the peripheral blood. Apoptosis was measured by staining with Annexin-FITC. HPC were stimulated moderately (supplemented with 3 growth factors, 3F = SCF + FLT-3 + IL-6) and intensively (supplemented with 5F = SCF + FLT-3 + IL-6 + IL-3 + G-CSF) with cytokines in serum-free short-term liquid cultures for 7 days. **Results.** Lenalidomide at low to intermediate concentrations (0. 01 - 0. 1μM), significantly increased the percentage of apoptotic HPC after incubation for 24 h with 3F. In the 3F and 5F liquid cultures however, lenalidomide at intermediate concentration (0. 1μM) increased proliferation (3F: 1. 76-fold, 5F: 1. 32-fold increase of the total cell number) and supported differentiation of HPC preferentially into the granulocytic and megakaryocytic (CD41+) lineage. With moderate cytokine stimulation (3F), the CD34+ cell number in the liquid cultures was not increased at low to intermediate concentrations of lenalidomide and reduced at 100μM by 34%. In contrast, expansion of CD34+ HPC with intensive cytokine stimulation was supported by lenalidomid at all concentrations (by up to 85%) except 100μM, where it was reduced by 50%. At 10 μM lenalidomide, also the proportion of colony-forming units, particular erythroid (BFU-E, CFU-E) was reduced. **Conclusions.** Although initially a low rate of apotosis may be observed, at concentrations up to 1 μM proliferation of hematopoietic progenitor cells *in vitro* is not significantly impaired by lenalidomide and may even be increased particularly with multiple cytokine stimulation, resulting in the development of granulocytic and megakaryocytic cells. Only at higher doses (10 μM and more), which are unlikely to be achieved *in vivo* during therapy, lenalidomide shows inhibiting effects on CD34+ HPC. Therefore, indirect rather than direct effects on HPC may contribute to suppression of hematopoiesis as observed during treatment with lenalidomid.

1395

CORRELATION BETWEEN HAEMOSIDERIN DEPOSITS IN BONE MARROW BIOPSIES AND SERUM MARKERS OF BODY IRON: VALIDATION OF A SEMIQUANTITATIVE METHOD OF ASSESSMENT OF PERLS STAINING

JM Raya, H Alvarez-Argüelles, T Martín-Santos, S Hernández-Rodríguez, ML Brito, A Martín-Herrera, L Hernández-Nieto
Hospital Universitario de Canarias, La Laguna - Tenerife, Spain

Background and Aims. Although the detection of hemosiderin pigment deposits (HPD) by Perls staining in bone marrow aspirates is a standardized procedure of diagnostic interest, iron deposits assessment in core biopsy specimens is more controversial. Our aim was to analyze the utility of a semiquantitative method to assess the iron content in bone marrow biopsies, comparing it with known serum markers of body iron: serum ferritin (SF) and transferrin saturation (TS). **Methods.** We examined 75 biopsy samples which were performed in our institution between 2004 and 2009, corresponding to diverse pathology. In addition, simultaneous values of SF and ITS were also collected. Eight of the 75 samples (11%) corresponded to patients with polycythemia vera, in which HPD were absent, and they were considered as negative controls. A subjective semiquantitative assessment with a gradient of 0-4 (from absent to abundant HPD), following the Jakkunen´s criteria for marrow aspirates modiffied by Stuart-Smith et al., was used. The preparations were examined independently by two observers. The results of microscopic examination in the biopsy material were compared with the determination of SF and TS, using the Spearman´s correlation coefficient for statistical analysis. **Results.** Perls staining offered the following distribution in the 75 samples: 7 cases (9%) with traces (grade 1), 23 cases (31%) with low deposits (grade 2), 21 cases (28%) moderate (grade 3) - and 16 cases (21%) with abundant deposits (grade 4). As mentioned above, samples of eight cases (11%) suffering from polycythemia vera, unsurprisingly corresponded to grade 0 (no HPD), being used as negative controls. The degree of coincidence in setting the gradation in each sample by two independent observers was 89%. When compared with serum FT and ST patients, we found a statistically significant correlation: the lowest values of FT and IST were directly correlated with a low degree of HPD and the highest values with a higher degree for the same (p<0. 001, both). **Conclusions.** The grading system used in our study is an adjusted method of assessing the iron deposits in marrow core biopsy; it was also reproducible between different observers. We find a close correlation between these deposits and parameters recognized as the most useful for assessing body iron stores, such as SF and TS.

1396

IMPAIRED MIGRATION CAPACITY OF GAUCHER DISEASE MONOCYTES

T Katz[1], N Bettman[2], H Rosenbaum[1], I Avivi[1]
[1]Rambam Health Care Campus, Haifa, Israel
[2]Bruce Rappaport Faculty of Medicine, Technion, Haifa, Israel

Background. Gaucher disease (GD) is a genetic lysosomal storage disorder, related to glucocerebrosidase deficiency. Monocytes and macrophages, normally representing the highest glucocerebrosidase activity amongst hematopoietic cells, tend to accumulate high levels of lysosomal glucocerebroside, resulting in infiltration of the reticuloendothelial system, including the spleen, liver and bone marrow, with foamy glucoceribroside-enriched cells. Monocyte recruitment and differentiation play a critical role in defense mechanisms against pathogens and inflammatory response. The chemokine SDF-1 (CXCL12) and its receptor CXCR4 are involved in regulation of migration of multiple cell types, including monocytes. **Aims.** To investigate the migratory capacity of GD-derived monocytes. **Methods.** Peripheral blood mononuclear cells (PBMCs) were isolated from untreated GD patients and healthy volunteers. The study was approved by the Institutional Review Board (IRB) of the Rambam Health Care Campus and all participants signed informed consent. Transwell migration assay was performed in the presence of either 500 or 1000 ng/ml SDF-1. PBMCs were allowed to migrate from the upper chamber through the polycarbonate membrane over 4 hours. Migrating cells were collected from the bottom chamber and were quantified by flow cytometry within the monocyte gate. Peripheral blood serum SDF-1 levels were determined by quantitative ELISA assay (Quntikine® R&D systems). For the evaluation of surface CXCR4 expression, monocytes were stained with CD184-APC conjugated monoclonal antibody. For glucocerebrosidase inhibition, PBMCs derived from healthy volunteers were incubated for 24 h with Conduritol B epoxide (CBE) (Sigma Aldrich, 500μmol/l) prior to detection of monocyte migration capacity. **Results.** Quantitative assessment of monocytes measuring the number of $CD14^+$ cells demonstrated their decreased amount in GD patients (n=14; an average of 5. $5x10^5$ cells/ml) compared with healthy volunteers (n=13; an average of $9x10^5$ cells/ml; p<0. 05). Migration capacity of monocytes obtained from GD patients (n=9) in response to SDF-1, was significantly lower than that observed in monocytes collected in healthy volunteers (n=6), approaching 6. 3% vs. 14%, p<0. 05, for SDF-1of 500 ng/ml, and 9% vs 21. 8%, p<0. 05, using SDF-1of 1000 ng/ml. CXCR4 surface expression on GD-derived monocytes was found to be lower than that of healthy donor-derived monocytes [44. 5% (n=11) vs. 59. 7% (n=7), p<0. 01]. However, serum levels of SDF-1 were significantly increased in GD patients compared to healthy subjects (2603pg/ml, n=10 vs 2039 pg/ml, n=10; p=0. 004). To evaluate the effect of glucocerebrosidase deficiency on monocyte migration, we assessed the influence of CBE, a specific inhibitor of glucocerebrosidase, on healthy monocytes. Initial treatment with CBE resulted in a 60% decrease in monocyte migration capacity in response to 1000 ng/ml SDF-1 compared to untreated cells. **Conclusions.** SDF1-mediated migration of GD monocytes was found to be impaired. This phenomenon can be partly explained by the low surface CXCR4 levels exhibited by monocytes, probably reflecting a negative feedback mechanism to the increased SDF-1serum levels, seen in these patients. Furthermore, the decreased monocyte migration may be related to the inhibition of glucocerebrosidase activity and occurs very early after inducing its blockade.

1397

INTERLEUKIN-1? PROMOTES THE EXPRESSION OF RECEPTORS FOR THE HEMATOPOIETIC CYTOKINE IN ADULT HUMAN DERMAL FIBROBLASTS

N Shirafuji, R Shirasaki, H Tashiro, T Matsuo, Y Oka, T Yamamoto, N Akiyama, K Kawasugi
Teikyo University, Tokyo, Japan

Background and Aims. In normal hematopoiesis, hematopoietic stem cells and stromal mesenchymal stem cells are reported to express some similar molecules like CD146, and are supposed to have relationship with each other. We recently reported that human interleukin 1β (IL-1β) stimulated bone-marrow stromal myofibroblasts to express a hematopoietic stem cell marker, CD34 (16th EHA, and 53rd ASH meeting). To characterize precisely the effects of IL-1β to the stromal cells, adult human dermal fibroblasts (HDF) were cultured with IL-1β, and the morphological and molecular changes were observed. Materials and **Methods.** HDF were purchased, and cultured in DMEM/F12 medium with 20% KSR with or without recombinant human IL-1β for 3 weeks. Cells were also cultured with IL-1β and recombinant human erythropoietin (EPO). The morphological changes and the expression of specific hematopoiesis-related proteins were analyzed at each 7 day. The concentration of hematopoietic growth factors in the culturing supernatants was also measured. **Results and Discussion.** When HDF were cultured with human IL-1β for 3 weeks, the expression of granulocyte colony-stimulating factor (G-CSF)-receptor, CD13, and SCL increased. When these IL-1β-stimulated cells were cultured in a non-coated dish, cells were floating, and budding of the cells was also observed. When HDF were cultured with IL-1β and EPO, the expression of transcription factor GATA-1 and CEBPA was significantly increased. And CD10, CD20, and CD14 were up-regulated. Vascular endothelial growth factor receptor type-2 also increased to be expressed. In the culturing supernatants IL-6 and G-CSF were secreted significantly. These observations indicate that IL-1β can stimulate to induce HDF toward hematopoietic cells and bone-marrow stromal cells. Now we determine the precise actions of human IL-1β to HDF using NOD/SCID transplantation model *in vivo*.

1398

PATTERN OF EXPRESSION OF BCL11A IN HEMATOLOGICAL MALIGNANCIES

G Pira, G Piras, A Uras, M Murineddu, AD Palmas, M Monne, GC Latte
"San Francesco" Hospital, ASL NUORO, Nuoro, Italy

Background. The B-cell leukemia 11A gene (*BCL11A*) is essential for normal B and T cells differentiation; it encodes a Krüppel-like zinc-finger protein and functions as a transcriptional repressor through its interaction with several proteins including *BCL6*, *COUP-TF II, SIRT1* and *NuRD* complex. Alternative pre-mRNA splicing of *BCL11A* produces multiple isoforms with different functional features and different subcellular and subnuclear compartmentalization. The relative ratios of *BCL11A* isoforms may determine specific transcriptional regulatory properties and may have a role in pathogenesis of leukemia. **Aims**. Here we evaluated the expression pattern of the *BCL11A* transcripts, XL, L, S and XS, in diagnostic samples from patients with hematologic malignancies in order to elucidate the role of *BCL11A* specific pattern of expression in the pathogenesis of hematologic malignancies. **Methods**. The expression levels of *BCL11A* alternative transcripts have been evaluated in 66 primary samples from patients with lymphoid (18 NHL, 27 CLL), and with myeloid malignancy (10 MPN, 11 CML). Relative quantification with primers specifically designed to detect the *BCL11A* isoforms was performed by real-time RT-PCR in comparison to ABL reference gene on ABIPrism 7500 (PE Applied Biosystems, Foster City, CA). Total RNA from tonsils and pool of non diseased bone marrows were used as calibrators. Expression levels were evaluated with the $2^{-\Delta\Delta Ct}$ method and presented as fold changes. To test differences between groups, Anova and Chi-squared tests were used. **Results**. *BCL11A* gene is expressed in all hematologic malignancies at different levels with the highest expression assessed in CLL samples. XL isoform was detected at levels of 1. 7 and 1. 6 fold changes in NHL and CLL cases, respectively. A 5. 6 fold changes expression level was observed in MPN group and 0. 8 fold in CML patients. Comparable levels of the L isoform was detected in NHL, CLL and MPN. The short isoform S showed a 3. 5-fold change levels in CLL and it was similarly expressed in NHL and MPN groups (with 1. 3 and 1. 55-fold expression changes). CML samples resulted in reduced levels of L and S isoforms with 0. 48-fold and 0. 37 fold change in the 100% of the patients. The medium expression levels of XS variant were of 2. 66-fold changes in NHL, 3. 8 in CLL, 3. 2 in MPN and 1. 2-fold in CML group. Lymphoid and myeloid malignancies showed the following pattern of expression L>XS>XL>S and XL=XS>L>S, respectively. Higher levels of L, S and XS transcripts were observed in the lymphoid with respect to the myeloid group with p values of 0. 02, 0. 03 and 0. 028, respectively. **Conclusions**. This study explores the expression pattern of *BCL11A* isoforms in samples from patients with lymphoid and myeloid malignancies. We found a peculiar expression pattern of *BCL11A* transcripts in CML samples. Results might contribute to the knowledge of the role of the transcription factor *BCL11A* in normal and malignant hematopoietic cells.

THE EFFECT OF VITAMIN D THERAPY ON HEMATOLOGICAL INDICES IN CHILDREN WITH VITAMIN D DEFICIENCY

A Soliman, A Elawwa, M Eldabbagh, R Ashour
Hamad Medical Center, Doha, Qatar

Background. Analysis of the non-classic actions of vitamin D(3) has highlighted a wide range of target tissues for the hormone 1,25-dihydroxyvitamin D(3) [1,25(OH)(2)D(3)]. Systemic or locally produced 1,25 (OH)(2)D(3) may play a role in modulating cell development processes such as hematopoiesis and lymphocyte differentiation. **Methods and Objectives.** We examined the effect of vitamin D3 therapy (10,000 IU/kg, IM) on Red cell indices and total and differential WBCs counts in 25 children (age = 6. 6 +/- 2 years) with vitamin D deficiency (Blood level < 15 ng/ml) before after 4 weeks of therapy. **Results.** There was no significant effect on RBCs count or indices before versus after correction of Vitamin D deficiency. Vitamin D therapy did not have any significant effect on WBC nor on the lymphocyte / neutrophil ratio. There was a small but significant increase in the platelet count after vitamin D therapy. **Conclusions.** In children with VDD, vitamin D therapy did not have significant effect on either RBC or WBC indices.

Table 1.

PRELIMINARY Results OF A PROSPECTIVE MULTICENTRIC BRAZILIAN STUDY SHOW AN UNBALANCE OF REGULATORY AND EFFECTOR CD4+ T LYMPHOCYTES PRE- AND POST-TREATMENT IN PATIENTS WITH CLASSICAL HODGKIN LYMPHOMA

O Baiocchi[1], J Silva[1], M Sales[2], A Penna[1], E Chaves[3], P Silva[1], M Assis[1]
[1]Universidade Federal de Sao Paulo, São Paulo, Brazil
[2]Universidade de São Paulo (USP), São Paulo, Brazil
[3]Hospital Santa Marcelina, São Paulo, Brazil

Background. Epstein-Barr virus (EBV) can be found latently infecting Reed-Sternberg (RS) malignant cells in approximately 50% of classical Hodgkin lymphoma (cHL) patients in Brazil. EBV signaling leads to an unbalance between effector and regulatory CD4 T lymphocytes in the tumor microenvironment, promoting the immune evasion of RS malignant cells. However, little is known about these lymphocytes subpopulations in the peripheral blood of patients with cHL and how treatment can modify this regulatory/effector ratio. **Aims.** In this study, we analyzed the regulatory and effector $CD4^+$ subpopulations in peripheral blood in patients with EBV related and non-related cHL and the impact of treatment on these cells. **Methods.** This is an open study and, so far, we included 46 patients. We selected the first 14 patients recruited who finished treatment until July 2011. Blood was drawn 1 to 4 months post-treatment. Seven healthy controls were also included in this study. Quantification of regulatory and effector T lymphocytes was done by flow cytometry using CD3, CD8,

CD4, CD25, Foxp3, CTLA-4, GITR, CD127 and interleukin-17 (IL17) antibodies and correlated to phenotypic and clinical parameters in uni- and multivariate models pre and post-treatment. For the present study, only cHL patients whose histology could be confirmed and EBV association established were studied. All patients were HIV negative and received ABVD chemotherapy protocol. **Results.** From the 14 cHL patients selected, 7 were EBV related and 7 EBV non-related. There was an inverse correlation between regulatory ($CD4^+CTLA4^+$ and $CD4^+GITR^+$) and effector T lymphocytes ($CD4^+IL17^+$) (p<0. 001 and p=0. 006, respectively) pre and post-treatment. Also, $CD4^+CD127^+$ lymphocytes were increased post-treatment, without reaching significant difference (p=0,058). $CD4^+CD25^{high}Foxp3^+$ cells were not different pre and post-treatment, although $CD4^+CD25^{high}CD127^{low}$ cells were decreased post-treatment (p<0. 001). When we stratified patients according to EBV presence on RS cells we found that the EBV related cHL group presented with significant difference in $CD4^+CD25^{high}Foxp3^+$, $CD4^+CTLA4^+$, $CD4^+GITR^+$, $CD4^+CD127^+$ and $CD4^+IL17^+$ T cells pre and post-treatment (p=0. 02, p=0. 03, p<0. 001, p=0. 03, p<0. 001, respectively). Interestingly, when we compared the EBV non-related group no difference was found in any $CD4^+$ subpopulations analyzed. **Conclusions.** Our results demonstrate increased regulatory T lymphocytes in cHL patients pre-treatment and an immunological recovery towards effector $CD4^+IL17^+$ T lymphocytes post-treatment. These results also highlight the importance of EBV in Hodgkin's lymphomagenesis and CD4 homeostasis. Further studies investigating the mechanisms in which EBV acts on this regulatory/effector unbalance will contribute not only to our understanding on the pathogenesis of cHL but also to the development of therapeutic strategies designed to manipulate regulatory activity. Given that the incidence of EBV-related cHL, disease presentation and severity are different in developing countries than in developed ones, we emphasize the importance of this ongoing Brazilian multicentric project

Hodgkin's lymphoma (HL) is regarded as the most typical example of a curable cancer. However, current treatment strategies based on risk stratification and response modulation are not precise enough. In addition, the predictive power of biological and morphological parameters is controversial and so far no prognostic models have reached wide acceptance. The aim of this study was to determine whether tissue based variables could add prognostic value to standard clinical parameters and contribute to better risk stratification of HL patients. We analyzed the prognostic relevance of 8 parameters in 85 advanced stage classical HL patients. Univariate analyses showed that Bcl-2 overexpression by HRS cells (>50%Bcl-2+HRS), elevated number of CD68+ tumor associated macrophages (>25%CD68+TAM), IPS>2, and bulky disease were associated with shorter OS (p=0. 007, p=0. 003 p=0. 000, p=0. 002, respectively) and lower EFS (p=0. 031, p=0. 035, p=0. 004, p=0. 014, respectively). Patients with total involvement of the lymph node by neoplastic and inflammatory cells (TLNI) had decreased OS (p=0. 017). Survivin, active caspase 3 and Ki-67 had no significant impact on both endpoints. The multivariate analysis identified >50%Bcl-2+HRS, >25%CD68+TAM, TLNI, IPS>2 and bulky disease as independent prognostic factors for OS (p=0. 025, p=0. 042, p=0. 003, p=0. 000, p=0. 003), and increased CD68+TAM, IPS>2 and bulky disease for EFS (p=0. 044, p=0. 009, p=0. 018), respectively. Based on the cumulative score of unfavorable prognostic factors for OS, a prognostic model was designed stratifying patients into 4 risk groups (low with 0-1, intermediate 2, high 3, very high 4-5 risk factors) and progressively worse 5-year OS (100%, 78%, 45%, 0% respectively, p<0. 001). Our findings support the concept of combining molecular and pathomorphological parameters with clinical data, in order to identify patients who might benefit from more effective primary treatment.

[3]Haematology Department, DAP, University of Bari, (BA), Italy
[4]Department of Medical Transfusion, Az. Osp. "Card. G. Panico", Tricase (LE), Italy

Background. Several prospective clinical trials using Rituximab to treat classical Hodgkin lymphoma (cHL) patients (pts) are ongoing. The rationale of its use includes Hodgkin and Reed Sternberg (HRC) cells CD20 expression, but also elimination of CD20 positive reactive B cells wich play a role in supporting HRS cells survival and in host immune response suppression. **Aims.** In our study, we evaluated the intratumoral B and T reactive infiltrate and correlated it with presenting features and clinical outcome in high risk cHL. **Methods.** Flowcytomether immunophenotyping of lymph node samples was performed at diagnosis in 11 immunocompetent advance stage cHL pts treated in our institution between January 2010 and December 2011. All pts received ABVD as first line chemotherapy. **Results.** Median age at diagnosis was 38,45 years (range 16-75), 8 pts (72,7%) were male, 3 (27,27%) had a bulky disease, 8 (72,72%) B symptoms, 2 (18,18%) had spleen involvement, 4(36,36%) extranodal disease,5 (45,45%) pts had an IPS score ≥ 3. The histology was nodular sclerosis in 7 (63,63%) and mixed cellularity in 4 (36,36%) pts (Table 1). The mean count of CD20 (CD20+) and CD3 (CD3+) positive reactive cells in our specimens were 14442,6/mL (range 52,3-52080) and 43073,16/mL (range 428-126480) respectively. Using an Anova-one-way analysis, a lower CD20+ mean was observed in pts with IPS≥3, spleen involvement, extranodal disease and B symptoms. In patients with**sym**ptoms, spleen involvement (p<0,05) and extranodal disease, was recorded an higher mean CD3+ to CD20+ cells ratio (ratio). These means differences are not significant at the 0,05 level because of low numbers of pts. At a median follow-up of 11,95 months, 9 pts had reached a complete remission (CR), 2 pts had experienced a relapse/refractory disease and had also a positive PET after two courses of chemotherapy (PET2). A lower CD20+ mean was also recordered in pts with positive PET2 and relapse/refractory disease (p=ns). Moreover the K to Lambda ratio (K/L ratio) was higher in pts with relapse/refractory disease and bulky disease (p<0,05). In one patient with primary chemoresistant disease, the K/L ratio was equal to 8, suggesting the presence of a monoclonal B cells infiltrate associated with poor prognosis. **Conclusions.** CD20+ reactive cells in the tumor microenvironment may be a target in new therapeutic approach and could have a prognostic impact. Moreover many studies describe circulating clonotipic B cells in cHL suggesting they may be the initianing cells for HL. In our experience the presence of a higher K/L ratio is statistically significant associated with relapse/refractory and bulky disease. Further investigations are needed to confirm the prognostic role of CD20+ reactive infiltrate and if flow-cytometric analysis is a usefull tool.

LYMPHONODE FLOW IMMUNOPHENOTYPE OF CD4+CD8-CD26-CD38+ LYMPHOCYTES IN HODGKIN LYMPHOMA

G Tagariello, R Di Gaetano, B Callegari, R Sartori, N Maschio, P Radossi, E Scarpa
Castelfranco Veneto Hospital, Castelfranco Veneto, Italy

Introduction. Hodgkin's lymphoma (HL) is characterized by a small population of neoplastic Reed-Sternberg (RS) cells and extensive infiammatory infiltrate of lymphocytes, plasmacells, eosinophils, and histiocytes similar to that found also in reactive samples. The nature of this infiltrate in HL is largely known: lym-

phocytes surrounding the RS cells are mostly CD4+ T that express activation markers and lack of CD26, an absence potentially relevant to the impaired immune response observed in the clinical course of HL. Flow cytometry (FC) has failed to identify RS cells in HL within the lymphonode biopsy, but it has been occasionally used to examine the lymphocytes surrounding neoplastic cells for distinguish HL infiltrates from reactive lymphoid hyperplasia (RLH) and to predict immune status of such those patients. Our approach was based on the evaluation of FC T CD3+CD4+ in HL infiltrating lymphocytes to compare them to the picture found in RLH and in normal lymphonodes (NL). **Methods.** fresh mechanically disaggregated cell suspensions (10 NL, 65 HL and 52 RLH) were stained with a set of monoclonal antibodies to lymphoid antigens (CD45 pan-leukocytes, CD19 for B lymphocytes, T-cell antigens such as CD3, CD4, CD8 and CD38 as markers of activation and CD26) and then analyzed by FC. **Results.** HL is richer in T-cell lymphocytes than RLH (CD3/CD19 2,9 vs 1,8) and in both groups CD4/CD8 ratio (respectively 6,5 and 6,9) is higher than in NL (CD4/CD8<3) . CD4+CD26+ is higher in NL and RHL, while is much lower in HL (respectively 70, 50 and 20; p < 0,0005). CD4+CD38+ was also higher in HL (43+17) compared to RLH (18+12). When we have analyzed together $CD4^+CD26^-CD8^-CD38^+$, the difference between HL (38%) and RLH (9%) was significantly different (p < 0,001). **Conclusions.** Since a $CD4^+CD26^-CD8^-CD38^+$ profile appears restricted to infiltrate in HL, immunophenotyping may represent a useful tool for speedy diagnosis (or suspect) and the detection of the anergic status in patients with Hodgkin lymphoma.

1404

OUTCOME AND PROGNOSTIC FACTORS IN PATIENTS WITH HODGKIN LYMPHOMA (HL) WHO REMAIN PET/CT-POSITIVE AFTER ABVD COMBINATION CHEMOTHERAPY: POTENTIAL APPLICATIONS FOR THE DESIGN OF SUBSEQUENT TREATMENT

[5]Department of Nuclear Medicine, Biomedical Research Foundation,Academy of Athens, Athens, Greece

Background. Patients with HL who remain PET/CT(+) after ABVD combination chemotherapy have a relatively unfavorable prognosis. Prognostic factors for the outcome of PET/CT(+) patients, especially after additional radiotherapy, have not been systematically studied. However, such factors may have a role in decision making between additional RT vs. salvage chemotherapy and autologous stem cell transplantation (ASCT). **Aims.** We aimed to identify predictive factors for the outcome of HL patients who remain PET/CT(+) after ABVD chemotherapy and are planned to receive additional RT. **Methods.** 311 patients with HL were treated with 4-8 cycles of ABVD from December 2004 to early 2011: 245 responders (CR, CRu, PR) underwent PET/CT after ABVD; 38 responders did not due to technical reasons. There were missing data for 6 patients, 3 died prematurely and 19 rapidly developed progressive disease prior to PET/CT assessment. Among 245 responders, 52 (21%) were PET/CT(+) and were retrospectively analyzed in terms of disease progression. **Results.** Characteristics of the 52 PET/CT(+) patients were as follows: median age 31. 5 years (15-73), 58% males, 77% nodular sclerosis, 27% stage III/IV, 19% B-symptoms, 10% ≥5 involved sites, 31% anemia, 18% significant leukocytosis, 10% severe lymphocytopenia, 56% ESR ≥50 mm/h, 31% elevated LDH, 39% albumin <4g/dL, 23% IPS≥3. The median SUVmax was 5. 2 (IQR 3. 7-8. 5) without any correlation with the above parameters. The majority of patients were irradiated (42/52 or 81%; median dose 3620 cGy; range 2880-4600). Ten (10) patients were not irradiated (too extensive disease 2, rapid progression 1, medical decision 1, refusal 1, findings judged borderline by treating physician 5). After a median follow-up of 29 months (2-67), 22/52 patients have experienced disease progression. The median SUVmax was 6. 7 versus 4. 1 for patients with and without disease progression respectively (p=0. 02). Progression free survival (PFS) was 73%, 63%, 51% and 46% at 1, 2, 3 and 4-5 years after PET/CT respectively. The 3-year PFS was 59% vs. 24% for patients with SUVmax < and ≥9 respectively (p=0. 0005). Among other factors, only anemia significantly affected PFS in univariate analysis (p=0. 01). In multivariate analysis, SUVmax ≥9 was the only independent prognostic factor for PFS (hazard ratio 3. 1; 95% CI: 1. 1-9. 2; p=0. 037) obscuring the significance of anemia (p=0. 17). The significance of SUVmax ≥9 was maintained, if the analysis was restricted to the 42 irradiated patients (3-year PFS 69% vs. 30%, p=0. 004). In 14 of the irradiated patients, a repeated PET/CT scan converted to negative: only 2/14 have relapsed for a 3-year PFS of 83%. **Summary and Conclusions.** Despite additional radiotherapy, patients with HL who remain PET/CT(+) after ABVD have a 50-60% risk of relapse over the next 4 years. Patients with lower SUVmax (optimal cut-off to be determined) may benefit more from additional radiotherapy, while more intense uptake was associated with an even higher risk of disease progression. These findings may facilitate the selection of optimal treatment in this patient subgroup with uncertain prognosis. The potential contribution of conventional prognostic parameters needs further investigation. Patients rendered PET/CT(-) after RT appear to be at lower risk of relapse.

1405

BRENTUXIMAB VEDOTINE IN HEAVILY TREATED HODGKIN LYMPHOMA, A RETROSPECTIVE SINGLE CENTER STUDY ON 30 PATIENTS

P Brice, H Monjanel, M Malphettes, L Deville, C Ram Wolff, MD Venon, P Franchi, C Thieblemont, C Benet, PL Zinzani
Hopital Saint Louis, Paris, France

Hodgkin lymphoma (HL) is a curable disease in up to 80% of patients but for the remaining relapsed patients after autologous stem cell transplantation (ASCT) no standard therapy is available. Anaplasic large cell lymphoma (ALCL) patients in relapse after CHOP have also a poor outcome. CD30 is expressed on the surface of HRS cells and in ALCL. Minimal clinical activity has been reported with unconjugated anti-CD30 antibodies. To enhance antitumor activity, the antitubulin agent monomethyl auristatin E was attached to the CD30-specific monoclonal antibody producing the antibody-drug conjugate brentuximab vedotin (BV). The phase I showed promising results (Younes NEJM 2010) and high reponse rates in two phase II studies both in HL & ALCL (Advani & Chen ASH 2010). **Aims**. This retrospective study was designed to evaluate the activity of single-agent BV in unselected rel/ref HL & ALCL in a single center given with the same indication as the phase II. Our primary outcomes are response rate, toxicity and, progression free survival (PFS) (calculated from the first dose of BV to progression). PATIENTS and **Methods**. From July 2009 to july 2011, 30 patients (14M/16F) with a median age of 31 years (19 -69y) received at least one dose of BV for 20 HL & 10 ALCL. Nine patients were in protocols and21 inthe name patient program . First line chemotherapy (CT) was ABVD in 17 cases and CHOP in 7, 11 patients were primary refractory and 7 patients received radiation therapy (RT). The median number of previous CT lines was at 4 (1 - 8) and 20/20 patients with HL received ASCT (two times in 10 cases) and 2 allotransplant . Before the first dose of BV, 21/30 patients were “on”chemotherapy and 9 had relapsed after response. Response was evaluated after 4 cycles with PET in 16 cases. **Results**. Two patients with refractory ALCL received only one course of BV and died rapidly from progressive disease. 28 patients are evaluable for response and PFS. The median number of cycles was 7 (1-16) and 5 patients are remaining on therapy. Haematological toxicity was mild with no transfusion and no growth factor support. 3 patients had grade 2 sensitive neuropathy, one hepatic toxicity rapidly reversible and one pulmonary toxicity when given shortly after mediastinal RT. The maximal response was CR/CRu in14 ptsand 4 PR with an overall response rate of 64% with higher CR rates in ALCL. The median PFS was at 8 months (range 3 -34+) and four patients with ALCL had received subsequent consolidation (ASCT n = 3 & NMT n =1), only 3 patients with HL had an allogeneic donor and none were able to receive the transplant. At the stopping date (December 2011), 6 patients had died from the disease and 13 had received further therapy. **Conclusions.** BV is effective in this heavily pretreated group of patients (mostly end-stage HL) even if the PFS is short because many responding patients relapsed after and all HL were heavily pretreated with 50 % having received two transplant.

1406

ABSOLUTE MONOCYTE COUNT AND CHEMORESISTANT HODGKIN'S LYMPHOMA

T Garrido, F Trigo, J Guimarães
Hospital São João, Porto, Portugal

Background. It has recently been described an association between a high absolute monocyte count (AMC) and low absolute lymphocyte/absolute monocyte ratio (LMR) in peripheral blood at diagnosis with inferior survival in Hodgkin's Lymphoma (HL) (Porrata *et al*. 2012). A connection between an

increased number of tumour-associated macrophages (TAM) and treatment failure had already been established (Steidl *et al.* 2010). Theoretically, the AMC is an estimate of the TAM. **Aims.** To correlate chemoresistant disease (CRD) to these new biomarkers and other well-known HL prognostic factors. **Methods.** We accessed the available full blood count at diagnosis and medical records of 95 patients with HL, negative for human immunodeficiency virus, diagnosed in our center from 2000 to 2010. We defined CRD as failure of first-line chemotherapy, high AMC as ≥ 900/mm^3 and low LMR as <1. 1. **Results.** The median age at diagnosis was 30 years-old [15;83] and 54. 7% of the patients were male. The median follow-up was 58 months [1;131]. All patients were treated with either ABVD (92) or BEACOPP (3) regimens, based on Ann Arbor staging system and International Prognostic Score (IPS) stratification, with or without radiotherapy. Eighteen (18. 9%) patients were submitted to autologous stem cell transplantation (ASCT) due to CRD (11) or relapse (7). Nine (9. 5%) patients died from disease progression/relapse (6), non-lymphoma related causes (2) and secondary neoplasm (1). Fifteen (15. 8%) patients had CRD after first-line treatment: 11 were submitted to ASCT, nine (81. 8%) of which achieved complete remission (CR) and 2 died prior to the 100th day of ASCT; 1 died before ASCT was performed; and 3 are currently receiving second-line treatments. Within the CRD group, thirteen (86. 6%) patients had high AMC (8), low LMR (2) or both (3). Eleven (52. 3%) out of 21 patients with high AMC had CRD, and seventy (94. 6%) out of 74 patients with low AMC did not (p<0. 0001). The mean AMC was superior (1. 00 vs 0. 64; p<0. 0001) for the CRD patients. CRD was also associated to advanced stage disease (III/IV) (p=0. 008), high white blood cell count (≥15x10^9/L) (p=0. 019), low LMR (p=0. 016), IPS ≥3 (p=0. 014) and hypoalbuminemia (<40g/L) (p=0. 04); but not with sex, age, histological classification, absolute lymphocyte count, haemoglobin or LDH levels at diagnosis. On multivariate analysis, AMC ≥ 900/mm^3 was highly and independently associated with CRD (OR: 16. 4[2. 8; 94. 2]; p=0. 002). Out of the 11 patients who relapsed from CR, only two (18. 2%) had high AMC (1 also relapsed after ASCT, and 1 other died). As expected, there was worse 5-year overall survival (OS) in patients with CRD (77. 5% vs 94. 2%; p=0. 048) and high AMC (78. 5% vs 95. 1%; p=0. 01) but no differences in progression-free survival (PFS). **Conclusions.** In our group of patients, a high AMC was strongly associated with CRD, but not with relapse from CR. Most of these chemoresistant patients, however, respond to ASCT, hence the lack of impact on PFS. Although this is a small series, we suggest that AMC may predict which patients will not respond to standard fist-line chemotherapy.

1407

ANALYSIS OF BONE MARROW REACTIVE CHANGES AND PET/CT DIFFUSE BONE MARROW UPTAKE IN STAGING OF HODGKIN LYMPHOMA

A Colpo[1], E De March[1], F Lessi[1], M Gregianin[2], M Ermani[1], R Zambello[1], L Alessandrini[1], L Iaria[1], F Marino[1], G Binotto[1], G Semenzato[1], L Trentin[1]
[1]University of Padua, Padua, Italy
[2]Istituto Oncologico Veneto (IOV)-IRCCS, Padua, Italy

Background. Bone marrow aspirate (BMA) and bone marrow biopsy (BMB) are usually performed in the staging assessment of Hodgkin Lymphoma (HL) patients. Despite a low incidence of bone marrow infiltration (BMI), a high percentage of patients is characterized by non-specific lesions, that could be related to high level of serum cytokines. These non-specific lesions indicate a reactive condition that is likely to account for the FDG-diffuse bone marrow uptake (BMU) frequently observed at initial staging imaging and that does not seem to be related to malignant involvement. **Aims.** To evaluate the significance of bone marrow reactive changes and FDG-diffuse BMU in initial staging of HL. **Methods.** 92 HL patients (median age 33 years, range: 16-79, 44 male, 48 female) undergoing staging BMA, BMB and PET/CT were included in this retrospective study. BMA and BMB data were obtained from the files of the Hematology and Pathology Units and reviewed by expert pathologists. PET/CT results were reviewed by a Nuclear Medicine expert. BMU was assessed visually according to liver uptake (0=below liver uptake, 1=corresponding to liver uptake, 2=above liver uptake), as previously described (Salaun PY et al., Eur J Nucl Med Mol Imaging, 2009). Clinical and laboratory characteristics were collected. **Results.** 92. 4% of patients had classical HL and 7. 6% had nodular lymphocyte predominant HL. 65. 2% had advanced stage disease. In 32. 6% of cases IPS was equal or higher than 3. BMB was positive for BMI in 6. 5% of patients, whereas focal skeletal FDG-uptake was seen in 9. 8%. BMB and PET/CT showed concordant results in 90. 2% of cases. BMA showed hypercellular marrow in 44. 6%, disgranulopoiesis in 61. 9%, myeloid hyperplasia in 5. 4%, eosinophil hyperplasia 29. 3%, dyserythropoiesis in 8. 7%, erythroid hyperplasia in 15. 2%, reactive lymphocytosis in 4. 3% and higher values of plasma cells in 10. 9% of smears. Overall bone marrow biopsy cellularity was 60. 2%, significantly higher than that of a control group (48%, p=0. 01). There was no statistical difference between the age distribution in the patient group and the controls (p=0. 8). Diffuse BMU was detected in 51. 6% of scans (grade 0: 8. 3%, grade 1: 29. 2%, grade 2: 62. 5%). Univariate analysis found a correlation between BMU and bone marrow biopsy cellularity (p=0. 05), hypercellular marrow at BMA (p=0. 02), myeloid hyperplasia (p=0. 003), erythroid hyperplasia (p<0. 001), WBC values (p=0. 02) and CRP level (p=0. 05). No statistical link was found between BMU and other factors analysed, in particular BMI, detected either by BMB or by PET/CT. After a median follow up of 36 months (range 7 - 88), the 2-year OS and PFS were 93. 1% and 82. 4%, respectively. By univariate analysis diserythropoiesis (p=0. 03), erythroid hyperplasia (p=0. 01), elevated CRP level (p=0. 03), PET-2 results (p=0. 07) and advanced stage (p=0. 04) were predictors of lower PFS, whereas only a positive PET-2 displayed an independent prognostic significance in the multivariate analysis (p<0. 001). Diserythropoiesis showed a trend toward significance (p= 0. 06, see Figure 1). **Conclusions.** Diffusely increased BMU is frequently seen at initial staging in HL patients and it is due to reactive changes seen at BMA and BMB. BMA findings, such as diserythropoiesis, are predictors of outcome.

[7]H Universitario de Santiga, Santiago de Compostela, Spain
[8]H Fundacion Alcorcon, Madrid, Spain
[9]H Puerta de Hierro, Madrid, Spain

Introduction. Lymphomatous meningitis (LM) in patients with Diffuse Large B Cell Lymphoma (DLBCL) is usually an early complication and with poor prognosis. Risk factors have been previously identified for this complication. DepoCyte is an extended released liposomal cytarabine formulation (LC) which has demonstrated better efficacy compared to standard cytarabine for the treatment of LM in one randomized clinical trial. **Aims.** The aim of this study is to evaluate efficacy and safety of intrathecal LC as prophylaxis of LM in DLBCL patients at high risk of CNS involvement. **Methods.** A retrospective study was carried out on 26 Spanish sites including patients diagnose with DLBCL and at risk of LM - defined by the presence of at least one of the following: retroperitoneal mass ≥10 cm; Waldeyer ring, sinus, vertebral or bone, and testicular involvement; LDH more than twice the upper normal limit; bone marrow involvement > 30% and serology VIH+. All patients had received LC as IT prophylaxis for LM in the period April 2005 - June 2011. Main endpoints were effectiveness (leptomeningeal involvement rate) and safety of the IT prophylaxis. **Results.** Data from 135 patients were analyzed. Baseline characteristics were: Mean age 57 ± 16 years (range: 18-80 years). Males/Female: 89/46;Ann Arborstage IV 71%. Systemic chemotherapy was the standard of the different

hospitals, all alkylating based regimens, being R-CHOP the most frequent one (96%). LC was administered as intrathecal prophylactic treatment for LM in all patients in doses of 50 mg. 124 patients completed the IT prophylaxis treatment with a mean of 2. 6 ± 0. 9 (range: 1-6) administrations of LC (11 patients died before finish prophylaxis), and with a median follow up of 19 months (range: 3-60 months) we reported no cases of LM. Just two patients (1. 48%) had CNS progression, both developed CNS parenchymal mass at the same time of systemic progression. We reported no adverse event in 89 (66%) patients. All adverse events were reversible, being headache the most common toxic effect 39 (29%) cases, and only 10% of patients had grade III or IV toxicity. Chemical arachnoiditis prophylaxis was given to 107 patients. **Conclusions.** This retrospective study shows that CNS prophylaxis with intrathecal LC in DLBCL patients at high risk of CNS involvement is effective and well tolerated.

1409

GEMCITABINE, DEXAMETHASONE AND CISPLATIN IS EFFECTIVE AS A SALVAGE CHEMOTHERAPY REGIMEN IN RELAPSED OR REFRACTORY HODGKIN'S DISEASE PRIOR TO ASCT

CM Precupanu, D Senecal, S Lissandre, M Delain, C Dartigeas, S Radesi, Y Venel, L Benboubker, O Herault, P Colombat, E Gyan
CHU Tours, Tours, France

Background. patients with refractory or relapsed Hodgkin's lymphoma are best treated with an approach involving high-dose chemotherapy and autologous stem cell transplantation (HDT-ASCT) However, in the absence of randomized trials of salvage regimens, the standard salvage option is unknown. In this context, the choice of a salvage regimen is guided by efficacy and toxicity. **Patients and Methods.** We retrospectively reviewed the data of our 33 consecutive patients with relapsed or refractory Hodgkin's lymphoma (median age 40, range 19-68) treated with the GDP regimen (gemcitabine 1000 mg/m2 on day 1 and 8, dexamethasone 40 mg orally days 1-4 and cisplatin 33 mg /m2/day days 1-3). Response was defined according to the IWG 2007 criteria, using PET-scan evaluation. **Results.** The overall response rate (CR + partial remission) was 63%. Eighteen (54,5%) patients achieved complete remission; three (9 %) partial remission and twelve (36,36%) patients had stable disease or progression . Twenty-two patients (66,6%) underwent HDT-ASCT. With median follow-up of 5 years, the OS was 82% for patients with complete or partial remission, and 41 % for patients with progressive disease (p = 0. 15). Age < 45 years, treatment with HDT-ASCT, and response to GDP was associated a significantly longer OS (p< 0,0001; p=0,001; p=0,015,respectively). **Conclusions.** GDP is a active regimen that compares favourably with previously published salvage regimens. Further prospective randomized studies in the setting or relapsed/refractory regimens would greatly help the therapeutic choice in this difficult patient population.

PROGNOSTIC VALUE OF PRETRANSPLANT FDG-PET IN PATIENTS WITH REFRACTORY AND RELAPSED HODGKIN LYMPHOMA TREATED WITH HIGH-DOSE CHEMOTHERAPY AND STEM CELL TRANSPLANTATION

B Puccini[1], L Rigacci[1], S Guidi[1], C Nozzoli[1], G Benelli[1], I Donnini[1], A Gozzini[1], B Bartolozzi[1], A Benci[2], P Bernardeschi[2], F Innocenti[1], A Bosi[1]
[1]AOU Careggi, Florence, Italy
[2]Hematology, Arezzo, Italy

Autologous stem cell transplantation (ASCT) is considered the standard salvage therapy for relapsed or refractory Hodgkin disease (HD). Recently publications have confirmed the role of 18F-fluoro-deoxyglucose positron emission tomography (FDG-PET) about the predictive value before ASCT. In this retrospective study we want to assess the predictive value of FDG-PET performed before ASCT for the clinical outcome such as progression-free survival (PFS) and overall survival (OS) in pts with HD. Between January 2005 and August 2011 in our Bone Marrow Transplant Unit were performed 41 autologous stem cell transplantation (ASCT) in patients with relapsed or refractory Hodgkin lymphoma. The median age was 31 years (range 18-58 years); at time of transplant 21 pts (51%) were in complete remission (CR), 5 pts (12%) in partial remission (PR) and 15 pts (37%) with refractory disease. The FDG-PET before ASCT was negative in 21 pts (51%) and positive in 20 pts (49%). After a median period of observation of 24 months (range 0-76 months) the overall survival (OS) was 94% in the FDG-PET-negative group and 31% in the FDG-PET positive group (p: 0. 0002). The progression free survival (PFS) was 95% and 33% (p: 0. 000) respectively for pts with FDG-PET negative and positive after a median time of observation of 14 months (range 0-76 months). After three months form ASCT 37 out 41 patients performed FDG-PET for restaging, the FDG-PET was negative in 26 pts (70%) and positive in 11 pts (30%). The PFS was 88% in the FDG-PET-negative group and 10% in the FDG-PET positive group (p: 0. 0000). The OS was 90% and 37% respectively in FDG-PET negative and FDG-PET positive scans (p:0. 0008). Sixteen out 20 pts FDG-PET pretrasplant positive performed an FDG-PET after transplant resulted negative in six pts (37. 5%). In multivariate analysis the FDG-PET pre ASCT and status disease pre-ASCT improved progression free survival (p 0. 000). Our results confirm that in patients with relapsed/refractory HL a negative pre-transplant FDG-PET is associated with a better OS and PFS. About one third of patients with a positive pre-transplant FDG-PET could be recovered by high dose therapy and transplant. Patients with persistent positive FDG-PET after transplantation are associated with a poor prognosis and should be considered for tandem ASCT, allotransplant or new drugs.

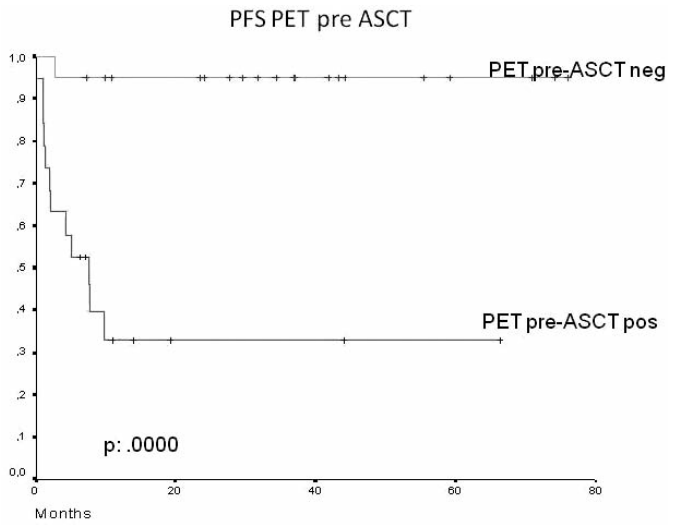

Figure 1.

1411

FEASIBILITY AND EFFICACY OF BCVPP REGIMEN IN VERY ELDERLY PATIENTS WITH HODGKIN'S LYMPHOMA. A SINGLE CENTER EXPERIENCE ON NINETEEN PATIENTS

S Ferrari[1], A Peli[1], A Re[1], A Antoniazzi[1], E Borlenghi[1], C Crippa[1], S Fisogni[2], F Facchetti[2], G Rossi[1]
[1]Hematology, Spedali Civili, Brescia, Italy
[2]Pathology I, Spedali Civili, Brescia, Italy

Background. While some age-adapted modifications of ABVD regimen have been proposed for elderly Hodgkin's lymphoma (HL) patients (pts), no specific chemotherapy regimens have yet been recommended for very elderly or elderly pts with severe comorbidities. The five-drug-combination BCVPP (Carmustine, Cyclophosphamide, Vinblastine, Procarbazine and Prednisone) has the advantage of avoiding anthracyclins and being potentially effective and tolerated in HL pts. **Aims.** We report on the therapeutic efficacy and tolerability of BCVPP regimen in a group of very elderly (≥80y) and elderly pts with severe comorbities unfit for anthracyclin-containing chemotherapy. **Methods.** Eligibility criteria included age older than 80, severe comorbidities (one grade 4 or at least 3 grade 3 according to Cumulative Illness Rating Score for Geriatrics - CIRS-G), relapse/refractoriness to ABVD or other regimens. BCVPP (Carmustine 100 mg/sqm iv d 1, Cyclophosphamide 600 mg/sqm iv d 1, Vinblastine 5 mg/smq iv d 1, Procarbazine 100 mg/sqm d 1-10 po, Prednisone 60 mg/sqm d 1-10 po) was administered every 42 days for a maximum of 6 cycles. Reduction of the doses was applied for adverse events and intolerance. **Results.** Nineteen pts have been treated (M/F ratio 1/1. 8). Median age was 77y (65-88). Eleven pts were unfit for dementia (1), grade-3 comorbidity (4) or grade-4 comorbidity (6) according to CIRS-G, 8 were aged ≥80y. Sixteen pts were treated upfront, while one was refractory/intolerant to low dose ABVD, one relapsed after ABVD and MOPP and one after radiotherapy for localized HL. Histology was nodular sclerosis in 10 pts, mixed cellularity in 5, lymphocytic depletion in 1 and classic NOS in 3. EBV LMP-1 was detected by immunohistochemistry in RS cells of 4/7 cases. Fourteen pts (74%) had advanced disease (7 stage III and 7 stage IV). Eleven pts (58%) presented with B symptoms and 12 (63%) with International Prognostic Score>2. The median number of cycles administered was 5 (range 1-6). In 11/19 (58%) pts doses were reduced. The mean administered dose of any drug was >75%. Hematologic grade 3-4 toxi-

city was seen in 8 (42%) pts (neutropenia in 7 and neutropenia and thrombocytopenia in 1). Nine pts experienced infectious complications: 5 pneumonia, 4 FUO, 1 CMV reactivation, 1 soft tissue infection and 1 disseminated HZV infection with meningoencephalitis 6 and 11 months after the end of therapy respectively. One pt died of ischemic stroke and 1 was lost to follow-up after 1 cycle. Of the 17 evaluable pts, ORR was 94% (12 CR/Cru, 4 PR, 1 NR). Relapse occurred in 4 pts after a median of 22 months (17-49). Three pts died of lymphoma, 4 of toxicity (3 pneumonia and 1 carmustine-related interstitial lung fibrosis), 2 of unrelated causes (1 ischemic stroke and 1 respiratory distress). Ten are alive (2 with progressive disease) after a median follow-up of 20 months (2-171). The actuarial 3-year PFS and OS were 39. 4% and 54% respectively. Our data are similar to those published in a recent series of elderly but younger pts. **Conclusions.** BCVPP regimen provides an effective and feasible therapeutic option for very elderly patients with HL.

1412

RELAPSED OR REFRACTORY (REL/REF) HODGKIN LYMPHOMA (HL) POST-AUTOLOGOUS STEM CELL TRANSPLANT (ASCT) - A RARE CANCER WITH NO STANDARD OF CARE

J Eaton[1], S Baculea[1], Y Liu[2], H Huang[2], C Hatton[3]
[1]Oxford Outcomes, Oxford, United Kingdom
[2]Millennium Pharmaceuticals, Inc., Cambridge, United States of America
[3]Churchill Hospital, Oxford, United Kingdom

Background. HL is the most common CD30-positive malignancy and accounts for ~10% of all lymphomas. Rel/ref HL post-ASCT is extremely rare, occurring in only 3-9% of HL patients in EU5. As a result of the small patient numbers, research into the epidemiology and disease burden of rel/ref HL post-ASCT is very limited. **Aims.** To describe the burden of HL post-ASCT in terms of its epidemiology and humanistic and economic burden, as well as to present the current treatment options for patients in this setting. **Methods.** A literature search for HL epidemiology data was conducted. A systematic literature review of clinical effectiveness and safety of available therapies in rel/ref HL post-ASCT was conducted in Medline/Medline in Process, Embase and the Cochrane Library, and targeted searches were conducted for HL clinical guidelines from institutions and organizations. Systematic reviews of economic and health-related quality of life studies in HL were also performed. **Results.** In the EU and European Economic Area the prevalence of HL has been estimated to range from 0. 017% to 0. 035%. This rate is below the orphan designation threshold in the EU (prevalence <5 cases/10,000 population). In EU5 countries there are an estimated 500 patients per year with rel/ref HL post-ASCT who would be eligible for further treatment. There is currently no consensus regarding recommendations from clinical guidelines for the treatment of patients with rel/ref HL post-ASCT. Current options, which include chemotherapy and allogeneic stem cell transplant (allo-SCT), are associated with high rates of toxicity or are limited by high-risk of treatment-related mortality and donor availability. Recent evidence suggests that 27-36% of patients with rel/ref HL post-ASCT receive allo-SCT compared to only 6-8% who receive a second ASCT. The median overall survival (OS) for patients who relapse following, or are refractory to, ASCT is 2. 4 years, while outcomes for patients who are refractory to ASCT or relapse within 1 year of therapy are particularly poor (median OS 1. 2 years). HL is the second most costly cancer overall, and has been estimated to be the most costly cancer in men and women of working age. HL affects adults who are economically active, with a median age at time of diagnosis of 38 years. As a result, the impact of lost productivity is likely to be substantial. In terms of the humanistic burden, many rel/ref HL patients suffer from debilitating B-symptoms, which include fever, night sweats and weight loss. The presence of B-symptoms is a marker for more advanced disease as it indicates systemic involvement. HL patients report chronic fatigue, decreased social, emotional and physical functioning, increased psychological distress, decreased sexual function and general health, and an impaired ability to carry out everyday activities. **Conclusions.** Rel/ref HL post-ASCT is rare, with no standard of care. These patients have a poor disease prognosis along with a significant humanistic and economic burden. Therefore, effective treatment approaches with a good safety profile are required.

1413

RESPONSE TO SALVAGE CHEMOTHERAPY CONDITIONS OUTCOME OF PATIENTS WITH HODKGIN'S LYMPHOMA SUBMITTED TO HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS TRANSPLANTATION

J Pinto, I Carvalhais, A Carneiro, F Príncipe, J Guimarães
Hospital S. Joao, Porto, Portugal

The majority of patients with Hodgkin's Lymphoma (HL) has sustainable complete remission with first-line chemotherapy. However, some patients relapse after therapy and pose a significant therapeutic challenge. High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) is a recognised second line therapy for HL. This retrospective study aimed to review the outcomes of ASCT in relapsed/refractory HL patients and the role of salvage therapy before ASCT. Data was collected from 41 consecutive patients that underwent ASCT between 1999 and 2011. All patients had the diagnosis of relapsed/refractory HL. The histological HL classification was Nodular Sclerosing (86. 2%) or Mixed-Cellularity (13. 8%) subtype and the majority (66%) had an Ann Arbor stage III or IV, at time of diagnosis. ESHAP (82. 4%) or ICE (17. 6%) was the salvage chemotherapy given. The overall response rate (ORR) after treatment was 86. 8% (84. 6% with ESHAP and 91. 6% with ICE, p=. 488) and 13. 2% had refractory disease. Subsequently, all patients were treated with high-dose chemotherapy (BEAM) followed by ASCT. The median age at transplant was 31(range:21-67). Median time to neutrophil and platelet recovery was 10 and 13 days, respectively. At day +100 post ASCT, two patients (4. 9%) maintained refractory disease and two patients (4. 9%) had died of sepsis - all these patients presented progressive disease at time of ASCT. The median follow-up was 29 months. The 5-year overall survival (OS) was 60. 3% +/-9. 6% (74. 2% for ESHAP-treated patients) and 5-year progression free survival (PFS) was 64. 8% +/-8. 3% (77. 3% for ESHAP-treated patients). Refractory disease at time of transplant was associated with significantly worse OS (5-year OS: chemo-sensitivity 63. 7% vs. refractory-disease 40%;p=. 010). On univariate analysis, no significant differences were observed regarding OS of gender, age, stage, time from diagnosis to ASCT (<12 vs. >12 months) and salvage chemotherapy regimen (ESHAP vs. ICE)In summary, ORR after salvage chemotherapy was high and this therapeutic approach followed by BEAM-ASCT is associated with a favourable 5-yr OS rate. No significant difference was observed between patients treated with ESHAP or ICE although there is a trend for better OS and PFS in ESHAP-treated patients. The optimal choice of salvage therapy remains unclear, because different regimens have not been directly evaluated in randomized trials. The ideal salvage regimen should produce a high response and not impair the ability to mobilize and collect peripheral blood stem cell for ASCT. Based in our experience, patients who had refractory disease at time of transplant might not benefit of high dose chemotherapy and ASCT; other novel therapeutic options should be pursued for this small group of patients.

1414

LONG-TERM OUTCOME OF ADOLESCENTS AND YOUNG ADULTS WITH HODGKIN LYMPHOMA TREATED IN ACCORDANCE TO THE MODIFIED PEDIATRIC PROTOCOL DAL-HD-90: A SINGLE CENTER EXPERIENCE IN RUSSIA

V Semochkin[1], E Arshanskay[2], V Ivanova[2], V Sotnikov[3], M Bobkova[1], V Lunin[2], S Kulikova[1], A Rumiantsev[1]
[1]Federal Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation
[2]City Clinical Hospital n. a. S. P. Botkin, Moscow, Russian Federation
[3]Russian Scientific Center of Roentgenoradiology, Moscow, Russian Federation

Background. About 3200 new cases of Hodgkin lymphoma (HL) diagnosed every year in Russia. HL occurs in all ages but adolescents and young adults (AYA) are most often affected. The standard of care for adolescents is undefined. Currently, they are inconsistently treated with either pediatric or adult protocols. The information about treatment of young adults with pediatric protocols is missing. **Aims.** The aim of this study was to evaluate the long-term results of therapy of AYA with HL by dint of the pediatric protocol in our center. **Methods.** During 03. 1995-12. 2009 in this study 99 (m-38, f-61) patients with median age 19. 2 years (range 15-29) with de novo HL was enrolled. All patients were treated according to the modified pediatric protocol DAL-HD-90 which is a combined-modality treatment regimen. Patients are allocated to three treatment groups (TGs) based on early- (TG1, n=11), intermediate- (TG2, n=34), and advanced-stage (TG3, n=54) disease. Involved field radiotherapy (IFRT) follows after a chemotherapy. The original protocol is modified in the following positions: (1) oral procarbazine was replaced by intravenous dacarbazine which was administered at 1 and 14 days at a dose of 375 mg/m^2; (2) young adults received vinblastine vice vincristine; (3) all patients with advanced stages of HL receiving 2 cycles of ODPA independently from gender, and (4) doses of IFRT were increased from 20-25 Gy to 30 Gy. The subjects with a poor response after 2 cycles of ODPA (stabilization or disease progression) have changed treatment on more intensive adult schedule of BEACOPP escalated. This change of therapy was considered as an event in the calculation of event free survival (EFS). The cutoff for data analysis was 12. 2011. EFS and overall survival (OS) were analyzed using the Kaplan-Meier method and the log-rank test. **Results.** Forty-nine adolescents (median - 16. 5, range 15-18 years) and 50 young adults (median - 19. 6, range 19-29 years) were available for the analysis. Median follow-up time was 9. 5 years. One patient lost to follow-up. Seven patients died

and all deaths were related to HL progression or relapse. Second malignancies occurred in 2 girls (ovarian and thyroid carcinomas). The probabilities of EFS and OS at 10 years (10y) were 91±9% and 91±9% (TG1), 88 ± 6% and 94±4% (TG2), and 73±7% and 92±4% (TG3), respectively. The probabilities of 10y-EFS in TG(1+2) patients were 89±5% versus 73±7% in TG3 patients (P=0. 095). As a result of poor early response after two cycles of ODPA the therapy was changed on the adult schedule BEACOPP escalated for 7 patients (TG1-1, TG2-1, TG3-5). Five patients in this group are alive with continuous complete response (CCR). Ten-year EFS and OS rates did not differ significantly between adolescents and young adults: EFS - 82±6% and 78±6%, respectively (P=0. 54); OS - 92±4% and 94±4%, respectively (P=0. 72). **Conclusions.** Our data confirm the rationality to use pediatric protocols in adolescents up to 18 years with HL. The outcome for young adults did not fundamentally different from that of adolescents.

1415

IPHOSPHAMIDE, GEMCITABINE, VINORELBINE (IGEV) CHEMOTHERAPY PLUS AUTOLOGOUS STEM CELL TRANSPLANTATION AS SALVAGE TREATMENT OF RELAPSED/REFRACTORY HODGKIN LYMPHOMA PEDIATRIC PATIENTS

A Sau, G La Barba, V Cecinati, D Onofrillo, S Falorio, G Fioritoni, F Angrilli
'Spirito Santo' Civic Hospital, Pescara, Italy

Background. Although most patients with Hodgkin Lymphoma (HL) will be cured with initial therapy, approximately 10-25% of patients relapse after first-line therapy or are primary refractory. Because of lack of randomized studies comparing various salvage regimens, it is not possible to identify one as superior to another. Thus, it is critical to select a salvage regimen that has the potential to induce a high response rate with low nonhematologic toxicity. **Aims.** To retrospectively evaluate the outcome of children affected by relapsed/refractory HL treated with salvage treatment consisting of IGEV chemotherapy plus a*utologous peripheral* blood *stem cell* transplantation (APBSCT) in our Institution. **Methods.** Pediatric patients, previously enrolled in AIEOP (Associazione Italiana Oncoematologia Pediatrica) LH 2004 protocol who relapsed or were primary refractory after first-line therapy received salvage treatment consisting of iphosphamide based regimen (IGEV) for 3/4 courses. Patients in complete remission (CR) PET/CT scan negative were submitted to APBSCT with BEAM conditioning regimen. PET/CT positive patients recieved a second line salvage treatment prior APBSCT. All patients received primary prophylaxis of febrile neutropenia with granulocyte *colony-stimulating* factor.

Table 1. Patient characteristics.

Patients	6 (n)	100 (%)
age yr, mean (range)		
at diagnosis	14.8 (11-17)	
at APBSCT	16.3 (12-18)	
Stage at diagnosis		
I-II	3	50
III-IV	3	50
AIEOP LH 2004 protocol risk group		
Gruop 1	0	0
Gruop 2	2	33
Group 3	4	66
Initial chemotherapy		
n. 4 COPP/ABV	4	33
n. 6 COPP/ABV	2	66
Status at salvage treatment		
Refractory	3	50
Relapsed	3	50

Results. From May 2008 to August 2011 six consecutive relapsed/primary refractory HL patients were treated. Clinical characteristics of patients are reported in Table 1. After IGEV regimen 4 patients achieved CR PET/CT negative (67%) and 2 patients were PET/CT positive (33%). The last 2 patients became PET/CT negative after second line salvage treatment consisting of *platinum-based* chemotherapy (ESHAP or DHAP). All patients received APBSCT. None of the patients experienced nonhematological toxicities. One patient, refractory to first line therapy, relapsed after 10 months from APBSCT and received BEACOPP salvage treatment followed by allogeneic bone marrow transplantation. All patients are alive and in CR PET/CT negative after a median follow-up of 11 months (range 5-45), so far. **Conclusions.** High dose chemotherapy followed by APBSCT has resulted in long-term disease-free survival in patients with refractory/relapsed HL. Response to pre-transplant salvage chemotherapy is the most important prognostic factor for outcome in this setting. IGEV is safe and effective salvage chemotherapy in adult HL patients, but there aren't data on pediatric safety and efficacy of this regimen. In our experience IGEV chemotherapy seems very effective in pediatric patients inducing high proportion of pre-transplant CR without relevant toxicities. Further investigations are warranted in a large cohort of patients in order to define the value of IGEV regimen in children affected by refractory/relapsed HL.

1416

THE IMPORTANCE OF PET/CT AS METHOD OF EVALUATION OF EARLY RESPONSE TO TREATMENT IN LH

C Gallegos[1], B De Rueda[1], JM Grasa[1], A Banso[2], P Giraldo[1]
[1]Miguel Servet Hospital, Zaragoza, Spain
[2]Losano Blesa Hospital, Saragosa, Spain

Background. The current standard treatment has increased the long-term survival from Hodgkin Lymphoma (HL) to more than 80% . However, the long-term adverse effects of treatment, such as secondary malignancies, cardiovascular and pulmonary complications, requires a risk-adapted lymphoma treatment with a early and accurate assessment of prognosis. **Aims.** The aim of this study is asses the importance of PET/CT as method of evaluation of early response to treatment in LH. **Methods.** Retrospective-prospective analytical study of a cohort of 61 patients diagnosed with Hodgkin Lymphoma at The Miguel Servet´s Hospital (Zaragoza, Spain), during the period 2002-2011. Treatment: Patients received first-line treatment based on the extent and manifestations of the disease, ABVD for stage I,II and IIIA and BEACOPP14 for stages IIIB and IV. Image study: All patients went under evaluation with PET/CT after 2 cycles of chemotherapy and at the end of 6 cycles of treatment. Hypermetabolic activity was considered positive when SUV > 2. 5. **Results.** Of 60 total patients, 58 were evaluated; 62 % (36) were men and 38 % (22) woman; the average age was 35. 2 ± 12. 9 years. For extra medical reasons no all patients were evaluated with PET/CT after 2 cycles of chemotherapy (total: 9). In 72. 4 % (42) of patients, early PET/CT performed after two cycles demonstrated non hypermetabolic disease activity. Of these 42 patients, 90. 4 % (38) were PET/CT negative at end of complete treatment with a progression free survival (PFS) at 24 months of 71 % vs 0 % for the group that had early PET/CT positive (P<0. 05); 47 patients had no disease activity as evidenced by CT/PET at end of treatment, in this group 80. 8 % (38) showed a localized stage at diagnosis; 11 patients had CT/PET positive at end of complete treatment, of this group 90. 9 % (10) showed an advanced stage at diagnosis. **Conclusions.** The PET/CT as a method for assessing the early response to LH treatment is useful, to be a strong predictor in PFS in HL. In cases of HL with localized stages at diagnosis and an interim CT/PET negative after two cycles of chemotherapy it could consider not doing a second study at end of treatment.

1417

RISK PROFILE OF RELAPSED/REFRACTORY HODGKIN LYMPHOMA PATIENTS TREATED WITH HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANT - A SINGLE CENTER EXPERIENCE

M Todorovic[1], B Balint[2], B Andjelic[1], J Bila[1], I Elezovic[1], D Antic[1], D Vujic[3], D Veljkovic[3], N Kraguljac-Kurtovic[1], D Sefer[1], D Stanisavljevic[4], B Mihaljevic[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Military Medical Academy, Belgrade, Serbia
[3]Institute for Mother and Children dr Vukan Cupic, Belgrade, Serbia
[4]Institute for Medical Statistics and Informatics, Faculty of Medicine, Belgrade, Serbia

Background. High dose therapy and autologous stem cell transplantat (SCT) has become the optimal therapeutic approach in patients with refractory and relapsed Hodgkin's lymphoma (HL). Historically, patients who relapsed after a full course of chemotherapy had a low chance for cure with second-line

treatment, with the duration of initial remission as significant predictor of subsequent response and relapse-free survival. There is intent to cure the disease in all stages, and long-term survival exceeds 85 percent for all stages. **Aims.** The aim of this study was to evaluate predictive value of clinical and laboratory parameters, as well the clinical course of relapsed and refractory patients with HL who were treated with high dose chemotherapy followed by autologous SCT. **Methods.** This retrospective study included 45 (25F/20M) patients - aged 30. 9 (20-46) years - with relapsed or refractory HL who were initially treated with ABVD therapy during the period 2005-2010. In the course of relapse or refractory disease, all patients received DHAP as salvage, and BEAM as conditioning regimen due to autologous SCT. **Results.** There were 13 patients in II CS defined as early unfavorable group, while 32 patients had advanced disease in III and IV CS. Treatment outcome on the initial ABVD therapy was as follows: CR in 19 (42. 2%), PR in 3 (6. 7%), SD in 11 (24. 4%), and PD in 12 (26. 7%) of patients. Among clinical characteristics bulky mediastinal mass was present in 60%, lymphadenopathy in 88. 8%, splenomegaly in 13. 3%, hepatomegaly in 8. 9%, and lung infiltration in 35. 6% of patients. Laboratory parameters demonstrated anaemia in 55. 6%, lekocytosis in 42. 2%, as well as lymphopenia and trombocytosis in 71. 1% patients. Low albumins were present in 71. 1%, and elevated ESR, CRP and beta2microglobulin in more than 90% of patients. Median duration of mobilzation (G-CSF 10µg/kgbm) was 6 days, CD34+ count was 8. 97 range 2-29 (x10E6/kgbm), median CD34+ cell viability was 79% (65-95%). Median duration of period for WBC engrftment was 13. 9 (9-19) days, and for PLT was 13. 1 (9-20) days. Deaths related to treatment toxicity were not recorded. Survival after auto SCT was 31 (1-45) months, and overall survival (OS) was 86 (12-144) months. Overall response rate at d+100 was 68. 8%, with 48% of CR. Survival analysis revealed that patients who achieved CR had significantly longer OS (p=0. 0001). Also, leukocytosis (p=0. 0001), lymphopenia (p=0. 026), trombocytosis (p=0. 0009), and anemia (p=0. 0185) had negative impact on OS. There was a strong trend toward worse OS in patients with bulky mediastinal tumor (p=0. 065). Using multivariate Cox regression analysis the most predictive prognostic factor for OS was treatment outcome at day +100. **Summary and Conclusions.** High-dose therapy and autologous SCT are adequate and safe therapeutic options for poor prognosis refractory/relapsed patients with HL, and posttransplant CR at day +100 could be the most predictive factor for long term survival.

Table 1.

Characteristics	No. of Patients	%
Total No. of patients	56

MICAFUNGIN AS PROPHYLAXIS OF INVASIVE FUNGAL INFECTION IN PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

DS Hong[1], SH Kim[1], J Yun[2], HJ Kim[2], KH Kim[2], S Bae[2], NS Lee[2], KT Lee[2], SK Park[2], JH Won[2], HS Park[2]

[1]Soonchunhyang University Bucheon Hospital, Bucheon-si, South-Korea
[2]Soonchunhyang University Hospital, Bucheon-si, South-Korea

Invasive fungal infection (IFI) such as candidiasis and mold infections cause significant morbidity and mortality in hematopoietic stem cell transplantation (HSCT). Although prophylactic antifungal therapy with fluconazole has become the standard care for these patients, it has been associated with the emergence of fluconazole-resistant Candida infections. Additionally, fluconazole is not reliably effective against invasive aspergillosis. Micafungin is a antifungal agent of the Echinocandin class. This drug have potent antifungal activity against both Candida spp. and Aspergillus spp. Moreover, micafungin is also effective against Fluconazole-resistant Candida albicans. Between January and December 2010, we conducted a retrospective study to evaluate the usefulness of the administration of micafungin (Mycamine®) as a prophylactic antifungal therapy for patients undergoing HSCT. The primary objective was to evaluate the treatment success, which was defined as the absence of proven, or probable IFI through the end of therapy and as the absence of proven or probable IFI through the end of the 4-week period after treatment . The secondary objective was incidence of micafungin-related toxicity. Adult patients with hematological and non-hematological malignancy undergoing auto & allo-HSCT were eligible for the study. Micafungin was started at a daily dose of 50 mg once a day intravenously over 1 hour from day 1 after HSCT. Therapy was continued until 3 days after hematological engraftment (defined as an absolute neutrophil count of over 500/uL after the nadir). Fifty-six patients were evaluated in this study. The median durations of administration of micafungin were 18 days (range 10-45 days). Prophylactic success was achieved in 55 patients (98. 2% of the 56 evaluable patients). One patient were diagnosed as having probable invasive pulmonary aspergillosis. Micafungin was well tolerated with no evidence of significant toxic effects in all cases. Prophylactic micafungin (50mg/day) is effective and safe in patients undergoing HSCT. Mild to moderate hepatic impairment does not warrant changes in dose. A multicenter, randomized study to determine the appropriate effective Dose of micafungin is needed.

1419

EVALUATE THE LABORATORY AND RADIOLOGICAL EXAMINATION FOR PREDICTING OUTCOME AND ADJUSTING EMPIRICAL ANTIFUNGAL THERAPY IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A MULTICENTER, RETROSPECTIVE STUDY

Y Ji[1], H Xiaojun[1], X Lanping[2], L Daihong[1]

[1]Institute of Hematology, Peking University, Beijing, China
[2]Institute of hematology, Peking University, Beijing, China

Background. Due to the difficulty of early diagnosis of invasive fungal diseases (IFDs), empirical antifungal therapy has been the standard practice for immunosuppressed patients with persistent fever after receiving broad-spectrum antibiotics, although more than a half of antifungal agents may be overused. In addition, there is no globally-recognized course of empirical treatment, which may result in continuing use of extra antifungal agents for a long period. **Aims.** In our retrospective multicenter study, we evaluate the laboratory and radiological evidence for predicting higher response rate of empirical antifungal therapy. Meanwhile, the proper duration of empirical treatment would be explored. **Methods.** From fifteen medical centers in China, 376 patients with hematological malignancies were enrolled. When persistent fever (T>37. 5ºC, >24hrs) was developed in patients, a diagnostic work-up was performed to identify the reason of fever, including culture of blood or samples from suspected infected sites, serum GM detection, radiological examination, etc. . Evidence of IFDs referred to any positive results of the above tests. As the initiation of antifungal therapy was determined by physicians, all patients were divided into three groups: group A contained patients who received preemptive antifungal therapy, group B contained patients who received empirical antifungal therapy and acquired evidence of IFDs within two weeks after initiation of antifungal treatment, and group C contained other patients who also received empirical therapy but were not included in group B. The duration of antifungal therapy and the agents were also decided by physicians in accordance with the guidelines. And the results of treatment were evaluated as response or failure according to the patients' signs and symptoms and the improvement of imaging lesions. **Results.** 87, 105 and 184 patients were allocated to group A, B and C respectively. The efficacy of treatment in group A was higher than that in groups B+C (59. 8% vs. 34. 9%, *P*<0. 001). And the efficacy in group B was significantly higher than that in group B (63. 8% vs. 18. 5%, *P*<0. 001). Among patients after intensive chemotherapy, the efficacy of preemptive strategy was higher than that in empirical strategy (64. 8% vs. 32. 0%, *P*<0. 001),

while they were comparatively close in patients undergoing HSCT (51. 5% vs. 39. 2%, *P*=0. 203). The median time from the onset of fever to initiation of antifungal therapy in groups A, B and C were 5, 4 and 4 days respectively, and the mean start time among patients who responded to antifungal treatment was not earlier than that in patients with failure outcome (4. 5±1. 72 vs. 4. 6±1. 97, *P*=0. 505). In group C, the low incidence of IFDs (one probable and two possible IFDs) and low efficacy of empirical antifungal therapy may suggest that more than two weeks of empirical antifungal therapy would not further benefit these patients. **Conclusions.** Positive evidence of IFDs could predict the higher response rate of empirical antifungal therapy. And the preemptive strategy may be more suitable for patients with relatively low incidence of IFDs, while for patients with high risks of IFDs the empirical antifungal therapy should be emphasized.

1420

MICONAZOLE MUCOADHESIVE BUCCAL TABLET IN PREVENTION OF HIGH DOSE THERAPY WITH AUTOLOGOUS STEM CELL TRANSPLANTATION (HDT/ASCT)-INDUCED MUCOSITIS - A PILOT STUDY

C Orvain, MP Moles-Moreau, M Mercier, S Francois, F Moal, E Parot-Schinkel, N Ifrah, M Hunault-Berger, A Tanguy-Schmidt
CHU d'Angers, Angers, France

Background. Mucositis is a major cause of morbidity in HDT/ASCT patients, especially responsible for pain, dysphagia, malnutrition and potential infectious portal of entry. Microbial colonization has a great implication in the mucositis pathogenetic pathway and so, yeast prevention with oral amphotericin B suspensions are usually given to these patients even tough there is no clear consensus. Miconazole mucoadhesive buccal tablet, a continuously released and well-tolerated anti-mycosis has shown efficiency in oral yeast treatment and could be an alternative to oral amphotericin B suspensions, whose tolerance can be difficult. **Aims.** To analyze tolerance and efficiency of miconazole mucoadhesive buccal tablet in mucositis prevention, in substitute to oral amphotericin B suspensions, the current reference treatment in our center. **Methods.** We compared 60 patients from whom informed consent was obtained and who received daily miconazole mucoadhesive buccal tablet from November 2008 to August 2011 with 44 control patients who received oral amphotericin B suspensions three times a day (one gargled dose and one swallowed dose) from January 2006 to the implementation of the study, treated in our center with HDT/ASCT. These patients were treated for either acute myeloid leukaemia with busulphan-melphalan, lymphoma with a BEAM conditioning regimen or for myeloma with high-dose melphalan. All patients received simultaneously chlorhexidine and bicarbonate based mouthwash. Neutropenia prevention usually consisted of filgrastim infusions for control patients and pegfilgrastim infusions for miconazole patients. No patient received antibiotic prophylaxis.

Table 1.

	Control group (n=44)	Miconazole group (n=60)	p
Age	49,11	51,28	0,2
Female patients	45%	43%	0,81
Acute myeloid leukemia	6,82%	3,33%	
Myeloma	38,64%	56,67%	
Lymphoma	54,55%	40,00%	0,17
Total hospital stay (days)	23,36	22,3	0,13
Hospital stay after engraftment (days)	16,36	15,3	0,09
Total CD34 (10^6/kg)	5,16	5,1	0,45
Neutropenia <500/mm3 (days)	8,07	7,42	0,13
Leucopenia <1000/mm3 (days)	8,11	7,77	0,28
Nefopam (days)	5,73	5,4	0,37
Nefopam doses	389	437	0,31
Morphine (days)	4,93	3,85	0,12
Morphine doses	125	121	0,44
Parenteral nutrition (days)	9,95	8,98	0,15
IV Antibiotics (days)	12,34	7,8	<0,0001
Antiviral (days)	10,5	16	<0,0001
IV Antifungal (days)	3,55	1,41	0,02
Yeast stool contamination	45%	37%	0,36

Results. The patients' characteristics were similar in both groups except a trend to more lymphoma patients in the control group. Miconazole patients tended to have less morphine use, shorter morphine use and shorter parenteral nutrition use in favour of less severe mucositis. Also, there was shorter antibiotic use which can be accredited to fewer infections in the miconazole group secondary to mucositis prevention with the acknowledgment that local practice changes can be considered as confusing factors (pegfilgrastim use, antiviral prophylaxis started on admission date in miconazole patients). Fewer intravenous antifungal treatment, less yeast stool contamination and no candidemia occurrence support that miconazole is a good fungal control option. The reduction of all of these parameters is responsible for a shorter hospital stay in the miconazole group. After sub-group analysis, these results were especially confirmed in myeloma patients with shorter hospital stay (14. 5 versus 16. 6 days after engraftment; p=0. 004), shorter morphine use (1. 82 versus 3. 59 days; p=0. 08), shorter parenteral nutrition use (7. 74 versus 8. 05 days; p=0. 38) and shorter antibiotic use (4. 29 versus 10. 59 days; p<0,0001) with similar mean neutropenia (<500/mm3) duration (5. 65 versus 5. 35 days; p=0. 19) whereas there was no improvement on any parameters in lymphoma patients. Six patients discontinued miconazole, and were not included in the analysis, three due to the impossibility of obtaining stable buccal adhesion, and three following trial withdrawal due to the investigator's discretion. **Conclusions.** Miconazole mucoadhesive buccal tablets, well tolerated in our patients, can be a cost-equivalent alternative to oral amphotericin B suspensions in preventing HDT/ASCT-induced mucositis with less intravenous antifungal use, especially in myeloma patients receiving high-dose melphalan conditioning regimen.

1421

PREVENTING INVASIVE FUNGAL INFECTIONS (IFI) USING ANTI-MOLD AZOLE ANTIFUNGALS IN PATIENTS RECEIVING HYPERCVAD

J Bednarik, J Cerny, M Ramanathan, N Fortier, L Shanahan, L Petrillo, C Cellulare, E Lichtman, L Spring, Z Zhou, R Nath
UMass Memorial Medical Center, Worcester, United States of America

Background. Fluconazole has long been the agent of choice for fungal prophylaxis in patients receiving intensive chemotherapy for hematologic malignancies, such as HyperCVAD. Invasive fungal infections secondary to mold are becoming an increasing issue in this population. Newer agents such as posaconazole and voriconazole have shown superior activity against mold in patients undergoing stem cell transplantation or induction chemotherapy for acute myeloid leukemia and are promising options in preventing IFI. **Aims.** 1) Determine incidence of IFI during HyperCVAD; 2) Evaluate efficacy of different antifungal agents fluconazole, posaconazole, and voriconazole in preventing IFI. **Methods.** A retrospective analysis of patients treated with HyperCVAD at our center between October 2006 and December 2011 was performed under an IRB approved protocol. Patients were evaluated until death, relapse, transplant, or completion of HyperCVAD therapy. Rituximab was given in patients who had CD20+ disease. Patients were given fungal prophylaxis with fluconazole, posaconazole or voriconazole. Due to drug interactions with vincristine, patients were instructed to hold their antifungal starting 24 hours prior to vincristine, restarting antifungal therapy 24 hours after administration of vincristine. **Results.** We identified and evaluated thirty-three patients. Median age was 57(range: 19-75), 64% ALL, 18% MCL, and 18% were other hematologic malignancies (CLL, MM, BL, DLCL, PTCL). Patients received a total of 146 cycles (median 5). Nine (27%) patients received fluconazole prophylaxis, while 24 (63%) received either voriconazole or posaconazole prophylaxis. Overall incidence of proven IFI was 6% (2/33), occurring only in the group who received fluconazole as prophylaxis (22%, p=0. 068). One case of IFI was speciated as *Aureobasidium pullulans* (patient alive after surgery, liposomal Amphotericin B and Allogeneic transplant), and the second case was *Fusarium* (patient died). There were no cases of resistant IFIs in patients receiving posaconazole or voriconazole. Increases in LFTs occurred in the 11% of patients, but were transient and related to treatment with chemotherapy. No patients developed grade 3/4 elevations in hepatic function. Drug interactions between azole antifungals and vincristine are a major concern which can lead to serious complications and delays in therapy. The common practice at our institution is to hold azole antifungals 24 hours prior to, during and 24 hours after vincristine is administered. Of our patients, 25/33 were evaluated for neuropathy. Nine of 25 (36%) patients developed grade 1/2 neuropathy. No patient developed grade 3 or higher neuropathy. **Summary and Conclusions.** The overall rate of IFI at our institution is lower than previously reported in the literature in groups using fluconazole alone as prophylaxis. The rate of breakthrough IFI in patients receiving antifungal prophylaxis was higher in the group using fluconazole (22% vs. 0%). This data shows IFIs are successfully prevented in patients receiving HyperCVAD by using broad spectrum antifungal agents.

1422

A TEAM-BASED, MULTIDISCIPLINARY APPROACH TO REDUCING PERIPHERALLY-INSERTED CENTRAL CATHETERS (PICC) COMPLICATIONS IN HAEMATOLOGICAL PATIENTS:A PROSPECTIVE STUDY

N Natalia, J Garcia Suarez, H Guillén, Y Martín, M Callejas, JJ Gil Fernández, E Magro, E Flores, M Calero, M Lopez Rubio, C Casco, T Pascual, JJ Arranz, MT Diaz, C Burgaleta
Hospital Principe de Asturias, Alcala de Henares, Spain

Introduction. Few data is available on clinicalefficiencyand safety of Peripherally-Inserted Central Catheters (PICC)in haematological patients (HP). Preliminary

data suggests a highrate ofPICC-relatedcomplicationsinthisgroup ofpatients. To highlightthe role of PICC in HP receivingintensive chemotherapy,a prospective studyof PICCwas conducted in our Unitfrom November 2010 to February 2012 to determine theincidence of PICC-relatedcomplicationsafter evidence-based interventions. **Methods.** Amultidisciplinary program was implemented involving healthcare professionals who insert and maintain PICCs:1) maximum sterile precautions during catheter insertion and aftercare;2)chlorhexidine preparation for skin antisepsis; 3) confirmed PICC tip placement by chest radiography; 4) information from weekly PICC line review;5) health-care managers allocating resources, and 6) patients capable of assisting (i. e. patient education regarding provision of their own catheter care). **Results.** Twenty-seven consecutive 5-Frenchpolyurethane double lumen PICC (Bard Access Systems, Salt Lake City, Utah, USA)were insertedin 20patients [M/F 13/7, median age 46. 25 years, range 11-77] for a total of 3750 days (average 138. 88, range 4-420+). Five patients had ALL, 5 AML, 6 aggressive NHL, 1 MDS/MPD, 2 MM; as to disease phase, 13 PICCs were atonset, 7 in complete response (5 consolidation and 2 intensify phase), and 7 at disease relapse. PICCs were successfully inserted in all cases (most of them in via cephalic vein). At insertion,platelets count was < 50 x 10^9/l in 6/27 cases (22. 2%), andWBC count was < 1. 0 x 10^9/l in 2/27 cases (7. 41%). Overall thirty PICC-relatedcomplications developed in 70. 37%of the catheters (5. 06 events/1000 catheter days). In order, frequency complications were: a) 20 (66. 6%) mechanical complications (5. 33/1000 catheter days), b) 9 (30%) PICC-related infections (2. 4/1000 catheter days), and c) 1 (3. 3%) symptomaticPICC-related thrombosis (0. 27/1000 catheter days);[see Table 1 for details]. Twenty-one PICCs were removed after an average period of 126 days (range 4-232); the reasons were: completion of treatment in 9 patients, death unrelatedto PICC in 3, voluntary retirement in 1 and catheter-related complications in 8 (3for local infection, 1 for thrombosis and 4 for accidental extraction). Six PICCs (48. 5%) are still in use for an averageperiod of 147,16 days (range16 - 295). Our PICC complications rate appears favourably with published series on non-tunneled and noncuffed central venouscatheters (CVC-related symptomaticthrombosis up to 25% and CVC-related infections 4. 68-6. 61events/1000 catheter days)in the haematological setting. **Conclusions.** Our data indicates that a multidisciplinarycompetence program to PICC seemsto be a useful, safe and promising alternative to conventionalCVC for haematological patients receiving intensive chemotherapy.

Table 1.

Complications	Number (%)	Per 1000 CVC days
PICCs related infections:	9 (30%)	2.4
- Definite CRBSI	0	0

EVALUATION OF BONE MARROW EXAMINATION IN PATIENTS WITH HEPATITIS C VIRUS INFECTION

A Asfour, M Ayoub, N Magid, A El Saharty
Ain shams university, Cairo, Egypt

Background. Over 170 million individuals are infected with Hepatitis **C** virus worldwide **.** Hepatitis **C** prevalence is higher in some countries in Africa and Asia. The report published by the Egyptian Demographic Health Survey [EDHS] stated that in Egypt there is an overall Anti-HCV antibody prevalence of 14. 7% [estimated to be about 12 million individuals] and the number of Egyptians estimated to be chronically infected was 9. 8% [about 8 million individuals] . Several extrahepatic manifestations have been reported in the natural history of hepatitis C virus infection. Up to 40-74% of patients infected with HCV might develop at least one extrahepatic manifestation during the course of their disease**.** Hematological manifestations are among the commonest extrahepatic manifestations of HCV infection. Patients with HCV infection can develop peripheral blood cell count abnormalities that are commonly attributed to hypersplenism, antiviral therapy, decreased thrombopoietin levels, and/or autoimmune mechanisms **.** Mixed cryoglobulinemias and lymphoproliferative diseases have an increased incidence with chronic hepatitis C. **Aims.** Evaluation of bone marrow findings in patients infected with hepatitis C virus presenting with peripheral blood cytopenias. **Methods.** This study was conducted on 35 patients with chronic hepatitis C virus infection presenting with monocytopenia,bicytopenia or pancytopenia. Patients were subjected to the following: history taking, physical examination and laboratory investigations including:Complete blood picture, Erythrocyte Sedimentation Rate(ESR) Lactate Dehydrogenase enzyme(LDH). Hepatitis C markers (Anti-HCV Ab using third generation ELISA technique) HCV RNA: using real -time PCR when possible. Bone marrow aspiration for morphological examination for all patients. Bone marrow trephine biopsy for histopathological examination when indicated. Overall BM cellularity, cellularity of myeloid, erythroid and megakaryocytes series. and BM infiltration, fibrosis, dysplasia and iron stores were assessed. Flowcytometry and cytogenetics in selected patients. Patients under interferon therapy, or with hepatocellular carcinoma were excluded from the study. **Results.** The spectrum of hematological findings among recruited patients was as follows11 cases (31. 44%) suffered from B-Non Hodgkins Lymphoma, 4 cases (11. 43%) suffered from Immune thrombocytoprnia, 1case(2. 86%) suffered from anemia of chronic disease, 1 case(2. 86%) suffered from aplastic anemia, 2 cases (5. 71%) suffered from Auto Immune Hemolytic Anemia, 3 cases (8. 57%) suffered from acute myeloid leukemias, 3 cases (8. 57%) suffered from acute lymphoblastic leukemia, 1 case (2. 86%) with chronic lymphocytic leukemia, 3 cases (8. 57%) with hypercellular bone marrow secondary to hypersplenism, 1 case (2. 86%) suffered from myelofibrosis, 3 cases (8. 57%) found to be MDS, 1 case (2. 86%) found to be Evan's syndrome and 1 case (2. 86%) with sideroblastic anemia. **Conclusions.** There was a wide variety of hematological diseases in patients with hepatitis C with peripheral cytopenias. B-NHL is the most frequently detected problem among recruited patients(31%) There were significant data involving relation of bone marrow dysplasia and fibrosis to age of patients

1424

COMPLIANCE WITH FEBRILE NEUTROPENIA MANAGEMENT AN EXPERIENCE FROM QATAR

M Yassin, H El-AYoubi, R Kamzoul, H El-Ghazouani
Hamad Medical Corporation, Doha, Qatar

Background. Febrile neutropenia (FN) is associated with significant morbidity and mortality. Managing infections in neutropenic patients remains a dynamic process, making necessary timely and efficient empirical antibiotic therapy. The implementation of critical pathways has been suggested as a strategy to improve clinical effectiveness implementation of a critical pathway seems to be an effective strategy to improve clinical outcomes in patients hospitalized with FN. **Aims.** This study evaluated the compliance with an institutional critical pathway for the management of FN and the impact on clinical outcomes at Al-Amal cancer centre in Qatar from January 2007 to December 2011 and presented with FN (186 episodes). **Patients and Methods.** We performed a cohort study that retrospectively included patients hospitalized from January 2009 to December 2011 (186 episodes). FN protocol for management of high risk patients consist of initial assessment on day 0 (History, physical exam, CBC, U&E, blood C/S, one from each lumens of the central line and one peripheral, coagulation profile, CRP, midstream urine culture, sputum for M/C/S, feces for M/C/S, swab for wound all wounds, CX-ray, taping fluid if any. Initial Antibiotics consists of Amikacin & Tazocin, and Vancomycin is considered in particular situations. Reassessment on day 3 if the patient remains a febrile, and if etiology identified to adjust to most appropriate treatment, continue antibiotic to complete the course of therapy, monitor resolution of infection, discontinue antibiotic if ANC > 0. 5. And if there is no etiology identified: continue same antibiotics, if clinically stable and no evidence of infection discontinue the antibiotics if ANC > 0. 5. If febrile, add vancomycin and consider early introduction of liposomal amphotherecin B, if patient is blastic or has prolonged neutropenia. A reassessment on day 5 continue same antibiotic until ANC > 0. 5 and stop antimicrobial with in 48 hours if the patient is afebrile. If patient remains febrile, monitor ANC and if its < 0. 5, blood culture negative, workup possible fungal infection, add liposomal amphotherecin B. **Results.** before the critical pathway was introduced. This study showed low rate of full compliance 142 episodes (76%) versus 44 episodes (24%) of violations after critical pathway implementation. The major violation of the protocol occurs mainly in ER. **Conclusions.** Despite the moderate adherence observed, we recorded decrease in-hospital all-cause mortality in the sample studied after protocol implementation. Implementation of a critical pathway seems to be an effective strategy to improve clinical outcomes in patients hospitalized with FN.

1425

IMPACT OF BLOOD STREAM INFECTIONS AND PSEUDOMONAS AERUGINOSA IN A HAEMATOLOGICAL DEPARTMENT: THE EXPERIENCE OF 3 YEARS

F Farina, E Casartelli, S Realini, L Verga, E Pogliani
Ospedale S. Gerardo, Monza, Italy

Background. Mortality rate of bloodstream infections (BSI) among neutropenic haematological patients ranges between 5-10%. Multi-drug-resistant pathogen has been associated with increased mortality. **Aims.** To determine the impact of

Pseudomonas Aeruginosa (Pa) on the outcome of haematological patients in our Institution, particularly Multi-Drug-Resistant Pa (MDRPa) and Extensive-Drug-Resistant Pa (EDRPa). **Materials and Methods.** From January 2008 and February 2011 we followed up 220 patients (pts) treated with high-dose chemotherapy and hospitalized at S. Gerardo Hospital,Monza,Italy. All strains were isolated in Haematological Department. Haematological disorders were: 159 acute myeloid leukemia (72%), 48 lymphoproliferative diseases (22%) and 13 others. Pts under 65 years old were 156/220 (71%). MDRPa and EDRPa are defined as literature reported (Falagas, Clinical Infectious Disease, 2008). **Results.** We have found 217 BSI from 220 pts and 29 Pa isolated from 31 pts. Mortality rata in BSI was 21/193 sepsis (10. 8%). 24 BSI were presented as a septic shock and in this group 15 pts were died (62. 5%). All pts were neutropenic and didn't receive any antibactirial prophylaxis. BSI-etiology and related mortality rate were: Candida 7 (1 death: 14. 3%), Clostridium 6 (0), Corynebacterium 7 (0), Enterobacter 13 (1 death: 7. 7%), Enterococci 32 (8 deaths: 25%), Escherichia Coli 59 (4 deaths: 6. 8%), Klebsiella 4 (2 deaths: 50%), Coagulase negative Staphilococci 45 (6 deaths: 13. 3%), Staphilococcus Aureus 5 (1 death: 20%), Stenotrophomonas 10 (4 deaths: 40%). In picture 1 is shown the relationship between etiology-incidence and its mortality: some pathogens were less frequent but they were related with a high mortality rate (Klebsiella, Enterococcus Faecium). On the other side, Escherichia Coli was the most frequent bug with the less mortality: deaths occurred in pts with relapse leukemia and poor prognostic status (no one was ESBL positive). Deaths related to Pa were 9/29 (31%) but splitting different Pa with the resistance profile, MDRPa had a mortality rate of 1/1 (100%) and EDRPa of 7/7(100%). All non MDRPa responded to first line therapy except 1 pt who died for multiorgan failure. Other Pa were resistant to fluoroquinolones and third generation cephalosporine. All EDRPa showed a resistance in carbapenemics and positive metallobetalattamasis, in all cases colimicin was the only active antibiotic. Both state of disease and number of previous hospitalization were not correlated with a different profile of resistance. The lack of temporal and physical proximity and the strains' genetic analysis had excluded the presence of a EDRPa or Pa out-break. **Summary and Conclusions.** Mortality data on Pa in our series are worsen than what is reported in literature (40% mortality for MDRPa in Trecarichi, Haematologica, 2011). Even though the numbers are small, the impact on survival is relevant (100% mortality for MDRPa-EDRPa). Since now, no active combination of antimicrobial therapy was effective to EDRPa. The emergence of MDRPa and EDRPa in our haematological pts is a new challenge for clinicians. This work wants to be the base of an epidemiology surveillance in order to understand if there is any better approach to infection in high-risk haematological pts.

INFECTION DUE TO STAPHYLOCOCCUS AUREUS IN PATIENTS WITH HEMATOLOGICAL DISEASES: PROGNOSTIC FACTORS OF BACTEREMIA AND SEVERE OUTCOME

M Bchir, R Jeddi, R Ben Amor, Y Ben Abdennebi, M Zarrouk, H Ben Neji, K Kacem, R Ben Lakhal, H Ben Abid, Z Ben Hadjali, B Meddeb
Aziza Othmana University Hospital, Tunis, Tunisia

Background. Staphylococcus aureus is a clinically significant pathogen, usually associated in causing high morbidity nosocomial infections in cancer patients. The aim of this study was to determine the risk factors associated with bacteremia and severe outcome in patients diagnosed with hematologic diseases and Staphylococcus aureus infections. **Results.** A total of 85 Staphylococcus aureus isolates were collected from 70 patients aged 2-81 years: 47 with acute leukemia (67. 1%), 14 with lymphoma (20 %), and 9 with other hematologic disorders (12. 9%). The median age of the patients was 27 years. M/F was 1. 9 (P=0. 0006). Isolates were collected mostly from bloodstream (43. 5%) and skin lesions (48. 2%). 32. 9% and 33. 3% of the isolates were resistant to oxacillin and amikacin respectively. 2 patients(2. 8%) developed Severe sepsis/septic shock and 2 patients (2. 8%) developed respiratory failure . Crude mortality due to septic shock and pneumonia occurred in 2 patients (2. 8%). Factors associated with risk of bacteremia due to Staphylococcus aureus were: WBC < 2 x 10^9/l (P=0. 01,OR 3. 5;95%CI: 1. 3-9. 6), absolute neutrophil count (ANC) <1. 5x10^9/l (P=0. 001;OR 9;95%CI:2. 2-35. 4),Calcium level <2. 1mmol/l (P=0. 022,OR 4. 2;95%CI:1. 1-15. 3),low alkaline phosphatase level <80 (P=0. 036,OR 3. 6;95%CI:1-12. 1), glycemia > 6. 4 mmol/l (P=0. 01,OR 4. 8;95%CI:1. 4-16. 3) and female gender (P=0. 037,OR 2. 6;95% CI:1-6. 8). Factors associated with severe complication and death were: Neutropenia (P=0. 03), low Hemoglobin level (P=0. 011), low platelet count (P=0. 015), high CRP level (P=0. 04) and high Procalcitonin level (P=0. 016). **Conclusions.** This study revealed that CRP and Procalcitonin level are markers of severity in patients with hematological diseases and infection due to Staphylococcus aureus.

1427

UTILITY OF 18F-FLUORINE DEOXYGLUCOSE POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY IN GUIDING ANTIFUNGAL THERAPY IN A PATIENT WITH DEEP-SEATED MUCORMYCOSIS

B Xu[1], L Liu[1], W Wu[2], Z Zha[1], YY Zhang[1], H Huang[1], F Fan[1]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China
[2]PET Center, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China

Background. Mucormycosis is a rapidly-progressive deep fungal infection primarily affecting patients with underlying metabolic or immunological compromise. The management of patients suffering mucormycosis is very challenging. **Aims.** This study aims to assess the roles of 18F- fluorine deoxyglucose positron emission tomography/computed tomography (FDG PET/CT) in the management of patients with deep-seated mucormycosis. **Methods.** A series of FDG PET/CT images and consequential changes of the treatment plan of a 23-year-old patient who suffered aplastic anemia and rhinocerebral mucormycosis were analyzed. **Results.** PET/CT demonstrated the lesion was 18F-FDG avid and detected some additional positive lymph nodes in both necks. The findings of the first PET/CT scan directed accurate biopsy and guided the initial therapy plan. The judgment of the follow-up PET/CT imaging leaded to the adjustment of antifungal regimen, and then the conclusion from the final PET/CT study resulted in the successful termination of the long-term antifungal therapy. **Conclusions.** FDG PET/CT appears to be a valuable modality for the diagnosis and guiding the antifungal therapy against deep-seated mucormycosis.

Figure 1.

1428

SAFETY AND EFFICACY OF ANIDULAFUNGIN TREATMENT IN PATIENTS WITH HAEMATOLOGICAL DISEASE

L Yañez[1], S Herraez[2], A Bermudez[1], C Martin[1], G Martin[1], J Hinostroza[1], A Insunza[1]
[1]Hospital Universitario Marques de Valdecilla, Santander, Spain
[2]Hospital Universitario Marques de Vadecilla, Santander, Spain

Background. Anidulafungin is a new echinocandin with broad-spectrum activity against *Candida* and *Aspergillus* species. It does not require dose adjustment in renal or hepatic insufficiency and shows few drug interactions. All of these characteristics are attractive for its use in haematological patients, however little experience has been reported. **Aims.** To analyze efficacy and safety of anidulafungin treatment in patients with haematological disease. **Methods.** Between September 2011 and January 2012, 16 patients (8 male, median age: 60 years (46-88) with haematological diseases (Acute leukaemia 4; MDS 3; NHL/CLL 4; Myeloma 2; Aplastic Anemia 1; chronic MPN 2) received anidulafungin for at least 5 days in our centre. Therapy was given as empirical treatment in neutropenic fever (5 chemotherapy, 5 allogeneic SCT and 1 aplastic anemia), as primary antifungal prophylaxis in non neutropenic high risk allogeneic patients (4) or as combined treatment of proven pulmonary aspergillosis (1). No previous history of invasive mold infection was reported. **Results.** Anidulafungin was given for a median of 9 days (5-53) and no patient developed breakthrough fungal infection. In all subgroups of patients, liver function tests (AST, ALT and GGT) were significantly lower ($p<0,05$) following therapy and we did not see statistical differences in bilirubin and creatinine levels. Median days of an absolute neutrophil count below 100/mm3 and 500/mm3 in patients who received empirical therapy were 13 (7-18) and 16 (10-22) respectively. In the allogeneic group, calcineurin inhibitor levels were similar before and after treatment and those patients who received primary prophylaxis (all included in allogeneic group) were severely immunocompromised because of high dose corticosteroid treatment (3) or anti-TNF therapy for refractory acute gut and liver GVHD (1). Combined use of anidulafungin and voriconazol was given to a patient with allogeneic SCT and severe chronic GVHD who developed proven pulmonary aspergillosis and respiratory insufficiency, with successful evolution. At this time, 6 patients died because of GVHD (1) or disease progression (5). **Conclusions.** In our experience, anidulafungin shows an excellent profile of efficacy and safety in haematological patients but this needs to be confirmed in longer studies.

1429

CLINICAL FEATURES, DIAGNOSIS AND MANAGEMENT OF HEMATOLOGIC PATIENTS WITH BACTEREMIA IN A GENERAL HOSPITAL

R Martos, R Martos, J Queizan, J Hernandez, A Perez, A Garcia Mateo, L Bermejo, C Olivier, S Valencia, R Fisac Herrero, M Martinez, P Fisac Martin, MJ Calmuntia
Hospital General de Segovia, Segovia, Spain

Background. Patients with hematologic malignancies who receiving chemotherapy develop severe neutropenia with negative impact on the evolution of infectious complications. Despite prophylactic measures, such as reverse protective isolation, HEPA filter, use of antibiotics with wide antibacterial spectrum, and use of stimulating factors hematopoietic growth cells, cases of sepsis causes high mortality and morbidity, therefore it is very important to optimize the management, diagnosis and treatment in this special situations. **Aims.** Evaluated cases of bacteremia and its management in hematological patients in relation to epidemiological characteristics, clinical data and infectious parameters. **Methods.** Retrospective study from January 2009 until December 2011. The starting point was all blood culture were ordered at this period, evaluate retrospectively epidemiological, clinical, and bacteriological characteristics and pharmacological treatment for those who were positive. **Results.** The total blood cultures requested in the period of 36 months were 780, of which [15%;n=115] were positive. In relation with the acquisition zone of blood cultures, 72%were obtained from peripheral access, 18% from central venous and 10% from subcutaneous reservoir. Positive blood cultures were in 49 patients, with an annual distribution of 18 patients in 2009, 13 in 2010 and 18 in 2011. The median age was 60. 8 years (range 20-81), with a predominance of males [n = 27 (55%)]. The pathologies was: 32 patients had myeloblastic leukemia, 9 patients with aggressive Non-Hogdkin ['Diffuse Large Cell (n = 8) and NHL' Mantle Cell '(n = 1)]. 5patients with Myelodysplastic Syndrome, and 3 patients with Multiple Myeloma. In relationship with active treated**:** 40patients (82%) had Active chemotherapy versus 9 patients (18%) who were of-treatment phase active. Figure 1. At the time of bacteremia, [63%;n = 31], had an absolute neutrophil count (ANC) less than 0. $5x10^9$/L [31%;n=15] ANC between 0. 5-1. $5x10^9$/L and [6%;n=3] had an ANC greater than 1. $5x10^9$/L. The bacteriological Results. [53%;n = 26] corresponded to Gram-positive cocci, [43%,n = 21] were Gram-negative bacilli and [4%;n=2] were fungi. Figure 2. The antibiotics used was:b-lactams (55%),glycopeptides (25%), quinolones (5%), nitroimidazoles (6%), antifungals (6%) and aminoglycosides (3%). 78% of patients have been dying due to the evolution of the disease, although none of them, the direct cause of death was immediate consequence of the infection. **Conclusions.** The active chemotherapy and the RAN low (less than 0. $5x10^9$/L) have shown in our series, as two clear risk factors for the development of sepsis in hematologic patients. By contrast, there are no large differences in tumor pathology base or chemotherapy protocol used. The type of germ has not significantly influenced the clinical course of patients in our study, although a high percentage of all positive blood cultures were from peripheral venous access extractions. No differences were found in relation to epidemiological factors (sex / age). Respect antibiotic treatment chosen, the use of broad spectrum antibiotics and the combination of them, and especially an early administration, have a very favorable influence on the resolution of the infection, with excellent data in our series. These data will be update in congress.

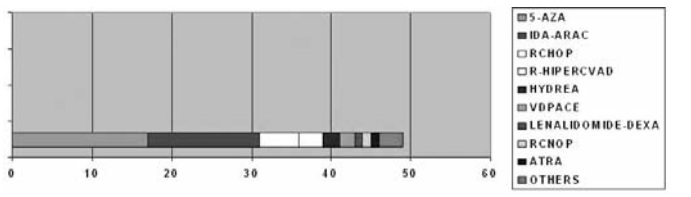

Figure 1. Chemotherapy treatments.

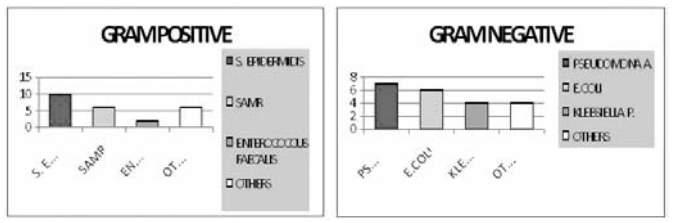

Figure 2. Types of germs in positive blood cultures.

1430

INVASIVE FUNGAL INFECTIONS IN HEMATOLOGIC MALIGNANCIES

V Djurasinovic, D Tomin, N Suvajdžic-Vukovic, A Vidovic, I Djunic, M Virijevic, N Colovic, D Antic, B Andjelic, I Elezovic, B Mihaljevic
Clinical Center of Serbia, Belgrade, Serbia

Background. Invasive fungal infections (IFI) are very frequent and serious complications after aggressive myeloablative regimens in patients (pts) with hematologic malignancies. **Aims.** To define possible prognostic factors for IFI in pts with hematologic malignancies. **Methods.** The data of 72 pts (m/f:41/31; Me age 53, range 20-76) . The majority of pts received prophylaxis for IFI: itraconazole 41 pts (57,1%) and fluconazole 19(26,2%). Diagnosis of IFI was performed according to EORTC criteria for possible,probable and proven infection, using mostly standard diagnostic procedures: blood cultures, serologic tests (galactomannan,anti Aspergillus IgM and candida-mannan), histopathological findings,X-ray, ultra sound and MSCT diagnostics. **Results.** The majority of pts 55(76,4%) had acute myeloid leukemia (AML) while other hematologic malignancies were rarer: acute lymphoblastic leukemia 6 pts,aplastic anemia 4 pts, Hodgkin¢s disease 2 pts, non-Hodgkin disease 2pts, chronic lymphocytic leukemia 2 pts and hairy cell leukemia 1 pt . IFI was diagnosed after induction therapy (th) in 40 pts(55,6%), "salvage" th in 18 pts (25%) and myeloablative th in remission in 14 pts (19,4%). There were 16 pts with invasive candidiasis (IC) (proven 13 pts, possible 3 pts),52 pts with invasive pulmonary aspergillosis (IPA) (proven 2pts, probable 20, possible 30 pts) and 2pts with proven invasive cryptococcosis and trychosporonosis, 2pts with zygomicosis. All pts had neutropenia with Me duration of 18 d (range:5-38), without significant differencies between IC and IPA . Pts with IC had more mucositis grade III and IV than pts with IPA, as well as pleural effusions ($p < 0,05$). Galactomannan test was twice positive in 20/52 pts(38,5 %), anti Aspergillus At IgM where positive at 13/20 (65 %) pts with probable and 12/30 (40%) pts with possible IA ($p>0,05$). Candida-mannan was positive once in proven IC pt. Pts with IC had Me survival of 4 wks, with mortality in 9/16 pts,while pts with IPA had Me survival of 16 wks and mortality in 31/52 pts. Me survival of other pts with IFI (1,5 wk) was more shorter vs pts with IC and

IPA (p < 0,05). All pts with fatal IFI had longer duration of neutropenia than other pts with IFI(Me 19,5 vs 15,5 d; p<0,05). Pts without any fungal prophylaxis had more deaths vs. pts with prophylaxis (p<0,05), as well as pts with IFI during induction or salvage th vs. pts receiving th in remission (p<0,05). **Conclusions.** The most significant risk factors for IFI in hematologic malignacies are: AML as a type of disease, myeloablative regimens used in induction and salvage th, prolonged period of neutropenia. IPA is the most prevalent form of IFI. IC should be considered in neutropenic febrile pts with pleural effusions and mucositis of high grade. Survival is shorter and the rate of deaths is bigger in pts with IFI during prolonged neutropenia after induction and salvage th, without prophylaxis, and in pts with IC and other fungal infections comparing to IPA.

1431

COMPARISON OF THE SIDE EFFECTS OF ANTIBIOTICS IN PATIENTS WITH THE DIAGNOSIS OF FEBRILE NEUTROPENIA

H Kurt[1], Ü Ergene[2]
[1]Celal Bayar University, Faculty Of Medicine, Manisa, Turkey
[2]Celal Bayar University, Faculty Of Medicine, Department Of Hematology, Manisa, Turkey

Objectives. Febrile neutropenia is a life-threatening complication that is common in patients with hematological malignancies. It is defined as a single oral body temperature over 38. 3°C or temperature over 38. 0°C lasting at least one hour, in cancer patients with an absolute neutrophil count below 500/mm^3 or in those with an absolute neutrophil count between 500 and 1000/mm^3 with a predicted further decrease within 24-48 hours in the absence of an external cause such as blood products or cytotoxic therapy. High-risk patients should be treated with parenteral antibiotics. **Methods.** Patients with febrile neutropenia who were hospitalized and treated in the hematology clinic of our hospital between January 2005 and December 2011 were retrospectively evaluated. **Results.** Forty (56. 3%) males and 31 (43. 7%) females between 20 and 76 years of age were included in the study. Of the patients, 62. 0% had a diagnosis of acute leukemia and 15. 5% had a diagnosis of lymphoma. Other diagnoses included myeloma, agranulocytosis, hairy cell leukemia and chronic leukemia. One hundred and twenty seven attacks were reviewed. Of these attacks, 74% were experienced by acute leukemia patients. No initial infection foci were identified in 50. 4% of the attacks. In patients with acute leukemia, combination therapy was preferred over monotherapy (p=0. 02). There were no significant differences between monotherapy and combination therapy in terms of efficacy and side effects. Side effects were more common with combination therapy, but the difference did not reach statistical significance. The most commonly preferred drug combination was imipenem plus amikacin (39. 4%). When imipenem plus ciprofloxacin was compared with imipenem plus amikacin, no significant differences were found in terms of efficacy and side effects (p=0. 18). When piperacillin/tazobactam plus ciprofloxacin and piperacillin/tazobactam plus amikacin were compared, side effects were more common in the amikacin group (p=0. 01). When combinations with imipenem and piperacillin/tazobactam were compared, the rate of antibiotic change was 60% and 27. 9% in the piperacillin/tazobactam and imipenem groups, respectively (p=0. 006). Imipenem combinations were more effective in reducing fever within the first 72 hours (p=0. 05). The rate of side effects was 11% with imipenem, 6. 5% with piperacillin/tazobactam, 11. 4% with ciprofloxacin and 16. 9% with amikacin. Side effects were significantly more common among patients using amikacin combinations (p=0. 02). The need for treatment modification was significantly higher in patients with neutropenia lasting for ≥ 10 days (p=0. 003). Side effects were observed during 25 attacks; 11 required antibiotic change. No side effect-related deaths were observed. Ten cases had skin rashes and urticaria, 2 cases had dyspnea and urticaria, 6 cases had nephrotoxicity (hypokalemia in one case), 4 cases had hepatotoxicity, 2 cases had generalized tonic-clonic convulsions and one case had autotoxicity. **Conclusions.** Each hospital should determine an antibiotic regimen appropriate for the bacterial flora of the hospital. In our hospital, imipenem combinations were more effective as empirical combination therapy. In consistent with the literature, there were no significant differences between combination therapy and monotherapy in terms of efficacy. Side effects of antibiotherapy were more common in patients receiving amikacin combinations.

1432

ORAL SEAWEED CALCIUM DERIVED FROM LITHOTHAMNION IS SAFE AND EFFECTIVE AND WELL TOLERATED AS ORAL LACTATE-GLUCONATE AND CARBONATE CALCIUM IN TUMOR LYSIS SYNDROME WITH RENAL FAILURE AND WATER OVERLOAD.

G Giordano[1], R Tambaro[1], N Perrotta[2], F D'Amico[1], G Sticca[1], C Di Falco[1], P Mondello[3]
[1]Fondazione "G. Paolo II", Campobasso, Italy
[2]Università "G. D'Annunzio", Chieti, Italy
[3]Policlinico "G. Martino", Messina, Italy

Background. Tumor lysis syndrome is a frequent complication in chemotherapy, characterized by hyperkaliemia, hypercalcemia, renal failure, hyperuricemia. Frequently patients need calcium support orally and intravenous. **Aims.** Aim of this study is to verify if in patients with iron overload and with limited intravenous calcium support oral seaweed calcium derived from lithothamnion is safe and effective as oral lactate- gluconate and carbonate calcium. **Methods.** Four patients, two with acute myeloid leukemia, one Burkitt lymphoma and one acute lymphoblastic leukemia presented a tumor lysis syndrome after chemotherapy. All patients were male. The two patients with acute myeloid leukemia were 45 and 52 y. o., the patient with acute lymphoblastic leukemia was 21 y. o., the patient with Burkitt lymphoma was 32 y. o. All patients showed renal failure (CrCl <30 cc/h) and severe hypocalcemia (Ca++ <3. 5 mEq/l). All patients received intravenous support with calcium chloride. The two patients with acute myeloid leukemia received oral lactate- gluconate and carbonate calcium 1 g tid, but the two patients with Burkitt lymphoma and acute lymphoblastic leukemia received oral seaweed calcium derived from lithothamnion 5g tid. **Results.** All patients restored a normal seric calcium level within 9 days. Patients receiving oral lactate- gluconate and carbonate calcium showed abdominal and gastric pain (VAS 7/10) and nausea and vomiting G3 and G4. Patients receiving oral seaweed calcium derived from lithothamnion showed no abdominal and gastric pain and nausea and vomiting G1. **Summary and Conclusions.** Oral seaweed calcium derived from lithothamnion seems to be safe and effective and well tolerated as oral lactate- gluconate and carbonate calcium in tumor lysis syndrome with renal failure and water overload. These data need a confirmation on a larger cohort of patients.

1433

POST CHEMOTHERAPY FEBRILE NEUTROPENIA IN HEMATOLOGIC MALIGNANCIES: CLINICAL CHARACTERISTICS AND OUTCOME

A Syrigou[1], M Iskas[1], A Antoniou[1], N Marvaki[1], P Baliakas[1], V Papadopoulos[2], C Kelaidi[1], C Lalayanni[1], R Saloum[1], D Sotiropoulos[1], A Anagnostopoulos[1]
[1]Department of Hematology and HCT Unit, G Papanicolaou Hospital, Thessaloniki, Greece
[2]Department of Hematology, Papageorgiou Hospital, Thessaloniki, Greece

Infections in neutropenic patients are a significant reason of morbidity and mortality. We present the clinical features and outcome of 52 febrile neutropenia cases in 42 inpatients of our department during a six month period. Only patients post chemotherapy were included, 18-77 years old. The diagnosis was acute myeloid leukemia in 30 (57%) of them, acute lymphoblastic leukemia in 13 (25%), mixed phenotype acute leukemia in 4 (0. 007%), non Hodgkin lymphoma in 3 (0. 06%), chronic lymphocytic leukemia in 1 and multiple myeloma in 1 of them. Chemotherapy regimens administered were idarubicin - cytarabine in 13 (25%), mitoxantrone - cytarabine in 20 (38%) and etoposide - cytarabine, R-HyperCVAD, R-CHOP and VAD in the rest. Only 1 patient had central venous catheter. During the last three months 19 (36%) had been previously hospitalised. Two (0. 04%) patients were in a single-bed room, 45 (86%) in two-bed room and 3 (0. 05%) in a four-bed. Median neutropenia duration was 14 (8-49) days. The type of infection was identified in 39 (75%) patients, being respiratory in 17 (32%), urinary in 10 (19%), soft tissue in 8 (15%) and bloodstream in 18 (35%). All patients received G-CSF for 11 (5-43) days and had fever for 3 (1-12) days. Gram negative bacteria prevailed in blood cultures. *Burkholderia cepacia*, which caused an epidemic in our department that period was isolated in 8 patients, *Klebsiella pneumoniae* in 3 patients, *Enterobacter cloacae* in 2, *Pseudomonas aeruginosa* in 2, *Acinetobacter baumanii* in 1, *Escherichia coli* in 1 and *Sphingomonas paucimobilis* in one. Only 2 patients had Gram positive blood infection with *Staphylococcus aureus*. Urine cultures showed *Enterococcus spp*, *Staphylococcus aureus*, *Enterobacter cloacae*, *Staphylococcus spp*, *Escherichia coli* and *Candida spp* in one patient each. Mucosal swab cultures showed *Stenotrophomonas maltophila* and *Achromobacter xylosoxidans* in two patients, whereas a patient with neutropenic colitis shed *Acinetobacter baumanii* in stool. *Acinetobacter baumanii*, *Burkholderia cepacia* and two of the *Klebsiella* species were multidrug resistant

strains producing carbapenemases. Death because of infection occurred in 11(21%) patients, in 8 of them attributed to resistant disease and isolation of multidrug resistant strains. Neutropenic fever outcome seems to be affected by primary disease and type of chemotherapy. Patients with acute myeloid leukemia who received anthracycline - cytarabine based regimens had the highest mortality rates in statistical analysis (p = 0. 031 and p = 0. 038 respectively). Moreover mortality tended to be higher in patients during first induction chemotherapy than during subsequent therapies (p = 0. 086).

1434

PRIMARY PROPHYLAXIS WITH VORICONAZOLE IN ADULTS PATIENTS WITH ACUTE MYELOID LEUKEMIA: 37 CASES

P Delgado Beltran, J Garcia-Zueco, L Costilla Barriga, D Rubio-Félix
University Hospital Miguel Servet, Zaragoza, Spain

Background. Invasive fungal infections (IFI) is an important cause of morbidity and mortality in patients with acute myeloblastic leukemia (AML). Patients with hematological malignancies and prolonged neutropenia are at high risk of IFI. The incidence of proven or probable fungal infections ranges from 5-24% among this selected high-risk patients. Deep and prolonged neutropenia in conjunction with some intensive chemotherapies are the main factors that contribute to IFI in this pathology. Because diagnosis is difficult and often delayed, prophylaxis is commonly used as treatment strategy. **Aims.** To evaluated the safety and efficacy of prophylaxis with voriconazole (VOR) in patients with AML. **Methods.** Patients diagnosed of LMA between January 2008 and September 2011 receiving chemotherapy (induction or consolidation) at diagnosis or of relapse, received oral prophylaxis with VOR. This drug was started at the same time to chemotherapy and continued until neutropenia recovery. Dosage was 200mg/12 hours after two loading doses of 400 mg. Patients unable to tolerate oral intake received VOR intravenously. Galactomannan antigenemia was measured twice a week. Neutropenic fever was managed according to IDSA guidelines and IFI diagnosis was defined according to MSG/EORTC criteria. **Results.** Retrospectively we evaluated 28 patients and 37 episodes. Mean age was 53,6 years (19-75), male/female 19/9. The mean days with neutropenia < 0. $1x10^9$/L was 19,4 (0-60) and < 0. $5x10^9$/L was 25,9 (8-60). The type of chemotherapy treatment was ICE (n=13), FLAG-IDA (n=11), LPA-2005 (n=4), others (n=9). Seventeen episodes occurs on induccion fase, 8 on consolidation, and 12 on relapse. Neutropenic fever ocurred in 34/37 (91,8%). Galactomannan antigenemia was possitive in 3 cases (8,1%). Total days with VOR prophylaxis were 29,4 (6-84). The antifungal therapy was modified in 10 cases (27%), most of them for persistent fever. Proven/probable IFI ocurred in 2 cases (5,4%), both of them caused by Aspergillus fumigatus. Toxicity was observed in 3/37 (8,1%), hepatic (1), psychiatric (1) and ophthalmic (1). **Conclusions.** In our experience voriconazole prophylaxis was safe and effective to prevent IFI in this patients, with well tolerance and minimal toxicity.

HYPEREOSINOPHILIC SYNDROME WITH PULMONARY NOCARDIOSIS

G Ozgur, I Erturk, O Nevruz, G Somak, F Avcu, M Guney, K Kaptan, T Cetin
Gulhane School of Medicine, Ankara, Turkey, Ankara, Turkey

Abstract. The hypereosinophilic syndromes (HES) are a group of disorders marked by the sustained overproduction of eosinophils, in which eosinophilic infiltration and mediator release cause damage to multiple organs [1-2]. Nocardiosis is an uncommon gram-positive bacterial infection caused by aerobic actinomycetes. Nocardiosis is typically regarded as an opportunistic infection especially in the patients who require prolonged glucocorticoid therapy [3]. We report a rare case of HES with pulmonary nocardiosis and empyema due to using long term corticosteroid. **Case Report.** A 32 year-old male patient was admitted to a local university hospital for dispne, chest pain and hemoptysis 8 months ago. Laboratory examination showed white blood cell count (WBC) 5,71 x 10^9/L, eosinophil 63,9 %. The peripheral blood smear and bone marrow biopsy showed eosinophilia. FIP1L1/PDGFRA rearrangement was positive. He was diagnosed HES and the treatment of high dose prednisolone was started. In the following 5 months prednisolone dose was reduced. Following the reoccurence of the same symptoms, dose was increased again. He was admitted to our hospital in February 2012 with the same symptoms. Physical examination revealed both of the lower zones of the lung sounds reduced and the liver and the spleen were palpable. Laboratory examination showed WBC count 7,8 x 10^9/L, eosinophil 0,2%, erithrocyte sedimentation rate 101 mm/h. In five days he had become febrile. For the treatment of HES imatinib 400 mg/day was started. Pulmonary computed tomography angiography revealed no pulmonary tromboemboly. There was a large pleural effusion (3,5 cm of wideness) in the left hemithorax. There were atelectasis by the pleural effusion. There were necrotic consolidation areas at the left lung upper lobe 8x9 cm and 4x5 cm at the right lung upper lobe. The thoracentesis was performed to the left pleual effusion. The empyema was diagnosed and thorax tube was placed for the drainage. Nocardia growed in the culture of pleural fluid. For the severity of the disease trimethoprim-sulfamethoxazole 3x2 gr/day, imipenem 4x500 mg/day, linezolid 2x600 mg/day were started. During the clinical follow-up his fever was controlled and the complaints disappeared. **Discussion.** Pulmonary involvement and hepatosplenomegaly are usual signs of HES. The best characterized and most frequently observed chromosomal aberration is an interstitial deletion on chromosome 4q12 resulting in the fusion of two genes, that for Fip1-like1 (FIP1L1) and PDGFRA [4]. For all patients with the FIP1L1/PDGFRA mutation (even if asymptomatic), imatinib mesylate is recommended for initial therapy, in preference to other available agents (Grade 1B). Nocardia spp have the ability to cause localized or systemic suppurative disease in immunocomprimised humans and animals [5-6]. Despite the success of TMP-SMX in the treatment of nocardiosis, combination therapy with other agents is warranted in patients with severe infections. In vitro susceptibilities and animal models of disease have demonstrated activity against Nocardia with a variety of antibiotics, including amikacin, imipenem, meropenem, and linezolid [7]

IS THE USE OF ANTIFUNGAL PROPHYLAXIS THERAPY IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LEUKEMIA NECESSARY?

Z Akcali
Celal Bayar University, Manisa, Turkey

Background. Invasive fungal infections (IFI) are serious cases of mortality in neutropenic patients. It is difficult to diagnose IFIs in neutropenic patients and this causes delay in diagnosis which has detrimental effects on prognosis. In order to treat these infections timely, prophylactic, empirical and preemptive treatment strategies are preferred instead of targeted antifungal therapy. **Aims.** The aim of the present study is to evaluate efficiency of empirical and pre-emptive treatment in patients with newly diagnosed acute leukemia without using prophylactic antifungal treatment. **Methods.** Between January 2007 and January 2012, febrile neutropenic attacks of 42 newly diagnosed acute leukemia patients were retrospectively analyzed in Manisa Celal Bayar University, Department of Hematology. In order to commence treatment in an early stage, instead of targeted antifungal therapy, prophylactic, empirical and pre-emptive treatment strategies were implemented. Pre-emptive treatment was considered to be a treatment, given in consideration of a clinical or laboratory diagnosis, which indicates a much higher invasive fungal disease risk in neutropenic patients than other patients. Empirical treatment was considered to be an antifungal therapy, given when patients who had gone under antibiotic therapy more than 5 days and who still had high fever. **Results.** 42 patients with acute leukemia treated with chemotherapy with persistent fever and suspected invasive fungal disease are evaluated in this study. 12 patients received empirical antifungal therapy, 10 patients received pre-emptive antifungal therapy and 20 patients did not receive any antifungal therapy. None of our patients died from invasive fungal diseases. Six patients died from other reasons. Two patients died from acute promyelositic leukemia and disseminated intravascular coagulation and two of them died from leukostasis. One of the remaining two patients died from subarachnoid hemorrhage and the other from cardiac arrest due to congestive heart failure. In empirical antifungal treatment, 7 patients received caspofungin, 3 patients received liposomal amphoterisin, 1 patient received vorikonazol and 1 patient received flukonazol. In pre-emptive treatment, 2 patients received caspofungin, 6 patients received liposomal amphoterisin B, and 2 patients received vorikonazol. In 5 of our patients Candida was found (3 patients Candida Albicans, 1 patient Candida Glabrata and 1 patient Candida Tropicalis). In two patients Aspergillus was isolated and in 3 patients yeast species were found. The average duration of antifungal treatment was 19 days in these series. **Conclusions.** No prophylactic antifungal agents were given to 42 newly diagnosed acute leukemia patients. 22 of those patients were given empirical and pre-emptive antifungal agents. For 20 of our patients antifungal treatment was not needed. None of those 42 patients died due to fungal infection. Studies with larger number of patients are yet needed to take a definitive position about prophylactic antifungal use in the treatment of newly diagnosed acute leukemia.

IMMUNOHISTOCHEMICAL EXPRESSION OF DNA DAMAGE RESPONSE MOLECULES IN MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

A Kefala[1], S Papageorgiou[1], A Tsanas[2], V Pappa[1], J Dervenoulas[1], E Patsouris[1], I Panayiotides[1], P Foukas[1]
[1]University of Athens, Medical School, Athens, Greece
[2]University of Oxford, Oxford, United Kingdom

Background. DNA double-strand breaks (DSB) may initiate genomic instability, thus contributing to carcinogenesis. Phosphorylation of NBS1, part of the MRE11-RAD50-NBS1 complex, leads to the phosphorylation of ATM; this, in turn, phosphorylates many substrate proteins, including the histone protein H2AX, whose rapid phosphorylation leads to γH2AX foci formation at nascent DSB sites. **Aims.** To assess the immunohistochemical expression of pNBS1, pATM and γH2AX in a series of bone marrow biopsies diagnosed with either myelodysplastic syndrome (MDS) or acute myeloid leukemia (AML) and to correlate this expression with the type of MDS, IPSS score and karyotype category. **Methods.** Bone marrow biopsies from 88 patients (73 with MDS and 15 with de novo AML) were used; complete blood count, peripheral blood smear and karyotype analysis were available in all cases. According to the updated (2008) WHO classification, 8 patients were diagnosed with RA, 3 with RARS, 23 with RCMD, 23 with RAEB-1 and 16 with RAEB-2. Sections from paraffin-embedded tissue were immunostained for pNBS1, pATM and γH2AX; at least 1000 marrow cells per case were assessed and the percentage of positive cells calculated. The control group consisted of 20 cases with reactive bone marrow histology. **Results.** The percentage of immunopositive cells for all three molecules was significantly higher in MDS and AML cases, than in reactive marrows (p<0. 05). Statistical analysis showed an overall increasing trend for all immunostain percentages, as disease severity increases. Concerning MDS cases, a higher percentage in high risk compared to low risk MDS cases was seen (p=0. 057 for pNBS1, p=0. 052 for γH2AX and p=0. 025 for pATM). Immunohistochemical expression of pNBS1 was significantly higher in MDS with abnormal versus normal karyotype (p=0. 002). Statistical difference was also found between low versus intermediate karyotype categories (p=0. 01). Moreover, our data suggest that the phosphorylation events of the three different DNA damage response (DDR) proteins (pNBS1, pATM, γH2AX) correlated among each other. In particular, there seems to be a strong correlation between pATM and γH2AX. (p=0. 007, p-values Spearman). **Conclusions.** The aforementioned results suggest that NBS1, ATM and H2AX, being major components of DDR, are activated in MDS and might be involved in AML transformation. Informed consent was obtained by all patients participating in the study. email address of presenting author: maria_kefala@yahoo. com

MUSASHI2 AND NUMB EXPRESSION IN NORMAL, MDS AND LMA BONE MARROW CELLS

J Pereira[1], M Lopes[1], F Traina[1], P Campos[1], J Machado-Neto[1], I Loranze-Metze[1], F Costa[1], S Olalla Saad[1], P Favaro[2]
[1]University of Campinas, Campinas, Brazil
[2]Federal University of Sao Paulo, Diadema, Brazil

Introduction. The Musashi2/NUMB pathway has recently been proposed as a potential molecular mechanism to explain differentiation and leukemic progression in myeloid leukemia. By exploiting mouse models of CML, it has been shown that NUMB inhibition, resulting from high levels of MSI2, is essential for development and maintenance of CML-blast crisis. Hence, the overexpression of *MSI2* resulted in increased cell cycle progression and cooperated with the BCR-ABL1 oncoprotein to induce an aggressive immature leukemia. Interestingly, as chronic phase CML progresses to blast crisis, expression of MSI2 is up-regulated and NUMB down-regulated, and modulation of this pathway can inhibit disease, suggesting that MSI2/NUMB pathway participates in disease progression. In AML and CML-blast crisis patients, MSI2 levels were inversely correlated with NUMB expression levels, and higher MSI2 expression was associated with the risk of relapse and death. **Aims.** We hypothesized that MSI2/NUMB pathway may participate in the physiopathology of MDS and its progression to AML. Thus, we characterized the expression of *MSI2* and *NUMB* in healthy control, MDS and in AML and correlated with clinical parameters. **Methods.** Bone marrows from 54 patients with MDS, 38 patients with AML, and from 19 healthy donors were analyzed (Table 1). All healthy controls and patients provided informed written consent and the study was approved by the ethics committee. All patients were untreated at the time of sample collection. *NUMB* and *MSI2* expression levels from total bone marrow were determined by quantitative PCR (q-PCR). **Results.** The comparison between healthy control and the MDS and AML groups for both genes, showed a significant decrease in *NUMB* expression in MDS (*P*=0. 004) and AML (*P*=0. 0001); a significant decrease in *MSI2* expression in the MDS group (*P*=0. 001), and a trend towards a decreased *MSI2* expression in the AML group (*P*=0. 1). *NUMB* expression was significantly lower than that of *MSI2*, in both MDS and AML patient samples (*P*<0. 05), but in the healthy control group, levels were similar. Interestingly, NUMB expression was statistically down-regulated in AML when compared with MDS (*P*=0. 006); the same was not observed for MSI2. *NUMB* and *MSI2* expression did not correlate significantly with clinical parameters (hemoglobin, percentage of blast in BM, number of cytopenias, FAB, WHO classifications and IPPS, for MDS; karyotype for AML), probably because of the small cohort of our study. **Conclusions.** Activation and inactivation of numerous oncogenes and tumor suppressor genes are described in MDS pathogenesis. NUMB has been implicated in cancer as a tumor suppressor; therefore, its down-regulation in MDS and AML, when compared to normal cells and in AML compared to MDS, suggests a role in the pathophysiology of MDS and also the progression of MDS to AML. Further studies are necessary to determine whether this is an independent event in the physiopathology of MDS and AML or if this has an impact on overall survival.

LONG-TERM EVOLUTION OF TYPE III ERYTHROCYTES DURING ECULIZUMAB TREATMENT IN PATIENTS WITH PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA

P Moncharmont[1], F Barraco[2], J Bernaud[1], A Raffin[1], M Michallet[2], D Rigal[1]
[1]EFS Rhone Alpes Site de Lyon Gerland, Lyon, France
[2]Department of Clinical Haematology CHLS, Pierre Benite, France

Background. Patients with paroxysmal nocturnal haemoglobinuria (PNH) are treated with eculizumab, a humanized monoclonal antibody against the com-

plement fraction 5 whose function is to inhibit the membrane attack complex. Usually, after 6 months of eculizumab treatment (MoTT), the number of red blood cells (RBC) bearing a complete deficiency of the glycosylphosphatidylinositol-linked proteins (type III cells) increases significantly. Nevertheless, study of type III RBC remains delicate as some patients still need RBC transfusion during treatment. **Aims.** To appreciate the evolution of type III RBC in patients with PNH clone after at least 12 MoTT. **Methods.** Were included in the study patients without RBC transfusion 2. 5 months at least before testing to rule out the impact of RBC transfusion on the results. A marker, the membrane inhibitor of reactive lysis, was studied on RBC by flow cytometry using a monoclonal antibody, anti-CD59. The presence of CD59- RBC and the size of the clone were evaluated. **Results.** Eight patients were selected: 4 with aplastic anaemia (AA) and PNH clone (n° 1-4), one of them (patient n°3) was transfusion dependent, and 4 patients with PNH (n°5-8), patient n° 5 suffering also from thrombocytopenia. Before treatment, CD59- RBC were at 12. 9%, 6. 1%, 51. 0% and 6. 6% in AA patients n°1 to 4, respectively. During treatment, the percentage of CD59- RBC decreased to 2. 7% in patient n°2 (31 MoTT) and to 1. 7% in patient n°4 (18 MoTT) and increased in the two other patients [n°1: 42. 7% (28 MoTT) and n°3: 95,8% (31 MoTT)]. In all patients with PNH, the size of the CD59- RBC clone had increased: from 4. 0% before treatment to 7. 1% in patient n°5 (42 MoTT), from 9. 5% to 13. 8% in patient n°6 (25 MoTT), from 17. 8% to 51. 1% in patient n°7 (27 MoTT) and from 1. 0% to 5. 5% in patient n°8 (27 MoTT). An increase was observed in patient n°5 despite a clinical course of AA. **Summary and Conclusions.** Two criteria were selected for this study: a long period of eculizumab treatment (over 12 months) and the absence of RBC transfusion 2. 5 months at least before testing. Results are heterogeneous in AA patients with PNH clone. A decrease of the CD59- RBC clone size was observed in half of these patients, which leads us to express that for this kind of patients this parameter does not seem a good marker to assess the efficiency of the treatment. Conversely, in PNH patients the size of the CD59- RBC clone increased: here this parameter could be used for the treatment monitoring provided that the two conditions of the study are respected.

1441

HEDGEHOG PATHWAY IS DEREGULATED IN MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

J Xavier[1], A Dias[1], P Latuf Filho[2], F Traina[1], J Vassallo[3], S Olalla Saad[1]
[1]Hemocenter/UNICAMP, Campinas, Brazil
[2]CIPED-FCM/ UNICAMP, Campinas, Brazil
[3]CIPED-FCM/University of Campinas, Campinas, Brazil

Background. Studies regarding self-renew in myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) show that blast colony formation is not confined to AML, but also occurs in patients with advanced MDS. Hedgehog pathway have an important role in self-renew of normal and leukemic stem cells and is upregulated in myeloid leukemias, however there are no studies regarding Hedgehog pathway in MDS. Hedgehog ligands (Sonic hedgehog [SHh], Indian hedgehog [IHh], and Desert hedgehog [DHh]) are produced by stromal cells and bind to the receptor Patched (PTCH). This binding causes activation of Smothened (SMO) receptor, resulting in downstream transcription of target genes. **Aims.** To evaluate Hedgehod pathway components in MDS and AML. **Methods.** Bone marrow (BM) samples were collected from 39 MDS (25 low risk,14 high risk-WHO 2008) patients and 26 healthy donors. Relative expression of PTCH and SMO were obtained by Real Time PCR. For immunohistochemistry, BM biopsies were collected from 4 AML patients, 3 MDS and 6 megaloblastic anemia (MA), used as control. The BM sections were stained with antibodies for IHh and DHh (1:50), the percentage of stained nucleated cells based on an average of 5 high-powered fields were considered. The acute myeloid cell lineage U937 was cultured with 15μM of cyclopamine, a Hedgehog inhibitor, or tomatidine, as control, for 24 and 48 hours followed by analysis of apoptosis by Annexin-PI staining, cell cycle by PI staining and proliferation by MTT assays. For clonogenic assays, U937 was maintained in methylcelulose for 20 days in the presence of 15 μM of cyclopamine or tomatidine. **Results.** Hedeghog receptors PTCH and SMO were overexpressed in MDS BM cells compared to normal BM as follow; PTCH: [median (min-max) healthy donors= 2. 23 (0. 42-9. 22); low risk= 6. 09 (0. 41-25. 28); high risk= 3. 97 (0. 42- 21. 01); healthy donors *vs* low risk p= 0. 02; healthy donors *vs* high risk p= 0. 02]; SMO: [healthy donors= 2. 33 (0. 00-16. 11); low risk= 14. 79 (1. 89- 41. 93); high risk= 34. 44 (8. 04- 164. 28); healthy donors *vs* low risk and healthy donors *vs* high risk p<0. 001]. In immunohistochemistry assays, the expression of Hedgehog ligants was also higher in AML BM cells and MDS when compared to control cells. For IHh, the number of stained cells in MDS were twice higher than MA (p=0. 02) and for DHh, the increase in AML *vs* MA was 4 folds (p= 0. 02). In order to investigate if Hedgehog inhibition affects self-renew in myeloid cells, we treated U937 cells, which express all components of this pathway, with cyclopamine and observed no affect in apoptosis, but cell accumulation in G1 phase (p=0. 01) and decrease of cell number in S phase (p=0. 0002). The cell cycle arrest reflected in 34% of proliferation decline (p=0. 007). In methylcellulose assays, cyclopamine causes abolishment of colony formation. **Conclusions.** As far as we know, this is the first study of the Hedgehog pathway in MDS. We observed overexpression of Hedgehog ligands and receptors as well as abolishment of colony formation after the pathway inhibition. Deregulation of Hedgehog in MDS and AML may be related to abnormal self renew.

1442

EFFECT OF LENALIDOMIDE TREATMENT ON THE EXPRESSION OF FLI1, EKLF, TP53, HDM2, PU. 1 AND IL-6 GENES IN 5Q- SYNDROME

A Jonasova[1], O Fuchs[2], M Vostry[2], A Kostecka[2], M Holicka[2], J Cermak[2], J Brezinova[2], K Michalova[3], R Neuwirtova[1]
[1]1. Internal department General Teaching Hospital, Charles University, Prague, Prague, Czech Republic
[2]Institute of Hematology and Blood Transfusion, Prague, Czech Republic
[3]Center of oncocytogenetics, General Teaching Hospital, Charles Univeristy, Pragu, Prague, Czech Republic

Background. Lenalidomide has improved the treatment of MDS with 5q deletion, inducing a hematologic (erythroid) and cytogenetic response in the majority of patients. The exact mechanisms of lenalidomide action explaining its effects on erythropoiesis are not clear thus far. We recently studied two transcription factors Fli1(Friend leukemia virus integration 1) and EKLF (Erythroid Krüppel like factor) involved in MEP (common megakaryocytic and erythroid progenitor) differentiation in MDS patients and showed significant decrease of EKLF and increase of Fli1 in 5q- syndrome (Neuwirtova et al, ASH 2011). There exists cross-antagonism between Fli1 and EKLF. Fli1 mRNA is target for microRNA-l45 (miR-145) localized in common deleted region of 5q. Haplo-insufficiency of miR-145 in 5q- syndrome stabilizes Fli1 mRNA and increases Fli1. Fli1 is also increased by IL-6. IL-6 is induced by haplo-insufficiency of miR-145 and miR-146a. Transcription factor PU. 1 is positive regulator of *Fli1* gene expression. In mice Fli1 regulates p53 via MDM2 (mouse double minute 2 or HDM2 in humans), an E3 ubiquitin ligase, which promotes p53 degradation in proteasomes. **Aims.** To study the changes in expression of above mentioned genes, which are conjectured to play a role in the pathogenesis of 5q- MDS, during the lenalidomide therapy course. **Methods.** We studied the expression of *Fli1*, *EKLF*, *TP53*, *HDM2*, *PU. 1* and *IL6* genes, which are supposed to play a role in the pathogenesis of 5q- syndrome, in the course of lenalidomide therapy in mononuclear cells isolated from peripheral blood of twelve MDS patients with 5q- (9 females, 3 males) of a median age of 70 years (range 55-78 years). Informed consent was obtained from all patients. All were transfusion dependent before treatment. Levels of specific mRNAs were determined by quantitative real-time PCR in total RNA isolated from blood. Relative levels of specific mRNAs were calculated to the level of housekeeping GAPDH mRNA. **Results.** The beneficial effect of lenalidomide was seen in 10 patients. Lenalidomide promoted induction of hemoglobin synthesis, which reflected the increase of EKLF mRNA levels and on the contrary decrease of the Fli1 mRNA. The decline in Fli1 mRNA levels was accompanied with the decrease of the platelet counts. The levels of Fli1 mRNA and EKLF mRNA oscillate after the normalization of hematopoiesis in the course of further lenalidomide therapy. Levels of p53 mRNA surprisingly did not show any clear decrease after lenalidomide treatment. On the contrary, levels of PU. 1 mRNA and IL-6 mRNA consistently increased in the majority of patients. HDM2 mRNA levels were lowered after lenalidomide treatment in most of examined 5q- patients. **Conclusions.** We can conclude that lenalidomide treatment is associated with elevation of EKLF mRNA levels and with decrease of Fli1 mRNA levels in majority of treatment-sensitive MDS patients with 5q- syndrome, which reflects the improvement of erythropoiesis, increase of hemoglobin and decrease of platelet production. Unexpectedly, we found consistent decrease of HDM2 expression, but any changes in TP53 expression and surprisingly PU. 1 and IL6 expression increased in almost all our patients, contrary to our expectations subsequent to others authors reports.

1443

USEFULNESS OF TRANSFERRIN SOLUBLE RECEPTOR DOSAGE AS A MARKER OF DYSERYTHROPOIESIS IN LOW RISK MDS

O Beyne-Rauzy, T Comont, V Demas, P Lay, P Cougoul, D Adoue, E Duchayne
Purpan Hospital, Toulouse, France

Background. Transferrin soluble receptor (Tf-SR) dosage is a useful tool to assess iron deficiency but it could also reflect the level of erythropoietic activity correlated with erythroblastic pool. **Aims.** We hypothetized that Tf-SR could be a marker of dyserythropoiesis in myelodysplastic syndromes (MDS). We decided to investigate the potential links between Tf-SR with (i) bone marrow erythroblastic pool, and (ii) other parameters such as: polychromatophilic erythroblast

(PCE) pool, MDS subtype, IPSS, endogenous EPO level, ferritin, reticulocytes response to EPO treatment if available. **Methods.** we reviewed 125 MDS patients, 65 were excluded (18 due to previous blood transfusion, 6 due to iron deficiency, 4 due to vitamin deficiency, 15 due to additional bone marrow failure, 7 due to uncertain diagnosis of MDS, 5 due to unavailable slides (bone marrow aspirate), renal failure (clearance of creatinin < 30ml/min). The 60 remaining patients were evaluated for dyserythropolesis by two different cytologists according to a pre-definite tool. Moreover two other groups were evaluated including 11 healthy subjects and 13 anaemic subjects of various causes (iron deficiency, B9 deficiency, renal failure). **Results.** 37 men and 23 women were included; mean age was 73. 3 years (56-93), including 5 RC, 13 RARS, 3 5q minus syndromes, 11 RCMD, 11 RCMD-RS, 10 RAEB-1et 7 RAEB-2. For 57 patients cytogenetic analysis was available, normal in 41 patients. A positive correlation between dyserythropoiesis and Tf-SR level was found in low risk MDS but not in high risk MDS. **Conclusions.** our study showed a positive correlation between Tf-SR level and erythroblastic activity as well as dyserythropoiesis intensity. Subsequent studies are needed to evaluate the Tf-SR during the course of the disease particularly on EPO therapy and to assess the prognosis value of this marker.

METHYLATION CHANGES IN CDKN2B AND CDKN2A GENES IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

H Cechova[1], K Pegova[1], R Zizkova[2], J Jencik[1], M Stankova[1], P Hrabakova[1], J Cermak[1]
[1]Institute of Haematology and Blood Transfusion, Prague, Czech Republic
[2]Institute of Heamatology and Blood Transfusion, Prague, Czech Republic

Background. Epigenetic *de novo* methylation of CpG islands is thought to be one of the key moments in malignant transformation of the cell. The most frequently tested genes are *CDKN2B* gene (cyclin-dependent kinase inhibitor gene) and its functional homologue *CDKN2A* gene. *CDKN2A* gene generates several transcript variants which differ in their first exons (isoform 1 and isoform 4). **Aims.** The methylation status of the *CDKN2B* and *CDKN2A* genes was studied in DNA samples isolated from bone marrow mononuclear cells (BM)-MNCs in Czech patients with myelodysplastic syndromes (MDS) and acute myeloid leukemia (AML) before treatment and during the course of the disease to evaluate its prognostic significance and association with clinical outcomes and disease progression. **Methods.** In our study methylation of these genes was studied in 63 patients with MDS, 2 with myelodysplastic/myeloproliferative neoplasms (MDS/MPN) and 13 with AML. Five patients were monitored during 5-azacytidine treatment. Twenty-six DNA samples from healthy donors (HD) were used as non-malignant controls. Methylation-specific multiplex ligation-dependent probe amplification (MS-MLPA) method with all associated techniques was used for detection. MS-MLPA kit enables simultaneously detect copy number variations and methylation changes of genes located in *CDKN2A-CDKN2B* region at 9p21. **Results.** We found that abberant methylation was present in the *CDKN2A* gene in 38% and in the *CDKN2B* gene in 77% of the patients in MDS group. The level of methylation was higher in the group of AML patients - 77% in *CDKN2A* gene and 100% in *CDKN2B* gene. In MDS patients, an aberrant methylation was associated with a tendency to disease progression towards more advanced forms according to the World Health Organization (WHO) classification and the International Prognostic Scoring System (IPSS). Significant differences in methylation level were observed between early and advanced forms of MDS in *CDKN2B* gene (P value < 0. 05) but not for *CDKN2A* gene. The trend of methylation in patients treated with azacitidine was analyzed in *CDKN2B* gene and correlated with the course of the disease. Increased methylation was connected with disease progression. **Summary.** We concluded that the methylation level of *CDKN2B* gene might be used as a marker of leukemic transformation in MDS. Our study indicates the role of hypermethylation as an important event in the progression of MDS to AML. Supported by the grant of MHCR 00023736.

DIFFERENTIAL EXPRESSION OF AURKA AND AURKB GENES IN BONE MARROW STROMAL MESENCHYMAL CELLS (MSCS) OF MYELODISPLASTIC SYNDROME (MDS): CORRELATION WITH G-BANDING ANALYSIS, SKY AND FISH

F Oliveira, A Lucena-Araújo, M Favarin, S Leite-Cueva, P Palma, E Rego, D Covas, A Fontes, R Falcão
Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil

Background. It has been demonstrated that genomic abnormalities of cells in the hematopoietic microenvironment could induce MDS and subsequent transformation to AML. Whether abnormalities associated with MSCs may contribute to pathogenesis of MDS and leukemias, and subsequently disease progression it is still not totally clear. **Aims**. In the present study we compare the expression profile of *AURKA* and *AURKB* in hematopoietic cells (HC) and MSCs of 48 MDS patients and 16 healthy donors (HD). Secondly, we correlate the cytogenetic findings obtained, with expression profile of *AURKA* and *AURKB.* **Methods**. Mononuclear cells (MNCs) were isolated from BM samples during initial diagnosis. MNCs from MDS and HD were cultured and collected after 3-4 passages for subsequent G-banding analyses, SKY, FISH, and RNA isolation. We also applied a panel of "MDS FISH probes"[t(3;3)/inv(3q), 5q-, 7q, +8 and 20q-] on MSCs in order to search for specific abnormalities of MDS. **Results**. We stratified the patients according the cytogenetic profile (normal vs. abnormal), for each group (HC and MSCs) and significant differences were observed (*AURKA* [mean value of $2^{-\Delta\Delta Ct}$±SD]: 3,649 ± 0,1059 N=18 vs. 4,604 ± 0,2743 N=23, p < 0,0001, in HD vs. normal karyotype HC; *AURKA* [mean value of $2^{-\Delta\Delta Ct}$±SD]: 3,649 ± 0,1059 N=18 vs. 7,992 ± 0,2416 N=32, p < 0,0001, in HD vs. normal karyotype MSCs; *AURKA* [mean value of $2^{-\Delta\Delta Ct}$±SD]: 4,604 ± 0,2743 N=23 vs. 14,70 ± 0,5661 N=25, p < 0,0001, in normal karyotype HC vs. abnormal karyotype HC; *AURKA* [mean value of $2^{-\Delta\Delta Ct}$±SD]: 7,992 ± 0,2416 N=32 vs. 11,72 ± 0,4951 N=16, p < 0,0001, in normal karyotype MSCs vs. abnormal karyotype MSCs). The higher expression of *AURKA* in HC and MCS, with altered karyotype versus normal karyotype, in the same population was also confirmed by FISH using a commercial probe for *AURKA* gene. We also found significant differences in HD vs. normal karyotype HC and normal karyotype MSCs for *AURKB*, respectively (*AURKB* [mean value of $2^{-\Delta\Delta Ct}$±SD]: 1,587 ± 0,05907 N=18 vs. 2,830 ± 0,1137 N=23, p < 0,0001 and vs. 3,082 ± 0,08036 N=32, p < 0,0001). However, when we compared normal vs. altered karyotype for HC and MSCs we found no difference between the groups. In MSCs with chromosomal abnormalities (CA), the karyotypes observed were different from those of their HC. FISH analysis on MSCs by using a "MDS FISH probes"revealed no MDS abnormalities in MSCs. Clonal abnormalities seen in MSCs by G-banding analysis were also confirmed by SKY and this observation confirms that CA showed in MSCs, from MDS patients, are not random. **Summary.** This investigation is the first attempt to correlate the gene expression profile of *AURKA* and *AURKB* in a cytogenetically stratified population of MSCs from MDS patients. In fact, both cells (HC and MSCs) may probably be altered in response to damage-inducing factors, and the presence of genomic abnormalities in MSCs suggests that an unstable bone marrow microenvironment may facilitate the expansion of MDS/leukemic cells. Financial support: FAPESP (Proc. 2007/52462-7 and 2011/01647-2)

DOWNREGULATION OF SPINT2 IN MYELODYSPLASTIC SYNDROMES MAY BE RELATED TO ABNORMAL MICROENVIRONMENT

F Roversi, J Machado-Neto, M Baratti, F Costa, F Traina, S Olalla Saad
University of Campinas, Campinas, Brazil

Background. Myelodysplastic syndrome (MDS) encompasses a group of clonal hematopoietic stem cell disorders characterized by ineffective hematopoiesis resulting in impaired differentiation and peripheral blood cytopenias. In MDS, there are evidences of defective bone marrow stromal cells supporting hematopoiesis, affecting development and apoptosis of hematopoietic stem cells. Microarray analysis of bone marrow stromal cells from patients with the MDS subtype refractory anemia with ringed sideroblasts (RARS), conducted by our group, identified low expression of *SPINT2 (*serine peptidase inhibitor) compared to normal bone marrow stromal cells. *SPINT2* corresponds to a matriptase which has tumor suppressor function, acting upon the inhibition of cell growth and induction of apoptosis by balancing between BAK and BCL2 proteins. SPINT2 downregulation was associated with prognostic and progression of solid tumors, including breast, cervical, hepatocellular carcinoma and medulloblastoma, nevertheless, there are as yet no studies on SPINT2 expression in MDS. **Aims.** Characterize SPINT2 expression in bone marrow stromal cells from normal donors and MDS patients. Furthermore, we evaluated the expression levels of SPINT2 in bone marrow cells from normal donors and MDS patients, compared among low-risk and high-risk MDS and correlated with laboratorial and clinical data. **Methods.** A total of forty-two patients with diagnosis of MDS, receiving no treatment, were included in the study; twenty-six samples from normal donors were used as controls. Patients were grouped into low-risk and high-risk disease, according to FAB, WHO classification and IPSS (Table 1). This study was approved by the National Ethical Committee Board. The stromal cells from MDS patients and normal donors were evaluated by FACS for the absence of CD34, CD45 and CD68 antigens after bone marrow mononuclear cells were isolated by Ficoll Hypaque gradients. Total bone marrow cells were submitted to RNA extraction after removal of erythrocytes by hemolysis. SPINT2 expression levels were determined by quantitative PCR. Data were expressed as the median [minimum-maximum]. For comparisons Mann-Whitney test was used. Spearman correlation analysis was used for ranking correlation tests. P-value <0. 05 was consid-

ered as statistically significant. **Results.** In stromal cells, we observed that the *SPINT2* expression was significantly decreased in MDS patients when compared with normal donors (0. 46 [0. 08-0. 77] versus 1. 16 [0. 76-1. 41], respectively; *P*=0. 005). Therefore, we found a significant decrease in *SPINT2* expression of total bone marrow MDS cells compared with normal cells (0. 83 [0. 03-4. 05] versus 1. 85 [0. 22-7. 60], respectively; *P*=0. 017). *SPINT2* expression was lower in both low-risk and high-risk patients when compared to normal subjects and demonstrated a significant positive correlation with peripheral blood neutrophils (*r*=0. 31, *P*=0. 04) and bone marrow granulocytes percentages (*r*=0. 31, *P*=0. 04). No correlation with age, hemoglobin, platelet, cytopenia, and blast percentage in bone marrow was found. **Conclusions.** *SPINT2 is* downregulated in stromal and total bone marrow cells and correlates with granulocyte number in MDS. These findings suggest a possible role of SPINT2 in MDS physiopathology and microenvironment abnormalities. Therefore, SPINT2 studies could help to better understand MDS bone marrow microenvironment and may be useful in the development of therapeutic strategies or as a potential source of biomarkers. INVESTIGATION OF OCT4A AND TOTAL OCT4 IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES(MDS) AND ACUTE MYELOGENOUS LEUKEMIA (AML)

E Verrou[1], E Katodritou[1], N Spyridis[1], K Zervas[1], V Kotoula[2]
[1]Theagenio Cancer Center, Thessaloniki, Greece
[2]Aristotle University, Thessaloniki, Greece

Background. The transcription factor OCT4 is an established regulator of stemness and pluripotency in embryonic stem cells. It has been postulated that reactivation of its expression occurs in somatic stem cells that have undergone carcinogenesis. The isolation of cDNAs encoding the OCT4 gene, demonstrated the existence of two isoforms of this transcription factor termed OCT4A and OCT4B that are generated by alternative splicing. The stemness properties are attributed to OCT4A, while OCT4B, localized in the cytoplasm, is currently considered of unknown function. Interestingly a novel OCT4 spliced variant has been recently discovered, OCT4B1, which has been also considered as a putative marker of stemness. The role of OCT4 isoforms in myeloid malignancies has been poorly studied. AIM: To investigate the RNA expression of OCT4A and of total OCT4 containing all variants in MDS and AML patients. **Methods.** Bone marrow aspirates from fifty seven patients, 27 RA/RARS/RCMD (group A), 13 RAEB1/RAEB2 (group B), 17 AML (group C) were studied. Relative expression of the above transcripts was assessed on total RNA with reverse transcription followed by real-time polymerase chain reaction (PCR). Special primers and probes were used in order to distinguish between the two different products. The data obtained were analyzed by using Kruskal-Wallis statistics. **Results.** The median relative expression level of OCT4A in group A was 0. 005(range: 0- 0. 72) and for groups B and C the median values were 0. 0003 (range: 0 - 0. 29) and 0. 008 (range: 0-0. 4) respectively. The median relative expression level of total OCT4 containing all variants in group A was 0. 63 (range: 0 - 48. 4) and for groups B and C the median values were 0. 17 (range: 0. 05-4. 05) and 0. 29 (range: 0-48. 9) respectively. Relative expression levels of both, OCT4A and total OCT4, were not significantly different among patient groups (p >0. 05, Kruskal-Wallis). **Conclusions.** Our results show that OCT4A and alternatively spliced variants are expressed in the haematopoietic compartment. The considerable difference among the values of the two measures, underlines the importance of a distinct and precise reference of the identity of different OCT4 derivatives. Although our results indicate that stemness properties of OCT4A may not contribute to the progression of MDS to AML more research is needed to elucidate the hypothesis that alternatively spliced transcripts of OCT4 may be implicated in MDS and AML pathogenesis.

SIVA, A PROAPOPTOTIC PROTEIN, IS DOWNREGULATED IN MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

J Machado-Neto[1], P Favaro[2], M Lazarini[1], R Ribeiro[1], P De Melo Campos[1], F Roversi[1], A Duarte[1], S Olalla Saad[1], F Traina[1]
[1]University of Campinas, Campinas, Brazil
[2]Department of Biological Sciences, Federal University of São Paulo, Diadema, Brazil

Background. The p53 tumor suppressor protein is a key transcription factor that regulates several signaling pathways involved in the cell response to stress, suppressing malignant transformation by cell cycle arrest, DNA repair, induction of apoptosis or initiation of senescence. Downregulation or inactivation of p53 is a common event in hematological malignancies, including acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) and has been related with poor prognosis. SIVA was initially described as a proapoptotic protein. In acute leukemia cell lines, both isoforms of SIVA (SIVA1 and SIVA2) play an important role in the apoptotic pathway induced through CD27 antigen by inhibition of BCL-XL, with consequent release of cytochrome C and caspases 9 and 3 activation. Additionally, activation of SIVA is capable of inhibiting NFkB and its role up the activation of BCL2 and BCL-XL. *SIVA* has recently been described as a transcriptional target of p53 and SIVA1 binds to p53 and modulates its stability. Despite the evidence that SIVA is an apoptosis-selective p53 target gene, the study of SIVA in primary hematopoietic cells has not been performed. **Aims.** To characterize *SIVA1*, *SIVA2 and TP53* expression in bone marrow cells from healthy donor, MDS and AML patients. **Methods.** We studied 22 healthy donors, 40 patients with MDS (FAB: 23 low-risk [RA/RARS] and 17 high-risk [RAEB/RAEBt]; WHO: 23 low-risk [RCUD/RCMD/RARS] and 14 high-risk [RAEB-1/RAEB-2]) and 29 AML patients at the time of diagnosis. *SIVA1, SIVA2* and *TP53* transcripts levels were determined by quantitative-PCR. Data were expressed as the median [minimum-maximum]. *Mann-Whitney* test and Spearman correlation analysis were used. **Results.** *SIVA1* and *SIVA2* transcripts were significantly decreased in MDS and AML cells compared with normal cells (*SIVA1*: 0. 79 [0. 15-10. 28], 0. 93 [0. 21-2. 23] *vs.* 2. 18 [0. 23-25. 88], respectively, *P*<0. 0001; *SIVA2*: 0. 99 [0. 29-3. 98], 0. 89 [0. 38-18. 14] *vs.* 4. 69 [0. 81-35. 53], respectively, *P*<0. 0001). No difference was observed between low-risk, high-risk MDS and AML. Spearman correlation analysis showed a significant positive correlation between *SIVA1* and *SIVA2* expression in normal (*r*=0. 74, *P*<0. 0001), MDS (*r*=0. 80, *P*<0. 0001), and AML (*r*=0. 81, *P*<0. 0001) cells, indicating a similar regulation for both isoforms of SIVA in hematopoietic cells. *TP53* expression was similar between normal, MDS and AML cells (1. 10 [0. 04-7. 32], 1. 03 [0. 03-33. 41] and 1. 53 [0. 27-9. 09], respectively); a slight increase in *TP53* was observed in AML comparing to MDS cells (*P*=0. 01). No correlation between *SIVA* and *TP53* expression were

noted. **Conclusions.** *SIVA1* and *SIVA2* expression are downregulated in MDS and AML cells compared to normal cells, suggesting that defective *SIVA* expression may be involved in the physiopathology of these diseases. *TP53* expression did not differ among the normal and malignant hematopoietic cells and did not correlate with *SIVA* expression. Other mechanisms of p53 regulation, as mutation, protein phosphorylation and degradation may contribute to the regulation of *SIVA* in MDS and AML cells. Induction of SIVA in MDS and AML cells may be attractive for these diseases, since SIVA upregulation has been associated with induction of apoptosis of leukemia cell lines.

1449

CYTOGENETIC CATEGORIES OF MYELODYSPLASTIC SYNDROMES (MDS) ACCORDING TO REVISED INTERNATIONAL PROGNOSTIC SCORING SYSTEM (R-IPSS)

S Gritsaev, I Martinkevitch, E Petrova, I Kostroma, M Ivanova, L Martinenko, A Sergeev, K Abdukkadirov
Russian Institute of Hematology and Transfusiology, St. Petersburg, Russian Federation

Background. The biological and clinical heterogeneity of MDS is the reason for further improvement of the stratification of MDS according to the risk of AML transformation and overall survival. **Aims.** To analyze the distribution of 197 de novo MDS patients with the agreement of R-IPSS karyotype. **Methods.** Standard Karyotyping. **Results.** The median age of patients was 64 y. o. (14-86). The bone marrow blasts was less than 5% in 90 patients (45. 7%). There was the correlation between age and BM blasts ≥5% (r=0. 159; p=0. 024). The chromosome aberrations were revealed in 129 patients (65. 5%). Next variants of karyotype were the common: normal (34. 5%), complex with >3 aberrations (19. 3%), not otherwise specified single and double abnormalities (16. 2%), del(5q) (10. 7%) and -7/7q- (6. 1%). Other chromosome abnormities referred to R-IPSS have been found in single patients or were not found at all, e. g. +19 or +21 as single aberrations. The karyotype of 2 patients with double aberrations and 22 patients with multiple lesions was in line with monosomal karyotype which is not mentioned in R-IPSS. The association of normal and complex karyotype with BM blasts (<5% and ≥5%) was determined (r=0. 469; p=0. 000). The distribution of patients according to R-IPSS prognostic variants of karyotype was next: very good (3. 0%), good (48. 2%), intermediate (25. 9%), poor (3. 6%) and very poor (19. 3%). In accordance with IPSS the karyotype of 52/197 patients (26. 4%) was categorized as intermediate one that is without any additional definition. And there were fewer patients with single or double abnormalities that were not otherwise specified and included in intermediate variant of R-IPSS karyotype - 32/197 (16. 2%). The last group was represented with 29 different chromosome aberrations as a sole abnormality in most of them. **Conclusions.** Not numerous contents of some R-IPSS variants and retained multiple chromosome lesions with undetermined prognosis are the reasons to look for new biological prognostic markers, e. g. genetic lesions.

1450

THE EFFECT OF CYCLINA1 ANTISENSE OLIGODEXYNUDEOTIDE ON PROLIFERATION REGULATION OF MYELODYSPLASTIC SYNDROME CELLS

J Jia
Peking University Institute of Hematology, Beijing, China

Background. The physiological role and the expression of cyclinA1 is different in various organisation cells or in tumor cells from different sources. Some reports showed that the overexpression of cyclinA1 could promot the growth of tumor cells, and the antisense structure could inhibit cell growth. **Aims.** To investigate the effect of cyclinA1 antisense oligodeoxynudeotide(ASODN) on mediating proliferation of myelodysplastic syndrome cells(MUTZ-1). **Methods.** CyclinA1 ASODN that complementary to the transcriptional initiation of cyclinA1 mRNA were used in vitro culture MUTZ-1 cell study. The protein and mRNA expression levels of cyclinA1 were detected by immunohistochemical method and RT-PCR et al. The cell apoptosis was detected by several methods. Electron microscopy, In site cell apoptosis detection kit, DNA gel electrophoresis and FCM . **Results.** In ASODN group, the protein or mRNA expression levels of cyclinA1 were significantly inhibited than those in control group (p<0. 01). The ratio of MUTZ-1 cell proliferation and CFU-MUTZ-1 were significantly inhibited. Morever, the inhibitory ratio was significantly increasing as the dose of ASODN increased. The apoptosis ratio□5. 97±0. 81%□in ASODN group was significantly higher than control group (1. 81±0. 72%)(P<0. 01). The morphologic study of MUTZ-1 cells in ASODN group showed smaller nuclei, few cytoplasm, lesser mitotic figure and lasser degree of atypia compared to the control group. The electron micrographs of MUTZ-1 cells in the ASODN group showed the characteristics of apoptosis (the apoptosis body): the chromatin condensed in masses at the periphery of nucleus, leaving the center filled with an electron-opaque material with mitochondria pyknosis in cytoplasm, and the nuclear fragmentation were seen, and the endoplasic reticulum was slightly extended in the condensed cytoplasm, but they were not seen in control group. We could also detect the DNA ladder in ASODN group. **Conclusions.** CyclinA1 ASODN with liposomal transfection has high inhibit the proliferation efficiency to the MUTZ-1 cells in vitro and has effect to induce the myelodysplastic syndrome cells to apoptosis. It can specifically inhibit it's protein and mRNA expression levels as well as the leukemia cell proliferations, which effect depends upon the concentration of ASODN. CyclinA1 have been demonstrated to play an important role in some biological phenomena such as proliferation and apoptosis, so cyclinA1 maybe a potential target for gene therapy in myelodysplastic syndrome.

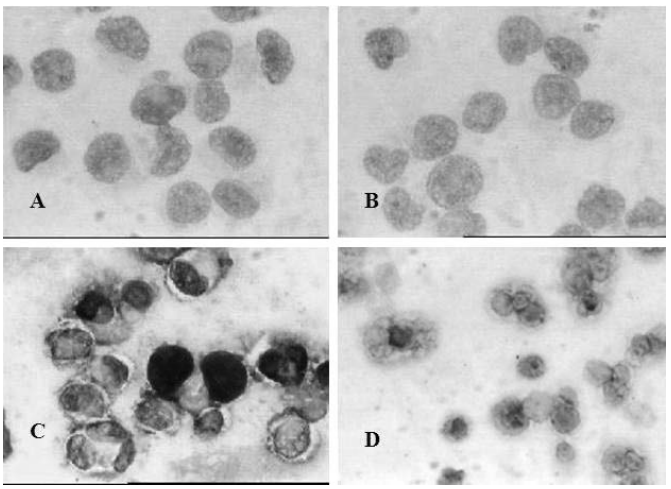

Figure 1. Apoptosis cells were detected by POD(×400). A: Control group; B: SODN group; C&D: ASODN group.

1451

INCREASED FREQUENCY OF THE MUTANT ALLELE G OF TLR4 RS4986790 POLYMORPHISM IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES

M Velegraki, M Klontzas, F Papadogiannis, A Batsali, S Mastrodemou, M Psyllaki, G Goulielmos, H Papadaki
University of Crete School of Medicine, Heraklion, Greece

Background. In patients with myelodysplastic syndromes (MDS), infection vulnerability does not always reflect the severity of neutropenia. This observation suggests that additional factors may predispose MDS patients to infections. **Aims.** Based on available evidence suggesting that the rs4986790 and rs4986791 Single Nucleotide Polymorphisms (SNP) of human toll-like receptor (*TLR)-4* may be associated with increased susceptibility to bacterial infections, we sought to examine the possible association between *TLR4* SNPs and infection susceptibility in MDS patients from a homogeneous Greek population. **Methods.** Genomic DNA was extracted from the bone marrow of 74 MDS patients and 221 unrelated healthy controls from the island of Crete. Genotyping for TLR4 rs4986790 and rs4986791 SNPs was performed by PCR - Restriction Fragment Length Polymorphism (RFLP), using the *Nco*I and *Hinf*I restriction enzymes, which digest the G allele-containing and T allele-containing PCR products for the rs4986790 and rs4986791 SNPs, respectively. Both undigested and digested PCR products were visualized in 3% agarose gel stained with ethidium bromide. To examine the possible correlation of the rs4986790 and rs4986791 polymorphic genotypes with MDS patient susceptibility to infections, we recorded the number of infections per patient tested, since the day of diagnosis. **Results.** No statistically significant difference was found in the frequency of infectious episodes between MDS patients carrying the risk allele and the MDS patients that did not carry the risk allele for either SNPs. This is probably explained by more recent data which show that only the mutant rs4986790/wild type rs4986791 haplotype is considered to correlate with susceptibility to Gram- infections, while the double heterozygous haplotype (mutant rs4986790 and mutant rs4986791) is considered to have a neutral phenotype which is indistinguishable from that of the wild type *TLR4.* Interestingly, among healthy controls, all carriers of the rs4986790 SNP also carried the minor allele of rs4986791, showing double heterozygosity for

rs4986790 and rs4986791. However, 28. 6% of MDS patients with the polymorphic genotype of rs4986790 had the wild-type genotype of rs4986791. Interestingly, the frequency of the minor allele G of the rs4986790 SNP was found significantly increased in MDS patients (4. 7%) compared to healthy controls (1. 6%) (P=0. 0295). Furthermore, the heterozygous polymorphic genotype A/G seemed to be more frequent among MDS patients (9. 5%) compared to controls (3. 2%) (P= 0. 0276). The frequency of the minor allele T and the polymorphic genotype C/T of rs4986791 SNP was also higher in MDS patients, although not at a statistically significant level. **Summary and Conclusions.** The presence of the polymorphic genotype of rs4986790 does not seem to correlate with MDS patients' vulnerability to infections. However, the frequency of the mutant allele G and the A/G genotype is significant higher in MDS patients compared to healthy controls, representing probably a genetically defined risk factor for MDS development.

1452

THE IMPACT OF OLD AND NEW PROGNOSTIC FEATURES ON THE SURVIVAL OF PATIENTS WITH MDS

I Lorand-Metze, S Reis-Alves, P Campos, G Harada, S Saad, F Traina
University of Campinas, Campinas, Brazil

Background. The evaluation of prognostic features in patients with myelodysplastic syndromes (MDS) has been important, due to the wide variability in clinical course, as well as for the evaluation of new treatment options. IPSS has been widely used, but the importance of cytogenetic findings was recently revised. Also, the prognostic importance of anemia and transfusion dependency has been recognized and included in the WPSS score. On the other hand, flow cytometry has been recently standardized for diagnosis of MDS, and the prognostic importance of some phenotypic features has been repeatedly shown. **Aims.** In a prospective study, we compared the influence of peripheral blood (PB) counts, bone marrow (BM) features, IPSS, WPSS, revised cytogenetic classification, and phenotypic abnormalities on the overall survival of patients with primary MDS. **Methods.** We studied 87 cases diagnosed by WHO criteria. BM immunophenotyping was performed using a four-color panel of monoclonal antibodies analyzing the mielomonocytic series. **Results.** mean age: 65 years. WHO types: 6 cases were RA, 1 5q- syndrome, 40 cases were RCMD, 13 cases were RCMD-RS and 27 were RAEB. According to IPSS, 32 were low risk, 32 were intermediate-1, 12 were intermediate-2 and 6 were high risk. In the univariate Cox analysis, degree of anemia (but not neutropenia and thrombocytopenia), IPSS, WPSS, revised cytogenetic risk stratification, a higher BM blast percentage (% BM blasts) as well as a higher number of total CD34+ cells and phenotypic abnormalities were associated with a shorter survival. In the multivariate analysis,only hemoglobin, % BM blasts and total CD34+ cells remained as independent risk factors. **Conclusions.** some variables generated by immunophenotyping of BM at diagnosis represent independent prognostic factors in MDS, and are important especially in a setting of patients with IPSS of low/intermediate risk and in cases with a normal karyotype. Supported by FAPESP, CNPq (INCTS) and MDS Foundation.

Background. Most MDS patients have anemia and many of them require red blood cells (RBC) transfusions leading to iron overload. The most simple test assessing iron overload is serum ferritin concentration . **Aims.** Assessment of hyperferritinemia incidence in MDS patients at the moment of MDS diagnosis. Correlation between hiperferritinemia, RBC transfusions and clinical outcome in patients suffering from MDS. **Methods.** 196 patients (106 men and 90 women, mean age 72) out of 975 Polish MDS Registry patients were included into the study. Due to statistical correctness only patients registered within 3 months since diagnosis were included. **Results.** Serum ferritin levels were available for 105 patients and follow-up data for 78 patients. Ferritin level above 1000 ng/mL was found in 28 patients (27%) (Group 1) and ferritin level ≤1000 ng/mL in 77 patients (73%) (Group 2). Most patients with significant hiperferritinemia were RBC transfusion dependant (85% of patients). Among patients with ferritin level ≤1000 ng/mL 49% were RBC transfusion dependant. Serum hemoglobin concentration was lower in Group 1 patients in comparison with Group 2 patients (8 g/dL vs 9,2 g/dL, p< 0,001). The most frequent MDS subtype in Group 1 patients was refractory anaemia (RA) (28%) (in contrary to patients with ferritin ≤1000 ng/mL - 13%) (p<0,05). There were no differences between studied groups in IPSS score. Mean follow up was 8 months. There was a trend for longer overall survival (OS) in RBC transfusion independent patients (mean OS not reached) when compared to RBC transfusion dependant patients (mean OS 857 days, p=0,08). Mean OS was not significantly statistically different in studied groups (mean OS in Group 1 not reached; 2- 22 months in Group 2) p Log-Rank = 0,38. No correlation was found between ferritin level and time to AML transformation. **Conclusions.** Hiperferritinemia >1000 ng/mL does not influence survival and time to AML transformation in MDS patients. The most frequent MDS subtype in patients with ferritin level >1000 ng/mL was MDS RA. Among patients with ferritin level >1000 ng/mL 85% were RBC dependent.

[9]Department of Hematology/Oncology, Kyungpook National University Hospital, Daegu, South-Korea

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a progressive disease caused by a somatic mutation in the *PIG-A* gene leading to deficiency of the complement protection proteins CD55 and CD59. Chronic, uncontrolled terminal complement activation leads to hemolysis, which is the underlying cause of the thromboembolism (TE), end organ damage, and early mortality associated with the disease. Lactate dehydrogenase (LDH) serum level of ≥1. 5 times the upper limit of normal (LDH ≥1. 5×) is a marker of uncontrolled complement activation. TE is the leading cause of death in PNH and accounts for 40%-67% of deaths in patients with PNH. **Aims.** To evaluate whether LDH ≥1. 5× at diagnosis is a suitable predictor of TE and mortality. **Methods.** This was a retrospective analysis of 224 patients with reported LDH levels at diagnosis

from the national PNH registry (N=301) in South Korea. **Results.** PNH patients with LDH ≥1. 5× at diagnosis had a 4. 8-fold greater mortality rate compared with an age- and gender-matched general population (AGMGP; *P*<0. 001), and in a multivariate analysis, LDH ≥1. 5× proved to be an independent predictor of mortality regardless of age, gender, or the presence of bone marrow disorder (OR=10. 57; 95% CI 1. 36-81. 93; *P*=0. 024). Patients with LDH <1. 5× had a similar mortality rate as the AGMGP (*P*=0. 824). A threshold LDH ≥1. 5× detected 93% of patient deaths and 96% of patients with TE. Attempting to potentially increase the specificity of identifying patients at risk of TE, an analysis was conducted with LDH threshold ≥3× or ≥5×. Neither LDH ≥3. 0× (OR 1. 8; 95% CI 0. 78-4. 09; *P*=0. 162) nor LDH ≥5. 0× (OR 2. 0; 95% CI 0. 91-4. 32; *P*=0. 082) were significant predictors of early mortality. Furthermore, LDH ≥3. 0× and ≥5. 0× only detected 67% and 47% of patients who experienced a TE, respectively. **Conclusions.** These data demonstrate that chronic uncontrolled complement activation as measured by LDH ≥1. 5× at PNH diagnosis is a strong and independent predictor of clinical complications and mortality in PNH patients. LDH ≥1. 5× clearly identifies PNH patients with a high risk of life-threatening complications and premature mortality (4. 8-fold) from the remaining population of PNH patients with normal survival. Thus, physicians should consider LDH ≥1. 5× as a strong indicator of risk for clinical complications and mortality that warrants early intervention.

1455

ELEVATED LDH IS ASSOCIATED WITH OCCURRENCE OF TE AND MORTALITY WITHIN 12 MONTHS OF ASSESSMENT IN PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA

[9]Division of Hematology Oncology, Pusan National University, Pusan, South-Korea

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired hematopoietic stem cell disorder caused by a somatic mutation in the *PIG-A* gene that leads to chronic uncontrolled terminal complement activation. The subsequent red blood cell (RBC) hemolysis with platelet and leukocyte activation causes life-threatening thromboembolic events (TE), chronic renal insufficiency, pain, severe fatigue, poor quality of life, and early mortality. Lactate dehydrogenase (LDH) serum level ≥1. 5x the upper limit of normal (LDH ≥1. 5x) is a marker of uncontrolled complement activation that has been used in multinational PNH clinical trials and was recently confirmed by our group as a sensitive marker for measuring risk of mortality and TE in patients with PNH. **Aims.** To evaluate the association of LDH ≥1. 5x with risk of TE and mortality, and to understand the impact of granulocyte clone size on the occurrence of TE and mortality. **Methods.** A retrospective analysis of a 301-patient national PNH data registry in South Korea was performed. Patients were aged 8-88 years (median 37 years), median PNH duration was 6. 6 years (1 month-41 years), median PNH granulocyte clone size was 48. 8%, and median LDH was >4x above normal. 76. 3% of patients had an LDH ≥1. 5x and 18% (n=54) had a history of TE. **Results.** A significant association was shown between LDH and the occurrence of TE within 12 months of LDH assessment: the odds of experiencing a TE were 4. 4x greater if LDH was ≥1. 5x compared with <1. 5x (Table 1; *P*=0. 020). Importantly, 82% (18/22) of the patients with LDH ≥1. 5x who had a TE at 12 months experienced this TE within the first 6 months. Furthermore, 5% (7/150) of patients with LDH ≥1. 5x died within 12 months following LDH assessment, reflecting a significantly higher mortality compared with 0% (0/51) among the <1. 5x cohort ([*P*=0. 004], Table 1). In contrast, there was no correlation between clone size and risk of TE or early mortality. In a multivariate analysis across all interquartile clone size categories, there were no significant differences in the risk of TE and mortality (Chi square *P*=0. 292 and 0. 247, respectively). **Conclusions.** Elevated LDH is a significant predictor of increased occurrence of TE and mortality within 12 months of LDH assessment. It has been suggested previously that large clone sizes may predict risk of TEs; however, our findings from this large cohort of patients show that neither TE nor death within 12 months was related to clone size. The 15% (22/150) incidence of TE within 12 months in patients with LDH ≥1. 5, with most TEs occurring within the first 6 months of an LDH reading, highlights the medical need and urgency for early therapeutic intervention in PNH patients with an elevated LDH.

Table 1. Thromboembolism and mortality at 1 year after LDH assessment.

	P value	LDH <1.5x, % (n/N)	LDH ≥1.5x, % (n/N)
Thromboembolism	*P*=0.020	4% (2/53)	15% (22/150)
Mortality	*P*=0.004	0% (0/51)	5% (7/150)

1456

SAFETY AND EFFICACY OF 5-AZACYTIDINE IN MDS PATIENTS WITH MODERATE RENAL IMPAIRMENT: A SINGLE CENTER EXPERIENCE

I Kotsianidis, E Douvali, M Papoutselis, E Spanoudakis, A Christoforidou, E Moustakides, A Tsakiroglou, D Margaritis, C Tsatalas
Democritus University of Thrace, Alexandroupolis, Greece

Background and Aims. The tolerability of 5-azacytidine allow its use in frail and/or elderly patients who comprise the majority of Myelodysplastic syndrome (MDS) population. Nevertheless, despite the increased incidence of renal impairment (RI) in older individuals, patients with RI were not included in the approval trials. As a result, the optimal use of 5-azacytidine in patients with RI is currently unknown. Only one single center, retrospective study addressed the efficacy and toxicity of 5-azacytidine in patients with RI, but no comparative analysis between patients with or without RI has been performed yet.

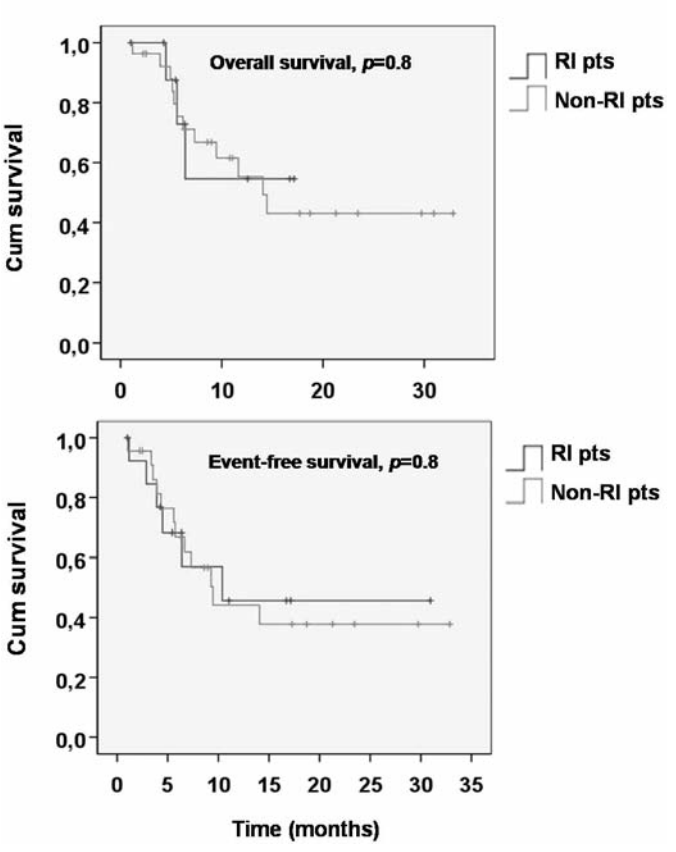

Figure 1.

Methods. We retrospectively analyzed 41 IPSS intermediate-2 and high-risk MDS patients (30 male, 11 female) with a median age of 73. 5 (range 55-81) years. Patients were classified according to WHO as RAEB-II (n=18), AML/MDS (n=5), CMML-II (n=8), MDS/MPN (n=4), RAEB-I (n=3) and RCMD (n=3). All patients had bilirubin level <2mg/dl, 11 (27%) had RI not requiring dialysis with median GFR 45 ml/min (range 22. 3-55, RI group) and 30 had median GFR 91 ml/min (73-140, non-RI group) as assessed by using the MRDM or the Cockroft-Gault formulas depending on patient's weight. Median follow up and number of completed cycles for all patients were 8. 6 months and 5(1-26), respectively. In all patients 5-azacytidine was started at 75mg/m2 SC for 7 days on 28-day cycles. Response to therapy and toxicity were evaluated using the IWG 2006 and NCI-CTC criteria, respectively. Significance of differences was assessed by Mann-Whitney U-test, Chi square or Fisher Exact tests as appropriate. Kaplan-Meier method and log-rank test were used for survival analysis. Event-free survival (EFS) was defined as the time from first 5-azacytidine administration to leukemic transformation or death. Results are presented as median values. **Results.** Patients with RI were significantly older than the non-RI ones (median age 76 vs 70, respectively, p=0. 004) and exhibited a trend for higher treatment discontinuation rate (54. 5% vs 23. 3%, respectively, p=0. 057). By contrast, no differences regarding gender, MDS subtype, transfusion needs and cytogenetics were noticed among the two groups. Likewise, patients with or without RI completed similar number of cycles (5 vs 7, respectively, p=0. 13) and displayed comparable rates of overall (not reached vs 14 months, p=0. 8) and event-free (10. 9 months vs 9,5 months, p=0. 8) survival (Figure 1), overall response (54. 5% vs 60. 7%, p=0. 9), dose adjustment (27. 3% vs 31%, p=0. 8), bleeding (45. 5% vs 38%, p=0. 8), infections (81% vs 72%, p=0. 73), days of hospitalization (14 vs 19. 5 p=0. 35) and grades 3-4 neutropenia (p=0. 14) and thrombocytopenia (p=0. 16). Renal function transiently deteriorated during the first 2 cycles, but then improved in 5/11 (45%) of patients with RI and 4/30 (13%) of non-RI group. Notably, adding the latter patients in the RI group did not alter the results of the comparisons. **Conclusions.** We conclude that 5-azacytidine is effective and safe in patients with moderate renal impairment who thus should be treated in a similar manner to patients with normal renal function. Transient decline in renal function may be observed in patients either with or without RI, but does not appear to affect the outcome.

1457

COMPASIVE USE OF 5-AZACITIDINE IN PATIENTS WITH LOW/INT-1 RISK MYELODYSPLASTIC SYNDROMES

D de Miguel, N Golbano, I San Roman, J Arbeteta, M Diaz, D Morales, S Herrero, D Subirá, B PInedo
Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. 5-azacitidine (AZA) significantly prolonged overall survival in higher-risk patients with myelodysplastic syndromes (MDS) in international phase III trial (AZA-001). However, data about efficacy of AZA in lower risk MDS are less consistent and only few studies have addressed this topic. **Aims.** Evaluate efficacy and security of AZA in low/int-1 risk MDS patients. Materials and **Methods.** we evaluate the efficacy and safety in low and intermediate-1 risk MDS patients. **Results.** In our institution, a total of 36 patients were treated with AZA between 2006 to February 2012. We evaluated 21 patients diagnosed according to WHO criteria as low/intermediate-1 International Prognostic Scoring System (IPSS) risk MDS. At baseline, median age was 76 year old (range 46-86), male/female ratio 10/11. Median time from diagnosis to Aza treatment was 39 months (range 1-192). 80,9% patients were transfusion-dependent, 85,7% had received a prior treatment (rhu-EPO+G-CSF 44,4%, only rhu-EPO 55,5%). Low/Int-1 risk patients received AZA dose of 75mg/sqm/d subcutaneously during days 1-7 by 6 treatment cycles, and before 6th cycle they received same schedule by 5 days, in a 28-day cycle. The median number of monthly cycles was 12 (range 2-50), and 76,2% and 57,14 % completed at least 6 and 9 treatment cycles, respectively. 76,2% patients had a hematologic response, 4,8% patients have not response, and 19% patients had a stable disease. Grade 3-4 adverse events documented in these patients were neutropenia (9,5%), anaemia (4,7%) and thrombocytopenia (7. 4%). Non-hematological adverse events: injection site reaction 19%, 19% constipation, 19% diarrhea and 9% fever. Response duration ranged from 4 to 43 months (median 12 months). There were no significant differences in response rate according to age, previous treatment, transfusion requirements, basal EPO and Hb pre-AZA. 3 patients were transformed to AML after median 7,7 cycles of AZA (2-13). **Conclusions.** 1. - 76,2% patients achieved a hematologic response. 2. - Time to response is early (3months), although some patients response later (5 cycles or more). 3. - Efficacy and safety of AZA treatment is a valid alternative in low/int-1 risk MDS patients.

1458

HEMATOLOGICAL IMPROVEMENT DURING IRON CHELATION THERAPY IN MDS/IM PATIENTS: THE 'REL' (RETE EMATOLOGICA LOMBARDA) EXPERIENCE

A Molteni[1], M Riva[1], L Borin[2], AM Pelizzari[3], F Guidotti[4], M Ubezio[5], M Bernardi[6], A Faricciotti[7], R Greco[1], E Morra[1]
[1]AO Niguarda Ca' Granda, MIlan, Italy
[2]H S. Gerardo, Monza, Italy
[3]Spedali Civili, Brescia, Italy
[4]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy
[5]Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy
[6]San Raffaele Scientific Institute, Milan, Italy
[7]AO "Salvini", Ospedale di Circolo, Rho, Italy

Background. Hematological improvement (HI) during iron chelation therapy (ICT) was first pointed out more than twenty years ago, both in Myelodysplastic Syndromes (MDS) and in Idiopathic Myelofibrosis (IM). This phenomenon seems to be more frequent after introduction of Deferasirox. However many questions about this topic need to be solved. **Aims.** To better understand frequency, duration and quality of HI during ICT. **Methods.** A multicentric retrospective data collection was conducted among 7 Lombard Hematological Centers afferent to "REL"(Rete Ematologica Lombarda") on MDS, MDS/MPD or IM patients treated with ICT for at least 6 months, up to 2 years of follow up. Transfusion requirement was defined as the number of RBC unit transfused in a three-month period. Data were tabulated and descriptive analysis was performed. IWG criteria of response published in 2000 (Cheson et al: Blood 96, 3671), was chosen instead of IWG 2006 criteria (Cheson et al: Blood 108, 419), because it was assumed that the possibility to split major and minor response was more appropriate in this model. All patients with a concomitant therapy that could influence HI were excluded from analysis. **Results.** On 53 patients, 49 were evaluable (45 MDS and 2 MDS/MPD and 2 IM). Median age was 67 years (range 24-27). Mean follow up was 18 months (range 6-24; median 24). All of them were transfusion dependent. Erythroid response was obtained in 15 patients (30. 6%): major in 4 (8. 1%) and minor in 11 (22%). Median time to response was 6 months (range 3-24). Median duration of response was 12 months (Figure 1). Notably none of the 4 patients who reached a major response showed a relapse before the end of observation period. Only 12 patients had platelet count less than 100. 000/mm^3. Of them 7 (58. 3%) had platelet response (6 major and 1 minor response). Median time to response was 5 months (range 1-14). In only one case there was the loss of response after 4 months. In the other cases response was maintained after 1 (2 cases), 8, 12 and 24 (2 cases) months. Only 16 patients were neutropenic (neuthrophils less than 1500/mm^3). Ten of them (62. 5%) showed a major response. Median time to response was 3. 5 months (range 1-16). In two cases response was lost after 1 and 3 months. In 4 cases response was maintained after 1, 10 and 21 (2 cases) months. In the other 4 cases response was lost and successively recovered, and still ongoing at the end of follow up. In 23 of the 49 patients (46. 9%) at least a minor response of some kind was seen. In only one case there was a tri-linear response. Bi-linear response was seen in 7 cases, all of them with erythroid response. In the remaining 7 cases of erythroid response only one patient had a further, not responsive, cytopenia (thrombocytopenia). **Conclusions.** HI after ICT seems to be more frequent than expected. In a not negligible number of cases HI is clinically relevant. Clinical and biological features than can influence HI need to be investigated.

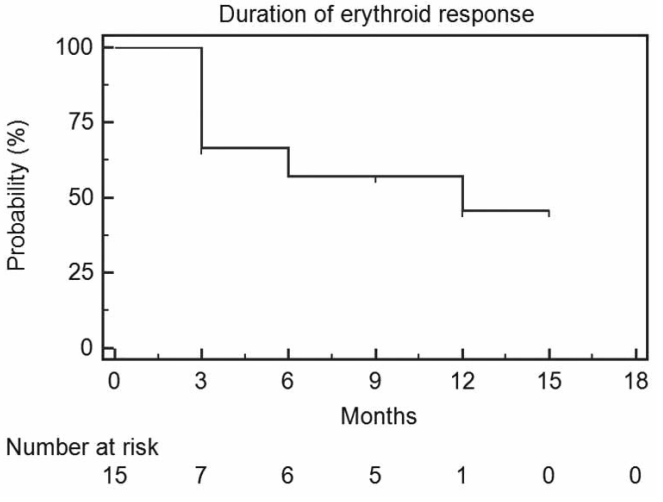

Figure 1.

1459

ANALYSIS OF SHORT-TERM EFFICACY OF LENALIDOMIDE IN PATIENTS WITH INTERMEDIATE-1 RISK MYELODYSPLASTIC SYNDROME WITHOUT 5Q DELETION

Y Yang
Jilin University First Hospital, Changchun, China

Objectives To evaluate the efficacy of lenalidomide in the treatment of the intermediate-1 risk non-del□5q□myelodysplastic syndrome□MDS□. **Methods** 30 patients were diagnosed as MDS by the peripheral blood count, bone marrow morphology and Cytogenetic analysis. There were 14 males and 16 females. the median age was 52 year- old (13 ~ 83). The average time from diagnosis to treatment was 4. 1 (0~9) months. cytogenetic analysis: All patients were classified by G-banding chromosome karyotype analysis and fluorescence in situ hybridization (FISH). We chose combined probes of +8, -5/5q-, -7/7q-, 20q-,-Y, -12/12p- in FISH detection. According to the WHO classification system, 6 patients were classified as RA□1 was RN□2 were RT□1 was RARS, 15 were RCMD□5 were MDS-U. 7 cases with 20q-,2 cases with +8□1 case with dup(1) (q22□31) and 4 cases were failed in karyotype analysis. Meanwhile, we found 4 cases with +8□7 cases with 20q-□3 cases with 12p-□16 cases with negative results in FISH test. According to the International Prognostic Scoring Systems (IPSS), 21cases got a score of 0. 5, 9 cases got a score of 1. 0 . we Revilmid 10 mg/d for 21 days every 28 day. All 30 cases were treated with lenalidomide 3 cycles at least, 20 of them received 4 cycles. **Results.**Before treatment, absolute neutrophil was 0. 95±0. 47×10^9/L, hemoglobin was 59. 1±16. 06 g/L, platelet was 30. 7±67. 8×10^9/L. After 2 cycles□30 cases□ ,absolute neutrophil was 1. 02±0. 59×10^9/L, hemoglobin was 61. 6±16. 8 g/L, platelet was 40. 2±18. 8×10^9/L. After 4 cycles□20 cases□ absolute neutrophil was 1. 28±0. 84×10^9/L, hemoglobin was 68. 6±14. 8g/L, platelet was 50. 1±85. 6×10^9/L. Lenalidomide had been shown the efficacy in patients with the Int-1 risk non-5q- MDS. Peripheral blood cell counts were improved after treatment 2 to 4 cycles. The Changes in Peripheral blood cell counts between the patients with 0. 5 scores less than 3 months from diagnosis to treatment and the patients with 1. 0 scores more than 3 months from diagnosis to treatment was statistically significant (P□0. 05). Platelet recovery in the former was faster and more obvious, platelet recovery was the fastest in the patients with 20q-. All patients got stable disease after 3 cycles, 14 cases with chromosome abnormalities by FISH test were found no cytogenetic response to the treatment. **Conclusions** Patients with the intermediate-1-risk non-del□5q□MDS treated with lenalidomide had not achieved complete hematologic remission, but could get hematologic improvement. At least, most patients needn't platelet transfusion and keep a safe platelet level without spontaneous bleeding□≥30×10^9/L□,at the same time, most patients achieved Erythrocytes transfusion independence (≥60g/L) after treatment.

1460

PNH CLONAL EXPANSION FOLLOWING STEM CELL TRANSPLANTATION FOR SEVERE APLASTIC ANEMIA: A RETROSPECTIVE ANALYSIS IN A BRAZILIAN HOSPITAL

M De Oliveira
Federal University of Parana, Curitiba, Paraná, Brazil

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a chronic and life-threatening hematopoietic stem cell disorder characterized by deficiency of the GPI-anchored complement inhibitory proteins CD55 and CD59 on blood cells. The resulting uncontrolled complement activation is responsible for chronic hemolysis and can lead to serious clinical morbidities including thromboembolism (TE) and chronic kidney disease (CKD), which have been shown to increase risk for mortality. While stem cell transplantation (SCT) remains the only potentially curative option for PNH, the risk for substantial morbidities and mortality still exist. In patients with PNH, up to 45% of patients receiving bone marrow transplantation die or develop graft-versus-host disease (GVHD); however, in patients with severe aplastic anemia (SAA), this may be the only option to address severe pancytopenia if immunosuppression therapy does not work. **Aims.** Presentation of case series demonstrating the appearance of PNH clones in SAA patients post-SCT. **Methods.** This study retrospectively analyzed 519 SAA patients who underwent SCT for severe pancytopenias between 1979 and 2012. SAA was defined by using the Camitta criteria, with marrow cellularity <25% overall or <50% with <30% hematopoiesis, and two of the following: neutrophil count less than 500/μL, anemia with corrected reticulocyte count <1%, or platelet count <20,000/μL. **Results.** Six patients (1. 2%) developed clinical and laboratory characteristics of PNH which were not present prior to SCT. At the time of SCT these patients, half of whom were female, median and range for select demographic and clinical characteristics were: age 21 years (17-38 years); absolute neutrophil count per μL 224 (88-576), platelet count per μL 6,000 (4,000-16,000), and number of transfusions before SCT 15 (4-45). All 6 patients were transplanted with bone marrow stem cells from HLA-identical siblings following administration of preparatory cyclophosphamide (200 mg/kg) and GVHD prophylaxis, including use of methotrexate plus cyclosporine. One patient developed grade II acute GVHD. PNH was confirmed by positive Ham/sucrose test in 2 patients and by flow cytometry in 4 patients (Table 1). The median time from SCT to clonal expansion was 101 months (range: 51-182 months). Two patients underwent a repeated SCT using the same donor and same GVHD prophylaxis, but using a preparatory regimen containing busulfan (8 mg/kg) plus fludarabine (125 mg/kg). As of January 2012, 1 patient had died due to severe pancytopenia 7 years after SCT; the remaining 5 patients are alive with no evidence of severe cytopenias. **Conclusions.** This is the first case series from our hospital in Brazil detailing the development and expansion of PNH clones following SCT in patients with severe pancytopenias. These findings demonstrate that while SCT is appropriate for SAA patients, it may lead to PNH clonal expansion in some patients. This case series demonstrates that it is important to monitor patients post-SCT for signs and symptoms of PNH. In light of recent data presented on prolonged survival and enhanced patient outcomes associated with eculizumab, these patients may be ideal candidates for this treatment choice when made available in Brazil.

Table 1. Percent deficient granulocytes and monocytes in 4 patients diagnosed with PNH using flow cytometry.

	Patient				Median
	1	2	3	4	
% deficient granulocytes	1.6	63.0	97.0	98.0	80.0
% deficient monocytes	2.5	77.5	99.6	99.9	88.6

1461

AZACYTIDINE 75MG/M2 X5 DAY IN MYELODISPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA REFRACTORY/RELAPSED PATIENTS: Results FROM A SINGLE CENTRE

JM Bergua, M Arcos-Carmona, J Prieto-Fernández, C Cabrera, F Carnicero, H Hernandez-Leyva, ML Begochea-Miranda, F Ibañez, M Martín-Mateos, N Bermejo, MC Salguero-Núñez
Hospital San Pedro de Alcántara. Cáceres, Cáceres, Spain

Purpose. To analyze the results of administration Azacytine (75mg/m^2x5 days) in myelodisplastic syndrome (MDS) patients and acute myeloid leukaemia refractory/relapsed (AML) on an outpatient basis. Each cycle was performed every 28 days at a dose of 75 mg/m^2X 5 days. Patients and schedule: 46 patients diagnosed of MDS or AML (September 2007-November 2010). We treat 25 patients with the diagnosis of MDS. IPSS was high in 3 (12%), intermediate II in 13 (52%), intermediate I in 8 (32%) and low in 1 patient. AML was the diagnosis of 21 patients. AML refractory to therapy were 3 (15%), secondary to MDS or myeloproliferative disease in 7 (35%) and AML de novo in older or not fit in 10 (50%). WHO categories were: AREB-1: 3; AREB-2: 3; RCMD:3; MDS-U: 2; LMM-2: 3; AML refactory or relapsed: 8; AML secondary to MDS: 10. 17 patients have secondary AML or SMD (1: after aplastic anemia; 1: prostate carcinoma treated with radiotherapy; 1: Hodgkin disease and autologous stem cell transplantation; 1: mastocytosis plus chronic lymphocytic leukema; 1: chronic Neutropenia; 1: rectal carcinoma; 1: Acute Promyelocytic leukemia, LMA-M5 trasplanted 3 years before and with a new -7q, 1: multiple myeloma; 1 polycytemia vera, 1: myelofibrosis; 1: renal carcinoma; 1: essential thrombocytemia). Cytogenetic risk: good: 24 patients; intermediate: 4 patients, high risk: 17 . Hydrea or thioguanine was permitted to control leukocyte counts in AML patients. Azacytidine was prescribed x 5 consecutive days (Monday to Friday) in an outpatient basis. Response criteria were evaluated each cycle and at 6th cycle by blood count and bone marrow aspiration (defined by IWG 2006). Non-responders patients were withdrawn of the treatment after 6th cycle. In cases of bone marrow response but cytopenia, the courses were delayed after the sixth cycle. **Results.** The median age of the 46 patients was 74,3 year (36,1-87,6). (Male/Women: 32/9). The median time to treatment was 1,8 months (0,0-38,53). The median number of cycles administrated was 7,5 (1-32). Response to treatment and survival: Bone marrow CR +PR at 6 months was 17 (38. 7%)(CR: 10; PR: 6). Transfusion independence, platelet and neutrophil responses were obtained in 17 patients. Median cycle to obtain response was the third cycles (1st- 7th). No differences in response were obtained

between MDS and AML. Median survival of all the patients was 13. 677. The median survival of AML group was 9,2 months; the median survival of MDS was 14,997 (p<0,3146) (the same or better than reported by Itzykson, MDS French group. Two AML patients obtained complete response). This trial was not comparative, but 5 days schedule seems as effective as 7 days treatment in very unfavourable prognostic patients.

Background. Hypomethylating agents improved clinical outcomes of myelodysplastic syndrome (MDS) patients. However, the treatment outcomes of patients who relapsed after azacitidine treatment has not been determined yet. **Aims.** The current study evaluated outcomes of salvage therapies for MDS patients who relapsed after azacitidine treatment. **Methods.** The outcomes of salvage treatment of 49 MDS patients who relapsed after previous azacitidine treatment were evaluated in the current study.

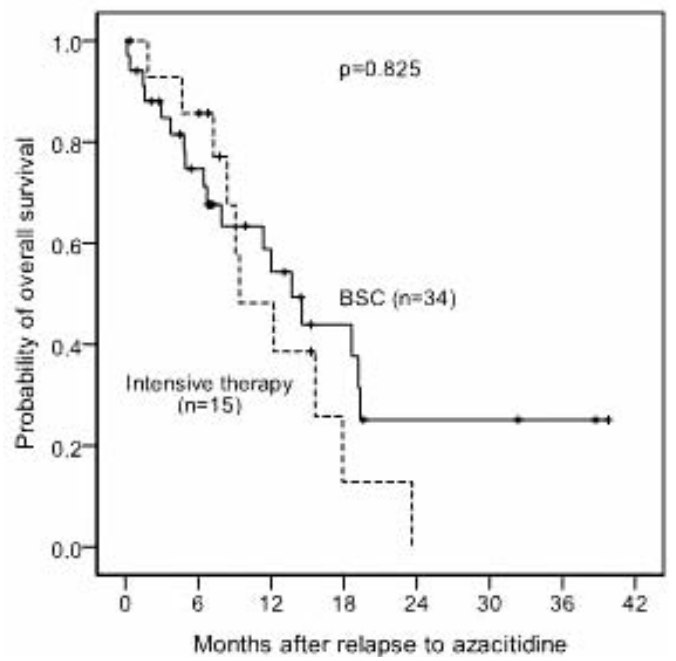

Figure 1. Survival rates after relapse to azacitidine treatment.

Results. Azacitidine was administered median 8 cycles (range 4-20 cycles) prior to relapse. Thirty-four patients were received best supportive care (BSC) after relapse to azacitidine and 15 patients were treated with salvage therapy; intensive chemotherapy for 6 patients, allogeneic stem cell transplantation for 2 patients and other hypomethylating therapy (decitabine) for 7 patients. Survival duration of relapsed patients after azacitidine was median 367 days (range 248-485 days). For BSC group, survival duration was median 367 days (range 248-485 days) with 1-year OS rate of 54. 3+9. 7% and for salvage therapy group, survival duration was median 282 days (range 136-427 days) with 1-year OS rate of 48. 2+15. 1% (p=0. 825). When considered to IPSS risk groups, the salvage therapies were not effective compared to BSC. Of the 31 IPSS low and intermediate-1 group, survival duration was median 436 days (range 298-573 days). One-year OS rate was 59. 9+11. 2% (BSC) and 54. 7+20. 1% (salvage therapy) (p=0. 977). Of the 18 IPSS intermediate-2 and high group, survival duration was median 272 days (range 215-328 days). One-year OS rate was 42. 1+17. 7% (BSC) and 41. 7+22. 2% (salvage therapy) (p=0. 473). **Conclusions.** Although azacitidine improved survival rates in MDS patients, outcomes of salvage therapy for patients who relapsed after azacitidine treatment was poor regardless of salvage therapy compared to BSC. So, active incorporation of intensive therapy to modify the disease course would be needed.

HOME AZACITIDINE (AZA) ADMINISTRATION IN MYELODYSPLASTIC SYNDROMES, CMML AND ACUTE MYELOID LEUKEMIA

M Iglesias-Fernández, M Pereira-Vázquez, E López-Ansoar, C Ulibarrena, M Pardo-Fernández, JL Sastre-Moral
Complexo Hospitalario Universitario de Ourense, Ourense, Spain

Background. AZA 75 mg/m^2/day x 7 days is the treatment of choice for high-risk MDS and a therapeutic option for AML in old patients. Prescribing recommendations insist in the administration of the drug by trained nurses or doctors. Due to the fact that our Outpatient Clinic remains closed on weekends, the compliance with the standard dosage of 7 consecutive days has been a difficult issue. Therefore, we devised a system in which the nurse-in-charge instructed relatives on the preservation and administration of AZA. Our hypothesis is that this way modality does not affect efficacy or tolerance. **Aims.** Trying the feasibility of 2 home-administered doses of AZA after 5 doses in the Outpatient Clinic, as a way of complying with the 7-day AZA regimen. **Methods.** The Hospital Pharmacy staff reconstituted the vial with 4 ml of sterile water for injection and distributed it in two syringes of 2 ml each. Both were delivered to the relative every day in an isothermal package and then administered to the patient without any other manipulation, subcutaneously, within a period of 8 hours. The relative willing to collaborate was trained from the first cycle, regarding the way of administration, the prevention of local side effects and the importance of preserving the environment of the drug. The nurse-in-charge finally assessed the skills and understanding before the final approval. Since this strategy implied a deviation from the rule, an informed consent was obtained for every couple patient/ relative, as well as an explicit authorization from the physician. **Result.** From August-2009, 23 patients (15 M / 7 F) were included in this home chemotherapy program. The mean age was 71. 25 yr. (range 41- 82). Diagnoses according to the WHO-2008 were AML (10), RCMD (4), AREB1 (3), AREB2 (2), AR / ARS (3), CMML (1); risk stratification according to IPSS for MDS were: high (1), INT-2 (6), INT-1 (4), 2 non applicable. A total of 149 cycles were administered with this modality (1-21 cycles per patient); no immediate complications led to hospital admission. No missing doses, failed administration or transgression in the preserving conditions were recorded. The rate of local reactions requiring intervention was similar to those reported with the standard regimen. Best recorded response after 4 - 9 cycles was:- AML: CR (1), PR (4), failure (4); 1 patient died after the 1st cycle. - MDS (IWG-2006 criteria): 4 not assessable (less than 4 cycles, due to early death, discontinuation or recent start of AZA); 2 failure; 1 stable disease, 4 partial response, 1 medullar response; 1 proceeded to allo-BMT. Hematological improvement was not considered. Further data and updating of the former would be provided on June-2012. **Summary and Conclusions.** Home administration of Azacitidine by relatives was safe and feasible, allowing the 7-day scheme when no facility is available on weekends. The core factors for the success of this strategy were: informed consent; willingness of relatives to participate; systematic education; collaborative Hospital Pharmacy.

CRITICAL ANALYSIS AND VALIDATION OF THE AZACITIDIN PROGNOSTIC SCORING SYSTEM (APSS)

T Noesslinger, H Tuechler, E Koller, A Schoenmetzler, F Keil, M Pfeilstoecker
Hanusch Krankenhaus, Vienna, Austria

Background. Azacitidin (AZA) significantly improves survival in higher-risk MDS patients compared to conventional treatments (AZA001 trial). With response rates of about 50% predictive factors are of major interest. Recently a AZA prognostic scoring system (APSS) was proposed (Itzykson,Blood 2011), considering ECOG performance status (≥2=1point), circulating blasts (present=1pt), RBC transfusion dependence (≥4 U/8wk=1pt) and the IPSS cytoge-

netics (good=0, int=1 and poor=2 pt) as variables and defining three significantly different prognostic subgroups: low (score 0), intermediate (1-3) and high risk (4-5) In a retrospective single center analysis we tried to validate this interesting tool. **Results.** Between 03/2009 and 04/2011 34 patients (21 males,13 females) with high risk MDS or AML evolving from MDS or with dysplastic features received AZA until progression. At time of the analysis, 20 pts are alive, nine of them still on treatment (total of 227 cycles). The median age at time of diagnosis was 72 years (range 48-90). 17 patients received AZA from diagnosis, the median time from diagnosis to treatment for the others was 7mo (range 1-54). The pts received in median 15 cycles (range 1-21) and, with 31 pts. evaluable, remission rates were: CR 22%, PR 10%, stable disease 22,5%, non-responder 45,5%. The med. survival duration was 37 months from time of diagnosis and 14,5 months from AZA onset. Focusing on the APSS risk factors, ECOG PS ≥2, RBC transfusion ≥4 units/8 weeks and circ. blasts were present in 44%, 71% and 59% of pts respectively. Cytogenetics were good, intermediate, and poor in 70%, 18% and 12%. 4 pts. (12%) were considered low, 24 (73%) intermediate and 5 (15%) high risk, being very good comparable to the distribution of the APSS (11%, 71% and 18% resp.). With a median f/u of 21,4 months (from diagnosis), 12,3 months (from start of AZA), median OS from time of diagnosis were 72, 37 and 7 months in patients with low, intermediate, and high risk score respectively. Accounting for the time of AZA treatment initiation survival data were 18, 13. 5 and 6 months respectively and the number of AZA cycles adminstered were 9, 8 and 4 respectively. **Conclusions.** The results of this single center analysis are in agreement with the AZA prognostic scoring system based on conventional prognostic factors. As in our opinion the specific predictive value of the APSS regarding response to AZA treatment remains unclear, comparative data of untreated higher risk patients will be presented at the meeting.

1465

IMPROVEMENT OF QUALITY OF LIFE IN PATIENTS WITH REFRACTORY ANEMIA WITH EXCESS OF BLASTS: ROLE OF 5'-AZACYTIDINE COMPARED WITH CONVENTIONAL CARE REGIMENS. A SINGLE CENTRE STUDY

G Monaco, M Troiano, E Attingenti, S Iaccarino, A Abbadessa
UOC di Oncoematologia, A. O. R. N. "Sant'Anna e San Sebastiano", Caserta, Italy

Background. 5'-azacytidine (5-AZA) is the current standard treatment for high-risk myelodysplastic syndrome, increasing overall survival in relation to conventional regimen (Fenaux,2010). **Aims.** We want compare quality of life, transfusion and hospitalization rate of patients with refractory anemia with excess of blasts (RAEB), observed in our division, before and after introduction of therapy with 5-AZA. **Methods.** Between 2006 and 2011 we observed 30 cases of RAEB (4 was RAEB type I and 26 RAEB type II); median age 72. 5 years (range 60-84 years). 19 received conventional care regimens (10 received only best supportive care, 5 low dose chemotherapy, 4 intensive chemotherapy), because 5-AZA wasn't yet available in our institution; 11 received 5-AZA at a dose of 75 mg/m2 per day for 7 days every 21 days. This therapy was given for a median of nine cycles (range 4-24 cycles). **Results.** For conventional care regimen group, median survival was 9 months (range 2-23 months); acute myeloid leukemia (AML) transformation occurred in 13 patients (68%) and median time to evolution was 4 months (range 1-20 months). In addition, there were frequent hospitalizations mainly for infectious causes, with an average of 3 days of hospitalization per month for patient. The mean monthly transfusional rate was 1. 9 units of packed blood red cells and 3. 9 units of platelets concentrates. In 5-AZA group, 4 patients died for other causes after a median of 4 cycles (range 3-10 cycles) with a median survival of 11 months (range 3-31 months). 7 patients are currently in therapy with 5-AZA with a median follow-up of 9 months (range 4-29 months). No evolution in AML was showed. The mean monthly hospitalization rate was 0. 6 days for every patient. The mean monthly transfusional rate was 1. 1 units of packed blood red cells and 0. 5 units of platelet concentrates. 8 patients (72%) of 5-AZA group was transfusion dependent at diagnosis. Five of this patients reached transfusion independence after a median of 3 cycles (range 2-7 cycles). *Discussion.* 5-AZA group showed a better quality of life compared with conventional care regimen group. Indeed, analysis of data reported above shows: 1) a clear reduction of hospital days (reduced to one-fifth), 2) a reduction of transfusional rate and early achievement of transfusion independence (in about 60% of transfusion-dependent patients), 3) improvement of performance status. **Conclusions.** Treatment with 5'-azacytidine improves quality of life in patients with refractory anemia with excess of blasts.

1466

CLINICAL FEATURES CONDITIONING HEMATOLOGICAL IMPROVMENT DURING IRON CHELATION THERAPY IN MDS/IM PATIENTS. THE 'REL' (RETE EMATOLOGICA LOMBARDA) EXPERIENCE

A Molteni[1], M Riva[1], AM Pelizzari[2], L Borin[3], M Nichelatti[1], F Guidotti[4], M Ubezio[5], M Bernardi[6], A Faricciotti[7], R Greco[1], E Morra[1]
[1]AO Niguarda Ca' Granda, MIlan, Italy
[2]Spedali Civili, Brescia, Italy
[3]H S. Gerardo, Monza, Italy
[4]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy
[5]Fondazione IRCCS Policlinico S. Matteo, Pavia, Italy
[6]San Raffaele Scientific Institute, Milan, Italy
[7]AO "Salvini", Ospedale di Circolo, Rho, Italy

Background. The possibility to have an hematological improvement (HI) during iron chelation therapy (ICT) has been described, but clinical or biological features than may be associated to this phenomenon are still unknown. **Aims.** To verify if some clinical features, detected before beginning of ICT, may influence HI. **Methods.** A multicentric retrospective data collection was conducted among 7 Lombard Hematological Centers afferent to "REL"(Rete Ematologica Lombarda") on patients with myelodysplastic syndrome (MDS), myelodysplastic/myeloprolifertive disease (MDS/MPD) or Idiopathic Myelofibrosis (IM). All patients were transfusion dependent and treated with ICT for at least 6 months, up to 2 years of follow up. According to IWG criteria of response published in 2000 (Cheson et al: Blood 96, 3671), were considered as responsive patients those with at least a mono-linear minor response in at least one of the three lineages. Some clinical features referring to the moment of the beginning of ICT were tabulated and analyzed with the usual descriptive methods. Comparison between categorical variables were carried out by Fisher's exact test; the logistic regression with one or two independent regressors was used to verify the possible existence of association between HI and categorical or continuous variables. **Results.** On 53 patients, 49 (45 MDS and 2 MDS/MPD and 2 IM) were evaluable. Of them 31 were male, and median age was 67 years (range 24-27). Mean follow up was 18 months (range 6-24; median 24). In 23 of them (46. 9%) we detected an HI as defined above. A possible correlation with the response was analized for the following variables: gender; age; transfusional burden (number of RBC unit in the three previous months); presence of neutropenia (<1500/mm^3); presence of thrombocytopenia (<100. 000/mm^3); iron chelator (deferasirox or deferoxiamine); seric iron, transferrin, ferritin, lactatedeidrogenase (LDH), epoetin; response to iron chelation (reduction of ferritin levels above 35% after 12 months). For MDS patients only, also the following were included in the analysis: diagnosis according to FAB and WHO, cytogenetic risk according to IPSS stratification, presence of bone marrow fibrosis and percentage of bone marrow cellularity. Univariate analysis shows that only the presence of neutropenia influences significantly HI (p< 0. 005). Among other parameters only LDH and epoetin seems to have ability to influence response, but they do not reach a statistical significance (respectively: p = 0. 06 and p = 0. 07; odds ratio: 0. 4% and 0. 2%). Bi-variate analysis were also performed considering neutropenia with LDH and neutropenia with epoetin as independent potential regressors: the presence of neutropenia maintained a predictive value on response in both models (respectively p =0. 003 and p = 0. 001). **Conclusions.** in this series the presence of neutropenia enhances the probability of HI during ICT. No other clinical predictive factor has been detected. This findings need to be confirmed in a larger and prospective court. Biological studies to identify patients with good chance to ameliorate cytopenias under ICT are also warranted.

1467

SECONDARY HEMATOLOGIC MALIGNANCIES IN PREVIOUSLY-TREATED PATIENTS WITH SOLID TUMOR

YH Choi[1], HJ Kang[2], I Na[2], HR Lee[2], JK Lee[2], YH Chang[2], S Yang[2]
[1]Dongnam Institute of Radiological and Medical Sciences, Busan, South-Korea
[2]Korea Institute of Radiological and Medical Sciences, Seoul, South-Korea

Background. Secondary hematologic malignances may occur as a late complication following various cytotoxic therapy, including chemotherapy, radiotherapy, or radioactive iodine therapy. **Patients and Methods.** We retrospectively analyzed 346 patients referred to our hospital for newly diagnosed leukemia or multiple myeloma from January 2000 to December 2009. There were 23 patients with a past history of cytotoxic therapy for solid tumor. **Results.** The median age was 61 years (range, 29-75). The median interval between secondary hematologic malignancy development after beginning cytotoxic therapy for various solid tumor was 33 months (range, 6. 6-59. 9). Solid tumors include breast cancer (n=7), thyroid cancer (n=4), cervix cancer (n=3), lung can-

cer (n=3), colorectal cancer (n=2), nasopharyngeal cancer (n=1), hepatocellular carcinoma (n=1), osteosarcoma (n=1), and pheochromocytoma (n=1). Secondary hematologic malignancy include acute myeloid leukemia (n=6), myelodysplastic syndromes (n=6), chronic myelogenous leukemia (CML) (n=5), multiple myeloma (MM) (n=3), acute lymphoblastic leukemia (n=1), and biphenotypic acute leukemia (n=1). Treatment modalities include chemotherapy alone (n=11, 47. 8%), radiation (RT) along (n=4, 17. 4%), both chemotherapy and RT (n=3, 13%), 131-iodine therapy (n=4, 17. 4%) and iodine-l31 metaiodobenzylguanidine (n=1, 3. 4%). Patients had received various cytotoxic agents, including alkylating agents (8 patients, 34. 8%) and topoisomerase 2 inhibitors (8 patients, 34. 8 %). In patients who received RT, one developed acute leukemia, 4 developed CML and 2 developed MM. Interestingly, 3 patients who received intracavitary RT for cervical cancer developed CML (n=2) or MM (n=1). **Conclusions.** The risk of secondary hematologic malignancies as a late complication following various cytotoxic therapies must be kept in mind and close monitoring and follow-up would be required.

AZACITIDINE IN CMML, REPORT OF THE SPANISH EXPERIENCE.

M Díez Campelo[1], E Such[2], M Calbacho[3], M Callejas[4], M Amigo[5], S Rojas[1], B Gonzalez[6], L Arenillas[7], S Brunet[8], E Luño[9], G Azaceta[10], MJ Arilla[11], M Azaceta[4], F Ramos[12], R García[13], M Cañizo[1]
[1]University Hospital of Salamanca, Salamanca, Spain
[2]Hospital de la Fe, Valencia, Spain
[3]Hospital Ramón y Cajal, Madrid, Spain
[4]Hospital Universitario Principe de Asturias, Madrid, Spain
[5]Hospital Morales Messeguerq, Murcia, Spain
[6]Hospital Universitario de Canarias, San Cristobal de la laguna, Spain
[7]Hospital del Mar, Barcelona, Spain
[8]Hospital de la Santa Cruz y San Pablo, Barcelona, Spain
[9]Hospital Central de Asturias, Oviedo, Spain
[10]Hospital Clínico Universitario de Zaragoza, Zaragoza, Spain
[11]Hospital de Sagunto, Valencia, Spain
[12]Hospital de León, León, Spain
[13]Hospital Virgen de la Victoria, Málaga, Spain

Background. Treatment of CMML remains a clinical challenge, with no drug demonstrating clear clinical benefit. AZA yielded a survival benefit in higher risk MDS and in a few patients with CMML and have been aproved for its use. **Methods.** A cohort of CMML pts (according to WHO 2008 classification) treated with AZA in Spain were reviewed. **Results.** Between 2006 and 2011, 36 CMML pts received AZA. The median age was 70 y (range 33-90), M 74%/F 26%. These registry includes 21 patients (58%) with CMML-1 and 15 patients (42%) with CMML-2. Myeloproliferative CMML (MP-CMML), was present in 18/36 patients, whereas 18/36 had myelodysplastic CMML (MD-CMML). Thus, the registry includes patients for whom AZA is currently not approved by the FDA/EMEA 25/36. Prior to AZA: palpable SM were present in 21% of patients, 60% of patients were in trasfusion dependence and 19% pts had received intensive chemotherapy. In the 29 patients in whom pretreatment cytogenetics were performed, 21, 5 and 3 could be grouped into IPSS good, intermediate and poor risk categories, respectively. The median number of cycles of AZA administered was 6 (range 1-24). The median OS was 1. 17 months. Detailed response and OS statistical analyses of various factors known or thought to influence prognosis are currently being analyzed, including MP-CMML vs. MD-CMML, CMML-1 vs. CMML-2, comparison of IPSS cytogenetic risk groups, as well as treatment-naïve vs. pretreated patients. In conclusion, in this population of partly pretreated, old patients with CMML, AZA was well tolerated and yielded substantial clinical and hematological benefit.

1469

CLINICAL ANALYSIS OF 18 PATIENTS WITH MYELODYSPLASTIC SYNDROME-REFRACTORY ANEMIA WITH EXCESS BLASTS(MDS-RAEB) TREATED WITH DECITABINE

Y Yang, W Li, SJ Gao, HQ Fan, H Lin, XM Shi, Z Liu
First Hospital of Jilin University, Changchun, China

Objective. To summarize the recent therapeutic effect and adverse reaction of treatment with decitabine in myelodysplastic syndrome-refractory anemia with excess blasts(MDS-RAEB). **Methods.** 18 patients with MDS-RAEB treated in our cancer centre from September 2009 to December 2011 were analyzed retrospectively□including 10 men and 8 women□ranged from 28 to 72 years old □median age was 49 years,11 patients were diagnosed as MDS-RAEB-2□7 patients were diagnosed as MDS-RAEB-1; Chromosome karyotype analysis: 6 patients were favorable karyotype, 6 patients were intermediate karyotype, 4 patients were unfavorable karyotype and the other 2 patients were unsuccessful to karyotype analysis. According to the IPSS risk criteria, 2 patients belonged to intermediate-1 risk group□14 patients belonged to intermediate-2 risk group, 2 patients belonged to high risk group. All patients were treated with decitabine dosing 20 mg/m^2/day for 5 days per cycle□the intermission of each cycle ranged from 4 to 6 weeks. 5 patients received 1 cycle, 8 patients received 2 cycles□4 patients received 4 cycles□1 patient received 6 cycles. **Results.** 3 patients achieved Complete remission (CR),among them, 1 patient achieved CR after 2 cycles of decitabine, the other 2 patients got CR after 3 cycles of decitabine. The chromosome karyotypes of the 3 patients were 20q-□The remission duration was longer than 18 months. 2 patients achieved molecule remission(FISH was negative) after 18 months. The CR patients received 4 cycles of decitabine treatment at least; 2 patients achieved partial remission (PR), 5 patients attained hematology improvement□HI□. on the whole□12 patients got benefit from the treatment with decitabine□including CR/PR/HI□ the overall response rate was 55. 6%. 4 patients stopped therapy because they progressed to acute leukemia during the treatment with decitabine. 1 patient died of the complication of septicemia and septic shock. The main adverse reaction was hematotoxicity, especially significantly after 1or 2 cycles of treatment□the absolute neutrophil count of 3 patients reduced to 0, 6 patients' reduced to below 0. 1×10^9, the period of agranulocytosis maintained 1-4 weeks □9 patients were infected after 1-2 cycles of the treatment□5 of them had serious infection□for example□perianal abscess, septicaemia, Pneumonia of fungal infection. the patients infected seriously were older patients and had the complications of chronic disease, for example, diabetes, chronic obstructive pulmonary disease□and long history of MDS. The hematotoxicity became mild after 4-6 cycles of the treatment, no cumulative toxicity, no hepatotoxicity or nephrotoxicity. **Conclusions.** The response rate of recent therapeutic effect of treatment with decitabine in MDS-RAEB achieved above 50%□ the main adverse reaction was hematotoxicity. **Key words.** MDS□Treatment; Decitabine

1470

SURVEY-BASED HEMATOLOGIST VIEW OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA: AN OPPORTUNITY FOR IMPROVEMENT OF DIAGNOSIS AND MANAGEMENT

A Alhejazi[1], J Cermák[2], P Cernelc[3], B Labar[4]
[1]King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia
[2]Institute of Hematology and Blood Transfusion, Prague, Czech Republic
[3]Department of Hematology, University Medical Centre, Ljubljana, Slovenia
[4]Medical School, University of Zagreb and University Hospital Centre, Zagreb, Croatia

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a genetic, progressive, life-threatening disorder characterized by chronic, uncontrolled terminal complement activation and hemolysis. The disease has a prevalence of 2. 0-15. 9 cases/million and a median age of onset of 33 years. Early diagnosis and intervention is critical; however, PNH is associated with diverse symptoms that often make diagnosis difficult to establish (average delay in diagnosis is 2. 5-3 years). 35% of patients with PNH die within 5 years of diagnosis. **Aims.** To assess clinicians' awareness of PNH, identify causes of delay in PNH diagnosis, determine the signs and symptoms that prompt clinicians to test for PNH, and gain insight into how PNH is managed in different regions. **Methods.** A survey comprising 43 questions was distributed to hematologists involved in the management of PNH throughout the Middle-East, North Africa, and Central and Eastern Europe. **Results.** Of the 70 physicians who completed the questionnaire, 90% were hematologists, with 33% specializing in hematologic oncology. Responders were familiar with PNH (91%) and with syndromes associated with PNH (myelodysplastic syndromes [97%]; aplastic anemia [96%]). 59% were currently managing ≥1 patient with PNH and 64% had diagnosed the disease within the past 3 years. Median time from clinical presentation to diagnosis was 6-9 months (range 3 months to 3 years). In general, patients with symptoms indicative of PNH were tested for the disease: 74% of patients with aplastic anemia, 42% with myelodysplastic syndrome, 74% with hemoglobinuria, 53% with unexplained thrombosis, 59% with Coombs-negative hemolytic anemia, and 47% with unexplained cytopenia. Almost all responders (98%) used flow cytometry to confirm diagnosis of PNH and the majority (77%) were aware that both erythrocytes and granulocytes or monocytes should be tested by flow cytometry to confirm diagnosis. Of the palliative medications prescribed to patients with PNH, blood transfusion was the most common (90% of patients), followed by immunosuppressants (48%) and iron supplements (42%). Almost all responders (98%) were aware of eculizumab; however, only 28% of patients were prescribed eculizumab. 17. 5% of patients underwent bone marrow transplantation (Middle-East and North Africa, 25%; Central and Eastern Europe, 10%). **Conclusions.** Within a population of hematologists with experience of

PNH, diagnosis may still take up to 3 years. The use of flow cytometry, the 'gold standard' for PNH diagnosis, is widespread, though greater awareness of the symptoms indicative of PNH is required. Palliative medications (immunosuppressants and iron supplements) are widely used despite having no impact on PNH[1]. Bone marrow transplantation is still used, particularly in the Middle-East and North Africa. This is despite its risk for substantial morbidities and mortality, and despite being indicated only for those patients with signs of bone marrow failure[2]. In spite of increased awareness of eculizumab effectiveness and its ability to reduce hemolysis and normalize survival[3], its use is not yet widespread in these regions. *Survey funded by Alexion. Authors received no financial support.*

IMPACT OF COMORBIDITY ON TREATMENT WITH 5-AZACITIDINE AND OUTCOME IN 39 PATIENTS WITH MYELODYSPLASTIC SYNDROME: A SINGLE CENTER POPULATION ANALYSIS

M Castelli[1], G Binotto[2], F Pavanello[2], M Ermani[3], R Zambello[2], G Semenzato[2]
[1]Department of Medicine, Hematology and Clinical Immunology Branch,, Padova, Italy
[2]Department of Hematology and Clinical Immunology Branch, Padua, Italy
[3]Department of Neuroscence, Padua, Italy

Background. Myelodysplastic syndromes (MDS) are a heterogeneous group of neoplastic disorders, with variable clinical course, originated from a clonal disorder of hematopoietic cell. MDS affects most frequently old individuals, who usually have an increased prevalence of comorbidities. Several studies are evaluating the impact of comorbidity on the natural history of the disease and on treatment decisions. The introduction of new hypomethylating agents, such as 5-azacitidine (AZA), extended the range of potentially curable people. **Aims.** To assess the impact of comorbidities, present at diagnosis, on the management and efficacy of therapy with AZA in patients with myelodysplastic syndrome. **Methods.** A retrospective analysis was conducted on 39 MDS patients admitted to our institution and treated with AZA. The diagnosis was established according to the 2008 WHO criteria; IPSS and WPSS prognostic scores were calculated. Comorbidities were defined according to three scales: CCI (Charlson comorbidity index), HCT-CI (hematopoietic cell transplantation-specific comorbidity index) and MDS-CI (myelodysplastic syndrome comorbidity index). The response to treatment with AZA was defined according to IWG 2006 criteria. **Results.** The mean age at diagnosis was 68 years and almost half of the patients was older than 70 years. The mean number of cycles was 6,13 (range 1-20); 51,3% performed less than 6 cycles. According to the three scales of comorbidity, on average 25% of patients had a high risk score. Comorbidity was not significantly correlated neither with a worst outcome nor with a less number of administered cycles. The overall response rate (complete response, partial response and hematological improvement) was 41%. The survival was associated with response to therapy (p=0. 002); a similar result was obtained considering survival related to stable disease (SD). **Conclusions.** At the time of staging MDS patients, it's important to characterize the clinical condition of the patient, in order to keep the most appropriate therapeutic approach. AZA is an effective and safe drug, despite of the comorbidity score, resulting as a valuable option in frail patients. Time of response is longer than conventional therapies. In patients with aggressive disease it is not easy to reach an optimal number of cycles. Furthermore, our data suggest that achievement of SD is associated with survival advantage in MDS patients.

BONE MARROW METASTASIS BY SOLID TUMORS: PREDICTION OF DIAGNOSIS AND PATIENTS OUTCOME

K Filanovsky[1], L Shvidel[1], E Feldberg[1], E Idelevich[2], M Shtalrid[3]
[1]Kaplan Medical Center, Rehovot, Israel
[2]Kaplan Medical Center Institute Oncology, Rehovot, Israel
[3]Kaplan Medical Center Institute of Hematology, Rehovot, Israel

Background. Bone marrow (BM) involvement is well-known complication of solid tumors witch generally affects treatment approach and patients outcome. **Aims.** In order to detect clinical and laboratory characteristics predicting spread to BM and survival of patients with metastatic malignancy, we analyzed and compared demographic data, localization of primary tumor and metastases, laboratory tests and BM aspirate and biopsy reports in patients with and without BM metastasis. **Methods.** We retrospectively evaluated data on 103 patients with metastatic solid tumors who underwent BM examination during the last decade. **Results.** Metastasis to BM was diagnosed in 72 cases, in 38 of them as a first evidence of malignancy. Pathologist was able to predict primary localization of the tumor in half of cases basing on BM biopsy only. Patients with and without BM involvement had comparable median age, gender distribution and pattern of the primary malignancy and metastatic spread. In univariate analysis, anemia (83% vs 61%; p=0. 015), thrombocytopenia (55% vs 16%; p<0. 001, with higher MPV 8. 73 vs 8. 17 fL p=0. 01, hypocellular/ dry tap marrow aspirate (58% vs 14%; p=0. 001) and leukoerythroblastic (LEB) blood smear (82% vs 0%; p<0. 0001) were found more commonly in patients with BM metastasis. In 92% of patients with LEB picture, the BM aspirate was hypocellular. At all, the marrow aspirate revealed cancer cells in 77% cases. The highest correlation rate of 93% between cytology and pathology reports was found in patients with prostate carcinoma. High (more than 2 upper limits, >2ULN) serum LDH and alkaline phosphatase levels were found more frequently in patients with BM metastasis (50% vs 16%; p=0. 002 and 35% vs 9%; p=0. 007, respectively). Multivariate analysis showed that thrombocytopenia <50x10^9/L (OR 14. 4; 95%CI, 1. 6-128; p=0. 02), hypocellular marrow aspirate (OR 7. 0; 95%CI, 1. 82-21. 2; p=0. 02) and alkaline phosphatase >2ULN levels (OR 6. 5; 95%CI, 1. 2-35. 3; p=0. 03) correlated with marrow involvement by biopsy. The diagnostic significance of the LEB picture was not calculated because of insufficient rate of records. Thrombocytopenia <50X10^9/L, LDH level >2ULN and primary presentation with BM metastasis vs BM spread occurring on follow-up were found to be main factors for poor outcome (median survival 0. 8 months (95% CI, 0. 1-1. 5) vs 4. 1m; (95%CI, 2. 0-6. 1); p<0. 001; 1. 8 months; (95%CI, 0. 5-3. 0) vs. 4. 7 months; (95%CI 3. 0-6. 3); p=0. 03 and 1. 8 months; (95% CI, 0. 3-3. 0 vs 4. 0 months (95%CI, 1. 3-6. 7); p=0. 03. **Conclusions.** Our results demonstrated that thrombocytopenia and high serum level of alkaline phosphatase correlate with BM metastasis in cancer patients. Although the diagnostic significance of the LEB picture was not calculated in the multivariate analysis, this finding correlated with hypoplastic aspirate that had been shown as a strong indication of BM involvement. Thrombocytopenia, high serum LDH and a finding of BM involvement at the time of malignancy primary diagnosis negatively affect overall survival

1473

APLASTIC ANEMIA IN PATIENTS OVER 60 YEARS OLD: EFFECTIVENESS AND SAFETY OF TREATMENT PROFILES

K Hurst, P Fuentes Galvez, C Bethencourt Mateos, A Bailén Garcia, ME Mingot Castellano, A Heiniger Mazo
HRU Carlos Haya, Málaga, Spain

Background. Aplastic anemia (AA) is a rare bone marrow failure syndrome characterized by peripheral pancytopenia and marrow hypoplasia. The incidence rate in patients over 60 years old is low. Due to the high morbidity and mortality related to bone marrow transplantation in older patients, immunosupresive therapy (IST) is the first line treatment. There is little evidence on the effectiveness and safety of IST in these patients. **Aims.** To describe the characteristics of patients over 60 years old with AA, and to analize the safety and effectiveness of treatment schemes, mortality rates and causes. **Methods.** We reviewed clinical histories of patients over 60 years old who suffer from AA at our hospital over the last four years. We collected data on age, sex, disease severity, treatment protocols and toxicities, type and duration of response to therapy, mortality and cause of death. Data source: clinical histories. Statistical desciption: non inferential because of the low level of patients. **Results.** Of 7 identified patients 1 was excluded due to incomplete follow-up. Of the 6 remaining patients all were female and they had a median age of 73 years (r, 63-87 years). 83% of them had a Charlson Index score of 2 or less (1 cardiovascular disease, 1 congestive heart failure, 1 peripheral vascular disease, 2 solid tumors and 2 cases of diabetes mellitus). 3 of the 6 patients had moderate AA, 1 severe AA and 2 very severe AA. 100% of patients received treatment with ciclosporin (CsA) in combination with other immunosuppresant drugs (in 3 cases associated with antithymocyte-globulin (ATG) and corticosteroids). After a median follow-up of 300 days (r, 90-1044 days), only 1 patient of the 6 responded to therapy, obtaining a partial response which lasted 953 days. Toxicities observed consisted of 3 cases of diabetes mellitus, 1 case of renal failure and 3 severe infections in three different patients. The only patient that responded to therapy developed a diffuse large B cell non-Hodgkin lymphoma 5 months after the diagnosis of AA, maintaining the acheived remission. At 15 months global survival was of 40% for non-responders, clearly inferior to the survival of the only responder. Causes of death were bacteremia, respiratory failure secondary to congestive heart failure and infection by Histoplasma capsulatum. **Conclusions.** AA is a disorder with a high mortality rate in over 60 year olds, but IST is generally well tolerated. While response rates are low, the

higher survival rates in responders clearly support the indication of IST, although the individualization of treatment decisions is fundamental due to the higher rate of co-morbidities in older patients.

COMPLICATIONS OF 5-AZACYTIDINE: THREE CASES OF SEVERE COLITIS IN A SINGLE CENTER COHORT

T Melchardt, L Weiss, L Pleyer, S Steinkirchner, R Greil, A Egle
Salzburg University Hospital, Salzburg, Austria

Background. The diagnosis of myelodysplastic syndrome (MDS) with high risk features according to the international prognostic scoring system (IPSS) results in a significant loss of lifetime in almost all patients, but allogenic stem-cell transplantation as the only curative option is not a valuable option for the majority of MDS patients due to age and co morbidity. 5-azacytidine (5-AZA) has shown a relevant benefit in terms of overall survival (OS) in patients with high-risk MDS in two randomized clinical phase III trials and based on these data about 549 patients 5-AZA was approved by the FDA in 2004 and by the EMA in 2008. The side effect profile of this drug seems favorable compared to conventional chemotherapy used for MDS or acute myeloid leukemia. However, rare side effects may have been overlooked in this cohort of patients. **Results.** Here we report a relevant incidence of hemorrhagic colitis in our single center cohort of 95 patients consecutively treated with subcutaneous 5-AZA between 2007 and 2011 in our tertiary cancer center within the Austrian Azacytidine Registry. Basic characteristics of the cohort have been presented in abstract form before (Pleyer et al.). 3 of 95 patients (3. 1%) developed severe colitis after a median of 1 month (range 1-2 months) of 5-AZA treatment. The median age was 81 years and 2 of the 3 patients were male. All had MDS with a high risk profile (2 cases of chronic myelomonocytic leukemia and 2 cases of refractory anemia with excessive blasts (RAEB)) and were treated with a median absolute dose of 140mg (100-150) for 7 days. Two of three patients had already known vascular complications before diagnosis of MDS (stroke and myocardial infarction). One patient was diagnosed with a severe hemorrhagic colitis at the end of the third cycle. The patient´s status deteriorated rapidly and after the diagnosis of colonic perforation colostomy had to be performed. Unfortunately, the patient developed a renal failure and died despite dialysis. Two other patients developed hemorrhagic colitis during or shortly after the first cycle of 5-azacytidine. After mesalazin treatment 5-AZA was continued in both cases after the resolution of the symptoms without further occurrence of colitis. **Conclusions.** To summarize we observed an incidence of 3 cases per 66. 8 person-years (4491 cases per 100. 000 person-years) in our cohort resulting in a much higher incidence compared with the incidence rates of colitis in the general population or in patients with older age and comorbidities (373 cases per 100. 000 person-years in patients older than 65 years with known COPD - Higgins et al. 2004). The reason for this relatively high incidence of colitis in our cohort is not clear. The reexposition in 2 patients without an adverse effect of 5-AZA makes a direct toxic effect on the mucosa or endothelial tissue very unlikely and we discuss whether the combination of anemia and constipation due to 5-HT(3) receptor antagonist and severe illness can explain the 3 cases of ischemic colitis. However, increased awareness for this complication in patients treated with 5-AZA should be warranted.

1475

SINGLE INSTITUTION EXPERIENCE OF 5-AZACITIDINE THERAPY IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES AND ACUTE MYELOID LEUKEMIA

A Freyrie, F Guidotti, G Reda, F Binda, A Cortelezzi
Hematology-BMT Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background. In intermediate-2 and high risk myelodysplastic syndromes (MDS), chronic myelomonocitic leukemia (CMML) with 10-29% marrow blasts, and acute myeloid leukemia (20% to 30% marrow blasts) 5-azacitidine induces hematologic responses and prolongs overall survival. **Aims.** We retrospectively evaluated the efficacy and tolerability of azacitidine in patients with MDS, CMML and AML in our institution, outside a trial setting. **Methods.** from 2009 to 2012, 25 patients affected by int-2 and high risk MDS, CMML or AML with marrow blasts < 30%, who were not candidates to aggressive therapy, have been treated with azacitidine at a dosage of 75mg/m2/d subcutaneously 7 days (schedule 5-2-2) every 28 days. The WHO diagnoses were: 17 MDS with IPSS risk int-2 or high, 6 AML with blasts 20-30% and 2 CMML. The median age was 72 (range 37-81), male to female ratio was 0. 6 and the median number of cycles received was 7 (range 1-26). **Results.** We evaluated 17 (68%) patients, (13 MDS, 3 AML, 1 CMML) who had received 4 or more cycles (median number of cycles 8, range 4-26; median age 71, range 37-81, male to female ratio was 0. 8). The overall response rate (ORR) was 10/17 patients (59%). According to International Working Group (IWG) 2006 criteria, we detected complete remission (CR) in five patients (29%) after a median of 5 cycles (range 4-6), hematologic improvement with bone marrow complete remission (marrow CR) in two patients (12%) after 6 and 11 cycles of therapy, hematologic improvement (HI) in three patients (18%) after 5 cycles (range 4-6), stable disease (SD) in 4 patients (23%) and progressive disease (PD) in three patients (18%) after 5 cycles (range 4-7). Median duration of response was 12 months (range 6-26); median overall survival, for all patients treated, from the beginning of azacitidine was 14. 4 months (range 7-33). No differences in response rate could be appreciated according to age, bone marrow fibrosis, cytogenetic and transfusion requirements. Seven out of eight transfusion dependent patients (87%) acquired transfusion-independence. In the responder group (ten patients) we observed only two significant infectious complications (mucositis and sinusitis) and only one hospitalization (median observation time 10 months, range 5-33). Among the seven non-responding patients, four (57%) required several admissions to hospital because of infectious or hemorrhagic complications (median observation time 15 months, range 7-33). **Summary and Conclusions.** Besides a high rate of response (ORR 59%, CR 29%), azacitidine was well tolerated. In particular the low rate of serious adverse events and of hospital admissions despite severe cytopenias, greatly improved quality of life and reduced utilization of standard medical resources. Azacitidine confirmed to be an active therapy in patients not candidate to high intensity treatment for age and/or comorbidities.

[11]Novartis Oncology, Mexico city, Mexico

Background. Primary Myelofibrosis (PMF) post - polycythemia vera MF (PPV MF), and post - essential thrombocythemia MF (PET MF) are Myeloproliferative Neoplasms (MPN), characterized by bone marrow fibrosis. Since is considered as a rare disease, data from the North American Association of Central Cancer Registries and the Surveillance, Epidemiology, and End Results program have estimated the annual incidence of BCRABL1-negative diseases to be 2. 1 per 100,000, with an overall 3-year survival rate of 80%. Current incidence in Mexico is unknown. The use of aspirin, hydroxyurea, and phlebotomy for PV and ET, and the use of androgens, steroids, chemotherapy, and radiation therapy for PMF continue to be the mainstay of therapy. The only potentially curative therapy is allogeneic hematopoietic stem cell transplantation, but treatment-related mortality remains high. The discovery of the JAK2-V617F mutation in 2005 has triggered the era of targeted therapeutic approaches for MF including JAK inhibitors. This report will focus on the characteristics of 22 MPN patients refractory to current available therapies in Mexico. **Aims.** To describe the principal characteristics of MPN patients refractory to current available therapies and evaluate the usefulness of demographic Myelofibrosis Clinical Assessment in a multi-institutional cohort of Mexico. **Methods.** We collected data from 22 patients including age, gender, institution (public or private); liver and renal function, complete blood cell count (CBC); subtype of disease; risk group, ECOG performance status, spleen size, and bone marrow fibrosis grade. **Results.** The median age was 63. 6 years; 47. 4% were female, 58% of patients proceeded from Private Health Institutions (PHI). Liver and renal function were adequate in 100% of patients, defined as direct bilirubin ≤ 2. 0 x ULN, and serum creatinine ≤ 2 x ULN; CBC analysis presented a peripheral blood blast count < 10%. 42. 1% of patients had PMF; 21% had PPV-MF; and 36% had PET-MF. 11% had Low risk; 53% intermediate-1 risk; 26% intermedi-

ate-2 risk; and 10% high risk. ECOG 0 was present in 21% of patients; ECOG 1, 63. 16%; ECOG 2, 10. 53%; and ECOG 3 in 5. 3%. Splenomegaly was found in 100% of cases; with 63% of splenomegaly less than 10cm; 26. 36% between 10 and 20cm; and 10. 53% more than 20cm. Spleen medium size was 10. 3 cm; BLCM. Bone marrow biopsy showed: No Fibrosis, 5%; Grade I, 42%; Grade II, 21%; Grade III. 32%. (Figure 1). **Conclusions.** Characteristics of MF patients of this multi-institutional cohort in Mexico, remark the disease's severity. The median age of patients was according with the literature reported (66 y. o.). In this cohort, most patients were from Private Health Institutions. And PMF was more frequent than PPV-MF and PET-MF.

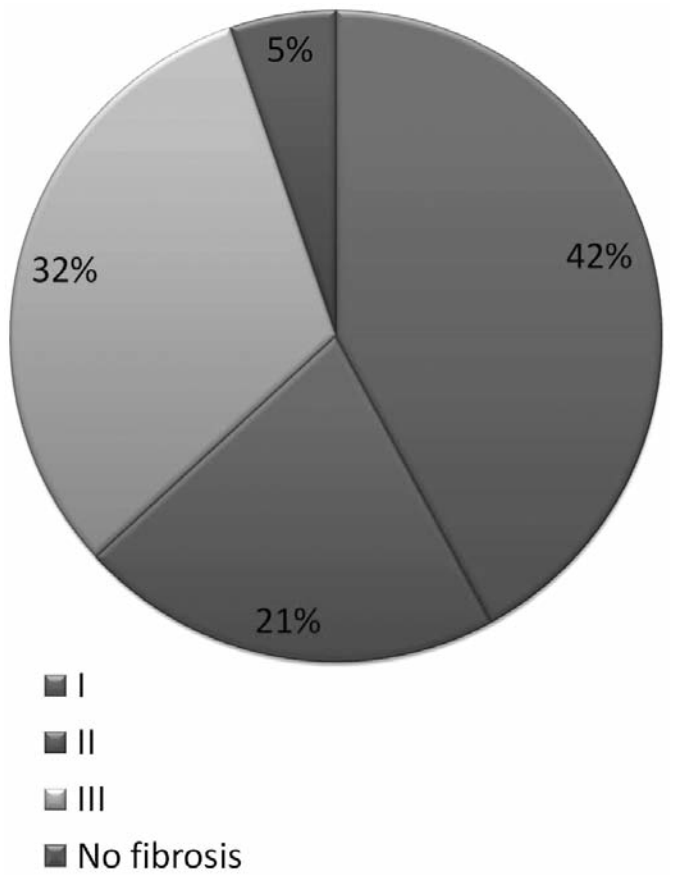

Figure 1. Grade of bone marrow fibrosis in patients with myelofibrosis in Mexico.

1477

TREATMENT OF CHRONIC MYELOMONOCYTIC LEUKEMIA WITH 5-AZACITIDINE: A CASE SERIES

F Moita[1], M Thorpe[2], A Almeida[1]
[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal
[2]School of Medicine, Flinders University, South Australia, Australia

Background. Chronic myelomonocytic leukemia (CMML) is a clinically heterogeneous clonal disease, recently classified as a mixed myelodysplastic/myeloproliferative disorder. Life expectancy is highly variable and there is currently no standard treatment. Stem cell transplantation remains the only potentially curative therapeutic strategy but only in highly selected patients. The previously documented hypermethylation of some genes in CMML indicates that hypomethylating agents could be an adequate targeted therapy in these patients and the efficacy of these agents is currently being tested in clinical trials. **Aim.** To evaluate the efficacy and toxicity profile of 5-azacitidine (AZA) in CMML patients. **Methods.** A retrospective analysis of patients diagnosed with CMML and treated with AZA in our institution between 2005 and 2010 was conducted. Diagnosis was established according to the World Health Organization 2008 criteria. AZA was administered subcutaneously, either as a seven-day regimen (75mg/m^2/day) or a five-day regimen (100mg/m^2/day), every 4 weeks. Patients received transfusions, antibiotics, and other supportive therapies, at the physician's discretion. Marrow response was assessed following the 6th treatment cycle and subsequent cycles were administered should there have been absence of disease progression. Responses were assessed according to the modified IWG criteria. **Results.** A total of eight patients were identified, with a median age at diagnosis of 66 years. Five were classified as non-proliferative CMML and the remaining as proliferative CMML. Seven cases fulfilled criteria for CMML-1 and one for CMML-2. Three patients had secondary CMML. All patients were transfusion dependent at diagnosis or soon after starting cytoreduction. Prior to AZA, five patients received cytoreductive therapy, one patient received erythroid stimulating agents, one thalidomide and other interferon, without any reduction in transfusion requirements. The overall response rate to AZA was 62. 5% (5 of 8), with 37. 5% complete responses (CR) and 37. 5% of cases with transfusion independence. Of note, a significant response rate was obtained in patients with proliferative CMML, with good control of leukocytosis and transfusion independence documented in 2/3 of these patients. With a median follow-up of 12 months, the median survival (from start of therapy) was 10 months and three patients are still being treated with AZA. Four patients have died, three from disease progression. Treatment was generally well-tolerated with no reported grade 3 or 4 toxicity except for one case of febrile neutropenia requiring hospital admission. **Conclusions.** In our series, AZA treatment was associated with an overall response rate of 62. 5%. Patients who achieved a CR had longer response durations. Interestingly, a significant response rate was also obtained in patients with proliferative CMML, encouraging the use of AZA in all forms of this disease. As the molecular pathogenesis of CMML is further elucidated, the number of available pharmacological treatment strategies will increase, leading to improved patient quality of life and outcomes.

1478

AUTO-IMMUNE HEMOLYTIC ANAEMIA AS INITIAL PRESENTATION OF MYELODYSPLASTIC SYNDROMES: REPORT OF THREE CASES

O Beyne-Rauzy, T Comont, M Dutertre, P Lay, P Cougoul, V Demas, D Adoue
Purpan Hospital, Toulouse, France

Background. auto-immune hemolytic anaemia (AIHA) represent a common manifestation of lymphoid disorders. **Aims.** we report three cases of AIHA associated with myelodysplastic syndromes (MDS). Two of them had favourable evolution either on specific MDS therapy or on corticosteroid therapy. **Case Report.** First case: 70 yrs old man developed one year after the diagnosis of MDS an acute anaemia with hemolytic features, biological tests showed red cell with auto-antibody. Outcome was good after 6 months period of corticosteroid therapy and slowly decrease of the dose. One year after the begining on therapy, no marker of relapse wes seen. Second case: 80 years old women was sent for severe anaemia due to 5q minus syndrome. Some hemolytic parameters revealed AIHA, corticosteroid was ineffective but lenalidomide at 5mg per day was effective in 15 days. One years after treatment discontinuation (polyglobulia) she remains in complete remission. Third case: 73 years old man with symptomatic anaemia. A the same time the diagnosis of RAEB-t (AML with 23% blasts) was performed. Irregular auto and alloantibodies were present. No transfusion was possible (severe reactions), no treatment gives results for the dinner. The patient died 15 years later with 2g/dl of hemoglobin level. **Conclusions.** evolutive profiles of AIHA in MDS differ from other situation. Corticotherpy are often uneffective (66%of cases).

1479

5-AZACITIDINE TREATMENT RESTORES RESPONSE TO EPOETIN THERAPY IN HIGH RISK MYELODYSPLASTIC (MDS) PATIENTS

M Volpe[1], A Volpe[2]
[1]A. O. San G. Moscati, Avellino, Italy
[2]Department of Hematology and Bone Marrow Transplantation, Avellino, Italy

5-Azacitidine(5-Aza) is an extremely valid therapeutic option in int-2/high risk MDS patients who can not undergo a bone marrow transplant procedure and is able to induce hematological responses and reduce the progression to acute myeloid leukemia in most of patients. Epoetin(Epo)therapy, differently by low risk MDS patients who obtain a high rate of erythroid responses, has no role in the setting of higher risk patients. Cause of the 5-Aza characteristics the response to the drug is not rapid but it generally takes at list three cycles to become evident with a progressive hematological and QoL improvement. For these reasons we have thought that the administration of Epo in int-2/high risk MDS patients who are on 5-Aza treatment and who begin to show some sort of erythropoietic response(expression of the MDS clone proliferative advantage reduction and the normal hematopoiesis expansion)could help to accelerate the hemoglobin rise, with a more rapid improvement in patients QoL. Three int-

2,three high-risk MDS patients and one AML patient have been treated with 5-Aza at our institution; some of them had a history of Epo therapy with no response. All patients were transfusion-dependent when they started 5-Aza. We decided to begin Epo therapy as soon as the patients showed some sort of initial erythroid response(Hb ≥ 8 g/dl for three consecutive determinations and an initial reduction in transfusional support need). All but one patient received α-Epo at a dose of 40. 000 IU/wk. All patients have shown a response to Epo (only one patient had to increase the dose to a twice weekly schedule)with a rapid improvement in QoL; in two of them the response has been extremely rapid and so impressive that we had to stop the drug. What is surprising is that these two patients had a very poor prognosis:- A 72 years old man with a high-risk MDS(complex cariotype, severe citopenia,high transfusional need:6 red blood cell unit/month)- A 60 years old female with a high-risk MDS secondary to high dose chemotherapy and bone marrow transplantation for NHL(-7 cariotype, severe citopenia and transfusional need:3 red blood cell unit/month)Cause of the low number of patients and the fact that it has been just a clinical study, it is not possible to draw any reasonable Conclusions. But as a regard to the results that we obtained it is our department policy to begin Epo therapy in the setting of int-2/high-risk MDS patients who are on 5-Aza and begin to show some sort of erythroid response

Background. Single nucleotide polymorphism genotyping microarray (SNP array) provides detailed information on chromosomal copy number imbalances. With such information, in addition to that from conventional chromosomal analysis, knowledge about the molecular pathogenesis of hematological malignancies including multiple myeloma (MM) has grown substantially.

Table 1. Frequencies and prognostic impact of chromosomal copy number abnormalities.

Copy number abnormality	Cases, n (%)	Prognosis	*p* value
1q+	20 (51.2)	-	0.082
3q+	12 (30.7)	-	0.893
5q+	10 (25.6)	-	0.716
6p+	8 (20.5)	-	0.538
7q+	12 (30.7)	-	0.618
9q+	16 (41.0)	-	0.223
11q+	15 (38.4)	-	0.365
15q+	15 (38.4)	-	0.058
ch 18+	5 (12.8)	-	0.550
19q+	17 (43.5)	-	0.065
del(8p)	11 (30.7)	-	0.155
del(13q)	15 (38.4)	poor	0.049*
del(16q)	6 (15.3)	-	0.190
del(17p)	5 (12.8)	-	0.118
del(22q)	7 (17.9)	-	0.217
All UPDs	17 (43.5)	-	0.193
NHD vs HD	16 (41.0)	poor	0.039*
NHD with 1q+ vs NHD without 1q+	8 (50.0)	poor	0.013*
HD with 1q+ vs HD without 1q+	12 (52.1)	-	0.965
NHD with del(13q) vs NHD without del(13q)	9 (56.2)	-	0.099
HD with del(13q) vs HD without del(13q)	6 (26.0)	-	0.542
deletion and UPD of *SEZ6L* (22q12.1)	11 (30.7)	-	0254.
HD with deletion or UPD of *SEZ6L* [(a)]	5 (27.7)	poor	0.040*
NHD with deletion or UPD of *SEZ6L* [(b)]	6 (37.5)	-	0.497

*indicates significant *p* value ($p < 0.05$).

+ indicates gain of chromosome.

(a) Compared with HD without deletion or UPD of *SEZ6L*.

(b) Compared with NHD without deletion or UPD of *SEZ6L*.

Abbreviations: ch, chromosome; del, deletion of chromosome; UPD, uniparental disomy NHD, nonhyperdiploid; HD, hyperdiploid; vs, versus *SEZ6L*, seizure related 6 homolog (mouse)-like

Aims. To investigate detailed genetic abnormalities which are related to pathogenesis of MM, we performed higher resolution SNP array which can provide more information on chromosomal copy number imbalances with higher quality. **Methods.** Genomic DNA, obtained from 39 bone marrow samples of MM patients and 11 cell lines, were analyzed by using 250K GeneChip SNP genotyping microarrays. The array data were analyzed with the copy number analyzer for GeneChips (CNAG) software for allele-specific copy number analysis (http://www. genome. umin. jp). The patients' clinical information were retrospectively obtained from the medical records. Kaplan-Meier survival curves were calculated using the SPSS software. **Results.** We identified accumulation of previously unidentified deletions and uniparental disomies in 22q12. 1. Among hyperdiploid MM, chromosomal imbalance of this locus provided poor prognosis ($p = 0.040$). By sequencing, a mutation was found in the seizure related 6 homolog (mouse)-like (*SEZ6L*) gene located at ch. 22q12. 1 in an MM cell line, NOP1. We further found isolated deletions in 17 genes, five of which are known tumor suppressor genes. Among these, deletion of protein tyrosine phosphatase, receptor type D (*PTPRD*) was found in 3 samples, including 2 from patients. Consistent with previous reports, non-hyperdiploid MM, deletion of 13q, and among non-hyperdiploid MM, gain of chromosome 1q were predictive of poor prognosis ($p = 0.039$, $p = 0.049$, and $p = 0.013$, respectively). However, our analysis revealed that unless accompanied by gain of chromosome 1q, the prognosis of non-hyperdiploid MM is comparable to that of hyperdiploid MM. **Conclusions.** We could find some candidate chromosomal copy number imbalances which might be related to pathogenesis and prognosis of MM. SNP array analyses provide significant information toward understanding the pathogenesis and prognosis of MM.

Backround. Monoclonal gammopathy of undetermined significance (MGUS) indicates an asymptomatic and potentially malignant state characterised by benign clonal proliferation of plasma cells secerning monoclonal immunoglobulin (MIG, M-protein) in the absence of malignant lymphocyte proliferation. It has been observed that in some patients, MGUS transforms into one of the malignant forms of monoclonal gammopathy. The well-known factors determining the risk degree of progression include in particular the quantity, M-protein type and the ratio of immunoglobulin free light chains (FLC) allowing the efficient stratification of MGUS patients. In addition, several authors consider the present suppression of polyclonal immunoglobulin levels to be a potential factor of progression. **Aims.** The study aimed at conducting a analysis of polyclonal immunoglobulin and heavy/light chain pair (HLC) levels in a group of MGUS patients. The polyclonal immunoglobulin levels and the levels of HLC alternative pairs were to be compared with a view to verify the degree of immune paresis depending on the MGUS risk degree. **Methods.** The analysed set comprised 130 serum samples of MGUS patients (102 IgG, 28 IgA) who were stratified into 4 risk groups (low, low-intermediate, high-intermediate, and high risk of transformation) according to the levels, M-protein type and FLC index values. FLC levels, polyclonal immunoglobulin levels, and HLC levels were determined by means of the SPA Plus turbidimeter platform. In the statistical analysis, Mann-Whitney U Test with Bonferroni correction was applied. **Results.** Comparison of the suppression degree of polyclonal immunoglobulin levels in individual risk classes in the IgG MGUS group brought significantly higher levels of IgA immunoglobulin in patients with low or low-intermediate risk as opposed to the group with high-intermediate risk (p = 0. 0001 and p = 0. 047 respectively). When analysing the MGUS group with IgA isotype, notably higher levels of IgM immunoglobulin were evident in the group with low-intermediate risk than in patients with high-intermediate or high risk (p = 0. 035 and p =

0. 017 respectively). In addition, the levels of alternative isotype pairs were compared among the individual risk groups of the IgG MGUS group. Patients with dominant IgGκ secretion showed significantly higher levels of the IgGλ alternative pair in the group of low and low-intermediate risk than in the group of high-intermediate risk (p = 0. 003 and p = 0. 006 respectively). In case of dominant IgGλ secretion, considerably higher IgGκ levels were detected in patients with low or low-intermediate risk than in the group of high-intermediate risk (p = 0. 0006 and p = 0. 009 respectively). **Conclusions.** The discovered connection between the degree of immune suppression depending on the MGUS risk level and especially the clearly visible benefit of determining the alternative HLC pairs contributes with another aspect to understanding the links between the biology, behaviour, and the potential malignant evolution of MGUS with the advantage of obtaining a well-measurable parameter. GENE EXPRESSIONS IN WHOLE BONE MARROW SAMPLES AND ASSOCIATION WITH OSTEOLYTIC BONE DISEASE IN MULTIPLE MYELOMA PATIENTS

I Kristensen[1], J Haaber[1], M Petersen[2], H Ditzel[2], N Abildgaard[1]
[1]Odense University Hospital, Odense C, Denmark
[2]University of Southern Denmark, Odense, Denmark

Background. The multiple myeloma (MM) plasma cell (PC) is dependent on the BM microenvironment. Most gene expression studies have been performed upon BM aspirates, which differ in cellular composition, or MACS isolated PCs. We used a new strategy to analyze gene expressions in snap-frozen BM biopsies, hereby coming close to what is "actually going on in the BM of MM patients". We analyzed the gene expression of known bone-regulating cytokines that predominantly are synthesized by stromal cells and that may be involved in the pathophysiology of myeloma osteolytic bone disease (OBD). **Aims.** To investigate the quantitative expression levels of bone-regulating cytokines: SDF1, GDF15, IL6 and IL6R, IL11, MIP1α and FGF2 in whole BM biopsies.

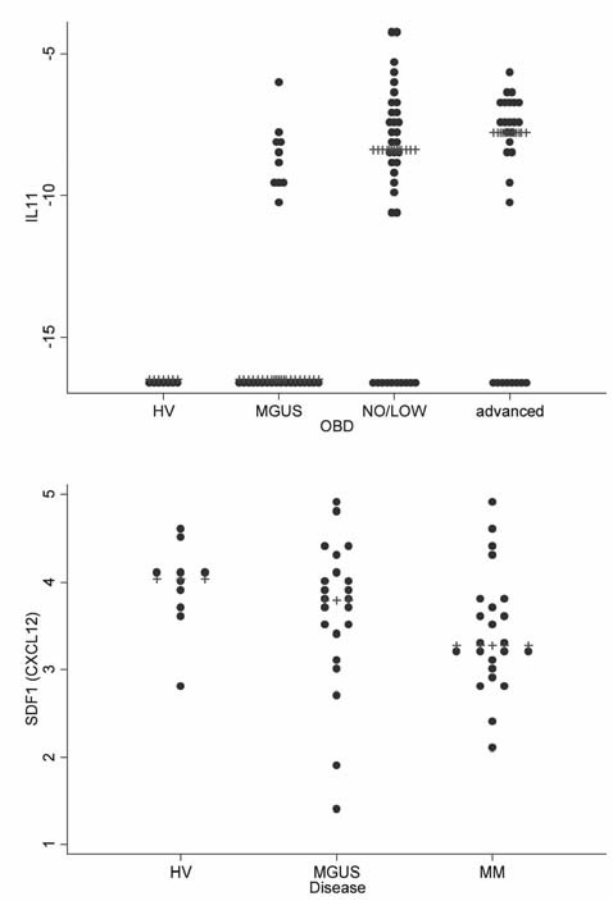

Fig 1. Delta Ct of significant genes.

Methods. During the diagnostic procedure we obtained an extra BM core biopsy which was snap-frozen. Biopsies where cut, homogenized and RNA was purified using the MagNa Pure Robot (Roche). cDNA was loaded for QPCR on 384-wells micro-fluidic cards (Applied Biosystems). Using 3 internal reference genes (ABL, GAPDH and GUS) the relative quantitative gene expression was calculated. OBD was evaluated using standard radiographs. All patients were untreated and did not receive bone-remodeling medicine. We examined 10 HV, 41 MGUS, and 71 untreated MM patients. Based on radiographic findings OBD was divided into NO/LOW and advanced, i. e. OBD in ≥2 regions. **Results.** The gene expression of IL-11 was significantly (p<0. 05) associated with OBD with increasing gene-expression with increasing OBD. FGF2, IL-6, GDF15, MIP1α and IL6R were not associated to OBD. CXCL12 associated significantly to disease state (HV vs MGUS vs MM). FGF2, IL-6, GDF15, MIP1α, and IL6R did not associate to disease stage (HV, MGUS or MM). **Discussion and Conclusions.** In our gene expression study reflecting the *in vivo* situation in MM, IL-11 was significantly associated to OBD. The use of whole snap-frozen BM core biopsies is a new method to evaluate gene expression in MM offering information on what is going on in the microenvironment. Furthermore, it is possible to investigate patients independent of degree of MM PC infiltration.

[2]University Hospital, Dijon, France

Multiple myeloma diagnosis and follow up are based on bone marrow plasma cell enumeration and monoclonal protein measurement. The estimation of monoclonal immunoglobulin production requires serum protein electrophoresis (sPE), serum immunofixation (sIF) and serum free light chain assay. A new immunoassay has been developed, based on the recognition of epitopes spanning the junction of the immunoglobulin's heavy and light chains, therefore allowing the measurement of IgA kappa (IgAk) and IgA lambda (IgAλ) heavy/light chain pairs. The aim of this study was to determine the clinical utility of this new assay for the diagnosis and follow up of myeloma patients. Ten non myeloma patients and 23 patients with IgA monoclonal gammopathies were enrolled. Total IgA, IgAk, IgAλ assays, sPE and sIF were performed at diagnosis and during follow-up. Post-treatment bone marrow residual disease was assessed by flow cytometry. At diagnosis, all myeloma patients had an abnormal IgAk/IgAλ ratio allowing a good discrimination between myeloma and non myeloma patients. During the monitoring of monoclonal immunoglobulin, we compared the concentration of IgAk or IgAλ to monoclonal spike estimation given by sPE when migrating in the γ region. The values of IgAk or IgAλ monoclonal isotypes gave an evolution profile that correlated well (R^2=0. 956) with the densitometric estimation of the monoclonal spike. For 2 patients who relapsed, the IgAk/IgAλ ratio became abnormal before sPE and sIF suggesting that this ratio could be an early marker for the disease relapse. For 4 patients under remission, the IgAk/IgAλ ratio was in accordance with the negative flow cytometry bone marrow residual disease evaluation, while the sIF was still slightly positive in 2 patients and became negative at the same time for the third patient or a month later for the fourth one. Concerning patients with disease progression (3 myeloma patients and 1 smoldering myeloma patient) we observed a progressive increase of the monoclonal isotype associated with the concomitant decrease of the non monoclonal isotype. The measurement of IgAk and IgAλ concentrations and the ratio evaluation gave clear information on the disease evolution. In conclusion, IgA heavy/light chain assay is an interesting tool that brings more insights in the myeloma biology. It provides automated, reproductible measurements of heavy/light chains of immunoglobulins. The values of IgAk or IgAλ can be used for monitoring myeloma. This will be even more useful when the monoclonal IgA comigrates on sPE with normal proteins in β region making impossible a reliable densitometric estimation. Moreover, the assay provides supplementary information on the non monoclonal isotype suppression or recovery. The very sensitive IgAk/IgAλ ratio provides an early appreciation of the response or relapse status.

HEVYLITE AS A BIOMARKER FOR MONITORING PATIENTS WITH IGM MONOCLONAL GAMMOPATHY AND ANTI-MAG NEUROPATHY

V Planche[1], L Arnaud[2], K Viala[1], M L'Hospital[1], M Miyara[1], J Leger[1], J Neil[1], V Leblond[1], L Musset[1]
[1]Hôpital Pitié Salpêtriere, Paris, France
[2]Hopital Pitié Salpêtriere, Paris, France

Background. Patients with neuropathy associated with anti-myelin-associated glycoprotein (MAG) antibodies and monoclonal IgM gammopathy constitute a distinctive clinical syndrome. Measurement of serum M-spike is used to monitor these patients; however, its resolution on serum protein electrophoresis (SPE) is sometimes impossible or inaccurate. The same applies to total IgM quantification by nephelometry (IgMneph). Recently, a new immunoassay, Hevylite® (Binding Site, Birmingham, UK), was developed to quantify separately IgMκ and IgMλ. The IgMκ/IgMλ ratio (HLC ratio) might provide true quantitative measurement of the IgM M-spike evaluating the involved monoclonal IgM compared to uninvolved polyclonal IgM. We sought to determine whether Hevylite™ assay can be used as a reliable marker for patients with anti-MAG neuropathy at diagnosis of IgM monoclonal gammopathy and to evaluate response to therapy as compared to the other tests currently available. **Methods.** The study was conducted in a series of 44 patients with anti-MAG neuropathy (30 monoclonal gammopathy of undermined significance (MGUS) and 14 Waldenström's Macroglobulinemia (WD)). All serum samples were collected prior and after chemotherapy (Chlorambucil or Rituximab) and were kept frozen at -80°C until subsequent use. Clinical response was defined as neuropathy stabilization or improvement after chemotherapy. M-protein was detected and quantified by SPE, then identified by Immunofixation electrophoresis (IFE) (Sebia, Evry, France). IgM anti-MAG antibodies were evaluated by ELISA (Bühlmann Laboratories, Basel, Switzerland). Hevylite™ measurements were performed by tubidimetry on SPA_{PLUS} analyser according manufacturer recommendations and compared with the normal range determined from normal sera (blood donors, n=147). Median (95th percentiles) were: IgMκ 0. 71g/L (0. 19-1. 63), IgMλ 0. 39g/L (0. 12-1. 01), HLC ratio 1. 81 (1. 18-2. 74). For ease of comparison, we mainly studied HLC ratio. **Results.** Before treatment, all 44 patients had monoclonal IgM detected by SPE and IFE, with only 24 (55%) having an IgM M-spike quantifiable on SPE. Thirty-nine patients (89%) had a monoclonal IgMκ and 5 a monoclonal IgMλ. All patients had anti-MAG antibody level higher than 1000 BTU (Bühlmann titer units) and abnormal HLC ratio using Hevylite™. For patients with IgMκ, a ROC curve showed that HLC ratio had 89% specificity, 42% sensitivity and AUC of 0. 72 to distinguish patients with WD from those with MGUS, for a cut-off ratio of 60. Thirty-eight patients (86%) responded clinically. In before/after treatment comparisons, neither HLC ratio (p=0. 83) nor M-spike on SPE (p=0. 74) were associated with disease course after chemotherapy, whereas we observed a significant decrease of anti-MAG activity for patients with clinical response (p=0. 04). **Conclusions.** We assessed the diagnostic and prognostic value of Hevylite™ assay in anti-MAG neuropathy associated with IgM MGUS or WD. Current laboratory assays have some limitations: IFE cannot quantify IgM; SPE and IgMneph are not sensitive enough to evaluate accurately involved IgM; anti-MAG activity is frequently above the limit of quantification. HLC ratio has the advantage of providing numerical results for all patients, especially for monitoring patients with MGUS. Hevylite™ needs further validation and might become the reference technique to monitor the IgM M-protein associated with anti-MAG activity.

ANALYSIS OF CHROMOSOMAL ABNORMALITIES ASSOCIATED WITH HIGHER RISK OF MALIGNANT TRANSFORMATION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

A Mikulasova, P Kuglik, H Greslikova, R Kupska, J Smetana, P Nemec, L Rihova, M Klincova, V Sandecka, R Hajek
BMG, Depart. of Pathological Physiology, Faculty of Medicine, Masaryk University, Brno, Czech Republic

Background. Monoclonal gammopathy of undetermined significance (MGUS) is a precancerosis permanently associated with higher risk of transformation into malignant disease. Similarly to multiple myeloma patients, specific chromosomal aberrations in bone marrow plasma cells (PCs) in MGUS persons were reported, especially del(13)(q14), del(17)(p13), *IGH* rearrangement, 1q21 gain and hyperdiploidy (Lopéz-Corral, L. *et al.,* Clin. Cancer Res. 2011). Some of them are considered to be prognostic factors determining potential risk of MGUS transformation to malignant condition. **Aims.** 1) Examination of specific chromosomal abnormalities in the MGUS persons by I-FISH. 2) Assessment of impact of phenotypically abnormal PCs (aPCs; $CD138^+CD19^-CD56^{+/-}$) separation on the frequency of monitored chromosomal abnormalities. 3) Evaluation of potential prognostic value of the observed chromosomal abnormalities. **Methods.** We analyzed 60 MGUS persons: 36M/24F; age median 64 years; follow-up median 26 months. By interphase fluorescence *in situ* hybridization (I-FISH) we examined following chromosomal abnormalities: del(13)(q14), del(17)(p13), *IGH* rearrangement, t(11;14), t(4;14), t(14;16), 1q21 gain and hyperdiploidy (+5, +9 and +15). The I-FISH was performed on PCs i. identified by fluorescence imunophenotyping (cIg-FISH technique) in 3% (2/60) cases; ii. separated by magnetic activated cell sorting (MACS) or fluorescence activated cell sorting (FACS) using $CD138^+$ marker in 63% (38/60) cases; and iii. separated by FACS using $CD138^+19^-56^{+/-}$ markers in 33% (20/60) cases. **Results.** In the cohort of 60 MGUS persons, we found del(13)(q14) in 21% (11/52) cases, del(17)(p13) in 2% (1/52) cases, *IGH* rearrangement in 71% (31/44) cases, t(11;14) in 50% (2/4) cases, t(4;14) in 10% (4/39) cases, t(14;16) in 6% (1/16) cases, 1q21 gain in 13% (6/48) cases and hyperdiploidy in 15% (7/47) cases. We observed that del(13)(q14) occurred significantly more frequently in persons with hyperdiploidy than with non-hyperdiploidy (67% vs. 17%, p<0,05), and in persons with 1q21 gain than without 1q21 gain (67% vs. 16%.; p<0,05). Comparison of MGUS subgroups with different PCs phenotype enabled to us to show that I-FISH analysis in aPCs allowed to significantly higher frequency of t(4;14) than I-FISH analysis in PCs with CD138+ phenotype (25% vs. 0%; p<0,01). Using stratification model for predicting the risk of MGUS transformation incorporating 3 risk factors (serum monoclonal immunoglobulin ≥15g/l, non-IgG subtype and abnormal FLC ratio) (Rajkumar, S. *et al.,* Blood 2005). MGUS persons were divided into three risk groups: low risk was in 27% (9/33) cases, low-intermediate risk was in 39% (13/33) cases and high-intermediate risk was in 33% (11/33) cases. High risk was not detected in any case. Analysis of frequency of monitored chromosomal abnormalities demonstrated that del(13)(q14) and two or more structural chromosomal abnormalities occurred significantly higher in low-intermediate risk group (45% and 46%) and high-intermediate risk group (33% and 18%) than in low risk group (both 0%; p<0,05). **Summary.** In this study, we confirm that all monitored chromosomal abnormalities, which usually occur in multiple myeloma, are present in MGUS. We also demonstrated that del(13)(q14) or presence of two or more structural chromosome abnormalities may indicate the higher risk of MGUS transformation to malignant condition. **Support.** The study was supported by grants MSM0021622434, GAP304/10/1395, NT11154, NT12425, NT12130.

1486

BORTEZOMIB DOWNREGULATES THE EXPRESSION AND PRODUCTION OF STROMAL CELL-DERIVED FACTOR-1 IN BONE MARROW STROMAL CELLS

HY Kim, YS Oh, IC Song, HJ Lee, HJ Yun, S Kim, DY Jo
Chungnam National University Hospital, Daejeon, South-Korea

Background. Stromal cell-derived factor-1 (SDF-1) is a chemokine that is expressed constitutively and produced in bone marrow stromal cells (BMSCs). Myeloma cells express CXCR4 and respond to SDF-1, resulting in the trafficking and localisation of these cells in the bone marrow (BM). SDF-1 alone has minimal or negligible effects on the survival and growth of myeloma cells *in vitro*. However, many reports are consistent with the SDF-1/CXCR4 axis being involved in the progression of myeloma and suggest that modulation of the SDF-1/CXCR4 axis could influence the biology of myeloma cells and the disease course. Bortezomib induces apoptosis and strongly inhibits the proliferation of myeloma cells, although the effects of bortezomib on BMSCs are not clear. We hypothesised that bortezomib affects the expression or production of SDF-1 in BMSCs. **Aims.** To define the effects of bortezomib on the expression and production of SDF-1 in BMSCs derived from both healthy individuals and patients with multiple myeloma. **Methods.** We investigated bortezomib-induced alterations in the expression and production of SDF-1 in the bone marrow stromal cell line MS-5 and in BMSCs obtained from three healthy individuals and three patients with multiple myeloma. The expression of SDF-1, CXCR4, and CXCR7 mRNA was analyzed using reverse transcriptase-polymerase chain reaction (RT-PCR) and real-time quantitative (RQ)-PCR. The production of SDF-1 was measured using Western blotting and an enzyme-linked immunosorbent assay (ELISA). **Results.** In a 3-day incubation of MS-5 cells, low-concentration (5 nM) bortezomib did not affect cell proliferation, whereas ≥50 nM bortezomib abolished cell proliferation. By contrast, bortezomib concentrations ≤500 nM did not affect apoptosis of the MS-5 cells over the 3-day period. Similar results were obtained with BMSCs from both healthy individuals and patients with myeloma. RQ-PCR revealed that bortezomib induced the downregulation of SDF-1 mRNA in a dose-dependent manner in MS-5 cells. Treating the cells with bortezomib at concentrations of 5, 50, and 500 nM for 24 h reduced the SDF-1 mRNA to 50, 20, and <10% of the control, respectively. Similar results were obtained with BMSCs from healthy individuals and patients with myeloma. Bortezomib induced the downregulation of SDF-1 production in a

dose-dependent manner in both MS-5 and BMSCs, as analyzed by Western blotting and confirmed by measuring SDF-1 concentrations in the 3-day culture supernatants of the cells. In line with these results, the supernatants from bortezomib-treated MS-5 cells induced MO7e cell chemotaxis to a much lower extent compared with non-treated cells. MS-5 cell monolayers were treated with bortezomib for 24 h, washed, and then overlaid with RPMI8226 cells. The migration of RPMI8226 cells under the monolayer was checked 24 h later, and the number of cobblestone areas was checked 5 days later. Both were reduced significantly in the bortezomib-treated monolayers compared with the non-treated monolayers, indicating that bortezomib-induced downregulation of SDF-1 was functionally active *in vitro*. **Conclusions.** Bortezomib affects not only myeloma cells but also BMSCs. Most notably, it downregulates the expression and production of SDF-1 in the cells irrespective of the presence of myeloma.

1487

HEAVY/LIGHT CHAIN (HLC) NEPHOLOMETERIC ASSAYS EFFECTIVELY MONITORS OLIGOSECRETORY MULTIPLE MYELOMA PATIENTS WHO CANNOT BE MEASURED BY OTHER SEROLOGICAL MARKERS

H Ludwig[1], P Young[2], L Mirbahai[2], N Zojer[3], D Milosavljevic[4], W Hübl[4], S Harding[2]

[1]Wilhelminenspital, Wien, Austria

[2]The Binding Site Group Ltd, Birmingham, United Kingdom

[3]Wilhelminenspital/Department of Medicine I / Center for Oncology and Hematology, Vienna, Austria

[4]Wilhelminenhospital / Central Laboratory (with bloodbank), Vienna, Austria

Background. Effective monitoring of multiple myeloma (MM) patients enables physicians to accurately assess patient's responses to therapy and make timely decisions regarding treatment changes. Approximately 1% of MM patients are oligosecretory, defined as less than 10g/L monoclonal immunoglobulin. Monitoring these patients using standard electrophoretic techniques represents a significant challenge. The introduction of the polyclonal serum free light chain (FLC) test (Freelite®) has improved the ability to monitor these patients and international guidelines now recommend their use when >100mg/L FLC can be measured at presentation. However, in a small subset of patient's FLC testing is of limited utility. Here we assess the utility of novel IgAk / IgAl nephelometic immunoassays and comment on their utility in oligosecretory patients. **Aims.** To assess the utility of HLC IgA measurements to monitor patients with IgA oligosecretory MM. **Methods.** HLC and FLC assays were performed retrospectively on stored sera from 11 oligo-MM patients (5 IgAk and 6 IgAl). Patients were followed from start of therapy and monitored in regular intervals during the course of their disease. **Results.** 5/11 IgA oligo-MM patients had iFLC >100mg/L at presentation (median 298mg/L, range 125-6700mg/L); each patient achieved a partial response (PR; >50% reduction FLC concentrations). 6/11 IgA patients had iFLC<100mg/L at presentation (median 32mg/L, range 16-57mg/L); all 6 of these patients had an abnormal HLC ratio at presentation. Overall, changes in HLC ratios were in accordance with the clinical assessment during patient monitoring. 5/6 patients responded to therapy; at maximum response 3 patients achieved a PR, 1 patient achieved a very good partial response (VGPR) and 1 patient achieved a near complete response (nCR). In each case the HLC IgA ratio reduced but remained abnormal. The remaining patients failed to respond to therapy, and maintained a stable, abnormal HLC ratio throughout monitoring. In 3/6 patients (2 IgAk / 1 IgAl), increasingly abnormal HLC ratios identified disease progression before either an increase in monoclonal proteins was identifiable by SPE (median: 195 days, range 104-445 days). One IgAk patient achieved a VGPR after 284 days; the response was maintained for 168 days before a relapse was identified by a 101% increase in monoclonal immunoglobulin. Increases in the HLC ratio indicated a relapse after 340 days, 112 days earlier than the traditional assessment. The patient responded to second line therapy and achieved a second VGPR after 601 days. Again increasingly abnormal HLC ratio identified a second relapse 104 days earlier than traditional assessment confirmed progression. In a second IgAk patient achieved a PR after 1941 days and increasingly abnormal HLC ratio identified relapse after 2341 days, 445 days before clinical assessments. Finally, in 1 IgAl patient who initial failed to respond to therapy, achieved a PR after 510 days. An increase in the patient's HLC ratio after 560 days indicated disease progression, 120 days before clinical assessments. **Conclusions.** HLC analysis allows the sensitive detection of monoclonal protein in oligosecretory MM patients. This sensitivity is a reflection of both the tumor production and isotype matched suppression and may aid in oligosecretory patient monitoring.

1488

ANALYSIS OF SERUM LEVELS OF THYMIDINE KINASE IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND MULTIPLE MYELOMA COMPARISON WITH IMAGING Methods 99MTC-MIBI SCINTIGRAPHY AND 18F-FDG PET/CT

J Bacovsky

University Hospital Olomouc, Olomouc, Czech Republic

Background. Proliferation is a independent prognostic factor and target for risk adapted treatment in multiple myeloma. Increased activity of thymidine kinase in serum is associated with higher proliferation rate in hematological malignancies. The imaging methods as 99mTc-MIBI scintigraphy or 18F-FDG PET/CT can imagine active myeloma lesions and their positivity is negative prognostic factor. **Materials and Methods**The analyzed group of 51 patients consisted of 14 (27,5%) individuals with monoclonal gammopathy of undetermined significance (MGUS) and 37 (72,5%) patients with multiple myeloma (MM). There were 25 female (49%) a 26 male (51%) in the group. The average age in the group was 63 years. Thymidine kinase (TK) in serum was evaluated by TK REA and TK 'the novel technique' We analyzed correlation of serum TK with biochemical markers reflecting activity of multiple myeloma (MM), e. g. B2M, LDH, free light chains ratio: kappa/lambda K/L, infiltration of bone marrow by plasma cells (Pl. b). The imaging methods as MIBI or PET/CT which imagine active myeloma lesions were done at the time of diagnosis in 20 patients. **Results.** We found a strong positive correlation between TK values by TK REA and TK 'the novel technique'(r=0,822). After extreme values were excluded, the correlation coefficient r=0,787. There was clear correlation of serum thymidine kinase with biochemical markers reflecting activity of multiple myeloma (MM), e. g. B2M, LDH, free light chains ratio: kappa/lambda K/L, infiltration of bone marrow by plasma cells (Pl. b). Correlation TK 'the novel technique' vs. B2M, LDH, K/L, Pl. b. TK REA - positive correlation of medium strength with B2M (r=0,527) and LDH (r=0,553). TK 'the novel technique' - positive correlation of medium strength with B2M (r=0,456), LDH (r=0,573) and weak to positive correlation of medium strength with Pl. b. (r=0,386). Mann-Whitney U test showed at the group of patients with MM (stage I, II or III) significantly higher values of TK REA and TK 'the novel technique'in comparison to patients in stage MGUS. Median TK REA was 6,0 at MGUS, resp. 9,5 at MM (p=0,004), median TK 'the novel technique' was 27,6 at MGUS, resp. 135,9 at MM (p = 0,008). Imaging methods MIBI or PET/CT were positive in 13 patients, and negative in 7 patients. Increased levels of serum thymidine kinase were observed in MIBI or PET/CT positive patients, but correlation did not reached significance level. TK 'the novel technique' vs. PET/CT, MIBI (0=negative / 1 or 2 =positive) (without extreme values of TK 'the novel technique' Mann-Whitney U test did not show significant difference in values of TK REA or TK 'the novel technique' between group of patients with positive and negative PET, MIBI result (p=0,501, resp. p=0,285). AUC = 0,775 - it means TK 'the novel technique' could be used as a predictor for multiple myeloma. **Conclusions.** Statistical analysis revealed significant correlation between serum levels of thymidine kinase and LDH and B2M. Increased levels of serum thymidine kinase were observed in MIBI or PET/CT positive patients, but correlation did not reached significance level. **Supported by grant** *IGA MZ ČR NT 12215-4/2011.*

[3]Selcuk University Meram Medical School, Ankara, Turkey, Ankara, Turkey

[4]Ankara University-Biotechnology Institute, Ankara, Turkey

[5]Ankara University Faculty of Medicine, Ankara, Turkey, Ankara, Turkey

Background. In the past several years, multiple recurring translocations,deletions and amplifications have been defined and mapped to the earliest stages of the developing MM clone. However gene expression profiling using SNPs have identified further abnormalities defining multiple clusters. Despite of all these efforts the molecular pathogenesis is still unclear. A complementary approach to the study of gene expression profiling is proteomic and molecular profiling. Fourier Transform Infrared (FT-IR) spectroscopy is a widely used and preferred method of infrared spectroscopy due to their speed and sensitivity for molecular profiling. With FT-IR, a complete molecular diversity of the samples(all types of organic and many types of inorganic compound) can be studied comparatively with a knowledge of the origins of the peaks(such as

lipids, proteins,carbohydrates,nucleic acids etc) and also the amount of the particular compounds,secondary-structures of proteins, post-translational modifications and protein-protein interactions can be determined. **Aims.** The aim of this study is to achieve molecular characterization of biomolecules in MM by using FT-IR spectroscopy and cluster analysis. **Methods.** Study group consisted of 6-MM, 4- monoclonal gammopathy of unknown significance (MGUS), 4-smoldering multiple myeloma(SMM) patients and 2-healthy controls who were selected from Ankara University Department of Hematology. Infrared spectra were obtained by Bruker-Tensor-27-FT-IR(Bruker-Optics,GmbH,Germany). Spectras from urine samples recorded in the mid-infrared-region, between 3800-850 cm^{-1} wave numbers and interferograms were accumulated for 32 scans at 4-cm^{-1} resolution at 22ºC in the single-bounce-ATR mode. All data collection, manipulation and analyses were performed by OPUS software(Bruker Optics). **Results.** According to our results, there are 9-significant peaks in FT-IR spectra of MM, SMM, MGUS and control samples (Figure 1A). It has been found out that absolute intensity of peaks were decreased in MM group compared to others groups. Second derivatives of absorbance spectra were calculated using Savitzky-Golay algorithm with 9-smoothing points. Relative intensity values of second derivative peaks in the Amid-I-region(1700-1590cm^{-1}) which were obtained by automated peak-picking were used to compare protein secondary structures (Figure-1C). Relative intensity of peaks in MM group were found to be decreased in 1680cm^{-1} and increased in 1650cm^{-1} compared to other groups (Figure-1D). These regions are known to represent C=O bonds in secondary structures of proteins. Cluster analysis(hierarchical clustering) was carried out by OPUS software and the results demonstrated two significant separation between MM, and SMM, MGUS and control groups (Figure-1B) and found to be clustered together as expected in normal diagnostic outcomes. Our preliminary findings show that FT-IR is feasible and replicable. During the congress comparison of findings between active-MM, SMM, MGUS and controls will be presented with protein profile datas. **Conclusions.** The current molecular technologies such as proteomics and molecular profiling are under development and is may be the reason why there is only one report on proteomics in MM(Micallef et al-2010). The advantages of overcoming the problem of uncoded genetic aberrations or inhibition by micro-RNAs and leading to direct measurement of proteins in quantity as well as demonstration of chemical structural changes may enhance the role of this technology in MM where secretory proteins and cytokines are essential elements.

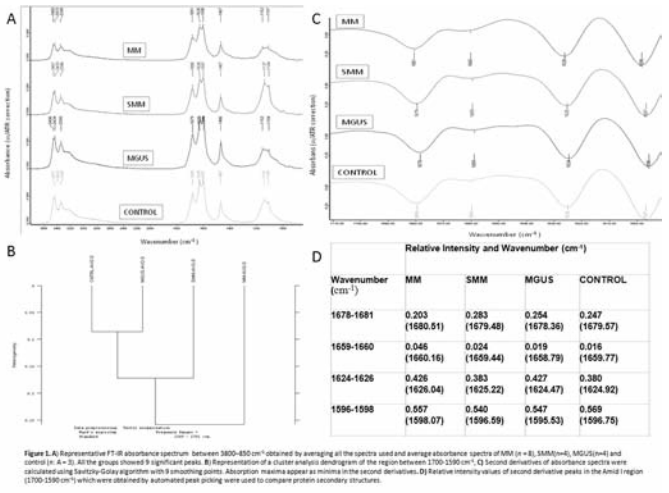

Figure 1. A) Representative FT-IR absorbance spectrum between 3800-850 cm^{-1} obtained by averaging all the spectra used and average absorbance spectra of MM (n = 8), SMM(n=8), MGUS(n=4) and control (n. 4 = 3). All the groups showed 9 significant peaks. B) Representation of a cluster analysis dendrogram of the region between 1700-1590 cm^{-1}. C) Second derivatives of absorbance spectra were calculated using Savitzky-Golay algorithm with 9 smoothing points. Absorption maxima appear as minima in the second derivatives. D) Relative intensity values of second derivative peaks in the Amid I region (1700-1590 cm^{-1}) which were obtained by automated peak picking were used to compare protein secondary structures.

EARLY B LYMPHOPOIESIS IN BONE MARROW IS SUPPRESSED WITH MULTIPLE MYELOMA PROGRESSION

M Ichii[1], K Oritani[1], Y Habuchi[1], H Sata[1], T Maeda[1], P Kincade[2], Y Kanakura[1]
[1]Osaka University Graduate School of Medicine, Osaka, Japan
[2]Oklahoma Medical Research Foundation,, Oklahoma, United States of America

Background. Detailed analysis of lymphoid lineage subsets is helpful for evaluation of immune status. We previously described subpopulations of $CD34^+$ early lymphocyte progenitors in marrow that differ in CD10 expression. CD10 intensity correlated well with ability to proliferate in vitro and with lymphoid-lineage gene expression. In addition, $CD34^+$ $CD10^{Hi}$ and $CD34^+$ $CD10^{Low}$ populations had unique patterns depending on their sources; cord blood, bone marrow (BM) and G-CSF mobilized peripheral blood. We have now analyzed other B-lymphocyte precursors, collectively termed hematogones. Their numbers are known to vary in hematological malignancy, marrow regeneration and immunodeficiency. Our $CD34^+$ $CD10^+$ subpopulations in part overlapped with early stage hematogones. Although it might have clinical relevance, levels of hematogones in multiple myeloma (MM) patients are poorly understood due to the difficulty in distinguishing them from MM cells. **Aims.** To evaluate percentages of hematogones in MM patients using multi-color flow cytometry and to study the association with disease characteristics. **Methods.** BM samples were collected after informed consent, using protocols approved by the Investigational Review Board of Osaka University Hospital. Samples from patients with measurable MM cells, after an interval of more than 2 months from the last chemotherapy or 1. 5 years after high-dose chemotherapy with auto PBSCT, were immunophenotyped by 5-color (CD34/CD38/CD10/CD20/CD45) flow-cytometric analysis. Hematogones were divided into 4 maturation stages: $CD34^+$ $CD10^{Hi}$ stage 1, $CD34^-$ $CD10^{Hi}$ $CD20^-$ stage 2-1, $CD34^-$ $CD10^{Low}$ $CD20^{Low}$ stage 2-2 and $CD34^-$ $CD10^-$ $CD20^{Hi}$ stage 3. We sought correlations with age, percentages of MM cells in BM, albumin, β2microglobulin (B2M), creatinine and hemoglobin. *p* values < . 05 were considered to be significant. **Results.** There were 19 patients aged 52 to 78 years. Eleven were newly diagnosed, and 5 received high-dose chemotherapy following auto PBSCT. MM cells were clearly detected with CD38, CD20 and CD45 intensities, and percentages determined by flow cytometric analysis were consistent with those from microscopic evaluation. This isolation strategy made us possible to study normal lymphopoiesis in MM patients. Age, albumin, creatinine and hemoglobin showed no significant relevance. However, patients with high B2M (> 3. 5 mg/dl) had significantly lower percentages of stage 1, 2-1 and 3 hematogones, while mature lymphocyte counts in peripheral blood were not associated. The same was true for untreated patients. The burden of MM cells (>30% in BM) also affected the distribution among hematogone stages. Percentages of $CD34^+$ $CD38^-$ hematopoietic stem cells and $CD34^+$ $CD38^+$ hematopoietic progenitor cells did not show any correlation with B2M or tumor mass, indicating that the suppression of early hematopoiesis in MM is lymphoid lineage restricted. **Summary and Conclusions.** Most studies concerning impairments in cellular and humoral immunity in MM focused on regulation of mature lymphocyte function. We now show that early stages in normal B lymphopoiesis are suppressed in myeloma BM. In addition, there was a negative correlation between hematogones and the prognostic factor, B2M. Our study suggests that BM hematogone percentages may be useful for predicting MM patient outcome.

1491

PROTEASOME 20S CONCENTRATION IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

A Kostur, A Kulczynska, M Galar, J Kloczko
Medical University of Bialystok, Bialystok, Poland

Background. The proteasome is a multicatalytic complex found in all eukaryotic cells. It is responsible for the degradation of many proteins which take part in cell development. During rapid cell turnover and growth proteasomes are released into the circulation and they can be measured in plasma by enzyme-linked immunoabsorbent assay (ELISA) techniques. Abnormally high level of proteasomes has been observed in leukemias, multiple myeloma and some solid tumors. Moreover, the concentration of circulating proteasome correlates with the disease state, and may have prognostic significance. **Aims.** The aim of our study was the assessment of the proteasome 20S concentration in the plasma of patients with newly diagnosed multiple myeloma (MM). **Materials and Methods.** The study included 30 patients with newly diagnosed MM (14 females, 16 men; mean age, 67. 3 years) and 15 healthy subjects (7 females, 8 men; mean age, 65. 7 years). The patients were followed-up in the Department of Hematology at the Medical University of Bialystok, Poland. All patients were divided into three groups based on international staging system (ISS): three patients at 1st stage, ten patients at 2nd stage and seventeen at 3rd stage. Approval for this study was obtained from the Local Ethic Committee. The concentration of proteasome 20S in the plasma was assayed using commercial test (20S/26S proteasome ELISA Kit, *Enzo Life Sciences)*. Statistical analysis was done using Shapiro-Wilk, Mann-Whitney and Spearman's tests. The statistical significance of the measured differences was determined using an alpha index of 0. 05. **Results.** Proteasome 20S concentration was significantly elevated in the patients with MM in comparison to healthy subjects (6. 63±4. 51µg/ml vs 3. 04±1. 34µg/ml, p=0. 004). Statistically significant correlations were found between proteasome 20S and albumin concentrations as well as between proteasome 20S concentration and serum LDH activity, but no correlation was found between proteasome 20S and β2-microglobulin concentrations (p=0. 64). The highest level of proteasome 20S was observed at 3rd stage of ISS score and the lowest at 1st stage. **Conclusions.** Our results confirm reports about increased concentrations of proteasome 20S in plasma of patients with

MM. The increased plasma concentration correlates with advancement of the disease.

SERUM HSP70 PROTEIN AND ANTI HSP70 ANTIBODIES IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS

J Piszcz, A Kulczynska, A Holownia, J Oleksiuk, K Mazgajska-Barczyk, A Kostur, L Bolkun, E Cichocka, D Lemancewicz, J Kloczko
Medical University of Bialystok, Bialystok, Poland

Background. Multiple myeloma (MM) is the second most common hematologic malignancy that despite of great progress in its treatment, still remains incurable. Heat shock proteins (HSPs) are molecular chaperones involved in a number of cellular functions in stress conditions. It is well established that plasmatic cells express HSPs including HSP70. It has also been suggested that an increased surface expression of heat shock proteins on apoptotic tumour cells results in the generation of potent antitumour T-cell responses. On the other hand HSP70 may influence on sensitivity and resistance of MM cells for chemotherapy. Additionally, anti HSP70 antibodies are known to play a role in immunological and neoplastic processes. However their significance in MM has not been documented. **Aims.** The aim of our study was the assessment of the HSP70 protein and anti HSP70 antibody concentration in the MM patients. Materials and **Methods.** The studied group consists of 34 newly diagnosed, symptomatic MM patients (aged 41 -85), males 19 and females 15. The patients were in 1-3 stages of MM according to ISS scale. All of studied patients required chemotherapy. A control group contains of 20 healthy individuals. Identification and quantitative assessment of HSP70 antigen was performed using Western Blott method using specific antibodies (SPA810, Stressgen). Quantitative determination of anti-human HSP70 antibodies in the serum was done using commercial test (anti HSP70 Elisa Kits, Stressgen). The results are presented as mean ± SEM. Statistical analyses were carried out using software Statistica. The normality of continuous variables was assessed using the Shapiro-Wilk's test. As the continuous variables were not normally distributed, nonparametric statistical methods were used (Mann-Whitney and Spearman's tests). **Results.** Analysis of clinical samples showed the presence of HSP70 proteins in the serum of MM patients. The mean antigen concentration in MM group was slightly higher than in the control, 167,3±36,3 ng/ml and 107±8,1 ng/ml (p=0. 12) respectively. However, the level of antiHSP70 antibodies was significantly lower in the patient in comparison to healthy population (254,3±29,7 ng/ml vs. 489,1±95,3 ng/ml; p=0. 02). There was noticed no statistical significant decreasing in antiHSP70 antibody concentrations in more advanced stages of the disease according to ISS (333,1±134,3 ng/ml at 1st, 273,8±69,9 ng/ml at 2nd, 231,7±28,7 ng/ml at 3rd). The study showed no correlations between protein and antiHSP70 antibody concentration and other parameters such as age, gender and some prognostic factors (LDH, albumin, ß2-microglobulin). **Conclusions.** The results confirmed the presence of HSP proteins and antiHSP70 antibodies in serum of MM patients. The significantly lower serum level of antiHSP70 antibodies in the patients may reflect a participation of this type of heat shock proteins in MM pathogenesis. Futher studies are required to elucidate prognostic significance of HSP70 proteins and antiHSP70 antibody during the course of MM.

[3]U. O. C. Cardiologia - A. O. Sant'Andrea - Sapienza Università di Roma, Rome, Italy
[4]U. O. C. Diagnostica di Laboratorio - A. O. Sant'Andrea - Sapienza Università di Roma, Rome, Italy
[5]U. O. C. Immunologia - A. O. Sant'Andrea - Sapienza Università di Roma, Rome, Italy

Background. Light-chain AL amyloidosis is the most common form of systemic amyloidosis and is associated with an underlying plasma cell dyscrasia. Circulation dysfunction is very frequent in AL amyloidosis patients, especially in those with a clinically-significant cardiac involvement, commonly resulting in moderate to severe heart failure depending on the extent and localization of amyloid deposits. MR-proANP (1-98), the stable mid-regional fragment of the active atrial natriuretic peptide prohormone (99-126), is widely considered an earlier predictive marker of cardiac impairment. In particular, it has direct correlation with NYHA functional class, so it's a powerful predictor of adverse outcome, especially if associated with elevated NT-proBNP values. MCP-1 chemokine plays a key role in the recruitment and activation of monocytes in sites of inflammation and it's actually considered an efficient marker in assessing the inflammatory activity in course of both multiple myeloma and systemic AL amyloidosis. **Aims and Methods.** Aim of the study is to investigate therapy induced modifications in circulation activity by MR-proANP and MCP-1 serum levels evaluation in patients with AL systemic amyloidosis. Blood samples were collected from 6 patients with systemic AL amyloidosis (median age 72. 8 yrs) admitted to our Unit and analyzed for serum MR-proANP (mean±SD) and MCP-1 levels (Kits Brahms MR-proANP Kryptor and Randox Evidence Biochips Arrays). According to age and disease risk stratification these patients were treated with upfront oral Mel-Dex association (Melphalan 9 mg/sm, Dexamethasone 20mg day 1-4 q28). From each patient 2 samples of peripheral blood were performed (T0 at exordium of disease, and T1 at conclusion of the first cycle of therapy). The blood was separated into plasma at the time of blood draw and frozen to -80°C. In the evaluation of results paired t test and Person correlation were performed. *P values ≤ 0. 05* were considered statistically significant. **Results.** MCP-1 levels were significantly higher in the sera of patients at the end of the first cycle of therapy (410. 10 ± 159. 70pg/ml) compared to exordium (333. 20 ± 148. 80 pg/ml; *p=0. 04*). MR-proANP serum levels were significantly decreased (141. 60 ± 45. 48 pmol/L) respect to baseline (183. 2 ± 76. 23 pmol/L; *p=0. 038, see Figure 1*). No positive correlation has been found between the two parameters. **Conclusions.** The high MCP-1 serum levels observed at the end of therapy can be expression of a persistent and increasing inflammatory activity during treatment. On the other hand, MR-proANP serum level reduction could suggest a coming moderate improvement of heart function, not clinically relevant at once. On the basis of our results, MR-proANP and MCP-1 can be used as effective biomarkers to understand the cardiac and microvascular inflammatory processes and their modifications in treated patients with systemic AL amyloidosis.

CHROMOSOMAL CHANGES IN HUMAN PERIPHERAL BLOOD LYMPHOCYTES: LINKS TO FAMILIAL PARAPROTEINEMIA

L Óskarsdóttir[1], H Steingrímsdóttir[2], V Haraldsdóttir[2], H Ögmundsdóttir[1]
[1]University of Iceland, Reykjavík, Iceland
[2]Landspitali University Hospital, Reykjavík, Iceland

Background. Monoclonal Gammopathy (MG) is caused by expansion of a single clone of B-lymphocytes. MG can be pre-malignant (MGUS) or malignant (multiple myeloma (MM), Waldenström's macroglobulinemia (WM)). The immunoglobulin produced can be of IgM, IgG or IgA type, depending on whether the clonal expansion has taken place after class switching. The incidence of MG increases with age and the probability of progression from MGUS to malignancy is about 1-1. 5% each year. IgM-MGUS is more likely to become WM but IgG- or IgA-MGUS can lead to MM. Families with multiple MG cases fall into these two categories, indicating different genetic backgrounds. Some

genomic changes in the progression from MGUS to malignancy have been identified. Translocations involving the IgH locus on chromosome 14q32. 3 and genomic instability, including chromosome losses are prevalent in MM but not WM. Little is known about genomic changes that lead to MGUS. More than 130 families worldwide with multiple cases of MGUS, with or without MM or WM have been reported. Based on published information, first degree relatives of MGUS patients have a three fold risk of developing MM and a two-fold risk of developing WM. An Icelandic family with high prevalence of MG was first reported in 1978. One third of healthy individuals in this family had hyper-responsive B-cells, producing significantly more Ig than B-cells from controls following mitogen-stimulation *in vitro*. The hyper-responsive B-cells survived over longer time in culture and showed prolonged expression of Bcl-2. Seven more families have been found in Iceland with high prevalence of MG and in three of these hyper- responders (HR) were identified. All four families with HR contain cases of both MM and WM. **Aims.** The aim of this study was to screen for chromosomal translocations and smaller genetic changes in peripheral blood B-cells from HR, related and unrelated controls. **Methods.** Breaks on chromosome 14q32. 3 were detected by interphase-FISH (Fluoricence *in situ* hybridization). Array-CGH (Comparative Genome Hybridization) was performed on isolated DNA from each person, screening for loss or gain in B-cells DNA vs. granulocytes by using 135. 000 probes throughout the genome. Conventional cytogenetic analysis was done on metaphases after culture for 7 or 14 days in an *in vitro* model of the germinal centre reaction. **Results.** FISH and conventional cytogenetic analysis did not show any significant differences between HR and controls. CGH analysis detected changes in Ig-genes in B-cells as expected. In addition, all B-cell samples showed marked gains and losses throughout the genome, presumably reflecting random effects of hypermutations during the germinal centre reaction. Significantly fewer gains were detected in HR vs. controls on 7 chromosomes. **Conclusions.** These results are consistent with a tendency towards developing WM rather than MM, with no evidence of excess IgH translocations but indications of relatively low germinal centre activity.

1495

OSTEOGENIC DIFFERENTIATION POTENTIAL OF HEALTY AND MULTIPLE MYELOMA BONE MARROW MESENCHYMAL STEM CELLS

A Aksoy[1], C Subasi[1], Z Ünal[1], Ö Mehtap[2], G Erman[1]
[1]Institue of Health Sciences, Kocaeli, Turkey
[2]Department of Hematology, Kocaeli, Turkey

Background. Multiple myeloma(MM) is a plasma cell malignancy that cause osteolytic bone lessions. In healty bone marrow osteoblast formation and differentiation from mesenchymal stem cells called bone formation and bone resorbtion by osteoclastic activity are in a balance. MM cells induce an imbalance between osteoblastic and osteoclastic activity by producing many inhibitory factors. Studies have shown that MM patients may have a reduction of bone formation markers such as alkaline phosphatase(ALP). **Aims.** In our study we examined osteogenic differentiation potential of mesenchymal stem cells derived from bone marrow (BM-MSCs) of MM patients and healty donors. **Methods.** Three patients with MM and 3 healty donors' BM-MSCs were obtained and cultured in appropriate conditions. At passage 3 after they characterized by flow cytometry and treated with osteogenic stimulatory medium for 30 days. The ALP activity assay were performed on the cells at 1.,3.,7.,14. and 21 was normalized by total protein concentration. In addition, at the end of 4 weeks osteogenic differentiation was assessed by staining with bone formation markers such as Alizarin Red S. The relative gene expressions of BMP-2, BMP-4 and ALPL were performed by Real time PCR. **Results.** The results demonstrate that in the 3. day of differentiation, the ALP activity started to increase in healty donors. But in MM there is no ALP activity up to 21 days. In Alizarin red S staining there were a few minor calcium nodules compared with healty donors. We compared gene expressions with healty donors and MM MSCs and the levels of these genes (BMP-2, BMP-4 and ALPL) were significantly reduced in MM-MSCs. **Conclusions.** Our data have shown that the reduction of expression of osteogenic genes in MM BM-MSCs and defect of ALP activity may be related with osteogenic disorders of MM in addition to presence of other tumorogenic microenviroment of bone marrow.

HYPERMETHYLATION OF TUMOR SUPPRESSOR GENES IN KOREAN PATIENTS WITH MULTIPLE MYELOMA

YH Chang[1], YE Kang[1], HS Jo[2], AC Oh[1], JK Lee[1], YJ Hong[1], SI Hong[1]
[1]Korea Cancer Center Hospital, Seoul, South-Korea
[2]CHA University, College of Medicine, Seongnam, South-Korea

Background. Aberrant DNA methylation is involved in the initiation and progression of carcinogenesis and includes hypermethylation of CpG islands of tumor suppressor gene promoters. Cyclin-dependent kinase 2A (*CDKN2A*), O^6-methylguanine DNA methyltransferase (*MGMT*), and E-cadherin (*CDH1*) are known to be hypermethylated in various neoplasms. **Aims.** We aimed to investigate the methylation status of tumor suppressor genes using pyrosequencing in Korean patients with multiple myeloma (MM). **Methods.** Three cell lines, ARH77, RPMI8226, and MC/CAR, and bone marrow aspirates from 10 patients with MM were analyzed by pyrosequencing. All the patients had given written informed consent. The methylation index (MtI) of each gene promoter was calculated as the average value of methylated cytosine [mC/(mC+C)]. Hypermethylation was defined as MtIs of *CDKN2A*>0. 047, *MGMT*>0. 053, *CDH1*>0. 081. **Results.** CpG island hypermethylation of promoters of *CDKN2A*, *MGMT*, and *CDH1* were found in all the MM cell lines. Mean MtIs of *CDKN2A*, *MGMT*, and *CDH1* in cell lines were 0. 937, 0. 250, and 0. 576, respectively. Hypermethylation of *CDKN2A*, *MGMT*, and *CDH1* were detected in 80% (8/10), 56% (5/9), and 89% (8/9) of the MM patients, respectively. Mean MtIs of *CDKN2A*, *MGMT*, and *CDH1* in the MM patients were 0. 108, 0. 093, and 0. 243, respectively, which were significantly higher than control group (P<0. 05). **Summary / Conclusions.** Our results suggest that hypermethylation of tumor suppressor genes (*CDKN2A*, *MGMT*, and *CDH1*) are frequent events in MM, which may an important role in the pathogenesis of MM. Pyrosequencing is useful for detection of methylation and it offers quantitative data and high throughput.

1497

VALPROIC ACID UPREGULATES NKG2D LIGAND EXPRESSION AND POTENTIALLY ENHANCES NATURAL KILLER CELL-MEDIATED CYTOLYSIS OF MYELOMA

J Shi, Y Tao, X Wu, X Meng, X Hu, Y Shao, J Hou
Department of Hematology; Shanghai Tenth People's Hospital, Tongji University,China

Objective. Although high-dose chemotherapy supported by autologous hematopoietic stem-cell transplantation can produce higher response rates than standard chemotherapy, multiple myeloma (MM) remains largely incurable by current therapeutic strategies. Clinical and preclinical data have been demonstrated that natural killer (NK) cells have an anti-myeloma effect. However, low NK cell activity affected the successful utilization of NK cell adoptive immunotherapy for myeloma. In this study, we investigated the effect of valproic acid (VPA), as a histone deacetylase inhibitor, on the expression of NKG2D ligands on human myeloma cell lines and primary myeloma cells derived from patients. We also evaluated the sensitivity of myeloma cells to NK cell-mediated lysis before and after treatment with VPA, and the possible underlying mechanisms. **Methods.** ARK, OPM2 and primary myeloma cells (n = 4) from patients with myeloma were cultured with VPA for 24 to 72 hours. To evaluate the effect of VPA on NKG2D ligand expression of myeloma cells, mRNA and protein expression of NKG2D ligands of myeloma cells were tested by Real time-PCR and flow cytometry. *51Cr release assay and* NKG2D antibody blocking experiments *were* combined to examine the susceptibility of myeloma cells to NK cell-mediated lysis in response to VPA and the possible killing mechanisms. **Results.** ARK and OPM-2 were treated with various concentrations of VPA. The most prominent upregulations of mRNA expressions of MICA ULBP2 and ULBP 3 were observed in the two tested myeloma cell lines. The enhancement of cell surface expression of MIC ULBP2 and ULBP 3 was detected by flow cytometry after cells treatment with VPA. A similar increase of surface expression of NKG2D ligands was obtained in VPA treated primary MM cells (n=4). VPA treatment of OPM2 showed higher sensitivity to NK cell lysis than untreated cells (specific killing: 72. 8±6. 2% vs 32. 1±3. 7% at E/T 10:1, p <0. 01). The killing of VPA treatment of patient myeloma cells by NK cells also significantly increased compared with control cells (specific killing: 46. 7±5. 6% vs 21. 6±4. 5% at E/T 10:1, n=4, p <0. 01). The enhancing effect of VPA was blocked by pretreatment of OPM2 cells with a combination of anti-MICA/B, anti-ULBP1,2,3 mAbs or pretreatment of NK cells with anti-NKG2D mAbs, indicating the contribution of NKG2D-NKG2D ligands interations to VPA-modulated lysis of myeloma. We also found that constitutive phosphorylated extracellular signal-regulated kinase (ERK) but not AKT signaling pathway may be involved in VPA-induced higher NKG2D ligand expression. **Conclusions.** Histone deacetylase inhibitor valproic acid could upregulate cell surface expression of NKG2D ligands, rendering myeloma cells more sensitive to NK cells, and thereby enhance NK cell-mediated lysis of myeloma. Our findings imply that regulation of the expression of NKG2D ligands by treatment with histone deacetylase inhibitors may be an attractive strategy for immunotherapy of myeloma. **Acknowledgments:** This work was supported by National Natural Science Foundation of China (81071856 and 30973450), Shanghai Pujiang Program (11PJ1407900) and Shanghai Tenth People's Hospital (10RD103 and 11SC103).

1498

IMPACT OF INCIDENCE GAIN(1)(Q21) FOR RELAPSED MULTIPLE MYELOMA PATIENTS TREATED WITH THALIDOMIDE OR BORTEZOMIB-BASED REGIMENS

J Smetana[1], K Berankova[2], R Zaoralova[2], P Nemec[3], H Greslikova[3], A Mikulasova[3], L Zahradova[4], M Almasi[5], R Hajek[4], P Kuglik[2]

Prognostic impact of specific chromosomal aberrations in relapsed multiple myeloma (MM) patients treated with the novel agents is briefly described. We analyzed the prognostic value of extended panel of chromosomal aberrations (del(13)(q14), del(17)(p13), t(4;14)(p16;q32), gain(1)(q21) and hyperdiploidy using I-FISH technique in a cohort of 127 relapsed MM patients treated with thalidomide or bortezomib-based protocols. In the thalidomide group, we found significant difference in overall survival (OS) between group of patients with and without gain(1)(q21)(15. 7 versus 41. 3 months; P=0. 004). We confirmed negative impact of cumulative effect of two or more cytogenetic changes occurring simultaneously on OS in the thalidomide group (20. 3 months vs. not yet reached; P=0. 039). We did not find any significant impact of studied aberrations on overall survival in the bortezomib cohort of patients. We conclude that bortezomib-based protocols are able to overcome the negative prognostic impact of tested chromosomal abnormalities in relapsed MM patients

Background. Angiogenesis has been found to be an essential component in the growth and progression of multiple myeloma (MM). Angiopoietins (Ang) are growth factors that play a critical role in the regulation of vessel formation. Among them, Ang-2 and its receptor Tie-2 appear to play an important role in tumor angiogenesis. **Aims.** The aim of the current study was to determine serum levels of circulating Ang-2 and its receptor Tie-2, in newly diagnosed MM patients and to estimate if there is any relationship between them and known markers of disease severity, such as C-reactive protein (CRP), beta-2 microglobulin (beta-2m), lactate dehydrogenase (LDH) and interleukin-6 (IL-6) serum levels as well as M-component value. **Methods.** We studied 55 newly diagnosed myeloma patients (29 male, 26 female, with mean age 66. 9±13. 7 years). According to Durie-Salmon staging system 8 had stage I disease, 25 stage II and 22 stage III. We also studied 30 of them in plateau phase, as well as 20 healthy controls. Ang-2, Tie-2 and IL-6 serum levels were determined by ELISA, using commercially available kits. The remaining variables were determined using standard laboratory methods. **Results.** Ang-2, IL-6, CRP, beta-2m and LDH serum levels, as well as M-component values, were higher in MM patients compared to controls (p<0. 001 in all cases). Ang-2 serum levels were also higher in advancing disease stages (p<0. 001) as well as in pre-treatment group compared to plateau phase (p<0. 001). On the contrary, Tie-2 serum levels did not show any significant difference in either case. We also found significant correlations between Ang-2 serum levels with CRP (r=0. 469 p<0. 001), beta-2m (r=0. 577 p<0. 001), LDH (r=696, p<0. 001) and IL-6 (r=0. 623 p<0. 001) serum levels. On the other hand, none significant correlation was found between Tie-2 serum levels and either marker of disease severity. **Conclusions.** Our results showed that Ang-2 serum levels, which reflect bone marrow neovascularization, are increased in MM patients and correlated with known markers of disease severity, such as beta-2m, IL-6, LDH and CRP. This finding indicates that Ang-2 could be used as a potential tumor marker for disease severity, as well as a possible target for MM treatment.

Matrix metalloproteinases (MMPs) are a family of structurally and functionally related proteinases characterized by the ability to degrade the extracellular matrix (ECM). Based on their substrate specificity and domain structure, MMPs were divided into subgroups. One of these subgroups is represented by gelatinases, which degrade gelatine and several types of collagen, like gelatinase A (MMP-2) and gelatinase B (MMP-9). MMPs are known to play a role in cell growth, invasion, angiogenesis, metastasis, and bone degradation, all important events in the pathogenesis of cancer. Multiple myeloma is a B-cell cancer characterized by the proliferation of malignant plasma cells in the bone marrow, increased angiogenesis, and the development of osteolytic bone disease. The first pathogenic step is a premalignant monoclonal gamopathy of undetermined significance (MGUS). In the progression from MGUS to MM, complex genetic events occur in the neoplastic plasma cell (PC), and in the bone marrow (BM) microenvironment, including induction of angiogenesis, suppression of cell-mediated immunity, and development of paracrine signalling loops involving interleukin-6, insulin-like growth factor 1, interferon α and vascular endothelial growth factor. Furthermore, although tumour progression is observed mainly within the bone marrow during the early stages of the disease, extramedullary spreading occurs during the terminal stage of the disease. Moreover, malignant cells can be detected in peripheral blood of many patients with MM, suggesting migration of myeloma cells outside the bone marrow. However, the role of MMPs in the development of MM is poorly understood. In the present study, we aimed to explore the role of MMPs, namely MMP-2, MMP-8 and MMP-9, in the pathogenesis of MGUS and progression to MM. A total of newly diagnosed 16 MGUS patients and 16 MM patients and 2 healthy individuals (controls) were included in this study. Expression of MMP-2, MMP-8 and MMP-9 was assessed on bone marrow plasma cells (PC) by flow cytometry using a four-color staining assay. The average MGUS patients' age is 72 years (42-90), 62,5% female and 37,5% male. The MM patients were 62% female and 38% male, with an average of age of 78 years (67-87). Our preliminary study shows that MGUS and MM PC patients have higher MMP expression levels compared with controls. On the other hand, MM patients show higher percentage of PC expressing MMP-9 when compared to MGUS patients. However, in $CD19^+/CD138^+$ PC the intracellular MMP expression levels are higher in MGUS patients when compared to MM, while in malignant PC ($CD19^-/CD138^+$) these differences are mainly observed in MMP-9. When analysed both PC patient population, we observed in $CD19^+/CD138^+$ PC an increase in MMP-2 and -8 expression levels and in the percentage of cells expressing these MMP compared with PC $CD19^-/CD138^+$. Besides that all MM patients are positive for at least to MMPs. Our findings suggest that PC MMP expression may be correlated with transition of MGUS to MM, promoting extramedullary spreading and disease evolution. Since MM remains incurable, confirmation of these results may contribute to a better understanding of MM biology and can lead to new therapeutic approaches.

LEVELS OF FREE LIGHT CHAINS IN THE SERUM OF NORMAL SUBJECTS AND PATIENTS WITH MONOCLONAL GAMMOPATHY

M Sanchez Navarro[1], E Bonmati Armenta[1], E Perez Gutierrez[1], S Garciá Linares[1], J Mora Vallellano[1], C Samaniego Sanchez[2]
[1]Hospital Universitario San Cecilio, Granada, Spain
[2]Facultad de Farmacia, Granada, Spain

Background. Monoclonal gammopathy (MG) is defined as a plasma cell lymphoproliferative disorder characterized by the production of a monoclonal immunoglobulin with expression of a single type of light chain. Monoclonal component (MC) detection in serum is important for diagnosis and monitoring of MG. **Aims.** To study the free light chains (FLCs) and the ratio kappa/Lambda in the serum of patients with a monoclonal component detected by serum protein electrophoresis (SPE). To evaluate their clinical utility as a biochemical marker for screening, diagnosis and monitoring of MG. **Methods.** Serum samples from 125 healthy subjects, 51-79 years of age, with estimated ratio of glomerular filtration (GFR) ≥90 mL/min and normal protein electrophoretic profile without detectable monoclonal component. We obtained serum samples from 104 patients and we detected monoclonal band by means of SPE and Immunotyping (IT): 68 samples were from patients with a monoclonal kappa light chain and 36 from patients with a monoclonal lambda light chain. The patients were between 57-78 years old, 59 of whom

were women and 45 men. SPE was performed by automated assay (Capillarys protein/Sebia) and calculated the MC (g/dL). IT was performed with a Capillarys Immunotyping/Sebia. FLCs were quantified with Freelite$^{TM)}$ reagent from The Binding Site and nephelometry on a Dade-Behring calculating kappa/lambda ratio. We estimate the glomerular filtration ratio by the Cockcroff-Gault formula. We used the statistical software SSPS to the compare the means of the patients and the control group. We calculate the correlation coefficient between the concentrations of MC (g/dL) and the concentration of FLCs (mg/dL). **Results.** In the control group FLCs of free kappa light chain ranges from 0. 6 to 1. 92 mg/dL (mean 1. 26 ± 0. 33), the free light chain lambda ranges from 0. 43 to 1. 8 mg/dL (mean 1. 14 ± 0. 33), the ratio k: L ranges from 0. 8 to 1. 48 (mean 1. 14 ± 0. 17). We have found a significant increase of FLCs in the pathological groups when compared to the reference group (p<0,001) and a positive correlation between the concentrations of MC and FCLs (r = 0. 81 and r = 0. 84 respectively). The ratio kappa/lambda is altered in all patients with MG (being higher than 1. 65 in MG with excess kappa FLC and lower than 0. 26 in MG with an excess of lambda FLC). **Conclusions.** The ratio kappa/lambda is an effective marker of clonality because there is complete consistency between the ratio K/L and the results of IT. In MG associated with FLCs, these proteins may be present in serum in small amounts and thus be difficult to detected by IT and often impossible to quantify on SPE. The incorporation of the determination of serum free light chains to the study of MG is recommended as an aid to diagnosis, prognosis and monitoring of patients.

TRAIL EFFECT ON OSTEOCLAST FORMATION IN MULTIPLE MYELOMA-BONE DISEASE

G Brunetti, R Miccolis, R Rizzi, A Oranger, G Mori, C Spinosa, A Giordano, P Curci, V Liso, G Specchia, S Colucci, M Grano
University of Bari, Bari, Italy

In physiological conditions OCs differentiation is finely controlled by macrophage colony stimulating factor (MCSF) and receptor activator factor of nuclear factor kappaB ligand (RANKL). In pathological conditions (<i*e.* bone resorptive diseases) several cytokines and growth factors are directely or indirectely implicated in osteoclastogenesis modulation. Among others, the tumor necrosis factor (TNF)-related apoptosis inducing ligand (TRAIL), belonging to the TNF superfamily of cytokines, seems to be implicated in OCs differentiation. However there are contradictory literature data on TRAIL effects on osteoclastogenesis process. Here, we investigated the effect of TRAIL on OC formation both in physiological conditions and multiple myeloma(MM)-bone disease by means of an osteoclastogenesis in vitro model consisting of peripheral blood mononuclear cells (PBMCs) obtained from healthy donors or patients with MM-bone disease. In particular the samples included peripheral blood (PB) from 32 MM patients at diagnosis (15 males and 17 females, median age 65. 5 +/- 8. 7) and 30 control subjects matched for age and sex with MM patients. In PBMCs from healthy donors, we demonstrated that TRAIL can directly induce OC formation, whereas an inhibitory effect on OC formation was observed when TRAIL was added with RANKL concomitantly. The levels of TRAIL were detected in the sera and in the media of PBMC cultures from the patients as well as from the same samples of control subjects using a human TRAIL enzyme-linked immunosorbent assay (ELISA) kit (supplied by Biomol Research Laboratories, Inc., Plymouth Meeting, PA, USA). In the culture media of PBMCs from the patients we detected high levels of TRAIL. To better understand the role of TRAIL in OC formation in MM-bone disease, we performed osteoclastogenesis experiments by culturing PBMCs from patients in the presence of different concentrations of a neutralizing anti-TRAIL mAb. Interestingly, the anti-TRAIL dose-dependent inhibition of spontaneous osteoclastogenesis was completely abolished by the RANKL addition in the same culture system. Our results suggest that, in an *in vitro* system, TRAIL and RANKL show different behaviour in MM-bone disease and normal conditions.

1503

CHROMOSOME 1Q GAIN IS A COMMON ADDITIONAL GENETIC ABERRATION IN RELAPSED MYELOMA PATIENTS

T Våtsveen[1], K Wader[2], LA Grøseth[3], HY Dai[2], H Aarset[2], A Sundan[3], M Børset[3], A Waage[3]
[1]Norwegian Institute of Science and Technology, Faculty of Medicine, Trondheim, Norway
[2]St Olavs Hospital, Trondheim, Norway
[3]Department of Cancer Research and Molecular Medicine, NTNU, Trondheim, Norway

Background. Multiple myeloma is a neoplasm of the antibody producing plasma cell. All myeloma cells have genetic aberrations. Primary immunoglobulin translocations and hyperdiploidy are all present in the premalignant condition MGUS. This is not the case with other common aberrations like deletion 13q and 17p, which usually increase in incidence and percentage of affected cells during disease progression. **Aims.** We had sequential samples from ten myeloma patients collected between 2006 and 2011 and wanted to find out if there were any genetic aberrational changes in the patient samples during disease progression. **Methods.** We used interphase fluorescence in situ hybridization to detect genetic aberrations. The probes covered the following loci: 14q32, 11q13, 4p16, 16q23, 6p21, 20q12, 8q24, 13q14, 2p11, 22q 17p, 1p and 1q21. 100 nuclei were scored for each sample. **Results.** For two of the patients we had three sequential samples, for the rest two samples. The most prominent finding was the gain of chromosome 1q21 in 6 of the patients after relapse. Patients with gain of chromosome 1q21 at diagnosis had both an increased copy number of 1q, and increased percentage of cells affected of the aberration. From one of the patients we were able to establish a cell line, URVIN. This cell line have a t(4;14). At diagnosis we found 54% deletion 13, normal chromosome 17 and amplification of chromosome 1q21. At relapse we found 86% deletion 13q, 68% deletion 17p and 87% deletion 1p. 1q21 was heterogeneous with 30% 3 copies, 29% 4 copies and 30% 5 copies. In the cell line, URVIN, all cells had deletion 13q, deletion 17p, deletion 1p and 3 copies of 1q. **Summary and Conclusions.** In our material, chromosome 1q amplification was the most common additional genetic aberration in relapsed myeloma patients.

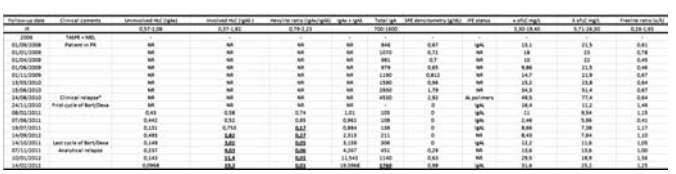
1504

SERUM FREE LIGHT CHAINS AND SERUM IMMUNOGLOBULIN SPECIFIC HEAVY/LIGHT CHAIN PAIRS ALLOWS IDENTIFICATION OF SPECIFIC CLONAL PRODUCTION

J Jimenez[1], N Barbosa de Carvalho[2], L Campos[2], M Requena[1],C De Larramendi[1]
[1]Hospital Severo Ochoa, Madrid, Spain
[2]The Binding Site, Barcelona, Spain

Background. A novel polyclonal immunoassay specific for the different light chain types of intact immunoglobulins (Igs) (heavy/light chain assays (HLC) together with the serum free light chain (FLC) test enables the measurement of changes in the production of clone specific Igs. By calculating the HLC ratio, the relationship between clonal and non-clonal plasma cells can be assessed. Increasing evidence indicates progressive clonal evolution and recently has been demonstrated the prognostic value of the HLC ratio together with sFLC ratios. A two tiered prognostic model employing the HLC and FLC tests have been proposed, and the use of these assays to analyze the clonal tide in patients with MM is becoming a realityCase presentation: A 66 year old man previously diagnosed in 1996 with a smoldering multiple myeloma (SMM) IgA lambda progressed to an IgA lambda multiple myeloma (MM) stage IIA in November 2004. At this time point patient presented normal cytogenetic. In September 2005 patient was treated with VMCP/VBAD (6 cycles) plus pamidronate achieving a partial response (PR). In 2006, patient presented a bone marrow infiltration of 20% with no osteolitic lesions and in June 2006 underwent a STEM cells -transplant achieving again a stable PR until August 2010. In August 2010 the patient suffered a clinical relapse suffering from acute back pain as result from a pathological fracture located in D10 and S2 vertebral body. M-spike was 2,92 mg/dL and sIFE presented different polymers if IgA. However, since patient first treatment, sFLC ratios were normal all the time contrasting with the results obtained with SPE and sIFE. After the second relapse the patient was treated with bortezomib/dexametasone with last cycle being applied at the end of October 2010. Interestingly, sFLC ratios were normal since the first PR (until the present day). In November 2011 a new "analytical"relapsed was observed by SPE and HLC but sFLC remains stable. The measurements of the uninvolved HLC were always immunosuppressed. The analytical follow-up is presented in the Table 1.

Table 1.



Conclusions. Last evidences indicates the possibility of diferent clones being envolved in diferent stages of the disease. Espeacialy nowadays, because of the use of powerfull and efective new agents, clonal tiding can be seen at diferent time points and sometimes diferent relapses can occur due to diferent expression of diferent clones. In these cases, sFLC together with HLC ratios could help us to distinguish these diferent clones and could orientate us in the future treat-

ment options. On the other side, due to the high sensitivity of HLC assays, the last relapse was detected aproximatly 3 months before SPE by showing a steadly increase of the monoclonal HLC pair and altered ratios.

1505

MULTIDRUG RESISTANCE 1 (MDR1) GENE AND ABC-FAMILY PROTEINS (MDR1 AND MRP1) IN MONCLONAL GAMMOPATHIES (MULTIPLE MYELOMA AND MONOCLONAL GAMMOPATHY OF UNCERTAIN SIGNIFICANCE)

C Geraldes[1], AC Gonçalves[2], E Cortesão[1], A Teixeira[1], J Nascimento-Costa[1], A Sarmento-Ribeiro[2]

[1]Hospitais da Universidade de Coimbra - CHUC, Coimbra, Portugal

[2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Background. Multiple myeloma (MM) is consistently preceded by a premalignant step, the monoclonal gammopathy of uncertain significance (MGUS). In the progression from MGUS to MM, complex genetic events occur in the neoplastic plasma cell (PC) and in the bone marrow (BM) microenvironment. A major limitation in the treatment of MM patients is the development of multidrug resistance (MDR) and a well-known responsible mechanism is the overexpression of ABC-transporter genes such as MDR1. P-glycoprotein (P-gp), encoded by MDR1 gene, is an ABC transporter involved in the efflux of a variety of anti-cancer drugs out of the cell and in the cross-resistance to structurally unrelated cytotoxic agents. MDR1 gene polymorphisms (C3435T and CYP3A4) could alter P-gp expression levels resulting in drug resistance. The MDR1 C3435T polymorphism was previously described to be involved in immunological response. Furthermore, a drug efflux-independent mechanism of drug resistance seems to be mediated by P-gp, namely the transport of phospholipids across the cell membrane, contributing to its antiapoptotic function. Other transporter proteins mediating drug resistance include the multidrug-resistance-associated protein (MRP) family, notably MRP1. Besides recent studies have indicated that specific mechanisms of MDR may be involved in refractory MM patients, the expressions of ABC family members have not been well worked out in MGUS and MM patients. **Aims.** To analyze the expression of ATP-binding cassette proteins, MDR1 and MRP1, in patients with monoclonal gammopathies (MGUS and MM) and to evaluate the involvement and prognostic role of MDR1 C3435T and CYP3A4 T673C polymorphisms in the development of monoclonal gammopathy and in the progression from MGUS to MM. **Methods.** For this purpose, 47 patients with monoclonal gammopathy (23 symptomatic untreated MM patients and 24 MGUS patients) and 51 healthy individuals (controls) were enrolled in the study. The expression of MDR1 and MRP1 proteins in plasma cells was performed by flow cytometry using monoclonal antibodies labeled with fluorescent probes. PCR-RFLP was used for the detection of C3435T and T673C polymorphisms, using the restriction enzymes MBOI (MDR1) and Alw261 (CYP3A4), respectively. Group comparisons were evaluated with the c2, Fisher's exact test and t-student test.

1506

NEUROLOGICAL MONITORING DURING BORTEZOMIB AND/OR IMIDS REDUCE THE DEVELOPMENT OF SEVERE PERIPHERAL NEUROPATHY IN MULTIPLE MYELOMA PATIENTS: A SINGLE CENTER EXPERIENCE

E Russo[1], V Federico[1], A Truini[2], A Levi[3], F Gentilini[3], G Biagioli[3], C Cartoni[3], G Cruccu[2], R Foà[3], MT Petrucci[3]

[1]Hematology, Rome, Italy

[2]Neurology, Sapienza, Rome, Italy

[3]Cellular Biotechnology and Hematology, Rome, Italy

Background. Dose-limiting peripheral neuropathy (PN) has been reported in up to 75% of multiple myeloma (MM) patients treated with Bortezomib and/or IMIDs, requiring dose reduction, delay or interruption of treatment. Careful neurological monitoring and early diagnosis of PN may prevent irreversible neurological damage. **Aims.** We performed a monocentric prospective study to investigate the possible benefit of regular neurological assessment in reducing the development of severe PN. **Methods.** All patients were evaluated before, during and after MM treatment by clinical and neurophysiologic assessment. The neuropathy was graded in levels 1 to 4 according to the National Cancer Institute-Common Toxicity Criteria version 3 [NCI-CTC]. Neuropathic pain intensity was expressed according to the patient-reported Numerical Rating Scale [NRS]. **Results.** Between March 2007 and June 2011, 100 consecutive patients were included. The clinical characteristics were: median age 59 years (32-77); 46 men and 54 women; 42 and 58 pts were, respectively, in Durie and Salmon stages I-II and III. Seventy-five patients received >2 lines of treatment (range 1-7). Sixty-three patients were treated with bortezomib, 31 with thalidomide, 25 with bortezomib-thalidomide combination and 51 with lenalidomide. After a median time of 22 months (range 1-171) from the start of treatment, 65 patients developed PN (56 sensitive, 9 sensitive-motory), 31 during first line therapy, 29 during second line and 5 after the second line of therapy. At the time of PN diagnosis, 26 patients were receiving bortezomib, 15 thalidomide, 20 the bortezomib-thalidomide association and 4 lenalidomide. In 2 cases, PN was diagnosed before the start of treatment. The median time to PN diagnosis was 2. 8 months for bortezomib, 10. 5 months for thalidomide and 2 months for bortezomib-thalidomide. There was no significant correlation between PN occurrence and cumulative dose of bortezomib (median 30 mg) and thalidomide (median 9. 900 mg). According to the NCI-CTC toxicity criteria, 25 patients developed grade 1, 34 grade 2, 6 grade 3, 0 grade 4 PN. Neuropathic pain occurred in 30 patients; the median NRS was 5. 5 (range 4-9) and it was treated with opioids and tricyclic antidepressants. After PN diagnosis, 18 patients required bortezomib/thalidomide dose reduction, 3 patients a temporary drug discontinuation and 5 patients treatment interruption, while 39 patients continued their treatment with close neurological assessment. With a median follow up of 56. 5 months (range 7-232), 28 patients showed PN resolution. In 6 cases, PN worsened during bortezomib retreatment. **Conclusions.** Our study shows that clinical and electrophysiological examination are useful in the early diagnosis of PN. Careful monitoring is required to guide the physician in dose adjustment, especially when bortezomib and thalidomide are used in combination, in order to avoid the development of grade 3-4 PN. With accurate neurologic monitoring only 7% of patients had stop treatment. Also the use of oral opioids and tricyclic antidepressants seems to be effective in reducing the intensity of the neuropathic pain, as well as the impact of this symptom on the patient's quality of life.

1507

EFFICACY OF BORTEZOMIB-BASED THERAPY IN RELAPSED/ REFRACTORY MULTIPLE MYELOMA: Results FROM AN ELECTRONIC BORTEZOMIB OBSERVATIONAL STUDY (EVOBS) FOR PATIENT ENROLLED IN RUSSIAN FEDERATION

K Abdulkadyrov, A Schmidt, S Voloshin, V Shuvaev, A Kuvshinov

Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background. The international, non-interventional electronic VELCADE observational study (eVOBS) is ongoing to prospectively evaluate the efficacy and clinical outcomes associated with bortezomib-based (BB) therapies for primarily relapsed/refractory multiple myeloma (MM) in the 'real-world' clinical practice setting. Here we report data of patient fromRussian Federation which were summarized and separated from entire population enrolled into the eVOBS study. **Aims.** With study enrollment now complete, we report patient demographics, baseline disease characteristics, and efficacy data for Russian eVOBS study population. **Methods.** Adult patients scheduled to begin BB therapy for the treatment of predominantly relapsed/refractory MM were eligible for enrollment into the study. Patients were enrolled at clinical practices and provided written informed consent which was obtained in accordance with the Declaration of Helsinki. Treatment history was retrospectively documented for 1 year prior to initiation of BB therapy. Prospective observational data were collected for up to 3 years after initiation of therapy to document efficacy data. All administered bortezomib doses and concomitant treatments (except for investigational therapies) were permitted. MM disease stage was assessed at the time of initiation of BB therapy using Durie-Salmon (DS) staging system. Responses were investigator-assessed and based on European Group for Blood and Marrow Transplantation, or M-protein criteria. Response data were censored at the start of subsequent therapy, and for deaths. **Results.** Total of 691 patients were enrolled between October 2006 and December 2010 (40% male, 60% female, median age 59. 6 years). The patients had stage II (42%) or stage III (51%) of the disease according DS system prior to treatment initiation. The median time from diagnosis to treatment initiation was 2. 0 years; the median time from the start of primary therapy to enrollment was 1. 8 years. The majority of patients (97%) included in Russia received BB therapy for relapsed/refractory MM; 3% of patients received bortezomib as their first-line therapy. The most common prior MM treatments documented within 1 year of starting BB therapy were melphalan-prednisone combination (29%), vincristine-doxorubicin-dexamethasone combination (9%), other primary and second-line regimens (7%); and 55% had no MM treatment in the previous year. 43% of patients received monotherapy with bortezomib, 36% - in combination with dexamethasone, 15% - with prednisone, and 6% - with other agents including thalidomide, lenalidomide . Most of patients (85%) received bortezomib at an initial dose of 1. 3 mg/m^2. At the data 86. 1% (overall response rate) of patients achieved a best response: complete response (33. 9%), near-CR (21. 0%), partial response (26. 8%), and minimal response (4. 4%). At the data cut-off (39 months from the study initiation) the median survival was not reached. The median progression-free survival time was 2. 9 years. 461/691 patients (66. 7%) discontinued treatment because of response (n=233; 33. 7%),

disease progression (n=54; 7. 8%), adverse events (n=31; 4. 5%), patients death (n=20; 2. 9%), other reasons (n=123; 17. 8%). **Conclusions.** Bortezomib, alone and combined with dexamethasone, is safe and effective in pretreated patients with relapsed/refractory MM in routine clinical practice. These results provide a useful comparator for data collected in the highly controlled clinical trial setting. Patients continue to be followed for long-term outcomes.

1508

RETROSPECTIVE ANALYSIS OF THROMBOCYTOPENIA IN RELAPSED MULTIPLE MYELOMA PATIENTS

M Sousa[1], F Campigotto[2], S Neuberg[2], L Warren[2], G Richardson[2], C Anderson[2], J Vanasse[1], P Laubach[2]
[1]Brigham and Women's Hospital, Boston, United States of America
[2]Dana Farber Cancer Institute, Boston, United States of America

Background. Despite improvement in clinical outcomes in recent years, multiple myeloma (MM) remains incurable and most patients relapse after initial therapeutic response. Thrombocytopenia remains a clinical challenge in patients with relapsed/refractory disease. High-grade thrombocytopenia at our institution is primarily managed with platelet transfusion and chemotherapy dose modification. **Aims.** We hypothesize that thrombocytopenia is an important variable in the management of relapsed MM. As there are currently no studies in the myeloma literature that assess the impact of thrombocytopenia, we conducted a retrospective chart-review to evaluate the impact of thrombocytopenia in relapsed MM. **Methods.** Participants included all patients with relapsed/refractory MM who enrolled on clinical trials at Dana Farber Cancer Institute between January 1, 2007 and December 31, 2009. As some patients participated in multiple clinical trials during this period, therapy administered to a particular patient in a single clinical trial is termed a "treatment regimen. "We determined the overall incidence of thrombocytopenia (platelet count < 150,000/mcl) and the incidence of more severe thrombocytopenia (platelet count < 100,000/mcl or < 75,000/mcl) at treatment initiation. Medical record data collected to assess the clinical impact of thrombocytopenia included the following: episodes of ≥ grade 3 thrombocytopenia, number of platelet transfusions per month, treatment delays and discontinuations due to thrombocytopenia, occurrence of bleeding events, and overall survival from start of initial clinical trial within this period. Point estimates with exact binomial confidence intervals and median and range are used to describe the data. The differences in platelet transfusion requirements were assessed by the Wilcoxon rank sum test. **Results.** Data was abstracted for 125 patients on 202 treatment regimens. 71 patients previously underwent autologous stem cell transplantation. The overall incidence of thrombocytopenia (platelet count < 150,000/mcl) at time of treatment initiation was 45% (90 of 202 regimens). In 45 regimens (22%, 90% Confidence Interval (CI) 18%, 28%) platelet count at time of treatment initiation was < 100,000/mcl. The platelet count at time of treatment initiation was < 75,000/mcl in 25 regimens (12%, 90%CI 9%, 17%). For regimens with platelet count < 100,000/mcl at study entry, median platelet transfusion requirement over 4 weeks was 1. 51 units (range 0-20. 29); in regimens with platelet count ≥ 100,000/mcl, the median plt transfusion requirement was 0 units transfusions per 4 week period (range 0-2. 9) ($p < 0.0001$). Twenty-five bleeding events were observed during a treatment regimen in 16 subjects. Treatment was delayed for 30 additional subjects due to thrombocytopenia, including 2 subjects removed from studies due to thrombocytopenia. Patients who began any therapy with a platelet count < 100,000/mcl experienced poorer overall survival compared to patients who began therapy with a platelet count ≥ 100,000/mcl (log-rank test, p=0. 0013) (Figure 1). Overall survival at 1-year among 125 pts was 77% (90% CI [70%;83%]).

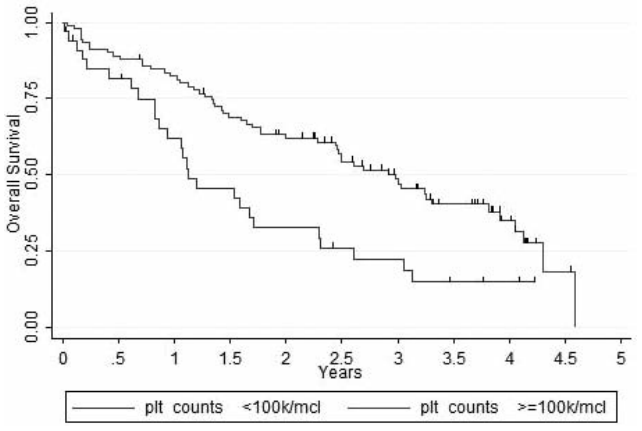


Figure 1.

Conclusions. Thrombocytopenia is a common problem in patients with relapsed/refractory MM, with poorer 1-year overall survival noted in patients with plt < 100,000/mcl at treatment initiation. Clinical studies assessing novel compounds to treat thrombocytopenia or minimize transfusion support are desperately needed in this patient population.

1509

FOLLOW UP OF MULTIPLE MYELOMA PATIENTS WITH RENAL IMPAIRMENT DURING A 10 YEAR PERIOD

K Uttervall[1], J Andreasson[1], J Liwing[2], P Näsman[3], J Aschan[2], H Nahi[1]
[1]Karolinska Institutet, Stockholm, Sweden
[2]Janssen AB, Sollentuna, Sweden
[3]Royal Institute of Technology KTH, Stockholm, Sweden

Background. Renal impairment (RI) is a relatively common feature of multiple myeloma (MM) and it has been shown in several studies that RI at diagnosis correlates to inferior survival, significant morbidity and increased early death rate. **Aims.** To compare the efficacy of bortezomib-based treatment to other anti-myeloma treatments during the course of the disease in patients presenting with creatinine ≥130 µmol/L. The primary endpoint of the study was renal response (RR) in 1st, 2nd and 3rd line treatment. Time to progression (TTP), time to next treatment (TTNT), overall survival (OS) and MM response were the secondary endpoints. **Methods.** All treated MM patients with a s-creatinine ≥130 µmol/L that were diagnosed in clinical practice between January 2000 and July 2010 at Karolinska Huddinge were selected. This s-creatinine limit was selected in an attempt to cover all MM patients with GFR <50 mL/min. A previous study from our centre analyzing a larger myeloma database also showed that patients with a s-creatinine ≥130 µmol/L had a worse median OS (less than 2 years) compared to those with s-creatinine <130 µmol/L (approximately 4. 7 years). The study population was divided into those receiving bortezomib (Bz) and those receiving other drug combinations (control group). **Results.** Of the 556 patients that were diagnosed and treated with MM between 1st of January 2000 and 1st of July 2010, 95 patients had an s-creatinine ≥130 µmol/L at diagnosis. Of the 95 patients, 52 also had RI in 2nd line and 25 in 3rd line treatment resulting in a total of 172 treatment occasions where anti-myeloma treatment was given to patients with renal RI. There was no significant difference regarding age, sex, hemoglobin, β2-microglobulin, calcium, or albumin between the Bz-group and the control group. In the Bz-group, in 1st line treatment, 11 of 12 patients (92%) improved their GFR compared to 57 of 83 (69%) in the control group (p=0. 049). In the 2nd and 3rd treatment line the overall RR was 19 and 43% in the Bz treated compared to 23 and 28% in the control group (p=0. 749, and p=0. 257). 4 of the 12 patients (33%) receiving Bz in 1st line reached complete renal response (CRrenal) vs. 38 of 83 patients (46%) in the control group. When analyzing all treatment lines together the MM response was better in the Bz-group with significantly higher overall response rate of 80%, compared to 41% (p=0. 026). Median TTP in 1st, 2nd and 3rd line in the Bz-group was 18, 6 and 10 months and in the control group 11, 10 and 8 months. Median survival time was 3. 4 years for the control group, whereas 62% of the Bz treated patients still were alive at median time of follow up. **Conclusions.** RI is still an important prognostic marker in MM. Bz-based regimens give a higher frequency of RR and MM response, thus indicating an advantage for bortezomib in comparison to other treatment regimes for MM patients with RI.

1510

BORTEZOMIB CAN OVERCOMES ISS AS PROGNOSIS FACTOR IN PATIENTS WITH MULTIPLE MYELOMA (MM) HAVING HIGH DOSE THERAPY (HDT)

S Auger[1], P Quittet[1], S Bouyha[1], P Latry[1], T Kanouni[1], M Orsini[2], JP Daures[2], JF Rossi[1]
[1]University Hospital Saint Eloi, Montpellier, France
[2]Biostatistical and Epidemiology, Montpellier, France

Background. The outcome for MM patients has changed since the introduction of Bortezomib. Despite therapeutic advances, HDT remains the treatment of choice for eligible patients. Standard prognosis systems (i. e., ISS and DS), cytogenetic or GEP have been mainly evaluated before new active drugs. Current data suggest that novel agents can overcome adverse prognostic factors, i.e., deletion 13q and t(4;14) at diagnosis. **Aims and Methods.** Using our patient's database, we analyzed standard prognostic factors and transplant modalities on PFS and OS for 306 consecutive MM patients undergoing HDT from 1997 to 2009. 83 patients received Bortezomib + Dexamethasone and 223, VAD as induction regimen. When patients underwent tandem HDT (n=84), we considered only the first HDT. According to the induction therapy, we eval-

uated the influence of age, sex, isotype, DS and ISS staging systems, status before and post HDT, number of lines of therapy, time of HDT from diagnosis, dose of re-infused CD34(+) cells, bone marrow plasma cell infiltration (BMPCP) and beta2-microglobulin (SB2M) at diagnosis on OS and PFS. Data processing was performed using SAS software packages 9. 2. PFS measured from the date of first PBSCT to the relapse (Kaplan-Meier product limit method), and OS, from diagnosis to death or last follow-up. The association of potential independent variables to PFS and OS was assessed by univariate analysis using Kaplan Meier method and Log Rank Test, then, by multivariate analysis through Cox proportional hazards model. **Results.** Median age was 61 years (34-73). Sex ratio M/F was 1. 17. Fifty-four percent were IgG, 29%, IgA, 17%, light-chain. Median number of CD34 cells is 5. 08 (1. 2-26) x106/Kg. Forty-five percent of patients had SB2M less than <3. 5mg/L. Forty-eight percent had BMPCP ≥ 30%. Forty-one percent of patients were ISS I, 29%ISS II and 30 ISS III. Clinical DS staging was shared in 7% of stage 1, 18% of stage 2 and 75 % of stage 3 at diagnosis. Eighty-one% of PBSCT were preceded with one line of treatment before transplant. Ninety percent of patients have undergone one HDT and 80 % have received only one line of induction treatment. Median PFS follow-up was 45 months for VAD induction regimen (VIR) and 10 months for Bortezomib induction regimen (BIR). In VIR group, Isotype, SB2M, BMCP, sex, and post-transplant response are significant for PFS in univariate model. In Cox's model, BMPCP, sex, isotype, and post-transplant response are significant. In contrast, after BIR, only post-transplant response remains a significant prognosis factor (p<0. 0001). Isotype (p=0. 41), SB2M (p=0. 62), BMCP (p=0. 4), are not significant. Median OS follow-up was 57 months for VIR and 21 months for BIR. In VIR group BMPCP, post-transplant response, isotype, SB2M, age at transplant, and ISS were the most consistent prognosis factors correlated with OS. In Cox's model only BMCP, post-transplant response, isotype and ISS are significant. In the BIR group, only post-transplant response is a significant factor correlated with OS (p=0. 05). ISS (p=0. 73) nor SDD (p=0. 89) are significant (Figure 1). **Conclusions.** Bortezomib modifies usual prognosis scoring system as ISS or SDD.

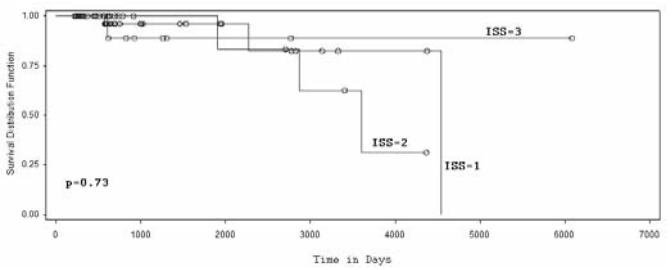

Figure 1. OS in Bortezomib group according to ISS.

GOOD CLINICAL ACTIVITY AND FAVOURABLE TOXICITY PROFILE OF BORTEZOMIB, FOTEMUSTINE AND DEXAMETHASONE (B-MUD) FOR THE TREATMENT OF RELAPSED MULTIPLE MYELOMA PATIENTS

S Mangiacavalli, L Pochintesta, F Cocito, A Pompa, C Pascutto, M Cazzola, A Corso
Fondazione IRCCS Policlinico San Matteo-University of Pavia, Pavia, Italy

Background. Fotemustine, a nitrosourea alkylating agent, has been shown effective as single agent in relapsed multiple mieloma (MM). The proteasome inhibitor Bortezomib represent a cornerstone for the treatment of MM. **Aims.** We explored the feasibility and the efficacy of the new combination bortezomib (B) + fotemustine (Mu) + dexamethasone (D) (B-MuD) in MM patients (pts) relapsed after at least one therapy. **Methods.** This phase II single-centre study has been approved by local ethical committee; all pts signed written informed consent. Experimental therapy consisted of escalating dose of Fotemustine (80-100 mg/m^2 i. v.) on day 1 associated to Bortezomib 1,3 mg/ m^2 i. v. on days 1,4,8,11 + Dexamethasone 20 mg orally on days 1-2, 4-5, 8-9, 11-12 of 21-day cycle for 6 cycles. The MTD of Fotemustine resulted to be 100 mg/m^2. Protocol was amended due to extra-hematological toxicity after the enrolment of the first five pts as follows: Fotemustine 100 mg/m^2 i. v. on day 1, once-weekly Bortezomib 1,3 mg/ m^2 i. v. on days 1, 8, 15, 22, Dexamethasone 20 mg i. v. on days 1, 8, 15, 22 for six 35-day cycles. **Results.** Twenty-four pts have been enrolled: M/F 13 (54%)/11(46%), median age 69 years (44-83), median number of previous therapies 2 (1-5). Previous treatments included autologous transplant in13 pts (54%), bortezomib in8 pts (33%), oral melphalan in11 pts (46%) and thalidomide in 15 (63%). Four pts discontinued for extra-hematological toxicity, 2 for progression. Twenty-two pts were evaluable for best response since completing at least 2 cycles. CR + VGPR was achieved in 11 patients (50%), 9 pts had PR (41%), 2 pts had SD (9%). Response rates on intention-to-treat-basis were as follows: CR 8%, VGPR 33%, PR 21%, SD 8%, Progression 4%. Median time to first response was 36 days (range 21-83) with a median DOR of 19. 4 months (95% CI 11. 6-23. 7 months). After a median follow-up of 24. 3 months (range 1. 6-32. 8 months), the median OS is 28. 5 months (95% CI 22. 1-NR), the median TTP and the median PFS are 20. 5 (95% CI 11. 9-22. 2 months) and 19. 1 (95% CI 11. 9-22. 2) months respectively. Median time to next therapy (TNT) was 16. 2 months (4-25. 2). As far as toxicity was concern, one-hundred and thirty-three AE of any grade were observed, 65 hematological (49%) and 68 (51%) non-hematological; among those there were 19 infections (14%), 31 neuropathies (23%), 18 gastrointestinal/metabolic events (14%). Thrombocytopenia was the most common AE. There were fifty-one (38%) grade 3-4 AE, most of which were haematological (66%). Eight SAE were observed: 5 infections, 2 neurological (1 disautonomic, 1 sensory-motor neuropathy), 1 gastrointestinal bleeding. Half of the events occurred during the first two cycles (49%), most were manageable, with 69% resolved or improved, 15% unchanged, 15% worsened. Need for dose reduction occurred in 65% of the events. **Conclusions.** Fotemustine in combination with dexamethasone and once-weekly bortezomib has a good clinical activity in relapsed MM pts, obtaining a high percentage of good quality and long-lasting response (50% of ≥VGPR, median DOR 19. 4 months). Safety data showed a good toxicity profile

1513

ASSOCIATION OF IL-17A AND IL-17F POLYMORPHISMS TO SUSCEPTIBILITY AND CLINICAL FEATURE OF MYELOMA IN JAPANESE PATIENTS

C Ushie[1], T Saitoh[1], N Moriyama[1], T Takani[1], A Iwasaki[1], H Handa[1], M Matsumoto[2], M Sawamura[2], J Isoda[2], H Ogawara[1], H Murakami[1]

[2]Nishi-Gunma Hospital, Shibukawa, Japan

Background. Multiple myeloma (MM) is characterized by unique clinical characteristics including anemia, bone lesions, and renal failure because of malignant plasma cell proliferation. The growth of plasma cell is dependent on a complex interplay among various cytokines, adhesion molecules and other factors in the tumor microenvironment. Dysregulation of several cytokines has been detected in some patients with MM, and was known to be associated with an adverse prognosis. Interleukin-17(IL-17) A and IL-17F are the members of the IL-17 cytokine family (IL-17A-F) responsible for the pathogenic activity of Th17 cells. Th17 was shown to play a pathogenic role in malignancy. Furthermore, it has been shown that IL-17 promotes myeloma cell growth in vitro and inhibits immune function in patients with MM. Polymorphisms of IL-17A (G-197A) and IL-17F (7488T/C) were studied in some diseases, including collagen disease and malignancy. However, there have been no previous reports of the influence of IL-17A and IL-17F polymorphism on the incidence and clinical outcome of MM. **Aims.** We examined the single nucleotide polymorphisms (SNPs) of IL-17A (G-197A) and IL-17F (7488T/C) in MM patients, and analyzed the relationship between IL-17A /IL-17F SNPs and the susceptibility and clinical features. **Patients and Methods.** We examined 93 patients [age range,35-83 years; stage Ⅰ(n=8), stage Ⅱ(n=23),stage Ⅲ(n=62); IgG (n=55), IgA (n=15),IgD (n=2),non-secretory(n=3), Bence Jones(n=18)] with MM and 150 healthy controls. Genomic DNA was isolated from peripheral blood using the DNA Kit (QIAGEN, Hilden, Germany). Genotyping was determined by the polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) technique. Genotype and allele frequencies were compared between the study groups using χ^2-test. The characteristics and laboratory features of MM patients with each IL-17A and IL-17F polymorphisms were compared using χ^2-tests and student t-tests. The Kaplan-Meier method was used in the calculation of overall survival. Overall survival curves were compared with the log-rank test. Probability values <0. 05 were considered statistically significant. **Results.** IL-17A G-197A genotype and allele frequencies were not significantly different between MM patients and controls (compared with AA and non-AA genotype, GG and non-GG genotype). In MM patients, IL-17A non-GG genotype was significantly associated with advanced international staging system (ISS). The frequency of ISS stage≧Ⅱ was significantly higher in non-GG genotype (non-GG vs GG genotype: 79. 1% vs 57. 1%,p<0. 05). The patients with non-GG genotype had significantly shorter survival from diagnosis than the patients with GG genotype (median of survival from diagnosis, non-GG vs GG genotype, 4. 4years vs 6. 3 years, p<0. 05). There were no significant difference in genotype and allele frequencies between MM patients and controls.

In the clinical characteristics, there was also no difference between patients with TT and TC genotype. **Conclusions.** These results suggested that the IL-17A (rs2275913, G-197A) polymorphism may be associated with the susceptibility and clinical feature of MM in Japanese patients.

1514

PROGNOSTIC CONTRIBUTION OF UNINVOLVED SERUM FREE LIGHT CHAINS (USFLC) IN MULTIPLE MYELOMA (MM)

E Koulieris[1], D Maltezas[1], T Tzenou[1], N Kafassi[2], V Bartzis[1], K Bitsanis[1], A Efthymiou[1], I Vardounioti[1], V Karali[1], E Nikolaou[1], M Dimou[1], P Tsaftaridis[1], M Angelopoulou[3], P Panayiotidis[1], G Pangalis[3], M Kyrtsonis[1]
[1]University of Athens, 1st Department of Propaedeutic Internal Medicine, Athens, Greece
[2]Laikon University Hospital, Department of Immunology, Athens, Greece
[3]University of Athens, Department of Hematology, Athens, Greece

Background. The prognostic value of serum FLC and their ratio FLCR in MM is now established. Although it is accepted that increased prognostic information provided by FLCR as compared to FLC is due to the fact that it reflects both monoclonal FLC serum levels and eventual suppression of the polyclonal secretion, the eventual prognostic contribution of usFLC per se has not been extensively studied. **Aims.** To study the possible prognostic contribution of usFLC with regard to time to first treatment (TFT) and overall survival (OS) in MM patients. **Patients and Methods.** 180 MM patients with available baseline serum FLC at diagnosis were studied. 25% of patients were in ISS stage 1, 25% in stage 2 and 50% in stage 3. MM type was IgG, IgA, light chain and IgD in 64, 22, 12 and 2% respectively. 116 patients were kappa-LC and 64 lambda-LC restricted. Serum FLCs were measured by nephelometry (FREELITE, The Binding Site Ltd. Birmingham, UK). FLCs values were considered depressed for any usFLC-kappa value below 0. 13 mg/L and any usFLC-kappa below 1. 04 that were the lowest normal range in our healthy control's group. Serum usFLCs were then assessed for time to first treatment (TFT) and overall survival (OS) by the Kaplan-Meyer method. Survival curves were compared by the log-rank test. **Results.** 25% of patients had depressed usFLCs. In patients with depressed usFLCs a reduced TFT was observed compared to the others (p<0. 0001), in addition their median OS was 32 months (range 1-63) versus 86 months (range 61-110) in patients with normal usFLCs (p=0. 01). **Conclusions.** Depressed usFLCs were shown to be an adverse prognostic factor in MM. Suppression of polyclonal immunoglobulins was part of Durie's MM minor diagnostic criteria; depressed usFLCs express the same. Their negative prognostic impact is very interesting given that it cannot be attributed to malignant plasma cells genetic defects but rather reflects a bone marrow microenvironment process related to the complex biology of this disease.

1515

HEMATOLOGIC SAFETY PROFILE OF SINGLE-AGENT CARFILZOMIB IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA FROM FOUR PHASE 2 STUDIES

A Nooka
Winship Cancer Institute, Emory University, Atlanta, United States of America

Background. Carfilzomib is a next-generation proteasome inhibitor that is currently being evaluated in patients with multiple myeloma (MM). The majority of patients with MM exhibit either disease- or therapy-related myelosuppression sometime in the course of their disease. Therefore, detailed evaluation of treatment-emergent hematologic safety data with carfilzomib is of significant interest. **Aims.** To report the hematologic safety profile for single-agent carfilzomib from 526 patients with relapsed and/or refractory (R/R) MM treated in four phase 2 studies. **Methods.** Patients treated with carfilzomib in trials PX-171-003-A0, PX-171-003-A1, PX-171-004, and PX-171-005 were included in the analysis. Patients with preexisting hematologic abnormalities of Grade 0-2 (Grade 0"'3 for 005) were eligible to enroll. Carfilzomib was dosed in all studies on Days 1, 2, 8, 9, 15, and 16 of a 28-day cycle (C). Doses were 20 mg/m^2 in C1 for all studies, escalating to 27 mg/m^2 in C2 as defined per individual protocol, except 005 (15 mg/m^2 in C1, 20 mg/m^2 in C2, and 27 mg/m^2 in C3). Thrombocytopenia, lymphopenia, neutropenia, and anemia were adverse events (AEs) of interest, and data on incidence, frequency, and severity were analyzed. Laboratory data were analyzed for trends over time. **Results.** Summary of hematologic events*Defined as death or immediate risk of death; AE resulting in inpatient or prolonged hospitalization, surgery, or disability (or could lead to without intervention); or congenital birth defect of offspring. In general, platelet counts trended down, reached a nadir by Day 8 of a 28-day treatment cycle, and normalized before the start of the next cycle. There was no evidence of cumulative thrombocytopenia or clinically significant episodes of bleeding associated with thrombocytopenia. Febrile neutropenia was reported in 1% of patients. No mortality due to hematologic AEs was reported. **Conclusions.** Hematologic AEs, although common with carfilzomib treatment, were infrequently dose limiting. Clinically significant Grade 3/4 cytopenias were both infrequent and transient. The hematologic safety profile of carfilzomib was similar to or better than currently approved MM therapies, providing further evidence of its acceptable safety profile in heavily pretreated MM patients and indicating its potential widespread use in this patient population.

1516

PLASMA CELL LEUKEMIA: SUSTAINED RESPONSES ARE POSSIBLE WITH INNOVATIVE TREATMENT STRATEGIES

A Nooka, J Kaufman, S Muppidi, R Harvey, C Gleason, L Heffner Jr, A Langston, D Casbourne, L Boise, S Lonial
Winship Cancer Institute, Atlanta, United States of America

Background. Despite markedly improved survival rates for MM, prognosis in a highly aggressive subset - plasma cell leukemia (PCL) remains dismal. Patients (pts) with primary PCL (pPCL) and with secondary PCL (sPCL) have a median overall survival (OS) of 11. 2 months (mo) and 1. 3 mo, respectively from the time of diagnosis (Tiedeman RE, 2008). CIBMTR data was encouraging in pts with pPCL showing progression free survival (PFS) of 34% and OS of 64% at 3 years (Mahindra A, 2011). Recently, GIMEMA group demonstrated that bortezomib-containing combinations as frontline therapy resulted in 55% OS and 42% PFS at 2 years (Arena GD, 2011). **Aims.** We evaluated our institutional experience in this high-risk subset of pts with intent to improvise outcomes with prolonged treatment strategies. **Methods.** We identified 28 pts (22 with pPCL and 6 with sPCL) among 1400 pts with plasma cell dyscrasias from our myeloma database from 01/2005 till 02/2012. Additional high risk features present include [(del17p -18&33%, t(4;14)-5&0%, t(14;16)-14&0% by fluorescence in situ hybridization or metaphase cytogenetics; hypodiploidy-32&33%,del13-40&50% for pPCL & sPCL pts, respectively. The endpoints of interest are PFS, OS, and response rates after ASCT and during maintenance. **Results.** In the pPCL subset, 20 of the 22 pts underwent initial bortezomib-based cytoreduction therapy (VTD-PACE in 12 pts; RVD/VTD in 13 pts). 21 pts underwent ASCT at a median of 6 months from time of diagnosis. Maintenance therapy post-ASCT was started in 12 pts with RVD (RVDm); 1 pt with bortezomib and 5 pts with lenalidomide. Overall median PFS is 66% at 3 years and OS is 73% at 4 years. Median PFS for pts on RVDm vs. no RVDm was 38 mo vs. 15 mo; p=0. 004. OS for pts on RVDm vs. no RVDm was 100% vs. 67%; p=0. 018. Achieving ≥PR vs. < VGPR post-ASCT (PFS: 38 vs. 14 mo; p=0. 002 and OS: 49 vs. 26 mo; p=0. 037) were significant for prolonged PFS and OS. Response rates for pPCL that underwent ASCT and maintenance are summarized in the Table 1. In the sPCL subset, median PFS is 3 months (0-9. 86) and OS is 3 months (0-11. 42). Duration from initial diagnosis of MM to diagnosis of sPCL >30 months vs. <30 months (median PFS: 1 mo vs. 8 mo and OS: 2 mo vs. 9 mo), presence of deletion 17p13 vs. none (median PFS: 1 mo vs. 8 mo and OS: 9 mo vs. 1 mo) are associated with worse outcomes. **Conclusions.** Cytoreduction with bortezomib-based regimens followed by early ASCT and continuing RVD maintenance delivers superior and sustained response rates and prevents early relapses in pPCL. Outcome data for sPCL are still disappointing and newer approaches should be considered. Safety data and tolerability of RVDm will be presented.

Table 1. Response rates for pPCL that underwent ASCT and maintenance.

	Pre-ASCT response (n=21)		Post-ASCT response (n=20)		Best response with maintenance (n=20)

ADVANCES IN THE TREATMENT OF MULTIPLE MYELOMA: SURVIVAL ANALYSIS OF 560 PATIENTS IN A TWENTY-FIVE YEARS PERIOD IN A SINGLE CENTER

D Nemet[1], A Ostojic[2], B Dreta[2], N Lucev[2], D Sertic[2], I Radman[2], I Bojanic[2], D Batinic[3], R Serventi-Seiwerth[2], S Basic-Kinda[2], I Aurer[3], N Durakovic[3], S Zupancic-Salek[2], M Mikulic[2], P Roncevic[2], D Pulanic[2], A Boban[2], J Kovacevic-Metelko[2], B Labar[2]

[1]University Hospital Center Zagreb and School of Medicine, Zagreb, Croatia

[2]University Hospital Center Zagreb, Zagreb, Croatia

[3]University Hospital Center Zagreb and University of Zagreb School of Medicine, Zagreb, Croatia

Background. Therapy of multiple myeloma (MM) has been greatly advanced by introduction of autologous hematopoietic stem cell transplantation (AHSCT) in 90's, and appearance of new potent drugs thalidomide, bortezomib and lenalidomide in the last decade. **Aims.** to assess the efficacy of new treatment modalities on survival of MM patients treated at the University Hospital Center, Zagreb. PATIENTS AND **Methods.** From 1985 till 2010, 560 consecutive MM patients (pts) were analyzed. Median age at diagnosis was 60 (range 28-89) years. Pts were divided into three groups according to time period of available treatment modalities: Group one treated from 1985-1995, period prior AHSCT (n=158, median age 63 [range: 31-87]); group two treated from 1996-2001, period with AHSCT (n=139, median age 58 [range: 29-87]); and group three treated from 2002-2010, period with AHSCT+bortezomib+thalidomide (n=263, median age 60 [range: 28-89]). Each group was subdivided in two subgroups according to age at diagnosis indicating eligibility for AHSCT (<65 and ≥65 years of age). Estimated median overall survival (OS) was calculated by Kaplan-Meier method. Differences between groups were tested by 2-tailed log-rank test with p value of <. 05 being statistically significant. **Results.** Median follow-up for entire cohort was 42. 5 (range: 1-267 months). Seventy-three pts were lost from follow-up after median time of 16 (range: 1-123) months. Estimated median OS was 69 (95%CI 59. 07-78. 93) months. For groups 1 and 2, estimated median OS were 38 (95%CI 29. 44-46. 56) and 47 (95%CI 36. 06-57. 94) months respectively, while for the group 3 estimated median OS was not reached for the median follow-up of 48 (range: 1-118) months. OS was significantly different between all groups: groups 1:2 (p=0. 009), groups 2:3 (p<0. 0001), groups 1:3 (p<0. 0001) (Figure 1). When adjusted for age, significance between groups 1 and 2 was not reached (p=0. 058) although showing trends for better OS in group 2. Statistically significant difference remained between groups 1:3 and 2:3 (p<0. 0001, for each). OS for patients younger than 65 are significantly better compared to patients with 65 years or older, in all three groups. **Conclusions.** The analysis of OS clearly showed significantly better outcome for pts treated with AHSCT, especially for younger patients. In most recent time period both younger and older patients showed better OS probably due to introduction of new treatment modalities with thalidomide or bortezomib. Results of the study are in accordance with other similar retrospective analyses.

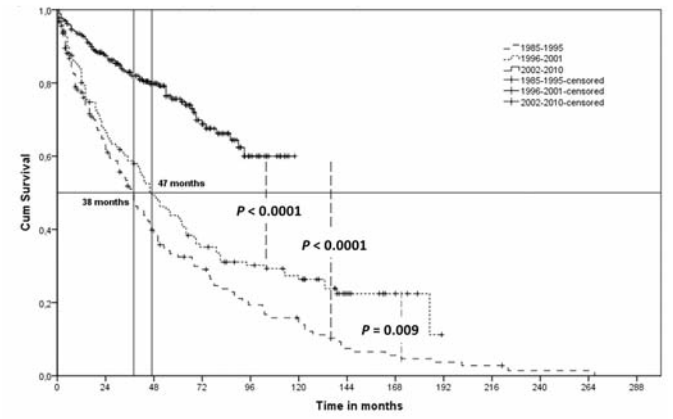

Figure 1. Overall survival for multiple myeloma patients in different periods.

LENALIDOMIDE COMBINED WITH LIPOSOMAL DOXORUBICIN AND LOW DOSE DEXAMETHASONE (RDD) FOR RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS: SAFETY AND EFFICACY

V Pavone[1], A Mele[2], C De Risi[2], B Rossini[2], D Carlino[2], S Sibilla[2], R De Francesco[2], G Greco[2], M Fina[2], P Ferrara[1], M Morciano[2], A Ostuni[1], V Pavone[2]

[1]Card. "G. PANICO" Hospital, Tricase (Lecce), Italy

[2]Department of Haematology, Haemopoietic stem cell transplantation, Tricase (Lecce), Italy

Background. Multiple Myeloma treatment has considerably changed in the past decade with improvement of response rates and overall survival. Nevertheless, the best treatment regimen for relapsed patients is not standardized. Lenalidomide is approved for treatment of relapsed myeloma. Previous trials have highlighted activity of Liposomal Doxorubicin in this setting of patients. **Aims.** We asses safety and efficacy of Lenalidomide,Liposomal Doxorubicin and low dose dexamethasone (RDd) in relapsed/refractory patients. **Methods.** between June 2008 to February 2012,35 patients were enrolled. Lenalidomide(25 mg/die,day 1-21), Liposomal Doxorubicin (30mg/mq i. v. on day 1) and dexamethazone (20 mg/die, day 1, 8, 15, 22) of 28 days cycle, was administered for 6 cycles (Induction Phase,IP). Patients in CR-PR(IMWG criteria) post IP received 3 other courses of RDd as consolidation. Responder patients allowed 10 mg/die Lenalidomide (day 1-21 every 35 days) until progression or treatment intolerance. Unresponsive patients discontinued treatment. **Results.** The characteristics of enrolled patients were summarized in Table 1.

Table 1. Patient characteristics at enrollment.

Patient Characteristics	N=35
Median age, y (range)	69 (46-81)
⩾ 65 years	21(60%)
Type of Myeloma, no. (%)	
IgGL/IgGK	8 (23%)/ 12 (34%)
IgAL/ IgAK	4 (11%) / 8 (23%)
Lambda	2 (6%)
Non secer	1 (3%)
Durie Salmon stage, no. (%)	
IIIA	27 (77%)
IIA	6 (17%)
IIIB	2 (6%)
ISS, no. (%)	
I	12 (36%)
II	13 (40%)
III	8 (24%)
Median Time since initial diagnosis, months	31 (5-185)
Median number of prior therapy, no.(range)	2 (1-6)
cycles>3	9 (26%)
Prior transplant, no. (%)	17(49%)
Prior thalidomide regimens, n (%)	19 (54%)
Prior Bortezomib regimens, n (%)	24 (69%)

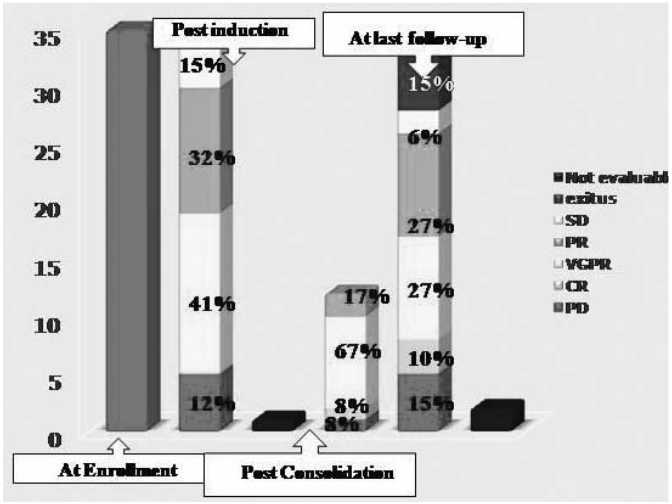
Nine patients (26%) were considered as high risk because of heavly pre-treatment. Nineteen (54%) and 24(69%) received,respectively,previous treatment with thalidomide or bortezomib,Seventeen patients(49%) received a previous autotransplant. The common side-effects during RDd were showed in Table 2.

Table 2. Incidence of haematological and extra-haematological toxicity.

Variable	All cases 35	WHO grade, n (%)			
		1	2	3	4
Haematological side effects					
Anemia	23 (66%)	15 (65%)	5 (22%)	3 (14%)	/
Thrombocitopenia	22 (63%)	14 (64%)	3 (14%)	5 (27%)	/
Neutropenia	33 (94%)	15 (45%)	10 (30%)	8 (26%)	/
Non-Haematological side effects					
Neuropathy	24 (69%)	19 (79%)	5 (21%)	/	/
Skin rash	4 (12%)	3 (75%)	1 (25%)	/	/
Fever	6(17%)	1	1		
Deep Venous Thrombosis	4(11%)				

No grade4 haematologycal toxicity was observed. The G-CSF support was required in 33 patients (94%). GradeI-III neutropenia was documented in 33 patients,however febrile neutropenia occurred in 6 patients (17%). The major extra-haematological adverse event was neuropathy occurred in 24 patients (69%). Deep venous thrombosis occurred in 4 patients (11%). Lenalidomide dose reduction or temporary discontinuation occurred in 8 (23%) and 17 (49%) patients, respectively. Patients aged ³65 years showed higher incidence of haematological toxicity (anemia 78%, p=0. 004, requiring erythropoietin; thrombocytopenia 77%, p=0. 01 and neutropenia requiring G-CSF support (100%,p=0. 08). Elderly patients delayed administration of RDd more frequently (77%vs 23%, p=0. 05). After IP, the overall response rate (ORR:11PR+14VGPR) was 73% (Figure 1). Four patients (12%) were in Stable Disease (SD). Four of responder patients relapsed (14%). Twelve patients completed the planned treatment. After consolidation, the ORR was 92%: 1CR (8%),8 VGPR (67%) and 2 PR(17%). No differences in terms of ORR were observed in elderly patients (p=0,8). Six of seven patients (86%) younger than 65years and refractory to first line therapy obtained at least a PR and were transplanted or are waiting for transplant. After a median follow-up of 15 months (2-37),5 patients(14%) died(3 for disease progression,1 for infection and 2 for transplant-TRM). Twenty-eight patients are alive:3 (11%) in CR,9 (32%) in VGPR,9(32%) in PR,2 (6%)in SD and 5(19%) in progression disease. The median TTP is 9months (3-25). Kaplan Meyer estimated 1,5yTTP is 52%. We analyzed the factors influenced TTP: only previous treatment with thalidomide seem to be correlated to a lower TTP (p<0,004). **Conclusions.** Our experience suggests that RDd is both tolerable and effective for second line Multiple Myeloma therapy. The response rate and quality of response considerably improve during the different phases of planned treatment. This combination should be considered appropriate treatment in patients with high risk refractory/relapsed Multiple Myeloma, who are aged>65 and/or received >2prior line therapies (including thalidomide,bortezomib and autotransplant). RDd is also an optimal therapy in refractory younger patients as bridge to transplant.

Figure 1. Response rates during the different phases of treatment.



1519

SUBCUTANEOUS VERSUS INTRAVENOUS ADMINISTRATION OF BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA: EXPERIENCE IN A SINGLE INSTITUTION

I Lopez San Roman, D De Miguel, N Golbano, M Diaz Morfa, D Morales, J Arbeteta, S Herrero, D Subira, B Pinedo
Hospital Universitario Guadalajara, Guadalajara, Spain

Background. Bortezomib (VELCADE) is approved in the US and Europe for the treatment of patients with multiple myeloma (MM) in both the frontline and the relapse settings. The recommended dose of bortezomib is 1. 3 mg/m2 administered as a 3- to 5-second bolus intravenous (IV) injection. As an alternative to IV delivery, subcutaneous (SC) administration of bortezomib may be a good option. **Methods.** 55 patients diagnosed of MM were treated between January 2007 until February 2012 with SC (24 patients) or IV (31 patients) bortezomib (1. 3 mg/m2 on days 1, 4, 8 and 11 every 21 days for a total of 6-8 cycles or 1. 3 3 mg/m2 on days 1, 4, 8, 11, 22, 25, 29 and 32 for 1 cycles and on days 1, 8, 22 and 29 for 8 cycles). The median of treatment cycles were 6 (2-13). One patient received Thalidomide (50 mg/day) after first cycle and another one after 6th cycle. SC injection sites were the thighs or abdomen, and the injection site was rotated for subsequent injections within a cycle. IV injections were administered at a concentration of 1 mg/ml as a 3- to 5-second IV push, and SC injections were administered at 2. 5 mg/ml. The primary endpoint was overall response rate (ORR; complete response [CR + PR]) after 6-8 cycles. Safety and tolerability of the two administration routes, including local tolerability of SC administration, were also assessed. **Results.** Because of treatment-emergent peripheral neuropathy it was necessary reducing the doses in 33% vs 41% of the patients in the sc and iv group respectively Thrombocytopenia (Grade 3 and higher) were reported in 4 of 24 (17%%) patients in the subcutaneous group and 13 of 31 (42%) in the intravenous group. 75 % of the patients were able to complete treatment. Overall response rate were similar in both groups. SC administration of VELCADE also demonstrated local tolerability. **Conclusions.** Rates of peripheral sensory neuropathy were lower with subcutaneous than with intravenous bortezomib, as were rates of diarrhoea and thrombocytopenia. None case of fatigue or hypotension were reported in the sc group. Subcutaneous administration of bortezomib is non inferior to the standard intravenous route in patients with multiple myeloma and seems tohave an improved systemic safety profile.

1520

LENALIDOMIDE IN POEMS SYNDROME

A Nozza[1], F Terenghi[2], R Mazza[3], E Nobile-Orazio[2], F Adami[4], P Merlini[5], C Briani[6], A Santoro[3]

[3]Hematology, Humanitas Cancer Center, Rozzano, Italy
[4]Department of Clinical and Experimental Medicine - University of Padua, Padua, Italy
[5]Center for Amyloidosis, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy
[6]Department of Neurosciences, University of Padova, Padua, Italy

Background. POEMS syndrome is a rare multisystemic disease. Vascular endothelial growth factor (VEGF) correlated with the activity of the disease and it could account for clinical manifestations. There are no controlled trials and no established treatment. Lenalidomide. has anti-angiogenic activity through inhibition of VEGF and TNF alpha. **Aims.** his study plans to evaluate efficacy of Lenalidomide in POEMS SYNDROME. **Patient sand Method.** From 10/09, we started a pilot study with Lenalidomide plus Dexamethasone(RD) in pts pretreated or with newly diagnosed POEMS syndrome. Lenalidomide 25 mg/day was given for 21 days in association with weekly Dexa 40 mg until tolerated or progression. Primary objective of this study was evaluation of clinical efficacy of RD combination in terms of improvement of either the disability caused by the neuropathy (ONLS) or organ specific symptoms after 6 cycles. Secondary objectives were improvement of muscle strength assessed by the expanded MRC sum score and improvement of sensation assessed by the INCAT sensory sum score. After first 6 cycle, pts were evaluated for response. At this time, 13 pts have been enrolled, (11 men and 2 woman), with median age of 51 yrs (range 45-76). All pts were pretreated and 2 had received transplant; in all pts was detected monoclonal component (MC) (IgAL in3 pts,IgGL in9 pts,cL light chain in 1) and sensory/ motor peripheral neuropathy. Sclerotic bone lesions was evident in6 pts, endocrinopathies in 9, skin changes in 9, peripheral edema in 10, organomegaly in 8, lymphoadenophaty in 4, papilledema in 7, hrombocytosis in4 pts. VEGF serum level was elevated in all patient with a median value of 3428 pg/ml (range 1400-8978). **Results.** 9 pts are still on treatment and received a median of 16 RD cycles (range 2-35). 8 pts are evaluable for response after 6 cycles. A clinical response, with improvement of all clinical manifestationsof disease, was observed in all pts. Neurological improvement, was evident already after 3 RD cycles, confirmed by nerve conduction studies after every 6 cycles. One patient with tetraparesis actually is able to walk without devices, and his upper limb strength is normal with improved sensory disturbances. Only in 3 patients MC disappeared. VEGF decreased in all treated pts: median 3428 pg/ml (range 1400-8978) before treatment to 1500 pg/ml (467-3579). 3 pts discontinued treatment:1 withdraw consent, 1 drop-out after 4 cycles wit progressive disease and 1 died for pulmonary infection on cycle 1. Lenalidomide reductions was necessary in3 pts (1 extraematological toxicity and 2 thrombocytopenia) and dexa in7 pts. **Conclusions.** Lenalidomide is efficacy and well tolerated in POEMS syndrome, with rapidly and continuous neurological improvements. Correlation between response and VEGF level was confirmed. At this time no responding pts experienced disease progression. The studyaccrual is still ongoing.

1521

SERUM FREE LIGHT CHAIN (FLC) AND HEAVY/LIGHT CHAIN (HLC) ASSAYS PROVIDE SENSITIVE AND QUANTITATIVE METHODS FOR MONITORING IGA MULTIPLE MYELOMA PATIENTS

L Mirbahai[1], P Young[1], S Harding[1], M Drayson[2]
[1]The Binding Site Group Ltd, Birmingham, United Kingdom
[2]The university of Birmingham, Birmingham, United Kingdom

Background. Serum protein electrophoresis (SPE) is the standard method for monitoring monoclonal immunoglobulin (M-Ig) concentrations in multiple myeloma (MM) patients. However, the utility of the test may be limited in patients with low M-Ig load, light chain only disease or when the M-Ig co-migrates with other serum proteins, typically in IgA MM patients. Furthermore, clonal evolution characterised by subtle changes in monoclonal protein expression may not be identifiable using standard electrophoretic techniques. **Aims.** To assess the utility of FLC and IgA HLC immunoassays as tools to monitor IgA MM patients. **Methods.** FLC and HLC were measured nephelometrically in retrospective serial samples from 30 IgA (20 IgAκ; 10 IgAλ) MM patients; results were compared with historic clinical evaluations. Survival analysis at maximum response was performed using SPSSv19. **Results.** At presentation, FLC ratios were abnormal in 29/30 and HLC ratios were abnormal in all 30 IgA MM patients, including 9 patients with non-quantifiable SPE. 27/30 patients responded to therapy (12 PR, 6 VGPR, 9 CR). The FLC ratio was abnormal in all patients achieving a PR and in 5/6 patients achieving a VGPR. The HLC ratio remained abnormal in all patients achieving PR or VGPR. In patients achieving CR, FLC and HLC ratios were normal in 5/9 and 4/9 patients, respectively. The 5 patients with an abnormal HLC ratio at CR had a shorter overall survival compared with 4 patients with a normal HLC ratio (median OS: 981 days v not reached; p=0. 019). During follow-up, FLC and HLC ratios were abnormal in 11/30 (37%) patients with non-quantifiable SPE. Furthermore, monitoring with HLC and FLC identified clonal changes in 3/30 (10%) patients. An IgAκ patient presented with 29g/L IgAκ and 92mg/L FLCκ, responded to therapy and achieved a VGPR after 243 days. At this time both HLC and FLC ratios decreased but remained abnormal. The patient subsequently relapsed after 713 days; HLC and FLC ratios both increased at this point. The patient responded to a second line of treatment and a secondary response was recorded after 798 days; HLC and FLC ratios reduced in line with this response but remained abnormal. The patients terminal relapse was characterised by an increasingly abnormal HLC ratio, however FLC production did not increase, suggesting a subtle change in M-Ig production. A second IgAk patient presented with 48g/L IgAκ and 400mg/L FLCκ. The patient achieved CR after 492 days which was characterised by normalisation of both HLC and FLC ratios. The patient relapsed after 1122 days which was characterised by IgAκ production only, with normal FLCκ production and FLC ratio. The patient responded to second line therapy; however HLC ratios did not normalise. The patients terminal relapse was characterised by both M-Ig and FLCk production. Clonal changes were identified in one further patient who had FLC escape 822 days following response. **Conclusions.** HLC provides a sensitive method for identifying and quantifying M-Igs that are difficult to detect by SPE. Furthermore, monitoring patients with HLC and FLC can detect clonal evolution which may be missed using standard techniques.

1522

ASSESSMENT OF IGA HEAVY/LIGHT CHAIN IMMUNOASSAY UTILITY IN MULTIPLE MYELOMA PATIENTS

J Young[1], S Stern[2], J Behrens[2], P Patel[2], L Hennessy[2], D Powner[1], S Harding[1], A Bansal[2]
[1]The Binding Site, Birmingham, United Kingdom
[2]St Helier Hospital, Carshalton, United Kingdom

Background. Current international guidelines recommend serum protein electrophoresis (SPEP) and serum free light chain (FLC) for the identification of monoclonal immunoglobulins (M-Ig), reflexed to immunofixation (IFE) for confirmation and typing. In the case of intact immunoglobulin monoclonal gammopathy of undetermined significance (MGUS) or multiple myeloma (MM) SPEP is also recommended to monitor the protein-Ig. However, co migration of the M-Ig with other serum proteins can make SPEP inaccurate, a common occurrence with IgA and IgM and less so with IgG M-Ig's. In these instances total immunoglobulin measurements are recommended. However, total immunoglobulin may be of insensitive as the patients respond to therapy or in cases of low M-Ig production it cannot distinguish between monoclonal and polyclonal immunoglobulins. Newly developed heavy/light chain (HLC) assays can be used to quantify IgAκ and IgAλ, enabling calculation of an IgAk/IgAl ratio. Here, we assess the utility of IgA HLC in the identification and monitoring of IgA monoclonal immunoglobulins, including those with difficult to quantify SPEP results. **Methods.** IgA HLC analysis was performed retrospectively on samples from 53 IgA (22 IgAk; 31 IgAl) MM patients at various stages of treatment attending the Haematology Dept atSt HelierHospital. The HLC IgAk/IgAl normal range was 0. 80-2. 04. **Results.** 10/53 (19%) samples (8 IgAk / 2 IgAl) had quantifiable IgA by SPE (median 5g/L, range 1-40g/L); all 10 samples had abnormal HLC ratios. Due to inaccuracies in SPEP measurement (such as co-migration with other proteins) in the remaining 43 samples (23 IgAk / 20 IgAk), total IgA measurements were used to quantify the immunoglobulin (median 5g/L, range 1-58g/L). In 14/43 samples total IgA levels were less than 5g/L; 8 of these samples had an abnormal IgA HLC ratio; the remaining 6 samples had a normal ratio, however no IFE data was available to determine if these patients had a persistent monoclonal protein. Sequential monitoring samples (median n= 5, range 2-9) were available for 23 patients, in 2/23 patients SPEP measurements were reliable and in each patient HLC accurately monitored patient responses. Of the remaining 21 patients whose monoclonal protein was measured using total IgA, there were similar results between HLC and total immunoglobulins in 11 patients during the period of assessment. In 10/21 patient total IgA was below 5g/L, in all cases abnormal HLC ratios indicated the presence of a monoclonal protein. Furthermore, in 3 patients HLC ratios provided additional information, in 2 patients an increasingly abnormal HLC ratio indicated relapse before the level of monoclonal protein exceed 5g/L. This relapse was identified due to sequential suppression of the uninvolved polyclonal IgA. In 1 patient originally characterised as a FLC MM patient an intact immunoglobulin producing clone was identified following chemotherapy. **Conclusions.** IgA HLC ratios are able to sensitively detect clonal production even when SPE is normal or when total IgA is within the normal range.

1523

IMPROVED SURVIVAL IN MULTIPLE MYELOMA: A POPULATION-BASED STUDY SINCE 1985

R Ríos Tamayo[1], E Molina Portillo[2], MJ Sánchez Pérez[2], JJ Jiménez Moleón[3], J Sainz Pérez[4], AM Hernández Vidaña[1], JM Pablos Gallego[1], R Leyva Ferrer[1], Y Moatassim de la Torre[1], M Jurado Chacón[1]
[1]University Hospital "Virgen de las Nieves", Granada, Spain
[2]Andalusian School of Public Health, Granada, Spain
[3]Dpt. of Preventive Medicine. University of Granada, Granada, Spain
[4]Pfizer-University of Granada-Andalusian Government Centre for Genomics, Granada, Spain

Background. A great effort has been made to improve overall survival (OS) in patients with multiple myeloma (MM). However, MM remains an incurable disease and progress in elderly people is still poor. **Aims.** To assess the OS pattern in MM using population-based data from The Granada Cancer Registry (GCR), during the last 27 years. **Methods.** All patients diagnosed with MM from 1985 to 2012 were registered in the GCR and included for OS analysis. Patients were initially assigned to three groups according to time of diagnosis: 1985-1994, 1995-2004 and 2005-2012. Clinical data were available from 1993 and we therefore divided patients in two groups: 1993 to 2002 and 2003 to 2012. On the basis of the age limit of 65 years, we constructed survival curves according to Kaplan-Meier method. Log-rank test was used to compare OS curves. The statistical package used was R. **Results.** 490 patients have been diagnosed with MM during the period of study, 226 men and 262 women (53,69 %). Median age was 67 years (21-91). Median OS was 25 months (19. 6-30. 4). There was a significant trend of increasing OS in the three groups (p=0. 0072). Patients diagnosed during the last decade (2003-2012) (n=174) had a better survival than patients diagnosed from 1993 to 2002 (n=207): median OS increased from 21 to 34 months (p=0. 002). This effect depends on the age group: for patients younger than 65, median OS improved from 25 to 49 months (p=0. 013); however, for those older than 65, the impact on median OS is 18 to 31 months (p=0. 130). We confirm the prognostic value of the International Staging System (p= 0. 0108). We found a significantly shorter OS for patients with a positive hepatitis C virus serology (p= 0. 0123). The body mass index (p= 0. 00266) and the M-protein type (p= 0. 0579) also might have a prognostic role. Conventional karyotyping is pathological only in 22%. FISH analysis is not routinely made until recently and is not available for comparison. **Conclusions.** MM is a heterogeneous disease with survival times ranging from a few days to more than ten years. Treatment strategy depends largely on age. Outside clinical trials, OS in real life patients with MM is still disappointing. Encouraging results have been shown with new agents combinations, but the impact in OS in the elderly needs to improve

1524

ELOTUZUMAB-ASSOCIATED INFUSION REACTIONS: INCIDENCE AND MANAGEMENT

S Jagannath[1], S Lonial[2], T Parli[3], R Brotherton[3], G Kroog[4], J Racenberg[4], MH Wang[3], A Singhal[3], P Richardson[5]
[1]Mount Sinai Medical Center, New York, United States of America
[2]Emory University School of Medicine, Atlanta, United States of America
[3]Abbott Biotherapeutics Corp., Redwood City, United States of America
[4]Bristol-Myers Squibb, Princeton, United States of America
[5]Dana-Farber Cancer Institute, Boston, United States of America

Background. Elotuzumab is a humanized monoclonal antibody (mAb) targeting CS1, a cell surface glycoprotein highly expressed on >95% of multiple myeloma (MM) cells. In a phase 1/2 study 1703, in patients with relapsed/refractory (RR) MM, elotuzumab plus lenalidomide and low-dose dexamethasone demonstrated an objective response rate of 82% in both phase 1 (n=28) (1) and in the combined treatment group of ongoing phase 2 (n=73) (2). Median progression-free survival has not been reached yet in the phase 2 study, after a median follow-up of 14. 1 months (2). Therapeutic proteins, including mAbs, can induce infusion reactions (IRs) associated with flu-like symptoms, which can be mitigated by premedication. Previous reporting of IRs after elotuzumab infusion was based on pre-defined adverse events (AEs) that could potentially be IRs and did not include investigator assessment of relationship to elotuzumab or reporting of IRs that led to infusion interruption (1,2). **Aims.** To report investigator-designated IRs (IDIRs), IRs resulting in infusion adjustment, and the impact of a premedication regimen on incidence and severity of IRs in the phase 1/2 study 1703. **Methods.** Patients (N=101) with RR MM received 5, 10, or 20 mg/kg of elotuzumab IV (days 1, 8, 15, and 22 every 28 days in first 2 cycles and days 1 and 15 of subsequent cycles), lenalidomide 25 mg PO (days 1-21) and dexamethasone 40 mg PO weekly. Thirteen phase 1 patients (n=28) received no premedication prior to elotuzumab infusion; 15 patients received partial premedication and were excluded from the analysis. All patients in the ongoing phase 2 study (n=73) received a premedication regimen of corticosteroids (IV methylprednisolone 50 mg or IV dexamethasone 8 mg), H1/H2 blockers, and acetaminophen prior to elotuzumab infusion. IDIRs were identified by the investigator as a sign/symptom of an elotuzumab-related IR, and independently as IRs requiring elotuzumab infusion adjustment - interruption, rate decrease, or discontinuation. **Results.** Table 1 summarizes the incidence and severity of IRs resulting in elotuzumab infusion adjustment in patients with and without premedication. Two patients not treated with premedication experienced grade 3/4 IRs and withdrew from treatment; no patient receiving premedication withdrew from treatment due to IR. After incorporation of premedication, grade 3 and all grade IDIRs were reported in 1/73 (rash, 1. 4%) and 9/73 (12. 3%) patients, respectively. No grade 4/5 AEs were reported. The most common IDIRs were nausea and pyrexia (4. 1% and 2. 7% of patients, respectively). **Summary and Conclusions.** Study protocol-guided, steroid-based premedication decreased the incidence and severity of elotuzumab-related IRs requiring elotuzumab infusion adjustment, and did not appear to affect clinical efficacy of the treatment. Assessment of IDIRs is a clinically relevant method of capturing elotuzumab-induced IRs. Analysis of IDIRs will continue in the current and ongoing randomized phase 3 studies (ELOQUENT-1; CA204-006; NCT01335399 and ELOQUENT-2; CA204-004; NCT01239797). 1. Lonial S, et al. *J Clin Oncol* 2012 (in press). 2. Lonial S, et al. *Blood* 2011; 118: Abstract 303.

Table 1.

	No premedication (n=13)		Premedication (n=73)	
	All grades n (%)	Grade 3/4 n (%)	All grades n (%)	Grade 3/4 n (%)
IR resulting in infusion adjustment	3 (23.1)	2 (15.4)	3 (4.1)	2 (2.7)

1525

COMPARISON OF EFFICACY OF IMMUNOGLOBULIN FREE LIGHT CHAIN (FLC), HEAVY CHAIN/LIGHT CHAIN (HLC) ASSAYS AND IMMUNOFIXATION (IFE) IN ASSESSMENT OF REMISSION IN MULTIPLE MYELOMA (MM)

M Kraj, B Kruk, A Szczepinski, K Warzocha
Institute Hematology and Transfusion Medicine, Warsaw, Poland

HLC separately measures in pairs the light chain types of each intact immunoglobulin (Ig) class generating ratios of monoclonal Ig/ non-involved polyclonal Ig concentrations; potentially improving assessment of monoclonal protein response. Normalization of FLC ratio is considered a higher level of complete remission (CR) in MM and has been incorporated into definition of stringent CR (sCR) in IMWG Uniform Response Criteria. Recently, there was reported that abnormal HLC after induction therapy has a high negative predictive value for identifying patients not achieving CR by uniform response criteria and is also associated with shorter progression free survival (PFS) after transplant. FLC ratio normalization had no impact suggesting that stringent CR criteria may need further validation (Hari et al. Blood 2011; 118: 1241). To compare IFE, HLC and FLC results in assessment of remission and to assess whether CR with using the FLC ratio and HLC ratio criteria is prognostic for PFS or overall survival (OS) we assayed fresh and stored sera from 44 MM(25 F19 M, median age 55 years, 26 IgG, 13 IgA, 1 IgD, 1 IgE, 2 Bence Jones, 1 nonsecretory); patients who underwent autologous stem cell transplantation (ASCT). Patients were followed since ASCT to date of this report. Serum protein electrophoresis (SPE) and IFEwere performed using Hydrasys 2 apparatus (SEBIA) and antisera from the same company. Serum FLC and HLC (IgGκ/IgGλ, IgAκ/IgAλ) measurements were made on a Siemens BN^{TM} II nephelometer using polyclonal antisera assays (Freelite^{TM}, and Hevylite^{TM}, Binding Site,Birmingham,UK). Of the 44 patients in 26 (59%) after ASCT normalization of serum FLC ratio occurred. In all these 26 patients with normal FLC ratio SPE did not reveal monoclonal component and in 22 (84. 6%) of them also normalization of HLC ratio was noted but in 5 (19%) patientsIFE was still positive. Concordance of three tests (IFE negative, HLC normal, FLC normal) was found in 19 (73%) patients. Among 22 patients with normalization of HLC ratio in 3 (13%)IFE-was positive. In 21 of 44 (47%) patients after ASCT normalization of FLC ratio documented sCR. In this group 5 (28%) patients relapsed. Median PFS was 24 months (range 7-35). In the group of patients with CR, VGPR and PR (n=20) 12 (60%) patients progressed. Median PFS was 12 months (range 13-74). Three patients did not respond. Median follow-up period after ASCT of patients with sCR is 22 months (7-64), of patients with CR, VGPR and PR 25 months (5-108) and of non responders 9 months (3-25). So far, one patient died. One our patient with IgAλ MM, sCR after ASCT and FLCλ clonal escape at relapse and at that time with negative IgAλ IFE and normal IgA HLC ratio illustrates the importance of serum FLC elevation for early detection of clinical relapse, in the absence of any other clinical and laboratory finding. **Conclusions.** IFEis more sensitive that HLC and FLC assays in detecting residual disease. CR with normalization of the HLC and FLC ratios have impact on PFS but not OS.

1526

MULTIPLE MYELOMA RELAPSE TREATED BY BORTEZOMIB WITH CYCLOPHOSPHAMIDE AND PREDNISOLONE

O Votyakova
The Federal Government Budget Institute “Russian Cancer Research Center”, Moscow, Russian Federation

Background. Bortezomib monotherapy is effective in 27% of patients with relapsed and refractory multiple myeloma (MM), 43% of patients had relapses after 1-3 lines of chemotherapy. Adding dexamethasone to bortezomib therapy improves outcomes by 12-18%. Alkylating agents (melphalan, cyclophosphamide) significantly increase the effectiveness of bortezomib treatment.
Aims. Our aim was to assess the efficacy and the toxicity of the program BCP (bortezomib, cyclophosphamide, prednisone) in patients with relapsed MM.
Methods. From 05. 2007 till 02. 2012 43 patients at the age of 22 to 83 years (median 60 years), with relapsed MM were treated with BCP: 18 women (42%), 25 men (68%). All patients had previously received treatment, from 1 to 8 lines of chemotherapy (median 3), 8 patients had previously received bortezomib (19%), 10 patients (23%) of high-dose chemotherapy with autologous hematopoietic stem cells. BCP program included 8 cycles of induction: bortezomib 1. 3 mg/m^2 intravenously on days 1,4,8,11, cyclophosphamide 200 mg intramuscularly in days 1,4,8,11,14, prednisolone 1 mg/kg per os with 1 to 8 days of the course with a gradual reduction in dose and the treatment stop on 13 day. The cycle was renewed for 22 days from the beginning of the previous one. Then 3 cycles of maintenance: bortezomib 1. 3 mg/m^2 intravenously on days 1,8,15 and 22, cyclophosphamide 200 mg intramuscularly every 4 days, prednisolone 1 mg/kg per os 1 to 8 days of the cycle with a gradual reduction the dose and the complete withdrawal on day 13 of treatment. The cycle was renewed for 36 days from the beginning of the previous one. Patients received 1 to 14 cycles (median 7). Efficacy of the treatment was assessed in 42 patients according to the criteria of the International Myeloma Working Group (IMWG, 2006). Toxicity assessed according to the criteria of Common Terminology Criteria for Adverse Events (version 3. 0). **Results.** Overall efficacy was 67%, complete, very good partial, partial response were obtained in 12%, 17% and 38% of patients, respectively. The duration of observation was from 2 to 48 months (median 21), median overall survival was 30 months, median time to progression - 14 months. Adverse events included grade 3-4 thrombocytopenia (9%), neutropenia (9%), infections (19%), weakness (15%). In 12% of the cases developed herpes zoster. Peripheral neuropathy grade 2 was observed in 46% of patients, grade 3 - 7%. **Conclusions.** BCP is highly effective treatment for patients with relapsed MM and has moderate toxicity. It is recommended to use prophylactic antiviral drugs and dosage adjustment of bortezomib in patients with manifestations of polyneuropathy during therapy.

1527

INCREASED SERUM TRANSFORMING GROWTH FACTOR-BETA (TGF-BETA) IS RELATED TO LONGER TIME TO FIRST TREATMENT (TFT) AND OVERALL SURVIVAL (OS) IN WALDENSTRÖM'S MACROGLOBULINEMIA (WM)

T Tzenou[1], E Koulieris[2], D Maltezas[2], K Bitsanis[2], I Vardounioti[2], V Bartzis[2], M Dimou[2], C Kalpadakis[3], T Vassilakopoulos[3], M Angelopoulou[3], G Pangalis[3], P Panayotidis[2], MC Kyrtsonis[2]

[1]Laikon General Hospital, Athens, Greece

[2]University of Athens, 1st Dept. of Propaedeutic Medicine-Hematology Research Lab, Athens, Greece

[3]University of Athens, Hematology Clinic, Athens, Greece

Background. TGF-beta has a tumor suppressor role by down-regulating cell proliferation. However, resistance to its effects was shown in malignant cells of B-lineage such as chronic lymphocytic leukemia (CLL) and multiple myeloma (MM) cells while, in the same time, suppression of normal B-lymphocytes and plasma cells was observed, as expressed by decreased polyclonal immunoglobulin (Ig) production. There are no reports, to our knowledge, on serum TGF-beta levels in WM. **Aims.** To study any possible relationship between serum TGF-beta and parameters of disease activity and survival in a series of WM patients at diagnosis. **Patients and Methods.** 34 patients were studied (25 males, 9 females); median age was 64 years. Lymph nodes were palpable in 21% and spleen in 6%. Hb <11g/L was observed in 56%, PLT <140x10^9/L in 9%, serum albumin <3. 5 g/dL in 10%, beta2-microglobulin ≥ 5. 5 mg/L in 45%, bone marrow (BM) lymphoplasmacytic infiltration was ≥50% in 57% of patients. Median IgM level was 1900 mg/dL. 12% of patients were asymptomatic at diagnosis while 88% were symptomatic and required treatment. Median follow-up was 101 months. Median TFT was 5 months. Sera, drawn at diagnosis, were frozen and then retrospectively analyzed; sera from 24 healthy individuals (HI) were tested as controls. Serum TGF-beta measurements were done by ELISA (R&D, quantiquine) according to the manufacturer's instructions. Statistical analysis was performed by IPSS software, version 15v. **Results.** Median serum TGF-beta levels were 42000 pg/ml (range 6300-615000) in patients and 57500pg/ml in HI (range 30000-110000). No correlations were found between clinical and laboratory variables of disease and TGF-beta levels. Importantly, however, patients with TGF-beta levels above median presented a longer TFT than the others (p=0. 02) as well as a longer OS (p=0. 01). **Conclusions.** Our results of longer TFT and OS in WM patients with increased serum TGF-beta levels, suggest that WM lymphoplasmacytes remain sensitive to the suppressive effect of TGF-beta. Further studies are needed to confirm these results.

[4]Hospital Universitario Rio Hortega, Valladolid, Spain

[5]Hospital Gregorio Marañon, Madrid, Spain

[6]Hospital Universitario General, Albacete, Spain

[7]Hospital Virgen de la Luz, Cuenca, Spain

[8]Hospital Virgen de la Salud, Toledo, Spain

Background. Lenalidomide is an inmunomodulatory drug used in the treatment of multiple myeloma (MM). Nowadays, treatment is maintained as long as the patient tolerates the drug and MM maintains response. Nevertheless, up to 40% of patients treated with lenalidomide suffer from grade 3-4 hematological toxicity being necessary dose reductions. Inmunomodulatory effect of lenalidomide is considered not to be related to dose. Until now there are no studies of the influence of dose intensity (DI) in quality and length of response. **Aims.** To compare the influence of DI of lenalidomide in response, progression free survival (PFS) and overall survival (OS) in patients with relapse MM treated with lenalidomide. **Materials and Methods.** DI of lenalidomide was calculated retrospectively in patients treated with lenalidomide for relapse or refractory MM. DI was calculated as median mg received per month at two points (from start lenalidomide to best response [1º DI] and from best response to end of treatment due to progression or death [2º DI]. In order to better comprehension, dose of lenalidomide is expressed as mg/day of 21-day/month cycle. 1ºDI was calculated in patients with a minimum of 2 cycles, and at least 4 weeks of treatment from best response was required for calculate 2ºDI. Patients with renal failure and primary refractory MM were excluded. **Results.** From January 2007 to December 2011, 71 patients were included in the study. Median age at lenalidomide treatment was 69 years old (40-85), median time from diagnosis to treatment with lenalidomide was 41 months (3-249), and half of the patients received at least 2 lines of treatments (1-6). Overall response rate (ORR)(≥PR) was 71,8% (18,3% CR, and 15,5% VGPR), 18 patients (28,2%) remain with stable disease. Median PFS and OS were 13 (3-50) and 16 months (5-60), respectively. PFS and OS since best response (PFSbr and OSbr) were also measured. Median PFSbs and OSbr were 6 and 12 months, respectively. Considering DI, median dose for 1ºDI was 18 mg/day/cycle (1,74-25). 47% of patients with 25 mg/day/cycle achieved CR vs. 32% for patients receiving lower doses (p:0,187), with shorter mean time to reach best response(18 vs. 33 weeks, p: 0,005). When we focused on 2ºDI, median dose was 11,93 mg/day/cycle (11,93-24,5). Interestingly, among patients receiving <15 mg/day/cycle vs. >15 mg/day/cycle a dramatic increase in PFSbr was observed (30 vs 6 months, respectively; p:0,025) and this was translated to an increased in OSbr (32 vs 14 months, respectively; p: 0,015) (Figure 1).

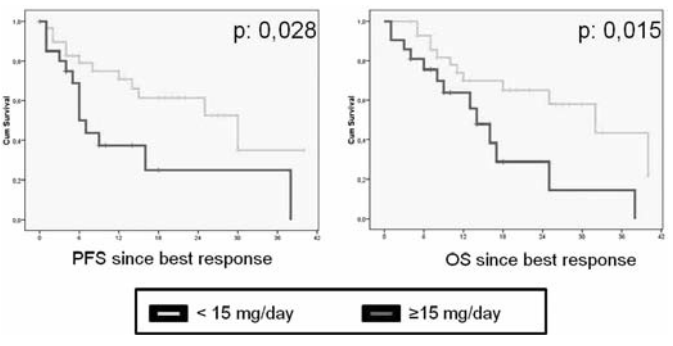

Figure 1. PFS and OS since best response.

Conclusions. For the best of our knowledge, this is the first study that correlates de dose intensity of lenalidomide with ORR and outcome in MM. We observed a trend toward better ORR was observed for patients receiving higher doses of lenalidomide, with shorter time to response. Nevertheless, once achieved best response, patients receiving lower doses of lenalidomide show higher PFS and this is translated into an increased in OS. The result of present study suggests a considerable inmunomodulatory role of lenalidomide in maintaining response. This surprisingly results should be prospectively confirmed.

ANALYSIS OF THE NUMBER OF COLLECTED CD34+ CELLS AFTER DIFFERENT INDUCTION REGIMENS IN PATIENTS WITH MULTIPLE MYELOMA UNDERGOING AUTOLOGOUS STEM CELL TRANSPLANTATION

V Hungria[1], E Crusoe[1], F Higashi[1], MP Camargo[1], E Miranda[2], A Quero[1], AC Marret[1], JC Barros[1], M Sampaio[1], AL Peres[1], P Cury[1], CS Chiattone[1], V Hungria[1]
[1]Santa casa sao paulo, São Paulo, Brazil
[2]Unicamp, Campinas, Brazil

Introduction. High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) remains the treatment of choice for patients with multiple myeloma (MM) eligible for this procedure. Until recently, the most commonly used induction therapy was the combination of vincristine, doxorubicin, and dexamethasone (VAD). Factors such as age, disease status, prior radiotherapy, treatment protocols, the mobilization regimen used and type of agent used for induction, especially alkylating agents, can influence the number of collected cells. The VAD regimen rarely results in failure to collect stem cells. Currently, several combinations of new drugs such as thalidomide, bortezomib and lenalidomide have been used for induction pre ASCT, with clearly superior results, as compared to VAD. However, there are few studies describing the impact of these new agents on the number of collected CD34+ cells, specifically for the CTD combination, which is widely utilized in our country. **Aims.** To analyze the number of CD34+ collected cells after three different induction regimens: VAD vs Cyclophosphamide + Thalidomide + Dexamethasone (CTD) vs Thalidomide + Dexamethasone (TD). **Patients and Methods.** A retrospective cohort of MM patients eligible for ASCT who underwent different induction regimens (VAD, TD and CTD) was studied. Data were collected from patients treated from January 2007 to July 2011. The appropriate cell number collection was greater than or equal to 2 x10^6/Kg. Patients with MM who underwent induction with VAD, TD or CTD were included. Mobilization was performed with the GCSF alone or GCSF+cyclophosphamide. We excluded patients who had received prior to ASTC more than six cycles or regimens other than those above. Statistical analysis was performed with SPSS 15. 0, through comparative analysis with ANOVA, Student's t test, Welch test and Tukey Post Hoc test. **Results.** A total of 80 MM patients submitted to ASCT was elected. Seven patients were excluded, with 73 analyzable patients remaining. The patients were 56% male. The median age at diagnosis was 55 years old (28-68). The immunoglobulin subtypes at diagnosis were: IgG = 50%, IgA = 23%, 19% = light chain, IgM = 1. 4% and non-secreting = 3%. The Durie-Salmon staging was: IIIA+B=88% and IIA+B=12%. The numbers by the induction + mobilization scheme were: VAD+(Cy+GCSF)=17 cases, VAD+GCSF=10, CTD+GCSF=14 and TD+GCSF= 31. The median number of induction cycles was three for VAD and four for TD and CTD. The median of collected CD34+ cells was: VAD + (Cy + GCSF)= 5. 9x10^6/Kg; VAD+GCSF=5. 28 x10^6/Kg, CTD+GCSF=2. 75x10^6/Kg and TD+GCSF=2. 85x10^6/Kg. The median number of collection apheresis for VAD+(Cy + GCSF), CTD and TD was once. The group that received VAD+GCSF required a median of 1. 5 times. The general analysis of the number of collected CD34+ cells showed differences among the groups, the VAD group having the advantage of a much larger number of collected cells (p <0. 0001). However, when analyzing the collection of CD34+ cells among the different groups that used only GCSF as mobilization, there were no differences (p=0,146). **Conclusions.** The CTD combination as induction followed by GCSF mobilization alone allowed for the collection of CD34+ cells in sufficient quantities to perform one ASCT, which is the most readily accessible treatment in our country.

1531

EXTRAMEDULLARY RELAPSE OF MULTIPLE MYELOMA: DISCORDANT RESPONSE TO TREATMENT OR PROGRESSION IN PATIENTS WITH MULTIFOCAL LESIONS

S Capalbo, G Palumbo, G Spinosa, MG Franzese, C Ferrandina, T Ruggiero
Ospedali Riuniti di Foggia, Foggia, Italy

Background. Extramedullary disease (EMD) is an uncommon manifestation of Multiple Myeloma (MM), characterized by high-grade histology, aggressive biological behaviour and very short survival. EMD may occur in MM patients with relapsed disease more often than in patients at diagnosis. Its incidence has increased during the last years, probably due to the prolongation of patients' survival and to the availability of more sensitive imaging techniques. Data focusing on the response to treatment and the outcome of EM MM according to the involved body sites are limited and controversial. **Aims.** The purpose of this study was to assess the different pattern of response to treatment between the involved sites. We report hereby a series of 15 MM relapsed patients with more than one EM lesions and that showed discordant response to treatment or progression from site to site. **Methods.** We retrospectively reviewed all relapsed MM patients observed at our Institution, who received at relapse Bortezomib based regimens (BBRs) and had a follow-up time of at least 6 months. In 15 cases (5. 8% of the 256 MM patients observed at our institution over a 7-year period) the relapse presented with multifocal lesions with involvement of soft tissues surrounding the skeleton in 65% of cases (paravertebral soft tissues, soft tissue arising from the skull or from the chest wall) and involvement of other sites (airways, skin, subcutaneous tissues, lymph nodes, pericardium, pleura, gastrointestinal tract, liver, kidney, abdominal pelvic masses, muscles) in the remaining 35%. The median number of EM sites per patient was 3 (range 2-5 sites per patient). Diagnoses were made from biopsy and/or clinical follow-up findings. **Results.** After 6 cycles of treatment, the EM masses showed discordant response to treatment or progression from site to site whereas the monoclonal protein (M protein) decreased in all cases. Masses arising from the bone with a soft tissue component showed a response to treatment (until complete disappearance in some patients) in 70% of cases; masses involving other sites showed a change in the size in 45% of cases. Cutaneous localizations had only a transient response followed by a rapid progression and the onset of several subcutaneous nodules. **Conclusions.** According to definition of EMMM, EM masses must not have risen from any bone, whereas masses arising from the bone with a soft tissue component should be defined extraosseous. Our case series indicates that, after uniform treatment (BBRs), EMMM shows discordant response to treatment or progression from site to site. Moreover, the response to treatment may differ between various involved sites in each patient with multifocal EM lesions. In our case series, when EMMM involves soft tissues surrounding the axial skeleton, the effect of the treatment is mainly better than in other cases. Finally, the response and the outcome are very poor when EMD is represented by skin involvement. Our data suggest that the progression of myeloma cell homing in different tissues may affect the response to therapy and the EM myeloma cells may become more tolerant to bortezomib in some sites rather than in others.

1532

EFFICACY OF THE COMBINATION THERAPY OF LIPOSOMAL ADRYAMICIN, BORTEZOMIB, CYCLOPHOSPHAMIDE AND DEXAMETHASONE (ABCD) IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS

A Romano[1], A Chiarenza[1], A Gorgone[2], L Schinocca[2], G Uccello[1], M Cavalli[1], P Fiumara[1], G Motta[1], G Palumbo[1], F Di Raimondo[1]
[1]University of Catania, Catania, Italy
[2]Department of Experimental Oncology, Mediterranean Institute of Oncology, Viagrande, Catania, Italy

Background. Bortezomib has shown significant activity in myeloma. In this multicenter trial, we assessed for the first time the combination of bortezomib, doxorubicin cyclophosphamide, and dexamethasone (ABCD) in the treatment of relapsed/refractory myeloma. **Patients and Methods.** Twenty-four patients were treated for a median of four 28-day cycles (1-6). Median age was 68 years (range, 51-78 years). Three had extra-medullar disease. All patients had been already treated with a median of 3 previous lines of treatment (range, 2-6): 38% were resistant to previous therapies and 62% were relapsed. Twenty-five percent of patients had undergone prior autologous transplantation, 25% prior anthracycline and 42% prior bortezomib-based regimens. Bortezomib was given at dosage 1. 3 mg/m2, and dexamethasone 40 mg I. V. on days 1, 4, 8, 15 plus liposomal doxorubicin 20 mg I. V. on days 1 and 15, and cyclophosphamide 100 mg per os for 15 days. **Results.** At least a partial remission (reduction M-protein > 50%, according to International Myeloma Working Group Criteria) was achieved in 50% of patients, including 8% of complete remissions and 21% of very good partial remissions (reduction M-protein > 90%, according to International Myeloma Working Group Criteria). Side effects were predictable and manageable, with prominent hematological (31% any grade), including grade 3-4 thrombocytopenia (9%), grade 3-4 anemia (17%). Non hematological toxicity affected 32% of administered cycles and included gastrointestinal disturbances (54%), peripheral neuropathy (8%) and infections (8%). After a median follow up of 22. 6 months, one-year progression-free survival was 27% and overall survival from the start of ABCD was 33%. Median time to progression was 8. 4 months. **Conclusions.** ABCD is an active salvage therapy with manageable toxicity in patients with relapsed/refractory myeloma.

1533

DESCRIPTION OF A RARE AND NOVEL DISEASE: TEMPI SYNDROME

A Schroyens[1], B Sykes[2], L Kwok[3], C Landgren[3], L O'Connell[4]
[1]Iniversity Hospital Antwerp, Edegem, Belgium
[2]Departments of Hematology-Oncology, Massachusetts General Hospital, Boston, United States of America
[3]Multiple Myeloma Section, National Cancer Institute, Bethesda, Maryland, United States of America
[4]Jane Anne Nohl Division of Hematology, University of Southern California, Los Angeles, CA, United States of America

We have previously described the TEMPI syndrome, a multisystem disease characterized by the pentad of Telangiectasias, elevated Erythropoietin and erythrocytosis, Monoclonal gammopathy, Perinephric fluid collections, and Intrapulmonary shunting. Here, we expand on the original description of the TEMPI syndrome and provide new data towards its successful treatment. Together, we have identified and are following four patients that demonstrate the five characteristic features. These patients developed their first symptoms of erythrocytosis in their thirties and forties and these symptoms have been slowly progressive. Telangiectasias are most prominent on the trunk, arms, hands, face and oropharynx. Tests for liver dysfunction and genetic screening for hereditary telangiectasia were negative, the VEGF level was normal. All patients had erythrocytoisis at the initial presentation with hematocrit values up to 64% and they were treated with phlebotomies. The serum Erythropoietin levels were elevated at diagnosis and the values rose to levels above 5000 mU/ml. A cause could not be determined. Imaging, hemoglobin oxygen affinity tests, hemoglobin electrophoresis, JAK2 and HIF-2alfa exon 12 gene sequencing did not elucidate the pathogenesis. An IgG Monoclonal gammopathy was identified: three patients had an associated kappa light chain and one a lambda light chain. The bone marrow biopsies revealed fewer than 10% plasma cells in three patients, consistent with a diagnosis of monoclonal gammopathy of undetermined significance and there were 30% plasma cells in the bone marrow of the last patient who had been followed fourteen years for erythrocytosis. There was no end-organ involvement. The progressive accumulation of bilateral Perinephric fluid collections is a striking and unique feature of the syndrome. The serous fluid was clear, low in protein, with few leucocytes and without cholesterol or triglycerides. Microscopic Intrapulmonary shunting with hypoxia was present in three patients and slowly progressed. Pulmonary hypertension was not detected with right heart catheterization. We speculate that the TEMPI syndrome is the end stage of a spectrum of associations that are reported in the literature: erythrocytosis and monoclonal gammopathy and monoclonal gammopathy and perinephric fluid collections. We hypothesize that the paraprotein is involved in the pathophysiology of the TEMPI syndrome. We cloned the heavy and light chain variable regions corresponding to the monoclonal protein of one of the patients, introduced them into an expression construct and have generated a monoclonal antibody that we are currently testing for its specificity. Treatment with the proteasome inhibitor bortezomib is ongoing in all patients after the dramatic resolution of all of the TEMPI syndrome characteristics was observed in one of them. We bring this novel syndrome to the attention of the hematology community hoping to identify more cases.

INCREASED BONE MARROW TOTAL VASCULAR AREA (TVA) CORRELATES WITH A MORE AGGRESSIVE DISEASE IN WALDENSTRÖM'S MACROGLOBULINEMIA (WM) PATIENTS

?? Tzenou[1], G Levidou[2], N Kavantzas[2], K Xirokosta[1], D Maltezas[1], P Korkolopoulou[2], E Koulieris[1], K Dimou[1], C Kalpadakis[3], T Vassilakopoulos[3], M Angelopoulou[3], P Panayiotidis[1], G Pangalis[3], E Patsouris[2], MC Kyrtsonis[1]
[1]University of Athens, 1st Dept of Propaedeutic Internal Medicine, Athens, Greece
[2]University of Athens, Department of Pathology, Athens, Greece
[3]University of Athens, Hematology Clinic, Athens, Greece

Background. Angiogenesis plays an important role in tumor progression by numerous mechanisms among which is the physical expansion of endothelial surface that gives tumor cells more opportunities to enter the circulation and spread. Very few studies have explored this issue in WM. **Aims.** To study the possible role of increased bone marrow (BM) neoangiogenesis in WM by evaluating microvessels in immunostained sections by computer image analysis. **Methods.** Angiogenesis was evaluated by CD34 immunostaining in BM trephine biopsy specimens from 36 WM patients at diagnosis. A digital camera connected to a bright field microscope was used. Pictures were examined with a standardized program to quantify the proportion between stained and total areas and to assess the number of microvessels (image analysis software). Two main parameters were evaluated, microvessel density (MVD) and total vascular area (TVA). Symptomatic patients (84%) received treatment while the others (16%) were regularly followed. Median time to first treatment (TFT) was 2 months while median overall survival was 89 months. Results of microvessels immunostaining were compared to patients and disease variables such as patients' age, sex, presence of lymphadenopathy or organomegaly, anemia, thrombocytopenia, increased LDH, beta-2 microglobulin, IgM levels and percentage of BM infiltration. Statistical analysis was performed by IPSS software, version 15v. **Results.** MVD ranged from 7 to 393 (median 32); TVA ranged from 2681 to 69160 μm^2 (median 27762). Patients with TVA above median had a statistically significant shorter TFT and OS (p=0. 03 for both) than the others. MVD failed to show correlation with TFT and OS. No correlation was found between TVA, as well as MVD, and other clinical and laboratory disease parameters. **Conclusions.** Increased TVA may prove a powerful predictor of TFT and OS in WM. Results need to be confirmed in larger studies.

[4]Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Belgrade, Serbia
[5]Clinical Center of Serbia,University of Belgrade, Serbia, Belgrade, Serbia

Backround. Myeloma multiple (MM) is a clonal neoplastic disease characterized by proliferation of malignant plasma cells in bone marrow which secrete monoclonal immunoglobulines. Stromal cells in bone marrow, which secrete cytokins such as interleukin 6, interleukin 10, tumor necrosis factor α and lymphotoxin α, play important role in pathogenesis of MM. The role of Toll-like receptors in pathogenesis of MM has been recently studied. Numerous studies signalize the association between single nucleotide polimorphysm (SNP) and risk for developing MM, prognosis and therapy response. **Aims** The goal of this study is to determine if there is association between different polymorphisms of genes for cytokines and toll-like receptors and clinical-laboratory characteristics of disease, and to acess whether any of genotypes was associated with increased risk for development MM or affect survival of patients. **Methods.** 45 patients and 115 healthy individuals were inrolled in this study. SNP for studied cytokins were identified with polymerase chain reaction followed by restriction fragment length polymorphism. **Results.** There was no significant statistical difference regarding distribution of genotypes between both groups except for GC genotype of IL6G(174)C polymorphisms, which was significantly more presented in group of patients. Logistic regresion method showed that the same genotype was independent risk factor for developing MM (p<0. 05, OR 2. 465, 95% CI 1. 105-5. 497). No correlation was found between other genotypes and susceptibility to MM. Tested polymorphisms didn't affect survival. The correlation between certain genotypes and clinical-laboratory characteristics of MM was found. **Conclusions.** Genetic factors may impact cell functioning, MM characteristics and therapy responce and represent a risk factor for MM developement

1536

F-FDG PET/CT FOR DETECTION AND LOCALIZATION OF SOLID NEOPLASMS IN PATIENTS WHIT MONOCLONAL GAMMOPATHY UNDETERMINED SIGNIFICANCE (MGUS

M Troiano[1], G Monaco[1], N Serao[2], G Di Ronza[2]
[1]Division of Hemathology, SUN, Napoli, Italy
[2]Division Radiology, "Federico II", Napoli, Italy

Background. A review of the literature shows discordant data on the association between monoclonal components and solid neoplasms. **Aims.** we want demonstrate possible usefulness of F-FDG PET/CT for detection of solid neoplasms in MGUS. **Methods.** 60 patients (M: 34, F: 26, age range: 65-78yrs) with MGUS diagnosed by standard criteria have been included in this perspective study. 30 patients showed a serum IgG (16 κ; 14 λ;), 6 an Ig M (4 κ; 2 λ), and 24 an IgA (10 κ; 14 λ;) monoclonal component. Total body PET-CT was performed in all patients, in addition to a standard radiographic scan of all bones. **Results.** An associated solid tumour was found in 16/60 cases (26,6%; 10M, 6F). An IgA monoclonal component has been detected in 10/16 (62,5%; 6M, 4F) patients. In this subgroup the associated neoplasms were: colorectal adenocarcinoma (6), non-small cell lung cancer (2), and clear cell renal carcinoma (2). Colorectal adenocarcinoma and infiltrating ductal breast carcinoma were respectively diagnosed in five patients presenting IgG monoclonal component. At last an IgM paraprotein was detected in a colorectal adenocarcinoma patient. **Conclusions.** Total body PET-CT allowed us to diagnose different neoplasms, in early stage, in patients with MGUS. We showed how, in our limited population, PET-CT is comparable in sensibility and specificity to complete bone standard radiography for the study of bone disease. Moreover, this diagnostic technique allowed the early detection of solid tumors. Interestingly, in 10/16 cases (62,5%) the associated neoplasia was localized at the bowel, and in this subgroup the monoclonal component was Ig A in 6/10 cases. This study, even if conducted on a limited population, suggests that PET-CT could be usefully considered in the diagnostic algorithm of MGUS in order to discover eventually associated solid neoplasms.

1537

PERIPHERAL BLOOD STEM CELL MOBILIZATION USING G-CSF ALONE FOR MM WITH THE MINIMAL RESIDUAL DISEASE COMPARED TO CYCLOPHOSPHAMIDE PLUS G-CSF

JE Jang, SY Hyun, DY Hwang, YD Kim, SJ Kim, JW Cheong, YH Min, JS Kim
Yonsei University College of Medicine, Seoul, South-Korea

Background. Autologous stem cell transplantation (ASCT) for multiple myeloma (MM) offers higher response rates and improved survival compared with conventional chemotherapy. However, the best method for peripheral blood progenitor cell (PBPC) mobilization in patients with MM remains controversial. **Aims.** We analyzed the efficacy of PBPC collection, complication, and the transplant outcome of G-CSF alone, compared to high-dose cyclophosphamide (HD-CY) + G-CSF as the regimen of PBPC collection for autologous transplantation in 54 patients with MM. **Methods.** In group I (n = 37), G-CSF, 10 μg/kg/day s. c., was used alone until the last day of collection, starting consecutive aphereses on the 5th day. In group II (n = 17), HD-CY, 4 g/m^2 i. v., was administered followed by G-CSF, 10 μg/kg/day s. c., until the end of collection, starting the leukaphereses after hematological recovery (WBC >5,000 x 10^6/L). **Results.** Both groups were comparable for age, sex and clinical prognostic features as well as previous therapies. However, in patients mobilized by HD-CY + G-CSF, the percentage of plasma cell in bone marrow prior to mobilization was significantly higher. (7. 15% vs. 1. 0%, p=0. 004). Median total yields of CD34+ cells had not significant differences between two groups (7. 86 x 10^6 cell/kg vs. 9. 0 x 10^6 cell/kg, P=0. 35). Successful collection more than 5. 0 x 10^6 CD34+ cells/kg and not failed collection of at least 2. 0 x 10^6 CD34+ cells/kg were achieved in similar proportions in the two groups(64. 9% vs. 64. 7%, P=0. 991 and 91. 9% vs. 76. 5%, P=0. 189). The significant differences of yields on day 1 ≥ 2. 0 x 10^6 CD34+ cells/kg were not observed either (56. 8% vs. 64. 7%, P=0. 581). Hospitalization for peripheral blood stem cell mobilization was longer in group II (9days vs. 18days, p<0. 001) and the treatment-related toxicity was greater in this group: 8 patients (47%) developed fever requiring antibiotics during the neutropenic period after HD-CY and seven (41%) patients required transfusion support. Among 54 patients, 44 underwent ASCT (14 and 30 belonged to the group I and II, respectively). After stem cell infusion, no significant differences of the median time to neutrophil engraftment (>0. 5 x 10^9/l) and platelet engraftment (>50 x 10^9/l) were observed between both groups (10days vs. 10days and 15days vs. 14days, respectively). Post transplant responses were not different in the two groups, with 70. 0% of patients improved or retained CR status after ASCT in the group I and 78. 6% in the group II (p=0. 722). Overall and progression-free survivals were similar in both groups. The overall survival were 80% and 71% (95% CI, ± 11% and ± 14%, p=0. 282) at 2 years. The progression-free survivals were 50% and 46% (95% CI, ± 16% and ± 11%, p=0. 745) at 2 years. **Conclusions.** These data suggest that adequate CD34+ cell collections can be achieved with G-CSF alone and G-CSF alone is cost-effective with less toxicity and with simplification of the procedure. G-CSF alone as mobilization regimen is reasonable at least in patients who were confirmed lower residual disease with bone marrow study prior to mobilization.

1538

EFFICACY AND SAFETY OF BORTEZOMIB-BASED RETREATMENT IN MULTIPLE MYELOMA (MM) PATIENTS RELAPSING AFTER BORTEZOMIB-CONTAINING FIRST-LINE THERAPY: A RETROSPECTIVE STUDY

Background. Multiple myeloma (MM) follows a relapsing course; hence, there is a need for multiple active therapeutic options after first-line treatment, including the possible re-use of front-line agents. Bortezomib-based combination therapies are increasingly used as first-line MM therapy, so there is a need for an assessment of the efficacy and safety of bortezomib retreatment in MM patients. **Aims.** This international, multicentre, non-interventional retrospective study aimed to assess the efficacy and safety of bortezomib-based retreatment in MM patients relapsing after bortezomib-containing first-line therapy. **Methods.** Eligible patients were aged ≥18 years with a positive diagnosis of MM; patients had previously responded (at least partial response [PR]) to bortezomib-containing first-line therapy (in the transplant or non-transplant settings), relapsed following a treatment-free interval (TFI) of at least 6 months; and received at least 3 cycles of bortezomib retreatment as second-line therapy, which had been completed at least 2 months prior to study start. Bortezomib retreatment dose and schedule were selected by the treating physician. Response was assessed by EBMT or IMWG criteria. **Results.** A total of 35 patients across 15 centres were identified; median age at time of diagnosis was 62. 7 years (range 34. 2-84. 0). Most patients received bortezomib in combination with dexamethasone (20 and 18 for first-line and retreatment, respectively). Median follow-up from bortezomib retreatment was 1. 2 years (range 0. 2-3. 2). Patients received a median of 4 cycles (range 1-9) as first-line treatment and 4 cycles (range 3-13) as retreatment (Table 1).

Table 1.

	Bortezomib first-line treatment	Bortezomib retreatment
Median treatment duration, cycles (range)	4 cycles (1–9)	4 cycles (3–13)
Best response		
CR	12	5
VGPR	8	8
PR	15	15
SD	–	5
PD	–	1
Unknown	–	1
Median time to best response, months (range)	2.1 (0.4–24.0)	2.3 (0.7–18.6)
Median duration of response, months (range)	30 (9–59)	15 (1–54)
Median PFS, months (range)	31.3 (11–60)	14.5 (1–56)

Best response to bortezomib as first-line therapy included 12 complete response (CR), 8 very good partial response (VGPR), and 15 PR; median time to best response was 2. 1 months (range 0. 4-24. 0), median duration of response was 30 months (range 9-59), and median progression-free survival (PFS) was 31. 3 months (range 11-60). Best response to bortezomib retreatment included 5 CR, 8 VGPR, 15 PR, 5 stable disease (SD), 1 progressive disease (PD), and 1 unknown, to give an overall response rate of 80%, including

a ≥VGPR rate of 37%; median time to response (n=28) was 2. 3 months (range 0. 7-18. 6), median duration of response was 15 months (range 1-54), and median PFS was 14. 5 months (range 1-56) (Table). Eleven of the 29 patients alive at study end (database lock: Dec 21, 2011) have not experienced disease progression, and 20 have not received subsequent therapy. Sixteen patients (46%) experienced at least one adverse drug reaction (ADR), including 10 patients during first-line treatment and 10 during retreatment; most ADRs were mild or moderate (48% and 33%, respectively). The most common ADRs were anaemia (n=4), peripheral sensory neuropathy (n=4; 3 during first-line treatment and 1 during retreatment), diarrhea, neutropenia, and thrombocytopenia (each n=3). **Conclusions.** Bortezomib retreatment, following relapse after bortezomib-containing first-line treatment, is associated with high-quality responses and prolonged PFS in MM patients with adequate first-line responses.

[4]Center for safety research, Royal Institute of Technology KTH, Stockholm, Sweden

Background. Bortezomib as single drug or in combinations is today an established therapy of multiple myeloma (MM) both in 1st line and as relapse medication. **Aims.** To assess the efficacy of Bortezomib in first and later lines in treatment hierarchy of MM and to assess the responses in re-treatment situations. **Methods.** Patients with symptomatic MM were selected from our institute between January 2000, and December 2010. The study included 243 consecutive patients who underwent treatment with Bortezomib in any line and out of those 119 (49%) were treated with an autologous stem cell transplant. As a number of patients were treated with Bortezomib at more than one treatment line, the total amount of Bortezomib treatment lines were 277; 77 (28%) in 1st line, 118 (43%), 50 (18%) and 32 (12%) in 2nd, 3rd and 4th treatment line, respectively. **Results.** In 1st line treatment 48% of the patients achieved nCR, 17% VGPR, 22% PR and 13% NR with an ORR of 87%, the median time to progression (TTP) was 18 months and median overall survival time (OS) was 51. 7 months. In 2nd, 3rd and 4th treatment line, the ORR was 77%, 68% and 57%, TTP was 9, 6 and 6 months respectively and OS was 39. 2, 24. 3 and 16. 8 months respectively. 8 patients underwent treatment with Bortezomib in 1st and 2nd line. The overall response rate (ORR) was 75% in 1st line and 62% in 2nd line. 13 patients received Bortezomib in 2nd and 3rd line. The ORR was 92% in 2nd line and 85% in 3rd line. 9 patients received Bortezomib in 3rd and 4th line. The ORR was 100% in 3rd line and 89% in 4th line. **Conclusions.** Bortezomib is known to be a relatively safe drug with good responses when used in 1st and 2nd line treatment of MM. We have shown that it is possible to get good responses even in a heavily pre-treated population. We have also shown that patients may get a good response with Bortezomib even if they have been treated with Bortezomib in a previous treatment line. Re-treatment is otherwise thought to be hindered by drug-resistance, but our results indicate that it may not be a major issue with Bortezomib.

TEACHING OLD DRUGS NEW TRICKS: RATIONALE FOR THE REDEPLOYMENT OF VALPROATE, AN ANTI-CONVULSANT, AND NICLOSAMIDE, AN ANTI-HELMINTHIC AGENT, AS A COMBINATION THERAPY AGAINST MULTIPLE MYELOMA

S Raffles, H Giles, M Jankute, B Merrick, C Bunce, M Drayson, F Khanim
University of Birmingham, Hatfield, United Kingdom

Background. Multiple Myeloma is a plasma B cell neoplasm which, despite recent advances in treatment, remains incurable. If untreated, most patients die from infection, renal impairment or anaemia within months of diagnosis. Current best treatments offer an overall 5-year survival of only 36% and relapse with resistant disease is a major cause of death. However, current treatments are associated with significant comorbidites rendering the majority of older patients, >70% of MM cases, ineligible for intensive treatment regimens. **Aims.** The aim of our study was to screen a panel of 100 licensed, well-tolerated drugs from the BNF for anti-MM activity. We demonstrate here that valproate and niclosamide (VaN) combination therapy has potent selective anti-MM activity that is mediated, in large part, through targeting the mitochondria of the tumour cells. **Methods.** MM cell lines and primary MM bone marrow samples were treated in vitro with valproate and/or niclosamide. Cell viability was determined using annexin V/propidium iodide staining and CellTiter blue assay. FLC levels were measured by Luminex. Mitochondrial function and health and oxidative stress levels were assayed using a panel of flow cytometric and immunofluorescence assays. QRT-PCR, immunoprecipitations and immunoblotting were used to measure levels of key oxidative stress response genes. **Results.** Niclosamide demonstrated potent anti-MM activity against cell lines and primaries and also induced a significant decrease in FLC secretion. Valproate had very little anti-MM activity on its own, however significantly potentiated the actions of niclosamide in vitro against MM cell lines and primaries when used as a combination treatment (VaN). Importantly, VaN had little impact on CD34+ blasts in vitro. MM cell death with VaN was associated with markers of both apoptosis and autophagic cell death. Our data shows that in MM cells niclosamide uncoupled oxidative phosphorylation causing depolarisation of the mitochondrial membrane, production of mitochondrial superoxide and reduced ATP production. Production of mitochondrial superoxide was significantly enhanced by valproate indicating that valproate might be disabling the anti-oxidant response of the MM cells. Valproate functions as a histone deacetylase inhibitor (HDACI) but non-histone proteins have also been reported to be regulated by acetylation state. Indeed, the majority of enzymes involved in metabolism have been shown to be acetylated. We demonstrate here that valproate in combination with niclosamide, enhanced mitochondrial superoxide production by regulating mRNA, protein levels and acetylation status of key genes involved in the antioxidant response including SIRT3, a mitochondrial deacetylase, and manganese superoxide dismutase (SOD2) a key regulator of mitochondrial superoxide levels. Importantly, no induction of mitochondrial superoxide was observed in normal donor cells. **Summary and Conclusions.** Our study demonstrates that valproate and niclosamide (VaN), at clinically achievable concentrations, have potent anti-MM activity. We demonstrate that this activity is tumour selective and is mediated by the generation of oxidative stress levels that are lethal for the MM cells. These data taken in the context of the known safety profiles of valproate and niclosamide, provide rationale for their use as a combination therapy in the treatment of elderly and relapsed and/or refractory MM.

1541

BORTEZOMIB IN COMBINATION WITH MELPHALAN AND PREDNISONE (MPV) AS FIRST LINE THERAPY IN FRAIL ELDERLY PATIENTS AFFECTED BY MULTIPLE MYELOMA

A Gagliardi, M Esposito, P Della Cioppa, A Lucania, L Mastrullo
UOC Ematologia ASL Napoli 1 Centro, Naples, Italy, Naples, Italy

Background. Bortezomib has proven to be safe and effective in MM patients not only as monotherapy but also given in combination with cytotoxic agents. Bortezomib-based combination regimens have induced clinical benefits with manageable toxicities and may ultimately lead to improvement in the duration of response and survival of patients in the first-line setting. The use of bortezomib, in combination with melphalan and prednisone, has shown remarkable benefits, especially in elderly frail patients. **Aims.** We evaluated the efficiency and safety of bortezomib in combination with melphalan and prednisone (MPV) as a starting regimen for the treatment of elderly frail patients affected by MM. **Methods.** In our institution we are following 28 elderly patients with stage II/III MM (15 Fand13 M, median age: 75 years, r. 67-85 years). All patients were not eligible for aggressive treatment protocols because they had, at diagnosis, one or more comorbidities. As first-line treatment all patients received Melphalan and Prednisone plus Bortezomib chemotherapy (Melphalan 8 mg/sqm p. o. d. 1, 2, 3, 4; Prednisone 75mg p. o. d. 1, 2, 3, 4; Bortezomib 1,3 mg/sqm i. v. d. 1, 8, 15, 22 every 36 days). **Results.** At a clinical re-staging after four courses of therapy a reduction of M-component > 50-75% was recorded in 22 patients while the remaining patients was in steady disease (SD). Thereafter all patients received further four courses of therapy. At the end of treatment 6 out of 28 patients achieved CR and the remaining showed VGPR or PR. At the present, (month +18) only two patients show a progression disease, while six patients are in CR and the remaining in PR or VGPR. **Conclusions.** Our results suggest that the combination of melphalan-prednisone-bortezomib is effective and well tolerated in the treatment of MM in elderly “frail”patients. The once-weekly dosing regimen of bortezomib did not cause adverse effects, particularly the neurological. Although there are several published data on the activity of the therapy based on the combination melphalan-prednisone-bortezomib, little is still known about the improvement in the duration of response and survival of elderly patients in the first or second line therapies.

COMBINATION THERAPY BASED ON BORTEZOMIB FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

C Cai, J He, Y Yang, H Han, G Zheng, W Zheng, W Wei, W Wu, Y Ye, S Shi, X Xie, L Li, Z Zhang, H Huang, H Huang, Z Zhen
The First Affiliated Hospital of Medical College, Zhejiang University, Hangzhou, China

Background. Novel drugs, such as bortezomib, have significantly improved the response rates in multiple myeloma (MM), but little has been reported on bortezomib-based therapies in Chinese patients. **Aims.** Here we report our results with combination therapy based on bortezomib in the Chinese population and investigat the efficacy and safety of Bortezomib-based therapies in previously untreated MM patients. **Methods.** Between 1st Feb. 2006 and 31st Dec. 2010, 102 consecutive newly-diagnosed patients with median age 59 years (range 31-86 years) with symptomatic MM were treated with combination therapies based on bortezomib including bortezomib plus dexamethasone (BD) and the triplet combinations of BD with adriamycin (BAD), cyclophosphamide (BCD), thalidomide (BDT). All patients received a median of three cycles of therapy (range 1-5). The IMWG criteria was used for response evaluation and toxicities were evluated according to the NCI Common Toxicity Criteria version 3. **Results.** The overall response rate (≥ partial response, PR) of all the patients was 85. 3% (including 27. 5% very good partial response (VGPR) and 23. 5% complete response/near complete response (CR/nCR). The median PFS for each arm was 12. 0 to 15. 0 months and without significant difference between the arms while the median OS for BDT arm was 35. 0 months, the median OS for other arms were not reached. The frequently observed toxicities were neutropenia, thrombocytopenia, fatigue, infection, herpes zoster, and peripheral neuropathy. Anti-viral agent acyclovir significantly reduced the incidence of herpes zoster (P =0. 004). A significant trend towards grade 2 or 3 peripheral neuropathy during BDT therapy was observed compared to the other groups (P =0. 028). **Conclusions.** Our experience indicated that combination chemotherapy of triplet combinations were superior to BD. Serious Adverse events were rare in the Chinese patients with MM who received bortezomi-based chemotherapy.

1543

CENTRAL SYSTEM NERVOUS MULTIPLE MYELOMA (CNS MM) RELAPSE/PROGRESSION FEATURES: A RETROSPECTIVE MULTI-CENTER STUDY

[7]Ematologia Azienda Ospedaliera "San Andrea" Roma, Roma, Italy
[8]Ematologia Azienda Ospedaliera San Camillo- Forlanini, Roma, Italy

Background. SNC MM relapse, defined as the detection of malignant plasma cells in the cerebrospinal fluid or in the intracranial sanctuary, is a rare event (1%) with a worse prognosis. To date the pathogenesis mechanisms remain unclear and the role of novel agents, intensive therapies, the prolonged overall survival and molecular basis are understood. **Aims.** In order to define the incidence, features and prognosis of CNS MM relapse this multi-center study was conducted. **Patients and Methods.** We revised 698 consecutive MM diagnoses admitted at 7 centers of GIMEMA MM Lazio from January 2006 to January 2011. **Results.** Among 6987 pts(1%),5 males, 2 females- median age 62y (49-67) had isolated CNS MM relapse. At MM diagnosis of these 3 were IgG k, 3 IgA (2 k, 1 λ), 1 IgD λ, 5/7 had D-S stage ≥II,2 ptsISS ≥3 and normal creatinine level in 5/7, BJ was positive in3 pts. BM involvement showed plasma cell < 10% in 2 cases. Baseline cytogenetics revealed high risk features in 2/2 pts studied. The CNS MM relapse sites included: brain in3 pts, spinal cord in3 ptsand leptomeningeal involvement in1 pt, respectively. In 3 cases early CNS relapsed occurred after first line therapy, in 2 after second and third-line therapy, respectively. At CNS MM occurrence relapse bone marrow infiltration was absent in 4/7 pts. Only in 2 cases B2Mg was >5, whereas elevated LDH levels has been detected in 4/7 pts. All the have been treated. 4 ptsreceived novel agents as bortezomib (2), lenalidomide (2), radiation therapy (3), conventional chemotherapy (1) without response in 6/7 cases. Median overall survival from MM diagnosis was 21 months (9-61) and from CNS MM 6 months (0,7-12) with only three patients being alive at 33, 37 and 60 months after MM. **Conclusions.** Novel agents have been proven to prolong OS and PFS in patients with MM. Nevertheless in the last years a prolonged follow up showed an increased atypical extramedullary relapses with a CNS involvement indicating that neoplastic plasma cells may display remarkable resistance to intensive conditioning regimens and exhibit immune escape mechanisms. Malignant and high proliferative plasma cell may migrate trough the hemato-encephalic barrier in the initial phases of disease and preserved from endovenous therapy may proliferate. Further elucidation of the factors predisposing patients with high-risk disease features to CNS MM involvement is needed.

1544

COMPLICATIONS LINKED TO TOTALLY IMPLANTABLE CENTRAL VENOUS DEVICES IN CHEMOTHERAPY OF MULTIPLE MYELOMA: A CASE SERIES OF 142 PATIENTS

JJ Alonso, J Barreiro, A Cánovas
Hospital Universitario de Cruces. UPV, Bilbao, Spain

Background. There are few references to the complications associated with totally implanted devices for chemotherapy in patients with multiple myeloma(MM). The necessity to maintain prolonged treatment may involve more frequent complications. **Aims.** We aimed to evaluate the complications of totally implanted devices, Port-a-Cath (PAC), used for chemotherapy in MM patients. **Patients.** Prospective observational study of MM patients treated with chemotherapy through PAC in our department (1995-2007). Antibiotic prophylaxis with cefazoline was prescribed before PAC implantation. The device was maintained indefinitely during treatment, unless complications requiring its removal occurred (infection, thrombosis or dysfunction). Primary thromboprophylaxis was not routinely prescribed. The diagnosis of PAC infection was based on in differential growth blood cultures taken from PAC versus peripheral vein, when PAC culture was positive two or more hours earlier than the peripheral culture, or a positive culture of exudate from the pocket was obtained. Associated thrombosis was diagnosed by ultrasound or computerised tomography scan . Upon diagnosis of PAC infection, systemic antibiotherapy and antibiotic lock was prescribed and PAC maintained unless clinical deterioration of the patient or pocket infection occurred, making removal of the device necessary. Informed consent was obtained in every patient. Statistical **Methods.** Fisher exact test, Student t, log-rank test, Kaplan-Meier survival tables and Cox regression multivariate binary logistic model. **Results.** 155 implanted PAC in 142 patients (55% male and 45% female) were included for analysis. Median age was 67 years (27-84). Subtype of monoclonal immunoglobulin: G in 46. 5%, A in 27. 7%, D or light chain in 25. 8%. The median duration of each PAC was 20. 9 months (0. 5-108); the median duration of chemotherapy by PAC 9 months (0. 3- 42). Twenty nine infections of PAC (27 bacteremia and 2 pocket infections) were detected in 25 patients (0. 2 /1000 days). Coagulase negative Staphylococcus(CNS) (43. 7%) was the most frequently isolated microorganism, followed by Gram negative rods (25%) and other Gram positive cocci (14. 3 %). Antibiotic lock along with systemic antibiotics was prescribed in 18 infections (62%), achieving the maintenance of the device in 17 (94%). PAC associated thrombosis was detected in three patients (0. 02/1000 days). The device was removed in 31 patients (20%): in 13 patients (8. 3%) because of infection and in the remaining because of dysfunction or end of treatment. The assessment of prognostic variables only showed a significant association between longer duration of chemotherapy and risk of infection (Student t: 3. 08; p = 0. 002), and between infection and the risk of removal of the device (chi2: 17. 2, p = 0. 00004). **Conclusions.** The registered frequency of PAC infection and thrombosis in our patients is similar to that described in other clinical settings (i. e, non myeloma patients), as well as the aetiology of infections, being CNS the most frequently implied. Antibiotic lock was remarkably efficacious to avoid removal of PAC devices. Consequently, PAC devices appear to be safe in the chemotherapy of MM patients, without involving a higher risk of infection or thrombosis than that observed in different clinical settings, despite the usually longer time of use of the devices in these patients.

1545

THE IMPACT OF THE NOVEL THERAPIES BEFORE AND AFTER FRONTLINE AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

CK Min[1], SE Lee[2], S Yang[1], BS Cho[2], KS Eom[2], YJ Kim[2], S Lee[2], HJ Kim[2], SG Cho[2], DW Kim[2], JW Lee[2], WS Min[2], JW Park[2]
[1]Seoul St. Mary's Hospital, The Catholic Univerisity of Korea, Seoul, South-Korea
[2]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, South-Korea

Background. High-dose therapy followed by autologous stem-cell transplantation (ASCT) is the standard of care for frontline therapy in younger patients with multiple myeloma (MM). During the past 10 years, novel agents such as thalidomide and bortezomib have been widely incorporated with improving the response rates. However, it is not clear whether such therapies are superior as induction treatment prior to transplantation or whether they may improve outcome as post-transplant maintenance therapy. **Aims.** To evaluate the association of survival outcomes in patients who underwent ASCT with or without the use of novel agents. **Methods.** We performed a retrospective analysis of 171 patients with MM who underwent ASCT within one year of diagnosis at our institute between 1999 and 2010, as part of first line therapy. **Results.** Their median age was 53 years (range, 34-65 years) and 90 (52. 6%) were male. Novel agents were administered to each patient as follows: before ASCT alone (n=41, 24. 0%), after ASCT alone (n=15, 8. 8%) and before and after the transplantation procedure (n=69, 40. 4%). Forty six (26. 9%) patients did not receive novel agents before and after ASCT. At a median follow-up of 43. 2 months, the 3-year overall survival (OS) and progression-free survival (PFS) rates were 66. 7% and 42. 0%, respectively. OS rates of the patients who received novel agents before and after ASCT were significantly increased compared to those with novel agents as induction therapy alone (P=0. 016) or those without novel agents (P=0. 020). In contrast, there was no difference between the patients who received post-transplant maintenance treatments regardless of use of the induction novel agents. Multivariate analysis showed that factors independently predictive of OS included achievement of CR after ASCT (P=0. 003), International Staging System (P=0. 026) and maintenance treatment with novel agents after ASCT (P=0. 034). **Conclusions.** These findings suggest that the integration of novel agents into the transplantation sequence is highly beneficial to patients with MM. In particular, administration of these agents after ASCT seems to more effectively improve OS.

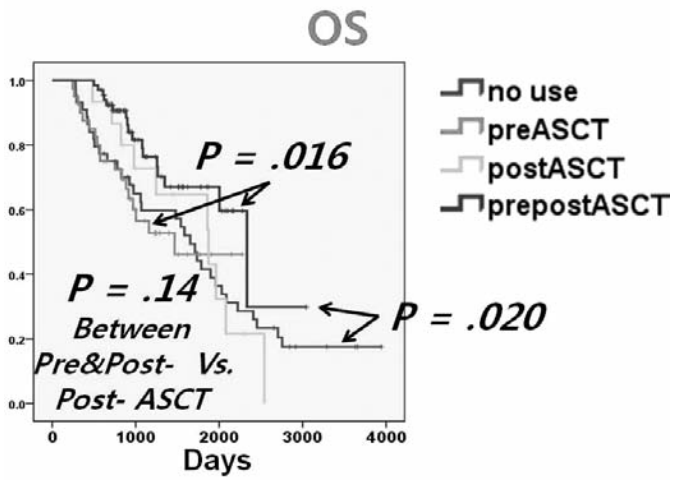

Figure 1.

1546

A NEW INDUCTION COMBINATION THERAPY (THALDODEX) FOR MULTIPLE MYELOMA. PRELIMINARY Results OF A PHASE II STUDY

S Sammassimo, A Agazzi, L Calabrese, P Minga, L Cannella, C Grossi, G Martinelli
European Institute of Oncology, Milan, Italy

Background. treatment for multiple myeloma is dramatically changed over the past 5 years. Before the advent of the new drugs, anthracycline containing regimens were considered the gold standard in induction. **Aims.** to investigate the efficacy and safety of an antracycline based treatment combining liposomal doxorubicin, Myocet, to steroids, Dexamethasone, and Thalidomide (ThalDoDex). **Methods.** from June 2007 to January 2012, ThalDoDex combination was delivered to 38 previously untreated multiple myeloma patients in preparation to autologous stem cell transplantation (ASCT). **Results.** median age was 56 years (range 42-72). Treatment schedule was as follows: Thalidomide 100 mg/day for 14 days then 200mg/day until the end of induction; Dexamethasone 40 mg days 1à4; Liposomal Antracycline (*MYOCET*) 50 mg/sqm day 1 for 4 cycles at 4 weekly intervals. LMWH 100UI/kg/day was added to all patients as DTV prophylaxis. The response criteria were defined according to Bladè et al. The population presented as follows: 10 patients were stage IIA and 24 patients stage IIIA and 4 IIIB; 22, 12 and 4 patients were ISS I, II, III respectively. Monoclonal immunoglobulin subtypes were as follows: IgG in 21 patients, IgA in 7 patients, IgD in 1 patient, light chains in 7 patients, plasma cell leukemia in 1 patient and no secretory multiple myeloma in the last one. Thirty-five cases are evaluable for response and the overall response rate (CR, nCR, VGPR, PR) was 74%: CR + nCR + VGPR 54%. Thirty-one of 35 patients underwent ASCT and 50% of these maintained a response ≥ VGPR after the procedure with a median follow up of 24. 9 months (range 4-51). None of the patients who achieved a CR after TALDODEX regimen have then experienced a disease progression after transplant. **Conclusions.** our experience suggests that ThalDoDex is effective and safe in newly diagnosed multiple myeloma patients undergoing autologous stem cell transplant. Although the relatively short follow up, none of patients achieving a CR after TALDODEX progressed: our data confirm the relevance of CR before ASCT.

INFECTION COMPLICATIONS IN AN UNSELECTED COHORT OF PATIENTS WITH MULTIPLE MYELOMA TREATED WITH LENALIDOMIDE COMBINATIONS

T Caravita[1], M Offidani[2], A Siniscalchi[1], S Gentili[2], P Caraffa[2], A Perrotti[1], D De Fabritiis[1], P Leoni[2]
[1]Oapedale S. Eugenio-Università Tor Vergata, Roma, Italy
[2]Clinica di Ematologia Azienda Ospedaliero-Universitaria Ospedali Riuniti, Ancona, Italy

Background. IMiDs exert various effects on the immune system, altering +cytokine production, regulating T cell costimulation and enhancing NK cell cytotoxicity. Particularly, IMiDs inhibit TNF□, playing an important role in immune response against bacterial and virus infections. Moreover, lenalidomide causes myelosuppression, mainly neutropenia that is an important risk factor for infections. **Aims and Methods.** We assessed the incidence, type and major factors affecting infections in 127 patients with MM receiving lenalidomide-based regimens. Median age was 67 years (40-88) and 53. 5% were older than 65 years. Fiftyfour patients (42. 5%) had newly diagnosed MM, whereas the remaining 73 (57. 5%) had relapsed/refractory disease. Among this group, 67% of patients received more than one line of therapy and 26% underwent APBSCT. ISS stage 2-3 and renal failure were recognized in 54. 5% and 8. 5% of patients, respectively; 15% had a ECOG PS □ 2. Eighty patients (63%) received lenalidomide plus dexamethasone and 47 (37%) lenalidomide combined with steroids and chemotherapy. Median number of lenalidomide courses was 6 (1-28) and 44% of pts developed neutropenia (26% grade 3, 8. 7 % grade 4). Nearly all patients (95%) received both trimethoprim-sulfamethoxazole as infections prophylaxis and granulocytecolony stimulating factor according to guidelines. **Results.** Twenty-six patients (20. 5%) developed infections resulting of grade 1-2 in 8 patients (6%) and 3-4 in the remaining 18 (14%). Two deaths (1. 5%) due to infections were observed. Type of infections were: pneumonia in 15 (58%), upper respiratory tract in 3 (11. 5%), FUO in 3 (11. 5%), septic shock by gram-negative microorganisms in 2 (8%), cholecystitis in 2 (8%) and VZV in one (4%). Risk of grade 3-5 infection was 16% at 12 months; 62. 5%, 69% and 94% of infections occurred at 3, 4 and 6 months, respectively. Among all the parameters evaluated in univariate and multivariate analysis, only ISS resulted as factor affecting severe infection development. Particularly, the risk of grade 3-5 infections at 6 months was 18% in patients with ISS 2-3, compared with 6% in those with ISS 1 (p=0. 034). A trend for a longer PFS in patients without infection (median PFS = 8 vs 16 months in patients with or without infections, respectively, p=0. 064) was documented; however, OS of patients developing infections was significantly shorter, compared to patients who did not develop infections (median OS=26 vs 33 months; p=0. 001). Multivariate analysis adjusted for age, PS, ISS, renal function and therapy with 2 or 3 drugs showed that infections significantly affected OS (HR=3. 2; 95%CI=1. 5-6. 7; p=0. 002). **Summary and Conlusions.** In clinical practice, infections represent a frequent complication in patients with MM receiving lenalidomide-based regimens and respiratory infections accounted for a large majority (nearly 70%). Nearly all patients who developed infections during the first 6 months of therapy and those with higher tumour burden have been found to be at higher risk. In conclusion, a broader antibiotic prophylaxis should be taken into consideration (ie TMP-SFZ plus fluoroquinolones) to prevent severe infections and ameliorate final outcome of MM patients at high risk (ISS 2-3) treated with lenalidomide combinations.

1548

A RETROSPECTIVE ANALYSIS OF THE CLINICAL RESPONSE RATE AND RENAL REVERSIBILITY OF THALIDOMIDE BASED REGIMES IN PATIENTS WITH MULTIPLE MYELOMA AND ASSOCIATED RENAL IMPAIRMENT

T Vatopoulou, J Jones, K Basnayake, T Corbett
Royal Sussex County Hospital, Brighton, United Kingdom

Background. Patients with multiple myeloma (MM) frequently have renal impairment (RI), a significant complication with adverse prognostic significance. Rap-

id reduction of free light chains is critical in reversing RI secondary to cast nephropathy. Thalidomide is the first immunomodulatory drug with proven activity in MM and does not require dose reduction in RI. However, there is limited experience with thalidomide in patients with RI, and the current treatment of choice is bortezomib with high dose dexamethasone. **Aims.** To assess the safety and efficacy of thalidomide, cyclophosphamide and dexamethasone (CTD) or thalidomide with dexamethasone (Thal-Dex) in patients with MM and RI, and to evaluate RI reversibility. **Methods.** This is an observational retrospective study of patients with MM and RI, treated with thalidomide containing regimens. Patients with MM were identified using pharmacy prescriptions for thalidomide (2006 to 2011). Patients with concomitant RI were subsequently identified from laboratory investigations at the time of treatment initiation. **Results.** We identified 23 patients, with moderate to severe RI (Table 1) treated with CTD (12), CTDa (3) and Thal-Dex (8). The median number of cycles was 5. Two patients proceeded to autologous stem cell transplantation. The overall response rate (ORR) in all patients with RI (at least partial response, PR) was 74% (Complete Response, CR = 2; Very Good Partial Response, VGPR = 10; PR = 2) excluding four patients lost to follow up. The overall renal response rate (ORRR) (at least Minimal Response, MR) was 65% (CR= 7, PR= 2, MR= 6) with four of five patients becoming dialysis independent. In the moderate RI group the ORR was 77% (CR = 2, VGPR=4, PR=1) and the ORRR was 55%, (CR = 5). In the severe RI group, the ORR was 70% with four patients lost to follow up (VGPR = 6, PR = 1) and the ORRR was 71% (CR = 2, PR = 2, MR = 6). The median progression-free survival was 549 days. After a median follow-up of 877 days, three patients had died. Nine patients had renal biopsies; eight showed cast nephropathy and one, established tubular atrophy with acute tubular damage. Four other patients had associated hypercalcamia (range 2. 79-3. 23mmol/l). In one case, correction of hypercalcaemia led to improvement of RI. Three patients had pre-existing chronic kidney disease, and there was no subsequent improvement of RI. With regards to toxicity, hyperkalaemia was noted in one patient with severe RI. Thalidomide was withheld for five days, and hyperkalaemia did not recur after reintroduction. Two patients had grade II neuropathy (WHO classification). In one patient, grade III neuropathy required thalidomide withdrawal. **Summary and Conclusions.** Our results demonstrate that CTD and Thal/Dex are well tolerated in MM patients with RI. The haematological and renal response rates are comparable to those reported with bortezomib. Patients with severe RI had excellent outcomes. Our data, along with the current literature demonstrate that thalidomide based regimes in RI are both well tolerated and effective. This data would support further clinical trials in myeloma comparing thalidomide with bortezomib containing regimes in patients with associated RI.

IMMUNOGLOBULIN'S SPECIFIC HEAVY/LIGHT CHAINS PAIRS ABNORMALITIES IN PATIENTS WITH MONOCLONAL GAMMOPATHY OF UNDETERMIDED SIGNIFICANCE

J Jimenez[1], N Barbosa de Carvalho[2], L Campos[2], M Requena[1], C De Larramendi[1]
[1]Hospital Severo Ochoa, Madrid, Spain
[2]The Binding Site, Barcelona, Spain

Introduction. Monoclonal gammopathy of undetermined significance (MGUS) is a condition in which a paraprotein is found in the blood during standard laboratory tests. It resembles multiple myeloma and similar diseases, but the levels of antibody (immunoglobulins) are lower, the number of plasma cells (white blood cells that secrete antibodies) in the bone marrow is lower, it has no symptoms or problems, and no treatment is indicated. However, multiple myeloma develops at the rate of about 1-2% a year, so clinicias recommend monitoring it yearly. Recently, the international myeloma working groups (IMWG) have established guidelines in order to stratify the risk of progression to multiple myeloma (MM). In this model, the amount and type of monoclonal protein together with ratio of serum free light chains (sFLC) are risk factors for progression. Recently, new assays that allow the identification and quantification of specific immunoglobulin heavy/light chains pairs (IgGk, IgGL; IgAk, IgAL; IgMk, IgML) have been developed. **Aims.** The aim of the present work is to study if MGUS patients also present specific heavy/light chains (HLC) alterations. **Materials and Methods.** A group of MGUS patients (N=59) was risk stratified according to the IMWG guidelines. All the patients had the serum M-spike quantified by serum protein electrophoresis, identified by serum immunofixation(sIFE) and serum free light chains (FreeliteTM, sFLC) were quantified by nephelometry. Immunoglobulin specific heavy/light chains pairs (IgGk, IgGL; IgAk, IgAL; IgMk, IgML) were also requested for all the study participants. The inclusion risk factors (IMWG) were: M-spike > 1,5 g/dL; type of immunoglobulin (Ig) by sIFE different from IgG; sFLC ratio < 0,26(L) or > 1,65(k)). All the patients were classified as High, High- intermediate, low-intermediate and low risk of progression according to the number of altered risk factors (3, 2, 1 or 0 respectively). The correlation between M-spike and monoclonal HLC pair was also established. **Results.** Among the selected MGUS population (2 biclonal; 32 IgG; 12 IgA; 13 IgM), 41% of the patients presented a low-intermediate risk of progression, 26 % had a low risk and a 33% presented a high-intermediate risk for progression. HLC ratios were altered in all except 2 IgG low risk patients. 30/32 IgG(94%); 11/12 IgA(92%); 12/12 IgM (100%) presented increased the monoclonal HLC. 15/32 IgG (47%); 9/12 IgA (75%) and 7/11(64%) MGUS pts presented the uninvolved HLC isotype immunosupressed. When the M-spike quantification was compared vs quantification of the monoclonal HLC pair, we found a moderate correlation for IgGk and IgAL (r2=0,51; r2=0,69), and very good correlations for IgGL, IgAk, IgMk, IgML (r2=0,81; r2=0,83; r2=0,80; r2=0,93). **Conclusions.** Due to the high sensitivity of the HLC ratio to indicate monoclonality, HLC assays could be of great utility to quantify monoclonal components, special those hidden by other proteins in patients with an IgA or IgM M-spike. Larger studies are need to determine the value of HLC assays as risk factor for progression however, immunosupresion of the uninvolved monoclonal isotype is seen frequently in MGUS patients and could play a role as progression marker.

1550

CONTEMPORARY INTRAVENOUS INJECTION OF BORTEZOMIB, MELPHALAN AND DEXAMETHASONE IN REFRACTORY AND RELAPSED MULTIPLE MYELOMA

A Romano[1], A Chiarenza[1], U Consoli[2], C Conticello[3], S Forte[4], C Vetro[1], G Uccello[1], M Cavalli[1], P Fiumara[1], G Palumbo[1], F Di Raimondo[1]
[1]University of Catania, Catania, Italy
[2]Ospedale Garibaldi, Division of Onco-Hematology, Catania, Italy
[3]Department of Experimental Oncology, Mediterranean Institute of Oncology, Viagrande, Catania, Italy
[4]IOM Ricerca srl, Viagrande, Catania, Italy

Background. Combination of Melphalan and Bortezomib is highly active in multiple myeloma (MM). However, several clinical pharmacokinetic studies have shown that melphalan has a short half-life in the plasma, and its absorption from the gastrointestinal tract is extremely variable. Considering the frequency of bortezomib-related gastrointestinal toxicity, it is reasonable to hypothesize that bortezomib could also hamper the melphalan absorption thus reducing its activity. **Aims.** To ensure that all the drugs were present in the plasma at the same time and at the most effective concentrations, we designed a protocol with the contemporary intra-venous (IV) administration of melphalan, bortezomib and dexamethasone (BMD). **Methods.** Fifty previously treated (median 2 previous lines) myeloma patients (33 relapsed and 17 refractory) were evaluated. Nine patients (18%) had already received bortezomib alone or in combination, and 35 patients (70%) had already received melphalan (17 at high dose as conditioning regimen for autologous stem cell transplantation and 18 as part of a standard melphalan- prednisone regimen). Bortezomib 1. 3mg/m^2 and melphalan 5 mg/m^2 were given IV contemporary to dexamethasone 40 mg in accord to bortezomib schedule 1,4,8,11 (*base*) or 1,8,15,22 (*weekly*), recycling after 14 days from the last dose; dexamethasone was administered orally the day after each injection, for a median of 4 cycles (1-6). **Results.** The overall response rate (ORR) was 62%, with high rate of complete responses (CR, 26%). After a median follow up of 24. 5 months, median PFS and OS were respectively 21. 6 and 33. 8 months without significant differ-

ences between *weekly* schedule (respectively 16. 2 and 23. 4 months) and *base* schedule (respectively 23. 6 and 34. 6 months). Independently from the adopted schedule, achieving at least partial remission (PR) improved PFS (35. 2 vs 9 months) and OS (unreached median vs 18 months). Side effects were predictable and manageable, with prominent haematological grade 3-4 toxicity, including thrombocytopenia (52%), anemia (24%) and neutropenia (18%). Gastrointestinal disturbances (27%) and peripheral neuropathy (13%) never exceeded grade 3. *Weekly* schedule was better tolerated than *base* schedule, and it did not required dosage reduction. **Conclusion.** BMD is an effective salvage regimen in relapsed/refractory myeloma patients with manageable and acceptable toxicity, especially when used in accord to the *weekly* schedule.

1551

IMPACT OF BORTEZOMIB IN THE SURVIVAL OF PATIENTS WITH REFRACTORY OR RELAPSED MULTIPLE MYELOMA WITH RENAL FAILURE. EXPERIENCE OF A SINGLE CENTRE.

B Hernández, C Calle, A Carreño, M Rodriguez, M Nebro, I Tallón, R Vanegas
Hospital General de Ciudad Real, Ciudad Real, Spain

Background. The introduction of Bortezomib (V) and the new biological treatments in recent years has improved overall survival (OS) of the patient with multiple myeloma (MM). There is insufficient information on the effect of these new therapies in patients with renal insufficiency (RI). **Aims.** We report our experience in patients with refractory or relapsed MM treated with V and analyze survival in groups with and without RI. **Methods.** 62 patients with Multiple Myeloma that had relapsed or were refractory to conventional chemotherapy were treated with V as a single drug or in combination (dexamethasone or doxorubicin). Demographic and clinical features, frequency and severity of RI (defined as Cr plasma ≥1, 5 mg/dl, excluded functional factors), acute hemodialysis (AHD) and chronic hemodialysis (CHD) have been assessed. Kidney function,paraprotein and Bence Jones protein were registered baseline, after 2 cycles of V (pre3) and at the end of the treatment (post). We analyzed overall survival by Kaplan Meier from diagnosis and since the beginning of V in both groups, with and without RI. Markers of development of RI have been identified by binary logistic regression. **Results.** Age at presentation was 65,58, SD: 11. 5 (37, 7-82, 1). 58. 8% were men. RI in 24/62 p (39%). Cr pre V: 3. 86 mg/dL, SD: 2,17(1,5-12,4), Bence Jones pre V: 147,8 mg/dL, SD: 110,6 (2-600) and quantification of monoclonal paraprotein preV: 2. 57 mg/dL, SD: 1. 9. Cr pre3: 3. 04 mg/dL, SD: 2. 4 (NS) and Cr post: 2. 69 mg/dL SD: 1. 4 (P = 0, 001). Paraprotein pre3: 1. 3 mg/dL, SD: 1. 7 (p = 0, 009) and post: 0. 54 (p = 0, 01). Bence Jones pre3: 62. 4 mg/dL, SD: 93,2 (P = 0, 02) and post: 71. 3 mg / dL, (NS). Associated hypercalcemia in 6/24 p (25%). 5/24 p (20. 8%) need AHD, with recovery of 3 patients and finally CHD in 6/62 p (9%). 50 % of women in RI group versus 37. 5% in the group without RI (p = 0, 04). Binary logistic regression analysis identifies age, sex and cuantification of light chain excretion at the diagnosis as predictors of RI. Overall survival of patients with RI was 1. 78 years (CI 95%: 1, 25-2, 3) versus 2. 02 years in those patients without RI (CI 95%: 1. 5-2. 5) NS. Patients who require AHD or CHD had worse survival than those patients with RI that do not require AHD/CHD, though this difference was not statistically significant. AHD: 0. 8 years (CI 95%: 0-1, 95) versus 3,028 years (CI 95%: 2, 4-3, 6) and CHD: 1. 1 years (CI 95%: 0-2, 3) vs. 3. 31 years (CI 95%: 2, 8-3, 8). **Conclusions.** In our experience Bortezomib is effective in the control of acute renal impairment in patients with refractory or relapsed multiple myeloma. Age, sex and ligeruria are identified as predictors of development of renal failure. We did not find differences in survival among the group with renal failure and the group without renal failure.

1552

EFFICACY OF INDUCTION TREATMENT WITH CYCLOPHOSPHAMIDE, THALIDOMIDE AND DEXAMETHASONE (CTD) CHEMOTHERAPY IN NEWLY DIAGNOSED MYELOMA PATIENTS ELIGIBLE FOR THE AUTOLOGOUS STEM CELL TRANSPLANTATION

J Bila[1], D Vujic[2], D Veljkovic[2], M Todorovic[1], D Sefer[1], M Kraguljac[1], D Antic[1], B Andjelic[1], M Smiljanic[1], S Jankovic[1], M Gotic[1], B Mihaljevic[1]
[1]Clinic of Hematology, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia
[2]Institute "Dr. Vukan Cupic", University of Belgrade, Belgrade, Serbia

Introduction. A novel agents like thalidomide, bortezomib and lenalidomide as optimal partners to standard and high-dose therapy followed by the autologous stem cell transplantation (ASCT), dramatically changed the course and prognosis of patients with multiple myeloma (MM). **Aims.** The aim of study was to analyze efficacy of the induction treatment with CTD chemotherapy in newly diagnosed MM patients (pts) eligible for the autoSCT. **Patients and Methods.** We have analyzed 57 newly diagnosed MM pts (32 male/ 25 female, mean age 55 yrs, range 40-65) treated with induction CTD chemotherapy. IgG myeloma was diagnosed in 31pts, IgA in 12pts, light chains in 11pts and non-secretory in 3pts. According to the clinical stage (CS, Durie-Salmon), patients were distributed as follows: II 20pts; III 37pts. Regarding ISS score, the group included: ISS1 10pts; ISS2 25pts; ISS3 22pts. Renal impairment was present in 5pts. Induction treatment according to the CTD regimen (Cyclophosphamide 500mg p. o. 1, 8, 15. day, Thalidomide 100mg/day p. o, Dexamethasone 40mg/day i. v. 1-4, 12-15. day of three-week cycle, mean no. 4 cycles, range 3-6 cycles) was applied in all patients. Stem cell mobilization was performed with combination of CAD chemotherapy and G-CSF, in 47/57 (81%) patients who achieved CR/VGPR/PR (IMWG criteria). Adequate number of CD34+ cells (>5x10e6/kg BW) was obtained in 40/47pts (85%). In 8/40pts (20%), mobilization and apheresis were performed twice in order to collect adequate number of CD34+ cells. High-dose therapy (HDT) with Melphalan 200mg/m² and ASCT were performed 4-8 weeks after mobilization in 35/47pts (74%), followed with Thalidomide maintenance (Thal 100mg/day, median duration 16m, range 6-24m) in patients with CR/VGPR/PR. Routine thromboprophylaxis was applied in all pts. **Results.** CTD induction treatment resulted with CR in 7/57pts (12,3%), and VGPR/PR in 40/57pts (70,2%). Further improvement of the response was obtained after HDT and autoSCT (CR 9/35pts, 25,7%; VGPR/PR 21/35pts, 60%). Median follow-up was 20m (6-36m). The 3-yrs probability of event-free, relapse-free and overall survival of 35/57pts treated with CTD+HDT+Thal was as follows: EFS 48%, RFS 60%, and OS 87%. The main reason for thalidomide discontinuation was peripheral neuropathy recorded in 21/35pts (60%) with occurrence of grade 3-4 toxicity in 6/35pts (17%). Thrombosis was not a risk in this setting. **Conclusions.** CTD chemotherapy represents highly effective and relatively safe induction in MM patients eligible for the autoSCT. HDT followed by Thalidomide maintenance improves quality and duration of the response, as well as overall survival, mainly due to the better quality of response and further reduction of tumor mass after HDT. However, recommended duration of such treatment is to be defined predominantly due to the limitations caused by the toxic effects.

1553

SINGLE-AGENT CARFILZOMIB VERSUS A BEST SUPPORTIVE CARE REGIMEN IN PATIENTS WITH RELAPSED AND REFRACTORY MULTIPLE MYELOMA: FOCUS (PX-171-011), A RANDOMIZED, OPEN-LABEL, PHASE 3 STUDY

R Hajek
University Hospital Brno, Brno, Czech Republic

Background. The proteasome inhibitor carfilzomib has demonstrated single-agent activity in phase 2 studies in patients with relapsed and refractory multiple myeloma (R/R MM). In PX-171-003-A1"'a single-arm study of carfilzomib monotherapy in heavily pretreated refractory patients"'37% of patients achieved > minimal response (MR), median time to progression was 3. 9 months, and median overall survival (OS) was 15. 5 months. Carfilzomib is currently under review by the US Food and Drug Administration for approval to treat R/R MM. **Aims.** Herein we describe the trial design and rationale for a phase 3 randomized study, FOCUS (CarFilzOmib for AdvanCed Refractory MUltiple Myeloma European Study), being conducted to compare OS after treatment with single-agent carfilzomib to a "best supportive care"(BSC) regimen (low-dose glucocorticoids with optional cyclophosphamide, plus comfort and palliative care). **Methods.** Patients must have received ≥3 prior regimens including bortezomib treatment (defined as ≥4 cycles at full dose as tolerated). Patients must have been responsive to ≥1 line of therapy and be either nonresponsive (≤ stable disease) or refractory to their most recent therapy. Eligible patients are randomized 1:1 (stratified by number of previous therapies and geographical region) to carfilzomib or BSC regimen. Target enrollment is 302 patients. Treatment schemes are:Treatment will continue until disease progression or unacceptable toxicity. Following confirmation of disease progression or discontinuation from study treatment, all patients will enter long-term follow-up for survival. Crossover is not allowed upon progression. The primary endpoint is OS, and secondary endpoints include progression-free survival, overall response rate, clinical benefit rate, disease control rate, duration of response, and safety. Disease assessments will be determined by study investigators and an independent review committee according to the International Myeloma Working Group Uniform Response Criteria (with MR per European Blood and Marrow Transplantation Group criteria). FOCUS began accruing patients in September 2010, and 141 patients are enrolled as of the end of January 2012. **Conclusions.** FOCUS will provide more rigorous data for carfilzomib, as this is the first carfilzomib study with OS as the primary endpoint and it will not be confounded by crossover. The larger study group will also provide more robust secondary response and safety results that will add to the data set from prior phase 2 studies. This phase 3 study of carfilzomib monotherapy for patients with R/R MM

will provide important information necessary to facilitate regulatory approvals around the world and to expand treatment options to meet the unmet need of these patients with advanced disease.

1554

FACTORS ASSOCIATED WITH INFECTIONS IN HOSPITALIZED PATIENTS WITH MULTIPLE MYELOMA: SINGLE CENTER EXPERIENCE

T Valkovic[1], V Gacic[2], J Ivandic[1], B Petrov[3], A Nacinovic-Duletic[1], D Petranovic[1], I Host[1]

[1]1. Department of Hematology, Clinical Hospital Center Rijeka, Croatia, Rijeka, Croatia

[2]2. Department of Hematology, Clinical Hospital Mostar, Bosnia and Herzegovina, Mostar, Bosnia-Herzegovina

[3]3. Department of Psychiatry, Clinical Hospital Mostar, Bosnia and Herzegovina, Mostar, Bosnia-Herzegovina

Background. The disease-related immunological defects, as well as therapy-related immunosupression, lead to increased risk for infective complications which are a major cause of morbidity and mortality in patient with multiple myeloma. Several risk factors increase susceptibility to infections and their understanding is crucial in order to fight against this complications. **Aims.** 1) to establish factors associated with infections in hospitalized myeloma patients at the Department of Hematology, Clinical Hospital Center Rijeka in a three year period 2) to see the incidence and the characteristics of infections in these patients. **Methods**. Retrogradely, from the hospital medical documentation, we processed 241 cases of patients with multiple myeloma who were hospitalized in our Department from January 2008 to December 2010. This study did not include patients who were treated with high dosage therapy and stem cell transplantation. The factors which could induce the infections, such as sex, age, stage of disease, International Staging System, renal failure, imunoparesis, neutropenia, ECOG Preformance Status, serum ferritin, different catheters, were compared and statistically analyzed in the group of patients with and without infections. The frequency and the basic characteristics of the identified infections (microbial agents, site, time of occurrence and outcome of infection, as well as the type of antitumor therapy at the time of infection) were also determined. **Results**. Infections were identified in 44 out of 241 (18, 25 %) cases of hospitalized patients. We established that the factors associated with the more frequent infections were: female sex (p=0,001), clinical stage of disease IIIB (p=0,007), increased serum creatinine levels (p=0,036), neutropenia (p=0,009), poor general condition (p<0,001), high serum ferritin level (p=0,001) and presence of catheters (p<0,001). The most common pathogens found were P. aeruginosa in 9 cases (16,6%), E. coli in 5 (9,25%) as well as Staph. epidermidis in 5 (9,25%) and Strept. foecalis in 5 cases (9,25%). The frequency of Gram-positive and Gram-negative pathogens was similar. In 17 (38,63%) cases we did not manage to isolate the agent. The most common sites of infections were urinary system in 16 cases (36,4%) and blood in 11 cases (25%). Infections generally occured in the later stage of the disease (relapsed/refractory patients) with the highest frequency in patients treated with bortezomib (30,2% of all cases with infections were treated with bortezomib-based therapy as third line of therapy). Fatal outcome occurred in 4 out of 44 cases (9. 09 %). **Conclusions.** This study established female sex, IIIB clinical stage, increased serum creatinine level, neutropenia, poor general condition, high serum ferritin and presence of catheters as possible risk factors for infections in hospitalized myeloma patients which can be contribution for better understanding and prevention of infections in myeloma patients.

POEMS SYNDROME TREATED WITH MELPHALAN HIGH-DOSE THERAPY AND AUTOLOGOUS BLOOD STEM CELL TRANSPLANTATION: A SINGLE INSTITUTION EXPERIENCE

B Thoennissen[1], N Thoennissen[1], F Fritz[1], A Hilbig[1], A Kerkhoff[1], R Liersch[1], U Krug[1], S Koschmieder[2], C Müller-Tidow[1], R Mesters[1], M Kropff[1], W Berdel[1]

[1]University of Muenster, Muenster, Germany

[2]University of Aachen, Aachen, Germany

Background. The acronyme POEMS syndrome stands for a rare multi-system disorder comprised of polyneuropathy, organomegaly, endocrinopathy, M protein and skin changes. Treatment of POEMS may include alkylator-based therapies, and/or a combination of dexamethasone either with anthracycline or melphalan (MDex). Some single centers reported efficacy of melphalan high-dose therapy (HDT) in combination with autologous blood stem cell transplantation (ABSCT) in small patient cohorts with progressive POEMS syndrome. **Aims.** This retrospective analysis aimed to evolve clinical end points including overall survival and clinical outcome of 5 patients with POEMS syndrome treated with melphalan HDT and subsequent ABSCT in our medical center. **Methods.** From 1996 until 2011, 5 patients were diagnosed with POEMS syndrome at the University Hospital of Muenster, Germany, based on the major and minor criteria for POEMS syndrome [Dispenzieri A, *Blood* 2007]. Median age at diagnosis was 44 years (range: 32 - 58). All but one patient had received conventional treatment regimens including anthracycline/dexamethasone or MDex before HDT. One patient was immediately prepared for HDT/ABSCT due to massive splenomegaly and high-grade polyneuropathy at the time of POEMS diagnosis. Between January 2002 and March 2011, all patients developed progressive disease, and therefore underwent melphalan HDT with subsequent ABSCT after giving their written consent. Peripheral blood stem cell collection was performed either following cytotoxic chemotherapy or steady state using stimulation with granulocyte colony-stimulating factor (G-CSF, 5 µg/kg/d s. c.). For cytotoxic mobilization, IEV chemotherapy [intravenous ifosfamide (2500 mg/m^2 day 1-3), epirubicin (100 mg/m^2 day 1) and etoposide (150 mg/m^2 day 1-3)], followed by G-CSF (5 µg/kg/d s. c.) was used. For HDT regimen melphalan 200 mg/m^2 was applied. The median number of CD34-positive cells transfused was 3. 93x10^6/kg (range 2. 1-5. 44). All patients were provided with prophylactic antibiotics and G-CSF (5 µg/kg/d s. c.), which was daily administered starting 24 hours after ABSCT until regeneration of peripheral neutrophils. Hematologic responses were defined according to the *International Myeloma Working Group criteria* [Rajkumar S *et al., Blood* 2011] and conferring to Dispenzieri [*Blood*, 2011]. VEGF testing was performed at the IMMUMED Laboratory, Munich, Germany. **Results.** After a median follow-up of 18 months (range: 11 - 120), all patients are alive and achieved clinical improvement especially of their neurological deficits. In two cases, HDT followed by ABSCT resulted in a complete hematologic response; in the additional three cases, partial responses (PR) were achieved including one very good hematologic PR. Only one patient with initial PR developed progressive disease nearly 2. 5 years after transplantation. Consequently, a second HDT with ABSCT was successfully applied resulting in clinical improvement and hematologic PR. High initial serum VEGF levels were available in two patients and were monitored after HDT and ABSCT. In accordance with literature, correlation was noted between the status of the disease and the corresponding VEGF level in both patients after melphalan HDT and ABSCT. Overall, no severe transplantation-associated complications such as engraftment syndrome or peri- or post-transplant death were noted. **Conclusions.** Melphalan HDT followed by ABSCT is an effective first line treatment for POEMS patients with progressing symptoms.

BORTEZOMIB-INDUCED PERIPHERAL NEUROPATHY IN MULTIPLE MYELOMA PATIENTS

C Lalayanni, M Iskas, A Antoniou, G Voutiadou, E Georgiadou, A Marvaki, C Apostolou, C Vadikoliou, D Mallouri, P Kaloyannidis, A Anagnostopoulos

Hematology Department and HCT Unit, G Papanicolaou Hospital, Thessaloniki, Greece

Bortezomib, a class A proteasome inhibitor, influences various cell signaling pathways and inhibits nuclear factor κB (NF κB). Bortezomib-induced peripheral neuropathy (BIPN) is a common adverse effect. We studied the incidence, risk factors and outcome of BIPN in 93 multiple myeloma (MM) patients. The study group consisted of 55 male and 38 female patients of median age 60 years (range 32-81) who received a median of 4 cycles (range 1-9) of bortezomib. Sixty-eight (73%) of them had advanced stage (refractory/relapsed) disease and 25 (27%) early stage disease. Among the latter, 8 received bortezomib as first-line treatment and 17 before HCT. Disease stage at diagnosis was III in 53 (56%) patients; paraprotein was IgG in 52 (56%), IgA in 23 (25%), IgD in 1 (1%), light chain only in 10 (11%), non secreting in 7 (7%). Eighteen (19%) of them had renal impairment at diagnosis with creatinine levels higher than 2 mg/dl. Bortezomib was co-administered with dexamethasone in 38 patients, anthracycline (PAD regimen) in 16, melphalan with corticosteroids (VMP regimen) in 8. BIPN was noticed in 55/93 (59%) patients after a median of 3 (range 1-7) cycles. In the majority of patients (47/55, 85%) neuropathy was grade 1 or 2. It was diagnosed mostly clinically, whereas 14 patents underwent electrophysiology testing. In all patients BIPN was sensory, in 29/55(53%) neuropathetic pain/nocturnal causalgia coexisted and only in 8/55(14%) motor neuropathy was observed. Four patients presented with bowel autonomic neuropathy, ie mild paralytic ileus. Patients treated earlier in the disease course (0-2 previous lines of treatment) had a similar BIPN incidence with heavily pretreated MM patients (53% and 60% respectively, p=ns). Twenty two patients (40%) needed treatment for BIPN such as pregabalin. Dosage or administration interval adjustment was necessary in 26/55 (47%) patients. Treatment was discontinued in 10/55 (18%) because of BIPN severity or patient denial. Bortezomib retreatment in 6 patients did not produce any additional neurotoxicity. BIPN recovered totally in 43/55 (78%) or gradually ameliorated in 12/55 (22%)

patients. In multivariate analysis, incidence and grade of BIPN did not correlate to factors as age, disease stage, renal impairment or other treatment-related toxicities (e. g. neutropenia, thrombocytopenia). However, there was a significant correlation to the cycles of bortezomib administration and the response to therapy. Conclusively BIPN is a common adverse effect of bortezomib. In most patients it is mild and self restricting. Timely diagnosis and application of dosage adjustment guidelines are important, as there is no specific or highly effective treatment.

1557

FAMILIAL MULTIPLE MYELOMA: DESCRIPTION OF FIVE FAMILIES WITH TWO FIRST-DEGREE RELATIVES DIAGNOSED WITH MM AND TWO FAMILIES WITH A THIRD CASE OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

V Hungria, P Cury, E Crusoe, A Quero, M Sampaio, AL Peres, F Parra, CS Chiattone, V Hungria
Santa casa sao paulo, São Paulo, Brazil

Introduction. The Familial Multiple Myeloma (fMM) frequency is 3. 2 per 1000 cases of Multiple Myeloma (MM), with an incidence of 0. 1 cases per million people per year, which ranks it as a very rare event. However, the risk of relatives developing MM is 1. 7 times and MGUS, 2. 9 times, greater than that of the general population. The finding of fMM may be due to environmental or hereditary cases with limiting factors described for husband and wife and monozygotic twins. **Case Studies.** Family1: The index case was a black man, aged 38, diagnosed with MM IgG kappa IIIA in 1998. In 2007, his brother, aged 59, was also diagnosed with MM IgG kappa IIIA. This family consists of ten siblings. During evaluation of the remaining eight brothers, with examination of protein electrophoresis and immunofixation serum and urine screening, we identified a case with a monoclonal peak less than 1. 5 g/dl and serum immunofixation monoclonal IgG kappa, characterizing an IgG Kappa MGUS case. In the two MM cases of this family, the same HLA profile - (A, B, C, DRB1, DQB1) was found. Family 2: The index case was a white woman, aged 44, diagnosed with MM IgG IIIA in October 2000. In 2009, his mother, aged 74, was diagnosed with MM IgA kappa IIIA. In this family with nine siblings, one died at two years old and others were investigated, identifying a monoclonal peak case with less than 1. 5 g / dl, serum immunofixation monoclonal IgA lambda, characterizing an MGUS IgA lambda case. Family 3: The index case was a white man, aged 67, diagnosed with MM IgG lambda IIIA in January 2008. His first cousin, white, aged 65, received a diagnosis of MM IgA kappa IIIA in June 2009. We performed an investigation of the brothers of the index case, who were normal. The second family was not investigated due to its limited access to our hospital. Family 4: The index case was a black man, aged 50, diagnosed with MM IgG kappa an ISS 1 in August 2007. His father, black, aged 82, received a diagnosis of MM IgA lambda IIIA in January 2010. The index case brothers are under investigation for the presence of gammopathy. Family 5: The index case was a white woman, aged 90, diagnosed with MM IgG kappa ISS1 in June 2004. His daughter, white, aged 64, was diagnosed with MM IgG kappa IIIA ISS3 in September 2011. She has a sister who is under investigation. **Conclusions.** The present study describes five families with more than one case of MM. In two of the five families, two MGUS cases were diagnosed. Moreover, in one family, the immunoglobulin subtype, as well as HLA, was identical. This is the first report of this finding in the literature. This study establishes a precedent for the diagnosis of familial MM, considered a risk factor for other members of the same family to develop some kind of gammopathy.

1558

SERUM IMMUNOGLOBULIN HEAVY/LIGHT CHAIN (HLC) AND FREE LIGHT CHAIN (FLC) CONCENTRATIONS AT DIAGNOSIS IN MULTIPLE MYELOMA (MM) AND IGM MALIGNANT LYMPHOMA (ML) PATIENTS WITH SURVIVAL EXCEEDING 10 YEARS

M Kraj, B Kruk, M Prochorec - Sobieszek
Institute Hematology and Transfusion Medicine, Warsaw, Poland

FLC assay measures circulating unbound kappa and lambda light chains and is of diagnostic and prognostic value in plasma cell disorders. HLC is a novel antibody based assay that targets the unique junctional epitopes between the heavy chain and light chain constant regions of intact immunoglobulin (Ig) molecules. It separately measures in pairs the light chain types of each immunoglobulin class generating ratios of monoclonal Ig/ background polyclonal Ig concentrations (i. e. IgGκ/IgGλ, IgAκ/IgAλ and IgMκ/IgMλ). (Bradwell et al. Clin Chem 2009, 55: 1646). To assess the prognostic impact of these assays we analyzed presentation stored serum samples from 23 MM(14 F9M, median age 52 years, range 32-78, 7 IgGκ, 6 IgGλ, 8 IgAκ, 2 IgAλ; ISS stage I: 16, stage II 6, stage III 1) and 12 ML (7F5M, 9 IgMκ, 3 IgMλ) patients with survival exceeding 10 years (up to 26 years) and 43 (19 MM, 24 ML) patients with survival not exceeding 5 years. All patients were diagnosed and follow-up for many years in our Institute. Serum FLC and HLC (IgGκ/IgGλ, IgAκ/IgAλ, IgMκ/IgMλ) measurements were made on a Siemens BN™ II nephelometer using polyclonal antisera assays (Freelite™ and Hevylite™, Binding Site,Birmingham,UK). Serum protein electrophoresis and immunofixation were conducted on a SEBIA Hydrasys II apparatus. In all patients HLC and FLC ratios were abnormal. In patients with survival exceeding 10 years: median values (and range) of HLC ratios were as follow: in MM IgGκ 11. 8 (7. 9-58. 5), IgGλ 0. 09 (0. 06-0. 35), IgAκ 20. 9 (5. 1-79. 3), IgAλ 0. 09, 0. 16, in ML IgMκ 104. 0 (4. 2-2680), IgMλ 0. 04 (0. 01-0. 05); median values (and range) of FLC κ/λ ratio were: in MM IgGκ 8. 56 (2. 35-99. 80), IgGλ 0. 09 (0. 03-0. 12), IgAκ 4. 29 (1. 45-31300), IgAλ 0. 09, 0. 26, in ML IgMκ 11 (2. 0-28), IgMλ 0. 13 (0. 08-0. 61). In patients with survival not exceeding 5 years: median values (and range) of HLC ratios were as follow: in MM IgGκ 43. 29 (2. 14-73. 79), IgGλ 0. 01 (0. 01-0. 09), IgAκ 189. 0 (102-742), IgAλ 0. 02 (0. 02-0. 06), in ML IgMκ 280. 0 (9. 63-3610), IgMλ 0. 01 (0. 01-0. 05); median values (and range) of FLC κ/λ ratio were: in MM IgGκ. 189(5-7620), IgGλ 0. 03 (0. 001-0. 08), IgAλ 0. 01;0. 001, inML IgMκ 531, IgMλ 0. 01, 0. 06. When patients were stratified according to their survival time > 10 years or < 5 years serum HLC and FLC ratios at diagnosis were less abnormal in patients with survival excceding 10 years (p=0. 03). However in patients with survival > 10 years highly abnormal HLC ratio (<0. 022 or > 45) was found in3 MMpatients (13. 6%) and 7 ML patients (58%) and highly abnormal FLC ratio (< 0. 1 or > 30) was found in 5 MM patients (23. 8%) and in 1 ML patient (8%). Conclusions. Serum heavy /light chain and free light chain measurements at MM diagnosis, provide prognostic information despite that even in MM patients with survival exceeding 10 years in 15% at diagnosis serum HLC and FLC ratios may be highly abnormal.

[4]Hospital Forlife, Komárno, Slovakia
[5]Military Hospital, Ružomberok, Slovakia
[6]Faculty Hospital, Banská Bystica, Slovakia
[7]University Hospital Bratislava, Bratislava, Slovakia

Background. Lenalidomide (LEN) in combination with dexamethasone has demonstrated significant improvements in progression free survival (PFS) and overall survival (OS) in patients with relapsed/refractory multiple myeloma who have received ≥ 1 prior therapy. San Miguel et al (Clinical Lymphoma,Myeloma&Leukemia, 2010) showed that in two large multicenter phase III trials (MM-009 and MM-010), continuing LEN plus dexamethasone after acheiving partial response leads to a significant survial advantage when controling for patient characteristics. In Slovakia, the approved length of LEN treatment according to local regulations is 8 cycles. Additional treatment could be reimbursed on exceptional basis. **Aims.** To conduct a clinical chart review (2/2010-7/2011) to collect data from relapsed/refractory multiple myeloma patients in everyday clinical practice and to evaluate the benefits of prolonged treatment (more than 8 cycles). **Methods.** At the time of this analysis, retrospective data were collected from 146 evaluable patients, 48. 63% male, median age 67 years. Patients had a median of 3lines of prior therapy and 41. 78% were starting second line treatment. Most patients (66,44%) were Durie-Salmon stage IIIA at time of starting lenalidomide treatment Patients received either LEN until disease progression (43 patients) or LEN until 8 cycles (103 patients). The majority of patients (98. 63%) received LEN in combination with a glucocorticoid, 17. 81% of those received dexamethasone,82,19% received other glucocorticoid. LEN dosage after 8 cycles was, 25 mg(4. 65%), 15mg(16. 28%) and 10 mg(79. 07%) . All patients received thromboprophylaxis. **Results.** After 8 cycles of LEN, 76. 72% acheived ≥PR(8. 91 % CR, 36. 99 % VGPR, 30. 82 % PR), 14% had stable disease, and 4. 79% had progressive disease, in 4,49% response not available . Median OS from the start of therapy was 37 months in LEN- continuing arm (95%CI, 30-44) and 32 months in LEN-8 month arm (95%CI, 21-43) . LEN continuing treatment did not result in significantly higher incidence of hematologic adverse events. Incidence of neutropenia (all grades) during the first 8 cycles was 35,62%, after 8th cycle was low, 4. 65%. One patient treated with 10 mg daily LEN continuing treatment experienced thrombosis. Two

patients treated with LEN continuing treatment experienced second primary malignancy (one lung cancer, one CLL). **Conclusion.** The results confirmed the survival benefit of prolonged LEN treatment. The results of this retrospective analysis provide the picture of unselected patients with RRMM in Slavokia The obtained data from this everyday clinical practice corresponds with the results of international clinical trials.

CNS MULTIPLE MYELOMA - A MULTICENTRE EXPERIENCE OF A RARE MANIFESTATION

D Lee[1], A Kalff[1], S Gangatharan[2], P Ho[3], A Bajel[4], D Ritchie[2], A Grigg[3], A Spencer[1]
[1]Alfred Hospital, Melbourne, Australia
[2]Peter MacCallum Cancer Centre, Melbourne, Australia
[3]Austin Health, Melbourne, Australia
[4]Royal Melbourne Hospital, Melbourne, Australia

Background. CNS involvement is a rare complication (1%) of systemic multiple myeloma (MM) and anecdotally appears to be becoming more prevalent in the era of novel therapy. CNS MM has a dismal prognosis with a reported median survival of 2 months and although there are reports of response to novel agents, data are inconsistent and there is no treatment consensus. **Aim.** To describe the clinical features, response to therapy and overall survival (OS) of patients with CNS involvement of systemic MM. **Methods.** Review of patient records from Jan 2000-May 2011 at 4 tertiary referral hospitals identified patients diagnosed with CNS MM defined by monoclonal plasma cells in CSF (meningeal myelomatosis) and/or radiological evidence of cerebral parenchymal plasmacytoma/leptomeningeal disease in the absence of an obvious alternative diagnosis in patients with systemic MM (biopsy not mandated for inclusion). A retrospective analysis of clinical and treatment data was performed. **Results.** Seventeen cases were identified., eleven with meningeal myelomatosis, three with leptomeningeal disease and three with intracranial plasmacytoma. At initial diagnosis, median age was 58 (41-70) years, 7 patients had ISS stage III disease, two presented with non-CNS extramedullary disease, and 3/10 evaluable had unfavourable cytogenetics. Lambda light chain restricted cases were predominant (11/17). Patients received a median of 3 therapies (1-4) prior to diagnosis of CNS MM, including autograft (n=16), allograft (n=2) and at least one of thalidomide (n = 14), lenalidomide (n = 4) or bortezomib (n =8). Median time to diagnosis of CNS MM was 36 months (1-114). Eight patients had concomitant progressive systemic disease,. Two patients demonstrated a shift in secretion from intact immunoglobulin to light chains ("light chain escape"). The most common clinical presentation was cranial nerve palsies (n=7) or headache (n=3). All patients received combinations of radiotherapy (RT) (n=12), intrathecal (IT) chemotherapy (n=8), systemic chemotherapy (n=3) and/or novel agents (bortezomib n = 2, thalidomide n = 5). The median OS from initial diagnosis was 47 (12-124) months but from time of diagnosis of CNS disease was only 4 (1-23) months. Those who received IT chemotherapy had superior OS [20 months vs. 2 months (p=0. 02)], but there was no improvement in survival for those who received RT (p=0. 91). CSF clearance was documented in the 2 of 11 patients who had positive CSF cytology and who received IT chemotherapy. Only 2 patients were alive at time of report (5 and 10 months post-diagnosis of CNS MM). Both received IT chemotherapy and bortezomib as part of their treatment. **Conclusions.** CNS MM is associated with a poor prognosis and currently has limited treatment options. Our cohort reflected many of the features and associations reported in the literature. Given the additional observation of light chain escape in two of our patients, we propose clinicians have a lower threshold for considering CNS involvement in patients with light chain escape who have suggestive symptoms. IT chemotherapy and bortezomib may be of benefit in selected cases but larger, prospective collaborative studies are required to test this observation. No conflicts of interest to disclose.

1561

MULTIPLE MYELOMA AND RENAL IMPAIRMENT: SURVIVAL TRENDS IN GREATER GLASGOW & CLYDE

A Laing, R Soutar, C Geddes
NHS Greater Glasgow & Clyde, Glasgow, United Kingdom

Background. New therapeutic agents shown to improve survival in multiple myeloma have become available over the past decade. Melphalan and prednisolone was the most commonly used chemotherapy in the 1990s. In 2000 thalidomide became available. In 2005 bortezomib and later lenalidomide became available as second line agents. Survival of patients with myeloma in Scotland has steadily improved over the last 30 years. Renal impairment is present in 20% at diagnosis and is associated with poor overall survival. **Aims.** We aimed to examine the baseline characteristics, treatment and survival trends of patients diagnosed with multiple myeloma and renal impairment presenting to renal services between 1990-2010. **Methods.** We identified 105 patients diagnosed with multiple myeloma from the Greater Glasgow & Clyde area with a presenting serum creatinine of greater than 130 micromol/litre using the electronic renal patient record (SERPR). Three cohorts were selected for analysis: 1990-99 (n=27), 2000-04 (n=29), 2005-10 (n=49). **Results.** The fact that the 1990-99 cohort had a lower mean age than the 2000-04 and 2005-10 cohorts (65. 5 v 70. 0 v 70. 0 years respectively; p=0. 13) and a lower proportion required long-term renal replacement therapy (RRT) from presentation (18. 5 v 44. 8 v 30. 6%; p=0. 1) suggests that more severe cases were less frequently diagnosed or referred to renal services in the earliest era. There was no statistically significant difference in overall actuarial survival between the 3 eras (median survival 1441, 488, 537 days respectively; p=0. 24 log rank). Analysis of patients not requiring long-term RRT from presentation showed no significant difference in overall survival or renal survival although there was a trend towards improved median overall survival between 2000-04 and 2005-10 eras (568 v 1022 days; p=0. 83). **Conclusions.** Multiple myeloma with renal failure remains a condition with poor outcome despite the availability of agents in the last decade that target the underlying disease process more effectively.

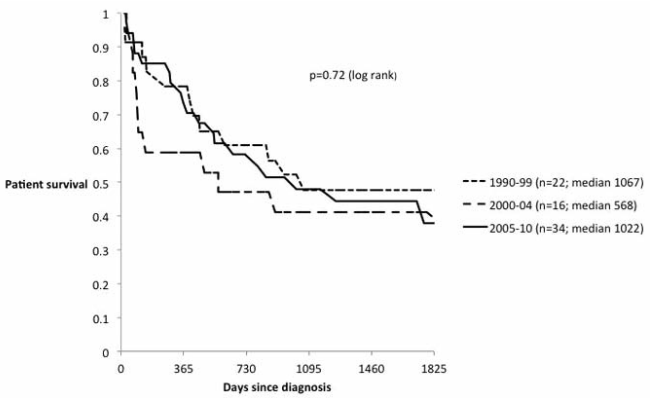

Figure 1. Patient survival for patients not requiring long-term dialysis at presentation analysed by era.

1562

AL AMYLOIDOSIS: A SINGLE CENTER EXPERIENCE

F Gentilini, E Russo, V Federico, A Levi, R Foà, MT Petrucci
'Sapienza' University of Rome, Rome, Italy

Background. Light chain (AL) amyloidosis is a plasma cell dyscrasia characterized by the pathologic production of fibrillar proteins comprised of monoclonal light chains which deposit in tissues and cause organ dysfunction. Standard treatment approaches include high dose Melphalan (HDM) followed by autologous hematopoietic stem cell transplantation (SCT) or oral Melphalan with Dexamethasone (MD) or prednisone (MP). The use of novel agents (Thalidomide, Lenalidomide and Bortezomib) has shown efficacy and continues to be explored. **Aims.** To evaluate the prognostic factors and the outcome of a cohort of 29 AL amyloidosis patients treated with standard therapy and followed at a single center**. Methods.** We performed a retrospective study of 29 AL amyloidosis patients diagnosed and managed between September 2000 and July 2011 at our center. The diagnosis was made by Congo red staining of subcutaneous fat obtained by aspiration and/or organ damaged biopsy when possible. **Results.** The patient series included 14 men and 15 women. The median ages was 67 years (39-85) with 14 patients younger than 65. The monoclonal component (MC) isotype was IgG in 34. 4% of cases, IgA in 20. 7% and micromolecular in 44. 8%; the median proteinuria was 5. 1 g/24h (0. 1-13. 6); the bone marrow plasma cell infiltration was >10% in 13 patients. The Mayo risk score was good-intermediate in 16/29 patients (55%) and high in 13/29 patients (45%). At diagnosis, organ involvement was: 89% renal, 45% cardiac, 20% hepatic, 10% tongue, 3% pulmonary. As first line therapy, 21 patients received MD or MP, 3 of whom achieved a complete hematologic response (CR) and 4 a partial response (PR); 4 of them obtained a partial organ's response. Eight patients had a stable disease (SD) and 6 progressive disease (PD). Among the 7 patients who underwent HDM plus SCT: 2 obtained a CR with a partial organ response, 1 a PR, 3 had a SD and 1 PD. Thereafter, 8 patients were treated with second-line therapy: 5 with Bortezomib-, 1 with Lenalidomide-, 1 with Thalidomide-based regimens and 1 with MD. Three of the latter patients

obtained a partial hematologic and organ response, 2 a SD and 3 showed PD. The median follow-up was 20 months (range 1-123), with an overall survival (OS) and a progression-free survival (PFS) rate at 2 years of 76% (95%IC 60-97%) and 58% (95%IC 41-84%), respectively. With regard to prognostic factors, thrombocytosis, plasma cell bone marrow infiltration, age, cardiac involvement, hypoalbuminemia and the Mayo risk score were analyzed by the log-rank test. Only the Mayo risk score proved statistically significant, with 2-year OS and PFS rates of 86% vs 48%(p=0. 002) and 73% vs 42% (p=0. 04), respectively. By multivariate Cox regression analysis, the Mayo risk score remained the only predictor of worse outcome, statistically related to OS (p=0. 02) and PFS (p=0. 0012). **Conclusions.** We confirm the Mayo risk score as the most predictive factor of OS and PFS in patients with AL amyloidosis. Our results allow to consider Melphalan as a valid therapy in selected patients. New drugs and SCT can further improve the outcome of AL amyloidosis patients.

1563

'NON-PRODUCER' PLASMA CELL MYELOMA MAY SYNTHESIZE UNASSEMBLED IMMUNOGLOBULIN HEAVY CHAIN: CLINICOPATHOLOGIC STUDY OF 4 CASES OF MYELOMA WITHOUT M-SPIKE OR DETECTABLE CYTOPLASMIC LIGHT CHAINS

E Wang[1], C Lu[2], M Stoecker[1], J Burchette[1], Q Huang[3]
[1]Duke University Medical Center, Durham, NC, United States of America
[2]University of California San Francisco, San Francisco, United States of America
[3]City of Hope National Medical Center, Duarte, United States of America

Background. Plasma cell myeloma without M-spike and detectable cytoplasmic light-chain is rare and has been previously defined as the non-producer variant. Clinicopathologic study of this variant of myeloma is limited to sporadic case reports, and its pathogenesis is currently unclear. We present a retrospective analysis of 4 cases of "non-producer"myeloma. **Aims.** To investigate the clinical presentation, pathological features and clinical outcome of "non-producer"myeloma. **Methods.** After institutional approval, 4 cases of plasma cell myeloma without detectable M-spike or cytoplasmic light-chain were collected. Of 4 cases, 2 were encountered among 512 total cases of myeloma registered at Duke University Hospital within the past 5 years. Clinical information, laboratory tests, pathologic evaluation, treatment and follow-up were retrospectively analyzed. **Results.** Of 4 cases, all are male patients. Median age at diagnosis is 59. 5 years (range 56-80). Three cases presented with mild-moderate anemia/thrombocytopenia, and the remaining case presented with multiple skin nodules. While none had M-spike detected in serum or urine, bone lytic lesions were identified in 3 of 4 cases. Other laboratory tests were relatively unremarkable, except for slightly increased/high normal creatinine/BUN in 2 cases, mildly decreased/low normal serum albumin in 1 case and mildly-moderately decreased serum immunoglobulin profile in 3 cases. All cases demonstrated bone marrow involvement by neoplastic plasma cells, ranging 5-90%, with median of 60%, and morphologically, the neoplastic plasma cells displayed lymphoplasmacytoid features. None showed rouleaux formation or circulating plasma cells. In 2 cases, the neoplastic plasma cells demonstrated relatively scant cytoplasm, raising the possibility of small B-cell leukemia/lymphoma with plasmacytic differentiation. Immunohistochemical analysis showed plasma cells were positive for CD56 in 2 cases and negative in the remaining cases. While none had cytoplasmic light chains detected, 2 cases were positive for cytoplasmic heavy-chain of γ isotype. Two cases expressed cyclin D1, corresponding to *CCND1/IGH* fusion detected by cytogenetic analysis, while the remaining cases were negative. Two cases had treatment and follow-up information available. One patient with solitary skin plasmacytoma was treated with radiotherapy but had a poor response and apparent disease progression 5 months after diagnosis. The other patient was treated with combined chemotherapy supported by autologous stem cell transplant and was alive with relatively normal laboratory tests 26 months later. **Conclusions.** "Non-producer"myeloma is extremely rare, comprising ~0. 4% of total myeloma cases per our data. While our cases showed no evidence of M-spike or significantly compromised renal function, as reported in non-secretory myeloma, they demonstrated other features suggestive of myeloma, including lytic bone lesions and/or reduced polyclonal immunoglobulins. Due to negative M-spike and lymphoplasmacytic morphology in some cases, the differential diagnosis may include small B-cell neoplasms with plasmacytic differentiation, which can be excluded by immunophenotypic analysis. Although cytoplasmic light-chain was absent in all 4 cases, expression of cytoplasmic heavy-chain of γ isotype in 2 of our cases raises the possibility that some of the previously defined "non-producer"myelomas may actually synthesize unassembled heavy chains. The clinical outcome of this variant requires further analaysis, including investigation of additional cases and longer follow-up.

1564

COMPARISON OF ESTABLISHED AND NEW SERUM FREE LIGHT CHAIN ASSAYS FOR THE DIAGNOSTIC ASSESSMENT OF MYELOMA KIDNEY

R Allchin[1], A Bevins[2], M Cook[1], P Cockwell[1], C Hutchison[1]
[1]University Hospital Birmingham, Birmingham, United Kingdom

Background. The development of sensitive immunoassays (Freelite®) for the quantification of serum free light chains (FLCs) has led to a paradigm shift in the diagnosis, assessment and monitoring of patients with plasma cell dyscrasias; highlighted by their inclusion in international guidelines. Acute kidney injury (AKI) secondary to myeloma kidney affects around 10% of patients with myeloma, and has a profound impact on patient morbidity and mortality. Improving outcomes in these patients relies on the rapid diagnosis and initiation of disease specific treatment. Recently, new immunoassays which use monoclonal antibodies, opposed to the original polyclonal antibodies, against FLCs have become commercially available. The purpose of this study was to compare the diagnostic sensitivity of these new monoclonal assays with the established polyclonal FLC assays in the context of individuals presenting with new severe AKI secondary to multiple myeloma. **Methods.** Sera from 28 patients with AKI secondary to multiple myeloma (17 lambda, and 11 kappa monoclonal proteins) was stored at -80ºC until thawed for the current study. Serum κ and λ FLC concentrations were measured by nephelometry, on a Dade-Behring BN®II Analyser, using particle-enhanced, high-specificity, homogeneous immunoassays (Freelite®, The Binding Site Group Ltd, Birmingham, UK) and monoclonal N-Latex FLC assays (Siemens Healthcare Diagnostic Products GmBh, Germany). **Results.** There was poor agreement between the two assays for the absolute values for both kappa (r^2=0. 87) and lambda (r^2=0. 3), neither reaching the required r^2=0. 95 by the clinical and laboratory standards institute (CLSI) guidelines. 5/28 (18%, Table 1) of patients were misclassified using the N-Latex assay with serum values below the nephrotoxic threshold of 500mg/L (median 221mg/L, range 1-493mg/L). In 1/17 patients the N-latex assay failed to identify monoclonal lambda light chain (Freelite=1810mg/L vs. N-Latex FLC=0. 5mg/L). **Conclusions.** A rapid identification of high levels of monoclonal FLCs in patients with AKI can allow earlier disease specific treatment and improved patient outcomes. The new N-Latex assay does not clearly identify patients at risk of AKI (FLC >500mg/L) and it can miss monoclonal lambda FLCs.

Table 1.

Patient	Multiple myeloma type	Freelite			N-Latex FLC			Missed by N-Latex FLC	Misclassified by N-Latex FLC as <500mg/L

VELCADITO: A MODIFIED VISTA SCHEME WITH VERY LOW DOSES OF BORTEZOMIB FOR THE TREATMENT OF FRAIL PATIENTS WITH MULTIPLE MYELOMA

J Wong Arteta, E Perez-Persona, M Quintana Razka, B Moreno-deGusmao, A Mendizabal, C Menchaca, I Oiartzabal, J Guinea, M Ardanaz
Txagorritxu Hospital, Virotia Gasteiz, Spain

Introduction. Patients diagnosed multiple myeloma (MM) older than 75 years old are infrarrepresented in clinical trials, therefore, chemotherapy in these patients has not been well-stablished. Bortezomid, melphalan and prednisone (VISTA trial) are widely used in these frail patients and it is associated with considerable neurological toxicity (overall: 44%, grade III-IV> 13%) being necessary bortezomib dose reduction and affecting quality of life of these elderly patients. **Aims.** Evaluate the efficacy and tolerability of a new scheme with very low doses of Bortezomib (Velcadito) in elderly patients diagnosed with MM. **Materials and Methods.** Velcadito scheme consisted on monthy cycles of bortezomib: 1. 0 mg/m^2, exclusively on days 1 and 4. Melphalan (9 mg/m^2) and prednisone (60mg/ m^2) were also administered on days 1 to 4 of each cycle. Only on first cycle, bortezomib was administered at dose of 1. 3 mg/ m^2 on 1, 4, 8 and 11 days. **Results.** Between 2008 and 2012, nineteen patients received Velcadito for the treatment of MM. 74% as first line and 26% as second of subsequent lines. Median age at treatment was 77 years old (68-71), and the median cycles received were 9 (2-16). Focussing efficacy, overall response rate

was 78,95% (26,32% complete response; 10,53% very good partial response; 42,11% partial response). Stable disease was achieved on 21,05% patients. Considering neurological toxicity 16% suffer from any grade of neuropathy, with only 1 patient (5%) with grade III-IV, developed in the fist cycle of bortezomib. The progression-free survival and overall survival was 10 (5-54) and 11 (5-57) months, respectively. **Conclusions.** Treatment with Velcadito scheme is feasible in elderly patients with overall response rates comparable toVISTA trial and with low neurological toxicity. This scheme show promising results and should be considered in elderly patients diagnosed with MM.

CLINICAL FEATURES OF HIGH-RISK MULTIPLE MYELOMA: A SINGLE CENTRE RETROSPECTIVE STUDY

P Curci, A Giordano, R Rizzi, M Delia, C Spinosa, M Leo, G Nardelli, G Lerario, G Specchia
Hematology University Bari, Bari, Italy

Background. The outcome of multiple myeloma has improved with the advent of novel drugs; nevertheless, some patients present refractory multiple myeloma or exhibit early relapse after an initial response. Ultra high-risk myeloma, defined as myeloma leading to death within 24 months, affects 15%-20% of patients (pts). **Aims.** The aim of the study was to evaluate the impact of diagnostic phase clinical and laboratory ultra high-risk myeloma parameters (HRM) on Response Rate (RR). **Materials and Methods.** Between October 2005 and March 2011, 14 pts with HRM (2 M (21%), 11 F (79%), median age 66. 5 years, range 51-81) were retrospectively selected from among 120 consecutive pts with de novo multiple myeloma. . According to ISS, 64% (9/14 pts) were in stage III, and 36% (5/14) in stage II; M protein type was IgG in 64% (9/14), IgA in 7% (1/14), BJ in 29% (4/14); a skeletal survey (with conventional skeleton radiography and magnetic resonance imaging) was done in all pts; 7% (1/14) presented extramedullary disease, abnormal LDH was present in 35% (5/14), 50% (7/14) showed bone marrow plasmacellular involvement >50%; 21% (2/14) showed a low (<1500/µl) absolute lymphocyte count; 93% (13/14) showed CD56 positivity at flow cytometric immunophenotypic analysis. Baseline treatment was Melphalan-Bortezomib-Prednisone in 50% (7/14), Bortezomib-Thalidomide-Dexamethasone in 14% (2/14), Bortezomib-Dexamethasone in 21% (3/14), Melphalan-Prednisone in 7% (1/14), Vincristine-Adriamycin-Dexamethasone in 7% (1/14). Response rate was: Partial Remission in 14% (2/14 pts) and Progressive Disease in 86% (12/14 pts) with 98% (13/14) of deaths due to progressive disease. Median overall survival was 11 months (range 1-26). **Results.** At univariate analysis a statistically significant correlation (p=0. 03) was observed between RR and the baseline lymphocyte count; no significant correlation was found with the other clinical and laboratory characteristics analyzed. **Conclusions.** Ultra high-risk myeloma affects a rare subset of patients that are difficult to recognize at diagnosis on the basis of standard staging systems and conventional prognostic factors. Our results indicate that a low absolute lymphocytic count at diagnosis can identify a subgroup with better prognosis among this cohort of patients and could be a useful tool for the characterization of HRM patients. Further studies in larger populations are needed to confirm our results.

ANALYSIS OF THE RESPONSE RATE BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) IN PATIENTS WITH MULTIPLE MYELOMA, COMPARING THREE DIFFERENT INDUCTION REGIMENS

V Hungria[1], E Crusoe[1], MP Camargo[1], F Higashi[1], E Miranda[2], A Quero[1], M Sampaio[1], AL Peres[1], P Cury[1], CS Chiattone[1], V Hungria[1]
[1]Santa casa sao paulo, São Paulo, Brazil
[2]Unicamp, Campinas, Brazil

Introduction. The chemotherapy regimen most commonly used until recently for the induction of MM patients, eligible for ASCT, was (VAD) doxorubicin + vincristine + dexamethasone. The overall response (OR) rates, obtained after induction, reached 50% in some studies that used VAD as induction. The use of new drugs, such as thalidomide, has shown a significant improvement in the induction response rate, reaching an OR above 80%. This response may reflect better event-free survival and better overall survival. In addition to all these factors, besides being the only novel agent available in the public health system, the oral mode of use, ease and low cost make thalidomide a desirable drug to combine with other drugs for induction regimens. **Aims.** To compare the response rates among three different induction regimens after pre-ASCT: TD (thalidomide + dexamethasone) vs. CTD (cyclophosphamide + dexamethasone + thalidomide) vs. VAD in patients undergoing ASCT. **Methods.** A retrospective cohort of patients with MM undergoing ASCT at a specialized hematology treatment center among January 2007 to June 2011 was studied. We included patients who underwent VAD-induction regimens (vincristine 0. 4mg/d/4 days+ doxorubicin 9mg/m2/d/4 days+ dexamethasone 40mg/d-1-4, 9-12, 17-20), CTD (cyclophosphamide 50mg/d / continuous + thalidomide 100-200mg/d-continuous+ dexamethasone 40mg/ weekly) and TD (thalidomide 100-200mg/d-continuous + dexamethasone 40mg/ weekly), and excluded patients who had received prior to ASTC more than six cycles or regimens other than those above. Statistical analysis was performed with SPSS 15. 0, through comparative analysis with ANOVA and Kaplan-Meier curves for survival, considering p <0. 05 as significant. **Results.** A total of 80 MM patients submitted to ASCT was elected. Seven patients were excluded, with 73 analyzable patients remaining. The patients were 56% male. The median age at diagnosis was 55 years old (28-68). The immunoglobulin subtypes at diagnosis were: IgG = 50%, IgA = 23%, 19% = light chain, IgM = 1. 4% and non-secreting = 3%. The Durie-Salmon staging was: IIIA+B=88% and IIA+B=12%. The numbers by induction + mobilization scheme were: VAD+(Cy+GCSF)=17 cases, VAD+GCSF=10, CTD+GCSF=14 and TD+GCSF=31. The median number of induction cycles was 3 (1-6) for VAD and 4 (3-6) for TD and 4(2-4) for CTD. The response rates above very good partial response (VGPR) after induction, were higher in the TD group (36%) and CTD (50%) group than in the VAD group (14%), (p=0. 039). (See Table 1.) The progression-free survival at 5 years for the entire group of patients was 43%, without difference between groups. (p=0. 27) The overall survival rate at 5 years was 71%, without difference among the groups, (p=0. 41). **Conclusions.** Patients who received CTD and TD as pre-ASCT induction regimens achieved better response rates above VGPR, when compared with the VAD regimen. (P = 0. 039). The CTD group showed a better response than the TD group, albeit without significance, but we attribute this to small cohort. An increased number of patients will probably show a significant difference between the CTD and TD groups.

Table 1. Response rate between three different induction regiments in MM patients.

	VAD	TD	CTD	TOTAL
CR	1 (4%)	3 (10%)	0	4
VGPR	3 (10%)	8 (26%)	7 (50%)	18

MEASUREMENTS OF SERUM INVOLVED FREE LIGHT CHAINS AFTER ADMINISTRATION OF ZOLEDRONIC ACID IN MULTIPLE MYELOMA PATIENTS SHOW DIVERSE CHANGES

T Hansen[1], C Nielsen[2], T Pedersen[3], N Abildgaard[3]
[1]University of Southern Denmark, Odense, Odense C, Denmark
[2]Department of Biochemistry, Esbjerg, Denmark
[3]Department of Hematology, Esbjerg, Denmark

Background. Aminobisphosphonates (aBP) are effective in the prophylactic treatment of the osteolytic bone disease seen in patients with multiple myeloma (MM). Treatment with aBPs leads to a decrease in skeletal related events. However, there are ongoing discussions as to whether or not aBPs have an anti-myeloma effect as well. Several *in vitro* studies have shown anti-myeloma effects, but only recently this has been confirmed in a clinical study, in which patients receiving zoledronic acid (ZOL), intravenously, had significantly increased overall survival compared to patients receiving orally administered clodronate. Other studies comparing pamidronate to placebo has failed to confirm a prolonged survival. Serum free light chain (sFLC) is a biomarker in MM, with a short serum half-life of 2-6 hours. Theoretically, the measurement of sFLC can be used as an early indicator of anti-myeloma activity. **Aims.** To assess whether measurements of sFLC, can demonstrate an anti-myeloma effect of the aBP, ZOL. **Methods.** Fifteen patients with clinically stable MM (based on stable levels of serum M-protein and immunoglobulins) absent from anti-myeloma therapy, were included. Informed consent was obtained. Mean age 67. 7 years (43 - 92 years). All patients received prophylactic treatment with ZOL, 4 mg i. v. Seven (47 %) patients were treated with ZOL for the first time. We collected serum samples before treatment with ZOL, after 4-6 hours, 1, 2, 3 and 4 days. A significant change in sFLC at a 95 % level was calculated as 1. 96 * $\sqrt{2}$ * $\sqrt{CVtotal^2}$. **Results.** Four (27 %) patients had a significant decrease in involved FLC (iFLC). In two patients the decline was transient. In 6 (40 %) patients no change were seen neither in iFLC nor the uninvolved FLC. In 2 (13 %) patients there was a significant rise in iFLC on day 5. Two (13 %) patients had a short rise in iFLC, falling back to baseline values. There were no differences in the results obtained from patients who had received ZOL before and the aBP naïve patients. **Summary and Conclusions.** Using the sensitive biomarker sFLC during treatment with ZOL we observed a significant decline in iFLC in a minor fraction (27%) of patients within few days after the administration. In 2 patients we observed a significant increase iniFLC. No change was observed in most of the patients. Thus, even though we observed a decline in 4 patients, there was no “clear picture”in the iFLC changes. Oppositely, the response in 4 patients could indicate an anti-myeloma effect of ZOL in some patients. Moreover, the potential anti-myeloma effect of ZOL may be dependent on a synergistic effect of another, simultaneously given, anti-myeloma therapy.

1569

NUMBER NEEDED TO TREAT (NNT) AS A MEASURE OF DRUG BENEFIT: LENALIDOMIDE VS. BORTEZOMIB AS INITIAL TREATMENT FOR MULTIPLE MYELOMA (MM)

G Dranitsaris[1], S Kaura[2]
[1]Augmentium Pharma Consulting, Toronto, Canada
[2]Celgene Corporation, Summit, United States of America

Background. Lenalidomide (LEN) and bortezomib (BORT) are active agents for the initial treatment of MM. LEN is administered 25 mg/day orally on days 1-21 of repeated 28-day cycles. The dosage of BOR is 1. 3 mg/m^2 intravenous dose on days 1, 4, 8 and 11 for eight three week cycles. Both agents have demonstrated an improvement in disease response, progression free (PFS) and overall survival (OS) as initial therapy in MM. NNT represents the number of patients that need to be treated with a new intervention in order to have one additional patient deriving benefit, and is a recognized and widely used to further interpret clinical benefits from randomized trials. **Aims.** In this analysis, the NNT approach was used to compare LEN and BORT as initial therapy in MM. **Methods.** The randomized trials for LEN (Zonder, 2010) and BORT (San Miguel, 2008) were reviewed. A key requirement for a NNT comparative analysis is that all outcomes be measured against a comparable control in similar patients. The NNT was then calculated for both agents with respect to disease response and PFS at 12 months by taking the reciprocal of the absolute differences in treatment effect between the experimental therapies and the control group. **Results.** For a response, LEN and BORT had a comparable NNT of 3 to 4 patients; in order to have one patient achieving a disease response. However, a difference in the NNT was noted for PFS at 12 months; only 4 patients would need to be treated with LEN for a patient remaining progression free compared to 6 with BORT. **Conclusions.** In situations of multiple numerical outcomes from randomized trials, the NNT approach is a simple and effective method to express the findings in a clinically meaningful way. In this analysis, it appears that patients treated with LEN are more likely to respond and to achieve a 12 month PFS than comparable patients treated with BORT. Possible reasons for this effect include differences in the trial population, extent of disease, and/or true differences in efficacy.

1570

LENALIDOMIDE OR BORTEZOMIB FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA (MM): A COMPARATIVE EFFECTIVENESS ANALYSIS USING INDIRECT STATISTICAL TECHNIQUES

G Dranitsaris[1], S Kaura[2]
[1]Augmentium Pharma Consulting, Toronto, Canada
[2]Celgene Corporation, Summit, United States of America

Background. Lenalidomide (LEN) and bortezomib (BORT) are both effective for the treatment of patients with relapsed/refractory MM. The former is administered 25 mg/day orally on days 1-21 of repeated 28-day cycles. The latter as a 1. 3 mg/m^2 intravenous dose on days 1, 4, 8 and 11 for eight, three week cycles. Currently, there are no data available from a head to head randomized phase III trial comparing LEN and BORT. **Aims.** In the absence of such data, an indirect comparison between LEN and BORT was performed in the relapsed/refractory MM setting. Such an analysis was feasible because comparable controls were used in the pivotal randomized trials and patients had similar baseline characteristics. **Methods.** Three pivotal randomized trials with LEN (n=2) and BORT (n=1) in the relapsed/refractory setting were identified. Patients within each trial had similar disease characteristics. Data in terms of response rate (RR), time to progression (TTP) and overall survival (OS) were extracted from the pivotal trials. An indirect statistical comparison between LEN and BORT was then performed on these endpoints using the method of Bucher et al. (1997), which partly maintains the benefits of randomization on the magnitude of benefit. **Results.** The analysis identified significant differences in efficacy between these drugs. Patients treated with LEN were significantly more likely to achieve a disease response (OR=1. 92; 95%CI: 1. 15 - 3. 20) and to have a prolongation in TTP (HR = 0. 64; 95%CI: 0. 44 - 0. 91). The analysis also identified a trend for an OS benefit in patients receiving treatment with LEN over BORT (HR = 0. 71; 95%CI: 0. 46 - 1. 11). **Conclusions.** Keeping in mind the caveats associated with cross trial comparisons, this indirect evaluation suggested increased effectiveness of LEN over BORT in MM patients with refractory/relapsed disease. These findings, along with its oral route of administration and established safety profile suggest that LEN should be the preferred agent for refractory/relapsed MM.

1571

CASE SERIES OF MULTIPLE MYELOMA PATIENTS WITH SOLITARY PLASMACYTOMAS

K Abdulkadyrov[1], S Voloshin[1], A Schmidt[1], V Shuvaev[1], A Kuvshinov[1], L Stelmashenko[1], Y Zueva[2], E Rusanova[2], M Gorchakova[2], K Slobodnyuk[2], V Manukovskiy[3]
[1]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation
[2]Saint-Petersburg Pavlov State Medical University, Saint-Petersburg, Russian Federation
[3]Military Medical Academy, Saint-Petersburg, Russian Federation

Background. Some patients with multiple myeloma (MM) has additional tumor masses that can affect various organs and worsen prognosis and treatment outcomes. Myeloma growth on extramedullary sites is a sign of more aggressive biological behavior of tumor. Some prognostic factors that could predict spread over bone marrow (BM) may be useful to initial stratification of patients to more aggressive therapy. **Aims.** To investigate possible correlations between laboratory findings and clinical outcome in patients with newly diagnosed symptomatic myeloma. **Methods.** Eighteen adult patients (median age - 55. 9 years; male - 11) with newly diagnosed MM were assessed. The diagnosis of active MM was made according to standard diagnostic workup (history and physical exam, serum albumin, quantitative immunoglobulins, beta-2 microglobulin, serum and urine electrophoresis, serum and urine immunofixation, serum and urine free light chain assay, BM aspiration and biopsy, BM multicolor flow cytometry (MFC) analysis with documentation of an aberrant surface phenotype of plasma cell (PC) population, plasmacytoma immunohistochemistry (IHC), BM cytogenetics and FISH, skeletal sur-

vey, computed tomography (CT), magnetic resonance imagine (MRI), or positron emission tomography (PET)/CT scan. We also studied their clinical findings with use of skeletal survey, CT, MRI and PET/CT during treatment phase and follow-up period. The BM MFC was performed at time of initial diagnosis. MM disease stage was assessed using Durie-Salmon and International staging systems. All the patients were treated with initial bortezomib-based therapy and bisphosphonates. Responses were investigator-assessed and based on EBMT and IMWG response criteria. **Results.** Seven patients (38. 9%) had solitary plasmacytomas at diagnosis which were detected using CT, MRI, PET/CT (3, 3, and 1 cases, respectively). Six patients (85. 7%) had osseous plasmacytomas, and 3/7 (42. 9%) - multiple (≥2) osseous plasmacytomas, whereas one patient had extraosseous (both breasts) plasmacytomas. Six/7 patients (85. 7%) was operated on; 5/7 (71. 4%) manifested with signs of vertebral column instability or spinal cord compression and was operated on before start of primary therapy. One patient (14. 3%) was operated on during primary therapy. During follow up period (2 years after first admission) 1/7 patient was diagnosed as having new osseous plasmacytoma which was successfully operated on. MFC was performed on 18 consecutive BM aspirates: CD38 and CD138 was expressed in 18 cases (100%), CD19 - 4 (22. 2%), CD56 overexpression - 5 (26. 3%), CD117 - 7 (38. 9%), CD20 were negative in all cases. Patient' PC phenotype detected on BM MFC and results of plasmacytoma IHC were identical. All the patients with plasmacytomas did not show CD117 expression (results of BM MFC and IHC assays). **Conclusions.** Our study shows that the presence of plasmacytomas correlate with the absence of CD117-expression of atypical PCs in patients with newly diagnosed symptomatic myeloma. There were not revealed any other correlations between results of laboratory studies and clinical course in our patients. These data demonstrates that the newly diagnosed patients with active myeloma require a very thorough evaluation including CT, MRI and/or PET/CT (preferable diagnostic tool) to rule out the presence of solitary plasmacytomas. Further studies are needed to confirm this proposal.

1572

ABSOLUTE LYMPHOCYTE COUNT IS NOT A PREDICTOR FOR SURVIVAL IN NEWLY DIAGNOSED ELDERLY PATIENTS WITH MULTIPLE MYELOMA

G Saccullo[1], R Bono[1], A Branca[2], C Cangialosi[3], S Mancuso[1], S Raso[1], G Quintini[1], M Lipari[1], F Fabbiano[3], V Abbadessa[1], G Specchia[4], F Di Raimondo[5], S Siragusa[1]

[2]P. O. Ferrarotto Alessi, Catania, Italy
[3]Ospedali Riuniti Villa Sofia-Cervello, Palermo, Italy
[4]Ospedale Giovanni XXIII, Bari, Italy
[5]Policlinico Ferrarotto, Catania, Italy

Background. Absolute lymphocyte count (ALC) > 1. 400 x10^9/l, as a surrogate marker of host immune status, has been reported to be an independent prognostic factor for clinical outcome in patients with previously untreated multiple myeloma (MM). However, most of the patients evaluated received stem cell transplantation (SCT); less evidence is available on elderly patients or those unable to SCT. **Aims.** To evaluate retrospectively the correlation between ALC, detected at the time of MM diagnosis, and clinical outcomes (first remission rate and overall survival) in patients older than 65 y. o. or those not eligible to SCT. **Methods.** Between 1998 and 2006, 103 consecutive patients were evaluated among four institutions; none of patients was neither uniformly treated nor part of a clinical trail. The primary endpoint was to assess the role of ALC, at the time of MM diagnosis, on overall survival (OS); secondary outcome was the correlation between ALC and rate of first complete remission. The OS was measured, by Kaplan and Meier analysis, from MM diagnosis to death or last follow-up. Patients that were lost to follow-up were censored in the survival analysis. Differences between survival curves were tested for statistical significance using the two-tailed log-rank test. **Results.** The median age for this cohort of 103 MM patients was 69. 4 years (+ 10. 8 years). Baseline characteristics (ISS, LDH, M Component, Haemoglobin Levels and Calcium) where not statistical significant. Three patients were lost to follow-up. Most of patients were treated with regimens containing Melphalan, Prednisone with/without Thalidomide. The median follow-up was 24. 3 months (range: 1-81 months). At the time of the analysis 17 patients had died. Of the 103 patients, 7 (7%) of the patients died of MM. ALC, as a continuous variable, was not identified as prognostic factor for overall survival (OS) (ALC < 1. 400 x10^9/l vs ALC > 1. 400 x10^9/l = HR 1. 214 (95%CI: 0. 222-6. 650; p=0. 823]). OS of MM patients with ALC > 1. 400 X10^9/l was 82 months vs 76 of those with ALC < 1. 400 x10^9/l (p= 0. 23) (Figure 1). ALC did not influence response rate of first complete remission (ALC < 1. 400 x10^9/l vs ALC > 1. 400 x10^9/l = HR 1. 538 [95%CI: 0. 662-3. 570; p= 0. 317]). **Conclusions.** This study showed that, in newly diagnosed MM, ALC is not an independent prognostic factor for OS and does not influence rate of first complete remission.

[2]Institute of Hematology, Catholic University, Rome, Italy
[3]Department of Hematology, Regina Elena National Cancer Institute, Rome, Italy
[4]Ospedale Sant'Eugenio, Rome, Italy

Background. The use of Interferon (IFN)-alpha for the induction and maintenance treatment in patients with multiple myeloma (MM) has yielded discordant results. The most important role of IFN is in responding patients when used as maintenance therapy after induction treatment. An overall modest prolongation in response duration, reported in the majority of studies, and the development of new agents have put this drug into disuse. However, in our clinical practice we have observed MM patients with a long overall survival (OS) when treated with IFN as maintenance therapy. **Aims.** We hereby analyzed the efficacy and toxicity of IFN used as maintenance therapy in MM patients over a prolonged time period. **Methods.** A retrospective analysis was conducted on 38 MM patients who received IFN as maintenance therapy for more than 24 months. **Results.** The patient series included 24 men and 14 women. The median age of the patients was 58 (range 35-74) years. Twenty-five were IgG, 8 IgA and 5 had light chain MM. Twenty-four and 14 had Durie and Salmon stages III and I/II, respectively. Two patients had serum creatinine levels >2 mg/dl. Twenty-nine patients had received at least one line of therapy and 9 >two lines. Twenty-eight have undergone an autologous stem cell transplant: one in 21 patients and two in 7. After induction therapy, the disease status was as follows: 15 patients were in complete remission (CR), 5 in very good partial response (VGPR) and 18 in partial response (PR). The median follow-up before starting IFN therapy was 13 months (range 3-54). IFN was administered as a single agent in 32 patients and in association with steroids in 6 patients. The weekly dose of IFN administered to all patients was 9 MU (3MU three times a week). The median duration of IFN maintenance was 68 months (range 13-242). After a median follow-up of 153. 5 (range 33-307) months, 8 patients continue IFN treatment, while 30 patients have discontinued: 12 for disease progression, 6 for toxicity, 1 for non-compliance, 1 for a second neoplasia after 45 months, 1 for a cerebral stroke and 9 for other causes. The OS rate at 12 years is 78%. The most frequent side effects recorded in our patients were flu-like syndrome **(8%) and hepatotoxicity (8%). Conclusions.** Today, IFN is rarely utilized in the management of MM patients. Nonetheless, our report indicates that some patients can witness a prolonged OS following the use of IFN as maintenance therapy. In our experience, the drug proved well tolerated and its toxicity, reported in the majority of studies, maybe overcome with the use of the pegylated form, at the moment under evaluation. It will be important to try to identify pre-

dictive factors that can help to recognize MM patients who can benefit from IFN maintenance treatment.

1574

BORTEZOMIB AND HIGH-DOSE MELPHALAN AS CONDITIONING REGIMEN BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA: EXPERIENCE IN A UNIVERSITARY HOSPITAL

D de Miguel, D Morales, I San Roman, N Golbano, M Diaz, J Arbeteta, S Herrero, D Subirá, B PInedo
Hospital Universitario de Guadalajara, Guadalajara, Spain

Background. The combination of bortezomib and high-dose melphalan (HDM) is an attractive approach to improve the efficacy of the conditioning regimen. Furthermore, this association was expected to be safe because bortezomib and melphalan do not share common toxicities (mainly neurologic toxicity for bortezomib and hematologic toxicity for HDM). We followed a phase 2 study of the Intergroupe Francophone du Myélome (IFM) (Blood 7 Jan 2010, 115 (1); 32-36). **Aims.** 1) to evaluate response rates after intensive therapy and to assess the toxicity of this new conditioning regimen. 2) To know the toxicity. **Methods.** 11 patients (5 males/6 females, median age 59 years (34-73). Myeloma type: 3 IgG, 5 IgA, 2 Bence Jones, and 1 plasmatic cells leukemia; Durie-Salmon: 3 IIA, 5IIIA, 2 IIB) with multiple myeloma were treated between February 2010 and February 2012 to receive bortezomib (1 mg/m2 × 4) and melphalan (200 mg/m2) as conditioning regimen (Bor-HDM). All patients received induction treatment with VCD (Bortezomid 1,3 mg/m2 D1, D4, D8, D11; Cyclophosphamide 600 mg/m2 D1, D8; Dexamethasone 40 mg D1, D4, D8, D11) 6-8 cycles/21 days. Overall, 81,8% of patients achieved at least PR, including 2 patients with CR (18,2%) before ASCT. Bortezomib was administered intravenously at 1 mg/m2 on days -6, -3, 1, and 4. Melphalan was administered intravenously at 200 mg/m2 on day -2. Peripheral blood stem cells (≥ 2 × 106 CD34+ cells/kg) were infused on day 0. Peripheral blood stem cells (median 2,83 × 106 (1. 97-3. 89). CD34+ cells/kg) were infused on day 0. **Results.** All patients received granulocyte growth factors. There was no engraftment failure. Neutrophils (ANC ≥ 0. 5 × 109/L) and platelets (≥ 20 × 109/L without transfusion) recovered in median times of 11 days (range, 11-13 days) and 13 days (range, 11-18 days), respectively. Patients were discharged from the transplantation unit in median times of 27,5 days (range, 21-25 days). There was one treatment-related death, at 11 days of candidiasis (C. glabrata). Some serious adverse events were reported: 1 Salmonella diarrhea, and 1 pneumonia. 5 bacteremias (45,4%) were documented: 4 *Staphylococcus epidermidis*, 1 *Enterococcus faecalis*, 1 *Pseudomonas aeruginosa.* . The most frequently reported grade 3 or 4 nonhematologic toxicities were mucositis of upper and lower digestive tract sites (72,7%). Other grade 1 or 2 adverse events were digestive (diarrhea, 18,2%). It should be noted that peripheral neuropathy (PN) was present at the time of ASCT,1 patients and did not get worse after Bor-HDM treatment. At time of reporting, median follow-up time from induction therapy was 24 months (range, 8-30 months). 2 patients relapsed at 3 and 9 months after ASCT, and they died of progressive disease. Evaluation of response rate at 100 days after ASCT have not changed. **Conclusions.** Our experience shows that bortezomib can safely be combined with HDM as a preparative regimen followed by ASCT. This regimen was well tolerated with no increased toxicity. Engraftment was not affected by the addition of bortezomib. PN did not worse after this conditioning regimen.

1575

STUDY OF EFFICACY RECOMBINANT HUMAN ERYTHROPOIETIN IN MULTIPLE MYELOMA PATIENTS WITH ANEMIA

N Romanenko, R Golovtshenko, I Kostroma, K Abdulkadyrov
Russian Research Institute of Hematology and Transfusiology, FMBA of Russia, Saint-Petersburg, Russian Federation

Background. Anemia in Multiple Myeloma (MM) patients can influence the efficacy of chemotherapy, survival rate and overall quality of life (QoL). Red blood cell (RBC) transfusions are routinely used to treat anemia. While recombinant human erythropoietin (rHuEPO) treatment has been shown to significantly increase hemoglobin (Hb) concentration, reduce the number of RBC transfusions and improve QoL in patients with chemotherapy induced anemia. **Aims.** To study efficacy rHuEPO (Epoetin alpha) in MM patients with anemia. To compare the results of treatment MM patients with anemia who had received only chemotherapy versus patients who had received chemotherapy and rHuEPO. **Methods.** There was done prospective study to investigate the effectiveness of rHuEPO therapy (n=65) and was compared to control group of patients (n=31) who hadn't been received rHuEPO. All patients (n=96) had been diagnosed multiple myeloma in second or third stage (by WHO classification). Anemia was determined in every patient (Hb level 5. 3-10. 0 g/dL). The median age of patients was 66. 5 years (range 26-84). If Hb concentration was <8. 0 g/dL, the patients were performed RBC transfusions before rHuEPO treatment. Epoetin alpha was injected subcutaneously on 40. 000 IU weekly (n=44) or on 10. 000 IU 3 times a week (n=21). Before start of rHuEPO treatment all patients have being received two or more cycles of chemotherapy (PAD, VD, MP or CVMP). The target Hb level was 12 g/dL and planned duration of rHuEPO therapy was within 16 weeks. The control group of patients was observed during 20 months. The positive response in both group was estimated as increasing Hb concentrating on 2. 0 g/dL or more and so achieving target Hb level (12 g/dL) during the period of rHuEPO therapy. **Results.** In the rHuEPO group of patients (n=65) mean baseline Hb concentration was 8. 87±1. 27 g/dL (median 9. 20 g/dL) and RBC count was 2. 80±0. 46×10^{12}/L (median 2. 85×10^{12}/L). 15 patients had Hb concentration <8. 0 g/dL (5. 3-7. 9 g/dL) therefore they were transfused 2-6 units of red blood until Hb increased up to 8. 0-9. 0 g/dL. The period of rHuEPO-therapy was from 4 to 16 weeks (mean 10. 0±3. 8 weeks). During the study period in the rHuEPO group the positive response was at 42 patients (64. 6%). Only 5 patients (33. 3%) were kept on RBC transfusion dependence. In whole rHuEPO group Hb concentration and RBC count increased from baseline to 11. 41±1. 96 g/dL (p<0. 01) and 3. 58±0. 75×10^{12}/L (p<0. 01), respectively. The patients with positive response more significantly increased Hb level from 9. 00±1. 14 to 12. 35±1. 31 g/dL (p<0. 001) and RBC count increased from 2. 82±0. 38×10^{12}/L to 3. 91±0. 51×10^{12}/L (p<0. 001). However, in control group patients positive response observed at 22. 6% (7 from 31). There were not significant difference of Hb concentration and RBC count in this group of patients (Hb increased from 8. 86±1. 18 to 9. 48±1. 42 g/dL (p>0. 05) and RBC increased from 2. 80±0. 51×10^{12}/L to 3. 01±0. 63×10^{12}/L (p>0. 05)). Besides, during the study period 6 (60%) from 10 patients had been receiving RBC transfusion. **Conclusions.** The study has shown that rHuEPO is effective at increasing Hb concentration, count of RBC and reducing RBC transfusion in MM patients with anemia.

1576

ERYTHROCYTE SEDIMENTATION RATE CANNOT BE USED TO RELIABLY EXCLUDE MULTIPLE MYELOMA

C Ogilvie, L Stirton, R Soutar
Gartnavel General Hospital, Glasgow, United Kingdom

Background. Early diagnosis is important in multiple myeloma to enable timely treatment and prevent end organ damage such as renal failure, bone lesions, hypercalcaemia and bone marrow failure. We were concerned that recent advice aimed at primary care physicians stated that a normal erythrocyte sedimentation rate (ESR) may be used to exclude a possible diagnosis of multiple myeloma. It was stated that 'normal levels of inflammatory markers are valuable in ruling out a few specific conditions, notably polymyalgia rheumatica, giant cell arteritis, myeloma and infection of hip revisions'. As per the British Committee of Standards in Haematology (BCSH) guideline we believe that all patients with suspected multiple myeloma should be investigated with screening tests including full blood count (FBC), ESR, urea, creatinine, calcium and importantly, electrophoresis of serum and concentrated urine. Furthermore a serum free light chain assay should be performed in any patient in whom there is a strong suspicion of myeloma and serum protein electrophoresis is negative. This assay is particularly important in the diagnosis of light chain only myeloma, non-secretory myeloma and amyloidosis in whom no monoclonal protein would be detected by routine serum electrophoresis. A recent review recommended serum free light chain assay to be used in conjunction with serum protein electrophoresis when screening for the presence or absence of a monoclonal plasma cell disorder such as myeloma. There is little published work investigating the value of inflammatory markers in the diagnosis or exclusion of myeloma. We therefore performed a concise study of our own patients. **Aims.** The aim of this study was to determine the value ofESRin the exclusion of multiple myeloma. **Methods.** The most recent 100 patients diagnosed with multiple myeloma at North Glasgow Hospitals were identified from our registry. Patient demographics, subtype of myeloma andESRvalue at presentation were obtained from the laboratory database. **Results.** ESRvalues were available in 89 cases. Subtypes of myeloma were recorded; IgG 49%, IgA 20%, Light chain myeloma 25%, IgE 1%, Amyloidosis 3%, Non-secretory myeloma1%; ensuring the sample was representative. The local normal range forESRis ≤12mm/hr. We found 10% of all patients to haveESR≤12mm/hr (within the strict normal range), 25% of patientsESR≤30mm/hr, 48% of patientsESR≤60mm/hr and 70% of patientsESR≤100mm/hr at time of diagnosis. In particular, all patients with amyloid and non-secretory myeloma had anESR≤30mm/hr and 68% of patients with light chain myeloma anESR≤60mm/hr. **Summary and Conclusions.** The low contribution of light chain to the value ofESRhelps explain these findings. ESRis mainly controlled by fibrinogen and other acute phase markers. The molecular weight of fibrinogen is more than ten times that of light chain, markedly limiting the potential effect a rise in light chain can have onESRvalue. This study demonstrates that a nor-

malESRcannot be used to confidently exclude a diagnosis of multiple myeloma, particularly when there is no monoclonal protein present.

1577

ANALYSIS OF FREE LIGHT CHAINS (FLCS) LEVEL IN PATIENTS (PTS) SUFFERING FROM MULTIPLE MYELOMA (MM) COMPLICATED WITH AMYLOIDOSIS ANTIBODY LIGHT (AL AMYLOIDOSIS)

L Usnarska-Zubkiewicz[1], J Holojda[2], J Debski[1], K Kuliczkowski[1]
[1]Wroclaw Medical University, Wroclaw, Poland
[2]Hematology Dept. of District Specialist Hospital, Legnica, Poland

Background. In AL amyloidosis, the amyloid deposits consist of monoclonal immunoglobulin light chains, which are producted by plasma cell clones. **Aims.** The aim of the study was to investigate the relationship between the serum kappa and lambda FLCs and the development of AL amyloidosis in pts suffering from MM. **Materials.** The investigations included 70 pts with MM, 40/30 F/M aged 28-83. In 37 pts MM was diagnosed recently, 33 persons were treated from 2 to 34 months. IgG myeloma was diagnosed in 34 pts, IgA in 16, IgM in 4, light chains disease in 6, non-secretory in 6, solitary plasmocytoma in 4 pts. Fifteen pts developed kidney failure. **Methods.** Amyloidosis was diagnosed on the basis of green-tinged amyloid deposits under a polarized light microscope in the adipose tissue from the abdominal fold. The level of serum FLCs was measured by means of the immunonephelometric method and expressed in mg/l. **Results.** Amyloidosis AL was diagnosed in 18 (25. 7%) pts suffering from MM, 9/9 F/M. In 6 (33%) persons with amyloidosis MM was freshly diagnosed, 12 (67%) revealed progression or recurrence of the disease. sFLCs κ level in 18 pts suffering from MM complicated with amyloidosis ranged from 0. 3 to 4780 (x=854. 5. SD=1289) and was higher (p=0. 039) than in the group without this complication: 0. 3 to 426. (x=68. 9. SD=98. 1). The highest sFLCs kappa level was in the group of 5 pts with MM complicated with amyloidosis and kidney failure; it was higher (p= 0. 0008) than in the group with kidney dysfunction but without amyloidosis and higher (p= 0. 001) in comparison to patients with amyloidosis and normal kidney function. The lowest level of sFLCs kappa was demonstrated in patients without amyloidosis and without kidney failure. Amyloidosis affected 12/45 pts suffering from myeloma with predominating light chain kappa, more often in IgG kappa myeloma (9/12 pts) than in IgA kappa (1/3 pts) (p = 0. 05). sFLCs λ level in pts suffering from myeloma complicated with amyloidosis and kidney failure, similarly to pts without kidney failure, was higher (p= 0. 05 and p= 0. 04) than in the group of myeloma without amyloidosis, regardless of the kidney function. Amyloidosis affected 6/19 pts suffering from MM with light chain λ. There was no predominance of any kind of myeloma with λ chain in the development of amyloidosis. In the group of 18 pts with amyloidosis, 16 revealed abnormal sFLCs κ levels (88. 8%), 14 (77. 8%) abnormal sFLCs λ. In the group of 52 pts without amyloidosis, abnormal sFLCs κ and λ levels were observed in 44 (84. 6%) and 24 (46. 1%) pts respectively (p= 0. 03). The κ/λ ratio in pts with amyloidosis ranged from 0. 0 to 5235 (x=465. 5. SD=1222) and it was higher (p= 0. 001) than in MM pts without amyloidosis: 0. 0 - 209. (x=26. SD=46). In both subgroups the values were higher than in the control group (p= 0. 0001). **Conclusions.** Patients suffering from MM complicated with amyloidosis reveal higher levels of sFLCs. The highest values of the above parameters were observed in MM pts with amyloidosis and kidney failure.

1578

A STUDY OF THE CARDIORESPIRATORY LATE EFFECTS IN PATIENTS WITH ADVANCED INTENSIVELY TREATED MULTIPLE MYELOMA

C Samuelson[1], Y Ezaydi[1], E Cachia[1], D Greenfield[1], S Ahmedzai[2], L O'Toole[1], J Snowden[1]
[1]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom
[2]University of Sheffield, Sheffield, United Kingdom

Introduction. Modern treatment strategies in myeloma have increased life expectancy, but late effects of treatment and disease have not been studied systematically. **Aims.** To define the prevalence, extent and character of cardiovascular and respiratory compromise and its effect on QOL in intensively treated advanced but stable myeloma patients. **Methods.** We present a cross-sectional, exploratory study of patients with myeloma who had received a transplant and at least one subsequent treatment for progressive disease, who are currently in plateau phase. Following informed consent, data collection comprised self-completed questionnaires, full history, clinical examination and relevant investigations. Statistical analysis: Spearman's rank correlation coefficient was used. Ethical approval: obtained from the Sheffield Ethics Research Committee. **Results.** 32 patients were recruited: 17 males; 15 females. Median age was 61 years (range 41-73); median duration from diagnosis 5. 5 years (range 2-12). Many patients had cardiovascular risk factors such as smoking and hypercholesterolemia, and mean total anthracycline dose was 189mg/m2 (range 0-360mg/m2). There was a significant positive correlation between dependent oedema and years since diagnosis and transplant; pain and pain interference [1] and a negative correlation with physical and role function [2]. 59% of patients also had a raised B-type natriuretic peptide (BNP) (>100pg/ml). 3 patients had abnormal echocardiographs, all of whom had raised BNPs. 3 other patients had abnormal ECGs, though these all had BNPs<100pg/ml. Median dyspnoea score was 33 (IQR 0-67). Respiratory function testing showed 66% and 52% of patients to have FEV1 and FVC (respectively) lower than 90% of their predicted value. 67% and 87% of patients respectively had MIP and MEP values below the predicted range. **Summary and Conclusions.** In this relatively small sample of intensively treated advanced stage myeloma patients there is significant evidence of early cardiovascular dysfunction as evidenced by the high proportion of patients with elevated BNP, with some showing evidence of left ventricular strain on ECG or echo, though this dysfunction as yet remains subclinical. Mild impairment of respiratory function was also frequently found, in spirometry testing (mixed obstructive and restrictive features) and symptomatic questioning. Screening and interventional strategies should be investigated further in the effective management of the consequences of advanced myeloma and its treatment with the aim of prolonging survival and optimising quality of life-
Funding. This study has been funded by MyelomaUK.

TREATMENT OF ELDERLY AND FRAIL MULTIPLE MYELOMA PATIENTS WITH LOW DOSE OF LENALIDOMIDE AND DEXAMETHASONE

G Palazzo[1], G Palumbo[2], G Pisapia[3], S De Donno[3], E Leggieri[3], A Tamburrano[3], R Francavilla[3], S Capalbo[2], E Iannitto[3]
[1]Ospedale SG Moscati, Taranto, Italy
[2]Department of Hematology "Ospedali Riuniti ", Foggia, Italy
[3]Department of Hematology,Oncology and BMT Unit "S. G. Moscati", Taranto, Italy

The treatment of elderly and frail patients with multiple myeloma is a clinical challenge. Lenalidomide is a very active drug but at the standard dose the toxicity in frail patients is substantial leading to both dose reduction and premature discontinuation of the treatment. Besides the dose also the duration of the treatment with lenalidomide is of great importance. Actually the rate and quality of clinical responses may continue to increase even after the sixth month of therapy. Therefore, a low dose-regimen could improve the safety profile allowing a steady administration of the drug and optimizing treatment outcome of these vulnerable patients. However, data on the clinical effectiveness of low dose lenalidomide regimens are scarce. We retrospectively analyzed a series of twenty relapsed-refractory frail MM patients considered ineligible for a standard dose lenalidomide and who received a lenalidomide dose ≤ 15 mg (l) in association with dexametasone 20 mg (d)Objective of this analysis was to evaluate the Overall Response Rate (ORR), Progression Free Survival (PFS) and toxicity. Patients characteristics are summarized in Table 1.

Table 1.

Patients	**20**
Age, median (range)	**70 (53-82)**
Age>75 (%)	**5 (25)**
Male/female	**11/9**
Comorbidities (%)	
Hepatic	**3 (15)**
Renal	**2 (10)**
Cardiac	**3 (15)**
None	**6 (30)**
STAGE	
I/II/III	**1/0/19**
A/B	**18/2**
Diagnosis IgG-κ/IgG-λ/IgA-κ/IgA-λ	**7/2/4/2**
Micromolecular l/κ	**4/1**
Median previous therapies(range)	**1(1-5)**
Previous ABMT(%)	**6 (30%)**
Dose of lenalidomide	
10mg n (%)	**17 (75)**
15mg n (%)	**3 (15)**
Cycles ld administered median (range)	**8 (1-24)**

Treatment consisted of low dose lenalidomide (10 mg 17 patients; 15 mg 3 patients) days 1-21, and dexametasone 20mg once a week. (ld)All patients were pretreated, 4 relapsed and 16 refractory to the last treatment (median previous therapies =1; range 1-5). Major causes of exclusion from a full dose RD were: age (5 pts; 25%) hepatic dysfuction (15%), renal dysfuction (10%), cardiac dysfuction (15%). The median time from diagnosis of MM to lenalidomide treatment was 37,7 months (range 7-144) and the median time from the last previuos treatment to ld was 13. 6 months (range:3-40 months)Thirteen patients attained a major response (ORR=55%; CR=10%; VGPR=20%; PR=25%), 2 progressed and 5 had a stable disease (35%). With a median follow-up of 13 months, the PFS and OS are 13. 3 months and 14. 7 months respectively. Five pts died due to progression or other causes related to MM. Treatment was well tolerated, with only two discontinuations due to toxicity (1 deep vein thrombosis; 1 diffuse and desquamating rash). Two patients required support with granulocyte colony-stimulating factor (GCSF) to continue treatment. The results of this retrospective analysis show that ld-RD regimen is well tolerated and clinically effective in frail and elderly MM relapsed-refractory patients. In our opinion, in this setting of highly vulnerable patients for whom the relief of symptoms and the containment of the neoplastic clone are major clinical goals, a tailored treatment with ld-RD seems a feasible and advisable therapeutic strategy. . ld= low dose lenalidomide and low dose dexametasone.

WALDENSTROM'S MACROGLOBULINEMIA:VALIDATION OF INTERNATIONAL SCORING SYSTEM (IPSS)

D Tomin, S Milicevic-Rasic, J Bila, A Bogdanovic, I Djunic, M Virijevic, B Andjelic, B Mihaljevic
Clinic for Hematology, CC Serbia, Belgrade, Serbia

Background. Waldenström macroglobulinemia (WM) is defined as lymphoplasmocytic lymphoma with bone marrow involvement and an IgM monoclonal gammopathy of any concentration. International prognostic scoring system for patients (pts) with WM (IPSS-WM) is very important prognostic factor for their survival providing risk-adapted therapy with better outcome. **Aims.** To analyze the clinical and laboratory data and treatment results in 20 pts with WM according to IPSS-WM. **Methods**: Diagnosis of WM was performed according to WHO 2008 classification. IPSS-WM is defined concerning 5 unfavorable factors(age >65 yrs, Hb ≤115 g/l, platelets ≤100x 10^9/l,serum beta 2MG >3mg/l, IgM paraprotein >70g/l) as low risk (≤1 factor except age),intermediate risk (2 factors or only age >65 yrs), or high risk (> 2 factors). **Results.** There were 15 males and 5 females (p<0,05),with Me age 69,5yrs (range 52-80),and 70% of pts over 65 yrs. According to IPSS-WM there were 4 (20%) pts with low,6 (30%) pts with intermediate and 10 (50%) pts with high risk . Symptomatic disease was presented in 35% pts, and 5/7 (71%) of those pts were with high risk IPSS. Also, all pts with hemorrhagic and hyperviscosity syndrome, lymphadenopathy and 90% of pts with organomegaly were in high risk group. Comparing to other risk groups high risk pts were also pts with higher sedimentation rate (60% pts with SE >100) and higher levels of CRP (87,5% pts), serum proteins (50% pts with proteins >80g/l),IgM paraproteins (Me 39,4 g/l),as well as more frequently hypoalbuminemia (50% pts with low albuminemia) and hypogammaglobulinemia (60% pts). Analysis of structure of risk factors in different risk groups showed that the most frequent unfavorable factors were: ≥65,anaemia ≤ 115 g/l and beta 2MG>3mg/l. In this 10yrs retrospective study pts were treated with different therapy modalities,mostly with chlorambucil (40% pts),regimens MP+VMCP (15% pts),FC+FMD (15% pts),COP+CHOP (10% pts) and without therapy in 20% pts. The best therapy response was in low risk group (75% pts with complete and partial response vs. 66,6% in intermediate vs. 30% in high risk group). Median survival was 41 months with overall survival (OS) after 2 yrs in 76,9% and 5 yrs in 29,9% pts. There were statistical significance between different risk groups (low,intermediate,high risk) in 2yrs OS (100%,100%,46,9%) and 5yrs OS (66,7%, 50%, 0%) (p<0,01). **Conclusions.** Our result confirms the literature data concerning the prognostic value of IPSS-WM for survival and risk-adapted therapy in WM pts. It may be useful for defining WM pts for more aggressive treatment including new therapy approaches .

1581

CLINICAL PRACTICE IN PRIMARY AL AMYLOIDOSIS: QUESTIONNAIRE SURVEY IN HOKKAIDO

T Hayashi[1], H Sakai[2], M Shindou[3], H Kouda[4], S Yamamoto[5], T Miyake[6], M Maemori[2], H Ikeda[1], M Nojima[1], H Yasui[1], T Ishida[1], Y Shinomura[1], T Fukuhara[7]

[4]Asahikawa Red Cross Hospital, Asahikawa, Japan
[5]Sapporo City General Hospital, Sapporo, Japan
[6]Asahikawa City General Hospital, Asahikawa, Japan
[7]Sapporo Kosei General Hospital, Sapporo, Japan

Background. Primary AL amyloidosis is a rare clonal plasma cell disorder characterized by a deposition of monoclonal light chains in various tissues and organs. Except for some relatively fit patients participating clinical trials, current status in clinical practice for patients with AL amyloidosis remains unclear due to its rarity and heterogeneity. **Aims.** The aims of this investigation are to convey a practical picture of the disease, its response to treatments, and outcomes in terms of organ function and survival of patients with AL amyloidosis in Hokkaido, Japan's northern islands, regardless of age, disease severity, or treatments. **Methods.** Hokkaido Hematology Study Group conducted a questionnaire survey about clinical practice for patients with AL amyloidosis diagnosed from January 1, 2006 to December 31, 2010. All patients were biopsy-proven and consecutively accumulated. Patients received treatments in local hematology centers, and regimens and doses were at the discretion of treating physicians. Organ involvement and treatment response were evaluated according to a consensus opinion from the 10th international symposium on amyloid and amyloidosis. **Results.** Data from 39 patients were accumulated from eleven secondary or tertiary referral centers for hematologic diseases in Hokkaido. Forty-nine percent were male and median age at presentation was 67 years (range 32 to 82). Median time from awareness of subjective symptom to the first visit to clinic was 39 days (maximum 7 years). Renal (49%) and cardiac (31%) presentations were predominant, followed by symptoms from gastrointestinal tract or neurological involvement. Most (89%) of the patients with renal symptoms have already suffered from nephrotic syndrome. Median time from the first visit of patients to the diagnosis was 64 days (range 7 to 367 days). Involvement of 1 organ was present in 9 patients, 2 organs were involved in 10, and 3 or more organs in the remaining 20. Distribution of organ involvement was as follows: kidney, 77%; gastrointestinal tract, 74%; heart, 49%; peripheral neuropathy, 23%; and liver, 15%. First-line treatment was with traditional regimen (like MP or VAD) in 8 cases, with novel agents (bortezomib or thalidomide) in 14. Fourteen patients received a high-dose melphalan with autologous stem cell transplantation (ASCT) as first line treatment. Hematologic CR observed in 11 (32%) cases, PR in 3 (9%), SD in 20 (59%); organ response was observed in 5 (16%) cases. At the time of analysis, median survival time from diagnosis was 524 days (range 51-1536 days). Cases of death include heart failure, infection, and renal failure; 13 patients have died within one year from diagnosis. Cardiac involvement, serum brain natriuretic peptide >200 pg/ml, and uric acid >7. 0 mg/dl were risk factors for death. Patient receiving ASCT with 200 mg/m^2 of melphalan pretreatment significantly prolonged survival. **Conclusions.** This study has revealed present status of clinical practice for patients with AL amyloidosis in designated area. The inclusion of most patients, regardless of disease severity, indicates a persistently poor prognosis among a substantial proportion of patients in a practical setting, and highlights the unmet need for improved diagnosis and treatment strategies.

1582

VALUE OF THE FREE LIGHT CHAIN ANALYSIS IN THE CLINICAL EVALUATION OF RESPONSE IN MULTIPLE MYELOMA PATIENTS RECEIVING ANTI-MYELOMA THERAPY

T Hansen[1], C Nielsen[2], T Pedersen[3], B Ambi[3], N Abildgaard[3]

[2]Department of Biochemistry, Esbjerg, Denmark
[3]Department of Hematology, Esbjerg, Denmark

Introduction. More than 95 % of patients with multiple myeloma (MM) have an increase of either κ or λ free light chains (FLC) in serum, or an abnormal κ/λ-ratio (rFLC). Since the FLC have a very short serum half-life of 2-6 hours, compared with the serum half-life of the intact immunoglobulin, being days to weeks, we would expect that measuring FLC could give us an advantage in the response evaluation of the therapeutic effects of a given anti-myeloma treatment. **Aims.** Assess the time to 50 % reduction of serum involved FLC ("clini-

cal"half-life, $t_{½}$) in MM patients receiving anti-myeloma therapy, and to determine if measurements of involved FLC (iFLC) provide faster, yet reliable, information on the effectiveness of a given anti-myeloma treatment. **Methods.** We measured the levels of iFLC in 18 patients with symptomatic MM before treatment, 1, 2, 3, 4, and 5 week days after the first anti-myeloma treatment, and 2, 3, and 6 weeks after. Informed consent was obtained. The patients were evaluated for response according to the international uniform response criteria. Serum half-life were calculated using the exponential regression model, based on the formula $y = b * a^x$. A significant reduction in FLC was defined as $\sqrt{2} * 1.96 * \sqrt{CVtotal^2}$. The patients were treated with bortezomib-, thalidomide-, or alkylator-based chemotherapy. **Results.** Seven (39 %) patients achieved VGPR or better, 4 (22 %) PR, 6 (33 %) SD, and 1 patient was not evaluable (died in first treatment). Four patients had iFLC below 100 mg/L, and only one of those showed a significant reduction in iFLC, while 3 had no reduction and therefore not evaluable $t_{½}$. Fifteen patients (83 %) had an initial significant reduction in iFLC. The half-life of iFLC was 4. 8 (2. 2 - 9. 6) days for patients achieving ≥ VGPR, 7. 2 (1. 8 - 18) days for patients achieving PR, and 4. 1 (2. 7 - 5. 6) days for patients with SD. The patients achieving ≥ VGPR all had an early response and a continued significant reduction of iFLC between second and third cycle of treatment. **Summary and Conclusions.** The serum half-life is very different (1. 8 - 18 days) in MM patients but not predictive of final response. Surprisingly, all patients with pre-treatment iFLC levels >100 mg/L showed early significant reduction, even patients with SD. To predict achievement of good response it is important to observe a continued decline in iFLC during the following treatment cycles. Our sampling is continuing and we will be able to present data on a larger cohort at the meeting.

PRELIMINARY EXPERIENCE OF THE SPANISH COMPASSIONATE USE REGISTRY OF BENDAMUSTINE IN PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA (MM R/R)

B Aguado[1], I Vicuña[1], I Krisnik[2], B Navas[3], C Alaez[3], M Royg[1], S Martínez[1], N García-León[1], A Alegre[1]
[1]Hospital La Princesa, Madrid, Spain
[2]Hospital puerta de hierro, Madrid, Spain
[3]Hospital Moncloa, Madrid, Spain

Background. Bendamustine is a dual alkylating agent with demonstrated efficacy in de novo MM and MM R/R. We present preliminary results from the experience of Spanish compassionate use registry of this agent in different treatment schedules of MM R/R, promoted by the GEM / PETHEMA Group (Study Benda-MMRR-11). This study has been approved by local ethical committee, CEIC, HUP, Madrid, Spain. **Patients and Methods.** 20 patients, 11 males and 9 females, with advanced MM R/R after several lines of previous treatment received a schedule containing Bendamustine. Median age was 63 (35-86), with a median of 6 previous rescue lines (1-9). Bendamustine dose used ranged between 90 and 100 mg/m2 iv on days 1 and 2 for each 28 days cycle. The median of cycles was 4 (1-8). The combinations used were: Bendamustine + Bortezomib + dexamethasone in 5 patients, Bendamustine + Dexamethasone in 5 patients, Bendamustine + Thalidomide + Prednisone in 9 cases and Bendamustine + Prednisone in one case. **Results.** In the 18 evaluable patients, overall response rate (ORR) was 49. 9%, with partial response (PR) of 33. 3%, complete response (CR) of 11. 1%. Minimal response (MR) was of 5. 5%, and stable disease (SD) was of 5. 5%. Progression was documented in 44. 4% of patients. In general, treatment was well tolerated; the most common adverse effect was hematological toxicity. We observed, grade 3-4 neutropenia in 38%, grade 3-4 thrombocytopenia in 33. 3% and grade 3-4 anemia in 22%. Among other toxicities noted infections in 16% of patients. **Summary.** Treatment with Bendamustine can be a therapeutic alternative in patients with MM R/R. Our results are consistent with published data in larger series of patients. More experience is needed with this agent, find the best combination and assess its grade of efficacy in earlier stages of myeloma evolution.

1584

BENDAMUSTINE COMBINATION THERAPY IS ASSOCIATED WITH POOR OUTCOME IN MYELOMA PATIENTS WITH ADVERSE CYTOGENETICS WHO RELAPSED FOLLOWING A PROTEASOME INHIBITOR AND ARE REFRACTORY OR INTOLERANT TO IMIDS

E Smith, R Popat, L Percy, J Dickson, S Cheesman, S D'Sa, K Yong, N Rabin
University College Hospital, London, United Kingdom

Background. Treatment options for MM patients who relapse following bortezomib and IMIDs remain limited, with a median overall survival of 9 months (Kumar et al, Leukemia 2012). At least part of this is due to the accumulation of adverse cytogenetic features with disease progression such that end stage patients frequently exhibit poor risk features. Therefore therapies must have activity in such patients to be of benefit. Bendamustine is a cytotoxic alkylating agent with pre-clinical activity in chemotherapy resistant MM. It has been increasingly used in the relapse/ refractory setting however its activity in high risk cytogenetic MM has not yet been determined. **Aims.** To determine the efficacy of bendamustine combination therapy in patients with relapsed and/ or refractory myeloma particularly those with adverse cytogenetic features. **Methods.** A retrospective single centre study of 13 patients with relapsed MM that received bendamustine 60mg/m^2 on days 1, 8, 15 of a 28 day cycle. 4 patients received corticosteroids whilst 9 received thalidomide (up to 100mg) in addition to corticosteroids. Responses were assessed by IMW response criteria and progression free survival (PFS), and overall survival (OS) assessed according to IMW consensus criteria. Interphase FISH was performed on CD138 selected cells. **Results.** Median age was 62 years (range 46-80) and patients had received a median of 4 prior lines of therapy (range 3-6). All patients received prior bortezomib and twelve patients (92%) received prior IMID (10 prior lenalidomide). Nine patients (69%) had disease progression on their last line of therapy whilst four (31%) had stable disease. Cytogenetic information was available on 10 patients (77%) of whom four (40%) had adverse cytogenetic features including 17 p deletion (n=1), t(4:14) (n=1) and chromosome 1 abnormalities (n=4). Patients received a median of 3 treatment cycles (range 1-6). Grade 3/4 treatment emergent toxicity was as follows: neutropenia (n=5), anaemia (n=1), thrombocytopenia (n=1) with ≥grade 2 infection in 5 patients. Overall response rate (≥PR) was 23% (PR 3; 23%, SD 3; 23%, PD 7; 54%) with a clinical benefit rate (≥SD) of 46%. After a median follow up of 3. 9 months (range 1. 0-11. 0), the median PFS was 3. 6 months. For those with adverse cytogenetics (n=4) the median PFS was 2. 7 months, compared to median PFS not yet reached for standard risk disease. The addition of thalidomide made no difference to response or PFS. Two (15%) died of progressive disease, 1 (8%) died of unrelated causes, and 9 (70%) remain alive (1 patient lost to follow up). The median OS has not yet been reached. **Conclusions.** For MM patients who have relapsed following bortezomib and predominantly refractory to IMID, the clinical benefit rate (≥SD) for bendamustine combination was 46% with no benefit with addition of thalidomide. Patients with adverse cytogenetic features had extremely poor outcomes (median PFS of 2. 7 months, compared to 3. 6 months whole group). Although a limited study, this suggests that such patients would not benefit from this approach and should be considered for combinations with other novel agents such as proteasome or HDAC inhibitors.

1585

ASSESSMENT OF BONE METABOLISM IN MULTIPLE MYELOMA

C Onishi[1], S Yano[2], T Okada[3], K Adachi[4], S Kumanomido[5], F Ikejiri[6], K Kawakami[7], M Inoue[8], T Miyake[9], T Takahashi[10], J Tanaka[11], J Suzumiya[12]

[3]Takahiro, Izumo, Japan
[4]Koji, Izumo, Japan
[5]Satoshi, Izumo, Japan
[6]Fumiyoshi, Izumo, Japan
[7]Koshi, Izumo, Japan
[8]Masaya, Izumo, Japan
[9]Takaaki, Izumo, Japan
[10]Tsutomu, Izumo, Japan
[11]Junko, Izumo, Japan
[12]Junji, Izumo, Japan

Background. Multiple myeloma (MM) is a plasma cell malignancy characterized by bone destruction with activated osteoclast (OC) and suppressed osteoblast (OB), which is sometimes associated with hypercalcemia. Increased levels of bone resorption marker such as urinary NTx and CTX-1 were observed in MM patients with osteolysis. Tartrate-resistant acid phospatase 5b (TRACP-5b) is one of bone resortion markers, which has recently been introduced. Since TRACP-5b, bone formation markers procollagen type I N-terminal propeptide (PINP) and bone alkaline phosphatase (BAP) are not affected by renal function, they may be suitable for the assessment of bone metabolism in MM. **Aims.** The aim of this study is to assess bone metabolism by TRACP-5b, PINP, BAP, and osteocalcin (OC) in untreated MM patients with progressive osteolysis. **Methods.** We measured serum concentrations of TRACP-5b by EIA (normal range are 170-590 and 120-420 mU/dL in men and women, respectively), PINP by double antibody radioimmunoassay (normal range are 19. 0-83. 5, 14. 9-68. 8, and 27. 0-109. 3 µg/L in men, premenopausal women, and postmenopausal women, respectively) and BAP by CLEIA (normal range are 3. 7-20. 9, 2. 9-14. 5, and 3. 8-22. 6 µg/L in men, premenopausal women, and postmenopausal women, respectively), and OC by IRMA (normal range is 2. 5-13. 0 ng/mL) in ten untreat-

ed MM patients (4 men, 6 women; age range, 49-82 years; mean age, 69 years) with osteolysis revealed by computer tomography. **Results.** The mean serum concentrations of Ca, Cr, TRACP-5b, PINP, BAP, and OC were 10. 8 mg/dl, 1. 49 mg/dl, 585. 1 mU/dL, 85. 2 µg/L, 28. 5 µg/L, and 8. 0 ng/mL respectively. Serum TRACP-5b levels were within normal range in 6 patients and higher than the normal range in the remaining 4 patients. In a simple regression analysis, TRACP-5b levels had a weak correlation with PINP levels (r=0. 50, p=0. 14), although they had no correlation with BAP (r=0. 09, p=0. 79) and OC (r=0. 19, p=0. 59). Serum PINP levels were higher than the normal range in 5 out of 10 patients, lower than the normal range in 2 patients, and were within the normal range in 3 patients. Mean serum Ca level was 10. 9 mg/dl in patients with high PINP levels whereas it was 8. 7mg/dl in other patients (p=0. 08). A weak correlation was found between basal levels of serum Ca and PINP (r=0. 36, p=0. 30), although there was no correlation between basal levels of Ca and BAP as well as TRACP-5b (r=0. 11, p=0. 77), suggesting a possible impairment of bone mineralization in patients with high PINP levels. **Conclusions.** TRACP-5b levels had a weak correlation with PINP but not with BAP and OC. We unexpectedly found the marked diversity of serum PINP levels in MM patients. The patients with high PINP levels had a tendency of hypercalcemia.

VELCADE-DEXAMETASONE CICLES UNTIL THE BEST RESPONSE FOLLOW BY AUTOLOGOUS STEM-CELL TRANSPLANTATION AS FIRST LINE OF THERAPY IN YOUNGER MULTIPLE MYELOMA PATIENTS

JM Bergua[1], J Prieto-Fernández[1], F Carnicero[1], F Ibañez[1], H Hernandez-Leyva[1], C Cabrera[1], M Martín-Mateos[1], J Groiss[2], R Ramos[3], C Scida[4], E Duvos[4], D Toral[5], M Arcos-Carmona[1]
[1]Hospital San Pedro de Alcántara. Cáceres, Cáceres, Spain
[2]Hospital Infanta Cristina, Badajoz, Spain
[3]Hospital de Mérida, Mérida, Spain
[4]Hospital de Coria, Coria, Spain
[5]Hospital de Don Benito, DonBenito, Spain

Purpose. Analysis of response to Velcade-Dexametasone treatment until maximum response before autologous stem-cell transplantation (ASCT) in patients newly diagnosed of Multiple Myeloma (MM). Protocol: Induction therapy: Velcade was administrated at dose of 1,3 mg on days 1,4, 8,11 of each cycle. Dexametasone at dose of 40 mg/m^2 on days 1-4, 9-12 and 17-20 of each cycle. Response was evaluated in the first day of each cycle performing proteinograme, inmunofixation in blood and urine. We determine maximum response when monoclonal component remain estable for two consecutive cycles. Mobilization: was performed with G-CSF. Melphalan at dose of 200 mg/m^2 was used as conditioning regimen in all the patients. No post-trasplant chemotherapy was permitted until relpse or progression. **Patients.** 21 consecutive patients of Hospitals of Extremadura from March 2009 to March of 2011. Men/Women: 8/13. Median age was 52,3 (41,7-68,9). Durie-Salmon estage was: IA: 6 patients, IIA: 4. IIIA: 7, IIIB: 4. IgG: 7 (33%), IgA: 6(28,5%), Bence-Jones 7(33%), non-secretor 1 (4,76%). Karyotype: Normal: 13 (61%); del 17p: 2(9,5%), t(11,14): 1, t(4,14): 1, add 14+t(11,14). 1, t(4;14): 1. Non-avaible: 2. Three patients presented plasmocytomas at diagnosis. Beta-2-microglobulin was 3,5 (1,8-12,07). Number of cycles administrated was 4(3-9). Median follow-up is 22,4 months (12,566-38,43 months). The median follow-up from ASCT was 9,6 (7,2-22). No-one patient died during induction therapy and during ASCT. The median of aphaeresis performed by patient was 1 (1-4) and the median CD34 cells obtained were 3,6x10^9/L (2,5-7,3x10^9/L). The number of complete responses after induction therapy were 7 (33%); partial response 12 (57%), and failure 2(9,5%). The number of patients in complete response three months after ASCT were 14 (66%). No patient has death. Six patients have relapsed and Five are in treatment with Lenalidomide-Dexametasone at a median time of 16 months after ASCT. **Conclusions.** Increasing the number of cycles of VD before ASCT is a feasible strategy to treatment of new diagnosed MM. The rates of CR and PR are comparable to three drugs scheme as Velcade-Thalidomide-Dexametasone (VTD).

1587

LENALIDOMIDE AS RESCUE THERAPY IN MULTIPLE MYELOMA: A SINGLE-CENTRE EXPERIENCE

B Gamberi, L Masini, L Tognazzi, F Merli
Hematology Unit, Department of Oncology, Azienda Ospedaliera ASMN, Reggio Emilia, Italy

Background. In recent years, new first line therapeutic strategies induce a high percentage of remissions in multiple myeloma (MM) patients, but, eventually, a great amount of patients relapses and requires further treatment. **Aims.** retrospective evaluation of response to lenalidomide and related toxicity in refractory/relapsed patients in a single centre real-life setting, outside of clinical trials. **Methods.** From October 2007 until November 2011, 47 MM patients have been included: 27 males, 20 females; median age 74 years (range, 50-89); 33 IgG, 6 IgA, 5 light chain, 3 non secretory. Eight patients (17%) had renal failure. Median time from diagnosis was 41 months (range 3-238 months) and 15 patients had received autologous bone marrow transplantation (ABMT) as first line approach. In 20 patients we used lenalidomide as second line (43%), in 14 patients as third line (30%), in 8 patients as fourth line (17%), in 3 patients as fifth line (6%) and in 1 patients as sixth and seventh line (2% respectively). Several combination were used: 2 CPR, 1 RAD, 1 MPR. Median number of cycles was 7 (range, 2-37), 13 patients are in active treatment; treatment was continued until progression. **Results.** According to IMWG criteria, 28patients (60%) achieved a response [1 (2%) CR, 10 (21%) VGPR, 17 (36%) (PR)], while 19 patients (40%) had a stable/progressive disease (SD/PR). Median PFS at 15 months was 60% and OS from the onset of lenalidomide was 47% at 24 moths. With a median follow up of 14 months (range, 4-44), 32 patients had progressed (68%) and 19 of them (40%) have deceased. Average response was 5 month (range, 1-27). No differences in obtaining response or in length of PFS due to age (less than vs greater than 65) or response (VGPR/CR vs PR) were found, while PFS is significantly better considering number of previous line of therapy (1-3 lines vs more than 3 lines;21 m. vs9 m) (p less than0,05). No difference has been shown in OS in the different groups. Furthermore we find a difference PFS in patients obtaining even only a partial response vs a stable disease (22 m. vs6 m; p 0,001). No difference has been shown in OS of the two groups. Grade 3/4 adverse event included 10 patients with neutropenia (21%), 2 patients with thrombocytopenia and fatigue (4%), 1 patient with rash (2%), 1 patient with lymphopenia (2%), cardiac failure, pneumonia (3%). Seven patients (21%) delayed or discontinued therapy due to toxicity. 11 patients (23%) had presented neuropathy during lenalidomide treatment. No secondary primary malignancies were found during lenalidomide treatment (only 5 patients (11%) were treated with more/equal 24cycles). **Conclusions.** This retrospective analysis shows effectiveness and safety of lenalidomide when used in routine clinical practice similar to those reported in clinical trials. In addiction it demonstrates the importance of obtaining even a partial response against a stable disease, at least in this setting of patients who are continuously treated until progression.

1588

IMPROVING RESPONSE RATE IN ELDERLY PATIENTS AFFECTED BY MULTIPLE MYELOMA USING LENALIDOMIDE AS PROLONGED THERAPY

A Gagliardi, S Improta, MR Villa, L Mastrullo
UOC Ematologia ASL Napoli 1 Centro, Naples, Italy, Naples, Italy

Background. lenalidomide is a new immunomodulatory drug with a dual mechanism of action: tumoricidal effect and immunomodulatory effect. It represents an important treatment option for multiple myeloma patient either as first line therapy, either in resistant/refractory disease or consolidation/maintenance therapy. In this way lenalidomide increases the available treatment options. **Aims.** In our Department, lenalidomide was administered in elderly patients affected by resistant/relapsing myeloma or as consolidation/maintenance therapy in patients with stable disease (partial remission) after induction therapy or more lines of chemotherapy. **Methods.** We treated 44 patients (23 M and 21 F) with median age of 70 years (range 66-81). We have evaluated 33 patients with a median follow up of 24 months. These patients were treated with lenalidomide at variable doses (5-25 mg/die p.o., according to tolerability of each patient, for 21 days every 28 days) alone as continuous treatment. We used enoxaparin for prophylaxis of venous thromboembolisms. Clinical restaging was performed after three, six and twelve courses of therapy. **Results.** At present we have observed in 24/33 patients a good impact on monoclonal component. 15 out of 33 patients previously in PR shifted to a better responce (5 to nCR or CR and 10 to VGPR). In the other 7, previously in stable disease, we observed, after a median of 8 courses of lenalidomide, a shift to a PR. Therapy was well tolerated in all patients and we didn't observed any significant adverse events. **Conclusions.** Lenalidomide as prolonged therapy can have an established role in a very bad subset of patients as the previously treated elderly myeloma patients. Our data demonstrate that lenalidomide improves response rate in these patients without causing severe complications.

1589

TREATMENT OF BENCE-JONES MULTIPLE MYELOMA WITH CHEMOTHERAPY WITH/WITHOUT STEM CELL TRANSPLANTATION-SINGLE CENTRE EXPERIENCE

A Zivanovic-Ivic[1], L Tukic[2], D Stamatovic[2], O Tarabar[2], S Marjanovic[3] L Madjaru[2], M Elez[2], J Knezevic[2], Z Tatomirovic[4], Z Mijuskovic[5], P Krstic[2]
[1]Clinic of Haematology, Military Medical Academy, Belgrade, Serbia
[2]Clinic of Hematology,MMA, Belgrade, Serbia
[3]Clinic of Haematology, MMA, Belgrade, Serbia
[4]Institut of Patology,MMA, Belgrade, Serbia
[5]Institut of Medical Biochemistry,MMA, Belgrade, Serbia

Background. Bence-Jones meyloma multiplex is a progressive disease characterized by excesssive numbers of abnormal plasma cells in the bone marrow and overproduction of incomplete immunoglobulins, containing only the light chain portion of the immunoglobulini. This type of myeloma occurs 15-20%. The median overall survival is approximately 4 years. Patient outcome in Bence-Jones myeloma has been remarkably improved due to the use of combination therapies including chemotherapy and stem cell transplantation. High-dose melphalan with autologus stem cell support has been an integral part of myeloma therapy for more than 25 years. **Aims.** A retrospective analysis of outcome of treatment Bence-Jones myeloma. **Patients and Methods.** Since 1995. until 2011. we were treated 54 pts (37 men and 17 female), average age 56 years (range 36-85). According to the clinical stage, patients were divided as follows: 3 pts ICS, 13 pts IICS, 38 pts IIICS. Regarding ISS score, the group included: ISS1 16 pts, ISS2 9 pts, ISS3 29 pts. Renal insufficiency was present in 30 pts. High risik pts was defined by the presence of following factors: b2M >5,5 mg/l, albumine<3,5gr/dl, CRP >6, high lactat dehydrogenase, renal failure, stage III. Patients treated with induction, consolidation and maintenance therapy. Conventional induction treatments were applied as following regimens: VAD (40), MP (9), CTD (1), PAD(2) and TAD (2). **Results.** Conventional chemiotherapy introductory clinical response was achieved in 35pts (65%) (MR-4 pts, PR- 14 pts, VGPR- 17 pts), while in 19 pts (35%) established disease was resistant. Transplantation had been done with 29 pts (54%), while 25 pts (46%) were treated with conventional chemotherapy adjusted to the vital age and comorbidity. In the group of pts with transplantation done tandem had been carried out with 9 pts and secondary SCT had been done in 4 relapsed pts. With 1 pts with tandem SCT allogenic(singen) SCT had been done. TRM is 3,4%. Maintenance therapy with Thalidomid had been done in 25 pts for 4-38 months. Impact of high risk factors on outcome/TTP/OS was of no significance, but the transplanted patients had significantly longer TTP (mediana 8 months vs 6 months, p=o,o11) and longer OS (mediana 42 months vs 20 months,p=0,0003). 20 pts (37%) of treated pts are living, while 34 pts (63%) died. Univariate log. regres. analysis showed that non-transplant patients are 10,41 times more likely to terminate lethal compared to transplant patients (RR 10,41(95%C. I. 43,47-2,52),p<0,001). **Conclusions.** Our study showed ASCT is a more effective method of treatment of patients with BenceJones myeloma compared to the conventional chemotherapy, but the results are still unsatisfactory. One of the major efforts to improve the results of intensive therapy and ASCT involves the integration of novel agents (proteasome inhibitors and immunomodulatory drugs) into the transplantation sequence.

1590

IGM MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE (IGM MGUS): BETWEEN THE ANALYTIC FINDING AND B-CELL MALIGNANCIES

I Murillo Flores, I Parra, J Quintero, M Andrade, P Giraldo
Hospital Miguel Servet, Zaragoza, Spain

Background. MGUS is common in the general adult population aged 50-60 years or older, the IgM subtype is the less common and the incidence of lymphoproliferative disorders associated with a monoclonal IgM component in the serum is a very rare disease, 1-2% of hematological malignancies. A personal history of the precursor condition IgM MGUS is associated with a risk of developing lymphoplasmacytic lymphoma/Waldenström´s macroglobulinemia LPL/WM and an increased incidence of second neoplasm has been reported in lymphoproliferative disorders. **Aims.** To describe demographic, clinical and outcomes features of our serie of patients with IgM MGUS. **Methods.** A review of medical records of patients diagnosed or followed by IgM MGUS between january 1990 and december2010 ina single center was performed. Data on clinical, biochemical, inmunological and cytogenetics features, therapy, second malignancies and the mortality were obtained. Recently we have incorporated the Hevylite measures IgMkappa and IgMlambda, separately, and apply to determine the IgM M-spike in our cohort. **Results.** A total of 27 patients were registered (M/F: 15/12), the median age was 67 (46-86) years. Diagnosis of IgM MGUS 11 / 41% and LPL/WM 16 / 59%: symptomatic 5 / 31% and smoldering 11 / 69%. At the time of diagnosis the patients had developed enlarged spleen (40%), visual disturbances (40%), neuropathy (20%), hyperviscosity symptoms (20%) and hepatomegaly (20%). We have analyzed the ratio IgMkappa/IgM-lambda as biomarker of malignancy significant. The incidence of second neoplasia was 15% and B-cell malignancies in first-degree relatives 8%. High b2-microglobulin (93%), increased sedimentation rate (74%), anemia (30%) and low platelet count (11%) were the most common analytical features. The median concentration of M-spike was 1. 43 mg/dL (0. 32 - 3. 49), 65% kappa subtype, proteinuria was not detected. The median bone marrow lymphoplasmacytic infiltration was 31. 5% (12. 6-82. 2), usually interstitial, and mast cells was seen in 35% of patient. Typical inmunophenotype (CD5- CD10-, CD19+, CD20+, CD23-) by flow cytometry in 52% of the patients and cytogenetic abnormalities in 5 / 19%: del(6q21): 60%, t(14q32): 40%, t(18q21): 20% and t(13q14): 20%. There were progression in 3 cases (to symptomatic LPL/WM, NHL's large cell-B brain) after an average follow-up of 12 years. The first-line therapeutic approachs was needed in 6 (22%) cases, with alkylating agent-based regimens 4 / 66%, rituximab 1/17% and R-COP 1 /17%, a partial response in all cases was obtained and relapse/progression in 4 / 66% cases. Plasmapheresis in one case by hyperviscosity syndrome. The median survival free of progression: 20 months Mortality: 4 / 15% patients: two by infection, one by progression and one by bleeding. **Conclusions.** In our experience, the discovery of IgM MGUS is not synonymous of malignancies, have been frecuently indolent (81%) and slow progression, 13. 6% to the 12 years of the diagnosis. We highlight the development of second malignancies in 15% of cases. Despite 59% of the cases met criteria of LPL/ MW only 22% received chemotherapy treatment. Future studies are need to define molecular markers that distinguish low - and high-risk precursors patients.

1591

REMISSION DURATION AND QUALITY OF RESPONSE IMPROVEMENT IN ADULT MULTIPLE MYELOMA PATIENTS WITH BORTEZOMIB MAINTENANCE POST AUTOLOGOUS STEM CELL TRANSPLANTATION: A SINGLE CENTRE EXPERIENCE

M Norata[1], V Bongarzoni[1], R Greco[2], F Pauselli[1], B Anaclerico[1], P Anticoli Borza[1], M Cedrone[1], A Chierichini[1], I Coppola[1], S Fenu[1], B Ronci[1], S Cortese[1], R Bruno[1], L Annino[1]
[1]Azienda Ospedaliera "San Giovanni- Addolorata", Roma, Italy
[2]Dipartimento di Ematologia. Ospedale Niguarda Cà Granda, Milano, Italy

Background. In the past decade single or tandem ASCT was considered the standard treatment in adult MM. However ASCT demonstrated to be not able to prevent disease progression. Thus in these years a post-ASCT maintenance based on bortezomib, thalidomide or more recently lenalidomide is becoming the consolidating approach in the aim to prolong and/or to improve post ASCT response. **Aims.** In December 2007 asingle center study has been activated to define the impact of Bortezomib single agent maintenance for 24 months a) on time to progression (TTP) and Time to Next Treatment (TNT) b) the feasibility and toxicity of this treatment. **Methods.** Between November 2006 to June 2009 14 MM pts- underwent single (2) or tandem (12) ASCT received Bortezomib maintenance (BG). Of these 9 were males and 5 females- median age 58 y (range 29-67y)- At MM diagnosis 9 were IgG (7 k, 2 λ), 3 IgA (1 k, 2 λ), 2 micromolecular (1k, 1 λ). As stage11 pts were D-S ≥III (13 A, 1B) and4 pts ISS ≥III, respectively. Baseline cytogenetic showed 13 q- in 5/13 pts studied. We considered as control group 13 pts-5 males and 8 females- median age 60(range 51-64 y)-underwent single (7) or tandem (6) ASCT. . Maintenance schedule consisted of Bortezomib as single agent given at dosage 1. 5 mg every 15 days until progression. Response was evaluated according to the International Myeloma Working Group criteria. Peripheral neuropathy (PN) was monitored before maintenance start, then every 3 mo by neurophysiologic motor and sensory conducting tests. **Results.** In the BG maintenance was started in a median time of 3. 1 mo (range 1. 7 -13. 7), from ASCT,8 ptswere in CR orVGPR, 6 PR. The overall response rate was 72%, with 57% CR+VGPR. As of February 2012, after a median maintenance time of 20 mo (range 4. 1 -24); 10/14 pts are alive. 7 (50%) in CR, 1 was lost to follow-up, 2 with progressive disease. It is surprising that FISH analysis in 4/5 progressive-relapsed disease during maintenance had 13q- abnormality at diagnosis. Since not all pts underwent 2nd ASCT, TTP and TNT was evaluated from 1st ASCT. In the BG median TTP is 32 mo, whereas in the CG median TTP is 12 mo (p<0. 005). Median TNT in BG is 34 mo whereas in the CG median TNT is 13 mo (p< 0. 005). At median follow up of 62 mo (38-71) median OS has not yet been reached in BG, In CG at median follow up of 96 mo (55-119) median OS is 58 mo (p= n. s.). Finally, none of pts in the BG experienced grade 3 or 4 haematologic toxicity and/or PN requiring dose reduction or drug discontinuation . **Summary and Conclusions.** the prolonged follow up confirms that Bortezomib-single agent maintenance in post-ASCT is active and safe to prolong TTP, TNT and able to improve response quality.

1592

CYCLOPHOSPHAMIDE THALIDOMIDE DEXAMETHASONE (CTD) AS FIRST-LINE THERAPY IN MULTIPLE MYELOMA. EXPERIENCE IN A HOSPITAL IN LIMA, PERU

D Del Carpio-Jayo, J Untama-Flores, J Navarro-Cabrera
HERM, Lima, Peru

Multiple myeloma is a common disease in our hospital presenting 40 to 50 new cases a year. We present a retrospective study of 41 patients undergoing chemotherapy CTD as first-line regimen in the Rebagliati Hospital - EsSalud of Lima, Peru, between May 2008 and December 2011. The age of patients was 31-76 years (mean: 41 y). Men 24 and women 17. Debut ISS score: I (8), II (14), III (10). The responses were: CR (8), VGPR (7), PR (17), SD (1) and PD (2). CR + VGPR: 42% (15), CR + VGPR + PR: 91% (32). Time to response 3-12 months (mean: 5 m). Progression-free survival (PFS): mean 14. 8 months (1. 4-39. 6 m). 15 patients underwent autologous BMT. CTD is an effective and inexpensive treatment of MM for countries with limited economic resources.

CYTOKINE PROFILES IN POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTEMIA: CLINICAL IMPLICATIONS

P Mossuz, E Pourcelot, C Trocme
Institute of Biology and Pathology, Grenoble, France

The most frequent complications of Polycythemia vera (PV) and Essential thrombocythemia (ET) are thrombosis and bleeding risks that influence decision of a specific therapy. One mechanism involved cytokines that put forward modulate haemostasis and thereby favour thrombotic events. The hypothesis of a clinical impact of plasma cytokines levels is reinforced by reports about the mechanism of JAK2 inhibitors on constitutional symptoms, consequence of the down-regulation of some cytokines levels. In this context we have initiated a comparative study of plasma cytokine expression profiles as a function of vascular complications and JAK2V617F status of PV and ET patients. From the plasma of seventeen patients diagnosed with PV and twenty one patients affected by ET, cytokine measurements were carried out using a multiplex cytokine assay. Cytokine chosen were pro-inflammatory cytokines: IL-1β, IL-6, IL-8, IL-12(p70), TNFα and IFNγ, anti-inflammatory cytokines: IL-4, IL-10, the MCP-1 chemokine and growth factors: GM-CSF, PDGF-BB, VEGF and HGF. Twenty two of these patients (10 PV and 12 ET) have experienced at least one thrombo- hemorrhagic manifestations. Comparing cytokine profiles between the group with and without vascular complications, no significant difference was observed except for IL-12(p70) for which the difference was hardly significant (p=0. 047). However, the subgroup of PV patients displayed a significant difference for IL-12(p70) (p=0. 025) and for GM-CSF (p=0. 040). No such difference was observed with the group of ET patients. We have also compared cytokine profile between ET and PV patients and we have clearly discerned different cytokine profiles with a statistical significance for IL-4 (p=0. 006), IL-8 (p=0. 003), GM-CSF (p=0. 026), IFN-γ (p=0. 007), MCP-1 (p=0. 009), PDGF-BB (p=0. 015) and VEGF (p=0. 017). Interestingly, all cytokine concentrations were higher in ET patients compared to PV ones. The same differences of cytokine profiles except for PDGF-BB were obtained between PV and ET patients who have had a vascular complication. Regarding JAK2 mutational status, we observed very few differences. Only TFNα (p=0. 042) and PDGF-BB (p=0. 019) were specifically impacted by JAK2 V617F status in PV and ET, respectively. In conclusion, our results suggest that PV and ET patients display significantly different plasma cytokine levels, although the link with JAK2 V617F only concerns TNFα for the PV group and PDGF-BB for the ET one. We also observed that IL12 (p70) and GM-CSF should be useful biomarkers of the vascular risk. Altogether these data suggest that cytokine profiles may impact significantly the phenotypic characteristics of PV or ET and they could influence the rational for JAK2 inhibitor prescription.

1594

ANGIOGENIC FACTORS EXPRESSION IN BONE MARROW AND PERIPHERAL BLOOD OF MYELOPROLIFERATIVE NEOPLASMS

O Mitrovic[1], D Markovic[1], B Beleslin-Cokic[2], D Đikic[1], M Perunicic[3], D Lekovic[3], L Jakovic[3], M Budec[1], G Jovcic[1], M Gotic[3], R Puri[4], V Cokic[1]
[1]Institute for Medical Research, Belgrade, Serbia
[2]Clinic of Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia
[3]Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia
[4]Tumor vaccines and Biotechnology Branch, Division of Cellular and Gene Therapies, Bethesda, United States of America

The microvessel density of bone marrow is increased in myeloproliferative neoplasm (MPN), associated with an enhanced expression of vascular endothelial growth factor (VEGF) as an inducer of angiogenesis. The nitric oxide (NO) mediated VEGF expression as well as the VEGF-mediated NO production by endothelial NO synthase (eNOS) are regulated by hypoxia inducible factor (HIF)-1 activity, depending upon the amount of produced NO. The aim of the study is to investigate the expression of major angiogenic molecules, and their correlation, in bone marrow and peripheral blood of MPNs. The bone marrow and granulocytes are examined for the expression of angiogenic factors VEGF, HIF-1 alpha, and eNOS using immunohistochemistry and Western blot. Microvessel density is assessed by immunostaining with CD34 antibodies. A somatic point mutation JAK2V617F is detected in 93% of polycythemia vera (PV), 64% of primary myelofibrosis (PMF) and 59% of essential thrombocythemia (ET) patients, out of total 95 MPN patients. Microvessel density is significantly higher in MPNs than in controls, being highest in PMF (35-37%), followed by ET and PV. The presence of JAK2V617F mutation augments the percentage of CD34-positive cells in MPNs. The percentage of VEGF-positive cells is increased in the bone marrow of PMF patients (6. 8%), more prominently than in other MPNs. The increase of V617F allele burden did not change significantly VEGF percentage in PV, although demonstrates elevation in ET patients from 4. 3% to 5. 6%. VEGF protein levels are also increased in granulocytes of MPN patients and correlate with JAK2V617F allele burden in PMF patients (up to 2. 5 fold). In contrast, eNOS protein levels are decreased in granulocytes of MPN patients, however less in patients with high JAK2V617F allele burden. The most prominent eNOS protein level (2. 7 fold) is observed in JAK2V617F homozygous form of PV. Low HIF-1 alpha protein levels are also more prominent in granulocytes of MPN patients with JAK2V617F mutation, with the highest level in PMF. The percentage of HIF-1 alpha-positive cells (3-8%) is also increased in the bone marrow of MPN patients. According to presented results, the microvessel density is increased in MPN with high JAK2V617F allele burden and angiogenic factors level in the bone marrow are in correlation with their levels in peripheral blood granulocytes. Moreover, VEGF is also enhanced in MPNs in accordance with HIF-1 alpha and opposite to eNOS. Therefore, the positive feedback between VEGF and eNOS is inversely regulated by HIF-1 alpha in MPNs.

[3]Hemocentro de Ribeirão Preto do HCFMRP-USP, Ribeirão Preto, Brazil
[4]Hospital Brigadeiro, São Paulo, Brazil
[5]Instituto de Tratamento do Câncer Infantil, São Paulo, Brazil
[6]Departamento de Clínica Médica da Faculdade de Medicina de Ribeirão Preto-USP, Ribeirão Preto, Brazil

Background. Polycythemia vera (PV), Essential thrombocythemia (ET) and Primary Mielofibrosis (PMF) are clonal haematopoietic stem cell malignances characterized by an accumulation of mature myeloid cells in bone marrow and peripheral blood in the absence of a definable stimulus. A specific point mutation in the Janus kinase 2 gene (JAK2V617F) has been identified in more than 90% of patients with PV and in 50%-60% of ET and PMF patients. However many aspects of pathogenesis such as how a single mutation can lead to three different diseases and the description of specifics diagnostic markers for each disorder remains unclear. Deregulation of apoptotic machinery may have a role in MPNs physiopathology. The better understanding of apoptosis and its potential modulation by galectin-1 and 3 in PV, ET and PMF patients' cells might unveil novel therapy targets. **Aims.** 1) To quantify *LGALS-1* and *LGALS-3* expression in $CD34^+$ hematopoietic stem cells and in leukocytes from PV, TE and PMF patients and controls; 2) To correlate the gene expression results of *LGALS-1* and *LGALS-3* with apoptosis-related genes from bcl-2 family. **Subjects and Methods.** Bone marrow (BM) $CD34^+$ cells and peripheral blood (PB) leukocytes from 26 PV patients (9 males and 17 females with a mean age of 62y), 26 ET patients (5males and 21 females with a mean age of 61. 1y) and 14 PMF patients (12 males and 2 females with a mean age of 63. 7y) were analyzed. The control group comprised 15 BM donors (9 males and 6 females, m=28. 5y) and 46 PB donors (16 males and 30 females, m=57. 8y). $CD34^+$ cells were enriched by using immunomagnetic isolation and peripheral leukocytes were obtained by Haes-Sterilmethod. Total RNA was extracted according to Trizol□' method and High Capacity® Kit was used to synthesize cDNA. The expression of *galectin-1* and *3* and apoptosis-related genes was performed by real time PCR. The gene expression results were given as $2^{-\text{Delta Delta Ct}}$. Statistical analyses were carried out by

Mann-Whitney and Spearman tests. **Results.** *GALECTIN-1* levels were decreased in ET (median=0. 66) and PMF (0. 73) leukocytes and in PV (0. 62) $CD34^+$ BM cells when compared to controls (0. 96; 0. 96; respectively) (p=0. 042; p=0. 009; p=0,018; respectively). *GALECTIN-3* levels were decreased in ET leukocytes (0. 081) in comparison to controls (0. 87) (p<0. 0001). ET $CD34^+$ cells (1. 18) showed higher levels of *GAL-1* than PV (m=0. 62) and PMF (0. 81) cells (p=0. 001; p=0. 002; respectively). ET leukocytes (0. 081) showed lower levels of *GAL-3* than PV (1. 23) and PMF (0. 58) (p<0. 0001; p=0. 0001; respectively). In addition, we found a positive correlation between *GAL-3* expression and anti-apoptotic gene *MCL-1* in leukocytes (r=0. 39; p=0. 02) and in $CD34^+$ cells (r= 0. 41; p= 0. 01). **Conclusions.** *GALECTIN-3* seems to be linked to *MCL-1* expression, an anti-apoptotic gene. We highlight the differences in *GAL-1* and *GAL-3* expression in ET compared with PV and PMF. The results indicate the involvement of these lectins in the MPN physiopathology.

TRANSCRIPTOMIC ANALYSIS OF NATURAL KILLER CELLS IN POLYCYTHEMIA VERA

T Costello[1], C Baier[2], R Chelbi[2], B Loriod[2], P Rihet[2]
[1]Assistance Publique des Hôpitaux de Marseille, Marseille, France
[2]TAGC, Marseille, France

Background. The Natural Killer cells (NK) cells are innate immunity with the ability to lyse tumor cells. Abnormalities of their cytotoxic capacities have been described in several hematologic malignancies. The polycythemia vera is a myeloproliferative disease characterized by the almost constant presence of a mutation of JAK2. **Aims.** The aim of our study is to determine whether this mutation may participate in NK function abnormalities that we previously described (Sanchez et al., Manuscript in preparation) in polycythemia vera. **Methods.** We chose an approach by transcriptome analysis to determine the different pathways of the physiology of NK cells that could be altered in polycythemia vera. NK cells were defined according to the classical phenotype CD3-CD16 + and CD56 + and isolated from healthy donors (controls) and patients with polycythemia vera (after obtaining their written consent). **Results.** Our preliminary data (Sanchez et al. Manuscript in preparation) showed a deficit of cytotoxic functions of NK cells despite a normal or even increased, there is no deficit of activating molecules and cytotoxic potential (perforin / granzyme) intact. This suggests that the functional deficit of NK could be related to one or abnormalities of signaling pathways. This led us to conduct an on-chip Agilent transcriptome, by comparing NK purified from patients with polycythemia vera compared with healthy subjects. Hierarchical clustering revealed a hundred differentially expressed genes and completely separated patients with disease from healthy controls. Several genes upregulated in patients emerge from the list as OSBP2, NELL2, while others are under expressed as IRF8, TNFRSF1B and SP3. **Conclusions.** The first results obtained show a list of genes differentially expressed between patients and controls. We continue the analysis of the different clusters and we construct a dynamic in silico model system for regulating cytotoxic functions of NK cells to explain the origin of their dysfunction in polycythemia vera.

T REGULATORY CELLS IN PERIPHERAL BLOOD OF PATIENTS WITH PRIMARY MYELOFIBROSIS

R Campanelli, G Fois, V Poletto, L Villani, P Catarsi, E Bonetti, V Rosti, G Barosi, M Massa
Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background. Primary myelofibrosis (PMF) is a clonal, neoplastic disorder of the hematopoietic stem cells, characterized by bone marrow fibrosis, anemia, increased number of circulating CD34+ cells and splenomegaly. Besides astenia, fever, pruritus and weight loss, a subset of patients display immune-related abnormalities that suggest an (auto)immune pathogenesis, such as antibodies to RBCs, ANA, AMA, RF, low levels of complement, and lupus-like anticoagulant. In addition, it has been reported a significant association between personal history of a broad span of autoimmune diseases and subsequent risk of myeloproliferative neoplasm (Kristinsson SY Haematologica 2010; 95:1216-1220). T regulatory cells (Tregs) are an immunosuppressive T cell subset that prevents autoimmunity, regulate T-cell homeostasis, and modulate immune responses against a variety of pathogens. The involvement of Tregs in blood diseases have been studied and there is accumulating evidence that these cells play a role in hematopoietic activity (Moon HW Korean J Lab Med 2011;31:231-237). **Aims.** to investigate the number of circulating Tregs, and to correlate them with main parameters of the disease in patients with PMF, disease controls with polycythemia vera (PV) or essential thrombocythemia (ET), and in healthy controls (CTRLs). **Methods.** We tested 44 patients with PMF (pre-fibrotic type, n=10, fibrotic type, n=28, post PV/ET MF,n=6) 5 with PV/ET, and 11 healthy subjects (CTRLs). All the subjects included in the study signed the informed consent. According with data from the literature, Tregs were evaluated as CD4+CD25+CD127low/neg cells by cytofluorimetric analysis of peripheral blood mononuclear cells (PBMNCs). Fivex10^6 cells were stained by PerCPCy5. 5-anti-CD4, Alexa488- anti-CD25, PE-anti-CD127 monoclonal antibodies (eBioscience). The evaluation of FoxP3, the molecule that definitely identify the regulatory function of a T cell, was performed by intracellular staining using the commercial fixation -permeabilization kit (eBioscience); the 70-90% of the CD4+CD25+CD127 low/neg cells were FoxP3+ (Koreth J NEJM 2011 365:2055-2066). Results, expressed as percentage of CD4+ cells, are shown as median (range). **Results.** The percentage of CD4+CD25+CD127low/neg Tregs was not significantly different among patients with PMF (1. 3%, 0. 1-6. 7), PV/ET (0. 7%, range 0. 1-4. 9) and CTRLs (1. 8%, range 0. 8-5. 3). No significant correlation was found between the percentage of Tregs and disease parameters such as disease duration, severity score, WBCs, PLTs, and IWG-prognostic score. When patients with PMF were divided according to the Hb levels, those with less than 10g/dl (n=8) had a percentage of circulating CD4+CD25+CD127low/neg Tregs (0. 8%, 0. 1-1. 7) significantly lower (p= 0. 02) than those with Hb levels equal or higher than 10g/dl (n=36) (1. 5%, 0. 1-6. 7), and those of CTRLs (1. 8%, range 0. 8-5. 3) (p= 0. 02). **Conclusions.** These preliminary data indicate a correlation between a low percentage of CD4+CD25+CD127low/neg Tregs and anemia in patients with PMF. It is well known that anemia in patients with PMF is a result of ineffective erythropoiesis, intra-vascular hemolysis and bleeding. However, data regarding an improvement in anemia following immuno-suppressive therapies, suggest a possible role of autoimmunity as a cause of anemia in patients with PMF.

1598

EFFECTOR / MEMORY CD4 POSITIVE CELLS PREVAIL IN THE LYMPHOCYTE POPULATION OF ESSENTIAL THROMBOCYTHEMIA (ET) PATIENTS

M Sedzimirska[1], A Lange[1], D Dlubek[2], D Drabczak Skrzypek[2]
[1]Lower Silesian Center for Cellular Transplantation, Wroclaw, Poland
[2]Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland

Patients with ET were investigated for selective trapping/expansion of T lymphocytes. For that, subpopulations of T lymphocytes were measured in blood and in marrow specimens. The following T cell subpopulations were determined: CD45RO-CCR7+, CD45RO+CCR7+, CD45RO+CCR7- for naive, central memory, effector memory and TEMRA cells respectively. The whole population of marrow and blood cells were labeled for the purpose of this study with the use CD4, CD25, CD45RO and CCR7 MoAb (Becton Dickinson, San Jose, CA, USA) followed by detection and analysis with the use of flow cytometry (FACS Calibur, Becton Dickinson) equipped with PCLysis program. Nineteen patients (F/M: 14/5, age 28-78 - median 60 yrs) with ET diagnosed according to the WHO criteria were studied. The platelets in blood ranged from 503 to 884 x10^3/ul (median 676 x 10^3), NAP score from 44 to 202 (median 104). 15 patients were positive for JAK 2 V617F mutation (13 heterozygotes, 2 homozygotes). Marrow cellularity was from 5 to 126 x10^3/ul (median 38 x 10^3/ul). Lymphocytes in the marrow were in proportions from 4,0% to 21% (median7,5 %, 3386/ul). Lymphocytes in blood ranged from 1300/ul to 4300/ul (median 2050/ul). Cytological evaluation of marrow aspirates revealed normal differentiation of erythroid and myeloid lineages, in contrast increased numbers of megakaryocytes, often enlarged, hyperlobulated and in clusters were found. In trephine biopsy specimens megakaryocytes were enlarged but other cell lineages looked rather normal and there was no fibrosis. Results.1. Proportions and numbers of naive T cells were similar in blood and in marrow2. CD45RO+CCR7- prevailed in marrow as compared to blood (141,6 - 3241,3 /ul, median 1281/ul vs 68,7 - 2437,5 /ul, median 631,2/ul, p=0,04 Wilcoxon Test for pairs). 3. there was a significant increase of CD4+CD25+ cells in the marrow as compared to blood (4,5-169,7/ul, median 36,2/ul vs 1,2-47/ul, median 9,1/ul; p=0,02 Wilcoxon Test for pairs) . Trephine biopsy investigation documented a high frequency of FOXP3 positive cells. In conclusion a selective increase of effector/memory CD4 lymphocytes (CD45RO+CCR7-) and their counterpart population of T regulatory (CD4+CD25+) cells suggests the presence of immune response in the marrow of ET cases

1599

ERG EXPRESSION IN A COHORT OF CHILDREN WITH MYELOPROLIFERATIVE DISEASE

G Geranio, M Putti, M Randi, E Bonamigo, M Pigazzi, G Basso
University of Padua, Padua, Italy

Background. ERG gene is involved in the pathogenesis of many cancers. ERG is necessary for haemopoiesis, angiogenesis, inflammation regulation

and osteogenesis. Recently, literature has shown ERG role in the regulation of hematopoietic stem cells and embryonic and adult megakaryocyte maturation. In particular, the overexpression of ERG induces an increase in STAT3 phosphorylation and increases intracellular levels of JAK2 and STAT5. In hematology ERG expression has been analysed only in cases of pediatric and adult acute leukemia. **Aims.** the study evaluates the role of ERG in the pathogenesis of myeloid proliferation in children followed for Essential thrombocytemia (ET), primary polyglobulia (PG) and Chronic Myeloid Leukemia (CML). ET and PG, quite rare in children, are myeloproliferative neoplasm (CMPN), but since they are not characterized by a specific marker of clonality, are difficult to classify. **Materials and Methods.** in 58 children (15 ET, 19 PG and 24 CML) aged less then 18 years, ERG expression was evaluated by Real Time PCR and compared to the expression in 14 healthy controls. ERG overexpression was detected when RQ ratio was >1. Within PG children, 2 children, brother and sister, had a congenital form; 1 child had father and grandfather with the same problem; 4 children had Down Syndrome (DS); 1 child had VHL mutation (Chuvash PG); 1 high oxygen affinity hemaoglobin. 4/15 ET children had JAK2V617F mutation and 1 had MPL W515S mutation**.** CML patients (all bcr/abl p210 positive)were analyzed both at diagnosis and in remission. **Results.** four out of the 19 children (21%) with PG had ERG overexpression, with no significant correlation with the PG characteristics. ERG overexpression was found in 7 ET (46%) and 3 of them (43%) carried JAK2V617F mutation. In contrast, within those with normal ERG expression only 1 was JAK2V617F (12. 5%). A slight correlation was found (albeit not statistically confirmed) with ERG overexpression and WBC count > 10 x 10^9/l. ERG elevated overexpression was found in the peripheral blood cells (PB) of all patients with CML, comparing to healthy children; in the bone marrow (BM) cells, ERG was expressed at the same level than HS and interestingly, at the same level than PB. CD34+ cells sorting showed that ERG expression was confined to this subset. CML analyzed during treatment with tyrosin kynase inhibitors showed a complete return to normal levels. **Conclusions.** ERG is heterogeneously expressed in these children; in PG, ERG expression is not helpful in directing pathogenetic suggestions. Clonal myloproliferation in CML is associated with CD34+ cells ERG overexpression and this is suppressed by TK inhibitors. In ET, correlation with JAK2V617F is suggested. Extension of this study is required to understand the role of ERG in myeloid proliferation, both clonal and non clonal**.**

THE INCIDENCE OF JAK2 V617F MUTATION IN RADIATION-ASSOCIATED BCR/ABL-NEGATIVE CHRONIC MYELOPROLIFERATIVE DISORDERS FOLLOWING THE CHERNOBYL ACCIDENT

S Klymenko[1], I Dmitrenko[1], O Kostyukevich[2], V Sholoyko[1], I Prokopenko[1], T Liubarets[1], O Mischenyuk[1]

[1]National Research Center for Radiation Medicine NAMS of Ukraine, Kyiv, Ukraine

[2]Center of Prophylactic and Clinical Medicine, Kyiv, Ukraine

Background. A recurrent specific JAK2 V617F mutation has been reported in bcr/abl-negative chronic myeloproliferative disorders (cMPDs), including polycythemia vera (PV), essential thrombocythemia (ET) and idiopathic myelofibrosis (IMF). The implication of this mutation in the pathogenesis of cMPDs is currently confirmed. Our study is the first to be interested in the status of the JAK2 V617F mutation in patients with cMPDs developed after radiation exposure. **Aims.** The aim of the study was to analyze whether radiation-associated cMPDs developed in clean-up workers at the Chernobyl NPP and inhabitants of Ukrainian territories with high contamination from radionuclide fallout differed from spontaneous cMPDs in terms of JAK2 V617F incidence. **Methods.** The cohort of patients in the study consisted of 118 unselected adult cMPDs patients, initially diagnosed between 2001 and 2012. Of these patients, 37 had experienced radiation exposure due to the Chernobyl accident (19 clean-up workers and 18 inhabitants of Ukrainian territories with high contamination from radionuclide fallout) and composed the group of radiation-associated cMPDs, and 70 developed spontaneous cMPD and served as controls. After informed consenting, mutation screening for JAK2 V617F in patients with PV, ET and IMF was performed by allele-specific polymerase chain reaction assay. **Results.** JAK2 V617F mutation was detected in 89 of the 118 patients with cMPDs. In particular, 95. 2, 50 and 55,3% of PV, ET and IMF cases, respectively, showed the mutation. The frequency of JAK2V617F mutation was similar among radiation-associated and spontaneous PV (18 of 19 vs. 41/43, *p*=0,92) and ET (1/2 vs. 8/16, *p*=1,0) cases, but it was lower in radiation-associated IMF than that in spontaneous IMF with the difference on the border of statistical significance (6/16 vs. 15/22 patients, *p*=0,06). **Summary and Conclusions.** We assess the status of the JAK2 V617F mutation in patients with radiation-associated cMPDs following the Chernobyl accident. Our data seem to confirm that the JAK2 V617F mutation incidence is similar in radiation-associated and spontaneous PV and ET patients. However, our findings are suggestive that JAK2 V617F mutation may by less common in radiation-associated compared to spontaneous IMF. The further studies are needed to provide insights into understanding of the molecular basis of radiation-associated cMPDs.

1601

FREQUENCY AND CLINICAL CORRELATES OF JAK2 46/1 HAPLOTYPE IN COMPARISON WITH JAK2V617F VARIANT IN ESSENTIAL THROMBOCYTHEMIA: SINGLE CENTER EXPERIENCE

I Panovska-Stavridis[1], L Cevreska[1], M Ivanovski[1], S Trajkova[1], A Stojanovik[1], D Dukovski[1], N Matevska[2], A Dimovski[2]

[1]University Clinic of Hematology-Skopje, Skopje, Macedonia

[2]Center of Biomolecular Sciencies, Faculty of Pharmacy-Skopje, Skopje, Macedonia

It is predicted that the inherited genetic background in the individual patients with myeloproliferative neoplasm (MPN) influences the disease susceptibility and the phenotype expression of the MPN. Several groups discovered that the germline JAK2 haplotype, tagged by the “C” allele of single nucleotide polymorphism (SNP) rs12343867 (C/T) is associated with the JAK2V617F positive MPN. Also, some recent studies showed equal distribution of this SNP among JAK2V617F negative MPN and questioned the role of this hyplotype in MPN patients. In order to extend further those observations we conduct a retrospective study. First, we assess the frequency of JAK2 46/1 haplotype in Essential thrombocyhemia (ET) patients in comparison with population controls. As second we evaluate the association of 46/1 with the JAK2V617F mutational status and the clinical characteristics in the series of patients with ET that were diagnosed and treated at the University Clinic of Hematology-Skopje, Republic of Macedonia. Ninthly five consecutive patients diagnosed with ET according to proposed criteria for diagnosis in 2008 by the World Health Organization were included in our study. The 46/1 tag SNP rs12343867 (C/T) was genotyped on a MxPro 3005P real-time PCR system (Stratagene, La Jolla, CA,USA) using the TaqMan SNP genotyping assay (Applied Biosystems, Foster City, CA, USA) according to the manufacturer’s instructions. The incidence of 46/1-linked C allele was significantly higher in ET (genotype: CC 13%, CT 60%, TT 27%; C-allele frequency: 43,7) than in population control (C-allele frequency 29%), P<0,01. Genotype distribution were similar among JAK2V617F positive/ JAK2V617F negative patients (genotype: CC 7/14%, CT 22/29%, TT 67/57%; C-allele frequency: 41/43%; P=0,76). The clinical characteristics of 46/1 positive and negative ET were comparable regarding all tested parameters such as blood counts, NAP score, rate of thrombotic and hemorrhagic complications, disease transformation and survival. Our results confirmed latest observations that JAK2 46/1 haplotype is susceptibility factor for developing ET independent of JAK2V617F mutational status and does not further affect the clinical course and prognosis of the disease.

1602

KL-VS FUNCTIONAL POLYMORPHISM OF THE KLOTHO GENE IS NOT ASSOCIATED WITH THE MYELOPROLIFERATIVE NEOPLASMS PHENOTYPES, BUT IT MIGHT MODULATE THE ACQUISITION RISK OF SOMATIC MUTATION JAK2 V617F

A Trifa[1], R Popp[1], A Cucuianu[2], C Coada[1], A Sarca[1], R Costache[1], M Militaru[1], I Pop[1]

[1]”Iuliu Hatieganu” University of Medicine and Pharmacy, Cluj-Napoca, Romania

[2]”Ion Chiricuta” Cancer Institute, Cluj-Napoca, Romania

Background. KL-VS functional polymorphism of the *KLOTHO* gene has been associated with longevity, and with a large spectrum of chronic degenerative diseases, or more recently with diverse cancers. Polycythemia vera (PV) and essential thrombocythemia (ET) are representative non-BCR-ABL myeloproliferative neoplasms (MPN), frequently positive for the somatic mutation *JAK2* V617F. **Aims.** To evaluate the relationship between the KL-VS polymorphism of the *KLOTHO* gene, and the occurrence of the MPN phenotype, and further between this polymorphism and the *JAK2* V617F somatic mutation. **Methods.** One hundred sixty-six patients with MPN (75 with PV and 91 with ET) with a known *JAK2* V617F status, and 95 controls were included in the study. The KL-VS polymorphism was genotyped in all patients and controls by a PCR-RFLP assay. **Results.** Thirty-three patients (19. 9%) had at least one KL-VS allele. There were 29 heterozygotes (17. 5%) and 4 homozygotes (2. 4%). Among the controls, there were 20 individuals harbouring at least a KL-VS allele (21. 1%), of which 19 heterozygotes (20%) and one homozygote (1. 1%). There was no significant difference regarding the distribution of the KL-VS polymorphism in patients compared to controls (OR = 0. 9; 95% CI = 0. 5 - 1. 5; p-value = 0. 74). In the whole cohort of patients, there were 118 patients (71. 1%) positive for

JAK2 V617F mutation. After stratifying for the *JAK2* V617F status, we found that the KL-VS polymorphism was enriched in V617F-positive compared to V617F-negative patients (OR = 2. 3; 95% CI = 0. 9 - 5. 5; p-value = 0. 05). **Summary and Conclusions.** Our preliminary findings suggest no significant relationship between the functional polymorphism KL-VS from the *KLOTHO* gene and the occurrence of MPN phenotypes (PV and ET). However, we found this polymorphism more frequently among patients positive for the *JAK2* V617F mutation, the most common molecular marker in PV and ET. Although the mechanism is unclear, this finding suggest a possible contribution of the KL-VS polymorphism to the risk of acquiring the V617F mutation.

1603

THE 'C' ALLELE OF JAK2 RS12343867 DESIGNATE THE GENETIC BASIS OF MYELOPROLIFERATIVE NEOPLASM IN THE MACEDONIAN POPULATION

I Panovska-Stavridis[1], N Matevska[2], M Ivanovski[1], S Trajkova[1], D Dukovski[1], A Stojanovik[1], L Cevreska[1], A Dimovski[2]

[1]University Clinic of Hematology-Skopje, Skopje, Macedonia

[2]Center of Biomolecular Sciencies, Faculty of Pharmacy-Skopje, Skopje, Macedonia

Polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF) are myeloproliferative neoplasms (MPNs) characterized in most cases by a unique somatic mutation *JAK2* V617F. Recent studies suggested that JAK2V617F positive MPNs are acquired preferentially on a specific constitutional germline JAK2 46/1 haplotype(46/1)which is tagged by the "C"allele of single nucleotide polymorphism (SNP)rs12343867 (C/T). Moreover, some studies investigated the potential role of the JAK2 46/1 haplotype at the MPN phenotype in context of the clinical presentation and the complication of the diseases. Our study was extend in order to examined the impact of the C allele of JAK2 rs12343867 (C/T) on MPNs in a Macedonian population and to evaluate the association of 46/1 with the JAK2V617F mutational status and the clinical characteristics in our MPNs patients. The study group consisted of 212 adult (>15 years) patients with MPNs that were diagnosed and followed at the University Clinic of Hematology- Skopje. According to the 2008 World Health Organization criteria 79patients were diagnosed as PV, 95 as ET, 10 as PMF and 28 were classified as atypical MPNs (aMPNs). The 46/1 tag SNP rs12343867 (C/T) was genotyped using the TaqMan SNP genotyping assay (Applied Biosystems, Foster City, CA, USA) according to the manufacturer's instructions. The JAK2 V617F mutation was analyzed by fluorescent allele-specific PCR followed by CE on ABI 310 Genetic analyzer. Associations with risk of MPN were estimated by odds ratios and their 95% confidence intervals using logistic regression. The incidence of 46/1-linked C allele was significantly higher in all MPN entities [PV (0. 538), ET (0. 437), PMF (0,464), and in aMPNs (0. 55)]in comparison with healthy controls (0. 290); (P<0,01 for all comparisons). The frequency of the JAK2V617F mutation ranged from 89%in PV, 67% in ET, 60% in PMF to 46,4% in the aMPNs. The frequency of the JAK246/1 C allele was significantly higher in the JAK2V617F positive patients with PV, PMF and aMPN; (p<0,01 for all comparisons) except in ET patients, in which genotype distributions were similar among JAK2V617F positive and JAK2V617F negative patients (genotype: CC 7/14%, CT 22/29%, TT 67/57%; C-allele frequency 41/43%; p=0,76)Correlations of the clinical features at diagnosis and long-term prognosis between the two JAK2 46/1 different MPNs groups revealed only that in ET patients risk for thrombosis (artherial and venous) was significantly associated with *JAK2* V617F mutation(38,5%;(P<0. 005), rather than with the 46/1. Our results confirmed latest observations that JAK2 46/1 haplotype contributes significantly to the occurrence of of *JAK2* V617F-positive and *JAK2* V617F-negative MPNs in the Macedonian population and it designate the genetic basis for predisposition to MPNs. They also showed that the JAK2 46/1 haplotype does not affect the clinical course and prognosis of the different MPNs.

1604

ATYPICAL MYELOPROLIFERATIVE DISORDER WITH BASOPHILIA, TRISOMY 4 AND HIGH TRYPTASE LEVELS

C Ulibarrena

Complexo Hospitalario Universitario de Ourense, Ourense, Spain

Background. Hematologic disorders with basophilia are so uncommon that there is not an specific entity for them, with exception of AML with recurrent t(6;9). We present the unique case of an asymptomatic female with blood basophilia, marrow basophilia and eosinophilia, myelofibrosis and amplification of PDGFRA due to trisomy 4. **Description.** 52 yr. -old female. In August/11 she underwent partial hepatectomy for a single metastasis, which primary was a cervical cystic adenoid carcinoma treated in 2008 with surgery and local radiation. In Oct. -11, significant basophilia was found in an hemogram. At this moment, she only described mild weight loss; she denied, fever, night sweats, recent skin lesions, itching, asthma, urticaria or episodes of angioedema/anaphylaxis. Physical exam: no hepatosplenomegaly / lympadenopathies. Lab. tests:- Hemogram: 4. 1· 10^9 leuc. /L; Hgb., 11'6 gr /dL; fL; 208· 10^9 plat. /L. Blood smear: 23% neutr.; 50% basophils, a minority of which with irregular distribution of granules; no mast cells. - Biochemistry: ALT, AST, LDH, creatinine, proteins within normal range. ESR, 15. Vit. B_{12} > 1500 pg/mL. Ferritin, 161 ng/mL. Reticulocytes 1. 89%. - Tryptase, 166 mg/dL (normal<12). Histamine, 0'89 mg/dL (N). Bone marrow exam. Aspirate: significant dysplasia in megakayocytic and erythroid lines; 27% basophils; 1% blasts. Biopsy: intertrabecular spaces fully occupied by a marked myeloid hyperplasia; 30-40% eosinophils in all maturative stages; % of blasts / CD34+ cells was normal; sparse mast cells not forming infiltrates; reticulinic myelofibrosis with focal areas of collagen. FISH: 80% cells with amplification of PDGFRA(4q12); no amplification of ETV6 (12p13); absence of t(9;22) and abnormalities in 5q31, 7q31, 8, 20q12. Cytogenetics: 48, XX, +4, +19 [20]. Molecular biology: absence of V617F· Jak2 and bcr/abl; absence of mutations of c-kit in basophils selected by sorting. HUMARA test: clonality. Flow cytometry: 1. 3% CD34+; absence of abnormal mast cells; 34% of aberrant basophils in a intermediate stage of maturation, CD45+, CD117+, CD25+, IgE++, CD38++, DR-, CD11b-, CD13+, CD16-, CD10-, CD34-, CD35+, CD64-, CD14-, Tdt-, CD56-, CD19-, CD3-, MPO-, CD22+, 7. 1 -, CD15-, CD123+++, CD203c-, CD33++. CT exam (after surgery): no splenomegaly; mild volume of intraperitoneal fluid; no pleural effusion. **Summary and Conclusions**. To sum up, this patient had a clonal proliferation of basophils, bone marrow eosinophilia and myelofibrosis, very high levels of serum tryptase (x12) and trisomy 4 without identified traslocations involving PDGFRA. These data allowed us to rule out mast cell disease, chronic myeloid leukemia and t(6;9) AML. However the adscription within WHO entities remains uncertain: "unclassifiable myeloproliferative or myelodysplastic / myeloproliferative neoplasm", "myeloid neoplasm with eosinophilia and abnormalities of PDGFRA", the last being the most appealing, even though the "abnormality"is a trisomy instead of a traslocation. This should not be an excluding criterion, since there is at least one analogous case of complex karyotpe involving chr. 4 (Score J. *Leukemia 2006;80,827*). The very high levels of tryptase, in the rank of mast cell disease, were the other remarkable fact (although expected), in the absence of allergic manifestations. Considering the lack of clinical expression, the only recommended therapy has been anti-histamine drugs (ebastine and ranitidine).

1605

PROGNOSTIC SIGNIFICANCE OF FLT3 AND NPM1 MUTATIONS IN MYELOID MALIGNANCIES

P Olim[1], P Sousa[1], A Gonçalves[2], L Mesquita[2], H Breda Coimbra[2], C Moucho[1], E Cortesão[1], A Espadana[1], J Carda[1], M Pereira[1], L Rito[1], C Geraldes[1], E Magalhães[1], I Sousa[1], R Afonso[1], M Gomes[1], A Teixeira[1], A Sarmento Ribeiro[2]

[1]Hospitais da Universidade de Coimbra - CHUC, Coimbra, Portugal

[2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Background. The fms-like tyrosine kinase 3 (FLT3) protein is a tyrosine kinase receptor wich gene is mutated in about one third of acute myeloid leukemia (AML) patients, being the *FLT3* internal tandem duplications (ITD´s) mutations associated with an adverse prognosis in this disease. In the long arm of chromosome 5 (5q35) is localized the gene that encodes a nucleolar phosphoprotein, Nucleophosmin (NPM1), which mutation in exon 12 is found in about a half of AML patients, giving a better prognosis. The mutational status role of these genes in Myeloproliferative Neoplasms (MPN) and Myelodysplastic Syndrome (MDS), is not well defined, namely their´s role as a potential marker of progression to AML. **Aims.** In this study was analyzed the frequency of the *NPM1* and *FLT3* genes in patients with AML, MPN and MDS, cytogenetically characterized, and analyzed their correlation with clinical parameters, disease progression, treatment response and prognosis/survival. **Methods.** To achieve our objectives, the *FLT3* and *NPM1*genes mutations was performed on genomic DNA extracted from peripheral blood (PB) or bone marrow (MO) samples of 76 patients with myeloid malignancies, including 52 with AML diagnosis, 19 with MNP´s and 5 with MDS, according to FAB (French-American-British) criteria and World Health Organization (WHO) (2008). Detection of *FLT3* gene mutations, in particular the Internal Tandem Duplications (ITD) and the D835 mutation was achieved after amplification by PCR (Polymerase Chain Reaction) and by RFLP (*Restriction Length Polymorfisms*) analysis, respectively, while the search for mutations of *NPM1* gene (exon 12) was carried out by gene sequencing. **Results.** The presence of *FLT3*-ITD and exon 12 of *NPM1* genes mutations were only identified in AML patients, while none of the MPN and MDS patients carried out this kind of mutation. However, in two MPN patients we found the NPM1 and in one D835 FLT3 mutation. The incidence of FLT3-ITD

and NPM1 exon-12 mutations in AML patients was 28 and 9,6%, respectively. These patients had higher white blood cell count and percentage of blasts. Our results show that patients positive for both mutations (*ITD +/NPM1 +*), were those in which the rate of complete remission (CR) was lower (34%), compared with that seen in patients without mutations (*ITD-/NPM1-*), or with those in witch only one mutation was identified (*ITD-/NPM1+* or *ITD+ / NPM1)*. The highest rate of CR was achieved in patients *ITD-/NPM1 +* (100%). The overall survival (OS) was much higher in patients without the *ITD* gene mutation (*FLT3/ITD* negative) as well as in patients with *NPM1* gene mutation (*NPM1* positive). **Conclusions.** These results suggests that the ITD mutation in the *FLT3* gene confers a worse prognosis for AML patients enrolled in the study, while *NPM1* gene mutations confers a favorable prognosis for these patients. Since the frequency of these genes mutations are more common in AML patients and confer distinct prognosis, early detection contribute to prognosis assessment and to individualized therapeutic approach directed at molecular targets. The detection of these mutations in patients with MPN and MDS may also have prognostic relevance, but larger studies are needed.

JAK2 MUTATIONS IN CHRONIC MYELOPROLIFERATIVE NEOPLASM; TOWARDS THE APPLICATION OF PERSONALIZED TREATMENTS FOR SAUDI PATIENTS

M Gari, F Al-Sayes, A Abuzenadah, A Chaudhary, A Dallol, M Al-Qahtani, G Damanhouri
King Abdulaziz University, Jeddah, Saudi Arabia

Background. The chronic myeloproliferative neoplasms (CMPN) are a group of clonal hematopoietic stem cell disorders in which large numbers of red blood cells, white blood cells, or platelets grow and spread excess in the bone marrow and the peripheral blood. Cytogenetic analysis of the t (9:22) and molecular detection of BCR-ABL is the main diagnostic criteria in Philadelphia positive CMPN (CML). The identification of non-receptor tyrosine kinase JAK2 mutations (exon 14 JAK2 V617F and exon 12) have significantly contributed to our understanding of the molecular mechanisms in the pathogenesis of Philadelphia negative CMPN such as polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (MF) patients. According to the revised WHO classification, JAK2 mutation is considered as a major diagnostic and clonal marker in Philadelphia negative CMPN which will play a major role in designing personalized treatments for the disease. **Aims.** To determine the frequency of JAK2 mutation in myeloproliferative neoplasms in western region of Saudi Arabia. **Methods.** JAK2 V617F mutation frequency is unknown in Saudi Arabia. Therefore, investigation of the JAK2 V617F mutation was carried out in DNA samples from 78 peripheral blood specimens corresponding to patients with polycythemia vera (PV) (n = 11), Chronic myeloid leukemia (CML) (n=45), essential thrombocythemia (ET) (n = 10), Primary myelofibrosis (PMF) (n = 12). We used polymerase chain reaction and direct DNA sequencing to detect the JAK2 mutation. **Results.** Overall, the incidence of the JAK2 V617F mutation was 91% in PV, 40% in ET, and 25% in PMF. This approach proved to be reliable and more sensitive in detecting the mutation. Two essential findings arose from our study. First, this technique could be carried out with DNA samples, even partially degraded, from routinely processed BM or peripheral blood specimens. Second, after correlation with morphological features, it turned out that the characteristics of the megakaryocytes were more specific than the mutational status of JAK2 in characterizing ET and PMF. **Conclusions.** Concerning PV, as expected, the incidence of the JAK2 mutation was higher, but the morphological criteria were misleading in some cases, strongly suggesting that the combination of both morphology and molecular data would enable the characterization of virtually all cases. JAK2 V617F mutation frequency along with accurate morphological characterization is very reliable tool in diagnosing and classifying CMPN in Saudi patients.

1607

PATIENTS' COMORBIDITIES AND OVERALL SURVIVAL IN PRIMARY MYELOFIBROSIS (PMF)

K Naqvi[1], M Tanaka[2], G Garcia-Manero[1], S Pierce[1], J Cortes[1], A Quintas-Cardama[1], G Borthakur[1], Z Estrov[1], H Kantarjian[1], S Verstovsek[1]
[1]UTMD Anderson Cancer Center, Houston, United States of America
[2]Baylor College of Medicine, Houston, United States of America

Background. Cancer patients often experience comorbidities that may affect their therapeutic options, outcome of therapy, and their prognosis. However, none of the prognostic scoring systems for PMF account for an impact, if any, of patients' comorbidities on their prognosis. **Aims.** The aim of this study was to determine the effect of comorbidities on the survival of patients (pts) with PMF. **Methods.** We reviewed the medical records of 349 consecutive PMF pts who presented to our institution from 2000 to 2008. The Adult Comorbidity Evaluation-27 (ACE-27) form, a validated 27-item comorbidity index for cancer pts, was used to assess the severity of comorbid conditions in these patients at the time of presentation. Demographic characteristics including age, performance status (PS), complete blood profile, karyotype, International Prognostic Scoring System (IPSS), stem cell transplant (SCT) and outcomes (leukemic transformation and survival) was also collected. Kaplan-Meier method and log-rank test were used to assess survival. Multivariate analysis (MVA) was performed using the Cox Proportional Hazards Model. **Results.** Of the 349 pts included in this study, 222 (64%) were male and 311 (89%) were white; median age at presentation was 62 years (20-82); median duration of follow-up was 37 months (range 0 - 133). The ACE-27 comorbidity scores were as follows: none, 125 pts (36%); mild, 128 (37%); moderate, 63 (18%); and severe, 33 (9%). Hypertension was the most common comorbidity (31%) followed by diabetes mellitus (14%). A total of 193 patients died, 41 (12%) suffered leukemic transformation and 27 (8%) patients underwent SCT. Overall median survival using the Kaplan-Meier method was 39 months. Median survival by ACE-27 scores was: 52, 38, 36 and 28 months for none, mild, moderate and severe comorbidity scores, respectively (p=0. 028). In addition to comorbidities, age >65 years, male gender, increased PS (by Zubrod Scale), white cell count >25K, platelets <100K, hemoglobin <10 g/dl, transfusion need, albumin <3. 5 g/dl, unfavorable karyotype, prior treatment, and increased IPSS risk reached statistical significance for survival (p<0. 05). Constitutional symptoms and peripheral blasts did not achieve statistical significance. In the MVA, advanced age (>65 years), PS of >=2, platelet <100K, transfusion need and IPSS (high risk category) continued to maintain prognostic significance. Comorbidities were not identified as an independent predictor of survival. However, significant interaction was noted between age and comorbidities (p<0. 01). Hence additional analysis excluding age was performed that identified comorbidities as an independent predictor of survival (p=0. 03). When stratified by age, patients <=65 years with comorbidities were noted to have a significantly lower survival (p=0. 02). A significant trend was also observed between the severity of ACE-27 comorbidity scores and survival in patients <=65 years (p=0. 001). In older patients (>65 years), comorbidities failed to predict survival. **Conclusions.** We observed significant effect of comorbidities on survival in patients with PMF <=65 years of age. Our study suggests that interventions aimed at improving comorbidities in younger patients with PMF may improve their overall outcome.

1608

A RETROSPECTIVE ASSESSMENT OF THE CLINICAL FEATURES AND SYMPTOMS OF 180 PATIENTS WITH MYELOFIBROSIS IN THE UNITED STATES

N Sarlis[1], J Kaye[2], D Mitra[2], JS Brown[1], L Piecoro[1], K Reith[1], T Mughal[3]
[1]Incyte Corporation, Wilmington, United States of America
[2]RTI Health Solutions, Research Triangle Park, United States of America
[3]University of Colorado Health Sciences Center, Denver, United States of America

Background. Myelofibrosis (MF) is a life-threatening myeloproliferative neoplasm characterized by debilitating symptoms (eg, fatigue, night sweats, pruritus, abdominal pain, and early satiety). Some patients also present with an enlarged spleen (splenomegaly), further adding to their disease burden. **Aims.** To characterize the clinical features and symptom profile of MF in patients with and without splenomegaly. **Methods.** This was a retrospective chart review conducted in April and May of 2011. Patients diagnosed with MF (primary MF, post-polycythemia vera MF, or post-essential thrombocythemia MF) between January 1, 2005 and March 31, 2010 were included in the analysis. The study was designed so that approximately half of the patients did not have splenomegaly (defined as any spleen enlargement palpable below the left costal margin). Patients were required to have at least 12 months of chart data following diagnosis of MF, and patients with splenomegaly were required to have an additional 12 months of chart data following first detection of splenomegaly. MF-related symptoms, including items from the Myeloproliferative Neoplasm Symptom Assessment Form (MPN-SAF), and treatments received were collated. Data collection occurred before the FDA approval of ruxolitinib for the treatment of intermediate or high-risk MF. **Results.** Charts for 216 patients were contributed by 57 physicians in the United States (80% hematologists/oncologists; 66% community practice). Data for 180 patients (102 with and 78 without splenomegaly) were eligible for analysis. Patients had a median age of 66 years, and 82% presented with intermediate-2 or high-risk MF by International Prognostic Scoring System criteria. All patients had significant comorbidities at the time of their diagnosis, most commonly hypertension, diabetes, dementia, and cardiovascular disorders. Patients with and without splenomegaly also reported a high frequency of MF-related symptoms at baseline. The occurrence of constitutional symptoms was similar in patients

with and without splenomegaly (weight loss 78% vs. 69%, night sweats 65% vs. 50%, and fever 54 vs. 53%, respectively); however, abdominal symptoms and early satiety were significantly (p<0. 05) more frequent in patients with splenomegaly (range 67% to 85%) vs. those without splenomegaly (range 37% to 50%). Most patients reported fatigue (93% and 87% with and without splenomegaly, respectively). Approximately half of the patients received treatment for MF during the time frame of the chart review, the most common being hydroxyurea and growth factors (including erythropoietin-stimulating agents). **Summary and Conclusions.** This large retrospective study of patients with MF demonstrated a high prevalence of comorbid conditions and debilitating MF-related symptoms, which occur regardless of the presence or absence of splenomegaly. These findings support current efforts to improve the treatment of MF by targeting both disease symptoms and spleen size. **Supported.** *Supported by Incyte Corporation. Dr. Mughal is a consultant for Incyte Corporation.*

THE ROLE OF JAK2-V617F MUTATION IN LEUKEMIC TRANSFORMATION OF MYELOPROLIFERATIVE NEOPLASMS

M Tevet, A Lupu, C Saguna, C Dragan, A Colita, G Barca
Coltea Hospital, Bucharest, Romania

Background. AND OBJECTIVES:JAK2 mutation is recurrent in myeloproliferative neoplasms (MPNs) and it is almost invariably associated with PV, but it occurs in the majority of patients with ET or PMF. The role in the pathogenesis of the various BCR-ABL1-negative myeloproliferative neoplasms (MPNs) remains unclear and its significance in leukemic transformation is a matter of even greater controversy. **Aims.** The aim of this study was to evaluate both the JAK2(V617F) mutational status of the rare cases in which blast crisis occurred in our institution and the response after intensive treatment. **Materials and Methods.** Between 2000 and 2011, 194 patients received diagnoses of BCR-ABL1-negative MPNs in our center (68 with PV, 50 with ET, and 59 PMF cases, as well as 13 MPN cases not otherwise classifiable). Of these patients, 21 developed leukemic transformation (5 with MF post PV, 3 with MF post TE,13 with PMF). The genotyping of the JAK2(V617F) mutation was performed by the amplification-refractory mutation system. **Results.** All the patients were tested for JAK2(V617F) in the chronic phase of their disease, and 18 of these patients were positive for JAK2(V617F). These 18 patients, 2 with PV, 4 with ET and the rest with PMF, also harbored JAK2(V617F) in the heterozygous state during blast crisis and even after intensive treatment in one of these patients. The other 3 cases that evolved to blast crisis did not harbor the JAK2(V617F) mutation before and after transformation. 20 patients died despite conventional or supportive treatment and 1 patient is still under treatment. **Conclusions.** The transformation of MPNs into acute leukemia is a rare phenomenon. In our study, all JAK2(V617F)-positive patients remained positive for this mutation after leukemic transformation, although in the heterozygous state, suggesting that JAK2(V617F) is not essential for transformation in these cases. The fact that all JAK2(V617F)-negative cases remained negative after blast crisis reinforces the theory that other molecular event(s) may play a role in the clonal heterogeneity of MPNs. Regarding the treatment, conventinal or supportive treatment do not seem to be a solution because of the poor outcome of acute myeloid leukemia secondary to MPN, so patients should be included in clinical trials of the novel JAK2 inhibitors.

1610

ESSENTIAL THROMBOCYTHAEMIA (ET): DISEASE SUBGROUPS AND PROGNOSTIC FACTORS IN 181 PATIENTS FROM A SINGLE CENTER.

O Tsopra[1], T Vassilakopoulos[1], P Tsirkinidis[2], M Dimou[1], I Vardounioti[1], S Kokoris[3], G Boutsikas[1], Z Galani[1], E Plata[1], P Tsaftaridis[1], K Petevi[1], A Kanellopoulos[1], V Bartzi[1], T Tzenou[1], A Bilalis[1], G Georgiou[1], N Vyniou[1], G Pangalis[4], J Meletis[1], M Kyrtsonis[1], P Panayiotidis[1], M Angelopoulou[1]
[1]Laikon hospital, Athens, Greece
[2]Current position 401 Army Hospital, Athens, Greece
[3]Current position Attikon Hospital, Athens, Greece
[4]Current position Athens Medical Center, Athens, Greece

Background. Essential thrombocythaemia (ET) is the most frequent myeloproliferative disorder characterized by a long natural history. The identification of JAK2V617F mutation facilitates the diagnosis and probably defines two distinct disease subgroups. **Aims.** Aim of the present study is to report the clinical and laboratory findings, the outcome, potential prognostic factors as well as the clinical importance of JAK2V617F mutation in patients with ET. **Methods.** 181 patients diagnosed with ET in a single center were retrospectively studied from 1998 to 2011. **Results.** The median age of our patients was 64 years (16-91), 72 were males and 109 females. At diagnosis 75% were asymptomatic, 17% presented either a thrombotic or a bleeding episode and 11% had splenomegaly. The JAK2V617F mutation was detected in 64/95 patients (67%). The median values of Ht, Hb, WBC and PLT were 42. 6% (30. 8-54. 7), 13. 9g/dL (9. 5-17. 3), 8. 48 x 10^9/L (4. 44-27. 4) and 781 x 10^9/L (468-2288) respectively. LDH levels were elevated in 25%, while the median serum erythropoietin level was 10. 2IU/mL. Bone marrow biopsy revealed the presence of typical megakaryocytes in clusters in 75%, while reticulin fibrosis was found in 29% with 8 cases showing grade 2 fibrosis. An abnormal karyotype was evident in 9%. The comparison between JAK2V617F(+) and JAK2V617F(-) patients showed that JAK2V617F(+) patients presented more frequently a major event at diagnosis (p=0. 05), had statistically significantly higher values of Ht (median: 44. 9% vs 39. 9% p<0. 001), Hb (median: 14. 5g/dL vs 13. 1g/dL p<0. 001), lower platelet counts (median: 698x10^9/L vs 892x10^9/L and lower MCV (median: 84. 5fl vs 88. 2fl). Antiplatelet treatment was administrated in 78%. Cytotoxic therapy was given in 80%, while the remaining patients were put under observation. The median interval from diagnosis to the initiation of cytotoxic therapy was 0. 8 months (0-115). First line treatment was hydroxyurea in 86%, anagrelide in 12% and interferon-a in 1%. Complete and partial response was achieved in 68% and 26% of the patients respectively, at a median time of 1. 64 months. Change of treatment was required in 11%. At a median follow up of 40 months (1. 1 - 207), 94% of the patients are alive with a 5- and 10-year overall survival (OS) of 96% and 87% respectively. Events were observed in 13 patients: 6 experienced a thrombotic episode, 5 progressed to myelofibrosis and 2 developed a second malignancy. Prognostic factor analysis revealed male gender (p=0. 001) and WBC counts ≥10X10^9/L (p=0. 001) as adverse factors for OS. Bone marrow fibrosis and the presence of an event at diagnosis were of marginal significance (p=0. 09). Furthermore, Hb<12g/dl and PLT<600X10^9/L at diagnosis correlated with a statistically significantly increased risk for the development of a thrombotic event *(p=0. 002* κα*ιp=0. 006,* respectively*),* while increased LDH at diagnosis correlated with increased risk for progression to myelofibrosis (p=0. 04)**. Conclusions.** T is characterized by an extremely favorable prognosis. Patients with lower hemoglobin levels and lower platelet counts present thrombotic events more frequently, while males and patients with leukocytosis are characterized by an inferior overall survival. Finally JAK2V617F(+) patients differ from JAK2V617F(-) ones regarding their hematological profile and mimic polycythaemia vera patients.

1611

ORIGINAL TOOL TO IDENTIFY OVERLAPPING MPN PHENOTYPES: TRANSITION INDEX

L Marano, M Gherghi, N Pugliese, M Picardi, G Ciancia, C Quintarelli, B Izzo, V Martinelli, F Pane
University of Naples Federico II, Napoli, Italy

Background. ET, PV and PMF are chronic Ph- myeloproliferative neoplasms (MPNs) characterized by the presence of the acquired mutation in JAK2 tyrosine kinase gene and by excessive production of mature hematopoietic cells. WHO 2008 diagnostic criteria precisely define these diseases, although there are some overlapping features with different clinical outcome that are not considered in WHO definition. **Aims.** As pure ET, ET with the PV-like phenotype, prefibrotic stage, and early PMF could be considered as a continuum, it might be useful to distinguish different cluster of patients and attribute a different prognostic score to each clinical entity. **Methods.** We analyzed 197 ET patients (diagnosis according to WHO 2008) using a multidimensional approach, the *Multiple Correspondence Analysis* (MCA) and the Automatic Classification (CA). MCA generates a Factorial Plain providing a flat view of the relationship between qualitative variables. 'Synthesis factors' independent of each other, were identified by a linear combination of initial variables. CA identifies criteria to define homogeneous groups of ET patients through graphical representation using dendrograms. The initial selected variables are the following: BM reticulin grade; clustering of megakaryocytes (MK) and/or atypical MK; WBC count (<7, 7-8. 5, 8. 5-10, 10-12, >12 x 10^3/mm^3); and dacryocytes and/or leukoerythroblastosis. The analysis has led to new variables, which have been determined by linear combinations of the initials. Among them we considered the one that better describes our initial sample. This new variable is a continuous variable, which called Transition Index (TI). This term was also inspired to define an overlapping tendency of different ET phenotypes. Thereafter, hierarchical cluster analysis has generated a hierarchy of clusters with different TI, represented as a dendrogram. We identified three main clusters: low TI (n=69), intermediate TI (n=112), high TI (n=16). **Results.** TI correlates with the percentage of patients harboring the $JAK2^{V617F}$ mutation, spleen volume at the time of diagnosis and its enlargement at follow-up, CD34+ cells count in the peripheral blood, iron stores, LDH, beta2-microglobulin and low Hb levels. No correlation was found between TI and response to treatment. Furthermore, a higher TI is associated with a greater frequency of thrombotic events. **Conclusions.** TI could represent an instrument to evaluate the degree of overlapping of a con-

tinuum of not well defined Ph- MPNs. This index identifies patients with different clinical phenotypes, most similar to PV or PMF, who do not match all the criteria for these diagnoses. High value of TI correlates with a worse prognosis and could suggest an intensive follow up or the need to adopt new therapeutic strategies.

1612

CLINICAL FOLLOW-UP OF PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS PRESENTING SKIN ULCERS DURING TREATMENT WITH HYDROXYUREA

R Latagliata[1], M Cedrone[2], N Villivà[3], C De Gregoris[4], M Breccia[5], A Spadea[6], M De Muro[7], F Vozella[5], B Anaclerico[2], S Felici[3], M D'Andrea[6], E Montefusco[8], F Spirito[9], S Leonetti Crescenzi[10], A Rago[11], U Recine[12], C Santoro[5], L Annino[2], G Cimino[11], G Avvisati[7], G Alimena[5], M Montanaro[4], A Andriani[3]

[11]Hematology - University "Sapienza" Polo Pontino, Latina, Italy
[12]Hematology - Santo Spirito Hospital, Rome, Italy

Background. Hydroxyurea (HU) is widely employed in the treatment of Myeloproliferative Neoplasms (MPN); however, painful skin ulcers are a limiting toxicity during HU treatment in >5% of patients. **Aims and Methods.** To evaluate the clinical impact of such complication on the outcome of these patients, we retrospectively revised 1001 cases (M/F 437/564, median age 65. 6 years, IR 55. 6 - 73. 7) with MPN consecutively diagnosed at 6 Centers in Rome who received HU treatment during the course of disease. **Results.** There were 537 patients with Essential Thrombocythemia (ET), 336 with Polycythemia Vera (PV), 102 with Primary Myelofibrosis (PMF) and 26 with unclassifiable Chronic Myeloproliferative Disorders (CMPD-u); 863 patients (86. 2%) received HU as 1st line treatment while 138 (13. 8%) as 2nd or 3rd line treatment. On the whole, 71 patients (7. 1%) developed painful skin ulcers after a median period of 54. 1 months (IR 27. 7 - 97. 6) from HU start; as concerns the site, in 56/71 patients (78. 8%) skin ulcers were located in the perimalleolar area while in the remaining 15 patients in other skin areas (localized to the head or to the extremities in 8 and 7 patients, respectively). When the skin ulcers occurred, HU treatment was continued at the same dosage in 11 patients (15. 4%), was reduced in 13 patients (18. 4%) and temporarily interrupted in 11 patients (15. 4%): the remaining 36 patients (50. 8%) needed a permanent drug discontinuation. Among these latter patients, pipobroman was started in 20 patients, anagrelide in 5, alpha-interferon in 3, melphalan in 3; in addition, no further treatment was given in 1 patient and 4 patients were lost to follow-up. As to ulcer resolution, 11/71 patients were not evaluable (2 too early, 9 lost to follow-up). Among the 60 evaluable patients, after a median period of 6. 3 months (IR 3. 6 - 11. 3) from the onset of the skin ulcers, 43 patients (71. 6%) had a complete resolution and 17 patients (28. 4%) had an improvement without complete resolution. The incidence of 2nd neoplasia [3/71 (4. 2%) patients with skin ulcers vs 73/930 (7. 8%) patients without skin ulcers] and blastic phase evolution [2/71 (2. 8%) patients with skin ulcers vs 41/930 (4. 4%) patients without skin ulcers] were not increased after the skin ulcer occurrence. After a median period from skin toxicity of 30. 7 months (IR 14. 3 - 63. 6), 9 patients were lost to follow-up, 11 patients died and 51 patients are still alive. **Conclusions.** Painful skin ulcers during HU treatment are a relatively common complication in MPN patients, require HU discontinuation in > 50% of cases and in a sizable rate of patients there is only a partial healing of skin lesion: however, this complication and the requested treatment changes do not seem to impact on the subsequent clinical follow-up of MPN patients.

1613

CLINICAL AND BIOLOGICAL FEATURES OF POLYCYTHEMIA VERA (PV) IN YOUNGER PATIENTS: A RETROSPECTIVE ANALYSIS ON 600 PATIENTS FOLLOWED IN THE LAZIO REGION DURING 40 YEARS

A Rago[1], R Latagliata[2], R Montefusco[2], M Cedrone[2], S Leonetti Crescenzi[2], F Spirito[2], E Cotroneo[2], N Villivà[3], A Andriani[2], M Breccia[2], A Spadea[2], M Montanaro[2], M De Muro[2], G Cimino[4]
[1]Department of Hematology, University "Sapienza", Polo Pontino Latina, Latina, Italy
[2]On Behalf of the Gruppo Laziale SMPC, Ph1 neg, Rome, Italy
[3]6Dept. of Hematology, Nuovo Regina Margherita Hospital, Rome, Italy
[4]Dept. of Cellular Biotechnologies and Hematology, "Sapienza" University Polo Po, Rome, Italy

Background. Less than 20% of Policythemia Vera (PV) patients are below 50 years of age at diagnosis and there are very few reports addressing this subset. **Aims.** To compare the clinical and biological features of younger (≤ 50 years) PV patients with adult PV patients (> 50 years). **Methods.** We evaluated retrospectively a cohort of 600 $JAK2^{V617F}$ positive PV patients (median age 61. 4, M/F 346/254) consecutively diagnosed at 11 hematologic Units in the Lazio region from 6/1969 to 1/2011; of them, 123 patients (M/F 75/48) aged ≤ 50 years (group A) and 472 (M/F 268/204) aged >50 years (group B). Diagnosis was made according to the criteria accepted at the time of patients diagnosis. **Results.** Hematological characteristics at onset (mean Ht, WBC and PLT counts) as well as gender distribution did not differ significantly between the two age subgroups; however, mean Hb was higher in younger patients as compared to adult patients (p=0. 04). There was a statistically significant difference in the previous thrombotic events (18/123 in group A vs 107/472 in group B, p=0. 04); in particular, splancnic vein thromboses (SVT) were more frequent in group A as compared to group B (p < 0. 05). On the contrary, thrombotic events during the course of disease did not differ between the two groups (18/123 in group A vs 64/472 in group B, p=0. 8) During the follow-up, 38/123 younger patients (30. 1%) needed to start a PLT-lowering treatment compared to 218/472 patients (46. 2%) aged > 50 years (p<0. 05): in addition, a treatment with phlebotomies only was more commonly employed in younger patients (105/123 vs 361/472, p=0. 02). There was no difference between the 2 groups as to evolution in myelofibrotic/leukemic phase (p=0. 3). **Conclusions.** Younger patients with PV seem to have a clinical presentation at diagnosis and a clinical course similar to patients aged > 50 years, apart from a higher incidence of SVT in the anamnesis.

1614

IMPROVING SURVIVAL TRENDS IN PRIMARY MYELOFIBROSIS: AN INTERNATIONAL STUDY

M Cervantes[1], B Dupriez[2], F Passamonti[3], A Vannucchi[4], E Morra[5], J Reilly[6], J Demory[2], E Rumi[3], P Guglielmelli[4], E Roncoroni[5], A Tefferi[7], A Pereira[1]
[1]Hospital Clínic, Barcelona, Spain
[2]Centre Hospitalier, Lens and Lille, Lille, France
[3]Policlinico S. Matteo, Pavia, Italy
[4]University of Florence, Florence, Italy
[5]University Milano-Niguarda, Milano, Italy
[6]Royal Hallamshire Hospital, Sheffield, United Kingdom
[7]Mayo Clinic, Rochester (MN), United States of America

Background. Despite the lack of major improvements in the treatment of primary myelofibrosis (PMF), there are recent indications that survival of patients might have increased over the years. **Aims.** The purpose of the present study was to ascertain whether survival prolongation has actually occurred in PMF and to identify which groups of patients have benefited from such improved survival. **Methods.** 802 patients diagnosed with PMF in four European countries were compared for presenting features and survival according to the diagnostic periods 1980-1995 (n= 434) and 1996-2007 (n= 368). Relative survival and PMF-attributable mortality were calculated by adjusting the patients' actuarial survival for that expected in a subset of the general population matched to the patients by age, sex, country of origin, and calendar year of diagnosis. Comparisons between groups of patients were done by Poisson regression. **Results.** Patients diagnosed between 1996 and 2007 had more often constitutional symptoms (31% versus 23%), but lower incidence of marked anemia (31% versus 39%), leukocytosis > 25 x 10^9/L (9% versus 13%), and blood blasts (27% versus 33%). The distribution of risk groups defined by the IPSS was comparable between the two periods. Median survival was 4. 6 years (95% CI: 4. 0-5. 1) for patients from 1980-1995 and 6. 5 years (95% CI: 5. 5-7. 4) for those from 1996-2007 (p< 0. 0001). Patients diagnosed in the more recent period showed improved relative survival, especially women, patients

younger than 65 years, and those with low or intermediate-1 risk disease. Incidence rates of PMF-attributable mortality at 5 and 10 years were significantly lower in the second period; this reduction in disease-specific mortality occurred across all patient subgroups, except in patients within the intermediate-2 or high risk categories of the IPSS. **Conclusions.** Survival of PMF is improving, except in the patients within the poor risk categories. This observation must be taken into account at the time of evaluating the survival impact of newer therapies for PMF, which are currently being tested in these patient subpopulations.

1615

IDIOPATHIC THROMBOCYTOPENIA (ITP)-LIKE PRESENTATION IN CHRONIC MYELOMONOCYTIC LEUKEMIA (CMML) AND OUTCOME

A Al-Kali, A Swedeh, M Litzow, M Elliott, A Wolanskyj, M Patnaik, K Begna, A Pardanani, C Hanson, A Tefferi, A Al-Kali
Mayo Clinic, Rochester, United States of America

Background. Chronic myelomonocytic leukemia (CMML) is one of the myelodysplastic syndrome/myeloproliferative neoplasm (MDS/MPN) overlap as per 2008 World Health organization (WHO). Cytopenias are commonly found, however, sole thrombocytopenia in the setting of normal hemoglobin raises the suspicion of immune causes. Autoimmunity is seen in patients with MDS and MPN, where its clinical significance is unknown. **Aims.** Describe the characteristics and outcome of patients diagnosed with idiopathic thrombocytopenia (ITP)-like presentation in CMML. **Methods.** A retrospective study of CMML patients diagnosed at Mayo Clinic between 3/1996-8/2011. An IRB protocol was approved. Patients were identified if they had ITP in their history, or have platelets < 50K in the setting of normal hemoglobin and no other possible explaining cause. Information was obtained from chart review and included demographics, autoimmune antibodies work-up, WHO-defined CMML as per pathology review at Mayo clinic. Survival curves and estimates were obtained using Kaplan-Meier through JMP software version 9. 0. **Results.** All 289 patients diagnosed with CMML at Mayo Clinic were screened where 10 (3. 5%) patients had ITP (diagnosed by treating hematologists). Median Age at diagnosis was 74 (range 39-81), WBC 7. 6 (2. 4-33. 4), hemoglobin 12 (10. 5-14. 8), platelets 53 (11-129), LDH 198 (111-424) with 7 being males (70%). All ten patients were classified as CMML1 and had diploid karyotype (but 1 patient had complex cytogenetics). Three of 10 patients had JAK2V617F mutation done, 2 (67%) of which were positive. Two of 8 available patients had splenomegaly, 5 had splenectomy (due to a prior ITP diagnosis) and 1 had no splenomegaly. Interestingly, ITP was diagnosed in 5/10 (50%) patients prior (median time to CMML 599 days) to CMML, 2 after of CMML (median time to ITP 163 days), while 3 patients were found to have thrombocytopenia and CMML simultaneously. Two of 10 (20%) cases were heralded by either MDS or MPN (925, 1399 days). Positive autoimmune antibodies were found in 4/8 (50%) patients (ANA), 1/6 (17%) patients (rheumatoid factor), and 0/1 patients (ANCA); while one patient had sweet syndrome. One patient had psoriasis and one had giant cell arteritis; no patient developed clinical systemic lupus or rheumatoid arthritis. All patients received prednisone for the management of ITP; 3 of which responded (30 %). Three patients received rituximab; 2 (67%) responded. Response to splenectomy was documented in 2/5 (40%) of patients. Three patients were given hypomethylating agents (2 decitabine, 1 azacytidine) for the management of CMML, none of which one achieved complete remission. Only one patient progressed to AML (296 days). Median overall survival was 1131 days in the ITP group compared to 503 days in the rest of the CMML group (p=0. 13 Wilcoxon). **Conclusions.** ITP-like presentation is an infrequent phenomenon in CMML patients and can either precede, follow or coincide with the diagnosis of CMML. It is usually present in low risk CMML and is suspected if no anemia coexisted. Two thirds of our patients did not respond to steroids and had to get splenectomy or second line agent rituximab. ITP-like presentation did not affect overall survival for CMML patients.

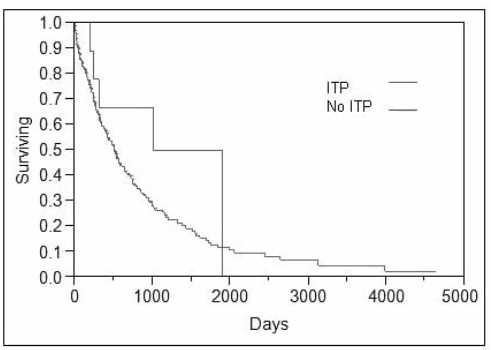

Figure 1. Overall survival.

1616

DIAGNOSTIC FEATURES AND OUTCOME OF PATIENTS WITH MYELOFIBROSIS: IMPACT OF JAK2V617F MUTATION

L Gandossini[1], E Elli[2], A Belotti[2], C Cecchetti[2], E Pogliani[2]
[1]S. Gerardo Hospital, Monza, Italy
[2]San Gerardo Hospital, Monza, Italy

Background. Myelofibrosis (MF) is a Philadelphia-negative chronic myeloproliferative disorder characterized by bone marrow fibrosis, progressive anemia and splenomegaly. Recently, JAK2V617F mutation has been detected in about 50% of patients with MF but real impact between JAK2 mutational status, diagnostic features and outcome is not completely known. **Aims and Methods.** We analysed 180 patients referred to our center with diagnosis of Idiopathic MF, prefibrotic MF, post-Polycythemia Vera (post-PV) and post-Essential Thrombocythemia (post-ET) MF, by WHO classification. The diagnosis of MF was made between 1985 and 2011 years. The aim of the study was to evaluate diagnostic features and therapeutic approaches of MF patients, and their outcome in term of thrombotic risk and overall survival (OS), with particular attention to impact of JAK2V617F mutation. T Student and χ^2 tests were used for statistical analysis. **Results.** The median age at diagnosis was 65 years (range 32-89 years). 110 patients (61%) presented Idiopathic MF, 6 (3. 5%) pre-MF, 21 (12%) post-PV and 38 (21%) post-ET MF. JAK2V617F mutational status was tested by qualitative molecular analysis in 152 pts: 77 patients (43%) resulted JAK2 positive (JAK2+). All 6 pre-MFI and 81% of post-PV MF were JAK2 mutatedAt time of diagnosis the median value of WBC count, Hb level and PLT count were 10. 3x10(e)9/L, 11. 8 g/dl and 373x10(e)9/L, respectively. A statistical difference between JAK2+ and negative (WT) group in term of Hb level (14 vs 11 gr/dl, p=0,0005) and WBC count (10 vs 8,5 x10(e)9/L, p=0,048) were observed. Thrombotic and hemorrhagic events, at diagnosis or during follow-up, occurred in 28 (15. 5%) and 12 patients (7%) respect to 16 (9%) and 8 patients (4. 5%), respectively. The incidence of thrombotic complications at diagnosis was greater in JAK2+ patients respect to JAK2WT (24% vs 13%, p=0,05)Regarding to therapeutic approaches, 69 patients (38%) received no therapy and 90 patients (50%) received myelosuppressive agents, with most necessity of cytoreduction for JAK2WT group (49% vs 22%, p=0,0001). 38 patients (21%) received blood transfusions with higher transfusion requirement in JAK2WT patients (42% vs 2,6% p=0,0001)According to Cervantes score, 10 patients (5%) were assigned to high risk (HR), 34 (19%) to intermediate risk-2 (IR-2), 70 (39%) to intermediate risk-1(IR-1), and 40 (22%) to low risk (LR) group. We observed a significant higher prevalence of JAK2V617F mutation in LR group respect to JAK2WT group (LR 52,5% vs 30%, p=0,001)83 patients (46%) are actually alive, after a median follow-up of 26 months. OS at 5 years was poorer for JAK2+ respect to JAK2WT patients (28,5% vs 40%, p=0,055). **Conclusions.** In our cohort of 180 MF patients, JAK2V617F mutation is associated with specific features at presentation and during follow-up, and correlate with clinical outcome. JAK2+ patients present at diagnosis higher Hb level and are less likely to require blood transfusion during follow-up. Also JAK2+ patients receive less cytoreduction and we note a trend for poorer outcome in JAK2+ patients. The incidence of thrombotic complications, instead, is greater in JAK2+ group.

1617

MYELOPROLIFERATIVE NEOPLASMS: CLINICAL PHENOTYPES, JAK2 MUTATIONAL STATUS AND ANGIOGENIC ACTIVITY

L Gercheva[1], A Zhelyazkova[1], M Tzaneva[1], G Balatzenko[2]
[1]University Hospital "St. Marina", Varna, Bulgaria
[2]National Specialised Hospital for Active Treatment of Haematological Diseases, Sofia, Bulgaria

Background. The Philadelphia-negative myeloproliferative neoplasms (MPNs) overlap in their clinical and biological features. A different JAK2 allele burden in these entities has long been noticed. Some data favour the hypothesis that the level of JAK2 (V617F) expression influences the MPN phenotype. We presume that there is a correlation between the JAK2 mutational status and the clinical phenotypes well as with the angiogenesis in the bone marrow. **Aims.** This study was aimed at analyzing newly diagnosed patients with MPNs with regard to some clinical features, risk stratification, $JAK2^{V617F}$ mutational status, bone marrow (BM) fibrosis and angiogenesis. **Methods.** Apart from the standard methods used routinely for the assessing of the BM features (H&E, Gomori), an anti-CD34 antibody was utilized as an endothelial marker to visualize the micro vessels (MV). The micro-vessel density (MVD) was assessed by counting all MV in 5 hot spots on a magnification 10x40. $JAK2^{V617F}$ expression was determined by RT-PCR. SPSS 17 was used for the statistical analysis. **Results.** Totally of 97 patients were analyzed (PV, n=47; IMF, n=31 and ET,

n=19), in 36 of them we estimated the MVD as well. The distribution according to the JAK2 mutational status was: wild-type(n=25), heterozygous type (n=43), homozygous type (n=29). Significantly increased MVD was established in the patients with PV and IMF comparing to ET patients, most prominently in IMF (p<0. 001). Considerably increased neovascularization was determined in $JAK2^{V617F}$ homozygous cases comparing to the wild type, with a borderline statistical significance (r=0. 34; p<0. 05). There was a statistically significant prevalence of grade 2/3 BM fibrosis in JAK2 positive MPN patients. In PV group, the JAK2 positivity (regardless of the mutational burden) correlated with the risk stratification (p<0. 01) and the homozygosity correlated with the splenomegaly (p<0. 001) and more prominent constitutional symptoms (p<0. 001). 74% of the IMF patients were found JAK2 positive and the heterozygocity was associated with significantly higher hemoglobin level (erythroid phenotype) and marked constitutional symptoms. Homozygous IMF patients showed significant leukocytosis (p<0. 01), thrombocytosis and tendency to an anaemia. In ET group, JAK2 positive patients (no homozygous patients were found) were associated with an erythroid phenotype and a tendency to a splenomegaly. No correlation was established between the JAK2 mutational status and the risk stratification in IMF and ET groups. **Conclusions.** Here, we confirm that the JAK2 mutational burden in IMF and ET correlates with different clinical phenotypes (erythroid, thrombocytemic) and could explain the phenotypic mimicry among these MPNs. As a common pathophysiological process it could not contribute to the distinction among the overlapping features in PV, ET and IMF patients. The other WHO diagnostic criteria should be used always to determine the most relevant diagnosis and thus the prognosis of the patient. The assessment of the MVD is an easily approachable method for a routine use and the level of an increased angiogenic activity could assist in distinguishing the disputable cases among the MPNs. Therefore, this process is worthy of a further investigation in MPN patients in the context of the JAK2 mutational status.

1618

CLINICAL SIGNIFICANCE OF JAK2 MUTATION IN PATIENTS WITH CHRONIC MPN AND EVALUATION OF IT AS A RISK FACTOR FOR HEMORRAGIC COMPLICATION IN THESE DISORDERS

M Tevet, A Lupu, C Saguna, C Dragan, A Colita, G Barca
Coltea Hospital, Bucharest, Romania

Background. JAK2 mutation is recurrent in myeloproliferative neoplasms (MPNs). It has been recognized as a thrombotic risk factor in MPNs, probably due to an increased myeloid proliferation and white blood cells (WBC) activation, but only few data are available about the effect of JAK2(V617F) on hemorrhagic risk. **Aims.** In our study we investigate the frequency of JAK2V617F mutation in a lot of 194 patients with MPNs diagnosed in our clinique and we evaluate the influence of the mutational status on hemorrhagic complication. **Methods.** JAK2V617F mutation was screened by allele-specific polymerase chain reaction (AS-PCR). We retrospectively analysed laboratory and clinical findings of 194 consecutive patients with MPNs to evaluate possible relationships between thrombosis, abnormal bleeding, peripheral blood count and overexpression of JAK2(V617F) mutational status. **Results.** JAK2V617F mutation was detected in 124 of the 194 patients with MPN. The frequency was similar among ET, IMF and MPD-U (P > 0. 05), but it was significantly lower than that in PV (P < 0. 05). The presence of JAK2V617F was found to be significantly correlative with middle age at diagnosis (P < 0. 01) and with higher hemoglobin levels and higher leukocyte counts (P < 0. 05). Significant difference was found in complication of vascular events between JAK2V617 positive and negative patients (P < 0. 05). Cytogenetic analysis was performed in 62 patients from the entire lot of 194. Among the subgroup with normal karyotype, JAK2V617F mutation was detected in 30% patients as compared with 90% of the patients from the subgroup with karyotypic abnormalities (which were 70% from those to whom we performed cytogenetic analysis). We also found an association between JAK2(V617F) mutation and thrombotic events before or at diagnosis (p<0. 003, OR=4. 44, 95% CI=1. 74-12. 4); no statistical correlation between the median value of JAK2(V617F) burden and an increased risk of thrombosis (p=0. 4, 95% CI= -22. 8-10. 4); significant relationships between mutated status and higher haematocrit, high WBC count and low platelet count. Moreover, the presence of the JAK2(V617F) mutation and a WBC count greater than 9. 2 x 10(9)/L were found to be independent factors related to thrombotic complications in multivariable analysis. The prognostic impact of JAK2 mutation status and WBC count on thrombosis was evaluated in the whole cohort. Finally, wild-type JAK2 was associated with a higher haemorrhagic risk in univariate analysis but only a platelet count greater than 1,022 x 10(9)/L was associated with an increased risk of bleeding in the multivariable analysis. **Conclusions.** The presence of JAK2V617F in MPNs is associated with the disease development. There is a correlation between JAK2V617F mutation in MPN and advanced age, higher leukocyte counts, hemoglobin level and vascular events. Our data confirm the role of both JAK2(V617F) as factor associated with an increased risk of thrombosis at the diagnosis and during follow-up in no treated patients. Moreover a WBC count over 9,2 x 10(9)/L1 was also strictly associated to an increased risk of thrombosis. Regarding bleedings, our statistical analysis allows to exclude the mutation protective role on haemorrhage.

1619

THE OXIDATIVE STATUS IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

Background. Essential Thrombocythemia (ET), one of the chronic myeloproliferative disorders, is a clonal disease in which thrombotic and hemorrhagic complications can be seen. Oxidative stress parameters are shown to be increased in patients of hemodialysis, lung cancer and cases of pulmonary embolism with ischemia. Yet, to our knowledge, no studies conducted investigating the oxidative status of the patients of ET. **Aims.** In the present study, we have planned to determine the serum levels oxidative parameters like the total oxidative status (TOS), total antioxidant status (TAS), oxidative stress index (OSİ), ischemia-modified albumin (IMA) and malondialdehyde (MDA) in ET patients. **Methods.** 43 ET patients (20 male, 23 female) and 20 healthy volunteers (control group) with similar age are enrolled in the study. Oxidative stress parameters (TOS, OSİ, TAS, MDA, İMA) are compared between control and patients at the time of diagnosis. The same parameters of the patients at the time of diagnosis and 6 months after the therapy were also compared. **Results.** Compared to control, oxidative status parameters like TOS, OSI and MDA are found to be significantly higher in patient group. TAS levels were significantly reduced in patients. IMA results were similar in patient and control group. After the therapy, OSI and MDA values were significantly reduced in patient group compared to the values before treatment. Following the treatment, TAS values showed a statistically insignificant increment. Similarly, TOS and IMA levels were found to be reduced but these changes did not reach to significance level. **Conclusions.** Our findings reveal that oxidative stress parameters increased but the compensative antioxidant capacity was significantly reduced in ET patients compared to healthy controls. The alterations observed in oxidative stress parameters of ET patients might be related to thromboembolic events.

1620

CLINICAL, HISTOLOGICAL AND LABORATORY ASPECTS IN PATIENTS WITH MPN PH- CARRYING TRISOMY 9

A Iurlo[1], M Grimoldi[2], U Gianelli[3], C de Philippis[4], T Radice[4], P Bianchi[4], E Fermo[4], A Benevento[2], S Buiatiotis[2], R Malgara[2], A Patrizi[2], G Bufamante[5], A Cortelezzi[4]

Background. The Myeloproliferative neoplasms (MPN) comprise several clonal haematological diseases that are thought to arise from a transformation in a hematopoietic stem cell. The three main Ph-negatives are Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Idiopathic Myelofibrosis (IMF). The main clinical features of these diseases are the overproduction of mature functional blood cells and long clinical courses. Trisomy 9 has been described in several haematological disorders, representing the third most frequent chromosome abnormality in Ph- neoplasms after 20q deletion of and trisomy 8. **Aims.** In this study we have analysed clinical, histological and laboratory features including *JAK2*V617F allele burden in MPN patients carrying trisomy 9, to understand if this cytogenetic anomaly is associated with some particular aspects. **Methods.** Cytogenetic analysis was performed on 325 MPN patients followed by our institution by QFQ-banding on unstimulated 24 hour cultured

bone marrow. *JAK2*V617F allele burden was measured on genomic DNA from granulocytes using JAK2 MutaQuant® Kit (Ipsogen). **Results.** Trisomy 9 was found in 13 cases (9 PV and 4 ET). In 10 of them it was the only chromosomic anomaly found, in one case it was associated with trisomy 8 and in the last two cases in complex karyotypes. Patients were regularly followed-up for a period of 10. 6 years (range 1-23 years). The median age of diagnosis was 62 years and M:F ratio was 1,2:1. Laboratory data revealed a mean Hb level of 16,7 g/dl, WBC count of 9657/mmc, while mean Plt count was 690. 000/mmc. Erythropoietin serum level was reduced in all patients and *JAK2*V617F mutation was found in almost all patients (mean allele burden 47,1%). Morphological analysis revealed that bone marrow cellularity was increased in all patients carrying trisomy 9; in particular, both erythropoiesis and granulopoiesis were increased with left shifting. In addition, in these patients there were more pleomorphism of the megakaryocytes, defined by the presence of small to giant megakaryocytes grouped together, more nuclear hyperlobulation, maturation defects, bulbous and naked nuclei. It is worth noting that Hb levels at diagnosis in the 4 ET patients were higher than normal but not enough for PV diagnosis; three out of them later evolved to PV. **Conclusions.** The above data demonstrate that trisomy 9 in our study is more frequent in PV. Patients with ET carrying this anomaly showed clinical, histological and laboratory characteristics similar to PV with a risk of evolving into overt PV, which is a relatively rare event. . Remarkably, all ET patients with trisomy 9 were positive for V617F mutation of *JAK2* gene, which is mapped on the short arm of chromosome 9.

[2]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

[3]Institute for Medical Research, Belgrade, Serbia

Background. The clinical course of essential thrombocythemia (ET) is marked by a higher incidence of thrombotic complications, which present the main cause of morbidity and mortality. Major predictors for thrombosis are age over 60 years and previous thrombosis. Myelosuppressive drugs can reduce the rate of thrombosis, but there is concern that their use raises the risk of transformation into acute leukemia. To solve this dilemma, the risk-oriented treatment strategy is recommended. **Aims.** We investigated the clinical and laboratory parameters associated with the risk of the occurrence of thrombotic events to identifying the subgroups of patients who will have the benefit from cytoreductive therapy. **Methods.** The study involved 207 consecutive ET pts who were diagnosed according the WHO criteria (with information of bone marrow biopsy at diagnosis) and followed from January 2000 to December 2010 at Clinic for Hematology, Clinical Center of Serbia, Belgrade. The median follow up of the study cohort was 64 months. **Results.** There were 137 females and 70 males with median age 57 years (range 18-85); median Plt count was 1067x10^9/L (range 497-3600); median WBC count 10. 5x10^9/L (range 5. 4-22. 8); median Hb 13. 9 mg/L (range 9-180); symptoms of ET had 104/171 (61%) mostly paresthesia and headache; history of hemorrhage had 4 pts (2%). Previous thrombosis had 29 pts (14%), 22 pts experienced arterial, 5 venous and 2 both. During the follow up, 11pts (5. 3%) developed thrombosis (7 arterial and 4 venous): 4/25 pts with a previous history of thrombosis and 7/171 without a history of thrombosis (p=0. 028). Median time of occurrence thrombotic event was 45months (range 6-130 months) after the diagnosis of ET. The thrombotic events at onset of disease were significantly related to age over 60 years (p=0. 02) but no relationship was found with number of leukocyte, platelets, gender and JAK2V617F mutation. Patients were divided into subgroups according to the presence of the four analyzed risk factors including age (over 60 years), count of Le (>10x10^9/L), count of Plt (>1500x10^9/L), and the presence at least one of the cardiovascular risk factor (tobacco use, hypertension, diabetes). The rate of thrombosis during the follow up was significantly higher in a subgroups of patients with two or more risk factors than in subgroups of patients without any or with presence of one risk factor (p=0. 001). **Conclusions.** Previous thrombosis and platelet count, generally accepted as very important risk factors for thrombosis were not associated with an increased risk in our group. The rate of thrombosis at the onset of disease has been confirmed to be related to the age over 60 years. Moreover, a better prediction of thrombotic risk was found in overview of the combination of risk factors. Patients with two or more analysed factors are at the high risk to develop thrombosis.

1622

CLINICAL CHARACTERISTICS OF JAPANESE ADULTS WITH INTOLERANT/REFRACTORY HIGH-RISK ESSENTIAL THROMBOCYTHEMIA - BASELINE DATA FROM A PHASE III, MULTICENTER, EFFICACY AND SAFETY STUDY OF ANAGRELIDE

Y Miyakawa[1], S Okamoto[1], I Hodgson[2], J Smith[2], B Abhyankar[2], Y Kanakura[3]

[1]Keio University, Tokyo, Japan

[2]Shire Pharmaceutical Development Limited, Basingstoke, United Kingdom

[3]Osaka University Hospital, Osaka, Japan

Background. Essential thrombocythemia (ET) is a myeloproliferative disorder associated with an increased risk of thrombohemorrhagic complications. A previous study reported significant clinical differences between patients with ET in Caucasian and Japanese populations, with a lower incidence of thrombosis in the latter[1]. Clinical characteristics have not previously been described in high-risk patients (>60 years of age; history of thrombosis; platelet count >1000x10^9/L) with ET who are intolerant or refractory to their existing cytoreductive therapy in a Japanese population. Ranimustine is currently the only licensed treatment for patients with ET in Japan, however, a number of cytoreductive therapies are available. **Aims.** The objective of this study is to assess the clinical characteristics of high-risk patients with ET who are intolerant or refractory to currently available cytoreductive therapy in Japan. **Methods.** High-risk patients aged ≥20 years with ET, diagnosed according to WHO criteria, who were intolerant or refractory to their existing cytoreductive therapy, were enrolled into the study, SPD422-308 (NCT01214915). Informed consent was obtained and baseline characteristics were recorded. Patients subsequently received a starting dosage of anagrelide (1mg/day), administered orally as 0. 5mg twice daily. After 1 week the dose was titrated to a patient-specific optimal dosage required to achieve a response. Patients are planned to receive treatment for 12 months. This study is sponsored by Shire Pharmaceuticals. **Results.** A total of 53 patients, 56. 6% females (n=30) and 43. 4% males (n=23), assessed to be intolerant (64. 2%, n=34) or refractory (35. 8%, n=19) to their existing cytoreductive treatment, were enrolled into the study. The median age at screening in the intolerant and refractory groups was 67 years (range, 36-86) and 61 years (range, 36-71), respectively. The median time from date of diagnosis until study enrollment was 6. 9 years (range, 0. 1-29. 1) and 7. 1 years (range, 0. 2-22. 2) for intolerant and refractory groups, respectively. Notably, four patients received cytoreductive therapy prior to being formally diagnosed. The median platelet count at baseline was 826. 5x10^9/L (range, 285-2130) and 1030x10^9/L (range, 601-2518), respectively. Baseline hematological values comparing patients who were intolerant or refractory to their existing cytoreductive therapy are summarized in Table 1.

Table 1. Hematological values at baseline comparing Japanese high-risk patients with ET who were intolerant or refractory to their existing cytoreductive treatment.

	Intolerant patients	Refractory patients
Number of patients (%)	34 (64.2)	19 (35.8)
Platelets (10^9/L) Median (range)	826.5 (285–2130)	1030 (601–2518)
Hb (g/dL) Median (range)	119 (69–150)	127 (86–159)
Hct (V/V) Median (range)	0.37 (0.21–0.51)	0.40 (0.26–0.50)
WBC (10^9/L) Median (range)	7.3 (2.4–29.2)	6.0 (2.7–27.4)

Hb – Hemoglobin; Hct – Hematocrit; WBC – White blood cells

The most common cytoreductive therapy that patients were refractory or intolerant to, prior to the first dose of study treatment, was hydroxycarbamide (96. 2%, n=51). **Summary and Conclusions**. This study provides important baseline data on a previously undescribed population of patients with ET, who are intolerant or refractory to their existing cytoreductive therapy. As expected, patients considered to be refractory to their existing cytoreductive treatment were observed to have a higher platelet count at baseline, compared with patients who were intolerant to their existing cytoreductive therapy. However, for both groups the median platelet count was higher than the recommended target of <400-600x10^9/L [2]. This study highlights the need for alternative treatment options in both refractory and intolerant high-risk patients with ET in Japan.

Background. The cytoreductive agents Hydroxyurea (HU), Anagrelide (ANA), and Interferon alpha (IFN) in ET patients are not rarely discontinued due to toxicity/side effects or inefficacy. Since HU, ANA, and IFN have different activity and toxicity patterns, the combined use of two drugs may result useful to overcome the inadequacy of a single drug. OBJECTIVETo evaluate the role of the cytoreductive combination therapy in the clinical management of ET patients. **Methods.** The RIT includes 2550 ET patients (PVSG or WHO criteria). A data analysis has been performed by distinguishing combinations on the basis of the first (baseline) drug and of the second (added) drug: HU+ANA, ANA+HU; IFN+ANA, ANA+IFN; HU+IFN, IFN+HU. Frequency, rate and reasons of discontinuation, and duration of the different combination therapies are considered. **Results.** A total of 118 (4. 6%) ET patients of the RIT received a combination therapy between March 1993 and May 2011, at median distance of 3 years from diagnosis. The patients, 49 males and 69 females, had at diagnosis: median age 48 years (range 5-79), median PLT count 979 x 10^9/L (range 490-2000), JAK2 V617F mutation (52%), disease related symptoms (39%), CV risk factors (43%). The patients performed globally 129 courses of combination therapy: HU+ANA (n 50), ANA+HU (n 20); IFN+ANA (n 19), ANA+IFN (n 5); HU+IFN (n 29), IFN+HU (n 6). In these 129 courses the baseline drug was represented by HU in 79 cases, ANA in 25 cases, and IFN in 25 cases, while the added drug was ANA in 69 cases, IFN in 34 cases, and HU in 26 cases. The combination therapy was interrupted globally in 73 out of 129 courses (57%), with lower frequency in the HU+ANA or ANA+HU courses (47%, 33 out of 70) and higher frequency in the other combination courses (68%, 40 out of 59). These 73 interruptions were due to HU withdrawal (27 courses, 37%), IFN withdrawal (23 courses, 32%), ANA withdrawal (18 courses, 25%), other reasons (5 courses, 6%). The most frequent reasons of drug withdrawal were: for HU toxicity/side effects (n 11), and inefficacy (n 6); for IFN toxicity/side effects (n 8), and inefficacy (n 4); for ANA toxicity/side effects (n 10). The rate of the baseline drug withdrawal was 20% for ANA (5/25 courses), 32% for IFN (8/25 courses), and 33% for HU (26/79 courses). The median duration of combination therapy was 9 months (range 0. 5-86) for all 129 courses, 12 months (range 0. 5-86) for the 56 ongoing courses, and 6 months (range 0. 5-68) for the 73 interrupted courses. The median duration was longer (15 months) for the HU+ANA or ANA+HU ongoing courses and lower (6 months) for the other ongoing courses. **Conclusions.** A cytoreductive combination therapy was reported in 118 (4. 6%) out of 2550 ET patients of the RIT. The combination HU+ANA or ANA+HU, compared with the other combinations, was the most frequent (54%, 70//129 courses), showed a longer duration (15 vs 6 months), and a lower rate of interruption (47 vs 68%).

1624

NEUROLOGICAL SYMPTOMS IN ESSENTIAL THROMBOCYTHEMIA: IMPACT OF JAK2V617F MUTATION AND RESPONSE TO THERAPY

E Elli, C Cecchetti, C Brambilla, A Belotti, L Gandossini, EM Pogliani
San Gerardo Hospital, Monza, Italy

Background. patients with Essential Thrombocythemia (ET) may present a wide spectrum of neurological symptoms (NS) at onset or during the course of disease, only in part resulting from previous thrombotic cerebral events. Sometimes NS may indicate a micro-vascular occlusive event however the risk factors and specific therapeutic strategy have not completely defined yet. **Aims and Methods.** we retrospectively described NS that occurred in 265 ET referred in our center from 1995 to 2011. We separately analysed NS secondary to thrombotic cerebral event (TCE) by the remaining functional ET-related NS, in order to identify clinical and biological features associated to NS and to assess the response of NS to therapy. **Results.** Overall, 86/265 patients (32. 5%) have presented whatever NS; 16/86 patients (18,6%) developed NS after TCE (transient ischemic attack or stroke), principally paresthesias (6) or instability and motor and sensitivity disturbances (10). The remaining 67 patients reported subjective and often transient and fluctuating NS, by frequency order: chronic paresthesias (36), cephalalgia (30), dizziness or hypotension (16), blurry vision (8), tinnitus (5), which we defined as ET-related NS. Six patients presented erythromelalgia as peripheral manifestation. Median age of NS patients was 55 years, with prevalence of female sex; JAK2V617F mutation was evaluated in 65/86 patients with prevalence of JAK2 positive versus negative patients (64,5% vs 35,5%). All patients received anti-platelet agent (low- dose aspirin or similar) at diagnosis; a cytoreductive treatment, instead, was reserved to TCE-patients and selected ET-related NS patients. In most TCE-patients, anti-platelet + cytoreductive treatment didn't lead to complete resolution of NS; in ET-related NS group, 27/64 patients (42%) achieved a complete response after anti-platelet treatment, alone (15) or associated with cytoreduction (12) to normalize platelet count. 58% of ET-related NS patients did not respond to anti-platelet treatment; 8 patients of whom (21,6%) improved NS after addition of citoreductive therapy. Patients not responsive to antiplatelet-only treatment appeared older (59 vs 46 years), but no other differences regarding laboratory features and JAK2 mutational status were demostrated. Therefore, we have subdivided patients with NS in two risk classes according to number of cardiovascular (CV) factors (low: 0; high > 1). Focusing on low risk CV group, we noted that the response rate to anti-platelet treatment was higher in JAK2 positive respect to JAK2 negative patients (50 % vs 25%). Overall, 85% of patients (73/86) with NS are alive with a median follow-up of 52 months (range: 1-312 months). **Conclusions.** We observe that 32,5% of ET-patients present NS. In the 80,7% of them (67/86) NS aren't secondary to TCE, so these are interpreted as ET-related NS. Mostly of these patients are female and seem to present higher prevalence of JAK2V617F mutation. Only 42% of ET-related NS responds to anti-platelet-only treatment¸ in particular in low risk CV group, the rate of response to anti-aggregation is higher in JAK2 positive respect to negative patients. The addition of cytoreductive therapy should be considered in ET-related NS refractory cases, suggesting the involvement of different mechanisms from micro-vascular disturbances, not fully understood yet, in ET-related NS pathogenesis

1625

UTILITY OF SPLEEN VOLUME EVALUATED WITH ULTRASOUND SCAN IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPN)

ML Randi, C Santarossa, S Simoni, N Vitturi, E Bonamigo, E Duner, F Fabris
University of Padua, Padova, Italy

Background. Splenomegaly is a common finding in MPN occurring in about 70% of polycythemia vera (PV), 10% of essential thrombocythemia (ET) and almost all primary myelofibrosis (PMF) since their diagnosis. It has been found that ultrasound scan (US) assessment is a sensitive method to evaluate splenomegaly in MPN. **Aims.** The present study evaluates the efficacy of US in detecting splenomegaly in MPN patients when palpation is not able to recognize splenomegalyMaterials and **Methods.** Spleen size was assessed in 50 patients with MPN (22 PV, 15 ET and 13 PMF, 21 males and 29 females, mean age 63±15 years) diagnosed in agreement with WHO 2008 criteria. We compared palpation (expressed as cm from the costal border) with US assessment. US studies have been performed by a single operator using an Aplio SSA-700A (Toshiba, Japan) instrument with a 2. 5/3. 5-MHz broadband curvilinear probe. Perimeter, longitudinal diameter, and area, defined as the maximum measurements with splenic borders and angles clearly defined, were measured, and volume (in milliliters) was calculated automatically. To obtain normal values of US measurements (longitudinal diameter 9-11 cm, area 27-45 cm^2 and volume 70-160 ml) we used 22 healthy volunteers. We applied c^2

test for categorical variables. **Results.** Splenomegaly was detected by palpation in 25 MPN (50%) and confirmed in all cases by US evaluation. In 14 (56%) out of the remaining 25 patients, US assessment showed increased spleen size. Spleen longitudinal diameter, area and volume were equally efficient in founding splenomegaly. The comparison between spleen palpation and spleen US assessment is summarized in the Table 1. **Conclusions.** We confirm that US assessment is a sensitive method for identifying non palpable splenomegaly in patients with MPN; however, we failed to found a higher sensitivity of spleen volume in detecting splenomegaly compared with measurement of longitudinal diameter and area in contrast to other Authors (Martinelli et al, Blood 2002, 99:4228). While in PMF splenomegaly is well recognized with physical examination, US assessment seems to be particularly useful in documenting small splenomegaly of ET and PV.

Table 1.

	Palpation Pos/neg	US Pos/neg	p
TOT (50)	25/25	40/10	0.003
PV (22)	11/11	19/3	0.02
ET (15)	4/11	9/6	0.03
MF (13)	10/3	12/1	NS

EVALUATION OF THE DIAGNOSTIC CRITERIA OF POLYCYTAHEMIA VERA IN EVERYDAY CLINICAL PRACTICE: THE RELEVANCE OF JAK2V617F MUTATION

P Tsirkinidis[1], T Vassilakopoulos[1], O Tsopra[1], M Dimou[1], I Vardounioti[1], G Georgiou[1], S Kokoris[2], E Plata[1], Z Galani[1], G Boutsikas[1], K Petevi[1], A Kanellopoulos[1], A Euthymiou[1], V Karali[1], A Bitsani[1], T Tzenou[1], G Pangalis[3], N Vyniou[1], J Meletis[1], M Kyrtsonis[1], P Panayiotidis[1], M Angelopoulou[1]

[1]Laikon hospital, Athens, Greece

[2]Current position Attikon Hospital, Athens, Greece

[3]Current position Athens Medical Center, Athens, Greece

Background. Polycythaemia vera (PV) belongs to the bcr-abl negative group of myeloproliferative disorders. The introduction of the JAK2V617F mutation, has led to a clearer description of this entity. **Aims.** Aim of the present study is to report the clinical and laboratory findings and the outcome of PV patients from a single center, as well as to evaluate the application of the new diagnostic criteria in everyday clinical practice. **Methods.** The WHO 2008 diagnostic criteria for PV were retrospectively applied in 61 patients diagnosed with PV between 1998 and 2011. Patients were distributed into 3 groups: Group I included patients who fulfilled both major criteria (increased Hb values for gender: Hb≥16. 5g/dL in women and Hb≥18. 5g/dL in men, or increased red cell mass and the presence of JAK2V617F mutation), group II included those who fulfilled the 1st major and two minor criteria (low/low-normal EPO levels and bone marrow biopsy consistent with PV). In this group JAK2V617F mutation was either unavailable or negative. Group III consisted of JAK2V617F(+) patients, who were diagnosed and treated as PV, but did not strictly fulfill the WHO 2008 criteria. **Results.** The median age of our patients was 64 years (29-91), 31 were males and 30 females. At diagnosis, 52% were asymptomatic, 21% had splenomegaly and 16% hepatomegaly. A major thrombotic or bleeding episode was reported at 30% with the most frequent being an arterial thrombosis/ischemia. JAK2V617F mutation was found in 36/38 patients (95%), median values of Ht, Hb, MCV, WBC and PLT were 53. 8%, 17. 3g/dL, 81. 8fl, 9. 050x10^9/L and 575x10^9/L respectively. LDH levels were elevated in 34%, while median serum erythropoietin levels were 6. 65 IU/mL (0-28. 4). Bone marrow biopsy revealed panmyelosis in 55%, fibrosis in 33% with grade 2 fibrosis in 3%, while 12% had an abnormal karyotype. First line treatment was hydroxyurea in 73%, while 24% were treated with phlebotomy only. Median time to the initiation of cytotoxic treatment was 0. 9 months (0-77). Antiplatelet and anticoagulation treatment was administrated in 77% and 7% respectively. The overall response rate to cytotoxic therapy was 95% with 63% complete and 32% partial remission. Median time to response was 2. 4 months. At a median follow up time of 38 months (0. 9-162) 5 deaths were recorded, with a 5- and 10-year overall survival (OS) of 92% and 77% respectively. Age >65 years (p=0. 029), increased LDH (p=0. 026) and the presence of a thrombotic/bleeding event (p=0. 048) at diagnosis were adverse prognostic factors for OS. The comparison of the 3 subgroups revealed statistically significant differences depicted in the Table 1: Subgroup III consists of cases that cannot be objectively classified as PV or essential thrombocythaemia (ET) and might represent the pre-polycythaemic phase of PV. **Conclusions.** Although the new diagnostic criteria of PV make the differential diagnosis between true PV and secondary erythrocytosis clear-cut, they cause difficulty in classifying patients between PV, ET and the pre-polycythaemic phase of PV. The biology of this disease subgroup is not known, while its clinical importance needs to be further elucidated.

Table 1.

	Group I N=23	Group II N=20	Group III N=20	p
Median Ht (%)	55,4	55,1	50,8	0,007

THE OXIDATIVE STATUS IN PATIENTS WITH POLYCYTHEMIA VERA

A Durmus[1], A Mentese[2], M Yilmaz[3], A Uzun[2], C Topal[4], A Alver[2]

[1]Kanuni Training and Research Hospital, Trabzon, Turkey

[2]Karadeniz Technical University, Faculty of Medicine, Dept. Of Biochemistry, Trabzon, Turkey

[3]Karadeniz Technical University, Faculty of Medicine, Dept. Of Hematology, Trabzon, Turkey

[4]Kanuni Training and Research Hospital, Internal Medicine, Dept. Of Nephrology, Trabzon, Turkey

Background. Polycythemia Vera (PV) is the most prevalent disease among chronic myeloproliferative disorders. In PV patients, before diagnosis or during follow-up period, life threatening thrombotic events can be observed. Oxidative stress parameters are shown to be increased in patients of hemodialysis, lung cancer and cases of pulmonary embolism with ischemia. However, to our knowledge, studies conducted investigating the oxidative status of the patients of Polycythemia Vera. **Aims.** In the present work, we have investigated the serum levels oxidative parameters like the total oxidative status (TOS), total antioxidant status (TAS), oxidative stress index (OSİ), ischemia-modified albumin (IMA) and malondialdehyde (MDA) in PV patients. **Methods.** 35 PV patients (20 male, 15 female) and 20 healthy volunteers (control group) with similar age are enrolled in the study. Oxidative stress parameters (TOS, OSİ, TAS, MDA, İMA) are compared between control and patients at the time of diagnosis. The same parameters of the patients at the time of diagnosis and 6 months after the therapy were also compared. **Results.** Compared to control, oxidative status parameters like TOS, OSI and MDA are found to be significantly higher in patient group. TAS levels were reduced (statistically not significant) in patients. IMA results were similar in patient and control group. After the therapy, TOS, OSI and MDA values were significantly reduced in patient group compared to the values before treatment. Following the treatment, TAS values showed a statistically insignificant increment. Similarly, IMA levels were found to be reduced but the change was not significant. **Conclusions.** Our findings showed that oxidative stress parameters increased but the compensative antioxidant capacity was significantly reduced in PV patients compared to healthy controls. The alterations observed in oxidative stress parameters of PV patients might be related to thromboembolic event.

1628

CHARACTERISTICS OF DIAGNOSTIC APPROACHES FOR ERYTHROCYTOSIS OF DIFFERENT GENESIS

M Sokolova, N Khoroshko, M Dmitrieva, M Nareyko, V Zhuravlev, M Egorova, N Moiseeva, E Gemdjan, Y Sahibov
Hematology Research Center, Federal State Budget Institution Ministry of Health, Moscow, Russian Federation

Background We suggest that the common laboratory parameters such as hemoglobin, red blood cell (RBC) number and hematocrit do not always adequately reflect the degree of absolute RBC mass due to possible variations of the plasma volume. Therefore only these values are not completely sufficient for diagnostics of hematological disorder. **Aims.** To investigate the diagnostic value of circulating RBC mass as a possible marker of absolute erythrocytosis in connection with hemoglobin, hematocrit, RBC number in the group of patients with preliminary diagnosis of polycythaemia vera (PV) and to demonstrate the distribution of the investigated patients into diagnostic groups. **Materials and Methods.** We evaluated 61 patients with erythrocytosis before the beginning of treatment, 9 females and 52 males, medium age was 46 years (18-82). Medium level of hemoglobin and hematocrit in females was 171g/l (143-190) and 52% (49-61) respectively. Medium level of hemoglobin and hematocrit for males was 187 g/l(168-196) and 57,8% (49-65), respectively. All samples of venous blood were taken in the morning. Count blood cells (CBC) with differential was performed by Coulter principle on Gen S ("Beckman-Coulter",USA) blood analyzer with preserving agent (ethylene diamine tetra acetate, EDTA). The circulating RBC mass and plasma volume were measured by radionuclide method (Cr-51). The results were calculated in accordance with the patient's body surface area and were interpreted according to the recommendations of International Committee for Standardization in Hematology (ICSH) (Pearson et al. 1995). Range of normal variations of RBC mass and plasma volume for healthy males and females were +/- 25% from the normal individual parameters. **Results.** PV was detected only in 19(31%) of 61 patients. 15 patients refused from further investigation. Among the remaining 46 patients 14 subjects had secondary erythrocytosis, among them 9 had absolute erythrocytosis (hypoxic) and 5 had idiopathic erythrocytosis. Relative ("apparent") erythrocytosis was detected in 13 cases. Measurement of circulating RBC mass allowed us to distinguish the groups of patients with absolute and relative erythrocytosis. We found that hemoglobin level over 185 g/l was confirmed by presence of absolute erythrocytosis only in 50% of males with PV, while 15% of males with secondary erythrocytosis could have an incorrect diagnosis due to "apparent"increased RBC mass. We defined statistically significant (P=0,001) difference of RBC mass in patients with PV and patients with "apparent"erythrocytosis: 166% and 111%, respectively. In patients with PV and absolute erythrocytosis the RBC mass was over the upper normal limit (more than 25%) while the patients with secondary erythrocytosis had RBC mass rate within the normal limits +/- 25%. Average plasma volume measurements in both groups of patients were at normal ranges: 95% и 81%, respectively (P=0,01). **Conclusions.** We consider that the RBC mass and plasma volume measurement is accessible, easy to perform and necessary procedure to distinguish the absolute and "apparent"erythrocytosis. It is important because rather common occurrence of different forms of erythrocytosis and in particular of the "apparent"erythrocytosis should determine different diagnostic approaches according to the specific clinical situation.

1629

DYSLIPIDEMIA AND MEAN PLATELET VOLUME - RISK FACTORS FOR THROMBOTIC EVENTS IN PATIENTS WITH PHILADELPHIA-NEGATIVE CHRONIC MYELOPROLIFERATIVE NEOPLASIAS

RG Mihaila[1], A Olteanu[2], R Dancu[2], I Lisan[2], A Catana[2], O Flucus[2], C Bus[2]
[1]Lucian Blaga University Sibiu, Sibiu, Romania
[2]Emergency County Clinical Hospital, Sibiu, Romania

Background. Patients with Philadelphia-negative chronic myeloproliferative neoplasias have an increased thrombotic risk. Increased mean platelet volume is known as an index of platelet activation and of thrombotic risk, like hypercholesterolemia. It is known that leukemic cells have an increased cholesterol metabolism, which they capture intracellular and use it for their own proliferation. **Purpose**: We aimed to analyze changes in lipids and platelets in patients with chronic myeloproliferations with and without a history of thrombotic accidents. **Materials and Methods.** There were included in the study all patients with Ph negative chronic myeloproliferative neoplasias, who were admitted in 2011, in the Hematology Department of Emergency County Clinical Hospital of Sibiu and appear in the electronic filing system ATLAS. We studied: age, gender, diagnosis, platelet count, mean platelet volume, cholesterol, triglyceride, treatment, thrombotic accidents, associated diseases. We note that the blood samples were analyzed in the laboratory, within 2 hours after withdrawing. Patient data were compared. Statistical analysis was performed with the arithmetic mean, standard deviation, Student t test and Pearson test. **Results.** The 50 patients had a mean age 61. 9+/- 13. 8 years. Distribution by gender: 31 women (62%), 19 men (38%). The average number of platelets was 356653. 1+/-259251. 3/mm3, average cholesterol - 173. 4+/-48. 53 mg/dl, average triglyceride 156. 17+/ -78. 36 mg/dl. From the entire group, 18 patients (36%) had a history of thrombotic accidents (8 ischemic stroke, 4 venous thrombosis, 3 myocardial infarctions, two episodes of disseminated intravascular coagulation, a Budd Chiari syndrome and a splenic infarction) (group A). The comparison of the biological data of patients in group A with those with no history of thrombosis (group B), showed that the first have significantly higher values of both triglyceride (193. 06+/-91. 10 mg/dl to 133. 23+/-60. 23 mg /dl) ($p<0.005$) and the mean platelet volume (11. 19+/-0. 84 fl, from 9. 94+/-0. 91fl) ($p<0.00005$) compared with patients without thrombotic history. In patients of group A (not in those of group B) cholesterol values were directly correlated with the triglyceride (r=0. 524) and mean platelet volume was inversely correlated with platelet count (r=-0. 237). So, the higher the mean platelet volume gets the lower the platelet count is and vice versa. In the entire group of 50 patients there was a direct correlation (less intense) between the cholesterol and triglyceride levels (r=0. 314) and between age and cholesterol levels (r=0. 260). **Conclusions.** The mean platelet volume is significantly higher in Ph negative chronic myeloproliferative neoplasia patients with a history of thrombotic accidents, than those without such history. The fact that, mean platelet volume of the patients with thrombotic history correlates inversely with platelet count, can explain why patients with essential thrombocythemia are predisposed to thrombosis at platelet values below 100000/mm^3, compared to those with values above 100000/mm^3, that are predisposed to bleeding. Patients with a history of thrombotic accidents have also higher triglyceride values, which is directly correlated with their cholesterol, which increases thrombotic risk.

1630

ANAGRELIDE IN THE TREATMENT OF ESSENTIAL THROMBOCYTHAEMIA (ET)

MR Villa[1], M Esposito[1], S Improta[1], A Onufrio[2], L Mastrullo[1]
[1]UOC Ematologia ASL NA1 Centro, Naples, Italy
[2]U. O. Anatomia Patologica Ospedale dei Pellegrini, ASL NA1 Centro Napoli, Naples, Italy

Background. Essential thrombocythaemia (ET), the most often occurring myeloproliferative disorder is a clonal malignant disorder arising from stem cell. The course of the disease is complicated by some severe thrombotic events and far less commonly by haemorrhagic phenomena. Treatment of ET consist of antiplatelet drugs (e. g. aspirin) and lowering platelet count (hydroxyurea or interferon alpha). Anagrelide is an oral imidazoquinazoline agent which is indicated in Europe for the reduction of elevated platelet counts in at-risk patients with essential thrombocythaemia who are intolerant of or refractory to their current therapy. **Aims.** We evaluated the use of anagrelide in ET patients, previously treated with hydroxyurea or interferon alpha. **Methods.** In our institution we are following 131 patients affected by ET (77 females and 54 males; median age 48 years, range: 27-85) according to PVSG criteria and WHO classification. 75 out of 131 patients were classified as low-risk, 31 as intermediate-risk and 25 as high-risk. The Val617Phe point mutation of Janus Kinase 2 gene (JAK2V617F) was found in 72 patients. **Results.** Anagrelide was used in 27 patients with ET from Jan. 2010 to Jan. 2012. Anagrelide, in the average dose of 2,0 mg (range: 1,0-3,5 mg) reduced platelet count in all patients. Median time of response was 3-4 weeks. Complete remission (platelet count < or = 450x10^9/l) was achieved in 25/27 patients, and only one patient had platelet count slightly above 450x10^9/l (but less than 600 x10^9/l). During the first two months of treatment with anagrelide some mild and transient side effects were noticed, e. g. headache in 7 (47%), fluid retention in 4 (27%), palpitations in 2 (13%), and diarrhoea in 2 (13%) patients, but all of them continued therapy. We have found no case in thrombotic events. **Conclusions.** Anagrelide proved to be a safe and effective drug for pre-treated ET patients. The positive results described in several studies may well lead to the next use of anagrelide as first line treatment in patients with high risk ET.

1631

ANALYSIS OF 74 PATIENTS WITH PRIMARY MYELOFIBROSIS - IPSS DISCRIMINATE PATIENTS WITH A WORSE CLINICAL EVOLUTION

I Lorand-Metze, B Benites, C Lima, M Delamain, G Oliveira, D Almeida, C De Souza, K Pagnano
University of Campinas, Campinas, Brazil

Background. The use of risk scores for classification of patients with primary myelofibrosis (PM) allows a better evaluation and to test new therapeutic

options for the patients. **Aims.** evaluation of clinical and laboratory features of consecutive cases of PM in order to assign them to the risk stratification according to the International Prognostic Scoring System (IPSS). Validation of this score in our clinical setting. **Patients and Methods.** retrospective study of patients with PM, diagnosed between 1992 and 2011 at our Institution. Patients' diagnosis was revised according to 2008 WHO diagnostic criteria. At diagnosis we evaluated peripheral blood cell counts, circulating blasts, JAK-2 V617F mutation, splenomegaly and constitutional symptoms. Patients were stratified according to IPSS score. Overall survival (OS) was calculated from diagnosis until last follow-up or death and progression-free survival (PFS) from diagnosis until progression to acute myeloid leukemia, last evaluation or death. Informed consent was asked for participation in the study from patients (or family when patient was dead). **Results.** We examined 74 patients. Median age = 71. 5 years (31- 92). At diagnosis: Hemoglobin =5. 4-16. 9 g/dL (median = 12. 2), white blood cell count = 0. 9 - 47. 3 x 10^9/L (median 11. 4) and platelets =76-1. 545 x 10^9/L (median 456). Thirty-one patients (42%) presented splenomegaly, and cytogenetic abnormalities were found in 1/37 evaluated (partial deletion of chromosomes 13 and 15). JAK2/V617F mutation was present in 47% of the cases, and was related to a worse OS in 10 years (39% *vs* 77%), though not statistically significant (P=0,448). Patients were stratified according IPSS classification in low risk: 15 (26%), intermediate-1: 23 (32%), intermediate-2: 19 (26%) and high risk: 15 (31%). Treatment: 66 patients (89%) were treated with Hydroxiurea, changed to anagrelide due to toxicity (3 leg ulcers) or lack of response (3 patients). Six patients used thalidomide and prednisone, 3 as initial treatment. Three patients were exclusively treated with transfusion support and three patients received no treatment. Two patients were submitted to splenectomy and 3 cases to splenic irradiation. One patient was submitted to allogeneic bone marrow transplantation, with complete remission of the disease. Thrombotic events were observed in 16% of the patients. The presence of V617F JAK-2 mutation was associated with thrombosis (p=0,037). During follow-up 15 patients died: 9 due to infections, 3 after blast crisis and 3 not related to MF. Patients with IPSS intermediate-2 and high risk presented a worse OS in 10 years (low: 92%; interm-1: 67,5%; interm-2: 28%; high risk: 32%) (P= 0,02). **Conclusions.** this study confirms the importance of IPSS for risk factor stratification. A correlation was found between V617F JAK-2 mutation with thrombosis. Support treatment with hydroxiurea is able to control low risk patients in the cellular phase of the disease. Patients with intermediate and high-risk disease are candidates to other therapeutic approaches, as bone marrow transplantation or experimental drug therapies.

1632

ANAGRELIDE IN MONOTHERAPY OR COMBINED WITH HYDROXYUREA YIELDS A HIGH RATE OF COMPLETE RESPONSE IN ESSENTIAL THROMBOCYTHEMIA

N Pugliese, L Marano, M Gherghi, C Quintarelli, B De Angelis, C Cerchione, S Errichiello, G Muccioli Casadei, G Beneduce, V Martinelli, F Pane
University of Naples Federico II, Napoli, Italy

Background. Hydroxyurea (HU) and Anagrelide (Ana) are effective in reducing platelet counts in patients with Essential Thrombocythemia (ET). Nevertheless Ana can be used as second line treatment for ET patients resistant or intolerant to first line therapy, according to its registration to EMEA. **Aims.** We want to describe our experience with these drugs and our clinical findings in terms of hematological response. **Patients and Results.** We evaluated 113 ET patients treated with HU, Ana or a combination of these drugs. Twelve patients were treated with anagrelide (Ana); of these, 2 patients asked for Ana as first line therapy while 10 were resistant to first line treatment after a median of 43 months. After 21 months of therapy, median Hb, PLT and WBC values were respectively: 13. 6 g/dl, 449 x10^3/mm^3 and 8665/mm^3 (data calculated as the median of these parameters for each patient, based on determinations made every two months). Six patients (50%) achived a complete response (CR) with PLT normalization; doses ranged from 1 to 1. 5 mg daily. Five patients experienced partial response (PR), with PLT < 600 x10^3/mm^3 or a decrease >50% from baseline; only one was resistant. Mild side effects (transient headache and palpitation) were observed in 30% of them. No advers reaction led to therapy discontinuation. Ninety-three patients received HU as first line therapy: 23. 6% achieved CR, 55. 4% PR and 21% were resistant to HU. Hb, PLT and WBC median value were respectively 13. 5 g/dl, 406 x10^3/mm^3 and 6570/mm^3. We used also combined HU and Ana therapy in 8 patients resistant to multiple line treatment, included busulfan (2 patients). We used 1 g daily of HU plus escalating Ana doses (from 1 to 2 mg daily), on the basis of their individual hematological responses. After a median of 23 months Hb, PLT and WBC median value were respectively 13. 7 g/dl, 456 x10^3/mm^3 and 7355/mm^3. Five patients (62,5%) achieved CR and 3 PR (HU 1 g plus Ana 2 mg daily). None was resistant to association therapy. **Conclusions.** Although groups treated with Ana plus HU or Ana as monotherapy could represent a selection bias because they include patients resistant to previous treatment, the rate of CR is higher in these groups, compared to those on HU therapy. Despite resistance to previous treatment Ana seems effective, with only one patient being resistant to this treatment. Nevertheless, Ana plus HU is more useful in controlling WBC count compared to Ana monotherapy. Combined therapy or Ana monotherapy should be considered also in patients with PR to HU, to try to achieve CR and the best control of platelet lowering.

1633

SPLEEN IS THE HIDDEN HITCH OF ESSENTIAL THROMBOCYTHEMIA

N Pugliese, L Marano, M Picardi, M Gherghi, G Ciancia, C Cerchione, C Quintarelli, V Martinelli, F Pane
University of Naples Federico II, Napoli, Italy

Background. Splenomegaly occurs in about 60% of Essential Thrombocythemia (ET) patients, and normalization in spleen size is one of the clinical-hematological criteria for assessment of response to treatment, according to the European Leukemia Net criteria, although it is referred only to craniocaudal diameter (CCd). **Aims.** This study aimed to investigate the most precise parameter between spleen volume (SV) and CCd in defining splenomegaly in ET patients and to predict the reciprocal impact of splenomegaly and clinical outcome. **Methods.** SV and CCd of 170 ET patients were measured by ultrasound at the time of diagnosis. The same operator performed all the measurements evaluating perimeter and longitudinal diameter while area and volume were calculated automatically. **Results.** As many as 69% of patients showed SV >250 mL (<250 is considered the normal value), while 48% of them had a CCd >11. 5 cm (<11 nv). Median SV and CCd were 360 mL and 11. 8 cm respectively. Although there was a correlation between SV and CCd (Pearson. 750), 25% of patients showed normal or reduced CCd and SV enlargement, at the same time. At follow up (median 56 months), they showed significant increases in SV (p<0. 001), median SV being 550 ml, with a 92% average increases. The correlation between SV and CCd (Pearson. 864) was stronger. When we correlated the difference in average SV with that CCd, we found a reduced correlation (Pearson. 24), because some patients (20%) showed SV enlargement with a simultaneous reduction in CCd. There is no statistically significant difference between hematological response and SV enlargement, although in no responder patients SV seemed to increase slight (p=0. 087). On the other hand, type of treatment influences SV independently to the response. IFN treated patients showed the highest increase (mean=670 mL; p=0. 001), followed by anagrelide (mean=639 mL; p=0. 017) and untreated (mean=481 mL; p=0. 023) patients. A no significant enlargement was observed in HU treated patients, p=0. 1. SV increased in both JAK2V617F and JAK2WT patients, p<0. 001 and 0. 002 respectively. We evaluated MF grading in 44 patients at follow up: in 34. 1% fibrosis worsened, in 36. 4% it was stable and in 29. 5% it improved. All patients had SV enlargement but the first group showed the highest increase. Patients in whom MF increased had the highest SV at baseline (p=0. 004). Patients with CR showed the lowest rate of MF worsening grade. In 55. 5% of anagrelide treated patients MF improved, against 33. 3% of those on HU and 26. 7% of those on IFN treatment. **Conclusions.** Spleen volume is the most discriminative and precise parameter to catch and monitor splenomegaly. Traditional ET treatments usually fail to reduce spleen size in patients, therefore volume normalization should be considered anecdotic. There is a difference in spleen response to different treatments and this finding should be better evaluated, in view of the newly available drugs that reduce spleen size. Further, highest SV at diagnosis should be considered prognostic of evolution tendency of the disease toward worsening of MF grade. This suggests the need for accurate monitoring in these patients.

1634

THE INCIDENCE OF THROMBOHEMORRHAGIC EVENTS IN ESSENTIAL THROMBOCYTEMIA. ROLE OF THE TREATMENT WITH ANAGRELIDE

R Mihaescu
UMFT, Timisoara, Romania

Background. Essential thrombocythemia (ET) is a myeloproliferative disorder characterized by persistent thrombocytosis. The recent discovery of JAK2-V617F mutation is a major break-through in understanding the molecular pathogenesis of the MPDs. Despite decades of clinical and laboratory research, relatively little has been accomplished concerning the pathogenesis as well as the identification of risk factors for thrombosis and bleeding in myeloproliferative disorders. Anagrelide is the latest addition to the therapeutic arsenal in platelet lowering therapy in myeloproliferative disorders especially in essential thrombocythemia (ET). Anagrelide selectively reduces the production of platelets by inhibiting megakaryopoiesis. Its efficacy is about a 70% in ET and the response

is rapid (in a few weeks). **Aims.** The incidence of thrombohaemorrhagic events at 45 patients with ET in a hemato-oncological center of Timisoara over a period of 3 years and to determine the efficacy and long-term safety of anagrelide. **Methods.** We included 45 patients with ET, 24 men and 21 women, with a median age of 39 years. Splenomegaly was present in (16,2%) patients and fibrosis in (22,3%) . The positive diagnosis is sustained by WHO criteria for ET:- sustained platelets count>450x10^9/l -bone marrow biopsy-demonstration of JAK2617V>F. 45% of patients received a prior treatment with one of two cytostatic agents and 55% received as a first line anagrelide. **Results.** The most important **t**hrombohemorrahagic events were: splenic thrombosis - 10,01%, cerebral thrombosis - 33,06%, pulmonary thrombosis - 5,21%, portal vein thrombosis - 2,32%, peripheral thrombosis - 9%, cutaneous bleeding - 6,10%, mucosal bleeding - 4%, upper gastrointestinal bleeding - 0,71% At 85 % of the patients treated with anagrelide platelet levels fall below <450x10^9/l. 25% developed toxic side effects as tachycardia. In the first two weeks of treatment 33% of the patients suffered from nausea and vomiting. **Conclusions.** Thrombosis in ET occurs in arterial, venous or microcirculatory locations. In general, arterial events predominate over venous events. Of importance, patients with ET have an unusually high rate of intra-abdominal (portal and hepatic) vein thrombosis and together account for a substantial proportion of identifiable causes of these potentially catastrophic events. Interestingly, young patients appear to be particularly vulnerable to this complication. There is increasing evidence to suggest an additional role by leucocytes that might partly explain the antithrombotic effects of myelosuppressive therapy. Complete remission (defined as a platelet count<400x10^9/l in symptomatic patients and 600x10^9/l in asymptomatic patients) was maintained in 75% of patients still treated with anagrelide. Long term efficacy was good, tolerance and safety were satisfactory and the cardiac toxicity was low. No thrombohemorrhagic events after introduction of Anagrelide in treatment of patients.

1635

IS JAK2 V617F GENE POINT MUTATION A RISK FACTOR FOR BLEEDING OR THROMBOSIS IN PATIENTS WITH MYELOPROLIFERATIVE DISEASE?

A Ugur Bilgin[1], M Yildirim[2]
[1]Konya Unv, Meram Medical School, Konya, Turkey
[2]Konya Unv. Meram Medical School, Konya, Turkey

JAK2 V617F gene point mutation in patients with myeloproliferative diseases (MPD) were firstly defined in 2005 and their prevalence by diseases is 90% for polycythemia vera (PV), 50-60% for essential trombocytosis (ET) and 50-60% for primary myelofibrosis (PMF). Currently, the disease course of the positive JAK2 V617F gene point mutation (JAK V617F$^+$) and especially the effect on bleeding/thrombotic complications still are not well-understood. In this study, the data of 94 patients with myeloproliferative disease (median age: 57 (20-80), PV: 39, ET: 49, PMF:(6) who were admitted to the hematology clinic of Meram Medical School, Konya University between 2000 and 2011 were evaluated retrospectively. The number of JAK V617F$^+$ cases was 40 (42. 5%), (median age: 61), the number of JAK 2 V617F$^-$ cases was 54 (57. 5%) (median age: 54). The ages of JAK V617F$^+$ cases were found to be significantly higher. When the distribution by the diseases was considered; it was found that the number of PV-JAK V617F$^+$ cases was 21 (54%), (median age: 66), the number of the negative cases was 18 (46%) (median age: 53). The median age of JAK V617F$^+$ cases was found to be significantly higher. The number of ET- JAK V617F$^+$ cases was 16 (33%), (median age: 60), the number of negative cases was 33 (67%) (median age: 51), and the age of the positive cases was again found to be significantly higher. But, There was no found significant difference between PMF- JAK2 V617F$^{+/-}$ in patients. When the bleeding/thrombotic event distribution was considered; there were no events in 38 (70%) of the JAK 2 V617F$^-$ cases, there was an event in 16 (30%) cases (n: 10 (18. 5%) bleeding, n: 6 (11%) thrombosis). There were no events in 16 (40%) of JAK V617F$^+$ cases and an event was seen in 24 (60%) (Bleeding: 17 (42. 5%), Thrombosis: 7 (17. 5%)). The event incidence in JAK V617F$^+$ cases was found significantly higher (60%). There were 21 PV- JAK V617F$^+$ cases (Bleeding: 11, Thrombosis: 5, total: 16 (71%)), 16 ET - JAK V617F$^+$ cases (Bleeding: 5, Thrombosis: 3, total: 8 (50%), 3 MPH- JAK V617F$^+$ cases (Bleeding: 1, Thrombosis: 0) total: 1 (33%). In cases with PV and ET, the incidence of the events including bleeding and thrombosis were significantly higher. Bleeding and thrombotic complications observed during the course of myeloproliferative diseases are among the most important morbidity and mortality causes. In the literature, there are studies reporting that the diagnosis of myeloproliferative diseases increases the thrombotic complication risk of JAK V617F$^+$, which has been started to be routinely used especially for PV. In this study, it was found that the ages of JAK V617F$^+$ patients were significantly high and there was an increased bleeding/thrombotic complication risk. In conclusion, in the light of the literature and our findings, it is possible to recommend a closer monitoring for bleeding/thrombotic complications of elderly MPD- JAK V617F$^+$

1636

CLINICAL OUTCOME OF 15 PREGNANCIES IN WOMEN WITH CHRONIC MYELOID LEUKEMIA AND CHRONIC MYELOPROLIFERATIVE DISEASES PH NEGATIVE - THE EXPERIENCE OF FUNDENI CLINICAL INSTITUTE, BUCHAREST, ROMANIA

I Ursuleac, E Niculescu- Mizil, M Vasilica, A Colita, O Georgescu, D Coriu
Fundeni Clinical Institute, Bucharest, Romania

The incidence of myeloproliferative diseases increases during the reproductive ages. Pregnancy in female patients with childbearing potential and chronic myeloproliferative disorders can occur accidentally or as their own wish. During the last 10 years in Fundeni Clinic of Hematology were registred 15 female patients with chronic myeloproliferative diseases (3 chronic myeloid leukemia, in chronic phase, treated with Imatinib, 6 essential thrombocythemia and 2 cases of polycythemia vera) who became pregnant . 8 complete healthy babies were born without delivery or post-partum complications. 1 patient with ET had 2 consecutive pregnancies. 3 patients underwent abortions (1 because of ectopic pregnancy, 2 on demand). A patient diagnosed with PV-ET jak2 positive and factor V Leiden had fetal loss because of recurrent placentar thrombosis and fetal involution. All the patients with ET and PV received low dose of Aspirin throughout pregnancy and prophylactic low molecular weight heparin in the 3rd trimester and 6 weeks postpartum. In high risk (5 cases)ET patients alpha interferon was the preferred cytoreductive therapy. There were no maternal complications after delivery and no fatal event. The hematologic response and an appropriate monitoring is the key for an event free pregnancy and an optimal delivery.

1637

HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH CHRONIC MYELOPROLIFERATIVE DISEASES

E Simonovic[1], L Macukanovic-Golubovic[2], M Mladenovic[1], V Colic[1]
[1]General Hospital, Leskovac, Serbia
[2]Clinic of Haematology, Clinical Centre Nis, Nis, Serbia

Myeloproliferative diseases (MPD) belong to the group of clonic malignant diseases of parent cell hematopoiesis, characterized by abnormal increase of one or several blood lines with normal or nearly normal maturing of those cells, both in bone marrow and in extramedullary hemotopoietic organs. According to the literature data, in patients with CML a tendency to bruises and bleeding was described in about 35% of patients. In patients with PV, hemorrhagic changes on the skin and visible mucous membranes are common as the disease progresses. Bleeding occurs in 15-18% of patients with IMF. Even 60% of patients with ET showed tendency to hemorrhage, which is a major cause of morbidity and mortality. The aim of the paper is to demonstrate the extent to which the hemorrhagic complications occur in patients with certain forms of chronic myeloproliferative diseases. The investigation included 219 subjects of both sexes, between 17 and 83 years of age with the diagnosis of MPD. The patients were divided into five groups: A. Chronic myeloid leukemia (CML)-group; B. Polycythaemia vera (PV)-group; C. Idiopathic myelofibrosis (IMF)-group; D. Essential thrombocythaemia (ET)-group; E. Myeloproliferative disease that cannot be classified (MPS)-group. During the investigations the methods of clinical examination were used, as well as laboratory examination methods (biohumoral parameters and coagulation status). In our investigation, hemorrhagic changes in terms of bruising, ecchymoses of the skin, epistaxes, gingival bleeding were described in 16% of patients with MPD. The presence of ulcer disease with hemorrhagic complications was observed in slightly less than a fifth of patients with MPD (19. 18%). In groups with PV, ET and MPS, between 30 and 40% of patients were with ulcer disease, which is statistically significantly higher percentage compared to the patients with CML. Also, a small percentage of our patients with ET have a hemorrhagic syndrome in terms of changes on the skin, but those patients have a significantly higher incidence of ulcer disease (35%), and thus the complications in terms of gastrointestinal bleeding in those patients were significantly higher. When the patients with PV and IMF are in question, there is an agreement with literature data in terms of hemorrhagic syndrome occurrence. Bleeding in MPD is caused by thrombocytopenia, qualitative platelet disorders, acquired factor V deficiency and vWF, disseminated intravascular coagulation. Thrombocytopenia occurs due to ineffective megakaryocytopoiesis, retention of platelets in the enlarged spleen and platelet decomposition due to DIC. The disorder of platelet function results in prolonged bleeding time, low platelet aggregation particularly on adrenalin and abnormal content of beta- thromboglobulin, 5-hydroxytryptamine and platelet factor 4. We have proved that the prevalence and severity of hemorrhagic complications are in statistical dependence on the type of MPD. Hem-

orrhagic complications often accompany chronic myeloproliferative diseases. Hemorrhagic syndrome in the form of changes on the skin and visible mucous membranes is more common in patients with IMF and CML during blast crisis phase, while the severe gastrointestinal bleeding was statistically and more significantly present in patients with ET and PV.

PREVALENCE OF JAK2V617F MUTATION AND ITS CLINICAL CORRELATION IN THAIS WITH MYELOPROLIFERATIVE NEOPLASM

S Chanprasert[1], N Suksomyos[1], C Maunpasitporn[2], R Ponlapat[2]
[1]Faculty of Allied Health Sciences, Chulalongkorn University, Bangkok, Thailand
[2]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Background and Aims. Myeloproliferative neoplasm(MPN) is a group of chronic myeloid cancers. According to the WHO 2008 recommendation, JAK2V617F mutation is a major diagnostic criterion for these diseases, particularly theP-hiladelphia chromosome-negative MPN. The prevalence of such mutation, however, has been reported differently in numbers based on the study population; rarely Thais. This study aims to explore the prevalence of the JAK2V617F mutation in Thai MPN patients and examine its correlation with clinical features. **Methods.** 103 Thai MPN patients, diagnosed according to the WHO 2008 criteria, were recruited and blood samples were taken for DNA isolation. JAK2V617F detection was explored using two PCR based techniques; AS-PCR and RFLP. Clinical data assessed at the diagnosed date were matched to the JAK2 mutation outcome. **Results.** The overall prevalence of JAK2V617F in MPN was 64. 1% (66/103); 59. 2% (29/49) in ET, 80. 6% (25/31) in PV, 70. 0% (7/10) in PMF, and 83. 3% (5/6) in MPN nos. None of the CML patients had the mutation (0/7). The mutant group had significantly higher red blood cells (P = 0. 030) and less bleeding history (P = 0. 011) than the wild-type (WT). We found no statistical difference of any clinical features between those two groups in ET, albeit some haematological parameters, white blood cell and platelet count, of the mutant were slightly higher than the WT without significance (P= 0. 098**,** and 0. 850). Haemoglobin, haematocrit and MCV of the mutant PV were lower than the WT while the red blood cells and platelets were higher. **Summary and Conclusions.** JAK2V617F does exist in Thai MPN patients. Its prevalence is close to other populations of different ethnicity. The mutant group displayed higher haematological parameters referring to contribution of the mutation to the disease. Nevertheless, other factors including vascular evidences and intracellular signal transduction molecules could altogether participate to cause the phenomenon.

STUDY OF MULTIPLE CANCER WITH THREE OR MORE CANCERS INCLUDING HEMATOPOIETIC MALIGNANCY -EXPERIENCE OF 17 CASES IN OUR DEPARTMENT

K Natori, S Ishihara, D Nagase, A Shibuya, Y Toyoda, Y Fujimoto, Y Kuraishi, K Shibuya, H Izumi
Toho University Medical Center Oomori Hospital, Oota-ku, Japan

Introduction. The recent advances in examination techniques and medical knowledge has enabled the early detection of cancer, and the indication for surgical treatment has been expanded by improved radical surgical techniques, changing cancer from a fatal disease to a treatable disease. In some cases, however, it has become difficult to determine the therapeutic policy when a solid cancer is detected during the treatment process. Herein, we report 27 cases with three or more cancers including hematopoietic organ tumor and solid cancer. **Methods.** Among 145 patients who were diagnosed as having hematopoietic malignancy and multiple cancer at our hospital during the period from 1988 to 2009, 27 patients with three or more cancers were selected as the subjects. **Results.** Among 145 patients with multiple cancer, including hematopoietic malignancy, 27 patients (18. 6%) had three or more cancers. The subjects (22 males and 5 females) included 25 patients with triple cancer and 2 patients with quadruple cancer. The median age at which triple cancer was diagnosed was 68 years old (42 - 86 years old), and the triple cancer developed as synchronous cancer in 9 patients and as metachronous cancer in 18 patients. The median age for patients with synchronous cancer was 67 years old, while that for patients with metachronous cancer was 68 years old. The 83 diagnoses among the 27 patients included esophageal cancer in 2 patients, stomach cancer in 11, bowel cancer in 8, hepatic cancer in 5, pancreatic cancer in 1, cholangiocellular cancer in 1, lung cancer in 7, renal cancer in 6, urinary bladder cancer in 2, prostate cancer in 5, thyroid cancer in 2, meningioma in 1, and hematopoietic malignancy in 31. Regarding the 18 patients with metachronous cancer, it was found that 9 patients were diagnosed as having developed 3 types of malignant tumor independently, that 7 patients developed the 3rd cancer after being diagnosed with double cancer, and that 2 patients simultaneously developed 2 types of malignant tumor after undergoing treatment for the 1st cancer. **Discussion.** Campbell et al. reported that the incidence of a 3rd cancer in patients who had developed a 2nd cancer would be 8. 94%, which is more than double the incidence of the 2nd cancer (3. 97%). It has been suggested that multiple cancers tend to develop in the organs that are predisposed for single cancer. In Japan, the incidence of multiple cancer, including stomach cancer and cancer of other digestive organs, is high, while the incidence of multiple cancer including skin cancer is high in the US and European countries. In the future, it is expected that development of multiple cancer will increase along with the advances of diagnostic techniques and improvement of therapeutic results. In the diagnosis and treatment of cancer patients, it will be important to always consider the possibility of multiple cancer, and to perform follow-up observation for patients who undergo radiotherapy and administration of anticancer drugs, paying sufficient attention to the development of metachronous cancers.

1640

CORRELATION BETWEEN HEMATOCRIT AND THROMBOTIC RISK IN OUR POLYCYTHEMIA VERA PATIENTS

S Cabibbo, A Antolino, O Manenti, G Garozzo, P Bonomo
Uos Ematologia Asp 7, Ragusa, Italy

Background. Polycythemia Vera (PV) is a disorder of haematopoiesis included within the myeloproliferative neoplasm in the forthcoming revised World Health Organization (WHO) classification. The discover of acquired recurrent molecular abnormalities in JAK2 has improved his diagnostic approach. The main goal of therapy is therefore to prevent thrombohemorrhagic complications and this is effectively and safely accomplished by the use of hydroxyurea, low-dose aspirin and phlebotomy to keep Hematocrit less than 0. 45L/L as recommended by the recently published ELN criteria. Other studies, however, have reported that it does not seem necessary to maintain patients at all time below such threshold. **Aims.** We would like to try to establish the association between moderately high hematocrit values (>0. 45L/L < 0. 50L/L) and thrombotic risk. **Methods.** We reviewed the medical charts of all patients with PV in our institution. In every case, the diagnosis of PV was reassessed using the updated criteria of the WHO and our hematocrit target was defined as less than 0. 45L/L according to the recently published ELN criteria. In all cases the occurrence of thrombosis and bleeding were registered. **Results.** In total 50 patients were included in the study. Their main clinical and haematological data at diagnosis are listed as below: Age 65y (mean value), Sex, male/female 25/25, cardiovascular risk factors n°25 (50%), PV-related symptoms n°20 (40%), Palpable splenomegaly n° 10 (20%), Leukocytes >10x109/L n° 25 (50%), Platelets > 500 x 109/L n° 25 (50%), JAK2 mutation n° 50 (100%). All the patients received antiplatelet therapy and median interval between diagnosis and HU start was 0. 3 years and the reasons for initiating HU were established according to SIE therapy guidelines. In the majority of patients the initial dose was of 1000 mg/day and it was subsequently adjusted to keep the hematocrit below 0. 45L/L. However in some cases (about 50%) during the follow-up we had a moderately high hematocrit values (>0. 45L/L < 0. 50L/L). Thrombosis and bleeding were not observed in all the cases and with the same rate over the periods in which patients remained with hematocrit less than 0. 45L/L versus the periods in which the same patients remained with hematocrit major than 0. 45L/L but less than 0. 50L/L. **Summary and Conclusions.** Thrombosis is the main cause of morbidity and mortality in Polycythemia vera and its pathophysiology is complex. Traditionally, increased hematocrit has been claimed as the main player, but the dynamic interactions between platelets, leukocytes, and the endothelium do probably represent a fundamental interplay in generating a thrombophilic state. Taken into consideration our results it would be advisable targeting the hematocrit at 0. 45L/L but it does not seem necessary maintain patients at all times below such threshold. Probably, the identification of plasma markers translating the haemostatic imbalance in patients with PV would be extremely helpful in order to better define the subgroup of patients with a significant clinical risk of thrombosis.

1641

IMPACT OF V617F MUTATION IN THE MANAGEMENT OF THROMBOTIC RISK IN PATIENTS WITH ESSENTIAL THROMBOCYTEMIA

B Terry, I Montero, R Cardesa, D Alonso, J Gonzalez, JF Falantes, ML Martino, I Espigado, JA Perez Simon
Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background and Aims. The V617F JAK-2 mutation, which occurs in 40-50% of patients with essential thrombocythemia, seems to be associated with an

increased thrombotic risk, although the therapeutic criteria have not been modified for this group. We have studied 66 patients with essential thrombocythemia (ET) and V617F mutation with the aim to rely clinical and laboratory characteristics and treatments received with thrombotic risk. **Patients and Methods.** We reviewed retrospectively the medical records of 66 patients diagnosed of essential thrombocythemia according to WHO criteria during the period of time between 1988th to April 2011. All of them were also positive for the V617F mutation PCR performed using allele-specific real-time. The median age group was 62. 5 years; 37,87% were male and 62,12% were women. 25% of patients had splenomegaly at diagnosis and a median of 805x10e9 platelets / L. According to international criteria for the treatment of ET, 27. 3% of patients were ASA antiplatelet therapy alone, 54. 5% received treatment with hydroxyurea + /-ASA, 10. 6% received treatment with anagrelide + /-AAS, the 3% was in the combined treatment with anagrelide and hydroxyurea plus 4. 5% received no treatment. The10,6% were homozygous for the mutation V617F JAK-2 and 89,4%were heterozygous. 66. 6% of patients had cardiovacular risk factors (diabetes, hypertension, hyperlipidemia) Using SPSS statistical application we analyzed the influence of ag, platelet count, presence of splenomegaly, treatments received and allelic burden on thrombotic risk. **Results.** 34. 8% of patients had a thrombotic event. We found a significant difference in platelet count in patients with thrombosis (median949x10e9 / L) versus those without (median 759x10e9 / L), with p= 0. 03%. The presence of cardiovascular risk factors in our group also conditioned increased risk of thrombosis (91. 3% Yes vs. No8. 7%, p = 0. 002%). The other factors analyzed showed no impact on the thrombotic risk. The group's overall survival was 91. 7%. **Conclusions.** The results in our group confirm the high risk of thrombosis in patients with essential thrombocythemia and JAK-2 V617Fmutation, with a thrombotic event producing in at least one of every 3 patients. The median platelet count in this group, less that recommended for initiating treatment in most of the accepted protocols for TE, and cardiovascular risk factors will be the determining of the therapeutic approach in V617F ET as a different clinic entity.

1642

CONTRIBUTION OF ARRAY COMPARATIVE GENOMIC HYBRIDIZATION TO PROGNOSTIC STRATIFICATION IN DIFFUSE LARGE B-CELL LYMPHOMA

R Nedomova, H Urbankova, T Papajik, Z Kubova, M Holzerova, P Mickova, S Reptova, V Prochazka, P Flodr, K Indrak, M Jarosova
University Hospital, Olomouc, Czech Republic

Background. Diffuse large B-cell lymphoma (DLBCL), a heterogeneous clinicopathologic entity, accounts for up to 40% of non-Hodgkin's lymphomas. Gene expression profiling confirmed the presence of three molecular prognostic subgroups - germinal center B-cell-like (GCB), activated B-cell-like (ABC) and primary mediastinal B-cell lymphoma (PMBL). Nevertheless, there is a need to identify genes with a critical function in DLBCL to stratify patients into prognostic subgroups without expression profiling. **Aims.** To study copy number alterations (CNAs) in DLBCL patients and to correlate them with cytogenetic and other molecular cytogenetic results to define the optimal approach for prognostic stratification. **Methods.** A single-center study comprising 51 DLBCL patients (24 males; median age at diagnosis 49 years). Thirty-two patients were histopathologically diagnosed as DLBCL, 18 patients as PMBL and one patient as gray zone lymphoma. ArrayCGH with BAC microarrays was used in 26 patients (Bluegnome, Cambridge, UK; K3 Leiden, Netherlands) and oligonucleotide microarrays 4x44K (Bluegnome and Agilent, Santa Clara, USA) were applied in 25 patients. Fifty patients were examined by conventional cytogenetics; FISH with different probes was applied in all patients. **Results.** Stratification criteria published by Staudt and Dave (2005) were used. ArrayCGH revealed CNAs in 28 (55%) patients. The most frequent losses were detected on chromosomes 1q, 4q, 6q, 13 and 17p; the most frequent gains on chromosomes 7, 8q, 9p and 12. Based on the results, all 28 patients were stratified into molecular subgroups. Using conventional cytogenetics, chromosomal changes were detected in 26 (51%) patients. The most frequent balanced chromosomal change was t(14;18) confirmed in 6 patients. *BCL2* duplication was confirmed in 5 patients. FISH analysis of 45 patients with locus-specific probes LSI IGH/MYC,CEP8 and/or LSI MYC DC (Abbott Molecular, Illinois, USA) revealed low frequency of translocations (1 patient) in the cohort but frequent presence of *CMYC* gene duplication (11/45 patients). The overall survival of patients with *CMYC* aberrations was shorter compared with those without them but a larger cohort is needed. The gain of the *JAK2* gene was studied in 25 patients with locus-specific probes ON JAK2 (9p24) Break (Kreatech, Amsterdam, Netherlands). Duplication and amplification were confirmed in 5 and 7 PMBL patients, respectively. Conventional cytogenetics, FISH and arrayCGH enabled detection of 28 (55%) patients with a complex karyotype. With all results obtained from cytogenetic and molecular cytogenetic methods, a total of 45 (88%) patients could be stratified. There were 11, 14 and 20 patients in the ABC, GCB and PMBL subgroups, respectively. **Conclusions.** Prognostic stratification based on arrayCGH was performed in 55% of patients. With a combination of all cytogenetic and molecular cytogenetic methods, a total of 45 (88%) patients were stratified. The results confirmed the benefit of arrayCGH for detecting CNAs in DLBCL for prognostic stratification but also to the necessity to supplement the result by FISH and cytogenetics to detect balanced changes of prognostic and stratification importance. The detection of all as well as cryptic copy number changes could possibly reveal differences in the oncogenic mechanisms in DLBCL. Supported by MZČR IGA NT 11103.

HNRNP B1 INHIBITS DNA DOUBLE-STRAND BREAK REPAIR BY INTERACTION WITH DNA-PK COMPLEX IN ADULT T-CELL LEUKEMIA

E Sueoka[1], R Tomimasu[1], N Sueoka-Aragane[1], A Sato[1], M Ide[1], T Hisatomi,[1], N Kuwahara[2], N Fukushima[1], E Matsuishi[2], S Kimura[1]
[1]Saga University, Saga, Japan
[2]Saga Prefectural Hospital Koseikan, Saga, Japan

Adult T-cell leukemia (ATL), an aggressive lymphoid malignancy caused by HTLV-1, is associated with a large variety of genetic alterations. We previously reported that heterogeneous nuclear ribonucleoprotein (hnRNP) B1 is bound to the DNA-dependent protein kinase (DNA-PK) complex, inhibits DNA repair in lung cancer cell lines; we therefore investigated the expression of hnRNP B1 and its effects on DNA repair activity in ATL cells. hnRNP B1 was overexpressed in 35 of 48 (73%) lymphoma tissues from ATL patients and the level of expression was correlated with serum soluble interleukin-2 (IL-2) receptor level. An increase in hnRNP B1 protein level occurred in the CD4-enriched cell fraction in asymptomatic HTLV-1 carriers and was associated with stage of the disease. The protein level of hnRNP B1 was associated with IL-2 stimulation in ATL cell lines, as well as normal CD4-positive T cells. Although constitutive expression of *hnRNP B1* mRNA without IL-2 stimulation was observed in ATL cell lines, transcriptional activation of *hnRNP B1* mRNA was induced by IL-2 stimulation in normal CD4-positive T cells. These results indicate that hnRNP B1 protein is induced by growth factor IL-2 in normal CD4 positive cells, mediated by transcriptional mechanisms, but in cancer cells *hnRNP B1* gene activation is IL-2 independent and constitutive. Functional analysis revealed that hnRNP B1 interacted with the DNA-PK complex and inhibited kinase activity of DNA-PK as well as double-strand DNA break repair in ATL cell lines. Our results suggest that overexpression of hnRNP B1 may play an important role in accumulation of genetic abnormality and disease progression of ATL mediated through inhibition of DNA-PK activity.

1644

CD4+ T-CELL POPULATIONS IN DIFFERENT MICROANATOMICAL LYMPH NODE COMPARTMENTS OF FOLLICULAR LYMPHOMA

N Tupitsyna[1], M Kovrigina[2], A Zeinalova[3], S Tumyan[1], D Osmanov[1]
[1]N. N. Blokhin Cancer Research Center, Moscow, Russian Federation
[2]Hematological Research Center, Moscow, Russian Federation
[3]N. N. Blokhin Cancer reseacrh center, Moscow, Russian Federation

Background. Subpopulations of CD4+ T-cells, including T-regulatory cells (Treg) in follicular lymphoma (FL) microenvironment play important role in control of malignant cell growth either directly or via influence on effector cell populations. **Aims.** To characterize CD4+ cells, its regulatory subpopulations (FOX-P3, PD-1) as well as CD8+ cells and to ascertain their relationships in different microanatomical lymph node compartments (follicular, interfollicular, when present - parafollicular and diffuse) in follicular lymphoma. **Methods.** We have studied 73 patients with follicular lymphoma. In all cases the diagnosis was confirmed with immunohistochemistry. Patients were investigated according to standard clinical and laboratory tests. Special quantitative study (percentage of positive cells within each compartment) of T-cell subpopulations (CD8, CD4, FOX-P3, PD-1) was done by immunohistochemistry on paraffin sections of FL biopsy specimens. **Results.** We have studied 73 FL patients (male - 26, female - 47) aged from 25 to 91 years (median - 58). Cytological grade II predominated (55 pts), grade I - 5, grade IIIa - 13. Stages according to Ann-Arbor classification were as follows: I -4 pts, II - 11, III - 10, IV - 46. Distribution according to FLIPI: good (score 0-1) - 15 pts, intermediate (score 2) - 13, poor prognosis (score 3-5) - 30; according to FLIPI2 - intermediate (1-2) - 15, high risk - 16. Distribution of different T-cell populations is given in Table 1. We did not found any negative correlations between numbers of cytotoxic (CD8) and regulatory/suppressor (FOX-P3, PD-1) T-cell populations in each microanatomical compartment. Moreover we noticed some strong positive correlations (p <0. 01 - <0,05) for some subpopulations studied. Number of CD8+ cells correlat-

ed with the total number of CD4+ lymphocytes and PD-1+ cells both for interfollicular and for intrafollicular populations, the same was true in cases with diffuse pattern of infiltration. This cytotoxic cell population (CD8) correlated with FOX-P3-cells only within follicules. CD4+ cells correlated with PD-1+ cells only in follicules and in diffuse areas of growth. Correlation between the number of regulatory cells (FOX-P3 and PD-1) was noted both within follicules and in interfollicular areas. No correlations noted for cells in parafollicular compartment may be explained by low number of cases in which this area may be clearly identified. **Conclusions.** Our data indicate that there are different numbers of CD4+, CD8+ and regulatory cell populations in different lymph node microanatomical compartments in FL. Elevated number of regulatory cells did not lead to reduction of cytotoxic cell population.

Table 1.

Subpopulation	Localization	Number cases	Range (%%)	M±m (%%)	Median
FOX-P3	interfollicular	47	1-30	12,4±1,2	10
	intrafollicular	62	1-30	10,5±0,9	10
	parafollicular	10	1-20	15,4±2,4	20
	diffuze	35	1-30	10,4±1,1	10
PD-1	interfollicular	50	3-80	19,6±2,1	15
	intrafollicular	63	2-60	22,7±1,9	20
	parafollicular	10	1-80	32,0±7,3	30
	diffuze	34	2-40	17,5±1,7	15
CD4	interfollicular	48	1-70	39,0±2,1	40
	intrafollicular	63	7-50	21,5±1,3	20
	parafollicular	5	8-80	32,6±12,6	30
	diffuze	33	2-50	24,6±2,5	20

BILATERAL BONE MARROW EXAMINATION FOR NON-HODGKIN'S LYMPHOMA STAGING: DIAGNOSTIC UTILITY IN THE MULTIPARAMETRIC FLOW CYTOMETRY ERA

L López-Anglada
Hospital Clinico de Salamanca, Salamanca, Spain

Background. Since the early 1970s, histopathological examination of bone marrow biopsy (BMB) is essential in the staging of non-Hodgkin's lymphomas (NHL). Bilateral BMB (BBMB) has been recommended, since several studies suggest it gives more accurate information than unilateral bone marrow biopsy (UBMB). However, the clinical value of this procedure has not been clearly established when other more sensitive techniques are used. We have retrospectively analyzed a series of 105 NHL patients with BBMB histological examination, in which four-color flow cytometry (FC) analysis was performed simultaneously. **Aim.** To evaluate BBMB's value when bone marrow FC analysis is used simultaneously in the routine staging of NHL. **Methods.** We analyzed 105 specimens from NHL patients, all of them with BBMB histological examination and four-color FC analysis on the BM aspirate performed simultaneously to the first BMB. When present, BM involvement was histologically classified as diffuse, nodular, interstitial and nodule-interstitial. Erythrocyte-lysed whole BM samples were stained using selected panels of monoclonal antibodies, using four-color direct immunofluorescence technique and according to previously well described methods, aimed to identify and characterize B and/or T neoplastic cells in BM. **Results.** Histological examination showed concordance in both BMB in 91% of cases (96/105), being both negative (BMB-/BMB-) in 73% (77/105) and positive (BMB+/BMB+) in 18% of cases (19/105). Histological discrepancies were seen in 9 cases, showing infiltration only in one of the BMBs (BMB-/BMB+). Therefore, performing a BBMB was determinant for a correct staging in 9% of cases (9/105 BMB-/BMB+). FC was positive in 6 of the 9 discrepant cases (BM-/BM+/FC+). Thus, the use of FC on the first BM aspirate would reduce the impact of performing a second BMB, since only 3% (3/105) of cases would have been considered negative when a second BMB have revealed BM involvement. Although FC was negative and concordant with histology in most BMB-/BMB- cases (87%; 67/77), interestingly in 10/77 cases (13%) showed a clonal population, revealing bone marrow involvement. As expected, cases with histological BM infiltration had higher levels of infiltration by FC than cases in which infiltration was only detected by FC, showing that FC has higher sensitivity in samples with low levels of infiltration. Taking into account the global series, the simultaneous use of FC and UBMB rises the detection of infiltration from 18% (19/105 cases BMB+/BMB+) with only one BMB, to 33% (35/105 cases: 19 cases BMB+/BMB+, 6 cases BMB-/BMB+/FC+ and 10 cases BMB-/BMB-/FC+), with a total improvement of 46% considering only cases with infiltration (16/35). In this context, a BBMB increased the detection of infiltration only by 3% [only 3 cases were negative in the first BMB with FC negative and showed infiltration in the second BMB (BMB-/BMB+/FC-)]. We have to consider also that a BBMB is an invasive procedure that implies costs, time and materials and supposes an important discomfort for the patient. **Conclusion.** According with our results we can conclude that the simultaneous use of UBMB and FC improves the detection of BM involvement and the staging procedure of NHL's, making a second BMB unnecessary.

1646

LYMPHOPROLIFERATIVE DISORDERS ASSOCIATED WITH THE SYNDROME OF ACQUIRED DEFICIENCY OF C1 INHIBIBITOR AND ANGIOEDEMA. RATE OF ASSOCIATION AND RESPONSE TO TREATMENT IN 48 PATIENTS

R Castelli, A Zanichelli, A Coerezza, L Maggioni, F Foieni, A Federici, M Cicardi
University of Milan, Milan, Italy

Background. Expansion of B lymphocyte clones against C1-INH, ranging from monoclonal gammopathies of uncertain significance (MGUS) to non Hodgkin's lymphoma (NHL), seems to underlay the pathogenesis of angioedema due to acquired C1-INH deficiency (AEE), either associated with auto antibodies or with lymphoprolipherative diseases. **Aims.** Here we report on the long term follow up of 48 patients with AAE with specific focus on the fate of lymphoproliferative disease. Patients were followed for a median of 6 years (range 1-25). **Results.** Auto antibodies to C1-INH were positive in 35 of 48 patients (13 IgG, 13 IgM, 5 IgA, 2 IgG-IgM, and 2 IgA-IgM). Nineteen patients (40%) fulfilled diagnostic criteria for MGUS. MGUS and auto antibodies to C1-INH coexisted in 13 patients all, but one, sharing the same heavy chain isotype. In 7, binding of the M component to purified C1-INH could be demonstrated. In 12 patients (25%) NHL was diagnosed. Based on WHO classification 10 patients had indolent lymphoma, 1 high grade malignant lymphoma, large B cell, and one had a transformed high grade malignant lymphoma large B cell. Ten of the 12 patients with NHL received conventional chemotherapy. **Conclusions.** Various degrees of recovery of biochemical and clinical features of AEE were observed in all patients treated with chemotherapy. Our data support the existence of a tight association between B cell prolypheration and AAE pathogenesis.

1647

MEASURING OF TOTAL CELL DIVISION (THYMIDINE-KINASE) ACTIVITY WITH NOVEL SENSITIVE NON-RADIOMETRIC METHOD IN NHL AND CLL: STRONG CORRELATION WITH DISEASE STAGE AND ACTIVITY

P Vit[1], K Indrak[2], T Papajik[2], J Bacovsky[3], P Petrova[4], M Bartkova[4], S Gronowitz[5]
[1]Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic

[3]Dept. of Internal Medicine III, University Hospital, Olomouc, Czech Republic
[4]Dept. of Clinical Biochemistry and Imunogenetics, University Hospital, Olomouc, Czech Republic
[5]Biovica AB, Uppsala Science Park, Sweden, Uppsala, Sweden

Background. Thymidine-kinase-1 (TK1) is a key enzyme expressed in the G1-S cell division stage to supply thymidine triphosphate necessary for cell division. Recent data show that pretreatment TK1 levels are predictive for survival of patients with non- Hodgkin´s lymphoma (NHL) or chronic lymphocytic leukemia (CLL). However, until now results are obtained with radioactive assays (TK-REA) with lower sensitivity and narrow detection range. **Aims.** To analyze the clinical-laboratory correlations of pretreatment TK1 levels analyzed with a novel non-radioactive high-sensitive method in unselected cohort of newly diagnosed patients with NHL and CLL and Hodgkin´s lymphoma (HL). **Methods.** Samples were obtained at time of diagnosis in 80 patients: 73 of them were diagnosed as lymphoma (diffuse large B-cell n=24, follicular n=3, marginal zone n=3, T-cell n=3 and Hodgkin lymphoma n=3, respectively) and 35 as CLL. In seven cases reactive (benign) lymphadenopathy was diagnosed. All samples were analyzed both with conventional TK-REA method and with a novel technique based on thymidine incorporation mediated by serum TK1 (DiviTum from Biovica Int AB, Uppsala, Sweden). Using novel method was mean TK1 value 590. 6±1260. 7 Du/L, median TK1 value was 195. 3 Du/L, TK-REA method assessed mean TK1 value 20. 4±22. 2 U/L (median 11. 8 U/L), both methods

showed strong correlation (r=0. 90, p<0. 001). We further analyzed patients with malignant lymphomas: median age was 64 years (range 22-89) with male predominance (M:F = 47:26), most of the patients (67%) had limited-stage disease (Ann Arbor stage I/II or Binet A/B), systemic symptoms were present in 43% and bulk >7cm in 30% of them. Beta-2-microglobulin (B2M) level was elevated >3mg/L in 21% and LDH in 32% of the cases. **Results.** Patients with reactive lymphadenopathy had significantly lower mean TK1 levels (163. 0±182 Du/L), compared to those with NHL, HL and CLL (631. 6±1312. 1 Du/L, p=0. 006). Mean TK1 level was significantly higher in patients with advanced disease stage (366. 8 vs 971. 0, p=0. 002), bulky disease (434. 4 vs 1036. 1, p=0. 006), systemic symptoms (335. 4 vs 979. 9, p<0. 001). Serum TK1 level was more than 3-fold higher in patients with high grade lymphoma than in low grade subtypes (317. 6 vs 1015. 0, p=0. 06) and 7-fold higher TK1 in patients with elevated LDH (209. 8 vs 1477. 7, p<0. 001). TK1 showed close correlation with LDH level (r=0. 79, p<0. 001). Trend was observed in correlation between maximum FDG avidity (SUV max.) on PET scan and TK1 level (r=0. 46, p=0. 07). On the other hand we found no correlation between TK1 and sex, age, B2M level and Ki-67 proliferating index. We found higher TK1 in CLL patients with unmutated IgVH status compared to those with mutated IgVH (607. 0 vs 166. 6, p=0. 002). **Conclusions.** The TK1 activity in specimens covers an extreme span - novel analytic method extends the detection range. It means that we are able to quantify higher levels than the conventional TK-REA method at time of diagnosis. We found a strong correlation between pretreatment TK1 levels and lymphoma stage and its aggressiveness.

Abstract. Extranodal Nasal-Type NK/T Cell Lymphoma is a distinct clinicopathological entity of non-Hodgkin's lymphoma, which is characterized by a highly aggressive clinical process and poor prognosis especially when disseminated or recurrent after radiotherapy. Human purinic/apyrimidinic endonuclease/redox factor-1 (hAPE/Ref-1) is a multifunctional protein involved in the repair of DNA damaged by oxidative. Because of its involvement in DNA repair and apoptosis-related signaling mechanisms, APE/Ref-1 is also being discussed as a novel target for tumor-therapeutic approaches. In studies, high level of APE1 expression is associated with an resistance to chemotherapeutic agents and adverse prognosis. And recent studies show that E3330, a small molecule inhibitor of the Ape-1/Ref-1 redox domain, induce inhibition of growth in cancer cell in vitro by specific inhibiting the function of APE/REF-1. E3330 blocks the in vitro growth of pancreatic cancer-associated endothelial cells and of the NK/T-cell lineage in our sdudy already and provides a potential therapeutic strategy in tumor . Thus far, no study has reported the experimental research on E3330 combined with chemotherapy in treating NK/T cell lymphoma. Therefore, we try to establish xenografted-nude mice model of human extranodal nasal type NK/T cell lymphoma and to investigate the effect of E3330 combined with adrinmycin on the human EN-NK/T-L xenografted-nude mice and its mechanism. **Methods.** EN-NK/T-L Xenografted-nude mice model was established by intraperitoneal injection of NK/T cell lymohoma cells SNK-6 . IC50 of E3330 for SNK-6 was calculated according to the result of MTT assay. Xenografted- nude mice were divided into four groups: Control group were given equal volume sodium□po□d1-7□ E3330 group were given E3330, 6mg/kg, po, d1-7□ADM group were given ADM, 0. 5mg/kg, ip,d1,4,7□E3330 + ADM group were given both E3330 and ADM, E3330, 6mg/kg, po, d1-7, ADM 0. 5mg/kg, ip, D1,4,7. The tumor weight and the survival rate of tumor-bearing mice were assayed, the apoptosis cells were determined by TdT-mediated Dutp Nick-end-Labeling(Tunel). Immunohistochemistry were used to study the expression of ki-67. Immunofluorescence were used to study the expression of APE/REF-1. **Results.** Nude mice model of human extranodal nasal type NK/T cell lymphoma was established successfully. The results showed that the expression level of APE/REF-1 was higher in tumor tissues compared with that in normal tissues (Fig 1 A 1B). The transplanted tumor volumes of mice were significantly smaller in E3330 + ADM group than those in other three groups(p<0. 05)(Table 1). The expression of ki-67 in E3330 + ADM group was lower than other groups(p<0. 05) (Fig 2 A 2B 2C 2D) and the apoptosis cells were increased in the same group(Table 2). **Conclusions.** Our study showed that E3330 + adrinmycin can significantly inhibit the growth of transplanted tumor of extranodal nasal type NK/T cell lymphoma Xenografted-nude mice .

THE ASSOCIATION OF FOLATE METABOLISM GENES POLYMORPHISMS WITH RISK OF AGGRESSIVE NON-HODGKIN'S MALIGNANT LYMPHOMA

O Berezina

Novisibirsk State Medical University, Novosibirsk, Russian Federation

Background. Non-Hodgkin›s lymphomas (NHLs) are a diverse group of malignant neoplasms, that affect lymphoid tissue. The major NHL subtypes is the aggressive Non-Hodgkin›s lymphomas, which most commonly diagnosed at advanced stages (III и IV). This fact implies that treatment efficiency will be low and disease prognosis will be poor. It is important to research new factors of the etiology of this disease, such as multiple single nucleotide polymorphisms (SNPs) in the genes implicated in various molecular pathways that lead to NHL. Among these genes are folate-metabolizing genes. **Aims.** The Aim of this study was to investigate the role of the C677T and A1298C SNPs in the *MTHFR* gene, A2756G in *MTR*, A66G in *SHMT1*, G1958A in *MTHFD1* and 844ins68 in *CBS* in genetic susceptibility to aggressive non-hodgkin's malignant lymphoma in the west-Siberian region. **Methods.** Eighty nine unrelated patients from the Novosibirsk City Haematological Center with aggressive NHL were investigated. Genomic DNA was isolated from leukocytes in venous blood and also from buccal epithelium, using the standart methods of DNA separation. A PCR-restriction fragment length polymorphism (RFLP) assay was used to detect the *MTHFD* G1958A and *CBS* 844ins68 SNPs. Genotiping of the *MTHFR*, *MTR*, *MTRR* and *SHMT1* gene SNPs was carried out by real-time PCR allelic discrimination with TaqMan probes. The alleles and genotype distribution of SNPs in patiens were compared with the distribution in healthy, white Russian subjects from Novosibirsk. **Results.** We determined the allele and genotype frequencies for the C677T and A1298C SNPs in the *MTHFR* gene, A2756G in *MTR*, A66G in *SHMT1*, G1958A in *MTHFD1* and 844ins68 in *CBS* gene in the NHL case and control groups. For all these SNPs, the genotype frequencies were in Hardy-Weinberg equilibrium in the control group. The polymorphisms G1958A *MTHFD1* and C1420T SHMT1 showed significant assotiation with aggressive NHL. Allele *1958A MTHFD1* was associated with decreased risk of diffuse large B-cell lymphoma (OR=0,429; C. I. [0. 279-0. 659], p<0,00008). Allele 1420T *SHMT1* was associated with increased risk in the group of another large B-cell non-hodgkin's lymphoma (OR = 1,862; C. I. [1,073 - 3,231], p < 0,026). Any association with indolent non-hodgkin's lymphoma was not revealed. **Conclusions.** Thus, single nucleotide polymorphisms G1958A *MTHFD1* and C1420T *SHMT1* may play a role in pathogenesis of non-hodgkin's malignant lymphoma. The bouth SNPs may cause to NHL through creating an imbalance between entities in folic acid metabolism.

[2]Komipharm International Co.,Ltd.,, Gyeonggi-do, South-Korea
[3]College of Pharmacy, Seoul National University, Seoul, South-Korea
[4]Department of Internal Medicine, Han Yang University College of Medicine, Seoul, South-Korea

Background. Arsenic compounds have been used in traditional medicine for several centuries. Especially, arsenic trioxide (As_2O_3) has been proven effective in acute promyelocytic leukemia, and also has been tried for the treatment of other hematological malignancies, including non-M3 type acute myelocytic leukemia, multiple myeloma. A drawback of As_2O_3 is to be administered intravenously. Sodium metaarsenite ($NaAs_2O_3$: code name KML001) is an orally bio-available arsenic compound with potential anti-cancer activity. However, the effect of KML001 has not been well studied in non-Hodgkin's lymphoma (NHL). **Aims.** Firstly, to determine the anti-tumoral effect of KML001 in NHL, and secondarily, to investigate the mechanism of anti-tumoral effect of KML001 in Jurkat and Jurkat R (adriamycin resistant cell) cell line. **Methods.** Eleven NHL cell lines were used in this study including Jurkat R cells. Cellular inhibition was measured by MTT assay. Expression of molecules was done by western blot. Analysis of cell cycle was used by flow cytometry. Transcriptional expression of catalytic subunit of telomerase, hTERT, and telomere length were done by real-time PCR. *In vivo* anti-tumoral effect was observed in nude mouse (Balb/c-nu/nu mouse) after inoculation of NHL cell line (Daudi). **Results.** KML001 inhibited the cellular proliferation in all NHL cell lines (IC_{50} of 5 x 10^{-8}M) as well as JurkatR cells (IC_{50} of 1 x 10^{-8}M) in a dose-dependent manner. KML001 (1 x 10^{-7}M) was induced G1 arrest which was associated with decreased expression of cyclin B1, cyclin E1, CDK1, CDK2, CDK4, and CDK6, and reduced kinase activities of CDK4 and CDK6 in Jurkat and JurkatR. In addition, KML001 increased the p21 and p27 levels in Jurkat and JurkatR cells. Expression of Bcl-2, Bcl-$_{XL}$, Mcl-1, proform of caspase-3, caspase-8, and caspase-9 was decreased, in contrast, expression of PARP was increased in Jurkat and JurkatR cells by KML001. Regarding the intracellular signaling, KML001 inhibited the activation of pSTAT1, 3, 5, NF-κB, pAKT, p-mTOR, p-GSK3 ß and pERK, while expression of pPTEN, pp38 and pJNK was up-regulated in Jurkat and JurkatR. Real-time PCR with RNA extracted from KML001-treated Jurkat and JurkatR cells showed a reduction of catalytic subunit of telomerase, hTERT, associated with a shortening of the telomere length. Furthermore, DNA damage molecule (γ-H2AX) was increased in KML001-treated in Jurkat and JurkatR cells. *In vivo* anti-tumoral activity of KML001 in a xenograft model of lymphoma cell line (Daudi) showed that tumor burden was significantly reduced (P < 0. 01) 42 days after oral feeding of KML001. Especially, *in-vivo* anti-tumoral effect of 3. 5 mg/Kg KML001 was comparable to that of doxorubicin (2. 5 mg/Kg, P < 0. 05). **Summary and Conclusions.** KML001 demonstrated anti-tumoral effect via various mechanisms including cell cycle arrest, induction of apoptosis, and inhibition of JAK/STAT, PI3K and MAPK pathways as well as targeting the telomere with DNA damage. Also, our results suggested that KML001 may overcome the resistance of chemotherapeutic agents. Furthermore, the sizes of tumor nodules in nude mice were reduced by KML001. Collectively, KML001 may be a candidate agent for the treatment of *de novo*, refractory and relapsed NHL.

EVIDENCE FOR REGULATION OF APOPTOSIS BY LMP1 ONCOPROTEIN OF EPSTEIN-BARR VIRUS IN PATIENTS WITH LOW GRADE B-CELL LEUKEMIC LYMPHOMAS

P Diamantopoulos[1], K Polonyfi[1], M Sofotasiou[1], A Galanopoulos[2], G Diamantopoulou[3], V Papadopoulou[1], F Kalala[1], M Angelopoulou[1], Variami[1], T Vassilakopoulos[1], M Siakantaris[1], A Anagnostopoulos[2], N Spanakis[3], J Meletis[1], NA Viniou[1]

[2]"G. Gennimatas" District General Hospital, Department of Clinical Hematology, Athens, Greece
[3]Department of Microbiology, Medical School, University of Athens, A, Greece

Background. In all EBV - associated malignancies, the virus displays a latency program of infection, which represents a restricted pattern of gene expression. Among the products of its genes, latent membrane protein 1 (LMP1) has been characterized as a potent transforming protein. LMP1 is expressed at widely different levels in cells of a single clone, a fact that may explain the stimulation of multiple distinct pathways, such as oncogenesis, cytotoxicity, and apoptosis. Studies in LMP1-positive cell lines have shown the coexisting apoptotic properties of LMP1. Survivin, a member of the inhibitor of apoptosis (IAP) family, is suggested to be an important regulator of the mitochondrial apoptotic pathway. The literature lacks information about the expression of LMP1 in the peripheral blood of patients with non-EBV-related lymphoproliferative diseases. **Aims.** To examine the apoptotic properties of LMP1 oncoprotein, in patients with low grade B-cell lymphomas, by studying the expression of survivin. **Patients and Methods.** Fifty-nine (59) patients with leukemic low grade B-cell lymphomas were included in the study. Informed consent was obtained from all patients. The patients' distribution to the individual lymphoproliferative diseases was as follows: chronic lymphocytic leukemia: 37, marginal zone lymphoma: 14, mantle cell lymphoma: 4, hairy cell leukemia: 2, follicular lymphoma: 2. Thirty-eight (64. 41%) patients were treatment naïve, while the rest had not been treated for the last 6 months We used, as a control group, 30 EBV-negative healthy adults. Peripheral whole blood specimens were obtained. Genomic DNA (QIAamp® DNA Blood mini kit - Qiagen) and RNA (Trizol protocol - Invitrogen, Carlsbad, CA) were extracted within 6 hours of collection. For the detection of EBV, a quantitative real time (qRT) PCR was performed for the BXLF-1 gene by using the EBV R-gene® Quantification COMPLETE kit (Argene). RNA from EBV-positive patients was tested by qRT-PCR, while RNA from all patients was tested by qRT-PCR to determine the levels of survivin and ABL expression. Primers and probes for the genes of interest, *LMP1, ABL*, *survivin* were chosen and qRT-PCR was carried out for each individual gene of each sample on LightCycler® 2. 0 (ROCHE, Mannheim, Germany). All reactions were performed twice. Relative gene expression (survivin vs. ABL) between normal and study blood samples was calculated by using the $2^{-\Delta C_T}$ method. Mann-Whitney U test was used for the statistical analysis of the results. **Results.** Twenty-five out of 59 patients (42. 37%) were EBV-positive, and 20 of them (80. 0%) expressed LMP1 (33. 89% of all patients). The levels of survivin were 4. 35 times higher in EBV-negative in comparison to EBV-positive patients (2-tailed p=0. 003), moreover they were 9. 2 times higher in LMP1-negative versus LMP1 positive patients (2-tailed p=0. 005). **Conclusions.** LMP1 expression in our patient series is higher (33. 89%) from the rates already reported in the literature. In our study, LMP1-positive patients express lower levels of survivin (p=0. 005), and this finding is in accordance to the hypothesis that LMP1 oncoprotein can induce apoptosis. We speculate that the apoptotic effect of LMP1 may be more profound in patients with low grade B cell lymphomas that are not causally correlated with EBV.

[3]Sidney Kimmel Comprehensive Cancer Centre at Johns Hopkins, Baltimore, United States of America
[4]Unidad Medica de Alta Especialidad. Clínica 25, IMSS, Monterrey, Mexico
[5]Centro de Genomica Unidad Morelos, UNAM, Cuernavaca, Mexico

Background. Diffuse Large B-Cell Lymphoma (DLBCL) is the most frequent subtype of Non-Hodgkin Lymphoma in the world (35%). Despite of R-CHOP chemotherapy, patients with DLBCL continue to relapse/refractory after treatment. For this reason, the search for biomarkers that could predict complete response (CR) and survival is important. Proteomics is in charge of the identification, quantification and characterization of the proteins in tumor cells. There are some descriptions about the proteomic profile of lymphomatous cellular line, but there are not any reports about the proteomic profile in serum in patients with DLBCL. **Aims**. We present the preliminary results from the serum profile using proteomic technology in patients involved by DLBCL. **Methods**. The serum from 18 patients with diagnosis of the novo DLBCL who were treated with R-CHOP and 8 healthy people (control cases) were analyzed. The technology Proteominer® was used. Proteins were separated in double dimension gels (2D-SDS-PAGE at 12%) and stained with Coumassi/silver. Spot lecture was done by the software PDQuest. The potential spots were cut and analyzed by Liquid Chromatography Mass Spectrometry. Clinical variables were also analyzed together with the proteomic profile results. **Results**. There were 8 proteins identified with differential expression in the serum of patients with DBCL, 2 of the inflammatory type (amyloid A and P) and antioxidant (GPX3). GPX3 was the most frequent protein observed in 72% of the cases, compared with the control group where was only observed in 12% (p=0. 009). This protein presented a sensitivity of 72% (CI95%: 49% to 85%), specificity of 87. 5% (IC95%: 63-98%) with a PPV of 93% (CI95%

68% to 99%) and NPV of 58% (CI95% 32 to 81%). The clinical characteristics of patients with GPX3 (+) compared with the GPX3 (-) were the followings: More frequent in males (54% vs 20%, respectively), older age, elevated LDH (64% vs 40%, respectively), worst ECOG (23% vs 0%,), advanced IPI score (intermediate and high; 46% vs 20% and 15. 4% vs 0%, respectively). Regarding overall rate response (ORR), that was higher in patients with GPX3 (+) vs. GPX3 (-). (100% vs. 66%, respectively p=0. 07). **Conclusions**. The proteomic profile at the serum level from patients with DLBCL has an inflammatory and antioxidant component in serum. The GPX3 was associated with variables of poor prognosis for DLBCL. GPX3 showed to be a potential biomarker for predicting ORR. Therefore, in our group we are evaluating the role of plasma GPX3 by ELISA in patients with DLBCL to attempt corroborate this data.

1653

GENOMIC IMBALANCES IN HCV-RELATED LYMPHOMAS ARE SIGNIFICANTLY CLUSTERING IN HIGH GRADE MALIGNANCIES

G Barba[1], C Matteucci[1], L Brandimarte[1], B Crescenzi[1], C Doglioni[2], A Pulsoni[3], M Ponzoni[2], C Mecucci[1]
[1]Hematology, University of Perugia, Perugia, Italy
[2]Pathology Unit, San Raffaele Scientific Institute, Milan, Milano, Italy
[3]Hematology, University "La Sapienza", Rome, Italy

Background. In HCV-related lymphomas, HCV supports mono- oligo- clonal B-lymphoproliferation, thus favouring selection of malignant clones. A role of HCV in pathogenesis is further documented by low grade lymphoma regression under antiviral treatment. However, as genetic damage accumulates, low grade lymphoma may evolve into a diffuse large B-cell tumour or a high-grade malignancy may be present from the beginning in the form of an aggressive B lymphoma. Genetic studies on these malignancies are still scarce. Using FISH and CGH in a series of 16 HCV positive patients we found a prevalence of trisomy 3q in low grade lymphomas and of 2q deletion in diffuse large B cell lymphoma (Matteucci et al Leukemia 2008;22:219-222). In 12 cases of HCV related splenic marginal zone lymphomas Novara et al (Hum Pathol 2009;40:1628-37) found recurrent deletions at chromosome 7q, 8p, 13 and 17p and recurrent duplications involving chromosome 17q, 18q, and Xp. A 3q duplication was confirmed in only one case. **Aims.** To increase knowledge of genomic changes in low- and high- grade HCV related Lymphomas. **Methods.** In a series of 18 patients with lymphomas histopathology showed marginal zone lymphoma (MZL, low grade lymphoma)in 5, diffuse large B-cell lymphoma (DLBCL, high grade) in 7, follicular lymphoma (FL) in 3, Hodgkin's lymphoma in 2 and multiple myeloma in 1. In all cases HCV infection was serologically demonstrated. Paraffin embedded tissue sections from pathological lymph nodes were used for DNA extraction in 17/18 cases. Peripheral blood cells were used for the other (DLBCL). Our analysis was based on Comparative Genomic Hybridization as the best technique in our hands to analyze genomic imbalances on archival samples. **Results.** A total of 71 imbalances (40 gains and 31 losses) were found. Most (28 gains and 16 losses) were found in high grade DLBCL, as expected. Two or more gains involved chromosomes 3, 5, 6, 7, 8, 9, and 17q, while losses were found at chromosomes 2, 6, 8, 9, and 17. Only 2 losses (10 q and 14q) were found in the 5 cases of MZL. Nine imbalances (4 gains at chromosomes 2, 8, 16, and 18) and 5 losses at chromosomes 1, 10, 16, 19, and 22 were found in 3 cases of follicular lymphoma). Overall 14 imbalances (5 gains at chromosomes 1, 6, 9, 14, and 21 and 9 losses at chromosomes 1, 2, 8, 10, 12, 16, 17, 19, and 20) were detected in multiple myeloma, while only normal results were obtained in the 2 samples of HD. **Conclusions.** Two isolated losses in MZL involved chromosome 10q and 14q, confirming ours and Novara's previous observations. A 10q loss was also found as an isolated change in one case of FL, thus emphasizing this lesion as an early event. A significantly higher genomic complexity (p<0. 05, Mann-Whitney test) emerged in high-grade lymphoma. Only 1 out of the 7 cases was normal. Interestingly, a 2q loss was confirmed in two DLBCL, and both cases showed concomitant 3q gain and a past history of low grade lymphoproliferation (Matteucci, Leukemia 2008).

1654

99MTC-TIOGLUCOSE AS A POTENTIAL IMAGING AGENT IN NON-HODGKIN LYMPHOMAS

E Riva[1], R Castelli[2], M Fernandez[2], J Chabalgoity[3], M Moreno[3], P Cabral[2]
[1]Facultad de Medicina, Hospital de Clinicas, Montevideo, Uruguay
[2]CIN, Facultad de Ciencias, Montevideo, Uruguay
[3]Laboratorio de Biotecnología, Facultad de Medicina, Montevideo, Uruguay

Background. Glucose metabolism has been shown to be increased in neoplastic cells. This altered metabolism confers them a selective advantage for survival and proliferation. Glucose analogs (eg. ^{18}FDG) are used to evaluate this increased metabolic activity in different neoplasms and its role has been validated in certain types of lymphomas. Obtaining glucose analogs labeled with ^{99m}Tc would be of interest, provided its low cost and high availability. **Aims.** Development and biologic evaluation of 1-tio-β-D-glucose (1TG) -^{99m}Tc. Evaluation as imaging agent in non-Hodgkin lymphomas (NHL). **Methods.** 2 mg of 1TG were added to 40 ul SnCl2 (80ug/ml) and 370 MBq $^{99m}TcO_4^-$ and incubated during 30 min at room temperature. *In vitro* stability of ^{99m}Tc-1TG was evaluated during 24 h. Radiochemical purity and stability were evaluated by means of different chromatographic systems: ITLC-SG, FM: MEK, NaCl 0. 9% and HPLC. *In vitro* biological evaluation was performed in A20murine NHL cells: blockage assays using 1TG and cold glucose were made. Internalization assays were evaluated at 4 and 37ºC. Biodistribution was assessed at 1 and 2 h in normal BALBc mice (n=3). **Results.** radiochemical purity of 1TG-^{99m} Tc was > 95% and remained stable during 24 h. A20 cell assays showed increased uptake of ^{99m}Tc-1TG at 2 h and blockage by the addition of cold 1TG. This uptake was not modified when cold glucose was used. Internalization studies at 4 and 37ºC suggest that ^{99m}Tc-1TG uptake is performed by active transport. Biodistribution at 1 and 2 h showed high blood clearence and renal elimination. Conclusions. Labeling of 1-TG - ^{99m}Tc was performed with high radiochemical purity and stability. Biological evaluation is that of an imaging agent. This results support the hypothesis that 1-TG - ^{99m}Tc may have a potential use as imaging agent in NHL and encourage further studies in animal models, which are now in courseì.

SYNERGY OF PRO-APOPTOTIC DRUGS IN SEZARY LYMPHOMA

T Costello, N Bonnet, P Poullin, B Kahn-Perles
Assistance Publique des Hôpitaux de Marseille, Marseille, France

Background. Sezary syndrome is a rare cutaneous T-cell lymphoma (CTCL) of poor prognosis characterized by erythroderma, lymphadenopathy and the presence of circulating Sezary cells. Current treatments are often associated with a partial and transient response, justifying the evaluation of new therapies. Expression profile studies have identified gene targets of potential interest in therapy of peripheral T-cell lymphomas. The HDACi suberoylanilideacide hydroxamic (SAHA) causes cellular death by apoptosis and cell cycle arrest of a wide variety of transformed cells. The treatment of SAHA refractory CTCL patients has a response rate of only 30%, suggesting the need for a combined chemotherapy approach. The MithramycineA inhibits the activity of transcription factors of the Sp3 family and modifies the expression of genes involved in apoptosis, angiogenesis and cell survival. Mithramycin A (MM-A) has not been evaluated in CTCL. **Aims.** The purpose of this study was to evaluate the combined effects of Saha + MM-A on Sézary cells. **Methods.** Sezary cells were obtained from four patients, the lineage Hut-78 cell line derived from the ATCC (Rockville, MD, USA). Activated CD4 + T-lymphocytes stimulated by IL-7 + anti-CD28 were chosen as the normal counterpart for Sézary. Resistant clones of Hut-78 were obtained by limiting dilution or by culture in progressive concentrations of Saha / MM-A. Effects of these drugs on cells were evaluated for proliferation, survival / viability, apoptosis and the cell cycle by FACS analysis, MTT test with Annexin V-7AAD and propidium iodide. The study of synergies between drugs was made by serial dilution of ED50 and analysis using the CalcuSyn (method of Chou and Talalay). Gene expression and miRNA profiling were performed on Agilent platform. **Results.** The treatment of Sezary cells by Saha and MM-A induced a dose an time-dependent apoptosis, with a synergistic effect of the two drugs. The normal CD4 + T cells activated by IL-7 + anti-CD28 were less sensitive to Saha and MM-A. Clones resistant to Saha, MM-A or both drugs were obtained and will be used in vitro model of resistance to cytotoxicity. **Conclusions.** The analysis of the transcriptome od cells exposed to cytotoxic drugs may specify the different path-

ways involved in response / resistance of Sezary cells to SAHA / MM-A. We focused our attention on the expression of genes involved in apoptosis, proliferation, cell cycle, the JAK / STAT pathway, the family of TNF-R, interleukins and their receptors, and the TCR siganling, these genes being identified as targets of SAHA.

1656

AQUAPORIN-4 EXPRESSION IN PRIMARY HUMAN CNS LYMPHOMAS CORRELATES WITH TUMOR CELL PROLIFERATION AND HETEROGENEITY OF THE VESSEL WALL

D Ribatti[1], B Nico[1], T Annese[1], R Tamma[1], V Longo[1], S Ruggieri[1], R Senetta[2], P Cassoni[2], A Vacca[1], G Soecchia[1]
[1]University of Bari Medical School, Bari, Italy
[2]University of Turin Medical School, Turin, Italy

Background. No literature data are available concerning the expression of aquaporin-4 in primary central nervous system lymphomas and the relationship between aquaporin-4 expression and the morphological characteristics of blood vessels. **Aims and Methods.** We have investigated this relationship in 24 human diffuse large B-cell primary central nervous system lymphomas by means of immunocytochemistry and confocal laser microscopy. **Results.** i) A high aquaporin-4 expression correlated with a high Ki-67 index and aquaporin-4 marked tumor and endothelial cells in cytoplasm and plasma membranes, while aquaporin-4 expression was low in tumor areas with a low Ki-67 index where few tumor cells were positive to aquaporin-4, and endothelial cells showed aquaporin-4 expression on their abluminal side. ii) Different type of cells participated to vessels formation: $CD20^+$ tumor cells and factor $VIII^+$ endothelial cells; $aquaporin\text{-}4^+$ tumor cells and $CD31^+$ endothelial cells; $CD20^+$ and $aquaporin\text{-}4^+$ tumor cells; glial fibrillary acidid $protein^+$ endothelial cells surrounded by glial fibrillary acidic $protein^+$ tumor cells. **Conclusions.** Overall, these data suggest the importance of aquaporin-4 in primary central nervous system lymphomas due to its involvement in cerebral edema formation and resolution and tumor cell migratory activity, and have documented that tumor microvasculature in lymphomas is extremely heterogeneous, confirming the importance of neoangiogenesis in the pathogenesis of lymphomas.

1657

DECREASED EXPRESSION OF CXCR4 CHEMOKINE RECEPTOR IN BONE MARROW AFTER CHEMOTHERAPY IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA IS A GOOD PROGNOSTIC FACTOR

G Mazur[1], A Butrym[1], M Jelen[1], I Kryczek[2], T Wróbel[1], D Dlubek[2], E Jaskula[2], A Lange[2], K Kuliczkowski[1]
[1]Wroclaw Medical University, Wroclaw, Poland
[2]L. Hirszfeld Institute of Immunology and Experimental Therapy, Wroclaw, Poland

Background. Chemokines and their receptors have been proved to be involved in cancer progression. CXCR4 chemokine receptor is widely expressed in normal tissues and plays an important role in development, mobilisation of haematopoietic stem cells, and trafficking of lymphocytes. CXCR4 is constitutively expressed on normal and malignant B lymphocytes derived from patients with B-cell lymphoproliferative disorders and has significant role in cell migration to lymph nodes and bone marrow. Overexpression of CXCR4 has been shown in thyroid and colon cancer. In breast cancer expression of CXCR4 is correlated with cancer metastases. Non-Hodgkin's lymphomas (nHL) constitute heterogeneous group of lymphoproliferative diseases, with different presenting features, clinical course and response to treatment. In Western countries majority of nHL's are B-cell origin. Lymphoma cells can localize not only to lymph nodes, but also can migrate to peripheral blood and metastase to other organs, including bone marrow. **Aims.** The purpose of this study was to determine CXCR4 gene expression in peripheral blood and bone marrow of non-Hodgkin's lymphoma patients before and after treatment. **Methods.** Samples of peripheral blood and bone marrow aspirates of 20 patients (9 females, 11 males; aged 26-73, median age 57 years) with B-cell nHL (7 follicular lymphoma, 4 mantle cell lymphoma, 3 small lymphocytic lymphoma, 3 marginal zone lymphoma, 2 diffuse large B-cell lymphoma, 1 Burkitt lymphoma) were taken at diagnosis and after chemotherapy. Gene expression was determined by the reverse transcription (RT)-polymerase chain reaction method. Expression was estimated from 0 AU (no amplificate signal) to 3 AU (maximal amplificate signal). Statistical analysis was performed using Wilcoxon and Cox test ($p<0,05$). **Results.** We observed high level of CXCR4 expression in most patients before treatment: in bone marrow: 3 AU - 10 pts, 2 AU - 8 pts, 1 AU - 2 pts. In peripheral blood: 3 AU - 14 pts, 2 AU - 4 pts, 1 AU - 1 pts, 0 AU - 1 pts. After chemotherapy significant decrease in CXCR4 expression was observed. Bone marrow: 3 AU - 5 pts, 2 AU - 7 pts, 1 AU - 5 pts, 0 AU - 3 pts ($p=0,03$). Peripheral blood: 3 AU - 2 pts, 2 AU - 6 pts, 1 AU - 10 pts, 0 AU - 2 pts ($p=0,0002$). There was a good response to treatment in patients with significant decrease of CXCR4 expression in bone marrow after treatment. Those patients had 10-fold lower risk of death ($p=0,03$). **Conclusions.** Decrease in CXCR4 expression in bone marrow of nHL patients after chemotherapy can be a good prognostic factor.

Table 1.

CXCR4 expression	Peripheral blood (before treatment) - N° of pts	Peripheral blood (after treatment) N° of pts	Bone marrow (before treatment) N° of pts	Bone marrow (after treatment) N° of pts
3 AU	14	2	9	5
2 AU	4	6	8	7
1 AU	1	10	2	5
0 AU	1	2	1	3

EVALUATION OF CD99 AS A PROGNOSTIC MARKER IN DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH RITUXIMAB INCLUDED IMMUNOCHEMOTHERAPY

J Park[1], J Hong[1], S Park[1], JY Ahn[1], J Sym[1], EK Cho[2], D Shin[1], D Shin[1], JH Lee[1]
[1]Gachon University Gil Hospital, Incheon, South-Korea
[2]University Gil Hospital, Incheon, South-Korea

Background. CD99 immunoreactivity has been documented in a variety of tumors, including lymphoid malignancies such as anaplastic large-cell lymphomas. However, few studies have investigated the prognostic impact of CD99 in diffuse large B-cell lymphoma (DLBCL). Lee et al reported that DLBCL with positive CD99 had inferior event-free survival (EFS) in a previous study (Acta Haematol 2011; 125:167-174), but this study included only 13. 7% of patients who were treated without rituximab included immunochemotherapy and needs re-evaluation. **Aims.** The purpose of this study is to evaluate prognostic impact of CD99 in patients with diffuse large B-cell lymphoma (DLBCL) treated with the standard immunochemotherapy, rituximab-cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP). **Methods.** Patients were included if they were diagnosed as DLBCL by a histologic confirmation, at least 18 years of age and with a complete set of clinical data and adequate paraffin-embedded biopsy specimen for immunohistochemistry (IHC) for CD10, MUM-1, BCL-6, and CD99. All of the patients were treated with 3-weekly R-CHOP immunochemotherapy. Using conventional paraffin embedding, immunoperoxidase staining and tissue microarrays, we retrospectively investigated CD99 expression in 72 DLBCL patients. **Results.** Patients were classified either germinal center B-cell (GCB) type (n = 39) or non-GCB type (n = 24) of DLBCL by classification proposed by Muris et al. There was no difference of event-free survival (p = 0. 769) and overall survival (OS; p = 0. 547) in the whole patient population. Among patients with GCB type, patients with positive CD99 showed superior EFS (2-year EFS 90. 9% vs. 55. 7%, p = 0. 016) and OS (2-year OS 66. 7% vs. 63. 8%, p = 0. 024), compared to those with negative CD99. On the contrary, among patients with non-GCB type, patients with negative CD99 showed superior EFS (2-year EFS 19. 0% vs. 60. 0%, p = 0. 036) and OS (2-year OS 33. 9% vs. 80. 0%, p = 0. 012), compared to those with positive CD99. **Summary and Conclusions.** Prognostic value of CD99 was absolutely contrary to each other according to Muris classification: it is good prognostic factor in patients with GCB type of DLBCL and vice versa.

1659

LACK OF ASSOCIATION OF HHV-6 WITH LEUKEMIC LOW GRADE B-CELL LYMPHOMAS

P Diamantopoulos[1], K Polonyfi[1], M Sofotasiou[1], N Spanakis[2], A Galanopoulos[3], G Diamantopoulou[2], T Iliakis[1], T Vassilakopoulos[1], M Angelopoulou[1], Variami[1], NA Viniou[1]
[1]National and Kapodistrian University of Athens, Laikon General Hospital, Athens, Greece
[2]Department of Microbiology, Medical School, University of Athens, A, Greece
[3]"G. Gennimatas" District General Hospital, Department of Clinical Hematology, Athens, Greece

Background. Human herpesvirus 6 (HHV-6) is a member of the herpesviridae and was first isolated and characterized from patients with lymphoproliferative

disorders. Like other herpesviruses, it remains latent in certain cells of the immune system after primary infection, and can be reactivated in immunocompromised hosts. Its DNA integrates into the human genome. Due to this property, the oncogenicity of the virus has been speculated early after its first detection. The pathogenetic role of HHV-6 in lymphoproliferative diseases has been of continued interest for the last 20 years. Several studies have been performed to shed light on this correlation. Their conflicting results are due to the different methods used to detect the virus, the diversity of specimens used for this purpose, as well as the wide spectrum of diseases under study. AimsThe aim of the study is to investigate the postulated correlation of HHV-6 infection with leukemic low grade B-cell lymphomas. Patients and MethodsForty-eight (48) patients with leukemic low grade B-cell lymphomas were included in the study. The distribution of the patients at the individual lymphoproliferative diseases was as follows: chronic lymphocytic leukemia 56. 25%, splenic marginal zone lymphoma 27. 08%, mantle cell lymphoma 8. 33%, hairy cell leukemia 4. 17%, and follicular lymphoma 4. 17%. Peripheral whole blood specimens were collected and genomic DNA was extracted by using QIAamp® DNA Blood mini kit (Qiagen). Quantitative real time PCR (QR-PCR) was performed for the U57 gene of HHV-6 by using the CMV HHV6,7,8 R-gene® Quantification COMPLETE kit (Argene). The study was performed on LightCycler® 2. 0 (Roche, Mannheim, Germany). The detection limit of the technique is <156 copies/mL. ResultsThe median age of the patients was 73 years (51-87). The male to female ratio was 1. 1. None of the examined specimens was found positive for HHV-6. ConclusionsThe prevalence of HHV-6 in healthy individuals from Greece has not yet been determined, but we are investigating the prevalence of the virus in blood donors. Studies from other parts of the world give a wide range (2. 9% in the United Kingdom to 40% in Spain) of HHV-6 DNA detection by PCR in the whole blood of healthy individuals, mostly blood donors. Our results support a lack of contribution of HHV-6 in the malignant transformation of leukemic low grade B-cell lymphomas, a result that is compatible with the results of another recent study from Spain.

1660

PRAME EXPRESSION IN NON-HODGKIN'S LYMPHOMA

S Paydas, M Ergin, A Acikalin, B Duman
Cukurova University, Adana, Turkey

PRAME (preferentially expressed antigen of melanoma) expression was determined in 63 cases with non-Hodgkin's lymphoma (NHL). Age range was between 18-79, male/female ratio was 35/28. Thirty five of the cases had diffuse large B cell leymphoma (DLBCL), 20 had low grade lymphoma (LGL), 6 had peripheral T cell lymphoma (PTCL) and 2 had mantle cell lymphoma (MCL). PRAME expression was detected in 21 of the cases; 10 of these cases had DLBCL, 7 had LGL and 4 had PTCL. PRAME expression was not found in 42 cases; 25 had DLBCL, 13 had LGL, 2 had PTCL and 2 had MCL. Totally 10 of the 35 cases with DLBCL and 7 of the 20 LGL had PRAME expression, respectively. No response to initial treatment and/or relapse occurred in 7 of 21 PRAME (+) cases and 16 of 42 PRAME (-) cases. Interestingly, central nervous system involvement occurred in 3 cases without PRAME expression while none of the cases with PRAME expression had central nervous system involvement. Progession free and overall survivals were compared in cases with or without PRAME expression.

1661

FAIRLY PATIENTS TREATED WITH AGGRESSIVE CHEMOTHERAPY

A Aviles, M Nambo
Mexican Institute of Social Security, Mexico,DF, Mexico

Background. Anthracyclyne-based chemotherapy regimens are the standar therapy for patients with diffuse large B-cell lympgoma (DLBCL), but such regimens may be poorly tolerated in frail patients (age >65 years, antecedents of cardiac disease oir abnormal ventricular left function). **Aims.** We analyzed the feasibility of a regimen that include pegylated liposomal doxorubicin (PLD) instead of doxorubicin in a CPOP regimen in untrated frail patients. **Results.** sixty-nine patients weren enrolled, in an intent-to treat analysis all were evaluable for efficacy and toxicity. Complete response was achieved in 50 cases (72%), three patients developed severe toxicity and were excluded, nine patients relapse . Thus,actuarial curves at 5-years showed that relapse-free survival was 78 % (95% Connfidence interval(CI) 71% to 84 %) and overall survival was 79% (95% CI: 70% to 85%). Two patients suffer myocardial infarctation, 3 and 6 years after treatment. **Conclusions.** These results, suggests that CPOP appears to be an acceptable alternative for frail patients with DLBCL.

1662

PROGNOSTIC IMPACT OF BCL6 GENE REARRANGEMENT IN DIFFUSE LARGE B-CELL LYMPHOMA

A Chekan[1], G Tumyan[1], A Kovrigina[2], D Bykov[3], P Zeinalova[1], M Kichigina[1], O Kolomeytsev[1], D Osmanov[1], S Lepkov[4]
[1]N. N. Blokhin Russin Cancer Research Center, Moscow, Russian Federation
[2]Hematological Scientific Centre, Moscow, Russian Federation
[3]I. M. Sechenov First Moscow State Medical University, Moscow, Russian Federation
[4]The Russian State Medical University, Moscow, Russian Federation

Background. The *BCL6* gene rearrangement is the most common genetic abnormality in diffuse large B-cell lymphoma (DLBCL), occurring in approximately 35% cases. The prognostic significance of the *BCL6* rearrangement in DLBCL has remained uncertain despite previous studies. **Aims.** The aim of study was investigating the frequency of *BCL6* rearrangement and BCL6 protein expression in two opposite groups of patients DLBCL with favorable and poor outcome. **Methods.** We retrospectively studied *BCL6* rearrangement by fluorescence in situ hybridization with break-apart probes and BCL6 protein expression by immunohistochemical staining of 56 paraffin-embedded specimens from patients (pts) DLBCL - 37 pts with relapse\refractory disease (poor prognosis - group 1) and 19 pts in complete remission more than 3 years (favorable prognosis -group 2). **Results.** In group 1 (37 pts) 60% were male, median age was 48 (range 15-81), 78% had advanced stages and 51% B-symptoms, > 1 extranodal sites involved 51% pts, 35% had received prior rituximab-containing therapy. After median follow-up of 32 months, median progression free survival was only 5 months, overall survival - 14 months. In favorable group 2 (19 pts) 58% were male, median age 46 (range 19-76), 84% had early stages. All pts in this group are alive without disease. *BCL6* rearrangement was detected in 84% of cases in poor prognosis group and only in 21% of cases in favorable group (p<0,001). BCL6 protein expression was not predictive of outcome in neither group and determined respectively 49% and 53% cases. No association was found between gene rearrangement and BCL6 protein expression. **Conclusions.** *BCL6* gene rearrangement correlated with high-risk clinical feature and was found to be an unfavorable prognostic marker in DLBCL. BCL6 protein expression was not associated with gene rearrangement and outcome of disease. Prospective analysis will be needed to clarify prognostic significance of chromosomal abnormality in DLBCL.

[16]Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

Background. There has been sparse information about primary breast lymphoma (PBL). Recently, several studies suggested some common features: predominant diffuse large B-cell lymphoma (DLBCL) histology, significant risk of central nervous system (CNS) relapse. **Aims.** The aim of this study is to investigate the clinical features and outcomes of PBL and also to find the factors associated with CNS relapse. **Methods.** We analyzed the data of 63 patients diagnosed with PBL from 1994 to 2009, who were identified from our nationwide sur-

vey. **Results.** The median age was 45 years (range, 20-73) and all were female. The Ann Arbor stage was I(37, 59%)/II(22, 35%)/III(4, 6%). ECOG performance status was 0 or 1 in 58 patients (92%) and serum LDH level was elevated in 23 (37%). Thus, the International Prognostic Index (IPI) was mainly low (50, 79%). The most common subtype identified was DLBCL (49, 78%), with the second most common subtype being extranodal marginal zone B-cell lymphoma of mucosa-associated lymphoid tissue (MALT; 6, 10%). Follicular lymphoma was identified only in one. T-cell lymphoma consisted of peripheral T-cell lymphoma, unspecified (PTCL-U; 4, 6%) and anaplastic large-cell lymphoma (ALCL), anaplastic lymphoma kinase (ALK) positive (1, 2%); ALCL, ALK negative (2, 3%). T-cell lymphoma had significantly more unfavorable characteristics such as presence of B symptom and poor performance status. Thus, the proportion of patients with low-intermediate/high-intermediate IPI was greater in the T-cell lymphoma group, although this was statistically nonsignificant (P=0. 095). The majority of patients (91%) received systemic chemotherapy ± radiotherapy as a curative treatment. Primary surgical resection ± axillary node dissection was performed in 29 patients (46%). Five of the 6 patients with MALT lymphoma were only treated with surgical resection. With a median follow-up of 49. 6 months (range, 4. 4-186. 0), estimated 5-year PFS and OS was 53. 1% (95%CI, 45. 9-60. 3) and 64. 8% (95%CI, 57. 8-71. 8). The PFS and OS of the B-cell lymphoma were significantly better than those of the T-cell lymphoma (PFS, 57. 3% vs 17. 9%, P=0. 007, respectively; OS, 71. 3% vs 17. 9%, P=0. 001, respectively). In multivariate analysis for OS, T-cell phenotype (hazard ratio [HR], 3. 41; 95% CI, 1. 12-10. 31) and low-intermediate/high-intermediate IPI (HR, 3. 89; 95% CI, 1. 26-12. 06) were independent prognostic factors for worse OS. Twenty-one patients experienced progressive disease following first-line therapy. Of these, 7 experienced CNS relapse, and cumulative incidence of CNS relapse at 3-year was 13. 1% (95% CI, 8. 5-17. 7). In multivariate analysis, serum LDH level was only independent predictor for CNS relapse (HR, 10. 31; 95% CI, 1. 20-88. 65). Interestingly, six patients (10%) received prophylactic intrathecal chemotherapy using methotrexate, and there was no CNS progression in these patients. **Conclusion.** DLBCL is the most predominant subtype in agreement with previous series. The survival of patients with B-cell phenotype was better than that of patients with T-cell lymphoma. Distant extranodal failures, especially in the CNS, are a major problem. And, elevated serum LDH level was identified as a risk factor for CNS relapse. Thus, despite the role of CNS prophylaxis are still not clear, it should be considered in PBL patients with elevated serum LDH level.

1664

PRALATREXATE PLUS BEXAROTENE IN PATIENTS WITH RELAPSED OR REFRACTORY CUTANEOUS T-CELL LYMPHOMA (CTCL): STUDY DESIGN AND PRELIMINARY Results FROM AN ONGOING, OPEN-LABEL, PHASE 1 DOSE-FINDING STUDY

PL Zinzani[1], L Geskin[2], YH Kim[3], L Chance[4], M Duvic[5]

[1]Institute of Hematology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy

[2]University of Pittsburgh School of Medicine, Pittsburgh, PA, United States of America

[3]Stanford University School of Medicine, Stanford, CA, United States of America

[4]Allos Therapeutics, Inc., Westminster, CO, United States of America

[5]University of Texas MD Anderson Cancer Center, Houston, TX, United States of America

Background. CTCLs are a subset of generally indolent, extra-nodal non-Hodgkin T-cell lymphomas presenting with skin lesions that can disseminate or become aggressive. Patients with early-stage CTCL receive skin-directed therapies, but refractory or late-stage patients require systemic or combination therapy. Pralatrexate is an antifolate approved in the United States for relapsed/refractory peripheral T-cell lymphoma. Pralatrexate demonstrated high activity and acceptable toxicity when used as a single agent in a phase 1 study in 54 patients with relapsed/refractory CTCL; 29 patients were treated at the optimal dose (15 mg/m^2/week for 3 of 4 weeks), with a 45% response rate.[1] **Aims.** Preclinical studies suggest that pralatrexate and bexarotene exert synergistic pro-apoptosis in CTCL cells.[2] The current study was designed to determine the recommended dose, safety, pharmacokinetics, and preliminary efficacy of pralatrexate plus oral bexarotene in patients with relapsed/refractory CTCL. Informed consent was obtained. **Methods.** Eligibility criteria include adult patients with CTCL (mycosis fungoides [MF] ≥ 1B, Sézary syndrome [SS], primary cutaneous anaplastic large cell lymphoma [ALCL]), ≥ 1 prior systemic therapy, and Eastern Cooperative Oncology Group performance status ≤ 2. The intended pralatrexate + bexarotene doses include 15 mg/m^2 + 150 mg/m^2 (Cohort 1), 15 mg/m^2 + 300 mg/m^2 (Cohort 2a), 10 mg/m^2 + 150 mg/m^2 (Cohort 2b), and 10 mg/m^2 + 300 mg/m^2 (Cohort 3). Pralatrexate is administered weekly via intravenous push for 3 of 4 weeks; bexarotene is self-administered orally daily with food; patients also receive vitamin B_{12} and folic acid supplementation. The standard 3 + 3 dose-escalation design is used to determine the maximum tolerated dose (MTD). Cohort escalation occurs upon dose-limiting toxicities (DLTs) in < 33% of patients in any cohort. The MTD is the highest dose with < 33% DLT incidence. The following are considered DLTs if they occur in cycle 1: ≥ grade 3 neutropenia (or granulocyte colony-stimulating factor administered), thrombocytopenia, treatment-related non-hematologic toxicity, hyperlipidemia, or hypothyroidism; and treatment-related adverse events causing bexarotene dose omission for ≥ 10/28 days or pralatrexate dose omission/reduction. **Results.** A total of 14 patients (6 female, 8 male; aged 39-85 years) have been treated (11 with MF, 1 with transformed MF, 1 with ALCL, and 1 with SS). The median number of prior therapies was 3 (range, 2-14). In Cohort 1, 0/3 patients experienced DLTs. In Cohort 2a, 2/3 patients experienced DLTs (≥ grade 3 neutropenia [n = 1] and ≥ grade 3 thrombocytopenia [n = 1]). The MTD was identified as pralatrexate 15 mg/m^2 + bexarotene 150 mg/m^2. Response data are available for 10 patients, as presented in Table 1. **Summary and Conclusions.** The MTD of the pralatrexate + bexarotene combination has been determined. Interim data indicate that the combination has been well tolerated and demonstrated robust activity, with 6 responses (1 complete response [CR]; 5 partial responses [PRs]) among the 10 patients with available response data. Enrollment is ongoing; detailed results, including an expanded cohort of 30 patients treated at the MTD, will be presented in the future.

SAFETY AND EFFICACY OF RITUXIMAB AND CHLORAMBUCIL IN COMBINATION AS FIRST-LINE TREATMENT IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA PATIENTS

G Martinelli, G Andreola, D Laszlo, P Minga, L Cannella, S Liptrott, S Sammassimo, M Linetti, L Calabrese, S Bassi

European Institute of Oncology, Milan, Italy

Background. first line treatment for follicular non Hodgkin lymphoma is still a controversial question. Usually patients needing treatment for this indolent disease receive Rituximab in combination with systemic chemotherapy: R-CHOP, R-CVP, R-Fludarabine and more recently R-Bendamustine are considered treatment of choice. We previously published our experience in low grade non Hodgkin lymphoma using combination of Rituximab plus Chlorambucil achieving approximately 90% of response rate with an manageable toxicity. **Aims.** here we report clinical results achieved in newly diagnosed follicular lymphoma patients considered for receiving systemic treatment. **Methods.** eighty-five patients (32 male, 53 female) with a median age of 58 years, all diagnosed with follicular lymphoma, were considered eligible to receive the combination of Rituximab and Chlorambucil with the following schedule: Rituximab standard dose weekly for four doses and Chlorambucil 6mg/mq for six weeks consecutively (induction phase) then, patients responding received a single dose of Rituximab and Chlorambucil for 14 days each month for an additional four months. **Results.** most patients were considered in stage III-IV (76%), one third of them

presented with bulky disease and B-symptoms were present in approximately 20%. The majority of patients were FLIPI 1-2, while 30% of them had extranodal involvement. After induction phase 97% of patients presented a clinical improvement and of consequence all these patients received the additional monthly treatment. Eighty patients completed the scheduled treatment and were evaluated at the end of therapy: 75% achieved a complete remission, 22% a partial remission. With a median follow up of 40 months, the median disease free survival was not reached. The 5 years disease free survival probability is 73%. **Conclusions.** our results confirm the clinical activity of the combination R-Chlorambucil as previously reported in low grade lymphoma patients. Complete response observed is similar to those reported with more aggressive combination regimens, confirming the relevant role of monoclonal antibody in the treatment of such indolent disease. The combination of R-Chlorambucil is safe and active treatment for newly diagnosed follicular non Hodgkin lymphoma patients and, considering its low toxicity profile, might be offered as valid alternative option for those patients unsuitable for aggressive chemotherapy.

1666

INCIDENCE, CLINICAL MANAGEMENT AND OUTCOME OF PERIPHERAL T-CELL LYMPHOMA: A POPULATION-BASED STUDY IN THE UK

G Smith[1], T Bagguley[1], D Painter[1], E Roman[1], R Johnson[2], A Jack[2], R Patmore[3]

[1]University of York, York, United Kingdom

[2]Leeds Teaching Hospitals, Leeds, United Kingdom

[3]Hull & East Yorkshire Hospitals NHS Trust, Hull, United Kingdom

Background. Peripheral T-cell lymphomas (PTCL) are a heterogeneous and rare group of disorders with approximately 400 cases diagnosed in the UK each year, accounting for nearly 5% of all non-Hodgkin lymphomas. Prognosis is considered to be poor for many patients, however, few population-based studies exist that examine the clinical management and outcome of these diseases. **Methods.** Cases of PTCL (>18 years old) diagnosed 2004-2010 were identified from a specialist population-based register of haematological malignancies - the Haematological Malignancy Research Network (www. HMRN. org). HMRN covers a population of 3. 6 million, and all diagnoses are made at a centralised specialist integrated diagnostic laboratory (www. HMDS. info) and coded to the latest WHO classification. Clinical information including demographic, prognostic, all treatment episodes and response data are routinely abstracted from medical records for each case using standardised abstraction forms and procedures. All patients are linked to the NHS Central Register for accurate survival data.

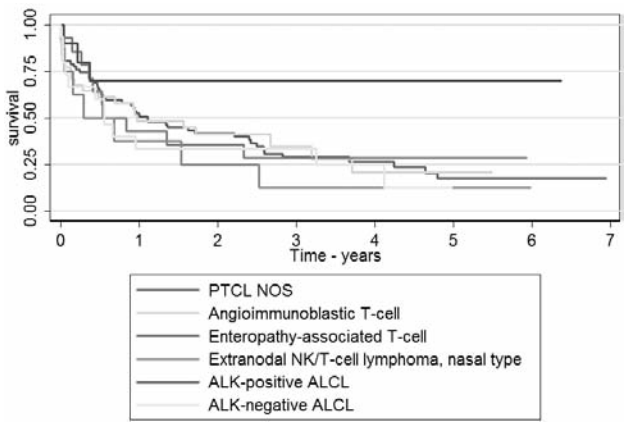

Figure 1. Kaplan Meier Survival Estimates by Peripheral T-cell Lymphoma Subtype.

Results. 150 PTCLs were ascertained over the six year period these comprised; peripheral T-cell NOS (45%), angioimmunoblastic T-cell (21%), ALK-negative anaplastic large cell lymphoma (10%), enteropathy-associated T-cell (9%), ALK-positive anaplastic large cell lymphoma (7%), extranodal NK/T-cell lymphoma, nasal type (5%), anaplastic large cell lymphoma - ALK status unknown (3%). The overall incidence rate was 0. 7 per 100,000 and the European standardised rate was 0. 6 per 100,000 (95% confidence intervals (95%CI) 0. 5-0. 7). Median age at diagnosis was 66. 9 years (range 22. 7-95. 6) and there was a male excess (sex-rate ratio, 1. 4: 95%CI 1. 0-1. 9). 55% of patients were diagnosed with advanced stage disease (III/IV). The majority of patients received chemotherapy as first line treatment (77%) and these were primarily CHOP based regimens (86%). 29% of patients were refractory to first line treatment or relapsed and went on to receive further treatment(s). Of those who had a response after first line treatment, median time-to-progression was 4. 9 months. There was variation in subsequent therapies used; for example at second line treatment 16 % of patients received DHAP, 14% had an autologous stem cell transplant and 13% were given gemcitabine-based regimens. Median survival for all patients was 12 months (range 0-82) and survival at 5-years was estimated to be 25%. There was marked variation in survival by subtype (figure). For those patients who received subsequent treatment(s), response was generally poor with a median survival from time of second line therapy of 9. 9 months (range 1. 4-59. 7). **Conclusions.** PTCLs have no standard treatment approach beyond first line therapy, resulting in heterogeneous treatment pathways. Prognosis is generally poor, and salvage treatment(s) appear to be ineffective for the majority of patients who receive them. HMRN is a large population-based study, which includes trial and non-trial patients, and the findings reflect the reality of the clinical management and outcome of PTCL.

[2]Division of Hematology, Department of Translational Medicine & IRCAD, Avogadro, Novara, Italy

[3]Division of Hematology, Department of Translational Medicine & IRCAD, Avogadro, Novara, Italy

[4]Oncology Institute of Southern Switzerland, Bellinzona, Switzerland

Background. There is increasing evidence of the microenvironment influence on the growth of different non-Hodgkin lymphoma (NHL) subtypes. Monocytes and lymphoma-associated macrophages have been shown to be associated with lymphoma cell survival and drug resistance. The absolute monocyte count has been recently reported to be associated with survival of follicular lymphoma and diffuse large B cell lymphoma. **Aims.** To assess the prognostic impact of absolute monocyte count (AMC) at diagnosis in mantle cell lymphoma (MCL) patients. **Patients and Methods.** One hundred forty-two MCL patients were selected out of 2,426 NHL cases recorded on the databases of the Oncology Institute of Southern Switzerland in Bellinzona (Switzerland) and the Division of Hematology of the Ospedale Maggiore della Carità in Novara (Italy), which include patients treated between 1980 and 2011. The AMC at the time of diagnosis was available in 98 cases, which are the object of the present analysis. Median age was 70 years (range 35-94 years); 83% had stage III-IV, 66% had intermediate-high/high International Prognostic Index (IPI) risk and 48% were at high risk according to the sMIPI (simplified MCL international prognostic index). Eighty-five pts (86%) were treated with chemotherapy, 34 (35%) had rituximab, 6 (7%) had front-line autologous stem cell transplantation.

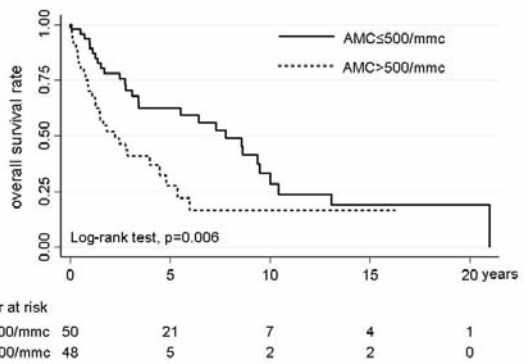

Figure 1.

Results. Median AMC at diagnosis was 500/mmc (range 50-9,000). The best cut-off value of AMC determined by the receiver operating characteristics (ROC) analysis based on dead/alive status was 504/mmc, very close to the median val-

ue, which was then chosen as a cutpoint for subsequent analysis. After a median follow up of 7 years (interquartile range, 3-16), 57 pts (58%) died. Five-year overall survival (OS) was 29% (95%CI, 14-45%) for patients with AMC >500/mmc versus 59% (95%CI, 42-73%) for patients with AMC ≤500/mmc (p 0. 006). In univariate analysis, increased AMC, elevated beta-2 microglobulin, elevated LDH, age>60, poor performance status, and poor-risk sMIPI showed a significant impact on OS. In multivariate analysis (Cox model), AMC >500/mmc at diagnosis remained an independent significant prognostic factor after adjusting for either the sMIPI or the IPI [HR, 2. 6 (95% CI, 1. 2-5. 9)]. **Conclusions.** AMC>500/mmc identifies poor-risk patients in MCL and may provide additional prognostic information over the most commonly used prognostic indices.

1668

IMPACT OF THE MICROENVIRONMENT ON THE PROGNOSIS OF PRIMARY BONE DIFFUSE LARGE B CELL LYMPHOMA

H Rajnai[1], L Koens[2], F Heyning[2], J Csomor[3], A Matolcsy[3], A Szepesi[3]
[1]Semmelweis University, Budapest, Hungary
[2]Department of Pathology, Leiden University Medical Center, Leiden, Netherlands
[3]1st Department of Pathology, Semmelweis University, Budapest, Hungary

Background. Primary non-Hodgkin lymphoma of the bone (PLB) is a rare neoplastic disorder, comprising 5% of extranodal lymphomas. Eighty percent of the PLB cases are diffuse large B-cell lymphomas (PBDLBCL). Overall, PLB carries a favourable prognosis. Although the microenvironment has a significant influence on the tumour cell growth, outcome of the disease and response to treatment, PBDLBCL has not been characterized with regards to the infiltrating reactive immune cells. **Aims.** To determine the prognostic significance of tumour cell microenvironment on the outcome of the disease and possible association with the germinal centre-B (GC-B) and activated B cell (ABC) phenotype. **Methods.** Forty-five cases of PBDLBCL diagnosed at the I. Department of Pathology Semmelweis University and Department of Pathology Leiden University were studied. The GC-B versus ABC subtype was determined by Tally's immunostaining algorithm based on the expression of GCET1, CD10, MUM1, FOXP1 and LMO2 antigens. Different components of the microenvironment, such as T cell subsets and macrophages of the microenvironment were analysed by immunohistochemistry using tissue microarrays (TMA). **Results.** A group of 45 patients with PBDLBCL was studied. Twenty-nine patients had single bone infiltration, while multifocal bone involvement (scored as stage IV) was noted in 11 cases. The mean IPI score was 1. 8. The overall survival was 80% with a median follow up of 51 months. Most patients received combination therapy in the form of surgical resection, poly-chemotherapy and radiotherapy. Thirty-two patients (71%) had a complete remission (CR), 9 patients died of the disease (20%), 4 had progressive disease (PD), 5 had partial response (PR) and died during therapy. For 4 patients the outcome was unknown. There was significant association between age and survival: 7 out of 9 patients >60 years of age died of disease. Stage and survival did not show any significant association: overall survival of stage I patients were 83% and 77% for stage IV. The number of tumour infiltrating T-lymphocytes represented by CD3 positive cells showed significant correlation with the outcome and with the phenotype of the tumour cells. Significantly higher number of tumour infiltrating CD8+ cytotoxic T cells and lower proliferation rate were observed in cases with CR compared to the patients with PR or PD disease. **Conclusions.** Our cohort of PBDLBCL patients had favourable outcome with 80% overall survival independent of tumour cell phenotype. Age at disease onset, tumour infiltrating CD3+ T cells and CD8+ cytotoxic T-cells and lower proliferation rate significantly correlated with patients' survival. The finding of a positive impact of tumour infiltrating T-cells in PBDLBCL is in accordance with earlier reports of nodal lymphomas, however our study is the first to show association between microenvironment and disease outcome.

1669

BENDAMUSTINE IN THE TREATMENT OF AGGRESSIVE NON HODGKIN LYMPHOMA. A RETROSPECTIVE ANALYSIS IN SPAIN

A de la Fuente[1], C Panizo[1], A Garcia-Noblejas[2], R Perez[3], T Gonzalez-Lopez[4], B Sanchez-Gonzalez[5], M Estévez[1], B Navas[6], J Tomas[1]
[1]MD Anderson CC Spain, Madrid, Spain
[2]H. U. La Princesa, Madrid, Spain
[3]H. U. Gregorio Marañon, Madrid, Spain
[4]H. General Yagüe, Burgos, Spain
[5]H del Mar, Barcelona, Spain
[6]Clínica Moncloa, Madrid, Spain

Introduction. Bendamustine is an alkylating-purine analog hybrid agent currently approved in EU for indolent non Hodgkin lymphoma, chronic lymphocytic leukemia and multiple myeloma; however the experience in aggressive lymphoma is limited. **Aims.** The aim of this study is to evaluate the efficacy and toxicity of Bendamustine in patients with aggressive lymphoma. **Methods.** We conducted a retrospective study to analyze the experience in Spain with Bendamustine alone or in combination in patients with aggressive lymphoma. Nine Spanish hospitals have participated in this study. Endpoints were overall response and complete response rate as *IWRv2003 criteria* and toxicity as *CTCAE v3. 0 of NCI scale*. **Results.** Between August 2009 and December 2011 a total of 30 patients with aggressive lymphoma were treated with Bendamustine in nine medical Institutions in Spain. Male/female: 16/14. Median age 76. 6 year (48-88). The histology subtypes were: DLBCL (23) T cell lymphoma (2) and other histology (5). Ann Arbor stage≥3: 25 cases with extranodal involvement in 22. ECOG≥2: 13 patients. Bendamustine treatment: 25 patients received Bendamustine as salvage therapy (relapse after CR 12 patients, NR or PR to previous line 13 patients), median of previous lines 3 (1-6). The other 5 patients received Bendamustine as frontline therapy. All patients received a 2 days schedule every 28 days; the most frequent Bendamustine dose/day was 90 mg/m2/day dose (80%). Combined treatment with Rituximab occurred in 84% cases. Median number of cycles: 4 (1-8). Response and outcome: A total of 28 patients completed treatment and were eligible for effectiveness assessment. The overall response rate was 56% (CR 23%; uCR 7%; PR 26%). At the time of reporting with a mean follow up of 20. 1 months 19 patients are alive and 7 in CR. All cases of death were progression related. Regarding toxicity, the most common adverse events were hematologic toxicity. Grade 3/4 neutropenia: 10 cases and only 3 episodes of febrile neutropenia. Grade 3/4 anemia: 6 cases. Extra-hematologic toxicity was infrequent and neither dose reduction nor treatment delays, nor hospitalization were influenced by it. No death was attributed to Bendamustine treatment. **Conclusions.** In summary this retrospective study shows that Bendamustine is safe and effective in aggressive lymphoma even in heavily pre-treated patients.

1670

AUTOLOGOUS STEM CELL TRANSPLANT FOR RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) IN THE RITUXIMAB ERA: A SINGLE INSTITUTION EXPERIENCE

M Terol, A Perez, L Garcvía-Sanchis, A Teruel, R Goterris, J Hernandez-Boluda, C Arbona, C Solano
INCLIVA, University of Valencia, Valencia, Spain

Background. Rituximab has become an essential key component in the first line treatment of DLBCL in combination with chemotherapy. However, there are limited data in the influence of prior rituximab exposure on the outcome of patients with relapsed/refractoty disease who received a stem cell transplantation as salvage therapy. **Aims.** To compare the outcome of relapsed/refractory DLBCL patients receiving an autologous stem cell transplant as salvage therapy in the rituximab era compared to non-rituximab exposed patients. Patients and **Methods.** We included 85 patients consecutively diagnosed of DLBCL between May 1991 and Nov 2010. They received high dose chemotherapy either conditioned with BEAC (n=) or BEAM (n=). Survival was calculated from date of transplant until death or last follow-up, and time to progression from date of transplant until progression or last follow-up. We employed the cox proportional model for univariate and multivariate analysis and survival curves were built with KM and compared with log rank test.

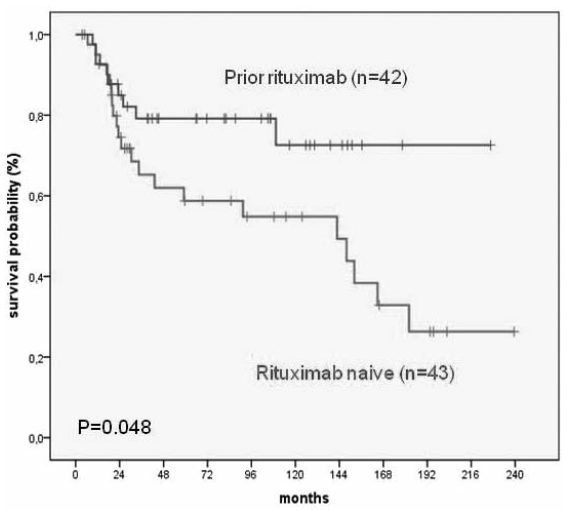

Figure 1.

Results. Median age was 50 years (19 to 66), sex male 46 (54%), histologies DLBCL 68, B rich T cell 9, mediastinal 6, unclassified 2. Stem cell source was: PB 65, bone marrow 6, both 13. Previous treatment: 1: 11 (13%), 2: 49 (58%), ≥3: 24 (29%). Pretrasplant disease response were: CR: 35 patients (41%), PR 29 (34%), non-response 15 (29%). Prior rituximab exposure: none 43 (52%) at any time (dg or salvage) 42 (48%). The main prognostic factors identified in the univariate analysis for both TTP and SRV were, pre-trasplant response (non-resp vs PR vs CR), prior rituximab, and first line treatment shorter than 12 months. In the multivariate analysis for SRV, only a first response duration less than 12 months (HR 9, CI 95% 2,05 to 3,95, p= 0,001)and pre-trasplant response (HR 3,87, CI 95% 1,32 to 11,4, p=0. 04) retained an independent significance. Patients who received rituximab either as part of induction/salvage chemotherapy or just in the salvage schedule had a longer TTP (5-year, 79,2 % vs 58,7%, p=0. 04) and SRV (5-year, 67,5% vs 51,6%, p=0,15) than the rituximab-naïve patients (Figure 1). However patients who received rituximab both at diagnosis and relapse had similar prognosis than the naïve ones. **Conclusions.** Patients with DLBCL exposed to rituximab who received an autologous stem cell transplantation as salvage therapy had a better prognosis in terms of progression and survival than naïve rituximab patients. This benefit seems to be restricted to patients exposed to the monoclonal as part of the salvage therapy.

1671

LOW-DOSE ETOPOSIDE AND CYTARABINE: A PALLIATIVE TREATMENT OPTION IN PATIENTS WITH REFRACTORY/RELAPSED DIFFUSE LARGE B CELL LYMPHOMA NOT ELIGIBLE FOR INTENSIVE SALVAGE CHEMOTHERAPY

S Hassan[1], S Montoto[2], J Gribben[2], J De Vos[1]
[1]St Bartholomew's Hospital, London, United Kingdom
[2]Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background. Up to 50% of patients with Diffuse Large B Cell Lymphoma (DLBCL) have refractory/relapsed disease following initial first-line chemotherapy. Prognosis is very poor in patients who fail to respond to or those considered unfit for salvage high-dose therapy with autologous stem cell support. The focus of treatment in these patients is palliation with the aim of improving quality of life. Following demonstration of activity in the salvage treatment of DLBCL in higher doses, a low dose chemotherapy regimen containing oral etoposide and subcutaneous cytarabine has been used at St Bartholomew's since 2008. This replaced the LD-56 chemotherapy regimen which had shown a response rate (RR) of 17% in this patient cohort. **Aims.** The aim of this review was to evaluate the RR and toxicity profile of this regimen in comparison to other low-dose chemotherapy schedules used in this palliative clinical setting. **Methods.** Data was collected on all patients who received this schedule between September 2008 and November 2011. Atotal of 20 patients with relapsed/refractory DLBCL were identified. Oral etoposide (100 mg/m2) and subcutaneous cytarabine (100 mg/m2) were both given on day 1-5 of a 21 day cycle. Treatment was given until disease progression, death, discontinuation due to toxicity or the achievement of remission status. The mean age was 69 years (range 35-81). Twenty percent of patients had an ECOG of >2. Evidence of extranodal disease was seen in 75% of patients and 80% of patients had an elevated LDH >480 IU/L. Patients had received one, two or three or more lines of previous treatment in 40%, 45% and 15% respectively. **Results.** A response was observed in 10 of 20 patients (50%). A partial response (PR) was seen in 7 patients (35%). Two of these 7 patients progressed following an initial response. Three patients (15%) achieved a complete response (CR): one stopped treatment at 5 cycles and 2 stopped following 6 cycles. Two of the patients who achieved CR were re-treated with the same chemotherapy regimen at the point of disease progression: one was treated with a further 4 cycles following a progression free survival (PFS) of 1 year and one was treated with a further 3 cycles following a PFS of 7 months. Only 2 out of the 20 patients (10%) stopped treatment due toxicity (worsened performance status and neutropenic sepsis). The median overall survival (OS) across all patients was 7. 9 months (range 1-39 months). In responders, the median OS was 13. 8 months. Receiving less than 3 lines of prior chemotherapy correlated with an improved overall response rate and overall survival. **Conclusions.** This regimen was effective in patients with refractory/relapsed DLBCL treated with palliative intend. A high response rate of 50% was documented which compares favourably to previously reported data. As an outpatient treatment with limited toxicity this schedule is an attractive palliative chemotherapy regimen for patients in this poor prognostic group. These results further emphasize the need for 'palliative' studies in DLBCL.

1672

BENDAMUSTINE IN PATIENTS WITH RENAL IMPAIRMENT: A RETROSPECTIVE SAFETY ASSESSMENT

B Nordstrom[1], K Knopf[2], D Teltsch[1], R Engle[1], H Beygi[3], J Sterchele[3]
[1]United BioSource Corporation, Lexington, United States of America
[2]California Pacific Medical Center, San Francisco, United States of America
[3]Teva Pharmaceutical Industries Ltd., Frazer, United States of America

Background. Patients with non-Hodgkin's lymphoma (NHL) and chronic lymphocytic leukemia (CLL) are at risk for renal impairment as the median age at diagnosis is >65 years. Bendamustine is a bifunctional alkylating agent with efficacy via several pathways and a manageable toxicity profile in NHL and CLL. **Aims.** There is a lack of published research on bendamustine in renally impaired NHL and CLL patients; therefore, a retrospective database analysis was designed to explore bendamustine's safety profile in this population. The study's primary aim was to evaluate laboratory toxicities in the NHL and CLL groups. **Methods.** In this retrospective study of 2 electronic medical record databases from US outpatient oncology practices, patients with NHL and CLL who had received ≥1 dose of bendamustine alone or with rituximab were identified and divided into investigator-defined subgroups: nonrenally impaired (creatinine clearance [CrCL] ≥40 or ≥60 mL/min) and renally impaired (CrCL <40 mL/min). The study collected data on the presence/absence and grade of ≥60 laboratory and physician-reported adverse events (AEs). Patients who received drugs with >5% risk of causing renal damage (eg, cisplatin, cyclosporine) were excluded. **Results.** Of 379 CLL patients, 42 had CrCL <40, 144 had CrCL ≥40-60, and 193 CrCL ≥60 mL/min; of 561 NHL patients, 62 had CrCL <40, 153 had CrCL ≥40-60, and 346 had CrCL ≥60 mL/min. Baseline characteristics were similar, except for more advanced age, shorter mean disease duration, and a slightly lower initial bendamustine dose in renally impaired patients. Mean total bendamustine exposure was 12 weeks for renally impaired vs 15 weeks for nonrenally impaired CLL patients, and ~16 weeks for both NHL groups. No statistically significant differences in laboratory toxicities were seen among the CLL groups, but renally impaired NHL patients had an increased risk for grade 3/4 thrombocytopenia (Cox hazard ratio [HR]: 2. 57; 95% CI: 1. 13, 5. 85) vs those with CrCL ≥60 mL/min. In combined CLL and NHL groups, only grade 3/4 BUN increase was significantly higher for renally impaired patients vs those with CrCL ≥40 mL/min (HR: 2. 36; 95% CI: 1. 15, 4. 86) or ≥60 mL/min (HR: 4. 46; 95% CI: 1. 79, 11. 14). **Summary and Conclusions.** Although sample size and time of exposure limit the power of this study, the results support the safety profile of bendamustine in renally impaired NHL and CLL patients. Increased risk was identified among renally impaired patients for only 2 of the ≥60 evaluated AEs: thrombocytopenia and increased BUN levels. Monitoring blood counts (including platelets) and renal function is probably prudent. Support - Teva Pharmaceutical Industries Ltd.

1673

EFFECTS ON BENDAMUSTINE PHARMACOKINETICS (PK) WHEN ADMINISTERED IN COMBINATION WITH RITUXIMAB IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA (NHL) AND MANTLE CELL LYMPHOMA (MCL)

M Bond[1], J Burke[2], E Hellriegel[1], P Robertson Jr. [1], L Phillips[3], E Ludwig[3], M Darwish[1]
[1]Teva Pharmaceutical Industries Ltd., Frazer, United States of America
[2]McKesson Specialty Health/US Oncology Research, The Woodlands, United States of America
[3]Cognigen Corporation, Buffalo, United States of America

Background. The PK profile of bendamustine as a monotherapy in adult patients is well described. Because elimination pathways of small molecules and monoclonal antibodies are distinct, a direct drug interaction between bendamustine and rituximab was not expected. **Aims.** To characterize the effect of rituximab on the PK profile of bendamustine when the 2 are used as combination therapy. **Methods.** In order to confirm the lack of a PK interaction, the population PK model that was developed based on bendamustine monotherapy (120 mg/m^2) was evaluated to determine its applicability to combination therapy (rituximab 375 mg/m^2 on day 1, bendamustine 90 mg/m^2 on days 1 and 2) in patients with NHL and MCL. Once the applicability was confirmed, model-predicted Bayesian bendamustine clearance (CL) values for monotherapy and combination therapy were generated and compared using the Wilcoxon signed rank test on the log-transformed CL values (alpha=0. 05). Patients from the open-label, phase 3 study of bendamustine in combination with rituximab provided informed consent. **Results.** The previously developed population PK model in patients receiving bendamustine monotherapy was used to generate 500 sets of single-agent bendamustine concentrations at the same sampling

times and bendamustine dosing regimens as those observed in the combination-with-rituximab study. Median, 10th, and 90th percentiles of observed bendamustine concentrations following combination therapy and simulated bendamustine concentrations following monotherapy exhibited similar patterns (see Figure 1). Although slightly greater than 10% of the observed data fall above (13%) or below (15%) the specific percentiles, the previously developed monotherapy population PK model was considered applicable to the data following combination therapy. The 25th to 75th percentiles of the bendamustine CL estimates were similar for combination and monotherapy with median values within 8% of each other. The 2-sided Wilcoxon signed rank test of the log-transformed CL values did not show a statistical difference between the 2 groups (P >0. 61). **Summary and Conclusions.** Comparison of bendamustine plasma concentrations and CL estimates in patients receiving bendamustine in combination with rituximab to those in patients receiving bendamustine alone indicate that rituximab does not affect systemic exposure to bendamustine. **Support.** Teva Pharmaceutical Industries Ltd.

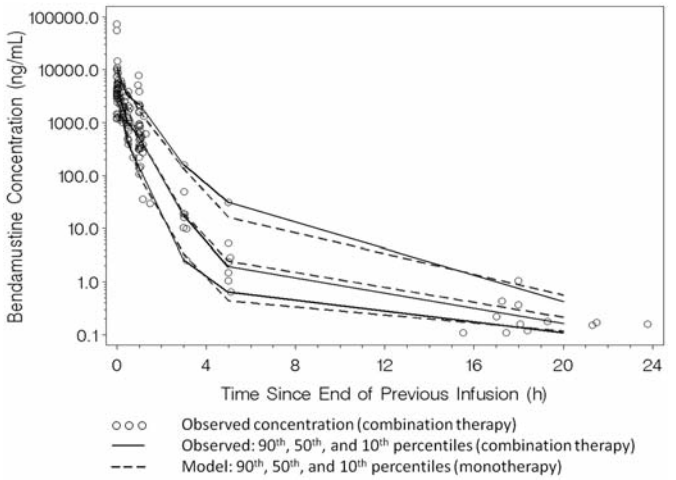

Figure 1. Observed (combination therapy) and model (monotherapy) Bendamustine plasma concentrations.

NEUTROPENIA IN PATIENTS WITH LYMPHOPROLIFERATIVE DISORDERS OF LARGE GRANULAR LYMPHOCYTES: ANALYSIS OF 38 ITALIAN PATIENTS

L Pavan[1], R Zanotti[2], E De March[3], A Colpo[3], M Cavraro[3], C Sissa[2], A Fragasso[4], P Leoni[5], L Arcaini[6], G Binotto[3], G Semenzato[3], R Zambello[3]
[1]University of Padua, Padua, Italy
[2]University of Verona, Department of Medicine, Section of Hematology, Verona, Italy
[3]Department of Medicine, Hematology and Clinical Immunology Branch, Padua, Italy
[4]Hematology Unit, Matera Hospital, Matera, Italy
[5]Division of Hematology, Ospedali Riuniti Ancona, Ancona, Italy
[6]Division of Hematology, University of Pavia, Pavia, Italy

Background. Chronic proliferations of large granular lymphocyte (LGL) are rare disorders characterized by expansion of cytotoxic T or NK cells. Relevant clinical featuresinclude neutropenia and anemia, either symptomatic or asymptomatic. It is widely accepted that symptomatic neutropenia requires treatment, however the best approach for asymptomatic neutropenia has not been established. Recently, severe neutropenia has been reported as a criterium for starting therapy. We report data on 38 cases with moderate or severe neutropenia at presentation either asymptomatic or symptomatic. Patients were admitted in different Italian Centers on behalf of GIMEMA group. **Aims.** To evaluate the more appropriate therapeutical approach for patients with LGL and neutropenia. **Methods.** Diagnosis of lymphoproliferative disorder of LGL was made according to published criteria (Semenzato et al, Blood 1997). Accordingly, 37 patients were diagnosed as LGL leukemia and 1 NK chronic lymphoproliferative disorder (NK-CLPD, WHO 2008). Severe neutropenia was defined as an ANC < 500/uL, moderate neutropenia as ANC between 500 and 1. 000/uL. Symptomatic neutropenia was defined as more than 2 febrile episodes/year or as 1 episode requiring hospitalization. Response criteria were defined according to Lamy and Loughran (Blood 2011). **Results.** Fifteen patients (39%; 5 with severe and 10 with moderate neutropenia) did not receive any treatment. The median duration of neutropenia in this group was 65 months (range 9-202 months). No life threatening infections were observed during follow up. Twentythree patients (61%) underwent immunosuppressive therapy: 16 due to neutropenia-related and 7 for neutropenia-unrelated reasons (joint pain, anemia and fatigue). In particular 11/20 (55%) of patients with severe neutropenia and 5/18 (28%) of patients with moderate neutropenia presented recurrent infections. The most common infections were muco-cutaneous (40%) and respiratory infections (23%). First line therapy consisted of methotrexate (MTX) at 7,5 mg/m^2/week in 47% of patients; cyclosporin A (CyA) at 2-3 mg/Kg/die in 43% of patients and cyclophosphamide (CY) at 50-100mg/die in 10% of patients. G-CSF was also used in 34% of patients. The median time to treatment was 11 months (range 0 - 173). Time to response to first line therapy ranged from 1 to 12 months with overall response rate of 69% (8 CR and 6 PR). The duration of response ranged from 5 to 120 months (mean 46 months). 30% of patients treated for neutropenia-related reasons needed a second line or more treatment still reaching CR/PR, whereas 2 patients died for sepsis. **Conclusions.** Neutropenia is one of the most common presenting features in LGL leukemia. According to published series, the most common types of infections seen in our patient group were mucocutaneous and respiratory tract infections. Treatment was restricted to symptomatic patients, regardless ANC. In our series we didn't observe any death for infection in the untreated group, even in the case of severe neutropenia. Accordingly, starting therapy on the basis of ANC may be at risks of overtreatment, exposing the patient to unnecessary long immunosuppressive regimens. A prospective randomized clinical trials comparing the two strategies (treatment on the basis of ANC versus no treatment) is needed to address this issue.

1675

ROLE OF CONSOLIDATIVE AUTOLOGOUS STEM CELL TRANSPLANTATION IN T-CELL LYMPHOMA PATIENTS: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS

V Stefoni, A Broccoli, E Derenzini, L Gandolfi, C Pellegrini, F Quirini, B Casadei, PL Zinzani
Institute of Hematology "L. & A. Seràgnoli", Bologna, Italy

Background. T-cell lymphomas(TCL) represent a rare and heterogeneous group of malignancies, exhibiting a poor outcome after conventional chemotherapy. **Aims.** To Evaluate role of ASCT in T-cell lymphomas. **Methods.** Our clinical database was retrospectively reviewed; patients with TCL who underwent Autologous Stem Cell Transplant (ASCT) as a front-line or at disease relapse/progression were considered eligible for evaluation. 34 patients (22 males, 12 females; median age 40. 74 years) received a consolidative ASCT after a median number of 2 (range: 1-11) previous lines of therapy. 14 patients had a peripheral T-cell lymphoma, not otherwise specified, 6 an anaplastic large cell lymphoma (ALK-negative in 2 cases),6 a lymphoblastic lymphoma, 3 an angioimmunoblastic lymphoma and2 a cutaneous anaplastic CD30-positive large cell lymphoma. The remaining three cases were a mycosis fungoides, a T/NK nasal type lymphoma and a pleomorphic lymphoma (according toKiel's classification), respectively. 28 patients presented with stage IV disease, with bone marrow involvement in 8 cases and B symptoms in 17 cases. 14 patients were transplanted in complete response (CR),3 in partial response (PR) and 16 with progressive disease (PD). Disease status was unavailable for 1 patient. **Results.** After transplantation, 24 patients achieved a CR, 4 were in PR, 1 had stable disease and 5 progressed. Overall response rate was 82. 36%, with a complete response rate of 70. 59%. 13 patients (38. 24%) could improve their best response after transplantation; a CR was obtained in 10 cases (29. 41%). 13 patients, all in response after ASCT, experienced disease relapse: 2 of them received an allogeneic bone marrow transplantation, and 1 underwent a tandem ASCT-allogeneic transplant. At a median follow-up of 4. 13 (range 0. 92-15. 03) years, 16 patients are still alive,14 in CR and2 in PR. 17 patients died, mainly for disease progression (14 cases). 10-year overall survival from ASCT is 31. 90%, with a median of 4. 92 years. **Conclusions.** ASCT appears effective as consolidation treatment for responding patients, as well as a feasible salvage therapy for those who relapse or progress.

[6]Department of Obstetrics and Gynecology, Medical University of Vienna, Vienna, Austria

[7]Department of Laboratory Medicine, Medical University of Vienna, Vienna, Austria

[8]Institute of Pharmacology, Center of Pharmacology and Physiology, Medical Univer, Vienna, Austria

[9]Institute of Pharmacology and Toxicology, Department of Biomedical Sciences, Vet, Vienna, Austria

Background. C-MYC translocations are observed in 10% of diffuse large B-cell lymphoma (DLBCL) and 30-50% of B-cell lymphoma, unclassifiable, with features intermediate between DLBCL and Burkitt lymphoma (B-UNC/DLBCL/BL). These lymphomas are associated with aggressive disease and dismal prognosis. Within this group attention has been paid to lymphomas with concurrent C-MYC and BCL2 translocations (double hit lymphomas) and triple hit lymphomas with additional breaks involving the bcl-6 gene locus. We have recently shown in mice that C-MYC&TP53 is associated with poor survival and can be abrogated by additional BCL2 alteration (Schuster *et al.,* Blood 2011). **Aims.** We performed a retrospective evaluation of the outcome of 28 patients with DLBCL or B-UNC/DLBCL/BL according to their genetic alterations and therapy (R-CHOP N=10 (36%) patients vs. B-ALL-GMALL containing HD-ARA-C, N=18, (64%) patients).

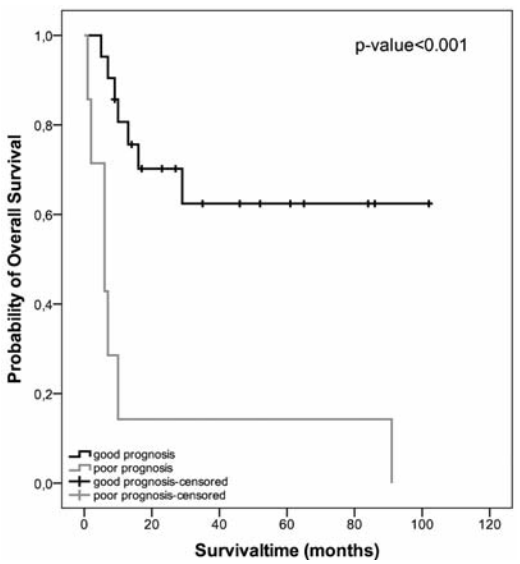

Figure 1. Overall survival of patients according to the new prognostic index.

Methods. C-MYC translocations were screened by FISH. Positive cases were assessed for BCL2 translocations and TP53 deletion by FISH. TP53 mutations were investigated by immunohistochemistry, positive cases were subjected to DNA sequencing. All cases were reviewed by two pathologists, and diagnoses were updated according to the new WHO-classification (2008). We grouped patients according to their genetic alterations in 4 categories (C-MYC only, C-MYC/BCL2, C-MYC/TP53 and triple hit). Statistical analyses were performed using SPSS 17. 0 (SPSS Inc., Chicago, USA) and R for Windows 2. 12. 1 (R Development Core Team) softwares. P-values < 0. 05 were considered as significant. Patient characteristics were tested for potential influence on the survival times using the Cox proportional hazards model in combination with all-possible-subset regression. Based on these results, a new index is suggested allowing for classification of risk. In analogy to international prognostic index (IPI), one point was assigned each to the risk factors 1) positive bone marrow infiltration, 2) high LDH at diagnosis, 3) C-MYC/ BCL2 translocation; two points were assigned to 4) C-MYC/TP53 mutation and no points to 5) presence of only the C-MYC translocation or 6) triple hit aberrations, respectively. The sum was calculated and 0-2 was classified as low versus 3-4 high risk. **Results.** All 28 patients (4 DLBCL, 24 B-UNC/DLBCL/BL) had C-MYC translocation. Nine (32%) patients had only C-MYC translocations, additional BCL2 alterations were found in 9 (32%) B-UNC/DLBCL/BL and TP53 somatic mutations in 6 (21%) patients (2 DLBCL, 4 B-UNC/DLBCL/BL). Four (14%) B-UNC/DLBCL/BL cases showed triple genetic alterations. 1) Overall survival (OS) was significantly different between the four groups (p=0,048). OS at five years was 75% for C-MYC, 71% for triple hit, 35% for C-MYC/BCL2 and 17% for C-MYC/TP53. 2) No significant difference was found between therapeutic regiments indicating no advantage for aggressive chemotherapy. 3) Using the novel prognostic score two groups with good and poor prognosis could be defined (Figure 1). **Conclusions.** Our data indicate that (i) simultaneous C-MYC and TP53 alterations confer high risk. This risk is considerably ameliorated when an additional BCL-2 aberration is present. (ii) GMALL-ALL protocol is non-superior to R-CHOP. (iii) The prognostic score integrating clinical and genetic features is able to predict outcome and should be evaluated in larger studies.

1677

NODAL PERIPHERAL T-CELL LYMPHOMA (PTCL): CHARACTERISTICS, PROGNOSIS AND OUTCOME OF 120 PATIENTS

M Angelopoulou[1], P Tsirigotis[2], Z Galani[3], M Moschogiannis[4], M Dimou[3], P Tsirkinidis[4], S Masouridi[3], G Gainarou[3], E Dimitriadou[3], S Sachanas[4], X Yiakoumis[4], V Pappa[2], L Papageorgiou[3], G Boutsikas[3], C Kalpadakis[3], P Flevari[3], K Koutsi[3], E Sinni[3], MC Kyrtsonis[1], P Panayiotidis[1], M Siakantaris[1], I Dervenoulas[2], I Meletis[1], G Pangalis[4], T Vassilakopoulos[1]

[1]National and Kapodistrian University of Athens, Laikon General Hospital, Athens, Greece

[2]National and Kapodistrian University of Athens, Attikon University Hospital, Athens, Greece

[3]Laikon General Hospital, Athens, Greece

[4]Athens Medical Center, Athens, Greece

Background. Peripheral T-cell Non Hodgkin lymphomas (PTCL) are rare diseases in the Western World. Among them, the most common entities are the nodal PTCL. Due to their rarity and difficulties in their diagnosis and classification, reports from large series are scarce in the literature. **Aims.** To record and analyze nodal PTCL patients' characteristics, outcome and prognostic factors. **Methods.** We retrospectively studied 120 consecutive patients with nodal PTCL diagnosed and treated in 2 University Hematology Units between1991-2011.

Table 1. Nodal PTCL patients' characteristics.

Patient characteristics	ALCL (%)	AITL (%)	PTCL-NOS (%)	p
Age>60	22	50	47	0.02
Male gender	71	49	71	0.07
Splenomegaly	7	49	19	<0.001
Bone marrow involvement	5	47	27	<0.001
B-symptoms	39	65	53	0.07
Stage III-IV	38	84	75	<0.001
PS≥2	10	35	12	0.01
E-sites≥2	13	42	31	0.02
Increased LDH	44	63	59	0.21
IPI				
Low	53	14	22	0.006
Low-intermediate	26	21	26	
High-intermediate	16	36	37	
High	5	29	15	
PIT (# factors)				
0	39	7	26	
1	44	25	26	0.001
2	15	32	33	
3-4	3	36	15	

Results. Median age at diagnosis was 57 years (13-91) with 40% being >60 years, 63% were male, 65% had clinical stage III-IV, 53% B-symptoms,19% PS≥2, 54% abnormal LDH, 54% extranodal disease (27% in ≥2 sites), 26%

bone marrow and 25% splenic involvement. Histology was as follows: 34% anaplastic large cell lymphoma (ALCL, 11% ALK+, 13% ALK-, 10% unknown), 31% angioimmunoblastic lymphoma (AITL) and 32% peripheral T-cell not otherwise specified lymphoma (PTCL-NOS). Table 1 presents patients' characteristics. Initial treatment was CHOP/CHOEP/ CNOP in 81%. At a median follow-up of 51 months the 5-year progression free survival (PFS) and overall survival (OS) were 39% and 54% respectively. 65 events of relapse/progression were recorded: 10 proceeded to autologous stem cell transplantation with 8/10 being cured, whereas 6/65 achieved long-term remission following 2nd line conventional chemotherapy. Only 5/65 patients who progressed or relapsed, did so after 2 years from diagnosis. Univariate analysis revealed that advanced stage (p=0. 02), elevated LDH (p=0. 02), ≥2 extranodal sites (p=0. 004) and non-anaplastic histology (p=0. 02) were statistically significant adverse prognostic factors for PFS. The aforementioned factors in addition to age>60 correlated with an adverse OS, as well (p=0. 04, 0. 02, 0. 045, 0. 02 and 0. 0004 respectively). Although both IPI and PIT had prognostic significance for PFS (p=0. 02 and 0. 03) and OS (both p=0. 02), they were particularly effective in separating the good prognosis patients but not those with a worse outcome. Multivariate analysis indicated that involvement of ≥2 extranodal sites (p=0. 02) was the sole significant prognostic factor for PFS, whereas age>60 years(p=0. 003) was the only significant parameter for OS. In addition ≥2 extranodal sites, and high LDH proved of marginal independent prognostic significance for OS(p=0. 06 and 0. 08 respectively). **Conclusions.** Nodal peripheral T- cell lymphomas are associated with poor prognosis. ALCL and AITL are characterized by distinct clinical and biological features. Disease can be successfully controlled in 40% of the patients with a low probability of relapse after the first two years. Extranodal involvement in ≥2 sites is a strong prognostic indicator, whereas IPI and PIT have a limited prognostic value.

1678

EXTRANODAL NK/T-CELL LYMPHOMA ASSOCIATED WITH REACTIVE HEMOPHAGOCYTIC SYNDROME:A RETROSPECTIVE STUDY

Y Zhang, H Hong
Fudan university Shanghai cancer center, Shanghai, China

Background. Extranodal NK/T-cell lymphoma associated hemophagocytic syndrome (NK/T-LAHS) is a rare life-threatening disorder, which has been mainly reported inAsia countries. It progresses rapidly, and the prognosis is usually poor. However, the pathogenesis and prognostic factors of NK/T-LAHS are not fully understood. **Aims.** To find out more about the disease, we conducted a retrospective study on the NK/T-LAHS patients diagnosed and treated by our hospital.

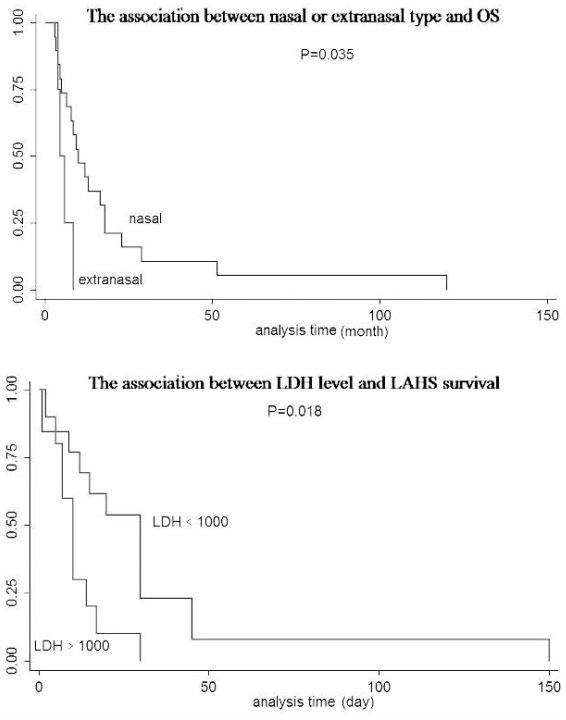

Figure 1. Survival rates analysis for NK/T-LAHS.

Methods. 23 NK/T- LAHS patients diagnosed between July 2006 and September2011 in Fudan University Shanghai Cancer Center were included. The information of clinical features, laboratory findings, treatment and prognosis of these patients were collected and analyzed. **Results.** Of the 23 NK/T- LAHS patients, the median age was 45 years old and 15(65. 2%) were male. 11(47. 8%) had an Ann Arbor stage of Ⅲ/Ⅳ; 19(82. 6%) cases originated from nasal cavity, nasal sinuses, and tonsil, while the other 4 (17. 4%) cases originated from colon, cervix, or skin. LDH levels were elevated in all 23 cases at the time of diagnosis, and 10(43. 5%) cases showed elevated LDH levels of more than 1000IU/L at the onset of HPS, which predicted a poor prognosis. NK/T-LAHS was characterized by fever, pancytopenia, liver dysfunction, and hypertriglyceridemia, but only 9 cases (39. 1%) were found hemophagocytosis in bone marrow. The median OS was 8. 5 months from the diagnosis of NK/T cell lymphoma, and the median LAHS survival time was 14 days. Chemotherapy and high-dose *glucocorticoids were not so effect to* NK/T-LAHS that almost 100% cases died soon. **Conclusions.** NK/T-LAHS usually occurs in the nasal type of NK/T cell lymphoma, but the prognosis of extranasal type is poorer. The rate of its definite diagnosis at the early stage is low. Most of the patients were died of multiorgan failure, infection and bleeding. The original lesion and LDH level may be prognostic factors. There was no effect treatment for NK/T-LAHS that it remains a challenge.

1679

SPLENIC MARGINAL ZONE LYMPHOMA FLOWS WITH AUTOIMMUNE HEMOLYTIC ANEMIA

H Julhakyan[1], A Magomedova[2], I Kaplanskaya[2], N Tsvetaeva[2]
[1]Hematological Scientific Center, Moscow, Russian Federation
[2]Hematological Research Center, Moscow, Russian Federation

Background. Splenic marginal zone lymphoma (SMZL) - B-cell indolent lymphoma which characterized by splenomegaly, bone marrow involvement and with immunophenotype of B-lymphocytes to the marginal zone of secondary follicles. It has a variety of clinical manifestations, immunological and cytogenetic features and often occurs with autoimmune hemolytic anemia (AIHA). Aims. The aim of our study was to determine the frequency and approaches to treatment of SMZL flows with AIHA. **Materials and Methods.** From January 2000 to February2012 intheHematologicalResearchCenter(Moscow, RF), observed 122 patients with SMZL, of which 8 (6. 6%) patients the disease proceeded with AIHA. The diagnosis of SMZL was established on the basis of clinical and immunophenotypic data. All patients were female; mean age was 63. 7 years (46-78 years). In all patients, the disease debuted with splenomegaly, bone marrow involvement and a clinical picture of hemolytic anemia: a sudden jaundice, increased levels of total bilirubin by free fraction, anemia, reticulocytosis and positive Coombs test. There was decrease of hemoglobin of 36 g/l to 94 g/l in peripheral blood, which was accompanied by a low increase in the number of reticulocytes. Increased LDH was observed in all cases and could indicate how the activity of the tumor and the intensity of hemolysis. Coombs test in a small titer was positive in all cases. M-component were found in all cases. Splenectomy was performed in all patients as first-line therapy. **Results.** In all patients after splenectomy observed clinical and hematological improvement, which manifested no signs of hemolysis (red blood cell count the hemoglobin level returned to normal, absence of reticulocytosis, the normalization of the concentration of LDH, negative Coombs test and the disappearance of M-component). Median duration of response was 58 months (from 38-90 months). In two patients after splenectomy in 41 and 43 months. respectively, were marked by signs of tumor progression and recurrence of hemolysis, which was the reason for the appointment of a standard dose of Rituximab and obtained a complete remission with disappearance of signs of hemolysis and bone marrow lesions. Duration of remission was 24 and 32 months respectively. **Conclusions.** SMZL often occurs with AIHA and characterized by a low increase in the number of reticulocytes, a good response to splenectomy. In the case of progression and/or renewal of hemolysis there was effective use of Rituximab.

1680

LARGE-CELL TRANSFORMATION OF SPLENIC MARGINAL ZONE LYMPHOMA

H Julhakyan[1], A Magomedova[2], I Kaplanskaya[2], R Samoylova[2], E Gemjyan[2]
[1]Hematological Scientific Center, Moscow, Russian Federation
[2]Hematological Research Center, Moscow, Russian Federation

Background. Splenic marginal zone lymphoma (SMZL) - indolent B-cell lymphoma, which is characterized with splenomegaly, bone marrow involvement and favorable course. **Aims.** The aim of our work was to study the frequency of occur-

rence of large-cell transformation in patients with SMZL, the course and treatment approaches. **Materials and Methods.** From January 2000 to February2012 inthe Hematology Research Center (Moscow, Russia), observed 122 patients with SMZL, of which 11 (9%) patients had signs of large-cell transformation. The diagnosis of SMZL was established on the basis of clinical and immunophenotypic data. Large-cell transformation was diagnosed by histological examination of the spleen removed (8 patients) and an average of 21. 7 months (3-51 months) after splenectomy at the time of progression for histological examination of peripheral lymph nodes. The average age was 56. 7 years (33-77 years). All patients had stage IV disease and B symptoms. Anemia was observed in 9 patients, leukopenia in 5 patients, leukocytosis in 3 patients, thrombocytopenia in 9 patients. Increased LDH was observed in all cases and the M-component in 6 patients. **Results.** Histological examination of bone marrow revealed focal small and medium-sized lymphoid cells infiltration of bone marrow, which was accompanied by a decrease in the number of normal hematopoietic cells. No signs of large-cell transformation (the presence of layers of large cells, abundant figures of mitoses in bone marrow) were found. In 8 patients larg-cell transformation were diagnosed at the time of splenectomy. Histological examination of spleen revealed blurring the picture of the structure of spleen, remained nodular growths. In the cellular layers of the composition was dominated by large lymphoid cells with rejuvenated chromatin structure of the nucleus and nucleoli expressed polymorphism. After splenectomy after an average of 21. 7 months (3-51 months) in three patients was developed disease progression with manifestation with massive lymphadenopathy. Histological examination of biopsies of lymph nodes revealed diffuse infiltration of large cells, abundant mitotic figures. According to the immunophenotypic study was observed of expression of activation markers (CD71, CD38). In most cases there was high proliferative activity (12-20%). All patients with large-cell transformation received chemotherapy CHOP-21 (4 patients with the addition of Rituximab). Complete remission duration of 36. 3 months on average (20-70 months) obtained in 7 (63. 6%) patients, partial response - in 2 patients. Two patients died of progressive disease and infectious complications. **Conclusions.** The large-cell transformation of SMZL can be diagnosed as at the time of splenectomy and after splenectomy in tumor progression. Chemotherapy CHOP-21 leads to complete remission in 63. 6% of patients for up to 3 years.

1681

TOXICITY PROFILES OF TWO PLATINUM-BASED SALVAGE REGIMENS, DHAP VERSUS ESHAP, IN RELAPSED/REFRACTORY LYMPHOMA

O Salim[1], T Toptas[2], L Undar[1], I Karadogan[1]
[1]Akdeniz University, Antalya, Turkey
[2]Marmara University, Istanbul, Turkey

Background. Platinum- or ifosfamide-based salvage therapies, such as ESHAP, ICE, and DHAP, are frequently used regimens in relapsed/refractory lymphomas. Few prospective studies demonstrated no superiority of these protocols against to each other. While DHAP and ICE can be applied in outpatient setting, ESHAP is administered at medical ward. The most important adverse effect of salvage therapies is hematologic toxicity. However, renal toxicity is an other important problem observed with platinum-based regimens. **Aims.** The aim of the study was to compare the hematologic and non-hematological toxicity profiles of two different platinum-based salvage chemotherapy regimens used in relapsed/refractory lymphoma. **Methods.** We evaluated 51 patients with HL and NHL who were treated with DHAP and ESHAP regimens (n=33 for ESHAP and n=18 for DHAP) between January 2000 and July 2010. These patients had received a total of 153 cycles (91 ESHAP and 62 DHAP). Data were retrospectively collected from patients' chart records and electronic patient inventory. **Results.** There were no significant differences regarding serious hematologic toxicities (grade 3-4) between two salvage regimens. Platelet and red blood cell transfusions were given to 28 (55%) and 27 (53%) patients, respectively. Febrile neutropenia occurred in 11 (21. 5%) patients. Treatment-related death was not observed. Renal toxicity, platelet transfusion requirement, febrile neutropenia, and treatment delay due to treatment toxicity were observed more frequently in DHAP group in univariate analysis. Receiving DHAP regimen was found to be an independent risk factor for renal toxicity (OR=23. 6, p=0. 03) in multivariate analysis. However, the number of platelet transfusions, febrile neutropenia, and treatment delay due to treatment toxicity has not reached statistical significance in the latter analysis. Time-to-next cycle interval following the first salvage cycle were longer in patients receiving ESHAP (median 35 days vs 27 days, p=0. 008). Overall response remained significantly higher in DHAP group in multivariate analysis (87% vs 48%, p=0. 04). There was no significant difference between two groups (ESHAP and DHAP) in terms of median survival. **Summary and Conclusions.** DHAP regimen is associated with higher response rates but has no survival advantage. Since it can be administered in outpatient setting, superior efficacy of DHAP can be partly explained by its use with regular intervals. Outpatient DHAP regimen may be preferred in clinics where inpatient facility is not capable to supply chemotherapy in regular intervals. Although the hematologic and non-hematologic toxicity profiles were similar, increased risk for renal toxicity should be considered for patients planned to receive DHAP regimen.

1682

CLINICAL FEATURES OF PRIMARY GASTROINTESTINAL TRACK NATURAL KILLER/T CELL LYMPHOMA

HA Jung, W Kim, S Kim, C Maeng, S Lee, W Chang, S Kim, K Kim, J Jang, C Jung
Samsung Medical Center, Seoul, South-Korea

Background. Extranodal natural killer/T cell lymphoma, especially those occurring in the GI tract is extremely rare. There were only few case reports, but no papers of investigation clinical features, analysis prognostic factor and description about optimal treatment strategies. **Aims.** We aimed to indentify clinical features of GI NK/T cell lymphoma and analysis treatment outcome. **Methods.** Between 2005 and 2011, 23 patients were diagnosed of GI NK/T cell lymphoma. We collected clinical finding including treatment outcome retrospectively. **Results.** The median age was 49 (range 17-72) and 69. 6% was male. Initial symptom or sign were abdominal pain (43. 5%), nasal obstruction symptom (30. 4%), hematochezia (17. 4%) and bowel perforation (13. 0%). 87% of patients were Ann Arbor stage III/IV AND 30. 4% patients has nasal cavity involvement. Each group for IPI score, 26. 1% for low, 30. 4% for low-intermediate, 34. 8% for high-intermediate and 8. 7% for high IPI score. However, 30. 4% patients had KPI score 2 and 56. 5% patients had KPI score 3 or 4. Most common involved site of GI was small bowel (ileum or jejunum). 19(82. 6%) patients died and median overall survival and progression free survival was 6. 2 months and 2. 3 months. First regimen was CHOP for 12 patients, SMILE for 5 patients and VIPD for 3 patients. 11 patients received 2nd line chemotherapy. Among chemotherapy, there was no difference of OS (5. 6months vs 9. 3 months vs 8. 1 months; *P*-value 0. 801) and PFS (3. 0months vs 2. 0months vs 3. 9months; *P*-value 0. 725). **Conclusions.** Primary GI NK/T cell lymphoma is highly aggressive malignancy which has poor OS and PFS.

1683

PREVENTION OF CHEMOTHERAPY-INDUCED NAUSEA AND VOMITING WITH PALONOSETRON IN PATIENTS WITH NON-HODGKIN'S LYMPHOMAS UNDERGOING REPEATED CYCLES OF MODERATELY EMETOGENIC CHEMOTHERAPY

B Choi[1], G Borsaru[2], D Voisin[3], N Di Renzo[4]
[1]Compassionate Cancer Center Group Hospital, California, United States of America
[2]Spitalu Clinic Coltea, Bucarest, Romania
[3]Helsinn Healthcare, Pambio Noranco, Switzerland
[4]Presidio Ospedaliero Vito Fazzi, Lecce, Italy

Background. Patients undergoing chemotherapy (CT) commonly receive repeated cycles of treatment. While chemotherapy-induced nausea and vomiting (CINV) is known to be a mostly feared side effect affecting patient qualityof life and leading to possible chemotherapy discontinuation. Associated increased health care resources and prevention of CINV in cycle 1 diminishes its potential in subsequent cycles. Therefore, optimizing antiemetic prophylaxis at initiation of CT is critical. Palonosetron (PALO), a potent 5-HT_3 receptor antagonist (RA) with a distinctly different pharmacokinetic and receptor binding profile, has demonstrated improved CINV protection compared to older 5-HT_3 RAs in multiple phase 3 and 4 single-CT-cycle clinical trials; however, few studies have evaluated PALO over multi-cycles of CT. **Aims.** This was a prospective, multicenter, single-arm study designed to assess the efficacy and safety of single IV doses of PALO 0. 25 mg in preventing CINV in chemotherapy-naïve patients with Non-Hodgkin's Lymphomas (NHL) scheduled to receive at least 2 and up to 4 repeated, consecutive cycles of single day moderately emetogenic chemotherapy (CHOP, R-CHOP or ProMACE-CytaBOM). **Methods.** Corticosteroids (prednisone) is one of the components of these regimens and were not added for antiemetic purposes. The primary efficacy endpoint was complete response (CR: defined as no emetic episode and no use of rescue medication) during the overall phase (0-120 hrs) following CT during each cycle. Secondary endpoints included CR during the acute and delayed phases (0-24h, 24-120 h respectively), and the evaluation of emesis-free patients' rate and nausea severity (according to a 100 mm VAS) during all 3 time intervals. The safety profile and adverse events were also assessed. Informed consent was obtained from all patients. **Results.** A total of 88 patients with either B-cell or T-cell NHL (91% and 9% respectively) received PALO during Total Study Cycles (TSC: 317; mean 3. 6; median 4). The majority of patients were males (60%) with a mean age of 59. 7 yrs who received either CHOP (47%) or R-CHOP (52%). Primary endpoint, CR overall rate reached 76. 7% in TSC. A

high rate of study patients, always > 86%, remained emesis free during each cycle, reaching 90. 5% emesis free patients in the overall phase of TSC. Complete protection, defined as no vomiting no rescue therapy and no more than mild nausea was achieved in the 72. 2% of all patients in the overall phase of TSC, and the 68. 8% of patients was nausea-free in the overall phase of TSC. A very low impact of nausea and vomiting on daily life activities was evidenced by using a modified FLIE questionnaire (121 out of 126 total score where 126 indicates no impact on daily life). PALO was well tolerated and showed a high safety profile over repeated cycles, with few adverse events possibly/probably/ definitely related to study drug, with a low incidence of the most frequent, i.e. headache and constipation (1% and 2% respectively) . **Conclusions.** PALO administered as a single fixed IV dose before chemotherapy has been showed to be very effective and safe on CINV prophylaxis in patients with NHL undergoing repeated cycles of moderately emetogenic chemotherapy.

Background. Primary adrenal non-Hodgkin's lymphoma is extremely rare, prognosis was known to be very poor. **Aims.** The objective of this study was to define clinical features and treatment outcomes of primary adrenal diffuse large B cell lymphoma (DLBCL).

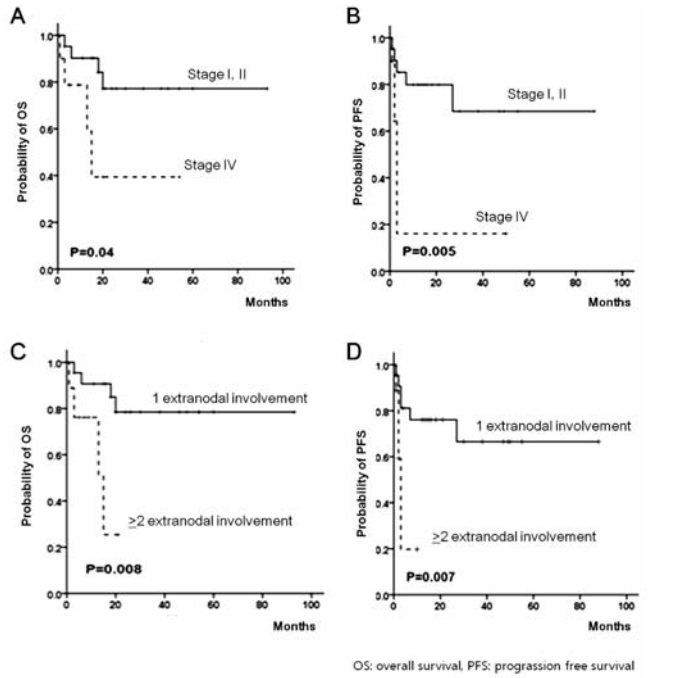

Figure 1. OS (A) and PFS (B) according to new staging system and OS (C) and PFS (D) according to modified number of extranodal involvement sites.

Methods. A retrospective study of 31 patients diagnosed with primary adrenal DLBCL treated with R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone) between 1998 and 2010 at 13 Korean institutions were analyzed in this study. **Results.** Median age was 64 years with male to female ratio 2. 8:1. Most common presenting symptom was an abdominal pain (41. 9%) with 53. 5 % of patients presenting with bilateral adrenal gland involvement. Lactate dehydrogenase was elevated in 24 of 28 (85. 7%) patients. Complete remission was 58. 1% and overall response rate was 87. 0% after R-CHOP chemotherapy. Two of relapsed four patients were occurred at central nerve system (CNS). The 2-year estimate for overall survival (OS) was 68. 3% and progression free survival was 58. 0%. There was no survival difference according to Ann Arbor staging, IPI scoring system and bilateral adrenal gland involvement. We defined new staging system and modified number of extranodal involvement regarding bilateral involvement as on extranodal site. Those factors were associated with OS, respectively (p=0. 04, p=0. 008) (Figure 1). **Conclusion.** This study suggested that treatment outcomes of primary adrenal DLBCL treated with R-CHOP was not poor contrary to previous report. New staging system and modified number of extranodal involvement could be a reasonable options to predict R-CHOP response. CNS prophylaxis added to initial treatment might be considered although absolute number of CNS relapse is not high.

1685

LUPUS ANTICOAGULANT, VENOUS THROMBOSIS AND OTHER AUTOIMMUNE PHENOMENA IN PATIENTS WITH SPLENIC MARGINAL ZONE LYMPHOMA: Results FROM THE VIENNA COOPERATIVE STUDY

J Haselboeck[1], T Sliwa[2], E Muelduer[3], T Noesslinger[4], I Pabinger[1], K Lechner[1], U Jaeger[1]

[1]Medical University Vienna, Vienna, Austria
[2]Hospital Hietzing, Vienna, Austria
[3]Wilhelminenspital, Vienna, Austria
[4]Hanusch Hospital, Vienna, Austria

Background. Splenic Marginal Zone Lymphoma (SMZL) is a low malignant lymphoma, which may be associated with immune-mediated paraneoplastic conditions. The association of the lupus anticoagulant (caused by a phospholipid antibody) with SMZL has been reported in a number of cases, but no systematic data on the prevalence of lupus anticoagulant (LA) in this lymphoma have been obtained. **Aims.** The aim of our study was to investigate the prevalence of LA in a large group of histologically well-defined SMZL. **Methods.** This was a retrospective cooperative study of four haematological centres in Vienna. Patients still alive at time of the data analysis were asked to visit the outpatient services of the respective centres. Blood was taken for coagulation studies (in particular lupus anticoagulant) and for other potential immune mediated conditions. Additionally, clinical haematological and coagulation laboratory data were obtained from archival material for all patients, including those who have died or did not attend the follow up examination. The study was approved by the ethics committees of all institutions. In case of prolongation of the Activated Partial Thromboplastin time (APTT-STA, Diagnostica Stago) appropriate clotting factors or activities were determined. If they were normal APTT was determined with a lupus sensitive reagent (PTT-LA, Diagnostica Stago) and if it was prolonged the ability of normal plasma to normalize the prolonged APTT was tested. If APTT was normalized a confirmation test according to ISTH recommendation was done (definite LA). **Results.** The study included 70 patients. 22 were untreated, 22 had undergone splenectomy alone and 26 chemotherapy (12 with and 14 without splenectomy). The median age of all patients examined for LA was 68 (range 32-91) years, and the male/female ratio was 44/26. Nine patients (12. 9%) had a definite LA. The median age of LA patients was 57 (range 32-74) years and the male/female ratio was 4/5. Three out of 9 LA patients (33. 3%) and 6 out of 61 non-LA patients (9. 8%) had a documented venous thromboembolism. Other immune mediated conditions in patients with LA were autoimmune hemolytic anemia in 4, and C1 esterase inhibitor deficiency in one case. **Conclusions.** The prevalence of LA is high in SMZL. LA in this lymphoma is associated with venous thromboembolism and other immune mediated conditions.

1686

COMBINATION OF RITUXIMAB-CHLORAMBUCIL AS 1ST LINE TREATMENT FOR GASTRIC MALT LYMPHOMA

M Siakantaris[1], X Yiakoumis[2], S Sachanas[2], M Moschoyiannis[2], P Tsirkinidis[3], P Korkolopoulou[4], MC Kyrtsonis[1], X Spiliadi[5], P Bobotsi[6], M Angelopoulou[1], C Kalpadakis[7], T Tzenou[1], H Papadaki[7], T Vassilakopoulos[1], G a Pangalis[2]

[5]Pathology Department, Athens Medical Center, Athens, Greece
[6]Gastroenterology Department, Athens Medical Center, Athens, Greece
[7]Haematology Department, University of Crete, Heraklion, Greece

Background. The mucosa associated-lymphoid tissue (MALT) lymphoma of the stomach is the most common extranodal marginal zone lymphoma. It is usually related with helicobacter pylori infection. The optimal treatment is still not defined in patients who do not present h. pylori infection or experience persisting or recurrent disease, after appropriate antihelicobacter medication. **Aims.** The study of characteristics results and follow up of patients with gastric MALT lymphoma who were treated with the rituximab-chlorambucil combination as 1st line chemotherapy regimen. **Patients and Methods.** Between 2002-2011 patients with MALT lymphoma who did not present helicobacter pylori infection or experienced a relapse or persisting MALT lymphoma after antihelicobacter medication were treated with the rituximab-chlorambucil combination. Rituximab (375mg/m2) was administered every 1st day of a 28day cycle and chlorambucil (10mg/d) for 10 days (2nd-12th day). This combination was repeated for 8 cycles and then patients received another 4 cycles with chlorambucil alone (10mg/d for 10 days/month). Their follow up was performed after 4th, 8th and 12th cycle and was consisted of gastroscopy as well as CT scan and bone marrow biopsy, when necessary. Only patients who have completed their 12 month treatment schedule are included in this analysis. **Results.** 31 patients were studied. Median age is 55 years and male to female ratio is 1:1. At diagnosis, 22 had a stage IEA disease, 5 stage II and 4 stage IVA disease with bone marrow infiltration. H. pylori infection was not documented in 6 patients. From the 25 patients, who received antihelicobacter medication on diagnosis, 5 required alternative antibiotic regimens, due to h. pylori resistance to standard treatment . In 22 patients (71%), complete remission (CR) was documented on 4th cycle (8 pts), 8th cycle (7) and 12th cycle (7). All patients with stage II and IV and 13/22 of stage I achieved CR. Partial remission (PR) was achieved in 5 patients, minimal residual disease (MRD) in 3 and stable disease in 1 patient. Five patients presented clonal IgVH rearrangement in the blood; 3/5 achieved only PR at the end of chemotherapy. Median follow up is 38 months. In 21/22 patients the disease remains in CR, while in one patient a transformation to diffuse large B cell lymphoma was observed, 3 months after the end of chemotherapy. In those who achieved a PR, a course with weekly rituximab monotherapy was performed (6 weekly rituximab infusions) and in all but one, a CR was documented. From those who presented MRD, 1 achieved CR 6 months after the end of chemotherapy and 2 remain in MRD. No complications were observed and all patients continued their daily activities throughout treatment. **Conclusions.** The rituximab-chlorambucil combination constitutes a safe and effective option in patients with gastric MALT lymphoma who require chemotherapy. The readministration of rituximab can achieve better results in cases of PR. The design of treatment schedule, as administered in our patients, provides a complication-free course with a satisfactory life quality, throughout therapy.

1687

HIGH-DOSE THERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION FOR RELAPSED FOLLICULAR LYMPHOMA: THE ARGENTINEAN EXPERIENCE

P García[1], D De Goycoechea[1], M Berro[2], J Tabar[2], S Yantorno[3], J Nappal[3], M Rivas[2], M Prates[3], S Molnar[4], M Rizzi[4], A Basquiera[1], G Jarchum[4], J Milone[3], G Kusminsky[2], J Garcia[1]
[1]Hospital Privado Centro Médico de Córdoba, Córdoba, Argentina
[2]Hospital Universitario Austral, Buenos Aires, Argentina
[3]Hospital Italiano, La Plata, Argentina
[4]Sanatorio Allende, Córdoba, Argentina

Background. since the introduction of rituximab in the treatment of Follicular Lymphoma (FL) the place of High Dose Therapy (HDT) and Autologous Stem Cell Transplantation (ASCT) as salvage therapy in the relapsed setting has been questioned. **Aims.** our objectives were to evaluate the long-term event-free survival (EFS) and overall survival (OS) rates of patients with relapsed or refractory FL who received HDT and ASCT as salvage therapy. **Methods.** we conducted a retrospective analysis of 44 consecutive patients with FL who received HDT and ASCT as salvage therapy in four Argentineans transplant centers from 1995 to 2011. **Results.** 44 patients were transplanted, median age 53 years (range 31-73); 32 (72. 7%) have received rituximab as part of their induction treatment previous ASCT. The conditioning regimens used were CBV 20 (45. 4%), BEAM 19 (43. 2%) and BEAC 5 (11. 4%). No conditioning regimen including TBI was used. The median time from diagnosis of FL to ASCT was 31 months (range 1-150). With a median follow-up of 31 months the median EFS was reached at 29 months and a plateau on the EFS curve was evident starting at 8 years post-ASCT. The median OS was not reached during follow-up, with 5 years projected OS of 63%. Median EFS for patients who received Rituximab as part of their induction treatment previous ASCT versus those who did not was 24 and 47 months respectively [HR 0. 59; IC (0. 25-1. 38); p=0. 24]. EFS rates were not significantly different in patients who received CBV, BEAM and BEAC as conditioning regimens. There were two cases of secondary malignancies (two urotelial carcinomas, one patient received CBV as conditioning regimen and the other BEAM); there were no reports of secondary MDS/AML. **Conclusions.** In this study 50% of patients were free from progression after 29 months of ASCT; HDT follow by ASCT can achieve long-term EFS in patients with relapsed or refractory FL.

1688

TREATMENT OF PERIPHERAL T-CELL LYMPHOMA WITH AN INTENSIVE PROTOCOL ACEP (ADRIAMYCIN,CYCLOPHOSFAMIDE,ETOPOSIDE AND PREDNISOLONE) AND IFOSFAMIDE SHOWING IMPORTANT RESPONSE AND OVERALL SURVIVAL RATES

M Salamoon
Syria, Damascus, Syria

Background. peripheral T-Cell Lymphoma is a group of lymphoid malignancies which has not the chance to be treated confidently as what happened in its counterpart B-Cell Lymphomas. And despite the studies which were retrospective in majority,treatment results still disappointed taking into consideration the aggressive clinical course of disease,so survival is not exceeding 2 years in median. **Aims.** to assessment response rate and overall survival at 5 years using a new intensive combination chemotherapy . **Methods.** patients were enrolled are diagnosed with PTCL confirmed by a reference pathologist treated with the new chemotherapy (ACEP)X 6 and Ifosfamide X 4 at Al-Bairouni university hospital and the study was approved by the Syrian Association of Clinical Oncology. **Results.** 25 patients underwent the treatment most of them have shown a complete response after the completion of the first six cycles (17/25) forming 68% of patients while another 5 patients became complete responders after the completion of treatment to reach to 22 patients still living at 5 years and an overall survival rate of 88%. **Conclusions.** (ACEP) and Ifosfamide seems to be a good choice in PTCLs in the light of good response and overall survival rates taking into account the acceptable toxicity profile but we still need a larger sample to make it an acceptable new combination chemotherapy for PTCLs patients.

1689

SAFETY AND EFFICACY OF RADIOIMMUNOTHERAPY WITH 90Y-RITUXIMAB IN PATIENTS WITH RELAPSED OR REFRACTORY CD20+ B CELL LYMPHOMA: A PILOT STUDY

M Vaes[1], K Muylle[1], D Vugts[2], N Meuleman[1], G Ghanem[1], T Guiot[1], B Vanderlinden[1], M Paesmans[1], G Van Dongen[2], P Flamen[1], D Bron[1]
[1]Institute Jules Bordet, Brussels, Belgium
[2]VU University Medical Centre, Amsterdam, Netherlands

Background. Both anti-CD20 antibodies (ibritumomab; Zevalin® and tositumomab; Bexxar®) currently used for radioimmunotherapy (RIT) of relapsed B cell non Hodgkin's lymphoma's are murine immunoglobulins. The use of chimeric antibodies such as rituximab for RIT may potentially increase immune-based anti-tumour activity, improve pharmacokinetics, and reduce immunogenicity (and hence facilitate repeated administrations). **Aims.** The aim of this pilot single arm phase I-II study is to evaluate the safety and efficacy of RIT with 90Yttrium-rituximab. **Methods.** This prospective single-centre study included patients with CD20+ B-cell lymphoma in partial remission or progressive disease after at least 1 line of therapy. The 90Y-rituximab was administered according to a similar schedule as currently approved by the European Medicines Agency for the treatment with 90Y-ibritumomab tiuxetan (Zevalin®). Each patient received:1) Dosimetry with 89Zirconium-rituximab-

PET/CT: i. v. -administration of rituximab at 250 mg/m² followed by the injection of the ^{89}Zr-labelled rituximab (3 mCi), with immuno-PET/CT performed 1h, 3 days and 6 days after tracer injection. 2) Therapeutic phase: one week later, the same infusion of cold rituximab followed by the injection of ^{90}Y-labelled rituximab (0. 3 mCi/kg if platelet count: 100000-150000/mm^3 and 0. 4 mCi/kg if platelet count: > 150000/mm^3). A baseline ^{18}FDG-PET/CT was performed before treatment and response assessment with ^{18}FDG-PET/CT was performed 3 months after the treatment and/or when progressive disease was clinically suspected. All patients signed a written informed consent. **Results.** 27 patients were included with a median age of 61 (range 29-73) years and a median of 2 (1-7) prior therapy regimens. Disease histologies included follicular lymphoma (n=14), predominant nodular lymphocytic CD20+ Hodgkin's lymphoma (n=3), marginal zone lymphoma (n=3), transformed follicular lymphoma (n=2), mantle cell lymphoma (n=2), diffuse large B-cell lymphoma (n=2) and small lymphocytic lymphoma (n=1). The overall response rate (ORR) was 85% (95% CI: 67%-94%), including 17 patients (63%) with complete metabolic response (CR) and 6 patients (22%) with partial responses (PR). Two patients had a stable disease and 2 patients a progressive disease. After a median follow-up of 103 weeks, the Kaplan-Meier estimated median progression-free survival was 51 weeks. Among follicular lymphoma's, the ORR was 100%, including 79% of CR and 21% of PR. Toxicities related to ^{90}Y-rituximab were primarily haematological with spontaneous recovery in all but one patient that needed autologous stem cell transplant for refractory thrombopenia. The incidence of grade 3-4 neutropenia, thrombopenia and anemia were 34%, 41%, and 7% respectively. Nadir blood counts occurred at 4 to 5 weeks following therapy for platelets and at 6 and 8 weeks for white and red cells respectively. Prior treatment with radiotherapy or autologous stem cell transplant as well as bone marrow involvement were not correlated with higher toxicities. Among the relevant long-term side effects, one patient previously treated with R-CHOP chemotherapy and autologous stem cell transplant developed secondary myelodysplasia 2 years after the RIT. **Conclusions.** The results of this study suggest that radioimmunotherapy with ^{90}Y-rituximab in patients with relapsed CD20+ B-cell lymphoma is safe, well tolerated and effective when the Zevalin® treatment schedule is used.

1690

NON-HODGKIN LYMPHOMA IN JORDAN: A RETROSPECTIVE ANALYSIS OF 852 CASES IN A TERTIARY CANCER CENTRE

A Addasi
KHCC, Amman, Jordan

Background. Lymphoma is the fourth most common newly diagnosed cancer inJordan, a small country with a population of 5. 85 million. The contribution Non- Hodgkin lymphoma (NHL) to the overall lymphoma burden inJordan, andthe relative frequencies of its major subtypes, have not been hitherto well characterized. OBJECTIVE: to characterize the clinico-pathological features of Non-Hodgkin lymphoma, and the relative contribution to the overall lymphoma burden, in patients referred to King Hussein Cancer Center (KHCC), the major cancer tertiary referral centre inJordan. **Patients and Methods.** A retrospective analysis was conducted of adults (>=18 years) lymphoma patients referred to KHCC, between1/1/2003and31/12/2010. Clinical features andhistological subtypes were prospectively established for all patients registered in the Lymphoma Service Database. Pathology review and submission of original paraffin blocks were mandated for all patients. **Results.** Over the 8 year period of 2003-2010,1329 lymphoma patients were referred to KHCC and registered in the Lymphoma Service Database, of whom 852 (64. 1%) were diagnosed with Non-Hodgkin lymphoma. Among this group all 852 patients were adults 18 years or older (100%), as children are treated in a different department. B-cell lymphomas formed (744) 87. 3% of the NHLs,whereas T-cell lymphomas formed (108)12. 7% of the total. Diffuselarge B-cell lymphoma was the most common subtype 432 (50. 7% ofall NHLs). Follicular centre-cell lymphomas, B-cell smalllymphocytic lymphoma, mantle-cell lymphoma, marginalzone B-cell lymphomas (including MALT lymphomas), and Burkitt lymphomaamounted to 66 (7. 7%),57(6. 6%), 12(1. 4%), and 24 (2. 8%) and12(1. 4%) respectively. Among the T-cell lymphomas, mycosis fungoides, anaplastic large-cell lymphomas of T/null-cell type, and peripheral T-cell lymphomas accounted for 6%,4. 3%, and 2. 9% of all cases, respectively. **Conclusions.**To our knowledge, this is the biggest NHL series to be reported inJordanto date. Non-Hodgkin lymphoma appears to constitute a smaller share of the lymphoma burden inJordan, as opposedEuropeand theUS. Clinico-pathological features, however, show important differences from those described in the rest of the world. Follicular lymphoma and mantle-cell lymphoma are less common inJordancompared toEuropeand theUSA. Peripheral T-cell lymphomas and T/NK-cell lymphomas of nodal and extranodal nasal types, which are common in many other Asiancountries, are also less prevalent. . DLBCL, as a result, formed a bigger proportion of NHL inJordan.

HEPCIDIN LEVELS IN DIFFUSE LARGE B CELL NON-HODGKIN LYMPHOMA

M Tisi[1], V Bozzoli[1], M Giachelia[1], G Massini[1], B Ricerca[1], F D'Alò[1], L Larocca[2], D Swinkels[3], M Voso[1], G Leone[1], S Hohaus[1]
[1]Institute of Hematology, Catholic University S. Cuore, Rome, Italy
[2]Institute of Pathological Anatomy, Catholic University S. Cuore, Rome, Italy
[3]Department of Laboratory Medicine (Clinical Chemistry/441), Radboud University N, Nijmegen, Netherlands

Background. Anemia is a frequent sign in patients with diffuse large B cell lymphoma (DLBCL) at diagnosis, and it is associated with unfavourable patient characteristics. A potential cause for anemia in Non-Hodgkin's lymphoma (NHL) is the abnormal iron-utilization, characteristic for the anemia of chronic disease, mediated from the liver-produced acute-phase peptide hepcidin. Overproduction of hepcidin leads in fact to iron-limited erythropoiesis, and inflammatory cytokines increase the expression of hepcidin. We recently showed that in patients with Hodgkin lymphoma IL-6 up-regulates hepcidin and elevated hepcidin levels resulted in iron-restriction and signs of anemia of chronic inflammation (Hohaus et al, J Clin Oncol, 2010; 28:2538). **Aims.** To assess the contribution of some principal players for erythropoiesis to the development of anemia in DLBCL: the iron-store regulator hepcidin, the hormone erythropoietin, and the inflammatory cytokine IL-6. Associations to other patients characteristics were also analyzed. **Methods.** We studied 53 patients with DLBCL (median age 61 years, range 16-78 years; 28 females and 25 males); a group of 24 healthy individuals (median age 41 years, range 18-63 years; 13 female, 11 males) was used as control. Plasma samples were analyzed for hepcidin levels using a combination of weak cation exchange chromatography and time-of-flight mass spectrometry (TOF MS); cytokine levels were determined using ELISAs and parameters of iron metabolism and acute phase reaction were all determined in the central laboratory of the Catholic University. Associations with patient characteristics were analyzed using standard statistics (STATA 10). **Results.** At diagnosis, 29 of 53 (55%) DLBCL patients had haemoglobin (Hb) levels <12 g/dl. Hepcidin plasma levels were significantly higher in DLBCL patients when compared to controls, independent of the presence of anemia (p=0. 001). Higher hepcidin levels were observed in patients with more aggressive disease characteristics, as elevated LDH levels (p=0. 0004), stage IV disease (p=0. 01), presence of B-symptoms (p=0. 03), and IPI score > 2 (p=0. 005). Hepcidin levels strongly correlated to ferritin (β=0. 77, p<0. 001), and to IL-6 levels (β=0. 3 p=0. 03), and inversely correlated to iron-binding capacity (β=-0. 36 p=0. 04), but not to haemoglobin and erythropoietin values. Haemoglobin values inversely correlated to IL-6 (β=-0. 36, p=0. 009) and erythropoietin levels (β=-0. 36, p=0. 009), however the observed/predicted erythropoietin levels were lower than 0. 8 in 26/29 (90%) of anemic DLBCL patients compared to 10/24 (42%) of non-anemic patients (p=0. 01) indicating a blunted erythropoietin response in anemic patients. In a logistic regression analysis including hepcidin, IL-6, and the O/P ratio of erythropoietin, Il-6 levels retained their significant impact on the risk of anemia (OR=1. 68, 95% C. I., 1. 01-2. 79; p=0. 044). **Conclusions.** Our findings suggest that hepcidin levels are associated with parameters of disease activity in DLBCL and are potentially up-regulated by IL-6. Elevated hepcidin levels result in iron-restriction, however a blunted erythropoietin response and, in particular, elevated Il-6 levels are associated with anemia in DLBCL.

1693

CONCORDANT BONE MARROW INVOLVEMENT MAINTAINS AN ADVERSE PROGNOSTIC SIGNIFICANCE IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP

F Gaudio[1], T Perrone[1], A Spina[1], S Scardino[1], G Nardelli[1], G Ingravallo[2], A Cimmino[2], A Napoli[2], G Specchia[1]
[1]Hematology - University of Bari, Bari, Italy
[2]Pathology - University of Bari, Bari, Italy

Background. The improvement in treatment outcomes of diffuse large B-cell lymphoma (DLBCL) observed following the introduction of Rituximab has altered previous views about risk assessment. Approximately 10% to 25% of patients (pts) with DLBCL exhibit bone marrow involvement with lymphoma at the time of diagnosis. Concordant bone marrow involvement has generally been associated with a poorer outcome but the impact of discordant involve-

ment remains less clear. **Aims.** The aim of this study was to examine the prognostic impact of (BM) involvement on response rate (RR), overall survival (OS) and progression-free survival (PFS) in 178 patients with de novo DLBCL. **Patients and Methods.** Between 2000 and 2010 we retrospectively analyzed 178 untreated DLBCL pts, newly diagnosed at our centre, with or without (BM) involvement. The median age was 59 yrs (16-89 yrs), 109 (61%) were males, 75 (43%) had B symptoms, 27 (15%) had extranodal dissemination >1, 49 (28%) had a high IPI score. The treatment protocol for front-line therapy included rituximab plus cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP). Progression-free (PFS) and overall survival (OS) were calculated according to the absence or presence of (BM) involvement and the presence of histological discordance or concordance between the primary site and the bone marrow. **Results.** A total of 41 (23%) of 178 pts had bone marrow involvement, concordant in 16 (9%) and discordant in 25 (14%). Median follow-up was 30 months (range, 1 to 120). The 41 pts with bone marrow involvement had a poorer prognosis compared with the group without (3 year progression-free survival, 56% vs 81% - p<0. 05).) PFS was inferior in those with concordant (p<0. 001) and discordant (p<0. 05) involvement, while OS was inferior only in those with concordant involvement (p<0. 001). Concordant involvement was associated with elevated lactate dehydrogenase, extranodal dissemination>1, IPI>2, performance status >2 and elevated beta 2 microglobulins. Complete remission (CR) rates were inferior in concordant bone marrow involvement as compared to discordant or no involvement (48% vs 59% vs 64%). **Conclusions.** Our data show that concordant, but not discordant bone marrow involvement, could represent a possible predictive factor of poor prognosis, which would help to identify a high risk subgroup of newly diagnosed DLBCL. To confirm these results, further large-scale and prospective studies will be required.

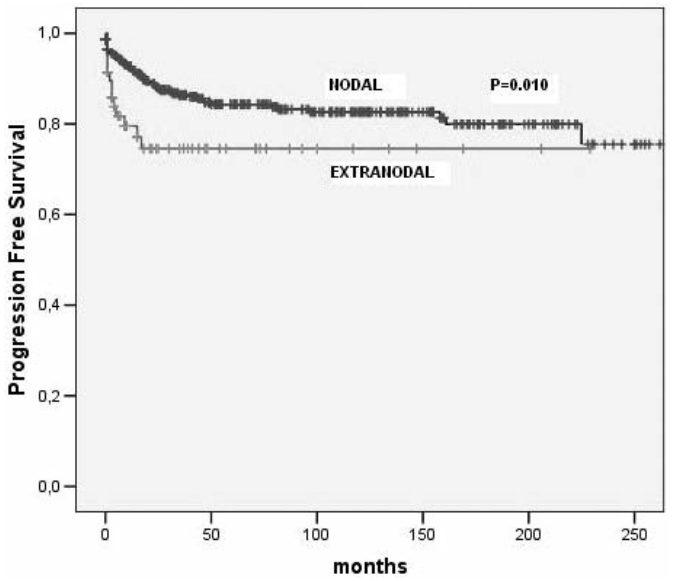

Figure 1. Progression free survival in patients with Hodgkin's lymphoma: nodal *vs* extranodal disease.

1694

THE GMALL-B-ALL/NHL PROTOCOL IS AN EFFECTIVE SALVAGE TREATMENT IN REFRACTORY AND RELAPSED AGGRESSIVE B-CELL LYMPHOMA

A Hüttmann, M Sakarou, U Dührsen
University Hospital, Essen, Germany

Background. The prognosis of refractory and relapsed aggressive non-Hodgkin lymphomas (NHL) is poor. After first-line treatment, platinum based salvage therapy followed by high-dose chemotherapy and autologous stem-cell transplantation may rescue 20% to 45% of patients. The B-ALL/NHL protocol, originally designed for the treatment of Burkitt lymphoma by the German Acute Lymphoblastic Leukemia study group, may be an alternative salvage regimen. Its main constituents are hyperfractionated alkylating agents (cyclophosphamide, ifosfamide) and high doses of protractedly infused antimetabolites (methotrexate, cytarabine) able to cross the blood - brain barrier. **Aims.** This study analysed the efficacy and toxicity of the B-ALL/NHL protocol in refractory and relapsed patients with aggressive NHL. **Methods.** This is a single center, retrospective analysis of outcomes in relapsed and refractory patients treated with the B-ALL/NHL protocol (with or without rituximab) between 1994 and 2010. 26 diffuse large B-cell lymphomas (DLBCL incl. variants and subtypes; median age 58 years (27-78), 7 transformed B-NHL (tB-NHL; median age 67 years (36-71), 3 T-cell-lymphomas (TCL; median age 58 years (29-63) and 6 mantle-cell lymphomas (MCL; median age 60 years (38-65) were analysed for overall survival (OS) and toxicities. **Results.** The main factor affecting response was the number of previous treatment lines. Three-year OS in DLBCL patients after a maximum of one previous treatment line was 44. 4%, compared with 7. 7% in patients in later treatment phases (p<0. 05). OS in patients refractory to first line treatment (progressive under first line therapy or remission lasting less than 6 months) was 20%. Three-year OS in tB-NHL and in MCL patients was 28% and 0%, respectively. In this cohort, 21% of treatment cycles had to be delayed, mainly due to prolonged bone marrow toxicity, neutropenic fever and mucositis. Grade 3 and 4 toxicities related to infectious causes were observed in 85. 5 % of patients. Treatment-related mortality was 4%. **Summary and Conclusions.** The B-ALL/NHL protocol is an effective salvage regimen for DLBCL and tB-NHL refractory to front line therapy or in first relapse. Treatment-related morbidity, mainly due to infectious complications, is high, but manageable and reversible. Treatment related mortality is not in excess of other salvage regimens.

1695

LYMPHOPENIA PREDICT FOR THE RISK OF FEBRILE NEUTROPENIA AFTER CHEMOTHERAPY

K Kacem[1], S Ben nasr[1], S Zriba[2], R Ben lakhal[1], Y Yahyaoui[1], H El benna[1], M Zarrouk[1], R Ben amor[1], Y Ben abdennebi[1], H Ben neji[1], R Jeddi[1], Z Bel Hadj Ali[1], H Ben Abid[1], B Meddeb[1]
[1]Aziza othmana hospital, Tunis, Tunisia
[2]Department of Internal Medecine, Military Hospital, Tunis, Tunisia

Background. Febrile Neutropenia (FN) is the most serious hematological toxicity of cytotoxic chemotherapy. Individual parameters of the patient contribute significantly to the risk of FN in addition to the type and dose of chemotherapy. **Methods and Aims.** We analyzed data of 193 cycles of chemotherapy given for 42 patients with aggressive lymphoma to evaluate the impact of lymphopenia on day 1, day 5, and day 8 on the occurrence of FN. **Results.** The median age was 33 years (15-68) with male/female sex ratio of 1. 8. Half of patients had classical Hodgkin lymphoma, one third with diffuse large B cell lymphoma and 12 % with T cell lymphoma. Stage I, II, III, and IV were observed in 2. 4%; 40. 5%; 21. 4%; and 35. 7% respectively. Cycles were composed of: 74 courses of BEACOPP, 116 cycles of CHOP and CHOP like and 3 of IGEV. FN occurred more frequently in female than in male (34. 6% vs 19 %; p= 0. 015). Stage IV was significantly associated with FN than other stage (36% vs 21. 6%; p=0. 045). FN was observed in 25. 4% of cases. We study the correlation between FN and lymphopenia ≤ 700/mm^3 on day 1, day 5, and on day 8. We noted an increase of the risk of FN by 2 fold (OR 2. 2) when lymphocytes count ≤700/mm^3 on day 1. Data for day5 were available only for 57 courses, explained the absence of impact of this parameter. Lymphopenia ≤ 700/mm^3 on day 8 was associated with a higher risk of FN (OR=2. 4; p=0. 02). Logistic regression study found that lymphopenia on day 8(≤ 700/mm^3) was not an independent factor to predictive FN. Moreover analyzes showed that this factor was significantly associated with increase of hematotoxicity (p=0. 02), duration of aplasia and of antibiotic therapy. We also concluded that hematotoxicity observed in the first cycle was a predictor factor for toxicity in later cycles (p=0. 03). **Conclusions.** Lymphopenia ≤ 700/mm^3 on day 1 and /or on day 8 of chemotherapy allowed selecting a group of patient candidate for prophylactic measures to FN.

1696

SMOKING AND NON-HODGKIN'S LYMPHOMA

Z Mozaheb
Mashhad University of Medical Science, Mashhad, Iran

Background. Non-Hodgkin lymphoma (NHL) is the fifth most frequently diagnosed cancer. The incidence of non-Hodgkin lymphoma has risen by at least 100 percent over the past five decades especially in the western, but the reason is not clear. Tobacco smoking is the important cause of several malignancies. Different studies show various effect of smoking on Non-Hodgkin lymphoma. To evaluate this effect, a case control study was carried out in NHL patients in a cancer center in Mashhad, Iran. **Methods.** We conducted a case-control study on NHL in Mashhad, which includes 170 NHL cases (mean age 52 years) were admitted to reference hospitals and outpatient clinic, and 190

controls (mean ages 46 years) were admitted for a wide spectrum of nonmalignant, non tobacco-related conditions. Trained interviewers administered a structured questionnaire to cases and controls during their visit from 2008 to 2010. **Results.** We found that if we only compare smoking with non-smoking, there is no significant effect of smoking on Non-Hodgkin's Lymphoma. In control group 21. 8%, and in case group 24. 7% were smoker (p=0. 521). But if we compare the amount of smoking, there was significant difference between case and control groups. 45% of patients smoke more than 15 cigars per day, but only 7. 9% of control group were smoked more than 15 cigar per day (p=0. 000). In this study the subtype of NHL based on WHO classification, in 38% of patients was diffuse large cell lymphoma and only 1. 4% was follicular lymphoma. **Conclusions.** Based on our study, only smoking is not a risk factor for Non-Hodgkin Lymphoma, but heavy smokers (smoke more than 15 cigars per day) are at risk for Non-Hodgkin's Lymphoma.

1697

R-ICE AS SALVAGE THERAPY FOR RELAPSED DIFFUSE LARGE B-CELL LYMPHOMA WITH PRIOR EXPOSURE TO RITUXIMAB: A MULTI-CENTER, PROSPECTIVE PHASE II TRIAL

Y Guo[1], X Hong[1], J Ma[2], Y Shi[3], Y Chen[4], L Yu[5], J Zhu[6], W Jiang[7], T Liu[8], J Jin[9], P Zou[10], D Wu[11], Z Shen[4]

[9]The First Affiliated Hospital of Medical School of Zhejiang University, Hangzhou, China
[10]Wuhan Union Hospital, Huazhong University of Science and Technology, Wuhan, China
[11]First people's Hospital of Soochow University, Suzhou, China

Background. The prognosis of patients with relapsed diffuse large B-cell lymphoma (DLBCL) after rituximab-containing first-line therapy is relatively poor. Rituximab, ifosfamide, etoposide, and carboplatin (R-ICE) was proved to be an effective salvage regimen for relapsed DLBCL. **Aims.** We aimed to prospectively evaluate the efficacy and safety of R-ICE in patients with prior rituximab exposure in a multi-center trial setting. **Methods.** DLBCL patients who had disease relapse after 6-8 cycles of first-line therapy of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone) could be enrolled in this trial. Patients without complete response (CR) or complete response unconfirmed (CRu) after R-CHOP were ineligible. Three cycles of R-ICE (rituximab 375 mg/m^2 day 1, ifosfamide 1600 mg/m^2 days 2-4, carboplatin area under the curve = 5 [maximum dose, 800 mg] day 3, and etoposide 100 mg/m^2 days 2-4) were given to eligible patients. For responding and young (less than 60 years) patients, high-dose therapy (HDT) and autologous stem-cell transplantation (ASCT) were recommended, but not mandatory in the protocol. For remaining patients, selections of subsequent treatment were at the discretion of their attending physicians. The primary endpoint of this trial was overall response rate and secondary endpoints included progression-free survival (PFS), overall survival (OS) and safety. **Results.** Thirty-two patients were enrolled with a median age of 55 years (range, 27 to 68). Other major patient characteristics were shown in Table 1. After 3 cycles of R-ICE, 25 (78. 1%) patients responded to the therapy. The CR/CRu and partial response (PR) rate were 50% and 28. 1%, respectively. Three patients developed early disease progression after 1 or 2 cycles. One patient refused further treatment after 1 cycle and was lost of follow-up. Among responding patients, 5 patients underwent HDT followed by ASCT and 9 patients received another 1 or 2 cycles of R-ICE. Other subsequent therapy included rituximab maintenance (1 patient), other salvage chemotherapy (5) and radiotherapy (4). Bone marrow suppression was the major toxicity. The rates of grade 3/4 leucopenia, anemia and thrombocytopenia were 37. 5%, 15. 6% and 37. 5%, respectively. Six (18. 8%) patients developed febrile neutropenia, but none died consequently. With a median follow-up time of 12 months (range, 7. 7 - 16. 3), 1-year PFS and OS rate were 53. 4% and 70. 7%, respectively. Sub-group analysis demonstrated that international prognostic index (IPI) before enrollment correlated with survival. In patients with IPI 0-2, 1-year PFS and OS rate were 67. 4% and 77. 9%, which were higher than those in patients with IPI 3-5 (18. 2% and 51. 4%) with statistically significant *P* values (0. 04 and 0. 033). Through multivariate analysis, IPI was also found to be the sole independent prognostic factor regarding PFS and OS. For patients with a longer relapse time (more than 12 months) after first-line therapy, there was a trend of significantly improved 1-year PFS and OS rate (71. 8% and 82. 1%) as compared with early relapse patients (35. 1% and 58. 3%). **Conclusions.** In relapsed DLBCL patients with prior rituximab exposure, R-ICE is still an effective salvage regimen with manageable toxicities. IPI remains a clinically significant prognostic factor in second-line setting.

[3]Clinical Center Nis, Clinic for Hematology, Nis, Serbia
[4]Clinical Center Kragujevac, Clinic for Hematology, Kragujevac, Serbia
[5]Clinic for Hematology, Clinical Center Serbia, Belgrade, Serbia

Background. The incidence of follicular non-Hodgkin lymphoma (NHL) increases with age and a high prevalence of comorbid conditions has been reported in these patients. So far, risk assessment in NHL has been mainly based on disease status. **Aims.** The objective of this study was to determine the prognostic impact of comorbidity on the survival of patients with NHL with the aim of developing novel tool for risk assessment. **Methods.** We conducted a retrospective cohort study of 65 patients with follicular NHL who received Rituximab+CHOP, identified in Registry of the Serbian Lymphoma Group. The comorbidity scores as Adult Comorbidity Evaluation-27 (ACE-27), Cumulative Illness Rating Scale (CIRS) and hematopoietic cell transplantation comorbidity index (HCT-CI) was used to assess concurrent presence of nonmalignant diseases. Data on demographics, disease status, treatment, and outcome were extracted from detailed review of the patients' medical charts and laboratory values at diagnosis and during the course of the disease. Kaplan-Meier methods and univariable and multivariable Cox regression were used to assess survival. A prognostic model incorporating baseline comorbidities was developed to predict survival. **Results.** According to ACE-27 and HCT-CI scales, comorbidity was present in 62% and 40% of patients in the followed cohort, respectively. Overall mean survival was 37,4 months. In univariate Cox regression analysis, both comorbidity indexes - ACE-27 and HCT-CI had a significant impact on overall survival (p=0,039; RR=2,197; 95%CI for RR 1,040- 4,641 and

p=0,039; RR=2,197; 95%CI for RR 1,040- 4,641) along with with FLIPI prognostic index (p=0,039; RR=2,197; 95%CI for RR 1,040- 4,641). CIRS scale were not found to affect the risk of overall death. Median overall survival time between ACE groups (none/mild *vs.* moderate/severe) was 39 *vs.* 30 months, respectively (p=0,056) while in HCT-CI groups (HCT-CI < 2 vs ≥ 2) was 37 vs 31 months (p=0,063). On multivariate regression analysis, only the HCT-CI index remained a prognostic factor (p=0,027; RR=1,666; 95%CI for RR 1,061-2,616) independent of FLIPI. **Conclusions.** Comorbidities have a significant impact on the outcome of patients with follicular NHL treated with Rituximab. A comprehensive assessment of the severity of comorbidities through the HCT-CI and ACE-27 scales helps predict survival in patients with follicular NHL.

1699

ACUTE RENAL FAILURE IN BURKITT'S LYMPHOMA PATIENTS UNDERGOING BL-M-04 TREATMENT PROTOCOL

A Lukina, E Baryakh, S Kravchenko, L Birukova, E Gemdjian, A Magomedova, A Kremenetskaya, A Vorobiev
National Research Center For Hematology, Moscow, Russian Federation

Background. Burkitt's Lymphoma (BL) - B -cell lymphoid neoplasm with high proliferative index approximates 100%, chromosomal abnormalities (t(8;14)(q24;q32), rarely - t(2;8)(p12;q24), t(8;22)(q24;q11)). Renal failure in BL patients can be caused by the tumor itself and appears during chemotherapy. The National Research Center for Hematology uses original high intensive protocol BL-M-04. **Aims.** To analyze reasons of Acute Renal Failure (ARF) and treatment results in BL patients. **Methods.** 13 previously untreated patients were included in our study (7 males and 6 females, median age of 24, spanning 15 to 57 years old). All patients had c-myc rearrangements and ARF. Patients with c-myc rearrangements, but without ARF comprised the control group (36 patients). All patients underwent chemotherapy in the National Research Center for Hematology between May 2003 and August 2011. Treatment was based on modified NHL-BFM-90 protocol - BL-M-04, including high dose of methotrexate (MTX) (1,5 g/m²), cytarabine (2 g/m²). The stage of disease was established according to Murphy S. B. classification. III, IV stage was diagnosed in 5 and 1 patients respectively. B-acute lymphoblastic leukemia (L3) was diagnosed in 7 patients. The ratio between patients with bone marrow involvement and those without was7:13 in the main group,9:36 in the control group. The differences between the compared groups were tested by non-parametric statistical analyses (Mann-Whitney U-test). The data was analyzed using SPSS, ver. 16. 0. Differences were considered significant at p ≤0. 05. **Results.** 12 patients from 13 were diagnosed with ARF at the moment of admission to hospital. In 5 patients it became greater after treatment started. In 1 case AFR appeared for the first time after chemotherapy began. The reasons for ARF at the time of admission to hospital were tumor lysis syndrome (TLS) and/or tumor kidney infiltration (5, 6 events respectively). 2 patients had urinary obstruction. After treatment started, TLS and/or MTX toxicity were the main causes (4 and 3 events respectively). Renal function impairment was observed when MTX was administered before ARF resolved (3 events), independently of dosage. Later MTX was administered only after AFR had disappeared. ARF resolved in a short time after treatment was started: during the pre-phase or first course A of chemotherapy (5 and 8 events respectively). Chemotherapy in BL patients with AFR was associated with an earlier myelotoxic agranulocytosis, (beginning on the 3rd day after chemotherapy finished, compared with the 5th day in the control group) (p=0. 04), longer myelotoxic agranulocytosis duration (12 days, compared with the control group - 7 days) (p=0. 04), higher mucositis degree (p=0. 05). Although 5 patients died (4 due to infectious complications, 1 due to thrombocytopenia), clinical remission was achieved in all patients. **Conclusions.** Hematological and gastrointestinal toxicity degree in BL-M-04 protocol is significantly higher in BL patients with ARF in comparison with the BL patients without ARF (p=0. 04). MTX should be administered only after ARF has resolved. Mortality in BL patients with ARF is significantly higher than in BL patients without ARF (33 % vs 10%, p = 0. 05).

1700

ASSESSMENT OF BONE MARROW INVOLVEMENT BY FDG-PET/CT IN PATIENTS WITH FOLLICULAR LYMPHOMA

I El-Najjar[1], T Szyszko[1], A Mc. Dowell[2], J Matthews[1], J Gribben[1], S Montoto[1]
[1]Queen Mary University, London, United Kingdom
[2]Barts and the London NHS trust, London, United Kingdom

Background and Aims. Bone marrow biopsy (BMB) is an essential part of the staging of follicular lymphoma (FL) patients as 40-60% of patients have involvement of bone marrow (BM) at presentation. However, given the patchy infiltration of BM in patients with FL, BMB -an unpleasant investigation- can miss disease not present in the biopsy area. Several studies evaluating the role of FDG-PET in assessing BM involvement have relied on visual analysis alone, which has proved inadequate. Against this background, the aim of this study was to assess the additional value of semi-quantitative assessment in predicting BM involvement in FL. **Patients and Methods.** A single centre retrospective analysis of 41 patients with grade 1-3a FL (median age: 64 years, range: 30 - 87; previously untreated: 30, at relapse: 11), who underwent FDG -PET/CT and unilateral BMB as part of the staging assessment is reported. The last treatment for patients included at relapse was given at least 3 months (range: 3 - 54) prior to the staging investigations. BM uptake was assessed both visually and with semi-quantitative analysis. On visual analysis, BM uptake was compared to the mediastinal blood pool (MBP) as a reference. Semi-quantitative analysis involved measuring the maximum SUV at the sternum, both iliac blades and the T12 vertebra. The single highest SUVmax, the average SUVmax (SUVav) for the 4 sites and the ratio of SUVav/MBP were compared to the BMB result by Welch test on SPSS. Optimal SUVmax, SUVav and SUVav/MBP cutoffs were defined by Receiver operating characteristic (ROC) curves. **Results.** Sixteen patients had a positive BMB. On visual analysis of the FDG-PET/CT, 7 patients had BM involvement (focal lesions in 6). Two patients deemed to have possible bone involvement on visual analysis of the FDG-PET/CT had negative BMB. Visual analysis had a sensitivity and a specificity of 31% and 92%, respectively, whereas the sensitivity and the specificity for SUVmax ≥2. 5 was 56% and 84%; those of SUVav≥2 were 63% and 96%, and the sensitivity and specificity of SUVav/MBP ≥1 were 88% and 80%, respectively. **Conclusions.** Visual assessment of FDG-PET/CT has a high specificity but a low sensitivity to detect BM involvement in FL patients. In contrast, semi-quantitative assessment can improve the sensitivity of FDG-PET/CT to predict BM involvement from 31% to 88%. Were these results confirmed in further prospective studies, they may help to select patients who might benefit from having a BMB because of likely involvement, with the potential to consider avoiding BMB in the rest.

Table 1.

Methods for assessment of BM involvement		BMB +VE	BMB -VE
FDG-PET/CT +VE on visual analysis (patients)		5	2
FDG-PET/CT – VE on visual analysis (patients)		11	23
SUV max (mean)	p= 0.02	2.8	2.0
SUV av (mean)	p=0.004	2.3	1.6
SUV av/MBP (mean)	p=0.001	1.4	0.9

1701

THE IMPACT OF COMORBIDITY BURDEN ON THE OVERALL SURVIVAL IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

B Andjelic[1], D Antic[1], V Nikolic[2], L Popovic[3], V Vukovic[1], B Mihaljevic[1]
[1]Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia
[2]Clinic for Hematology, Clinical Center Nis, Nis, Serbia
[3]Oncology Institute of Vojvodina, Novi Sad, Serbia

Background. After the introduction of R-CHOP as standard treatment of Diffuse Large B-cell Lymphoma (DLBCL), treatment results significantly improved. Still, there are patients who didn't have benefit from this. The main task of investigators focused on prognostic factors is to identify the patients at high risk for poor outcome. Modern oncological studies includes a comprehensive evaluation of comorbidity as an important predictor of the outcome because of the role of competing risk. **Aims.** The objective of this study was to assess the prognostic impact of the Adult Comorbidity Evaluation-27 (ACE), Modified Cumulative Illness Rating Scale (M-CIRS) and Hematopoietic Cell Transplantation -specific comorbidity index (HCT-CI) on the overall survival in patients with DLB-

CL. **Methods.** This retrospective study included 145 patients diagnosed with DLBCL in the period May 2008-August 2010 in three centers, identified in DLBCL Register of the Serbian Lymphoma Group. All the patients were treated with R-CHOP in the front line therapy. Information on comorbidity was extracted from patient's history and ACE-27, M-CIRS and HCT-CI comorbidity indexes were calculated. Univariate and multivariate survival analyses were performed using Cox's proportional hazards regression models. **Results.** The median age was 56. 3±14. 1. Overall mean survival was 35. 4±1. 5 months. According to both ACE-27 and HCT-CI categories, patients with severe combidities had significantly lower overall survival, respectively (p=0. 007 and p=0. 030). The overall survival of patients with M-CIRS over the median for the selected group didn't differ from patients with M-CIRS below the median. Furthermore, in univariate regression analysis International Prognostic Index (IPI), Revised-IPI (R-IPI) and age adjusted IPI (aaIPI) were identified as predictors of overall survival, respectively (p<0. 001; p<0. 001; p<0. 001). Final multivariate prognostic model included aaIPI and HCT-CI as the most important predictors of overall survival (P < 0. 001 and p=0,012). **Summary and Conclusions.** A comprehensive assessment of the severity of comorbidities through the ACE-27 and HCT-CI comorbidity indexes helps predict overall survival, while the aaIPI and HCT-CI are the most important predictors of overall survival in patients with DLBCL.

1702

OUTCOME OF PATIENTS WITH PCNSL TREATED OUTSIDE CLINICAL TRIALS: A RETROSPECTIVE STUDY

A Hart[1], J Baars[1], MJ Kersten[2], D Brandsma[1], H van Tinteren[1], D de Jong[1], M Spiering[2], L Dewit[1], W Boogerd[1]
[1]Antoni van Leeuwenhoek Ziekenhuis, Amsterdam, Netherlands
[2]Academic Medical Center, Amsterdam, Netherlands

Background. Primary CNS lymphoma (PCNSL) accounts for approximately 4% of newly diagnosed central nervous system tumours. The current knowledge and guidelines are mainly based on results obtained in clinical trials. However, due to the often poor performance status and cognitive impairment, many patients are treated outside studies. **Aims.** The aim of this study was to get more insight into the nature, course of disease and outcome of HIV negative patients with PCNSL who are treated outside clinical trials. **Methods.** This is a retrospective study of all HIV negative patients with PCNSL diagnosed between 2000 and 2010, treated outside clinical studies in the Antoni van Leeuwenhoek hospital and Academic Medical Center in Amsterdam. The data were retrieved from the registries of both hospitals. The following data were investigated: age, sex, performance status (PS), comorbidities, presence of other immunodeficiencies than HIV infection, presenting symptoms, the PCNSL prognostic score at presentation, pathology, treatment, response, duration of response, acute and late toxicities, overall, event- and recurrence free survival (OS, EFS, RFS) and cause of death. RFS was considered only for patients with response to chemo- and/or radiotherapy. RFS was defined as time from diagnosis to date of recurrence or death, whatever happened first; OS as time from diagnosis to death and EFS as time from diagnosis to any disease failure for all patients. The study was approved by the Ethics Committees of both hospitals. **Results.** Fifty-two patients were identified. The characteristics and treatment are summarized in the Table 1.

Table 1.

Characteristics	No. of patients
Total	52 (27 male)
Median Age (years)	64,5 (range 43-83)
Performance status: 0-2 respectively (resp.) 3-4	33 resp. 19
PCNSL Prognostic score	
Complete	25
0-2 resp. ≥ 3	10 resp. 15
Incomplete (no cerebrospinal fluid data: 25; LDH unknown :2)	27
0-2 resp. ≥ 3	17 resp. 10
Presenting symptoms	
Focal neurological deficits	40
Cognitive dysfunction	26
Decreased consciousness	19
Epilepsy	17
Headache	15
Behavioural changes	14
Walking disturbances	12
Nausea/vomitus	11
Number of sites involved	
Single resp. multiple	29 resp. 23
Location of sites	
Supratentorial tumor	43
Infratentorial tumor	2
Both supra-and infratentorial tumor	6
Leptomeningeal involvement	6
Ocular involvement	1
Time between first symptoms and diagnosis in months	1,5 (range 0-34)
Time between diagnosis and treatment in months	0,5 (range 0-20)
Treatment and response	
High dose MTX based chemotherapy alone	16: 6 CR; 2PR; 4 PD; 4 NE (NE=not evaluable, died before evaluation)
Radiotherapy (RT) alone	10: 4 CR; 4 PR; 1 PD; 1 NE (1 lost for FU before evaluation)
High dose MTX based chemotherapy and RT	18: 12 CR; 3 PR; 2 PD; 1 SD
No treatment	8

In 14 patients, no histological confirmation of the diagnosis PCNSL could be retrieved. The reasons were: poor PS, danger of severe neurological damage due to biopsy, high intracranial pressure with danger of cerebral herniation. All patients with histological verification had a diffuse large B-cell lymphoma. In 27 patients, no complete PCNSL prognostic score could be calculated mainly due to the risks to do a lumbal puncture. All patients were treated with corticosteroids: 32 patients had a clinical response. 8 patients received no further chemo- or radiotherapy due to poor PS and rapid deterioration despite corticosteroids. With a median follow up of 63. 1 months, 34 patients had died: 29 due to PCNSL (14 from primary tumor, 15 after recurrence), 4 due to toxicity of chemotherapy and 1 due to epileptic seizure while in CR. Four patients were lost for follow-up (FU). The date of last contact was chosen to determine the OS and RFS in patients lost to FU. With a median FU of 63. 1 months, median RFS for 32 responding patients was 23. 8 months (95% CI 15. 9-not applicable), median OS for all patients 24. 4 months (95% CI 11. 5-39. 8), median EFS 14 months (95% CI:7. 3-24. 4). **Summary and Conclusions**. The results are in line with those published in prospective series. The inability to obtain liquor in 25/52 patients indicates that protein content of liquor is a less usable prognostic factor. Lack of histology in 14 patients excluded them from trial participation. In order to obtain more knowledge about PCNSL, a central international registry could be of value.

1703

DIFFUSE LARGE B-CELL LYMPHOMA IN KOREA: ITS DISTINCT EPIDEMIOLOGY AND CLINICAL FEATURES

YC Ahn, SJ Park, JH Park, JE Kim, DH Yoon, C Suh
Asan medical center, Seoul, South-Korea

Background. Non-Hodgkin lymphoma (NHL) is the tenth common malignancy and WHO age-standardized incidence rate is 8. 3 per 100,000 for both sex in Korea. Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of NHL with heterogeneous clinical presentations and biological behaviors but there are rare collective data on its epidemiology and clinical features. **Aims.** This study aims to review comprehensive clinical features and to determine factors affecting survival of DLBCL in Korean.

Table 1. Extranodal involvements at initial diagnosis.

Extranodal sites (total 563 patients, total 889 sites)	Frequency	%, total sites [a]	%, total patients [b]
Gastrointestinal	*221*	*24.9*	*39.3*

Pituitary	1	0.1	0.2
Other abdominal structure (Adrenal, omentum, pancreas, GB, biliary, peritoneum)	*70*	*7.9*	*12.4*

Methods. A total of 716 pathology-confirmed DLBCL patients in single center, between 2000 and 2009, were enrolled. We retrospectively reviewed clinical and survival data to find factors affecting clinical outcome. **Results.** 389 men (54. 3%) and 327 women were diagnosed DLBCL at a median age of 56 years (range, 15 - 92). 286 patients (39. 9%) were over 60 years old and 36 (5. 1%) were less than 30 at diagnosis. 57 patients (8. 0%) were ECOG performance status more than 1, 404 (56. 4%) were Ann Arbor stage of III or IV, 191 had extranodal involvement more than 1 (26. 7%) and 416 (65. 4%) had abnormal initial serum lactate-dehydrogenase (LDH). Also, 35 in 474 patients (7. 4%) had chromosomal abnormality in bone marrow. 584 patients received chemotherapy alone, 15 radiotherapy alone, 65 chemotherapy followed by radiotherapy. The other 23 and 29 received surgery and best supportive care, respectively. A total of 556 patients were identified to have 1631 lymph node (LN) involvements (Most common were abdominal followed by cervical and mediastinal LNs, but no cases of infraclavicular and popliteal LNs were found). And 563 patients had 889 extranodal sites (Most common were gastrointestinal organs followed by head and neck area. Rare presentations such as prostate, female adnexa, vulva, pituitary and cerebrospinal fluid were found). After median follow-up of 41. 9 months (range 0. 1 - 140. 9), 716 patients showed 5-year survival rate of 62%. 680 evaluable patients revealed response rate of 89. 9% (Rituximab added cases were 92. 2% and no rituximab cases 86. 5%). Adding rituximab to CHOP chemotherapy did not show statistically significant gain in overall survival and event free survival. Prognostic models such as International prognostic index (IPI), age-adjusted IPI, revised IPI were all well correlated with overall survival differences by risk stratification in Rituximab plus CHOP treated patients. In case of Revised IPI, 5-year survival rate in very good risk group (0 risk factor), good risk (1 or 2 risks), poor risk (more than 2 risks) respectively showed 84%, 65% and 50% (log rank p=0. 01). Multivariate analysis showed 4 factors were independent in our study: Age > 60 (HR = 2. 38, 95% CI 1. 71 - 3. 23, p < 0. 001), B symptoms (HR=1. 78, 95% CI 1. 27 - 2. 50, p = 0. 001), Abnormal LDH (HR 1. 66, 95% CI 1. 11 - 2. 48, p = 0. 013), Chromosomal abnormality in bone marrow (HR = 1. 72, 95% CI 1. 04 - 2. 86, p=0. 036). **Conclusions.** DLBCL is clinically heterogeneous, variable in treatment outcome. This single ethnicity study on epidemiology, clinical features and survival necessitates further clinical researches to refine our understandings of DLBCL.

1704

CAN LEVEL OF EBV-DNAEMIA PREDICT DEVELOP OF A POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDER?

M Troiano[1], G Monaco[1], ML Vigliotti[1], B Casale[2], A Abbadessa[1]
[1]UOC di Oncoematologia, A. O. R. N. "Sant'Anna e San Sebastiano", Caserta, Italy
[2]IPAS, A. O. R. N. "V. Monaldi", Napoli, Italy

Background. Post-transplant lymphoproliferative disorders (PTLDs) are a spectrum of lymphoid neoplasms, occurring in solid organ of immunosuppressed subjects or in bone marrow transplant recipients. PTLDs commonly derive from B-cell lineage and are associated with Epstein-Barr virus (EBV) infection. **Methods.** We retrospectively analyzed seven cases of PTLDs between 2000 and 2011. Five were males, one female, their mean age was 55 years (range: 15-72). Transplanted organs were heart (3 cases), kidney (3 cases), and liver (1 case). EBV DNA load was performed by quantitative polymerase chain reaction. **Results.** We labelled as early PTLD which occurred within 12 months after transplant. In our patients, median time after transplant to diagnosis of PTLD was 9 (early) and 190 (late) months. Histological and immunohistochemical analysis revealed diffuse large B-cell lymphoma in three subjects, multiple myeloma in a patient, anaplastic large cell lymphoma in one, marginal zone lymphoma in another one and lymphoplasmacytic lymphoma in the last patient. EBV serology was positive in five cases before transplant and in six after it. Median viral load was 2400 copies/mL (range: 400-10000 copies/mL). Currently, four patients are alive and three patients have died. *Discussion.* A review of the literature shows that more than 90% of EBV-related PTLDs commonly arise within one year after transplant. We observed a late PTLD onset in 4/6 cases. Two patients who developed PTLD within one year after transplantation had higher EBV-DNA load (median: 6000 copies/mL). Other four patients, with PTLD late onset, a lower viral load was detected (median: 550 copies/mL). It has been reported patients with undetectable or low EBV viral load within six months after transplant do not develop PTLDs, while a chronic high EBV load is a predictor of de novo or recurrent PTLDs. *Conclusions.* We think that PTLD late onset in our patients, could be related to their low EBV viral load. To date, it is not clear which threshold value of EBV-DNA can be considered predictive of PTLD development. High viral load or a rising trend could define higher risk patients, so frequent EBV load monitoring is mandatory.

1705

EXPRESSION OF KI 67AND CASPASE 3 WITH ANALYSIS OF SELECTED PROGNOSTIC FACTORS INFLUENCING ON OBTAINING 1ST AND 2ND DISEASE REMISSION IN PATIENTS SUFFERING FROM LYMPHOMAS

L Hajac[1], L Usnarska-Zubkiewicz[2], E Filipczyk-Cisarz[1], K Kuliczkowski[2]
[1]Lower Silesian Oncology Center, Wroclaw, Poland
[2]Katedra i Klinika Hematologii, Nowotworów Krwi i Transplantacji Szpiku AM, Wroclaw, Poland

Background. One of the most significant factor determining biology, clinical picture and effectiveness of therapy in lymphomas is the proliferation index, which can be characterized with Ki 67 expression. Main therapy in these diseases is chemotherapy, which efficacy could be in a large degree depending on both proliferation and apoptotic processes, as cytostatics are also functioning as drugs promoting apoptosis. Caspase 3 is of crucial importance in the process of apoptosis and though its expression may be correlated to response to chemotherapy. Prognostic factors for response to chemotherapy in these disorders shall help to individualize therapy and to improve its so far unsatisfactory efficiency. It particularly refers to recurrent disease, where it is often difficult to set a unified standard of care. **Aims.** Objective of this trial is to find more about expression of caspase 3 and it dependence to Ki 67 in lymphomas and to evaluate whether type of caspase 3 expression is a prognostic factor for response to treatment in particular types of lymphomas. Classical risk factors like IPI (International Prognostic Index), disease stage, age, serum LDH level and efficiency of first line treatment were also tested for influence on result of second treatments. In search for additional prognostic factors also other conventional variables like BMI (Body Mass Index), kind and quantity of extranodal involvement, degree of bone marrow involvement were tested for their significance. **Methods.** The project is retrospective, concerning patients with recurrent lymphomas treated in Lower Silesian Oncology Center and in Department of Haematology of Wrocław Medical University. Data was acquired by examination of expression of Ki 67 and caspase 3 with use of immunohistochemical analysis on tissue material from Department of Patology of Wrocław Medical University and Department of Pathology of Lower Silesian Oncology Center. Data was also acquired from patients' medical documentation. **Results.** Statistic analysis operates on group of 131 cases. In 68 patients it was possible to examine expression of Ki67and caspase 3. Low Ki 67 index (<5%) correlated with diffuse caspase 3 expression, while lymphomas with high proliferation index presented mild caspase 3 expression (p=0,04). Patients with Ki 67 (>30%) appear to have shorter OS counting for both 1st and 2nd line treatment (p=0,009) and tendency for worse PFS (p=0,09). Expression of caspase 3 did not influence ORR, PFS or OS in aggressive lymphomas, but it shows a trend of better OS in patient with mild expression in low grade lymphomas (see chart). Primary and restaged IPI, symptomatic disease, WHO PS status, LDH serum level, hemoglobin serum level, peripheral eosinophilia and number of CT cycles was found to influence PFS and/or OS, while extranodal involvement, BMI and restaged AnnArbor scale did not show significance. **Summary and Conclusions.** Expression of caspase 3 and probably also process of apoptosis correlates to proliferation index in lymphomas and might be a prognostic factor in indolent lymphomas. Prognostic factors for recurrent disease may differ from those known to be ones for first line therapy.

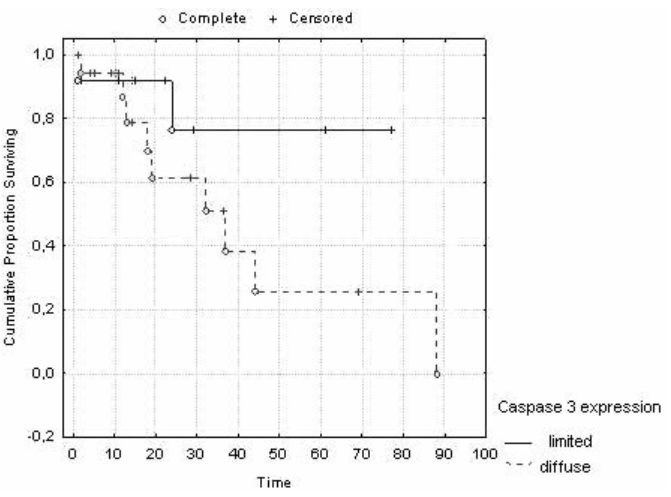

Figure 1. Cumulative proportion surviving (Kaplan-Meier).

1706

A RETROSPECTIVE REVIEW OF THE MANAGEMENT AND OUTCOMES OF ALL ELDERLY DLBCL PATIENTS DIAGNOSED OVER THE LAST FIVE YEARS AT THE NORTHERN CENTRE FOR CANCER CARE [NCCC]

E Hurst, G Jackson, G Jones, T Menne, A Lennard
Freeman Hospital, Newcastle upon Tyne, United Kingdom

Background. 40% of patients diagnosed with DLBCL are over 70 years. Elderly patients have a poorer prognosis as they have a reduced response to standard chemotherapy but more significantly struggle to tolerate treatment. Standard treatment at the NCCC for DLBCL is 21 day CHOP-R for six cycles or reduced to 3 cycles with radiotherapy in limited stage disease. Extremely elderly patients i. e. > 80 years would be given a one meter squared CHOP-R dose. **Aims.** The aim of this case series is to assess treatment tolerability by examining chemotherapy dose intensity, adverse events, inpatient days, ITU admissions and deaths during treatment. **Methods.** All patients over 70 years who have been diagnosed with DLBCL in the past five years at the NCCC have been included in the retrospective analysis. Data was collected from a review of case notes and computerized records. **Results.** 53 patients were diagnosed with DLBCL in the past five years at NCCC. This group had an average age of 77. 6 years with a broad range of disease stages [stage I 20%, stage II 29%, stage III 22% and stage IV 29%] and IPI scores [low 18%, intermediate low 33%, intermediate high 29% and high 20%]. Overall response rates to treatment were CR 68%, PR 28% and PD 5%. At an average follow up of 31. 2 months the overall survival was 47%. Chemotherapy tolerability varied widely. 41% of patients received the chemotherapy treatment as planned however, 37% required either a dose reduction or omission due to adverse events and 22% of patients died during treatment. The inpatient burden also varied with 35% of patients not being admitted at all but of the 65% who required inpatient stay the duration of admission varied to a maximum of 156 days. Overall the average inpatient days required during chemotherapy was 20. 6 days with 6% of patients requiring ITU support. G-CSF prophylaxis became standard practice in 2009, however its introduction did not significantly reduce admission rates [p=0. 3]. Neutropenic sepsis was the commonest adverse event [38%] followed by peripheral neuropathy [20%] VTE [8%] and cardiac events [6%]. **Conclusions.** This retrospective review demonstrates that elderly patients with DLBCL are a heterogeneous group. It shows that elderly patients can be treated effectively and gain long term survival however, treatment toxicity is significant. Only 41% of patients could tolerate the planned chemotherapy and 65% of patients were admitted during treatment. Improvements in treatment tolerability through improved selection of patients for curative treatment, steroid pre-phases and individualization of therapy to patient co-morbidity will be essential with an aging population.

1707

HIGH FLIPI RISK FOLLICULAR LYMPHOMA: COMBINING HISTOLOGICAL GRADE, ERYTHROCYTE SEDIMENTATION RATE AND HYPOALBUMINEMIA CAN ADDITIONALY CONTRIBUTE IN PROGNOSIS

B Andjelic, M Todorovic, D Antic, J Bila, B Mihaljevic
Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background. The widely accepted Follicular Lymphoma International Prognostic Index (FLIPI) divides patients in three risk group based on score of present unfavorable parameters (hemoglobin < 12 g/dL, age > 60 years, nodal sites > 4, elevated LDH, Ann Arbor Clinical stage 3 or 4). The estimated 5 years survival depending on FLIPI score is around 90% (0-1), 80% (2) and 50% (3-5), respectively. **Aims.** The aim of this study was to analyze the prognostic value of routinely used clinical and laboratory parameters which are not included in FLIPI index, in patients with high FLIPI risk. **Methods.** The retrospective analysis was performed on 57 patients with newly diagnosed follicular lymphoma (FL) with high risk according to FLIPI and with high tumour burden according to GELF94 criteria, diagnosed and treated at Clinic for Hematology, Clinical Center of Serbia, in the period April 2000-December 2006. In the first line, the patients were treated with R±CHOP or R±CVP. In the first relapse they were treated with fludarabine based regimens, R±FC or R±FND. The characteristics examined as possible risk factors were histological grade, bulky disease (the diameter of tumor >7 cm), ECOG performance status (ECOG PS), erythrocyte sedimentation rate (ESR) and serum albumin level. Receiver operating curve was used to determine the optimal cutoff value for ESR in prediction of overall survival for our group of patients. Survival functions were estimated using the Kaplan-Meier method and compared using the log-rank test. A multivariate analysis was performed to evaluate the potential predictive value of the examined characteristics as a risk factor. **Results.** The median follow up was 58 months (range 5-122 months). Bulky disease was present in 22 (38. 6%) patients. ECOG PS>1 on presentation had 18 (31. 6%) patients. Histological grade 1, 2 or 3a was present in 29 (50. 9%), 19 (33. 3%) and 9 (15. 8%) pts, respectively. Twenty-five patients (43. 9%) had ESR higher or equal than 45 mm/h. Serum albumin level below normal limit was observed in 28 (49. 1%). The patients with histological grade >1, ESR ≥45 mm/h and hypoalbuminemia had significantly lower overall survival (p=0. 015; p=0. 001; p=0. 008, respectively), while there was a trend toward worse overall survival in patients with ECOG > 1 (p=0. 075). Multivariate Cox regression analysis identified histological grade >1, ESR ≥45 mm/h and hypoalbuminemia as independent risk factors for poor outcome. Based on cumulative score of unfavorable prognostic factors, patients who had 0 or 1 unfavorable factors had significantly higher 5-year overall survival compared to patients with 2 or 3 risk factors (75% vs. 24. 1%, p=0. 000). **Summary and Conclusions.** Modern clinical researches are having the aim to individualize treatment approach based on risk for poor outcome. Our findings suggest that some newly diagnosed high FLIPI risk FL patients require more effective treatment, which should be defined in new prospective studies.

1708

RIT WITH 90Y-IBRITUMOMAB TIUXETAN IMPROVES THE RESPONSE IN AGGRESSIVE NON-HODGKIN LYMPHOMA

A Montes Limon, M Andrade Campos, I Murillo Flores, JM Grasa Ülrich, P Lievano, T Baringo, P Giraldo Castellanos
Hospital Universitario Miguel Servet, Saragosa, Spain

Background. Add-on standard treatment of aggressive non-Hodgkin's lymphoma (NHL) with ^{90}Y Ibritumomab tiuxetan (^{90}Y-IT) (Zevalin®) has become an efficient alternative. **Aims.** The aim of this study is to present the analyzed updated results on treatment outcome obtained from our cohort treated with ^{90}Y-IT according to current clinical practice. **Subjects and Methods.** From September 2005 to February 2012, 19 aggressive lymphoma (AL) patients treated in the same center were included in a clinical protocol conducted by a multidisciplinary team. Inclusion criteria were: CD20+ LNH Mantle Cell Lymphoma (MCL) or Diffuse Large B cell Lymphoma (DLBCL) patients with neutrophils ≥ 1. 5 x 10^9/L, platelets ≥ 100 x 10^9/L, bone marrow lymphocytes CD20+ ≤ 25%. 7 patients were treated as consolidation of a first line chemotherapy; decision to treat was made by the multidisciplinary team according to characteristics of cases. All patients received 0. 4 mCi /kg IV of ^{90}Y-IT and response was evaluated 12 weeks after by PET/CT. Endpoints: objective response rate (ORR), progression free survival (PFS), overall survival (OS) and safety. Other clinical prognostic factors were observed to assess their possible influence upon treatment value.

Table 1. Means and medians for progression free survival time.

Type of Lymphoma	Mean[a]				Median			
	Estimate	Std. Error	95% Confidence Interval		Estimate	Std. Error	95% Confidence Interval	
			Lower Bound	Upper Bound			Lower Bound	Upper Bound
MCL	27.213	4.482	18.427	35.998	27.000	7.379	12.538	41.462
DLBCL	39.000	6.062	27.118	50.882	.	.	.	.

a. Estimation is limited to the largest survival time if it is censored.

Table 2. Means and medians for overal survival time.

Type of Lymphoma	Mean[a]				Median			
	Estimate	Std. Error	95% Confidence Interval		Estimate	Std. Error	95% Confidence Interval	
			Lower Bound	Upper Bound			Lower Bound	Upper Bound
MCL	58.500	.500	57.520	59.480	58.000	.	.	.
DLCBL	33.833	7.033	20.048	47.619	.	.	.	.

a. Estimation is limited to the largest survival time if it is censored.

Results. Until February 2012, 19 AL patients had received treatment with ^{90}Y-IT; 10 MCL (52. 6%), 9 DLBCL (47. 4%), 16 completed follow-up and were taken into analysis; M/F 10/9 (73. 6%/26. 4%); mean age 66. 9 (53-79) years for MCL and 53 (35-87) years for DLBCL; ECOG 0-1 82. 35%. According IPI score distribution: 0-1: 31. 25%, >1: 69. 75%. Previous therapy schedules: 1-2 (52. 6%), >2 (47. 4%). Median follow-up time: 46. 8 months. Mean estimated OS for MCL was 67. 6 months (50-84), median OS was 62 (37-86) and mean PFS was 27 months (95% CI: 18. 42-35. 99). For DLBCL mean OS was 85 months (53. 37-118. 45), median OS was 84 months (46. 44-121. 55), mean PFS was 39 months (95% CI: 27. 11-50. 88). Status before treatment was: relapsed but Complete Response (CR) after chemotherapy: 2 patients for MCL and 6 DLBCL;

relapse and refractory with active disease after chemotherapy (PR): 2 MCL and 1 DLBCL and as consolidation after first-line chemotherapy in CR: 4 MCL cases and 3 DLBC cases. 13 patients achieved CR, 8 MCL and 5 DLBCL; 2 MCL patients and 1 DLBCL only achieved PR/stabilization of the disease. Until now only 6 (40%) patients have relapsed, 4 MCL (27%). Mortality related to relapse was reported in only one MCL case that relapsed 15 months after treatment and died 3 years later. Safety: thrombocytopenia was the most frequent (42. 1%) hematological toxicity, median time to 2. 8 weeks, grade 3-4 only occurred in 21% of patients; neutropenia occurred in 31. 5%, and the median time for recovery was 3 and 2 weeks respectively. In 2 patients (10. 52%) red cell transfusion was required and 4 (21. 5%) needed platelet transfusion. The most frequent non hematological toxicity was asthenia. None secondary malignancies have been observed. **Conclusions.** In our experience ^{90}Y Ibritumomab tiuxetan (Zevalin®) is a safe and effective consolidation therapy in aggressive NHL, permitting achievement of sustained CR and prolonging PFS. Further studies on the impact of outcomes in this population are needed.

1709

LATE-ONSET NEUTROPENIA AFTER RITUXIMAB TREATMENT IN B-CELL LYMPHOMA: A SINGLE CENTRE EXPERIENCE

T Perrone[1], F Gaudio[1], S Scardino[1], A Mastrorosa[1], A Spina[1], F Laddaga[1], G Ingravallo[2], A Cimmino[2], G Specchia[1]
[1]Hematology University of Bari, Bari, Italy
[2]Pathology University of Bari, Bari, Italy

Background. Recent studies have reported the occurrence of late onset neutropenia (LON) in 3%-27% of patients (pts) treated with Rituximab-based therapies. LON is defined as grade 3-4 neutropenia developing several weeks after Rituximab infusion; the aetiology is not completely understood. Several hypotheses have been proposed to explain this occurrence: infections, the production of antineutrophil antibodies, expansion of large granular lymphocyte (LGL) populations that may induce neutrophil apoptosis through Fas and Fas-ligand interactions. According to anther hypothesis, the interaction between B-cell recovery and stroma-derived factor-1 (SDF-1) inhibits neutrophil egress from the bone marrow. Immunoglobulin G Fc receptor polymorphism has also been suggested in the aetiology of LON. In addition, purine analogues, high dose therapy, AIDS are considered to increase the risk of LON. **Aims.** The aim of our study was to evaluate the incidence and clinical relevance of WHO grade 3/4 LON in pts treated with Rituximab-based therapy. **Methods.** We examined 238 B-cell lymphoma pts treated with Rituximab in our institution between 2008 and 2011; 124 (53%) of them had an indolent lymphoma. In9 pts(4%) the neutrophil count fell below 0. 5 x 10e9/L a few weeks after the last Rituximab infusion. Pts median age was 63 years (range 19-92). Histology was Follicular Lymphoma in 3 cases (33%), Marginal Zone lymphoma in 3 (33%), SLL in 2 (23%) and DLBCL in 1 (11%). Seven (78%) pts had bone marrow involvement. Four pts(44%) developed LON after first line therapy that was RCHOP in 3 (33%) and RFC in 1 (11%); 5 (55%) pts, in relapse, had received previous chemotherapy (containing fludarabine in three cases, 60%) when LON occurred. **Results.** LON appeared after a median of 103 days (range 40-140) from the last Rituximab infusion and median duration was 57 (14-236) days. When LON occurred 7 (78%) pts were EBV positive with high IgG levels, while no viral reactivation or autoimmune disorder was documented. Bone marrow examination revealed hypocellularity and maturation arrest of the myeloid series in 7 (78%) cases and normal cellularity in 2 (23%). Four pts (44%) had decreased immunoglobulin concentrations. Only 2 (23%) episodes of pulmonary pseudomonas infection were documented during the neutropenia period. Three pts (33%) had fever. All pts received corticosteroids and5 pts(55%) had GCSF treatment, but the clinical course of LON was not affected by these treatments, being always self-limiting with complete resolution of marrow impairment. **Conclusions.** In our experience an indolent histology, bone marrow involvement and high EBV IgG levels seem to be related to the onset of delayed neutropenia. A transitory myelosuppressive effect of Rituximab could have a role in the pathogenesis of LON in our cohort of pts. The treatment of LON is not well defined. A watchful waiting approach is appropriate in the majority of patients. Further biological and prospective studies are needed to better clarify the pathogenesis, clinical impact and treatment of LON.

1710

THERAPY FOR THE PATIENTS WITH DIFFUSE B-CELLS LYMPHOMA(DBCL) ASSOCIATED WITH CHRONIC HEPATITIS C (HCV)

S Lepkov[1], O Kolomeytsev[2], S Lepkov[1], I Subortseva[3], A Kovrigina[4], A Chekan[2], T Kondratieva[2], G Tumyn[2], S Kosura[1], O Ettinger[1], P Zeynalova[2], G Storozhakov[1], M Sinicina[4]
[1]Moscow Medical University by N. I. Pirogov, Moscow, Russian Federation
[2]Cancer Research Center by N. N. Blochina, Moscow, Russian Federation
[3]MAPGE MHR, Moscow, Russian Federation
[4]Hematology Scientific Center, Moscow, Russian Federation

The relationship between lymphoproliferative disorders and infectious agents has been studied for many decades. Epidemiological studies have linked hepatitis C virus (HCV) infection to B-cell non Hodgkin's Lymphomas (B-NHL). According the data of WHO classification in 2008 HCV infection takes part in etiopathogenesis diffuse B-cells lymphomas and those tumors may be virus associated. In a large pooled analysis of combined data from several countries, demonstrated that presence of HCV infection was linked not only to marginal zone lymphoma, considered an indolent course B-NHL, but also to diffuse large B-cell lymphoma (DLBCL), a high-grade B-NHLIn CRC by N. N Blokhina in the period 2000-2011 we observed 556 patients with NHL with diagnosed lymphoma were also surveyed of chronic viral infection. DBCL has been diagnosed in 296 patient, of them in 88 patients HCV was determined by polymerase chain method in blood. Serum level HCV RNA was from negative to 5x10^5 c/ml. Of those 88 patients in 24 patients the disease was diagnosed in I-II stage, in 64 - в III-IV stage. The age of the patients varied from 16 y. o. to 76 y. o, the median was 47 y. o. The correlation between male and female was 2:1. Before therapy 57 patients had ALT to be over normal. Mediana was 3. 1 normal. Among those 88 pts in 56 pts have GCB immunohistochemistry type and 32 pts - was non-GCB type. All 88 patients were treated by immunochemotherapy R-CHOP. In pts GCB group complete remission(CR) was reached in 31(56%) pts, 15(27%) developed partial remission(PR) and 10 pts without effect. Median follow up CR was 28 months, PR- 14months. In pts non-GCB group complete remission(CR) was reached in 15(47%) pts, 10(31%) developed partial remission(PR) and 7 pts without effect. Median follow up CR was 14 months,PR-5 months. During immunochemotherapy serum level HCV RNA has increased at 51 of 88 pts. Median increased level RNA and ALT was after 4. 5 course R-CHOP. Level ALT was from 2 to 50 norm, median- 7. 5 norms. The treatment was stopped at 13 pts because of hepatic toxicity. **Conclusions.** Without initial liver dysfunction, HCV-infected pts with DLBCL can experience a similar outcome compared to their HCV-negative counterparts when treated with standard chemotherapy/immunotherapy despite differences in the presentation of the disease. A significant proportion of patients with HCV + DLBCL develop liver toxicity often leading to interruption of treatment.

1711

IS INTENSIVE CHEMOTHERAPY ASSOCIATED WITH SUPERIOR OUTCOME IN PERIPHERAL T-CELL LYMPHOMA NOS AND ALK-VE ANAPLASTIC LARGE CELL LYMPHOMA?

A Lawrie[1], E Tighe[2], J Culligan[2]
[1]University of Aberdeen, Aberdeen, United Kingdom
[2]NHS Grampian, Aberdeen, United Kingdom

Background. The mature T cell lymphomas are an uncommon and heterogeneous group of disease entities. They account for approximately 10% of all lymphoid malignancy and generally carry a poor prognosis. Peripheral T cell lymphoma not otherwise specified (PTCLNOS) is the commonest form of mature T cell lymphoma, accounting for approximately half of all cases. A number of studies have attempted to evaluate the value of treatment intensification, but no firm conclusion has been reached. For over a decade our centre has favoured an aggressive approach for newly diagnosed patients with PTCLNOS, usually consisting of several cycles of salvage type intensive chemotherapy followed by high-dose chemotherapy (BEAM) with autologous stem cell rescue delivered in first response, if the patient is deemed fit enough. A similar approach is adopted for patients presenting with anaplastic large cell lymphoma, ALK-1 negative (ALCL). **Aim.** To determine whether intensive chemotherapy is associated with superior outcome in peripheral T-cell lymphoma (not otherwise specified) and ALK1 negative anaplastic large cell lymphoma. **Methods.** Laboratory records, multidisciplinary team meeting notes and local cancer audit records were searched to identify cases between 1999 and 2011. Where available, case notes were reviewed to confirm eligibility, and gather clinicopathological data and information on clinical outcome and treatment toxicity. Survival analyses were performed using Kaplan-Meier curves and compared using log-rank testing. **Results.** Data was available on 31

patients, of whom 29 had received treatment. 11/ 29 (37. 9%) patients were treated intensively. 12/21 patients with PTCLNOS had a response to treatment (CR or PR), while 5/8 patients with ALCL responded. The overall response rate was 58. 6% (17/29). The median duration of follow-up was 11 months (range 0. 1 to 168 months). There was a trend towards improved overall survival in patients receiving intensive chemotherapy compared with non-intensive (median 49 months vs 6 months), however this was not statistically significant (Figure 1). A trend towards longer progression-free survival in patients achieving a response was also seen with intensive treatment. The international prognostic index was strongly predictive of overall survival (median survival 57 vs 3 months, p<0. 0001). Patients with limited stage disease had significantly longer survival than those with advanced stage disease (57 vs 5 months, p<0. 05). Similarly, elevated LDH, bone marrow involvement and the presence of B symptoms were all predictive of shorter overall survival. There was no significant difference in survival between patients diagnosed with ALCL and PTCLNOS. **Summary.** In this small, single-centre, retrospective study we do not show any significant differences in clinical outcome in patients with PTCLNOS or ALCL with relation to treatment intensity. We chose to exclude all other forms of T-cell lymphoma except PTCLNOS and ALK1-negative ALCL to achieve homogeneity. Nevertheless, the low numbers of patients identified limit the power of this study and this has been a common theme in previous studies. Furthermore, the retrospective approach clearly introduces bias. We intend to expand this study nationally in order to increase statistical power, but there remains insufficient evidence to conclude that intensive treatment is superior in this setting.

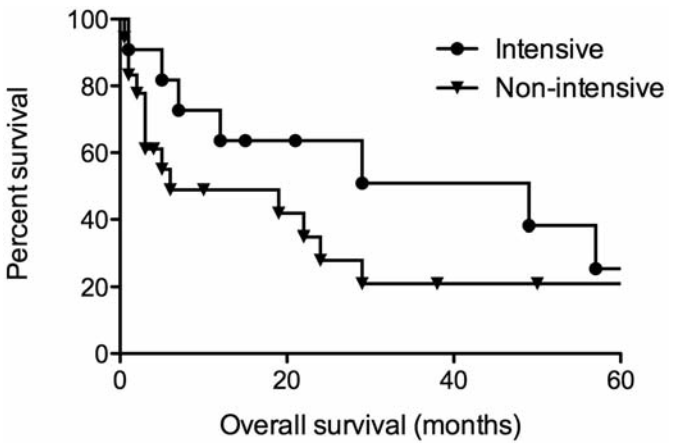

Figure 1. Overall survival by treatment intensity.

1712

CD5-POSITIVE SPLENIC MARGINAL ZONE LYMPHOMA

H Julhakyan[1], A Magomedova[2], I Kaplanskaya[2], R Samoylova[2], V Ryjko[3], T Obukhova[1], S Kravchenko[2]
[1]Hematological Scientific Center, Moscow, Russian Federation
[2]Hematological Research Center, Moscow, Russian Federation
[3]Hematological Resaesrch Center, Moscow, Russian Federation

Background. Splenic marginal zone lymphoma (SMZL) is a well recognized B-cell neoplasm which characterized by splenomegaly, bone marrow involvement, immunologically by typical phenotype of marginal zone cells. In rare cases there were CD5-positive variants of disease. **Aims.** The aim of our study was to investigate the characteristics of a CD5-positive SMZL. **Materials and Methods.** The study included 6 patients (5 men and 1 woman), who were observed in Hematological ResearchCenter (Moscow,Russia), from January 2000 to February2012. In all cases the diagnosis of SMZL was based on immunophenotyping of peripheral blood lymphocytes and hystochemistry of bone marrow. Immunophenotypic analysis has shown the expression of mature B-cells antigens (CD19, CD20, CD22, FMC7, sIg) and absence of CD10, CD23, CD43, CyclinD1. In all cases, there was coexpression of antigens CD5/CD19. The average age of patients was 61. 5 years (range 46 to 86 years). At the time of diagnosis were recorded B-symptoms, massive or giant splenomegaly. In neither case is not marked peripheral and visceral lymphadenopathy. M-component is not detected in any case. In the peripheral blood of all patients had varying degrees of severity of the three sprout cytopenia. Histological examination of bone marrow revealed involvement by lymphoma. Given the coexpression of antigens CD5/CD19, with the differential diagnosis of cytogenetic study carried out by FISH to detect the translocation t(11;14)(q13;q32). Also there was performed a molecular study by PCR to identify overexpression of CyclinD1. In neither case was not detected t(11;14)(q13;q32) and overexpression of CyclinD1. All patients were given abdominal discomfort and cytopenic syndrome performed splenectomy. **Results.** After splenectomy, all patients had marked clinical and hematological stabilization, which manifested as the disappearance of B symptoms, normalization of peripheral blood count and LDH. All patients are alive. Mean follow-up 68. 7 months. (32-112 months). **Conclusions.** Classically SMZL characterized by the absence of expression of antigen CD5. CD5-positive lymphomas in the literature respond poorly to various treatments and the expression of CD5 antigen is considered as a marker of aggressive disease course. In our study, because of the small number of patients on the prognostic significance of the findings are not possible, though, after splenectomy, all patients had long-term clinical and hematological improvement.

1713

FEASIBILITY OF ANTHRACYCLINE BASED TREATMENT IN UNSELECTED ELDERLY DLBCL PATIENTS

T Melchardt, L Weiss, C Hufnagl, D Neureiter, R Kemmerling, G Hopfinger, R Greil, A Egle
Salzburg University Hospital, Salzburg, Austria

Background. Diffuse large B cell lymphoma (DLBCL) is one of the most common Non-Hodgkin Lymphoma (NHL) and comprises about 20% of all newly diagnosed lymphoid neoplasms. The mean age at diagnosis is 65 years in the Caucasian population and therefore a substantial proportion of patients comprises elderly people > 75 years. Nevertheless, this population is underrepresented in almost all clinical trials of DLBCL and treatment related toxicity mainly due to anthracycline treatment is a major concern. New regimens or attenuated schedules of anthracyline based chemotherapy may be an option in elderly patients. However, substantial evidence is available that anthracyclines are of significant importance in the treatment. Therefore, several concepts e. g. Charlson index of comorbidity (CI) are under investigation to define factors guiding the management of elderly DLBCL patients. **Methods.** We retrospectively analyzed and characterized 83 consecutively diagnosed patients > 75 years with aggressive B-cell lymphoma (78 cases of DLBCL and 5 cases of follicular lymphoma grade 3) from January 2003 until January 2012 treated at our tertiary cancer center by chart-based review. **Results.** 84% of the patients were treated with an anthracycline, 88% were treated with rituximab and overall 82% of the patients received a combination of anthracycline and rituximab based therapy. The median overall survival (OS) in all patients regardless of treatment was 43 months. Patients treated with an anthracycline and rituximab had a better median OS than patients not eligible for this combination (54 vs 6 months p< 0. 0001). Patients deemed not eligible for combination therapy were significant older, had a worse ECOG status and a higher CI. The cohort of patients treated with an anthracycline and rituximab had a median age of 79 years and 57% (39/68) were > 80 years and 50% had a CI > 1. In this group there was no significant difference in the median OS in patients <80 or >80 years old (49 vs 54 months). Patients with a serum albumin level > 3,5g/dl had a trend to a better OS (59 vs 27 months p=0. 11), but β2-microglobulin levels < 3mg/l could significantly predict a better OS (69 vs 30 months p=0. 019). 68% of the patients received > 5 cycles of therapy with a median cumulative anthracycline dose of 256 mg/m^2. Since 2007 liposomal doxorubicine was available at our department, 70% of 44 patients eligible for an anthracycline treatment received this new formulation because of suggested lower toxicity. Despite significant older age, a significant worse ECOG status and a trend to a higher CI in patients treated with liposomal doxorubicine there was no difference in the median OS compared to patients receiving conventional doxorubicine. **Conclusions.** Considering the OS data of our unselected cohort we think that all patients with DLBCL should be offered curative immunochemotherapy with the goal of a full dosed anthracycline regimen regardless of age. Only the small proportion of patients with severe comorbidities should be excluded from this approach. The prospective use of comorbidity indices or maybe also markers of pharmacogenetics may better inform our choices in the future.

1714

PRIMARY NON-HODGKIN LYMPHOMA OF THE FEMALE GENITAL TRACT: CLINICAL Results OF A RETROSPECTIVE ANALYSIS OF SINGLE INSTITUTION

A Gardellini, P Bertazzoni, F Gigli, D Laszlo, A Vanazzi, R Pastano, L Calabrese, SJ Liptrott, C Grossi, G Martinelli
European Institute of Oncology, Milan, Italy

Background. Primary extranodal lymphomas of the female genital tract account only for 1. 5% of all non-Hodgkin lymphomas (NHL). The most common subtype is the diffuse large B-Cell lymphoma (DLBCL) more often affect-

ing uterus. A few series have been reported referring to a single or few cases collected in the review of Lagoo et al. There is no widely accepted consensus on the incidence, diagnostic procedure modality, treatment and prognosis. **Aims.** A retrospective analysis has been performed collecting data on patients with female genital tract NHL, to verify the incidence, response to treatment and overall survival. **Methods.** The study population consisted of all female patients (22) with NHL of genital tract treated in our Institute during the period 2000-2009. All patients gave written informed consent. Response has been evaluated according to Cheeson criteria 2007. **Results.** Median age was 52 years (31-79). Sixteen patients presented a diagnosis of DLBCL while 6 patients presented an indolent lymphoma: 4 extranodal marginal zone-B cell lymphoma (MZL), and 2 follicular lymphoma. In 12 out of 22 patients (55%) the uterus was involved as primary site or with other genital organs: 10 patients presented DLBCL, and 2 MZL. Thirteen patients presented Ann Arbor stage I-II (5 presented bulky disease), while 9 presented stage III-IV (3 patients with bulky disease). Five patients presented B symptoms at the moment of diagnosis: night sweats in all cases and, in one case also weight loss. Five patients presented also pelvic pain and/or bleeding. Patients with DLBCL any site received R-CHOP or R-CHOP like regimen for a maximum of 6 cycles; 14 out of 16 patients achieved CR. Two patients relapsed and died for progression disease. Two additional patients in PR received a second line of chemotherapy (including autologous transplantation) obtained a persistent CR. With a median follow-up of 3 years (0. 9-15. 34) 87% of patients are alive and disease free with a median PFS and OS not reached. Within the 6 patients with low grade lymphoma (4 MZL and 2 follicular) 4 were treated as first line with chlorambucil (plus Rituximab in two cases), 1 patient with R-CHOP and the other one with R-CEOP regimen. Five out of 6 patients obtained a CR and only one patient a stable disease with an ORR of 83%. **Conclusions.** Our retrospective study confirms that the most frequent histology of primary extranodal lymphoma of the female genital tract is the DLBCL and the most frequent organ involved is the uterus. However, the incidence of MZL is not negligible: in our experience they represent approximately 20% of all malignant lymphoma. Outcome of patients with high grade lymphoma of female genital tract receiving antracycline containing regimen in combination with rituximab seems to be very favorable since about 80% of them is still alive and free of disease with a median of three years of follow-up. A large retrospective analysis on female genital tract lymphoma is ongoing on behalf of IELSG with the aim to collect a large number of patient providing sufficient information on clinical behavior on such uncommon disease.

1715

RITUXIMAB AS MAINTENANCE TREATMENT IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMAS (DLBCL). A SINGLE CENTER EXPERIENCE

N Giannakoulas[1], M Befani[2], M Palassopoulou[2], E Bouronikou[2], P Zikos[3], K Zisaki[2], D Nasi[2], V Papadopoulos[2], E Perdikouri[2], G Vassilopoulos[2], P Matsouka[2]

[1]University Hospital of Larissa, Larissa, Greece

[2]Hematology Department, University Hospital of Larissa, Larissa, Greece

[3]Hematology Division, General Hospital Ag. Andreas,, Patras, Greece

Background. The addition of Rituximab in CHOP like first line treatment in DLBCL has significantly improved the progression free survival and in some studies the overall survival of patients of any age. The role of Rituximab as a maintenance treatment in aggressive lymphomas after the achievement of complete response remains under investigation. **Aims.** The aim of our study was the assessment of the role of maintenance treatment with Rituximab in patients with aggressive lymphomas after the achievement of complete response with R-CHOP like regimens. **Methods.** Fifty patients (28 male, 22 female, median age 69, range 17-88) with aggressive B cell lymphomas (45 patients with DLBCL,2 pts with primary mediastinal lymphoma, 2 patients with mantle cell lymphoma and 1 with follicular grade 3) received maintenance therapy with Rituximab after the completion of chemotherapy and the achievement of complete remission. The lymphoma was nodal in 29 cases and extranodal in 21 cases. The IPI was low in29 pts, low-inter in14 pts, inter-high in6 pts and high in 1 patient. Adjuvant radiotherapy was given to9 pts, mainly to extranodal sites of lymphoma involvement. 1st line treatment was R-CHOP (median number of cycles 6, range 3-6) in 46 patients, R-CVP in3 pts and MACOP-B in 2 patients with primary mediastinal lymphoma. The vast majority of the patients received maintenance with Rituximab (375 mg/m2 every 3 months for one year) with median time of initiation 1. 8 months after confirmation of remission. The median number of Rituximab cycles was 4 (range 2-8). **Results.** After a follow up of 34 months (range 30-38 mo) 49 out of 50 patients are alive. The 3-year probability of survival is 98%. Eight patients relapsed (7 within the first year after remission). The probability of relapse is 22. 7% for the whole group of patients. Factors that affect the probability of relapse in multivariate analysis were the histologic type (DLBCL vs others) and the serum albumin while hemoglobin and b2 microglobulin were of marginal significance. Age, sex, IPI, performance status, serum LDH, and nodal or extranodal involvement were not significant parameters in univariate and multivariate analysis. **Conclusions.** Our cohort of patients with aggressive lymphomas who received maintenance therapy with Rituximab after remission showed marginally increase in progression free survival in comparison with previous studies. It is apparent that well organized randomized studies are needed in order to clarify the advantage of maintenance therapy with Rituximab in patients with aggressive lymphomas who receive R-CHOP like regimen as standard 1st line therapy.

1716

EFECTIVITY AND SAFETY OF BENDAMUSTINE-RITUXIMAB IN AGED PATIENTS WITH RELAPSED OR REFRACTORY LYMPHOMA

A Cánovas, G Barreiro, JJ Alonso

Hospital Universitario de Cruces, Bilbao, Spain

Background. Bendamustine is a drug with alkylating and antimetabolite properties, with proved activity in relapsed or refractory indolent lymphomas in association with Rituximab. Because of its only moderate toxicity can be safely applied in elderly patients. **Aims.** We present our experience on treating relapsed or refractory low-grade lymphomas and mantle cell lymphomas with the combination of bendamustine and rituximab (BR). **Patients and Methods.** Prospective and observational study of all consecutive patients with relapsed or refractory low-grade lymphoma or mantle cell lymphoma treated with BR since April the 24th 2008 to January 31st 2012. Informed consent was obtained in every patient. Modified Cheson criteria (2007) were used to assess response. Adverse effects were classified using the WHO toxicity criteria. Bendamustine (90mg/m2 daily) was administered the first and second days of each cycle. Rituximab (375mg/m2) was administered a week before the first cycle, the first day of every cycle and four weeks after the last one. Cycles were administered every four weeks to a maximum of six. Patients were evaluable for response if they have received at least two cycles of BR. **Statistical Methods.** Student t, Fisher exact test, Kaplan-Meier tables, log-rank test, Cox multivariate binary logistic and proportional hazard regression. **Results.** Twenty patients were included, 10 females. Mean age: 70 years (44-85); 55% of them were older than 70 years. Diagnosis was follicular lymphoma (FL) in twelve patients, mantle cell lymphoma (MCL) in three, small cell lymphocytic lymphoma (SCLL) in two, lymphoplasmacytic lymphoma (LPL) in two and MALT lymphoma in one. Seventeen patients had relapsed disease and three were refractory to previous treatment schedules. Mean time from diagnosis was 5,5 years (2,6-13,3). Mean number of previous therapies was 3 (1-5), and two patients (one FL and one MCL) have undergone an ASCT. The median number of cycles administered was 4 (mean 4,3; 1-6). Complete response (CR) was achieved in 14 patients (70%) and partial response in 2 (10%). Three patients (15%) showed no response and one was not assessable. None of prognostic variables analyzed (age, sex, functional status, lymphoma type, number of previous treatment and time from diagnosis) was significantly associated with response or toxicity. The median time to treatment failure (TTF) was 19,2months. Median survival (SV) from the BR treatment onset was 25 months (median observation of live patient: 14,4 months). We analyzed prognostic variables in relation to TTF and SV and none was significant. Adverse events were grade 3 or 4 neutropenia in seven patients (35%) and grade 3 or 4 thrombocytopenia in four (20%). An episode of febrile neutropenia and another of coagulase negative staphylococcus bacteriemia associated with indwelling catheter were reported. There was one hepatitis C reactivation. **Summary and Conclusions.** Treatment with BR was effective in a high percentage of our patients with relapsed or refractory low-grade lymphoma. Of note, tolerability and safety were good and the probalility of response and its durability was independent of age. This results confirm the effectiveness of B/R in elderly patients

1717

SURVIVAL AND CLINICAL CHARACTERISTICS OF CHILDHOOD ANAPLASTIC LARGE CELL LYMPHOMA, SINGLE CENTRE EXPERIENCE

M Kourti[1], V Sidi[2], V Hatzidimitriou[3], I Fragkandrea[4], E Papakonstantinou[2], D Koliouskas[2]

[1]Hippokration General Hospital, Thessaloniki, Greece

[2]Pediatric Oncology Department, Hippokration General Hospital, Thessaloniki, Greece

[3]1st Pediatric Department, Aristotle University of Thessaloniki, Thessaloniki, Greece

[4]Radiotherapy Department, Royal Marsden Hospital, London, United Kingdom

Background. Anaplastic large cell lymphoma (ALCL) is a rare disease in children accounting for 10% to 15% of all childhood non-Hodgkin lymphomas

whose diagnosis and treatment have largely evolved since its initial description in 1985. ALCL is characterized by the proliferation of large pleiomorphic cells of a T/null phenotype that tend to invade the lymph node sinuses and express the Ki1/CD30 antigen. **Aims.** Aim of this study is to report the clinical manifestation and therapy outcome in a cohort of children diagnosed with ALCL and treated in our Department. **Patients and Methods.** We retrospectively reviewed our experience in the field, and report our single institution experience in a series of 8 children diagnosed with ALCL and treated in our Department from January 1995 until December 2010. **Results.** The median age was 6 (range 4-12), 7 male and 1 female, including two children with null phenotype. Lymph nodes were involved in 57% (4/7) of patients. Extranodal disease was found in 43% of the cases, including visceral involvement in 57% (4/7) and bone lesions in 14%. Bone marrow and CNS disease were not encountered. ALK abnormalities were evaluated in 3 patients by assay for the t(2;5)(p23;q35) translocation by RT-PCR and were all found positive. One patient (6%) was stage I by St Jude classification, 3 patients stage II and 4 stage III. Therapeutic strategy included short pulse NHL-BFM90 in 2 patients and HN 97 (MRC) in 5 patients. The patient with bone lesion received chemotherapy according to HN97 and local irradiation, and autologous stem cell transplantation. All patients are alive and disease-free. The median follow-up of the whole population is 10. 7 years and the maximum 14 years. **Conclusions.** Although the optimal treatment is still unknown, current treatment regimens are highly efficacious. Nevertheless, in the future treatment strategies should focus on the refinement of the balance between treatment burden and individual patient risk for failure.

1718

CHARACTERISTICS OF THE PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME COMPLICATED WITH LYMPHOMA: A SINGLE CENTER EXPERIENCE

T Niu, YQ Li, QM Yu, J Li, JR Yang
West China Hospital, Chengdu,Sichuan, China

Objective. The present study was aimed to improve the understanding of diagnosis and treatment of patients with primary Sjögren's syndrome (pSS) complicated with lymphoma by investigating the clinical characteristics,treatment and prognosis. **Methods.** The data of clinical features, laboratory findings, therapeutic response and follow-up of patients with primary Sjögren's syndrome complicated with lymphoma from January 2006 to January 2011 in our single center were retrospectively analyzed. **Results.** Totally twelve inpatients with pSS complicated with lymphoma were diagnosed, who accounted for 1. 29% of newly-diagnosed lymphoma inpatients during the same period. The main pSS manifestations were xerostomia (n=12), xerophthalmia (n=12) and parotidomegaly(n=6). The characteristic serologic changes were hyperimmunoglobulinemia (n=10), hypocomplementemia (n=7) and decrease of CD_4 T cell number (n=4). The main lymphoma manifestations were lymphadenectasis (n=10) and splenomegaly (n=6). In our study, non-Hodgkin's lymphoma (NHL) was the most common type, accounting for about 91. 7% (11/12) and Hodgkin's lymphoma (HL) accounted for about 8. 3% (1/12). The main pathological subtype was diffuse large B cell lymphoma (DLBCL) (n=5). Extranodal involvement (ten patients) was common, most frequently in the livers (n=3) and the lungs (n=3). About 83. 3% (10/12) patients were in advanced stages, Ann Arbor stage III-IV, at diagnosis. All patients received treatment with combination chemotherapy regimens. Most of the NHL patients received CHOP-like regimens, and the HL patient received AVD regimen. After a median follow-up of 22 months (range 2-54 months), overall survival was 9/10. Except two patients were lost follow-up, two patients was in CR (complete response), four were in PR (partial response), three were in PD (progressive disease) and one patient died from infection during the treatment. Correlation between serum complement level and prognosis of 12 patients with pSS complicated with lymphoma showed that lower C3 and C4 levels presented with poor prognosis. **Conclusions.** The patients with pSS complicated with lymphoma were not rare clinically. It was characterized for these patients by typical serological changes, such as hyperimmunoglobulinemia, hypocomplementemia and decrease of CD_4 T cell number, NHL as the major pathological type, higher frequency of extranodal involvement, advanced stages at diagnosis and expected unfavorable prognosis.

1719

A COLLABORATIVE NATIONWIDE LYMPHOMA STUDY IN LEBANON: INCIDENCE OF VARIOUS SUBTYPES AND ANALYSIS OF ASSOCIATIONS WITH VIRUSES

Z Otrock[1], J Saab[1], G Aftimos[2], F Nasr[3], F Farhat[4], S Khairallah[2], G Abadjian[3], M Ghosn[3], H Sidani[5], A Ibrahim[5], A Tawil[1], C Ghorra[3], Z Meguerian[6], W Mokaddem[7], W Dayeh[4], Z Salem[1], G Chahine[3], N Bitar[8], A Mugharbel[5], J Makdessi[6], C Khater[9], M El Hajj[6], D Abi Gerges[10], C Sfeir[6], J Kattan[3], K Ibrahim[4], M Saade[11], H Sadek[12], R Mahfouz[1], M Kharfan-Dabaja[1], G Zaatari[1], A Bazarbachi[1]

[9]Trad Hospital, Beirut, Lebanon
[10]Middle East Institute of Health, Beirut, Lebanon
[11]Rizk Hospital, Beirut, Lebanon
[12]Bekaa General Hospital, Bekaa, Lebanon

Background. Incidence of various Hodgkin (HL) and non-Hodgkin lymphoma (NHL) subtypes and association with viruses in Lebanon are not known. **Aims.** We have conducted a prospective study that assessed the incidence of lymphoma subtypes and evaluated possible associations with various viruses in adult patients with newly diagnosed lymphomas in Lebanon. **Methods.** This is a nationwide study that included 272 adult patients (138 males, 134 females; ≥18 years) diagnosed with various subtypes of lymphoma in Lebanon in 2007. Clinical and pathology data was collected in a data sheet form which comprised available pathology material for each subject which was reviewed according to the 2001 World Health Organization (WHO) classification system by a panel of expert pathologists. Peripheral blood was withdrawn for serology testing for the following viruses: HCV, HIV, EBV, and HTLV-I. **Results.** HL comprised 32. 7% (n=89) of cases while NHL represented 67. 3% (n=183). Consistent with the published literature, nodular sclerosis was the most predominant HL subtype (n=57/89). Among NHL, B-cell NHL represented 88% (n=161/183) while T-cell NHL represented 9% (n=17/183) whereas in 2. 7% (n=5/183) it was not classifiable. The B-cell NHL comprised predominantly diffuse large B cell lymphoma (74 cases; 46%), and follicular lymphoma (37 cases; 23%) (Figure 1).

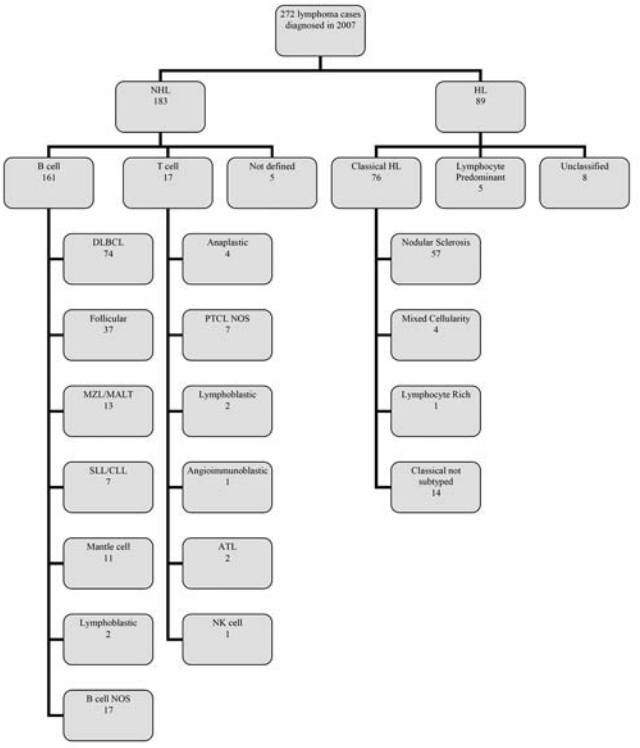

Figure 1. Distribution of the 272 lymphoma cases by subtypes.

Pathology review of 81 cases showed 87. 6% concordance rate. Serology was negative for HCV in 122 tested cases. HIV was positive in 2 cases (1 NHL, 1 HL). Two adult T cell leukemia/lymphoma were HTLV-I positive. EBV IgG were positive in 108/122 (88. 5%) cases (69/79 NHL, 39/43 HL). Also, 38 EBV seropositive cases [27 NHL (24 B-cell type and 3 T-cell type) and 11 HL] were studied for EBV genome expression using EBV-encoded RNA (EBER)-*in situ* hybridization. EBER expression was positive in 8 (21%) cases, of which 6 were HL and 2 were T-cell NHL. **Conclusions.** The distribution of lymphoma subtypes in Lebanon appears similar to that of Western countries. The observed diagnostic concordance rate of 87. 6% is particularly noteworthy and provides a sense of assurance regarding the quality of pathological readings. The high rate of EBV positivity in HL and T-cell lymphoma by EBER is noteworthy and deserves further investigation.

1720

PROGNOSTIC IMPACT OF SERUM VITAMIN D CONCENTRATION LEVEL IN PATIENTS WITH LYMPHOID MALIGNANCIES

S Aref[1], L Ebrahim[2], E Azmy[3]
[1]Mansoura University, M3011ansoura, Egypt
[2]Hematology Unit, Clinical Pathology Department,Mansoura Faculty of Medicine, Mansoura, Egypt
[3]Clinical Hematology Unit, Mansoura Faculty of Medicine, Mansoura, Egypt

The incidence of lymphoid malignancies has been increasing rapidly. Despite growing evidence for a relationship between serum vitamin D level and solid tumor risk, far less is known about the relationship between vitamin D and the risk of hematologic malignancy. This study aimed to assess the prognostic relevance of serum Vit D level in patients with certain types of lymphoid malignancies. The study was carried out on 75 B-CLL and 120 NHL patients as well as 10 normal healthy controls. For all patients and normal controls serum Vit D were assayed by ELISA. Serum Vit D concentrations level was significantly decreased in both B-CLL and NHL patients as compared to matched controls (P =0. 000*). In B-CLL patients serum Vit concentrations level was significantly negatively correlated with other prognostic factors (CD 38%) (r = -0. 630, P = 0. 001*), ZAP 70% (r = -0. 603, P= 0. 001) and Binet staging (r = -0. 874, P = 0. 000). More over, in NHL patients serum Vit D concentrations was significantly negatively correlated with performance status (r = -0. 373, P= 0. 04), IPI (r = -0. 413, P = 0. 02) but insignificantly correlated with staging (r=-0. 281, P = 0. 132). B-CLL and NHL patients with seriously deficient serum Vit D level concentrations had significantly shortened life span (P =. 0000*). So, serious Vit D insufficiency represents significant poor prognostic factor in B-CLL and NHL patients.

EPIDEMIOLOGICAL DATA OF VENEZUELAN PATIENTS WITH LYMPHOMA. IMPROVEMENT OF THE OUTCOME OF FOLLICULAR LYMPHOMA (FL) AND DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) WITH R-CHOP VS CHOP

A Müller[1], M Morales[1], G Acquatella[1], M Torres[1], C Reboso[1], E Tovar[1], D Chiquin[1], M Villegas[1], A Soyano[2], M Guevara[1], N Noriega[1], N Croce[3], L Capote[4]
[1]Instituto de Oncología y Hematología, Caracas, Venezuela
[2]Venezuelan Institute for Scientific Research (IVIC), Caracas, Venezuela
[3]Escuela de Salud Pública (UCV), Caracas, Venezuela
[4]MPPS, Caracas, Venezuela

Background. Lymphomas are among the most frequent hematological neoplasias in Venezuela. **Aims.** To evaluate epidemiological data of lymphoma patients treated at the Oncology-Hematology Institute and other Public and Private Clinics in Caracas, Venezuela, during the last 14 years and to compare the efficacy of the treatment R-CHOP vs CHOP in FL and DLBCL. **Methods.** Diagnosis was established by lymph node biopsies, histopathology and immunohistochemistry, complemented with X rays and TACs. **Results.** Out of 1812 lymphoma patients, 1214 were diagnosed as non-Hodgkin lymphoma (NHL, 65. 1%), 598 as Hodgkin Lymphoma (HL, 34. 9%). Subtypes of HL: Nodular Sclerosis (244; 129 female, 115 male; average age 32. 4 years-old (18-65), Mixed Cellularity (109%; 37 female, 72 male; average age 22. 3 years-old (18-56), Lymphocyte Predominance (17; 6 female, 11 male; average age 22. 6 years-old (18-67), Lymphocyte Depletion (21; 6 female, 15 male; average age, 22 years-old (20-42). Staging of HL patients: I: 5. 5%, II: 44%, III: 31. 1%, IV: 19. 4%. They were treated with different protocols (MOPP, ABVD, STANDFORD V, HYBRIDO, COPP/ABVD, COPP/EBVD) according to the year treatment was initiated, and since 2004 with BEACOPP and in some cases radiotherapy. Subtypes of NHL: DLBCL (442), FL (293), MALT lymphoma (121), Peripheral T cell (7), Mantle Cell lymphoma (4); miscelaneous (mycosis fungoides, immunoblastic, anaplastic, Lymphoblastic, Burkitt or Cutaneous B cell lymphoma) (248). Of the FL 45% had high FLIPP, while 60% of the DLBCL had intermediate high IPI score with high-risk prognostic factors; only 15% of cases had low risk lymphoma. They were treated with different protocols according to the year of diagnosis: CHOP, CHOP Bleo, MACOB B, ATT, HyperCVAD, and CHOP MTX and since 2004 with R-CHOP. 29 patients were treated with CHOP, 55 patients with R-CHOP. The R-CHOP as induction in FL *de novo* and Rituximab as maintenance produced 46 % CR and 56% PR. The CR increased to 77% after two years of Rituximab maintenance during four-year observation. Global survival in FL was 89. 5% for R-CHOP vs. 50% for CHOP; the survival free of events in FL was 89. 8 for R-CHOP vs. 39. 1% for CHOP. The CR for DLBC lymphoma was 68%. The global survival in DLBCL was 92. 1% for R-CHOP vs. 67. 9% for CHOP and the survival free of events in DLBCL was 90% for R-CHOP vs. 44% for CHOP (p = 0,002). The patient age influenced the survival while other variables (sex, type of lymphoma or stage) did not have impact in survival free of events period. An improvement in the outcome of lymphoma patients occurred when the patient was treated with R-CHOP. **Conclusions.** The most frequent HL subtype was nodular sclerosis (62. 6%), mainly women and young adults; Lymphocyte Predominance and Lymphocyte Depletion were only 4. 3 % y 5. 4%. The most frequent NHL subtype was DLBCL, followed by FL. The distribution of the subtypes of lymphoma in Venezuela follows the same pattern reported in other populations. The global survival and the survival free of events were improved with R-CHOP. At this time this must be the treatment of choice.

1723

THE ROLE OF REGULAR CT IN FOLLOW-UP AFTER THE TREATMENT OF LYMPHOMAS

S Filonenko, I Kriachok, A Martynchyk, I Titorenko
National Cancer Institute, Kyiv, Ukraine

Background. Despite annual improvement of therapy results of lymphoma patients certain group of these patients will have relapse of the disease. There is no definite opinion should the regular CT be done in the follow-up (FU) period for the detection of relapse. **Aims.** The aim of the study was evaluation of the role of regular CT in the FU period after the completion of the treatment of lymphomas.

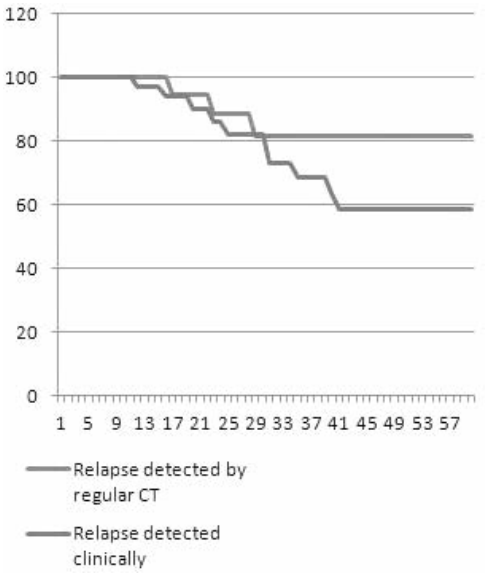

Figure 1. 5-year OS rate in the groups of patients in which relapse was detected by regular CT and clinically.

Methods. In the period of 2008-2011 years 58 patients with Hodgkin's Lymphoma (HL) (22 patients) and Non- Hodgkin's Lymphoma (NHL) (36 patients) were treated in the relapse of the disease diagnosed at least 4 months after

the end of the initial treatment FU period was 9-196 months (median 34 months) in the whole group of patients, 14-89 months (median 31 months) - in the group of NHL patients and 9-196 months (median 46 months) - in the group of HL patients. The FU strategy was based on the regular visits to the physician every 3-12 months (patient complaints, disease history were evaluated, physical examination and blood tests were performed) and CT performing every 6-12 months corresponding to the period of observation. **Results.** Relapses were detected in the period 4-190 months after the completion of the initial treatment (median 13 months). In the group of HL they were detected in the period 4-190 months (median 27 months), in the group of NHL - 4-69 months (median 12 months). 62% of relapses were assumed clinically, 64% - in HL group and 61% - in NHL group. In the group of indolent lymphomas 58% of relapses were assumed clinically, in the group of aggressive lymphomas - 65% (p>0. 05). Significant difference was detected in the overall survival (OS) in the group of patients in which relapse was detected by CT compared to the group of patients in which relapse was detected clinically. Median survival wasn't reach in both groups. 5-year OS was 58. 6±9. 9% in the group of patients in which relapse was assumed clinically and 81. 8±9. 2% in the group of patients with CT assumption of relapse (p<0. 05). **Conclusions.** Symptoms of relapse and clinical examination of patients play the most common role in the assumption of the relapse in patients with lymphomas even in case of regular CT examination. However this study revealed the benefit in the OS in the group of patients in which relapse was detected by regular CT. More precise role of this diagnostic method should be evaluated in large prospective studies.

1724

HIGH INCIDENCE OF LATE DEATHS AFTER RITUXIMAB COMBINED CHEMOTHERAPY: A 20-YEAR RETROSPECTIVE FOLLOW-UP STUDY IN PATIENTS WITH DLBL

M Ide, M Uemura, Y Kawachi, Y Izumi
Takamatsu Red Cross Hospital, Takamatsu Kagawa, Japan

Background and Aims. In Japan, rituximab was generally used for patients with diffuse large B cell lymphoma (DLBL) after 2003 (rituximab era), and rituximab combined Chemotherapy has greatly improved outcomes. We treated 121 patients (69 men and 52 women, median age 68 years, range: 19 to 93 years) with DLBL in 20 years (1990-2009), and analyzed their prognosis retrospectively to overall survival curve (OS) at single institute. **Patients and Methods.** 121 patients were treated in 20 years. 56 patients (34 men and 22 women, median age 67 years, range: 37 to 93 years) were treated without rituximab (CHOP-like regimen 48 patients and other therapy 8 patients in pre-rituximab era), 65 patients (36 men and 29 women, median age 69 years, range: 19 to 86 years) were treated with rituximab in rituximab era (R-CHOP regimen 62 patients, other chemotherapy 3 patients). The over-all survival curve of 120 patients with DLBL was analyzed using the log-rank test and expressed as Kaplan-Meier plots.

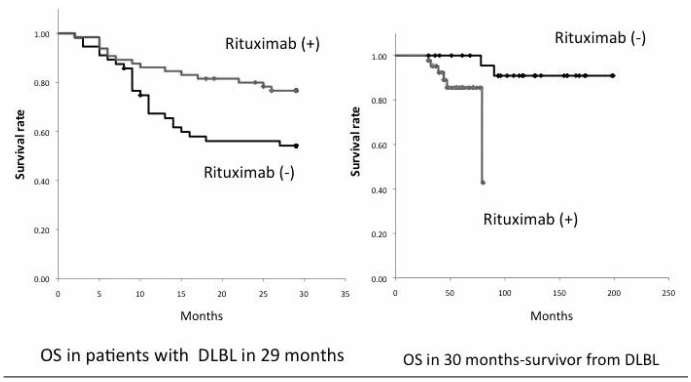

Figure 1. OS in patients with DLBL.

Results. In 29 months after diagnosis, overall survival curve was significantly (P<0. 05) prolonged rituximab treated patients (29 months over-all survival rate is 76. 9%) than patients without rituximab therapy (29 months over-all survival rate is 55. 4%). 28 patients (17 men and 11 women, median age 62 years, range: 41 to 77 years) without rituximab therapy and 43 (24 men and 19 women, median age 68 years, range: 19 to 85 years) patients with rituximab therapy have been followed up after 30 months. We analyzed for overall survival curve limited to survivor from DLBL after 30 month later. From 30 months later after diagnosis, 6 rituximab treated patients died (3 patients died due to secondary malignancy, and 3 patients died due to DLBL relapse), and only 2 patients without rituximab therapy were died (one patient died due to secondary malignancy and one patient died due to haemolytic anaemia). In over 30 month-survivor from DLBL, the over-all-survival curve of survivor with rituximab (72 month over-all survival rate is 88. 3%) is significantly (P<0. 05) shorter than survivor without rituximab (72 month over-all survival rate is 100%). **Conclusions.** Rituximab combined chemotherapy is effective for DLBL. However, it is necessary to long-term follow-up because of increasing late death from over 30 month later after diagnosis.

1725

FOLLICULAR LYMPHOMA TREATMENT. 10 YEARS FOLLOW UP. ONE CENTER EXPERIENCE

E Nesterova, S Kravchenko, E Gemdjian, A Magomedova, V Vorobyev, E Baryach, M Litvinenko, A Kremenetskaya
National Research Center for Hematology, Moscow, Russian Federation

Background. There are no follicular lymphoma treatment standards. Clinical management of patients ranges from observation without therapy to high-dose chemotherapy followed by autoSCT or alloSCT. Most commonly used chemotherapy programs are R-CVP, R-CHOP and R-F(M)C. **Aims.** Assess of treatment results in the National Research Center for Hematology, Moscow, Russia from 2001 to 2011. PATIENTS AND **Methods.** The results of therapy of 82 patients with follicular lymphoma treated from 2001 to 2011. The analysis included 34 men (41%), 48 women (59%). The mean and median age was 53 years (range: 27-83 years). Patients were divided into groups according to the FLIPI criteria: I risk group - 28 (34%), II - 15 (18%), III - 39 (48%). In 14 cases (17%) it was I histological grade of follicular lymphoma, in 40 (49%) - II, in 28 (34%) - IIIAB. Induction courses were R-CVP, R-CHOP and R-F(M)C. The KaplanMeier method was applied to calculate the overall survival (OS) and event-free survival (EFS). **Results.** Most patients received induction courses with anthracyclines: R-CHOP (n=32) and CHOP (n=9). 13 patients received R-FMC, 3 - CVP, 3 - R-CVP. Non-program courses were made to 15 patients. 7 patients are under observation without treatment (Median (Med) 35 months). In the first relapse patients after R-CVP received R-CHOP, in the second relapse - R-FMC. In the first relapse after R-CHOP patients received R-FMC, and in following relapses - non-program treatment. The 5-year overall survival (OS) after R-CVP, R-CHOP, R-FMC courses was 71%, 63%, 99% respectively (p=0. 05) (Figure 1).

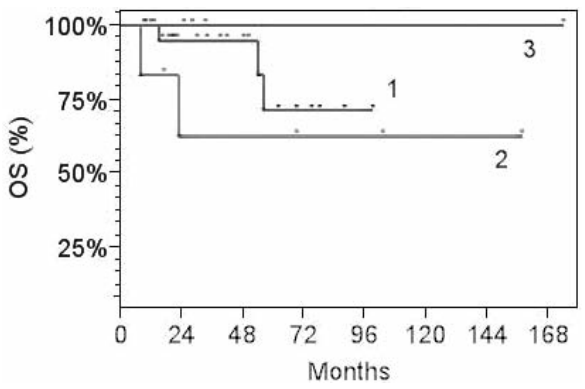

Figure 1. Overall survival (OS) after R-CVP (1), R-CHOP(2), R-FMC(3).

Event-free survival (EFS) during 5-years in R-CVP group was 42% (Med 56 months), R-CHOP - 21% (Med 39 months). 3-years EFS in R-FMC group was 38% (Med 32 months, p=0. 05) (Figure 2).

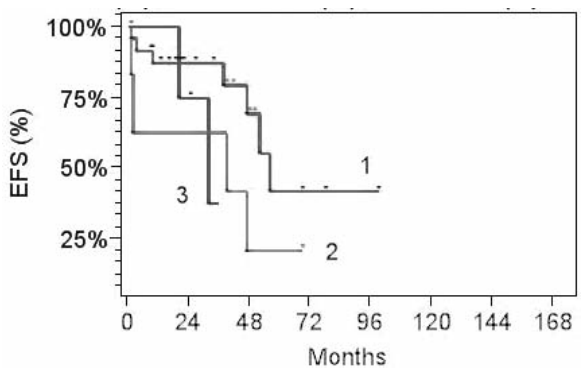

Figure 2. Event-free survival (EFS) after R-CVP (1), R-CHOP(2), R-FMC(3).

Patients with I and II histological types received R-CHOP and R-FMC equally. Anthracycline-based courses were selected for patients with III histological grading. 21 (26%) patients died (Med 24 months, in 80% FLIPI was III-IV). 10 of them died from resistant tumor progression in retroperitoneal space during 4 years from putting the diagnosis (Med 47 months, 5 patients with II grade, 5 patients with IIIAB grade). These 10 patients were 53% of all patients with bulky disease in retroperitoneal space (n=19). The 5-year OS in the group without retroperitoneal bulky disease (first group) was 98% (p = 0,001), but with the bulky disease (second group) - 50% (Med 56 months) (Figure 3).

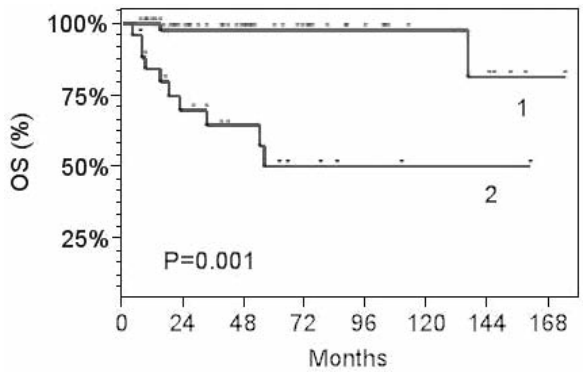

Figure 3. OS in the group without retroperitoneal bulky disease (1), with the bulky disease (2).

Probability of death during the first 5 years in the second group is 10 times higher than in the first group. All deaths in the second group occurred within the first 5 years after treatment (mean time to death is 42 months). The 5-year EFS was 58% (Med 72 months) and 42% (Med 48 months) (p = 0,05) respectively (Figure 4). Probability of relapse and progression is 1,5 times higher than in the first group.

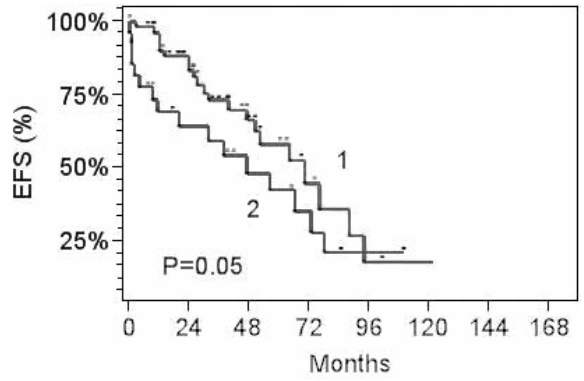

Figure 4. EFS in the group without retroperitoneal bulky disease (1), with the bulky disease (2).

Conclusions. The results indicate that III - IV stage follicular lymphoma with the bulky in the retroperitoneal space is an independent predictor of poor prognosis. Possibly, this group of patients needs early intensification of treatment.

1726

ORBITAL LOCALIZED MANTLE CELL LYMPHOMA

V Paredes Henao[1], JM Jorge Medina[1], F Fina Climent[2], E Domingo Domenech[1], S Santiago Mercadal[1], V Vicent Romagosa[2], E Esmeralda de la Banda[2], A Lucas[1], A Fernandez de Sevilla[1], E Gonzalez-Barca[1]
[1]Institut Catala d'Oncologia, Barcelona, Spain
[2]Hospital Bellvitge, Barcelona, Spain

Background. Mantle Cell Lymphoma (MCL) is an aggressive lymphoma diagnosed in the majority of the cases in advanced stages. The orbital extra nodal affection is infrequent. **Aims.** To describe the characteristics, evolution, treatment and survival data among the patients diagnosed with orbital MCL. **Materials and Methods.** From August 1992 to December 2010, medical records of patients diagnosed of MCL at the Institut Català d'Oncologia Hospital Duran i Reynals were reviewed. Eighty-six MCL patients were identified, 7 of whom were diagnosed in the orbita. Pathology reports, histological sections and immunohistochemical-stained slides were reviewed. Two cases in which diagnosis was not confirmed were excluded. **Results.** Five (5. 8%) orbital MCL patients were identified, and three of them (3. 5%) had localized disease. The median age of patients with localized disease was 75 yr (39-79). Two of them were women. Clinical presentation consisted in a non bulky unilateral orbital mass. None of the 3 patients had B symptomsThe biopsy showed a lymphoid infiltration with follicular growth pattern in one case and a vaguely nodular and diffuse growth pattern in the other 2 cases. All the cases were positive for CD5 and Cyclin-D1. Sox11 staining has been requested and it is pending. Treatment of these patients consisted on 6 cycles of CHOP chemotherapy in one patient and combined therapy with 3 cycles of CHOP-like chemotherapy and involved-field radiotherapy in the other two. All of them achieved complete remission. With a median follow-up of 35. 3 months, one patient progressed in Waldeyer region and achieved a second complete response after involved field radiotherapy. All of them are alive and disease free. **Conclusions.** Localized orbital MCL is a rare presentation but should be considered in the differential diagnosis of lymphomas in this area. Growth pattern and immunohistochemistry is comparable with nodal MCL. Responses to treatment are good and clinical evolution seems to be more indolent that their nodal counterpart.

1727

PRIMARY CEREBRAL LYMPHOMA- SINGLE INSTITUTION EXPERIENCE 2004-2011

E Hurst, S Evans, J Lewis
Freeman Hospital, Newcastle upon Tyne, United Kingdom

Background. Primary Cerebral Lymphoma (PCL) is a rare form of lymphoma. In 2009, the IELSG published results of a randomised control trial demonstrating the benefit survival of adding high dose cytarabine to the standard chemotherapy of high dose methotrexate [HDMX]. However, toxicity was greater following the addition of cytarabine with 8% dying of sepsis and 44% of patients [vs. 2. 5%] requiring a dose reduction. Given the better survival seen in the cytarabine arm it was added to local PCL treatment protocols. Due to concerns over its toxicity, cytarabine was introduced at a 50% dose of that in the published trial. Also, treatment outcomes of PCL have often been hampered by high levels of neuro-cognitive toxicity often attributed to radiotherapy. **Aims.** 1] To assess the outcome of PCL treatment to see if treatment changes in 2009 have improved patient survival and if so, is it comparable with published series given the dosing reductions used. 2] To assess the functional cognitive ability of patients at diagnosis and one year post treatment by assessing ability to live independently. **Methods.** All patients diagnosed with PCL over the past eight years were included in a retrospective review. Data was collected from case notes. **Results.** 26 cases of PCL were identified retrospectively (16 male and 10 female) with an average age of 58. 9 years. 15 patients [58%] received first line chemotherapy, 10 patients [38%] were treated with radiotherapy alone due to poor performance status. One renal transplant recipient had neither modality and was successfully managed with reduction in immunosupression alone. Chemotherapy for patients treated up to 2009 [10 patients] was HDMX alone and for 5 patients treated after 2009 was HDMX with HD Cytarabine. All patients receiving the HDMX and cytarabine post 2009 protocol received the full dose intended with no dose reductions. All cycles were supported with pegylated GCSF administration. Consolidatory radical radiotherapy was delivered following completion of chemotherapy. CR at 3 months post treatment was 92% [24/26 patients] and current survival at 34. 2 months mean follow up is 65% [17/26 patients]. Of the 9 patients who have died, 7 died from progressive disease, one died of pneumonia and one died of an Alzheimer's like illness. Overall survival at 12 months was 70%, at 24 months was 62% and at 36 months was 38%. Patients treated with the addition of high dose cytarabine currently have an average follow up of 28 months and all are in remission. With regards assessment of cognitive function there was an overall improvement in their functional level one year post treatment [61 vs. 50% living independently]. This is contrary to the perceived toxic effects of treatment and likely reflects reduced tumour burden. **Conclusions.** Our outcomes in PCL are comparable to modern published series. It is our view that when appropriate selection criteria are applied that HDMX with HD cytarabine, at a dose level approx 25% below that achieved overall in IELSG trial, is a tolerable and efficacious regimen.

1728

PREVIOUS RITUXIMAB EXPOSURE DOES NOT AFFECT CLINICAL OUTCOMES OF HIGH-DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM-CELL TRANSPLANTATION IN PATIENTS WITH RELAPSED OR REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA

S Park, DH Yoon, S Kim, C Park, J Huh, C Suh
Asan Medical Center, University of Ulsan College of Medicine, Seoul, South-Korea

Background. Salvage chemotherapy followed by high-dose therapy and autologous stem-cell transplantation (ASCT) has been the standard treatment for relapsed or refractory diffuse large B-cell lymphoma (DLBCL). With the beginning of rituximab era, the role of rituximab in the salvage treatment is currently under investigation, and in that context, it has become an issue that prior rituximab exposure may affect the efficacy of rituximab in salvage treatment. In addition, the relationship between rituximab exposure in the first-line treatment and the response to salvage treatment including ASCT but without rituximab has not been investigated. **Aims.** In the present study, we investigated the association of previous rituximab exposure with the clinical outcomes of salvage treatment without rituximab and ASCT in patients with relapsed or refractory DLBCL. **Patients and Methods.** Eighty nine patients with relapsed or refractory DLBCL have undergone ASCT in the Asan Medical Center from April 1994 to August 2011. Among them, 19 and 25 patients were treated with CHOP and RCHOP, respectively, as the first line treatment. Event free survival (EFS) and overall survival (OS) were calculated from the start of conditioning regimen to event or deaths. **Results.** Baseline characteristics between the two groups were not significantly different, including age, prior chemotherapy before ASCT, age-adjusted IPI score at the time of ASCT, Ann-arbor stage, the time from diagnosis to relapse or progression (T/rel) and disease status before ASCT (complete response [CR] versus partial response [PR]). ESHAP regimen was the most frequently used salvage regimen in both groups (47% in CHOP and 68% in RCHOP group, p=0. 208). BEAC (63%) and BUCYE (64%) protocols were the most frequently used conditioning regimen in CHOP and RCHOP group, respectively. With a median follow-up duration of 86 months, median EFS and OS were not significantly different (CHOP vs RCHOP, EFS, 4. 1 months vs 6. 7 months, p=0. 636; OS; 8. 0 months vs 10. 4 months, p=0. 635, respectively). Response rates to ASCT which include CR and PR, were 74% and 88% in CHOP and RCHOP groups, respectively (p=0. 459). Only age-adjusted IPI score at the time of ASCT (2 or 3) was the independent prognostic factor affecting OS in both univariate and multivariate analyses (HR 4. 60, p=0. 001 and HR 4. 63, p=0. 002, respectively). Multivariate analysis also showed that prior rituximab exposure did not affect OS (HR 1. 20 95% CI, 0. 57-2. 50, p=0. 636). **Conclusions.** Prior exposure to ritiximab does not seem to affect the clinical outcomes of salvage treatment without rituximab and ASCT treatment in patients with relapsed or refractory DLBCL.

1729

CODOX-M/IVAC AS TREATMENT FOR AGGRESSIVE B-CELL NHL: UNICENTRIC EXPERIENCE

C Cerrato, M Diaz-Morfa, I Lopez San Roman, D De Miguel, N Golbano, D Subira, M Morales, S Herrero, J Arbeteta, F Fuertes, B Pinedo
University Hospital of Guadalajara, Guadalajara, Spain

Objectives: To analyse results of remission, survival and complications related to CODOX-M/IVAC treatment in patients diagnosed of NHL-DLBCL, NHL-DLBCL-Burkitt-like or anaplastic NHL-DLBCL. **Patients and Methods.** Between October 2005 and December 2011, 19 consecutive patients (52. 6% men) were diagnosed in our institution from NHL-DLBCL (n=12, 63. 2%), NHL-DLBCL-Burkitt-like (n=5, 26. 3%) and anaplastic NHL-DLBCL (n=2, 10. 5%). Six patients had previously received another chemotherapy regimen. The international prognostic index (IPI) was: Low (n=4, 21%), intermediate-low (n=4, 21%), intermediate-high (n=8, 42%) and high (n=3, 16%). Ki67 was studied in 17 patients and 11 (65%) showed >90%. C-myc was studied in 10 cases and the rearrangement resulted positive in 3 of them (30%). The median age was 58 years (range:14-76). Twenty-six per cent (n=5) of the patients were over 65 years-old. Intensive chemotherapy regimen administrated to patients under 65 years-old was CODOX-M-R (2 cycles): Rituximab 375mg/m2 (day 1), cyclophosphamide 800mg/m2 (day 1) and 200mg/m2 (days 2,3,4 and 5), adriamicin 40mg/m2 (day 1), vincristine* 1. 5mg/m2 (without maximum. Days 1 and 8) and methotrexate* 1200mg/m2 administrated in 1 hour and 240mg/m2/h in 23 hours and intrathecal cytarabine (days 1 and 3) and intrathecal methotrexate (day 15). IVAC-R (2 cycles): Rituximab 375mg/m2 (day 1), Ifofosfamide* 1500mg/m2 (days 1,2,3,4 and 5), etoposide 60mg/m2 (days 1,2,3,4 and 5), cytarabine* 2gr/m2/12 h. (days 1 and 2) and intrathecal methotrexate (day 5). [* Ajusted for patients >65 years]. **Results.** Fifteen patients (88. 23%) responded to treatment: 87% (n=13) as complete remission (CR) and 13% (n=2) as partial remission (PR). Relapse rate was 11. 7% (n=2). Two patients (10. 5%) died because of sepsis after first CODOX-M. Treatment was interrupted in 2 patients, one because progression and another because neurotoxicity. A microbiological documentation of infection was demonstrated in 89. 5%. Seven patients (36. 8%) suffered from invasive fungal infection (6 oropharingeal candidiasis and 1 mandibular aspergillosis). The rate of severe mucositis (grade 3-4) was 31. 6% (n=6). The days of neutropenia and hospitalization after each cycle are shown in Table 1. Overall survival (OS) was 73%±10% with a median follow-up of 32 months (range:1-60), progression-free survival (PFS) was 77. 8%±15. 2%. Overall survival was higher in patients with high or intermediate-high than in patients with low or intermediate-low IPI (91% vs. 63%) (p=0. 18). Mortality related to was 10. 5% (n=2). **Conclusions.** CODOX-M/IVAC is a good therapeutic option for aggressive B-NHL with a rate of response of 88%, PFS of 78% and an OS of 73%. However, a high rate of infections and long hospitalizations should be considered before selecting patients for this therapy.

Table 1.

	NEUTROPENIA Median (range)	HOSPITALIZATION Median (range)
1st CODOX-M	10 days (1-21)	23 days (17-43)
1st IVAC	6 days (0-11)	18.5 days (8-40)
2nd CODOX-M	13 days (1-34)	28 days (15-48)
2nd IVAC	6 days (0-15)	17.5 days (5-37)

1730

FDG-PET CT SCAN CONTRIBUTION IN DIAGNOSIS AND INITIAL STAGING OF INDOLENT LYMPHOMAS

X Yiakoumis[1], G Pangalis[1], S Sachanas[1], M Moschoyiannis[1], P Tsirkinidis[2], M Angelopoulou[3], V Prassopoulos[4], F Rontogianni[5], C Kalpadakis[6], T Vassilakopoulos[3]
[1]Athens Medical Center, Athens, Greece
[2]Haematology Department, 401 Military Hospital, Athens, Greece
[3]Haematology Department, University of Athens, Athens, Greece
[4]Nuclear Medicine Department, YGEIA Hospital, Athens, Greece
[5]Nuclear Medicine Department, Evangelismos Hospital, Athens, Greece
[6]Haematology Department, University of Crete, Heraklion, Greece

Background. FDG PET-CT scan (PET) contributes in the diagnosis and follow-up of patients with lymphoma. Its role is mostly defined in aggressive lymphomas while its use in initial diagnosis of indolent lymphoproliferative diseases is not adequately studied. **Aims.** The study of PET contribution at initial diagnosis and staging of patients with indolent lymphomas who underwent the usual staging with CT and bone marrow biopsy for the evaluation of their disease. **Methods.** Between 2003-2011 patients with indolent lymphomas underwent staging with standard methods (CTs, blood and bone marrow histological, immunophenotypic and molecular studies) as well as PET, at diagnosis of their disease. Patients' characteristics were studied and comparison of findings with standard methods and PET findings was performed. **Results.** From a total of 55 patients who were studied, 22 were diagnosed with follicular lymphoma, 22 with marginal zone lymphoma (7 splenic, 7 primary bone marrow, 5 extranodal, 3 nodal), 6 with SLL, 2 with mantle cell lymphoma and 3 with Castleman disease, NK and T-LGL leukemia, respectively. The disease stage, as shown by standard staging methods was early (I and II) in 22 patients and advanced (III and IV) in 34 patients. In early stage patients, PET uncovered less disease sites in 6 patients and more sites in 4, compared to CT. On the contrary, in advanced stage patients, PET demonstrated less disease sites in 3 and more disease sites in 19 patients, compared to standard CT scan. Mean value of PET uptake in early stages was 5,93±2,73 and in advanced stages 5,73±3, a difference not statistically significant. From 26 patients in whom bone marrow infiltration was documented with standard bone marrow studies, PET was able to trace bone marrow infiltration only in 5 (19%). Moreover, while 18 patients presented splenomegaly in CT, PET disclosed abnormal splenic uptake in 9 of them. Specifically, in patients with splenic marginal zone lymphoma who all had splenomegaly, PET indicated abnormal uptake of the spleen in 71%. Additionally, in all patients with primary bone marrow lymphoma who by definition do not present splenomegaly, PET did not present an abnormal splenic uptake. On the contrary, in 2 patients with follicular lymphoma an abnormal splenic

uptake was seen without evidence of splenomegaly. **Conclusions.** PET can contribute in identification of more disease sites of indolent lymphomas and could be used when stage or sites confirmation is crucial for the selection of the appropriate treatment strategy. It can not be safely used for the diagnosis of bone marrow infiltration and should not substitute standard bone marrow studies in indolent lymphomas. The precise role of PET scan in the identification of spleen infiltration by indolent lymphomas needs further elucidation.

1731

COMPARISON OF RITUXIMAB-CHLORAMBUCIL(R-CHL) COMBINATION WITH OTHER FIRST LINE TREATMENTS IN MANTLE CELL LYMPHOMA (MCL) PATIENTS: EXPERIENCE FROM 6 CENTERS IN GREECE

S Sachanas[1], I Kotsianidis[2], T Vassilakopoulos[3], N Konstantinou[4], P Repousis[5], K Girkas[5], E Michali[6], P Tsirigotis[7], I Dervenoulas[7], N Anagnostopoulos[6], M Moshoyiannis[1], X Yiakoumis[1], H Papadaki[8], C Kalpadakis[8], P Panayiotidis[3], M Kyrtsonis[3], K Papanastasiou[9], P Matsouka[10], M Angelopoulou[3], G Pangalis[1]
[1]Athens Medical Center, Phychikon Branch, Athens, Greece
[2]University of Thrace, Alexandroupolis, Greece
[3]University of Athens, Athens, Greece
[4]Theagenio Hospital, Thessaloniki, Greece
[5]Metaxa General Hospital, Athens, Greece
[6]G. Gennimatas General Hospital, Athens, Greece
[7]Attikon General Hospital, Athens, Greece
[8]Haematology Department, University of Crete, Heraklion, Greece
[9]Ag. Savvas General Hospital, Athens, Greece
[10]University of Thessalia, Larissa, Greece

Background. MCL is associated with poor prognosis with a median survival of 3-5 years. Treatment approach of MCL is still quite challenging and therapeutic options are variable and controversial. Our Unit has adopted the combination of R-Chl, a completely different therapeutic strategy of low toxicity producing high response rates,as first line treatment in patients with MCL. **Aims.** To compare the R-Chl combination as first line treatment in MCL patients with other first line treatments in terms of response and safety. **Patients and Methods.** Patients diagnosed with MCL using established criteria in 6 Hematologic Centers in Greece, from June 2003 until August 2011, were included in this study. Patients with the blastic variant of the disease were excluded from the analysis. They were classified in 4 groups according to the treatment protocol administered as follows: - First group (A): patients received the R-Chl combination - Second group (B): patients received the Rituximab-CHOP regimen - Third group (C): patients received the HyperCVAD regimen - Fourth group (D): patients received other therapies. **Results**. 65 patients (51 male) were analysed in the study. Their median age was 69 years (range 32-97)Twenty-three patients (36%) classified in group A,24 patients (37%) in group B,while 10 (15%) and 8 patients(12%) in groups C and D respectively. In group D, 5 patients received the Rituximab-COP combination, 1 received Riruximab as a single agent while 1 received the FCR regimen and 1 an mTOR inhibitor. Three patients(12%) in group A were in high intermediate/high prognostic group according to IPI score whereas 13(54%), 5(50%) and 6(75%) patients in groups B,C and D respectively. Moreover 2 patients were in high prognostic group according to MIPI score while 9(38%), 3(30%) and 4(50%) patients in groups B,C and D respectively. Treatment toxicity is shown in Table 1.

Table 1.

Group	A	B	C	D
		#	(%)	
Neutropenia grade III-IV	–	9 (38)	8 (80)	–
Febrile neutropenia	–	2 (8)	6 (60)	–
Anemia grade 3-4	–	3 (13)	5 (50)	–
Thrombocytopenia grade 3-4	–	–	8 (80)	1 (13)
Toxic Deaths	–	–	1 (10)	–
Hospitalization #patients -Median duration (days)	4-(10)	10-(12)	8-(95)	2-(4)

5-year overall survival was 70% for all patients while 5-year overall survival for the patients received the R-Chl combination and for those received therapies other than the aforementioned combination was 90% and 60% respectively (p:0,21). **Conclusions.** High response rates were achieved by both the aggressive and less aggressive treatment regimens. Patients who received aggressive therapies presented with more unfavorable disease characteristics compared to those who received the R-Chl combination and demonstrated more frequent severe complications attributed to therapy. The R-Chl combination is extremely efficient especially for a fraction of patients who have indolent disease characteristics.

1732

CLINICAL FEATURES PRIMARY EXTRANODAL DIFFUSE LARGE B-CELL LYMPHOMA (PEDLBCL)

I Subortseva[1], I Poddubnaya[1], A Kovrigina[2]
[1]Russian Medical Academy for Post-Graduate Education, Ministry Health of Russia., Moscow, Russian Federation
[2]2Head Department of Pathology, Russian Hematological Center, Ministry of health,, Moscow, Russian Federation

Background. PEDLBCL arise from tissue other than lymph nodes and even from sites which normally contain no lymphoid tissue. The purpose of our work was revealing of adverse prognostic factors. **Methods.** We evaluated the clinical features and outcomes 42 patients who were treated in Russian Blockhin Cancer Research Center between 2000 and 2010. **Results.** Localisation of the primary lesion was important prognostic factor: 5-years overall survival(OS) was 88% in stomach lymphoma, 80% in bones lymphoma, 60% in testis lymphoma;(p=0,4). 5-years event free survival(EFS) was 75% in stomach lymphoma, 70% in bones lymphoma, 50% in testis lymphoma;(p=0,6). Patients age varied from 19 till 82 years (median was 56 years). Patients more 60 years was 18 (43 %). 5-years OS ≥60 years old was 61 %, and patients <60 - 83%;(p=0,03). 5-years EFS elderly was - 56%, at young age - 79% (p=0,03). I-II stages have been established at 26 cases(61 %), IV stage was established at 16 cases (39 %) PEDLBCL. If at I-II stages 5-yearsOS - 77%, at IV - 63%(p=0,2). 5-years EFS at the localised stages of disease was 69%, and at advanced stage - 56%(p=0,4). At case involving 1 extranodal zone 5-years OS it was equal 80%, more than 1 zones - 68%(p=0,6). 5-years EFS at involved of 1 zone was 73%, at case of the widespread form disease 55%(p=0,5). The general ECOG condition, corresponding 0-1 points, has been noted at the majority of patients - 26 (62%). 5-years OS was 62% at ECOG>2, and 81 % at ECOG 0-1(p=0,2). 5-years EFS in poor performance status at the moment of beginning treatment was53 % and at a satisfactory condition - 69%(p=0,2). LDH>N was in 40 % (17 from 42 cases): 5-years OS at ЛДГ ≤450IU - 81%, at ЛДГ >450IU - 62%(p=0,8). 33 (78%) patients were included into group of the favorable prognosis (low and low/intermediate groups of risk of early progressing), and 9 (22%) the adverse prognosis (high/intermediate and high degrees of risk of early progressing). 3-years OS was 56 % at patients with high and high/intermediate risk and 86 % at patients with low and intermediate/low risk (p=0,3). Distinct negative prognostic value renders primary refractory to chemotherapy: 3-years OS was 93% at achievement complete remission, and 36% at patients with resistant form of disease (p=0,0001). **Conclusions.** Unfavourable prognostic factors are nodal localisation of the primary disease lesion, the age is more 60 years, ECOG score >2, LDH level >450IU,advanced disease at the moment of diagnostics (IV stage, involving more than 1 extranodal zone, «bulky»), high/intermediate and high degrees of risk of early progressing, resistant form of lymphoma to I line therapy.

1733

PROGNOSTIC SIGNIFICANCE OF CD5 IMMUNOEXPRESSION IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH IMMUNOCHEMOTHERAPY

O Markovic[1], Z Marisavljevic[1], V Cemerikic-Martinovic[2], B Filipovic[1], J Hajder[1], S Radovanovic[1], T Martinovic[3], B Mihaljevic[4]
[1]KBC Bezanijska kosa, Belgrade, Serbia
[2]Beolab, Department of Hematopathology, Belgrade, Serbia
[3]Institute of Histology, University of Belgrade, Belgrade, Serbia
[4]Institute of Hematology, KCS, Belgrade, Serbia

Background. CD5+ DLBCL is a clinically distinct subgroup of DLBCL that is associated with poor prognosis. **Methods.** In this study, we have analyzed immunoexpression of CD5 in group of 55 DLBCL patients treated with immunochemotherapy. The diagnosis of DLBCL was made according to the Revised European-American Lymphoma Classification. The expression of CD5

has been evaluated semiquantitavely as a percentage of tumor cells. **Results.** Immunoexpression of CD5 has been found in 10(18. 2%) patients. Expression of CD5 ranged from 30 to 100%. Patients with CD5+ DLBCL was more closely associated with many aggressive clinical features or parameters than CD5- DLBCL: Namely, immunoexpression of CD5 was in significant correlation with advanced clinical stage (III, IV) (p=0. 023), performance status (p=0. 036) and presence of extranodal localization (p=0. 047). The overall International Prognostic Index score was thus significantly higher for the patients with CD5+ DLBCL than for those with CD5- DLBCL (p =0. 016). Immunoexpression of CD5 was found to be unfavorable factor for therapy response (p=0. 026). In addition, the patients with CD5 expression had significantly the shorter survival than CD5+ shorter survival (67. 1 vs 30. 2 months) (p=0. 012). **Conclusions.** These results confirmed that CD5+ DLBCL constitute an unfavorable prognostic subgroup of DLBCL in patients treated immunochemotherapy.

1734

CYCLOPHOSPHAMIDE AND METHOTREXATE ORAL COMBINATION CHEMOTHERAPY REGIMEN FOR NON-HODGKIN LYMPHOMA: LOW DOSE METRONOMIC THERAPY

HJ Kim, B Han, MY Kang, DR Choi, HS Kim, JH Kwon, G Jang, JH Kim, HY Kim, JY Jung, HH Song, DY Zang
Hallym University Medical Center, Anyang, South-Korea

Background. Metronomic chemotherapy, which is defined by the frequent, repetitive administration of chemotherapeutic drugs at relatively low doses, and without prolonged drug-free break, is an emerging strategy to fight cancer. The mechanisms of metronomic therapy have been unveiled as tumor anti-angiogenesis and multitargeted therapy. Many patients, especially elderly person, with recurrent lymphoma are unable to tolerate intensive therapies. Metronomic chemotherapy offers a novel, potentially less toxic yet effective treatment strategy. **Aims.** We assessed the response, progression-free survival, overall survival and the toxicity of metronomic chemotherapy in patients with non-Hodgkin lymphoma. **Methods.** A retrospective analysis was performed on 13 non-Hodgkin lymphoma patients (6 male, 7 female) who were treated with cyclophosphamide and methotrexate (CM) regimen for more than one month. They received oral cyclophosphamide (50 mg every day) and oral methotrexate (2. 5 mg 2 times/week) until there was disease progression or unacceptable toxicity. The study was conducted in accordance with the Declaration of Helsinki including all current amendments, and the study protocol was approved by the local ethics committee. **Results.** Among 13 patients (median age 80 years, range 44-88), 6 patients had diffuse large B cell lymphoma (DLBCL), 2 mantle cell lymphoma, 2 angioimmunoblastic T cell lymphoma, 1 MALToma, 1 marginal zone B cell lymphoma (MZBCL) and 1 small lymphocytic lymphoma (SLL). CT regimen was used as 1st line therapy for a DLBCL patient who had refused standard R-CHOP chemotherapy, and used as maintenance therapy for a MZBCL and a SLL patient. Others were relapsed / refractory lymphoma patients. Thirty-one percent of patients had previously received 2 or more treatments. Twelve of 13 patients are evaluable for response. The overall best response rate is 46% (2 complete response and 4 partial response), with 15% achieving stable disease. Median treatment duration was 4. 8 months (range 1. 5 - 25. 7). Twelve patients discontinued the therapy and the reasons were disease progression (7), infection (2), poor performance status (1) and patient's or doctor's decision (2). Median overall and progression-free survivals were 27. 1 and 9. 9 months, respectively. The median response duration was 15 months. Only 4 patients could be managed with further salvage chemotherapy. The CM regimen was generally well tolerated. The most common toxicity was myelosuppression (leukopenia 77%, Grade 3 23%); and two patients with grade 3 infection were reported. There was no treatment related mortality. **Conclusions.** Metronomic therapy with oral CM regimen administered for continuous, prolonged periods represents an active, easily tolerated approach to management of patients with recurrent non-Hodgkin lymphoma, particularly for extremely old patients who have difficulties to apply aggressive salvage chemotherapy or hematopoietic stem cell transplantation.

1735

HIGH DOSE CHEMOTHERAPY WITH AUTOLOGOUS STEM CELL SUPPORT FOR PRIMARY CNS LYMPHOMA: A SINGLE INSTITUTE EXPERIENCE IN JAPAN

E Kondo, T Ichikawa, Y Maeda, K Matsuoka, N Fujii, K Shinagawa, M Tanimoto
Okayama university hospital, Okayama, Japan

Background. The prognosis of primary CNS lymphoma (PCNSL) still remains dismal, with high rates of local relapse and consequent death. Although many groups have reported that high dose chemotherapy with autologous stem cell transplantation (HDC/ASCT) improve survival in PCNSL patients, the treatment is not widely used in Japan. We report the results of HDC/ASCT for PCNSL in our hospital. **Methods.** Immunocompetent patients with PCNSL were included. Treatment consisted of two to four courses of HD-MTX/CHOP +/- rituximab and two to three courses of HDMTX/IFO +/- rituximab, then stem cell harvest, followed by HDC/ASCT. Progression free survival (PFS) was measured from start of chemotherapy to first documentation of progression, last follow up or death. **Results.** Between June, 2009 and January, 2012, nine patients underwent ASCT for PCNSL. Median age at diagnosis was 64 years old (range 56-74). Median time from diagnosis to transplant was 6. 4 months (range 4. 8 to 7. 2). Disease status at transplant: First CR 8 patients, PR one patient. The median $CD34^+$ cell number collected was 1. 97 x 10^6/kg body weight (range, 1. 4 to 3. 6). The median numbers of leukaphereses was four (range two to six). Median follow-up period after ASCT was 13. 1 months (range 1. 1 through 33. 7). The first five patients received Busulfan/Thio-tepa conditioning, whereas the others received Busulfan/Melphalan conditioning, due to unavailability of Thio-tepa after 2010 in Japan. Two patients have relapsed at 5. 7 and 7. 7 months after ASCT. Both two patients are alive after additional therapy. Two patients died by respiratory distress and an accident. Median overall survival and progression free survival from transplant have not been reached. Two year overall and event free survival are 72. 9% and 68. 6%, respectively. **Conclusions.** Although there is limitation related to unavailability of the drugs in Japan (e.g., thio-tepa, BCNU), our result suggests that HDC/ASCT for PCNSL demonstrates improved overall survival when compared to historical controls. Further prospective study is warranted.

1736

VERY GOOD OUTCOME OF PRIMARY GASTRIC DIFFUSE LARGE B CELL LYMPHOMA (DLBCL) AFTER CONSERVATIVE TREATMENT INCLUDING CHEMOTHERAPY WITH OR WITHOUT RITUXIMAB

S Falorio, S Pascale, G Fioritoni, F Angrilli
Spirito Santo Civic Hospital, Pescara, Italy

Background. Gastric DLBCL has been treated with various modalities including surgery, chemotherapy, and radiotherapy alone or in combination. Historically, surgical resection of tumor was believed to be the mainstay of treatment with or without additional therapy Surgical resection surely provides definitive diagnosis and reduces the tumor bulk immediately. This approach, however, was questioned and several studies showed the benefit of conservative treatment with chemotherapy with or without radiotherapy. **Aims.** To retrospectively evaluate the efficacy of conservative treatment with CHOP chemotherapy with or without Rituximab in primary gastric DLBCL. **Methods.** Between 8/2001 and 9/2011, 19 nongastrectomized patients (pts) with gastric DLBCL have been admitted in our institution. Diagnosis was made by endoscopic histologic specimens without gastric surgery in all cases. Disease evaluation was performed with gastroscopy, whole-body computed tomography and bone marrow biopsy at diagnosis and at the end of treatment. Until 12/2004, treatment consisted of CHOP/CHOP-like chemotherapy (5 pts) and, subsequently, of CHOP/CHOP-like chemotherapy in combination with Rituximab (14 pts). All pts received supportive oral treatment with proton pump inhibitors and antiacids. Corticosteroids were administered intravenously or intramuscularly. **Results.** Eleven patients were male and 8 female, with a median age of 62 years (46-81). According to Lugano staging system,9 ptswere in stage I,6 ptswere in stage II-1,2 ptsin stage II-2 and1 ptin stage IIE and IV respectively. B-symptoms were present in8 ptsand aaIPI 2-3 in2 pts. At diagnosis, endoscopy showed neoplastic ulcers in14 ptsand HP positive specimens in7 pts. Today 18/19 pts completed planned treatment. Pts received a median number of 6 courses of chemotherapy with or without Rituximab. After CHOP/CHOP-like chemotherapy alone, 3/5 pts (60%) achieved complete remission (CR). The 2 partial responder pts achieved CR after radiotherapy and partial gastrectomy, respectively. All14 ptswho received R-CHOP combination achieved CR (100%). After a median follow up of 58 months (6-126) OS and RFS are 100%. Considering as treatment failure the need of adjunctive radiotherapy or surgery after chemotherapy, only 2 failures occurred in the group of pts treated without Rituximab. Finally, all pts were treated as outpatients and we didn't observe gastrointestinal bleeding or perforation during treatment. **Conclusions.** In the recent years, conservative approaches such as radiation therapy and / or chemotherapy are generally favoured as opposed to surgical resection in the management of primary DLBCL, because of morbidities and poor quality of life associated with gastrectomy. The role of radiotherapy had been established in the management of limited-stage DLBCL in the preprituximab era. However, radiotherapy may not be preferred today as much considering the long-term toxicity of radiation exposure. Rituximab has an established role in the management of DLBCL, but information on its role in primary gastric DLBCL is limited. However, in our experience R-CHOP combination was a safe and highly effective therapy for gastric DLBCL and represent, now, gold standard treatment for pts affected by Gastric lymphoma in our institution.

1737

T(14;19)(Q32;Q13) IS POOR PROGNOSTIC FACTOR IN SPLENIC MARGINAL ZONE LYMPHOMA

H Julhakyan[1], A Magomedova[2], I Kaplanskaya[2], R Samoylova[2], T Obukhova[1], S Kravchenko[2]
[1]Hematological Scientific Center, Moscow, Russian Federation
[2]Hematological Research Center, Moscow, Russian Federation

Background. Splenic marginal zone lymphoma (SMZL) is a well recognized B-cell neoplasm which is characterized by splenomegaly, bone marrow involvement, immunologically by typical phenotype of marginal zone cells. The most frequent cytogenetic findings are involvement of chromosomes 1, 3, 7 and 8. The t(14;19)(q32;q13) is a rare cytogenetic abnormality has been reported in B-CLL. **Aims.** To describe the clinical, immunomorphological findings in t(14;19)(q32;q13)-positive SMZL. **Methods and Results.** In Hematological Research Centre, Moscowbetween January 2001 and May 2011 were identified three cases SMZL with t(14;19)(q32;q13). All patients were males with age 51, 58, 67 y. o. Lymphoma presented with B-symptoms, high level of LDH, splenomegaly and enlarged splenic hilar lymphnodes. The hemoglobin was 92 g/l, 110 g/l, 122 g/l. All patients had normal count of leukocytes with an absolute lymphocytosis (lymphocytes count 72 x 10^9 g/l, 79 x 10^9 g/l, 83 x 10^9/l) and thrombocytopenia. Morphological examination of peripheral blood and bone marrow lymphocytes showed that all lymphocytes are atypical with wide cytoplasm and nuclear indentation. In all cases there was nodular type of bone marrow involvement. Immunophenotypic analysis has shown the expression of mature B-cells antigens (CD19, CD20, CD22, FMC7, sIg) and absence of CD10, CD23, CD5, CD43, CyclinD1. Two patients were treated with CHOP-21 regimen without any response. They progressed with spleen enlargement and decreased of thrombocytes counts. All 3 patients undergo splenectomy. Weight of spleen was 1800 g, 2083 g, 2850 g. Histological examinations of spleen specimens show massive nodular pattern (involvement of the white and red pulp) associated with diffuse invasion of the sinuses. In all cases there was high mitotic activity. All patients demonstrated progression after splenectomy during 3-6 months that was characterized by increase of leukocytes count (range 45, 4 - 101, 8 x 10^9 /l), high level of LDH, appearance of peripheral and visceral lymph nodes. Considering the increase leucocytes, presence of lymphadenopathy in all cases CHOP-21, R-FMC regimen were used. All patients died of disease progression and infectious complications. Time of observation was 21, 30, 34 months. **Conclusions.** The t(14;19)(q32;q13)-positive SMZL is distinct variant which is characterized by rapid progression after splenectomy, poor responses to chemotherapy and short survival. So t(14;19)(q32;q13) may be regarded as a poor prognostic factor.

1738

IMMUNOHISTOCHEMISTRY IN STAGING BONE MARROW BIOPSY SPECIMENS: A USEFUL ADJUNCT FOR MORPHOLOGICAL DIAGNOSIS IN NON HODGKIN'S LYMPHOMA

S Arami[1], A Svec[2]
[1]NHS, Newcastle upon Tyne, United Kingdom
[2]James Cook University Hospital, Middlesbrough, United Kingdom

Background. Morphological examination of bone marrow trephine biopsy represents a standard method for non-Hodgkin's lymphomas (NHL) staging. Immunohistochemistry staining of bone marrow trephine specimens by using a panel of antibodies has been used in haematological malignancies due to its high applicability and sensitivity at diagnosis. However, the routine use of immunohistochemistry in the clinical settings when there is no obvious morphological (light microscopic) evidence of lymphoma in the bone marrow trephine, is not yet well established. **Aims.** To assess the value of immunohistochemistry (by using a standard basic panel of anti-CD20 and anti-CD3 staining) in detecting involvement by NHL in routinely processed bone marrow trephine specimens, which show no obvious morphological involvement with lymphoma. **Methods.** This study involved 38 randomly selected paraffin wax embedded, formalin fixed bone marrow trephine specimens from three teaching hospitals between February 2011 and February 2012. Thirty patients (79%) had B-cell NHL: diffuse large B cell lymphoma (DLBCL) 45% (n=17), follicular lymphoma (FL) 18% (n=7), marginal zone lymphoma (MZL) 10% (n=4), mantle cell lymphoma (ML) 8% (n=3), Burkitt's lymphoma (BL) 5% (n=2). Eight cases (21%) had T/NK lymphomas. There was no obvious morphological evidence of bone marrow infiltration as all samples were reviewed by two examiners. All specimens were stained with the anti-CD20 and anti-CD3 antibodies. **Results.** Concordant results were found in 35 samples (92%), as both investigations were reported negative. 3 of the 38 cases (8%) which showed no morphological evidence of involvement by NHL on routine stains, were positive on immunohistochemistry. Considering histology, discrepant results were noted more frequently in T/NK lymphomas (25%; 2 of 8 cases) comparing to B-cell NHLs (3%; 1 case of DLBCL). In all three cases the lymphoid infiltrates had diffuse pattern. **Summary and Conclusions.** Our results indicate that immunohistochemistry can detect a subgroup of NHL patients with bone marrow involvement beyond discriminatory level of conventional stains (Haematoxylin & Eosin and Giemsa), thereby contributing to accuracy of staging. In our view, rational application of immunohistochemistry is a cost-effective & valuable method in routine investigation of staging bone marrow trephine biopsies.

1739

ULTRASOUND-GUIDED TRANSTHORACIC BIOPSY WITH FULL-CORE CUTTING NEEDLE TRUCUT IS EASY, EFFECTIVE AND SAFE FOR THE HISTOLOGICAL DIAGNOSIS OF MEDIASTINAL LYMPHOMA

A Chiappella[1], R Cristofori[2], E Rolfo[3], D Novero[4], R Bruna[1], D Caracciolo[1], A Castellino[1], P Pregno[1], P Riccomagno[1], M Zanni[1], M Ladetto[1], U Vitolo[1]
[1]Hematology 2, San Giovanni Battista Hospital and University, Torino, Italy
[2]Thoracic Surgery, San Giovanni Battista Hospital and University, Torino, Italy
[3]Ultrasonographic Vascular Unit, San Giovanni Battista Hospital and University, Torino, Italy
[4]Pathology Department, San Giovanni Battista Hospital and University, Torino, Italy

Background. The development of a mediastinal mass is often associated with a clinical emergency. Primary mediastinal B-cell lymphoma (PMBCL) is usually characterized by symptomatic superior vena cava syndrome and pleural or pericardial effusions with cardiac tamponade at diagnosis. Fine-needle aspiration is a well-established technique to obtain cytological specimens, but it is not useful to a correct lymphoma characterization. Nowadays, mediastinoscopy or invasive thoracic surgery still represent the standard procedures to provide diagnosis in this subset of patients. **Aims.** The aim of the study was to determine the contribution of ultrasound (US)-guided transthoracic biopsy with full-core cutting needle trucut in the diagnosis of PMBCL. **Methods.** By the end of 2010, patients afferred to our Institution for suspected diagnosis of lymphoproliferative disease with bulky mediastinal mass were evaluated by a multidisciplinary team. The team consisted of an hematologist, a thoracic surgeon and a radiologist expert in ultrasonographic vascular assessment. A computed-tomography assessment of the thorax was performed for staging. In presence of a lymph nodal mass of the anterior mediastinum, patients underwent US-guided transthoracic biopsy with full-core cutting needle trucut. Biopsy was performed with BioPince Full-Core biopsy instrument, 16 Gauge. BioPince technology was based on "tri-axial"cut and capture cannula system, designed to harvest diagnostic quality specimens while reducing the risk of crush artefact and tissue fragmentation. **Results.** From December 2010 to October 2011, six patients with clinical suspect of primary mediastinal B-cell lymphoma with anterior mediastinum mass underwent US-guided transthoracic biopsy with full-core cutting needle trucut. All patients were women, median age was 32 (19-50) years. Clinical emergency was determined by: superior vena cava syndrome in four, three of them with pericardial effusion with cardiac tamponade, vocal cord paralysis in one and endovascular dissemination with compression of innominate vein. US-guided transthoracic biopsy with full-core cutting needle trucut was performed at a median of two days after first clinical evaluation. All patients underwent chest X-ray after biopsy; no complications were observed. No patients required hospitalization for the procedure or prolongation of the hospitalization. All biopsy were successful, with proper harvested cylindrical full core specimens. At least two or three samples were collected in each biopsy for histological diagnosis; median length of harvested specimens was 1. 2 cm, range 0. 3 cm to 2. 3 cm. Histological characterization, with immunohistochemical analysis and Ki67 evaluation, was available in all cases. This technique allowed to start first infusion infusion of chemotherapy at a median of 8 (3-14) days after first clinical evaluation or 5 (2-11) days after biopsy. **Conclusions.** US-guided transthoracic biopsy with full-core cutting needle trucut was a promising technique in diagnosis of primary mediastinal B-cell lymphoma or other mediastinal mass. This not invasive approach allowed good quality of histological specimens, with shortening of the time of diagnosis and rapid starting of chemotherapy treatment.

1740

PRIMARY BONE LYMPHOMA - THE REPORT OF 19 CASES

G Gaman, A Gaman
University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background. Primary bone lymphoma is a rare entity (5%) of extranodal non-Hodgkin lymphoma. Predominant manifestations at presentation are pain,

pathological fracture or appearance of a tissular mass. Approximately (50%) of presented cases were in stage IV of the disease. Histopathologically, primary bone lymphoma represents a diffuse B large cell lymphoma. Aim of study: to analise a group of 19 patients with primary bone lymphoma. **Methods.** We have reviewed the clinical manifestations, outcome and treatment of 19 patients diagnosed with primary bone lymphoma, between 1997 and 2011, in the Clinic of Hematology from Craiova . Five patients were females and 14 patients were males, aged 67 between 79. The inaugural symptom was pain (8 patients), a soft a tissue mass (4 patients) and pathological fracture (7 patients). Disease localisation at diagnosis was in the tibia (9 patients), the vertebra (6 patients), the mandibula (3 patients) and the femur (1 patient). 50 % of patients were in stage I of disease and 50% in stage IV. All patients were treated with chemotherapy. CHOP (7), BLEO-CHOP (12), followed by radiotheraphy to the primary site. Autologous blood stem cell transplantation was performed in two cases. **Results.** Nine patients out of 19 achieved complete response and relapse was observed in 4 patients. Nine patients died due to the progresson of the disease. Up to now, 10 patients are alive with no evidence of disease (52%). **Conclusions.** Optimal regimens for the treatment of primary bone lymphoma have not been firmly established. Anyway, our observations and literature data indicate that the response rate and the disease free survival is higher with the combination of radiotherapy and chemotherapy.

1741

TREATMENT Results OF PATIENTS WITH PRIMARY NON-HODGKIN'S LYMPHOMA OF THE TESTIS- A RETROSPECTIVE STUDY FROM A SINGLE HEMATOLOGICAL CENTRE

L Ivanyi, É Marton, M Plander, Z Engert, C Tóth
Univ Teach Hosp Markusovszky, Szombathely, Hungary

Background. Primary testicular lymphoma is a rare subgroup among extranodal non-Hodgkin's lymphomas(nHl) with poor prognosis because of its aggressive clinical behaviour due to high grade histological features developed in mainly elder population. Orchiectomy followed by combination immunochemotherapy are traditional treatment methods with a rather inferior outcome. **Aims.** In a retrospective survey we discuss the clinical presentation,patholgical feature and treatment results of patients (pts) with primary testicular lymphoma (PTL) diagnosed and treated in our hematological centre between 2000-2011. **Patients and Methods.** During this period from 313 pts treated with aggressive nHl in eight pts (age 23 to 86, median of 60 years) with testicular swelling underwent to semicastration primary testicular lymphoma (in seven pts with diffuse,large B-cell origin and in one with Burkitt-like lymphoma)was diagnosed (8/313, 2. 5%). According to the Ann Arbor staging system limited stage I-IIE in seven, advanced stage in one patient were observed. All pts except one (only radiotherapy)were getting rituximab added to CHOP regimen(R-CHOP,6 or 8 cycles in every 21 or 28 days). Central nervous system (CNS)prophylaxis was used in only case and no contralateral testis preventive irradiation was used. **Results.** With a median follow-up of 38 months,after semicastration used R-CHOP treatment resulted in seven pts complete remission, however, two pts died(one due to progression, one other in remission from pulmonary solid tumour). Disease-free(1-140,median of 32 months)and overall survival rates (5-144,median of 38 months) were achieved. 3-year DFS and OS both revealed to be 50%, respectively. **Conclusions.** Our relatively favourable treatment results could mainly be explained with the excess of pts with early-stages in which after early surgical remove of testicular lymphoma combined immunochemotherapy seemed to be sufficient to prevent localized and also distant relapses,in spite of no regular prophylaxis of the CNS,relapse was also not occured.

1742

PRIMARY CUTANEOUS DIFFUSE B LARGE CELL NON-HODGKIN LYMPHOMA IN FIRST-DEGREE BLOOD RELATIVES

N Colovic[1], M Todorovic[1], M Perunicic-Jovanovic[2], M Colovic[1], B Mihaljevic[1]
[1]Medical Faculty, University Belgrade, Belgrade, Serbia
[2]Clinic of Hematology, Clinical Center Serbia, Belgrade, Serbia

Aims. The occurrence of non-Hodgkin's lymphoma (NHL) in several members of one family is uncommon and the real risk of lymphoma aggregation and mechanisms are uncertain. We present two brothers, whose mother died of gastric NHL, in whom in a period of 4 years cutaneous B diffuse large cell non-Hodgkin lymphoma appeared on the skin of the head and resolved on immunovhemotherapy with R-CHOP (rituximab and adriblastine, cyclophospahmiede, oncovine and prednisone). **Case Reports.** Case 1. A 44-year-old man, anesthesiologist, presented with a 16-year history of occipital and parietal alopecia and scalp itching. During the last year of the disease on the scalp appeared small nodules and crustae. The treatment with cortiocsteroids had no effect on the lesions. In November 2006, standard laboratory data indicated that the patient had a leukocytosis of 29 x 109/l (seg 69%, lymphocytes 20%, monocytes 11%), a fibrinogen of 7. 76 g/l and a mildly elevated LDH at 680 U/l (normal values 313-618 U/l). Bone marrow aspirate and biopsy, abdominal, chest and pelvis CT scan were negative for systemic lymphoma. CT scan of the head was normal except for the scalp soft-tissue abnormality. Histology from a scalp nodular biopsy showed dermal lymphoid infiltrates with numerous centroblasts, immunoblasts and centrocytes. Imunohistochemistry of the neoplastic cells showed that they were CD20+,CD79alfa+, bcl-2-, CD30-, CD3-, CD5-, CD10-, bcl-10-, MUM-, bcl-6+, CD138-. Ki-67, was positive in up to 60-80% cells. This finding corresponds to a transformation of the low-grade PCFCL to a high-grade diffuse large B-cell lymphoma. The patient was treated with R-CHOP protocol with excellent response and he is in remission ever since. Case 2. A 44-year male, truck driver presented with itching, alopecia and small cutaneous livid nodules on the scalp, the largest in diameter 2x2. He was treated with protocol CHOP for B NHL of the same localization 26 years earlier in his 18 year of life. He was in remission since than. Otherwise physical finding was normal. Chest and abdominal CT scan was normal. Bone marrow biopsy showed normal haematopoiesis. Laboratory data including CBC were in the normal range. Histology of the scalp nodules showed dermal and hypodermal infiltration with tumor tissue composed of large cells, with scarce cytoplasm and large oval, or irregular vesicular nucleuses, some were multinucleated. Immunohistochemistry of the neoplastic cells was as follows: Tdt-, PAX-5+, CD20+, CD3-, CD5-/+, CD10+/-, bcl-2-/+, MUM-1-, CD30-, cyclin D1-, Ki-67+ in 80% of cells. The finding corresponds to high grade diffuse B large cell lymphoma. The patient is under R-CHOP treatment with excellent response. **Conclusions.** Primary cutaneous non-Hodgkin's lymphoma (PCNHL) is a heterogeneous group of lymphoproliferative disorders characterized by their indolent course, virtually exclusive skin involvement and the absence of systemic disease. The presented cases are consistent with previous findings of familial aggregation of NHL. In this case environmental risk factors are unknown but as they were living together it is possible that environmental factors in addition to genetic might have played some part in the development of NHL in this family.

1743

THE EFFICACY OF INTERFERON-α IN NON CUTANEOUS PERIPHERAL T CELL LYMPHOMAS

M Moschoyiannis[1], G Pangalis[1], S Sachanas[1], C Kalapadakis[2], X Yiakoumis[1], T Vasilakopoulos[3], M Angelopoulou[3]
[1]Athens Medical Center, Phychikon Branch, Athens, Greece
[2]Haematology Department University of Krete, Heraklion, Greece
[3]Haematology Department University of Athens, Athens, Greece

Background. Peripheral T- cell lymphomas (PTCL) are a heterogeneous group of uncommon malignancies that represent approximately 12% of all lymphomas. Prognosis is poorer compared to B cell counterpart and despite various intensive regiments relapses are very common. Interpheron-α (INF-α) has long been known as an active agent in a variety of diverse malignancies. **Aims.** Based on the knowledge of successful management of cutaneous T cell lymphomas (T-NHL) with INF-α, we present our experience on administrating INFα in patients with non cutaneous PTCL. Patients and **Methods.** The retrospective study included 15 patients with non cutaneous PTCL who were treated with INF-α in our departments at a point of their disease course between February 1992 and July 2007. Patients received INF-α at a dose of 3-5MUI per day or 3-5MUI three to four times per week and the minority of them pegylated INF-α due to adverse reactions of classical INF-α. We isolate and present the group of 5/15 patients who received INF-α after failing standard therapy approach or as first line treatment due to personal reasons and achieved long term complete remissions (CR). **Results.** 2 male and 3 female patients with a median age of 30 years (range 18-50), two with T-NHL NOS, one with anaplastic large cell lymphoma (ALCL) ALK unknown, one with ALCL ALK+ and one with ALCL ALK- were studied. All 5 patients at diagnosis were either clinical stage I or II, with a good performans status, absence of B symptoms, no bulky disease and LDH within normal range. 3/5 patients had extranodal location of the disease at diagnosis (2 tongue, 1 lip). All but one received INF-α beyond first line treatment with combined chemotherapy (two second line treatment and two third line treatment after rescue and autologous stem cell transplantation). 3/4 patients were treated with CHOP regiment and 1/4 with ALL regiment as first line treatment. 4/4 patients relapsed after a median time of 7 months (range 2 to 30). One patient received INF-α as first line treatment due to 12th week of pregnancy at diagnosis. 5/5 patients are in CR, with a median follow up of 53 months (range 12 to 83) (Table 1). No major adverse reactions were noticed and all 5 patients

continued their treatment with no need of discontinuation. **Conclusions.** INF-α may have a beneficial role in a subset of patients with non-cutaneous PTCL who are refractory to standard therapy. These findings need to be further studied.

Table 1.

Pt	A/G	Dgn	Clinical stage	IPI	Reg. before INF Initiation	TTRel after 1st line Treatment	INF Cycles	Current Status

MATURE T CELL LYMPHOMA: EPIDEMIOLOGIC FEATURES AND THERAPEUTIC RESPONSE

K Kacem[1], S Zriba[2], S Kefi[1], R Ben lakhal[1], S Ben nasr[1], H Ghédira[2], R Ben amor[1], M Zarrouk[1], Z Manaï[1], H Ben neji[1], Y Ben abdennebi[1], R Jeddi[1], Z Bel Hadj Ali[1], H Ben Abid[1], F M'Sadek[2], B Meddeb[1]
[1]Aziza othmana hospital, Tunis, Tunisia
[2]Department of Internal Medecine, Military Hospital, Tunis, Tunisia

Background. T Cell Lymphoma accounts for only about 10% of all cases of Non-Hodgkin Lymphoma. **Methods and Aims.** We conducted a retrospective study including patients diagnosed with mature T cell lymphoma between 2001 and 2010 to determine the epidemiological features, the prognostic factors and to focus on therapeutic outcomes. **Results.** 43 patients were diagnosed with a median age of 47 (10-84). A male preponderance was noted with a sex ratio (M/F) of 3. 2. Systemic symptoms and PS (>=2) were present respectively in 41 % and 68 % of patients. The most common histological subtypes were: peripheral T cell (NOS) (35% of cases), Anaplastic T Cell lymphoma (ALCL) (25%), Angioimmunoblastic lymphoma (AIL) (25%) and T/NK nasal type in only 4 patients (9%). Advanced stages (III-IV) were observed in three quarters of patients. Organ involvement was found in 24 patients (55.8%). Extranodal spread of the disease with BM being the most frequent site (37.5%) followed by lungs (25%), liver (12.5%), skin (8. 3%), pleura (8.3%) and adrenal glands(8. 3%). Bulky disease was present in 8 patients (18.6%). The laboratory investigation showed elevated serum LDH (> 1normal) in 27 cases (62%). IPI scoring was available in all patients, accordingly 29 patients (67. 4%) had an IPI≥ 2 and 14 patients (32. 5%) had an IPI (0-1). 3 patients died before any treatment. The patients older than 65 years were treated by a mini CEOP regimen with a median number of courses of 6 (1-8), those under 65 years old received standard CHOP and CHOP-like regimen (CHOEP, ACVBP) with a median number of cycles of 4 (1-8). 2 children aged of 10 and 11 years received pediatric regimens, respectively LMB01 C3 and EORTC protocols. Only 32 patients were assessable for treatment response: 13 patients achieved CR (32.5%), 11 patients had PR (27. 5%), 3 patients had stable disease (SD) (7.5%) while 5 patients progressed. 5 patients died before assessment of treatment response with mortality rate of 12. 5 %. Response therapy was not recorded in 3 patients. Relapse rate was 25%. All relapses occurred within the first 12 months. The autologous SCT was performed in 7 patients, among them 5 were in first response. The median overall survival (OS) and event-free survival (EFS) were respectively 15. 25 and 17. 75 months. In univaried analysis, none of the following factors (LDH, stage, IPI) significantly affected OS and EFS. **Conclusions.** The epidemiological characteristics were similar to published data; however, our therapeutic results were poor compared to literature. In our series, no factor had been identified as significantly associated with poor OS and EFS due to the sample size.

1745

RA-36, NOVEL THROMBIN BINDING DNA APTAMER EXHIBITS HIGH INHIBITORY POTENTIAL AND SPECIFICITY FOR BLOOD COAGULATION

G Zavyalova[1], V Golovin[1], V Pavlova[2], M Kopylov[1]
[1]Moscow State University, Moscow, Russian Federation
[2]Gene Biology Institute RAS, Moscow, Russian Federation

Background. G-quadruplex-based DNA aptamers for human thrombin represent promising pharmaceuticals having high anticoagulant activity, rapid clearance from the bloodstream, and availability of DNA antidote. The successful examples are well described minimal G-quadruplex 15-TBA (Bock et al., Nature, 1992, v. 355, 564-566), elongated with hinge and duplex regions 31-TBA (Ikebukuro et al., Nucl. Acids Res., 2005, v. 33, e108), and developed recently modular aptamer RA-36 (PCT 2010/000750, December 13, 2010). RA-36 was shown to possess high inhibitory efficiency and low toxicity *in vivo*. **Aims.** High specificity of aptamers minimizes side-effects but at the same time leads to difficulties when choosing animal model for preclinical trials. In this work target- and species-specificity of DNA aptamers were investigated thoroughly. **Methods.** Enzymatic turbidimetry-based assay and fibrinogen and plasma clotting assays were used. **Results.** The experiments with human, bovine, porcine, rabbit, rat, and mouse thrombins have revealed the species-specificity of aptamers. In particular, mouse and rabbit thrombins gave heightened IC50 values in enzymatic and clotting assays. 15-TBA was shown to inhibit human, bovine, porcine, and rat thrombins with the same inhibition constants and types; whereas 31-TBA and RA-36 inhibited these thrombins with variable efficiency and inhibition type indicating that the G-quadruplex elongation does implement the subtle regulation of thrombin-fibrinogen interaction. A set of tests on blood clotting cascade was performed to investigate target-specificity of the aptamers. RA-36 aptamer was shown to inhibit plasma and blood clotting in all tests implied thrombin addition or generation and not to inhibit all other tests, including amidolytic activity of thrombin. The only exception represents ecarin and reptilase tests, which implies, correspondingly, meizothrombin and reptilase as fibrinogen clotting reagents. Thus, some cross-reactivity was observed for proteins with fibrinogen binding site. **Summary.** Given all together, the results indicate high target- and species-specificity of RA-36 characterizing it as new promising anticoagulant with minor side-effects. This work was supported by the Ministry of Education and Science, the State contract №- 16. 512. 11. 2009.

OXIDATIVE STRESS MEDIATED APOPTOSIS BY DISULFIRAM/COPPER COMPLEX IN CD34+CD38-KG1A CELLS IS REGULATED BY C-JUN-AMINO-TERMINAL KINASE AND NF-?B PATHWAY

B Xu[1], S Wang[2], P Shi[2], Z Zha[1], X Guo[2], L Yu[2], YY Zhang[1], S Zhou[2]
[1]Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China
[2]Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, Guangdong Province, China

Background. Acute myeloid leukemia (AML) is a hierarchical disease initiating by a rare population of cells known as leukemia stem cells (LSCs), which play the central role in the relapse and refractory of AML and represent a critical target for therapeutic intervention. CD34+CD38-KG1a cells, a subpopulation of the KG1a leukemia cell lines, have been demonstrated previously to meet the properties of stem cells and could be used as the cell model for LSCs research. Previous studies indicated that Disulfiram (DS), an anti-alcoholism drug, have a significant potential in the treatment of human cancers and this antineoplastic activity was enhanced in the present of copper (Cu). We presumed that DS might have the potential of targeting LSCs in a Cu-dependent manner. **Aims.** To determine the cytotoxicity of DS and DS/Cu complex in LSCs model CD34+CD38-KG1a cells and investigate the underlying molecular mechanisms related with oxidative stress, c-Jun-amino-terminal kinase(JNK) and NF-κB pathways. . **Methods.** CD34+CD38-KG1a cells were sorted from KG1a cell lines by fluorence-activated cell sorting (FACS) analysis. The cytotoxity of DS or DS/Cu complex on CD34+CD38-KG1a cells was detected using MTT assay. Annexin-V/PI and DCFH-DA were employed for apoptosis and intracellular ROS level analysis by flow cytometric analysis. Western blot was adopted for protein expression of NF-E2-related factor 2 (Nrf2), p65, JNK and p-JNK. **Results.** CD34+CD38- cells occupy about (50. 135±4. 53) % of the KG1a cell lines, after FACS sorting, more than 95% of the cells were labeled for CD34+CD38-. DS was highly toxic to CD34+CD38-KG1a cells with IC_{50}48h=6. 269 ±1. 466μM and IC_{50}72h=2. 61 ±0. 931μM, respectively. The cytotoxicity was enhanced by combining use of low concentration of CuCl2 (1μM) with IC_{50}48h=1. 028±1. 017μM and IC_{50}72h =0. 83±0. 937μM. DS induced CD34+CD38-KG1a cells into apoptosis, but the apoptotic population

was massively increased by exposed to DS/Cu complex. Nrf2 is an important regulator to deal with oxidative stress. Western blot showed DS/Cu complex but not DS alone inhibited Nrf2 nuclear translocation. ROS levels are predominantly regulated by the transcription factor Nrf2, consistently. DS/Cu induced intracellular ROS generation. The p-JNK protein expression was up-regulated in CD34+CD38-KG1a cells treated with DS/Cu while p65 protein was down-regulated. In addition, the antioxidant N-acetyl-L-cysteine (NAC) attenuated DS/Cu complex-induced apoptosis, restored Nrf2 nuclear translocation and reversed p-JNK expression. **Conclusions.** DS/Cu complex potentiated cytotoxicity to CD34+CD38-KG1a cells through apoptosis induction. The death-signaling pathway revealed that Nrf2 inhibition and ROS generation, followed by activation of JNK as well as suppression of NF-κB pathways were involved.

1747

CLINICAL FEATURES AND OUTCOME OF 16 PATIENTS WITH PNH TREATED WITH ECULIZUMAB IN SAO PAULO - BRAZIL

D Ghidettti M. Catarino[1], A Carvalho[2], T Xavier Carneiro[1], F Blumm Ferreira[1], E Rizzatti[3], M Arruda[2], M Oliveira Barros[2], M Yamamoto[2], M Figueiredo[2], C Arrais Rodrigues[1]
[1]Hospital Sírio Libanês, São Paulo, Brazil
[2]Universidade Federal de Sao Paulo, São Paulo, Brazil
[3]Fleury Medicina e Saúde,, São Paulo, Brazil

Introduction. Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare clonal hematopoietic stem cell disease characterized by intravascular hemolysis, constitutional symptoms, bone marrow failure and thrombosis. Intravascular hemolysis occurs because erythrocytes become more susceptible to the terminal complement pathway. Eculizumab, a monoclonal antibody against complement C5 fraction, is the first effective drug to treat hemolysis and its consequences in patients with PNH. **Aims.** Our goal was to analyze clinical and laboratory features and flow cytometry studies from 16 patients receiving eculizumab in two centers inSao Paulo-Brazil. **Methods.** The Informed Consent was obtained by personal interview with all patients that participated in this study. Sixteen consecutive patients with PNH were prospective analyzed. Patients were followed clinically and by routine laboratory tests in order to evaluate response to treatment. Besides, PNH clone size in erythrocytes, granulocytes and monocytes were assessed by multiparametric flow cytometry before and after treatment was started. **Results.** Median age was 35 years (range: 22-81), 10 (63%)were female and most patients (11 cases - 69%) had classical PNH. Two patients had aplastic anemia and 3 had myelodysplastic syndrome in association with PNH. All patients had frank chronic hemolysis. All patients had large granulocyte and monocyte clones (at least 50%). Median clone size was 30% in red blood cells (range: 5-63%), 78% in neutrophils (range: 55-99,5%) and 88% in monocytes (range: 69-99,9%). Eight patients (50%) had history of venous thromboembolism and 4 of these (50%) were still receiving anticoagulation at the eculizumab was started. Three patients were receiving anticoagulation for primary prophylaxis. Median time between onset of symptoms and diagnosis was 18 months (range: 0-85), and between diagnosis and eculizumab treatment start was 40 months (range: 2-267). Median follow-up time was 57 months (range: 8-286); and median time of eculizumab treatment was 12 months (range: 1-41). There was a significant reduction in the LDH levels: median LDH level was 1841 U/L (range: 797-4319) pre-treatment and 501U/L (range: 200-789, $p < 0.0001$) at week 5. There was also significant reduction in transfusion requirement, most patients becoming transfusion independent. There was also a significant improvement in quality of life assessed by FACIT (functional assessment of chronic illness therapy) questionnaire. After eculizumab was started, there were no episodes of venous or arterial thromboembolism. There was no significant change in clone size after eculizumab treatment. **Summary and Conclusions.** in this series of Brazilian patients, treatment with eculizumab was highly effective in controlling chronic hemolysis, reducing transfusion requirement and improving quality of life.

ENALAPRIL MALEATE HAS CYTOTOXIC EFFECT IN HL 60 LEUKEMIC CELLS BY ALTERING STAT SIGNALING PATHWAY

F Sahin[1], O Purclutepe[2], HD Kiper[2], B Tezcanli[3], N Selvi[3], CB Avci[3], Y Baran[4], B Kosova[3], G Saydam[2]
[1]Ege University Hospital, Bornova Izmir, Turkey
[2]Internal Medicine, Ege University Hospital, Izmir, Turkey
[3]Medical Biology, EUTF, Izmir, Turkey
[4]Molecular Biology, IYTE, Izmir, Turkey

Background. Many chemotherapeutic agents have been used in the treatment of acute leukemia, but not yet provided a definitive treatment. Angiotensin converting enzyme inhibitors have been evaluated in many medical conditions other than hypertension including therapy of malignancies due to the potential role of ACE in homeostasis of certain type of tissues such as bone marrow. There are recently some reports indicating the changes of angiotensin-renin system in pathological conditions in bone marrow. **Aims.** In this study, we aimed to evaluate the cytotoxic and apoptotic effects of enalapril on human HL60 acute leukemia cells and to clarify the roles of signal transducers and activator of transcription proteins (STATs) on enalapril induced cell-death. **Methods.** In this study acute leukemia cell line HL60 was treated with enalapril maleate in dose and time dependent manner. Cell viability was assessed at 0, 24th,48th,72 nd and 96 th hour with trypan blue dye-exclusion method and its cytotoxcicity was checked by XTT method. Apoptotic analyses were performed by AnnexinV-EGFP staining method and fluorescence microscopy. Expression levels of STAT3, -5A and -5B genes were analysed in enalapril-treated HL60 cells by qRT-PCR. **Results.** According to the results obtained in our experiments, enalapril was found to induce cytotoxicity in HL 60 cells in dose and time dependent manner. Its IC50 dose was calculated as 7 microM. In HL60 leukemia cells treated with doses of 7 micromolar enalapril, time-dependent expression of STAT3 was investigated with PCR method and it was showed the partially reduced STAT3 expression in enalapril-treated cells when its compared with control group. This reduction was not statistically significant ($p>0.05$). STAT 5A expression was significantly decreased in enalapril treated cells and this difference was statistically significant ($p<0.05$). STAT 5B expression was not changed significantly in enalapril-treated cells when its compared with control group ($p>0.05$). When we assessed the apopitosis with Annexin V method in enalapril treated HL-60 cells, it was detected that there was a slight increase in the number of apoptotic cells within first 48 hours. **Summary and Conclusions.** Taken together all these data showed for the first time that enalapril has significant anti-cancer potential for the treatment of acute leukemia. It is needed to have further studies to clarify the interaction of signalling pathways as an underlying mechanism of enalapril-induced cytotoxicity in HL60 leukemic cells.

1749

PRACTICAL EXPERIENCE WITH A NEW APPLICATION MODE OF RITUXIMAB: A RETROSPECTIVE SURVEY ON THE ADMINISTRATION OF SUBCUTANEOUS RITUXIMAB AMONG STUDY NURSES INVOLVED IN THE CLINICAL DEVELOPMENT PROGRAM

P Sayyed[1], M Shaw[2], G Schnetzler[1]
[1]F. Hoffmann-La Roche Ltd, Basel, Switzerland
[2]Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Background. Subcutaneous (SC) administration of rituximab has been made possible by co-formulation with recombinant human hyaluronidase (rHuPH20). Compared with standard intravenous (IV) infusion over several hours, rituximab SC may be injected in approximately 6 minutes, typically administered by nurses. This could potentially benefit both patients and healthcare providers. The clinical development program of rituximab SC is based on three randomized clinical trials, which for NHL used a fixed dose of 1400 mg rituximab in an injectable volume of 11.7 ml. Subcutaneous injection of this volume and quantity of monoclonal antibody is unprecedented, and so all aspects of clinical utility and practicality of the rituximab SC injection need to be assessed. Study protocols advise to inject rituximab SC manually into the abdomen using a 27-gauge needle at an injection rate of approximately 2 ml/min. **Objectives.** The aim of the survey was to gain feedback from nurses who are actively participating in rituximab SC clinical trials on different aspects of the rituximab SC administration protocol. **Methods.** A questionnaire in English (later translated into Italian, Spanish, French, and German) was developed by the sponsor for the assessment of nurses' overall impression of using rituximab SC, their experience with the process of rituximab SC administration, aspects of patient care in the context of rituximab SC administration, and potential areas for improvement of the injection. The questionnaire comprised 26 items, with most answers based on a 4-point Likert scale and options for free text answers. Study nurses at investigational sites, who had administered rituximab SC injections to at least one patient, were invited to participate in this internet-based, anonymous, and voluntary survey. The survey was conducted between November 3 and December 19, 2011. **Results.** The survey was sent to 71 sites; 65 questionnaires were completed in full and included in this analysis. The nurses treated a total of 166 patients, with most nurses (63%) having administered 1-5 injections. The majority (72%) reported that SC administration was 'easy' or 'very easy'; however, 55% felt that SC administration of rituximab required a significant amount of physical effort. Approximately, half of those surveyed felt that rituximab SC could be administered at a faster rate without additional stress/pain to the patient, or that administration could be easier using a larger needle. Most nurses (88%) found that during administration of rituximab SC it was easy to hold a conversation with the patient receiving the injection, with only

5% of nurses reporting that it felt unpleasant being close to the patient for the SC injection period of 6 minutes. Overall, nearly all nurses (95%) rated the overall experience with rituximab SC as 'positive' or 'very positive' and would recommend it to patients (95%). **Conclusions.** This survey revealed that nurses generally considered SC administration to be easy and would recommend it to patients. Nurses felt that the mode of administration allowed for conversation and easy interaction with the patient. Further improvements to the method of administration could be explored.

1750

A NOVEL AGENT, KL-21, HAS SIGNIFICANT ANTICANCER POTENTIAL ON CHRONIC LYMPHOCYTIC LEUKEMIA CELLS BUT NOT ON HEALTHY CELLS

Y Baran[1], A Gokbulut[2], M Yasar[3]
[1]Izmir Institute of Technology, Izmir, Turkey
[2]Izmir Institute of Technology, Department of Molecular Biology and Genetics, Izmir, Turkey
[3]Naturin Natural Products, Izmir, Turkey

Background. Chronic lymphocytic leukemia (CLL) originates from antigen-stimulated mature B lymphocytes that either avoid death by external signals or die by apoptosis. Chromosomal translocations are rare in CLL and no specific mutations have been identified yet. Therefore, cytogenetic lesions are not likely to be a inducing factor in CLL. Chemotherapy, radiotherapy, biotherapy, transplantation of hematopoietic progenitors and monoclonal antibody immunotherapy are used for the treatment of CLL. However, these standart treatment methods are not sufficient to remove all CLL cells and have their own side effects. Therefore, developing new strategies or agents that could eliminate CLL cells has vital importance. **Aims.** The aim of this study to examine antiproliferative, cytostatic and apoptotic effects of KL-21 (produced by Naturin Natural Products Company, İzmir, Turkey) on 232B4 CLL cells. We also aimed to determine any adverse effects of KL-21 on healthy BEAS-2B human bronchial epithelial cells. **Methods.** Antiproliferative effects of KL-21 on 232B4 and BEAS-2B cells were determined by MTT cell proliferation assay. Apoptotic effects of KL-21 were determined by changes in caspase-3 enzyme activity, loss of mitochondrial membrane potential, and Annexin-V staining by flow cytometry. Cytostatic effects of KL-21 were examined using DNase-free RNase and propidium iodine by flow cytometry. **Results.** 232B4 and BEAS-2B cells were treated with increasing concentrations of KL-21 (0. 0001-1 µg/µl) for 24, 48 and 72 hours and their proliferation was examined by MTT assay. There were significant decreases in proliferation of 232B4 CLL cells in a dose- and time dependent manner while KL-21 showed no cytotoxic effects on BEAS-2B healthy cells. IC50 values of KL-21 at 24, 48 and 72 hours were calculated from cell proliferation plots and found to be 0,2-, 0,1, and 0,08 µg/µl, respectively. Increasing concentrations of KL-21(0. 001- 1 µg/µl) increased caspase-3 enzyme activity, induced loss of MMP and triggered apoptosis significantly. There were 2-, 3-, 23-, 52- and 112% increases in caspase-3 enzyme activity; 31-, 45-, 260-, 312-, and 1340% increases in loss of MMP; and 16-, 23-, 28-, 77- and 228% increases in apoptotic cells in response to 0. 001, 0. 01, 0. 05, 0. 1 and 1 µg/µl KL-21, respectively, as compared to untreated 232B4 control. Treatment of 232B4 cells with KL-21 (0. 0001-1 µg/µl) for 48 hours resulted in a significant increase in G0/G1 and G2 phases while decreased S phase cell population as compared to untreated controls. **Summary and Conclusions.** Our results, in agreement with eachother, showed that KL-21 inhibits proliferation and cell cycle progression and induces apoptosis in a CLL cell specific way while it has no effect on healthy cells. Our data can suggest potential use of KL-21 for the treatment of CLL. The mechanisms of KL-21 induced apoptosis is under investigation in our laboratory both *in vitro* and *in invo*.

MULTIPOTENT VDELTA2-NEGATIVE GAMMA-DELTA T-CELLS AFTER CMV-REACTIVATION IN ALLOGENEIC STEM CELL TRANSPLANTATION

Hantschel[1], S van Dorp[2], S Kersting[2], F Pietersma[2], S Hol[2], V Marcu-Malina[2], S Becke[3], B Plachter[3], D van Baarle[2], J Kuball[2]
, Switzerland
[2]University Medical Center Utrecht, Utrecht, Netherlands
[3]University Medical Center of the Johannes Gutenberg-University, Mainz, Germany

Background and Aims. Human cytomegalovirus (CMV) infections and relapse of disease remain major problems after allogeneic stem cell transplantation (allo-SCT), and adoptive transfer of antigen-specific αβT-cells has been proposed as a treatment strategy. However, transfer of antigen-specific αβT-cells is substantially hampered by their MHC-restriction and the fact that sufficient numbers of e. g. CMV-reactive αβT-cells can be exclusively isolated from CMV-positive donors. Great promise as an alternative strategy, with a potential use for very broad patient population, arises from the non-MHC-restricted target-recognition of cancer cells and virally-infected cells by γδT-cells. Therefore, we investigated the role of γδT-cells after allo-SCT and CMV infection. **Results and Conclusions.** An increase in selectively Vδ1-positive γδT-cells was observed in CMV-reactivating patients from CMV-positive conventional donors. Even more important, γδT-cell expansions were also observed after CMV-negative cordblood transplantation. However, in contrast to expansions from CMV-positive donors, γδT-cells from cordblood donors did not only include Vδ1-positive but also Vδ3-positive cells. Expanded Vδ2-negative γδT-cells were not only able to lyse CMV-infected fibroblasts, but also to partially mature dendritic cells (DCs) and to kill primary leukemic blasts. In order to investigate whether these different functions observed in γδT-cells which expand after CMV-infection are restricted to one cell type or to a diverse γδT-cell-repertoire which expands after CMV-infection, γδT-cells were further cloned by limiting dilution. CMV- and leukemia-reactivity were restricted to the same clonal population and separated from DC-maturation capacities of Vδ2-negative T-cells. Finally, γδT-cell receptor (TCR)-gene transfer experiments indicated that here-isolated Vδ2-negative γδTCRs selectively mediate anti-leukemia-reactivity and that activation of T-cells also depends on the presence of NKG2D. This makes CMV-reactive γδT-cells e. g. from cordblood donors as well as individual Vδ2-negative γδTCRs interesting candidates for adoptive immunotherapy strategies.

1752

THROMBOCYTOPENIA AS FIRST MANIFESTATION OF COELIAC DISEASE-CASE REPORT

V Djurasinovic, N Suvajdžic-Vukovic, S Andrejevic, I Djunic, A Sokic-Milutinovic, D Tomin
Clinical Center of Serbia, Belgrade, Serbia

Introduction. Coeliac diseasse (CD) is the most frequent chronic misdiagnosed diseasse. For its development needs genetic predisposition and other factors. Incidence is 1/133 and between relatives 1/21. Besides gastroenterologic manifestations there are a big number of hematologic manifestations of CD (most frequent: anemia, thrombocitosys, IgA deficiency;rearly: thrombocytopenia, leukopenia, koagulation disorders, lymphomas and tromboembolic complications). We report a case of newdiagnosed CD with thrombocytopenia as only manifestation. **Case Report.** Female patient (pt), 55 years old, was examined because of thrombocytopenia- $43x10^9$ /l. Other parameters of blood cell count, biochemical analysis and virusological analisys where normal. Bone marrow aspirate showed megacariocytic thrombocytopenia. Indirect imunofluorescence (IIF) reveled presence of significant level of anti-endomisial antibodies (EMA). Because of thrombocytopenia at that moment gastrointestinal byopsi did not done. Gasteointestinal passage showed malapsortion. We started with gluten free diet without corticosteroid therapy. For one month platelet number normalised and remained normal untill nowdays- for 15 monts. After platelet normalisation gastrointestinal biopsy was done and confirmed CD. Pt was screened for Hashimoto thyreoiditis and diagnose was confirmed. She takes thyreosubstitutional therapy. As far as we know there are only three published cases like this. **Conclusions.** CD has many clinical manifestations and among population, very often, is a silent diseasse together with other autoimmune diseasses. It was showen that in some pts who were on gluten free diet hematological parameters where normalised, thus we recomend serological examination for CD in cases of autoimmune cytopenias, especialy in thrombocytopenia.

1753

IL-10 AND IL-17 GENE POLYMORPHISMS IN ADULT IDIOPATHIC THROMBOCYTOPENIC PURPURA

M Yilmaz[1], T Tat[2], N Erkut[3], N Ermantas[3], Y Alp[4], M Ikbal[4], A Alver[5]
[1]Karadeniz Technical University, Faculty of Medicine, Trabzon, Turkey
[2]Karadeniz Technical University, Faculty of Medicine, Dept. of Internal Medicine, Trabzon, Turkey
[3]Karadeniz Technical University, Faculty of Medicine, Dept. of Hematology, Trabzon, Turkey
[4]Karadeniz Technical University, Faculty of Medicine, Dept. of Medical Genetics, Trabzon, Turkey
[5]Karadeniz Technical University, Faculty of Medicine, Dept. of Biochemistry, Trabzon, Turkey

Background. In adults ITP is primarily characterized by increased platelet destruction, it is chronic, acquired and organ specific autoimmune disorder.

When the literature is analysed, many investigations about interleukin-10 and interleukin-17 gene polymorphisms in rheumatoid arthritis, Behçet's disease, Graves' disease, ulcerative colitis, asthma, atopic dermatitis, celiac disease in which autoimmune disorder is associated with their pathogenesis are seen and there are significant differences in some of them. In ITP which is an immune-mediated disorder there are a few study. **Aims.** In this study we aim to investigate IL-10 (-592 A/C) and IL-17 (A126G) gene polymorphisms and their serum levels in patients with ITP and control groups. **Methods.** We examined 50 patients with ITP and 50 healthy controls for IL-10 and IL-17 gene polymorphisms and 32 patients with ITP and 32 healthy controls with ELISA for plasma levels. **Results.** After the investigation of IL-10 (-592 A/C) and IL-17 (A126G) gene polymorphisms and their plasma levels in patients with ITP and control groups, no significant differences can be found in IL-10 (-592 A/C) and IL-17 (A126G) gene polymorphisms and IL-17 serum levels between patients with ITP and control groups. However IL-10 serum levels are significantly higher in patients groups compared to control groups (p:0,003). In addition we investigate the relationship between age, sex, treatment respond and platelet count in diagnosis in patients, IL-10 (-592 A/C) and IL-17 (A126G) gene polymorphisms and their plasma levels in patients with ITP but there is no significant differences between groups. **Conclusions.** The result of this study - there is no significant differences in IL-10 (-592 A/C) and IL-17 (A126G) gene polymorphisms and IL-17 serum levels between patients with ITP and control groups- demonstrates that there may be no contribution of them in developing ITP. IL-10 serum levels are significantly higher in patients groups compared to control groups. There are lots of contradictory results in IL-10 serum levels in ITP patients. Large prospective studies of cytokine gene polymorphisms are needed to determine the role they play in ITP.

A NOVEL ADAMTS13 MUTATION IN THROMBOTIC THROMBOCYTOPENIC PURPURA PRESENTED IN AN OLD PATIENT

S Guvenc, V Hancer, F Hindilerden, R Diz-Kucukkaya
Istanbul Bilim University, Istanbul, Turkey

Background. Thrombotic Thrombocytopenic Purpura (TTP) is a rare life-threatening disorder characterized by classic clinical pentad (thrombocytopenia, microangiopathic hemolytic anemia, fever, renal and neurologic abnormalities). It is associated with a deficiency of ADAMTS13 (a disintegrin and metallo-protease with thrombospondin type 1 motif, 13) that is responsible for cleaving large multimers of the von Willebrand factor. In adults, deficiency of ADAMTS13 are frequently caused from acquired production of antibodies to ADAMTS13. Inherited forms of deficiency is associated with mutations of the ADAMTS13 gene located on chromosome 9q34 and first acute episode of TTP usually presented in childhood. **Aims.** We herein report a case of TTP with new ADAMTS13 mutation whose first episode presented at the age of 61 and refractory to plasma exchange (PEX). **Case presentation and Methods.** A 61 year-old man was admitted to another university clinic in Turkey with headache, fever, hematuria and somnolonce. In examination, body temperature was 38,4ºC and widespread echymosis was noted. Laboratory was revealed thrombocytopenia (platelets 32x10^9 /L) and anemia (Hb 9,2 g/dl) with high creatinine (2,4 mg/dl) and LDH (930 U/L) levels. Schistocytes and decreased thrombocytes was noted in peripheral blood smear. With clinical and laboratory findings, patient was diagnosed as TTP and methylprednisolone 1 mg/kg and PEX for one volüme/day were started. After 22 cycle of PEX, thrombocytes was increased to 150x10^9 /L but LDH levels was continued to be high and schistocytes still found. Vincristine 2 mg was given and patient was accepted as refractory to PEX. Splenectomy was adviced but he refused. He admitted to our hematology clinic for evaluation after 1 month without PEX therapy. He had no any physical and neurological finding in our examination. Laboratory investigations were as follows; Platelets 123x10^9 /L, Hb 13,3 g/dl, Creatinine 0,51 mg/dl, LDH 427 U/L (NR 125-240 U/L). He was using methylprednisolone 32 mg/day. We performed ADAMTS13 gene analysis. The 7, 10, 11, 12 and 13 and 14th exons of ADAMTS13 gene were amplified on genomic DNA using HibriGen 2X PCR master mix (HibriGen Biotechnology R&D, Istanbul, TURKEY) according to the manufacturer's specifications. PCR products were genotyped by automatic DNA sequencing in a sequencer (ABI 3130xl, Applied Biosystems, Fosters City, USA) using dye terminator cycle sequencing kit (Applied Biosystems, Fosters City, USA). Heterozygous S553I mutation was found in exon 14 of the gene (Figure 1). Methylprednisolone tapered and patient closely followed without any treatment. After 4 months on follow-up, patient is in remission without any clinical and laboratory finding of TTP. **Conclusions.** We found a new ADAMTS13 gene mutation which caused TTP at the age of 61. To date, we did not find any report showing ADAMTS13 exon 14 S553I mutation. ADAMTS13 gene mutation must be considered in patients with TTP especially who is refractory to PEX and ADAMTS13 gene analysis must be performed without regarding any age group of patients before the decision of splenectomy.

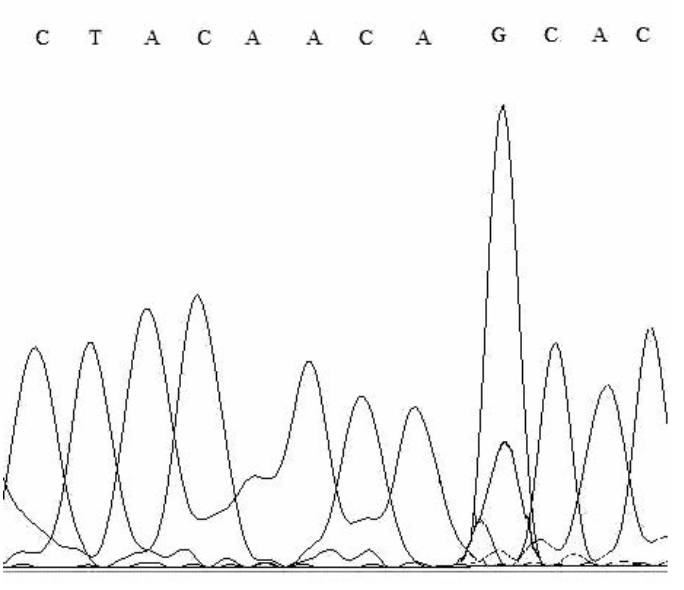

Figure 1. S553I heterozygous mutation in the ADAMTS13 gene.

1755

AN EXPERIENCE WITH LOW DOSE RITUXIMAB FOR THE TREATMENT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA: A RETROSPECTIVE ANALYSIS OF SIX PATIENTS

K Raza, P Murphy, J Quinn, P Thornton
Beaumont Hospital, Dublin, Ireland

Background. In recent years, rituximab, at a standard dose of 375mg/m^2 has emerged as a valuable treatment option for patients with refractory immune thrombocytopenic purpura (ITP) inducing responses in up to 50% of patients. In fact, recently reported studies have suggested that a lower dose of rituximab (100 mg weekly for four weeks) may be an effective treatment regimen for refractory ITP. Such an approach has the potential to both reduce toxicities and also reduce healthcare associated costs. Rituximab is a chimeric monoclonal antibody which binds to the CD20 antigen on B cells and is highly effective in depletion of these cells. As a result of this depletion of B cells, a decrease in antiplatelet auto antibodies probably occurs, thus abrogating the thrombocytopenia. **Objectives.** To investigate the activity and safety of low dose rituximab in previously treated symptomatic ITP. **Methods.** Retrospective analysis of six patients with refractory ITP treated with a fixed dose regimen of rituximab (100mg weekly for 4 consecutive weeks). **Results.** Six patients were identified with chronic ITP. All patients had received two or more lines of prior treatment. Four patients had pre-treatment platelet counts below 20 x 10^9/L and two patients had platelet count of 20-30 x 10^9/L. Platelet responses were recorded 8-12 weeks post-treatment. One patient (male, age 46 years) had minimal but durable response (platelet 30-50 x 10^9/L) and remained asymptomatic. Second patient (female, age 76 years) showed no improvement in platelets. She required further treatment with pulse of dexamethasone to achieve stability (platelet 50 x 10^9/L). No response was observed in third patient (female, age 46 years) who required IVIG to maintain her platelets between 30-50 x 10^9/L. Fourth patient (male, age 42 years) failed to achieve any response (platelet < 10 x 10^9/L). He achieved complete response with romiplostim (platelets 121 x 10^9/L). Fifth patient had no response to low dose rituximab. She then received standard dose rituximab to which she had a partial response (platelet 56 x 10^9/L). Sixth patient (female, age 30 years) required no further treatment after low dose rituximab with platelet count 50-60 x 10^9/L. Thus 2 out of 6 patients had a minimal to partial response and were asymptomatic. Remaining four patients required further treatments after failure of low dose rituximab. **Conclusions.** This study shows that low dose rituximab produced significant overall response only in 2 out of 6 (33%) patients which is rather disappointing when compared to that seen with standard dose rituximab. Our experience with low-dose rituximab in this small group of patients suggests that further randomized trials are warranted involving a much larger number of patients with refractory ITP, preferably comparing standard with low dose rituximab before it is incorporated into standard treatment protocols.

1756

GENETIC ASSOCIATION OF INADEQUATE ANTIPLATELET EFFECTS OF ASPIRIN AND CLOPIDOGREL IN PATIENTS WITH CORONARY ARTERY DISEASE (CAD): A PRELIMINARY STUDY

V Arya, M Bhargava, A Saraf, A Mohanty, J Sawhney
Sir Ganga Ram Hospital, Delhi, India

Background. Combination therapy with clopidogrel and low dose aspirin is the current standard of care in the management of patients with Coronary Artery Disease (CAD) including acute coronary syndromes (ACS). Between 4-30% of patients treated with conventional doses of clopidogrel show an inadequate platelet response. This may partly be done to underlying genetic diversity among individuals. Platelet resistance to aspirin is reported to affect <1% of patients as tested by light transmission aggregometry (LTA). To the best of our knowledge, no studies are available in the Indian population of genetic polymorphisms which may affect platelet response by these antiplatelet agents. **Aims.** To evaluate whether genetic polymorphisms are related to altered response to aspirin and clopidogrel. **Methods.** A total of 27 patients with CAD/ACS who were stable on dual anti platelet therapy (Clopidogrel 75 mg OD and aspirin 150 mg OD), were investigated along with age and sex matched 28 controls. Demographic and clinical data was collected on a predesigned clinical proforma. Platelet function testing by light transmission aggregometry was done with 4 agonists (ADP 2µM and 10µM, Epinephrine 5µM, Collagen 2µg/ml, Arachidonic Acid 0. 75mM) in each patient/control. After meta analysis the criteria employed for the Aspirin resistance was mean platelet aggregation ≥70% with 10µM ADP and ≥20% with 0. 75mM of Arachidonic acid. Aspirin semi responders were defined as those meeting only one of the above criteria. Clopidogrel resistance was defined as <10% decrease from the baseline in platelet aggregation in response to ADP 2 & 10µM. Semi responders were defined as 10-29% (<30%) decrease from the baseline. A baseline mean platelet aggregation obtained from 28 controls. Polymorphisms CYP2C19*2, CYP2C*3, CYP3A5*3 and PLA1/A2 were genotyped by PCR-RFLP. **Results.** Since arachidonic acid induced aggregation was adequately inhibited in all patients, no aspirin resistance was found. ADP induced aggregation, however was highly variable among patients. While no clopidogrel resistance was observed, 13(48%) patients were semi responders to clopidogrel. had higher frequency of the *2 Allele of CYP2C19 as compared to responders (p=0. 004). The mutant homozygous and heterozygous genotypes (*2/*2 or *2/*1) of CYP2C19 was found to be significantly higher in clopidogrel semi responders than in responders patients (100% vs 35. 7%, p=0. 0006 respectively). Also ADP (10µl) showed significantly reduced platelet inhibition in patients with mutant homozygous/ heterozygous genotypes ((*2/*2 or *2/*1) of CYP2C19 as compared to patients with wild type (*1/*1) genotype (p=0. 0001). **Conclusions.** There was significantly higher frequency of mutant genotype of CYP2C19 in clopidogrel semi responders as compared to responders. The clopidogrel response to antiplatelet drugs was inadequate (semi responders) in those with mutant genotypes. These preliminary findings suggest that polymorphisms may be associated with inadequate response to antiplatelet drugs.

1757

THROMBOCYTOPENIA IN NEONATES: CAUSES AND OUTCOMES

E Ulusoy, O Tufekci, N Duman, A Kumral, G Irken, H Oren
Dokuz Eylul University, Izmir, Turkey

Neonatal thrombocytopenia is defined as a platelet count <150,000/mm³ in any neonate of a viable gestational age. Thrombocytopenia is one of the most common hematologic abnormality in the neonatal period. This study which is purposed to decrease prevalence of thrombocytopenia by eliminating preventable factors and to determine the treatment and clinical outcomes of neonates with thrombocytopenia, in the neonates admitted to neonatal service and neonatal intensive care unit, is designed as a retrospective study. In 3515 neonate the thrombocytopenia prevalence is found 3. 8 % of all neonates (1. 3 % in terms, 12% in preterms) and 12 % in those admitted to the neonatal intensive care unit. Sepsis and IUGR are found as the most common causes of thrombocytopenia. The analysis of the prevalance of thrombocytopenia according to years revealed that the highest prevalence was in the year 2008 by 5. 3 %, and the lowest prevalance was in the year 2011 by 2. 4%. When the caues of thrombocytopenia were analysed, it is seen that sepsis was the most common reason between years 2007-2009, whereas IUGR took place in 2010. On the other hand, thrombocytopenia caused by metabolic disorders, drugs and asfixia was more common in 2011. The median day of determination of thrombocytopenia was found as 1st posnatal day, median nadir platelet count was found as 6th day, median improvement day was found as 10th day. Median platelet count was 50,000/mm³. Severe thrombocytopenia was found in 26 % of neonates and %11 of thrombocytopenic neonates had major hemorrhage. Intracranial hemorrhage ratio was 5. 9 % and all of these patients were preterm. The incidence of hemorrhage increased with severity of thrombocytopenia. Severe thrombocytopenia was significantly higher in mechanically ventilated neonates. Platelet transfusion was given to 33% of neonates and the mortality rate was increased in these neonates. Thrombocytopenia improved in 93 % of patients and persisted in %4 of patients. Death occurred in 3% of neonates with thrombocytopenia but the causes of death in those patients were not attributable to thrombocytopenia. In conclusion, we found that the prevalance of thrombocytopenia decreased significantly during recent years and the distribution of causes of thrombocytopenia according to years changed in our neonatal service and neonatal intensive care unit. This study shows that rate of thrombocytopenia can be lowered by eliminating prevantable factors of thrombocytopenia in neonates and as a result, complications and risks of thrombocytopenia and platelet transfusion can be decreased.

1758

DEVIATIONS FROM NORMAL VALUES OF LEUKOCYTE AND ERYTHROBLAST PARAMETERS IN COMPLETE BLOOD COUNT IS A MESSENGER FOR PLATELET ABNORMALITIES

C Beyan, K Kaptan, A Akyol Erikci
Gulhane Military Medical Academy, Ankara, Turkey

Background. Automated blood cell counters have undergone a formidable technological evolution owing to the introduction of new physical principles for cellular analysis and the progressive evolution of software. The results have been an improvement in analytic efficiency and an increase in information provided with new parameters. **Aims.** In this case report, we imply the incompatibilities between uncorrected leukocyte count (UWBC), leukocyte count (WBC), and erythroblast count (NRBC) might be predictors for morphological and numerical abnormalities of platelets. **Methods.** A 61 year old male patient had the diagnosis of ''diffuse large B-cell lymphoma'' six years ago and after chemotherapy was still in remission. He was hospitalized for high fever, fatigue, acute renal failure and bibasilar crepitant rales. Complete blood count revealed UWBC 63. 5 x10^9/l, WBC 22. 1 x10^9/l, NRBC 21. 4 x10^9/l, and platelets 197 x10^9/l. On peripheral blood smear examination we detected 5% neutrophils, 22% band forms, 61% metamyelocytes, 5% myelocytes, 1% promyelocyte, 2% myeloblasts, 2% lymphocytes and 2% eosinophils. We also detected rare erythroblasts and large platelets with profuse platelet clumps. Routine biochemical analysis revealed high fasting glucose, blood urea nitrogen, creatinine, SGOT, alkaline phosphatase, direct and indirect bilirubin, albumin, and lactate dehydrogenase. Erythrocyte sedimentation rate was 100 mm/hour, and serum ferritin was 2 944 ng/ml. High resolution computed tomography of thorax revealed bilateral diffuse infiltrations, nodular opacities, right pleural effusion, and mediastinal lymphadenopathies.

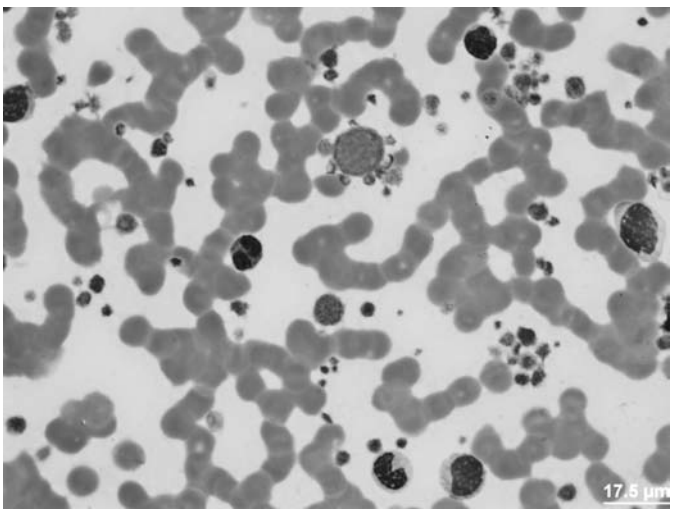

Figure 1. Peripherall blood smear.

Results. Clarithromycin and imipenem/cilastatin were administered for probable diagnosis of pneumonia. Bone marrow examination had myeloid hyperplasia but nothing significant else. No endobronchial mass was detected in bronchoscopy, but mucopurulent secretion was present in right upper and lower lobes. Biopsy reports were non-neoplastic bronchial mucosa epithelium. Sputum, blood, urine cultures, sputum mycobacterial examination and serum galac-

tomannan antigen were negative. After general condition, fever, acute renal failure, signs and symptoms relieved, he was discharged. **Conclusions.** When we subtracted WBC and NRBC from UWBC (=20. 0 x10^9/l), a significant cell group was composed of big platelets. It is probable that this ratio is higher than calculated. Rare erythroblasts in peripheral blood smear with high NRBC values support the idea of large platelets as cellular origin. In fact, peripheral blood smear revealed large, profuse platelet clumps contradictory to platelet count (Figure 1). We conclude that complete blood counts should be examined carefully, despite the essential role of automation in the modern hematology laboratory, microscopic control of pathologic samples (peripheral blood smear) remains indispensable, so much so that in certain cases, it alone is diagnostic.

1759

ITP SUCCESSFUL TREATMENT WITH ELTROMBOPAG FOLLOWING MULTI-THERAPY FAILURE (INCLUDING ROMIPLOSTIM)

G Tagariello, R Sartori, P Radossi, N Maschio, E Scarpa, C Tassinari
Castelfranco Veneto Hospital, Castelfranco Veneto, Italy

Immune thrombocytopenia (ITP) is an heterogeneous autoimmune disorder characterized by low blood count of PLTs with o without muco-cutaneous bleedings. Recent studies have found an increased incidence and prevalence of ITP in elderly people and the presence of additional co-morbidities makes the choice of the treatment more challenging. TPO receptor agonists have been recently licensed for patients who underwent splenectomy or when the operation is contra-indicated. Randomised trials report high response rate in refractory post-splenectomy patients, but a proportion still remains thrombocytopenic to both the drugs and no studies have described results after the switch from a TPO to another. Case report: this 84-year-old man was admitted to our hospital in January 2008 because of the haemorrhagic syndrome characterized by petecchiae, ecchymoses and epistaxis. Blood tests demonstrated severe thrombocytopenia with platelet count of 3x10^6/ml, WBC 12x10^6/ml and Hb of 12. 6 g/l. A bone marrow aspirate was consistent with a diagnosis of ITP, revealing an increased number of megakaryocytes. 1 g/kg/die I. V. Ig for two days plus oral prednisone at the dose of 1 mg/kg/d were administered without any platelet response. Over the following weeks the patient experienced further muco-cutaneos bleedings and anaemia, which required blood and platelets transfusions. We considered splenectomy no feasible at that moment and the patient started rituximab 175 mg / weekly for four weeks, without any result. Afterwards when the patient experienced another hemorrhagic event he was treated with I. V. Ig and platelet transfusions again until he was then enrolled (after 14 months from diagnosis) in the experimental trial AMG 531 (Romiplostim) and although he was treated up to the maximum recommended dosage of 10 µg/kg, he did not obtain and PLTs increase. The patient after a period of stable low platelets count (10 x 10^6/ml) experienced a new major GI hemorrhagic event that required bloodand platelets transfusions. So having no other chance, 17 months later the patient underwent splenectomy without serious adverse events but unfortunately without any PLTs increase. Concurrently with another major hemorrhagic event, due to a bladder papilloma, that required blood transfusions, the patient started treatment with eltrombopag(in the meanwhile licensed for ITP in Italy) and after four weeks at the dose of 50 mg/day we observed a platelets count over 100x10^6/ml which is maintained stable until now (20th week). No increase of liver enzymes or other adverse events were registered. Both eltrombopag and romiplostim are currently licensed for treatment in adults with chronic ITP who have failed to corticosteroids, immunoglobulins and splenectomy. Romiplostim and Eltrombopag both take a new approach to treat ITP, instead of reducing platelets destruction, these drug stimulate thombopoiesis, with a different cellular mechanism. Because both drugs take nearly 30% failure, the possibility to switch from a drug to another may increase the chance of success also in the subgroup of the very multi-therapy resistant patients.

1760

SUCCESSFUL MANAGEMENT OF A SMALL INFANT WITH KASABACH MERRITT PHENOMENON USING VINCRISTINE: A CASE REPORT

M Economou[1], A Tsigka[1], A Papagianni[1], V Chatzidimitriou[1], M Papouli[1], A Kattamis[2], N Gompakis[1], F Papachristou[1]
[1]Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece
[2]Agia Sophia Hospital, Athens, Greece

Introduction. Kasabach-Merritt Phenomenon (KMP) is characterized by profound thrombocytopenia, microangiopathic hemolytic anemia, a consumptive coagulopathy and an enlarging vascular lesion. The syndrome develops in infancy and is associated with a high morbidity and mortality rate. **Aims.** To present a case report of successful management of KMP in an infant using vincristine, after the failure of combination of corticosteroids and propanolol. **Case presentation.** Newborn female, of uncomplicated twin pregnancy, was born with a giant hemangioma located in the right thigh. From the first hours of life she was treated with combination of corticosteroids and propanolol, however, there was no improvement in the size of the lesion and severe, persistent thrombocytopenia, anemia and hypofibrinogenaemia developed. Until the 45th day of life, despite therapy, the tumor showed dramatic increase in size, with occupation of the whole limb and the major part of the abdomen. Due to extremely low values of platelets, hemoglobin and fibrinogen, the neonate was treated with daily administration of red blood cells, platelets and cryoprecipitate. The resistance to administered treatment and the risk of serious bleeding led to the decision of starting vincristine the 45th day of life. The drug was administered at a dose of 0. 05 mg/kg in weekly intervals. During the first week of therapy hematological parameters improved rapidly and on the second week the infant had no need for blood products. The third week the number of platelets and fibrinogen were normal for the infant's age, the size of the tumor had shrunk dramatically (reduction in tumor perimeter6 cm) and it's location was limited in the thigh. Until today, the infant has received 10 doses of vincristine, without experiencing any side effects and with continuous improvement of the clinical picture. **Conclusions.** Administration of vincristine proved to be safe and effective, where other drugs had failed in managing a small infant with Kassabach Meritt phenomenon.

1761

PLATELET MORPHOLOGIC INDICES IN PATIENTS WITH PRIMARY HYPERPARATHYROIDISM

M Dalamaga[1], G Sotiropoulos[2], K Karmaniolas[2], M Triantafilli[2], M Pantelaki[3], K Daskalopoulou[3], A Lekka[2]
[1]Attikon General University Hospital, Athens, Greece
[2]NIMTS General Hospital, Athens, Greece
[3]ELPIS General Hospital, Athens, Greece

Background. Primary hyperparathyroidism (P-HPT) is characterized by the autonomous production of parathyroid hormone (PTH) resulting in hypercalcemia which represents the most common cause of hypercalcemia in the outpatient setting, in patients without an underlying malignancy. Nowadays, most patients are asymptomatic and identified incidentally on routine serology. Patients with P-HPT present an increased risk for cardiovascular disease and hypertension. The exact role of P-HPT on platelet function remains largely unknown. Platelet parameters and especially mean platelet volume (MPV), an important determinant of platelet function, morphology and activation, constitutes a novel emerging risk factor for atherosclerosis and its complications such as coronary heart disease. It has been suggested that P-HPT could represent a risk factor for cardiovascular disease, especially coronary heart disease. MPV, platelet distribution width (PDW), platelet count (PLT) have not been studied in depth in P-HPT. **Aims.** The purpose of the present study was to compare the platelet count as well as the platelet indices MPV and PDW in asymptomatic patients with P-HPT and in age-, gender and body mass index (BMI)-matched healthy subjects as well as to investigate whether P-HPT may present a predictive significance in the determination of platelet morphology. **Methods.** In a cross-sectional study between 2007 and 2011, we have evaluated eighteen patients with P-HPT due to a parathyroid adenoma, prior to any therapeutic intervention (parathyroid surgery) (15 women and 3 men) with a mean age: 49. 05 ± 8. 1 years (range: 33-64 years) and a double number of healthy subjects (30 women and 6 men) with a mean age: 51. 02 ± 9. 3 years (range: 32-66 years). Healthy subjects were matched (2 controls to one patient) on gender, age (±5 years), body mass index (± 1. 5 kg/m^2) and year/month of diagnosis (±1 month). None of the subjects (patients and controls) presented any infectious and neoplastic conditions, diabetes mellitus, hypertension and dyslipidemia. To assess thrombopoiesis, we have determined platelet indices using the Sysmex 9000 analyzer. Statistical analysis of data was performed with IBM-SPSS® statistical package version 20 for Windowssoftware. **Results.** Cases with P-HPT presented significantly higher MPV (mean ± SD: 12. 2 fL ± 0. 44) and PDW (mean ± SD: 15. 76 % ± 0. 9) than controls (mean MPV ± SD: 10. 77 fL ± 0. 78, p<0. 001 and mean PDW ± SD: 13. 69 % ± 1. 21, p<0. 001). Moreover, patients with P-HPT exhibited a higher number of platelets per mm^3 than healthy controls (mean PLT in patients: 298 x 10^3/mm^3 ± 33 versus mean PLT in controls 263 x 10^3/mm^3 ± 37, p=0. 002). In a linear regression model, adjusting for age, gender and BMI, the presence of P-HPT was the most significant determinant of MPV and PDW levels (p=0. 001). **Conclusions.** These results suggest that patients with P-HPT tend to present an augmented platelet size. Elevated platelet activation could contribute to an increased risk of cardiovascular complications observed in P-HPT. Further larger studies are needed in order to evaluate the contribution of platelet parameters to the risk for cardiovascular complications in patients with P-HPT.

1762

EFFICACY EVALUATION OF RITUXIMAB THERAPY IN IDIOPATHIC THROMBOCYTOPENIC PURPURA REFRACTORY TO CORTICOSTEROIDS TREATMENT

V Burnasheva, Y Shatokhin, E Kuzub, E Grankina, I Snegko, O Shatokhina, O Belega
Rostov State Medical University, Rostov-on-Don, Russian Federation

Background. The mainstay of initial therapy of idiopathic thrombocytopenic purpura (ITP) has included corticosteroids, but in steroid-refractory patients splenectomy is the treatment of choice. In the majority of cases splenectomy is associated with high risk of hemorrhagic complications, and in 30% cases the desirable results are not achieved. Those whom splenectomy and steroid therapy fail to cure are treated empirically and in most cases durable remissions are not attained. Due to this fact,researches of prognostic criteria for the therapy with rituximab as well as developing the definitive courses are essential and crucial for the practical medicine. **Aims.** The goal of the study is to analyze the efficacy of rituximab treatment in patients suffering from ITP. **Methods.** 32 patients were included into the assay. Among them: 14 patents received the therapy with rituximab following failed significant response to splenectomy performed on an average 3,8 years ago; 18 patients were treated with rituximab after previous three ineffective courses with steroids without splenectomy. All the patients received rituximab at a dose of 375 mg/m^2 intravenouslyonce weekly for 4 weeks. 3 patients who had splenectomy performed in the past received 4 doses of Nplate during the chemotherapy course. The follow up continued for 16 months. In view of development of severe trombocytopenia in all the patients before the rituximab therapy, IgG products were administered intravenously for 5 days. **Results.** The positive effect of rituximab therapy was observed in 6 patients (43%) from splenectomy group. After immunoglobulin G infusions the platelets counts rose by 32,5% before the administration of rituximab. 8 patients from splenectomy group showed no effect neither from immunoglobulin, nor from rituximab therapy. Among the group of patients without previous splenectomy the platelets count reached the normal values in 78% (14 patients) within 2,1 months. All these patients had increase in platelets count by 44. 2% after injections of immunoglobulins G. Initially, there was an elevated level of immunoglobulins G by 74,7% compared to normal values and decrease of relative count of CD20 lymphocytes in all the patients who responded positively to the therapy with IgG. **Conclusions.** Rituximab can be used as a first-line therapy for ITP in patients who had splenectomy performed as well as in patients without surgery. To assess the potential rituximab therapy efficacy the following prognostic criteria can be used: the elevated level of IgG in blood without evidence of acute infection; positive response to IgG products treatment.

1763

IMMUNE THROMBOCYTOPENIC PURPURA OF CHILDHOOD WHAT IS THE BEST TREATMENT?

I Yildiz[1], N Ozdemir[1], S Soylu[1], T Celkan[1], S Karaman[2], A Canpolat[3], H Apak[1]
[1]Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey
[2]Istanbul University, Faculty of Medicine, Istanbul, Turkey
[3]Goztepe State Hospital, Istanbul, Turkey

Background. Immune thrombocytopenic purpura (ITP) is an acute self-limited disease of childhood, resolving mostly within 6 months with or without treatment. Bleeding is usually less than expected and severe hemorrhage is seen in less than 1% of children. Treatment options are steroids, IVIG or anti-D Ig. **Aims.** To share our experience of 32 years of different treatment modalities used for ITP. **Methods.** Fivehundred-fortyone children (M/F: 1. 1; mean age: 5. 32 ± 3. 67 years) with ITP, referred to our unit between 1978 and 2010 were evaluated retrospectively with regard to their clinical, laboratory features, etiological factors and different therapeutic modalities used. **Results.** Nine percent of the cases were less than 1 year old. In 30% of the patients, there was a recent history of infection and/or vaccination. Most frequent symptoms were echymoses and petechiae, severe central nervous system bleeding was seen only in 0. 8% of the patients. Mean initial platelet count was 19. 353/mm3. The 491 acute ITP patients were treated initially as follows; 134 (27%) by IVIG, 133 (27%) by high dose methylprednisolone (HDMP), 101 (20%) by standart dose steroids (SDP), 13 (2%) by anti-D Ig. Twent-two percent were followed without treatment. When the response to different treatment modalities was evaluated; response rate was 84. 2% in patients treated by HDMP, 77. 6% treated by IVIG and 89. 1% treated by SDP. The response duration was 16. 8 ± 13. 0 days, 3. 8 ± 3. 3 days and 3. 0 ± 2. 1 days in patients treated with SDP, HDMP and IVIG respectively. **Conclusions.** IVIG, standart and high dose steroids are all successful treatment options with similar response rates. The duration of response is slower in patients treated with SDP compared to IVIG and HDMP.

1764

IMMUNE THROMBOCYTOPENIA IN THE ELDERLY: CLINICAL COURSE IN 525 PATIENTS FROM A SINGLE CENTER IN CHINA

H Zhou
State Key Laboratory of Experimental Hematology, Institute of Hematology and Blo, Tianjin, China

Background. Immune thrombocytopenia (ITP), which is often diagnosed in the elderly, is a hematologic disorder characterized by thrombocytopenia induced by autoimmune mechanism. **Aims.** In this retrospective study, we evaluated the clinical features, the risk of bleeding and the response to various treatment options in elderly ITP patients (age≥60 yr) at our center from 1980 to 2009. **Methods.** We retrospectively analyzed the medical records of 525 aged Immune thrombocytopenia (ITP) patients (325 females and 200 males) from 1980 to 2009. The median age was 66 years (range 60-91 years) and the median platelet count was 20×109/L (range 1-95×109/L) at diagnosis. The median duration of follow-up was 35 months (range 1-253 months). **Results.** At diagnosis, 461 patients (87. 8%) had symptoms or signs of bleeding. The risk of bleeding was significantly related to platelet count (OR: 0. 956; 95% CI: 0. 944-0. 967). Among all the 525 patients, we found 328 patients (62. 5%) had comorbidities. One hundred and forty-four patients (27. 4%) received no treatment, of which 22 cases achieved CR spontaneously. The first-line treatment included corticosteroids and/or intravenous immunoglobulin. The total response rate was 58. 9% (165 of 280 patients), and this rate was not significantly related to platelet count, sex, bleeding signs and age (the 60-74-year group vs. the 75-91-year group). Only fourteen patients (2. 7%) underwent splenectomy. In the evaluable 23 patients who died during follow up, seven deaths were considered to be directly attributable to hemorrhage induced by thrombocytopenia. **Conclusions.** In conclusion, there are more females in the ITP patients over 60 years of age. The risk of bleeding is quite high in elderly ITP patients, but life-threatening bleeding events rarely occur. This retrospective review represents the largest collection of elderly patients diagnosed with ITP in China in a single center.

DISEASE PRESENTATION AND MANAGEMENT PRACTICES OF CHILDHOOD IMMUNE THROMBOCYTOPENIC PURPURA

T Hassan, M Hesham, M Tharwat
Zagazig University, Zagazig, Egypt

Background. ITP is the most common acquired bleeding disorder of childhood, accompanied by many controversies in diagnosis and management. It is a heterogeneous bleeding disorder with a diverse natural history. Treatment differs worldwide in terms of when to treat, what treatment to use and the need for hospitalization. **Aims.** We aimed to report our experience with such heterogenous disease through describing the detailed epidemiological features, clinical presentations, disease course and treatment modalities and to evaluate the influence of different factors on outcome, course and development of SLE in children with ITP. **Methods.** Retrospective study of the medical records of 202 children with ITP who were diagnosed, treated and followed up at pediatric hematology unit of Zagazig university hospital, between January 2005 and December 2010. **Results.** Mean age of patients was 4. 56 ± 2. 9 years with male to female ratio of 1. 1:1. Mean initial platelet count was 17. 2 ±10. 6 X 10^9/l . Cutaneous bleeding alone was found in 61% of patients, epistaxis in 23. 3%, bleeding gums in 15. 8%, urogenital bleeding in 3% and gastrointestinal bleeding in 2. 5% of patients. Intracranial hemorrhage was reported in only two patients during the study period. 20. 3% of patients were managed conservatively with spontaneous recovery. No significant difference in platelet counts at days 3,7 and 14 after treatment between patients receiving steroids only, IVIG only, or both steroids and IVIG. 17. 8% of patients developed chronic ITP and 3% developed SLE. Predictors of Chronicity were female gender, older age and ANA positivity. Anti D, Splenectomy, Azathioprine, Danazole and Rituximab were tried with varying results. **Summary and Conclusions.** ITP is a self limiting disorder with 80% of patients having acute disease and recovery . Steroids and IVIG are equally effective as a first line therapy. Despite of the good initial response to Anti D, Danazole, Azathioprine and splenectomy, many patients experienced relapse. Large studies about novel therapies such as Rituximab are needed. ANA test is a useful screening test that predicts initial response to steroid therapy, development of chronicity and risk of progression to SLE.

1766

A COMPARATIVE STUDY OF PLATELET (PLT), AND THEIR AVERAGE VOLUME (MPV), IN PATIENTS WITH TYPE 2 DIABETES MELLITUS AND ON HEALTH PEOPLE

S Patiakas[1], S Patiakas[2], N Giannakoulas[3], F Girtovitis[4], S Chatzizisi[5], K Rousos[6]
[1]General Hospital of Kastoria, Greece, Kastoria, Greece
[2]Blood Donation Department of General Hospital of Kastoria, Kastoria, Greece
[3]Hematological Department of Universal Hospital of Larissa, Larissa, Greece
[4]Universal Hospital of Thessaloniki "Achepa",, Thessaloniki, Greece
[5]General Hospital of Thessaloniki "Saint Dimitrios", Thessaloniki, Greece
[6]Health Center of "Alexandria" - General Hospital of Veria, Veria, Greece

Background and Aims. To evaluate both the number and the average volume of platelets in diabetes mellitus patients, and compared our results with those of healthy, since the average volume of platelets is directly related to the activity, which as we all know contribute the onset of cardiovascular diseases. **Methods.** A total of 106 cases studied diabetes mellitus(DM) patients (61 males and 45 females, average age 66. 8 years), and 85 healthy persons (47 males and 38 females) approximately average age 70. 2 years, who examined in the outpatient hypertension and atherosclerosis department of the Psychiatric Hospital of Thessaloniki. In all recorded platelet count (PLT) and average volume (MPV), while in 78 of the 106 patients with (DM) were measured additionally prices haemoglobin glycosylated (HbA1c), as determined by the automatic biochemical analyzer using the chemiluminescence. **Results.** Regarding the number of platelets was observed between the two groups no statistically significant difference (p> 0,05). Throughout, the MPV was statistically highly increased (p <0,001) in the patients with compared with (DM) the healthy group. Specifically, the patients had (DM) average MPV 12,6 fl (79 by 106, a rate 74. 5% were abnormal), while for healthy controls was 8,6 fl. (Only 15 of 85, ie 17. 6% rate, showed elevated MPV). Indeed, further investigation showed correlation of MPV (13,9 fl) with cardiovascular events (acute myocardial infarction and stroke in 16 and 12 cases from the total of 106 (DM), respectively), while the levels of the MPV is not proved to be related, nor sex, and even with levels of HbA1c. **Conclusions.** It turns out therefore that the MPV in patients with type 2 (DM) is significantly increased compared to the health general population, which implies an additional and independent cardiovascular risk factor. Therefore, in (DM) group, should do, an regular monitoring for cardiovascular disease, but without forgetting, and frequent monitoring of blood profile.

1767

THE MORPHOLOGICAL CHANGES OF PLATELETS CAN ABERRANTLY INCREASE THE VALUE OF IMMATURE PLATELET FRACTION DURING COLD STORAGE

K Miyazaki, T Aoki, T Katayama, M Higashihara
Kitasato University School of Medicine, Sagamihara, Japan

Background. Reticulated platelet percentage (RP%) is a useful marker of thrombopoiesis, and helpful for differential diagnosis in thrombocytopenic patients. For measurement of RP%, immature platelet fraction (IPF%) is determined using the automated hematology analyzer in a simple and reproducible way between laboratories, although it has some limitations. The IPF% rises during storage at 4˚C, and the aberrant increase is also observed in some myelodysplastic syndrome patients especially with karyotypic abnormalities. However, the reason has still remained to be clarified. **Aims.** We investigated the shape change and activation status of platelets during cold storage in order to elucidate the mechanisms of the aberrant increase of IPF. **Methods.** The IPF and IPF% were determined using Sysmex XE-2100 automatic hematology analyzer in the blood samples of healthy donors before and after storage at 4˚C for 24 hr. Platelet count and other parameters of platelet, such as MPV, PDW and P-LCR were measured simultaneously. Phosphorylation of myosin light chain was also examined to estimate activation status. The morphological changes of platelets were also examined on the blood film. **Results.** The IPF and IPF% was significantly increased during storage, accompanied with the shape change and myosin phosphorylation, which indicated platelet activation. Morphologically, each platelet increased in size with fewer granules probably due to degranulation, and a couple of platelets stuck to each other to form a few small clumps. For further investigation, we examined the blood samples with previously recognized mild EDTA-induced platelet aggregation. The IPF% significantly increased in EDTA-anticoagulated blood compared to other anticoagulants such as heparin. **Conclusions.** Although the mechanisms seem to be complicated, the morphological changes such as degranulation and enlargement of platelets can play a significant role in aberrant increase of IPF% during cold storage.

1768

EFFECT OF ANTI-CD20 MONOCLONAL ANTIBODY (RITUXIMAB) IN IMMUNE THROMBOCYTOPENIA. EXPERIENCE IN A PERUVIAN HOSPITAL

JL Untama, D Del Carpio, J Navarro
HNERM, Lima, Peru

Objective. We describe the response to Rituximab in immune thrombocytopenia in adult patients of Rebagliati Hospital which belongs to social security system. **Materials and Methods.** is a retrospective, descriptive and observational study. We reviewed the medical records of adult patients with immune thrombocytopenia who received Rituximab after failure to reach or maintain Response with at least one line of treatment, from 2005 until December 2010. According to the consensus of the international working group on ITP, it was considered: i. Response: platelet count > 30 000 and at least double the initial platelet count, ii. Complete Response: platelet count> 100 000 and no signs of bleeding. **Results.** A total of 24 courses of Rituximab 375mg/m2 each week for 4 weeks were assessed, mean age of patients was 48. 6 ± 17. 6 years (range, 25 - 80) with a male/female ratio of 1/3, and a mean of previous treatments of 2. 8 ± 1. 46 (range, 1 - 6). Response was reached after 18 courses (75%), in a mean time of 11. 9 ± 11. 8 weeks (range, 0. 7 - 37. 4), mean duration of response of 15. 9 ± 12. 7 months (range, 3. 3 - 55. 3 months) and 12 patients still remain in response until last follow up (mean 18. 6 ± 14. 3 months; range, 3. 3 - 55. 3 months). Similarly, Complete Response was reached in 14 of 23 courses evaluated (60%) in a mean time of 17 ± 15. 9 weeks (range, 0. 7 - 62. 3 weeks), with a mean duration of complete response of 10. 1 ± 7. 3 months (range, 2. 3 - 25. 2 months), 5 patients still remain in Complete Response until last follow up (mean, 16. 9 ± 8 months; range, 8 - 29 months). We found that splenectomized patients has a greater chance of maintain the response obtained compared with non splenectomized patient (8 vs 4 patient; OR: 4), and similar results for Complete Response (4 vs 1 patient; OR: 14). **Conclusions.** Rituximab is a good alternative in patients with ITP who failed at least one line of treatment.

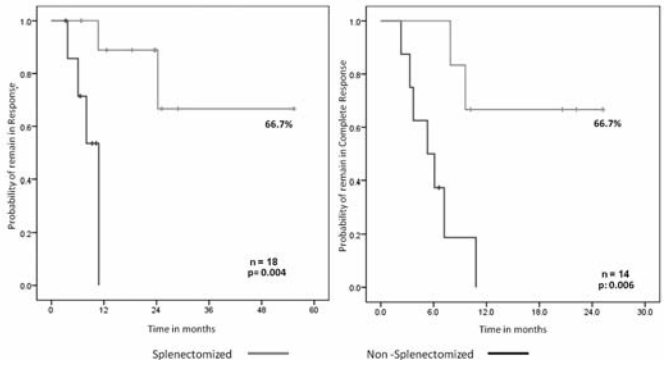

Figure 1. Kaplan-Meier estimates of probability for remain in response, and complete response in ITP patients after use of Rituximab by splenectomized status. Rebagliati Hospital - 2011.

1769

EFFICACY AND SAFETY OF ELTROMBOPAG TREATMENT FOR PATIENTS WITH REFRACTORY OR RELAPSED CHRONIC IMMUNE HROMOCYTOPENIA (ITP)

A Gaman, G Gaman
University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background. Chronic immune thrombocytopenia (ITP) is an autoimmune disease characterized by low platelet counts due to increased platelet destruction and suboptimal platelet production. Eltrombopag, a non-peptide oral platelet growth factor, increased platelet counts in adults with chronic ITP . It has been revealed that it stimulates TPO-dependent cell lines via JAK2 and STAT-signaling pathways to proliferation, megakaryocyte differentiation and platelet production. **Aims.** To evaluate efficacy and safety of eltrombopag treatment for patients with refactory or relapsed chronic ITP. **Methods.** we studied 43 patients with chronis ITP hospitalized in the Clinic of Hematology of Craiova (Romania) between 2009-2011 (informed consent obtained). All patients were initially treated with corticosteroids (prednisone or high dose dexamethasone) and 8 of them were splenectomized. Nine patients with refractory or relapsed chronic ITP and platelet counts ≤ 30. 000/μl were treated with eltrombopag at a starting dose of 50 mg daily. At patients who did not respond to eltrombopag 50 mg after 30 days the dose was increased to 75 mg daily. Patients who achieved platelet

counts ≥ 150. 000/ µl on eltrombopag 50 mg had their dose reduced to 25 mg daily. Patients with a prior history of arterial or venous thrombosis and known risk factors for thrombosis and patients with a history of cardiovascular disease were excluded from the eltrombopag treatment. **Results.** Six patients responded at eltrombopag 50 mg daily (platelet counts ≥ 150. 000/ µl) after the first month of treatment and dose has been reduced to 25 mg daily. Two patients responded after two months of treatment at a dose of 50 mg daily and one patient was refractory to this treatment after three months of treatment at a dose of 75 mg daily and was splenectomized. Headache was observed in two patients, one patient developed an increase in ALT and hyperbilirubinemia; no patient had thromboembolic events. **Conclusions.** Eltrombopag treatment at the initially dose of 50 mg daily was efficient and safe in 88% cases; a single patient was reluctant and splenectomized. Because the group was small in size statistical significance was not achieved. In the future, we are planning a study on a larger group of patients in order to clarify the results of eltrombopag therapy in chronic ITP.

SIMVASTATIN AND AMLODIPINE INDUCED THROMBOCYTOPENIA IN THE SAME PATIENT: A DOUBLE TROUBLE

Z Cvetkovic[1], N Suvajdzic[2], D Celeketic[3], M Panic[4], A Novkovic[3]
[1]Clinical Hospital Centre Zemun, Belgrade, Serbia
[2]Clinic of Haematology Clinical Centre of Serbia, Belgrade, Serbia
[3]Department of Haematology Clinical Hospital Centre Zemunl, Belgrade, Serbia
[4]Department of Cardiology Clinical Hospital Centre Zemun, Belgrade, Serbia

Background. Drug induced thrombocytopenia (DITP) is a serious but rare side-effect of a wide range of medications. DITP is often misdiagnosed as acute immune thrombocytopenic purpura (ITP). The aetiology of DITP is complex and at least six distinct mechanisms have been identified by which drug-induced antibodies can promote platelet destruction. Amlodipine and simvastatin have rarely been implicated in DITP. Amlodipine is a dihydropyridine calcium-channel antagonist that reduces the influx of extracellular calcium into cardiac and vascular smooth muscle cells via L-type calcium channels. Simvastatin is a prodrug metabolised in the liver to form simvastatin acid, an inhibitor of HMG-CoA reductase. Both agents are recommended in hypertensive diabetic patients. In a systematic review of case reports two cases of amlodipine-induced DITP and four cases of simvastatin-induced DITP have been reported so far. **Aims and Methods.** We present a patient who exhibited in a short period three successive episodes of DITP, first two on amlodipine (induction and rechallange), and the third on simvastatin. **Results.** A 78-year-old female with type 2 diabetes mellitus, dyslipidemia, hypertension, stabile angina pectoris, bronchial asthma, and chronic nephropathy was referred to the hospital due to 3-day history of easy bruising, signs of skin and wet purpura and isolated severe thrombocytopenia of $1x10^9$/L. She had been on long-term treatment with a number of drugs, and also received a short course of amlodipine, 2 weeks before admission. Serum creatinine and blood urea nitrogen were 328 µmol/l and 15. 0 mmol/l respectively, cholesterol was 6. 7 mmol/L, LDL-cholecterol 4. 5 mmol/L and triglicerides were 2. 8 mmol/L while all other analyses, including autoimmune screens, viral and coagulation tests were within normal ranges. Peripheral blood smear ruled out psudothrombocytopenia and bone marrow aspirate was unremarkable. Standard treatment for ITP (prednisolone 1mg/kg) was initiated with no improvement in platelet count in following days. Than amlodipine, being the last introduced drug, was discontinued. Platelet count showed sustained increase to $126x10^9$/L on day 7 when corticosteroids were fully discontinued. She was discharged from hospital on day 17 with platelet counts of 165x109/L. Simvastatin, which was taken for several years and was discontinued for three months, was reinduced due to dyslipidemia by endocrinologist on d27. Immediately after ingestion of first dose she felt generalized pruritus and referred to hospital with generalized urticaria where drop in platelet count to $98x10^9$/L was registered. Simvastatin was ceased, and platelets after further decrease to $65x10^9$/L on day 30, in following days showed sustained rose to $226x10^9$/L and remained stable in next four months. Than she took by accident one tablet of amlodipine (10mg) causing immediate drop in platelet count to $35x10^9$/L, so fulfilling Georges clinical criteria for definitive level of evidence for DITP. **Conclusions.** As of our knowledge, this is the first case report on successive DITPs on two widely prescribed drugs. Concomitant administration of calcium-channel blockers and statins has multiple beneficial effects on cardiovascular system, but on the other hand may enhances a chance for drug induced hypersensitivity and makes the identification of causing drug or drugs almost impossible.

1771

THROMBOPOIETIN RECEPTOR AGONIST IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIC PURPURA: CLINICAL EXPERIENCE

L Costilla Barriga, G Caballero Navarro, A Rubio Martinez, P Giraldo Castellanos, D Rubio-Félix
University Hospital Miguel Servet, Zaragoza, Spain

Background. Inmune thrombocytopenic (ITP) in adults is a chronic autoimmune disorder characterized by low platelet counts (PC) and mucocutaneous bleeding due to accelerated platelet destruccion and suboptimum platelet production. Many treatments have focused on reduction of platelet destruction; nowadays the thrombopoietin-receptor agonist (Tpo-RA), Romiplostin and Eltrombopag, are new treatment modalities and exerting their effect by stimulating platelet production, alone or in combination with existing therapies, reducing the risk of bleeding. **Aims.** To describe our experience with the Tpo-RA therapy in patients with chronic ITP: platelet counts, bleeding clinical, decrease or discontinuation of concomitant ITP drugs, rescue medication in emergency**,** incidence and severity of adverse events and treatment-related mortality. **Patients and Methods.** Retrospectively we have analyzed 15 patients with chronic ITP in our center, 2 male and 13 female, median age 63 years, range 16-79; 4 splenectomized and 11 nonsplenectomized, treated with Tpo-RA (Romiplostin n=11 and Eltrombopag n=4). All patients received other ITP drugs as mantenance therapy (eg. costicosteroids, immunoglobulins (IVIG), danazol, azathioprine, rituximab), most of them corticosteroids and IVIG. Romiplostin and Eltrompopag were initiated and monitored according to recommendation described in specification sheet. Hematological response (HR) was defined as PC >=50,000/uL, during 4 or more weeks, without modification of the drugs doses. **Results.** HR was achieved in 11 patients (73. 3%). The median of PC before the treatment was 25,000/uL (4,000-85,000) and post treatment was 90,000/uL (15,000-203,000). The median dose needed to reach HR was Romiplostin 3 ug/kg/week (1-10) vs. Eltrombopag 75 mg/day (50-75). The median time to response was 2 weeks (0-11) and the duration 9 weeks (0-21). Improvement on clinical bleeding was observed in 6 patients (40%) in spite of the absent HR. Concomitant ITP drugs were reduced and discontinued in the 86. 7 % (n=13) and 80 % (n=12) respectively. Rescue medication (corticosteroids and IGIV) was needed in 60 % (n=9) of the patients. Eighty percent of the patients (n=12) did not present any adverse effect related to treatment and the 20% (n=3) showed thrombocytosis and slight haemorrhagic episodes after the treatment discontinuation. PC generally returned to baseline values within 2 weeks after the end of the treatment. None of the patients showed clinical signs or features indicative of bone marrow dysfunction or myelofibrosis. Mortality related to treatment was not observed; a patient died due to pulmonary chronic disease. **Summary and Conclusions.** The news therapeutics (Tpo-RA) are effective and well tolerated treatment for patient with ITP diagnosis. The aim of these therapies is to obtain a safety level that allows diminish the risk of bleeding. In our experience many patients were able to reduce or discontinue other medications and decrease bleeding episodes without few adverse events. This results added to the previous information are similar to the bibliography described up to the date, but it is necessary to increase our experience about that.

1772

A CASE WITH PSEUDOTHROMBOCYTOPENIA WHO SHOWS DIFFERENT FEATURES: TEMPERATURE-INDEPENDENT PSEUDOTHROMBOCYTOPENIA COMPLETE WITH CITRATE AND INCOMPLETE WITH ETHYLENEDIAMINETETRAACETIC ACID AND HEPARIN

C Beyan, K Kaptan, A Akyol Erikci
Gulhane Military Medical Academy, Ankara, Turkey

Background. Pseudothrombocytopenia (PTP) is a phenomenon due to agglutination of platelets in the complete blood count tube anticoagulated with ethylenediaminetetraacetic acid (EDTA) leads to falsely low platelet counts. **Aims.** Herein, a case with PTP who shows different features is presented. **Case Report.** A 62 year-old woman referred to our Hematology department from Medical Oncology department because of evaluation of thrombocytopenia. She had colon cancer and colectomy operation was performed two and a half years ago with no need for chemotherapy or radiotherapy. At the time of operation, platelet counts were normal. She had variations in platelet counts during the last year. She has been using lansoprazole for gastroesophageal reflux disease and diosmin/hesperidin for hemorrhoidal complaints for five years. Complete blood count measurements were performed in tubes with citrate and EDTA. Fresh blood samples revealed platelet counts 19 $x10^9$/l in EDTA and 4 $x10^9$/l in citrate tubes. Peripheral blood smear revealed 61% neutrophils, 27% lymphocytes, 9% monocytes, 3% eosinophils with normocytic and normochromic erythrocytes. Platelet clumps were present with mean 9. 3 platelets in every

x1000 magnification. Because of false manipulation of laboratory personnel, the same samples were recounted after three hours platelet values were 50 x10^9/l in EDTA and 10 x10^9/l in citrate tubes, respectively. After these contradictious results, a 24-hour platelet count profile was made by using different anticoagulants (Table 1). According to 24-hour platelet count profile with different anticoagulants, our case had different features from classical EDTA-dependent PTP: PTP was observed in the fresh blood with EDTA, citrate and heparin independently from temperature changes (warm antibodies, not cold agglutinin). In the presence of citrate, antibodies bind platelets more effectively (complete antibody); this effect was incomplete in the presence of EDTA and heparin (incomplete antibody). Therefore, the variations of platelet counts in different hours were observed. Sodium fluoride which is a glycolysis inhibitor explains the false results in tubes with only EDTA and true results in tubes with EDTA combined with sodium fluoride. Sodium fluoride causes inhibition of glucose utilization by platelets in test tube. This leads inhibition of morphological changes of platelets and prevents the formation of PTP. **Conclusions.** As a conclusion, our case which has a temperature-independent PTP complete with citrate and incomplete with EDTA and heparin shows different features from classical EDTA-dependent PTP. True platelet count could be made with addition of sodium fluoride into EDTA.

Table 1. 24-Hour platelet count profile with different anticoagulants.

	0.hour (fresh)	1.hour	2.hour	4.hour	7.hour	24.hour
K_2EDTA 7.2 mg/4.0 ml blood	7*	67	66	51	35	13
Tri-Sodium Citrate 9:1/4.5 ml blood	4	13	20	18	17	17
Lithium Heparin 95 iu/4.0 ml blood	15	22	28	25	34	50
**Sodium Fluoride /K_3EDTA/4.0 ml blood	89	74	69	90	78	20

* Platelet counts were given as x10^9/L.
** This tube contains EDTA and sodium fluoride which causes inhibition of glucose utilization by cells. These tubes are mainly used for glucose and lactate analysis.

1774

IS IT FEASIBLE TO DISCONTINUE TREATMENT WITH ROMIPOOSTIM IN ITP PATIENTS WITH MAINTAINED COMPLETE RESPONSE?

Y Ramos[1], M Perera[2], J López[3], A Suárez[3], M Gordillo[3], D Fiallo[3], B Sevillano[3], T Molero[3]
[1]Dr. Negrín, Las Palmas, Spain
[2]Universitary Hospital Dr. Negrín, Las Palmas, Spain
[3]University Hospital Dr. Negrín, Las Palmas, Spain

Background. Primary immune thrombocytopenia (ITP) is an adquired disease characterized by an isolated thrombocytopenia antibody-mediated with destruction and an inadequate production. The main objective of the treatment is to avoid the hemorrhage by keeping the platelets level in a safety range (>20-30x109/L). Although the vast majority of patients respond to steroids (first line), there remains a group of patients who show refractories or steroids dependence, in these cases, it should be considered the use of a second line (splenectomy and thrombopoyetin analogues (a-TPO). The choice of the second line should be an individual decision. The recent incorporation of a-TPO has meant an improvement in the quality of life of these patients by offering them an specific, effective and safety treatment. Its use is limited to adult patients who show refractories to splenectomy or when it is contraindicated or rejected by the patient. **Case Report.** We present two patients with non-splenectomized refractory ITP, who started treatment with Romiplostim reaching manteined complete response (CR) for one year after that we decided discontinue the treatment. 1st: 58 yo male patient with history of ischemic cardiopathy diagnosed of ITP with severe thrombocytopenia <10x10^9/L and cutaneous hemorrhages in July 2008. There was no response after appropriate steroid treatment. Second line treatment is considered, rejecting the splenectomy because of the cardiopathy. 18 months after the diagnosis, refractory disease was stablished, he started treatment with a-TPO. CR with Romiplostim was reached (3ug/kg/week). After 7 months of follow-up and being in CR, it was decided to space out the dose to every 4 weeks. 12 moths after the beginning of Romiplostim, the patient continues in CR. Then, it was decided to definitely discontinue the treatment. Currently, the patient keep a platelet count in the normal range after one year without treatment. 2nd: 19 yo female patient with history of hepatitis B was diagnosed of ITP with metrorrhagia and platelet count <10x10^9/L in July 2010. There was no response after appropiate steroid treatment. The patient rejected the splenectomy. Treatment with a-TPO (Romiplostim) was started 3 months after diagnosis, reaching CR (1. 2 ug/kg/week) After one year being in CR, it was decided to decrease the weekly dose, maintaining the platelet count in the normal range. In December of 2011, the treatment was definitely discontinued. **Conclusions.** Splenectomy is considered the most suitable option as second line treatment with high rate of complete remissions. Besides, exist cases of spontaneous remissions after pharmacologyc treatment in adults with ITP. For this reason, it's advisable to delay the splenectomy at least 6-12 months after diagnosis. A-TPO allow us to achieve CR and delay the splenectomy during this leeway. Although prospective studies are needed, it seems reasonable that patients with maintained CR could finally do without the A-TPO. It does not exist a consensus recommendation related to the withdrawal of the drug. In our cases we used to different alternatives Perhaps it could be considered the progressive weekly decrease of the dose in good responders after one year of treatment, until definitive withdrawal of the drug

1775

ONE YEAR FOLLOW UP STUDY OF ROMIPLOSTIM IN THE TREATMENT OF CHILDREN WITH CHRONIC IMMUNE THROMBOCYTOPENIA

G Mokhtar, A Tantawy, I Ragab, N Hazaa, H Gomaa
Faculty of Medicine,Ain Shams University, Cairo, Egypt

Background. Romiplostim, a thrombopoietic agent with demonstrated efficacy against immune thrombocytopenia is still poorly studied in pediatric age group. **Aims.** Our study aimed to assess the sustained efficacy and safety of romiplostim in the treatment of refractory chronic ITP in children. **Methods.** Ten patients with chronic ITP refractory to standard first and second lines of therapy were recruited from the Pediatric Hematology Unit, Children's Hospital, Ain Shams University, Cairo, Egypt. Therapy was initiated in JUN 2010 through JUL 2011. Romiplostim dose was started as 1µgm/kg/week and the dose was escalated by 1 µg/kg/week according to platelet count. The primary end point was the number of weeks with platelet response, defined as a platelet count ≥50 × 10^9/L. **Results.** Patient age ranged 3. 4 years-15. 2 years(median 5. 5 years),and the disease duration from 13 months-7. 3 years(median 2. 4 years), none was splenectomized. Initial short term rise of platelet count above 100×10^9/L then declined and stabilized at 50-70x10^9/L; regular weekly doses was effective in maintaining platelet count above 50×10^9/L and platelet count rapidly decreased below 20×10^9/L after interrupted therapy. Median dose needed to achieve a platelet count above 50 X10 ^{9}/L was 6ug/kg, and mean duration to achieve this count is five weeks. Most adverse events were mild and transient with no serious adverse events. **Conclusions.** In conclusion, Romiplostim therapy shows variable responses; maintenance doses should be individualized; the drug was well tolerated in studied Egyptian children with ITP .

1776

RITUXIMAB THERAPY FOR ADULTS WITH CHRONIC AND REFRACTORY PRIMARY IMMUNE THROMBOCYTOPENIA

AM Moldovianu
Fundeni Clinical Institute, Bucharest, Romania

Background. In Immune Thrombocytopenic Purpura, platelets are coated with an IgG autoantibody that prompts its premature destruction and, as a result, different grades of peripheral thrombocytopenia become evident. It is important to remember that most patients with ITP do not encounter bleeding problems and it is probably is not necessary to maintain a normal platelet count in all individuals. Treatment is indicated in patients with platelet counts < 30. 000/µl or with bleeding symptoms. First line treatment is traditionally with corticosteroids. In case of failure to steroids, splenectomy induces a 65% response rate. However, almost 30% of adults with ITP fail to respond to standard therapies (steroids, IVIg, anti D) and they develop a chronic refractory disease. If a patient becomes refractory, some alternatives are available such as splenectomy, immunosuppressive drugs, immunomodulatory agents, Rituximab or TPO receptor agonists (second line therapies). **Aims.** Our first objective is to observe the efficacy and safety of Rituximab treatment in adult patients with ITP. A second purpose is to demonstrate the role of Rituximab therapy for chronic and refractory ITP in order to create a "bridge"between standard first line treatment and splenectomy in patients with severe thrombocytopenia and with high bleeding risk. **Methods and Results.** Although the role of Rituximab in treatment of ITP is uncertain, studies have shown that it may work by reduction of antiplatelet antibodies, loss of antigen presentation and resolution of T cell abnormalities (↑ number of Tregs CD4+CD25+Foxp3+). We successfully used Rituximab therapy in case of 2 female patients with chronic and refractory ITP as a "salvage treatment"in order to achieve safe platelet counts before splenectomy. It

was administered as a weekly infusion of 375 mg/m^2 for 3 consecutive weeks and patients did not experienced any adverse effects. In both cases, there was an early pattern of response and their platelet counts were > 75. 000/µl at 28 days after initial dose of Rituximab. During postsplenectomy follow-up period (4-7 months) both patients achieved a complete remission (> 150000/µl). **Conclusions.** Although it is an "off-label"treatment strategy, Rituximab appears to be a safe and good alternative for adults with refractory ITP.

1777

ELTROMBOPAG IN THE MANAGEMENT OF HEAVILY PRETREATED PATIENT WITH CHRONIC PRIMARY IMMUNE THROMBOCYTOPENIA: A COST-EFFECTIVENESS ANALYSIS IN BRAZIL

J Musacchio
COI - Clinicas Oncológicas Integradas, Rio de Janeiro, Brazil

Background. Primary immune thrombocytopenia is characterized by accelerated platelet destruction. Treatment goal includes bleeding prevention by increasing platelet count to stable, safe range. Eltrombopag (Revolade, GlaxoSmithKline), a thrombopoietin (TPO) nonpeptide mimetic that binds to and activates the TPO receptor leading to increased production of megakaryocytes and platelets in bone marrow. **Aims.** The cost-effectiveness of the thrombopoietic receptor agonist eltrombopag versus standard-of-care (SoC) in chronic primary immune thrombocytopenia from an individual heavily pretreated patient viewpoint was assessed. **Methods.** Disease management and model pathways derived from clinical guidelines (PCDT). Health states comprised controlled (>=50,000 platelets/mm3) and uncontrolled ITP (<50,000 platelets/mm3). Time-horizon was continuous, not applied. Cost inputs (drugs, hospital, laboratory, and physician visits) were from public reimbursement databases (BPS/SIGTAP). Eltrombopag price was according to government acquisition requirements (PMVG). Costs were in 2012 Brazilian currency (1BRL=0. 60USD). **Results. Case Report.** The patient is a 62-year-old caucasian woman with a medical history of asymptomatic thrombocytopenia in 2007. After physical examination, and a performance of bone marrow biopsy and aspiration, the patient was diagnosed with primary immune thrombocytopenia. Prednisone was initiated at the dose of 1,5mg/kg/day, with no improvement over a course of 3 months; therefore, immunoglobulin 1g/kg for twice was done, with platelets counts remaining low and never exceeding 20. 000/mm3. Considering the lack of response to corticosteroids and immunoglobulin, immunodepressors were initiated as azathioprine, danazole, and dexametasone in pulses, with no response. Also, rituximab was prescribed for twice. At entirely, the patient received 8 cycles of weekly rituximab over the following months. Because of the heavily treatment, she went to intensive care unit and stayed there for two months, due to a severe pulmonar infection and extended candidiasis esophagitis, that needed thracheostomy. At the time she came to us, she was using prednisone 100mg alternating to 120mg per day, and has just received immunoglobulin 1g/day for two days for nine times in the last two and a half months. Her platelet count was 2,000/mm3. Given the failure of the above therapies, we began eltrombopag, a TPO receptor agonist. After three weeks of treatment with oral eltrombopag at 50 mg daily, the patient's platelet count increased from 2,000 to 6,520/mm3. Six weeks after initiation of eltrombopag, the patient's platelet count increased to 45,200/mm3. In eleven weeks, the platelet count reached 249,000, and the dose was decreased to 25 mg. Nowadays, the patient is well, receiving eltrombopag at 25 mg with no corticosteroids, and with controlled primary immune thrombocytopenia. At the Table 1, the costs for eltrombopag and SoC were calculated and compared. Summary and **Conclusions.** Estimated treatment cost for primary immune thrombocytopenia throughout a 6-month period was BRL21,779 for eltrombopag plus SoC, and BRL153,010 for SoC. Eltrombopag is cost-effective at current international willingness-to-pay (approximately USD50,000/QALY). When higher or repeated immunoglobulin doses are needed for chronic ITP, eltrombopag becomes cost-saving to the Brazilian Ministry of Health.

Table 1.

		Resource use and costs			
		Pre-intervention		Post-intervention	
Treatments	Unit	Total units	Costs	Total units	Costs

HEMOSTATIC ABNORMALITIES IN CIRRHOSIS AND TUMOR-RELATED PORTAL VEIN THROMBOSIS

S Ayaz[1], H Alkim[2], N Sasmaz[3], P Oguz[3]
[1]T Yuksek Ihtisas Hastanesi, Ankara, Turkey
[2]Bakirkoy Dr Sadi Konuk Training and Research Hospital,, Istanbul, Turkey
[3]Turkiye Yuksek Ihtisas Teaching and Research Hospital, Ankara, Turkey

Aims. In order to investigate the relationship between hemostatic abnormalities and portal vein thrombosis (PVT) in hepatocellular carcinoma (HCC). **Methods.** platelets, prothrombin time (PT), activated partial thromboplastin time (aPTT), thrombin time, fibrinogen, D-dimer, fibrinogen degradation products (FDPs), protein C, protein S, antithrombin, plasminogen, antiplasmin, coagulation factors (CFs) V, VII, VIII, IX, XI, and XIII, von Willebrand factor (vWF), prothrombin fragment 1 + 2 (PF 1 + 2), tissue-type plasminogen activator (tPA), and plasminogen activator inhibitor 1 (PAI-1) were studied in patients with HCC, cholangiocarcinoma, and metastatic liver tumors and in cirrhosis patients with or without PVT. **Results.** Platelet, antithrombin, protein C, plasminogen, and CFs V, VII, IX, XI, and XIII levels of HCC group were found lower and PT, aPTT, thrombin time, vWF, FDPs, PF 1 + 2, tPA, and PAI-1 levels were higher than the control group. Summary: Our findings suggested that the abnormalities of coagulation and fibrinolysis systems have some role in provoking thrombosis of portal veins in HCC, in addition to the invasion of portal veins by hepatoma cells.

1779

HEALTH-RELATED QUALITY OF LIFE RESEARCH IN HEMATOLOGICAL PATIENTS

V Djurasinovic
Clinical Center of Serbia, Belgrade, Serbia

Background. EORTC QLQ-C30 as a reliable and valid measure of the quality of life of cancer patients in multicultural clinical research settings. **The purpose.** Our purpose is to determine the differencess between patients with different hematological diseases related to help, pain perception, trouble sleeping, weakness, nausea, appetite, vomiting and fatigue as well as differences in overall quality of life in regard to gender, phase of disease, educational level and employment. **Methods.** A pilot research in a form of a cross sectional study has been conducted at the Department of Clinical Hematology at the Clinical Center of Serbia. The EORTC QLQ-C30 questionnaire has been used. The study includes 50 men (56,2%) and 39 women (43,8%)-average age 52 (21-79)years. 27 (30,3%) patients (pts) with Acute leukemia(AL), 16 (18%) pts with Chronic lymphocytic leukemia (CLL), 12 (13,5%) pts with diffuse large B-cell non-Hodkin lymphoma (NHLDBCL), 8(9 %) pts with non-Hodgkin lymphoma folliculare (NHLF), 9 (10,1%) pts with multiple myeloma (MM) and 9(10,1%) with Hodgkin's disease(HD), 6 (6,7%) pts with thrombocytopenia (ITP) and 2 (2,2%) pts with hemophilia. Data processing was used in the SPSS package. THE **Results.** Most pts had a medium level of education 56(62,9&), high level 14(15,7), primary ili low level 9 (10,1%), higher level 7(7,9%), postgraduate 2(2,2%) and illiterate 1(1,1%). Among them 34(38,2&) were employed, unemployed 29(32,6%) and pensioners 26(32,6%). Phase of disease: initial-40(45%) pts, remission (receving consolidational therapy)- 15(16,8%) pts and relapsed/refractary disease-34 (38,2%). Help with eating, dressing, using the toilet and pain perception was significantly different for patients with MM and hemophilia($p<0,05$). Trouble sleeping was most manifested in AL and CLL patients. Weakness, appetite, nausea, vomiting, fatigue did not differ in groups ($p >0,05$). Tension was most manifested in MM, hemophilia and ITP patients. Overall Health did not differ between the groups, but the overall quality of life is better and significantly differ in NHLDBCL, CLL, hemophilia and HD related to AL, NHLF, MM and ITP. There is also found a gender difference. Male pts had higher quality of life. **Conclusions.** The patients with MM disease have the lowest level of quality of life comparing with other hematological malignacies. The overall quality of life in this group did not depend from phase of disease, educational level and employment.

1780

AN ESTIMATION OF POTENTIALLY AVOIDABLE AND AMENABLE DEATHS IN SPAIN, 2009 BY RARE HEMATOLOGIC DISEASES

E Sánchez-Valle[1], M Gómez-Roncero[2], M Sanjurjo[3], M Carroquino[4], M Posada de la Paz[4]
[1]Hospital de Valdepeñas, Valdepeñas, Spain
[2]Hospital Virgen de la Salud de Toledo, Toledo, Spain
[3]Hospital Universitario La Paz, Madrid, Spain
[4]Instituto de Investigación de Enfermedades Raras (ISCIII), Madrid, Spain

Background. Rare Diseases or Orphan Diseases (RD) are life-threatening or chronically debilitating diseases with a prevalence lower than 5 cases per 10,000 people, in terms of the prevailing European threshold. Many of the Hematologic Diseases are rare, but while diagnosis for some of them is relatively easy, for others it is delayed, resulting problems with appropriate accurate treatment. Some deaths are considered preventable with timely and effective healthcare: Avoidable and Amenable Deaths, Premature Mortality. These concepts evolve with therapies' improvement. **Aims.** In this work we attempt to estimate the burden of potentially avoidable and amenable deaths inSpain, 2009 from Hematologic Rare Diseases. **Methods.** We use the Anonymous Microdata of Deaths with Cause in Spain, 2009 of the Spanish National Statistics Institute. Rare Hematologic Diseases are selected from Orphanet, after that the equivalence to the International Classification of Diseases (ICD) is searched. To select deaths which would appear to be potentially avoidable we use Hematological Knowledge: the existence of a known effective treatment. In order to choose the amenable deaths we take those accepted in previous scientific literature. **Results.** Despite the limitations of the methods, and the difficult identification of some of the RD in the ICD, this work shows the deaths in Spain, 2009, by Rare Hematologic Diseases, with potentially avoidable and amenable deaths highlighted. There were 1249 deaths as a consequence of Myelodysplastic and Myeloproliferative Diseases. Most of the Myelodysplastic syndromes were diagnosed as "unspecified". More than 230 deaths could be attributed to potentially avoidable deaths, mainly Bleeding Disorders, Anemias, and Hemochromatosis. There were 51 additional deaths secondary to "Human Immunodeficiency Virus disease resulting in other types of Non-Hodgkin Lymphoma". There were 374 cases that could be considered to be due to classically defined potentially amenable deaths (159 by Hodgkin Lymphoma between ages 0 to 74, and 215 by Leukaemia, people 0 to 44 years). According to the incidence data reported in previous literature many of theHematological RD were not even diagnosed. **Conclusions.** In order to prevent potentially significant avoidable premature mortality, there is a need to improve the current knowledge in Rare Hematologic Diseases, evolving in the prophylaxis whenever possible, and later in the identification, characterization, and diagnosis, and moving forward in the sooner and appropriate treatment. The aim of this work is to contribute to foster awareness of Rare Hematologic Diseases.

1781

CHEMOTHERAPY SAFETY PERFORMANCE: Results FROM A MULTI CENTRIC PROSPECTIVE ANALYSIS

AM Pelizzari[1], M Ciofi degli Atti[2], P Trucco[3], M Cavallin[3], F Lorenzi[4], M Raponi[2]
[1]Spedali Civili Brescia, Brescia, Italy
[2]Ospedale Pediatrico Bambino Gesù, Roma, Italy
[3]Politecnico, Milano, Italy
[4]Astir S. r. l., Milano, Italy

Background. Risk assessment is crucial for proactively deal with patient safety, and standardised tools are needed to guarantee generalisation and comparability of results. This approach is even more relevant for patients who receive high risk medications, such as chemotherapy. **Aims.** We describe the first Italian experience of setting up and validation of a standardised method for multi centric risk analysis, as part of the Strategic Program: "Towards a complete competence framework and an integrated solution for patient safety in chemotherapy"funded by the Italian Ministry of Health. The Project involved 12 chemotherapy services (Ward andDayHospital) of 9 Italian hospitals. **Methods.** The proposed method starts from the configuration of the present chemotherapy process: the S-Failure Mode Effects Criticality Analysis (S-FMECA) tool shows a complete, codified and validated process mapping of all elementary activities, obtained by means of both literature review and structured interviews to healthcare professionals. In each elementary activity, the analysts identified specific Failure Modes on the basis of a taxonomy of 22 different Error Modes (EM), derived from a review of 48 selected papers about medication errors. All the ways a specific EM may occur are freely described by the analysts for each elementary activity (error dynamics). Rating Scales of Severity, Occurrence, and Detection have been defined to guide the analysts in calculating the Risk Priority Number (RPN) of each activity. The Analytic Hierarchy Process has been adopted to calibrate the four-level Severity Rating Scale through experts' judgments. ADelphimethod has been used to refine the assessment among the participant units. **Results.** The revision of assessments derived from a first application of S-FMECA, considering the risk profiles of the other participants, has allowed the refinement of data. In the subsequent analysis (through the web application FEMC@), several inconsistencies have been deleted. The process consists of seven phases (Patient Admission, Visit, Prescription, Preparation/Dispensing, Distribution, Administration and Patient Monitoring/Discharge). On average, "Preparation"is the phase with the highest RPN (25. 44% of the overall risk), while "Wrong Patient"is the riskiest EM, carrying 17. 10% of the total risk. Clinical centres with similar characteristics have been grouped in clusters and compared each other. No relevant difference in terms of total risk was found comparing computerized and paper-based prescriptions. **Summary and Conclusions.** The proposed S-FMECA method meets the requirements of transparency, reproducibility, and comparability of results. This approach allows an effective benchmark analysis not only of risk values for each phase in the chemotherapy process but also between clusters of similar processes. The results were summarized in reports, distributed to all participants and made public in Workshops, facilitating the comparison with the other Italian services. The web application FMEC@ was particularly appreciated by clinical operators, for whom risk management is typically a complementary subject with respect to their education and practice. On the basis of this results, a continuous monitoring of clinical risk associated to chemotherapy has been implemented by applying statistical quality control charts, according to the ERASMO method.

1782

IS DEPRESSION A PROBLEM FOR PATIENTS WITH MALIGNANT HEMOPATHIES?

RG Mihaila[1], R Dancu[2], I Lisan[2], A Catana[2], O Flucus[2], C Bus[2]
[1]Lucian Blaga University Sibiu, Sibiu, Romania
[2]Emergency County Clinical Hospital, Sibiu, Romania

Background. The diagnosis of malignant hemopathy is a dramatic event in the life of patient in question, with serious repercussions, including common disorders in the individual psyche. The relationship between the psyche and cancer was much discussed. If the mind influence on cancer development is controversial, the psyche is involved at least in quality of life and patient compliance to treatment and thus to its success or failure, with direct consequences for patient survival. **Aims.** We aimed to study the epidemiology and clinical characteristics of patients with hematologic malignancies with and without depression, in order to draw practical Conclusions on their management. **Methods.** We used the Beck's Depression Inventory II to examine 36 consecutive patients, hospitalized in the Hematology Department of Emergency County Clinical Hospital, Sibiu, in February this year, who had a malignant hemopathy diagnosis. We noted gender, age, type of proliferation, the presence of complete remission and diagnosis age (in months). Data were statistically analyzed using the arithmetic mean, standard deviation, Student t test and Pearson test. **Results.** The mean age was 56. 58+/-16. 93 years, the distribution by gender: 21 men (58. 33%) and 15 women (41. 6%). 16. 6% of women and 30. 55% of men were under 60 years. 25% of women and 27. 78% of men were over 60 years. Of the total, 28 (77. 78%) had a diagnosis of AML, MM, NHL, LH and 8 (22. 22%) other diagnoses. Of the 77. 78%, 11 (39. 29%) were in complete remission and 17 (60. 71%) - without complete remission. Mean disease duration was 19. 78+/-23. 43 months. Average score obtained from BDI II was 13. 61+/-8. 72. 5. 57% had severe depression, 16. 6% - moderate, 25% - mild; 47. 23% of patients had a depression score over 13, minimum score for the diagnosis of depression. Only 23% of those with depression were in complete remission, compared with 60% of those without depression. The total duration of disease progression for the 17 patients with depression was 420 months, compared with 292 months - for the others. There was a direct moderate correlation between age and the score obtained (r=0. 44). Regarding gender, women are significantly more often depressed than men (p<0. 05). **Summary.** About half of hospitalized patients suffer from a depressive disorder, most with a mild-moderate form, started during the progression of their hematologic malignancies. Depression is more common in patients with long-term disease, in those who did not obtain complete remission and with age. Women are more commonly affected by depression than men. Elderly and patients with a long and less responsive to treatment malignant hemopathy and especially women will need the attention of clinicians for possible psychotherapy and/or psychiatric treatment, not to jeopardize the results of hematologic therapy.

1783

END-OF-LIFE, PALLIATIVE CARE AND PLACE OF DEATH: FINDINGS FROM A POPULATION-BASED COHORT OF PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

D Howell[1], M Howard[2], R Patmore[3], H Wang[1], E Roman[1]
[1]University of York, York, United Kingdom
[2]York Teaching Hospital, York, United Kingdom
[3]Castle Hill Hospital, Hull, United Kingdom

Background. This is the first population-based study to address the dearth of empirical evidence about end-of-life, palliative care and place of death in patients with hematological malignancies. Patients with these complex diseases are recognized as being less than half as likely to receive Specialist Palliative Care (SPC) and over twice as likely to die in hospital compared to those with other cancers. The underpinning reasons for this divergence are unknown, although a lack of integration between hematology and SPC has been suggested. **Aims.** To describe the clinical pathways of patients diagnosed with specific hematological malignancies from diagnosis to death, with emphasis on SPC input, place of death and transitions from life prolonging to palliative approaches to care. **Methods.** This study is nested within the UK's Hematological Malignancy Research Network (HMRN - www. hmrn. org): a distinctive collaboration between researchers, a clinical hematology network and a centralized diagnostic laboratory. HMRN routinely collects demographic, treatment, prognostic and outcome data on all patients newly diagnosed with a hematological malignancy (>2,000 per year in a population of around 3. 6 million). The present investigation focuses on acute myeloid leukemia, diffuse large B-cell lymphoma and myeloma in patients > 18 years, that were diagnosed between 2005-2008, and who died before 2010 (n=356). Medical records were abstracted from diagnosis to death using a bespoke day-by-day calendar approach, whereby all hospital episodes were recorded, including information on treating specialities, SPC referrals/input and place of death, as well as decisions around treatment choices, changes in the focus of care, resuscitation status and use of the Liverpool Care Pathway. **Results.** The median age of patients was 74 (range 18-94). Median time from diagnosis to death was 10 months (range 0-54). Approximately one-third of patients were referred for SPC input, which occurred more frequently in patients with longer survival. Hospital was the most common place of death (72%), and in some instances this was the preferred place, whilst only 7% died in a hospice. No evidence was found in the medical records of a discussion about place of death for the majority of patients; however, many of these died soon after diagnosis or were still being treated with curative intent. Individual pathways and the timing of the transition to a palliative approach to care varied greatly by diagnostic group. Further data analysis is on-going and will be presented in the near future. **Conclusions.** The majority of patients with hematological malignancies die in hospital. Many do not receive SPC input; however, it is unclear whether this represents unmet need or whether these needs are met by others - such as haematology clinical nurse specialists. It is our intention to build on this study to promote understanding of end-of-life care in this disease group and we are presently conducting further research to explore reasons why hospital deaths predominate.

1784

RISK MODELS FOR PREDICTING CHEMOTHERAPY-INDUCED NEUTROPENIA IN PATIENTS WITH SOLID TUMORS AND MALIGNANT LYMPHOMA

D Petrovic, D Jovanovic, L Popovic
Institute of Oncology Vojvodina, Novi Sad, Serbia

Background. Myelosuppression represents a major toxicity of sistemic cancer chemotherapy associated with considerable morbidity, mortality, and cost. **Aims.** The objective of this study was to develop a model to predicting neutropenia in patients with solid tumours and malignant lymphoma initiating chemotherapy. **Methods.** The study population consisted of 141 patients with solid tumors (56 breast and 40 colon cancer patients) and 45 patients with malignant lymphoma who were beginning a new chemotherapy regimen. Patients had received standard-dose adjuvant chemotherapy for breast (Flourouracil, Adriamycin, Cyclophosphamide) and colon cancer (5 Flourouracil/folinic acid). Patients with lymphoma had received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicin,Vincristine and Prednisone). Neutropenic events reported included neutropenia (defined as an absolute neutrophil count [ANC] 1. 0-1. 5 x 10^9/L [Grade 2] or absolute neutrophil count 0. 5-1. 0 x 10^9/L [Grade 3] or absolute neutrophil count <0. 5 x 10^9/L [Grade 4] with or without body temperature ≥ 38°C). A predictive logistic regression model was developed. Two approaches to modeling were attempted. The pretreatment approach used only pretreatment predictors and the conditional approach included, in addition, blood count information obtained in the first cycle of treatment. **Results.** In the current study, 50 patients (35. 4%) experienced 1 or more neutropenic events during six cycles of therapy. Neutropenic events occurred in a significant proportion of patients (overall 35. 4%, breast 44. 0%, colorectal 10. 0%, lymphoma 46. 0%). The pretreatment model was less successful of predicting neutropenic events (c-statsitic=0. 70) than conditional model. Conditional model was good predictor of subsequent events after cycle 1 (c-statistic=0. 74). Pretreatment absolute neutrophil count (ANC <3. 5 x 10^9/L) was an excellent predictor of events in subsequent cycles (P=0. 002, odds ratio 4. 04) and chemotherapy regiment (P=0. 001, odds ratio 9. 59). The depth of the first-cycle ANC was a significant predictor of events in subsequent cycles (P=0. 009, odds ratio 2. 27). Decline in white cell count during the first cycle of therapy was a significant predictor of neutropenic events (P=0. 030, odds ratio 1. 81). R-CHOP therapy was associated with significant increases in risk over FA/FU therapy (P=0. 000, odds ratio 13. 58) even after accounting for the decline in white cell count during the first cycle and ANC nadir. The sensitivity and specificity of the pretreatment model were 52% and 81% respectively, and the positive and negative predictive values were 54% and 75% respectively. The sensitivity and specificity of the conditional model were 46% and 89% respectively, and the positive and negative predictive values were 70% and 75% respectively. **Conclusions.** It is possible to rank patients according to their need of supportive care based on blood counts observed in the first cycle of therapy. This analysis has implications for patient management and prophylaxis. Additional prospective research is needed to develop more accurate and valid risk models.

1785

COMPARISON OF SYMPTOM BURDEN OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

L Williams, T Mendoza, M Sailors, P Ault, A Garcia-Gonzalez, C Cleeland, J Cortes
The University of Texas MD Anderson Cancer Center, Houston, Texas, United States of America

Background. Hematopoietic stem cell transplantation (HSCT) is an intensive therapy that may cure or control a variety of hematological malignancies. During the first 3 months following HSCT, patients develop symptom burden that interferes with daily activities. Chronic myeloid leukemia (CML) often requires continuous tyrosine kinase inhibitor (TKI) treatment with long-term survival rates of > 80%. TKIs are considered relatively well-tolerated. However, long-term therapy that produces even mild symptoms may produce a substantial burden for patients. **Aims.** The aim of this study was to compare the symptom burden experienced by patients with CML to the symptom burden of patients undergoing HSCT. **Methods.** This is a retrospective analysis of data from a study of symptom burden in 142 patients with CML and a merged data set of 305 patients undergoing HSCT. Both groups responded multiple times to symptom questions on M. D. Anderson Symptom Inventory (MDASI) modules specific for their particular disease and treatment. Symptom burden was measured using the area under the curve (AUC) of the mean of the 5 most severe symptoms for each group. **Results.** The CML patients were slightly older (mean = 51. 8 years; standard deviation [sd] = 13. 4) than the HSCT patients (48. 9, sd =12. 7), more were female (54% versus 43%), more were employed (57% versus 17%), more had better performance status at baseline (ECOG 0-1 = 97% versus 42%), and they had been diagnosed longer (5. 7 years, sd = 4. 8 versus 1. 8, sd = 2. 3). Most CML patients were in chronic phase (97%) on TKI therapy (95%); 42% of the HSCT patients received an allogeneic HSCT. The MDASI assesses symptoms on a scale of 0 (symptom not present) to 10 (symptom as bad as can be imagined). The CML patients responded to 20 symptom items every 2 weeks for 1 year. The HSCT patients from 4 different studies responded to 13 common symptom items at least weekly for the first month following HSCT and then weekly or monthly until 3 months after HSCT. Symptom burden was defined as the AUC of the composite of the 5 most severe symptoms for each group (See Table 1). Because of the difference in the measurement time periods which impacts the AUC, we calculated the average daily mean AUC (CML = 1. 9, HSCT = 2. 3). For the CML patients to reach the AUC that the HSCT patients experienced in 90 days would take 108 days, a difference of only 18 days. **Summary and Conclusions.** TKI therapy for CML has been considered to produce minimal side effects. However, the symptoms experienced by patients with CML on TKI therapy produce burden in approximately 3 ½ months that equates to that of the most intense 3-month period of HSCT. The daily AUC for CML was stable over 1 year, whereas the daily AUC for HSCT was declining at 3 months. Extended over years, this CML burden is substantial. This burden is likely to impact patient functioning and may decrease compliance with therapy. Attention is needed to developing interventions to decrease this unexpectedly high burden.

Table 1. Symptom Burden AUCs for CML patients for 1 year and HSCT patients for 3 months.

CML – 1 year				HSCT – 3 months			
Symptom	N	Mean AUC	Standard Deviation	Symptom	N	Mean AUC	Standard Deviation
Fatigue	142	867.6	704.09	Fatigue	305	257.3	158.11
Muscle soreness	142	670.3	677.10	Physical weakness	305	221.6	159.03
Disturbed sleep	142	666.7	708.50	Lack of appetite	305	200.8	148.34
Drowsiness	142	666.3	631.11	Disturbed sleep	305	189.2	140.09
Trouble remembering	142	551.3	558.87	Pain	305	155.4	134.29
Symptom burden	142	687.3	579.82	Symptom burden	305	205.3	125.60

1786

PROVIDING APPROPRIATE GENETIC INFORMATION TO HEALTHY CARRIERS OF HEMOGLOBINOPATHY IS A WELCOME AND SAFE INITIATIVE: THE LATIUM EXAMPLE

P Giordano[1], A Amato[2], M Lerone[2], P Grisanti[2], L Gizzi[2], J Kaufmann[1]
[1]Leiden University Medical Center, Leiden, Netherlands
[2]Centro Studi Microcitemie, Roma, Italy

Background. Due to massive migration the incidence of hemoglobinopathies is now a day higher in non endemic Northern Europethen in the endemic Southern and Mediterranean countries. Long experience from these countries has shown that diagnose and information of healthy carriers is a welcome and safe initiative. Nevertheless Ethical objections have been raised against informing healthy carriers. **Aims.** To register the opinion and feelings of (presumed) unaware healthy hemoglobinopathy carriers, receiving information on their carrier status. To show to colleagues from non endemic countries involved in primary prevention that properly provided information is a welcome and safe initiative. **Methods.** We have been routinely screening all secondary school children from theLatiumregion (Rome & Central Italy) for several decades, using standard hematological methods. After screening all parents received a standard reassuring letter informing them on the results of the screening and were invited for confirmation of the trait and for additional explanation if needed. During the visit we have collected 259 interviews from parents of students who were provisionally diagnosed hemoglobinopathy carriers. **Results.** We have analyzed 219 interviews (84. 5%) from indigenous subjects and 40 from ethnic minorities (15. 5%). The average age of the parents was 45. 5 years. Only 51 (19. 7%) had previous knowledge of their carrier status while the rest was unaware. When reading the letter with the provisional diagnostic result of their child, emotions that could be considered disagreeable were present in about 60% of the cases. Nevertheless, the information was experienced as welcome, clear and useful by 100% of the participants. Asked about the option of prenatal diagnosis (PD) in case of genetic risk, 85. 7% and 87. 5% of the autochthonous and allochthonous interviewed, declared either to be in favor or eventually to consider PD while only 14. 3% and 12. 5% would not consider it for various reasons. **Discussion.** In spite of ethical objections made in some non endemic countries, we have demonstrated that, if undesirable feelings are present in some of the subjects during the very first reading of the letter, these are only temporary and disappear shortly after or during the visit to the center later on. Significantly, satisfaction and understanding of the advantage of knowledge was registered in 100% of the cases during our enquiry.

ARE TRANSFUSIONS FOR MYELODYSPLASIA (MDS) AN ACCEPTABLE TREATMENT TO PATIENTS?

J Twiss[1], S McKenna[1], S Crawford[1], J Wilburn[1], K Loth[2]
[1]Galen Research Ltd, Manchester, United Kingdom
[2]Celgene, London, United Kingdom

Background. Although the main treatment for MDS is blood transfusions, scarce information is available on patients' experiences of the treatment. Only one relevant study could be identified which reported that patients have a preference for being transfusion independent (Szende et al. Valuation of transfusion-free living in MDS: results of health utility interviews with patients. (2009). *Health Qual Life Outcomes*, 7:81). **Aims**. To investigate MDS patients' experiences with transfusions. **Methods.** Qualitative, unstructured interviews were conducted with MDS patients. Verbatim transcripts were produced and subjected to Interpretative Phenomenological Analysis (IPA). IPA aims at gaining an understanding of patients' experiences from their own perspective. Themes are generated based on issues identified during the interview process. **Results.** The sample included 23 patients with blood transfusion experience (male = 11 (47. 8%); mean (SD) Age=65. 3 (11. 2) mean (SD) time since diagnosis=5. 4 (4. 0)). Of the patients interviewed, 9 (39. 1%) were currently receiving regular transfusions, 5 (21. 7%) had been transfusion dependent previously and 9 (39. 1%) had some transfusion experience. Five major themes were identified in the analyses; positive aspects of transfusions, the cyclic nature of symptoms, transfusion-related limitations on functioning, associated iron chelation therapy and problems with actually receiving the transfusions. Transfusions were perceived positively by some patients as they relieve patients' everyday symptoms. However, these benefits diminish between transfusions leading to cycles of good and poor symptoms, functioning and psychological distress. Limitations to patients' lives resulted from frequent and often long trips to hospital. Negative experiences with the iron chelating drug Deferoxamine were reported by the 3 patients receiving this treatment. The drug is generally administered subcutaneously by means of a battery operated pump and is usually worn for several hours a day causing pain and discomfort. The transfusions were also reported to be boring, uncomfortable and at times painful. **Conclusions.** Transfusions can have a large negative impact on patient's lives. The results suggest there is a need for alternative forms of treatment for patients with MDS. Further quantitative work assessing patients' experiences with transfusions is required.

DISCLOSURE OF A DIAGNOSIS OF MYELODYSPLASTIC SYNDROME: IMPROVING PATIENTS' UNDERSTANDING AND EXPERIENCE

C Besson[1], H Elmaaroufi[2], S Rannou[3], N Guirimand[4], L Cartron[5], S Jenny[6], P Fenaux[3], P Festy[6], A Leplege[7]
[1]CHU Bicêtre, Le Kremlin_Bicêtre, France
[2]Hôpital Militaire, Rabat, Morocco
[3]APHP, Le Kremlin Bicêtre, France
[4]Université de Rouen, Rouen, France
[5]Université Paris VII, Paris, France
[6]CCM, Paris, France
[7]Paris VII, Paris, France

Background. How a diagnosis of cancer is disclosed can affect the patient's subsequent psychological morbidity. The specialized terminology of blood malignancies may not be immediately understandable to all patients. **Aims.** We set out to survey how diagnosis of myelodysplastic syndrome (MDS) is announced inFrance and how disclosure is experienced and understood by patients. **Methods.** All 150 members of the French MDS patient support group were sent a questionnaire covering demographic characteristics, circumstances, feelings concerning disclosure, expectations, experiences and comments. In addition, 46 of them were interviewed by a hematologist to collect clinial data concerning their disease. **Results.** Disclosure was experienced negatively by 45% of the 73 patients who returned a useable questionnaire. In retrospect, patients felt they should have been given fuller information at the time of disclosure. They complained it was difficult to understand their disease and the word cancer was mentioned by eight patients. Almost all patients (94%) thought that comprehensive, accurate information should be provided at disclosure, even if the truth might be hard to cope with. However, more than half of the patients also expressed a wish for information tailored to their needs (75%) and for reassurance from the physician (54%), even if that means withholding potentially disturbing information. **Conclusions.** Many patients experience disclosure negatively, frequently finding that the information provided is insufficient and feeling that MDS was not well understood as a disease. Hematologists disclosing MDS diagnosis to patients may benefit from following the same guidelines as oncologists, recommending delivery of comprehensive, understandable information. They clearly recommend using clear, straightforward terminology without avoiding the word cancer when appropriate.

SALVAGE RADIOTHERAPY, IMPROVES QUALITY OF LIFE LYMPHOMA HODGKIN PATIENTS, AFTER CHEMOTHERAPY FAILURE

D Puric
Institute of Oncology and Radiology of Serbia, Belgrade, Serbia

Background. Fox and Lippman have concluded in 1987 y., during follow up 17 patients with advanced Hodgkin lymphoma, that salvage radiotherapy is of significant benefit in patients with advanced Hodgkin's disease relapsing after combination chemotherapy in nodal and/or pulmonary, previously unirradiated sites. Yet, the use of involved-field radiotherapy after chemotherapy for advanced Hodgkin's lymphoma remains controversial. **Aims.** To evaluate efficacy of salvage radiation therapy, in patients with Hodgkin's disease after

chemotherapy failure. **Methods and Materials.** During 2010 and 2011, 5 patients with persistent or recurrent Hodgkin's lymphoma after chemotherapy were treated with salvage radiotherapy. Treatment consisted of extended field radiotherapy to areas of bulky or symptomatic disease. The volume irradiated was mantle field in three patients, inverted-Y in two, and involved-field in one. Total radiation doses ranged from 20 to 40. 0 Gy. Patient characteristics were: age 40-74 years; progressive disease 1/6; stabile disease 2/6; late relapse 2/6; 'B' symptoms 2/6; CS IVB 1/5 and CS IIIB 4/5. Assessments were made using EORTC QLQ-C30(QOL) and the MFI-20(Multidimensional Fatique Inventory questionnaire). Median follow up time was 12 months. **Results.** One patient achieved a complete response. Partial remission was achieved in one patient, MR in two patients and SD in one patient. All patients improved Karnofsky performance status and became asymptomatic . Improvement over time was observed for all scales. Salvage therapy was generally well-tolerated and resulted in no treatment-related deaths. **Conclusions.** Salvage radiotherapy gives significant contribution for improving quality of life and should be considered an option for patients with advanced Hodgkin's disease following chemotherapy failure.

QUALITY OF LIFE IN PATIENTS WITH HEMATOLOGICAL NEOPLASIC DISSEASES

C Cotoraci, A Sasu, H Grossmann, A Mustea, A Hermenean, L Mos, A Varga, S Fildan
Vasile Goldis Western University of Arad, Arad, Romania

The Oncohematologic patient suffers deep somatic and psychological changes while establishing his diagnosis and treatment. In this study the authors have evaluated patient's perception over their own situation and emotional interaction with surrounding sociological factors. A simple and easy testing system including 10 areas of activity, psychodynamic interaction and daily life issues from patients's lifes was elaborated and used by the authors to a group of 65 patients from the Hematology Clinic of Arad and to a control group. A further analysis was to compare the mean values obtained for each of the ten domains of the questionnaire and the items corresponding to each area depending on the variables investigated. Results demonstrated that depending of gender, age, severity of dissease as well as other factors, there is a difference in patient's evaluation. In all items related to health, the patients get results that show lower satisfaction compared with healthy persons. We realise that although in terms of health and professional field the patients have much lower satisfaction compared to healthy people, the disease brings a change of perspective on life and on relationships. Patients are more satisfied than healthy people in certain areas, which provide them anchors they need to deal with the situation in which they live: leisure, relationship with their mate, relationship with their relatives. Family support is particularly important in the fight that oncological patients have to bear with their disease and treatment. As a conclusion, the authors underlined that there can be no promising medical treatment without including social and psychological factors of patients situation during time of hospitalization. Quality of life in oncohematological patients is given by a number of factors, including both health and social relationships, professional and daily life conditions. Perception of quality of life differs in the oncohematological patient to the healthy individual, being perceived differently by gender, stage of disease. The authors also concluded that changes of medical team's view and approach towards the onco-hematological patient are needed. Defining onco-hematological illness as a holistic complex ensemble of somatic and psychological pathological factors this indicates the need for new concepts of treatment in the future.

IMPLICATION OF POLYMORPHISMS OF BMP6 IN OSTEONECROSIS AMONG SCA PATIENTS IN TUNISIA

L Chaouch[1], M Ben Jbara[1], I Ben Mansour[1], I Moumni[1], M Kalai[1], D Chaouachi[1], R Hafsia[2], A Ghanem[3], S Abbes[1]
[1]Pasteur Institute, Tunis, Tunisia
[2]Department of Biological Hematology. Hospital Aziza Othmana, Tunis, Tunisia, Tunis, Tunisia
[3]Department of Biochemistry. Hospital of Traumatology, Tunis, Tunisia

Background. The skeletal manifestations of sickle cell disease are the result of changes in bone and bone marrow caused by the chronic tissue hypoxia that is exacerbated by episodic occlusion of the microcirculation by the abnormal sickle cells. Furthermore, the occurrence of osteonecrosis is under the control of some modifier gene. BMP6 (Bone morphogenetic protein) has been reported as associated with osteonecrosis in sickle cell anemia (SCA). **Aims.** Herein, we entend to study the impact of rs267196, rs267201, rs408505 and rs449853 of BMP6 gene in the occurrence of osteonecrosis among sickle cell patients in Tunisia. **Methods.** Our study involved 100 SCA pediatric patients among whom 50 have osteonecrosis. Rs267196, rs267201, rs408505 and rs449853 of BMP6 gene were analysed for all subjects by PCR/sequencing. We used the software package Arlequin (version 3. 01) for Hardy-Weinberg equilibrium test. Genetic differences according to the presence or not of osteonecrosis were evaluated applying exacts tests to genotypic or allelic contingency tables using compare 2(version 1. 02). **Results.** Our findings show that all samples were found to be in Hardy-Weinberg equilibrium (p>0. 05) for the studied polymorphisms. Furthermore, the distribution of genotypes between SCA patients according to the presence or not of osteonecrosis revealed that patients carried genotype AT of rs 267196 and genotype AG of rs267201 present a high risk factor for developing osteonecrosis OR=5. 66 and OR= 4. 55 respectively. As for rs408505 and rs449853 of BMP6 gene no significant association was found among SCA patients. **Conclusions.** Altogether our data provide that BMP6 can play an important role in developing osteonecrosis.

A NEW MUTATION OF THE PGK1 GENE DETECTED IN AN ITALIAN PATIENT AFFECTED BY PHOSPHOGLYCERATE KINASE DEFICIENCY

P Bianchi[1], E Fermo[2], L Chiarelli[3], M Maggi[3], L Mandarà[4], A Marcello[2], C Vercellati[2], W Barcellini[2], A Cortelezzi[1], G Valentini[3], A Zanella[2]
[1]Foundation Irccs Cà Granda Ospedale Maggiore Policlinico, Milan, Italy
[2]Hematology 2 Unit, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milan, Italy
[3]Dipartimento di Biologia e Biotecnologie "L. Spallanzani" Università degli Studi, Milan, Italy
[4]Azienda Sanitaria Provinciale di Ragusa - Ospedale Maria Paternò Arezzo, U. O. s. d, Ragusa, Italy

Background. Phosphoglycerate kinase (PGK) is a key glycolytic enzyme that catalyzes the reversible phosphotransfer reaction from 1,3-bisphosphoglycerate (1,3-BPG) to MgADP to form 3-phosphoglycerate (3-PG) and MgATP. Two isozymes encoded by two distinct genes are present in humans: PGK1 gene is located on Xq-13. 1 and encodes an ubiquitous protein of 417 amino acids, whereas PGK2 is testis-specific. PGK1 deficiency is characterized by mild to severe haemolytic anaemia, neurological dysfunctions and myopathy; patients rarely exhibit all three clinical features. Nearly 40 patients have been reported, 27 of them characterized at DNA or protein level, and 20 different mutations have been described. Recently, we performed biochemical characterization of all PGK1 mutant enzymes to investigate the genotype-phenotype relationship (1). **Aims.** The aim of the study was to characterize at molecular level the first mutation of PGK1 gene found in an Italian patient affected by PGK deficiency. **Methods.** Genomic DNA and total RNA were extracted from leukocytes; the codifying region and intronic flanking regions of PGK1 gene were analyzed by direct sequencing. The PGK1 mutant was obtained from *E. coli* as recombinant protein, purified to homogeneity as previously indicated (1), and assayed for its thermostability and kinetic properties. **Results.** The patient, born from unrelated Italian parents with negative family history, showed at birth neonatal jaundice. During an infective episode at the age of 4, he had haemolytic anaemia (Hb 8. 6 g/dL, reticulocytes 19%, unconjugated bilirubin 0. 91 mg/dL, LDH 445 U/L), increased CPK values (2483-U/L) and respiratory distress. The study of RBC glycolytic enzymes displayed a drastic reduction of PGK activity (41. 8 U/gHb ref. 287-392). The patient was re-examined at the age of25 inoccasion of his sister's first pregnancy. He displayed compensated haemolytic anaemia (Hb 14. 1 g/dL, reticulocytes 6. 6%) and severe myopathy. IQ test indicated mild-moderate mental retardation. PGK1 gene sequencing revealed the new missense mutation c. 1112 T>A (Ile371Lys). The mutation was not found among 100 normal alleles, and even if located in the third last nucleotide of exon 9, it doesn't alter the mRNA splicing. Family study confirmed the X-linked transmission of the disease. Ile371Lys mutation falls in a highly conserved region of the enzyme, near the nucleotide binding site. The mutant enzyme shows reduced catalytic rates toward both substrates (*k*cats, twelve-fold higher than wild-type) and a decreased affinity toward Mg-ATP (apparent *K*m, 6-fold higher than wild-type). Moreover, it lost half of its activity after nearly 9-min incubation at 45°C, a temperature that did not affect the wild type enzyme ($t_{1/2}$ higher than an hour). **Conclusions.** The highly perturbed catalytic properties of the new variant Ile371Lys, combined with protein instability, account for the PGK deficiency found in the patient and correlate with the clinical expression of the disease.

UNUSUAL HAEMOGLOBIN VARIANTS IN OMAN; PITFALLS IN DIAGNOSIS

A Al-Riyami[1], S Al-Zidjali[2], D Gravell[2], S Al-Kindi[2], N Fawaz[2], S Daar[2]
[1]Sultan Qaboos University Hospital, Muscat, Oman
[2]SQUH, Muscat, Oman

Background. Oman is located on the southeast coast of the Arabian Peninsula. With its unique location, and with its historical connections with the African and Asian continents, many common hemoglobinopathies are present, including the thalassemias, HbS, HbD and HbE. HPLC (high performance liquid chromatography) is a cost effective method of screening for most of the abnormal haemoglobins. Additional tests will increase costs. However, unusual hemoglobinopathies can be encountered and can be mis-diagnosed. **Aims.** To ascertain whether HPLC alone can be used to identify abnormal haemoglobins found in the Omani population. **Methods.** Both complete blood counts (CBC) on a Cell Dyn 4000 automated blood cell counter (Abbott Diagnostics, Santa Clara, CA, USA) and HPLC using the VARIANT IITM instrument (Bio-Rad Laboratories, Hercules, CA, USA) were performed for the blood samples referred for testing for underlying hemoglobinpathy. All newborns born at the hospital were also screened by cord blood HPLC. In addition, all blood samples found to have a mean corpuscular volume (MCV) of less than 70 fL and/or mean cell Hb (MCH) of less than 24 pg undergo analysis. If an abnormality is noted on HPLC analysis (abnormal peaks, abnormal proportion of a variant Hb, incompatibility with hematological parameters), a secondary test is always performed to confirm the diagnostic assumption. This is done through alkaline & acid gel electrophoresis and/or molecular analysis. **Results.** Using the above protocol, 5 unusual hemoglobins variants that needed additional testing were identified. These included:1. Hemoglobin Dhofar [β 29 (GGC-GGT) gly-gly, β 58 (CCT-CGT) pro-arg] is unique to Oman and associated with thalassaemic phenotype. This hemoglobin can be mistaken as Hemoglobin D on HPLC and electrophoresis, but is found at reduced qualities (8. 8%-21. 5% in heterozygotes, 26%-59. 7% in homozygotes). 2. Hemoglobin S Oman: with two β mutations [β6 Glu->Val (HbS mutation) and β121 Glu->Lys (Hb O Arab mutation)]. The heterozygous state results in a mild to moderate sickling syndrome. This hemoglobin can be mistaken for HbC on HPLC and runs close to the C band on alkaline gels. 3. Delta globin variant with Codon 16 mutation can be observed in heterozygotes, homozygotes, and in combination with HbS, HbC, and beta thalassemia. This variant runs in the S window in a very small percentage that can be missed. Underestimation of true A2 level can lead to missing the diagnosis of beta thalassemia trait. 4. Hemoglobin Sheffield [β58(E2)Pro->His] is a phenotypically silent hemoglobin that coelutes in the HbA2 window on HPLC, and can be erroneously diagnosed as HbE. However, it is silent on electrophoresis. 5. β globin promoter -71 C>T mutation. This hemoglobin causes a mild beta+ thalassemic phenotype, increases HbA2 levels in the heterozygous state. When present with an abnormal haemoglobin eg Hb S, the result may be erroneously diagnosed as Hb S trait. **Summary and Conclusions.** If only HPLC is used for diagnosis, pitfalls can occur due to unusual hemoglobin variants. A second confirmatory test should always be done besides HPLC, and in some cases tertiary testing may be necessary.

1794

ALPHA GLOBIN GENE COPY NUMBER VARIATIONS LEADING TO A FULL ?-THALASSEMIA PHENOTYPE SPECTRUM: A RETROSPECTIVE STUDY

J Martinez-Nieto, L Vinuesa, F de la Fuente-Gonzalo, P Ropero, F Gonzalez, B Pérez, E Fontanés, A Villegas, J Díaz-Mediavilla
Hospital Clínico San Carlos, Madrid, Spain

Introduction. β-thalassemias are caused by a heterogeneous group of genetic alterations characterized by a deficient synthesis (β+) or an absence (β0) of β globin chains in that locus. Thalassemic phenotypes include asymptomatic cases (thalassemia minor; in most heterozygote forms of β-thalassemia) and patients suffering a transfusion dependent severe form of the disease (thalassemia major; in homizygote or double heterozygote patients). β globin chain production in the red cells is the main phenotype modifier in β-thalassemia. Nevertheless, the are other modifiers that can ameliorate the severity of the phenotype (elevated HbF levels) or enhance it (increased α/β ratio caused by extra α globin gene copies). **Aims.** This is a descriptive study showing a cohort of β-thalassemia patients (β+ or β0) carrying heterozygous or homozygous αanti 3. 7Kb duplications (ααα/αα or ααα/ααα conditions, respectively). **Methods.** Hematometric data were obtained in a GENS Coulter. Quantification of HbA2 and HbF levels was done by HPLC (Variant II). Screening for β gene mutations was performed by sequencing and α globin copy number was measured by Multiplex Ligation-dependent Probe Amplification (MLPA) technique. Patients were divided in four groups according to their genotype: Group1 (β0 plus ααα/ααα); group2 (β0 or severe β+ plus ααα/αα); group3 (mild β+ plus ααα/ααα) and group4 (mild β+ plus ααα/αα). A total of 38 patients were included in this study. **Results.**The following β gene mutations have been included here: βCD39 (β0 condition, 15 cases); βIVS-I nt-1 (β0 condition, 12 cases); βCD82/83 (-G) (β0 condition, 2 cases); βIC (ATG >) (severe β+ condition, 1 case); βIVS-II nt-654 (severe β+ condition, 1 case) βIVS-I nt-110 (severe β+ condition, 5 cases) and βIVS-I nt-6 (mild β+ condition, 2 cases). Results are summarized in figure 1. DISCUSSION. Here we show a cohort of patients with all the possible combinations between both β+ or β0 gene mutations and the αanti 3. 7Kb duplication. The phenotype manifestations widely differs between patients, presenting severe β-thalassemia (major or occasionally transfusion thalassemia intermedia), mild thalassemia intermedia and β-thalassemia trait. Severe thalassemia is observed in patients with the greater α/β imbalance. These cases correspond to β0 mutations associated with ααα/αααα, in which β chain production is severely compromised (patients I and II-I). Mild thalassemia intermedia phenotype is observed when a β0 or severe β+ mutation is present in association with αanti 3. 7Kb duplication in heterozygous state (ααα/αα), thus, α/β imbalance is not as prominent as seen in the patients mentioned above. Interestingly, this phenotype is seen in patient with the mild IVS-Int-6 β+ mutation associated to ααα/αααα. In this particular case α/β imbalance is caused mainly by the α globin over expression. Thalassemia trait is shown by patient XXVI-II (mild β+ mutation plus ααα/αααα) and one patient in group2 (β0 mutation plus -α3. 7/αααanti 3. 7, with no net α copy number variation). In both patients α/β ratio should be similar but reached with different α and β chain contributions in each case. The different phenotypes exposed here manifest how important issue is the α/non-α globin chain production in order to modulate the β-thalassemia clinical expression.

Table 1. Results summary.

A CASE OF CONGENITAL RED CELL PYRUVATE KINASE DEFICIENCY ASSOCIATED WITH HEREDITARY SPHEROCYTOSIS

C Vercellati, A Marcello, E Fermo, P Bianchi, C Boschetti, A Iurlo, A Zanella, W Barcellini
Hematology 2 Unit, Foundation IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy

Pyruvate kinase (PK) deficiency, transmitted as an autosomal recessive trait, is the most common erythroenzymopathy of glycolytic pathway (prevalence of 1:20,000) associated with chronic non spherocytic hemolytic anemia from mild to severe. More than 180 mutations in the *PK-LR* gene have been so far reported, and genotype-phenotype correlation has been established for some of them. Hereditary Spherocytosis (HS) is the most common congenital hemolytic anemia in Caucasians, with an estimated prevalence ranging from 1:2000 to 1:5000. The main clinical features are hemolytic anemia from compensated to severe, variable jaundice, splenomegaly and cholelythiasis. The molecular defect is highly heterogeneous, caused by proteins involved in the attachment of cytoskeleton to the membrane integral domain (spectrin, ankyrin, band 3 and protein 4. 2). We describe a case of PK deficiency associated with HS. The propositus was a 13 years-old Italian male with neonatal jaundice and need of blood transfusion (Hb 5. 8 g/dL) during an infectious episode. At the time of the study Hb was 13. 9 g/dL, MCV 81. 8 fL, reticulocytes 207x10^9/L, unconjugated bilirubin 2. 16 mg/dL, LDH 605 U/L, haptoglobin <20 mg/dL. The peripheral blood smear examination showed the presence of spherocytes (16%) and some ovalocytes (2%). The study of the most important red cell enzymes

revealed reduced PK activity (59% of normal). Direct sequencing of *PK-LR* gene showed compound heterozygosity for the 994A mutation (Gly332Ser) and the -148T variant localized the erythroid specific promoter region. The presence of spherocytes in peripheral blood smear prompted us to investigate for the coexistence of HS. Erythrocyte osmotic fragility was decreased and SDS-PAGE analysis of red cell membrane proteins revealed a 30% spectrin reduction. Family study demonstrated a heterozygous condition for the 994A mutation in the father, who also displayed comparable enzyme deficiency, whereas promoter variant -148T was detected in the mother and in the brother. No red cell membrane abnormalities were present in the family members, although positive EMA binding test and increased osmotic fragility were found in the father and brother. The co-existence of HS and PK deficiency is very rare event, only few cases are described to date. Clinical, family and molecular studies allowed the determination of the interrelationship between the two RBC abnormalities in the patient and his relatives. The reduced PK activity in the propositus and his father is justified by heterozygous 994A mutation. The more severe clinical picture in the propositus could be caused by the coexistence of HS and by the presence of -148T mutation, that although it seems not to have effects on *PK-LR* mRNA expression, is often detected in PK deficient subjects with heterozygous PK mutations.

1796

HOMOZYGOUS AND HETEROZYGOUS HEMOGLOBIN S ASSOCIATED WITH HEMOGLOBIN G-PHILADELPHIA

F de la Fuente-Gonzalo, P Ropero, J Martínez-Nieto, L Vinuesa, E Fontanes, C Seri, E Bolaños, F González, A Villegas, J Díaz-Mediavilla
Hospital Clínico San Carlos, Madrid, Spain

Background. Electrophoresis of hemoglobins (Hb) and HPLC techniques are usually sufficient for the identification of HbS. However, the association with an α-globin chain structural variant produce results difficult to interpretate with these methods. This is caused by the formation of a new Hb that contains both the two abnormal β and α-globin chain variants. **Aims.** In this paper we present the electrophoretic, chromatographic and molecular association of an heterozygous HbS and another homozygous HbS with the α-chain variant G-Philadelphia. **Methods.** Case 1: 49-years-old man referred with a sickle cell anemia diagnosis. Case 2: asymptomatic 31-years-old woman. The Hbs' study was made by electrophoresis at alkaline pH (8. 6), and acid pH (6. 0), capillary electrophoresis, ion exchange HPLC and reverse phase HPLC. We studied the existence of an α-thalassemia by gap-PCR. Molecular analysis was completed by automatic sequencing of PCR amplification products of genes α_1, α_2 and β. **Results.** In case 1, by alkaline pH electrophoresis were observed three Hbs, one at the level of HbA (corresponding to $\alpha^A\beta^A$ transfused Hb), another at the level of HbS, G, D (corresponding to $\alpha^A\beta^S$ Hb) and the last one at the level of HbC, E, O-Arab (corresponding to $\alpha^G\beta^S$ Hb). Only two bands were observed at acid pH, one at the level of HbA, E, D (corresponding to $\alpha^A\beta^A$ transfused Hb) and another at the level of HbS, O-Arab (corresponding to $\alpha^G\beta^A$ and $\alpha^G\beta^S$ Hbs). By ion exchange HPLC three elution peaks corresponding to αAβA Hbs (transfused), $\alpha^G\beta^A$ and $\alpha^G\beta^S$ were showed. By reverse phase HPLC 4 peaks corresponding to β^S, β^A, α^G and α^A chains were observed. In case 2, by ion exchange HPLC were observed 4 elution peaks corresponding to $\alpha^A\beta^A$, $\alpha^A\beta^S$, $\alpha^G\beta^A$ and $\alpha^G\beta^S$. By reverse phase HPLC were observed 4 peaks corresponding to β^S, β^A, α^G and α^A β^S chains. Both patients had a loss of a functional alpha gene by the 3. 7 Kb deletion in one allele. The sequencing of the gene in the molecular study of first case showed GAG → GTG mutation at codon 6 of β gene in the homozygous state and in the second case in the heterozygous state (β6 (A3) Glu>Val). In sequencing of the α genes was demonstrated the AAC → AAG mutation at codon 68 of the $\alpha_2\alpha_1$ hybrid gene formed by the deletion of 3. 7 kb in both cases (α68 (E17) Asn> Lys). **Conclusions.** The sickle cell anemia may be due to the combination of HbS with others Hbs or thalassemic syndromes. This event make the diagnosis more difficult. In both cases, the integration of electrophoretic, chromatographic and molecular studys allowed for a correct diagnosis.

1797

CHARACTERIZATION OF 3 HEMOGLOBINOPATHIES THAT PRESENT CYANOSIS AND DESCENT OF THE SATURATION OF 02

F de la Fuente-Gonzalo, P Ropero, J Martínez-Nieto, L Vinuesa, B Pérez, C Seri, F Medina, F González, A Villegas, J Díaz-Mediavilla
Hospital Clínico San Carlos, Madrid, Spain

Background. Structural hemoglobinopathies along with thalassemia are the most common monogenic disorders worldwide. Depending on the nature and location of the substituted aminoacid are to determine changes in the stability, solubility and function of the hemoglobin molecule that are ultimately responsible for the clinical manifestations of hemoglobinopathies. **Aims.** To present the molecular characterization of three hemoglobins variants that his suspicion was conducted by the existence of a decrease in oxygen saturation with cyanosis. **Methods.** We studied 3 cases (1: M/35 years old, 2: M/34 years old, 3: F/19 years old) referred to have decreased oxygen saturation and cyanosis. In all 3 cases, by ion exchange HPLC abnormal hemoglobin was eluted behind the HbA. By reverse phase HPLC was separated abnormal α chain in the first 2 cases and an abnormal β chain in the third. **Results.** In sequencing of the globin genes was observed:Case 1: CAC>TAC mutation at codon 58 of α_2 gene in heterozygous state that determines the change of histidine by tyrosine, known as Hb M-Boston (α_2 58 (E7) His→Tyr). Case 2: CAC>TAC mutation at codon 94 of α_2 gene in heterozygous state that determines the change of aspartic by asparagine, known as Hb Titusville (α_2 94 (G1) Asp→Asn). Case 3: CAT>TAT mutation at codon 63 of the β gene in heterozygous state that determines the change of histidine by tyrosine, known as Hb M-Saskatoon (β63 (E7) His→Tyr). **Conclusions.** In the Hb M- Boston and M-Saskatoon changing the proximal histidine for tyrosine at heme group at the anchor of α and β chains respectively. This fact, determines that the heme central iron was oxidized permanently to yield up an electron and therefore it can not capture oxygen, this is the cause of the decrease in oxygen saturation and cyanosis. In Hb Titusville aspartic changing by asparagine at position G1 of α chain, that it was involved in the $\alpha_1\beta_2$ contact and determines the stabilization of the Hb in conformation T or deoxy therefore has a low affinity for oxygen being the reason of decreased oxygen saturation and cyanosis. The possibility of the presence of one structural hemoglobinopathies must be taken into account in cases of cyanosis and decreased oxygen saturation without apparent cause. Although not present a significant clinical impact, their confirmation saves people carrying large and unnecessary studies.

1798

BCL-2 LEVELS IN PATIENTS WITH THALASSEMIA MINOR

I Yavasoglu[1], G Sargin[1], G Kadikoylu[1], A Karul[2], Z Bolaman[1]
[1]Adnan Menderes University Medical Faculty, Division of Hematology, Aydin, Turkey
[2]Adnan Menderes University Medical Faculty, Department of Biochemistry, Aydin, Turkey

Background. Antiapoptotic proteins such as bcl-2 and bcl XL may play a role on the long-life of erythroid progenitor cells. Data about these proteins in patients with thalassemia minor is limited. **Aims.** We aimed to investigate the levels of bcl-2 in patients with thalassemia minor. **Methods.** Ninety-seven patients (60 female and 37 male, with mean age of 29 ±21 years) with thalassemia minor were enrolled to this study. Thalassemia minor was diagnosed with complete blood count, family history, and HbA2 levels using by HPLC. 23 healthy persons (17 female and 6 male, with mean age of 58 ± 9 years) were received as a control group. Whole blood cell counts were analyzed with Beckman-Coulter instrument. The levels of bcl-2 were measured by using commercial ELISA kit (Biosource Cat No: TMA 0311, Camarillo, California, USA). Mann-Whitney U test were used for statistically comparison of results and p< 0. 05 was accepted as statistically significant. **Results.** There was no statistically significant between patients with thalassemia minor and control group for the level of bcl-2 (p>0. 05). Mean corpuscular volume (MCV), the levels of hemoglobin and bcl-2 were given (Table 1). **Summary and Conclusions.** Beta chains are damaged in thalassemia minor. Therefore, it is expected that premature death of red blood cells are related to apoptosis. The level of bcl-2 (antiapoptotic protein) in was statistically non-significant higher in thalassemia minor than control. The mean age of control group was higher than thalassemia minor and it is known that older age is risk for more apoptosis. The evaluation of other proteins (bad, bax, etc.), pathways (CD 95 fas ligand) associated with apoptosis and higher number of patients will contribute to determine about this topic.

Table 1. MCV, the levels of hemoglobin and bcl-2 in patients with thalassemia minor and control group.

	Thalassemia minor (n: 97)	Control (n: 23)	p-value
hemoglobin (g/dl)	11,4±1,3	13,7 ±1,1	<0.001
MCV (fl)	64±8	86 ±3,4	<0.001
level of serum bcl-2 (ng/ml)	34.2±7.6	32.7±13	>0.05

HEMOCHROMATOSIS AND PROTHROMBOTIC MUTATIONS CO-INHERITANCE COULD REPRESENT A RELATIVE SELECTION ADVANTAGE DURING PREGNANCY AND CHILD BIRTH

M Dicato[1], G Mahon[2], B Metzger[2]
[1]Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg
[2]Fondation Recherche Cancer et Sang, Luxembourg, Luxembourg

Background. Iron deficiency is a frequent situation in premenopausal women and even more so in pregnancy. One can postulate that having a hemochromatosis gene, present in up to 10% in the Caucasian population, could therefore represent a biological advantage. In the Caucasian population prothrombotic mutations are also present with an allele frequency of about 4 to 7% for V Leiden (VL) and 1 to 3 % for prothrombin (PT). These mutations account for an increased risk of thromboembolic events and this risk is considerably magnified during pregnancy. **Aims and Methods.** One could reasonably expect that the disadvantage of a thrombophilic mutations is offset by some other selection advantage, especially in the pregnant state, explaining their present day prevalence. Because of this hypothesis we studied the genotype frequencies of hemochromatosis (C282Y and H63D) and the prothrombotic state (PT, VL and MTHFR) in samples we had in our DNA bank from random healthy volunteers. We included MTHFR, though it is rather a polymorphism, present in about 40% of the Caucasian population in our area, and its prothrombotic effect is not significant when not associated to other risk factors. **Results.** Table 1. H63D and VLeiden alleles correlate significantly, p= 0. 0448. **Conclusions.** We suggest that the association of increased iron absorption and a decrease of bleeding risk during childbirth could have resulted in a selection advantage for each entity and even more so for a combination of both. From a Darwinian point of view the heterozygosity association of VL and H63D is remarkable, as the prevalence of VL is higher than PT and that H63D increases moderately iron absorption but is a negligible risk factor for deleterious clinical hemochromatosis.

Table 1. Pair-wise tests of association between the two sets of genotype frequencies.

N of individuals	119	151	124
	PT	VL	MTHFR
C282Y	p= 0.0034	p= 0.959	p=0.872
H63A	p= 0.782	p= 0.0448	p= 0.053

SNPS POLYMORPHISM OF ?-GLOBIN CLUSTER AMONG TUNISIAN SICKLE CELL PATIENTS: IMPLICATIONS FOR CLINICAL DIVERSITY

I Moumni[1], I Benmansour[1], L Chaouech[1], M Ben Mustapha[1], S Sassi[1], D Chaouchi[1], F Mellouli[2], K Douzi[1], A Zorai[1], S Abbes[1]
[1]Pasteur Institut of Tunisia, Ariana, Tunisia
[2]Centre de greffe de la moelle osseuse, Tunis, Tunisia

Background. The sickle cell disease (SCD) is the most common single gene disorder in the world. In spite of the discovery of the molecular basis of SCD, the causes of the phenotypic heterogeneity of the disease remain unclear. This heterogeneity cannot be explained by the single mutation in the beta-globin gene alone but may be attributed to genetic single nucleotide polymorphisms (SNPs) in the β-globin gene cluster. **Aims.** We evaluated the effects of polymorphic markers within the β-globin gene cluster on HbF expression and clinical diversity in Tunisian patients. **Methods.** Haplotype analysis was carried out by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and the framework polymorphism was established by direct sequencing, we examined the locus control region hypersensitive sites two (LCR-HS2) of the β-globin gene (AT)xN(AT)y, an IVSII to γ^A and γ^G gene $(TG)_n(CG)_m$ and the region of 5' to β-globin gene (AT)xTy repeat motifs. Correlation of these various haplotypes and SNPs with HbF expression and clinical data was studied. **Results.** Of the various polymorphic markers analysed, only the LCR HS2 (AT)xN(AT)y sequence configurations were significantly associated with increased HbF levels, and the 5' region of β-globine gene (AT)xTy were significantly associated with disease severity, suggesting that the β-globin gene cluster exerts a significant effect on HbF and clinical expression in sickle cell patients. **Summary and Conclusions.** The discovery of SNPS implicated in different phenotypes will help understanding of the physiopathology of the disease and aid to increase our ability to predict clinical severity.

GHRELIN GENE POLYMORPHISM IN VITAMIN B12 DEFICIENCY

S Akarsu, O Gun, S Akarsu, E Etem, S Aydin
Firat University Faculty of Medicine, Elazig, Turkey

Background. Vitamin B12 is seen in 3-66% of the cases. In our country, it is detected in 5. 9% of the adolescents in the 7-17 age group. Ghrelin stimulates appetite, and food intake. Appetite is regulated by cerebral center. Ghrelin containing neurons were detected in the arcuate nucleus of hypothalamus. One of the clinical features of vitamin B12 deficiency is loss of appetite. In iron deficiency anemia which is also a nutritional anemia, loss of appetite was detected although at a lesser extent. Decrease in the ghrelin level or some polymorphisms (promoter -501 A/C, Arg51Gln, Leu72Met, Gln90Leu) developing in its gene might be the common etiologic factor for both types of nutritional anemia. **Aims.** In vitamin B12 deficiency, levels of ghrelin, and the stated 4 polymorphisms were analyzed to clarify whether or not these factors might be the cause of this disease state. **Methods**. Forty-two cases with vitamin B12 deficiency, and equal number of healthy controls were evaluated. Informed consent was obtained. Ghrelin (achyl ve deachyl ghrelin) levels, and promoter -501 A/C, Arg51Gln, Leu72Met ve Gln90Leu polymorphisms in its gene in patients, and control subjects were investigated. Independent Samples t test was used, and p<0. 05 values were considered significant. **Results.** In patients, and controls, levels of achyl (14. 510. 0 pg/ml, and 24. 214. 2 pg/ml, respectively) and deachyl ghrelin (242. 3206 pg/ml, and 394. 0170 pg/ml, respectively)were determined (p<0. 05). Statisticaly -501 A/C polymorphism in ghrelin gene as CC genotype is found increased frequency in patient group (p<0. 05). For Gln90Leu polymorphism in group heterozygot Gln/Leu genotype is found in increased frequency (p<0. 05). **Summary.** Lower levels of ghrelin are observed in vitamin B12 deficiency. Further studies are needed to determine the potential contribution of gene polymorphisms to the development of vitamin B12 deficiency.

1802

EFFECTS OF IRON DEFICIENCY ANEMIA AND ITS TREATMENT ON GHRELINS, OBESTATIN AND HEAT SHOCK PROTEIN 70

S Akarsu[1], T Kasar[2], S Akarsu[3], S Aydin[4]
[1]University of Firat, Faculty of Medicine, Elazig, Turkey
[2]Harput State Hospital,, Elazig, Turkey
[3]University of Firat, Faculty of Medicine, Department of Pediatric Hematology, Elazig, Turkey
[4]Firat University Faculty of Medicine, Division of Biochemistry,, Elazig, Turkey

Background. In the human body there exists a positive correlation between iron stores, and ghrelin levels. Under stressful conditions, mostly heat shock protein 70 (HSP70) is affected. Release of HSP 70 is stimulated by ghrelin. The exact levels of HSP70 in iron deficiency anemia (IDA) are unknown. **Aims.** The impact of IDA, and its oral treatment on increased levels of (HSP70 in settings with higher tissue stress induced by both ghrelin which is both an antioxidant, and a food intake stimulant, and also obestatin with opposing effects was investigated. The association of pica with these parameters was also examined. **Methods**. The study population included 28 patients with IDA, and 28 healthy controls. **Results.** While acyl ve desacyl ghrelin values were lower (p<0. 05) in IDA than those of the control subjects, with treatment ghrelin levels in both groups climbed to relatively higher levels (p>0. 05) than the control group. In IDA obestatin levels were higher than the control values (p<0. 05) which still persisted at elevated levels during the treatment period (p>0. 05) With treatment of IDA, the levels of acyl, and desacyl ghrelin increased, contrarily obestatin values fell down. Also, the concentration of HSP 70 in IDA, and during its therapy (peak value) was above control values (p>0. 05). Acyl ghrelin, desacyl ghrelin, and HSP70 levels were increased in the pica group, while obestatin was found to be decreased (p>0. 05). In the pica group obestatin/acyl ghrelin, and obestatin/desacyl ghrelin ratios were comparatively higher (p<0. 05). **Summary and Conclusions. .** In IDA decrease in ghrelin, and increase in obestatin levels are observed, while HSP 70 remains the same. Increases in obestatin/acyl ghrelin, and obestatin/desacyl ghrelin ratios might be responsible for the pica disorder.

1803

ASSOCIATION OF NT +20 (C>T) AND IVS-II-745 (C>G) β GENE MUTATIONS IN CIS

F de la Fuente-Gonzalo, P Ropero, J Martínez-Nieto, L Vinuesa, B Pérez, C Seri, F Medina, F González, A Villegas, J Díaz-Mediavilla
Hospital Clínico San Carlos, Madrid, Spain

Background. The 5 'UTR of the β gene is an area that is transcribed but not translated. 5 'UTR is involved in post-transcriptional gene regulating, favoring and stabilizing the mRNA translation. To date, have been described mutations in the nucleotide +22 (G>A) and +33 (C> G) by different mechanisms mild decrease of β gene expression leading to β+ phenotype or silent. Also described a mutation at nucleotide +20 (C>T) in the database 'Human Hemoglobin Variants and thalassemias' (http://globin. bx. psu. edu/hbvar/menu. html) to cause β^+ thalassemia resulting in a phenotype of thalassemia minor in heterozygous cases and thalassemia intermedia associated with β^+ IVS-II-745 (C>G) mutation. **Aims.** We report our experience in eight cases in which we have found mutations nt +20 (C>T) and IVS-II-745 (C>G). MethodsWe have study five families, a total 10 patients. Three thalassemia major transfused dependent and the rest (7) thalassaemia trait. Molecular characteization was made by automatic sequencing of β gene globin and the α-thalassemia by stripAssay. **Results.** Table 1. **Conclusions.** The presence of both mutations nt +20 (C>T) and IVS-II-745 (C>G) in homozygous state in one patient (III_1) with thalassemia major suggests that these mutations were found in cis in the same allele. This finding had been corroborated by another cases of thalassemia major (I_2 and IV_3) in which both mutations nt +20 (C>T) and IVS-II-745 (C>G) were inherited in cis from one of the parents ($I_1$and IV_1) and the other mutation [CD8(-AA) and CD39(C>T)] was presented in the other parents (I_3 and IV_2). The phenotypic expression of the other cases (II and V), which showed only mutations nt +20 (C>T) and IVS-II-745 (C>G), were of a minor thalassemia as in I_1 and IV_1, suggesting that also in these cases are in cis in the same allele. These results suggest, contrary to reports in the database "Human Hemoglobin Variants and thalassemias', that the mutation nt +20 (C>T) would be a polymorphism that is associated with the mutation and IVS- II-745 (C>G) in cis and not likely to influence gene expression.

Table 1. Summary of hematogical parameters, genotype and phenotype of the patients.

Patients	Sex/Age	Hb (g/dL)	MCV (fL)	HbA2 (%)	HbF (%)	Genotype	Phenotype

CARDIAC MAGNETIC RESONANCE VERSUS ECHOCARDIOGRAPHY FOR THE ASSESSMENT OF CARDIAC VOLUMES AND FUNCTION IN THALASSEMIA INTERMEDIA PATIENTS

A Meloni[1], C Ascioti[2], S Renne[2], R Trunfio[3], B Piraino[4], C Paci[5], L Gulino[1], C Salvatori[1], M Lombardi[1], A Pepe[1]
[1]Fond. G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy
[2]Struttura Complessa di Cardioradiologia-UTIC, P. O. "Giovanni Paolo II", Lamezia Terme, Italy
[3]Centro Microcitemico, Presidio Ospedaliero Locri - A. S. L. n. 9, Locri, Italy
[4]U. O. Genetica e Immunologia Pediatrica, Policlinico "G. Martino", Messina, Italy
[5]Centro Trasfusionale, Ospedale S Maria alla Gruccia, Montevarchi, Italy

Background. Cardiac Magnetic Resonance (CMR) and Echocardiography (US) are applied in parallel to thalassemia intermedia (TI) patients for cardiac evaluation and ongoing monitoring. It is important to know whether the results of each technique are interchangeable, and thereby how the results obtained utilizing one technique can be applied using another. These aspects are unexplored in TI. **Aims.** Tthe aim of this study was to evaluate the agreement of left ventricular volumes and ejection fraction (EF) by CMR and US. **Methods.** 74 TI patients (38 M and 36 F; mean age 36. 7±10. 9 yrs) patients were studied with both echo and CMR (1. 5T) within 3 months of each other. All TM patients were enrolled within the MIOT (Myocardial Iron Overload in Thalassemia) network where CMR exams were performed in 8 sites using homogeneous and validated procedures. Steady-state free procession cine images were acquired during 8-second breath-holds in sequential 8-mm short-axis slices from the atrio-ventricular ring to the apex to assess biventricular function parameters quantitatively in a standard way, using MASS® software. Previously demonstrated inter-center variability for the quantification of cardiac function was 6. 3%. Echocardiographic studies were carried out in 9 echo labs linked to the thalassemia centers. LV volumes and LVEF were measured by two-dimensional echocardiography using the biplane Simpson's formula. Paired-samples t-test or Wilcoxon test, correlation coefficient, intraclass correlation (ICC), and Bland & Altman plot were used to compare CMR and US parameters. **Results.** Table 1 shows the CMR and US parameters, quoted as mean ± standard deviation (SD), and the results of the comparison between the two techniques. All US volumes were significantly underestimated, especially the end-diastolic volume index, while the US EF was significantly higher than the CMR EF. The correlation between US and CMR end-diastolic and stroke volume indexes was significant, but with a very low coefficient; while the correlation for the ejection fraction was acceptable. The ICC was unsatisfactory for all volumes and good for the ejection fraction. The widest Bland Altman plot range was found for the end-diastolic volume index. **Conclusions.** In a moderately large CMR versus echocardiographic comparative study in TI patients, metrics of LV volume index and function showed significant systematic inter modality differences. In particular, the US volumes were systematically underestimated. This suggests that serial measurements of volumes and function in TI should be performed using the same method and if it is available the more reproducible CMR technique.

Table 1.

LEVELS OF ENDOGENOUS ERYTHROPOIETIN AND ERYTHROPOIETIN RECEPTOR EXPRESSION IN PATIENTS WITH LYMPHOMAS AND ANAEMIA

A Lyamkina[1], T Pospelova[2], I Nechunaeva[2]
[1]Novosibirsk State Medical University, Novosibirsk, Russian Federation
[2]Novosibirsk State Medical Universaty, Novosibirsk, Russian Federation

Background. Erythropoietin (EPO) plays a key role in the adaptation of erythropoiesis to the metabolic needs for oxygen. Inadequate EPO production is one of the causes of anemia in patients with hematological malignancies and

solid tumors. **Aims.** We investigated the levels of serum erythropoietin (s-EPO), EPO receptors on the surface of erythrokariocytes bone marrow, we evaluated the efficacy of recombinant erythropoietin (rh-EPO) in patients with lymphoproliferative disease and anemias. **Methods.** We examined 109 patients with lymphoproliferative disorders and anemia (indolent and aggressive lymphoma, Hodgkin's disease, multiple myeloma). Serum erythropoietin (s-EPO) were studied in all patients. The level of expression of the erythropoietin receptor was investigated on the surface of erythropoietin - sensory cells of the bone marrow in 23 people. **Results.** The average level of EPO was 46,8 ± 8,16 mIU / ml in patients with indolent lymphomas. He was reduced (16,8 ± 2,55 mIU / ml) in 24 persons (60%). The average level of EPO was 36,9 ± 7,97 mIU / ml in patients with aggressive lymphomas. He was reduced (16,4 ± 2,35 mIU / ml) in 31 patients (79. 5%). The average level of EPO was 30,6 ± 8,07 mIU / ml in patients with Hodgkin's disease, decreased (20,9 ± 2,44 mIU / ml) in 14 (82. 3%). The average level of EPO was 38,8 ± 12,42 mIU / ml in patients with multiple myeloma, decreased (17,6 ± 3,91 mIU / mL) in 8 patients (61. 5%). Thus, the EPO has been inadequate in 70. 7% of surveyed patients in all groups of patients. The average number of EPO-R-positive (EPO-R +) cells 22,2 ± 4,23% in the bone marrow. The average number of erythrokariocytes was 24,1 ± 4,06% in the bone marrow. The number of EPO-R-positive cells (26,4 ± 4,81%) corresponds to the number erythrokariocytes in the bone marrow (26,4 ± 4,75%) only 73. 9% of cases. The number of EPO-R-positive cells (10,2 ± 3,93%) was significantly lower than the number of erythrokariocytes in the bone marrow (17,7 ± 4,26%) with 26. 1% of the patients (ρ <0,0001). **Conclusions.** Thus, these data indicate a significant role in the inadequate production of erythropoietin in the pathogenesis of anemia in patients with lymphomas. Reduced expression of erythropoietin receptors on the surface of erythroid cells in the bone marrow is one of the causes of anemia in some patients with lymphomas and anemia. This can cause resistance erythrokariocytes bone marrow to endogenous erythropoietin and the ineffectiveness of therapy with recombinant human erythropoietin. 6. Key words: erythropoietin, anemia, lymphoproliferative disease.

1806

NEONATAL SCREENING FOR HEMOGLOBINOPATHIES IN PUBLIC HOSPITALS ACROSS LEBANON

A Inati[1], E Khoriaty[2], R Halaby[1], H Abbas[1], A Sweid[1], M Berro[1]
[1]Lebanese American University, Byblos, Lebanon
[2]Children's Hospital Boston, Boston, United States of America

Background. Hemoglobinopathies are among the commonest inherited blood disorders. The most prevalent hemoglobinopathies are thalassemias and sickle cell disease (SCD). SCD, the most frequent inherited monogenic disorder in the world, is characterised by hemolytic anemia, vasoocclusion and end organ dysfunction. The true prevalence of sickle cell disease and other abnormal hemoglobin variants in Lebanon is not known and is best determined through a neonatal screening program. Objectives:The primary objective of this neonatal screening was to determine the prevalence of SCD and other inherited hemoglobin disorders in Lebanon by examining 10,000 neonates from all public hospitals. Secondary study objectives included characterizing the demographic features of affected newborns and carriers and deciphering the exact genetic variants of abnormal hemoglobins detected. **Methods.** Neonates born in all public hospitals throughout Lebanon had each 3 drops of blood drawn on a filter paper in the first 3 days of their life. High pressure liquid chromatography (HPLC) was performed on these samples in a single central lab. HPLC results were forwarded to the principal investigator. The families of all neonates with abnormal HPLC results were contacted for rereconfirmation. Pertinent demographic information was collected. Parental consent was obtained prior to phlebotomy. **Results.** Among the 7248 neonates who underwent HPLC testing, 152 (2. 09%) had abnormal hemoglobins detected: 84. 21% had HbS, 8. 55% HbD; 3. 95% HbC and 3. 29% HbO Arab. Geographical clustering of these 152 neonates was noted in 2 regions: North Lebanon (50. 66%) and South Lebanon (30. 26%). Notably, the difference in the rate of consanguinity between parents of neonates with abnormal hemoglobins and those of neonates with normal hemoglobins was not statistically significant. **Summary and Conclusions.** This is the first nationwide neonatal screening campaign for inherited hemoglobin disorders aimed at targeting 10,000 neonates from all Lebanese territories. The prevalence rate of abnormal hemoglobins is comparable to that of beta thalassemia which has recently received significant national recognition in Lebanon and where affected patients receive optimal treatment in a single comprehensive center. This situation contrasts greatly with sickle cell disease where some patients don't have access to modern treatment due to lack of national awareness about this disease and to suboptimal and delayed diagnosis at times. The geographical clustering of abnormal hemoglobins in the Northern and Southern regions requires further investigation and tracing of the ethnic origin of affected neonates residing in these 2 regions. Additionally, awareness campaigns about hemoglobinopathies particularly sickle cell disease emphasizing the benefits of premarital carrier detection, neonatal screening and early implementation of modern treatment, need to be initiated in these areas of high prevalence. Moreover, the lack of significance of consanguineous marriage to the carrier status of the abnormal gene was an unexpected finding and may indicate a high gene frequency of the sickle gene and genes for the other abnormal hemoglobins . This study still aims at screening an additional 2752 neonates to reach its 10. 000 target. Moreover, DNA has been collected for mutational analysis of afflicted individuals and detailed genetic studies are currently being established.

1807

CLINICAL APPLICATION OF RECOMBINANT ERYTHROPOIETIN IN β-THALASSAEMIA INTERMEDIA

D Asadov, B Hasanova, X Alimirzoeva, A Mammadova
Institute of Hematology and Transfusiology, Baku, Azerbaijan

Background. The basic method of anemia correction at β-thalassemia is blood transfusion. However, together with high therapeutic effect this method has serious complications: transfusion transmitted infections, alloimminization, iron overload. Augmentation of fetal hemoglobin represents a direct approach to reduce the globin chain imbalance and ineffective erythropoiesis characteristic of β-thalassemia without blood transfusions. 5-Azacytidine, cytarabine, vinblastine, hydroxyurea, and arginine butyrate have been demonstrated to augment HbF synthesis in animals and in patients with β-hemoglobinopathies. **Aims.** The studies objective is to research the efficacy of recombinant erythropoietin (epoetin alfa) as alternative method of treatment β-thalassemia intermedia. **Methods.** Study involved 57 patients with β-thalassemia intermedia (22 women and 35 men). An informed consent form was signed by the patients or their parents. Control group of 20 patients with β-thalassemia intermedia didn't receive recombinant erythropoietin (rEPO). In all observed patients was defined levels of hemoglobin (Hb), red blood cells (RBC), hematocrite (Ht), erythrocyte indexes (MCV, MCH, MCHC), hemoglobin fractions (HbA, HbA2, HbF), serum iron, serum ferritin, serum erythropoietin before and after administrated rEPO. **Results.** In all patients the levels of erythropoietin was elevated. All patients received rEPO (during 16 weeks) at the dose - 10000 IU subcutaneously 3 times a week. Each 8 weeks treatment's efficacy was estimated. The study showed that, in 44 patients receiving rEPO, Hb level increased more than 2 g/dl, in 11 patients this rate was between 1 g/dl - 2 g/dl. But in two patients increasing of Hb level wasn't observed. The majority of patients reported increse of fetal hemoglobin (HbF) levels. Iindicators of serum iron and serum ferritin are reliably reduced. Blood transfusion wasn't requaired during treatment with rEPO and consequently it avoided iron overload. At the same time, regardless of treatment's effectiveness, even in cases, where Hb level wasn't increased, improvement of patients' cheerfulness and good mood were revealed. **Conclusions.** Thereby, we can come to the conclusion that rEPO prescriptions had high effectiveness and diminished the requirement of patients with β-thalassemia intermedia to hemotransfusion and iron-chelating drugs, and improving the quality of life of patients.

1808

GENDER BUT NOT IRON OVERLOAD INCREASES THE RISK OF BONE DISEASE IN PATIENTS WITH THALASSEMIA MAJOR

K Al-Khabori, N AL-Huneini, S Al-Farsi, S Hussein, K Panjwani, A Al-Maniri, F Daar
Sultan Qaboos University Hospital, Muscat, Oman

Introduction. Bone disease is a recognized complication in patients with thalassemia major. The disease is a risk factor. We hypothesized that patients with increasing iron overload have higher risk of osteoporosis. **Aims.** We planned to estimate the prevalence of osteopenia and osteoporosis in patients with thalassemia major receiving regular blood transfusions and iron chelation therapy. We also planned to estimate the impact of iron overload on the prevalence of osteopenia and osteoporosis in these patients. **Methods.** Bone density measurements are done after the age of 20 years as a routine part of thalassemia management in our institution. We retrospectively analyzed 76 patients with thalassemia major who were at least 20 years old. We classified them into the following categories: osteoporosis (lumbar and/or femoral Z scores of -2. 5 or less) and osteopenia (lumbar and/or femoral Z scores of -1. 0 or less and >-2. 5). We collected data on age, gender, height, weight, ferritin level when scan was done, diabetes status and hypoparathyrodism. We used multivariable ordinal logistic regression to estimate the impact and adjust for gender, age, body mass index (BMI) and ferritin. **Results.** We evaluated 76 consecutive patients with thalassemia major treated at our tertiary care center.

There were 37 females and 39 males with a mean age of 22. 8 years (standard deviation [SD] 3. 5, range 20-33). The mean weight and height were 55. 5 kg (SD 12. 1, range 36. 4-91. 5) and 1. 6 meter (SD 0. 1, range 1. 4-1. 83) respectively. The mean BMI was 22 (SD 4, range 15-35). The median ferritin level was 1550 ng/ml (not normally distributed, range 50-14538). Fourteen and 10 patients had non-insulin and insulin dependent diabetes mellitus respectively. Nine patients had hypoparathyrodism. Osteopenia and osteoporosis was seen in 30 (39%, 95% confidence interval [CI] 28-51) and 39 patients (51%, 95% CI 40-63) respectively. In the multivariable ordinal logistic regression, only gender (male vs. female) was statistically significant for predicting bone disease (odds ratio [OR] 3. 4, 95% CI 1. 3-8. 7, p=0. 012). Ferritin level did not impact on the development of bone disease (OR 1. 0, p=0. 193). **Conclusions.** Bone disease (osteopenia and osteoporosis) is very common in patients with thalassemia major on regular blood transfusion despite being on iron chelation therapy. This may be due to the fact that these patients are living longer. Gender but not iron overload increases the risk of bone disease. A larger confirmatory study is needed.

1809

HEMOGLOBIN LEVEL AS A PREDICTOR OF HEMOLYTIC CRISES IN PATIENTS WITH SICKLE CELL TRAIT

AC Godoy Molias, I Cuadrado Orden, M Recasens Flores, M Andrade Campos, MT Cortés Villuendas, J Lao Romera, R Pazo Cid, D Rubio Félix
Hospital Universitario Miguel Servet, Zaragoza, Spain

Background. homozygous hemoglobinopathy S is a serious disease affecting all organs, with high mortality rates. To be a carrier of sickle cell trait is not a disease, although it has been reported that some of them may develop clinical feature of sickle cell disease such as vaso-occlusive crises and acute chest syndrome. **Aims.** to assess whether sickle cell trait carriers develop clinical manifestations of sickle cell disease. To determine whether there is any correlation between biological parameters and the typical complications of sickle cell disease in carriers. **Methods.** this retrospective study recruited patients with structural hemoglobinopathy S from the spanish health district of Zaragoza (367,110 inhabitants), between june 2006 and december 2011. Patients variables assessed at diagnosis: total leukocyte count, hemoglobin level, hematocrit, mean corpuscular volume, percentage of HbS and HbF. Epidemiological and clinical parameters, such as presence or absence of vaso-occlusive crisis, hemolytic crisis, acute chest syndrome, infections, hospital admissions related to clinical manifestations of sickle cell disease and thrombotic events were also assessed. **Results.** in 128 patients hemoglobinopathy S were detected. 105 patients were HbA/HbS (sickle cell trait). 52 men (49. 5%) and 53 women (50. 5%). 5. 7% were of European origin, 37. 1% American, 54. 3% African and 2. 9% Hindu. The median age at diagnosis was 31 years (1-79). 11 patients (10. 5%) had at least one vaso-oclussive crisis, 21 patients (20%) had an infectious process, requiring admission to hospital, 3 patients (2. 9%) a thrombotic event, 3 patients (2. 9%) at least one hemolytic crisis. No acute chest syndrome was found. Mean number of hospitalization days related to complications of sickle cell anemia was 3. 14 days (1. 36 to 4. 92), without related mortality. HbA/HbS patients with a leukocyte count over $10x10^9$/L had a 4 times more risk of developing vaso-occlusive crises than those with lower count, OR 4. 03 (0. 88 to 18. 28, p = 0. 055). On the other hand, the sickle cell trait carriers who had a hemoglobin (Hb) less than or equal to 12 g/dL at diagnosis had more hemolytic crisis (3 events vs 0, P = 0. 039). No statistically significant correlation with other laboratory parameters and clinical manifestations was found. **Summary and Conclusions.** an Hb level of less than or equal to 12 is significantly correlated with a higher risk of hemolytic crisis in patients with sickle cell trait. In our experience this parameter as well other laboratory markers could be useful to predict complications in this setting.

1810

DEFERASIROX FOR THE TREATMENT OF CHRONIC IRON OVERLOAD IN PEDIATRIC ONCOLOGY PATIENTS - A SINGLE CENTER EXPERIENCE

Y Ktena, A Athanasiadou, M Adamaki, G Lambrou, M Moschovi
Aghia Sofia Children's Hospital, National University of Athens, Athens, Greece

Background. Iron chelation has not been studied adequately in the pediatric oncology population, despite the fact that many patients are heavily iron overloaded secondary to blood transfusions administered due to the bone marrow suppressing effects of chemotherapy. Hemosiderosis can add to the oxidative stress and multiple endocrine abnormalities that these patients are already experiencing. Deferasirox is an oral iron chelator that can potentially be used to improve the morbidity and mortality in this patient group. **Aims.** To report the efficacy and safety of deferasirox in the clinical setting of an academic pediatric oncology center. **Methods.** Thirteen patients (7 male, 6 female, mean age 11. 04 years, SD=3. 99, range=2. 37-16. 31) with pediatric malignancies in remission and iron overload secondary to multiple blood transfusions during chemotherapy were monitored prior to deferasirox administration for an average of 26 months (SD=17, range 2-45). MRI iron studies were performed prior to initiation of chelation therapy. Deferasirox was administered for an average of 6 months (SD=4. 5, range=0. 3-18. 2) to children that were either severely iron overloaded as assessed by MRI, or had ferritin levels persistently >2500 µg/dl. Dosage was 20 mg/kg/day for 10 patients and 30 mg/kg/day for 3 patients. All patients had completed chemotherapy, were chelation-naïve, and did not receive blood transfusions during the entire follow-up period. Ferritin, urea, creatinine, transaminases, and bilirubin were recorded at 4-8 week intervals. The rate of change in ferritin before and during deferasirox treatment was assessed using piecewise linear mixed effects models. **Results.** Patient characteristics and MRI findings are presented in Table 1. Two patients discontinued deferasirox shortly after initiation of treatment due to skin rash. One patient reported mild gastrointestinal disturbances that subsided after the first week of treatment. One patient presented with acute renal failure 4. 8 months after treatment initiation and fully recovered with supportive measures within one week after cessation of deferasirox. Other factors may also have contributed to renal impairment, including concomitant medications and poor fluid intake. The mean monthly rate of change in ferritin levels was -10. 8 µg/l before initiation of treatment (95% CI: -19. 8 to -1. 8, p=0. 02) and -93. 6 µg/l during deferasirox treatment (95% CI: -118. 1 to -69. 1, p<0. 001). The difference in the monthly rate of change in ferritin levels before and after treatment initiation was -82. 8 µg/l (95% CI: -111. 6 to -53. 9, p<0. 001). **Summary and Conclusions.** Deferasirox was effective in reducing the iron burden in pediatric oncology patients. The adverse effects were easily monitored and managed in the clinical setting. This oral iron chelator could prove to be a useful tool in the field of pediatric oncology. Further research is needed to accurately define its use.

FRUCTOSAMINE AS GLUCEMIC MARKER IN PATIENTS WITH THALASSEMIA

I Fotopoulou[1], M Kaskani[1], S Paratiras[1], P Michail[2], H Doliotis[3], A Bistitha[2], L Bouradas[3], D Kastamoniti[2], R Papageorgiou[2], A Spiliopoulou[2], A Nikolopoulou[1]
[1]Qeneral Hospital Saint Andrews, Patras, Greece
[2]Child Hospital Karamandanio, Patras, Greece
[3]University Hospital Ioannina, Ioannina, Greece

Purpose. The measurement of fructosamine in patients with thalassemia and diabetes mellitus type I and II and its credibility as a glucemic marker in comparison with the measured HbA_1c in these patients. **Methods.** A prospective case control study was conducted in the Laboratory of Haematology in St. Andreas Hospital of Patras, Greece, during the year 2010 including patients with thalassemia and diabetes mellitus type I and II undergoing treatment. None of the patient suffered from hyperthyroidism, hypercholesteremia or liver disease and all patients had normal values of serum total protein and albumin. Both HbA_1c and fructosamine as glucemic markers were measured. Measurements of HbA_1c were made using the Menarini HPLC method(High perform-

ance liquid chromatography-HA 8160) and those of fructosamine using the ROCHE liquid chromatography method (Integra 400). **Results.** The study included 128 type I and II diabetes mellitus patients (mean age 33. 4 +/-8. 9 years) and 41 controls. Among the diabetic patients, 32% were patients with thalassemia major and 33% were patients with thalassemia minor. We observed significantly higher mean levels HbA1c and fructosamine in patients with thalassemia and diabetes mellitus type I and type II. Was calculated mean level HbA1c 7. 1% (SD 1. 51,) and mean level fructosamine 292. 43mmol/l (SD 64. 70,) p< 0. 0001. **Conclusions.** In patients with thalassemia and diabetes mellitus a routine measurement of fructosamine every 45 days is required, in order to evaluate the adequacy of the diabetes treatment. This specific test is preferable and corresponds to the HbA_1c measurement, especially in patients with thalassemia major, as HbA_1c (due to the pathophysiology of this hemoglobinopathy and because of the frequent blood transfusions) underestimates the real mean level of glucemia.

1812

IRON DEFICIENCY ANEMIA AS THE INITIAL MANIFESTATION OF UNDERLYING MALIGNANCIES

C Liu, Y Hong, T Chiou, C Tzeng
Taipei Veterans General Hospital, Taipei, Taiwan

Background. Iron deficiency anemia (IDA) is a manifestation of many underlying diseases. **Aims.** We would like to investigate the frequency of, risk factors for, and prognosis of IDA as the initial manifestation of underlying malignancies over a 12-year period in Taiwan. **Methods.** We extracted 5,512 patients with iron deficiency anemia from a nationwide health registry in Taiwan during the period 1997-2008. The frequency for IDA as the initial manifestation of underlying malignancies was determined. Standardized incidence ratios (SIRs) of cancers were calculated to compare the cancer incidence of IDA patients to general population. The specific types of cancer were addressed. **Results.** A total of 319 (5. 79%) IDA patients developed cancer within the study period (SIR 2. 46; 95% confidence interval [CI] 2. 20-2. 75). One hundred and fifty-two (2. 76%) patients who developed cancer within one year presented with IDA as the initial manifestation of underlying malignancies (SIR 5. 88; 95% CI 4. 98-6. 89). The risks of head and neck (SIR 1. 66, 95% CI 0. 83-2. 96), stomach (SIR 4. 68, 95% CI 3. 20-6. 61), colon and rectum (SIR 5. 23, 95% CI 4. 23-6. 40), liver and biliary (SIR 2. 73, 95% CI 1. 94-3. 73), pancreas (SIR 2. 86, 95% CI 1. 05-6. 22), uterus (SIR 3. 52, 95% CI 1. 76-6. 29), bladder (SIR 4. 14, 95% CI 2. 37-6. 73), kidney (SIR 3. 70, 95% CI 1. 85-6. 62), and hematologic malignancies (SIR 3. 46, 95% CI 2. 05-5. 47) increased. Among all age and sex groups, males aged 18-39 had highest SIR. **Conclusions.** Patients who presented with IDA had six-fold higher risk of cancer development within the first year. IDA might be the initial manifestation of underlying malignancies, especially in young males.

1813

ARE CARDIAC R2* VALUES DEPENDENT ON THE USED IMAGE ANALYSIS APPROACH?

A Meloni[1], H Rienhoff[2], A Jones[2], A Pepe[1], M Lombardi[1], J Wood[3]
[1]Fond. G. Monasterio CNR-Regione Toscana and Institute of Clinical Physiology, Pisa, Italy
[2]FerroKin BioSciences, Inc, San Carlo, California, United States of America
[3]Dept. of Pediatrics, Division of Cardiology, Children's Hospital Los Angele, Los Angeles, United States of America

Background. Cardiovascular magnetic resonance (CMR) R2* has become a widely used technique for monitoring cardiac iron overload in patients with different types of hemoglobinopathies. The R2* value is obtained by fitting the CMR signal at different echo times (TEs) to an appropriate decay model. Patients with heavy cardiac iron burden (T2* < 10 ms) exhibit rapid signal, leading to a plateau in the later echo images. Two approaches have been used to address this. The first one (truncation model) consists in discarding the late 'plateau' points and fitting the remaining ones with a single exponential model. The second approach is to fit the signal to an exponential decay plus a constant offset. **Aims.** Our aim was to determine whether systematic differences were present between R2* values obtained with these two approaches. **Methods.** Single-center cohorts were used to compare black blood and bright sequences separately and a multi-center cohort of mixed bright and black blood studies was used to compare robustness and generalizability of the comparison. The R2* value within a region of interest (ROI) drawn in mid-ventricular septum was assessed by the same operator using each of the two methods in turn. Truncated exponential estimates were calculated with CMRTools that uses a truncated, single ROI method ($R2^*_{CMRTools}$). Exponential plus constant (Exp-C) estimates were calculated using a rapid pseudo-pixelwise (PPW) implementation written in MATLAB. A distribution of R2* values within the septal ROI was produced and the mean and median from this distribution were obtained ($R2^*_{PPW\text{-}mean}$ and $R2^*_{PPW\text{-}median}$, respectively). To distinguish whether differences in measured R2* values resulted from the underlying fitting model or from the use of a PPW rather than a region-based approach, we performed Exp-C fits to a single ROI ($R2^*_{PPW\text{-}ROI\_based}$). **Results.** Table 1 shows the results for the two methods. No differences could be distinguished based upon whether a white or black blood sequence was examined. The two fitting algorithms gave similar R2* values, with R-squared values exceeding 0. 997 and CoV of 3-4%, indicating excellent stability of both techniques. *Results using the PPW method yielded a small systematic bias (~3%) that became apparent in patients with severe iron deposition (R2* >100 Hz). This disparity, however, disappeared when Exp+C fitting was used on a single ROI suggesting that the use of pixel-wise mapping was responsible for 3% bias, rather than the fitting model.* In the multicenter cohort the strong agreement between R2* values obtained with the two fitting approaches was reconfirmed, proving high generalizability of our results. **Conclusions.** Cardiac R2* values are independent of the signal model used for its calculation over clinically relevant ranges; pixelwise fitting generate insignificantly greater R2* estimates at high iron concentrations. The overall variability among the considered techniques is exceeding small allowing clinicians to compare results among centers using these disparate approaches with confidence.

Table 1.

	Paired t-test		Regression Analysis				Bland Altman		CoV (%)
	Mean Values (Hz)	P	Slope	P for Slope ≠1	Intercept (Hz)	R-squared	Mean diff (Hz)	Limits (Hz)	
a) First single-center cohort: black blood images (N=42)									
$R2^*_{Iron\text{-}mean}$ vs $R2^*_{CMRTools}$	48.5±54.7 vs 48.2±53.1	0.945	1.031±0.005	<0.0001	1.176±0.379	0.999	0.3	4.4 to 5.1	3.53

ASSESSMENT OF SERUM ERYTHROPOIETIN AND ANTI-ERYTHROPOIETIN ANTIBODIES LEVELS IN ANEMIC CHRONIC HCV INFECTED PATIENTS

A Abd Elhamid, K Khalil, H Seleem, G Tawfeek, G ElGhazalawy, A Hassan, N ElNemr
Suez Canal University, Faculty of Medicine, Ismailia, Egypt

Background. Chronic anaemia frequently associate with chronic HCV infection is one of the potential factors predicting the risk of morbidity and mortality; and may have a negative impact on the current standard treatment for HCV infection, the etiologic role of endogenous erythropoietin and anti-erythropoietin is controversial. **Design of the Study.** A descriptive cross sectional study **Objectives of the Study.** To assess levels of the circulating erythropoietin and anti-erythropoietin antibodies in HCV positive chronic liver disease patients with chronic anemia. **The study Population.** A total of eighty chronic HCV infected patients were included. *The study group:* Sixty Anti-HCV positive patients with chronic anemia (54 (67. 5%) males and 26 (32. 5%) females), they were subdivided into three subgroups according to Child-Pugh classification. *the Control Group*: twenty Anti-HCV positive patients with normal peripheral hemogram. **Methods.** Medical histories, clinical examination, complete liver function tests, test for HCV antibodies and detection of HCV RNA by RT-PCR were carried out. Complete blood picture & reticulocytic count, serum ferritin, assessment and quantification of serum Erythropoietin and Anti-Erythropoietin antibodies using ELISA technique. **Results.** Statistical analysis of the obtained data showed a statistically significant decrease in the mean values of Hb concentration, hematocrit values, and reticulocytic count in child B & child C subgroups compared to that of child A subgroup. There is statistically significant increase among the mean values of Serum ferritin among different child classes of anemic group child A (144 ± 63), child B (380 ± 76) and child C (611 ± 70)

(p < 0. 001). The mean values of serum erythropoietin in the anemic group (50. 48 ± 44. 7) were significantly higher than that of non anemic group (9. 3 ± 6. 8) (p0<001). There is statistically significant difference among the mean values of Serum erythropoietin among different child classes of anemic group child A (27. 25 ± 10. 7), child B (42. 65 ± 25. 9) and child C (66. 82 ± 63. 8). Anti-erythropoietin antibodies were positive only in 7 patients (11. 7%) of anemic group child C class. There is statistically significant negative correlation between erythropoietin and HB (r = -0. 5, p < 0. 001), negative correlation between erythropoietin and hematocrit (r = -0. 3, p < 0. 01), a positive correlation between erythropoietin and serum ferritin (r = -0. 6, p < 0. 001), **Conclusions and Recommendations.** data obtained in the present study including high ferritin, increased endogenous erythropoietin and low frequency of anti-erythropoietin in the anemic HCV infected patients could indicate failure of iron utilization during erythropoiesis, defective appropriate response of the hematopoietic stem cells (target tissue irresponsiveness). The role of exogenous recombinant erythropoietin in circumventing this irresponsiveness.

[5]Department of Epidemiology, Michigan State University, Michigan, United States of America

[6]B) Biomedical Research and Informatics Core, Michigan State University, Michigan, United States of America

[7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Background. Sickle cell disease (SCD) is the most common inherited genetic disorder in sub Saharan Africa and it is associated with early mortality and lifelong morbidity. Early diagnosis is essential in enabling parents / carers to institute appropriate care and preventive therapy. Alkaline gel electrophoresis (paper chromatography) is widely used in SCD screening in developing countries however this method is insensitive in the first six months of life and has been associated with inadvertent errors. High Performance Liquid Chromatography (HPLC) is a reliable tool for newborn SCD screening. **Aims.** The aim of study was to ascertain parental knowledge / perception of their offspring's haemoglobin phenotype prior to testing and actual validated laboratory test results. **Methods.** Children aged less than 5 years of age across several communities inKaduna and Katsina states (North West zone) and the Federal Capital Territory of Nigeria were offered free screening for sickle cell anaemia during June 2010- March 2011. The programme was part of a research project on establishing a sustainable cohort of children with sickle cell haemoglobinopathy for the purpose of providing them with comprehensive health care. Following pre-test counselling, informed consent for testing was obtained from the parent or guardian of child before testing. A short questionnaire was then administered to obtain basic demographic information and parental knowledge of their child's previous haemoglobinopathy screening result, if applicable. The information given by the parent or guardian was corroborated with the results obtained from HPLC testing performed as part of the screening programme. This study was approved by the Institutional Review Boards of the Federal Capital Territory (FCT),KadunaState andKatsina State,Nigeria and Institutional Review Board of Michigan State University, United States of America. **Results.** A total of 11,684 children aged less than 5 years of age were enrolled on to the screening programme. The parents/guardians of 199 (2%) of these children indicated on questioning that their child had previously been tested for SCD. However the parents were not aware of the test results in 57 (28%) children; 13 of these children were found to have SCD. Of the 142 (71%) children, whose parents claimed prior knowledge of their haemoglobin phenotype, the results given by the parents were incorrect in 28 (20%) children. We identified 283 new cases of SCD in 11, 485 children who had not been previously tested. **Conclusions.** There is the need to promote public awareness and provide education on SCD including the benefit of early diagnosis. Improvement and monitoring of laboratory diagnostic services are urgently required in order to provide accurate diagnostic test results to patients. In addition this must be supported by appropriate genetic counselling and referral for care. Availability of written results following testing is strongly advocated as part of the primary health care in this setting, given the prevalence of SCD and the potential impact of this knowledge on patient care.

IS IT NECESSARY TO MONITOR PNEUMOCOCCAL VACCINE TITRES IN SICKLE CELL ANAEMIA PATIENTS EVERY YEAR?

M Varghese, H Conroy, R Geoghegan, C Mc Mahon

Our Lady's Childrens Hospital Crumlin Ireland, Dublin, Ireland

Background. Patients with sickle cell anaemia are hyposplenic and hence more prone for pneumococcal infection. The risk of this can be reduced by the administration of specific pneumococcal vaccines. The current Irish immunisation schedule recommends 3 doses of Prevnar® in children less than 1 year. Children with Sickle cell disease above 2 years are given 1 dose of pneumovax® and repeated in 3-5 years. Pneumococcal IgG titres more than 20u/ml is considered protective against Pneumococcal infection. Booster doses are recommended if the titres fall below this level. **Aims.** To determine the rate and efficacy of pneumococcal vaccine in children with Sickle cell disease and to assess the need for revaccination. **Methods.** All patients with Sickle cell disease received Pneumococcal vaccination as per Immunisation guidelines following diagnosis. Titres were measured on an yearly basis. An audit of sickle cell patients who received Pneumococcal vaccination over 5 years (2003 - 2008) was undertaken. Pneumococcal vaccine serology was obtained from the hospital laboratory database and vaccination details from patient records. **Results.** 232 patients were included in the study of which 120 were males and 112 females. Age varied from 2to 21 years. In 198 (85%) patients Pneumococcal titres remained above 20 u/ml at the end of the study period although the titres showed a gradual fall over the years. Pneumococcal titres fell below the protective levels in 34 patients (15%) on follow up. In 16 patients rate of fall occurred in the 2nd year,10 in 3rd year, 1 in the 4 th year and 2 in the 5 th year . The lowest trough levels was 10 u/ml. 4 patients failed to mount an adequate immune response. **Conclusions and Summary.** Pneumococcal vaccine titres were found to fall each year in the cohort of sickle cell patients studied . In 15% of patients the levels fell below the protective levels and needed booster doses. Hence the titres should monitored on an yearly basis.

1817

DIAGNOSTIC PERFORMANCE OF THE RETICULOCYTE HAEMOGLOBIN EQUIVALENT FOR FUNCTIONAL IRON-DEFICIENCY ANEMIA IN HAEMODIALYSIS PATIENTS

K Chalvatzi[1], P Dimitriadis[1], A Nikolaidou[1], A Sioulis[2], D Pantelidou[3], P Chalkia[3], M Karamouzis[4], E Diza[1]

[3]Haematology Section,Aristotle University of Thessaloniki, AHEPA General Hospital, Thessaloniki, Greece

[4]Biochemistry Laboratory, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece

Introduction. The administration of recombinant human erythropoietin (rhEPO) in patients undergoing chronic haemodialysis increases haematocrit levels but the increased demand of iron for erythropoiesis leads to functional iron deficiency anaemia. The usefulness of reticulocyte haemoglobin equivalent (RET-He) measurement in peripheral blood samples is studied for the diagnosis of iron deficiency anaemia in children and in elderly. **Aims.** The aim was to determine the RET-He values, that characterize functional iron deficiency anaemia in chronic haemodialysis patients, based on the classical method of transferrin saturation measurement. **Materials.** Seventy five patients, undergoing chronic haemodialysis treatment at Nephrology Department of AHEPA University Hospital, were considered for inclusion in this study. All patients received ery-

thropoietin, and iron was administered intravenously to maintain the haemoglobin level between 10 and 12 mg/dL. A Roche/Hitachi Modular System P800 was used to determine the concentrations of iron using spectrophotometric analysis, and transferrin using immunoturbidimetric assay. Transferrin saturation (TSAT) was calculated as follows: serum iron (µg/dl) x 100 divided by transferrin (mg/dl) x 1. 25. RET-He was measured with the automated hematology analyzer Sysmex XE-5000. Receiver operator characteristic curve (ROC) was constructed to evaluate the diagnostic performance of the Ret-He for iron-deficiency anemia. **Results.** Mean values ± standard deviation of TSAT and Ret-he were 35. 8±20. 5%, and 31. 4±3. 8pg, respectively. A statistically significant correlation was found between Ret-he and TSAT (r=0. 265, p=0. 031). Transferrin saturation below 20% constitutes criterion for iron-deficiency diagnosis in hemodialysis patients. ROC curve, after the maximal product of sensitivity x specificity, revealed that iron deficiency could be diagnosed by using a Ret-He cutoff level of 30. 7 pg, with a sensitivity of 76. 1%, and a specificity of 75%. The area under the curve was 0. 795 with 95% confidence interval, 0. 669-0. 921, with p<0. 0001. **Conclusions.** Our study showed a good diagnostic efficacy of RET-He for evaluation of patients requiring iron support. RET-He could be a useful marker to guide and monitor iron treatment in dialysis patients.

1818

PREOPERATIVE USE OF RECOMBINANT HUMAN ERYTHROPOIETIN AND IRON SUCROSE TO DECREASE BLOOD TRANSFUSIONS IN PULMONARY TUBERCULOSIS PATIENTS AFTER SURGERY (PILOT STUDY)

V Demikhov[1], V Dobin[2], A Nikolaev[3], N Inyakova[1], D Oskin[2], E Morshchakova[1]
[1]Fed Research Center for Ped Hematol, Oncol and Immunol named D. Rogachov, Ryazan, Russian Federation
[2]Ryazan State Medical University named I. P. Pavlov, Ryazan, Russian Federation
[3]Ryazan Regional Tuberculosis Hospital, Ryazan, Russian Federation

Background. Tuberculosis is a chronic, infectious disease that primarily attacks the lungs. In cases of strong drug-resistant strains of *Mycobacteria tuberculosis* and some others, the patients may undergo operative intervention to remove the infected areas. In these cases postoperative anemia are usual. A retrospective review of 60 operated patients indicated that approximately 50% of them had anemia and 20% of anemic patients received blood transfusions after surgery immediately. Postoperative anemia is harmful for these patients as it impairs rehabilitation and hospitalization time them. **Aims.** To evaluate the ability of preoperative use of recombinant human erythropoietin (rHuEPO, epoetin alfa) and iron sucrose intravenously to decrease allogenic blood transfusions and the associated risks in patients undergoing surgical treatment of pulmonary tuberculosis. **Methods.** The trial protocol was approved by the Ethical Committee of Federal Research Center for Pediatric Hematology, Oncology and Immunology named D. Rogachova, Moscow, Russia. Nine pulmonary tuberculosis patients aged 24 to 53 years those who had high risk to receive blood transfusions after planned operative intervention were enrolled into the trial after providing informed consent. Mean Hb values before rHuEPO administration were 125. 3±10. 53 g/L, mean serum ferritin levels - 33. 2±21. 14 µg/L. The trial medication 600 IU epoetin-alfa/kg body weight per week was administered subcutaneously on preoperative days 14, 7, and day of operation. The exclusion criteria were diastolic blood pressure greater than 100 mm Hg, hematocrit level greater than 0. 45, Hb level over 140 g/l, platelet count greater than 500×10^9/L. All patients received 100 mg (5 ml) iron sucrose intravenously twice weekly during two weeks before operation and one more on operation's day. Blood loss was quantified by weighing sponges and measuring suction volume intraoperatively and subtracting the volume of the irrigation fluid. After operative intervention we evaluated Hb concentrations and serum ferritin levels during four weeks and blood transfusion's volume and quantity. **Results.** Perioperative blood loss were from 165 to 1350 mL (403. 1±249. 96 mL). None of all patients who received rHuEPO and iron sucrose has not required perioperative blood transfusions. The mean Hb concentrations in operated patients in 1 day after surgery were 122. 0±14,82 g/L. Mean serum ferritin levels in patients to four week of observation composed 87. 7±42. 98 µg/L. No influence of epoetin therapy on blood pressure, laboratory safety variables, or the frequency of specific adverse events was observed. **Conclusions.** This study suggests that in pulmonary tuberculosis patients, who has high risk to receive blood transfusions after planned operative intervention, preoperative use of epoetin alfa combined with iron sucrose treatment is an efficient method to decrease perioperative transfusion requirements and to increase perioperative Hb concentration. Moreover, we expect that preoperative epoetin alfa treatment might also improve rehabilitation of patients after surgery and enable reduction in hospitalization time.

1819

ERYTHROPOIETIN PROVIDES A USEFUL STRATEGY FOR TREATING PREOPERATIVE ANEMIA IN PLANNED ELECTIVE ORTHOPAEDIC SURGERY

M Qureshi[1], I Momoh[2], M Bankes[1], P Earnshaw[1], D Radia[1], C Harrison[1]
[1]Guy's Hospital, London, United Kingdom
[2]King's College Hospital, London, United Kingdom

Background. Major orthopaedic surgery can require transfusion of significant quantities of allogeneic blood, which carries risks of infection, allergy and incompatibility. Furthermore, reduced supply of blood components and high costs of blood preservation impact on health economics. Recent progress in the development of a blood-based assay for prion infection by variant Creutzfeldt-Jakob Disease (vCJD) may reduce infection risk, but correspondingly may further reduce the availability of red cells for transfusion. **Aims.** To evaluate erythropoietin as a strategy for correcting preoperative anemia before major orthopaedic surgery. **Methods.** Erythropoietin therapy was considered for patients with moderate anemia scheduled for planned primary total hip replacement (THR) or revision THR or total knee replacement (TKR). Data was also collected from one patient who received erythropoietin regimens on two occasions prior to right acetabular revision procedure, because of religious objections to a blood transfusion. Patients were assessed for haemoglobin (Hb) and haematinics 21 days before surgery, and weekly thereafter. Patients with Hb 10-13 g/dL were administered weekly erythropoietin subcutaneously. Two patients were included at the clinical discretion of the investigator who had initial Hb 9. 8 g/dL and 9. 9 g/dL respectively. The protocol encouraged weekly erythropoietin from 21 days before surgery unless Hb >14 g/dL. Erythropoietin was not administered on the day of surgery except in two patients who joined the study 14 days before surgery. All patients received postoperative thromboprophylaxis. **Results.** We identified 30 episodes of care for 29 patients with a mean age of 73. 4 years (48 to 88 years) and pre-erythropoietin mean Hb of 11. 3 g/dL. 22 episodes of care achieved three erythropoietin injections at weekly intervals, and 8 episodes of care achieved only two erythropoietin injections. The mean Hb of all patient episodes on the day of surgery was 12. 9 g/dL. For male patients, the post-erythropoietin mean Hb was 12. 7 g/dL and 60% (n=5) had Hb within normal range according to the WHO criteria. For female patients, the post-erythropoietin mean Hb was 12. 9 g/dL and 88% (n=25) had Hb within normal range. Surgery without blood transfusion was performed in 90% (27 of 30) of episodes of care. Of the remaining three episodes, blood transfusion was required in only one, due to severe perioperative haemorrhage unrelated to treatment. **Conclusions.** Transfusion risk and paucity of blood components require imaginative solutions, particularly in the UK where vCJD risk is germane. Our results from a small cohort of patients confirms recent findings from the European Erythropoietineitin Alfa Surgery Trial (EEST) that administration of preoperative erythropoietin is associated with a low transfusion rate and few complications amongst a selected population group. Interestingly, in contrast with the EEST, our study did not administer erythropoietin on the day of surgery for most episodes of care. Further studies should be undertaken to establish an optimal erythropoietin regimen, including evaluation of the longer acting Erythropoiesis Stimulating Agents.

1820

WHEN WATER DOESN'T CLEAR THE SMUT FROM THE SMOKE: SECONDARY POLYGLOBULIA CAUSED BY ACCIDENTAL CO-INTOXICATION RELATED TO EXCESSIVE WATER-PIPE SMOKING

N Bonadies, A Tichelli, A Rovo
University Hospital Basel, Basel, Switzerland

Background. Tobacco smoking with a water-pipe (Shisha) is increasingly popular among young people and adolescents. Burning charcoal is used to heat flavoured tobacco, which is inhaled with a hose by drawing the smoke through a water-bowl. The proponents of water-pipe smoking claim that tobacco inhalation though the water makes the smoke much "cleaner"than conventional cigarette smoking. However, a recent analysis of toxicant yields, as assessed by a smoking machine, reported that the content of nicotine, CO, polyaromatic hydrocarbons, volatiles aldehydes and "tar"inhaled during 1-2 hours of water-pipe smoking were equivalent to an impressive amount of 100 to 200 cigarettes! **Case Report.** We report on a young student and American Football player complaining of reduced concentration capacity and declined physical performance associated with polyglobulia. In his first visit to our outpatient clinic the patient denied symptoms related to myeloproliferative neoplasms (itching, erythromelalgia, and constitutional symptoms) or cigarette smoking. His personal history was uneventful and the clinical assessment showed an athletic, slightly overweight and hypertensive patient with a noticeable facial plethora but without lymphadenopathies or organomegalies. The peripheral blood smear showed an isolated increase of

the hemoglobin concentration to 201 g/l (hematocrite 55%) with suppressed serum erythropoietin. The molecular analyses for JAK2 Exon 12 and 14 mutations as well as for the BCR-ABL fusion transcript were negative. In his second visit, the patient disclosed his daily Shisha-smoking habit that was usually lasting for one to two hours a day and occasionally accompanied by nausea, dizziness and one even a syncopal episode. He explained having started his excessive Shisha-smoking after break-down of the relation-ship with his girl-friend six month ago. Moreover, we learned from the patient that Shisha-smoking was trendy in his American Football player peer-group. The blood gas analysis revealed a hemoglobin carbon monoxide (COHb) of 6. 1%, in line with an accidental CO intoxication induced by excessive water-pipe smoking. The patient stopped immediately his habit and the blood-values returned to normal ranges within a month. **Summary and Conclusions.** To the best of our knowledge, this is the first case-report of secondary polyglobulia caused by accidental CO intoxication related to excessive water-pipe smoking. Due to the increasing popularity of water-pipe smoking and the anticipated health risks, we urge the policy makers to spread information on the relevant toxicities of water-pipe smoking by means of the currently running tobacco prevention programs.

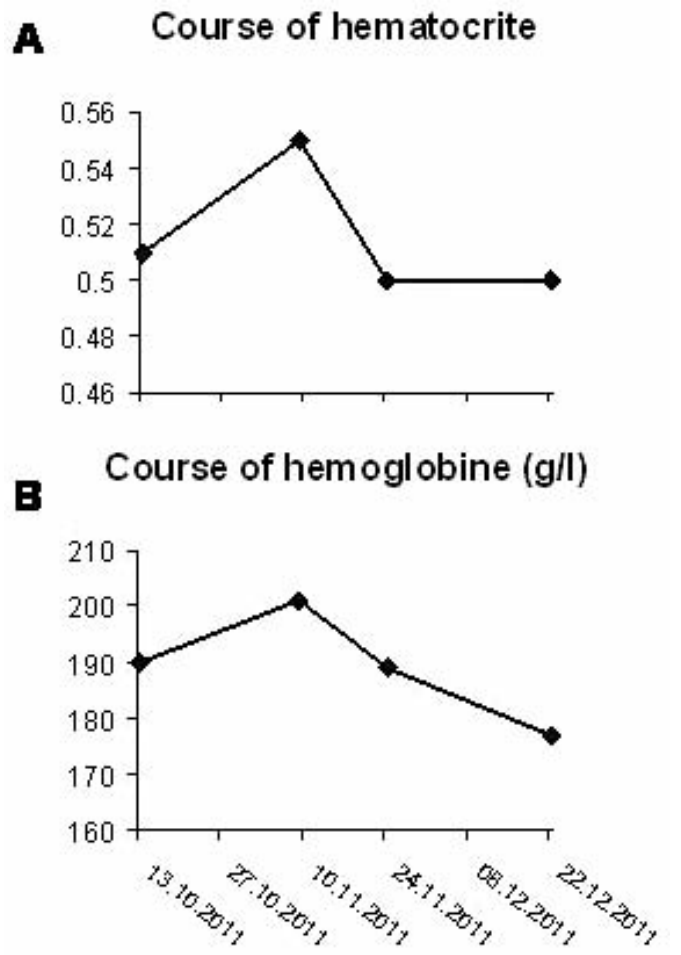

Figure 1. Course of hematocrite and hemoglobin after stopping water-pipe smoking on 10. 11. 2011.

1821

CLINICAL AND LABORATORY FEATURES OF 26 PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA IN SAO PAULO -BRAZIL

A Garcia Carvalho[1], D Ghidetti Mangas Catarino[2], T Xavier Carneiro[1], F Blumm Ferreira[2], E Gil Rizzatti[3], M Arruda[1], M Oliveira Barros[1], M Yamamoto[1], M Figueiredo[1], C Arrais Rodrigues[1]

[1]Universidade Federal de São Paulo, São Paulo, Brazil

[2]Hospital Sírio Libanês, São Paulo, Brazil

[3]Fleury Medicina e Saúde, São Paulo, Brazil

Background. Paroxysmal nocturnal hemoglobinuria (PNH) is a rare disease, due to a clonal somatic mutation in the hematopoietic progenitor cells that become susceptible to complement-mediated hemolysis. The clinical course is extremely variable, characterized by hemolytic anemia, cytopenias and thrombotic risk. To date, there are few data on clinical features of PNH in Brazilian patients. **Aims.** To characterize clinical and laboratory features of patients with PNH in two centers in Sao Paulo, Brazil. **Methods.** Twenty six patients were evaluated. Informed consent was obtained by personal interview with all patients that participated of this study. Median age was 35 years (range: 22-81year), of which 16 female (62%). Diagnosis and clone size determination were performed by multiparametric flow cytometry. Median follow up time was 45 months (range: 4-310). **Results.** Most patients had classical PNH (19 cases, 73%), followed by PNH in the setting of other bone marrow failure syndrome (5 patients, 19%) and subclinical PNH (2 patients, 8%). Hemoglobinuria was the most frequent symptom reported by 80% of patients, followed by fatigue (69%) abdominal pain (42%) headache (30%) and dysphagia (26%). Erectile dysfunction was reported by 30% of male patients. Ten patients (38%) had a history of venous thromboembolism: deep vein thrombosis/pulmonary embolism in 4 cases, intra-abdominal veins in 3 cases (Budd-Chiari, mesenteric, portal e renal vein), and 2 cases in atypical sites (retinal and submammarian). Two patients had arterial thrombosis: two cases of ischemic stroke and one case transient ischemic attack. Currently, 4 patients are receiving anticoagulation: 2 for primary prophylaxis. Median between the start of symptoms and the diagnosis was 11 months (range: 2-133 months). At diagnosis, median hemoglobin level was 10. 5 g/dL (range: 4. 3-13. 5 g/dL), WBC 4. $7x10^9$ (1. 2-14. $2x10^9$), platelets $125x10^9$ (10-$829x10^9$), LDH 1,130 U/L (278-3989U/L), and creatinine 0. 9 mg/dL (0,54-1,51 mg/dL). Flow cytometry data was available for 22 patients at diagnosis: median erythrocyte PNH III (CD59 negative) clone was 26% (range: 0. 5-67%), median PNH II (CD59 partial deficiency) clone 28% (5-66%), monocyte CD14 negative clone 83% (2-99. 9%) and granulocyte CD24 negative 75% (2-99. 6%). Most patients (73%) had a granulocyte clone larger than 50% and 5 patients (19%) larger than 90%. Immunosuppressive therapy had been used by 17 patients (65%): 9 patients (35%) had used steroids, 3 (12%) steroids and cyclosporin, and 5 (19%) steroids, cyclosporin, and antithymocytic or antilymphocytic globulin. Twenty patients (77%) had received transfusions. Currently, 16 patients (62%) are on treatment with eculizumab. **Summary and Conclusions.** We observed a large proportion of patients presenting hemoglobinuria, with history of thrombosis and large clones. These features might be attributable to a bias selection of more severe cases referred to tertiary centers in Brazil. Besides, there was a large number of patients receiving steroids and immunosuppressive therapy, although most patients had classic PNH, emphasizing the need for national standardization of PNH management.

1822

ERYTHROPOIESIS RESPONSE MARKERS TO HYDROXYUREA THERAPY IN PATIENTS WITH SICKLE CELL DISEASE

K Chalvatzi[1], A Nikolaidou[1], D Pantelidou[2], P Chalkia[2], E Diza[1]

[1]Hematology Laboratory, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece

[2]Haematology Section,Aristotle University of Thessaloniki, AHEPA General Hospital, Thessaloniki, Greece

Introduction. The use of hydroxyurea (HU) in sickle cell disease (SCD) patients, either with homozygous sickle cell anaemia or with double heterozygosity of sickle cell anaemia and beta thalassemia (HbS/beta-thalassaemia) reduced the incidence of painful crises, transfusion requirements, hospital admissions and acute chest syndrome. Previous studies have suggested that despite the myelosuppression on haematopoiesis, HU shows a beneficial effect on SCD erythropoiesis. Reticulocyte haemoglobin equivalent (RET-He) is considered to be an actual indicator reflecting functional iron availability for bone marrow erythropoiesis, and could be used as an early marker of erythropoiesis during HU treatment. **Aims.** The purpose of this study was to further examine erythropoiesis activity in patients with HbS/ beta-thalassaemia using the reticulocyte haemoglobin equivalent (RET-He) parameter. **Methods.** Fifty seven iron-sufficient patients with HbS/beta-thalassaemia were included in the study, based on transferrin saturation values (TSAT) (>20% criterion for inclusion). TSAT was calculated as follows: serum iron (μg/dl) x 100 divided by total iron-binding protein (μg/dl). Haematological parameters RET-He, mean corpuscular volume (MCV), haemoglobin (Hb), red blood cell count (RBC), absolute reticulocyte number (RET#), and platelet count (PLT) were determined in automated analyzer SYSMEX XE-5000 (Sysmex Corporation, Kobe, Japan). Fetal haemoglobin (HbF), and sickle haemoglobin (HbS) were quantified using high performance liquid chromatography (HPLC), using Variant Bio-Rad HPLC (Bio-Rad Laboratories, Hercules, CA, USA). **Results.** The patients were divided in two groups according to HU treatment. The first group consisted of 37 patients treated with HU, and the

second group of 20 non-HU treated patients. In the first group the mean values ± standard deviation of the parameter tested were for RET-He: 25,7±4,1pg, MCV:83,5±8,2fL, Hb:9,8±1,5g/dl, RBC:3,5±0,7M/µl, RET#:19,7±10,8x10^4/µl, PLT:267±151. 3K/µl, HbS:67,1±7,8%, HbF:21,1±8,3%. In the second group were respectively 21±2. 6pg, 64,5±5,5fL, 8,9±0,9g/dl, 4,2±0,69M/µl, 26,2±13,1x10^4/µl, 366,6±189,6K/µl, 75,2±6,8%, 10,3±6,4%. Significantly increased values with p<0. 05 revealed for RET-He, HbF, MCV, and Hb in the patients treated with HU compared to the non-HU treated, whereas the HbS, red blood cell count, absolute reticulocyte number, and platelet count were found significantly decreased (p<0. 05). **Conclusions.** The mean values for reticulocyte count in both groups were increased in response to tissue hypoxia and haemolysis, Although, the significant decrease of reticulocyte count during hydroxyurea therapy could be suggestive of myelosuppression or decrease in haemolysis as a result of hydroxyurea therapy, the increase of Ret-he (p<0. 05) in the HU group is supportive of bone marrow erythropoiesis activation. Among the changes that found in the haematological parameters examined, due to administration of HU, the RET-He could be added, in order to be used as an early marker of response to the HU-therapy in patients with HbS/beta-thalassaemia. Further investigation is needed in order to confirm this finding.

1823

THALASSEMIA INTERMEDIA AND CONGENITAL DYSERYTHROPOIETIC ANEMIA (CDA) LEAD TO IRON OVERLOAD IN THE ABSENCE OF REPEATED BLOOD TRANSFUSIONS

R Grosse, R Fischer, P Nielsen
University Hospital Hamburg-Eppendorf, Hamburg, Germany

Background. Some patients with chronic anemia like β-thalassemia intermedia (TI) or congenital dyserythropoietic anemia (CDA) rarely or never need transfusion therapy. However, irrespective of their transfusion status, they develop substantial iron overload. The enhanced erythropoiesis results in hepcidin suppression, leading to increased iron absorption in the gut and increased release of recycled iron from the reticulo-endothelial system (Origa et al, 2007). Body iron levels can be determined by measurement of serum ferritin and of liver iron concentration (LIC). It has been shown in several studies of patients with TI that the relation between serum ferritin and liver iron is different from that in ß-thalassemia major (Origa et al, 2007; Pakbaz et al, 2007; Taher et al, 2008). **Aims.** We aim to determine the body iron load of non-transfused TI or CDA patients and to compare LIC and serum ferritin as markers for iron overload. **Methods.** We measured LIC and ferritin in 15 patients (5 CDA, 10 TI, median age 27 years, range 10-59 years) who were never or minimally transfused. LIC was measured by SQUID biomagnetic liver susceptometry. **Results.** The median LIC in our cohort was 1900 µg Fe/g-liver (in vivo wet weight), range 200 - 4900, and median ferritin 677 µg/l, range 101 - 2119. The correlation of age with LIC was more significant (r = 0. 72, p=0. 003) than with serum ferritin (r=0. 59, p=0. 02), while the correlation of LIC with ferritin was similarly significant (r=0. 56 (p= 0. 03). When judged by serum ferritin only, 11 patients would not have been deemed to require iron chelation therapy (SF < 1000 µg/l). However, 3 of them had LIC levels between 1000 and 2000 µg Fe/g-liver, and a further 4 patients had LIC levels > 2000 µg Fe/g-liver, which is a clear indicator of severe liver siderosis. **Conclusions.** More than 60% of patients with only moderately elevated ferritin (< 1000 µg/l) show clear liver siderosis as measured by LIC. Thus, serum ferritin systematically underestimates body iron load. Patients with non-transfused TI or CDA need direct assessment of liver iron concentration to guide therapy. The study is ongoing and we will present further analysis of a larger cohort of patients.

1824

SPLENIC FEATURES IN SICKLE CELL ANEMIA AND IN SICKLE BETA-THALASSEMIA PATIENTS

G Graziadei, A Marcon, M Soldarini, C Cesaretti, I Gandolfi, MD Cappellini
Foundation IRCCS “Ca’ Granda” Ospedale Maggiore Policlinico, Milan, Italy

Background. Sickle Cell Disease (SCD) is one of the most common severe monogenic inherited disorder worldwide. The haemoglobin polymerization, leading to erythrocyte rigidity and vaso-occlusion, is central to the pathophysiology, as well as chronic anaemia, haemolysis, and vasculopathy are crucial for the clinical outcome. Sickle Cell Anemia (SCA) and Sickle beta-Thalassemia (T-SCD) are multiorgan diseases with similar findings associated with episodes of acute crisis and progressive organ damage. **Aims**. This is a retrospective study aimed to compare the clinical and splenic findings of SCA patients with T-SCD patients cared at Hereditary Anemia Centre, Foundation IRCCS “Ca’ Granda”Ospedale Maggiore Policlinico, in Milan, Italy. **Methods**. Mutation analysis of the beta globin gene was performed by direct DNA sequencing by the ABI Prism 310 genetic analyzer. Clinical and haematological parameters were evaluated by routine tests and physical examination according to guidelines for SCD follow-up. **Results**. Sixteen SCA and 43 T-SCD patients were studied. The beta-mutations detected in T-SCD were severe (beta°) in 86%, moderate (beta$^+$) in 11. 5% and mild (beta^{++}) in 2. 5% of patients respectively. The mean age was 38±10 years, and the mean follow-up is 20±6 years. In SCA group 5/16 (31. 2%) and in T-SCD group 17/43 (39. 5%) were male. In SCA HbF mean levels was 7. 3±5. 4% and in T-SCD 10. 1±7. 1%, while Hb total was around 95 g/l, similar in both groups. Comparing SCA and T-SCD patients, there were not statistically significant differences in the prevalence of clinical manifestations, including stroke, leg ulcers, priapism, bone pain crisis, except for spleen features. Splenectomy was performed in 2/16 (12. 5%) SCA patients vs 21/43 (48. 8%) T-SCD (*p*-value < 0. 001). Splenomegaly was absent in SCA patients, while was detected in 11/22 (50%) T-SCD. Fourteen/16 (87. 5%) SCA patients had functional asplenia. Splenic infarctions were present only in T-SCD patients (7/22; 31. 8%), in particular in 5/11 (45%) of patients with splenomegaly and in 2/11 (18%) of patients with normal spleen size (*p* value < 0. 001). No spleen lesions were detected in SCA patients. All the patients were only occasionally transfused; however T-SCD patients were slightly more transfused than SCA patients during life. In all the T-SCD patients in which the first blood transfusion was performed in childhood, we observed normal spleen sizes. Eighteen/43 (41. 8%) T-SCD patients and 6/16 (37. 5%) SCA were treated with hydroxyurea started in the adult life. **Conclusions**. These data suggest that T-SCD patients, particularly those with severe beta mutations have similar clinical course than SCA patients. T-SCD patients develop splenomegaly that correlate with the age of first transfusion: in particular when the first blood transfusion occurs in the childhood, the development of splenomegaly and spleen infarct seem to be prevented.

1825

THE EFFECTS OF ORAL FERROUS GLUCONATE SUPPLEMENTATION ON HEALTH-RELATED QUALITY OF LIFE IN NON-CANCER PATIENTS WITH IRON DEFICIENCY ANEMIA

V Semochkin
Federal Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background. It is known that iron deficiency is characterized by a variety of adverse effects on the physical and intellectual spheres of human. However, data on the effects of mild iron deficiency anemia (IDA) and its treatment on quality of life (QoL) are limited. **Aims.** To examine whether changes in hemoglobin (Hb), serum ferritin and iron levels were associated with changes in QoL in response to oral iron supplementation in a patients with IDA. **Methods.** Forty-four patients with anemia diagnosed as Hb level ≤ 12. 0 g/dl were enrolled in this study. In addition to the direct presence of anemia, iron deficiency confirmed the changes at least one of the following biochemical parameters: (1) serum iron levels < 6. 6 mmol/l; (2) unsaturated iron binding capacity > 64 mmol/l; (3) concentration of transferrin > 3. 6 g/l; (4) transferrin saturation < 18. 4% and/or (5) serum ferritin < 5 ng/ml. All patients were treated with oral ferrous gluconate (Tot’hema®, Laboratoire Innotech International, France) at the dose of 50 mg twice daily for at least 3 months. Assessment of patients, including adverse events, hematological and biochemical blood tests, and QoL was performed before treatment (point 0) and at 1 and 3. 5 months. QoL was assessed using a general questionnaire SF-36 (version 2. 0). Analysis of the QoL was carried out for 43 (98%) patients, and 1 patient with later diagnosed colon cancer was removed. **Results.** The median age was 42 years (range 20-84). All patients were female. The most common causes of IDA were gynecologic - 18 (41%) and gastrointestinal tract hemorrhages - 5 (11%). Normalization of Hb levels (15. 0 ±3. 4 g/dl vs. baseline 10. 2 ±0. 3 g/dl, P<0. 05) was confirmed at 1 month of therapy in all patients. Increased levels of serum iron (15. 8 ±1. 6 mkmol/l vs. baseline 6. 9 ±0. 8 mkmol/l, P<0. 05) and ferritin (14. 3 ±1. 6 g/dl vs. baseline 6. 0 ± 0. 7 g/dl, P<0. 05) were also confirmed. After 9 months of a normal Hb levels 12. 7 ±0. 4 g/dL (normal values 12. 3-15. 3) and serum ferritin - 16. 9 ±3. 7 ng/ml (normal values 5-148) was maintained. Improving QoL was documented after 3. 5 month of treatment on all physical and mental scales of SF-36. The only factor in the improvement of QoL was an increase in Hb levels (Figure 1). The graph shows the ratio between the average values of QoL after therapy (3. 5 months) compared with baseline (0 months) for patients with an increase in Hb levels <20% (n=14) and ≥ 20% (n=30). The increase in Hb levels was accompanied by significant improvements in ‘Mental Component of Health - MH» (1. 34 ±0. 17 vs. 0. 87 ±0. 14, P<0. 05) rather than ‘Physical Component of Health - PH» (1. 10 ±0. 08 vs. 0. 96 ±0. 07, P>0. 05). Increase in lev-

els of serum iron and ferritin as well as the adverse events associated with therapy had no effect on QoL. **Conclusions.** Only an increase in Hb levels, but an increase of serum iron and ferritin levels impact on QoL in patients with IDA treated with oral iron.

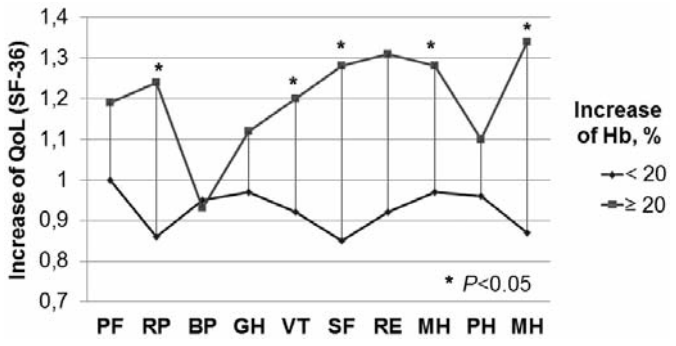

Figure 1. The increase in hemoglobin levels correlated with improved QoL.

CONGENITAL METHEMOGLOBINEMIA CAUSED BY HEMOGLOBIN M SASKATOON HETEROZIGOTE (?-63CAT ? TAT, HIS ? TYR): DISCREPANCY ON DIAGNOSIS

L Costilla Barriga[1], V Recaséns Flores[1], T Cortés Villuendas[1], G Pérez Lungmus[1], P Ropero[2], F González[3], A Villegas[3]
[1]University Hospital Miguel Servet, Zaragoza, Spain
[2]San Carlos HospitaL, Madrid, Spain
[3]San Carlos Hospital, Madrid, Spain

Background. Hereditary methemoglobinemia caused by hemoglobin M (Hb-M), is a rare disorder, due to a structural defect in the alpha or beta globin chains of the hemoglobin, producing a permanent oxidation of heme iron to the ferric state. The ferric hemes of methemoglobin are unable to bind oxygen, with an impared oxygen delivery to the tissues and lifelong cyanosis. **Case Report.** A 22-month-old female, born by cesarean section because of fetal distress, Apgar score 3 at first minute and 9 at five minutes. History of chronic cyanosis since birth, without associated jaundice. No relevant family history, or trigger medication administration. Examination: Moderate failure to thrive with adequate statural development, good performance status, adequate level of consciousness. Central cyanosis and on nail beds; cardiac or pulmonary causes of cianosis were excluded; soft and depresible abdomen, no palpable organomegaly. Oxygen saturation by pulse oximetry: 97%. Functional and structural assessment of the cardiopulmonary system within normal limits. Laboratory: Macroscospically, the blood was dark brown chocolate color, and not modified after oxygenation. Complete blood count: Hbg: 11 g/dL, Hct: 34 % MCV: 86,8 fl. Leukocytes 10,3 x 10^9/L with normal diferential count, Platelets: 292 x 10^9/L, HbF: 0,05 %. Slight hemolysis component, with good reticulocyte response. Parametres of ferric metabolism, seric levels of folic acid and vitamin B_{12} were normal. Hemoglobinopathies studies:Hb electrophoresis on cellulose acetate (pH 8,6): bands of anomalous migration were not observed. The apparently normal fractions presented a chocolate-coloured dye. HPLC: an anomalous peak of 10. 3% was detected in window C at 143 seconds, which suggested the presence of an anomalous hemoglobin. Spectrometry: an anomalous slope in the curve of Hb was appreciable, with a peak of extinction at 602 nm. Reaction was not observed with the addition of potassium cyanide and with the subsequent addition of ferricyanure, peaks of extinction were observed at 490 nm and 602 nm. Eritrocitary enzymes: Glucose 6-phosphate dehydrogenase: 9,5 IU/gHb (N. V: 7-12), Pyruvate kinase: 43,3 IU/gHb (N. V: 9-15). Unstable hemoglobins test: Isopropanol positive (++), Heat test: negative. $P_{50}O_2$: 39 mmHg (N. V: 26,8mmHg): decreased oxygen affinity. Molecular biology: the analysis of the β globin showed a C→ T substitution at codon 63. This leads to a replacement of histidine (CAT) by tyrosine (TAT) at the β 63 (E7), Hb-M Saskatoon. **Diagnosis.** Congenital methemoglobinemia by Hb-M Saskatoon heterozigote (β-63CAT → TAT, His → Tyr). A clinical/laboratorial discrepancy exists, owing to cyanosis since birth which suggests an alteration of the alpha globin chains, unlike the molecular biology study was compatible with an alteration of beta globin chains. **Conclusions.** Chronic cyanosis secondary to HbM is usually the only one sign of presentation. In some patients, the anemia with mild hemolytic component is developed, according to the type Hb-M, which is well tolerated due to the decreased affinity by the oxygen, characteristic of this alteration. It is advisable to perform a familiar study and genetic advice.

1827

ASSESSMENT OF THE EFFICACY AND SAFETY OF INTRAVENOUS IRON SUCROSE IN THE TREATMENT OF IRON DEFICIENCY ANEMIA (IDA)

F Alwan, A Alshami, H Muhammed, A Shibib
The National Center of Hematology, Baghdad, Iraq

Background. Iron deficiency is the most common form of anemia worldwide. It is an important health issue in developingcountries and a frequent cause of anemia even inWestern Europe. The treatment for iron deficiency anemia consists of replacement iron either orally or parenterally. Patients with iron deficiency anemia (IDA) who need intravenous iron are normally treated with iron dextran. One of the major side effects of iron dextran is severe (sometimes fatal) anaphylactic reaction, which can develop in about 1% of patients. On the other hand, iron sucrose another intravenous iron preparation that has improved safety and ease of administration. **Aims.** The aim was to evaluate the therapeutic effectiveness and safety of intravenous iron sucrose therapy in adult patient with IDA. **Methods.** A prospective study conducted at the national center of hematology/Almustansiriya university, Baghdad. it included 168 patients diagnosed as iron deficiency anemia from May 2009 to october 2011. All patient gave their written informed consent. complete blood count, reticulocyte count, serum iron, total iron-binding capacity . and serum ferritin done for all patients. Total dose of Iron sucrose Venofer® was calculated and administered in a weekly successive session in which total dose in each session not exceed 500 mg elemental iron in 500 ml 0. 9% normal saline infusion over 3-4 hour . Charts of patients were reviewed and key labratory tests were done before the start of treatment, 2 weeks and 1 month after starting the treatment. Response was defined as an increase in the hemoglobin level of 2 g/dl or greater after starting the treatment. At the same time, the reason for starting the IV iron therapy and the toxicity associated with treatment was evaluated. The paired t test was used to assess hemoglobin response. **Results.** Median age of the patients was 28 years range from 16 to 66 years. Ten patients (5. 9%) were male while 158 (94. 1%) were female. Before treatment, The mean hemoglobin, MCV, serum iron and serum ferritin values were 8. 1 g/dl, 65. 42 fl, 3. 67 mmol/l and 9. 30 ng/ml pre-infusion and 11. 4 g/dl, 78. 95 fl,15. 20 mmol/l and 66. 78 ng/ml after 1 month of treatment ($p < 0.001$), respectively mild reaction was noted in 4 patient only in form of numbness and itching at the infusion site in 4 patients (all of them received 500 mg iron sucrose in one session patients. The therapy was generally well-tolerated and major side effects were observed The mean duration to achieve the Hb level of 11 gm/dl or more was 4 weeks. **Conclusions.** Our data showed that intravenous iron sucrose Venofer®, which is currently not the standard of care for treatment of IDA in non-dialysis-dependent patients has very good response. It is well tolerated and has no major side effects. **Disclosures**. Off Label Use: iron sucrose Venofer® for iron deficiency anemia in non-dialysis dependent patients.

Table 1. Comparison of the results of the main laboratory variables used at the beginning and after 1 month of treatment with IV iron sucrose (IS) administred to 168 patients with iron deficiency anemia.

variable	Before IS Infusion Mean (SD) min-max	After IS Infusion Mean (SD) min-max	P value
Hb level (g/dl)	8.1 (1.30) 5,40-10,60	11.4 (1.36) 9,0-14,80	<0.001
S. Iron level (Mmol/L)	3.67 (11.91) 0,70-59,00	15.20 (24.97) 5,00-115,00	<0.001
TS (%)	9.23 (2.49) 6.00 to 19.00	23.12 (15.06) 11.00 to 48.00	<0.001
MCV (fl)	65.42 (6.96) 53,00-84,00	78.95 (4.97) 70,40-93,00	<0.01
Ferritin level (ng/dl)	9.30 (4.02) 1,00-14,80	66.79 (82.39) 5,30-383,00	<0.001

SD = standard deviation, Min = minimum, Max =maximum,
MCV = mean corpuscular volume; TS = transferrin saturation

1828

COMPOUND HETEROZYGOSITY OF THE -101 C?T SUBSTITUTION OF THE ?-GLOBIN PROMOTER WITH OTHER THALASSAEMIA MUTATION. MOLECULAR, HAEMATOLOGICAL AND CLINICAL PHENOTYPE IN FIVE CASES

S Theodoridou[1], V Stavrou[1], A Teli[1], M Economou[2], E Vlahaki[1], A Agapidou[1], O Karakasidou[1], V Aletra[1], E Boutou[3], A Balassopoulou[3], V Delaki[3], E Voskaridou[3]
[1]Hippokration Hospital, Thessaloniki, Greece
[2]Aristotle University, Thessaloniki, Greece
[3]National Thalassaemia Centre, Athens, Greece

The β-Thalassaemias constitute an heterogeneous group of disorders with a reduction of β-chain synthesis. The interaction of silent with classic β-Thalassaemia mutations results in the clinical phenotype of Thalassaemia Intermediate. Among the silent β-Thalassaemias the -101 C→T substitution from the Cap site within the distal CACCC box is considered the most common silent mutation in the Greek population. Heterozygotes of the -101 C→T substitution have normal or borderline hematological indices. Compound heterozygotes with mild non-transfusion-dependent Thalassaemia Intermediate of the -101 C→T mutation with other β-Thalassaemia mutations have been identified due to the progress in molecular diagnosis. We report the molecular, haematological and clinical phenotype of 5 cases of compound heterozygotes of -101 C→T mutation in combination with IVSII-745, β-87, IVSI-110, and -101 C→T. The hematologic analyzer, Coulter ONYX, was used to determine red cell indices (RBC, Hb, Ht, MCV, MCH, RDW). Bio-Rad Variant Haemoglobin Testing System (Bio-Rad Labs., Hercules, CA), the 'ß Thalassaemia Short' program, an automated Cation Exchange - High Performance Liquid Chromatography (CE-HPLC) instrument was used for the quantification of HbA, F, A2, S, C, and other haemoglobins. Haemoglobin A2 levels were also quantified by column microchromatography (Hb A2 Helena Lab.). Serum ferritin levels were measured by micro-Elisa technique (Abbot Lab.). Of the five patients, one was diagnosed during childhood, one in infancy and three in adult life. All patients have satisfactory growth and development. Only one patient with the -101/IVSI-110 combination had mild splenomegaly and erythroblasts presence in the peripheral blood smear but was never transfused. In three of the cases Hb A2 levels were increased. The homozygote of the-101 C→T /-101 C→T had a very mild clinical phenotype as a heterozygote of β-Thalassaemia. The only 45 days baby is followed up. The genotype and phenotype expression correlation gives important information for the genetic counseling of couples at risk and helps to predict the prognosis in each patient.

Table 1.

mutation	101/IVSII 745	-101/-101	-101/β-87	-101/IVSI-110	-101/IVSII 745
Age (years)	35	35	45 days	53	8
Hb(g/dl)	9,1	12,5	9,4	10,2	10,7
Ht(%)	29,1	37	27,3	32	32,5
MCV(fl)	60,4	4,980	85	62	54,3

RETROSPECTIVE ANALYSIS OF PATIENTS WITH VITAMIN B12 DEFICIENCY WHO WERE FOLLOWED AND TREATED IN PEDIATRIC HEMATOLOGY DEPARTMENT

C Albayrak[1], Ü Çelik[2], D Alabayrak[2], E Özyürek[2], T Fisgin[2], F Duru[2]
[1]Ondokuz Mayis University Medical faculty, Samsun, Turkey
[2]Ondokuz Mayis University Medical Faculty, Samsun, Turkey

Aims. In this study, the analysis of the frequency, demographic features, causes of deficiency, other diseases, the clinical and laboratory features of the patients with vitamin B12 deficiency and the evaluation of the outcome of treatment are aimed. **Methods.** The records of the 145 patients with vitamin B12 deficiency aged 0-18 years (0-215 months) followed between January 2006 and December 2010 in Ondokuz Mayis University Faculty of medicine, department of Pediatric Hematology analyzed retrospectively. **Results.** The frequency of vitamin B_{12} deficiency was observed at least 2. 8 %. 82 (57%) patients were female, 63 (43%) patients were male and the frequency was higher in females and between 0-2 years and 12-17 years (in adolescents). The mean of weaning the of infants was 9,6±3,81 months and it delayed. 77% of the mothers had vitamin B_{12} deficiency. There was no correlation between the vitamin B12 levels of infants and their mothers. The most frequent symptoms on admission of patients were pallor (43%), fatigue (40%), anorexia (32%), insufficient weight gain(23%), vomiting (18%). 43% of the patients had pallor on skin and mucosa, 29% had growth failure, 18% had development delay, 15% had apathy-irritability. The mean vitamin B_{12} level was 145±37,3 pg/ml, the mean hemoglobin level was 9,82±2,96 g/dl, the mean MCV was 81,8±15,46 fl. The 57% of patients had anemia, 16% had neutropenia, 17% had bicytopenia, 9% had thrombocytopenia, 4% had pancytopenia, 30% had macrocytosis. The 57% of patients had iron deficiency, 5% had parasite infestation, 5% had HP infection, 3% had celiac disease, 2% had FMF and history of colchicum use. The 97% cause of vitamin B12 deficiency was nutritional. Even though all patients had vitamin B12 deficiency, only 44% of them had higher homocystein levels. In treatment group, 51% of patients received cyanocobalamine oral route, 49% received IM. The IM treatment was more effective than oral route. The four of 116 patients (3. 5%) had complication after treatment. **Conclusions.** This study showed that vitamin B12 deficiency is frequent in children in samsun and surrounding cities. The disease becomes widespread first two years and between 12-17 years. This indicates that these ages are at risk. To prevent vitamin B12 deficiency in infants, its level must be evaluated in pregnant and mothers of infants and foods of animal origin must be suggested. Vitamin B_{12} deficiency must be evaluated as a public health problem and the prevalence studies must performed regional and in country and new solutions must produced.

1830

THE SUCCESSFUL TREATMENT OF RESISTANT FORM OF AUTOIMMUNE HEMOLYTIC ANEMIA BURDENED WITH VIRAL HEPATITIS B AND C WITH RITUXIMAB (MABTHERA)

F Nikulina[1], N Tsvetaeva[1], T Garanzha[2], E Shurhina[1], N Khoroshko[1]
[1]Hematology Research Center, Federal State Institution of Ministry of Health, Moscow, Russian Federation
[2]Hematology Research Center, Federal State institution of Ministry of Health, Moscow, Russian Federation

Autoimmune hemolytic anemia (AIHA) - is characterized by the production of autoantibodies to red blood cell (Rbc) surface antigens with destruction of red blood cells by complement and reticuloendothelial system. The scientists have accumulated much experience in treatment of refractory form of AIHA with Rituximab (Mabthera) during last few years. But the patients with the viral hepatitis are restricted in treatment with this medicine. **Methods and Results.** We observed 20 patients (age 21-67 y) with resistant form AIHA (19 - AIHA, 1- Evans syndrome), with duration time 6-72 month. They have been resistant for steroid therapy, splenectomy, immunosuppressive drugs (azatioprine, cyclophosphamide). In hemolytic period (Hb 35-67 g/l) they have been treated with Rituximab (Mabthera) 375 mg/m^2, 2 weekly doses. This short treatment was enough as B lymphocytes became undetectable in all patients (CD19-0%, CD20-0%). Four of the 20 patients suffering also with resistant form AIHA exibited hepatitis B or C (n=2 and n=2). The patient with Evans syndrome was diagnosed as manifesting hepatitis B after 2 weeks therapy with Mabthera (he was transfused by the Rbc for 2 months). He had an acquired hepatitis with skin jaundice. The Hb level was 98 g/l (after steroid therapy), tr- 18x10^9, ret-80%$_0$, bilirubin rise, was 4 times of norm, ALT, AST - 6 of norm, LDG - 5 of norm, and it was found that virus level has raised in 3 of normal value. All parameters were normalized after 2 weeks treatment with lamivudin (100mg). Treatment with lamivudin has been lasting for 2 years. After 6 month of therapy evaluated reduction of viral load in 2 times that of the normal and were not determined after 1 year of treatment. Remission of AIHA was achieved in a 1 month after Mabthera therapy applied. The second course of Mabthera was carried out during of lamivudin treatment for a year, in the interval time of the hemolysis appearing again. The virus activation was not detectable. The second patient with chronicle hepatitis B received the Mabthera therapy when severe hemolysis developed (Hb 35 g/l, ret-220%$_0$). This patient had hard complications - vein tromboses of legs, pneumonia and sepsis (Gr+). He has been in artificial lung ventilation for 29 days. During this period replication of the virus hepatitis B was not observed and new infectious complications were not revealed. Remission of AIHA was achieved in 1,5 months. Other 2 patients with hepatitis C didn't demonstrate hepatitis C virus replicationafter treat-

ment with Mabthera, remission period in patients with AIHA was reached in 9,12,15,24 months. **Conclusions.** The patients with resistant form of AIHA with hepatitis B, could receive the treatment of Mabthera in combination with antiviral drug - lamivudin. For the patients with hepatitis C - in periods without exhibition of viral hepatitis activity, a constant laboratory control of hepatitis C marker is recomended.

1831

TRANSFUSION-DEPENDENT CLINICAL PHENOTYPE IN PATIENTS WITH COMBINED HETEROZYGOSITY FOR A SILENT (+1480 C>G) AND CLASSIC BETA-THALASSEMIA MUTATIONS: REPORT OF 4 CASES

[2]Haemoglobinopathy Prevention Unit, Hippokration General Hospital of Thessalonik, Thessaloniki, Greece

[3]Department of Medical Genetics, Medical School, University of Athens, Athens, Greece

Background. The beta-thalassemias are a group of inherited disorders of red blood cells resulting from reduced or absent production of the beta-globin of hemoglobin and characterized by considerable molecular and clinical heterogeneity. Carrier-ship of a silent beta-thalassemia mutation becomes clinically apparent when co-inherited with a typical beta-thalassemia mutation. The clinical phenotype of the above combination is usually that of mild, non transfusion-dependant thalassemia intermedia. **Aims.** To report the cases of 4 patients with double heterozygosity for a silent (+1480 C>G) and typical beta-thalassemia mutations, resulting to a transfusion-dependent clinical phenotype. **Patients.** Patients involved are 4 boys aged 8 to 9 years old (mean age: 8. 7 ± 0. 5), diagnosed with thalassemia at the age of 2 to 6. 5 years. Main hematological parameters were as follows: Hb 8. 25 ± 0. 24 g/dl (7. 3 - 8. 8), MCV 60. 6 ± 5. 3 fl (57-67. 5), MCH 16. 5 ± 3. 8 pg (11 - 19. 8), HbF 11. 6 ± 7. 4% (2. 6 - 29). The first patient was a double heterozygote for the +1480 (C>G) and the CD39 mutation, while the second patient was a double heterozygote for the +1480 (C>G) and the IVS1-1 mutation. Due to facial and skeletal changes, both patients were put on a regular transfusion program from the ages of 7 and 6 years, respectively. The third patient was doubly heterozygous for the IVS1-110 and +1480(C>G) mutations. Due to hypersplenism he was put on an early transfusion program. Finally, the fourth patient was doubly heterozygous for the IVS1-110 and +1480(C>G) mutations. He had incomplete follow-up until the age of 9, when he was referred to our center and immediately put on regular transfusions due to splenomegaly and concomitant hypersplenism. It must be noted that an excess of alpha-globin genes was not detected in any of the patients. **Conclusions.** Although combined heterozygosity for a silent and a typical beta-thalassemia mutation usually results to a non-transfusion dependent thalassemia phenotype, there are severe clinical exceptions. When managing with such patients, evaluation of both genotype and clinical parameters is imperative. Genetic guidance remains difficult in such cases.

1832

DEFERASIROX EFFICACY IS INDIPENDENT BY IMPROVEMENT OF IRON OVERLOAD BIOCHEMICAL MARKERS IN TRANSFUSION DEPENDENT MYELODYSPLASTIC PATIENTS

M Volpe[1], A Volpe[2]

[1]A. O. San G. Moscati, Avellino, Italy

[2]Department of Hematology and Bone Marrow Transplantation, Avellino, Italy

Iron chelating therapy (ICT) has become an important therapeutical opportunity in chronic transfusion dependent anemia as the one most myelodysplastic (MDS) patients suffer from, since the availability of oral chelating drugs as Deferasirox. ICT allows these patients to be prevented by iron overload organ damage (heart, liver) which has been demonstrated to negatively affect their life expectancy. There's evidence that some transfusion dependent chronic anemic patients who are on ICT show an improvement in hematological parameters and that a few of them experience a reduction in transfusional need (probably related to the reduction of: oxidative stress in erythroid bone marrow precursors, ROS generation, lipid peroxidation and free iron levels. It is also thought that iron chelating agents can let iron become available for erythropoiesis). That's what we have seen in eleven transfusion dependent MDS patients(5 RA, 2 RARS-T, 1 CMMoL, 1 RARS, 1 RCMD, 1 RAEB-1)who started oral ICT (Deferasirox). We have seen an improvement in hemoglobin level and a reduction in transfusional need. This effect has appeared to be evident in most of the patients within a few months; none of them went on to other therapies that could be able to modify erythropoiesis. What seems interesting is that these positive effects appeared to be independent by significative modification of iron overload biochemical markers as the most widely used ferritin concentration. Another result we have noted has been a progressive reduction in liver enzymes concentration in patients who showed biochemical evidence of liver damage before beginning ICT. Also this effect appeared to be independent by a significative modification of ferritin levels. All these results have been noted also in those patients who had to be treated with ICT doses lower than conventional ones because of sever comorbidities they were affected by (as renal function impairment). The possible explanation to our results is that Deferasirox is able to induce(especially at lower doses as demonstrated in "in vitro"models)intracellular oxidative stress processes reduction (independent by the effects on ferritin concentration, marker of iron overload). According to this we think that ICT may have a role in the setting of transfusion dependent anemic MDS patients even if used at low doses especially if we keep in mind that most of these patients are old and have comorbidities that can prevent them by using conventional doses.

PATTERNS OF THERAPY AND ETIOLOGY PROFILE OF SEVERE IRON DEFICIENCY ANEMIA IN PEDIATRIC PATIENTS: 10 YEARS EXPERIENCE

K Kalumba, P Monagle, C Barnes, N Pati, S Jones

Royal Children's Hospital, Melbourne, Australia

Background. Management of severe iron deficiency anemia in hospital setting ranges from oral iron therapy to red cell transfusion. Our study assessed patterns of therapy and their outcome as well as aetiology profile in children admitted with severe iron deficiency anemia at the Royal Children's Hospital in Melbourne, Australia. **Aims.** Despite the fact that iron deficiency is recognized as a chronic condition, a significant number of children with severe iron deficiency continue to receive red cell transfusion. The aim of this study is to determine therapy patterns and etiology profile among the children admitted with severe iron deficiency anemia. To our knowledge, this is the largest retrospective study so far addressing such a question. **Methods.** A retrospective study of children, 2months to 18 years (mean: 6. 2 year), admitted to RCH with severe iron deficiency anemia (Hb < 70 g/L) and serum ferritin < 15 ug/L) between January 1998 and December 2008. Results analysis was performed using statistics package social software (SPSS)Mann-Whitney U test was used for statistics analysis. **Results.**

67 patients identified: 31 male, 36 female, aged 2 months to 18 years (Mean: 6. 2 years). Overall poor diet was a leading cause of severe iron deficiency anemia (65. 6%) followed by GIT disorder (23. 4%). However the latter was more common in 10 - 18 years age group. Hb level ranged from 19 - 69 g/L (Mean: 48. 3 g/L) and serum ferritin was 1 - 14 ug/L (Mean: 2. 6 ug/L). No patients were compromised on admission. Red cell transfusion and oral iron were the most common initial therapies 46. 3% and 47% respectively, while iron infusion was used only in 6. 0% of cases. Hb level below 50 g/L was treated with red cell transfusion in 64. 5% of cases. In terms of etiology, GIT bleed was treated with red cell transfusion in 25. 8%. There was no significant difference in outcome across the 3 groups. However the oral iron group had a statistically significant shorter length of stay of 2. 6 days compared to red cell transfusion group of 4. 6 days (Z = - 2. 773, p < . 05). This could be due to the difference in medical complexity of the patients. **Conclusions.** Poor diet remains the main cause of iron deficiency in young children, followed by GIT disorders. Severe iron deficiency anemia is a chronic condition. In the absence of end organ hypoxia and significant difference in outcome, transfusion as the primary therapy appeared over-utilised, with exception of patients with concomitant acute blood loss.

1834

EVALUATION OF THE MICROVOLT T-WAVE ALTERNANS IN PATIENTS WITH THALASSEMIA MAJOR

Z Karakas, S Cekic, K Yalin, AK Bilge, K Nisli, R Eker Omeroglu
Istanbul University, Istanbul, Turkey

Backround. Cardiac complications due to iron overload are the primary causes of mortality in patients with Thalassemia major. Cardiac effects have been lately identified due to delayed appearance of related symptoms. Microvolt T-wave alternans (M-TWA) could be associated with ventricular arrhythmias and sudden cardiac deaths. There have been no studies about M-TWA in patients with beta thalassemia major up to now. **Aims.** Aim of this study to analyse the M-TWA test that can be used for early identification of cardiac effects in patients with thalassemia major with no cardiac symptoms. **Methods.** 40 patients aged between 12 and 44 years (mean 23. 6±7. 2), diagnosed as thalassemia major were included in this study. QTc dispersion (QTcd) was determined by calculating the difference between the greatest and the least QTc in the ECG. During the stress exercise tests, heart rates were allowed to reach 120-130/min and their M-TWA were calculated in this interval by Modified Moving Average (MMA) method, and the test was considered to have positive result regarding the values over 20 μV. Time-based heart rate changes parameters measured automatically from the 24-hour rhythm holter records (average HR, SDNN, SDANN, SDNN Index, RMSSD, pNN50) of the patients were recorded. Cardiac and liver iron measured by MRI (T2* and R2 respectively). Statistical analysis was made by using SPSS program with Mann-Whitney U test. **Results.** Mean ferritin level of the patients was found to be 1982. 1±1872. 5. QTc dispersion was over the limit value of 50 ms in 13 patients (35%) and mean QTc was 39. 9±19. 3. M-TWA was found to be positive in 15 patients (44. 1%). While a statistically significant association between the ferritin level and QTcd and M-TWA was not found, QTcd was observed to be significantly higher in patients with M-TWA positivity. While average HR was found to be significantly higher in patients whose ferritin level, one of the parameters of heart rate variability, was over 2500 μg/L compared to the patients whose ferritin level is below 2500 ng/ml, SDANN, SDNN-24, SDNN-I which are from the another group of parameters were found to be significantly lower. There was no statistically significant correlation between TWA positivity and cardiac iron load (T2* values). With these results obtained we conducted in patients with asymptomatic thalassemia major, it was seen that there has been no significant correlation between ferritin level and QTc dispersion and M-TWA, but there was a significant correlation between ferritin level and heart rate variability which is an indicator of the influence occurred in the sympathovagal system. **Conclusions.** Cardiac iron (high ferritin and low T2* values) is not sufficient in demonstrating the cardiac status of the patients. We recommend noninvasive tests; QTc dispersion, M-TWA in order to suggest cardiac complications who have no cardiac symptoms. This study supported by Istanbul University research Fund.

1835

CONCENTRATIONS OF HEMOGLOBIN AND BILIRUBIN AMONG FEMALE STUDENTS WITH ALPHA-THALASSEMIA, BETA-THALASSEMIA AND IRON DEFICIENCY ANEMIA

CS Huang[1], YY Huang[2], MJ Huang[2]
[1]Changhua Christian Hospital, Changhua, Taiwan
[2]Cathay General Hospital, Taipei, Taiwan

Background. The comparisons of hemoglobin (Hb) and bilirubin concentrations among university students with α-thalassemia, β-thalassemia and iron deficiency anemia (IDA) have not yet being reported in Taiwan. **Aims.** The aim is to investigate whether Hb and bilirubin values are different or not among Taiwanese female students with α-thalassemia, β-thalassemia and IDA. **Methods.** A total of 1723 female university freshmen who attended a regular physical examination were enrolled in underwent diagnosis for α-thalassemia by PCR, β-thalassemia by PCR-restriction fragment length polymorphism (RFLP) and for IDA by measurements of serum iron, iron binding capacity and ferritin, respectively. The five known variations of the UDP-glucuronosyltransferase (UGT) 1A1 gene {polymorphisms at nucleotides □¬3279 (T>G), □¬53 [A(TA)$_6$TAA>A(TA)$_7$TAA], 211 (G>A), 686 (C>A) and 1091 (C>T)} were determined by PCR-RFLP. **Results.** Among the 1723 female students, 136 individuals whose mean corpuscular volume was ≤80 fL. Out of the 136 students, 109 subjects agreed to participate in further study. Finally, 26 students were diagnosed being IDA patients, 48 were heterozygous α-thalassemia carriers and 31 were heterozygous β-thalassemia carriers, respectively. Hb concentration in 13 of the 48 heterozygous α-thalassemia carriers and 28 of the 31 heterozygous β-thalassemia carriers was <12. 0 g/dL (anemia). Then hemoglobin and bilirubin values were compared for the 13 α-thalassemias, the 28 β-thalassemias and the 26 IDA students. Hb concentration was lower in the IDA students [mean (SD): 10. 0 (1. 14) g/dL] than in the α-thalassemias [11. 2 (0. 46) g/dL] (P<0. 001) and in the β-thalassemias [11. 1 (0. 56) g/dL] (P<0. 001). The prevalence of Hb <10. 0 g/dL was statistically different among the three groups (P<0. 001). Bilirubin value was higher in the β-thalassemias [15. 2 (7. 33) μmole/L] than in the IDA students [10. 1 (3. 69) μmole/L] (P = 0. 005), while it was at statistical margin when β-thalassemias were compared with α-thalassemias [10. 7 (2. 97) μmole/L] (P = 0. 056). Among the subjects with α-thalassemia, β-thalassemia and IDA, the prevalence of hyperbilirubinemia (bilirubin value >17. 1 μmole/L) was significantly different (P = 0. 047), while variation status in the UGT1A1 gene was not statistically different (P = 0. 990). **Conclusions.** Concentrations of both hemoglobin and bilirubin are different among female students with α-thalassemia, β-thalassemia and IDA. Those differences are attributable to less Hb production and then less bilirubin formation in the subjects with IDA, not attributable to different variation status in the UGT1A1 gene among those three groups.

1836

THE XMNI POLYMORPHISM MAY DETERMINE THE MAJOR OR INTERMEDIA TYPE OF ?ETA-THALASSEMIA

M Banan[1], H Bayat[1], S Mohammadparast[1], A Azarkeivan[2]
[1]University of Social Welfare and Rehabilitation Sciences, Tehran, Iran
[2]Blood Transfusion Organization, Tehran, Iran

Background. The major (TM) or intermedia (TI) type of β-thalassemia is determined by the β-globin mutations (primary modifiers) as well as genetic factors which affect the α- to β-globin chain imbalance (secondary modifiers). Probable examples of secondary modifiers include the fetal hemoglobin (HbF) quantitative trait loci (QTLs): the XmnI polymorphism, Bcl11A, and the HBS1L-MYB intergenic region. **Aims.** The aim of this study was to investigate the possible correlation of these QTLs with β-thalassemia type. **Methods.** A retrospective association study was performed. To this end, >400 Iranian β-thalassemia cases were examined. To circumvent the effect of primary modifiers, only TM and TI patients having the same β-globin mutations were considered. Furthermore, β-thalassemia patients carrying α-globin mutations or deletions were excluded. Using this approach, a cohort (n=63) consisting of 27 TM and 36 TI patients with seven distinct β-globin mutations was obtained. **Summary.** Contrary to Bcl11A and HBS1L-MYB SNPs, the XmnI T/T genotype correlated strongly with β-thalassemia type in this cohort (P<0. 001).

1837

IS IRON DEFICIENCY ANEMIA ASSOCIATED WITH MIGRAINE? IS THERE A ROLE FOR ANXIETY AND DEPRESSION?

G Pamuk[1], M Top[2], M Uyanik[1], Y Celik[3], O Yurekli[4]
[1]Trakya University Medical Faculty, Edirne, Turkey
[2]Edirne State Hospital, Department of Psychiatry, Edirne, Turkey
[3]Trakya University Medical Faculty, Department of Neurology, Edirne, Turkey
[4]Sema Hospital, Department of Internal Medicine, Istanbul, Turkey

Background. Previous studies showed that anxiety and/or depression, social and attention deficit problems were more frequent in children with iron deficiency anemia (IDA). Similarly, an association between serum ferritin levels and depression in the absence of IDA has been reported in adults. **Aims.** In this study, we determined the frequency of migraine headache in IDA patients and whether it was related to anxiety, depression and somatization. **Methods.** We

included 127 consecutive IDA patients into the study. All patients were asked validated questions about headache and migraine face to face. They were administered validated questionnaires for anxiety-depession (HADS) and somatization. The quality of life (QoL) disturbance associated with headache was marked on a 0-10 VAS. All patients gave written informed consent to participate into the study. **Results.** Of all IDA patients, 79. 5% defined headache at any time of their life. In addition, 36. 2% of all IDA patients fulfilled the criteria for migraine. IDA patients with migraine were more frequently smokers, had significantly lower hemoglobin and mean corpuscular volume (MCV) values (p values <0. 05). The IDA group with migraine had significantly higher mean anxiety score (p=0. 046), and headache-related QoL disturbance score (p=0. 021) than the IDA group without migraine. Migraine patients with aura had lower hemoglobin values (p=0. 02), higher depression scores (p=0. 005) and higher migraine-related QoL disturbance scores than others (Table 1). **Summary and Conclusions.** IDA patients have a high frequency of migraine headache. The presence of anxiety and depression have great influence on the presence of migraine in IDA patients.

Table 1. The comparison of anxiety and depression scores in IDA patients with and without migraine.

	IDA with migraine	IDA without migraine	p
n	46	81	-
Headache-related QoL disturbance (0-4)	1.89±1	1.49±0.8	**0.021**
HADS-Anxiety score	9.42±5.2	7.7±4.2	**0.046**
Anxiety (HADS-A >11)	16 (35.6)	13 (17.3)	**0.024**
HADS-Depression score	8.13±5.1	6.64±4.1	0.081
Depression (HADS-D >7)	20 (44.4)	32 (42.7)	0.85

1838

THERAPEUTIC ISOVOLEMIC ERYTHROCYTOAPHERESIS FOR IRON OVERLOAD IN HEREDITARY HEMOCHROMATOSIS, AN EFFICACY AND SAFETY ASSESSMENT

I Parra Salinas[1], A Montes Limon[1], M Andrade[1], V Recasens Flores[1], J Garcia-Erce[2], V Gonzalez Rodriguez[1], A Godoy[1], T Cortes Villuendas[1], G Perez-Lungmus[1], D Rubio-Felix[1]
[1]Miguel Servet Hospital, Zaragoza, Spain
[2]San Jorge Hospital, Huesca, Spain

Background. Erythrocytoapheresis (EA) removes 2-3 times more the amount of red blood cells and iron than a conventional phlebotomy. **Aims.** The aim of the study is to assess the efficacy and tolerability of isovolemic EA in patients diagnosed with hereditary hemochromatosis (HH) and iron overload. **Patients and Methods.** Observational, descriptive study. Period of study: 2001-2011. Data obtained from electronic database and clinical registries of 39 patients diagnosed with HH. Collected data: gender, age, HFE genetic mutation, total number of procedures, number of procedures till therapeutic goal (serum ferritin level < 50 ng/mL for at least 30 days), time to reach therapeutic goal, procedure related complications, use of other treatments, blood analytic parameters at the beginning and when reaching therapeutic goal. Statistical analysis was performed with informatic program. **Results.** 39 cases. M/F ratio: 28/11. Mean age 54 ± 14,3 years. EA were performed each 3-4 weeks untill response. Iron depletion was achieved in 29(74,35%) patients after a median of 15(1-108) months of treatment and a median of 11(2-42) EA sessions. Mean of total sessions per patient was 15(4-65). Previous phlebotomies in 22 (56,4%) patients. Further maintenance sessions in 27(69,2%) patients. Response were Patients did not achieved response 10 (25,64%). The mean volume of red blood cells and iron removed in each EA was 315,38±58 mL and 258mg respectively. Effects of EA on AST, Serum iron (SI), Ferritin (Ft), Transferrin saturation Index (TSI) and Hemoglobin (Hb) are shown on the table. Concomitant treatments: recombinant human erythropoietin 3, folic acid 19, iron chelators 4, vitamin B_{12} in 7. Adverse effects were well tolerated in all patients, the more frecuent: hypotension 8, catheter-related problems 7, paresthesias 4, presyncope 1 and syncope 1. **Conclusions.** In our experience as previously published, EA has proven to be an efficient, safe and well tolerated therapeutic approach for iron overload in HH. EA permits collection of massive amounts of red blood cells with mild or none complications wich is an important advantage in patients with comorbidities and leads to a better therapeutic adherence. Cost-effectiveness must be evaluated.

Table 1.

	Patients with response	Patients without response
Number of patients	29	10
HFE gen mutations	Homozygous C282Y: 17 (58.6%) Double heterozygous: 6 (20.6%) Homozygous H63D: 3 (10.3%) N/C282Y: 2 (6.9%) N/H63D: 1 (3.4%)	Homozygous C282Y: 3 (30%) N/C282Y: 3 (30%) Doble heterozygous: 2 (20%) Homozygous H63D: 1 (10%) N/H63D: 1 (10%)
AST before EA (U/L)*	43.44 ± 41.04	29.80 ± 8.13

1839

THE EFFICACY OF VITAMIN K2 ON BONE MINERAL DENSITY IN CHILDREN WITH BETA THALASSEMIA MAJOR

MA Ozdemir, K Yilmaz, U Abdulrezzak, S Muhtaroglu, T Patiroglu, M Karakukcu, E Unal
Erciyes University, Faculty of Medicine, Kayseri, Turkey

Background. Osteopathy in thalassemia major has emerged as a topic of interest since optimized transfusion regimens and iron chealtions has dramatically improved the survival of the patients suffering from thalassemia major and increased the life expectancy. **Aims.** The aim of this prospective, monocentric pilot study was to investigate the effect of a dietary supplement with vitamin K2 (50 mcg menaquinone-7) on the bone mass in children with thalassemia major. **Methods.** After baseline investigation of the bone mass and bone formation related biochemistry (including carboxylated and undercarboxylated osteocalcin), twenty children (12 girl, 8 boys; age varied 3 to 18 years) with beta thalassemia major, who were under regular blood transfusion, chelations therapy, and followed at the Erciyes University, Medicine Faculty, Division of Pediatric Hematology, has enrolled to this study, and reinvestigated for the same parameter at the 6th and 12th months of the treatment. The results of three points were evaluated to assess the effect of dietery supplement with vitamin K2. **Results.** We detected significantly improvement of the bone mineral density and Z score at the lumbar spine and femur neck areas of the patients at the 6th and 12th months. We also found a decrease at the ratio of undercarboxylated osteocalcin to carboxyl osteocalcin, however this was not found to be at the level of significance. **Summary and Conclusions.** Although the natural course of the osteopathy is worsening or at least stabilization, we clearly find a clear positive effect of MK-7 on the bone health of the patients with TM. Supplementation of MK-7 is a physiological way, on the other hand the cost and the benefit of this vitamin seems advantageous compared with the cost and side effect of more complicated drugs such as calcitonin, clodronate, alendronate, pamidromate, and zoledronic acid. Further prospective, double-blind, multicentre, placebo controlled studies are required to elucidate the clouds of debates on the effect and cost-effectiveness of vitamin K2 on the bone disease in patients with thalassemia major.

1840

THE STUDY OF MORBIDITIES AND MORTALITY OF TRANSFUSION DEPENDENT BETA THALASSEMIA PATIENTS (SINGLE CENTER EXPERIENCE)

G Mokhtar, N Elsherif, M Gadalallah, H Ali
Ain Shams University, Cairo, Egypt

Background. the improvement of Quality and duration of life of transfusion-dependent B Thalassemia patients over the last ten years discloses several complications due to the underling disorder, iron overload and the treatment with iron chelators. **Aims.** Our aim was to assess the morbidity patterns of transfusion-dependent thalassemia patients, and compare the outcomes in

relation to age of onset, type, duration and compliance to iron chelation therapy and frequency of blood transfusion. **Methods.** This retrospective study included 447 transfusion dependent β-thalassemia patients who are attended the Pediatric Hematology/oncology Clinic, Ain Shams University Children's Hospital over the last 10 years in the period between January 2000 and January 2010. Data was collected from the patients or their caregivers, as well as by reviewing follow up sheets for examinations and investigations done to detect morbidities as well as iron chelation therapies given including type, duration, compliance. Determination of mortality rate and the causes of death was also done. **Results.** Results revealed that the most common morbidities were endocrinal (44. 7%) followed by cardiovascular (41. 3%) and hepatic(40. 5%) then renal (4%). The different Iron Chelation Therapy groups showed a comparable prevalence of different morbidities. The mortality rate was 1. 5% and infection was the most common cause of death. The 5,10,20 years survival rate among the studied patients was 80%, 50%, 20% respectively. **Conclusions.** In the past 10 years the survival and morbidity rate in our center have markedly improved as result of regular blood transfusion, new iron chelators, better compliance and knowledge of the patients.

1841

THE OUTCOME OF BLOOD TRANSFUSION PROGRAMMES FOR CEREBRO-VASCULAR EVENTS IN A PAEDIATRIC POPULATION WITH SICKLE CELL DISEASE

G Butler, R Geoghegan, H Conroy, C Mc Mahon
Our Lady's Childrens Hospital Crumlin, Dublin, Ireland

Background. Cerebro-vascular events (CVE) are a major cause of morbidity and mortality in sickle cell patients. The use of Trans Cranial Doppler (TCDs) measurements to predict risk of stroke in this population has been well documented (STOP trial). The Stroke prevention study in sickle cell disease showed a 90% reduction in risk of stroke with the use of transfusion programmes. Chronic blood transfusion (CBT) is the accepted standard of care for primary and secondary stroke prevention. As part of routine screening, magnetic resonance imaging and angiograms of the brain are carried out in this patient population. **Aims.** To audit the sickle cell patients on chronic transfusion programme as part of primary and secondary stroke prevention in a Paediatric Tertiary referral centre, assessing patient age, sex, haemoglobinopathy, indication for transfusion, MRI/A results, TCD results and characterise changes in TCD/MRI results with treatment and associated changes in haematologic parameters. **Methods.** Retrospective chart review of 39 patients. **Exclusion criteria.** Patients on CBT for a non-neurovascular indication. **Results.** There were 39 patients in total with a M:F ratio of 0. 86:1. All patients were HbSS. The age range was 3 - 19 with a median age of 8. 18. Indications for CBT included - Abnormal MRI/A brain 36. 1%, Abnormal TCDs 33. 3%, Clinical event (CVA/TIA/Seizure) 19. 5%, Both abnormal MRI/A & TCDs 8. 3% and Clinical event plus abnormal MRI/A or TCDs 2. 8%. 10. 3% of the patients are receiving regular exchange transfusions. 61. 5% receive top up transfusions whilst 28. 2% received initial exchange transfusions and subsequently commenced a top up programme. **Outcomes.** No patients on CBT programmes had CVE or further CVE during treatment. 15% of patients with abnormal MRI/A brain pre transfusion programmes improved, 65% remained stable while only 5% worsened on subsequent scans. 6 patients developed antibodies during treatment. All patients on top-up transfusion programmes required iron chelation treatment with subcutaneous desferrioxamine or oral deferasirox. **Conclusions.** Chronic blood transfusion is successful in the management of CVE but it has significant side effects. Nevertheless it remains our treatment of choice for neurological events in paediatric sickle cell patients.

1842

CHANGES IN IRON LOAD LEVELS, MODE OF THERAPY AND SOMATOMETRIC PARAMETERS IN YOUNG PATIENTS WITH THALASSEMIA MAJOR

A Kattamis[1], P Delaporta[2], K Stokidis[2], S Boiu[2], A Moira[2], D Kyriakopoulou[2], V Ladis[2]
[1]University of Athens, Athens, Greece
[2]First Department of Pediatrics, University of Athens, Athens, Greece

Background. The availability of new oral chelators is a major advance in the treatment of patients with transfusion-dependent thalassemia. Better efficacy of these novel therapeutic modalities, mainly due to improved compliance, is expected to result in improved hemosiderosis status and decreased complication rate. **Aims.** In this retrospective study we evaluated changes over the past decade in iron load, in the use of iron chelators, and in the somatometric parameters in young patients with thalassemia major (TM). **Methods.** All the patients with TM, followed in our unit, who were <18years old on the 31st of December 2001 (Group A) and on the 31st of December 2011 (Group B) were included in this study. The mean values of the serum ferritin levels during the past year from the time points were calculated and the iron chelation treatment during the time points was recorded. The age at the time of splenectomy was recorded. The z-scores, reflecting the somatometric parameters measured within 6 months from the time points were calculated based on 2000 CDC growth charts. The statistical analysis was performed using the STATGRAPHICS Centurion XVI software. **Results.** The results are summarized in the Table 1. During the last decade, a steady decrease of new births of patients with TM has been observed, reflecting the efficacy of Thalassemia prevention program. Splenectomy seems to play a less siginifcant role in current therapeutic approach. The use of chelators has changed from deferoxamine (DFO) to oral chelation therapy with deferiprone (DFP) and deferasirox (DFX). No statistically significant differences were observed between the two groups regarding serum ferritin levels and the patient height, weight and BMI z-scores (p=0,1, p= 0,41, p= 0,16, p=0,37 respectively). **Conclusions.** Oral chelation has become the preferable mode of treatment of hemosiderosis in young patients with TM. Despite the expected improved compliance no significant differences were observed regarding ferritin levels or the somatometric values of our patients.

[6]NMTS, Athens, Greece

5-Pyrimidine Nucleotidase is an endo-erythrocytic iso-enzyme. Its function is to catalyze the clearance of pyrimidine ribonucleotides which comes from DNA deconstruction. The reduction of the enzyme reactivity leads to summation of pyrimidine products in the erythrocyte so that its life span increases, consistently of hemolytic anemia. 5-P Nucleotidase (5PN) insufficiency is inherited in an autosomic recessive pattern and is one of the most important causes of inherited non- spherocytic anemia along with G-6PD and pyruvate kinase insufficiencies. It is characterized by hemolytic anemia, splenomegaly and intense basophilic stippling. There are several reports in the literature concerning the reduction of reactivity of 5PN in patients with intermediate and heterozygous β thalassemia. However the co-existence of 5PN in a patient with α thalassemia is rare. We report the clinical and hematological findings of a 25 years old woman who referred to our hemoglobin prevention unit due to her pregnancy (6th week). From her past medical record, it was already known of being carrier of 5PN insufficiency . Hematological data of the propositus were as follows: Hb:10,7 gr/dL, Ht:34%, RBC:4,35*106, MCV:77 FL, MCH:24,7 pg, RDW:16,2% with ferritin levels between normal values. Microscopic examination of a stained

peripheral blood smear showed severe anisocytosis, microcytosis and basophilic stippling. The biochemical analysis of hemoglobin with HPLC showed normal values of hemoglobin A2 (HbA2:2,4%) and hemoglobin F (HbF:0,5%) while no pathological fraction of hemoglobin was observed. Due to an unclear hematologic picture of the husband, who was suspected of being heterozygous for thalassemia, we performed a genetic analysis of DNA of the patient. Molecular analysis showed that she was heterozygous of the mild mutation of α thalassemia (-α 3,7). In conclusion, the mismatches between the hematological parameters of the pregnant patient and the usual hematological phenotype which is related with α thalassemia (-α 3,7) are due to the lack of 5PN. The co-existence of hereditary lack of 5PN and heterozygous α- thalassemia is extremely interesting due to the fact that it isn't until now mentioned in the literature.

LINEAR GROWTH AND CIRCULATING INSULIN-LIKE GROWTH FACTOR-I CONCENTRATIONS IN CHILDREN WITH IRON DEFICIENCY ANEMIA AFTER TREATMENT

A Soliman, A Elawwa, M Eldabbagh
Hamad Medical Center, Doha, Qatar

Objective. To assess linear growth of patients with Fe deficiency anemia (IDA) before and after in relation to their hematologic parameters and IGF-I concentration before and after treatment with iron. **Methods.** Forty children (aged 17. 2 +/- 12. 4) months with iron deficiency anemia were studied with 40 healthy normal age-matched children (controls). Patients were treated with iron syrup or drops to supply 6 mg/kg/day. Growth (weight, length and head-circumference) and hematological parameters were measured and IGF-I concentrations measured before and 3 and 6 months after treatment. **Results.** Growth parameters (weight, length and head-circumference) and hematological parameters were studied for 6 months after iron therapy. At presentation, patients with IDA had low Hb (8. 2 +/- 1. 2 g/dl), hematocrit (29 +/- 2. 8), MCV (61. 5 +/- 8. 1), and MCH (19 +/- 3. 2) which improved significantly after treatment to (11. 2 +/- 1 g/dl, 70. 6 +/- 6. 8, 23. 4 +/- 2. 9 and 18. 9 +/- 5 respectively). Before treatment children with iron deficiency they had length standard deviation score (LSDS) = - 1. 2 +/- 1, annualized growth velocity (GV) = 7. 5 +/- 2. 2, GV SDS = -1. 42 +/- 0. 6 and BMI = 13. 5 +/- 1. 2. After 6 months their LSDS = -0. 6 +/- -0. 9, annualized GV = 13. 2 +/- 4. 4 cm/year, GVSDS = 1. 7 +/- 0. 5, and BMI = 14. 2 +/- 1. 1). Circulating IGF-I increased significantly after treatment (52 +/- 18. 8 ng/ml) vs before treatment (26. 5 +/- 4. 2 ng/ml).

1845

IRON DEFICIENCY ANEMIA, CONSTIPATION AND ROLE OF MILK IN CHILDREN AGED 6 - 30 MONTHS.

M Lakkaraja, L Small, M Frank, A Solomon, N Kucine, M Wissert, N Haq, J Bussel
Weill Cornell Medical College, New York, United States of America

Background. Iron deficiency is the most common nutritional deficiency in the world and young children and pregnant women are at a higher risk of developing it. Anemia is defined as a Hemoglobin (Hgb)level of less than the 5th percentile for age. Constipation is defined as a delay or difficulty in defecation, present for 2 or more weeks. The most common food allergy with an incidence of 2 - 3 percent in the first year of life is cow's milk allergy. Studies have shown a relation between constipation and milk allergy in infants and young children. Children with milk allergy develop iron deficiency secondary to colitis and blood loss in stool. We believe that constipation, iron deficiency, and milk allergy may be more often interrelated than has been previously suspected and therefore that constipation and Hgb level may be related. **Aims.**To determine whether there is a relationship between constipation and Hgb in healthy infants and toddlers and the response to iron therapy. **Methods.** In this ongoing prospective study, we administered the National Health Sciences Constipation (NHS) for children to parents of 6 - 30 month old children attending the outpatient clinic who were having routine CBCs or Hemoglobin and Hematocrit done on that visit. Constipation was diagnosed by a score of ≥ 2 on the NHS questionnaire. Additional questions were asked about family history (diseases, allergies, constipation and anemia); about the child (medications, illnesses and diet); and whether the mother was breast-feeding and her diet history focusing on dairy. Comparisons were made between children with and without constipation. **Results.** Currently, there are 84 children (49 females) between 9 and 30 months old, mean 17 months. 30/84 children were constipated (score ≥ 2) and 29 children had a score of 1 on NHS survey. There was no significant difference in Hgb between children with and without constipation(p=0. 66). However, the level of constipation was inversely proportional to the Hgb level (Figure 1). There were 20 children with Hgb <11 of which 7 were constipated, and 13 were not constipated. There was a trend to a higher Hgb in children with score 0 compared to score 1 (p=0. 07). Constipation in the child (but not Hgb) was related to both of a history of allergies in the child or family and a family history of constipation. No racial differences were noted in either children who were anemic or children who had constipation. **Conclusions.** There is a weak negative correlation between the level of constipation and Hgb. A combined history of allergies in the child or in the family and a family history of constipation predict constipation in the child. Relatively few children were anemic due to iron fortification of foods. We will monitor response to iron therapy in children with anemia because we believe that constipation will negatively impact compliance. The study is ongoing and we plan to make it a multi institutional study to observe the findings in a varied population. More children with milk allergy can thus be included too.

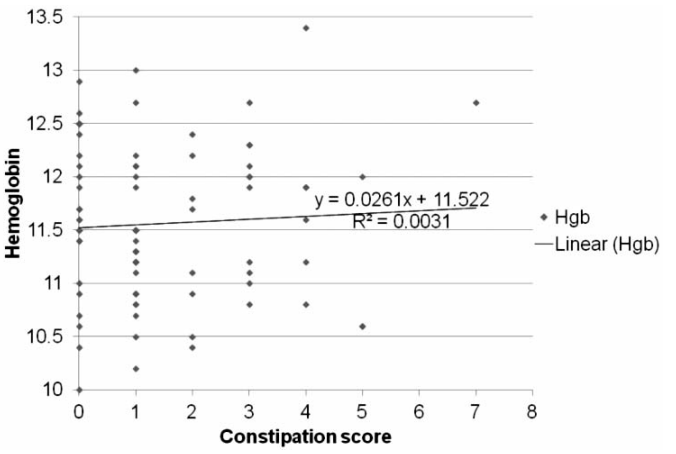

Figure 1. Constipation score and Hemoglobin (Hgb).

1846

WHAT ABOUT MILK ?

T Magalhaes Maia, JP Carda, ML Ribeiro
Centro Hospitalar de Coimbra, Coimbra, Portugal

Background. Iron deficiency anemia (IDA) strikes more than 2 billion people around the world. One of the main risk groups, with a prevalence of 20. 1%, is composed by children aged 4 months to 4 years. These children are prone to risk factors like prematurity, recurrent infections and parasitosis, but, with no doubt, the early weaning of breastfeeding, the early introduction of cow milk (CM) and it excessive consumption (>500 ml/day), are the main determinants for iron deficiency. During the first 6 months of life, breast milk meets the full-term newborn iron needs; after that period it is necessary to offer complementary food rich in bioavailable iron. CM has iron with low bioavailability and low density and an excess of calcium and proteins that interfere with the absorption of iron from other food. Thereby, consumption of CM in excess reduces the total amount of iron absorbed from the diet and replaces other possible sources of this nutrient. **Aims.** Evaluate the contribution of excessive consumption of cow milk in the etiology of children iron deficiency anemia (IDA)and draw attention to the problem of excessive consumption of milk as the main cause of IDA in the first years of life. **Methods.** Observational, retrospective and descriptive study in children with microcytic/hypochromic anemia (mhA) referred to the consultation of a Central Hematology Children's Department between January 1 and December 31, 2010. Anemia, hypochromia, microcytosis and low ferritin were defined according to the WHO guidelines (2001). Multiple variables were surveyed and data was processed using the IPSS ® v. 17. **Results.** Among a total of 148 first consultations, 64 were related to mhA and 42 out of 64 were IDA (66%). In the IDA group (62% male), the median age was of 28 months and 90% started food diversification at 4 months, 31/42 had excessive consumption of CM (mean 1000ml/day), 3/42 were ex-preterm infants, 5/42 had chronic diarrhea (3 with giardiasis), 6 (14%) had recurrent infections. Median hematological parameters (HP) at diagnosis: hemoglobin 9. 6 g/dL, MCV 66 fL, MCH 21pg, RDW 16% and ferritin 5µg/L. All were treated with oral iron (3mg/kg/day), only 7 needed iv iron. After correction of dietary errors and an average of 4-6months under oral iron, all children had normal HP and ferritin> 30. **Conclusions.** The prevalence of IDA in all our pediatric hematology first consultation was 28%. This is a high number of children if we take into account that we are a Central hospital, indicating that pediatricians and general practi-

tioners are not fully aware of this so common problem. The main cause of IDA was the excessive consumption of CM representing 66% of the first consultations for mhA. The use of CM instead of other dietary products rich in bioavailable iron, is a high risk factor for IDA and can lead to unnecessary investigations to elucidate the etiology of anemia. Questions as simple as: -what about milk? How much does he/she drinks?- can make the diagnosis, reassure parents and avoid future complications of chronic iron deficiency anemias.

1847

DEFERASIROX AND DEFEROXAMINE COMBINATION THERAPY: A CASE OF MANAGEMENT OF IRON OVERLOAD IN MYELODYSPLASTIC SYNDROME IN AN HEPATOPATHIC PATIENT.

C Cerchione, G Cerciello, R Della Pepa, M Matarazzo, F Alfinito, F Pane
Università "Federico II", Napoli, Italy

Myelodysplastic syndromes (MDS) are characterized by ineffective hematopoiesis, cytopenias, and a risk of transformation to acute myeloid leukemia (AML). Because the median age of the MDS onset is in the seventh decade, most patients are ineligible for potentially curative hematopoietic stem cell transplantation. Although other treatments are now available, the standard treatment for many MDS patients remains supportive care. Most MDS patients eventually become red blood cell (RBC) transfusion dependent, risking iron overload, which may lead to cardiac, hepatic, and endocrine dysfunction. Adverse effect of RBC transfusion dependence on survival was sufficiently significant that it was incorporated into the World Health Organization Prognostic Scoring System (WPSS) for MDS. Guidelines in MDS recommend chelation with an evidence of iron overload: elevated serum ferritin, iron related organ dysfunction, or chronic RBC transfusions. Deferasirox is a well tolerated oral iron chelator drug that produces relevant benefits but, because of its potential hepatotoxicity, it is not recommended for patient with hepatic diseases. A 62-year-old man, affected by HCV positive cirrhosis and MDS (Refractory Anaemia, IPSS 0. 5) started recombinant Erythropoietin therapy but it was ineffective and he underwent to a RBC transfusion program (2 blood package pro month). At a ferritin serum concentration near 700 ng/mL iron chelation therapy with deferoxamine was purposed in consideration of patient hepatic disease: compliance to subcutaneous injection was very bad, transfusion need increased exponentially until to 2 blood package pro week and serum ferritin concentration reached, in 12 months, the level of 6198 ng/mL.

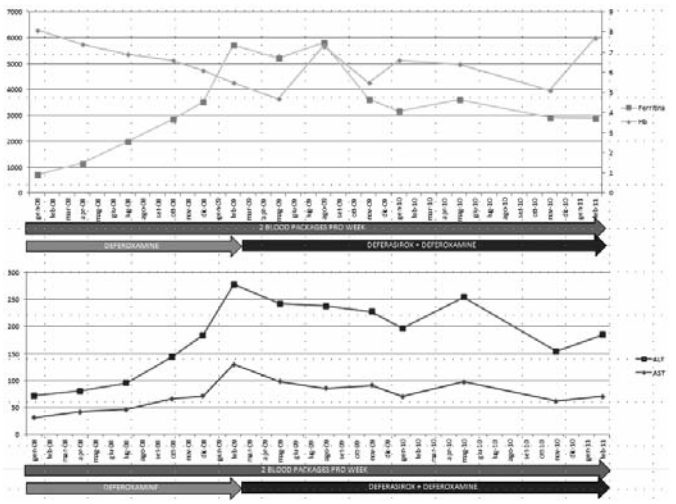

Figure 1.

Since high levels of ferritin correlate with a very dangerous condition for hepatic cells, therapy with deferasirox was started but at reduced dosage (10 mg/kg/die). Before treatment start an accurate study of hepatic, renal and cardiac functions was performed. After three months serum ferritin concentration was not modified as well as other biochemical parameters, then deferasirox dosage was gradually increased reaching 30 mg/kg/die after two months and no liver damage was observed. After five months of iron chelation therapy with deferasirox at full dosage serum ferritin concentration remained very high (5098 ng/mL). Then, considering all risks related to transfusion dependent secondary hemochromatosis, with patient informed consent, a combined iron chelation therapy with deferasirox (30 mg/kg/die) and deferoxamine (2 g/day for 5 days/week) was established and after 3 months serum ferritin concentration lowered to 3000 ng/mL. In that period, Haemoglobin concentration decreased significantly, so the patient started to receive 2 RBC package pro week and, after two years of combined iron chelation therapy, serum ferritin concentration is at a stable level nearby under 3000 ng/mL. During treatment, an accurate monitoring of hepatic, renal and cardiac functions was performed: no alterations have been noted (Figure 1). Moreover, no serious adverse event has been observed during iron chelation therapy. The patient, after a 4-years period of transfusion therapy, died from septic shock. In conclusion, management of iron overload using combined therapy with deferasirox and deferoxamine is a safe and useful therapeutic choice in critical transfusion-dependent iron overload in MDS patients with preexisting hepatic disease.

1848

GROWTH AND ENDOCRINOLOGIC COMPLICATIONS IN BETA-THALASSEMIA MAJOR IN QATAR

A Soliman, M Yassin, A Elawwa, R Ashour
Hamad Medical Center, Doha, Qatar

Background. The combination of transfusion and chelation therapy has dramatically extended the life expectancy of thalassemic patients. The main objective of this study is to determine the prevalence of Growth and endocrine complications in children and adults with thalassemia major. **Methods.** One hundred and sixty patients entered the study. Physicians collected demographic and clinical and anthropometric data including history of therapies and pubertal status. Serum levels of 25(OH) D, calcium, phosphate, iPTH were measured. Thyroid function was assessed by free T4 and TSH. Growth hormone (GH) - insulin -like growth factor I (IGF-I) axis was evaluated in patients with short stature (< 10th percentile for age and sex). Basal gonadotrophin levels (LH and FSH) and sex steroid levels were evaluated in adolescents and adult patients. **Results.** Short stature was seen in 62% and low IGF-I in 85% of our patients. Hypogonadism was seen in 61 % of boys and girls > 14 years of age and primary hypothyroidism was present in 5%. About 24 % of patients had more than one endocrine complication with mean serum ferritin of 2818 ± 1212 micrograms/lit. In 52% of patients serum levels of 25(OH) D below 10 nmol/l and glycemic abnormalities were detected in 28% of them. **Conclusions.** High prevalence of Growth and endocrine complications among our thalassemics signifies the importance of early diagnosis and management.

Table 1. Summary of results for thalassemic patients >6 years of age.

Number	160
Age (years)	17.1+/- 10.5 years
Sex	74 F + 86 M
Short stature HtSDS < -2	62%
Low IGF-I (IGF-I < -2 SD)	85%
GHD (Peak GH < 7 ng/ml) (n = 42)	45%
Impaired Glucose tolerance (OGTT)	22.00%
Diabetes mellitus (FBG > 7.2 or 2h BG > 11.1)	6.00%
Hypothyroidism (low free T4 and/or high TSH)	5%
Hypocalcemia (Ca < 2 mmol/L)	7.50%
Hyperphosphatemia (> 1.9 mmol/L)	8.10%
Hypoparathyroidism	7.50%
Vitamin D Deficiency (25 OHD < 20 ng/ml)	52%
Impaired liver function (elevated ALT)	22.00%
Cardiomyopathy (clinical and/or echocardiography)	31%
Hypogonadotropic hypogonadism in patients >14 y (n = 79)	61%

1849

SIROLIMUS AS MAINTAINANCE TREATMENT IN AN INFANT WITH LIFE-THREATENING MULTI-RESISTANT PRCA/AIHA

M Miano[1], V Poggi[2], L Banov[1], F Fioredda[1], C Micalizzi[1], J Svahn[1], M Calvillo[1], AC Molinari[1], F Gallicola[1], G Montobbio[1], C Dufour[1]
[1]G. Gaslini Children's hospital, Genoa, Italy
[2]Santobono-Pausillipon Hospital, Naples, Italy

Background. Autoimmune Haemolytic Anaemia (AIHA) is a rare disease in children. Clinical symptoms of Acute AIHA can be very severe in infants, and a rapid treatment is mandatory. Children who do not respond or relapse need further therapeutic approaches but no controlled studies have ever been performed on their use. **Case Report.** We report a case of a nine month old boy with severe life-threatening resistant Pure Red Cell Anemia (PRCA)/Autoimmune Haemolytic Anemia (AIHA) within the frame of an undiagnosed immune-mediated disease. Diagnostic work-up also included both functional and genetic evaluation for FAS mediated apoptosis but did not recognize any

infective/immunological cause. The phenotype of the disease appeared to be changing overtime. Phases of prevalent intra-medullary haemolysis were alternated by more typical peripheral extramedullary one. Prednisone 3 mg/kg was administered as first line treatment in association with 2 doses Erithropoietin 450 mg/kg for the prevalence of intra-medullary haemolysis. Second and further line attack therapies of the seven relapses occurred during the next 12 months, unsuccessfully included i. v. Immunoglobulin, 3 course of Rituximab 375mg/m2, 4 doses of Cyclophosphamide 10 mg/m2, 3 courses of Alentuzumab 0. 2 mg/kg, followed by other immunosuppressive drugs administered as maintenance treatments such as Prednisone 2 mg/kg, Cyclosporine 5 mg/kg, Methotrexate 10mg/m2, Michophenolate 650 mg/m2. Massive haemolysis episodes also needed to be controlled by erithro-exchange transfusions. After failure of all above mentioned therapies, the patient was successfully treated with splenectomy followed by 3 doses of Fludarabine 20mg/m2 and Sirolimus 2 mg/m2 as maintenance treatment. During the next 18 months of follow-up, the child maintained good clinical conditions with haemoglobin levels and haemolysis indexes within the normal range. **Conclusions.** Due to the high number of immunosuppressive approaches used in a very short period, it's not possible to define which was the successful one. Frequent relapses might have been caused by the lack of both a complete de-bulk of the trigging cells and an underlying ineffective maintenance therapy. Splenectomy and sirolimus administration might have played a concomitant role in the resolution of both mechanisms. Although in our patient there was no evidence of any FAS related defect, the Sirolimus mediated lymphocytes apoptosis and the increase of regulatory T cells could have had a role in the control of an underlying undiagnosed immune-mediated disorder.

1850

HEMOLYTIC CRISIS IN AN OLD WOMAN WITH LATE ONSET FAVISM: ROLE OF AGE RELATED X- CHROMOSOME INACTIVATION AND DECOMPENSATED DIABETES

G Monaco, M Troiano, S Iaccarino, E Attingenti, M Iovine, A Abbadessa
UOC di Oncoematologia, A. O. R. N. "Sant'Anna e San Sebastiano", Caserta, Italy

Introduction. We describe a case of an old woman with severe hemolytic anemia in course of decompensated diabetes associated to low levels of glucose 6 phosphate dehydrogenase (G6PDH). **Case Report.** An 80 years old woman, affected by diabetes and ischemic cardiopathy, comes to our attention for weakness, jaundice, hypercromic urine, dyspnea. Blood tests show severe hemolytic anemia: Hb 6. 8 g/dl, total bilirubin 13 mg/dl, LDH 1800 UI/l, reticulocytosis, severe hemoglobinuria. Coombs tests are negative; paroxysmal nocturnal hemoglobinuria is excluded. Other exams show hyperglycemia (400 mg/dl) and ketoacidosis. Patient refers to have eaten fava beans the day before. We decide to perform red cells transfusion. After 5 days, thanks to clinical improvement, we decide to discharge the patient. After one month, she performs blood sample for dosing levels of G6PDH that result very low. **Discussion.** G6PDH deficiency is an X-linked recessive hereditary disease characterized by low levels of G6PD, a metabolic enzyme involved in pentose phosphate pathway and important for red blood cells metabolism. Patients with this disease may show non-immune hemolytic anemia secondary to different causes, commonly infection or exposure to certain drugs or chemicals. G6PD deficiency is closely linked to favism, a disorder characterized by a hemolytic reaction to consumption of fava beans. Symptomatic patients are almost exclusively male due to X-linked transmission. Female carriers can be symptomatic for unfavorable preferential inactivation (lyonization) of the X chromosome. The consequence of skewed inactivation of X-chromosome is expression of the mutant allele. Skewing of X chromosome inactivation has been linked to elderly age. Old women, heterozygous for G6PD mutations, have a higher risk to develop a G6PDH deficiency (Au et al, J of Gerontology 2006). In a diabetic G6PD-deficient subject, hemolysis may occur as result of hypoglycemia, blood glucose normalization, ketoacidosis in the African but not Mediterranean variant, and following administration of metformin or glibenclamide (Galtrey et Panthasali, J Med Case Reports 2008). Patient of described case, may have developed a G6PDH deficiency in elderly age for effect of unfavorable lyonization. Infact, during her life, ingestion of fava beans has never induced particular problems. Furthermore, hemolytic crisis could be trigger by ketoacidosis secondary to decompensated diabetes. **Conclusions.** G6PDH deficiency should be suspected in older woman with decompensated diabetes, in case of not otherwise specified non-immune hemolytic anemia.

1851

THE COMPARISON OF NUCLEATED RED BLOOD CELLS WITH DIFFERENT AUTOMATED BLOOD CELL COUNTERS IN PATIENTS WITH THALASSEMIA MAJOR AND ITS CLINICAL VALUE

M Karakukcu[1], T Patiroglu[2], E Unal[3], F Mutlu[2], Y Altuner Torun[4], C Karakukcu[5], A Ozturk[6], M Ozdemir[2]
[1]Erciyes Univesity, Faculty of Medicine, Kayseri, Turkey
[2]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology,, Kayseri, Turkey
[3]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology, Kayseri, Turkey
[4]Emel Mehmet TARHAN Children Hospital, Division of Pediatric Hematology, Kayseri, Turkey
[5]Kayseri Research and Training Hospital, Department of Clinical Biochemistry, Kayseri, Turkey
[6]Erciyes University, Faculty of Medicine, Department of Biostatistics, Kayseri, Turkey

Background. The presence of nucleated red blood cells (NRBC) in the peripheral blood of patients with thalassemia major (TM) has long been known but its clinical important, however is less known. Modern hematology analyzers allow for rapid and accurate NRBC counts. The levels of NRBC present a good relationship with ineffective erythropoiesis. **Aims.** We wish to measure NRBC by two different automated blood cell counters and compare the results to the manual peripheral blood smear and flow cytometry as a gold standard. We also aimed to research about any relation between values of NRBC and ferritin as a marker of follow up in patients with TM. **Methods.** Samples from children with transfusion dependent TM were analyzed by two automated blood cell counters [Sysmex XE 2100 (A) and Advia 2120i (B)] and compared with the results of peripheral blood smear and flow cytometry. **Results.** Fifty one children (30 girls and 21 boys; mean age 12. 7±7. 7 year, mean ferritin value 1894±1194 ng/ml) with TM treated with regular packed erythrocytes transfusion and iron chelation agents at Erciyes University, Children's Hospital, Kayseri, Turkey, were enrolled to this prospective study. The measured mean hemoglobin values, mean reticulocyte percent, NRBC percent, NRBC count were 9. 2±1. 3 gr/dl (A), 9. 5±1. 2 gr/dl (B); 4. 6±6. 5% (A), 4. 5±5. 6% (B); 41. 3±91. 8%(A), 35. 9±83. 8%(B); 6. 1±13. 2 x 10^3/µl (A), 6. 0±14. 3 x 10^3/µl (B), respectively. The automated blood cell counters failed to measure NRBC in 1 sample (A), 5 samples (B) and the result of NRBC count found as zero in 8 samples (A), 18 samples (B). Flow cytomery showed very low values (<1%) of NRBC count in 8 samples. Linear regression analysis showed that the value of R^2 were 0. 60 (A), 0. 51 (B); whereas the y value were 4. 23+0. 15x (A), 5. 10+0. 16x (B) when compared to flow cytometry as a gold standard, respectively. **Summary and Conclusions.** This study underlined that modern hematology analyzers allow for rapid and accurate NRBC counts. Sysmex XE 2100 looks more accurate especially at low values of NRBC. Advia 2120i showed no result for low values of NRBC; however it is more accurate at high values of NRBC. We did not found any correlation between NRBC and ferritin values in two counters.

1852

SURVIVIN EXPRESSION IN BLOOD OF PATIENTS WITH LUNG CANCER

G Kapellos[1], A Polonyfi[1], N Nektarios Alevizopoulos[2], M Michael Vaslamatsis[2], H Gogas[1], E Eleftherios Spartalis[1], P Periklis Tomos[1], A Athanasios Aissopos[1], M Mantzourani[1]
[1]Laiko Hospital, Athens, Athens, Greece
[2]Evangelismos Hospital, Athens, Greece

Backround. Lung cancer is one of the leading causes of death worldwide, with an increasing incidence and poor prognosis. Survivin, a member of the Inhibitors of Apoptosis Protein (IAP family), has been implicated in the pathophysiology of cancer with apoptosis and cell division and its expression could be informative for the development and relapse of disease. **Aims.** In this study *SURVIVIN* expression was estimated in peripheral blood of patients with small and non small lung cancer (SCLC and NSCLC) and compared to healthy volunteers. **Methods.** Peripheral blood samples of twenty lung cancer patients, 51 with NSCLC and 8 with SCLC, and 30 healthy volunteers, as control group, were obtained. For quantitative evaluation of *SURVIVIN* mRNA expression hybridization PCR methods were used. **Results.** Survivin's mRNA levels expression in peripheral blood is:low-detected in samples of healthy volunteers (m. v. ±sem sur/abl=0,132±0,004**)** determing the basal state of expression under physiological conditions6 times higher in lung cancer patients (m. v. ±sem sur/abl=1±0,02, p=0,004) compared to controls. 9,5 times higher expressed in NSCLC patients than controls (m. v. ±sem sur/abl=1,2±0,03,p=0,001) and 5,54 times more expressed in SCLC (m. v.

±sem sur/abl=0,693±0,069, p=5,2. 10^{-5}) compared to control group. **Conclusions.** The increased expression levels of *Survivin* in patients blood with lung Cancer could be indentified to progressive disease. Also, it is possible to attribute to circulated malignant cells. Finally, determining the levels of expression of *SURVIVIN* mRNA, could provide an informative marker of evaluating the gravity, the development and the relapse of the disease and furthermore a useful tool for selecting or differentiating of the therapy strategy.

1853

CIRCULATING ENDOTHELIAL CELL NUMBER CAN PREDICT EFFICACY OF COLLECTION OF CD34+ CELLS DURING MOBILIZATION PROCEDURE

A Szmigielska-Kaplon, A Krawczynska, M Czemerska, A Pluta, B Cebula-Obrzut, K Szmigielska, P Smolewski, T Robak, A Wierzbowska
Medical University, Lodz, Poland

Background. Circulating endothelial cells (CEC) in patients with hematological malignancies are assessed as non - invasive marker of angiogenesis. The other spectrum of interest is evaluation of CEC in the context of their influence on mobilization of hematopoietic stem cells (HSC) to peripheral blood. **Aims.** The aim of our study was to assess CEC and their subsets and correlate them with factors predicting successful mobilization of HSC in patients with hematological malignancies. **Methods.** Thirty eight patients were enrolled to the study (19 F, 19 M) at median age of 56,5 years. The group consisted of patients with multiple myeloma (26), lymphoma (10) and acute myeloid leukemia (2). The patients were mobilized with chemotherapy and G-CSF. For CEC evaluation venous blood samples were collected at different time points: before chemotherapy (Cht0), 1 day after chemotherapy (Cht+1), at the day of G-CSF beginning (G0), after the 1 day of G-CSF (G+1) and at the day when CD34+ cells were at least 10/µl -day of first apheresis (A). CEC were evaluated by 4 colour flow-cytometry. Circulating endothelial progenitor cells (CEPC) were defined as CD45-/CD34+/CD31+/CD133+ cells. Apoptotic CEC (apoCEC) were defined as CD146+/Annexin V+ cells. **Results.** Median (Me) number of CEC was 10,5 /µl and it decreased at G0 day (Me 8,3/µl, p=0,00006, compared with baseline), was stable at day G+1 (Me 8,4/µl, p=0,0008) and at A day (Me 8,0, /µl, p= 0,0002) as well as at A+1 day (Me 8,5/µl, p=0,007). We divided patients according to the number of days of G-CSF treatment before 1 apheresis (days of GCSF) into "early"(Me) mobilizers. We observed significantly higher baseline CEC in "early mobilizers"(Me 12,5/µl, range 6,7-21,9/µl) than in the "late mobilizers"group (Me=9,9/µl, range 3,8-21/µl, p=0,043). In "early mobilizers"we detected higher number of CEPC at G0 day (Me 1,3/µl, range 0,6-3,5/µl) than in the "late mobilizers"group (Me 0,8/µl, range 0,3-1,9/µl, p=0,05). CEPC at G+1 day was also higher in "early mobilizers"(Me=1,5/µl, range 0,8-2,2/µl) than in "late mobilizers"(Me=0,8/µl, range 0,3-1,9/µl, p=0,01). There was a trend for adverse correlation of baseline CEC number with the number of days of G-CSF (r= -0,33, p=0,06). Number of CEPC at G0 and at G+1 days correlated adversely with number of days with G-CSF administration (r= -0,42, p=0,035 and r= -0,49, p=0,04, respectively). Patients were divided according to number of aphereses needed to obtain minimal number of cells for transplantation (2 x 10^6/kg) into two groups: "highly efficient"(1 apheresis was enough) and "low efficient"mobilizers (2 or more aphereses were needed). Median ApoCEC at G +1 day was lower in "highly efficient"(Me=3,1/µl, range 1,9-5,4/µl) than in "low efficient"mobilizers (Me=5,1/µl, range 2,4-6,8/µl, p=0,02). ApoCEC at G+1 day correlated with the number of aphereses (r=0,48, p=0,038). **Conclusions.** CEC and the subsets CEPC and apoCEC measured at the time of G-CSF beginning can predict efficacy of HSC collection. CEC and the subsets as low-cost, non-invasive parameters need further evaluation in context of mobilization efficacy

1854

PRETRANSPLANT DONOR AND RECIPIENT CMV SEROSTATUS AND OUTCOME OF RIC ALLOGENEIC SCT FOR MULTIPLE MYELOMA IN THE ERA OF CMV PRE-EMPTIVE THERAPY

J Elcheikh, R Devillier, R Crocchiolo, S Furst, C Faucher, AM Stoppa, A Granata, C Oudin, P Ladaique, D Coso, B Calmels, C Lemarie, R Bouabdallah, C Chabannon, D Balise
Institut Paoli Calmettes, Marseille, France

In the era of cytomegalovirus (CMV) pre-emptive therapy, it is unclear whether CMV serostatus of donor or recipient affects outcome of allogeneic hematopoietic stem cell transplantation (allo-SCT) among patients with Multiple Myeloma (MM). Were followed retrospectively between January 2000 and January 2011, 99 consecutive patients who underwent reduced-intensity conditioning (RIC) allo- SCT for MM in our cancer centre at Marseille. All patients had serial weekly monitoring for CMV viremia using antigenemia assay (pp65 antigen) or quantitative polymerase chain reaction (PCR) at least one by week. Patients also received prophylaxis against the herpes simplex virus with oral valacyclovir (500 mg x 2/day) followed by initiation of pre-emptive therapy with Gancyclovir IV 5mg/kg x2/day for two weeks the 5mg/kg/day for other 2 weeks in patients who become positive. Median age of patients was 53 years (27-67), including 59 males and 40 females. The median age of donor was 46 years (0-71), including 46 males and 53 females. Using either matched sibling/family (73%) or unrelated donors (27%). Graft source was peripheral blood stem cells in 88 patients (89%), bone marrow in 9patients (9%), and cord blood in 2 (2%). All patients received a RIC regimen before transplantation using the combination of Fludarabine, busulfan and Anti thymoglobulin (ATG)-based (68%), or Fludarabine and Total body irradiation (TBI) based (31%). Based upon CMV serostatus, patients were classified into low risk (donor [D]-/recipient [R]-) 17 patients (17,1%), intermediate risk (D+/R-) 14 patients (14,1%), or high risk (D-/R+, 31 patients (31,3%) or D+/R+, 37 patients (37,3%)). Pre-transplant CMV seroprevalence was 68% in recipients, 51% in donors. CMV reactivation was seen in 39 patients (39%). The median time between allo-SCT and CMV reactivation was 61 days (26-318). All patients were treated with antiviral therapy with responses seen in 36 patients (92%). Twenty three of them (59%) were on corticotherapy for graft versus host disease (GvHD) treatments. Three patients (3%) developed CMV disease at a median of 38days (26-49) post allo-SCT. Only 2 patients (2%) died because CMV reactivation associated with acute GvHD. At a median follow up of 43 months (range 6-93), 43 patients (43%) are alive with a significantly higher survival among patients without CMV reactivation (27%) as compared with patients with CMV reactivation (16%; P=0. 059). CMV serostatus was the most important risk factor with incidence of 50% in the high-risk group compared with 29% in the intermediate risk and 0% in the low-risk group (P=0. 001). Figure 1. On univariate analysis, CMV status adjusted for donor type, diagnosis, disease stage, recipient age and donor age, female-to-male graft, graft source, and year> < 2006, use of ATG during conditioning and corticotherapy has no impact on Overall Survival, Progression Free Survival or Transplant Related Mortality. Other significant risk factors identified included acute GvHD (P=0. 006). On a multivariate analysis, CMV serostatus, acute GvHD remained independent predictors of CMV reactivation. In conclusion, donor and recipient CMV serologic status is a significant pre-transplant determinant for outcome in high-risk MM patients undergoing RIC allo-SCT only if associated with acute GVHD.

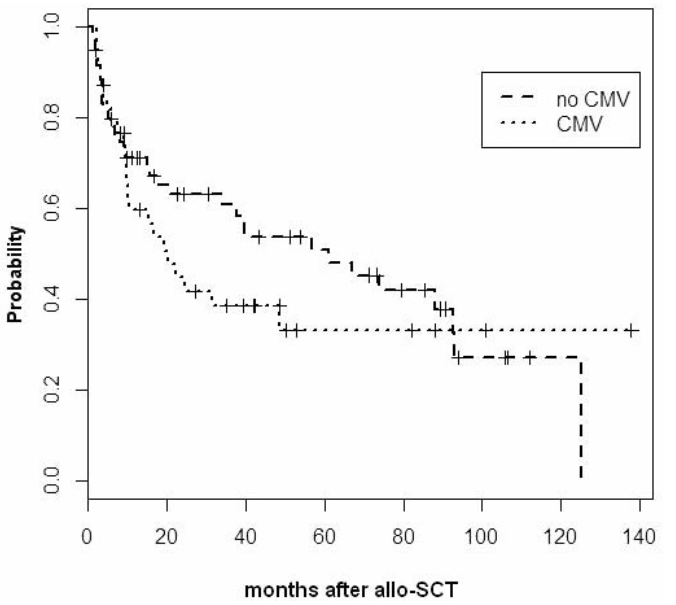

Figure 1. Overall survival OS.

[2]Etablissement Français du sang, Caen, France

Background. There are today considerable concerns regarding the appropriate use of health care resources. Published clinical research data (Jagannah and al.

1997; Morabito and al.,2002 and Ferrara and al.,2004) reported total outpatient management which required qualified medical and nursing staff at home. We decided to realise semi-ambulatory autologous peripheral stem cell transplantation (ASCT): conditioning and reinfusion of stem cell at the hospital, five following days at home and readmission at the hospital for the management of the aplasia. . The closest published model described by Anastasia et al (2009) reports only 5% of 123 ASCT readmission before day 5. **Aims.** The purpose of this study was to analyse our experience of early discharge 2 days after high-dose melphalan followed ASCT (Day 0) and re-admission on Day +5. **Methods.** From April 2005 to July 2011, among ninety-four patients received Melphalan 200 mg/m^2 with ASCT, fifteen patients received ASCT on an inpatient basis and seventy-nine patients were treated in outpatient model. All patients presented a multiple myeloma (IgGκ=30; IgGλ=18; free light chain=17; IgAκ=2; IgAλ=5 patients). Patient were treated in first line by bortezomib (n=61) and with anthracyclines (n=31). After first line treatment, 5/79 patients were in complete response, 63 in partial remission and others patients were in partial response after a second line treatment. When they came back home, patients had the ward phone number and a date for their hospitalisation five days later. Antibiotic prophylaxis was not used. All patients received G-CSF. At Day+5, patients were hospitalised in room without positive-pressure but with protective isolation during the neutropenic period. **Results.** Of the 79 procedures eligible for our mixed inpatient-outpatient management regimen, none required early re-admission for complications. Full engraftment was achieved in all cases. Median âge was 58 years (range 31-71). Sexe ratio was 33/46. Median neutrophils count at day 1 and day 5 were respectively 3,56 (range 11,2-1,41) and 0 (range 0-88). Median platelets count at day 1 and day 5 were 214 (range 41-473) and 94 (range 94-204). During home period, digestive toxicities occurred in 28 patients: 3 oral mucositis (1 patient with grade 4 mucositis), 10 had associated diarrhea, 7 had vomiting and 6 anorexia. Two patients presented fever at home just before coming back in the hospital without septic choc. During hospitalisation, 69 patients experienced febrile neutropenia. Median duration of fever was 2 days (range 0-10). 23 patients presented clinical infection, 17 patients had documented infection by positive blood stream. Median duration of antibiotic treatment was 5 days (range 0-22). Median time to discharge (from Day 0) was 12 days (range 8-22). There was no mortality by on Day +100. **Conclusion.** Our experience of early discharge after ASCT with re-admission on Day +5 is safe and feasible with acceptable frequency of hematological and extra-hematological toxicities. The regimen allows reduced hospital stay and hence cost savings. This method generated economy of 395 hospitalisation days.

Background. High dose chemotherapy followed by autologous stem cell transplantation (ASCT) has become the standard approach for relapsed or high risk non-Hodgkin's lymphoma (NHL). Several different high dose therapy (HDT) conditioning regimens have been used for non-Hodgkin's lymphoma (NHL), such as BEAM (carmustine, etoposide, cytosine arabinoside, melphalan), BEAC (carmustine, etoposide, cytosine arabinoside, cyclophosphamide), and CBV (cyclophosphamide, carmustine, etoposide). Carmustine is an active drug in the HDT of NHL but the supply of carmustine is limited in some countries including Korea. Intravenous busulfan containing regimens as conditioining regimen have been used for both allogeneic and autologous stem cell transplantation in patients with hematologic and non -hematologic malignancies. The purpose of this prospective multicenter phase II study was evaluate the efficacy and safety of iv busulfan/melphalan/etoposide regimen as a conditioining regimen for high dose chemotherapy in the patients with relapsed or high risk NHL. **Methods.** Patients with relapsed or primary refractory NHL or chemosensitive high risk NHL underwent high dose chemotherapy followed by ASCT at 12 centers in Korea. The conditioning regimen consisted of iv busulfan 3. 2mg/kg/day i. v. on days -8, -7 and -6, etoposide 400mg/m2/day i. v. on days -5 and -4 and melphalan 50mg/m2/day i. v. on days -3 and -2. **Results.** Fifty one patients were enrolled onto the study. Main subgroups were DLBCL (n=25, 49%) and T cell lymphoma (n=19, 37%). At the time of ASCT, the disease status of patients was as follows: 13 patients were high risk in remission, 16 were primarily refractory to inducton therapy, 15 patients were in chemosensitive relapse. All patients had successful stem cell engraftment with a median time to neutrophil recovery of more than 500/mm3 of 10 days (range, 2 to 30 days). Platelet recovery of more than 20,000/mm3 was seen after a median of 10 days (range, 2 to 51 days) with delayed recovery in one patient. Treatment related toxicities included nausea/vomiting in 28 patients (55%), diarrhea in 28 patients (55%) and mucositis in 33 patients (65%), which were grade I or II in the majority of cases. Grade I/II hepatic toxicities occurred in 24% (n=12) and grade III in 6% (n=3). There were no VOD and treatment related death. The median duration of hospitalization for ASCT was 30 days (range, 12 to 80 days). Forty one patients (80%) achieved a complete response 1 month after ASCT, while three patients showed progressive disease. At a median follow up of 14. 7 months, 21(41%) patients exhibited a relapse or progression, while 11 patients had died of disease and one patient had died of heart failure. The estimated 2-year overall and progression free survival for all patients was 64% and 40%, respectively. **Conclusions.** This preliminary analysis suggests that conditioning regimen of i. v. busulfan/melphalan/etoposide would be well tolerated and effective in patients with relapsed or high risk NHL. Accordingly, this regimen may be regarded as an important treatment option to substitute for BEAM regimen.

1857

MYOCARDIAL FUNCTION ASSESSMENT IN CHILDREN UNDERGOING AUTOLOGOUS HEMATOPIOTIC STEM CELL TRANSPLANTATION

Y Al-Tonbary, M Sarhan, A El-Ashry, M Al-Marsafawy, K Matter
Mansoura University, Mansoura, Egypt

Background and Aims. With an increasing number of survivors after bone marrow transplantation (BMT), more interest is focused on the long-term adverse effects. Subclinical cardiac involvement appears to be common in adults after BMT, but only a few previous reports of cardiac function after BMT concern pediatric patients. **Methods.** A prospective case-control study performed between September 2009 and December 2010. Nineteen consecutive patients (14 males and 5 females) with mean age 10. 73±2. 90, and normal cardiac function (LVFS >30%) undergoing autologous hematopoietic stem cell transplantation (HSCT). The underlying disease was Hodgkin lymphoma in 10 patients, Non-Hodgkin lymphoma in 5 patients and acute myeloid leukemia in 4 patients. Tissue Doppler imaging (TDI) echocardiographic measurements were obtained according to the guidelines of the American Society of Echocardiography. Informed consent was obtained. **Results.** The lateral mitral annulus in the patients before HSCT showed significant reduced mitral systolic annular (Sm) velocity (p<0. 0001), mitral early diastolic annular (Em) velocity (p<0. 0001), mitral late diastolic annular (Am) velocity (p0. 02) and prolonged isovolumetric relaxation time (IRT) (p<0. 0001) in comparison to control, while mitral Em/Am ratio and isovolumetric contraction time (ICT) remain unchanged. Comparing the same data before and after HSCT revealed significant reduced mitral systolic annular (Sm) velocity (p<0. 0001), mitral early diastolic annular (Em) velocity (p0. 0005) and mitral Em/Am ratio (p0. 004), with higher mitral late diastolic annular (Am) velocity (p0. 02) and prolonged ICT (p0. 003) and IRT (p0. 002) in patients after HSCT. Lateral tricuspid annulus in the patients before HSCT showed significant reduced tricuspid systolic annular (Sm) velocity (p0. 0002), tricuspid early diastolic annular (Em) velocity (p<0. 0001) and tricuspid Em/Am ratio (p0. 003) while higher tricuspid late diastolic annular (Am) velocity (p0. 006) and prolonged ICT (p<0. 0001) in comparison to control, whereas the ICT remain unchanged. Comparing the same data in the patients before and after HSCT revealed significant reduced tricuspid systolic annular (Sm) velocity (p<0. 0001), tricuspid early diastolic annular (Em) velocity (p0. 031) and tricuspid Em/Am ratio (p<0. 0001) while higher tricuspid late diastolic annular (Am) velocity (p<0. 0001), prolonged ICT (p<0. 0001) and IRT (p<0. 0001) after HSCT. The mid interventricular septum in the patients before HSCT showed significant reduced systolic (Sm) velocity (p<0. 0001) and Em/Am ratio (p<0. 0001) in comparison to control while early diastolic (Em) velocity and late diastolic (Am) velocity showed no changes. Comparing the same data before and after HSCT revealed significant reduced systolic (Sm) velocity (p<0. 0001), early diastolic (Em) velocity (p<0. 0001) and higher Em/Am ratio (0. 03), whereas late diastolic (Am) velocity showed no change in patients after HSCT. LV Tei index was found to be higher in patients before HSCT in comparison to control (p<0. 0001) and remains higher in the patients after HSCT (p0. 76). RV Tei index showed the

same changes observed for theLV. **Conclusions.** Subacute cardiac toxicity is common after HSCT, even in patients with apparently normal left ventricular function. TDI could detect the subtle abnormalities in the systolic and diastolic functions before HSCT and their deterioration after the HSCT which can imply that the conditioning regimen may affect cardiac function after HSCT.

1858

PREVENTIVE EXTRACORPORAL PHOTOPHERESIS USE AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR HEMATOLOGICAL MALIGNANCIES: A PROSPECTIVE MULTICENTER STUDY

M Michallet[1], O Hequet[2], M Detrait[1], M Sobh[1], S Morisset[1], A Praire[1], V Plattner[3], D Bertram[3], V Schreiber[3], C Bulabois[4], JY Cahn[4], P Drillat[2], C Makowski[2], I Yakoub-Agha[5], V Coiteux[5], C Noel[5], A Lionet[5], F Garban[4]
[1]Centre Hospitalier Lyon Sud, Pierre Bénite, France
[2]EFS, Lyon, France
[3]DRC - CHU de Lyon, Lyon, France
[4]CHU de Grenoble, Grenoble, France
[5]CHRU de Lille, Lille, France

Background. Graft versus host disease (GVHD) remains a major complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) leading to significant negative impact on patients survival and quality of life. The recent use of extracorporal photopheresis (ECP) in the treatment of chronic GVHD has resulted in very promising results especially in patients with cGVHD refractory to immunosuppressive agents. **Aims.** We conducted this prospective multicenter study to evaluate the toxicity at day 100 and efficacy of ECP introduced early (day 21 post-transplantation) in patients with hematological malignancies receiving allo-HSCT from related and unrelated HLA identical donors. **Methods.** We included adult patients of age ≤ 65 years who were in response before allo-HSCT and received reduced intensity conditioning (RIC) followed by allo-HSCT for hematological malignancies from 10/10 HLA related or unrelated donor. At day 21 post-allo-HSCT and in the absence of corticoid-resistant acute GVHD, ECP was initialized twice weekly during two consecutive weeks and then once weekly the weeks later, in total, 8 ECP sessions had to be done. At day 100 post allo-HSCT, ECP toxicity evaluation was done according to the NCI/NIH common toxicity criteria (version 3). Other outcomes on efficacy and survival were also assessed. **Results.** Between June 2009 and March 2011, 10 patients were included, 6 males and 4 females of median age 61 years [54-65]. There were 4 AML (all in CR1 before allo-HSCT), 2 NHL (1CR1 and 1CR3), 2 CLL (1VGPR3 and 1CR3) and 2 MM (1 CR2 and 1 PR2). All patients received Fludarabine - Busilvex - ATG based RIC. Peripheral blood stem cell (PBSC) was used in all patients, 5 from HLA identical related donors and 5 from HLA identical unrelated donors. Patients received allo-HSCT after a median time of 6. 6 months [4. 5-8. 7] from diagnosis. Sex matching was: F→M:2, F→F:2, M→F: 2 and M→M:4. All patients engrafted, the median time to neutrophils and platelets recovery were 17. 5 days (13-19) and 9. 5 days (0-13) respectively. At day 21, no corticoid-resistant aGVHD were observed, ECP was administered for all patients; 8 patients completed the 8 ECP sessions while one patient received 4 sessions (due to GVHD activation) and one patient received 5 sessions (due to EBV lymphoproliferation). There were 2 patients with aGVHD (1grade I at day 17 and 1 grade IV at day 37). cGVHD was observed in 4 patients [3 limited (at days 100, 141 and 180) and 1 extensive (after DLI + lenalidomide) at day 365. After a median follow-up of 13. 3 months (2-24), one patient died due to septic choc while relapsing, 9 patients are alive, 7 are in CR, 1 in PR and 1 in relapse, none of the patients present active chronic GVHD. The ECP was well tolerated, there were only 2 serious adverse events (SAE) with grade ≥ 4 (one febrile neutropenia and one septic choc) both not related to ECP procedure, **Conclusions.** ECP has resulted in very acceptable rates of GVHD. This procedure has been well tolerated; similar larger prospective studies are needed to validate its use in a preventive way.

1859

ORAL FLUDARABINE WITH LOW DOSE TBI CONDITIONING FOR ALLOGENEIC PBSC TRANSPLANT ACHIEVES EFFECTIVE DONOR ENGRAFTMENT WITH REDUCED RISK OF SEVERE NEUTROPENIA

S Patil
Alfred Hospital, Melbourne, Australia

Background. Allogeneic HSCT conditioned withlow dose TBI and intravenous (i.v.) fludarabine results in reduction in NRM, however, is associated withhighgraft rejection rate. Use of bone marrow instead of G-CSF mobilisedPBSC, and low CD 34+ and CD3+ cell doses are the factors associated withhigher graft failure rates. RICHSCT withoral fludarabine, in combination witheither melphalan or busulfan, results in adequate donor engraftment. However, no data exist withregard to donor engraftment kinetics in patients athigher risk of graft rejection i. e. treated withoral fludarabine in combination witha single fraction of 2 Gy TBI. **Aims.** To study early donor chimerism in allogeneic HSCT usingRIC withoral fludarabine and 2 Gy TBI. **Methods.** Patients withAMLand MM who had at least an 8/8-matching (HLA - A, - B, -Cw and -DR) sibling or an unrelated adult donor were transplanted withPBSCs following conditioning withoral fludarabine 48 mg/m^2/day days -4 to -2; and 2 Gy TBI on day 0. Post transplant immunosuppression consisted of cyclosporin 3 mg/kg b. d. starting day -3 and mycophenolate mofetil 15 mg/kg b. d. starting 4-6hours after stem cell infusion. Donor/recipient mixed chimerism was assessed based on peripheral blood lymphoid (CD3+) and myeloid (CD33+) cells, by short tandem repeat polymerase chain reaction on days 30, 60, 90 and 180. Inadequate CD3+ chimerism (< 90% CD3+) was managed with early withdrawal of immunosuppression &/or infusion of donor lymphocytes. **Results.** Seven males and 7 females underwent HSCT for either MM (N=12) or AML(N=2). For MM patients, allogeneic HSCT was part of a planned tandem autograft-allograft procedure, using a sibling (n = 7) or unrelated (n = 7) donor. Five unrelated donors were mismatched either at HLA-DP (4) or -DP and -DQ(1). Six donor recipient pairs were sex mismatched. The median CD34+ cell dose was 7. 11 x 10^6/kg (range: 2. 39 - 23. 96 x 10^6) and the median CD3+ dose was 225 x 10^6/kg (range: 136 - 469 x 10^6). No grade III/IV gastrointestinal toxicity was seen. Median neutrophil nadir count was 0. 58 x 10^9/L, which was significantly lower compared tohistorical data using i. v fludarabine at equivalent dose (Figure 1). Red cell transfusion was required in four patients and platelet transfusion in two. No mortality was seen by day +180. Six patients achieved ≥90% CD3+ donor chimerism by day 30, 8 by day 60 and 10 by day 90 (3 patients not yet reached this milestone). In CD 33+ lineage, 12 patients achieved ≥90% donor chimerism by day 30 and in all 14 by day 60. The donor chimerism kinetics is shown below (Figure 2). One patient each required withdrawal of immunosuppression and donor lymphocyte infusion to improve donor chimerism, which was effective. **Conclusions.** Oral fludarabine and 2 Gy TBI based conditioning is well tolerated withless severe neutropenia than i. v fludarabine. The lymphoid engraftment is delayed but similar to i. v. fludarabine. Thus, oral fludarabine appears to be an effective and safe conditioning for outpatient allogeneic HSCT.

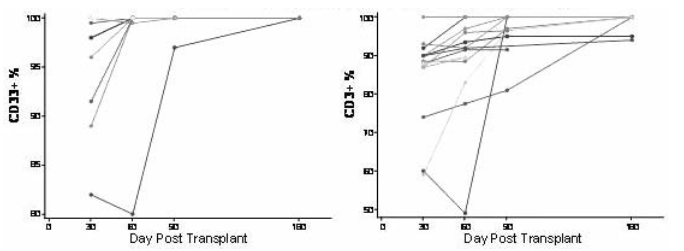

Figure 2. Chimerism kinetics and neutropenia.

1860

LONG-TERM FOLLOW-UP OF REDUCED-INTENSITY ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR REFRACTORY OR RELAPSED FOLLICULAR LYMPHOMA

T Mori, Y Ono, J Kato, A Yamane, S Okamoto
Keio University School of Medicine, Tokyo, Japan

Background. Although allogeneic hematopoietic stem cell transplantation (HSCT) is considered the only curative treatment for refractory or relapsed follicular lymphoma, transplant-related mortality (TRM) greatly interferes with the success. A variety of reduced-intensity conditionings (RICs) have been used to reduce TRM, but an optimal conditioning for follicular lymphoma has not been ful-

ly established. **Aims.** To evaluate the safety and efficacy of RIC for follicular lymphoma, we retrospectively evaluated the long-term outcome of allogeneic HSCT for follicular lymphoma with a RIC regimen consisting of fludarabine and melphalan. **Patients and Methods.** Nineteen patients (age: 34-58) with relapsed or refractory follicular lymphoma were conditioned with fludarabine (125 mg/m^2) and melphalan (140 mg/m^2), and received bone marrow or peripheral blood stem cells from a human leukocyte antigen (HLA)-identical sibling (n=6) or bone marrow from an HLA-matched unrelated donor (n=13). For the prophylaxis of graft-versus-host disease (GVHD), cyclosporine A or tacrolimus with short-term methotrexate was given. **Results.** There were no early deaths before engraftment, and all patients achieved engraftment. Three patients died of extensive-type chronic GVHD (n=2) or bacterial infection (n=1) without disease progression. With a median follow-up period of 75. 2 months (range: 33. 3-111. 9 months), 16 patients were alive without disease progression. Both the 5-year overall and progression-free survival rates were 84. 2% (95% CI: 67. 7%-100%). **Conclusions.** These results strongly suggest that allogeneic HSCT with RIC using fludarabine and melphalan could be a promising treatment choice for refractory or relapsed follicular lymphoma. For further improvement of the outcome, optimal management of GVHD should be explored in this setting.

1861

DIFFERENT RISK FACTORS AND ECONOMICAL RESOURCES RELATED TO BK VIRUS-ASSOCIATED HEMORRHAGIC CYSTITIS FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION

M Michallet[1], L GILIS[1], N Tedone[1], G Billot[2], M Sobh[1], M Detrait[1], H Labussière[1], F Nicolini[1], S Ducastelle[1], F Barraco[1], Y Chelghoum[1], X Thomas[1], F Ader[3]

[1]Centre Hospitalier Lyon Sud, Pierre Bénite, France

[2]Service de Virologie - CHU de Lyon, Lyon, France

[3]Service de Maladies Infectieuses et Tropicales - CHU de Lyon, Lyon, France

Introduction. Virus-associated hemorrhagic cystitis (HC) is a major cause of morbidity and mortality following allogeneic hematopoietic stem cell transplantation (allo-HSCT). **Aims.** To reveal the different risk factors associated to the occurrence of BK virus-associated HC (BKvHC) and evaluate its economical impact. **Materials and Methods.** We conducted this retrospective analysis on patients who received allo-HSCT for any hematological malignancy between January 2007 and December 2011 at our institution. The incidence of BKvHC was assessed. Different transplantation and disease characteristics were evaluated to study their impact on the BKvHC occurrence. A medico-economical study including days of hospitalization and transfusions was done. **Results.** Among 304 patients who received allo-HSCT, there were 42 (14%) who developed BKvHC. The median time of occurrence was 37 days (9-361) post allo-HSCT and it lasted for a median time of 20 days (1-155). Cidofovir treatment was initiated in 38 (90%) patients resulting in 63% of clinical response at 2 weeks and 71% at 5 weeks, among them 63% were cured. In multivariate analysis, the factors associated with a higher risk of developing BKvHC were: transplants from unrelated donors including cord blood transplants (OR 2,8; 95% CI 1. 30-6. 38; p < 0. 01) and the existence of HLA mismatch (OR 2. 3; 95% CI 1. 09-5. 11; p < 0. 05). Patients with BKvHC needed significantly longer time of hospitalization (65. 8 vs 45. 1 days; p < 0. 001), more red blood cells and platelets transfusions units [(21 vs 6. 3; p < 0. 001) and (28. 8 vs 9. 2; p < 0. 001) respectively]. **Conclusions.** We showed that donor type and cells source including the HLA matching play a major role in the occurrence of BKvHC. The consideration of these parameters in the allo-HSCT settings should have a positive outcome on its incidence and a significant medico-economical impact especially on hospitalization time and transfusions. Larger prospective studies are needed in order to validate our findings.

USE OF MESENCHYMAL STEM CELLS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: Results OF COMPASSIONATE USE IN A SINGLE CENTER

O Lopez-Villar, E Villaron, F Sanchez-Gujo, M Lopez-Parra, S Muntion, L Lopez-Corral, L Vazquez, MD Caballero, J San Miguel, C Del Cañizo

University Hospital of Salamanca, Salamanca, Spain

Background. In recent years the use of mesenchymal stem cells (MSC) for the treatment of complications in the alogeneic hematopoietic transplant setting is increasing. Graft-versus-host disease (GVHD) is the most frequent indication for this treatment, but a number of other complications have been also treated such as graft failure or haemorrhagic cystitis. **Aims.** The aim of this work is to analyse the outcome of patients treated in our institution with MSC in the compassionate use program. **Patients and Methods.** Patients: 23 patients have been treated with MSC in our institution in the compassionate program during 2010 and 2011. Median age was 51 years (range 2-62). Three children received an allogeneic transplantation for non-neoplastic diseases, the remaining had been diagnosed of an haematological neoplasia (6 acute leukemias, 5 lymphomas, 2 chronic lymphocytic leukemia and 7 myelodysplatic syndrome or myeloproliferative disorder). The indication for MSC use was: refractory acute GVHD-11, refractory extense chronic GVHD-2, graft failure-3, GVHD with cytopenia-2, and 5 patients had a cytopenia without other signs of GVHD. All patients received bone marrow derived MSC from a third party donor. MSC EXPANSION AND ADMINISTRATIONCells were expanded in the GMP facility of our institution according to established protocols. Briefly mononuclear cells were obtained by density gradient and platted in culture flasks with culture medium supplemented with platelet lysate. After confluence was reached cells were trypsinized and replated for 2-3 passages. Then cells were frozen in individual doses. Informed consent was obtained from both, patients and donors according to institutional rules. **Results.** A total of 112 infusions have been performed. Cells were thawed and iv administered after dexchlorpheniramine and hydrocortisone treatment. No side effects were reported during or after infusion. A median 4 infusions (range 1-12) have been administered. The median number of cells in each dose was 1x10^6/Kg of patient (range 0,6-3). Globally 19 out 23 treated patients showed some response. The results are shown in Table 1. **Conclusions.** MSC administration is safe as treatment of severe complications in the allogeneic stem cell transplantation setting. The number of cells and of doses needed to obtain the optimal response need to be determined.

Table 1.

Number of patients that achieved complete response	Number of patients that achieved complete remision	Number of patients that achieved partial response	Number of patients with no response
Acute GVHD n=11	5	4	2
Chronic GVHD n=2	0	2*	0
GVHD + cytopenia n=2	1	1	0
Graft failure n=3	2	0	1
Peripheral cytopenia n=5	4**	0	1
Total n=23	12	7	4

* One of them reached CR of gut GVHD but no response of liver GVHD

** Three out 4 patients relapses and were threated with a second course of MSC. Two of them maintained CR (3 and 4 months respectively until now)

1864

CONVENTIONAL VS. LARGE VOLUME APHERESIS FOR ALLOGENEIC AND AUTOLOGOUS STEM CELL TRANSPLANTS

B Balint[1], D Stamatovic[1], M Todorovic[2], G Ostojic[1], M Elez[1], J Bila[2], D Vucetic[1], B Andjelic[2], B Mihaljevic[2]

[1]Military Medical Academy, Belgrade, Serbia

[2]Clinical Center of Serbia, Belgrade, Serbia

Background. The collection and clinical use of adequate number of stem cells (SCs), harvested by leukapheresis, is necessary for effective treatment of hematological disorders by transplant. **Aims.** The goals of this study were: to obtain an optimized protocol for harvesting sufficient quantity of viable SCs and to compare the hematopoietic reconstitution after autologous transplants in different clinical settings. **Methods.** In this study, SC transplants - 112 allogeneic from matched sibling healthy donors and 128 autologous - were performed in the management of patients with severe aplastic anemia, leukemias (ALL, ANLL, CML), multiple myeloma, Hodgkin's and non-Hodgkin's lymphoma, and extragonadal non-seminal germ cell tumor. Cell mobilization was achieved with rHuG-CSF (5-10 mg/kgbm/day and 12-16 mg/kgbm/day in allogeneic and autologous setting). SC-apheresis procedures (generally one and occasionally two) were performed using blood cell separators COBE-Spectra and Spectra-OPTIA (CaridianBCT, USA). The first SC-apheresis was accomplished when the leukocyte cont was 5-10x10E9/L and CD34+ count 30-50/mL in peripheral blood

(autologous) or on the 5th day 4-5 hour after the last rHuG-CSF administration (allogeneic). The processed blood volume during one apheresis was 24. 3 L for one SC transplant in average. **Results.** Using a minimal target dose of CD34+ cell count (3x10E6/kgbm), performing one apheresis procedure for 86% recipients sufficient number of SCs were obtained. The MNC yield was 10. 1x10E8/kgbm in allogeneic and 8. 1x10E8/kgbm in autologous setting. The mean CD34+ yields for allogeneic and autologous transplants were 8. 1x10E6/kgbm and 6. 5x10E6/kgbm, respectively. The ratio of primitive CD34+ cell subpopulation CD34+/CD90+ was higher (1. 7±1. 5% vs. 1. 3±0. 8%) in autologous SC harvest. Hematopoietic reconstitution was achieved on the 10. 4th vs. 12. 4th day for leukocytes and the 14. 05th vs. 17. 4th day for platelets when allogeneic vs. autologous SC transplants were applied. **Summary and Conclusions.** Improved CD34+ cell yield with acceptable primitive CD34+ subpopulation ratio was obtained, as well as consequential rapid hematopoietic reconstitution were observed when large volume apheresis was performed using higher (12-16 mg/kgbm/day) rHuG-CSF doses.

1865

IRF AND IPF AS PREDICTORS OF HAEMATOPOIETIC RECOVERY AFTER ALLOGENEIC TRANSPLANTATION IN CHILDREN AND ADULT PATIENTS

AP Gonçalo
IPO-Porto, Porto, Portugal

Haematopoietic progenitor cell transplantation may be the treatment of choice for patients with malignant haematological diseases. In the post transplant period it is particular relevant to evaluate the haematological engraftment of these patients. Last generation haematology analysers offer an alternative way to evaluate the PB immature fractions which may also give indications of haematopoietic recovery. Amongst these, the immature reticulocyte fraction (IRF) and immature platelet fraction (IPF), in peripheral blood samples, could play an important role as early indicators of transplant's success. Traditionally, neutrophils (NEUT) (D500 NEUT>0. 5 x 10^9/ L) and platelets (PLT) (D20 PLT>20 x10^9/L) counts are used to evaluate the haematological engraftment of transplanted patients. The aim of the present study was to evaluate the predictive value of IRF (D IRF>10%), and IPF (D IPF>7%), in the haematological recovery of adult (n=60) and paediatric (n=21) patients undergoing allogeneic transplantation, together with the classical parameters. Related or unrelated progenitor cell grafts were obtained: Cord Blood (CB) and Bone Marrow (BM) for paediatric patients and Peripheral Blood Stem Cells (PBSC) for both groups of patients, who were followed since transplant day throughout all hospitalization period. Patient Peripheral Blood (PB) samples were collected in EDTA tubes and analyzed in the automatic hematology analyzer Sysmex XE-5000. The classical parameters of the CBC, namely the concentration of leucocytes, NEUT and PLT were obtained together with the new parameters IRF and IPF. The haematopoietic recovery of both groups of patients is summarised in Table 1, comparing median days to recovery for classical parameters and new parameters.

Table 1. Haematopoietic recovery of adults and paediatric patients.

	NEUT	PLT	IPF	IRF
Adults (n=60)				
All	14(11-28)	11(8-40)	10(6-30)	10(4-33)
Relat (47)	14(11-18)	10(8-29)	9(6-16)	10(4-14)
Unrelat (13)	15(12-28)	21(11-40)	13(9-30)	15(9-33)
Paediatric (n=21)				
All	15(10-22)	15(11-32)	11(8-22)	13(9-22)
Relat (5)	15(12-16)	13(12-19)	10(8-17)	11(10-13)
Unrelat (16)	15(10-22)	17(11-32)	12(8-22)	13(9-22)
CB (4)	16(13-18)	22(13-30)	14(9-22)	11(9-17)
BM (4)	17(12-19)	18(12-27)	12(8-17)	15(11-22)
PBSC (13)	15(10-22)	14(11-32)	11(8-20)	12(10-19)

For adult patients we observed an anticipation of IRF recovery by 4 days in comparison with NEUT recovery (10 *vs* 14 days), and by one day of IPF in comparison with PLT (10 *vs* 11 days). Patients receiving unrelated grafts experienced further delay in their PLT recovery (13 *vs* 21 days). For paediatric patients we observed an anticipation of IRF recovery by 2 days in comparison with NEUT recovery (13 *vs* 15 days), and by 4 days of IPF in comparison with PLT (11 *vs* 15 days). All paediatric patients receiving any sort of unrelated grafts experienced further delay in their recovery, in particularly CB recipients. In this subgroup we observed an anticipation of IRF recovery by 5 days in comparison with NEUT recovery (11 *vs* 16 days), and by 8 days of IPF in comparison with PLT (14 *vs* 22 days). With this study we conclude that IRF and IPF predict the haematopoietic recovery of patients. For allo-transplanted patients receiving unrelated grafts that prediction is even more noteworthy and clinically very relevant. The results observed in children transplanted with CB allografts are encouraging as they may be the first indication of the success of the transplant, although a large number of patients is needed to confirm these findings. From this study IRF and IPF emerge as potential useful tools in haematopoietic transplantation.

ASSESSMENT OF LIVER FIBROSIS WITH FIBROSCAN IN THALASSEMIA MAJOR POTENTIAL CANDIDATES FOR HEMATOPOIETIC STEM CELL TRANSPLANTATION

A Hamidieh[1], H Poustchi[2], B Shazad[3], M Jalili[3], M Behfar[3], A Jalali[3], R Malekzadeh[2], A Ghavamzadeh[2]
[1]Tehran University of Medical Sciences, Tehran, Iran
[2]Digestive Diseases Research Center - Tehran University of Medical Sciences, Tehran, Iran
[3]Hematology-Oncology & SCT Research Center- Tehran University of Medical Sciences, Tehran, Iran

Background and Aims. To assess the diagnostic accuracy of Fibroscan in patients with β-thalassemia major (TM) who are candidates for hematopoietic stem cell transplantation. **Methods.** The study contained 58 patients prospectively recruited with TM (median age: 8 years; range: 2. 6-20 years; male: 65. 5%). All patients underwent liver stiffness measurement using Fibroscan. The results were expressed in Kilopascal (KPa) units. The specimens were scored according to the Ishak system. The diagnostic value of TE was compared with the histological fibrosis stage using linear discriminant analysis (the area under the receiver operating characteristic curves (AUROCs)). **Results.** Twenty -six patients (44. 8%) had mild fibrosis, 12 (20. 7%) had moderate and 2 (3. 4%) had severe fibrosis. Fibroscan values were significantly correlated with Pesaro's classification for thalassemia (p <0. 001), iron deposition (p<0. 037) and fibrosis stage (p=0. 008). Median Fibroscan values in patients with severe (stage 3-5), mild or no fibrosis were 4. 5 (3. 0-13. 0) kPa and 4. 0 (2. 5-9. 0) kPa (P = 0. 000), respectively. To predict high fibrosis stages (stage ≥ 3) with cut-off of 4. 35 kPa, AUROC was 0. 670 (95% confidence interval [CI]: 0. 508-0. 833) with 76. 9% sensitivity (95% CI: 70. 8-81. 8) and 57. 8% specificity (95% CI: 53. 3-60. 3). **Conclusions.** Fibroscan appears to have a high diagnostic accuracy of fibrosis stage in TM patients who are potential candidates for hematopoietic stem cell transplantation . It can also be used as a valuable tool to follow-up the liver status in patients with TM after transplantation. Further studies with more cases are required to achieve reliable results for practical application.

1867

PROGNOSTIC SIGNIFICANCE OF PRE-TRANSPLANT RESPONSE STATUS IN PATIENTS WITH MULTIPLE MYELOMA

T Toptas[1], I Kaygusuz-Atagunduz[2], C Adiguzel[2], T Firatli-Tuglular[2]
[1]Van Training and Research Hospital, Van, Turkey
[2]Marmara University Hospital, Division of Hematology, Istanbul, Turkey

Background. There are several prospective and retrospective studies exploring the impact of pre-transplant response status on disease outcomes in patients with multiple myeloma. However, Conclusions of these studies are controversial. While almost a half claims that it has a prognostic impact on myeloma endpoints, others found no association. **Aims.** We aimed to investigate the impact of pre-transplant response depth on myeloma outcomes. **Methods.** We retrospectively analyzed the data of a total of 56 patients with multiple myeloma who underwent autologous stem cell transplantation (SCT) between 2000 and 2010 in Marmara University Hospital, Division of Hematology. Response status was defined according to IMWG criteria. Primary endpoint was time to progression (TTP: time elapsed between transplantation and progression or progression-related death). Secondary endpoints were progression-free survival (PFS: time from transplantation to progression or any death), time-to-next-treatment (TNT: time from transplantation to next treatment, relapse, or any death), and overall survival (OS: time from transplantation to any death or last contact). Post-hoc power analysis revealed that study show a hazard ratio (HR) of 0. 5 with a power of 72% and an overall two-sided type I error of 5%, with use of a two-sided log-rank test. **Results.** Time-to-transplantation, median follow-up, and treatment related mortality were 12 (6-36) months, 32 months, and 3. 6%, respectively. For all cohort, median PFS, TTP, TNT, and OS were 25, 32, 47, and 84 months respectively. 5- and 10-year OS were 60. 9%, and 26. 6%. The proportion of patients who achieved ≥ very good partial

response (VGPR) before transplantation was 41. 9%. Post-transplant ratio of patients with ≥VGPR estimated to be 75. 8%. There were no significant differences between patients with a pre-transplant response ≥VGPR and partial response (PR) in terms of PFS (median 33 vs 24 months, p= 0. 3), TTP (not reached vs 25 months, p= 0. 2), TNT (not reached vs 33 months, p= 0. 09), and OS (not reached vs 71 months, p= 0. 8) (Figure 1). **Conclusions.** Patients with multiple myeloma who achieve PR or ≥VGPR before transplantation have similar disease outcomes. Since only 30% of patients will have a ≥VGPR with novel agents, at least PR is a reasonable pre-transplant treatment goal.

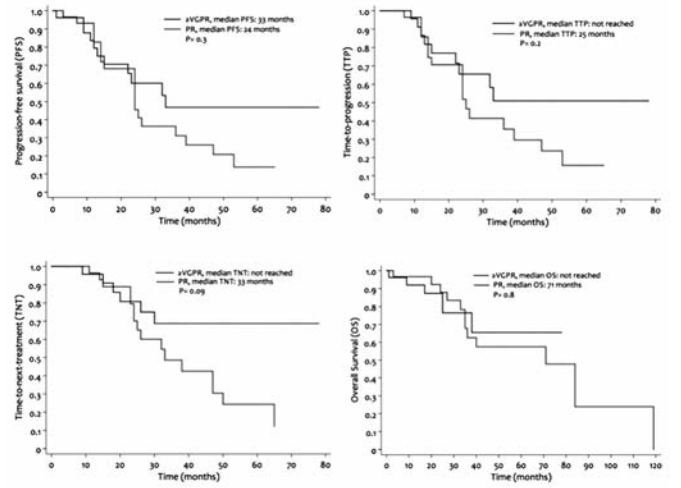

Figure 1.

WHAT IS THE CONTRIBUTION OF HOST-DERIVED CMV IMMUNITY AFTER ALLOGENEIC TRANSPLANTATION FOLLOWING NONMYELOABLATIVE CONDITIONING?

C Menten-Dedoyart[1], E Castermans[2], M Hannon[3], S Ormenese[3], Y Beguin[2], F Baron[3]
[1]ULg belgium, Liège, Belgium
[2]ULg-CHU, Liège, Belgium
[3]GIGA-ULg, Liège, Belgium

Background. It has been suggested that host-derived CMV-specific immunity could persist in patients given grafts following nonmyeloablative conditioning. **Aims.** In the current study, we challenged this hypothesis by assessing chimerism levels among CMV-specific CD8+ T cells around days 40, 100 and 180 after allo-HCT in a cohort of 24 patients given allogeneic grafts after nonmyeloablative conditioning. **Methods.** Data from 24 patients given unmanipulated peripheral blood stem cells (PBSC) after nonmyeloablative conditioning were included in this study. Detection of CMV-specific CD8+ T cells was performed on previously cryopreserved peripheral blood mononuclear cells (PBMCs) according to the combinatorial encoding method of CMV pMHC multimers. CMV specific and unspecific CD8+ T cells were sorted into distinct tubes. DNA was isolated from cell pellets to assess their chimerism. **Results.** Only 4 of 17 CMV-seropositive recipients given grafts from CMV-seronegative donors had a higher by >25% proportion of cells of recipient origin among CMV-specific CD8+ T cells (ranging from 32. 4 to 100%) than among remaining CD8+ T cells on day 100 after transplantation. The 2 patients with CMV-specific CD8+ T cells that were >99% of recipient origin on day 100 had relatively high counts of CMV-specific CD8+ T cells on that day (13. 1 and 14. 7 cells/μL). **Conclusions.** these results demonstrate that high numbers of CMV-specific CD8+ T cells of recipient origin could be present after allo-HCT, although in a minority of nonmyeloablative recipients.

1869

FEASIBILITY OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA OLDER THEN 65 YEARS

A Tempescul, JC Ianotto, JR Eveillard, G Guillerm, C Berthou
Teaching Hospital Brest, Brest, France

Introduction. Autologous peripheral stem cell transplantation is the standard therapy for the treatment of lymphoma into the young patient who expresses poor prognostic factors at diagnosis or at relapse (high IPI). Only few data are available on the feasibility and outcome of such procedures in patients over 65 years. **Aims.** We conducted a single centre, retrospective, study on the feasibility and the results of autologous transplantation in patients carrying a lymphoma, aged 65 or over, compared to younger patients. **Patients and Methods.** Over a period of 10 years we identified 151 patients with lymphoma who performed autologous stem cell transplantation at BREST (France) transplantation centre. 95 patients were under 65 years and 56 patients were older. We compared two populations in terms of number of units of red blood cells and platelets transfused, number of days of neutropenia and incidence of complications related to transplantation procedure. **Results.** No statistically significant difference was seen, between the two populations, for the number of units transfused (CG: 2. 9/3. 7 p - 0. 21 and CPA: 4. 51/4. 18, p - 0. 58). The only significant difference (p - 0. 0006) is the duration of aplasia: 11. 22 days for younger patients and 11. 81 days in elderly patients. The mortality rate associated with the procedure (MRT) is similar in both groups of patients with 2 deaths in each arm. There was no statistically difference between the two populations, regarding the OS (40,91/38. 33, p-0. 11) and DFS (39. 4/33. 18, p-048). **Conclusions.** In our study we found that there was no significant difference between the two populations (over or under 65 years) for the number of units of blood and platelet transfusions. Only the difference of days of neutropenia appears to be significant and it is for the young patient. The autograft procedure remains under certain conditions, a possible treatment option for patients older than 65 years treated for lymphoma.

1870

HEMATOLOGICAL RECOVERY AND EARLY RISK INFECTION: EFFECT ON THE EVOLUTION AFTER AUTOTRANSPLANTATION

E Romero Fernandez, M Morado, M Canales, R Arrieta, A Rodriguez De La Rua
La Paz University Hospital, Madrid, Spain

Background. Absolute lymphocyte count (ALC) < or=500/μl on day(D)15 post-autologous haematopoietic stem cell transplantation (HSCT) has been proposed as an independent risk factor in the outcome undergoing HSCT in patients (P) with hematologic malignancies **Aims.** The aim of study is to compare the influence of ALC, absolute neutrophil count (ANC) and absolute platelet count (APC) recoveries on the risk of early infection (REI) post-HSCT (D< or =30) and survival **Methods.** Medical records of 113 P (59 non Hodgkin lymphoma (NHL), 22 Hodgkin lymphoma (LH) and 32 multiple myeloma (MM)) receiving autologous-HSCT between January 2006 and March 2012 in La Paz University Hospital were reviewed. The analysis of the relationship between hematological recovery post-HSCT (ALC>500/μl on D15, APC>20000/μl on D15 and ANC>500/μl on D12), REI, overall survival (OS) and progression-free survival (PFS) was performed by Mann-Whitney U test, Chi-Square test and log rank test, we also applied survival curves of Kaplan-Meier and Cox regression model **Results.** Median of days required to ALC>500/μl was 14 (range: 12-17), ANC>500/μl was 14 (range: 12-16) and APC>20000/μl was 12(range: 10-15). We found statistically significant differences between REI and ALC500/μl at that D (60% vs. 36%, p=0. 02; OR 2. 69 (CI95%:1. 23-5. 85)) and ANC500/μl at that D (37% vs. 61%, p=0. 0017; OR 2. 73 (CI95%: 1. 22-6. 07)). We found no significant association between REI and APC20000/μl (63%vs. 41%, p=0. 09; OR 2. 50 (CI95%: 0. 95-6. 57)). There is a significant relationship between post-HSCT survival and hematological recovery so that, ALC>500/μl on D15 (n=67) is associated with better PFS and OS, than ALC below this limit (n=46): PFS 65 months (m) (CI95%: 58-72) vs. 31 m (CI95%: 20-41), p<0. 0001 and OS126 m (CI95%:117- 134) vs. 54 m (CI95%: 55-74), p<0. 01; APC>20000/μl on D15 (n=90) is associated with better PFS but no OS, than APC below this limit (n=23): PFS 56 m (CI95%: 48-63) vs. 33 m (CI95%: 18-48, p<0. 007 and OS 118 m (CI95%:108-129) vs. 61 m (CI95%: 47-75), p<0. 116; ANC>500/μl on D12 (n=39) is not associated with better PFS or OS, than ANC below this limit (n=74): PFS 48 m (CI95%: 40-57) vs. 56 m (CI95%: 45-68), p<0. 217 and OS 119 m (CI95%: 104-134) vs. 71 m (CI95%: 65-77), p<0. 787. Multivariate analysis showed that P those to reach ALC 500/μl after D15 and P with HL or MM have higher risk of relapse with HR 4. 56 (CI95%: 2. 3-9. 04), p<0. 001 and HR 2. 56(CI95%:1. 17-5. 63), p=0. 019 **Conclusions.** 1) The study shows that P with ALC<500/μl on D15 have 3 time more probability of REI and P with ANC<500/μl on D12 have 2 time less probability. 2) We confirm positive prognosis impact of ALC>500/μl on the evolution after autotransplantation. 3) No achieve APC 20000/μl on D12, is a worse prognosis factor for PFS but no affect to OS or REI 4) NHL has lower risk of relapse after autologous- HSCT.

1871

AUTOLOGOUS PERIPHERAL BLOOD HEMATOPOIETIC STEM CELL TRANSPLANTATION(HSCT) FOR HEMATOLOGIC MALIGNANCIES IN SHIRAZ,SOUTH OF IRAN

M Ramzi, R Vojdani, H Nourani, M Zakerinia, M Dehghani, H Haghighinejad
Shiraz University of Medical Sciences, Shiraz, Iran

Background. Hematologic malignancy currently represents the main indication for HSCT. clearly, autologous and allogeneic HSCT are established therapies in many of hematologic malignancies. High dose therapy(HDT) supported by autologous HSCT are the preferred choice for lymphoproliferative disorders and multiple myeloma. **Aims.** Bone marrow transplantation was established in Shiraz University of medical sciences in1993. since 2003, stem cell sources from bone marrow changed to peripheral blood in our center and we started peripheral blood autologous stem cell transplantation for hematologic malignancies. In this article we have presented results of autologous stem cell transplantation in our center during 7 years. **Methods.** Between Jan 2004 and Nov 2011, 253 patients with diagnosis of hematologic malignancies including Hodgkin's lymphoma(HD), non-Hodgkin's lymphoma(NHL),Acute myelogenous leukemia (AML)and multiple myeloma(MM)underwent autologous peripheral blood stem cell transplantation in our center in Shiraz university of medical sciences. Patients were treated by intensive chemotherapy followed by reinfusion of non-cryopreserved autologous stem cells. The pretransplant conditioning chemotherapy regimen were CEAM (lomustin,etoposide,cytarabine and melphalan)for Lymphoma,busulfan and etoposide for AML and melphalan for multiple myeloma patients. **Results.** During this time, 68 HD patients with median age 28 years (range;16-50),67 NHL patients with median age 29 years(range;18-55), 74 MM patients with median age 53 years(range;31-70)and 44 AML patients with median age 27(range;17-51) underwent autologous peripheral blood stem cell transplantation. The median time to platelet count > 20×10^9/L was 15 days (range;9-35). The median time to ANC > 0. 5×10^9/L was 12 days (range;8-27). All patients have engrafted and there were not graft failure in this study group. 100 days transplant related mortality rate was 2. 7% in MM, 2. 9% in HD, 4. 4% in NHL and4. 6% in AML group respectively. **Conclusions**. Our data reflects the important role of HDT followed by HSCT in improvement of outcome for a variety of hematologic malignancies in our center. We concluded high dose therapy rescued with non- cryopreserved auto SCT is safe and effective method that is feasible in our patients.

1872

SECONDARY CANCERS FOLLOWING STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

M Muftuoglu[1], N Gurses[1], F Sargin[2], S Kalayoglu-Besisik[2]
[1]Istanbul School of Medicine, Istanbul, Turkey
[2]Istanbul School of Medicine Division of Hematology, Istanbul, Turkey

Background. Hematopoietic stem cell transplantation (HSCT) is an indispensable tool to treat hematologic disorders while secondary cancers may develop as a result of inherent genetic predisposition and high-dose therapy-induced genetic damage. Secondary cancers remain as a devastating late complication following HSCT. We aimed to investigate the frequency and clinical course of secondary malignancies in patients who underwent HSCT and survived more than 100 days. **Methods.** We reviewed the case files of 452 patients (Hematologic malignancy n: 460, Non-malignant hematologic disorders no:9) who underwent allogeneic and autologous stem cell transplantation in our center between 1993 and 2010. One hundred and three patients were excluded from further analysis (Early mortality n:97, insufficient data:6). We recorded type and median time to development of secondary malignancies, primary indications for HSCT and conditioning regimens. **Results.** The eligible 359 patients were subjected to further analysis. Eight patients developed 9 malignancies at a mean of 35. 8 ±3. 8 months (median 24 months, range 4-135 months) following HSCT for a cumulative incidence of 2,2% (Table 1). The mean age at diagnosis of primary disease was 38. 7 ± 13. 1 years while the mean age at diagnosis of secondary malignancies was 41. 6 years. These secondary cancers involved salivary glands (1 mucoepidermoid carcinoma), bone marrow (2 acute myeloid leukemias), brain (primary CNS lymphoma), bladder (1 transitional cell carcinoma), surrenal gland (1 pheochromocytoma), breast (1 invasive ductal carcinoma in situ), peritonial cavity (1 primary peritoneum carcinoma) and thyroid gland (1 papillary carcinoma, follicular variant). All patients with secondary solid cancers were treated successfully whereas patients with secondary hematologic malignancies succumbed to disease progression. **Discussion.** It is a well-known fact that incidences of lymohoma, leukemia, glioblastoma, malignant melanoma, lung cancer and rectal adenodcarcinoma are significantly increased in comparison to sex and age-matched healthy subjects. Risk of developing secondary cancer gradually increases over time. Employment of anti-thymocyte globulin, T-cell depletion, HLA-mismatch, presence of graft versus host disease are found to be related to increased risk of secondary malignancy formation. As a consequence, we recommend that patients be screened for potential secondary cancers. Early diagnosis enables early intervention, thus providing improved survival rates.

Table 1. Demographic and clinical features of patients with secondary malignancies following HSCT.

Patients	Sex/age	HKHN Indication/ Source	Secondary Malignancy	GVHD	Mean time to SM	Management
1	M/42	AML 1.CR/ allo-HSCT	Mucoepidermoid carcinoma	Negative	34 months	Surgery+RT, complete response
2	M/19	Hodgkin's Disease 3.CR/Autologous PBSCT	AML preceded by MDS	Nonapplicable	17 months	Died after Allo-HSCT
3	M/31	AML 1.CR/allo-PBSCT	Primary CNS Lymphoma	Chronic GvHD	4 months	Died, unresponsive to CT+RT
4	M/29	Hodgkin's Disease 2.CR/Autologous PBSCT	AML	Nonapplicable	24 months	Died due to AML
5	M/54	Multiple myeloma partial remission/Autologous PBSCT	Transitional carcinoma of bladder	Nonapplicable	17 months	Surgery, complete response
5	M/54	Multiple myeloma partial remission/Autologous PBSCT	Pheochromocytoma	Nonapplicable	44 months	Surgery, complete response
6	F/47	Multiple myeloma Complete remission/Autologous PBSCT	Invasive ductal carcinoma in situ	Nonapplicable	24 months	Surgery, complete response
7	F/56	Multiple myeloma Complete remission/Autologous PBSCT	Papillary carcinoma, follicular variant	Nonapplicable	23 months	Surgery+ RAI, complete response
8	F/32	Chronic myeloid leukemia/ Chronic Phase	Primary Peritoneum Carcinoma	Nonapplicable	135 months	Surgery and chemotherapy, complete response

POST-TRANSPLANT CYTOMEGALOVIRUS REPLICATION DETECTED BY REAL-TIME PCR IS ASSOCIATED WITH A DECREASED RELAPSE RISK: A JAPANESE SINGLE INSTITUTE STUDY

Y Takiuchi[1], H Hashimoto[2], T Takeda[1], F Funayama[1], Y Yamauchi[1], A Aoki[1], O Ono[1], A Arima[1], N Nagano[1], T Tabata[1], M Matsushita[1], I Ito[3], T Takahashi[3], N Nagai[4], S Shimizu[5], I Ishikawa[1]

[4]Kansai Electric Power Hospital, Osaka, Japan
[5]Tokyo Medical and Dental University Medical Research Institute, Tokyo, Japan

Background. Recent publication from Germany reported cytomegalovirus (CMV) replication early after allogeneic stem cell transplantation (allo-SCT) decreased relapse risk in AML patients. In Japan, unlike Western countries, over two-third of adults have been infected with CMV in their childhood. The relevance of CMV replication to relapse might be different. **Aims.** To evaluate the relevance of CMV replication, which was evaluated by using real-time polymerase chain reaction (PCR), to relapse after allo-SCT. **Methods.** We retrospectively analyzed 72 cases with hematological malignancy who underwent allogeneic transplantation between April 2008 and November 2011 in our hospital. CMV replication was monitored weekly. We used PCR to detect CMV replication because pp65 antigenemia is not suitable at the time of low WBC count. We set the cut-off value of CMV positivity as 500copy/ml. Preemptive viral therapy using ganciclovir or foscarnet was initiated to CMV-positive patients. Relapse of malignancy was evaluated by bone marrow examination performed at day 28, 100, and as needed thereafter. As for lymphoma cases, PET-CT was performed when relapse was suspected. This study was approved by institutional review board. **Results.** A total of 53 patients were CMV-positive and 19 were negative. Each CMV-positive/negative group contained 33/14 cases of myeloid malignancy (AML, MDS, CML, MPD) and 9/3 cases of ALL, 8/0 cases of NHL and 3/2 cases of other diseases. There were no significant difference as for patients' sex, age, donor type, donor/recipient CMV serology, disease status, stem cell source, and preparative regimen within both groups. A total of 16 patients relapsed at a median of 126 days□range, 28-755 days□. Although univariate analysis did not show statistical significance, the cumulative incidence of relapse (CIR) at one year tended to be lower in CMV-positive group than CMV-negative one (18. 7% vs. 34. 8%, HR 0. 58; 95% CI 0. 22-1. 50; *P* =0. 26). In the each subgroup of patients with myeloid malignancy (n=47), advanced disease status (n=45), surviving free of relapse at day100 (n=25), CIR also tended to be lower in CMV-positive group. Univariate analysis in all patients also indicated that myeloablative preparative regimen and non-advanced disease status had a tendency to decrease CIR (*P* <0. 1). Multivariate analysis of

CIR in all patients which included preparative regimen, disease status and CMV positivity as covariates showed that CMV positivity was independently correlated with reduced relapse risk (HR 0. 388; 95% CI 0. 15-0. 97; *P* =0. 045). In this study, most of CMV-positive patients were in advanced disease status, which might be the reason why univariate analysis of CMV positivity did not show significant result. **Conclusions.** This is the first report that revealed CMV replication, demonstrated by real-time PCR, is an independent factor associated with reduced relapse risk after allo-SCT.

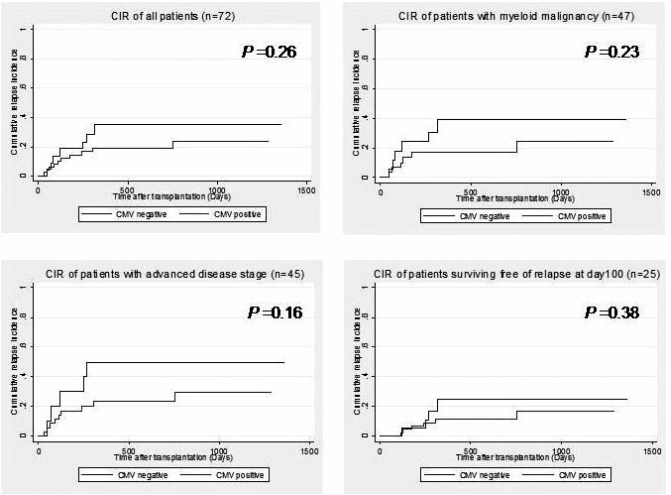

Figure 1. Cumlative relapse incidence [CIR] of all patients and subgroups.

[6]Universidad de Salamanca, Salamanca, Spain

Background. CD3+CD4-CD8- T-cells can suppress alloimmune responses. However, the mechanisms by which these cells regulate immune responses and their role in the immune recovery after hematopoietic stem cell transplantation (HSCT) remain unknown. **Aims.** To compare the distribution of different subsets of T-cells and NK cells after unrelated allogeneic transplant in patients receiving umbilical cord blood (UCB), bone marrow (BM), or peripheral blood stem cells (PBSC). **Methods.** T-cells (CD4+/CD8+/CD4-8-/CD4+8+), and NK cells subsets (lineage negative and 56++16-/56+16++) were quantified by multiparametric flow cytometry at 6 sequential time points (at engraftment, and at days 3, 7, 14, 21 and 60 after engraftment). Overall, 34 patients (19 male; median age 13y, range 1-63y) receiving a UCB (n=15), BM (n=14) or PBSC (n=5) unrelated HSCT were studied. The most common diagnosis was acute leukemia (ALL, 12 cases; AML, 10; CML, 5; aplastic anemia/MDS, 6; Hodgkin lymphoma, 1; SCID, 1). Most patients received myeloablative conditioning (MAC) regimens (73%). Antithymocyte globulin (ATG) was used in 38% and total body irradiation (TBI) in 41% of cases. Median time to neutrophil engraftment was 18 days (range: 12-45). Median follow up time was 6 months. **Results.** As compared to BM/PBSC, UCB was associated with a delayed neutrophil engraftment (28 days vs. 17 days; p=. 01), and a trend to lower counts of all T-cell in the first 3 weeks. At day 14 after engraftment, the median number of total T CD3+ cells was 149/uL for UCB vs. 828/uL for BM/PBSC recipients (p=. 0004). The median number of CD4-CD8- T-cell was significantly lower in UCB recipients as compared to BM and PBSC at all times during the first 3 weeks (median 2/uL vs. 22/uL at day 3, p=. 001; 2/uL vs. 13/uL at day 7, p=. 003; 3/uL vs. 27/uL at day 14, p=. 005; and 3/uL vs. 45/uL at day 21 after engraftment, p=. 04). At day 60, Total T and CD4- 8- cells counts were comparable between UCB and BM/PBSC recipients (11/uL vs. 30/uL, p=. 13). No significant differences were observed between both groups as regards the distribution of NK cells subsets at any time. There was no significant influence of MAC, ATG or TBI on the differences in T-cell counts observed between the two groups. **Conclusions.** UCB recipients have lower counts of CD4-/CD8- T-cells during the first weeks after HSCT as compared to BM or PBSC recipients. The impact of this finding on the transplant outcome remains to be determined.

1875

RISK-ADAPTED DONOR LYMPHOCYTE INFUSION TO PREVENT RELAPSE IS INDICATED IN ALL PATIENTS WITHOUT GVHD AFTER T CELL DEPLETED MYELOABLATIVE ALLOGENEIC STEM CELL TRANSPLANTATION FOR AML

M Eefting, P von dem Borne, C Halkes, S Kersting, E Marijt, J Veelken, J Falkenburg
LUMC, Leiden, Netherlands

Background. The aim of allogeneic stem cell transplantation (HSCT) for acute myeloid leukemia (AML) is curation by a graft-versus-leukemia (GVL) effect mediated by alloreactive donor T-cells. However, donor T-cells may also induce graft-versus-host-disease (GVHD) after HSCT. T-cell depletion (TCD) reduces GVHD but increases relapse rates. Relapse may be prevented by pre-emptive post-HSCT donor lymphocyte infusion (DLI) by reintroducing the GVL-effect. Early DLI may be effective but can cause severe GVHD, whereas late DLI will cause limited GVHD but early relapses may occur. Patients with full-donor chimerism (FD) have been reported to have a low incidence of relapse, whereas patients with mixed-chimerism (MC) are considered to have a high risk of relapse. **Aims.** In this study, we investigated whether in AML/MDS patients following myeloablative (MA) conditioning DLI could be postponed to 6 months after TCD-HSCT. In addition, we investigated whether in patients with FD chimerism pre-emptive DLI could be omitted. **Methods.** 39 patients underwent MA TCD-HSCT for AML (n=34), high risk MDS (n=4, median IPSS 2) or CMMol (n=1) between 2002 and 2007. Of the 34 AML patients, 7 had a very-poor-risk monosomal-karyotype (VPR), and 25 were poor-risk (other unfavorable cytogenetics/molecular abnormalities and/or transplantation in CR2). Conditioning was performed with cyclophosphamide-TBI, TCD with CD34+cell-selection (n=6) or alemtuzumab *in vitro* (n=33). Six months after HSCT patients were evaluated for active GVHD, i. e. requiring systemic immune-suppression. In the absence of GVHD chimerism was measured. In case of MC, patients with a related donor (n=32) were scheduled to receive 3. 0x10^6 CD3+cells/kg and patients with an unrelated donor (n=7) received 1. 5x10^6 CD3+cells/kg. Primary endpoint was relapse, secondary endpoint was non-relapse mortality. **Results.** After HSCT, only 8% of patients developed grade 3-4 acute GVHD. During the first 6 months, 4 patients (10%) died of non-relapse mortality (NRM) and 8 patients (21%) relapsed (4 poor-risk and 4 VPR). Six of the remaining 27 patients had active GVHD at 6 months, and were not eligible for DLI. Twelve patients were eligible for DLI because of MC. Three of these 12 patients relapsed before DLI was given (1 poor-risk and 2 VPR). Median time to DLI was 210 days (range 143-315 days). After DLI, 2 patients suffered a relapse (1 poor-risk, 1 MDS) and 2 died of NRM. Nine patients without GVHD were FD and therefore initially did not receive pre-emptive DLI. Four of these 9 patients relapsed during follow-up (all poor-risk). Another 4 patients converted to MC and were treated with DLI, of whom none relapsed. After DLI, only one patient developed >grade 1 acute GVHD. Relapses were observed in patients without conversion in chimerism only. **Conclusions.** Relapses frequently occurred within the first 6 months after myeloablative TCD-HSCT in patients with very-poor-risk AML. These patients should receive DLI early after transplantation. Furthermore, the high relapse rate in patients with FD chimerism without GVHD indicates a lack of GVL-effect in these patients, indicating that these patients should also be treated with pre-emptive DLI.

1876

EFFICACY OF APREPITANT IN PREVENTING HIGH-DOSE MELPHALAN-INDUCED NAUSEA AND VOMITING IN PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

M Sakurai, T Mori, J Kato, A Yamane, S Kohashi, S Okamoto
Keio University School of Medicine, Tokyo, Japan

Background. High-dose melphalan has been commonly used alone or in combination with other agents for the conditioning of hematopoietic stem cell transplantation (HSCT). High-dose melphalan has a potential to cause both acute and delayed unacceptable emesis. Although melphalan is categorized as a moderately emetogenic agent, there is little data regarding the level of emetogenecity of its high-dose administration. Therefore, an optimal antiemetic regimen has yet to be established in this setting. **Aims.** The primary aim of this study is to evaluate the antiemetic efficacy of aprepitant in patients receiving

high-dose melphalan as a component of conditioning of HSCT. **Patients and Methods.** Fifty-three patients who underwent allogeneic HSCT at Keio University Hospital (Tokyo, Japan) after being conditioned with high-dose melphalan (70 mg/m^2/d for 2 days) in combination with fludarabine (125 mg/m^2) were retrospectively evaluated. Data were collected from the institutional data bases and the medical records. Until the introduction of aprepitant, 40 patients received only the standard antiemetic regimen consisting of ondansetron 4 mg every 12 hours and iv steroid on the 2 days of melphalan administration (Control). Thirteen patients received aprepitant orally for 5 days (125 mg followed by 80mg for 4 days) in addition to the standard regimen (Aprepitant group). Incidence and number of vomiting from the first day of melphalan administration through 10 days after transplantation were compared between the two groups. **Results.** There were no significant differences in age, sex, diagnosis and source of stem cells between the two groups. The complete protection (no emesis/vomiting) rate was 92% (12 of 13 patients) in Aprepitant group which was significantly higher than 33% (13 of 40) in the Control (P<0. 001). One patient in Aprepitant group vomited only once, while median number of vomiting during the observation period was 2 (range: 0-37) in the Control (P<0. 001). There were no significant side effects considered due to aprepitant. **Conclusions.** These results strongly suggest that addition of aprepitant could be superior to the standard antiemetic regimen with ondansetron in preventing high-dose melphalan-induced nausea and vomiting.

1877

HIGH RATE OF EBV REPLICATION FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION - PRELIMINARY DATA OF A ROUTINE MONITORING POLICY

S Gerull, M Stern, C Bucher, D Heim, J Halter, H Hirsch, J Passweg
University Hospital Basel, Basel, Switzerland

Epstein-Barr Virus (EBV) reactivation is an important complication following allogeneic stem cell transplantation (HSCT) with a wide range of clinical presentations, ranging from asymptomatic replication to aggressive post-transplant lymphoproliferative disorder (PTLD). While the latter clearly requires systemic treatment, the value of asymptomatic EBV replication remains unclear. Furthermore, while monitoring of high-risk patients is recommended, routine monitoring of all patients is not always performed. Following 2 fatal cases of highly aggressive PTLD, we have installed routine monitoring following HSCT in our transplant unit. Here we present preliminary data of this monitoring policy. We performed a retrospective analysis of the first 30 patients who received an allogeneic transplant after implementation of routine monitoring. EBV load was measured in whole blood using a real-time polymerase-chain-reaction assay. Monitoring was performed weekly during the first month posttransplant and at least monthly thereafter. In case of EBV replication, monitoring frequency was increased, and patients were regularly examined for signs of PTLD. The decision to administer preemptive treatment in the absence of PTLD was made at the discretion of the treating physician and was based on clinical condition as well as the absolute level of EBV load. Patients with biopsy proven PTLD were treated with rituximab. Patient characteristics are shown in Table 1.

Table 1.

	n=30
Disease	
Acute myeloid leukemia	7
Myelodysplastic syndrome	6
Acute lymphatic leukemia	4
Multiple myeloma	4
Lymphoma	6
Myeloproliferative neoplasm	1
Aplastic anemia	2
Donor	
Identical sibling donor	10
Matched unrelated donor	15
Mismatched unrelated donor (9/10)	3
Haploidentical donor	2
Stem cell source	
Peripheral blood stem cells	26
Bone marrow	4
Conditioning	
Myeloablative	19
Reduced intensity	11
Containing ATG	16

Patients were transplanted between May and November 2011. After a median follow up of 4. 5 months (1-6), 17 (57%) patients showed EBV replication posttransplant. The median time to first positive result was 28 days (5-146). The median EBV peak level was 14'237 (range 541-3'257'101). 16 patients showed no clinical signs of PTLD, while one patient had biopsy proven PTLD. This patient and 4 others were treated with 1 to 5 doses of rituximab. In the patients without PTLD, the decision to treat was based on poor clinical condition in two patients with rapidly progressing hepatopathy and fulminant acute respiratory distress syndrome (ARDS), respectively, though it remained unclear whether the poor condition was associated with EBV replication. One patient was treated due to intense immunosuppression following treatment for severe GvHD, and finally one patient was treated due to rapidly rising EBV levels following anti-thymocyte globuline (ATG). Of the 30 patients, 6 died due to relapse (n=2), GvHD (n=1), pulmonary venoocclusive disease (n=1), sepsis (n=1) and ARDS (n=1). Of the deceased patients, 4 had had EBV replication, but no deaths were deemed to be attributable to EBV. Small patient numbers precluded extensive analysis of risk factors for EBV replication. However we observed a strong correlation of EBV replication with ATG-containing conditioning, a well known risk factor, with EBV replication in 14 of 16 patients (88%) who received ATG compared to 3 of 14 (21%) patients who did not receive ATG (p=0. 001). In summary, in this preliminary analysis of routine EBV monitoring, we observed a high rate of EBV replication in 57% of patients, but only one case of PTLD, with ATG being an important risk factor. However, only a randomized trial can show whether EBV monitoring and preemptive treatment strategies lead to decreased morbidity and mortality.

1878

COMPARATIVE STUDY OF LARGE VOLUME APHERESIS EFFICACY IN MULTIPLE MYELOMA AND LYMPHOMA

R Pérez-López[1], A García-Hernández[2], MJ Majado[2], M Blanquer[2], MJ Romero[1], V Cabañas-Perianes[2], C Funes[2], E Salido[2], J Moraleda[3]
[1]Hosital General Universitario Rafael Mendez, Lorca, Murcia, Spain
[2]Hospital U Virgen de la Arrixaca, Murcia, Spain
[3]Universidad de Murcia, Murcia, Spain

Background and Objectives. In the mobilization of hematopoietic progenitor cells from the bone marrow, apheresis has been described to have a mobilizing effect, so that the processing of more than three volume blood volumes increase the yield of peripheral blood progenitor cells (PBPCs). For this reason large volumes apheresis (LVA) are processed in some centres, independently of the pathology. **Aims.** The aim of this study is to establish if harvest efficiency of LVA varies according to the diagnosis. Multiple myeloma (MM) and Lymphoma were studied because they are the most frequent indication of autologous transplant. Materials and **Methods.** LVA performed in the past ten years in our hospital are reported. PBPCs were obtained using a continuous blood cell separator (Fenwal CS3000; Baxter, Deerfield, IL). Four times the calculated blood volume was processed in each apheresis. Mononuclear cells (MNC), CD34+ cells and clonogenic CFU-GM, BFU-E and CFU-GMM measures were performed: in peripheral blood pre-apheresis, in the product obtained after the first two volumes (1st bag) and after the second two volumes (2nd bag). Total pre-apheresis values (TPAV) were calculated according to the estimated total blood volume of the patient. Recovery of these variables in each one of the two bags was calculated as percentage of TPAV. Student-t test was used for comparison between MM and Lymphoma group results. **Results.** A total of 150 apheresis, performed to 61 patients with MM, and 184 performed to 68 patients with Lymphoma (50NHL and 18 HD) were included in the study. Results are shown in the following Table 1.

Table 1.

Variables	Lymphoma (n=184)	Multiple Myeloma (n=150)	p
CD34+ cells x10^9/L Pre-apheresis	10.545±1.73	22.05±2.61	<0.001
CD34+ cells Recovery 1st bag (%)	111.44±10.14	100.43±6.20	0.378
CD34+ cells Recovery 2nd bag (%)	133.03±8.05	134.36±10.99	0.921
MNC Recovery 1st bag (%)	391.80±224.88	155.63±15.28	0.356
MNC Recovery 2nd bag (%)	267.27±57.71	371.95±85.45	0.295
CFU-GM Recovery 1st bag (%)	308.47±51.26	378.34±60.83	0.377
CFU-GM Recovery 2nd bag (%)	383.87±83.62	340.42±56.28	0.681
BFU-E Recovery 1st bag (%)	272.13±54.67	204.51±42.44	0.323
BFU-E Recovery 2nd bag (%)	321.02±93.86	222.04±34.69	0.296
CFU-GEMM Recovery 1st bag (%)	317.51±60.01	332.99±81.60	0.880
CFU-GEMM Recovery 2nd bag (%)	562.53±194.47	361.82±62.67	0.312
Progenitor cells recovery after the first two blood volumes processed (1st bag) and after the second two volumes (2nd bag), expressed as mean± standard error of the mean			

CD34+ cells pre-apheresis were significantly higher in MM (22. 05 CD34+ cells

x10^9/L) than in lymphoma (10. 54 CD34+ cells x10^9/L), p < 0. 001. CD34+ cells recoveries were significantly higher in the second bags compared with the first ones in both pathologies (p < 0. 001). However, no significant difference in LVA efficacy in recovery of CD34, MNC and colony forming units (CFU-GM, BFU-E and CFU-GEMM) was found between MM and lymphoma. **Conclusions.** LVA is equally effective in these patients, independently of the pathology; more than 100% of the TPA values are recovered in each one of the two bags. The 2nd bag recovery (equal or higher than the 1st) corroborates the mobilizing role of the apheresis procedure.

1879

AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION IS A HIGHLY EFFECTIVE SECOND LINE OF TREATMENT FOR PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

M Krawczyk-Kulis, A Kopinska, I Grygoruk-Wisniowska, G Helbig, S Kyrcz-Krzemien
Medical University of Silesia, Katowice, Poland, Katowice, Poland

Diffuse large B-cell lymphoma (DLBCL) remains one of the most frequently seen non-Hodgkin lymphoma (NHL) with an aggressive disease course. It estimates that only 40-50% of patients (pts) may be cured with chemo - and radiotherapy; the remaining pts subset remains partially chemosensitive or resistant. High dose chemotherapy (HDT) followed by autologous haematopoietic stem cell transplantation (AHSCT) is a method of choice for the pts who didn't achieve complete remission (CR) after R-CHOP or CHOP treatment. We present 80 pts with DLBCL who were underwent AHSCT between January 1999 and April 2011 in our Department. There were 47 male and 33 female, with a median age of 52. (range 18-68 yrs). Ann Arbor staging at diagnosis was as follows: II- (n=11), III- (n=17), IV- (n=32); 48 of pts manifested B-symptoms. 50 of pts had an aged-adjusted IPI 2 or 3, 8 pts - IPI 4. Clinical manifestation at diagnosis included: hepatomegaly (n=16), splenomegaly (n=19), enlargement of the lymph nodes (n=39), bone marrow infiltration (n=7), lung infiltrates (n=5), digestive system involvement (n=9), CNS (n=4), tonsils (n=3). Initially, all were treated CHOP but 65 of them received chemotherapy with rituximab and achieved partial response (PR) which was defined as the reduction of measurable disease by ≥50% without the appearance of any new lesions. Patients with PR proceeded to high dose chemotherapy (HDT) followed by AHSCT. Stem cells were collected from peripheral blood after IVE chemotherapy (IVE - ifosfamide 3g/m2 iv in 1-3d, etoposide, epirubicine 50mg iv in1d) in 67 patients, in 9 with other treatment and subsequent administration of granulocyte-colony stimulating factor (G-CSF) at a dose of 10ug/kg/d, starting from +5 day of chemotherapy till the last day of collection. G-CSF alone (10ug/kg/d) was used in 4 remaining patients. Collections were performed using Optia Spectra. All patients collected the sufficient number of CD34+ cells for AHSCT procedure. Conditioning regimens preceeding AHSCT consisted of CBV in 73 cases, BEAM in 6 and LACE in one. A median number of transplanted CD34+ cells was 3,97 (1. 25 - 35. 76x10^6/kg). All patient successfully engrafted. Hematopoietic recovery was as following: WBC count > 1,0x10^9/L after median of 12 days (range 8-16 days),ANC> 0,5x10^9/L after median of 14 days (range 8-17 days) and platelet count >20x10^9/L after median of 14 days (range 7-21 days). None of pts die due to AHSCT (TRM 0%). The major complications after AHSCT were rare and included: bacterial infections of the respiratory tract (n=15), viral infections (n=10), oral mucositis (n=9). 145 months' disease free survival (DSF) was estimated to be 86% with a 145 months' overall survival of 88%. 69 patients achieved CR after AHSCT (86,3%). Six pts underwent second AHSCT and 4 of them achieved CR. At the last contact, 75 pts are alive with a median follow-up period of 56 months (range 3-145). 5 patients died due to disease progression. HDT followed by AHSCT seems to be highly effective and safe procedure for DLBCL patients.

1880

THE SECOND AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION IS A HIGHLY EFFECTIVE TREATMENT FOR MULTIPLE MYELOMA PATIENTS WHO DIDN'T ACHIEVE COMPLETE REMISSION AFTER THE FIRST AHSCT

M Krawczyk-Kulis, I Grygoruk-Wisniowska, A Kopinska, G Helbig, G Bober, S Kyrcz-Krzemien
Medical University of Silesia, Katowice, Poland, Katowice, Poland

High dose chemotherapy (HDT) followed by autologous haematopoietic stem cell transplantation (AHSCT) is a standard method of treatment for the patients (pts) with multiple myeloma (MM) under 70 year old. This therapy prolongs disease free survival and time to relapse. In our Department 298 pts with MM were underwent AHSCT till April 2011, what was 21% of whole 1405 haematopoietic stem cell tansplantation. 56 pts who didn't achieve complete remission(CR) after the first AHSCT were undergone the second AHSCT. Stem cells were collected from peripheral blood after IVE (ifosfamide 3g/m2 iv in 1-3d, etoposide, epirubicine 50mg iv in1d) or Endoxan 2,0-4,0g/m^2 chemotherapy and subsequent administration of granulocyte-colony stimulating factor (G-CSF) at a dose of 10ug/kg/d, starting from +5 day of chemotherapy till the last day of collection. Collections were performed using Optia Spectra. The second transplantation were underwent in VGPR (33%), PR(n= 56%), SD (11%). Tandem transplantation was performed for 90 days from the first AHCT in 8 pts, and the other underwent the second AHSCT within the next 3 months. The conditioning regiments preceeding AHSCT in all pts consisted of Melfalan 140-200mg/m^2. The median number of transplanted CD34+ cells was 4,6 (1. 8 - 16,7x10^6/kg). All patient successfully engrafted. Hematopoietic recovery was as following: WBC count > 1,0x10^9/L after median of 14 days (range 12-20 days) and platelet count >50x10^9/L after median of 15 days (range 12-21 days). The major complication after AHSCT was mucositis which was observed in 50%pts (n=28). None of pts died due to AHSCT (TRM 0%). 10 years' overall survival for tandem AHSCT estimated 52% in comparison to37% for single AHSCT (p=0,03). The tandem AHSCT procedure seems to be safety and highly effective therapy for prolongation overall survival in myeloma multiple patients, who didn't achieved CR after first autologous transplantation.

1881

EFFICACY OF SUPLATAST TOSILATE AND THE MOLECULAR MECHANISM OF PRURITUS IN POST-TRANSPLANT CHILDREN

H Yagasaki, M Kato, H Shichino, M Chin, H Mugishima
Nihon University, Tokyo, Japan

Background. Patients who undergo stem cell transplantation often develop skin pruritus. For these patients, we have tried various drugs including antihistamines and anti-allergic medications, but they have shown poor efficacy. Suplatast tosilate has recently been developed as a unique treatment that selectively inhibits the production of Th2-type cytokines, such as IL4 and IL5, which reduces the production of IgE and the infiltration of eosinophils into tissue. To date, suplatast tosilate has been licensed only in Japan and authorized exclusively for asthma and atopic dermatitis. Because of the specificity of its pharmacological action, we performed a pilot study of suplatast tosilate treatment with 7 post-transplant children with pruritus. **Aims.** To elucidate the clinical efficacy of suplatast tosilate for post-transplant pruritus and to retrospectively identify biomarkers or factors associated with the outcome of this treatment. **Methods.** Seven patients who developed pruritus after stem cell transplantation (5 boys and 2 girls aged 8 months to 12 years) received suplatast tosilate (6-8 mg/kg/day). The clinical response was compared before (point 1) and at 7 days after the treatment (point 2). In addition, the lymphocyte count, Th1/Th2-type lymphocyte fraction, eosinophil count, and the level of Th2-type cytokines (IL4 and IL5) in the peripheral blood were measured at both points. **Result.** Itching disappeared completely within 7 days after treatment in 3 of 7 patients (UPN1, UPN2, UPN3). All 3 patients who achieved a clinical response presented with pruritus within 100 days after transplantation, and 2 patients presented with acute graft *vs* host disease (GVHD). In these 2 patients, the level of IL5 decreased after treatment (10. 3 pg/mL at point 1 and < 3. 9 pg/mL at point 2 in UPN1, 31. 2 pg/mL at point 1 and < 3. 9 pg/mL at point 2 in UPN3); whereas the Th1/Th2 ratio increased (2. 3 at point 1 and 3. 8 at point 2 in UPN1, 1. 8 at point 1 and 14. 2 at point 2 in UPN3). In contrast, the total lymphocyte count, eosinophil count, and the levels of IL4 and IgE did not change significantly. **Conclusions.** Suplatast tosilate may have a promising effect in patients who present with intractable pruritus with acute GVHD and a high level of IL5. The observation that the proportion of Th2-type lymphocytes and the level of IL5 decreased in 2 patients who achieved a complete response suggests that the abnormal T cell profile in the early stage after transplantation may be involved in the pathophysiology of pruritus. Although such pruritus is often neglected, the use of this drug may obviate the additional use of steroids to suppress immune reconstitution and improve patients' quality of life. The present results are encouraging for children with post-transplant pruritus, suggesting a large prospective study is warranted to better determine the efficacy of this treatment.

1882

SUCCESSFUL STEM CELL TRANSPLANTATION IN HOMOZYGOUS ALPHA-THALASSEMIA 1: THE FIRST CASE IN ASIA

B Pongtanakul[1], K Sanpakit[2], V Chongkulwatana[1]
[1]Siriraj Hospital, Bangkok, Thailand
[2]Department of Pediatrics, Bangkok, Thailand

Homozygouse alpha-thalassemia 1 is the most severe thalassemia disease. This group of patients presents with hydrops fetalis and always dies before or shortly after birth. We reported successful stem cell transplantation in homozygouse

alpha-thalassemia 1. A Thai girl was born at 32 weeks of gestational age (birth weight 1,300 gm) with hydrops fetalis by cesarean section. Her mother was 33 years old came to our hospital because of toxemia of pregnancy and prenatal ultrasonography showed hydrops fetalis with massive ascites. Her hemoglobin at birth was 6. 8 g/dl. She was intubated, abdominal, pleural paracentesis and total blood exchange transfusion immediately after birth. Her hemoglobin typing before total blood exchange transfusion was 100% of hemoglobin Bart's and DNA analysis showed homozygouse alpha-thalassemia 1 (South East Asian deletion). After she was stable from preterm complications, she was started on hypertransfusion every 3-4 weeks and kept pre-transfusion hemoglobin at 9-10 g/dl since the age of 3 months. She has 6/6 HLA matched with her older sister. She was underwent stem cell transplantation at the age of 1 year and body weight of 9. 6 kg. The conditioning regimen consisted of busulfan 1. 2 mg/kg/dose every 6 hours intravenously for 4 days and cyclophosphamide 50 mg/kg/day for 4 days. GVHD prophylaxis was cyclosporine and short course metrotrexate. The stem cell source was bone marrow and total CD 34 counts was 9. 41x10^6cells/kg. Her transplantation complications were febrile neutropenia and mucositis. She had WBC engraftment at day+17 and DNA showed full donor chimerism at day+25. On day+112, DNA showed mixed chimerism with 41% of recipient's DNA but hemoglobin was still stable. Cyclosporine was stopped and she received donor lymphocyte transfusion (DLI) at the dose 1x10^7cells/kg of CD3 from her sister every 2 weeks. After 4 times of DLI, she could achieve full donor chimerism. Now, she is 4 years old with post transplantation for 3 years and her DNA is still full donor chimerism. Her hemoglobin is 13 g/dl, normal hemoglobin typing and she never receives blood transfusion for almost 2. 5 years. Her developmental milestones are up to her age. **Conclusions.** Homozygouse alpha-thalassemia 1 can be cured with stem cell transplantation. Preterm delivery with immediate total blood exchange transfusion, hypertransfusion and proceed to stem cell transplantation is possible treatment strategy to cure from this fatal disease. From our knowledge, this is the first successful stem cell transplantation in homozygouse alpha-thalassemia 1 in Asia.

1883

ALLOGENEIC STEM-CELL TRANSPLANTATION FOR THERAPY-RELATED ACUTE MYELOID LEUKEMIA (T-AML) AND MYELODISPLASTIC SYNDROME (T-MSD): A SINGLE CENTER EXPERIENCE.

B Vannata[1], L Laurenti[1], P Chiusolo[1], F Sorà[1], N Piccirillo[1], I Innocenti[1], E Metafuni[1], J Bajer[2], MT Voso[1], S Sica[1], G Leone[1]
[1]Hematology Institute Università Cattolica Roma, Roma, Italy
[2]Istituto di Genetica, Università Cattolica Roma, ROMA,Italy, Rome, Italy

Background. WHO 2008 defined Therapy-related myeloid neoplasm category includes acute myeloid leukemia (t-AML), myelodisplastic syndrome (t-MDS) and myelodisplastic/myeloprolipherative neoplasms (t-MDS/MPN) occurring after chemo- and/or radiotherapy administered to treat a previous neoplasms or a non neoplastic disorders. They account for 10-20% of all cases of AML, MDS and MDS/MPN. The prognosis of these patients is worse than their de novo counterpart, with a 5-year overall survival (OS) of less than 10%. **Aims.** Our retroprospective study has the purpose to analyse the role of allogeneic stem cell transplantation (aSCT) in this setting of diseases. **Methods.** Our analysis includes 17 patients (10 female,7 male) with median age of 53 years (range 29 - 64), observed at ourInstitute of Hematology, receiving aSCT between September 1999 and January 2012. All patients were treated for a primary neoplasm with chemo- and/or immuno- and/or radiotherapy (median number of 2 lines of therapy). Primary neoplasms consisted of 7 hematologic malignancies (2 B-CLL/SLL, 1 low-grade NHL, 3 DLBCL, 1 HL) and 10 solid tumors mainly breast cancer (7/10). The median time between the first treatment to tAML/tMDS/MPN was 33 months (range 12-144 months). Seven patients had AML, 9 MDS and 1 Ph+ ALL. Karyotype was available for 14/17 patients: 2 abnormalities of chromosome 7, 4 normal karyotype, 2 complex karyotype, 1 patient with 16 monosomy/+13, 1 del(11)(q14;q23), 1 t(9;22), 1 t(9;16), 1 del(20) and 1 was hypodiploid. Thirteen/17 patients received an induction treatment before aSCT: 10 patients chemotherapy, 2 5-azacitidine, 1 both treatments. Five/17 patients (29%) received conditioning regimen in complete remission (CR). A myeloablative conditioning (MAC) was used in 29. 5% of patients (BuCy2), while a nonmyeloablative transplantation was preferred for the remaining 70. 5% (8 patients FluTTMel, 4 BuFlu). GVHD prophylaxis included cyclosporine and MMF in more than 50% of the patients. All 9 patients receiving matched unrelated donor (MUD) aSCT were treated with additional immunosuppressive therapy. G-CSF mobilized peripheral blood hematopoietic stem cells were used in all patients. Median HCT-CI was 3 (range 0-3). **Results.** Three patients died within one month after aSCT (17. 7%). Early deaths were attributable to infectious complications and acute GVHD. Two patients are too early to be evaluated. Among 12 surviving at least 100 days after aSCT we reached a response rate of 83% (10/12). Two patients relapsed after 4 and 12 months respectively after aSCT and both of them died from their disease at 3 and 5 months respectively. At a median follow-up of 27 months (range 4-136), 6 patient are alive in cCR (35%). **Conclusions.** As reported in the literature the only curative option in these patients is represented by aSCT. We report data from a small series referring to our centre. All patients eligible for aSCT underwent eventually transplantation. Despite an high TRM, high risk cytogenetic and disease status at transplantation (71% with active disease), 6 patients (35%) are in cCR at a median FUP of 27 months. We confirm that aSCT is a feasible approach although this subset of patients per se has a high HCT-CI.

1884

THE COMBINATION OF TACROLIMUS AND SIROLIMUS IN HIGH-RISK ALLOGENEIC HSCT WITH BU-FLU CONDITIONING

SK Park[1], SH Kim[1], JH Won[1], DS Hong[1], SB Bae[1], J Yun[1], KH Kim[1], HJ Kim[1], HS Park[1], JH Moon[2], SK Sohn[2]
[1]Soonchunhyang University Hospital, Bucheon, South-Korea
[2]Kyungpook National University Hospital, Daegu, South-Korea

Background. GVHD remains a major cause of morbidity and mortality after allogeneic HSCT. The combination of sirolimus (Sir) and tacrolimus (Tac) has resulted in a low incidence of acute GVHD and reduced transplant-related toxicity in several studies. We sought to confirm the efficacy of sirolimus in combination with Tac for GVHD prophylaxis in unrelated HSCT. **Methods.** 65 patients received peripheral blood stem cells from unrelated donor (n=60) or mismatched sibling donor (n=5) after conditioning regimen consisting of busulfan and fludarabine. And patients were treated with 3 different regimens for GVHD prophylaxis: CsA/MTX (n=20), Tac/MTX (n=21), and Tac/Sir (n=24). **Results.** The incidence of grade II-IV acute GVHD in Tac/Sir group was lower than other groups (25% for Tac/Sir vs 45% for CsA/MTX, 43% for Tac/MTX). The day-100 NRM in Tac/Sir group was also lower than other groups. The VOD of liver was developed in five cases (one with CsA/MTX, two with Tac/MTX, and two with Tac/Sir). Only one case of thrombotic microangiopathy developed in the Tac/Sir group. The incidence of CMV or EBV reactivation in Tac/Sir group was higher than other groups. To evaluate immunologic recovery around D+100 day, there was no significant difference in immune reconstitution. **Conclusions.** The combination of tacrolimus and sirolimus is well tolerated and may be helpful in deceasing the risk of acute GVHD and NRM in case of high risk allogeneic HSCT. However, we need more efforts to find ways to differentiated strategy according to the risk of acute GVHD because of its adverse effects.

FOUR CASES OF PROGRESSIVE MULTIFOCAL LEUKOENCEPHALOPATHY AFTER STEM CELL TRANSPLANTATION

MS Infante[1], M Kwon[2], D Serrano[3], C Encinas[4], G Rodriguez Macias[5], P Font[6], S Osorio[7], J Anguita[8], J Gayoso[9], J Diez Martin[10]
[1]Hospital Gregorio Marañon, Madrid, Spain
[2]Mi Kwon, Madrid, Spain
[3]David Serrano, Madrid, Spain
[4]Cristina Encinas, Madrid, Spain
[5]Rodriguez Macias Gabriela, Madrid, Spain
[6]Patricia Font, Madrid, Spain
[7]Santiago Osorio, Madrid, Spain
[8]Javier Anguita, Madrid, Spain
[9]Jorge Gayoso, Madrid, Spain
[10]Jose Luis Diez Martin, Madrid, Spain

Background. Progressive multifocal leukoencephalopathy (PML) is a rare subacute demyelinating disease of the central nervous system (CNS) caused by polyomavirus (JCV/BKV). In immunocompromised patients it is caused by reactivation of latent infection. Altought in the context of stem cell transplantation (SCT) PML is a rare complication, it must be ruled out in transplanted patients (autologous or allogeneic) with neurological symptoms. Limited data ara available on caracteristics of PML in this setting. There is currently no effective therapy to control Polyomavirus, and the prognosis is dismal in most cases. **Aims.** To describe a series of 4 patients transplanted in our institution with neurological symptoms who were diagnosed with PML. **Results.** The characteristics of the patients are listed in Table 1. Four patients who underwent tandem autologous (1) and allogenic SCT (2,3,4) between 2004 and 2011, were diagnosed with PML. All patients had controlled hematological disease (1 RP, 2 VGPR, 3

CR, 4 RC) at the time of PML diagnosis. All patients has been heavely treated and 2 patients were receiving inmunosuppression (IS) at the time of PML diagnosis. Clinical manifestations have been heterogeneous. Only in 2 patients the lesions described on MRI were consistent with PML (1,3). PCR in CSF was diagnostic in all four cases: JCV (1,3,4) and BKV (2), and tests for other causes, including other viruses, bacteria, fungi and tuberculosis, were negative. IS tapering and treatment with mefloquine/citalopram[1] were started, however all patients in our series progressed and died in a median of 2 months after the diagnosis of PML. **Conclusions.** PML in the context of allogeneic or autologous transplantation should be suspected in patients with neurological symptoms,especially in those with poor immune reconstitution, such as alternative donor transplant recipients. Patients in our series had received several lines of therapy, including previous autologous SCT in 3. The clinical presentation of PML can be very heterogeneous, and not always the radiological pattern is consistent with the suspicion of PML, therefore CSF PCR for Polyomavirus should be included in the diagnostic work-up in this setting.

SAFETY AND QUALITY OF HAEMATOPOIETIC STEM CELLS FOR TRANSPLANTATION

E Spiniello, A Pontari, O Iacopino, P Scaramozzino, I Callea, R Fedele, E Massara, M Martino, G Irrera
Azienda Ospedaliera B. M. M. - Ospedale Morelli, Reggio Calabria, Italy

Background. It is known that biological and functional properties of haematopoietic stem cells (HSCs), which are commonly used in treatment of malignant and non-malignant diseases, play a crucial role in influencing the outcome of the transplant, considered as achievement of a rapid and durable granulocytes-platelets recovery. Because this is particularly related to CD34+ cells content of the graft, an important aspect is to ensure an adequate cryopreservation and storage of autologous HSCs to guarantee their integrity until the transplant. **Aims.** Based on this consideration, we standardized an internal protocol of quality controls to evaluate the main biological properties of the graft and to obtain its validation. At the same time we could predict, approximately, just at collection time, the real CD34+ cells count expected at the transplant. **Methods.** The most common parameters recognized as indicators of quality are total nucleated cells (TNC), mononuclear cells (MNC), cell viability, CD34+ cells count, colony forming unit-Granulocyte Macrophage (CFU-GM), microbial and minimal residual disease (MRD) contamination. In 2011, we analyzed 63 cryopreserved autologous peripheral blood stem cells (PBSCs) collections. The timing of our protocol is reported as follows. Collection and processing: PBSCs, collected using a leukapheresis cell separator (Fresenius COM-TEC), were assessed for TNC, MNC, CD34+ cells (ISHAGE Protocol, FacsCalibur, BD), cell viability (7-AAD), CFU-GM, microbial and MRD contamination. At this step we calculated, using MNC% value, the probable CD34+ performance. After 30 days of cryopreservation and storage in liquid N2: revaluation of cell viability (trypan blue) on aliquots stored together with PBSCs unit and evaluation of approximate CD34+ count expected at release. This test is also performed immediately before the transplant to verify the effective performance of the cellular product. At transplant: after thawing and washing, we evaluated TNC, MNC, CD34+, cell viability (7-AAD, trypan blue) and microbial contamination to definitively establish the quality of the graft before releasing. **Results.** The data are shown as mean value. At collection: TNC 180x10E8 (r. 130-210); MNC 67,9% (r. 40-87), CD34+ 4x10E6/Kg (r. 0,54-7,4), CD34+ performance 2,7x10E6/Kg (r. 0,38-5,2). After 30 days of cryopreservation: cell viability 67% (r. 39-82), CD34+ performance 2,6x10E6/Kg (r. 0,33-5,1). At transplant: TNC 158x10E8 (r. 114-184); cell viability 68,8% (r. 42-92), CD34+ 2,8x10E6/Kg (r. 0,37-5,8). We also compared the data obtained at collection and after 30 days of cryopreservation to the results obtained at release. We observed a satisfying recovery for each parameter tested, in line with our expectations, and a reproducibility at every time points of the protocol. These data are shown as percentage of recovery: TNC 88,6% (r. 62-100); TNC viability 69% (42-94); MNC 78% (r. 50-93); CD34+ 71% (r. 43-99). No case of microbial contamination. **Conclusions.** Our protocol allow us to validate the graft, monitoring all the different steps of PBSCs production, from collection until distribution. Furthermore, we have the possibility to keep the critical points of this process under control. Just at collection time we are able to establish the effective performance of cryopreserved PBSCs, particularly referred to the CD34+ cells count. This could be mainly explained by the close correlation existing among MNC collected, cell viability and CD34+ amount.

1888

INFLUENTIAL FACTORS IN THE DAYS OF HOSPITALIZATION FOR THE AUTOLOGOUS STEM CELL TRANSPLANT

D Díaz Canales, L González Díaz, A Martín Cerezo, M Barrios García, MA Cuesta Casas, MJ Pascual Cascón, AI Heiniger Mazo
HRU Carlos Haya, Málaga, Spain

Objective. We analyze the factors of risk that present influence in the increase of the days of hospitalization in patients admitted for an autologous stem cell transplant (autoHSCT). **Methods.** We study 155 patients submitted to autoHSCT in the last 5 years (2007-2011): 103 men (66,5 %) and 52 women (33,5 %) with median age 49 years (SD 12,9). The diagnoses were: monoclonal gammapathy in 43,2 % (67 patiens), lymphoid malignancies in 48,4 % (75 patients), acute leukemia in 7,1 % (11 patients) and other diseases 1,3 % (2 patients). Before to the autoHSCT. 39,5 % (61 patients) had more of two lines of treatment. About of the status of the disease pre-trasplant: complete remission in 75 patients (48,4 %), partial remission in 62 patients (40 %) and disease in progression 18 patients (11,6 %). We realize univariate and multivariate analysis with the following factors: age, sex, diagnosis, lines of treatment before autoHSCT, Sorror index, status pre-trasplant, use of total body irradiation in the conditioning, time of recovery of neutrophil (>0,5 x10^9/L two consecutive days), need of total parenteral nutrition (TPN), infection and the engrafment syndrome. **Results.** With the multivariate analysis, we find the following significant factors: diagnosis (RR=6,75), Sorror index (RR=3,07), status pre-trasplant (RR=0,4), use of TPN (RR=3,13) and the infection (RR=9,81). Other studied factors were not significant. With more of 20 days of hospitalization: the patiens with monoclonal gammapathy, lymphoid malignancies and acute leukemia in a 38,8 %, 78,7 % and 81,8 %, respectively (p<0,002); the patients with Sorror index major or equal 1, 63,5 % (Vs. 58 % Sorror index=0), (p<0,10); complete remission, partial remission and disease in progression with 70,7 %, 48,4 % and 66,7 %, respectively (p=0,06); the TPN more tan 7 days, 77,5 % (Vs. TPN < 7 days: 62,9 %; p<0,10) and the infection during the autoHSCT, 67,5 % Vs. no infection 37,5 % (p<0,05). **Conclusions.** In our series were determinant factors in the increase of the number of days of hospitalization the diagnosis, the Sorror index, the status pre-trasplant, the use of TPN and the infection. We do not find statistically significant relation when we analyze the sex, the age, the previous lines of treatment, the use of corporal total irradiation in the conditioning, the time of recovery of the neutrophils and the engranfment síndrome.

1889

USE OR RITUXIMAB IN ACUTE AND CHRONIC GRAFT-VERSUS-HOST DISEASE (GVHD) POST ALLOGENEIC HEMATOPOIETIC CELL-TRANSPLANTATION

S Patel[1], J Cavenagh[2], J Gribben[2], J De Vos[1]
[1]St Bartholomew's Hospital, London, United Kingdom
[2]Department of Haemato-Oncology, Barts Cancer Institute, London, United Kingdom

Background. Graft-versus-host disease is a well recognized and frequent complication after allogeneic hematopoietic cell transplantation (HCT). It carries significant morbidity and mortality particularly if steroid-refractory. There is evidence to suggest the involvement of B-cells in the pathophysiology of GVHD, particularly in chronic GVHD. The use of Rituximab, a monoclonal anti-CD20 antibody, in the treatment of GVHD, has limited evidence. Observational studies have shown a clinical response rate of up to 70% in patients treated with Rituximab for steroid-refractory chronic GVHD. **Aims.** We reviewed all of our patients treated with Rituximab for either acute or chronic GVHD post allogeneic HSCT between January 2005 and January 2012. **Methods.** Our electronic chemotherapy prescribing system was used to identify all patients who had rituximab for this

indication. The clinical notes were used to extract data on patient demographics, transplant details, presentation and grading of GVHD, the organ(s) affected and timing and outcome of Rituximab use. **Results.** Out of a total 274 allogeneic HCTs (235 mini-allogeneic HCTs) Rituximab was used for treatment of GVHD in 16 patients (6%), all post reduced intensity conditioning (RIC) transplants. For all 16 patients peripheral blood stem cells were the source. Only one patient received a Campath containing conditioning regimen. GVHD-grading is assumed severe though poorly documented. 7 patients (44%) had acute GVHD (skin, gut and a combination of both); 9 (56%) patients had chronic GVHD (8 skin, 2 in combination with liver and gut, and 1 liver). Response was poor in almost all patients: 5 patients died during Rituximab treatment (31%), all in the acute GVHD setting. Only 2 patients (13%) had a documented response: 1 in chronic GVHD (and remains well) and 1 acute GVHD although this patient went on to have two further lines of GVHD treatment. The remaining 9 patients (56%) had no documented response and received further lines of treatment. There was no consistency in agents used after initial ciclosporin and steroids treatment failed. Rituximab was third or fourth line treatment in all cases. Four patients (25%) are currently alive (mean age 36 years). The median overall survival (OS) post-transplant was 23 months. The median time from development of GVHD to commencing Rituximab was 2 months. In the 12 deceased patients (75%) the median time from rituximab treatment to death was 5 months; their mean age was 56 years. None of the patients with gut GVHD survived, either acute or chronic. **Conclusions.** Response to Rituximab was disappointing in both acute and chronic GVHD. In the acute GVHD setting no significant benefit was seen and the majority of patients died during or within a month of Rituximab therapy, reflecting the high mortality associated with acute, severe steroid-refractory GVHD. In the chronic GVHD setting as well there was no significant benefit seen. It has to be acknowledged however that no clear consistency was seen in the prescribing pattern of Rituximab with regard to when (which line) and for which indication to prescribe it; This is in keeping with the current lack of strong evidence or guidelines.

1890

SAFETY AND EFFICACY OF EAM REGIMEN FOLLOWED BY AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION FOR RELAPSED AND REFRACTORY HODGKIN LYMPHOMA ADULTS

M Bekadja, S Osmani, S Talhi, N Yafour, M Brahimi, A Arabi, B Entasoltan, R Bouhass
University of Oran, Oran, Algeria

Objectives. The efficacy of high-dose chemotherapy followed by autologous stem cell transplantation (ASCT) for refractory or relapsed Hodgkin's lymphoma (HL) has been reported, but an optimal conditioning regimen has not been determined. Several chemotherapy preparative regimens are used, however, there has not been a randomized clinical trial to support the superiority of one regimen over another. We report treatment results achieved for refractory or relapsed HL in adult patients with a new conditioning regimen. Patients and **Methods.** From March to December 2011, all patients with HL were treated with high-dose Etoposide (800 mg/m²), Aracytine (8g/m²) and Melphalen (140 mg/m²) (EAM) followed by reinfusion of peripheral ASCT. **Results.** A total of 18 patients were retrospectively evaluated. The median age was 27 years (range; 17-47), median number of CD34+ cells was 3, 86 x 10^6/l (2,71 - 6,15). All patients had a full haematopoietic reconstitution. Median time to achieve neutrophils > 500 /µl was 13 days (range; 10-19) and median time to achieve an unsupported platelet count >20000/µl was16 days (range; 14-25). Toxicities included grade 4 hematologic in 18/18 patients, grade 3 mucositis in 4, grade 3 infectious in 2. No case of transplant-related mortality occurred. After a median follow up of 8 months, all patients are alive and all are in continuous CR. In conclusion, the EAM regimen would be an effective and tolerable conditioning regimen with acceptable engraftment and toxicity for ASCT for refractory or relapsed HL. Although these outcomes are encouraging, longer follow-up is required and comparison with other traditional ASCT regimens used for patients with refractory or relapsed HL is warranted.

1891

FAVORABLE OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR SEVERE APLASTIC ANEMIA USING FLUDARABINE, CYCLOPHOSPHAMIDE, ATG WITH OR WITHOUT LOW-DOSE TBI

S Kohashi, T Mori, J Kato, A Yamane, S Okamoto
Keio University School of Medicine, Tokyo, Japan

Background. Because of the toxicity and high rate of graft rejection, the standard conditioning regimen for severe aplastic anemia (SAA) has yet to be established, and a variety of reduced-intensity conditioning regimens using fludarabine have been reported. **Aims.** We have retrospectively evaluated the safety and efficacy of allogeneic HSCT for SAA using fludarabine, cyclophosphamide, and ATG with or without low-dose TBI. **Patients and Methods.** Six patients (median age 30 (range: 22-61)) with SAA who underwent allogeneic bone marrow transplantation from an HLA-identical sibling (n=3) or an HLA-matched unrelated donor (n=3) were evaluated. Conditioning included fludarabine (120 mg/m^2), cyclophosphamide (100 mg/kg), and ATG (Thymoglobulin; 3. 75 mg/kg). In addition, 2 Gy of TBI (with ovarian shielding for young female patients) was delivered for heavily transfused patients or HSCT from an unrelated donor. For the prophylaxis of graft-versus-host disease (GVHD), cyclosporine A or tacrolimus with short-term methotrexate was given. **Results.** The transplant procedure was generally well-tolerated, and there were no life-threatening complications. All patients achieved engraftment and became transfusion independent. Full donor chimerism was confirmed at day 28 after transplantation. Only one patient developed acute GVHD (grade II) and none developed chronic GVHD. With a median follow-up period of 6. 8 months (range: 4. 4-14. 3 months), all patients are alive and in good performance status. The recovery of menstruation was observed in all 3 evaluable young female patients at 3, 7, and 8 months after transplantation, respectively. **Conclusions.** These results suggest that fludarabine, cyclophosphamide, and ATG with or without low-dose TBI could be a promising conditioning of allogeneic HSCT for SAA both from sibling and unrelated donor. In addition, this conditioning with ovarian shielding in TBI is considered to have a minimal adverse effect on ovarian function in female patients.

PNEUMONIA IN AUTOLOGOUS STEM CELL TRANPLANTATION RECIPIENTS: DOES IT REPRESENT NEGATIVE PROGNOSTIC FACTOR FOR OUTCOME?

M Fina, A Mele, R De Francesco, G Greco, S Sibilla, B Rossini, D Carlino, C De Risi, M Morciano, P Ferrara, A Ostuni, V Pavone
"Card. G. PANICO" Hospital, Tricase (Lecce), Italy

Background. Autologous stem cell transplantation (ASCT) has become a curative therapy for the majority of Hematologic malignancies. Infections remain the most significanti causes of morbidity and mortality. **Aims.** the aim of our study was to describe incidence, etiology, mortality and risk factors of infections and mainly of pneumonia complications in our series of patients. **Methods.** in our institution 173 patients underwent ASCT from March 2005 to December 2011. 108 were male and 65 were female. Median age was 54 (range 16-74). Underlying disease, conditioning regimen, status of disease at the time of transplantation, number of previous therapies are described in Table 1.

Table 1. Patients characteristics.

N patients 173		
Sex	Male 108 (62%)	Female 65 (38%)
Age	Median	54
	Range	16-76
Underlying disease	NHL + HD	96 (55.5%)
	MM	68 (39.3%)
	AML	3 (1.7%)
	OTHER	6 (3.5%)
Disease status at transplant	Responsive	146 (85%)
	Unresponsive	27 (15%)
Conditioning Regimen	BEAM or BEAM like	69 (40%)
	MELPHALAN	71 (41%)
	Z BEAM	19 (11%)
	OTHER	14 (8%)
Number of previous therapy	Median	2
	Range	1-4
Febrile Neutropenia	106 (62%)	
Days of Neutropenia	Median	10
	Range	7-29
Type of Fever	FUO	44 (41.5%)
	Micro biol. documented	43 (40.5%)
	Pneumonia	19 (18%)

Median duration of neutropenia was 10 days (range: 7-29). Infectious complications occurred in 106 patients: 44 FUO, 43 micro biologically documented fever, 19 pulmonary infections. 7 of these were micro biologically documented: 2 Pseudomanas Aeruginosa, 2 Escherichia Coli, 2 Staphilococcus Hominis, 1 Klebsiella Pneumoniae. No pulmonary Aspergillosis was documented. **Results.** We analyzed the impact of some clinical parameter on the occurrence of infection and in particular of pneumonia. There are no statistically differences concerning the type of conditioning regimen, the underlying disease, mucositis, age > 55 years, gender, sex, number of prior lines of chemotherapy and the duration of neutrope-

nia (more or less than 10 days)Moreover we evaluated the differences in terms of transplant related mortality (TRM). TRM in our series is 8% at 30 days and 12. 7% at 100 days. On the other and the TRM of patients who developed any infections is statistically significant higher both at 30 days (13% versus 0% p 0. 005) than at 100 days (19% versus 2% p 0. 002). In this setting of patients the difference of TRM between pneumonia and other infectious complications was analyzed. TRM at 30 days was respectively 15. 6% versus 12. 6% (p 0. 7); TRM at 100 days was 26. . 3 versus 17. 2 (p 0. 3). **Summary.** infections are the major causes of morbidity and mortality in patients with different hematological diseases after ASCT. The incidence of pneumonia in our series seems higer than in other cohort of patients described in litterature (18% versus 8%) but it doesn't seem to correlate with worse TRM and outcome . Now we are planning a multicenter study to better detail the incidence of pneumonia and correlated risk factors after ASCT.

1893

HALLUCINATION AND INSOMNIA AS A SIDE EFFECT OF PLERIXAFOR IN A 3-YEAR-OLD GIRL WITH RELAPSED WILMS TUMOR IN THE SETTING OF NEPHROBLASTOMATOSIS

M Karakukcu[1], E Unal[2], F Mutlu[3], T Patiroglu[3], M Ozdemir[3]
[1]Erciyes Univesity, Faculty of Medicine, Kayseri, Turkey
[2]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology, Kayseri, Turkey
[3]Erciyes University, Faculty of Medicine, Division of Pediatric Hematology, Kayseri, Turkey

Background. After several randomized studies, plerixafor was approved in adult patients in 2009 by the European Medicines Agency for use in combination with filgrastim to enhance mobilization of hematopoietic stem cells to peripheral blood. Plerixafor reversibly inhibits stromal cell-derived factor-1-a/CXCR4 binding, as a result of which CD34+ cells are mobilized into circulation. **Aims.** Although the treatment is well tolerated in adult population, some adverse effects such as diarrhea, nausea, vomiting, fatigue, joint pain, headache, dizziness, anxiety, sleeplessness, injection-site redness, and irritation have been reported. Experience in children, however, is extremely limited. We report our experience in 3-years-old girl with relapsed Wilms tumor in the use of this drug. **Case Report.** A 3 year-old girl admitted to hospital with abdominal pain. On physical examination, a left abdominal mass was discovered. Abdominal ultrasound showed three mass at the left kidney. She was operated and the mass was completely resected. The pathological examination showed Wilms tumor in the setting of nephroblastomatosis According to radiological and pathological findings she was diagnosed as stage IV Wilms tumor with unfavorable histology. She underwent a radiation and chemotherapy protocol for Wilms tumor recommended by Turkish Pediatric Oncology Group. At 7th month of the planned chemotherapy the patient showed multiple metastases at liver, local radiation to liver relapse was performed and 2 courses Ifosfamide, carboplatin and etoposide (ICE) was given. After the 2nd course of ICE it was failed to mobilize the hematopoietic stem with filgrastim; so after obtaining parent's informed consent form, plerixafor was administered subcutaneously (240 μg/kg) prior to apheresis. The mobilization was performed successfully but the patient showed hallucination and insomnia after 12 hours of the administration of plerixafor. The blood electrolytes, EEG, thyroid function test and brain MRI found to be normal. The patient underwent hydroxyzine treatment for two days and the symptoms disappeared within 48 hours. **Results.** According to our knowledge, we report the first pediatric experience of hallucination and insomnia as a side effect of plerixafor in the English medical literature. **Summary and Conclusions.** This case illustrates that the plerixafor is an effective agent for mobilization of hematopoietic stem cells in children; however clinicians must be vigilant about the possible side effect of hallucination and insomnia. Further studies are necessary to evaluate this side effect in childhood.

1894

GUILLAIN-BARRE SYNDROME AFTER STEM CELL TRANSPLANTATION: SINGLE CENTER EXPERIENCE

M Muftuoglu[1], E Osmanbasoglu[1], S Kalayoglu-Besisik[2], F Sargin[2]
[1]Istanbul School of Medicine, Istanbul, Turkey
[2]Istanbul School of Medicine Division of Hematology, Istanbul, Turkey

Background. Guillain-Barre syndrome (GBS) is a uncommon and unusual complication in the setting of solid organ and hematopoietic stem cell transplantation (HSCT). We intend to report three cases of GBS following autologous and allogeneic HSCT. **Method.** We retrospectively reviewed our transplantion records. Three patients out of 517 transplants (271 allogeneic HSCTs, 245 autologous HSCTs) carried out between 1993-2011 developed GBS posttransplant. Demographic features, clinical courses, predisposing conditions and management strategies are summarized (Table 1). **Results.** Case 1: A 57-year-old male patient diagnosed with Hodgkin's Disease underwent autologous HSCT. He suffered from frequent upper tract respiratory infections posttransplant. Five months after HSCT, a diagnosis of GBS was made on development of sensory-motor lower extremity-limited demyelinating polyneuropathy. He was treated with intravenous immunoglobulin (IVIG) with significant improvementCase 2: A 20-year-old male with a diagnosis of acute myeloid leukemia underwent HSCT from full-match sibling donor. He presented with acute GVHD involving skin, oral mucosa and liver after 7 months posttransplant. He was treated with high dose methylprednisole and cyclosporine. Pneumonia and cytomegalovirus reactivation ensued and treated accordingly. Infectious complications prolonged hospital stay. Two months after his admisson, parasthesia accompanied by ascending motor weakness of four extremities and peripheral fascial paralysis developed, leading to inability to walk without support at the end of one week. He was treated with IVIG 400 mg/m2 for 5 days. We proceeded to plasmapheresis as a result of unresponsiveness to IVIG after 2 weeks. The patient responded dramatically with full motor recovery. With regard to etiological factors, GBS was preceded with lower respiratory and urinary tract infections. Serological markers were negative all but for anti-CMV IgM positivity whereas CMV-DNA was negative. Case 3: A 37 year-old female, diagnosed with Ph (+) acute lymphoblastic leukemia, recieved allogeneic HSCT from her full-match sist er. Acute GVHD developed in early period with complete resolution following therapy. She was diagnosed with GBS involving lower extremities, leading inability to walk and take care of herself. IVIG 400 mg/m2 for 5 days was commenced. The patient responden gradully and began walking without assistance one week later. No antecedent infection was detected. **Discussion.** GBS is a heterogenous disorder mediated by a multitude of pathogenic mechanism and exceptionally rare following HSCT. Different underlying mechanisms following HSCT may contribute to development of GBS. A higher rate of infections and GVHD may predispose to GBS posttransplant. IVIG and plasmapheresis remain the treatment of choice for patients recieving HSCT. Therapy should be implemented effective immediately.

Table 1. Demographic and clinical features.

Patient	Age/Sex	Diagnosis	Type of HSCT	Time interaval	Conditioning Regimen	GVHD	Predisposing condition	Management
1	57 male	Hodgkin's Disease	Autologous PBSCT	5 month	BEAM	Nonapplicable	Acute sinusitis	IVIG
2	20 male	AML	Allo-HSCT BM	7 months	BU/CY	Skin oral mucosa, liver aGVHD	Respiratory, urinary infections, CMV reactivation ?	IVIG + plasmapheresis
3	37 female	Ph+ ALL	Allo-HSCT BM	12 months	BU/CY	Skin, acute GVHD	None	IVIG

EFFECT OF GRANULOCYTE COLONY-STIMULATING FACTOR MOBILIZATION ON THE EXPRESSION PATTERNS AND CLONALITY OF TRAV AND TRBV REPERTOIRE

Q Liu[1], L Xuan[1], XL Wu[2], MQ Wu[1], Y Zhang[1], H Liu[1], Z Fan[1], J Sun[1]
[1]Nanfang Hospital, Southern Medical University, GuangZhou, China
[2]Institute of Hematology, Medical College, Jinan University, Guangzhou, China

Background. The immune modulatory effect of granulocyte colony-stimulating factor (G-CSF) on T cells resulted in an unexpected low incidence of graft-versus-host disease (GVHD) in allogeneic peripheral blood stem cell transplantation (allo-PBSCT). Recently, αβ+T cells are identified as the primary effector cells for GVHD. However, whether G-CSF could influence the repertoire of αβ+ T cells (TRAV and TRBV repertoire) remains unclear. **Aims.** To investigate the effect of G-CSF mobilization on the T cell receptors (TCR) of αβ+ T cells (TRAV and TRBV repertoire), as well as the association between the changes of TCR repertoire and

GVHD in patients undergoing G-CSF mobilized allo-PBSCT. **Methods.** The complementarity-determining region 3 (CDR3) sizes of 29 TRAV and 24 TRBV subfamily genes were analyzed in peripheral blood mononuclear cells (PBMCs) from 20 donors before and after G-CSF mobilization, using RT-PCR and genescan technique. **Results.** The numbers of detectable TRAV and TRBV subfamilies, as well as the expression frequencies of most TRAV and TRBV subfamilies decreased at different levels after G-CSF mobilization. The expression frequency of TRAV27 after mobilization was significantly lower than that before mobilization (P=0. 031). Most TRAV and TRBV subfamilies revealed polyclonality from pre-G-CSF and G-CSF-mobilized samples. Oligoclonality was detected in TRAV and TRBV subfamilies in 2 donors before mobilization and 6 donors after mobilization, predominantly distributed in TRBV16. Significant positive association was observed between the variable clonality of TRBV22 gene repertoire after mobilization and low incidence of GVHD in recipients (P=0. 042, OR=12. 500). **Conclusions.** G-CSF mobilization has an effect on the expression patterns and clonality of *TRAV* and *TRBV* repertoire. This alteration might play a role in mediating GVHD in G-CSF mobilized allo-PBSCT.

T CELL RECEPTOR V? REPERTOIRE WAS DIFFERENTLY USED BETWEEN GRAFT-VERSUS-HOST DISEASE AND GRAFT-VERSUS-LEUKEMIA IN ACUTE LYMPHOCYTIC LEUKEMIA WITH TCF3-PBX1

H Tashiro, T Yamamoto, Y Oka, R Shirasaki, T Matsuo, N Akiyama, K Kawasugi, N Shirafuji
Teikyo University School of Medicine, Tokyo, Japan

Background and Aims. Many clinical reports indicate that graft-versus-host disease (GVHD) and graft-versus-leukemia (GVL) are difficult to be separated, and sometimes GVHD becomes serious when a transplanted patient relapses and immunosuppressant is reduced to induce GVL effect. We recently experienced one acute lymphocytic leukemia (ALL) case with TCF3-PBX1 who relapsed after allogeneic hematopoietic stem cell transplantation (HSCT). This patient achieved complete remission (CR) with a discontinuation of immunosuppressant. Fortunately, the patient's GVHD was controllable, and the patient is still alive and well. We analyzed blood T cell receptors (TCRs) obtained from this patient to understand better GVHD and GVL. Case: A 40 year-old Japanese man was suffered from ALL with TCF3-PBX1 in November, 2009. He was treated with chemotherapy, and achieved CR; however, before allogeneic HSCT his ALL relapsed. He was transplanted with unrelated bone marrow donor from JMDP in June, 2010, and achieved CR. On day 200 his ALL relapsed, and cyclosporine-A and prednisolone were stopped. Soon after a discontinuation of immunosuppressant he achieved CR. GVHD worsened to grade III in liver, and immunosuppressant started again. His GVHD was well-controlled, and his ALL maintains CR until now. Materials and **Methods.** The institutional ethical committee approved this study, and he was given informed consent. His leukemic blasts, blood after achieving CR, and liver biopsy specimen when his GVHD worsened, were collected. Blood lymphocytes were cultured with the irradiated his ALL blasts (GVL model) or liver cells (GVHD model) in RPMI1640 medium with 10% FCS and 100 ng/mL of recombinant human interleukin-2 for 14 days. Then RNA was extracted, and TCR Vα and Vβ usages were analyzed with RT-PCR using the specific primers for subfamilies and the constant region of α or β. **Results.** In GVHD model and GVL one, TCR Vα and Vβ were oligoclonally used. Several subfamilies were demonstrated in both models. Vα10, 11, and 12 were preferentially used in GVHD model but not in GVL. Vβ 2, 4, and 5. 1 were observed in GVHD model but not in GVL. And, Vβ 6, 7, 10, 12, and 14 were demonstrated in GVL model but not in GVHD. Discussion: In both GVHD and GVL model TCR Vα and Vβ were preferentially used, and some difference was observed. Importantly, some Vβs were used in GVL model but not in GVHD. We previously reported that vascular endothelial growth factor C, its receptor type-3, and lymphduct neogenesis-related genes were expressed in ALL with TCF3-PBX1. These proteins may contribute to the preferential TCR Vβ usage in GVL model. We now isolate single T cell clone that induces GVL effect but not GVHD, and determine the leukemia-specific antigen for GVL effect.

1897

ASSOCIATION OF MEAN PLATELET VOLUME WITH NEONATAL INNATE FACTORS AND THE NUMBER OF TOTAL NUCLEATED CELLS AND CD34+ CELLS IN CORD BLOOD

HR Lee[1], EY Roh[2], JH Yoon[2], KS Han[2], BJ Kim[3], S Shin[2]
[1]Gyeongsang National University Hospital, Jinju, South-Korea
[2]Seoul National University College of Medicine, Seoul, South-Korea
[3]SMG - SNU Boramae Medical Center, Seoul, South-Korea

Background. Cord blood (CB) is an attractive stem cell source compared to bone marrow (BM) or peripheral blood (PB) in hematopoietic stem cell transplantation. Mean platelet volume (MPV), which is a measure of platelet size, is a potential marker of platelet activation. It has been recently reported that MPV of CB correlates with the hematopoietic parameters, such as the numbers of TNC and CD34+ cells. Therefore, MPV are considered as one of the hematopoietic parameters of CB. **Aims.** We investigated whether the MPV of CB is associated with the hematopoietic parameters of CB donated by Korean neonates and maternal and neonatal factors. **Methods.** A total of 10,577 units were enrolled among CB donated to the Seoul Metropolitan Public Cord Blood Bank (Allcord), during the period from October 2006 through August 2009. The enrolled CB units were donated from Korean. We measured the associations between the MPV of CB and CB volume, the numbers of total nucleated cells (TNCs), CD34+ cells, and CD34+ cells/TNCs in CB; and the influence of maternal age and neonatal factors, such as gender of neonates, gestational age, and birth weight on the MPV of CB. We also analyzed these associations and influences according to the ABO blood groups of the neonates. **Results.** MPV of CB significantly correlated with the CB volume (r = 0. 121, $P < 0.001$), and with hematopoietic parameters, such as the numbers of TNCs (r = 0. 110, $P < 0.001$), CD34+ cells (r = 0. 174, $P < 0.001$), and CD34+ cells/TNCs (r = 0. 157, $P < 0.001$). Although the MPV showed no association with maternal age (r = 0. 003, p = 0. 739) and gender of the neonates (male, 9. 479 ± 0. 6092 fL; female, 9. 479 ± 0. 6149 fL), it showed a significant negative correlation with the gestation age (r = -0. 102, $P < 0.001$) and a significant positive correlation with the birth weight (r = 0. 023, $P = 0.020$). In analysis according to the ABO blood groups of neonates, CB blood type O showed higher MPVs ($P = 0.002$) than other blood types of CB, especially comparing with the neonates of blood type B. Also, CB blood type O showed higher numbers of TNCs ($P = 0.013$), CD34+ cells ($P < 0.001$), and CD34+ cells/TNCs ($P < 0.001$) than other blood types of CB. The neonates of blood type O showed significantly high number of TNC, especially comparing with the neonates of blood type A. In comparing the number of CD34+ cells of CB unit, the neonates of blood type O showed significantly higher number than the other blood types. Also, the neonates of blood type O showed significantly higher CD34+ cells/TNC than the other blood types. **Conclusions.** Considering these associations of MPV with hematopoietic parameters and the influences of neonatal factors on the MPV, MPV can be considered as a hematopoietic parameter of CB.

1898

BONE MARROW SEEMS TO BE THE BEST SOURCE OF MESENCHYMAL STEM CELLS TO REPAIR INJURED LIVER

A Briquet, F Comblain, A Halleux, S Dubois, A Gothot, C Lechanteur, Y Beguin
University of Liège, Liège, Belgium

Background. Several genetic hepatic metabolic diseases alter physical and neurological development as well as life expectancy of affected children. The only potential curative option to date for these patients is a liver transplant. Given the shortage of organs, development of cellular sources other than human liver is urgent. **Aims.** The main objective of this project is to demonstrate the feasibility of treating liver metabolic diseases by MSC transplantation. **Methods.** Human MSC from umbilical cord (UC-MSC), bone marrow (BM-MSC) or liver (L-MSC) were transplanted into NSG mice after CCl_4-induced liver injury. In order to support MSC homing towards injured liver, we induced expression of the CXCR4 receptor on their surface. NSG mice received 3 CCl_4 3% IP injections per week during 4 weeks. 48h after the last injection, mice received 500,000 MSC by intravenous tail injection. We injected UC-MSC, BM-MSC or L-MSC (CXCR4- or CXCR4+). We examined MSC homing by real-time PCR and MSC function by quantitative image analysis of sirius red staining and blood enzyme analysis. **Results and Conclusions.** Data confirm that CCl_4 treatment induced hepatic fibrosis. PCR showed that human MSC, after injection in mice, were found partly in their liver. In addition, BM-MSC seemed to be the most promising cells. Indeed, they stabilized the rates of plasma albumin and alanine amino-transferase of mice. Moreover, these cells decreased hepatic fibrosis. CXCR4 expression did not improve the homing nor function of MSC. BM-MSC CXCR4+ or UC-MSC or L-MSC (expressing CXCR4 or not) seemed less effective. These results need to be confirmed in a larger number of animals.

1899

MIGRATION AND DIFFERENTIATION OF TRANSPLANTED BONE MARROW-DERIVED CELLS INTO PERIODONTAL TISSUES PROMOTED BY MECHANICAL STRESS

T Kawakami[1], H Tsujigiwa[2], K Nakano[1], M Tomida[1], R Muraoka[1], H Nagatsuka[2]
[1]Matsumoto Dental University Graduate School of Oral Medicine, Shiojiri, Japan
[2]Okayama University Graduate School, Okayama, Japan

Aims. Bone marrow-derived cells have abilities of cell migration and differentiation into teeth and related tissues/organs, especially into periodontal ligament

fibroblast cells [1,2]. In this examination using a bone marrow transplantation model, we examined the effect of orthodontic mechanical stress to the transplanted bone marrow-derived cell migration into periodontal tissues. **Methods.** Bone marrow derived cells from green fluorescence protein (GFP) transgenic mice were transplanted into 8 week-old female C57BL/6 immunocompromised recipient mice (n=10), which had undergone 10 Gy of lethal whole-body irradiation. After successful transplantation (about one month period), 5 mice received orthodontic mechanical stress using the Waldo method 5 times in 5 weeks; and 5 mice were compared as control without receiving orthodontic mechanical stress. After that, the regional tissues were removed and fixed in formalin fixative. Paraffin-embedded sections were immunohistochemically analyzed using a Dako Envision + Kit-K4006 (Dako,Glostrup,Denmark) and a primary anti-GFP-polyclonal rabbit antibody (#598; 1/500; MBL,Nagoya,Japan). For semiquantitative evaluation of immunohistochemical staining, the following procedures were performed. First immunohistochemical images with same magnification from the periodontal tissues were prepared and pixel density was counted for each image. Then typical immunohistochemically positive staining part was defined as positive area. The pixel number of positive area in the periodontal tissue was compared with the previously calculated total pixel number of the periodontal tissue and the ratio was obtained. **Results and Discussion.** We examined the transplanted bone marrow-derived cell migration into periodontal tissues. The immunohistochemistry revealed that GFP-positive cells were detected in the periodontal tissues, both in the experimental and control specimens. The GFP-positive cells histopathologically differentiated into some cell types. The fluorescence IHC and TRAP staining techniques demonstrated these cells were detected as osteoclasts and macrophages. Furthermore, GFP-positive cells gathered adjacent blood vessels. The data suggest that GFP-positive bone marrow-derived cell migrate into periodontal tissues and differentiate periodontal tissue component-cells. In the experimental group, there were numerous GFP-positive cells appearing in the experimental periodontal tissues which received intermittent stimulation of orthodontic mechanical stress, but there were few GFP-positive cells in the control specimens. As a results of the examination group specimens and control group, the ratio of pixel number in the examination group showed 5. 77 ± 3. 24 % (mean ± SD); and that in the control group, 0. 71±0. 45 % (mean ± SD). The examination group was significantly greater than that of control group (Mann-Whitney U test: p<0. 001). Thus, these data indicated that orthodontic mechanical stress acts as a possible promoting factor of transplanted bone marrow-derived cell migration into periodontal tissues, and of differentiation to fibroblasts. **Conclusions.** These results suggest that orthodontic mechanical stress induces transplanted bone marrow-derived cell migration and differentiation into periodontal tissue.

OPTIMIZATION OF CRYOPRESERVATION CONDITIONS FOR MESENCHYMAL STEM CELLS USED FOR BONE REPAIR

A Briquet, A Halleux, C Lechanteur, Y Beguin
University of Liège, Liège, Belgium

Background. The utilization of tissue engineering in the repair of bone defects has shown great promise recently. In combination with appropriate biomaterials and growth factors, bone marrow-derived mesenchymal stem cells (MSC) have been proven to significantly enhance bone repair in large animal fracture models. MSC banking is feasible but the optimal technique of cryopreservation must be developed. **Aims.** First, we tested different cryoprotectants (CPA) (DMSO and/or trehalose and/or sucrose) and different concentrations. Then, we studied speed of freezing process as well as technique of elimination of CPA after thawing process. **Methods.** $2x10^6$ cells were transferred to a cryovial containing each CPA solution. Cryovials were immediately frozen at -80°C during 24h then transferred into a liquid nitrogen cylinder at -196°C. After 1 week, the vials were removed from liquid nitrogen, placed in a 37°C water bath. Then, cellular suspension was washed twice with cold culture medium. Viability was analyzed with a Trypan blue dye exclusion assay. Cell proliferation of cryopreserved MSC was determined after 7 days of culture. **Results.** No significant differences in viability percentage were detected among cryopreservation solutions with 5% and 10% DMSO independent of addition of trehalose or sucrose. When cells were cryopreserved with 2,5% DMSO, fewer than 30% of MSC were viable. Proliferation didn't change significantly after thawing process in 15 media tested. However, proliferation tends to be more important when MSC are frozen in 5% DMSO + trehalose. When MSC were freezed with a freezing container (-1°C/min) and when DMSO were washed drop by drop, viability percentage reached more than 90%. **Conclusions.** In conclusion, it would be possible to replace standard CPA (10% DMSO) by a solution with 5% DMSO + 60mM trehalose. It is preferable to freeze the cells in a progressive way and to wash slowly the cells.

1901

THROMBIN GENERATION AND CONVENTIONAL COAGULATION MARKERS IN PATIENTS WITH LOW PT AND/OR APTT

E Papakonstantinou[1], E Yfantis[2], A Theofani[2], A Skourbouti[2], P Georgoutsou[2], C Sereti[2], P Safioleas[2], C Manti[2]
[1]Hospital, Agia Paraskevi, Greece
[2]Thriassion Hospital, Eleusina, Greece

Background. The endogenous thrombin potential (ETP) represents the balance between pro- and anti-coagulable processes in plasma and can be used to identify hypo- and hyper-coagulabiltiy. The ETP assay offers a new measure of global coagulability. The ETP Assay is a functional assay for quantification of thrombin generation capacity. The evaluation of the reaction kinetic of the thrombin generation allows potential value for clinical diagnosis, drug monitoring and epidemiology. Recently a test has become available to routinely measure the endogenous thrombin generation potential (ETP) by Dade Behring (Germany). Results are automatically calculated by the BCS® System with the ETP analysis software. Some investigators believe that patients with low values of conventional coagulation tests (PT/INR, aPTT) have an increased incidence of thrombosis. Extensive coagulation studies have not yet been deriving a stable model of thrombosis in those patients. As a preliminary step to larger clinical studies we investigated the effect on ETP values of patients presenting low values on Conventional coagulation tests (PT/INR, aPTT). **Aims.** The comparison of ETP values and conventional coagulation markers between controls and patients with low PT and/or aPTT. **Methods.** 120 samples, of consecutive patients with low values of conventional coagulation tests PT/INR and/ or aPTT, and 30 samples of controls were investigated for PT/INR, APTT, and ETP parameters. We considered low values for INR less than 1 and aPTT lower than 26 seconds. We used the chromogenic method on the fully automated Behring Coagulation System (BCS) for the measurement of thrombin generation parameters. **Results.**The patients were 45 males and 75 females . There were no significant differences between them according either conventional coagulation tests or ETP parameters. We had 32 patients with low PT/INR and aPTT, 104 patients with both low PT/INR, and 43 patients with aPTT values less than 26 seconds and 120 patients with low PT/INR and / or aPTT. Although all the results were significant, except Cmax parameter, the most significant differences were observed in low PT/INR group. (Table 1). **Summary and Conclusions.** The automated ETP test can play an important role in the evaluation of haemostatic function in patients with low values in conventional coagulation tests. A potential clinical implication of these findings is that the laboratory investigation of the coagulation function, presently performed with the PT and APTT, is inadequate to assess the true risk of thrombosis. Perhaps the measurement of thrombin generation might be more suitable to evaluate the thrombotic risk. Although plausible, this hypothesis needs to be sustained clinically by a prospective study.

Table 1.

MANIFESTATION AGE OF THROMBOLISM IN THROMOPHILIA

G Gaman, A Gaman
University of Medicine and Pharmacy of Craiova, Craiova, Romania

Background. Thrombophilia is diagnosed in 45-50 % of patients suffering from thromboembolic events. More than 8% of thrombosis cases present combined hereditary thrombophilic defects. For most of them, life-long treatment with anticoagulants is recommended. Severity of thrombophilia can be calculated from the manifestation age of thromboembolism. Different thrombophilic states were examined to find out whether combined defects really are more dangerous than single defects really and do require life long anticoaguagulation. **Aims.** To report our experience of treating 655 patients (150 male, 505 female), with an average age at diagnostic of 41 ± 12years. **Methods.** In all patients, we determined fibrinogen, antithrombin III, PT, APTT, protein C, protein S, antithiphospholipid antibodies, factor V Leyden, homocysteine, prothrombin G 20210 A, and MT HRF (667 T)-polymorphisms were checked. **Results.** Thrombophilic defects were detected in 241 patients;MTHFR polymorphism and hyperhomocysteinemia were found in 67 of them. 83 patients presented factor V mutation, in 24 protein S was deficient, in 12 protein C was deficient, in 13 patients prothrombin polymorphism was present and in 42 anthiphospholipid syndrome was detected. Six patients had a combination of three and 19 of two such defects. Manifestation age of thromboembolism in patients without coagulation defects was of 41 ± 12 years. In patients with coagulation defects, manifestation age was not significantly earlier, except for patients with anthithrombin deficiency (16 ± 2 years). Patients with combined defects presented a manifestation age of 32 ± 12 years (3 defects) and 33 ± 11 years (2 defects). **Conclusions.** Based on the manifestation age of thromboembolism, combined thrombophilic defects do not seem to be more severe than single defects. Therefore, life-long oral anticoagulants are not necessary in every patient with combined thrombophilic defects.

1903

CONGENITAL CAVAL AND PELVIC VEIN ABNORMALITIES AS A RISK FACTOR FOR RECURRENT DVT IN YOUNG PATIENTS

M Kennedy, T Sklyar, S Macrino, G McLean
WPAHS, Pittsburgh, United States of America

Background. During the embryogenesis, the inferior vena cava (IVC) develops from 3 pairs of embryonic veins. Disruption of this process may result in condition known as IVC agenesis. Idiopathic deep venous thrombosis (DVT) presents a clinical challenge regarding duration of anticoagulation therapy, when no apparent risk factors are identified. When a young patient presents with extensive DVT, congenital anomalies of the IVC preventing efficient venous blood flow from lower extremities may be the reason. **Aims.** We report 5 patients presenting with juvenile idiopathic DVT without apparent family history of venous thrombosis. **Methods.** Retrospective chart review. **Results.** See attached Table 1 for the clinical details that established the diagnosis of congenital IVC anomaly.

Table 1.

Patient (sex)	Age at presentation (years)	Presentation	Provoking factors	Anatomy
DB (M)	24	Bilateral DVT of common iliac veins	None	Absence of the subrenal segment of the IVC
	28	Bilateral DVT of common iliac, internal and external iliac, and common femoral veins	Prolonged travel	
DT (F)	19	Bilateral DVT of femoral veins	OCP	Azygos continuation of the IVC
	21	Left lower extremity DVT	None	
BH (M)	Newborn	Renal vein thrombosis	None	Azygos continuation of the IVC
	13, 14	Left iliofemoral thrombosis, with recurrence	None	
	15	Right lower extremity DVT	None	
	23	DVT of right popliteal and distal femoral veins	None	
SB (F)	13	Left common iliac vein thrombosis, including femoral, saphenous veins	None	Azygos continuation of the IVC
	16	Bilateral DVT of common iliac veins, including chronic thrombus in IVC	None	
AS (F)	29	Bilateral DVT of common iliac veins	Prolonged travel	Hypoplasia both common iliac veins

Conclusions. Young patients presenting with idiopathic DVT require extensive workup including hereditary thrombophilia, autoimmune and neoplastic disorders. Inferior vena cava agenesis is another risk factor that should be considered, especially in patients without family history of venous thrombosis or distinct thrombophilia. Imaging studies, such as CTA venography, should be included in the workup. In majority of cases long-term anti-thrombotic therapy is warranted.

1904

LUPUS ANTICOAGULANTS IN KOREAN PATIENTS WITH ACUTE ISCHEMIC STROKE

SY Cho, HJ Lee, JT Suh, TS Park, HJ Yoon
Kyung Hee University Hospital, Seoul, South-Korea

Background. Antiphospholipid antibodies (APAs), including Lupus Anticoagulant (LA), anticardiolipin antibodies and anti beta-2 glycoprotein I (ab2-GPI), are capable of causing endothelial damage which subsequently can leads to thrombosis. **Aims.** Recently, it has been reported that pediatric cerebellar stroke associated with elevated ab2-GPI. Because cardiovascular involvements are common feature of antiphospholipid syndrome, we studied prevalence rates of LA especially in patients with acute ischemic stroke. **Methods.** Dilute Russell's viper venom time test was done to screen the presence of LA in STA-R (Diagnostica Stago, Inc.). Other autoantibody tests were done using ELISA methods. This study involved 358 patients, 224 males and 134 females (mean age 48. 26 years), with acute ischemic stroke who visited our hospital from August 2008 to July 2011. **Results.** Male to female ratio was 1:1, and the median age was 52. 5 years. In total patients, 8 individuals showed the increased LA result (range 1. 28-67. 5) and 50% of patients (4/8) presented significantly increased LA results (Table 1). Of these patients, one female had rheumatism (multiple sites, unspecified) as an underlying disease and showed all positive results in the 3 kinds of APAs. In these 8 patients with positive LA results, 4 patients had decreased protein S activity levels, and decreased protein C activity levels were found in 2 patients. **Conclusions.** A prospective study should be followed to investigate pathophysiology of LA and other APAs such as ab2-GPI in ischemic stroke. Moreover, further studies are needed to confirm the importance of transient and persistent APAs and their prognostic implications.

Table 1. Characteristics of patients with the positive LA result in 358 patients with acute ischemic stroke.

Case number	Age (y)	Gender	LA**	aCL (U/mL)	ab2-GPI (U/mL)	APA (U/mL)	Anti-dsDNA (U/mL)
1	28	F	+(67.5)	+IgM (40.0)	NA	+IgG (12.0), +IgM (46.0)	-
2	34	F	+(59.4)	-	-	-	-

THROMBOLYSIS WITH RECOMBINANT TISSUE PLASMINOGEN ACTIVATOR IN SEVEN CHILDREN

B Birol, A Meral Günes, E Semizel, O Bostan, M Sezgin Evim
Uludag University, Bursa, Turkey

Background. The information about the thromboembolic events, the optimal treatment choice, the dose and duration of antithrombotic therapy in children are limited. More clinical data are required. Recombinant tissue plasminogen activator (r-tPA) is increasingly used in pediatric thrombosis. **Results.** We retrospectively analyzed the clinical course of 7 children (9. 3±2. 1 years; 34 day to 16 year) with arterial thrombosis (n:1) and intracardiac thrombosis (n:6). The children were treated with r-tPA. The dose ranged between 0. 2-0. 4mg/kg/h infused for 3 to 4 hours. This dose was repeated between 2 to 7 times till the thrombolysis was achieved. Treatment side effects were closely monitored.

Complete clote lysis was achieved in all cases. None of them had severe bleeding except mild recurrent epistaxis occurring in 2 cases. **Conclusions.** In conclusion, r-tPA is an effective and safe therapy under close haemostatic control in children.

1906

THROMBIN GENERATION PARAMETERS IN VARIOUS HYPERCOAGULABLE STATES

E Papakonstantinou[1], E Yfantis[2], A Theofani[2], A Lakoumenta[2], A Lavda[2], C Pegos[2], K Safioleas[2], C Manti[2]
[1]Hospital, Agia Paraskevi, Greece
[2]Thriassion Hospital, Eleusina, Greece

Background. The endogenous thrombin potential (ETP) represents the balance between pro- and anti-coagulable processes in plasma and can be used to identify hypo- and hyper-coagulabiltiy. The ETP assay offers a new measure of global coagulability. Recently a test has become available to routinely measure the endogenous thrombin generation potential (ETP) by Dade Behring. Acute myocardial infraction (AMI) is a hypercoagulable state. Thrombosis correlates significantly with MM. The role played by coagulation system in multiple myeloma (MM) thrombosis is unclear. People with myeloproliferative disorders (MPD) have an increased incidence of both arterial and venous thrombosis. Some investigators believe that patients with low values of conventional coagulation tests (PT/INR, aPTT) have an increased incidence of thrombosis. Extensive coagulation studies have not yet been derived a stable model of thrombosis in those patients. As a preliminary step to larger clinical studies we investigated the effect on ETP values in those patients. **Aims.** Comparison of ETP values inbetween controls, AMI, MM, MPD and patients with low PT and/or aPTT. **Methods.** 31 patients with AMI were included. Blood was sampled on admission. 18 consecutive samples of MM patients. 24 patients with MPD [10 essential thrombocythaemia (ET), 2 atypical MPDs, 9 polycythaemia vera (PV), 2 chronic myeloid leukaemia (CML) and 1 mastocytosis] were recruited . 120 samples, of consecutive patients with low values of conventional coagulation tests PT/INR and/ or aPTT, and 30 samples of controls were investigated for ETP parameters. We considered low values for INR less than 1 and aPTT lower than 26 seconds. We used the chromogenic method on Behring Coagulation System for the measurement of thrombin generation parameters. **Results.**The results are statistically significant (p< 0. 05) with the exception of ETP in MM and Cmax in low PT/APTT group. MPD patients with ET compared with patients with PV had decreased tlag (24 vs 34. 8), tmax (67. 7 vs 84. 1) but increased Cmax (113. 3 vs 80) and ETP (409. 1 vs 312. 2). ET patients had increased ETP compared to control group (409. 1 vs 395). (Table 1). **Summary and Conclusions.** Although AMI is a hypercoagulable state, AMI ETP is comparable to the values of ETP in controls. ETP appears to take a rather width range of values in AMI. In MM group although ETP had not statistical significance the other parameters were significant. Thrombotic tendency in MPDs, by ETP parameters, did not emerge in this study except the increase of ETP in ET compared to the control group. Increased ETP values were characteristically observed in low PT/APTT group. The automated ETP test can play an important role in the evaluation of haemostatic function in patients in a hypercoagulable state. A potential clinical implication of these findings is that the laboratory investigation of the coagulation function, presently performed with the PT and APTT, is inadequate to assess the true risk of thrombosis. Perhaps the measurement of thrombin generation might be more suitable to evaluate the thrombotic risk. Although plausible, this hypothesis needs to be sustained clinically.

Table 1.

	CONTROL	AMI	MM	MPD	LOW PT/APTT
tlagsec	19.2	41.4	24	29	29
tmax sec	54	86.2	91	77	75

COMPARATIVE STUDY OF CORRELATION D-DIMER WITH THE TYPE OF NEOPLASM AND THE PRESENCE OR NOT METASTASIS IN PEOPLE WITH TUMOR AND IN THE GENERAL POPULATION

S Patiakas[1], N Giannakoulas[2], F Girtovitis[3], S Chatzizisi[4], K Rousos[5], I Xanthakis[6]
[1]General Hospital of Kastoria, Greece, Kastoria, Greece
[2]Hematological Department of Universal Hospital of Larissa, Larissa, Greece
[3]Universal Hospital of Thessaloniki "Achepa",, Thessaloniki, Greece
[4]General Hospital of Thessaloniki "Saint Dimitrios", Thessaloniki, Greece
[5]Health Center of "Alexandria" - General Hospital of Veria, Veria, Greece
[6]General Hospital of Thessaloniki "Papageorgiou",, Thessaloniki, Greece

Background and Aims. To study the values of d-dimer in neoplastic patients, both in relation to the type of tumor, and the presence or absence of metastases, and compare our results with those in the general population, because as we know, the d-dimer, resulting from the breakdown of fibrin, an indicator of activation of fibrinolysis and increased not only in thrombosis and pulmonary embolism, but also in cases of malignancy. **Materials and Methods.** We studied a total of 82 cancer patients (39 men and 43 women), average age 70. 4 years. Everyone was measured with the help of an automatic analyzer using the immunotholosimetrias levels of d-dimer (the lowest price was set at 250 ng /ml), while the results were compared with the group of 80 people (normal controls), roughly similar age (average: 65. 8 years). Followed by a statistical study of our data using the statistical package SPSS. **Results.** The average rate of d-dimer was: 1715 ng /ml in 11 cases of endometrial cancer (of which 6 with metastases), 1498 ng /ml in 19 women with breast cancer (11 with metastases), 1192 ng / ml in 12 patients with ovarian cancer (7 with metastases), 545 ng /ml for 22 patients with lung Ca (12 with metastases) and 512 ng /ml for those with Ca colon (18 patients of which 5 with metastases). Similarly, in the control group the average rate was 217 ng /ml. **Conclusions.** Therefore: 1)The average rate of d-dimer in all forms of cancer are greatly increased, compared with the general population. 2)The higher values observed in endometrial cancer and breast cancer, and 3)In all forms of cancers, no statistically significant correlation exists between the presence of metastases and increased d-dimers.

1908

BLOW-UP PLASMIN GENERATION: A THEORETICAL STUDY OF THE FIBRINOLYTIC REGULATORY SYSTEM

K Guria[1], A Gagarina[1], G Guria[2]
[1]Moscow Institute of Physics and Technology, Moscow, Russian Federation
[2]National Center for Hematology, Moscow, Russian Federation

Blood coagulation system (BCS) is responsible for thrombi formation and bleeding stoppage, while fibrinolytic system (FS) is responsible for the dissolution of thrombi and recovery of blood supply. Under normal physiological conditions, there is a dynamic balance between these two systems. A disruption of this balance may lead to thromboses and embolism or, on the contrary, to bleeding and blood loss. Therefore the investigation of the regulatory mechanisms governing these two systems certainly is a matter of great scientific and practical interest. According to modern views, the processes of thrombolysis under normal physiologic conditions develop relatively slowly in comparison with thrombi formation processes. However, some of the clinically observed phenomena (such as the disseminated intravascular blood coagulation (DIC)) show that besides the processes of gradual clots dissolution, a rapid thrombi lysis may also occur in the organism. Obviously, a possibility to control the activation of such rapid fibrinolysis is a matter of great clinical interest, both for the purposes of thrombosis treatment and blood loss prevention. The aim of the present work was to reveal the possible mechanisms that could lead to the switching of the regulatory system to rapid thrombolysis. For this purpose we analyzed the network of kinetic reactions involved in the regulation of fibrinolysis. Summarizing the available scientific data, we derived a detailed graph-scheme representing the interaction of key substances such as plasminogen, plasmin, prourokinase, urokinase, tissue plasminogen activator, fibrin, prekallikrein, kallikrein, XI and XII factors of BCS. Analysis of the positive feedback loops existing in this network of reactions enabled us to distinguish a block of reactions forming the central catalytic core, that is responsible for the eventual autocatalytic generation of plasmin and urokinase. After the subsequent reduction of the detailed graph-scheme we eventually derived a mathematical model describing the kinetics of FS regulatory processes in terms of differential equations. Using the obtained mathematical model we investigated the problem of existence and stability of stationary states of the fibrinolytic regulatory system. It was established that within a wide range of parameters the system has a ground state, characterized by relatively small concentrations of active enzymes, and stable with respect to subcritical perturbations of active enzymes concentra-

tions. On the other hand, supercritical perturbations exceeding the activation threshold value lead to abrupt (blow-up) generation of plasmin in the system. Thus the proposed model offers an explanation of rapid-evolving fibrinolytic processes as a result of threshold activation of blow-up plasmin generation. Parametric diagrams of stability of the ground state were built. It was shown that blow-up generation of plasmin may be caused not only by a supercritical perturbation of active enzyme concentrations, but also by the change of system parameters leading to a loss of stability of the ground state. We hope that the results obtained in this work will be of interest not only to researchers specializing in the investigation of FS regulation, but also to specialists in clinical hematology.

1909

DISTRIBUTION OF THE CEREBRAL VENOUS SINUS THROMBOSIS IN GRAN CANARIA UNIVERSITY HOSPITAL DR. NEGRIN

M Gordillo Martin, M Perera, I Balda, B Sevillano, Y Ramos, D Fiallo, T Molero
HU Doctor Negrin, Las palmas de gran canaria, Spain

Background. Cerebral venous sinus thrombosis (CVST) is a rare disease of the central nervous system that represents 0. 5% of all the strokes. This disease is associated with an overall mortality of 9%. It usually affects young adults with acquired or congenital thrombotic risk factors. Clinical manifestations are produced by two basic mechanisms: thrombosis of the brain veins and sinus causing intracranial hypertension, infarction and edema. The diagnosis is made using imaging techniques such as CT-SCAN and MRI, in young patients showing typical clinical manifestations. **Aims.** Revision of the patients diagnosed of CVST from the year 2000 to nowadays, evaluating their clinical and biological conditions. **Results.** 24 patients with ages from 20 to 77 were diagnosed of CVST using imaging techniques: 17 women (70 %) and 7 men (30 %). 60 % of the events were localized in the superior longitudinal sinus. In 30 % of cases, there was more than one affected sinus. 20 (84 %) patients had a screening thrombophilia test performed which included: resistance to activated C protein, molecular study of Factor V Leyden and G20210 mutation., study of the inhibitors (AT, PrC, PrS), fibrinolysis proteins (PLAT, PAI1f and plasminogen) lupic anticoagulant, anti cardiolipin antibodies, anti beta 2 glycoprotein and serum homocysteine levels; finding some kind of alteration in 10 (50%) of these patients. (Table 1). The risk factors that were found were: the intake of oral contraceptive medication, obesity, sedentarism, puerperium, smoking, collagenosis and neoplasia. Of the 7 patients who were taking oral contraceptive pills, 3 presented a FII G20210 mutation. One of these patients presented also high levels of homocysteine. Most of the patients begun therapy with heparin and anti vitamin K medication, without observing recurrence of the event. **Conclusions.** CVST is a disease etiologically related mainly with infectious processes, but nowadays it is considered secondary to a state of hypercoagulability in young adults, associated to a confirmed thrombophilic state. Its outcome, sometimes fatal, considerably improves with a prompt diagnosis followed by an early anticoagulant treatment. Our results correlate with the limited existing bibliography, showing a predominance of the feminine sex and the affected sinus. We have found biological trombophilic alterations in 10 patients out the 20 that were analyzed, and also vascular risk factors, being the most frequent one the intake of contraceptive oral medication. The duration of the anticoagulant treatment is controversial, coming from 6 months up to indefinite; depending on the observed procoagulant alterations, the severity of the clinical manifestations, recurrence and the persistence of the vascular risk factors. The relation between the evolution and early treatment, makes it necessary the clinical suspect in young women with associated risk factors and headache, who come to the emergency service.

Table 1.

Congenital alterations	N. of patients (%)	Acquired alterations	N. of patients (%)
Heterozygous state for FIIG20210*	3 (27%)	Hyperhomocysteinemia*	4 (36%)
Protein S deficit	1 (10%)	Lupic anticoagulant	3 (27%)

*1 patient showed both alterations

1910

THROMBOTIC MICROANGIOPATHY WITH SEVERE RENAL FAILURE SECONDARY TO BETA-INTERFERON TREATMENT FOR MULTIPLE SCLEROSIS

C Orvain, JF Augusto, G Marc, JF Subra, J Sayegh
CHU d'Angers, Angers, France

Background. Thrombotic microangiopathies (TMA) are a heterogeneous group of diseases characterized by a mechanic hemolytic anemia, platelet consumption, and organ failure due to endothelial injury and development of microthrombi. Some TMA are due to a severe defect in ADAMTS 13, a plasma enzyme involved in the cleavage of von Willebrand factor (VWF) multimers into smaller and less adhesive VWF forms. ADAMTS 13 deficiency can either be hereditary or acquired due to autoantibodies that alter the protein function. Such secondary forms can be caused by drugs, pregnancy, bone marrow transplantation, HIV infection, systemic lupus erythematosus, or malignancy. In the literature, alpha-interferon is known to induce autoimmune manifestations including cases of alpha-interferon-induced TMA due to ADAMTS 13 autoantibodies. Although, beta-interferon can induce local reactions, no systemic autoimmune manifestations were reported. We report herein the first case of TMA due to ADAMTS 13 autoantibodies in a patient receiving beta-interferon treatment. Case report: A 52 years old male patient with multiple sclerosis treated since 2008 with beta-interferon was admitted to the emergency for dyspnea. The patient had no other medical conditions and received no other treatment. Renal function was normal a few months before admission. For two weeks preceding his admission, he was experiencing severe headaches due to severe arterial hypertension which was resistant to standard treatment. On admission, physical examination showed severe arterial hypertension (185/114 mmHg) associated with tachycardia (110/min) and signs of diffuse hyperhydration. Dipstick showed major proteinuria and microscopic hematuria. Biological investigations confirmed TMA with hemolytic anemia (hemoglobin at 5. 9 g/dL, LDH at 6N, low haptoglobin levels and elevated reticulocyte count) and thrombopenia at 75 G/L with severe anuric renal failure (creatininemia at 1131 µmol/L, uremia at 35. 5 mmol/L). Urinary analysis revealed proteinuria of glomerular profile (1. 60 g/day). Emergency hemodialysis was undertaken and plasma exchanges associated with plasma infusions were started promptly. Immunological investigations found an undetectable ADAMTS 13 activity due to a circulating anti-ADAMTS 13 antibody. There was no complement activation and antinuclear antibodies were present. Renal biopsy confirmed the diagnosis with severe arteriolar and glomerular TMA involving 50% of the glomerulus. After eight sessions of plasma exchanges associated with plasmatherapy, the hemolytic process could be stopped and plasmatherapy was discontinued. Meanwhile, steroids were introduced at the dose of 1 mg/kg/day and beta-interferon treatment was discontinued in the hypothesis of an autoimmune process secondary to beta-interferon treatment. There was no renal recovery and patient remained hemodialysis-dependent. During follow-up, ADAMTS 13 activity was still very low associated with recurrence of hemolysis and thrombopenia leading us to initiate rituximab treatment in addition to plasma exchanges associated with plasma infusions. **Conclusions.** This case demonstrates that beta-interferon treatment can be responsible for anti-ADAMTS 13 antibody-induced TMA and severe renal failure.

1911

PROTROMBOTIC COAGULATION ABNORMALITIES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA BEFORE AND AFTER START OF THE THERAPY

E Hait
Russian Research Institute of Haematology and Transfusiology, Saint-Petersburg, Russian Federation

Background. Patients with multiple myeloma (MM) have an increased risk of thromboembolic complications. The pathogenic mechanism of the increased activity of FVIII is unclear, but may be explained by neovascularization in the bone marrow stroma. It is known that the chemotherapy causes the activation of blood coagulation in myeloma patients. Extremely high level of FVIII may be a sign of hypercoagulation and risk factor of cardiovascular disease. **Aims.** To investigate activity of FVIII before and after start of the treatment in patients with newly diagnosed MM. **Methods.** We investigated platelet-poor plasma from 25 patients with newly diagnosed MM (age 51-78); 13(52%) persons had the primary thrombotic history and 12(48%) did not have thrombotic anamnesis. Control group comprised 82 ages-, sex-matched healthy individuals. The FVIII activity was measured before and after start of induction therapy. Differences were evaluated with non-parametric statistical methods (Wilcoxon test, Statistica 6. 0) and significance assumed for p< 0, 05. **Results.** FVIII activity in patients without thrombotic history did not differ from the control group before start of the therapy. However, it significantly increased during the induction treatment. FVIII activity in patients with primary thrombotic history was higher compared to the control group in both periods (Table 1). **Summary:** FVIII activity increased in patients with newly diagnosed multiple myeloma, especially in the group with primary thrombotic history. Activity of FVIII in patients without thrombotic history was significantly higher then the patients with it after start of the treatment.

Table 1.

Patients	Without thrombotic history (n=12)	With thrombotic history (n=13)
Laboratory parameters	FVIII:C (%) Me	FVIII:C (%) Me
Before therapy	166,0	240,5*
After start of therapy	264,0*,**	198,0*

*- p< 0,05 for difference with controls** - p< 0,05 for difference with values before therapy.

1912

SUCCESSFUL USE OF FONDAPARINUX IN A CHILD WITH HEPARIN-INDUCED THROMBOCYTOPENIA, RELATED TO ANTIPHOSPHOLIPID SYNDROME AND PROTHROMBIN G20210A MUTATION

H Tokgoz[1], U Caliskan[1], M Demir[2]
[1]Konya University Meram Faculty of Medicine, Konya, Turkey
[2]Trakya University Medical Faculty, Edirne, Turkey

Background. Heparin induced thrombocytopenia (HIT) is an immune-mediated disorder characterized by the development of antibodies against the complex of platelet factor 4 (PF-4) and heparin. Documentation of antibodies against PF4-heparin complexes is necessary but not sufficient for diagnosis of HIT. When the diagnosis of HIT is confirmed or suspected, all forms of heparin should be discontinued and other non-heparin anticoagulants should be administered such as argatroban, bivaluridin, lepirudin. **Aims.** This case presentation aims that fondaparinux is an effective alternative treatment for children with HIT. We also emphasized some difficulties of pediatric thrombosis such as HIT and APS. **Case Report.** A 12 year-old-boy was developed deep vein thrombosis (DVT). Risk factors for initial thrombosis are antiphospholipid syndrome (APS) and heterozygous mutation for prothrombin G20210A mutation and methylenetetrahydrofolate reductase (MTHFR-C677T) gene. Anticoagulant therapy with warfarin for 12 months was effective, but discontinuation of warfarin after 12 months resulted in recurrence of DVT. Unfractioned heparin (UFH) was initiated during the acute period of DVT, but HIT was developed. Transition from unfractioned heparin to fondaparinux resulted in successful anticoagulation for a period of platelet recovery. **Conclusions.** This case highlights several difficulties in pediatric HIT cases. It is difficult to management of patients with HIT, especially in the presence of prothrombotic genetic risk factors and APS. The use of fondaparinux may be an alternative treatment modality for effective anticoagulation in the acute period of pediatric thrombosis in cases of HIT.

1913

EVALUATION OF THROMBOPHILIA IN WOMEN WITH RECURRENT PREGNANCY COMPLICATIONS

A Gaman, G Gaman
University of Medicine and Pharmacy of Craiova, Craiova, Romania

Introduction. Inherited or acquired thrombophilia is associated with a high risk of pregnancy complications (preeclampsia, intrauterine fetal death, intrauterine growth restriction, pregnancy loss). Methylenetetrahydrofolate reductase (MTHFR) mutations, prothrombin G 20210A mutations, factor V Leiden G1691A and antiphospholipid syndrome cause thrombophilia. **Aims.** to evaluate the risk factor of thrombophilia in women with recurrent pregnancy complications. **Methods.** we studied 38 women with a history of recurrent pregnancy complications (median number of pregnancy complications: 3), age between 20 - 45 years, during a year (2011). Detection of thrombophilic mutations was made by Polymerase Chain Reaction and anticardiolipid antibodies by ELISA (IgG and IgM), with a confirmatory test of at least 12 weeks apart from the first measurement. **Results.** in 30 women (80%) diagnosis of thrombophilia was confirmed: twenty-one had MTHFR mutations (7 homozygous, 14 heterozygous), four had prothrombin G20210A mutation, in one case factor V Leiden was detected and in four cases anticardiolipid antibodies. In 40% of cases, other risk factors were associated (age > 40 years, smoking, obesity). **Conclusions.** Thrombophilia is associated with a high risk of pregnancy complications and a thrombophilic evaluation should be performed in women with recurrent pregnancy loss.

1914

A SURVEY OF THROMBOPHILIA RISK FACTORS AND MARKERS IN IRANIAN PATIENTS WITH DEEP VEIN THROMBOSIS

G Janbabai[1], M Ahmadinejad[2], A Sharifpour[3], M Davoodi[1], M Taghipour[1], R Sharifian[1], T Farazmandfar[1], F Hassannataj[1], R Shekarriz[1]
[1]Cancer Research Center, Sari, Iran
[2]Blood Transfusion Organization, Tehran, Iran
[3]Internal Medicine Department, Sari, Iran

Background. Thrombophilia is an abnormality of blood coagulation that can cause problems such as the deep-vein thrombosis (DVT). **Aims.** In this study we evaluated the effect of hereditary factors on thrombophilia. **Methods.** 95 DVT patients received heparin therapy followed by warfarin for six months. Then warfarin was stopped, and heparin therapy was continued for two more weeks. Thrombophilia factors and other markers were examined in these patients. **Results.** 37 patents (38. 9%) were male and 58 were (61. 1%) female. 18. 94% of patients had increased levels of homocysteine. 10. 52 % of patients had elevated levels of factor VIII. 21. 05% of patients had elevated levels of factor V-Leiden. **Concolusion**:DVT was most common in females. DVT was significantly associated with a history of thrombosis, OCP use and positive family history. Elevated levels of homocysteine and factor VIII, and S protein deficiency were common.

1915

USE OF FIBRINOGEN CONCENTRATE IN THE INFANT AND NEONATAL POPULATION

S Loingsigh, C Buckley, M Williams, B Nolan, C McMahon
Our Lady's Children's Hospital, Crumlin, Dublin 12., Dublin, Ireland

Background. Acquired hypofibrinogenaemia can develop for a number of reasons including disseminated intravascular coagulation and massive transfusion and in the neonatal population, prematurity or congenital liver dysfunction are other possible causes. Fibrinogen concentrate (FC) was first studied in congenital hypofibrinogenaemia or dysfibrinogenaemia but in older children (6 years and up) and adults. There is little, if any, data available on administration in infants and neonates to guide dosage. In 2009, the Irish Blood Transfusion Service withdrew cryoprecipitate - made in Ireland- (except in some very well defined circumstances) and replaced it with fibrinogen concentrate for use in hypofibrinogenaemic states. This decision was made on the basis of a perceived lower risk of transmission of variant Creuzfeldt-Jaeger Disease with the latter product. Our institution is a tertiary referral paediatric centre which performs all neonatal cardiac surgery on the island of Ireland. **Aims.** To record the dose of FC given, clinical background/indication of patients receiving FC and increment of fibrinogen level found on laboratory testing. **Methods.** We identified the patients who received fibrinogen concentrate since its introduction through blood bank records. The notes were then procured and reviewed with respect to clinical background and exact dose of FC administered and weight of child. The dose per kilogram of body weight was calculated. Laboratory parameters prior to and following FC administration were recorded as were any other blood products administered. Not all patients had a repeat fibrinogen level done on the day they received FC so levels the following day were recorded as post dose levels. **Results.** We identified 49 patients under the age of 12 months who received fibrinogen concentrate amounting to 74 episodes as some had repeated infusions. 27/49 were neonates and they accounted for 40/74 transfusions. The recommended dose at our institution for fibrinogen concentrate is 70-100mg/kg. 9/74 episodes used doses lower than 70mg/kg and 6/74 doses higher than 100mg/kg. Data on weight was not obtained in 6/74. Fibrinogen levels prior to and following FC infusion where available were recorded. 1/74 did not have a baseline fibrinogen level. 4/74 did not have a fibrinogen level done within 24 hours of infusion. On 3/74 occasions fibrinogen level post infusion was lower than the baseline level despite receiving 70-100mg/kg FC. On one occasion, there was no change in level. All other patients' repeat fibrinogen levels were higher on repeat. The range of fibrinogen level increment varied from 0. 02 to 2. 71 (0. 13-1. 88 in neonatal group). Patients were grouped into cardiac, liver and other groups depending on the main issue necessitating the use of FC. 25/49 patients required cardiac surgery, 6/49 had liver disease and the remainder had varying pathologies. **Summary and Conclusions.** Whilst FC has been in use for many years, there is a remarkable paucity of data regarding its use in neonates and young children. Our findings suggest that whilst our recommended dose is effective for the

majority of patients, there are a substantial number who require higher or repeated doses and monitoring is required.

1916

PREDICTIVE SCORE FOR EFFECTIVE BLEEDING CONTROL USING RECOMBINANT ACTIVATED FACTOR VII IN PERIOPERATIVE NON-HEMOPHILIC PATIENTS

P Rujirojindakul, P Rujirojindakul, E McNeil
Prince of Songkla University, Hat Yai, Songkhla, Thailand

Background. Recombinant activated factor VII (rFVIIa) has been increasingly used to control life-threatening bleeding following trauma or surgery. Although growing evidences from widespread rFVIIa use may define the efficacy and safety outcomes, there is currently no validated prediction score available to identify non-hemophilic patients undergoing surgery who should have benefits for the off-label use. **Aims.** The purpose of this study was to develop a predictive score based on preoperative parameters to predict effective bleeding control in non-hemophilic surgical patients received perioperative rFVIIa. **Methods.** Between 1 September 2004 and 31 December 2009, a retrospective study was conducted in Songklanagarind Hospital, an 853-bedded tertiary care hospital in southern Thailand. The primary outcome was efficacy of bleeding control defined as patients did not need surgical re-exploration for hemorrhage within 24 hours after rFVIIa administration while the definition of ineffective bleeding control was patients died or needed re-operation due to hemorrhage. The secondary outcomes were units of blood or blood component administered within 24 hours before and after the first dose of rFVIIa. Multivariate logistic regression analysis was performed to develop a new prediction score. The total score of each patient with effective bleeding control was included in a multiple logistic regression equation for conversion to the predictive index. The best cut-off was derived from the ROC curves. To facilitate the clinical use, the probability of effective bleeding control was calculated for each quartile predictive score. **Results.** A total of 320 bleeding episodes from 243 non-hemophilic patients underwent surgery were analyzed. Effective bleeding controls were demonstrated in 153 patients (63%). Mean age and preoperative routine laboratory results were similar in both effective and ineffective groups. The median rFVIIa doses were 87. 3 μg/kg (IQR; 65. 5, 109. 1) in the effective group and 93. 8 μg/kg (IQR; 73. 8, 118. 6) in the ineffective group (p = 0. 13). The overall in-hospital mortality rate was 40%: 41 patients (26. 8%) were in the effective group and 56 patients (62. 2%) were in the ineffective group (p < 0. 001). After rVIIa therapy, the units of blood and blood component transfusion was significantly lower in the effective group (data shown as median (IQR): packed red cell (3 (2,6) vs 6 (3,11), p<0. 001); fresh frozen plasma (4 (3,7) vs 7 (3,15), p<0. 001); platelet concentrate (4, (0,10) vs 10 (0,15), p<0. 001). Multivariate analysis identified four variables as independent predictors for effective bleeding control after rFVIIa administered: timing of rFVIIa administration, intraoperative blood loss, postoperative INR values, and postoperative total unit of platelets transfusion. Using the final regression model, the area under the ROC curve was 0. 844. The rFVIIa successful scores and the probability of effective bleeding control with rFVIIa were shown. (Table 1). **Summary.** The use of this new prediction score may support decision making to identify patients with high probability of effective bleeding control from rVIIa therapy.

Table 1. Prediction of effective bleeding control scores with rVIIa therapy.

Predictors	Categories	Scores
Timing of rFVIIa administered	Pre- or pre- and intra-operative Intra-operative Post-operative Intra- and post-operative	0 44 31 28
Intraoperative blood loss	Per 1,000 mL	-1
INR values after the first dose of rVIIa administered	Normal Prolonged No data	0 -14 -15
Total units of platelet transfusion after the first dose of rVIIa administered	Per unit	-0.6

Score ranges	Probability of effective bleeding control
Less than or equal to -10	10%
-10 to 6.0	50%
5.9 to 23	82%
More than 23	94%

1917

REJUVENATION TREATMENT OF STORED RED BLOOD CELLS PARTIALLY IMPROVES THEIR HEMODYNAMIC/MECHANICAL PROPERTIES

G Barshtein[1], D Arbell[2], O Zelig[3], N Manny[3], S Yedgar[4]
[1]The Faculty of Medicine, Hebrew University, Jerusalem, Israel
[2]Pediatric Surgery, Hebrew University Hadassah, Jerusalem, Israel
[3]Blood Bank, Hadassah Hospital, Jerusalem, Israel
[4]Biochemistry Dep., The Faculty of Medicine, Hebrew University, Jerusalem, Israel

Background. Routine cold-storage of blood units in the blood bank induces deterioration of red blood cell (RBC) flow-affecting properties (FP), specifically deformability, self-aggregability, and adherence to blood vessel wall endothelia cells (EC), as well as their mechanical and osmotic fragility. This phenomenon progresses with storage duration and becomes significant already at the second week of storage. Since stored RBC (St-RBC) with impaired FP induces circulatory disorders, the transfusion of RBC with impaired FP may introduce a risk to blood recipients. To reduce this risk, a post-storage treatment has been proposed, by incubation of stored (St-RBC) units with "rejuvenating"supplements (sodium pyruvate, inosine, adenine and sodium phosphates) prior to transfusion. Previous studies with *in vitro* rejuvenation treatment of St-RBC have shown improvement, to different degrees, in red cells ATP and 2,3-DPG levels, deformability, mechanical and osmotic fragility. However, these studies differed in the storage protocols, in particular in employing St-RBC units with or without pre-storage leukoreduction, while leukoreduction is practiced only in part of the blood banks, depending on the policy of specific country's health authority. **Aims.** The present study was undertaken to systematically examine the efficacy of rejuvenation in rectifying storage-induced damage to RBC stored without leukoreduction. **Methods.** Non-leukoreduced St-RBC were treated with rejuvenation solution ("Rejuvesol") and their adhesion to cultured human microvascular EC and deformability, as well as osmotic and mechanical fragility were determined using a cell flow-properties analyzer (CFA) which provides comprehensive characterization of RBC hemodynamic/mechanical properties in large RBC population as function of shear stress. Concomitantly, we determined the level of RBC surface phosphatidylserine (PS), a mediator of RBC/EC adhesion and RBC splenic clearance, as well as intracellular levels of free radicals and Ca^{++}. These measures were compared with those of the respective untreated St-RBC and of freshly-donated RBC (same unit, pair-test). **Results.** Cold storage induced strong elevation of St-RBC/EC adhesion, cell rigidity, osmotic and mechanic fragility, concomitantly with intracellular Ca^{++} and reactive oxygen species (ROS) level. Increasing RBC adhesion correlated with translocation of PS to RBC surface, a known mediator of RBC/EC adhesion. Post-storage rejuvenation of St-RBC partially reversed these measures, except for PS translocation (80% reversal) and the corresponding RBC/EC adhesion which was completely reversed to that of freshly-collected RBC. **Conclusions.** Previous studies have shown that the mechanical behavior of RBC is affected by a number of structural changes, among them surface area/volume ratio, membrane and skeleton condition (protein cross-linking), and surface charge. All these are irreversibly altered during RBC storage. In accordance with that the present study shows that deformability and fragility of not-leukoreduced St-RBC are only partially reversed by rejuvenation treatment. Since leukoreduction has been shown to decrease storage-induced damage, it is likely that rejuvenation of leukoreduced St-RBC would yield better results. On the other hand, this does not apply to RBC/EC adhesion, which is completely reversed by rejuvenation treatment even with not-leukoreduced St-RBC.

1918

EVALUATION OF IRON OVERLOAD AND CARDIAC FUNCTION BY T2* MAGNETIC RESONANCE IMAGING IN ACUTE LEUKAEMIA SURVIVORS

L Tomlins, M Dennis
Christie NHS Trust, Manchester, United Kingdom

Patients with acute leukaemia require supportive blood transfusions to facilitate potentially curative therapy. Consequently they are at risk of iron overload which can manifest as organ failure eg. heart, renal and liver. Additionally these patients are exposed to high dose anthracycline chemotherapy increasing the potential for late cardiac toxicity. Iron loading is most commonly assessed through serum ferritin levels. However it is established that serum ferritin correlates poorly with organ damage. There is increasing evidence that T2* magnetic resonance imaging (MRI) is able to accurately quantify myocardial and hepatic iron loading through non invasive means. It has additionally been proposed that T2* MRI can identify patients at risk of symptomatic heart failure, making it attractive method for assessing patients who have received anthracycline chemotherapy. A single centre retrospective audit was conducted in adults patients attending clinic between Jan 2010 and Dec 2010 who had

received intensive chemotherapy, with raised serum ferritin levels (>1000µg/l) to evaluate the use of T2* MRI scans. 16 patients (13 AML, 1 ALL and 2 AA) were available for evaluation. The age range at diagnosis was 18-70yrs (median 45yrs) and were between 2 and 10 years from treatment (median 6 yrs). T2* MRI studies were performed using a 1. 5T CMR (Avanto, Siemens). Myocardial T2*, hepatic T2* and LV function were measured. Myocardial iron loading (MIL) was catagorised according to the following results criteria; negative ≥ 20ms, mild 20-14 ms, moderate 14-10ms and severe <10ms. Liver iron loading (LIL) was catagorised as; negative ≤2mg/g) >6. 3ms, mild (2-5mg/g) 6. 3-2. 7ms, moderate (5-10mg/g) 2. 7-1. 4 and severe (>10mg/g) ≤1. 4ms. Patients' had received a median of 42 units of blood (range 11-81) and had a serum ferritin of between 1069µg/l and 6571µg/l. There was no correlation between the number of blood transfusions and serum ferritin level. T2* Cardiac MRI did not identify MIL in any patient (0/16). 10 patients (10/16 = 63%) had mild LIL, however no patients had moderate or severe LIL. There was no correlation between serum ferritin levels and the presence of LIL. 7/16 (44%) patients had an abnormal cardiac function. These were either grade 1 or 2 diastolic dysfunction (n=1 and 2 respectively) or impaired LV systolic function (n=4). 4 of these patients had known cardiac disease therefore identifying 3 patients, who had no other cardiac risk factors, with sub clinical cardiac dysfunction. Although there was no clear correlation between cumulative anthracycline dose and heart function, there was evidence of cardiac impairment in patients who had received even small amounts of anthracycline chemotherapy (range 95mg/m2 -362mg/m2). We have shown that patients who have successfully undergone intensive therapy for acute leukaemia are at risk of cardiac dysfunction as demonstrated by T2*, although we could find no evidence of iron loading as a contributing factor in this heavily transfused group of patients. Routine assessment with serum ferritin appears unnecessary. While hepatic iron loading does not appear to be a major problem in this population, T2* MRI is useful in assessing the severity of hepatic iron loading.

1919

STUDY OF RESIDUAL LYMPHOCYTES IMMUNOPHENOTYPE IN THE PHOTOCHEMICALY TREATED PLATELET CONCENTRATES TRANSFUSED TO ONCOHEMATOLOGICAL PARTIENTS

M Ogorodnikova[1], T Zabotina[2], A Borunova[2], A Onufrievich[1], E Ogorodnikova[2], O Rukavitzin[1]

[1]N. N. Burdenko Main Military Clinical Hospital, Moscow, Russian Federation
[2]N. N. Blochin Cancer Research Center, Moscow, Russian Federation

Background. Contamination of platelet concentrates (PC) by viable donors lymphocytes can lead to transfusion-associated graft versus host disease. Photochemical treatment (PCT) of PC with amotosalen and long-wavelength ultraviolet A (UVA) has been developed to prevent transfusion complications, associated with pathogens and donors leukocytes. The mechanism of action of PCT is non-selective inactivation of pathogens DNA and RNA. **Aims.** The aim of this study was to evaluate the impact of PCT on residual lymphocytes immunophenotype. **Methods.** We used an experimental model of PC in the form of pooled random-donor PC, to perform investigation of residual lymphocytes subpopulations. 16 PC were obtained by the buffy coat method (five buffy coats were pooled) with centrifugation and were suspended in 65% platelet additive solution. PCT of PC were performed with 150µM amotosalen and 3,6 J/cm^2 UVA light. We studied four groups of samples obtained from each PC: 16 samples after PCT on Day 1 and 16 - on Day 5 of storage, 16 untreated samples on the same days. All samples were investigated by flow cytometry. Lymphocytes were identified by the binding of the PE Cy-7-conjugated anti-CD45 antibodies. Lymphocytes (CD45+ cells) were stained with a FITC-conjugated monoclonal antibodies against CD3 (T-lymphocytes), against CD19 (B-lymphocytes) and with PE-conjugated antibodies against CD16CD56 (NK-cells) for gating lymphocytes subpopulations. **Results.** The number of CD3+ cells in untreated samples on Day 1 was 59,06±8,75. PCT of PC was not lead to statistically significant changes (p=0,37) in the number of T-lymphocytes on Day 1. The same number of CD3+ cells (p=0,87) were detected in untreated samples on Day 5. There were not observed differences between PCTed samples on Day 5 and on Day 1 (p=0,68), and between PCTed samples on Day 5 compared with untreated samples on Day 1 (p=0,48). The percentage of B-lymphocytes and NK-cells in untreated samples on Day 1 were 20,3±7,79% and 12,86±4,39% respectively. The same number of CD19+ cells (p=0,17) and CD16+CD56+ (p=0,59) were detected in untreated samples on Day 5. The percentage of B-cells in PCTed PC remained unchanged (p=0,14) on Day 1, whereas the percentage of NK-cells tended to decrease (p=0,05). The results of comparative evaluation of PCTed samples stored for 1 and 5 days demonstrated no differences in the distribution of lymphocyte subpopulations (p=0,68 for B-cells and p=0,2 for NK-cells). The data of comparative analysis of lymphocyte subpopulations in PCTed samples on Day 5 and in untreated samples on Day 1 showed that percentage of CD16+CD56+ cells decreased (p=0,008), and the percentage of CD19+ cells increased (p=0,007) significantly. The results of the distribution of lymphocytes subpopulations presented in Table 1. **Summary and Conclusions.** Inactivation of residual lymphocytes genetic material with PCT of PC was not lead to lymphocytes death during 5 days of PC storage. PCT did not significantly alter the distribution of lymphocyte subpopulations although there appeared to be a modest selective depletion of CD16+CD56+ NK-cells. Thus, these results show that subpopulations of T- and B- lymphocytes are the most stable, while the NK-cells - the most sensitive to PCT.

Table 1. Lymphocytes subpopulations in platelet concentrates (*mean ± standard deviation).

Lymphocytes CD markers (M ± SD *, %)	Untreated PLT Day 1	Untreated PLT Day 5	PCTed PLT Day 1	PCTed PLT Day 5
T-lymphocytes (CD3+)	59,06±8,75	58,63±6,31	60,87±9,65	61,16±6,46
B-lymphocytes (CD19+)	20,3±7,79	21,77±7,33	22,83±5,52	23,94±6,74
NK-cells (CD16+CD56+)	12,86±4,39	13,47±6,46	10,07±3,8	9,36±3,65

1920

PLATELET GRANULE CONTENT RELEASE IN PLATELET CONCENTRATES DURING STORAGE

M Marchetti, A Vignoli, C Tartari, L Russo, E Diani, C Giaccherini, C Verzeroli, A Falanga
Ospedali Riuniti di Bergamo, Bergamo, Italy

Introduction. Platelet activation during storage of platelet concentrates (PC) is an important event and can affect the clinical effectiveness of platelet transfusions. Platelet activation can be estimated through the measurement of proteins specifically located in platelet granules. **Aims.** In this study we evaluate the effect of storage on the expression and release of hemostatic and angiogenic proteins in of PC obtained from buffy coats by standard procedures. **Methods.** 15 (n per blood group: 5 O, 6 A, 4 B) PC were prepared from pools of buffy coats at the Ospedali Riuniti of Bergamo and sampled the day of preparation (D0) and after 3 days of storage (D3). 11 PC (type O=5, type A=6) were prepared by the Fenwal system, and 4 PC (type B) by the Terumo TACSI system. Samples were centrifuged to separate platelets (PLT) from supernatants (S-CP), and both preparations were tested for antigenic levels of P-selectin, vWF (vWF:Ag), Thrombospondin (TSP-1) and VEGF by ELISA. vWF was also measured as activity (vWF:Act) by the collagen binding assay. **Results.** At D0, platelets of A group showed the highest levels of all the molecules analyzed, while B the lowest. The storage caused an overall reduction in the content of the molecules, which varied according to the type of molecule and blood group. Particularly, platelets of B group showed the greatest reductions over time for all the markers. The decrease in platelet granule content was associated to a parallel increase in the correspondent S-PC. P-selectin and VEGF levels showed the greatest increment (+195%), followed by TSP-1 (+86%) and vWF:Ag (+49%), while vWF:Act remained unchanged. In S-CP of B group we observed the greatest increments in TSP-1 (+113%), VEGF (+447%) and P-selectin (+238%) levels. **Conclusions.** At baseline, platelets from A group possess the highest levels of vWF, TSP-1 and VEGF. During storage, platelet degranulation caused an accumulation of these proteins in S- PC. PC of B group showed the highest increase of angiogenic molecules over time. The different preparation method of PC of group B might be responsible of the differences observed.

1921

PATIENT TIME BURDEN ASSOCIATED WITH RED BLOOD CELL TRANSFUSIONS IN CANCER PATIENTS RECEIVING CHEMOTHERAPY IN OUTPATIENT CENTERS IN FRANCE

M De La Orden[1], C Levaché[2], MP Desrosiers[3], M Stolar[3], K Payne[3], E Donahue[3], S Shreay[1]

[1]Amgen Inc., Uxbridge, United Kingdom
[2]Polyclinique Francheville, Perigueux, France
[3]United BioSource Corporation, Dorval, Canada

Background. Anaemia is a common complication in patients with cancer receiving chemotherapy. The European Cancer Anaemia Survey estimated that the incidence of anaemia among patients receiving chemotherapy ranges

from 62. 4% in gastrointestinal/colorectal cancer to 88. 3% in gynecological cancer. Anaemia in patients with cancer can be treated with red blood cell (RBC) transfusions. Patient time burden associated with a treatment is an important factor to consider when measuring the benefits and challenges of a therapy. To date, no research studies aimed at estimating the patient time burden of RBC transfusion to treat anaemia have been identified. **Aims.** The aim of this study is to estimate the patient time burden associated with outpatient RBC transfusion treatment indicated for chemotherapy induced-anaemia (CIA) in patients in France with non-myeloid malignancies. **Methods.** A retrospective chart review of patients with cancer receiving an RBC transfusion was conducted at 8 outpatient centers selected to represent standard of care in France. Patients with a diagnosis of non-myeloid malignancy who received an outpatient RBC transfusion indicated for CIA within a 3 month eligibility period from August 01, 2010 to October 31, 2010 were identified at each site. Patients were randomly selected and screened for study eligibility. Medical records that documented patient and treatment characteristics and time spent in the clinic during a patient's transfusion visit were used to quantify the outpatient RBC transfusion time. Total RBC transfusion time for one unique transfusion visit per patient was measured as: time elapsed from pre- to post-transfusion vital sign assessment and from transfusion start to stop time. Additional data were also collected, including: elapsed time from haemoglobin (Hb) level testing to transfusion, elapsed time from blood draw for compatibility testing to transfusion; estimated transfusion day travel time and distance calculated with mapping software on the basis of patient address information; and clinical and demographic information. **Results.** A total of 128 patients (60. 9% male, mean age 64. 0 years [standard deviation: 12. 8]) were enrolled in the study. The four most frequent diagnoses were: lung cancer (25. 8%); gynecological cancer, (16. 4%); urological cancer (14. 8%); and gastrointestinal/colorectal cancer (14. 8%). The mean elapsed time between pre- and post-vital sign assessment was 3. 8 hours (95% CI: 2. 0-5. 6), including a mean of 3. 2 hours (95% CI: 2. 4-4. 0) spent on the transfusion itself. Hb level testing (mean pre-transfusion Hb level: 7. 9 g/dL [standard deviation: 0. 8]) and blood draw for compatibility testing were completed in a mean of 26. 1 hours (95% CI: 5. 1-47. 1) and 9. 9 hours (95% CI: 1. 0-18. 9) prior to transfusion, respectively. Patient one-way mean travel time to the transfusion centre was 37. 7 minutes (95% CI: 32. 6-42. 9) and mean distance travelled was 28. 0 km (95% CI: 15. 3-40. 8). **Conclusions.** In France, the management of CIA is a time consuming activity for patients with cancer as they are required to travel to a specific clinic, undergo blood testing (including Hb and compatibility testing) and endure the transfusion procedure itself. This burden should be considered when deciding on an anaemia treatment preventing the need for transfusions. More time efficient treatment alternatives are clearly warranted.

1922

A RETROSPECTIVE ANALYSIS OF USE OF PROTHROMBIN COMPLEX CONCENTRATE FOR REVERSAL OF ANTICOAGULATION WITH WARFARIN IN A LARGE CENTRE

K Raza, E O'Gribin, P Murphy
Beaumont Hospital, Dublin, Ireland

Introduction. Prothrombin complex concentrate (PCC) is indicated for the emergency reversal of warfarin therapy in patients with major bleeding manifestations or requiring urgent surgical procedures and for coagulation defects in liver disease. PCC nominally contains blood coagulation factors II, VII, IX, X, protein C and protein S as active ingredients. It also contains sodium and heparin (100-250 IU per vial) as excipients. **Objective.** We performed a retrospective analysis of use of PCC in a tertiary hospital in order to ascertain its dose, indications for use, efficacy (INR before ad after PCC administration), use of other blood products and its safety. **Methods.** Forty-four patients who had received PCC over a 12 months period between December 2008 and January 2010 were identified from blood transfusion records. PCC was administered in accordance with hospital protocols. The median dose of PCC prescribed was 2000 IU (range 1000 - 3000 IU). The most common reasons for anticoagulation were identified to be atrial fibrillation (n=18) and venous thrombosis (n=13). PCC use was approved by haematology team in 7 cases. All patients were anticoagulated with warfarin except one. Most decisions to treat with PCC were from nephrology for renal transplant patients (27%) followed by medical (23%), surgical (23%) and emergency department (11%). International normalised ratio (INR) was measured before and after the administration of PCC. **Results.** 23 patients with bleeding (52%) and 21 non-bleeding patients (48%) received PCC. INR was measured and documented within one hour of PCC administration in 28 patients (61%) and within 24 hours in 41 patients (91%). Time to infusion from prescription was unknown in a significant number of patients (n=29) due to lack of documentation. Only 19 patients (43%) received vitamin K (15 of 23 bleeding patients and 4 of 21 non-bleeding patients) prior to PCC administration. INR was recorded to be >1. 5 in 43 patients (98%) before the administration of PCC. After PCC administration INR was <1. 5 in 34 patients (83%) within next 24 hours. Blood products were used sparingly (red cells to 16, plasma to 7, fibrinogen concentrate to 1 and platelets to 2 patients) within 48 hours of PCC administration. No serious adverse events were recorded. **Conclusions.** These results clearly demonstrated the efficacy and safety of PCC in patients requiring rapid warfarin reversal. There was considerable reduction in the use of other blood products during the 24 hour period after PCC administration. Partial or complete response was seen in 37 patients (84%). The data also identified a significant number of patients who did not receive concurrent vitamin K (57%). In a significant number of patients (n=16) INR was not measured within one hour of PCC administration. The monitoring of INR within one hour and 24 hours of PCC administration is recommended to ensure sustained and effective reversal of warfarin. This may highlight an ongoing educational need.

1923

PREGNANCY IN SICKLE CELL DISEASE: MATERNAL AND FETAL OUTCOMES IN OUR PATIENTS RECEIVING PROPHYLACTIC BLOOD EXCHANGE TRANSFUSIONS

S Cabibbo, C Fidone, V Spadola, P Bonomo
Uos Ematologia Asp 7, Ragusa, Italy

Background. Sickle cell disease (SCD) encompasses inherited anemias due to beta globin mutations that result in the formation of sickled red cells and increased red cell turnover. The complications of SCD are both acute and chronic, and this combination results in significant morbidity, high healthcare utilization over the lifespan, and increased premature death. Whereas many avenues have been explored to manage complications of SCD as they arise, renewed attention has been focused on pregnancy management because during pregnancy the risk for preeclampsia and deep venous thrombosis is increased and occlusion of placenta blood vessels with rigid deformed erythrocytes can cause repeated miscarriages and intra-uterine fetal death. Blood exchange transfusion can prevent these complications by reducing the concentration of abnormal hemoglobin S. **Aims.** To describe perinatal and maternal outcomes for pregnant women with sickle cell disease (SCD) receiving prophylactic blood exchange transfusions. **Methods.** This was a retrospective cohort study, covering the period from January 2001 to December 2011, which included all pregnant women with SCD followed up at our institution inSicily. We managed 12 pregnancies in 10 patients (7 SS, 3 S/b-thalassemia) that were in care because of a history of severe sickling complications. 3 Patients had a history of one or more pregnancies with severe maternofetal complications when treated in other institutions without receiving prophylactic blood exchange transfusion. In our institution all the patients received manually or automated Red cell exchange using a Spectra-Cobe blood cell separator when the haemoglobin S (HbS) was more than >50% and the aim was to achieve a proportion of HbS below 30% and a hemoglobin level between 9 and 11 g/dL. The maternal and perinatal outcomes were compared to those of the same pregnant women when treated in other institutions not receiving prophylactic blood exchange transfusion. **Results.** We performed 40 automated and 24 manually red cell exchange. No serious maternal complication was observed, no fetal or perinatal death occurred and no low birth weight. **Summary and Conclusions.** Our study suggests that women with severe sickle cell disease, even if they have a serious obstetrical history, can carry their pregnancy to term, without major obstetric complications, through a combination of early management (first trimester) by a multidisciplinary team and a suitable policy of prophylactic manually or automated red cell exchange transfusion

1924

CLINICAL OUTCOMES OF ABO INCOMPATIBLE RBC TRANSFUSIONS

S Mahjoub, E Chakroun, H Baccouche, Z Manai, N Ben Romdhan
Hopital La Rabta, Tunis, Tunisia

Background. ABO mismatch blood transfusion is one of seriousness events related to blood components administration. **Aims.** We performed a retrospective review of ABO-incompatible RBC transfusions from our institution during four years (2007-2011). **Results.** Within the period of observation, 20 ABO mismatches were detected (effective transfusions and near miss events). 12 ABO mismatches were detected when blood samples are studied for pre-transfusions tests (mistake in sample collection or identification and one case of usurpation of identity). Of 8 patients who received more than 50 ml of incompatible blood, 4 (50%) manifested signs or symptoms related to the incompatible transfusion but none died. Hypotension, hemoglobinuria, postoperative bleeding were detected in survivors. In the half of our cases (4 patients), there were no associated signs or symptoms due to the incompatible transfusions.

Conclusions. ABO incompatible RBC transfusion does not inevitably mean death or even occurrence of symptoms. Awareness of staff at the bedside and laboratory of the potential for errors is one of the most effective tools for detecting and preventing transfusion errors.

TRANSFUSION RELATED PULMONARY COMPLICATIONS: A SINGLE CENTRE EXPERIENCE

C Alarcon Gil, E Martinez Revuelta, JM Garcia Gala, C Buesa Garcia, F Garcia Menendez-Tevar
Hospital Universitario Central de Asturias, Oviedo, Spain

Background. Transfused related acute lung injury (TRALI) is a major cause of transfusion related morbidity and mortality. Its real incidence is unknown because is an underdiagnosed entity and remains a challenge to the practicing clinician. An immune mechanism is recognized in most cases of TRALI, related with anti-HLA class I and class II or anti-HNA antibodies in donor´s plasma. Non-immune mechanisms include the age of stored blood, neutrophil-priming agents released in stored cellular blood components and bioactive lipids. **Aims.** To review the experience on Transfusion related pulmonary complications in the last 12 years in a tertiary-care teaching hospital. MATERIALS AND **Methods.** Transfusion reactions notified between January 2000 and December 2011 were reviewed. Cases of transfusion related respiratory symptoms, including dyspnoea and desaturation, were selected. Age, sex, diagnosis, clinical course and outcome, type of blood component and age of product at time of transfusion were reviewed. Clinical charts were reviewed by three independent observers and a consensus diagnosis and degree of imputability was assigned. **Results.** 64. 559 patients were transfused in the last 12 years in the Hospital Universitario Central de Asturias. 288. 599 blood components were administered. 554 transfusion reactions were notified. In 40 patients (7. 2%) respiratory symptoms were present. A chest-X ray was performed in only 10 patients. No serologic studies were performed. The median age was 62 years (range 21-73), 38 patients (95%) were older than 50 years; 22 were female (55%). Packed red blood cells (all of them leucorreduced) were the most commonly blood component associated with transfusion related respiratory symptoms in our Centre, 25 cases (62. 5%9, followed by platelets, 11 cases (27. 5%) and fresh frozen plasma, 4 cases (10%). Packed red blood cells involved in transfusion reactions had more than 14 days of storage in 30 cases (75%). The most frequent diagnosis was hematologic malignancy, during the induction phase of chemotherapy, 26 patients (65%), followed by cardiac surgery, 8 patients (20%). Only 3 patients (7. 5%) were defined as possible TRALI in according to degree of imputability. No deaths were attributed to TRALI. **Conclusions.** Real incidence of transfusion related acute lung injury, which frequently is not recognized or misdiagnosed, has not been stablished. It´s important an adequate clinical diagnosis, including x-Ray and serologic studies, in order to stablish appropriate therapeutic measures and effective preventive measures. Hematologic malignancies, cardiac surgery and prolonged storage time of packed red blood cells were associated with transfused related respiratory symptoms, as previously reported in the literature.

PRBC MEMBRAINE MECHANICAL FRAGILITY - SOURCES OF VARIABILITY IN A BLOOD BANK INVENTIORY

M Tarasev[1], K Alfano[1], S Chakraborty[1], M Bertholf[2], A Zubair[3]
[1]Blaze Medical Devices, Ann Arbor, United States of America

Background. Red Blood Cell (RBC) membrane Mechanical Fragility (MF) had been proposed as a candidate metric of storage lesion with potential relevance to cells' performance post-transfusion *in-vivo*. While a number of studies demonstrated loss of RBC deformability/increase of fragility during cells' storage, the clinical relevance of this effect remains to be proven. Focus on storage time, however, typically ignores variability in pRBC due to donor-to-donor differences, as well as due to differences in manufacturing processes and storage practices. These, largely storage time-independent confounding factors, can significantly impact the properties of pRBC membrane in blood bank inventories which can potentially result in a variable in-vivo performance of cells even of the same storage age. **Aims.** To determine the impact, if any, of donor-related and manufacturing-related variables on pRBC properties in blood bank inventory. **Methods.** 102 pRBC samples, all irradiated, prepared by either Whole Blood donation (WBD) or through apheresis collection (AC) and leukoreduced either at 4-6 ºC or at room temperature (Warm Leukoreduction, WL), were collected from 4 test segments, combined, and characterized by storage time (AGE), total hemoglobin (HBT), auto hemolysis (AH), blood type, and donor demographics. To obtain variable-parameter fragility profiles, mechanical stress was applied using a bead mill with the oscillation frequency held at 50Hz while durations were varied between 0. 5 and 45 minutes. Fragility profiles were described in terms of hemolysis levels at particular durations (H), the inverse thereof (S), and the slope of the fragility profile curve (K). **Results.** MF parameters of pRBC varied significantly between the units with differences reaching 100-fold for selected parameters. Manufacturing variables were found to be the most significant predictor of MF accounting for 10 to 40 percent of the observed variability. Manufacturing-related aspects including the type of blood collection and leukofiltration, blood bag types, storage solutions and in-bag hemoglobin concentration were tightly cross correlated resulting in uncertainty in the determination of the underlying cause of variability. Donor demographic, including donor age, hemoglobin at donation, gender and race were poorly correlated with MF. AGE and time since irradiation were similarly poorly correlated with MF likely due to their contribution being substantially smaller than variability due to manufacturing and donor-specific differences. Unaccounted for variability in MF parameters is likely due to donor-to-donor variability due to varying cells' biological age at donation and potential individual donor differences in membrane composition. **Conclusions.** Donor-to-donor differences are indicated as a single most significant factor responcible for MF variability-Cold leukoreduction and/or apheresis collection may be preferable manufacturing approaches for preserving pRBC plasticity, although further work will be needed to account for confounding effects. Optimization of manufacturing practices has the potential to significantly impact in-vitro MF of pRBC in storage. **Disclosures.** This work was supported in part by Blaze Medical Devices of Ann Arbor, MI.
