About EHA

The European Hematology Association (EHA) is a non-profit scientific association that represents European medical professionals with an active interest in hematology.

The Annual Congress, organized in a major European City, offers the opportunity to learn about new data from basic, translational and clinical research and gives access to knowledge that directly impacts the clinical practice. Not only the size of the congress increased over the years but also the first steps towards creating an education and career development program were taken.

Educational needs are the focus of our continuing medical education program. Not only through live events, but also through the EHA Learning Center, a recently launched online platform. EHA supports high quality science: we encourage research by creating a network and sharing knowledge.

EHA offers education and training and supports the careers of hematologists in Europe and travelling to Europe through its fellowships and grants program. Different fellowships are available for basic, translational and clinical researchers both in their early or advanced career.

As the largest organization of hematologists in Europe, EHA has taken it upon itself to serve and further their political interests. We advocate for you on the EU level for more research funding, improved research environment and better access to hematology care.

More information about EHA activities can be found at ehaweb.org.

EUROPEAN HEMATOLOGY ASSOCIATION

NOW 50% DISCOUNT ON MEMBERSHIP FEES FOR THE REMAINDER OF 2015

Become a member of EHA for 2015!

Support our mission to promote excellence in patient care, research and education in hematology.

Join more than 4,000 members from over 100 countries worldwide and enjoy membership benefits that open opportunities for both professional and personal development within the field of hematology.

BECOME A MEMBER!

- Full Membership € 155
- Junior Membership € 20
- Health Care Affiliated Professional Membership € 90
- Emeritus Membership € 90

ENJOY OUR MEMBERSHIP BENEFITS ALL YEAR ROUND

EUROPEAN HEMATOLOGY ASSOCIATION

haematologica

Journal of the European Hematology Association
Owned & published by the Ferrata Storti Foundation

Word of Welcome

We are proud that this year we can, together with you, celebrate 20 years of the annual congress of the European Hematology Association. On behalf of the EHA Board and the Scientific Program Committee we are therefore pleased to introduce to you this year's anniversary Abstract Program.

The Scientific Program Committee has compiled an exciting and topical program of Simultaneous Oral and Poster Sessions from over 2200 submitted abstracts. The poster sessions have a slightly different setup this year. A selection of posters will be presented in the traditional Poster Walks. More time will be dedicated to discussion of the important research presented there, so look out for the Poster Walk Moderators in their fashionable red baseball caps! There will also be E-posters available on the E-poster screens, for which a specific time is allocated during the Poster Browsing Time at the end of each Walk. The simultaneous oral sessions have now been spread over three days (Friday to Sunday), with the five Best Abstracts to be presented during the Presidential Symposium on Friday afternoon.

For the second year running, we have invited "late breaking abstracts" for "hot" data that were not available by the time of the regular submission deadline. The most exciting results have been selected and will be presented in the two dedicated sessions on Sunday morning. There are also late breaking posters that will be included in the poster walk of the relevant topic.

All posters can be viewed on the E-poster screens from Friday morning to Saturday evening and are also available on the EHA Learning Center, for which delegates have complimentary access after the congress: learningcenter.ehaweb.org.

On behalf of the EHA Board, the committees and all the people involved in this years' EHA congress, we thank you for coming to Vienna and wish you a good meeting.

David Grimwade
Chair Scientific Program Committee 20th Congress

EUROPEAN HEMATOLOGY ASSOCIATION

Information for readers, authors and subscribers

Haematologica (print edition, pISSN 0390-6078, eISSN 1592-8721) publishes peer-reviewed papers on all areas of experimental and clinical hematology. The journal is owned by a non-profit organization, the Ferrata Storti Foundation, and serves the scientific community following the recommendations of the World Association of Medical Editors (www.wame.org) and the International Committee of Medical Journal Editors (www.icmje.org).

Haematologica publishes editorials, research articles, review articles, guideline articles and letters. Manuscripts should be prepared according to our guidelines (www.haematologica.org/information-for-authors), and the Uniform Requirements for Manuscripts Submitted to Biomedical Journals, prepared by the International Committee of Medical Journal Editors (www.icmje.org).

Manuscripts should be submitted online at http://www.haematologica.org/.

Conflict of interests. According to the International Committee of Medical Journal Editors (http://www.icmje.org/#conflicts), "Public trust in the peer review process and the credibility of published articles depend in part on how well conflict of interest is handled during writing, peer review, and editorial decision making". The ad hoc journal's policy is reported in detail online (www.haematologica.org/content/policies).

Transfer of Copyright and Permission to Reproduce Parts of Published Papers. Authors will grant copyright of their articles to the Ferrata Storti Foundation. No formal permission will be required to reproduce parts (tables or illustrations) of published papers, provided the source is quoted appropriately and reproduction has no commercial intent. Reproductions with commercial intent will require written permission and payment of royalties.

Detailed information about subscriptions is available online at www.haematologica.org. Haematologica is an open access journal. Access to the online journal is free. Use of the Haematologica App (available on the App Store and on Google Play) is free.
For subscriptions to the printed issue of the journal, please contact: Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, E-mail: info@haematologica.org).

Rates of the International edition for the year 2015 are as following:

	Institutional	*Personal*
Print edition	*Euro 500*	*Euro 150*

Advertisements. Contact the Advertising Manager, Haematologica Office, via Giuseppe Belli 4, 27100 Pavia, Italy (phone +39.0382.27129, fax +39.0382.394705, e-mail: marketing@haematologica.org).

Disclaimer. Whilst every effort is made by the publishers and the editorial board to see that no inaccurate or misleading data, opinion or statement appears in this journal, they wish to make it clear that the data and opinions appearing in the articles or advertisements herein are the responsibility of the contributor or advisor concerned. Accordingly, the publisher, the editorial board and their respective employees, officers and agents accept no liability whatsoever for the consequences of any inaccurate or misleading data, opinion or statement. Whilst all due care is taken to ensure that drug doses and other quantities are presented accurately, readers are advised that new methods and techniques involving drug usage, and described within this journal, should only be followed in conjunction with the drug manufacturer's own published literature.

Direttore responsabile: Prof. Edoardo Ascari; Autorizzazione del Tribunale di Pavia n. 63 del 5 marzo 1955.
Printing: Tipografia PI-ME, via Vigentina 136, Pavia, Italy. Printed in April 2015.

haematologica
the hematology journal

The origin of a name that reflects Europe's cultural roots.

Ancient Greek

αἷμα [haima] = blood
αἵματος [haimatos] = of blood
λόγος [logos]= reasoning

Scientific Latin

haematologicus (adjective) = related to blood

Scientific Latin

haematologica (adjective, plural and neuter, used as a noun) = hematological subjects

Modern English

the hematology journal
2012 JCR® Impact Factor = 5.935

Haematologica/The Hematology Journal, as the official organ of the European Hematology Association (EHA), aims not only to serve the scientific community, but also to promote European cultural identity.

IMPROVED OVERALL SURVIVAL WITH AUTOLOGOUS TRANSPLANTATION *VS* CYCLOPHOSPHAMIDE-LENALIDOMIDE-DEXAMETHASONE IN NEWLY DIAGNOSED MYELOMA: A PHASE 3 TRIAL

F. Gay[1,*] M. Genuardi[1], R. Hajek[2], M.T. Petrucci[3], L. Pour[4], A.P. Falcone[3], M. Offidani[3], F. Patriarca[3], P. Corradini[3], M. Gilestro[1], N. Pescosta[3], A.M. Carella[3], P. Finsinger[3], A.M. Liberati[3], D. Petrò[3], S. Pulini[3], S. Oliva[1], F. Di Raimondo[3], A. Spencer[5], M. Boccadoro[1], A. Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy, [2]Faculty of Medicine, University of Ostrava and Department of Haematooncology, University Hospital Ostrava, Ostrava, Czech Republic, [3]Italian Multiple Myeloma Network, GIMEMA, Italy, [4]Department of Hematology and Oncology, University Hospital Brno, Brno, Czech Republic, [5]Alfred Health-Monash University, Melbourne, Australia

Background: High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) improves survival in multiple myeloma (MM) patients. The introduction of novel agents has challenged the role of ASCT at diagnosis.
Aims: We conducted a multicentre international randomized phase 3 trial to compare ASCT with conventional chemotherapy plus lenalidomide in patients ≤65 years with newly diagnosed MM. The primary endpoint was progression-free survival (PFS), the secondary endpoints included safety and overall survival (OS).
Methods: Eligible patients ≤65 years of age with newly diagnosed MM were enrolled. All patients received lenalidomide-dexamethasone induction (four 28-day cycles of lenalidomide 25 mg day 1–21 and low-dose dexamethasone 40 mg day 1, 8, 15, 22) followed by stem cell mobilization. Patients were randomized to receive consolidation with 2 cycles of MEL200-ASCT (melphalan 200 mg/m^2 with stem-cell support) or cyclophosphamide-lenalidomide-dexamethasone (CRD) [six 28-day cycles of cyclophosphamide (300 mg/m^2 day 1, 8, 15), dexamethasone (40 mg days 1, 8, 15, 22) and lenalidomide (25 mg days 1–21)].
Results: Three-hundred and eighty-nine patients were enrolled in the trial. Patient characteristics were well balanced between MEL200-ASCT and CRD. After a median follow-up of 4 years, the median PFS was 42 months for MEL200-ASCT and 28 months for CRD (HR 0.67, 95% CI 0.48-0.93, P=0.014). The 4-year OS was 87% for MEL200-ASCT and 71% for CRD (HR 0.51, 95% CI 0.28-0.93, P=0.028). The advantage in PFS and OS for MEL200-ASCT *vs* CRD was noticed in most of the analysed subgroups. The rate of grade 3-4 hematologic (84% *vs* 26%, P<0.001) and non-hematologic (39% *vs* 22%, P=0.008) adverse events (AEs) was higher in the MEL200-ASCT arm compared with the CRD arm. The main non-hematologic AEs were infections (19% with MEL200-ASCT *vs* 6% with CRD, P=0.004) and gastrointestinal AEs (20% with MEL200-ASCT *vs* 5% with CRD, P<0.001). Toxicities were however manageable. Despite the increase in grade 3-4 AEs with MEL200-ASCT, the rate of serious hematologic (0% *vs* 2%, P=0.49) and extra-hematologic AEs (7% *vs* 10%, P=0.393) was similar between MEL200-ASCT and CRD arms. No toxic deaths were reported in the MEL200-ASCT arm; 1 patient died of septic shock in the CRD arm. Four patients who went off protocol before consolidation developed a second primary malignancy (SPM): 1 renal cancer, 1 breast cancer, 1 squamous cell carcinoma, 1 gastrointestinal cancer. Eight patients randomized to MEL200-ASCT developed a SPM: 6 squamous cell carcinomas, 1 melanoma, and 1 prostate cancer. Five patients randomized to CRD developed an SPM: 1 squamous cell carcinoma, 1 renal cancer, 1 breast cancer, 1 gastrointestinal cancer and 1 glioblastoma.
Summary and Conclusions: MEL200-ASCT significantly prolonged PFS and OS in comparison with CRD. No increase in serious AEs, toxic deaths, and SPMs were reported with MEL200-ASCT.

Background: Panobinostat (PAN), a potent pan-deacetylase inhibitor (pan-DACi), targets aberrations in multiple myeloma (MM) biology, including epigenetics and protein metabolism. In the PANORAMA 1 phase 3 clinical trial, the addition of PAN to bortezomib (BTZ) and dexamethasone (Dex; PAN-BTZ-Dex) led to a clinically relevant and statistically significant increase in median progression-free survival (PFS) of ≈ 4 months compared with placebo (Pbo) + BTZ and Dex (Pbo-BTZ-Dex) in patients (pts) with relapsed or relapsed and refractory MM.
Aims: To better characterize the efficacy and safety of PAN-BTZ-Dex within pt populations with limited treatment options by presenting a subgroup analysis of pts from the PANORAMA1 trial based on prior treatment.
Methods: The study design was described previously (San-Miguel JF, *et al. Lancet Oncol.* 2014;15:1195-1206). For this subanalysis, pts were analyzed for efficacy and safety based on prior treatment characteristics, including receipt of prior immunomodulatory drugs (IMiDs); BTZ + IMiDs; and BTZ + IMiDs and ≥2 prior lines of therapy.
Results: A summary of efficacy based on prior treatment is provided in the Table. Consistent or better efficacy benefit for the PAN arm was observed across all subgroups analyzed. The benefit in median PFS was particularly noteworthy among the largest subgroup in this analysis, pts who received prior IMiDs. A total of 485 pts (63%) received prior IMiDs (PAN-BTZ-Dex [n =245] or Pbo-BTZ-Dex [n =240]). Among these pts, the median PFS as determined by investigator assessment for the PAN arm was 12.3 months (95% CI, 10.25-13.83) *vs* 7.4 months (95% CI, 6.01-7.89) for the Pbo arm (hazard ratio [HR] 0.55; 95% CI, 0.44-0.70). The overall response rate for these pts was 62% (95% CI, 55.6%>68.1%) *vs* 50% (95% CI, 43.3%>56.5%), and ≥near complete response (nCR) rate was 29% (95% CI, 23%>34.7%) *vs* 13% (95% CI, 8.9%>17.8%) in the PAN and Pbo arms, respectively. Common grade 3/4 adverse events and laboratory abnormalities in each arm included thrombocytopenia (67% *vs* 36%), lymphopenia (54% *vs* 41%), neutropenia (37% *vs* 13%), diarrhea (26% *vs* 8%), and asthenia/fatigue (25% *vs* 12%). The percentage of on-treatment deaths in each arm was 7.1% *vs* 4.2%. The safety profile was consistent among the other subgroups analyzed.

Tabella 1. Efficacy of PAN-BTZ-Dex and Pbo-BTZ-Dex among patient subgroups classified by prior treatment history

	Prior IMiD (n = 485)		Prior BTZ + IMiD (n = 193)		Prior BTZ + IMiD and ≥ 2 prior lines (n = 147)	
	PAN-BTZ-Dex (n = 245)	Pbo-BTZ-Dex (n = 240)	PAN-BTZ-Dex (n = 94)	PAN-BTZ-Dex (n = 99)	PAN-BTZ-Dex (n = 73)	Pbo-BTZ-Dex (n = 74)
PFS, months (95% CI)	12.3 (10.3-13.8)	7.4[a] (6.0-7.9)	10.6 (7.6-13.8)	5.8[b] (4.4-7.1)	12.5 (7.3-14.0)	4.7[c] (3.7-6.1)
ORR, % (95% CI)	62 (55.6-68.1)	50 (43.3-56.5)	58.5 (47.9-68.6)	41.4 (31.6-51.8)	58.9 (46.8-70.3)	39.2 (28.0-51.2)
nCR/CR, % (95% CI)	29 (23.0-34.7)	13 (8.9-17.8)	22.3 (14.4-32.1)	9.1 (4.2-16.6)	21.9 (13.1-33.1)	8.1 (3.0-16.8)

[a] HR, 0.55; 95% CI, 0.44-0.70
[b] HR, 0.52; 95% CI, 0.36-0.76
[c] HR, 0.47; 95% CI, 0.32-0.72

Summary and Conclusions: PAN-BTZ-Dex demonstrated efficacy, with consistent increases in median PFS and nCR/CR rates compared with the Pbo arm among pt subgroups with a clear unmet need, including an increase in PFS of nearly 5 months among pts who received prior IMiDs. The safety profile across these subgroups was consistent with that in the overall PANORAMA 1 population, with the exception of the frequency of on-treatment deaths, which was more similar between treatment arms across each subgroup.

S103

A RANDOMIZED, OPEN-LABEL, PHASE 2 STUDY OF BORTEZOMIB AND DEXAMETHASONE WITH OR WITHOUT ELOTUZUMAB IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA

(ABR), Redwood City, [13]Bristol-Myers Squibb, Wallingford, United States, [14]Azienda Ospedaliero Universitaria San Giovanni Battista di Torino-Ospedale Molinette, Torino, Italy

Background: Elotuzumab, an immunotherapeutic monoclonal antibody (mAb), recognizes Signaling Lymphocytic Activation Molecule F7 (SLAMF7), a protein highly expressed on myeloma cells and natural killer cells. Elotuzumab targets and kills SLAMF7-expressing myeloma cells by direct activation of natural killer cells with minimal effect on normal tissues. Elotuzumab demonstrated enhanced activity when combined with bortezomib in a preclinical myeloma model,[1] and elotuzumab/bortezomib showed encouraging clinical activity in a Phase 1 study.[2]

Aims: This Phase 2 open-label study (NCT01478048, CA204-009) aimed to investigate the efficacy and safety of elotuzumab + bortezomib/dexamethasone (Bd) compared with Bd alone in patients (pts) with relapsed/refractory multiple myeloma (RRMM).

Methods: Pts with RRMM who had received 1–3 prior therapies were given elotuzumab + Bd (EBd) or Bd in 21-day (Cycles 1–8) or 28-day Cycles (9+) until disease progression or unacceptable toxicity. Dosing schedule: elotuzumab (10 mg/kg IV) weekly Cycles 1–2, Day 1 and 11 Cycles 3–8, then Day 1 and 15; bortezomib (1.3 mg/m^2 IV/SC) Day 1, 4, 8, and 11 Cycles 1–8, then Day 1, 8, and 15; dexamethasone 20 mg on non-elotuzumab days, 8 mg PO + 8 mg IV on elotuzumab days. The primary endpoint was progression-free survival (PFS; ITT population) according to IMWG criteria. In this proof-of-concept study, a 2-sided 0.30 significance level was specified to test for PFS difference between arms; p≤0.3 was considered significant. The study had 80% power to detect a hazard ratio (HR) of 0.69 with 103 events. Informed written consent was obtained for all participants.

Results: In total, 152 pts (median age 66 years) were randomized to either EBd (77) or Bd (75). At data cut-off (12 Sep 2014), 18% of pts treated with EBd *vs* 10% of pts treated with Bd remained on therapy. The median number of treatment cycles was 12 with EBd and 7 with Bd. Discontinuation was mainly for disease progression (52%). HR for PFS was 0.71 (70% CI 0.58, 0.87; p=0.08). One-year PFS rate was 39% (95% CI 28%, 50%) in the EBd group *vs* 32% (95% CI 21%, 44%) in the Bd group, and 2-year PFS rate was 24% (95% CI 13%, 36%) in the EBd group and 6% (95% CI 1%, 19%) in the Bd group (Figure). PFS HR (EBd *vs* Bd), adjusting for prognostic factors, was 0.58 (70% CI 0.47, 0.72; p=0.01). The median PFS observed with EBd was 9.7 months, *vs* 6.9 months with Bd. Overall response rate was 66% with EBd *vs* 63% with Bd. Early overall survival (OS) results revealed a HR of 0.61 (70% CI 0.43, 0.85); 1-year OS rate was 85% (95% CI 75%, 92%) in the EBd group *vs* 74% (95% CI 62%, 83%) in the Bd group (Figure). Forty deaths (17 EBd, 23 Bd) were observed at the time of analysis, mainly due to disease progression. Follow-up for OS continues. Grade 3/4 adverse events (AEs) were reported in 51 (68%) pts with EBd treatment *vs* 45 (60%) with Bd. AEs ≥Grade 3 that occurred in ≥15% of pts in each group were thrombocytopenia (7 [9%] in EBd group; 13 [17%] in Bd group) and infections (14 [19%] in EBd group; 11 [15%] in Bd group). Infusion reactions (IRs; all Grade 1–2) occurred in 7% of pts treated with EBd. There were no IRs at the maximum planned 5 mL/min infusion rate.

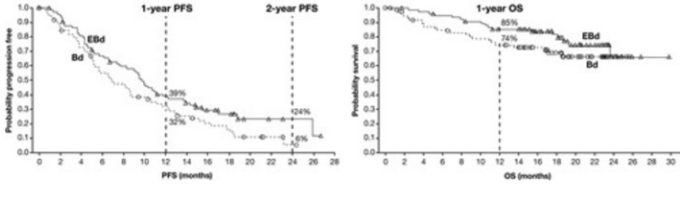

Figure 1. Progression-free survival (PFS) and overall survival (OS)

Summary and Conclusions: This study met the primary endpoint: PFS was longer with EBd than with Bd. More pts continued on EBd than Bd and early OS data favor EBd. Rate of IRs was low with EBd, and IRs were manageable with premedication. In pts with RRMM, elotuzumab, an immunotherapeutic mAb, provides clinical benefit with limited added toxicity when combined with Bd *vs* Bd alone.

NEOD001 DEMONSTRATES CARDIAC AND RENAL BIOMARKER RESPONSES IN A PHASE 1/2 STUDY IN PATIENTS WITH AL AMYLOIDOSIS AND PERSISTENT ORGAN DYSFUNCTION

M. Liedtke[1,*] H. Landau[2], R. Comenzo[3], D. Seldin[4], B. Weiss[5], J. Zonder[6], J. Walling[7], G. Kinney[8], M. Koller[8], M.A. Gertz[9]

[1]Stanford University School of Medicine, Stanford, [2]Memorial Sloan-Kettering Cancer Center, New York, [3]Tufts Medical Center, [4]Boston University, Boston, [5]University of Pennsylvania, Philadelphia, [6]Karmanos Cancer Institute, Detroit, [7]JW Consulting, Hillsborough, [8]Prothena Biosciences Inc, South San Francisco, [9]Mayo Clinic, Rochester, United States

Background: Light chain (AL) amyloidosis results from an accumulation of misfolded proteins that cause the dysfunction of vital organs (eg, heart and kidneys). Current therapeutic approaches target the plasma cells that produce the pathogenic light chain proteins and are typically associated with significant adverse effects. There is a substantial need for a safe and effective therapy that specifically targets the misfolded proteins responsible for the underlying organ dysfunction. NEOD001, a monoclonal antibody that targets these misfolded proteins, is hypothesized to neutralize circulating soluble protein aggregates and to clear insoluble aggregates from organs. We report data from a phase 1/2 dose-escalation/expansion study of NEOD001 in patients with AL amyloidosis and persistent organ dysfunction (NCT01707264).

Aims: The primary aims of this study were to determine the maximum tolerated dose/recommended phase 2 dose (RP2D) and the safety and tolerability of single-agent NEOD001 when administered to patients with AL amyloidosis. Secondary and exploratory objectives included pharmacokinetics (PK), immunogenicity, and hematologic and best organ responses based on consensus criteria.

Methods: Patients who completed ≥1 previous anti–plasma cell systemic therapy, had partial response or better, did not require additional chemotherapy, and had persistent organ dysfunction received NEOD001 intravenously every 28 days (q28d). Dose levels of 0.5, 1, 2, 4, 8, 16, and 24 mg/kg were evaluated in a 3+3 study design. Informed consent was obtained from all patients.

Results: As of September 30, 2014, 27 patients in 7 cohorts received 209 infusions. Mean treatment duration was 8 months. No deaths, drug-related serious adverse events (AEs), discontinuations due to drug-related AEs, dose-limiting toxicities, or antidrug antibodies were reported. The most frequently reported AEs were fatigue, cough, and dyspnea. 24 mg/kg was selected as the RP2D. PK data support intravenous dosing q28d. Of the 14 patients evaluable for cardiac biomarker assessment, 50% met criteria for cardiac response (NT-proBNP: 30% reduction), and 50% achieved disease stabilization (Figure). Of the 14 renal evaluable patients, 43% met criteria for renal response (24-hour urine protein: 30% reduction), and 57% achieved disease stabilization (Figure).

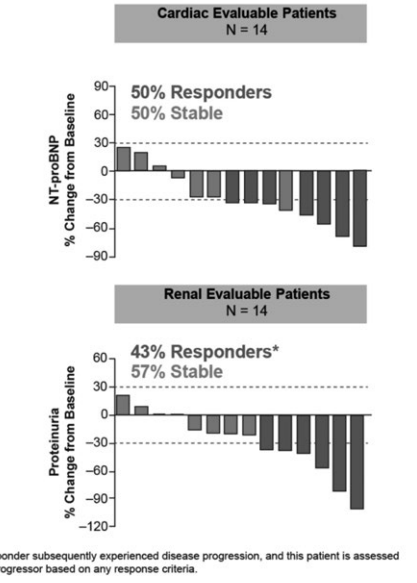

Figure 1. Change from baseline of cardiac response (NT-proBNP) and renal response (24-hour urine protein) in organ-evaluable patients.

Summary and Conclusions: Monthly infusions of NEOD001 were safe and well tolerated. 24 mg/kg was the RP2D. The cardiac response rate was 50%, and the renal response rate was 43%. These organ response rates compare favorably to those reported with traditional chemotherapy. The phase 2 expansion phase is ongoing. A phase 3 study has been initiated. Antibody therapy may represent a new therapeutic platform for the management of AL amyloidosis.

Background: The combination of melphalan, prednisone, and thalidomide (MPT) is considered a standard treatment (Tx) option in many countries for patients (pts) with newly diagnosed multiple myeloma (NDMM) who are ineligible for stem cell transplant (SCT). The FIRST trial is the largest prospective phase 3 trial conducted in pts with NDMM ineligible for SCT. In this study, patients were treated with lenalidomide plus low-dose dexamethasone administered until disease progression or unacceptable toxicity (Rd continuous), Rd for 18 cycles (Rd18), or MPT for 12 cycles. At the planned primary analysis for OS, Rd continuous was associated with improved progression-free survival (PFS) and an overall survival (OS) advantage *vs* MPT (Benboubker, *N Engl J Med*, 2014).
Aims: This abstract presents an updated analysis of OS and other efficacy measures that was not initially planned but was requested by regulatory authorities.
Methods: Pts were randomized 1:1:1 to 1 of 3 Tx arms: Rd continuous (28-day cycles), Rd18 (28-day cycles), or MPT for 12 cycles (42-day cycles). Eligible pts (aged ≥18 yrs) had symptomatic NDMM and an Eastern Cooperative Oncology Group performance status of 0-2 and were ineligible for SCT. Pts were excluded if they had received prior anti-myeloma Tx, had specified laboratory abnormalities, or had a history of malignancy, other than multiple myeloma, within the past 3 yrs. The primary endpoint was PFS (Rd continuous *vs* MPT; primary comparison). Secondary endpoints included OS, overall response rate, and safety. Time from randomization to second disease progression (PFS2) or death was included as an additional analysis.
Results: A total of 1623 pts were randomized; 535 pts received Rd continuous, 541 received Rd18, and 547 received MPT. At the time of data cutoff (March 3, 2014), 91 pts remained on Tx with Rd continuous. Across all Tx arms, 697 pts (42.9%) died; 38.9% of pts treated with Rd continuous died compared with 42.1% and 47.7% of pts treated with Rd18 and MPT, respectively. With a median follow-up of 45.5 mos, median OS was 58.9 mos (95% CI, 56.0-not evaluable [NE]) with Rd continuous *vs* 56.7 mos (95% CI, 50.1-NE) for pts treated with Rd18 and 48.5 mos (95% CI, 44.2-52.0) for pts treated with MPT. For comparison of OS with Rd continuous *vs* MPT, the hazard ratio (HR) was 0.75 (95% CI, 0.62-0.90). For the updated PFS analysis based on investigators' assessment, the median was 26.0 mos for pts treated with Rd continuous compared with 21.0 mos with Rd18 and 21.9 mos with MPT. The HR between Rd continuous and MPT was 0.69 (95% CI, 0.59-0.80). The majority of second-line Tx were bortezomib-based (55.7%). PFS2 events occurred in 58% of pts, and the median PFS2 was extended with Rd continuous *vs* Rd18 and MPT (42.9 *vs* 40.0 and 35 mos, respectively), with an HR for Rd continuous *vs* MPT of 0.74 (95% CI, 0.63-0.86). The mean durations of Tx for pts who received Rd continuous, Rd18, and MPT were 22.5, 12.6, and 11.9 mos respectively. Updated safety data will be presented.
Summary and Conclusions: The OS and PFS benefits observed in the original analysis were maintained with Rd continuous. Rd continuous was better tolerated than MPT. The safety profile remained consistent with the interim analysis. Improvements in PFS2 suggest that the benefit of Rd continuous is retained through second-line therapy without inducing resistance. These findings confirm Rd continuous as a new standard of care for pts with NDMM ineligible for SCT.

Treatment and outcome in non-Hodgkin lymphomas

Background: In spite of the improvement of the disease control obtained with the intensive chemo-immunotherapy in adult patients with MCL with or without autograft (ASCT) the rate of relapse and death is still high. Recent data showed that a therapeutic strategy including a maintenance in responding patients to chemoimmunotherapy can prolong the response duration and clinical outcome of MCL patients
Aims: In 2008 the Fondazione Italiana Linfomi (FIL) designed the phase III trial MCL0208, to evaluate the efficacy and safety of lenalidomide as maintenance therapy in patients with MCL achieving at least a Partial Response (PR) after an upfront intensive chemotherapy with rituximab (R) and ASCT (NCT02354313). This trial was approved by the Ethical Committee of all partecipating centers. Herein, we present the analysis of clinical and molecular response after the chemotherapy with Rituximab (R) and ASCT, one of the secondary objectives of MCL0208 study.
Methods: Adult patients aged<66 years, with advanced stage MCL without clinically significant comorbidities are enrolled. The primary end-point of the study is the 2-year PFS from randomization. Patients receive 3 cycles of R-CHOP-21, followed by R-HDS which includes: R-high-dose cyclophosphamide (R-HD-CTX) (4g/m2), 2 cycles of R-high-dose Ara-C (R-HD-Ara-C) (2g/m2 q12x3 d), followed by BEAM and ASCT. CD34+ cell harvest is performed after the first course of R-HD-Ara-C. A second harvest will be performed after the second course of R-HD-Ara-C, if prior harvest is PCR+. After ASCT, responding patients are randomized between maintenance with lenalidomide (15 mg days 1-21 every 28 days) or observation for 24 months. Minimal Residual Disease (MRD) is examined at diagnosis, after R-HDCT, before and after ASCT, during maintenance/observation and during follow-up every six months. The total number of patients to be enrolled is 300.
Results: From May 2010 to November 2014, 260 patients have been enrolled by 48 italian and 1 international (Lisboa, Portugal) cancer centers. The median age was 57 years (IQR 51-61), predominantly male (80%) and the majority of patients presented with adverse features such as: advanced stage (98%), poor ECOG-PS (24%), bulky disease (>5 cm) (33%), elevated LDH (31%), BM infiltration (76%) and intermediate-high MIPI (53%). Nine percent of patients had blastoid variant. Among the 260 enrolled patients, 187 completed R-HDS (72%). Ultimately, 168 patients (65%) proceed to ASCT and 146 (56%) have been randomized between lenalidomide or observation. At the time of the present analysis according to Cheson (JCO 2007) of 202 patients evaluable for final response

137 (68%) reached CR after RHDS and 156 (77%) after ASCT. Regarding MRD a molecular marker was found in 87% of cases. Before ASCT a complete molecular response (CMR) on PB and BM were 72% and 53% by nested PCR and 80% and 67% by RQ-PCR. After ASCT CMR on PB and BM were 79% and 50% by nested PCR and 86% and 73% by RQ-PCR. After a median follow-up of 19 months the 2-year PFS and OS were 77% and 88%, respectively. As expected with intensive regimens there was an hematological toxicity, particularly CTC grade 3-4 neutropenia (38% of cycles) and thrombocytopenia (31% of cycles), but the infections were recorded only in 17% of patients and the treatment-related deaths (TRD) were 1.6%.
Summary and Conclusions: RHDS with ASCT is a feasible regimen with limited toxicity in a multicenter setting and produces an high rate of durable responses. These promising results are supported by the high rate of molecular responses by RQ-PCR.

S107

IMPACT OF PRIOR TREATMENT ON PFS FOR RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA PATIENTS RANDOMIZED TO LENALIDOMIDE VS INVESTIGATOR'S CHOICE: A SUBGROUP ANALYSIS OF THE PHASE II MCL-002 (SPRINT) STUDY

Background: Clinically meaningful and statistically significant improved activity was shown for lenalidomide, an immunomodulator with antineoplastic and antiproliferative effects, over single-agent investigator choice (IC) treatment in the MCL-002 (SPRINT) study of relapsed/refractory (R/R) patients with mantle cell lymphoma (MCL).
Aims: Evaluate the potential impact of prior therapy on progression-free survival (PFS) in R/R MCL patients randomized to lenalidomide *vs* IC.
Methods: Patients were randomized to lenalidomide (25 mg/day PO on days 1-21/28 days) or single-agent IC (rituximab, gemcitabine, fludarabine, chlorambucil, or cytarabine). The primary endpoint of this phase II study was PFS; prespecified exploratory analyses of PFS by subgroups were conducted.
Results: Following a median of 2 prior therapies, 254 R/R MCL patients were randomized 2:1 to lenalidomide (n=170) or IC (n=84). The preferred single-agent IC therapy was selected for each patient prior to randomization. Overall, the median PFS was significantly improved for lenalidomide *vs* IC (8.7 *vs* 5.2 months; HR=0.61, *P*=0.004). Exploratory analysis of PFS by central review based on selected IC treatment showed that lenalidomide provided a reduction in the risk of progression or death *vs* each IC treatment. Compared with lenalidomide and taking into account small patient numbers per IC group, the risk reduction in PFS was 22% *vs* rituximab (n=27), 56% *vs* gemcitabine (n=20), 42% *vs* fludarabine (n=18), 43% *vs* chlorambucil (n=11), and 8% *vs* cytarabine (n=8). Subgroup analysis of PFS by central review based on prior treatment-related subgroups favored the use of lenalidomide overall. Several subgroups showed statistically improved PFS for lenalidomide over IC, including patients with ≥2 prior systemic antilymphoma therapies, >1 prior relapse, refractory to last prior treatment, prior rituximab exposure, no prior hyperCVAD±rituximab or stem cell transplantation, ≥6 months time from last therapy (≥230 days from last prior rituximab), and <3 years from diagnosis to study treatment. The only category without risk reduction (but statistically insignificant) was ≥4 prior systemic antilymphoma therapies, partly explained by low patient numbers in each arm. Treatment group was the main effect associated with significantly better PFS by univariate Cox regression analysis (HR=0.619; *P*=0.004), and was highly significant in the multivariate analysis (HR=0.384). Other factors associated with significantly better PFS by both univariate and multivariate analysis were <3 prior systemic antilymphoma therapies, and ≥230 days from last prior rituximab.
Summary and Conclusions: Subgroup and regression analyses of the primary study endpoint PFS showed superiority for lenalidomide over IC therapy in providing consistent clinical benefit in patients with R/R MCL irrespective of prior treatment history.

S108

LONG-TERM OUTCOME OF 490 PATIENTS WITH EARLY-STAGE EXTRA-NODAL MARGINAL ZONE LYMPHOMA

J. Yahalom[1,*] S. Teckie[1], S. Qi[1], M. Hsu[2], S. Lovie[1], M. Chelius[1], A. Noy[3], C. Portlock[3]
[1]Radiation Oncology, [2]Epidemiology and Biostatistics, [3]Medicine, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Localized early-stage extra-nodal marginal zone lymphoma (MZL) presents with heterogeneous organ involvement and is treated with various modalities, including resection, radiotherapy, and, infrequently, systemic therapy. We report the long-term outcome of a large cohort of extra-nodal MZL and assess the impact of patient and disease characteristics, organ site, and treatment strategy on disease control and survival.
Aims: To study patient characteristics and long-term outcome of a large cohort of patients with early-stage localized extra-nodal marginal zone lymphoma
Methods: We identified 490 consecutive patients with stage IE or IIE MZL referred between 1992 and 2012 to Memorial Sloan Kettering Cancer Center. Pathology was confirmed by hematopathologists at our institution. Patient and disease factors as well as treatment types were analyzed for association with relapse-free survival (RFS), overall survival (OS), and cumulative incidence of relapse.
Results: Median follow-up was 4.8 years. Median patient age was 60 years and 57% were female. Ann-Arbor stage was IE in 89%. Most common sites were stomach (32%), orbit (14%), lung (12%), skin (12%), and parotid (5%). Radiotherapy alone (RT) was the initial treatment in 50% of patients, followed by surgical resection (30%), observation (9%), immunotherapy (4%), and chemotherapy (2%). Five-year OS and RFS were 90% and 64%, respectively; 10-year OS and RFS were 73% and 45%. Disease-specific death was 1.3% at 5 years and 1.8% at 10 years. Cumulative incidence of progression/relapse was 29% by 5 years and 39% by 10 years. Amongst the 384 patients with complete response (CR), 99 patients experienced relapse. On multivariable analysis, initial treatment type and primary disease site were independently associated with RFS and relapse (all $p<0.005$). All disease sites (HR>2.0, $p\leq0.01$) except for thyroid ($p=0.8$) had worse RFS relative to stomach. Compared with RT, chemotherapy or immunotherapy had worse RFS (HR 2.2, $p=0.004$) while surgery was no different ($p=0.52$). After RT, only 11 patients experienced in-field failure, with a 5-year cumulative incidence of 2.4%. Most common location of relapse after CR was distant; relapses were also observed in paired untreated organs, such as the orbit, salivary gland, and breast. Crude rate of transformation to pathologically-confirmed large-cell lymphoma was 2% (11 patients). Second tumors in irradiated sites developed in 3 patients: 2 of these were breast ductal carcinoma *in situ* cured with surgical resection.
Summary and Conclusions: Overall and cause-specific survival are excellent in early-stage extra-nodal MZL. Treatment with RT or surgery was associated with longer RFS and reduced the need for salvage. Relapses are common after initial remission, and most frequently occur in distant sites. Transformation to large cell lymphomas is rare. Stomach cases are less likely to relapse than other anatomic primary sites, perhaps in part because the entire organ is irradiated, *versus* other sites that are either bilateral or where only part of the organ is treated, such as the skin and lung. This study supports the use of local therapies to treat stage IE and IIE MZL.

S109

A DOSE-ESCALATION STUDY OF THE BCL-2 INHIBITOR VENETOCLAX (ABT-199/GDC-0199) PLUS BENDAMUSTINE (B) AND RITUXIMAB (R) IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) NON-HODGKIN'S LYMPHOMA (NHL)

S. de Vos[1,*] C. Flowers[2], D. Wang[3], L. Swinnen[4], N. Fowler[5], E. Reid[6], J. Cordero[7], M. Gifford[7], D. D'Amico[7], M. Dunbar[7], M. Zhu[7], A. Salem[7], S.H. Enschede[7], J.L. Ricker[7], D. Chien[7], R. Humerickhouse[7], M. Kozloff[8]
[1]Department of Medicine, University of California Los Angeles, Los Angeles, [2]Winship Cancer Institute, Emory University, Atlanta, [3]Hematology/Oncology, Henry Ford Hospital, Detroit, [4]Johns Hopkins University, Baltimore, [5]The University of Texas MD Anderson Cancer Center, Houston, [6]University of California San Diego, La Jolla, [7]AbbVie, North Chicago, [8]Ingalls Hospital, Harvey, United States

Background: Venetoclax is a selective, potent, orally bioavailable BCL-2 inhibitor that has shown single agent activity in patients with R/R NHL. The current study evaluates venetoclax in combination with an immunochemotherapy regimen, BR, an active regimen widely used to treat patients with NHL.
Aims: The primary objectives were to assess safety, pharmacokinetics (PK), and determine the maximum tolerated dose (MTD) and recommended Phase 2 dose of the combination. Secondary objectives evaluated preliminary efficacy.
Methods: Dose escalation used a 3+3 design on a 28 day (d) cycle (C) with 3 venetoclax schedules: 3, 7, and 28 d/C. The BR regimen was 6 C: B (2 d/C, 90mg/m^2) and R (1 d/C, 375mg/m^2). DLTs for dose escalation were assessed during C1. Responses were first assessed on C3 d1. Patients who completed venetoclax + BR with continued tolerability and without disease progression could continue venetoclax monotherapy up to 2 yrs.

Results: As of January 9 2015, 33 patients were treated: 20 (61%) FL, 10 (30%) DLBCL, and 3 (9%) MZL. The median age was 62 (29-90) yrs. All had prior R or R-combination, of which 32 (97%) had R-based chemotherapy and 8 (24%) had prior B or BR. Sixteen (48%) patients are active; 17 discontinued (12 PD, 2 AE, 1 withdrew consent, 1 non-compliance, and 1 completed the induction regimen). Median time on study was 90 d (1–876); 15 (45%) completed 6 C of the combination. The most common AEs (in >25%) were nausea (58%), anemia, neutropenia (each 42%), thrombocytopenia, diarrhea (each 39%), hyperglycemia (36%), and vomiting, hypokalemia, fatigue (each 27%). The most common grade 3/4 AEs (in >10%) were neutropenia (30%), leukopenia, thrombocytopenia, lymphopenia (each 21%), and anemia (18%). The most frequent SAE was febrile neutropenia (9%). There were no drug-related AEs that led to death. DLTs are summarized in the table. Preliminary PK results suggest that co-administration of BR did not significantly impact venetoclax PK. Twenty-nine patients were evaluable for objective response: 6 (21%) CR and 13 (45%) PR. The ORR was 66% in all patients and 74% in patients with FL.

Tabella 1.

Cohort	1	2	3	4	5	6	7[a]	8[a]
Patients, n	4	4	4	3	3	4	5	6
Venetoclax, mg	50	100	100	100	200	200	400	400
Schedule, d/C	3	3	7	28	28	7	7	28
DLTs, n								
Thrombocytopenia					1			
Febrile neutropenia					1			
Stevens-Johnson Syndrome[b]								1

[a]Post-amendment to G-CSF prophylaxis and DLT criteria; [b]Primary reasonable possibility due to allopurinol; pt discontinued

Summary and Conclusions: Preliminary data demonstrate a tolerable safety profile of venetoclax + BR. Early responses were seen across all cohorts in this heavily pretreated patient population. The MTD has not been reached; cohort 9 is enrolling at 600 mg 28 d/C.

Background: Extranodal natural killer/T-cell lymphoma (ENKTL), nasal type, is a rare type of non-Hodgkin lymphoma with poor prognosis because tumor cells are frequently resistant to anthracycline-containing chemotherapy such as CHOP due to expression of the multidrug-resistant p-glycoprotein. As a result, the treatment strategy for ENKTL has changed to non-anthracycline based regimens such as SMILE (steroid, methotrexate, ifosfamide, L-asparaginase, and etoposide) with or without radiotherapy. Thus, concurrent chemoradiotherapy followed by non-anthracycline based chemotherapy is recommended for localized disease whereas intensified chemotherapy such as SMILE is for advanced disease. However, there is no proven prognostic model for ENKTL in the era of this new treatment strategy because previous prognostic models were developed by analyzing patients who were treated with CHOP or CHOP-like regimens.
Aims: This study is to explore risk factors for poor progression-free survival (PFS) and overall survival (OS) in ENKTL, and establish a prognostic model for ENKTL patients treated with non-anthracycline based treatment.
Methods: This is a retrospective cohort study using anonymized information from patients with ENKTL. The following criteria are required: (1) Patients diagnosed with ENKTL, nasal type between January 1, 1995 and December 31, 2012; (2) Patients treated with non-anthracycline based therapy as an initial treatment. The pathology of initial diagnosis was reviewed by designated pathologists.
Results: The data of 557 patients were from 32 hospitals from six Asian countries (Korea, Japan, Hong Kong China, Singapore, Taiwan, and Malaysia) and 6 hospitals from five Western countries (France, Germany, Denmark, Sweden, and USA). Thirty cases were excluded from the analysis due to following reasons: Missing follow-up data, different pathology from ENKTL, and different treatment regimens containing anthracycline. Thus, 527 patients were analyzed, and male (n =341) was predominant compared to female (n =186). 70% of patients were ≤60 years at diagnosis whereas 30% was older than 60 years. Two-thirds of patients had stage I/II (n =346) and nasal tract was most commonly involved extranodal site (n =421, 80%). Bone marrow involvement was observed in 83 patients (16%), and distant lymph nodes were involved in 86 patients (16%). With a median follow-up of 45 months (IQR: 22-65 months), 306 patients (58%) were alive at the time of analysis and the event of progression-free survival occurred in 272 patients including relapse or progression (n =187). The median OS was 76 months (95% CI: 51-101 months) and PFS was 32 months (95% CI: 20-45 months). The multivariate analysis for OS and PFS showed a significant association of four parameters with survival outcomes: age >60, stage III/IV, distant lymph node involvement, and non-nasal tract involvement (P <0.001). Thus, the prognosis of patients with age >60, stage III/IV and distant lymph node involvement was poor, and patients who did not involve nasal tract also showed worse OS and PFS than patient with nasal tract involvement. Thus, we gave one score for each parameter. According to the sum of scores, patients with score 0 or 1 were grouped as low risk, score 2 was intermediate, and score 3 or 4 was high risk. This new risk model showed a strong association with OS and PFS (Figure 1). Among 328 patients who were initially evaluated for EBV DNA in blood, 189 patients (58%) showed detectable level of EBV DNA. The multivariate analysis including EBV DNA titer focused on these 328 patients showed that aforementioned four parameters and the presence of EBV DNA were independently associated with OS and PFS. Thus, we proposed another risk model for patients who had EBV DNA data with these five parameters consisting of low (score 0/1), low-intermediate (score 2), high-intermediate (score 3), and high risk (score 4/5).

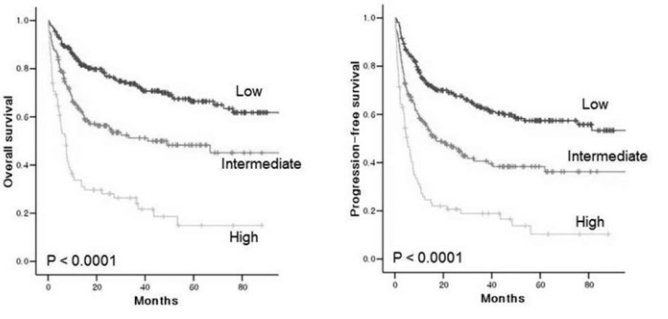

Figure 1.

Summary and Conclusions: Our multinational, multicenter retrospective study proposed a new prognostic model for newly diagnosed ENKTL patients who were treated with non-anthracycline based treatment. It consists of age >60, stage III/IV, distant lymph node involvement, and no involvement of nasal tract. Our finding will be validated by currently ongoing study with an independent cohort including China.

CHIMERIC ANTIGEN RECEPTOR (CAR)-MODIFIED T CELLS TARGETING CD19 INDUCE SUSTAINED REMISSIONS IN CHILDREN AND YOUNG ADULTS WITH RELAPSED/REFRACTORY ALL

S. Maude[1,*] P. Shaw[2], R. Aplenc[1], D. Barrett[1], C. Barker[1], C. Callahan[1], C. Grupp[1], S. Lacey[2], B. Levine[2], J. Melenhorst[2], L. Motley[1], S. Rheingold[1], D. Teachey[1], C. June[2], S. Grupp[1]
[1]The Children's Hospital of Philadelphia, [2]University of Pennsylvania, Philadelphia, United States

Background: Relapsed/refractory pediatric acute lymphoblastic leukemia (ALL) poses a substantial therapeutic challenge. Targeted immunotherapy using chimeric antigen receptor (CAR)-modified T cells combines the specificity of an antibody's single chain variable fragment (scFv) with intracellular T cell signaling domains, delivering T cells with potent cytotoxicity to antigen-expressing tumor cells. We previously reported complete remissions and prolonged persistence in children and adults with ALL treated with CD19-specific CART cells (CTL019). We now report on outcomes and longer follow-up of the first 40 patients with relapsed/refractory ALL treated on the pediatric trial of CTL019 in the largest cell therapy experience reported to date.
Aims: Establish the safety and efficacy of CTL019 for patients with relapsed/refractory CD19+ ALL.
Methods: After informed consent, T cells collected from the patient were transduced with a lentiviral vector encoding a CAR composed of anti-CD19 scFv, CD3z, and 4-1BB domains, activated/expanded *ex vivo* with anti-CD3/anti-CD28 beads, cryopreserved, and then infused. 35/40 patients received lymphodepleting chemotherapy the week prior to cell infusion.
Results: Of 40 patients aged 5-22y (median 11y) with CD19+ ALL, 33 had detectable disease prior to CTL019 cell infusion, while 7 were negative for minimal residual disease (MRD). 28 had relapsed after prior stem cell transplantation (SCT). A median of $3.6x10^6$ CTL019 cells/kg ($0.98\text{-}17x10^6$/kg) were infused in 1-3 fractions. At assessment 1 month after infusion, 37/40 (93%) were in a complete remission (CR). MRD <0.01% by flow cytometry was achieved in 34 patients. A CR rate of 86% was achieved in 22 patients with an M3 marrow (>25% marrow lymphoblasts) at infusion. With median follow-up 7 mo (1-31 mo) as of January 1, 2015, 26 patients had ongoing CR, with only 5 receiving subsequent therapy (1 donor lymphocyte infusion [DLI], 4 SCT), 6-month EFS was 72% (95% CI, 59-89%), and OS was 77% (95% CI, 64-92%). CTL019 cells were detected in the CSF and 4 patients with CNS2a disease at infusion have experienced ongoing CRs in CSF. Ten patients subsequently relapsed, 5 with CD19(-) disease. CTL019 persistence was accompanied by B cell aplasia, which continued up to 30 months in patients with ongoing CR. Cytokine release syndrome (CRS) was seen in almost all (37) patients. Dramatic elevations in ferritin were observed, suggesting an association of macrophage activation syndrome with CRS. Severe CRS requiring hemodynamic or respiratory support occurred in 33% of patients, was associated with high pre-treatment disease burden and with elevations in CRP and IL6 after infusion. Severe CRS was rapidly reversed in each case with the anti-IL6R agent tocilizumab, demonstrating the importance of IL6 in driving CRS.
Summary and Conclusions: Single-agent CTL019 immunotherapy can induce potent and durable responses in patients with relapsed/refractory ALL. CRS was effectively controlled with IL6 blockade. Long-term disease control is possible without subsequent stem cell transplantation.

S112

EFFICACY AND SAFETY OF CD19-TARGETED 19-28Z CAR MODIFIED T CELLS IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY B-ALL

J. Park[1,*] I. Riviere[1], X. Wang[1], Y. Bernal[1], T. Purdon[1], E. Halton[1], K. Curran[1], C. Sauter[1], M. Sadelain[1], R. Brentjens[1]
[1]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Adult patients with relapsed or refractory (R/R) acute lymphoblastic leukemia (ALL) have dismal prognosis. We previously reported high anti-tumor activity of autologous T cells genetically modified to express 19-28z chimeric antigen receptor (CAR) targeting CD19 in adult patients with ALL.
Aims: Herein, we report the long-term outcome of our phase I clinical trial in adults with R/R ALL (NCT01044069).
Methods: Adult patients with R/R B-ALL underwent leukapheresis, and T cells were transduced with a gammaretroviral vector encoding a CAR construct composed of anti-CD19 scFv linked to CD28 and CD3ζ signaling domains (19-28z). All patients received conditioning chemotherapy followed by $1–3x10^6$ 19-28z CAR T cells/kg.
Results: 33 patients have been treated, and 32 patients are evaluable for response. The median age was 54 years (range, 22-74). 12 patients (36%) had Ph+ ALL, 11 patients (33%) had prior allogeneic stem cell transplant (allo-SCT), and 14 patients (42%) had ≥3 prior lines of therapy. At the time of CAR T cell infusion, 16 had morphologic disease (>5% blasts in BM) and the remaining 16 patients had minimal residual disease (MRD). 13/16 patients with morphologic disease (81%) and 16/16 patients with MRD (100%) were in complete remission (CR) after 19-28z CAR T cell infusion, yielding an overall CR rate of 91% (29/32). Of the 28 MRD evaluable patients, MRD negative CR rate was 82%. 11 patients underwent allo-SCT following the CAR T cells. As of 1/25/15, the median follow-up was 5.1 months (range, 1.0-37.6+), with 14 patients having ≥6 months of follow-up. 6-month overall survival (OS) rate of all patients was 58% (95% CI: 36-74). Among the patients who achieved CR, OS rate at 6 months for patients who had allo-SCT *vs* no allo-SCT following CAR T cells was 70% (95% CI: 33-89) *vs* 61% (95% CI: 29-82; p=0.30). Severe cytokine release syndrome (sCRS) requiring vasopressors or mechanical ventilation for hypoxia was observed in 7 patients, effectively managed with IL-6R inhibitor and/or corticosteroids.
Summary and Conclusions: 19-28z CAR T cells can induce a high CR rate of 91% in adult patients with R/R ALL. The risk of sCRS correlates with disease burden and can be effectively managed. These findings strongly support the use of 19-28z CAR T cells in adults with R/R ALL and warrants investigation in a phase 2 trial.

Josep Carreras Leukemia Research Institute, Universitat Autonoma de Barcelona, Badalona, Spain

Background: Tyrosine kinase inhibitors such as imatinib induce a high rate of complete hematologic remission (CHR) in Philadelphia positive (Ph+) acute lymphoblastic leukaemia (ALL), but the overall prognosis particularly in elderly patients (pts.) remains poor, primarily due to relapse. Nilotinib is a potent ABL kinase inhibitor (TKI) approved for treatment of CML. Data on its efficacy in Ph+ ALL are limited.
Aims: The EWALL (European Working Group for Adult ALL) initiated a prospective, investigator-initiated multicenter European clinical trial to examine the efficacy and safety of nilotinib in conjunction with a chemotherapy backbone in elderly patients (above 55 years of age) with newly diagnosed Ph+ ALL.
Methods: Male or female pts. >55 years with untreated Ph+ and/or BCR-ABL1 positive ALL were eligible if they had a WHO performance status of 0-2, adequate organ function and had signed written informed consent. The trial was conducted in accordance with the principles of the Declaration of Helsinki and was approved by the ethics committees of all participating centres (registered under NCT01528085). After a pre-phase with dexamethasone (Dex) and cyclophosphamide (optional), nilotinib was administered at 400 mg BID and given continuously thereafter. During induction, nilotinib was combined with vincristine (VCR) and Dex, repeated weekly for 4 weeks. Consolidation cycles consisted of nilotinib 400 mg BID, methotrexate (MTX) and asparaginase for cycles 1, 3 and 5 and cytarabine for cycles 2, 4 and 6. Maintenance phase consisted of nilotinib, 6-MP, MTX and Dex/VCR. The primary end-point is the rate of pts. without an event (defined as relapse, death, SAE or study treatment discontinuation) at 12 months, secondary endpoints were the rate of CHR after

induction, death during induction or in CHR, event free (and overall) survival, the rate of molecular response defined by BCR-ABL/ABL ratios <0.1% (MMR) and <0.001% (CMR), respectively.

Results: As of December 2015, 56 pts. (25 male, 31 female) have been enrolled. Median age is 65 years (55-85 years), twelve pts. are older than 70 years of age. To date, all pts. are evaluable for safety and 47 pts. are evaluable for efficacy. The CHR rate is 87 %, one pt. was refractory (2%), one pt. had a partial remission (2%). One pt. died during induction therapy (2%), three pts. discontinued therapy before CR evaluation. With a median follow-up of 5.5 months, 34 of the 41 pts. who achieved CR are in CCR and 3 pts. relapsed, two of whom had discontinued study treatment to undergo allogeneic SCT. 11 pts. with documented induction response have discontinued study treatment prematurely because of transfer to allogeneic SCT, as explicitly permitted by the protocol. 9 pts. of them are transplanted. 11 pts. discontinued for various other reasons. The rate of molecular remission (MMR) after induction (25 pts. evaluable) was 45.5 %, with 5 pts. having undetectable BCR-ABL1 transcripts. During consolidation, 30 of 40 pts. (80%) had a MMR, and BCR-ABL transcripts were undetectable in 10 of 40 pts. (20%). Tolerability has been acceptable. Infectious events and neutropenic fever predominated, individual SAEs included metabolic, cardiovascular, neurologic, renal and hepatic events.

Summary and Conclusions: Nilotinib in conjunction with chemotherapy according to the EWALL-PH-02 protocol is highly effective and well tolerated in elderly pts. with newly diagnosed Ph+ ALL. Molecular response rates are high and MRD levels in responding pts. continue to decrease with time.

S114

INOTUZUMAB OZOGAMICIN IN COMBINATION WITH LOW-INTENSITY CHEMOTHERAPY (MINI-HYPER-CVD) FOR THE FRONTLINE THERAPY IN ELDERLY PATIENTS (≥60 YEARS) WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

E. Jabbour[1,*], S. O'Brien[2], D. Thomas[1], K. Sasaki[1], G. Garcia-Manero[1], M. Konopleva[1], T. Kadia[1], F. Ravandi[1], G. Borthakur[1], R. Garris[1], J. Cortes[1], H. Kantarjian[1]

[1]Leukemia, MD Anderson Cancer Center, Houston, [2]Leukemia, University of California, Irvine, Irvine, United States

Background: Older patients (pts) with ALL have a significantly worse outcome. This is primarily due to poor tolerance of intensive chemotherapy. Addition of targeted non-myelosuppressive therapy to effective low-intensity chemotherapy might improve outcome. CD22 expression occurs in >90% of pts with ALL. Inotuzumab ozogamicin (INO) is a CD22 monoclonal antibody bound to a toxin, calecheamicin, and has shown single-agent activity in relapsed/refractory ALL (Kantarjian *et al.* Lancet Oncology 2012).

Aims: To determine the efficacy of INO in combination with mini-hper-CVD assessed by objective response rate, progression-free, and overall survival and to assess the side effects of this treatment.

Methods: Pts ≥60 years (yrs) with newly-diagnosed B-cell ALL were eligible. The chemotherapy was lower intensity than conventional hyper-CVAD and referred to as mini-hyper-CVD (cyclophosphamide and dexamethasone at 50% dose reduction, no anthracycline, methotrexate at 75% dose reduction, cytarabine at 0.5 g/m^2 x 4 doses). Rituximab and intrathecal chemotherapy were given for first 4 courses. INO was given on Day 3 of each of the first 4 courses. The first 6 pts received 1.3 mg/m^2 for cycle 1 followed by 0.8 mg/m^2 for subsequent cycles; Pts 7 onwards received 1.8 mg/m^2 for Cycle 1 followed by 1.3 mg/m^2 for subsequent cycles.

Results: Thirty-three pts (20 men, 13 women) have been treated so far. Pts characteristics and outcome are summarized in Table 1. Median age is 69 yrs (range, 60-79). Median follow-up is 15 months (mos) (range, 2-35). Of the 30 pts evaluable for response (three pts started in CR; two achieved with single-agent steroids and one with one course of HCVAD), 29 pts (97%) achieved CR/CRp (24 CR, 5 CRp). All pts achieving CR have also achieved flow-cytometric MRD negative status, in 79% at the time of CR achievement. Grade 3-4 toxicities included infections (n=29; 88%), prolonged thrombocytopenia (n=25; 76%), hyperglycemia (n=17; 52%); hypokalemia (n=11; 33%); increased bilirubin (n=8; 24%); increased ALT (n=7; 21%), and intracranial hemorrhage (n=4; 12%). Grade 2 veno-occlusive occurred in 2 (7%) pts (7%). At the last follow-up, 24 (73%) pts are alive, and 23 (70%) are in CR. Nine (27%) pts died: 1 had primary refractory ALL and died after the first salvage; 2 relapsed after receiving 3 and 2 courses only due to prolonged myelossuppression and died of disease progression; and 6 died in CR from pneumonia complications (n=1), sepsis and multiple organ failure (n=1), gun-shot wound (n=1), renal failure and metabolic encephalopathy (n=1), complications due to dementia (n=1), and unknown (n=1). One pt received allogeneic stem cell transplantation. The 2-year progression-free survival and overall survival rates were 85% and 70%, respectively. The mini-hyper-CVD (n=33) appears superior to the historical HCVAD +/-rituximab (n=46) in similar patient population (2-year survival rates 78% and 38%, respectively; Figure 1).

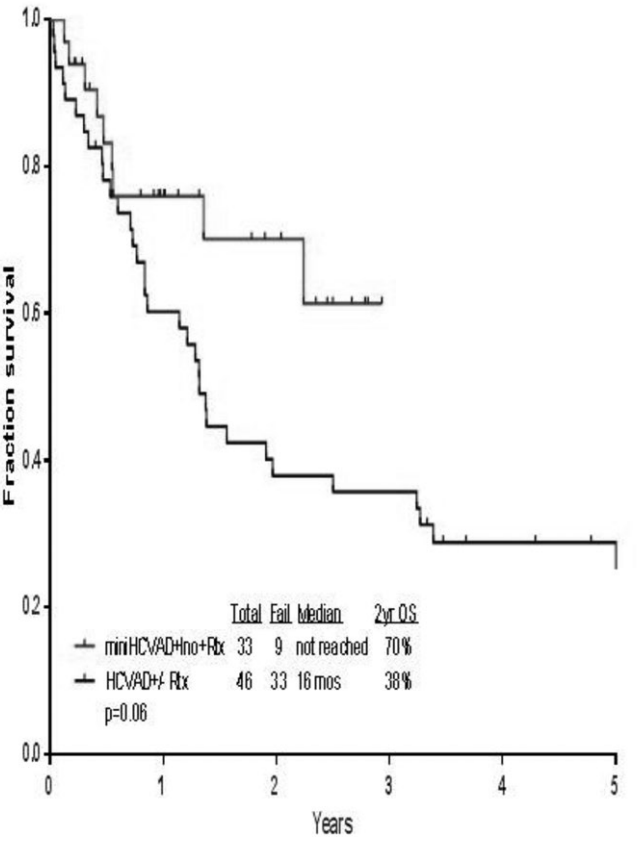

Figure 1. Survival with mini-HCVD-INO *vs* HCVAD +/-Rituximab in frontline ALL

Tabella 1. Patient characteristics and outcome

Parameter	Category	N (%)/Median [Range]
Follow-up (mos)		15 [2-35]
Age (yrs)		69 [60-79]
Performance Status (ECOG)	0-1	29 (88)
WBC		3.5 [0. 6- 111.0]
Karyotype	Diploid	9 (33)
	Miscellaneous	18 (55)
	Insufficient metaphases/ Unknown	4 (12)
CD22		98 [72-100]
CD20	≥ 20%	23/33 (70%)
CR		24 (80)
CRp		5 (17)
No response		1 (3)
ORR		29 (97)
Cytogenetic CR	17 abnormal at start	17 (100)
Neg MRD at D21 overall	(5 not done / 3 CR at start)	19 (79) 32 (100)
Early death		0
2-year PFS %		85
2-year OS %		70

Summary and Conclusions: The combination of INO with low-intensity mini-hyper-CVD chemotherapy is safe and shows encouraging results (96% CR/CRp) in the frontline setting in older pts with ALL. These results appear to be better than those achieved with a chemotherapy alone approach and may become the new standard of care for frontline treatment of older pts with ALL.

S115

BLINATUMOMAB SAFETY AND ACTIVITY IN OLDER PATIENTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA IN TWO PHASE 2 STUDIES

H. Kantarjian[1,*] A. Stein[2], R. Bargou[3], C. Grande[4], R. Larson[5], M. Stelljes[6], J. Benjamin[7], C. Jia[7], M. Topp[8]
[1]Department of Leukemia, MD Anderson Cancer Center, University of Texas, Houston, TX, [2]City of Hope, Duarte, CA, United States, [3]Würzburg University Medical Center, Comprehensive Cancer Center Mainfranken, Würzburg, Germany, [4]Hospital Universitario 12 de Octubre, Madrid, Spain, [5]University of Chicago, Chicago, IL, United States, [6]University of Muenster, Muenster, Germany, [7]Amgen Inc., Thousand Oaks, CA, United States, [8]Universitätsklinikum Würzburg, Würzburg, Germany

Background: Treatment options for older patients with relapsed/refractory acute lymphoblastic leukemia (ALL) are limited. Blinatumomab is a bispecific T-cell engager (BiTE®) antibody construct that directs cytotoxic T cells to CD19-expressing B cells, and is approved in the US for treatment of Ph-negative relapsed/refractory ALL. In two phase 2 adult studies of blinatumomab (Topp MS, *et al.* J Clin Oncol. 2014;32:4134-40; Topp MS, *et al.* Lancet Oncol. 2015;16:57-66), 69% and 43% of patients, respectively, achieved complete response (CR) or CR with partial hematologic recovery (CRh*).
Aims: We report pooled data for the combined subsets of older patients (≥65 years).
Methods: Patients with relapsed/refractory, Ph-negative B-precursor ALL received open-label blinatumomab by continuous intravenous infusion (4 weeks on/2 weeks off). Patients achieving CR or CRh* after two cycles could receive three consolidation cycles. Response was assessed by bone marrow aspiration and complete blood count with differential. CR required blasts <5%, ANC >1000/μL and platelets >100,000/μL. CRh* required blasts <5%, ANC >500/μL and platelets >50,000/μL. Minimal residual disease (MRD) was detected by ASO-PCR of Ig heavy chain loci.
Results: A total of 36 older patients (median age 70 years, range 65-79) received blinatumomab for a median (range) of 2 (1-6) cycles. Twenty (56%) patients achieved best response of CR/CRh* within two cycles, including 14 (39%) CR and 6 (17%) CRh*. Among patients who responded to blinatumomab, 16 (80%) had an MRD response; of these, 12 (60%) had complete MRD response (undetectable MRD) and 4 (20%) others had detectable MRD but with $<10^{-4}$blasts. With median follow-up of 18.2 months, median (range) relapse-free survival was 7.4 (1.0-34.0) months. With median follow-up of 29.4 months, overall survival among patients was 5.5 (0.3-41.9) months. Ten (28%) patients were alive at last follow up, including 6 in sustained remission. Two (10%) of the patients who responded to blinatumomab underwent allogeneic hematopoietic stem cell transplantation (HSCT) after blinatumomab therapy. Treatment-emergent adverse events (AE) CTCAE grade ≥3 were reported for 31 (86%) patients, most commonly febrile neutropenia (22%) and neutropenia (19%). Neurologic AE occurred in 26 (72%) patients, including grade ≥3 events for 28%. One (3%) patient had grade ≥3 cytokine release syndrome. Of 7 fatal AEs reported in patients, none were considered related to treatment.
Summary and Conclusions: Older patients (≥65 years) with relapsed/refractory ALL in two phase 2 studies of single-agent blinatumomab had similar treatment responses and tolerability compared with patients in the overall study populations.

Molecular pathogenesis of AML

S116

CLONAL ARCHITECTURE DEFINES DISTINCT MECHANISMS FOR ACCUMULATION OF GENOMIC OR CHROMOSOMAL LESIONS IN ACUTE MYELOID LEUKEMIA

P. Hirsch[1,2,*] R. Tang[2], H. Boutroux[1], C. Marzac[3], F. Fava[2], H. Lapillonne[3], G. Leverger[4], O. Legrand[2], M. Mohty[2], L. Douay[3], C. Bilhou-Nabera[3], F. Delhommeau[1,3]
[1]UMR_S 938, CDR Saint-Antoine, Sorbonne Universités, UPMC Univ Paris 06, [2]Hôpital Saint-Antoine, Service d'Hématologie clinique et de thérapie cellulaire, [3]Hôpital Saint-Antoine & Hôpital Armand-Trousseau, Service d'hématologie biologique, [4]Hôpital Trousseau, Service d'Hématologie et d'Oncologie Pédiatriques, APHP, Paris, France

Background: Mutations in epigenetic regulators such as *DNMT3A, TET2, and ASXL1* have been shown to occur with ageing, leading to clonal pre-leukemic hematopoiesis, which may evolve into acute myeloid leukemia (AML) once additional lesions have accumulated. Studies of clonal architecture and pre-leukemic hematopoietic stem cells (HSCs) of AML with normal karyotype suggest that *DNMT3A* mutations, but not other sub-clonal mutations, are the pre-leukemic initiating events and the hallmark of relapse reservoir.
Aims: It is unknown whether AML carrying other mutations or chromosomal lesions have a clonal architecture and reservoirs of pre-leukemic HSCs similar to those of *DNMT3A* mutant AML. To address this point we analyzed the clonal architecture and evolution at relapse of a series of AML with both normal and abnormal karyotype, *i.e.* MLL rearrangement, t(8;21), inv(16), del(20q), +8, del(7), and complex karyotype (CK).
Methods: Molecular and cytogenetic analyses were performed at time of diagnosis (n=58 patients) and relapse (n=20). Exome analysis (n=9) and targeted sequencing (122 genes, n=53) were performed using Illumina platforms. Variants were validated by Sanger sequencing. Somatic mutations were assessed using remission samples or T cells. Cells from 14 patients (8 with abnormal karyotype) were grown in methylcellulose and individual colonies were picked for genotyping and FISH analysis.
Results: We found 234 lesions (median=4/patient) including 190 mutations in 60 genes. 36% of lesions target epigenetic regulators (DNMT3A, TET2/3, IDH1/2, MLL, polycombs, del(20q)), with a frequent (34%) occurrence of multiple epigenetic events. 24 % of lesions involve proliferative events (FLT3, RAS signalling, +8), and 17% affect transcription or splicing factors, NPM1, and ubiquitin ligases. Mutations in other pathways (NOTCH, WNT, DNA repair, cohesin), CBF translocations, and other chromosomal abnormalities account for 22% of the total. FISH and genotyping analysis of 1,873 individual colonies revealed that lesions involving epigenetic regulators, including MLL and 20q rearrangements, occur frequently as first events (11/14). Analysis of variant allele frequencies (VAF), FISH results, and relapse samples allowed us to build the clonal phylogeny for 38 of the 44 remaining AML. Overall, a recurrent order of events was observed, with CBF translocations and epigenetic abnormalities as first events (37/52) and signalling or proliferation lesions as last ones (29/52). In 17 cases this order was not observed, suggesting a distinct mechanism of leukemogenesis, especially in patients with CK or chromosome 7 abnormalities (n=7). Clonal composition changed in 14/20 samples at relapse. In one patient, a second AML occurred on donor transplanted cord blood HSCs. In another patient, a chronic myelo-monocytic leukemia developed after 9 years on an *ASXL1*-mutant minor clone already detected at time of diagnosis. Changes in relative VAF of *IDH1, IDH2, TET3, WT1, NF1,* and *ZRSR2* variants were observed in 5 patients. Seven samples carried events not detected at diagnosis (t(1;6), gain of chromosome 8, and *ZRSR2, SETBP1, RUNX1, PTPN11, KDM6A, CEBPA* variants), while in 9 cases, lesions were lost at relapse (*KDM6A, NPM1, PTPN11, WT1, DSCAM, POLR2A, TET2, UBEJ1, RUNX1, IDH1, BCOR, FLT3,* trisomy8). In all 14 patients harbouring an initial epigenetic lesion, the event persisted at relapse.
Summary and Conclusions: Our results identify 2 groups of AML suggesting 2 ways for leukemogenesis. The 1st group includes cases with CK and chromosome 7 lesions, which may result from chromosome or DNA maintenance defects. For instance, *TP53* mutations are frequent in CK AML. The 2nd group is characterized by early epigenetic events, including *DNMT3A, TET2,* and *ASXL1* mutations, which always persist at relapse. These events may lead to an over-expansion of mutant HSCs. In these pre-leukemic cells the increased mitotic rate may result in a faster accumulation of replication errors and mutations than in normal HSCs.

S117

IDENTIFICATION OF RUNX1/ETO TARGETS REQUIRED FOR LEUKAEMIC PROPAGATION

N. Martinez[1,*] L.M. McKenzie[1], S. Nakang[1], A. Ptasinska[2], S.A. Assi[2], C. Bonifer[2], O. Heidenreich[1]
[1]Northern Institute for Cancer Research, Newcastle University, Newcastle upon

Tyne, [2]School of Cancer Sciences, University of Birmingham, Birmingham, United Kingdom

Background: RUNX1/ETO is a driver leukaemic fusion protein produced by the translocation t(8;21) and accounts for 10-12% of Acute Myeloid Leukaemia (AML) cases. RUNX1/ETO is required for maintaining the leukaemic phenotype influencing both leukaemic clonogenicity and growth. Currently the molecular mechanism(s) by which it regulates leukaemic self-renewal and propagation are just beginning to be unravelled. In our previous work, we characterised the core-transcriptional network driven by RUNX1/ETO required to maintain the t(8;21) AML phenotype (Ptasinska *et al.*, 2014).
Aims: We have now functionally characterised the significance of individual members of this network for leukaemic self-renewal by performing targeted RNAi screens both in tissue culture and in a xenotransplant setting.
Methods: To that end, we intersected RNAseq, CHIPseq and microarray data and identified a set of 103 genes comprising both direct RUNX1/ETO target genes and genes potentially cooperating with such targets. For the RNAi screens, we used a Doxycycline (Dox)-inducible lentiviral RNAi library covering each gene of this set with at least 3 shRNAs. We transduced two t(8;21)-positive AML cell lines (Kasumi-1 and SKNO-1) with this library and performed parallel screens employing colony formation and long-term suspension culture assays in the *in vitro* arm, and intrafemoral transplantation of highly immunodeficient NSG mice for the *in vivo* screen. Both test series contained Dox and no Dox groups. RNA and genomic DNA were isolated from transduced cells and subjected to targeted Next Generation Sequencing. Changes in shRNA pool compositions were identified by comparison of the corresponding Dox and no Dox groups using DESEQ.
Results: The analysis of the *in vitro* screen demonstrated that l RUNX1/ETO shRNA constructs rapidly disappeared upon induction under all *in vitro* conditions, confirming the central role of RUNX1/ETO in maintaining t(8;21) AML, while levels of non-targeting control shRNA genes did not change during the course of the experiments. Moreover, *RUVBL1* (Pontin) shRNAs were depleted in agreement with our previous finding of a dependence of t(8;21) AML cells on this factor. In addition, shRNAs targeting *KIT* which in both cell lines carries the activating mutation N822K, disappeared. These combined results demonstrate the functionality of this targeted screen. Most importantly, the top hits of this *in vitro* screen identified a group of self-renewal genes including those encoding the ubiquitin ligase gene *SKP2* and Cyclin D2 (*CCND2*). The more stringent *in vivo* screen confirmed *CCND2* as a RUNX1/ETO target gene relevant for leukaemic propagation. Notably, this screen also identified several new genes, which had not scored in the *in vitro* setting. This included several genes involved in ubiquitination (*UBASH3B, UBE2L6*), regulation of G proteins (*GPRC5C, ARHGEF12, ARHGEF3*), transcriptional control (*ID1, KLF2, ERG*) or glycolysis (*SCL2A3, PFKP*). Importantly, several shRNAs targeting genes such as *NOTCH2, SLA* or *LAPTM5*, which are repressed by RUNX/ETO, were also depleted in the *in vivo* screen emphasising our previous observation that leukaemic self-renewal and propagation is driven by a dynamic equilibrium between RUNX1 and RUNX1/ETO.
Summary and Conclusions: We are now further characterising the contribution of these different target genes to the leukaemic self-renewal and propagation both *in vitro* and *in vivo*. The ultimate aim of our studies is the identification of RUNX1/ETO dependent pathways, whose combined inhibition may phenocopy the loss of this hard-to-target initiator and driver of leukaemogenesis.

S118

THE ROLE OF 2-OXOGLUTARATE DEPENDENT DIOXYGENASES IN NORMAL HAEMATOPOIESIS AND ACUTE MYELOID LEUKEMIA

C. Sepulveda[1,*] A. Guitart[1], M. Vukovic[1], T.I. Panagopoulou[1], L. Allen[1], A. Lengelling[2], P. J. Ratcliffe[3], K.R. Kranc[1]
[1]MRC Centre for Regenerative Medicine, [2]The Roslin Institute, Edinburgh, [3]Nuffield Department of Clinical Medicine, Henry Wellcome Building for Molecular Physiology, Oxford, United Kingdom

Background: The finely tuned regulation of haematopoietic stem and progenitor cells (HSPCs) is crucial to ensure a normal haematopoiesis. Its dysregulation can generate leukaemic stem cells (LSCs) which are difficult to eliminate with current therapies, placing a focus on identifying novel therapeutic targets to eradicate LSCs. Emerging studies have described that key oncometabolites (such as succinate and fumarate) are main inhibitors of 2-oxoglutarate dependent dioxygenases (2-OGDO), a family of enzymes that have been reported to play an important role in leukaemogenesis. Here two of these 2-OGDO, Jmjd6 (a jumonji protein associated with alternative splicing) and Phd2 (a prolyl hydroxylase that controls hypoxic response), were investigated in normal haematopoiesis and acute myeloid leukaemia (AML).
Aims: The aim of this study is to investigate the role of two 2-OGDO (*Phd2* and *Jmjd6*) in the development and/or maintenance of AML LSCs.
Methods: To elucidate the role of *Jmjd6* in normal haematopoiesis, we generated a *Jmjd6* conditional knock-out within the haematopoietic system (*Jmjd6$^{fl/fl}$;Vav-iCre*) and fully characterized it. To study the role of *Jmjd6 and Phd2* in leukaemogenesis, purified HSPCs from *Jmjd6$^{fl/fl}$;Vav-iCre* and *Phd2$^{fl/fl}$;Vav-iCre* mice were transduced with retrovirus expressing respectively *Mll-AF9* and *Meis1/Hoxa9*. These transformed cells were characterized *in vitro* (*e.g.* colony forming cell assay) and their leukemic potential was assessed by transplantation. The *Mll-AF9* knock-in (*Mll-AF9$^{KI/+}$*) transgenic model was also used to determine levels of mRNA expression.
Results: In normal haematopoiesis studies, mice lacking Jmjd6 specifically within the haematopoietic system presented hyposplenism and reduced spleen cellularity. Although these mice have normal numbers of stem and progenitor cells (namely Lin$^-$Sca-1$^+$c-Kit$^+$ (LSK)), the distribution within this compartment is perturbed, leading to an accumulation of more committed progenitor cells. This phenotype functionally correlates with the reduced engraftment exhibited by mice transplanted with cells lacking *Jmjd6* upon transplantation with either *Jmjd6$^{fl/fl}$;Vav-iCre* HSCs or total bone marrow (BM) when compared to controls. Preliminary data from the leukaemic studies showed that the absence of Jmjd6 does not impact on the generation of pre-leukaemic stem cells (pre-LSC). Conversely, LSCs from the transgenic *Mll-AF9$^{KI/+}$* mouse model have decreased *Jmjd6* mRNA transcript levels. *in vitro, Meis1/HoxA9* transformed *Phd2*-deficient cells showed increased proliferation and lower apoptosis however, *in vivo*, mice transplanted with cells lacking *Phd2* developed disease later than the respective controls.
Summary and Conclusions: Deletion of *Jmjd6* in the haematopoietic system leads to an accumulation of committed progenitor cells that have a decreased self renewal capacity and, therefore, a compromised repopulating capacity. The deletion of Jmjd6 did not affect the *in vitro* generation of pre-LSC cells. With regard to *Phd2*, it was observed a delay in AML initiation in mice transplanted with *Phd2* KO pre-LSCs. Taken together, these data unravel a new role for *Jmjd6* as a player in normal haematopoiesis and suggest that *Phd2* may act as tumor suppressor in AML.

S119

CONVERGENCE OF SOMATIC MUTATIONS WITHIN THE JAK-STAT SIGNALLING PATHWAY IN A NOVEL RUNX1-MUTATED PEDIGREE

K. Tawana[1], J. Wang[1], P. A. Király[2], K. Kállay[3], G. Benyó[3], G. Kriván[3], J. Csomor[2], J. Fitzgibbon[1], C. Bödör[2,*]
[1]Centre for Haemato-Oncology, Barts Cancer Institute, London, United Kingdom, [2]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, [3]Pediatric Haematology and Stem Cell Transplantation Unit, United St. István and St. László Hospital, Budapest, Hungary

Background: Germline mutations in the transcription factor *RUNX1* confer an autosomal dominant predisposition to familial platelet disorder (FPD) and myelodysplasia/acute myeloid leukaemia (MDS/AML). The penetrance of mutations varies with approximately 40% of carriers developing overt malignancy, whilst others remain asymptomatic or manifest mild to moderate FPD. We describe a novel *RUNX1*-mutated family, where 3 young siblings presented with secondary AML, providing a rare opportunity to compare the molecular events initiating disease (*Figure 1A*).
Aims: To genetically profile somatic aberrations in multiple cases of MDS/AML from a novel FPD/AML pedigree
Methods: We performed whole exome sequencing (WES) on bone marrow (BM) DNA from 4 siblings with MDS/AML with an average exonic coverage of 96x. Peripheral blood (PB) DNA samples from both healthy parents were also sequenced to enable exclusion of inherited variants in the 4 children. Acquired mutations, copy number aberrations (CNA) and loss of heterozygosity (LOH) were then defined across the four siblings. Key mutations were confirmed with Sanger sequencing, whilst further verification of CNA was performed using multiplex ligation-dependent probe amplification (MLPA).
Results: Direct Sanger sequencing of the 4 siblings (II.1-II.4) and their mother (I.1) revealed the germline *RUNX1* mutation, p.R201X. *Figure 1B* summarises the clinical timeline, with the key molecular and cytogenetic lesions detected in MDS/AML from each sibling. Their mother (45y) remains an asymptomatic carrier, with no peripheral cytopenias. The dizygotic twins (II.1 and II.2) presented within a period of 2 weeks at 5y, both with hepatosplenomegaly and pancytopenia. BM morphology of each twin revealed AML with dysplastic and myelomonocytic features. Significant somatic chromosomal aberrations included gain of 21q (II.1), monosomy 7 and deletion of chromosome 9q (II.2). Ten years later, sibling II.4 also presented at 5y with monocytosis. BM examination revealed myelomonocytic AML with dysplastic features and a normal cytogenetic profile. Sibling II.3 is now 14y, her BM examination revealed multi-lineage dysplasia and normal cytogenetics. WES revealed molecular addiction to JAK2 signalling in 3 siblings (II.1, II.2 and II.4). II.2 and II.4 both acquired *JAK2* V617F mutations, with homozygosity of the mutant allele observed in II.2 due to 9p acquired uniparental disomy (aUPD). In II.1, we detected a somatic mutation in *SH2B3 (p.R392Q),* with apparent homozygosity caused by aUPD of 12q. The p.R392Q mutation was localised to the SH2 domain, which normally binds both mutant and WT isoforms of JAK2, inhibiting their phosphorylation. Further somatic mutations occurred in *CDC27* (anaphase promoting complex, II.2 and II.4), RBBP8 (DNA double-strand break repair, II.2) and *U2AF2* (spliceosome complex, II.4). Notably, all 3 siblings with somatic JAK2-signalling lesions had aggressive disease. Both twins died within a year of presentation, II.1 due to relapse and II.2 from chemotherapy-refractory disease. Sibling II.4 relapsed after 13 months and is currently in CR2 following allogeneic HSCT.

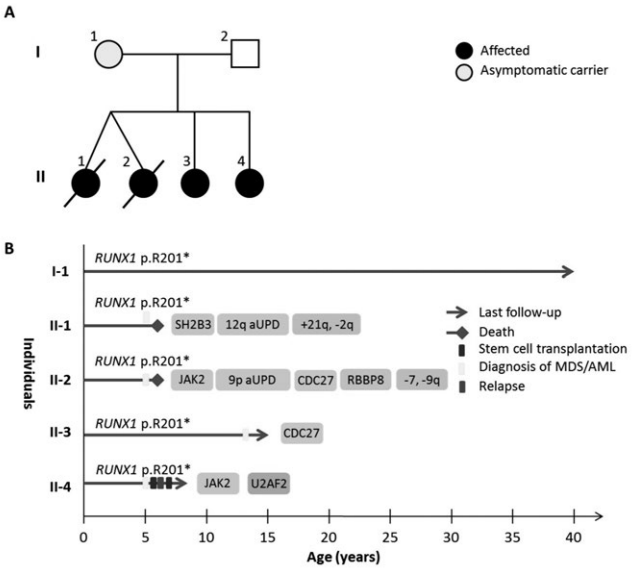

Figure 1.

Summary and Conclusions: We describe a novel FPD-AML pedigree demonstrating convergence of lesions within the JAK-STAT signalling pathway in 3 siblings with MDS/AML. Since *JAK2* mutations are reported in <5% of sporadic *RUNX1*-mutated AML, our findings suggest somatic mutations in FPD/AML may be enriched within distinct signalling pathways, often associated with aUPD to increase the mutant allele burden within tumours.

S120

HIF-2A IS A TUMOUR SUPPRESSOR IN AML

M. Vukovic[1,*] A.V. Guitart[1], K. Kranc[1]
[1]MRC Centre for Regenerative Medicine, University of Edinburgh, Edinburgh, United Kingdom

Background: Normal and malignant haematopoiesis occur under hypoxic conditions. Hif-1α and Hif-2α regulate gene expression to facilitate adaptation to low oxygen tension. Several studies investigated the role of Hif-1α and Hif-2α in acute myeloid leukaemia (AML). These studies used shRNA knockdown in human AML samples to show that *HIF-1α* and *HIF-2α* knockdown compromised the ability of AML samples to reconstitute AML upon transplantation into recipient mice, suggesting that HIF-1 and HIF-2 are potential therapeutic targets for AML. However, a recent study demonstrated that conditional genetic deletion of *Hif-1α* did not compromise the development and maintenance of mouse leukaemic stem cells (LSCs) and on the contrary, accelerated the development of AML, indicating that *Hif-1α* is a tumour suppressor in AML. To date, the effect of conditional deletion of *Hif-2α* has not been examined in AML.
Aims: To investigate the requirement of *Hif-2α* in the development and maintenance of AML leukaemic stem cells.
Methods: We generated *Hif-2α*$^{fl/fl}$;*Vav-iCre* mice that lack *Hif-2α* specifically within the hematopoietic system. We retrovirally co-transduced BM c-Kit$^+$ cells with oncogenes *Meis1a* and *Hoxa9* and serially re-plated them to establish pre-leukaemic stem cells (pre-LSCs). Retrovirally transduced cells were subjected to *in vitro* assays in normoxia and hypoxia or transplanted into lethally irradiated primary recipients, and subsequently into secondary recipients. We next generated *Mll-AF9*$^{KI/+}$*; Hif-2α*$^{fl/fl}$;*Vav-iCre* mice and controls and transplanted Lin$^-$Sca-1$^+$c-Kit$^+$(LSK) cells from these mice into primary recipients, and Lin$^-$Sca-1$^-$c-Kit$^+$(LK) cells into secondary recipients.
Results: *Hif-2α*-deficient and control cells displayed similar re-plating capacity and generated comparable numbers of colonies, but had increased proliferative capacity. Thus, *Hif-2α* is not required for *in vitro* transformation and generation of pre-LSCs but suppresses their proliferation. Transplantation of pre-LSCs to primary recipients demonstrated that a smaller proportion of recipients of *Hif-2α*-deficient pre-LSCs remained leukaemia-free, and therefore succumbed to AML faster than recipients of control pre-LSCs. However, secondary recipients of both *Hif-2α*-deficient and control LSCs generated aggressive AML with similar latency. In concordance with these data, recipients of *Mll-AF9*$^{KI/+}$*; Hif-2α*$^{fl/fl}$;*Vav-iCre* succumbed to AML faster compared to recipients of control LSK cells, whereas, secondary recipients of both genotypes generated AML with similar latency.
Summary and Conclusions: Deletion of *Hif-2α* in pre-LSCs accelerates development of LSCs and shortens AML latency induced by *Mll-AF9* and its downstream effectors *Meis1* and *Hoxa9*. Surprisingly, established LSCs lacking *Hif-2α* efficiently propagate aggressive AML. We conclude that while *Hif-2α* suppresses the development of AML, it is not required for LSC maintenance. Therefore, HIF-2 is unlikely to be a broad therapeutic target in AML and the benefit of HIF inhibition should be carefully re-examined in all subsets of AML.

CLL - Biology: Interacting determinants of CLL ontogeny and evolution

Background: Fludarabine, cyclophosphamide and rituximab (FCR) is the gold-standard first-line regimen in medically fit patients with chronic lymphocytic leukemia (CLL); however, despite good response rates most patients will eventually relapse. Besides *TP53* aberrations, the mechanisms leading to relapse after FCR treatment are currently poorly understood.
Aims: To characterize the genetic mechanisms underlying relapse following treatment with FCR using whole-exome sequencing (WES).
Methods: Forty-one CLL patients receiving FCR with either a partial response (PR, with ≥4 cycles of treatment completed) or a complete response (CR, ≥1 cycle of treatment completed) were selected. Pre-treatment and relapse samples (mean time to relapse 3.2 years, range 0.7-10.9), together with matched germline DNA for 28 patients, were analyzed by WES. Well-established bioinformatics tools and pipelines were used to process raw sequencing reads, enabling the identification of somatic mutations and also facilitating the analysis of copy-number aberrations (CNA) and absolute cancer cell fractions (CCF).
Results: Amongst the 28 patients with matched germline DNA, 1191 somatic variants (>10% allele frequency) were found in the pre-treatment samples and 1334 in the relapse samples, with an average of 15.2 (range, 3-24) and 17.6 (range, 2-32) non-silent mutations per case, respectively. Mutations were predominantly missense substitutions (81%) and less frequently frameshift or in-frame insertions/deletions (14%) or nonsense mutations (5%). As expected, at relapse, a high proportion of cases harbored mutations in genes previously linked to adverse prognosis in CLL: *TP53* (n=8; 19.5%), *NOTCH1* (n=8; 19.5%), *ATM* (n=7; 17%), *SF3B1* (n=6; 14.6%), *NFKBIE* (n=4; 9.8%), *EGR2* (n=4; 9.8%) and *BIRC3* (n=3; 7.3%). Intriguingly, a large proportion of cases also harbored mutations in *RPS15* (n=8; 19.5%), a gene encoding a component of the 40S ribosomal subunit. High allele frequencies were observed for *RPS15* mutations at both time points (range, 29%-56%), and all mutations were missense variants residing within a 7 amino-acid evolutionarily conserved region. Besides its role in protein translation, RPS15 has been shown to stabilize p53 by interfering with the MDM2-p53-MDMX network and inhibiting MDM2-mediated p53 degradation. Characterization of two recurrent *RPS15* mutations in the HCT116 colorectal cancer cell line transiently expressing either wild-type (wt) or mutant RPS15 revealed impaired ability of RPS15^{P131S} and RPS15^{G132A} in regulating endogenous p53. As both mutations map within the region that interacts with MDM2, this finding strongly suggests that binding of RPS15^{P131S} and RPS15^{G132A} to MDM2 is less efficient compared to wt protein thus leading to more pronounced p53 degradation. Finally, by calculating the absolute CCF for all mutations at both time points allowed monitoring of clonal heterogeneity over time. All 24 cases with available exome-derived CNA data showed mutations expanding ≥0.3 in CCF between the time points (mean 7.4 mutations, range 1-21). Among recurrently mutated genes, i) *RPS15* remained stable over time, ii) *TP53*, *EGR2*, *NOTCH1* and *BIRC3* mutations expanded or remained stable, and iii) for *SF3B1* and *ATM* mutations both increasing and decreasing CCFs were observed.

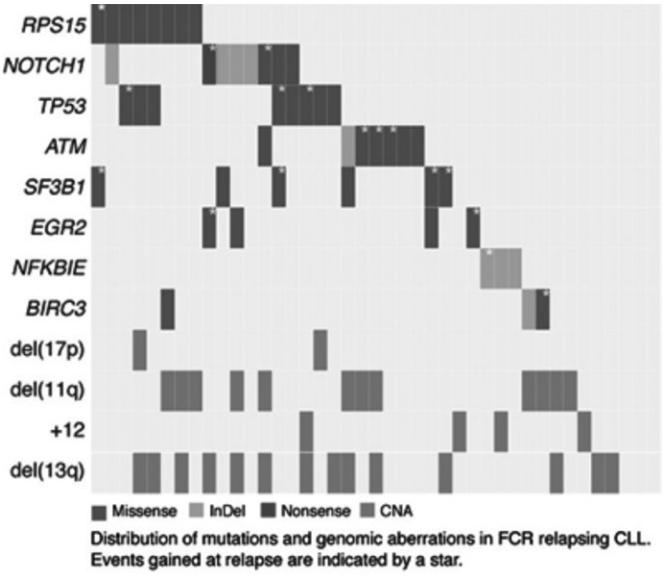

Figure 1.

Summary and Conclusions: We provide novel insights into the heterogeneous genetic landscape of CLL relapsing after FCR treatment with our most prominent finding being recurrent *RPS15* mutations (19.5%) and with *in vitro* studies of *RPS15* mutations pointing to a novel mechanism for p53 dysregulation in CLL.

S122

IN VITRO AND *IN VIVO* ANTILEUKEMIC ACTIVITY OF BEPRIDIL IN CHRONIC LYMPHOCYTIC LEUKEMIA IS ASSOCIATED WITH INHIBITION OF THE NOTCH1 PATHWAY

P. Sportoletti[1,*] S. Baldoni[2], B. Del Papa[1], P. Aureli[1], E. Dorillo[1], E. Varasano[1], D. Cecchini[1], T. Zei[1], A. Di Tommaso[2], F. De Falco[3], S. Plebani[2], V. Amico[2], G. Roti[4], K. Stegmaier[4], E. Rosati[3], B. Falini[1], M. Di Ianni[2], F. Falzetti[1]

Background: In chronic lymphocytic leukemia (CLL), NOTCH1 is constitutively expressed promoting leukemia cell survival and resistance to apoptosis (Rosati et al, Blood 2009). Additionally, *NOTCH1* PEST mutations have emerged as one of the most frequent somatic alterations in CLL, affecting up to 20% of patients (Sportoletti et al, Leukemia 2014). Thus, inhibiting NOTCH1 activity represents a potential therapeutic opportunity for this disease and the incorporation of NOTCH1 pathway antagonists may improve standard CLL treatment. Targeting NOTCH1 has been a therapeutic strategy of interest in many cancers. However, the use of gamma secretase inhibitors (GSI) evaluated in clinical trials showed on target toxicities suggesting the need for the discovery of more selective NOTCH1 pathway antagonists that preferentially target NOTCH1 *versus* NOTCH2 or that target mutated receptors compared to wild-type. Recently, an expression-based screen identified several calcium modulators as a potential strategy to target NOTCH1 (Roti et al, Cancer Cell 2013). Among numerous ion flux modulators validated to induce a NOTCH1 off signature, one of the top hits was the clinically relevant calcium channel blocker, bepridil, used to treat patients with cardiac disease. Bepridil demonstrated anti NOTCH1 modulating activity in T-ALL by a mechanism unique from GSI (Roti et al, ASH 2009).
Aims: The goal of the study was to evaluate whether bepridil exerts antitumor activity in primary CLL cells *in vitro* and in a xenotransplant model and whether these effects are associated with NOTCH1 inhibition.
Methods: *in vitro*, we evaluated NOTCH1 expression in primary CLL cells after 24 hours of bepridil treatment using western blot and flow cytometric analysis. We also measured apoptosis using annexin V/propidium iodide staining and by assessing PARP, MCL-1 and NOXA expression. *in vivo*, CLL cells were transplanted into NSG mice and engraftment was evaluated after 28 days of bepridil treatment.
Results: Bepridil treatment reduced the viability of primary CLL cells at a 2.5 μM *concentration.* In treated CLL cells, viability significantly decreased to 23.8±20.2% compared to 41.5±21.8% of the vehicle control (N=40, p <0.0001). Conversely, bepridil did not affect viability of normal T cells from CLL patients nor the viability of B and T cells from healthy donors, demonstrating that bepridil selectively impairs the viability of B neoplastic cells compared to normal hematopoietic cells. Bepridil significantly increased the percentage of annexin V/propidium iodide positive apoptotic CLL cells compared to vehicle treated cells (49.2±20.9% *vs* 29.3±15.3% N=34 p<0.0001). These apoptotic effects were supported by the detection of increased PARP degradation (p<0.05), significant reduction of MCL-1 protein expression (p<0.001) and a 5-fold up-regulation of *NOXA* transcript levels. Induction of apoptosis with bepridil treatment in cultured CLL cells was not correlated with ZAP-70 expression, *IGVH* rearrangement or *NOTCH1* mutation status. However, the NOTCH1 pathway was inhibited at concentrations of bepridil that induced apoptosis. Specifically, flow cytometric analysis of cultured CLL cells (N=15) demonstrated that bepridil significantly reduced the surface expression of NOTCH1 compared to vehicle (32.8±19.2% *vs* 50.6±18.9% respectively, p<0.05). As previously reported in T-ALL bepridil treatment lead to down regulation of the trans-membrane bound portion of NOTCH1. Notably, NOTCH2 protein level remained unchanged in bepridil treated CLL samples compared to vehicle (N=3), supporting a preferential effect of bepridil on NOTCH1. Interestingly, we observed that CLL cells co-cultured with different stromal layers (including primary mesenchymal cells, HS5 and OP9 cell lines) fail to apoptose upon bepridil treatment. The addition of a CXCR4 antagonist restored bepridil efficacy, suggesting a synergistic effects against the survival stimuli of the stroma. Finally, we established CLL NSG primagrafts and tested bepridil in this leukemia model. Strikingly, flow cytometry analysis revealed a statistically significant decrease in human CD45+CD19+CD5+ percentage in the spleen of bepridil-treated mice compared to vehicle (1.9±1% *vs* 10.8±10%, N=13, p<0.05). As anticipated by our results *in vitro* bepridil treatment did not have a major effect in the neoplastic bone marrow cell population of treated animals.
Summary and Conclusions: In conclusion, we showed that bepridil reduced viability and increased apoptosis in primary CLL cells *in vitro*. This antileukemic effect is associated with the inhibition of the NOTCH1 signal. Moreover, this clinically relevant drug demonstrated efficacy in controlling splenic disease in a mouse model of human CLL, suggesting a potential for rapid translation to clinical testing.

S123

HIGH-THROUGHPUT T-CELL RECEPTOR GENE REPERTOIRE PROFILING IN CHRONIC LYMPHOCYTIC LEUKEMIA SUBSET #4: FURTHER EVIDENCE OF ANTIGENIC STIMULATION

A. Vardi[1,*] E. Stalika[1], A. Gkoufas[1,2], M. Karipidou[3], C. Maramis[1,2], V. Bikos[4], S. Pospisilova[4], A. Anagnostopoulos[3], N. Maglaveras[1,2], I. Chouvarda[1,2], K. Stamatopoulos[1,5], A. Hadzidimitriou[1,5]
[1]Institute of Applied Biosciences, CERTH, [2]Laboratory of Medical Informatics, Medical School, Aristotle University of Thessaloniki, [3]Hematology Department & HCT Unit, G.Papanikolaou Hospital, Thessaloniki, Greece, [4]Central European Institute of Technology, Masaryk University and University Hospital Brno, Brno, Czech Republic, [5]Department of Immunology, Genetics and Pathology, Rudbeck Laboratory, Uppsala University, Uppsala, Sweden

Background: Chronic lymphocytic leukemia (CLL) is characterized by a remarkably restricted immunoglobulin (IG) gene repertoire, mainly attributable to the existence of subsets of patients with stereotyped B-cell receptor (BcR) IGs strongly implying clonal selection by a restricted set of antigens. Our preliminary high-throughput, next-generation sequencing studies of the T-cell receptor beta chain (TRB) gene repertoire in CLL cases from various subsets indicated repertoire skewing, pointing to antigenic selection of the T cells as well, which is relevant in view of the bidirectional CLL-T cell interactions.
Aims: We performed in-depth profiling of the TRB gene repertoire in CLL subset #4 which became our focus for the following reasons: (i) it is the most indolent subgroup of CLL patients identified thus far; (ii) previous studies have strongly supported ongoing antigenic stimulation attested by the intraclonal diversification of the clonotypic IG.
Methods: We studied 11 untreated CLL subset #4 cases and a healthy control. RNA was isolated from peripheral blood mononuclear cells (n=12) or purified $CD4^+$ and $CD8^+$ T cells (n=2 CLL cases). Two patients were studied overtime. TRBV-TRBD-TRBJ gene rearrangements were amplified on cDNA according to the BIOMED2 protocol and subjected to paired-end NGS (MiSeq Illumina Platform). The experimental design allowed sequencing of the complementarity determining region 3 (CDR3) twice/read, so as to increase the accuracy of results. Computational processing of raw data was performed using a purpose-built algorithm and a bioinformatics platform was developed for IMGT/HighV-QUEST metadata clustering and analysis.
Results: Overall, 12,261,280 TRBV-TRBD-TRBJ reads were produced (median 397,035 reads/sample, median Q-score 38.4). Poor quality, incomplete, out-of-frame and unproductive rearrangements were filtered out. For repertoire analyses, clonotypes (*i.e.* TRB rearrangements with identical TRBV gene usage and amino acid CDR3 sequence) rather than single rearrangement reads were considered (median 77020 distinct clonotypes/sample, 54733 singletons *versus* 22287 expanded). Among the 53 functional TRBV genes identified, 5 predominated: *TRBV12-3/12-4* (9.9%), *TRBV29-1* (8.6%), *TRBV19* (7.5%), *TRBV5-1* (5.5%), and *TRBV6-5* (4.9%), collectively accounting for 36.4% of the TRBV repertoire. Comparison of the TRBV gene repertoire of $CD8^+$*vs* $CD4^+$ cells showed that *TRBV19* was overrepresented in the CD4+ compartment (9.4% *versus* 6.9%, p<0.001). The TRB repertoire was significantly more oligoclonal in CLL compared to the healthy control (median frequency of the predominant clonotype: 3.6% *versus* 0.47%, respectively, p<0.001), and this skewing stemmed mainly from the $CD8^+$ rather than the $CD4^+$ compartment (median

frequency of the predominant clonotype 10.7% *versus* 1.0%, respectively, p<0.001). Cluster analysis of all CLL cases identified 37303 different clonotypes (excluding singletons) shared by different patients and not present in the healthy control. The longitudinal analysis of 2 cases showed contrasting results, with 14.6% of all expanded clonotypes persisting over time in one case, but only 0.06% in the other. In the former case, 5 of the persisting clonotypes ranked among the 10 most expanded within the patient's T cell repertoire, whereas in the latter case only minor clonotypes persisted.

Summary and Conclusions: Our study provides large-scale evidence of TR repertoire skewing and oligoclonality in CLL subset #4, strongly supporting antigenic selection. The nature of selecting antigens remains to be elucidated.

S124

CLL SUSCEPTIBILITY SNPS IN MBL SIBLINGS OF CLL PATIENTS

V. Nteleah[1,*] M.T. Koning[1], C.A. van Bergen[1], D. Pfeifer[2], M. Griffioen[1], S. Kielbasa[3], H. Veelken[1]
[1]Hematology, Leiden University Medical Center, LEIDEN, Netherlands, [2]Hematology, University Medical Center Freiburg, FREIBURG, Germany, [3]Medical Statistics, Leiden University Medical Center, LEIDEN, Netherlands

Background: Genome-wide association studies have identified 37 SNPs in 26 loci that confer risk of CLL. Here, we analyse genomic DNA from a prospective cohort of CLL patients that have an MBL sibling for the presence of these CLL risk alleles.
Aims: To investigate whether CLL risk loci are also prevalent in MBL cells found in a sibling.
Methods: Whole blood of siblings of patients with confirmed CLL patients was screened with informed consent and ethical approval for presence of a distinct $CD19^{+}CD5^{+}CD20^{low}CD79b^{low}$ population by flow cytometry. If such an MBL population was present, genomic DNA from granulocytes of both CLL patient and MBL sibling was isolated from the same blood sample. All cases with sufficient available DNA were subjected to whole exome sequencing (WES) based on SureSelect Human All Exon V4 kit (Agilent) capture on the HiSeq2000 (Illumina) platform to an average coverage of 40x. Sequence reads were filtered and mapped to the human reference genome (GRCh37). Analysis of gene copy numbers and heterozygosity was performed by either 10K, 250K, SNP6, or CytoscanHD arrays (Affymetrix). In addition, PCR was performed on 35 reported CLL susceptibility alleles and analyzed by direct Sanger sequencing of gel-purified amplicons (PCR Clean-Up System, Promega). The frequency of all risk alleles was compared to healthy individuals from the literature by Fisher's exact test.
Results: Screening of 160 siblings of CLL patients identified 19 MBL siblings (MBL prevalence: 11.9%) from 16 CLL patients. In all but 2 MBL, the clonal B-cell count was <100/ul. Genomic data from 13 CLL and 14 MBL cases, including 12 complete CLL/MBL pairs are described in this report. Nine of total of 37 CLL susceptibility SNPs could be called on WES data obtained from 5 CLL and 4 MBL cases. 18 CLL risk SNPs could be analyzed on SNP arrays as indicated by a median call rate of at least 98%. The combined SNP array and WES data permitted analysis of 23 SNP of 15 loci. By targeted re-sequencing on 10 CLL and 6 MBL cases, the total number of analyzed risk SNPs was increased to 35 of the 37 known CLL risk alleles. 16 risk alleles were statistically overrepresented in combined CLL and MBL compared to the healthy population (Table). Out of these 16 SNPs, 11 were significantly overrepresented in CLL and nine in MBL, respectively. SNP rs11083846 was significantly overrepresented in MBL only but not in CLL or in the combined CLL and MBL cases.

Tabella 1.

Summary and Conclusions: Our data provide an independent validation of 16 of 35 previously reported CLL risk loci using combined SNP array, WES, and Sanger sequencing data on a unique prospectively assembled cohort of co-occurrence of CLL and MBL in siblings. No discrepancies were observed between the various analysis platforms. Besides providing genetic correlates for a familial susceptibility in CLL, the shared presence of these risk loci in CLL and their MBL siblings indicate a causal role for clonal premalignant B-cell expansion. These risk alleles therefore appear to contribute to the initiation of a CLL-like phenotype, but further endogenous or exogenous triggers are required to drive MBL to CLL.

S125

GENETIC PROFILE OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH ULTRA-STABLE DISEASE

S. Raponi[1,*] M. Marinelli[1], I. Del Giudice[1], S. Bonina[1], J. Wang[2], L. Cafforio[1], C. Ilari[1], M. Messina[1], S. Tavolaro[1], A. Bonafede[1], F. R. Mauro[1], D. Rossi[3], G. Gaidano[3], A. Guarini[1], R. Rabadan[2], R. Foà[1]
[1]Cellular Biotechnologies and Haematology, Sapienza University of Rome, Rome, Italy, [2]Biomedical Informatics, Center for Computational Biology and Bioinformatics, Columbia University, New York, United States, [3]Translational Medicine, Amedeo Avogadro University of Eastern Piemont, Novara, Italy

Background: Chronic lymphocytic leukemia (CLL) shows an extremely heterogeneous clinical course. Beside cases with aggressive disease requiring immediate treatment and those with an initial indolent phase followed by progression, there are patients who do not progress for decades. Next generation sequencing (NGS) technologies have allowed a further understanding of the molecular complexity of CLL. In the present study, we characterized 41 ultra-stable CLL cases by whole exome sequencing (WES), ultra-deep NGS and copy number aberration (CNA) analysis. Ultra-stable disease was defined as absence of progression for at least 10 years from diagnosis.
Aims: To investigate the so far unexplored mutational profile and CNA load of ultra-stable CLL patients.
Methods: Peripheral blood samples from 20 ultra-stable CLL patients were used for WES analysis (Illumina HiSeq2000), including paired germline DNA in 14. Sanger sequencing (ABI PRISM 3100) was used to validate WES mutations and to screen the recurrency of mutated genes identified in ≥2 cases by WES, in a second cohort of 21 ultra-stable CLL samples. Bad prognosticator genes (*NOTCH1-BIRC3-SF3B1-TP53)* were also investigated. Subclonal *TP53* mutations were examined by ultra-deep NGS (Roche-454 GS Junior) in 36 cases. CNA analysis (Affymetrix Cytoscan HD arrays) was performed in 30 cases.
Results: WES analysis of the 14 cases having paired germline DNA predicted 83 non-silent somatic mutations in 81 genes, with a mutation load of 6 mutations/case (range: 1-12). The remaining 6 cases without germline DNA were analyzed to assess the recurrence of mutations identified in the former cohort and to investigate those with known significance. Three genes were recurrently mutated: *RBM46, KLHL6, UBR5.* Since *RBM46* was the most recurrent among ultra-stable CLL (3 cases, 15%) and never reported in other CLL WES studies, Sanger sequencing of the whole codifying region was performed on the screening cohort with no additional mutated case identified. Interestingly, none of the genes with known adverse prognostic impact was found mutated in 41 ultra-stable CLL, including *ATM* and *MYD88* in the WES cohort. Unexpectedly, ultra-deep-NGS of *TP53* revealed subclonal mutations in 2/36 cases (5.5%). One case after 19 years from diagnosis showed 4 mutations with a median allele frequency (AF) of 1.55% (range 0.9-1.79), corrected for tumor representation, and developed a clinical progression soon after the inclusion in the study; after therapy, a clonal *TP53* mutation expansion occurred. The second case showed 1 subclonal mutation (AF 5.2%) after 29 years from diagnosis; for the subsequent 4 years she remained in clinical spontaneous regression of CLL but developed a breast cancer. AS-PCR validation of these subclonal mutations is ongoing. CNA analysis identified 31 lesions represented by 90% of losses and 10% of gains, giving a CNA load of 1/case. Twelve cases (40%) showed no lesion, 9 (30%) showed isolated del(13q), 5 cases (17%) del(13q) with additional non-canonical CNAs and 4 cases (13%) a median of 1 non-canonical CNAs. There was no recurrent CNA beside 13q deletion, as well as no CNA with known poor prognostic significance.

Tabella 1. Biological and clinical features of 41 ultra-stable CLL patients

Gender	25 M/16 F
Age (years)	51 (range: 29-73)
Binet stage	40 A; 1 B
CD38 positive (cut-off 30%)	0/0
IGHV mutated	41/41
Follow-up from diagnosis (years)	16 (range: 10-34)

Summary and Conclusions: Ultra-stable CLL show no driver mutations or CNAs. No new recurrent lesion associated to a highly stable course was identified. We found two cases with *TP53* subclonal mutations with an extremely divergent clinical history, which could be due to the subclonal architecture complexity and to the chemotherapy selective pressure in the case with clonal evolution.

Stem cell transplantation: Clinical 1

S126

OUTCOMES OF OLDER PATIENTS EXPERIENCING REDUCED INTENSITY CONDITIONING ALLOGRAFT: RESULTS OF THE NCRI AML16 TRIAL

N. Russell[1,*] R. Hills[2], L. Kjeldsen[3], M. Dennis[4], C. Craddock[5], R. Clark[6], A. Burnett[7]
[1]Department of Haematology, Nottingham University Hospitals, Nottingham, [2]HCTU, Department of Haematology, Cardiff University School of Medicine, Cardiff, United Kingdom, [3]Rigshospitalet, Copenhagen, Denmark, [4]Department of Haematology, Christie Hospital, Manchester, [5]Department of Haematology, Queen Elizabeth Hospital, Birmingham, [6]Royal Liverpool University Hospital, Liverpool, [7]Blackwaterfoot, Isle of Arran, United Kingdom

Background: Reduced Intensity conditioning (RIC) is increasingly offered to older patients who are to undergo a stem cell transplant. We have previously shown that a RIC allograft, particularly from a sibling donor is beneficial in intermediate risk patients between the ages of 45-64, and may have advantages over myeloablative conditioning in patients aged 35-44. Based on this analysis of the UK NCRI AML15 trial in younger patients, the current recommendation within the NCRI AML trials is to transplant intermediate risk patients with a RIC allograft if a sibling is available excluding those who are NPM1+/ FLT3 wt.
Aims: We here present similar analyses from the UK NCRI AML16 trial extending this experience to older patients.
Methods: The UK NCRI AML16 trial ran from 2006-2012 and randomised patients, generally aged 60+, suitable for intensive chemotherapy between Daunorubicin/Ara-C (DA) and Daunorubicin/Clofarabine (DClo), both with or without Mylotarg, or between DA with or without etoposide and with or without ATRA. Patients could be randomised between 2 or 3 courses of therapy and maintenance or not with azacitidine. Because only 4/225 transplants took place in patients over the age of 70, attention was restricted to patients who were aged less than 70 years, achieved remission, and did not have core binding factor leukaemia. A total of 963 patients were studied, with transplant in first remission given to 162 patients (sibling allograft n=51, MUD n=93; other/unknown n=18). Follow-up is complete to 1st January 2014 with median follow-up for survival from CR of 46.3 months. Comparisons of confirmed allogeneic transplant in 1st remission *versus* not are carried out using Mantel-Byar analysis to allow for time to transplant, with patients censored at the time of non-RIC allo transplant.
Results: Among the 144 allografts, 93 had intermediate risk cytogenetics, 19 adverse risk, and 32 were unknown. In transplanted patients, survival from transplant was 36% at 5 years, and while the survival for sibling allografts (42%) was better than that for MUDs (37%) this did not reach statistical significance (p=0.2), and 84% of transplants in adverse risk cytogenetics were from an unrelated donor. In analyses adjusted for Wheatley risk group there was no significant difference in outcome (HR 1.27 (0.80-2.03) p=0.3). When comparing allograft *versus* no allograft, survival was significantly improved (35% *vs* 20%, HR 0.75 (0.61-0.93) p=0.006). When stratified by Wheatley risk group, there was no evidence of any interaction (p-value for trend 0.5), and the adjusted hazard ratio, allowing for differences in Wheatley group between transplant and no transplant was 0.76 (0.61-0.94), p=0.008 reflecting the consistent benefit. When considering type of transplant, sibling allograft performed consistently better than MUD in Mantel-Byar analyses across the risk groups (overall sibling 41%, MUD 35%, no SCT 20%; good risk 47% *vs* 42% *vs* 26%; standard risk 38% *vs* 34% *vs* 25%; poor risk, not reached *vs* 23% *vs* 8%).
Summary and Conclusions: The results are consistent with those seen in our analysis of AML15 While, particularly as patients get older, there will be selection for transplant on the basis of fitness, the analysis adjusted for clinical features of the disease shows that RIC transplant in first remission appears an attractive option for older patients with AML. While no significant difference was seen between sibling and MUD allograft, even after adjusting for Wheatley risk, outcomes are better in all Wheatley groups with sibling allografts.

S127

REDUCED INTENSITY CONDITIONING (RIC) ALLO TRANSPLANTATION IS ASSOCIATED WITH SUPERIOR LONG-TERM DISEASE CONTROL IN RELAPSED/REFRACTORY GRADE I/II (G-I/II) FOLLICULAR LYMPHOMA

E. Klyuchnikov[1,*] U. Bacher[2], N. Kröger[1], P. Hari[3], K. W. Ahn[3], D. Maloney[4], S. Smith[5], A. Sureda[6], J. Carreras[3], M. Hamadani[3]
[1]Department for Stem Cell Transplantation, University Cancer Center, Hamburg, [2]Department for Hematology/Oncology, University of Göttingen, Göttingen, Germany, [3]CIBMTR, Medicine, Medical College of Wisconsin, Milwaukee, [4]Clinical Research Division, Fred Hutchinson Cancer Center, Seattle, [5]Section of Hematology/Oncology, The University of Chicago, Chicago, United States, [6]Servei d'Hematologia, Institut Català d'Oncologia, Hospital Duran i Reynals, Barcelona, Spain

Background: We compared long-term outcomes of allogeneic transplantation (alloHCT) *vs* autologous (auto) HCT in pts with G-I/II follicular lymphoma (FL) in the rituximab-era.
Aims: To compared survival outcomes following autoHCT *vs* alloHCT in G-I/II FL, when either modality is used as the *first* transplantation approach.
Methods: Adult pts with relapsed/refractory G-I/II FL undergoing 1st RIC alloHCT or 1st autoHCT reported to Center for International Blood and Marrow Transplant Research during 2000-12 were eligible. Pts with large cell transformation and those not receiving rituximab before HCT were excluded.
Results: Characteristics of 518 pts included in this analysis are shown in **Table 1**. AlloHCT pts were younger, more heavily pretreated, had more advanced stage disease, had longer interval between diagnosis and HCT, more extranodal involvement and were chemotherapy resistant compared with auto-HCT pts. The 5-year adjusted probabilities of non-relapse mortality (NRM), relapse/progression, progression-free survival (PFS) and overall survival (OS) of autoHCT *vs* alloHCT groups were 5% *vs* 26% (p<0.0001); 54% *vs* 20% (p<0.0001); 41% *vs* 58% (p<0.001) and 74% *vs* 66% (p=0.05), respectively. Cumulative incidence of second malignancies at 5 years did not differ significantly (alloHCT=8%; autoHCT=5%). On multivariate analysis (MVA) autoHCT was associated with reduced NRM (RR=0.21; p<0.0001) and time varying effects were seen on other outcomes. Within the first 5 and 11months post HCT, auto-and alloHCT had similar relapse/progression and PFS. AutoHCT was associated with a higher risk of relapse/progression beyond 5 months post HCT (RR=4.4; p<0.0001), and worse PFS (RR=2.9; p<0.0001) beyond 11 months post HCT, respectively. In the first 24 months post HCT, autoHCT was associated with improved OS (RR=0.41; p<0.0001), but beyond 24months with inferior OS (RR=2.2; p=0.006). A landmark analysis of pts alive and progression-free at 2-years post HCT confirmed these observations, showing no difference in NRM between the auto-and alloHCT groups, but significantly higher risk of relapse/progression (RR=7.3; p<0.0001) and inferior PFS (RR=3.2; p<0.0001) and OS (RR=2.1; p=0.04) following autoHCT.

Tabella 1.

Background: Primary refractory AML is associated with a dismal prognosis. Approximately one third of patients younger than 60 years, and 50 % of older patients, with newly diagnosed AML fail to achieve complete remission (CR) with standard induction chemotherapy. Allo-SCT in the setting of active disease is an alternative but highly debatable strategy. The increased availability of UD and the use of reduced-intensity conditioning (RIC) regimens have opened the possibility for transplantation to a larger number of patients in comparison to standard myeloablative regimens (MAC).
Aims: The current study aimed to assess outcomes in a cohort of 381 primary refractory AML patients who received allo-SCT from an UD (10/10 or 9/10). Primary refractoriness was defined as failure to achieve CR within 60 days after starting induction.
Methods: Patients with primary refractory AML reported between 2000 and 2013 to the registry of the Acute Leukemia Working Party of the EBMT were included in this study. The major endpoints were to assess overall survival (OS), leukemia-free survival (LFS), relapse incidence (RI), and non relapse mortality (NRM).
Results: Median age was 50.5 (range, 18-74) years and 56% were males. Median time from diagnosis to allo-SCT was 111 (range, 60-178) days. 51 % received a MAC regimen, and 49% a RIC regimen. Peripheral blood stem cell (PBSC) was the main stem cell source (94.8%). The median follow-up was 18 months(range, 1.2-153). 296 patients received a matched UD (10/10) and 85 a mismatched UD (9/10). Engraftment was achieved in 95.2% of cases. 70.4% patients reached CR after allo-SCT. At 2 years, the cumulative incidences of acute GVHD≥2 and chronic GVHD (cGVHD) were 35.5% and 25.8%, respectively. At 2 years, OS and LFS rates were 34.3% and 28.3%. RI was 46.4% and NRM 25.1%. In multivariate analysis, 2 predictive factors were associated with lower OS: cytogenetics (poor *vs* intermediary; HR=2.00, 95%CI,1.25-3.18, p=0.004) and positive CMV status of the recipient (HR=1.52, 95%CI,1.09-2.11, P=0.01), whereas Karnofsky status at transplant ≥80% (KS) was associated with better OS (HR=0.65, 95%CI,0.43-0.98, p=0.04) (Fig1). The same factors were predictive for LFS: cytogenetics (HR=1.86, 95%CI,1.19-2.92, p=0.01) and positive CMV status of the recipient (HR=1.46, 95%CI, 1.07-1.99, p=0.02) were negative predictive factors, whereas KS was a positive one (HR=0.61, 95%CI,0.41-0.91, p=0.02). In multivariate analysis for RI, cytogenetics was the only risk factor associated with increased relapse (HR=1.92, 95%CI,1.15-3.19, p=0.001). As for NRM, patient gender (female *vs* male) and KS were factors associated with lower NRM (HR=0.49, 95%CI,0.29-0.84, p=0.01; HR=0.41, 95%CI,0.22-0.76, p=0.004), while CMV positive status was the only factor associated with higher NRM (HR=1.96, 95%CI=1.11-3.43, p=0.02).

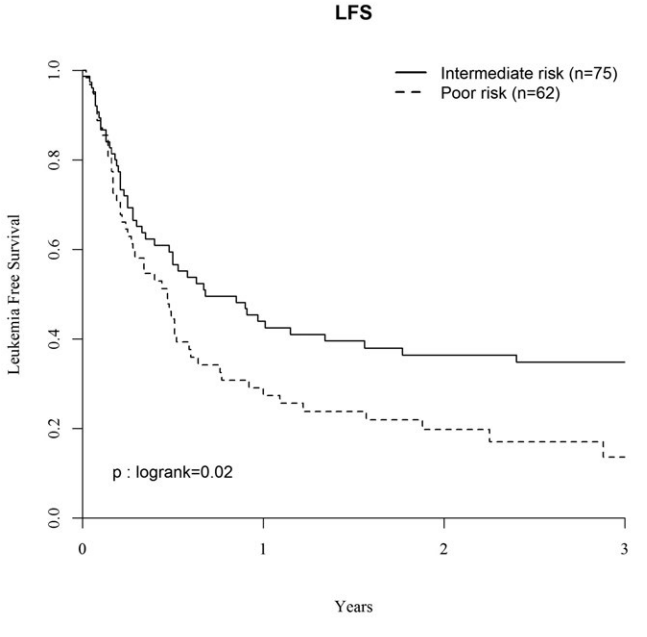

Figure 1.

Summary and Conclusions: Unrelated donor transplantation (10/10 or 9/10) may rescue about one third of the patients with primary refractory AML. Moreover, this study identifies cytogenetics, KS, and CMV status as major prognostic factors. Finally, these data pave the way not only for improving patients' selection, but also for investigating more intensive additional approaches relying on sequential conditioning regimens (debulking phase followed by RIC) and/or post-transplant treatments such as 5-azacytidine, prophylactic donor lymphocytes infusions, or targeted therapy which further improve results in this devastating group of patients.

Background: ALL is rare in patients older than 60 years, and is associated with poor prognosis with chemotherapy alone, with reported leukemia-free survival (LFS) rates below 20%**.** When feasible, allogeneic stem cell transplantation (allo-SCT) is an attractive treatment option for those patients. However due to comorbidites, non-relapse mortality (NRM) can be a limiting factor.
Aims: This study aimed to evaluate the results and risk factors associated with outcome of allo-SCT in ALL patients older than 60 years, and who received a reduced-intensity conditioning (RIC) regimen prior to allo-SCT between 2001 and 2012.
Methods: 117 patients with fully documented data could be identified and analyzed. Median age at time of allo-SCT was 63 (range, 60-75) years, with 34 patients (29%) being older than 65. 57% of patients had a Karnosky performance status ≥90%. Median year of allo-SCT was 2009. Median follow up was 37 (range, 10-134) m. 82 patients (70%) were transplanted in CR1, 19 (16%) in CR2 and CR3, and 16 (14%) in more advanced disease. Of 109 patients with available cytogenetics data, 53 (49%) harboured t(9;22) at diagnosis. Conditioning regimen included fludarabine and busulfan (Bu-Flu) for 34% of patients, 26% had a low-dose TBI-based regimen, while 20% received fludarabine and melphalan. ATG was used in 41% of cases. Fifty-two (45%) of patients were transplanted with an HLA-identical-sibling donor (MSD). Graft source was peripheral blood stem cells in 95% of cases.
Results: At 2 years the probabilities of LFS, and overall survival (OS) were 35% and 47%, respectively. The cumulative incidences (CI) of NRM, relapse incidence (RI), and chronic GVHD were 22%, 43%, and 38%, respectively. In univariate analysis, disease status was associated with LFS, RI and OS: LFS rate was 25% for CR2 and 13% for advanced *vs* 41% for CR1 (p<0.01), RI rate was 70% for CR2 and 63% for advanced *vs* 33% for CR1 (p<0.01), OS rate 40% for CR2 and 19% for advanced *vs* 54% for CR1 (p<0.01). Patients transplanted from a MSD had a higher RI (56% *vs* 33%) compared to those transplanted from unrelated donors (UD, p<0.01). Factors associated with NRM were the use of Bu-Flu (NRM was 13% for Bu-Flu *vs* 26% in other regimens) (p=0.05)) and Karnofsky-score ≥90% (NRM was 14% for KPS<90% *vs* 31% KPS ≥90%) (p<0.05)). In multivariate analysis, factors associated with LFS were disease status (advanced disease, HR=3.6, p<0.01) and CR2, HR=1.90, p=0.04), and the use of unrelated donors (HR=0.60, p=0.03). Disease status was associated with better OS (HR=0.28, p<0.001). On the other hand, advanced disease status, use of a MSD, performance status <90% was associated with a higher RI (HR=4.64, p<0.01, HR=2.38, p=0.06, HR=2.25, p<0.05 respectively). NRM was lower for patients with performance status ≥90% and for those receiving the Bu-Flu regimen (HR=0.48, p=0.06 and HR=0.33, p<0.05, respectively).
Summary and Conclusions: Allo-SCT after RIC is a feasible and effective option for patients with ALL older than 60 years with LFS of 35% and OS of 47%. The results were better for patients transplanted in CR1, and with good performance status.

S130

ALLO-HSCT FOLLOWING RIC FOR ELDERLY PATIENTS (60 YEARS AND OLDER) WITH HEMATOLOGICAL MALIGNANCIES USING UNRELATED DONORS: A RETROSPECTIVE STUDY OF THE SFGM-TC

J. Elcheikh[1,*] P. sfumato[2], N. fegeux[3], M. mohty[4], S. vigouroux[5], I. yakoub-agha[6], G. socié[7], J. cornillon[8], N. ifrah[9], J.O. bay[10], M. michallet[11], D. blaise[1], R. Peffault de Latour[7]
[1]transplantation, [2]Institut Paoli Calmettes, Marseille, [3]transplantation, mont-

pellier, montpellier, [4]transplantation, saint antoine, paris, [5]transplantation, bordeaux, bordeaux, [6]transplantation, University Hospital Center, Lille, France, lille, [7]transplantation, saint louis, paris, [8]transplantation, nantes, nantes, [9]transplantation, angers, angers, [10]transplantation, clermontferrand, clermontferrand, [11]transplantation, lyon, lyon, France

Background: The use of unrelated donors (URD) in patients aged of 60 years or more has drastically increased in the past few years. To date, there are only limited data on URD allo-HSCT in elderly patients (60 years or more).
Aims: The purpose of the current study is to describe outcomes in a large cohort of patients aged 60 years or older, who received a RIC URD allo-HSCT in recent years.
Methods: Between 2008 and 2012, 516 consecutive patients aged of 60 years or more, who received a first allo-HSCT for hematological malignancies from an URD after a RIC regimen in France were included. Conditioning regimen was fludarabine-based in 91% of the patients. Two groups of patients were defined: patients with age at allo-HSCT less than 65 years old ("URD<65 group", n=374) and patients who were aged of 65 years old or more ("URD ≥65 group", n=142).
Results: Patient characteristics were similar between the 2 groups. The median follow-up was 36 months (range, 0.36-73.5) for URD<65 group and 32 months (range, 0.03-72) for URD≥65 group. During evolution, the cumulative incidence (CI) of grade II–IV acute GvHD was 32% in URD<65 group and 32% in URD≥65 group (p=0.975) while the CI of chronic GvHD at 2 years was 25 % and 26%, respectively (p=0.701). CI of non-relapse mortality (NRM), disease free survival (DFS) and overall survival (OS) were not different between the 2 groups Multivariate analysis for NRM, DFS and OS show that age by itself has no influence on outcomes.
Summary and Conclusions: These data suggest equivalence of outcome between URD<65 group and URD≥65 group after RIC URD allo-HSCT. Age by itself thus appears not to be a limitation in this particular population of elderly patients.

Biology in MDS

[1]Division of Haematology, Department of Internal Medicine, Centro Hospitalar de São João, Porto, Portugal, [2]Laboratory of Hematology, Radboud university medical center, Nijmegen, Netherlands, [3]Department of Pathology & Tumor Biology, Kyoto University, Kyoto, Japan, [4]Department of Human Genetics, [5]Department of Hematology, Radboud university medical center, Nijmegen, Netherlands

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematopoietic neoplasms characterized by bone marrow dysplasia and one or more peripheral blood cytopenias. Underlying this heterogeneity is a variety of genetic abnormalities. Within the bone marrow and blood of an individual patient, several clones of cells with their own set of mutations may be present simultaneously. During the course of the disease, the clonal composition may change and additional genetic defects can be acquired. Patient-specific (sub)clonal architectures may contribute to the heterogeneity of MDS, both in terms of clinical manifestations and response to treatment.
Aims: We studied the clonal composition of MDS on the basis of somatic mutation profiles, the long-term diachronous changes in clonal architecture throughout the course of the disease, and the correlations between clonal architecture/evolution and clinical parameters and treatment response.
Methods: Bone marrow and blood samples from 12 patients with low-to intermediate-risk MDS with long follow-up times (2.5-11 years) were collected at regular intervals (5-19 sampling moments/patient). Whole-exome sequencing was applied on the first and last and several intermediate time points for each patient. In total, 64 samples were used for whole-exome sequencing, to an average depth of 110x. Cultured T-cell DNA was used as reference. In addition, the same samples were analyzed using high resolution SNP-arrays. From this, in total 348 different acquired somatic mutations were identified in 300 different genes. In order to be able to quantify the presence of these mutations with high accuracy, for all mutations specific assays were developed for amplicon-based deep sequencing (IonTorrent, with a coverage of ≈ 10,000 x). This was used to measure the mutational burden at the different sampling time points.
Results: The median number of validated cancer-associated gene mutations per patient was 14 (range 10-26) and 3 (range 0-5) for well-known, recurrently mutated driver mutations in MDS. Integrated analysis revealed the clonal architecture and its evolution over time. Both linear and branched evolution were present in different patients. Diverse patterns of clonal evolution, ranging from a single clone remaining stably dominant for many years, to cases with highly dynamic shifts in the subclonal composition were observed. Five patients were treated with lenalidomide, four of which achieved complete remission. In one of these patients, clinical complete remission was accompanied by molecular remission (mutations <1%), followed by a relapse after acquisition of a *TP53* and *RELN* mutation in the original clone, containing six other mutations. One doubly-*TET2*-mutated patient, treated with EPO and G-CSF displayed a branched evolutionary process with two competitive subclones: an initially major *NRAS*-mutated subclone and a minor *RRAS*-mutated subclone. Over the course of two years, the *RRAS*-mutated subclone became dominant with subsequent transformation to AML.
Summary and Conclusions: Our study demonstrates that great diversity in clonal composition and evolution underlies the clinical heterogeneity of MDS. In some patients, clonal composition was very stable over time, whereas in others, a highly dynamic pattern was observed. Our findings emphasize the importance of genetically unbiased disease monitoring and the development of therapeutic strategies aiming to eradicate multiple different clones.

S132

INITIAL ANALYSIS OF THE PHENOTYPIC CONSEQUENCES OF SF3B1 K700E MUTATION EXPRESSION *IN VITRO* AND *IN VIVO*

V. Sathiaseelan[1,*] A. Mupo[2], A. Pance[1], S. Pacharne[2], N. Manes[2], F. Law[1], E. Papaemmanuil[3], P. Campbell[3], G. Vassiliou[2], N. Bolli[3]
[1]Wellcome Trust Sanger Institute, Cambridge, United Kingdom, [2]Haematological Cancer Genetics, [3]The Cancer Genome Project, Wellcome Trust Sanger Institute, Cambridge, United Kingdom

Background: Myelodysplastic syndromes (MDS) are clonal hematopoietic stem cell disorders characterized by dysplastic hematopoiesis in the bone marrow and peripheral blood cytopenias. The splicing factor *SF3B1* is the most commonly mutated gene in MDS and is mainly found in refractory anemia with ring sideroblasts (RARS). *SF3B1* mutations are missense, heterozygous and clustered, suggesting they are gain-of-function with a causal link to the development of RARS. Nevertheless, *in vitro* studies are hampered by the inability

to clone the full length *SF3B1* cDNA and model the effect of its mutation in cell lines. Few reports on *Sf3b1* knock-down mice have not convincingly recapitulated the features of its somatic mutations in RARS.
Aims: We therefore targeted the *Sf3b1* locus of mouse embryonic stem cells (ESC) to create a conditional allele encoding the most common mutation *Sf3b1*^{K700E} to assess the phenotypic consequences of its expression *in vitro* and *in vivo*.
Methods: The C57BL/6N ESC line JM8 was targeted by homologous recombination. Albino pseudopregnant females were injected allowing for chimera screening based on coat color. One mouse carrying germline transmission was selected and its heterozygous offspring was crossed to Tg(*Mx1*:Cre) mice. *Sf3b1*^{K700E} expression was then elicited in the bone marrow with pIpC injection to activate the Cre recombinase. In parallel, Cre was overexpressed in ESC to generate clones with constitutive *Sf3b1*^{K700E} expression to perform *in vitro* work. WT and mutant ES cells were analyzed in basal conditions and after differentiation into haematopoietic cells. For the latter procedure, cells were allowed to grow into embryoid bodies that were subsequently dissociated with trypsin and cultured in a hematopoietic cytokines mix.
Results: WT and mutant *Sf3b1* ESC showed proliferation rates and colony morphologies similar to native ESC. Upon differentiation, >80% of cells expressed the pan-hematopoietic marker Cd45, with no difference between genotypes. Erythroid differentiation in particular was efficient as confirmed by an increase in transcription levels of the globin genes, that was reduced in *Sf3b1* mutant cells. Nevertheless, gross morphology was similar in WT and mutant cells. Flow cytometry showed a marginal decrease in the percentage of Cd71^{low}/Ter119^{hi} cells for the mutant genotype, but no major differences in the frequency of expression markers of stem and progenitor, myeloid and megakaryocytic cells. By unsupervised clustering of gene expression profiles, we found that WT and mutant cells cluster closely together in the undifferentiated state, whereas differentiation causes mutant cells to acquire a dramatically different expression profile than WT cells. Mutant differentiated cells showed an excess of downregulated genes, among which known players in congenital sideroblastic anemias (*Abcb7, Glrx5*, and *Scl25A38*). Gene ontology analysis showed downregulation of several biological processes, including the respiratory electron transport chain and regulators of mitochondrial ion transport as shown previously, but also processes involved in RNA metabolism like translation initiation and pre-mRNA splicing. Initial analysis of conditional *Sf3b1*^{K700E} expression in mice showed that heterozygous animals display no overt sign of disease at our median follow-up of 116 days. In turn, peripheral blood counts post-pIpC injection show that hemoglobin is significantly decreased at one (17.2 *vs* 14.2 gr/dl, p=0.001) and two months (16.7 *vs* 15, p=0.006) in mutant animals, with no difference in white cell and platelet counts. Analysis of bone marrow cells by flow cytometry showed a 2-fold decrease in Cd71^{low}/Ter119^{hi} (p=0.02) cells for the mutant genotype, suggestive of a late maturation defect. Lastly, iron stain of bone marrow cells showed an increment of iron-laden macrophages and occasional ringed sideroblasts in the mutant animals.
Summary and Conclusions: Our data closely recapitulates initial observations in human samples and suggests mutated *Sf3b1* expression leads to defective erythroid maturation. Our mouse model will allow better characterization of the molecular pathways altered by the mutation and the analysis of modifiers of this phenotype.

S133

IN VIVO TREATMENT BY LENALIDOMIDE CHANGES THE CLONAL EVOLUTION OF HEMATOPOIETIC STEM PROGENITOR CELLS OF NON DEL(5Q) LOW RISK MDS PATIENTS

V. Chesnais[1,*] A. Renneville[2], A. Toma[3], M. Passet[4], A. Gauthier[4], A. Lefèvre[1], J. Delaunay[5], C. Rose[2], A. Stamatoullas[6], O. Beyne-Rauzy[7], P. Fenaux[8], F. Dreyfus[9], C. Preudhomme[2], M. Fontenay[14], O. Kosmider[14], E.L. Groupe Francophone des Myelodysplasies[9]
[1]Institut Cochin, Paris, [2]CHRU Lille, Lille, [3]Hematology, Hopital Henri Mondor, Creteil, [4]Hematology, AP-HP Hopitaux Universitaires Paris Centre, Cochin, Paris, [5]CHU Nantes, Nantes, [6]Centre Henri Becquerel, Rouen, [7]CHU Toulouse, Toulouse, [8]Hopital Saint louis, [9]AP-HP Hopitaux Universitaires Paris Centre, Cochin, Paris, France

Background: Recurrent somatic mutations are thought to support MDS initiation and progression. Recently, studies have highlighted the clonal evolution of MDS which could be affected by treatments. Lenalidomide (Len) is designated as a second line treatment in non-del (5q) transfusion-dependent (TD) ESA-resistant low/int-1 MDS patients, which achieve an erythroid response in 30% of cases.
Aims: To investigate whether mutations may represent molecular markers of sensitivity to Len, we used next generation sequencing to examine 26 recurrently mutated genes in non-del(5q) MDS patients treated by Len. We also investigated the clonal evolution of hematopoietic stem progenitor cell (HSPC) following this therapy.
Methods: Bone marrow mononuclear cells (BMMC) were collected in 99 patients at screening, in 15 patients (6 non responder and 9 responder) after 4 cycles of treatment within 4 to 8 months after treatment initiation. For 8 responder, 3 to 5 sequential samples were collected until the 26th month of follow-up. Samples were genotyped by next generation and Sanger sequencing approaches. Clonal architecture of CD34^{+}CD38^{-}HSPC was determined by the genotyping of single cell-derived clones expanded on murine MS5 stromal cells, in 5 patients at screening and was also monitored after 4 cycles of treatment.
Results: On the global cohort, four genes had a mutation frequency over 10%: *SF3B1* (73%), *TET2* (46%), *ASXL1* (20%), *DNMT3A* (20%). As judged on variant allele frequencies (VAF), *SF3B1* and *DNMT3A* mutations were mostly clonal while *TET2* and *ASXL1* mutations were clonal or subclonal. The presence of *DNMT3A* mutations was linked to the response to Len. Among the 15 patients with a follow-up after 4 cycles, VAF were stable in 5/6 non-responder, while a subclonal *NRAS* mutation became visible in one case. Among responder patients, a significant decrease of VAF was observed in 5/9 cases. VAF detected in total BMMC mirrored the mutation representation in HSPC compartment. Furthermore, genotyping of recurrent mutations in individual HSPC described the clonal hierarchy. In some cases, the founding clone was the dominant clone, while in other cases it preceded its appearance. Subclonal mutations either colonised the dominant clone or defined a new independent clone. After 4 cycles of treatment, the dominant clone collapsed in 3/5 patients. In two responder patients, the dominant *SF3B1/DNMT3A*^{mut} clone either completely disappeared in favor of the founding *DNMT3A*^{mut} pre-leukemic clone or obviously decreased in favor of a minor *SF3B1ex14*^{mut}*/DNMT3A*^{mut}clone. In a 3rd case, the dominant *SF3B1/TET2*^{mut} clone decreased in favor of founding *SF3B1*^{mut} clone. In the two other cases, dominant clones *SRSF2/TET2*^{mut} or *SRSF2/TET2/ASXL1*^{mut} remained stable. Long term follow-up of VAF in 8 responder until 26 months after the beginning of treatment identified an increase of the dominant mutations and/or the emergence of mutations in *EZH2*, *TP53* or *ASXL1* genes in 4/5 patients concomitantly with the loss of response.
Summary and Conclusions: Len is able to modify the clonal evolution of non del(5q) low/int-1 MDS by targeting the dominant clone in HSPC compartment, in cases affected by *DNMT3A* and *SF3B1* mutations. Conversely, emergence of subclones can be observed before or at the time of treatment failure. Extended analysis to a larger number of patients will confirm that the clonal evolution under treatment must be monitored.

S134

SRSF2 P95H MUTATION RESULTS IN IMPAIRED STEM CELL REPOPULATION AND COMPROMISED HEMATOPOIETIC DIFFERENTIATION IN MICE

A. Kon[1,*] S. Yamazaki[2], K. Kataoka[1], T. Yoshizato[1], Y. Shiozawa[1], M. Sanada[1], K. Yoshida[1], Y. Yamazaki[2], Y. Shiraishi[3], S. Miyano[3,4], M. Nakayama[5], H. Koseki[6], H. Nakauchi[2,7], S. Ogawa[1]
[1]Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, [2]Division of Stem Cell Therapy, Center for Stem Cell Biology and Regenerative Medicine, [3]Laboratory of DNA Information Analysis, Human Genome Center, [4]Laboratory of Sequence Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, [5]Laboratory of Medical Genomics, Department of Human Genome Research, Kazusa DNA Research Institute, Chiba, [6]Laboratory for Developmental Genetics, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan, [7]Institute for Stem Cell Biology and Regenerative Medicine, Stanford University School of Medicine, Stanford, CA, United States

Background: Recent genetic studies have revealed frequent and specific pathway mutations involving multiple components of the RNA splicing machinery in myelodysplasia. Among these, *SRSF2* mutations are more prevalent in CMML subtype and are associated with poor prognosis. Mutations showed a prominent hotspot involving proline 95, causing either P95H, P95L, or P95R conversion. The molecular mechanism by which *SRSF2* mutations lead to myelodysplasia remains largely unknown.
Aims: This study aimed to clarify the role of *SRSF2* mutations in the development of myelodysplasia through the analysis of *Srsf2 P95H* conditional knock-in mice.
Methods: We first generated a heterozygous conditional knock-in mouse model of *Srsf2 P95H* mutation and crossed them with *Vav1-Cre* transgenic mice. We then performed detailed analysis of hematological phenotype of *Srsf2 P95H* knock-in mice and also evaluated their reconstitution ability in competitive transplantation experiments.
Results: Heterozygous *Srsf2 P95H* conditional knock-in mice exhibited no significant change in total peripheral blood (PB) counts compared to wild-type mice at 8-15 weeks after birth. Bone marrow (BM) cellularity and spleen weight showed no obvious difference between *Srsf2 P95H* and wild-type mice. Analysis of hematopoietic stem and progenitor cells fractions showed significant decrease of the frequency of HSCs in *Srsf2 P95H* mice compared to wild-type mice. On the other hand, there were no significant differences in the number of more differentiated progenitor cells including multipotent progenitor (MPP) cell fractions, myeloid progenitors (MEPs, CMPs, and GMPs) and lymphoid progenitors between *Srsf2 P95H* and wild-type mice. We next performed non-competitive transplantation experiments to assess the cell intrinsic effects of *Srsf2 P95H* mutations. 3 months after transplantation, recipient mice transplanted with *Srsf2 P95H* BM cells showed significant leukopenia due to impaired lymphopoiesis and anemia. Flow cytometrical analysis revealed decreased numbers of HSCs and MPPs fractions, whereas there were no sig-

nificant changes in MEPs, CMPs, and GMPs in BM. The frequency of erythroid progenitor populations was significantly reduced in *Srsf2 P95H* mice in BM and spleens. The population of B cell lineage also decreased at as early as pre-pro B cell stages. These observations suggested that *SRSF2 P95H* mutations lead to impaired stem cell functions and ineffective hematopoiesis, resembling the phenotype of MDS. Subsequently, we assessed the reconstitution capacity of whole BM cells from *SRSF2* mutant mice in competitive transplantation experiments. The donor chimerism of *Srsf2 P95H*-derived cells in PB was significantly lower than that of wild-type cells. At 4 months post transplantation, chimerism of *Srsf2 P95H*-derived cells was remarkably lower than that of wild-type cells in the fractions of HSCs, MPPs, CMPs, MEPs, GMPs and CLPs. Furthermore, the reduced donor chimerism for *Srsf2 P95H* mutants was recapitulated in secondary transplantation experiments. Finally, we have not observed overt MDS phenotypes in none of these *Srsf2*-mutant mice or transplantation models.
Summary and Conclusions: Our results demonstrated that heterozygous P95H mutation of *Srsf2* lead to deregulation of hematopoietic stem cells that was evident from reduced competitive repopulation in lethally irradiated mice and impaired hematopoietic differentiation. *SRSF2* mutation by itself does not seem to be sufficient to develop MDS but to require additional genetic and/or epigenetic events for overt MDS phenotype.

S135

CSNK1A1 BEHAVES LIKE A TUMOR SUPPRESSOR GENE AND MUTATIONS IN CSNK1A1 ASSOCIATE WITH MUTATIONS IN SPLICEOSOMAL GENES IN MYELODYSPLASTIC SYNDROME WITH ISOLATED DEL(5Q)
M. Meggendorfer[1,*] H. Michael[2], A. Tamara[1], H. Claudia[1], S. Susanne[1], K. Wolfgang[1], T. Felicitas[2], H. Torsten[1]
[1]MLL Munich Leukemia Laboratory, Munich, [2]Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: Deletion of 5q is one of the most frequent cytogenetic aberrations in myelodysplastic syndromes (MDS). The WHO category of myelodysplastic syndrome with isolated del(5q) describes an own entity showing good prognosis and also demonstrating response to specific treatment such as lenalidomide. However, in some patients the disease evolves to secondary AML. The underlying pathogenic mechanisms are still under debate. Recently, *CSNK1A1* was found to be frequently mutated in MDS with del(5q) irrespective of the presence of additional cytogenetic lesions. *CSNK1A1* is located on 5q32 in the commonly deleted region.
Aims: To analyze mutations in *CSNK1A1* in correlation to other gene mutations as well as to clinical data and prognostic information in MDS with isolated del(5q).
Methods: We investigated 115 patients (82 female, 33 male) presenting with MDS with isolated del(5q) that were strictly diagnosed according to WHO classification 2008 with respect to cytomorphology and cytogenetics (blasts below 5% in the bone marrow and 5q deletion sole). All patients were analyzed for mutations in *ASXL1*, *BCOR*, *BRAF*, *CBL, CSNK1A1*, *DNMT3A*, *ETV6*, *EZH2*, *FLT3*-TKD, *GATA1*, *GATA2*, *IDH1*, *IDH2*, *JAK2*, *KIT*, *NRAS*, *KRAS*, *MPL*, *NPM1*, *PHF6*, *RUNX1*, *SF3B1*, *SRSF2*, *TET2*, *TP53*, *U2AF1*, and *WT1*. The libraries were generated with the ThunderStorm (RainDance Technologies, Billerica, MA) and the Access Array System (Fluidigm, San Francisco, CA) and both libraries were sequenced on a MiSeq instrument (Illumina, San Diego, CA). Missense variants not yet described in any public database were excluded from statistical analyses.
Results: In the total cohort the most frequently mutated genes were *DNMT3A* and *TP53* (21/115, 18% each), followed by *SF3B1* (18/115, 16%), *TET2* (13/113, 12%), *CSNK1A1* (11/115, 10%), *ASXL1* (9/115, 8%), and *JAK2* (7/115, 6%). The mutation frequencies of all other analyzed genes were below 5%, respectively. In only 35/115 patients (30%) no gene mutation was identified. Therefore, *CSNK1A1* is the fifth most frequently mutated gene in MDS with isolated del(5q). All *CSNK1A1* mutations were missense mutations in either amino acid Glu98 (n=9) or Asp140 (n=2). Investigating concomitant gene mutations with *CSNK1A1* mutations resulted in two cases showing no additional gene mutation. The other nine cases showed mutations in *ASXL1* (n=2), *DNMT3A* (n=2), *SF3B1* (n=3), *SRSF2*, *TET2*, or *U2AF1,* respectively. Interestingly, five of the eleven cases (46%) presented with an additional mutation in one of the spliceosomal genes *SF3B1* (n=3), *SRSF2* (n=1), or *U2AF1* (n=1) (*vs* only 16% in *CSNK1A1* wildtype, p=0.034). No correlation of *CSNK1A1* mutations with age, sex, white blood cell count, hemoglobin level, platelet count, as well as bone marrow blast count were found. There was also no prognostic impact of *CSNK1A1* mutations on overall survival. Furthermore we raised the question if the *CSNK1A1* mutations occur more likely in the del(5q) cell clone or in the remaining cells. Therefore, we compared the percentage of del(5q) positive cells by evaluation of the corresponding FISH data with the mutation load of *CSNK1A1* and found a significant correlation (r=0.761, p=0.006), suggesting that *CSNK1A1* mutations occur more likely in the del(5q) cell clone and is therefore affected on both alleles.
Summary and Conclusions: 1) *CSNK1A1* is the fifth most frequently mutated gene in MDS with isolated del(5q). 2) Cases with mutations in *CSNK1A1* frequently associate with mutations in one of the spliceosomal genes *SF3B1*, *SRSF2*, or *U2AF1*. 3) *CSNK1A1* mutations are most likely present in the del(5q) clone.

Red cells: Novel clinical aspects

S136

LUSPATERCEPT (ACE-536) INCREASES HEMOGLOBIN AND DECREASES TRANSFUSION BURDEN AND LIVER IRON CONCENTRATION IN ADULTS WITH BETA-THALASSEMIA: PRELIMINARY RESULTS FROM A PHASE 2 STUDY
A. Piga[1,*] S. Perrotta[2], C. Borgna-Pignatti[3], M.R. Gamberini[3], A. Melpignano[4], E. Voskaridou[5], V. Caruso[6], A. Filosa[7], Y. Aydinok[8], X. Zhang[9], D. Wilson[9], A. Laadem[10], M. Sherman[9], K. Attie[9]

Perrino", Brindisi, Italy, [5]Laiko General Hospital, Athens, Greece, [6]Garibaldi Hospital, Catania, [7]AORN "A.Cardarelli", Naples, Italy, [8]Pediatric Hematology, Ege University, Izmir, Turkey, [9]Acceleron Pharma, Cambridge, MA, [10]Celgene Corporation, Summit, NJ, United States

Background: Luspatercept, a fusion protein containing modified activin receptor, is being developed for the treatment of beta-thalassemia (β-thal). Luspatercept binds to GDF11 and other ligands in the TGF-β superfamily to promote late-stage erythroid differentiation. Luspatercept corrected the effects of ineffective erythropoiesis in a thalassemia mouse model (Suragani R, Blood 2014) and was well tolerated and increased hemoglobin (Hb) in a phase 1 clinical study (Attie K, Am J Hematol 2014).
Aims: This is an ongoing, phase 2, multicenter, open-label, dose-finding study to evaluate luspatercept in adults with transfusion-dependent (TD) or non-transfusion dependent (NTD) β-thal. Efficacy outcomes include Hb increase in NTD patients, reduced RBC transfusion burden in TD patients, and liver iron concentration (LIC) by MRI.
Methods: Inclusion criteria included age ≥18 yr and either being TD or NTD β-thal with baseline Hb <10.0 g/dL. Luspatercept was administered SC every 3 wks for up to 5 doses with a 2-month follow-up. Six sequential cohorts (n=up to 6 each) were treated at escalating doses from 0.2 to 1.25 mg/kg. An expansion cohort (n=30) is ongoing; patients who complete the core study may be eligible to enroll in a 12-month extension study.
Results: Preliminary data (as of 16-Jan-2015) were available for 35 patients treated for 3 months. Median age was 35 yr, ranging from 20-57 yr, and 86% had prior splenectomy. TD β-thal patients (n=11). Transfusion burden prior to treatment ranged from 4 to 8 units/12 weeks. All 10 (100%) evaluable patients achieved the primary endpoint of >20% decrease in transfusion burden over 12 weeks (includes 1 patient with only 8 weeks) compared with the 12 weeks prior to treatment (median 67%, ranging from 43 to 100%). The 5 TD β-thal patients in the higher dose groups with baseline LIC ≥5 mg/g dw who were on chronic iron chelation therapy (mean duration 2.5 yr) had a mean LIC decrease of 17% by week 16; this decrease in LIC correlated with a decrease in transfusion burden. NTD β-thal patients (n=24). Mean baseline Hb was 8.3 g/dL, ranging from 6.5 to 9.6 g/dL. Three of 7 (43%) patients in the higher dose groups achieved the primary endpoint of increase in Hb >1.5 g/dL sustained for ≥2 weeks (mean duration 9 weeks) compared with 0 of 17 (0%) patients in the lower dose groups. The 5 NTD β-thal patients in the higher dose groups with baseline LIC ≥5 mg/g dw (includes 3 patients on iron chelation therapy) had a mean LIC decrease of 18%; this decrease in LIC correlated with an increase in hemoglobin. All 3 β-thal patients with chronic leg ulcers at baseline (2 NTD, 1 TD) had substantial, rapid healing, beginning 4-6 weeks after the first dose of luspatercept. Luspatercept was generally well tolerated, with no related serious adverse events reported to date. Adverse events were mostly mild-moderate and the most frequent related adverse events (>10% patients) were bone pain, headache, myalgia, and pain in extremity.
Summary and Conclusions: Luspatercept treatment for up to 3 months was well-tolerated, increased Hb levels in NTD patients, and decreased transfusion requirement in TD patients with β-thalassemia. Both TD and NTD β-thal patients had decreases in LIC at therapeutic doses, and healing of leg ulcers occurred in 3 of 3 patients. These changes represent a significant reduction in disease burden for patients with β-thalassemia. Phase 3 studies of luspatercept in β-thalassemia are planned.

S137

INTERIM RESULTS FROM A PHASE 2A, OPEN-LABEL, DOSE-FINDING STUDY OF SOTATERCEPT (ACE-011) IN ADULT PATIENTS (PTS) WITH BETA-THALASSEMIA
M.D. Cappellini[1,*] J. Porter[2], R. Origa[3], G.L. Forni[4], E. Voskaridou[5], A.T. Taher[6], A. Laadem[7], F. Galactéros[8], D. Miteva[7], V. Sung[9], R. Chopra[7], J.B. Arlet[10], J.A. Ribeil[10], J. Zou[7], N. Chen[7], K.M. Attie[11], M. Garbowski[2], G. Graziadei[1], M. Balocco[4], O. Hermine[10]
[1]Ca' Granda Foundation IRCCS, University of Milan, Milan, Italy, [2]University College London, London, United Kingdom, [3]Università degli Studi di Cagliari, Ospedale Regionale per le Microcitemie, Cagliari, [4]Ente Ospedaliero Ospedali Galliera, Genoa, Italy, [5]Laiko General Hospital, Athens, Greece, [6]American University of Beirut, Beirut, Lebanon, [7]Celgene Corporation, Summit, United States, [8]Groupe Hospitalier Henri Mondor, Créteil, France, [9]Celgene Corpora-

tion, San Francisco, United States, [10]Hôpital Necker-Enfants Malades, Institut Imagine, Paris, France, [11]Acceleron Pharma, Cambridge, United States

Background: Beta-thalassemias are characterized by ineffective erythropoiesis leading to anemia, iron overload, and organ failure. Sotatercept (ACE-011) is a novel and first-in-class activin type IIA receptor fusion protein that acts on late-stage erythropoiesis to increase the release of mature erythrocytes into circulation (Carrancio S, *et al.* Br J Haematol 2014;165:870-82). RAP-011, a murine version of sotatercept, was effective in a mouse model of beta-thalassemia, thereby supporting the clinical development of sotatercept for beta-thalassemia (Dussiot M, *et al.* Nat Med 2014;20:398-407).
Aims: To determine a safe, tolerable, and effective dose of sotatercept in pts with transfusion-dependent (TD) beta-thalassemia major (TM) and pts with TD or non-transfusion-dependent (NTD) beta-thalassemia intermedia (TI).
Methods: In this ongoing phase 2a, multicenter, open-label, dose-finding study, pts received sotatercept subcutaneously once every 3 weeks; enrollment up to 1.0 mg/kg is complete and analysis ongoing. Efficacy was assessed by hemoglobin (Hb) increase from baseline for NTD pts and RBC transfusion burden reduction for TD pts. Safety was assessed by NCI-CTCAE v4.0. All pts provided informed consent. ClinicalTrials.gov identifier: NCT01571635.
Results: 30 of 46 pts (65%) in the sotatercept 0.1, 0.3, 0.5, 0.75, and 1.0 mg/kg dose groups were NTD (28 TI, 2 Hb-E/beta-thalassemia) and 16 (35%) were TD (12 TM, 4 TI). Of 30 NTD pts, 6, 6, 6, 7, and 5 were included in the different dose groups, respectively; mean baseline Hb for NTD pts was 8.3 g/dL (range 5.9–10.7). Rates of Hb response for NTD pts are shown in the Table. Area under the curve and peak concentration of sotatercept increased with dose (data not shown). Increased exposure was associated with higher mean Hb increases over 9 weeks for NTD pts (r =0.78, P <0.0001) and with reduced transfusion burden over 24 weeks for TD pts (r =0.74, P <0.01). Among TD pts evaluable for efficacy, 8 of 14 pts (57%) showed a ≥20% reduction in transfusion burden on treatment *versus* 6 month transfusion burden at baseline, whereas ≥50% reduction was observed for 1 of 5 pts in the 0.75 mg/kg dose group and 1 of 2 pts in the 1.0 mg/kg dose group; treatment of the 0.3, 0.5, 0.75, and 1.0 mg/kg groups is ongoing. Overall, sotatercept was well tolerated and 25 of 46 pts (54%) remain on treatment; 19 (41%) pts have been on treatment for ≥1 year, 8 (17%) for ≥22 months, and 2 (4%) for ≥2 years. Grade ≥3 treatment-related adverse events leading to discontinuation were seen in 4 pts: worsening grade 3 bone pain in 1 TD pt in the 0.1 mg/kg group; grade 3 ventricular extrasystoles in 1 NTD pt in the 0.5 mg/kg group; and grade 3 hypertension in 2 NTD pts in the 0.75 mg/kg group. Overall, 3 pts discontinued due to lack of efficacy: 1 pt in each of the 0.1, 0.3, and 1.0 mg/kg dose groups. Updated safety and efficacy data will be presented.

Tabella 1. Rates of Hb response for NTD pts.

	Sotatercept dose					
	0.1 mg/kg (n = 6)	0.3 mg/kg (n = 6)	0.5 mg/kg (n = 6)	0.75 mg/kg (n = 7)	1.0 mg/kg (n = 5)	Total (n = 30)
Hb increase ≥ 1.0 g/dL from baseline sustained for ≥ 12 weeks	0	4 (67)	4 (67)	6 (86)	1 (20)	15 (50)
Hb increase ≥ 1.5 g/dL from baseline sustained for ≥ 12 weeks	0	2 (33)	2 (33)	5 (71)	1 (20)	10 (33)

All values are expressed as n (%)

Summary and Conclusions: These preliminary data suggest long-term treatment with sotatercept can increase Hb levels and decrease transfusion burden with a favorable safety profile in pts with beta-thalassemia. These data suggest an exposure-dependent effect for sotatercept. MDC, JP, and OH contributed equally to this abstract.

S138

PHASE 1 MULTIPLE ASCENDING DOSE STUDY OF THE SAFETY, TOLERABILITY, AND PHARMACOKINETICS/PHARMACODYNAMICS OF AG-348, A FIRST-IN-CLASS ALLOSTERIC ACTIVATOR OF PYRUVATE KINASE-R, IN HEALTHY SUBJECTS

H. Yang[1,*] E. Merica[1], Y. Chen[1], M. Cohen[2], R. Goldwater[3], H. Kim[1], P. Kosinski[1], C. Kung[1], M. Goldwasser[1], B. Silver[4], L. Utley[1], S. Agresta[1]
[1]Agios Pharmaceuticals, Cambridge, [2]MBC Pharma Solutions, Newtown, [3]PAREXEL, Baltimore, [4]Bruce A. Silver Clinical Science and Development, Dunkirk, United States

Background: Pyruvate kinase (PK) deficiency is a rare genetic disorder of metabolism resulting in chronic hemolytic anemia, with comorbidities including iron overload and multi-organ dysfunction. Approximately 180 mutations in the *PKLR* gene are recognized to cause functional deficiency of the PK-R isoform. Defective glycolysis in red blood cells leads to increases in the metabolic precursor, 2,3-diphosphoglycerate (2,3-DPG), and deficiency of the product, adenosine triphosphate (ATP). AG-348 is an oral allosteric activator of both wild type and multiple mutant PK-Rs. We report here a multiple ascending dose (MAD) trial of AG-348.
Aims: To assess safety, tolerability, and pharmacokinetics/pharmacodynamics (PK/PD) of AG-348 in healthy volunteers and identify a dosing schedule for future trials in patients with PK deficiency.
Methods: A phase 1, single-center, randomized, double-blind, placebo-controlled MAD study (NCT02149966) was conducted in healthy men and women (18–60 years) in 6 sequential cohorts (each cohort: n=6 AG-348, n=2 placebo [P]). Subjects gave informed consent and received oral AG-348 at 15–700 mg twice daily (q12h) or 120 mg once daily (q24h) for 14 days with follow-up to Day 29. Adverse events (AEs), laboratory parameters, ECGs, and vital signs were monitored. Plasma AG-348 concentrations and whole blood 2,3-DPG and ATP levels were measured in serial blood samples for PK/PD assessment. Hormone levels were monitored due to pre-clinical data suggesting potential modulation.
Results: 48 subjects (42M/6F), mean age 41.5 (range, 25–60) years, enrolled. Final, un-blinded safety data showed ≥1 AE in 16/36 (44%) AG-348-treated and 4/12 (33%) P subjects. Treatment-related AEs (≥1) were noted in 11/36 (31%) AG-348-treated and 3/12 (25%) P subjects. All treatment-related AEs were mild or moderate in severity (only one grade 3 event) and often reversible despite continued dosing. The most frequent AG-348-related AEs were nausea and headache, 5/36 (14%) for each (P: nausea 0/12 [0%]; headache 1/12 [8%]). Gastrointestinal AEs occurred in AG-348-treated subjects only at the highest dose, 700 mg q12h. One grade 3 AE occurred (AG-348 700 mg q12h, elevated liver function tests [LFTs], which resolved after treatment discontinuation). There were 4 AG-348 discontinuations: due to AEs in 2 subjects (grade 2 drug eruption, 60 mg q12h; grade 3 elevated LFTs, 700 mg q12h), and 2 subjects withdrew consent (both had grade 1/2 nausea and grade 1/1 vomiting; both at 700 mg q12h). The highest well-tolerated dose was 360 mg q12h (doses between 360 and 700 mg were not explored). Plasma AG-348 exposure was dose dependent, with low to moderate variability in the PK parameters of AG-348 and its metabolite AGI-8702. There was a dose-dependent decrease in 2,3-DPG and increase in ATP with the effects plateauing at 360 mg q12h. Decrease in 2,3-DPG was robust after Dose 1, while the increase in ATP occurred gradually and was strongly evident at Day 8. Change from baseline in 2,3-DPG and ATP plateaued at ~300 µg/mL (~50% decrease) and ~175 µg/mL (~50% increase), respectively. After final Day 14 dose, 2,3-DPG returned to levels similar to baseline between 72 and 120 hours. ATP levels remained elevated through 120 hours post dose (Figure). Details of all un-blinded data will be presented.

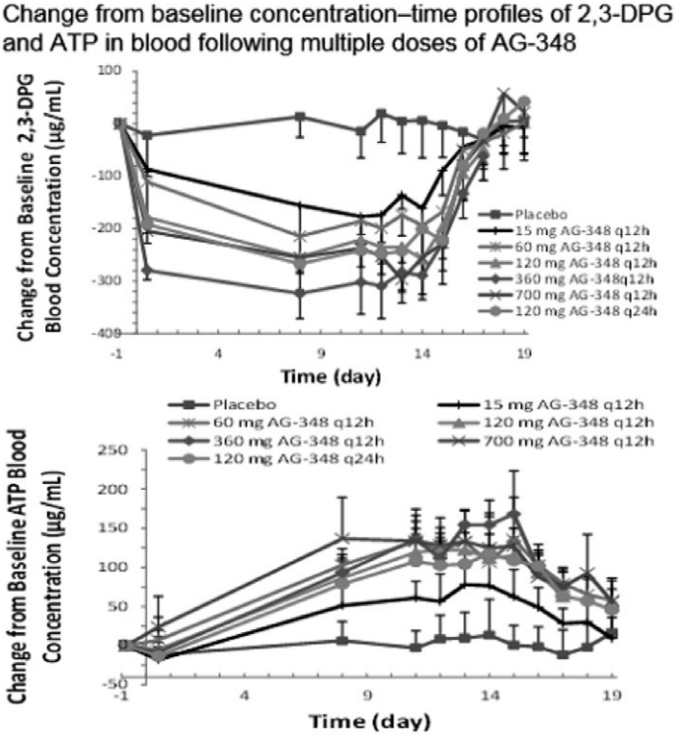

Figure 1.

Summary and Conclusions: AG-348 showed a robust 2,3-DPG/ATP PD glycolytic profile at well-tolerated doses in healthy volunteers. The results support proceeding with a planned phase 2 trial in patients with PK deficiency.

S139

THE SINGLE-UNIT BLOOD TRANSFUSION: EXPERIENCE AND IMPACT IN HAEMATOLOGY PATIENTS

A. Allameddine[1,*] M. Heaton[2], H. Jenkins[2], S. Andrews[2], B. Sedman[2], C. Poarada[2]
[1]Pathology department, Royal Oldham Hospital, Oldham-Manchester, [2]Royal Oldham Hospital, Oldham, United Kingdom

Background: The Pennine Acute Trust (PAT) is one of the largest non-teaching general hospitals in the UK with an average 30.000 units of blood products are transfused yearly. The Hospital Transfusion Team (HTT) overseeing the transfusion practice, conducted few audits to assess the appropriateness of blood transfusion. These showed that an average of 15-25% of blood transfusion is given inappropriately for various reasons, including the lack of intervention, prevention and diagnosis of anaemia. This has been similarly confirmed by the National Comparative Audits of blood transfusion(1).
Aims: The introduction of the Patient Blood Management (PBM) as a patient-focused model, along with the adoption of a restrictive transfusion triggers, resulted in one of the most effective measures to reduce the inappropriate blood usage, with consequent major benefit for the health care system. The implementation of the single-unit transfusion can considerably reduce the total RBC requirement, as shown in a study of Berger et al (2012), where a change from a double to single-unit transfusion resulted to be safe and achieved a 25% reduction of transfusion requirements(2).
Methods: The HTT introduced the single unit policy for patients without active bleeding in all hospital wards. This involved dispensing one RBC unit at a time. Clinicians were asked to consider each unit transfused as an independent clinical decision and to request the 2nd unit if clinically indicated, after the patient been re-assessed. Recommendations were given to all clinicians to consider alternatives to transfusion, especially, those known with iron deficiency or those with expected transient drop of their haemoglobin level, following treatment, bleeding or sepsis. The main indications suggested for the 2nd unit either the Hb remains<70g/l or patient with on-going chest pain or rise of the haemoglobin less than 8g/l.
Results: The single-unit transfusion policy was introduced in PAT in January 2014. The data analysis within the haematology inpatient ward on the first 12 months of introduction of the policy, and compared with same period of 2013 and matched with the same number of patients, are very encouraging. The analysis revealed an average 31% compliance to single unit policy compared to 10% in 2013. This has resulted in the reduction of the number of RBC units transfused by patient from an average of 3.71 units per patient in 2013 to 3.03 in 2014, with consequent saving of 18% of total units of blood, equivalent to 260 units with a saving of around 40.000 euro/year.
Summary and Conclusions: The introduction of the single unit transfusion policy could result in up to 18% reduction in red blood cell usage in a population with haemato-oncological disorders. These data are very encouraging and demonstrate that the long-standing concept of two RBC units transfusion necessary for an adequate increase of the haemoglobin level must be critically revised. The introduction of this policy will help reducing blood usage, maintain adequate blood supply and optimise healthcare resources. However, further work is needed to improve compliance among clinicians. The introduction of the single unit policy did not have significant impact on the frequency of transfusion. The 72 hours pre-transfusion compatibility specimen expiry allows enough time to consider further transfusion without performing further tests. Although more transfusion events may have occurred in some cases, the overall reduction in transfusion requirement would compensate for the extra work undertaken within the transfusion laboratory.

RAPID REVERSAL OF RED BLOOD CELL SICKLING PROMOTED BY PEGYLATED CARBOXYHEMOGLOBIN BOVINE GAS TRANSFER PROPERTIES

R. Jubin[1,*] P. Buontempo[1], C. Buontempo[1], R. Yglesias[1], Y. Chen[1], A. Abuchowski[1]
[1]Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, United States

Background: Sickled Red blood cells (RBCs) have increased rigidity restricting their passage through the microvasculature and cause vasoocclusive crisis (VOC). PEGylated carboxyhemoglobin bovine (Sanguinate™; SG) was designed to release carbon monoxide (CO) to reduce vasoconstriction, counteract inflammatory responses as well as deliver O_2 to hypoxic tissues. Early intervention of VOC with SG treatment could limit the crisis event and reduce pain severity while providing a timely crisis resolution.
Aims: SG treatment effects were evaluated under controlled conditions to determine its capacity for gas exchange with RBCs obtained from healthy and Sickle Cell Disease (SCD) volunteers.
Methods: Carboxyhemoglobin and oxyhemoglobin levels were monitored to determine dose and time effects as well as the repetitive capacity of SG to facilitate gas transfer processes. RBC treated samples were analyzed by light microscopy and image capture flow cytometry to visualize and quantify the effects of SG treatment on reversing sickled SCD RBC. PEG bovine serum albumin (PBSA) product was used as a control.
Results: SG addition to normal oxygenated RBC resulted in CO and O_2 exchange between RBC and SG that followed mass balance and reached equilibrium in closed system. Kinetic analysis revealed SG rapidly transferred its CO component to oxygenated RBC with concomitant O_2 loading of SG. Using experimentally loaded RBC with CO and SG with O_2 produced similar reciprocal gas exchange results. Additionally the primary RBC/ SG reaction products were isolated and cycled demonstrating the ability of SG to continually facilitate gas transfer through multiple exposure events. Similar studies using SG, oxygenated SG (produced by an RBC exchange reaction) or PBSA control were conducted with SCD RBC. Sickling was induced by incubation of RBC in a hypoxic chamber for 3 hours prior to SG or control treatments. After 2 hours of treatment, cells were fixed by addition of glutaraldehyde. Photomicroscopy showed a marked reduction in the sickled RBC population with both SG or oxygenated SG treatments but not with the PBSA control (Figure 1). Results from imaging flow cytometry further supported the microscopy findings and revealed a significant quantitative reduction in the percentage of sickled RBC levels.

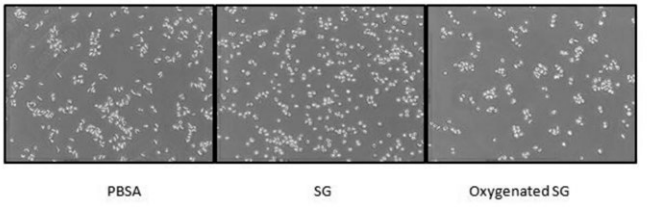

Figure 1. *SG Treatment of Sickled RBC*. Hypoxic SCD RBC treated with SG, oxygenated SG or PBSA for 2 hrs prior to fixation and image capture (40X mag).

Summary and Conclusions: RBCs are negatively impacted by repetitive HbS polymerization/de-polymerization cycling and treatments that reverse RBC sickling during a VOC event could be expected to provide broad clinical benefits. SG was designed to promote CO and O_2 transfer in a concentration dependent manner providing physiological supplementation of O_2 transport/delivery in conditions of hemolytic or ischemic anemia. Additionally since ASH 2015, anti-inflammatory activity on LPS activated samples has been quantified by qPCR and flow cytometry of a selected panel of inflammatory markers. SG pre-treatment of normal and SCD whole blood significantly decreased inflammatory cytokine RNA and protein levels. Studies are ongoing examining the effect of SG on hypoxia induced inflammation. These *ex vivo* data demonstrated for the first time that under controlled conditions, a therapeutic agent serves as an active gas transport agent providing either CO or O_2 to sickled RBCs, prompting rapid unsickling and significant decrease in inflammation markers. Furthermore, image capture flow cytometry provided a quantitative measurement of sickled RBC fraction decrease. This mechanism may provide a useful biomarker test in future clinical studies to monitor SG treatment effects on SCD patients.

Thrombosis and vascular biology

THE THROMBIN INHIBITOR DABIGATRAN IMPAIRS CANCER CELL GROWTH AND PROGRESSION

F. Vianello[1,*] L. Sambado[2], P. Prandoni[3], A. Goss[4], F. Fabris[2]
[1]Medicine, Haematology and Clinical Immunology, [2]Medicine, [3]Department of Cardiothoracic and Vascular Sciences, University of Padova, Padova, Italy, [4]Department of CardioMetabolic Disease Research, Boehringer Ingelheim Pharma GmbH & Co. KG,, Biberach an der Riss, Baden-Württemberg, Germany

Background: Advanced malignancy often correlates with activation of the coagulation system, termed cancer coagulopathy, which is associated with increased mortality rates. Thrombin, a blood-derived serine protease, is the main effector of the coagulation cascade. There is convincing evidence that thrombin, by PAR-1 receptor, regulates numerous critical cellular events, including cell proliferation, cell adhesion, angiogenesis, and invasion. Dabigatran is a selective direct thrombin inhibitor that reversibly binds to thrombin. Dabigatran-bound thrombin is unable to cleave and activate PAR-1.
Aims: The purpose of this study is to explore if dabigatran may affect mechanisms favouring tumor growth by interfering with thrombin-induced PAR-1 activation.
Methods: The U87 glioblastoma cell line, the MCF-7 breast adenocarcinoma cell line and the endothelial cell line HUVEC, all expressing PAR-1, have been used for our experiments. Cell proliferation was measured by a colorimetric assay suitable for determining the number of viable cells. Cell death was quantitated by FACS analysis with PI/annexin. For RNA analysis, Real Time PCR was performed on a ABI PRISM 2600 instrument using SYBR Green. Protein expression was measured by WB analysis. Chemotaxis was studied using transwell plates. Endothelial cord formation was evaluated on Matrigel by enumerating branching points (tube formation) with an inverted microscope.
Results: Exposure of tumor cells to thrombin significantly increased cell proliferation as measured by MTS conversion. Using this approach, dabigatran was effective in antagonizing thrombin-induced proliferation in a dose-dependent manner. In our experimental system, U87 cells underwent cell death when cultured in starving medium. As thrombin has been shown to activate protein kinases interfering with caspases-dependent cell death, we thought to evaluate this property in U87 starved cultures. We found that the fraction of double positive annexin/PI cells was significantly lower in presence of thrombin and this protection was lost when dabigatran was coincubated with thrombin. We then evaluated the regulation of cell cycle proteins by thrombin and dabigatran. In particular, we evaluated the expression of cyclin D1 (promoting cell cycling) and p27 (inhibiting cell cycling) in U87 and MCF-7 starved cultures. Thrombin led to down-regulation of p27 with concomitant induction of cyclin D1. When dabigatran was added to cultures, the pattern of inhibition of growth observed in presence of starving medium was restored (Figure1 A). Treatment of MCF-7 cells with thrombin determined a slight but significant increase of the fraction of cells in S phase. The effect of thombin on cell cycle was completely antagonized by dabigatran. We then evaluated the expression of pro-angiogenetic proteins, Twist and GRO-a, in MCF-7 cells and HUVEC cells following exposure to thrombin and dabigatran. We found that thrombin was significantly effective in inducing up-regulation of Twist and GRO-a mRNA in MCF7 and HUVEC cell lines. Expression of Twist was brought down to control levels when dabigatran was added to colture. WB analysis confirmed RT-PCR results (Figure1 B). We also found that the chemoattractant effect of thrombin on tumor cells was lost in presence of dabigatran, and this effect was directly related to dabigatran concentrations. Finally, vascular tube formation in HUVEC cells was increased in presence of thrombin and the induction of tube formation was progressively lost with dabigatran (Figure1 C).

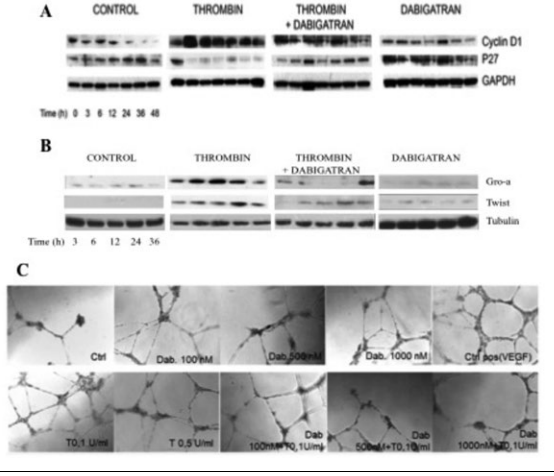

Figure 1.

Summary and Conclusions: Our data support a role of thrombin in inducing the proliferation, migration and pro-angiogenetic effects of tumor cells in-vitro. Dabigatran has shown activity in antagonizing all these effects, thereby impairing tumor growth and progression. In-vivo models may help to understand the relevance of this pathway.

S142

OPTIMAL DURATION OF ANTICOAGULANT THERAPY FOR THE TREATMENT OF CANCER-ASSOCIATED THROMBOSIS

C. Chai-Adisaksopha[1,*] M. Crowther[1], A. Iorio[1], J.M. Martín-Antorán[2], L. López-Montes[3], M. del Valle Morales[4], I. Pons[5], M. Ciammaichella[6], F. Martín-Martos[7], M. Monreal[8]
[1]Medicine, McMaster University, Hamilton, Canada, [2]Haemostasis and Thrombosis, Hospital Río Carrión, Palencia, [3]Internal Medicine, Hospital de Can Misses, Ibiza, [4]Internal Medicine, Hospital del Tajo, Madrid, [5]Internal Medicine, Hospital de Igualada, Barcelona, Spain, [6]Emergency Internal Medicine, Ospedale St. John, Rome, Italy, [7]Internal Medicine, Hospital General Universitario Santa Lucía, Murcia, [8]Internal Medicine, Hospital Universitari Germans Trias I Pujol, Barcelona, Spain

Background: Cancer-associated thrombosis is associated with a high risk of recurrent thrombosis despite "usual intensity warfarin"; anticoagulant therapy, specifically low-molecular weight heparin, reduces the risk of recurrent thrombosis compared with warfarin. However, the optimal duration of treatment in patients with cancer associated thrombosis remains unclear.
Aims: To evaluate the effects of treatment duration on the outcomes in patients with cancer-associated thrombosis.
Methods: Consecutive patients with symptomatic venous thromboembolism [VTE] (deep vein thrombosis or pulmonary embolism) were prospectively enrolled in the RIETE registry. The patient were categorized into 2 group according to received treatment duration (<6 months *vs* ≥6 months). All the patients were followed up to 5 years from treatment start date. The primary outcome was recurrent VTE and the secondary outcomes were all-cause mortality, VTE-related death and major bleeding.
Results: A total of 4,460 patients with cancer-associated thrombosis were enrolled in the analysis. Of these, 2,937 patients received anticoagulant for less than 6 months, and 1,523 received anticoagulants for more than 6 months. Patients receiving anticoagulant therapy for less than 6 months had an increased risk of recurrent thrombosis (hazard ratio [HR] 2.86, 95% confidence interval [CI] 2.22 to 3.70) when compared to patients received anticoagulant for more than 6 months. The risk of all-cause mortality and VTE-related death were significantly increased higher in patients treated for less than 6 months, HR 5.88 (95%CI 5.00 to 6.67) and HR 6.25 (95% CI 3.03 to 14.29), respectively. We did not observe increased major bleeding in patients who were treated for more than 6 months, HR 0.26 (95% CI 0.19 to 0.38).

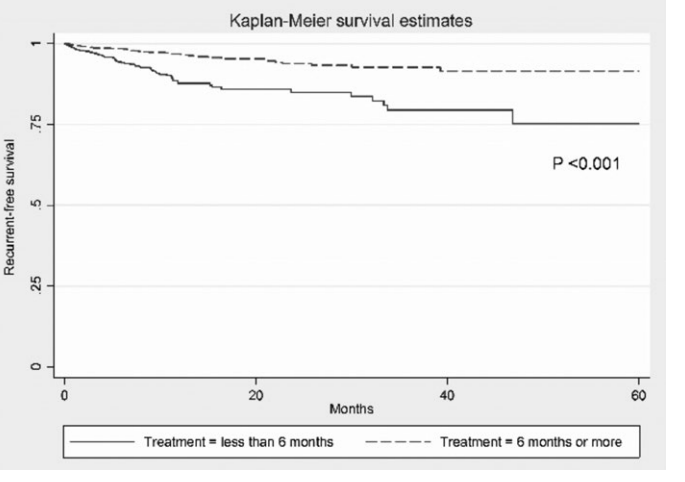

Figure 1.

Summary and Conclusions: We demonstrate that patients with cancer-associated thrombosis patients have a higher risk of recurrent VTE, VTE-related death and all-cause mortality if their anticoagulants are not continued beyond six months from diagnosis.

S143

DEVELOPMENT OF A PREDICTIVE SCORE FOR THE IDENTIFICATION OF LYMPHOMA PATIENTS AT RISK FOR THROMBOEMBOLISM

D. Antic[1,*] N. Milic[2], M. Todorovic[1], J. Bila[1], B. Andjelic[1], V. Djurasinovic[3], A. Sretenovic[3], V. Vukovic[3], J. Jelicic[3], S. Nikolovski[3], M. Biljana[1]

[1]Clinical Center Serbia, Clinic For Hematology. Medical Faculty, University In Belgrade, [2]Institute for medical statistics, Medical faculty Belgrade, [3]Clinical Center Serbia, Clinic for hematology, Belgrade, Serbia

Background: There is a paucity of data that pertain to thrombosis in patients with lymphoproliferative diseases. In few published studies the rate of thrombotic complications in lymphoproliferative disease is highly variable ranging from 1.5% up to 59.5% because of the different study types (prospective or retrospective, with hospitalized or ambulatory patients), types of disease (indolent *vs* aggressive) and the disease stage, there are few prediction tools for estimating the risk of thrombosis but they are based on studies performed on hospitalized medical patients without cancer or on hospitalized neutropenic cancer patients without special consideration to hematological malignancies
Aims: Aim of our study was to determine incidence of thromboembolic (TE) events in patients with non Hodgkin lymphoma (NHL), Hodgkin lymphoma (HL) and chronic lymphocytic leukemia (CLL) who were treated in our institution. Also, we assessed predictive model for chemotherapy-associated thrombosis developed by Khorana and create new model for the identification of lymphoma patients at risk for thromboembolism
Methods: We reviewed all medical records of patients with with NHL, HL and CLL diagnosed according to the World Health Organisation classification and treated at our institution between January 2006 and December 2014.
Results: A total of 1054 patients, with malignant lymphoma were eligible for analysis: 576 patients were men (54.6%) and 478 were women (45.4%), and mean age was 54.0 years. A total of 510 patients (48.4%) had high-grade lymphoma, 211 had low-grade lymphoma (20.0%), 153 had Hodgkin lymphoma (14.5%), and 75 (7.1%) had other forms of lymphoma; HLL had 105 (10.0%) patients. In group of our lymphoma patients, 72 (6.8 %) had at least one TE. A total of 40 patients were men and 32 women. Thromboembolic events included deep vein thrombosis (38.9%), jugular vein thrombosis (12.5%), pulmonary embolism (11.1%), CNS thrombosis (6.9%), superficial vein thrombosis (2.8%), acute myocardial infarction (1.4%) and other (26.4%). In total of 49 pts (68%) thrombosis occurred during treatment or up to 3 months after completion of therapy, whereas in 23 pts (32%) thrombosis was diagnosed prior to therapy. Patients with aggressive NHL had significantly higher incidence of TE (8.6%) compared to all other types of lymphoma patients (RR=2.1; 95%CI for RR 1.2-3.6; p=0.009) (incidences of TE in low NHL, HL and other forms of limphoma were 4.3%, 3.3% and 6.7%). Pts with HLL had 8.6% incidence of TE. Patients with high grade lymphomas, overweight patients (BMI>25 kg/m2), patients with reduced mobility (ECOG>2), and patients with recent operative procedure (<4 weeks) had increased risk for thrombosis (p<0.05 for all). No difference regarding age, gender or disease stage was found. Based on previously mentioned risk factors a new TE risk model was developed for patients with lymphoma (excluding HLL). Patients who had at least two out of four risk factors fall into high risk group for TE (RR=13.0; 95%CI for RR 7.4-23.0; p<0.001). Predictive model for chemotherapy-associated TE developed by Khorana was also evaluated on this group of patients (RR=7.0; 95%CI for RR 3.3-14.7; p<0.001). In multivariate analysis our newly developed model for TE events in lymphoma patients were predictor of TE events and independent from Khorana model.
Summary and Conclusions: Prediction tools for estimating the risk of TE events in lymphoma patients have not been established but our newly developed model should be used in addition to chemotherapy-associated model in guiding best practice in the prevention of thromboembolism in patients living with lymphoma.

S144

PRESENCE OF JAK2V617F MUTATION IN ENDOTHELIAL CELLS FROM BUDD-CHIARI SYNDROME PATIENTS IS NOT CORRELATED WITH PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASM

R. Helman[1,2,*] F. Santos P.S.[1], P.V. Campregher[1], L.C. Marti[1], T.S. Datoguia[1], N. Hamerschlak[1], M. Miyaji[1], E. Matta HA[1], C.S. Chiattone[2], W.O.Pereira[1]
[1]hematology, Hospital Israelita Albert Einstein, [2]hematology, Irmandade Santa Casa São Paulo, Sao Paulo, Brazil

Background: The role of the endothelial cell in the pathogenesis of Ph-negative MPNs is still not elucidated. Some have reported the presence of the JAK2V617F mutation in endothelial colony forming cells (ECFC) isolated from peripheral blood in patients with Ph-negative MPNs (Teofili L et all, Blood 2011). Others, however, did not find such an association (Piaggio G et al, Blood 2009). In patients with Budd-Chiari Syndrome (BCS), the JAK2V617F mutation has been found in endothelial cell (ECs) isolated by micro dissection from liver biopsies in patients both with and without MPN (Sozer S et al, Blood 2009). Besides the JAK2V617F mutation, other mutations (*e.g.* ASXL1, TET2, DNMT3A, SRSF2) have been described in patients with Ph-negative MPNs, but their presence has not been evaluated in patients with BCS who carried the JAK2V617F mutation.
Aims: 1. To evaluate the presence of the JAK2V617F mutation in CECs from patients with BCS both with and without concomitant Ph-negative MPNs; 2. To determine the mutational landscape of granulocytes in patients with BCS who harbored the JAK2V617F mutation but did not have the clinical diagnosis of a Ph-negative MPN.
Methods: We identified 10 patients from our institution who had a diagnosis of BCS and harbored the $JAK2^{V617F}$mutation in granulocytes. Three patients died from hepatic failure before they could be evaluated by bone marrow biopsy, so 7 patients remain for the analysis. All patients were investigated for the presence of Ph-negative MPNs with bone marrow trephine biopsy. ECs assays were performed according to the method of Hill. Briefly, Ficoll-Paque density gradient–isolated mononuclear cells were plated on fibronectin coated 6-well dishes with EndoCult medium (Stem Cell Technologies) for 48 hours, when non adherent cells were recovered and re-plated in a new dish at 10^6/mL concentration. After an additional 5 days, adherent cells were plucked and analyzed by flow cytometry. The ECs population was sorted using a FACS Aria BD Biosciences sorter according to the following phenotype: CD45-PerCP-negative, CD31-FITC-positve, VEGFR2-PE-positive, CD34-PECy7-positive, CD133-APC-negative. The presence of the $JAK2^{V617F}$mutation was investigated by allele-specific PCR. Paired DNA (sorted CD66b-granulocytes/skin biopsy) from 3 patients with JAK2V617F-positive BCS without a clinical diagnosis of Ph-negative MPN was subjected to whole exome sequencing on a Illumina HiSeq 2000 platform using Agilent SureSelect kit. Tumor coverage was 150x and germline coverage was 60x. Somatic variants calls were generated by combining the output of Somatic Sniper (Washington University), Mutect (Broad Institute) and Pindel (Washington University), followed by in-house filters to reduce false positive calls.
Results: We were able to obtain CECs from all 7 patients. The purity of the CECs populations obtained was over 96% in all cases. Among the 7 patients with BCS, five did not have any clinical feature of a Ph-negative MPN, with a normal bone marrow biopsy. The JAK2V617F mutation was positive in the CECs from 5 cases, including 3 patients who only had BCS. In one patient with BCS solely the reaction did not work, and in another the JAK2 was wild-type in the ECs. The mutation was positive in CECs from both patients with myelofibrosis and BCS. Three patients with BCS solely were evaluated by whole exome sequencing. The only known pathogenic abnormality found was the JAK2V617F mutation, albeit at a low allele fraction (5%, 6%and 12.6%).
Summary and Conclusions: The presence of the JAK2V617F mutation in CECs from patients with BCS who did and did not have a diagnosis of Ph-negative MPN suggest that the mutation plays an important role in the development of vascular complications in these patients. Further studies with a larger number of patients are needed to precisely define the importance of CECs in the pathogenesis of MPNs. The sole presence of the JAK2V617F mutation in circulating granulocytes at a very low allele fraction in patients with BCS without Ph-negative MPNs suggest that these patients have a pre-malignant clone that would probably remain undiagnosed had it been not for the development of hepatic venous thrombosis.

S145

HIGH-DOSE CORTICOSTEROID ASSOCIATED WITH CATHETER-RELATED THROMBOSIS AFTER ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

X.H. Zhang[1,*] F.E. Feng[1], Q.M. Wang[1], X.L. Zhu[1], J.M. Zhang[1], F.R. Wang[1], W. Han[1], Y. Wang[1], H. Chen[1], Y.H. Chen[1], L.P. Xu[1], K.Y. Liu[1], X.J. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: Allogeneic haematopoietic stem cell transplantation (Allo-HSCT) recipients are at increased risk of thrombotic complications, most of which are catheter related. Catheter-related thrombosis (CRT) remains challenging in allo-HSCT patients. On one hand, the incidence of CRT varies considerably depending on clinical factors. CRT has major consequences for patients who are already vulnerable, including pulmonary embolism. On the other hand, the benefit of anticoagulation must be weighed against the substantially increased risk of bleeding. However, the underlying pathogenesis of CRT remains unclear. From a clinical perspective, it would be helpful to identify the risk factor of CRT in allo-HSCT patients.
Aims: The aim of this study was to examine the incidence and risk factors of CRT in allo-HSCT recipients.
Methods: We performed a retrospective nested case-control study in patients following allo-HSCT. Patients were reviewed retrospectively from all recipients who underwent allo-HSCT between July 2007 and June 2014 at Peking University People's Hospital, Beijing. Transplantation protocols (donor selection, HLA typing, stem cell harvesting, conditioning therapy, and GVHD prophylaxis) were conducted according to our previously protocols. Thrombotic episodes were diagnosed based on the clinical suspicion of the physician (pain, swelling, etc.) with subsequent central venous catheter (CVC) or peripherally inserted central catheter (PICC) thrombosis confirmed by duplex ultrasound. Cases with CRT and controls were matched for time of HSCT (±5 days), age at HSCT (±5 years) and type of insertion (CVCs or PICC).
Results: During the 6-year period, CVC and PICC were placed in 923 patients undergoing allo-HSCT. A total of 38 patients (4.11%) developed catheter-related thrombosis, among which 12 were associated with CVCs, and 26 were associated with PICCs. The median duration from catheter insertion to thrombosis was 97 days. Among patients with CRT, 20 patients were classified as high risk before transplantation, and 7 experienced relapse. On average, patients received 4.5 rounds of pre-HSCT chemotherapy. Despite reports of an associ-

ation between thrombosis and infection, no patient with CRT experienced a central line-associated bloodstream infection in our study. No significant differences were noted in terms of primary disease, donor type, conditioning regimen and catheter type between cases and controls. On univariate analysis, high-risk classification and relapse were associated with CRT. Grade III-IV GVHD is strongly correlated with CRT. Exposure to high-dose corticosteroids and cyclophosphamide is also related to thrombotic complications. No correlations between CRT and blood counts, coagulation markers, hyperlipidaemia or hypoalbuminaemia were noted in the laboratory values analysed. Multivariate regression analysis identified grade III-IV GVHD and exposure to high-dose corticosteroids as independent risk factors for the development of catheter-related thrombosis after allo-HSCT.

Summary and Conclusions: In conclusion, we demonstrate that CRT occurs among patients following allo-HSCT. The use of high-dose corticosteroids is correlated with the onset of CRT. However, the efficacy and safety of thromboprophylaxis in this population requires further discussion.

Quality of life and health economics

LEVELS OF DISCORDANCE BETWEEN PATIENTS' AND PHYSICIANS' PERCEPTIONS OF PATIENTS' HEALTH-RELATED QUALITY OF LIFE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA-A CROSS-CULTURAL PERSPECTIVE

M.T. Petrucci[1,*] C. Kyriakou[2], X. Leleu[3], P. Murphy[4], P. Bacon[5], P. Lewis[6], H. Gilet[7], B. Arnould[7], I. Vande Broek[8]

[1]Division of Hematology, Department of Cellular Biotechnology and Hematology, Sapienza University of Rome, Rome, Italy, [2]Royal Free and Northwick Park hospitals, London, United Kingdom, [3]CHRU-Hôpital Huriez, Lille, France, [4]Beaumont Hospital, Dublin, Ireland, [5]Celgene International Sarl, Boudry, Switzerland, [6]Celgene GmbH, Munich, Germany, [7]HEOR & Strategic Market Access, Mapi, Lyon, France, [8]Iridium Kankernetwerk, Sint-Niklaas, Belgium

Background: Patients' Health-Related Quality of Life (HRQoL) is important, particularly in the relapsed/refractory multiple myeloma (RRMM) setting. Exploring levels of concordance between physicians' and patients' perceptions of HRQoL could improve physicians' understanding of patients' feelings and help in daily patient management. Findings of our study previously published for the overall population showed no major discordance between ratings of HRQoL/functioning domains, but major discordance between the perceptions of physicians and patients for symptom domains.

Aims: To compare between countries the difference in physicians' and patients' perceptions of HRQoL and symptoms.

Methods: An observational study was conducted in Italy, Germany, France, UK/Ireland and Belgium in RRMM patients starting 2nd or 3rd line treatment. Patients and physicians completed three EORTC questionnaires: Quality-of-Life Core Questionnaire (QLQ-C30), with 15 domains (*Global Health Status/QOL, Physical Functioning, Role Functioning, Emotional Functioning, Cognitive Functioning, Social Functioning, Fatigue, Nausea and Vomiting, Pain, Dyspnea, Insomnia, Appetite Loss, Constipation, Diarrhea* and *Financial Difficulties*); QLQ-Multiple Myeloma (QLQ-MY20), with four domains (*Disease Symptoms, Side-Effects of Treatment, Body Image* and *Future Perspective*); QLQ-Chemotherapy-Induced Peripheral Neuropathy (QLQ-CIPN20) with three domains (*Sensory scale, Motor scale* and *Autonomic scale*). Intra Correlation Coefficients (ICC) were calculated to compare patient and physician scores (ICC<0.40 showing major discordance). The difference in patient and physician scores was compared across countries using ANOVA.

Tabella 1. Comparison of EORTC scores reported by physicians and patients at baseline, overall and by country

EORTC	Domain	Total (N=258)		UK/Ireland (N=42)		Germany (N=33)		France (N=43)		Italy (N=83)		Belgium (N=57)		P-value[c]

[a] Difference = patient score – physician score

[b] In blue, major discordant scores (ICC <0.40) with better HRQoL/functioning or symptoms score reported by physician than by patient; In yellow, major discordant scores (ICC <0.40) with worse HRQoL/functioning or symptoms score reported by physician than by patient

[c] p-value from ANOVA comparing the mean difference in physician/patient score between countries; * p<0.05; ** p<0.01; *** p<0.001

Results: The population included 33 physicians who enrolled 258 patients (mean age=70; 54% male; mean time since diagnosis=3 years). At baseline, 251 (97%) sets of EORTC questionnaires were completed by patients and 252 (98%) by physicians. Based on ICC (Table 1), most of the domains with major discordance observed between patients and physicians were symptom domains, in all countries but Italy. In almost all cases, physicians underestimated the level of symptoms experienced by their patients. However, major discordance was not observed on the same symptom domains across countries. The number of domains showing major discordance also differed, ranging from none (Italian sites) to nine (UK/Irish sites). Variations across countries were observed on the level of patient-physician discordance, with statistical significance reached for four out of 14 symptom domains. For HRQoL/functioning domains, major patient-physician discordance was also not observed on the same domains across countries. Furthermore, the number of domains showing major discordance differed, ranging from none (French sites) to five

(Belgian sites). Depending on domain and country, physicians either underestimated or overestimated their patients' HRQoL/functioning. Variations across countries were observed on the level of patient-physician discordance, with statistical significance reached for six out of eight domains. The highest variations (p<0.001) were observed for Physical Functioning, Social Functioning, Pain and Future Perspective domains.
Summary and Conclusions: Major discordance was observed across countries on symptom domains, with physicians consistently underestimating their patient's symptoms. However, the specific symptom domains concerned varied between countries. An even more variable picture was observed for HRQoL/functioning domains. This supports the importance to also consider patients' view of their own health.

Emanuele", Catania, [19]Department of Hematology, "S. Eugenio Hospital", Rome, Italy, [20]Department of Hematology, Affiliated Hospital of Liaoning University of Traditional Chinese Medicine, Shenyang, China, [21]Department of Hematology, S. Giovanni-Addolorata Hospital, Rome, Italy

Background: Higher-risk myelodysplastic syndromes (MDS) are rarely curable and have a poor prognosis, with short life expectancy. Thus it becomes essential for physicians to accurately evaluate the patients' wishes and preferences in light of the risks, benefits and appropriateness of treatment.
Aims: The primary aim was to investigate the accuracy of physicians' perception of patients' health status and the patients' preferences for involvement in treatment decisions. A secondary objective was to investigate physicians' attitude toward patient involvement in treatment decisions and to examine factors influencing physicians to be more patient inclusive or exclusive in the shared decision-making process.
Methods: We investigated 280 high-risk MDS patients paired with 68 physicians to evaluate physician-patient agreement on preferences for involvement in treatment decisions and self-reported health status. Control Preferences Scale (CPS) and the questionnaire EORTC QLQ-C30 were used to evaluate these parameters, respectively. Simple and weighted κ-coefficient was used to assess the degree of physician-patient agreement. The following variables were ascertained: physician gender and age; the overall number of years in practice; the number of years of experience in treating MDS patients.
Results: The median age of the physicians was 44 years (range 28-64) and their median duration of medical practice was 16 years, with a median of 11 years of expertise in MDS. Analysis was based on 280 patient-physician dyads. Overall concordance was 49% for physician perception of patient preferences for involvement in treatment decisions, with a weighted K-coefficient indicating poor concordance. In 36.4% of comparisons there were minor differences and in 14.6% there were major differences. In 44.7% of the patients preferring a passive role, physicians perceived them as preferring an active or collaborative role. The only factors independently associated with the physicians' attitude toward less involvement of their patients in clinical decisions were absence of the patient's request for prognostic information (P=0.001) and judging the patient as having a poor health status (P=0.036). The degree of agreement between physicians and patients in evaluating overall health status was low. Agreement on health status was found in 27.5% of cases. Physicians most frequently tended to overestimate health status of patients who reported low-level health status (Figure)

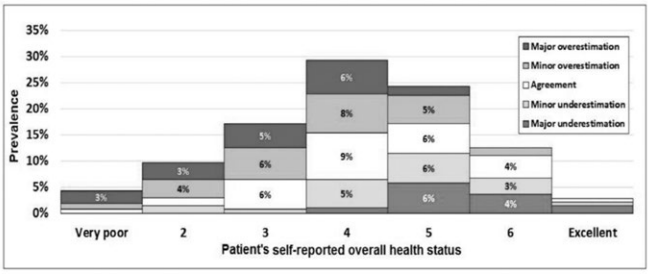

Figure 1.

Summary and Conclusions: Physicians treating MDS patients often have difficulty in understanding what their patients' preferences are and some do not consider the patients' preferences to be important. General concordance on physicians' perception and patients' health status was present in slightly less than one third of comparisons. In particular, physicians tended to overestimate the health status of patients reporting low levels for this parameter. Physicians need to improve their perception of patients' health status in view of the important implications associated with assessment of patient eligibility for inclusion in clinical trials. Moreover, clinicians need to be provided with decision aid tools that can improve their perceptions and communication skills.

S148

AN ONGOING MULTINATIONAL OBSERVATIONAL STUDY IN MULTIPLE MYELOMA (PREAMBLE): A PRELIMINARY REPORT OF DISEASE IMPACT ON QUALITY OF LIFE

D. Cella[1,*] P. Moreau[2], D. Kuter[3], H. Goldschmidt[4], C. Davis[5], A. Oukessou[5], O. Sy[5], S. Joo[5], L. Annemans[6]
[1]Northwestern University, Evanston, United States, [2]University Hospital, Nantes, France, [3]Massachusetts General Hospital Cancer Center, Boston, United States, [4]Heidelberg University Hospital, Heidelberg, Germany, [5]Bristol-Myers Squibb, Princeton, United States, [6]Ghent University and Brussels University, Ghent, Belgium

Background: Multiple myeloma (MM) is associated with high morbidity and mortality. In recent years, immunomodulatory drugs (IMiDs) and proteasome inhibitors (PIs) have been approved for MM treatment based on their ability to improve patient (pt) survival. However, a greater understanding of quality of life (QoL) in patients treated with IMiDs and PIs is needed.
Aims: PREAMBLE (Prospective REsearch Assessment in Multiple Myeloma: an oBservationaL Evaluation; NCT01838512) is an ongoing, prospective, multinational, observational cohort study designed to better understand the real-world clinical effectiveness of IMiDs, PIs, and IMiD+PI in pts with relapsed/refractory MM (RRMM). We report QoL data for pts enrolled with ≥6 months' follow-up.
Methods: PREAMBLE includes pts with RRMM aged ≥18 years who have received ≥1 prior therapy and who initiated treatment with an IMiD, PI, or IMiD+PI <90 days prior to or 30 days after enrollment. Administration is according to standard clinical practice. Data are collected at baseline (BL) and every 3 months during Year 1, then every 6 months in Years 2 and 3, or until discontinuation. Data extraction for the present analysis was performed on 12 December 2014. The EuroQol 5 Dimensions (EQ-5D) questionnaire and the European Organisation for Research and Treatment of Cancer (EORTC) QoL Questionnaire-Core 30 (QLQ-C30) were used to assess disease burden. Minimally important differences for EQ-5D and QLQ-C30 have been estimated at 0.06–0.09 (for all cancers)[1] and 6–17 (for MM),[2] respectively.
Results: At the time of data extraction, 273 pts had ≥6 months' follow-up (96% completion rate at BL). Median BL EQ-5D score was 0.69, compared with 0.8 in the general US population[3] and 0.6–0.7 in other MM studies.[4,5] At BL, there was no difference in median EQ-5D score regardless of number of prior lines of therapy. At Month 6, there was a trend towards improvement in median EQ-5D score with increasing numbers of prior lines of therapy (1: 0.69; 2: 0.69; >2: 0.76; 3: 0.76; >3: 0.76). At BL, pts reported some or severe pain and discomfort (63.4% [some] and 14.1% [severe]), anxiety and depression (45.5% [some] and 5.3% [severe]), and inability to conduct usual activities (52.9% [some] and 10.6% [severe]). More pts receiving IMiDs (19.4%) reported severe pain and discomfort at BL than those receiving PIs (8.3%) or IMiD+PI (11.1%). Median QLQ-C30 global health status (GHS) score at BL and Month 12 was 58.3 and 66.7, respectively, compared with 75 (general population), 66.7 (colorectal cancer pts), 66.7 (all cancer pts),[6] and 57–68.7 (previous MM studies).[4,5] Median QLQ-C30 GHS improved over time in pts treated with 3 prior lines of therapy or with IMiDs (Table; higher score=better QoL). At BL, fatigue and pain placed the greatest burden on pts, but improved over time (Table; higher score=worse symptoms).

Tabella 1. Patient-reported QoL outcome measures

EORTC QoL measures	Baseline	6 months	12 months
GHS (EORTC QLQ-C30, median)*			
All patients	58.3	66.7	66.7
By lines of prior therapy			
1	58.3	62.5	50.0
2	50.0	58.3	66.7
>2	58.3	66.7	58.3
3	66.7	83.5	83.3
>3	50.0	66.7	50.0
By class of therapy			
IMiD	50.0	58.3	66.7
PI	66.7	66.7	62.5
IMiD+PI	58.3	66.7	66.7
Individual symptoms (mean)†			
Fatigue			
All patients	46.8	43.0	40.5
By lines of prior therapy			
1	45.1	46.1	41.9
2	47.0	40.5	35.3
>2	50.3	39.9	47.2
3	45.6	33.3	49.2
>3	53.9	45.8	44.4
Pain			
All patients	38.6	34.6	32.8
By lines of prior therapy			
1	36.5	37.3	38.1
2	44.1	35.5	31.2
>2	34.5	27.1	23.6
3	37.7	28.9	19.0
>3	31.9	25.5	30.0

*EORTC QLQ-C30: 0–100 scale; higher score=better health status/QoL
†EORTC QLQ-C30 symptoms: 0–100 scale; higher score=worse symptoms

Summary and Conclusions: Preliminary analysis suggests that MM continues to place a high burden on pts despite new therapies. Although functional scores show a high level of function, pts are particularly troubled by pain, discomfort, and fatigue. As data mature and more pts are enrolled, PREAMBLE will shed light on MM burden and its management.

HOSPITAL VERSUS HOME CARE FOR PATIENTS WITH HEMATOLOGICAL MALIGNANCIES IN CURATIVE OR TERMINAL PHASE: USE OF THE RESOURCES ANALYSIS, SYMPTOM BURDEN AND COST-EFFECTIVENESS STUDY

C. Cartoni[1,*] A. Tendas[2], F. Efficace[3], P. Niscola[2], S. Soldati[3], G.A. Brunetti[1], E. Meloni[4], C. Minotti[1], L. Cupelli[2], M.G. Marini[5], L. Reale[5], N. Martone[5], R. Foà[1], G. Alimena[1], P. de Fabritiis[2], F. Mandelli[4]

Eugenio Hospital", [3]Italian Group for Adult Hematologic Diseases (GIMEMA), Data Center and Health Outcomes Research Unit, [4]Italian Association against Leukaemia-Lymphoma and myeloma (AIL), Rome, [5]ISTUD Foundation, Milano, Italy

Background: Hospitalization of patients with hematological malignancies often is an inappropriate setting of care since the economic and clinical advantage of the home care is not established.

Aims: To compare the costs, the use of resources, the effectiveness of hospitalization *versus* a program of hematologic home care, funded in partnership by charity and public health service.

Methods: Prospective, observational study. According to disease status two groups of patients were analyzed for 6 weeks: i) in curative phase, for supportive care or for early palliative simultaneous care; ii) in terminal phase, for end of life-care. A mean weekly cost (MWC) for the provider was built of health professional, laboratory, drugs and transfusions costs. Use of resources and costs for families were evaluated, as well as a MWC for the families. To evaluate an economic advantage between settings of care, cost-minimization analysis (CMA) was performed as well as incremental cost-effective analysis (ICER), comparing the relative costs and outcomes (occurring infections). Patient-reported symptoms over time (once per week) were measured with the M.D. Anderson Symptom Inventory (MDASI). This brief self-reported questionnaire consists of 19 items assessing symptom severity (13 items) and symptom interference (6 items).

Results: Out of 119 patients, 60 were cared at hospital, 59 at home, with a prevalence older age, worse anemia, performance status and self-efficiency score in the home care group (<0.001). Infections at first second and third week occurred more frequently in the hospital than in the home-care group (p<0.05). Mean No. of transfusions was similar in both groups. Hospital care was significantly related to a higher MWC (3,830.6 €) and lower cost for families (78.7 €), compared to home care (MWC 931.4 € and 123.2 €, respectively). At home the highest cost driver was for health providers, at hospital for drugs. Compared to hospitalization, CMA showed for home care a weekly-2899.2 € save for the health provider and +44.5 € charge for the family. Patients' families in terminal phase suffered of a mean weekly extra charge of 126.1 €. Cost-effectiveness analysis showed an advantage for home care, with an ICER – 11,315.1 € of prevented days of care for infection for all patients. No statistically significant changes in the two groups (hospital *versus* Home care) over time were found in the mean scores for symptom severity (p=0.139) and symptom interference (p=0.284).

Summary and Conclusions: Although patients at home were older and in worse clinical conditions, in this study the actual determined standard cost of home care resulted one-third of the hospital cost regardless of the phase of disease. In this setting home care resulted also cost-effective by saving money because of a lower number of occurring infections. Also, symptom burden was not different between groups suggesting that symptom management at home is feasible.

S150

HEALTH RESOURCE UTILIZATION WITH CONTINUOUS LENALIDOMIDE TREATMENT (TX) IN ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (NDMM)

K. Weisel[1,*] D. Vogl[2], A. Corso[3], M. Delforge[4], K. Song[5], M.A. Dimopoulos[6], J. Cavenagh[7], C. Hulin[8], P. Rodon[9], B. Arnulf[10], R. Foa[11], A. Oriol[12], S. Guo[13], J. Catalano[14], C. Gibson[15], J. Van Oostendorp[15], A. Ervin-Haynes[15], T. Facon[16]

[1]University Hospital Tuebingen, Tuebingen, Germany, [2]University of Pennsylvania, Philadelphia, United States, [3]Policlinico San Matteo Universita Di Pavia, Pavia, Italy, [4]University Hospital Leuven, Leuven, Belgium, [5]Vancouver General Hospital, Vancouver, BC, Canada, [6]National and Kapodistrian University of Athens, Athens, Greece, [7]St Bartholomew's Hospital, London, United Kingdom, [8]CHU Nancy–Brabois, Nancy, [9]Centre Hospitalier de Blois, Blois, [10]Hôpital Saint-Louis, Paris, France, [11]Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, Italy, [12]Institut Català d'Oncologia, Hospital Germans Trias i Pujol, Barcelona, Spain, [13]EVIDERA, Lexington, United States, [14]Frankston Hospital, Frankston, Australia, [15]Celgene Corporation, Summit, United States, [16]Service des Maladies du Sang, Hôpital Claude Huriez, Lille, France

Background: MM is an incurable condition associated with high Tx costs. NDMM resource consumption is driven by Tx-related hospitalization, which is highest during periods of uncontrolled disease, such as after diagnosis and during relapses (Arikian SR, ASH 2014 [abstract 2656]; Gaultney JG, *J Clin Pharm Ther*, 2013). In the pivotal FIRST trial, continuous Tx with lenalidomide plus low-dose dexamethasone (Rd continuous) was compared with fixed-duration Rd (Rd18) or fixed-duration Tx with melphalan, prednisone, and thalidomide (MPT), each for 18 mos, in NDMM pts aged ≥65 yrs and ineligible for stem cell transplant (SCT).

Aims: This analysis quantified the rates of hospitalization and medical utilization with Rd continuous based on data collected in the FIRST trial.

Methods: The FIRST trial (N =1623) is a pivotal, multinational, randomized, open-label phase 3 study. Resource utilization data was collected until patients discontinued study Tx, presented here with a median follow-up of 37 mos (data cutoff =May 24, 2013). The rates of hospitalization and medical utilization for patients treated with Rd continuous (n =535) were plotted for up to 48 mos to assess whether Rd continuous increased resource utilization over time. Procedures during the Tx period (18 mos) were compared between the 2 fixed-duration Tx arms using negative binomial regression.

Results: Resource utilization among pts treated with Rd continuous declined over time (Figure). The annualized hospitalization rate in the first 3 mos was 3.2 times higher than the average rate for the remaining 45 mos of follow-up (2.02 *vs* 0.62); medical utilization was 4.2 times higher than average (5.66 *vs* 1.34). After 4 yrs of Rd continuous Tx, hospitalization and medical utilization rates were estimated to be 83% and 84% lower, respectively, than those observed in the first 3 mos of Tx, reflecting the long-term disease control observed with Rd continuous. The highest hospitalization rates (per pt-yr) were associated with infections (0.20), musculoskeletal disorders (0.06), cardiovascular disorders (0.06), and respiratory and thoracic disorders (0.05). The mean length of stay per admission was 14.08 days (SD, 21.19). The highest medical utilization rates (interventions per pt-yr) were associated with blood transfusions (0.76), general imaging procedures (0.21), respiratory and thoracic imaging procedures (0.20), and therapeutic interventions (0.09). Hospitalization rates were 0.91 (Rd18) and 0.79 (MPT) per pt-yr of follow-up during the Tx period of 18 mos, adjusted rate ratio (RR) of 1.11 (95% CI, 0.92-1.35; *P* =0.27). The equivalent rates for medical utilization were 3.00 (Rd18) and 2.85 (MPT) inter-

ventions per pt-yr (RR =0.99 [0.81-1.22]; *P* =0.95). A comparison between the 2 fixed-duration arms showed no significant difference in the rates of medical procedures and hospitalizations.

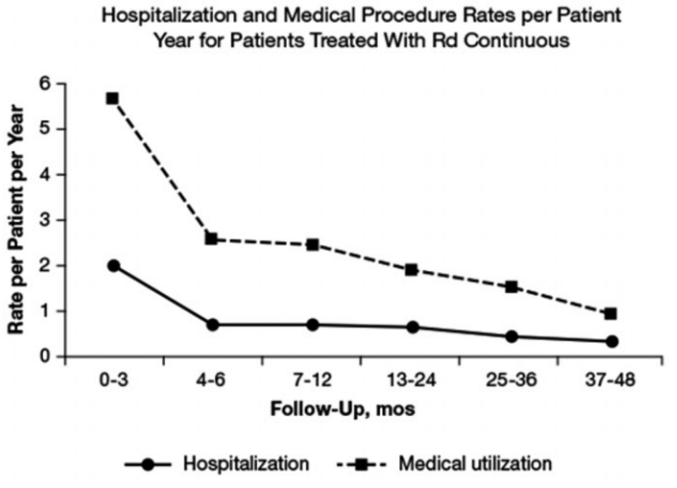

Figure 1.

Summary and Conclusions: The rates of resource utilization among pts treated with Rd continuous dropped substantially after the first 3 mos of Tx and gradually declined thereafter. The findings suggest that Tx with Rd continuous does not require a consistently high use of medical and hospital resources. Note that data on resource utilization were collected only while pts were receiving Tx. Additionally, future analysis should include all costs generated by healthcare resource utilization throughout pt Tx, including costs associated with relapses and Tx-free intervals.

DISTINCTIVE GENOTYPES WITH PRENATAL ORIGINS IN INFANT T-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA

M.B. Mansur[1,2], F.W. van Delft[1], S.M. Colman[1], C.L. Furness[1], J. Gibson[3], M. Emerenciano[2], H. Kempski[4], E. Clappier[5], H. Cave[5], J. Soulier[6], M.S. Pombo-de-Oliveira[2], M. Greaves[1], A. Ford[1,*]
[1]Centre for Evolution and Cancer, The Institute of Cancer Research, London, United Kingdom, [2]Paediatric Haematology-Oncology Program, Research Centre, Instituto Nacional de Câncer, Rio de Janeiro, Brazil, [3]Centre for Biological Sciences, University of Southampton, Southampton, [4]Paediatric Malignancy Cytogenetics Unit, Institute of Child Health & Great Ormond Street Hospital, London, United Kingdom, [5]Department of Genetics, Robert Debré Hospital, [6]Haematology Laboratory, Saint-Louis Louis Hospital, Paris, France

Background: ALL in infants is often associated with *MLL* rearrangements (*MLL-r*), a high leukocyte count at diagnosis, an immature or pro-B-cell lineage immunophenotype ($CD10^-$) and an *in utero* origin. Infant T-ALL (iT-ALL) is a very rare and poorly defined entity with a poor prognosis.
Aims: The overall aims of this study were to determine the molecular profile of iT-ALL (CNAs, LOH) and to investigate the possible prenatal onset of genetic abnormalities in iT-ALL.
Methods: The availability to us of a unique series of thirteen iT-ALL cases (≤12 months) allowed us to perform matched Genome-Wide SNP6.0 arrays accompanied by NGS (WES). Q-PCR and FISH were used to confirm the SNP-array findings and a 'Backtracking' approach with neonatal blood spots was used to investigate the early onset of these abnormalities.
Results: At diagnosis the median age was nine months, there was no predominance of gender and a high leukocyte count ($\geq 50.10^3$) was observed in 12/13 cases. Immunophenotype analyses revealed that six patients presented a T-IV profile, five T-III, one presented T-I and another a T-II profile. The T-I case (BR4) also expressed classical myeloid markers that, according to previously published criteria, suggest an Early T-cell Progenitor (ETP) leukaemia. All samples were analysed at diagnosis for various classical T-ALL abnormalities. Results showed four cases were mutated for *NOTCH1*, patient BR1 presenting a combined *NOTCH1/FBXW7* mutation, while one case (FR5) harboured a sole *FBXW7* mutation. Three cases presented *PTEN* alterations and all patients were *IL7R* WT. *MLL-r* was confirmed in three cases. Distinct from childhood T-ALL, we observed no infants with either *STIL-TAL1*+ or *TLX3*+. All diagnostic samples were analysed by SNP-array to identify CNAs/LOH. A recurrent somatic chr3 deletion was observed in 3/13 cases. These losses result in the complete deletion of *MLF1* and have not previously been described in ALL. Case FR4 harboured a large 11q14.1-11q23.2 deletion that includes the important 'driver' gene *ATM*, while patient BR5 presented a 13q14.2 deletion that involved *RB1*. Akin to non-infant paediatric T-ALL we observed a *PTEN* deletion in patient BR6 and two further cases with an 11p13 deletion that could lead to *LMO2* activation. However, we observed a lower frequency of *CDKN2A/B* deletions (38%) than found in paediatric T-ALL (70%). WES analyses for BR4 showed mutations in 22 genes previously described to play a relevant role in tumourigenesis and all tested mutations were found in the patients' Guthrie card DNAs, so confirming their presence before birth. For patient BR6 *MLL-r*, *NOTCH1* mutation and *PTEN* deletion (usually considered a postnatal event) were also detected as prenatally acquired alterations.
Summary and Conclusions: In summary, we have genetically analysed a unique series of a rare subtype of paediatric leukaemia; iT-ALLs. We find the genotypes are varied but, overall, different from those of T-ALL in older children and adults. A novel aberration (for acute leukaemia), *MLF1* deletion, was present as a recurrent abnormality in 3/13 cases. Finally, we have provided evidence that some of the genetic abnormalities, including a *PTEN* deletion, were prenatally acquired.

P152

DETAILED GENOME ANALYSES REVEAL EXTENSIVE RAG-MEDIATED REARRANGEMENTS IN ADULT ACUTE LEUKEMIA SUBSETS

M. Sanders[1,*] R. Hoogenboezem[1], C. Exalto[1], A. Szabo[1], A. Zeilemaker[1], M. Pratcorona[2], J. Koenders[1], P. van Geel[1], A. Schelen[1], B. Beverloo[3], J. Cornelissen[1], A. Rijneveld[1], P. Valk[1]
[1]Hematology, Erasmus Medical Center, Rotterdam, Netherlands, [2]Hematology, Hospital Clínic de Barcelona, Barcelona, Spain, [3]Clinical Genetics, Erasmus Medical Center, Rotterdam, Netherlands

Background: Acute leukemia is characterized by a multi-step accumulation of genetic alterations in hematopoietic stem or progenitor cells. Recent next-generation sequencing (NGS) efforts led to the identification of novel genetic alterations in pediatric acute lymphoblastic leukemia (ALL) subsets, however, their

frequencies, co-occurrence in adult ALL and mutational origin remain unknown. Recent deep-sequencing efforts in pediatric *ETV6-RUNX1*-rearranged ALL cases demonstrated RAG-mediated deletions as the dominant underlying mutational process (Papaemmanuil *et al.*, Nature genetics 2014), however, this analysis was not extended to other ALL subgroups.

Aims: Our goal is to determine novel mutational patterns and to reveal novel mechanisms underlying adult ALL subgroups through integrative analyses of DNA mapping array and NGS data.

Methods: We generated genome-wide copy number profiles of 53 adult B-cell ALL (B-ALL), 20 adult T-cell ALL (T-ALL) cases using Affymetrix 6.0 DNA mapping arrays and 100 adult acute myeloid leukemia (AML) cases using Affymetrix 500K DNA mapping arrays. In addition, 5 B-ALL cases were selected for whole exome sequencing and targeted resequencing of the breakpoint boundaries with the Illumina HiSeq2500.

Results: In comparison to array-based genome characterization studies performed on ALL cohorts, we observed a substantial higher frequency of genetic lesions of well-known lesions in pediatric ALL, *e.g.*, *CDKN2A/B* (44%), *IKZF1* (23%), and *PAX5* (11%). Strikingly, we demonstrated that all T-ALL cases acquired copy number alterations perturbing the *CDKN2A/B* pathway. Interestingly, joint analysis of ALL and AML cases revealed a recurrent deletion affecting both the genes encoding NF1 and SUZ12 in 3 T-ALL and 5 AML cases, an aberration recently shown to be recurrent with concomitant mutations in melanoma and gliobastoma multiforme. We selected 5 representative B-ALL cases with extensive genetic deletions of promoters or gene bodies of genes involved in lymphoid development. Strikingly, all cases belong to the *BCR-ABL1* or *BCR-ABL1*-like ALL subgroup. In total 102 somatic mutations were detected, however, no recurrent somatic mutations were detected. In total, we detected 64 genetic deletions resulting in 128 breakpoints. *De novo* motif detection revealed the RAG-affiliated heptamer sequence CACAGTG (E=5.68x10^{-91}) for 121 out of 128 breakpoints (94.5%). Cryptic recombination signal sequence (cRSS) detection revealed that 58 out of 64 deletions (90.6%) had a 12-bp or 23-bp spacer cRSS on one or both sides of the deletion. We observed that 54 out of the 64 (84.3%) resolved rearrangements demonstrated the incorporation of non-templated sequences at the breakpoint boundaries. Chip-Seq data from the B-lymphoblastic cell line GM12878 revealed that the breakpoint boundaries are enriched for H3K4me3, H3K27ac and RNA polymerase II binding. These epigenetic alterations are typical for V(D)J-foci undergoing RAG-mediated rearrangements. Strikingly, we detected complex insertions or deletions (indels) in cRSS sequences located in promoters of genes associated with leukemogenesis, *e.g. BTLA*, often in addition to large deletions. Further screening for these open-and-shut joints in the *BTLA* promoter revealed 8 additional B-ALL cases in which at least one *BTLA* allele was affected, comprising 6 *BCR-ABL1*/*BCR-ABL1*-like and 2 B-ALL cases with unknown affiliation.

Summary and Conclusions: We demonstrated in a B-ALL subgroup comprising mainly *BCR-ABL1*/*BCR-ABL1*-like ALL cases extensive RAG-mediated rearrangements, as previously shown in *ETV6-RUNX1*-rearranged ALL. Frequently, these cases acquired kinase-activating lesions (Roberts *et al.*, NEJM 2014), providing further grounds for researching associations between these lesions and RAG-mediated rearrangements.

P153

AGE SPECIFIC INCIDENCE OF PARTNER GENE AND SECONDARY ABNORMALITIES IN MLL POSITIVE ACUTE LYMPHOBLASTIC LEUKAEMIA (ALL)

A.S. Gabriel[1,*] A. Enshaei[1], J. Taylor[1], A. Erhorn[1], C. Schwab[1], L. Rai[2], A. Fielding[2], N. Goulden[3], A. Vora[4], C.J. Harrison[1], A.V. Moorman[1]
[1]Leukaemia Research Cytogenetics Group, Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, [2]Department of Haematology, Royal Free and UCMS, [3]Department of Haematology, Great Ormond Street Hospital, London, [4]Department of Haematology, Sheffield Children's Hospital, Sheffield, United Kingdom

Background: MLL gene rearrangements (MLL-t) define a unique subgroup in 5-10% patients with ALL. However, there is still heterogeneity in clinical outcomes and genetic composition. The incidence of MLL-t varies by age accounting for 80% infant, 3% children and 10% adults. Patients harbouring MLL-t have a poor outcome relative to their age-matched counterparts and are typically assigned to high risk treatment protocols. The frequency and clinical relevance of the partner gene and cooperating lesions is unclear.

Aims: We investigated the age-specific frequency of partner genes and the spectrum of additional abnormalities in 368 MLL-t cases treated on UK clinical trials over a 20 year period.

Methods: Cytogenetic and FISH analysis was performed on pre-treatment bone marrow samples using the Vysis MLL break apart probe, Kreatech Poseidon MLL fusion probes [t(4;11)(q21;q23), t(11;19)(q23;p13), t(9;11)(p21;q23) and t(6;11)(q27;q23)] and a home-grown AF10 break-apart probe. Copy number alterations (CNA) were assessed by high resolution Affymetrix arrays: SNP6 (n=14) or CytoscanHD (n=12).

Results: Among the 368 patients the most prevalent translocations were t(4;11) n=225 (64%), t(11;19) n=61 (17%), t(9;11) n=28 (8%), t(10;11) n=12 (3%) and t(6;11) n=10 (3%). Seventeen patients harboured other rare partners while the partner gene could not be determined in 15 patients. The presence of t(4;11) was age-dependent: infant (<1 year) 78/137 (57%); young children (1-9 years) 35/77 (48%); older children (10-14 years) 19/33 (58%); young adults (15-24 years) 27/30 (90%); and adults 66/76 (87%). The majority of MLL-t cases had B-cell precursor ALL (93%) but 24 (7%) patients had T-ALL and these were commonly older children and younger adults (11/24, 46%) and included 11 (46%) cases with t(11;19). In order to address the question of outcome heterogeneity by partner gene, we examined the outcome data for 47 patients (1-24 years) treated on UKALL2003 where patients with MLL-t were treated on the high risk arm. There was no evidence that the t(4;11) conveyed an inferior outcome compared with other MLL-t: 5 year event-free and overall survival rates were 74% v 70%, p=0.7 and 74% v 83%, p=0.5, respectively. Among 347 cases with successful cytogenetics, 116 (33%) cases had at least one additional chromosomal abnormality (ACA) whilst in the remaining 225 cases only the 11q23 abnormality was observed. A total of 299 ACA were counted, averaging 0.8 per case but with some variation by age (0.43, 0.70, 0.51, 0.83 and 0.32 in infants, young children, older children, young adults and adults, respectively) as well as partner gene (0.48 in t(4;11) and 1.34 in non-t(4;11)). The most common ACA were gain of chromosomes X, 6, and 8 as well as loss of 17p and i(7q). CNA analysis of 14 children and 12 adults with t(4;11) (n=22) and t(11;19) (n=4) revealed a total of 87 CNA, mostly gains (n=58). SNP array analysis of 24 patients revealed at least one CNA per case and an average of 3.3 per case. This average is fewer than that reported in other cytogenetic subgroups using lower resolution arrays (6-7 per case). Although the number of CNA was low and many were private, the increased resolution offered by the CytoscanHD array identified several regions of the genome which were recurrently affected by CNA and warrant further investigation, including 2q26~31 and 15q26.

Summary and Conclusions: In conclusion, although the number of secondary abnormalities in MLL-t is low there is evidence that it is related to both the partner gene and the age of the patient. In addition, when treated as high risk on a contemporary protocol all children and young adults with a MLL-t can achieve good OS rates.

P154

PROGNOSTIC AND THERAPEUTIC IMPLICATIONS OF RAS/RTK PATHWAY MUTATIONS IN DIFFERENT AGE COHORTS OF B-LINEAGE ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS WITHOUT KNOWN FUSION TRANSCRIPTS

M. Messina[1,*] S. Chiaretti[1], N. Peragine[1], F. Di Giacomo[1,2], V. Gianfelici[1], A.L. Fedullo[1], G. Ceglie[1], A. Piciocchi[3], V. Apicella[1], P. Fazi[3], G. te Kronnie[4], A.M. Testi[1], M. Vignetti[1,3], A. Vitale[1], A. Guarini[1], R. Foà[1]
[1]Hematology, Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, [2]Department of Molecular Biotechnology and Health Science, and Center for Experimental Research and Medical Studies (CeRMS), University of Torino, Torino, [3]Fondazione GIMEMA Onlus, Rome, [4]Laboratorio di Oncoematologia, Dipartimento di Pediatria, Università di Padova, Padova, Italy

Background: We previously reported (Messina *et al*, EHA19 ABSSUB-4428) that 27% of B-lineage acute lymphoblastic leukemia without known fusion transcripts (B-NEG ALL) carries RAS/RTK pathway mutations. In particular, *FLT3* mutations were specific of patients older than 15 years, being detected in 9.8% of adolescents/young adults (AYA) and 12.3% of adult cases, while only in 2% of children. On the contrary, *KRAS* and *NRAS* mutations clustered in the pediatric cohort: indeed, they collectively accounted for 30% of pediatric cases and only 14.7% of AYA and 14% of adults. The prognostic role of these mutations has been investigated only in specific ALL subgroups with contrasting results. Moreover, being druggable, these mutations represent an attractive target also from a therapeutic perspective.

Aims: 1) To determine the prognostic impact of RAS/RTK pathway mutations in children, AYA and adult B-NEG ALL. 2) To assess the sensitivity of B-NEG ALL primary cells to gene or pathway specific inhibitors.

Methods: The impact on overall survival (OS) and disease-free survival (DFS) of RAS/RTK pathway mutations was evaluated in 150 B-NEG ALL patients (49 children, 55 AYA, 46 adults) with a median follow-up of 65 months and by grouping AYA and adults, whose mutational profile and therapeutic regimens were comparable. OS and DFS curves were estimated by Kaplan-Meier product-limit method and compared using the log-rank test (SAS software v9.4). Annexin V/7AAD apoptotic test (BD Bioscience), MTT (Sigma Aldrich) and ^{3}H-thymidine (Perkin Elmer) proliferation assays were performed to assess the sensitivity of ALL cells carrying mutations of *FLT3*, *KRAS*, *NRAS* to increasing doses (0.1-10 μM) of selected inhibitors of tyrosine kinases (dasatinib, ponatinib), *FLT3* (quizartinib, crenolanib) and of the PI3K/mTOR/MEK pathway (rapamycin, BEZ235, selumetinib). Drugs were added at time 0 and viability was measured after 72 hours. Cells were plated at 1x10^{6}/ml and each condition was run in triplicate.

Results: Survival analyses showed that AYA and adult B-NEG ALL patients harboring RAS/RTK gain-of-function mutations (*i.e.*ITD and D835 *FLT3* mutations and *KRAS*/*NRAS*G12-13 mutations)displayed a shorter OS at 4 years when compared to WT cases (18% *vs* 49.5%, 95% CI 5.4-59.3 and 38.1-64.4, p=0.074) and also a significantly shorter DFS (p=0.020), being 20% at 4 years

(95% CI 5.8-69.1) compared to 49% (95% CI 35.8-67) for WT cases. At variance, in the pediatric cohort the survival of RAS/RTK mutated cases resembled that observed in WT cases.*in vitro* sensitivity experiments showed that quizartinib and crenolanib (0.1 μM) reduced the proliferation rate of B-NEG ALL primary cells from 3 patients carrying *FLT3* ITD mutations. Indeed, after 72 hours of treatment, quizartinib reduced the percentage of proliferating cells to 31.4±7.9% and crenolanib to 44.1±23.1%. Interestingly, also the 3rd generation multi-target TK inhibitor ponatinib was highly active. Similarly, primary cells from 3 samples harboring *NRAS* or *KRAS* mutations were sensitive to PI3K/mTOR/MEK inhibitors (0.1 μM): in particular, BEZ235 reduced the percentage of proliferating cells to 18.3±12%, rapamycin to 37.3±25.9% and selumetinib to 54.1±12.3%. The same inhibitors also exerted a pro-apoptotic effect in all the samples tested. On the contrary, the non-specific compounds (ruxolitinib and tofacitinib) proved ineffective.

Summary and Conclusions: RAS/RTK pathway mutations are a common event in B-NEG ALL with a different distribution across age cohorts. We conclusively show that these mutations negatively impact on AYA and adult outcome. Our results indicate that the routinary screening of RAS/RTK signaling members in B-NEG ALL may i) improve the risk stratification of AYA and especially adults, whose outcome is still unsatisfactory; ii) open the way to targeted therapeutic strategies, as suggested by *in vitro* experiments.

P155

DUAL SMALL MOLECULE INHIBITORS TARGETING G9A AND DNMTS: A NOVEL STRATEGY FOR TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA

E. San Jose-Eneriz[1], X. Agirre[1], M.O. Rabal[2], A. Vilas-Zornoza[1], E. Miranda[1], A. Ugarte[2], N. Casares[3], V. Segura[4], I. Martin-Subero[5], G. Castellano[5], M. Garcia Fernandez de Barrena[3], J.R. Rodriguez-Madoz[1], S. Roa[1], M.J. Garcia-Barchino[1], J.A. Sanchez[2], J.J. Lasarte[3], M.A. Avila[3], J.A. Martinez-Climent[1], J.F. San Miguel[6], J. Oyarzabal[2], F. Prosper[1,6,*]
[1]Oncology Division, [2]Small Molecule Discovery Platform, [3]Gene Therapy and Hepatology Area, [4]Bioinformatics Unit, Center for Applied Medical Research, Pamplona, [5]Institut d'Investigacions Biomediques August Pi I Sunyer (IDIBAPS), Barcelona, [6]Hematology Service, Clinica Universidad de Navarra, Pamplona, Spain

Background: The indisputable role of epigenetics in hematological malignancies, along with the fact that unfavorable epigenetic alterations might be reversible, has favored the development of novel epigenetic drugs. Although according to the Structural Genomics Consortium there are 377 known epigenetic proteins, currently most epigenetic drugs are inhibitors of DNA methyltransferases (DNMTS) and histone deacetylases (HDACS). Therefore, many epigenetic targets remain to be discovered and exploited.

Aims: The overall goal of our study is the identification of new epigenetic targets and design new small molecules against these targets in Acute Lymphoblastic Leukemia (ALL), with the final aim of improving the treatment and life quality of ALL patients.

Methods: We carried out a screening using a panel of small interfering RNAs (siRNAS): we interfered the expression of 134 genes belonging to the main protein families implicated in the epigenetic mechanism regulation in several cell lines of ALL and determined the effect of the interference in cell proliferation.

Results: In this way, we identified the histone H3 Lysine 9 (K9H3) methyltransferase G9a as a potential target in hematological malignancies. In order to corroborate the results obtained, we nucleofected a greater number of cell lines with two different siRNAs against G9a. As expected, inhibition of G9a expression induced a significant decrease in cell proliferation. Besides, treatment of ALL cell lines with the G9a inhibitors BIX01294 and UNC0638 induced a decreased in cell proliferation. All these data suggest that G9a is an ideal epigenetic target for the treatment of ALL. As DNMT1 and DNMT3B were also overexpressed in ALL cell lines and patient samples and DNTM1 and G9a directly cooperate in coordinated DNA and H3K9 methylation during cell division, we designed and synthesized small molecules with dual activity against G9a and DNMTs. We selected those compounds that presented an optimal affinity against G9a and DNMTs (biochemical assay) and a good *in vitro* G9a-DNMT activity inhibition, decreasing H3K9me2 and 5-methylcytosine (5mC) marks. CM-272 was selected as the lead compound, showing an important *in vitro* anti-tumoral effect with GI_{50} values lying in the nanomolar concentration range. In fact, CM-272 was significantly more active than reference compounds BIX01294 and UNC0638 (G9a inhibitors) or 5-azacytidine and decitabine (DNMTs inhibitors). Moreover, the dual small molecules induced apoptosis in addition to decrease cell proliferation. In order to elucidate the mechanism of action of CM-272 we performed a genome wide RNA-sequencing analysis with and without CM-272 treatment in ALL derived cell lines. In this analysis we observed that CM-272 induces type I interferon response and immunogenic cell death in ALL cell lines. Finally, we performed ADME, toxicity and pharmacokinetic studies in order to carry out the *in vivo* analysis in human CEMO-1 ALL mouse model. Treatment of mice engrafted with CEMO-1 cells with CM-272 induced an *in vivo* decrease of the H3K9me2 and 5mC marks, which was accompanied with a significant prolonged overall survival of treated mice (90.8 days) in comparison with control group (57.3 days). This is the first evidence of *in vivo* efficacy of G9a inhibitors.

Summary and Conclusions: In conclusion, we have identified and validated G9a as an epigenetic target for the treatment of ALL and we have developed dual small inhibitory molecules against G9a-DNMTs. Finally, our results show the therapeutic activity of G9-DNMT small inhibitory molecules in models of ALL and suggest that these compounds may be of clinical value in the treatment of patients with ALL.

P156

CLONAL ARCHITECTURES OF BCR-ABL+ BCP-ALL: IMPLICATIONS FOR ANTI B-CELL DIRECTED THERAPY

M. Bartels[1,*] I. Nagel[2], S. Ussat[3], O. Ottmann[4], H. Pfeifer[4], H. Trautmann[1], S. Böttcher[1], N. Gökbuget[4], M. Kneba[1], H.H. Oberg[3], R. Siebert[2], M. Brüggemann[1]
[1]2nd Medical Department, [2]Institute for Human Genetics, [3]Institute for Immunology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, [4]2nd Medical Department, University Hospital, Frankfurt, Germany

Background: B-cell directed immunotherapies turned out to be effective in the treatment of adult patients with B-cell precursor acute lymphoblastic leukemia (BCP-ALL). However, a lack of target antigen expression in ALL subpopulations may constitute a potential mechanism of relapse and persistence.

Aims: To gain inside in potential mechanisms of resistance to B-cell specific immunotherapies by tracing the distribution of driver mutations within relevant immunophenotypic compartments differing in target antigen expression in a cohort of 27 *BCR-ABL*-fusion positive (*BCR-ABL*+) adult BCP-ALL cases.

Methods: Cryo-conserved samples from initial diagnosis of 27 adult *BCR-ABL*+ BCP-ALL patients treated within the GMALL 07/2003 trial were flow sorted onto slides and screened for *BCR-ABL* and concurrent *CDKN2A/B* and *PAX5* deletions by fluorescence *in situ* hybridization (FISH) using one customized (PAX5) and two commercial probes (Vysis LSI BCR/ABL Dual Color, Dual Fusion Translocation probe, Vysis LSI CDKN2A/CEP 9; both Abbott Molecular, Illinois, USA). The following populations were investigated: CD34+38-19-10-3-, CD34+38+19-3-, CD34+19+20-3-, CD34+19+20+3-, CD34-19+20+3-, CD34-19-20-3+, CD34+19-13/33+10-3/16-, CD34-19-13/33+10-3/16-, CD34-19-13/33+10-3/16+.

Results: Cells with a *BCR-ABL* fusion were detected not only in the B-cell compartment but also in CD19-negative multipotent progenitors (MPP) and in myeloid precursor cells in 8/9 cases expressing the M-*BCR-ABL* transcript, 2/12 patients carrying the m-*BCR-ABL* variant, in 2/3 with both transcripts and in 2/3 cases with unknown *BCR-ABL* transcript. In the remaining patients *BCR-ABL*+ cells were found exclusively within the CD19+ compartment. In 8/10 cases with concurrent *CDKN2A/B* deletions the latter were only found within the CD19+ compartment including one patient with *BCR-ABL*+ MPP. One patient with a unique *BCR-ABL*+ CD16+ compartment showed *CDKN2A/B* deletions also in the MPP and the myeloid compartment. In 4 patients distribution patterns of concurrent *PAX5* deletions resembled the affection patterns of their *CDKN2A/B* deletions. Examination of copy number alterations (CNA) of *ABL*, *BCR* and *BCR-ABL* suggested an evolution of diverse *BCR-ABL*+ subclones in 8/27 patients. The onset of subclonal diversification was observed within the B-determined CD34+19+ compartment in 6/8 cases. However, in two cases diverse *BCR-ABL*+ subclones were detectable within the multipotent CD34+38-19-compartment. Also 6/10 cases with *CDKN2A/B* deletions showed subclonal patterns regarding CNA of 9p21 and the centromeric region of chromosome 9. In these patients we observed the highest burden of *CDKN2A/B* deletions within the CD20+ leukemic compartment.

Summary and Conclusions: Our findings reveal distinct patterns of subclonal evolution in adult *BCR-ABL*+ BCP-ALL. They confirm that the t(9;22) frequently represents an antecedent event in the genesis of BCP-ALL which may occur prior to B-lineage determination. Conversely, leukemic clones were exclusively detected within the CD19+ compartment in other patients. Concurrent deletions of *CDKN2A/B* and *PAX5* are frequently restricted to the CD19+ compartment but may also originate from preleukemic MPP in patients with a *BCR-ABL*+ CD16+ compartment. In the context of B-cell directed treatment, these observations may account for both: resistance and effectiveness. A lack of target antigen expression in leukemic subclones may lead to resistance against CD19 or CD20 directed therapy, however, targeted treatment may eradicate clones with the most complex genetic profile. Our observations may help to define new stratification markers in future chemo-immunotherapeutic regiments for *BCR-ABL*+ BCP-ALL patients.

P157

RESTORING IKAROS TUMOR SUPPRESSION AS A THERAPY FOR HIGH-RISK LEUKEMIA

C. Song[1,*] C. Gowda[1], X. Pan[1], Y. Ding[1], S. Mudhusami[1], Z. Ge[1,2], M. Muschen[3], K. Payne[4], S. Dovat[1]
[1]Pediatrics, Penn State University College of Medicine, Hershey, United States, [2]Hematology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [3]Pediatrics, University of California San Francisco, San Francisco, [4]Pathology and Human Anatomy, Loma Linda University, Loma Linda, United States

Background: Ikaros (*IKZF1*) is a master regulator of hematopoietic differentiation and functions as a tumor suppressor. High-risk acute lymphoblastic leukemia (ALL) characterized by *Ikaros deletion and/or mutation* has a very poor prognosis and high relapse. Treatment is challenging for the high-risk leukemia with Ikaros deregulation because its tumor suppressor mechanisms are not well understood and targeted therapies are not available. Casein Kinase II (CK2) activity is dramatically increased in ALL. CK2 directly phosphorylate Ikaros and suppress Ikaros function. We hypothesize that CK2-mediated down-regulation of Ikaros function also plays an important role in ALL leukemogenesis, and CK2 inhibition will restore Ikaros leukemia suppressor activity.
Aims: To understand the mechanism underlying restoring Ikaros tumor suppressor activity in B-ALL and the therapeutic effect of CK2 inhibition for leukemia therapy.
Methods: Chromatin immunoprecipitation coupled with next generation sequencing (ChIP-SEQ) was used to identify the Ikaros binding targets in B-ALL cells and also the chromatin state of Ikaros targets by characterizing the binding profiling of histone modification markers. Microarray and RNA-seq were used to determine gene expression profiling. The qChIP assay was used for further analysis of protein-DNA association in leukemia cell line and primary leukemia cells. The Ikaros shRNA knockdown and retroviral transduction were used for its function analysis on gene expression and cell proliferation. Human-derived leukemia xenograft mouse model was used to observe the effect of CK2 inhibition on restoring Ikaros tumor suppressor activity and leukemia development with Xenogen IVIS 50 living imager.
Results: The genome-wide Ikaros and histone deacetylase 1 (HDAC1) binding sites were identified in the B-ALL leukemic cells. Ikaros controls cellular proliferation in leukemia by repressing cell cycle regulatory genes and the phosphatidylinositol (PI3K) pathway. Ikaros represses its target genes by forming heterochromatin through two distinct epigenetic mechanisms, one *via* recruitment of HDAC1 histone deacetylase (results in H3K27me3) and the other an HDAC1-independent mechanism (results in H3K9me3). CK2 inhibition result in the increase of more suppressive chromatin in promoter of Ikaros targets for cell cycle progress and PI3K pathway. Moreover, CK2 inhibitor has effect on gene suppression of Ikaros targets and result in cell proliferation arrest of B-ALL cells in an Ikaros-dependent manner. These data indicates CK2 inhibition restore Ikaros function in B-ALL cells. Targeted CK2 inhibition has a strong therapeutic effect on high-risk leukemia cells *in vivo* with both leukemia cell xenograft mouse model and patient-derived leukemia xenograft mouse model through restoring Ikaros leukemia suppressor activity.
Summary and Conclusions: We found the novel, Ikaros-mediated mechanisms of epigenetic regulation that contribute to tumor suppression in leukemia, demonstrated that cellular proliferation is controlled by the CK2-Ikaros axis and identified therapeutic efficacy of a novel therapeutic approach for high-risk leukemia-restoration of Ikaros tumor suppressor activity via inhibition of CK2.

P158

THE STEMNESS INHIBITOR, BBI608, REDUCES THE SELF-RENEWAL OF BCR-ABL1 POSITIVE LEUKEMIA CELLS

T. Tauchi[1,*] S. Okabe[1], S. Katagiri[1], K. Ohyashiki[1]
[1]Internal Medicine, TOKYO MEDICAL UNIVERSITY, Tokyo, Japan

Background: Hematopoietic stem cells and leukemic stem cells share common features, including self-renewal, the capacity to differentiate, resistance to apoptosis, and limitless proliferative potential. Despite these similarities, several stemness factors, such as Hedgehog, Wnt, Notch, and b-catenine show differential activation in normal *versus* leukemia stem cells. BBI608 is an oral first-in-class stemness inhibitor which inhibits the Stat3, b-catenine and Nanog patheways. In a phase I study, BBI608 demonstrated telerability as well as signs of anti-cancer activity in patients with solid tumors.
Aims: We investigated the molecular mechanisms by which BBI608 regulates the self-renewal of primary BCR-ABL1 positive leukemia cells *in vivo*.
Methods: To identify the leukemia-propagating cell fraction of BCR-ABL1-positive leukemia, we serially transplanted human leukemia cells from patients with chronic myeloid leukemia blast crisis (n=1; T315I BCR-ABL1) or ponatinib-resistant Ph-positive acute lymphoblastic leukemia (n=2, Y253H/E255K/T315I BCR-ABL1 and T315I BCR-ABL1) into NOD/SCID/IL-2gc-/-mice. The cell fractions with CD34+CD38-CD19+ and CD34+CD38+CD19+ could self-renew and transfer the leukemia in NOD/SCID mice. To investigate the effects of BBI608 on self-renewal and the relevance as a therapeutic target in ABL-tyrosine kinase-resistant BCR-ABL1 positive leukemia, we examined the activity of BBI608 against CD34+CD38-CD19+, CD34+CD38+CD19+ fractions transferred NOD/SCID mice *in vivo*. NOD/SCID mice were injected intravenously with BCR-ABL1 positive cells then treated with BBI608 (20 mg/kg; p.o.) for 28 days.
Results: All mice demonstrated the engraftment of leukemia by flow cytometry. However, the treatment with BBI608 reduced the population of CD34+CD38-positive cells. We isolated human CD45+ cells from the spleen of mice from each treatment group and injected equivalent numbers of leukemia cells into secondary recipients. Following 30 days, all mice received BCR-ABL1 cells from vehicle treated mice engrafted with leukemia. In contrast, leukemia engraftment was not detected in recipient mice (n=6) from BBI608-treated donors. These results demonstrate the persistent effects of BBI608 on long term self-renewing BCR-ABL1-positive leukemia cells. We further examined the effects of Stat3/Nanog pathway modulation on *in vitro* clonogenic growth. CD34+CD38-CD19+ cells from T315I BCR-ABL1 (n=2) and WT-BCR-ABL1 (n=1) cells were treated with 2 mM of BBI608 for 72 hrs, washed free of drugs, and plated in quadruplicate in methylcellulose. At 14 days, colonies were counted as initial plating. The representative plate was then washed and cells were re-suspended and re-plated. After an additional 14 days, colonies were counted as secondary re-plating. Clonogenic recovery of untreated cells was normalized to 100% and plating results from all treatment groups were expressed as % control. BBI608 had only minimum effects on colony formation after initial plating over control cells. However, upon serial re-plating, secondary colony formations were significantly inhibited by BBI608 ($p<0.001$). To identify the mechanisms that limit the self-renewal of BCR-ABL1-positive cells by BBI608, NOD/SCID mice engrafted with T315I-BCR-ABL1-positive CD34+ CD19+ fractions were treated with BBI608 (20 mg/kg; p.o.) for 14 days. BBI608 induced the expressions of p21Cip1, cleaved PARP and reduced the expression of BMI-1, phospho-Stat3, c-Myc, Sox-2, and Bcl-XL.
Summary and Conclusions: Our preclinical results indicate that BBI608 have potential as an important option for controlling the drug-resistant leukemia initiating cells in BCR-ABL1 positive leukemia. It is expected that the BBI608 may become extremely useful therapeutic interventions in a number of hematological neoplasms, including BCR-ABL1 positive leukemia, where the persistence of cancer stem cells.

TP53 MUTATIONS IN PHILADELPHIA NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) DEFINE A GROUP OF VERY HIGH RISK PATIENTS: A NEXT GENERATION SEQUENCING (NGS) STUDY

M.L. Guinea Montalvo[1,*] S. Salmoiraghi[1], G. Ubiali[1], M. Tosi[1], B. Peruta[1], E. Oldani[1], C. Boschini[1], A. Kohlmann[2], S. Chiaretti[3], T. Intermesoli[1], R. Bassan[4], O. Spinelli[1], A. Rambaldi[1]
[1]Hematology and Bone Marrow Transplant Unit, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [2]Personalized healthcare and biomarkers, Innovative Medicines, AstraZeneca, Macclesfield, United Kingdom, [3]Department of Cellular Biotechnologies and Hematology, Sapienza University of Rome, Rome, [4]Hematology, Ospedale dell'Angelo, Mestre-Venezia, Italy

Background: The Prognosis of adult patients with Acute Lymphoblastic Leukemia (ALL) is estimated at diagnosis on the basis of conventional clinical and biological characteristics and during treatment by the molecular or immunophenotypic evaluation of Minimal Residual Disease (MRD). New biological and molecular features are needed at diagnosis to guide prompt therapeutic strategies. Recently, few studies on heterogeneously treated cohorts of adult ALL patients reported that *TP53* mutations are frequent and correlate with poor response to induction therapy and short survival, but their real impact on ALL outcome is still undefined.
Aims: To investigate the incidence of *TP53* alterations at diagnosis and correlate them with the clinical outcome of 171 adult Philadelphia-negative ALL patients homogeneously treated in the context of a prospective clinical trial (NILG 09/2000, ClinicalTrials.gov identifier:NCT00358072)(Bassan R et al, Blood 2009 and BJC 2014).
Methods: One hundred fourteen B and 57 T-ALL patients were studied (median age 34,6 years, 97 male). Exons 4 to 11 of the *TP53* gene were analyzed on diagnostic DNA and in 3 cases also on relapse DNA by Next Generation Sequencing (NGS, 454 Roche platform). Results were validated, when possible, by Sanger sequencing. Disease-free survival (DFS) and Overall survival (OS) were estimated by the Kaplan Meier method. The log-rank test was used to compare survival probabilities between subgroups of patients.
Results: *TP53* mutations occurred in 8% of patients (14/171) with a higher prevalence in B lineage ALL (9,6 *vs* 5,3% in T-ALL). The allele burden ranged from 5 to 97% pointing out that *TP53* alterations can be present at diagnosis in minor leukemic clones. All alterations were identified in the DNA binding domain region and led to missense or frame-shift mutations introducing a premature stop codon. The found alterations were 12 single nucleotide changes, 2 duplications (4 and 8 nucleotides) and one 11 base pair insertion. The same *TP53* mutations were seen at diagnosis and relapse in three patients for whom DNA was available at both time points, suggesting the presence of a clone bearingmutated*TP53* since disease onset. By univariate analysis, *TP53* mutations were strictly related to older age ($p=0.0003$) but not to other clinical feature. In our cohort, the presence of a *TP53* mutation did not affect CR achievement but relapse rate was significantly higher in mutated cases ($p<0.0001$) (Figure1a). Moreover, patients with mutated *TP53* showed a significantly shorter DFS and OS compared to wild-type patients (DFS $p=0.0007$, OS $p=0.0011$) (Figure 1b-c). NGS analysis also revealed single nucleotides changes that were reported as polymorphism (SNP) in IARC and dbSNP databases. One patient bearing a *TP53* mutation also revealed an unbalanced SNP distribution along the *TP53* sequence confirming the known karyotypic monosomy of chromosome 17. Similarly, other 3 patients showed a *TP53* SNP unbalance without a karyotipic evidence, thus suggesting a cryptic *TP53* gene deletion.

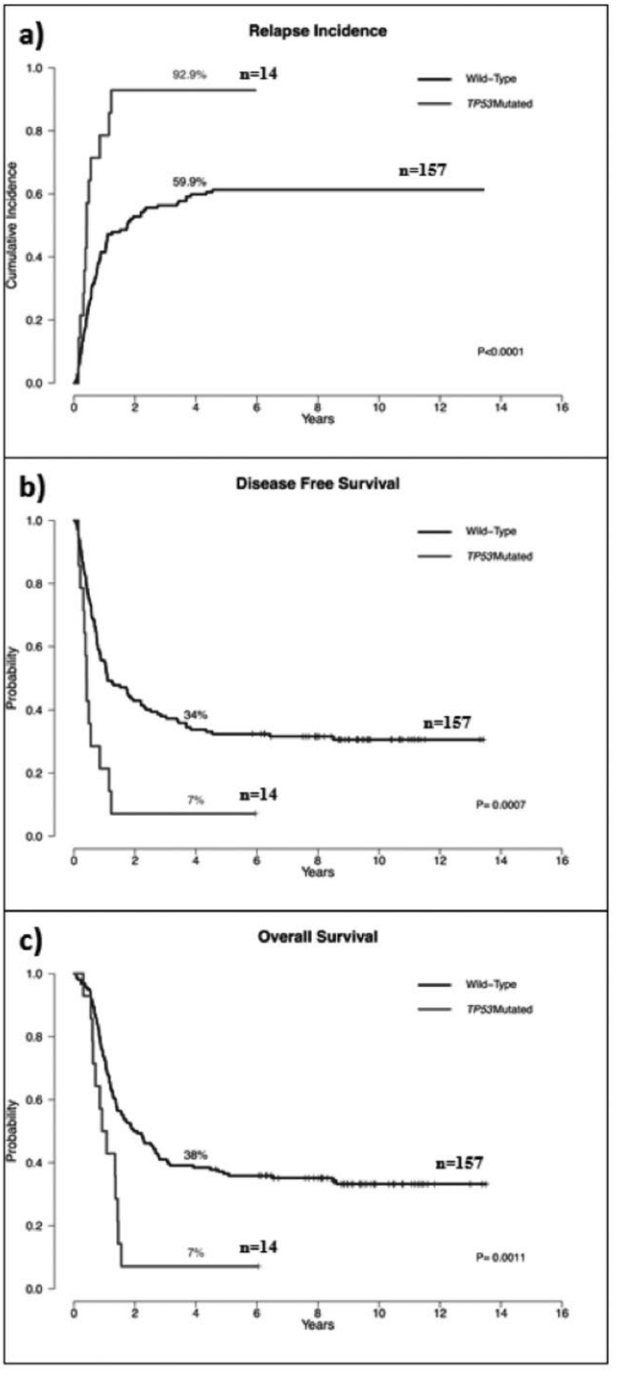

Figure 1. Relapse Incidence (a), Disease Free Survival (b) and Overall Survival (c) in *TP53* mutated vs Wild-type Ph-negative adult ALL. Percentages are indicated at 4 years.

Summary and Conclusions: In our adult ALL cohort, mutated *TP53* does not impair CR achievement, but it identifies a group of patients with higher relapse-rate and dramatically shortened DFS and OS. Therefore, *TP53* aberrations detection must be included in the diagnostic work up of adult ALL to guide treatment strategies. The use of highly sensitive NGS is crucial to identify also minor *TP53* mutated clones that may lead to disease recurrence and to reveal *TP53* gene deletions not detected by conventional karyotype.

P160

TUMOR SUPPRESSOR GENES IKZF1 AND BTG1 COOPERATE IN ACUTE LYMPHOBLASTIC LEUKEMIA DEVELOPMENT AND GLUCOCORTICOID THERAPY RESISTANCE

R. Marke[1], E. Tijchon[1], D. van Ingen Schenau[1], J. Boer[2], M. Demkes[1], L. van Emst[1], L. van der Meer[1], R. Kuiper[3], P. Hoogerbrugge[1], M. den Boer[2], F. van Leeuwen[1], B. Scheijen[1,*]
[1]Laboratory of Pediatric Oncology, Radboud university medical center, Nijmegen, [2]Pediatric Oncology, Erasmus MC-Sophia Children's Hospital University Medical Center, Rotterdam, [3]Human Genetics, Radboud university medical center, Nijmegen, Netherlands

Background: Previously, we and others have shown that IKZF1 (IKAROS) gene deletions and mutations independently predict poor prognosis in children with BCP-ALL, and IKZF1 gene alterations have now been incorporated in the risk stratification of Dutch pediatric BCP-ALL patients. However, it remains to be established whether loss of IKZF1 function has a direct impact on chemotherapy responses. Our recent findings show that loss of IKZF1 function promotes resistance towards glucocorticoid-induced apoptosis in normal and leukemic B-cells, which correlates with attenuation of the transcriptional response to glucocorticoids. Furthermore, the effect of other genetic aberrations on therapy outcome of *IKZF1*-deleted patients has not been fully addressed. Our analysis has revealed that the event-free survival of *IKZF1*-deletion positive patients is negatively affected by the co-occurrence of *BTG1* deletions. In addition, *BTG1* deletions appear to occur more frequently in patients with IKZF1 gene alterations (19%) compared to an unselected cohort (9%).
Aims: Westudied the genetic interaction between IKZF1 and BTG1 in leukemia development and glucocorticoid therapy responses using knockout mouse models and human leukemia cell lines.
Methods: Mice haplodeficient for *Ikzf1* were crossed onto a C57BL/6J *Btg1* knockout background and mice were monitored for spontaneous leukemia development over a time period of 18 months. Additionally, glucocorticoid response was determined in lymphoid cells isolated from compound *Ikzf1*$^{+/-}$;*Btg1*$^{-/-}$mice by MTS assay and AnnexinV staining and compared to *Ikzf1*$^{+/-}$, *Btg1*$^{-/-}$and wild-type B cells. Additionally, sensitivity towards glucocorticoid induced apoptosis was determined in human leukemia cell lines displaying loss of IKZF1 and BTG1 function.
Results: We observed a significant acceleration in the onset of T acute lymphoblastic leukemia in mice heterozygous knockout for both *Ikzf1* and *Btg1*, which was even further enhanced in *Ikzf1*$^{+/-}$;*Btg1*$^{-/-}$animals. These leukemias were characterized by clonal TCRb rearrangement and aggressive infiltration into secondary organs. B-cells isolated from 8 to 14 weeks-old *Ikzf1*$^{+/-}$;*Btg1*$^{-/-}$ animals without any signs of leukemia disease were highly resistant against glucocorticoid-induced apoptosis. Similarly, human leukemia cell lines displaying loss of IKZF1 and BTG1 function showed a glucocorticoid-resistant phenotype that was even stronger than by loss of IKZF1 alone.
Summary and Conclusions: Together, our findings establish *BTG1* as a tumor suppressor gene that genetically interacts with *IKZF1* during leukemic transformation and strongly potentiates the IKZF1-mediated glucocorticoid resistance phenotype in normal and leukemic B cells.

Acute lymphoblastic leukemia - Clinical 1

INFLUENCE OF BASELINE FACTORS ON OUTCOMES IN PATIENTS (PTS) WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL) TREATED WITH BLINATUMOMAB

M.S. Topp[1,*] N. Gökbuget[2], S. O'Brien[3], A. Stein[4], C. Jia[5], S.J. Forman[4], R. Bargou[6], A.K. Fielding[7], L.T. Heffner, Jr.[8], R.A. Larson[9], S. Neumann[10], T. Maniar[11], D. Nagorsen[11], H. Kantarjian[12]
[1]Medizinische Klinik und Poliklinik II, Universitätsklinikum Würzburg, Würzburg, [2]Department of Medicine II, Goethe University, Frankfurt, Germany, [3]Chao Family Comprehensive Cancer Center, University of California Irvine Medical Center, Orange, CA, [4]City of Hope, Duarte, CA, [5]Research and Development, Amgen Inc., South San Francisco, CA, United States, [6]Comprehensive Cancer Center Mainfranken, Universitätsklinikum Würzburg, Würzburg, Germany, [7]Department of Hematology, University College London Medical School, Royal Free Campus, London, United Kingdom, [8]Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA, [9]University of Chicago, Chicago, IL, United States, [10]Medical Department II, University Schleswig Holstein in the City Hospital, Kiel, Germany, [11]Global Development Oncology, Amgen Inc., Thousand Oaks, CA, [12]The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: Blinatumomab is a bispecific T-cell engager (BiTE®) antibody construct with dual specificity for CD19 on B-lineage cells and CD3 on T cells. Blinatumomab showed efficacy in Philadelphia-chromosome-negative (Ph–) R/R ALL in a large, multicenter, single-arm, phase 2 study (Topp *et al. Lancet Oncol.* 2015;16:57-66) and is now approved in the United States for this indication.
Aims: To evaluate associations between pt baseline characteristics and outcomes in the phase 2 study.
Methods: Pts (≥18 years) with Ph– B-precursor R/R ALL (primary refractory after induction; relapse <12 months after 1st remission; relapse <12 months after HSCT; relapse or refractory after 1st salvage), ≥10% bone marrow blasts [BMB], and ECOG performance status ≤2 were included in the study. All pts provided informed consent. Blinatumomab was given by continuous IV infusion (4 weeks on, 2 weeks off) for ≤5 cycles (cycle 1: 9µg/d days 1–7, then 28µg/d; subsequent cycles: 28µg/d). The primary endpoint was complete remission (CR, ≤5% BMB, ≥100 000 platelets/µL, absolute neutrophil count [ANC] >1000/µL) or CR with partial hematologic recovery (CRh, ≤5% BMB, >50 000 platelets/µL, ANC >500/µL) within 2 cycles. Associations of baseline factors (platelet count, prior salvage, BMB, peripheral blood blasts, age, geographic region, prior HSCT, number of prior relapses, and lactate dehydrogenase [LDH]) with CR/CRh and overall survival (OS) were assessed using the Cochran-Mantel-Haenszel test and univariate and multivariate logistic regression.
Results: Of the 189 pts treated with blinatumomab, 81 (43%) achieved CR/CRh within 2 cycles. Median (95% CI) relapse free survival was 5.9 (4.8–8.3) months; median (95% CI) OS was 6.1 (4.2–7.5) months. CR/CRh was seen in all groups, including 11 of 25 pts (44%) ≥65 years of age, 29 of 64 pts (45%) with prior HSCT, 52 of 125 pts (42%) without prior HSCT, and 11 of 32 pts (34%) with ≥3 prior salvages. Pts with <50% BMB at baseline were more likely to respond to blinatumomab treatment; 43 of 59 pts (73%) with <50% BMB achieved CR/CRh, while 38 of 130 pts (29%) with ≥50% BMB achieved CR/CRh. In the final multivariate model, lower BMB and higher platelet count were associated with CR/CRh; higher platelet count and lower LDH were associated with longer OS (Table).

Tabella 1.

Response (CR/CRh)			
	OR	95% CI for OR	*P*[a]
Platelet Count (10^9/L)			0.0341
< 50 vs ≥ 100	0.3	(0.1–0.8)	
50 to < 100 vs ≥ 100	0.3	(0.1–1.0)	
BMB			< 0.0001
< 50% vs ≥ 50%	5.1	(2.5–10.5)	
Survival (OS[b])			
	HR	95% CI for HR	*P*[c]
Platelet Count (10^9/L)			< 0.0001
< 50 vs ≥ 100	4.2	(2.3–7.8)	
50 to < 100 vs ≥ 100	2.6	(1.3–5.4)	
LDH			0.0082
≥ 230 vs < 230	1.9	(1.2–3.1)	

[a]*P* value based on logistic regression model (Wald test). [b]OS model controlled for age.
[c]*P* value based on Cox proportional hazard model. OR: odds ratio. HR: hazard ratio.

Summary and Conclusions: In this analysis, low baseline BMB count was associated with response to blinatumomab. This supports administration of blinatumomab when disease burden is low. For pts with higher tumor burden, cytoreduction/higher blinatumomab doses may be considered. Responses to blinatumomab have been observed in pts in remission with minimal residual disease (Gökbuget *et al. Blood.* 2014;124:379), suggesting that pts have low biologic resistance to blinatumomab even after intensive chemotherapy.

P162

CHARACTERIZATION OF LEF1 HIGH EXPRESSION AND NOVEL MUTATIONS IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA

Z. Ge[1,*] X. Guo[1], R. Zhang[1], J. Liu[1], M. Li[1], C. Song[2], S. Dovat[2], J. Li[1]
[1]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [2]Pennsylvania State University Medical College, Hershey, United States

Background: Aberrant activation of the Wnt pathway plays pathogenetic roles in tumors and has been associated with adverse outcome in acute lymphoblastic leukemia (ALL). Lymphoid enhancer binding factor 1 (*LEF1*), a key mediator of Wnt signaling, has been linked to leukemic transformation, *and LEF1* mutations have been identified in T-ALL.
Aims: To characterize the *LEF1* high expression and novel mutations in Chinese adult ALL.
Methods: Bone marrow (BM) samples from 131 newly diagnosed patients (82 male and 49 female) with ALL (87 B-ALL, 43 T-ALL and 1 T-/B-ALL) were collected between June 2008 and July 2013 at the First Affiliated Hospital of Nanjing Medical University. All the patients provided their written informed consent in accordance with the Declaration of Helsinki before enrollment in the study. The study was approved by the Institutional Review Board of the Nanjing Medical University. We screened mutations of*LEF1*exons 2 and 3, the hotspot regions in T-and B-ALL with the pretreatment BM samples of the cohort. The *LEF1* mutations were created by site-direct mutagenesis and confirmed by sequencing.The transient luciferase assay was performed in HEK293T cells using the Promega' luciferase assay reagents and measured with luminometer following the manufacture's instruction. The colorimetric cell proliferation assay (WST-1 reagent from Roche Applied Science) was performed in Nalm6 and Molt4 leukemia cells stably expressed LEF1-WT or its mutants. The Whitney U –test for quantitative parameters, a $\chi 2$ test for qualitative parameters, and Kaplan –Meier survival analysis were used in the cohort study. All statistical analyses were performed using the SPSS 17.0 and $p<0.05$ was considered statistically significant.
Results: Patients were divided into high and low*LEF1*expression groups (Q4 *vs* Q1-Q3). We found *LEF1* was highly expressed in 25.0% adult ALL patients and *LEF1* high expression was associated with high-risk leukemia factors (high WBC, Philadelphia chromosomepositive and complex karyotype), shorter event-free survival (EFS), and high relapse in patients with B-ALL. In addition, *LEF1* high expression was observed to associate with high mutation rate of *Notch1* and *JAK1* in T-ALL. Moreover, we identified 2 novel *LEF1* mutations (K86E and P106L) in 4 of 131 patients with ALL, and those patients with high-risk ALL (high WBC, complex karyotype). These results suggest a role for *LEF1* mutations in leukemogenesis. We further explored the effect of the mutations on cell proliferation and found both mutations significantly promoted the proliferation of ALL cells. We also observed the effect of *LEF1* and its mutations on the transcription of its targets, *c-MYC* and *Cyclin D1*. We found *LEF1* increased the promoter activity of its targets *c-MYC* and *Cyclin D1*, and *LEF1* K86E and P106L mutants further significantly enhanced this effect. We also observed that the *c-MYC* and *Cyclin D1* mRNA levels were significantly increased in patients with *LEF1* high expression compared with those with low expression.
Summary and Conclusions: Our findings indicate high *LEF1* expression and mutations are associated with high-risk leukemia. Our data also revealed that *LEF1* high expression and/or gain-of-function mutations are involved in leukemogenesis of ALL.

Luigi Gonzaga, Orbassano, Italy

Background: Tyrosine Kinase Inhibitors (TKI) have been shown to be very effective for the treatment of Acute Lymphoblastic Leukemia (ALL), with a Complete Hematologic Response (CHR) rate close to 100%, and a high rate of Complete Cytogenetic and Molecular responses (CCgR and CMR). However, when they are used alone, as single agents, most patients relapse, so that they are currently used in combination with chemotherapy and as a preparation to allogeneic stem cell transplantation (SCT). Since Ph+ ALL is more frequent in the elderly, many patients cannot tolerate intensive chemotherapy and are not eligible for SCT. We have explored if the administration of two TKIs, Nilotinib (NIL) and Imatinib (IM) can improve the results without increasing the toxicity.
Aims: To evaluate the response and the outcome of Ph+ ALL patients treated with the sequential administration of NIL and IM, and to investigate the type and number of BCR-ABL kinase domain mutations developing during and after the study.
Methods: We have designed a study (ClinicalTrials.gov. NCT01025505) in which patients more than 60 years old or unfit for intensive chemotherapy and SCT where treated with two TKIs, NIL 400 mg twice daily, and IM 300 mg twice daily, alternating for 6 weeks for a minimum of 24 weeks (study core) and indefinitely in case of response. The 6-weeks rotation schedule was respected, irrespectively of temporary discontinuations. The primary end-point was the rate of Disease Free Survival (DFS) at 24 weeks (4 courses of treatment); the secondary end points included the evaluation of CHR, CCgR and CMR rates. Mutation analysis was performed by nested RT-PCR amplification of the *ABL* kinase domain of the *BCR-ABL* transcript (codons 206 through 421). Amplified products were screened by denaturing-high performance liquid chromatography (D-HPLC). Samples scored positive for the presence of sequence variations were then subjected to direct automatic sequencing to characterize the mutation.
Results: 39 patients have been enrolled in 15 Italian hematologic Centers (median age 66 years, range 28-84, M/F=19/20). Among these, 8 patients were unfit for standard chemotherapy or SCT (median age 50 years, range 28-59). 27 patients were p190, 5 were p210 and 7 were p190/p210. After 6 weeks of treatment, 37 patients obtained a CHR (95%) and 2 a PHR (5%). All the patients were evaluable for response after 12 weeks of treatment: 35 patients were still in CHR (90%), 2 relapsed (5%) and one patient died. 25/26 patients who have completed the study core (24 weeks), were in CHR, and 22 continued therapy in the protocol extension phase.Thus, the OS at 1 year is 82%, and 64% at 2 years (median follow up 34.9 months, range 3.5-42.4 months). Overall, 25 patients relapsed, with a median time to relapse of 9.2 months (range 1.2-28.4 months), for a DFS of 48.7% at 12 months. Most of mutations detected at relapse were T315I, E255K, E255V and Y253H. Further details about Cytogenetic and Molecular responses, and about Adverse Events will be provided on site.
Summary and Conclusions: In this small cohort of Ph+ ALL elderly/unfit patients, the rates of relapse and progression were not likely to be different from the rates observed with Imatinib alone. It's important to notice that the mutations that occurred at the time of relapse were sensitive to other TKIs (Dasatinib and Ponatinib).

[1]Department of Hematology, University Hospital Schleswig-Holstein, Kiel, Germany, [2]Department of Pediatric Hematology, Great Ormond Street Hospital, London, United Kingdom, [3]Central European Institute of Technology, Masaryk University, Brno, Czech Republic, [4]Centro Ricerca Tettamanti, University of Milano Bicocca, Monza, [5]Hematology, Department of Molecular Biotechnologies and Health Sciences, University of Torino, Torino, Italy, [6]CLIP, Department of Paediatric Haematology/Oncology, Charles University Prague, Prague, Czech Republic, [7]IBMCC-CSIC, Hospital Universitario de Salamanca-IBSAL, Salamanca, Spain, [8]Bristol Genetics Laboratory, Southmead Hospital, [9]Department of Pediatric Haematology, Bristol Royal Hospital for Children, Bristol, United Kingdom, [10]Department of Immunology, Erasmus MC, Rotterdam, Netherlands

Background: Amplicon-based next generation sequencing (NGS) of immunoglobuline (IG) and T-cell receptor (TR) gene rearrangements to quantify minimal residual disease (MRD) in lymphoid neoplasms is already the focus of intense research, development, and application. This is mainly due to its potential to overcome limitations of the current molecular gold standard, real-time quantitative (RQ)-PCR, as it avoids laborious design and testing of patient specific assays and allows quantification of MRD with a more specific readout than RQ-PCR. However, standardization, quality control and validation of the technology in a multicentre, scientifically controlled and independent setting is highly warranted, but currently lacking.
Aims: To investigate an optimized IG/TR based NGS approach (including quality controls and calibrators) for sensitive and quantitative MRD assessment in lymphoid neoplasms within the EuroClonality NGS Consortium.
Methods: Within a European Multicentre trial a newly designed quality controlled one-step IGH NGS approach was tested in seven institutes (Kiel, Salamanca, Milano, Bristol, London, Prague, and Torino). Serial dilutions of diagnostic DNA and follow-up samples of thirty B-cell precursor ALLs with known complete IGH rearrangements as well as a set of positive and negative controls were analysed. All samples were spiked with pre-defined copy numbers of five reference IGH sequences. One-step PCR was used for library preparation with sets of FR2 primers harbouring sample specific barcodes and 500ng DNA per sample (75.000 copies), subsequently being sequenced with the Illumina V2 kit on the Illumina MiSeq NGS platform. Purpose-built bioinformatics methods were used to analyse data. MRD results of ALL follow-ups were compared to results of EuroMRD based RQ-PCR.
Results: A total of 312 samples were sequenced within 24 deep sequencing runs producing 168 million reads. Regression analysis of reference IGH allele reads was used to calculate the read coverage per copy, and correct for different B-cell content per sample. Ratios of reads between pairs of reference IGH alleles were highly consistent in intra-and inter-centre analyses, independent of the total number of reads in the sample. This high consistency in the usage of the reference IGH alleles was confirmed through redundancy analysis based on normalized reads (adjusted p-value=0.24). When outliers were identified, indicating poor assay performance, those were excluded from further analysis. The IGH gene rearrangements of all 27 pooled positive B-cell line controls were identified in all centres with a high intra-and inter-centre consistency. NGS based MRD analysis in 116 ALL follow-up samples revealed MRD positivity in 69/116 samples, and RQ-PCR in 66/116 samples, with a good overall concordance between both approaches (R^2=0.81). Discrepancies mainly affected samples with low MRD levels being consistent with Poisson sampling.
Summary and Conclusions: The approach newly developed by the EuroClonality NGS Consortium shows great promise to allow for quality controlled NGS based MRD analysis in a multicentre setting with a high intra-and inter-laboratory reproducibility. The critical next step, as part of the Consortium´s strategy, involves validation of this technology, prior to its implementation into routine practice, within multicentre clinical trials, in a scientifically controlled, independent, and multidisciplinary setting.

RETREATMENT WITH BLINATUMOMAB AFTER CD19-POSITIVE RELAPSE: EXPERIENCE FROM 3 TRIALS IN PATIENTS WITH RELAPSED/REFRACTORY B-PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL)

M.S. Topp[1,*] M. Stelljes[2], G. Zugmaier[3], P. Barnette[4], L.T. Heffner, Jr.[5], T. Trippett[6], R. Bargou[7], C. Jia[8], J. Benjamin[9], M.R. Litzow[10]
[1]Medizinische Klinik und Poliklinik II, Universitätsklinikum Würzburg, Würzburg, [2]Department of Medicine/Hematology and Oncology, University of Münster, Münster, [3]Amgen Research (Munich) GmbH, Munich, Germany, [4]Pediatric Hematology/Oncology, Primary Children's Hospital, Salt Lake City, UT, [5]Winship Cancer Institute, Emory University School of Medicine, Atlanta, GA, [6]Memorial Sloan-Kettering Cancer Center, New York, NY, United States, [7]Comprehensive Cancer Center Mainfranken, Universitätsklinikum Würzburg, Würzburg, Germany, [8]Research and Development, Amgen Inc., South San Francisco, CA, [9]Research and Development, Amgen Inc., Thousand Oaks, CA, [10]Division of Hematology, Mayo Clinic, Rochester, MN, United States

Background: Blinatumomab is a bispecific T-cell engager (BiTE®) antibody construct designed to link CD19-positive B cells to cytotoxic T cells and induce tumor cell lysis. Blinatumomab recently showed efficacy in Philadelphia-chromosome-negative (Ph–) R/R ALL in a large, multicenter, single-arm, phase 2 study (Topp *et al. Lancet Oncol.* 2015;16:57-66).
Aims: To determine the potential benefit of retreatment with blinatumomab among patients with R/R ALL who had previously responded to blinatumomab.
Methods: In this combined analysis, we evaluated outcomes among patients with R/R ALL enrolled in 3 open-label, phase 2 studies (NCT01471782: pediatric and adolescent R/R ALL, study 205; NCT01209286: adult R/R ALL, study 206; and NCT01466179: adult R/R ALL, study 211) who had a CD19-positive hematological relapse after initial response to blinatumomab and were retreated with blinatumomab. Patients were <18 (study 205) or ≥18 (studies 206 and 211) years of age with Ph– R/R B-precursor ALL. All patients or their legal representatives provided informed consent. Blinatumomab was given by continuous IV infusion for up to 5 cycles. A cycle was 4 weeks on, 2 weeks off. The primary endpoint of the 3 studies was complete response or complete response with partial recovery of peripheral blood counts within the first 2 cycles. Patients who relapsed following a response that lasted ≥3 months could receive up to 3 cycles of retreatment; patients with GVHD or CNS involvement were ineligible.
Results: A total of 11 patients received retreatment with blinatumomab (study 205, n=2; study 206, n=5; study 211, n=4). Seven patients (64%) were male; mean (range) age was 31 (4–77) years. At the time of initial treatment, 9 patients (82%) had ≥1 line of prior salvage chemotherapy; 7 (64%) had prior HSCT. Among the 10 patients who achieved hematological remission during the 2 cycles of initial treatment, the median (range) duration of response prior to

relapse was 9 (3–11) months. Five patients (45%) had HSCT between the first blinatumomab response and relapse. Outcomes and adverse events (AEs) during retreatment are shown in the Table. Four of 11 patients (36%) with R/R ALL who relapsed following an initial response to blinatumomab responded to retreatment with blinatumomab. One patient was retreated a second time and achieved a complete response.

Tabella 1. a≤5% marrow blasts and full, partial, or incomplete recovery of peripheral blood counts. bThere were no grade 4 or grade 5 neurologic AEs.

	Retreated Patients (n=11)
Median (range) duration of retreatment, days	28 (4–85)
Hematological remission (responders), n (%)	4 (36%)a
Minimal residual disease (MRD) responses among responders, n (%)	
MRD<10-4	4 (100%)
Complete MRD responses	1 (25%)
Patients with any AEs, n (%)	10 (91%)
Grade≥3 AEs	8 (73%)
Grade≥3 neurologic AEs	3 (27%)b
Cytokine release syndrome	0 (0%)

Summary and Conclusions: Our results suggest that patients with R/R ALL who have responded to treatment with blinatumomab and have then relapsed may respond to retreatment. Overall, rates of AEs during retreatment were in line with recent clinical experience with blinatumomab.

Background: Central nervous system acute lymphoblastic leukemia (CNS-ALL) is a major clinical problem. Prophylactic therapy is neurotoxic and a third of the relapses involve the CNS. We have previously reported that increased expression of interleukin 15 (IL-15) in leukemic blasts is associated with increased risk for CNS-ALL. As IL-15 is a strong activator of natural killer (NK) cells we hypothesized that NK cells may be involved in regulating CNS leukemia.
Aims: To characterize the role of IL-15 and NK cells in CNS-ALL.
Methods: We have created two in-vivo mouse models: Syngeneic S49 T lymphoma leukemia in BALB/c and human ALL cell lines and primary human ALL xenografts in NOD/SCID and NOD/SCID/IL2Rγ null (NSG) mice. NK cells were manipulated in-vivo by antibody mediated depletion and by human peripheral blood NK (PBNK) cell therapy of xenografted mice. In-vivo studies were complemented by in-vitro killing assays and NK ligand and receptor characterization. Results from mouse models were verified by a case-control study involving RNA and flow cytometry analyses of diagnostic bone marrow leukemia samples from prospective BFM trials of childhood ALL. Ethical approvals were obtained for all mouse and human experiments.
Results: Transplantation of IL-15 expressing S49 leukemia cells in neonatal mice caused marked isolated CNS and ophthalmic leukemia and activation of NK cells. A human B-cell precursor ALL cell line, 018Z, expressing endogenous IL-15 caused isolated CNS leukemia in NOD/SCID, an immunodeficient mouse strain with proficient NK cells. Yet it caused systemic CNS/peripheral leukemia in NSG mice that lack NK cells. Antibody mediated depletion of NK cells in NOD/SCID mice resulted in aggressive combined systemic and CNS leukemia, suggesting that induction of NK cells prevented peripheral but failed to control CNS leukemia. Therapeutic experiment with human PBNK confirmed that NK cells do not enter the brain even in the presence of leukemic infiltration. The killing of human leukemia lymphoblasts by NK cells depended on the expression of the NKG2D receptor. These findings were confirmed in primary human ALLs. The degree of peripheral/CNS leukemia of seven independent primary human ALL xenografts in NOD/SCID mice significantly correlated with IL-15 expression and in-vivo activation of NK cells (P<0.04). Expression of NKG2D receptor evaluated by qRT-PCR and by flow cytometry of NK cells infiltrating diagnostic bone marrows of children treated by BFM protocols for ALL correlated with subsequent CNS involvement (P=0.001). Conversely, the expression of secreted inhibitory "decoy" NK ligands ULBP1 and ULBP3 inversely correlated with CNS positivity (P<0.0001)
Summary and Conclusions: The CNS may be an immunological sanctuary for ALL cells protected from NK cell activity. Markers of activation of NK cells (higher IL15, NKG2D and lower (ULBP1+ULBP3)/ULBP2 ratio) at the time of diagnosis of ALL may be biomarkers for increased risk of CNS relapse. Addition of CNS prophylactic therapy should be considered in NK based therapeutic protocols for hematopoietic malignancies.

Background: Clinical significance of CD20 expression in adult acute lymphoblastic leukemia (ALL) has been evaluated previously, showing that the expression of CD20 was correlated with a bad prognosis in ALL. The addition of rituximab to the conventional treatment showed a promising result in a prospective observational study in a center, although no well-designed prospective interventional study has been performed until now.
Aims: This prospective study has been performed to find out the efficacy and safety of rituximab plus multiagent chemotherapy for patients with CD20-positive acute lymphoblastic leukemia.
Methods: Subjects with newly diagnosed ALL who aged ≥15 years old and were in their good condition were eligible when their leukemic blast cells of bone marrow aspirate express ≥20% of CD20 antigens at time of diagnosis. All patients received induction treatment composed of vincristine/prednisolone/daunorubicin/L-asparaginase (for Ph-neg) or imatinib (for Ph-pos) plus rituximab (375mg/m^2) at day 8. After achieving hematologic complete remission (HCR), subjects received five cycles of consolidation therapy with concomitant rituximab followed by 2 years of maintenance (non-alloHCT). Allogeneic hematopoietic cell transplantation (alloHCT) could be performed whenever after achieving HCR. All subjects received 8 times of rituximab during the whole treatment, irrespective of the adoption of alloHCT-if he/she continued to alloHCT during the consolidation, rituximab was administered monthly from day 90 of alloHCT. Data from 103 patients who were treated with the same cytotoxic drug combination without rituximab in Asan Medical Center from 1997 until 2010 were collected as a historical control group. Toxicity was graded according to National Cancer Institute Common Toxicity Criteria (version 4.0). Data were frozen up in May 2014 for this interim analysis.
Results: Thirty six subjects were eligible for interim analysis-3 subjects were excluded for various causes. The median age of subjects was 42.0 (range 18-71), 31% of them were Ph-positive and 75% were high risk. The median value of CD20 expression was 52.5%. Hematologic CR (HCR) rate was 97% and only one subject failed to achieve HCR owing to death in aplasia during induction. Fourteen subjects received allogeneic hematopoietic cell transplantation (alloHCT) after achieving HCR. Median number of consolidation therapy was 3, and rituximab was introduced 5 times (median) to each subject-rituximab was skipped only 3 times during the cytotoxic chemotherapy schedules of all subjects. After 11.5 months of median follow-up for surviving subjects, the 1-year and 21 –month relapse-free survival (RFS) were 71.5% and 49.1%, respectively, which were significantly higher than those of historical control (55.5% and 38.9%, *p*=0.041). The overall outcomes were not significantly dif-

ferent by the risk group, Ph-status, and the performance of alloHCT. Whereas, the 1-year RFS of subjects with high CD20 expression level (the same or more than the median value) was superior to those with low level (91.7% *vs* 46.4%, *p*=0.033), and this difference of outcome was not observed among the historical control group. Hematologic/non-hematologic toxicity profiles were all tolerable. Only 10 times of infusion-related adverse events associated with rituximab happened, except 1 episode of grade-3 anaphylaxis. Especially, the incidence of acute graft-*versus*-host disease (GVHD) of ≥grade 2 was 21%, and that of chronic GVHD was 21%, which were all tolerable.
Summary and Conclusions: In this interim analysis of the prospective study, combination of rituximab with multiagent chemotherapy was feasible; all adverse events were tolerable, and all the outcomes were not inferior to the results of our historical control. Based on these results, we will continue to recruit subjects up to a total of 77 ones. (Clinicaltrials.gov NCT01429610).

ADAM28 OVEREXPRESSION REGULATED THROUGH PI3K/AKT PATHWAY IS ASSOCIATED WITH POOR PROGNOSIS IN DE NOVO ADULT B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

X.H. Zhang[1,*] C.C. Wang[1], Q.M. Wang[1], F.E. Feng[1], X.L. Zhu[1], Q. Jiang[1], S.M. Yang[1], H. Jiang[1], H.H. Zhu[1], J. Lu[1], T. Zhao[1], L.P. Xu[1], K.Y. Liu[1], X.J. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: B-cell acute lymphoblastic leukaemia (B-ALL) in adults is a very challenging disease. Most patients will go into complete remission, but relapse often occurs. Relapse following remission induction chemotherapy remains the major barrier to patient survival, and relapse is an important part of overall mortality in B-ALL patients after haematopoietic stem cell transplantation. Many relapse patients are currently stratified as standard risk; therefore, additional more accurate biomarkers for relapse and prognosis are needed to improve patient stratification. ADAM28 is an ADAM (a disintegrin and metalloproteinases) metalloproteinase that can cleave myelin basic protein. Studies have demonstrated that ADAM28 is overexpressed in several human tumours and is related to cell proliferation and lymph node metastasis (Takashi Ohtsuka, *et al*. Int. J. Cancer 2005). To date, no information is available on the prognostic role of ADAM28 in B-ALL.
Aims: The aim of this study was to assess ADAM28 expression levels with regard to the potential role of ADAM28 as a prognostic biomarker in B-ALL.
Methods: In total, 50 consecutive patients with de novo B-ALL and 23 healthy donors were enrolled in this study. After obtaining informed consent, ADAM28 expression levels were analysed by flow cytometric assessment and real-time quantitative polymerase chain reaction. Relapse-free survival (RFS), event-free survival (EFS) and overall survival (OS) data after a 2-year follow-up were prospectively collected for prognostic evaluation. *in vitro*, B-ALL cells were isolated from the bone marrow of patients to assess the effect of arsenic trioxide (ATO) on ADAM28 expression. Using selective pharmacologic inhibitors, the PI3K/Akt pathway was demonstrated to be involved in the regulation of ADAM28 expression.
Results: Our data are the first to demonstrate that ADAM28 expression in leukaemic cells from B-ALL patients was significantly increased compared with donor bone marrow cells (P=0.0003). A significant inverse correlation was observed between ADAM28 levels in bone marrow cells and serum expression levels (r^2=0.7512; P=0.0025). Despite considerable variability in expression levels in B-ALL cells, ADAM28 levels were not associated with established risk factors, such as white blood cell count at diagnosis, immunophenotype and karyotype. However, patients experiencing disease relapse or death exhibited significantly increased ADAM28 expression compared with those with a favourable outcome (p=0.0043). Notably, ADAM28 overexpression was associated with a lower probability of relapse-free survival and event-free survival (P<0.001) and was a significant prognostic factor (P=0.010, 0.003, respectively) in a multivariate analysis. *in vitro*, the expression of ADAM28 in leukaemic cells from B-ALL patients was inhibited by ATO in a time-and dose-dependent manner. A significance increase in migratory activity was noted in B-ALL cells overexpressing ADAM28 using the Boyden chamber method. The PI3K/Akt pathway inhibitor down-regulated ADAM28 expression and decreased cell migratory activity.
Summary and Conclusions: Our results are the first to indicate that ADAM28 overexpression in B-ALL patients is correlated with poor outcome. ADAM28 overexpression in B-ALL identifies patients with a high risk of early relapse and reduced RFS, EFS and OS. ADAM28 overexpression enhances cell migration, which is potentially regulated by the PI3K/Akt pathway. These data suggest that ADAM28 might serve as a novel biomarker to evaluate the prognosis of B-ALL and a potential therapeutic target in B-ALL patients.

Background: The prognosis for adult acute lymphoblastic leukemia (ALL) patients with central nervous system (CNS) involvement (CNS+ patients) who received allogeneic hematopoietic stem cell transplantation (allo-SCT) remains unclear.
Aims: We compared the clinical outcomes of allo-SCT in CNS+ patients with those in CNS-patients, and also evaluated prognostic factors for CNS+ patients.
Methods: Clinical data for patients were collected from the Japan Society for Hematopoietic Cell Transplantation database (TRUMP). The eligibility criteria for this study were as follows: diagnosis of ALL or acute biphenotypic leukemia, aged more than 16 years, allo-SCT between 2005 and 2012, and first SCT. Burkitt leukemia or lymphoblastic lymphoma and secondary leukemia were excluded from this study.
Results: Data for 2582 patients including 136 CNS+ patients and 2446 CNS-patients were used for analysis. As compared with CNS-patients, CNS+ patients were younger (median age: CNS+ 36.5 years *vs* CNS-40 years, *P*=0.02), higher frequency of T-cell phenotype (*P*=0.03), had worse disease status at SCT (CR at SCT: CNS+ 55.9% *vs* CNS-80.5%, *P*<0.01) and had worse performance status (PS) at SCT. A myeloablative dose of total body irradiation was more frequently used for CNS+ patients. Other characteristics were not different between the two groups. Incidence of neutrophil engraftment was marginally worse in CNS+ patients (Gray, *P*=0.07), and mortality rate before engraftment was significantly higher in CNS+ patients (Gray, *P*=0.04). Incidences and severity of acute graft-*versus*-host disease (GVHD) and chronic GVHD were not different between CNS+ patients and CNS-patients. Incidence of relapse was higher in CNS+ patients (Gray, *P*=0.02), and the rate of CNS relapse was also higher (9.7% in CNS+ patients *vs* 2.3% in CNS-patients, *P*<0.01). CNS+ patients developed CNS complications more frequently than CNS-patients (*P*=0.02). Incidences of other transplant-related complications and transplant-related mortality were not different between the two groups. At the median follow-up day of 1000 after SCT (range: 15-3137 days), 3-year overall survival (OS) rates were 41.2% in CNS+ patients and 55.8% in CNS-patients, and the difference was statistically significant by univariate analysis (log-rank, *P*<0.01). However, in patients who received SCT in CR, there was no difference in OS rates between CNS+ and CNS-patients (log-rank, *P*=0.38). We performed multivariate analysis (MVA) using Cox's proportional-hazards regression model to adjust the differences of variables. In the MVA, CNS involvement at diagnosis had not an unfavorable effect on OS (hazard ratio: 1.08, 95% confidence interval: 0.85-1.38, *P*=0.53), on the other hand, age, disease status and PS at SCT remained significant prognostic factors for OS. In the MVA focusing in patients who had CNS involvement at diagnosis, disease status and PS at SCT were significant risk factors for OS, and age of the patient was marginally significant.
Summary and Conclusions: Patients who had CNS involvement showed unfavorable OS due to poor disease status and poor PS at SCT. Patients who achieved CR and/or good PS before SCT showed preferable OS even if they had CNS involvement.

P170

REDEFINE CLINICAL RISK CLASSIFICATION IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA USING INITIAL ABSOLUTE LYMPHOCYTE COUNT

K. Suppipat[1,*] P. Fungpipat[1], J. Sophonpan[2], D. Sosothikul[1]
[1]Pediatric Hematology and Oncology unit, Department of Pediatrics, Faculty of Medicine, Chulalongkorn University, [2]Department of Biostatistics, HIV-NAT research collaboration, Thai Red Cross AIDS Research Center, Bangkok, Thailand

Background: Excellent outcome in childhood acute lymphoblastic leukemia (ALL) treatment has been achieved by using risk-stratified therapy. Children with ALL are currently stratified based on various clinical and molecular characteristics to a specific risk group in order to receive an appropriate therapeutic

regimen. Post induction Minimal Residual Disease (MRD) has been used routinely to identify higher risk patients that previously resided in standard risk group by clinical classification. However, the use of MRD is still limited in most developing countries due to the high complexity and high cost of MRD testing. Therefore, a new basic clinical marker is needed to facilitate a better risk classification for children with ALL in resource-limited countries. Absolute lymphocyte count (ALC) during and post induction therapy which is a routine clinical testing has recently been found to associate with treatment outcome in children with ALL.

Aims: To define the level of ALC during induction chemotherapy that has a meaningful correlation to ALL treatment outcomes in Thai children.

Methods: A retrospective cohort of 200 newly diagnosed pediatric ALL patients treated at King Chulalongkorn Memorial Hospital during January 1996-August 2012 were reviewed.The study was approved by Chulalongkorn University Institutional Review Board. ALC level during and post induction period was documented together with other established risk factors. Lowess smoothing Martingale residuals plot was used to determine the optimal cut-point of ALC level. Univariate analysis was performed using Cox proportional hazards model. Multivariate models were developed including covariates with P<0.1 in univariate models and hazard ratios (HR) were estimated with 95% confidence interval. Overall survival and event free-survival were analyzed using the method described by Kaplan and Meier**.**

Results: High ALC at induction Day 1 (ALC-1) and/or Day-28 (ALC-28) were associated with favorable outcome in ALL treatment. Children with ALC-1≥800 cells/μL or ALC-28≥1,860 cells/ μL had a significantly better 10-year overall survival (10Y-OS) [85% (ALC-1≥800 cells/μL) *versus* 60% (ALC-1<800 cells/μL), P<0.001 and 90% (ALC-28≥1,860 cells/ μL) *versus* 75% (ALC-28<1,860 cells/ μL), P=0.02] and 10-year event free survival (10Y-EFS) [80% (ALC-1≥800 cells/μL) *versus* 55% (ALC-1<800 cells/μL), P=0.005 and 80% (ALC-28≥1,860 cells/ μL) *versus* 76% (ALC-28<1,860 cells/ μL), P =0.63]. We can define prognostic subgroups in more details when combining ALC-1 and ALC-28. Children with ALC-1<800 cells/ μL and ALC-28<1860 cells/μL displayed the worse treatment outcome compared to other groups (10Y-OS=52%, HR=6.9, P=0.001 and 10Y-EFS=48%, HR=4.3, P=0.002). Furthermore, ALC can sub-classify the treatment outcome of patients in each established clinical risk group. Standard risk patients with high ALC-1 had a significantly better 10-Y OS [90% (ALC-1≥800 cells/μL) *versus* 60% (ALC-1<800 cells/μL), P=0.01] (Figure1A) and 10-Y EFS [80% (ALC-1≥800 cells/μL) *versus* 45% (ALC-1<800 cells/μL), P=0.002] (Figure1B). Similarly, High ALC-1 in high risk patients also predicted better 10Y-OS [77% (ALC-1≥800 cells/μL) *versus* 50% (ALC-1<800 cells/μL), P=0.05] and 10-Y EFS [80% (ALC-1≥800 cells/μL) *versus* 62% (ALC-1<800 cells/μL), P =0.14].

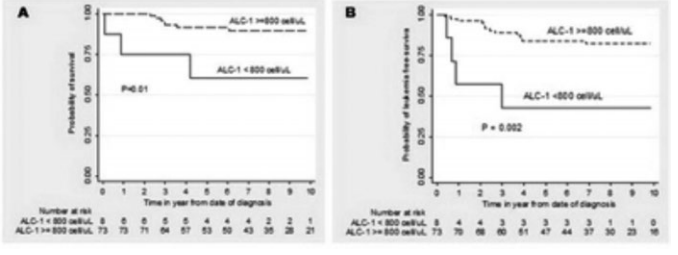

Figure 1. Kaplan-Meier estimate of overall survival (A) and event free survival (B) among standard risk group with high and low ALC-1.

Summary and Conclusions: Unlike most studies which focused mainly on the end of induction ALC, our finding indicated that ALC-1 and/or ALC-28 are new powerful independent prognostic factors in pediatric ALL**.** ALC; which is a simple and readily available clinical tool, can potentially be used as an additional clinical factor to improve risk classification for children with ALL in resource-limited countries.

Acute myeloid leukemia - Biology 1

THE CXCR4 ANTAGONIST BL-8040 DIRECTLY AFFECTS AML BLASTS BY INDUCING THEIR TERMINAL DIFFERENTIATION AND BLOCKING SURVIVAL SIGNALS

Y. Pereg[1,*] M. Abraham[2], S. Klein[2], H. Wald[2], O. Eizenberg[2], B. Bulvik[2], L. Russovsky[1], A. Vainstein[1], A. Aharon[1], T. McQueen[3], A. Al-Rawi[3], N. Pemmaraju[3], G. Borthakur[3], J. Cortes[3], M. Andreeff[3], A. Peled[4]
[1]BioLineRx Ltd., Jerusalem, [2]Biokine Therapeutics Ltd, Ness Ziona, Israel, [3]The University of Texas MD Anderson Cancer Center, Houston, TX, United States, [4]Biokine Therapeutics Ltd and Hebrew University Hospital, Ness Ziona, Israel

Background: Acute Myeloid Leukemia (AML) is a heterogeneous group of diseases characterized by uncontrolled proliferation and survival of hematopoietic stem and progenitor cells. An important characteristic of AML blasts is their ability to avoid terminal differentiation into mature cells. The chemokine CXCL12 and its receptor CXCR4 are key players in the retention of AML blasts in the protective bone marrow (BM) microenvironment. The CXCL12/CXCR4 axis is also critical for the survival and maintenance of AML blasts in their stemness state. In addition, CXCR4 overexpression is associated with poor prognosis in AML patients. We have studied the effect of BL-8040 (BKT140) on the survival, proliferation and differentiation of human AML blasts, using in-vitro systems, AML mice model and correlative studies in human samples obtained from the ongoing relapsed/refractory AML clinical trial (NCT01838395).

Aims: Tostudythe effect of BL-8040 on the survival, proliferation and differentiation of human AML blasts.

Methods: The ability of BL-8040 to induce differentiation of AML blasts was tested in-vitro using MV4-11, HL-60, THP-1, NB4 and U937 cells. The in-vivo effect of BL-8040 on differentiation, survival and apoptosis of human AML MV4-11 cells was tested using AML model of NOD scid gamma (NSG) mice. In humans, as part of an ongoing Phase IIa clinical trial (NCT01838395) samples from subjects who signed informed consent, were evaluated for differentiation and survival of AML blasts following two days of BL-8040 monotherapy.

Results: We have studied the signaling pathways involved in the survival of AML blasts. Our results revealed that these cells are dependent on both, increased survival factors mediated by the PI3K/mTOR/AKT axis and reduced apoptotic potential attributed to increased BCL2 expression. Treatment of AML cells with BL-8040 directly inhibited cell growthand increased cell death. This BL-8040 effect was mediated by inhibition of the mTOR and AKT signaling and by down regulation of BCL2 expression *in vitro* and *in vivo*. Moreover, the treatment with BL-8040 distinctively induced myelomonocytic and granulocytic differentiation *in vitro* and *in vivo*. In the clinical setting, two days of BL-8040 monotherapy triggered a dramatic decrease in the amount of leukemic blasts in the BM in the majority of patients (9/10 patients tested). This decrease was accompanied by an increase in the number of blasts positively stained for apoptosis using cleaved caspase 3 antibody (6/8 patients tested). Furthermore, in the majority of treated patients (7/10 patients tested) the reduction in the number of leukemic blasts in the BM was associated with induction of monocytic and granulocytic terminal differentiation.

Summary and Conclusions: Treatment with BL-8040 as a single agent rapidly and efficientlyinduces cell death of AML cells both in-vitro andin-vivo. This effect is mediated by reduction of the expression of BCL2 and by blocking the survival signals through the PI3K/mTOR/AKT pathway. Furthermore, the present study demonstrates for the first time that CXCR4 inhibition is associated with terminal differentiation of AML blasts in patients. By relieving the differentiation block that characterizes AML blasts along with blockade of survival signals, BL-8040 affects AML blasts survival. Moreover, the current study highlights an important role for BL-8040 as a differentiation therapy which has the potential to translate into clinical benefit.

P172

TARGETING ABERRANT NCAM (NEURAL CELL ADHESION MOLECULE; CD56) EXPRESSION IN ACUTE MYELOID LEUKEMIA

D. Sasca[1,*] O. Kriege[1], K. Kunz[1], A. Schüler[1], J. Szybinski[1], E.M. Fehr[1], P. Haehnel[1], M. Theobald[1], L. Bullinger[2], T. Kindler[1]
[1]Department of Hematology, Oncology and Pneumology, University Medical Center of Mainz, Mainz, [2]Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: Acute myeloid leukemia (AML) is a heterogenous disease of the hematopoietic progenitor cell driven by the subsequent acquisition of genetic alterations. Although new technologies (*e.g.* NGS) have substantially contributed to our understanding of the genetic complexity of the disease, cellular consequences often remain elusive. Approximately 20% of AML patients show strong expression of CD56 (neural cell adhesion molecule; NCAM), a cell surface marker typically found in natural killer cells. Expression of NCAM is asso-

ciated with poor overall survival, however, the functional role of aberrant NCAM expression has not been investigated to date.
Aims: The goal of this study is to examine the biological role of NCAM in AML and to explore whether NCAM represents a potential therapeutic target.
Methods: The function of NCAM was investigated in several human AML cell lines. Cells were infected with lentivirus expressing a Doxycyclin-inducible shRNA directed against NCAM or scrambled shRNA. Genetically modified cells were analyzed for proliferation, cell death and downstream signaling pathways. In addition, we performed xenotransplantation experiments to explore the role of NCAM as a therapeutic target. Upstream regulatory mechanisms were investigated by DNaseI-hypersensitive assays and modified qRT-PCR mapping. To analyze NCAM effects at the stem cell level we made use of a well-established murine MLL-AF9 leukemia model using C57BL/6 wild-type or NCAM-/-mice and performed serial replating assays and bone marrow transplantation experiments.
Results: NCAM was expressed in several human cell lines (NOMO1, MOLM-14, THP1, SKM1 and others) at high levels and correlated with MLL-rearranged leukemias. Knockdown of NCAM using three different shRNA clones caused diminished proliferation, G1-arrest and finally apoptotic cell death. Suppression of NCAM sensitized leukemic blasts to genotoxic stress *in vitro* and prolonged survival of mice in xenotransplantation experiments. Applying DNaseI-hypersensitivity assays we demonstrate accessible binding sites for the transcription factors MEIS1, MEF2c and STAT1. shRNA-mediated knockdown of MEIS1, MEF2c and MLL-AF9 resulted in downregulation of NCAM cell surface expression, suggesting an upstream regulatory role for MLL-AF9. Analysis of downstream signaling pathways upon knockdown of NCAM demonstrated activation of SMAD2/3, p38 and upregulation of CDKN1a. To analyze NCAM expression in leukemia-initiating cells (LICs), we infected wild-type and NCAM-/-derived bone marrow cells with MLL-AF9 expressing viral particles and transplanted syngeneic recipient mice. Analysis of wild-type LICs ($Lin^-c\text{-}Kit^+CD34^+FcgR^+$) demonstrated strong surface expression of NCAM, whereas normal HSCs ($Lin^-c\text{-}Kit^+Sca1^+$) were NCAM-negative. Recipients of $NCAM^{-/-}$-MLL-AF9_cells developed acute leukemia with prolonged disease latency, and in colony assays replating activity was diminished. $NCAM^{-/-}$MLL-AF9 cells had lower CD117 and Gr-1 expression, but higher expression of Mac-1 and, in some samples, aberrant B220 co-expression. To analyze whether aberrant NCAM-expression is essential to maintain self-renewal activity we currently perform serial bone marrow transplantation experiments.
Summary and Conclusions: Targeting aberrant expression of NCAM by shRNA-mediated gene knockdown demonstrated strong antileukemic activity *in vitro* and sensitized leukemic blasts to genotoxic stress. *in vivo*, depletion of NCAM resulted in prolonged disease survival in syngeneic and xenotransplantation experiments and diminished self-renewal capacities. Our data suggest that NCAM represents a promising therapeutic strategy and likely targets AML cells at the LIC level.

P173

GENETIC AND EPIGENETIC EVOLUTION DURING THE PROGRESSION OF CYTOGENETICALLY NORMAL ACUTE MYELOID LEUKEMIA (CN-AML)

S. Vosberg[1,2,3,4,*] P.A. Greif[1,2,3,4], L. Hartmann[1,2,3,4], K.H. Metzeler[1,2,3], D. Schumacher[3], F. Pastore[3], K. Bräundl[1,2,3], E. Zellmeier[3], B. Ksienzyk[3], N. Konstandin[3], S. Schneider[3], A. Graf[5], S. Krebs[5], H. Blum[5], M. Neumann[6], C.D. Baldus[6], S.K. Bohlander[7], Y. Assenov[1], C. Plass[1], S. Wolf[1], S. Wiemann[1], W. Hiddemann[1,2,3,4], K. Spiekermann[1,2,3,4]
[1]German Cancer Research Center (DKFZ), [2]German Cancer Consortium (DKTK), Heidelberg, [3]Internal Medicine III, University Hospital LMU Munich, [4]Clinical Cooperative Group Leukemia, Helmholtz Zentrum München, [5]Laboratory for Functional Genome Analysis (LAFUGA), Gene Center LMU Munich, München, [6]Department of Hematology and Oncology, Charité University Hospital Berlin, Berlin, Germany, [7]Department of Molecular Medicine and Pathology, The University of Auckland, Auckland, New Zealand

Background: Clonal evolution in acute myeloid leukemia (AML) has been previously described either in studies of large patient cohorts with focus on only a restricted number of AML-associated genes or in smaller series of relapsed patients studied by genome-wide techniques.
Aims: To better understand the genetic and epigenetic mechanisms of relapse and therapy-resistance of AML, we performed exome sequencing and DNA-methylation profiling of matched bone marrow or peripheral blood samples taken at diagnosis, remission and relapse from 47 patients with cytogenetically normal AML (CN-AML) with a median age at diagnosis of 65 (range 21-89).
Methods: Paired-end sequencing (Illumina) with a mean target coverage of >100x resulted in an average of 95% of the exome covered at least 10-fold. Variants at diagnosis or relapse were called with a minimum variant allele frequency (VAF) of 20%. Mutations with a VAF≤5% at remission were defined as somatic, whereas mutations in known AML-associated genes (n=40, *e.g. DNMT3A*, *IDH2*, *SRSF2*) with VAF>5% at remission were considered as persistent during remission. After exclusion of common germline polymorphisms (dbSNP 138; MAF≥1%) and known error-prone genes (*e.g. MUC4*), we filtered for mutations with translational consequences and validated them by custom genepanel sequencing (HaloPlex, Agilent) with a mean target coverage of >300x. On average, 94% of the target region was covered at least 20-fold. DNA-methylation was analyzed using Illumina Infinium HumanMethylation450 BeadChip technology.
Results: Overall, 104 genes were recurrently mutated, while 7 genes were recurrently altered only at diagnosis (*e.g. CBL*) and 16 genes were recurrently altered only at relapse (*e.g. KDM6A*, *SRSF2*, *SF3B1*). The median number of somatic mutations per patient was 7 at diagnosis and 8 at relapse, whereas a gain or loss of mutations could be detected in 41 patients (87%). A median of 1 mutation is lost in relapse (*e.g. FLT3* point mutations, range 0-5), a median of 2 mutations were acquired during AML progression (*e.g. WT1*, range 0-5) while mutations in several AML-associated genes (*e.g. DNMT3A*) remained stable during the course of disease. In 60% of patients, the major clone at diagnosis remained predominant at relapse whereas expansion of a subclone during disease progression was observed in 40% of patients. A total of 5 patients acquired chromosomal alterations at relapse, with trisomy 8 as the only recurrent chromosomal abnormality present in 3 patients. A total of 22 patients (47%) had persistent mutations at remission with 40/54 (74%) mutations showing a dynamic pattern in their VAFs (relative change ≥20%). *DNMT3A* was the most frequently affected gene (Figure 1A), and patients with persistent *DNMT3A* mutation had a significantly shorter relapse-free survival compared to patients with not-persisting *DNMT3A* mutation (Figure 1B, n=13, median 270 days, range 81-586 *vs* n=7; median 508 days; range 235-1697; p=0.012). *DNMT3A* R882 mutations correlated with a specific DNA-methylation profile, characterized by hypomethylation of HOX genes at diagnosis. Of note, even at remission we were able to measure the *DNMT3A* R882 mutation-specific DNA-methylation pattern in patients with persistent mutations at VAF≥25%. These results suggest altered DNA-methylation at the pre-leukemic stage.

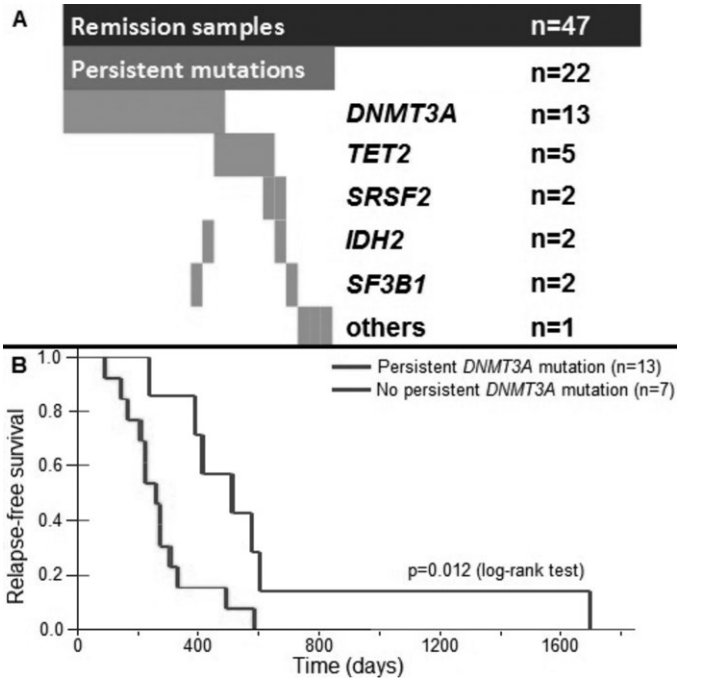

Figure 1.

Summary and Conclusions: In summary, our findings provide insights into the genetic and epigenetic evolution during the course of disease in a large cohort of relapsed CN-AML. Information about the dynamics of genetic lesions (*e.g.* persistent or relapse-specific mutations) may have prognostic applications and provide the basis for tailored approaches to treat or to prevent relapse of AML.

P174

GENOTOXIC STRESS MODULATES EVI1 INTERACTION WITH CTBP1 IN ACUTE MYELOID LEUKAEMIA CELLS

M. Schneider[1,*] R. Paredes[1], D.J. White[1], A. Pierce[1], A.J. Williamson[1], A.D. Whetton[1], S. Meyer[1,2,3]
[1]Stem Cell and Leukaemia Proteomics Laboratory, Institute of Cancer Sciences, University of Manchester, [2]Department of Paediatric Oncology, Royal Manchester Children's Hospital, [3]Department of Paediatric and Adolescent Oncology, University of Manchester, Manchester, United Kingdom

Background: EVI1 proto-oncogene overexpression is associated with adverse prognosis in acute myeloid leukaemia (AML). EVI1 is a DNA binding transcriptional regulator. It forms complexes with multiple protein partners including chromatin re-modellers and transcriptional repressors, such as C-terminal binding protein (CtBP). Understanding EVI1 protein interaction dynamics will be important for novel therapeutic approaches.

Aims: The identification and characterisation of EVI1 protein interactions modulated by EVI1 phosphorylation.
Methods: EVI1 phosphorylation was detected by MIDAS mass spectrometry in EVI1 overexpressing AML SB1690CB cells. Flag-tagged wild type EVI1 and phosphorylation site mutated constructs were generated. Mouse bone marrow or HEK293T cells overexpressing the constructs were used for re-plating experiments, co-immunoprecipitation and immunofluorescence. Genotoxic stress was induced by 2Gy radiation and hydrogen peroxide(H_2O_2) treatment.
Results: We detected EVI1 phosphorylation at the C-terminal SQSP motif (serine858 and860). EVI1 constructs with alanine-mutated phospho-sites (A/A-EVI1) maintained the EVI1 transforming capabilities in transduced mouse bone marrow serial replating experiments. Proteomic interactome studies comparing WT-and A/A-EVI1 in an overexpression system confirmed interaction with co-repressor CtBP1. Co-immunoprecipitation showed significantly reduced CtBP1 binding with A/A-EVI1 compared to WT-EVI1 after induction of DNA damage. Higher levels of co-immunoprecipitated CtBP1 bound to EVI1 in damaged *versus* undamaged cells were confirmed in SB1690CB cells. Immunofluorescence analysis showed significantly higher co-localisation of WT-EVI1 with CtBP1 and reduced co-localisation of A/A-EVI1 with CtBP1 after DNA damage compared to undamaged cells.
Summary and Conclusions: Genotoxic stress induces EVI1 C-terminal phosphorylation and modulates EVI1 interactions with the co-repressor CtBP1. This links the DNA damage response to transcriptional repression in EVI1 overexpressing AML.

P175

COMBINING IMMUNE CHECKPOINT INHIBITION WITH AMG 330 TO ENHANCE T CELL MEDIATED LYSIS OF PRIMARY AML CELLS

C. Krupka[1,2,*] F. Lichtenegger[1,2], F. Brauneck[1,2], P. Kufer[3], R. Kischel[3], G. Zugmaier[3], T. Köhnke[1,2], T. Altmann[1,2], S. Schneider[1], M. Fiegl[1], K. Spiekermann[1], P. Bäuerle[3], W. Hiddemann[1], G. Riethmüller[4], M. Subklewe[1,2]
[1]Department of Internal Medicine III, Klinikum der Universität München, [2]Clinical Co-operation Group Immunotherapy, Helmholtz Institute Munich, [3]AMGEN Research (Munich) GmbH, [4]Institute for Immunology, Ludwig-Maximilians-University Munich, München, Germany

Background: Bispecific T-cell engaging (BiTE®) antibody constructs are very efficient in recruiting and activating T cells. Through the strong T-cell activation, proinflammatory conditions are generated, favouring the upregulation of immune checkpoint molecules on cancer cells. Blockade of immune-suppressive receptor-ligand interactions could potentially enhance BiTE® mediated cytotoxicity.
Aims: In this study we tested the relevance of immune checkpoint molecules on CD33/CD3 BiTE® antibody construct (AMG 330) mediated lysis of primary AML cells in *ex vivo* cytotoxicity assays.
Methods: The expression profiles of PD-L1 (n=123), CD277 (n=70) and ILT3 (n=55) were assessed by flow cytometry (Specific fluorescence intensity, SFI) in newly diagnosed AML patient samples. A long-term culture system supporting the growth of primary AML cells for up to 36 days *ex vivo* was used to determine the functional relevance of immune checkpoint molecules on AMG 330 mediated lysis. The long-term culture system enabled us to analyze the dynamic process of inhibitory molecule expression and receptor-ligand interaction over time.
Results: No constitutive expression could be detected for PD-L1 at primary diagnosis in 83.7% of the cases. In contrast, constitutive expression of CD277 and ILT3 was detected in 77% and 100% of patient samples respectively. As has been reported previously, the expression pattern of immune checkpoint molecules can be modulated through proinflammatory conditions. Therefore, the expression profile of the inhibitory molecules on different AML cell lines and primary AML cells after addition of IFN-γ and TNF-α was analyzed. PD-L1 was strongly induced on AML cell lines and primary AML cells (mean fold change SFI: AML cell lines 3.5, n=6; primary AML cells 9.2, n=6). In contrast, no further increase in ILT3 expression levels was detected (mean fold change SFI: AML cell lines 0.7, n=5; primary AML cells 1.2, n=3). The cytokine-mediated upregulation of other immune checkpoint molecules including CD277 on AML cells is currently being evaluated. In several studies it was shown, that BiTE® antibody constructs induce strong T-cell activation, which is accompanied by secretion of IFN-γ and TNF-α. Using our long-term culture system we observed a considerable upregulation of PD-L1 on primary AML cells after 1-4 days of *ex vivo* cytotoxicity assay (SFI control BiTE® (cBiTE®) *vs* AMG 330 1.8: 9.4, *p<0.0001;* n=27). Blocking of the PD-1/PD-L1 interaction significantly enhanced AMG 330 mediated lysis efficacy (% lysis: AMG 330 58% *vs* AMG 330+α-PD-1/PD-L1 blocking antibody 75%, n=9, *p=0.03)* which was accompanied by a significant increase in T-cell proliferation (fold change $CD2^+$ cells: cBiTE® 0.8 *vs* cBiTE®+α-PD-1/PD-L1 blocking antibody 1.0, *p=0.06*; AMG 330 8.0 *vs* AMG 330+α-PD-1/PD-L1 blocking antibody 11.1, n=9, *p=0.008*). In addition, IFN-γ secretion was significantly enhanced (IFN-γ secretion: cBiTE® 7.8 pg/ml *vs* cBiTE®+α-PD-1/PD-L1 blocking antibody 16.5 pg/ml, *p=0.03;* AMG 330: 1573 pg/ml *vs* AMG 330+α-PD-1/PD-L1 blocking antibody: 2060 pg/ml, n=8, *p=0.008)*. The functional relevance of other immune checkpoint molecules in AMG 330 mediated lysis efficacy is currently being evaluated in analogous experiments.
Summary and Conclusions: AMG 330-mediated cytotoxicity is modulated by blockade of inhibitory molecules on AML cells. Our results support the use of combinatorial approaches of BiTE® antibody constructs with PD-1/PD-L1 immune checkpoint blockade.

P176

DIFFERENTIAL RESPONSIVENESS OF PML-RARA CARRYING VARIOUS POINT MUTATIONS TO ARSENIC TRIOXIDE

J. Liu[1,*] H. Zhu[1], H. Jiang[1], Q. Jiang[1], X. Huang[1]
[1]Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Expression of the fusion gene, promyelocytic leukemia (*PML*)–retinoic acid receptor-α (*RARA*), initiates acute promyelocytic leukemia (APL) and plays a crucial role in APL pathogenesis. Arsenic trioxide cures APL through targeting PML-RARA oncoprotein for degradation and further eradicating the malignant cells. A growing amount of evidence supports arsenic trioxide as a front-line drug in APL treatment and the overall survival of APL patients has been improved dramatically. Unfortunately, there are not a few patients developed arsenic resistance during therapy and their outcomes were extremely dismal. Previous study has reported that A216V and L218P mutation in the PML moiety of PML-RARA were detectable in two APL patients at relapse. More recently, we identified a mutational hot spot (including previously reported A216V, newly identified S214L, A216T, L217F and S220G) within PML-RARA transcripts from 9 of 13 patients with relapsed APL. Whether all these acquired mutations play a role underlying the mechanism of clinical arsenic resistance are still unknown.
Aims: To explore if each of the identified mutations virtually plays a role and functions similarly underlying the mechanism of arsenic-resistance.
Methods: The recombinant plasmids of wild type and mutant PML-RARA were transfected into cultured Hela cells followed by the treatment with or without As_2O_3. The protein levels and cellular localization were detected by immunoblotting and immunofluorescence analysis. A retrospective analysis was performed to validate whether various point mutations of PML-RARA functioned distinctly in APL patients. The morphological characteristics and the expression levels of PML-RARA transcripts in bone marrow of included patients were monitored before and after reinduction treatment with arsenic.
Results: Immunoblotting analysis showed that total protein levels of PML-RARA mutants with L217F or S220G were significantly decreased upon As_2O_3 treatment (regular dose), similar with the phenotype of wild type PML-RARA. This finding was in parallel with the enhanced nuclear matrix association and SUMOylation of L217F and S220G mutant proteins triggered by As_2O_3. Whereas mutants with A216V, S214L or A216T did not respond to As_2O_3 treatment in the same experimental conditions. Importantly, the varying responsiveness of different point mutations to arsenic observed *in vitro* was conserved in the clinical setting. Relapsed APL patients respectively with A216V, S214L or A216T mutation had strong resistance to the reinduction therapy with arsenic. Temporarily moderate drug resistance was found in a patient with S220G mutation. In contrast,one patient with L217F mutation achieved a complete remission after reinduction treatment. Furthermore, we showed that high dose of As_2O_3 was capable to reverse the primary arsenic resistance driven by indicated mutations in the PML B2 domain of PML-RARA in cultured cells.
Summary and Conclusions: Our results reinforce the correlation of genetic mutations found in the PML part of PML-RARA transcript with arsenic resistance during APL therapy. We also propose a novel insight regarding that the acquired mutations exhibited varying responsiveness to arsenic treatment both *in vitro* and *in vivo*. Our findings may help in predicting the prognosis and selecting more effective strategies for the management of relapsed APL.

P177

SURVIVAL PREDICTION AND IDENTIFICATION OF KEY PROGNOSTIC PROTEINS IN ACUTE MYELOID LEUKEMIA USING REVERSE PHASE PROTEIN ARRAY

E. Joffe[1,*] Y.H. Qiu[2], N. Zhang[3], S.E. Neely[4], Y. Suk-Young[3], K.R. Coombs[5], S.M. Kornblau[2]
[1]Hematology and Bone Marrow Transplantation, Davidoff Cancer Center-Rabin Medical Center, Petah-Tikva, Israel, [2]Department of Leukemia, [3]Bioinformatics and Computational Biology, University of Texas MD Anderson Cancer Center, Houston, Texas, [4]Department of Statistics, Brigham Young University, Provo, Utah, [5]Biomedical Informatics, Ohio State University, Columbus, Ohio, United States

Background: Novel proteomic technologies, allow for accurate and rapid profiling of the cellular protein ecosystem in Acute Myeloid Leukemia (AML). The high throughput data they generate could be used to build better prognostic models, to identify new targets for therapy, and to individualize treatment.
Aims: To use high-dimensional survival models to identify key prognostic proteins in AML and to compare the performance of proteomics based survival models to that of commonly used prognostic factors.

Methods: We used reverse-phase protein array (RPPA) to measure the level of total and phosphorylated expression of 230 proteins in leukemia-enriched cell samples from 384 newly diagnosed AML patients. We used Cox regressions with the Least Absolute Shrinkage and Selection Operator regularization to construct multivariate prediction models for overall and relapse-free survival (OS&RFS) and to identify the key prognostic proteins. To calculate coefficients and evaluate model performance we employed a 100 iteration bootstrapping procedure. We repeated the analyses for the subset of patients with normal karyotype AML and younger patients (≤60).
Results: Multivariate prognostic models based on proteomics performed at least as well as models based on commonly used prognostic covariates including age, sex, performance status, prior malignancy or hematological disease, cytogenetics and FLT-ITD mutation analysis (C-Index 0.71 *vs* 0.69 respectively for RFS). Multivariate survival models highlighted multiple proteins associated with survival. Of these, the most pronounced were ARC, IGFBP2, INPP5D, TP53 and CCND3 which appeared in univariate and multivariate analyses. STAT3, XIAP, and CDK2 were identified only by multivariate models, suggesting they are of relevance only in the context of the expression of other proteins. In younger patients we further identified SMAD5, phospho-ERBB2, phospho-MTOR, and CCNE2. Genetic alterations associated with many of these proteins have been previously implicated in the pathogenesis of AML and provide an external validation to our results. For most however this work is the first evaluation of their prognostic significance. Finally, using proteomics based risk scores we were able to discern subgroups of patients with differing survival. This risk stratification outperformed stratification based on cytogenetics. Further, we identified distinct subgroups among patients with a normal karyotype (RFS not-reached, 150 and 39 weeks, p<0.0001). Our results bare a considerable similarity to risk stratification based on genetic alterations presented in other studies, though the validity of such a comparison is limited due to variability in patient populations and a lack of standardized reporting.

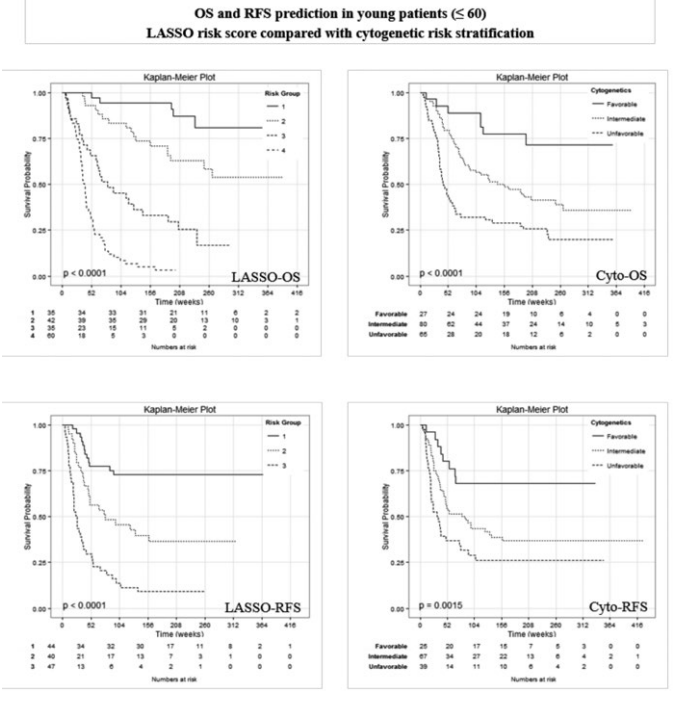

Figure 1.

Summary and Conclusions: RPPA is an efficient tool for rapid and high throughput proteomic profiling. Using the proteomic data with advanced survival modeling can reliably identify multiple proteins with a significant prognostic value as targets for future research and novel therapeutics.

P178

MICRORNA-182, C/EBPA AND E2F GENERATE AN AUTOREGULATORY FEEDBACK NETWORK WHICH IS DYSREGULATED IN ACUTE MYELOID LEUKEMIA

A.A. Wurm[1,*] M. Alberich-Jorda[2], P. Zjablo*v*skaja[2], D. Gerloff[1], D. Braeuer-Hartmann[1], C. Katzerke[1], J.U. Hartmann[1], S. Fricke[3], N. Hilger[3], D.G. Tenen[4], D. Niederwieser[1], G. Behre[1]
[1]Hematology/Clinical Oncology, University Leipzig, Leipzig, Germany, [2]Institute of Molecular Genetics, Academy of Sciences of the Czech Republic, Praque, Czech Republic, [3]Fraunhofer Institute for Cell Therapy and Immunology, Leipzig, Germany, [4]Harvard Medical School, Boston, MA, United States

Background: The transcription factor CCAAT enhancer binding protein alpha (C/EBPα) is a master regulator of granulopoiesis and is inactivated in approximately 50% of all acute myeloid leukemia (AML) cases. MicroRNAs, a class of small non-coding RNAs, were identified as important regulators of normal hematopoiesis and leukemia development. We have already shown that microRNAs, such as miR-223, miR-34a and miR-30c, are essential elements in C/EBPα triggered granulocytic differentiation.But to our knowledge nothing is known about inactivation of C/EBPα by microRNAs in acute myeloid leukemia.
Aims: Functional characterization of miR-182 in AML.
Methods: We used Next Generation Sequencing to detect novel C/EBPα related microRNAs. To investigate the function of miR-182, we used several *in vitro* and *in vivo* systems, including cell lines, primary AML cells and a transplantation based mouse model.
Results: In this study, we identified a novel network between C/EBPα, miR-182 and E2F. In a next generation sequencing approach based on inducible K562-C/EBPα-ER cell line, we found miR-182 strongly downregulated by wild-type C/EBPα. We could further demonstrate an inverse correlation between C/EBPα protein amount and miR-182 expression level in several biological systems, including leukemic cell lines, G-CSF treated primary human CD34$^+$ progenitor cells *in vitro* and sorted murine bone marrow subpopulations *in vivo*. Additionally, we found elevated miR-182 expression levels in lineage-negative, c-kit-positive myeloid progenitors of *CEBPA* Knock-Out mice. To discover the mechanism how miR-182 is blocked by C/EBPα, we analyzed the minimal promoter region of miR-182 and performed chromatin immunoprecipitation (ChIP). Here, we could demonstrate a strong binding of C/EBPα to the miR-182 promoter, particularly to a conserved E2F binding site. Because E2F is a well known inhibitor of C/EBPα function, we tested whether E2F also effects miR-182 expression. An overexpression of E2F1 in U937 cells leads to an elevated miR-182 expression level. In addition, we measured the expression of miR-182 in bone marrow from AML patients regarding to their CEBPA mutation status. We could show that only patients with mutations in the C-terminal region of C/EBPα showed increased miR-182 expression levels, while patients with N-terminal CEBPA mutations revealed no abnormal miR-182 expression compared to healthy donors or AML patients with no CEBPA mutation. The C-terminal domain of C/EBPα is necessary for E2F inhibition. These findings illustrate the importance of C/EBPα-E2F interaction during miR-182 regulation. Next, we found a highly conserved binding site of miR-182 in the 3'UTR of CEBPA itself, suggesting a possible negative feedback loop. To test this, we performed overexpression of miR-182 in U937 cells, umbilical cord blood mononuclear cells (UCB-MNCs) and primary blasts from AML patients. Here, we observed a strong reduction of C/EBPα protein after miR-182 overexpression in all cell types. Furthermore, we could demonstrate a direct binding of miR-182 to the 3'UTR of *CEBPA* via luciferase activity assay. Finally, we were interested in the functional impact of miR-182 in myeloid differentiation and leukemia development. We showed that stable overexpression of miR-182 blocks granulocytic differentiation in G-CSF treated 32D cells and enhances replating capacity of primary mouse bone marrow mononuclear cells. Moreover, we could demonstrate that enforced expression of miR-182 in mouse Lin-Sca-1+c-Kit+ early hematopoietic progenitors by lentiviral infection leads to a strong reduction of mature Mac1+Gr1+ granulocytes in the peripheral blood *in vivo*.
Summary and Conclusions: Taken together, we identified miR-182 as novel oncogenic microRNA that directly blocks C/EBPα during myeloid differentiation and leukemia development. Thus, our data display a potential new strategy for therapeutics in C/EBPα dysregulated AML.

P179

THE LEUKEMIA-ASSOCIATED RUNX1/ETO ONCOPROTEIN CONFERS A MUTATOR PHENOTYPE

V. Forster[1,*] M. Nahari[1], N. Martinez-Soria[1], A. Bradburn[2], A. Ptasinska[3], S. Assi[3], H. McNeill[1], C. Bonifer[3], O. Heidenreich[1], J. Allan[1]
[1]Northern Institute for Cancer Research, Newcastle University, Newcastle upon Tyne, [2]Institute for Cancer Research, London, [3]Cancer Cell Biology and Epigenetics, University of Birmingham, Birmingham, United Kingdom

Background: One of the key processes in oncogenesis is the transition from a premalignant to a fully malignant state. The chromosomal translocation (8;21) is an initiating event in acute myeloid leukaemia (AML) and generates the *RUNX1/ETO* fusion gene.*RUNX1/ETO* drives self-renewal, but is insufficient for leukaemogenesis, requiring further mutations for transformation. We postulated that this leukaemic fusion protein may affect the acquisition of mutations.
Aims: In this project, our aims were to investigate whether and how RUNX1/ETO impacts on the acquisition of secondary mutational hits, thereby promoting the generation of fully developed leukaemia.
Methods: We investigated the effect of*RUNX1/ETO*expression on susceptibility to spontaneous and exposure driven mutation in TK6 cells. After lentiviral transduction with *RUNX1/ETO*, we isolated TK6 clones withvarying levels of *RUNX1/ETO*expression. We used the *PIGA* assay as an initial measure of spontaneous and exposure-induced mutation. Loss of this glycosyl-phosphatidylinositol(GPI) anchor protein results in an absence of GPI-linked proteins from the cell membrane, including CD55 and CD59.Cells that are simultaneously negative for two GPI-linked proteins are considered to be*PIGA*mutants

and are detected using fluorochrome-conjugated antibodies and analysed by flow cytometry. We also used the*thymidine kinase(TK)* gene as a second mutational target for exposure-induced mutation.
Results: We determined the *PIGA* mutation frequency (M*f*) in several independent *RUNX1/ETO*-expressing and vector control clones 8-10 weeks after initial cloning. The mean *PIGA* M*f* in *RUNX1/ETO* clones (7.5×10^{-4}) was 5 times higher than in vector control clones (1.5×10^{-4}) (p=0.032). We next investigated whether *RUNX1/ETO* cells were sensitive to mutagenesis following exposure to genotoxic agents. Fusion protein positive and vector control clones were exposed to sub-cytotoxic doses of doxorubicin (100nM) or ionising radiation (3Gy), and M*f* was measured 2 weeks after treatment. The mean treatment-induced *PIGA* M*f* was strongly increased in *RUNX1/ETO* clones compared to vector control clones following doxorubicin (Mean M*f* =6.5×10^{-4} *vs* 2.1×10^{-4}, p=0.09) or radiation treatment (Mean M*f* =5.9×10^{-4} *vs* 2.1×10^{-4}, p=0.008). This was confirmed by assaying at the *TK* locus, where mean treatment-induced M*f* was also significantly higher in RUNX1/ETO cell clones compared to vector control clones following either doxorubicin (Mean M*f* =3.5×10^{-6} *vs* 4.3×10^{-7}, p=0.014) or radiation treatment (Mean M*f* =6.4×10^{-6} *vs* 1.5×10^{-6}, p=0.002). For both *PIGA* and *TK*, the M*f* in vector control clones following doxorubicin or radiation treatment was not significantly different from mock-treated cells. Additionally, using ChIP, we showed that RUNX1/ETO directly binds to and represses the OGG1 base-excision repair DNA glycosylase and that RNAi mediated depletion of *RUNX1/ETO* in t(8;21) cell lines significantly increases OGG1 transcript and protein levels, providing a plausible reason for the increased M*f* shown in RUNX1/ETO cells.
Summary and Conclusions: We have shown that RUNX1/ETO predisposes to the acquisition of mutations, both spontaneously and after treatment with genotoxic agents. RUNX1/ETO actively promotes the acquisition of secondary mutations thereby expanding genetic heterogeneity in the population from which malignant clones can emerge. We also suggest that late-relapse in t(8;21) AML may be due to the presence of RUNX1/ETO positive, genetically unstable pre-leukaemic clones in the bone marrow, which are prone to mutation acquisition, leading to leukaemia relapse.

P180

EVALUATION OF MINIMAL RESIDUAL DISEASE IN CHILDREN WITH CORE BINDING FACTOR ACUTE MYELOID LEUKEMIA-RESULTS OF THE FRENCH MULTICENTER ELAM02 TRIAL

H. Lapillonne[1,2,*] A. Marceau-Renaut[3], M.M. Coude[4], P. Ballerini[5], C. Ragu[6], N. Duployez[3], A. Petit[7], O. Fenneteau[8], W. Cuccuini[9], C. Preudhomme[3,10], G. Leverger[2,7]
[1]Hematology, AP-HP, Trousseau Hospital and UPMC Paris 6, [2]Hematology, INSERM, UMR_S938 CDR Saint-Antoine, Paris, [3]Hematology, Lille University Hospital, Lille, [4]Hematology, AP-HP Saint-Louis Hospital, [5]Hematology, [6]Pediatric Hematology and Oncology, AP-HP, Trousseau Hospital, [7]Pediatric Hematology and Oncology, AP-HP, Trousseau Hospital and UPMC Paris 6, [8]Hematology, AP-HP, Robert Debré Hospital, [9]Cytogenetic, AP-HP Saint-Louis Hospital, Paris, [10]U837, Team 3, INSERM, Lille, France

Background: Acute myeloid leukemia (AML) with t(8;21)(q22;q22) or inv(16)(p13q22) chromosomal rearrangement corresponding to the RUNX1-RUNX1T1 or CBFb-MYH11 fusion transcripts respectively, belongs to the core binding factor (CBF) AML, a favorable-risk subgroup of AML. Nonetheless, 30% of patients with CBF-AML relapse. Prognostic factors have been identified in adult studies to detect patients at higher risk of relapse, such as older age, high white blood cell count, additional cytogenetic abnormalities or gene mutations, and minimal residual disease response to therapy. Especially in adult CBF-AML patients, it has been shown that a log reduction under 3-log in transcript level after 2 courses of chemotherapy, was associated with a significant increased risk of relapse. In children CBF-AML accounts about 20% of de novo AML with an unexpected relatively high incidence of relapse in the RUNX1-RUNX1T1 subgroup. There is need to identify factors able to predict a high risk of relapse. Few studies have reported the prognostic relevance of minimal residual disease in pediatric CBF-AML.
Aims: The main aim of the study was to quantify and follow the minimal residual disease of CBF fusion transcripts during therapy in order to determine its prognostic relevance and to identify patients who might benefit of allogeneic hematopoietic stem cell transplantation in first complete remission in the future protocol.
Methods: 438 children were treated between 2005 and 2011 in the French pediatric ELAM02 trial. We focused on 97 patients with CBF-AML including 61 AML with t(8;21)(q22;q22) and 36 AML with inv(16)(p16q22). RUNX1-RUNX1T1 and CBFb-MYH11 transcripts were quantified by real-time PCR at diagnosis, and after each course of chemotherapy (MRD1, MRD2, MRD3, MRD4) according to the trial design.
Results: Patients with inv(16)(p16q22) AML had higher WBC and more frequent CNS involvement than those with t(8;21)(q22;q22). N/K-RAS mutations were more frequent in the inv(16)(p16q22) subset, ASXL2 mutations more frequent in t(8;21)(q22;q22) subset, whereas KIT gene mutations were equally frequent in both subsets. At diagnosis, the median fusion transcript ratio was higher in RUNX1-RUNX1T1 patients [258.7, range 20-1685] than in CBFb-MYH11 patients [94.4, range 31.5-447]. Incidence of relapse was 39.3% and 16.7% in t(8;21) and inv(16) respectively. In the RUNX1-RUNX1T1 subset, MRD log reduction evaluation shows that 19 (41%) of 46 patients at MRD2 and 8 (21%) of 38 patients at MRD3 did not reach 3-log reduction in fusion transcript ratio level. In the CBFb-MYH11 subset, MRD log reduction evaluation shows that 20 (67%) of 30 patients at MRD2 and 18 (67%) of 27 at MRD3 did not reach 3-log reduction in fusion transcript ratio level. The 5-year DFS was not significantly different at any point between MRD positive and MRD negative in both subgroups: 48±11% *versus* 49±12% at MRD2 and 48±10% *versus* 37±17% at MRD3 in RUNX1-RUNX1T1 subset and 100% *versus* 79±9 at MRD2 and 89±10% *versus* 75±11% at MRD3 in CBFb-MYH11 subset. The 5-year disease free survival (DFS) was 53±2% in all-ELAM02, 53±7% in t(8;21) and 80±7% in inv(16). Similarly the 5-year overall survival (OS) did not shown any significant difference and was 71±2% in all-ELAM02, 87±4% in t(8;21) and 100% in inv(16) subgroups.
Summary and Conclusions: In the ELAM02 trial we confirmed how frequent CBF-AML patients are slow-responders to chemotherapy but we were unable to confirm the prognostic impact of 3-log MRD reduction to predict relapse as in adult. Of note, children did not received anti-CD33 for chemotherapy as it was in published adult trials. Furthermore comparison between flow-cytometry and fusion transcript MRD could be helpful in CBF-AML.

Acute myeloid leukemia - Clinical 1

HIGH PROGNOSTIC VALUE OF PRE TRANSPLANT MINIMAL RESIDUAL DISEASE ASSESSMENT BY COMBINED WT1 EXPRESSION AND FLOW CYTOMETRY IN ACUTE MYELOID LEUKEMIA PATIENTS

F. Guolo[1,*] F. Galaverna[1], P. Minetto[1], L. Giannoni[1], C. Ghiggi[2], D. Guardo[1], S. Bagnasco[1], M. Clavio[1], C. Di Grazia[3], A.M. Raiola[3], N. Colombo[1], R. Grasso[1], A. Kunkl[4], M. Miglino[1], R.M. Lemoli[1], M. Gobbi[1], A. Bacigalupo[3]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, [2]First Division of Hematology and Bone Marrow Transplantation, [3]Second Division of Hematology and Bone Marrow Transplantation, [4]Department of Pathological Anatomy, IRCCS AOU San Martino-IST, Genoa, Italy

Background: Allogeneic bone marrow transplantation (BMT) offers the greatest chance of cure for most patients affected by acute myeloid leukemia (AML). Persistence of disease or high levels of pre BMT minimal residual disease (MRD) have been reported to predict relapse risk after BMT. WT1 expression levels and multicolor flow cytometry (MFC) are the most widely used tools to evaluate MRD.
Aims: We recently reported that combined MRD evaluation by WT1 and MFC after induction therapy strongly impacts on relapse risk in AML patients.The aim of the present study was to perform the same MRD assessment in the pre BMT setting in order to evaluate its reliability in predicting relapse after transplant.
Methods: We retrospectively analyzed outcome of 257 AML patients with both WT1-based and MFC-based MRD evaluation on bone marrow samples before transplant. Median age at transplant was 44 years. One hundred thirty-three patients were transplanted in first, 54 in second and 72 in third or subsequent complete remission. Induction regimens included fludarabine-containing regimens or standard "3+7" induction. Median follow-up was 48 months (95% CI 37.5-50.5 months). Relapse-free survival (RFS) was calculated from the time of transplantation until last follow-up or documented leukemic relapse. Overall Survival (OS) was calculated from the time of transplantation until death by any cause or last follow-up. A positive MFC MRD was defined by the presence of no less than 25 clustered leukemic cells/10^5total events (threshold of $2.5x10^{-4}$residual leukemic cells) at four-color flow-cytometry. Real-time PCR for WT1 was performed on DNA Engine 2 (Opticon®, MJ Research®). WT1 copy number/Abl copy number $500x10^4$ was used as cut-off value for abnormal WT1 expression.
Results: Eighty-nine relapses (35%) were reported. Median RFS was 84 months. The probability of disease relapse was significantly affected only by disease status (first or subsequent CR, p<0.001) and MRD status before transplantation, measured with any method (p <0.001). Specifically, MFC-MRD was the strongest predictor of longer relapse free survival (p <0.001) since only two relapses occurred in the eleven MFC-MRD negative patients. Among MFC-MRD positive patients a further stratification of risk is obtained by the evaluation of WT1 MRD status that was able to identify patients with significantly worse RFS (p <0.01, Figure1). Multivariate RFS analysis revealed that the combined MRD evaluation was the only independent predictor of RFS (p <0.001). The predictive value of MRD resulted independent from induction schedules, donor type, disease status at BMT and risk group. Similarly, univariate OS analysis showed that BMT year, disease status at BMT and MRD evaluation with any methodic significantly influenced OS duration (p <0.001, <0.001 and <0.001, respectively). Multivariate OS analysis confirmed that combined MRD evaluation was an independent strong predictor of long survival, alongside with BMT year and disease status at BMT (p <0.003, <0.001 and <0.002, respectively)

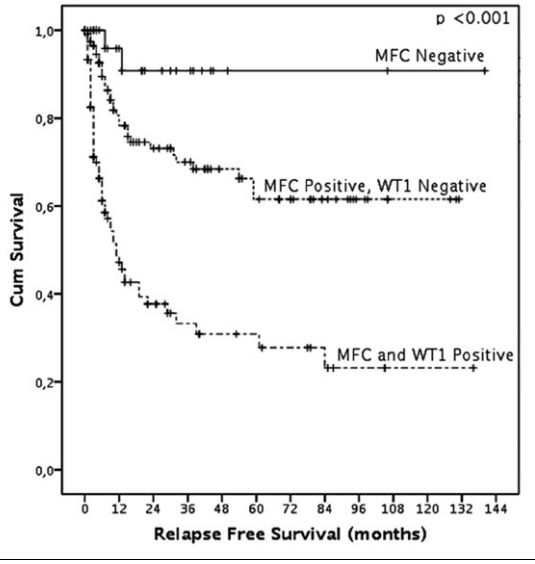

Figure 1. RFS according to risk group

Summary and Conclusions: Pre transplant MRD evaluation by WT1 and MFC on bone marrow samples is a reliable predictor of relapse risk. Patients with both negative pre-BMT MRD markers have a significantly longer DFS, while patients with both positive MRD markers display an higher risk of relapse. Identifying patients who are at higher relapse risk may allow to modulate post BMT follow up, with the aim of detecting disease recurrence earlier and/ or applying pre-emptive therapeutic strategies in order to delay or prevent AML relapse.

P182

A COMPARISON OF DAUNORUBICIN/ CLOFARABINE AND FLAG-IDA IN HIGH RISK ACUTE MYELOID LEUKAEMIA: RESULTS FROM THE UK NCRI AML17 TRIAL

A. Burnett[1,*] N. Russell[2], L. Kjeldsen[3], D. Milligan[4], A. Hunter[5], R. Clark[6], M. Dennis[7], R. Hills[8]
[1]Blackwaterfoot, Isle of Arran, [2]Department of Haematology, Nottingham University Hospitals, Nottingham, United Kingdom, [3]Rigshospitalet, Copenhagen, Denmark, [4]Birmingham Heartlands Hospital, Birmingham, [5]Leicester Royal Infirmary, Leicester, [6]Royal Liverpool University Hospital, Liverpool, [7]Department of Haematology, Christie Hospital, Manchester, [8]HCTU, Department of Haematology, Cardiff University School of Medicine, Cardiff, United Kingdom

Background: We have previously shown that consolidation of high risk patients with high dose ara-c was less effective than combination chemotherapy (including etoposide amsacrine and mitoxantrone) (Burnett AK *et al.* J.Clin.Oncol. *31*,3360-3368, 2013). In the NCRI AML17 Trial (ISRCTN55675535) 3215 untreated non-APL adults, generally <60 years, were given an initial induction course of Daunorubicin/Ara-C with or without Etoposide and/or Gemtuzumab Ozogamicin (GO). On recovery patients were assigned a risk group. To be high risk patients required to fulfil one of the following criteria: 1) Group A: in CR but with adverse features assimilated into a validated risk score (based upon cytogenetics, age, presenting WBC, secondary disease and response to course 1 of therapy) predicting an expected survival of around 24% (Burnett AK et al *Blood* 108 (11):10, 2006) ; 2) Group B: not in CR after a second induction course; or 3) Group C: relapsed disease.
Aims: We compared Daunorubicin/C.lofarabine with FLAG-Ida in a randomised fashion in patients who were high risk.
Methods: 393 patients were identified (311 group A; 5 group B; and 77 group C) and randomised 2:1 between Daunorubicin ($50mg/m^2$ days 1,3 and 5) + Clofarabine ($20mg/m^2$ days 1-5) or FLAG-Ida (Fludarabine $30mg/m^2$ d2-6, Ara-C $2g/m^2$/day d2-6, G-CSF days 1-7 and Idarubicin 8 mg/m^2 on days 4,5,6). All high risk patients were candidates for allo-BMT. For the purpose of this analysis groups B & C are combined.
Results: Overall 393 patients entered the comparisons of DClo *vs* FLAG-Ida: 311 in group A and 82 in groups B+C. The characteristics of group A and of B+C were: median age 55 (18-69) and 47 (19-63); de novo 221 and 78; secondary disease or high risk MDS 90 and 4; performance score >1 13 and 3; cytogenetics favourable 0 and 14; cytogenetics intermediate 151 and 58; cytogenetics adverse 160 and 3. The median follow up is 25.8 months for group A and 12.7 months for group B+C. In group A, the median number of courses received was 1 for FLAG-Ida and 2 for DClo. The overall survival at 4 years for group A was 35%. RFS was 46% in the FLAG-Ida patients *vs* 34% in those on DClo (HR 1.25 (0.89-1.75) p=0.2). Survival was non-significantly superior in the FLAG-Ida patients (48% *vs* 30%, HR 1.30 (0.95-1.79) p=0.10). The objective of the chemotherapy was to deliver patients to allograft. 53% of FLAG-Ida and 56% of DClo received a transplant. When the RFS and OS are censored at time of transplant the RFS was FLAG-Ida 22% *vs* DClo 18%, and OS was 22% *vs* 22%. The overall survival at 3 years for group B+C was 20%. CR was achieved in 2/2 refractory and 18/25 relapsed patients allocated FLAG-Ida *vs* 1/3 and 41/52% for DClo. Survival was non-significantly better in the FLAG-Ida patients (35% *vs* 11%, HR 1.26 (0.73-2.17) p=0.4). 56% of FLAG-Ida and 65% of DClo received a transplant. When the OS are censored at time of transplant the OS at 18 months was FLAG-Ida 38% *vs* DClo 30%. If groups A, B+C are analysed together using standard meta-analytic approaches, the hazard ratio for survival favours FLAG-Ida (HR 1.29 (0.98-1.70) p=0.07). Although FLAG-Ida resulted in slower count recovery and required significantly more supportive care (RBC and platelets/ antibiotics/ hospital days), it resulted in survival which was not inferior to DClo.

Tabella 1.

AML17: Overall Survival
High risk randomisation

	Deaths/Patients DClo	Deaths/Patients FLAG–Ida	Statistics (O–E)	Statistics Var.	O.R. & 95% CI (DClo : FLAG–Ida)
Type of patient:					
Post Course 1	122/207	49/104	10·3	38·6	1.30 (0.95, 1.79)
Relapsed/Refractory	40/55	17/27	3·0	12·9	1.26 (0.73, 2.17)
■ **Total:**	**162/262**	**66/131**	**13·2**	**51·5**	**1.29 (0.98, 1.70)**

0·0 0·5 1·0 1·5 2·0
DClo better | FLAG–Ida better

Test for heterogeneity (2 groups): χ^2_1 = 0·0; P = 0·9; NS

Effect 2P = 0·07

Summary and Conclusions: FLAG-Ida resulted in at least as good survival when compared with DClo for high risk patients in remission or relapsed or refractory patients.

Acknowledgements: This study received research support from Cancer Research UK. Genzyme/Sanofi provided Clofarabine for the trial.

P183

FLUDARABINE-CONTAINING INDUCTION INCREASES MINIMAL RESIDUAL DISEASE CLEARENCE AND IMPROVES SURVIVAL IN AML PATIENTS WITH CONCOMITANT NPM1 AND FLT3-ITD MUTATIONS

F. Guolo[1,*] P. Minetto[1], M. Clavio[1], D. Damiani[2], E. Toffoletti[2], A. Michelutti[2], E. Simenone[2], L. Giannoni[1], D. Guardo[1], J. Agnelli[1], N. Colombo[1], R. Grasso[1], F. Ballerini[1], A. Kunkl[3], M. Miglino[1], R.M. Lemoli[1], M. Tiribelli[2], M. Gobbi[1]
[1]Chair of Hematology, Department of Internal Medicine (DiMI), University of Genoa, IRCCS AOU San Martino-IST, Genoa, [2]Division of Hematology and Bone Marrow Transplantation, University of Udine, Udine, [3]Department of Pathological Anatomy, IRCCS AOU San Martino-IST, Genoa, Italy

Background: The negative prognostic impact of FLT3-ITD mutations in acute myeloid leukemia (AML) patients is well known. This unfavorable effect is mostly due to high relapse rate and short disease free survival (DFS). On the contrary, NPM1 gene mutation has been shown to confer a good prognosis. The co-existence of both mutations is common with most groups reporting a predominant negative prognostic impact of FLT3.
Aims: We performed a retrospective analysis of the outcome of 124 de novo AML patients carrying FLT3 and/or NPM mutation receiving a fludarabine containing regimen or conventional daunorubicin and cytarabine (3+7) schedule as front line treatment, with the aim of evaluating whether the combination of fludarabine to Ara-C and anthracycline may increase DFS in FLT3 or NPM mutated patients, especially in double-mutated patients.
Methods: One-hundred twenty four consecutive FLT3-ITD and/or NPM1 positive non M3 AML patients (age 17-78 years) treated in two Hematology centers of Northern Italy were retrospectively included in this study. In center 1, all patients received FLAI-5 regimen (fludarabine 30 mg/sqm and ARA-C 2g/sqm on days 1 to 5 plus idarubicin 10 mg/sqm on days 1-3-5), whereas in center 2 patients were given either FLAI or 3+7 induction. Overall 90 patients received FLAI, and 34 patients received 3+7 regimen. In both centers, patients with FLT3-ITD mutation underwent allogeneic bone marrow transplantation (BMT) in first complete remission if feasible. Minimal residual disease was evaluated on marrow samples in most patients using multicolor flow-cytometry (MFC) and NPM expression levels. Demographical, cytogenetic and molecular characteristics were comparable in the series of patients treated in the two centers and in patients receiving the two induction regimens.
Results: Two patients (5.9%) died during first induction in the 3+7 arm,whereas two patients (2.2%) died in the FLAI arm, mostly due to infections. One further patient in the FLAI arm died during second cycle. Overall 60-days mortality was therefore 4%. After two induction cycles, 105 patients achieved CR (88%) and 14 did not respond (16%). Forty-two/105 (40%) CR patients underwent BMT in first CR. CR rate after cycle 1 was significantly higher in FLAI-5 cohort (86% *vs* 69%, p<0.05). Patients treated with FLAI-5 had significant higher probability of achieving MRD clearance, both on NPM and MFC-based evaluation (p<0.001 and p<0.05, respectively, Figure 1A and D). After a median follow up of 51 months, 2-year DFS was 53.4% (median 101 months). DFS duration was significantly influenced by induction type (p <0.001, Figure1 B), risk group, status for FLT3 and NPM1, NPM-MRD and MFC-MRD status (p <0.03, p<0.05, p<0.05, p<0.001, p<0.01, respectively). Survival did not significantly differ between patients achieving MFC-MRD negativity with FLAI 5 or "3+7". Among patients with FLT3-ITD and concomitant NPM mutation, the difference between FLAI and 3+7 cohorts in term of DFS was higher (p <0.0001, Figure 1 C). No significant DFS difference was observed in FLT3-ITD/NPM wild type patients. Overall Survival analysis led to similar results.

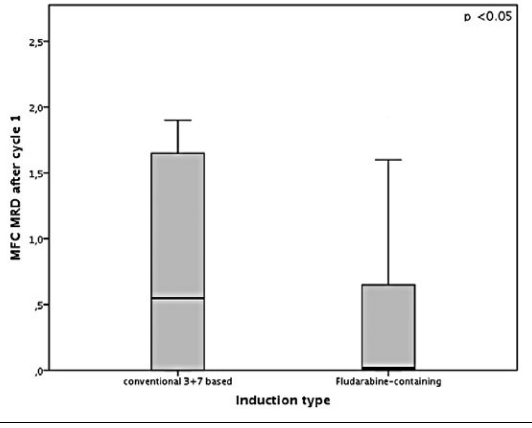

Figure 1. A: Multicolor Flow Cytometry MRD levels after cycle 1

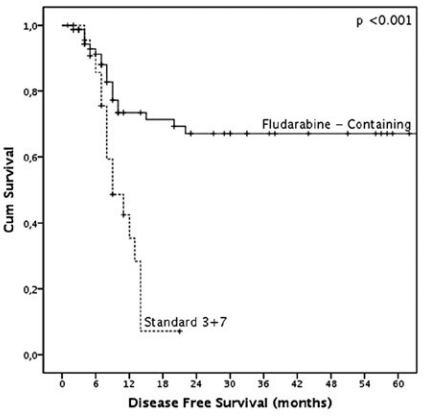

Figure 1. B: DFS in All Patients according to induction therapy.

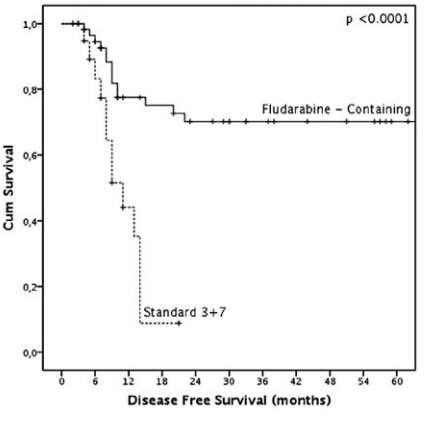

Figure 1. C: DFS in NPM1 Patients according to induction therapy.

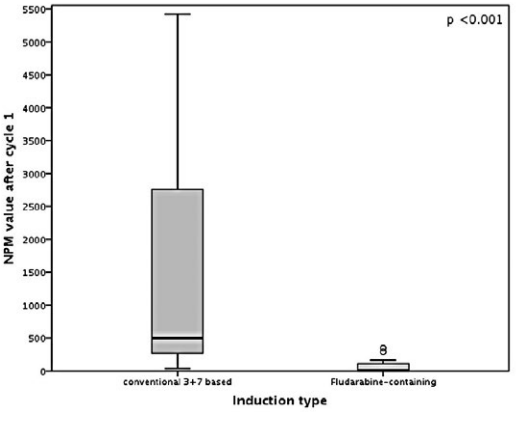

Figure 1. D: NPM1 MRD levels after cycle 1.

Summary and Conclusions: Despite the small size of patients cohorts and the potential bias due to the retrospective nature of the analysis, our study seems to indicate that fludarabine containing induction improves quality of response in patients carrying NPM1 mutation compared to 3+7 regimen. It is possible that the favorable impact of adding Fludarabine to Ara-C and anthracycline in double mutated AML patients may overcome the negative prognostic impact of FLT3-ITD.

P184

THE EFFECT OF AZACITIDINE ON HEALTH-RELATED QUALITY OF LIFE (HRQL) IN OLDER PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML): RESULTS FROM THE AZA-AML-001 TRIAL

M.D. Minden[1,*] H. Dombret[2], J.F. Seymour[3], R.M. Stone[4], S. Alibhai[1], A. Nixon[5], A. Kudlac[5], S. Songer[6], C. Beach[6], C. Bartiromo[6], H. Döhner[7]
[1]Princess Margaret Cancer Centre, Toronto, Canada, [2]Hôpital Saint Louis, Institut Universitaire d'Hématologie, University Paris Diderot, Paris, France, [3]Peter MacCallum Cancer Centre, East Melbourne, Australia, [4]Dana Farber Cancer Institute, Boston, United States, [5]PRMA Consulting Ltd, Fleet, United

Kingdom, [6]Celgene Corporation, Summit, United States, [7]Universitätsklinikum Ulm, Ulm, Germany

Background: Older patients (pts) with AML generally have a poor prognosis. While treatment (Tx) may extend overall survival (OS) for pts with AML, it may also cause significant toxicity and impairment of HRQL (Cheng, *Leukemia*, 2014). In the large, international, phase 3 AZA-AML-001 study, median OS for older pts with AML treated with azacitidine (AZA) was 10.4 months *vs* 6.5 months for pts who received conventional care regimens (CCR; HR=0.85; p=0.1009) (Dombret, EHA, 2014). HRQL was a prespecified secondary endpoint of the study.
Aims: To evaluate changes in HRQL during Tx among pts in AZA-AML-001.
Methods: Pts were aged ≥65 years with newly diagnosed *de novo* or secondary AML (>30% bone marrow blasts). Before randomization, pts were preselected to receive 1 of 3 CCR per investigator choice: induction chemotherapy, low-dose cytarabine (LDC), or best supportive care only. Pts were then randomized to AZA or CCR, in which case, they received their preselected Tx. Most pts (n=312, 64%) were preselected to receive LDC. HRQL was assessed by EORTC QLQ-C30 questionnaire at baseline, day 1 of every other Tx cycle, and at the end-of-study visit, which occurred at different time points for individual pts. Analyses included only pts who completed the baseline and at least 1 post-baseline HRQL assessment. An HRQL-specific statistical analysis plan (SAP) was finalized before database lock. HRQL changes were evaluated prospectively for the AZA and CCR cohorts, and *post hoc* for the pt subgroup preselected to LDC who received AZA or LDC. Four of the 15 QLQ-30 domains were prespecified in the SAP as most relevant: Fatigue (primary), Global Health Status/QoL, Physical Functioning, and Dyspnea (secondary). HRQL was evaluated through cycle 9 (~32 to 34 weeks) due to subsequent small cohort sizes. A prespecified 10-point minimally important difference (MID) threshold represents meaningful change.
Results: Rates of HRQL assessment compliance were fairly high overall (>77% both Tx groups) except at the end-of-study visit (AZA=42%, CCR=37%). Overall, 157 AZA pts and 134 CCR pts were evaluable for HRQL (the AZA-AML-001 ITT population included 488 pts, AZA N=241, CCR N=247). The rate of attrition of evaluable pts during early Tx was higher in the CCR arm than in the AZA arm. During Tx, mean change from baseline scores with AZA or CCR showed general improvement in the 4 relevant domains (Figure). Few changes were statistically significant (p<0.05) and fewer met the MID threshold. Pts receiving CCR achieved meaningful improvement in Fatigue (cycles 7, 9) and Global Health Status/QoL (cycle 9). No HRQL detriment was seen with AZA or CCR during Tx. Notably, scores varied substantially among individual pts in both Tx groups. Within the LDC preselection group, HRQL outcomes with AZA and LDC were largely consistent with the primary HRQL analysis (Figure). Pts receiving AZA achieved meaningful improvement in Fatigue (cycle 9).

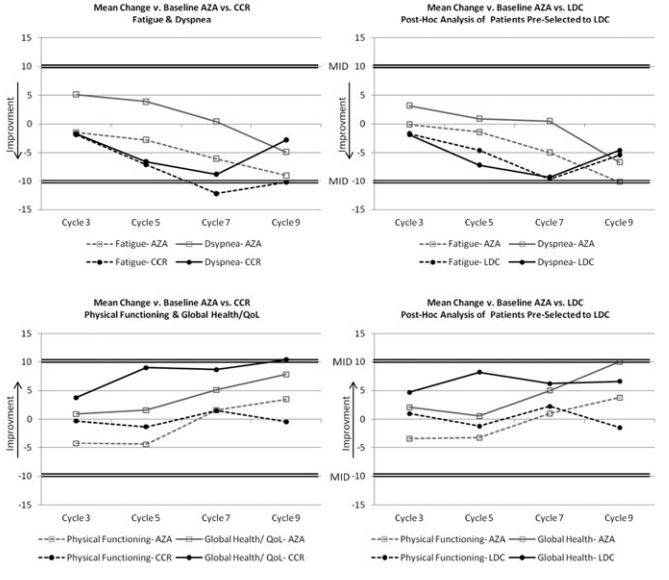

Figure 1. Mean Changes from Baseline EORTC QLQ-30 Domain Scores.

Summary and Conclusions: During Tx, AZA and CCR were associated with general improvement in HRQL in the 4 relevant domains, but improvements were not consistently meaningful. Importantly, for these 4 domains, there was no meaningful HRQL deterioration at the group level during Tx. Results were largely similar for AZA *vs* LDC.

P185

DEFINITION OF CURE IN ADULT PATIENTS WITH ACUTE MYELOID LEUKEMIA

G.N. Tamamyan[1,*] G. Borthakur[1], J. Cortes[1], F. Ravandi[1], E. Jabbour[1], N. Pemmaraju[1], N. Daver[1], M. Ohanian[1], S. Pierce[1], M. Konopleva[1], H. Kantarjian[1], T. Kadia[1]

[1]Department of Leukemia, University of Texas MD Anderson Cancer Center, Houston, United States

Background: Advances in diagnosis, treatment, and supportive care have improved rates of complete remission (CR) in adult patients (pts) with newly diagnosed acute myeloid leukemia (AML). Unfortunately, disease relapse is common, accounting for the majority treatment failure, and explaining the marginal improvements in long-term survival. However, there are subsets of pts who achieve CR and continue to maintain very long term remissions, without relapse-the so-called 'cure-fraction'. Although long-term follow-up of AML pts is standard, the time point after which a patient is considered 'cured' of AML is a critical piece of information for both pts and physicians.
Aims: The aim of the current study is to clarify the definition of cure in adult pts with AML in 1stCR.
Methods: For the purposes of the study, cure was defined as the point after which the probability of relapse (POR) was ≤5%. In subgroups where this probability was not achievable in the first 5 yrs, a threshold of ≤10% was applied. Pts who had received an allogeneic stem cell transplant were excluded. Pts with acute promyelocytic leukemia (APL) were analyzed separately and not included in the larger AML cohort. We evaluated the cumulative risk of relapse, time to relapse, relapse-free survival, and overall survival in a cohort of pts treated at our institution from 2000-2012, with a median follow up of 26.2 months.
Results: A total of 1096 pts were analyzed (median age 57, range [18-88]), of whom 159 (14.5%) had APL. Of the remaining 937 pts, 493 (53%) were age ≥60 yrs, and 444 (47%) were <60 yrs. In pts with APL, the POR after 1 and 2 yrs was ≤5% and ≤1%, respectively. In the entire (non-APL) cohort, the POR level of ≤5% was achieved after 4 yrs in CR. In pts <60 yrs, the POR of ≤5% was achieved after 3 yrs in CR. In pts ≥60 yrs, the POR of ≤5% was not achieved in the time of follow-up. In these pts, we observed a POR of ≤10% after 4 yrs in CR. In pts with core-binding factor (CBF) AML, the POR was ≤5% at 2 yrs and ≤1% at 3 yrs after CR. In pts with diploid karyotype a POR of ≤5% was achieved after 3 yrs in CR and in the non-diploid pts after 5 yrs in CR.(Figure 1).

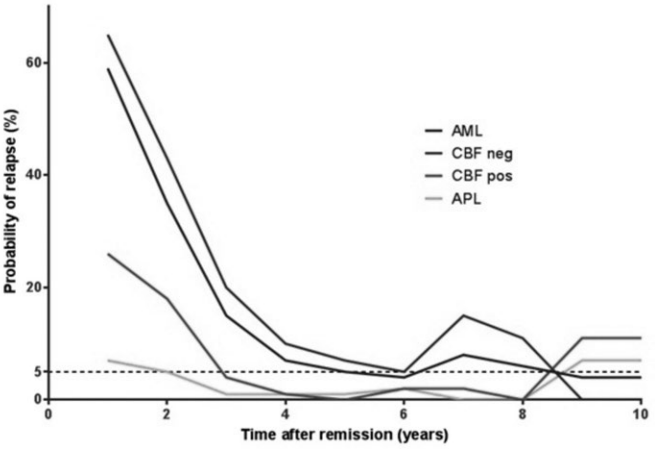

Figure 1. The illustration shows the correlation between the probability of relapse and the time passed from achieving the 1st complete remission for the each subgroup of patients. Abbreviations: AML (acute myeloid leukemia), CBF neg (core-binding factor negative AML), CBF pos (core binding factor positive AML), APL (acute promyelocytic leukemia).

Summary and Conclusions: Although late relapses were observed, using a threshold of ≤5% for POR, pts with APL and CBF AML may be considered 'cured' 1 and 2 yrs after achieving a CR, respectively. In younger pts with AML, cure may be considered after 3 yrs in CR, while older pts did not achieve a POR ≤5% during our follow-up. Using a POR of ≤10%, a 'cure' in older pts may be considered after 5 yrs in CR.

RESIDUAL HEMATOPOIETIC STEM CELLS REFLECT MINIMAL RESIDUAL DISEASE AND PREDICT OUTCOME IN ACUTE MYELOID LEUKEMIA

W. Wang[1,*] S. Raffel[2], V. Hoang[1], I. Hoffmann[1], B. Saeed[1], K. Miesala[1], A. Trumpp[2], A.D. Ho[1], C. Lutz[1]

[1]Department of Medicine V, University of Heidelberg, [2]Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, Germany

Background: It has been demonstrated that functionally normal hematopoietic stem cells (HSC) can be separated from leukemic cells in a subgroup of patients with acute myeloid leukemia (AML) using the $CD34^+CD38^-ALDH^+$ phenotype. Our recent studies further showed that patients suitable for this separation can

be identified prospectively by their low percentages of cells with high ALDH activity (ALDH$^+$ cells) (<1.9%; ALDH-rare AML) and that these patients represent a cohort with favorable outcome. However, frequencies of residual HSC varies within this subgroup and individuals with very low numbers appear to have extremely poor survival.
Aims: In this study we sought to investigate the relationships of residual HSC to survival and disease status in diagnostic AML and follow-up samples. We further aimed to test if HSC numbers correlate to leukemia initiation potential in xenotransplantation assays.
Methods: Between 2012 and 2013 bone marrow (BM) aspirates of 73 ALDH-rare AML patients were collected after written informed consent and patients stratified according to HSC frequencies determined by 34$^+$38$^-$ALDH$^+$ cells in HSC$^-$AML (□0.01% of total MNC) and HSC$^+$ AML (≥0.01% of total MNC). HSC numbers were determined by FACS-analysis at diagnosis and various follow-up time-points. Engraftment potential was evaluated by transplantation of 2x10e6 bulk AML cells in immune deficient NOD/SCID-IL2R^{null} (NSG) mice.
Results: Survival analysis showed that HSC$^-$AML represents a subgroup of patients with significantly worse overall survival (OS) (mean: 455 days) and disease-free survival (DFS) (mean: 209 days), compared to HSC$^+$ AML (mean OS: 878 days; mean DFS: 896 days). Survival analysis of patients with cytogenetic intermediate-risk also showed significantly worse OS and DFS for HSC$^-$AML with mean OS of 439 days, compared to 872 days for HSC$^+$ AML and mean DFS of 218 days, compared to 848 days. We also analyzed matched sample series from diagnosis, various remission time points and relapse (if available), and found that HSC recovered after chemotherapy in cases that achieved complete remissions. However, in cases of persistent disease HSC remained rare. Correlation of disease status to HSC numbers during therapy revealed that residual HSC are a reliable qualitative marker of minimal residual disease with a negative correlation to frank or molecular relapse. To test if HSC numbers correlate to leukemia initiation potential we transplanted 44 AML cases in NOD/SCID-IL2R^{null} (NSG) mice and observed only abnormal engraftment (47% AML-and 53% no engraftment) upon transplantation of HSC$^-$cases. In contrast HSC$^+$ cases mostly lead to normal, multi-lineage engraftment (79%).
Summary and Conclusions: Frequency of residual HSC reliably predicts outcome in AML patients and the quality of NSG mouse engraftment. Our AML stratification strategy is especially helpful in identifying cases with poor prognosis in the intermediate-risk group with HSC$^-$AML representing patients with poor overall and disease free survival. In addition HSC frequency can also be used as a qualitative marker of MRD status tabling it as indicator of BM-niche occupation of persistent leukemic cells.

Medizinische Klinik und Poliklinik im Städtischen Krankenhaus, Kiel, Germany, [11]Hôpital Purpan-CHU de Toulouse, Toulouse, France, [12]Memorial Sloan-Kettering Cancer Center, New York, NY, United States, [13]The University of Chicago, Chicago, IL, United States, [14]Sunesis Pharmaceuticals, Inc., South San Francisco, CA, United States, [15]Medical University of South Carolina, Charleston, SC, United States, [16]University of California, Los Angeles, Los Angeles, CA, United States

Background: Increasing numbers of older patients with acute myeloid leukemia (AML) receive allogeneic hematopoietic cell transplant (HCT) due to wider donor availability and improvements in supportive care that reduce transplant-related morbidity/mortality. HCT in patients ≥60 y/o with first relapsed or refractory (R/R) AML were examined from VALOR, a large phase 3 adaptive design, randomized, double-blind, placebo-controlled trial evaluating vosaroxin plus cytarabine (vos/cyt) *vs* placebo plus cytarabine (pla/cyt) [NCT01191801].
Aims: The aim of this posthoc subgroup analysis was to assess outcomes of HCT in patients ≥60 y/o with R/R AML.
Methods: Patients were randomized 1:1 to receive cyt (1 g/m^2 IV over 2 hr, d 1-5) plus either vos (90 mg/m^2 IV over 10 min, d 1 and 4; 70 mg/m^2 in subsequent cycles) or placebo. We assessed complete remission (CR) rates prior to HCT, posttreatment HCT rates, HCT outcomes, and overall survival (OS) by treatment arm in R/R AML patients ≥60 y/o.
Results: Overall, 451 patients ≥60 y/o received vos/cyt (n=226) or pla/cyt (n=225). Posttreatment HCTs were performed in 47 (20.8%) patients on vos/cyt and 44 (19.6%) patients on pla/cyt. Of the 91 HCT patients, 27 had achieved CR after vos/cyt *vs* 16 after pla/cyt. An additional 7 patients (vos/cyt) and 6 patients (pla/cyt) received subsequent therapy and went on to achieve CR, resulting in totals of 34 vos/cyt *vs* 22 pla/cyt patients who achieved CR prior to transplant. Median OS for patients who underwent posttreatment HCT on the vos/cyt arm was 20.2 mo *vs* 12.2 mo on the pla/cyt arm (HR 0.699; one sided P=0.088). There were no clinically meaningful differences between treatment arms with respect to transplantation type, complications associated with HCT (including graft-*vs*-host and veno-occlusive disease), 100-day mortality, or achievement of engraftment.
Summary and Conclusions: While HCT rates were comparable between treatment arms in this older R/R AML population, higher pretransplant CR rates in the vos/cyt arm enabled more patients ≥60 y/o to undergo transplant while in CR as compared to the pla/cyt arm. With median OS lengthened by 8 months, a trend toward an OS benefit was observed for vos/cyt-treated patients. Additional follow-up is being conducted to further assess the impact of vos/cyt treatment on posttreatment HCT. Funded by Sunesis Pharmaceuticals, Inc., South San Francisco, CA.

P188

RELAPSE CHARACTERISTICS AND RISK FACTORS FOR CENTRAL NERVOUS SYSTEM INVOLVEMENT IN ACUTE PROMYELOCYTIC LEUKAEMIA IN THE ORAL ARSENIC TRIOXIDE ERA-A 13-YEAR FOLLOW-UP STUDY

H. Gill[1,*] A. Leung[1], E. Tse[1], Y.L. Kwong[1]
[1]Medicine, The University of Hong Kong, Hong Kong, Hong Kong

Background: Arsenic trioxide (As_2O_3)-based regimensareeffective in inducing a remission in more than 90 percent of relapsed APL. Treatment failure following As_2O_3 and central nervous system (CNS) involvement is associated with a poor prognosis. The optimal post-remission therapy in relapsed APL is undetermined. Identifying the clinicopathologic characteristics and risk factors for CNS relapse will be a useful guide to stratify patients to the most optimal post-remission therapy.
Aims: The aim of this study was to prospectively evaluate the clinicopathologic characteristics and risk factors for CNS involvement in patients with relapsed APL treated with oral arsenic trioxide-based therapy.
Methods: A total of 188 patients with APL were prospectively followed for 13 years, of whom 71 patients had relapsed APL. The clinicopathologic characteristics at relapse were determined. Prognostic factors for CNS involvement at relapse were determined.
Results: There were 41 men and 30 women, at a median age of 43 (21–78) years. The leukemia was *de novo* in 68 patients (five of which were of microgranular variant morphology), and therapy-related in 3 patients. Additional karyotypic abnormalities were seen in 11 patients (15.5%). Internal tandem duplication of the fms-like tyrosine kinase 3 gene (*FLT3*-ITD) was detected in 13 patients. During prior first complete remission (CR1), only 15 patients (21.1%) had received oral-As_2O_3 based maintenance. A second complete remission (CR2) was achieved with an oral-As_2O_3-based re-induction in all patients in first relapse, who then received oral As_2O_3-based consolidation and maintenance. At relapse, the median leucocyte count and peak leucocyte count was 2.7 (0.4–94.7) x 10^9/L and 9.2 (0.6–130.4) x 10^9/L, and the median platelet count was 59 (7–281) x 10^9/L. APL differentiation syndrome (DS) occurred in 11 patients (15.5%) during relapse. At a median follow up of 93 (21–392) months, 28 patients (39.4%) had two or more relapses. In the whole cohort of patients, the patterns of relapses were: isolated bone marrow (BM), N=54 (76.1%); concurrent BM and CNS, N=9 (12.7%); and isolated CNS, N=8 (11.3%). In total, 22 patients relapsed during oral As_2O_3-based maintenance at various disease stages. On univariate analysis, factors significantly associated with CNS relapse included peak leucocyte count at diagnosis >20 x 10^9/L (P=0.03), oral As_2O_3-based maintenance at CR1 (P=0.004), leucocyte count at R1 >10 x 10^9/L (P=0.04), 2 or more relapses (P<0.001), and relapse during oral As_2O_3-based maintenance (P<0.001). On multivariate analysis, peak leucocyte count at diagnosis >20 x 10^9/L (P=0.04) and relapse during oral As_2O_3-based maintenance (P=0.01) were significantly associated with CNS involvement at relapse. CNS involvement at relapse predicted worse overall survival (HR=4.19; P=0.002; 95% CI:1.72-10.19).
Summary and Conclusions: CNS involvement was associated with a poor prognosis. High peak leucocyte count at diagnosis and relapse during oral As_2O_3-based therapy were the main risk factors.

P189

PROSPECTIVE STUDY ON 220 NEUTROPENIC EPISODES IN 109 AML PATIENTS. ROLE OF BED-SIDE ULTRASOUND (BUS) IN NEUTROPENIC ENTEROCLITIS (NEC): INCIDENCE AND SURVIVAL WITH DIFFERENT CHEMOTHERAPY REGIMEN

E. Benedetti[1,*] B. Bruno[2], R. Morganti[1], M. Petrini[1]
[1]Dipartimento di Ricerca Traslazionale e delle Nuove Tecnologie in Medicina

e Chirurgia, Hematology Unit Ospedale S. Chiara Pisa, Pisa, [2]Hematology Turin, University of Turin, Turin, Italy

Background: Neutropenic enterocolitis (NEC) is a life threatening complication of leukemic and solid tumors patients (pts) treated with chemotherapy (CHT) with mortality rate up to 50-100%. It's a clinical syndrome in neutropenic patients (pts) characterized by abdominal pain (AP), fever (F) and diarrhoea (D). Ultrasound (US) was used to evaluate bowel-wall thickening (BWT), and >4 mm is considered diagnostic of NEC. Perforation occurs in 5%>10% of cases. Early diagnosis is crucial to start conservative medical management (CMM) which appears the optimal strategy for most cases.
Aims: To evaluate prospectively if Bed-side-US(BUS) can detect early signs of NEC and guide a prompt treatment (CMM or surgical) in order to reduce mortality and to evaluate the impact of different CHT regimens on mucosal damage and NEC occurrence
Methods: in the last 7 years all AML pts admitted in Our Hematology Unit wards at University of Pisa (Italy), undergoing chemotherapy (CHT) were enrolled (n=109). Abdominal US was performed, baseline before treatment, and as only one symptom (or a combination) appeared within 12h from onset: F and/or D and/or AP in CHT-related neutropenic pts.
Results: N=220 chemotherapy-related neutropenic episodes (NE) occurred in 109 pts. N=17 episodes of NEC were diagnosed (7.7 %incidence rate). N=2 pts had 2 separate episodes of NEC and both survived. CHT regimens received (total number of cycles/NEC episodes) was: 3+7 (Idarubicin+ARAC) N=62/10, Idarubicin (AML-M3) N=9/1, 3+3+5 (Idarubicin,VP-16,ARAC) N=48/3; 2+5 (Idarubicin+ARAC) N=24/1; Clofarabine (40mg) N=5/0; Clofarabine (20mg) 14/0; Clofarabine+ARA-C (Cofa 20mg) N=18/1; FLANG N=13/1; HD-ARA-C (3gr/mq for 3 consecutive days) N=26/0. Overall 3 pts died out of 17 NEC episodes (mortality rate 17.6%). All pts were promptly treated as soon as BUS was diagnostic of NEC. Overall 3 pts died /17 NEC episodes (17.6% mortality rate).Median time to response from beginning of CMM was 24h and the first sign of was a decrease in AP followed by F, D and BWT. Amelioration of symptoms occurred with pts still neutropenic. Symptoms at Dx were:F+AP+D N=9, F+D N=1, F+AP N=1, Dia+AP N=4,D N=0, F N=0, AP N=2. Fever at Dx was absent in N=6 episodes (35%). Statistically (St) CHT regimens mostly associated with NEC were: 3+7 odds ratio (OD) 6.00 (P<0.0001), 3+3+5 OD=1.75 (P<0.0001). There was not a St significant association of the following CHT regimens with NEC occurrence: Clofarabine (20 or 40mg) N=0 NEC, 2+5 (P=0.125), Idarubicin (AML-M3) (P=0.111), Clofa 20mg+ARAC (P=0.167), HD-ARAC N=0 NEC, FLANG (P=0.143). The association of ARAC to Clofarabine *vs* Clofarabine (20 or 40mg) alone was not St significant in NEC occurrence (P=0.9). The likelihood of NEC Dx in a discriminant model (Bayes theoreme) for pts with BWT and AP=100%, AP+D=100%, AP+D+F=100%,AP+F=100%.
Summary and Conclusions: BUS allowed to detect early signs of NEC and to start prompt treatment in this life threatening complication, with a 76% survival rate. With BUS pts do not live the isolation room. Early diagnosis and intervention allowed to reduce mortality. Images of BUS and CT were superimposable. Fever is not a condition sine qua non for NEC diagnosis. Different chemotherapy regimens do have a different impact on mucosal damage. A prompt BUS in neutropenic patients as just one symptom presents allows to make early diagnosis of this life threatening complication and guide prompt treatment (conservative or surgical) eventually reducing mortality.

Acute myeloid leukemia - Clinical 2

P190

MGA GUIDED INTENSIVE INDUCTION WITH HIGH DOSE CYTARABINE PLUS IDARUBICIN IN 149 AML ELDERLY PATIENTS

D. Capelli[1,*] F. Saraceni[1], M. Chiarucci[1], A. Poloni[1], G. Discepoli[2], P. Leoni[1], A. Olivieri[1]
[1]Department of Haematology, Ospedali Riuniti di Ancona, [2]Department of Cytogenetic, Ospedale Salesi, Torrette di Ancona, Italy

Background: The poor outcome of elderly AML patients is mainly due to the biological properties of the disease and their frailty. To improve both the efficacy and the tolerance of chemotherapy, different approaches have been tried and tested in this setting.
Aims: We explored the feasibility and efficacy of an intensive induction regimen in elderly AML patients evaluated by a simplified Multidimensional Geriatric Assessment (MGA).
Methods: 149 consecutive AML patients older than 59 years, have been prospectively evaluated by MGA: 91 patients (61%) who resulted fully or partially fit, were eligible forintensive induction chemotherapy; the remaining 58 frail patients received best supportive care (BSC). Frail patients turned out to be older, have a poorer PS score and significantly more secondary and poor prognostic karyotype AML than the fit subgroup of patients. In this latter group only 6.2% of patients had favourable-risk cytogenetics while 40.7% had unfavourable-risk cytogenetics. Thirty-six patients had a secondary disease and 3 patients had a 3 WHO performance status (PS) score. The induction chemotherapy consisted in the association of High-Dose Aracytin, combined with a single high-dose of Idarubicin, combined with Amifostine, in order to reduce the toxicity.
Results: Among the 91 patients who received intensive treatment the overall chemotherapy-related mortality rate (TRD during induction and consolidation) was 14.2% while the induction TRD rate was 5.5%. The main toxicity of the intensive induction chemotherapy consisted in myelosuppression with neutrophils (>1,500/µl) and platelets (>20,000/µl) recovery was achieved on days +15 and +16 respectively, with a median duration of hospitalization of 30 days (range: 15-69); we did not observe severe extrahematological toxicities. Sixty-seven (73%) patients achieved the Complete Remission (CR) and 61 received intensive consolidation, followed by ASCT, SCT or Gemtuzumab Ozogamicin, depending on mobilization outcome and donor availability.On intention to treat basis the 8-year OS of the 91 patients receiving intensive induction, was 20%, with a median duration of 11.4 months, significantly higher than that observed in the 58 BSC patientssince all died within 18 months with a median OS of 1.5 months (p<0.001). Patients with poor cytogenetic, no hyperleukocytosis and those with hyperleukocytosis ≥50,000/µl had respectively a 1.8and 3 relative risk of dying when compared with other patients (p=0.005) (Figure 1).

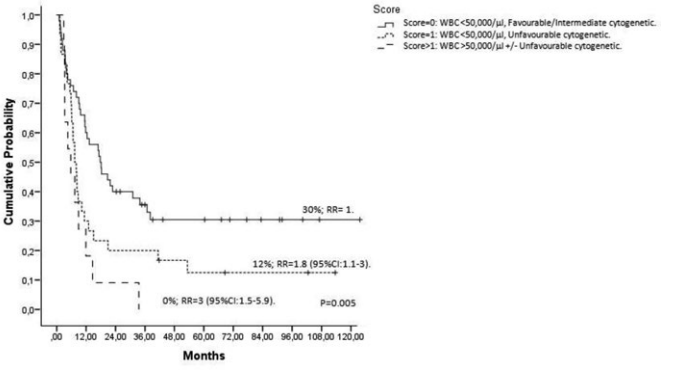

Figure 1. OS in 91 AML elderly patients by prognostic score.

Summary and Conclusions: Our simplified MGA selected 60% of elderly AML patients eligible for an intensive, feasible and effective protocol, making tailored post-consolidation possible in 53.8% of patients with long term survival double that reported in the literature.

P191

CD200 EXPRESSION IS ASSOCIATED WITH INFERIOR RESPONSE AND POOR SURVIVAL IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

M. Tiribelli[1,*] D. Raspadori[2], A. Michelutti[1], M. Cavallin[1], S. Santina[2], E. Toffoletti[1], E. Simeone[1], A. Geromin[1], M. Medeot[1], R. Fanin[1], M. Bocchia[2], D. Damiani[1]
[1]Division of Hematology and BMT, Azienda Ospredaliero-Universitaria di Udine, Udine, [2]Department of Hematology, University of Siena, Siena, Italy

Background: The evasion of immune system by neoplastic cells is emerging

as a mechanism of survival after conventional chemotherapy both in cells of hematologic and solid tumors. Many molecules with "immune attenuator" activity have been identified over the last years; among them, CD200 has a central role by inhibiting different effectors in immune response and has been associated with poor prognosis in several cancers, including acute myeloid leukemia (AML).

Aims: In the present work we investigated the aberrant expression of CD200 in 244 adult AML (173 "de novo" and 71 secondary) to evaluate its impact on response to therapy and on survival. Secondary aim was to evaluate the possible association of CD200 expression with particular subsets of disease.

Methods: Two hundred forty-four patients with non-promyelocytic AML treated at our two Institutions were included in this analysis. Blast cells immunophenotype and CD200 expression were evaluated by multiparametric flow cytometry.

Results: CD200 aberrant expression was found in 137/244 cases (56%), with significantly higher frequency in secondary compared to "de novo" AML (52/71, 73% *vs* 85/173, 49%; p=0.0006). No association was found according to age and FAB classification, but CD200 positivity was higher in CD34+ cases (99/129, 77% *vs* 36/113, 32%; p<0.0001). CD200 expression was associated with FLT3 unmutated status (105/170, 62% *vs* 17/46, 37%; p=0.004) and with NPM wild-type status (99/145, 68% *vs* 19/65, 29%; p=0.001). Considering cytogenetic profile, CD200 expression was more frequent in the unfavorable group (44/67, 66%) than in favorable/intermediate ones (74/153, 48%; p=0.01). Complete remission (CR) was obtained in 73% of CD200 negative and in 58% of CD200 positive patients (p=0.01). The negative impact of CD200 expression on CR was confirmed also in multivariable analysis (HR: 0.49, 95%CI: 0.20-0.95; p=0.04). With a median follow-up of 56 months, 107 patients (44% of the total) were alive. Overall survival (OS) was significantly lower in CD200 positive patients, with 3-year OS of 45%, compared to 31% in the CD200-negative group (p=0.01) [Fig 1]. Moreover, a strong association was observed between intensity of CD200 and survival, as patients with high CD200MFI (>11) had a 3-year OS of 10% compared to 40% in CD200 negative or low-expressing cases (p=0.03). In multivariable analysis CD200 expression intensity retained its negative impact on OS (HR: 0.59, 95%CI: 0.32-98; p=0.04). Finally we evaluated the effect of CD 200 expression in patients with unfavorable karyotype: 3-year OS was 39% in CD200 negative and 12% in CD200+ patients (p=0.045).

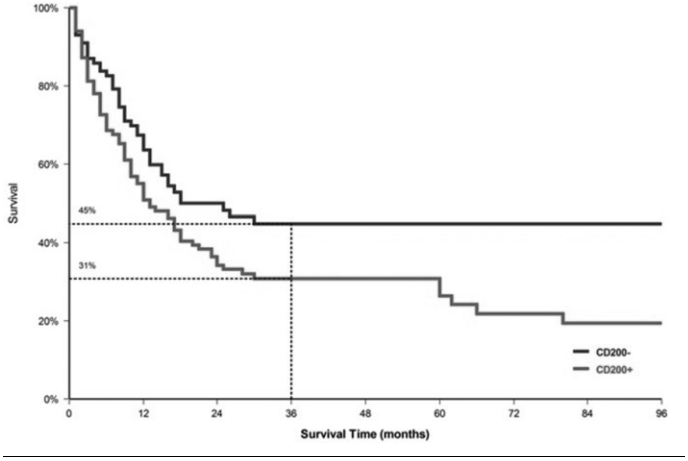

Figure 1.

Summary and Conclusions: Aberrant CD200 expression is associated with low remission rate and poor survival in AML. The negative effect is particularly evident in the unfavorable cytogenetic group. New therapeutic strategies directly targeting CD200 or modulating the tolerant microenvironment induced by CD200 should be explored to improve the still largely unsatisfactory results of conventional chemotherapy.

P192

NOVEL FUSIONS AND POINT MUTATIONS DETECTED IN NEWLY DIAGNOSED AML PATIENTS BY RNA-SEQ IDENTIFY POTENTIAL NEW TREATMENT OPTIONS

C. Cecchetti[1,*] R. Piazza[2], A. Pirola[2], V. Magistroni[2], C. Donadoni[2], C. Mezzatesta[2], B. Bianchi[2], L. M. Borin[1], M. Fumagalli[1], C. Gambacorti-Passerini[2]

[1]Dept. of Hematology, San Gerardo Hospital, [2]Health Sciences, University of Milano Bicocca, Monza, Italy

Background: Specific genetic alterations in AML represent a critical information for both diagnosis and treatment choice.

Aims: 20 AML patients at diagnosis were subjected to RNA-Seq to identify gene fusions; mutations and indels in a predefined set of 45 genes were also evaluated.

Methods: RNA sequencing data were generated using an Illumina Genome Analyser IIx following standard library-prep protocols. Alignment to the reference GRCh38/hg38 genome was performed using STAR. Alignment data were processed using Samtools. Single nucleotide and small indels detection was performed using in-house software and applied to the following list of genes involved in AML pathogenesis (CEBPA, NPM1, FLT3, RUNX1, MLL, WT1, EZH2, NF1, MECOM(EVI1), KIT, H-RAS, K-RAS, TET2, IDH1, IDH2, DNMT3A, BCOR, BCORL1, NUP98, ASXL1, ABCB5, BAALC, CEP72, DIP2C, ROBO1, KLC1, TP53, IGFBP7, SETBP1, JAK2, NRAS, NOTCH1, CDKN2A, MPL, SF3B1, BRAF, PTPN11, SRSF2, IKZF1, GATA1, MYD88, ATM, CBL, PHF6, BCL2). The presence of fusions was assessed using FusionAnalyser.

Results: We identified a total of 10 fusions and 29 single nucleotide variants with a median number of 1 single nucleotide variant per patient (range 0-4). 5 patients had fusions that were previously detected with standard techniques (1AML-ETO, 3 PML-RARA and 1 CBFB-MYH11); for all these patients known fusions were confirmed by RNA-sequencing. In 5 patients previously unreported fusions were detected. Two of them were already known from the literature (ZMYM2-FGFR1 and MLL-MLLT10) and 3 were new (ETS2-ERG, WDFY3-WAS and KDM2B-ETV6). Thus the number of fusions present in this cohort of patients was doubled when compared to fusions identified by standard techniques. The ZMYM2-FGFR1 is particularly interesting, because it is potentially targetable by using drugs such as ponatinib, dovitinb or nintedanib; indeed, *in vitro* treatment of patient cells with nanomolar concentration of ponatinib caused a potent and specific growth inhibition (see figure). Among the patients in whom point mutations were identified, new treatment options could have been selected in 14 out of 20 cases, harboring mutations in genes such as NOTCH1, IDH1/2, RAS, KIT, TET, EZH2 and KMT2A.

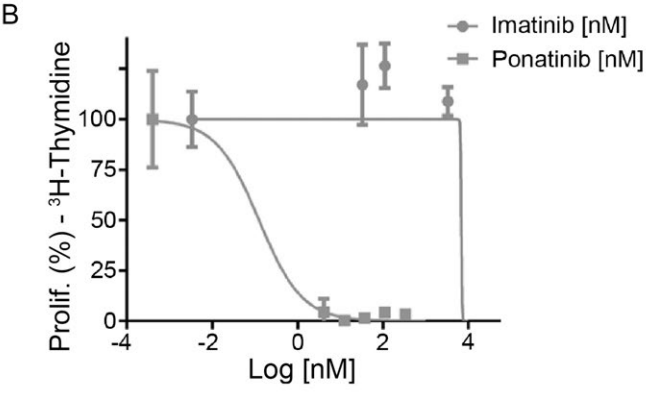

Figure 1.

Summary and Conclusions: NGS technologies, such as RNA-Seq, can result useful to identify genetic lesions and to tailor treatment in AML patients.

P193

SALVAGE REGIMENT WITH FRACTIONATED GEMTUZUMAB OZOGAMICIN, INTERMEDIATE DOSE CYTARABINE AND MITOXANTRONE (MYLODAM) FOR REFRACTORY AND RELAPSED AML: A SINGLE CENTER EXPERIENCE

A.C. Mamez[1,*] P. Hirsch[1], F. Isnard[1], S. Lapusan[1], M.T. Rubio[1], E. Grignano[1], C. Marzac[2], A. Vekhoff[1], M. Mohty[1], O. Legrand[1]

[1]Hématologie clinique, [2]Laboratoire d'hématologie, Hôpital Saint Antoine, Paris, France

Background: Gemtuzumab ozogamicine (GO, mylotarg ®) has been used for

refractory or relapsing AML with a response rate of 30% when used alone and 60% when used in combination with other chemotherapy. In the largest published study reporting the combination of a single dose of mylotarg® 9mg/m^2 with mitoxantrone and intermediate dose of cytarabine in relapsed AML, the 2 years OS and EFS were 41% and 33% respectively. Concerns about hepatic toxicity have limited mylotarg® use, particularly for patients who had previously received SCT. Several studies have shown good results and reduced toxicity when using mylotarg® in a fractionated dose schedule.

Aims: In this study, we report a one center experience of a new association with fractionated mylotarg® 3mg/m^{2}on day 1, 4, 7, mitoxantrone 12mg/m^{2}on day 1 to 3 and cytarabine 1g/m^2/12h on day 1 to 5 (MYLODAM), for refractory or relapsed CD33+ AML.

Methods: Twenty-four patients were treated with MYLODAM between January 2012 and December 2014. Median age at time of treatment was 55 years old (range 19-67). Seven patients received the MYLODAM salvage course for primary refractory CD33+ AML, 7 for relapsed AML after chemotherapy and 10 for relapsed AML after stem cell transplant (2 auto-SCT, 8 allo-SCT, in a median time between transplant and MYLODAM of 300 days). Cytogenetic risk groups were distributed as follow: 7 adverse karyotype, 9 intermediate risk and 7 favorable risk. Among the 12 patients with normal karyotype, 6 had NPM1 mutation and 5 had FLT3 ITD mutation. After reaching CR or CRp, 8 patients received at least one consolidation containing GO and 19 underwent allogeneic transplant (3 second allo-SCT, 16 first allo-SCT).

Results: Overall response rate was 19/24 (79%), including 6 CR and 13 CRp (with incomplete platelet recovery). One year estimated OS and EFS were 62 % and 60% respectively. Median OS and EFS were not reached, with a median follow-up of 12 months (figures 1A and 1B). We found no significant difference in terms of EFS and OS whether patients had refractory disease, post transplant or post chemotherapy relapse (p=0.41). Minimal residual disease was under the threshold of detection after salvage therapy for 11/ 15 responding patients with molecular evaluation (5/6 with NPM1 mutation, 5/6 with WT1 over expression and 1/3 for AML1-ETO transcript). The median duration of thrombopenia (<50G/L) and neutropenia (<500/mm^3) were 49 and 42 days respectively, for patients reaching CR or CRp. Early death (<30 days) occurred for one patient. Liver toxicity was frequent (elevation of transaminase levels: grade 0-1: 38%, grade 2-3: 54%, grade 4: 8% and hyperbilirubinemia ≥grade 2 in 2 cases). We report 2 cases of sinusoidal obstruction syndrome, none of them having received previous SCT; one patient died 18 days after the beginning of chemotherapy, the other patient was treated with defibrotide and is still alive.

Figure 1A:

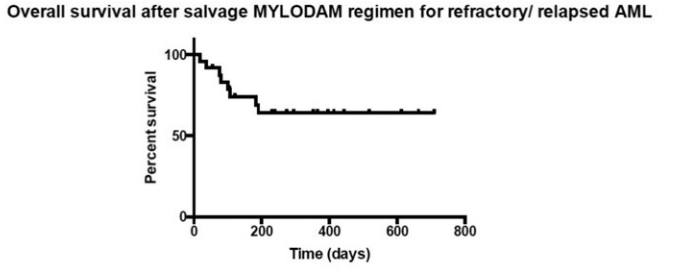

Figure 1B:

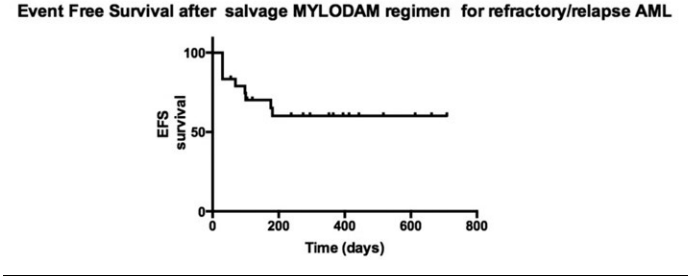

Figure 1.

Summary and Conclusions: MYLODAM is an efficient salvage regimen for refractory and relapse CD33+ AML. This combination based on fractionated mylotarg® has an acceptable safety profile, even for the 10 patients who were treated after SC transplant.

P194

EARLY PERIPHERAL BLAST CELL CLEARANCE PREDICTS MINIMAL RESIDUAL DISEASE STATUS AFTER INDUCTION IN ACUTE MYELOID LEUKEMIA

F. Mannelli[1,*] G. Gianfaldoni[2], I. Cutini[2], S. Bencini[2], M. I. Bonetti[2], M. Piccini[2], B. Scappini[2], V. Ponziani[2], F. Pancani[2], A. Bosi[2]
[1]Hematology, [2]University of Florence, Florence, Italy

Background: Identification of patients (pts) with acute myeloid leukemia (AML) having high likelihood to respond to standard therapy and those with low probability to do well and being candidates for more aggressive treatment is of major clinical importance. Most prognostic factors are surrogate for disease's chemosensitivity; among them, genetics is the most relevant, representing the framework of European Leukemia Net (ELN) risk stratification. It defines subgroups with relatively good survival (ELN-favorable) and at the opposite a category with poor prognosis (ELN-adverse). However, in the absence of genetic determinants, ELN system merges pts with heterogeneous diseases. At any rate, the response to induction therapy remains a powerful prognostic parameter, expressing actual chemosensitivity of AML cells. In responsive pts, minimal residual disease (MRD), usually evaluated after induction or consolidation cycles, is an accurate tool to refine risk category. We have previously demonstrated that an earlier assessment, based on the speed of peripheral blast clearance (PBC) as assessed by flow cytometry during induction therapy, strictly correlated with AML outcome.

Aims: To correlate PBC after the first 3 days of induction therapy with MRD assessment after induction at hematopoietic recovery.

Methods: Eligible pts had untreated non-M3 AML according to the World Health Organization criteria and were treated according to a standard induction therapy. At diagnosis, bone marrow (BM) aberrant leukemia-associated immunophenotypes (LAIP) were identified by flow cytometry. We quantified LAIP+ cells by single platform before treatment on day 1 and then following the first 3 days of therapy (day 4). PBC of each individual pt was expressed as the ratio between absolute LAIP cell count on days 1 and 4 converted to a logarithmic scale. By ROC curves we identified 1.5 log as the most accurate cut-off separating pts with high and low PBC index, respectively (PBC-hi, PBC-lo). In pts achieving CR after a single induction cycle, we searched for LAIP+ cells in BM expressing MRD as percentage on overall BM cellularity; pts were considered MRD+ when LAIP+ cells were detected as at least 0.01% of total BM cells.

Results: Between 2007-2013, 104 pts achieving CR had available LAIP and were studied both by PBC and MRD after induction. As concerns PBC, 34 (32.7%) pts were PBC-lo and 70 (67.3%) were PBC-hi. PBC status significantly correlated with ELN prognostic stratification of patients (p=0.0007). Regarding MRD, 50 (48.1%) pts were classified as MRD+ and 54 (51.9%) as MRD-. MRD status correlated with ELN categories as well (p=0.0067). Both PBC and MRD influenced disease-free and overall survival in univariate analysis. Most important, PBC was able to predict MRD status after induction; specifically, 45/70 (64.3%) PBC-hi and 9/34 (26.4%) PBC-lo pts were MRD-negative, respectively (Fisher's test p=0.0004). The combination of both parameters separated two categories of patients with favorable (PBC-hi/MRD-) and very poor (PBC-lo/MRD+) outcome, as depicted in Figure 1. Discordant cases showed intermediate prognosis.

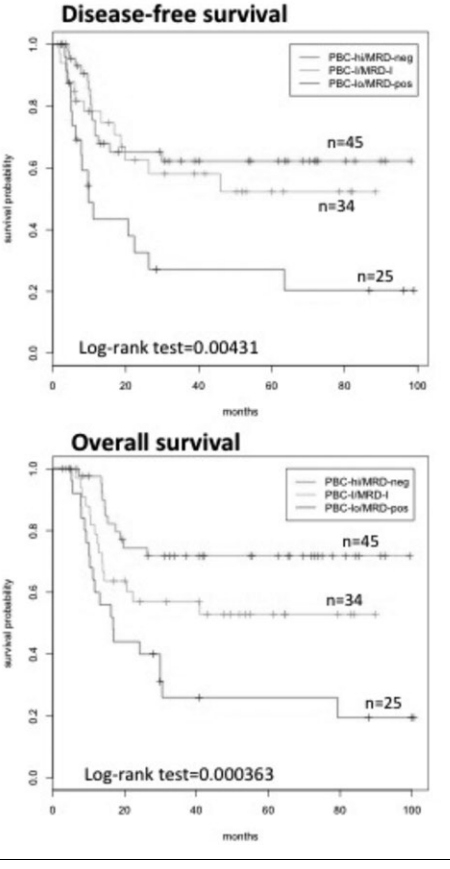

Figure 1.

Summary and Conclusions: PBC is very early and powerful outcome predictor in AML, providing a real time quantification of AML burden reduction in the first days of chemotherapy. PBC well correlated with MRD status after induction and the combination of both parameters identified pts with strikingly different outcome.

P195

MICRODUPLICATION 17Q21.31 AND 17P11.2 ASSOCIATE WITH AML DIAGNOSIS OR RESPONSE TO THE THERAPY

E. Jaskula[1,2], M. Mordak-Domagala[2], A. Sobczynska-Konefal[2], M. Sedzimirska[2], A. Lange[3,*]
[1] L. Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, [2]Lower Silesian Center for Cellular Transplantation with National Bone Marrow Donor Registry, [3]L. Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland

Background: Genetic work on leukemia documented the predictive power of chromosomal abnormalities as to the response to treatment. GTG and FISH techniques are of clinical value. More recently, it became apparent that heritable or acquired characteristics of non transcribing portion of the genome may influence the risk of cancer and the response to the treatment.
Aims: In the present study we looked at the copy number variations (CNV) to document the possible relations between the pattern of CNV in some regions of the genome and the risk of AML course in patients with normal karyotype (NK). This approach is supported by the observation that CNV pattern influences the expression of genes being in their vicinity; therefore, their examination offers better inside into genetic potential of leukemic cells. In an advent of the wide use of specific kinase inhibitors in the treatment of AML patients with Flt3 mutation we investigated the relation between the presence of this mutation and the CNV abnormalities to find out whether Flt3 internal tandem duplication (ITD) mutation associates with a more complex genetic background in NK patients.
Methods: 82 patients with AML (median age: 57,5 years old (range 21-81 years), 79 primary and 3 secondary AML) were investigated. GTG karyotyping was technically valid in 70 patients and in 25 FISH analysis was performed (XY, inv(3),-5/5q-,-7/7q-,+8, MLL, RUNX1, PML/RARA or RARA, inv(16) and MLL). Patients without abnormalities (46 patients) were classified as those with NK. Twenty six patients were Flt3 ITD positive. All fit patients received chemotherapy with intention to treat. Unfit patients were on the low dose AraC. All patients who proceeded to the consolidation therapy phase and those unfit having a stable number of blasts at three month after the treatment started were classified as good responders all others as poor. DNA was extracted from mononuclear cells (Ficoll separation) of the marrow aspirated at the diagnosis. One microgram portions of DNA were subtracted to the analysis employing WG Catalog NimbleGene 12x270K (Roche) and Catalog Agilent Cancer CGH+SNP 180K microarrays according to the manufacturer's instruction then were scanned in the Roche NimbleGene MS 200 instrument. Data was analyzed with the use of Nexus 7.5 (BioDiscovery) program.
Results: The difference in CNV was compared between Flt3 ITD positive and negative NK AML patients. It was found that the difference in the number of CNV was statistically significant only in the analysis of chromosome region chr17q21.31: 41576590-41682478. Flt-3 negative but not Flt3 ITD positive patients had CNV gains in that region (25% *vs* 0%, p=0.03). The presence of these microduplications barely affected their response to the treatment (37% *vs* 16%, n.s.). Working further on the relationship between the response to the treatment and CNV gains in chromosome 17. We found that NK patients with CNV gains in 17p11.2: 19065233-19083457 responded poorly to the induction therapy (66% *vs* 13%, P=0.013) and suffered from poor survival (p=0.037). Notably, none of the 7 patients having gains in the 17p11.2 region had TP53 mutation evaluated by the FISH technique.
Summary and Conclusions: From the present study we cannot conclude whether CNV abnormalities found in two chromosome 17 regions are inherited or acquired; however, these genetic traits may affect either the risk of leukemia (NK patients) or response to the treatment and survival in NK AML patients.
Supported by INNOMED/I/1/NCBR/2014 CellsTherapy grant

P196

THE SIGNIFICANCE OF RELATIVE MUTANT LEVEL FOR C-KIT MUTATION IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA BY ALLELE-SPECIFIC REAL-TIME PCR

E. Han[1,*] W. Jang[1], A. Kwon[1], M. Kim[1], Y. Kim[1]
[1]Laboratory medicine, Catholic university of the Medicine, Seoul St Mary's Hospital, Seoul, Korea, Republic Of

Background: The chromosomal aberrations such as t(8;21)(q22;q22), which result in *RUNX1-RUNX1T1* translocation, and inv(16)(p13q22)/t(16;16)(p13;q22), which result in *CBFβ-MYH11* translocation are collectively referred to as core binding factor acute myeloid leukemia (CBF AML). CBF AML is associated with a relatively good prognosis although some CBF AML cases are difficult to manage due to relapse. Recently, *c-KIT* mutations have been identified as a poor prognostic factor. However, the prognostic impact of *c-KIT* mutation still remains controversial. In this study, we investigated the relationship between *c-KIT* mutations and prognosis in CBF AML patients using highly sensitive detection method, quantitative allele-specific real-time PCR.
Aims: We performed this study to evaluate the prognostic impact of qualitative and quantitative determination of *c-KIT* mutations in CBF AML using highly sensitive method, although there have been few studies on detection of *c-KIT* mutations using allele-specific real-time PCR.
Methods: We analyzed the *c-KIT* mutations in 111 newly diagnosed adult CBF AML patients (74 with t(8;21) and 37 with inv(16)) in St. Mary's Hospital from April 2009 to July 2013. DNA isolated from paired bone marrow samples at the time of disease relapse and complete remission was also investigated. We used allele-specific real-time PCR to detect D816 and N822 mutations in *c-KIT* exon 17 and determined exon 8 mutations using direct sequencing analysis.
Results: Of the total 111 patients, 62% (69/111) and 8% (9/111) had c-KIT mutations in exon 17 and 8, respectively. CBF AML patients with a *c-KIT* exon 17 mutation showed significantly higher percentage of blasts in bone marrow aspirates at diagnosis (77.0% *vs* 73.0%, *P* =0.031), and significantly lower *WT1* expression (0.5 *vs* 0.7, *P* =0.048) than those without a mutation. CBF AML patients with *c-KIT* exon 17 mutations had worse event free survival (EFS) than patients without mutations. The estimated 5-year EFS rates were 86.1% for patients without mutations and 61.5% for patients with mutations (*P* =0.022). The estimated 3-year EFS was the lowest in patients with high mutant allele level (37.5%, *P* =0.003). In multivariate analyses, the high level of *c-KIT* exon 17 mutant alleles was associated with a statistically significant adverse impact on both OS (HR, 7.4, *P* =0.001) and EFS (HR, 4.6; *P* =0.004). Of the 17 relapsed patients, 15 had *c-KIT* mutations at diagnosis. *C-KIT* mutations were lost at relapse in 5 patients, and 2 patients who harbored double *c-KIT* mutations at diagnosis lost the major mutations while retaining the minor at relapse. *C-KIT* mutations showed the mutation disappeared at complete remission. There was a similar trend between the level of *c-KIT* mutant and the fusion transcripts in serial analyses.
Summary and Conclusions: The small populations of leukemic cells with *c-KIT* mutations could be detected by high sensitive quantitative method and high mutant level was associated with poor outcome. The quantitative measurement of the *c-KIT* exon 17 mutant allele burden could be a valuable tool in evaluation of prognosis at diagnosis and for subsequent patient monitoring.

Medizinische Klinik und Poliklinik im Städtischen Krankenhaus, Kiel, Germany, [12]Institut Universitaire du Cancer de Toulouse Oncopole, Université de Toulouse III, CHU de Toulouse, Toulouse, France, [13]Memorial Sloan-Kettering Cancer Center, New York, [14]Sunesis Pharmaceuticals, Inc., South San Francisco, [15]Cytel, Inc. and Harvard School of Public Health, Cambridge, [16]Medical University of South Carolina, Charleston, United States

Background: Prognosis for older patients with relapsed or refractory (R/R) acute myeloid leukemia (AML) is poor, with lower response rates and shorter survival compared with younger patients. Safe and effective salvage regimens are urgently needed. Vosaroxin is a first-in-class anticancer quinolone derivative that is active in AML, is minimally metabolized, evades P glycoprotein receptor–mediated efflux, and has activity independent of p53 status. VALOR, a phase 3, randomized, double-blind, placebo-controlled trial, evaluated vosaroxin plus cytarabine (vos/cyt) *vs* placebo plus cytarabine (pla/cyt) in patients with R/R AML (NCT01191801).
Aims: To evaluate the efficacy and safety of vos/cyt *vs* pla/cyt in patients ≥60 yrs of age enrolled in the VALOR trial.
Methods: Patients were randomized 1:1 to receive cytarabine (1 g/m^2 IV over 2 hr, d 1-5) plus either vosaroxin (90 mg/m^2 IV over 10 min d 1 and 4; 70 mg/m^2 in subsequent cycles) or placebo. Up to 2 induction and 2 consolidation cycles were administered. Eligible patients had refractory disease (persistent disease after induction, or first complete remission [CR1] duration <90 d) or were in first relapse (early relapse: CR1 duration of 90 d to 12 mo; late relapse: CR1 duration of 12 mo to 24 mo). Patients had 1-2 cycles of prior induction

chemotherapy including at least 1 cycle of anthracycline/anthracenedione and cytarabine. Randomization was stratified by age (<60, ≥60 yrs), disease status (refractory, early relapse, late relapse), and geographic location (US, non-US). Primary endpoints were overall survival (OS) and 30-and 60-day mortality. Here we report results of predefined subgroup analyses in patients ≥60 yrs.
Results: Between Dec 2010 and Sept 2013, 711 patients were randomized at 101 sites; 63% (n=451) were ≥60 yrs (n=226 randomized to vos/cyt and n=225 to pla/cyt). At final analysis, OS was improved with vos/cyt in patients ≥60 yrs (7.1 mo *vs* 5.0 mo with pla/cyt; HR=0.75; *P*=0.003) (**Figure**). Event-free survival was also improved (2.1 mo *vs* 1.3 mo with pla/cyt; HR=0.61; *P*<0.0001). CR was achieved in 31.9% of patients ≥60 yrs treated with vos/cyt *vs* 13.8% treated with pla/cyt (*P*<0.0001). Responses were durable; median leukemia-free survival among patients ≥60 yrs who achieved CR was 10.3 mo with vos/cyt *vs* 6.5 mo with pla/cyt (*P*=0.20). The rate of subsequent allogeneic transplant in patients ≥60 yrs was 20.2%. In a predefined sensitivity analysis in which patients were censored at allogeneic transplant, the survival benefit in patients ≥60 yrs was maintained (6.7 mo with vos/cyt *vs* 5.0 mo with pla/cyt; HR=0.75; *P*=0.009). Thirty-day and 60-day all-cause mortality in patients ≥60 yrs was similar between treatment arms (30-day: 10.2% *vs* 9.0%; 60-day: 20.4% *vs* 22.6% with vos/cyt *vs* pla/cyt, respectively). Serious AEs in the ≥60 population were more common with vos/cyt treatment (57% *vs* 33% with pla/cyt); most common serious AEs were febrile neutropenia (9.3% with vos/cyt *vs* 5.9% with pla/cyt), sepsis (9.3% *vs* 5.0%), pneumonia (7.5% *vs* 4.5%), bacteremia (7.5% *vs* 2.3%), and stomatitis (4.4% *vs* 1.8%). Serious and non-serious cardiac, renal, neurologic, and hepatic AEs were comparable between treatment groups.

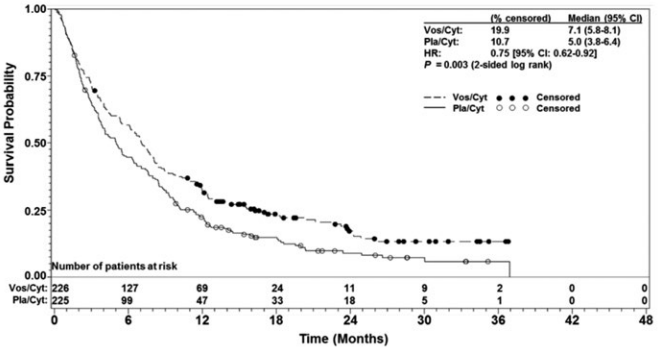

Figure 1. OS in patients age ≥60 years, by treatment arm (n=451).

Summary and Conclusions: The addition of vosaroxin to cytarabine improved OS and increased CR rates without increasing early mortality in older patients with R/R AML, a population with few treatment options. The additional toxicity observed in the vosaroxin arm was acceptable in light of the benefit received. VALOR results support the use of vos/cyt as a standard of care in patients ≥60 yrs of age with R/R AML.

CLL - Biology: Microenvironmental interactions

P198

IMPORTANCE OF THE B-CELL RECEPTOR ISOTYPE FOR SIGNALING AND FUNCTIONAL RESPONSES IN B CELLS FROM PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

E. ten Hacken[1], S.O'Brien[2], W.G. Wierda[1], A. Ferrajoli[1], Z. Estrov[1], M.J. Keating[1], C. Scielzo[3], P. Ghia[3], F. Caligaris-Cappio[3], J.A. Burger[1,*]
[1]Leukemia, [2]MD Anderson Cancer Center, Houston, United States, [3]IRCCS Ospedale San Raffaele, Università Vita-Salute San Raffaele, Milano, Italy

Background: B-cell receptor (BCR) signaling is a central pathogenetic mechanism in chronic lymphocytic leukemia (CLL). CLL cells express immunoglobulins of both IgM and IgD isotypes, but the relevance of these isotypes for signaling and functional responses remains incompletely understood.
Aims: The aim of the present study is to characterize functional differences between IgM and IgD signaling.
Methods: Purified CLL cells from 73 CLL patients (40 M-CLL and 33 U-CLL) were stimulated with anti-IgM and anti-IgD; phosphorylation levels of the BCR-related molecule HS1 and of the downstream kinase ERK was analyzed in serial samples after 2, 5, 15, 30, and 60 minutes of stimulation by Western Blot and flow cytometry; BCL6 expression were analyzed after 3, 6, 9, 12, 24 hours of stimulation by Western Blot. 48-hour cell viability was analyzed by flow cytometry; CCL3 and CCL4 chemokine production was measured by ELISA after 3, 6, 9, 12, and 24 hours of stimulation.
Results: sIgM and sIgD levels were significantly higher in U-CLL. Relative surface expression of IgM was 34.81±5.346 in M-CLL, as compared to 85.71±10.51 in U-CLL (p<0.0001). Relative surface expression of IgD was 32.30±4.463 in M-CLL, as compared to 59.74±8.054 in U-CLL (p=0.0048). Anti-IgM stimulation protected CLL cells from *in vitro* apoptosis to a greater extent than anti-IgD and this difference was more evident when considering the U-CLL subset of patients, which showed a mean relative viability after anti-IgM stimulation of 178±21.79% as compared to anti-IgD stimulation, which only reached 114.6±7.171% (p=0.0023). IgM stimulation induced protracted HS1 and ERK phosphorylation, up to 30 minutes following receptor engagement. In contrast, IgD stimulation induced short-lived phosphorylation of both proteins. CCL3 and CCL4 chemokines were secreted only after IgM stimulation, and surprisingly low, if any, induction was noted after IgD stimulation. When U-CLL cells were stimulated with 10 mg/mL anti-IgM, CCL3 levels in the surnatants were 2155±719.1 pg/mL, as compared to 96.70±23.38 pg/mL after 10 mg/mL anti-IgD. CCL3 and CCL4 chemokine secretion peaked after 9-12 hours of IgM stimulation, and was concomitant to BCL6 down-regulation, in particular in U-CLL cases. Interestingly, when CLL cells were co-cultured for 14 days with NLCs, relative surface IgM levels were down-modulated from 47.36±18.95 to 41.39±16.08 in M-CLL (p>0.05), and from 80.01±18.19 to 43.45±7.824 in U-CLL (p=0.0195). Consistent to this finding, CCL3 and CCL4 chemokines were secreted in CLL-NLC cocultures, in particular in U-CLL cases. The mean CCL3 levels in U-CLL surnatants were 923.9±250.8 pg/mL, as compared to 256.7±117.3 pg/mL for M-CLL (p=0.0062); CCL4 levels were also higher in U-CLL, but did not reach statistical significance.
Summary and Conclusions: IgM stimulation induces more durable signaling responses, increased CLL-cell survival, CCL3 and CCL4 secretion, and concomitant BCL6 down-regulation, in particular in U-CLL. In contrast, IgD responses are more transient and have no effect on CLL-cell survival or chemokine secretion. BCL6 is a known transcriptional repressor of the CCL3 gene in normal B cells, and our findings suggest that this mechanism is also recapitulated in CLL cells. In addition, stimulation provided by NLCs is associated with IgM receptor downmodulation and CCL3 and CCL4 chemokine secretion in U-CLL. Taken together, these evidences support the prevalence for IgM signaling in CLL pathogenesis.

Background: Studies of the B cell receptor immunoglobulin (BcR IG) in chronic lymphocytic leukemia (CLL) revealed that ~30% of cases can be assigned to stereotyped subsets. In our previous publication of 7,596 CLL BcR IG gene sequences, we focused on 19 major subsets, collectively accounting for 12% of the cohort. This process was based on the implementation of stringent criteria focusing on high sequence relatedness. However, we have been aware of BcR IG sequences similar to those in or even between major subsets, yet set apart due to not fulfilling the adopted criteria.
Aims: We systematically searched for previously obscured sequence relatives of major BcR IG stereotypes with the aim of obtaining a wider, better connected, and thus more insightful view into IG repertoire restriction in CLL.
Methods: Sequence relatives of major subsets were sought for through applying a series of criteria in reference to each respective subset: (i) usage of the same IGH genes, (ii) VH CDR3 length difference ranging from-2 to +2 amino acids (aa); and, (iii) expression of the same VH CDR3 sequence motif. A total of 20331 productive IGHV-IGHD-IGHJ gene rearrangements from a multi-institutional series of CLL patients were evaluated, with assignment to major subsets performed with purpose-built bioinformatics methods.
Results: Overall, 2450/20331 (12.1%) CLL sequences formed the 19 major subsets, each containing 44 to 548 sequences. The relative frequency of each major subset was highly similar between the present and the previous analysis, justifying their consideration as major. The quest for sequence relatives to major subsets was performed individually for each subset. For major subsets with mutated IGHV genes (M-CLL), generally, very few non-subset sequences showed adequate VH CDR3 similarity, and even these utilized different IGHV genes, thus not satisfying our search criteria. Amongst subsets with unmutated IGHV genes (U-CLL), a striking case of relatedness was observed between major subsets #1 (501 cases) and #99 (70 cases), characterized by the usage of the same IGH genes and the presence of a shared QWL motif at the same positions within VH CDR3. Their single important difference concerned VH CDR3 length (subset #1: 13 aa, subset #99: 14 aa). For the remaining major U-CLL subsets, certain subsets remained "unique", contrasting others for which we identified closely related sequences we now deem as "satellite" subsets. In particular, in the case of subset #8 (IGHV4-39) we identified two "satellite" subsets that consisted of 35 and 10 cases and displayed relative sizes of 37.6% and 10.8% (compared to subset #8), respectively. Even more pronounced was the case of subset #31 (IGHV3-48), with its "satellite" comprising of 51 sequences and a relative size of 86.4% compared to subset #31, thus almost equal to its established relative.
Summary and Conclusions: Major M-CLL stereotyped subsets remained isolated, with unique sequence characteristics. In contrast, a clear trend was evident for many major U-CLL subsets in having "satellites", potentially functionally equivalent, and often large in size. These findings could be attributed to the intrinsic differences between M-CLL *versus* U-CLL subsets in terms of IG gene repertoire and VH CDR3 features. Considering that major stereotyped subsets may indeed represent distinct disease subgroups, our highlighting of higher-order sequence relations has implications for clinicobiological research aimed at dissecting the heterogeneity of CLL towards identifying distinct profiles that would assist in clinical decision making.

P200

SPECIFIC T-CELL IMMUNE RESPONSES AGAINST AUTOANTIGENS RECOGNIZED BY CHRONIC LYMPHOCYTIC LEUKEMIA CELLS

J. Zaleska[1,*] K. Skorka[1], M. Zajac[1], A. Karczmarczyk[1], M. Karp[1], W. Tomczak[2], P. Wlasiuk[1], K. Stamatopoulos[3,4,5], K. Giannopoulos[1,2]
[1]Department of Experimental Hematooncology, [2]Department of Hematooncology and BMT Unit, Medical University of Lublin, Lublin, Poland, [3]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, [4]Hematology Department and HCT Unit, G. Papanicolaou Hospital, [5]Institute of Applied Biosciences, Centre for Research and Technology-Hellas, Thessaloniki, Greece

Background: The etiology of chronic lymphocytic leukemia (CLL) remains elusive, but there is growing evidence indicating a role of autoimmunity as well as relevance of antigen stimulation in pathogenesis of CLL. Appearance two groups of patients with mutated and unmutated status of the rearranged immunoglobulin heavy variable *(IGHV*) genes and more frequent occurrence of B-cell receptor (*BCR*) gene sequences, that are virtually-identical in unmutated CLL suggest that an unknown antigen could be involved in development of CLL. Recent studies proved occurrence of monoclonal antibodies directed against cytoskeletal proteins including non-muscle myosin heavy chain IIA (MYHIIA), vimentin, and cofilin-1, that are exposed on the surface during apoptosis. These molecules could represent autoantigens recognized by the specific BCR of the CLL cells.
Aims: Current study aimed to characterize response of T cells specific to epitopes derived from three autoantigens including MYHIIA, VIM and CFL1.
Methods: *MYH9, VIM,* and *CFL1* genes expression was analyzed using qRT-PCR in 212 CLL patients. HLA-A2-restricted epitopes derived from MYHIIA, cofilin-1 and vimentin were selected *in silico* using 2 independent prediction algorithms. The affinity of MHC class I-restricted peptides was determined by cellular-peptide binding affinity assay utilizing T2 cell line. Mixed lymphocyte peptide cultures (MLPC) were performed to define immunogenicity of synthesized peptides *in vitro.* To detect specific immune response ELISpot assays for specific IFN-γ release were evaluated. Finally, the frequency of the specific T cells directed against selected peptide with the highest along with detailed phenotypical characteristics was assessed using dextrameric peptide-specific complexes in 7-colour flow cytometry panel *ex vivo*.
Results: In CLL patients analyzed with qRT-PCR *CFL1* overexpression in comparison with healthy volunteers was found, while there were no differences in *MYH9* and *VIM* expressions between CLL and HV. The *in silico* analyses followed by *in vitro* HLA-A2 cellular-peptide binding assay enabled to define 9 immunogenic peptides derived from MYHIIA, vimentin and cofilin-1. MLPC with ELISpot assays revealed higher specific cytotoxic immune response for peptides derived from MYHIIA in 4/6 (66.7%), vimentin 7/8 (87.5%) and cofilin-1 5/8 (62.5%) in CLL patients in comparison with healthy volunteers 3/8 (37.5%).Multicolor flow cytometry panel demonstrated low frequencies of autoreactive peptide-specific T cells against MYHIIA, vimentin and cofilin-1 in CLL patients *ex vivo*; most of detected cells presented effector-memory phenotype. Results obtained from functional assays were compared with mutational status of *IGHV* genes in CLL patients including subset analysis. Interestingly, we found 6 CLL patients with stereotypic BCR represented subset clones subset no.2 [*IGHV3-21*M], subset no.4 [*IGHV4-34M*], subset no.5 [*IGHV1-69*UM], subset no.34 [*IGHV1-69*UM], subset no. 59 [*IGHV1-58*UM] and subset no. 64B [*IGHV3-48*UM]. All of these patients demonstrated reactivity against peptides derived from MYHIIA, vimentin or cofilin-1. Interestingly, we found presence of autoreactive cofilin-1-derived peptide specific cytotoxic T lymphocytes in patient characterized by subset no. 5 [*IGHV1-69UM*] *ex vivo*.
Summary and Conclusions: The presence of autoreactive T lymphocytes that might be involved in pathomechanism of CLL during stimulation of an autoreactive B cells in proliferative compartment, indicate on important role of autoimmunity in the pathogenesis of CLL. Autoantigenic stimulation through apoptotic cells could lead to the proliferation of leukemic cells, possibly maintained or at least accompanied by autoreactive T cells.

P201

STEM CELL FACTOR KLF4 IS EPIGENETICALLY INACTIVATED AND REPRESSED BY NOTCH SIGNALING IN CLL

D. Mertens[1,2,*] K. Filarsky[2], R. Claus[3], C. Plass[4], H. Döhner[1], P. Lichter[5], S. Stilgenbauer[1]
[1]Internal Medicine III, University Ulm, Ulm, [2]Mechanisms of Leukemogenesis, DKFZ, Heidelberg, [3]Internal Medicine I, University Freiburg, Freiburg, [4]Epigenomics, [5]Molecular Genetics, DKFZ, Heidelberg, Germany

Background: Whole genome sequencing revealed CLL as a disease of the genome and epigenome characterized by somatic mutations and aberrant DNA-methylation. A number of genes have already been identified that show aberrant DNA methylation in CLL cells. Examples are *e.g.* ZAP70 that is involved in B cell and T cell signaling and whose promoter DNA-methylation is correlated with its decreased expression. Of note, DNA-methylation of a single CpG dinucleotide is important for ZAP70 expression and predictive of prognosis. Similarly, the

MYB proto-oncogene is directly methylated in CLL, WNT signaling activation has been related to hypermethylation of WNT inhibitor genes and also miRNA transcriptional deregulation in CLL has been linked to aberrant DNA-methylation. DNA-methylation has been reported to be stable over time in leukemic cells of CLL patients and to be similar in resting and proliferative compartments. Of interest, in addition to comparison with healthy tissue, recent publications have shown intratumor heterogeneity of DNA methylation. We therefore focused on identifying functionally relevant aberrant DNA-methylation of promoters in CLL that correlates with transcriptional activity and is therefore most likely to impact on gene regulation. With this approach we could identify the stem cell factor KLF4 to be epigenetically deregulated in CLL, and could further show that this defect is possibly caused by aberrant activation of NOTCH1.
Aims: To identify genes that: display an aberrant DNA-methylation in their promoter in CLL cells; whose promoter DNA methylation correlates with their transcriptional activity; to understand their functional role in the cellular pathomechanism of CLL.
Methods: In order to uncover the impact of aberrant DNA-methylation on the transcriptional profile of CLL cells, gene expression and methylation array profiling was performed in CLL-and B-cells using standard and custom microarrays. Methylated DNA was precipitated using a methyl-cytosin binding fusion protein (MCIp) and detected with arrayed 60bp oligonucleotides that span all RefSeq human gene promotors-3.8 to +1.8kbp from the transcriptional start sites. Functional analyses of candidate epigenetically deregulated genes were performed using transient transfections in primary CLL cells and subsequent phenotypic analysis of target gene expression and apoptosis of transfected cells. In addition, NOTCH1 signaling was inhibited in primary CLL cells using g-secretase inhibitors to assess the impact on KLF4 levels.
Results: 1866 genes were differentially expressed in CLL ($log_2FC \leq |1|$, $p \leq 0.05$). DNA-methylation covered a greater heterogeneity in CLL cells compared to the healthy counterpart. In total, 2191 genes displayed aberrant methylation within their promoter ($log_2FC \geq |0.5|$, $p \leq 0.05$). However, only 33 of these genes also showed a significant negative correlation between expression and methylation, including CBX7, ADRB2, CXCR3, LILRA4 and KLF4. We focused on the transcriptional regulator KLF4 that was recently shown to play an important role in B cell development and maturation and to act as tumor suppressor in NHL and cHL. KLF4 downregulation was correlated in CLL with hypermethylation in a region downstream of its TSS. Expression was also correlated with levels of BCL2 family members BAK, BAX, BCL2 and with the cell cycle regulator CCND1. Inhibition of NOTCH1 signaling, which is constitutively activated and frequently mutated in CLL patients, led to re-expression of KLF4 in 8 patient samples and 6 leukemia-and lymphoblastoid cell lines, indicating regulation by NOTCH1 in B cells. Intriguingly, ectopic overexpression of KLF4 in CLL cell lines resulted in the deregulation of genes involved in signaling pathways including BCR signaling.
Summary and Conclusions: The detected epigenetic deregulation of the stem cell factor KLF4 is possibly caused in CLL by aberrant activation of NOTCH1. It underlines a defect in the developmental program of CLL and suggests aberrant arrest of CLL cells in a terminally differentiated state.

P202

NOTCH2 AND NOTCH3 HAVE OPPOSITE ROLES IN THE REGULATION OF APOPTOSIS IN CLL CELLS

R. Hubmann[1,*] M. Araghi[1], S. Schnabl[1], M. Hilgarth[1], E. Ponath[1], M. Reiter[1], D. Demirtas[1], U. Jäger[1], M. Shehata[1]
[1]Comprehensive Cancer Center, Medical University of Vienna, Vienna, Austria

Background: Chronic lymphocytic leukemia (CLL) cells express constitutively activated NOTCH2. We have recently shown that the NOTCH2 transactivation inhibitor gliotoxin induces apoptosis in CLL cells by a mechanism involving the induction of *NOTCH3*. However, the regulation and possible functions of NOTCH3 in resting and activated CLL cells remain to be clarified.
Aims: To elucidate the different roles of NOTCH2 and NOTCH3 in CLL cells we compared the effects of gliotoxin and the clinical relevant γ-secretase inhibitor (GSI) RO4929097 on CLL cells *in vitro*.
Methods: The dose and time dependent effects of these compounds on CLL cell viability and on the induction of apoptosis, respectively, was determined by MTT-assays and by FACS analysis. The influence of gliotoxin and RO4929097on the expression of *NOTCH* and apoptosis related genes was analysed by RT-PCR.
Results: Gliotoxin rapidly induced apoptosis in all CLL cases whereas RO4929097 affected CLL cell viability only in a subgroup of cases after a prolonged incubation time. All *NOTCH1* mutated CLL samples clustered in the RO4929097 sensitive group. Chronic activation of CLL cells with low doses of PMA (1ng/ml) enhanced NOTCH2 signaling, inhibited spontaneous apoptosis, and strongly induced the proliferation marker *MYC* mimicking the proliferative compartment in the lymphoid microenvironment. Inhibition of NOTCH2 by gliotoxin led to the concomitant induction of homotypic NOTCH3 signalling as indicated by the induced mRNA expression of *NOTCH3* and its ligands *JAG2* (in unstimulated CLL cells) or *DLL1* (in PMA activated CLL cells) together with an upregulation of the activation induced cell death (AICD) mediator *NR4A1*. In contrast, RO4929097 inhibited NOTCH3 signalling, *NR4A1* transcription, and counteracted gliotoxin mediated apoptosis in GSI resistant CLL cases indicating a tumour suppressive role for NOTCH3 in the leukemic cells. In line with this hypothesis, the downregulation of NOTCH2 activity in unstimulated CLL cells *in vitro* was associated with upregulation of *NOTCH3* mRNA expression and increased spontaneous apoptosis especially in CLL samples derived from Rai/Binet I/A patients. In this context, RO4929097 inhibited *NOTCH3* and *NR4A1* expression an inhibited spontaneous apoptosis depending on the GSI sensitivity of NOTCH2.
Summary and Conclusions: In summary, these data indicate that NOTCH2 and NOTCH3 have counteracting roles in the regulation of CLL apoptosis which should be considered in therapeutic approaches aimed to target NOTCH signaling in CLL. Constitutive active NOTCH2 might inhibit tumour suppressive NOTCH3 signaling in CLL cells thereby enabling the activation dependent progredient expansion of the malignant clone. Thus, gliotoxin selectively targets oncogenic NOTCH2 signalling in a wide spectrum of CLL cases while GSIs may be effective onlyin a subgroup of CLL patients including *NOTCH1* mutated cases.

P203

EXPRESSION AND FUNCTIONAL ROLE OF CORTACTIN IN AGRESSIVENESS AND DIFFUSION OF CHRONIC LYMPHOCYTIC LEUKEMIA

V. Martini[1,*] C. Gattazzo[1], F. Frezzato[1], V. Trimarco[1], G. Chiodin[1], F. Severin[1], M. Pizzi[1], F. Marino[1], A. Visentin[1], G. Semenzato[1], L. Trentin[1]
[1]University, Padua, Italy

Background: Cortactin is an actin-binding protein involved in several cell functions, *i.e.* the assembly and the organization of cytoskeleton. Its overexpression was observed in several human cancers and experimental data support the role of cortactin in metastatic capability through the regulation of cell motility and the release of matrix metalloproteinase-9 (MMP-9). The activity of this protein is regulated by its phosphorylation in Tyr residues by Src kinase family. We previously demonstrated that in leukemic cells from CLL patients the Src kinase Lyn is overexpressed, activated and involved in the resistance to apoptosis. Recently, we found that cortactin is overexpressed in patients with CLL.
Aims: Here we investigated the involvement of cortactin in the release of MMP-9 and, therefore, in the progression of CLL.
Methods: Blood samples were collected from 7 controls and 17 CLL patients. Informed consent was obtained according to the Declaration of Helsinki. Untouched peripheral blood B cells were purified using the *RosetteSep* for human B cells isolation kit. The samples that were used had at least 95% of normal CD19+ or neoplastic CD5+/CD19+ cells, as assessed by flow-cytometry (FC). Purified B cells (2×10^6cells/ml) were cultured in RPMI medium with or without CXCL12 (100ng/ml) for the evaluation of MMP-9 production. MMP-9 release by neoplastic B cells was also investigated after cortactin silencing in 4 patients expressing high level of cortactin. The protein was silenced by *SMART*pool siRNA collection (Dharmacon, Thermo Scientific), according to the manufacturer's instructions. Immunohistochemical (IHC) staining was performed on formalin-fixed, paraffin-embedded tissue sections using a fully automated platform.
Results: By IHC and FC we confirmed the increased expression of cortactin in CLL patients with respect to controls. Moreover, we identified to groups of patients: one characterized by high expression the other by low expression of protein. By gelatin zymography we found that the release of MMP-9 by neoplastic B cells correlated to the expression of cortactin after 5 and 24-hrs culture. To investigate whether cortactin was involved in MMP-9 secretion in CLL, a cortactin-targeted siRNA silencing system was used to knockdown this protein in 4 patients with high cortactin expression. We found that following cortactin knockdown, leukemic cells showed a defect in MMP-9 secretion, as assessed by ELISA test. This protease also showed a decreased gelatinolytic activity in culture medium, confirming the hypothesis that cortactin is involved in the regulation of MMP-9 secretion in CLL malignant cells. Finally, we found that the incubation of leukemic cells with PP2 or other kinase inhibitor, decreased Tyr phosphorylation level of cortactin and shut down the release of MMP-9 in culture medium, also following CXCL12 triggering.
Summary and Conclusions: The overexpression of cortactin in neoplastic B cells and the correlation between cortactin levels, activity and MMP-9 release suggest a role of this protein in metastatic invasion and in the CLL aggressiveness. In addition, cortactin might represent a biomarker for diagnosis and prognosis as well as target for new therapeutic strategies.

P204

ROLE OF HAUSP/PTEN NETWORK IN CHRONIC LYMPHOID LEUKEMIA PATHOGENESIS AND THERAPY

G. Carrà[1,*] C. Panuzzo[1], D. Torti[1], G. Parvis[1], S. Crivellaro[1], A. Guerrasio[1], G. Saglio[1], A. Morotti[1]
[1]Department of Clinical and Biological Sciences, University of Turin, San Luigi Hospital, Turin, Italy

Background: PTEN tumor suppressor was shown to play a role in Chronic Lymphocytic Leukemia (CLL). In particular, it was demonstrated that PTEN is phosphorylated in the tail by Casein Kinase II, favoring its inactivation. Further-

more, it was also proposed that PTEN levels are significantly reduced in some CLL patients. PTEN tumor suppressive functions are also regulated by proper cellular compartmentalization through mono-ubiquitination. In particular, PTEN mono-ubiquitination promotes PTEN nuclear localization, while PTEN de-ubiquitination by HAUSP promotes PTEN nuclear exclusion with dramatic consequences on the tumor suppressive function.
Aims: Assessment of the biological role of CKII/HAUSP/PTEN network in CLL in order to evaluate HAUSP as a rheostat in the regulation of PTEN. Evaluation of the therapeutic role of HAUSP inhibitors in CLL.
Methods: Primary CLL cells were collected from untreated and informed patients accordingly to ethical committee approved protocol, during routinely diagnostic procedures. Cells were enriched in CD19 fraction using the Miltenyi anti CD19 kit. CLL CD19 cells were used for different analyses. Immunofluorescence was performed to investigate PTEN cellular compartmentalization. Protein samples were used for HAUSP and PTEN protein levels quantification and evaluation of those proteins regulated by HAUSP (p53, p21, MDM2). The same material was used for PTEN ubiquitination, PTEN phosphatase assay and Casein Kinase II kinase assay. Transfected CLL cell lines with GFP-PTEN and mutant constructs were used to evaluate the contribution of PTEN in promoting growth arrest and/or apoptosis induction. HAUSP inhibitors were used in CLL cell lines and proliferation and apoptosis were evaluated with MTT technology and Annexin V-FITC/Propidium PE detection by flow cytometry.
Results: By immunofluorescence we observed that a portion of CLL patients is characterized by PTEN nuclear exclusion. PTEN protein levels did not correlate with cellular compartmentalization, suggesting that the two phenomena are regulated by different mechanisms. Forcing PTEN expression into the nucleus of a CLL cell line, with a PTEN-NLS expressing vector, was associated with strong apoptosis induction and growth arrest. These observations suggest that PTEN is functionally inactivated in CLL. Next, we assessed PTEN ubiquitination in CLL primary cells. We observed that PTEN is de-ubiquitinated, clearly demonstrating a direct role of HAUSP in PTEN nuclear exclusion of CLL cells. Our data suggested a dual regulatory mechanisms that activate HAUSP towards PTEN. HAUSP could be either over-expressed and/or regulated by Casein Kinase II, which phosphorylates HAUSP on serine residues. Interestingly, treatment of CLL cells with HAUSP small molecule inhibitors is associated with re-localization of PTEN into the nucleus, which in turn promotes cell growth arrest and apoptosis induction.
Summary and Conclusions: Our data demonstrate that (1) PTEN is functionally inactivated by nuclear exclusion in CLL; (2) PTEN can be reactivated in CLL through HAUSP and Casein Kinase II inhibitors, with significant therapeutic implications.

P205

UPREGULATED COBLL1 IN CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL) PATIENTS WITH UNMUTATED IGHV IDENTIFIES A COHORT WITH INFERIOR PROGNOSIS

H. Plesingerova[1,2,*] P. Janovska[3], L. Poppova[1,2], A. Shaik[3], Z. Jurcickova[4], A. Libra[4], K. Plevova[1,2], J. Machac[5], I. Slapak[5], S. Pavlova[1,2], P. Ovesna[6], J. Kotaskova[1,2], M. Doubek[2], S. Pospisilova[1,2], V. Bryja[3]
[1]Molecular Medicine, Central European Institute of Technology, Masaryk University, [2]Center of Molecular Biology and Gene Therapy, Department of Internal Medicine-Hematology and Oncology, University Hospital Brno, [3]Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, [4]GENERI BIOTECH, s.r.o., Hradec Kralove, [5]Clinic of Pediatric Ear, Nose & Throat Diseases, Faculty of Medicine, University Hospital Brno, Masaryk University, [6]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic

Background: Chronic lymphocytic leukaemia (CLL) is a heterogeneous disease; patients are stratified into two prognostic groups with either mutated (M-CLL) or unmutated (U-CLL) *IGHV*. CLL cells are also characteristic by upregulated expression of a transmembrane tyrosine-protein kinase (ROR1), a member of Wnt/planar cell polarity (PCP) pathway, which influences migration of CLL cells and chemotaxis. We have identified recently Cordon-bleu protein-like 1 (COBLL1) as a ROR1 binding partner. The significance of COBLL1 for CLL patient stratification remains unknown.
Aims: Our aim was (i) to examine expression of *COBLL1* in CLL cells and (ii) to analyse *COBLL1* expression in relation to the patients' prognosis.
Methods: We analysed *COBLL1* expression in 174 previously untreated patients (82 U-CLL, 92 M-CLL) by qRT-PCR and correlated the results with prognostic markers (*TP53* defect, *IGHV* status, del 11q, del 13q, trisomy 12, *ATM, BIRC3*, *MYD88* and *NOTCH1* mutation). We also examined how chemotaxis of CLL cells towards chemokines CCL19 and CXCL12 differs depending on *COBLL1* expression (11 M-CLL, 10 U-CLL *COBLL1*-low, 6 U-CLL *COBLL1*-high).
Results: *COBLL1* expression in CLL cells is heterogeneous. *COBLL1* is upregulated in all M-CLL (M-CLL *vs* U-CLL, p<0.0001, Mann Whitney test), whereas its expression in U-CLL shows a bimodal pattern and distinguishes two prognostically different subgroups. Intriguingly, the U-CLL *COBLL1*-high patients suffer from more aggressive disease than the U-CLL *COBLL1*-low patients, which results in their shorter time to first treatment (TTFT), time to second treatment (TTST) and overall survival (OS) (TTFT: medians 20 *vs* 33 months, p=0.0226; TTST: 36 *vs* 57, p=0.0055; OS: 75 *vs* 207, p=0.0037, Mantle Cox test). Analysis of biological markers revealed lower somatic hypermutation load in U-CLL *COBLL1*-high cells (p=0.0062, Mann Whitney test). No other genomic differences which might result in survival differences within U-CLL patients have been found. Frequency of *TP53* defect was not statistically significant (29% U-CLL *COBLL1*-high *vs* 22% U-CLL *COBLL1*-low). Therefore, we analysed the cell migration abilities of U-CLL *COBLL1*-high towards chemokines CCL19 and CXCL12 and found impaired migration compared to M-CLL and U-CLL *COBLL1*-low cells (CCL19: M-CLL *vs* U-CLL *COBLL1*-high, p=0.0182, Mann Whitney test). In basal migration, the trend was reversed, *i.e.* basal migration of U-CLL *COBLL1*-high cells was increased compared to the M-CLL and U-CLL *COBLL1*-low cells.
Summary and Conclusions: *COBLL1* expression in CLL cells differs dramatically and identifies a novel subgroup within U-CLL patients with inferior prognosis. Their shorter survival cannot be explained by any other prognostic marker tested. Aggressive disease course of U-CLL *COBLL1*-high patients can be a result of a deregulated response to microenvironment stimuli caused by deregulated Wnt/PCP pathway. Supported by MUNI/A/1180/2014, IGA NT13493-4/2012, GACR P301/11/0747, 15-29793A, CZ.1.07/2.3.00/30.0009.

EXTRACELLULAR VESICLES FROM MESENCHYMAL STROMAL CELL MICROENVIRONMENT PROTECT CHRONIC LYMPHOCYTIC LEUKEMIA B-CELLS FROM APOPTOSIS

E. Crompot[1,*] M. Van Damme[1], H. Duvillier[2], K. Pieters[1], P. Mineur[3], N. Meuleman[2], D. Bron[2], L. Lagneaux[1], B. Stamatopoulos[1]
[1]Jules Bordet Institute/ULB, [2]Jules Bordet Institute, bruxelles, [3]Grand Hopital de Charleroi, Gilly, Belgium

Background: The interactions between chronic lymphocytic leukemia (CLL) cells and the microenvironment (primarily composed by mesenchymal stromal cells-MSC) play an important role in promoting the increased survival of leukemic B cells. Extracellular vesicles (E*Vs*) produced by leukemic cells and the microenvironment may be implicated in this cross-talk. E*Vs*, including microparticles and exosomes, are small plasma membrane fragments with sizes ranging from 0.01 to 1µm, and contain products specific to the original cell, such as microRNA, mRNA and proteins.
Aims: Our objective is to assess the role of E*Vs* in the cross-talk between malignant cells and their microenvironment.
Methods: Ultracentrifugation at 150000 x g during 1h was applied to isolate E*Vs* from supernatant of MSC culture. Protein concentration was measured by BCA kit and Nanodrop. Different concentrations of E*Vs* were added to CLL-B-cells to evaluate their impact on cell proliferation and survival. PKH67 labeling and qRTPCR were performed to prove the inclusion of E*Vs* in CLL B-cells (18 samples were analyzed).
Results: We first demonstrated that E*Vs* from MSCs are able to enter in CLL B-cells. By flow cytometry with PKH67-labelled E*Vs*, we observed that 44.2, 93.8 and 100% of CLL B-cells had integrated fluorescent E*Vs* after 1, 3 and 24h respectively. Two highly expressed mRNA (collagen and fibronectin) in MSC, also detected in MSC-derived E*Vs* by qRTPCR, were increased in CLL-B cells after 24h of incubation with E*Vs* confirming EV-mediated mRNA transfer to target cells. Further analysis of apoptosis in CLL cells were assessed by flow cytometry using an Annexin/7AAD staining: addition of increasing concentrations of E*Vs* showed a protective effect on CLL B-cells from cell death (mean increase of 11% of live cells, n=19/p-value=0.007).
Summary and Conclusions: We demonstrated, by two methods, that MSC-derived-E*Vs* enter into CLL B-cells. These vesicles protect CLL cells from spontaneous apoptosis and affect mRNA expression involved in CLL cell functions. This study provides evidence of the critical role played by E*Vs* in the interactions between leukemic cells and their microenvironment.

P207

FUNCTIONAL INVOLVEMENT OF THE SRC KINASE LYN IN THE SURVIVAL OF CHRONIC LYMPHOCYTIC LEUKEMIA CELLS VIA MAINTENANCE OF ANTI-APOPTOTIC B CELL RECEPTOR SIGNALING

V. Vondey[1,*] M. Kuckertz[1], E. Göckeritz[1], M. Hallek[1], G. Krause[1]
[1]Dept. I of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: The Src family tyrosine kinase Lyn shows high protein levels and activity in chronic lymphocytic leukemia (CLL) cells and pharmacological inhibitors of Lyn cause apoptosis.
Aims: In a chemical genetics approach using inhibitor-resistant mutant kinases, the functional roles in CLL pathogenesis of the Src kinases Lyn and Lck and of Abl were validated with the aid of Src/Abl inhibitors in current clinical use or development. To dissect the effects of these inhibitors with relatively broad selectivity and to unequivocally assign partial contributions to blocked Lyn activity, we monitored the protection from inhibitor effects by mutant Lyn with a modified binding pocket.
Methods: For this purpose the CLL-derived, EBV-transformed lymphoblastoid

cell line JVM-3 was retrovirally transduced to express Lyn-T319I or wild type (WT) in addition to endogenous Lyn. Cellular survival of JVM-3 cells and CLL samples after inhibitor treatment was determined by annexin V/7AAD staining. Signaling analysis was performed using Western Blotting and electrophoretic mobility shift assays. Transient down-regulation of Lyn expression was achieved after nucleofection with specific siRNA. In addition, the impact of Src/Abl inhibitors on purified Lyn and Abl was determined in a FRET-based kinase activity assay.

Results: The activity of purified Lyn and Abl was inhibited to similar degrees by Src/Abl inhibitors at >5000-fold lower concentration as required for cytotoxicity for malignant B cells and more strongly by dasatinib than bosutinib. JVM-3 cells showed similar sensitivity for Src-Abl inhibitors as CLL cells isolated from patients' blood, *e.g.* approximately 2.5 times higher cytotoxicity of bosutinib than dasatinib. The activating autophosphorylation of the activation loop tyrosine of Src kinases was diminished by Src-Abl inhibitors in parental JVM-3 cells and in transductants expressing Lyn-WT, but maintained with Lyn-T319I expression. In the same manner survival of JVM-3 cells was reduced in the presence of Src-Abl inhibitors and rescued by expression of Lyn-T319I, but not by Abl-T315I. Src-Abl inhibitors as well as siRNA knock-down of Lyn led to phosphatidylserine exposure, increased poly(ADP)ribosyl polymerase cleavage and reduced Mcl-1 levels. Stronger cell killing by siRNA knock-down of Lyn than of Lck corresponded to a higher degree of protection from inhibitor-induced apoptosis by Lyn-T319I than by Lck-T316I. In the presence of Src/Abl inhibitors, Lyn-T319I restored the activating phosphorylation of the direct Lyn substrates Syk and phospholipase C-γ and of Akt at serine 473, as well as the DNA binding activity of the transcription factors NFκB and STAT3. Lyn determined the maintenance of high levels of the anti-apoptotic protein Mcl-1 mainly via transcriptional mechanisms.

Summary and Conclusions: The described chemical genetic approach permitted to confirm a functional role of Lyn at nodes of anti-apoptotic signalling networks and to quantitatively compare the contributions of Lyn and other kinases.

P208

THE COMBINATION OF ARSENIC TRIOXIDE AND IBRUTINIB INDUCES SYNERGISTIC APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKAEMIA THAT IS POTENTLY ASSOCIATED WITH PI3K-AKT DOWN-REGULATION

X.H. Zhang[1,*] R. Feng[2], Y. Kong[1], S.M. Yang[1], Q. Jiang[1], H. Jiang[1], M. Lv[1], L.P. Xu[1], K.Y. Liu[1], X.J. Huang[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Departments of Hematology, Beijing Hospital, Ministry of Health, Beijing, China

Background: Chronic lymphocytic leukaemia (CLL) is generally treated by chemoimmunotherapy, and there is an unmet medical need for novel targeted therapies or combination therapies. Ibrutinib is an efficient therapeutic agent for CLL. However, some patients do not respond to ibrutinib, and the long-term safety of ibrutinib has not been established. (Chung *et al.*, Pharmacotherapy2014) By combining ibrutinib with other agents, higher responses are expected in CLL patients. Our previous study also suggested that arsenic trioxide (As_2O_3) induces CLL cell apoptosis and serves as an efficient therapeutic agent for CLL alone or in combination with other agents.

Aims: The aim of the study is to investigate whether As_2O_3 combined with ibrutinib inhibits CLL cell proliferation synergistically *in vitro* and *in vivo*.

Methods: The CLL cell line MEC1 and primary B lymphocytes (PBL) from CLL patients were used to examine the effects of As_2O_3 and ibrutinib alone or in combination on CLL proliferation and apoptosis. The combinatorial effects of As_2O_3 and ibrutinib on the growth and apoptosis of MEC1 cells and PBLs were evaluated. Chou–Talalay analyses were preformed to evaluate the combinatorial effects of As_2O_3 and ibrutinib on CLL cells *in vitro*. To identify the possible signal pathway involved in the synergistic effect, microarray analysis was conducted on PBLs from 5 independent patients with CLL before and after treatment with As_2O_3 and ibrutinib alone or in combination. *in vivo* studies were conducted using MEC1 cells xenografted in BALB/c nude mice. Human MEC1 cells were inoculated subcutaneously into nude mice to establish a human leukaemia xenograft model.

Results: The effect of the As_2O_3 and ibrutinib combination is synergistic in CLL cells. The combination of As_2O_3 and ibrutinib has a minor effect on the viability of normal peripheral blood lymphocytes. The results from the gene expression profiling analysis indicate that As_2O_3 causes the down-regulation of PI3K target genes. Ibrutinib exerted only modest effects on PI3K-AKT signatures, whereas the combination had an even more profound effect compared with As_2O_3 alone. Signatures associated with NF-κB were strikingly down regulated by ibrutinib and to a lesser extent by As_2O_3. Finally, STAT3 target genes were reduced by treatment with ibrutinib; As_2O_3 had a lesser effect. The cytotoxicity of combination therapy was associated with increased Caspase-3,-8,-9 and Bax expression and a more effective reduction of PI3K-AKT. In an adoptive transfer MEC1 mouse model of CLL, As_2O_3in combination with ibrutinib affected disease progression. In this model, the$As_2O_3$and ibrutinib combination resulted in tumour regression and inhibited CLL progression more dramatically than either drug alone. The combination of As_2O_3 with ibrutinib induces significantly more tumour cell apoptosis. The expression of p-AKT proteins was significantly reduced, whereas the expression of Caspase-3 and Bax increased in the combination therapy group.

Summary and Conclusions: The combination of As_2O_3 and ibrutinib inhibits tumour growth and induces apoptosis synergistically in CLL cells *in vitro* and *in vivo*. The combination induces a minor effect on the viability of normal peripheral blood lymphocytes. The combinatorial effect against CLL cells is mediated by Caspase pathway activation and the inhibition of PI3K-AKT. The combination of As_2O_3 and ibrutinib may have clinical potential for CLL treatment.

Chronic lymphocytic leukemia - Clinical 1

Papanicolaou Hospital, Thessaloniki, Greece, [11]Hematology Department, Hospital Clinic, Barcelona, Spain, [12]Hematology Department, Nikea General Hospital, Pireaus, Greece, [13]Department of Medicine, Solna, Clinical Epidemiology Unit, Karolinska Institutet, Stockholm, [14]Lund University and Hospital Department of Hematology, Lund Stem Cell Center, Lund, Sweden, [15]Department of Pathology, University of Barcelona, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) patients with somatically hypermutated IGHV genes (M-CLL) within their B-cell receptor immunoglobulin (BcR IG) generally display favorable biological profiles with an indolent disease course. However, neither the biological background nor the clinical presentation and outcome of M-CLL is uniform, thus justifying the quest for parameters that would assist in refining prognosis.
Aims: Development of a novel prognostic index tailored to M-CLL.
Methods: Cox-regression models were used to assess the impact of demographic, clinical, genomic and immunogenetic features on time-to-first-treatment (TTFT) in 1359 M-CLL cases.
Results: Main features of the studied cohort were as follows: median age: 64 years (22-92); males: 810/1359 (60%), Binet A/B/C: 1169/79/53 (90%/6%/4%); CD38 expression (CD38+): 161/1225 (13%). Except for del(13q) (494/836, 59%) and trisomy 12 (+12, 142/1072, 13%), other genomic aberrations were relatively rare [del(11q): 49/1076 (4.5%), *TP53* abnormality (*TP53*abn) *i.e.* del(17p) and/or *TP53* mutations: 52/1144 (4.5%), *NOTCH1* mutations (*NOTCH1*m): 23/1333 (2%), *SF3B1*m: 33/897 (4%), *MYD88*m: 23/556 (4%)]. Borderline mutated IGHV genes (germline identity, GI: 97-97.99%) were expressed by 101 cases (7%). Thirty-three (2.5%) and 26 (2%) patients were assigned to stereotyped subsets #4 (IGHV4-34/IGKV2-30) and #2 (IGHV3-21/IGLV3-21), respectively. All the aforementioned parameters were evaluated for their impact on TTFT, using univariate regression analysis. As expected, Binet stage C at diagnosis emerged as the most powerful marker (HR: 9.44, 95% CI, 7.45-11.97, p<0.0001). Among the remaining cases (Binet A/B), representing 96% of the cohort, the following parameters were significantly associated with shorter TTFT: Binet B (HR: 7.35, 5.51-9.81, p<0.0001), subset #2 membership (HR: 4.24, 2.32-7.76, p=0.0001), CD38+ (HR: 2.62, 1.98-3.50, p<0.0001), *TP53*abn (HR: 2.56, 1.64-4, p=0.0003), +12 (HR: 1.75, 1.27-2.41, p=0.002), male gender (HR: 1.52, 1.2-1.9, p=0.004). In contrast, a trend for favorable outcome was observed for subset #4 membership (HR: 0.43, 0.16-1.18, p=0.06). Taking into consideration the above HRs as well as median TTFT, we defined 4 groups among Binet A/B patients (n=934) with different TTFT (Figure 1): (i) high risk (n=88, 9%): Binet B or subset #2 membership (median TTFT: 2.1 years, 65% and 85% probability of treatment initiation (TI) at 5 and 10 years from diagnosis, respectively); (ii) intermediate risk (n=199, 22%): Binet A and occurence of one or more of: CD38 expression/*TP53*abn/+12 (median TTFT: 12 years, 33% and 45% TI at 5 and 10 years, respectively); (iii) low risk (n=619, 66%): Binet A with no CD38+/*TP53*abn/+12 (median TTFT: not yet reached, 15% and 25% TI at 5 and 10 years, respectively); and (iv) very low risk (n=28, 3%): subset #4 membership (median TTFT not yet reached, 0% and 10% TI at 5 and 10 years, respectively).

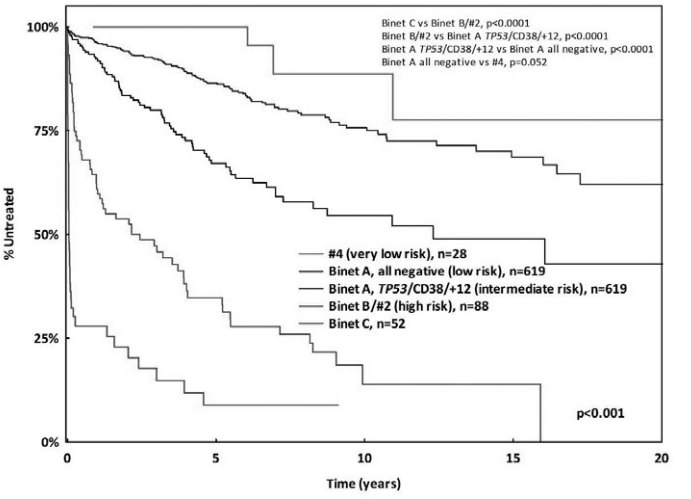

Figure 1. Kaplan-Meier curves for time-to-first-treatment (TTFT) in M-CLL.

Summary and Conclusions: We report a simple prognostic index for M-CLL capable of identifying patients who will experience short TTFT as well as those who will probably never require treatment, applicable even within early clinical stage CLL. At the ends of the clinical spectrum described by this novel index lie stereotyped subsets #2 (aggressive) and #4 (indolent). This further highlights the importance of distinct BcR IG configuration, likely linked to distinct immune signaling, for CLL ontogeny and evolution and indicates that subclassifying M-CLL based on stereotypy is relevant in the context of everyday routine practice.

P210

LONG-TERM FOLLOW-UP OF A PHASE IB TRIAL OF IDELALISIB IN COMBINATION WITH CHEMOIMMUNOTHERAPY (CIT) IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) CLL INCLUDING PATIENTS WITH DEL17P/TP53 MUTATION

J. Barrientos[1,*] S. Coutre[2], S. De Vos[3], I. Flinn[4], N. Wagner-Johnston[5], M. Schreeder[6], J. Sharman[7], T. Boyd[8], K. Rai[1], J. Leonard[9], B. Sorensen[10], A. Viggiano[10], T. Jahn[10], R. Furman[9]

Background: Idelalisib (IDELA) (Zydelig™) is a first-in-class PI3Kδ inhibitor approved in combination with rituximab for patients with relapsed CLL.
Aims: To determine the safety and clinical activity of idelalisib in combination with 6 commonly used chemo-immunotherapeutic agents for the treatment of R/R CLL.
Methods: Patients with R/R CLL were treated continuously with 150 mg BID oral IDELA and a limited number of cycles (C) of CIT to evaluate safety and efficacy of combination regimens. Patients could enroll in extension study after 48 weeks. Responses were evaluated by published criteria (Hallek 2008; Cheson 2012).
Results: 114 patients (37F/77M) median age 65 (range 41-87) years enrolled with: extensive prior therapies (median: 3, range 1-9), refractory disease (51%), high-risk Rai (60%), del17p/*TP53* mutation (29%), del11q (13%), unmutated *IGHV* (79%). Median exposure was 14.6 (range 0-49) months. 61 patients (54%) enrolled in extension study. 21 (34%) were continuing on study. Most common and select AEs independent of causality (any Grade/Gr ≥3): diarrhea/colitis (52%/19%), pyrexia (45%/4%), cough (37%/1%), nausea (29%/1%), fatigue (32%/4%), pneumonia (23%/15%), dyspnea (22%/3%), rash (21%/4%), pneumonitis (4%/4%). AST/ALT elevation Gr ≥3 was seen in 12%. Most common reasons for discontinuation were AEs (25%) or PD (25%). 2 patients discontinued due to AST/ALT elevation, 1 due to Richter's transformation. 20 (18%) deaths were reported on study; 6 patients experienced PD before death. ORR was 82.5% in all patients, 70% in patients with del17p/*TP53* mut, and 87% among patients without. SD/PD was reported in 10%/3%. Median overall PFS was 26.1 months, 20.3 months for patients with del17p/*TP53* mut, and 36.8 months for patients without. Median OS for all patients or patients with del17p/*TP53* mut was not reached. Estimated OS at 36 months was 73.1% for all patients, 57.3% for patients with del17p/*TP53*, and 78.3% for patients without.

Tabella 1.

Idelalisib +						
Rituximab (R) N = 19	Ofatumumab (O) N = 21	Bendamustine (B) N = 18	BR N = 15	Fludarabine (F) (oral) N = 12	Chlorambucil (Chl) N = 15	ChlR N = 14
8 wks	up to 6 C				up to 12 C	

Summary and Conclusions: IDELA in combination with CIT shows a manageable safety profile without increased toxicities and has substantial clinical activity in heavily pretreated, refractory, and high-risk CLL including presence of del17p/*TP53* mutation. Phase 3 trials of IDELA with O or BR in patients with R/R CLL are ongoing (NCT01659021, NCT01732926).

A RANDOMISED DE-ESCALATION STUDY OF ORAL FLUDARABINE, CYCLOPHOSPHAMIDE AND RITUXIMAB IN FIT ELDERLY PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA: WELL TOLERATED AND SUPERIOR OUTCOMES WITH FCR

S. Mulligan[1,*] D. Gill[2], W. Renwick[3], P. Turner[4], M. Latimer[5], L. Berkahn[6], D. Simpson[7], P. Campbell[8], C. Forsyth[9], R. Harrup[10], N. MacKinlay[11], G. Cull[12], B. Kuss[13]
[1]Haematology, Royal North Shore Hospital, Sydney, [2]Princess Alexandra Hospital, Brisbane, [3]Royal Melbourne Hospital, [4]Austin Hospital, Melbourne, [5]Canberra Hospital, Canberra, Australia, [6]Auckland City Hospital, [7]North Shore Hospital, Auckland, New Zealand, [8]Geelong Hospital, Geelong, [9]Gosford Hospital, Gosford, [10]Royal Hobart Hospital, Hobart, [11]Royal North Shore Hospital, Sydney, [12]Haematology, Sir Charles Gairdner Hospital, Perth, [13]Flinders Medical Centre, Adelaide, Australia

Background: Fludarabine (F), cyclophosphamide (C) and rituximab (R) gave superior progression free (PFS) and overall survival (OS) *versus* (*vs*) FC in the CLL8 Study.
Aims: We aimed to assess the safety, tolerability and efficacy of FCR based therapy in elderly patients (pts).
Methods: Previously untreated pts with CLL aged≥65 were randomised to one of 3 therapy arms: (i)*FR5*: F 24mg/m^{2}po D1-5 + R (375mg/m^{2}cycle 1, 500mg/m^{2}cycles 2-6) iv D1, (ii)*FCR3*: F 24mg/m^{2}po and C 150mg/m^{2}po D1-3 + R iv D1 or (iii)*FCR5*: F 24mg/m^{2}po+ C 150mg/m^{2}po D1-5 + R iv D1 all at 4 weekly intervals for an intended 6 cycles. Cycles could be delayed up to 2 weeks for grade 3+ toxicity, and if unresolved by 2 weeks were off study.
Results: The eligible cohort was 116. Median age was 71 (range 65-82) years; 78 males (67%) and 39 females (33%). Binet stage was progressive A-19 (16.2%), B-55 (47.0%), C-43 (36.8%). Response and grade 3+ toxicity data are shown in the table. All 6 protocol cycles were completed in 69% but less on FCR5 44% *vs* FR5 89% and FCR3 76% (p<0.001). FCR3 *vs* FR5 was not statistically significant (NSS). Reasons for non-completion were death, intercurrent illness, withdrawn consent, stable or progressive disease, unacceptable toxicity and doctor decision.

Tabella 1.

Response 2 months Post-Rx or at Rx end	Treatment arm			Total (n=116)
	FR5 (*N*=37)	FCR3 (*N*=41)	FCR5 (*N*=38)	
Complete remission (CR) BM Confirmed	10 (27%)	18 (44%)	17 (45%)	45 (39%)
CR (Bone Marrow confirmed)	9 (24%)	13 (32%)	8 (21%)	30 (26%)
CR-i (BM confirmed)	1 (3%)	5 (12%)	9 (24%)	15 (13%)
Total MRD Negative in PB	14 (38%)	21 (51%)	30 (79%)	65 (56%)
Nodular Partial Remission (nPR)	11 (30%)	13 (32%)	3 (8%)	27 (23%)
Partial Remission (PR)	10 (27%)	5 (12%)	4 (11%)	19 (16%)
Stable Disease (SD) / PD / early death	2 (6%)	2 (4%)	1 (3%)	5 (5%)
Overall Response Rate (ORR)	35 (95%)	39 (95%)	37 (97%)	111 (96%)
At least 1 grade 3+ AE	21 (57%)	34 (83%)	35 (92%)	90 (78%)
Early cessation due to toxicity	2 (5.6%)	1 (2.4%)	13 (34%)	16 (14%)

Toxicity was lower with FR5 compared to FCR3 and FCR5 (p=0.004) (FCR3 *vs* FCR5 NSS). Dose delay occurred in 43 pts (37%): FR5 32%, FCR3 34%, FCR5 44% (p=0.653), but early cessation due to toxicity was more common with FCR5 (p<0.001). 11/13 pts stopping early due to toxicity received ≥3 cycles of therapy (mean 3.5). ITT full dose FCR5 CR rates were significantly higher (79%), but also higher rates of incomplete marrow recovery, haematological toxicity and earlier cessation of therapy.
Summary and Conclusions: Final analysis shows oral FCR therapy is generally safe and well tolerated in CLL pts aged ≥65 years requiring first-line treatment, *when early stopping is utilised if prolonged toxicity occurs.* Toxicity was mostly hematological and manageable. Response rates were very high with ORR of 95% and 97% and CR rate of 44% and 45% with reduced dose and full dose FCR. Full dose FCR is highly effective and while cessation due to toxicity appears important, a dose intensity effect may exist. Dose reduced FCR provides a balance of effectiveness, safety and tolerability as first-line therapy for fit elderly pts.

P212

CLINICAL ASSESSMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA SAMPLES FOR SOMATIC HYPERMUTATION STATUS BY NEXT-GENERATION SEQUENCING AND SANGER SEQUENCING

M. Arcila[1], Y. Huang[2,*] K. Hutt[2], J. Panganiban[2], T. Baldi[1], K. Nafa[1], J. Thornes[2], J. E. Miller[2], M. Klass[2]
[1]Diagnostic Molecular Pathology Laboratory, Memorial Sloan-Kettering Cancer Center, New York, [2]Invivoscribe Technologies, Inc., San Diego, United States

Background: Somatic hypermutation (SHM), is an important process to increase the affinity of immunoglobulin molecules. The presence of ≥2% SHM is an important prognostic factor for CLL patients. The current method used to determine SHM status requires two steps: a PCR/capillary electrophoresis (CE) to detect clonality, followed by Sanger sequencing. This multistep approach is labor intensive and time consuming. We developed the next generation sequencing (NGS) LymphoTrack® assays to address these limitations. Here we report the results of a pilot study of SHM detection using both the NGS and CE/Sanger approaches from 50 anonymized, blinded CLL samples.
Aims: to assess the clinical performance of NGS SHM assay
Methods: LymphoTrack® SHM assays have been developed for both the MiSeq and PGM NGS platforms. Both assays and NGS platforms were used in this study. The MiSeq SHM Assay employs two master mixes. One amplifies genomic DNA between the upstream leader (VHL) region and the downstream joining (J) region of the IGH gene. The other amplifies from the framework1 (FR1) to J region. Amplicon products from VHL/J primers span the entire variable (V) region. Amplicon products from FR1/J primers encompass portions of the FR1 region to the downstream J region. The PGM Assay only employs FR1/J primers. The proprietary V and J consensus primers were designed and adapted to enable the PCR products to be sequenced on either the MiSeq or PGM platform. Multiplexed PCR was followed by amplicon purification using the AMPureXP PCR system. Purified equimolar amounts of amplicons were pooled to form a library which was loaded onto the MiSeq or PGM. The sequencing data was analyzed using Invivoscribe LymphoTrack® bioinformatics software, generating frequency distributions, DNA sequences, V-J assignment and usage, and SHM status. DNA from clinical samples was obtained from Memorial Sloan-Kettering Cancer Center.
Results: The analytical performance of the SHM assays was evaluated using contrived samples, with known V-J rearrangement and SHM status. For limit of detection (LOD), limit of blank (LOB), linearity, and precision and reproducibility (P/R) the assay demonstrated excellent linearity (R^2>0.99), sensitivity of 2.5% for clonality, and reproducibility (<20% CV). In addition, good concordance (R^2>0.99) was demonstrated between the NGS assay and the traditional method of using gel extraction and Sanger sequencing in evaluating the SHM status of cell line DNAs. The clinical performance of the LymphoTrack® SHM assays was evaluated on 50 CLL samples that have also been tested using the traditional CE/Sanger method. NGS assays were able to detect all 50 samples while 2 samples were non-evaluable by CE/Sanger method and were excluded from comparison. Between the LymphoTrack® FR1 MiSeq and CE/Sanger, 100% concordance has achieved for SHM status with linear regression of R^2=0.91 for SHM rates. The LymphoTrack SHM FR1 MiSeq assay is in 100% agreement with the LymphoTrack SHM FR1 PGM assay for both SHM status and rates. Only one discordant sample between the FR1 MiSeq and Leader MiSeq for SHM status, resulting a 98% concordance for SHM status and linear regression of R^2=0.98 for SHM rates.
Summary and Conclusions: A comprehensive NGS assay has been developed for both MiSeq and PGM platforms that identifies clonal IGH V-J rearrangements, associated specific V-J region DNA sequences and determines the SHM status in CLL specimens. This NGS assay has demonstrated excellent clinical concordance for determining SHM status with the traditional method.

HEALTH RELATED QUALITY OF LIFE AND PATIENT REPORTED OUTCOMES IN PATIENTS RECEIVING OFATUMUMAB MAINTENANCE VERSUS OBSERVATION IN THE PROLONG TRIAL

M. van Oers[1], K. Kuliczkowski[2], L. Smolej[3], M. Petrini[4], F. Offner[5], S. Grosicki[6], M.D. Levin[7], I. Gupta[8], J. Phillips[8], V. Williams[9], S. Manson[10,*] S. Lisby[11], C. Geisler[12]
[1]Academisch Medisch Centrum and HOVON, Amsterdam, Netherlands, [2]SPSK 1, Wroclaw, Poland, [3]University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic, [4]Azienda Ospedaliero Universitaria Pisana, Pisa, Italy, [5]Universitair Ziekenhuis Gent, Gent, Belgium, [6]Department of Cancer

Prevention, Faculty of Public Health, Silesian Medical University, Katowice, Poland, [7]Albert Schweitzer Ziekenhuis and HOVON, Dordrecht, Netherlands, [8]GlaxoSmithKline, Collegeville, [9]GlaxoSmithKline, Research Triangle Park, United States, [10]GlaxoSmithKline, Uxbridge, United Kingdom, [11]Genmab, [12]Rigshospitalet-Koebenhavn, Copenhagen, Denmark

Background: The randomized phase III PROLONG study in 474 relapsed CLL patients in remission after 2nd or 3rd line induction treatment has demonstrated a statistically significant improvement in PFS by ofatumumab maintenance treatment as compared to observation: 29.4 months *versus* 15.2 months respectively (HR=0.50, p<0.0001; van Oers, 2014).
Aims: However, given that a watch and wait strategy is the current standard of care and patients were treated for up to 24 months with ofatumumab maintenance, it is important to assess the impact of maintenance therapy on health related quality of life (HRQoL).
Methods: During the PROLONG trial, the QLQ-C30 and the QLQ-CLL16 patient questionnaires were administered in all pre-progression patients during both treatment and during the follow up stage. Primary endpoints in patient reported outcomes were health related quality of life as reported by the QLQ-C30 questionnaire and a B-symptom index including patient reported symptoms of fatigue, night sweats, temperature changes and weight loss as reported by the QLQ-C30 and QLQ-CLL16 questionnaires.
Results: In HRQoL, there was no statistical difference (p=0.14) or clinically relevant difference between the arms at any time point measured during treatment with the ofatumumab arm demonstrating a mean 0.2 point decline in HRQoL on a scale of 0-100 and the observational arm demonstrating a mean 1.9 point decline in HRQoL. The B symptom index demonstrated a minor worsening across all B symptoms in patients in the observation arm (p=0.002): during treatment with ofatumumab no change occurred in B symptoms (0.0 on a 0-100 scale) whereas in the observation arm there was a 2.8 point worsening. There was a trend to a difference between the arms as to the question about worry for future health, where patients on ofatumumab reported to be less likely to worry (4 point difference on 0-100 scale, p=0.06).
Summary and Conclusions: These results clearly demonstrate that ofatumumab maintenance therapy does not negatively affect HRQoL. At present it is not known whether the observed differences in the B symptom index and future health score are based on the psychological effects of being treated instead of watchful waiting, or reflect improved quality of remission upon ofatumumab maintenance.

QUALITY OF LIFE BENEFITS OF IDELALISIB WITH RITUXIMAB FOR PATIENTS WITH PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKAEMIA

W. Sullivan[1], D. Lee[1], R. Perard[2,*] L. Ysebaert[3], V. Leblond[4]
[1]BresMed Health Solutions, Sheffield, [2]Gilead Sciences Europe, Uxbridge, United Kingdom, [3]Hematology, IUCT-Oncopole, Toulouse, [4]Hematology, Hôpital Pitié-Salpêtrière, Paris, France

Background: Patients with chronic lymphocytic leukaemia (CLL) experience disease-related symptoms including fatigue, dyspnea, abdominal pain, weight loss, lymphadenopathy and sleep disturbances. Robust data on health-related quality of life (HRQL) in the form of utility scores for CLL patients are, however, scarce. Longitudinal EQ-5D data were collected in a phase III randomized controlled trial of idelalisib with rituximab *versus* rituximab monotherapy for patients with previously treated CLL unsuited to cytotoxic therapy (Study 116, ClinicalTrials.gov Identifier: NCT01539512). These data can provide further insight into the health-related quality of life (HRQL) of CLL patients.
Aims: This study aims to analyse longitudinal EQ-5D data from Study 116 to better understand the HRQL of previously treated patients receiving further treatment for CLL, and more specifically to gain insight on the HRQL profile associated with idelalisib with rituximab for previously treated CLL.
Methods: EQ-5D questionnaires were administered in Study 116 at baseline and at regular intervals: Weeks 2, 4, 6, 8, 12, 16, 20, 24, 30, 36, 42, 48, every 12 weeks thereafter prior to disease progression, and at the end of treatment. A generalised estimation equation (GEE) regression was carried out to determine absolute HRQL scores across treatment arms and whether there was a difference in quality of life between idelalisib with rituximab and rituximab monotherapy while patients were receiving treatment. GEE regression was used as this method accounts for potential autocorrelation of patient quality of life scores.
Results: Compliance rates for EQ-5D completion were good (>70%) across all time points and in total there were 1,667 observations over both treatments arms. Table 1 shows estimated mean HRQL estimates for patients receiving treatment in Study 116, across treatment arms. Estimated utility was high across treatment arms, and a significant treatment effect was found (p=0.031), with patients receiving idelalisib with rituximab having a better quality of life than those receiving rituximab monotherapy (absolute difference of 0.0652).

Tabella 1. EQ-5D estimates for patients receving treatment in Study 116

Treatment arm	Estimate	Standard Error
R utility	0.7475	0.0159
IR treatment effect vs. R	0.0652	0.0216
IR utility	0.8127	

Key: IR, idelalisib with rituximab; R, rituximab

Summary and Conclusions: The tolerability and efficacy profile of idelalisib with rituximab may provide previously treated CLL patients with high quality of life, both in absolute terms and in relation to treatment with rituximab monotherapy.

P215

CHRONIC LYMPHOCYTIC LEUKEMIA MD ANDERSON CANCER CENTER PROGNOSTIC INDEX IS SUCCESSFUL BUT STILL CAN BE IMPROVED BY INCORPORATING SERUM LDH LEVEL

G. Gunes[1], Y. Buyukasik[1], N. Alayvaz Aslan[2], U.Y. Malkan[1], I.C. Haznedaroglu[1], H. Demiroglu[1], H. Goker[1], S. Etgul[1], T. Aslan[1], S. Balaban[1], O.I. Ozcebe[1], S. Aksu[1], S. Karakus[3], N. Sayinalp[1,*]
[1]Hematology, Hacettepe University, School of Medicine, Ankara, [2]Hematology, Ondokuz Mayis University, Samsun, [3]Hematology, Baskent University, Ankara, Turkey

Background: MD Anderson Cancer Center (MDACC) nomogram and prognostic index is an easy prognostication system in chronic lymphocytic leukemia (CLL) because it depends on routinely available parameters (Blood 2007; 109: 4679). External validation of this prognostication system has been done recently (Br J Haematol 2014; 167: 224). Lactate dehydrogenase (LDH) level has prognostic value in many lymphoid neoplastic disorders. However to the best of our knowledge no routinely used prognostication system in CLL uses the LDH level.
Aims: In this study we aimed to test the prognostic value of MDACC scoring system in a multicenter CLL cohort and to investigate if incorporation of LDH could improve the MDACC index.
Methods: All previously untreated CLL patients who were admitted between 1997 and 2014 with available lab and clinical data for MDACC prognostic scoring and survival analysis and a baseline serum LDH level were included in the study. Patients with comorbidities affecting survival expectation and/or serum LDH level were eliminated. Survival analyses were done according to the Kaplan Meier method. Cox regression analysis was done to determine if MDACC index and LDH were independently associated with survival. If both parameters were independently associated with survival, deriving an integrated scoring method depending on Cox regression analysis odds ratios of the MDACC index and LDH was intended. All statistical tests were done using SPSS v17.

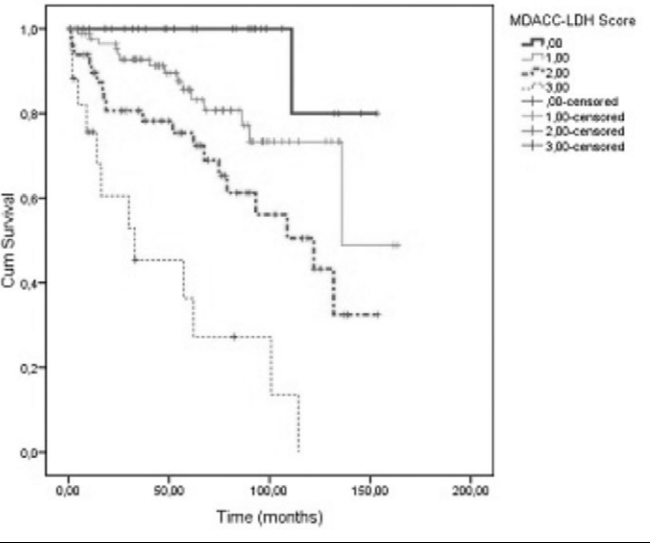

Figure 1. MDACC-LDH scores corresponded to survival durations.

Results: The cohort was composed of 326 patients (207 male, 119 female; median age [range] =63 [31-93], median f/u duration=53.5 months). The

patients in low, intermediate and high MDACC index categories at diagnosis composed 16%, 68%, and 16% of the cohort, respectively. 112 (36.6%) patients had an elevated LDH level at diagnosis. Both MDACC index (not reached, 131.8 [14.9, 102.5-161], and 62.1 [3.8, 54.5-69.6] months median [standard error, 95% confidence interval] survival durations in low, intermediate and high risk groups respectively, p=.000) and LDH level (not reached *versus* 81.1 [12.7, 56-106.1] months, p=.000) were very closely and independently (Exp(B)=2.59, p=.000 for MDACC score and Exp(B)=2.63, p=.000 for LDH) associated with overall survival. All 3 MDACC risk groups could be effectively subdivided into 2 different prognostic subgroups depending on associated normal or increased LDH level. Depending on these results 0, 1 and 2 points were assigned to the MDACC low, intermediate and high risk groups, respectively. Normal and high LDH levels corresponded to 0 and 1 points. The cumulative MDACC-plus-LDH (MDACC-LDH) score divided the patients into 4 distinct prognostic groups. MDACC-LDH scores 0 (17% of the patients), 1 (48%), 2 (26%), and 3 (9%) corresponded to median (standard error, 95% confidence interval) survival durations of not reached, 135.8 (incomputable), 122 (24.1, 74.7-169.3), and 33 (22.6, 0-77.4) months, respectively (p=.000) (Figure 1). MDACC-LDH scores 1 and 2 could be merged together for practical reasons leading to low (0 points), intermediate (1 or 2 points) and high (3 points) MDACC-LDH score levels.

Summary and Conclusions: In conclusion, MDACC index is a successful prognostic index in treatment-naïve CLL. Serum LDH level can divide each MDACC prognostic group into two different subgroups. MDACC index and LDH can be successfully incorporated into a new score.

P216

GENETIC BASIS OF HAIRY CELL LEUKEMIA (BRAF) REVEALS HIGH FREQUENCIES OF MUTATIONS IN BRAF V600E, U2AF1 AND MAP2K1 GENES

S. Gaware[1,*] N. Rabade[1], A. Bibi[1], S. Chaudhary[1], A. Chakraborty[1], A. Goyal[1], S. Munot[1], P. Tembhare[1], P.S. [1], H.S. [1], B. Bagal[2], U. Dangi[2], H. Jain[2], M. Sengar[2], N. Khattry[2], H. Menon[2], S. Gujral[1], N. Patkar[1]
[1]Hematopathology Laboratory, [2]Department of Medical Oncology, Advanced Centre for Treatment Research and Education in Cancer (ACTREC)-Tata Memorial Centre, Navi Mumbai, India

Background: Hairy cell leukemia is a distinct B cell neoplasm with characteristic morphological and immunophenotypic features. The somatically acquired V600E mutation of the *BRAF* gene has been recently described as a molecular marker of hairy cell leukemia. In those cases which are *BRAF* negative mutations in *MAP2K1* and RNA spliceosome encoding gene *U2AF1* have recently been described.
Aims: Identification of baseline frequencies of BRAFV600E, MAP2K1 and RNA spliceosome encoding gene U2AF1 in a large series of HCL in our centre.
Methods: Genomic DNA was extracted from stained bone marrow aspirate smears of hairy cell leukemia patients. DNA was subjected to a modified ARMS PCR technique followed by capillary electrophoresis on an ABI3500 genetic analyzer. The PCR was designed to amplify a 200bp control product, a 142bp *BRAF* V600E specific amplicon and a 92bp wild type specific amplicon. Exons2 & 3 of *MAP2K1* and exon2 of *U2AF1* genes were sequenced in *BRAF* negative cases by Sanger sequencing.
Results: Majority of patients 89.1% (41/46) with a morphological and immunophenotypic diagnosis of HCL were positive for *BRAF* V600E mutation. Of the five patients that were *BRAF* negative a single patient harboured P124L mutation in exon2 of MAP2K1 gene. This mutation has been described in papillary carcinoma of the thyroid but not in patients of HCL.
Summary and Conclusions: Conclusions: Our findings point that analysis of *BRAF* mutations is a potential diagnostic tool to distinguish HCL from other B-cell lymphomas with similar features such as the HCL variant and splenic marginal-zone lymphoma. This distinction is clinically relevant, since HCL, but not HCL-like disorders, responds to therapy with interferon or purine analogues.
Summary: *BRAF*V600E mutation present in 89.1% patients of HCL in our cohort represents a reliable molecular marker for the accurate diagnosis of hairy cell leukemia.

P217

LLC-LENAR-08 A PHASE I/II STUDY LENALIDOMIDE-RITUXIMAB IN RELAPSE/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

A. De La Fuente[1,*] M. Gonzalez[2], P. Giraldo[3], F. de la Cruz[4], M.J. Terol[5], J.A. Perez Simon[4], G. Rodriguez[6], C. Montalban[1], J.F. Toas[7], R. de Oña[1]
[1]Hematology, MD Anderson CC Madrid Spain, Madrid, [2]Hematology, H. U. Salamanca, Salamanca, [3]Hematology, H. U. Miguel Servet, Zaragoza, [4]Hematology, H. U. Virgen del Rocio, Sevilla, [5]Hematology, H. U. Clinico de Valencia, Valencia, [6]Hematology, H. U. Reina Sofia Cordoba, Cordoba, [7]Hematology, Bupa-SLA Madrid, Madrid, Spain

Background: Phase II studies showed lenalidomide monotherapy is active in relapsed and refractory CLL. A synergistic activity between rituximab and lenalidomide against CLL has been suggested and a previous study has evaluated the combination of lenalidomide and rituximab in this population with encouraging results (J Clin Oncol, 2012,31: 584), but the optimal dose and schedule for this combination remains unknown.
Aims: The endpoint in phase I of this study is to define the optimum dose of lenalidomide in combination with rituximab in R/R CLL patients. The endpoint in phase II is to evaluate effectiveness and toxic profile of the resulted schedule.
Methods: We carried out a multicenter phase I/II study on R/R CLL patients, in the dose finding phase we started with a continuous lenalidomide daily dose of 2,5mg and rituximab (375mg/m2 cycle 1 and 500mg/m2 cycles 2-6/28 days) with cohorts of 3 patients (if no DLT move to a higher dose; if one DLT occurred in the cohort expand 3 more patients). In the second phase we evaluated efficacy (*NCI WGC criteria*), toxic profile (*CTCAE v3.0 scale)* OS and TTP with *Kaplan Meier.* Study registered in ClinicalTrials.gov:NCT01185262.
Results: We reported our completed Phase I/II study, 29pt from 7 Spanish sites were enrolled, 4 of them were screening failures because criteria not fulfilled, and 5 withdrew consent to participate before starting treatment. Median age 75 yr (45-86), male/female 11/9, ECOG 0/1/2: 7/12/1, median time from diagnosis 7.8 yr, median number of previous lines 2 (1-4) all but 2 pt had received fludarabine. In phase I the MTD of lenalidomide was 15 mg. Effectiveness: In phase II ORR 7 pt (53%), all PR, estimated TTP 15.4 months, estimated OS 21.9 months. Toxicity: 34 SAE were reported, in 6 cases treatment was discontinued definitively (infection 4 pt, progressive multifocal leukoencephalopathy 1pt, amyotrophic lateral sclerosis 1pt). Grade 4 neutropenia was the main adverse event associated with the regimen.
Summary and Conclusions: In our experience 15 mg is the MTD of daily lenalidomide in combination with rituximab every 28 days in R/R CLL patients. The combination was effective and well tolerated with a 53% ORR and 21.9 months estimated OS.

LB218

IBRUTINIB COMBINED WITH BENDAMUSTINE/RITUXIMAB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA/SMALL LYMPHOCYTIC LYMPHOMA (CLL/SLL): FIRST RESULTS FROM A RANDOMIZED, DOUBLE-BLIND, PHASE 3 STUDY

Background: Despite considerable therapeutic advances, virtually all patients with CLL/SLL will relapse and bendamustine/rituximab (BR) is often used in this case. Ibrutinib is a first-in-class, once-daily, oral covalent inhibitor of Bruton's tyrosine kinase, an essential enzyme in the B-cell receptor signaling pathway and a key mechanism promoting disease progression in B-cell malignancies. Clinical trials of ibrutinib have demonstrated a favourable benefit/risk profile in several B-cell malignancies, including previously-treated CLL, leading to the approval of ibrutinib single agent therapy in multiple countries.
Aims: The international, multicentre, double-blind, placebo-controlled phase 3 HELIOS study evaluated the efficacy and safety of ibrutinib in combination with BR (ibrutinib+BR) compared with placebo plus BR (placebo+BR) in patients with previously treated CLL/SLL. The preplanned interim analysis reported here showed that the primary end point was met, upon which the Independent Data Monitoring Committee recommended unblinding the study.
Methods: Patients were randomized 1:1 to receive BR (≤6 cycles) with either ibrutinib (420 mg daily) or placebo. Stratification factors included whether the patient was refractory to purine analogs and the number of prior therapies. Patients with del17p (>20% of cells) were excluded. The primary end point was independent review committee (IRC)-assessed progression-free survival (PFS). Secondary end points included IRC-assessed overall response rate (ORR) and overall survival (OS).
Results: In total, 578 patients were randomized (289 per arm); median age was 64 yrs; 38% had Rai Stage III/IV disease; median of 2 prior therapies. Six cycles of BR were completed in 81.9% and 77.4% of patients in the ibrutinib

and placebo arms, respectively. At a median follow-up of 17.2 months, IRC-assessed PFS was significantly longer with ibrutinib+BR *vs* placebo+BR (median not reached *vs* 13.3 months; HR: 0.203, 95% CI: 0.150-0.276, *P*<0.0001); PFS results were consistent across all subgroups. IRC-assessed ORR was 82.7% *vs* 67.8% (*P*<0.0001) and the rate of complete response/complete response with incomplete marrow recovery (CR/CRi) was 10.4% *vs* 2.8% with ibrutinib+BR *vs* placebo+BR, respectively. Investigators reported ORRs of 86.2% *vs* 68.9%, P<0.0001, and rates of CR/CRi of 21.4% *vs* 5.9%, respectively. Median OS was not reached (HR 0.628: 95% CI 0.385, 1.024; *P*=0.06). Ninety patients (31%) in the placebo+BR arm with confirmed progressive disease crossed over to receive ibrutinib, as permitted per the protocol. The incidence of most adverse events (AEs) was similar between arms. The most common all-grade AEs with ibrutinib+BR and placebo+BR respectively were neutropenia (58.2% *vs* 54.7%) and nausea (36.9% *vs* 35.2%); the most common grade 3/4 AEs were neutropenia (53.7% *vs* 50.5%) and thrombocytopenia (15.0% each arm). Rates of grade 3/4 atrial fibrillation were 2.8% and 0.7%, and major hemorrhage were 2.1% and 1.7%.

Summary and Conclusions: The addition of ibrutinib to BR significantly reduced the risk of progression or death by 80% compared with placebo+BR. The ORR was also significantly improved with ibrutinib+BR *vs* placebo+BR. Safety of ibrutinib+BR was consistent with the known profiles for ibrutinib and for BR. The data further support ibrutinib as an important treatment option for patients with previously treated CLL/SLL.

Background: The addition of anti-CD20 monoclonal antibody (mAb) rituximab to the FC chemotherapy combination has shown improved response rates, progression free survival, and overall survival compared to FC alone in previously untreated and relapsed CLL. Ofatumumab is a human anti-CD20 mAb that is more effective than rituximab when used as monotherapy in patients with CLL that is refractory to fludarabine and alemtuzumab, and has shown activity in patients with rituximab-refractory CLL. Ofatumumab has also shown activity in combination with chlorambucil and bendamustine in patients with previously untreated CLL, as well as maintenance monotherapy in patients with relapsed CLL.

Aims: This report describes the clinical effect of ofatumumab in combination with fludarabine and cyclophosphamide (OFC) *vs* fludarabine and cyclophosphamide (FC) alone in a randomised phase III study in patients with relapsed CLL (Study COMPLEMENT 2; OMB110913).

Methods: Patients with relapsed CLL (progressive disease after ≥6 month response to at least one prior therapy) who required therapy per the 2008 NCI-WG guidelines were randomised (1:1) to receive either OFC or FC. F and C were administered as intravenous (IV) infusions (F: 25mg/m^2, Days 1-3 every 28 days for 6 cycles; C: 250mg/m^2, Days 1-3 every 28 days for 6 cycles). O was also administered as IV infusions (Cycle 1: 300mg day 1 and 1000mg day 8, subsequent cycles: 1000mg at day 1). O premedication included acetaminophen, antihistamine and glucocorticoid. The primary endpoint was progression-free survival (PFS) assessed by an Independent Review Committee (IRC) and secondary endpoints included overall response rate (ORR), time to next CLL therapy (TNT), overall survival (OS), and safety.

Results: 365 patients from 18 countries were randomized, 359 received treatment. Baseline demographics and disease characteristics were balanced between the two arms. Median age was 61 years. All Binet stages were represented (A 16%, B 55%, C 28%), and 6% of patients had 17p deletion. Median duration of treatment for both arms was 6 cycles. PFS assessed by the IRC was prolonged in the OFC arm (28.9 months) compared to the FC arm (18.8 months, HR=0.67 [95%CI=0.51, 0.89]; p=0.0036). The ORR (95% CI) by IRC assessment was 84% (77%, 89%) for OFC and 68% (60%, 74%) for FC (p=0.0004). Median OS was 56.4 months in the OFC arm and 45.8 months in the FC arm (HR=0.78; [95%CI=0.56, 1.09]; p=0.1404) with a median follow-up of 34 months. Grade ≥3 AEs from start of treatment to 60 days post last dose occurred in 74% of patients given OFC and in 69% of patients given FC. Grade ≥3 infusion reactions were reported in 9% of patients given OFC and in 3% given FC. Grade ≥3 cytopenias in both arms included neutropenia (OFC: 53%; FC: 39%), thrombocytopenia (OFC: 14%; FC: 25%), and anaemia (OFC: 8%; FC: 12%). Grade ≥3 infections were reported in 19% of patients given OFC and in 14% given FC.

Tabella 1. Baseline Characteristics, Time to event Endpoints and Response.

	OFC (N=183)	FC (N=182)
Characteristic	**Median (range)**	
Age, years	62 (38-83)	61 (32-90)
	% of patients	
Male	57	64
Rai Stage III–IV at screening	32	35
Binet Stage C at screening	28	29
Del 17p	4	8
Del 11q (no 17p)	24	20
Unmutated IGHV	68	69
Time-to-event endpoints	**Median (95% CI), months**	
Progression-free survival (IRC)	28.9 (22.8,35.9)	18.8 (14.4,25.8)
	HR: 0.67 (0.51,0.89); p=0.0036	
Time to next therapy	48.1 (40.5,60.4)	40.1 (32.1,48.4)
	0.72 (0.50,1.03); p=0.0613	
Overall survival	56.4 (44.2,nr)	45.8 (37.3,nr)
	HR: 0.78 (0.56, 1.09); p=0.1404	
Response	**% of patients**	
Best OR (95% CI) (IRC)	84 (77%,89%)	68 (60%,74%)
	P=0.0004	
Complete response (IRC)	28	8
Partial response (IRC)	55	59
Stable disease (IRC)	11	28
Progressive disease (IRC)	0	0
Not evaluable (IRC)	4	2
Missing (IRC)	1	2

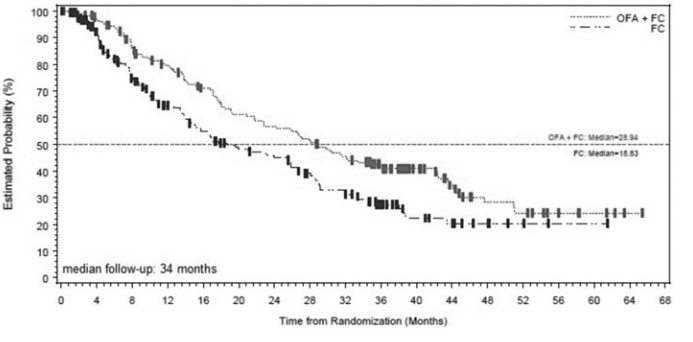

Figure 1. Kaplan-Meier Graph of IRC-assessed Progression Free Survival.

Summary and Conclusions: The results of this randomised study of ofatumumab added to FC demonstrate clinically important improvements in efficacy compared with FC alone, and the combination of OFC showed a manageable side effect profile in patients with previously treated CLL.

Chronic myeloid leukemia - Biology

P218

NON GENOMIC LOSS OF FUNCTION OF TUMOR SUPPRESSORS IN CML: BCR-ABL PROMOTES P53 NUCLEAR EXCLUSION THROUGH THE INTERACTION WITH IKB-ALPHA

S. Crivellaro[1,*] C. Panuzzo[1], G. Carrà[1], A. Volpengo[1], F. Crasto[1], E. Gottardi[1], A. Guerrasio[1], G. Saglio[1], A. Morotti[1]
[1]Clinical and Biological Sciences, University of Turin, Orbassano, Italy

Background: The function of tumor suppressors (TS) can be tightly controlled by various non-genomic mechanisms, such as epigenetic silencing, regulation by non-coding RNAs and post translational modifications. The identification of mechanisms that cause non genomic loss of function of TS could have tremendous consequences from the therapeutic standpoint. Targeting pathways that inactivates TS could indeed promote the re-activation of a specific tumor suppressor with strong biological consequences. IκBα is commonly known as the inhibitor of the transcription factor (TF) NFκB, which in turn regulates the transcription of many genes involved in immune and inflammatory responses, as well as genes regulating cell proliferation and survival, including IκBα itself. IκBα is also able to physically interact with the tumor suppressor protein p53. In the 20% of blast crisis Chronic Myeloid Leukemia (CML) patients, p53 is mutated, while it was never found mutated/deleted during the chronic phase of the disease.
Aims: The aim of this study was to demonstrate that BCR-ABL promotes the formation of a ternary complex with IκBα and p53 in the cytoplasm causing loss of p53 tumor suppressive nuclear pool.
Methods: HEK293T and HeLa cells transfected with IκBα expression vector alone or in combination with Bcr-Abl expression vector and primary cells collected from CML patients at the diagnosis were analysed by immunofluorescence, immunoprecipitation and western blot in order to evaluate IκBα and p53 protein levels, interactions and cellular compartmentalization. Furthermore, kinase assays have been performed with purified proteins to examine the phosphorylation status of IκBα. CML/healthy subjects and transfected cell line mRNA were analysed for NFKBIA (IκBα) and p21 expression by Real-TimePCR
Results: While assessing the cellular compartmentalization of IκBα in BCR-ABL transfected HeLa cells, we observed that IκBα is expressed mostly in the cytosol, while in parental HeLa cells IκBα showed a cyto/nuclear localization. Similarly, primary CML cells are characterized by IκBα expression exclusively in the cytosol. Using BCR-ABL transfected cells, we demonstrate that BCR-ABL physically interacts with IκBα through the BCR portion of the chimeric protein BCR-ABL. *in vitro*, BCR-ABL does not appear to directly phosphorylate IκBα on tyrosine residues. Next, we investigated whether BCR-ABL regulates IκBα expression and stability. RealTimePCR analysis does not show IκBα mRNA expression differences between normal and CML BM, and between empty and BCR-ABL transfected cell. Incubation of BCR-ABL positive cells with proteasome inhibitor MG-132 shows that BCR-ABL regulates IκBα protein stability at a post-translational level. IκBα is known to negatively regulate the NFkB pathway through the interaction with p65 subunit. Importantly, it was also reported that IκBα can interact with the p53, with consequent inhibition of some of its functions. Interestingly, here we observed that in CML primary cells, p53 is also delocalized into the cytosol and that IκBα is physically bound to both p53 and BCR-ABL in the cytosol of CML cells. The delocalization of p53 is associated with impairment of its function. The p21 mRNA levels, a downstream gene of p53, are indeed markedly reduced in CML primary cells, compared to normal bone marrow.
Summary and Conclusions: In this work, we demonstrate that BCR-ABL promotes p53 nuclear exclusion through the interaction with IκBα. Our data suggest that expression of BCR-ABL could promote non genomic loss of function of the tumor suppressor p53.

P219

TRANSCRIPTION FACTOR MEF2C IS UPREGULATED DURING CML DISEASE PROGRESSION AND INHIBITS C/EBPA EXPRESSION

S. Chakraborty[1,*] S. Agatheeswaran[1]
[1]Institute of Life Sciences, Bhubaneswar, India

Background: Although tyrosine kinase inhibitors (TKI's) have revolutionized CML therapy, the disease progresses to advanced blast crisis which is characterized by differentiation arrested blasts. The progression primarily happens due to the presence of secondary mutations and/or C/EBPα down regulation. MEF2C belongs to the MEF2 (Myocyte enhancer factor) family of proteins which comes under MADS–box group of transcription factors. MEF2C expression is abundant in CMP (Common Myeloid Progenitors) and gradually decreases with granulocytic commitment and differentiation. Earlier it was shown that C/EBPα regulates the myeloid specific miRNA-223 and we have recently shown that miRNA-223 negatively regulates *MEF2C* in CML.
Aims: Given that MEF2C antagonizes myeloid differentiation it may repress the C/EBPα transcription and play a significant role in CML disease progression.
Methods: Affymetrix Genechip® Human exon 1.0 ST arrays (Affymetrix, Inc, USA) were used for the hybridization. Blood samples were collected from CML-BC patients with their consent and the study was approved by Institutional human ethicalcommittee. RQ-PCR was performed in Light cycler 480 II with LC 480 SYBR Green master mix reagent. ANOVA and correlation statistics was performed by using Graphpad Prism software 5.0.
Results: *MEF2C* is a confirmed target of miR-223 and its expression was negatively correlated with miR-223 expression in CML samples. To identify the genes targeted by MEF2C, microarray experiment was performed in K562 cells treated with scrambled and MEF2C siRNA. Among the differentially expressed genes, a total of 21 genes which are known to have a role in myeloid differentiation were detected using GO analysis. Four transcription factors including the C/EBPα were among the 21 genes. C/EBPα up regulation was validated by RQ-PCR in the cells. To understand the relationship between *MEF2C* and *C/EBPα* in CML, we deduced their expression pattern from publicly available Radich CML dataset GSE4170. We observed the existence of a negative correlation between *MEF2C* and *C/EBPα* and found that MEF2C expression was significantly up regulated whereas *C/EBPα* expression was significantly down regulated with CML disease progression. *C/EBPα* mRNA expression was also up regulated in imatinib treated 32D BCR-ABL cells. This shows that C/EBPα can also be regulated at mRNA level in CML progression. MEF2C expression also showed a positive correlation with the blast count, the clinical parameter which is used to determine the stage of the disease. We have also isolated peripheral blood mononuclear cells (PBMC) from a CML-BC patient and the blast cells were treated *ex-vivo* with 2μM imatinib. Imatinib treatment was able to reduce MEF2C protein and up regulate *C/EBPα* and *CSF3R* mRNA expression. We found the existence of a MEF-2 binding site in the C/EBPα promoter. The MEF-2 binding site was found to be highly conserved between human and mouse. Since role of mouse MEF2C α1 isoform is established in antagonizing the myelopoiesis we cloned the mouse C/EBPα promoter and performed a luciferase assay with MEF2C α1 isoform and found that MEF2C significantly represses the *C/EBPα* promoter.
Summary and Conclusions: The study shows that MEF2C expression increases with CML disease progression and it is BCR-ABL dependent since addition of imatinib was able to reduce MEF2C protein. MEF2C also negatively regulates the C/EBPα promoter as it affects the luciferase activity. Thus MEF2C up regulation was associated with decreased *C/EBPα* mRNA expression which can favour disease progression.

P220

MESENCHYMAL STEM CELLS FROM CML PATIENTS REGULATE MYELOID DERIVED SUPPRESSOR CELLS ACTIVATION

C. Giallongo[1,*] N. Parrinello[1], D. Tibullo[1], P. La Cava[1], A. Romano[1], A. Chiarenza[1], F. Stagno[1], P. Vigneri[1], G.A. Palumbo[1], F. Di Raimondo[1]
[1]Division of Hematology, Azienda Policlinico-OVE, University of Catania, Catania, Italy

Background: The complex interplay between cancer cells and immune system allows neoplastic cells to evade immune surveillance and expand. Recently, it has been demonstrated that a subpopulation of myeloid cells, defined as "myeloid-derived suppressor cells" (MDSCs), plays an important role of immune escape in chronic myeloid leukemia (CML) patients inducing T cell tolerance. Mesenchymal stem cells (MSCs) are a heterogeneous population of stromal adult stem cells with immunomodulatory properties that contribute to form a cancer stem niche where tumor cells are protected and sustained in their growth.
Aims: The aim of this study was to evaluate the influence of MSCs on expansion and activation of MDSCs in CML patients.
Methods: In a first instance, using real time PCR, we evaluated the expression of immune modulatory factors (arginase 1, NOS2, COX2, TNFα, TGFβ, IL6, IL10, IL1β) by CML MSCs (n=8) compared with healthy donors (HD) ones (n=6). Human peripheral blood mononucleated cells (PBMCs) isolated from healthy volunteer donors were cultured alone and with CML or HD MSCs (1:100 ratio). After one week, PBMCs were collected and MDSCs were then isolated using anti-CD66b magnetic microbeads. The phenotype of MDSCs (identified as CD11b+CD33+CD14-HLADR-cells) was confirmed by cytofluorimetric analysis.
Results: CML MSCs showed higher COX2,TGFβ and IL6 expression ($p<0.05$). Subsequently, we investigated the capacity of MSCs from CML patients and HD to generate MDSCs. The immunosuppressive capacity of the generated MDSCs was analyzed. Myeloid cells were co-cultured with autologous CFSE-labeled T cells stimulated by phytohaemagglutinin (PHA). Only MDSCs generated by co-culture with CML MSCs were suppressive, decreasing T cell proliferation of 31±12% ($p<0.01$) while myeloid cells generated by co-culture with HD MSCs and control (isolated from PBMCs cultured in medium alone) did not show any suppressive effect on T cell proliferation. Analyzing the expression of immune modulatory factors by MSCs after 48 h of co-culture with PBMCs, we observed higher expression of IL10 and TGFβ ($p<0.05$) andIL6 ($p<0.01$) by CML MSCs than HD ones. These data suggest that multiple mechanisms are involved in MDSCs induction by CML MSCs.
Summary and Conclusions: From our experiments we can conclude that MSCs from CML patients are able to generate and activate MDSCs and might favor cancer immune evasion in CML patients.

DO ENDOTHELIAL CELLS BELONG TO THE PRIMITIVE LEUKEMIC CLONE IN CML? ROLE OF EXTRACELLULAR VESICLES

T.L. Ramos[1,*] L.I. Sánchez-Abarca[1], G. López-Ruano[2], A. Hernández-Hernández[2], M. Hernández-Ruano[1], S. Muntión[1], S. Preciado[1], M. Giner Calabuig[1], B. Rosado[3], N. de las Heras[4], M. González[1], F. Sánchez-Guijo[1], C. del Cañizo[1]
[1]Servicio de Hematología, IBSAL-Hospital Universitario de Salamanca, [2]Departamento de Bioquímica y Biología Molecular, Universidad de Salamanca-IBSAL, Salamanca, [3]Servicio de Hematología, Hospital General de Segovia, Segovia, [4]Servicio de Hematología, Complejo Hospitalario de León, León, Spain

Background: The expression of BCR/ABL in hematopoietic stem cells is a well defined primary event in chronic myeloid leukemia (CML). Some reports have described the presence of BCR-ABL on endothelial cells from CML patients, hypothesizing that the disease may arise in a primitive hemangioblastic cell. On the other hand, it has been described that extracellular vesicles (E*Vs*) released by CML leukemic cells are involved in angiogenesis modulation in the disease and that endothelial cells can incorporate them.
Aims: To assess if E*Vs* released from BCR-ABL$^+$ cells carry inside the oncogene and if their incorporation into endothelial cells leads to the expression of both BCR-ABL mRNA and the oncoprotein in the recipient endothelial cells.
Methods: For the study K562 cells and primary samples of newly diagnosed CML patients were used (after signed informed consent was obtained) as well as the endothelial EA.hy926 cell line. For E*Vs* isolation and characterization, E*Vs* obtained from K562 cell culture medium and plasma from CML patients were isolated by differential centrifugation and characterized by transmission electron microscopy and Western blot. For incorporation assays, E*Vs* from K562 cells and from plasma of CML patients were incubated with the EA.hy926 cell line for 4, 24, 48 and 72h. The incorporation was analyzed by flow cytometry and fluorescence microscopy. Total RNA from E*Vs* or cells was extracted using TRIzol Reagent and the expression was quantified by using commercial TaqMan Universal Mastermix and the Step One Plus Real-Time PCR System. The polyclonal rabbit anti-human c-ABL (BCR-ABL) antibody was used and the proteins were visualized using the enhanced chemiluminescence system.
Results: E*Vs* from K562 cells and plasma from newly diagnosed CML patients were isolated and characterized and they showed the typical cup-shaped morphology and were positive for the exosome marker CD63. By RT-PCR, the presence of BCR-ABL RNA in the E*vs* from both K562 cells and plasmatic E*Vs* of CML patients was demonstrated. Next it was verified by flow cytometry and fluorescence microscopy that after 24h of culture K562-derived E*Vs* were incorporated into EA.hy926 cells The presence of mRNA BCR-ABL on endothelial EA.hy926 cells that incorporated the E*Vs*-K562 for 4h, 48h and 72h was also detected by RT-PCR. In addition, the presence of BCR-ABL mRNA in EA.hy926 cell line after incubation with plasma-derived E*Vs* from CML patients was detected. The presence of BCR-ABL on endothelial cells incubated with Philadelphia+ E*Vs* was also confirmed by Western blot.
Summary and Conclusions: Endothelial cells acquire BCR-ABL RNA and the oncoprotein after incubation with E*Vs* released from Ph+ positive cells (either from K562 cells or from plasma of newly diagnosed CML patients). This results challenge the hypothesis that endothelial cells may be part of the Philadelphia+ clone in CML.

P222

PPAR-GAMMA LIGANDS INCREASE ANTILEUKEMIC ACTIVITY OF 2ND AND 3RD GENERATION TYROSINE KINASE INHIBITORS IN CHRONIC MYELOID LEUKEMIA CELLS

E. Glodkowska-Mrowka[1,*] P. Mrowka[2]
[1]Department of Laboratory Medicine and Clinical Immunology of Developmental Age, [2]Department of Biophysics and Human Physiology, Medical University of Warsaw, Warsaw, Poland

Background: Introduction of imatinib into clinical practice revolutionized the treatment of BCR-ABL1-positive leukemias and allowed for successful development of new tyrosine kinase inhibitors (TKIs). So far several 2nd and 3rd generation TKIs has been approved for the treatment of chronic myeloid leukemia (CML). Unfortunately, a significant number of patients do not benefit from the therapy because of TKIs resistance or severe drug toxicity. Recently, the success of 2nd and 3rd generation TKIs in CML was shadowed by the reports on serious side effects of these drugs including increased risk of cardiovascular events in patients treated with nilotinib and ponatinib. Pioglitazone, peroxisome proliferator-activated receptor gamma (PPAR-gamma) ligand used in the treatment of type 2 diabetes, reduces cardiovascular risk in various clinical settings and is currently tested for secondary prevention after ischemic stroke and transient ischemic attack in patients with diabetes. In addition, although it is not classic anticancer drug, pioglitazone exerts antitumor activity and is used to potentiate various anticancer therapies in pre-clinical and clinical trials. Therefore we decided to study the influence of PPAR-gamma ligands, including pioglitazone, on 2nd and 3rd generation TKIs efficacy.
Aims: Comprehensive analysis of the influence of PPAR-gamma ligands on antileukemic properties of 2nd and 3rd generation TKIs in chronic myeloid leukemia cell line K562.
Methods: To study the cytotoxicity of PPAR-gamma ligands (pioglitazone, prostaglandin J2, rosiglitazone) and TKIs (dasatinib, nilotinib, bosutinib and ponatinib) XTT and trypan blue exclusion assays were used. The influence of the studied drugs on cell proliferation and clonogenic potential was studied using APO-BRDU and clonogenic assays. Western blotting analysis was used to study proteins involved in the regulation of cell cycle (p21, p27, cyclin D1) and apoptosis (cleaved caspase 3 & 9). In addition, phosphorylation of CrkL was measured as a marker of BCR-ABL1 kinase activity inhibition. Activation of caspase 7 was measured using fluorescent microscopy. Cell cycle was analysed using propidium iodide DNA staining (flow cytometry).
Results: PPAR-gamma ligands synergistically increased cytotoxicity of dasatinib, nilotinib, bosutinib and ponatinib (Figure1A). In addition, pioglitazone significantly enhanced the antiproliferative effect of the studied TKIs. Moreover, the addition of pioglitazone induced cell cycle arrest in G0/G1 and sensitised CML cells to TKIs as observed by increased number of cells in subG1 phase in TKI + pioglitazone group (Figure1B). Cell cycle arrest was confirmed by Western blotting analysis of p21, p27 and cyclin D1. In result of cell cycle arrest, pioglitazone significantly increased proapoptotic activity of TKIs as observed in Western blotting (cleavage of caspase 3 & 9) and microscopy (caspase 7 activity).

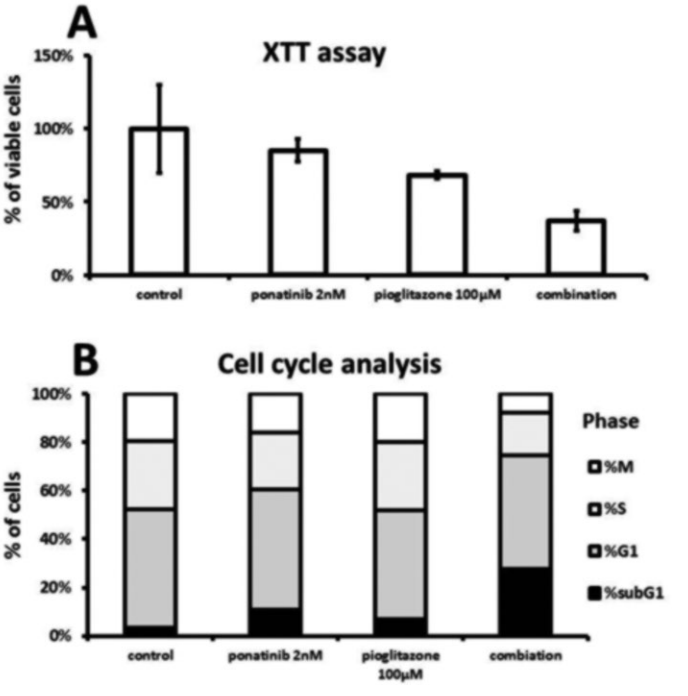

Figure 1.

Summary and Conclusions: Reduction of cardiovasular risk after administration of pioglitazone observed in patients with type 2 diabetes suggests that this drug can be useful in prevention of severe complications related to administration of 2nd and 3rd generation TKIs. In addition to its influence on cardiovascular risk, pioglitazone may enhance therapeutic efficacy of 2nd and 3rd generation TKIs through induction of cell cycle arrest and sensitization of CML cells to TKI-induced apoptosis. Therefore, the addition of pioglitazone to standard CML therapy may become potent treatment modality for the patients treated with 2nd and 3rd generation TKIs and increased cardiovascular risk.

P223

IDENTIFICATION OF BRD4 AS A NOVEL MOLECULAR TARGET IN PH+ CML

B. Peter[1,2,*] G. Stefanzl[1], S. Cerny-Reiterer[2], D. Berger[1], J. Zuber[3], P. Valent[1,2]
[1]Department of Internal Medicine I, Division of Hematology and Hemostaseology, [2]Ludwig Boltzmann Cluster Oncology, Medical University of Vienna, [3]Research Institute of Molecular Pathology (IMP), Vienna, Austria

Background: Chronic myeloid leukemia (CML) is a hematopoietic stem cell disease defined by leukemic expansion of myeloid progenitor cells and the BCR/ABL1 oncoprotein that promotes growth and survival of leukemic cells. In most patients growth of clonal cells can be kept under control by BCR/ABL1 tyrosine kinase inhibitors (TKI), including imatinib. For patients who develop resistance or intolerance against imatinib, second-line and third-line TKI (nilotinib, dasatinib, bosutinib, ponatinib) are available. However, in advanced CML, patients may develop resistance against most or all TKI. Therefore, current

research is attempting to identify novel drug targets in CML, in order to overcome TKI resistance. One class of promising targets may be epigenetic regulators of cell growth. In acute myeloid leukemia (AML), the epigenetic reader BRD4 has recently been introduced as a novel drug target; and the BRD4-targeting drug JQ1 was found to induce growth inhibition in AML cells. However, so far, little is known about the expression and function of BRD4 in CML cells.
Aims: In this study we examined the expression of BRD4 in CML cells and asked whether BRD4 serves as a target of therapy in this leukemia.
Methods: BRD4 expression was determined by qPCR and immunocytochemistry and the effects of JQ1 on proliferation and survival of CML cells were evaluated by ^{3}H-thymidine uptake and Annexin V staining.
Results: Both CML cell lines investigated, namely KU812 and K562, express BRD4 mRNA and the BRD4 protein. The BRD4-targeting drug JQ1 was found to inhibit proliferation in KU812 cells in a dose-dependent manner (IC_{50}: 0.25-0.75 μM). Interestingly, however, no substantial growth-inhibitory effect of JQ1 was seen in K562 cells (IC_{50}: >5 μM). Moreover, we were able to show that JQ1 inhibits growth of primary CML cells with IC50 values ranged between 0.1 to 5 μM. Corresponding results were obtained when analyzing cell survival. In particular, JQ1 was found to induce apoptosis in KU812 cells but did not induce apoptosis in K562 cells. In addition, we were able to show that KU812 cells and K562 cells display MYC mRNA. Exposure to JQ1 was followed by a decrease in expression of MYC mRNA levels in both cell lines. Similar results were obtained by Western blotting where JQ1 was found to decrease the expression of the MYC protein in KU812 and K562 cells. Moreover, we were able to show that MYC expression in CML cells is BCR/ABL1-dependent. Imatinib, nilotinib, ponatinib and dasatinib were found to decrease expression of MYC mRNA as well as MYC protein expression in K562 cells and KU812 cells. Finally, we were able to show that JQ1 cooperates with imatinib, nilotinib, ponatinib and dasatinib in producing growth inhibition in KU812 cells and K562 cells.
Summary and Conclusions: Together, our data show that BRD4 serves as a potential target in CML cells, and that the BRD4-blocker JQ1 synergizes with BCR/ABL TKI to induce growth-inhibition. Whether BRD4 inhibition is a pharmacologically meaningful approach in patients with TKI-resistant CML remains to be determined.

P224

QUANTITATIVE EVALUATION OF BOTH POINT MUTATED AND ALTERNATIVELY SPLICED BCR-ABL IN CML-CP PATIENT WITH SUBOPTIMAL MOLECULAR RESPONSE TO IMATINIB: RESULT OF HIGHLY-SENSITIVE, DEEP SEQUENCING STUDY

J. Yuda[1,*] T. Miyamoto[1], J. Odawara[2], Y. Ohkawa[2], K. Miyamura[3], M. Tanimoto[4], K. Yamamoto[5], M. Taniwaki[6], M. Aoki[7], H. Okada[7], K. Akashi[1]
[1]Medicine and Biosystemic Science, Kyushu University Faculty of Medicine, [2]Department of Advanced Medical Initiatives, Kyushu University, Fukuoka, [3]Japanese Red Cross Nagoya First Hospital, Nagoya, [4]Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, [5]Aichi Cancer Center, Nagoya, [6]Kyoto Prefectural University of Medicine, Kyoto, [7]Novartis Pharma K.K, Tokyo, Japan

Background: Tyrosine kinase inhibitors (TKIs) have dramatically improved outcomes of chronic myeloid leukemia (CML) patients. However, a fraction of patients fail in TKI treatment. One of the major mechanisms of resistance to TKIs is point mutations in the BCR-ABL kinase domain (KD). Alternatively-spliced (AS) BCR-ABL transcript variants, such as retention of 35bp intronic nucleotides at Exon 8/9 splice junction (Ins35) are important obstacles to achieve optimal response to TKI (Gaillard JB, *et al.* Mol Cancer Ther 2010; T O'Hare, *et al.* Blood 2011). This BCR-ABL variant possesses a stop codon in KD residues, resulting in generation of "function dead" BCR-ABL. However, this variant showed structural changes, resulting in a failure to TKI bindings. We hypothesized that the emergence of these BCR-ABL variants may render such CML clones insensitive to TKIs, contributing to the persistence of CML clones.
Aims: We evaluated both point mutated and AS BCR-ABL variants in pts with suboptimal response (SoR) to Imatinib (IM) by highly-sensitive assay system.
Methods: In the Study to Evaluate Nilotinib (NIL) in CML Patients with Suboptimal Response (SENSOR, NCT0104387), all pts with SoR—complete cytogenetic response but no major molecular response (MMR) after ≥18 months (mo) of frontline IM, were switched to NIL 400mg BID. cDNA was synthesized from extracted RNA samples, and BCR-ABL was amplified by long-range nested PCR method. These amplicons were deeply sequenced to detect BCR-ABL variants by using HiSeq 1500 (illumina) (Figure 1). The cumulative amounts of AS BCR-ABL are defined as the area under the curve from baseline to 24 mo after switching to NIL. These cumulative amounts are thought to be a potential persistence of AS BCR-ABL.
Results: Of 45 pts enrolled in the main study, 41 pts were evaluated for BCR-ABL variants. At 24 mo, 10 pts could not achieve MMR, whereas 27 pts could achieve MMR, including 5 pts with MR4.0. The remaining 4 pts could not be evaluated serially. The remaining 4 pts could not be evaluated serially. We analyzed 422 samples from 41 pts who have at least one sample: 412 samples with an average sequence depth on ABL-1 exon 8 achieved over 1,000 were considered as reliable for further statistical analysis. Two types of splicing variants became evident: the Ins35 and the Intron 8-retained BCR-ABL that possesses inappropriately spliced Intron 8 of ABL-1. AS BCR-ABL transcript variants were detected in all 41 pts and serially detected during NIL treatment. A representative cumulative curve in a patient who could not achieved MMR is shown in Figure 2. After switching NIL, AS BCR-ABL was serially detected at any points fo treatment. In addition, various point mutations were detected all along during NIL treatment at any depth of molecular response (Table 1). We analyzed the relationship between the cumulative amounts of Ins35 for 0-24 mo and molecular response rate: These cumulative amounts had an impact on the achievement rate of MMR (Table 2).

Table 2: Cumulative amounts of BCR-ABL^{Ins35bp} for 0-24M and molecular response rate at 24 mo after switching to nilotinib

	MR4.0 (n=5)	MMR including MR4.0 (n=27)	No MMR (n=10)
Median (% month) [range]	0.14407 [0.0259-0.2909]	0.20851 [0.0247-2.9180]	1.28703 [0.3154-12.7419]

Figure 1.

Summary and Conclusions: Our highly-sensitive quantification system revealed that cumulative amounts of Ins35 for 0-24 mo might correlate with failure to achieve MMR after switching to NIL. Point mutations were detected in only 1 patient (K219N) out of 10 pts who could not achieve MMR at 24 mo. In contrast, AS BCR-ABL was detected in all 10 pts, suggesting that AS BCR-ABL might be related to SoR to TKIs rather than point mutation. These data suggest that CML clones with AS BCR-ABL may not be addicted to BCR-ABL kinase activity and were difficult to eradicate by TKI alone. Thus, quantification of AS BCR-ABL variants might be a beneficial method to predict clinical outcomes and to find out the mechanism of TKI resistance in CML pts.

Spedali Civili di Brescia, Brescia, [9]Department of Oncology and Hematology, "Seràgnoli" Institute of Hematology, Bologna University School of Medicine, Bologna, [10]Reparto di Ematologia con Trapianto di Midollo Osseo, Ospedale Santa Maria della Misericordia, Perugia, Italy

Background: The identification of the BCR-ABL transcripts for the purpose of molecular diagnosis is actually based on conventional RT-PCR. The novel RT-Q-LAMP molecular method represents a semi-automated alternative, which allows rapid differential detection of BCR-ABL p190 and p210 fusion transcripts in a close, single step format.
Aims: Evaluation of the Q-LAMP assay performances on archived RNA samples previously tested by conventional qualitative RT-PCR .
Methods: BCR-ABL RT-Q-LAMP is a fluorescent isothermal method for retro-

transcription, amplification and differential detection of the Minor (p190) and Major (p210) t(9;22) transcripts and the endogenous Gusb RNA, that acts as internal control. The test result is obtained starting directly from patient RNA in a single, sixty minute step. RT-Q-LAMP is carried out on the Liaison IAM instrument that incubates at constant temperature, displays fluorescent signals in real time and return final elaborated data. Overall 165 samples (111 BCR-ABL positive, 54 negative) consisting of archived RNA (500ng per reaction), have been tested and the results compared with one previously obtained by RT-PCR. 11 samples presented a chemical contamination, showing A260/A230 ration below 1 (0,24-1). Further 8 rare isoform samples (e19a2 n=3; e6a2 n=3; e8(-44nt)/+(intr abl1 30nt)/a2 n=1; p210 presenting a deletion in the fusion region) have been also analysed.
Results: The RT-Q-LAMP and RT-PCR data resulted fully concordant (100%). 3 samples initially discordant (negative by RT-PCR, weakly positive by Q-LAMP) have been further investigated by Quantitative PCR confirming the positive status. The positive samples have been identified by Q-LAMP in, as average, 22,7 minutes and 18,3 minutes for the p190 and p210 respectively. The 11 samples presenting poor A260/A230 ratio have been detected in 20,8 min as average. The rare isoforms e19a2 and e6a2 have been amplified, as well as the p210 positive sample presenting a deletion in the fusion region, which prevents quantitative PCR from amplification. The rare isoform e8(-44nt)/+(intr abl1 30nt)/a2, detectable by nested RT-PCR did not produce amplification in Q-LAMP.The negative samples presented amplification of the housekeeping gene, validating the result. Q-LAMP also demonstrated robustness to contamination by extraction chemical reagents. The close tube format and the ready-to-use lyophilized reagents provided an easier the set-up that may decrease the classical risks of multistep procedures. The software elaborates and stores the data ensuring traceability. The limitations identified are the inability to distinguish the p210 b2a2 from the b3a2 isoform and to detect the rare isoforms in which the exon 2 of ABL is deleted.
Summary and Conclusions: The Q-LAMP technique produced results concordant with RT-PCR, in a much lower time-to-results (about 20 minutes). The Q-LAMP method represents a valid option for reliable and rapid detection of BCR-ABL and the one step, close tube format could easily be adopted in not highly specialized centers for an effective diagnosis of Philadelphia Positive Leukemias.

DYNAMIC EXPANSION AND FUNCTIONAL TUNING OF NATURAL KILLER CELLS IN CHRONIC MYELOID LEUKEMIA

P. Rodrigues Santos[1,2,*], P. Couceiro[1], J. Almeida[1], D. Queirós[1], D. Gomes-Silva[3], V. Alves[2], L. Růžičková[4], P. Freitas-Tavares[4], M. Santos-Rosa[2]
[1]Lab Imunologia e Oncologia, Centro de Neurociências e Biologia Celular, [2]Instituto de Imunologia, [3]Lab Imunologia e Oncologia, Faculdade de Medicina da Universidade de Coimbra, [4]Hematologia, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Previous studies indicate that Natural Killer (NK) cells are deficient in Chronic Myeloid Leukemia (CML) patients, although the mechanisms behind the dysfunction are not completely understood. Current therapeutic strategies influence these innate lymphoid cells and successful results may be partially explained by the advantageous effects on their cytotoxicity against cancer cells. Due to recent advances in the knowledge of NK cell´s biology, there is an increasing interest in mapping NK-cell responses in cancer.
Aims: The aim of the present study was to analyze NK cells in CML patients and the effect of therapy and dose-dependent mechanisms on essential features of NK cells.
Methods: In this study, we analyzed blood samples from 67 CML patients treated with IFN-α and/or different generations of tyrosine kinase inhibitors (TKI). Extended analysis of NK-cell receptor repertoire and functional properties was performed by multiparametric flow cytometry, cell sorting, Luminex xMAP technology and real-time quantitative PCR.
Results: Relative frequency of NK cells was found reduced at CML diagnosis and recovered after treatment. CML therapy induces an increase of $CD62L^{+}CD56^{bright}$ NK cells, associated to the capacity of migration to secondary lymphoid organs. Activation of NK cells and the increased expression of CD137 and CD137L were interpreted as a significant effect of therapy response. Activatory (KIR2DS1) and inhibitory (KIR2DL1, KIR2DL2) receptors were found altered in CML. The expression of KIR2DS1 by $CD56^{dim}CD16^{+}$ NK cells was highest in CML patients undergoing Dasatinib therapy. Treatment also increased the NKG2C/NKG2A (activatory/inhibitory) ratio. Lower expression of NKp30 and NKp44 was compensated by the increase of $NKp46^{+}$ NK cells. Production of IFN-γ and suppression of TGF-β+ and IL-10+ NK cells was also a beneficial effect of treatment protocol. IFN-γ production decreased with an increased TKI dose. Dasatinib induced the expression of KIR2DS1 (activating receptor) on NK cells, improving NK cell ability to kill cancer cells.
Summary and Conclusions: NK cells are affected during CML and current therapeutic protocols ameliorate NK-cell performance. In the future, combination of NK cell-based immunotherapy with pharmacological interventions should be investigated in order to eradicate cancer cells and discontinuation of therapy.

IS THE HIGH-THROUGHPUT DROPLET DIGITAL PCR A NEXT-GENERATION TECHNOLOGY FOR ACCURATE AND SENSITIVE BCR-ABL1 QUANTIFICATION FOR DEEP MOLECULAR RESPONSE MONITORING IN CML?

H. Zizkova[1,*] K. Zemanova[1], H. Klamova[1], J. Zach[1], E. Motlova[1,2], S. Saussele[3], F.X. Mahon[4], K. Machova Polakova[1]
[1]Institute of Hematology and Blood Transfusion, [2]University of Chemistry and Technology, Prague, Czech Republic, [3]III. Med. Klinik, Universitätsmedizin Mannheim, der Universität Heidelberg, Mannheim, Germany, [4]Hôpital Haut Lévêque, Centre Hospitalier Universitaire, Bordeaux, France

Background: A sensitive and standardized monitoring of deep molecular response (MR) based on BCR-ABL1 transcript level quantification is an essential part of CML tyrosine kinase inhibitor (TKI) stopping trials. Detailed laboratory recommendations, developed as a part of the European Treatment and Outcome Study (EUTOS) for CML, to enable testing laboratories to score MR in a reproducible manner based on reverse transcription quantitative PCR (RT-qPCR) has been recently published (Cross *et al.* Leukemia 2015). A new quantification technology droplet digital PCR (ddPCR) is tested in more and more laboratories with promising high quantification accuracy and sensitivity.
Aims: To assess differences in accuracy and sensitivity of BCR-ABL1 transcript levels quantification using ddPCR and standardized RT-qPCR. In addition to that to compare the levels of BCR-ABL1 at mRNA and DNA levels measured by ddPCR.
Methods: The RT-qPCR used in our EUTOS $MR^{4.5}$ laboratory is standardized having regularly validated conversion factors for data reporting in the international scale (IS) using ABL1 or GUSB control genes. The system QX-200 (Biorad) was used for ddPCR. The same RT-qPCR primers and probes were applied for ddPCR. Unlike to singleplex RT-qPCR, TaqMan probes were differently labelled for multiplex ddPCR. Using each method all samples were analyzed in doublets.
Results: The WHO certified ERM-AD623 standards (n=6) were used to compare the quantification accuracy of both methods. Obtained gene copies ratios (BCR-ABL1/ABL1 and BCR-ABL1/GUSB) in the standards by singleplex RT-qPCR were in range 0.63-1.11 (Me=0.85). Singleplex ddPCR determined ratios in range 0.92-1.29 (Me=1.02). Multiplex ddPCR improved quantification accuracy with ratios 0.93-1.0 (Me=0.99).
Samples of 31 CML patients treated with TKIs with BCR-ABL1 mRNA levels ranging 0.01-10% IS were used for data comparison. The Bland-Altman bias plot was used to determine bias between RT-qPCR and ddPCR showing antilog bias 0.54-fold in 31 paired results.
To compare BCR-ABL1 detection sensitivity of both methods we tested 66 samples from the time of $MR^{4.0}$ confirmation and after TKI discontinuation of 7 patients enrolled in the EURO-SKI study (Europe Stops TKI in CML). The total number of paired results from RT-qPCR *vs* ddPCR of samples with BCR-ABL1 mRNA levels below 0.01% IS was 37 with determined antilog bias 0.23-fold. The number of BCR-ABL1 negative samples by RT-qPCR *vs* ddPCR was 26/66 in $MR^{4.5}$-$MR^{5.0}$ sensitivity *vs* 6/66, respectively. Moreover, 26 samples of 4/7 EURO-SKI patients were assessed by ddPCR for the levels of genomic BCR-ABL1 fusions using patient-specific assays. We found significant correlation between DNA and mRNA BCR-ABL1 levels ($r=0.9038$, $P<0.0001$).
Summary and Conclusions: We found a higher quantification accuracy of ddPCR in contrast to RT-qPCR for which standard calibration curves need to be performed to mathematically calculate cDNA copy numbers in unknown samples. This probably represents an important variable. We found comparable results of both methods for BCR-ABL1 mRNA quantification within the range 0.01-10% IS. Approximately a log higher BCR-ABL1 mRNA levels in EURO-SKI $MR^{4.0}$-$MR^{5.0}$ samples were detected by ddPCR in comparison to RT-qPCR, assuming that higher sensitivity of ddPCR may be important for TKI stopping treatment management. Interestingly, BCR-ABL1 DNA and mRNA levels measured by ddPCR correlated significantly. A larger cohort of samples needs to be analyzed to elucidate the clinical importance of DNA measurement. Supported by MZCR project no. 00023736 and EURO-SKI research consortium.

Chronic myeloid leukemia - Clinical 1

Background: In the Evaluating Nilotinib Efficacy and Safety in Clinical Trials–Newly Diagnosed Patients study (ENESTnd), nilotinib (NIL) demonstrated improved efficacy *vs* imatinib (IM) throughout 5 y of follow-up (f/u), with higher rates of major molecular response (MMR; *BCR-ABL*on the International Scale[BCR-ABL^{IS}] ≤0.1%) and MR$^{4.5}$(BCR-ABL^{IS} ≤0.0032%). The protocol was amended in January 2012 to extend the f/u period to 10 y, from the initial 5 y, to collect further data on efficacy parameters, including deep molecular response and survival, and on safety. Here, we report 6-y f/u data.
Aims: The efficacy and safety of NIL *vs* IM were evaluated in adult patients (pts) with newly diagnosed Philadelphia chromosome–positive (Ph+) chronic myeloid leukemia (CML) in chronic phase (CP).
Methods: Pts were randomized to NIL 300 mg twice daily (n=282), NIL 400 mg twice daily (n=281), or IM 400 mg once daily (n=283). "On core treatment" analyses included all events that occurred during core treatment with the assigned study drug. "On study" analyses included all events that occurred during core treatment, extension treatment, or posttreatment f/u. Progression and survival data were collected prospectively every 3 mo for 5 y, then every 6 mo, including after discontinuation of study treatment.
Results: After a minimum f/u of 6 y, more pts remained on core treatment in the NIL 300 mg and 400 mg arms than in the IM arm (53.5%, 55.2%, and 44.9%, respectively). In both NIL arms, cumulative rates of MMR and MR$^{4.5}$ by 6 y were higher than in the IM arm (Table). In all 3 arms (NIL 300 mg, NIL 400 mg, and IM), MR$^{4.5}$rates by 6 y were highest in pts with BCR-ABL^{IS} ≤1% at 3 mo (73.6% [106/144], 75.0% [102/136], and 72.1% [31/43], respectively) and lowest in pts with BCR-ABL^{IS} >10% at 3 mo (8.3% [2/24], 21.4% [6/28], and 15.9% [14/88], respectively); more pts on NIL *vs* IM achieved BCR-ABL^{IS} ≤1% and fewer pts on NIL *vs* IM had BCR-ABL^{IS} >10% at 3 mo. By 6 y, fewer pts on NIL *vs* IM had progressed to accelerated phase/blast crisis (AP/BC) on study and on core treatment (Table). Since the 5-y data cutoff, 1 new progression to AP/BC on study (NIL 300 mg arm, ≈5 y after discontinuation of core treatment) was reported; no new progressions on core treatment were reported. Fewer deaths due to advanced CML occurred in the NIL arms than in the IM arm. Since the 5-y data cutoff, 5 deaths were reported, including 3 on core treatment and 2 on study after discontinuation of core treatment (Table); no new deaths due to advanced CML occurred in any arm. The safety profiles of NIL and IM were consistent with previous reports. Very few events of pleural effusions, pericardial effusion, or pulmonary edema occurred in any arm (Table). More pts in the NIL arms than in the IM arm had cardiovascular events (CVEs); CVEs were reported at a consistent frequency within each arm throughout the study (Table). A recent protocol amendment allowed for a dose reduction to NIL 300 mg twice daily in pts in the NIL 400 mg twice daily arm, and a subsequent dose increase to the originally assigned 400 mg twice daily dose, based on a pt's individual benefit/risk assessment.

Tabella 1.

ENESTnd 6-y Data	Nilotinib 300 mg Twice Daily (n = 282)	Nilotinib 400 mg Twice Daily (n = 281)	Imatinib 400 mg Once Daily (n = 283)
Pts still on study,[a] n (%)	231 (81.9)	238 (84.7)	224 (79.2)
Pts still on core treatment, n (%)	151 (53.5)	155 (55.2)	127 (44.9)
MMR, % (*P* value vs IM[b])	77.3 (< .0001)	79.0 (< .0001)	61.1
MR$^{4.5}$, % (*P* value vs IM[b])	55.7 (< .0001)	54.8 (< .0001)	32.9
Progressions to AP/BC[c] on study, n (*P* value vs IM[b])	11 (.0661)	6 (.0030)	21
Progressions to AP/BC[c] on core treatment	2 (.0059)	3 (.0185)	12
Estimated rates of 6-y OS, % (*P* value vs IM[b])	91.6 (.7085)	95.8 (.0314)	91.4
Deaths due to any cause, n	21	11	23
Deaths due to advanced CML,[d] n	6	4	16
Deaths after 5-y data cut-off,[e] n	3	1	1
AEs of interest (all causes, all grades), n (%)	**n = 279**	**n = 277**	**n = 280**
Peripheral edema	28 (10.0)	40 (14.4)	56 (20.0)
Fluid retention	0	2 (0.7)	7 (2.5)
Pleural effusion	5 (1.8)	3 (1.1)	3 (1.1)
Pericardial effusion	2 (0.7)	2 (0.7)	3 (1.1)

Pulmonary hypertension	0	2 (0.7)	1 (0.4)
Retinal vein occlusion	1 (0.4)	0	0
Thrombophlebitis	1 (0.4)	3 (1.1)	0
Superficial thrombophlebitis	0	1 (0.4)	0
Deep venous thrombosis	1 (0.4)	1 (0.4)	1 (0.4)
CVE[f]	28 (10.0)	44 (15.9)	7 (2.5)
IHD[f]	14 (5.0)	28 (10.1)	6 (2.1)
ICVE[f]	4 (1.4)	9 (3.2)	1 (0.4)
PAD[f]	12 (4.3)	9 (3.2)	0
Other[f,g]	4 (1.4)	3 (1.1)	0
CVEs by y of treatment,[f,h] n (%)			
< 2 y	8 (2.9)	16 (5.8)	2 (0.7)
≥ 2 y to < 4 y	11 (3.9)	10 (3.6)	2 (0.7)
≥ 4 y to < 6 y	6 (2.2)	15 (5.4)	2 (0.7)
≥ 6 y to < 8 y	3 (1.1)	3 (1.1)	1 (0.4)

AE, adverse event; AP/BC, accelerated phase/blast crisis; CVE, cardiovascular event; ICVE, ischemic cerebrovascular event; IHD, ischemic heart disease; MMR, major molecular response (BCR-ABL^{IS} ≤ 0.1%); MR$^{4.5}$, molecular response 4.5 (BCR-ABL^{IS} ≤ 0.0032%); OS, overall survival; PAD, peripheral artery disease.
[a] On core or extension treatment or in posttreatment f/u.
[b] *P* values are nominal, provided for descriptive purposes only, and were not adjusted for multiple comparisons.
[c] Includes progressions to AP/BC or deaths due to advanced CML.

Summary and Conclusions: NIL continued to demonstrate improved efficacy over IM, with higher rates of molecular response, fewer progressions, and fewer deaths due to advanced CML. No new safety signals were detected. Results from ENESTnd continue to support use of NIL 300 mg twice daily as a standard-of-care frontline therapy option for pts with newly diagnosed Ph+ CML-CP.

P229

ENESTCMR 4-Y RESULTS: PATIENTS (PTS) WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) AND RESIDUAL DISEASE MORE LIKELY TO ACHIEVE DEEP MOLECULAR RESPONSE FOLLOWING SWITCH TO NILOTINIB (NIL)

Ltd., Hyderabad, India, [15]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States, [16]Centre for Cancer Biology, SA Pathology, University of Adelaide, Adelaide, Australia

Background: ENESTcmr has demonstrated that switching to NIL results in higher rates of deep molecular response *vs* continued imatinib (IM) in pts with CML-CP with residual disease after long-term IM treatment; among pts without major molecular response (MMR; *BCR-ABL1* ≤0.1% on the International Scale [IS]) after ≥2 y of IM, substantially higher rates of MMR were also observed with switching to NIL *vs* continuing IM.
Aims: Here we present results with 4 y of follow-up.
Methods: The phase 3 ENESTcmr study evaluated pts with Philadelphia chromosome–positive (Ph+) CML-CP with complete cytogenetic response but with detectable *BCR-ABL1* by real-time quantitative polymerase chain reaction (RQ-PCR; sensitivity of ≥4.5 logs) on the IS after ≥2 y of treatment with IM. Pts were randomized to receive NIL 400 mg twice daily (BID; n =104) or continue IM (400 or 600 mg once daily [QD]; n =103). Crossover to the NIL arm was allowed

for pts in the IM arm with detectable *BCR-ABL1* transcripts after 2 y on study or with treatment failure/confirmed loss of response (≥2 consecutive assessments) at any time.

Results: Of 103 pts randomized to the IM arm, 46 crossed over to NIL, most commonly due to detectable *BCR-ABL1* after 2 y (n =41/46; 89%). The 4-y cumulative incidence of $MR^{4.5}$ (*BCR-ABL1*^{IS} ≤0.0032%) among pts without $MR^{4.5}$at baseline (intention-to-treat analysis; NIL, n =98; IM, n =96) was 52% (51/98 pts) in the NIL arm and 42% (40/96 pts) in the IM arm (nominal *P* =.1318; Table). Among the 46 pts who crossed over to NIL, 20 (43%) achieved $MR^{4.5}$by the end of the study (13 achieved $MR^{4.5}$for the first time [5 of these pts did not have an RQ-PCR evaluation at the crossover visit], 4 maintained $MR^{4.5}$, and 3 regained $MR^{4.5}$ that was lost prior to crossover). When excluding responses achieved after crossover to NIL, 52% of pts in the NIL arm *vs* 28% of pts in the IM arm (nominal *P* =.0004) achieved $MR^{4.5}$ by 4 y. Median time to $MR^{4.5}$ was 24 months in the NIL arm and was not reached in the IM arm by 48 mo. At 2 y, 78 pts were eligible for crossover to NIL due to molecular detectable disease; of these, 13/41 pts who switched to NIL *vs* 5/37 pts who remained on IM achieved undetectable disease by 4 y. The safety profiles of NIL and IM were consistent with previous reports. By 4 y, cardiovascular events were reported in 13 pts in the NIL arm (ischemic heart disease [IHD], 4; cerebrovascular event [CVE], 4; peripheral arterial disease [PAD], 7), 3 pts who crossed over from IM to NIL (IHD, 1; CVE, 1; PAD, 1), and 2 pts in the IM arm (excluding events after crossover; IHD, 1; CVE, 1). The median time on treatment was 3.9 y in the NIL arm and 4.0 y for pts in the IM arm who did not cross over; for pts who crossed over from IM to NIL, median time on treatment was 2.1 and 1.8 y before and after crossover, respectively.

Tabella 1.

	NIL 400 mg BID (n = 98)	IM 400 or 600 mg QD (n = 96)	*P* Value[a]
$MR^{4.5}$ in pts without $MR^{4.5}$ at baseline (intention-to-treat analysis)	n (%)	n (%)	
By 1 y	32 (33)	13 (14)	.0020
By 2 y	42 (43)	20 (21)	.0006
By 3 y	46 (47)	35 (37)	.1146
By 4 y	51 (52)	40 (42)	.1318
$MR^{4.5}$ in pts without $MR^{4.5}$ at baseline (excluding responses achieved after crossover[b] to NIL)			
By 3 y	46 (47)	25 (26)	.0015
By 4 y	51 (52)	27 (28)	.0004

[a] *P* values are nominal and are provided for descriptive purposes only.
[b] On study, crossover to the NIL arm was allowed for detectable *BCR-ABL1* transcripts after 2 y or treatment failure/confirmed loss of response at any time on IM.

Summary and Conclusions: Results from ENESTcmr showed that for pts with Ph+ CML-CP and residual disease after ≥2 y of IM treatment, more pts achieved $MR^{4.5}$with switching to NIL (52%) *vs* continuing IM (42%; when accounting for confounding effects of crossover, 28%) by 4 y. In addition, more pts with detectable disease at 2 y who switched to NIL than those who remained on IM were able to achieve undetectable disease by 4 y. Overall, results from ENESTcmr suggest that an earlier switch to NIL (at randomization) allows earlier achievement of $MR^{4.5}$ *vs* remaining on IM or delaying switch to NIL (at crossover) and enables a larger proportion of pts to achieve deeper molecular responses and become eligible for treatment-free remission trials sooner.

P230

DEEP MOLECULAR RESPONSE TO NILOTINIB AS FIRST-LINE TREATMENT OF BCR-ABL+ CML

Luigi Gonzaga" University Hospital, Orbassano (TO), [18]Department of Hematology and Oncology "L. e A. Seràgnoli", University of Bologna, Bologna, Italy

Background: In the ENESTnd trial, nilotinib (NIL) showedsuperior efficacy compared to imatinib (IM); based on these results, NIL has been approved for frontline treatment of chronic myeloid leukemia (CML). The treatment-free remission (TFR) is an emerging treatment goal in CML and a sustained deep molecular response (DMR, MR4 or better) is a pre-requisite to achieve TFR. The 5-year update from the ENESTnd trial showed a superiority of NIL over IM in terms of achievement of DMR, but differences concerning the stability of DMR have not been reported yet. Independent studies are extremely relevant to confirm and to extend the results of company-sponsored trials.

Aims: To assess the efficacy of NIL as first-line treatment in terms of achievement of DMR and stability of DMR

Methods: A phase 3b study was conducted by the GIMEMA CML WP (CML0811; NCT01535391). The primary endpoint was the rate of MR4 at 24 months. Key secondary objectives: evaluation of the kinetics of molecular response and stability of DMR, assessment of the safety profile, evaluation of the outcome. The starting NIL dose was 300 mg BID, with dose escalation to 400 mg BID (in absence of safety issues)in case of suboptimal response or failure (ELN 2009 criteria), with the exception of progression to ABP or BCR-ABL mutations insensitive to NIL. The molecular response was assessed in GIMEMA standardized molecular laboratories (Labnet network). The MR4 was defined as either detectable disease ≤0.01% BCR-ABL or undetectable disease with ≥10.000 ABL copies; the MR4.5 was defined as either detectable disease ≤0.0032% BCR-ABL or undetectable disease with ≥32.000 ABL copies. Sustained MR4 or MR4.5: MR4 or MR4.5 for at least 1 year a, with at least 3 evaluable analysis. A prospective evaluation of glucose metabolism and serum lipids was performed. All the analysis were performed according to the ITT principle.

Results: 130 CML patients in early chronic phase have been enrolled in 32 italian hematologic centers; median age, 50 years (range 18-85); high risk patients, 22%, 6% and 8% according to Sokal, Euro and EUTOS scores, respectively; clonal chromosomal abnormalities in Ph+ cells at baseline, 5%; e13a2 BCR-ABL transcript, 34%. The median follow-up is 29 months (24-37 months). At the last contact, the patients still on treatment with NIL were 100/130, 77% (86 with 600 mg, 9 with 300 mg or less, 5 with 800 mg daily), while 30/130 patients, 23%, permanently interrupted the study drug for the following reasons: 3% progression to ABP, 5% failure or suboptimal response (dose escalation not feasible or not effective), 8% adverse events, 1% TFR, 5% other reasons (including consent withdrawal and pregnancy). At 3 months, 80% of patients had BCR-ABL transcript levels <10%; at 6 months, 78% of patients had BCR-ABL transcript levels <1%. The major molecular response rates at 12 and 24 monthswere 57% and 65%, respectively. The rates of MR4 at 6, 12, 18 and 24 months were 12%, 28, 31% and 46%, respectively. Seventy-six patients (58%) achieved a MR4 at least once; the patients with a sustained MR4 were 39/76 (51%, or 30% of the total). The rates of MR4.5 at 6, 12, 18 and 24 months were 2%, 7%, 11% and 17%, respectively.Eleven patients achieved a sustained MR4.5. A significant increase of glycosylated hemoglobin was not observed. The total cholesterol, and both LDL and HDL cholesterol fractions significantly increased during treatment. Triglicerid concentrations had not significant variations. Six patients (5%) had a cardiovascular event, including myocardial infarction and arterial thrombosis. All the patients are still alive.

Summary and Conclusions: The molecular response rates seem to be superior to the historical data of IM. NIL 300 mg BID as frontline treatment of BCR-ABL+ CML, with dose optimization in case of non optimal response, may improve the proportion of patients able to discontinue TKI treatment. Due to the metabolic effects, a baseline selection is important to maximize the therapeutic benefit and to minimize the cardiovascular risks.

P231

SMOOTHENED (SMO) INHIBITOR LDE225 COMBINED WITH NILOTINIB IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) RESISTANT/INTOLERANT (R/I) TO AT LEAST 1 PRIOR TYROSINE KINASE INHIBITOR: A PHASE 1B STUDY

O. Ottmann[1,*] A. Charbonnier[2], F. Stegelmann[3], M. Breccia[4], J.L. Steegmann[5], E. Olavarria[6], S. Jevtic[7], M. Cota[7], N. Scheuer[7], J.H. Lipton[8]
[1]J.W. Goethe Universitat, Frankfurt, Germany, [2]Institut Paoli-Calmette, Marseille, France, [3]Klinik für Innere Medizin III, Universitätsklinikum, Ulm, Germany, [4]Department of Cellular Biotechnologies and Hematology, Sapienza University, Rome, Italy, [5]Instituto de Investigación Sanitaria, Hospital Universitario de la Princesa, Madrid, [6]Servicio de Hematologia, Hospital de Navarra, Pamplona, Spain, [7]Novartis Pharma AG, Basel, Switzerland, [8]Princess Margaret Cancer Centre, Toronto, Canada

Background: Currently available therapies may have limited potential to eliminate leukemic stem cells (LSCs). LDE225 is an antagonist of the transmembrane protein SMO, which plays a role in the Hedgehog (Hh) pathway. Inhibition of the Hh pathway diminished survival signals in LSCs and increased the sensitivity of LSCs to tyrosine kinase inhibitors (TKIs).[1]Preclinical studies[2] have shown synergistic effects between SMO inhibitors and BCR-ABL TKIs. This combination is being explored in early phase clinical trials.

Aims: We evaluated the feasibility of the combination of nilotinib (NIL), a potent BCR-ABL TKI and LDE225 in patients with Philadelphia chromosome-positive CML in chronic phase R/I to at least 1 prior TKI.

Methods: This phase 1b, single-arm, multicenter study had the primary objective of determining the maximum tolerated dose (MTD) and/or the recommended phase 2 dose (RP2D) of LDE225 (planned doses of 400/600/800 mg once daily) in combination with NIL 400 mg twice daily. Dose-limiting toxicities (DLT) were identified during the first 8 weeks of dosing. An adaptive Bayesian logistic regression model guided by the escalation with overdose control principle was used. Secondary objectives included safety, pharmacokinetics, and efficacy (as measured by the kinetics of molecular and cytogenetic responses).
Results: Eleven patients (cohort 1 [LDE225 400 mg + NIL]: n=4; median age 58 years; cohort 2 [LDE225 600 mg + NIL]: n=7, median age, 46 years) were enrolled. The median duration of exposure to study treatment in cohort 1 and cohort 2 was 11.27 and 8.25 months, respectively. Two patients in cohort 2 experienced 1 DLT (elevated creatine phosphokinase [CPK]: n=1, grade [G] 3; n=1, G4). One patient in cohort 1 experienced 1 serious adverse event (SAE; G4 elevated CPK), and 2 patients in cohort 2 experienced 2 SAEs each (G4 elevated CPK + G1 elevated troponin T and G3 appendicitis + G2 sepsis). The most frequently occurring (>30%) adverse events (AEs; all grades) in the overall patient population included alopecia (73%), elevated CPK (64%), dysgeusia (64%), muscle spasms (64%), folliculitis (46%), and weight loss (37%). AEs leading to study discontinuation included 1 patient in cohort 1 (G1 elevated CPK) and 4 patients in cohort 2 (G1 folliculitis, G3 folliculitis, G2 dysgeusia, and G2 alopecia). No deaths occurred during the study. No other clinically significant laboratory abnormalities were observed during the study. One patient in cohort 1, who had a major molecular response (MMR; ≤0.1% BCR-ABL^{IS}) at baseline, achieved deep molecular response (MR$^{4.5}$; ≤0.0032% BCR-ABL^{IS}) temporarily at 2 months and 1 patient who had no MMR at baseline achieved MMR post baseline (from 1 month until 9 months). In cohort 2, 1 patient who had no MMR at baseline achieved MMR at 12 months. The study was terminated early, as the benefit of addition of LDE225 to NIL did not appear to outweigh additional risks in patients with CML.

Tabella 1.

Treatment-Related AEs: All Grades, n (%)[a] (> 30% Incidence) (Safety Set)	LDE225 200 mg qd[b] + Nilotinib 400 mg bid n = 1	LDE225 400 mg qd + Nilotinib 400 mg bid n = 3	LDE225 600 mg qd + Nilotinib 400 mg bid n = 7	All Patients N = 11
Any AE	1 (100)	3 (100)	7 (100)	11 (100)
Alopecia	1 (100)	3 (100)	4 (57)	8 (73)
Blood CPK increase	1 (100)	3 (100)	3 (43)	7 (64)
Dysgeusia	1 (100)	0	6 (86)	7 (64)
Muscle spasms	0	2 (67)	5 (72)	7 (64)
Folliculitis	1 (100)	0	4 (57)	5 (46)
Responses, n (%)[a]	**LDE225 400 mg qd + Nilotinib 400 mg bid n = 4**		**LDE225 600 mg qd + Nilotinib 400 mg bid n = 7**	
	Baseline	**12 mo[c]**	**Baseline**	**12 mo[c]**
MR$^{4.5}$	0	0	1 (14)	0
MMR	2 (50)	2 (50)	2 (29)	2 (29)
CCyR	3 (75)	3 (75)	7 (100)	5 (71)
MCyR	3 (75)	3 (75)	7 (100)	5 (71)

AE, adverse event; bid, twice daily; CCyR, complete cytogenetic response; CPK, creatine phosphokinase; MCyR, major cytogenetic response; MMR, major molecular response (≤ 0.1% BCR-ABL^{IS}); MR$^{4.5}$, ≤ 0.0032% BCR-ABL^{IS}; qd, once daily.

[a] All percentages have been rounded to the nearest hundredth.
[b] One patient in the assigned LDE225 400 mg + nilotinib 400 mg group received LDE225 200 mg qd during the e study due to a dosing error. For safety-related analyses, this patient was analyzed according to this treatment gr
[c] MR$^{4.5}$ and MMR rates at 12 mo; CCyR and MCyR rates by 12 mo.

Summary and Conclusions: The MTD was not determined; no RP2D for the combination of NIL and LDE225 was found with respect to an acceptable risk/benefit ratio for patients with CML. No evidence of clinical benefit or impact of the combination was observed. The SAEs of elevated blood CPK were consistent with the safety profile of LDE225. No significant AEs were seen due to NIL. Study outcomes were similar to another phase 1 study, which showed lack of efficacy and tolerability when a SMO inhibitor was used in combination with dasatinib.[3]

Background: LASOR is the only randomized study evaluating IM dose escalation *vs* switch to NIL in pts with Philadelphia chromosome–positive (Ph+) CML-CP and suboptimal response to frontline IM. When accounting for crossover, results from the 1-y analysis demonstrated an overall benefit of switching to NIL *vs* IM dose escalation.
Aims: Here we present final results from LASOR with 2 y of follow-up.
Methods: Adult pts (N =191) with CML-CP and a complete hematologic response but suboptimal CyR, defined per 2009 European LeukemiaNet (ELN) criteria (no CyR ≥3 to <6 mo [Ph+ >95%], no partial CyR ≥6 to <12 mo [Ph+ 36%–95%], or no complete CyR [CCyR] ≥12 to <18 mo [Ph+ 1%–35%] on IM 400 mg once daily [QD]), were randomized to receive NIL 400 mg twice daily (BID; n =96) or IM 600 mg QD (n =95). The primary endpoint was CCyR at 6 mo after randomization. Consistent with standard of care at the time of the study, pts were allowed to cross over to the alternate treatment arm for failure to achieve CCyR by 6 mo or development of intolerance/loss of response at any time. As a result, additional analyses were performed to evaluate the effects of crossover.
Results: Crossover was more frequent in the IM arm (56 pts [60%] crossed over to NIL) than in the NIL arm (13 pts [14%] crossed over to IM). Among pts who crossed over, median time to crossover (from 1 day after randomization to the last known date a pt took randomized study drug) was 6 mo in each arm; the most common reasons for crossover were lack of CCyR after 6 mo (IM, 31%; NIL, 6%), intolerance (IM, 17%; NIL, 5%), and loss of best CyR (IM, 8%; NIL, 1%). The median time on randomized treatment (including time to crossover for crossover pts and time on treatment for pts who did not cross over) was 22 mo with NIL and 8 mo with IM. Median time on alternative treatment after crossover was higher for pts who switched to NIL (16 mo) *vs* IM (6 mo). Accounting for crossover by considering pts who crossed over without achieving response by the time point as nonresponders, 66% of pts on NIL *vs* 40% on IM achieved CCyR by 1 y (nominal *P* =.0005; Table). Overall, the CCyR rate by 1 y was 67% in the NIL arm *vs* 63% in the IM arm (nominal *P* =.6509; intention-to-treat [ITT] analysis). When considering pts who crossed over without achieving response by the time point as nonresponders, 42% of pts on NIL *vs* 19% of pts on IM achieved a major molecular response (MMR; *BCR-ABL1* ≤0.1% on the International Scale) by 1 y (nominal *P* =.0009; by 2 y, 51% and 26%, respectively [nominal *P* =.0006]). MMR was achieved by 42% of pts randomized to the NIL arm and 28% of pts randomized to the IM arm by 1 y (nominal *P* =.0688; ITT analysis) and by 51% and 48%, respectively, by 2 y (nominal *P* =.7729). Estimated rates of 2-y event-free survival (EFS) are reported in the table. The safety profile of both drugs was similar to that reported at 1 y. Cardiovascular events occurred in 5 pts on NIL (ischemic heart disease, n =4; peripheral arterial occlusive disease and arteriosclerosis, n =1) and 0 pts on IM.

Tabella 1.

	NIL 400 mg BID (n = 96)	IM 600 mg QD (n = 95)		NIL 400 mg BID (n = 96)	IM 600 mg QD (n = 95)

By 2 y	72	75	.7440	70	41	.0001
MMR[d]						
By 1 y	42	28	.0688	42	19	.0009
By 2 y	51	48	.7729	51	26	.0006

	NIL 400 mg BID (n = 96)	IM 600 mg QD (n = 95)	Crossover to NIL (n = 56)	Crossover to IM (n = 13)
EFS on treatment[e]				
KM-estimated 2-y EFS (95% CI), %	67 (54-77)	52 (20-76)	-	-
Hazard ratio vs NIL (95% CI)	.851 (0.486-1.492)		-	-
P value[b] vs NIL	.5739		-	-
KM-estimated 2-y EFS before crossover[f] (95% CI), %	71 (59-81)	58 (34-76)	-	-
Hazard ratio vs NIL (95% CI)	1.048 (0.554-1.983)		-	-
P value[b] vs NIL	.8848		-	-
KM-estimated 2-y EFS after crossover (95% CI), %	-	-	66 (35-85)	39 (1-82)
Hazard ratio vs NIL (95% CI)	-	-	.382 (.103-1.419)	
P value[b] vs NIL	-	-	.1363	

KM, Kaplan-Meier.
[a] For analyses by indicated time points, pts who achieved the response prior to crossover and by the indicated time point were considered as responders.
[b] *P* values are nominal and are provided for descriptive purposes only.
[c] Pts with missing cytogenetic evaluations by the indicated time point were considered as nonresponders.
[d] Pts with missing polymerase chain reaction evaluations by the indicated time point or with atypical transcripts at baseline were considered as nonresponders.
[e] Date of event is the earliest date of any of the following events during treatment on study: death due to any cause, progression to accelerated phase or blast crisis, loss of partial CyR, loss of CCyR, loss of complete hematologic response. Time is censored at the date of the last on-treatment assessment for patients without an event.
[f] For patients who crossed over to the alternate treatment arm without an event, time is censored at the date of crossover.

Summary and Conclusions: With 2 y of follow-up and accounting for crossover, final results from LASOR demonstrated clinically meaningful improvements in CCyR and MMR in pts who switched to NIL following suboptimal CyR (2009 ELN criteria) with frontline IM. Although the primary endpoint (ITT analysis) was not met, data accounting for crossover suggest such pts (classified as warning/failure according to current ELN recommendations) may be more likely to achieve recommended ELN treatment milestones with switch to NIL *vs* IM dose escalation.

Medizinische Klinik, Universitätsklinikum Eppendorf, Hamburg, [5]Klinik für Hämatologie und Onkologie, Klinikum, Bayreuth, [6]Praxis für Hämatologie, Landshut, [7]Medizinische Klinik 5 und Ambulantes BehandlungsCentrum, Klinikum Nürnberg-Nord, Nürnberg, [8]Onkologische Praxis, Moers, [9]Fachabteilung für Blut-und Tumorerkrankungen, Robert-Bosch-Krankenhaus, Stuttgart, [10]Klinik für Hämatologie, Hämostaseologie, Onkologie und Stammzelltransplantation, Medizinische Hochschule, Hannover, [11]BU Onkologie, Novartis Pharma GMBH, Nürnberg, Germany, [12]Northwestern Medicine Developmental Therapeutics Institute, Chicago, IL, United States, [13]Klinik für Innere Medizin II, Universitätsklinikum, Jena, Germany

Background: For chronic myeloid leukemia (CML), many treatment options have been established. So far, none of them provided a statistically significant and clinically relevant survival advantage as compared with the others. Thus, endpoints like health-related quality of life (HRQoL) move into focus. HRQoL might become essential for deciding on treatment strategies. Data on HRQoL in CML are rare (Efficace *et al.*, 2011), especially for patients receiving second generation tyrosine kinase inhibitor treatment.
Aims: We evaluated HRQoL in German patients of the ENEST1st study (Evaluating Nilotinib Efficacy and Safety in clinical Trials as First-Line Treatment, NCT01061177). Main interest was the comparison of HRQoL between diagnosis and during treatment and the presence of adverse events and symptoms.
Methods: The EORTC QLQ-C30 questionnaire (including global health status and five functioning scales) and an ad-hoc 15-item symptom scale were sent out to German participants of the study after informed consent was given at diagnosis (visit 1, V1), month 3 (V2), month 6 (V3), month 12 (V4), month 18 (V5), and at the end of the study (month 24, V6). Patients with completed questionnaires at visits 1 and 6 were included in this analysis; patients ending the study prior to 24 months were counted as visit 6 at their last QoL assessment. Incomplete questionnaires were not considered. Functional scales and global health status of the EORTC questionnaire were calculated in accordance with Aaronson (1993) and Fayers (2001). With functional scales and global health status ranging from 0 to 100, 8 points are regarded as a minimally important difference suggesting benefit or harm (Efficace *et al.*, 2013). Results at V1 and V6 were compared with the Wilcoxon signed rank test handling zeros and ties as suggested by Pratt (1959). Level of significance was 0.05.
Results: A total of 133 patients consented to the sub-study, 53 patients were included in this analysis. The median age was 50 years (range 19-83), 40% were female, and 7.6% had a high Euro score (Hasford *et al.*, 1998). This was comparable with the total study cohort (n=1164) with a median age of 53 (range 18-91) and 9.1% Euro-high risk. The results of all patients of the EORTC-QLQ-C30 items are summarized in Table 1. For most items, the score at diagnosis did not substantially decrease or increase over time. However, there was an increase of social and role functioning for all patients. Despite minimally important differences in social and role functioning, results of global health status and the functional scales at V1 and V6 were not statistically significantly different. Regarding symptoms there was a substantial change in skin problems. At diagnosis patients scored skin problems not at all (n=32), a little (n=10), quite a bit/very much (n=6), whereas at last visit the numbers were 12, 17 and 19 respectively. Other symptoms like edema, joint pain, weight loss, sexual function and headache were scored equally. Skin adverse events were documented according WHO as grade 1 in 22, grade 1 or 2 in 7 and grade 3 in 2 patients.

Tabella 1.

	Visit 1			Visit 6			p-value
Variable	N	Mean	Standardd eviation	N	Mean	Standard deviation	
Global health status / QoL	50	63	19	49	71	22	ns
Role functioning	50	70	28	49	78	29	ns
Social functioning	50	72	28	49	81	24	ns
Emotional functioning	50	65	24	49	70	25	ns
Physical functioning	50	85	14	49	84	20	ns
Cognitive functioning	50	84	21	49	80	23	ns

ns=not significant

Summary and Conclusions: The HRQoL of CML patients increased over time under first-line treatment with nilotinib with the exception of cognitive functioning. However, the differences were not statistically significant which might be due to low patient numbers. Regarding the ad hoc symptom scale, skin problems showed the most notable changes.

P234

PONATINIB EFFICACY AND SAFETY IN HEAVILY PRETREATED LEUKEMIA PATIENTS: 3-YEAR RESULTS OF THE PACE TRIAL

Background: Ponatinib is an approved oral tyrosine kinase inhibitor (TKI) with potent activity against native BCR-ABL and resistant mutants, including the T315I mutant.
Aims: The phase 2 PACE trial evaluated the efficacy and safety of ponatinib (starting dose 45 mg once daily).
Methods: Patients with chronic myeloid leukemia (CML) or Philadelphia chromosome–positive acute lymphoblastic leukemia (Ph+ ALL) resistant/intolerant to dasatinib/nilotinib or with T315I were enrolled in PACE (NCT01207440) and gave informed consent. Of 449 patients, 58% received ≥3 prior TKIs. Arterial occlusive events (AOEs) led to recommended dose reduction in October 2013. Exposure-adjusted incidence rates of new AOEs were calculated as (number of first events in interval)/(total exposure for interval in patient-years) x 100. Rates for later intervals exclude patients with prior events.
Results: As of October 6, 2014: 33% of all patients and 45% of chronic-phase (CP)-CML patients remained on study. Median follow-up was 34.2 (0.1–48.6) months overall and 38.4 (0.1–48.6) months for CP-CML patients. Main reasons for discontinuation were progression (21% overall, 9% CP-CML) and adverse events (AEs) (15% overall, 17% CP-CML). Among CP-CML patients, 59% achieved major cytogenetic response (MCyR), 39% achieved major molecular response (MMR) or better, and 22% achieved MR4.5. Responses were durable, with an estimated 83% of responders maintaining MCyR at 3 years; estimated rates of progression-free survival and overall survival at 3 years were 61% and 82%, respectively. Among accelerated-phase CML, blast-phase CML, and Ph+ ALL patients, estimated rates of overall survival at 3 years were 59%, 9%, and 16%, respectively. Treatment-emergent AEs in ≥25% of patients were thrombocytopenia (43%), abdominal pain (42%), rash (41%), constipation (37%), headache (37%), dry skin (36%), fatigue (30%), pyrexia (29%), arthralgia (29%), hypertension (28%), nausea (28%), and neutropenia (25%). Rates of AOEs (any/serious) were 22%/17%, including cardiovascular (12%/8%), cerebrovascular (8%/6%), and peripheral vascular (8%/6%) events. Rates of venous thromboembolic events (VTEs; any/serious) were 5%/4%. Of the 99 patients with AOEs, 42 remained on study and 33 were still in MCyR. Exposure-adjusted incidence rates of new AOEs (events per 100 patient-years) were 14.5 in Year 1, 14.1 in Year 2, and 10.8 in Year 3. Exposure-adjusted incidence rates of new VTEs (events per 100 patient-years) were 3.5 in Year 1, 1.8 in Year 2, and 1.8 in Year 3. One year after recommended dose reduction, 61 (95%) of 64 CP-CML patients maintained MCyR, 44 (94%) of 47 CP-CML patients maintained MMR, and 5 (7%) of 70 ongoing patients without a prior AOE had an AOE.
Summary and Conclusions: Ponatinib continues to provide deep, durable responses in heavily pretreated patients, particularly those with CP-CML. One year after recommended dose reduction, responses were maintained and incidence of new AOEs was low. A dose-ranging trial of ponatinib in refractory CML to evaluate benefits and risks is currently planned.

P235

RESPONSES AT EARLY LANDMARK TIME POINTS ARE ASSOCIATED WITH OUTCOMES IN HEAVILY PRETREATED CP-CML PATIENTS (PTS) TREATED WITH PONATINIB

M. Müller[1,*] M. Baccarani[2], M.W. Deininger[3], F. Guilhot[4], A. Hochhaus[5], T.P. Hughes[6], N.P. Shah[7], M. Talpaz[8], S. Lustgarten[9], V.M. Rivera[9], T. Clackson[9], F.G. Haluska[9], J.E. Cortes[10]
[1]Universitätsmedizin Mannheim, Mannheim, Germany, [2]University of Bologna, Bologna, Italy, [3]Huntsman Cancer Institute, University of Utah, Salt Lake CIty, United States, [4]Inserm CIC 1402, CHU de Poitiers, Poitiers, France, [5]Jena University Hospital, Jena, Germany, [6]Institute of Medicine and Veterinary Science, Adelaide, Australia, [7]University of California San Francisco, San Francisco, [8]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [9]ARIAD Pharmaceuticals, Inc., Cambridge, [10]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Ponatinib is a potent approved oral tyrosine kinase inhibitor (TKI) active against native and mutant BCR-ABL, with substantial activity in pts resistant or intolerant to dasatinib or nilotinib or with the T315I mutation. In pts treated with TKIs in the first-and second-line settings, responses at early (landmark) time points correlate with positive long-term outcomes.
Aims: Since landmark analyses are limited for populations treated with multiple prior TKIs, this analysis describes the impact of achieving early landmark responses with ponatinib on long-term outcomes in CP-CML pts in the ongoing PACE trial.
Methods: Retrospective landmark analyses of CP-CML pts (n=267) excluded pts who: dropped out before landmark time, had response at baseline, had missing or unevaluable assessments (<20 [13] metaphases examined for CCyR [MCyR]) at landmark time, or progressed before landmark time (for PFS). Pts gave informed consent. Molecular responses (International Scale; BCR-ABL ≤0.1% [MMR], ≤1%, and ≤10%) and cytogenetic responses (Ph+ metaphases ≤35% [MCyR] and 0% [CCyR]) at 3 and 6 months and their association with outcomes are reported. Log-rank test was used to calculate *P* values. Data cutoff: 6 Oct 2014; median follow-up: 38.4 (0.1–48.6) months.
Results: Of 267 CP-CML pts, 60% received ≥3 prior TKIs. Median age: 60 (18–94) years; median time from diagnosis: 7 (0.5–27) years. At 3 months, 48%, 39%, 49%, 34%, and 14% had achieved MCyR, CCyR, BCR-ABL ≤10%, BCR-ABL ≤1%, and MMR, respectively. These pts typically had better PFS and OS after 2 years, compared with those not achieving responses, although PFS and OS were high in general (**Table 1**). Molecular response at 3 months was also associated with achievement of MR4.5 over time. At 6 months, 62%, 52%, 55%, 49%, and 29% had achieved MCyR, CCyR, BCR-ABL ≤10%, BCR-ABL ≤1%, and MMR, respectively. Achievement of these responses was positively associated with PFS/OS after 2 years (**Table 1**).

Tabella 1. Association of Early Responses With 2-Year PFS and OS

	Based on 3-Month Response						Based on 6-Month Response					
	n	PFS	*P*	n	OS	*P*	n	PFS	*P*	n	OS	*P*
MCyR	97	87%	<0.0001	100	91%	0.0066	117	83%	<0.0001	118	91%	0.0617

No MMR	180	67%		197	84%		129	65%		150	88%	

Kaplan-Meier PFS/OS estimates calculated from landmark time; progression = death, AP/BP development, CHR loss in absence of CyR, MCyR loss, or increasing WBC without CHR

Summary and Conclusions: Rapid, deep reduction in BCR-ABL levels with ponatinib was associated with improved long-term outcomes in this heavily pretreated population. These data demonstrate that achieving early cytogenetic and molecular responses with ponatinib treatment has a significant prognostic value in heavily pretreated pts.

P236

LONG-TERM FOLLOW-UP OF PONATINIB EFFICACY AND SAFETY IN PATIENTS (PTS) WITH THE T315I MUTATION IN THE PHASE 1 AND PHASE 2 (PACE) TRIALS

M. Baccarani[1,*] M.J. Mauro[2], J.E. Cortes[3], A. Hochhaus[4], T.P. Hughes[5], F. Guilhot[6], M.W. Deininger[7], H.M. Kantarjian[3], N.P. Shah[8], D. Bixby[9], I.W. Flinn[10], S. Lustgarten[11], V.M. Rivera[11], F.G. Haluska[11], T. Clackson[11], M. Talpaz[9]
[1]University of Bologna, Bologna, Italy, [2]Memorial Sloan Kettering Cancer Center, New York, [3]The University of Texas MD Anderson Cancer Center, Houston, United States, [4]Jena University Hospital, Jena, Germany, [5]Institute of Medicine and Veterinary Science, Adelaide, Australia, [6]Inserm CIC 1402, CHU de Poitiers, Poitiers, France, [7]Huntsman Cancer Institute, University of Utah, Salt Lake City, [8]University of California San Francisco, San Francisco, [9]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [10]Sarah Cannon Research Institute, Nashville, [11]ARIAD Pharmaceuticals, Inc., Cambridge, United States

Background: Ponatinib is the only oral tyrosine kinase inhibitor (TKI) approved for use in refractory CML or Ph+ ALL pts that inhibits the BCR-ABL T315I mutant, which is uniformly resistant to other approved TKIs.
Aims: The long-term efficacy and safety of ponatinib in pts with the T315I mutation is reported based on pooled data from the ongoing phase 1 and PACE trials.
Methods: The phase 1 trial (NCT00660920) evaluated safety and antileukemic activity of ponatinib (2–60 mg qd) in pts with resistant/refractory hematologic malignancies (N=81), and the PACE trial (NCT01207440) evaluated efficacy and safety of ponatinib (45 mg qd) in pts with CML or Ph+ ALL who were resistant/intolerant to dasatinib/nilotinib or who had the T315I mutation (N=449). All pts gave informed consent. The T315I mutation was detected at baseline by Sanger sequencing at a central laboratory. PFS and OS data were collected in PACE only.
Results: Pooled data from 147 pts with T315I in the phase 1 (n=19) and PACE (n=128) trials are reported. Among 76 CP-CML, 19 AP-CML, 26 BP-CML, and 26 Ph+ ALL pts, median age was 50, 52, 47, and 62 y, respectively; median time since diagnosis was 4.6, 6.3, 2.3, and 1.3 y; and 86%, 84%, 96%, and 73% received ≥2 prior TKIs. At the time of analysis (26 September 2014 for phase 1; 6 October 2014 for PACE), median follow-up for pts with T315I was 36 (1.5–70) mo, 21 (3.1–45) mo, 2.9 (0.4–9) mo, and 2.7 (0.1–40) mo for CP-CML, AP-CML, BP-CML, and Ph+ ALL pts, respectively; 50%, 26%, 0%, and 4% remained on study. Pts discontinued primarily for disease progression (13%, 26%, 62%, and 46% in CP-CML, AP-CML, BP-CML, and Ph+ ALL, respectively) and AEs (12%, 16%, 15%, and 4%). Median dose intensity was 34, 38, 44, and 45 mg/d in these groups. Among CP-CML pts, 75% achieved MCyR; 72%, CCyR; 61%, MMR; 45%, MR4; and 37%, MR4.5. Responses were durable; 83% and 81% of CP-CML pts were estimated to maintain MCyR and CCyR, respectively, for 3 y. Among AP-CML, BP-CML, and Ph+ ALL pts, MaHR rates were 58%, 27%, and 38%, respectively. In phase 1, 11/12 CP-mo and median OS was not reached (3-y OS rate was 63%); for 24 BP-CML and 22 Ph+ ALL pts in PACE, median PFS/OS was 4.1/6.9 mo and 2.6/6.5 mo, respectively. Treatment-emergent AEs in ≥30% of all T315I pts were generally grade 1/2 and included: rash, 42%/55% (of total/CP-CML pts); abdominal pain, 39%/42%; headache, 39%/46%; nausea, 36%/41%; dry skin, 34%/49%; fatigue, 34%/39%; constipation, 33%/36%; and pyrexia, 32%/26%. Arterial occlusive events (AOEs) occurred in 21%/32% of total/CP-CML pts and included cardiovascular (13%/18%), cerebrovascular (8%/12%), and peripheral vascular (8%/13%) events. Venous thromboembolic events (VTEs) occurred in 8%/7% of total/CP-CML pts. Exposure-adjusted incidence rates of new AOEs and VTEs (events per 100 pt-years) were 13.0 and 5.0, respectively, among total pts, and 12.8 and 2.7, respectively, among CP-CML pts.
Summary and Conclusions: Ponatinib continues to provide deep and durable responses with up to 6 y of follow-up in CP-CML pts with the T315I mutation, in whom effective treatment options are limited. The response rates and safety profile observed among T315I pts were comparable to, if not better than, those observed among all pts with refractory CML or Ph+ ALL in the phase 1 and PACE trials.

P237

MINIMUM FOLLOW-UP OF 4 YEARS FOR ONGOING PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) IN A PHASE 1 TRIAL OF PONATINIB

M. Talpaz[1,*] J.E. Cortes[2], H.M. Kantarjian[2], N.P. Shah[3], D.L. Bixby[4], I.W. Flinn[5], T.J. O'Hare[6], S. Hu[7], V.M. Rivera[7], T. Clackson[7], M.G. Conlan[7], F.G. Haluska[7], B.J. Druker[8], M.W. Deininger[6], M.J. Mauro[9]
[1]Comprehensive Cancer Center, University of Michigan, Ann Arbor, [2]The University of Texas MD Anderson Cancer Center, Houston, [3]University of California San Francisco, San Francisco, [4]Comprehensive Cancer Center, University of Michigan, Ann Arbour, [5]Sarah Cannon Research Institute, Nashville, [6]Huntsman Cancer Institute, Salt Lake City, [7]ARIAD Pharmaceuticals, Inc., Cambridge, [8]Oregon Health & Science University Knight Cancer Institute, Portland, [9]Memorial Sloan Kettering Cancer Center, New York, United States

Background: Ponatinib, an approved oral tyrosine kinase inhibitor (TKI), has potent activity against native BCR-ABL and resistant mutants, including the T315I mutant.
Aims: The safety and antileukemic activity of ponatinib were evaluated in patients with resistant/refractory hematologic malignancies in this phase 1 trial. This analysis includes a minimum follow-up of 4 years for ongoing patients, the longest follow-up of ponatinib-treated patients to date.
Methods: Patients (N=81) received ponatinib (2–60 mg once daily) in this ongoing, open-label, dose-escalation trial (NCT00660920; enrollment, 2008–2010; data cutoff, 26 September 2014). All patients gave informed consent. The median follow-up for all 43 CP-CML patients was 49.9 (1.7–69.9) months; minimum follow-up for the 22 CP-CML patients who remained on study at data cutoff was 50.2 months.
Results: Data for CP-CML patients are reported. Median age was 55 years;

time since diagnosis was 6.6 years. 60% of patients had received ≥3 prior TKIs; 63% had BCR-ABL mutations (28% had T315I). At the time of analysis, 22 (51%) of 43 CP-CML patients remained on study. The most common reasons for discontinuation were adverse events (AEs; 26%) and progression (9%). Among the 43 treated CP-CML patients, major cytogenetic response (MCyR) was 72%; complete cytogenetic response (CCyR), 65%; major molecular response (MMR), 56%; MR4, 42%; and MR4.5, 28%. Responses were durable (**Table 1**). Median durations of response (MCyR, CCyR, and MMR) were not reached. Of the 22 ongoing patients at data cutoff, 18 (82%) were in CCyR, and 17 (77%) had MMR or better (6 had MMR, 1 had MR4, and 10 had MR4.5). The most common treatment-emergent AEs were rash (65%), fatigue (60%), abdominal pain (58%), headache (58%), and arthralgia (53%). Rates of arterial occlusive events (AEs/serious AEs) were 40%/30%, including cardiovascular (30%/21%), cerebrovascular (9%/7%), and peripheral vascular (14%/9%) events. Rates of venous thromboembolic events (AEs/serious AEs) were 5%/0%.

Tabella 1. Stability of Response in CP-CML Patients Treated With Ponatinib.

	Responders n	Lost Response na	Maintain Response at 4 Years,% (95% CI)b
MCyR	31	8	68 (44–84)
CCyR	28	8	70 (48–84)
MMR	25	11	52 (30–70)

[a]Failed to meet criteria for response at any single time point after initial response
[b]Kaplan-Meier estimate

Summary and Conclusions: These data in CP-CML patients represent the longest follow-up with ponatinib. With 4-year minimum follow-up for ongoing patients, ponatinib continues to provide benefit to CP-CML patients with prior TKI failure. Risks and benefits should be evaluated when using ponatinib in this population.

Myelodysplastic syndromes - Clinical 1

P238

HYPOPLASTIC MYELODYSPLASTIC SYNDROME (H-MDS): DISTINCT CLINICO-BIOLOGICAL FEATURES AND PROGNOSTIC RELEVANCE

C.Y. Yao[1,*] H.A. Hou[1], W.C. Chou[1], S.J. Wu[1], B.S. Ko[1], C.Y. Chen[1], S.C. Hsu[1], C.C. Li[1], S.Y. Huang[1], M. Yao[1], J.L. Tang[1], W. Tsay[1], H.F. Tien[1]
[1]Division of Hematology, Department of Internal Medicine, National Taiwan University Hospital, Taipei City, Taiwan, ROC

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of hematologic malignancies characterized by clonal expansion of bone marrow (BM) myeloid precursors with impaired differentiation. It remains unclear whether hypoplastic MDS (h-MDS) is a distinct clinicopathologic entity that differs from normo-/hypercellular MDS (NH-MDS) in terms of clinical and biological features.
Aims: We aim to investigate the clinic-biologic features of h-MDS and its prognostic relevance in a large cohort of MDS patients.
Methods: A total of 369 *de novo* MDS patients diagnosed according to the 2008 World Health Organization (WHO) criteria at the National Taiwan University Hospital who had complete clinical data and cryopreserved BM cells for study were recruited into the analysis. Hypoplasia was defined as less than 30% of the cellularity in the BM biopsy specimen. The clinical features, cytogenetics, molecular mutations of 17 genes, and treatment outcomes were compared between h-MDS and NH-MDS patients.
Results: Among the 369 patients, 103 (27.9%) were diagnosed as having h-MDS. The patients with h-MDS had lower WBC count, peripheral blood and BM blast percentage than those with NH-MDS (P=0.024, P=0.001 and P<0.0001, respectively). Refractory anemia (RA) was more common in h-MDS patients, whereas RA with excess blasts (RAEB) occurred more frequently in NH-MDS patients. h-MDS was associated with lower risk MDS, including low and intermediate-1 risk by International Prognostic Scoring System (IPSS) (34.2% *vs* 14.8%, P<0.0001), or very low and low risk by revised IPSS (IPSS-R) (41.1% *vs* 20.9%, P<0.0001). Clonal chromosomal abnormalities were detected in 154 (45.2%) of 341 patients who had chromosomal data. There was no difference in the distribution of karyotypes between patients with h-MDS and NH-MDS. To investigate the interaction of genetic alterations in the pathogenesis of h-MDS, a mutational screening of 17 genes was performed. The patients with h-MDS had lower incidences of *RUNX1, ASXL1, DNMT3A, EZH2* and *p53* mutations than those with NH-MDS (3.9% *vs* 14.4%, P=0.003; 6.9% *vs* 22%, P<0.0001; 2.9% *vs* 12.8%, P=0.003; 0% *vs* 5.3%, P=0.013, 2.9% *vs* 11%, P=0.013, respectively).
With a median follow-up duration of 46.9 months (range, 0.1-250.7 months), the cumulated incidence of acute leukemic transformation at 5 years was 18.5% for h-MDS patients and 41.1% for NH-MDS patients (P=0.001). Further, the patients with h-MDS had longer median overall survival (OS) than those with NH-MDS (113.7 months *vs* 29.1 months, P<0.001). In subgroup analysis, the survival difference between h-MDS and NH-MDS patients was more significant in lower-risk group. In multivariate analysis, h-MDS was an independent favorable prognostic factor for OS (relative risk 0.651, 95% CI, 0.427–0.992, P=0.046) irrespective of age, IPSS-R, and gene mutations.
Summary and Conclusions: Our findings provided evidence that h-MDS is a distinct clinico-biological subgroup of MDS and is inversely associated with RUNX1, DNMT3A, ASXL1, P53 and EZH2 mutations. Patients with h-MDS have better leukemia-free survival and OS.

P239

LONG-TERM OUTCOME OF LOWER RISK MDS PATIENTS RECEIVING ESA, AND IMPACT OF POST ESA TREATMENTS ON SURVIVAL: A RETROSPECTIVE STUDY FROM THE GFM, DUSSELDÖRF, AND GESMD REGISTRIES

S. Park[1,*] C. Kelaidi[2], J.F. Hamel[3], M. Diez Campelo[4], J. Schemenau[5], R. Sapena[6], C. Mueller-Thomas[7], K. Goetze[7], O. Beyne Rauzy[8], A. Stamatoullas[9], A. Guerci[10], D. Bordessoule[11], P. Cony-Makhoul[12], S. Courby[13], S. Cheze[14], C. Rose[15], N. Vey[16], E. Wattel[17], U. Germing[18], G. Sanz[4], P. Fenaux[19], F. Dreyfus[6]
[1]HEMATOLOGIE CLINIQUE, CHU de GRENOBLE, 38043 GRENOBLE Cedex 09, [2]Avicenne, Bobigny, [3]Statistiques, CHU d'Angers, Angers, France, [4]Salamanca, Salamanca, Spain, [5]Dusseldorf, Dusseldorf, Germany, [6]Cochin, Paris, France, [7]Munchen, Munchen, Germany, [8]toulouse, toulouse, [9]Rouen, Rouen, [10]nancy, nancy, [11]Limoges, Limoges, [12]Annecy, Annecy, [13]Grenoble, Grenoble, [14]Caen, Caen, [15]Lille, Lille, [16]IPC Marseille, Marseille, [17]Léon Bérard, Lyon, [18]Dusseldorf, Dusseldorf, [19]Saint-Louis, Paris, France

Background: Up to-50% of lower risk MDS patients respond to ESA, with a median duration of response of 2 years, most responders relapsing and becoming RBC transfusion dependent (TD). In a previous work on 253 such patients, we found that outcome was largely dependent on whether ESA failure occurred

early (primary failure or relapse <6 months), or later (Kelaidi, Leukemia 2013). However, only few patients in that cohort had received, after ESA failure, treatments other than RBC transfusions.
Aims: In this larger study, gathering the data from the French (GFM), German (GMDS) and Spanish (GESMD) registries, we also analyzed whether second line treatments could influence survival.
Methods: 991 lower risk MDS patients included in French (GFM), German (GMDS) and Spanish (GESMD) registries between 1999 and 2013, and treated by ESA were analyzed. Median age was 76.5y, with 55.9%males, WHO diagnosis: RA (11.6%), RCMD (31.8%), (12.9%) RAEB-1, RARS(24.7%),RCMD-RS (7.9%), (3,2%) MDS-U, del 5q (1.9%), Median Hb level at onset of ESA was 9.4g/dl, and 36.8% patients were RBC-TD, median EPO level was 57.8 IU/l (range 0-28000). IPSS-R was very low (20.2%), Low (57,8%), Int (18.7%) High (0.03%) pts. OS was evaluated from ESA failure.
Results: Erythroid response (HI-E, IWG criteria) was 66.5%. 331 pts had primary resistance and 277 relapsed after a response. Median response duration in relapsing patients was 17 months. 27 patients out of 108 had progressed at ESA failure (26%). After ESA failure, 195 patients received second, third and fourth line treatments other than RBC transfusions, including azacytidine (AZA) (n=131), lenalidomide (LEN) (n=62) thalidomide (n=27), LD araC (7), ATRA+EPO (n=18), HSCT and ATG in 4 pts each. Considering only the second line treatments after ESA failure (called TX1), 82 pts received AZA (ORR 41,6%) and 37 LEN (ORR 29,7%). 18 pts received AZA and (after AZA failure) LEN (seq 1), and 10 LEN and (after LEN failure) AZA (seq2). There was an ORR of 8/18 (44%) in seq 1 and 4/10 (40%) in seq 2 (with no response to LEN but subsequent response to AZA). Among the patients who progressed at TX1 (n=26), 18 received AZA, 2 LEN and the others low dose chemotherapy. Baseline WHO diagnosis (RARS and RARS-T *vs* others, HR 0.58, p=0.002) and IPSS-R (very low and low *vs* int/high, HR 0.71, p=0.04) predicted better OS. In a multivariate Cox model, receiving a second line treatment (considered as time-dependent variable) did not influence OS, but second line treatment with AZA (and not with LEN) was associated with improved OS and lower AML progression risk in patients with ESA response >1 year (HR 0.158, p=0.02 for OS, HR 0.18, p=0.03 for AML progression risk). Among the patients receiving AZA at TX1 (n=82), 18 had progressed either to RAEB-2 or AML.
Summary and Conclusions: Baseline RARS(-T) and lower IPSS-R predicted better outcome after ESA failure. AZA, as second line treatment, improved OS and AML risk in pts with ESA response >1 year, a finding requiring confirmation in prospective studies.

P240

EVALUATION OF DYSPLASIAS IN 1979 PATIENTS WITH MYELODYSPLASTIC SYNDROMES COLLECTED IN A GERMAN-AUSTRIAN DATA SET TO APPROACH THE HETEROGENEITY OF THE DISEASE

M. Pfeilstöcker[1,2,*] H. Tuechler[3], K. Nachtkamp[4], U. Platzbecker[5], A. Schönmetzler[1], W.R. Sperr[6], R. Stauder[7], C. Strupp[4], P. Valent[2,6], U. Germing[4]
[1]3rd Med Dept, Hanusch Hospital, [2]LB Cluster Oncology, [3]Hanusch Hospital, Vienna, Austria, [4]Hematology-Oncology-Immunology, University, Düsseldorf, [5]Hematology &stemcell transplant, university clinics, Dresden, Germany, [6]Div. Hematology, Med University, Vienna, [7]Hematology/Oncology, Med University, Innsbruck, Austria

Background: Dysplasias are a hallmark of MDS, they are mandatory for diagnosis, define classifications, and may play a role in prognosis and prediction. Their relative and combined impact regarding other and newer parameters also on different endpoints (leukemic *vs* non-leukemic mortality) remains to be defined.
Aims: Aim of the study was to redefine the role of dysplasias in MDS using a larger multicenter database by evaluating correlations with other parameters, characterising diagnostic and prognostic entities according to dysplasias including their specific prognostic impact.
Methods: Patients: 1979 primary MDS patients without disease modifying treatment were analysed retrospectively: median age: 73 years, 53% male, median survival: 32 months, median follow up: 66 months. Statistical methods: besides correlations, relative dominances of each dysplasia are described by odds of discordant pairs as they are less sample dependent than marginal proportions. Multiple regressions and Cox-models including interactions were used to quantify their impact on cytopenias and prognosis, particularly on non-leukemic mortality.
Results: Dysplasias were found in 90.3 % for erythroid, 75.7% myeloid and 70.4% for megakaryocytic lineages, respectively. Unilineage dysplasia was found in 18.0%, bilineage in 27.6%, trilineage in 54.4% of patients. Correlations between dysplasias were generally weak, most prominently a positive correlation between dysmeylo-and dysmegakaryopoiesis was noted. Anemic patients had significantly more erythrodysplasia whereas myeloid and megakaryocytic dysplasia coincided with neutropenia and thrombocytopenia, respectively, although details regarding age, sex, and monocyte count remain to be explored. Dominance of erythroid dysplasia becomes less pronounced in subentities (FAB, WHO) associated with higher risk. Dysplasias are evenly distributed among different LDH and Ferritin levels as well as in cytogenetic risk groups (IPSS 1996 and IPSS-R 2012 definitions) and IPSS. Bone marrow blast categories and IPSS-R, IPSS-R-age, and WPSS risk groups show fading dominance of erythrodysplasia with higher risk. Regarding prognosis, dysplasias without adjustment for other parameters showed marked differences between uni-, bi-and trilineage dysplasias (Dxy =0.15), especially in low risk cases and with normal cytogenetics. In Cox models myeloid and megakaryocytic dysplasias had more impact on leukemic transformation than on overall survival, erythrodysplasia was dominant regarding non leukemic mortality. Inclusion of an interaction term for joint erythroid and myeloid dysplasias enhances prognostic models. Inclusion of dysplasias in Cox models using patients stratified according to IPSS-R shows no significant impact for single or combined dysplasias or dysplasia interactions.
Summary and Conclusions: Dysplasias play an important independent role in MDS, which is more pronounced in low risk and normal karyotype cases. Dichotomisation in uni-*vs* multilineage dysplasia may not be justified given the differences between bi-and trilineage cases. Although dysplasias do not provide additional prognostic power for IPSS-R stratified patients as their prognostic value is already included in parameters and cutpoints used in this system, they may support specific models for different mortality risks (leukemic *versus* non leukemic) and consequently provide more meaningful classifications for this heterogeneous disease. Dysplasias may contribute to a multidimensional model of MDS composed of anemina, proliferation, and infection/bleeding.

P241

RANDOMIZED, PLACEBO (PBO)-CONTROLLED, PHASE I/II TRIAL OF THE THROMBOPOIETIN RECEPTOR AGONIST ELTROMBOPAG (EPAG) IN THROMBOCYTOPENIC PATIENTS WITH ADVANCED MYELODYSPLASTIC SYNDROMES (MDS)

U. Platzbecker[1,*] R.S. Wong[2], S. Araujo[3], J. Feigert[4], J. Bennett[5], C. Messam[6], F. Mannino[6], Y. Mostafa Kamel[6], S. Dougherty[6], G. Chan[6], A. Giagounidis[7]
[1]Universitätsklinikum Carl Gustav Carus, Dresden, Germany, [2]Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, Hong Kong, [3]Hospital das Clínicas-UFMG, Belo Horizonte, Minas Gerais, Brazil, [4]Virginia Cancer Specialists, Arlington, [5]University of Rochester Medical Center, Rochester, [6]GlaxoSmithKline, Collegeville, United States, [7]Marien Hospital, Düsseldorf, Germany

Background: EPAG, an oral thrombopoietin receptor agonist, increases platelets (PLTS) in chronic immune thrombocytopenia (TCP), hepatitis C virus-associated TCP, and severe aplastic anemia. In patients (pts) with advanced MDS or acute myeloid leukemia (AML) and severe TCP, EPAG has shown to improve PLTS compared to PBO, leading to potential improvements in morbidity of severe TCP, progression-free survival (PFS), and overall survival (OS).
Aims: To explore the safety, tolerability, and efficacy of EPAG in pts with advanced MDS (baseline bone marrow [BM] blasts <20%) from study PMA112509.
Methods: Informed consent was provided. Pts with relapsed/refractory MDS, ineligible for antileukemic therapies, with 10–19% BM blasts and PLTS <30×10^9/Lwere randomized to EPAG 50 mg once daily (increased every 2 weeks in pts without PLT response, up to 300 mg [East Asian pts, 150 mg]) or PBO for 6 months. Standard supportive care and disease-modifying treatments were allowed.
Results: Overall, 32 pts with MDS (EPAG, n=18; PBO, n=14) were enrolled. All pts received ≥1 prior therapy, including hypomethylating agents (HMAs) or induction chemotherapy. Fewer EPAG than PBO pts had poor prognosis karyotype, but median baseline BM blast % was similar (Table). Most pts received the maximum dose (EPAG, n=10 [56%]; PBO, n=8 [57%]). Adverse events (AEs) (EPAG, n=17 [94%]; PBO, n=13 [93%]), Grade ≥3 AEs (EPAG, n=13 [72%]; PBO, n=8 [57%]), drug-related AEs (EPAG, n=10 [56%]; PBO, n=6 [43%]), and AEs leading to withdrawal (EPAG, n=5 [28%]; PBO, n=4 [29%]) were reported. The most common AEs on therapy or <30 days from the last dose were diarrhea (n=6; 33%), constipation (n=5; 28%), and pyrexia (n=5; 28%) for EPAG pts and pyrexia (n=6; 43%), back pain (n=4; 29%), epistaxis (n=4; 29%), and febrile neutropenia (n=4; 29%) for PBO pts. The most common Grade ≥3 AEs on therapy or <30 days from the last dose in either arm were febrile neutropenia, anemia, pneumonia, and sepsis. A total of 5 EPAG (28%) and 6 PBO (43%) pts died on therapy or <30 days from the last dose; primary cause of death in both arms was disease under study. Of 14 (EPAG, n=9; PBO, n=5) pts with post-baseline BM exam results, 8 (5 [56%] and 3 [60%], respectively) developed ≥20% BM blasts during treatment. PLT transfusion independence for ≥8 weeks was reported for 5 EPAG (28%) and 3 PBO (21%) pts. Grade ≥3 hemorrhages were reported in 2 EPAG (11%) and 3 PBO (21%) pts. More EPAG *vs* PBO pts started HMAs during the study (4 [22%] *vs* 2 [14%], respectively). Median PFS (Figure) was 16.1 weeks for EPAG *vs* 7.7 weeks for PBO (hazard ratio [HR]=0.61; *P*=0.1531). Median OS was 34.0 weeks for EPAG *vs* 15.4 weeks for PBO (HR=0.70; *P*=0.3844).

Tabella 1. Baseline Characteristics.

	EPAG (N=18)	PBO (N=14)
Poor prognosis karyotype, n (%)	5 (28)	8 (57)
	Median (Range)	
BM blast, %	11 (10–18)	12.8 (10–19)
Platelets,a×109/L	19.8 (2–60)	13.5 (5–38)

[a]Baseline PLT count was derived using an average of PLT counts during screening, except within 3 days of PLT transfusion.

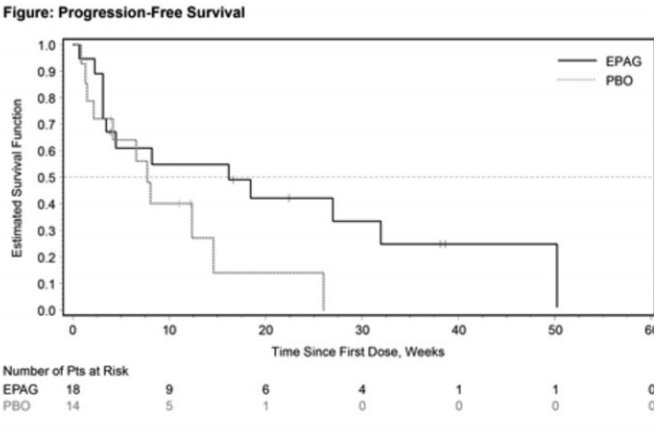

Figure 1. Progression-Free Survival

Summary and Conclusions: EPAG ≤300 mg was well tolerated in pts with advanced MDS. No obvious differences in blast % change were noted in pts receiving EPAG *vs* PBO. Pts receiving EPAG showed a trend toward fewer Grade ≥3 hemorrhages. Differences in PFS and OS may be influenced by the direct effect of EPAG, MDS treatments initiated, or imbalances in the proportion of pts with poor prognosis karyotype. Additional studies with EPAG in MDS and AML are ongoing. This study (NCT00903422) was funded by GlaxoSmithKline.

P242

THE EFFECT OF LENALIDOMIDE ON HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH MYELODYSPLASTIC SYNDROMES: RESULTS FROM THE MDS-005 TRIAL

V. Santini[1,*] A. Almeida[2], A. Giagounidis[3], C. Bartiromo[4], A. Hoenekopp[5], S. Guo[6], C. Beach[7], A. Altincatal[6], C. Wu[8], B. Skikne[7], J. Zhong[8], H. Hu[4], P. Fenaux[9]

[1]Dipartimento di Medicina Sperimentale e Clinica, AOU Careggi, University of Florence, Firenze, Italy, [2]Departamento de Hematologia, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal, [3]Hematology, Marien Hospital Düsseldorf, Düsseldorf, Germany, [4]Market Access & Outcomes Research, Celgene Corporation, Summit, United States, [5]Hematology and Oncology, Celgene International, Boudry, Switzerland, [6]Evidera, Lexington, [7]Hematology and Oncology, [8]Biostats, Celgene Corporation, Summit, United States, [9]Service d'Hématologie Séniors, Hôpital Saint-Louis, Université Paris 7, Paris, France

Background: Health-related quality of life (HRQoL) is compromised among patients with transfusion-dependent anemia due to myelodysplastic syndromes (MDS). In the phase 3 MDS-005 study, significantly more lenalidomide-treated patients with MDS achieved RBC transfusion independence (TI) *versus* placebo (26.9% *vs* 2.5%; *P*<0.001; Santini V, *et al.* Blood 2014;124:abstract 409); assessment of HRQoL was a pre-specified secondary endpoint.
Aims: The current analysis evaluated changes in HRQoL between treatment arms in the MDS-005 study.
Methods: In MDS-005, transfusion-dependent patients with International Prognostic Scoring System-defined Low or Intermediate-1-risk MDS without del(5q), unresponsive or refractory to erythropoiesis-stimulating agents, were randomized to lenalidomide (n=160) or placebo (n=79). Patients with RBC-TI ≥56 days or erythroid response by Day 168 (24 weeks) continued double-blind treatment until erythroid relapse, disease progression, unacceptable toxicity, or consent withdrawal. HRQoL was assessed using the European Organization for Research and Treatment of Cancer QLQ-C30 questionnaire at baseline, Week 12, Week 24, every 12 weeks thereafter, and at discontinuation. Analyses were performed among patients who completed a baseline HRQoL assessment and had ≥1 post-baseline assessment (lenalidomide, n =122; placebo, n =56). Changes from baseline were analyzed; 5 HRQoL domains were pre-selected as clinically relevant: Fatigue, Dyspnea, Physical Functioning, Emotional Functioning, and Global Quality of Life. Between-group comparisons were limited to weeks 12 and 24 due to low patient numbers after 24 weeks. A post hoc analysis assessed the impact of RBC-TI on pre-selected HRQoL domains. Clinically meaningful improvement in HRQoL was defined as a score difference of at least 10 points *versus* baseline.
Results: Questionnaire compliance rates were high (>72% in almost all visits) and not significantly different across all assessment visits (*P*>0.05). At Week 12, mean changes in HRQoL scores from baseline were similar between treatment arms across pre-selected domains. At Week 24, lenalidomide was associated with benefit *versus* placebo in all pre-selected domains; after adjusting for baseline scores, benefit was only significant for Emotional Functioning (*P*=0.047). For lenalidomide patients with RBC-TI and/or erythroid response at Week 24 who continued treatment, an improving trend in all pre-selected domains was observed. In a post hoc analysis, RBC-TI was associated with significant improvement (*P*<0.01) across all pre-selected domains, with benefit also exceeding the pre-specified threshold for clinically meaningful improvement in all 5 domains.
Summary and Conclusions: At Week 24, treatment with lenalidomide was associated with benefit compared with placebo across all 5 pre-selected HRQoL domains relevant to MDS; however, after adjusting for baseline scores, benefit was only significant for Emotional Functioning. Further improvement *versus* baseline was observed after Week 24 for patients continuing treatment with lenalidomide. RBC-TI was associated with statistically significant (*P*<0.01) and clinically meaningful improvement in all 5 pre-selected domains. These data may be important given the superior effect of lenalidomide over placebo in achievement of RBC-TI and highlight the beneficial effects of lenalidomide on HRQoL in this patient population.

P243

IMPACT OF MDS ON HEALTH-RELATED QUALITY OF LIFE: A COMPARISON OF IPSS LOW-AND INT-1 RISK MDS PATIENTS FROM THE EUROPEAN LEUKEMIANET MDS (EUMDS) REGISTRY AND EUROPEAN REFERENCE POPULATIONS

Background: A prospective, multicenter European Registry (EUMDS) for newly diagnosed IPSS low and intermediate-1 Myelodysplastic Syndromes (MDS) was initiated by the European Leukemianet (ELN) to assess demographic data, disease-management and clinical course. Health-related quality of life (HRQoL) has become an important patient reported outcome (PRO) to address patients' needs and to tailor individualized therapy planning.
Aims: To analyze the impact of MDS on HRQoL as compared to a reference population.
Methods: The EQ-5D (European quality group 5 dimensions) descriptive system was introduced in EUMDS at initial diagnosis and at follow-up visits every six months. EQ-5D data from MDS-patients were compared with population norms published by the Euroqol Group (www.euroqol.org).
Results: So far, 1814 EUMDS patients from 17 European countries diagnosed between December 2007 to December 2014 were included in the EUMDS. 1490 (82.1%) patients with a median age of 74.2 years (range 18.7-95.3) and 61.9% male, completed an EQ-5D questionnaire at the time of inclusion to the registry. Moderate or severe restrictions in HRQoL were observed in a significant proportion of MDS patients in the different dimensions of EQ-5D: mobility in 41%, self-care in 13%, usual activities in 36%, pain/discomfort in 49%, and anxiety/depression in 40%, respectively. Mean visual analog scale (VAS) in EUMDS patients was 69.6±20.3 (mean, standard deviation). Population norms were available for nine European countries: age and sex-matched analysis reveal a significantly (p<0.05) higher proportion of restrictions in MDS in the dimensions anxiety/depression in eight, in usual activities in six, and in mobility and in self-care in four out of nine countries. Remarkably, problems in the dimension pain/discomfort were significantly more often observed in the reference population than in MDS in two countries; in one country a trend towards

significance was observed (p=0.07). It was possible to compute an index score for seven countries, which translates the five dimensions of EQ-5D into a single value, ranging from a score of 1 indicating no problems to a score of 0 indicating death. Compared to age-and sex-matched simulated populations using the population norms, EUMDS patients from France (n=340; mean [sd]: 0.69 [0.29]; p<0.001), Germany (26; 0.82 [0.28]; p<0.05), the Netherlands (48; 0.79 [0.20]; p<0.001) and Spain (120; 0.75 [0.32]; p<0.001) were characterized by significantly lower EQ-5D index scores than the corresponding reference populations. Visual analogue scores (VAS) in MDS ranged from 62.1 [20.5) (mean [sd]) in France to 73.4 [16.8] in Denmark. Four out of nine countries revealed significantly (p<0.05) lower VAS-values in MDS as compared to age-and sex-matched simulated populations based on the reference values. Significant differences were observed in France: n=340; VAS 62.08 [20.52]; p=0.02; The Netherlands: 48; 71.19 [16.61]; p=0.04; Sweden: 100; 67.45 [20.91]; p<0.001 and the United Kingdom: 252; 71.31 [20.14]; p=0.01.

Summary and Conclusions: This study demonstrates for the first time profound restrictions in self-reported health in VAS as well as in all dimensions of the EQ-5D, with the exception of pain/discomfort, in MDS-patients at diagnosis as compared with reference populations. Thus, the relevance of HRQoL in treatment algorithms and as an endpoint in clinical studies and registries is supported. This analysis will form the basis for the design of MDS-specific assessment scores.

P244

SPRESAS (SPANISH REGISTRY OF ERYTHROPOIETIC STIMULATING AGENTS STUDY): THE LARGEST RETROSPECTIVE STUDY OF TREATMENT WITH ESAS IN LOWER RISK MDS

M. Díez Campelo[1,2,*] J.I. Lorenzo[3], L.I. Benlloch[2], J. Dávila[2], T. Bernal[2], E. Luño[2], M. López-Pavia[2], E. Such[2], F. Ramos[2], M. Calabuig[2], H. Pomares[2], B. González[2], B. Background: Anemia is the most frequent cytopenia in lower-risk MDS. Erythropoietic-stimulating agents (ESAs) are commonly used in these patients.
Aims: The aims were (1) to collect the largest lower risk (IPSS low and int-1) series of MDS patients with anemia treated with ESAs, describe their results, and (2) to compare the outcomes of this ESA cohort (in terms of progression to AML and OS) with those of a cohort of lower risk RBC transfusion dependent untreated patients from the Spanish MDS Registry (SUPP cohort).
Methods: Data from 959 patients with MDS according to FAB and WHO criteria were recorded in Spresas (SPanish Registry of Erythropoietic Stimulating Agents Study). 237 cases were excluded from the study (23 treated with potential modifier agents, 38 with secondary MDS, 24 with IPSS >int-1 risk, 97 patients with Hb level >11 g/dL, 31 diagnosed after Dec 31, 2011 (pre-fixed end of recruitment period), and 24 with incomplete data). The remaining 722 anemic patients with low/int1 risk IPSS de novo MDS and sufficient follow-up data available (530 in ESAs and 192 in SUPP cohort) were included in the analysis and are the basis of this report. Response to treatment was evaluated according to IWG 2006 response criteria and a multivariate logistic regression analysis was used to identify independent predictors of erythroid response. OS and AML evolution (WHO criteria) were defined as the time between EPO introduction (or diagnosis in SUPP arm) and the corresponding event or last follow up (July 2014) and were analyzed using univariable and multivariable Cox proportional hazards regression methods.
Results: In the ESAs-treated population median age was 77 years (interquartile range [IQR] 25%>75%: 21-95 y), according to WHO 2008 there were 48 RCUD (9.2%), 176 RCMD (33.8%), 101 RARS (19.4%), 18 RAEB-1 (3.5%), 2 RAEB-2 (0.4%), 32 CMML (6.2%) and 3 MDS-U (0.6%) and the IPSS risk group was low in 66% (N=308) and Int-1 in 34% (N=158). Median Hb level at start of treatment was 9.6 g/dL (4-10.9). Among 329 patients with this data available, 185 patients (56%) were RBC transfusion dependent before ESAs treatment. Median time from diagnosis to ESAs treatment was 92 (1-5683) days. Among 484 with this data available 27.5% of patients received epoetin α, 19.9% epoetin β, 49.6% darbepoetin α, and 3%other epoietin. Doses and schedules were those usually employed in MDS. Among 470 patients (88.6%) evaluable for response the rate of erythroid response was 64.6%. To determine whether treatment with ESAs had an impact on disease progression and OS, outcome of ESAs cohort was compared to that of the SUPP cohort. After a median follow up of 3.12 years, 72 patients had developed AML (14%) and 209 had died (40%). Median overall survival (OS) was 6.7 and 2.6 years, for ESAs and SUPP cohorts, respectively (p<0.001). Response to treatment significantly improved outcome (data not shown). Median time to progression to AML was similar in both cohorts (p=NS), with 1, 2 and 5 years AML-free survival (LFS) of 95%, 92%, and 82% for ESAs patients and 96%, 92% and 88% for the SUPP group.

Summary and Conclusions: The present study, the largest retrospective series regarding ESAs treatment in lower risk MDS patients reported so far, shows that, using conventional survival statistical analysis, treatment with ESAs results in improved OS and does not increase the risk of AML evolution. Spresas study was partly supported by Janssen

P245

MDS-005 STUDY: EFFECT OF BASELINE ENDOGENOUS ERYTHROPOIETIN ON RBC TRANSFUSION INDEPENDENCE IN LENALIDOMIDE-TREATED PATIENTS WITH LOW OR INTERMEDIATE-1-RISK MYELODYSPLASTIC SYNDROMES WITHOUT DEL(5Q)

V. Santini[1,*] J.S. Li[2], A.S. Swern[2], A. Almeida[3], A. Giagounidis[4], T. Fu[2], A. Hoenekopp[5], C. Beach[6], B. Skikne[6], P. Fenaux[7]
[1]Dipartimento di Medicina Sperimentale e Clinica, AOU Careggi, University of Florence, Firenze, Italy, [2]Biostats, Celgene Corporation, Summit, United States, [3]Departamento de Hematologia, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal, [4]Hematology, Marien Hospital Düsseldorf, Düsseldorf, Germany, [5]Hematology and Oncology, Celgene International, Boudry, Switzerland, [6]Hematology and Oncology, Celgene Corporation, Summit, United States, [7]Service d'Hématologie Séniors, Hôpital Saint-Louis, Université Paris 7, Paris, France

Background: In the phase 3 MDS-005 study, lenalidomide treatment was associated with significant achievement of RBC transfusion independence (TI) for ≥8 weeks in 26.9% of RBC transfusion-dependent patients with International Prognostic Scoring System (IPSS) Low or Intermediate-1-risk myelodysplastic syndromes (MDS) without del(5q), unresponsive or refractory to erythropoiesis-stimulating agents (ESAs; *P* <0.001 *vs* placebo) (Santini V, *et al.* Blood 2014;124:abstract 409).
Aims: This analysis evaluated the impact of baseline erythropoietin (EPO) levels on RBC-TI in lenalidomide-treated patients with MDS.
Methods: Patients were randomized 2:1 to oral lenalidomide 10 mg once daily (5 mg for patients with creatinine clearance 40–60 mL/min) or placebo. Rates of RBC-TI for ≥8 consecutive weeks were analyzed according to baseline EPO levels prior to randomization (≤500 *vs* >500 mU/mL) in patients treated with lenalidomide.
Results: Of 160 lenalidomide-treated patients, 5 had missing baseline EPO data, 97 had EPO ≤500 mU/mL, and 58 had EPO >500 mU/mL; 125 (78.1%) of all patients and 94 of 97 (96.9%) patients with EPO ≤500 mU/mL received prior ESAs. Patients with EPO ≤500 mU/mL were slightly older than those with EPO >500 mU/mL (median age: 72 *vs* 68 years), had a longer duration of MDS (median: 3.7 *vs* 2.2 years), and lower RBC transfusion burden (median: 3.0 *vs* 3.8 packed RBC units/28 days). Among patients with EPO ≤500 mU/mL and prior ESA use, 35.1% achieved RBC-TI ≥8 weeks, whereas only 9.4% of patients with EPO >500 mU/mL and no prior ESA use had a response. Overall, there was an increasing linear trend in rates of RBC-TI ≥8 weeks across patients with decreasing EPO levels: 15.5%, 23.3%, 33.3%, and 42.5% for EPO levels >500 (n =58), 200 to ≤500 (n =30), 100 to ≤200 (n =27), and ≤100 mU/mL (n =40), respectively (Fisher's exact *P* =0.023; linear trend test *P* =0.002). A similar trend was seen in patients who had received prior ESAs.
Summary and Conclusions: In patients with IPSS lower-risk MDS without del(5q), response to lenalidomide correlated with endogenous serum EPO levels in a linear fashion. Baseline EPO ≤100 mU/mL was associated with RBC-TI ≥8 weeks in >40% of patients. Patients with EPO ≤500 mU/mL had higher response rates *versus* EPO >500 mU/mL. Patients with higher EPO levels may be less responsive due to intrinsic defects in erythroid signaling pathways, including STAT5, JAK2, and lipid raft assembly, which are believed to be restored or stimulated by lenalidomide (Ximeri M, *et al.* Haematologica 2010;95:406-14; McGraw KL, *et al.* PLoS One 2014;9:e114249). These results suggest it may be possible to identify a subset of patients with lower-risk MDS without del(5q) who can be more sensitive to lenalidomide.

P246

PROGNOSTIC IMPACT OF CHROMOSOMAL TRANSLOCATIONS IN MYELODYSPLASTIC SYNDROMES AND CHRONIC MYELOMONOCYTIC LEUKEMIA PATIENTS. A STUDY BY THE SPANISH GROUP OF MYELODYSPLASTIC SYNDROMES

M. Nomdedeu[1,*] X. Calvo[1], A. Pereira[1], A. Carrió[1], C. Gómez[1], A. Arias[1], C. Muñoz[1], F. Solé[2], E. Luño[3], J. Cervera[4], T. Vallespí[5], E. Such[4], G. Sanz[4], J. Grau[6], A. Nacional de Investigaciones Oncológicas, Madrid, [13]Hospital Universitario Reina Sofía, Córdoba, [14]Hospital Universitario 12 de Octubre, Madrid, [15]Hospital Son Llàtzar, Palma de Mallorca, [16]Hospital La Princesa, Madrid, [17]Hospital Virgen de la Luz, Cuenca, [18]Complexo Hospitalario de Pontevedra, Pontevedra, [19]Hospital General de Valencia, Valencia, Spain

Background: Chromosomal translocations are an uncommon finding in myelodysplastic syndromes (MDS) and chronic myelomonocytic leukemias (CMML). Whether translocations other than t(3q) have a specific prognostic significance in these entities has never been examined in detail.
Aims: To analyze the prognostic impact of translocations in the context of the IPSS-R cytogenetic scoring system.
Methods: We evaluated 2014 patients from the Spanish Registry of MDS with a diagnosis of MDS or CMML (WHO 2008) and an abnormal karyotype by conventional cytogenetic analysis. The main study outcomes were survival from diagnosis and transformation into acute myeloid leukemia (AML). Survival curves were drawn using the Kaplan-Meyer method and compared by the log-rank test. The Cox regression model was used for the multivariate adjustment of factors predicting survival. The cumulative incidence of AML was estimated by taking non AML-related death as a competing risk, and adjusted for other predictive factors by means of the Fine and Gray regression method. Statistical comparisons were done by the Mann-Whitney U-test for continuous data, and the chi-square test for categorical factors. Stata, version 11, software (www.stata.org) was used for the statistical analysis.
Results: Translocations were identified in 168 patients (T-group). As compared with the 1484 patients with abnormal karyotype without translocations (non-T group), patients in the T-group were younger, had lower Hb, neutrophils and platelets in peripheral blood and more blasts in bone marrow. The T-group included a significantly larger proportion of patients with refractory anemia with excess of blasts and higher scores in both the cytogenetic and the global IPSS-R (p<0.0001). At the time of analysis, 905 (55%) patients had died. Median follow-up for survivors was 1.3 years (range, 0.2 to 20 years). The actuarial survival for all patients was 2.6 years (95% C.I, 2.4 to 2.9). Median survival for the T-group was significantly shorter compared to the non-T group (0.98 years [95% CI, 0.82 to 1.2] *versus* 2.86 years [95% CI, 2.58 to 3.32]), respectively (p<0.001) (figure1A). After adjustment for the IPSS-R cytogenetic category, no significant difference between the two groups was found (1.16 years [95% CI, 0.95 to 1.42] *versus* 1.65 years [95% CI, 1.55 to 1.75]), (ns) (figure 1B). Three-hundred and forty-three patients (20.75%) had developed AML after a median follow-up of 1.52 years (95% CI, 0.2-11.2) from the diagnosis of MDS, while 605 patients had died without progression to AML. Seven hundred and five patients were censored alive at the time of analysis. Presence of translocations was associated with an increased incidence of AML at the univariate analysis (subhazard rate (SHR): 1.5, 95% CI: 1.1-2.1;p=0.008) (figure 1C). Nevertheless, this association dissapeared after the multivariate adjustment for the IPSS-R cytogenetic risk category (SHR: 0.95, 95% CI: 0.68-1.35; p=0.78) (figure1D).

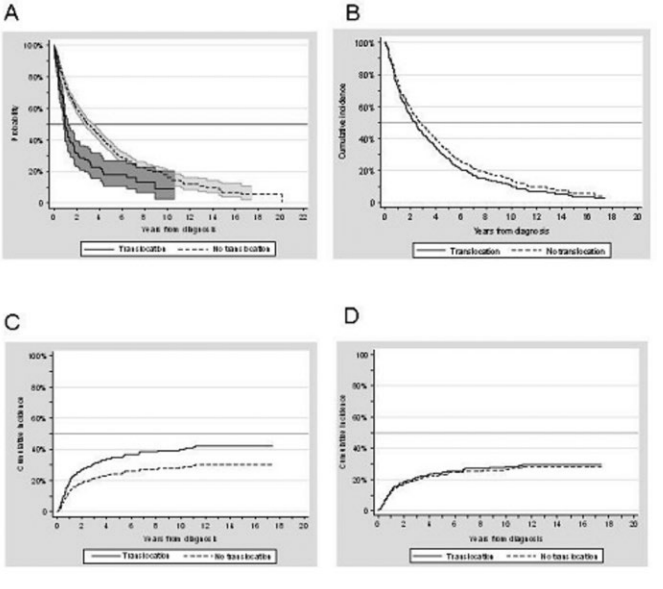

Figure 1.

Summary and Conclusions: In our study, the presence of translocations clearly identified a subgroup of patients with a more aggressive MDS and with a poorer IPSS-R cytogenetic prognosis. When a raw analysis of the prognostic impact of translocations was made, a significant worse survival and an increased risk of AML transformation were found in the T group. However, translocations lost their prognostic impact after adjustment for the IPSS-R cytogenetic category. This results suggest that translocations are a surrogate marker for other poor prognosis cytogenetic aberrations instead of being causally related to the poorer outcomes.

P247

SUPERIOR LONG-TERM OUTCOMES OF LOWER RISK MDS PATIENTS WHEN TRANSPLANTED IN RESPONSE COMPARED TO RELAPSED OR REFRACTORY TO HMA

Y.J. Lee[1,*] J.H. Moon[1], S.K. Sohn[1], J.S. Ahn[2], H.J. Kim[2], M.K. Song[3], H.J. Shin[3], W.S. Lee[4], S.M. Lee[4], Y.D. Joo[5], H. Kim[6], D.Y. Kim[7], H.S. Lee[8], Y.S. Kim[8], Y.Y. Cho[9]
[1]Hematology/Oncology, Kyungpook National University Hospital, Deagu, [2]Hematology/Oncology, Chonnam National University Hwasun Hospital, Hwasun, [3]Hematology/Oncology, Busan National University Hospital, [4]Hematology/Oncology, Inje University Busan Baik Hospital, [5]Hematology/Oncology, Inje University Haewoondae Baik Hospital, Busan, [6]Hematology/Oncology, Ulsan University Hospital, Ulsan, [7]Hematology, Asan Medical Center, Seoul, [8]Hematology/Oncology, Kosin University Gosper Hospital, Busan, [9]Hematology/Oncology, Daegu Catholic University Medical Center, Deagu, Korea, Republic Of

Background: Allogeneic hematopoieic cell transplantation (Allo-HCT) is generally recommended for lower-risk myelodysplastic syndrome (LR-MDS) patients with relapsed or refractory to HMA treatment. It is still under debate when LR-MDS patients should be transplanted in response or at the time of loss of response.
Aims: This study retrospectively evaluated the outcomes of allo-HCT who transplanted in response or relapsed/refractory to HMA treatment.
Methods: The data of 307 patients diagnosed with LR-MDS from Oct 1992 to Jul 2013 were retrospectively evaluated. To address the time dependence of allo-HCT, the methods of Simon and Makuch and the Mantel-Byar test was used.
Results: Among 307 patients with LR-MDS, 200 patients were treated with HMA. Sixty-three (31.5%) patients showed response (CR/PR/HI) to HMA and 119 (59.5%) were relapsed/refractory (SD/PD). Prior to Allo-HCT, 7 patients were in response and 26 patients in relapsed/refractory. Median time to allo-HCT were 2.8 years in responders and 1.9 years for patients with relapsed/refractory. Among HMA responders, the 5-year overall survival (OS) rate were 83.3% with allo-HCT (n=7) and 34.2% with continued HMA treatment (n=53) (p=0.07). Among patients with relapsed/refractory, the 5-year OS rate were 47.0% with allo-HCT (n=26) and 29.4% with BSC after HMA treatment (n=93) (p=0.45). There showed a trend in the benefits of OS for patients treated with allo-HCT in response compared to allo-HCT in SD/PD (p=0.17). In the multivariate analysis, ECOG-PS 2-3 (HR 3.030, p=0.006), IPSS blast ≥0.5% (HR 2.003, p=0.018), poor cytogenetic risk group (HR 12.362, p<0.001), and non-response to HMA (HR 2.487, p=0.001) were unfavorable factors for OS among LR-MDS patients.

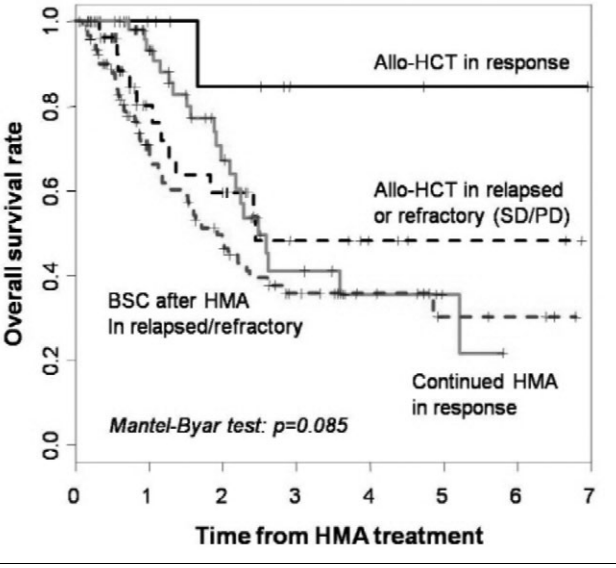

Figure 1.

Summary and Conclusions: Allo-HCT in response to HMA showed superior OS compared to allo-HCT in relapsed/refractory after HMA for patient with LR-MDS. To elucidate best time points of allo-HCT for LR-MDS patients, a large scale study will be needed.

ABERRANT EXPRESSION PROFILES OF HLA-G AND IMMUNOGLOBULIN-LIKE TRANSCRIPTS (ILTS) IN ACQUIRED APLASTIC ANEMIA

Y.X. Sun[1,*] Q. Feng[1], Y.Y. Yu[1], J. Ma[1], X. Li[1], J. Peng[1]
[1]Qilu hospital, Shandong University, Jinan, China

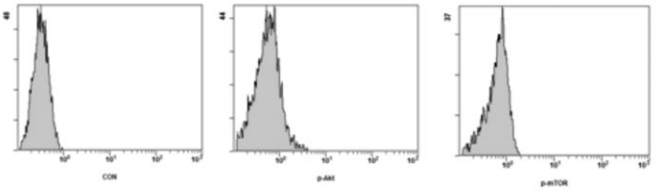
Background: Human leukocyte antigen-G (HLA-G) is a non-classical MHC class I molecule characterized by low polymorphism, restricted tissue distribution and spliced transcripts which encode four membrane-bound (HLA-G1-G4) and three soluble (HLA-G5-G7) isoforms. HLA-G interacts with multiple cell subsets such as T cells and B cells, and exerts powerful immune suppressive effects by binding to its receptors immunoglobulin-like transcripts (ILTs). As a paradigm of bone marrow failure syndrome, acquired aplastic anemia (AA) is thought to be a specific autoimmune disease for the aberrant T-cell immune homeostasis, whereas the function of humoral immunity in acquired AA remains elusive. It is reported that humoral immune responses to hematopoietic antigens can be detected in AA patients, and these humoral immune responses may be useful in unraveling the disease pathophysiology of AA. However, there has been no data referred to the role of HLA-G in acquired AA.
Aims: The study was performed to investigate whether HLA-G and its two main receptors (ILT2 and ILT4) were involved in acquired AA.
Methods: Human bone marrow mononuclear cells (BMMCs) and bone marrow plasma were obtained from 20 severe AA (SAA) patients, 13 moderate AA (MAA) patients and 16 healthy control subjects. All the AA patients were newly diagnosed and had not received any specific treatment. The concentration of soluble HLA-G in bone marrow plasma was determined by enzyme-linked immunosorbent assay. The relative expression level of HLA-G, ILT2 and ILT4 in BMMCs was quantified by real time polymerase chain reaction. Besides, the percentages of membrane-bound HLA-G$^+$, ILT2$^+$ and ILT4$^+$ cells amongst CD4$^+$, CD8$^+$, CD14$^+$ and CD19$^+$ BMMCs were analyzed by flow cytometry.
Results: The concentration of soluble HLA-G in the marrow plasma of AA patients was much higher than that in healthy controls but no difference was found between SAA and MAA patients. At transcriptional level, the ILT2 mRNA expression on BMMCs in AA group was elevated compared with control group while the HLA-G mRNA level was similar in the two groups. In addition, the percentage of CD19$^+$lymphocytes among BMMCs was increased in AA group, and the proportion of ILT2-expressing cells among CD19$^+$ BMMCs in AA patients was significantly higher than that in healthy controls. In AA group the percentage of CD19$^+$ BMMCs was negatively correlated with the counts of neutrophils, platelets or reticulocytes in peripheral blood. No significant difference was observed for the expression of membrane-bound HLA-G, ILT2 and ILT4 on the surface of CD4$^+$, CD8$^+$ or CD14$^+$BMMCs between AA patients and healthy controls.
Summary and Conclusions: Together, our data demonstrated that HLA-G/ILT2 was aberrantly expressed in AA patients' marrow cells especially in the CD19$^+$ lymphocytes, which indicated HLA-G/ILT2 may play a role in the abnormal humoral immunity in AA. Blocking HLA-G/ILT2 interaction might be a novel therapeutic strategy for acquired AA.

P249

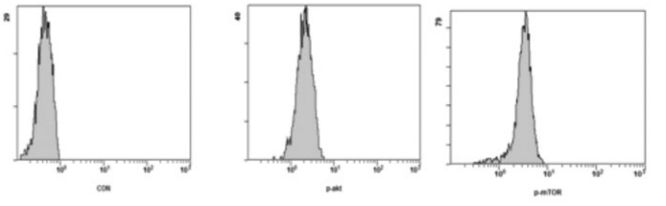
THE MTOR SIGNALING PATHWAY IS ACTIVIVED IN T CELLS OF APLASTIC ANEMIA

H. Zhu[1], W. Shen[1], K. Miao[1], J. Li[1], G. He[1,*]
[1]hematology, the first affiliated hospital of nanjing medical university, nanjing, China

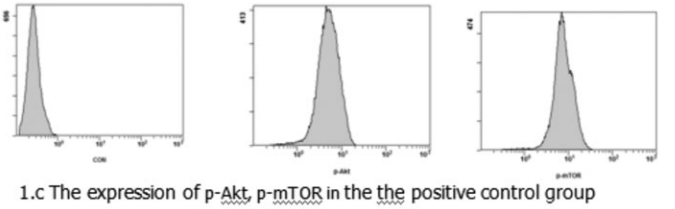
Background: Aplastic anemia (AA), an unusual hematologic disease, is the paradigm of the human bone marrow failure syndromes, The pathophysiology is immune mediated in most cases, with activated cytotoxic T cells implicated.As known to all, there are two signal transduction pathways for T cells' activation, TCR/CD3 as signal 1 heralds antigen recognition whereas cosignal molecules(such as CD28, CTLA-4) as signal 2 refers to the integrated sum of environmental cues. MTOR is an evolutionarily conserved PI3-kinase family member that plays a central role in integrating environmental cues in the form of amino acids, energy, and growth factors. Recently, an increasingly important role for mTOR in directing T cell activation and differentiation has become apparent.
Aims: To explore the roles of the positive and negative factors of mTOR (Mammalian target of rapamytin) signal pathway of the pathogenesis of aplastic anemia (AA).
Methods: (1) To analyze the expression of the positive factors (p-Akt, p-mTOR, p-TSC, p-P70S6K, p-S6, p-4EBP1) and the negative factor (Sirt1) in CD3$^+$ T cells selected by immunomagnetic beads of 21 aplastic anemia patients'(AA group) and 16 healthy persons' (control group) peripheral blood samples by flow cytometry. (2) To compare the difference of Sirt1/p-Akt, Sirt1/p-TSC, Sirt1/p-mTOR, Sirt1/p-4EBP1, Sirt1/p-P70S6K, Sirt1/p-S6 between the AA group and the control group. Analyze the correlation of absolute neutrophil count (ANC) and lymphocyte count (Ly) with the ratios.
Results: 1.The expression of p-Akt, p-TSC, p-mTOR, p-P70S6K, p-S6, p-4EBP1 in CD3+ T cells of the aplastic anemia patients were (8.31±2.28), (41.68±23.72), (14.02±11.51), (14.10±9.46), (20.17±11.75), (137.49±108.58), respectively. The expression of p-Akt, p-TSC, p-mTOR, p-P70S6K, p-S6, p-4EBP1 in CD3+ T cells of the control group were (3.11±0.85), (15.74±9.14), (3.17±1.06), (3.81±1.49), (3.02±0.79), (29.91±17.78), respectively. So, the expression of all the phosphorylated molecules in aplastic anemia patients were obviously higher than the control group, (P<0.05, Figure1, Table 1).2. The expression of the negative factor Sirt1 in CD3+ T cells of aplastic anemia patients was (10.85±6.15) which had no significant with the control group (9.67±2.91), (P=0.52, Table 1).3. The ratios of Sirt1/p-Akt, Sirt1/p-TSC, Sirt1/p-mTOR, Sirt1/p-4EBP1, Sirt1/p-P70S6K in the AA group were much lower than the control group, (P<0.05, Table 2).4. There were positive correlation between ANC and the ratios of Sirt1/p-TSC, Sirt1/p-mTOR, Sirt1/p-4EBP1, Sirt1/p-P70S6K and negative correlation between Ly and the ratios of Sirt1/p-mTOR, Sirt1/p-4EBP1 in AA group, (P<0.05, Table 3).



1.a The expression of p-Akt, p-mTOR in the healthy control group.



1.b The expression of p-Akt, p-mTOR in the AA group



1.c The expression of p-Akt, p-mTOR in the the positive control group

Figure 1.

Tabella 1. The expression of the factors in the three groups (Mean±SD)

	Control n=21	AA n=16	CEM
p-mTOR	3.17 ± 1.06	14.02 ± 11.51[ab]	31.64 ± 17.37[c]
p-Akt	3.11 ± 0.85	8.31 ± 2.28[ab]	19.50 ± 4.72[c]
p-TSC	15.74 ± 9.14	41.68 ± 23.72[ab]	103.9 ± 20.09[c]
p-P70S6K	3.81 ± 1.49	14.10 ± 9.46[ab]	35.36 ± 15.35[c]
p-4EBP1	29.91 ± 17.78	137.49 ± 108.58[ab]	264.74 ± 42.01[c]
p-S6	3.02 ± 0.79	20.17 ± 11.75[ab]	46.78 ± 14.70[c]

Compared with healthy controls, [a]P<0.05, [c]P<0.05,
Compared with healthy controls, [b]P<0.05;

Tabella 2. The rations of Sirt1/mTOR in the control and AA groups (Mean±SD)

	Control n=21	AA n=16	P
Sirt1/p-Akt	3.75 ± 0.98	1.05 ± 0.32	0.000
Sirt1/p-TSC	0.96 ± 0.89	0.24 ± 0.08	0.031
Sirt1/p-mTOR	3.89 ± 1.52	0.75 ± 0.34	0.000
Sirt1/p-4EBP1	0.72 ± 0.18	0.09 ± 0.05	0.010
Sirt1/p-P70S6K	3.14 ± 1.20	0.60 ± 0.19	0.000
Sirt1/p-S6	3.82 ± 1.32	0.67 ± 0.29	0.000

Tabella 3. The correlation of Sirt1/mTOR with ANC and Ly in AA group

	r	P
NE and Sirt1/p-TSC	0.700	0.011
ANC and Sirt1/p-mTOR	0.708	0.010
ANC and Sirt1/p-4EBP1	0.806	0.002
ANC and Sirt1/p-P70S6K	0.667	0.018
Ly and Sirt1/p-mTOR	-0.684	0.014
Ly and Sirt1/p-4EBP1	-0.620	0.032

Summary and Conclusions: (1) The mTOR signal pathway in T cells of aplastic anemia is activated, and the expression of Sirt1 in AA group relatively insufficient. (2) the ratios of Sirt1 with the phosphorylated molecules of mTOR signal pathway showed: the mTOR pathway in AA group migrated than the normal, which resulted in increased lymphocyte percentage and inhibition of hematopoiesis.

P250

THE PREVALENCE OF GATA-2 MUTATION AMONG PEDIATRIC PATIENTS WITH MYELODYSPLASTIC SYNDROME IN CZECH REPUBLIC

M. Novakova[1,*] M. Zaliova[1], E. Fronkova[1], M.W. Wlodarski[2], A. Janda[2], M. Sukova[3], Z. Zemanova[4], V. Campr[5], O. Zapletal[6], T. Kuhn[7], D. Pospisilova[8], K. Lejhancova[9], E. Vodickova[10], J. Trka[1], J. Stary[3], O. Hrusak[1], E. Mejstrikova[1]

Background: Germline mutation in GATA-2 transcription factor was recently identified in patients with immunodeficiency, familiar and sporadic myelodysplastic syndrome (MDS) and lymphoedema. Germline mutation in GATA-2 represents the most frequent genetic cause of MDS among children. Detailed prevalence of GATA-2 mutation among pediatric patients with MDS or aplastic anemia (AA) was not so far estimated.
Aims: Our aim was to define the prevalence of GATA-2 mutation among children with MDS or aplastic anemia in Czech Republic.
Methods: Since 1998 there were 27 Czech pediatric patients diagnosed with MDS refractory anemia with excess blasts (RAEB) or RAEB in transformation (RAEBt). The final diagnostic algorithm including histopathological investigation for discrimination of MDS subtype refractory cytopenia (RCC) and AA was introduced in 2005. Therefore only RCC/AA patients diagnosed in 2005-2014 were included: 32 RCC patients and 41 AA patients. Fanconi anemia as a cause of bone marrow failure was excluded in all patients. The coding part and the intronic enhancer region of *GATA2* gene was sequenced in all patients with available material, except for 2 patients with RAEB emerging on the background of Fanconi anemia and morbus Recklinghausen (in total 22 patients with RAEB/RAEBt, 31 RCC and 38 AA were analyzed). Immunophenotyping using flow cytometry was performed in bone marrow and peripheral blood. Levels of intronRSS-Kde recombination excision circles (KREC) were measured in peripheral blood and bone marrow with the aim to describe the level of B cell production.
Results: GATA-2 mutation was found in 9 patients with MDS: in 3 RAEB/RAEBt and in 6 RCC patients. As expected there was no AA patient with GATA-2 mutation. Patients with GATA-2 mutation frequently harbored cytogenetic abnormalities including monosomy 7 and trisomy 8. Interestingly one patient did not have any cytogenetic abnormality, however her father died of MDS harboring monosomy 7. In total 7 patients had monosomy 7, 1 patient had trisomy 8 and one patient had simultaneously monosomy 7 and trisomy 8. The prevalence of GATA-2 mutation within patients with monosomy 7 and trisomy 8 was 41% and 29%, respectively. Considering patients with monosomy 7 only, patients with GATA-2 mutation had significantly lower KRECs in peripheral blood and tend to have lower number of B cells in bone marrow. However, at the time of birth there was no major decrease in KRECs in 3 out of 4 analyzed Guthrie cards from GATA-2 mutated patients, indicating postnatal impairment of B cell production. The only one patient with low KRECs at birth developed MDS RAEB at the age of 4 and is the youngest patient in our cohort. Except for this patient, all other GATA-2 mutated patients were older than 11 years at time of diagnosis (median 17y). Two patients with GATA-2 mutation died: one of CMV pneumonitis, another one of AML with a phenotypic switch to BCP ALL.
Summary and Conclusions: So far published cohorts of patients were mainly identified based on clinical symptoms (*i.e.* immunodeficiency, familiar AML/MDS or lymphoedema). The incidence of GATA-2 mutation among pediatric MDS RCC, MDS RAEB/RAEBt and AA patients is 19%, 14% and 0%, respectively. However, the real prevalence could be higher since not all the introns are sequenced. Interestingly mutation in GATA-2 transcription factor can be identified even in patients without any cytogenetic abnormality. Diagnosis of GATA-2 mutation is important for genetic counselling and potential identification of GATA-2 mutation in a family donor before stem cell transplantation. *Supported by GAUK 802214, IGA NT/14534-3, UNCE 204012*

P251

EVALUATION OF BONE MARROW MICROVESSEL DENSITY IN PATIENTS WITH APLASTIC ANEMIA AND ITS ROLE IN PREDICTING OUTCOME TO THERAPY

S. Venkatesan[1,*] A. Purohit[1], M. Aggarwal[1], M. Mahapatra[1], P. Manivannan[1], S. Tyagi[1], H. Pati[1], R. Saxena[1]
[1]Hematology, All India Institute Of Medical Sciences, New Delhi, India

Background: Bone marrow (BM) microenvironment plays a crucial role in the growth of hemopoietic cells and BM function, which in turn depends on an intact microvasculature. Our study assesses the microvessel density (MVD) in the BM biopsy of aplastic anemia (AA).
Aims: To examine BM angiogenesis by assessing MVD in patients with aplastic anemia (AA), to compare these values with those obtained in control BM, to correlate the MVD values with the severity of AA and with the response to therapy (Anti Thymocyte Globulin (ATG), cyclosporine (CSA), and androgens).
Methods: Bone marrow biopsy specimens from 60 patients with AA and 17 controls were studied. There were 33 patients with non severe AA (NSAA), 12 patients with severe AA (SAA) and 15 patients with very severe AA (*VS*AA). MVD was calculated on sections stained immunohistochemically for CD34. 35 patients (58.33%) received only androgen (Stanazolol 2 mg/kg/day in three divided doses) due to poor socioeconomic status of patients, 22 patients (36.66%) were treated with androgen and CSA (5 mg/kg/day in two divided doses) while 03 patients (05%) were given ATG (40mg/kg for four days) and CSA.
Results: The patient age ranged from four to 72 years with median age at presentation being 22 years. Majority of the patients were males (40/20); male to female ratio was 2:1. The duration of symptoms ranged from one to sixty months (median =two months). The commonest symptom being weakness/fatigability noted in all cases followed by bleeding manifestations (66.66%) and fever (40%). 53 patients (88.33%) gave transfusion history at presentation with a range of one to 50 transfusions (median=four). Patients with AA exhibited reduced BM cellularity which ranged from 5% to 20%. As assessed by CD34 immunohistochemistry, the mean BM MVD in AA group was 1.28±0.36, being significantly lower than that in control group (6.80±1.59, P<0.001). MVD of SAA and NSAA patients were 1.16±0.35 and 1.49±0.27, respectively, being significantly different (P=0.003). MVD of *VS*AA was 0.93±0.25 and the difference with NSAA is significant, however there was no significant difference between SAA and *VS*AA. Response was assessed in those patients (n=31) who had a minimum follow up of six months. Of those cases, four had partial response (PR) while four patients had complete response (CR) at the end of six months follow up. It was found that MVD was higher among responders (mean MVD 1.96±0.16) as against non responders (mean MVD 1.26±0.25). The difference in mean MVD between these two groups was statistically significant with a p value of (P<0.001).
Summary and Conclusions: Our study is unique in the sense it is one of the largest to study the BM MVD in 60 cases of AA. In addition we compared the mean MVD count of those cases that had shown either PR or CR with mean MVD count of non responders. Our study shows that AA is associated with reduced BM angiogenesis. Upon quantification of angiogenesis, it is seen that the BM MVD reduces with the severity of the disease. Also the patients responded to therapy had significantly higher MVD than the non responders at presentation and hence may predict the behavior of the disease. This particular

finding was not reported in the earlier studies. This observation advances our knowledge about the role of microenvironment in the pathogenesis of AA and this critical finding may have implications for new concepts relating to therapy and outcome of this disease. It may guide future research towards looking at the option of using pro-angiogenic drugs in treatment of AA. The promotion of MVD in bone marrow and the improvement of microenvironment may induce hemopoiesis and create a new way to cure aplastic anemia.

P252

IMMUNOPHENOTYPIC PROFILING OF ERYTHROID PROGENITOR-DERIVED EXTRACELLULAR VESICLES IN DIAMOND-BLACKFAN ANAEMIA: A NEW DIAGNOSTIC STRATEGY

S. Macrì[1,*] E. Pavesi[1], R. Crescitelli[1], A. Aspesi[1], C. Vizziello[2], C. Botto[3], P. Corti[4], P. Quarello[5], P. Notari[2], U. Ramenghi[3], S. Ellis[6], I. Dianzani[1]
[1]Health Sciences, University of Eastern Piedmont, [2]Chemical Clinical Analysis laboratory, SCDU, Azienda Universitaria Ospedaliera Maggiore della Carità, Novara, [3]Pediatric Haematology, Department of Public Health and Pediatric Sciences, University of Turin, Turin, [4]Pediatric Haematology, San Gerardo's Hospital, Monza, [5]Pediatric Onco-Hematology, Regina Margherita Children's Hospital, Turin, Italy, [6]Department of Biochemistry and Molecular Biology, University of Louisville, Louisville, United States

Background: Diamond-Blackfan Anaemia (DBA) is a rare inherited pure red cell aplasia. Patients with DBA exhibit a macrocytic normochromic anaemia and reticulocytopenia. Erythroid progenitors (BFU-E and CFU-E) in bone marrow (BM) show a proapoptotic phenotype and their number is reduced. DBA is considered as the prototype of ribosomopathies. Heterozygous mutations in one of 13 ribosomal protein (RP) genes have been found in about 65% of patients. Diagnosis of DBA is hampered by the overlapping clinical presentation with other BM failure syndromes such as Fanconi Anaemia (FA), Shwachman-Diamond syndrome (SDS), Dyskeratosis Congenita (DC) and Transient Erythroblastopenia of Childhood (TEC). The absence of unique diagnostic features for the disease makes DBA a diagnosis of exclusion, finally confirmed by mutation analysis.
Aims: As an alternative strategy for developing a more inclusive assay for possible use in DBA diagnosis we turned to the study of extracellular vesicles (E*Vs*) whose presence may be altered as a consequence of the loss of erythroid progenitor cells in the marrow of these patients.
Methods: E*Vs* have been isolated from plasma of patients with DBA and appropriate controls by differential centrifugations and analysed by flow cytometry. Three markers have been used to characterise E*Vs* derived from cells of the erythroid lineage: CD34, CD71 and CD235a. EV immunophenotypic profiles of 8 patients with DBA, 22 healthy controls and 10 patients with other congenital or acquired anaemias (non-DBA) have been performed.
Results: Among the three EV clusters we found, only the CD34+/$CD71_{low}$ population showed a statistically significant difference between DBA patients and controls ($p<0.05$). This population, representing late erythroid progenitors, is substantially less represented in DBA patients as compared to controls. This finding is in agreement with the low level of erythroid progenitors in the patients' BM. The assessment of Receiver Operating Characteristic (ROC) curves demonstrated the potential use of the CD34+/$CD71_{low}$ population as a diagnostic tool. Area under the ROC curve (AUC) values suggest that this test has an excellent accuracy to discriminate DBA patients from healthy controls, from non-DBA patients and also from all other individuals under study.
Summary and Conclusions: These data overall suggest that the EV assay we devised may be useful to improve DBA diagnosis as a quicker and less invasive alternative to erythroid cultures. It should be noted that this assay is performed from peripheral blood, is amenable to transfused patients and requires two working days, whereas erythroid progenitors growth requires 15 working days and needs to be performed using a bone marrow sample in DBA patients.

P253

ALTERATION OF HEME METABOLISM IN A CELLULAR MODEL OF DIAMOND-BLACKFAN ANEMIA

S. Mercurio[1], A. Aspesi[2], L. Silengo[1], F. Altruda[1], I. Dianzani[2], E. Tolosano[1], D. Chiabrando[1,*]
[1]Department of Molecular Biotechnology and Health Sciences., University of Torino, Torino, [2]Department of Health Sciences, University of Eastern Piedmont, Novara, Italy

Background: Diamond-Blackfan anemia (DBA) is a congenital pure red cell aplasia often associated with skeletal malformations. Mutations in ribosomal protein coding genes, mainly in RPS19, account for the majority of DBA cases. The molecular mechanisms underlying DBA pathogenesis are still not completely understood. Alternative spliced isoforms of FLVCR1 (Feline Leukemia Virus subgroup C Receptor 1) transcript coding for non-functional proteins have been reported in some DBA patients. Consistently, a phenotype very close to DBA has been described in animal models of FLVCR1 deficiency. FLVCR1 gene codes for two proteins: the plasma membrane heme exporter FLVCR1a and the mitochondrial heme exporter FLVCR1b. Loss of FLVCR1a causes heme accumulation in cytosol while the lack of FLVCR1b leads to mitochondrial heme overload. The coordinated expression of both FLVCR1 isoforms regulates an intracellular heme pool, necessary for proper expansion and differentiation of erythroid precursors.
Aims: The aim of the work is the investigation of the role of FLVCR1 isoforms in a cellular model of DBA.
Methods: TF1 cells expressing two different inducible shRNAs against RPS19 were compared to that expressing an inducible shRNA against a scramble sequence. Cells were examined after 4 days of doxycycline treatment which causes the downregulation of RPS19. FLVCR1 isoforms levels and heme content were evaluated. K562 cells stably expressing a shRNA against FLVCR1a or both FLVCR1a/1b isoforms were compared to that expressing a shRNA against a scramble sequence. To stimulate erythroid differentiation, K562 cells were stimulated with 0.5 M sodium butyrate for 72 hours. Heme content, in vitro erythroid differentiation, cell proliferation, cell cycle, apoptosis and oxidative stress were analyzed.
Results: RPS19-downregulated TF1 cells show a reduction of both *FLVCR1a* and *FLVCR1b* mRNA levels. Consistently, RPS19-downregulated TF1 cells accumulated heme in both cytosol and mitochondria. It has already been reported that RPS19-downregulated TF1 cells showed reduced proliferation, a G0/G1 arrest and increased apoptosis. To investigate whether the loss of FLVCR1 isoforms could affect these processes, we took advantage of K562 cells with a specific downregulation of FLVCR1a or both FLVCR1a/1b. FLVCR1a-downregulated K562 cells showed cytosolic heme overload, reduced proliferation and increased *in vitro* differentiation whereas loss of both FLVCR1a and FLVCR1b causes mitochondrial heme overload, reduced proliferation and decreased *in vitro* differentiation. Both FLVCR1a-and FLVCR1a/1b-downregulated K562 cells showed cell cycle arrest at G0/G1 and increased apoptosis, following the stimulation of *in vitro* erythroid differentiation.
Summary and Conclusions: Taken together, these data indicate that the downregulation of FLVCR1 isoforms in K562 cells leads to a phenotype similar to DBA. Thus, we proposed that alteration of heme metabolism could contribute to defective proliferation and apoptosis of DBA erythroid progenitors. Further work is needed to completely define the role of FLVCR1 isoforms in the pathogenesis of DBA.

Ospedale Civico, Palermo, Italy

Background: Neutropenia is a disorder characterized by a reduction of absolute neutrophil count (ANC) below the lower limit, which is $1.0x10^9$/L in Caucasian children up to age 1y, whereas from >1 year to adulthood it is 1.5 $x10^9$/L. Neutropenia is defined as mild if ANC is between 1.0 and $1.5x10^9$/L, moderate if between 0.5 and $1.0x10^9$/L, and severe if $<0.5x10^9$/L. Autoimmune neutropenia of infancy (AIN) is a disorder characterized by mild bacterial infections and a tendency to resolve spontaneously.
Aims: To provide clinical, biochemical and hematological insights through the analysis of a reasonably sized cohort of patients.
Methods: a retrospective analysis of all patients diagnosed with AIN, enrolled between 1.01.2002 and 1.06.2014 in the Italian Neutropenia Registry of AIEOP (Associazione Italiana Onco-Ematologia Pediatrica). The Indirect Granulocyte Immunofluorescence Test (GIFT) was used to detect circulating auto-antibodies reacting with purified granulocytes from donors who were not genotyped for Human Neutrophil Antigens. Italian Guidelines recommend repeating GIFT at

least 4 times if negative at first; after 4 negative tests neutropenia is defined as "idiopathic".
Results: We analyzed 157 AIN patients. The sensitivity of GIFT after 1, 2, 3, and 4 assays was 61.8%, 73.1%, 78.7%, and 81.8% respectively. The characteristics of the patients are shown in Table I. The median age at onset was 0.70y (range 0.005–4.59): 82% of the children were under 18 months of age at presentation. Three patients (1.9%) were under one month of age at onset, and 13.2% of all patients born preterm. Median ANC at onset were 0.45 1x10^9/L, with the following distribution: 56.0% ≤0.500x10^9/L, 38.2% between 0.501 and 1.0x10^9/L, and 5.7% >1.0x10^9/L. Diagnosis of AIN was made by chance in 29.3%, and in 70.7% on the basis of a suspected immunodeficiency or during a hospitalization due to fever or infections. 89% of the cohort recovered spontaneously and the median age of resolution was 2.14y, with a median disease duration of 1.30y: 85% of the children recovered at less than 5y, and 13 patients recovered spontaneously at 5-11y of age. Among all the analyzed parameters in the Cox model only age of appearance (p=0.00029) and absence of monocytosis (p=0.015) were statistically associated with higher recovery percentage. Lower age at presentation was also associated with reduced duration of disease (p=0.028). Recovery was abrupt in 67.4% of patients; in the remaining 32.5% there was an intermittent neutropenia, with a median time of definitive healing from the first normal blood count of 0.65 year. Bone marrow was examined in 53 children and was normal in all but 2 patients who showed a moderate decrease of myeloid cellularity. A transient positivity of direct antiglobulin test (DAT) and a selected IgA deficiency were present in 6.8% and 3% respectively: both associations did not impact the probability of spontaneous recovery. 44% of children were hospitalized for fever or infectious, but only 15 patients (9.6%) suffered from severe infections (sepsis, pneumonia, skin/*soft* tissue *abscesses, or meningitis/encephalitis),* without long-term consequences. G-CSF was administered "on demand" only in severe infections in 11 patients.

Tabella 1. Clinical characteristics of AIN cohort

	Patients (157)
Male	64.3%
Median age at onset (years)	0.70
Median age at diagnosis (years)	1.06
Median age at resolution	2.14
Median duration (years)	1.30
Recovery	89.1%
Median WBC at onset (x10^9/L)	6.1
Median ANC at onset (x10^9/L)	0.45
Leukopenia at onset	40.7%
Monocytosis at onset	19.3%
Increased IgG at onset	6.0%
Selective IgA deficiency	3%
Severe infections	9.6%
DAT positivity	6.8%
BM examination/normal appearance	34.4%/96.2%

Summary and Conclusions: This is the second largest cohort of AIN patients ever reported. Our analysis confirms that GIFT assay has a reasonable sensitivity on repeated testings and shows the following new findings that may affect clinical management of the disease: (i) AIN is frequently found in children born preterm; (ii) lower age at presentation is associated with reduced duration of the disease. (iii) AIN can be associated with other immunological abnormalities like transient positivity of DAT and low IgA serum level; (iii) AIN patients are often hospitalized for infections but severe infections occur in less than 10% of patients; (iv) recovery from AIN may be after age of 5 years and in one third of patients ANC normalizes alternating normal to neutropenic values over a timespan >6 months.

P255

PRELIMINARY DATA ON THE OUTCOME OF BONE MARROW TRANSPLANTATION IN CONGENITAL DISKERATOSIS. AN ANALYSIS FROM THE EUROPEAN GROUP FOR BONE MARROW TRANSPLANTATION (EBMT)

[1]Istituto Giannina Gaslini, Genova, Italy, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Centro Interdipartimentale di Biostatistica e Bioinformatica, Roma, Italy, [4]University of Minnesota, Minneapolis, United States, [5]Hospital St Louis, Paris, France, [6]Great Ormond Street Hospital Children's Charity, London, United Kingdom, [7]King Faisal Specialist Hospital & Research Centre, Rhyad, Saudi Arabia, [8]Hadassah University Hospital, Jerusalem, Israel, [9]St Mary Hospital, London, United Kingdom, [10]Ospedale San Martino, Genova, Italy, [11]Hopital Necker, Paris, France, [12]Ospedale Infantile Regina Margherita, Torino, Italy, [13]Hospital Vall d'Hebron, Barcelona, Spain, [14]Fondazione IRCCS Polclinico San Matteo, Pavia, Italy, [15]Shariati Hospital, Teheran, Iran, [16]Sydney Children's Hospital, Sidney, Australia, [17]Our Lady's Children's Hospital, Dublin, Ireland, [18]Istituto Giannina Galini, Genova, Italy

Background: Dyskeratosis congenita (DC) is an inherited telomeropathy characterized by mucocutaneous features (oral leukoplakia, nail dystrophy, abnormal skin pigmentation), bone marrow failure and organs' compromision (mainlylung and gastrointestinal tract). Haematopoietic Stem cell Transplantation (HSCT) is the only definitive treatment to restore hematopoiesis, but increased organ toxicity has been reported after transplant. To the best of our knowledge, extensive reports on its outcome are lacking.
Aims: To collect data on the outcome of HSCT in DC by analyzing data from the European Society for Blood an Bone Marrow Transplantation (EBMT)
Methods: All patients registered in the EBMT data base and affected with DC were considered eligible to the study. Data about type of HSCT, characteristic of donors, source of cells, incidence of acute and chronic GvHD were collected.
Results: A total of 84 patients affected with DC who underwent HSCT from 1979 to 2013, entered the study. Females were 23% of the cohort. Median age at diagnosis of DC was 5.7 years (0-33y), while median age at HSCT was 12.3 years (range 0.56-41y). Median time from diagnosis to HSCT was 22 months (0.62-278 mo). The cell source was bone marrow (BM) in 60%, peripheral blood (PB) in 26% and cord blood (CB) 14%. Thirthy-three percent of patients were engrafted from a matched related and 50% from an matched unrelated donor. Fourteen percent were mismatched related and unrelated HSCT. Engraftment was documented in 88 % of subjects: 6.5 % had primary graft failure and 4% lost the engraftment. Overall 25 patients (33 %) died, and 59 were alive (67%). Causes of death were: rejection graft/ loss of graft 28%, infections 24%, non-infectious interstitial pneumonia 16%, multi-organ failure 12%, secondary malignancies 12%, GvDH in 8%. Lung injury was present in more than one third of the subjects who died. Transplant related mortality of the whole cohort was 18% . Acute GVDH occurred in 67% of the cohort, mainly of grade I and II (31%) and grade III in 6% of the cohort. No grade IV aGvHD has been documented. The 5-year OS and EFS (death, relapse, second tumours, primary and secondary graft failure being the events) were 63 % and 51% respectively. Of note EFS curve did not show a plateau. Analyzing data during the first 12 months of follow up, OS was 87% for patients aged 0-12 years and 75% for subjects who underwent transplant at age >12 years (p=0.23). The time between the diagnosis and transplant (>24 months and <24 months) did not significantly impact on the 5 years-OS which was assessed respectevely at 72% and 53% (p=0.14). Again, looking at the first 12 months of follow up, OS and EFS according to source of cells seemed not significantly differ, even if a precocious fall in the curve was observed for CB and PB rather than for BM.
Summary and Conclusions: HSCT may be an option in DC patients, but the never reached plateau for the EFS curves points out the high risk morbility of this disease. Lung involvement represents the main cause of death for both GvHD and infections. Lung status before HSCT, irrespective to bone marrow failure, has to be weighted regarding the choice of HSCT. Future data comparing outcome of DSK transplanted and non transplanted patients will be useful to definitely understand if any patients' risk stratification regarding HSCT can be applied.

P256

SOLUBLE CD163 AS A MARKER FOR MACROPHAGE ACTIVATION IN CHILDREN AND ADOLESCENTS WITH GAUCHER DISEASE: RELATION TO PULMONARY AND BONE INVOLVEMENT

A.A. Adly[1,*] E. Ismail[2]
[1]pediatrics, [2]clinical pathology, Ain Shams University, cairo, Egypt

Background: Bone and lung involvement are two major causes of morbidity in Gaucher disease (GD). The soluble form of CD163 (sCD163) is a valuable diagnostic biomarker for monitoring diseases with increased macrophage activation.
Aims: We determined sCD163 levels in 30 children and adolescence with GD compared with 30 healthy controls and assessed the relation to phenotypes, disease severity and complications.
Methods: Thirty GD patients (10 had type 1 and 20 had type 3) were recruited from the regular attendants of the Pediatric Hematology Clinic, Pediatric Hospital, Ain Shams University. All patients were under regular enzyme replacement therapy (ERT) using recombinant glucocerebrosidase. Patients were studied stressing on skeletal, pulmonary or neurological manifestations and history of splenectomy. All studied patients were clinically asymptomatic for pulmonary hypertension. Screening for pulmonary hypertension was done by the non-invasive Doppler echocardiograpghy. Measurement of bone mineral

density (BMD) was performed by dual energy X-ray absorptiometry (DXA). Hematological profile, plasma chitotriosidase activity, D-dimer and sCD163 levels were assessed.
Results: The mean Z score for GD patients with normalBMD was-0.7±0.1. Patients with osteopenia had a mean Z score of-1.9±0.9 while the mean Z score for those with osteoporosis was-3.4±1.1. Patients with GD had significantly higher sCD163 than healthy controls (median [IQR], 7750 [4000] ng/mL *versus* 980 [460] ng/mL; p<0.001). Comparison between patients with type 1 and type 3 GD revealed that the incidence of squint, dysphagia, developmental delay and pulmonary hypertension risk was higher among type 3 GD patients (p<0.05). D-dimer, chitotriosidase activity and sCD163 levels were significantly increased in type 3 GD patients compared with type 1 (p<0.05). Severity score index (SSI) was higher among type 3 GD than type 1 (p<0.001). Other variables including DXA findings were similarly distributed among both GD groups (p>0.05). sCD163 was significantly elevated in GD patients with dysphagia (p=0.026), developmental delay (p=0.033), pulmonary hypertension risk (p<0.001) or abnormal BMD (p=0.031) than those without. GD patients receiving ERT every 2 weeks had lower levels than those under ERT more than 2 weeks (p<0.001). sCD163 was positively correlated to age, disease duration, SSI, WBC count, D-dimer and chitotriosidase activity. Multiple regression analysis showed that TRV, D-dimer and chitotriosidase activity were independently related to sCD163 in GD patients (r^2=0.768; p<0.001). The cutoff value of sCD163 at 9400 ng/mL could differentiate GD patients with and without pulmonary hypertension risk with a sensitivity of 90% and specificity of 95% %, area under the curve 0.975 and 95% confidence interval 0.681-1.0; p<0.001.
Summary and Conclusions: sCD163 is a biomarker for clinical assessment of macrophage proliferation and activity that would help in risk prediction of bone and lung involvement. Assessment of sCD163 levels may provide a potentially valuable tool for monitoring the response to ERT in GD patients.

P257

THE PROGNOSIS OF ACQUIRED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN ADULTS IS HEAVILY AFFECTED BY A COEXISTING VIRAL INFECTION: ANALYSIS OF A SINGLE INSTITUTION SERIES OF 35 PATIENTS

C. Cattaneo[1,*] M. Oberti[1], A. Passi[1], A. Re[1], A. Peli[1], M. D'Adda[1], V. Orlando[1], M. Petullà[1], C. Lamorgese[1], P. Tozzi[1], G. Rossi[1]
[1]Spedali Civili, Brescia, Italy

Background: Hemophagocytic lymphohistiocytosis (HLH) is a often fatal hyperinflammatory syndrome, mainly occurring on a genetic basis in the paediatric population. In adult patients (pts) acquired HLH can develop as a complication of many disorders, which may lead to similar deregulated immune response of the paediatric form. Early diagnosis is essential in order to avoid a fatal outcome. HLH-04 criteria have been validated in the paediatric setting, but are often difficult to apply to the adult population, since they include genetic and immunological parameters difficult to obtain in due time. Indeed, a readily applicable diagnostic score (HScore, Fardet 2014) has been recently proposed in order to facilitate the clinical diagnosis of acquired HLH.
Aims: To confirm the diagnosis of acquired HLH made in a single institution series of adult pts with HLH-04 criteria, by applying the HScore and to identify prognostic factors associated with clinical outcome.
Methods: Hscore diagnostic criteria were applied to a series of 35 pts with HLH diagnosed according to HLH-04 criteria during a 11-year period. The following variables of potential prognostic significance were considered: sex, age, underlying haematological disease, severity of anemia (<9g/dl), neutropenia (<1000/mcl) and thrombocytopenia (<100000/mcl), hypertrigliceridemia (>265 mg/dl), hypofibrinogenemia (<150 mg/dl), ferritin >10000 ng/ml, bilirubin >2 mg/dl, LDH>2N, morphological signs of HLH, concomitant viral infection, response to treatment.
Results: Median age of the 35 pts was 54 (range 17-81), M/F ratio was 20/15. In 26/35 (74.3%) pts an underlying haematological disease was present (2 Multicentric Castleman Disease, 10 B-cell Non Hodgkin Lymphoma [NHL], 14 T/NK-cell NHL); an autoimmune disorder was observed in 4 (11.4%) patients (1 Still Disease, 1 undifferentiated connective tissue disease, 2 haemolytic anemia); in 5 (14.3%) no underlying disease was identified. A concomitant infection by EBV was observed in 10 pts, CMV in 8, HHV8 in 6 and HIV in 1. Hyperferritinemia, fever and splenomegaly were present in more than 90% of pts, whereas bone marrow hemophagocytosis in 51% of cases only. According to HScore, 34/35 patients had a >75% and 32/35 >93% probability of HLH. Two pts did not receive any treatment; the remaining 33 pts were treated with different schemes, including steroids (30), i.v. Ig (20), antiviral agents (15), rituximab (9), chemotherapy (14), HLH-04 protocol (3), cyclosporine (2). Ten of the 29 evaluable pts responded. After a median follow-up of 649 days, 8/35 pts are alive. Four-year overall survival (OS) and HLH-free survival (HFS) were 17±7.9%SE and 23±8.2%SE, respectively. By univariate analysis, age >50y, treatment failure and a concomitant viral infection were predictive of fatal outcome. Notably, median OS of pts with and without a concomitant viral infection

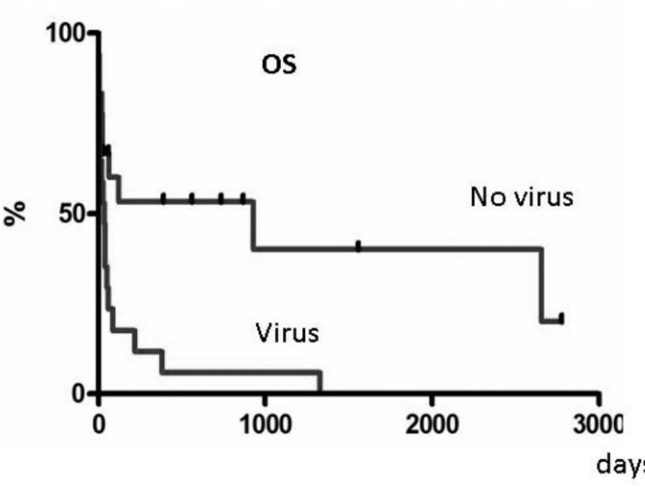

Figure 1.

Summary and Conclusions: Acquired HLH is not rare in adults and may be a dangerous but not uniformly fatal syndrome. HScore could be easily applied and showed high concordance with HLH-04 criteria for its diagnosis. An underlying haematological diseases, particularly T/NK-cell, but also B-cell NHL was the most frequent cause of acquired HLH. However a diagnosis of lymphoma did not influence HLH outcome, whereas, in addition to older age and lack of response to treatment, the presence of a concomitant viral infection, particularly herpetic, was a dismal prognostic factor and predicted a rapid fatal outcome. A better control of coexisting viral infections is warranted to improve the outcome of acquired HLH.

Multiple myeloma - Biology 1

Eugenio, Roma, [6]Ospedale Niguarda Ca' Granda Hematology, Milano, [7]Ematologia Ospedale San Francesco, Cagliari, [8]Azienda Ospedaliera San Giuseppe Moscati, Avellino, [9]Medicina interna universitaria Guido Baccelli dell'Ospedale Policlinico, Bari, [10]Azienda Ospedaliera di Cosenza, Cosenza, [11]Reparto di Ematologia e Trapianto di Cellule Staminali dell'Ospedale San Camillo, Roma, [12]Ematologia Ospedale Santa Maria delle Croci, Ravenna, Italy, [13]Department of Hematology, Erasmus Medical Center Rotterdam, Rotterdam, Netherlands, [14]Myeloma Unit, Division of Hematology, University of Torino, Torino, Italy

Background: Array-based technology has been showing a great impact on clinical cancer cytogenetic, especially on genetically heterogeneous disease, such as Multiple Myeloma (MM), where relevant lesions might be the hallmarks of different patients' subgroups, thus becoming of clinical relevance as well. The phase III EMN02 study was designed to compare Bortezomib, Melphalan, Prednisone with high-dose Melphalan and autologous stem cell transplantation after a bortezomib-based induction, for newly diagnosed MM patients.
Aims: Here we present the comprehensive, high throughput genomic profile performed at diagnosis in a subset of patients, in order to perform correlations with response to induction therapy.
Methods: Data obtained from 170 patients, treated with bortezomib-cyclophosphamide-dexamethasone (VCD) as induction therapy prior to randomization, have been analyzed. Highly purified CD138+ bone marrow plasma cells were profiled by SNPs array (Affymetrix 6.0 and CytoScanHD® chip). ChAS (Affymetrix) and Nexus Copy Number™ 7.5 (Biodiscovery) software were used to perform CNAs analyses and clinical correlations, respectively.
Results: Presenting MM cases were studied by SNPs array in order to compute CNAs and acquired loss of heterozygosity (LOH) in the tumor. The frequency distribution of the more relevant CNAs among the 170 MM cases is summarized in table 1. A subgroup of 13/170 (7.6%) cases is characterized by the absence of any macro CNAs (either gains or losses): these cases are mainly characterized by LOH events on chr. 1, 8 and 16, where putative tumor suppressor genes are located (*e.g. PLEKOH1* and *SIAH1* on chr.1 and 16, respectively). In order to identify novel chromosomal lesions impacting the response to therapy, we compared the CNAs profile of the extreme response categories, *i.e.* ³CR and SD. Either the absence of CNAs, or the presence of any of the renown prognostically relevant ones does not significantly impact on the response to induction therapy. On the contrary, two novel lesions resulted highly significant: (1) a 42.9Kb CN gain on chr.11q22.1-22.2, which only includes the Hippo pathway mediator *YAP1*, which significantly characterizes 6% of ³CR patients, as compared to 54% of SD ones (p=0.002); (2) an extended CN loss on chr.14q13.1-13.3, including genes implicated in the progression on cancer (*e.g. NKX2-8*), which significantly characterizes 62.5% of £CR patients, as compared to 4% of SD ones (p<0.001).

Tabella 1.

CNA	locus	gene (Kb)	positive	full gene	partial	LOH	response prediction
TP53 CN loss	17p13.1	25	15/170 (8.8%)	13/170	2/170	4/170	no
Rb1 CN loss	13q14.2	232	85/170 (50%)	74/170	11/17'	-	no
CKS1B CN gain	1q32.1	6	52/170 (30.5%)	52/170	-	12/170	no
MDM4 CN gain	1q32	144	57/170 (33.5%)	55/170	2/170	-	no
CDKN2C CN loss	1p32.3	7.7	20/170 (11.7%)	19/170	1/170	29/170	no
FAF1 CN loss	1p33	675	24/170 (14.1%)	16/170	8/170	30/170	no
FAM46C CN loss	1p12	29	37/170 (21.7%)	37/170	-	5/170	no
WWOX CN loss	16q23	1400	35/170 (20.6%)	26/170	9/170	12/170	no
CCND1 CNA	11q13	17	79/170 (46.5%)	-	-	1/170	no
CCND3 CNA	6p21	148	27/170 (15.9%)	-	-	3/170	no
MAFB CNA	20q11.2	4.4	23/170 (13.5%)	-	-	6/170	no
no CNAs	-	-	13/170 (7.6%)	-	-	+	no
YAP1 CN gain	11q22.1	160	71/170 (42%)	63/170	8/170	-	yes
CN loss	14q13.1	-	23/170 (13.5%)	-	-	3/170	yes

Summary and Conclusions: The reconstruction of high-throughput virtual karyiotype by SNPs array in a cohort of homogeneously treated, newly diagnosed MM cases offered the opportunity to obtain a comprehensive overlook of each patient's sub-chromosomal anatomy. This allowed both to perform a detailed patients' stratification at diagnosis and to identify, among the whole spectrum of CNAs, those having an impact on the response to therapy.

P259

RELATIONSHIP BETWEEN INHIBITION PROFILE OF B1, B2 AND B5 PROTEASOME SUBUNITS AND CYTOTOXIC ACTIVITY OF PROTEASOME INHIBITORS IN MULTIPLE MYELOMA

A. Besse[1,*] M. Kraus[1], J. Bader[1], L. Besse[1], B.T. Xin[2], G. de Bruin[2], H.S. Overkleeft[2], C. Driessen[1]

[1]Hematology/Oncology, Kantonsspital St Gallen, St. Gallen, Switzerland, [2]Gorlaeus Laboratories, Leiden Institute of Chemistry and Netherlands Proteomics Centre, Leiden, Netherlands

Background: The use of proteasome inhibitors (PI) with the first-in class drug Bortezomib (Btz) has improved the outcome of multiple myeloma (MM) patients. However, Btz resistance frequently emerges in patients with advanced disease. The second generation PI Carfilzomib (Cfz) and additional PI (including ixazomib, delanzomib, oprozomib, ONX-0914 (PR-957)) are in advanced clinical development. All these PI by design target the β_5 subunit of the proteasome, the rate-limiting protease, except for ONX-0914, which targets the β_{5i} immunoproteasome subunit. The proteasome in addition contains β_1 and β_2 protease subunits that differ from β_5 in their substrate specificity. The degree of cytotoxicity of PI varies with the degree of co-inhibition of proteasomal subunits $\beta_{1/1i}$ and/or $\beta_{2/2i}$, in addition to $\beta_{5/5i}$. Btz-refractory MM cells upregulate activity of β_2, the subunit not targeted by Btz. The "optimum" pattern of proteasome inhibition to reach maximum cytotoxicity in MM, either Btz-sensitive or Btz-resistant is unknown, as well as the individual patterns of proteasome subunit inhibition(*i.e.* co-inhibition of β_1 and/or β_2) of the non-approved PI in MM.
Aims: (I) To assess the impact of co-inhibition of proteasome subunits activity (β_{1i}, $\beta_{1/1i}$, $\beta_{2/2i}$, β_{5i}, $\beta_{5/5i}$) on cytotoxicity in Btz-sensitive and Btz-resistant MM cells; (II) to analyse the subunit inhibition pattern of PI in clinical development in relation to their cytotoxic activity.
Methods: We developed a set of subunit-selective proteasome inhibitors as well as fluorophore-labelled activity-based probes (ABP) capable to visualize the individual activities of the β_1, β_2, β_5-subunits of the constitutive and immunoproteasome in intact cells. Equimolar concentrations of PI were used to assess the inhibition profiles of the different drug candidates. Btz-resistant MM cell lines were generated by continuous drug exposure from AMO-1 cells (AMOaBtz,). Viability was estimated by MTS and plotted against the inhibition of the individual β-subunits (alone or with various combinations of proteasome inhibitors). In addition, recently synthetized inhibitors with dual specificity for $\beta_{2/2i}/\beta_{5/5i}$ (Xin550, Xin551) were used to improve the efficacy of proteasome inhibition in PI resistant cells.
Results: Table 1: Cytotoxic effect of selective inhibition of individual subunits of the proteasome (β_1, β_2, β_5) or immunoproteasome (β_{1i}, β_{5i}) alone or in combination, in intact MM cells, either sensitive or resistant to Btz (wt/aBtz); no (-) low (+), intermediate (++), high (+++) effect.

Tabella 1.

AMO (wt /aBtz)	O	ß1i	ß5i	ß1/1i	ß2/2i	ß5+5i
O	- / -	- / -	- / -	- / -	+ / -	+++ / -
ß1i			- / -	- / -	+ / -	+++ / -
ß5i				- / -	++ / -	+++ / -
ß1/1i					++ / -	+++ / -
ß2/2i						+++ / +++
ß2/2i + ß1/1i + ß5i	+++/+					
ß2/2i + ß1/1i + ß5/5i	+++ / +++					

Summary and Conclusions: ABP is a reliable tool for analysis of proteasome subunit activity in intact cells. Viability of Btz-sensitive MM cells can be maximally reduced by selective inhibition of β_5-type activity, so that additional β_1 and/or β_2-targeted proteasome inhibition does not increase cytotoxicity. In contrast, co-inhibition of $\beta_{2/2i}$ in addition to β_5 is required to achieve meaningful cytotoxicity in Btz-resistant MM cells. Inhibition of $\beta_{1/1i}$, either with β_5 or $\beta_{2/2i}$, has no additional cytotoxic effect (Table 1). Further, Xin550/ Xin551, inhibitors of β_2/β_5 are able to overcome resistance to Btz *in vitro*. Novel PI drug candidates showed considerably less co-inhibition of either β_1 or β_2 subunits, compared to Cfz or Btz, which correlated with a lower cytotoxic activity, in particular against Btz-resistant MM cells.

P260

LSD1 IMPAIRS OSTEOCLASTOGENESIS AND EPITHELIAL-MESENCHYMAL TRANSITION IN MM AND ENHANCES HDAC INHIBITORS ACTIVITY

M. Gkotzamanidou[1,2,*] J. Martín Sanchez[3], M. Kemal Samur[4], M. Fulciniti[5], K.C. Anderson[2], N.C. Munshi[2,6]

[1]Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Alexandra General Hospital, Athens, Greece, [2]Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States, [3]Hematology 2, Hospital Universitario Virgen del Rocío, Instituto de Biomedicina de Sevilla (IBIS)/CSIC/Universidad de Sevilla, Seville, Spain, [4]Department of Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Harvard School of Public Health, Boston, MA, [5]Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School,

Boston,MA, [6]Boston Healthcare System, West Roxbury,MA, United States

Background: Lysine-specific demethylase 1 (LSD1), a FAD-dependent histone demethylase which selectively removes mono-and di-methyl groups from H3K4, H3K9 residues leading to either repression or activation of transcriptome. LSD1 forms a co-repression complex with HDAC1, HDAC2, mSin3a and MMSET, while the IMIDs cause cell cycle arrest in Multiple Myeloma (MM) by modifying the chromatin structure of the p21WAF-1 promoter through LSD1 demethylation.
Aims: Here, we study the functional role of LSD1 in MM pathogenesis and its contribution in aggressive traits of myeloma disease.
Methods: The expression level of LSD1 transcript and its prognostic role was evaluated in publically available datasets of MM patients (GSE2113, GSE16122). We utilized MM.1S, OPM2, LP1 and RPMI-8226 human myeloma cell lines (HMCLs). Osteoclastogenesis was evaluated by using double TRAP/ALP staining and by estimating the mRNA expression levels of osteoblast markers (APL, BSP, OC). Cell viability and proliferation was evaluated by CellTiter Glo and 3[H]Thymidine uptake assays. Immunoblot analysis was performed using antibodies against LSD1, HDAC1,2, H3K4me2/3, H3K9me2/3. We evaluated the expression of LSD1 in bone marrow paraffin embedded specimen from 10 newly diagnosed MM patients. The epithelial-mesenchymal transition (EMT) was evaluated by using the transwell migration assay, invasion and wound healing assays.
Results: First, we observed significant overexpression of LSD1 in patients with symptomatic MM and Plasma Cell Leukemia (PCL) (p<.001). The expression of LSD1 in a panel 45 HMCLs was also pronounced. We confirmed the expression and both its nuclear and cytoplasmic localization in HMCLs and primary bone marrow plasma cells from newly diagnosed, relapsed MM and PCL patients (N=10). LSD1 was highly expressed in bone marrow specimen of MM patients and the higher expression was positively correlated with presence of bone fractures at diagnosis. LSD1 knockdown in LP1 and MM1S cells resulted in modest cytotoxicity. After a combination silencing of JARID1 members and LSD1 we were able to observe a further significant decrease in survival of MM cells lacking JARID1C and LSD1, indicating that the overlapping demethylation of H3K4 is of high importance for the cell survival. We examined the post-translational histone modifications after LSD1 knockdown and as expected, we observed significant increase of K4me2/3 and K9me2 marks, but more interestingly, alteration of acetylation status of K9. Moreover, we observed that LSD1 depletion enhances significantly the cytotoxicity effect of LBH589. LSD1 depletion resulted in significant reduction of mRNA levels by using real-time PCR and protein expression by immunoblotting of HDAC1 and HDAC2. Furthermore, we sought to investigate the impact of LSD1 in EMT. LSD1 depletion in MM1S and LP1 cells inhibited significantly the migratory potency. More importantly, MM cells lacking LSD1 expressed significant lower levels of E-cadherin, N-cadherin and Vimentin evaluated by immunoblotting and immunocytochemistry. We confirmed the suppression of EMT-involved gene expression by performing a PCR-microarray assay. Finally, given the presence of osteolytic lesions as a hallmark of disease, and consequent impact on outcome, we evaluated the impact of LSD1 on osteoblast differentiation and osteoclastogenesis. LSD1 depletion and pharmacological inhibition (S2101) resulted in significant inhibition of osteoclastogenesis and RANKL-induced resorption and survival of OCs. In contrast, LSD1 overexpression confirmed the upregulation of Wnt/b-catenin pathway suggesting a possible underlying mechanism for the osteoclastogenesis potency in MM patients with high expression of LSD1.
Summary and Conclusions: Our data suggest a promising epigenetic approach in myeloma therapeutics by targeting the deregulated LSD1-methylome in MM patients.

S1P MODULATOR FTY720 TARGETS OSTEOCLASTOGENESIS IN CXCR4-BASED MULTIPLE MYELOMA SYSTEMIC XENOGRAFT MODEL

K. Beider[1,*] E. Rosenberg[1], H. Bitner[1], A. Shimoni[1], M. Leiba[1], M. Koren-Michowitz[1], S. Klein[2], D. Olam[2], L. Weiss[2], M. Abraham[2], A. Peled[2], A. Nagler[1]
[1]Bone Marrow Transplantation, Sheba Medical Center, Ramat Gan, [2]Goldyne Savad Institute of Gene Therapy, Hadassah Hebrew University Hospital, Jerusalem, Israel

Background: Bone disease is one of the hallmarks of multiple myeloma (MM) leading to substantial morbidity and disability. Bone lesions result from abnormally increased osteoclast (OC) formation and activation. Studying the underlying mechanism may help to develop new therapeutic targets to treat MM associated osteolytic lesions and related complications.
Aims: Sphingosine-1-phosphate (S1P) was shown to play important role in osteoclast biology. Previously we reported that S1P modulator FTY720 exhibits potent anti-myeloma effect *in vitro* and *in vivo* in novel disseminated xenograft model of MM. We report now the effect of FTY720 on formation and activation of OCs and their functional sequel in MM model.
Methods: The *in vitro* effect of FTY720 was tested onOCsandOCprecursors from healthy donors, and on bone marrowmesenchymalstromal cells (BMSCs). *in vivo* model of BM-disseminated humanmyelomawas used to evaluate FTY720 anti-MM andboneactivities.
Results: The generated OCs expressed the genes encoding for S1P1 and S1P2 receptors and enzyme SPHK1, tested by RT-PCR. Treatment with FTY720 significantly reduced *in vitro* formation of TRAP+ OCs, resulting in 90% inhibition following 1 μM treatment, and complete abolishment of OC formation at 2.5 μM FTY720 (p<0.0001). Furthermore, FTY720 significantly reduced the expression of genes associated with OC activation. Thus, expression of osteoactivin, cathepsin K, NFATc1, OSCAR, RANK, RANTES, MT1-MMP and MMP9 genes were significantly down-regulated in FTY720-treated OC cultures (p<0.001). Mechanistically, FTY720 abrogated RANKL-induced Erk1/2 phosphorylation in OC progenitors. In addition, FTY720 targeted the microenvironment components-MM cells and BMSCs, suppressing the expression of osteoclastogenic factors. mRNA levels of MIP1a, RANTES, MCP-1 and RANKL were significantly reduced in both MM cells (RPMI8226, CAG, OPM-2) and BMSCs upon FTY720 treatment (p<0.001). Moreover, FTY720 altered the ability of myeloma and stroma cells to promote OC formation, and concomitantly FTY720 overcame OC-mediated support and drug resistance of MM cells. Thus, FTY720 was able to disrupt the deleterious cross-talk between the MM tumor cells and the OCs. Next, we evaluated the effect of FTY720 on OC activation *in vivo* taking advantage of our novel xenograft model of CXCR4-overexpressing MM cells that results in typical BM involvement accompanying by significant increase in number of TRAP+ murine OC. Treatment of MM-bearing mice with FTY720 (10 mg/kg) effectively targeted the MM cells in the BM milieu. Correspondingly, FTY720 significantly reduced mRNA levels of murine OC differentiation marker genes in BM, including those encoding cathepsin K, integrin β3, OSCAR, RANTES and RANKL (p<0.001). This effect correlated with increased numbers of circulating CD11c+ and F4/80+ monocytes, with OC precursors in both cell populations. Concomitantly, significantly increased numbers of TRAP+ OCs were generated *in vitro* from PBMCs of FTY720-treated animals in comparison to vehicle-treated controls (p<0.001). To investigate whether OC precursor migration is affected by FTY720, we evaluated the *in vitro* migration of human monocytes toward CXCL12, well-known chemo-attractant of OC precursors. FTY720 completely blocked CXCL12-induced migration of CD14+ cells and significantly reduced their surface CXCR4 expression. These results suggest novel mechanism of action of FTY720, affecting both S1P and CXCR4 pathways, reducing the attachment of the OC precursors to the bone and thus leading to their mobilization to the blood.
Summary and Conclusions: Our observations uncover new roles of S1P pathway in OC formation and activation in MM, delineating a novel mechanism of FTY720 targeting OC formation and migration *in vitro* and *in vivo* and providing preclinical rationale for its therapeutic application in patients with MM bone disease.

P262

PTC-209, A TRANSCRIPTIONAL SMALL MOLECULE INHIBITOR OF BMI-1, DEMONSTRATES POTENT ANTI-MYELOMA ACTIVITY *IN VITRO*

A. Bolomsky[1,*] H. Ludwig[1]
[1]Department of Internal Medicine I, Wilhelminenspital, Wilhelminen Cancer Research Institute, Vienna, Austria

Background: BMI-1 is a putative oncogene reported to be overexpressed in multiple myeloma (MM) compared to normal bone marrow plasma cells. Silencing of BMI-1 was shown to induce apoptosis, to impair proliferation and to sensitize malignant plasma cells to bortezomib. However, therapeutic agents specifically targeting BMI-1 were not available so far.
Aims: Here we investigated PTC-209, a novel transcriptional repressor of BMI-1, for its activity in MM.
Methods: We confirmed overexpression of BMI-1 in MGUS (n=44), SMM (n=12) and MM (n=414) compared to normal BM plasma cells (n=22) in a publically available gene expression dataset (Zhan *et al.*, 2006). Preclinical activity of PTC-209 was analysed in a panel of 8 human MM cell lines (HMCLs) as well as in human umbilical vein endothelial cells (HUVECs) and during osteoblast development.
Results: BMI-1 expression was significantly elevated in all 7 GEP-defined molecular subgroups analysed (median expression value 12409 in MM *vs* 8183 in BM plasma cells, *P*<0.0001). Interestingly, BMI-1 expression was especially increased in the CD2 (median expression value: 15965) and lower in the poor prognostic proliferation (median expression value: 9759) and MMSET (median expression value: 10860) associated molecular subgroups. Treatment with PTC-209 significantly decreased viable cell numbers in MM cells with IC50 values <2 μM in 6 of 8 HMCLs tested (range: 0.21-5.68 μM). The combination of PTC-209 with either pomalidomide or carfilzomib led to additive and synergistic drug activity, especially in the PTC-209 resistant HMCL U266. Mechanistically, PTC-209 induced a G1 cell cycle arrest in MM cells which was accompanied by a significant downregulation of cyclin D1 and MYC as well as upregulation of p16, p21 and p27. Induction of apoptosis was confirmed by Annexin-V/7-AAD staining and increased levels of PARP cleavage. We observed upregulation of NOXA after 5h (up to 3.23±1.06 fold induction at 2.5μM, *P*=0.02) and downregulation of MCL-1 after 20h (up to 0.84±0.07 fold reduction at 1 μM, *P*<0.0001) suggesting that these molecules mediate the apoptotic pathway of PTC-209. Importantly, the pro-apoptotic activity of PTC-209 was upheld in co-

culture of MM cells with BM stromal cells. In the MM microenvironment, PTC-209 impaired tube formation (>90% reduction at 1 μM, *P*<0.0001) of HUVECs in a dose dependent manner. Similarly, PTC-209 led to a dose-dependent decrease of osteoblast formation evidenced by a reduction in alkaline phosphatase activity (62% reduction at 1 μM, *P*<0.0001) and matrix mineralization. The latter might be attributed to the close interaction of BMI-1 and the Wnt signaling pathway. We indeed observed a strong induction of the Wnt signaling inhibitor DKK-1 after treatment of MM cells with PTC-209 for 5h (up to 6.86±3.23 fold induction at 2.5 μM, *P*=0.03).

Summary and Conclusions: Our data reveal therapeutic targeting of BMI-1 by PTC-209 as a promising novel therapeutic intervention for MM. We confirmed overexpression of BMI-1 in MM highlighting its role as attractive drug-target. In line with this, PTC-209 showed potent anti-MM activity in 7 of 8 HMCLs tested. Moreover, PTC-209 demonstrates synergistic activity with pomalidomide and carfilzomib, overcomes BM stromal support, impairs angiogenesis and affects the expression of several prominent "MM-genes" known for their essential role in the proliferation and survival of MM (*e.g. CCND1*, *MYC*, *MCL-1*). Upregulation of *DKK-1* suggests that the osteoblast suppressive effect of PTC-209 might be overcome by concurrent antibody treatment. Further studies will clarify the role of PTC-209 in bone remodelling and corroborate its potent anti-MM activity.

POMALIDOMIDE ENHANCES THE ACTIVATION OF ANTI-MYELOMA SPECIFIC T CELLS IN HEALTHY DONORS AND MULTIPLE MYELOMA PATIENTS

J. Dai[1,*] B. Neuber[1], M. Engelhardt[1], S. Medenhoff[1], M. Schmitt[1], A.D. Ho[1], H. Goldschmidt[1,2], M. Hundemer[1]

[1]Department of Internal Medicine V, University of Heidelberg, Heidelberg, Germany, [2]National Center for Tumor Diseases, University of Heidelberg, Heidelberg, Germany

Background: Pomalidomide is an IMiD® (immunomodulatory drug)that maintain the immune modulating as well as anti-tumor effects similar to the parental compounds thalidomide and lenalidomide. It has been reported to be the most potent IMiD® compoundso far. The immune modulating effects of pomalidomide include activation of NK cells, enhancement of dendritic cell function, and control of regulatory T cells. Pomalidomide has been used in clinic for the treatment of multiple myeloma (MM). However, the exact mechanism of this IMiD® is still unclear.

Aims: The aim of our study was to investigate the immunmodulatory effects of pomalidomide especially on anti-myeloma specific T cells, which are able to recognize and kill the myeloma cells.

Methods: For our study we have applied an *in vitro* model using autologous dendritic cells to facilitate the expansion of antigen-specific T cells against the MM-antigen HM1.24. The expansion of the antigen-specific T cells from 16 healthy donors and 6 patients with plasma cell dyscrasias (symptomatic MM, smoldering MM and monoclonal gammopathy of undetermined significance) were conducted in the presence or absence of pomalidomide. The cells were incubated with pomalidomide for 12 or 21 days. We analysed the number of the anti-myeloma specific T cells by IFN-y ELISpot, and quantified the secretion of granzyme B and IL-6 from the specific T cells by ELISA.

Results: We found that pomalidomide was able to enhance significantly the number of anti-myeloma specific T cells of healthy donors (p ≤.05) and patients with plasma cell dyscrasias (p ≤.05). In addition, a longer duration of the IMiD®-exposure on T cells (21 days *vs* 12 days) induced a higher frequency of the specific T cells. We observed a significantly enhanced secretion of granzyme B in 7 healthy donors (p ≤.05) and in 4 patients with plasma cell dyscrasias (p ≤.05); thus providing evidence for pomalidomide´s effects on cytotoxicity of anti-myeloma specific T cells. Exploring the role of immune modulating cytokines by ELISA, we found that pomalidomide significantly enhanced the IL-6 secretion from anti-myeloma specific T cells of 16 healthy donors (p ≤.05) and 4 patients with plasma cell dyscrasias. Interestingly, the IMiD® lenalidomide has been reported to induce a blockade of IL-6 release. Accordingly, our previous work showed that IL-6 inhibited the activation of anti-tumor specific T cells. However, in the present study, pomalidomide demonstrated an enhancement of IL-6 release from anti-myeloma specific T cells.

Summary and Conclusions: In conclusion, we have provided evidence that pomalidomide was able to enhance activation and cytotoxicity of anti-myeloma specific T cells. In addition, we have defined the role of pomalidomide on the enhancement of IL-6 secretion. This knowledge might explain partly the mechanism of activity of this drug in patients with MM.

P264

LENALIDOMIDE INCREASES HUMAN DENDRITIC CELL MATURATION MODULATING BOTH MONOCYTE DIFFERENTIATION AND MESENCHYMAL STROMAL CELL INHIBITORY PROPERTIES

F. Costa[1,*] M. Bolzoni[1], R. Vescovini[1], D. Toscani[1], F. Accardi[1], P. Storti[1], V. Marchica[1], D. Guasco[1], B. Dalla Palma[1], F. Aversa[1], N. Giuliani[1]

[1]Clinical and Experimental Medicine, Università degli Studi di Parma, Parma, Italy

Background: The immunomodulatory drugs (IMiDs®) have several mechanisms of action including the activation of T lymphocytes and natural killer cells, direct anti-tumor effect on myeloma cells and anti-angiogenic and osteoclastogenic effects. However their use to reverse tumor-mediated immune suppression and amplify multiple myeloma (MM)-specific immunity is currently being explored and particularly the effects of Lenalidomide (LEN) on antigen presenting cells is not yet fully known.

Aims: In order to clarify this issue in this study we investigated the potential effect of LEN on maturation of both human progenitors and mature Dendritic Cells (DCs) and on the immunosuppressive properties of human mesenchymal stromal cells (hMSCs) on DCs.

Methods: DCs were differentiated *in vitro* from $CD14^+$ cells, purified either from peripheral blood (PB) of 6 healthy donors (HDs) or both PB and bone marrow (BM) samples of a cohort of 9 patients with MM including 5 with symptomatic MM and 4 with smoldering MM (SMM). Differentiation of monocyte-derived DCs (mo-DCs) were induced by the treatment with granulocyte macrophage colony-stimulating factor and Interleukin (IL)-4 for 8 days and tumor necrosis factor (TNF) α for the last 24hrs. We added LEN at different concentrations (0,1-2 μM) during all the differentiation period or for the last 48hrs of culture. LEN concentrations were chosen according to the serum levels found in pharmacokinetic studies on patients treated withLEN ranging from 5 mg to 25 mg. At the end of culture period, non-adherent cells were analyzed for DC maturation markers (CD83, HLA-DR, CD80, CD86 and CD209) by flow cytometry. Circulating mature DCs were also obtained by an immunomagnetic kit and treated with LEN for 48hrs. Moreover mo-DC differentiation was performed in the presence of conditioned media (CM) of hMSCs treated for 5 days with LEN (0,1-2μM). The expression of soluble factors involved in DC development was tested in hMSCs treated with LEN for 24hrs by both gene expression profiling (Affymetrix® gene chips) and real time PCR. Finally PB $CD3^+$ cells were *in vitro* activated by ionomycin and phorbol myristic acetate for 72hrs, and then treated with LEN for 48hrs. CM was collected either to measure pro-survival DC cytokine levels or to treat precursors or mature mo-DCs for 48hrs.

Results: LEN treatment induced a reduction of both number and % of mature mo-DC as compared to untreated controls, either in HD's and in patient's samples. On the other hand, LEN treatment significantly increased the median intensity expression of CD86 (LEN 0,1μM *vs* control, *p*=0,008) and CD209 (LEN 0,1μM *vs* control *p*=0.0004) but not of CD80 by mo-DCs derived from BM. This effect was observed either in symptomatic MM or SMM patients but not in HDs. Similarly increased CD209 expression has been also seen in mo-DCs derived from PB (LEN 0,1μM *vs* control *p*=0,0014) in both MM and SMM patients. The possible indirect effect of LEN on DCs was further investigated. Interestingly LEN blunted the inhibitory effect of hMSCs on mo-DC differentiation and down-regulated *IL6* but not *TGFB1*, *IL8*, *TNF* and *HGF* gene expression. Moreover LEN increased the production of the pro-survival DCs factor receptor activator of nuclear factor κB ligand (RANKL) by activated T cells compared to controls.

Summary and Conclusions: LEN reduces the number of DCs but increases the expression of mature DC markers both directly and indirectly, reducing the immunosuppressive properties of hMSCs. These evidences underline a possible new effect of IMiDs® on the alloreactivity against MM cells.

P265

P21-ACTIVATED KINASE 4 (PAK4) REGULATES MULTIPLE MYELOMA (MM) CELL GROWTH AND SURVIVAL BY MODULATION OF CRITICAL TRANSCRIPTIONAL PATHWAYS: THERAPEUTIC APPLICATION OF PAK4 ALLOSTERIC INHIBITORS

M.T. Fulciniti[1,*] S. Oliva[1,2], N. Amodio[3], A. Roccaro[1], R. L. Bandi[1], H. Daisy[1], A. Cagnetta[1], W. Senapedis[4], E. Baloglu[4], K.C. Anderson[1], I. Ghobrial[1], N.C. Munshi[1]

[1]Jerome Lipper Multiple Myeloma Disease Center,, Dana Farber Cancer Instiute, Harvard Medical School, Boston, MA, United States, [2]Myeloma Unit, Division of Hematology, University of Torino, Torino, [3]Departement of experimental and clinical medecine, Magna Graecia University, Salvatore Venuta campus, Catanzaro, Italy, [4]Karyopharm Therapeutics Inc, Newton,MA, United States

Background: PAK4 is a member of p21-activated kinase (PAK) family of serine/threonine kinases. It is activated in cancer cells, where it regulates a wide range of cellular processes including cytoskeleton reorganization, cell proliferation, survival and motility. However, the role of PAK4 in multiple myeloma (MM) is not established yet.

Aims: To investigate the expression and functional role of PAK4 in MM cells and to evaluate impact of orally bioavailable PAK4 allosteric modulators (PAMs) on MM cell growth and survival, providing evidences for a novel therapeutic approach for the treatment of MM

Methods: The expression of PAK4 and phosphorylated(p)-Pak4 Ser474 was assessed by immunoblot analysis. Both gain of-and loss of function studies

were performed to investigate functional and molecular impact of PAK4 on MM cells. Apoptotic cell death was analyzed by flow cytometry following Annexin-V and propidium iodide (PI) staining. Cell proliferation and viability were measured by [3H]-thymidine and CellTiter-Glo (CTG) assays, respectively. TOP/FOP-flash reporter assays were performed to examine B-catenin-mediated TCF/LEF transcriptional activity.
Results: We have demonstrated a differential expression and sub-cellular localization of PAK4 and (p)-Pak4 Ser474 in different multiple myeloma cell lines, primary MM cells and PBMCs. In a gain-of-function study, over-expression of PAK4 in deficient MM cells (RPMI8226 and U266) significantly increased cell proliferation and survival *in vitro* and *in vivo*. Conversely, in a loss-of-function study, conditional knock-down of PAK4 expression decreased MM cell proliferation and survival. With a significant impact of PAK4 on MM cell growth, we identified a class of orally bioavailable PAK4 allosteric modulators (PAMs). We observed inhibition of MM cell growth and survival after treatment with PAMs even in the presence of bone marrow microenvironment with no significant effect on normal PBMCs, suggesting a favorable therapeutic index in MM treatment. Furthermore, time and dose dependent induction of both intrinsic and extrinsic apoptotic pathways and G2/M arrest was observed after treatment with PAMs. Importantly, orally bioavailable PAMs given daily were able to inhibit tumor growth and prolong overall survival *in vivo* in two murine models of human myeloma. PAK4 is a nucleo-cytoplasmic shuttling protein that is imported into the nucleus, promoting TCF/LEF transcriptional activity and leading to B-catenin stabilization. Furthermore, nuclear import of PAK4 accompanies the import of B-catenin and increases TCF/LEF transcriptional activity. TOP/FOP-flash reporter assays were performed to examine whether B-catenin-mediated TCF/LEF transcriptional activity was modulated through PAK4 in myeloma cells. The results showed that PAK4 silencing significantly reduced TCF/LEF transcriptional activity in MM cells, highlighting the vital role that PAK4 plays in mediating the nuclear localization and oncogenic activity of B-catenin. Furthermore, after PAK4 inhibition we also observed a decrease expression levels of two B-catenin targets, cyclin D1 and c-myc, which are known to play a critical role in the myeloma pathobiology.
Summary and Conclusions: PAK4 plays an important cellular and molecular function in myeloma and its inhibition with a new class of PAK4 allosteric modulators provides a novel therapeutic approach for the treatment of MM. Further experiments are ongoing, to clarify the pathway and downstream effectors of PAK4 both in the nucleus and cytoplasm.

P266

BONE MARROW-MEDIATED DRUG RESISTANCE IS PROMOTED BY JAGGED-INDUCED NOTCH PATHWAY IN MULTIPLE MYELOMA

S. Garavelli[1,*] E. Lazzari[1], M. Colombo[1], A. Paoli[1], N. Platonova[1], S. Galletti[2], K. Todoerti[3], A. Neri[2], R. Chiaramonte[1]
[1]Department of Health Sciences, University of Milano, [2]Department of Clinical Sciences, University of Milano, Fondazione IRCCS Policlinico, Milano, [3]Laboratory of Pre-Clinical and Translational Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture, Italy

Background: Multiple myeloma (MM) rapresents 10% of all hematological malignancies and is caused by the accumulation of malignant plasma cells in the bone marrow (BM). Although treatments with new drugs (immunomodulators and proteasome inhibitors) are increasing patients' survival, MM is still incurable because of the development of endogenous or BM mediated drug resistance. Therefore it is crucial to find new therapeutic targets. The dysregulated expression of two Notch ligands, Jagged1 and 2, hyperactivates Notch pathway both in MM cells and in bone marrow stromal cell (BMSC). Several Notch downstream effectors support MM cell growth, survival and proliferation, *i.e.* IL-6, SDF-1alfa, CXCR4, NF-kB, VEGF and IGF.
Aims: The aim of this study was to investigate the role of Notch signaling in endogenous and BMSC-promoted drug resistance in MM.
Methods: U266 and OPM2 MM cell lines were cultured alone in complete RPMI-1640 medium or co-cultured with murine (NIH3T3) or human (HS5) BMSC cell lines in DMEM medium supplemented with 10% V/V FBS. MM cells were either kept in suspension for 24 hours or plated on BMSC monolayer for 24h, then the MM cell lines were treated with drugs (Mitoxantrone, Bortezomib or Melphalan) for additional 24 hours. Apoptosis assay: HS5 cells were stained with PKH26 red fluorescent dye (Sigma-Aldrich) before co-culturing to allowed flow-cytometric detection of MM cells co-cultured with BMSCs. Cells were stained with Annexin V-FITC and processed with Cytomics FC500 software (Beckman Coulter). RNA interference: Silencing of Jagged1 and Jagged2 was obtained by transient expression of two specific siRNAs (Stealth Select RNAiTM siRNA system, Life Technologies). Quantitative PCR reactions were carried out on a 7500 Fast Real-time PCR system (Applied Biosystems) using the MaximaTM SYBR Green/ROX qPCR Master Mix (Dasit). Anti-apoptotic protein such as SDF-1alfa, CXCR4, Bcl-2, Survivin and ABCC1 were analyzed by flow cytometry using appropriate antibodies.
Results: Jagged1 and 2 silencing in OPM-2 and U266 cells is able to reduce the expression of anti-apoptotic genes *i.e.* SDF-1alfa, CXCR4, Bcl-XL, Bcl-2, Survivin and ABCC1. At the same time, MM cells with reduced levels of Jagged1 and 2 showed an increased sensivity to different drugs commonly used in MM therapy such as Bortezomib, Mitoxantrone and Melphalan. We investigated the underlying mechanism showing that MM cells and BMSC interaction resulted in the activation of Notch signaling in both cell types. When co-coltured with human or murine BMSCs, we observed that MM cells showed increased drug resistance due to: first of all, an increased expression of anti-apoptotic genes in MM cells among which SDF-1alfa, CXCR4, Bcl-XL, Bcl-2, Survivin and ABCC1; secondary, BMSC release of soluble factors, *i.e.* SDF-1alfa and VEGF, relevant for MM cell growth and survival. Interestingly, Jagged1 and 2 silencing in MM cells could reverse all gene and protein expression changes and BMSC protective effect. All these results were confirmed both at gene expression and protein level.
Summary and Conclusions: The evidence that Jagged-1 and 2 silencing affect endogenous and BMSC-induced drug resistance in MM cells supports the use of a Jagged-targeted approach in MM therapy alone or in a combination with common drugs.

Maria della Misericordia Hospital, Institute of Nuclear Medicine, Udine, Italy, [13]German Cancer Center, Department of Nuclear Medicine, [14]German Cancer Center, Department of Radiology, Heidelberg, Germany

Background: The probability of progression of smoldering multiple myeloma (SMM) into symptomatic disease (MM) is highly variable and therefore the identification of sub-groups of patients (pts) at different risk of progression is a relevant end point. FDG-PET/CT is a reliable technique for assessing early skeletal involvement and the presence of osteolytic lesions identified by this imaging technique has been recently incorporated in the updated criteria for the diagnosis of MM. However, no data are available regarding the impact of PET/CT FLs in the absence of underlying osteolyses in SMM on time to progression (TTP) into MM.
Aims: To address this issue, we prospectively studied a cohort of 120 pts with SMM with PET/CT.
Methods: By study design, all the pts were studied with PET/CT at presentation of the disease. Bone marrow involvement was described as negative, diffuse or focal. The number of FLs, as well as size and associated standardized uptake values (SUV) were recorded. For each FL, the presence of eventual underlying osteolytic lesion was investigated by the CT part of the scan; pts with osteolytic lesions were excluded from the study, as they were considered as having MM. Laboratory follow-up took place every 3-4 months. Skeletal progression was defined by the appearance of one or more sites of osteolytic bone destruction, pathological fractures and/or soft masses at PET/CT or MRI. The start of systemic therapy was defined as the date of event for the analysis of TTP.
Results: Baseline patient characteristics were as follows: median age 61 years, IgG isotype 73%, median M component 2.4 g/dL, ISS stage I 77%, median bone marrow plasma cell (BMPC) 27%, median serum involved/uninvolved FLC ratio 14.27. PET/CT was negative in 101/120 pts (84%) and positive in 19/120 (16%) of them; 8 pts had 1 FLs, 3 pt 2 FLs, 6 pts more than 3 FLs and 2 pt a diffuse bone marrow involvement. Median SUV max value was 4.7 (range 2.5-10.7). BMPC was significantly superior for patients with positive PET/CT (p=0.024). In 91 pts a baseline axial or WB-MRI was available as well and resulted positive in 27% of them. Ten per cent, 11% and 13% of the pts were having more than 60% BMPC, FLC ratio ≥100 and more than 1MRI FL, respectively. With a median follow-up of 2.2 years, 62% of the pts remained in the asymptomatic phase while 38% of them progressed to MM, in a median time of 4 years, including 21% with skeleton involvement, with/without the appearance of other CRAB symptoms, and 17% with exclusive serological signs of progression. The relative risk of progression of the pts with a positive PET/CT was 3.00 (95% CI 1.58-5.69, P=0.001). Moreover, the relative risk of skeletal progression was 4.44 (95% CI 1.97-10.02, P<0.001), with a median TTP of 2.2 years for pts with positive PET/CT *vs* 7 years for those with negative PET/CT (Figure 1). The probability of progression within 2 and 3 years for pts with positive PET/CT was 58% and 66%, respectively, *vs* 33% and 42% for negative pts. Results did not significantly differ after pts with early MM according to the updated criteria were excluded from the analysis. A multinomial logistic regression analysis showed that PET positivity was significantly related to progression with skeletal involvement while BMPC superior than 60% to the exclusive serological one.

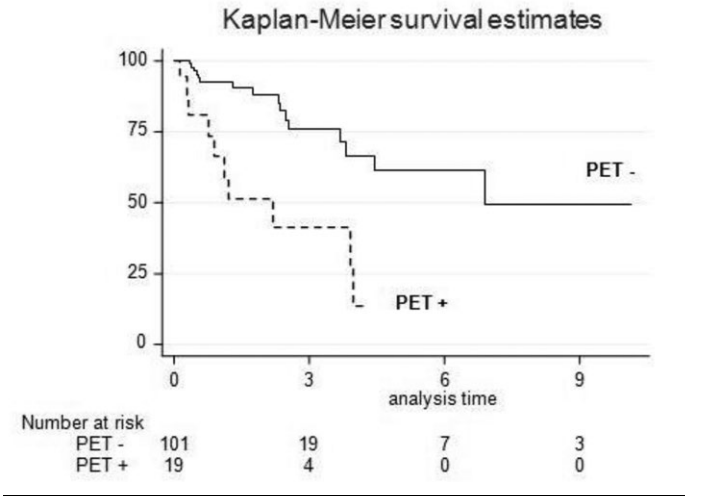

Figure 1.

Summary and Conclusions: In conclusion, approximately 16% of the pts with SMM have a positive PET/CT, mainly with few FLs, with a low FDG uptake. PET/CT positivity significantly increased the risk of progression of SMM into MM. PET/CT could become a new risk factor to define high risk SMM. Further studies are warranted to find and optimal cut off point of FLs and/or SUVmax to capture the higher risk of progression at 2 year and to merge with other prognostic factors.

P268

ANALYSIS OF OUTCOMES BY RESPONSE FOR PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA IN THE PHASE 3 PANORAMA 1 STUDY OF PANOBINOSTAT OR PLACEBO PLUS BORTEZOMIB AND DEXAMETHASONE

P. Moreau[1,*] J. San-Miguel[2], V. Hungria[3], S.S. Yoon[4], M. Beksac[5], M. Dimopoulos[6], A. Elghandour[7], W. Jedrzejczak[8], A. Guenther[9], T. Na Nakorn[10], N. Siritanaratkul[11], R. Schlossman[12], J. Hou[13], S. Lonial[14], J.H. Lee[15], H. Einsele[16], M. Sopala[17], B.-R. Bengoudifa[17], C. Corrado[17], P. Richardson[12]

Background: Panobinostat (PAN) is the first pan-deacetylase inhibitor (pan-DACi) to demonstrate a statistically significant and clinically relevant increase in median progression-free survival (PFS) in a phase 3 clinical trial of patients (pts) with relapsed or relapsed and refractory multiple myeloma (MM). In the PANORAMA 1 trial, pts randomized to receive PAN + bortezomib (BTZ) and dexamethasone (Dex; PAN-BTZ-Dex) demonstrated a median PFS of 12.0 months *vs* 8.1 months for pts who received placebo (Pbo) + BTZ and Dex (Pbo-BTZ-Dex; hazard ratio [HR], 0.63; *P*<.0001).
Aims: To determine the effect of clinical outcomes based on the level of response achieved.
Methods: Overall response rate, including rate of near complete/complete response (nCR/CR) and partial response (PR) per modified European Society for Blood and Marrow Transplantation (mEBMT) and stringent CR (sCR)/CR/very good PR (VGPR) per International Myeloma Working Group (IMWG) and duration of response (DOR) were analyzed. A landmark analysis at 6, 12, 18, and 24 weeks by response status using a Cox regression model was conducted to determine PFS in pts who achieved nCR/CR *vs* PR per mEBMT or sCR/CR/VGPR *vs* PR as per IMWG criteria.
Results: The rate of nCR/CR was significantly higher for PAN-BTZ-Dex *vs* Pbo-BTZ-Dex (27.6% *vs* 15.7%; nominal *P*=.00006). Per IMWG criteria, the rate of sCR/CR/VGPR was also higher for the PAN-BTZ-Dex arm (36% *vs* 24%; nominal *P*=.00001). The DOR per mEBMT criteria for pts with nCR/CR, ≥PR, and PR was 18.4, 13.1, and 9.0 months, respectively, in the PAN-BTZ-Dex arm and 14.5, 10.9, and 8.8 months, respectively, in the Pbo-BTZ-Dex arm. The landmark analysis by mEBMT and IMWG criteria is shown in the Table. At the 12-week landmark, a median PFS of 16.5 months was observed

for pts with CR/nCR and 10.3 months for pts with PR in the PAN-BTZ-Dex arm (hazard ratio [HR], 0.40; 95% CI, 0.25-0.65) and a median PFS of 14.1 months for pts with CR/nCR and 9.7 months for pts with PR in the Pbo-BTZ-Dex arm (HR, 0.62; 95% CI, 0.36-1.07). By IMWG criteria, the landmark analysis at 12 weeks demonstrated a median PFS of 15.9 months for pts with ≥VGPR and 8.1 months for pts with PR in the PAN-BTZ-Dex arm (HR, 0.36; 95% CI, 0.21-0.62) and a median PFS of 14.4 months for pts with ≥VGPR and 7.6 months for pts with PR in the Pbo-BTZ-Dex arm (HR, 0.39; 95% CI, 0.22-0.68).

Tabella 1. Landmark Analysis of Progression-Free Survival

Modified EBMT Criteria			
Landmark time	Number of responses at landmark time: ≥ nCR/PR	Median PFS at landmark time: ≥ nCR/PR, months	HR (95% CI)
6 weeks			
PAN-BTZ-Dex	12/57	Not estimable/12.6	0.33 (0.12-0.89)
Pbo-BTZ-Dex	3/57	15.8/10.2	0.85 (0.19-3.90)
12 weeks			
PAN-BTZ-Dex	49/107	16.5/10.3	0.40 (0.25-0.65)
Pbo-BTZ-Dex	23/122	14.1/9.7	0.62 (0.36-1.07)
18 weeks			
PAN-BTZ-Dex	76/104	16.5/10.9	0.43 (0.29-0.65)
Pbo-BTZ-Dex	41/126	14.6/10.4	0.54 (0.35-0.82)
24 weeks			
PAN-BTZ-Dex	84/96	19.0/12.0	0.40 (0.27-0.59)
Pbo-BTZ-Dex	46/112	14.9/11.8	0.57 (0.38-0.87)
IMWG Criteria			
Landmark time	Number of responses at landmark time: ≥ VGPR/PR	Median PFS at landmark time: ≥ VGPR/PR, months	HR (95% CI)
6 weeks			
PAN-BTZ-Dex	12/36	16.5/6.9	0.29 (0.08-1.03)
Pbo-BTZ-Dex	8/28	Not estimable/7.6	0.35 (0.10-1.22)
12 weeks			
PAN-BTZ-Dex	57/52	15.9/8.1	0.36 (0.21-0.62)
Pbo-BTZ-Dex	32/74	14.4/7.6	0.39 (0.22-0.68)
18 weeks			
PAN-BTZ-Dex	82/51	16.5/8.8	0.33 (0.21-0.52)
Pbo-BTZ-Dex	62/71	13.1/9.5	0.50 (0.33-0.75)
24 weeks			
PAN-BTZ-Dex	93/47	17.0/9.5	0.31 (0.20-0.49)
Pbo-BTZ-Dex	69/58	13.4/11.2	0.60 (0.39-0.92)

Summary and Conclusions: A higher proportion of deep responses (≥nCR or ≥VGPR) was achieved with PAN-BTZ-Dex, and the DOR was longer and was associated with a prolonged PFS. Results were consistent by mEBMT or IMWG. Overall, these data further support achievement of deeper responses as a treatment goal in pts with relapsed/refractory MM.

P269

WEEKLY CARFILZOMIB WITH DEXAMETHASONE FOR PATIENTS WITH RELAPSED OR REFRACTORY MULTIPLE MYELOMA: UPDATED RESULTS FROM THE PHASE 1/2 STUDY CHAMPION-1 (NCT01677858)

J. Berenson[1,*] A. Cartmell[2], R. M. Lyons[3], W. Harb[4], D. Tzachanis[5], R. Boccia[6], R.M. Rifkin[7], P. Patel[8], S. Dixon[8], J. Berdeja[9]
[1]Institute for Myeloma & Bone Cancer Research, Los Angeles, [2]Comprehensive Blood and Cancer Center, Bakersfield, [3]US Oncology and Cancer Care Centers of South Texas, San Antonio, [4]Horizon Oncology Center, Lafayette, [5]Cedars-Sinai Medical Center, Los Angeles, [6]Center for Cancer and Blood Disorders, Bethesda, [7]US Oncology Research Inc., Denver, [8]Onyx Pharmaceuticals, Inc., an Amgen subsidiary, South San Francisco, [9]Sarah Cannon Research Institute, Nashville, United States

Background: Carfilzomib is a selective proteasome inhibitor that is approved in the United States for the treatment of relapsed and refractory multiple myeloma. The approved dosing schedule for carfilzomib is a 2–10 minute IV infusion on days 1, 2, 8, 9, 15, and 16 of a 28-day cycle (starting dose: 20mg/m^2 [cycle 1]; escalated to a target dose of 27mg/m^2 in cycle 2).
Aims: Herein we present updated results from a multicenter, single-arm, phase 1/2 study (CHAMPION-1; NCT01677858) evaluating the safety and efficacy of weekly carfilzomib with dexamethasone (Kd) in patients with relapsed or refractory multiple myeloma (RRMM).
Methods: Patients who received 1−3 prior regimens were eligible. All patients provided informed consent. In the phase 1 portion, patients received carfilzomib as a 30-min IV infusion on days 1, 8, and 15 of a 28-day cycle using a 3+3 dose-escalation scheme. All patients received carfilzomib at 20 mg/m^2 on day 1 of cycle 1; subsequent dose cohorts received 45, 56, 70, or 88 mg/m^2 in successive cohorts until the maximum tolerated dose (MTD) was reached for use in the phase 2 portion of the study. Patients received dexamethasone 40 mg (IV or oral administration) on days 1, 8, 15, and 22 of cycles 1–8; dexamethasone was omitted on day 22 in cycles ≥9. In the phase 2 portion, patients are receiving carfilzomib at the recommended dose from the phase 1 portion (carfilzomib dose of 20 mg/m^2 on cycle 1, day 1 escalating to the MTD for subsequent doses) with the same dose and schedule for dexamethasone. Kd is being administered until disease progression or unacceptable toxicity.
Results: Results are presented for patients treated at the MTD (70 mg/m^2) in the phase 1b and phase 2 portions of the study. As of January 7, 2015, 104 patients (phase 1, n=15; phase 2, n=89 patients) were enrolled at the MTD; the study is fully enrolled. Median patient age was 68.5 years (range, 41–88). Patients received a median of 1prior regimen (range, 1–3); 48% of patients had received 2 or more prior regimens. A total of 82% of patients had received prior bortezomib (BTZ), 48% of patients were BTZrefractory, 28% were lenalidomide (LEN) refractory, and 16% were refractory to BTZ and LEN. Preliminary median carfilzomib treatment duration was 5.3 months (range, 0.03–18.8). The overall response rate (≥partial response) was 72% (95% confidence interval [CI]: 63%–81%); the clinical benefit rate (≥minimal response) was 80% (95% CI: 71%–87%). Kaplan-Meier median PFS was 10.6 months (95% CI: 7.2–not estimable). Seven patients (7%) discontinued treatment due to an adverse event (AE). The most common hematologic AEs (all grade) were anemia (24%), thrombocytopenia (18%), and neutropenia (8%). The most common nonhematologic AEs (all grade) were fatigue (48%), nausea (32%), and insomnia (30%). The most common grade ≥3 hematologic AEs were thrombocytopenia (6%), anemia (5%), and neutropenia (4%). The most common grade ≥3 nonhematologic AEs were fatigue (9%), dyspnea (6%), and back pain (6%). Four patients died on study: 1 patient had sepsis, respiratory distress, pneumonia, and acute renal failure; and 1 patient each had acute renal failure, cardiopulmonary arrest, and disease progression.
Summary and Conclusions: At the MTD (70 mg/m^2), weekly Kd is demonstrating acceptable safety and tolerability with promising efficacy in patients with RRMM. Updated results will be presented at the meeting.

P270

EARLY MORTALITY IN ELDERLY NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS TREATED WITH NOVEL AGENTS: A POOLED ANALYSIS OF TWO LARGE RANDOMIZED PHASE III TRIALS

A. Larocca[1,*] S. Bringhen[1], M.T. Petrucci[2], M. Offidani[2], L. De Paoli[2], G. Pietrantuono[2], L. Baldini[2], T. Guglielmelli[2], V. Magarotto[1], M. Cantonetti[2], A. Nozza[2], A. Evangelista[3], S. Spada[1], N. Giuliani[2], M. Grasso[2], R. Marasca[2], V. Montefusco[2], I. Vincelli[2], F. Morabito[2], C. Nozzoli[2], L. De Rosa[2], M. Cavalli[2], A.M. Carella[2], R. Hajek[4], M. Boccadoro[1], A. Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Turin, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, [3]Unit of Clinical Epidemiology, Azienda Ospedaliero-Universitaria Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, [4]Faculty of Medicine, University of Ostrava and Department of Haematooncology, University Hospital Ostrava, Ostrava, Czech Republic

Background: Early mortality in elderly multiple myeloma (MM) patients is usually attributed to combined effects of active disease and co-morbid factors. Before the introduction of novel agents, toxic deaths within 60 days from start of conventional treatment occurred in 10% of patients (Augustson BM. J Clin Oncol 2005, 36:9219), mainly due to infection and renal failure. The use of novel agents has considerably improved MM outcome at the expense of newer toxicity.
Aims: The aim of this analysis is to study early deaths not related to disease progression during treatments with lenalidomide or bortezomib. We analyzed individual patient data from two large multicenter randomized trials to assess the rate and the causes of death, their predictability and whether current management strategies have reduced their frequency.
Methods: A total of 1,173 newly diagnosed MM patients ineligible for autologous transplantation due to age or co-morbidities enrolled in the Gruppo Italiano Malattie EMatologiche dell'Adulto (GIMEMA) and European Myeloma Network (EMN) trials from May 2006 to September 2012, were studied. Patients in the GIMEMA MM-03-05 trial (N=511) received bortezomib-containing regimens (Palumbo A. J Clin Oncol 2014, 32:634) and those in the EMN01 trial (N=662) lenalidomide-containing regimens (Magarotto V. Blood 2014, abs ASH).
Results: A total of 1146 patients could be evaluated for this analysis. Within 24 months from start of therapy, 207/1146 patients (18%) died for any causes, 61/1146 (5%) died due to adverse events. Toxic deaths within 60 days occurred in 12 patients (1%) with a linear increase over time of 1% every 6 months (Figure 1). There was no difference in the incidence of toxic deaths between patients receiving bortezomib-containing regimens (31 pts, 6%) and those receiving lenalidomide-containing regimens (30 pts, 5%, p=0.32). The incidence of toxic deaths was significantly higher in patients older than 80 years (11/107 [10%], p=0.005). Twenty-nine percent of deaths were attributable to cardiac complications (18 pts), 18% to infections (17 pts) and 15% to vascular complications (9 pts). By comparing the cause of toxic deaths between the 2 different treatment regimes, there was no significant difference in the proportions of cardiac events, infections, vascular events or other causes. In a multivariate analysis, age (HR 1.09 per 1 year increase, p=0.002) and ISS score (HR 3.81, p=0.01 ISS 2 *vs* ISS 1; HR 5.69, p=0.002 ISS 3 *vs* ISS 1) did increase the risk of death but poor performance status did not (HR 1.25, p=0.59). Greater tumor burden and activity (ISS) increased the risk of death because such deaths occurred before the maximal beneficial effect of therapy in reducing tumor load: 92% of patients dying from toxicity within 2 months of start of therapy had achieved a suboptimal response (8 not available, 3 SD, 1 PR, ORR 8%).

	2	6	12	18	24
Toxicity	1.1(0.5 to 1.6)	1.9(1.1 to 2.6)	3.4(2.3 to 4.5)	4.7(3.5 to 6)	5.4(4 to 6.7)
Other	0.6(0.2 to 1.1)	2(1.1 to 2.8)	4.8(3.5 to 6.1)	8.7(7 to 10.4)	13.2(11.2 to 15.3)

Figure 1. Cumulative incidence of death due to AEs or due to any other causes

Summary and Conclusions: Novel, more effective and more rapid therapies have reduced the risk of toxic deaths as compared to conventional treatments. Nevertheless one-third of early deaths occurred primarily due to cumulative specific drug-related toxicities. Improvement in supportive therapy together with prevention and prompt recognition/treatment of complications are urgently needed to reduce the risk of toxic deaths. The 2-fold higher risk of toxic mortality in octogenarians indicates the need for a careful assessment of frail patients who may benefit from a gentle or even palliative approach.

P271

MAINTENANCE THERAPY WITH LENALIDOMIDE IN ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: A POST-HOC ANALYSIS OF THE EMN01 TRIAL

V. Magarotto[1,*] S. Bringhen[1], M. Offidani[2], G. Benevolo[2], F. Patriarca[2], C. Palladino[1], A.P. Falcone[2], D. Rossi[2], O. Villani[2], C. Musolino[2], C. Conticello[2], S. Pulini[2], P. Omedè[1], R. Zambello[2], T. Guglielmelli[2], A. Ledda[2], A.M. Liberati[2], R. Hajek[3], M. Boccadoro[1], A. Palumbo[1]
[1]Myeloma Unit, Division of Hematology, University of Torino, Torino, [2]Italian Multiple Myeloma Network, GIMEMA, Italy, [3]Faculty of Medicine, University of Ostrava and Department of Haematooncology, University Hospital Ostrava, Ostrava, Czech Republic

Background: Lenalidomide maintenance showed to be effective in terms of progression free survival (PFS) in patients with newly diagnosed multiple myeloma (NDMM) ≥65 years or not eligible for autologous stem cell transplantation. Recently, the geriatric assessment has emerged as a fundamental strategy to evaluate patients' frailty and consequently to select the most appropriate treatment for elderly MM patients [Palumbo A, *et al.* Blood. 2015].
Aims: In a post-hoc analysis, we classified patients enrolled in the EMN01 trial according to the new geriatric assessment in order to evaluate safety and efficacy of Lenalidomide-containing maintenance in fit, unfit and frail NDMM patients.
Methods: In the EMN01 phase III trial, patients with NDMM were randomized to receive induction treatment with Lenalidomide-dexamethasone or Melphalan-Prednisone-Lenalidomide or Cyclophosphamide-Prednisone-Lenalidomide. After induction, patients were randomized to receive maintenance with Lenalidomide alone (10 mg on days 1-21 in 28-day cycles) or plus Prednisone (25 mg every other day in 28-day cycles), until disease progression or intolerance. The geriatric assessment was performed and included age, comorbidities (according to Charlson Comorbidity index), Activity of daily living and Instrumental Activity of Daily Living scores.
Results: Six-hundred-forty-three patients started induction treatment. Patients were classified as fit (n=280), unfit (n=202) and frail (n=161). During induction, 30 patients (11%) discontinued treatment due to adverse events (AEs) in the fit group and 38 patients (23%) in the frail group (p=0.0006). Deaths not related to progressive disease were 4 in the fit group (mainly due to stroke [n=2]) and 17 in the frail group (mainly due to cardiologic AEs [n=7] and infections [n=3]). Four-hundred-two patients started maintenance treatment: 192 in the fit, 121 in the unfit, and 89 in the frail groups. During maintenance, at least one grade ≥3 hematologic AE was reported in 24 patients (13%) in the fit and 13 patients (15%) in the frail groups. At least one grade ≥3 non-hematologic AE was recorded in 12 patients (6%) in the fit and 12 patients (13%) in the frail groups (p=0.04), and were mainly cardiologic AEs and infections. After a median follow-up of 30 months since the beginning of maintenance, median PFS was 24 months in fit and 27 months in frail patients (HR=1.136, CI 0.808-1.596, p=0.464). Median overall survival (OS) was not reached; at 24 months, OS was 90% in fit and 76% in frail patients (HR 2.804, CI 1.665-4.723, p=0.0001). In the frail group, 101 patients (63%) did not reduce any drug doses during induction, and 49 (49%) of them started maintenance; whereas 60 patients (37%) reduced drug doses during induction, and 40 (67%) of them started maintenance. The difference between the two groups of frail patients who began maintenance was statistically significant (P=0.02).
Summary and Conclusions: The benefit of maintenance therapy in frail patients is controversial. Frail patients who reduced doses at induction tolerated therapy better and had a higher probability to start maintenance. Therefore, an induction treatment tailored to the frailty status allows a higher number of patients to complete induction, and to start and benefit from lenalidomide maintenance.

P272

OUTCOMES FOR OLDER PATIENTS WITH REFRACTORY OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA TREATED WITH POMALIDOMIDE + LOW-DOSE DEXAMETHASONE IN THE STRATUS (MM-010) TRIAL, A SINGLE-ARM, PHASE 3B STUDY

A. Palumbo[1,*] P. Moreau[2], M.A. Dimopoulos[3], P. Corradini[4], M. Cavo[5], M. Delforge[6], K.C. Weisel[7], H. Goldschmidt[8], M. Petrini[9], M. F. Kaiser[10], A. Slaughter[11], M. Simcock[11], J. Herring[12], T. Peluso[11], L. Sternas[12], M. Zaki[12], E.M. Ocio[13]
[1]University of Torino, Torino, Italy, [2]University Hospital Hôtel-Dieu, Nantes, France, [3]National and Kapodistrian University of Athens, Athens, Greece, [4]Fondazione IRCCS Istituto Nazionale Tumori, University of Milano, Milano, [5]Bologna University School of Medicine, Bologna, Italy, [6]University Hospital Leuven, Leuven, Belgium, [7]University Hospital Tübingen, Tübingen, [8]German Cancer Research Center, University Hospital Heidelberg, Heidelberg, Germany, [9]University of Pisa, Pisa, Italy, [10]The Royal Marsden Hospital, Surrey, United Kingdom, [11]Celgene International Sàrl, Boudry, Switzerland, [12]Celgene Corporation, Summit, United States, [13]Hospital Universitario de Salamanca. Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain

Background: The survival of patients (pts) with multiple myeloma (MM) decreases with increased age (Pulte et al, *Oncologist*, 2011), and those with advanced disease who have exhausted treatment (Tx) options with newer agents have a poor prognosis (Kumar et al, *Leukemia*, 2012). The oral agent pomalidomide (POM) has anti-myeloma, stromal cell inhibitory, and immune modulatory effects (Quach et al, *Leukemia*, 2010; Mark et al, *Leuk Res*, 2014). In the pivotal MM-003 trial, Tx with POM + low-dose dexamethasone (LoDEX) prolonged progression-free survival (PFS) and overall survival (OS) *vs* high-dose DEX and had a tolerable safety profile in pts with refractory or relapsed and refractory MM (RRMM; San Miguel et al, *Lancet Oncol,* 2013). In MM-003 and in the pivotal phase 2 trial, MM-002, Tx with POM + LoDEX provided significant PFS and OS benefits across various age groups; tolerability and dose intensity were unaffected by age (Weisel et al, *Blood,* 2013; Jagannath et al, *J Clin Oncol*, 2013).
Aims: STRATUS is a multicenter, single-arm, open-label, European phase 3b trial designed to further evaluate safety and efficacy of POM + LoDEX in a large pt population. This analysis examined pt outcomes by age (≤65 *vs* >65 yrs and ≤70 *vs* >70 yrs).
Methods: RRMM pts with progressive disease (PD) during or within 60 days of their last line of Tx (refractory to their last prior Tx) were included. Other eligibility criteria included age ≥18 yrs, measurable M-protein in serum or urine, lenalidomide and bortezomib failure after ≥2 consecutive cycles of each (alone or in combination), and adequate prior alkylator therapy. Pts with absolute neutrophil count <800/μL, platelets <75,000 or <30,000/μL for pts in whom <50% or ≥50% of bone marrow nucleated cells were plasma cells, respectively, or creatinine clearance <45 mL/min were excluded. Pts received POM 4 mg D1-21 + LoDEX 40 mg (20 mg for pts aged >75 yrs) D1, 8, 15, and 22 of a 28-day cycle until PD or unacceptable toxicity. Thromboprophylaxis was required for all pts. Primary endpoint was safety; key secondary endpoints included overall response rate (ORR; ≥partial response), duration of response (DOR), PFS, and POM exposure. Outcomes were analyzed by pt age at baseline (≤65 *vs* >65 yrs and ≤70 *vs* >70 yrs).
Results: As of Sep 15, 2014, 604 pts have been enrolled. 599 received POM + LoDEX; 46% were ≤65 yrs, 54% were >65 yrs, 69% were ≤70 yrs, and 31% were >70 yrs. Pts were heavily pretreated (median 4-5 prior Tx). Median follow-up was 9.3 mos. Median relative dose intensity was similar independent of pt age (range, 0.93-0.94). The most frequent grade (Gr) 3/4 treatment-emergent adverse events (TEAEs) across age groups were neutropenia, anemia, thrombocytopenia, and infections (Table). Discontinuation of POM due to TEAEs was infrequent in pts aged ≤65 (7%), >65 (11%), ≤70 (7%), and >70 (14%) yrs. ORRs ranged between 32% and 38% for all age groups. Median PFS was also similar, regardless of age (4.1-4.7 mos; Table). Updated data will be presented at the congress.

Tabella 1. Safety and Efficacy Outcomes

Parameter	≤ 65 yrs (n = 274)	> 65 yrs (n = 325)	≤ 70 yrs (n = 415)	> 70 yrs (n = 184)
Grade 3/4 hematologic TEAEs in ≥ 10% of pts, %

Median PFS, mos	4.2	4.2	4.1	4.7

[a] Includes the preferred terms deep vein thrombosis and pulmonary embolism; [b] Includes the preferred terms neuropathy peripheral, peripheral sensory neuropathy, paresthesia, hypoesthesia, polyneuropathy, peripheral motor neuropathy, peripheral sensorimotor neuropathy, and dysesthesia.

DOR, duration of response; ORR, overall response rate; PFS, progression-free survival; pt, patient; TEAE, treatment-emergent adverse event; VTE, venous thromboembolic event.

Summary and Conclusions: The results show that POM + LoDEX is efficacious and tolerable in RRMM pts regardless of age (≤65 *vs* >65 yrs and ≤70 *vs* >70 yrs). Across the age groups, the safety profile and relative dose intensity were similar. PFS and response rates were also similar and consistent with previous findings. The data support the use of 4 mg of POM as an effective starting dose, and the use of POM + LoDEX, regardless of age, in RRMM pts.

P273

THE STRATUS (MM-010) TRIAL: A SINGLE-ARM, PHASE 3B STUDY EVALUATING SAFETY AND EFFICACY OF POMALIDOMIDE + LOW-DOSE DEXAMETHASONE IN PATIENTS WITH REFRACTORY OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA

M.A. Dimopoulos[1,*] A. Palumbo[2], P. Corradini[3], M. Cavo[4], M. Delforge[5], K. Weisel[6], E. Ocio[7], F. Di Raimondo[8], A. Oriol[9], M. Simcock[10], N. Miller[10], A. Slaughter[10], T. Peluso[10], L. Sternas[11], M. Zaki[11], P. Moreau[12]

[1]National and Kapodistrian University of Athens, Athens, Greece, [2]University of Torino, Torino, [3]Fondazione IRCCS Istituto Nazionale de Tumori, Milano, [4]Bologna University School of Medicine, Bologna, Italy, [5]University Hospital Leuven, Leuven, Belgium, [6]University Hospital of Tuebingen, Tuebingen, Germany, [7]Hospital Universitario de Salamanca & Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain, [8]University of Catania, Catania, Italy, [9]Institut Català d'Oncologia, Hospital Germans Trias i Pujol, Barcelona, Spain, [10]Celgene International Sàrl, Boudry, Switzerland, [11]Celgene Corporation, Summit, United States, [12]University Hospital Hotel-Dieu, Nantes, France

Background: Survival outcomes of patients (pts) with relapsed/refractory multiple myeloma (RRMM) have improved with introduction of newer agents (Kumar, *Leukemia*, 2014). However, there are few effective treatment (Tx) options for pts with RRMM who failed Tx with bortezomib (BORT) and lenalidomide (LEN). As a result, these pts have shortened overall survival (OS; Kumar, *Leukemia,* 2012). Pomalidomide (POM) is a distinct oral immunomodulatory agent with direct anti-myeloma, stromal cell inhibitory, and immune modulatory effects (Quach, *Leukemia,* 2010; Mark, *Leuk Res*, 2014). Pivotal trials demonstrated higher overall response rates (ORRs) with POM + low-dose dexamethasone (LoDEX) *vs* POM alone and significantly extended PFS and OS *vs* high-dose DEX (San Miguel, *Lancet Oncol*, 2013; Richardson, *Blood*, 2014). Refractoriness to LEN and/or BORT (including LEN as last prior Tx) did not affect outcomes with POM + LoDEX.

Aims: STRATUS is a multicentre, single-arm, open-label, phase 3b trial designed to further evaluate safety and efficacy of POM + LoDEX in RRMM pts.

Methods: Pts with refractory or relapsed and refractory disease (progressive disease [PD] on or within 60 days of last prior Tx), prior BORT and LEN Tx failure, and adequate prior alkylator therapy were eligible. Pts with absolute neutrophil count <800/μL, platelets <75,000 or <30,000/μL (for pts with <50% or ≥50% of bone marrow nucleated cells as plasma cells, respectively), creatinine clearance <45 mL/min, hemoglobin <8 g/dL, and peripheral neuropathy (PN) grade (Gr) ≥2 were excluded. POM 4 mg was administered D1-21 of a 28-day cycle in combination with LoDEX 40 mg/day for pts aged ≤75 yrs or 20 mg for pts aged >75 yrs on D1, 8, 15, 22 until PD or unacceptable toxicity. Thromboprophylaxis was required for all pts. Follow-up continued for Tx, OS, and second primary malignancy until 5 yrs post-enrollment. Primary endpoint was safety, and key secondary endpoints included ORR (≥partial response), duration of response (DOR), PFS, OS, POM exposure, and cytogenetic analyses. STRATUS is registered with ClinicalTrials.gov (NCT01712789) and EudraCT (2012-001888-78).

Results: As of Sep 15, 2014, 604 pts were enrolled. Median age was 66 yrs (range, 37-88); median time since initial diagnosis was 5.2 yrs (range, 0.5-27.1). Pts were heavily pretreated with a median of 5 prior Tx (range, 2-18); 95% of patients were LEN refractory, and 78% were refractory to both LEN and BORT. Median follow-up was 9.3 mos. The most frequent Gr 3/4 Tx-emergent adverse events (TEAEs) were hematologic, including neutropenia (42%), anemia (29%), and thrombocytopenia (22%); Gr 3/4 non-hematological toxicities included pneumonia (11%) and fatigue (5%). Gr 3/4 venous thromboembolic events were infrequent (1%), and Gr 3/4 PN was 1%. 5% of pts withdrew due to adverse events. Median PFS and OS were 4.2 and 11.9 mos, respectively (Figure). ORR was 35%; 7% pts achieved ≥very good partial response, and 1% achieved a complete response. Median DOR was 6.8 mos. In pts refractory to prior LEN or LEN and BORT, similar PFS (4.2 and 4.1 mos), OS (12 mos each), and ORR (34% and 35%) were observed. Updated data will be presented at the congress.

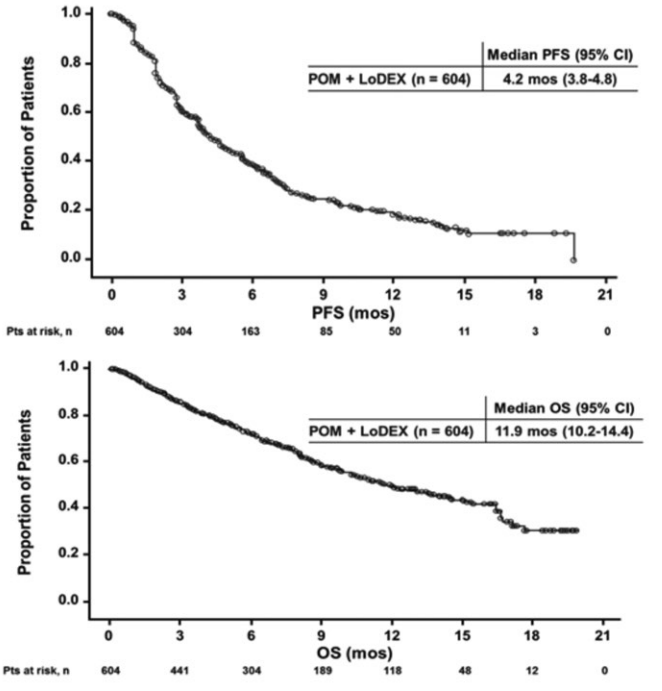

Figure 1.

Summary and Conclusions: Safety and efficacy of POM + LoDEX in the STRATUS trial was consistent with results from pivotal trials of POM + LoDEX. Efficacy outcomes were similar regardless of prior refractoriness to LEN, BORT, or LEN + BORT. This study confirms previous analyses demonstrating that POM + LoDEX is a standard of care for RRMM pts in whom LEN and BORT Tx has failed.

P274

IMPACT OF RENAL IMPAIRMENT ON OUTCOMES AFTER TREATMENT WITH LENALIDOMIDE AND LOW-DOSE DEXAMETHASONE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA: FIRST TRIAL RESULTS

Background: Renal impairment (RI) is reported in ≈ 20% to 40% of patients (pts) with multiple myeloma (MM) at diagnosis and is associated with a negative

impact on survival (Rajkumar, *Mayo Clin Proc,* 2005). The pivotal phase 3 FIRST trial represents the largest data set in transplant-ineligible newly diagnosed MM (NDMM) pts with various levels of RI. In this pt population, continuous lenalidomide plus low-dose dexamethasone (Rd continuous) improved progression-free survival (PFS; HR =0.72; *P* <0.01) and provided an overall survival (OS) benefit (HR =0.78; *P* =0.02) *vs* melphalan-prednisone-thalidomide (MPT; Benboubker, *N Engl J Med,* 2014).

Aims: This subanalysis was conducted to determine the impact of RI on PFS, OS, and time to second anti-myeloma Tx (AMT) in NDMM pts treated with Rd continuous or MPT.

Methods: NDMM pts ineligible for transplant were randomized to 3 Tx arms: Rd continuous until progression (n =535); Rd for 18 cycles (Rd18; 72 weeks; n =541); or MPT for 12 cycles (72 weeks; n =547). Enrolled pts were categorized according to their renal function; pts requiring dialysis were excluded. The starting dose of lenalidomide was modified based on renal function: 25 mg once daily (QD) for normal renal function (creatinine clearance [CrCl] ≥80 mL/min) or mild RI (CrCl ≥50 and <80 mL/min), 10 mg QD for moderate RI (CrCl ≥30 and <50 mL/min), and 15 mg QD for severe RI (CrCl <30 mL/min). The melphalan dose was reduced by 50% in pts with moderate or severe RI. The primary endpoint was PFS in pts treated with Rd continuous *vs* MPT. Secondary endpoints included OS, time to second AMT, safety, and improvement in renal function. Improvement in renal function was defined as a positive shift in renal function subgroup from baseline to the most extreme post-baseline CrCl value during active Tx. Renal response as defined by IMWG criteria (Dimopoulos, *J Clin Oncol*, 2010) was also assessed to show similar results across both CrCl and estimated glomerular filtration rate (eGFR).

Results: The median follow-up was 37 mos (data cutoff, May 24, 2013). PFS benefit was seen with Rd continuous *vs* MPT (HR =0.66-0.76) or Rd18 (HR =0.66-0.82) in all RI groups. OS results showed a benefit of Rd continuous *vs* MPT (HR =0.59-0.81) or Rd18 (HR =0.74-0.88) in all groups except severe RI (HR =1.03 *vs* MPT and 1.31 *vs* Rd18). Rd continuous compared with MPT extended time to second AMT in all renal groups (HR =0.54-0.83). Improvement in renal function was observed across all Tx groups, but appeared greater in pts treated with Rd continuous than those treated with Rd18 or MPT. Per IMWG criteria 24%, 28%, and 20% of pts had a renal response with Rd continuous, Rd18, and MPT Tx, respectively. Rate of complete renal response was 20.0% with Rd continuous, 27.4% with Rd18, and 14.3% with MPT. Most common grade 3/4 adverse events for these Tx were anemia, neutropenia, and thrombocytopenia.

Tabella 1. PFS, Interim OS, and Time to Second AMT in Renal Subgroups

	Normal Renal Function[a] (CrCl ≥ 80 mL/min) n (%) = 389 (24)	Mild RI[a] (CrCl ≥ 50 and < 80 mL/min) n (%) = 715 (44)	Moderate RI[a] (CrCl ≥ 30 and < 50 mL/min) n (%) = 372 (23)	Severe RI[a] (CrCl < 30 mL/min) n (%) = 147 (9)

Rd continuous vs Rd18	0.79 *P* = 0.22	0.79 *P* = 0.07	0.56 *P* < 0.01	0.98 *P* = 0.95
Rd18 vs MPT	0.88 *P* = 0.46	0.84 *P* = 0.16	0.92 *P* = 0.62	0.94 *P* = 0.80

[a] According to Cockroft-Gault formula.

[b] Nominal *P* values are presented for multiplicity assessments, which need to be taken into consideration before making clinical interpretations.

Summary and Conclusions: PFS, interim OS, and time to second AMT outcomes generally improved across all Tx groups in pts with normal renal function and those with mild or moderate RI. Rd continuous was well tolerated, with a consistent safety profile across renal subgroups. Renal function also improved more in pts treated with Rd continuous *vs* Rd18 or MPT. Results of this analysis support the use of Rd in NDMM pts in most RI subgroups.

P275

AN OPEN-LABEL, MULTICENTER, PHASE 1B STUDY OF DARATUMUMAB IN COMBINATION WITH POMALIDOMIDE-DEXAMETHASONE AND WITH BACKBONE REGIMENS IN PATIENTS WITH MULTIPLE MYELOMA

M.V. Mateos[1,*] P. Moreau[2], R. Comenzo[3], J. Bladé[4], L. Benboubker[5], J. de la Rubia[6], T. Facon[7], J. Fay[8], X. Qin[9], T. Masterson[9], J. Schecter[10], T. Ahmadi[9], J. San-Miguel[11]

[1]University Hospital of Salamanca/IBSAL, Salamanca, Spain, [2]University Hospital of Nantes, Nantes, France, [3]Division of Hematology-Oncology, Tufts Medical Center, Boston, MA, United States, [4]IDIBAPS, Hospital Clinic de Barcelona, Barcelona, Spain, [5]CHU Tours Hopital Bretonneau, Tours, France, [6]Doctor Peset and Universidad Católica "San Vicente Mártir", Valencia, Spain, [7]Centre Hospitalier Régional Universitaire de Lille, Lille, France, [8]Baylor Institute for Immunology Research, Dallas, TX, [9]Janssen Pharmaceutical Research & Development, Spring House, PA, [10]Janssen Pharmaceutical Research & Development, Raritan, NJ, United States, [11]Clinica Universidad de Navarra, Navarra, Spain

Background: Daratumumab (DARA) a human anti-CD38 IgG1κ MAb has shown robust, durable, single agent activity with deep responses and favorable safety in patients with multiple myeloma (MM) relapsed from or refractory (RR) to ≥2 prior therapy lines as well as in combination with lenalidomide (LEN) and dexamethasone (D) in relapsed or RRMM.

Aims: This ongoing open-label, 4-arm, multicenter, phase 1b study (NCT01998971) evaluated the safety and tolerability of DARA combined with pomalidomide (POM)-D and three backbone MM treatments: bortezomib (V)-D, V-thalidomide(T)-D, V-melphalan (M)-prednisone (P).

Methods: Patients (up to 100) in the DARA+POM-D arm were RR to ≥2 lines of therapy including 2 consecutive cycles of LEN and V. Newly diagnosed patients were included in the DARA+VD (n=6) and DARA+VTD (n=12) arms (irrespective of transplant eligibility) and DARA+VMP arm (transplant ineligible; n=12). Patients received DARA 16 mg/kg and approved label or standard of care of each treatment: POM-D (DARA qw, 2 cycles; q2w, 4 cycles; q4w remaining cycles); VD and VTD (DARA qw, 2 cycles; q3w, 16 cycles); VMP (DARA qw, 1 cycle; q3w, 8 cycles). Data were evaluated by an independent data safety monitoring board.

Results: Data from 49 patients with RRMM (DARA+POM-D [n=24]) and newly diagnosed MM (DARA+VD [n=6], DARA+VTD [n=11], DARA+VMP [n=8]) are presented. Median (range) durations of follow-up in days: DARA+POM-D, 29 (1-286); DARA+VD, 193 (151-218); DARA+VTD, 164 (9-274); DARA+VMP, 267 (63-295). There was little additional toxicity when DARA was added other than DARA-specific infusion related reactions (24/49 patients). Most occurred on Cycle 1 Day 1 and were mainly grade 1/2 (3/53 grade 3, no grade 4). All infusions were completed except 1 discontinuation (grade 3 hypoxia possibly DARA-related). Median (range) numbers of DARA infusions were: DARA+POM-D, 4 (1-20); DARA+VD, 13 (8-15); DARA+VTD, 8 (2-13); DARA+VMP, 16 (6-18). Other adverse events (AEs) were consistent with the non-DARA agents. 6 patients had serious AEs: pneumonia (n=3; possibly DARA-related; 1 likely POM-related), indirect Coombs test interference (n=1; DARA-related), and 1 each of non-DARA-related soft tissue infection, diarrhoea, pre-renal failure, hyperviscosity syndrome, cardiac failure, mental status change. The most common AEs were hematologic toxicity, likely related to POM or backbone therapies. Study discontinuations were 3 in the DARA+POM-D arm (death after disease progression [PD], physician decision, disease progression) and 1 in the DARA+VD arm (death; neutropenic sepsis, 60 d post-ASCT). Patients were not on study treatment at time of death. Efficacy dataset (n=35) had >1 post-baseline assessment: DARA+POM-D (n=11); DARA+VD (n=6); DARA+VTD (n=10); DARA+VMP (n=8). The overall response rates were 54.5% in the DARA+POM-D arm and 100% in the newly diagnosed groups. Responses deepened with continued treatment. In the DARA+POM-D arm there were 2 stringent complete responses, 1 very good partial response (VGPR), 3 partial responses (PR), 2 minimal responses, 2 stable disease, and 1 PD. In the DARA+VD arm there were 3 VGPRs and 3 PRs and in the DARA+VTD arm there was 1 complete response, 2 VGPRs and 7 PRs. In the DARA+VMP arm there were 4 VGPRs and 4 PRs. Median (range) times to first responses in days were: DARA+POM-D, 31 (29-57); DARA+VD, 23.5 (22-44); DARA+VTD, 22 (21-43); DARA+VMP, 22.5 (22-135).

Summary and Conclusions: DARA plus POM-D or with backbone MM therapies was well tolerated, with little significant additional toxicity, encouraging efficacy and deepening responses.

P276

OUTCOMES OF PATIENTS WITH PRIMARY REFRACTORY MULTIPLE MYELOMA IN THE ERA OF NOVEL THERAPIES

N. Majithia[1,*] S.V. Rajkumar[2], A. Dispenzieri[2], M. Gertz[2], M. Lacy[2], B. Francis[2], S. Hayman[2], D. Dingli[2], L. Hwa[2], J. Lust[2], S. Russell[3], P. Kapoor[2], R. Go[2], R. Kyle[2], S. Kumar[2]

[1]Internal Medicine, [2]Hematology, [3]Molecular Medicine, Mayo Clinic, Rochester, United States

Background: With the introduction of new drugs and use of multidrug combinations, lack of initial response to therapy in patients with newly diagnosed multiple myeloma (NDMM) has decreased considerably. Previous studies have shown that high dose therapy, in those eligible, is able to overcome resistance to conventional drugs, though long-term outcomes remain inferior among the rest of the patients. It is not clear if the outcomes of patients with primary refractory disease have changed with uniform introduction of newer therapies.
Aims: We performed this retrospective review to compare outcomes of patients with primary refractory multiple myeloma with outcomes of primary responders, specifically in the era of novel therapies. We also sought to identify characteristics predisposing to primary refractory disease.
Methods: We identified 816 patients with NDMM who started treatment after January 1, 2006, were seen at Mayo Clinic within 30 days of initiating treatment, and in whom details of the initial treatment regimen were available. Only patients who had consented to participation in research were included, and the study was performed with the approval of the Mayo Clinic IRB.
Results: The median age of the study cohort was 67 years; 59% were male. The median estimated follow up for the entire group was 4.3 years; 41% had died at the time of the analysis. The median overall survival (OS) for the entire group was 5.7 years from the beginning of treatment. Either a proteasome inhibitor or an IMiD was part of the initial induction therapy in 84% patients, with both an IMiD and a proteasome inhibitor combination used in 9%. The remaining 7% received steroid-based treatment, in most cases along with melphalan or cyclophosphamide. Response could be assessed in 669 (82%) patients, with a PR or better seen in 557 (83%) patients. Primary refractory disease (SD or progression) was seen in 112 patients (17%) overall, and was seen in 16% of those receiving a novel agent compared with 28% of those not receiving a novel agent (P <0.01). The median OS from start of therapy was significantly shorter for the primary refractory group at 3.6 years (95% CI 2.8-4.8) compared with 7.6 years (95% CI 6-8.6) for the responding patients (P <0.001). In a multivariable analysis including age >65 years, ISS stage 3, abnormal LDH, BMPC% >60%, PCLI >1%, serum creatinine >=2 mg/dL, high-risk FISH and primary refractoriness, only primary refractory disease, age >65, high-risk FISH and high LDH were independently prognostic for OS. Other than the lack of use of a novel agent, only a high-risk FISH was associated with primary refractoriness.

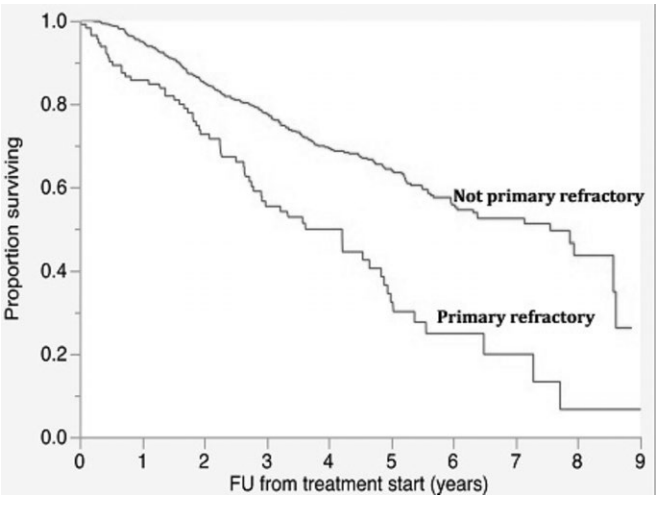

Figure 1.

Summary and Conclusions: In the current era, primary refractoriness to induction therapy with proteasome inhibitor or IMiD containing regimens is associated with significantly inferior outcomes among patients with NDMM. These patients, when identified, should be studied in clinical trials specifically designed for this high-risk condition.

Multiple myeloma - Clinical 2

Background: Treatment (Tx) with melphalan, prednisone, and thalidomide (MPT) is a standard option for patients (pts) with newly diagnosed multiple myeloma (NDMM) who are ineligible for autologous stem cell transplant (SCT; Facon, *Lancet Oncol*, 2007; Fayers, *Blood*, 2011; NCCN Guidelines, Multiple Myeloma, V3.2015). The pivotal phase 3 FIRST trial assessed the efficacy of lenalidomide plus low-dose dexamethasone administered until disease progression or unacceptable toxicity (Rd continuous) *vs* Rd for 18 cycles (Rd18) and MPT in pts with NDMM ineligible for SCT. Rd continuous improved overall survival (OS), progression-free survival (PFS), and response rate *vs* MPT (Benboubker, *N Engl J Med,* 2014).
Aims: This analysis examined PFS and OS in pts treated with Rd continuous *vs* MPT and Rd18 by quality of response (ie, ≥very good partial response [VGPR]).
Methods: Pts with symptomatic NDMM who were not candidates for SCT were randomized 1:1:1 to Tx with Rd continuous (n =535), Rd18 (n =541), or MPT for 12 cycles (72 weeks; n =547). The primary endpoint was PFS. Secondary endpoints included OS, response rate (as assessed by International Myeloma Working Group criteria), time to response, duration of response (DOR), time to Tx failure, time to next antimyeloma Tx, health-related quality of life, and safety.
Results: As of the data cutoff date of May 24, 2013 for the final PFS analysis, the median follow-up was 37.0 mos. In pts who achieved a complete response (CR), greater benefit was observed with Rd continuous compared with MPT or Rd18 (Table); median PFS with Rd continuous was not reached *vs* 44.6 mos with MPT (HR =0.28; *P* <0.01) and 45.2 mos with Rd18 (hazard ratio [HR] =0.29; *P* <0.01). For pts who achieved ≥VGPR, PFS with Rd continuous (NR) was longer than with MPT (34.7 mos; HR =0.55; *P* <0.01) or Rd18 (31.0 mos; HR =0.46; *P* <0.01). Across all response categories (including CR), pts treated with Rd continuous *vs* MPT or Rd18 achieved longer DOR. The DOR in pts who achieved ≥partial response in the intent-to-treat population was 35 mos with Rd continuous, nearly a year longer than the DOR observed with MPT (22.3 mos; HR =0.63; *P* <0.01) or Rd18 (22.1 mos; HR =0.60; *P* <0.01). Pts who achieved a CR with Rd continuous had a longer DOR than whose who achieved a CR with Rd18 (NR *vs* 43.6 mos; HR =0.29; *P* <0.01), and results were similar for pts who achieved ≥VGPR (NR *vs* 29.9 mos; HR =0.46; *P* <0.01). A higher proportion of pts who achieved a CR were progression-free after 36 mos with Rd continuous (88%) *vs* Rd18 (55%) or MPT (62%). OS data for pts treated with Rd continuous *vs* MPT or Rd18 showed no significant differences by response.

Tabella 1.

PFS and DOR in Pts With NDMM	CR (n = 209)	≥ VGPR (n = 618)	≥ PR (n = 1140)	≤ SD (n = 483)	ITT (N = 1623)

CR, complete response; DOR, duration of response; HR, hazard ratio; ITT, intent-to-treat; MPT, melphalan, prednisone, and thalidomide; NR, not reached; PFS, progression-free survival; PR, partial response; Rd, lenalidomide plus low-dose dexamethasone; Rd18, lenalidomide plus low-dose dexamethasone for 18 cycles; SD, stable disease; VGPR, very good partial response.

Summary and Conclusions: For all responders, PFS and DOR were longer in pts treated with Rd continuous *vs* MPT or Rd18. The benefits of Rd continuous were more pronounced in pts who achieved a greater depth of response (≥VGPR). These data suggest that continuing Tx after achieving best response aids in delaying disease progression, particularly for those pts achieving a VGPR or CR. Longer follow-up may be required to assess the impact of continuous treatment on OS for good responders in pts receiving Rd continuous *vs* MPT or Rd18.

LACK OF RESPONSE IMPROVEMENT BEYOND DAY +100 AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN ABSENCE OF MAINTENANCE THERAPY IN MULTIPLE MYELOMA

C. Fernández De Larrea[1,*] J. Dávila[2], I. Isola[1], E. M. Ocio[2], L. Rosiñol[1], R. García-Sanz[2], M.T. Cibeira[1], N. Tovar[1], M. Rovira[1], M. V. Mateos[2], J. San Miguel[3], J. Bladé[1]

[1]Amyloidosis and Myeloma Unit. Department of Hematology, Hospital Clinic. IDIBAPS, Barcelona, [2]Hospital Universitario de Salamanca, Instituto de Investigación Biomédica de Salamanca (IBSAL), Centro de Investigacion del Cancer (IBMCC-USAL, CSIC), Salamanca, [3]Clínica Universitaria de Navarra, Centro de Investigación Médica Aplicada (CIMA), Pamplona, Spain

Background: Patients with multiple myeloma (MM) achieving complete remission (CR) have a significant longer survival than patients who obtain less than CR. This is particularly established after high-dose chemotherapy followed by autologous stem-cell transplantation (ASCT). The response evaluation is usually done at day +100 after ASCT. Of interest, recent observations have shown that improvement in the response can be observed beyond day +100 after ASCT and that these late responders would have a better outcome than patients without this improvement.
Aims: The objective of the present study has been to evaluate the rate and outcome of patients who improve their response beyond day +100 after ASCT, with and without maintenance therapy.
Methods: One hundred and forty-four patients (63M/81F, median age 55 years; range 29 to 69) from Hospital Clínic de Barcelona (90) and Hospital Universitario de Salamanca (54) who underwent ASCT with melphalan-based conditioning between October 1992 and November 2013 were studied. The entry criteria were: 1) chemosensitive disease at the time of ASCT, 2) have received single ASCT, 3) less than CR at day 100 post-ASCT, and 4) minimum follow-up of one year. Medical records of all patients were reviewed. Responses were determined at 3, 6, 9 and 12 months after ASCT, according to the EBMT criteria. 27 (18.8%) of the patients had extramedullary disease at diagnosis.
Results: At day +100 post ASCT, 52.1% of the patients had achieved partial response (PR), 39.6% very good partial response (VGPR) and 8.3% were in minimal response. After a median follow-up of 66 months, the median OS for the whole series was 6.8 years (IC 95% 4.5 to 9) and the median PFS was 2.9 years (IC 95% 2.4 to 3.4). There were no significant differences in outcome between the two centers. Seventy four patients (51.4%) did not receive any maintenance and only one of them showed any upgrade in her response. This patient improved their response from VGPR to CR beyond 100 days after ASCT. The remaining 70 patients (48.6%) received maintenance therapy, mainly interferon (53; 36.8%), with glucocorticoids in 29 cases (20.1%); thalidomide (4.9%) or thalidomide plus bortezomib (6.9%). Twelve patients (8.3%), improved response beyond day +100 after ASCT: five of them with interferon (two associated with glucocorticoids), 4 bortezomib plus thalidomide and 2 single agent thalidomide. The outcome of these patients was better than those who did not upgrade their response in terms of PFS and OS (p=0.024 and p=0.01, respectively).
Summary and Conclusions: A minority of patients receiving maintenance therapy after ASCT upgrades their response and this finding is associated with better outcome. In contrast with previously published data, in our series the improvement in response beyond day +100 after ASCT in patients non receiving maintenance therapy is exceedingly rare. This fact must be taken into account when making treatment decisions based on the response status after ASCT.

P279

RICOLINOSTAT (ACY-1215) THE FIRST SELECTIVE HDAC6 INHIBITOR IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED & REFRACTORY MULTIPLE MYELOMA: PHASE 1B & EARLY PHASE 2 RESULTS

N. Raje[1,*] W. Bensinger[2], D. Lebovic[3], S. Lonial[4], S. Jagannath[5], C. Acre-Lara[6], A. Rosko[7], W. Harb[8], N. Bahlis[9], J. Supko[1], D. Tamang[10], S. Jones[10], C. Wheeler[10], P. Richardson[11]

[1]Massachusetts General Hospital, Boston, [2]University of Washington, Seattle, [3]University of Michigan, Ann Arbor, [4]Emory University, Atlanta, [5]Mount Sinai Hospital, New York City, [6]Medical College of Wisconsin, Milwaukee, [7]Ohio State University, Columbus, [8]Horizon Oncology Center, Lafayette, United States, [9]Tom Baker Cancer Center, Calgary, Canada, [10]Acetylon Pharmaceuticals Inc., [11]Dana Farber Cancer Institute, Boston, United States

Background: Ricolinostat, an oral selective HDAC6 inhibitor, is well tolerated as monotherapy (Raje *Blood* 2012;120:4061) and demonstrates potent synergistic activity with lenalidomide (Len) and pomalidomide (Pom) in preclinical models (Quayle *Blood* 2013;122:1952). Pan-HDAC inhibitors vorinostat (Dimopoulos *Lancet Oncology* 2013;14:1129-40) and panobinostat (San-Miguel *Lancet Oncology* 2014;15:1195-206) are active in multiple myeloma (MM) in combination with bortezomib (Btz) and Len, but have toxicities (thrombocytopenia, fatigue, and gastrointestinal events) which limit dosing exposure. Ricolinostat, in combination with Len and dexamethasone (Dex) demonstrates clinical activity and a manageable safety profile at doses up to 160 mg twice daily (BID) for 21 consecutive days (Yee *Blood* 2014;124:4772).
Aims: ACE-MM-102 is a phase 1b/2 trial in relapsed and refractory MM patients who have received at least two cycles of a proteasome inhibitor and Len containing regimen and who have progressed on or within 60 days of the last therapy.
Methods: Phase 1b was a 3+3 design which explored ricolinostat 160 mg daily (QD) orBID combined with Pom (4 mg) for 21 days of a 28 day cycle with Dex (40 mg) on days 1, 8, 15 and 22. Patients had measurable disease, adequate bone marrow reserve and hepatic function with creatinine clearance >45 mL/min. Patients with non-secretory MM, prior Pom or HDAC inhibitor therapy were excluded. Bone marrow cytogenetics were obtained at entry. Peripheral blood samples were obtained for pharmacokinetic (PK) and pharmacodynamic (PD) assessment of acetylated tubulin and histones. Patients with serum free light chain-only disease were excluded from phase 2.
Results: 7 patients were treated in phase 1b: 3 at 160 mgQD and 4 at 160 mgBID. Median age was 66 and the majority received >3 lines of prior therapy. No dose limiting toxicities (DLTs) were observed. At 160 mg QD, 1 patient had grade 3 fatigue and 1 patient had grade 3 neutropenia both attributed to Pom. In the 160 mgBID cohort, all 4 patients had grade 2 diarrhea and 2 of 4 patients had grade 4 neutropenia attributed to Pom. 1 patient continues on study after 10 cycles; the other 6 phase 1b patients were withdrawn for progressive disease at 2-4 cycles. Following safety review committee (SRC) review, phase 2 opened at a dose of 160 mg BID, with SRC review to occur after 6 patients had completed one cycle of therapy. 3 of the 6 patients had grade 3 diarrhea requiring ricolinostat dose reduction in cycle 2. Other treatment emergent toxicities included fatigue, neutropenia, hypertension, thrombocytopenia and anemia that were mostly low grade. Although no DLTs were observed, reduction of the dose from 160 mgBID toQD for ongoing and future patients was recommended to maintain treatment at a therapeutic exposure for as long as possible. PK of ricolinostat was similar to that observed in combination with Btz and Len. There was no evidence of ricolinostat accumulation or drug-drug interaction with Pom.As of February 2015, 27 patients have been enrolled in phase 2; 11 were dose reduced toQD after initial 160 mgBID dosing and 16 started at 160 mg QD. 6 patients have withdrawn due to progressive disease (2), low-grade AEs (2), physician decision (1) or patient decision (1). 21 phase 2 patients remain on study after a median of 2 (1-5) cycles.
Summary and Conclusions: Ricolinostatappears well tolerated and can be safely administered in combination with Pom and Dex in patients with relapsed and refractory MM.Updated safety, PK, PD and preliminary clinical activity data will be presented as phase 2 enrollment continues.

PROGRESSION-FREE SURVIVAL 2 (PFS2) IS THE MOST SIGNIFICANT PROGNOSTIC FACTOR OF LONG-TERM SURVIVAL IN THE ERA OF NOVEL AGENTS: A SINGLE GREEK MYELOMA CENTER EXPERIENCE

E. Katodritou[1,2,*] S. Papadaki[1], G. Polychronidou[1], N. Spyridis[1], N. Karabatzakis[1], A. Pentidou[1], S. Palaska[1], K. Kokoviadou[2], E. Vlachaki[2], D. Markala[2], E. Yiannaki[2], V. Perifanis[2], E. Verrou[1], V. Gastari[1], P. Konstantinidou[1], E. Terpos[2]

[1]Hematology, Theagenion Cancer Center, Thessaloniki, [2]Greek Myeloma Study Group, Athens, Greece

Background: The term "long-term survivor" (LTS) in Oncology refers to patients alive for more than 10 years and according to published studies conducted before the use of novel agents, 3-4% of Multiple myeloma (MM) patients belong to this group. The current literature include very limited data regarding LTS in the era of novel agents.
Aims: The aim of this study was to described the incidence, disease characteristics and prognostic factors of LTS MM patients.
Methods: We checked the database of a single Greek myeloma center for the presence of LTS. Pearson's χ^2test, Mann-Whitney *U* test, and One-way ANOVA were used for comparisons; $p<0.05$ was considered statistically significant. Progression Free Survival (PFS) was estimated from the time of MM diagnosis until progression or death from any cause; OS was estimated from the time of MM diagnosis until the last follow up or death; PFS2 was defined as the time from MM diagnosis to second objective disease progression, or death from any cause whichever first. Prognostic factors for LTS were determined with a cox regression model.
Results: Among 648 consecutive MM patients diagnosed and treated between 1989-2013, we identified 50 LTS (7.7%; M/F: 23/27, median age: 65 years,

range: 47-72 years). LTS were younger and most of them presented with ISS stage I/II compared to all others who served as controls (p<0.001). In addition, LTS had higher hemoglobin, lower creatinine and lower β2 microglobulin at diagnosis compared to controls (p<0.05). Bence Jones proteinuria and immunoparesis at diagnosis presented less frequently in LTS; recovery of immunoparesis after 1st line treatment was more common in LTS (p<0.05); 72% of LTS received novel agent-based combinations (NAC) during the course of MM. The number of patients treated with NAC and the response rate after 1st line therapy, did not differ between LTS and the control group; LTS received more frequently autologous transplantation at 1st line, NAC at 2nd line and IMiD-based regimens at any line, compared to controls (p<0.05). After a median follow up of 12 years (range: 2-180 months), 28/50 LTS *vs* 84/598 MM patients were alive (p<0.001); 13 LTS patients died from MM and 9 patients died from irrelevant causes. The median PFS and OS for LTS *vs* controls was 81 months (95% CI: 56-105) *vs* 17 months (95% CI: 15-19) and 200 months (95% CI: 180-219) *vs* 33 months (95% CI: 30-36), respectively (p<0.05). In the univariate analysis PFS, PFS2, period of diagnosis (*i.e.* before or after 2000), 1st line treatment, 2nd line treatment and treatment at any line with conventional therapy *vs* NAC were independent predictors of long-term survival (p<0.05). Baseline disease characteristics or quality of response did not predict for LTS. In the multivariate analysis, PFS2 was the only positive predictor for long-term survival (p<0.001; HzR: 0.98. 95% CI: 0.96-0.99); 28% of patients with PFS2 ≥4 years were alive after 10 years compared to 0.2% of those with PFS2 <4 years.

Summary and Conclusions: The percentage of LTS has increased in the era of novel agents. LTS present with more favorable disease characteristics at diagnosis compared to other MM patients, but none of those predicted for long-term survival. PFS2 proved to be the most significant prognostic factor of long-term survival, whereas quality of response failed to show a prognostic value, suggesting that disease control during the initial phase of MM, where sensitive clones still prevail and there is no drug resistance, should be the main goal of the treatment strategy. Finally, 1/3 of patients who displayed disease control of ≥4 years after 2 treatment lines, enjoyed a long-term survival and most importantly, more than 20% of them could be considered as "cured" from MM, challenging the dogma of incurable disease.

P281

OBESITY AND RISK OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE: A POPULATION-BASED STUDY

M. Thordardottir[1,*] E. Lindqvist[2], S.H. Lund[1], R. Costello[3], D. Burton[3], N. Korde[4], S. Mailankody[3], G. Eiriksdottir[5], L.J. Launer[6], V. Gudnason[1,5], T.B. Harris[6], O. Landgren[2,4], S.Y. Kristinsson[1,2]

[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [2]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [3]Multiple Myeloma Section, National Cancer Institute, National Institute of Health, Bethesda, MD, [4]Myeloma Service, Division of Hematologic Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, United States, [5]Icelandic Heart Association, Kopavogur, Iceland, [6]National Institute on Aging, National Institute of Health, Bethesda, MD, United States

Background: All multiple myeloma (MM) cases are preceded by the premalignant state, monoclonal gammopathy of undetermined significance (MGUS), an asymptomatic condition that needs no treatment. The etiology of MGUS and MM is to a large extent unknown. Two studies on the association between obesity and MGUS have been conducted with conflicting results, despite a reported association between obesity and MM.

Aims: The aim of this study was to determine if obesity is associated with an increased risk of MGUS and light-chain MGUS (LC-MGUS) in a population-based screened cohort of individuals above the age of 65 years using extensive number of markers for current and early life obesity. Secondly, the aim was to examine whether progression to MM was affected by obesity.

Methods: This study was based on participants from the Age, Gene/Environment Susceptibility-Reykjavik Study (AGES-RS), consisting of 5764 men and women above the age of 65 years. Serum protein electrophoresis (SPEP) and serum free light-chain assay were performed on all subjects to identify MGUS and LC-MGUS. Obesity measures were performed at baseline, and participants were additionally asked about their weight at the age of 55 and 25 years and their lifetime max weight. The measures at baseline included were weight (kg), body mass index (BMI) (kg/m^2), percent body fat, fat (kg), fat-free mass (kg), waist circumference (cm), total body fat area (cm^2), and visceral and subcutaneous fat area (cm^2). Weight was measured using a digital scale and height using a stadiometer, measures were performed multiple times and a mean number found. Percent body fat, fat and fat free mass were calculated from bioelectric impedance, a commonly used method for estimating body composition. Computed tomography imaging of the abdomen was performed to calculate total body fat area, visceral fat area, subcutaneous fat area, and abdominal circumference. Abdominal circumference was additionally measured multiple times and a mean number found. The participants were followed prospectively until 2013 and information on MM diagnosis was collected through hospitals, nursing homes, and mortality records. The association with MGUS and LC-MGUS was analyzed using logistic regression and Cox proportional-hazard regression was performed to test whether progression to MM was affected by obesity. Adjustment was made for age and gender.

Results: A total of 299 (5.2%) MGUS cases and 33 (0.6%) LC-MGUS cases were identified. No association was found between any of the obesity markers and MGUS or LC-MGUS. Results for MGUS, presented as OR with 95% CI, were: $BMI_{baseline}$ 0.99 (0.97-1.02), BMI_{55y} 1.01 (0.97-1.05), BMI_{25y} 0.99 (0.94-1.04), weight 1.00 (0.99-1.01), max weight 1.00 (0.99-1.01), percent body fat 0.99 (0.97-1.02), fat 1.00 (0.98-1.02), fat free mass 1.00 (0.98-1.02), total body fat 1.00 (1.00-1.00), visceral fat 1.00 (1.00-1.00), subcutaneous fat 1.00 (1.00-1.00), CT waist circumference 1.00 (0.99-1.01), and measured waist circumference 1.00 (0.99-1.01). BMI ≥25 at the age of 55 affected MM progression (HR 3.20; 95% CI 1.15-8.88) (Table).

*Effect of obesity on MGUS. Logistic regression, adjusted for age and gender

^{L}Effect of obesity on LC-MGUS. Logistic regression, adjusted for age and gender

¶Effect of obesity on progression from MGUS to MM. Cox survival analysis, adjusted for age and gender

Abbreviations: BMI - Body Mass Index, OR - Odds Ratio, HR - Hazard Ratio, CI - Confidence Interval.

Summary and Conclusions: In this large population-based cross-sectional study aimed at evaluating the association between obesity and MGUS, we did not find an association between several obesity markers and MGUS or LC-MGUS. However, BMI ≥25 at the age of 55 years seemed to affect progression from MGUS to MM. Future studies are needed to clarify underlying mechanisms for this finding. Taken together, we were unable to confirm the previously reported association between MGUS and obesity.

P282

POST AUTOLOGOUS STEM CELL TRANSPLANTATION MAINTENANCE IN MULTIPLE MYELOMA. SINGLE CENTER EXPERIENCE OF 18 YEARS: A MARKED SURVIVAL ADVANTAGE WITH INTERFERON

G. Varga[1,*] D. Lévai[1], P. Reményi[2], G. Mikala[2], M. Réti[2], L. Gopcsa[2], Á. Bátai[2], Z. Csukly[2], L. Lengyel[2], É. Torbágyi[2], A. Barta[2], J. Fábián[2], T. Masszi[1,2]

[1]Haematology, 3rd Department of Internal Medicine, Semmelweis University, [2]Department of Haematology and Stem Cell Transplantation, St. Istvan and St. Laszlo Hospital, Budapest, Hungary

Background: Interferon (IFN) maintenance was widely used in multiple myeloma (MM) during the 90s and early 2000s but then was mostly abandoned. The reasons of its decline were side effects, trials showing only marginal or no benefit and the emergence of new, highly effective drugs. However maintenance still has a very significant role in MM, and in this setting, drugs modulating the immune system play the most important part.

Aims: To study the effect of maintennce on post ASCT survival we analyzed the outcome of post-ASCT maintenance in 548 MM patients transplanted in our centre over 18 years.

Methods: Progression free survival (PFS) was calculated from the day of ASCT and overall survival (OS) from the first chemotherapy. The analyses were carried out using the SPSS (version 20.0) software package.

Results: 93 (17%) patients had IFN, 127 (23.2%) thalidomide (thal) at the discretion of the treating physician. 42 (7.7%) had both drugs as maintenance for a period of time mostly subsequently, but sometimes parallel. Maintenance strategies changed over the years. Between 2001 and 2008 half of the patients had maintenance. IFN was used from 1998 to 2011, but the majority of the patients had it between 2002 and 2008. Thal was increasingly used from 2000 until 2008, and then it was only occasionally employed in patients with poor response. Post-ASCT maintenance was more common after no-novel agent and thal based protocols. Thal was used in 34.1% after thal based, 12.2% after bortezomib and in 33.1% following no-novel agent based induction. IFN was employed in 20.5% after thal, 9.2% after bortezomib and 24.8% after no novel agent containing protocols. Patients with any maintenance had a 7 month PFS benefit [33 (28.9−37.1) *vs* 25.9 (22.6−29.2) months; p=0.044] and a 15 month OS advantage [101.4 (91.3−111.5) *vs* 86.1 (71.5−100.7); p=0.070]. With thal the difference was not significant, however with IFN there was a significant PFS [35.5 (31.3−39.7) *vs* 25.9 (22.6−29.2); p=0.017] and an even more pronounced OS [122.4 (79.6−165.1) *vs* 86.1 (71.4−100.8); p=0.006] benefit (Figure

1). The patients having the best results were those who had both maintenance drugs [PFS 38.7 (15.5−61.9), OS 150.4 (102.2−198.6)]. The positive effect of IFN maintenance was more prominent in patients with PR (OS benefit 52.8 months; p=0.01) than those in CR (OS difference 39.7 months; p=0.088). IFN maintenance was confirmed as a highly significant independent protective factor in multivariate analysis (PFS p=0.030; OS p=0.003) while thal was not (PFS p=0.736; OS p=0.165).

Fig 1.

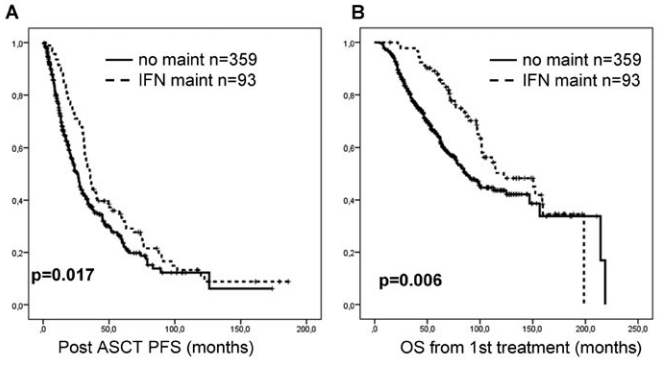

Figure 1.

Summary and Conclusions: The marked survival advantage in the IFN treated patients was beyond what the randomized interferon trials conducted back in the nineties indicated. Although, patient selection might have had a role in this, analyzing the distribution of presentation prognostic markers and post ASCT responses revealed no detectable imbalances. One possible explanation could be an interplay between thal and IFN, two drugs both exploiting the immune system in different ways.

P283

WHOLE BODY DIFFUSION WEIGHTED MRI SCANNING IN PATIENTS WITH MYELOMA. INCIDENTAL FINDINGS-THE ROYAL MARSDEN EXPERIENCE

A. Wale[1], C. Pawlyn[2,*] M. Kaiser[2], C. Messiou[1]
[1]Department of Radiology, [2]Royal Marsden NHS Foundation Trust, Sutton, United Kingdom

Background: The recent consensus statement from the International Myeloma Working Group has introduced the role of whole body MRI in the management pathway for patients with multiple myeloma. Whole body MRI is now recommended for all patients suspected of having smouldering or asymptomatic myeloma (Dimopoulos JCO 2015). The speed, coverage and high sensitivity of whole body diffusion weighted MRI (WB DW-MRI) and the capability to quantify both burden of disease and response to treatment has led to increasing implementation at leading centres worldwide for imaging malignant marrow disease. We have been offering a WB DW-MRI service for patients with myeloma since 2011. However the high sensitivity of this imaging technique will undoubtedly lead to detection of incidental findings.
Aims: The aim of this study was to determine the incidence of incidental and extramedullary findings from WB DW-MRI studies performed in myeloma patients.
Methods: Between January 2012 and October 2014 177 WB DW-MRI examinations were performed for 80 patients with myeloma at the Royal Marsden Hospital, UK. Scans and reports were retrospectively reviewed to determine whether the patient had active marrow involvement, extramedullary disease and if incidental findings were identified. Advice for management of equivocal findings was also documented.

Tabella 1.

Indeterminate findings	Number of examinations
Cutaneous nodule	2
Liver lesion	3
Lymphadenopathy	2
Hydronephrosis	1
Paratesticular mass query hernia	1
Adrenal nodule	1
Solid thyroid nodule	1
Rectal lesion	1
Colitis	1
Lung abnormality	1
Summary of non-equivocal findings	**Number of examinations**
Vertebral / sacral abnormality ie fracture or haemangioma	9
Other benign visceral or pulmonary abnormality ie pyelonephritis, cysts, gallstones	18
Other MSK / spinal abnormality ie avascular necrosis or degenerative	29

Results: 132/177 (75%) WB DW-MRIs showed evidence of active marrow involvement (80 focal, 45 diffuse, 7 both). 18/177 (10%) examinations in 9 patients identified extramedullary myeloma in the liver in 7 examinations, in muscles in 12 examinations, in the retroperitoneum in 4 examinations and in the dura in 1 examination. This was confirmed by response to treatment at follow up in all cases. 67/177 (38%) examinations in 47 patients had incidental findings. Some examinations identified multiple incidental findings so a total of 70 incidental findings were documented. 14/70 incidental findings (20%) were indeterminate. Guidance on further management of indeterminate lesions was given in 13/14 examinations in 14 patients (93%). Half of these indeterminate findings were addressed by clinical correlation and the remaining half required further investigation. The incidental findings are summarised in the table:

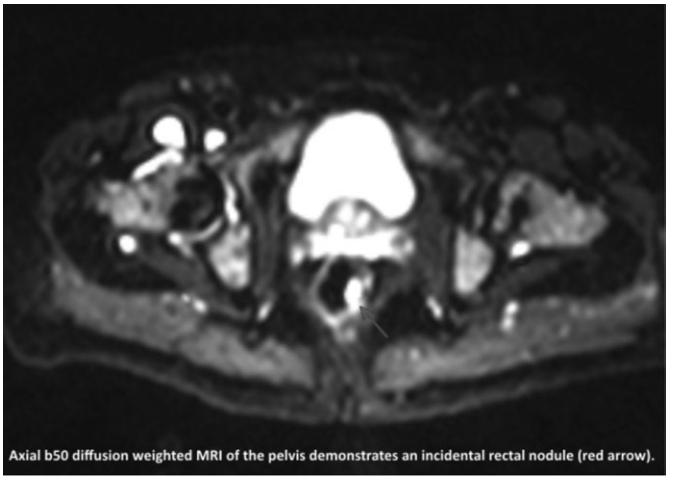

Figure 1.

Summary and Conclusions: Incidental findings are common in WB DW-MRI examinations but only a minority are equivocal requiring further action. The use of WB DW-MRI in patients with myeloma is likely to increase and hence we will need to develop strategies to manage incidental findings. The reporting radiologist should facilitate this by specifically expressing a level of concern and making suggestions regarding the need for further investigations. WB MRI is also likely to increase detection of asymptomatic extramedullary myeloma which may change our perspective of the disease.

P284

PATTERNS OF TOTAL COST OF CARE BY AGE GROUP FOR PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM)

S. Arikian[1,*] G. Binder[2], C.J. Gibson[2], H. Hu[2], Y. Nagarwala[2], M. Hussein[2], F.A. Corvino[1], A. Surinach[1], S. Usmani[3]
[1]Genesis Research, Hoboken, [2]Celgene Corporation, Summit, [3]Levine Cancer Institute/Carolinas Healthcare System, Charlotte, United States

Background: Clinical evidence supporting longer treatment (Tx) durations for patients (pts) with newly diagnosed multiple myeloma (NDMM) raises economic questions. Previous analysis showed that relapsed myeloma pts incurred higher monthly costs once they advanced to later lines of Tx (Gaultney, *J Clin Pharm Ther*, 2013). There is limited information on the cost patterns of MM pts by age group, before and after their first relapse.
Aims: This claims analysis evaluated patterns of total costs of care, from Tx initiation until progression, for NDMM pts and for newly relapsed pts by age group, across Tx, using time to next therapy (TTNT) as a proxy measure for progression.
Methods: Using a large US claims database, NDMM pts were identified based on the first claim associated with a diagnosis of MM (ICD-9-CM code 203.0X) between 2006 and 2013. Pts with claims for stem cell transplant (SCT) were excluded. This cost analysis focused on NDMM and relapsed MM pts, aged <75 and ≥75 yrs, receiving lenalidomide (LEN)-or bortezomib (BORT)-based Tx, where complete claim history was available from Tx onset to initiation of subsequent Tx. Using methods similar to those described by Gaultney (*J Clin Pharm Ther,* 2013), pts' average monthly drug and medical costs were determined, and differences in baseline measures between pt groups were evaluated using the Charlson Comorbidity Index (CCI).
Results: 2843 NDMM pts (1862 pts aged <75 yrs; 981 pts aged ≥75 yrs) and 1361 second-line MM pts (978 pts aged <75 yrs; 383 pts aged ≥75 yrs) were identified. For 41% and 29% of NDMM and second-line pts, respectively, complete data through initiation of subsequent Tx was available and used for cost determination. Monthly total costs for NDMM pts were $15,734 in the first 3 mos of Tx and declined each quarter to approximately $5000/mo at 18+ mos. For second-line therapy, initial monthly costs were more than $13,876 and also declined quarterly (Figure 1). Quarterly cost reduction patterns were consistent

across Tx, lines of therapy, and age groups. TTNT for NDMM pts was 28.1, 24.7, and 33.6 mos for the overall, age <75 yrs, and age ≥75 yrs populations, and TTNT was longer in pts initiated on LEN-based regimens compared with those initiated on BORT. We compared cohorts of pts initiated on each Tx and followed them for a common time period equal to the longer median TTNT of the 2 Tx (LEN): 35 mos in pts aged <75 yrs and 39 mos in pts aged ≥75 yrs. Monthly costs averaged $7941 in the LEN cohort *vs* $12,261 in the BORT cohort of pts aged <75 yrs. For pts aged ≥75 yrs, monthly costs averaged $6879 in the LEN cohort *vs* $7544 in the BORT cohort. Cost differences were due to higher average monthly medical costs for pts treated with BORT; average monthly drug costs were similar. CCI scores were similar across Tx.

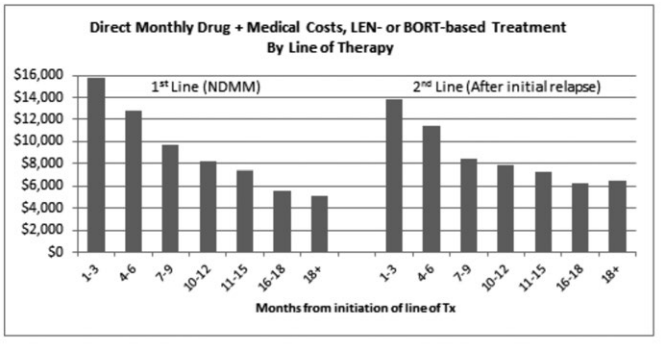

Figure 1.

Summary and Conclusions: For a population of NDMM pts receiving either LEN-or BORT-based Tx without SCT, followed until TTNT, total monthly drug and medical costs per pt declined steadily over time, decreasing by two-thirds over the TTNT period. Costs returned to near-baseline levels when pts began second-line therapy, then declined similarly. This pattern of cost decline was consistent regardless of age, Tx, or line of therapy. This may suggest that further extending the time to progression for NDMM pts may yield economic benefits for each month of extension before relapse. Average monthly total costs over 3 years were lower for NDMM pts initiated on LEN-based Tx due to longer periods with below-average costs prior to initiating second-line therapy.

P285

ENCOURAGING PRELIMINARY DATA IN ONGOING OPEN-LABEL PHASE 1/2 STUDY OF SAFETY AND EFFICACY OF MELFLUFEN AND *DEXAMETHASONE FOR PATIENTS WITH RELAPSED AND RELAPSED-REFRACTORY MULTIPLE MYELOMA

V. Magarotto[1,*] P. Sonneveld[2], P. Voorhees[3], C. Paba-Prada[4], T. Plesner[5], U.H. Mellqvist[6], C. Byrne[7], J. Harmenberg[8], E. Nordström[8], A. Palumbo[1], P. Richardson[4]

[1]Turin University Hospital, Turin, Italy, [2]Erasmus, Rotterdam, Netherlands, [3]University of North Carolina, Chapel Hill, NC, [4]Dana Farber Cancer Institute, Boston, MA, United States, [5]Vejle Hospital, Vejle, Denmark, [6]Södra Älvsborgs Hospital, Borås, Sweden, [7]Oncopeptides AB, Miami, FL, United States, [8]Oncopeptides AB, Stockholm, Sweden

Background: Melflufen is a potent and highly lipophilic alkylator designed for efficient targeting of tumor cells. In contrast to other alkylating agents that are hydrophilic, the lipophilicity of melflufen leads to rapid and extensive distribution into tissues and cells where it can bind directly to DNA or is readily metabolized by intracellular peptidases into melphalan. With targeted delivery of alkylating metabolites to tumor cells (such as multiple myeloma) melflufen exerts a higher anti-tumor activity compared with standard of care alkylator melphalan but with a similar safety profile.
Aims: To study the safety and efficacy of melflufen and dexamethasone (dex) in combination for patients with relapsed-refractory multiple myeloma (RRMM).
Methods: Melflufen is evaluated in combination with low dose dex in a Phase 1/2 study in RRMM. Phase 1 evaluated 4 dose levels of melflufen on day 1 with dex on days 1, 8 and 15 of 21 day cycles in a standard 3+3 design, with an additional 20 patients added at the MTD in Phase 2.
Results: Phase I was completed in September 2014. No dose limiting toxicities (DLTs) were observed in the first three dose cohorts (15, 25 and 40 mg melflufen). 4 of 6 patients at the highest dose, 55 mg, experienced DLTs of prolonged and severe neutropenia and thrombocytopenia, manageable with dose delays and appropriate treatment. The maximum tolerated dose (MTD) was established at 40 mg melflufen every 21 days combined with 40 mg dex weekly. As of 16 Jan 2015, 16 patients were treated at the MTD. Median time from initial diagnosis to first dose of melflufen was 5.5 years (1-15). Median number of prior therapies was 4 (2-11). All patients had been exposed to IMiDs, proteasome inhibitors and alkylators and 15 were at least single-refractory. 8 were double-refractory and 6 were alkylator-refractory. Treatment-related Grade 3 and 4 adverse events were reported in 69% of patients; neutropenia 50%, thrombocytopenia 44%, fatigue and leukopenia 12% each, anemia, febrile neutropenia and lymphopenia each occurred in 6% of patients. 10 patients were evaluable for response (defined as received ≥2 cycles with appropriate assessments). The overall response rate (≥PR) was 60%. The clinical benefit rate (≥MR) was 70%. Time to initial clinical benefit and response was rapid with 70% of patients achieving MR or better after only 1-2 cycles, and 50% of patients responding (≥PR) after 1-3 cycles. Of note, 1 patient that only achieved SD to previous melphalan 200 mg/m^2 with ASCT responded with a PR following only 1 cycle of 40 mg melflufen. Four patients discontinued treatment following 10, 6, 4 and 2 cycles for reasons other than progression. Three continue to maintain response off therapy, at time of data cut for 9.5, 9.2 and 4.6 months respectively. The fourth patient continues to maintain SD, 9.6 months at time of datacut. Median time on treatment was 3.4 months (1.3-7.8) with 5 patients still ongoing.
Summary and Conclusions: Melflufen plus low dose dex is tolerated and has promising activity in this advanced RRMM population. The MTD was established at 40 mg every 21 days with dex 40 mg weekly. In the first 10 evaluable patients treated at the MTD, all heavily pre-treated, 6 responded to treatment with PR. Responses are rapid and durable. Based on these early results the protocol will be amended to include 55 patients in Phase 2 to further characterize response. Updated information will be presented at the time of the conference.

P286

ANALYSIS OF PATIENTS WITH REFRACTORY OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA AND RENAL IMPAIRMENT TREATED WITH POMALIDOMIDE + LOW-DOSE DEXAMETHASONE IN THE PHASE 3B STRATUS TRIAL (MM-010)

K. Weisel[1,*] M.A. Dimopoulos[2], A. Palumbo[3], P. Corradini[4], M. Cavo[5], M. Delforge[6], E.M. Ocio[7], A. Vacca[8], M. Hansson[9], M. Blanchard[10], N. Millller[11], T. Peluso[11], L. Sternas[12], M. Zaki[12], P. Moreau[13]

[1]University Hospital Tübingen, Tübingen, Germany, [2]National and Kapodistrian University of Athens, Athens, Greece, [3]University of Torino, Torino, [4]Fondazione IRCCS Istituto Nazionale Tumori, University of Milano, Milano, [5]Bologna University School of Medicine, Bologna, Italy, [6]University Hospital Leuven, Leuven, Belgium, [7]7Hospital Universitario de Salamanca & Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain, [8]University of Bari Medical School, Bari, Italy, [9]Skane University Hospital, Lund University, Lund, Sweden, [10]Hospital Ramón y Cajal, Madrid, Spain, [11]Celgene International Sàrl, Boudry, Switzerland, [12]Celgene Corporation, Summit, United States, [13]University Hospital Hotel-Dieu, Nantes, France

Background: Overall survival (OS) of patients (pts) with refractory or relapsed and refractory multiple myeloma (RRMM) has been extended by treatment (Tx) with newer agents, such as lenalidomide (LEN) and bortezomib (BORT); however, shortened OS is observed in pts who relapse on or who become refractory to Tx (Kumar et al, *Leukemia*, 2012). Renal impairment (RI), a major cause of death in this pt population, (Korbet et al, *J Am Soc Nephrol,* 2006) occurs in ≈ 20% to 40% of MM pts (Kastritis et al, *Haematologica,* 2007). In RRMM pts who failed LEN and BORT Tx, pomalidomide + low-dose dexamethasone (POM + LoDEX) extended progression-free survival (PFS) and OS *vs* high-dose dexamethasone in the phase 3 MM-003 trial. This included pts with moderate RI (creatinine clearance [CrCl] <60 mL/min; Weisel et al, *J Clin Oncol,* 2013). Efficacy of POM + LoDEX was similar across renal function subgroups in the MM-002 trial, in which pts with serum creatinine ≥3 mg/dL were excluded (Vij et al, *Clin Lymphoma Myeloma Leuk*, 2013).

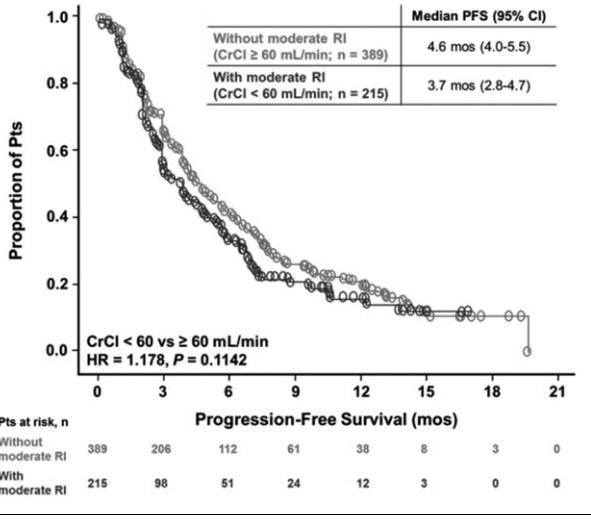

Figure 1.

Aims: STRATUS is a multicenter, single-arm, open-label phase 3b trial designed to further evaluate the safety and efficacy of POM + LoDEX in RRMM pts, including those with varying degrees of renal insufficiency.
Methods: RRMM pts (progressive disease [PD] during or within 60 days of last line of Tx), aged ≥18 yrs, with measureable M-protein levels in urine or serum and ≥2 prior Tx, who failed LEN and BORT after ≥2 cycles of each (alone or in combination), and who received adequate prior alkylator Tx were eligible. Pts with CrCl <45 mL/min were excluded. POM 4 mg was administered D1-21/28-day cycle and LoDEX 40 mg/day (20 mg for pts aged >75 yrs) on D1, 8, 15, and 22 until PD or unacceptable toxicity. Thromboprophylaxis was required for all pts. Primary endpoint was safety, and key secondary endpoints included, overall response rate (ORR; ≥partial response), duration of response (DOR), PFS, OS, and POM exposure.
Results: As of Sep 15, 2014, 604 pts were enrolled; 599 received POM + LoDEX, and 36% had moderate RI (CrCl <60 mL/min) at baseline. After a median follow-up of 9.3 mos, the most frequently reported grade (Gr) 3/4 hematologic treatment-emergent adverse events (TEAEs) in pts with moderate RI *vs* those without moderate RI (CrCl ≥60 mL/min) were neutropenia (39% *vs* 44%), anemia (33% *vs* 27%), and thrombocytopenia (22% *vs* 21%). The most frequent Gr 3/4 non-hematologic TEAE was infection (29% *vs* 30%). Dose reductions due to TEAEs were similar in pts with moderate RI *vs* those without moderate RI (19% *vs* 17%); 12% *vs* 7% discontinued POM due to TEAEs. Gr 3/4 venous thromboembolic events and peripheral neuropathy were infrequent, regardless of renal status. Median relative POM dose intensity was similar between subgroups (0.94 in pts with moderate RI *vs* 0.93 in pts without moderate RI). In pts with moderate RI *vs* those without moderate RI, ORR was 37% *vs* 33%, median DOR was 6.0 *vs* 7.9 mos, and median PFS was 3.7 *vs* 4.6 mos (*P* =0.1142; Figure). The median Tx duration for pts with moderate RI *vs* without moderate RI was 3.7 *vs* 4.3 mos. Updated data will be presented at the congress.
Summary and Conclusions: This analysis demonstrated that in pts with moderate RI, POM + LoDEX has a manageable safety profile and is efficacious. Tolerability and efficacy were similar in pts with or without moderate RI and consistent with results from the pivotal MM-002 and MM-003 trials. There was a trend toward longer PFS in pts without moderate RI. Two ongoing trials, MM-008 (US) and MM-013 (EU), are evaluating RRMM pts with severe RI.

Multiple myeloma - Clinical 5

Background: Several studies have analysed the prognostic impact of high values of sFLC or sHLC and their abnormal ratios in Multiple Myeloma (MM), most of them retrospectives. Currently, the normalization of sFLC or HLCr after treatment has been proposed as a good response biomarker.
Aims: To investigate the prognostic impact of sFLCr and sHLCr at diagnosis and after treatment in MM patients in the context of three GEM/PETHEMA clinical trials (GEM2005MENOS65, GEM2005MAS65 & GEM2010MAS65).
Methods: Among a total of 819 patients, treated according to the GEM2005MENOS65, GEM2005MAS65 & GEM2010MAS65 GEM/PETHEMA trials, serum samples for sFLC and sHLC analyses were available at diagnosis in 623 and 183 of the patients, respectively. After induction, regardless of the achieved response, it was available in 308 cases for sFLCr and 89 for sHLCr. All patients in which sHLC assay was analysed were IgG or IgA-MM. The sHLC and sFLC assays (HEAVYLITE® and FREELITE®, The Binding Site, Birmingham, UK) were performed on an automated nephelometer (BNII, Dade Behring/Siemens, Marburg, Germany). The sPE assay was performed by capillary electrophoresis (V8, Helena Biosciences Europe), and sIFE was performed for γ, α, μ, κ, and λ Ig chains (SAS-3 & SAS-4, Helena Bioscience Europe).
Results: At diagnosis, 92% of the sFLCr and sHLCr were abnormal, which had no impact in prognosis; even when we considered "very pathological" (VP) sFLCr values (0.03-32)[FIGURE 1A]. Establishing several cut-offs, we note that VP-sHLCr values (<0.29 or >73) at the time of diagnosis showed an increased risk of progression (p=0.006)[FIGURE 1B], confirmed by multivariate analysis — age [p=0,003; OR 1.04 (1.01-1.06)]; LDH [p=0.03; OR 0.4 (0.26-0.94)]; VP-sHLCr [p=0.01; OR 1.78 (1.14-2.78)]; high *vs* low risk FISH [p=0.02; OR 1.75 (1.11-2.74)]. Interestingly, absolute HLC-involved-Ig values show linear correlation with absolute values of MP by sPE (p=0,000; Pearson's r=0.676) and the presence of uninvolved HLC pair suppression had no prognostic impact in our series (OS p=0.89; PFS p=0.57). After treatment, regardless of the achieved response, a normal sFLCr or a normal sHLCr do not imply a better prognosis in our series. Concerning the sFLCr, among the 130 patients in CR after induction no prognostic differences were observed between patients with a normal (0.26-1.65) *vs* pathological sFLCr.

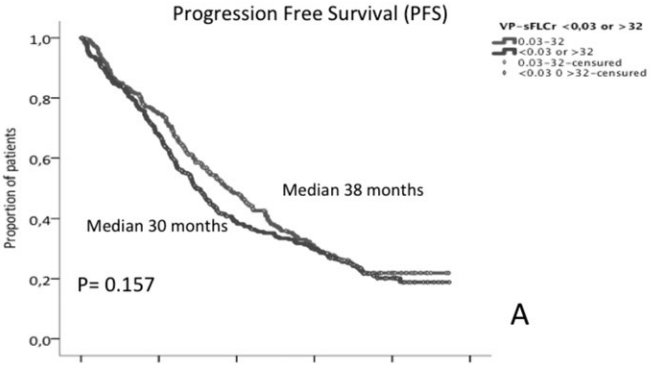

Figure 1 A.

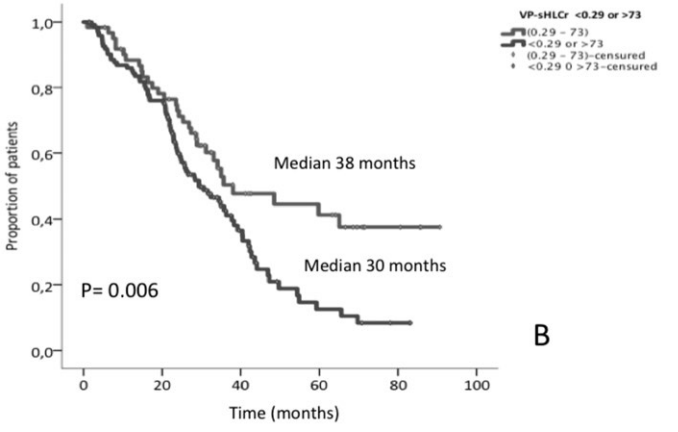

Figure 1 B.

Summary and Conclusions: VP-sHLCr values (<0.29 or >73) at diagnosis could suggest a greater risk of progression. Since the HLC-involved-Ig values show a strict linear correlation with values of MP by sPE,its clinical utilityis debatable.The sHLC non-involved pair suppression at diagnosis wasn't related to worse prognosis, nor did a normal sFLCr or sHLCr at diagnosis seem to imply differences in prognosis. However, in CR, a normalization of the sFLCr doesn't correlate with a better prognosis in our series, what opens up controversy about the value of the current IMWG criteria for sCR.

P288

RISK OF VARICELLA-ZOSTER VIRUS INFECTION IN MYELOMA PATIENTS WITHOUT BORTEZOMIB TREATMENT

C.J. Liu[1,*] Y.C. Liu[2], Y.C. Hong[3], F.C. Ku[4], J.P. Gau[1], P.S. Ko[1], S.C. Chen[1], T.J. Chiou[5], C.H. Tzeng[1]
[1]Division of Hematology and Oncology, Taipei Veterans General Hospital, [2]Department of Medicine of Yang-Ming Branch, Taipei City Hospital, Taipei, [3]Division of Hematology and Oncology, Kaohsiung Veterans General Hospital, Kaohsiung, [4]Department of Hematology and Oncology, Show Chwan Memorial Hospital, Changhua, [5]Division of Transfusion Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, ROC

Background: Patients with multiple myeloma have an increased risk of varicella-zoster virus (VZV) infection, which has been established, especially with the use of bortezomib. However, few studies have discussed the risk of VZV infection in myeloma patients without bortezomib treatment.
Aims: We conducted a nationwide population-based study to investigate the risk of VZV among myeloma patients and the association between non-proteasome inhibition therapies and development of VZV.
Methods: We recruited patients with newly diagnosed multiple myeloma from Taiwan's National Health Insurance database between January 1, 2000 and December 31, 2011. Patients who were aged under 20 years or with antecedent VZV were excluded. Each myeloma patient was matched with four age-, sex-, and comorbidity-matched individuals. All participants were followed up until VZV development, death, dropout from the National Health Insurance program, initiation of bortezomib treatment, or the end of 2011. The Kaplan-Meier method was employed for estimation of cumulative incidence. Hazard ratios (HRs) of VZV risk compared between the two cohorts were calculated by Cox proportional regression analysis. In addition, therapeutic agents were put into Cox models as time-dependent covariates to avoid immortal time bias.
Results: This study consisted of 3,677 patients with multiple myeloma and 14,708 matched individuals, with a median age of 67 years (interquartile range 58–75). Four hundred eighteen VZV infections developed among 3,677 myeloma patients, with a follow-up of 6083.8 person-years. The incidence of VZV infection was 5.93 times higher in the myeloma cohort than in the matched cohort (68.7 *vs* 12.0 per 1,000 person-years), with an age-, sex-, and comorbidity-adjusted HR of 6.02 (95% confidence interval [CI] 5.30–6.83; *P* <0.001). The multivariable Cox proportional hazard models showed thalidomide treatment (adjusted HR 1.33; 95% CI 1.04–1.69; *P* =0.022), cytotoxic chemotherapy (adjusted HR 1.34; 95% CI 1.02–1.77; *P* =0.036) and hematopoietic stem cell transplantation (adjusted HR 2.80; 95% CI 2.09–3.75; *P* <0.001) as independent risk factors determining the subsequent VZV in myeloma patients.
Summary and Conclusions: Our study reveals an increased risk of VZV infection among myeloma patients without bortezomib therapy. Treatment with thalidomide, cytotoxic chemotherapy, or hematopoietic stem cell transplantation is associated with a higher risk of VZV infection in myeloma patients.

VENETOCLAX (ABT-199/GDC-0199) IN COMBINATION WITH BORTEZOMIB AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: PHASE 1B RESULTS

P. Moreau[1,*] A.A. Chanan-Khan[2], A. Roberts[3], A. Agarwal[4], T. Facon[5], D. Lebovic[6], C. Touzeau[1], D. Darden[7], L. Morris[7], J. Ross[7], A. Salem[7], W. Munasinghe[7], M. Zhu[7], J. Leverson[7], S. Enschede[7], R. Humerickhouse[7], S. Harrison[8]
[1]CHU de Nantes, Hotel Dieu-HME, Nantes, France, [2]Mayo Clinic, Rochester, United States, [3]Royal Melbourne Hospital, Melbourne, Australia, [4]The University of Arizona Cancer Center, Scottsale, United States, [5]CHRU Lille, Hopital Huriez, Lille, France, [6]University of Michigan University of Michigan Cancer Center, Ann Arbor, [7]AbbVie, North Chicago, United States, [8]Peter MacCallum Cancer Centre, Melbourne, Australia

Background: The anti-apoptotic proteins BCL-2 and MCL-1 promote multiple myeloma cell survival. Bortezomib (BTZ) can inhibit MCL-1 activity by increasing the MCL-1 antagonist, NOXA. Venetoclax is a selective, orally bioavailable, small-molecule BCL-2 inhibitor, which enhances BTZ efficacy in multiple myeloma xenograft models. This Phase 1 study evaluates venetoclax with BTZ and dexamethasone (Dex) in patients with relapsed/refractory multiple myeloma.
Aims: Objectives include safety, pharmacokinetics, preliminary efficacy, and maximum therapeutic dose of venetoclax with BTZ and Dex.
Methods: Patients received venetoclax (50-500 mg PO daily) in cycles 1-11 per designated dose escalation cohorts (continual reassessment method); BTZ (1.3 mg/m^2 SC, days 1, 4, 8, 11) and Dex (20 mg PO, Days 1, 4, 5, 8, 9, 11, 12) in cycles 1-8 (21 days), BTZ+Dex days 1, 8, 15, 22 in cycles 9-11 (35 days), and venetoclax alone in cycle 12 and beyond.
Results: 32 patients were enrolled as of 12/18/2014: median age 65; 12/20 female/male. 12 were ISS stage I, 7 stage II, 10 stage III. Median (range) prior therapies: 5 (1–15). 26 patients received prior BTZ (10 were refractory), 26 had prior lenalidomide, and 20 had autologous hematopoietic stem cell transplant. Adverse events (AE; all grades) occurring in ≥20% patients: constipation (41%), diarrhea (38%), peripheral edema (28%), thrombocytopenia (31%), peripheral neuropathy (28%), insomnia (28%), dyspnea (25%), and anemia (22%). Grade 3/4 AEs (≥10%): thrombocytopenia (25%) and anemia (13%). 14 patients had serious AEs: none were assessed as venetoclax-related. Reasons for discontinuation (n=17): disease progression (PD; n=14), AEs (n=2: adenocarcinoma, cardiac and respiratory decompensation), consent withdrawal (n=1). 3 deaths occurred (due to PD); 1 dose-limiting toxicity at 300 mg (cardiac decompensation attributed to Dex). No tumor lysis syndrome occurred. Dose-normalized venetoclax exposure when given with BTZ+Dex (n=30) was similar to venetoclax alone.
Summary and Conclusions: Venetoclax with BTZ and Dex has an acceptable safety profile in heavily pretreated multiple myeloma patients. This combination targeting BCL-2 and MCL-1 resulted in anti-tumor activity and longer time on study in patients naïve or sensitive to prior BTZ. Dose escalation continues at 600 mg.

Tabella 1.

Preliminary efficacy (best response) by BTZ status

n (%)	Refractory (n=10)	Sensitive (n=16)	Naïve (n=6)
Stringent complete response (sCR)	0	1 (6)	0
Complete response (CR)	0	0	2 (33)
Very good partial response (VGPR)	0	2 (13)	1 (17)
Partial response (PR)	0	7 (44)	2 (33)
Minimal response (MR)	1 (10)	0	0
Stable disease (SD)	3 (30)	4 (25)	0
Disease progression (PD)	4 (40)	1 (6)	1 (17)
Discontinued	2 (20)	1 (6)	0
Overall response rate (sCR+CR+VGPR+PR)	0	10 (63)	5 (83)
Median (range) time on study, months	1.3 (0.3–4.8)	5.0 (0.7–9.5)	5.0 (1.4–9.4)

P290

RETROSPECTIVE REFINING OF DIAGNOSIS IN 286 MGUS AND SMM PATIENTS ACCORDING TO THE UPDATED IMWG CRITERIA. CLINICAL IMPLICATIONS

M.C. Kyrtsonis[1], E. Nikolaou[1,*] T. Tzenou[1], V. Bartzis[1], A. Bitsani[1], S. Kotsanti[1], M. Dimou[1], T. Iliakis[1], M. Angelopoulou[1], T. Vassilakopoulos[1], P. Panayiotidis[1]
[1]University of Athens-Medical School, Laikon General Hospital of Athens, Athens, Greece

Background: With the recent publication of updated criteria for the diagnosis of multiple myeloma by the IMWG, a subset of patients formerly diagnosed as having asymptomatic MM (SMM) or monoclonal gammopathy of undetermined significance (MGUS), should be reclassified.
Aims: To retrospectively discriminate the subset of patients that present today diagnostic discrepancy and to evaluate eventual damage, if any.
Methods: 286 patients (147 diagnosed as SMM and 139 as MGUS), diagnosed and followed-up in our section, were studied. Patients were re-diagnosed according to factors susceptible to change the diagnosis according to the new IMWG criteria, namely the existence of IgA or IgG >30g/L or urinary moclonal protein of 500 mg/24h or more, that could shift MGUS to SMM and, with regard to an eventual shift from SMM to MM, the existence of plasma cell infiltration equal or more than 60% and the presence of at least one osteolytic lesion on more sensitive methods than x-rays. Anemia, hypercalcemia and renal impairment were already taken in account initially and are not reassessed. Statistical analysis was performed by standard methods with the SPSS v21.0 software.
Results: No MGUS patient had IgA or IgG >30g/L or urinary moclonal protein of at least 500 mg/24h, so no change were made. The new criteria did not taken into account serum free light chain (FLC) measurements or ratio (FLCR). Five patients had an FLC value >100mg/L and 6 an FLCR >8 but although Kaplan-Meier curves separated well, the statistical difference in evolution rates for patients with the aforementioned FLC/FLCR values was not significant perhaps due to the small number of patients. With regard to SMM patients, 25 of them had at least one osteolysis by sensitive radiology methods (CT, MRI) in the absence of bone pains or other end-organ damage-related symptomatology; they should however be considered as having symptomatic MM. Their median time to treatment initiation was 34 months (range 15-53) and their median overall survival since diagnosis was 80 months (range 36-124). In addition, other 9 patients had more than 60% bone marrow plasma cell infiltration and should also be considered as suffering from symptomatic MM, although presenting no other symptoms. This second patients' subgroup had a shorter median time to treatment initiation of 6 months (range 5-7) and their median overall survival since diagnosis was 60 months (range 10-110). In total, the diagnosis of 34 patients (23%) of the present series should change according to the IMWG updated criteria for the diagnosis of multiple myeloma.
Summary and Conclusions: The diagnosis of MGUS patients did not change with the application of the new IMWG updated MM criteria, on the contrary the diagnosis of 23% of SMM patients changed. This was totally justified for patients with more than 60% bone marrow plasma cell infiltration, but is somewhat controversial in the case of patients with existing but not extensive skeletal disease.

P291

IS A DEEP RESPONSE THE KEY TO SUCCESSFUL TREATMENT OF MULTIPLE MYELOMA?

J. Liwing[1,*] B.M. Heeg[2], S. Karstorp[1], M. Postma[3], R. Silvennoinen[4], M. Putkonen[5], P. Anttila[6], K. Remes[5], N. Abildgaard[7], A. Waage[8], H. Nahi[1]
[1]Department of Medicine, Karolinska Institutet, Stockholm, Stockholm, Sweden, [2]Ingress-health, Rotterdam, [3]Unit of PharmacoEpidemiology & PharmacoEconomics, Institute of Science in Healthy Aging & health caRE (SHARE), Groningen, Netherlands, [4]Kuopio University Hospital, Kuopio, [5]Turku University Hospital, Turku, [6]HUS, Helsinkki, Finland, [7]Department of Hematology, Odense University Hospital, Odense, Denmark, [8]Department of Hematology, St Olavs Hospital, Trondheim, Norway

Background: Several authors have highlighted the importance of a deep response to chemotherapy in multiple myeloma (MM), especially in first line.
Aims: The objective was to assess which patient/treatment/disease characteristics are prognostic for a deep response. Also, to assess whether the deep response is prognostic for overall survival (OS) independent of treatment, treatment line and patient/disease characteristics.
Methods: A retrospective analysis was performed on 2960 MM-patients from 24 hospitals in Denmark, Finland, Norway and Sweden. The database contained information on patient baseline characteristics such as age, gender, ISS stage, albumin, creatine, and MM type, which were recorded at start of first line therapy. The following outcomes were considered; response, time to next line of treatment (TTNT) and OS. The following categories of response were differentiated: progressive disease (PD), no response (NR), partial response (PR), very good PR (VGPR) and equal or better than near complete response (>=nCR). To identify prognostic factors for response, univariate and multivariate multinomial regression were conducted with response as dependent and patient baseline characteristics and type of treatment as independent variables. To assess whether response is an independent predictor of OS, multivariate cox-proportional hazard models were run for the first four lines of treatment.
Results: Patients in the dataset were on average 67 years old, 48% were male, 28%, 41% and 31% in ISS stages I, II and III, respectively. Multinomial regression showed that type of treatment, age, ISS type and MM type were significant prognostic factors for response in first line. In second line, first line response, type of treatment and age were significant prognostic factors for response in second line. Multivariate cox-regression showed that in first line patients with NR, PR, VGPR and >=nCR had significant lower hazard ratio's (HRs) 0.61 (0.43-0.85), 0.56 (0.41-0.78), 0.34 (0.22-0.51) and 0.36 (0.24-0.54) respectively compared to PD. Age, Albumin, Calcium and Beta-2-microglobulin levels were also significant prognostic factors for OS with HRs of 1.03 (1.01-1.04), 0.98 (0.96-0.99), 1.41 (1.11-1.79) and 1.02 (1.01-1.03) respectively. The following categorical variables also were significant prognostic factors for first line OS; type of treatment, ISS-stage and MM type. For second line OS multivariate cox-regression showed that patients with PR, VGPR and >=nCR had significant lower HR's 0.58 (0.46-0.73), 0.42 (0.3-0.58), 0.4 (0.27-0.6) compared to PD respectively. Age also had a significant HR of 1.02 (1.01-1.03). For third line OS multivariate cox-regression showed that patients with NR, PR, VGPR and >=nCR had significant lower HR's 0.67 (0.5-0.89), 0.37 (0.27-0.51), 0.32 (0.21-0.5), 0.18 (0.1-0.34) compared to PD respectively. Age also had a significant HR of 1.01 (1.00-1.02). For fourth line OS multivariate cox-regression showed that patients with PR, VGPR and >=nCR had significant lower HR's 0.45 (0.31-0.64), 0.31 (0.19-0.52) and 0.39 (0.21-0.73) compared to PD respectively. Age was also identified as a significant prognostic factor.
Summary and Conclusions: Type of treatment, age, ISS type and MM type were significant prognostic factors for response in first line. For second line response, the significant prognostic factors were response in first line, type of treatment and age. Moreover, multivariate cox-regressions shows that in the first four lines of treatment, response is an independent prognostic factor for OS. Future research should include genetic prognostic factors, which were not collected in our dataset and could therefore not be assessed.

P292

FAMILY HISTORY OF LYMPHOPROLIFERATIVE DISEASE ASSOCIATED WITH A SUPERIOR SURVIVAL IN MULTIPLE MYELOMA: A POPULATION-BASED STUDY

K. Aradóttir[1,*] S.H. Lund[1], M. Björkholm[2], L.R. Goldin[3], I. Turesson[4], O. Landgren[5], S.Y. Kristinsson[12]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [2]Department of Medicine, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [3]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, United States, [4]Department of Hematology and Coagulation Disorders, Skåne University Hospital, Malmö, Sweden, [5]Myeloma Service, Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Multiple myeloma (MM) is characterized by a neoplastic proliferation of plasma cells in the bone marrow and overproduction of monoclonal immunoglobulins in serum or urine. MM is preceded by a premalignant condition called monoclonal gammopathy of undetermined significance (MGUS). Familial aggregation of MM and MGUS has been reported by several authors. The role of genetic factors in the pathogenesis of multiple myeloma is also indicated by emerging data. However, the underlying genetic cause of the disease is uncertain and the impact of family history on survival is unknown.
Aims: The aim of our study was to compare survival in MM patients with family history of lymphoproliferative disorders (LPD) to MM patients without family history of LPD.

Methods: MM patients and their first-degree relatives were identified using the nationwide Swedish Registries. Information on malignancies in relatives of MM patients was obtained by record-linkages to the Swedish Cancer Registry. A positive family history of LPD was defined as MM patients having at least one first-degree relative diagnosed with MM, chronic lymphocytic leukemia (CLL), non-Hodgkin's lymphoma (NHL), Waldenström's macroglobulinemia (WM), or Hodgkin's lymphoma (HL). We performed a cox proportional hazard model and adjusted for age, sex, and year at diagnosis.
Results: A total of 13,947 MM patients diagnosed in 1958-2005 were included of whom 332 had a linkable first-degree relative with LPD. When compared to MM patients without family history of LPD, MM patients with a family history had a borderline significant decreased risk of death (HR 0.89; 95% CI 0.79-1.00, p=0.0549). When stratified by age there was a significant difference in patients 70 years of age or younger (0.83; 0.71-0.98, p=0.0298), but not older (Figure 1). A better survival was also found in male MM patients with family history than with sporadic disease (0.83; 0.71-0.98, p=0.0297). There was no statistical difference by family history among female MM patients (Figure 1).

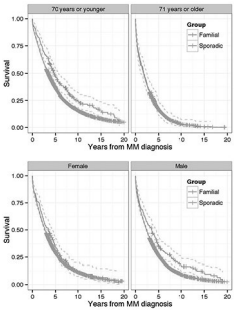

Figure 1.

Summary and Conclusions: In this large population-based study we showed for the first time that there is a trend toward superior survival in MM patients with family history of LPD, compared to MM patients without family history. Interestingly, survival in MM patients younger than 70 years was significantly better in the familial group (compared to sporadic). Lastly, male patients with family history of LPD had a significantly lower risk of death. Our findings suggest that familial MM may be associated with less agressive nature or better response to therapy, at least in subgroups of patients. The underlying molecular explanations for our findings are yet unknown and need to be established by further research.

P293

PARENTAL LONGEVITY AND SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA AND MGUS

I S. Sverrisdottir[1,*] S.H. Lund[2], I. Turesson[3], M. Björkholm[4], L.R. Goldin[5], O. Landgren[6], S.Y. Kristinsson[7]
[1]Landspitali, National University Hospital, [2]Faculty of Medicine, University of Iceland, Reykjavik, Iceland, [3]Skåne University Hospital, Malmö, [4]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, [5]Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, [6]Myeloma Service, Division of Hematology Oncology, Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, United States, [7]Department of Hematology, Landspitali, National University Hospital, Reykjavik, Iceland

Background: In the general population, parental longevity is associated with an increased life expectancy. However, studies on specific diseases and parental longevity have shown conflicting results. A few studies on multiple myeloma have identified host characteristics that have an influence on the patient's prognosis, such as socioeconomic status, poor performance status, and co-morbidity. Longevity as a host factor among patients with multiple myeloma has never been studied in relation to outcome. Recent studies focusing on the myeloma precursor, monoclonal gammopathy of undetermined significance (MGUS), have implied that host biology plays an important role in relation to malignant transformation.
Aims: Our aim was to study the effect of parental longevity on the survival of patients with multiple myeloma and MGUS.
Methods: A total of 1,815 patients with multiple myeloma, 1,407 MGUS patients as well as 8,267 population-based controls for multiple myeloma patients and 5,595 controls for MGUS were included in the study. We compared the risk of death, using Cox's proportional hazards regression (adjusting for age, gender, and year of diagnoses), among multiple myeloma and MGUS patients with a history of parental longevity to those patients without a long-lived parent. Longevity was defined as exceeding 90 years of age or living to the 90th percentile.
Results: Among multiple myeloma patients, a history of parental longevity was not associated with a decreased risk of death (hazard ratio (HR=0.92; 95% confidence interval (CI) 0.81-1.05, Table). Having one long-lived parent or both did not have an effect (HR=0.91; 95% CI 0.80-1.04 and HR=1.02; 95% CI 0.72-1.44, respectively). A history of parental longevity among MGUS patients was associated with a significant decrease in risk of death (HR=0.69; 95% CI 0.53-0.91, Table). The risk of death decreased when one parent was long-lived (HR=0.69; 95% CI 0.52-0.91). However, based on few numbers, when both parents were long-lived the risk of death was decreased but not statistically significant (HR=0.72; 95% CI 0.34-1.53).

Tabella 1. Relative risk of death for patients with multiple myeloma and MGUS in relation to parental longevity.

	Multiple Myeloma		MGUS	
Category	HR (95% CI)	p-value	HR (95% CI)	p-value
Parental history of longevity	0.92 (0.81 – 1.05)	0.21	0.69 (0.53 – 0.91)	0.0079
One parent long-lived*	0.91 (0.80 – 1.04)	0.18	0.69 (0.52 – 0.91)	0.0098
Both parents long-lived*	1.02 (0.72 – 1.44)	0.92	0.72 (0.34 – 1.53)	0.39

*HR = Hazard Ratio, CI = Confidence Interval

Summary and Conclusions: In this first, to our knowledge, study on parental longevity and survival among multiple myeloma and MGUS patients, we conclude that a history of parental longevity is associated with superior survival among MGUS patients, which may reflect the impact of host biology in relation to overall survival. However, parenteral longevity does not decrease the risk of death for patients with multiple myeloma. This finding probably reflects the poor outcome of the malignancy itself which seems to outweigh the positive effects of parental longevity.

P294

SERUM B-CELL MATURATION ANTIGEN IS A NOVEL PROGNOSTIC INDICATOR FOR MULTIPLE MYELOMA PATIENTS AND CORRELATES WITH CLINICAL STATUS AND SURVIVAL

J. Berenson[1,*] M. Ghermezi[1], S. Vardanyan[1], N. Harutyunyan[1], M. Spitzer[1], J. Gottlieb[1], A. Berenson[1], C. Andreu-Vieyra[2], M. Li[1], C. Wang[1], E. Sanchez[1], R. Swift[3], H. Chen[1]
[1]Institute for Myeloma & Bone Cancer Research, [2]Oncotherapeutics, [3]James R. Berenson, MD, Inc., West Hollywood, United States

Background: B-cell maturation antigen (BCMA) is a tumor necrosis factor receptor family member that is expressed on normal and malignant B-cells. Our group has recently shown that BCMA is present in the serum of multiple myeloma (MM) patients (pts) and that its levels may correlate with their clinical status and overall survival (OS).
Aims: We analyzed the relationship between serum BCMA levels and monoclonal (M)-protein levels as well as the relationship of BCMA to response status, progression-free survival (PFS) and OS in a large cohort of MM pts.
Methods: Serum was obtained on 227 MM pts following informed consent. Enzyme-linked immunosorbent assay (ELISA) was used to determine serum BCMA levels (R&D Systems). The Mann-Whitney test was used to assess the differences between clinical status groups. Kaplan-Meier analysis and multivariate Cox regression models were also used. Kaplan-Meier survival of MM pts was determined from the time of initial serum BCMA measurement to death or the date of last follow-up. PFS of MM pts was evaluated from the time of serum BCMA measurement to date of first disease progression. Cox-proportional hazards regression was utilized to determine the predictive influence of serum BCMA and various other factors including age, creatinine, hemoglobin, ISS stage, and bone disease on OS and PFS. *P*-values less than 0.05 were considered statistically significant. Changes in serum BCMA levels were correlated with serum M-protein levels for 44 MM pts during their course of disease. Similarly, serum BCMA levels were correlated with bone marrow and PET scan findings for non-secretory disease (NSD) pts.
Results: Serum BCMA levels correlated with the patient's clinical status at the time of its determination (P <0.0001). Specifically, pts with ≥PR had significantly lower serum BCMA levels (median, 52.49 ng/mL) than those with stable and progressive disease (median, 124.8 ng/mL; P <0.0001). Changes in serum BCMA levels highly correlated with changes in serum M-protein levels among 44 consecutive MM pts that had multiple determinations made during their course of disease. Notably, pts with NSD showed a direct correlation between changes in serum BCMA levels and their clinical status as reflected by PET scan and bone marrow findings during their course of disease. PFS was markedly longer among pts with serum BCMA levels below than among those with levels above the median (P =0.006). We divided pts into quartiles based on their serum BCMA levels. Pts in quartiles 1-3 had a longer PFS compared to pts in quartile 4 (P <0.0001). Among all 227 pts, the 36-month OS of pts whose serum BCMA levels were above the median (≥102 ng/mL) was significantly lower than among those whose levels were below the median (P =0.02). In the multivariate regression analyses, serum BCMA levels significantly correlated with only OS (P =0.0003). In contrast, age, bone disease status, serum creatinine, hemoglobin, and ISS staging did not correlate with OS. Lastly, serum BCMA levels were independent of ISS staging and serum creatinine levels.

Summary and Conclusions: BCMA is a novel serum marker that can be used to follow the course of disease in MM patients. Serum BCMA levels are elevated in patients with MM. Levels of this marker also correlate with clinical status, predict PFS and OS, and provide patients with NSD a way to follow their disease course.

P295

THE NOTCH LIGANDS JAGGED1 AND 2 ARE A POTENTIAL THERAPEUTIC TARGET IN MULTIPLE MYELOMA-ASSOCIATED BONE DISEASE

M. Colombo[1,*] S. Garavelli[1], K. Todoerti[2], A. Paoli[1], N. Platonova[1], S. Galletti[3], A. Neri[3], R. Chiaramonte[1]
[1]Dept. Health Sciences, Università degli Studi di Milano, Milano, [2]Laboratory of Pre-Clinical and Translational Research, IRCCS-CROB, Referral Cancer Center of Basilicata, Rionero in Vulture, [3]Dept. Clinical Sciences and Community Health, Università degli Studi di Milano, Milano, Italy

Background: Bone disease is still a relevant issue in multiple myeloma (MM), since it not only affects patients quality of life but it also promote tumor growth and survival, finally contributing to the fatal outcome of this disease. The Notch oncogenic pathway is dysregulated in MM, due to the hyperexpression of the Jagged 1 and 2 ligands. This alteration improve the ability of MM cells to establish pathological interactions with the bone marrow (BM) niche, finally promoting tumor progression. Notch is also a key regulator of bone tissue remodeling and skeletal development.
Aims: The aim of this work was to provide a rationale for the targeting of the two Notch ligands Jagged 1 and 2 in MM-driven bone disease. To address this issue we assessed: the role of the Notch pathway in MM-associated osteoclastogenesis; the effects of Jagged1/2 silencing on the ability of MM cells to activate the Notch pathway in OCLs and boost bone resorption.
Methods: OCL differentiation of Raw264.7 cells was induced by treating them with 50ng/ml mRANKL or co-culturing with MM cells or their conditioned medium (CM). After 5-7days cells were stained using the TRAP Kit and counted. DAPT was used at a concentration of 50μM. Select RNAi^{TM} siRNA system (Invitrogen) was used according to the manufacturer's guidelines for the selective knockdown of Jag1 and Jag2. Jagged1 recombinant peptide was used at 0.5μg/ml. anti-RANKL neutralizing antibody was used at 0.1μg/ml.Total RNA was isolated using TRI-Reagent. cDNA was prepared through MMLV reverse transcriptase, then quantitative PCR (qPCR) was performed by Maxima SYBR Green qPCR Master Mix.RANKL was quantify by ELISA Assay and flow cytometry.
Results: Our findings indicate that the autonomous release of RANKL (Receptor activator of nuclear factor kappa-B ligand) by MM cells is essential for their ability to boost osteoclastogenesis. Interestingly, RANKL release is Notch-dependent, since Jagged1/2 silencing in MM cells causes the inhibition of the Notch pathway and impairs their ability to secrete RANKL and to stimulate osteoclasts (OCLs) differentiation and activity. MM-derived Jagged are also able to directly activate the pro-osteoclastogenic Notch signaling in neighboring pre-OCLs, boosting their differentiation. Moreover, Jagged1/2 are essential for the interaction of MM cells with BM stromal cells (BMSCs), that can further enhance the osteoclastogenic potential of tumor cells. Jagged1/2 withdrawal blocks the cross-talk between MM cells and the surrounding BMSCs and pre-OCLs, finally causing a decrease in the formation of mature OCLs and in bone resorption.
Summary and Conclusions: Our study provided the first evidence that two Notch ligands dysregulated in MM, Jagged 1 and 2, play an essential role in myeloma-induced osteoclast differentiation and bone resorption activity. Jagged ligands can trigger Notch signaling in the same MM cells, resulting in the release of the key osteoclastogenic factor RANKL, and may also activate Notch signaling in the neighboring osteoclast progenitor further promoting their differentiation. Finally, we demonstrated that MM cells are able to crosstalk with BMSCs which are able to stimulate low-RANKL expressing myeloma cells, to release higher amount of RANKL and acquire osteoclastogenic ability. Importantly, BMSC support can be prevented by silencing Jagged ligands on myeloma cells. All together, our results demonstrate that the two Notch ligands Jagged1 and 2 represents two new promising therapeutic targets in MM-associated bone disease.

LB296

BORTEZOMIB, DEXAMETHASONE, THALIDOMIDE AND MELPHALAN (VDT-MEL) PREPARATIVE REGIMEN RESULTS IN A VERY HIGH STRINGENT CR (SCR) RATE IN MULTIPLE MYELOMA (MM)

K. Nadiminti[1,*] L. Dozeman[1], A. Schultz[2], A. Tricot[2], S. Bell[3], F. Zhan[1], K. Abbi[1], G. Tricot[1]
[1]Hematology,Oncology and Bone marrow transplant, [2]Holden Cancer Center clinical trials support core, [3]Biostatistics core alliance, University of Iowa Hospitals and Clinics, Iowa City, United States

Background: The role of autologous stem cell transplant (ASCT) in the treatment of myeloma has been well established and Melphalan 200mg/m^2 has been the standard preparative regimen of choice. Although the introduction of novel agents improved the treatment of myeloma significantly, data about their role in preparative regimens are very scarce.
Aims: The purpose of this study is to understand the toxicity and efficacy of novel agents used in combination with high-dose melphalan as a new preparative regimen.
Methods: Retrospective analysis was performed on all patients who received an ASCT with the VDT- Mel during 2012- 2014. IRB approval was obtained. To determine which variables were significantly associated with the odds of achieving a sCR post-transplant, logistic regression models were applied. All statistical testing was two-sided and assessed for significance at the 5% level using SAS v9.4 (SAS Institute, Cary, NC). Clinical end points were treatment- related toxicity and quality of response
Results: 97 patients underwent 149 transplants and toxicity was analyzed at 100 days; 45 patients underwent single and 52 had tandem transplants (TT), respectively; 66 patients received early and 31 salvage transplantation. Median age was 59 y. Best responses were 58% sCR, 20%CR, and 9.5% VGPR. For patients receiving early transplantation, the sCR rate was 61%, and for TT patients, 62%. Only early *versus* salvage transplantation was significant for achieving sCR with a hazard ratio: 3.18 (P =0.02). Grade 3 and 4 non-hematologic toxicities were related to infections in 54%; 100 day mortality was 2% and 3.8% for single and TT, respectively. Median time to ANC>500/μL was 12 days in both early and late transplantation.
Summary and Conclusions: This study shows that VTD-Mel is a well-tolerated preparative regimen. Importantly, the sCR rate was significantly higher than in other published studies. Since sCR is an early surrogate marker for progression-free and overall survival, it appears likely that this regimen will be superior to melphalan alone and may become the new standard preparative regimen for ASCT in myeloma. This is the largest study performed to date evaluating this novel preparative regimen.

LB297

SIGNIFICANT IMPACT OF MINIMAL RESIDUAL DISEASE (MRD) STATUS ON SURVIVAL OUTCOMES IN PATIENTS WITH MULTIPLE MYELOMA (MM) WHO ACHIEVE COMPLETE RESPONSE (CR): A META-ANALYSIS

N. Munshi[1,*] H. Avet-Loiseau[2], A. Rawstron[3], R. Owen[3], A. Thakurta[4], P. Sherrington[5], A. Georgieva[6], K. Anderson[1], W. Gregory[7]
[1]Dana-Farber Cancer Institute, Boston, United States, [2]Unit for Genomics in Myeloma, Institut Universitaire du Cancer, Toulouse, France, [3]St James's University Hospital, Leeds, United Kingdom, [4]Celgene Corporation, Summit, NJ, United States, [5]Celgene International, Boudry, Switzerland, [6]Excerpta Medica, Amsterdam, Netherlands, [7]University of Leeds, Leeds, United Kingdom

Background: Most patients with MM eventually relapse, suggesting that a residual disease which cannot be detected by conventional assessment persists, even in patients achieving CR with treatment.
Aims: To assess the impact of MRD status on survival outcomes in patients with MM who achieved CR.
Methods: A PubMed search was performed to identify studies published between January 1990 and September 2014, with ≥20 newly-diagnosed patients with MM. Patients requiring treatment and who had MRD evaluation results were included in this meta-analysis. Analysis was restricted to techniques with a limit of detection of 0.01% or lower. If primary data were not accessible, survival graphs were used to derive individual survival and censoring times. Data were adjusted for the different proportions of MRD patients in different studies using a method that considers time-dependent effects (Gregory WM, Br J Cancer 1988). *P*-values are for adjusted log-rank χ^2 tests.
Results: A total of 302 published articles were retrieved and 25 articles were identified through the reference sections of recently published articles. Of these, 18 reported overall survival (OS) or progression-free survival (PFS) results, as well as MRD status. Overall, 2,208 pts were evaluated for MRD by methods including multiparameter flow cytometry (n=1,606), PCR (n=492), or high-throughput sequencing (n=110). Nine publications reported conventional CR at the time of MRD measurement; however only 4 represented unique data sets. In total, there were 496 evaluable patients (362 were MRD-negative and 134 MRD-positive). The presence of MRD predicted shorter PFS (odds ratio [OR] 0.36; 95% confidence interval [CI] 0.26–0.50; $P < 0.0001$). Median PFS was 60 months for MRD-negative patients *versus* 36 months for MRD-positive patients; PFS at 3 years was 72% *versus* 50%, respectively and at 5 years was 50% *versus* 29%. MRD-negativity reduced the odds of death by 59% (OR 0.41; 95% CI 0.26–0.63; $P < 0.0001$); median OS was not reached for MRD-negative patients *versus* 82 months for MRD-positive patients. OS was higher for MRD-negative patients *versus* MRD-positive patients at 3-years (93% *vs* 79%) and 5-years (78% *vs* 60%). Presence of MRD was predictive of outcome in patients with adverse cytogenetic profiles. Overall, 37% of MRD-negative patients *versus* 7% of MRD-positive patients were progression-free at 8 years. There was no significant difference between studies in the impact of achieving MRD-negativity on outcome, indicating that the predictive value of MRD status does not depend on the type of treatment.
Summary and Conclusions: These results show that MRD negativity, as determined by various high-sensitivity methods, predicted for substantially bet-

ter PFS and OS in patients with MM who had achieved CR. Furthermore, nearly all MRD-positive patients had disease progression within 8 years, whereas a third of MRD-negative patients remained progression-free. This large cohort, meta-analysis confirms that MRD status is a crucial marker of long-term outcomes in patients with MM. It is, therefore, a key endpoint in MM clinical trials and clearly also has an important role as a surrogate marker of OS.

Biology of MPN

P296

INCREASED AND PROLONGED STAT5 ACTIVATION DETECTED FOR A JAK2 E846D GERMLINE MUTATION IN THE SPECIFIC CONTEXT OF EPO RECEPTOR

K. Kapralova[1,2,3,*] M. Horvathova[3], C. Pecquet[1,2], J. Kucerova[3], D. Pospisilova[4], E. Leroy[1,2], B. Kralova[3], S.N. Constantinescu[1,2], V. Divoky[3]
[1]de Duve Institute, Université catholique de Louvain, [2]Ludwig Institute for Cancer Research, Brussels, Belgium, [3]Department of Biology, Faculty of Medicine and Dentistry, Palacky University, [4]Department of Pediatrics, University Hospital and Faculty of Medicine and Dentistry, Olomouc, Czech Republic

Background: Somatic mutations of a gene that encodes the *Janus kinase 2* (JAK2) are the most observed disease-causing events of the myeloproliferative neoplasms (MPN). Recently, germline JAK2 mutations have been described in cases with familial MPN, exhibiting hereditary thrombocytosis.
Aims: To characterize a novel JAK2 germline mutation found in a patient with erythrocytosis.
Methods: The effect of JAK2 E846D mutation was functionally analyzed using Ba/F3-EPOR cells (immunoblots, BrdU, MTT, inhibitors assays) and JAK2-deficient γ2A cells (reporter luciferase assay).
Results: The patient was diagnosed with increased red cell mass, facial plethora and splenomegaly at the age of 15. The bone marrow aspirate showed features typical for MPN. Two heterozygous mutations were found by targeted analyses; E846D in JAK2 inherited from the mother and Q157H in PHD2 (SNP rs61750991) inherited from the father. Erythroid progenitors derived from the patient and his parents were hypersensitive to erythropoietin (EPO), however only the patient exhibited the erythrocytosis phenotype. *In silico* modeling of JAK2 showed that the substitution of Glu by a residue one CH2 shorter, namely Asp, in the kinase domain might result in a formation of a tighter salt bridge to residue K926, more difficult to disrupt upon returning of JAK2 to its inactive state. This leads to a prolonged activation of JAK2 kinase.
Ba/F3 JAK2 E846D stable transfectants have revealed EPO-induced increased and prolonged JAK2 and STAT5 activation detected by immunoblots assessing active forms of JAK2 and STAT5. This was subsequently confirmed by luciferase assay in γ2A cells that detected higher and prolonged cytokine-induced levels of STAT5 transcriptional activity. Surprisingly, among the STAT family members, the E846D substitution significantly increased only STAT5 transcriptional activity and only in the presence of EPO receptor but not with TPO or G-CSF receptors. Two JAK2 inhibitors (Ruxolitinib, AZ-960) reduced the prolonged STAT5 activation; the E846D variant exhibited similar sensitivity as oncogenic JAK2 V617F. Although the E846D did not support growth factor independence of Ba/F3 cells as V617F, increased STAT5 activity was detected also in the condition without cytokines in transcriptional assays. In addition, Ba/F3 JAK2 E846D transfectants showed improved survival in EPO-limiting conditions when compared to JAK2 wild-type (wt) cells. Cell cycle studies demonstrated that upon growth factor starvation JAK2 E846D cells re-enter faster into S phase in low EPO concentrations, when compares to JAK2 wt.
Summary and Conclusions: The germline JAK2 E846D mutation emerged as the main disease causing event in our patient. It causes EPO hypersensitivity and erythroid hyperproliferation due to increased and prolonged JAK2/STAT5 signaling. This mutation gives this phenotype only in the context of the EPO receptor, explaining the erythrocytosis *in vivo*. We propose that the disease is a hereditary myeloproliferative disorder with incomplete penetrance; we observed full clinical phenotype in the patient and intermediate phenotype in the mother, the genetic background likely contributing to the extent of disease expression. *Grants support: P301/12/1503, NT13587-4, CZ.1.07/2.3.00/20.0164, CZ.1.07/2.3.00/30.0041 from Czech Republic; MEXP31C1, ARC10/15-027, FRIA PhD fellowship from Belgium.*

Background: Polycythemia Vera (PV), Essential Thrombocythemia (ET) and Primary Myelofibrosis are myeloproliferative neoplasms (MPN) characterized by a clonal proliferation of hematopoietic progenitors that results in an overproduction of mature blood cells. Several molecular abnormalities have already been described in progenitor cells such as *JAK2* or *CALR* mutations which activate the STAT signaling pathway causing an enhanced and uncontrolled proliferation of progenitor cells. In parallel, leucocyte and platelet functional alterations have been reported in MPN patients. Nevertheless, little is known about functional and protein alterations of erythrocytes despite their implications in PV. Initial studies showed that abnormal red blood cell (RBC) adhesion to endothelial cells in PV, which can cause vascular complications, could be due to the activation of Lu/BCAM by the JAK2V617F/Akt/Rap1 pathway.
Aims: In this context, we have developed an integrative study of RBC proteome in PV and ET looking for protein deregulations that could be related to functional RBC alterations and MPN physiopathology.
Methods: Seeing as hemoglobin is a big impediment to the study of the RBC proteome, we developed one technique based on the capture of low abundant proteins by ferromagnetic beads surrounded by chemical surfaces. This hemoglobin depletion was used on 48 samples (PV, ET and controls) before MS analysis which allowed us to select, according to their proteomic profile, the five most representative patients of each subgroup for LC MS/MS analysis (LTQ Orbitrap).
Results: Quantitative comparative analysis distinguished 1019 proteins among which 51 were upregulated in PV and 86 in ET compared with controls. Furthermore, functional comparison using *Ingenuity Pathway Analysis* software showed that the Ras GTPase family pathway was deregulated in both MPN patients. Specifically, *Ras GTPase-activating like protein IQGAP1* was overexpressed in ET and PV compared with controls ($p<0.05$). Additionally, mass spectrometry result verification by westernblot not only highlighted IQGAP1 overexpression in PV and ET compared with controls ($p<0.01$) but also depending on patient genotype (*JAK2V617F>CALR+*,$p<0.05$; *JAK2->CALR+,* $p<0.05$). IQGAP1 is a scaffold protein that regulates several pathways including Ras GTPase ones. Therefore, we explored connections between IQGAP1 and Rho GTPases (Ras GTPase subfamily) demonstrating direct links between IQGAP1 and Rac1, Cdc42 and RhoA in patient RBCs. Moreover, we found that the Rho subfamily protein recruitment profile by IQGAP1 was different between *JAK2+* patients where it linked activated Rac1 but not RhoGDI (Rho GTPase inhibitor). Conversely, in *CALR+* patients, IQGAP1 co-precipitated with RhoGDI but didn't with Rac1, underlining a different impact of IQGAP1 overexpression between *CALR+* and *JAK2+* patients. We also found that calreticulin protein was expressed in erythrocytes independently of *JAK2* or *CALR* mutation but it didn't interact with IQGAP1. Finally, we showed that p21 activated kinase 1 (PAK1), a Rho GTPase effector implicated in cell motility, and its phosphorylated form (PAK1-P), co-precipitated with activated Rac1 as well as with IQGAP1.
Summary and Conclusions: Our data showed a deregulation of IQGAP1-Rho-GTPase signaling that could be implicated in erythrocyte adhesion alterations and thereby in vascular complications via the activation of the cytoskeleton motility protein PAK1. Differential recruitment of RhoGDI and Rac1 between *CALR+* and *JAK2+* patients might induce variations of PAK1 activation and thereby take part in variations of vascular risk among different genotypes.

CRITICAL ROLE OF HIS499 IN REGULATING THE DIMERIZATION AND FUNCTION OF THE HUMAN THROMBOPOIETIN RECEPTOR AND RESTRAINING THE REPERTOIRE OF ASPARAGINE PATHOGENIC MUTATIONS

E. Leroy[1,*] J.P. Defour[1], T. Sato[2], S. Dass[2], V. Gryshkova[1], S. Myat Marlar[1], J. Staerk[3], S.N. Constantinescu[1], S.O. Smith[2]

Background: The thrombopoietin receptor (TpoR) is a member of the type-I cytokine receptor family that regulates the proliferation and differentiation of megakaryocytes, as well as stem cell homeostasis. Tpo binding mediates dimerization of the extracellular domain of the receptor, which imparts a specific orientation on the receptor's transmembrane (TM) and intracellular (IC) domains. TpoR can autonomously dimerize in the presence of asparagine substitutions in its TM domain leading to its activation, as it is the case with the Essential Thrombocythaemia associated mutant «TpoR S505N».
Aims: We aim to determine the molecular mechanisms regulating TpoR dimerization and function in the context of the asparagine mutant S505N, and whether TM asparagine mutations other than S505N could be identified in MPNs.
Methods: First, we took advantage of differences in the murine and human TpoR sequences and we performed asparagine-scanning mutagenesis on the receptors TM domain. We used a combination of transcriptional activity and cellular growth to map out the inactive and active orientations of the transmembrane helices. Second, we assess TpoR dimerization by using a split luciferase reporter. Third, we used protein segments corresponding to the receptor transmembrane and juxtamembrane domains in order to complete polarized IR and solid-state NMR spectroscopy**.**
Results: Asparagine mutants in the transmembrane domains of the murine and human TpoR did not display the same biologic effects; while mTpoR exhibited several active conformations; only one variant of hTpoR (S505N) was consistent with constitutive signaling. Our studies indicate that this discrepancy could be attributed to the eltrombopag (Promacta/Revolade; GlaxoSmithKline, London, UK) target, His499, only present in the human TpoR TM domain. Indeed, by point mutational studies, we showed that His499 was responsible for protecting the human receptor from activation by several Asn mutations. By spectroscopy, using short peptides, we showed that His499 accounts for a change in the conformation and secondary structure of the transmembrane helix and shifts the monomer-dimer equilibrium toward monomer for the human TpoR. Strikingly, replacement of His499 by Leu, the residue at the corresponding position in the murine TpoR induces dimerization of these peptides. When His499 is replaced by Leu in the human TpoR, asparagine substitutions at several different TM positions activate oncogenic signaling, like in the case of the murine TpoR.
Summary and Conclusions: We show that His499 is critical for dimerization of human TpoR and orientation-dependent activation. Using alignments of TpoRs from different species and other cytokine receptors we show His499 in TpoR evolved from primates and we discuss its possible role in evolution in preventing oncogenic activation by multiple asparagine substitutions.

COMBINED CONSTITUTIVE CANONICAL AND NON-CANONICAL HH SIGNALING CAUSED BY DEPLETION OF PATCHED 2 INDUCES A MYELOPROLIFERATIVE PHENOTYPE AND TRANSFORMS CHRONIC MPNS INTO ACUTE LEUKEMIAS

C. Klein[1,*] A. Kuhn[1], S. Kissel[1], D. Pfeifer[1], L. Illert[1], M. Follo[1], J. Duyster[1], R. Oostendorp[2], C. Dierks[1]
[1]Innere Medizin-Hämatologie/Onkologie, Universitätsklinikum Freiburg, Freiburg, [2]Medizinische Klinik des Klinikums rechts der Isar, München, Germany

Background: MPNs frequently transform into leukemias, but the factors driving this process are not understood. Aberrant Hedgehog (HH) ligand secretion, as frequently found in MPN and CML, not only induces constitutive Smoothened-dependent canonical HH-signaling causing GLI1 transcription, but also causes PTCH1-dependent non-canonical HH signaling leading to constitutive ERK activation. HH-ligands do not only act on malignant cells, but also stimulate the surrounding niche cells, driving dual pathway activation in both compartments. Previous results in CLL show, that HH ligand induced dual pathway activation causes primary resistance to SMO-inhibitors. Combined canonical- and non-canonical pathway activation was so far never investigated regarding hematopoietic development and leukemic transformation.
Aims: Evaluate the effects of combined activated canonical and non-canonical HH signaling within hematopoietic and niche cells in normal and malignant hematopoiesis, especially regarding acceleration of myeloproliferative diseases into leukemias.
Methods: Human PB samples of CML (BCR-ABL), AML and MPN (Jak2V617F$^+$) patients were analyzed concerning canonical-and non-canonical HH signaling activation. The phenotype of Ptch2$^{-/-}$mice mimicking over-activated canonical and non-canonical HH signaling was described and this model was used for *in vivo* transplantation experiments. Therefore hematological or niche Ptch2$^{-/-}$was analyzed and combined with Jak2V617F or BCR-ABL regarding disease development.
Results: Our investigations show, that excess HH ligand secretion is present in MPNs and CMLs, while absent in AML, and constitutively activates canonical-and non-canonical HH-signaling. Furthermore 70% of MPN-and CML-cases display loss of the Ptch1-competitive Ptch2 receptor. Depletion of the Ptch2 receptor *in vitro* and *in vivo* recapitulates overactivation of both pathways (canonical-and non-canonical HH signaling), while depletion of Ptch1 only reflects constitutive Gli1 activation (canonical). Ptch2$^{-/-}$mice develop a pronounced hematopoietic phenotype with leukocytosis driven by an increase in neutrophils and monocytes, anemia, loss of B-and T-cells combined with a strong increase of cKit$^+$ progenitors in the peripheral blood and increased extramedullary hematopoiesis causing splenomegaly reflecting a MPN phenotype. LKS (lin$^-$cKit$^+$Sca1$^+$) cells residing within the BM (bone marrow) showed enhanced cycling properties causing exhaustion and loss of LKS cells over time, but improved stress hematopoiesis after 5-FU treatment. Niche change experiments show that cytopenias and loss of LKS cells are caused by overactivated HH signaling within the niche cells, causing depletion of osteoblasts and alterations of essential niche factors like *Cxcl12, Scf, Angiopoietin* or *Jagged1*. In contrast, the hematopoietic Ptch2$^{-/-}$is responsible for leuko-

cytosis and even promotes LKS expansion and replating capacity *in vitro*. Interestingly, depletion of Ptch2 in the niche or within hematopoietic cells dramatically altered Jak2V617F driven pathogenesis causing transformation of a non-lethal chronic myeloproliferative disease into an agressive AML-like disease with up to 30% blasts in the peripheral blood. In contrast, the BCR-ABL-driven leukemia was exclusively accelerated by the cell intrinsic Ptch2$^{-/-}$, but not by cell extrinsic HH activation.

Summary and Conclusions: Combined constitutive canonical and non-canonical HH activation induced by depletion of Ptch2 causes a MPN phenotype driven by cell intrinsic, but mainly cell extrinsic mechanisms and accelerates myeloproliferative diseases caused by Jak2V617F and BCR-ABL into acute leukemias. These finding suggest combined canonical-and non-canonical HH pathway inhibition as a potential treatment option to prevent disease progression in myeloproliferative diseases.

P300

PROSPECTIVE ISOLATION OF NOVEL POPULATIONS OF MEGAKARYOCYTE-AND ERYTHROID-PRIMED MEGAKARYOCYTE-ERYTHROID PROGENITORS DEMONSTRATES MEGAKARYOCYTE-BIASED LINEAGE COMMITMENT IN PRIMARY MYELOFIBROSIS

B. Psaila[1,2,*] D. Iskander[1], A. Mead[3], A. Roy[1], D. Milojkovic[1], A. Chaidos[1], S. Loaiza[1], V. Caputo[1], N. Ashley[3], A. Karadimitris[1], I. Roberts[1,3]
[1]Haematology, Imperial College London, London, United Kingdom, [2]Hematopoiesis, National Human Genome Research Institute, National Institutes of Health, Bethesda, United States, [3]MRC Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom

Background: In Primary Myelofibrosis (PMF), mutations in the JAK-STAT pathway result in clonal myeloproliferation and abnormal megakaryopoiesis. Increased low-ploidy/immature megakaryocytes (MKs) are a diagnostic hallmark, and aberrant MK expression of fibro-angiogenic cytokines mediates BM fibrosis. The increased MKs in PMF have been attributed to increased MK proliferation, inhibited endoreduplication and apoptosis. MKs and erythroid (E) cells arise from a common progenitor (MEP). Due to lack of precise immunophenotypic definitions of both MEP and early committed MK progenitors (MKP), whether biased commitment to the MK lineage also contributes to aberrant megakaryopoiesis in PMF has not been properly explored.

Aims: Using current strategies, immunophenotypic MEP are a negatively defined, heterogeneous population. To enable detailed investigation of megakaryopoiesis in PMF we sought 1) To determine whether MEP cells primed/poised for MK differentiation and early committed MKs could be identified by their surface antigen expression 2) To prospectively isolate and compare these populations in PMF and controls.

Methods: Peripheral blood CD34+ progenitors from healthy mobilized donors (n=7) and JAK2+PMF (n=10) were analysed using previously validated immunophenotyping (Weissman *et al*). A novel strategy was then developed to examine expression of MK and E-associated antigens CD71, CD41 and CD42 within CD123-CD45RA-CD34+CD38+MEP. Specific MEP populations were FACS-isolated for functional/molecular studies at population and single-cell level using lineage-specific liquid cultures, clonogenic assays and transcriptional profiling (Taqman/Fluidigm).

Results: To capture the earliest stages of megakaryopoiesis, we first examined myeloid progenitor populations and found a higher % of immunophenotypically-defined MEP in PMF *vs* controls (P<0.05). Three MEP fractions were identified by their expression of CD71 and CD41. Prospective isolation of these populations demonstrated that CD71+CD41+MEP had highest MK colony forming activity ("MK-MEP"), while CD71+CD41-MEP showed highest E colony forming activity ("E-MEP"). Notably, MK-MEP, although MK-"primed", retained the ability for erythroid differentiation, giving rise to BFU-E colonies and GlyA+CD71hi mature erythroblasts, and CD71+CD41-MEP gave rise to MKs. Isolating populations from early*in vitro* MK cultures confirmed that CD71hiCD41-CD42-and CD71+CD41+CD42-cells were bipotent and could give rise to either MK or E, and CD71loCD41hiCD42+MKP were the first identifiable *committed* MKP with no E potential. Single cell and population transcriptional profiling with a panel of 43 mega-erythropoiesis genes confirmed that MK-MEP and E-MEP possessed MK and E gene expression signatures. Bivariate Pearson correlation analyses suggested that gene expression was strongly correlated between single cell E-and MK-MEP replicates (>0.7), with greater heterogeneity among total MEP. Comparing PMF and control MEP *ex vivo* demonstrated higher %MK-MEP in PMF (P=0.01). Further, a higher % of MK-MEP expressed CD42 in PMF(P=0.003) and MK-MEP from PMF patients showed more pronounced MK bias with reduced E colony forming activity and higher expression of MK-*vs* E-associated genes (increased Fli1/PF4 in tandem with reduced EKLF).

Summary and Conclusions: Co-expression of CD71 and CD41 allows for prospective identification of bipotent MEP cells that are primed/poised for MK *vs* E differentiation, while CD42 marks commitment to the MK lineage. Functional/molecular profiling indicate that MK-MEP and E-MEP represent homogeneous populations within the more heterogeneous MEP. In PMF, although the frequency of immunophenotypically-defined MEP appears higher, this is due to increased MK-committed CD42+MKPs. Together with reduced BFU-E output, this suggests a bias towards megakaryopoiesis at the expense of erythropoiesis at the level of the MEP. Abnormal regulation of mega-erythropoiesis in PMF may underlie the pathologically expanded MKs and refractory anaemia, and the ability to prospectively identify these populations enables further detailed molecular characterization in PMF and related disorders.

P301

HIGH RESOLUTION CYTOGENETIC MAPPING AND WHOLE EXOME SEQUENCING REVEAL A COMPLEX PATTERN OF CHROMOSOME 6P ABERRATIONS IN PATIENTS WITH MYELOID MALIGNANCIES

Background: Chromosomal aberrations, together with somatic mutations, contribute to disease onset and progression in myeloid malignancies. The detection of these aberrations in patients has allowed identification of genes involved in the disease pathogenesis. Chromosome 6 shows high complexity of aberrations detected in patients. We previously showed that *JARID2* is a target for deletions amplified to homozygosity by 6pUPD (uniparental disomy). However, *JARID2* is not mutated in the rest of the patients with 6pUPD. This implies that other genes are possibly targets of chromosome 6p (chr 6p) aberrations.

Aims: Identification of target genes of chromosome 6p aberrations in patients with myeloid malignancies, using cytogenetic mapping and whole exome sequencing.

Methods: Peripheral blood samples (n=913) were collected from patients with myeloproliferative neoplasms (MPN), post-MPN acute myeloid leukemia (AML), myelodysplastic syndrome (MDS) post-MDS AML, de novo AML (dnAML) and chronic myeloid leukemia (CML), along with written informed consent, in compliance with local ethics committees. Genomic DNA was isolated from whole blood, granulocytes or mononuclear cells. Affymetrix Genome-Wide Human SNP 6.0 arrays and Genotyping Console software were used for detecting deletions, gains and UPDs. Whole exome sequencing was performed, using the TruSeq DNA sample prep kit and exome enrichment kit (Illumina), on the Illumina HiSeq2000 instrument. Data was analyzed with the GATK Haplotype Caller code. Variants were filtered for exonic and splice site variants, located in the affected region of chr 6 (individually defined for each sample). An allelic frequency filter of >50% was introduced in samples with UPD and gains of chr 6p. All variants were validated by Sanger sequencing. For 2 patients T lymphocyte DNA was used as control tissue DNA.

Results: We combined all chr 6 aberrations, detected by SNP microarrays, from 913 patient samples. A total of 41 chromosomal aberrations were detected on chr 6p in 25 patients (7 MPN, 2 progression phase MPN, 7 post-MPN AML, 2 post-MDS AML, 6 dnAML, 1 CML). Deletions represented 54% of events (n=22). Six patients harbored 6pUPD, two of which had focal deletions of *JARID2* amplified to homozygosity by UPD. An additional small deletion mapped to *JARID2*. Two independent UPD events were detected in one patient. The aberration map was complemented with exome sequencing data from 4 selected patients: 1 with a deletion (post-MPN AML), 2 with a UPD (post-MPN AML, dnAML) and 1 with a chr6 trisomy (secondary myelofibrosis). One somatic, 8 germline and 9 mutations of unknown origin were validated. None of the mutations were found in multiple patients. The somatic L521R mutation in *FAM65B* was amplified by the trisomy. Overlap of the mutations with chromosomal aberrations identified a commonly affected region containing genes *NCR3* and *PSORS1C1*. Trisomy amplified a germline *PSORS1C1* P38 frameshift mutation, whereas the *NCR3* R96Q mutation was amplified by UPD. A focal gain overlapped with a UPD-amplified *UHRF1BP1* S506P mutation.

Summary and Conclusions: Intersecting microarray data from a large pan-myeloid cohort of patients with exome sequencing data of 3 accelerated phase MPN/post-MPN AML and 1 dnAML patient resulted in identification of 4 novel genes, in addition to *JARID2*, as putative targets of chr6p lesions. As the position of the genes does not overlap with all 6pUPDs, it remains possible that mutations in regulatory regions or epigenetic events are targets amplified by 6pUPD in patients with myeloid malignancies.

P302

DNA METHYLATION PROFILING OF SORTED CELLS FROM MYELOFIBROSIS PATIENTS REVEALS ABERRANT EPIGENETIC REGULATION OF IMMUNE PATHWAYS AND IDENTIFIES EARLY MPN DRIVER GENES

H.M. Nielsen[1,2,*] C.L. Andersen[1,3], L.S. Kristensen[1], F. Asmar[1], T.A. Kruse[4], M. Thomassen[4], T.S. Larsen[5], V.H. Skov[3,4], E. Sørensen[6], H. Ullum[6], C. Riley[7], L.L. Hansen[2], O.W. Bjerrum[1], H.C. Hasselbalch[3], V. Punj[8], K. Grønbæk[1]
[1]Department of Hematology, Rigshospitalet, Copenhagen, [2]Department of Biomedicine, Aarhus University, Aarhus, [3]Department of Hematology, Roskilde Hospital, Roskilde, [4]Department of Clinical Genetics, [5]Department of Hematology, Odense University Hospital, Odense, [6]Department of Clinical Immunology and Blood Bank, Rigshospitalet, Copenhagen, [7]Department of Hematology, Herlev Hospital, Herlev, Denmark, [8]USC Epigenome Center, University of Southern California, Los Angeles, United States

Background: Primary myelofibrosis (PMF) belongs to the heterogeneous group of chronic myeloproliferative neoplasms (MPN) together with essential thrombocytosis (ET) and polycythemia vera (PV). It has been suggested that these neoplasms represent a biological continuum from early cancer stage (ET, PV) toadvancedMF. Multiple studies report frequent mutations in epigenetic regulators. However, the association to epigenetic changes and the role of epigenetic aberrations in different cell populations is still unknown.
Aims: We therefore performed DNA methylation profiling of sorted cells from MF patients to unravel pathways contributing to disease phenotype and gain insight into MF pathogenesis. As an aberrant DNA methylation pattern may be an early event in tumorigenesis and may be crucial for progression of the malignant clone towards the more aggressive forms of MPN, we further aimed to identify candidate driver genes.
Methods: Peripheral blood samples from 16 MF patients and BM (bone marrow) and peripheral blood from 3 healthy age matched controls were sorted in CD34+ cells, granulocytes and mononuclear cells, and analysed for differential methylated regions using Illumina Infinium HumanMethylation 450K BeadChip. Candidate genes were validated by pyrosequencing in a second cohort of 30 MF patients where DNA was extracted from full blood (PB). To identify potential driver genes, the DNA methylation status of candidate genes was likewise analyzed in PB from a larger cohort consisting of 60 ET and PV patients.
Results: The number of differentially methylated CpG sites between MF cells and the respective counterparts from healthy donors differed extensively among the three cell populations analyzed. In MF CD34+ cells 1628 CpG sites were differentially methylated compared to normal CD34+ cells, and 519 and 213 differential methylated CpG sites were observed in MF granulocytes and MF mononuclear cells, respectively (Δβ was set to 0.2 with an adjusted p-value <0.05, T-test). Differentially methylated genes were mainly involved in cancer and embryonic development pathways in both the MF CD34+ cells and granulocytes, while mononuclear cells also showed aberrant methylation of genes involved in the inflammatory disease pathways. MF granulocytes showed significant aberrations in pathways involving immunological diseases, cell death and survival. Candidate genes have been identified and validation is ongoing. Interestingly, a gradual increase of the DNA methylation level of*TRIM59*was observed from the healthy controls (31%) over ET (53%) to PV (64%) and MF (65%). ET patients could be distinguished from both healthy controls (*P*=0.0004, Mann-Whitney test) and from the more progressed stages PV and MF (*P*=0.0132, Mann-Whitney test) based on the*TRIM59*DNA methylation level.*TRIM59*promoter methylation could, however, not discriminate between PV and MF (*P*=0.4721, Mann-Whitney test).
Summary and Conclusions: Genome-wide DNA methylation profiling of sorted MF blood cells provided an exclusive insight into the pathways that contribute to the MF phenotype at a cell specific level. The MF CD34+ cells had the highest number of differential methylated CpG sites (n=1628) when comparing to granulocytes (n=519) and mononuclear cells (n=213) and should be cells of choice when exploring new treatment strategies. Interestingly, the mononuclear compartment show aberrant methylation of inflammatory genes supporting a role of aberrant immune regulation in the pathogenesis of MPN. Earlier studies have failed to identify aberrant methylation in early ET and PV, however, our preliminary data on the methylation of individual genes (*TRIM59*promoter methylation) shows that early MPN driver genes may be identified. Further studies are ongoing to unravel the power by which DNA methylation can discriminate between reactive thrombocytosis and ET. These data will be presented at the meeting.

P303

SEQUENTIAL EVALUATIONS OF CALR MUTANT BURDEN IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS

C. Cavalloni[1,*] E. Rumi[2], V. Ferretti[2], D. Pietra[2], I.C. Casetti[1], E. Sant'Antonio[1], M. Bellini[1], C. Milanesi[2], M.R. Renna[2], C. Astori[2], M. Cazzola[3]
[1]Department of Molecular Medicine, University of Pavia, [2]Department of Hematology Oncology, Fondazione IRCCS Policlinico S. Matteo, [3]Department of Hematology Oncology, Department of Molecular Medicine, Fondazione IRCCS Policlinico S. Matteo, University of Pavia, Pavia, Pavia, Italy

Background: Recently, somatic mutations of *CALR*, encoding calreticulin, have been found in most patients with essential thrombocythemia (ET) or primary myelofibrosis (PMF) with nonmutated *JAK2* and *MPL*. Previous studies have reported that most *CALR* mutations are heterozygous. Data regarding sequential evaluations of *CALR* mutant burden are still lacking.
Aims: We studied the variation of *CALR* mutant burden during follow-up in a large cohort of *CALR* mutated myeloproliferative neoplasms (MPN) compared to *JAK2* (V617F) mutated patients matched for diagnosis.
Methods: Inclusion in the current study required availability of clinical data at diagnosis and during follow-up and at least two DNA samples to assess variations of mutant allele burden. A total of 94 *CALR* mutated patients (60 ET, 29 PMF, 5 post-ET myelofibrosis) were collected from our database at the Department of Hematology Oncology Pavia, Italy. This cohort was compared with a cohort of 218 *JAK2* mutated patients with similar diagnosis (170 ET, 44 PMF, 4 post-ET MF). The evaluation of *CALR* mutant burden was done comparing the height of the mutated and wild type picks. A quantitative real-time polymerase chain reaction (qRT-PCR)-based allelic discrimination assay was employed for the quantification of the *JAK2* (V617F) allele. For each patient we calculated the variation from first to last evaluation and the slope between sequential assessments (*i.e.* the slope of the regression line with allele burden as outcome and time as covariate).
Results: 91 of 94 *CALR* mutated patients remained positive at the second evaluation, except for three of them who underwent bone marrow transplantation, that were indeed excluded from further analyses. All of the 3 leukemic evolutions were still *CALR* mutated. Statistical analysis was carried on ET and PMF, due the low number of post-ET MF.Considering first and last evaluation, we observed a significant increase in the median value of mutant *CALR* in ET patients (45.5% *vs* 49%, Wilcoxon signed-rank test *P*=0.007), while it remained stable over time in PMF (51% *vs* 51%, *P*=0.428). Median values of slope were positive both in ET (0.05% increase of *CALR* mutant alleles/month) and in PMF (0.02% increase of *CALR* mutant alleles/month). Mann Whitney U test showed a trend toward a difference between natural and therapy-related slope in ET (*P*=0.09) but not in PMF (*P*=0.126). Then we calculated the slope in a corresponding cohort of *JAK2* mutated ET and PMF: the slope was 0.01% (0.01% increase of *JAK2* V617F alleles/month) both in ET and in PMF, with a significant difference between natural and therapy-related slope in ET (*P*=0.031). To evaluate the effect of the type of mutation (*CALR vs JAK2*) on the slope of mutant burden adjusting for the effect of diagnosis (PMF *vs* ET), we performed a multivariate linear regression in all untreated patients (to avoid the potential influence of cytoreduction). Among patients with a positive slope (n=71, 14 ET *CALR*; 7 PMF *CALR*; 41 ET *JAK2*; 9 PMF *JAK2*), the increase of mutant burden was significantly higher in *CALR vs JAK2* (β=0.26, p=0.009) with no difference between diagnosis (p=0.603).
Summary and Conclusions: The increase of mutant burden during time is higher in *CALR* patients respect to *JAK2* regardless of diagnosis.

P304

NDEL1-PDGFRB FUSION GENE IN JUVENILE MYELOMONOCYTIC LEUKEMIA ASSOCIATED WITH RESISTANCE TO TYROSINE KINASE INHIBITORS

K. Byrgazov[1,*] R. Kastner[1], G. Hoermann[2], M. Gorna[3], M. Koenig[4], O. Hantschel[5], O. Haas[4], P. Valent[6], M. Dworzak[7], C. Urban[8], T. Lion[1]
[1]Molecular Microbiology, Children's Cancer Research Institute, [2]Department of Laboratory Medicine, Medical University of Vienna, [3]CeMM Research Center for Molecular Medicine, [4]Cytogenetics and FISH, Children's Cancer Research Institute, Vienna, Austria, [5]School of Life Sciences, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland, [6]Department of Internal Medicine I, Medical University of Vienna, [7]Department of Pediatrics, St. Anna Children's Hospital, Vienna, [8]Department of Pediatrics and Adolescence Medicine, Medical University of Graz, Graz, Austria

Background: A novel fusion gene NDEL1-PDGFRB was identified in a child with juvenile myelomonocytic leukemia (JMML) with no mutations in NF1/RAS/PTPN11/cCBL. Malignant disorders displaying fusion genes involving PDGFRB are generally sensitive to imatinib (IM) (Chan *et al.*, 2014), but the patient relapsed on IM and subsequently on nilotinib (NIL) treatment after initial response.
Aims: Unravel molecular mechanisms underlying acquired resistance to tyrosine kinase inhibitors (TKIs), and determine *in vitro* sensitivity to different TKIs.
Methods: Cytogenetic, FISH and 5'-RACE analyses were used to identify the translocation. A point mutation in the PDGFRB TKD was detected by Sanger sequencing of overlapping amplicons in peripheral blood specimens from the time of relapses and diagnosis. Protein modelling was done on SWISS-MODEL and I-TASSER servers using available crystal structures of VEGFR2 and CSF-1R TKDs. To test the TKI responses, BaF3 cells constitutively expressing retrovirally introduced NDEL1-PDGFRB constructs (BaF3-N-Pb) were tested in viability assays against a panel of TKIs.
Results: Reciprocal translocation t(5;7)(q33;p11.2) encoding a novel fusion gene NDEL1-PDGFRB was identified in the patient. The chimeric mRNA contains the 5´exons 1-5 of NDEL1 encoding the dimerization domain fused in frame to the PDGFRB exons 10-22 encoding the transmembrane (TM) and

tyrosine kinase (TKD) domains. Point mutation converting Asp850 into glutamate (D850E) in the activation loop (A-loop) was identified from the time of both relapses, but not diagnosis. Modelling of PDGFRβ TKD suggested that the mutation D850E may result in higher activity of the TKD and resistance to type II TKIs, in line with the observed failure of IM and NIL treatment. However, the model suggested sensitivity to type I TKIs such as dasatinib (DAS) and midostaurin (PKC412). BaF3-N-Pb^{WT} cells were sensitive to IM (IC_{50} =60 nM), NIL (100 nM), sorafenib (SOR; 20 nM), DAS (5 nM) and PKC412 (20 nM). Conversely, BaF3-N-Pb^{D850E} cells exhibited high IC_{50} to the type II TKIs IM (>2500 nM), NIL (1000 nM) and SOR (2500 nM), but retained sensitivity to the type I TKIs DAS (20 nM) and PKC412 (5 nM). Activating mutations in the A-loop of RTKs such as PDGFRA (D842V), FLT3 (D835V) or c-Kit (D816V) associated with resistance to type II TKIs were described in different tumor entities. However, the mutation D850E in the PDGFRβ TKD with apparent insensitivity to IM, NIL, and SOR revealed a different pattern of resistance than the same amino acid exchange at the corresponding site of PDGFRα (D842E) in the FIP1L1-PDGFRA fusion gene which had been previously shown to be sensitive *in vitro* to IM (4 nM), NIL (12.5 nM), and SOR (0.25 nM) (von Bubnoff *et al*., 2011). Protein modelling of PDGFRβ TKD suggested that the distinct properties of PDGFRβ TKD carrying D850E may be attributed to the poorly conserved residue in +3 position to the mutated D850. In PDGFRβ, it is arginine (R853), as opposed to histidine (H845) in PDGFRα. Mutation R853H in PDGFRβ carrying D850E reduced its kinase activity and restored *in vitro* sensitivity to type II TKIs.

Summary and Conclusions: To our knowledge, this is the first observation of an exchange between two negatively charged amino acids in a tyrosine kinase PDGFRβ associated with a major change in responsiveness to TKI treatment. The ongoing further investigation of this finding may extend our understanding of structural interactions leading to TKI resistance and activation of tyrosine kinases in MPNs.

P305

IDENTIFICATION AND CHARACTERIZATION OF PUTATIVE NEOPLASTIC STEM CELLS IN PATIENTS WITH MAST CELL LEUKEMIA

G. Eisenwort[1,2,*] B. Peter[1,2], K. Blatt[2], S. Cerny-Reiterer[1,2], G. Hoermann[3], I. Sadovnik[2], M. Bilban[3], T. Rülicke[4], M. Willmann[5], J. Schwaab[6], A. Reiter[6], W.R. Sperr[1,2], C. Mannhalter[3], P. Valent[1,2]

[1]Ludwig Boltzmann Cluster Oncology, [2]Department of Medicine I, Division of Hematology and Hemostaseology, [3]Department of Laboratory Medicine, Medical University of Vienna, [4]Institute of Laboratory Animal Science, [5]Department for Companion Animals and Horses, Small Animal Clinic, Internal Medicine, University of Veterinary Medicine, Vienna, Austria, [6]Department of Hematology and Oncology, University Hospital Mannheim, Mannheim, Germany

Background: Leukemic stem cells (LSCs) have been identified as an important therapeutic target in human leukemia and other related hematologic disorders. Systemic mastocytosis (SM) is a rare hematopoietic neoplasm characterized by abnormal growth and expansion of mast cells (MCs) in the bone marrow (BM) and other organ systems. Whereas patients with indolent SM (ISM) have a normal life-expectancy, patients with more advanced forms of SM have a grave prognosis. In these patients, neoplastic MCs are usually resistant against conventional drugs and various targeted drugs. MC leukemia (MCL) is the rare leukemic variant of advanced SM, defined by a rapid expansion of immature MCs in various hematopoietic organs and a poor prognosis with short survival. Although MCL is considered a stem cell disease, little is known about the origin and phenotype of MCL-initiating LSCs.

Aims: We examined the phenotypic and functional characteristics of putative LSCs in patients with aggressive SM (ASM, n=12) and MCL (n=6) by flow cytometry.

Methods: Highly enriched, sorted LSCs were injected into NOD-SCID-IL-2Rg$^{-/-}$mice exhibiting human membrane-bound SCF (NSG_{SCF}).

Results: We found that disease-initiating and propagating LSCs reside within a $CD34^+$fraction of the MCL clone. Whereas cell fractions containing $CD34^+$ cells as well as highly enriched $CD34^+$ cells engrafted in NSG_{SCF} mice with a MCL-like disease, no substantial engraftment was produced by MC-rich but stem cell-depleted, $KIT^+/CD34^-$ cell fractions obtained from the same patients. Moreover, we were able to confirm long-term engraftment by successful serial transplantations into secondary recipient mice. As assessed by flow cytometry, the $CD34^+/CD38^-$ MCL LSCs were found to co-express several stem cell markers, including aminopeptidase-N (CD13), leukosialin (CD43), Pgp-1 (CD44), the IL-3R alpha-chain (CD123), AC133 (CD133) and CXCR4 (CD184). In addition, in several of the patients examined, MCL LSCs were found to display IL-1RAP, a surface antigen that is otherwise expressed in CML LSCs but is not expressed in normal stem cells. In addition, MCL LSCs were found to express various cell surface targets, including CD33 and CD52. By contrast, MCL LSCs did not express CD2, CD25, CD26 and CLL-1. In patients with ISM and ASM, the $CD34^+/CD38^-$ stem cells exhibited a similar surface marker profile compared to MCL, but expressed higher levels of CD117, lower levels of CD133, and did never express IL-1RAP. Subsequently, we examined the effects of target-specific antibodies. As assessed by flow cytometry, the CD52-targeting antibody alemtuzumab was found to induce lysis of $CD34^+/CD38^-$cells in all MCL samples analysed. Furthermore, pre-incubation of MCL cells with alemtuzumab prior to injection into NSG_{SCF} mice resulted in a significantly reduced engraftment.

Summary and Conclusions: In conclusion, our data show that the MCL clone originates from a primitive hematopoietic stem cell. In addition, our data indicate that MCL LSC express a number of clinically relevant surface targets, including CD33, CD52 and CD117 (KIT). These observations may lead to the development of novel LSC-eradicating treatment concepts in this highly aggressive and drug-resistant form of leukemia.

P306

COMORBIDITY AND ITS IMPACT ON ALL-CAUSE MORTALITY IN DANISH PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS FROM 1994-2013: A POPULATION-BASED MATCHED COHORT STUDY

M. Bak[1,*] E. Meulengracht Flachs[2], A.D. Zwisler[3], K. Juel[2], H. Frederiksen[4], H.C. Hasselbalch[1]

[1]Department of hematology, University Hospital Roskilde, Roskilde, [2]National Institute of Public Health, University of Southern Denmark, Copenhagen, [3]National Center for Rehabilitation and Palliation, University of Southern Denmark and Odense University Hospital, [4]Department of hematology, Odense University Hospital, Odense, Denmark

Background: Comorbidities are frequent in patients with myeloproliferative neoplasms (MPNs), and studies show increased comorbidity already at time of diagnosis. Furthermore studies in different cancer types, show an impact of comorbidity on all-cause mortality. Neither the overall comorbidity, nor the impact of it on all-cause mortality, have been widely investigated in large epidemiological studies including both MPN patients and matched controls.

Aims: To describe comorbidity in myeloproliferative cancer patients in Denmark compared with matched controls and assess impact of comorbidity on all-cause mortality in different MPN subgroups.

Methods: We conducted a population based cohort study, including all patients, age 18+ or older, with a first listed diagnosis of MPN: essential thrombocythemia (ET), polycythemia vera (PV), myelofibrosis (MF), unclassifiable MPN (MPN-U) and chronic myeloid leukemia (CML) in the Danish National Registry of Patients, between 1994-2013. Follow-up status was determined through linkage to the Danish Civil Registration System, and started 30 days after the first diagnosis date of MPN =index date, and continued until death, emigration, or end of 2013, whichever came first. Comorbidity prevalence at the index date was measured using an adapted version of the Charlson comorbidity index (CCI), within a ten-year period preceding index date. Codes corresponding to MPN diagnosis were excluded to allow comparison of overall non-MPN cancer comorbidity. To compare CCI with the background population, we identified ten sex and age matched individuals, without MPN, for each corresponding MPN patient. Patients and matched controls were classified into four diagnostic calendar periods (1994-1998, 1999-2003, 2004-2008, 2009-2013) and in five groups by CCI score (0, 1, 2, 3, ≥4). Prevalence of comorbidity in MPN patients and controls were compared using chi-square test and t-tests for average CCI score. Impact of comorbidity on all-cause mortality was analysed by Kaplan-Meier plots and Cox regression. Patients and controls with CCI score 0 in each group was used as reference in all analyses. We adjusted for period of diagnosis, smoking related and alcohol related conditions (yes/no) and for CML patients before/after year 2000 to allow for the introduction of tyrosine kinase inhibitor treatment.

Results: We included 9,868 patients (ET=2,735, PV=3,324, MF=603, U-MPN=1,849, CML=1,357) and a total of 98,627 matched controls. Our results show a higher percentage of patients than controls with CCI score >0 and differences between MPN patients and controls were observed for mean CCI, with significant higher CCI score in all MPN subgroups (p<0.0001) (table 1). All-cause mortality for CCI score 0, was significantly increased in all MPN subgroups compared to controls, except for ET (p=0.12) (table 1). Furthermore data showed increased all-cause mortality with increasing CCI score for both MPN patients and controls, but the influence of increasing CCI had lower impact in all MPN subgroups than in controls (P<0.05) and ET and PV patients with comorbidity had lower mortality than corresponding controls.

Tabella 1. Percentage of CCI score >0, mean CCI (± standard deviation) and hazard ratios of all-cause mortality between patients and controls without comorbidity (95%-confidence intervals).

MPN group	% CCI score > 0		Mean CCI [SD]		All-cause mortality HR (95 % CI)	
	Patients	Controls	Patients	Controls	Patients / Controls	P-value
ET	47.5	28.8	0.95 [±1.43]	0.61 [±1.30]	1.09 (0.98-1.22)	0.12
PV	48.2	30.4	0.95 [±1.44]	0.64 [±1.31]	1.21 (1.11-1.31)	<0.001
MF	52.9	35.9	1.34 [±1.84]	0.78 [±1.43]	3.21 (2.73-3.76)	<0.001
U-MPN	56.4	35.8	1.27 [±1.69]	0.76 [±1.40]	2.20 (1.99-2.44)	<0.001
CML	45.6	26.4	1.16 [±1.81]	0.55 [±1.24]	2.43 (2.16-2.74)	<0.001

Difference in mean CCI between patients and controls: P value < 0.0001 for all analysis.

Summary and Conclusions: MPN was associated with significantly increased comorbidity compared to the general population and patients with no comorbidity had higher all-cause mortality, except for ET patients. Comorbidity was associated with increased all-cause mortality in all MPN groups and controls, but impact of increasing CCI was different within the groups. Remarkably ET and PV patients with comorbidity had lower mortality than controls.

Myeloproliferative neoplasms - Clinical 1

P307

IMPACT OF JAK2, CALR OR MPL MUTATION STATUS ON PREGNANCY OUTCOME IN PATIENTS WITH ESSENTIAL THROMBOCYTEMIA

E. Rumi[1,*] I. Bertozzi[2], I.C. Casetti[1], C. Cavalloni[1], E. Sant'Antonio[1], M. Bellini[1], V.V. Ferretti[1], C. Milanesi[1], E. Peroni[2], D. Pietra[1], C. Astori[1], M.L. Randi[2], M. Cazzola[1]
[1]Department of Hematology Oncology Fondazione IRCCS Policlinico S. Matteo, Pavia, [2]Department of Medicine-DIMED, University of Padua, Padua, Italy

Background: Essential thrombocytemia (ET) may occur in women of childbearing age. Pregnancy may therefore be an issue in the clinical management of young women with ET. Previous studies have reported live birth rates of 50 to 70% and spontaneous abortion rates of 25% to 50%, mostly during the first trimester. The pathogenesis of pregnancy complications is poorly understood. Indeed, the association between *JAK2* (V617F) mutation and poor pregnancy outcome is uncertain, while data regarding the impact of the other MPN-associated driver mutations are lacking.
Aims: We studied the impact on pregnancy outcome of the three MPN driver mutations (*JAK2*, *MPL*, *CALR*) in a large cohort of pregnant ET patients.
Methods: Inclusion in the current study required availability of clinical data at diagnosis and during pregnancy, and at least one DNA sample to assess mutation status. A total of 155 pregnancies that occurred in 94 patients with ET were collected from 2 centers (Department of Hematology Oncology Pavia, and Division of Internal Medicine Padova). All patients were screened for *JAK2*, *MPL* and *CALR* mutations with previously reported methods.The 4 genotypic subgroups (*JAK2* mutated, *MPL* mutated, *CALR* mutated, and triple negative) were compared in terms of pregnancy outcome. Pregnancy complications included fetal loss (first-, second-or third-trimester miscarriage), intrauterine growth retardation (IUGR), and maternal complications.
Results: Of 94 ET patients studied, 59 (62.8%) carried *JAK2* (V617F), 19 (20.2%) carried *CALR* mutations, 2 (2.1%) carried *MPL* mutations, and 14 (14.9%) were triple-negative. The hemoglobin value at diagnosis was the only hematological parameter that differed according to mutation status, being higher in *JAK2* (V617F)-mutated patients (*P*<0.001). Three pregnancies that were terminated with voluntary abortion were excluded from this analysis. Overall, 72 of 152 pregnancies (47.4%) were complicated: 46 (30%) by fetal loss (37 during the first trimester, 6 during the second, 3 during the third), 18 (11.8%) by maternal complications, and 13 by IUGR (8.6%). The rate of complications (including both fetal and maternal complications) was not influenced by mutation status (Fisher's exact test *P* 0.134). When we restricted the analysis to late pregnancy losses, a relationship with *JAK2* (V617F) mutation (*P* 0.027) was found: second-and third-trimester miscarriage occurred in 9.4% of *JAK2* (V617F) pregnancies *vs* none of *MPL*/*CALR*/triple-negative pregnancies. Considering the potential role of calendar year at pregnancy, we observed that the rate of pregnancy complications before 2007, was higher than that reported after 2007 (54% *vs* 35%, *P* 0.028). Then, we performed a multivariate analysis considering calendar year (before or after 2007) and mutation status (*CALR vs JAK2*/*MPL*/triple negative). In multivariate analysis we found that the occurrence of pregnancy before 2007 correlated with a poorer outcome (OR 2.4, *P* 0.024), and the presence of *CALR* mutation showed a trend toward a lower rate of pregnancy complications (OR 0.4, *P* 0.059).
Summary and Conclusions: The presence of *JAK2* (V617F) mutation is associated with late pregnancy losses. The outcome of pregnancy seems to be influenced by calendar year, suggesting an improvement in our management strategy. Pregnancies occurring in *CALR*-mutated patients show a trend toward a better outcome than those occurring in *JAK2*-mutated or *MPL*-mutated or triple negative patients.

P308

QUALITY OF LIFE IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS COMPARED TO NORMAL INDIVIDUALS-CASE-CONTROL EVIDENCE OF SIGNIFICANT IMPAIRMENT

A. Duncombe[1,*] G. Titmarsh[2], M.F. McMullin[3], R. Mesa[4], R. Scherber[4], A. Dueck[4], F. De Vocht[5], L. Fritschi[6], M. Clarke[2], L.A. Anderson[2]
[1]Department of Haematology, UNIVERSITY HOSPITAL SOUTHAMPTON, Southampton, [2]Centre for Public Health, [3]Centre for Cancer Research and cell biology, Queen's University Belfast, Belfast, United Kingdom, [4]Division of Hematology and Medical Oncology, Mayo Clinic Cancer Center, Rochester, United States, [5]School of Social and community medicine, University of Bristol, Bristol, United Kingdom, [6]School of Public Health, Curtin University, Perth, Australia

Background: The myeloproliferative neoplasms (MPNs) including polycythaemia vera (PV), essential thrombocythaemia (ET) and primary myelofibrosis (PMF) arediseases of hemopoietic stem cell originthat causesignificant morbidity and mortality. Comparisons betweensymptom burdenof MPN cases and those of the general population have not previously been reported.
Aims: The aim of the study was to compare the quality of life experienced by patients with classic MPNs (PV, ET, PMF) with that of age and sex matchedindividuals with no evidence of MPN.
Methods: The myeloproliferative neoplasm symptom assessment form (MPN-SAF) is a reliable and validated clinical tool used for assessing MPN patient symptom burden. A pilot case-control study of MPN, called the 'MyelOproliferative neoplasmS: An In-depth Case-Control study' (MOSAICC), recruited MPN patients and controls in Belfast, Northern Ireland and Southampton, England. The MPN-SAF was completed by cases and, for the first time, by non-blood relatives andindividuals from primary care centres all without evidence of MPN to act as controls. Mean symptom scores were compared between cases (n=106) and controls (n=124). Mean scores in cases were then compared to published data on 1446 MPN patients from the Mayo Clinic, USA. Mean scores in cases from the UK and USA studies were then combined and compared with controls.
Results: MPN cases had significantly higher mean scores than controls for 26 of the 27 symptoms measured (p<0.05). Fatigue was the most common symptom in cases and controls (92.4% and 78.1% respectively). Patients with PMF reported the worst symptomatic burden (88.3%) which was significantly higher than that reported by PV cases (p<0.001). Female MPN patients suffered worse symptomatic burden than males (p<0.001). Compared to MPN cases in the USA, UK cases reported similar symptom burden in all categories exceptlower satiety (p=0.046).Combining the UK and USA cases resulted in an increase in significance of reported symptoms compared with the controls. Interference with work was reported in 77.4% of cases compared with 54.8% of controls (p<0.001). Abdominal pain occured in 46.4% of cases *versus* 20.3% of controls (p<0.001). Sexual problems were experienced by 60.9% of cases against 27.9% of controls (p<0.001). Bone pain occurred in 49.3% of cases compared with 19.7% of controls (p<0.001).Overall QoL was impaired in 78.4% compared with 57.4% of controls (p<0.001).
Summary and Conclusions: This novel study demonstratesthe significant morbidity experienced by MPN patients compared to controls and the similarities between patients in the UK and USA highlighting the common need to manage disease burden. For the first time the MPN-SAF has been shown to be a good discriminatory tool to assess the extent of symptoms in MPN patients compared to normal individuals.

P309

PREDICTORS OF SURVIVAL IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

D. Lekovic[1,*] M. Gotic[1,2], D. Sefer[1], O. Mitrovic-Ajtic[3], V. Cokic[3], N. Milic[2,4]
[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical faculty, [3]Institute for Medical Research, [4]Institute for Medical Statistics, University of Belgrade, Belgrade, Serbia

Background: Standard risk stratification for overall survival (OS) in patients with essential thrombocythemia (ET) is based on advanced age and history of thrombotic events. Recently, International Prognostic Score for ET (IPSET) incorporated also leukocytosis in prognostic model.
Aims: was to establish additional risk factors for OS in ET patients.
Methods: The study was conducted on 244 consecutive patients with ET who were diagnosed according to WHO criteria and treated at the Clinic for Hematology, CCS, from January 2000 to January 2012. The following parameters at diagnosis of ET were taken into consideration to find prognostic risk factors for OS: age, sex, leukocyte and platelet count, hemoglobin level, *JAK2* mutational status, splenomegaly and thrombotic events (previous and during the follow-up). We also analysed influence of cardiovascular (CV) risk factors on survival. We considered as main CV risk factors presence of arterial hypertension, diabetes mellitus and hyperlipidemia while smoking attitude was considered as additional CV risk factor.
Results: Mean age at the time of diagnosis was 56 years (range: 18-85 years) and 68% of patients were women. After the median follow up of 7 years, 32 deaths were documented (13.2%). The 5-and 10-years OS was 95.9% and 79.7% respectively. Patients with CV risk factors had increased risk of death (HR=2.33). In present study, univariate Cox analysis identified following risk factors as unfavorable predictors of survival: age≥60 years (p<0.001), leukocyte count ≥$10x10^9$/L (p=0.004), previous thrombosis (p=0.002), presence of CV risk factor (p=0.048) and CV risk factor ≥1 plus active tobacco use (p=0.012). Accordingly, we assigned risk scores based on hazard ratios (HR) to age≥60 (HR=7.2; 2 points), 1 previous thrombosis (HR=1.19; 1 point), ≥2 previous thrombosis (HR=5.7; 2 points), leukocyte count ≥$10x10^9$/L (HR=3.15; 1 point), presence of main CV risk factor (HR=2,33; 1 point) and CV risk factor ≥1 plus active tobacco use (HR=2,08; 2 points). A final 4-tiered prognostic model named Cardio-IPSET was thus developed, as low (score 0-1), intermediate-1 (score 2-3), intermediate-2 (score 4) and high risk (score 5-7) with median survivals were: not reached for the low risk group (81 patients), not reached for the intermediate-1 risk group (92 patients), 122 months for the intermediate-2 (47 patients) and 97 months for the high risk group (24 pts) (log rank=52.154, *p*<0.001). Multivariate regression analysis confirmed the statistical significance of new Cardio-IPSET prognostic model (*p*<0.001, HR 3.169, 95%CI 2.186-4.594) as only independent predictor of OS in ET patients. This new model displayed a better hazard ratio profile compared to the standard risk stratification (log rank=23.262, p<0.001) and IPSET (log rank=40,010, *p*<0.001). In addition, patients who developed arterial thrombosis during the follow-up had significantly shorter survival then those who did not develop the arterial thrombosis (97 months *vs* 140 months, *p* <0.001).

Summary and Conclusions: The addition of CV risk factors allows better prognostic assessment by delineating the intermediate risk category and improved identification of the high-risk patients. Accordingly, inclusion of CV risk factors is essential for individualizing assessment and optimizing the treatment of ET patients in term to improve their outcome.

P310

ELEVATED HEMOGLOBIN CONCENTRATION AND RISK OF ACUTE MYOCARDIAL INFARCTION AND VENOUS THROMBOEMBOLISM

M. Hultcrantz[1,*] A. Modlitba[2], S.K. Vasan[2], A. Sjölander[2], K. Rostgaard[3], O. Landgren[4], H. Hjalgrim[3], S.Y. Kristinsson[1,5], G. Edgren[1,2]
[1]Department of Medicine, Division of Hematology, Karolinska University Hospital and Karolinska Institutet, [2]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, [3]Department of Epidemiology Research, Statens Serum Institut, Copenhagen, Denmark, [4]Multiple Myeloma Service, Memorial Sloan Kettering Cancer Center, New York, United States, [5]Faculty of Medicine and Department of Hematology, University of Iceland and Landspitali National University Hospital, Reykjavik, Iceland

Background: Patients with polycythemia vera (PV) and elevated hemoglobin (Hb) concentration are at an increased risk of cardiovascular disease and venous thromboembolism (VTE). In earlier studies, patients without PV but elevated Hb were at increased risk of cardiovascular events. However, these studies were carried out before the discovery of *JAK2*V617F in the year 2005 and a number of patients with idiopathic erythrocythosis were later diagnosed with PV. Thus, there is paucity of data on the risk of vascular events in persons with an elevated Hb concentration with no known PV diagnosis.
Aims: To assess the risk of acute myocardial infarction (MI) and VTE in relation to Hb concentration among healthy blood donors without PV.
Methods: The study was based on the Scandinavian Donations and Transfusions (SCANDAT2) database, which includes nationwide data on blood donations including donor identity, date of donation, as well as current Hb from Sweden and Denmark since the 1960's and 1980's, respectively. From SCANDAT2, all donors who had performed at least one donation between 1987 and 2012 were identified. Through the nationwide Swedish and Danish Patient and Cancer Registers, information on events of MI and VTE (deep venous thrombosis and pulmonary embolism) as well as relevant co-morbidities was obtained. Patients with a diagnosis of PV were excluded. The association between Hb concentration and risk of MI or VTE was assessed using pooled logistic regression adjusted for age, sex, calendar period, country of birth, and co-morbidity. We also fitted conditional, person-adjusted models, where each individual was compared to him-/herself. Hb concentration was considered time-dependently, allowing values to change with time. Separate analyses were carried out for men and women. Results are presented as odds ratios (ORs) with 95% confidence intervals (CIs).
Results: In total, 1.6 million blood donors with a total of 22.5 million Hb measurements were included. Median age at first donation was 33.2 years, 50% of donors were women and 65% were from Sweden. The risk of MI increased gradually with higher Hb in both men and women. In the standard, adjusted model, women with Hb ≥16.5 g/dL were at 3-fold increased risk of MI (OR=3.00; 95% CI 1.95-4.62) compared to women with an Hb of 12.0-13.4 g/dL (Table). Similarly, the OR for MI in men with Hb ≥17.5 g/L was 3.49 (95% CI, 2.81-4.33) compared to those with Hb 13.0-14.4 g/dL. In the conditional model, where each subject serves as his or her own control, risks were attenuated. A slight increase in risk of MI remained in men with Hb ≥17.5 g/L (OR=1.29, 1.05-1.57) but no significantly elevated risk in women with Hb ≥16.5 g/L (OR=0.91, 0.56-1.48). For VTE, the standard model revealed a pattern with elevated risks both at subnormal Hb in men with Hb <13.0 (OR=1.61, 1.33-1.95), and a gradually increasing risk with higher Hb (Table). Again, the association largely disappeared in the person-specific conditional model. For women there was no association between current Hb and VTE risk in the standard model and an inverse association in the conditional model.

Tabella 1. Relative risk of myocardial infarction and venous thromboembolism among female and male blood donors in relation to hemoglobin concentration.

Hemoglobin concentration (g/dL)	Myocardial infarction			Venous thromboembolism		
	Number of events	Standard, adjusted model*	Conditional adjusted model†	Number of events	Standard, adjusted model*	Conditional adjusted model†
		Odds ratio (95% confidence interval)			Odds ratio (95% confidence interval)

15.0-15.9	110	2.84 (2.29-3.52)	0.96 (0.66-1.39)	82	1.23 (0.98-1.55)	0.55 (0.41-0.73)
≥16.0	22	3.00 (1.95-4.62)	0.91 (0.56-1.48)	9	0.93 (0.48-1.79)	0.27 (0.18-0.42)
Men						
0.80-12.9	133	1.01 (0.84-1.20)	0.89 (0.76-1.04)	118	1.61 (1.33-1.95)	1.11 (0.91-1.35)
13.0-14.4	1 684	1.00 (ref)	1.00 (ref)	991	1.00 (ref)	1.00 (ref)
14.5-15.9	3 198	1.36 (1.28-1.45)	1.13 (1.01-1.25)	1 672	1.15 (1.06-1.24)	1.20 (1.05-1.38)
16.0-17.4	1 098	2.14 (1.98-2.31)	1.20 (1.04-1.39)	385	1.26 (1.12-1.42)	1.09 (0.90-1.33)
≥17.5	90	3.49 (2.81-4.33)	1.29 (1.05-1.57)	18	1.38 (0.86-2.19)	0.89 (0.66-1.19)

*Adjusted for country, attained age, calendar year, and comorbidity (chronic obstructive pulmonary disorder, cancer, diabetes mellitus, atrial fibrillation, obstructive sleep apnea syndrome, hypertension, angina pectoris).
†Person-specific model with hemoglobin concentrations adjusted for country, attained age, calendar year, and comorbidity (chronic obstructive pulmonary disorder, cancer, diabetes mellitus, atrial fibrillation, obstructive sleep apnea syndrome, hypertension, angina pectoris).

Summary and Conclusions: These findings imply that an elevated Hb can serve as a marker of an increased risk of MI and VTE. In addition, a subnormal Hb can indicate an elevated risk of VTE. However, when each subject served as his/her own control, the risk elevations largely disappeared, indicating that the risk is most likely driven by additional underlying co-morbidities and cannot exclusively be attributed to the Hb elevation itself. Nonetheless, an elevated Hb signals the need for thorough assessment of cardiovascular risk factors.

P311

IMPACT OF DYNAMIC BLOOD COUNT FOLLOW-UP ON VASCULAR COMPLICATIONS IN 217 PV PATIENTS

A. Enblom[1,*] E. Lindskog[2], F. Girodon[3], H. Hasselbalch[4], D. Hersby[4], M. Bak[4], P. Johansson[2], B. Andreasson[2]
[1]Sunderby Hospital, Luleå, [2]NU hospital group, Uddevalla, Uddevalla, Sweden, [3]Laboratoire d'hématologie CHU, Dijon, France, [4]Hematology,Roskilde University Hospital, Roskilde, Denmark

Background: Vascular complications and are risks for patients with polycythemia vera (PV).
Aims: To investigate if blood counts, with respect to different treatments, influence the complication rate and/or survival during the course of the PV disease.
Methods: 217 PV patients from Uddevalla Sweden, Luleå Sweden, Roskilde Denmark and Dijon France were included. The mean follow-up time was 6.2 years per patient. Blood values and co-morbidity were recorded at diagnosis, during treatment and at the time of any complication were retrieved.
Results: At the time of diagnosis the median age 70 years, hemoglobin (Hb) level was 17.6 g/dL, hematocrit (Hct) 55%, white blood count (WBC) 10.9 x10^9/L and platelets (Plt) 512x10^9/L. LDH was elevated in 136 of 156 patients. 38 patients (median age 77 years) experienced vascularevents during follow-up, 40 patients (median age 72 years) had non-vascular complications and 139 patients (median age 66) had no complications. Both complication groups had significantly higher age compared to the patients without complications (p<0.01). No significant differences were found in Hb, Hct, WBC or Plt. Elevated LDH at diagnosis was significantly more frequent in the patient group with vascular complications compared to the patients without (p<0.01). The main treatmentswere Hydroxyurea (HU) (139 patients), Phlebotomy (Phl) only (55 patients) and other (interferon, busulfan or pipobroman in 23 patients). No significant survival differences were found between the HU and Phl groups (p=0.6), even though the median age was 72 and 66, respectively. A total of 78 PV patients (36%) had recorded complications during the observation time. There were 35 vascular complications, 16in the139 HU patients compared to 15in the 55 patients on Phl (p=0.013). Blood values at the time for complication were compared to the mean for the yearly controls for the patients without complications, 41% with vascular events compared to 20 in the group without had WBC >10 x10^9/L(p=0.042). The differences between the groups as regards Hct and Plt were not significant.The survival for HU treated patients with need for, at least, one phl per year was significantly better than for HU treated patients without or need for less than one Phl per year (p=0.019). Fig 1

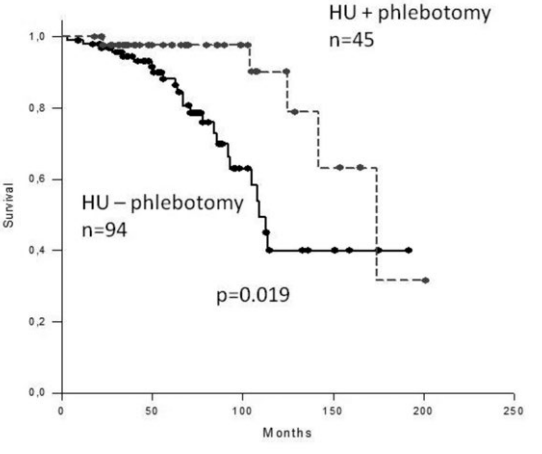

Figure 1. Survival of 139 Hydroxyurea treated PV patients, with and without need for phlebotomy.

Summary and Conclusions: We did not find any association between blood counts at the time of diagnosis and complication rate during follow-up, whereasLDH was found in a larger proportion of the patients with vascular events. Complications appeared in 36% of the patients. Vascular events were recorded in 16 % of the patients, being significantly more frequent in the group of patients treated with Phl only as compared to the patients treated with HU (p=0.013), despite the fact that that their median age was significantly lower (66 and 72 years, respectively). ELN criteria for HU resistance/intolerance have been established, including need for Phl, WBC >10 x10^9/L and Plt >400 x10^9/L. In

this study we found a significantly better survival for patients on HU with need for Phl compared to patients with less than one Phl per year, comparison with findings for "masked PV" could be made.We also found that elevated WBC seemed to be a risk factor for complications, whereas Plt levels did not influence complication rate. We conclude that elevated LDH at the time of diagnosis and high WBC during the corse are risk factors for future vascular complications in PV. HU therapy is associated with, at least, equal survival compared to treatment with Phl only. Need for complementary Phl to HU treated patients is safe.

P312

SPLEEN ENLARGEMENT IS A RISK FACTOR FOR THROMBOSIS IN ESSENTIAL THROMBOCYTHEMIA: EVALUATION ON 1097 PATIENTS AND VALIDATION ON 792 PATIENTS

A. Andriani[1,*] R. Latagliata[2], B. Anaclerico[3], A. Spadea[4], A. Rago[5], A. Di Veroli[6], F. Spirito[7], R. Porrini[8], M. De Muro[9], S. Crescenzi Leonetti[10], N. Villivà[1], C. Palandri[12]
[1]Hematology, Nuovo Regina Margherita Hospital, [2]Cellular Biotechnologies and Hematology, Policlinico Umberto I, [3]Hematology, San Giovanni Hospital, [4]Hematology, Regina Elena Hospital-IFO, Rome, [5]Hematology, University Sapienza-Polo Pontino, Latina, [6]Hematology, University Tor Vergata, [7]Hematology, San Camillo Hospital, [8]Hematology, Sant'Andrea Hospital, [9]Hematology, University Campus Biomedico, [10]Hematology, Sandro Pertini Hospital, Rome, [11]Hematology, Belcolle Hospital, Viterbo, [12]Hematology, University of Bologna, Bologna, [13]Cellular Biotechnologies and Hematology, University Sapienza, Rome, Italy

Background: Spleen enlargement is present in about 10-20% of Essential Thrombocythemia (ET) patients at diagnosis and is a feature clinically easy to assess, confirmable by echography and with a very low chance of misinterpretation. Nonetheless, the clinical and prognostic role of splenomegaly has been seldom evaluated.
Aims: The present study aimed to correlate spleen enlargement with baseline disease characteristics and outcome, with particular focus on thrombotic risk.
Methods: From 1979 to 2010, 1097 ET patients retrospectively collected in the database of the Lazio Cooperative Group were evaluable for spleen enlargement at diagnosis and were included in the primary analysis. The results of the main Lazio cohort were validated in 792 ET patients who were diagnosed and followed in the Bologna University Hospital between 1979 and 2013.
Results: In the Lazio cohort, ***s***pleen was enlarged in 213/1097 (19.4%) patients; in most cases (92%) splenomegaly was mild (<5 cm). Patients with splenomegaly were predominantly male, with higher platelet count, lactate dehydrogenase levels and JAK2V617F mutation load. Despite comparable use of cytoreductive/antiplatelet therapies in the two groups, the cumulative risk of thrombosis at 10 years was significantly higher in patients with baseline splenomegaly (23% *versus* 11% in patients without splenomegaly, p=0.007) (Figure 1a). In multivariate analysis exploring risk factors for thrombosis, splenomegaly retained its negative prognostic role, together with older age and previous thrombosis. In the validation Bologna cohort, 55 out of 792 (7%) ET patients carried baseline splenomegaly. Overall, 113 (14.3%) patients experienced a thrombotic event during follow-up. At 10 years, the cumulative incidence of thrombosis was 31.5% and 17.4% in patients with or without splenomegaly, respectively (p=0.039) (Figure 1b); splenomegaly confirmed its impact on thrombosis also in multivariable analysis.

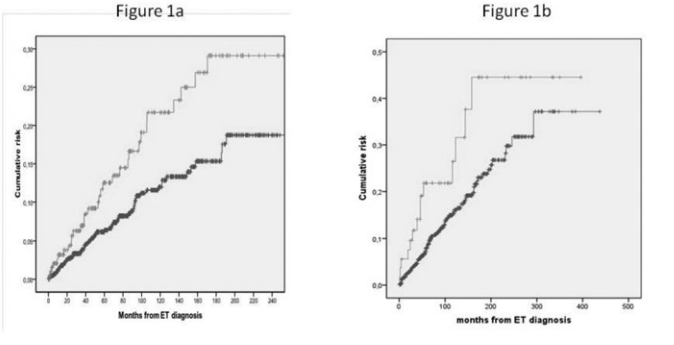

Figure 1 - Cumulative risk of thrombosis according to spleen enlargement at diagnosis in the 1097 patients of the leading Lazio cohort (Figure 1a) and in the 792 patients of the validation Bologna cohort (Figure 1b). In patients with spleen enlargement (green line), the cumulative risk of thrombosis at 10 years was 23% and 31.5% in the Lazio and in the Bologna cohorts, respectively, compared to 11% and 17.4% in patients without baseline spleen enlargement (blue line) (*p=0.007* and *p=0.039*).

Figure 1.

Summary and Conclusions: Baseline splenomegaly seems to be an independent additional risk factor for thrombosis in non-strictly WHO-defined ET patients. This data could be useful in the real-life clinical management of these patients.

P313

CLINICAL VALUE OF SPLENIC VOLUME MEASURED BY COMPUTED TOMOGRAPHY AS A NOVEL PROGNOSTIC FACTOR IN PATIENTS WITH PRIMARY MYELOFIBROSIS

M.K. Song[1,*] J.S. chung[2], Y.D. Joo[3], S.N. Lim[3], G.W. Lee[4], S.M. Lee[5]
[1]hematology, Pusan National University Yangsan Hospital, Yangsan, [2]hematology, Pusan National University Hospital, [3]hematology, Busan Haeundae Paik Hospital, Busan, [4]hematology, Gyeong-Sang National University Hospital, Jinju, [5]hematology, Busan Paik Hospital, Busan, Korea, Republic Of

Background: Until now, due to less reliable method based on physical examination (PEx) to measure spleen size, prognostic clinical value of splenomegaly have been devalued. Therefore, several clinical studies failed to demonstratethe significant prognostic value of spleen enlargement in primary myelofibrosis (PMF), although splenomegaly is a major characteristic associated with the adverse clinical features.
Aims: We evaluated whether spleen volume (SV) in computed tomography (CT) would accurately predict clinical outcomes in PMF.
Methods: A total of 188 patients with PMF who received abdomen CT at diagnosis, were enrolled. SV was quantitated from the cross-sectional images by using 3-dimensional analytical *volume* software (*Voxar*, Ltd., Edinburgh, United Kingdom). The computer automatically contoured the spleen in each CT slice and calculated the SV in cubic centimeter (cm^3). In order to evaluate prognostic significance of SV by CT, we compared the prognostic values of several prognostic factors present at the time of diagnosis: sex (male or female), age (≥or <65 years), the presence of constitutional symptoms, hemoglobin (Hb) level (≥or <10 g/dL), platelet (PLT) counts (≥or <100×10^9/L), white blood cell (WBC) counts (≥or <25×10^9/L), presence of peripheral blood (PB) circulating blasts (≥or <1 %), red blood cell (RBC) transfusion dependency, the presence of JAK2-V617F mutation, MF grading according to the ECSS (MF-3 or <MF-3), and the presence of unfavorable cytogenetic abnormalities such as complex karyotype or sole or two abnormalities including +8,-7/7q-,-5/5q-, i(17q), 12p-, inv(3), or 11q23 rearrangement.
Results: In ROC curve, SV by CT more accurately predicted prognosis than spleen length by PEx (p <0.001). Ideal cut-off value, 378.1 cm^3 of SV divided with high and low volume status. Low SV status had superior leukemia-free survival (LFS) and overall survival (OS) compared with high status (p <0.001, p <0.001). In univariate and multivariate analyses, old age (LFS, HR =1.864, 95% CI =1.217-3.056, p =0.004; OS, HR =2.102, 95% CI =1.381-3.190, p =0.001), low Hb level (LFS, HR =1.793, 95% CI =1.302-2.923, p =0.023; OS, HR =1.786, 95% CI =1.053-3.029, p =0.021), high WBC counts (LFS, HR =2.051, 95% CI =1.287-3.269, p =0.003; OS, HR =1.892, 95% CI =1.197-2.989, p =0.006), PB circulating blasts ≥1 % (LFS, HR =1.590, 95% CI =1.024-2.469, p =0.029; OS, HR =1.699, 95% CI =1.064-2.598, p =0.020), unfavorable cytogenetic abnormalities (LFS, HR =1.808, 95% CI =1.371-1.987, p =0.025; OS, HR =1.802, 95% CI =1.104-2.945, p =0.028), and high SV status (LFS, HR =2.633, 95% CI =1.368-5.069, p =0.004; OS, HR =2.641, 95% CI =1.404-4.967, p =0.003) were independently associated with survivals. By using the independent prognostic factors, each patient was assigned according to sum of 0-6 adverse points. The six score groups were consolidated into 5 risk groups according to intergroup survival differences ; low risk group (0 risk factor), intermediate-1 risk group (1 risk factor), intermediate-2 risk group (2 risk factors), high risk group (3 risk factors), and very high risk group (≥4 risk factors, Figure A and B).

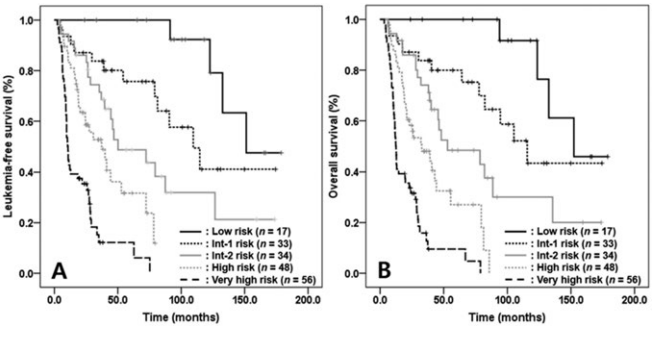

Figure 1.

Summary and Conclusions: High SV status measured by CT had a qualification as a remarkable risk factor at diagnosis to predict survivals in PMF. Therefore, we could develop the novel prognostic scoring system model including splenomegaly by the imaging modality in PMF.

New Information: Submitted to ASCO 2015. New information includes additional safety data such as dose reductions, dose interruptions and reason for dose modification.

Background: Treatment options for patients (pts) with MF are limited. A significant proportion present with disease-related thrombocytopenia, an independent survival risk factor. Others develop treatment-emergent thrombocytopenia on currently available therapies. These pts represent an underserved population. PAC is a potent multikinase inhibitor of JAK2/FLT3 and has exhibited minimal myelosuppression in early phase MF studies.

Aims: The open-label PERSIST-1 (NCT01773187) trial compared the efficacy and safety of oral PAC *vs* BAT in PMF, PPV-MF, and PET-MF.

Methods: JAK inhibitor naïve pts were randomized 2:1 to oral PAC 400mg once daily or BAT stratified by DIPSS risk (Int-1 or Int-2 *vs* High) and platelet (plt) count (<50,000/μL *vs* 50,000 to <100,000/μL *vs* ≥100,000/μL). Eligibility criteria included: DIPSS Int-1, Int-2, or High risk; ANC >500/μL; no restriction on plt or hemoglobin; palpable splenomegaly ≥5 cm; and baseline total symptom score (TSS) ≥13 using the MPN Symptom Assessment Form (MPN-SAF). The primary endpoint was the proportion of pts achieving ≥35% spleen volume reduction (SVR) at Week 24 (WK24) by centrally-reviewed MRI or CT. The secondary endpoint was the proportion achieving ≥50% reduction in TSS at WK24 using MPN-SAF.

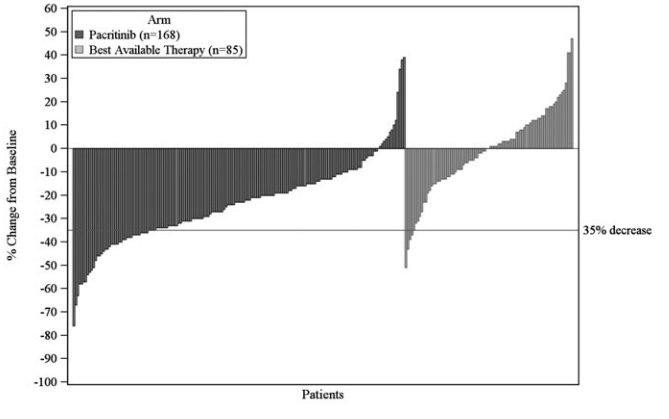

Figure 1.

Results: 327 pts were enrolled (PAC: 220, BAT: 107), 62% with PMF; 32% had plt counts <100,000/μL and 16% had plt counts <50,000/μL; 75% were JAK2V617F-positive. Median time from diagnosis was 1.0 y (PAC) and 1.6 y (BAT). Median baseline spleen volumes were 2006 cm^3(PAC) and 2153 cm^3 (BAT) and TSSs were 20 (PAC) and 23 (BAT).Estimated median duration of treatment was 16.2 mo (PAC) and 5.9 mo (BAT). SVR rates at WK24 were 19% for PAC *vs* 5% for BAT (p=0.0003) in intent-to-treat (ITT) and 25% *vs* 6% (p=0.0001) in pts evaluable at baseline and WK24 (figure). Progressive disease was not required for crossover after week 24. 79% of BAT pts crossed over to PAC (median 27 weeks). TSS (V1+V2) response rates were 25% for PAC *vs* 7% for BAT (p<0.0001) by ITT, and 41% *vs* 10% in evaluable pts (p<0.0001). Patient Global Impression of Change improvement on PAC (81%) was significantly higher than on BAT (21%) in evaluable pts (p<0.001). PAC significantly improved SVR rates irrespective of baseline plt counts. In pts with <100,000 and <50,000 plt/μL, SVR rates were 17% for PAC *vs* 0% for BAT (p=0.009), and 23% *vs* 0% (p=0.045) by ITT, respectively, and 24% *vs* 0% (p=0.007) and 33% *vs* 0% (p=0.037) in evaluable pts, respectively. In baseline RBC transfusion-dependent pts (PAC: 35, BAT: 15), 26% of PAC pts became RBC transfusion independent *vs* 0% of BAT pts (p=0.043). The most common adverse events (AEs) through WK24 for PAC were gastrointestinal (GI): diarrhea, nausea, and vomiting. Grade (Gr) 3 GI AEs rates were 5%, <1%, and <1% respectively (no Gr 4). Gr 3-4 hematologic AEs occurring in >2% were similar for PAC *vs* BAT: anemia (17% *vs* 15%) and thrombocytopenia (12% *vs* 9%). PAC AEs were similar in thrombocytopenic and non-thrombocytopenic pts. 90% of PAC pts did not require any dose reduction. AEs leading to dose reduction included diarrhea (3%) and anemia (2%). Dose interruptions occurred in 22% (median duration 7 days) with 6% due to diarrhea, 3% thrombocytopenia, and 2% anemia.

Summary and Conclusions: PAC dosed 400mg once daily was well tolerated with minimal dose modifications and induced clinically and statistically significant and meaningful SVR and meaningful symptom control even in pts with severe thrombocytopenia. PAC therapy also resulted in RBC transfusion independence in a significant proportion of pts.

DYNAMIC ROLE OF THE IRF4-PU.1 AXIS IN IBRUTINIB-RESISTANT WALDENSTRÖMS MACROGLOBULINEMIA

K. Chitta[1,*] A. Paulus[1], S. Akhtar[1], M. Kuranz-Blake[1], A. Novak[2], S. Ansell[2], M. Gertz[2], R. kyle[2], C. Rivera[1], V. Roy[1], J. Foran[1], P. Martin[3], M. Coleman[3], T. Sher[1], S. Ailawadhi[1], A. Chanan-Khan[1]
[1]Mayo Clinic, Jacksonville, [2]Mayo Clinic, Rochester, [3]Weill Cornell Medical Colleage, New York, United States

Background: Waldenströms macroglobulinemia (WM) is a rare and incurable non-Hodgkin's B-cell lymphoma that is defined by lymphoplasmacytic infiltration of the bone marrow and lymphoid tissue with increased monoclonal IgM protein production. Aberrant activation of B-cell receptor (BCR) signaling, results in neoplastic transformation of B-lymphocytes. Recent investigations using small molecule inhibitors have validated Bruton's tyrosine kinase (BTK), one of the components of the BCR signaling hub, to be a druggable target. Ibrutinib (PCI-32765), an irreversible BTK inhibitor has shown clinical efficacy in CLL, mantle cell lymphoma (MCL) and Waldenströms macroglobulinemia (WM). Ibrutinib binds to cysteine-481 of the BTK protein and blocks its phosphorylation, resulting in termination of BCR-mediated activation of cells, leading to tumor cell death. Despite the clinical success of ibrutinib, WM patients achieve only partial response and invariably acquire resistance to the drug, resulting in aggressive relapse of the disease. A mutation of Cys^{481}-Ser in BTK (ibrutinib-BTK binding site) has been reported to be one of the reasons for the development of ibrutinib resistance (IR). To understand the mechanisms resulting in acquisition of IR, we established and characterized several models of IR-WM.
Aims: To evaluate the significance of IRF4-PU.1 axis in the development of ibrutinib resistance
Methods: Ibrutinib was obtained from Pharmacyclics, CA. Validated human WM models (BCWM.1, RPCI-WM1 and MWCL.1 cell lines) were used for the study. shIRF4 clones of WM cell lines. qRTPCR, Western blotting, MTS assay, Flow cytometry.
Results: Exposure of WM models for prolonged periods of time with progressively increasing concentrations of ibrutinib resulted in outgrowth of IR tumor clones. IR cells displayed 2-20 fold resistance to ibrutinib compared to their respective parental cell lines as determined by MTS assay. Sequence analysis of the BTK gene in all the IR cell lines revealed no mutation at Cys^{481} suggesting that in an acquired IR state, resistance to ibrutinib can be developed independent of BTK Cys^{481} mutation. BTK was constitutively phosphorylated at Y^{223} and Y^{551} in all the cell lines tested and this was inhibited by ibrutinib at a concentration as low as 1mM. Phosphorylation of other kinases in the cascade such as SYK (Y^{323} and $Y^{525/526}$) and PLCg2 (Y^{759} and Y^{1217}) were also inhibited while AKT phosphorylation at both Ser^{473} and Thr^{308} was consistently increased in presence of ibrutinib. Interestingly, we found p-BTK levels to be markedly reduced in IR cells. Ibrutinib reversal experiments suggested that while continuous presence of ibrutinib was needed for the inhibition of BTK phosphorylation, a stable IR state was maintained for ≥1 month with no loss of cell viability upon reintroduction of ibrutinib, suggesting the cells reliance on a parallel survival pathway, independent of BTK phosphorylation. Focused mRNA (Nanostring nCounter assay) and immunoblot analysis revealed significant changes in the expression profiles of several cellular elements. These included transcription factors such as PU.1, IRF4, STAT1 and 3 suggesting a reprogramming of critical cellular networks, with IRF4 emerging as central in IR cells, indicated by altered expression of its downstream targets. We assessed the significance of IRF4 in IR cells by silencing IRF4 expression through IRF4-shRNA. The results indicated that down regulation of IRF4 by itself has minimal effect on ibrutinib sensitivity of IR cells. However, treatment of WM cells with all trans retinoic acid (ATRA), which is known to upregulate PU.1, induced dose dependent cytotoxicity in these cells suggesting involvement of PU.1 (and its shifting partnership with IRF4) in ibrutinib-resistance.
Summary and Conclusions: Here we demonstrate that in the absence of BTK Cys^{481} (ibrutinib binding site) mutation, an IR state is associated with reprogramming of transcriptional networks to overcome ibrutinib-induced toxicity. Moreover, this results in activation of parallel survival pathways directed by an altered IRF4-PU.1 axis, which is associated with sensitivity of WM cells to Ibrutinib.

P316

KDM5 INHIBITION LEADS TO INCREASED H3K4ME3 LEVELS AND CELL DEATH IN GERMINAL CENTRE LYMPHOMA CELL LINES INDEPENDENT OF MLL2 MUTATION STATUS

L. Koniali[1,*] J. Heward[1], C. Loveday[1], L. Wilkins[1], M. Ishfaq[2], J. Wang[1], J. Okosun[1], G. Packham[2], J. Fitzgibbon[1]
[1]Centre for Haemato-Oncology, Barts Cancer Institute, Queen Mary University of London, London, [2]Cancer Sciences Unit, University of Southampton Faculty of Medicin, Southampton, United Kingdom

Background: Follicular lymphoma (FL) and the germinal centre B-cell (GCB) subtype of diffuse large B cell lymphoma (GCB-DLBCL) account for nearly 40-50% of cases of Non-Hodgkin lymphomas (NHL). Whole exome and targeted resequencing studies demonstrated an epigenetic addiction in these germinal centre lymphomas with many biopsies harbouring mutations in histone methyl (*MLL2*, *EZH2*) and acetyltransferases (*CREBBP*). Loss of function mutations in *MLL2* (also referred to as *KMT2D)* are detected in >30% of GCB-DLBCL and 90% of FL cases and are expected to lead to a reduction in levels of the chromatin mark H3K4me3 (histone 3 lysine 4 trimethylation), which is associated with active transcription. We therefore set out to assess whether stabilising this H3K4me3 mark, by directly targeting the KDM5 family of H3K4me3 demethylases (KDM5A/B/C/D), offers a means to ameliorate the effects of these mutations and provide a rationale for a therapeutic opportunity.
Aims: EpiTherapeutics have developed a specific inhibitor against the KDM5 family of demethylases (EPT001). The aim of this study was to determine the potency of KDM5 inhibition in GCB-DLBCL lymphoma cell lines based on their *MLL2* mutation status and restoration of H3K4me3 levels.
Methods: The mutational profile of 10 GCB-DLBCL cell lines was characterised via targeted deep sequencing, using Fluidigm-MiSeq and further validated by Sanger sequencing. Expression of the KDM5 isoforms and downstream targets of KDM5 were assessed by qRT-PCR. Cell lines were exposed to increasing concentrations of EPT001 and cell proliferation and apoptosis were assessed using the Guava EasyCyte Plus system. In parallel, cell cycle analysis was performed by propidium iodide staining and flow cytometry. Immunoblotting was used to establish the effect of treatment on a range of epigenetic histone marks (H3K4me1/2/3, H3K27me3/Ac, and H3k36me2).
Results: MLL2 mutations were detected in 6 of the 10 cell lines tested. All 4 KDM5 isoforms (A-D) are expressed in these cell lines with a predominance of A and C. Exposure to EP1001 in all 10 lines resulted in a concentration dependent increase in global H3K4me3 (range 1.4-4.8 fold at 48 hrs). Of note, elevation of H3K4me3 was independent of *MLL2* mutation status. A striking reduction in proliferation and an induction of apoptosis were observed in 2 cell lines (SU-DHL-6, OCI-LY-18) both at low nanomolar concentrations (GIC_{50}: <5nM) and this was accompanied by a concentration dependent accumulation of cells in the G_1/S-phase and a concomitant loss of G2/M phase. Treatment did not result in any measurable differences in expression of established KDM5 targets as assessed by qRT-PCR.
Summary and Conclusions: Inhibition of KDM5 family of demethylases is sufficient to induce cell cycle arrest and induction of apoptosis in at least some GCB-DLBCL cell lines. This appears independent of *MLL2* mutation status even in cell lines harbouring homozygous mutations. RNA-seq and ChIP-seq are in progress to assess changes in gene expression that accompany KDM5 inhibition and H3K4me3 elevation in sensitive and resistant cell lines.

P317

MICRORNA 203 CONTROLS T-CELL LYMPHOMAGENESIS BY TARGETING IL-2 RECEPTOR SIGNALING

U. Ralfkiaer[1,*] M. Jansson[2], K. Kopp[3], A. Willerslev-Olsen[3], F. Asmar[1], T. Krejsgaard[3], P. Brown[1], R. Gniadecki[4], A. Woetmann[3], A. Lund[2], N. Odum[3], K. Gronbaek[1]
[1]Hematology, Copenhagen University Hospital, [2]Centre for Epigenetics, Biotech Research and Innovation Centre, University of Copenhagen, [3]International Health, Immunology and Microbiology, University of Copenhagen, [4]Dermatology, Copenhagen University Hospital, Copenhagen, Denmark

Background: The pathogenesis of primary cutaneous T-cell lymphoma (CTCL) is poorly understood, and early CTCL lesions are difficult to diagnose. We have previously identified and validated a 3 microRNA (miR) classifier (miR-155, miR-203 and miR-205), which can separate CTCL from benign inflammatory skin disorders with >95% accuracy. Subsequently, we showed that miR-155 enhances proliferation and is induced by STAT5a. MiR-203 has been shown to repress stemness during normal keratinocyte differentiation, and in solid tumors, miR-203 has been shown to be silenced by promoter hypermethylation.
Aims: The role of miR-203 in CTCL pathogenesis has not previously been described, however since miR-203 down regulation is a hall mark of CTCL,we have investigated the transcriptional regulation and function of miR-203 in primary CTCL biopsies and cell lines.
Methods: Two IL-2 independent CTCL cell lines (MyLa2059 and PDB2B), and two IL-2 dependent CTCL cell lines (SeAx and SeZ4) were analyzed in this study. In addition, biopsies from 21 primary CTCL (Mycosis Fungides (MF), Sezary syndrome, cutaneous T-cell lymphoma, NOS, and cutaneous anaplastic large cell lymphoma) from 21 patients were included. Promoter hypermethylation of miR-203 was studied by methylation specific melting curve analysis, and miR-203 expression by RT-qPCR. CTCL cell lines were treated by hypomethylating agents (HMAs), and were transfected with miR-203 mimic or non-template-control by electroporation. Proliferation was measured by 3H-

Thymidine and apoptosis by MMT assays. Cells transfected with miR-203 mimic and non-template-control were examined by Affymetrix RNA expression arrays (GeneChip Human Gene 2.0 ST). Cloning was done according to the manufacturers' recommendation and luciferase reporter assays were performed using the Dual-Glo system (Promega). Protein levels were analyzed by flow cytometry.
Results: We found that a member of our CTCL classifier, miR-203, is epigenetically silenced by DNA methylation in all examined CTCL cell lines and in 9 of 21 (43%) of primary CTCL samples. MiR-203 expression can be up-regulated by HMAs *in vitro*, and induction of miR-203 reduces cell viability and decreases cell proliferation. Affymmetrix array analysis of miR-203 mimic *vs* non-template-control cells identified 19 significantly differentially expressed genes (P<0.5/log fold change>2), including the novel miR-203 target molecule IL2RB, which is essential for IL-2 induced JAK/STAT signaling. QPCR and FACS analysis confirmed this up-regulation both at the mRNA and protein level. The IL-2 dependent cell line SeAx showed significantly more profound down-regulation of IL2RB in miR-203 transfected cell lines. Luciferase reporter assays of a construct containing the IL2RB 3' untranslated region confirm that IL2RB expression is regulated by miR-203. Thus, we suggest that targeted down regulation of miR-203 in CTCL promotes IL-2/STAT driven T-cell lymphomagenesis
Summary and Conclusions: We provide the first evidence that miR-203 is an epigenetically silenced tumor suppressor in primary CTCL, including early MF lesions. Our functional studies show that miR-203 keeps the level of IL2RB in check. Thus, we suggest that epigenetic down-regulation of miR-203 and IL2RB up-regulation are important early and driving events in CTCL pathogenesis.

Background: Burkitt´s lymphoma (BL) is an aggressive mature B-cell lymphoma. The hallmark genetic lesion of BL is a translocation of the *MYC* gene to an IG-locus. In addition, recent studies identified recurrent mutations of *TCF3* and *ID3* in a large proportion of BL. Oncogenic activation of MYC promotes cell growth, but also activates a stress response via the *TP53* pathway. Similarly, aberrant mitogenic signaling induces oncogene-induced senescence. Therefore, all BL depend on cooperating lesions that promote survival and cell growth. Up to 50% of BL carry mutations in the tumor suppressor p53 leading to an impaired response to the stress signals from oncogene activation. In the presence of functional *TP53*alternative mechanisms of *TP53*inactivation are frequently observed in cancer, including loss of $p14^{ARF}$ locus or overexpression of the main p53 inhibitors, MDM2 or MDM4. In BL, aberrations in the p53-pathway have not been systematically investigated and their role in the pathogenesis of MYC-driven lymphoma is not known.
Aims: Our aim was to identify driver lesions specific to BL without *TP53* mutation promoting tumor survival and growth.
Methods: We analyzed differential copy number changes (CNA) and gene expression in 67 BL and 205 diffuse large B cell lymphoma (DLBCL) from the Molecular Mechanisms of Malignant Lymphoma (MMML) consortium according to their *TP53* mutation status. For an unbiased functional analysis, we performed an RNAi drop-out screen on a panel of representative BL cell lines (n=8) with defined genetic background.
Results: In order to identify *TP53*-dependent viability genes, we chose 4 BL cell lines that carry mutations in *TP53* and show impaired p53 pathway response and 4 cell lines with wild-type *TP53* and an intact p53 pathway. These cells were infected with a pooled shRNA library targeting ~5000 genes with 5-6 shRNAs per gene. Toxic shRNAs were identified by comparison of the shRNA counts on day 2 and day 14 after infection as determined by high-throughput sequencing (Figure 1A). As expected, shRNAs targeting common viability genes as ribosomal and proteasomal proteins showed the strongest depletion in all cell lines. We identified 81 genes that showed increased toxicity in cell lines with wild-type *TP53* (Figure 1B) and 88 genes that were significantly enriched for toxicity in mutant *TP53* cell lines. The strongest genes classifying wild-type *TP53* were involved in the p53 pathway and cell cycle control. Integration of our RNAi viability data with CNA and gene expression analysis from BL patients showed, that the gene with the highest p53-dependent toxicity was located within a minimally gained region associated with wild-type *TP53* patients. Validation studies confirmed the p53-dependent cytotoxicity in single gene knock-down experiments and demonstrated that toxicity was caused by strong cell cycle arrest (Figure 1C).

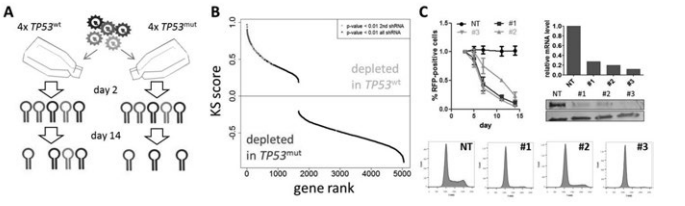

Figure 1.

Summary and Conclusions: BL is known to be driven by the oncogene MYC and mitogenic signaling. Cooperating lesions as mutation of *TP53* are needed to escape oncogene-driven apoptosis and senescence. In the presence of functional p53, we identified an alternative disease driver in BL with wild-type *TP53* controlling cell cycle progression, which may be exploited therapeutically.

P319

COMBINED 3D IMMUNO-FISH ANALYSIS OF PRIMARY HODGKIN (H) AND REED-STERNBERG (RS) CELLS REVEALS DISRUPTION OF TELOMERE-TRF2 INTERACTION AND IDENTIFIES HODGKIN'S LYMPHOMA SHELTERIN ASSOCIATED DISEASE

H. Knecht[1,*] N. Johnson[1], T. Haliotis[2], D. Lichtensztejn[3], S. Mai[3]
[1]Medicine, [2]Pathology, Jewish General Hospital, McGill University, Montréal, [3]Cell Biology, University of Manitoba, Winnipeg, Canada

Background: In Hodgkin's lymphoma (HL) derived H-cell lines the transition from H-to RS-cells is associated with progression of 3D telomere dysfunction, major changes in the telomere protecting shelterin complex, chromosomal rearrangements and formation of giant "zebra" chromosomes. Analogous findings are observed in a post-germinal center B-cell *in vitro* model for Epstein-Barr-virus (EBV)-associated HL. In this experimental system the EBV encoded oncogene LMP1, also expressed in EBV-associated HL, mediates multinuclearity through downregulation of TRF2. (Blood 2015 Jan 7.[Epub ahead of print]). Thus, the 3D interaction of telomeres and TRF2 appears to be primordial in the formation of H-and RS-cells.
Aims: Our previous findings obtained with H-cell lines and diagnostic, deparaffined lymph node biopsy slides were consistent with a shelterin-associated pathogenesis of HL (reviewed in Cancers 2013, 5:714). These findings were reinforced by our recent *in vitro* model for EBV-associated HL. The aim of the present investigation is to test our results and hypothesis on primary H-and RS-cells allowing the 3D analysis of the entire nuclear content.

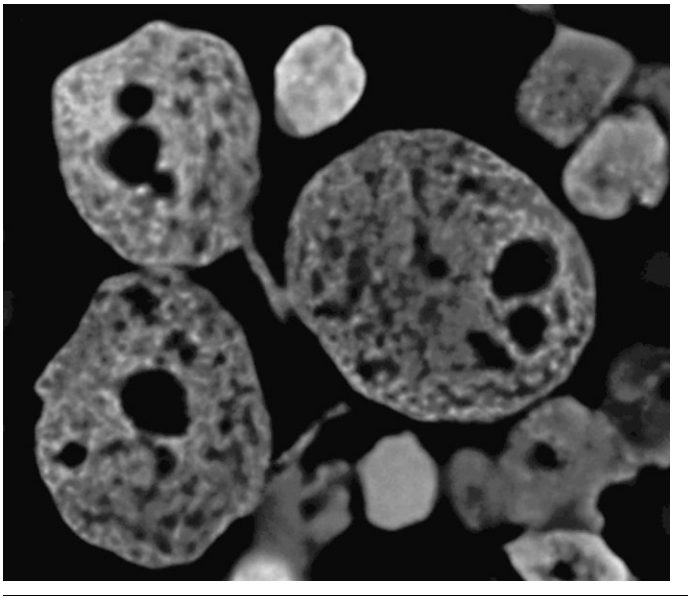

Figure 1.

Methods: Combined TRF2-Telomere 3D immuno-FISH analysis (Blood 2015 Jan 7. data supplement) was performed on cultured BJ-5ta normal diploid

fibroblasts and B-cell rich suspensions (negative selection) of diagnostic lymph nodes for HL, cultured for 24-36 hours after thawing. Quality of H-and RS-cells was assessed by Wright-Giemsa staining. Lymphocytes, H-and RS-cells of six classical HL were analyzed, one of them with LMP1 positive tumor cells.
Results: Whereas all BJ-5ta normal diploid control fibroblasts and many lymphocytes showed an intact 1:1 quantitative and qualitative tight 3D interaction of TRF2-Telomeres, with mainly mid-to large-sized telomeres, H-cells displayed a variable pattern of disruption of steric interaction ranging from few to many TRF2-deprotected and often short telomeres. These changes were more pronounced in RS-cells. By far the most important loss of TRF2 expression, gradually progressing from H-to RS-cells, was identified in the LMP1-expressing case. In one further case of clinically aggressive disease, some lymphocytes had already lost TRF2 signals. In this case huge multinucleated RS "ghost" cells without any telomeres but inter-nuclear DNA-bridges (image) were observed. Interestingly, in these RS cells TRF2 was still identified. In a third case bi-nucleated RS-cells with grossly different nuclear telomere content of nucleus one and nucleus two were present.
Summary and Conclusions: The 3D TRF2-Telomere interaction is disrupted in primary H-and RS-cells and this process starts in B-lymphocytes. The identified changes are major and analogous to those of the telomere-shelterin complex reported in H-and RS-cells of H-cell lines. Advanced TRF2-associated telomere deprotection is observed in EBV-associated HL and confirms the hypothesis of our *in vitro* model for EBV-associated HL. The unique 3D cytological appearance and behavior of H-and RS-cells is best explained by the designation of HL as a shelterin associated disease. The telomere-shelterin complex is a "plaque tournante" in the pathogenesis of HL and a potential therapeutic target.

P320

A NOVEL ULTRA-DEEP SEQUENCING METHOD FOR TRACKING OF DRIVER MUTATIONS IDENTIFIES THE MYD88 L265P MUTATION IN EARLY HAEMOPOIETIC PRECURSORS IN DIFFUSE LARGE B CELL LYMPHOMA
Y. Jeelall[1], A. Ziolkowski[2], D. Andrews[3], M. Field[3], S. Jain[4], C. Goodnow[3], M. Cook[3], D. Talaulikar[25,*]
[1]Australian National University, [2]Haematology, Canberra Hospital, [3]John Curtin School of Medical research, Australian National University, [4]Anatomical Pathology, Canberra Hospital, [5]Haematology, Australian National University, Canberra, Australia

Background: Activated B cell diffuse large B-cell lymphoma (ABC-DLBCL) is characterised by a poorer clinical outcome compared to patients with germinal centre (GC-DLBCL) with >50% patients failing standard first line chemo-immunotherapy. The NFkappaB signature is upregulated in patients with ABC-DLBCL with gain-of-function somatic mutations identified in genes involved in this pathway including the MYD88 gene. However, the exact point in ontogeny at which this mutation arises is not known.
Aims: We investigated the cellular origin of the MYD88 L265P mutation using a novel ultra-deep sequencing assay as the presence of somatic mutations in earlier haemopoietic precursors could potentially account for treatment failure and act as a reservoir for future relapses.
Methods: We identified an initial cohort of 46 DLBCL samples from the ACT Haematology Research Tissue Bank and screened them for somatic mutations using a custom next-generation sequencing approach. A Haloplex custom library preparation kit was used to develop an automated library and samples were sequenced using the MiSeq and HiSeq2500. We identified 5 patients with MYD88 L265P mutations. For each case, we then performed bulk cell sorting on 3 non-clonal populations-T cells characterised by CD3 expression, myeloid cells characterised by CD13/CD33 expression and non-clonal B cells with the opposite light chain to that expressed by the lymphoma clone. For all cases, single cell sorting and whole genome amplification was also performed. An ultra-deep sequencing assay was developed based on Kinde's approach to screen for rare cells bearing somatic mutations amongst normal non-clonal populations[Kinde et al,Proc Natl Acad Sci U S A,2011 Jun 7;108(23):9530-5]. By the addition of nucleotide barcodes in forward and reverse primers during the PCR amplification process, we have eliminated processing and sequencing errors, and have developed an assay capable of identifying very low numbers of non-lymphoma cells with gain-of-function MYD88 mutations (~ 0.001%)-cell line titration experiments.
Results: We have tested the assay on5 cases presenting with ABC DLBCL heterozygous for the MYD88 L265P mutation. In 3 cases, the MYD88 mutation was limited to the clonal population; it was not identified in bulk sorted non-clonal B cells, T cells or myeloid cells. In the remaining 2 cases, the mutation was identified in non-clonal B-cells and T cells but not in myeloid cells. Whole genome amplificationfrom non-clonal single B-cells in both cases was subjected to Sanger sequencing for MYD88 and IgHV.This analysisconfirmed thatnon-clonal B cells lacking expression of the lymphoma specific IgHV (IgHV 4-39*01) were heterozygous for the MYD88 mutation,indicating thepresence of the mutation in early precursors. We postulate that the MYD88 mutation arises in the CD20 negative common lymphoid progenitor pool in 2 casesfrom our cohort but is limited to the lymphoma clone in others.
Summary and Conclusions: Varying cellular origin of the MYD88 L265P mutation may account for some of the disease heterogeneity seen in MYD88-driven DLBCLs. Further, early origin of MYD88 L265P driver mutation in CD20 nagetive early precursors is a likely cause of treatment failure with Rituximab. Such cases may potentially respond better to Ibrutinib as the bruton's tyrosaine kinase is expressed in CD20 nagteive B-cell precursors.

P321

TRANSLOCATIONS AND CLONALITY DETECTION IN LYMPHOPROLIFERATIVE DISORDERS BY CAPTURE-BASED NEXT-GENERATION SEQUENCING. A PILOT STUDY BY THE EUROCLONALITY-NGS CONSORTIUM
D. Wren[1], B. Walker[1], M. Bruggemann[2], M. Catherwood[3], C. Pott[2], K. Stamatopoulos[4], A. Langerak[5], D. Gonzalez[1,*]
[1]Molecular Diagnostics, The Royal Marsden NHS FT, London, United Kingdom, [2]Second Medical Department, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, [3]Department of Hemato-Oncology, Belfast City Hospital, Belfast, United Kingdom, [4]CERTH, Institute of Applied Biosciences, Thessaloniki, Greece, [5]Department of Immunology, Erasmus MC, University Medical Centre, Rotterdam, Netherlands
Background: Detection and characterization of clonal *IG/TR* rearrangements and translocations in lymphoproliferative neoplasms provides critical information in the diagnostic pathway in several clinical scenarios and is a valuable tool to address research questions around B and T cells. This includes ascertaining the clonal nature of lymphoid proliferations, characterization of translocations in lymphomas and leukemias, characterization of CDR3 regions for MRD target identification and stereotyping analysis, amongst others. Until now, collecting this information required a combination of different methodologies, such as Gene-scanning/heteroduplex analysis, FISH and Sanger sequencing.
Aims: This is a pilot study to assess the feasibility of a comprehensive *IG* and *TR*genes NGS protocol to detect *IG* and *TR* rearrangements in lymphoproliferative disorders as a new tool for clonality diagnosis. Additionally, the pilot aims to assess the feasibility of discovering novel translocation partners in lymphoma and leukemia patients, potentially leading to more accurate diagnostic classification and novel therapeutic options.
Methods: As part of the EuroClonality-NGS consortium, we have designed a capture-based protocol covering the coding V, D and J genes of the IG/TR regions, as well as switch regions in the IGH locus. The assay uses Nimblegen (Roche Molecular Systems) capture baits spanning a total of 180kb and the products are analyzed on a MiSeq Illumina sequencer and MiSeq v3 sequencing chemistry with 2 x 120bp pair-end reads. This design allows the identification of D-J and V(D)J rearrangements as well as chromosomal translocations involving *IG/TR* genes by Next-generation sequencing (NGS). We piloted this approach for clonality and translocation detection in a cohort of 21 peripheral blood, bone marrow and fresh-frozen samples (3 precursor B-cell acute lymphoblastic leukemias [B-ALL], 4 Burkitt lymphoma [BL], 5 chronic lymphocytic leukemias [CLL], 2 splenic marginal zone lymphomas [SMZL], 2 diffuse large B cell lymphomas [DLBCL], 2 follicular lymphomas [FL], 2 precursor T-cell lymphoblastic leukemias [T-ALL] and 1 T-cell non-Hodgkin lymphoma [T-HNL]) with well-characterized translocations by FISH/Karyotype and/or clonal rearrangements by PCR and Sanger sequencing.
Results: We were able to detect the described *IG/TR* translocation in 18/21 samples, including translocations into the J, D and switch regions of the *IG/TR* genes. Three samples failed to produce results, two concerned fresh-frozen lymphomas with low quality DNA, and one concerned a technical error in a B-ALL case. The translocation partner and the breakpoint was identified in 15/18 evaluable cases, including *CRLF2, MYC, BCL11A, BCL2, CCND3, IRF4, BCL11B,* and *TLX1*. In three cases with only karyotyping data available, a translocation involving the IGH locus was identified with no clear leukemia/lymphoma-related genes in the neighboring regions of the reciprocal chromosome, suggesting the potential for new translocation partners and/or mechanism of disease. In all 14 samples with well-characterized D-J/V(D)J rearrangements by PCR and sequencing, NGS was able to detect the same rearrangements. These included *IGH* and *IGK/IGL* rearrangements in B-cell proliferations and *TRB, TRG* and *TRD* in T-cell proliferations. Additionally, aberrant clonal rearrangements were seen that were not detected with conventional PCR-based approaches (*e.g.* IGKV to IGK intron).
Summary and Conclusions: The EuroClonality NGS *IG/TR* capture-based approach is a promising tool for the simultaneous detection and characterization of *IG/TR* translocation and rearrangements in a clinical setting. A formal pan-European validation study is underway within the EuroClonality-NGS consortium.

Background: Nodular lymphocyte predominant Hodgkin lymphoma (NLPHL) is a rare type of Hodgkin lymphoma. In contrast to Hodgkin-Reed-Sternberg cells in classical Hodgkin lymphoma, lymphocyte predominant (LP) cells, the tumor cells in nodular lymphocyte predominant Hodgkin lymphoma, show functional variable region genes of immunoglobulins with ongoing somatic hypermutation. Chronic B cell receptor (BCR) stimulation has been proposed to play a central role in the pathogenesis of NLPHL. However, the mechanisms underlying this stimulation are poorly understood.
Aims: Aim of the study was to identify potential target antigens of B cell receptors of LP cells, with emphasis on autoantigens and bacterial structures.
Methods: Recombinant Fabs were constructed of corresponding variable region heavy and light chain genes from LP cells isolated by laser capture microdissection from cryopreserved specimens.
Results: Fabs of 9 cases were constructed. When tested on a protein macroarray derived from human fetal brain to detect autoantigenic structures as the targets of the LP cell BCR, ribosomal protein S27a and pyruvate carboxylase (PC) were identified as target antigens of two individual Fabs. When tested on the lysates from 10 bacterial strains, the recombinant BCR of 2 additional patients reacted with the lysate from Moraxella catarrhalis (MC), a common bacterium colonizing the upper respiratory tract, which expresses a 200 kD IgD-binding protein (MID/hag) enabling MC to bind to the Fc part of IgD and thus activate IgD carrying B-cells. Interestingly, the BCRs of the two patients reactive with MC were derived from LP cells of IgD+ NLPHL, which are known to represent a peculiar clinical subgroup of NLPHL, affecting the cervical lymph nodes of young people (median age: 21 years) with a strong male predominance (23:1). Analysis of additional IgD+ NLPHL cases revealed that the LP cell BCR of 4/5 IgD+ NLPHL cases reacted specifically with the DNA-directed RNA polymerase subunit beta' of MC (rpoC), a protein of 155 kD. Serum was available from 1 patient with rpoC-specific LP cell-BCR and was shown to contain polyclonal antibodies reactive against rpoC.
Summary and Conclusions: This study shows an association between MC and IgD+ NLPHL, suggesting a causal role of MC in the pathogenesis of IgD+ NLPHL. MC is capable of binding to the Fc fragment of LP-BCR of the IgD type via its IgD-binding domain and can mediate chronic antigenic stimulation of B-cells with specificity of MC-rpoC. The presence of polyclonal serum antibodies against MC-rpoC in patients with IgD+ NLPHL suggests that NLPHL is the result of a clonal evolution from a polyclonal B-cell response against MC-rpoC. Our findings are fundamental for the understanding of the pathogenesis of this peculiar clinical subtype of NLPHL and might have relevance for the prophylaxis and treatment of this disease.

P323

COMBINED CHEMOIMMUNOTHERAPY (R-CVP) IS AN EFFECTIVE TREATMENT FOR HIV-NEGATIVE, HHV-8 POSITIVE PATIENTS WITH MULTICENTRIC CASTLEMAN'S DISEASE

A. Fragasso[1,*] C. Mannarella[1], A. Ciancio[1], O. Scarciolla[1]
[1]UO Ematologia Matera, Matera, Italy

Background: Castleman disease is a rare and heterogeneous lymphoproliferative disorder: the unicentric type includes hyaline vascular and plasma cell variants, while the multicentric disease (MCD) is predominantly of the plasma cell or mixed variant. The aetiology is poorly understood; the potential roles of HHV-8 are suggested in several studies. MCD is also associated with HIV infection. No standard treatment has been established for MCD patients: steroids, chemotherapy, rituximab, thalidomide, bortezomib, antiviral therapy, and IL-6 inhibitors have been used.
Aims: We have reported a complete hematologic remission and virologic response to chemoimmunotherapy R-CVP in a HIV negative, HHV-8 positive patient (Leukemia Lymphoma, 2008); in the following years we have treated MCD patients with R-CVP in order to assess the effectiveness of this treatment.
Methods: Six HIV negative, HHV-8 positive patients (5 men, 1 woman, median age 77 years, range 69-80 years) with MCD were diagnosed in our Hematology Unit over a eight-year period. The patients' characteristics are described in Table 1. Five patients were initially treated by chemoimmunotherapy R-CVP combination (cyclophosphamide 750mg/m2 on day 1, vincristine 2mg on day 1, prednisone 40mg/m2 per day orally on days 1 to 5, rituximab 375mg/m2 on day 8 of the first cycle and then on day 1 of each cycle) every 3 week for 6-8 cycles. Patient n° 3 was initially diagnosed with a associated thrombotic thrombocytopenic purpura (TTP) and treated with steroids, plasma exchange and rituximab.
Results: Four patients out of five, four completed the planned treatment. In patient n°1 to clear residual disease (on immunofixation electrophoresis a persistent monotypic IgG kappa was found) a maintenance treatment with rituximab 375mg/m2 once every 2 months for 4 cycles was made. In the 4 patients CT scan and PET scan documented a complete remission (CR); the HHV-8 clearance was also obtained. Patient n° 1 died after a 63 months follow up with a ischemic cardiopathy. Patients n°4, n°5, n°6 are alive with a follow up respectively of 2, 1 and 62 months. Patient n° 2 initially refused treatment; 1 year later chemoimmunotherapy was started because of the disease worsening with transfusion-dependent anemia. After the first cycle this treatment was stopped for hematologic toxicity. With his informed consent the patient was treated with bortezomib and valganciclovir, but she died one month later with pseudomonas aeruginosa sepsis. Patient n° 3 obtained a partial remission with 9 plasma exchange and rituximab, but refused further therapies and died one month later.

Tabella 1.

Patient	Sex	Age (years)	Histologic diagnosis	Manifestation	Laboratory	Associated diseases
1	M	78	Mixed cell type	Constitutional symptoms, edema and pleural effusion, hepatosplenomegaly	Anemia, monoclonal gammopathy	
2	F	79	Hyaline-vascular type	Constitutional symptoms, lymphoadenomegaly	Anemia	Kaposi's sarcoma HCV infection
3	M	76	Plasma cell variant	Constitutional symptoms, lymphoadenomegaly, hepatosplenomegaly	Anemia, thrombocytopenia	Thrombotic thrombocytopenic purpura
4	M	75	Mixed cell type	Constitutional symptoms, lymphoadenomegaly, hepatosplenomegaly	Anemia, monoclonal gammopathy	Diabetes mellitus
5	M	69	Mixed cell type	Constitutional symptoms, lymphoadenomegaly	Monoclonal gammopathy	Kaposi's sarcoma
6	M	80	Mixed cell type	Constitutional symptoms, lymphoadenomegaly, hepatosplenomegaly	Anemia, thrombocytopenia	

Summary and Conclusions: In HIV negative HHV-8 positive MCD patients the illness can be fatal if not or lately treated. Chemoimmunotherapy is an effective treatment for these patients and is able to attain a clinical response with associated undectectable HHV-8 viral load.

LB324

GENETIC ALTERATIONS OF IMPORTANCE FOR THE TRANSFORMATION OF FOLLICULAR LYMPHOMA TO DIFFUSE LARGE B-CELL LYMPHOMA

A. Kwiecinska[1,*] C. Wu[2], K. Ichimura[3], M. Berglund[4], N. FCC de Miranda[2], A. Dinets[1], L. Sulaiman[1], V.P. Collins[3], C. Larsson[1], A. Porwit[5], Q. Pan-Hammarström[2], S. Bajalica Lagercrantz[1]
[1]Department of Oncology and Pathology, Karolinska Institute/ University Hospital Solna, [2]Division of Clinical Immunology and Transfusion Medicine, Karolinska Institute, Stockholm, Sweden, [3]Department of Pathology, Addenbrooke's Hospital, Cambridge, United Kingdom, [4]Department of Bioscience and Nutrition, Karolinska Institute/University Hospital Huddinge, Stockholm, Sweden, [5]Departement of Pathobiology and Laboratory Medicine, University of Toronto, University,Health Network, Toronto General Hospital, Toronto, Canada

New Information: CGH array data was published at Genes Chromosomes Cancer. 2014 Sep;53(9):750-68. New NGS data has never been submitted before. None of these results has ever been submitted or presented at another event.
Background: Transformation of low malignant follicular lymphoma (FL) to the more aggressive diffuse large B-cells lymphoma (DLBCL) has been associated with new genetic events during the disease course. The number of recent evidences suggests that mutations in several genes such as *p53, EBF1, MYD88* are acquired during transformation. In studies of genomic copy number alterations associated with transformation from FL to DLBCL, gains involving 2p, 12q13-14, 18q21, Xq as well as losses of 1p36, 6q, 17p were earlier described.
Aims: To identify further genetic alterations of importance for transformation by analysis of sequential tumor samples from FL-DLBCL transformation using array comparative genomic hybridization (array-CGH) and whole-exome sequencing (WES).

Methods: Material: 81 tumours from 60 patients í29 *de novo* DLBCL (dnDLBCL), 31 *transformed* DLBCL (tDLBCL), 21 concordant FL including 15 paired tumours (FL and tDLBCL). Methods:Immunohistochemistry, 1 Mb array-CGH, NGS Illumina HiSeq2000
Results: Using array-CGH, we identified a gain of 2p15-16.1 as a potential prognostic marker of transformation as it was more commonly found in tDLBCL in comparison with dnDLBCL (p<0,001). This chromosomal region encompasses, among others, genes involved in NFkB pathway such as *REL, USP34, COMMD1, OTX1,* and of known importance for lymphomagenesis as *BCL11A*. Notably, a high level amplification of 2p15-16 was also detected in FL prior to transformation, indicating an early event of importance for this process. Furthermore, we compared CGH-array data with WES results in a smaller group of patients with available consecutive lymphoma samples and had access to a multiple sample case with four subsequent FL (FL1-FL4) and two tDLBCL (D1-D2) tumours. We focused on alterations appearing in the FL tumour just prior to the DLBCL transformation *i.e.* FL4-D1, thus in the peri-transformation phase. A number of mutations were identified affecting genes such as *CHD4, WDR33, FOXO4, PPP1R15B, DOCK4, SERPINI2, NPY5R,* and *MROH5*.
Summary and Conclusions: Having access to subsequent samples from patients with consecutive FLs and tDLBCLs we were able outline the sequential order of genetic alterations of importance for the transformation process. Using array-CGH we found copy number changes that by WES were found to encompass mutated genes, showing that these two methods complement and strengthens each other in pinpointing crucial genetic events. Our studies revealed that clonal evolution of transformed tumours occurs rather according to branching than linear model.

LB325

THE TYK2 PATHWAY AS A NOVEL THERAPEUTIC INTERVENTION SITE IN AGGRESSIVE T-CELL LYMPHOMA

N. Prutsch[1,*] T. Sanda[2], S. Turner[3], S. Kubicek[4], B. Boidol[4], U. Jaeger[5], I. Simonitsch-Klupp[1], A.I. Schiefer[1], M. Mueller[6], L. Wu[7], L. Kenner[1], O. Merkel[1]

Background: Anaplastic large cell lymphoma is a CD30 positive, aggressive Non-Hodgkin T-cell lymphoma mainly affecting children or young adults. Anaplastic lymphoma kinase (ALK) inhibition has shown remarkable success in targeted therapy of non small cell lung cancer and in ALCL where ALK kinase fusion proteins have initially been identified in 60% of ALCL patients (ALCL, ALK+). However, treatment with ALK inhibitors inevitably leads to resistance development. Moreover, the tumour drivers in ALK- ALCL remain still elusive making the identification of new therapeutic targets an imperative.
Aims: We have recently identified Tyrosine kinase 2 (TYK2) fusion proteins in the context of ALCL. Here we describe high expression of TYK2, a member of the Janus kinase family (JAK1, JAK2, JAK3, TYK2) in human ALCL samples and pathway dependence on TYK2 in all ALCL subtypes. By using TYK2 knock down as well as TYK2 kinase inhibitors we demonstrate the therapeutic relevance of our findings.
Methods: TYK2 immunohistochemical stainings were performed in human ALCL tissue microarrays (ALK+, ALK-). Lentiviral transduction mediated shRNA knock-down of TYK2, JAK1 and STAT1 was performed in human ALCL cell lines. Knock-down and activation of downstream targets was shown by Western blot and IHC. Efficacy of JAK1 and TYK2 inhibitors (Bay-18, Symansis; TYK2_1 and JAK1_1, Genentech) was analysed by XTT and cell titer glow assays as well as Western blot analysis. The *in vivo* relevance of TYK2 was assessed via straight TYK2 knockout (TYK2 -/-) in a *CD4*-NPM-ALK ALCL mouse model.
Results: Tumor cell specific IHC staining revealed strong TYK2 expression in both ALK+ and ALK- ALCL patient samples. ShRNA mediated TYK2 or JAK1 gene knockdown resulted in strong induction of apoptotic cell death. Analysis of TYK2 downstream targets (STAT1, STAT3, STAT5) revealed distinct p-STAT1 reduction after small molecule TYK2 inhibition. Accordingly, shRNA mediated gene knockdown of STAT1 revealed an essential function for ALCL cell survival. Treatment with selective small-molecule inhibitors of TYK2 resulted in dramatically reduced cell proliferation in ALCL cell lines but not in peripheral blood mononuclear (PBMC) and JURKAT T-ALL control cell lines, suggesting novel therapeutic options through TYK2-pathway inhibition in T-cell lymphomas. TYK2 knockout in *CD4*-ALCL mice resulted in a complete rescue of the early lethality phenotype.
Summary and Conclusions: Our results indicate a strong TYK2-pathway dependence in ALCL (ALK+ and ALK-). We identified a novel therapeutic strategy by taking advantage of recently developed small molecule inhibitors. Ongoing *in vivo* experiments using *CD4*-NPM-ALK transgenic ALCL mice in which TYK2 is conditionally knocked out in T-cells as well as treatment of patient derived ALCL tumor cells with these inhibitors will systematically assess the therapeutic potential of our findings.

Aggressive lymphoma - Therapy and Prognostication

Background: Transformation of Chronic Lymphocytic Leukaemia (CLL) to diffuse large B cell lymphoma (DLBCL) (Richter's syndrome, RS) is rare (2-15%) (1–3) but associated with a very poor prognosis. Despite dose-intense chemotherapy (4–8), little has improved outcomes, with the median overall survival (OS) remaining approximately 8 months. These regimens can also cause significant toxicity. Patients are often elderly, immunosuppressed, and co-morbid. Ofatumumab is a fully human anti-CD20 IgG1κ monoclonal antibody that targets a B-cell epitope which is distinct from that targeted by rituximab. It displays increased binding affinity and a longer dissociation time compared to rituximab, improving complement dependent cellular cytotoxicity (9,10); a mechanism with the potential to overcome apoptosis-resistance. Given the prevalence of TP53 disruption in RS (11), ofatumumab is a non-toxic agent with a sound rationale to test (off label) with CHOP (CHOP-O).
Aims: To evaluate the safety, feasibility and activity of CHOP-O in induction and maintenance for newly diagnosed RS. The primary objective was overall response rate (ORR) according to standard criteria (12) after 6 cycles of CHOP-O. Secondary objectives include progression free survival (PFS), OS, safety and tolerability.
Methods: This single arm, multi-centre, non-randomised phase II NCRI feasibility study recruited 43 patients with newly diagnosed RS across 10 UK centres. Eligibility included: ≥18 years, PS 0-3, known or newly diagnosed CLL and newly diagnosed, untreated RS. Eligible patients received CHOP-O for 6 cycles, followed by 6 cycles of O-maintenance (8 weekly). The trial was run in accordance with the Declaration of Helsinki. All patients gave informed consent. Histology results were reviewed locally for study inclusion to replicate 'real life', and later for central review.
Results: Characteristics: 43 patients were recruited of which 36 patients are currently evaluable (1 pending). Table 1 summarises in detail their main characteristics. 73% were over 60 years, and most were male. Over half of patients had received a fludarabine and cyclophosphamide based regimen as prior treatment for CLL. Baseline PET CT was performed in 42% of enrolled patients, with no clear change of scanning frequency occurring over recruitment. **Response:** The ORR to induction was moderate. 66% responded (PR or CR) after four cycles of CHOP-O, although this reduced to 44% ORR (CR 25%, PR 19%) at the end of induction. 17 patients started maintenance with 8 completing maintenance, and 5 currently still continuing. The median PFS was just over six months (95% confidence interval (CI) 4.87-14.96 months), with no clear plateau on the survival curve. The current median OS was 11.4 months (95% CI 6.38 months-NR), consistent with outcomes described in the literature using R-CHOP and platinum-based regimens (6–8,13). Five patients received platinum-containing salvage at progression, but none completed a stem cell transplant. **Safety:** CHOP-O was typically well tolerated. 15 episodes of neutropenic fever were reported and grade 3-4 neutropenia was noted on 14 occasions. 46 additional non-neutropenic infections were noted, of which 21 were serious adverse events (SAE). A single SAE as the result of an ofatumumab-induced infusion reaction was reported. There were no treatment related deaths. **Further Evaluation:** The diagnostic tissue is currently undergoing further molecular genetic testing, and central review analysis. This data will be presented alongside an update on patient outcome. Within this study we also plan to prospectively validate the two scoring systems devised in RS (1,7). **Feasibility:** This was the first UK-wide prospective study in RS and is the largest ever prospective study performed to date. It therefore proves the feasibility of studying novel combinations in a rare disease when national collaboration is successful. The study was completed in 3.5 years, only just behind the predicted schedule. It is important that further studies are performed in a collaborative manner to study novel agents in this difficult-to-treat disease.

CR rate post induction	
CR	9/36 (25%)
<CR	27/36 (75%)
Ongoing induction	1

Summary and Conclusions: This study proved that it is feasible to perform clinical trials in RS and answer important questions. It is likely that CHOP-O does not considerably improve outcomes compared with R-CHOP in RS.

P325

A PHASE 1 TRIAL OF CUDC-907, AN ORAL, FIRST-IN-CLASS, DUAL INHIBITOR OF HDAC AND PI3K, IN PATIENTS WITH REFRACTORY OR RELAPSED LYMPHOMA AND MULTIPLE MYELOMA

Y. Oki[1,*] J. Berdeja[2], M. Patel[3], I. Flinn[2], J. Gerecitano[4], S. Neelapu[1], A. Copeland[4], A. Akins[3], M. Clancy[5], J. Viner[5], J. Wang[5], A. Ma[5], A. Younes[4]
[1]Department of Lymphoma and Myeloma, The University of Texas MD Anderson Cancer Center, Houston, [2]Sarah Cannon Research Institute, Nashville, [3]Sarah Cannon Research Institute/Florida Cancer Specialists, Sarasota, [4]Memorial Sloan Kettering Cancer Center, New York, [5]Curis, Lexington, United States

Background: The importance of histone deacetylase (HDAC) and phosphatidylinositol 3-kinase (PI3K) pathways in lymphoma coupled with anti-tumor synergy observed in preclinical studies by concurrent inhibition of both enzymes support clinical testing of CUDC-907, an oral inhibitor of class I and II HDAC as well as class I PI3K enzymes. Anti-tumor effects of CUDC-907 have been demonstrated in cultured cells and xenograft models of B-cell lymphoma and multiple myeloma via inhibition of PI3K/AKT, JAK/STAT and MAPK pathways as well as modification of the tumor microenvironment.
Aims: The primary objective of this ongoing trial is to determine the maximum tolerated dose (MTD) or biologically effective dose (BED) and recommended Phase 2 dose (RP2D) of CUDC-907 in subjects with relapsed/refractory (RR) lymphoma and multiple myeloma (MM). The secondary objectives are to assess the safety and tolerability, pharmacokinetics, biomarker activity, and preliminary anti-cancer activity of CUDC-907.

Methods: This first-in-human trial used a standard Phase 1 3+3 design to examine CUDC-907 in patients with RR lymphoma or MM. CUDC-907 was orally administered using 3 different dosing schedules; once daily (QD), intermittent twice (BIW) or thrice weekly (TIW), and five days on/two days off (5/2) in 21-day cycles. Dosing started at 30 mg for the QD schedule and 60 mg for the other schedules, escalating in 30 mg increments.
Results: 51 subjects received CUDC-907 up to a maximum of 60 mg for the QD and 5/2 schedules and 150 mg for the intermittent schedules. Dose limiting toxicities occurred in 3 subjects: G4 hyperglycemia and G3 diarrhea (both in the same patient) at 60 mg QD, G3 hyperglycemia at 150 mg BIW and G3 diarrhea at 150 mg TIW. The most common treatment-related adverse events (AEs) were diarrhea (45%), fatigue (31%), nausea (20%) and thrombocytopenia (14%). The most common treatment-related AEs of Grade ≥3 intensity included thrombocytopenia (14%), neutropenia (4%) and diarrhea (4%). Among 41 subjects evaluable for disease response, 4 objective responses were observed: 1 subject with diffuse large B-cell lymphoma (DLBCL) achieved complete response (CR) in Cycle 2 (60 mg 5/2), 2 subjects with transformed follicular lymphoma (t-FL/DLBCL) achieved partial response (PR) in Cycles 4 and 26 (30 mg QD and 150 mg BIW, respectively), and 1 subject with DLBCL achieved PR in Cycle 4 (60 mg QD). To date, stable disease (SD) lasting for a median of 101 days (40-717) has been observed in 22 (54%) subjects including Hodgkin Lymphoma (HL) (n=9); DLBCL and t-FL/DLBCL (n=3); and MM (n=3).

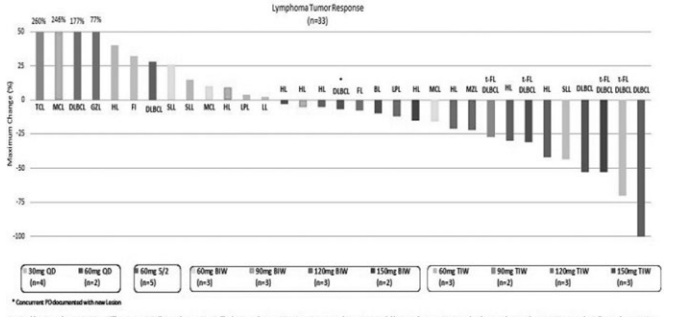

Figure 1.

Summary and Conclusions: The safety profile of CUDC-907 is similar to that of other HDAC and PI3K inhibitors. Reversible gastrointestinal, hematologic, endocrine and other AEs have been managed with standard interventions or dose interruption. In this first-in-human trial, CUDC-907 has achieved objective responses and durable disease control across multiple tumor types and dosing schedules. MTD was not reached in the 5/2 schedule, which was selected for expansion in patients with DLBCL and MM based upon CUDC-907's toxicity and efficacy profile across various schedules tested in this study population.

P326

A PHASE 1 STUDY OF PATIENTS WITH RELAPSED OR REFRACTORY B-CELL MALIGNANCIES TREATED WITH A PI3K DELTA INHIBITOR (INCB040093) ALONE OR IN COMBINATION WITH A SELECTIVE JAK1 INHIBITOR (INCB039110)

T. Phillips[1], A. Forero-Torres[2], T. Sher[3], C. Diefenbach[4], M. Talpaz[1,*] P. Scherle[5], R. Schaub[5], L. Zhou[5], J. Pulini[5], L. Leopold[5], M. Spear[5], P. Barr[6]
[1]University of Michigan, Ann Arbor, MI, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Mayo Clinic, Jacksonville, FL, [4]New York University Perlmutter Cancer Center/New York University School of Medicine, New York, NY, [5]Incyte Corporation, Wilmington, DE, [6]University of Rochester Medical Center, Rochester, NY, United States

Background: Inhibition of the PI3K and JAK-STAT pathways may be efficacious in B-cell malignancies because of their contribution to tumor growth and survival both directly and through modulation of the tumor microenvironment. Furthermore, inhibiting both pathways may result in synergistic efficacy due to JAK-STAT augmentation of B-cell receptor activation of the NFκB pathway.
Aims: To determine the safety, efficacy, and pharmacodynamics of INCB040093 alone or in combination with INCB039110 in patients with relapsed or refractory B-cell malignancies.
Methods: Adults with relapsed/refractory B-cell malignancies were eligible for this ongoing dose escalation study with expansion cohorts. Patients received INCB040093 monotherapy (100 mg once daily, 100 mg twice daily, 150 mg twice daily, or 300 mg once daily) or INCB040093 in combination with INCB039110 (INCB040093: 150 mg daily, 100 mg twice daily, or 150 mg twice daily; INCB039110: 400 mg or 600 mg once daily). Safety, efficacy, and pharmacodynamics were evaluated.
Results: A total of 83 patients have been enrolled, including patients with follicular lymphoma (n=19), classical Hodgkin lymphoma (cHL; n=17), diffuse large B-cell lymphoma (DLBCL; n=15), chronic lymphocytic leukemia/small lymphocytic lymphoma (n=13), and other subtypes (n=19). At baseline, the median age was 61 years and 70% of patients were men. The median number of prior regimens received was 4 and 24% of patients had undergone prior hematopoietic stem cell transplantation. The median exposure during the study was 185 days (range: 5–491+ [ongoing]) for INCB040093 alone and 99 days (range: 6–337+ [ongoing]) for INCB040093 + INCB039110. The most common adverse events were fatigue(28%), headache(19%), and pyrexia(19%) and the most common grade ≥3 adverse event was pneumonia(6%). The most common laboratory abnormalities were liver enzyme elevations and cytopenias. One patient had a dose-limiting toxicity of gastrointestinal bleed secondary to gastric DLBCL regression on INCB040093 100 mg twice daily. INCB040093 100 mg twice daily and INCB040093 100 mg twice daily + INCB039110 400 mg once daily were selected as the dosing regimens for expansion cohorts based on the incidence of liver enzyme elevations with INCB040093 and cytopenias with INCB040093 + INCB039110 at higher doses. At the selected doses, pAKT was decreased by ≈90% at trough on INCB040093 and IL-6–induced pSTAT3 was decreased an average of 65% on INCB039110. Of 75 evaluable patients, 28 responses have been reported. In evaluable patients with cHL (n=15), the objective response rate was 60%, which included 3 complete responses. Both patients enrolled with the non-germinal center B-cell–like subtype of DLBCL experienced complete responses.
Summary and Conclusions: Treatment with INCB040093 alone or in combination with INCB039110 was tolerable and resulted in partial and complete responses in this heavily pretreated population of patients with relapsed or refractory B-cell malignancies. Based on these results, the study was expanded to enroll additional cohorts of patients with relapsed/refractory B-cell malignancies such as DLBCL and cHL, and a phase 2 study was initiated in patients with relapsed/refractory cHL.

P327

UBLITUXIMAB + TGR-1202 DEMONSTRATES ACTIVITY AND FAVORABLE SAFETY PROFILE IN RELAPSED/REFRACTORY B-CELL NHL AND HIGH-RISK CLL

M.A. Lunning[1,*] J.M. Vose[1], N.H. Fowler[2], L. Nastoupil[2], J.A. Burger[3], W.G. Wierda[3], M.T. Schreeder[4], T. Siddiqi[5], C.R. Flowers[6], J.B. Cohen[6], S. Blumel[1], M. Miguel[2], E.K. Pauli[4], K. Cutter[4], B. Phye[5], P. Sportelli[7], H.P. Miskin[7], M.S. Weiss[7], S. Vakkalanka[8], S. Viswanadha[9], S. O'Brien[10]
[1]Lymphoma, University of Nebraska Medical Center, Omaha, [2]Lymphoma, [3]Leukemia, MD Anderson Cancer Center, Houston, [4]Clearview Cancer Institute, Huntsville, [5]Hematology, City of Hope National Medical Center, Duarte, [6]Lymphoma, Winship Cancer Institute, Emory University, Atlanta, [7]TG Therapeutics, Inc., New York, United States, [8]Rhizen Pharmaceuticals SA, La Chaux-de-Fonds, Switzerland, [9]Incozen Therapeutics, Hyderabad, India, [10]University of California Irvine Cancer Center, Irvine, United States

Background: Ublituximab (UTX) is a novel anti-CD20 mAb that has been glycoengineered for enhanced ADCC. TGR-1202 is a novel once daily oral PI3Kδ inhibitor with demonstrated clinical activity in B-cell lymphoma and notably absent hepatotoxicity associated with similar agents. The combination of UTX + TGR-1202 showed strong synergistic activity *in-vitro* (Lugano 2013).
Aims: This Phase 1 trial evaluates the safety and efficacy of the combination of UTX + TGR-1202 in patients with heavily pre-treated rel/ref NHL and CLL.
Methods: A 3+3 designwas utilized with rel/ref NHL and CLL patients accruing independently. Informed consent was obtained on all patients. There were no limits on number of type of prior therapies. Patients refractory to prior PI3K or BTK inhibitorswere eligible. UTXwas administered D 1, 8, 15 of Cyc 1 & 2, followed by D 1 of Cyc 4, 6, 9 & 12. TGR-1202was administered orally once-daily. Primary endpoints: Safety and dose limiting toxicities (DLT). Secondary endpoints: Efficacy (ORR, CR rate) with criteria as follows: CLL per Hallek 2008 and NHL per Cheson 2007.

Tabella 1.

Type	TGR-1202 Higher* Dose					Type	TGR-1202 Lower** Dose				
	Pts (n)	CR (n)	PR (n)	ORR n (%)	PD (n)		Pts (n)	CR (n)	PR (n)	ORR n (%)	PD (n)
CLL/SLL	3	-	3	3 (100%)	-	CLL/SLL	7	-	4	4 (57%)	-
DLBCL	4	2	1	3 (75%)	1	DLBCL	3	-	-	-	2
FL/MZL	7	1	4	5 (71%)	-	FL/MZL	4	-	1	1 (25%)	-
Richter's	1	-	1	1 (100%)	-	Richter's	-	-	-	-	-
Overall	15	3	9	12 (80%)	1	Overall	14	-	5	5 (36%)	2

*Higher Dose = 1200 original formulation and 600 or > micronized
**Lower Dose = 800 original formulation and 400 micronized

Results: 37 patients were enrolled and evaluable for safety: 13 CLL/SLL, 12 FL, 9 DLBCL, 2 MZL and 1 Richter's transformation. Med age 64 yo (range 29-86); 24 M/13 F; median # prior treatment regimens =3 (range 1-9). Day 1 infusion reactions (3% G 3/4), neutropenia (32% G 3/4), diarrhea (3% G 3/4) and nausea (0% G 3/4) were the most commonly reported adverse events, regardless of causality. To date, TGR-1202-related hepatotoxicity has not been observed. One DLT occurred: a patient with Gr 3 neutropenia at study entry which worsened (cohort 1). A dose-response relationship was observed with

TGR-1202; greater clinical activity was observed at higher doses. 29/37 were evaluable for efficacy (7 too early and 1 was ineligible) with best response to treatment as follows: To date, of the 29 patients evaluable for response, 87% (13/15) in the higher dose cohorts remain progression-free compared to 43% (6/14) in the lower dose cohorts. All but 1 of the CLL patients remain progression-free with a median follow up time of 9 months (range 2-12+ mos).
Summary and Conclusions: The chemotherapy free combination of UTX + TGR-1202 is highly active and well tolerated in patients with both indolent and aggressive rel/ref NHL and CLL. Dose escalation continues with enrollment ongoing at the highest dose cohort and in recently opened expansion cohorts.

Background: Rituximab (R) in combination with cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) is currently the most widely used first-line therapy for Diffuse Large B-cell Lymphomas (DLBCL). However, many patients, including elderly and/or frail patients, may not tolerate the toxicities associated with this regimen. Recent data suggested that bendamustine plus rituximab (BR) was superior in effectiveness and tolerability compared to R-CHOP in the treatment of indolent and mantle cell lymphomas. Preliminary data have shown a promising activity in DLBCL, both in the relapsing and upfront setting.
Aims: We investigated the safety and efficacy of BR combination in elderly patients affected by diffuse large B-cell lymphoma and defined as frail according to CGA.
Methods: Eligible patients were elderly patients (>70 years) with a newly diagnosed DLBCL not suitable for R-CHOP-based chemotherapy. All patients were evaluated by Comprehensive Geriatric Assessment (CGA) according to ADL, IADL and CIRS-G and were considered FRAIL if the following criteria were met: in patients aged 70-80 ADL<4 or IADL<5 or 1 grade 3 comorbidity or >8 grade 2 comorbidities; in patients older than 80 years ADL>5 or IADL>6 or 5-8 grade 2 comorbidities. Patients received bendamustine at a dose of 90 mg/m^2 daily on days 1 and 2 of each 28-day cycle along with rituximab on day 1 for up to 6 cycles. The study evaluated the complete response rate (CRR), and treatment safety. Secondary end points included progression free survival (PFS) and overall survival (OS).
Results: From February 2012 to February 2014, 49 patients were enrolled in 24 Italian centers. The majority (both 59%) were male and stage III-IV. The median age was 82. Overall, 83% (38) of the patients was older then 80 years and at CGA evaluation showed unfavourable 3 (68%, 26), 2 (26%, 10), and 1 (5%, 2) criteria. 25 patients completed all planned cycles of chemotherapy. The most frequent comorbidities were cardiovascular (37%) metabolic (11%) and respiratory diseases (7%). 24 patients discontinued the treatment (12 progressions of disease, 8 adverse events, 4 deaths). The adverse events that led to treatment discontinuation were: persistent cytopenia (3), worsening general condition (2), coronary acute syndrome (1), second tumor (1), febrile neutropenia associated to infection (1). Among four patients not receiving at least2 courses of BR, 2 progressed. The overall response rate in 47 evaluable patients was 64%, with 26 patients (55%) achieving a complete response. At the last analysis performed with a median follow up of 10 months (1-31), 13 progressions and 4 relapse have been observed. The 2-years PFS and OS were 43% and 59%.
Summary and Conclusions: Combination therapy with BR demonstrates low toxicity profile in this high risk population. The promising results on activity can encourage clinicians to considered BR for the treatment of FRAIL elderly patients with DLBCL not eligible for R-CHOP.
Disclosures: No relevant conflicts of interest to declare.

CD56 NEGATIVE EXTRANODAL NK/T CELL LYMPHOMA SHOULD BE REGARDED AS A DISTINCT SUBTYPE WITH POOR PROGNOSIS

L. Wang[1,*] Z.J. Xia[1], H.Q. Huang[2], Y.J. Zhang[3]
[1]Hematologic Oncology, [2]medical oncology, [3]Sun Yat-sen University Cancer Center, Guangzhou, China

Background: The majority cases of extranodal NK/T cell lymphoma (ENKTL) have a natural killer cell origin, and a small minority has clonal T cell receptor rearrangements and appears to be derived from cytotoxic T cells, which usually featured by CD56 negative expression. Previous results about the clinical and prognostic significance concerning CD56 expression status are controversial due to small sample size and the heterogeneity nature of this disease.
Aims: We aimed to define the prognostic value of CD56 expression in ENKTL.
Methods: The complete data of 288 patients with early stage upper aerodigestive tract ENKTL were retrospectively reviewed.
Results: 183 patients (63.5%) had stage I disease, and the primary tumor site of 204 patients (70.8%) was in nasal cavity. 60 patients (20.8%) were categorized to CD56 negative ENKTL group. There were more patients with primary tumor site in extranasal upper aerodigestive tract (43.3% *vs* 25.4%, P =0.011) and poor ECOG score (8.4% *vs* 2.2%, P =0.036) in CD56 negative group. There were no significant correlations between CD56 expression status and gender, age, lactate dehydrogenase (LDH) level, Ann-Arbor stage, B symptoms and IPI score (P >0.05). At a median follow-up time of 69 months, the 5-year and 10-year PFS rate were 52% and 41% respectively, and the 5-year and 10-year OS rate were 69% and 68% respectively. Patients with primary tumor site located in nasal cavity or CD56 positive expression had significantly superior PFS and OS (P <0.05). In multivariate Cox regression model that included age, Ann Arbor stage, LDH level, primary tumor site, and CD56 expression status, all these five factors remained to be independent prognostic factors. In subgroup analysis according to primary tumor site location, CD56 expression status significantly correlated with survival outcomes in patients with primary nasal cavity involvement, however, it lost the prognostic value in patients with primary extranasal upper aerodigestive tract involvement (P >0.05).
Summary and Conclusions: In this largest cohort of early stage ENKTL ever reported, we found that CD56 negative ENKTL had significantly inferior survival outcomes, indicating CD56 negative ENKTL should be regarded as a distinct phenotype and optimal treatment strategies need to be evaluated further for this entity.

P332

DEFINING IMMUNOGLOBULIN SOMATIC HYPERMUTATION IN DE NOVO DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: POTENTIAL APPLICATION FOR PROGNOSIS AND RISK STRATIFICATION

I. Kirsch[1,*] Z. Xu-Monette[2], T. Snyder[1], K. Young[2]
[1]Adaptive Biotechnologies, Seattle, [2]University of Texas MD Anderson Cancer Center, Houston, United States

Background: Diffuse large B cell lymphoma (DLBCL) is a heterogeneous group of diseases with variable clinical presentation, morphologic features, genomics, gene expression signature and prognosis. Some of the variability in patient course and response to therapy is likely to represent a function of developmental stage and/or specific pathway of transformation. We have been engaged in a detailed investigation of the molecular and clinical features of a large cohort of patients with DLBCL at the MD Anderson Cancer Center. Through these analyses we have begun to subcategorize this patient population based on these distinctive clinical and biological parameters. In this current aspect of our investigation we have explored the prevalence of somatic hypermutation (SHM) of the immunoglobulin loci in these de novo DLBCL patients using the platform of multiplex PCR and high-throughput sequencing (immunoSEQ) developed by Adaptive Biotechnologies, Inc. It has previously been established that the presence or absence of somatic hypermutation is an independent prognostic factor in patients with chronic lymphocytic leukemia (CLL). The ultimate goal of this collaborative effort is to determine if a similar biological mechanism between somatic hypermutation and prognosis exists within the population of DLBCL patients or subset and to relate the presence of SHM to clinical, pathological, and molecular aspects of this disease.
Aims: In this study, we investigated whether the immunoSEQ (Adaptive Biotech) assay could be used to reliably discriminate dominant clones in diagnostic specimens from patients with DLBCL with regard to rearrangement status of the immunoglobulin heavy and light (kappa and lambda) chains and the presence or absence of SHM.
Methods: The study group consisted of 200 DLBCL patients treated with R-CHOP. Patients with primary mediastinal large B-cell lymphoma, primary cutaneous DLBCL, primary central nervous system DLBCL, and DLBCLs transformed from a low-grade B-cell lymphoma or associated with HIV infection

were excluded. Genomic DNA was extracted from FFPE sections of diagnostic lymph node specimens of patients with DLBCL. Immunoglobulin heavy and light chain sequences were then independently amplified using multiplex PCR with optimized primer sets. Following high-throughput sequencing, a bioinformatics pipeline clusters the sequences into distinct clonotypes to determine overall frequencies and to identify diagnostic clones. V, (D,) and J genes are also identified for each clonotype, and point mutations that are not known germline allele variants are assigned as somatic hypermutation events.
Results: Using both the IgH and IgL (kappa and lambda) we have been able to identify an index trackable sequence in 90%+ of the samples (we identify an index diagnostic sequence or sequences in about 70% of the cases using each assay individually). Using a definition of SHM as >2% point mutations in the observed V gene, the samples can be split into three distinct categories: 1, V(D)J or VJ rearranged with SHM (50-55%); 2, V(D)J or VJ rearranged without SHM (10-25%) and 3, DJ only evident (20-40%). The vast majority of complete V(D)J rearrangements are in-frame.
Summary and Conclusions: The IgH and IgL immunoSEQ assays are robust in their ability both to identify dominant sequences in diagnostic lymph node specimens from patients with DLBCL and to distinguish those clones in which evidence of somatic hypermutation is present. The distribution of SHM in these samples lends itself to potential correlative and stratifying analyses on this well-characterized patient cohort, and likely have significant application in other aggressive B-cell lymphoma patients.

P333

A PHASE 1 STUDY OF PATIENTS WITH RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA TREATED WITH A PI3K DELTA INHIBITOR (INCB040093) ALONE OR IN COMBINATION WITH A SELECTIVE JAK1 INHIBITOR (INCB039110)

A. Forero-Torres[1], P. Barr[2], C. Diefenbach[3], T. Sher[4], R. Schaub[5], L. Zhou[5], J. Pulini[5], L. Leopold[5], M. Spear[5], M. Talpaz[6,*] T. Phillips[6]
[1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Rochester Medical Center, Rochester, NY, [3]New York University Perlmutter Cancer Center/New York University School of Medicine, New York, NY, [4]Mayo Clinic, Jacksonville, FL, [5]Incyte Corporation, Wilmington, DE, [6]University of Michigan, Ann Arbor, MI, United States

Background: Efficacy of treatment options for patients with relapsed or refractory classical Hodgkin lymphoma (cHL) is limited. Preclinical and early clinical evidence suggests that blocking the JAK-STAT or PI3K pathways may be efficacious in cHL, both directly and through modulation of the tumor microenvironment. Furthermore, blocking both pathways may provide synergistic efficacy.
Aims: To determine the safety, efficacy, and pharmacodynamics of INCB040093 alone or in combination with INCB039110 in patients with relapsed or refractory cHL.
Methods: Adult patients with relapsed or refractory B-cell malignancies, including patients with cHL, were enrolled in this ongoing, open-label, dose escalation study. Patients received INCB040093 monotherapy (100 mg once daily, 100 mg twice daily, 150 mg twice daily, or 300 mg once daily) or INCB040093 in combination with INCB039110 (INCB040093: 150 mg daily, 100 mg twice daily, or 150 mg twice daily; INCB039110: 400 mg or 600 mg once daily). Safety, efficacy, and pharmacodynamics were evaluated. Results from patients with relapsed or refractory cHL are reported herein.
Results: A total of 17 patients with relapsed or refractory cHL have been enrolled. At baseline, the median age was 34 years and 59% of patients were men. The median number of prior treatment regimens was 5, 82% of patients had undergone prior hematopoietic stem cell transplantation, and all patients had received brentuximab vedotin therapy prior to study entry. The median exposure to treatment in this study was 209 days (range: 22+ [ongoing]–388). The most common nonhematologic adverse events (all grades) in patients with cHL were fatigue (41%), headache(35%), and decreased appetite(35%). Pneumonia(12%) was the only nonhematologic grade ≥3 adverse event to occur in >1 patient. All-grade neutropenia, thrombocytopenia, and anemia occurred in 47%, 47%, and 41% of patients, respectively. Grade ≥3 thrombocytopenia occurred in 18% of patients. No patients with cHL experienced a dose-limiting toxicity. Of 6 evaluable patients receiving INCB040093 monotherapy, the objective response rate (ORR) was 50% (including 1 complete response [CR]); of 9 evaluable patients receiving INCB040093 + INCB039110, ORR was 67% (including 2 CRs). In this limited dataset of proximate dose cohorts, a dose response in efficacy was not evident. INCB040093 100 mg twice daily and INCB040093 100 mg twice daily + INCB039110 400 mg once daily were selected for expansion based on pharmacodynamics and the safety profile of higher dose levels in the overall study population. At the selected doses, ORR in the cHL cohort was 50% for INCB040093 monotherapy and 75% (including 1 CR) for INCB040093 + INCB039110.
Summary and Conclusions: INCB040093±INCB039110 was generally well tolerated in this heavily pretreated population of patients with relapsed or refractory cHL. Although the number of evaluable patients is limited, efficacy compares well to approved therapies and investigational agents for cHL. This activity warranted further investigation of INCB040093 alone and in combination with INCB039110 in patients with relapsed or refractory cHL, and a phase 2 study has been initiated.

P334

ROUTINE BONE MARROW BIOPSY IN PET/TC ERA FOR HODGKIN LYMPHOMA STAGING

L. Irene[1,*] Z.S. Josune[1], S.A. Maialen[1], R.A. Gonzalo[2], U.B. Iratxe[3], L.M. Carmen[4], A.R. Maria[1], C.E. Izaskun[1]
[1]Hematology, Hospital Universitario Donostia, [2]Onkologikoa, [3]Epydemiology, [4]Hospital Universitario Donostia, San Sebastian, Spain

Background: Accurate staging is crucial in stratifying treatment in Hodgkin Lymphoma (HL). Bone marrow involvement (BMI) detection traditionally requires a BM biopsy (BMB), an invasive procedure. Some studies have shown that 18F-fluoro-2-deoxy-D-glucose Positron Emission Tomography/Computed Tomography (FDG-PET/TAC) scanning is more sensitive than BMB in detecting BMI in HL. Although baseline FDG-PET-CT is recommended, it is not considered mandatory as a staging tool.
Aims: To determine whether BMB is still providing useful staging information now that FDG-PET/CT is available at baseline.
Methods: We retrospectively identified all patients with newly diagnosed HL between January 2008 and December 2014 in our center and evaluated those with a baseline staging with FDG-PET/CT and BMB. 70/83 BMB were bilateral. We classified the bone FDG uptake patterns as: negative (negative and reactive, [those with diffuse symmetrical uptake]) and positive (focal). Clinical stage, risk evaluation and treatment plan were determined with and without the contribution of BMB results according to the Ann Arbor classification and the guidelines from the German Hodgkin Study Group.
Results: 91 new cases of HL were identified. Eighty three patients (91%) had both FDG-PET/CT and BMB at baseline. The median age was 36 years and the male/female ratio was 1.77. 43, 13 and 17 patients had stage II, III and IV, respectively. Fifteen (18%) had BMI by FDG-PET/CT and 5 (6%) by BMB. BMB underestimated 11 patients (13.2%) which had focal positive uptake by FDG-PET/CT. None of the patients with BMI by BMB was assigned to stage I to II disease by FDG-PET/CT. We identified one case with positive BMB but no FDG skeleton uptake by FDG-PET/CT, although this case was already stage IV on the basis of liver uptake. Therefore, none of the 83 patients would have been allocated to another treatment on the basis of BMB results. However, 3/15 patients assessed to stage Ito II by CT where upstaged to stage IV by FDG-PET/CT. Skeletal FDG-PET/CT lesions identified patients with positive and negative BMBs with a sensitivity and specificity of 80% and 85.9%, respectively. The positive and negative predictive values of skeletal FDG-PET/CT lesions for BMB results were 26.7% and 98.5%, respectively.
Summary and Conclusions: In this retrospective analysis of patients staged by FDG-PET/CT and BMB, the omission of BMB would not have changed the treatment strategy in any case. Our results suggest that FDG-PET/CT may be an appropriate method to replace BMB to assess bone marrow infiltration in newly diagnosed HL. We should confirm in further studies that BMB has little to offer in staging patients with HL in the FDG-PET/CT era and becomes an unnecessary and painful procedure.

P335

THE PROGNOSTIC VALUE OF BIOLOGICAL MARKERS IN PEDIATRIC HODGKIN LYMPHOMA

Pediatrica I Policlinico, Bari, [19]Ospedale Regionale per le Microcitemie, Cagliari, [20]A.O.U Meyer, Firenze, [21]Centro di Riferimento Oncologico Aviano, Aviano, [22]Azienda Ospedaliera Universitaria, Ospedale Sant'Anna, Ferrara, Italy

Background: The outcome in pediatric classical Hodgkin's lymphoma (cHL) is excellent when combined modality therapy is used. Over the last two decades it has been tried to identify prognostic factors that allow the identification of children who are likely to benefit from reduced intensity treatment and patients at higher risk of treatment failure. Many biological and inflammatory markers at diagnosis have been proposed as having a prognostic value, but very few have been validated in childhood.

Aims: To explore the significance of biological and inflammatory markers in a large population of 769 children affected by cHL.
Methods: By using the database of patients enrolled in A.*i.e.*O.P. (Associazione Italiana di Emato-Oncologia Pediatrica) trial LH2004 for pediatric cHL, we identified 769 patients treated from June 1, 2004 to April 1, 2014 with ABVD (doxorubicin, bleomycin, vinblastine, and dacarbazine), or hybrid COPP/ABV (cyclophosphamide, vincristine, prednisone, procarbazine, doxorubicin, bleomycin and vinblastine) regimens. We considered the following data at diagnosis: age, sex, stage, white blood cell count, absolute lymphocyte count (ALC), absolute monocyte count (AMC), absolute eosinophil count (AEC), absolute neutrophil count (ANC), platelet count (Plts), 1-hour erythrocyte sedimentation rate, ferritin, albumin, hemoglobin; ALC/AMC ratio, ANC/ALC ratio, and AEC/ALC ratio were also considered. All prognostic factors were first analyzed as continuous variables, except for the A-B categorization, sex and stage. However, since these continuous variables are more likely to be of clinical significance if categorized in binary form, we performed a ROC analysis to find some reasonable cutoff value. Bivariate survival analysis was performed using Kaplan Meier curves and log-rank test. Multivariate survival analysis was performed using a Cox proportional hazards model. We also performed an Internal Bootstrap Validation (IBV) of the model with 800 repetitions.
Results: There were 361 female patients (46.9%), and 408 males (53.0%); 454 patients (59.0%) were in category A and 315 (40.9%) in category B. There were 27 stage I patients (3.5%), 397 stage II (51.6%), 177 stage III (23.0%) and 168 stage IV (21.8%). Histologically, 636 patients (82.7%) were classified as nodular sclerosis, 81 (10.5%) as mixed cellularity, 7 (0.9%) as lymphocyte depleted, 8 (1.0%) as lymphocyte rich, and in 37 (4.8%) no histological subtype was reported. There were 108 (14.0%) events: 71 were relapses, 37 progressions (pathologically-confirmed recurrence within 3 months of the end of therapy). On bivariate analysis with variables in binary form, under the identified cutoffs, 5-year freedom from progression (FFP) survival was significantly lower in patients with stage IV or elevated values of ferritin (≥209 ng/ml), AEC (≥0.493x10^9/L) and Plts (≥537 x10^9/L): 73.4% *vs* 83.9% for stage IV, 66.0% *vs* 86.5% for ferritin, 71.6% *vs* 84.9% for AEC and 66.3% *vs* 82.4% for Plts. Moreover in the Cox multiple regression model for FFP with variables in binary form the hazard ratios were 2.08, 2.72, 3.05 and 2.65 for Stage (IV *vs* others), Ferritin, AEC and Plts respectively. The IBV showed that the model based on these 4 Risk Factors (RFs) was not over-fitted. A different Cox regression model for the total number of RFs in each child is shown in table I.

Tabella 1. Cox regression model for total number of RFs from our categorical model (*vs* 0 risk factors).

Number of risk factors	Number of cases	p	hazard ratio	95% CI	5 years FFP	95% CI
0	227				90.4%	85.5 – 95.6

Concordance=0.719 (se =0.035)						
Rsquare = 0.099 (max possible = 0.782)						
Likelihood ratio test = 47.21 on 3 df, p=3.129e-10						
Wald test = 59.1 on 3 df, p=9.144e-13						
Score (logrank) test = 100.4 on 3 df, p=0						

Summary and Conclusions: Using the combination of 4 simple RFs it is possible to classify the patients into subgroups with very different outcomes.

Stem cell transplantation - Clinical 1

P336

EVI1 EXPRESSION ASSOCIATES WITH HIGHER CUMULATIVE INCIDENCE OF RELAPSE IN PATIENTS WITH ACUTE MYELOID LEUKEMIA RECEIVING HEMATOPOIETIC CELL TRANSPLANTATION WITH NON-MYELOABLATIVE CONDITIONING

M. Bill[1,*] M. Jentzsch[1], K. Schubert[1], T. Lange[1,2], J. Grimm[1], M. Knyrim[1], S. Leiblein[1], G.N. Franke[1], V. Vucinic[1], W. Pönisch[1], M. Cross[1], G. Behre[1], D. Niederwieser[1], S. Schwind[1]
[1]Hematology, University of Leipzig, Leipzig, [2]Hematology, Asklepios clinic, Weißenfels, Germany

Background: Prognosis of acute myeloid leukemia (AML) patients (pts) is still dismal. Therefore, more personalized therapeutic strategies are required. Allogeneic hematopoietic cell transplantation (HCT) represents a therapy offering potential cure. Non-myeloablative conditioning (NMA) is increasingly used in pts that are ineligible for conventional conditioning. The ecotropic viral integration site 1 (*EVI1*) gene maps to chromosome 3q26 & encodes a transcription factor that has an important role during embryogenesis. In AML, the gene is well known as a part of a fusionprotein in pts with inv(3)(q21q26.2) or t(3;3)(q21;q26.2) that are recognized as a distinctive entity in the WHO classification.
Aims: The presence of *EVI1* expression has been described as a predictor of poor outcome. Whether the expression of *EVI1* also associates with outcome in AML pts undergoing NMA-HCT, with a therapeutic approach mainly based on an immunological graft-*versus*-leukemia effect, remains unknown.
Methods: We analyzed 136 pts (median age, 64 years [y]; range 22–75y) who received NMA (Fludarabine 30mg/m^2 at day-4 to-2 & 2Gy total body irradiation [TBI] at day 0 [n=131; 96.3%] or Fludarabine 30mg/m^2, Cytarabine 2g/m^2 & Amsakrine 100mg/m^2 at day-12 to-9, Cyclophosphamide 40mg/kg at day-4 to-3, ATG/TG day-3 to-1 & 4 Gy TBI day-5 [n=4; 2.9%])-HCT at the University of Leipzig between May 2000 & August 2012, with pretreatment bone marrow material available. Donors were human leucocyte antigen (HLA)-matched related (n=23, 16.9%) or HLA-matched (n=81; 59.6%) or mismatched (>=1 antigen; n=32; 23.5%) unrelated. 26.5% (n=36) had acute graft-*versus*-host disease (GvHD; >=grade 2) & 44.1% (n=60) (14.3% (n=15) limited; 33.1% (n=45) extensive) chronic GvHD. The mutation status of *NPM1* & *CEBPA* gene & *FLT3*-ITD status were assessed at diagnosis. Pts were grouped according to the European LeukemiaNet (ELN) classification in favorable (n=32; 23.5%), intermediate-I (n=36; 26.5%), intermediate-II (n=26; 19.1%) & adverse (n=38; 27.9%). Presence of selected surface markers was assessed using flow cytometry at diagnosis. *EVI1* expression was measured by RT-PCR & normalized to *18S*. The normalized expression of *EVI1* in the cell line SKOV3 was used to define EVI1 positive (EVI1+) expressers, *i.e.* pts with an expression higher than 0.1 relative to the *EVI1* expression of SKOV3 in the ddCT method were labeled EVI1+.
Results: Median follow-up for pts alive was 4.3y. 21.3% (n=29) pts were EVI1+. At diagnosis EVI1+ pts' blasts were more often CD7 (*P*=.001) & CD56 (*P*=.023) positive. Regarding cytogenetics, EVI1+ pts had more often a monosomal karyotype (*P*<.001) & a monosomy 7/del7 (*P*=.003), but less frequent a normal karyotype (*P*=.024). Two pts in the set had an inv3 and were both EVI1+. EVI1+ pts were less often *NPM1* mutated (*P*=.014). Furthermore, EVI1+ associated with a lower white blood cell count at diagnosis (*P*=.016). Regarding the cumulative incidence of relapse (CIR), EVI1+ pts had a significant higher CIR (*P*=.010; Figure 1B). EVI1+ associated with shorter overall survival (OS; *P*=.063; Figure1B), by trend. The median 2y-OS was 34.7% for EVI1+ pts compared to 51.8% for EVI1 negative pts. Analyzing the ELN groups, these findings could only be recovered in the adverse group by trend (*P*=.089 and *P*=.095, respectively).

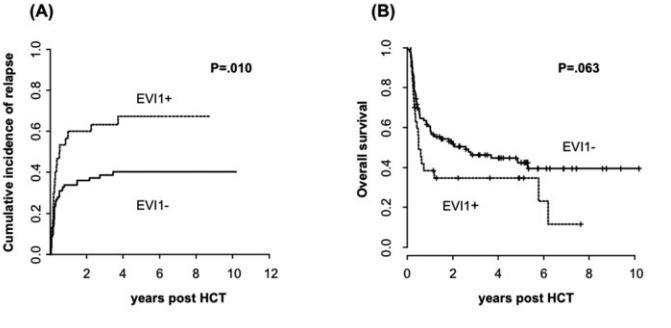

Figure 1.

Summary and Conclusions: In conclusion, the *EVI1* expression associated with worse outcome and higher CIR in NMA-HCT treated AML pts. Pretreatment *EVI1* expression may refine the risk stratification for AML pts undergoing NMA-HCT.

P337

SUPPORTIVE CARE AND INFECTIOUS COMPLICATIONS IN CORD BLOOD AND HAPLOIDENTICAL STEM CELL TRANSPLANTATION IN ADULTS WITH HIGH RISK HEMATOLOGIC DISEASES

J. Elcheikh[1,*] R. crocchiolo[2], A. vai[2], S. furst[1], S. bramanti[2], B. sarina[2], A. granata[1], R. devillier[1], C. faucher[1], B. mohty[1], S. harbi[1], R. bouabdallah[1], N. vey[1], A. santoro[2], C. chabannon[1], P.J. weiller[1], L. castagna[2], D. blaise[1]
[1]transplantation, INSTITUT PAOLI CALMETTES, marseille, France, [2]transplantation, humanitas, rozzano, Italy

Background: Infections due to post transplant immune deficiency are a major problem following allogeneic stem cell transplantation, particularly in patients receiving cord blood (CBT) or haploidentical transplants (haplo-SCT).
Aims: To our knowledge, there are only some heterogeneous studies comparing this important issue in this setting.
Methods: We evaluated the incidence and type of infectious complications that occurred in these two types of transplant for 150 patients, 81 cord blood and 69 haploidentical, who received the same conditioning regimen: fludarabine (Flu), cyclophosphamide (Cy) and low dose TBI (2 Gy) combination in the two groups. The GVHD prophylaxis consisted of Cyclosporine A (CsA) and MMF in all patients in the two groups. In the Haplo group all patients received also 50 mg/kg Cy at day 3 and 4 post transplant. Of note, supportive care was the same during the whole study period. CMV infection management was also homogeneous.
Results: The median times to neutrophil and platelet recovery were 20 d (14-39) and 29 d (14-50) after Haplo and 22 d (6-67) and 41 d (18-80) after CBT. All supportive care measures included red blood cell, platelet transfusions, antibiotics days, parenteral nutrition days and hospitalization time were significantly increased in CBT group. (p=0.0001). While incidence of infections appeared similar in both types of transplant, viral infections were more frequent than bacterial or fungal infections and were the most common cause of death in both groups. During the first year after stem cell transplant, the CBT group had 154 episodes of infection (31 infection episodes per 1,000 patient-days) *versus* 125 of the haplo patients (39 per 1,000 patient days). Viral infections were most common in both groups (83 *vs* 60 episodes) in CBT *vs* haplo group respectively. Patients in the haplo group were 1.2 times (95% CI: 1.1 to 2.5) more likely to have a viral infection (p=0.07). Pneumonia was the most common clinical syndrome and was higher in the haplo group 28% *vs* 11% in CBT. Both pneumonia and bacteremia prevalence occurred within the first 100 days in the majority of CBT patients while haplo patients had a bimodal distribution with more than one third of bacteremia episodes after 6 months post-transplant. Survival analysis showed that transplant source (CBT *versus* Haplo) did not have a significant effect on the probability to have an infection episode. (p=0.10) Bacterial, fungal and CMV infections still quite frequent and contributed to higher mortality in CBT *vs* haplo (p=0.06). The first cause of mortality was the viral infection (12 (15%) 3 (4%) p=0.060) followed by the bacterial infection cause (4 (5%) *vs* 3 (4%)) and the fungal infection (1 (1%) *vs* 0) in CBT and haplo group respectively.
Summary and Conclusions: Our study is unique in comparing adult patients with advanced hematologic malignancies who received the same reduced-intensity conditioning regimen, which offers a common base for comparing the infections in these two types of transplant. In our hands, outcome is better for haplo donor decreasing the need of supportive measures and facilitating to perform the transplant in time. Haploidentical transplants are a good and promising alternative option for high risk hematologic patients who lack an HLA-matched donor. Collectively, the impact of infectious complications after haplo-SCT was different from that in CBT patients, suggesting that a more intensive strategy for infection control in haplo patients is required to reduce infectious mortality.

P338

AUGMENTED CONDITIONING WITH TARGETED MOLECULAR RADIOTHERAPY PRIOR TO AUTOLOGOUS STEM CELL TRANSPLANTATION IN MYELOMA: RESULTS OF A PHASE II RANDOMISED CONTROL TRIAL WITH IMPROVED CR RATE POST ASCT

K. Orchard[1,*] S. MacKinnon[2], J. Langford[3], R. Chakraverty[2], D. Richardson[1], M. Guy[4], J. Thom[5], P. Lloyd-Evans[6], M. Jenner[1], T. Maishman[7], K. Cozens[7], L. Stanton[7], A.M. Quigley[8], D. McCool[8], P.S. Chan[8], C. Wickham[9], P. Johnson[10]
[1]Haematology, University Hospital Southampton, Southampton, [2]Haematology, Royal Free Hospital and UCL, London, [3]Targeted Radiotherapy Group, University of Southampton, [4]Medical Physics, [5]Radiopharmacy, University Hospital Southampton, Southampton, [6]Bristol Institute for Transfusional Sciences, Clinical Biotechnology Centre, Bristol, [7]Southampton Clinical Trials Unit, University of Southampton, Southampton, [8]Dept of Nuclear Medicine, [9]Dept of Medical Physics, Royal Free Hospital, London, [10]Cancer Sciences, University of Southampton, Southampton, United Kingdom

Background: Autologous stem cell transplantation (ASCT) remains important as consolidation therapy for patients with myeloma, improving rate and duration of response. The standard conditioning treatment with high dose melphalan has remained unchanged for 3 decades, further increase in the intensity of therapy is limited by toxicity to non-haematopoietic organs. We developed TMRT with a radiolabelled monoclonal antiCD66 that targets bone marrow, plasma cells and lymphoid tissue as a vector for delivering high dose radiation to sites of disease. We report the results of a Phase II RCT demonstrating improved sCR/CR responses using the radiolabelled mAb.
Aims: Trial Design:A randomised, multi-centre, non-blinded Phase II study comparing two treatment conditioning schedules prior to ASCT. Arm A TMRT plus high dose melphalan *vs* Arm B high dose melphalan alone. Primary objective:To determine the efficacy of TMRT delivered by an Yttrium-90 (^{90}Y)-radiolabelled murine antiCD66 monoclonal antibody given in addition to high dose melphalan (200mg/m^2) in terms of disease response in patients undergoing ASCT for multiple myeloma. Secondary objectives: Engraftment, time to disease progression, time to next treatment, overall survival, HAMA formation.
Methods: Twenty-five patients were recruited out of a planned 90. All patients had confirmed multiple myeloma, were in PR/vgPR following chemotherapy and were scheduled to receive autologous stem cell transplantation. Randomisation was stratified by disease risk (low/high). Patients randomised to receive TMRT received an infusion of indium-111 labelled antiCD66 to allow imaging and organ dosimetry calculation. Patients with favourable dosimetry received an infusion of ^{90}Y-labelled antiCD66, at an activity of 37.5MBq/kg lean body weight as outpatients 14 days prior to scheduled ASCT. Patients in both arms were admitted two days before ASCT and given high does melphalan. All patients were managed post ASCT as per centre protocols. Disease response was assessed pre-ASCT and at 3, 6, 9 and 12 months using EBMT response criteria. Logistic regression, adjusting for risk group, was used to analyse the primary endpoint (alpha 15% 1-sided).
Results: Twenty-five patients were randomised: 12 to Arm A; 13 to Arm B. Twelve patients in each arm were available for analysis. Myeloma sub-type, gender, patient's age and risk group numbers were similar in each arm. Median infused ^{90}Y-activity 2.31GBq, range 1.61-2.74GBq. Median radiation doses to organs BM 32.10Gy (17.2-34.7), liver 4.70Gy (1.7-12.0), spleen 28.55Gy (7.4-34.0), renal 2.90Gy (2.1-3.6), pulmonary 3.45Gy (1.2-4.0), whole body 0.85Gy (0.8-1.2). Toxicities were similar in each arm.

Tabella 1.

Disease status	Pre transplant		Post transplant	
	Arm A	Arm B	Arm A	Arm B
sCR/CR	0	0	6	3
vgPR	7	7	6	6
PR	5	5	0	3

All Arm A patients showed a response improvement, 3 Arm B patients had stable disease with no change (2 PR, 1 vgPR).
Summary and Conclusions: The study achieved its primary endpoint demonstrating a statistically significant improvement in the complete response rate for patients in Arm A compared to Arm B (50% *vs* 25%, odds ratio [85% 1-sided CI]: 0.277 [0.102, 0.753]). This is the first demonstration in an RCT of effective augmentation of the conditioning prior to ASCT that improves the response rate post transplant without additional toxicity. Eudract: 2006-003424-12. The study was managed by Southampton Clinical Trials Unit Sponsor: University of Southampton NHS Foundation Trust Funding: Leukaemia & Lymphoma Research;ECMC core funding.

P339

ALLOGENEIC STEM CELL TRANSPLANTATION RECIPIENTS REQUIRING INTENSIVE CARE: DELAY BETWEEN ORGAN DYSFUNCTION AND REFERRAL TO THE INTENSIVE CARE UNIT AND TIME SPENT ON ORGAN SUPPORT IMPACT SURVIVAL

C. Orvain[1,*] F. Beloncle[2], S. Thépot[1], A. Kouatchet[2], S. Francois[1], P. Guardiola[3], A. Corby[1], P. Asfar[2], M. Hunault-Berger[1], N. Ifrah[1], A. Schmidt-Tanguy[1]
[1]Maladies du Sang, [2]Réanimation Médicale, [3]Plateforme SNP, Transcriptome et Epigénomique, CHU Angers, Angers, France

Background: Although the prognosis of patients with hematological malignancies admitted to the intensive care unit (ICU) has improved over the past years, it remains poor in allogeneic stem cell transplantation (SCT) recipients and thus admission of these patients to the ICU remains controversial.
Aims: We aimed to assess the prognostic factors of survival in ASCT recipients with a special interest on graft-*versus*-host disease (GVHD), the requirement for organ support, the timing between the occurrence of organ dysfunction and ICU referral, the time spent with each organ support, and the time since ICU admission at initiation of each organ support.
Methods: All allogeneic SCT recipients between 2002 and 2013 who were admitted to the medical ICU in our center were included. Details on patients, graft procedures, GVHD, ICU admission, and outcome were collected from individual medical records. The need for oxygen therapy, the presence of low blood-pressure (systolic arterial pressure <90 mmHg), altered mental status, elevated serum creatinine (≥1.5 times baseline or ≥0.3 mg/dL increase), and total bilirubin (>34 µmol/l) defined respiratory, hemodynamic, neurological,

renal, and liver dysfunctions, respectively. Potential prognostic factors were explored by logistic regression analysis for ICU and hospital discharge. Cox regression analysis was performed for overall survival (OS).
Results: Of 344 patients who underwent ASCT during the study period, 92 patients (27%) were admitted to the ICU. No demographic or SCT parameter was associated with ICU or hospital discharge, or with overall survival. 66% patients could be discharged from the ICU and 46% from hospital whereas one-year survival was 24%. At the time of referral to the ICU, 12 patients had 3 or 4 organ dysfunctions and only 4 of these patients (25%) could be discharged alive from the hospital *versus* 57/80 patients (71%) with 0 to 2 organ dysfunctions (OR: 12, 95% CI: 1.5-94, p=0.02). Patients who were admitted until 3 days following the first signs of organ dysfunction were more likely to be discharged alive from the hospital (41/80 patients, 51%) than those who were presenting with symptoms for more than 3 days before admission to the ICU (1/12 patients, 8%) (OR: 1.3, 95% CI: 1-1.8, p =0.03). Grade 2-4 acute GVHD (37%) had a significant impact on hospital discharge (11/34 patients alive, OR: 2.4, 95% CI: 1-5.8, p=0.05) but not with ICU discharge (20/34 patients alive, p=0.25). Mortality was greatly associated with the number of organ failures: one-year OS rates were 31%, 27%, 23%, and 0% among patients with 0 (26 patients, 28%), 1 (26 patients, 28%), 2 (26 patients, 28%), and 3 to 4 (14 patients, 15%) organ failures, respectively (HR: 1.7, 95% CI: 1.4-2.1, p<0.001). Neither time spent with invasive mechanical ventilation nor time from ICU admission to the initiation of this life-supporting intervention was associated with hospital survival. There were no survivors in patients for whom vasoactive drugs and/or renal replacement therapy were initiated after day 1. There were no survivors for those who received vasoactive drugs for more than 2 days and for those who received renal replacement therapy for more than 5 days. The Sepsis-related Organ Failure Assessment (SOFA) better distinguishes outcome of patients when performed day 2 onward. Patients who had a stable or worsening SOFA at day 2 had greater hospital mortality (OR: 2.8, 95% CI: 1.1-7, p=0.03).
Summary and Conclusions: ASCT recipients, even with GVHD, might be considered for transfer in the ICU as soon as they present first signs of organ dysfunction and before they have too many organ dysfunctions. A reappraisal should probably be performed after 48 hours of ICU.

P340

OUTCOME AND PROGNOSTIC FACTORS IN FLAMSA SEQUENTIAL CHEMOTHERAPY FOLLOWED BY RIC AND HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR HIGHER RISK AML AND MDS PATIENTS
A. Sutra Del Galy[1,*] S. François[1], V. Seegers[2], A. Schmidt-Tanguy[1], A. Bouvier[3], L. Baranger[4], M. Hunault-Berger[1], N. Ifrah[1], P. Guardiola[2], S. Thépot[1]
[1]Service des maladies du sang, [2]Plateforme SNP, Transcriptome, Epigénomique, [3]Laboratoire de Biologie Moléculaire, [4]Laboratoire de Cytogénétique, C.H.U., Angers, France

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the only potentially curative approach in refractory or relapse acute myeloid leukemia (AML) and higher risk myelodysplastic syndrome (MDS). Sequential cytoreductive chemotherapy including fludarabine, aracytine and amsacrine (FLAMSA) followed by reduced intensity conditioning (RIC) and HSCT gives promising results in this unfavorable group. However, little is known concerning prognostic factor associated with this treatment approach.
Aims: This study aims to defined prognostic factors of overall survival (OS) and early relapse after FLAMSA-based conditioning in higher risk AML or MDS patients.
Methods: We retrospectively reviewed consecutive patients (pts) in our institution undergoing an SCT for high-risk myeloid malignancy after FLAMSA-RIC between March 2006 and June 2014. We evaluated transplantation related mortality (TRM) and early relapse defined before 90 days after transplantation. The uniformly used conditioning regimen was 4 days of Fludarabine (30 mg/m2/d), Amsacrine (100 mg/m2/d) and Aracytine (2 g/m2/d) followed by 4 days of Busulfan (13,6 mg/kg/day) after 3 days of rest. Antithymocyte globulin (Genzyme® 6 mg/kg), ciclosporin and mycophenolate mofetil were use for graft-*versus*-host disease (GvHD) prophylaxis.
Results: Among 73 pts with a median age of 54 years (19-69), 51 (70%) were AML and 22 (30%) pts were MDS. In AML pts, transplantation indication was refractory disease for 24 (47%), secondary AML for 19 (37%), relapse for 8 (16%). In MDS pts (including 7 RAEB-T), 18 (81,8%) were high or very high R-IPSS and 9 (41%) were previously treated with demethylating agents, 4 (18%) with intensive chemotherapy and 9 (41%) were untreated and transplanted upfront. Median leucocytosis and bone marrow blast before conditioning was 3,41 G/L (0,21-39) and 5% (0-90) respectively. Cytogenetics was adverse in 22 (30%) and intermediate in 51 (70%) pts and among them 15 had unfavourable genotype (FLT3-ITD). Sorror score before transplantation (HCT-CI) was higher or equal to 3 in 34 (47%) pts. Thirty-seven (51%) pts received HLA-identical sibling transplantation and 36 (49%) pts received transplantation from unrelated donors. Source of stem cells was mobilized peripheral blood stem cell for 64 (88%), bone marrow for 5 (7%) and cord blood for 4 (5%) pts. Eighteen (25%) pts experienced grade III-IV acute GvHD and 9 (12%) severe chronic GvHD according to NIH classification. After a median follow-up of 58,8 months, OS at 24 and 48 months was 38,4% and 27% respectively. The 2-years TRM was 31,5%. In univariate analysis, performans status >2 (p=0,041), adverse cytogenetics (according to MRC classification, p<0,001), pre transplant leucocytosis >10 G/L (p=0,015) and pre transplant bone marrow blasts (p=0,011) were associated with poorer overall survival. Neither age, HCT-CI nor number of CD34+ transfused were associated with outcome. Only intermediate cytogenetics (p=0,02) was associated with superior overall survival in multivariate analysis. Thirteen (18%) pts relapsed before the 90 days. In univariate analysis, leucocytosis >10 G/L, higher bone marrow blast and adverse cytogenetic were associated with early relapse (p=0,003; p=0,001; p=0,021 respectively). The pre transplant leucocytosis >10 G/L (p=0,042) and higher bone marrow blasts (p=0,01) remains prognostic factors of early relapse in multivariate analysis.
Summary and Conclusions: Despite median age of 54 years, high HCT-CI and high-risk diseases, FLAMSA-based HSCT was feasible with acceptable TRM. The 2-years overall survival (38,4%) is encouraging for this very high-risk population and only adverse cytogenetics remains prognostic factor for survival. Proliferative diseases before conditioning are associated with a high risk of early relapse. New therapeutic approaches, for those pts need to be tested in order to improve the HSCT outcomes.

P341

PRE-TRANSPLANT QUANTITATIVE MONITORING OF NPM1 MUTATION SIGNIFICANTLY PREDICTS OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN NORMAL KARYOTYPE AML IN COMPLETE REMISSION
M. Karas[1,*] K. Steinerova[1], S. Vokurka[1], A. Jungova[1], M. Hrabetova[1], D. Lysak[1], P. Jindra[1]
[1]Hematology and Oncology dpt., Charles University Hospital Pilsen, Pilsen, Czech Republic

Background: detection and the level of minimal residual disease (MRD) affects prognosis of AML patients (pts) treated with intensive chemotherapy alone. But impact of MRD in the setting of allogeneic hematopoietic stem cell transplantation (alloHSCT) especially in pts with normal karyotype AML in complete remission (CR) is less clear.
Aims: with the aim to evaluate the potential role of pre-transplant MRD we studied impact of pre-transplant MRD level on outcome of alloHSCT in 60 consecutive pts with normal karyotype AML harboring NPM1 mutations in complete remission. MRD level was determined using quantitative real-time polymerase chain reaction (qPCR) for detection of NPM1 mutations.
Methods: from 2/2005 to 9/2014 60 consecutive pts with median of age 54 years (range, 30-66 years) with normal normal karyotype AML harboring NPM1 mutations (53% FLT3/ITD positivity) in 1st CR (45 pts) and 2nd CR (15pts) underwent myeloablative (16 pts) or reduced-intensity (44 pts) alloHSCT (27% HLA identical related, 50% HLA matched unrelated, 23% HLA mismatched unrelated). Source of stem cells was in 80% peripheral blood and in 20% bone marrow. MRD level was determined using real-time qPCR for detection of NPM1 mutations before start of conditioning regimen from bone marrow. Pre-transplant prognostic factors (age, type of donor, donor recipient sex combination, CMV status, type of conditioning regimen, source of stem cells, number of CR, FLT3/ITD status, MRD level) were included in the univariate and multivariate statistical analysis.
Results: all pts fully engrafted with ongoing CR after alloHSCT. 36 pts (60%) developed aGVHD and 24 pts (40%) developed chGVHD. With median follow-up 52 months (range, 4-101 months) 35 pts (58%) are alive. 16 pts (27%) relapsed and 13 of them died. 12 pts (20%) died due to NRM. The estimated probabilities of 3-years EFS and OS are 54% and 59%. Statistical analysis showed that only age over 63 years and MRD level affected alloHSCT outcome in multivariate analysis. Pre-transplant MRD level 10 NPM1mut/10000 ABL copies had the strongest statistical significance. The estimated probabilities of 3-years relapse incidence, EFS and OS were for pts with low MRD level (≤10 NPM1mut copies) 6%, 72% and 75% and for pts with high MRD level (>10 NPM1mut copies) 31%, 35% and 40%.
Summary and Conclusions: our data show that pre-transplant quantitative assessment of NPM1 mutation in pts with normal karyotype AML harboring NPM1 mutation in CR provides important prognostic information, which as an independent prognostic factor predicts transplant results.

P342

EARLY RELAPSE FOR FOLLICULAR LYMPHOMA (FL) AFTER AUTOLOGOUS STEM CELL TRASPLANTATION (HDT/ASCT) CARRIED OUT IN 1ST OR SUBSEQUENT COMPLETE RESPONSES (CRS) DEFINES PATIENTS AT HIGH RISK FOR DEATH

Background: Despite gains in survival with immunochemotherapy and HDT/ASCT intensification, a considerable number of patients with FL die from the lymphoma. A strong correlation between quality of response and better progression-free survival (PFS) and overall survival (OS) in FL patients is well known. Early relapse of disease within 24 months of HDT/ASCT has been suggested as defining a group of patients with very low survival.
Aims: In this retrospective analysis, our interest is to study patients undergoing HDT/ASCT in CR at the moment of transplantation, in order to analyze survival and basal characteristics of patients relapsing early; within the first 24 months from the procedure.
Methods: FL patients undergoing HDT/ASCT in 1st or subsequent CRs from 1989 to 2007 and reported to the GELTAMO registry were studied .Two groups were defined: patients with relapse or and/or death ≤2 years from HDT/ASCT (early relapse group) and a reference group without relapse or death within 2 years of diagnosis. Survival probability was estimated by the Kaplan-Meier method. A Cox model evaluated the effect of early relapse on OS.
Results: A total of 405 patients were analyzed (mean age 47 years, female sex 53%). Two hundred and three patients received HDT/ASCT in 1st CR, 43% of them requiring more than one therapy line to achieve CR and 202 in subsequent CRs (174 in 2nd CR and 28 in 3rd CR). Median follow-up from HDT/ASCT was 11, 8 years. An early relapse was observed in 20, 5% (83/405) of patients. For patients undergoing HDT/ASCT in 1st CR, 16% (33/203) had early relapse compared to 25% (50/202) of patients who underwent ASCT in subsequent CRs (*P*=0.02). Early relapse following HDT/ASCT was dramatically and significantly related to worsened OS, both in transplanted in 1st CR (HR of 15.5; 95% CI 14.9—16.1), and in subsequent CRs (HR of 8; 95% CI 7.6—8.4), compared with those not progressing so soon. Median OS for patients with early relapse was 44 months compared to OS median not reached in the reference group ($P<10^{-5}$). OS was 39% *vs* 96% at 5 years, 28% *vs* 88% at 10 years and 21% *vs* 82, 5% at 15 years for the early relapse and the reference group, respectively. OS curves for patients transplanted in 1STCR and in subsequent CRs are shown in the figure. Multiple logistic regression analysis showed that older age (*P*=0.05), male sex (*P*=0.05), high LDH (*P*<0.1), high B_2 microglobuline (*P*<0.1) and the presence of more than 4 nodal areas affected were associated with early relapse (*P*<0.1).For patients undergoing ASCT in 1st CR male sex (p=0.05), high LDH (*P*=0.04), more than 4 nodal areas affected (P=0.01), age adjusted IPI (*P*<0.1) and FLIPI (*P*<0.1) were associated with early relpse. The poor outcome of these FL patients was independent of the use of Rituximab previously to ASCT. For patients undergoing HDT/ASCT in 2nd/3rd CR duration of first remission less than 12 months selected a subgroup of patients at high risk for early relapse (P=0.02).

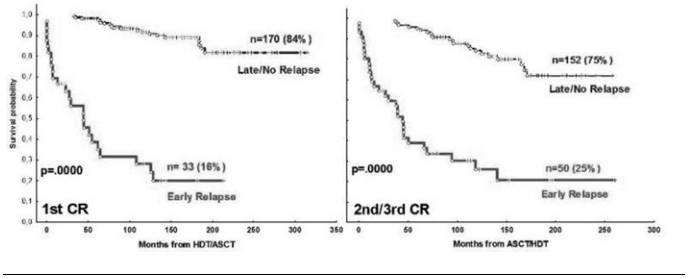

Figure 1.

Summary and Conclusions: Relapse of FL within 2 years after HDT/ASCT intensification carried out at 1st or subsequent CR is associated with really poor outcomes. Male sex, older age, high B_2 microglobuline, high LDH, the presence of more than 4 nodal areas affected and duration of first remission less than 12 months conferred a significantly high risk for early relapse. Patients undergoing HDT/ASCT at first CR relapsed early less frequently that those transplanted at subsequent CRs (P=0.02), however relapsing within 2 years of HDT/ASCT defines a unique category of patients at substantially increased risk of death, independently of having been transplanted in 1ST or in subsequent CRs. These high-risk patients need further study in directed prospective studies of FL biology and clinical trials.

P343

HEMATOPOIETIC STEM-CELL TRANSPLANTATION FOR T-CELL LARGE GRANULAR LYMPHOCYTE LEUKEMIA: A RETROSPECTIVE STUDY OF THE EUROPEAN SOCIETY FOR BLOOD AND MARROW TRANSPLANTATION (EBMT)

[1]Service d'Hématologie Clinique, Centre Hospitalier Universitaire de Rennes, [2]INSERM UMR 917, INSERM, Rennes, [3]EBMT Lymphoma Working Party Office, EBMT, Paris, France, [4]Policlinico Universitario Tor Vergata, Roma, Italy, [5]Centre Hospitalier de Versailles, Le Chesnay, France, [6]Universitäts kilinikum, Freiburg, Germany, [7]Institut Universitaire du Cancer, Toulouse, France, [8]Azienda Ospedaliera Bianchi Melacrino Morelli, Reggio Calabria, Italy, [9]Evangelismos Hospital, Athens, Greece, [10]Hôpital d'Instruction des Armées Percy, Clamart, France, [11]Centro di Riferimento Oncologico, Aviano, Italy, [12]University Hospital, Maastricht, Netherlands, [13]University Hospital, Antwerp Edegem, Belgium, [14]Gazi Universitesi Tip Fakültesi Hastanesi, Ankara, Turkey, [15]Klinikum Grosshadern, Munich, Germany, [16]St. James's Hospital, Dublin, Ireland, [17]University of Heidelberg, Heidelberg, Germany

Background: Large Granular Lymphocyte (LGL) leukemia is a rare lymphoproliferative disorder characterized by clonal expansion of either $CD3^+$ cytotoxic T lymphocytes or $CD3^-$NK-cells. Although usually considered as an indolent disease, most patients will require therapy based on immunosuppressive drugs such as methotrexate, cytoxan or ciclosporin. Treatment of rare aggressive forms and refractory patients remains elusive and prognosis is dramatically poor. For such patients, high-dose intensification may be proposed. However, the feasibility and efficacy of both allogeneic (allo) and autologous (auto) hematopoietic stem cell transplantation (HSCT) in LGL leukemia has not been evaluated so far and data are only limited to few sporadic case reports.
Aims: The aim of the present study was to investigate the feasibility and efficacy of allo-HSCT and auto-HSCT in T-cell LGL leukemia.
Methods: Fifteen patients treated by allo-HSCT or auto-HSCT for T-cell LGL between January 2004 and November 2011 were included in this EBMT multicenter registry-based retrospective study. Baseline information and transplantation characteristics of selected patients were downloaded. Centers were then contacted to provide written diagnostic reports in order to confirm the diagnosis of LGL and additional data. Probabilities of disease-free survival (DFS) and overall survival (OS) were calculated using the Kaplan-Meier estimate.
Results: Most patients had an advanced disease with multi-organ involvement (n=9) and were heavily pretreated with poly-chemotherapy (n=11). Median time from diagnosis to transplantation was 15 months (range: 7-211). Ten patients received an allo-HSCT at a median age of 49 years (range 29-66): at transplantation, 3 patients were in complete remission, 6 in partial response and 1 presented with refractory disease. Conditioning regimen was reduced intensity in 6 patients and peripheral blood progenitor cells were used in all but one patient. Engraftment was obtained for all patients. Grade II-IV acute GVHD was observed in 4 patients. Of the 7 patients surviving past day 100, 2 developed extensive and 1 limited chronic GVHD. The main cause of death after allo-HSCT was infection whereas relapse accounted only for a single death. Five patients were still alive after a median follow-up of 30 months (range: 19-95), translating into a 2-year DFS and OS of 50% (95%CI, 18% to 75%). Auto-HSCT was performed in 5 patients with a median age 49 years (range: 38-57): 3 of them were in complete remission and 2 in partial remission at the time of transplantation. Conditioning regimens were BEAM (carmustine, etoposide, cytarabine and melphalan) in 4 patients and TAM6 (cytarabine, melphalan, Total Body Irradiation 12 Grays) in 1 patient. Two patients relapsed at 1 and 31 months post auto-HSCT and died. One patient did not obtain a complete remission after HSCT but is still alive after a follow-up of 40 months. Two patients remain alive and disease-free 27 and 52 months post HSCT, respectively. For the entire group, 2-year DFS and OS were 43% (95%CI, 16% to 67%) and 60% (95%CI, 32% to 79%), respectively.
Summary and Conclusions: Here, we report the first cohort of patients treated by HSCT for T-cell LGL leukemia. Despite the small number of patients, HSCT appears as a potential therapeutic option in rare aggressive and relapsing forms of T-LGL leukemia.

P344

UPDATED RESULTS OF THE MAYO CLINIC RISK ADAPTED ALGORITHM FOR PERIPHERAL BLOOD STEM CELL MOBILIZATION UTILIZING G-CSF AND PLERIXAFOR

R. Ferzoco[1,*], I. Micallef[1], J. Winters[2], S. Ansell[1], F. Buadi[1], D. Dingli[1], A. Dispenzieri[1], D. Gastineau[2], M. Gertz[1], S. Hashmi[1], S. Hayman[1], W. Hogan[1], D. Inwards[1], P. Johnston[1], P. Kapoor[1], M. Lacy[1], M. Litzow[1],

M. Patnaik[1], L. Porrata[1], S. Kumar[1]
[1]Hematology, [2]Transfusion Medicine, The Mayo Clinic, Rochester MN, Rochester, United States

Background: The likelihood of successful mobilization has improved with the addition of Plerixafor to G-CSF in ASCT. Due to its high cost, risk adapted algorithms were instituted to identify patients who would benefit from plerixafor.
Aims: We aimed to assess the appropriateness of our risk adapted algorithm in selecting appropriate patients to receive plerixafor.
Methods: The current algorithm was instituted in December 2009. Mobilization commences with GCSF alone; plerixafor is added if day 4 PBCD34 is <10/μL for single transplant, <20/μL for multiple transplants, day 1 yield is <1.5 million CD34/kg, or subsequent yield is <0.5 million CD34/kg. Goal of collection varied by disease and by number of intended transplants (3-5 million CD34/kg/transplant). The results of this mobilization strategy are presented here.
Results: We studied 1080 mobilizations in 1068 patients using the current protocol between June 2010 and December 2013; 548 MM (51%), 327 NHL (30%), 144 amyloidosis or light chain deposition disease (AL/LCD; 13%) and 61 Hodgkin's (6%). Overall, 55.4% of patients required plerixafor (MM 58%, NHL 61%, AL/LCD 35%, HL 46%). The majority (77%) of patients initiated plerixafor on day 4 for low PB CD34 count; 23% started beyond 4 days for suboptimal CD34 collection. There was no difference between the diagnoses in terms of the need to initiate plerixafor for low PB CD34 or for suboptimal CD34 collection. Median days of plerixafor was 2 (IQR 1-3); 42% and 22% required >2 days and >3 days, respectively. More patients with NHL (50%) needed >2 days of plerixafor *vs* MM (41%), HL (40%) and AL/LCD (23%); p =0.004. The median number of CD34 cells collected was 7.4 million/kg (IQR 5.2-9.9). Median CD34 collection was highest for MM and AL/LCD, reflecting the practice to collect for more than one transplant. Overall 9 (<1%) and 22 (2%) patients collected <2 million and <2.5 million CD34 cells/kg, respectively. More patients with NHL (4%) collected <2.5 million/kg compared with MM (1%), AL/LCD (2%) and HL (0%), p=0.02. The median number of days of apheresis was 2 (IQR 1-3) and was higher in the NHL group (p=0.002). The median CD34 collected per day was 3.6 million/ kg (IQR 2-5.8); higher in MM and AL/LCD *vs* NHL and HL (p <0.001). The median CD34 collection was very similar for those patients getting plerixafor *versus* those not requiring plerixafor (p=0.26). The median time to ANC and platelet engraftment were 14 days (IQR 13-16) and 13 days (IQR 12-15), respectively. While there was no difference in ANC engraftment, platelet engraftment was longer among patients requiring plerixafor.
Summary and Conclusions: This data confirms the effectiveness of this risk adapted algorithm in over 1000 patients over 4 years. The mobilization failure rate remains low. Approximately 45% of patients did not require plerixafor, supporting the use of this risk adapted algorithm to select appropriate patients who require plerixafor.

P345

POST-TRANSPLANT CYCLOPHOSPHAMIDE (PT-CY) IS EFFECTIVE TO PREVENT GVHD AFTER T-CELL REPLETE HAPLOIDENTICAL PERIPHERAL BLOOD STEM CELL TRANSPLANTATION (HAPLO-SCT)

A. Granata[1,*] S. Fürst[1], L. Castagna[2], R. Devillier[1], J. El Cheikh[1], S. Harbi[1], C. Faucher[1], A. Charbonnier[3], A.M. Stoppa[3], T. Aurran[3], B. Calmels[4], C. Lemarie[4], C. Picard[5], R. Crocchiolo[6], R. Bouhabdallah[3], C. Chabannon[4], N. Vey[3], D. Blaise[1]
[1]Transplant and Cellular Therapy Unit, Institut Paoli Calmettes, Marseille, France, [2]Transplant Unit, Humanitas Cancer Center, Milan, Italy, [3]Hematology Department, [4]Cell Therapy Facility, Institut Paoli Calmettes, [5]Immuno-Genetics Laboratory, EFS, Marseille, [6]Transplant Unit, Humanitas Cancer Center, Milan, France

Background: PT-Cy has been developed as GVHD prophylaxis after T-cell-replete Haplo-SCT. Initially, bone marrow has been considered as the preferred stem cell source because of the known higher risk of GVHD after PBSC transplantation. However, there is no evidence that this observation is applicable after Haplo-SCT using PT-Cy. For practical reasons we early decided to use PBSC rather BM in this setting.
Aims: The objective was to evaluate the outcome of patients receiving PBSC from a related haploidentical donor, using PT-Cy as GVHD prophylaxis.
Methods: Patients receiving a Haplo-SCT between March 2012 and December 2014 from 2 centres were included with following criteria: 1) high risk haematological disease requiring Haplo-SCT in the absence of matched related and unrelated donors; 2) PBSC as graft source; 3) PT-Cy 50 mg/kg at day +4 and +3 used as part of GVHD prophylaxis. Study end points were the cumulative incidences of acute and chronic GVHD, non-relapse mortality (NRM), cumulative incidence of relapse (CIR) as well as progression free (PFS) and overall survival (OS). Additionally, we analysed the composite endpoint GVHD and relapse free survival (GRFS) for which the occurrence of relapse, death or sever chronic GVHD were considered as relevant events.
Results: We analysed 102 patients (pts) with a median age of 57 years (range: 22-73). Fifty-two (51%) and 50 pts (49%) had myeloid and lymphoid diseases, respectively. Seven pts (7%) with refractory AML received sequential RIC regimen after intensive chemotherapy. Thirty-seven pts (36%) had high or very high according to Disease risk index (DRI), while 64 pts (63%) had a HCT-CI of 3 or more. Sixteen (16%) previously relapsed after a first allogeneic transplantation. Conditioning regimens were classified as non-myeloablative (cyclophosphamide (Cy)+fludarabine (Flu)+2 Gy TBI [n=69, 68%]), reduced intensity (Cy + Flu + busulfan at 200 mg/m² total dose (Bu200) [n=4, 4%] or Bu200+Flu+ thiotepa (TT) [n=10, 10%]) and myeloablative with reduced toxicity (Bu at 400 mg/m² total dose + Flu + TT [n=12, 12%]). CSA+MMF or FK+MMF were started on day +5 for additional GVHD prophylaxis to PT-Cy in 96 (94%) and 6 (6%), respectively. All but 2 pt engrafted (2%). Median time to ANC and PLT reconstitution was 21 (14-47) and 35 (10-134) days, respectively. The median CD34+ and CD3+ infused cells were 5.1x10e6/kg (range 1.9-14.8) and 262x10e6/kg (range 59-587), respectively. Day-100 grade II-IV and III-IV acute GVHD was 31% and 8%, respectively; 2-year all grades and sever chronic GVHD was 18% and 2%, respectively. CD34+ and CD3+ cell dose did not influence the incidence of acute and chronic GVHD (median cut off). After a median follow-up of 15 months (1-31), NRM at 100 days and 2 years were 12% and 23%, respectively. Relapse occurred in a median time of 3.3 months (0.5-14) after Haplo-SCT, resulting in a 2-year CIR of 24%. PFS, OS and GRFS estimation at 2 years were 53%, 55% and 48%, respectively (Figure 1). Among the 17 AML patients who were transplanted in CR, the 2-year NRM, CIR, and OS were 27%, 15% and 58%, respectively.

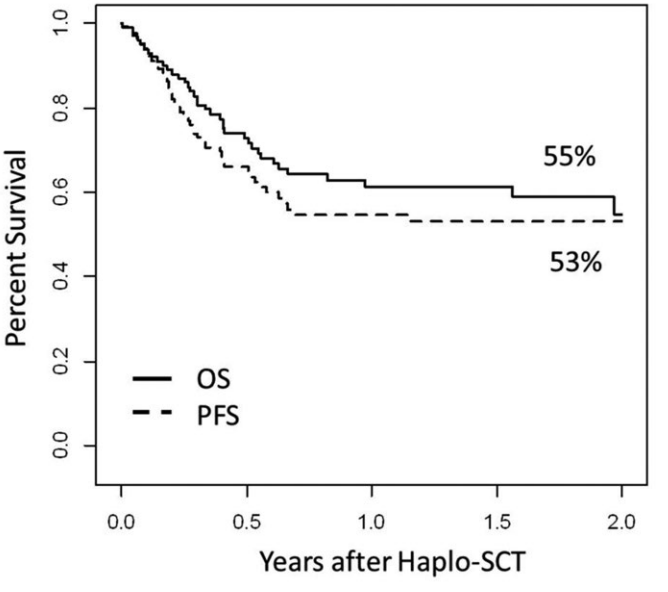

Figure 1.

Summary and Conclusions: Our results suggest the feasibility of Haplo-SCT using PBSC and PT-Cy for high risk haematological malignancies. Notably, no increased incidence of GVHD and NRM was observed comparing to bone marrow grafts. Importantly, for healthy donors, this source graft avoids risks related to the use of general anaesthetic, necessary for bone marrow harvest. With regard to the advanced pt characteristics our results are encouraging but need further evaluation with longer follow-up.

P346

COMPARABLE OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION REGARDLESS OF DONOR SOURCES IN PEDIATRIC NON-MALIGNANT DISEASE

J.K. Suh[1], J.J. Seo[1,*] S.W. Lee[1], K.N. Koh[1], Y.U. Cho[2], E.S. Choi[1], S. Jang[2], H.J. Im[1], C.J. Park[2]
[1]Pediatrics, [2]Laboratory medicine, Asan Medical Center, Seoul, Korea, Republic Of

Background: Allogeneic hematopoietic stem cell transplantation (Allo-HSCT) is a curative therapy in some non-malignant pediatric diseases including bone marrow failure, metabolic disease, immune deficiency, and so on. However, allo-HSCT is still challenging in these disease due to the risk of TRM and GVHD. Therefore, we analyzed the outcomes of allo-HSCT in pediatric non-malignant disease, and compared the outcomes according to donor types.
Aims: We performed this study to estimate transplant outcomes of pediatric non-malignant diseases, to analyze the efficacy of HSCT from alternative donors in pediatric non-malignant diseases. and to find the fators affecting transplant outcomes of pediatric non-malignant disease.
Methods: We retrospectively reviewed the medical records of 55 pediatric patients with non-malignant disease who received allo-HSCT at Asan Medical Center Children's Hospital from January 2009 to November 2014. Thirty-six patients had SAA, 7 had inherited bone marrow failure syndrome (1 Fanconi anemia, 2 CAMT, 1 CDA, 1 Pearse syndrome, 1 PRCA, 1 Kostmann syndrome),

6 had primary immune deficiency (1 IPEX, 2 WAS, 3 CGD), 5 had HLH, and 1 had Krabbe disease. To analyze the efficacy of HSCT, we investigated overall survival (OS), event-free survival (EFS), incidence of TRM, cumulative incidence (CI) of acute and chronic GVHD, incidence of graft failure (GF).
Results: Of the 55 patients, 40 were male and 15 were female. Median age at HSCT was 12.9 years (range, 0.7-21.7). Seventeen patients received HSCT from MSD (MSD-HSCT), 16 patients from URD (URD-HSCT) and 22 patients from haploidentical family donor (HFD-HSCT). Six patients (11%) experienced graft failure (GF). Of the 6 patients, 5 patients achieved engraftment after additional HSCT, and the remaining 1 survived with autologous recovery. Four patients died of TRM, and one died of disease. TRM at 1 year and 2 years for all patients were 4% and 6%, respectively. TRMs at 2 years were not different according to the donor type (0% for MSD-HSCT, 14% for URD-HSCT, 5% for HFD-HSCT; *P*=0.06). The CIs of aGVHD grade I-IV and cGVHD were 40% and 20%. However, CIs of severe aGVHD grade≥III and extensive cGVHD were just 15% and 9%. There was no differences in incidences of acute GVHD and chronic GVHD according to the donor type. At a median follow-up of 34.7 months (range, 1.6-69.3), the 3-year OS were not different according to the donor types (93% for MSD-HSCT, 87% for URD-HSCT, 95% for HFD-HSCT; *P*>0.05).
Summary and Conclusions: Given the high survival outcomes and low TRM, our study suggests that allogeneic HSCT could be safe treatment modality to the children with non-malignant disease. Especially, HSCT from alternative donor could be beneficial to patients who lack MSD. However, a larger multicenter study is needed to verify our results.

Stem cell transplantation - Clinical 3

P347

NO NEGATIVE IMPACT OF AGE ON OUTCOME OF REDUCED-INTENSITY ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ELDERLY PATIENTS WITH ACUTE MYELOID

J. Aoki[1,*] H. Kanamori[1], M. Tanaka[1], T. Fukuda[2], H. Ogawa[3], K. Iwato[4], K. Ohashi[5], H. Okumura[6], M. Onizuka[7], M. Yoshitomo[8], A. Shigematsu[9], N. Kobayashi[10], Y. Morishima[11], M. Hirokawa[12], Y. Atsuta[13,14], Y. Takami[15]
[1]Kanagawa Cancer Center, Yokohama, [2]National Cancer Center Hospital, Tokyo, [3]Hyogo College of Medicine, Hyogo, [4]Hiroshima Red Cross Hospital and Atomic-bomb Survivors Hospital, Hiroshima, [5]Cancer and Infectious Disease Center Tokyo Metropolitan Komagome Hospital, Tokyo, [6]Toyama Prefectural Central Hospital, Toyama, [7]Tokai University School of Medicine, Kanagawa, [8]Tenri Hospital, Nara, [9]Hokkaido University Hospital, [10]Sapporo Hokuyu Hospital, Sapporo, [11]Aichi Cancer Center Research Institute, Nagoya, [12]Akita University Hospital, Akita, [13]Japanese Data Center for Hematopoietic Cell Transplantation, [14]Nagoya University Graduate School of Medicine, Nagoya, [15]Aichi Medical University, Aichi, Japan

Background: In recent year, reduced intensity conditioning (RIC) is developed and increasingly used in allogeneic hematopoietic stem cell transplantation (allo-HSCT) for elderly acute myeloid leukemia (AML) patients. Increasing age is a repeatedly found significant risk factor for worse prognosis after allo-HSCT among AML patients. However recent studies showed conflict results regarding the association between age and outcome in the setting of RIC.
Aims: We conducted a large-scaled, nationwide retrospective study to examine the impact of age on RIC transplantation outcomes for elderly AML patients and other prognostic factors.
Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. Patients with AML (excluding acute promyelocytic leukemia) aged 50 years or older who underwent RIC allo-HSCT from related or unrelated donor between January 2008 and December 2012 were extracted from the database. Patients who underwent second or more HSCT were excluded. We retrospectively analyzed the clinical impact of patient age on outcome of allo-HSCT. Patients were divided into the following four group for analysis: 50 to 54, 55 to 59, 60 to 64 and ≥65 years old. Outcomes after allo-HSCT of four age groups were compared. Overall survival (OS) was estimated by the Kaplan-Meier method and was compared using a log-rank test. Relapse and nonrelapse mortality (NRM) were considered competing risk events for each other and were compared using Gray's test. In a multivariate analysis, the Cox proportional hazard model and Fine-Gray methods were used for OS and cumulative incidence of relapse and NRM respectively, using the following variables: gender, donor source, disease status at allo-HSCT, graft *versus* host disease (GVHD) prophylaxis, donor-recipient gender mismatch, ABO mismatch, cytogenetic risk category and hematopoietic cell transplant comorbidity index (HCT-CI).
Results: Of the 757 patients, 89 patients (11.8%) were 50-54 years old, 249 patients (32.9%) were 55-59 years old, 301 patients (39.8%) were 60-64 years old and 118 patients (15.6%) were 65 years old or older. Higher proportion of patients aged 60-64 years received graft from ABO matched donor, although difference was not significant (P=0.06). There was no difference in other factors, including gender, disease status, cytogenetic risk category, HCT-CI, donor source, gender mismatch and GVHD prophylaxis. The 3-year OS (47.8%, 45.2%, 37.9% and 36.6% for patients aged 50-54, 55-59, 60-64 and ≥65, respectively, P=0.24) and NRM (24.0%, 22.8%, 29.2% and 27.6% for patients aged 50-54, 55-59, 60-64 and ≥65, respectively, P=0.49) were not significantly different among 4 age groups. In multivariate analysis, age had no significant effect on both OS and NRM after adjusting for covariates. On the other hand, a multivariate analysis showed mismatched related donor (HR 1.80; 95%CI 1.13-2.87; P=0.01) and HCT-CI ≥3 (HR 1.51; 95%CI 1.04-2.17; P=0.03) were associated with higher NRM; non-CR at allo-HSCT (HR 2.51 95%CI 2.01-3.14; P<0.001), mismatched related donor (HR 1.44; 95%CI 1.04-1.97; P=0.03) and HCT-CI ≥3 (HR 1.46; 95%CI 1.14-1.87; P=0.003) were risk factors for worse OS.
Summary and Conclusions: The current study showed increased age had no significant adverse impact on RIC allo-HSCT outcome and pre-transplantation comorbidity has more impact than age in older AML patients.

P348

THE IMPACT OF ANTITHYMOCYTE GLOBULIN ON THE OUTCOME OF UNRELATED CORD BLOOD TRANSPLANTATION FOR CHILDREN WITH HIGH-RISK OR ADVANCED HEMATOLOGICAL MALIGNANCIES

C. Zheng[1,*] Z. Luan[2], J. Fang[3], X. Sun[4], J. Chen[5], C.K. Li[6], S. Hu[7], Y. Zhu[8], Z. Sun[1]
[1]Anhui Provincial Hospital, Hefei, [2]Navy General Hospital of People's Liberation Army, Beijing, [3]Sun Yet-sen Memorial Hospital, [4]Guangzhou Women and Children's Medical Center, Guangzhou, [5]Shanghai Children's Medical Center, Shanghai, [6]Prince of Wales Hospital, Hong Kong, [7]the Children's Hospital of

Soochow University, Suzhou, [8]West China Second University Hospital of Sichuan University, Chengdu, China

Background: Acute graft-*versus*-host disease (GVHD) is the most important cause of death after allogeneic hematopoietic stem cell transplantation (allo-HSCT), and antithymocyte globulin (ATG) has been used in the conditioning regimens to prevent the severe GVHD in this setting. But the role and potential efficacy of ATGin patients receiving cord blood transplantation (CBT) remains controversial.
Aims: In the present study, we retrospectively compared the outcomes of routine GVHD prophylaxis (cyclosporine-based regimens) plus pre-transplantation ATG (ATG group) to routine GVHD prophylaxis alone (non-ATG group) in children with high-risk or advanced hematological malignancies receiving unrelated CBT.
Methods: The study included patients younger than 18 years at transplantation with hematological malignancies who received unrelated CBT between February 2000 and August 2013 at 8 child blood disease centers in China. Total of 207 patients enrolled in the study, and patients were divided into 2 groups: those who received ATG (n=98) and those who received no ATG in the conditioning regimens (n=109).
Results: The cumulative incidence of platelet recovery on day 100 was significantly lower in the ATG cohort as compared with the non-ATG cohort (77.3% *vs* 89.8%) (p=0.046). There was no significantly difference in the incidence of grade II–IV acute and chronic graft-*versus*-host disease (GVHD), and transplant-related mortality (TRM) between the two groups (p =0.76, 0.57, 0.46). The incidence of CMV infection was significantly higher among the ATG group patients compared with that among the non-ATG group patients (p=0.003). The 5-year cumulative incidence of relapse was significantly higher in the ATG cohort (30.7% *vs* 15.4%) (p=0.009). The overall survival (OS) in the non-ATG group was slightly higher than the ATG cohort (64.1% *vs* 52.1%, p=0.093), and the leukemia-free survival (LFS) in the non-ATG cohort was significantly higher than the ATG cohort (56.6% *vs* 37.7%, p=0.015).
Summary and Conclusions: Our study demonstrated that, for high-risk or advanced childhood hematological malignancies receiving unrelated CBT, the omission of ATG in the conditioning had a faster platelet recovery, a comparable GVHD and TRM, a significantly lower relapse risk, and an improved long-term survival compared to the inclusion of ATG in the conditioning.

P349

TCR REPERTOIRE DIVERSITY ASSESSED WITH IMMUNOSEQUENCING IS ASSOCIATED WITH PATIENT MORTALITY FOLLOWING CORD BLOOD TRANSPLANT

R. Emerson[1,*] S. Nikiforow[2], F. Milano[3], A. Sherwood[1], A. Papermaster[3], K. Guthrie[3], C. Carlson[3], E. Warren[3], J. Ritz[2], H. Robins[3], C. Cutler[2], C. Delaney[3]
[1]Adaptive Biotechnologies, Seattle, [2]Dana Farber Cancer Institute, Boston, [3]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: Immunosequencing represents a promising, fast and relatively inexpensive method to assess the reconstitution of effective cellular immunity following stem cell transplantation and has the potential to identify patients at higher risk of developing life-threatening complications and treatment-related mortality.
Aims: Diversity of the T-cell repertoire can provide a measure of immune competence. We hypothesized that restoration of TCR repertoire diversity would be associated with overall survival after UCBT.
Methods: In order to study the clinical impact of T-cell receptor (TCR) diversity in the setting of umbilical cord blood transplantation (UCBT), we retrospectively analyzed samples from 76 patients in 2 independent study cohorts at separate institutions. At Fred Hutchinson Cancer Research Center (FHCRC), we followed 34 patients with hematological malignancies who underwent myeloablation and primarily double UCBT (2 single cord). This cohort was composed of 11 pediatric and 23 adult patients (median age, 26.5yrs), primarily with acute leukemia (n=26), 50% of whom had evidence of MRD at UCBT. They received fludarabine, cytoxan or treosulfan, and total body irradiation (TBI) with cyclosporine and mycophenylate mofetil as GvHD prophylaxis. At Dana-Farber Cancer Institute (DFCI), we followed 42 adult patients (median age, 52.3 yrs), 19 with acute leukemia, 18 of whom had evidence of disease at UCBT. All patients received-reduced-intensity conditioning with fludarabine, melphalan, and anti-thymocyte globulin (ATG) followed by double UCBT with tacrolimus and sirolimus as GvHD prophylaxis. DFCI participants were selected to have predominantly cord T cell chimerism. We analyzed peripheral blood pre-transplant, and at 1, 2, 3, 6 and 12 months after UCBT, based on sample availability. We performed high-throughput sequencing of rearranged (TCR) loci to track presence and frequency of individual T cell clones in each patient across time-points, as well as to calculate estimated diversity of the TCR repertoire as a whole. We correlated our measure of TCR repertoire diversity with clinical outcome, using one-year survival as our primary endpoint.
Results: For the combined group of 63 patients with samples available 3 months after UCBT, 19 subsequently died within 1 year of transplant. Patient with treatment-related mortality had significantly lower TCR repertoire diversity at 3 months than other patients; when analyzed as 2 independent cohorts, the 29 patients at FHCRC with samples at 3 months after UCBT demonstrated significantly lower TCR repertoire diversity in TRM patients (p=0.04), as did the 34 patients with samples available 3 months after transplant at DFCI (p=0.02). In a univariate survival analysis using both cohorts, low TCR diversity at 3 months post-transplant was significantly associated with treatment-related mortality (TRM; p=0.0006 by logrank test; see Figure). This result remained significant at p=0.006 in a multivariate analysis including several other clinical variables (patient age and CR2+ at transplant were associated with TRM in the multivariate analysis; %CD3+ at 3 months and GVHD were not).

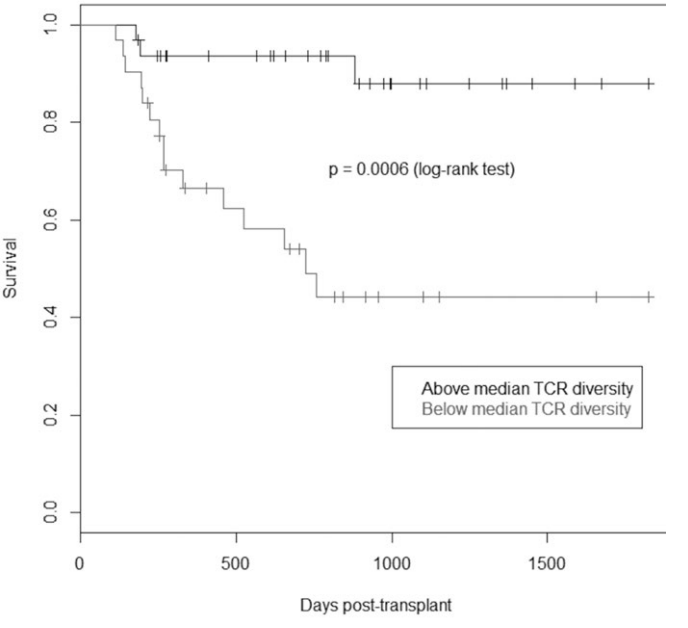

Figure 1.

Summary and Conclusions: In this study, we demonstrate that measurement of TCR repertoire diversity generated using high-throughput sequencing genes at 3 months after UCBT is significantly correlated with subsequent TRM mortality within the first year. Low T cell diversity in the peripheral blood as soon as 3 months may therefore be an early indicator of inadequate immune reconstitution and could potentially be used to tailor monitoring and therapy after UCBT in several clinical contexts.

P350

NEUROREGENERATIVE POTENTIAL OF INTRAVENOUS INFUSION OF G-CSF FOLLOWED BY MOBILIZED PERIPHERAL BLOOD MONONUCLEAR CELLS IN CHILDREN WITH CEREBRAL PALSY

Y.H. Lee[1,*] W.J. Rah[1], J.H. Moon[1], H. Koh[2], H.R. Kang[1], H.J. Eom[3], Y.J. Lee[4], J.Y. Kim[5], Y.Y. Choi[5], K. Park[6], M.J. Kim[6]
[1]Department of Pediatrics, Hanyang University Medical Center, [2]Department of Translational Medicine, Hanyang University Graduate School of Biomedical Engineering, [3]Blood and Marrow Transplantation Center, [4]Department of Radiology, [5]Department of Nuclear Medicine, [6]Department of Rehabilitation Medicine, Hanyang University Medical Center, Seoul, Korea, Republic Of

Background: Up to now most of the cells used in cell therapeutics have been mesenchymal stem cells (MSCs). However, mononuclear cells from cord blood or granulocyte-colony stimulating factor (G-CSF)-mobilized peripheral blood mononuclear cells (mPBMCs) may be an alternative option. In addition, cellular components other than purified HSCs and MSCs could play important roles in tissue regeneration.
Aims: We performed a randomized, double-blind, cross-over study to assess the neuroregenerative potential of intravenous infusion of G-CSF followed by mPBMCs in children with cerebral palsy (CP).
Methods: Children with the non-severe type of CP were enrolled in this study. G-CSF was administered for 5 days, when mPBMCs were collected by apheresis and cryopreserved. One month later (M1), recipients were randomized to mPBMCs or placebo infusion, and switched at 7 months (M7). We assessed the efficacy of treatment over 13 months after the G-CSF injection using various tools for evaluating motor and cognitive function, as well as brain magnetic resonance imaging-diffusion tensor imaging (MRI-DTI) and brain positron emission tomography (PET).
Results: Fifty-seven patients aged 4.3±1.9 (2~10) years and weighing16.6±4.9 (11.6~56.0) kg were enrolled; data for the mPBMCs collected from them were total nucleated cell counts 5.97±1.99×10^{8}/kg, CD34+ cells

3.07±2.1×10^6/kg. Forty-seven patients for whom serial data were available were included in this analysis. After randomization, functional changes noted by parents and neurodevelopmental tests showed tendencies to improve with no significant differences between the mPBMC group and the placebo group. Brain MRI-DTI revealed that fractional anisotropy (FA) in the splenium of mPBMC group (p=0.048) and the right corona radiata of placebo group (p=0.045) comparatively increased to similar extents, although increasing tendencies in FA values in most regions of interest after infusion of mPBMCs or placebo were noted without statistical significance. Additionally, in a subgroup analysis, in the diplegia children, FA values in the mPBMC group were significantly higher than in the placebo group in the left midbrain (p=0.044) and right temporal lobe (p=0.05), and lower in the right midbrain (p=0.022). In the brain PET analysis, we noted increased metabolism in 9 patients (19.1%) in the mPBMC group and in 8 patients (17.0%) in the placebo group, though the increases were not statistically significant. Interestingly, the parents noted functional improvements between the time of G-CSF infusion (M0) and the time (M1) when the children were randomized to the two groups in 27 (57.4%) of the total of 47 patients. Furthermore, there were significant differences in score changes of neurodevelopmental tests between a span of M0-M1 and M1-M7 or M7-M13 in both groups.

Summary and Conclusions: Although we did not detect any additional effect of mPBMC reinfusion, functional and anatomical changes were noted in the brains of CP children after receiving G-CSF followed by mPBMCs. Interestingly, we observed significant differences in score changes of neurodevelopmental tests between a span of M0-M1 and M1-M7 or M7-M13, which suggests that G-CSF administration on its own, without mPBMC collection and reinfusion, may be beneficial in countering neurological impairment in children with CP.

P351

PRE-ENGRAFTMENT SYNDROME AFTER UNRELATED CORD BLOOD TRANSPLANTATION: THE CLINICAL CHARACTERISTICS AND STRATIFIED INTERVENTION TREATMENT

B. Tang[1,*] X. Zhu[1], C. Zheng[1], H. Liu[1], L. Geng[1], X. Wang[1], K. Ding[1], X. Wan[1], L. Zhang[1], Z. Sun[1]
[1]Hematology, Anhui Provincial Hospital, Hefei, China

Background: Pre-engraftment syndrome (PES), a clinical entity of unknown pathogenesis, has been described in patients receiving umbilical cord blood transplantation(CBT). Although a uniform definition is lacking, PES is commonly defined as noninfectious fever and various other clinical findings before neutrophil engraftment, including skin rash, pulmonary infiltrates, and diarrhea, jaundice, or weight gain. However, PES remains poorly characterized, the prognosis and appropriate management of PES are also unclear.

Aims: The aim of this study was to investigate the incidence, risk factors, clinical outcomes of PES in CBT recipients and establish a prognosis assessment score system to guide the stratified intervention treatment.

Methods: Between June 2006 and April 2014, a total of 204 consecutive hematological malignancies patients underwent UCBT in Anhui Provincial Hospital were analyzed. All the patients received TBI-based(n=119) or $BuCY_2$ based(n=85) myeloablative conditioning. Cyclosporine and mycophenolate mofetil were used as GVHD prophylaxis. A retrospective analysis of 94 patients between June 2006 and March 2012 was first done to find out the poor prognostic risk factors of PES. Then we made a PES score system according to the high risk factors, and between April 2012 and April 2014, 88 patients with PES in 110 patients were given stratified intervention treatment.

Results: In all 204 patients, PES developed in 154 patients (75.5%) at a median of 7 days after UCBT. Risk factors for developing PES included TBI-based myeloablative conditioning and double units CBT. The age, sex, weight, underlying malignancy, BM status at CBT, HLA match, ABO compatibility, total infused TNC dose and total $CD34^+$ cell dose had no impact on PES incidence. Of the 94 patients in the period of June 2006 and March 2012, the cumulative incidence of grade II to grade IV acute GVHD by 100 days after CBT was higher in patients with PES than in those without PES (52.5% *versus* 20.3%, P <0.01). The cumulative incidence of neutrophil engraftment at 42d after CBT was also higher in patients with PES than in those without PES (97.5% *versus* 78.0%, P <0.05). PES occurrence did not impact chronic GVHD, treatment-related mortality, relapse, overall survival(OS) or disease-free survival(DFS). But we found that PES occurred in 7 days (<7days), over three or more clinical symptoms, poor effectiveness of MP (ineffectiveness within in one week) were the poor prognostic risk factors of PES. So we made a PES score system according to 3 high risk factors, the existence of one risk factor was defined as 1 point, and no risk factors with 0 score. We found that the higher the PES score, the lower the OS(P<0.001). Then between April 2012 and April 2014, 88 patients with PES in all 110 patients were given stratified intervention treatment, patients with 1 high risk factor were treated with MP 1 mg/kg/d, and patients with 2 or more high risk factors were treated with MP 2 mg/kg/d. If MP was invalid or the disease progressed, anti-CD25 antibody was timely used. After the stratified treatment according to the PES score system, the prognosis of severe PES(score 2+3) was significant improved by 1-year OS between the two different periods (June 2006 to March 2012 and April 2012 to April 2014) (26.4% *versus* 65.1%) (*P<0.05*).

Summary and Conclusions: PES seems to be common after CBT and may be associated with enhanced engraftment and aGVHD incidence. We have established a prognosis assessment score system according to poor prognostic risk factors of PES and for the first time put forward a new insight for PES stratified intervention treatment. Severe PES patients could be benefit from active treatment.

P352

OUTCOME AFTER RELAPSE OR PROGRESSION FOLLOWING FIRST ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN WITH ACUTE LEUKEMIA. A RETROSPECTIVE ANALYSIS FROM THE SFGM-TC

Background: Hematopoietic stem cell transplantation (HSCT) has contributed to improved outcome in childhood acute leukemia (AL). However, post-HSCT relapse is associated with a dismal prognosis and its optimal treatment remains unclear.

Aims: We aimed to compare patients' related factors and treatment strategy, in case of relapse or progression postallogeneic HSCT in children with AL in a recent ten-year period.

Methods: A total of 334 children who received a first allogeneic HSCT for ALL or AML from January 2000 to December 2009 experienced a relapse or progression thereafter. They were treated in the 33 centers of the SFGM-TC, among them 286 cases were analysable. Primary endpoint was overall survival (OS) after diagnosis of relapse or progression post first HSCT whatever the treatment post relapse was.

Results: 286 patients (113 females and 173 males) with a median age of 8.9 years at transplantation (range: 0.52-17.99) were included. Diseases were 151 ALL (B-ALL, n=125; T-ALL n=29), 123 AML. At transplantation, 234 patients were in complete remission (CR) (CR1 n=122, CR2 n=94, CR3 n=18) . Donors were matched related siblings (36%), mismatched related (4%), matched unrelated (18%), mismatched unrelated (24%), unrelated without precision (16%) or syngenic (2%). Stem cell source was bone marrow, peripheral stem cells, umbilical cord blood in 65%, 12%, 23% of cases, respectively. Median time from diagnosis to first HSCT was 263 days. 91% children received myeloablative conditioning and 55% received TBI. Acute GVHD after first HSCT occurred in 157 patients (grade I n=62 grade II to IV n=94). Median delay from first HSCT to failure was 182 days. Treatments for relapse after first HSCT consisted in chemotherapy alone (n=107), chemotherapy followed by second HSCT (n=70), supportive and palliative care (n=68), combination of chemotherapy and DLI (n=28), or DLI only (n=13). With a median follow up of 1315 days (range 58;4182), median OS duration after relapse was 149 days. Median survival duration in days according to therapy was as follows [confidence interval]: DLI after chemotherapy =407 [156;658], Second allograft: 391 [264;518], chemotherapy: 174[118;239], DLI alone: 140 [10;270], Palliative care: 43 [33;53] . Cox model analysis showed the following hazard ratio, when comparing to the best line of treatment, ie chemotherapy+DLI; second allograft HR 1.41, (p=0.20), chemotherapy alone; HR 2.05, (p=.008), DLI HR 2.00 (p=0.08), palliative care HR=5,7, (p<.001). The time interval from transplantation to relapse was also associated with prognosis: when comparing to relapses occuring within the first 90 days, day 90-179, day 180-269,and ≥270 days yielded hazard ratios of respectively .549, .479 and .293 (p ≤.003). There was no impact on outcome from the following variables: gender, age at transplant, leukemia subtype,type of conditioning, TBI, GVHD occurrence after thefirst transplant,stem cell source.

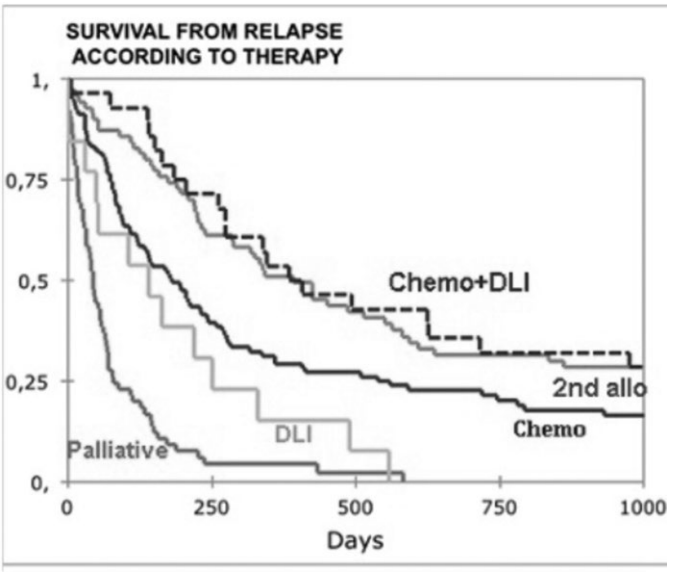

Figure 1.

Summary and Conclusions: The therapeutic choice after post transplant relapse is a sensitive decision influenced by several factors. However, this study highlights the positive role of immunotherapy: the longest survival was achieved either through a second HSCT or through a combination of chemotherapy and DLI, both yielding similar long-term results.

Background: The major pitfall affecting clinical trials of high-dose therapy (HDT) followed by autologous stem cell transplant (ASCT) in lymphomas is the high heterogeneity of histological entities. As a consequence, the statistical power is reduced when we focus on a specific histological subset, and data are often not conclusive. We previously demonstrated (Visani et al, Blood 2011) the safety of a new conditioning regimen with bendamustine, etoposide, cytarabine, and melphalan (BeEAM) prior to ASCT in resistant/relapsed lymphoma patients (EUDRACTnumber2008-002736-15). The regimen showed long-lasting significant anti-lymphoma activity, with a 3-year PFS of 75%. However, that study enrolled both Hodgkin and non-Hodgkin lymphoma patients.
Aims: We designed a phase II study to evaluate the efficacy of the BeEAM conditioning in resistant/relapsed diffuse large B-cell non-Hodgkin lymphoma (DLBCL) patients.
Methods: The study was registered at European Union Drug Regulating Authorities Clinical Trials (EudraCT) N. 2011-001246-14. Until now, 57 patients (median age 54 years, range 19-69) were enrolled. At the time of writing,44 patients with resistant/relapsed diffuse large B cell non-Hodgkin lymphoma are evaluable. The primary end-point of the study is to evaluate the 1-year complete remission rate. Fixing the lowest acceptable rate as 55% and the successful rate as 70%, with a significance level alpha=0.05 and a power 1-beta =0.90, the sample size was estimated in 88 patients.
Results: Briefly, 33/44 patients had advanced stage disease (III-IV), 14 were primary refractory and 30 had relapsed after a median number of 2 lines of therapy (range: 2-3). Eleven patients had 1 or more relevant comorbidities (range: 1-5). 22 patients were in II or subsequent CR after salvage therapy, whereas 19 were in PR and 3 had progressive disease. A median number of 5.90x10^6CD34+/kg cells (range 2,8-9,42) collected from peripheral blood was reinfused to patients. All patients engrafted, with a median time to ANC>0.5x109/l of 10 days. Median times to achieve a platelet count >20x10^9/l and >50x10^9/l were 12 and 16 days respectively. Ten out of 44 patients presented a fever of unknown origin (23%), whereas 21 patients (47%) presented a clinically documented infection. All patients received G-CSF after transplant for a median time of 8 days (range: 8-13). One patient died due to an incomplete hematological recovery after transplant, producing an overall transplant related mortality of 2.7%. Thirty-eight out of 44 patients are evaluable up to now for response to treatment. 31/38 (81.5%) obtained a CR, 3/38 a PR, whereas 4/38 did not respond to therapy. After a median follow-up of 12 months after transplant (range 2-30), 4/38 patients were refractory, 7/38 relapsed, and 27/38 (71%) are still alive, in continuous CR.
Summary and Conclusions: The stringent inclusion criteria at enrollment allowed theevaluation ofthe impact of HDT with Bendamustine followed by ASCT in a highly selected population of patients with DLBCL only. Accordingly, our data preliminary provide the evidence that the Benda-BEAM regimen is safe and has promising high efficacy in resistant-relapsed aggressive diffuse large B cell lymphoma patients.
Acknowledgements: The study was supported in part by AIL Pesaro Onlus. Mundipharma Italy is grateful acknowledged for providing Bendamustine free of charge.

TREATMENT OF CHRONIC GRAFT VERSUS HOST DISEASE WITH A COMBINATION OF B-CELL DEPLETION AND TYROSINE KINASE INHIBITION, PRELIMINARY RESULTS

L. Van Der Wagen[1,2,*] L. te Boome[2,3], M. Schoordijk[4], E. Meijer[4], J. Kuball[1,2]
[1]Laboratory of Translational Immunology, [2]Hematology, University Medical Center Utrecht, Utrecht, [3]Hematology, Haga Hospital, The Hague, [4]Hematology, VU Medical Center Amsterdam, Amsterdam, Netherlands

Background: Chronic Graft *Versus* Host Disease (cGVHD) affects about 60% of all patients receiving an allogeneic HSCT and surviving beyond day 100. Incidence of cGVHD is rising because of the widespread use of Peripheral Blood Stem Cells (PBSC) as stemcell source. Patients with cGVHD have high morbidity and mortality rates. Patients require long term use of immunosuppressive drugs, mainly corticosteroids, which lead to development of severe side effects. Therefore new therapies are urgently needed.
Aims: We tested whether the sequential therapy of the anti CD20 antibody rituximab followed by a 6 month treatment period with the tyrosine kinase inhibitor nilotinib is a good treatment strategy for patients with sclerotic cGVHD.
Methods: We treated 19 patients with a combination of 4 weekly infusions of rituximab followed by a 6 month period of treatment with nilotinib (300mg b.i.d.). Patients were evaluated monthly for 13 months and sequential blood samples and skin biopsies were analyzed. All patients gave informed consent before enrollment.
Results: 3 patients experienced severe side effects from either rituximab or nilotinib treatment and therefore were taken off study. Of the remaining 11 patients who thus far have completed the study protocol, 65% showed a response (4 patients went from NIH scoring 'severe' to 'moderate', 1 patient went from NIH scoring 'moderate' to 'no cGVHD'). There is also a significant decrease in cGVHD affected body surface area (Figure 1). Moreover, two out of four patients who suffered from severe ulcerations at the start of the study had a complete resolution of ulcers at the end of the treatment period. Patients with a (partial) response also showed a decrease in self attributed severity of cGVHD and their immunosuppressive drugs could be tapered.

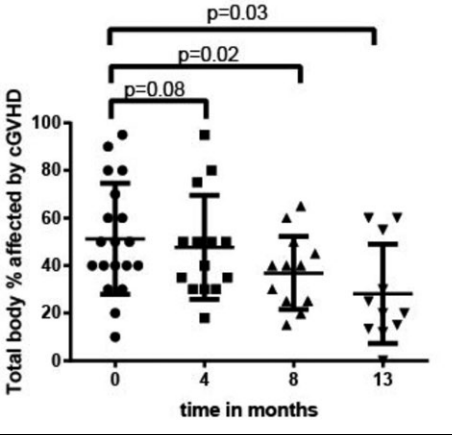

Figure 1. Percentage of total body surface area affected by chronic Graft versus Host Disease is plotted against time in months after start of the study. Each dot represents 1 patient. P-values are calculated by means of Wilcoxon matched-pairs signed rank test.

Summary and Conclusions: The sequential therapy of B-cell depletion and tyrosine kinase inhibition provides a new and interesting alternative treatment option for this difficult and heavily pretreated patient category.

P355

LOW-DOSE DECITABINE COMBINED WITH MODIFIED BUCY AS CONDITIONING REGIMENT FOLLOW BY ALLOGENEIC STEM CELL TRANSPLANTATION FOR THE TREATMENT OF ADVANCED AML/MDS PATIENTS

X. Shi[1], L. Ge[1], A. Sun[1], X. Zhu[1], H. Qiu[1], Z. Jin[1], M. Miao[1], C. Fu[1], X. Ma[1], F. Chen[1], S. Xue[1], Y. Han[1], M. Xue[1], X. Tang[1,*] D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative treatment options to hematologic malignancies. However, majority of patients with refractory or resistant hematologic malignancies can not achieve remission before transplantation. It is necessary to design a safe and affective conditioning regimento reduce the tumor burden, improve theremission rate, decrease thetransplantation related mortality andimprove disease-free survivalin patients with advanced acute myloid leukemia(AML) and myelodysplastic syndrom(MDS). One of the promising drugs of epigenetics is decitabine (DAC), which has a significant effect on a variety of hematologic malignancies including MDS and advanced AML. Furthermore, decitabine can not only up-modulate the tumor-associated antigen express on surface of leukemia cells to increase graft-*versus*-leukemia (GVL) effect but also can reduce the incidence of graft-*versus*-host disease (GVHD) by increase the number of regulatory T Cells (Tregs).
Aims: Therefore, this clinical study will investigate the security and efficacy of conditioning regimen containing low-dose decitabine combined with modified BUCY regimen for advanced AML/MDS patients and explore the role of immunomodulatory activity post transplantation.
Methods: 20 cases of patients with advanced AML/MDS underwent allo-HSCT with low-dose decitabine (integral dose100mg/m^2) combined with modified BUCY conditioning regimens.
Results: 19/20 (95%) patients achieved complete remission and hematopoietic reconstitution after transplantation.The median time of neutrophil and platelet recovery were 12 (10-22) and 14.5 (12-35) days respectively. The transplantation-related mortality (TRM) rate was 0.The cumulative rate of aGVHD and cGVHD were 25.6% and 48.3%.And the cumulative rate of aGVHD for grade III and IV were 10.6%. The cumulative relapse rate was 26.7%. During a median follow-up of 246 (19-613) days,15 patients weredisease free survival.The estimated 2-year overall survival (2yr-OS) rate was 78%.The 2 year disease-free survival (2yr-DFS) rate was 62.6%. Furthermore, Therewasnosignificantdifferenceof the estimated 2-yr OS and DFS between patients with or without DNMT3A mutations or abnormalities of chromosome 7 and complex chromosomal karyotype.
Summary and Conclusions: 1.It is feasible to use conditioning regimen containing low-dose decitabine combined with modified BUCY regimen before allo-HSCT.The treatment were well tolerated and transplantation-related mortality (TRM) rate was 0. 2..The incidence of aGVHD and cGVHD were not increased in this setting. 3. 92.3% patientsachieved complete remission with salvage allo-HSCT with ralative high 2-yr rate of OS and DFS. 4.Theprognosisand survival of the patients with complex chromosomal karyotype or chromosome 7 abnormalities or DNMT3A mutation may be improved by treating with decitabine containing conditioning regimen.

P356

STUDY OF PERIPHERAL STEM CELLS MOBILIZATION AS A TREATMENT LINE FOR PEDIATRIC IDIOPATHIC DILATED CARDIOMYOPATHY

M. El-Shanshory[1,*] S. abdou[2], W. El-Shehaby[3], A. Fathey[4]
[1]Pediatrics, Faculty of Medicine, [2]Clinical pathology, [3]Pediatrics, Faculty of Medicine, Tanta University, Tanta, [4]Pediatrics, Ministry of Health, Fayom, Egypt

Background: Mobilizing hematopoietic stem cells may be a promising intervention to the treatment of idiopathic dilated cardiomyopathy (IDCM) in infant and children.
Aims: Evaluating the efficacy of granulocyte-colony stimulating factor (G-CSF) as a therapeutic modality in pediatric idiopathic dilated cardiomyopathy (IDCM).
Methods: This randomized clinical trial was conducted on 15 pediatric patients with IDCM admitted at Cardiology Unit, Pediatric Department, Tanta University Hospital. They were subjected to history taking, clinical examination, total CPK, CK-MB isoenzyme, and peripheral blood CD34+ cell assessment before and at day 6 after subcutaneous G-CSF injection for 5 consecutive days. Echocardiography was done before and one month after therapy.
Results: Clinical improvement in the form of regression of patients ROSS heart failure classes. Increased percentage of CD34+ mobilized cells from the bone marrow, and significant increase in blood counts especially white blood cells 6 days after G-CSF injection. Significant improvement in echocardiographic data evaluating systolic function of the heart (Ejection fraction, Fractional shortening and systolic velocity at mitral annulus. But, with no significant correlation between increased percentage of CD34+ cells and improvement in echocardiographic parameters.

Tabella 1. Modified Ross H.F Classes before and after one month from receving G-CSF therapy.

Modified Ross H F classification	Before		After	
	No.	%	No.	%
Class I	0	0.0 %	3	20 %
Class II	**4**	**26.7%**	**5**	**33.3%**
Class III	8	53.3 %	4	26.7%
Class IV	3	20 %	2	13.3%

Tabella 2. Systolic functions of the heart among studied group before & one month after receving G-CSF therapy.

Echo finding	Before		After		P-value
	Mean	SD	Mean	SD	
FS %	16.9	±4.1	**21.88**	±5.6	**<0.001****
EF %	39.8	±6.1	**49.1**	±8	**<0.001****
S-wave (mm/sec)	0.08	±0.05	0.16	±0.1	0.05*

*: Significance, **: High significance

Summary and Conclusions: Administration of G-CSF may be beneficial in improving systolic functions of the heart in pediatric idiopathic dilated cardiomyopathy.

Hematopoiesis, stem cells and microenvironment

IKAROS CONTRIBUTES TO B CELL TOLERANCE BY MODULATING MAPK ACTIVITY

B. Heizmann[1,*] A. Macias-Garcia[1], M. Sellars[1], H. Dali[2], J.L. Pasquali[2], S. Muller[2], P. Kastner[1], S. Chan[1]
[1]Hematopoiesis and leukemogenesis in the mouse, Institut de Génétique et de Biologie Moléculaire et Cellulaire (IGBMC),, Illkirch, [2]Institut de Biologie Moléculaire et Cellulaire (IBMC), Strasbourg, France

Background: B cell differentiation is a multiple process that involves the dynamic activation and silencing of hundreds of genes. The Ikaros transcription factor is a key regulator of B cell differentiation and function. The IKZF1 gene, which encodes the Ikaros transcription factor, was recently identified as a susceptibility locus for systemic lupus erythematosus (SLE), and leukocytes from SLE patients have reduced IKZF1 mRNA levels, suggesting a possible link between Ikaros loss and SLE development.
Aims: How Ikaros deficiency may contribute to SLE is presently unknown.With this study, we want to understand the biological processes influenced by Ikaros resulting in defectiveB cell tolerance associated with autoimmune disorders.
Methods: To study the function of Ikaros transcription factor as a regulator of peripheral B cell maturation, activation, and tolerance, we used hypomorphic and B cell conditional knock-out models for Ikaros.
Results: We show that mice with Ikaros null B cells spontaneously produce high levels of IgM autoantibodies associated with SLE (against chromatin/nucleosomes, double-stranded DNA, all histones), demonstrating a direct role for Ikaros in generating autoreactive B cells. Naive Ikaros null B cells are hyperreactive to B cell receptor (BCR) induced stimulation and show a diminished requirement for secondary co-stimulatory signals, with enhanced survival and increased proliferation. Unexpectedly, Ikaros deficiency induces gene expression changes in naive B cells that render them poised for activation. Freshly isolated Ikaros null B cells show defects in the MAPK signaling pathway that result in enhanced and sustained phosphorylation of p38 and ERK-1/2 upon activation. Inhibition of p38 and ERK activity rescues the hyper-reactive phenotype. Interestingly, Ikaros deficiency in B cells is not sufficient for progression to a pathological state as mutant mice do not develop clinical signs of lupus, suggesting that Ikaros deficiency functions as a trigger for disease initiation but is not sufficient for SLE progression.
Summary and Conclusions: Altogether, our results implicate Ikaros as a novel negative regulator of BCR signaling which helps to maintain B cell tolerance to self-antigens during maturation by modulating MAPK events downstream of the BCR.

HIGH-THROUGHPUT SIRNA SCREENING REVEALS GATA-2 UPSTREAM TRANSCRIPTIONAL MECHANISMS IN HEMATOPOIETIC CELLS

Y. Saito[1,*] T. Fujiwara[1,2], M. Kobayashi[1], M. Suzuki[1], Y. Okitsu[1], N. Fukuhara[1], Y. Onishi[1], K. Ishizawa[1], H. Harigae[1,2]
[1]Hematology and Rheumatology, [2]Molecular Hematology/Oncology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Hematopoietic stem cells (HSCs) are capable of self-renewing and differentiating into all blood cell types. The transcription factor GATA-2 is expressed in HSCs and progenitor cells and is essential for cell proliferation, survival, and differentiation. Recently, studies of aplastic anemia, MonoMAC syndrome, and lung cancer demonstrated a mechanistic link between GATA-2 and human pathophysiology. GATA-2-dependent disease processes have been extensively studied; however, GATA-2 upstream transcriptional mechanisms remains poorly understood.
Aims: We conducted high-throughput screening analysis of siRNA libraries to identify novel factors involved in GATA-2 regulation.
Methods: Human hematopoietic cell lines, YN-1 (Endo *et al*, 1993), K562, KG1a, Jurkat, U937, and NALM6 were analyzed. GATA-2 regulatory element was cloned into luciferase plasmid (pGL4.20, Promega) and mutation within the *cis*-element was introduced using a site-directed mutagenesis kit (Agilent). For siRNA screening, we targeted 995 genes encoding transcription factors from the siPerfect transcription factor library (RNAi Co., Ltd.). YN-1 cells stably expressing *GATA-2* +9.9/1S-luciferase were transfected with each siRNA duplex by 96-well plate GenomONE-Si (Ishihara Sangyo), and luciferase activity was analyzed using a ONE-Glo Luciferase Assay System (Promega). siRNA-mediated knockdown (Dharmacon) and CRISPR/Cas9-mediated knockout (Invitrogen) were conducted with nucleofector (Lonza).
Results: GATA-2 transcription involves two different exons, a distal (1S) and proximal (1G) promoter, with the former being considered important in hematopoietic cells (Pan *et al*, 2000). We first demonstrated that GATA-2 1S transcript was most abundantly expressed in YN-1 cells. Next, using transient luciferase analysis to determine the optimal configuration for siRNA screening, we demonstrated that 1S promoter fused to a +9.9 kb intronic enhancer and involved in MonoMAC syndrome pathogenesis (Johnson *et al*, 2012), exerted the highest promoter activity. Disruption of the GATA binding motif within the +9.9 kb enhancer resulted in a significant decrease in +9.9 kb/1S luciferase activity. Next, we established a stable YN-1 cell line expressing *GATA-2* +9.9 kb/1S-luciferase and demonstrated significantly diminished luciferase activity following knockdown of BRG1, a previously reported GATA-2 regulator (Sanalkumar *et al*, 2014). Following siRNA library screening, 10% of genes with the highest luciferase activity repression after their knockdown were initially selected from each 96-well plate (n =83), which included potential GATA-2 regulators of GATA1, GFI1B, and ERG. The list of candidate genes was further refined based on their potential importance in hematopoiesis. CITED2, previously reported as a CBP/p300-dependent transcriptional co-activator involved in pathogenesis of bone marrow failure (Chen *et al.* Blood 2007; Kranc *et al.* Cell Stem Cell 2008), and EGR1, a transcription factor involved in HSC homeostasis as well as leukemogenesis (Min *et al.* 2008; Stoddart *et al.* 2014), were subsequently identified. siRNA-mediated knockdown of CITED2 and EGR1 led to significant *GATA-2* downregulation. Further, CRISPR/Cas9-mediated knockout of CITED2 resulted in significant *GATA-2* downregulation. We are currently performing a molecular analysis how CITED2 and EGR1 affect GATA-2 expression.
Summary and Conclusions: Our approach represents a powerful tool for identifying GATA-2 regulatory mechanisms and may lead to the development of novel therapeutic approaches for human diseases, including bone marrow failure syndromes.

P359

FUMARATE HYDRATASE IS AN ESSENTIAL REGULATOR OF EMBRYONIC AND ADULT HAEMATOPOIETIC STEM CELL

A.V. Guitart[1,*] M. Vukovic[1], Z. Sas[1], M. Vila[1], C. Sepúlveda[1], T. Panagopoulou[1], L. Allen[1], P. Pollard[2], N. Morton[3], A. Finch[2], K.R. Kranc[1,2]
[1]MRC Centre for Regenerative Medicine, [2]Edinburgh Cancer Research UK Centre, [3]Queen's Medical Research Institute, Edinburgh, United Kingdom

Background: Lifelong adult haematopoiesis critically depends on rare multipotent haematopoietic stem cells (HSCs). HSCs reside in niches within the foetal liver (FL) during embryogenesis and the bone marrow (BM) after birth. These specific microenvironments allow HSCs to maintain a particular metabolic status that is essential to preserve their properties. Quiescent long-term HSCs rely on glycolysis but switch to oxydative phosphorylation in order to comply with the energetic demands of self-renewing or differentiation. However, the tricarboxylic acid (TCA) cycle's contribution to HSC metabolism remains poorly understood.
Aims: The aim of this study is to elucidate the role of the TCA cycle in haematopoiesis by deleting one of the key enzymes, fumarate hydratase (FH), that drives the hydration of fumarate into malate.
Methods: In order to determine the role of FH within the haematopoietic system, we opted for an *in vivo* genetic loss of function approach. We crossed floxed *Fh1* conditional mice with Vav-iCre mice to induce a constitutive haematopoiesis-specific *Fh1* deletion.
Results: We demonstrate that *Fh1* is indispensable to the haematopoietic system as its deletion is embryonic lethal. Indeed, *Fh1* deletion leads to complete foetal liver failure resulting in a severe defect in differentiation coupled with an expansion of the most primitive cell compartments. Using a different mouse model, we validated these results in the adult by reproducing the phenotype after conditional deletion (*Mx-Cre*). Metabolic analysis of haematopoietic cells lacking *Fh1* (combining LC/MS and SeaHorse approach) revealed that in addition to harbouring a compromised TCA cycle, *Fh1*-deficient cells exhibit a higher cellular concentration of fumarate. In order to discriminate which of these two metabolic changes triggers the observed phenotypes we reintroduced the cytosolic isoform of Fh1 thereby restoring intracellular fumarate concentration while maintaining the TCA cycle impairment. We demonstrate that this genetic addition is enough to rescue the embryonic lethality, the multilineage differentiation potential and the self-renewing capacity of HSCs upon transplantation.
Summary and Conclusions: With this study, we demonstrated an absolute requirement for *Fh1* for embryonic and adult haematopoiesis. From the dual function of Fh1 we established that while the mitochondrial isoform of Fh1 is largely dispensable for HSC maintenance and multilineage differentiation, efficient clearance of fumarate from the cytoplasm by the cytosolic isoform of Fh1 is fundamental.

P360

DECODING THE CENTRAL ROLE OF RCOR1 IN PROLIFERATION AND DIFFERENTIATION OF HAEMATOPOIETIC STEM AND PROGENITOR CELLS IN ZEBRAFISH

C. Labalette[1], K. Georgopoulou[1], D. Stemple[2], G. Jarvis[3], A. Cvejic[1,*]
[1]Haematology, University of Cambridge, [2]Wellcome Trust Sanger Institute, [3]Department of Physiology, Development and Neuroscience, University of Cambridge, Cambridge, United Kingdom

Background: The corepressor Rcor1 was initially discovered as a novel genetic determinant of platelet number in meta-analyses of genome wide association stud-

ies (GWAS) for mean platelet volume and platelet count. More recently, it has been suggested to play a role in terminal differentiation of murine erythrocytes.
Aims: However, the mechanisms by which *rcor1* affects haematopoiesis during development and what transcription factors it mediates its effect through remain unclear.
Methods: To address this lack of knowledge, in this study, we used already validated methods of reverse genetics in zebrafish.
Results: Here we report on the novel role of Rcor1 in proliferation of haematopoietic stem and progenitor cells (HSPCs) during zebrafish embryonic development. Indeed, knock down of Rcor1 activity resulted in enhanced proliferation of HSPCs after their migration to the caudal haematopoietic tissue, which is the zebrafish equivalent to the mammalian foetal liver. This expansion of HSPCs was accompanied by a block in differentiation. Interestingly, the loss of transcription factor *gfi1aa* (*gfi1aa*$^{sa18719/sa18719}$) completely phenocopied the rcor1 defect in proliferation of HSPCs. However, analysis of *gfi1aa*$^{sa18719/sa18719}$ mutant HSPCs revealed that they had normal differentiation capacity. We further show that inhibition of Notch signalling partially rescued the ability of *rcor1*-depleted HSPCs to undergo differentiation.
Summary and Conclusions: Taken together, our data suggest that Rcor1 mediates the complex interplay between HSPC proliferation and differentiation by modulating the activity of diverse transcription factors.

DUVELISIB (IPI-145) INHIBITS MALIGNANT B-CELL PROLIFERATION AND DISRUPTS SIGNALING FROM THE TUMOR MICROENVIRONMENT THROUGH MECHANISMS THAT ARE DEPENDENT ON PI3K-DELTA AND PI3K-GAMMA

M. Peluso[1], K. Faia[1], D. Winkler[1], S. Sharma[1], N. Patel[1], K. White[1], V. Palombella[1], K. McGovern[1], J. Kutok[1,*]
[1]Infinity Pharmaceuticals, Cambridge, United States

Background: In indolent non-Hodgkin lymphoma (iNHL) and chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), the neoplastic B cells rely upon support from non-neoplastic cells within their microenvironment for proliferation and survival. Support cells include T cells, myeloid-derived cells, and mesenchymal stromal cells, which provide phosphoinositide-3 kinase (PI3K)-dependent survival and growth signals for the neoplastic cells, as well as signals that maintain the tumor microenvironment (TME). Duvelisib (IPI-145) is an oral dual inhibitor of PI3K-δ and PI3K-γ in clinical development for iNHL and CLL/SLL.
Aims: To better understand the roles of the PI3K-δ and PI3K-γ isoforms in mediating signaling between the tumor and TME cells in B-cell malignancies,Infinity's potent PI3K isoform-selective compoundsthat targeteither PI3K-δ or PI3K-γ with >100-fold selectivity over other PI3K isoforms were utilized in *in vitro* experiments.
Methods: A mixture of cytokines (CD40L/IL-2/IL-10) was utilized in an assay that recapitulated TME-induced malignant B-cell proliferation.
Results: Duvelisib inhibited CD40L/IL-2/IL-10-induced proliferation of primary CLL cells with an average EC50 in the sub-nanomolar range. The use of PI3K isoform-selective inhibitory compounds revealed these proliferative signals are PI3K-δ dependent, as the PI3K-δ-selective inhibitor was more active than the PI3K-γ-selective inhibitor. While these experiments established the PI3K-δ dependence of TME-derived cytokines on CLL cell proliferation, the role of PI3K-γ in key functions such as the directed migration of non-malignant immune cells of the TME was also tested. The stromal chemokine, CXCL12, resulted in upregulation of phospho (p)-AKT in the CD3+ T cell populations in CLL patient PBMCs. Using isoform-selective inhibitors, the increase in CXCL12-induced pAKT in CD3+ T cells was found to be mediated by PI3K-γ. Chemotactic assays demonstrated reduced migration of total CLL PBMCs towards CXCL12 in the presence of the PI3K-δ and PI3K-γ inhibitor duvelisib. Flow cytometric analyses of these migrating cells revealed that duvelisib had the greatest effect on CXCL12-induced migration of T-cell population. Utilizing PI3K isoform-selective compounds, the inhibition of T-cell migration toward CXCL12 was found to be a PI3K-γ mediated process, as the PI3K-γ-selective inhibitor was more potent than the PI3K-δ-selective inhibitor in blocking T-cell migration. Myeloid-derived cells can also support CLL cell survival as components of the TME. Murine bone marrow cells were polarized *in vitro* into M2-macrophages with MCSF and IL-4. This polarization was blocked by the PI3K-g-selective inhibitor but not the PI3K-d-selective inhibitor. Finally, co-cultures of M2 macrophages with CLL cells led to extended CLL cell survival. These data show that macrophage polarization toward an M2 phenotype is dependent upon PI3K-γ and that M2-cells can support CLL cell survival.
Summary and Conclusions: T cells and myeloid cells provide a survival and proliferative advantage to malignant CLL cells within the TME. The role of PI3K-γ in the migration and polarization of these cells supports the potential for therapeutic benefit from inhibition of PI3K-γ. By inhibiting both the PI3K-δ and PI3K-γ isoforms, duvelisib is uniquely positioned to inhibit key signals important in the pathogenesis of B-cell malignancies.

P362

BONE MARROW ADIPOGENESIS BY ACTIVATING PPARΓ SIGNALING INHIBITS POSTINJURY RECOVERY OF MOUSE HEMATOPOIETIC STRESS MODEL

W. Lu[1,*] R. Zhu[2], W. Wang[1], S. Wang[1], Y. Feng[1], K. Liu[1]
[1]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Institute of Hematology, Peking University People's hospital, [2]Centre of Excellence in Tissue Engineering, Peking Union Medical College hospital, Beijing, China

Background: Adipocytes have been considered as passive tissue filler of bone marrow(BM) niche for a long time.However, recent reportsshow thatadipocyte-rich BM harbored a decreased frequency of progenitor cells. Furthermore, "fatless" mouse BM cells exhibit improved engraftment after transplantation. Our previous studies alsoreveal that hematopoietic recovery is accelerated by using PPARγ inhibitor BADGE after chemotherapy. However, it is still unclear how adipocytes affect hematopoietic recovery under stress conditions. In our study, we set out to test the hypothesis that adipocytes could affect the function and migration of hematopoietic stem cell(HSC) following hematopoietic stress.
Aims: To investigate the effect of BM adipogenesis on the function and migration ofHSC in response to stress in mice.
Methods: For induction of hematopoietic stress, C57BL/6J female mice(6-8 weeks, 18-20g, n=90) were administrated once by intraperitoneal injection with 250mg/kg 5-Fu. Rosiglitazone group animals were fed 5g chow/d containing 0.15mg/g.d rosiglitazone before 5-Fu. BADGE group animals were administered 60mg/kg/d BADGE following chemotherapy. To observe the level of BM adipogenesis, tibias were collected and detected by histopathology. PPARγ, aP2, adiponectin mRNA level was evaluated by RT-PCR. Peripheral blood cells(PB) and BM mononuclear cells(BMMNC) were counted using the hematology analyzer. The number of progenitor cell in BM were analyzed by colony-forming cell assay. Immunophenotype and cell cycle of hematopoietic stem cells were quantitatively estimated by flow cytometry.
Results: We found that BM adipogenesis could be successfully induced by rosiglitazone treatment under homeostatic condition. Rosiglitazone treatment mice exhibited normal hematopoiesis compared with control group, as indicated by normal levels of blood and BM cellularity. In response to 5-Fu induced hematopoietic stress, mice exhibited hypocellular BM with dilated sinus. Compared to control group, adipocytes number in BM of rosigolitazone group mice was increased and the expression of PPARγ, adiponectin was also significantly higher in rosiglitazone group. After treatment with 5-Fu, all groups showed similar nadirs of WBC and BMMNC. On recovery, however, WBC and BMMNC increased more slowly in rosiglitazone group mice. HGB and platelet counts didn't show similar pattern of delayed recovery after 5-Fu treatment in rosiglitazone group. As a cytotoxic agent, 5-Fu induces a multistep BM stress response by killing actively cycling cells, causing the number of BM cells to decline, followed by proliferation, differentiation and mobilization of HSPCs. We observed that rosigalitazone group mice had increased percentage of LSK compared to control groups while a decreased percentage of GMP and CLP cells at d14 after 5-Fu. Meanwhile, we found a 1.5-fold reduction of CFU-G counts in rosiglitazone group BM. However, we didn't find any difference of LSK cell counts in PB and spleen, and cell cycle of LSK cells was also not affected by treatment of rosiglitazone. These results indicated that BM adipocytes maintain the number of LSK cells in BM while impair myeloid and lymphoid differentiation, which may explain the delayed hematopoietic recovery in rosiglitazone group. Finally, we treated rosiglitazone mice with an PPARγ inhibitor BADGE for 2 weeks to check if such effects were reversed. Surprisingly, there was a twofold increase in the proportion of LSK cells in the spleen at d14. Moreover, WBC and BMMNC counts of BADGE groups were elevated compared to rosiglitazone group and the proportion of LSK of BADGE treated BM was decreased compared with rosiglitazone group at d14.
Summary and Conclusions: Our studies revealed that PPARγ induced BM adipogenesis could inhibit the differentiation of HSC while maintain them in undifferentiated state. These results may suggest a plausible mechanism for the impaired hematopoiesis in patients with fatty bone marrow and provide new evidence for benefits of PPARγ inhibitor treatment to improve hematopoietic recovery.

P363

A CROSSTALK IS MEDIATED BY THE NOTCH PATHWAY BETWEEN THE HAEMATOPIETIC STEM CELLS AND THEIR STROMAL MICROENVIRONMENT

A. Audia[1,*] F. Anjos Afonso[1]
[1]Cancer Research UK, London, United Kingdom

Background: The very well conserved Notch pathway is known to be important in many aspects of haematopoiesis. The Notch ligands are expressed in the stromal bone marrow microenvironment and interact with Notch receptors expressed on the haematopoietic stem cells and progenitors (HSCs/HSPCs) in order to maintain their immature and quiescent phenotype (Anjos Afonso *et al.*, 2013).
Aims: The cell autonomous role of the Notch pathway has been recently elu-

cidated in human HSCs/HSPCs maintenance. However little is known about the non-cell autonomous role played by the Notch pathway in the stromal microenvironment.

Methods: The long-term culture (LTC) assay has been used as a model to study the interaction mediated by the Notch pathway between the HSPCs and the MS-5 stromal cell line *in vitro* and *in vivo*. For *in vivo* studies it has beenused a technique recently established in the laboratory. MS-5 stroma and HSPCs cells were pre-seeded in gel-foam scaffolds that were, after few days, implanted in the back of mice for 8 or more weeks.

Results: In this study, for the first time, is shown that the HSPCs activate the Notch pathway in the MS-5 stromal cells through Notch2 receptor (Fig1 A). The activation of the pathway induces an increase in the expression of Notch ligands Jag1, Jag2 and Delta4 and of Notch2 receptor in the stromal cells (Fig1 B). Thus, enhancing in a positive feed-back loop the activation of the Notch pathway in the HSPCs and in the MS-5 cells (Fig1 C and D). These data suggest that a cross-talk mediated by the Notch pathway is happening between the HSPCs and the stromal cells. Interestingly, in absence of Notch activation in the stroma, the HSPCs are pushed to proliferate and differentiate loosing their LTC-IC and *in vivo* engraftment potentials after co-culture (Fig2). However, the inhibition of the cross-talk mediated by Notch inhibitors (GSIs) trigger a stronger phenotype, confirming the cell autonomous role played by Notch in HSPCs maintenance *ex vivo* (Fig3). These results have been confirmed using human primary Mesenchymal Stem Cells (MSCs).

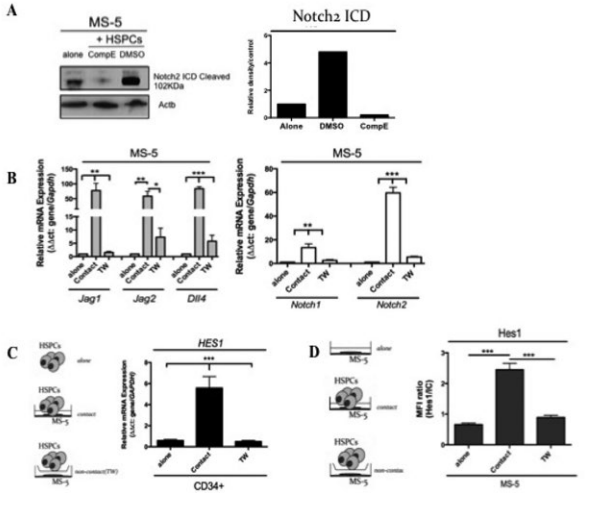

Figure 1.

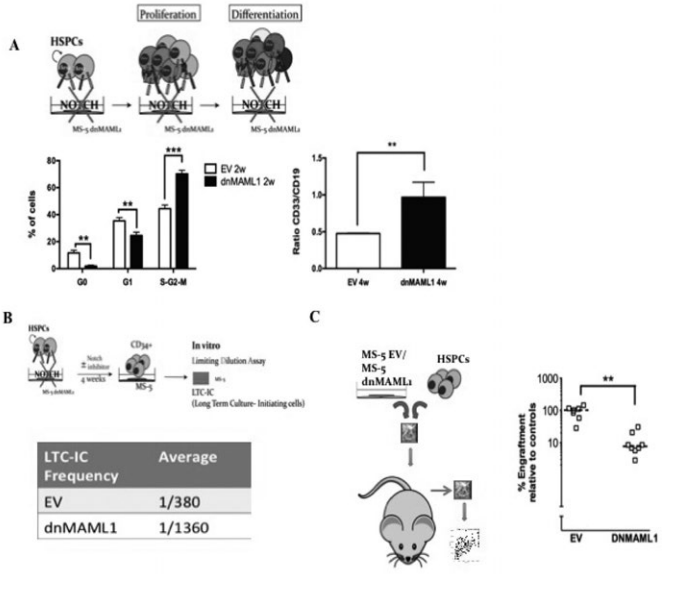

Figure 2.

Summary and Conclusions: These results show that a crosstalk mediated by the Notch pathway between the HSCs and the stromal microenvironment is fundamental to maintain the properties of the HSPCs*ex vivo*.A better understanding of the molecular mechanism involved in the crosstalk mediated by the Notch pathway between the haematopoietic cells and the stromal microenvironment would not only help in the optimization of their *in vitro* expansion for clinical purposes, but also in a better understanding of the role of Notch in haematological malignancies.

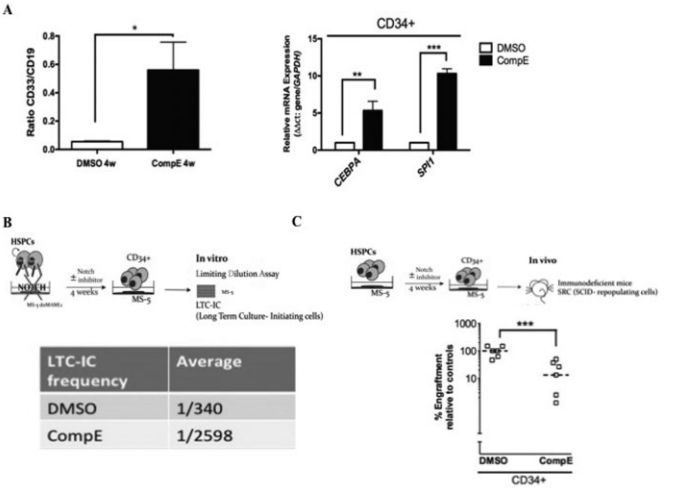

Figure 3.

P364

A CRITICAL ROLE FOR O-GLCNACYLATION IN MURINE FETAL LIVER AND ADULT HEMATOPOIESIS

S. Soma[1,*] Y. Fukuchi[2], S. Okamoto[1], H. Nakajima[1]
[1]Division of Hematology, Department of Medicine, Keio Univeisity School of Medicine, [2]Department of Pathophysiology, Hoshi University School of Pharmacy and Pharmaceutical Sciences, Tokyo, Japan

Background: Posttranslational modifications such as phosphorylation or glycosylation are crucial for regulating protein function. Among these, glycosylation of serine or threonine residues with *O*-linked N-acetylglucosamine (*O*-GlcNAcylation) by *O*-linked N-acetylglucosamine Transeferase (OGT) is particularly important, as this modification regulates various cellular processes through numerous targets including signaling molecules or transcription factors. Dysregulation of *O*-GlcNAcylation is critically linked to metabolic or degenerative diseases (*i.e.* diabetes, Alzheimer disease), tumorigenesis and aging. However, a role of *O*-GlcNAcylation in hematopoiesis still remains elusive.

Aims: To investigate the role of *O*-GlcNAcylation by *Ogt* in normal hematopoiesis.

Methods: We utilized *Ogt* conditional knockout mice (*Ogt*-cKO) to delineate the role of O-GlcNAcylation in hematopoietic system. To accomplish hematopoietic-specific or inducible deletion of *Ogt*, *Ogt*-cKO mice were crossed to Vav-Cre transgenic (Tg) or Mx-Cre Tg mice, respectively. Since *Ogt* is located on X-chromosome, $Ogt^{flox/Y}$ or $Ogt^{flox/flox}$ mice were considered to be equivalent.

Results: Since both $Ogt^{flox/flox}$ Vav-Cre^{+}and $Ogt^{flox/Y}$Vav-Cre^{+} mice were embryonic or perinatal lethal, we analyzed E14.5 fetal liver cells (FLs) to examine the effect of *Ogt* loss in FL hematopoiesis. Quantitative RT-PCR and western blot analysis showed that *Ogt*-mRNA and OGT protein were absent in $Ogt^{flox/Y}$ Vav-Cre^{+}or $Ogt^{flox/flox}$ Vav-Cre^{+} FL cells, indicating that floxed-alleles created a null mutation. Interestingly, the number of FL cells was remarkably decreased in $Ogt^{flox/Y}$ Vav-Cre^{+}or $Ogt^{flox/flox}$ Vav-Cre^{+} embryos as compared to the wild-type (WT) counterparts. In contrast, the percentage of lineage^{-}Sca-1^{+}c-kit^{+} (LSK) cells was significantly increased in $Ogt^{flox/Y}$ Vav-Cre^{+}or $Ogt^{flox/flox}$ Vav-Cre^{+} FLs. Surprisingly, these *Ogt*-deficient LSK cells completely lacked clonogenic activity in methylcellulose culture *in vitro*, and a few surviving cells did not form secondary colonies in serial replating assays. Furthermore, when 3,000 LSK cells from either $Ogt^{+/Y}$Vav-Cre^{+} or $Ogt^{flox/Y}$Vav-Cre^{+}were transplanted into lethally irradiated recipient mice along with 200,000 recipient-type whole BM cells, $Ogt^{flox/Y}$Vav-Cre^{+}donor-derived cells were scarcely detectable in peripheral blood(PB) of recipient mice at 3 weeks after transplantation, while more than 50% of PB cellswere donor-derived in mice recieving $Ogt^{+/Y}$Vav-Cre^{+}LSK cells. These data suggest that *Ogt* is critical for proliferation, differentiation and self-renewal of FL hematopoietic progenitors (HPCs).

We next examined $Ogt^{flox/Y}$Mx-Cre^{+}and $Ogt^{+/Y}$Mx-Cre^{+} mice to investigate the role of *Ogt* in adult hematopoiesis. Ogt deletion was initiated via five intraperitoneal injections of polyinosinic–polycytidylic acid (pI-pC) at dose of 400 μg/body, and then complete blood cell counts were monitored every 2 weeks. Interestingly, the number of white blood cells, red blood cells and platelets were decreased over time in *Ogt*-deleted mice. At four weeks after pI-pC injection, the percentages of hematopoietic stem cells (HSCs) (CD48^{-}LSK, CD150^{+}CD48^{-} LSK) in *Ogt*-deleted mice were significantly decreased as compared to those of WT mice.We then evaluated competitive repopulating activity of *Ogt*-deficient cells. 1,000,000 bone marrow (BM) cells from either $Ogt^{flox/Y}$ Mx-Cre^{+} or Ogt$^{+/Y}$

Mx-Cre+ mice (CD45.2+) were transplanted with the equal number of competitor cells (CD45.1+CD45.2+) into lethally irradiated CD45.1+ recipient mice. 4 weeks after transplantation, pI-pC was administered to the recipient mice to delete floxed alleles. The result showed that the percentage of *Ogt*-deleted cells was remarkably decreased at 2 weeks after pI-pC injection and it progressively decreased over time. These data suggest that *Ogt* is essential for competitive and long-term repopulating capacity of BM-HSCs.
Summary and Conclusions: The *O*-GlcNAcylation by *Ogt* plays a critical role for maintaining homeostasis of FL and BM hematopoiesis in mice.

LB365

EXPLORING THE ROLE OF KIT LIGAND AT THE ONSET OF HEMATOPOIESIS
E. Azzoni[1], C. Nerlov[1], M. De Bruijn[*]
[1]MRC Molecular Haematology Unit, Weatherall Instititute of Oxford, University of Oxford, Oxford, United Kingdom

Background: Hematopoietic stem cells (HSCs) are generated during mammalian development from hemogenic endothelium in the major arteries through a process called endothelial-to-hematopoietic transition. The extrinsic and intrinsic factors that orchestrate this process are poorly understood. Kit ligand (KitL; also known as Stem Cell Factor/SCF) is a cytokine that plays a pivotal role in the adult bone marrow HSC niche, and it is thought to act on several cell types during embryogenesis. It is known that the absence of KitL causes a significant reduction in the fetal liver HSC pool and leads to death *in utero* with severe anaemia. However, it is currently unclear where, when and how the hematopoietic defect originates in embryos lacking KitL, and what is the precise role of this cytokine in the first steps of hematopoiesis.
Aims: Here we use a novel KitL transgenic reporter mouse line to map expression of this cytokine in the microenvironment of the Aorta-Gonad-Mesonephros (AGM) and yolk sac hematopoietic sites in the developing embryo, and investigate the effect of loss of KitL in these pre-liver sites of hematopoiesis.
Results: We show that KitL expressing cells are found in the microenvironment of all hematopoietic sites of the E8.5-E10.5 mouse embryo. Loss of KitL as assessed in *Steel* mutant (*Sl/Sl)* embryos showed smaller and less proliferative hematopoietic clusters in the dorsal aorta and in the yolk sac. Already at E10.5, homozygous *Steel* mutants show a reduction in pre-HSC numbers, yolk sac erythropoiesis, and fetal liver cellularity. At E11.5 these mutants display decreased progenitor numbers in all hematopoietic sites.
Summary and Conclusions: Our data suggest that, contrary to earlier reports, Kit signalling plays a role in early pre-liver hematopoiesis. In addition, our data identified a previously unrecognized role for KitL in the maturation and/or expansion of hematopoietic progenitors originating from the yolk sac, that could contribute to the anaemia observed later in development. Ongoing studies aim at elucidating the mechanism by which KitL exerts its role in early hematopoiesis.

Red blood cells and iron - Biology

DEREGULATION OF GENES RELATED TO IRON AND MITOCHONDRIAL METABOLISM IN REFRACTORY ANEMIA WITH RING SIDEROBLASTS
M. Del Rey[1,2,*] R. Benito[1,2], C. Fontanillo[1,2], F.J. Campos-Laborie[1,2], K. Janusz[1,2], M. Abáigar[1,2], M. Hernández-Sánchez[1,2], R. Cuello[3], D. Borrego[3], J. De Las Rivas[1,2], K.I. Mills[4], J.M. Hernández-Rivas[1,2,5]
[1]IBMCC, Centro de Investigación del Cáncer (CIC), Universidad de Salamanca-CSIC, [2]IBSAL, Instituto de Investigación Biomédica de Salamanca, Salamanca, [3]Servicio de Hematología, Hospital Clínico de Valladolid, Valladolid, Spain, [4]Centre for Cancer Research and Cell Biology, Queen's University Belfast, Belfast, United Kingdom, [5]Servicio de Hematología, Hospital Universitario de Salamanca, Salamanca, Spain

Background: The presence of *SF3B1* gene mutations is a hallmark of Myelodysplastic Syndrome with ring sideroblasts (MDS-RS) and could be related to the iron accumulation in these patients. However, the mechanisms underlying that characterize the MDS-RS are not completely understood.
Aims: In order to gain insight in the molecular basis of MDS-RS, an integrative study of the expression and mutational status of genesrelated to iron andmitochondrial metabolism was carried out.
Methods: A total of 231 low-risk MDS patients (50,3% MDS-RS, 49,7% refractory cytopenia with unilineage dysplasia patients-RCUD) and 81 controls were studied. The gene expression profile was analysed using the Human Genome Expression Array (U133 Plus 2.0) from Affymetrix. Array-based sequence capture (Roche NimbleGen) followed by next-generation sequencing (Roche GS FLX Titanium sequencing platform) was used to analyze 39 genes related to iron and mitochondrial metabolism. The genes were selected according to our previous gene expression data. Spliceosome-related genes were studied using an amplicon sequencing design in GS Junior Instrument (Roche Applied Science). In addition, Sanger sequencing was carried out.
Results: Patients with refractory anemia with ring sideroblasts (RARS) showed a differential expression of 1145 genes compared to controls. Interestingly, 38% (266 genes) of the over-expressed genes were related to iron and mitochondrial metabolism. The comparison between RARS and RCUD patients showed a set of 192 differentially expressed genes: 33% (42 genes) of the over-expressed genes were also related to iron and mitochondrial metabolism. *ALAD* and mitochondrial transporters *SLC25* (*SLC25A37* and *SLC25A38*) genes were overexpressed in RARS. Most of the MDS-RS patients (94,3%) carried mutations in any spliceosome-related gene. In addition, our analysis of the *ALAD* gene identified two polymorphisms (rs8177807 and rs2228083) in exon 6 and located 49 bases from each other. The occurrence of both polymorphisms ("variant haplotype") was more frequent in MDS-RS (12%) than in members of the other groups analyzed (5%). (p=0.07). Furthermore, an un-described variant in the exon 7 was found in the *ALAD* gene in one RARS patient with a mutation in *SF3B1*. The positively charged arginine residue (R174) was replaced by an uncharged cysteine residue. The three-dimensional structure showed that R174 residue is completely buried into the monomeric structure and the protein was predicted to be potentially damaging. The variant was not found in any of the control samples or in those analyzed from RCUD patients. An over-expressed gene-signature of 71 genes was identified between patients with *SF3B1* mutations and patients without the mutations. Interestingly, *GDF15* was overexpressed in patients showing *SF3B1* mutations. In addition, other genes such as *PPP2R5B*, *PPP1R16A* and *DDIT4L*, related to *SF3B1* and *GDF15*, were up-regulated in the mutated group. A functional analysis with this gene set showed two deregulated pathways: porphyrin biosynthesis and heme biosynthesis (p<0.001).
Summary and Conclusions: The deregulation of genes involved in iron and mitochondrial metabolism provides new insights in our knowledge of MDS-RS. Our study revealed mutations in spliceosome-related genes in almost 100% of the MDS-RS. The presence of variations identified in *ALAD* gene could have a possible role in the predisposition to disease (as a first event) as well as contributing to the pathogenesis of MDS-RS where spliceosome-related genes mutations could be the trigger cause.

THE PRESENCE OF HEMOGLOBIN S IS ASSOCIATED WITH MIRNA DEREGULATION IN CD34+-DERIVED ERYTHROID CELLS
T.A. Fornari[1,*] C. Lanaro[1], K.Y. Fertrin[1], N. Conran[1], S.T. O Saad[1], F.F. Costa[1]
[1]Hematology and Hemotherapy Center, State University of Campinas, Campinas, Brazil

Background: Sickle cell disease (SCD) is a recessive genetic abnormalitycaused by a point mutation of the *HBB* gene (Glu6Val) that results in theproduction of hemoglobin S (HbS), leading to chronic hemolysis andvaso-occlusion. In addition to its ability to polymerize under hypoxicconditions, HbS may give rise to increased oxidative stress caused by freeheme and iron secondary to its intrinsic instability. MicroRNAs (miRNAs) canmodulate post-transcriptional erythroid-specific regulators.

Aims: The aim of thisstudy was to investigate miRNA expression profiles and the possiblepost-transcriptional role of these molecules associated with the presence ofHbS in sickle cell trait and in compound heterozygosity for HbS and δβ-thalassaemiaSicilian type.
Methods: We obtained samples from individuals from the same family with sickle cell trait (β^S/β^A),two sickle-δβ-thalassaemia Sicilian type patients ($\beta^S/\beta^{\delta\beta}$), two δβ-thalassaemia Sicilian type heterozygotes($\beta^{\delta\beta}/\beta^A$) and normal control ($\beta^A/\beta^A$).CD34$^+$-derived erythroid cells werecultured for 13 days and used to determine the miRNA expression profile.miRNAs were hybridized using an Agilent miRNA microarray platform and theprofiles were subjected to bioinformatics data analysis using GeneSpringsoftware (v11.0). Different databases, such as miRBase (Release 21),TargetScan (Release 6.2) and microRNA.org (Release 2010) were used todetermine the predicted targets of miRNAs. The RNAhybrid tool (BiBiServ) wasused to find the minimum free energy hybridization of each miRNA and apossible target gene.
Results: Twenty five miRNAs were up-regulated in$\beta^S/\beta^{\delta\beta}$ and in β^S/β^A compared to β^A/β^A and $\beta^{\delta\beta}/\beta^A$. *In silico* analysis showedthat eight miRNAs target genes involved in cellular adhesion (*CD36, ICAM4*,and *ITGB1*), antioxidant defense mechanisms (*CAT*, catalase), and hemoglobinaffinity for oxygen (*BPGM* and *MINPP1*, 2,3-bisphosphoglycerate mutase andphosphatase, respectively). *CD36, ICAM4*, and *ITGB1* are possible targets ofthe miR-17, 20a and 20b and the latter is additionally targeted by miR-29b,29c and 30e. The *CAT* gene is also targeted by miR-30e as well as by miR-148aand 148b. *BPGM* is targeted by miRs 20a and 20b, while *MINPP1* is onlytargeted by miR-30e. We also found hemopexin (*HPX*), a major heme-bindingprotein, is a possible target of miR-26b.
Summary and Conclusions: Our data suggest that,in an *in vitro* model, the presence of HbS is associated with miRNAderegulation that may be associated to pathologic processes found *ex vivo* in reticulocytes and mature erythrocytes from SCD patients. Financial supportby FAPESP and CNPq/INCTS.

ORAL IRON SUPPLEMENTS INCREASE HEPCIDING AND DECREASE ABSORPTION FROM DAILY OR TWICE DAILY DOSES: STUDIES WITH STABLE IRON ISTOPIC LABELS IN YOUNG WOMEN

D. Moretti[1,*] J. Goede[2], C. Zeder[3], T. Harold[4], M. Alida[5], B. Gary[6], S. Dorine[7], Z. Michael[1]
[1]Laboratory of Human Nutrition, ETH Zürich, [2]Hematology, Unioversity Hospital Zürich, [3]ETh Zürich, Zürich, Switzerland, [4]Radboud University Medical Centre, Nijmegen, [5]Wageningen University, Wageningen, Netherlands, [6]College of Physicians and Surgeons, Columbia University, New York, United States, [7]Laboratory Medicine, Translational Metabolic Laboratory, Radboud University Medical Centre, Nijmegen, Netherlands

Background: Oral iron supplementation is used to treat iron deficiency, but absorption is often low and correction is variable.
Aims: Determine the duration and magnitude of the plasma hepcidin (pHep) response induced by oral iron (Fe) supplements and concomitantly measure bioavailability in healthy iron depleted young women.
Methods: After randomization of 42 subjects with plasma ferritin<20 µg/L, pHep (measured by C-ELISA), iron status and inflammation markers were monitored at regular intervals. On day 1, no supplements were given (control day). On days 2 and 3, subjects received iron supplements containing 40, 60, 80, 160 or 240 mg Fe as $FeSO_4$ as either single or two consecutive daily doses extrinsically labeled with stable iron isotopes $^{54}FeSO_4$, $^{57}FeSO_4$ or $^{58}FeSO_4$. Iron bioavailability was measured by assessing the isotopic enrichment of erythrocytic iron 14 days after administration.
Results: Both Fe dose (P<0.05) and time of day (P<0.05) were associated with increase in pHep. Compared to control days, pHep was significantly higher at 8h and 24h after administration for 60, 80, 160 and 240 mg (P<0.05) but not for 40 mg Fe. Total Fe absorption from the Fe dose on the second day of the consecutive administration compared to a single Fe dose on the first day was not significantly decreased for 40 mg, but was decreased by 37% for 80 mg, 31% for 160 mg and 45% for 240 mg (for all, P<0.01). Fractional absorption was highest from the 40 mg dose. With twice per day dosing (60 mg Fe) the afternoon dose was less bioavailable (P<0.05).
Summary and Conclusions: In Fe-depleted women, consecutive day doses of supplemental Fe at 60 mg or above increase pHep and decrease fractional Fe bioavailability, while a dose of 40 mg does not. These important new data will help guide optimal dosing regimens for Fe supplements in women.

P368

RED BLOOD CELL GLYCOLYTIC INHIBITION ALTERS INTRACELLULAR ION CONCENTRATIONS, LEADS TO DECREASED DEFORMABILITY, AND UPREGULATES EXPRESSION OF CLEARANCE SIGNALS

R. Huisjes[1,*] L. Verhagen[1], B. van Oirschot[1], W. van Solinge[1], R. Schiffelers[1], R. van Wijk[1]
[1]Department of Clinical Chemistry and Haematology, UMC Utrecht, Utrecht, Netherlands

Background: enzymopathies is group of metabolic disorders of the erythrocyte that leads to decreased intracellular energy production. Energy deprivation ultimately results in premature clearance from the circulation in the spleen (extravascular hemolysis). The precise mechanism by which energy-deprived cells are recognized and cleared is largely unknown. One candidate mechanism could involve disturbed ion balance due to defective function of ATP-dependent ion channels in the red cell membrane, with consequent expression of clearance signals, and loss of red blood cell deformability.
Aims: To investigate the effect of energy-depletion on ion channel function, the exposure of clearance signals on the surface of the red cell, and red blood cell deformability in a model for energy-depleted red blood cells.
Methods: Isolated erythrocytes were resuspended in HEPES buffered Ringers solution (pH=7.4) and incubated overnight at 37ºC with 1mM D-glucose and various concentrations (5-10mM) of 2-deoxy-D-glucose. 2-deoxy-D-glucose (2dDg) is a glycolytic inhibitor acting on hexokinase, thereby serving as a model for energy-depleted red blood cells. Intracellular calcium was analysed by flow cytometry with fluo-4 AM as a fluorescent calcium probe and intracellular sodium and potassium concentrations were measured by flame photometry. ATP was measured using the CellTiter-Glo Luminescent Cell Viability Assay. Deformability of erythrocytes was measured using osmotic gradient ektacytometry by LoRRca. Expression of phosphatidylserine (Annexin-V) and CD47 on the erythrocyte membrane was examined by FACS.
Results: Upon incubation with various concentrations of 2-deoxy-D-glucose (2dDg) sodium levels (39 mM *vs* control 8 mM) were increased in a dose-dependent manner. Potassium (51 mM *versus* control 82 mM) and ATP concentrations (23 nM *versus* 7 nM) were decreased following treatment with 2dDg. FACS analysis revealed increased intracellular concentration of calcium and increased expression of CD47 and phosphatidylserine after incubation with 2dDg. Osmotic gradient ektacytometry showed decreased deformability after incubation with 2dDg, reflected by a decreased EI_{max} (maximal Elongation Index, Figure). When compared with ektacytometry curves from a patient with either hexokinase or pyruvate kinase deficiency, similar curves were obtained. Importantly, osmotic gradient ektacytometry curves of erythrocytes incubated with 2dDg are comparable (Figure).

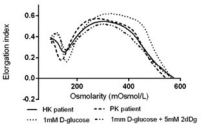

Figure 1.

Summary and Conclusions: Glycolytic inhibition alters intracellular red blood cell ion concentrations, and causes decreased deformability of erythrocytes. The decreased deformability as seen in 2dDg-incubated erythrocytes is comparable with the decreased deformability seen in patients with hexokinase and pyruvate kinase deficiency. Moreover, glycolytic inhibition is associated with upregulation of removal signals CD47 and phosphatidyl serine on the erythrocyte membrane. Loss of deformability and upregulation of removal signals in energy-deprived red blood cells may play a role in the premature removal of erythrocytes in red blood cell enzymopathies.

P369

MODIFIED ACTRIIB-MFC FUSION PROTEIN (RAP-536) INCREASES FUNCTIONAL RED BLOOD CELLS AND IMPROVES SICKLE CELL DISEASE PATHOLOGY WITH OR WITHOUT HYRDOXYUREA IN A MURINE MODEL

R.N. Suragani[1,*] R. Li[1], S. Cawley[1], S. Pearsall[1], R. Kumar[1]
[1]ACCELERON PHARMA, Cambridge, United States

Background: Sickle cell disease (SCD) is characterized by the presence of the sickle hemoglobin variant (HbS) of the b-globin gene. Under hypoxic conditions, HbS polymerizes, causing irreversibly sickled red blood cells (RBC). Manifestations of SCD include increased reticulocytes, splenomegaly, impaired blood flow due to intravascular sickling, and vaso-occlusive crises. The only approved therapy for SCD is hydroxyurea (HU), which decreases irreversibly sickled cells and painful events.. However, myelosuppression is a dose limiting toxicity and ~1/3 of patients do not respond to HU therapy, thereby highlighting the need for alternative treatment strategies
Aims: Luspatercept (ACE-536) is a modified type IIB activin receptor-Fc fusion protein[1] which acts as a ligand trap for members of the TGF-b superfamily to promote late-stage erythroid differentiation. In a murine model of b-thalassemia, RAP-536 (murine ortholog of ACE-536) corrected anemia and mitigated disease complications of b-thalassemia[2]. In this study, we evaluated RAP-536 as a monotherapy and in combination with HU in a murine model of SCD
Methods: SCD mice[3] (β^S/β^S, 6 and 12 weeks old) were dosed with RAP-536 (10 mg/kg, twice weekly SC) or TBS (VEH) control (N=4-6/group). Combination treatment with HU (100 mg/kg, i.p.) and RAP-536 (10 mg/kg SC) twice weekly for 3 months was compared with vehicle or HU monotherapy. Non-symptomatic compound heterozygote (β/β^S) littermates were used as controls (N=5/group).

Results: RAP-536 significantly decreased spleen weight (-16.4%) and serum bilirubin (-40.8%, *P<0.01*) compared to VEH, indicating decreased hemolysis. RAP-536 increased RBCs (+20%, *P<0.01*) and decreased reticulocytes (-30%, *P<0.05*). Blood smears from RAP-536 treated SCD mice displayed a 40-60% decrease in number of irreversibly sickled erythrocytes. In 6-week old SCD mice, RAP-536 treatment resulted in increased oxy-hemoglobin (+41.3%, *P=0.06*), functional oxygen saturation (+40.9%, *P=0.06*), oxygen content (+65.2%, *P=0.05*), and oxygen carrying capacity (+14%, *P<0.05*), and reduced carboxy-hemoglobin (-25.2%, *P<0.05*) compared to VEH. Histologic analysis of RAP-536 treated SCD mice showed substantial reduction in vascular congestion and damage in lung, spleen and kidneys, as well as reduced thickening of the alveolar wall compared to VEH. These data are consistent with reduced RBC sickling and qualitative improvements in SCD pathology in mice treated with RAP-536 monotherapy. We then evaluated RAP-536 in combination with HU in SCD mice. Treatment with HU alone reduced spleen weight (-20.2%, *P<0.05*), reticulocytes (-23.7%, *P<0.05*), phosphatidyl serine exposure on RBC membranes (-22.2%, *P<0.05*), and hemolysis (-48.4%, *P<0.05*) compared to VEH. The addition of RAP-536 to HU therapy further decreased splenomegaly (-50.7%, *P<0.05*), phosphatidyl serine exposure (-35.6%, *P<0.001*) and hemolysis (-55%, *P<0.01*) compared to VEH. The combination also further reduced vascular damage and congestion compared to VEH or HU monotherapy.
Summary and Conclusions: RAP-536, alone or in combination with HU, substantially improves RBC morphology and sickle cell disease pathology in SCD mice. Luspatercept (ACE-536) is currently being tested in Phase 2 clinical trials in MDS and β-thalassemia, and merits evaluation in SCD patients.

QUANTIFICATION AND VISUALIZATION OF DIETARY IRON UTILIZATION UNDER ERYTHROPOIETIC STIMULATION BY USING STABLE IRON ISOTOPE 57FE AND MASS SPECTROMETRY

Y. Matsuo-Tezuka[1,*], Y. Sasaki[1], M. Noguchi-Sasaki[1], K. Yorozu[1], M. Kurasawa[1], K. Kondo[1], M. Kihara[1], Y. Shimonaka[1]
[1]Product Research Department, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan

Background: Epoetin beta pegol (C.E.R.A.) is a novel, long-acting erythropoiesis-stimulating agent; once-monthly administration of C.E.R.A. effectively maintains hemoglobin levels in renal anemia patients. We previously demonstrated that C.E.R.A. promotes iron absorption through the reduction of serum hepcidin levels and subsequent up-regulation of the iron transporters, divalent metal transporter 1 (DMT1) and ferroportin. However, utilization of dietary iron following C.E.R.A. administration has not yet been fully quantitatively analyzed.
Aims: In this study, we used the stable iron isotope ^{57}Fe as a tracer of dietary iron incorporation. The primary objective was to quantify the utilization of dietary iron for erythropoiesis and its distribution into hematopoietic and iron storage tissues under C.E.R.A. stimulation by using inductively coupled plasma mass spectrometry (ICP-MS). We also attempted to visualize the incorporation of dietary iron into newly synthesized heme in the spleen by using high-resolution Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR MS).
Methods: To trace the incorporation of dietary iron into hematopoietic and iron storage tissues, we used a diet containing 200 ppm of the stable iron isotope ^{57}Fe instead of natural iron (^{57}Fe-diet). As a control, we used a diet containing 200 ppm of natural iron (control diet). C57BL/6NCrl mice fed the control diet were switched to the ^{57}Fe-diet immediately after being intravenously injected with 10 μg/kg of C.E.R.A. or vehicle. On Day 2, 5, 8, and 14 after administration, mice were killed by exsanguinations under anesthesia with isoflurane, and iron parameters and hematological parameters were analyzed. To quantify dietary iron incorporation, the content of hemoglobin containing ^{57}Fe in red blood cells and ^{57}Fe levels in bone marrow cells, spleen and liver were measured by ICP-MS. To visualize newly synthesized heme containing ^{57}Fe (^{57}Fe-heme), on Day5 after C.E.R.A. administration we spatially mapped ^{57}Fe-heme in the spleen by FT-ICR MS imaging.
Results: Compared with the vehicle-treated group, the C.E.R.A.-treated group showed a reduction in hepcidin levels from Day 2 to Day 8 and higher levels of hemoglobin. On Day 14, the content of hemoglobin containing ^{57}Fe in red blood cells was significantly higher in the C.E.R.A.-treated group than in the vehicle-treated group (3.6±0.7 g/dL *vs* 1.5±0.2 g/dL). ^{57}Fe levels in hematopoietic tissues (*e.g.* bone marrow cells and spleen) and iron storage tissues (liver) were also increased until Day 14 after C.E.R.A. administration. On Day 5, newly synthesized ^{57}Fe-heme in the spleen was more obviously detected in the C.E.R.A.-treated group than in the vehicle-treated group.
Summary and Conclusions: The present study focused on the effect of C.E.R.A. on dietary iron incorporation and utilization for erythropoiesis. We demonstrated that C.E.R.A. stimulated the effective use of dietary iron for erythropoiesis both in a quantitative manner with ICP-MS and in a visible manner with FT-ICR MS. Using these tools, we could trace dietary iron dynamics from incorporation to utilization for erythropoiesis or to retention in hematopoietic tissues such as bone marrow and spleen. It is well-known that abnormal iron metabolism contribute to the development of renal anemia. Therefore, our methods can not only provide useful information to understand iron metabolism under hematopoietic stimulation in basic research, but could be helpful in clinical applications.

P371

FIVE NEW CASES OF HEXOKINASE DEFICIENCY: BIOCHEMICAL AND MOLECULAR CHARACTERIZATION OF A NOVEL SPLICE SITE MUTATION AND 2 NOVEL MISSENSE MUTATIONS IN HK1

P. Koralkova[1,*] R. Mojzikova[1], P. Timr[2], J.L. Vives Corrons[3], C. Macartney[4], V. Divoky[1], R. van Wijk[5]
[1]Department of Biology, Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, [2]Department of Pediatrics, Hospital České Budějovice, České Budějovice, Czech Republic, [3]University Hospital Clínic de Barcelona, Barcelona, Spain, [4]Royal Belfast Hospital for Sick Children, Belfast, United Kingdom, [5]Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Hexokinase (HK) deficiency is a very rare cause of hereditary nonspherocytic hemolytic anemia (HNSHA). Hexokinase is one of the key regulatory enzymes of glycolysis, on which the red blood cell is totally dependent the production of ATP. Deficiency of HK disrupts cellular metabolism, which ultimately results in HNSHA. To date, 24 cases of hexokinase deficiency have been described. Only four of them have been characterized on the DNA level. We here describe five new cases and 3 novel mutations in *HK1*.
Aims: Characterize a genetic defect in patients who were found to be HK-deficient by spectrophotometrically determined red blood cell HK and pyruvate kinase (PK) enzymatic activities.
Methods: PK/HK ratio was applied to evaluate the effect of age-related increases in enzymatic activity. To confirm the diagnosis, DNA sequence analysis of *HK1* was performed by Sanger sequencing. Novel mutations were characterized by biochemical methods (K_m for glucose and Mg.ATP, pH stability and thermolability) and molecular studies (RT-PCR, quantitative RT-PCR, and Western Blot analysis on *ex vivo* cultured patient erythroblasts).
Results: DNA sequence analysis of *HK1* of 5 patients with suspected HK deficiency revealed a total of 5 different mutations in *HK1*. Three of them were novel (Table, novel mutations in bold). In *silico* analysis of mutations p.His868Tyr and p.Thr601Met by Polyphen-2 and SIFT predict that both substitutions are not tolerated. Both are located in the catalytic region, and kinetic properties are likely to be impaired upon mutation. Kinetic studies of the p.His868Tyr HK mutant showed that its affinity for ATP was indeed markedly decreased (3.2-times), whereas the affinity for glucose was slightly increased (Table). The molecular effects of the novel splice site mutation c.876-2A>G in intron 7 was studied on mRNA isolated from *ex vivo* cultured erythroblasts from the patient's father, who was heterozygous for this mutation. RT-PCR analysis showed the presence of normal as well as two aberrant mRNAs species. The aberrantly spliced transcripts lacked either exon 8 or both exons 8 and 9. Quantitative RT-PCR analysis showed that expression levels of the normally spliced mRNA variant were down-regulated 3-times compared to normal. These findings were confirmed on the protein level by Western blot analysis of HK from nucleated erythroid cells (Figure).

Tabella 1. Biochemical and molecular data of HK-deficient patients

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5
HK [0.8 – 1.5]	0.64	0.58	0.71*	1.14*	0.65
PK [6.1 – 12.3]	12.3	12.6	3.25*	12.5*	12.2
PK/HK ratio [4.8 – 11.9]	19.2	21.7	9.50*	10.90*	18.7
Allele 1	-193A>G	-193A>G	c.281A>G p.Arg94Gln	**c.2602C>T p.His868Tyr**	**c.1802C>T Thr601Met**
Allele 2	**c.876-2A>G**	**c.876-2A>G**	c.281A>G p.Arg94Gln	**c.2602C>T p.His868Tyr**	Normal
Km Mg.ATP [0.99-1.59]	1.11	1.42	0.94	4.22	ND
Km glucose [0.09 - 0.13]	0.07	0.06	0.26	0.15	ND
Thermal stability	Slightly decreased	Slightly decreased	Heat labile	ND	ND
pH stability	Normal	Normal	Normal	ND	ND

*HK [1.09 – 1.65], PK[5.12 – 5.78], PK/HK [3.60 – 6.30]; *HK [0.62 – 1.26], PK [8.40 – 15.2], PK/HK [7.2 – 15.6]; ND- not determined

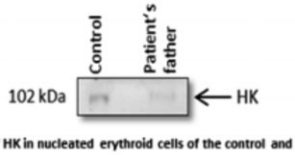

Figure: Detection of HK in nucleated erythroid cells of the control and patient's father.

Summary and Conclusions: We report 5 mutations in *HK1* in 4 unrelated families. Three of them, c.876-2A>G, Thr601Met, and p.His868Tyr have not been previously reported. The pathogenic nature of novel mutations was confirmed by molecular and biochemical studies. Our results contribute to a better

understanding of the genotype-to-phenotype correlation of HK deficiency, a very rare enzyme disorder of the red blood cell. *Supported by Ministry of Health of Czech Republic, grant NT/13587 and IGA_LF_2015_015.*

P372

CHRONIC PSYCHOLOGICAL STRESS STIMULATES MEDULLARY ERYTHROPOIESIS BY MODULATING LOCAL NITRIC OXIDE PRODUCTION

M. Budeč[1,*] S. Vignjević[1], D. Marković[2], V. Čokić[3], O. Mitrović Ajtić[1], M. Diklić[3], G. Jovčić[3]
[1]Department of neuroendocrinology, [2]Department of Immunology, [3]Department of Experimental Hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

Background: Stress elicits an integrated neuroendocrine response disturbing the homeostasis of different physiological systems. Thus, the experimental studies have shown that chronic psychological stress stimulates erythropoiesis but molecular mechanisms underlying this stress response remain to be elucidated. There is evidence that stress increases nitric oxide (NO) synthesis as well as that NO can modulate hematopoiesis.
Aims: This study was undertaken to investigate whether NO is involved in the regulation of erythropoiesis during chronic psychological stress using restraint experimental model and NO synthase (NOS) inhibitor Nw-nitro-L-arginine-methyl ester (L-NAME).
Methods: Adult male CBA mice were randomly assigned to following groups: 1) restraint group exposed to 2 h daily restraint stress during 7 consecutive days; 2) L-NAME + restraint group, treated with L-NAME (50 mg/kg, s.c.) 30 min prior to daily restraint; 3) L-NAME group, received only the daily dose of L-NAME; and 4) control group, simply handled daily. In the bone marrow, the number of erythroid progenitors *burst forming units-erythroid (*BFU-E) and colony-forming unit-erythroid (CFU-E) was determined using colony assays. The expression of neuronal NOS (nNOS) and endothelial (eNOS) in the bone marrow cells was evaluated by both Western blot and immunohistochemistry. In addition, the expression of nuclear factor kappa B (NFκB) subunit p65 was assessed by Western blot in the nuclear fraction of bone marrow cells.
Results: Chronic psychological stress significantly increased the number of BFU-E and CFU-E cells in the bone marrow. Inhibition of NOS activity by L-NAME completely abolished the effect of repeated restraint on erythroid progenitors. Similar to restraint stress, L-NAME alone induced a significant increase in the frequency of erythroid progenitor cells compared to controls. To further investigate a role of NO in regulation of erythropoiesis during chronic stress, we evaluated the expression of nNOS and eNOS in bone marrow cells. The results, obtained by Western blot analysis, demonstrated significantly decreased expression of nNOS in cytoplasmatic fraction of bone marrow cells following chronic restraint stress. Although not statistically significant, a similar trend was observed for eNOS in restrained mice. In accordance, a few nNOS- and eNOS-immunoreactive cells were detected within the bone marrow of chronically stressed animals. Furthermore, the activation of NFkappaB, known to induce the expression of NOS isoforms, was evaluated by its active nuclear component p65. Consistent with decreased expression of nNOS, the data showed that chronic psychological stress significantly attenuated the expression of p65 in the nuclear fraction of bone marrow cells.
Summary and Conclusions: Taken together, obtained results demonstrate for the first time that signal molecule NO modulates medullary erythropoiesis during chronic psychological stress. These findings are of importance because chronic psychological stress, as a part of modern style of life, may be involved in the pathogenesis of hematological malignancies.

RECOMBINANT HUMAN ERYTHROPOIETIN-INDUCED ERYTHROPOIESIS REGULATES HEPCIDIN EXPRESSION OVER IRON IN A RAT MODEL

S. Ribeiro[1,*] P. Garrido[2,3], J. Fernandes[2], S. Rocha[1], P. Rocha-Pereira[4], E. Costa[1], L. Belo[1], F. Reis[2,3], A. Santos-Silva[1]
[1]UCIBIO, REQUIMTE, Department of Biological Sciences, Laboratory of Biochemistry, Faculty of Pharmacy, University of Porto, Porto, [2]Laboratory of Pharmacology & Experimental Therapeutics, Institute for Biomedical Imaging and Life Sciences (IBILI), Faculty of Medicine, University of Coimbra, [3]CNC.IBILI, University of Coimbra, Coimbra, [4]Health Sciences Research Centre, Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal

Background: Iron has essential roles in several physiological processes, including red blood cell formation. Stimulation of erythropoiesis increases iron demand in bone marrow. Hepcidin, a small peptide produced by hepatocytes, plays a central role in regulating iron by promoting internalization and degradation of ferroportin, the only known cellular iron exporter. Several factors regulate hepcidin expression, as erythropoiesis, erythropoietin (EPO) and iron levels; however, the impact of each factor is not well established.
Aims: We aimed to study the effect of recombinant human erythropoietin (rHuEPO) therapy on erythropoiesis and on iron metabolism in a rat model.
Methods: Male Wistar rats, 12 weeks old, were divided in 5 groups: control group and rHuEPO-treated groups (100, 200, 400 and 600 IU/kg bw/week) during 3 weeks. Hematological and iron data were evaluated, as well as, the expression of several genes involving iron metabolism. Mann-Whitney test was used to evaluate differences between groups.
Results: One week rHuEpo treatment to healthy rats caused a dose-dependent increase in erythrocyte count, hemoglobin concentration, hematocrit and reticulocyte count. At the end of the protocol (3 weeks), rHuEPO-treated groups (200, 400 and 600 IU) showed higher values for these parameters, as compared to control group, except for the reticulocyte count that was reduced in the 200 IU rHuEPO-treated group. After 3 weeks of treatment, iron and ferritin levels do not differ between groups, transferrin levels reduced in the 100, 200 and 600 rHuEPO-treated groups, whereas transferrin saturation increased in the 200, 400 and 600 rHuEPO-treated rats. Liver hepcidin mRNA levels increased in the 200 IU rHuEPO-treated animals, as well as, the mRNA levels of the up-regulatory hepcidin mediators (*tfr2*, *hjv*, *bmp6*); in contrast, reduced mRNA levels of matriptase-2, an inhibitory modulator, were found. The 400 and 600 IU treated groups presented reduced levels of hecpidin mRNA and of the up-regulatory hepcidin mediators, and an increase in mRNA levels of matriptase-2. Serum EPO rat levels increased in the 200 IU rHuEPO-treated group, at the same extent we found an increase in liver EPO and EPO receptor mRNA levels. Extramedullary erythropoiesis was found in the spleen of 600 IU rHuEPO-treated group.
Summary and Conclusions: An increasing EPO stimuli leads to a rise in reticulocyte/erythrocyte production, which seems to be supported by an increase in iron absorption and mobilization, as suggested by the increase in transferrin saturation. However, the erythropoiesis stimuli triggered by the 200 IU rHuEPO dose seems to overwhelmed the bone marrow capacity, as showed by the decrease in reticulocyte production. Strengthening this hypothesis we found an increased serum EPO levels and liver mRNA expression of EPO and EPO receptor. At higher EPO stimuli, such as 600 IU rHuEPO dose, the increase in erythrocyte production is also supported by extramedullary erythropoiesis. The increase in hepcidin expression in the 200 IU rHuEPO-treated group seems to result from the reduction in erythropoiesis (an inhibitory stimuli for hepcidin production), as the transferrin saturation presents a similar value in the 600 IU rHuEPO-treated group. Actually, it seems that erythropoiesis prevails over iron regulation on hepcidin production. Supported by FCT (PTDC/SAU-TOX/114253/2009 and SFRH/BD/79875/2011) and POPH/FSE.

P374

MICRO-RNA CANDIDATES FOR REGULATION OF FETAL HEMOGLOBIN IN SICKLE CELL ANEMIA

C.R. Bonini-Domingos[1,*] G.C.S. Carrocini[1], W. Araujo Jr[2], C.C. Lobo[3]
[1]Biology, UNESP, Sao Jose do Rio Preto, [2]Medicine, USP, Ribeirao Preto, [3]Hematology, HEMORIO, Rio de Janeiro, Brazil

Background: Due to the important role of maintaining the hemoglobin in the metabolic activity, many factors are known to regulate the expression of globin genes, specifically gamma-globin genes. MicroRNAs (miRs) are endogenous regulatory elements, non-coding, small size, that act on gene regulation in post-transcriptional level. The miRs differential expression in sickle cell anemia and beta thalassemia homozygous has been studied and identified differences in miRNA expression in individuals with sickle cell anemia in relation to individuals without anemia.
Aims: We aimed to evaluate differential expression of miRNAs selected from in silico analysis and characterized as candidates for regulation of gamma-globin genes (HBG1 and HBG2) in subjects with sickle cell anemia in order to identify novel components involved in modulating levels of Hb F.
Methods: Peripheral blood samples from 20 individuals adults-10 with Hb AA and 10 with Hb SS (Bantu haplotype and HU use) were collected, regardless of gender. The quantification of the hemoglobin fractions was performed by HPLC-Ultra 2 (Trinity Biotech®). The homozygous for Hb S and the Bantu haplotype was confirmed by PCR-RFLP. MicroRNAs were selected from in silico analysis, through databases miRNApath (http://lgmb.fmrp.usp.br/mirnapath), Diana Lab (http://diana.cslab.ece.ntua.gr/microtiter /), Ferrolab (The miR ontology database) (http://ferrolab.dmi.unict.it/miro/), TargetScan (http://www.targetscan.org/), miRecords (http: // mirecords .biolead.org /) and miRBase (http://www.mirbase.org). Were considered candidates for regulation of Hb F levels the elements listed in at least three of the databases used.Reticulocytes were isolated and the microRNA extraction was performed with use of the kit miRvana miRNA Isolation Kit (Ambion®). CDNA synthesis (RT-PCR) was performed using the High Capacity cDNA Reverse Transcription Kit Kit (Applied Biosystems). For analysis of expression of microRNAs (qRT-PCR) reactions were performed by TaqMan MicroRNA Assay Detection System (Applied Biosystems). Statistical analyzes were performed with Statistica 8 software (Statsoft®), GraphPad Prism version 5 (GraphPad Software, San Diego, USA) and R version 3.1.1 Statistics (http://www.r-projet.org). We considered Statistically significance was $p < 0.05$.
Results: The in silico analysis shown 20 miRNA indicated as a candidates for regulation of Hb F. Quantitative analysis showed that 14 miRNAs showed significant differential expression: miR-449th, miR-449b, miR-34c-5p, miR-4795-3p, miR-96, miR-26b, miR-151-3p, miR-210, miR-15a, miR-16-1, miR-451, miR-144, miR-221 and miR-222. Only miR-34c-5p showed higher expression levels in the group with sickle cell anemia. Higher levels of expression of miR-221 and

miR-222 in the control group enhancing the performance of these two elements as possible negative regulators of the Hb F levels. miR-449th, miR-449b and miR-4795 were highly expressed in the control group.The miR-34c-5p, was more expressed in the group with sickle cell disease and was correlated with miR-26b (ρ=0.7). The miR-221 and miR-222 were correlated with each other (ρ=0.7) and miR-151-3p (ρ=ρ=0.72 and 0.98, respectively). Furthermore, miR-96 showed more correlations in the group with sickle cell anemia.
Summary and Conclusions: Our results shown the presence of differentially expressed miRNAs predicted the regulation of gamma-globin genes among Hb AA individuals with low levels of Hb F and individuals with sickle cell anemia with increased Hb F induced by treatment with HU. Some of these elements have validated and compared with the erythropoiesis regulation of gamma-globin genes, whereas other miRNAs have not yet been associated with these procedures.

LB375

POSSIBLE INTERPLAY OF MICRORNA AND TRANSCRIPTION FACTORS DURING IN VITRO ERYTHROID CULTURE OF CD34+ CELLS IN SICKLE CELL ANEMIA

R. Ferreira[1,*] C. Lanaro[1], M.A.C. Bezerra[2], A. da Silva Araujo[3], D.M. de Albuquerque[1], F.F. Costa[1]
[1]Hematology and Hemotherapy Center, University of Campinas, Campinas, [2]Center of Biological Sciences, Federal University of Pernambuco - UFPE, [3]Hematology and Hemotherapy Center of Pernambuco, HEMOPE Foundation, Recife, Brazil

Background: The clinical severity of the sickle cell anemia (SCA) can be affected by a number of modifying factors including HbF levels and the coinheritance of alpha-thalassemia. Furthermore, key regulators such as microRNAs (miRs) and transcription factors (TFs) are involved in the regulatory mechanism of HbF production, however this regulatory mechanism is unclear.
Aims: To investigate miRs and TFs expression during *in vitro* erythroid differentiation in normal and SCA erythropoiesis.
Methods: Peripheral blood CD34$^+$ cells were isolated from 4 patients who presented homozygous HbS genotype (HBSS) and from 4 healthy subjects (CON). The cells were cultured in a liquid system stimulating erythropoiesis and collected on days 7, 10, and 13 to analyze miRs and the TFs expression profile. *In silico* prediction was performed by TargetScanHuman software v 6.2 to verify possible interactions between miRs and TFs.
Results: Quantitative PCR showed that two miRs were down-regulated during HBSS erythropoiesis: miR-223 on days 7 and 10, and miR 486-3p on day 10 (P<0.05). Seven miRs were up-regulated: 146a-5p, 221 and 222 on day 10, and 15a, 144-3p, 150-5p and 155-5p on day 13 (P<0.05). *NFE2*, *SP1*, *ETO2* and *FOXO3* were decreased on day 13 (P<0.05), while *LMO2* and *LDB1* were up-regulated on days 10 and 13, respectively (P<0.05). Increased levels of *TAL1* were observed on days 10 and 13 (P<0.05). *GATA1* expression did not change significantly. *In silico* analysis predicted miR interactions for the 3' untranslated region of TFs : 146a-5p–*NFE2*, miR-155-5p– *SP1*, miR-221–*FOXO3*, miR-222 – *FOXO3*, miR-486-3p–*LDB1*, and miR-486-3p–*TAL1*. Studies have shown that mice lacking the transcription factor NF-E2 present hemolytic anemia, while the downregulation of *ETO2* and *SP1* contributes to the activation of TFs involved in the *GATA1*-complex, such as *LDB1*, *TAL1* and *LMO2.* Based on our preliminary results, the upregulation of these TFs may be associated with the decreased expression of *ETO2* and *SPI1* in HBSS cultures. We also suggest that the miRs-targets 155, 15a, 486-3p and 146a-5p may be contributing to changes in the expression of these TFs. Studies demonstrated that miRs 15a and 150-5p regulate the TF *cMYB* and its downregulation leads to an increase in HbF levels. Our results of low levels of *cMYB* with concomitant increases in these miRs in HBSS cultures are in agreement with the previous studies. An association of high miR-144-3p expression with a severe anemia phenotype in SCA, oxidative damage and hemolysis of HBSS erythrocytes cells has been previously described. Additionally, up-regulation of *FOXO3* correlated to an antioxidant gene expression response, which protects erythroid cells from cellular stress. We also found the high levels of miR-144-3p in HBSS cultures and also showed a downregulation of *FOXO3,* which may be associated with upregulation of its miRs-target 221/222.
Summary and Conclusions: Our data show relevant associations between miRNAs and their possible targets during *in vitro* erythroid differentiation. These results suggest that miRNAs represent a class of molecules that may contribute to hematopoietic process and may have a role in physiopathology of SCA.

Lurie Children's Hospital of Chicago, Chicago, IL, [7]Clinic for Special Children, Lancaster General Hospital, Lancaster, PA, [8]Lucile Packard Children's Hospital, Stanford University, Palo Alto, CA, [9]Primary Children's Hospital, University of Utah, Salt Lake City, UT, [10]Phoenix Children's Hospital, Phoenix, AZ, [11]Duke University Medical Center, Durham, NC, [12]UMass Memorial Children's Medical Center, Worcester, MA, [13]St. Jude Children's Research Hospital, Memphis, TN, [14]DDC Clinic for Special Needs Children, Middlefield, OH, [15]Agios Pharmaceuticals Inc, Cambridge, MA, United States

Background: PKD is the most common glycolytic defect causing congenital non-spherocytic hemolytic anemia. An international, multicenter Natural History Study (NHS) has been established to collect retrospective and prospective clinical data on PKD patients (pts).
Aims: To categorize PKD clinical severity based on degree of anemia, transfusion history, and splenectomy status and to identify predictors and prevalence of complications in the severity groups.
Methods: 105 pts with PKD enrolled on the PKD NHS at 14 IRB approved sites from March 2014 to January 2015. Pts were randomly assigned to either the test set (n=75) or future validation set. For this analysis, baseline and retrospective enrollment data were included from the 75 test set pts. PKD pts were categorized into 4 distinct severity groups (Gp1-Gp4), with increasing severity of the disease: Gp1. Never regularly transfused +/-prior acute transfusions; Gp2. Regular transfusions prior to splenectomy (SPL), post-SPL baseline hemoglobin (hb) >8.7 g/dl; Gp3. Regular transfusions prior to SPL, post-SPL baseline hb ≤8.7 g/dl; and Gp4. Splenectomized and currently regularly transfused. Gp2 and 3 were regularly transfused prior to SPL and transfusion independent after SPL and are distinguishable by post-SPL baseline hb. The median hb (8.7 g/dl) from Gp2 and 3 was used to discriminate between pts who were less anemic *versus* more anemic. Ordinal logistic regression models were used to test for association between clinical characteristics and severity group.
Results: The Table shows the characteristics of Gp1-4. In Gp1, only 42% of pts were splenectomized. Younger age at diagnosis (p=0.04) was significantly associated with increased severity of disease. There were no significant differences in groups based on gender, ethnicity, or race. There was a significant trend for increasing ferritin (p=0.03) and liver iron concentration (LIC, p=0.04) with increasing PKD clinical severity, and more severe groups were more likely to have received chelation therapy (p<0.01). Some Gp1 pts developed iron overload despite the absence of a history of regular transfusions. There was also a trend for higher rates of cholecystectomy (p=0.01) with increasing clinical severity. For certain complications, there was no evidence to support an association with clinical severity, including aplastic crises (overall rate 16%), extramedullary hematopoiesis (12%), and pregnancy complications of the affected mother (55%), as well as the requirement for exchange transfusion in the newborn period (44%). The reticulocyte count was incrementally higher with increasing clinical severity in the non-regularly transfused groups from Gp1 to Gp3 (p=0.02), even after controlling for splenectomy status. As expected, multiple genotypes were found in this cohort. Pts with the common, Amish, homozygous 1436G>A mutation were found in Gp1, 2, and 3, which may indicate a contribution of other genetic or environmental factors to clinical severity.

Tabella 1. Demographyc and Clinical Features of the Classification Groups of Clinical Severity in PKD.

Severity Group Characteristics	Group 1: Never Regularly Transfused, +/-Acute Transfusion	Group 2: Regularly Transfused before SPL, Less Anemic (Hb >8.7 g/dl)	Group 3: Regularly Transfused before SPL, More Anemic (Hb ≤8.7 g/dl)	Groups 4: Currently Regularly Transfused after SPL	P-value
n[1]	24	16	19	6	
Age at enrollment (years) Median (range)	18.9 (1.7-69.9)	24.5 (3.1-44.4)	19.2 (4.5-49.2)	13.0 (7.9-27.9)	0.06[2]
Age at diagnosis (years) Median (range)	1.8 (0-60.3)	0 (0-5.4)	0.4 (0-35.1)	2.6 (0-13.8)	0.04[2]
Hb (g/dl) Median (range)	10.1 (6.4-14.2)	9.3 (8.8-10.9)	8.0 (6.2-8.6)	8.1 (6.7-9.2)	NA
Reticulocyte Count (%) Median (range)	9.6 (1.6-82.9)	30.9 (8.2-61.0)	36.2 (5.4-61.2)	21.4 (2.4-27.7)	0.02[3]
MCV (fL) Median (range)	97.2 (76.0-119.7)	109.7 (101.1-133.4)	115.3 (89.7-128.0)	96.4 (84.8-100.0)	0.01[3]
Cholecystectomy	7/24 (29%)	6/16 (38%)	14/19 (74%)	3/6 (50%)	0.01[2]
History of chelation	1/23 (4%)	3/16 (19%)	9/18 (50%)	3/6 (50%)	<0.01[2]
Ferritin (mg/ml) Median (range)	403 (48-2623) n=9	625 (327-3106) n=15	642 (324-2134) n=12	1696 (308-5630) n=6	0.03[2]
LIC (mg/g DW) (median, range)	7.5 (4.9-8.0) n=4	5.8 (2.0-10.0) n=12	8.7 (3.0-11.8) n=7	46.0 n=1	0.04[2]

[1]Non-splenectomized, regularly transfused infants (n=10) were excluded from groups, because patients were considered too young for splenectomy and too early to be categorized in Groups 2-4. Hb = hemoglobin; SPL = splenectomy; NA: Factor is associated with classification of severity
[2]P-value of testing the association of a given factor with the level of severity (groups 1-4).
[3]P-value of testing the association of a given factor with the level of severity (groups 1-3).

Summary and Conclusions: The PKD NHS represents the largest cohort of pts with PKD assembled to date. We have identified 4 distinct severity groups, based on transfusion history, degree of anemia, and splenectomy status. Complications, such as cholecystectomy and iron overload, are correlated with severity of disease. Categories of severity will be validated in the next 75 PKD pts enrolled on the PKD NHS, and prospectively followed in this cohort for at least two years. This classification may be helpful for determining monitoring and treatment practices in this rare anemia.

P376

EFFICACY AND SAFETY OF VITAMIN C AS AN ADJUVANT TO IRON CHELATION THERAPY IN YOUNG PATIENTS WITH B-THALASSEMIA MAJOR: A RANDOMIZED PROSPECTIVE TRIAL

M. Elalfy[1,*], A.A. Adly[1], E. Ismail[2], O. Elalfy[1]
[1]pediatrics, [2]clinical pathology, Ain Shams University, cairo, Egypt

Background: Ascorbate deficiency is common in iron overloaded subjects and may modulate iron distribution. Animal studies showed that ascorbate replacement in the presence of desforaxamine (DFO) can markedly improve urinary iron elimination.
Aims: To investigate the effects of vitamin C as an adjuvant therapy to the three used iron chelators in moderately iron overloaded young vitamin C-deficient β-thalassemia major (β-TM) patients in relation to tissue iron overload.
Methods: This randomized prospective study was registered in the ClinicalTrials.gov (NCT02083575). Inclusion criteria were moderately iron overloaded β-TM patients who had vitamin C deficiency, without clinical symptoms of cardiac dysfunction and with serum ferritin (SF) >1000-2500 ng/mL and cardiac T2* >10 ms. Of two-hundred ninety β-TM patients screened for eligibility, 180 were enrolled. Patients were randomly assigned into 3 groups (60 patients in each group) receiving DFO, DFP or DFX. Patients in each of the 3 chelation groups were further randomly divided into 2 subgroups according to vitamin C supplementation. Thirty patients in each chelation group received morning oral vitamin C in a dose of 100 mg daily. All patients received vitamin C (group A) or no vitamin C (group B) were followed-up for one year with assessment of transfusion index, hemoglobin, iron profile, liver iron content (LIC) and cardiac magnetic resonance imaging (MRI) T2*.
Results: Baseline clinical, laboratory and radiological variables were similarly distributed among β-TM patients with and without vitamin C supplementation and also, among patients on the three used chelating agents. Transfusion index, serum iron, serum ferritin (SF), transferrin saturation (Tsat) and LIC were significantly decreased among group A β-thalassemia patients after vitamin C supplementation compared with baseline levels ($p<0.05$). Hemoglobin and vitamin C levels as well as cardiac MRI T2* were significantly increased at the end of treatment ($p<0.001$). No significant difference was found between baseline and study end as regards any of the studied variables among thalssemia patients who did not receive vitamin C therapy (group B). After vitamin C supplementation, DFO-treated patients had significantly lower transfusion index ($p=0.004$), serum iron ($p<0.001$), SF ($p<0.001$), Tsat ($p<0.001$) and LIC ($p<0.001$) while hemoglobin ($p<0.001$) and cardiac MRI T2* ($p=0.017$) were increased compared to baseline levels. Patients on DFP or DFX showed non-significant improvement in hematological variables. Cardiac MRI T2* was significantly higher among DFP-treated patients ($p=0.002$) while LIC was significantly decreased in patients receiving DFX after vitamin C supplementation ($p<0.001$). When the three thalassemia subgroups were compared post therapy, DFO-treated patients had the highest hemoglobin ($p=0.046$) and vitamin C levels ($p=0.038$) with the lowest iron ($p=0.032$), SF ($p=0.021$) and Tsat ($p=0.033$) compared with the other two subgroups. No significant difference was found between the 3 groups as regards LIC or cardiac MRI T2*. Baseline vitamin C levels were negatively correlated to SF and LIC ($p<0.001$).
Summary and Conclusions: vitamin C supplementation to patients with β-TM represents a potential therapeutic adjuvant agent increasing the efficacy of iron chelation therapy, decreasing transfusion frequency and elevating hemoglobin levels. Vitamin C in a dose of 100 mg possibly potentiates the efficacy of DFO more than DFP and DFX in reducing iron burden in the moderately iron overloaded vitamin C-deficient β-TM patients, with no adverse events.

P377

TREATMENT OF IRON DEFICIENCY ANAEMIA OF LATE PREGNANCY WITH A SINGLE INTRAVENOUS IRON POLYMALTOSE OR FERRIC CARBOXYMALTOSE VERSUS ORAL IRON SULPHATE: A PROSPECTIVE RANDOMIZED CONTROLLED STUDY (TIDAL)

A. Khalafallah[1,2,3,*] A. Chuang[4], C. Kwok[5], C. Yan[4], A. Hyppa[6], R. Mathew[7], V. Gares[8], A. Dennis[5], P. Falloon[9], V. Gebski[8], T. Pavlov[5]
[1]Haematology, Launceston General Hospital, [2]Faculty of Health Sciences, [3]Menzies Research Institute, University of Tasmania, [4]Medicine, [5]Obstetrics and Gynaecology, Launceston General Hospital, Launceston, Australia, [6]Medicine, University of Saarland, Homburg, Germany, [7]School of Medicine, University of Tasmania, Launceston, [8]Clinical Trials Centre, NHMRC, Sydney, [9]Pharmacy, Launceston General Hospital, Launceston, Australia

Background: Conferring the World Health Organisation (WHO) statistics, iron deficiency anaemia (IDA) is the most common nutritional deficiency disorder in the world, affecting at least two billion people, with pregnant women and young children at particularly high risk. If IDA in pregnancy is not managed properly, it may have a significant effect on mothers and babies with serious maternal and neonatal consequences. Therefore, we are proposing a pragmatic solution by employing in our trial intravenous iron that is considered an effective and safe tool in replenishing the iron stores and hence, eliminating serious consequences of IDA.
Aims: To assess the improvement in predelivery haemoglobin and iron stores after treatment with the standard care with oral iron *versus* the standard IV iron formulation "iron polymaltose" (long duration infusion) *versus* newly available IV "iron carboxymaltose" (short duration infusion) therapy in pregnant Tasmanian women, Australia.
Methods: A three arm randomised controlled trial (RCT) that aims to evaluate the treatment effects on Tasmanian pregnant women with iron deficiency anaemia, with (A) standard treatment with oral iron sulphate 325mg (elemental 105 mg) daily until delivery *versus* (B) a single dose of IV 100 mg iron polymaltose (IPM) administered over 60 minutes *versus* (C) a single dose of IV ferric carboxymaltose (FCM) administered over 15 min. We recruited 246 pregnant women after informed consentbetween September 2013 and August 2014 at our tertiary referralcentre. Median age was 28 years (range, 18-47) with a median and mean gestational age of 27 weeks. Median baseline serum ferritin level was 9 mcg/Lwith a median serum transferrin saturation of 13%.
Results: The ferritin level was significantly higher in FCM group against both Oral iron andIPM group ($p<0.001$) with a difference of 73.9 mcg/L. However, no difference was noted between the IVgroups with each IV iron showing significantly higher ferritin at 4 weeks and pre-delivery compared to oral iron.The ferritin is significant in FCM group against both oral and iron polymaltose groups ($p<0.001$) but there were no significant differences against FCM and IPM groups in terms of Hb or ferritin increment. Hb levels increased significantly at 4 weeks in FCM group compared to oral iron group ($p=0.05$) however the difference declined in pre-delivery Hb ($p=0.07$) with more apparent increase in terms of ferritin compared to the oral group at both 4 weeks and pre-delivery time points ($p<0.0001$). Cord blood ferritin was significantly higher in both IV iron groups against oral iron groups with p values of 0.05 in FCM and 0.03 in IPM without such difference in terms of cord Hb increment ($p=0.2$ and 0.8 respectively).A cost effectiveness analysis showed the total cost of administration of 1000mg of FCM is less than a similar dose of IPM and both were more economical than oral iron in terms of effectiveness.No blood transfusion was recorded in the IV iron groups, however two patients in the oral group received 2 units of blood each, however statistically not yet significant ($p=0.2$)
Summary and Conclusions: We compared two different single IV iron infusion in set of 1g *versus* 4 weeks of oral iron sulphate 325mg daily (total dose 9.1g) for the treatment of moderate IDA of pregnancy. It is of interest that IV dose compromise 1/9 of the oral dose and showed significant superior results than oral iron at 4 weeks of treatment in both ferritin and Hb levels. Even the benefits extended in terms of ferritin increment till the delivery time point ($p<0.001$), where the patients received in average a total of 27 g of oral iron *versus* 1g for the IV groups. Our data indicate thatFCM application during pregnancy is safe and leads to improved efficacy and improvement of iron stores compared to oral iron in pregnancy-related ID. There were no significant difference between FCM and IPM groups. However, FCM is considered cost effective and more-convenient to the patients. **Trial registration:** (http://www.ANZCTR.org.au/ACTRN12613000853741).

HYDROXIUREA PRESCRIPTION, AVAILABILITY AND USE FOR CHILDREN WITH SICKLE CELL DISEASE IN ITALY:RESULTS OF THE ITALIAN ASSOCIATION OF PEDIATRIC HEMATOLOGY ONCOLOGY (AIEOP) MULTICENTER SURVEY

R. Colombatti[1,*] G. Palazzi[2], N. Masera[3], L.D. Notarangelo[4], E. Bonetti[5], P. Samperi[6], A. Barone[7], G.C. Del Vecchio[8], M.E. Guerzoni[2], P. Corti[3], F. Menzato[1], G. Russo[6], L. Sainati[1]
[1]Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, [2]Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università degli Studi di Modena, Modena, [3]Pediatric Department, San Gerardo Hospital, Monza, [4]Pediatric Onco-Hematology, Spedali Civili, Brescia, [5]Pediatric Onco-Hematology, Azienda Ospedaliera Universitaria Integrata Borgo Roma, Verona, [6]Department of Pediatrics, Pediatric Hematology and Oncology, University of Catania, Catania, [7]Department of Pediatrics, Azienda Ospedaliera di Parma, Parma, [8]Pediatria, Policlinico di Bari, Bari, Italy

Background: Hydroxyurea (HU) is widely recommended for treatment of children with Sickle Cell Disease (SCD) in developed countries, but information about its use comes mainly from studies performed in adults or in the United States. The National Guidelines for the Management of SCD in Childhood in Italy issued in 2012 by the Italian Association of Pediatric Hematology Oncology (AIEOP; www.aieop.org) strongly recommend HU treatment for specific disease complications; a chapter dedicated to HU therapy is included in the Guidelines. In Italy, where newborn screening is not available in most Regions, children can receive HU free of charge from Pharmacies or Hospitals located near home

upon presentation of the rare disease certificate and a HU prescription made by a physician. The only formulation available in Italy is the 500 mg capsule, not divisible. Data regarding the use of HU for children with SCD in our country are lacking.
Aims: To evaluate HU prescription, availability and use in children (<19 yrs) with SCD in Italian Pediatric Centers through a national survey.
Methods: The 22 Pediatric Hematology Oncology Units of the AIEOP were invited to participate to the survey. Eight Centers in 4 different Regions responded. Data were retrospectively collected from clinical charts in each center and included in a dedicated excel database for analysis.
Results: Out of 441 Children followed in 8 Centers, 173 (39%) were prescribed HU: 98 M, mean age at diagnosis 30 months (range 0-198 months). 72% are African, 18% European, the remaining from Middle East/South America. 94% are SS/Sβ°, 3% SC, 3% SB+/Other. Mean age at HU beginning is 90 months (range 11-221) but is higher in SC patients (120 months, range 46-165). While in 70% of the children the diagnosis of SCD is made before 3 yrs of age, less than 10% begins HU before 3 yrs. Indications for HU therapy are: 29% recurrent Vaso-occlusive crisis, 20% recurrent Acute Chest Syndrome, 16% both, 24% anemia <7 g/dl, 1% retinopathy, 1% refusal of transfusion, 9% various causes. Mean starting dose is 16 mg/kg (range 6-30), mean dose reached after 6 months is 21 mg/kg (range 10-32). 87% of the patients use the 500 mg Oncocarbide capsule, 6% a galenic prepared according to patients' weight and drug dosage pro kg, 2% the 100 mg Siklos tablets, purchased from abroad. Frequently, parents had to split the capsule or change to non-daily drug schedule (2-3 times weekly) due to the limited availability of a pediatric formulation adequate for low weights. 62% of the HU prescriptions by pediatric hematologists occurred after 2012. Surprisingly, 6 Centers (36/173 patients) use combination of HU treatment coupled with chronic transfusion (exchange or top up). Most children (>95%) achieved good hematological and clinical response after 6 months of HU treatment and 158/173 are still on HU with a mean FUP of 4 yrs (range 2 months-10 yrs); reasons for interruption were lack of clinical response with start of a transfusion program or bone marrow transplantation. No major complication have been reported.
Summary and Conclusions: This is the first survey regarding the use of HU in children with SCD in Italy, a European country with a recent increase of SCD patients. Among other results, we underline the significant number of children receiving treatment, the majority having begun HU after 2012, year of the National Guidelines publication. Some criticisms have been identified, mainly associated with no pediatric formulation available (low dose tablets or syrup), the relative high age of HU beginning, and a maximum dose lower than recommended.

P379

NOVEL SICKLE CELL DISEASE DIAGNOSTIC DEVICE DEMONSTRATES HIGH PERFORMANCE AT THE POINT OF CARE

J. Kanter[1,*] C. Roberts[2], X. Yang[2], J. Kim[2]
[1]Pediatrics, Medical University of South Carolina, Charleston, [2]BioMedomics Inc, Durham, United States

Background: Sickle cell disease (SCD) is one of the most common inherited blood disorders in the world[1,2]. Although newborn screening for SCD has become standard of care in many high-resource countries, many low-resource areas remain unable to diagnose patients at early age due to the expense and difficulty of current testing mechanisms[3]. Furthermore, current standard of care testing methodology (hemoglobin electrophoresis, iso-electric focusing, and high-performance liquid chromatography) take time to perform and results are often delivered to affected families (or individuals) weeks after the initial testing is performed. To improve the diagnosis of individuals worldwide with SCD, a point of care test is needed. According to the College of American Pathologists, a point of care (POC) test is designed to be used where the patient is located, does not require permanent dedicated space, and can be performed outside the physical facilities of the clinical laboratories. Having a low cost, portable POC test for SCD will a). Greatly enhance the capacity for diagnosis in rural or low-resource areas b). Reduce the time between testing and diagnosis and c). Improve the ability to deliver results, counseling, and education at the time of testing.
Test: To address this gap in technology, we have developed a novel, innovative point of care (POC) test for sickle cell disease (SCD) or sickle cell trait (SCT). This **Sickle SCAn™ test kit** is a rapid, qualitative lateral flow immunoassay kit for the identification of sickle cell disorder of hemoglobin A, S, and C. The test requires five microliters of blood added to a provided, buffered loaded Module to release hemoglobin by lysing erythrocytes. The resulting hemolyzed solution is dropped on to the sample inlet of the Sickle SCAn™ cartridge. The treated sample flows through the test cartridge in order to interact with antibody-conjugated colorimetric detector nanoparticles and travel to the capture zones. A total of four detection lines are possible including hemoglobin variants A, S, C and a control (compound heterozygotes will show all hemoglobin present, see Figure). Prior to this clinical study, an ex-vivo laboratory testing using venous blood samples was performed. Sickle SCAn™ was compared to hemoglobin electrophoresis and HPLC using guidelines. Patient samples (n=126) were collected and measured in duplicate on both systems. Sickle SCAn™ performance compared to hemoglobin electrophoresis based diagnosis demonstrated >99% specificity and sensitivity for samples of HbAA, HbAS, HbSS, HbSC, and HbAC. The Sickle SCAn™ limit of detection for hemoglobin A, S, and C was determined to be 20%, 1%, and 2%, respectively.
Aims: To assess the level of agreement between sickle cell disease genotype measured using the Sickle SCAn™ device by finger stick at the true point of care compared to known genotype of affected individuals.
Methods: IRB approval was obtained from the Medical University of South Carolina to test current SCD patients and their families using a POC device. 75 patients provided informed consent to undergo capillary sampling at the MUSC SCD clinic. Blood was obtained using a standard lancet and was collected using the capillary sampler provided in the testing kit and added to the buffered loaded module. After inverting the module x 2, the hemolyzed samples were dropped onto the inlet of the Sickle SCAn™ cartridge. Results were read within 120 seconds. Patients of all ages were included in the trial. Those who had received a blood transfusion within the last 60 days or family members whose hemoglobin genotype was not confirmed were excluded. Patients on Hydroxyurea were included in sample analysis. 43 patients met inclusion/exclusion criteria and are included in the results below.
Results: Forty-three patients with HbAA, HbAS, HbAC, HbSS and HbSC were included. Patients ranged in age from 5 weeks-72 years. The majority of individuals were 16-32 years of age. Hemoglobin of individuals tested ranged from 5.9g/dL to 14g/dL. Sample results are shown below with confirmed genotypes (table 1).

Tabella 1.

Number of Samples	Sickle SCAn™ test result	Confirmed Genotype
16	S	14 HbSS
		2 HbSB0
		1 HbSB+
7	SC	7 HbSC
12	AS	1 HbSD
		11 HbAS
3	AC	3 HbAC
5	A	5 HbAA

The Sickle SCAn™ test performed favorably with only 1 false negative result (patient with confirmed HbSD disease). In 43 subjects, this test detected the correct A, S, C presence with an overall diagnostic accuracy of 97.7%. Detailed data is shown in table 2 below.

Tabella 2.

	Sensitivity (95% CI)	Specificity (95% CI)
SCD (HbSS, HbSC, HbS +-thal, HbS 0-thal)	100% (87-100)	100% (84-100)
Sickle trait (AS	100% (74-100)	96.9% (84-99)
C trait (AC)	100% (44-100)	100% (91-100)
Normal (AA)	100% (57-100)	100% (91-100)

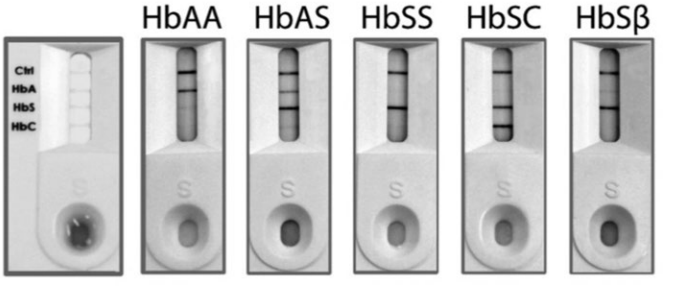

Figure 1.

Summary and Conclusions: Results indicate the Sickle SCAn™ test is highly specific and sensitive for the diagnosis of SCD at the point of care using a capillary blood samples. The Sickle SCAn™ test is especially innovative in its use of lateral-flow immunoassay technology which favors its use for large-scale screening efforts in low-resource settings. In practice, this means the test does NOT require electricity or high-level equipment. The results are easily interpreted with the naked eye with detection lines that are interpreted visually (similar to a home pregnancy test). Our goal is to make POC testing widely accessible with the same level of sensitivity and quantitation specificity as complex and expensive central lab tests. The Sickle SCAn™ test kit includes everything needed for performing SCD diagnostics outside of the laboratory setting. Further testing in children less than 6 months of age is in progress to assess the feasibility of Sickle SCAn™ test for newborn screening.

P380

TRANSCRANIAL DOPPLER IN A EUROPEAN COHORT OF SICKLE SC PEDIATRIC PATIENTS

R. Colombatti[1,*] S. Padayachee[2], C. McMahon[3], M. Casale[4], C. Hemmaway[5], P. Rampazzo[6], L. Sainati[7], B. Inusa[2]
[1]Department of Child and Maternal Health, Azienda Ospedaliera Università di

Padova, Padova, Italy, [2]Guy's and St.Thomas Hospital, London, United Kingdom, [3]Our Lady's Children's Hospital, Dublin, Ireland, [4]Secondo Policlinico, Università di Napoli, Napoli, Italy, [5]NHS, London, United Kingdom, [6]Axienda Ospedaliera Università di Padova, [7]Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy

Background: Sickle Cell Disease (SCD) is the most frequent severe genetic disease worldwide. It's the most prevalent genetic disorder in France and the UK; its frequency is steadily rising in several European countries, including Italy and Ireland. Sickle SC disease (HbSC) is the second commonest form of SCD after sickle cell anaemia (HbSS/HbSB°) and accounts for 25–30% of cases. Neurological events are among the most frequent and disabling complications in children with SCD with an important impact on quality of life, health and educational system costs. Overt stroke, silent infarcts and psycho-cognitive impairment are reported to occur also in HbSC disease, although at a lower frequency than in HbSS. Studies suggest that the life-time risk of stroke in HbSC is 2–3%. At present, a screening program is available for stroke prevention using Transcranial Doppler (TCD) according to the Stroke Prevention Trial criteria, but only for HbSS/HbSB° patients. There is no specific evidence to guide stroke prevention in HbSC. TCD ranges of velocities in the Middle Cerebral Artery (MCA) and in the distal Internal Carothid Artery (dICA) used to stratify patients with HbSS/HbSB° in risk categories might be inappropriate for HbSC patients. The Sickle Cell Anaemia transcranial Doppler Educational Study (SCATES) is a Multicenter European Educational Study to facilitate a screening program with the purpose to achieve systematic evaluation of stroke risk in children. It has the objectives to standardize TCD application in different European Settings and make TCD a common practice in routine health care of children with SCD across United Kingdom, Ireland and Italy.
Aims: To determine mean reference values of velocities in MCA and dICA in a European prospective cohort of children with HbSC. To evaluate possible clinical and hematological risk factors of high velocities in HbSC disease.
Methods: TCD was performed at least once a year in children with HbSC disease aged 2-18 years. TCD, clinical and hematological data were prospectively collected in clinical charts and transferred in a web based dbase for statistical analysis. Descriptive statistics and regression analysis were performed.
Results: 227 HbSS and 61 HbSC were enrolled in SCATES. In HbSC patients mean MCA velocity was 95.70 cm/sec (range 54.3-132, SD 19.07) and dICA was 79.81 cm/sec (range 29-138, SD 19.29), while in SS patients velocities were much higher: MCA was 122.47 cm/sec (range 57-190, SD 24) and dICA was 107 cm/sec (range 61-176, SD 22.21). Bootstrap analysis allowed to define a mean velocity in the MCA of 98.68 cm/sec (95%CI 93.75-103.60 (N), 94.00-103.77 (P), 94.06-103.92 (BC)). There was no significant correlation between high velocities in the MCA or dICA in HbSC patients and any clinical or hematological parameters except for Diastolic Blood Pressure (p 0.030, 95%CI 0.0939-1.593). Evaluation of Magnetic Resonance Imaging (MRI) available for 15 patients did not show any correlation between stenosis and TCD velocities of the corresponding vessels.
Summary and Conclusions: This is the largest cohort of pediatric patients with HbSC disease evaluated for stroke risk using a standardized protocol, reproducible across Europe. Mean velocities are lower than the reported ones for HbSS/SB° patients and could aid in defining stroke risk categories for this group. Diastolic Blood Pressure is an important risk factor and prompts to a regular Blood Pressure monitoring and control in children with HbSC.

P381

INTRAVENOUS IRON CARBOXYMALTOSE VERSUS STANDARD CARE IN THE MANAGEMENT OF POSTOPERATIVE ANAEMIA: A PROSPECTIVE RANDOMIZED CONTROLLED TRIAL

A. Khalafallah[1,2,3,*] V. Khelgi[4], R. Al-Badri[5], E. Robinson[4], C. Yan[4], J. Tan[4], R. Khan[5], H. Nguyen[5], B. Krikby[5]
[1]Menzies Research Institute, [2]Faculty of Health Sciences, University of Tasmania, [3]Haematology, [4]Medicine, [5]Surgery, Launceston General Hospital, Launceston, Australia

Background: Data from literature suggest that by having postoperative normal Haemoglobin (Hb), patients will recover significantly better after major surgery. There is growing evidence that improving the recovery period after surgery will impact on overall outcome of the surgical procedures. Despite the significant efforts in management of the preoperative, it has been found that there is a significant, although unknown, number of patients who have postoperative iron deficiency anaemia. Furthermore, there is no data regarding prevalence and management of postoperative iron deficiency anaemia and the requirement of blood transfusion in patients who undergo different surgeries.
Aims: This study is aiming to show that repleted iron stores and hence improved haemoglobin post-operatively, will improve outcomes of major surgery. Furthermore, this approach is aiming to minimise requirement for blood transfusion and the patient's stay in hospital and to lower the overall cost of procedures and to relieve the extra burden on health systems.
Methods: A prospective randomized controlled study was offered after an informed consent to adult patients who are 18 years old and above with documented Hb level at day 1 postoperatively between 70 and 120 g/L and reduced iron stores with ferritin <100 or iron saturation <20%. Patients were randomized between standard care *versus* active intervention with a single intravenous iron carboxymaltose infusion. Assessment during hospital stay and at 4 weeks was conducted to measure patients' outcomes. During the period between December 2014 and March 1st 2015, we have recruited 106 patients postoperatively after major surgery at the Launceston General hospital, a tertiary referral hospital for Northern Tasmania, Australia. Male to female ratio was 52:54 with median age of 65 years (range, 22:90). Vast majority of patients underwent major orthopaedic surgery (68), then come abdominal (18) and genitourinary surgery (12), and others (8).
Results: Mean day 1 postoperative Hb was 103 g/L with a median of 105 g/L. At four weeks assessment of Hb, there was a significant increase of mean Hb in the intervention group to 131 g/L with reduction in transfused blood units *versus* Hb of 116 g/L in the standard care group (p<0.01).Intravenous single iron carboxymaltose was commenced in average of 1000 mg as short infusion over 15 minutes and was well tolerated by the patients postoperatively.
Summary and Conclusions: Our data show the feasibility and safety of applying iron carboxymaltose in the postoperative anaemia setting. Delays in the identification of patients with preoperative anaemia may delay both, proper anaemia management and the operative procedure. We employed a pragmatic alternative or complementary approach to preoperative assessment for anaemia at day 1 postoperatively. A significant number of surgical patients who lost blood during surgery with an underlying iron deficiency could benefit from postoperative management with iron infusion. The new therapy with iron carboxymaltose was well tolerated. Further trials to assess our novel approach in treatment of the post-operative anaemia are warranted.
Trial registration: The study was approved by the Tasmanian Human Research Ethics Committee, Australia and registered in the Australian New Zealand Clinical Trials Registry (http://www.ANZCTR.org.au/ACTRN12614001261606).

P382

ORAL HIGH DOSE LIPOSOMIAL IRON SUPPORT IS SAFE, FAST, WELL TOLERATED AND COST-EFFECTIVE AS INTRAVENOUS IRON IN SIDEROPENIC ANEMIA. MULTICENTRIC RANDOMIZED STUDY

G. Giordano[1,*] F. d'amico[2], A. commatteo[3], G. berardi[4], D. berardi[5], B. carabellese[6], R. gigli[3], M. magri[3], A. licianci[3], L. di marzio[3]
[1]medicine, Regional Hospital "A. Cardarelli", Campobasso, [2]Foundation "J. Paul II", campobaso, [3]Regional Hospital "A. Cardarelli", [4]family medicine, Campobasso, [5]University "La Sapienza", Rome, [6]nuclear medicine, Regional Hospital "A. Cardarelli", Campobasso, Italy

Background: In iron deficiency anemia support with intravenous iron allows a faster anaemia correction and a faster ferritin increase than iron sulfate. Frequently iron sulfate and intravenous iron generate adverse events as hypotension, urticarioyd reactions, shock, epygastralgia, constipation or diarrhea. High doses of oral iron frequently are poorly tolerated because of adverse events.
Aims: Aim of this study is to verify if high doses of oral liposomial iron are safe, cost-effective and well tolerated as standard doses of intravenous ferrigluconate in patients with iron deficiency anemia.
Methods: We considered two group of patients (RANDOMIZED 1:1) with iron deficiency anemia without other relevant comorbidities. In group A M/F was 2/3, 7 patients had haemorragic gastritis, 3 hemorragic enteric bleeding angiodysplasia, 10 hypermenorrhaea, median level of hemoglobin (Hb) was 8 g/dl (R 7-10), median ferritin level was 10 ng/ml (R 3-20), with a normal level of CRP or ESR, and received liposomial iron 30 mg 4 tablet/day. In group B M/F was 1/3, 9 patients had haemorragic gastritis, 1 hemorragic enteric bleeding angiodysplasia, 10 hypermenorrhaea, median level of Hb was 8.5 g/dl (R 8-9.5), median ferritin level was 8 ng/ml (R 2-18), with a normal level of CRP or ESR, and received iv sodium ferrigluconate 62.5 mg iv in NS 100 ml in 3 h/day. The median treatment costs in each group were calculated considering the monthly global treatment cost for each patients in the treatment period. This provided an estimate of the costs, independent of the precise cost of the drug, but tied to the final outcome (efficacy) of the therapeutic strategy used during the observation period.
Results: In group A, 1 g Hb increase was observed after a median of 8 days (R 7-12), a target Hb level of 12 g/dl was achieved in a median time of 4 weeks (R 2-4) with a median cost of € 110/months (R 92-162), 6 (30%) patients showed adverse events (3 epigastralgia, 3 diarrhoea). In group B, 1 g Hb increase was observed after a median of 7 days (R 6-10), a target Hb level of 12 g/dl was achieved in a median time of 3.5 weeks (R 1.5-4) with a median cost of €326/months (R 250-360), 4 (20%) patients showed adverse events (2 hypotension, 2 urticaria and headhace).
Summary and Conclusions: Oral high dose liposomial iron support is safe, fast, well tolerated and cost-effective as intravenous iron in sideropenic anemia. This study needs confirmation on a larger cohort of patients.

P383

SURVIVAL AND CAUSES OF DEATH IN PATIENTS WITH ALPHA-AND BETA-THALASSAEMIA IN A DEVELOPING COUNTRY: THE FIRST REPORT FROM THAILAND

V. Viprakasit[1,*] S. Jansutjawan[2]
[1]Department of Pediatrics and Thalassemia Center, [2]Department of Pediatrics, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: α-and β-thalassemia (thal) syndromes are the most common genetic condition found in Thailand and other Southeast Asian countries. It is expected that >40% of Thai population are carrier for thal and haemoglobinopathies resulting in >600,000 Thai people expected to have thalassemia diseases. With recent advances on thalassaemia management *i.e.* stem cell transplantation, transfusion support, iron monitoring and chelation, survival of transfusion dependent thalassaemia (TDT) in particular; β thal major have increased significantly in developed countries in the past recent years. However, there was limited data of thalassaemia survival and the causes of death in developing countries and none from Thailand. Additionally no data on survival of a less severe thalassaemia; Non Transfusion Dependent Thalassaemia (NTDT) is available.
Aims: To evaluate survival and causes of death of Thai patients with β thal major,β thal/Hb E and α thalassaemia (Hb H and Hb H/Hb CS) who received their treatment under standard health care system in Thailand.
Methods: We retrospectively analysed our hospital registry for patients who were diagnosed at our department since 1974 until December 2013. The diagnosis of thalassaemia syndromes was performed based on the standard clinical evaluation, haematology, haemoglobin and/or molecular analyses. After our diagnosis, most patients were referred back to be treated locally at their primary or secondary health care centers. All patients from our registry were verified and determined their survival through our National Health Registry database (started in 1996). Their death rate and causes of death were evaluated and compared with those of age-sex matched general Thai population during 2004-2013. Survivals were analysed by the Kaplan-Meier and compared by different syndromes, sex, decade of birth cohort (<1990, 1991-2000 and >2001) using the log-rank test. A statistically significant difference was defined at $p<0.05$.
Results: Total 4,303 thalassemia patients with the oldest patientborn in 1961 were registered in which 2,623, 317, 691 and 672 wereβ thal/Hb E,β thal major, Hb H and Hb H/CS, respectively. Sixty five percentage of these patients (n=2,570) could be identified using the National database at Ministry of Public Health, Thailand. The ratio of male: female was around 50:50 across all syndromes. The mean ages±SD of alive patients were 22.35±10.61, 17.63±7.71, 24.86±12.16 and 20.83±9.54 in β thal/Hb E (n=1,650), β thal major (n=165), Hb H (n=386) and Hb H/Hb CS (n=414), respectively. Patients withβ thal major (28 death; 17%) had the highest death rate (7.5 times over matched population controls) followed byβ thal/Hb E (146 death; 9.1%) (3.1 times compared to controls) while patients with α-thalassaemia (Hb H (6 death; 1.6%) and Hb H/Hb CS (9 death; 2.2%) who were all NTDT had the same mortality as general population. The majority of β thal major died from anemia and very few due to heart failure suggesting most patients received inadequate transfusion and only 20% of patients could reach their forth decade of life (**Figure 1A**). Up to 50% ofβ thal/Hb E patients that around 70% of them were NTDT phenotype could live to the age of 50 (**Figure 1A**). Infection was the major cause of death inβ thal/Hb E possibly related to splenectomy that widely practiced for such condition in Thailand. The majority of Hb H patients died from accidents and other natural causes not related to underlying disease similar to general population. Increasing survival was observed, although not statistically significant, inβ thal major patients who born in recent birth cohorts (**Figure 1B**) suggesting an improvement of thalassaemia care in general. There was no difference on survival by different sex for all thalassemia syndromes.

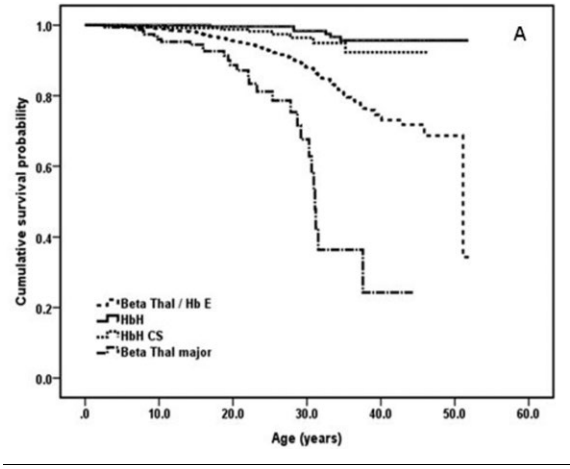

Figure 1. A) Kaplan-Meier srvival curves for all types of thalassaemia syndromes in Thailand; and B) by birth cohort in β thal major.

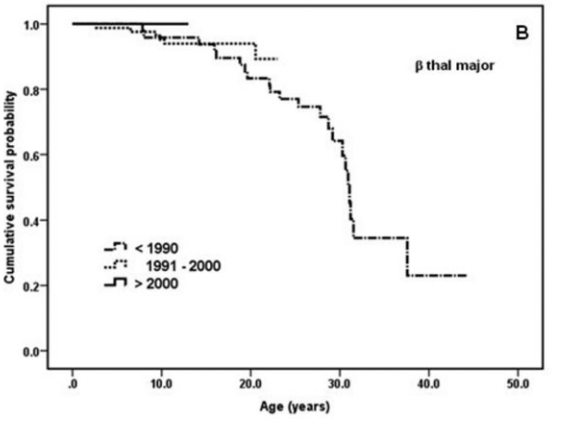

Figure 1. A) Kaplan-Meier srvival curves for all types of thalassaemia syndromes in Thailand; and B) by birth cohort in β thal major.

Summary and Conclusions: For the first time, our data suggest that survival and causes of mortality were different among thalassaemia syndromes; α-thalassaemia had a comparable survival to general population while the survival of β-thalassaemia was remarkably poor compared to those of developed countries. This suggests that management of severe thalassaemias in a developing country remains suboptimal and an improvement on standard of care is urgently required to enhance a long –term survival of these highly prevalent conditions.

P384

LONG-TERM FOLLOW-UP ON YOUNG PEDIATRIC PATIENTS TREATED WITH DEFERASIROX

E. Vichinsky[1,*] A. El-Beshlawy[2], A. Al Zoebie[3], F. Bernaudin[4], S. Koussa[5], T. Chotsampancharoen[6], A. Vorog[7], P. Gupta[8], M. Elalfy[9]
[1]Children's Hospital & Research Center Oakland, Oakland, United States, [2]Cairo University, Cairo, Egypt, [3]Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates, [4]Centre Hospitalier Intercommunal, Créteil, France, [5]Chronic Care Center, Hazmieh, Lebanon, [6]Songklanagarind Hospital, Songkhla, Thailand, [7]Novartis Pharmaceuticals Corporation, East Hanover, United States, [8]Novartis Healthcare Private Limited, Hyderabad, India, [9]Ain Shams University, Cairo, Egypt

Background: The oral iron chelator, deferasirox (DFX), is approved for the treatment of transfusional hemosiderosis in both adult and pediatric patients. Safety data from 52 pediatric patients, aged 2–<6 years, who received DFX for 1 year, in registration studies were consistent with other age groups. Majority of adverse events (AEs) were transient in duration and of mild to moderate in severity. In order to collect long-term data on the safety and efficacy of DFX in young children, a 5-year observational multinational registry study was initiated.
Aims: To evaluate the long-term safety and efficacy of DFX in an unselected population of children aged 2–<6 years at enrollment and with transfusional hemosiderosis.
Methods: Pediatric patients (2–<6 years of age) receiving DFX according to local prescribing information were enrolled and followed for up to 5 years. The primary objective was to evaluate the safety profile of DFX, specifically, renal and hepatic function. Growth and sexual development, and long-term efficacy measured by serum ferritin, were also assessed. This interim analyses reports data for up to 61 months since study initiation.
Results: Of 268 evaluable patients, 99 completed, 107 (mean age, 3.3±1.2 years) patients had ≥4.5 years of clinical data, 126 discontinued, and 43 were ongoing at time of data cut off. Diagnoses included: β-thalassemia (n=177, 66.0%), sickle cell disease (n=52, 19.4%), Diamond–Blackfan Anemia (n=12, 4.5%), and other anemias (n=27, 10.1%). Most common reasons (>5%) for study discontinuation were "others" (20.1%), lost to follow up (7.5%), and protocol deviation (5.2%), while 11 (4.1%) patients discontinued due to AEs. There was one fatal event due to graft *versus* host disease. Mean±SD of DFX exposure was 43.1±21.5 months and average±SD actual dose was 25.9±6.6 mg/kg/day. Median serum ferritin decreased from 1708 to 1050 ng/mL after 61 months. Most common AEs related to DFX for the overall population and for those completing ≥4.5 are presented in Table 1. Serious AEs (SAEs) regardless of relationship to study drug were seen in 86 (32.1%) patients, most common (≥5%) being pyrexia and pneumonia in 24 (9%) and 15 (5.6%) patients, respectively. Of 107 patients, 31 (29.0%) had SAEs. Of these 3 SAEs in 2 (1.9%) patients were suspected to be related to study-drug, including accidental overdose, increase in aspartate aminotransferase (AST) and increase in alanineaminotransferase (ALT). At data cut off, 227 (85%) patients had serum creatinine (SrCr) ≤upper limit normal (ULN); 7 (2.6%) patients had SrCr increases >33% and >ULN on 2 consecutive measurements. In patients completing 4.5 years, 2 (1.9%) patients had SrCr increases >33% compared to baseline

and >ULN on 2 consecutive measurements. These cases were resolved without dose adjustments. Increases in ALT >5xULN and 10xULN were observed in 6 (2.2%) and 4 (1.5%) patients, respectively. In patients completing ≥4.5 years, elevated ALT >5xULN on 2 consecutive post-baseline assessments was seen in 1 (0.9%) patient and resulted in drug interruption. Elevated ALT >10xULN on 2 consecutive post-baseline assessments was observed in 2 (1.9%) patients and drug was not interrupted.

Tabella 1. Most common investigator-assessed drug-related AEs (≥4 patients, from the overall population).

Most common investigator-assessed drug-related AEs (≥4 patients) by preferred term*		
AEs, n%	Overall Population (Safety Set) (N=267)*	Patients (Safety Set) (N=107)
Patients with investigator assessed drug-related AE(s), n (%)	102 (38.2)	43 (40.2)
ALT increased	37 (13.9)	12 (11.2)
AST increased	26 (9.7)	6 (5.6)
Transaminases increased	13 (4.9)	5 (4.7)
Rash	13 (4.9)	5 (4.7)
Vomiting	12 (4.5)	6 (5.6)
Blood creatinine increased	10 (3.7)	3 (2.8)
Abdominal pain	8 (3.0)	3 (2.8)
Liver function test abnormal	8 (3.0)	8 (7.5)
Diarrhea	5 (1.9)	3 (2.8)
Proteinuria	5 (1.9)	1 (0.9)
Hepatocellular injury	4 (1.5)	1 (0.9)
Blood bilirubin increased	4 (1.5)	1 (0.9)
Hepatic enzyme increased	4 (1.5)	1 (0.9)
Hematuria	4 (1.5)	2 (1.9)

AEs, adverse events; ALT, alanine aminotransferase; AST, aspartate aminotransferase.
*Safety set defined as, all patients who received at least one dose of deferasirox over the analyzed period and had at least one post-baseline safety assessment

Summary and Conclusions: The results show a favorable safety profile of DFX with long-term treatment in pediatric patients of 2–<6 years age. Reported increases in ALT parameters above 5 times ULN were consistent with previous studies. Conversely, increases in SrCr were lower than those observed in previous studies. These results continue to support that DFX is effective in decreasing serum ferritin levels in the pediatric population.

Infectious diseases, supportive care 1

P385

COMPARISON OF MICAFUNGIN AND LIPOSOMAL AMPHOTERICIN B FOR EMPIRICAL ANTIFUNGAL THERAPY IN FEBRILE NEUTROPENIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A RANDOMIZED CONTROLLED TRIAL

Y. Fujisawa[1,*] T. Oyake[1], N. Sugawara[1], R. Sasaki[2], Y. Tsukushi[3], I. Hanamura[4], Y. Fujishima[1], Y. Aoki[1], S. Kowata[1], S. Ito[1], Y. Ishida[1]
[1]Hematology and Oncology, Internal Medicine, Iwate Medical University School of Medicine, Morioka, [2]Hematology, Internal Medicine, Iwate Prefectural Chubu Hospital, Kitakami, [3]Hematology, Internal Medicine, Hachinohe Red Cross Hospital, Hachinohe, [4]Hematology, Internal Medicine, Aichi Medical University School of Medicine, Nagoya, Japan

Background: Invasive fungal infections (IFIs) incur significant morbidity and mortality among neutropenic patients after chemotherapy. The risk for IFIs is related to the intensity and duration of neutropenia, and varies from 2 to 40%. Mortality rates associated with documented IFIs are considerable, reportedly ranging from 30% to 60%. Empirical antifungal therapy is the standard care for neutropenic patients with hematological malignancies (HEM) who remain febrile despite broad-spectrum antibacterial treatment. Several antifungal agents including voriconazole (VRCZ) or liposomal amphotericin B (L-AMB) have been studied as empirical therapies for febrile neutropenia (FN). However, limited data are available concerning the efficacy of micafungin (MCFG) in febrile neutropenic patients with HEM.
Aims: We conducted a randomized, cooperative group, open-label trial comparing MCFG (150 mg once daily) with L-AMB (2.5 mg/kg once daily) as first-line empirical antifungal treatment for FN patients with persistent fever of HEM.
Methods: Eighty hospitalized FN patients with persistent fever of HEM (AML 56, ALL 8, MDS-AML 7, MDS (RAEB) 3, NHL 4, MM 2 cases) were randomized to each drug group (MCFG, 40; L-AMB, 40). The study drug was started to administer as empiric antifungal therapy at least for 5 days without severe drug toxicity, and the efficacy and safety were evaluated.The efficacy end point was a favorable overall response, as determined by a five-component end point according to the criteria of Walsh et al (N Engl J Med 2004; 351: 1391).
Results: At the time of enrolment, there were no significant differences in the demographics or baseline characteristics between the two groups. The mean treatment duration for MCFG and L-AMB was 16 and 15 days, respectively. There were no significant differences in clinical efficacy between the two treatments (MCFG group, L-AMB group), evaluated based on: (1) successful treatment of baseline fungal infection (no evaluation), (2) absence of breakthrough fungal infection (90.0% *vs* 92.5%, p=0.692), (3) survival for ≥7 days after study completion (87.5% *vs* 85.0%, p=0.745), (4) premature study discontinuation due to poor efficacy (22.5% *vs* 20.0%, p=0.784), and (5) resolution of fever during neutropenia (55.0% *vs* 52.5%, p=0.822). However, discontinuation due to drug-related adverse events occurred less frequently in the MCFG group (12.5% *vs* 35.0%, p =0.018). In safety evaluation, total adverse events were less often in the MCFG group than in the L-AMB group (25.0% *vs* 47.5%, P=0.036).
Summary and Conclusions: MCFG was as effective as L-AMB, and better tolerated than L-AMB as empirical antifungal therapy in FN patients with HEM.

P386

CAN THERAPEUTIC DRUG MONITORING OPTIMISE EXPOSURE OF PIPERACILLIN IN FEBRILE NEUTROPENIC PATIENTS WITH HAEMATOLOGICAL MALIGNANCIES? A RANDOMISED CONTROLLED TRIAL

F.B. Sime[1], M. Roberts [1], I. S. Tiong[2], J. Gardner [2], S. Lehman [2], S. Peake[2], U. Hahn[2,*] M. Warner[2], J. Roberts[3]
[1]University of South Australia, [2]The Queen Elizabeth Hospital, Adelaide, [3]The University of Queensland, Brisbane, Australia

Background: Conventional antibiotic doses may recurrently fail to offer adequate exposure in febrile neutropenic patients due to disease-related pharmacokinetic (PK) changes. Therapeutic drug monitoring (TDM) guided dose optimisation is recommended to improve antibiotic exposure although this has not been described for piperacillin in febrile neutropenic patients.
Aims: To describe piperacillin exposure in febrile neutropenia patients and determine whether TDM can be used to increase the achievement of piperacillin pharmacokinetic/pharmacodynamic (PK/PD) targets at PK 'steady state'
Methods: In a two-arm prospective randomised controlled study (Australian New Zealand Registry, ACTRN12615000086561), patients were subjected to TDM for three consecutive days. Dose was adjusted in the intervention group to achieve a free drug concentration above the minimum inhibitory concentration for 100% of the dose interval (100% $fT_{>MIC}$) which was also the primary outcome measure. The secondary PK/PD target was 50% $fT_{>MIC}$. Duration of fever and days to the recovery from neutropenia were recorded.
Results: Thirty-two patients were enrolled. Initially, patients received 4.5g piperacillin-tazobactam eight or six hourly along with gentamicin co-therapy in

30/32 (94%) patients. At the first TDM, 7/32 patients (21%) achieved 100% $fT_{>MIC}$ and 12/32 patients (38%) achieved 50% $fT_{>MIC}$. Following dose adjustment, 69% of the intervention *versus* 19% of the control patients (p=0.012) attained 100% $fT_{>MIC}$, and 94 % of intervention *versus* 31% of control patients (p=0.001) achieved 50% $fT_{>MIC}$. After the third TDM, the proportion of patients attaining 100% $fT_{>MIC}$ improved from a baseline 19% to 73% in the intervention group while it declined from 25% to 7% in the control group. No difference was noted in the duration of fever and days to recovery from neutropenia.
Summary and Conclusions: Conventional doses of piperacillin-tazobactam may not offer adequate piperacillin exposure in febrile neutropenic patients. TDM provides useful feedback of dosing adequacy to guide dose optimisation.

P387

PREDICTORS OF MORTALITY IN 100 PATIENTS WITH NEUTROPENIC ENTEROCOLITIS AFTER CYTOTOXIC AGENTS FOR ACUTE MYELOID LEUKEMIA

N. Pugliese[1,*] P. Salvatore[2], D. V. Iula[2], M.R. Catania[2], F. Chiurazzi[1], M. Raimondo[1], G. Beneduce[1], R. Della pepa[1], F. Pane[1], M. Picardi[1]
[1]Hematology, [2]Molecular Medicine and Medical Biotechnology, University of Naples Federico II, Naples, Italy

Background: Neutropenic enteroclitis (NEC) is a life-threatening complication of intensive chemotherapy regimen in patients with acute myeloid leukemia (AML) and the optimal treatment of patients with NEC remains controversial.
Aims: This retrospective study analyzed the predictors of mortality for NEC occurring in AML patients undergone to intensive chemotherapy, in order to evaluate the optimal management and the risk factors.
Methods: From January 2002 to December 2012, among 100 patients developing NEC, 30 received chemotherapy protocols based on standard doses of cytarabine (CY) (100 mg/m^2 daily), 19 intermediate doses (1000 mg/m^2 daily) and 51 high doses (6000 mg/m^2 daily). Empirical treatment regimen was defined as the initial antibiotic therapy of neutropenic fever while post-US treatment regimen was the antibiotics used at the time of ultrasonographic (US) diagnosis of NEC. The outcome measured was death within 30 days of the NEC onset. Survivor and nonsurvivor groups were compared.
Results: The overall mortality rates at 30 days after the diagnosis of NEC was 23%. We observed no significant differences in the clinical, ultrasonographic and microbiological characteristics of NEC episodes between survivors and unsurvivors. Patients in the latter group were more likely to have received cytotoxic agent schedule based on high-dose CY (p<0.001). Front-line tigecycline (TYG)-sparing antibiotic regimen (p=0.006) was associated to a higher mortality. Among the 37 patients, whose post-US antibiotic regimens were classified as 2-drug combinations, 13 (35%) died whereas 10 of the 63 patients (16%) who received 3-drug combination regimens died (p=0.02). Mortality rates within the post-US antibiotic combination regimen sub-groups were: 14% (1/7) for those treated with TYG plus piperacillin-tazobactam; 20% (1/5) for those treated with TYG plus meropenem; 33% (2/6) for those treated with meropenem plus daptomycin; 43% (3/7) for those treated with meropenem plus amikacin; 50% (6/12) for those treated with piperacillin-tazobactam plus amikacin; 0% (0/17) for those treated with TYG, meropenem and daptomycin; 14% (2/14) for those treated with meropenem, amikacin and teicoplanin; 22% (4/18) for those treated with ceftazidime, amikacin and teicoplanin; and 29% (4/14) for those treated with piperacillin-tazobactam, amikacin and teicoplanin. The only multidrug regimen of the post-US phase that was significantly more common in the survivor group (p=0.036) was the combination of TYG, meropenem and daptomycin. Overall, the 30-day survival distributions were also significantly different in patients treated with regimens including TYG *vs* regimens sparing TYG in the empirical, post-US and/or post-antibiogram phases of treatment [21/23 patients (91%) *vs* 56/77 (73%) patients, respectively; p=0.01]. Logistic regression analysis indentified cytotoxic schedule based on high-dose CY for hematological remission induction (p<0.0001) and 2-antibiotics combination (p<0.0001) as independent predictors of 30-day mortality, whereas front-line TYG-including regimens (p<0.0001) and post-US combination therapy with TYG, meropenem and daptomycin (p=0.013) were associated with a lower risk of mortality.
Summary and Conclusions: Our study represents the largest cohort of patients with NEC analyzed to evaluate the impact of several factors on mortality. High-CY doses are associated with higher incidence and mortality for NEC in AML patients. Prompt administration of TYG in patients with neutropenic fever as empirical therapy, preceding US diagnosis of NEC, seems to be effective. As for post-US antibiotic therapy, treatment with 3 drugs and overall TYG including regimen seems to improve survival for NEC.

P388

THE ASSOCIATION OF COMBINED ANTIBODY DEFICIENCY AND CHEMOTHERAPY REPRESENTS A HIGH-RISK FACTOR OF NON-NEUTROPENI MAJOR INFECTION IN CLL

A. Visentin[1,2,*] N. Compagno[1,2], S. Imbergamo[1], F. Frezzato[1,2], F. Cinetto[1,2], R. Zambello[1,2], F. Piazza[1,2], G. Semenzato[1,2], C. Agostini[1,2], L. Trentin[1,2]
[1]Hematology and Clinical Immunology brach, Department of Medicine, Padua University School of Medicine, [2]Venetian Institute of Molecular Medicine, Padua, Italy

Background: Chronic lymphocytic leukemia (CLL), the most common leukemia in western is still an incurable disease and infections are the major cause of morbidity and mortality. Susceptibility to infections in CLL patients can be an intrinsic characteristic of the disease or due to chemo-immunotherapy.
Aims: In this study we will identify a clinical subset of patients characterized by a very high risk of major infectins, in which Ig replacement therapy (IgRT) should be appropriate.
Methods: We retrospectively analyzed clinical and biochemical data of 706 patients referred to the Hematology and Clinical Immunology Unit of Padua University Hospital. In this series, we identify patients with at least one episode of major infections (MI), defined as those events requiring inpatient management and/or intravenous antibiotic treatment; we excluded chemotherapy related neutropenic MI. FISH analysis (n=450), CD38 expression (n=529), ZAP70 (n=502), IGHV (n=473), TP53, NOTCH1, BIRC3, SF3B1 (176 genes tested) mutational status, were evaluated at diagnosis or before starting treatment. Staging and Ig levels were collected at the time of the MI; for patients who didn't complain any MI we recorded the last available data. We used ROC curve analysis, Mann-Whiney, Fisher exact or Chi-square, Log-rank test, Kaplan-Meier method and Cox model when appropriated. Time to MI (TTMI) was calculated from the date of initial presentation to the MI event or last known follow-up (censored).
Results: 79 patients had 98 MI events, 67 were pneumonia (5 pulmonary aspergillosis), 27 sepsis, 2 meningitides, 1 uveitis and 1 endocarditis. Ig levels were significantly lower in patients with a history of MI with respect to patients who did not experience any serious infections (p<0.0001). Some clinical and biological markers were more common in patients with a history of MI (del 17p [p<0.0001], unmutated IGHV [p<0.0001], CD38$^+$ [p=0.0205], Rai stage III-IV [p<0.0001] and needed treatment [p<0.0001]) than patients without any MI event. No differences were found for ZAP70 expression, TP53, NOTCH1, BIRC3, SF3B1 gene mutations. Using ROC analysis we identified the best Ig isotype cut-offs to identify patients at high risk to development a MI event *i.e.* 7.44g/L for IgG, 0.79g/L for IgA and 0.21g/L for IgM. In the univariate analysis, pretreated patients and subjects with combined antibody deficiency (CAD, *i.e.* low levels of IgG and IgA or IgM) had a shorter TTMI with respect to patients who did not need a specific CLL therapy (239 months *vs* not reached, p<0.0001) or those with only IgG deficiency or Ig within normal range (239 months *vs* 270 *vs* not reached, p<0.0001), respectively. By multivariate analysis the HR in treated patients and those presenting a CAD were 2.98 and 3.10 respectively (p<0.0001 in both cases). We evaluated the importance of the presence of a combination of these two markers using a unique model. Median TTMI was significantly shorter in patients who had both a history of treatment and a CAD than in subjects presenting only one of this prognostic marker (i.e treatment history or CAD presence) (217 months *vs* 258 *vs* not reached, p<0.0001). These data were also confirmed in multivariate analysis.
Summary and Conclusions: We, herein, demonstrated that previously treated patients with CAD carried the highest risk of contracting a major infection during their clinical history. Furthermore, we described the half of incidence of MI (0.044 *vs* 0.019 MI/people-year) in a small cohort of patients with such clinical phenotype after IgRT.

P389

EMERGING RESISTANT BACTERIA STRAINS IN ACUTE LEUKAEMIA PATIENTS: IS THERE STILL A ROLE FOR FLUOROQUINOLONE PROPHYLAXIS? RESULTS OF A PROSPECTIVE STUDY BY THE RETE EMATOLOGICA LOMBARDA (REL)

C. Cattaneo[1,*] P. Zappasodi[2], S. Ferrari[3], F. Pavesi[4], C. Annaloro[5], C. Skert[6], E. Todisco[7], A. Ferrario[8], V. Saccà[9], L. Verga[10], A. Passi[1], E. Borlenghi[1], M. Da Vià[2], V. Mancini[3], G. Mometto[5], C. Basilico[8], R. Cairoli[3], A. Nosari[3], G. Rossi[1]
[1]Spedali Civili, Brescia, [2]Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, [3]A.O. Ospedale Niguarda Ca Granda, [4]San Raffaele Scientific Institute, [5]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, University of Milan, Milano, [6]Chair of Hematology, Unit of Blood Diseases and Stem Cell Transplantation, University of Brescia, Brescia, [7]Humanitas Cancer Center, Rozzano-Milano, Milano, [8]Azienda Ospedaliera Universitaria, Ospedale di Circolo e Fondazione Macchi, Varese, [9]Department of Internal Medicine, Hematology, Ospedale Valduce, Como, [10]San Gerardo Hospital, Monza, Italy

Background: Multiresistant (multiR) bacteria are emerging pathogens in haematologic cancer patients (pts). The antibiotic pressure, including fluoroquinolones (Fq) prophylaxis, may be one of the factors responsible for this phenomenon.
Aims: In order to better define the very recent epidemiology and outcome of bloodstream infections (BSI) in a real-life setting, we planned a prospective study collecting all consecutive febrile/infectious episodes occurring in acute leukaemia (AL) pts admitted to 9 haematological institutions participating to REL.
Methods: From Dec-12 to Dec-14, all febrile/infectious episodes were record-

ed. The following data concerning BSI were analysed: age, gender, type/phase of leukaemia, neutropenia, Fq prophylaxis or other antibiotic treatment, presence of central venous catheter (CVC), concomitant pulmonary infiltrates, antibiotic resistance.
Results: In 293 AL pts (M/F 174/119; median age 55y, range 18-80; AML/ALL 238/55), 433 BSI were diagnosed. In 246 (56.8%), BSI occurred in pts on Fq prophylaxis and in 72 (16.6%) in pts already receiving systemic antibiotic therapy. In 94 (21.7%) pneumonia was also present. Gram-positive cocci (GPC) were isolated in 194/433 BSI (44.8%), Gram-negative rods (GNR) in 164 (38.3%), polymicrobial (PMB) aetiology in 68 (15.7%) and fungi (F) in 5 (1.1%). Coagulase-negative staphylococci (CoNS) were the most frequent GPC (130/433, 30%); *S. aureus*, *S. viridans* and enterococci were observed in 10 (2.3%), 24 (4.6%) and 52 (12%) cases, respectively. Methicillin-resistant strains accounted for 76.4% of all staphylococci and vancomycin-resistant for 1.9% of enterococci. Fq resistance was detected in 50.2% of all GPC. GPC aetiology was associated with CVC-related BSI (OR 1.7, CI 1.1-2.6, p=0.009), and was typical of pts not in complete remission (OR 0.7, CI 0.4-0.9, p=0.04). Considering GNR, Enterobacteria were isolated in 155 BSI (35.8%) and *P. aeruginosa* in 37 (8.3%). GNR occurred more frequently during consolidation cycles (OR 1.8, CI 1.2-2.8, p=0.003). Frequency of Enterobacteria BSI was also higher during consolidation cycles in comparison with other AL phases (OR 2.5, CI 1.7-3.9, p<0,0001) and neutropenia was a risk factor (OR 2.2, CI 1.1-4.5, p=0.04). Fq resistance was observed in 88/155 (56.8%) Enterobacteria; in 84.1% of cases it was detected during Fq prophylaxis. ESBL+ strains, which accounted for 21.3% of Enterobacteria, were also associated with previous antibiotic exposure, including Fq prophylaxis (OR 4.05, CI 1.3-12.4, p=0.01). Carbapenemase producing (CP) strains occurred in 9% of Enterobacteria. Among *P. aeruginosa* strains, 21.6% were multiR. Thirty-day mortality was 8.5% (37/433); it was lower, although not significantly so, for GPC (6.7%) in comparison with GNR (9.1%) and PMB BSI (13.2%). CP Enterobacteria or multiR *P. aeruginosa* BSI but not ESBL+ strains were independent predictors of death (30d mortality: 30.8%; OR 5.7, CI 1.9-16.8, p=0.002). Furthermore, having relapsed/resistant AL (18.3%; OR 4.7, CI 2.1-10.4, p=0.0002) and the presence of concomitant pulmonary infiltrates (26.6%; OR 7.5, CI 3.4-16.1, p<0.001) significantly correlated with the risk of death.
Summary and Conclusions: The proportion of multiR GNR is becoming a major problem in our real-life prospective study and negatively impacts on prognosis of AL pts, as well as a concomitant diagnosis of pneumonia during BSI. Fq prophylaxis is not protective against multiR pathogens and it is associated to Fq resistance and to ESBL+ strains. The role of Fq prophylaxis in AL leukaemia patients should be reconsidered.

P390

PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND ACUTE RESPIRATORY FAILURE FROM UNDETERMINED ETIOLOGY ARE AT HIGHEST RISK OF DYING: A GRRR-OH STUDY

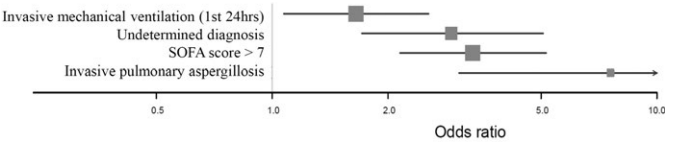
Background: Acute respiratory failure (ARF) is the most frequent complication in patients with hematological malignancies (HM), occurring in 20% to 50%, and is associated with high morbidity and mortality. ARF etiologies are numerous, and despite extensive diagnostic investigations, some patients remain with undetermined ARF etiology.
Aims: We sought to appraise the relation between an undetermined ARF etiology and mortality in a large cohort of critically ill patients with HM, and secondary, the yield of the bronchoalveolar lavage (BAL) in this population as compared with non-invasive tests.
Methods: A post-hoc analysis from a prospective multicenter study of 1011 critically ill hematological patients performed by the French and Belgian research network on critical respiratory diseases in patients with malignancies (Groupe de recherche en réanimation respiratoire en onco-hématologie, GRRR-OH) was conducted. All patients with ARF were included in the statistical analysis. ARF etiology was sought by noninvasive diagnostic tests or bronchoscopy and BAL. Relationship between ARF etiology and hospital mortality was assessed using a multivariable model adjusting for confounders.
Results: Seven hundred and one patients with respiratory symptoms were reviewed and 604 patients with ARF were included. There were mainly males (61%) with a median age of 60 [50-70]. The most prevalent HM were acute myeloid leukemia (AML, 28%) and non-Hodgkin lymphoma (NHL, 27%). Twenty three percent of the patients were in complete or partial remission. One hundred and seven patients (17.7%) were allogeneic hematopoietic stem cell transplantation recipients. Twenty percent of the population had a performans status of more than 1, 47% had a SOFA score over 7 and 30% were neutropenic. At ICU admission, the median respiratory rate was 32 [26-38]/min and two-thirds of the patients had 2 or more quadrants involved on chest radiography. Two hundred and fifty patients (41.4%) needed invasive mechanical ventilation at day 1. Patients were classified into four etiological categories: infectious etiologies (44.4%), non-infectious diagnoses (32.6%), opportunistic infection (10.1%) and undetermined (12.9%), with corresponding mortality rates of 39.2%, 35%, 55.7% and 60%, respectively. Overall hospital mortality was 42.2%. One hundred and fifty five patients had BAL (25,6%), with no impact on hospital mortality or rate of undetermined diagnosis as compared with non-invasive tests (16.8% *vs* 11.8% respectively, p=0.10). By multivariate analysis, factors associated with hospital mortality were invasive pulmonary aspergillosis (OR =7.57 (95% CI 3.06-21.62); p<0.005), invasive mechanical ventilation in the first 24 hours (OR =1.65 (95% CI 1.07-2.55); p=0.02), a SOFA score >7 (OR =3.32 (95% CI 2.15-5.15); p<0.005) and an undetermined ARF etiology (OR =2.92 (95% CI 1.71-5.07); p<0.005) (Figure).

Tabella 1. Multivariate analysis of risk factors for hospital mortality.



Summary and Conclusions: In patients with hematological malignancies and ARF, up to 13% remain with undetermined ARF etiology despite comprehensive diagnostic workup. Undetermined ARF etiology is independently associated with hospital mortality. Studies to better guide second line diagnostic strategies are warranted.

P391

APREPITANT PREVENTS NAUSEA AND VOMITING AFTER A HIGH-EMETOGENIC DOSE OF CYCLOPHOSPHAMIDE FOR PBSC HARVESTING: A PHASE III, DOUBLE-BLINDED, RANDOMIZED, PLACEBO-CONTROLLED TRIAL

L. Flenghi[1,*] E. Bonifacio[1], G. Reboldi[2], C. Muzi[1], S. Ballanti[1], F. Falcinelli[1], F. Lotti[1], M. Capponi[1], E. Agliani[1], B. Falini[1]
[1]Medicina Clinica e Sperimentale, Hematology, [2]Medicina Clinica e Sperimentale, MISEM, Perugia, Italy

Background: Peripheral blood haematopoietic stem cells for autologous transplantation are often mobilized by means of highly emetogenic, intermediate doses of cyclophosphamide which are administered in an out-patient regimen. As prophylaxis of chemotherapy induced nausea and vomiting (CINV) Aprepitant, a 5-HT3 receptor antagonist, is recommended in combination with dexamethasone and a 5-hydroxytryptamine 3 (5-HT_3) receptor antagonist. Since aprepitant moderately inhibits CYP3A4, concomitant administration with cyclophosphamide might decrease cyclophosphamide clearance, thus impairing efficacy of autologous stem cell mobilization.
Aims: This study was designed to determine whether the aprepitant-palonosetron-dexamethasone regimen was better than palonosetron-dexamethasone therapy in preventiing CINV and to assess its impact upon stem cell harvesting and toxicity.
Methods: This single centre, randomized, double-blinded, placebo-controlled phase III trial was conducted in patients who received a highly emetogenic cyclophosphamide IV chemotherapy (3 g/m^2) for autologous PBSC harvesting. Efficacy of retching and vomiting, rescue medication, severity of nausea and overall quality of and safety data were obtained from the patient's daily diary (days 1-5) which reported episodes life. The Functional Living Index-Emesis questionnaire was completed on days 1 (before starting chemotherapy) and 6 (after chemotherapy). All side effects were recorded daily.
Results: A total of 122 patients were enrolled and randomized. The analysis was performed according to the intention-to-treat principle. Primary endpoint: When the 2 groups were compared, the number of patients with no emetic episodes and no rescue medication in the first 120 hours post-chemotherapy, was significantly lower in the aprepitant group (*p*.0114). Secondary endpoints: Acute (*p*.0272) and delayed (*p*.0039) complete response rate, complete control rate (*p*<.0001), number of emetic events (*p*.0003) and the impact of nausea and vomiting on daily life (*p*<.0001) were also significantly better in the aprepitant group. The adverse event rate and stem cell harvest (*p*.821) were not significantly different.
Summary and Conclusions: The aprepitant regimen more effectively prevented CINV and weakened its impact on daily life without impairing the efficacy of autologous PBSC mobilization and harvesting in patients treated with highly emetogenic, intermediate doses of cyclophosphamide.

P392

A PROSPECTIVE STUDY ON BED-SIDE ULTRASOUND IN NEUTROPOENIC ENTEROCOLITIS (NEC): 76 NEC OUT OF 1680 NEUTROPENIC EPISODES. EARLY ULTRASUOND DIAGNOSIS REDUCES MORTALITY

E. Benedetti[1,*] B. Bruno[2], M. Petrini[1], I. Bertaggia[1]
[1]Dipartimento di Ricerca Traslazionale e delle Nuove Tecnologie in Medicina e Chirurgia, Hematology Unit Ospedale S. Chiara Pisa, Pisa, [2]U.O Ematologia Trapianti di midollo Torino, University of Torino, Torino, Italy

Background: Neutropenic enterocolitis (NEC) is a life threatening complication of leukemic and solid tumors patients (pts) treated with chemotherapy (CHT) with mortality rate up to 50%. It's a clinical syndrome in neutropenic patients (pts) characterized by abdominal pain (AP), fever (F) and diarrhoea (D). Ultrasound (US) was used to evaluate bowel-wall thickening (BWT), and >4 mm is considered diagnostic of NEC. Perforation occurs in 5%>10% of cases. Early diagnosis is crucial to start conservative medical management (CMM) which appears the optimal strategy for most cases.
Aims: Aims:to evaluate prospectively if Bed-side-US(BUS) can detect early signs of NEC and guide a prompt treatment (CMM or surgical) in order to reduce mortality.
Methods: In the last 7 years all pts admitted in Our Hematology/BMT Unit wards at University of Pisa (Italy), undergoing chemotherapy (CHT), autologous or allogeneic transplant (AutoTx,AlloTx) were enrolled. Abdominal US was performed, baseline before treatment, and as only one symptom (or a combination) appeared within 12h from onset: F and/or D and/or AP in CHT-related neutropenic pts.
Results: Out of 1680 neutropenic pts 76 episodes were identified (4.7%). Seven pts had 2 separate episodes of NEC. Disease diagnosis were HD (N=10), ALL (N=8), AML(N=21),MM (N=9) and NHL (N=28). Treatment received was intensive CHT (N=35), AutoTx (N=37) and AlloTx (N=4). At time of diagnosis (Dx) symptoms were: F+AP+D 48%, F+D 4%, F+AP 1%, AP+D 34%,D 3%,AP 9%. F alone were never present at diagnosis of NEC. At Dx, F was absent in 35/76 NEC episodes (46%) and in 17/76 F never developed and 18/76 had delayed onset of F (from 10h to 72 h) from NEC Dx. There is a trend but not a statistical (St) significant difference in mortality among the 3 F groups (P=0.09). As control group (CG) we considered pts with CHT related mucositis and pts restaged with US during neutropenia in absence of symptoms. A total of N=509 pts were randomly chosen in the CG. None of them had BWT. Overall 11 pts died (14.5%) without a St difference between 1 or 2 episodes (P=0.309) of NEC. Treatment was CMM in 92% of pts, and was promptly started as BUS diagnosis was made. Mortality in pts treated with CMM was 11.5%. Six pts underwent surgery, guided by US features, during neutropenia, and 50% are alive. Median BWT was 8.6 mm in surviving pts (range 4.2-30mm) and 11mm in deceased (range 9.3-15mm). Authors have suggested BWT to be prognostic of outcome; in our study pts with >10mm had 60% survival. Median time to response from beginning of CMM was 24h and the first sign of was a decrease in AP, while median time to death was 26h (range 10.5-72h). The likelihood of NEC Dx in a discriminant St model (Bayes theoreme) for pts with BWT and AP=98.8%, AP+D=99.9%, AP+D+F=100%, AP+F=99.9%, D+F=5%.
Summary and Conclusions: BUS allowed to detect early signs of NEC and to start prompt treatment in this life threatening complication, which was CMM in 92% with a 88.5% survival rate. With BUS pts do not live the isolation room. Early diagnosis and intervention allowed to reduce mortality. US guided surgical intervention with 50% survival rate. Images of BUS and CT were superimposable. Fever is not a condition sine qua non for NEC diagnosis. A prompt BUS in neutropenic patients as just one symptom presents allows to make early diagnosis of this life threatening complication and guide prompt treatment (conservative or surgical) reducing mortality.

Transfusion medicine

STREAMLINING THE MANAGEMENT OF BLOOD GROUP O RH NEGATIVE BLOOD STOCK: A SINGLE CENTRE IRISH EXPERIENCE

E. Groarke[1,*] L. O'Brien[2], M. Kiely[2], S. Joyce[2], J. Gleeson[3], A. Korobeinikov[3], C. Fell[3], M. Golding[3], I. Kubat[3], T. Jetka[3], E. Lynch[3], A. Magdalina[3], S. Mitchell[3], N. Smith[2], E. Cahill[2], S. Quane[2], J. Power[4], D. O'Keeffe[1], M. Leahy[1], H. O'Leary[1]
[1]Department of Haematology, [2]Blood Transfusion Laboratory, University Hospital Limerick, [3]MACSI, Department of Mathematics, University of Limerick, Limerick, [4]Munster Regional Transfusion Centre, Irish Blood Transfusion Service, Cork, Ireland

Background: Group O Rh D negative blood is an important resource as it is can be transfused to patients of all blood types. According to most recent figures from the Irish Blood Transfusion Service, 8% of the general population are blood group O Rh D negative, but 14% of all blood used in clinical practice is group O Rh D negative. Inappropriate usage (use of O Rh D negative blood for non O Rh D negative patients on an elective rather than emergent basis that is greater than 3 days from expiry of the red cell concentrate (RCC)) and use of short dated group O Rh D negative blood (RCC less than 3 days to expiry) frequently occurs. This should be minimised given both the importance of this blood group and its scarcity. However, the use of short-dated O Rh D negative blood is acceptable to avoid wastage when all reasonable efforts have been made to give it to O Rh D negative patients.
Aims: To develop a system to minimise inappropriate use of group O Rh D negative blood within the UL Hospitals.
Methods: In 2011, a strategy was adopted within the UL Hospital group in Ireland to streamline stock management of group O Rh D negative blood supply. The UL Hospital group is made up of the main university hospital (the hub) and 5 other clinical sites. The Munster Regional Transfusion Centre, a branch of the Irish Blood Transfusion Service (IBTS), supplies blood to the UL Hospitals (ULH). Currently, ULH maintains 16 units of emergency O Rh D negative blood in the 5 satellite off site hospitals. Prior to 2011, these were supplied via the hub. In 2011, a mathematical model developed by the Mathematics Applications Consortium for Science and Industry (MACSI) in the University of Limerick determined that replenishing the oldest emergency stock in any of the six hospital sites (the hub plus 5 satellite sites) from the source as opposed to from the hub and moving the oldest stock in the satellite sites to the hub would improve O Rh D negative stock management and reduce inappropriate use. Stochastic simulation was used to prove that the mathematical model would work in real time. Use of group O Rh D negative blood was then audited before (2009), immediately after (2011) and 3 years after (2014) implementation of this model.
Results: The breakdown of usage of our group O Rh D negative red cell concentrate was audited, paying particular attention to inappropriate usage and use of short dated group O Rh D negative blood. The initial audit (2009) showed that the rate of inappropriate use was 22% and the rate of transfusion of short dated O Rh D negative units to non-group O Rh D negative patients was 21%. Following implementation of the model (2011), the rate of inappropriate use and short dated use had markedly improved at 8% and 6%, respectively. A repeat audit performed 3 years later (2014) showed that the rate of inappropriate use was 0% and rate of short dated use was 13.7%.
Summary and Conclusions: Our audit shows that the rate of inappropriate use of group O negative Rh D negative blood has reduced to 0 with our current group O Rh D negative blood stock management system. The use of short dated group O Rh D negative blood did increase from 6% to 13.7%. This remains well below the pre 2011 figure of 21% and illustrates the improved management implemented. In conclusion, this audit shows an effective blood stock management system for O Rh D negative blood that minimises wastage and is likely to be directly applicable to other hub and spoke model hospital networks. Future efforts may include requisition of newer blood to the hub to prevent short dating.

P394

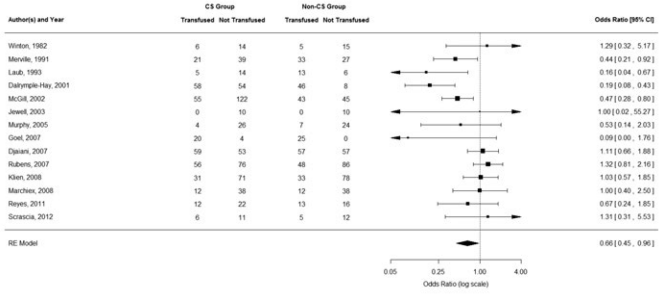
CELL SALVAGE DURING CARDIAC SURGERY MAY DECREASE RED BLOOD CELL TRANSFUSION: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Al-Khabori[1,*] A. Al-Riyami[1], S. Siddiqi[2], H. Al-Sabti[2]
[1]Hematology, [2]Surgery, Sultan Qaboos University Hospital, Muscat, Oman

Background: Red blood cell transfusion in cardiac surgery is known to be associated with increased morbidity and mortality. The use of the cell salvage (CS) as a blood conservative strategy in cardiac surgery has been under debate with conflicting results from different studies.
Aims: We examined the current evidence behind the use of the CS by performing a systematic review and meta-analysis of existing randomized clinical trials that assessed the impact of the CS use on red blood cell (RBC) transfusion.

Methods: We searched MEDLINE, CENTRAL, American Society of Hematology and bibliographies of relevant studies (all searched July 2014) for randomized clinical trials comparing CS *versus* non-CS strategies in cardiac surgeries. We performed a meta-analysis using random effects model (DerSimonian-Laird) to estimate the pooled odds ratio and used I^2 statistic to assess the heterogeneity.
Results: Total of 587 citations were retrieved, out of which 14 trials were eligible for inclusion with a total of 1661 patients (899 in the CS group and 762 in the non-CS group). The vast majority of patients had coronary artery bypass graft surgery. All trials used shed blood for CS. In the CS group, 345 patients (38%) received RBC transfusion compared to 340 patients (45%) in the non-CS group. The odds of receiving blood transfusion were lower in the CS group (odds ratio of 0.66, 95% confidence interval [CI]: 0.45-0.96; Figure). Nevertheless, there was substantial heterogeneity between the trails in the outcome [I^2 of 60% (95% CI: 19-87%) which was statistically significant (P<0.01).

Tabella 1.



Summary and Conclusions: Available evidence suggests that the use of CS during cardiac surgery as a blood conservative strategy may decrease RBC transfusion with a reasonable effect size. However, these findings need to be taken with caution, given the substantial between-study heterogeneity in the outcome. We therefore recommend a large randomized controlled clinical trial to confirm these findings.

P395

IMMUNOGLOBULIN PROPHYLAXIS AGAINST HUMAN T CELL LYMPHOTROPIC VIRUS TYPE I PREVENTS INFECTION IN A HUMANIZED MOUSE MODEL

T. Mizukami[1,*] K. Nojima[1], C. Matsumoto[2], W. Kuribayashi[1], R. Sobata[2], M. Kuramitsu[1], K. Furuhata[1], S. Matsuoka[1], K. Okuma[1], S. Masahiro[2], K. Tadokoro[2], K. Yamaguchi[1], I. Hamaguchi[1]
[1]Department of Safety Research on Blood and Biologicals, National Institute of Infectious Diseases, [2]Central Blood Institute, Japanese Red Cross Society, Tokyo, Japan

Background: Adult T-cell leukemia (ATL) is a malignant disease caused by infection with human T-lymphotropic virus type 1 (HTLV-1). Only about 2–5% of HTLV-1-infected patients develop ATL, but prevention of HTLV-1 infection is the most effective strategy to eradicate ATL. After the introduction of HTLV-1 antibody screening of blood donations by the Japanese Red Cross, detection of HTLV-1 infections caused by transfusion has ceased. However, HTLV-1 infection continues to spread via breastfeeding and sexual intercourse. In Kyushu, an endemic area of Japan, pregnant HTLV-1 carriers are recommended against breastfeeding, and this policy has successfully reduced the number of HTLV-1 vertical infections. Despite this recommendation, 3–5% of HTLV-1 infections are still due to the virus passing from mother to child, and the number of HTLV-1 infections in non-endemic areas is increasing. Thus, an effective anti-viral agent is still needed to inhibit HTLV-1 infection. At present, there is no effective vaccine or anti-viral agent for HTLV-1, although it has recently been shown that anti-HTLV-1 antibody is effective in preventing mother to infant infection in a rabbit model of HTLV-1.
Aims: In this study, we aimed to develop an effective HTLV-1 immunoglobin isolated from HTLV-1 carriers that were screened at the Japanese Red Cross and to test whether HTLV-IG can prevent HTLV-1 infection in a humanized mouse model.
Methods: First, we developed and standardized effective screening methods to evaluate and characterize the anti-viral effect of HTLV-1 positive plasma. To monitor the infectivity and the ability to form syncytia we used MT-2, a HTLV-1-harboring T-lymphoblastoid line that can infect normal cells. Cocultures of 10^3 MT2 and 10^5 Jurkat cells treated with mitomycin C (MMC; 50 µg/mL) were successfully used to evaluate HTLV-1 infectivity.
Results: We found that HTLV-1 positive plasma, which was isolated from an HTLV-1 carrier who had a proviral load over 4, can effectively inhibit both HTLV-1 infection and syncytia formation. We purified HTLV-IG from the HTLV-1 positive plasma and evaluated its effect in a humanized mouse model, NOG (NOD.Cg-Prkdcscid Il2rgtm1Sug/Jic). Mice were treated with HTLV-IG for 5 days before HTLV-1 infection. HTLV-1 infection of 6-week-old NOG mice was carried out by injection with MMC+ MT-2 (10^5) 3 days after the mice received a transfer of human peripheral blood mononuclear cells (PBMC; 10^7). At day 11 post-infection, more than 80% of human CD45+ cells were found in the PBMC from the abdominal cavity and spleen. In those tissues at day 11 post-infection, HTLV-1 infection was observed in the untreated infected mice, but not in the HTLV-IG-treated mice. HTLV-1-infected cells, CD3+/CD4+/CCR4+/CD25+, were detected in the spleen, liver, and lung in the control MT-2-treated mice, but no HTLV-1-infected cells were observed in these tissues in the HTLV-IG-treated mice, even though their T cells (CD3+/CD4+ and CD8+) were normally colonized. These data suggest that HTLV-IG inhibits both HTLV-1 infection and the infiltration of HTLV-1-infected cells to the target tissues in a humanized mouse model.
Summary and Conclusions: We developed a screening method for evaluating the anti-viral effect of HTLV-IG. Our results show that HTLV-IG effectively inhibits both HTLV-1 infection and the infiltration of HTLV-1-infected cells into various types of tissues in a humanized mouse model. Our model is suitable for evaluating and confirming the anti-viral effect of HTLV-IG.

P396

ENDOGENOUS THROMBIN POTENTIAL FOLLOWING HEMOSTATIC THERAPY WITH 4-FACTOR PROTHROMBIN COMPLEX CONCENTRATE: A 7-DAY OBSERVATIONAL STUDY OF TRAUMA PATIENTS

G. Papakitsos[1,*] A. Kapsali[2], T. Papakitsou[3]
[1]Anesthetic, Gharta, [2]Private Clinic, ARTA, [3]GHMessologi, Messologi, Greece

Background: Purified prothrombin complex concentrate (PCC) is increasingly used as hemostatic therapy for trauma-induced coagulopathy (TIC).
Aims: However, the impact of PCC administration on coagulation status among patients with TIC has not been adequately investigated.
Methods: In this observational, descriptive study, data relating to thrombin generation were obtained from plasma samples gathered prospectively from trauma patients upon emergency room (ER) admission and over the following 7 days. Standard coagulation tests, including measurement of antithrombin (AT) and fibrinogen, were performed. Three groups were investigated: patients receiving no coagulation therapy (NCT group), patients receiving fibrinogen concentrate only (FC group), and patients treated with PCC and fibrinogen concentrate (FC-PCC group).
Results: The study population (77 patients) was predominantly male (84.4 %); mean age was 40 +/-15 years and mean injury severity score was 25.6 +/-12.7. There were no significant differences between the three study groups in thrombin-related parameters upon ER admission. Endogenous thrombin potential (ETP) was significantly higher in the FC-PCC group compared with the NCT group on days 1 to 4 and the FC group on days 1 to 3. AT levels were significantly lower in the FC-PCC group from admission until day 3 (*versus* FC group) or day 4 (*versus* NCT group). Fibrinogen increased over time, with no significant between-group differences after ER admission. Despite ETP being higher, prothrombin time and activated partial thromboplastin time were significantly prolonged in the FC-PCC group from admission until day 3 to 4.
Summary and Conclusions: Treatment with PCC increased ETP for several days, and patients receiving PCC therapy had low AT concentrations. These findings imply a potential pro-thrombotic state not reflected by standard coagulation tests. This is probably important given the postoperative acute phase increase in fibrinogen levels, although studies with clinical endpoints are needed to ascertain the implications for patient outcomes. We recommend careful use of PCC among trauma patients, with monitoring and potentially supplementation of AT.

P397

HIGH LEVEL OF UNDERSTANDING FOR BLOOD TRANSFUSIONS IN PATIENTS CAN BE ACHIEVED BY EXPERT STAFF FROM THE TRANSFUSION UNIT

H. Furumaki[1,*] C. Yamada[1], H. Fujihara[1], M. Tuduki[1], S. Nagai[1], H. Shibata[1], K. Ishizuka[1], M. Kaneko[1], H. Watanabe[1], A. Takeshita[1]
[1]Transfusion and Cell Therapy, Hamamatsu University School of Medicine, Hamamatsu, Japan

Background: Enough understanding for blood transfusion is essential for patients treated with a blood transfusion. The American Association of Blood Banks (AABB) and other societies concerned with blood transfusions have recommended the minimum acceptable requirements for obtaining informed consent (IC). Specifically, the doctor should give each patient a sufficient amount of information on the procedure as well as the opportunity to ask questions. We have recently initiated a new service in which expert staff from the transfusion unit provide patients with basic information on the blood transfusion procedure. This new system has drastically improved patient understanding of blood transfusion.
Aims: The difference in the level of understanding for each basic fact related to blood transfusion was assessed between two groups of patients that were, or were not, provided with information from staff of the transfusion unit.
Methods: Expert staff from the transfusion unit started to provide patients with basic information on blood transfusion before further disease-specific explanation by the primary doctor (transfusion group; n =253). The effectiveness of this approach was assessed by comparison with a group of patients that were furnished with information by the doctors only (doctor group; n=74). We carried

out a questionnaire survey of patients to analyze the depth of understanding of blood transfusion from July to October 2013 and October to December 2014. The level of understanding in patients before blood transfusion was compared between the two groups. Statistical analyses were performed by the Chi-square test using the SAS analysis suite (Tokyo, Japan). Probability values less than 0.05 were considered statistically significant.
Results: The level of understanding for each issue was as follows. For precautions during blood transfusion, 88% of patients answered "Completely" or "Mostly" in the transfusion group, but only 26% in the doctor group. For requirement of tests for post-transfusion-transmitted infections, 90% answered "Completely" or "Mostly" in the transfusion group, but only 33% in the doctor group. For the scheme of blood transfusion, 90% answered "Completely" or "Mostly" in the transfusion group, while 36% in the doctor group. For agreement for signing a consent form, 94% answered "Completely" or "Mostly" in the transfusion group, but only 50% in the doctor group. For a sense of ease in receiving a blood transfusion, 86% answered "Completely" or "Mostly" in the transfusion group, but 45% in the doctor group. Patients were also asked for ten risks associated with blood transfusion after being given the explanation. The results are summarized in the figure, and the representative results were shown as follows. In the transfusion group, a good understanding was obtained in 94% of patients for "Allergenic reaction", 90% for "Fever", 85% for "Hepatitis virus" and 74% for "HIV". By contrast, in the doctor group, a good understanding was obtained in 49% of patients for "Allergenic reaction", 30% for "Fever", 42% for "Hepatitis virus" and 39% for "HIV. Notably, TRALI, TACO and GVHD were understood by only about 10% of patients in the doctor group. There were significantly higher degrees of understanding in the transfusion group (P <0.001). For the other issues, the degree of understanding was significantly higher in the transfusion group than in the doctor group (P <0.001). The significances were more prominent than our previous smaller study.

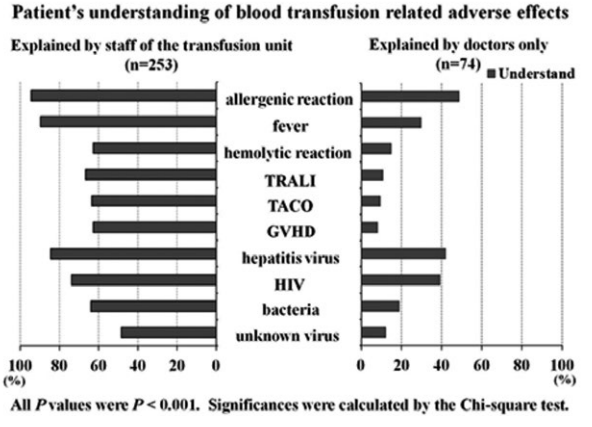


Figure 1.

Summary and Conclusions: Providing patients with information on blood transfusion by expert staff from the transfusion unit prior to further explanation by the primary doctors was found to be useful. All of the issues related to blood transfusion were significantly better understood by the patient after input from the transfusion unit staff. Intervention by the transfusion unit in this field will be useful for the process of obtaining IC and achieving high-quality transfusion therapy.

P398

INTRAVENOUS HIGH-DOSE IRON SUPPLEMENTATION FOR BLOOD DONORS WITH IRON DEFICIENCY

S. Macher[1,*] C. Drexler[1], T. Stojakovic[2], I. Lindenau[3], M. Schröck[3], C. Reinprecht[3], N. Sareban[1], K. Amrein[3]
[1]Department of Blood Group Serology and Transfusion Medicine, [2]Clinical Institute of Medical and Chemical Laboratory Diagnostics, [3]Division of Endocrinology and Metabolism, Department of Internal Medicine, Graz, Austria

Background: Iron deficiency (ID) is one of the most common nutritional deficiencies worldwide. It is highly prevalent in premenopausal women and also frequently found in industrial countries. About 23% of the population participates in blood donation programs. Blood donations often contribute to ID, but for donor clearance, only a capillary hemoglobin (Hb) threshold is required. However, Hb does not reliably predict iron stores. ID is associated with restless legs syndrome, cognitive and physical symptoms and an increased risk for preterm birth. Currently, only in anemic donors, iron supplementation is routinely recommended. Oral iron substitution is often associated with significant gastrointestinal side effects and poor compliance.
Aims: In our ongoing study, we compare the effect of a single intravenous high-dose iron carboxymaltose preparation (1000mg) for blood donors with iron deficiency (IV) with the effect of a corresponding dose (10g) of oral iron over 10 weeks (PO).
Methods: In our randomized, controlled clinical trial we include male and female blood donors (whole blood and platelet apheresis) who fulfill the criteria of a predonation hemoglobin value of ≤13.5g/dl and a ferritin value of ≤30ng/ml (target sample size 160 in total). Stratified by gender, participants are randomized with a web-based randomization tool to IV or PO in a 1:1 ratio. 12 weeks after the first visit hemoglobin and ferritin values of both groups are determined.
Results: Out of 306 donors with Hb ≤13.5g/dl, 187 (61%, 166 female, 21 male) had a ferritin value of ≤30ng/ml and of these, 112 had a ferritin ≤15ng/ml.
To date, 32 participants (27 female, 5 male) have completed the trial. Hb and ferritin levels after treatment are shown in the Table. No serious adverse events occurred. Before iron treatment, but after donation, mean Hb and ferritin levels were 11.5±0.7g/dl and 6.5±3.9ng/ml.

Tabella 1. Hb and ferritin values (mean±SD) 12 weeks after iron supplementation

	IV, n=16	PO, n=16	P value
Hb (g/dl)	13.5±0.5	13.5±0.5	n.s.
Ferritin (ng/ml)	116.1±70.7	27.6±15.5	<0.01

In the IV group, 2/16 participants (12.5%) still had ferritin values <30ng/ml after iron supplementation (both of whom donated blood after their first visit) compared to 8/16 (50%) participants of the PO group.
Summary and Conclusions: Iron deficiency is common in blood donors, especially in females. Both IV and PO iron supplementation improves iron stores but IV iron is more effective. The diagnosis and treatment of this common condition could be useful both for donors and transfusion medicine services.

P399

MORTALITY REDUCTION WITH A MASSIVE TRANSFUSION PROTOCOL IN A NON-TRAUMA UNIVERSITY MEDICAL CENTER

N. Martinez Calle[1,2,*] F. Hidalgo[1], A. Alfonso[2], R. Leucumberri[2], M. Hernández[2], J.A. Paramo[2]
[1]Anaesthesia and Critical Care, [2]Hematology, Clínica Universidad de Navarra, Pamplona, Spain

Background: Management of massive bleeding requires rapid hemostatic control and timely blood product support. Our center has developed a non-trauma massive transfusion protocol (MTP) that includes blood product supply and use of adjuvant pro-coagulant agents.
Aims: We aimed to evaluate the impact of a MTP on patient outcome.
Methods: Retrospective-observational study in patients treated with our MTP between January 2006-December 2012, and an historical cohort (year 2005) as control. MTP consisted in a goal-directed transfusion strategy with early use of adjuvant procoagulant medications (fibrinogen, aFVII, prothrombin complex concentrates or antifibrinolytics). Primary endpoints were 24-h and 30-day mortality. Secondary endpoints were: 1) Fresh frozen plasma/Red blood cells (FFP:RBC) and platelet/RBC transfusion ratios, 2) Time to first FFP unit, and 3) Pro-coagulant agents frequency of use. A multivariate logistic regression model was used to establish associations with 30-day mortality.
Results: 324 patients were included (67% male, median age 61yr). Analysis was divided into two periods (2006-2009 and 2010-2012). RBC use remained stable, with a progressive increase in FFP and pro-coagulant agents use after MTP implementation. A statistically significant increase in FFP:RBC ratio was observed after the MTP (p=0.03), without differences in PLT:RBC ratio. Time to first FFP showed a tendency to reduction (p=0.08). A significant reduction in 30-day mortality was seen (25% in 2006-2009; 20% in 2010-2012; 38% in 2005, p=0.037), with unchanged 24-h mortality. Multivariate logistic regression model showed an independent effect of MTP on 30-day mortality.

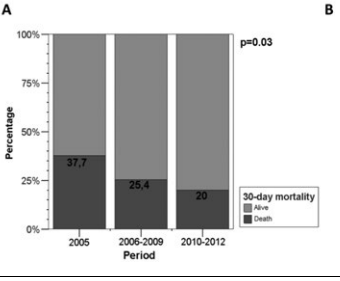

Figure 1. (A) 30-day Mortality reduction after massive bleeding protocol implemetation. (B) Results of the multivariate logistic regression model for 30-day mortality.

Summary and Conclusions: An independent association between the non-trauma MTP implementation and 30-day mortality has been found, with a parallel improvement in transfusion ratios. MTP might be valuable for non-trauma patients, and may have an effect on survival not entirely dependent on the improved transfusion ratios.

Platelet disorders

THE TAIL MUTATIONS OF MYH9 INHIBIT THE DISASSEMBLY OF NON-MUSCLE MYOSIN IIA

K. Miyazaki[1,*] S. Komatsu[2], H. Jung[3], M. Higashihara[1], R. Craig[3], M. Ikebe[2]
[1]Department Of Hematology, Kitasato University School of Medicine, Sagamihara, Japan, [2]Department of Cellular and Molecular Biology, The University of Texas Health Science Center at Tyler, Tyler, [3]Department of CellBiology, University of Massachusetts Medical School, Worcester, United States

Background: MYH9 disorders include autosomal dominant macrothrombocytopenias with leukocyte inclusion bodies. These disorders were caused by heterozygous mutations in MYH9, the gene encodes non-muscle myosin heavy chain-IIA. However, It has yet remained to be clarified how these mutations make an impact on the molecular property of myosin. In order to address this issue, we need to examine the whole myosin hexamer, consisting of a pair of heavy chains, essential light chains and regulatory light chains, because it has been known that interaction between the tail and the head-neck domain is critical for regulation of non-muscle myosin filament formation. We have overcome difficulties and successfully produced the recombinant non-muscle myosin hexamer as a whole molecule.
Aims: To clarify the effects of the tail mutations on the molecular property of non-muscle myosin IIA.
Methods: We used Baculovirus expression system, and successfully produced functional recombinant myosin hexamer, and analyzed the Mg^{2+}-ATPsase activities and ability of filament formation, wild type and two representative tail mutants, namely p.Asp1424His and p.Glu1841Lys.As *in vivo* analysis, we overexpressed GFP-tagged MYH9, wild type and tail mutants in NIH3T3 cells, and examined the localization.
Results: The ATPase activities of these mutants were essentially the same as the wild type, indicating that these tail mutations don't influence the motor activity of non-muscle myosin IIA. Non-muscle myosin forms large head to head aggregation in the absence of ATP. However, both mutants failed to disassemble to monomers upon the addition of ATP in contrast to the wild type. Additionally electron microscopic analysis also revealed that they impaired the ATP-induced disassembly of myosin filaments, and produced large aggregates. For further investigation on the single molecule, we studied at reduced protein concentration using rotary shadowing. In the presence of ATP, the wild type myosin monomers predominantly presented a compact shape with two folds in the tail. On the other hand, two tail mutants predominantly formed an extended conformation. Additionally the p.Glu1841Lys mutant proned to stick to each other even at low protein concentration in the presence of ATP. Next we overexpressed GFP-tagged MYH9, wild type and two tail mutants in NIH3T3 cells. Wild type MYH9 diffusely localized in cytoplasm. In contrast, both tail mutants accumulated to the myosin filaments, where the regulatory light chains were phosphorylated, suggesting that these mutants were unable to disassemble once they formed filaments.
Summary and Conclusions: These tail mutations hampered the ATP-induced formation of folded conformation thus stabilizing the myosin aggregates. They disturbed the normal assembly-disassembly dynamics of myosin filaments, thus inhibiting dynamic actomyosin cytoskeletal rearrangements. These effects may cause the clinical features of MYH9 disorders to some extent.

P401

PLATELET PROGENITORS AFTER LEAVING BONE MARROW

S. Kowata[1,*] K. Murai[2], T. Oyake[1], S. Ito[3], Y. Ishida[1]
[1]Hematology/Oncology, Iwate Medical University School of Medicine, [2]Hematology, Iwate prefecture hospital, [3]Oncology, Iwate Medical University School of Medicine, Morioka, Japan

Background: *in vitro* observations have indicated that preplatelets, which are anucleate discoid particles that can reversibly into proplatelet fragments, are one of platelet progenitos from cultured megakaryocytes (MKs) (Thon JN, *et al.* JBC 2010). Recently, we identified that bone marrow (BM) MKs form and release two types of platelet progenitors, using intra-vital imaging and ultrastructural analysis of mice BM (Kowata S, *et al.* Thrombosis and Haemostasis 2014). However, *in vivo*, how the platelet progenitors translate into individual platelets after leaving BM remains poorly understood.
Aims: To elucidate whether platelet progenitors have an ability of conversion into individual platelets *in vivo* and *in vitro*.
Methods: We isolated platelet progenitors from whole blood of green fluorescence protein (EGFP) transgenic mice by the centrifugation (100 g, 15 min) after the intra-peritoneal injection of anti-platelet antiserum (APS). Mature platelets were isolated from whole blood of GFP mice by the centrrifugation (100 g, 15 min). *in vivo*: The freshly enriched progenitor isolates or mature platelets, both of which were positive for EGFP, were transfused into wild type mice. The peripheral blood was obtained and analyzed by flow cytometry continually. The EGFP positive platelets in platelet gate were counted. *in vitro*: The freshly enriched progenitor isolates were cultured in IMDM medium at 37°C. The continual change of their characteristics in the shape and size were assessed using fluorescent microscopy with high resolution. Time lapse images of the processes were also captured.
Results: During an acute thrombocytopenic period after the APS injection, platelet progenitors increased remarkably in whole blood from vena cava. The length and size of platelet progenitors was extremely varied (Figure 1). The maximum length of platelet progenitor was more than 200 μm. These data were confirmed by our previous study of intra-vital imaging of BM MKs (Thrombosis and Haemostasis 2014). *in vivo*: Flow cytometric analysis showed that there was a time-dependent increase in EGFP platelet number in the gate of mature platelet, after the injection of EGFP positive platelet progenitors. The control was carried out using EGFP positive platelets instead of platelet progenitors. (0 h: 100%, 6h: 111±10.4%, 12h: 105±6.3% n=3, control 0 h: 100%, 6h: 86±8.8%, 12h: 73±5.3% n=3, Data were shown as % of the number of EGFP positive platelets at 0 h). These data suggest that the infused platelet progenitors convert into mature platelets *in vivo* as time passed. *in vitro*: The platelet morphogenesis from platelet progenitors was observed as highly dynamic process, shown as follows. (1) A long proplatelet made several formation cleavage furrows, where it snapped, making short proplatelets. Then, they snapped to become the platelet-sized particle. (2) Oval proplatelet, which was several times bigger in diameter than mature platelet, extended to short proplatelet. Then it snapped to become the platelet-sized particle.

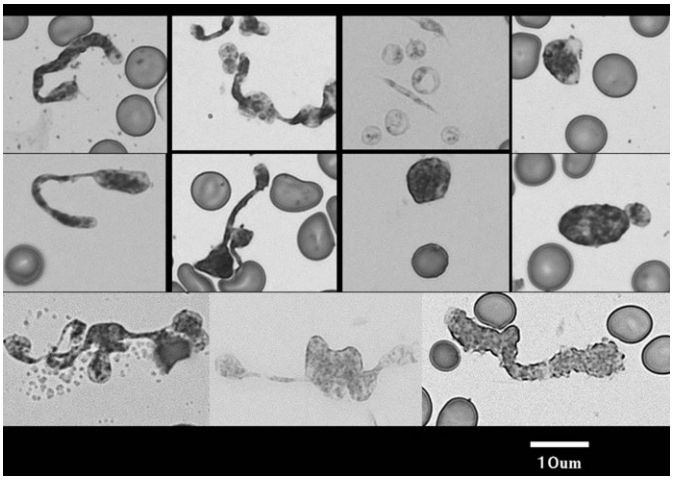

Figure 1.

Summary and Conclusions: These data indicated that, after leaving BM sinusoid, these platelet progenitors convert into individual platelets in the blood stream.

P402

HELICOBACTER PYLORI INFECTION INFLUENCES THE SEVERITY AND TREATMENT RESPONSE IN CHRONIC HEPATITIS B COMPENSATORY CIRRHOTIC PATIENTS WITH THROMBOCYTOPAENIA

X.H. Zhang[1,*] Y. He[1], Q.M. Wang[1], F.E. Feng[1], X.L. Zhu[1], Y.D. Xie[2], H. Ma[2], H. Wang[2], L.P. Xu[1], K.Y. Liu[1], X.J. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking University People's Hospital, Peking University Institute of Hepatology, Beijing, China

Background: Thrombocytopaenia is a frequent complication of liver cirrhosis, and ITP is closely related with *H. pylori* infection. Several studies illuminate the associations between *H. pylori* and viral hepatitis, but most of the studies focus on hepatitis C and *H. Pylori* infection.There is no information availableon the association between *H. pylori* infection and hepatitis B compensatory cirrhosis with thrombocytopaenia.T. Umemura *et al.* reported that *H. pylori* seropositivity potentially contributes to thrombocytopaenia in patients with HCV infection. Therefore, we wanted to determine whether *H. pylori* infection plays a role in compensatory cirrhosis in chronic hepatitis B patients with thrombocytopaenia.
Aims: The aim of this projectis to explore the role that *H. pylori* infection plays in chronic hepatitis B compensatory cirrhotic patients with thrombocytopaenia.
Methods: A total of 255 patients were enrolled in the study. All of the patients were received nucleoside analogs (NA) therapy and were screened for *H. pylori* infection. Patients were divided into three groups according to the different therapy administered and the state of *H. pylori* infection: patients without *H. pylori* infection and receiving NA therapy alone (N=146); patients with *H. pylori* infection and receiving NA therapy alone (N=48); patients with *H. pylori* infection and receiving *H. pylori* eradication treatment combined with NA therapy (N=61). Clinical laboratory parameters and platelet response to the treatment were compared between three groups.
Results: In hepatitis B patients experiencing compensatory liver cirrhosis who were infected with *H. pylori,* platelets counts were significantly reduced compared with non-infected patients (31 *vs* 60×10^9/L, respectively, P<0.01).For

long-term follow-up, the platelet count was significantly increased in HBV/*H. pylori* co-infection patients who received NA combined *H. pylori* eradication treatment compared with the other two groups who received NA alone (P<0.01). The titre of anti-*H. pylori* IgG was significantly correlated with thrombocytopaenia severity and inversely correlated with platelet count. *H. pylori* infection is an independent risk factor of thrombocytopaenia (P<0.01).
Summary and Conclusions: In conclusion, we are the first to report that thrombocytopaenia is significantly correlated with *H. pylori* infection in compensatory liver cirrhosis of chronic hepatitis B patients. The platelet response after 2 years follow-upis markedly increased in HBV/*H. pylori* co-infection patients who received NA combined *H. pylori* eradication treatment. *H. pylori* infection is an independent risk factor of thrombocytopaenia. Therefore, *H. pylori* may partly contribute to thrombocytopaenia in HBV patients. NA combined with *H. pylori* eradication treatment may prove beneficial in chronic hepatitis B compensatory cirrhotic patients infected with *H. pylori.*

P403

ELEVATED PLATELET AGGREGATION AND ACTIVATION ARE ASSOCIATED WITH PROLONGED ISOLATED THROMBOCYTOPAENIA VIA REDUCED B2-GPI AFTER ALLO-HAEMATOPOIETIC STEM CELL TRANSPLANTATION

X.H. Zhang[1,*] J.Z. Zhao[2], Y. Zhou[1], J.M. Zhang[1], X.L. Zhu[1], J. He[3], F.R. Wang[1], L.P. Xu[1], K.Y. Liu[1], H. Wang[2], X.J. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking University People's Hospital, department of clinical laboratory, [3]Peking University People's Hospital, department of Rheumatology and Immunology, Beijing, China

Background: Prolonged isolated thrombocytopaenia (PT) remains a serious complication after allogeneic haematopoietic stem cell transplantation (allo-HSCT). Recent studies have demonstrated that several risk factors, including the stem cell source, disease status, graft-*versus*-host disease (GVHD), and cytomegalovirus (CMV) infection, are proposed to be associated with PT after allo-HSCT. PT is an independent risk factor for a poor prognosis after allo-HSCT. The pathogenesis of PT after allo-HSCT remains unknown. Our previous studies demonstrated that recurrence and engraftfailure are strongly associated with PT; increased platelet turnover from impaired platelets and increased platelet consumption have been demonstrated. β2-GPI is a major target for antibodies in Apl, and β2-GPI antibodies contribute to decreased platelets in APS patients. Hulstein*et al.* revealed that β2-GPI inhibits the vWF-dependent functions of platelet adhesion and aggregation. In present study, the function of β2-GPI was investigated in PT after allo-HSCT. Minimal data are available on β2-GPI involvement in platelet activation and aggregation in this setting.
Aims: The aim of this study was to explore whether decreased β2-GPI levels contribute to the enhanced of platelet activation and aggregation in PT after allo-HSCT.
Methods: A total of 56 consecutive patients with PT and 60 control patients after allo-HSCT were enrolled at our centre. β2-GPI Ag and anti-β2-GPI antibody levels were measured by ELISA, and vWF Ag and vWF activity levels were detected using an automated coagulation analyser. Platelet aggregation and CD62p and PAC-1 expression were confirmed using a Chrono-log aggregation analyser and flowcytometry.
Results: The β2-GPI antigen in PT was significantly decreased compared with control (164.2±12μg/ml *vs* 234.2±16μg/ml; P<0.01), and the β2-GPI antigen was negatively correlated with platelet aggregation(P<0.01). The aggregation ratio in PT was significantly increased compared with control(39±7.5% *vs* 23±8.5%; p=0.0317). A significant difference was noted after 90 days of allo-HSCT (P<0.01). Additionally, anti-β2-GPI IgG in PT was markedly increased (1.78±0.46*vs* 0.94±0.39 U/ml; P<0.01). No significant differences were noted between the two groups regarding vWF antigen levels, and vWF activity was increased in PT (133.06±30.50% *vs* 102.17±25.90%; P<0.01). β2-GPI antigen levels and vWF activity were negatively correlated (P<0.01). Platelet aggregation was induced by ADP in combination with various concentrations of β2-GPI. The aggregation ratio gradually decreased in PTwith increasing β2-GPI. CD61, CD62p and PAC-1 expression in platelets was higher in the patients with PT after allo-HSCT(33.6±11.6%*vs* 8.5±3.5%,p=0.000; 42.4±7.6% *vs* 6.8±2.2%, p=0.000; 20.6±7.9% *vs*6.1±2.0%, p=0.000; respectively).
Summary and Conclusions: β2-GPI antigen is obviously decreased in patients with PT and is closely related to increased platelet activation and aggregation. β2-GPI significant inhibit platelet aggregation in patients with PT, suggesting that it may be involved in the pathogenesis of PT after allo-HSCT.

Background: Pregnancy and delivery represent hemostatic challenges to women with inherited platelet function disorders (IPFD). Information on outcomes and management of IPFD in pregnancy is scarce, and the limited data available in literature, mainly deriving from case reports or small case series, suggest that major bleeding is very common.
Aims: To improve knowledge on this matter we performed a retrospective, multicentric study aimed at systematically collecting and analyzing pregnancy outcomes in a series of women with IPFD. The study was promoted by the *SWG on Thrombocytopenias and platelet function disorders* of the EHA.
Methods: Twelve centers around the world took part in the study, and 34 women with 5 different forms of IPFD confirmed by specific diagnostic criteria were enrolled, obtaining data on a total of 65 pregnancy and 48 newborns. Data on spontaneous bleeding tendency, way of delivery, hemostatic prophylaxis, bleeding at delivery and its management, as well as newborns' status, were recorded.
Results: Spontaneous bleeding diathesis did not worsen during gestation, and no severe bleeding episodes were reported during this period. Miscarriage and preterm birth incidence was similar to that observed in the normal population. Prophylactic platelet transfusions were given in 30% of cases and 73% of deliveries were vaginal. Severe bleeding events requiring blood transfusion were observed in 12.5% of deliveries, in all cases occurring in women with Glanzmann thrombasthenia (GT). Of note, 50% of deliveries in women with GT needed therapeutic blood transfusions, while no women with delta storage pool disease (delta-SPD), Hermansky-Pudlak syndrome, P2Y12 defect or defect of thromboxane A2 receptor required this treatment. However, mild bleeding was reported also in some women with the latter diseases. More than half of women with GT who received prophylactic platelet transfusions experienced severe hemorrhages at delivery, suggesting that platelet transfusion alone may be inadequate and better preventive treatments are required in this condition. No women died of delivery-related causes or received hysterectomy to stop bleeding. Neither the 9 neonates who inherited the mothers' illness nor the unaffected infants experienced bleeding at birth. Statistical analysis found significant association between excessive bleeding at delivery requiring transfusion and a history of grade 3 or 4 (OR 23.4) of WHO bleeding scale. The risk of bleeding was also significantly increased in women with GT compared with delta-SPD (OR 41.6). No significant correlations were found between severe bleeding requiring blood transfusion at delivery and the way of delivery, the age of the mother, severe bleeding at previous surgical interventions and the status of primipara; no significant correlation was found with prophylactic platelet transfusion as well.
Summary and Conclusions: The risk of bleeding at delivery in women with IPFD varies according to diagnosis and previous spontaneous bleeding diathesis. Prophylactic platelet transfusions in women with GT do not ensure that childbirth occurs without major hemorrhages in the mother, this indicating the need for better regimens of preparation to delivery in this condition.

P405

PREDICTION OF SEVERE ADAMTS13 DEFICIENCY IN PATIENTS WITH THROMBOTIC MICROANGIOPATHIES

J.M. Nieto[1,*] F. De La Fuente-Gonzalo[1], A. Villegas[1], F.A. Gonzalez[1], M.P. Martin[1], C. Trujillo[1], L. Garcia-Paredes[1], M. Saez[1], R. Martinez[1], P. Ropero[1]
[1]Hematology, Hospital Clinico San Carlos, Madrid, Spain

Background: Thrombotic microangiopathies (TMA) are a rare and heterogeneous group of diseases that include Thrombotic Thrombocytopenic Purpura (TTP), Hemolytic Uremic Syndrome (HUS) and other TMAs secondary to several conditions (ie, cancer and hematopoietic stem cell transplant). TTP is characterized by an extreme ADAMTS13 deficiency. Plasma exchange therapy and immunosuppression are the current treatment for TTP but are ineffective for most other forms of TMA. Assays exploring ADAMTS13 activity are limited to only some specialized reference laboratories. We performed an analysis of our TMA registry to identify clinical features which may allow a rapid and reliable prediction of an acquired ADAMTS13 deficiency.
Aims: The primary goal was to identify cut-offs for variables that would prove

useful in excluding the possibility of TTP, in order to facilitate a more suitable therapy based on the etiology of the TMA.
Methods: The Registry included 242 patients with TMA. All the statistical analyses were performed on a final cohort of 174 adults (including secondary TMAs) in which all the data for subsequent analyses were available. Secondary TMAs were included in the study because it provides a real-world setting for the analysis. A subset of variables was considered from a clinical standpoint as potential predictors of low ADAMTS13 activity. Patients with severe acquired (<5% of normal activity) ADAMTS13 deficiency (n=55) were compared to patients with detectable (≥5%) ADAMTS13 activity (n=119). Then, for the statistically significant variables (age, platelet count and creatinine), we generated receiver operator characteristics (ROC) curves and compared area under the curve (AUC) values to find cut-offs helping in the prediction of a severe ADAMTS13 deficiency (thresholds of 68 years old for age, 2.0 mg/dL for creatinine and 44×10^9/L for platelet count). Finally, we conduct multivariate logistic analysis to test if a model with combined variables improves the prediction capability of the variables taken alone. A fourth variable (absence of Hematopoietic Stem Cell Transplant (HSCT) in the patient) performed well in the multivariate analysis and was included in the final model.
Results: The combined model (table 1) had an AUC of 0.925, thus improving the prediction capability of the individual variables. The percentage of correct predictions of the model was 89,7%. Patients with severe ADAMTS13 deficiency had platelets ≤44×10^9/L, creatinine ≤2,0 mg/dL, age ≤68 years old and did not undergo HSCT (Odds Ratio 64,0; p <0,001). If all the four criteria are met, the probability of TTP is 82,5%. If any of the conditions is not met, the probability of TTP drops to 6,8%.

Tabella 1.

Variables included	Condition in severe ADAMTS13 deficiency	AUC	% of correct predictions	Specificity	Sensibility	Negative Predictive Value	Positive Predictive Value
Creatinine	≤2.0 mg/dL	0,925	89,7% 8 false - 10 false+	91.6%	85.5%	93.2%	82.5%
Platelet	≤44×10^9/L						
Age	≤68 years						
HSCT	Absent						

Summary and Conclusions: TTP share features of atypical HUS and secondary TMAs. Our results may enable the rapid exclusion (if any of the conditions is not met) and accurate diagnosis of TTP (if all the four criteria are met) using readily available laboratory data and this could help to choose the suitable therapy for different pathophysiological groups. Three out of 8 false negatives were TTP relapses that were misclassified due to a high platelet count. This could be explained because the patients were already diagnosed and advised that they have to be promptly hospitalized in a relapse. Within the 10 false positives, 30% of the cases were shown to be associated to gastric or breast tumors days after ADAMTS13 testing. Therefore, if ADAMTS13 test results normal in a patient who met all the four conditions, a diagnosis of TMA secondary to cancer should be suspected.

P406

PDGF-BB PROTECTS BONE MARROW MESENCHYMAL STEM CELLS AGAINST APOPTOSIS AND SENESCENCE THROUGH THE P53/P21 PATHWAY IN PATIENTS WITH IMMUNE THROMBOCYTOPAENIA

X.H. Zhang[1,*] J.M. Zhang[1], Q.M. Wang[1], F.E. Feng[1], X.L. Zhu[1], M. Lv[1], H.X. Fu[1], L.P. Xu[1], K.Y. Liu[1], X.J. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China

Background: Immune thrombocytopaenia (ITP) is characterized by platelet destruction and megakaryocyte dysfunction resulting from autoantibodies induced by the polarization of Th1 and deficient regulatory T cells. Mesenchymal stem cells (MSCs) display not only stem cell multipotency but also robust immunosuppressive properties. However, MSCs from ITP patients do not exhibit conventional proliferative abilities and thus exhibit defects in immunoregulation, suggesting that MSCs impairment might be a mechanism involved in ITP. In addition, reversal of the defects in MSCs may represent an attractive therapeutic alternative. Platelet-derived growth factor (PDGF) improves growth and survival in various cell types. Moreover, PDGF promotes MSCs proliferation. However, the effects of PDGF on MSCs in patients with ITP have not been fully characterised.
Aims: The aim of this study was to investigate the molecular pathways underlying the increased apoptosis and senescence and to analyse the*in vitro*effectsofPDGFon MSC from patients with ITP
Methods: Bone marrow MSCs were derived from primary ITP patients and healthy donors. Gene expression profilechanges in MSCs from ITP patients and controls wereinvestigated by DNA microarray analysis. RT-PCR and Western blot were employed for molecular expression analyses. Cellular senescence was detected using the CCK-8 assay, cell cycle analysis and senescence-associated β-galactosidase (SAb-gal) assay. Apoptosis was assessed by nuclear staining and flow cytometry. Mitochondrial membrane potential (MMP) was investigated by JC-1 staining.
Results: Microarray analysis revealed that the expression of p53, p21, and the apoptosis regulators Caspase-3,-9, and-8 were increased in ITP MSCs compared with controls. ITP MSCs expanded more slowly and appeared larger in size and flattened. ITP MSCs exhibited increased senescence as demonstrated by decreased proliferative capacity and increased SAb-gal positive cells and G0/G1 cells. The increased apoptosis rate was detected in ITP MSCs compared with normal controls. Molecular changes involving the intrinsic apoptosis pathway were assessed. A decreased Bcl-2/Bax ratio and MMP levels were observed, which leads to cytochromeC release from mitochondria and consequently activates Caspase-9 and Caspase-3 in ITP MSCs. Moreover, Fas and FasL expression and Caspase-8 activation, which are associated with the extrinsic apoptosis pathway, were up-regulated in ITP MSCs, suggesting that both the intrinsic and extrinsic pathways account for enhanced apoptosis. p53 and p21 mRNA and protein expression were up-regulated in ITP MSCs, whereas the inhibition of p53 with PFT-αmarkedly inhibits apoptosis and senescence. PDGF-BB treatment significantly decreased p53 and p21 expression and increased surviving expression in. In addition, the apoptotic rate and number of senescent cells in ITP MSCs were reduced after PDGF-BB treatment.
Summary and Conclusions: Increased apoptosis and senescenceare noted in ITP MSCs. Both the intrinsic and extrinsic pathways participate in excessive apoptotic induction. For the first time, we demonstrate that PDGF-BB protects MSCs against apoptosis and senescence in patients with ITP. This protective effect of PDGF-BB is likely mediated via the p53/p21 pathway, thus potentially providing a new therapeutic alternative for immune thrombocytopaenia.

P407

EFFICACY OF PROPHYLACTIC SINGLE DONOR PLATELETS (SDP) TRANSFUSION IS RELATED TO THE TIME OF STORAGE AND NOT TO THE ABO COMPATIBILITY IN CHILDREN WITH MALIGNANCY

D. Adamidou[1,*] A. Markantonatou[1], E. Avramidou[1], M. Oikonomou[1], A. Filippou[1], A. Chroni[1], C. Papadopoulou[1], E. Abatzoglou[1], V. Sidi-Frankandrea[1], M. Kourti[1], E. Papakonstantinou-Athanasiadou[1], T. Karafoulidou[1], D. Koliouskas[1], S. Theodoridou[1]
[1]Ippokratio Hospital Thessaloniki, Thessaloniki, Greece

Background: The prophylactic transfusion of apheresis platelets remains the gold standard in order to avoid spontaneous bleeding in children undergoing intensive chemotherapy protocols. Due to inventory constrains, several times transfusion services are issuing ABO mismatched platelets.
Aims: To provide descriptive data based on our centre's experience with regard to platelet increments post prophylactic transfusions in children with malignancy and investigate for factors that could be related to the effectiveness of SDP transfusion.
Methods: We retrospectively analysed data from a 3 years period (2011-2014) on the prophylactic SDP use on 48 children (25 boys/23 girls) with a median age of 7(2.5-14)years diagnosed with haematologic or solid malignancies (29 ALL, 3 AML, 4 NHL, 2 Wilms' tumor, 4 Ewing sarcoma, 3 myeloblastoma, 2 neuroblastoma and 1 rhabdomyosarcoma). Transfusion efficacy was assessed based on the corrected count increment (CCI) that takes into consideration the difference in platelet counts pre and post transfusion together with the number of platelets transfused as well as the patients' body surface area. Response was evaluated at 24 hours post transfusion and any CCI <$5x10^3$ was considered inadequate. Patient related (age, gender, disease, ABO/D, previous exposure to SDP or random platelets, status at last follow up) as well as product related (duration of storage, ABO/D, apheresis machine) factors were recorded and included in the analysis.
Results: In total 228 transfusions, meeting the inclusion criteria were analysed. In 146 (64%), patients received ABO identical SDPs whereas in 48 (21%) and 34 (15%) children received SDPs with major or minor ABO mismatch respectively. The mean value of CCI was 17.9 (0-66.4)x$10^3$and transfusion refractoriness was noticed in 35 SDPs administration (15%). The median SDP age was 2.59 (0.5-5) days and each child received 3(1-21) prophylactic transfusions. Previous exposure to SDP was recorded in 207 transfusions (136 with major mismatch) whereas random platelets transfusion had preceded the current transfusion in 189 cases (37 with major mismatch). In a univariate analysis a strong negative correlation was found between the time of SDP storage and the transfusion efficacy (p<0.002). In case of refractoriness (CCI <$5x10^3$) the mean product age was 3.35 days, significantly longer compared to that of the efficacious transfusions (2.47 days) (p<0.003). At the contrary the ABO compatibility between the patient and the transfused SDP did not influence the CCI (18.5, 16.7 and 17 x10^3forABO identical and with major and minor mismatch respectively). When CCI was analysed by the patients' ABO blood type significant differences were found between groups with patients on group B showing the modest response (CCI 12.8 x10^3).
Summary and Conclusions: Based on our findings, prophylactic transfusion of fresh SDPs (<48 hours) leads to bigger platelet increments while transfusion of older SDP is related to refractoriness. Interestingly enough, opposite to literature, we found no correlation between the ABO compatibility status and the SDP transfusion efficacy. This could partly be explained by the strong immunosuppression that our study population suffers due to both the underlying disease as well as the chemotherapy received. In summary for children with malignancy, should a prophylactic platelet transfusion is needed the first choice should be to provide fresh SDP ideally of the same ABO, without though firm restrictions on the use of other ABO blood types if the first are not available.

Procoagulant states

IMPACT OF HIGH ON-TREATMENT PLATELET REACTIVITY ON 5-YEAR MORTALITY IN PATIENTS AFTER MYOCARDIAL INFARCTION

M. Jakl[1,2], R. Sevcik[3], I. Fatorova[4], J.M. Horacek[2,4,*]
[1]1st Department of Internal Medicine-Cardioangiology, University Hospital and Charles University, Faculty of Medicine, [2]Department of Military Internal Medicine and Military Hygiene, University of Defense, Faculty of Military Health Sciences, Hradec Kralove, Czech Republic, Hradec Kralove, Czech Republic, [3]Hjärtkliniken NÄL, NU-Sjukvården, Trollhättan, Sweden, [4]4th Department of Internal Medicine-Hematology, University Hospital and Charles University, Faculty of Medicine, Hradec Kralove, Czech Republic

Background: High on-treatment platelet reactivity (HTPR) is expected to be a negative prognostic factor in patients with coronary artery disease. However, long-term results in patients with acute myocardial infarction are lacking.
Aims: The aim of the study was to assess the relationship between HTPR and five-year mortality in patients with acute myocardial infarction.
Methods: We performed a prospective cohort study of 198 patients with acute myocardial infarction. In these patients, the response to aspirin and clopidogrel was assessed by impedance aggregometry. According to their response to antiplatelet treatment, the patients were divided into groups with adequate response, dual poor responsiveness (DPR), poor responsiveness to aspirin (PRA) and poor responsiveness to clopidogrel (PRC). After five years, the myocardial infarction recurrence and overall mortality were assessed.
Results: Five-year mortality was significantly higher in all groups of patients with HTPR compared with patients with sufficient response to antiplatelet treatment: in PRA patients 38.1 % *vs* 19.2 %, p <0.01, in PRC patients 45.2 % *vs* 17.3 %, p<0.001 and in DPR patients 50.0 % *vs* 19.9 %, p<0.05. Risk of repeated myocardial infarction was also increased (HR 4.0, 95 % CI 1.25-11.5, p<0.05 for DPR, HR 4.37, 95 % CI 1.51-12.77, p<0.01 for PRA, HR 3.25, 95 % CI 1.11-9.36, p<0.05 for PRC). In a multivariable analysis, HTPR and left ventricle systolic dysfunction were proven to be independent predictors of mortality.

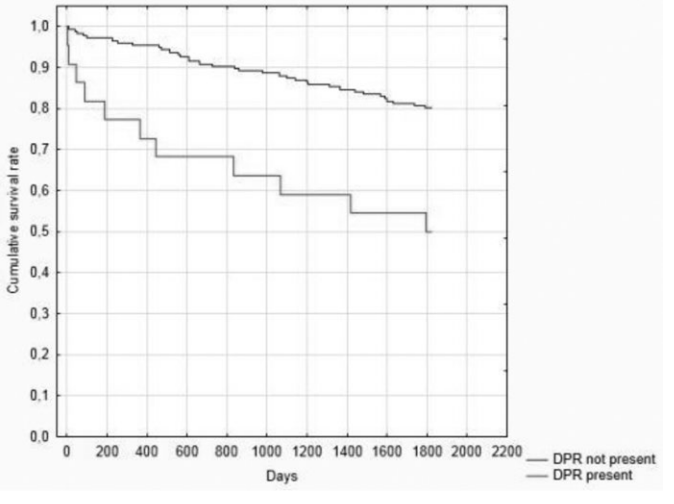

Figure 1.

Summary and Conclusions: PRA, PRA and DPR are independent predictors of increased five-year mortality and risk of repeated myocardial infarction.

P409

NEUTROPHILS CONTRIBUTE TO THE GENERATION OF PROCOAGULANT PLATELETS BY A MYELOPEROXIDASE INDEPENDENT MECHANISM

L. Pasalic[1,2,*] L. Abeynaike[1], E. Glaros[3,4], S. Thomas[3], P. Hogg[1], V. Chen[1,5]
[1]Prince of Wales Clinical School, University Of New South Wales, [2]Haematology, ICPMR, Pathology West, [3]School of Medical Sciences, [4]Centre for Vascular Research, University Of New South Wales, [5]SEALS Pathology, Prince of Wales Hospital, Sydney, Australia

Background: The procoagulant subset of highly activated platelets has been associated with increased pathological thrombotic states such as ischemic stroke and sepsis. Increased generation of reactive oxygen species has been implicated in procoagulant platelet formation, thus we postulated a role for activated neutrophils, and in particular neutrophil myeloperoxidase (MPO), in procoagulant platelet associated occlusive thrombosis. We have shown a novel marker for procoagulant platelets, trivalent arsenical GSAO, identifies procoagulant, necrotic platelets in a whole blood flow cytometry assay and enables direct visualization of fibrin supporting platelets in occlusive thrombi after 8% $FeCl_3$ injury.
Aims: We aimed to use GSAO to study the role of activated neutrophils and MPO in generation of procoagulant platelets *in vitro* and *in vivo*.
Methods: Thrombus formation in the 8% $FeCl_3$ model of thrombosis in the murine cremasteric arterial circulation was visualized using high speed confocal intravital microscopy in presence of GSAO and fluorochrome-conjugated anti-fibrin, and anti-CD42b antibodies. 1A8 anti-Ly6G antibody administered via intraperitoneal injection was used to achieve neutrophil depletion, which was confirmed by flow cytometry after 48 hours. Thrombus formation was induced by 8% ferric chloride.
Results: Compared with controls, neutrophil–depleted C57Bl6 mice demonstrated decreased GSAO+ platelets, decreased occlusive thrombi and reduction in fibrin formation indicating a role for neutrophils in formation of procoagulant platelets *in vivo*. We examined whether the mechanism for this neutrophil effect involved MPO and downstream oxidants. However, ex-vivo addition of hypochlorous acid to washed human platelets did not induce formation of procoagulant platelets. In murine models, there was no difference in generation of procoagulant platelets at rest or after agonist stimulation in MPO-/-mice *versus* wild type C57Bl6 controls. There was also no difference in stimulus-induced procoagulant subset when mice were exposed to increased circulating MPO via 30 day continuous intravenous infusion of human MPO using a small animal pump compared with saline control mice.
Summary and Conclusions: Thus, neutrophils are important for the generation of procoagulant, fibrin supporting platelets *in vivo*. However, the mechanism is not via MPO.

P410

RELEVANT ROLE OF VON WILLEBRAND FACTOR IN EXPERIMENTAL SEPSIS BY CECAL LIGATION AND PUNCTURE IN MOUSE

S. Kasuda[1], H. Matsui[2], K. Hatake[1], M. Sugimoto[2,*]
[1]Legal Medicine, [2]Regulatory Medicine for Thrombosis, Nara Medical University, Kashihara, Japan

Background: Sepsis is a serious inflammatory response syndrome, in which systemic activation of both inflammatory and coagulation pathways are provoked by severe microbial infection. In addition to the known hemostatic functions, von Willebrand factor (VWF) is assumed to participate in a cross-talk between inflammation and thrombosis. However, little is known about the detailed mechanisms or relevant role of VWF functions in inflammation.
Aims: We therefore studied the physiologic relevance of VWF-dependent inflammatory responses in a mouse model of experimental sepsis by cecal ligation and puncture (CLP).
Methods: The mouse CLP was performed according to the established standard protocol (Rittirsch D, *et al*., Nat Protoc, 2009). Briefly, mouse cecum was ligated distal to the ileocecal valve under laparotomy, punctured with 18 gauge needle and gently pressed until a small drop of stool appeared. The cecum was returned to the peritoneal cavity and 200 mL of saline was injected into the cavity to avoid dehydration before body wall and skin incision were closed with a 4-0 Sofsilk. We compared20 wild-type (WT) and 20 VWF-gene deleted (knock-out; KO) mice (from The Jackson Laboratory, Bar Harbor, ME), all of which were 10-12 weeks of age, healthy and fertile. Excess blood loss was not observed in all (WT or KO) mice during the CLP operation.
Results: Kaplan-Meier analysis revealed the significantly (p <0.05) lower survival rate of KO mice than that of WT (KO; 20.0% *vs* WT; 60.0% at the Day 7 of CLP). The impaired survival rate of KO mice was restored by the bolus administration of human VWF (n=22, 2.5 U/mouse) to an extent comparable to that of WT. Peripheral blood analysis at 24 hours after CLP showed the severe leukocytopenia and neutrophil decrease in KO mice, as compared to WT. In addition, formation of walled-off abscess was confirmed at the peri-cecal space in all the WT and KO mice alive even at the Day 7 of CLP, while such focal abscess formation was not found in mice died before the Day 3 of CLP.
Summary and Conclusions: Our results altogether indicate that VWF could play a role on the recruitment or accumulation of neutrophils for microbial killing at the local inflammatory focus. VWF-mediated platelet aggregate formation in peripheral capillary vessels then could shut down the local microcirculation, thereby blocking systemic microbial expansion as a crucial biological defense mechanism.

P411

A NOVEL ASSAY DEMONSTRATES PROCOAGULANT PLATELETS ARE INCREASED IN PATIENT UNDERGOING CORONARY ANGIOGRAPHY WITH DIFFERENTIAL EFFECTS BY ANTI-PLATELET AND ANTI-COAGULANT THERAPY

L. Pasalic[1,2,*], H. Campbell[1], E. Wing-Lun[3], P. Hogg[1], D. Connor[4,5], D. Muller[3,5], V. Chen[1,6]
[1]Prince of Wales Clinical School, University Of New South Wales, [2]Haematology, ICPMR, Pathology West, [3]Cardiology, St Vincent's Hospital, [4]Haematology Research Laboratory, St Vincent's Centre for Applied Medical Research, [5]St

Vincent's Clinical School, University Of New South Wales, [6]SEALS Pathology, Prince of Wales Hospital, Sydney, Australia

Background: Procoagulant platelets are a subset of activated platelets that support thrombin generation. Excess procoagulant platelets are involved in pathological thrombosis. Study of procoagulant platelets is hampered by the lack of specific and sensitive marker. Recently, we have developed a novel assay for procoagulant platelets using a cytoplasmic necrosis marker, GSAO that identifies necrotic/procoagulant platelets in whole blood flow cytometric assay.
Aims: We postulated that platelets from patients with coronary artery disease (CAD) have heightened propensity to stimulus-induced procoagulant phenotype, which may be modified by antiplatelet agents (APA).
Methods: Following an informed consent, 216 blood samples from 60 patients were collected during coronary angiography from radial/femoral and coronary arteries. Thrombin (2 U/mL) or a combination of thrombin (2 U/mL) and collagen (10 µg/mL) were used to induce procoagulant platelet in diluted re-calcified whole blood. Previously, we established a normal response profile to thrombin and thrombin/collagen stimulation in healthy controls. Linear mixed effects models were used to explore the effect of antiplatelet agents and the presence of angiographically-confirmed CAD on platelet procoagulant propensity.
Results: Compared to healthy controls, study participants undergoing coronary artery angiography had higher proportion of procoagulant platelets at baseline (4.1% *vs* 0.4%, P<0.0001) and in response to thrombin/collagen (31.7% *vs* 13.3%, P<0.0001). Controls and patients without CAD showed a marked synergistic increase in procoagulant platelet generation with dual agonist (thrombin/collagen) stimulation compared to either agonist alone. In contrast, patients with angiogram-confirmed CAD reached maximal procoagulant potential with thrombin stimulation alone. Aspirin alone had no effect on stimulus-induced procoagulant platelet subset, however patients on dual antiplatelet therapy (DAPT) demonstrated reduced thrombin/collagen-induced procoagulant platelets compared to no APA (OR 0.61, P=0.0295). Patients receiving intravenous unfractionated heparin showed marked reduction in procoagulant platelets regardless of the stimulus: thrombin (OR 0.32, P<0.0001) thrombin/collagen (OR 0.38, P=0.0001).
Summary and Conclusions: Compared to healthy volunteers, platelets in patients undergoing coronary angiography showed increased procoagulant potential, which was favorably modified by DAPT but not aspirin alone. Novel cytoplasmic necrosis marker, GSAO has potential as a biomarker in coronary disease.

P412

SUITABILITY OF THE CAPE BABOON IN HUMAN-TARGETED ANTI-PLATELET STUDIES

W. Janse Van Rensburg[1,*] P. Badenhorst[2], J. Roodt[3]
[1]Haematology and Cell Biology, [2]Internal Medicine, UNIVERSITY OF THE FREE STATE, [3]Haematology and Cell Biology, National Health Laboratory Service, BLOEMFONTEIN, South Africa

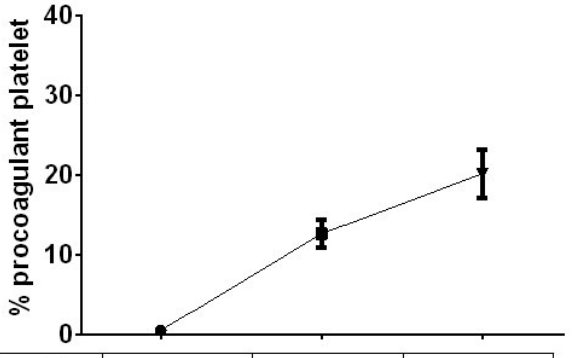
Background: Animal models play an integral part in the drug development process and are among other things used to test the pre-clinical safety and efficacy of anti-platelet agents. Non-human primates are considered to be the most suitable animal model for anti-platelet studies. However, limited data exist on the molecular make-up of some commonly used non-human primate species, such as the Cape baboon (*Papio ursinus*). For this reason, concerns are raised regarding the translatability of results obtained with these models to humans.
Aims: The aim of our study was to compare four commonly targeted platelet receptors ($P2Y_{12}$, GPIIb/IIIa, GPVI, and GPIbα) between the Cape baboon and human.
Methods: We performed light transmission aggregometry (LTA), surface-receptor quantification, and Sanger DNA sequencing on baboon platelets and compared it with normal human results.
Results: Baboon ADP-, arachidonic acid-, and collagen-induced platelet aggregation results were significantly different compared to normal human results, even with increased agonist concentrations. However, the differences in collagen-induced aggregation results were not clinically relevant because all except one result (at 8-µg/ml) fell within the normal human reference range. At double the highest human concentration for ristocetin (2.5-mg/ml) baboon platelets gave statistically similar results.
Baboon quantification results showed a 37%, 27% and 25.5% increase in GPIIb, GPIIIa, and GPIbα, respectively. GPVI quantification failed due to non-reactive monoclonal antibodies. P2Y12 quantification was not possible, as no commercial monoclonal antibodies were available at the time of the study.
The P2Y12 protein sequences were 98.8% similar. It differed by four amino acids, none of which have been described as functionally essential. The GPVI protein sequence showed 95% similarity. It included a 14 amino acid difference and a three amino acid deletion. One change was in a region where an amino acid change has been implicated in reduced collagen-induced platelet aggregation in humans. Two differences were directly adjacent to a collagen-binding amino acid. The deletion was within the signaling area of GPVI. Exon 28 of GPIIb failed to sequence. The GPIIb protein sequence for exon 1-27 was 98.2% similar and for exons 29-30 there was 98.3% similarity. There was an 18 amino acid difference. Only one conservative amino acid change was in the ligand-binding region. The GPIIIa protein sequence was 99.6% similar, with three amino acid changes. Again, only one conservative substitution was in the ligand-binding region. 54 amino acid changes were found in GPIbα. The protein sequences of the signal peptide, vWF-binding-, PEST/macroglycoprotein-, transmembrane-and cytoplasmic domains showed 93.8%, 89.4%, 57.9%, 90.5% and 95.0% similarity, respectively. 246 bases in the PEST/macroglycoprotein domain of GPIbα failed to sequence. However, they were in a notoriously variable region. However, no radical amino acid substitutions were found at functionally vital sites.
Summary and Conclusions: Sequentially and functionally baboon P2Y12, GPIIb/IIIa, and GPIbα is comparable to humans. Non-reactive antibodies and changes in critical amino acids caused the baboon GPVI to be not comparable to humans. For this reason, the Cape baboon is deemed a suitable animal model for the evaluation of human-targeted anti-platelet agents directed against P2Y12, GPIIb/IIIa, and GPIbα, but not against GPVI.

P413

CHARACTERIZATION OF PROCOAGULANT PLATELETS IN WHOLE BLOOD USING A NOVEL CELL DEATH MARKER

L. Pasalic[1,2,*] H. Campbell[1], P. Hogg[1], V. Chen[1,3]
[1]Prince of Wales Clinical School, University Of New South Wales, [2]Haematology, ICPMR, Pathology West, [3]SEALS Pathology, Prince of Wales Hospital, Sydney, Australia

Background: Procoagulant platelets are implicated in the pathogenesis of arterial thrombosis disorders including coronary events, ischaemic stroke and sepsis outcomes. However, our understanding of the contribution this platelet subset has been hampered by the lack of a suitable marker for clinical studies. We have previously reported that a novel cell death marker, GSAO, identifies the procoagulant platelet fraction in assays using washed human platelets.
Aims: Here we present a flow cytometry-based, non-lyse assay for detection of procoagulant platelets in whole blood, which reduces volume of blood required, improves throughput, and enables the interactions between platelets and leukocytes within a physiological matrix.
Methods: Following informed consent, blood was collected from healthy volunteers.15 µL of citrated blood was diluted in 96-well plate wells with a buffer (HBSS, pH 7.35) containing GPRP (2.5 mM), $CaCl_2$ (2.5 mM)±various agonist(s) to 50 µL. Incubation at room temperature was stopped after 10 min by adding 150 µL of HBSS. 20 µL aliquots were stained for 15 min at room temperature with GSAO AF647 (2 µM), CD62P PE (KO2.3), CD45 BUV395 (HI30), and CD41a BV510 (HIP8) in 100 µL final volume. Fixation with 2 volumes of PamFix for 5 min was followed by a single wash step with 10 volumes of HBSS with 0.35% HSA (HBSS/HSA). Resuspended cells were analysed on an LSRFortessa flow cytometer. The lowest FSC threshold was used to acquire 10,000 platelets defined as $CD41a^+/CD45^-$.
Results: At baseline, <1% of platelets showed the procoagulant phenotype. Thrombin (EC_{50} 0.8 U/mL) consistently induced largest PP subset (12.6%±5.1%) whereas collagen (EC_{50} 37 µg/mL) was significantly less potent (1.5%±0.4%). Compared to collagen, GPVI agonist, CRP induced somewhat stronger procoagulant response. However, the maximal procoagulant platelet response (15.8%±7.1%) was induced by a synergistic combination of submaximal doses of thrombin and collagen (Figure 1). The thrombin-induced response was replicated fully by PAR1 agonist TFLLR-NH_2 (EC_{50} 10.2 µM), and only partially by PAR4 stimulation with AYPGKF-NH_2 (EC_{50} 66.9 µM) indicating that the thrombin effect is PAR1 mediated. Stimulation with ADP up to 200 µM failed to induce any increase in PP subset consistent with the concept that the procoagulant response is induced by strong agonists.



Thrombin (2 U/mL)	-	+	+
Collagen (10 µg/mL)	-	-	+

Figure 1.

Summary and Conclusions: The whole blood procoagulant platelet assay makes it feasible to investigate the pathological roles of procoagulant platelets in in mouse models of disease and to explore the potential of GSAO as a biomarker of disease in large scale clinical cohorts including cardiovascular and sepsis settings.

P414

NO DIRECT ASSOCIATION BETWEEN ON-TREATMENT PLATELET REACTIVITY AND BLEEDING EVENTS FOLLOWING CORONARY INTERVENTION AND DUAL ANTIPLATELET THERAPY: A POST HOC ANALYSIS OF THE PRASFIT-ACS STUDY

M. Nishikawa[1,*] S. Miyazaki[2], Y. Ikeda[3], T. Isshiki[4], H. Ogawa[5], T. Kimura[6], H. Yokoi[7], M. Nakamura[8], S. Saito[9]
[1]Clinical Research Support Center, Mie University Hospital, Tsu, [2]Kinki Universaity School of Medicine, Osaka, [3]Waseda University, [4]Teikyo University Hospital, Tokyo, [5]Kumamoto Uiversity School of Medicine, Kumamoto, [6]Kyoto University School of Medicine, Kyoto, [7]Fukuoka Sanno Hospital, Fukuoka, [8]Toho University Ohashi Medical Center, Tokyo, [9]Shonan Kamakura General Hospital, Kamakura, Japan

Background: Few studies have examined the relationship between the pharmacodynamics of antiplatelet drugs and the risk of clinically significant bleeding following percutaneous coronary intervention for treating acute coronary syndrome (ACS).
Aims: We examined the associations between the pharmacodynamics of prasugrel and clopidogrel and the incidence of bleeding events in the acute and chronic phases after PCI.
Methods: We performed a post hoc analysis of the PRASFIT-ACS (PRASugrel compared with clopidogrel For Japanese patIenTs with ACS undergoing PCI) study of patients in whom platelet reactivity was determined as P2Y12 reaction units (PRU; VerifyNow® P2Y12 assay) or vasodilator-stimulated phosphoprotein-platelet reactivity index (VASP-PRI). Japanese patients were randomized to prasugrel (loading/maintenance dose: 20mg/3.75 mg/day) or clopidogrel (300mg/75mg/day), both in combination with aspirin, for 24–48 weeks. The bleeding outcome was a composite of TIMI major, minor, and clinically relevant bleeding.
Results: Overall, 66/685 (9.6%) and 65/678 (9.6%) of prasugrel-and clopidogrel-treated patients, respectively, experienced major, minor, or clinically relevant bleeding. PRU and VASP-PRI at 5–12 h or in steady state conditions (at 4 weeks) were not associated with the risk of bleeding in the acute (to day 3) or chronic (from day 4 to 14 days after treatment discontinuation) phases of treatment, respectively. The incidence of bleeding was not increased in patients with very low on treatment platelet reactivity (defined as PRU <85 or VASP-PRI <16).
Summary and Conclusions: No direct association observed in the pharmacodynamics of prasugrel and clopidogrel with the risk of bleeding in this cohort of Japanese ACS patients following PCI.

P415

CYSTATHIONINE BETA SYNTHASE (CBS) GENE 844INS68 POLYMORPHISM IN SICKLE CELL DISEASE PATIENTS: FREQUENCY OF VASO-OCCLUSIVE CRISIS

G.M. Ezzat[1,*] I. Youssry[2], S. Sofy, [3]S. Elgawhary[1]
[1]Clinical Pathology, Faculty of Medicine, Fayoum University, Fayoum, [2]Pediatric hematology & BMT unit, Cairo university, Faculty of Medicine, Cairo., [3]Clinical Pathology, Fayoum General Hospital, Fayoum, Egypt

Background: Sickle cell disease is (SCD) is a chronic hereditary hemolytic anemia characterized by a hypercoagulable and inflammatory state which can lead to vaso-occlusive episodes. Increased serum homocysteine level is an independent risk factor for thromboembolism and cardiovascular disease and is therefore of interest in sickle cell disease. The 844ins68 polymorphism, occurring on the Cystathionine Beta Synthase (CBS) gene which controls the CBS enzyme activity, is accompanied by hyperhomocysteinemia. This mutation, in homozygous or heterozygous state, lowers CBS enzyme activity and is thus considered an independent risk factor for artery occlusion.
Aims: To determine the frequency of the 844ins68 CBS gene polymorphism and its contribution to hyperhomocysteinemia and vaso-occlusive episodes in sickle cell anemia and sickle beta thalassemia patients.
Methods: Nineteen sickle cell anemia, 32 sickle beta-thalassemia and 2 sickle trait subjects together with 42 age and sex matched healthy controls were included after approval of the institutional ethical committee. All patients/guardians signed an informed consent. Fasting serum homocysteine level was measured using immunonephlometry. The CBS 844ins68 polymorphism was detected using conventional PCR.
Results: A significant increase in fasting serum homocysteine level (p-value <0.001) was found in subjects with either thehomozygous or heterozygous variant compared to wild type subjects. A significant increase in the frequency of vaso-occlusive crisis (VOC) was found in SCD patients exhibiting these variants (p-value =0.05). Positive correlation was found between fasting serum homocysteine level and frequency of VOC (r=0.36, p-value=0.009).
Summary and Conclusions: The 844ins68 polymorphism of the CBS gene is a risk factor for VOC and hyperhomocysteinemia in sickle cell disease.

P416

THE DANISH LYMPHOMA REGISTRY HAS A HIGH COVERAGE AND HIGH DATA QUALITY

B. Arboe[1,*] T.C. El-Galaly[2], M.R. Clausen[3], M.K. Nygaard[2], P.S. Munksgaard[2], D. Stoltenberg[4], J. Soenderskov[1], P. Brown[1]
[1]Department of Hematology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, [2]Department of Hematology, Aalborg University Hospital, Aalborg, [3]Department of Hematology, Aarhus University Hospital, Aarhus, [4]Department of Hematology, Copenhagen University Hospital, Herlev, Herlev, Denmark

Background: The Danish Lymphoma Registry, LYFO, prospectively includes all lymphoma patients that are diagnosed at Danish hematology departments. It was founded in 1982, and became nationwide from January 2000. It contains detailed information on more than 20,000 patients and is characterized by a very high coverage (>90%); however, the validity of LYFO has not previously been assessed in detail.
Aims: The purpose of this study is to validate data quality and coverage of LYFO.
Methods: A random sample of 3% (N=364) was made from all the patients in LYFO. In addition, four subtypes of lymphomas were validated in detail; CNS lymphomas (N=370), Diffuse Large B-Cell Lymphomas (N=159), Peripheral T-Cell Lymphomas N=141), and Hodgkin Lymphomas (N=672). For all patients date of diagnosis, histological subtype, ECOG performance status and Ann Arbor stage were validated. For each subgroup additional variables were included, *i.e.* treatment, relapse and lab test results. A total of 1,706 patients from the period 2000-2012 were included. The positive predictive values (PPV*s*) of selected variables were calculated for each subgroup and for the entire cohort of patients. Information from medical records was used as reference standard. Data coverage was tested by merging of LYFO with the Danish Cancer Registry (DCR) for the period 2000-2011.
Results: Table 1 shows the joined cohort validation (N=1706). PPV's were above 90% both in the joined cohort and for each subgroup, except for SR and Albumin, which only were validated for Hodgkin Lymphomas. DCR and LYFO contained information on 13,100 lymphoma patients; 11,350 patients appeared in both registries, 12,084 in LYFO and 12,366 in DCR, giving a coverage of 93.9% for LYFO, and 91.8% for DCR. For the 1,016 patients not registered in LYFO, 469 patients were never referred to a hematology department. For 357 patients without clinical lymphoma diagnosis, 105 patients had an unconfirmed pathology diagnosis and 82 patients were diagnosed by autopsy. Registration was missing in the remaining 190 patients. For the 734 patients only registered in LYFO, 56% had indolent lymphoma. Overall survival (OS) was significantly better for patients not registered in DCR, whereas patients not included in LYFO had significantly worse OS. For 10,452 of the 11,350 patients registered in both LYFO and DCR the date of diagnosis +/- one month was consistent (92.1%), in 581 patients the difference was 1-6 months, in 75 patients 6-12 months, and finally in 242 patients the difference exceeded one year.

Tabella 1. Validation for the joined cohort, N=1706

Variable	Number of correctly coded records/number of relevant records reviewed	PPV (%) (95% CI)
Histological subtype	1678/1701	98.7 (98.0;99.1)
Date of diagnosis (±14 days)	1605/1699	94.5 (93.3;95.5)
Ann Arbor Stage (1-2/3-4)	1588/1701	93.4 (92.1;94.5)
Performance status (0-1/2-4)	996/1022	97.5 (96.3;98.3)
LDH above upper limit	948/972	97.5 (96.4;98.4)
Extranodale involvement(0-1/>1)	346/363	95.3(92.6;97.3)
Planned treatment	354/363	97.5 (95.4;98.9)
Chemotherapy	879/885	99.3 (98.5;99.8)
Immunotherapy	799/815	98.0 (96.8;98.9)
Radiotherapy	831/858	96.9 (95.5;97.9)
Relapse	531/550	96.6 (94.7;97.1)
Albumin	521/599	87.0 (84.0;89.6)
SR	411/531	77.4(73,6;80.9)

Summary and Conclusions: The information registered in LYFO is characterized by high validity with PPV's of 77-100% and a high coverage of more than 93%. The fact that only patients in contact with specialized hematology departments are registered in LYFO explains the majority of the discrepancy between LYFO and DCR, since only 190 patients referred to a hematology department, were not registered. For patients missing in DCR it is a plausible explanation that the majority had indolent lymphomas with sparse inpatient contacts. This is supported by the fact that the median OS was dismal for patients registered in DCR only. In conclusion, LYFO is a unique nationwide clinical database characterized by high validity, good coverage and prospective data entry. Therefore LYFO is a valuable resource for future lymphoma research.

P417

QUALITY OF LIFE IN RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA PATIENTS TREATED WITH LENALIDOMIDE *VS* INVESTIGATOR'S CHOICE: MCL-002 (SPRINT) TRIAL

S. Rule[1,*] L. Arcaini[2], J. Walewski[3], A. Skotnicki[4], D. Belada[5], J. Mayer[6], J. Alexeeva[7], B. Afanasyev[8], A. Kuzmin[9], W. Jurczak[10], K. Kaplanov[11], S. Voloshin[12], J. Radford[13], S. Le Gouill[14], T. Biyukov[15], M. Patturajan[16], M.L. Casadebaig-Bravo[17], D. Mahmoud[18], X.H. Hu[18], M. Trněný[19]
[1]Derriford Hospital, Plymouth, United Kingdom, [2]Fondazione IRCCS Policlinico San Matteo & Department of Molecular Medicine, University of Pavia, Pavia, Italy, [3]Maria Sklodowska-Curie Memorial Institute and Oncology Centre, Warsaw, [4]Jagiellonian University Medical College, Krakow, Poland, [5]Charles University Hospital and Faculty of Medicine, Hradec Králové, [6]University Hospital Brno, Brno, Czech Republic, [7]Federal Medical Research Center, [8]First Pavlov State Medical University of St. Petersburg, St. Petersburg, [9]Republican Clinical Oncology Dispensary, Kazan, Russian Federation, [10]Jagiellonian University, Krakow, Poland, [11]Volgograd Regional Clinical Oncology Dispensary Number 1, Volgograd, [12]Russian Research Institute of Hematology and Transfusion, St. Petersburg, Russian Federation, [13]The University of Manchester and The Christie NHS Foundation Trust, Manchester, United Kingdom, [14]CHU Nantes, Nantes, France, [15]Celgene International Sàrl, Boudry, Switzerland, [16]Clinical Research and Development, Celgene Corporation, Summit, [17]Celgene International Sàrl, Boudry, [18]Celgene Corporation, Summit, United States, [19]Charles University Hospital, Prague, Czech Republic

Background: Measurement of health-related quality of life (QoL) is especially important in patients with relapsed/refractory (R/R) mantle cell lymphoma (MCL), as they generally receive multiple lines of therapy over the course of their disease. The European multicenter MCL-002 (SPRINT) phase II study was the first randomized study of lenalidomide *vs* investigator's choice (IC) in R/R MCL patients with ≤3 relapses on prior therapy and who were ineligible for intensified treatment or stem cell transplantation.
Aims: Examine health-related QoL in R/R MCL patients receiving lenalidomide *vs* IC.
Methods: Patients were randomized 2:1 to receive lenalidomide (25 mg/day on days 1-21 of each 28-day cycle until progressive disease or intolerability *vs* single-agent IC (chlorambucil, cytarabine, fludarabine, gemcitabine, or rituximab). As a planned secondary study endpoint, QoL was measured using the EORTC QLQ-C30 at baseline, after cycles 2, 4, 6, and 8, and at treatment discontinuation. EORTC QLQ-C30 included 5 functional domains, 9 symptom scales, and 1 global health status/QoL scale. Changes from baseline QoL score at each visit for the primary (global health status/QoL) and secondary domains (physical function and fatigue) and their 95% confidence intervals were calculated. A mixed model was employed to analyze differences in mean domain/scale scores between the treatment arms to account for repeated measurements of QoL during follow-up visits. Patients with ≥10 percentage point change (clinically meaningful) for each domain/scale at one or more visits were compared between the two groups using the Chi-square test.
Results: 254 patients (lenalidomide n=170, IC n=84) were enrolled in the trial. QoL data completion declined from 93% at screening to 51% at treatment discontinuation during the course of the study, with higher non-compliance rates typically seen among IC than among lenalidomide patients. QoL was maintained (non-deterioration: no worsening >10 points) with lenalidomide from baseline through last treatment cycle for evaluated primary and secondary QoL domains. Patients treated with lenalidomide reported similar QoL *vs* IC single agents across all domain/scale scores and at each follow-up visit. A trend towards higher rates of clinically meaningful improvement in QoL was observed in lenalidomide treated patients across most function and symptom domains/scales at one or more follow-up visits. Statistically significant QoL differences (≥10%) comparing lenalidomide *vs* IC treatment arms were identified for physical function (24% *vs* 8%, *P*=0.003) and pain (29% *vs* 18%; *P*=0.047).
Summary and Conclusions: Patients with R/R MCL maintained their QoL while receiving lenalidomide despite a longer duration of treatment compared with single agent IC therapy. In addition, patients receiving lenalidomide experienced higher rates of clinically meaningful improvement in QoL for physical function and pain.

P418

QUALITY OF LIFE AND SYMPTOM PROFILE IN LYMPHOMA PATIENTS IN COMPLETE REMISSION AFTER AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION (AHSCT)

D. Fedorenko[1], V. Melnichenko[1], N. Mochkin[1], K. Kurbatova[2], T. Ionova[1,*]
[1]Hematology, National Pirogov Medical Surgical Center, Moscow, [2]Biostatistics, Multinational Center for Quality of Life Research, Saint-Petersburg, Russian Federation

Background: It is now clearly established that cure or control of the underlying malignancy is not necessarily accompanied by full restoration of health or quality of life (QoL) in long-term survivors. Self-reported QoL and symptom assessment may be a useful tool to identify patient benefits and risks of AHSCT at long-term follow-up.
Aims: We aimed to examine QoL in lymphoma patients in complete remission at long-term follow-up after AHSCT as compared with population norms and to evaluate symptom profile in this patient population.
Methods: A total of 80 patients with lymphomas (non-Hodgkin lymphomas-36, Hodgkin lymphoma-44) in complete remission after AHSCT with the follow-up of at least 12 months were enrolled in the study. Mean of follow-up period was 18 months. Mean age-34.6 yrs (SD=9.9); male/female 38/42. QoL was assessed using generic questionnaire SF-36; for symptom assessment MDASI was used. To compare patient population with normative data the sample from population norm (PN) data base adjusted to age and gender (n=72) was used. For comparisons t-test for independent samples or Mann-Whitney test was used. Distribution of patients according to the grades of QoL impairment was analyzed: no QoL impairment (Integral QoL index similar to the one in normative population sample), mild (25% decrease from a PN), moderate (25-50% decrease), severe (50-75% decrease) and critical (>75% decrease).
Results: QoL parameters in lymphoma survivors were similar to the ones in normative population for the majority of scales: physical functioning-85.4 *vs* 85.3, role-physical functioning-74.0 *vs* 77.0, bodily pain-80.4 *vs* 80.0, general health-63.9 *vs* 64.0, vitality-68.9 *vs* 65.3, social functioning-86.8 *vs* 86.0, role-emotional functioning-85.6 *vs* 87.0, mental health-74.0 *vs* 70.0. No statistically significant differences between patient group and normative population were obtained. In the most cases patients experienced mild (ratings-1–4) symptoms; 22 % of patients experienced at least one moderate-to-severe (ratings ³5) symptom. QoL parameters were significantly lower ($p<0.001$) in the patient group with moderate-to-severe symptoms as compared with the ones who did not have moderate-to-severe symptoms. The majority of patients (n=58; 73.4%) had no QoL impairment; 7 patients (8.8%) exhibited mild QoL impairment, 7 patients (11.4%)-moderate QoL impairment; and 5 patients (6.4%)-severe QoL impairment. There were no patients with critical QoL impairment. The common symptoms in lymphoma survivors were sleep disturbance (70%), fatigue (67%), memory loss (55%), shortness of breath (52%), numbness (49%), and sadness (39%). Severity of fatigue and sleep disturbance was 1.1 and 1.4 in patients with no QoL impairment, and 5.1 and 4.5 in the group with different grades of QoL impairment, respectively.
Summary and Conclusions: In conclusion, lymphoma patients in complete remission at the mean follow-up of 18 months after ASHT had QoL parameters similar to normative data. The vast majority of patients exhibited either no or mild to moderate QoL impairment. The most common symptoms in lymphoma survivors were sleep disturbance, fatigue, memory loss, and shortness of breath. In the majority of cases they were of mild severity. The subgroup of patients with moderate-to-severe symptoms was identified; these patients experienced significant QoL impartment. Clinical self-reported symptom assessment in lymphoma patients in complete remission after ASHCT provides an important opportunity to promote proactive management of transplant-related side effects and maintain or improve their QoL.

P419

GERMAN PATIENT AND PHYSICIAN PREFERENCES FOR RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA TREATMENT OUTCOMES: A DISCRETE CHOICE EXPERIMENT

J. Eriksson[1,*] E. Landfeldt[1], S. Ireland[2], P. Musingarimi[3], C. Jackson[4], E. Tweats[4], M. Gaudig[5]
[1]MAPI, Stockholm, Sweden, [2]Janssen EMEA Business Intelligence, [3]Janssen Health Economics & Market Access EMEA, High Wycombe, [4]Adelphi Research UK, Bollington, United Kingdom, [5]Janssen Health Economics & Market Access EMEA, Neuss, Germany

Background: Despite the availability of a wide number of treatments for relapsed/refractory (r/r) mantle cell lymphoma (MCL), no standard of care has emerged. There are no studies evaluating preferences for treatment outcomes for r/r MCL.
Aims: This study was a discrete choice experiment (DCE) designed to elicit preferences for r/r MCL treatment outcomes among patients and physicians experienced in treating MCL in Germany.
Methods: 6 treatment attributes with 3 levels each were identified through lit-

erature review and qualitative interviews with 6 hematologists and 5 r/r MCL patients; overall survival (OS; Levels: 3,2,1 years), progression-free survival (PFS; 2,1,0.5 years;), fatigue (no to mild, mild relieved by rest, mild not relived by rest), nausea (no, mild, moderate), risk of serious infection (low, moderate, high), treatment administration (oral pill daily at home, monthly infusion at hospital, weekly infusion at hospital). The mean relative attribute importance was assessed in a DCE using a Hierarchical Bayes model. Patients were asked to base choices on their own preferences. Physicians were asked to make their choices as if they were patients. 19 r/r MCL patients and 50 physicians completed the online DCE survey.
Results: The analysis of mean relative attribute importance revealed that OS (38%), treatment administration (17%) and risk of serious infection (16%) were the most important treatment choice attributes to r/r MCL patients, followed by PFS (11%), fatigue (10%) and nausea (8%). The most important attributes to physicians were OS (44%), risk of serious infection (16%) and PFS (15%), followed by fatigue (11%), treatment administration (8%) and nausea (7%).
Summary and Conclusions: OS is the most important treatment attribute to both German r/r MCL patients and treating physicians, however, the relative importance of the other attributes differ between patients and physicians. Our results suggest the importance of mode of administration to patients may be underestimated by physicians. The results may be used to guide what treatment endpoints to include in clinical trials for the purpose of designing trials that reflect the needs of the patients.

P420

COST EFFECTIVENESS OF BORTEZOMIB, RITUXIMAB, CYCLOPHOSPHAMIDE, DOXORUBICIN AND PREDNISONE FOR THE FIRST-LINE TREATMENT OF MANTLE CELL LYMPHOMA PATIENTS NOT ELIGIBLE FOR STEM CELL TRANSPLANTATION

M. van Keep[1,*] K. Gairy[2], D. Seshagiri[3], P. Thilakarathne[4], D. Lee[5]
[1]BresMed, Utrecht, Netherlands, [2]Janssen-Cilag, High Wycombe, United Kingdom, [3]Janssen-Cilag, Neuss, Germany, [4]Janssen-Cilag, Beerse, Belgium, [5]BresMed, Sheffield, United Kingdom

Background: Mantle cell lymphoma (MCL) is a rare type of non-Hodgkin's lymphoma, incorporating the worst aspects of aggressive and indolent lymphoma subtypes; it progresses quickly and is typically incurable. In the UK, patients unsuitable for haematopoietic stem cell transplantation (HSCT) primarily receive rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP). Although most patients initially respond to this therapy, the durability of these responses is limited, and the majority of patients relapse within 2 years. The LYM-3002 trial demonstrated that the use of bortezomib, rituximab, cyclophosphamide, doxorubicin and prednisone (VR-CAP) close to doubled progression-free survival (PFS) relative to R-CHOP (24.7 *vs* 14.4 months; HR=0.63, p<0.001). Duration of overall response for VR-CAP was more than double that of R-CHOP (median of 36.5 *vs* 15.1 months), resulting in an increase in treatment free interval of almost 20 months *vs* R-CHOP (median of 40.6 *vs* 20.5 months).
Aims: To assess the cost effectiveness of VR-CAP compared with R-CHOP as first-line treatment for patients with MCL unsuitable for HSCT, from the perspective of the UK National Health Service (NHS).
Methods: A cost-effectiveness model was constructed based upon line of treatment, progression status and survival. The model has a 20-year time horizon, extrapolating LYM-3002 clinical trial data using parametric models that were fit to PFS and overall survival (OS) Kaplan–Meier curves. The patient population was assumed to be the same as in the LYM-3002 trial with demographic data taken from US, Canadian and Western European patients. Utilities were derived from EQ-5D data from the clinical trial, supplemented with data from published literature for long-term health status. Costs were included for drugs, administration, adverse events and medical resources such as blood transfusions and haematologist visits. Drug dosing and concomitant medications, adverse events, blood transfusions and second-line treatment information were taken from the LYM-3002 trial data. Other resource use, such as blood tests and haematologist visits, was based upon UK clinician advice. Probabilistic and structural sensitivity analyses were conducted to assess the uncertainty of the results.
Results: Total lifetime costs in the VR-CAP arm were £45,185 compared to £27,460 in the R-CHOP arm. Treatment with VR-CAP resulted in an increase in life years (7.67) compared to R-CHOP (6.66). The same is seen for quality-adjusted life years (QALYs), 4.14 and 3.35 for VR-CAP and R-CHOP, respectively. Thus the additional cost associated with VR-CAP is partially offset by additional benefit; resulting in an incremental cost-effectiveness ratio of £22,227. In probabilistic sensitivity analysis, there was an 83% chance that VR-CAP was cost effective at the standard UK threshold of £30,000 per QALY gained. The model was most sensitive to assumptions regarding the extrapolation of PFS and OS and utility associated with post-progression from second-line treatment.

Tabella 1.

Model results	VR-CAP	R-CHOP	Difference
Clinical outcomes			
Median PFS, months	26.5	15.0	11.5
Median predicted OS, months	75.0	62.6	12.4
Mean predicted life years (over a patient lifetime)	7.67	6.66	1.01
QALYs	4.14	3.35	0.80
Cost outcomes			
Medication and administration	£27,195	£9,290	£17,905
Monitoring	£11,715	£10,741	£974
Next line of treatment	£6,275	£7,429	-£1,155
Total	£45,185	£27,460	£17,725
ICER – Cost/life year	£17,631		
ICER – Cost/QALY	£22,227		

Key: ICER, incremental cost-effectiveness ratio; OS, overall survival; PFS, progression-free survival; QALYs, quality-adjusted life years; R-CHOP, rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone; VR-CAP, bortezomib, rituximab, cyclophosphamide, doxorubicin and prednisone.

Summary and Conclusions: Based upon data from the LYM-3002 trial, VR-CAP is a cost-effective treatment for previously untreated patients with MCL who are unsuitable for HSCT in the UK.

P421

COST COMPARISON OF HEMATOPOIETIC STEM CELL TRANSPLANTATION AND CONVENTIONAL THERAPY FOR PATIENTS WITH THALASSEMIA MAJOR IN CHINA

W. Tan[1], C. Li[1,*] X. Wu[1], Y. He[1], X. Feng[1], J. Liao[1], H. Liu[1], W. Xu[1], Y. Ren[1]
[1]Pediatrics, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: The conventional therapy (CT) for b-thalassemia major (TM) consists of regular transfusion and iron-chelating therapy for lifetime. However, the high cost of CT can lead to poor compliance. Hematopoietic stem cell transplantation (HSCT) provides an alternative option for TM patients. To our knowledge, recent data of China has not been available in the literature on cost comparison between HSCT and CT, leading to debate on selection of treatment for patients with TM.
Aims: To compare the lifetime undiscounted mean cost (UMC) of HSCT with UMC of CT in the TM patients and to investigate the relationship of the clinical features to cost outcomes of HSCT.
Methods: We estimated UMC of 93 TM-HSCTs in 2011 with a median age of 6 years (range, 3-16) and a median follow-up time of 3.6 years (range, 3.1-4.1). The relationship between the UMC of HSCT and patient characteristics were analyzed. The UMC of 93 TM-HSCTs was compared with UMC of CT based on total 1526 TM patients. Age was used as matching variant, and the mean cost of each age was calculated, then cumulative cost was further adjusted for age in patients.
Results: UMC of TM-HSCT was CNY (Chinese Yuan) 235,254/USD 37,664 (95% confidence interval (CI) CNY208,081-262,719/USD 33,293-42,035) with mean hospital stay of 60.5 days (95% CI 49-71). With the addition of the UMC of CNY 345,317/USD55,251 for 20 years of follow-up, total undiscounted lifetime (55 years) cost of TM-HSCT were CNY 465,975/USD 74,602. However, the corresponding costs of patients undergoing CT were CNY 2,101,488/ USD336,238 and CNY 7,489,519/ USD1,198,323 respectively. Patient characteristics were helpless to predict the costs. HLA-mismatched transplants increased significantly UMC of HSCT than matched transplants (USD 35,818 *vs* USD 52,771; p<0.001). The development of GVHD were associated with higher costs (USD 63,933 *vs* USD 44,547; p =0.001).

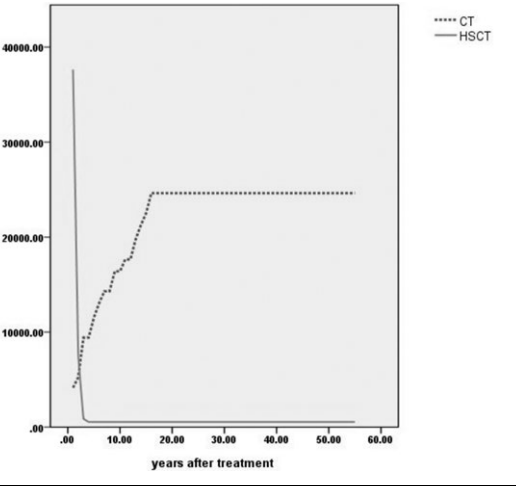

Figure 1.

Summary and Conclusions: Cost comparison of HSCT and CT suggests that HSCT is an efficient and high cost-effective treatment for TM patients. Mismatched donor transplant increases the cost of HSCT.

P422

CROSS-CULTURAL DEVELOPMENT OF FOUR EORTC QUESTIONNAIRES TO ASSESS QUALITY OF LIFE IN PATIENTS WITH HODGKIN LYMPHOMA, NON-HODGKIN LYMPHOMA AND CHRONIC LYMPHOCYTIC LEUKAEMIA

S. Malak[1,*] S. Oerlemans[2], F. Efficace[3], A. Bredart[4], C. Kyriakou[5], L. Daniëls[6], C. Creutzberg[6], K. Cocks[7], M. Sztankay[8], S. Pallua[8], G. Caocci[9], S. Molica[10], W. Chie[11], L. van de Poll-Franse[2]
[1]Hematology, Hôpital René Huguenin-Institut Curie, Saint-Cloud, France, [2]Research department, The Netherlands Comprehensive Cancer Organization, Eindhoven and Tilburg University, Netherlands, [3]Data Centre, Italian Group for Adult Hematologic Diseases (GIMEMA), Rome, Italy, [4]Unité De Psycho-Oncologie, Institut Curie, Paris, France, [5]Service Trust, North West London Hospitals National Health, Middlesex, United Kingdom, [6]Department of Radiotherapy, Leiden University Medical Centre (LUMC), Leiden, Netherlands, [7]Trials Unit, University of York, York, United Kingdom, [8]Department of Psychiatry and Psychotherapy, Innsbruck Medical University, Innsbruck, Austria, [9]Hematology, Department of Medical Sciences, University of Cagliari, Cagliari, [10]Ematologia, Azienda Ospedaliera Ciaccio, Catanzaro, Italy, [11]Institute of Epidemiology and Preventive Medicine, National Taiwan University, Taipei, Taiwan, ROC

Background: Advances in the management of patients with lymphoma or chronic lymphocytic leukaemia (CLL) have changed the survival outcomes dramatically the last two decades. The number of new agents for these patients is increasing and quality of life (QoL) is becoming a primary objective. Unfortunately, questionnaires to assess disease-specific QoL among patients with Hodgkin lymphoma (HL), high-grade non-Hodgkin lymphoma (HG-NHL), low-grade non-Hodgkin lymphoma (LG-NHL) and CLL are lacking.
Aims: This study describes the combined development of four disease-specific QoL questionnaires for patients with HL, HG-NHL, LG-NHL and CLL to supplement the European Organization for Research and Treatment of Cancer (EORTC)-QLQ C30 core cancer questionnaire.
Methods: Questionnaire development was conducted according to guidelines from the EORTC Quality of Life Group. Phase I comprised generation of QoL issues relevant to patients. Phase II included operationalization and assessment of item relevance. In phase III, items were pretested in a cross-cultural sample representing all four malignancies to assess issues such as comprehensibility and intrusiveness of items. Data were analysed per malignancy.
Results: Seventy-five QoL issues were identified through focus groups and systematic literature searches. Semi-structured interviews with 80 health-care professionals and with 245 patients (75 HL, 66 HG-NHL, 41 LG-NHL and 63 CLL) resulted in a provisional module of 39 items representing items relevant for all or at least one of the four malignancies. In phase III this was further tested in 67 HL, 117 HG-NHL, 67 LG-NHL and 86 CLL patients with different phases of disease and treatment from five European countries. Results from the interviews, clinical experiences and statistical analyses resulted in a questionnaire with 27 items for HL (EORTC QLQ-HL27), 29 items for HG-NHL (EORTC QLQ-NHL-HG29), 20 items for LG-NHL (EORTC QLQ-NHL-LG20) and 17 items for CLL (EORTC QLQ-CLL17). The items are conceptualized in several multi-item scales: symptom burden, physical condition/fatigue, worries/fears health and functioning, emotional impact (not in the CLL module), neuropathy (only in the HG-NHL module).
Summary and Conclusions: This study provides four modules for use in clinical trials and observational research in conjunction with the EORTC QLQ-C30 for assessment of QoL for patients with HL, HG-NHL, LG-NHL and CLL. Phase IV of the questionnaire development will start in 2015 and comprises international field testing of the four questionnaires, *i.e.* EORTC QLQ-HL27, QLQ-NHL-HG29, QLQ-NHL-LG20 and QLQ-CLL17.

P423

INCREASED TREATMENT COST ASSOCIATED WITH MANTLE CELL LYMPHOMA DISEASE PROGRESSION

R.L. Wade[1,*] H.X. Hu[2], J.Y. Chen[1], D. Mahmoud[2], S. Le Gouill[3]
[1]Health Economics and Outcomes Research, IMS Health, Plymouth Meeting, [2]Global Market Access, Celgene Corporation, Summit, United States, [3]Haematology Department, CHU Nantes and UMR892 INSERM, Nantes, France

Background: While recent advances in the treatment of mantle cell lymphoma (MCL) have increased remission rates and time to relapse, the cost of treatment has not been well described.
Aims: This study evaluated the cost of care across the first, second, and third treatment lines (1L/2L/3L) in patients with MCL.
Methods: MCL patients were identified in the IMS PharMetrics Plus database containing de-identified health plan claims on >100 million U.S. lives. All patients had ≥2 MCL claims (ICD-9-CM: 200.4X) at least 30 days apart between 2008 and 2012, no MCL claim 6 months prior to the initial claim (index), and continuous enrollment in the health plans for ≥3 months post-index. Monthly costs were calculated from the beginning of each line of therapy and up to 24 months post-index. Patients receiving autologous stem cell transplant (ASCT) during 1L treatment were analyzed separately. The 1L was defined as a MCL treatment with all agents administered within 90 days of the index and a new line was determined when restarting therapy following a 90 day gap in a previous line, or addition of a new agent >90 days from the start of the previous line.
Results: A total of 872 patients (mean age 63 years, 72.0% male) were selected, of whom 172 (19.7%) received ASCT, 334 (38.3%) and 119 (13.6%) were followed to the end of 2L and 3L, respectively. For patients who relapsed/were refractory while on 1L treatment, the median TTNT was 350 days for pts after ASCT (n=54) and 422 days for non-ASCT pts from initiation of 1L treatment to the beginning of 2L (n=280). For patients receiving ASCT, the mean monthly cost between diagnosis and the start of 2L treatment was $12,565 with the highest mean monthly cost occurring between months 4 and 6 ($43,703). Pharmacy, inpatient, and outpatient costs accounted for approximately 26%, 47%, and 27%, respectively. For non-ASCT patients, the mean monthly cost following diagnosis to the next line treatment was $5,964, with the highest mean monthly cost occurring in the first 3 months ($24,363). For these patients, pharmacy, inpatient, and outpatient costs accounted for approximately 43%, 27%, and 30%, respectively. For all patients, monthly 1L costs stabilized at about 16 months to approximately $4,000. Upon initiating 2L and 3L therapy, monthly costs rose to $21,660 and $22,718 over the first three months, respectively, then followed by a pattern of reduction similar to what was seen in 1L treatment. For 2L and 3L therapy, pharmacy costs made up approximately 45% of all costs, with inpatient and outpatient costs each accounting for 25%>30% of remaining costs. Inpatient costs rose to 47% of total costs during months 4-6 after the initiation of 3L therapy.
Summary and Conclusions: Treatment costs for MCL were the highest during the first 3 months of treatment in each line of therapy then declined and stabilized to about 25%>30% of the initial costs. This pattern suggests that prolongation of time to progression may yield economic as well as humanistic benefits. Patients receiving ASCT incurred more than twice the expense compared with those not receiving ASCT during 1L therapy.

P424

A MODEL-BASED ASSESSMENT OF THE BENEFITS AND RISKS OF PONATINIB VERSUS BOSUTINIB IN THIRD-LINE TREATMENT OF CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML)

S. Cartier[1], A. Parthan[2], L. McGarry[3,*] M. Weinstein[4]
[1]Optum, Burlington, Canada, [2]Optum, Sunnyvale, [3]Ariad, [4]Harvard School of Public Health, Boston, United States

Background: Ponatinib is a potent oral 3rd-generation tyrosine kinase inhibitor (TKI) with evidence of better efficacy than 2nd-geneation TKIs in 3rd-line treatment of CML (Lipton 2014), but with potentially higher risk of vascular occlusive adverse events (AEs). Bosutinib, a 2nd-generation TKI, differs in both efficacy and characteristic AEs.
Aims: A model was developed to quantify the benefit-risk difference between ponatinib and bosutinib for CP-CML patients after failure of 2 previous TKIs, in terms of survival and quality-adjusted survival.
Methods: The Excel-based model uses estimates of treatment response, in terms of complete cytogenic response (CCyR) at 12 months, and AEs to quantify the overall benefit-risk difference with ponatinib *vs* bosutinib using common metrics: outcomes of survival and quality-adjusted survival are measured in life-years (LYs) and quality-adjusted life-years (QALYs) accrued over patients' remaining lifetimes. Quality of life (QoL) is quantified using health-state utilities, where each health state is assigned a value from 0 (death) to 1 (perfect health). A decision tree captures the risk of transient AEs, assumed to occur immediately upon start of treatment that may cause death or short-term decrements to QoL, but if not fatal, have no long-term consequences. Chronic AEs occur either immediately or over time and have both short-and long-term consequences. AEs of interest are grade 3 or 4 affecting survival and/or QoL that differed between treatments in clinical trials, including cardiovascular, hematologic, and gastrointestinal AEs, as well as blindness and amputation. In an ensuing Markov model, patients are assigned to health states based on treatment response and their most serious previous chronic AE. In each 3-month Markov cycle, patients are at risk of incident chronic AEs and of dying from prior or incident chronic AEs, CML, or age-specific other causes. Each cycle, patients accrue LYs, and QALYs reflecting response status, less any QoL loss for their most serious chronic AEs. In the base case, the model applies an evidence-based difference in utility between responders and non-responders, but assumes no survival advantage for responders. Treatment response was estimated from a recent synthesis of CML studies, estimating 60% response for ponatinib and 22% for bosutinib. Rates of AEs were derived from published literature and prescribing information. Utility decrements for responders/non-responders and AEs, and mortality for AEs were estimated from published literature. Extensive sensitivity and scenario analyses were conducted.
Results: In the base case assuming response confers no survival advantage, patients receiving ponatinib *vs* bosutinib accrue 0.43 fewer LY (9.5 *vs* 9.9, respectively) of survival. When LY are adjusted for QoL, ponatinib provides an

additional 0.24 QALYs *vs* bosutinib (Figure). In scenario analyses where response is assumed to confer a 5% survival advantage, patients on ponatinib are estimated to survive an additional 0.37 years (10.8 *vs* 10.4 LY, respectively) *vs* bosutinib and accrue 7.9 *vs* 7.0 QALYs.

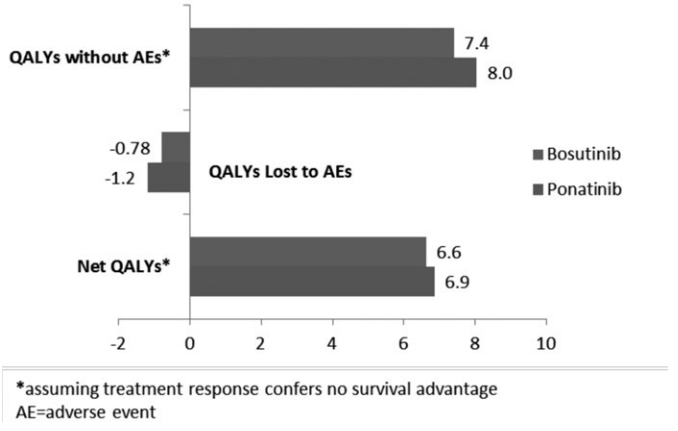

Figure 1. Estimated lifetime quality-adjusted life-years (QALYs) for 3rd-line CP-CML patients treated with ponatinib versus bosutinib.

Summary and Conclusions: Given the assumptions and limitation of this analysis, we found that in 3rd-line CP-CML patients, the positive effect of ponatinib' s higher efficacy on quality of life more than offsets losses due to AEs, even if no survival advantage for treatment responders was assumed. This analysis highlights the need to consider the negative effect of non-response as well as AEs on patients' quality of life and survival when evaluating alternative treatments in CML.

P425

A COST-UTILITY ANALYSIS OF DEFERIPRONE COMPARED TO DESFERRIOXAMINE AND DEFERASIROX FOR THE TREATMENT OF CHRONIC IRON OVERLOAD IN PEOPLE WITH THALASSAEMIA: AN ITALIAN ADAPTATION OF THE UK MODEL

A. Meloni[1,*] M.G. Neri[1], A. Bentley[2], A. Hanif[2], A. Pepe[1]
[1]CMR Unit, Fondazione G. Monasterio CNR-Regione Toscana, Pisa, Italy, Pisa, Italy, [2]Abacus International, Oxfordshire, United Kingdom

Background: In thalassemia major (TM) three chelators are available to treat chronic iron overload due to blood transfusions: subcutaneous desferrioxamine (DFO), oral deferiprone (DFP) and oral deferasirox (DFX).

Aims: This study evaluated the relative cost effectiveness of the three chelators in monotherapy.

Tabella 1.

	Rx cost p.a.(€)	Administration costs p.a. (€)	Monitoring costs p.a. (€)	AE costs p.a. (€)	Total costs (€)	QALYs
Scenario 1: iron chelators impact cardiac morbidity and mortality. Time horizon: 5 years.						
DFP	24,401	0	1,439	0	25,840	3.921
DFX	151,546	0	1,378	0	152,924	3.825
DFO	78,683	16,735	1,106	0	96,524	3.242
Scenario 2: iron chelators impact only cardiac mortality. Time horizon: 5 years.						
DFP	24,401	0	1,439	0	25,840	3.925
DFX	151,546	0	1,378	0	152,924	3.851
DFO	78,683	16,735	1,106	0	96,524	3.263
Scenario 3: iron chelators impact only cardiac morbidity. Time horizon: 5 years.						
DFP	24,401	0	1,439	0	25,840	3.921
DFX	151,546	0	1,378	0	152,924	3.899
DFO	78,683	16,735	1,106	0	96,524	3.304
Scenario 4: iron chelators are all equivalent. Time horizon: 1 year. No discount.						
DFP	5,222	0	308	0	5,530	0.840
DFX	33,054	0	307	0	33,360	0.840
DFO	17,162	3,650	241	0	21,053	0.712

Methods: Patients enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) project and who received monotherapy with a single iron chelator for at least 18 consecutive months were evaluated for assessment. The cost-effectiveness model was adapted from the previously published UK model (Bentley A *et al.* Pharmacoeconomics 2013;31:807–22). Based on literature data, it was assumed that all three iron chelators had comparable efficacy in controlling serum ferritin and liver iron concentration, wherea 4 different efficacy-based scenarios were explored in respect to cardiac morbidity and mortality using Markov-type models. Treatment costs reflect the Italian market: Incremental costs and quality-adjusted life-years (QALYs) were calculated for each iron chelator, with cost effectiveness expressed as incremental cost per QALY.
Results: Within the MIOT project, none of the adverse events (AE) considered in the UK model (neutropenia, agranulocytosis, Franconi syndrome, hepatitis) were detected for the 193 TM patients who had been received the same chelator for at least 18 months and were considered as reference group. The table shows costs and QALYs in the different modelled scenarios. For the first three scenarios a 5-year period was considered per patient while for the last scenario a 1-year time horizon was used and the discount rate of 3.5% was not applied. DFP was the dominant strategy in all scenarios, providing greater QALY at a lower cost.
Summary and Conclusions: The results of this analysis indicate that, from an Italian perspective, DFP is the most cost-effective treatment available for managing chronic iron overload in β-thalassaemia patients. Use of DFP in these patients could therefore result in substantial cost savings.

Background: HDT followed by ASCT remains the gold standard for treatment of NDMM patients who are able to tolerate the procedure. Following ASCT, consolidation with novel agents for a fixed time period (or number of cycles) can improve outcomes. However, there are currently few published data on BTZ consolidation therapy, although a study by the Nordic Myeloma Study Group has reported results in BTZ-naïve patients (Mellqvist *et al.* Blood 2013).
Aims: The results from two large randomized controlled phase 3 studies were combined to investigate BTZ consolidation or OBS in patients with NDMM both with and without prior BTZ treatment.
Methods: MMY3012 (NCT00416273; 222 patients aged ≤60 yrs) and MMY3013 (NCT00416208; 158 patients aged 61-75 yrs) recruited adults with NDMM who underwent induction therapy followed by ASCT. Patients were randomized 1:1 to receive BTZ consolidation (1.6 mg/m² IV days 1, 8, 15, 22; 4x35-day cycles) or OBS, 60-120 days after ASCT. The primary endpoint was progression-free survival (PFS) from the start of induction; secondary endpoints included response rate, overall survival (OS), and safety. Factors affecting PFS were also assessed by post-hoc multivariate analysis. Responses were assessed per EBMT response criteria, with VGPR as an additional category. Adverse events (AEs) were graded per NCI-CTCAE v3.0.
Results: In 371 randomized patients, median age was 59 yrs (35-76); 62% were male, 14%/84% were Durie-Salmon stage II/III. Of the 278 patients assessed for cytogenetics, 37% were classified as high-risk (32% del13q, 10% t(4;14), 6% del17p). Overall, 50% of patients had received prior BTZ therapy; the most common induction regimen was VCD (40%). Others included dexamethasone/idarubicin (14%), dexamethasone (13%), VAD (9%), adriamycin/dexamethasone (6%) and VD (6%). In the overall study population, patients who received BTZ-based induction showed a trend towards improved PFS (HR 1.24; 95% CI: 0.97, 1.59; p=0.084) by unadjusted Cox regression analysis. Outcomes for patients receiving BTZ consolidation or OBS only are shown in the Table 1 (median follow-up 50 months from start of induction). PFS was significantly improved by approximately 6 months, but there was no improvement in OS. In a post-hoc exploratory multivariate analysis, BTZ consolidation remained a predictor for PFS (HR 0.69; 95% CI: 0.51, 0.93; p=0.016). There appeared to be an increased risk of progression in patients with high-risk cytogenetics (HR 1.45; 95% CI: 1.05, 1.99; p=0.025) or those with <VGPR at baseline (HR 1.44; 95% CI: 1.05, 1.98; p=0.024). Age >60 had no effect on PFS (HR 1.24; 95% CI: 0.87, 1.77; p=0.240); neither did the use of non-BTZ induction (HR 1.17; 95% CI: 0.83, 1.66; p=0.375).

Table 1.

	BTZ (N=186)	OBS (N=185)	HR (95% CI)	P-value

*Response-evaluable patients
†Cox proportional hazards regression model
‡Univariate Cox regression

Summary and Conclusions: These data indicated that a fixed period (4 cycles) of BTZ consolidation was beneficial in NDMM patients with or without prior BTZ exposure. A higher proportion of patients achieved ≥VGPR after BTZ consolidation than OBS. PFS was significantly improved, but there was no improvement in OS at data cutoff, possibly related to limited follow-up and the use of effective salvage options. Subgroups that seemed to benefit from BTZ consolidation were patients with <VGPR and those with high-risk cytogenetics; age and BTZ pretreatment did not affect PFS. The BTZ dosing regimen was generally well-tolerated.

cals, Inc., an Amgen subsidiary, South San Francisco, United States, [19]University of Nantes, Nantes, France, [20]University of Torino, Torino, Italy

Background: Previously reported results from ASPIRE (NCT01080391; N=792 patients) showed that carfilzomib, lenalidomide, and dexamethasone (KRd) significantly improved progression-free survival (PFS) *vs* lenalidomide and dexamethasone (Rd) in patients with relapsed multiple myeloma, with a favorable benefit-risk profile (Stewart *et al. N Engl J Med* 2015;372:142-52).
Aims: A secondary analysis of efficacy and safety results from patients treated with KRd or Rd after first relapse (1 prior line of therapy) *vs* ≥2 prior lines of therapy in the ASPIRE study is presented.
Methods: Adults with relapsed multiple myeloma who received 1-3 prior lines were eligible. Patients were randomized (1:1) to KRd or Rd. All patients received lenalidomide (25 mg) on days 1-21 and dexamethasone (40 mg) on days 1, 8, 15, and 22 of a 28-day cycle. Patients in the KRd arm received carfilzomib as a 10-min infusion on days 1, 2, 8, 9, 15, and 16 during cycles 1-12 (20 mg/m^2 [days 1 and 2 of cycle 1]; 27 mg/m^2 thereafter). Carfilzomib was omitted on days 8 and 9 during cycles 13-18 and was not administered beyond 18 cycles. All patients provided informed consent.
Results: Median PFS for patients receiving 1 prior line (n=341) was 29.6 months (95% confidence interval [CI]: 23.2-33.5) for KRd *vs* 17.6 months (95% CI: 15.0-22.2) for Rd (hazard ratio [HR]: 0.694; *P*=.0083). Median PFS for patients receiving ≥2 prior lines (n=451) was 25.8 months (95% CI: 22.2-31.0) for KRd *vs* 16.7 months (95% CI: 13.9-22.0) for Rd (HR: 0.688; *P*=.0017). Best overall responses in patients who received 1 *vs* ≥2 prior lines of therapy are presented in the Table 1. Overall response rates (partial response or better) were 87.0% (KRd) *vs* 70.1% (Rd) in patients with 1 prior line and 87.3% (KRd) *vs* 64.4% (Rd) in patients with ≥2 prior lines. In patients with 1 prior line, 33.7% (KRd) *vs* 7.0% (Rd) achieved a complete response (CR) or better, including 12.5% (KRd) and 3.2% (Rd) who achieved a stringent complete response (sCR). In patients with ≥2 prior lines, 30.2% (KRd) *vs* 10.9% (Rd) achieved a CR or better, including 15.6% (KRd) and 5.0% (Rd) who achieved a sCR. Adverse events (AEs) grade ≥3 were reported in 85.7% (KRd) and 79.9% (Rd) of patients who received 1 prior line of therapy and 81.9% (KRd) and 81.3% (Rd) of patients who received ≥2 prior lines. AEs of interest (grade ≥3; grouped terms) included dyspnea (1 prior line: 2.7% [KRd] and 2.6% [Rd]; ≥2 prior lines: 3.3% [KRd] and 1.7% [Rd]); cardiac failure (1 prior line: 3.3% [KRd] and 1.9% [Rd]; ≥2 prior lines: 4.3% [KRd] and 1.7% [Rd]); ischemic heart disease (1 prior line: 4.9% [KRd] and 1.3% [Rd]; ≥2 prior lines: 1.9% [KRd] and 2.6% [Rd]); hypertension (preferred term; 1 prior line: 3.8% [KRd] and 0.6% [Rd]; ≥2 prior lines: 4.8% [KRd] and 2.6% [Rd]); and acute renal failure (1 prior line: 3.3% [KRd] and 3.2% [Rd]; ≥2 prior lines: 3.3% [KRd] and 3.0% [Rd]).

Table 1. Best overall responses by prior line of therapy (1 *vs* ≥2).

	1 Prior Line of Therapy		≥2 Prior Lines of Therapy	
	KRd (n=184)	Rd (n=157)	KRd (n=212)	Rd (n=239)
Best Overall Response, n (%)[a]				
Stringent Complete Response	23 (12.5)	5 (3.2)	33 (15.6)	12 (5.0)
Complete Response	39 (21.2)	6 (3.8)	31 (14.6)	14 (5.9)
Very Good Partial Response	78 (42.4)	57 (36.3)	73 (34.4)	66 (27.6)
Partial Response	20 (10.9)	42 (26.8)	48 (22.6)	62 (25.9)
Overall Response Rate (ORR), n (%)[a]	160 (87.0)	110 (70.1)	185 (87.3)	154 (64.4)
95% Confidence Interval of ORR[b]	(81.2–91.5)	(62.2–77.1)	(82.0–91.4)	(58.0–70.5)

[a]Determined by Independent Review Committee according to IMWG-URC. Patients evaluated for ORR had a best overall response of partial response or better.
[b]Clopper–Pearson interval.

Summary and Conclusions: The use of KRd led to a 1-year improvement in median PFS *vs* Rd after first relapse, and a 9-month improvement in median PFS *vs* Rd in patients with ≥2 prior lines of therapy, with similar HRs. KRd had a favorable benefit-risk profile compared with Rd after 1 and ≥2 prior lines of therapy in patients with relapsed multiple myeloma.

S428

THE QUADRUPLET COMBINATION OF CARFILZOMIB, CYCLOPHOSPHAMIDE, LENALIDOMIDE, AND DEXAMETHASONE IS SAFE AND WELL TOLERATED AS INDUCTION THERAPY FOR NEWLY DIAGNOSED, TRANSPLANT ELIGIBLE, MYELOMA PATIENTS

C. Pawlyn[1,2,*] F. Davies[1,3] D. Cairns[4], C. Collett[4], J. Jones[1,2], M. Kaiser[1,2], A. Chalmers[4], A. Striha[4], D. Milligan[5], J. Lindsay[6], C. Chapman[7], D. Allotey[8], S. Shafeek[9], K. Karunanithi[10], G. Cook[11], N. Russell[12], M. Drayson[13], R. Owen[14], W. Gregory[4], G. Jackson[15], G. Morgan[1,3]

Background: Triplet regimens containing an immunomodulatory agent (IMiD), proteasome inhibitor (PI) or both, are standard induction therapy for myeloma (MM) patients. Attempts to improve responses with quadruplets containing bortezomib and lenalidomide led to increased toxicity without improving outcomes. New generation PIs such as carfilzomib, with less off-target activity and better toxicity profiles are now available and recent data from the ASPIRE trial demonstrate that the triplet carfilzomib, lenalidomide, dexamethasone is safe and effective at relapse. Therefore, it is important to define whether a quadruplet combining carfilzomib and lenalidomide at induction can improve outcomes whilst minimising additional toxicity. The UK NCRI Myeloma XI trial is the first large, phase III study aiming to answer this question with the addition of the quadruplet carfilzomib, cyclophosphamide, lenalidomide and dexamethasone (KCRD) experimental arm to the transplant eligible (TE) pathway. Overall the trial seeks to establish the optimum induction and maintenance approaches for all newly diagnosed MM (NDMM) patients with almost 4000 recruited to date.
Aims: To assess the safety and tolerability of KCRD in TE, NDMM.
Methods: In 2013, the TE pathway of the NCRI Myeloma XI trial was amended to include an assessment of the quadruplet carfilzomib (20/36mg/m^2 IV D1-2,8-9,15-16. 20mg/m^2 only cycle 1 D1-2), cyclophosphamide (500mg PO D1,8), lenalidomide (25mg PO D1-21), dexamethasone (40mg PO D1-4,8-9,15-16). This up-front quadruplet is being compared to the sequential strategy of triplet IMiD combinations (with thalidomide or lenalidomide) followed by additional PI triplet therapy (with bortezomib) for those with a suboptimal response (<VGPR) prior to ASCT. Treatment is given to max. response/unacceptable toxicity before proceeding to ASCT, followed by a maintenance randomisation. Here we report a safety analysis for the KCRD regimen.
Results: Following informed consent 257 patients have commenced KCRD treatment to date. KCRD is well tolerated with patients completing a mean of 4.2 cycles (±1.17), median 4 (range 1-7) prior to transplant. Dose modifications have been required in 63% of KCRD patients (55% with modifications to carfilzomib, 38% to lenalidomide). Data for study drug-related toxicity in patients who have completed at least one cycle of KCRD show a low incidence of grade 2-4 neuropathy (sensory 1.2%, motor 4.4%), all grade infusion reactions (4.4%) and thrombo-embolism (5%). Grade 3-4 haem toxicities were: 14.5% neutropenia, 6.9% thrombocytopenia, 7.5% anaemia. There were few reported cases of cardiac or renal failure so we looked for ARs suggestive of these previously reported side effects, finding grade 3-4 dyspnoea in only 1.3%. Serious adverse events suspected to be due to trial medications have occurred in 41% of patients receiving KCRD with the majority due to infections or cytopenias. Overall the toxicity profile is similar to that reported previously for patients receiving the CRD triplet, despite the addition of carfilzomib.
Summary and Conclusions: These results suggest that KCRD, an outpatient delivered 4-drug regimen combining second generation IMiD and PI drugs, is well-tolerated and safe in TE NDMM patients. With no significant additional toxicity over 3-drug combinations and a favourable profile when compared to other 4-drug regimens, KCRD represents a highly promising induction option. Longer follow-up is awaited to assess the efficacy and tolerability compared to a sequential IMiD/PI strategy.

S429

EFFECT OF AGE ON EFFICACY AND SAFETY OUTCOMES IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA RECEIVING LENALIDOMIDE AND LOW-DOSE DEXAMETHASONE (RD): THE FIRST TRIAL

Background: Combination therapy with melphalan-prednisone-thalidomide (MPT) is considered a standard treatment (Tx) option for patients (pts) with

newly diagnosed multiple myeloma (NDMM) who are ineligible for stem cell transplant (SCT; Facon, *Lancet Oncol*, 2007; Fayers, *Blood*, 2011; NCCN Guidelines, Multiple Myeloma, V3.2015). The pivotal, randomized, international, multicenter phase 3 FIRST trial demonstrated that first-line use of lenalidomide continuous plus low-dose dexamethasone (Rd continuous) improved progression-free survival (PFS) compared with MPT (HR=0.72; *P* <0.001). An overall survival (OS) analysis also showed improvement, with a 22% reduction in risk of death with Rd continuous *vs* MPT (HR=0.78; *P*=0.02) (Benboubker, *N Engl J Med,* 2014).

Aims: To determine PFS, OS, and DOR outcomes stratified by age of patients with NDMM in the FIRST trial.

Methods: NDMM pts ineligible for SCT were randomized 1:1:1 to Tx with Rd continuous (28-day cycles) until disease progression (n=535); 18 cycles (72 wks) of Rd (Rd18; n=541); or 12 cycles (72 wks) of MPT (n=547). Starting doses were reduced in pts aged >75 *vs* those aged ≤75 yrs: dexamethasone (20 *vs* 40 mg), melphalan (0.20 *vs* 0.25 mg/kg), and thalidomide (100 *vs* 200 mg). The primary endpoint was PFS. Secondary endpoints included OS, overall response rate (ORR), time to response, duration of response (DOR), time to Tx failure, time to second anti-myeloma Tx, health-related quality of life, and safety.

Results: This analysis based on the final PFS analysis using a data cutoff of May 24, 2013, with a median follow-up of 37 mos. The proportion of pts aged ≤75 yrs and >75 yrs was 65% (n=1056) and 35% (n=567), respectively. Pt characteristics, including rate of adverse cytogenetics, were well balanced across all Tx arms. In pts ≤75 yrs, ISS stage III disease was detected in 37% of those treated with Rd continuous or Rd18 and 36% of pts treated with MPT. In pts >75 yrs, these rates were 47% with Rd continuous or Rd18 and 50% with MPT. Severe renal impairment (CrCl <30 mL/min) was observed in 6%, 8%, and 8% of pts ≤75 yrs *vs* 13%, 11%, and 15% of pts >75 yrs (Rd continuous, Rd18, and MPT, respectively). PFS and OS outcomes favored Rd continuous over MPT in both age groups. Median PFS was 27.4 mos in Rd continuous pts *vs* 21.8 mos in MPT pts aged ≤75 yrs (HR=0.68; *P* <0.001); HR for pts aged >75 yrs was 0.81 (*P*=0.11; Table 1). PFS for Rd continuous *vs* Rd18 pts was also increased in both age groups (HR=0.68; *P* <0.001 and HR=0.75; *P*=0.03, respectively). OS showed an improved trend for Rd continuous *vs* MPT in pts aged ≤75 yrs (HR=0.77; *P*=0.06) and >75 yrs (HR=0.80; *P*=0.16). ORR was consistently higher with Rd continuous *vs* MPT in pts aged ≤75 yrs (77% *vs* 66%) and >75 yrs (71% *vs* 55%). Median DOR with Rd continuous was longer *vs* MPT in pts aged ≤75 yrs (40 *vs* 22 mos) and pts >75 yrs (31 *vs* 24 mos). Hematologic and non-hematologic adverse events (AEs) were as expected for Rd and MPT, with no relevant differences in Grade 3/4 toxicity between pts ≤75 yrs and >75 yrs. Tx discontinuation due to AEs was comparable across Tx and age groups.

Table 1. PFS, OS, and response.

	Aged ≤ 75 Yrs			Aged > 75 Yrs		
ITT population	Rd continuous (n = 349)	Rd18 (n = 348)	MPT (n = 359)	Rd continuous (n = 186)	Rd18 (n = 193)	MPT (n = 188)
Median PFS, mos	27.4	21.3	21.8	21.2	19.4	19.2
3-yr PFS, %	46	25	23	35	19	22
PFS, HR (95% CI); *P* value						
Rd continuous vs MPT	0.68 (0.56-0.83); *P* < 0.001			0.81 (0.62-1.05); *P* = 0.11		
Rd continuous vs Rd18	0.68 (0.55-0.83); *P* < 0.001			0.75 (0.58-0.98); *P* = 0.03		
3-yr OS, %	74	70	67	63	58	54
OS, HR (95% CI); P-value						
Rd continuous vs MPT	0.77 (0.59-1.01); *P* = 0.06			0.80 (0.59-1.09); *P* = 0.16		
Rd continuous vs Rd18	0.88 (0.67-1.16); *P* = 0.36			0.94 (0.69-1.29) ; *P* = 0.70		
Response rate (≥ PR), %	77	77	66	71	66	55
Median duration of response (≥ PR), mos	40	23	22	31	20	24

HR, hazard ratio; ITT, intent to treat; MPT, melphalan-prednisone-thalidomide; OS, overall survival; PFS, progression-free survival; PR, partial response; Rd, lenalidomide-dexamethasone; Rd18, 18 cycles of Rd.

Summary and Conclusions: Regardless of age (≤75 *vs* >75 yrs), Rd continuous extended PFS with an OS benefit *vs* MPT in NDMM pts. Rd continuous was generally well tolerated in both age groups. DOR was improved with Rd continuous *vs* MPT and Rd18, irrespective of age. Rd continuous represents a new standard of care for pts in the first-line setting independent of age.

Background: Novel agents including proteasome inhibitors (PI) and immunomodulatory agents (IMiDs) have provided improved treatment outcomes for patients with multiple myeloma (MM). The majority of patients with MM still unfortunately relapse, with very limited options after PI and IMiD-based treatment. Daratumumab (DARA) is a human anti-CD38 IgG1κ mAb and has previously shown single agent activity and good tolerability in relapsed/refractory MM (Lokhorst HM *et al.* ASCO 2014).

Aims: This ongoing phase 2 study (NCT01985126) evaluated DARA monotherapy in the FDA breakthrough therapy designation population: MM patients with ≥3 prior lines of therapy including a PI and an IMiD, or double refractory to a PI and IMiD. Preliminary results are reported.

Methods: MMY2002 is a 2-part, open-label, international, multicenter study. In part 1 stage 1, 34 patients were randomized to DARA 8 mg/kg (n=18) q4w or 16 mg/kg (n=16) qw for 8 weeks, q2w for 16 weeks, then q4w in a Simon-2-stage design to determine the most effective dose. Subsequently, 90 additional patients were enrolled in the 16 mg/kg DARA group. The primary endpoint was overall response rate (ORR) by independent review (IRC).

Results: Data for the 16 mg/kg DARA group are presented (n=106). The median time from diagnosis was 4.8 years and patients received a median of 5 prior treatment lines. A total of 80% of patients received prior autologous stem cell transplants. Seventy five percent of patients were ISS stage 2 or higher. Ninety-six percent of patients were refractory to their last line of therapy and 95% were refractory to their last PI and IMiD. The proportions of patients refractory to other to agents included pomalidomide (63%), carfilzomib (48%) and alkylating agents (78%). Adverse events (AE; ≥20%) included fatigue (39.6%), anemia (33.0%), nausea (29.2%), thrombocytopenia (25.5%), back pain (22.6%), neutropenia (22.6%), cough (20.8%). Infusion-related reactions (IRR, 42.5%) were mainly grade 1/2 during the first infusion with 4.7% of patients with grade 3 IRRs. No grade 4 IRRs were reported and no patients discontinued the study due to IRRs. Five patients (4.7%) discontinued treatment due to AEs and none of these AEs were assessed by the investigator to be DARA-related. The ORR (IRC assessed) was 29.2%, with 3 stringent complete responses, 10 very good partial responses, and 18 partial responses. The ORR was consistent across clinically relevant subgroups. The median duration of response was 7.4 months. The median time to progression was 3.7 months. Median overall survival (OS) has not been reached and the estimated 1-year OS rate is 65%. After a median follow up of 9.4 months 14/31 (45.2%) of responders remain on therapy.

Summary and Conclusions: In a heavily pre-treated MM population (95% refractory to last PI and IMiD), DARA at 16 mg/kg showed meaningful durable single agent activity, with deep responses and a favorable safety profile.

CLL: Novel agents

VENETOCLAX (ABT-199/GDC-0199) COMBINED WITH RITUXIMAB INDUCES DEEP RESPONSES IN PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA

A.W. Roberts[1,*] S. Ma[2], D. Brander[3], T. J. Kipps[4], J.C. Barrientos[5], M.S. Davids[6], M.A. Anderson[1], M. Choi[4], C. Tam[7], L. Magee[1], J. Kreutzer[2], R. Singh[3], J. Kim[4], B. Dimovski[7], T. Mason-Bright[8], B. Prine[8], M. Zhu[8], R.A. Humerickhouse[8], J.F. Seymour[7]

[1]Royal Melbourne Hospital and Walter and Eliza Hall Institute of Medical Research, Parkville, Australia, [2]Northwestern University, Chicago, [3]Duke University Medical Center, Durham, [4]University of California San Diego, La Jolla, [5]Hofstra North Shore-LIJ School of Medicine, Lake Success, [6]Dana-Farber Cancer Institute, Boston, United States, [7]Peter MacCallum Cancer Centre, Melbourne, Australia, [8]AbbVie, North Chicago, United States

Background: Venetoclax is a selective, orally bioavailable BCL-2 inhibitor. Single agent venetoclax induces responses in ~80% of pts with relapsed/refractory chronic lymphocytic leukemia (CLL)/small lymphocytic lymphoma (SLL). Pts were enrolled in a phase 1b, open-label, dose-escalation, multicenter study of venetoclax plus rituximab (R), to determine safety, PK and efficacy. We have previously reported the recommended phase 2 dose for venetoclax in this combination to be 400 mg/day.
Aims: The goal of this analysis was to determine the response rate and minimal residual disease status and to update the safety profile for the combination.
Methods: Eligible pts began treatment with 20 or 50 mg venetoclax daily, increasing weekly to final cohort doses of 200-600 mg. After the weekly lead-in phase, monthly R was added (at 375 mg/m^2 and then 500 mg/m^2) for 6 doses. Responses were assessed using iwCLL criteria, including CT scan and bone marrow (BM) biopsy at the end of combination therapy (7 months). MRD was assessed in local laboratories using ≥4 color flow cytometry on cells in BM and blood (minimum sensitivity of 0.01%).

Table 1.

Best Response		
	All pts n=49	del17p n=9
ORR, n (%)	41 (84)	7 (78)
CR/CRi	20[a] (41)	3[b] (33)
PR	20 (41)	4 (44)
nodular PR (nPR)	1 (2)	0 (0)
PR unconfirmed[c]	4 (8)	1 (11)
Stable disease (SD)	1 (2)	0 (0)
Progressive disease (PD)	2 (4)	0 (0)
Discontinued prior to assessment[d]	1 (2)	1 (11)

[a]6/20 CRi;
[b]2/3 CRi;

[d]Fatal TLS event; No other fatal TLS events occurred after protocol modification

BM MRD Status, n (%)			
	MRD-negative	MRD-positive	Not evaluable
CR/CRi	13	5	2
PR/nPR	10	10	1
Other	1[e]	1[f]	6[g]
Total	24/49 (49)	16/49 (33)	9/49 (18)

[e]PR unconfirmed;
[f]SD;
[g]No sample

Results: Accrual is complete with 49 pts (48 CLL/1 SLL) of median age 68 (50-88) years enrolled in 5 dose escalation cohorts (n=41) and a safety expansion cohort at 400 mg/day (n=8). The median number of prior regimens was 2 (1-5). Forty-five (92%) had prior R; 14/49 (29%) were R-refractory. Twenty-eight (57%) had prior fludarabine (F); 9/49 (30%) were F-refractory. Of 46 pts with available data, 9 (20%) had del17p; 19/27 (70%) with available data had unmutated IGVH. Eleven pts have discontinued the study: 6 due to PD, 2 due to AEs (neuropathy, TLS), and 3 withdrew consent. The median time on study as of Jan 21, 2015 was 13 (0.03-28) months. The overall response rate (ORR) was 84% (41/49), with 20 (41%) achieving either a complete response (CR) or CR with incomplete marrow recovery (CRi). MRD was evaluable in 40 pts. MRD-negativity in BM was achieved in 13/20 (65%) pts with CR/CRi and in 24/49 (49%) pts overall. Responses are summarized in the Table 1. Only 3/41 (7%) responders have progressed (at 5, 8 and 12 months). Six pts stopped daily venetoclax after achieving CR/CRi. These pts continue in follow up and all have maintained a response after a median time of 12 months (0-21) off venetoclax. Treatment-emergent AEs in >25% were neutropenia (53%), diarrhea and nausea (each 47%), upper respiratory tract infection (41%), pyrexia (37%) and fatigue, headache and cough (each 33%). Grade 3/4 AEs in >10% were neutropenia (51%), thrombocytopenia (16%) and anemia (14%). There was 1 treatment-emergent AE that led to death (TLS) and there were 2 deaths after PD.
Summary and Conclusions: The combination of venetoclax and R has a tolerable safety profile and induces deep and durable responses, with 41% of pts achieving CR/CRi and 49% of pts achieving MRD negativity in BM. A phase 3 trial comparing venetoclax and R *versus* bendamustine and R in pts with previously treated CLL is underway.

S432

TGR-1202, A NOVEL ONCE DAILY PI3K-DELTA INHIBITOR, DEMONSTRATES CLINICAL ACTIVITY WITH A FAVORABLE SAFETY PROFILE, LACKING HEPATOTOXICITY, IN PATIENTS WITH CLL AND B-CELL LYMPHOMA

H.A. Burris III[1,2,*] M.R. Patel[1,3], T.S. Fenske[4], O.A. O'Connor[5], C. Deng[5], D.M. Brander[6], M. Gutierrez[7], S. Jones[1], J. Kuhn[8], H.P. Miskin[9], P. Sportelli[9], S. Vakkalanka[10], I. Flinn[1,2]

[1]Sarah Cannon Research Institute, [2]Tennessee Oncology, Nashville, [3]Florida Cancer Specialists, Sarasota, [4]Medical College of Wisconsin, Milwaukee, [5]Center for Lymphoid Malignancies, Columbia University Medical Center, New York, [6]Duke University Medical Center, Durham, [7]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, [8]University of Texas Health Science Center at San Antonio, San Antonio, [9]TG Therapeutics, Inc., New York, United States, [10]Rhizen Pharmaceuticals SA, La Chaux-de-Fonds, Switzerland

Background: TGR-1202 is a novel, next generation PI3Kδ inhibitor which lacks the hepatotoxicity associated with other PI3Kδ inhibitors and is active in patients (pts) with advanced heme malignancies (ASH 2014).
Aims: Herein we present updated safety and efficacy results from a Ph I study of TGR-1202 in pts with rel/ref CLL and B-cell lymphoma.
Methods: TGR-1202 administered orally once-daily following a 3+3 dose escalation design. Eligible pts have rel/ref B-cell non-Hodgkin lymphoma (NHL), chronic lymphocytic leukemia (CLL), or other B-cell malignancy and an ECOG PS ≤2. Endpoints: safety, PK/PD, and efficacy.
Results: As of Feb 2015, 58 pts evaluable for safety including CLL, FL, Hodgkin's (HL), DLBCL, MCL, and MZL. Median age 63 yo (range: 22-85), 72% male, ECOG 0/1/2: 19/38/1, median prior Tx: 3 (range: 1-14), 48% refractory to prior Tx. Safety: The only Gr≥3 AE in ≥10% of pts was neutropenia (10%). AEs (all grades, all causality) in >20% of pts were limited to diarrhea (34%), fatigue (31%), nausea (29%), and cough (26%). All diarrhea events Gr1/2, except one Gr3 event occurring in a pt in Cyc 1, which persisted for 2 days and resolved without dose interruption. Notably, in contrast to similar agents, no drug-related hepatotoxicity or colitis has been observed to date (ave time on study 7 Cyc). 2 episodes of Gr3 fatigue at 1800 mg of a new micronized formulation met the criteria for DLT. Expansion cohorts are open at 800 mg (CLL) and 1200 mg (NHL). Efficacy: A strong exposure-response relationship has been observed. Of 14 evaluable CLL pts, 13 (93%) achieved a nodal PR (median nodal ↓ of 76%), of which 7 (50%) achieved a PR per Hallek 2008 criteria. Responses have been limited in pts with DLBCL and HL. Of the 12 evaluable FL pts, 8 (67%) remain on study progression-free (range 7-99+ weeks), with 3 achieving a PR, notably being the 3 pts exhibiting the highest TGR-1202 plasma concentrations.
Summary and Conclusions: TGR-1202 is well tolerated in pts with rel/ref heme malignancies with no reported hepatotoxicity or colitis (41% of pts on study 6+ Cyc) and promising activity in CLL and NHL. Enrollment continues in expansion cohorts.

S434

EARLY CLINICAL ACTIVITY AND PHARMACODYNAMIC EFFECTS OF DUVELISIB, A PI3K-DELTA, GAMMA INHIBITOR, IN PATIENTS WITH TREATMENT-NAÏVE CLL

S. O'Brien[1,*] K. Faia[2], K. White[2], M. Douglas[2], K. Allen[2], J. Kutok[2], J. Sweeney[2], V. Kelly[2], I. Flinn[3], J. Byrd[4], H. Stern[2]

[1]MD Anderson Cancer Center, Houston, [2]Infinity Pharmaceuticals, Cambridge, [3]Sarah Cannon Research Institute, Nashville, [4]The Ohio State University Medical Center, Columbus, United States

Background: Signaling via PI3K-δ and PI3K-γ has distinct and complementary effects on malignant B-cells and nonmalignant immune cells in chronic lymphocytic leukemia (CLL). Duvelisib, an oral dual inhibitor of PI3K-δ,γ, has

shown clinical activity in a phase 1 study, IPI-145-02 (O'Brien, ASH 2014; Flinn, ASH 2014; Horwitz, ASH 2014).
Aims: The activity of duvelisib monotherapy in patients with treatment-naïve CLL from this study are reported here.
Methods: Following dose escalation, an expansion cohort of treatment-naïve CLL patients was enrolled (n=18). Response was based on iwCLL (2008) criteria. Safety included AEs and laboratory assessments. Pharmacodynamic assessments included peripheral blood (PB) flow cytometry for phospho-S473 AKT (pAKT) and Ki67, and measurement of serum chemokines and cytokines. Numbers of PB T-cell subsets were also monitored.
Results: As of Oct 2014, 18 treatment-naïve CLL pts received duvelisib 25 mg BID. The best ORR per iwCLL was 82% (PRs in 14/17 evaluable patients) with a median time on treatment of 53 weeks (range 8-69). Ten patients remain on treatment, while 8 discontinued, including 6 patients due to AEs. AEs overall were mostly Grade 1 or 2. The most common ≥Grade 3 AEs were neutropenia (7/18) and ALT/AST increase (3/18). Inhibition of pAKT in CLL cells was rapid following a single dose and sustained through Cycle 2 Day 1 (C2D1). A reduction in the Ki67 proliferative fraction in both CLL and T-cells was also observed. Duvelisib resulted in reductions in the median serum levels of CCL3, CCL4, CCL17, CCL22, CXCL10, CXCL13, IL-10, IL-12p40, MMP-9, IL-16, and TNFα to ≤50% of baseline at C1D8 and/or C2D1 ($p < 0.01$).
Summary and Conclusions: Duvelisib 25 mg BID shows clinical activity in treatment-naïve CLL pts. The inhibition of pAKT and Ki67 in CLL cells suggests duvelisib inhibits the PI3K pathway and suppresses malignant cell proliferation in treatment-naive CLL patients. In addition, the effect of duvelisib on serum chemokines, cytokines, and T-cell proliferation suggests that modulation of the tumor microenvironment may contribute to the observed early clinical activity of duvelisib in patients with treatment-naïve CLL. These data support the further development of duvelisib in treatment-naïve CLL, including combinations with other targeted therapies.

S435

ADHERENCE AND DOSE INTENSITY FOLLOWING ADMINISTRATION OF THE IBRUTINIB 420 MG DOSE IN PATIENTS WITH PREVIOUSLY TREATED CLL

Background: Ibrutinib is a first-in-class, once-daily, oral, covalent inhibitor of Bruton's tyrosine kinase (BTK). Pharmacokinetic analyses have shown that ibrutinib is rapidly absorbed, extensively distributed, and rapidly eliminated from systemic circulation after oral administration (Advani, JCO 2013, Poggesi, AACR 2014). In a study of BTK occupancy in peripheral blood, ibrutinib achieved complete or near complete occupancy of the BTK active site (median >90%) at 4 hours which was maintained at 24 hours following administration of the 420 mg once-daily dose (O'Brien, Lancet Oncology 2013). PK/PD analysis of BTK engagement at different dose levels predicted that at the lower doses of 140 or 280 mg fewer patients would attain complete BTK occupancy (Poggesi, AACR 2014).
Aims: To evaluate the effect of the ibrutinib 420 mg once-daily dose adherence on independent review committee-assessed progression-free survival (PFS) in patients with previously treated CLL from the phase 3 RESONATE trial.
Methods: Dose intensity was defined as the proportion of actually administered *vs* planned doses of ibrutinib 420 mg. Dose intensity was also defined in the first 8 weeks to compare statistically with post-week 8 PFS. Steady-state AUC/C_{max} was estimated per NONMEM modeling using 2 timepoint samples (weeks 1 and 4). Missed doses had to be consecutive. Mean duration of missed doses was based on the sum of all consecutive days of missed dose for each patient.
Results: Patients treated with ibrutinib (n=195) had a mean dose intensity of 95% (median 100%) with 8.3 months of treatment. Of all patients with dose reductions (4.1%), 3.6% had 1 dose reduction and 0.5% had 2 dose reductions due to adverse events. Only diarrhea led to dose reduction in >1 patient in the ibrutinib arm (n=3). The majority of dose interruptions were restarted at 420 mg as per protocol. There were fewer PFS events in patients not missing ibrutinib doses (n=136) *vs* those missing (n=59) ibrutinib doses for ≥8 consecutive days (13% *vs* 31%, respectively), with median PFS of NR *vs* 11 months, respectively. The mean duration of missed doses was 26 days for patients missing ≥8 days. For patients missing ≥2-7 days consecutively (n=33), the mean duration of missed doses was 6 days; 103/195 patients did not miss >1 day. Patients with higher dose intensity experienced longer PFS compared to those with lower dose intensity (median NR *vs* 11 months). This trend was confirmed (HR=0.4 [*P*=0.0127]) using an adjusted mean dose intensity of 96% in the first 8 weeks and post week-8 PFS. In patients with del17p CLL (n=63), p53 mutation (n=61), or del11q CLL (n=63), those with higher dose intensity also had a lower rate of progression or death events compared to those with lower dose intensity (18% *vs* 42%, 9% *vs* 29%, 14% *vs* 16%, respectively). Dose reduction due to diarrhea, infection, and arthralgia occurred in patients with del17p (n=2), p53 mutation (n=3), but not del11q CLL. No difference was seen in median PFS with lower *vs* higher ibrutinib exposure (AUC or C_{max}) in the 179 patients receiving ibrutinib 420 mg with PK assessment at weeks 1 and 4. Patients receiving ibrutinib without concomitant CYP3A inhibitors had similar outcomes.
Summary and Conclusions: Improvement in PFS is associated with a higher mean dose intensity of ibrutinib, with patients missing more than 1 week of treatment experiencing more PFS events. This improvement in PFS is seen regardless of del17p, del11q, or p53 mutation status. These results support sustained adherence to the once-daily ibrutinib 420 mg dose in patients with previously treated CLL.

Translational studies in ALL

S436

TYROSINE KINASE FUSION GENES IN PEDIATRIC BCR-ABL1-LIKE ACUTE LYMPHOBLASTIC LEUKEMIA

J.M. Boer[1,*] J.R. Marchante[1], A. Boeree[1], G. Escherich[2], H.A. de Groot-Kruseman[3], R. Pieters[1,3,4], M.L. den Boer[1,3]
[1]Department of Pediatric Oncology/Hematology, Erasmus MC-Sophia Children's Hospital, Rotterdam, Netherlands, [2]COALL-German Cooperative Study Group for Childhood Acute Lymphoblastic Leukemia, Hamburg, Germany, [3]DCOG-Dutch Childhood Oncology Group, The Hague, [4]Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands

Background: Pediatric B-cell precursor acute lymphoblastic leukemia (BCP-ALL) with the *BCR-ABL1* fusion gene forms a small high-risk patient group with a poor prognosis. Approximately 15% of BCP-ALL shows gene expression similar to *BCR-ABL1*-positive disease and a similar unfavorable prognosis. This group shows a high frequency of B-cell development gene aberrations, especially *IKZF1* deletions and tyrosine kinase activating lesions (Den Boer *et al.* Lancet Oncol 2009; Mullighan *et al.* N Engl J Med 2009; Roberts *et al.* Cancer Cell 2012, N Engl J Med 2014; Van der Veer *et al.* Blood 2013).
Aims: To detect the clinical value (frequency, prognosis and drugability) of tyrosine kinase fusions in childhood B-cell precursor ALL.
Methods: This study comprised 204 children with BCP-ALL in 3 Dutch trials (DCOG ALL-8, 9, 10) and 2 German trials (COALL 06-97, 07-03) including 92 previously described *BCR-ABL1*-like cases identified by hierarchical clustering and 112 non-*BCR-ABL1*-like B-other cases. Characterization included RT-PCR and FISH to detect fusions involving *ABL1*, *PDGFRB*, *JAK2* and *CSF1R*, copy number analysis, and Sanger sequencing of *JAK1* exons 13, 14 and *JAK2* exons 16, 20, 21.
Results: We identified 12 tyrosine kinase activating fusion genes among 73 *BCR-ABL1*-like cases tested (16%) and none among 87 B-other cases. Four *EBF1-PDGFRB*, two *PAX5-JAK2*, *ZMIZ1-ABL1*, and *SSBP1-CSF1R* fusions were confirmed by RT-PCR. Four cases showed split FISH and/or breaks on DNA copy number arrays for *PDGFRB*, *ABL1*, or *JAK2* with unknown fusion partners. *IKZF1* deletions occurred more frequently in tyrosine kinase fusion cases compared with B-other (55% *vs* 32%), and were enriched for rare, *i.e.* other than exon 4-7 or full deletion, variants (46% *vs* 18%). *JAK2* mutations (mainly in exon 16) were present in 7/70 B-other and 2/82 *BCR-ABL1*-like cases. *JAK2* mutations co-occurred with high *CRLF2* expression and had no prognostic impact. The cumulative incidence of relapse (CIR) in the *BCR-ABL1*-like group with tyrosine kinase fusions (5-yr CIR 25%±13%) was comparable with the remaining *BCR-ABL1*-like group (5-yr CIR 33%±5%), and worse than the B-other group (5-yr CIR 18%±4%; overall Gray p-value 0.06). Of the 12 tyrosine kinase fusion cases, 4 were late responders who only achieved remission after day 33 of induction therapy. Of 8 patients receiving a prednisone window before start of induction therapy, 3 showed a poor prednisone response on day 8. Day 15 punctures showed M2 or M3 marrows in 7/9 cases. Minimal residual disease PCR at the end of induction was high (TP1 and TP2 $\geq 10^{-3}$) in 5 and intermediate (TP1 $\geq 10^{-3}$, TP2 $< 10^{-3}$) in 2/8 cases. Leukemic cells from 3 *EBF1-PDGFRB* patients were sensitive to imatinib in *ex vivo* cultures, compared with lack of cytotoxic response in 4 *EBF1-PDGFRB*-negative samples, 2 of which even showed growth on imatinib. Combination of imatinib with prednisolone resulted in further growth inhibition in *ex vivo* cultures from 2/3 *EBF1-PDGFRB* patients.
Summary and Conclusions: Tyrosine kinase fusion genes were found in 16% of DCOG/COALL *BCR-ABL1*-like cases, representing ~3% of total BCP-ALL. *JAK2* mutations were infrequent and not associated with *BCR-ABL1*-like in our cohort. Tyrosine kinase fusion cases were characterized by poor initial response to treatment, had an unfavorable clinical outcome compared to remaining non-*BCR-ABL1*-like B-other ALL cases but had a comparable unfavorable outcome to *BCR-ABL1*-like ALL without tyrosine kinase fusions. Imatinib worked additive to prednisolone in *EBF1-PDGFRB* patient cells, indicating that this inhibitor may be clinically used in combination with at least prednisone.

S437

THE PREDICTIVE STRENGTH OF NEXT GENERATION SEQUENCING MINIMAL RESIDUAL DISEASE DETECTION FOR RELAPSE COMPARED WITH CURRENT METHODS IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Kotrova[1,*] K. Muzikova[1], E. Mejstrikova[1], M. Novakova[1], V. Bakardjieva-Mihaylova[1], K. Fiser[1], J. Stuchly[1], C. Pott[2], M. Bruggemann[2], J. Stary[3], J. Trka[1], E. Fronkova[1]
[1]CLIP, Department of Pediatric Haematology and Oncology, 2nd Medical School and University Hospital Motol, Prague, Czech Republic, [2]II. Medizinische Klinik und Poliklinik, UNIVERSITÄTSKLINIKUM Schleswig-Holstein, Kiel, Germany, [3]Department of Pediatric Haematology and Oncology, 2nd Medical School and University Hospital Motol, Prague, Czech Republic

Background: Minimal residual disease (MRD) monitoring using antigen receptor-based quantitative PCR (qPCR) became a gold standard in the management of acute lymphoblastic leukemia (ALL), despite being technically and financially demanding. MRD detection based on next generation sequencing (NGS) of antigen receptor genes rearrangements allows for a highly specific and sensitive detection of MRD without the need for labourious optimization of patient-specific assays.
Aims: To establish MRD detection by NGS of immunoglobulin heavy chain (*IGH*) rearrangements and compare MRD levels at BFM-protocols stratification timepoints with qPCR and flow cytometry (FC).
Methods: The libraries for sequencing were prepared from 450ng of diagnostic bone marrow DNA and 50ng of polyclonal DNA. Two-round PCR was used for library preparation: in the 1st round the *IGH* rearrangements were amplified with Biomed-2 FR3 primers. In the 2nd round of PCR sequencing adaptors and barcodes were attached. Libraries were sequenced on Ion Torrent PGM/Ion Proton sequencers. For detection of reads containing the clonal sequence from diagnosis we used our own bioinformatics algorithm.
Results: We sequenced 213 samples from 63 patients with childhood ALL treated according to the AIEOP-BFM-ALL 2000 protocol and 14 more patients with relapse from previous and current frontline treatment protocols with the median coverage 719,904 reads per sample. Eighty-four (39.4%) samples were negative by both methods. Sixteen (7.5%) samples were positive by NGS and negative by qPCR, and 16 (7.5%) samples were positive by qPCR and negative by NGS. This caused a shift in risk group stratification in 30% of patients, mainly between standard risk and intermediate risk group patients. The overall correlation of both methods was good (R^2=0.71). NGS approach detected significantly higher MRD than qPCR at day 33 in patients who later relapsed (p=0.001). NGS-MRD positivity at day 33 seems to provide a more accurate prediction of relapse than qPCR-MRD positivity (Figure 1A). At day 78, the predictive value of NGS was comparable to qPCR (Figure 1B). Combined day 33 and 78 MRD used for defining of SR, IR and HR (+SER) groups on BFM trials gave again similar results as qPCR (Figure 1C). Similarly to FC, low NGS MRD defined a group with excellent prognosis at day 15.

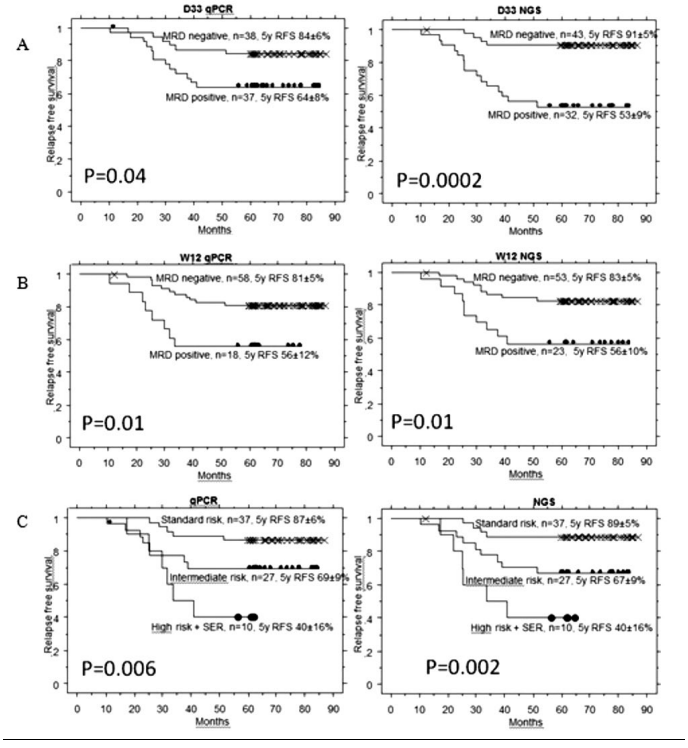

Figure 1.

Summary and Conclusions: NGS will speed up the process of MRD detection and provide results at early time points, which is currently not possible due to the long time needed for qPCR preparations. The correlation of NGS and qPCR was good with the majority of the differences below the reproducible sensitivity of methods, which caused shifts mainly between SR and IR groups. We showed that day 33 NGS MRD levels were higher than qPCR MRD levels in patients who subsequently relapsed, which was reflected in a slightly better prediction of relapse based on d33 NGS. The outcome of patients stratified into risk groups by combined d33/d78 MRD was similar for NGS and qPCR, despite the 30% of patients being differently stratified by NGS. At present, the main drawback of the Ig/TCR-exploring NGS methods is the lack of standardization both in the experimental setting and in data analysis. Therefore, the European network "EuroClonality NGS Consortium",

has been formed to optimize and standardize NGS workflow..Before NGS based MRD can safely replace qPCR for treatment guiding in ALL, robust results on comparability of both methods by standardized methodology should be validated within prospective clinical trials.
Supported by IGA NT14343, GAUK 394214 and CZ.2.16/3.1.00/24022OPPK.

HIGH THROUGHPUT SEQUENCING AS A MEASURE OF EARLY RESPONSE TO THERAPY IN CHILDHOOD ALL

I. Kirsch[1,*] D. Williamson[1], B. Wood[2], M. Loh[3], H. Robins[4]
[1]Adaptive Biotechnologies, [2]University of Washington, Seattle, [3]University of California at San Francisco, San Francisco, [4]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: Early response to induction chemotherapy has been demonstrated to be one of if not the most significant prognostic factors in the outcome of children with acute lymphoblastic leukemia. Multiparametric flow cytometry (mpFC) has been the routinely used methodology in the US for the determination of this response. New high throughput sequencing (HTS) technologies of rearranged immune receptor (TCR and Ig) genes have raised the possibility of a more accurate, sensitive, and standardizable approach to determination of early response to therapy in ALL patients.
Aims: In this study, we investigated whether the Adaptive Biotechnologies immunoSEQ assay of IgH (immunoglobulin heavy chain (VDJ/DJ) and TCRG (T-cell receptor gamma) would be able to quantify residual disease at the end of induction therapy for children with ALL and be of prognostic value with regard to outcome (relapse free survival and overall survival) in these patients.
Methods: This study involved a total of 432 patients enrolled on COG clinical trials AALL0331 and AALL0232 for whom mpFC measurement of residual disease was <0.1% and for whom outcome data are available.
MpFC was performed at the University of Washington and Johns Hopkins as part of the evaluation for MRD. Genomic DNA was extracted from frozen bone marrow specimens collected at diagnosis and at day 29 post the start of induction therapy. High throughput sequencing of CDR3 regions of IGH and TCRG was performed on all samples. Diagnostic and d29 matched samples from a given patient were sequenced and dominant (>5%) clonal CDR3 sequences from diagnosis were searched for in the corresponding d29 sample. An exact 100 base pair match was required for identification of the sequence as residual disease in the follow-up sample. Both the presence and the frequency of the MRD clone relative to the total IGH repertoire and total nucleated cell population were determined.
Results: The assays defined the dominant clonal sequences in >90% of the patients. Approximately 60% of this subgroup was found to have residual disease present at d29. Clones from some of the patients demonstrated a single "trackable" sequence while clones from other patients demonstrated multiple trackable sequences either within or between the two immune receptor loci being assessed. Approximately, 50% of the residual disease detected by HTS was beneath the level of sensitivity of mpFC and therefore previously read out as MRD negative. Correlations between mpFC and HTS and independent correlations of each of these two methodologies with outcome will be presented.
Summary and Conclusions: This is the largest patient cohort studied to date for which mpFC, HTS, and outcome data are all available. This study allows an informative assessment of the capability of HTS to determine early response to induction chemotherapy and the relevance of that determination to patient outcome.

GENOMIC DNA BREAKPOINTS IN MLL AND TRANSLOCATION PARTNER GENES IN A LARGE COHORT OF INFANTS WITH ACUTE LEUKEMIA

G. Tsaur[1,*] C. Meyer[2], A. Kustanovich[3], A. Popov[1], T. Riger[1], E. Fleischman[4], O. Sokova[4], Y. Olshanskaya[5], E. Matveeva[5], O. Streneva[1], E. Shorikov[1], S. Tsvirenko[6], L. Saveliev[6], R. Marschalek[2], L. Fechina[1]
[1]Regional Children's Hospital # 1, Research Institute of Medical Cell Technologies, Ekaterinburg, Russian Federation, [2]Diagnostic Center of Acute Leukemia, Institute of Pharmaceutical Biology/ ZAFES, Goethe-University of Frankfurt, Frankfurt am Main, Germany, [3]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus, [4]N.N. Blokhin Russian Cancer Research Center Russian Academy of Medical Science, [5]Federal Research Institute of Pediatric Hematology, Oncology and Immunology, Moscow, [6]Ural State Medical University, Ekaterinburg, Russian Federation

Background: Acute leukemia (AL) in infants is characterized by high incidence of *MLL* gene rearrangements.
Aims: To evaluate the relation between genomic DNA breakpoints in *MLL* and translocation partner genes (TPGs) and clinical parameters of infant AL.
Methods: 87 infants (32 boys (37%) and 55 girls (63%), median age 4.9 mo) with *MLL*-rearranged acute lymphoblastic leukemia (ALL) (n=63), acute myeloid leukemia (AML) (n=22) and mixed phenotype acute leukemia (MPAL) (n=2) were included in the current study. Genomic DNA breakpoint detection in *MLL* gene and translocation partner genes (TPGs) was performed by long-distance inverse PCR (LDI-PCR). Exon-intron numbering of *MLL* gene was done according to I. Nilson *et al.*, 1996.
Results: Majority of ALL cases was characterized by presence of *MLL-AF4* fusion gene (FG) (n=35;55%), less frequently *MLL-MLLT1* (n=12;22%), *MLL-MLLT3* (n=8;13%) and others were found (Table 1). The most common breakpoint location within *MLL* gene in ALL patients was intron 11, detected in 31 cases (49%), less frequently breakpoints in intron 10 (n=13;21%) and intron 9 (n=9;14%) were found. The highest variability of *MLL* breakpoints was found in *MLL-AF4*-positive patients: only 15 of 35 (43%) had breakpoints in intron 11. The most stable pattern of *MLL* genomic DNA breakpoints was observed in *MLL-MLLT1*-positive patients: 9 of 14 (64%) had breakpoints in intron 11. In AML patients the most prevalent FG was *MLL-MLLT3* (n=8;36%). The remaining ones are listed in Table 1. The most frequent breakpoint location was intron 9 (n=10;45%), less often they were found in intron 10 (n=5;23%) and 11 (n=4;18%). The most stable pattern was revealed for *MLL-MLLT10* FG: *MLL* breakpoints in 4 of 5 (80%) cases were found in intron 9 (Table 1). In TPGs the most frequent breakpoint locations were as follows: in *AF4*-intron 3 (n=25;69%) and intron 4 (n=7;19%); in *MLLT1*-non-coding region between *ACER1* and *MLLT1* (n=9;60%) and intron 1 (n=5;33%); in *MLLT3*-intron 5 (n=13;81%); in *MLLT10*-intron 8 and intron 9 (n=2;33% each); in *EPS15*-intron 1 (n=3;75%). The pattern of breakpoints locations in TPGs was similar in ALL, AML and MPAL cases. Distribution of DNA breakpoints in *MLL* gene was similar in boys and girls and did not depend on type of TPG. ALL patients who had breakpoints in intron 11 were significantly younger (median 3.0 mo, range 0.03-11.6) than all others (median 5.6 mo, range 0.7-11.9) (p=0.025) and than patients with *MLL* breakpoints in intron 9 (median 6.6 mo, range 3.1-11.9) (p=0.017). For AML cases we did not find any relation between age and breakpoints locations. We estimated prognostic significance of *MLL* breakpoint locations in 46 cases of infant ALL homogenously treated by MLL-Baby protocol. 5-year EFS was significantly lower in patients with breakpoint in intron 11 (n=29) in comparison to patients with breakpoints localized from intron 7 to exon 11 (n=17) (0.16±0.07 *vs* 0.38±0.14 p=0.035). While cumulative incidence of relapse was remarkably higher in the first group of patients (0.80±0.33 *vs* 0.56±0.20 p=0.020). Median follow-up time was 36 months. Although in Cox regression model including breakpoint position together with age, immunophenotype, initial WBC count, initial CNS involvement, type of *MLL* rearrangement, absolute blast number at day 8 of dexamethasone profase, minimal residual disease (MRD) at time point 4 (TP4) of MLL-Baby protocol, the only significant covariate was the presence of MRD at TP4 (HR 3.160, 95% CI 1.159-17.815, p=0.021).

Table 1.

Institut de Cancérologie de la Loire, Saint Priest En Jarez, [15]Pediatric Hematology, AP-HP, GH HUEP, Trousseau Hospital, Paris, [16]Hospital Pediatric Hematology, Grenoble, [17]Hospital Pediatric Hematology, Angers, [18]Erytech Pharma, Lyon, France, [19]Synta Pharmaceutical Corp, Boston, United States, [20]Pediatric Hematology, Université Libre de Bruxelles, Brussels, France

Background: Asparaginase is a cornerstone in the treatment of ALL, but its utility is limited by toxicities including hypersensitivity. Clinical allergy is associated with inactivation of asparaginase by antibodies (A-Abs), which can also neutralize asparaginase without any clinical signs of hypersensitivity (silent inactivation). ERY001 improves pharmacokinetics, tolerability and maintain circulating asparaginase (ASPA) activity due to the protective barrier of the erythrocyte membrane.
Aims: The study aimed at evaluating the efficacy and safety of ERYASP
Methods: This open, randomized international Phase 3 study enrolled pts with relapsed ALL. The co-primary endpoints were the duration of ASPA activity >100IU/L and the incidence of ASPA hypersensitivity during induction. Key secondary endpoints were complete remission (CR), minimal residual disease (MRD), event free survival (EFS) and overall survival (OS).The study was powered to detect 3-fold difference in the incidence of allergic reactions between treatments. Pts (n=80), aged 1-55 years were randomized to ERY001 (150 IU/kg, n=26 or L-ASP (10,000 IU/m², n=28), or to ERY001-exp (prior allergy, n=26).
Results: In the non-allergic pts, ERY001 significantly reduced the incidence of ASPA hypersensitivity (0% *vs* 43%; p<0.001). ASPA activity >100 IU/l was 21±5 *vs* 9±8 days in ERY001 and L-ASP, respectively (p<0.001). The CR rate: ERY001 (65%, 95% CI: [51.6:89.8]) *vs* L-ASP (39%, 95% CI: [23.3:63.1]; p=0.026). Allograft was successfully performed in 65% of ERY001 *vs* 46% of L-ASP. The proportion of patients who achieved MRD<10^{-3} in F1-F2/VANDA was 35% and 25% in ERY001, and L-ASP arms, respectively. At 12 mo, EFS rate was 65% and 49% in ERY001 and L-ASP arm, respectively. Treatment with ERY001 was well tolerated.
Summary and Conclusions: ERY001 provides an alternative option for patients with relapsed ALL, which is well tolerated and efficacious.

Stem cell transplantation: Clinical 2

DROPLET DIGITAL PCR FOR DNMT3A AND IDH1/2 MUTATIONS TO IMPROVE EARLY DETECTION OF ACUTE MYELOID LEUKEMIA RELAPSE AFTER ALLOGENEIC HSCT

C. Brambati[1,*] E. Xue[1,2], C. Toffalori[1], S. Galbiati[3], L. Crucitti[2], R. Greco[2], A. Crippa[4], L. Chiesa[1], N. Soriani[3], B. Mazzi[1], C. Tresoldi[4], J. Peccatori[2], M.G. Carrabba[2], M. Bernardi[2], M. Ferrari[3], V. Lampasona[3], F. Ciceri[2], L. Vago[1,2]
[1]Unit of Molecular and Functional Immunogenetics, [2]Hematology and Bone Marrow Transplantation Unit, [3]Genomics for the Diagnosis of Human Pathologies Unit, [4]Immunohematology and Transfusion Medicine, IRCCS San Raffaele Scientific Institute, Milano, Italy

Background: Despite the considerable improvement documented over the last two decades in the outcome of allogeneic Hematopoietic Stem Cell Transplantation (allo-HSCT) for Acute Myeloid Leukemia (AML), disease relapse still represents a major unsolved issue, and efforts are aimed to anticipate relapse detection and treatment to the Minimal Residual Disease (MRD) stage. Recent studies demonstrated that mutations in the DNMT3A and IDH1/2 genes occur very early during the step-wise process of leukemogenesis, possibly representing disease founder mutations and thus optimal markers for MRD tracking.
Aims: To investigate the clinical utility of ultra-sensitive tracking of DNMT3A, IDH1 and IDH2 mutations as post-transplantation MRD monitoring technique.
Methods: By conventional Sanger sequencing, we screened for 6 mutations of interest (DNMT3A R882H and R882C, IDH1 R132C and R132H, IDH2 R140Q and R172K) 86 AML diagnosis samples from patients who underwent allo-HSCT. 113 bone marrow samples collected longitudinally over time from the 23 patients who carried at least one of the mutations were analyzed by ultra-sensitive droplet digital PCR (ddPCR) assays. As controls, we tested bone marrow samples collected at diagnosis from 11 patients typing negative for the mutations, and peripheral blood samples from 19 healthy individuals. ddPCR assays were performed using the Bio-Rad QX100 system: each sample was tested in duplicates, employing 25 ng of genomic DNA in each reaction well. Samples with a mutant-to-wild-type ratio above 0.1% were considered positive. ddPCR results were compared to those obtained testing the same samples by quantitative PCR (qPCR) assessment of the WT1 gene transcript and of hematopoietic chimerism.
Results: All the samples which resulted positive by conventional sequencing were confirmed by ddPCR, and in all of them the population carrying the mutant allele, quantified by ddPCR, consistently exceeded the morphological count of leukemic blasts, suggesting the presence of the mutation also in apparently normal bone marrow hematopoietic cells. All the samples tested at post-transplantation relapse remained positive for the mutations present at diagnosis, except for one case, originally carrying both DNMT3A and IDH2 mutations and typing negative for the latter at relapse. This observation might argue against the putative role of IDH mutations as leukemia-founder events, and suggests that, when present, DNMT3A could represent a more reliable MRD marker. When post-transplantation remission samples were tested, 55/60 (92%) of those harvested from 7 patients who remained long-term leukemia-free (median follow-up after allo-HSCT: 24 months) resulted negative for the mutations of interest. 4/5 of the samples which resulted positive belonged to the early time-points of a single patient who progressively decreased the mutation burden until becoming negative. 6/7 patients who relapsed presented at least one sample harvested during apparent disease remission which resulted positive by ddPCR, anticipating hematological relapse of at least one month. Of notice, only 3 of those relapsed patients had displayed WT1 transcript overexpression and only one had displayed host chimerism above the 1% threshold.
Summary and Conclusions: Although the small number of patients included in this preliminary analysis warrants for caution, ddPCR for DNMT3A and IDH1/2 mutations appears extremely promising, displaying very high specificity and sensitivity in relapse prediction, and comparing favorably with current qPCR-based post-transplantation monitoring techniques.

S442

KIR2DS4 AND ITS VARIANT KIR1D ARE ASSOCIATED WITH AGVHD, CMV AND OS AFTER SIBING RELATED HLA MATCHED TRANSPLANTATION FOR PATIENTS WHOSE DONORS BELONG TO KIR GENE HAPLOTYPE A

X. Wu[1,*] Y. Yao[1], X. Bao[1], X. Tang[1], H. Zhou[1], Y. Han[1], C. Fu[1], A. Sun[1], X. Ma[1], J. Chen[1], Y. Xu[1], J. He[1], D. Wu[1]
[1]The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Hematopoietic stem cell transplantation (HSCT) outcomes of donor and recipient KIR genotypes have been extensively studies. However, the association of KIR2DS4 and its variant KIR1D with outcomes in patients who transplanted from a donor for KIR haplotye A after sibing related HLA matched transplantation has not been explored.
Aims: To the association of KIR2DS4 and its variant KIR1D with outcomes in patients who transplanted from a donor for KIR haplotye A after sibing related HLA matched transplantation.

Methods: To study this, 165 patients transplanted from KIR gene haplotype A were genotyped and divided into three groups: 2DS4+/1D- (two intact KIR2DS4 alleles), 2DS4+/1D+ (heterozygous), 1D+/1D+ (homozygous for the deletion variant KIR1D). No difference of the recovery of neutrophils and platelets was observed in the three groups.
Results: The cumulative incidences of Grade III-IV acute GVHD were 28.94%, 14.11% and 44.44%, respectively, in the 2DS4+/1D-, 2DS4+/1D+ and 1D+/1D+ groups within day+100 (*P*=0.0159). Multivariate analysis identified 1D+/1D+ was an independent risk factor for aGVHD (HR=4.221, 95%CI 1.470-12.124, P=0.007). In contrast, the cumulative incidences of chronic GVHD, 3-year cumulative relapse, and treatment-related mortality displayed no significant difference. The rate of CMV reactivation were 46.96%, 20.16% and 53.25% in the 2DS4+/1D-, 2DS4+/1D+ and 1D+/1D+ groups (P=0.0017). Multivariate analysis identified 2DS4+/1D+ was an independent protective factor for CMV reactivation (HR=0.268, 95%CI 0.125-0.574, P=0.001). Although the overall survival (OS) showed no difference in the first year, the OS of 2DS4+/1D- group showed a significant superiority over the other groups after one year (P=0.0361). In the disease stage of advanced patients, the 3-year probability of DFS were 51.06%, 34.01% and 0% in the 2DS4+/1D-, 2DS4+/1D+ and 1D+/1D+ group (P=0.0314).
Summary and Conclusions: Collectively, our data suggest that the KIR 2DS4/1D allelic variance is associated with the outcome of sibling related HLA matched HSCT, and donor subclassification of KIR 2DS4/1D alleles should be consider in this setting.

S443

HUMAN ATRIAL NATRIURETIC PEPTIDE (HANP) THERAPY IN THE EARLY PHASE AFTER ALLOGENEIC STEM CELL TRANSPLANT (ALLO-SCT) PREVENTS DEVELOPMENT OF CHRONIC KIDNEY DISEASE (CKD): RESULTS FROM A PHASE 2 STUDY

H. Shimizu[1,*] T. Ishizaki[1], N. Hatsumi[2], S. Takada[2], A. Yokohama[1], T. Saitoh[1], T. Sakura[2], H. Handa[1]
[1]Hematology, Gunma University, [2]Leukemia Research Center, Saiseikai Maebashi Hospital, Maebashi, Gunma, Japan

Background: Reducing late complications in allo-SCT recipients is an urgent issue in the field of transplant. One of the most serious complications is renal impairment, which reportedly develops in around 20% of long-term survivors. hANP is commercially available in Japan, and preserves postoperative renal function in patients undergoing cardiovascular surgery. These findings inspired us to investigate the renoprotective effects of hANP administration in allo-SCT recipients.
Aims: The primary objective was to determine the safety, toxicity, and efficacy of hANP administration in the early phase after allo-SCT.
Methods: A prospective phase II study of hANP therapy for preventing renal impairment in allo-SCT recipients was conducted with the permission of the institutional review board. Eligible subjects underwent allo-SCT for the first time between 2009 and 2013 without any restrictions on underlying disease, donor source, or conditioning regimen. After obtaining written informed consent, hANP administration was started the day before transplant at a dose of 0.025 μg/kg/min. This dose was adjusted according to blood pressure and urine volume. Results were compared between the study group and control group who had undergone allo-SCT between 2006 and 2013. We selected a control cohort at the rate of one to three, using an optimal matching method for the following nine factors: age; sex; underlying disease; disease status; conditioning intensity; conditioning with or without total body irradiation (TBI); human leukocyte antigen disparity; donor type; and estimated glomerular filtration rate (eGFR) at baseline.
Results: Eighteen patients (9 men, 9 women; median age, 45 years; range, 18-64 years) were enrolled in this study. Underlying diseases were acute leukemia (n=6), myelodysplastic syndrome (n=6), and others (n=6). Eight, seven, and three patients received transplants from related donors, unrelated donors, and cord blood, respectively, and most patients were conditioned with TBI-containing myeloablative regimens. Median duration of hANP administration was 16 days (range, 3-46 days). Two patients experienced grade 2 hypotension attributable to hANP administration, but both cases resolved immediately upon discontinuation of hANP administration. In addition, hANP administration was discontinued in two patients, due to grade 4 bacterial meningitis and grade 4 sepsis, respectively. For matched-pair analysis, 54 patients were selected, and no significant differences in clinical characteristics were identified between the study and control groups. Although mean eGFR kept declining after transplant in both groups, hANP administration maintained eGFR at a significantly higher level until 30 days after transplant (p <0.001). Incidences of acute kidney injury within 30 days after transplant did not differ significantly between groups, but that within 90 days was significantly lower in the study group (11.1%) than in the control group (40.7%; p=0.023). The incidence of CKD by 1 year after transplant was significantly reduced in the study group (0%) compared to the control group (42.9%; p=0.005). Two-year cumulative incidence of non-relapse mortality and 2-year overall survival rates were similar between groups.
Summary and Conclusions: Our findings demonstrated that hANP administration in the early phase after allo-SCT offers excellent renoprotective effects, resulting in a significant reduction in CKD development, without any serious adverse events in allo-SCT recipients. These findings should be confirmed in a prospective, randomized manner in the near future.

S444

ALLOGENEIC TRANSPLANTATION FOR MYELOFIBROSIS: HIGH DOSE INTENSITY AND EARLY DISEASE STATE ARE FAVORABLE PROGNOSTIC FACTORS.

U. Popat[1,*] R. Bassett[1], J. Chen[1], A. Alousi[1], P. Anderlini[1], S. Ahmed[1], S. Ciurea[1], C. Hosing[1], R. Jones[1], P. Kebriaei[1], I. Khouri[1], Y. Nieto[1], A. Olson[1], B. Oran[1], M. Qazilbash[1], G. Rondon[1], E. Shpall[1], S. Verstovsek[1], B.S. Andersson[1], R. Champlin[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: The Best conditioning regimen, *i.e.* one that is both safe and efficacious for treatment of patients with myelofibrosis (MF) is not known. After observing a higher relapse rate in the initial cohort receiving a reduced intensity regimen, we increased the intensity of the conditioning regimen for subsequent patients, hypothesizing that increased dose intensity delivered with pharmacokinetic- (PK-) dose guidance will reduce the relapse rate without increasing non-relapse mortality (NRM), and thereby improving overall outcome.
Aims: To report final results of a prospective phase II clinical trial of Fludarabine (Flu) and busulfan (bu) conditioning in MF patients with a median follow-up of 5 years.
Methods: Patients with advanced MF were eligible if they had adequate organ function and at least 9/10 HLA matched related or unrelated donor. All 46 patients received fludarabine 40 mg/m^{2}x4 (day -5 to -2), and in the first 15 (bu low group) IV busulfan 130 mg/m^2/dayx2 was given after the Flu dose on days -3,and -2). Of the remaining 31 (bu high group), 27 received IV busulfan dose to a target daily systemic exposure, AUC, of 4000 μmol-minx4, given on day -5 to -2, (total course AUC of 16,000 μmol-min) and 4 patients received a fixed dose of 100 mg/m^2/dayx4 (days -5 to -2), each Bu dose was preceded by the day's Flu dose.
Results: 23 males and 23 females with a median age of 58 years (27-74) had intermediate (27 Int-2, 1 Int-1) or high-risk (18) disease as per Dynamic international prognostic scoring system plus (DIPSS plus) criteria. Donors were matched sibs (19), matched unrelated (23), or mismatched unrelated (4).All patients engrafted with a median time to neutrophil engraftment of 13 (0-27) days and a median time to platelet engraftment of 24 (0-268) days. The Cumulative incidence (CI) of grade II-IV, grade III, and IV acute GVHD, and Chronic GVHD were 22%, 7%, and 40%, respectively. With a median follow up of surviving patients of 5.1 years (range 1-8.3 years), 3 year overall survival (OS), event-free survival (EFS), cumulative incidence (CI) of non-relapse mortality (NRM), and CI of relapse were 69%, 48%, 13%, and 39%, respectively. Multivariate Cox regression analysis showed that Bu-high dose (HR 0.44; P=0.07) was associated with lower relapse rate. Bu-high dose (HR 0.5; P=0.09), DIPSS plus high (HR 2.69; P=0.02) and Age (HR 1.05; P=0.08) were predictors of EFS (Figure 1). DIPSS plus high (HR 5.99; P=0.001) and Age (HR 1.07; P=0.03) were adverse predictors of OS.

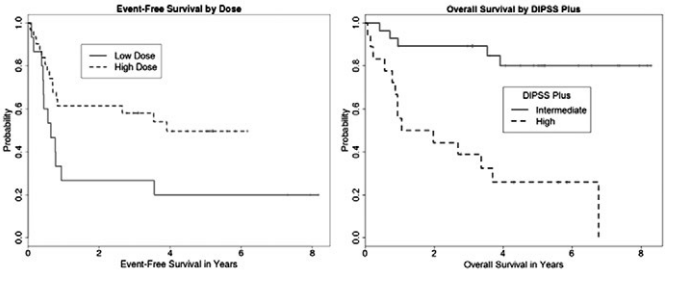

Figure 1.

Summary and Conclusions: Allogeneic transplantation results in long-term survival in patients with myelofibrosis with better outcome seen in earlier phase of the disease. PK guided myeloablative busulfan (AUC 16,000 μmol.min) appears promising in reducing relapse rate without increasing non-relapse mortality.

S445

UPDATED RESULTS OF A MULTICENTER PHASE I/IB STUDY OF CTLA4 BLOCKADE WITH IPILIMUMAB FOR RELAPSED HEMATOLOGIC MALIGNANCIES AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

M.S. Davids[1,*] H.T. Kim[1], C. Costello[2], D. Avigan[3], Y.B. Chen[4], P. Armand[1], E.P. Alyea[1], J. Hedlund[5], P. McSweeney[6], R. Liguori[1], J. Ritz[1], E.D. Ball[2], A. Bashey[7], R.J. Soiffer[1]
[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, [2]Division of BMT, University of California San Diego Moores Cancer Center, La Jolla, [3]BMT Program, Beth Israel Deaconess Medical Center, [4]BMT Program, Massachusetts General Hospital, Boston, [5]New England Cancer Specialists, Scarborough, [6]Colorado Blood Cancer Institute, Denver, [7]Blood and Marrow Transplant Group of Georgia, Northside Hospital, Atlanta, United States

Background: Patients with hematologic malignancies (HM) who relapse after alloHCT often have a dampened graft *versus* tumor (GVT) effect and limited

treatment options. Immune checkpoint modulation with CTLA4 blockade could be a novel pharmacologic strategy to augment GVT to restore the anti-tumor activity of the graft.

Aims: This is an ongoing multicenter phase I/Ib study of the CTLA4 blocking antibody ipilimumab to treat patients (pts) with HM of any histology who relapse after alloHCT. The primary aims are to determine the MTD and evaluate safety. Secondary aims include assessments of efficacy and changes in immune cell phenotype.

Methods: After informed consent was obtained, ipilimumab was given off-label at 3 mg/kg or 10 mg/kg IV every 3 weeks for 4 cycles of induction, followed by maintenance dosing every 12 weeks up to 1 year. Disease-specific response criteria were assessed at the mid-point (7 weeks), end of induction (13 weeks), and throughout maintenance. Immunophenotyping was performed by 8-color flow cytometry and analyzed by FACSDiva.

Results: Twenty-seven pts have received treatment to date. In phase I, 6 pts were treated at 3 mg/kg and 7 pts were treated at 10 mg/kg. An MTD was not reached, and 14 pts subsequently enrolled in the phase Ib expansion cohort at 10 mg/kg. The median number of prior therapies excluding transplant was 3 (range 2-11), and 19/27 (70.4%) of pts had received prior therapy for post transplant relapse. Histologies included AML (n=11), cHL (n=7), NHL (n=4), and MDS (n=2), and 1 pt each had MM, MPN, and ALL. The median age at enrollment was 58 yrs. (range 22-75). Immune-related adverse events (irAEs) were observed in 4 pts, including pneumonitis (n=1 gr2, n=2 gr4), diarrhea (n=2 gr 1), ITP (n=1 gr2), and colitis (n=1 gr 3), and were reversible with steroids, with 3 pts able to resume ipilimumab. Four DLTs leading to discontinuation have been observed, including cGVHD (n=2, both liver, gr 3), aGVHD (n=1, gut, gr 2), and TRM (n=1) due to presumed sepsis in the context of severe irAEs. Seventeen patients discontinued due to progressive disease, and 6 patients remain on active treatment. In an interim efficacy analysis, while none of the 5 evaluable pts treated at 3 mg/kg responded, 8 of the 20 (40.0%) evaluable pts treated at 10 mg/kg had anti-tumor activity. Six pts achieved formal response by disease-specific criteria, including a cHL patient with a PR with dramatic reduction in nodal and extranodal disease and a marrow CR at 7 weeks (see Figure 1), a MM pt with a PR with near resolution of a lung plasmacytoma, and four pts with AML who achieved CR, including two with leukemia cutis and one with myeloid sarcoma. The median follow-up time among survivors is 5.5 mo., and 6 mo. OS is currently 66%. Immunophenotyping studies revealed that while the absolute numbers of both T_{reg} and T_{conv} cells increased slightly after ipilimumab, the ratio of T_{reg}/T_{conv} decreased (range 24% to 41% decrease).

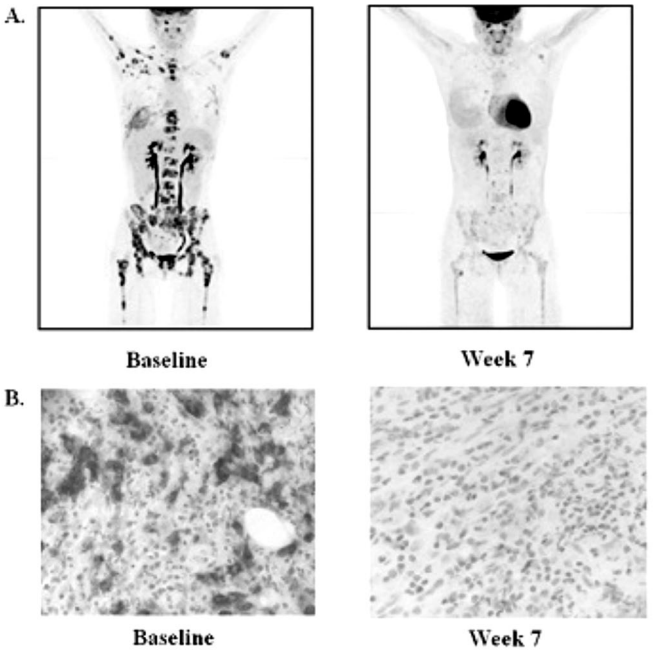

Figure 1. Baseline and week 7 re-staging studies in a classical Hodgkin lymphoma patient after 2 doses of ipilimumab at 10 mg/kg. A. PET/CT scan and B. bone marrow (CD30 stain).

Summary and Conclusions: While some toxicity including irAEs and GVHD was seen with ipilimumab 10 mg/kg in pts with relapsed HM after alloHCT, substantial anti-tumor activity was also observed in pts with both lymphoid and myeloid malignanices, including highly chemorefractory diseases such as leukemia cutis and myeloid sarcoma. The T_{reg}/T_{conv} cell ratio decreased with treatment, consistent with enhancement of GVT. Immune checkpoint modulation with CTLA4 blockade may be a promising new therapeutic approach for post alloHCT relapse, and is worthy of exploration in future studies.

MPN: Prognosis and treatment

RISK FACTORS FOR THROMBOHEMORRHAGIC AND TRANSFORMATION EVENTS IN 3649 HIGH-RISK PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA: RESULTS FROM THE PROSPECTIVE LONG-TERM OBSERVATIONAL EXELS STUDY

G. Birgegård[1,*] C. Besses[2], M. Griesshammer[3], L. Gugliotta[4], C. Harrison[5], M. Hamdani[6], H. Achenbach[7], J.-J. Kiladjian[8]
[1]Department of Haematology, Uppsala University, Uppsala, Sweden, [2]Department of Haematology, Hospital del Mar-IMIM, Barcelona, Spain, [3]Hematology and Oncology, Johannes Wesling Medical Center, Minden, Germany, [4]Department of Haematology, 'L e A Seragnoli', St Orsola-Malpighi Hospital, Bologna, Italy, [5]Department of Haematology, Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [6]Global Biometrics, Shire Pharmaceuticals, Wayne, United States, [7]Research and Development, Shire GmbH, Zug, Switzerland, [8]APHP, Hôpital Saint-Louis, Centre d'Investigations Cliniques, Paris, France

Background: The observational EXELS study (NCT00567502) is the largest prospective cohort of high-risk patients (pts) with essential thrombocythemia (ET) reported to date.

Aims: Study objectives included safety, pregnancy outcomes, and efficacy (measured by incidence of thrombohemorrhagic events and platelet reduction) of anagrelide (ANA) compared with other cytoreductive therapies (CRTs). The multivariate (MV) analysis aimed to identify risk factors for thrombohemorrhagic/transformation events.

Methods: Eligible pts were enrolled across 13 European countries between 2005 and 2009. Data were collected every 6 mo for 5 yrs. Event rates are presented as number of pts per 100 pt-yrs exposure and by treatment at registration. A Cox proportional hazards model was used for the MV analysis to predict events based on certain risk factors. All pts provided informed consent. This study was sponsored by Shire Pharmaceutical Development Ltd.

Results: 3649 pts were categorized according to treatment at registration: ANA (n=804), ANA+other CRT (n=141), other CRT (n=2666), and no CRT (n=38). More than 80% of pts received either hydroxycarbamide (HC) or ANA. Median age was lower in the ANA (55.5 yrs) *vs* other CRT group (70.0 yrs). Thrombohemorrhagic and malignancy event rates are displayed in Table 1. Median platelet counts in the ANA *vs* other CRT group were 443 *vs* 428x10^9/L, respectively, at baseline, and 402 *vs* 430x10^9/L, respectively, at the time of major thrombotic event. Median white blood cell (WBC) counts in the ANA *vs* other CRT group were 8.8 *vs* 6.0x10^9/L, respectively, at baseline, and 9.0 *vs* 6.2x10^9/L, respectively, at the time of major thrombotic event. 64 pts transformed to myelofibrosis (MF) and 31 to acute leukemia (AL). In pts who had only ever received either ANA or HC, the rate of transformation to MF was higher in the ANA *vs* HC group (0.78 *vs* 0.17), whereas transformation to AL was higher in the HC *vs* ANA group (0.22 *vs* 0). Non-hematological malignancy event rate was higher in the other CRT *vs* ANA group. MV analysis identified both a history of thrombohemorrhagic events and age ≥65 yrs at baseline as risk factors for predicting thrombohemorrhagic (hazard ratio [HR] 1.91 and 1.67), major thrombotic (HR 2.05 and 2.14), arterial thrombotic (HR 1.81 and 1.90), venous thrombotic (HR 3.70 and 3.27), and transformation to AL/myelodysplasia (MDS) events (HR 2.17 and 3.36). Presence of baseline cardiovascular risk factors increased the risk of major thrombotic (HR 1.38) and arterial thrombotic events (HR 1.65), while baseline hypertension was a risk factor for thrombohemorrhagic events (HR 1.33). ET diagnostic criteria (WHO *vs* PVSG) and aspirin at registration were not identified as risk factors for thrombohemorrhagic events. Time since diagnosis (5-<10 yrs; ≥10 yrs) and baseline platelet count increase of 100 units above normal (≤450x10^9/L) were both identified as risk factors for transformation to MF (HR 3.38; 4.38 and 5.34).

Table 1.

Treatment at registration	ANA N=804		Other CRT N=2666		ANA + other CRT N=141	
Event	Pts (events) n	Event rate	Pts (events) n	Event rate	Pts (events) n	Event rate
Total thrombohemorrhagic events	65 (81)	2.47	226 (278)	2.41	5 (6)	1.37
Major thrombotic events	43 (52)	1.62	194 (231)	2.06	4 (5)	1.09
Arterial thrombotic events	39 (48)	1.47	147 (175)	1.55	4 (5)	1.09
Venous thrombotic events	4 (4)	0.15	51 (56)	0.53	0	0
Major hemorrhagic events	24 (29)	0.89	42 (47)	0.43	1 (1)	0.27
Transformation to:						
Myelofibrosis	28 (28)	1.04	29 (29)	0.30	7 (7)	1.91
Acute leukemia	2 (2)	0.07	27 (27)	0.28	2 (2)	0.53
Myelodysplasia	0	0	12 (12)	0.12	0	0
Non-hematological malignancy	12 (13)	0.44	123 (140)	1.29	2 (2)	0.54

ANA, anagrelide; CRT, cytoreductive therapy; Pts, patients

Summary and Conclusions: In this large prospective study population, MV analysis identified the following baseline risk factors for thrombohemorrhagic events: history of thrombohemorrhagic events, age ≥65 yrs, cardiovascular risk factors, and hypertension. In contrast, within each treatment group, the baseline platelet and WBC counts do not appear to be significantly different at the time of major thrombotic events. A history of thrombohemorrhagic events, age ≥65 yrs, time since diagnosis, and platelet count increase of 100 units above normal were identified as baseline risk factors for transformation to AL/MDS/MF.

Background: RESPONSE, an ongoing, multicenter, open-label, phase 3 trial, compared the efficacy and safety of ruxolitinib (Rux) with best available therapy (BAT) in patients with polycythemia vera who are resistant to or intolerant of hydroxyurea. Primary analysis results - at 48 weeks from last patient first treatment (LPFT) - have been published (Vannucchi. *NEJM* 2015;372(5):426-435).
Aims: To perform a second preplanned analysis assessing the long-term efficacy and safety of Rux 80 weeks after LPFT.
Methods: Patients ≥18 years of age, who were resistant to or intolerant of hydroxyurea per modified ELN criteria, with splenomegaly, and phlebotomy requirement to control hematocrit (Hct) were eligible. Patients were randomized 1:1 to receive open-label Rux 10 mg BID or BAT; the latter was selected based on investigator's choice. Patients randomized to BAT could cross over to Rux from week 32. The primary response was a composite of (1) achieving a ≥35% reduction from baseline in spleen volume by imaging at week 32 and (2) Hct control without phlebotomy through week 32 (defined as no phlebotomy eligibility between weeks 8 to 32 with no more than 1 phlebotomy eligibility from randomization to week 8). Durability of the primary response, Hct control, spleen volume reduction, complete hematologic remission (CHR), as well as long-term safety, were evaluated.
Results: Overall, 222 patients were randomized (Rux, 110; BAT, 112). At the week 48 analysis, 93 (84.5%) patients randomized to Rux (Rux arm) were still receiving treatment (median exposure, 81 weeks); at the data cutoff for the week 80 anaysis, 91 (82.7%) patients in the Rux arm were still receiving treatment (median exposure, 111 weeks). No patients remained on BAT at the data cutoff for the week 80 analysis, compared with 3 patients at the week 48 analysis. The primary endpoint was achieved in 23 (20.9%) patients in the Rux arm *vs* 1 (0.9%) patient in the BAT arm (P <0.0001). Among the responders in the Rux arm, only 1 patient lost this response (Figure 1). Overall, 60.0% of Rux patients *vs* 19.6% of BAT patients achieved Hct control without phlebotomy through week 32; patients achieving Hct control in the Rux arm had an 89% probability of maintaining this response for 80 weeks from the time of initial response. Of the 98 patients on Rux at week 32, 89.8% did not have a phlebotomy between weeks 32 and 80. At week 32, 38.2% *vs* 0.9% of patients in the Rux *vs* BAT arm achieved a ≥35% reduction in spleen volume; all Rux patients maintained their response. At week 32, CHR was achieved in 23.6% of Rux patients and 8.9% of BAT patients, with Rux responders having a 69% probability of maintaining CHR for 80 weeks. Among patients who discontinued, 5 of 10 in the Rux arm with available data for the Pruritus Symptom Impact Scale at their end-of-study visit rated their pruritus as "very much improved." Nonhematologic adverse events were mainly grade 1 or 2; the most common in the Rux arm included headache (21.8% at the week 80 analysis [ie, entire follow-up] *vs* 20.9% at the week 48 analysis), diarrhea (20.0% *vs* 19.1%), pruritus (20.0% *vs* 17.3%), and fatigue (17.3% *vs* 17.3%). Grade 3 or 4 anemia and thrombocytopenia in the Rux arm did not increase from the week 48 analysis, occurring in 1.8% and 5.5% of patients, respectively. Treatment discontinuation due to adverse events remained low in the Rux arm (4.5%).

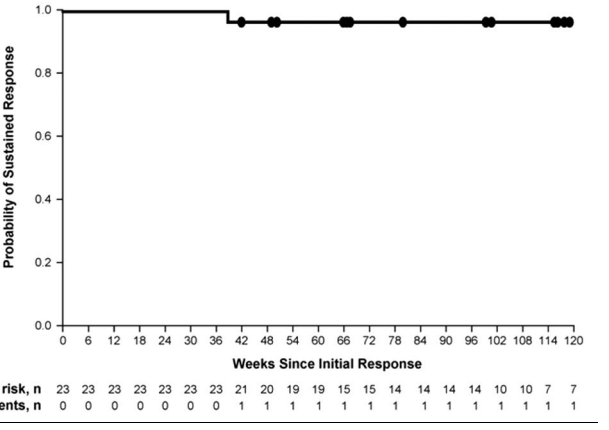

Figure 1. Durability of primary response with rux.

Summary and Conclusions: In the RESPONSE study, Rux benefit was durable and treatment remained generally well tolerated, with 82.7% still receiving Rux at a median exposure of 111 weeks.

S448

RUXOLITINIB (RUX) IN COMBINATION WITH 5-AZACYTIDINE (AZA) AS THERAPY FOR PATIENTS (PTS) WITH MYELOFIBROSIS (MF)

N. Daver[1,*] J. Cortes[1], L. Zhou[1], N. Pemmaraju[1], E. Jabbour[1], G. Borthakur[1], Z. Estrov[1], G. Garcia-Manero[1], H. Kantarjian[1], S. Verstovsek[1]

[1]Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: AZA is a DNA methyltransferase (DNMT) inhibitor with a modest response rate (20-25%) and duration (4 months) in MF. Ruxolitinib and azacytidine may target distinct clinical and pathological manifestations of myelofibrosis.
Aims: To determine the efficacy and safety of the combination in pts with MF.
Methods: A sequential approach with single-agent RUX 15 mg orally twice daily (if platelets 100-200) or 20 mg twice daily (if platelets >200) continuously in 28-day cycles for the first 3 months followed by the addition of AZA 25 mg/m2 on days 1-5 of each 28-day cycle starting cycle 4 was adopted. The AZA dosage could be gradually increased to a maximum of 75 mg/m2. Pts would be treated on study for 15 months followed by continuation of the combination off-study at the discretion of the treating physician.
Results: 35 pts were enrolled between March 2013 and October 2014. 22 (63%) had received a median of 2 (1-3) prior therapies for MF. 31 pts remain alive after a med follow-up of 15.4 (3.4-22.8) months. Study is ongoing. 28 pts have been on the study for at least 6 months and are evaluable for response. International Working Group for Myelofibrosis Research and Treatment 2013 (IWG-MRT) objective responses were noted in 23 (82%), including PR in 1, CI for spleen and total symptom score (TSS) in 5 (18), CI for TSS and hemoglobin in 2 (7), CI for TSS only in 9 (32), and CI for spleen only in 6 (21). Responses occurred in 14 of 18 (78%) previously treated patients and 9 of 10 (90%) untreated pts (P=0.42). Median time to all responses was 1.0 month (0.8-7.5 months). Median time to CI in spleen size was 1.9 months (0.9-6.6), to CI TSS was 1.0 months (0.8-7.5), and CI Hb was 2.1 months (1.1-8.9). A reduction in the baseline $JAK2^{V617F}$ allele burden was noted in 11 of 13 serially evaluable responders with 2 of the responders demonstrating a >50% reduction in allele burden. Serial evaluation of bone marrow fibrosis revealed a documented reduction in EUMNET fibrosis score in 6 of 22 (27%) evaluable responders, after a median of 8 months (5-13) on therapy. Only 5 of the 35 (14%) pts have not required a dose interruption/dose adjustment. The med time to first dose interruption/dose adjustment was 28 days (6-634). Among the 30 pts who needed a dose interruption/adjustment, 27 needed it within 3 months of initiation of the combination. The first change was a dose reduction in 17 pts and a dose interruption in 5 pts. AZA was the agent interrupted in 4 of these pts: 1 never started AZA, 1 didn't resume AZA and 2 resumed AZA at same dose. The reasons for the first dose interruption were thrombocytopenia (n=2), neutropenia (n=1), knee replacement (n=1), and pneumonia (n=1). The first change was a dose increase in 8 pts. AZA was the first drug to be increased in 1 and RUX in 7. The reasons for dose increase were leukocytosis (n=3), progressive splenomegaly (n=1), thrombocytosis (n=2), and suboptimal response (n=3). At the time of submission, 8 patients completed the predefined 15 months on the study, and 20 pts remain on study. Reasons for discontinuation in the remaining 7 pts included AML transformation (n=2), toxicity (n=2), lack of response (n=1), death (n=1), and patient preference (n=1). 4 pts experienced grade 3/4 non-hematological

toxicity including fatigue (n=2), nausea (n=1), pneumonia (n=1), respectively (Table 1).

Table 1. Baseline characteristic (N=35).

Characteristic	N (%) / [range]
Med age, years	66 (47-87)
Male	20 (57)
Prior treatment	22 (63)
ECOG PS < 1	34 (97%)
Diagnosis	
Post-essential thrombocytosis MF	8 (23)
Post-polycythemia MF	8 (23)
Primary MF	19 (54)
Splenomegaly	31 (89)
Med WBC x 10^9/L	13.3 (2.2-60.6)
Med hemoglobin g/dL	10,1 (6.8-16.2)
Med platelets x 10^9/L	259 (126-835)
Med LDH value	1865 (452-4907)
Peripheral blood blasts ≥ 1%	22 (63)
EUMNET fibrosis grade	
MF-1	4 (11)
MF-2	15 (43)
MF-3	16 (46)
JAK2 +	23 (66)
Med JAK2 allele burden	71 (4-95)
Karyotype	
Diploid	21 (60)
Abnormal	13 (37)
Insufficient metaphases	1 (3)

Summary and Conclusions: Administration of RUX with AZA was feasible and resulted in improved response rate. The sequential addition of AZA was well tolerated with a lower incidence of early discontinuation than what has been seen with other ruxolitinib combination therapies. A sequential rather than concomitant approach may be considered when administering ruxolitinib combinations.

S449

EXCELLENT LONG-TERM PROGNOSIS OF IMATINIB-TREATED FIP1L1-PDGFRA POSITIVE EOSINOPHILIA-ASSOCIATED MYELOPROLIFERATIVE NEOPLASM IN CHRONIC OR BLAST PHASE

G. Metzgeroth[1,*] J. Schwaab[1], M. Jawhar[1], N. Naumann[1], W.-K. Hofmann[1], N.C. Cross[2,3], A. Fabarius[1], A. Reiter[1]
[1]III. Medizinische Klinik, Universitätsmedizin Mannheim, Mannheim, Germany, [2]Wessex Regional Genetics Laboratory, Salisbury, [3]Faculty of Medicine, University of Southampton, Southampton, United Kingdom

Background: FIP1L1-PDGFRA (FP) is the most common fusion gene in eosinophilia-associated myeloproliferative neoplasms (MPN-eo) and is exquisitely sensitive to treatment with imatinib. The vast majority of FP positive (FP+) patients (pts) are diagnosed in chronic phase (CP) but rarely also in myeloid or lymphoid blast phase (BP).
Aims: To evaluate the long-term prognosis of FP+ pts in CP or BP on imatinib.
Methods: Here we present the long-term follow-up of 62 imatinib-treated FP+ pts in CP (n=50) or BP (n=12). Median age was 49 years (range 19-70) with a striking male predominance (61/62, 98%). All pts were treated with imatinib (100-400mg/d) for a median of 79 months (range 2-140).
Results: In CP, complete molecular remission (CMR) was observed after 6, 12 and 24 months in 26/48 (54%), 35/42 (83%) and 38/39 (97%) of pts, respectively, as investigated by qualitative nested RT-PCR. The median duration of CMR was 73 months (range 3-129). Imatinib was reduced to 2-3x100mg/week in 15 pts for a median of 28 months (range 1-96) and no relapse has yet been observed. Imatinib was stopped in 4 pts with 3 pts remaining in CMR for 2, 19 and 20 months, respectively. One patient relapsed after 12 months but rapidly achieved second CMR after rechallenge with imatinib. In BP, imatinib was used as monotherapy (n=7) or after intensive chemotherapy (n=5). All pts achieved durable CMR (median 95 months, range 66-132). Overall, imatinib was well tolerated and no grade III-IV toxicities were observed. At the time of analysis, 3 pts had died (CP, n=1; BP, n=2) but no death was disease- or treatment-related. Two pts developed a secondary resistance, 7 and 10 months after start of imatinib. A T674I point mutation in the ATP-binding domain of FIP1L1-PDGFRA was identified in one patient while the mechanism of resistance in the second patient remained unknown. Because treatment with nilotinib and/or sorafenib did not result in significant remissions, both pts received an allogeneic stem cell transplantation (SCT) 5 and 8 months, respectively, after detection of imatinib-resistance. Both pts achieved a rapid complete hematologic remission. One patient has been in stable CMR for 48 months while the second patient died 18 months after SCT in ongoing CMR.
Summary and Conclusions: Treatment with imatinib in FP+ MPN-eo is associated with an excellent long-term prognosis, even if pts are initially diagnosed in myeloid or lymphoid BP. Complete remissions are rapidly achieved, are durable and can be maintained with low-dose imatinib. Discontinuation of imatinib may be feasible in some cases. Primary resistance has not yet been reported and secondary resistance seems to be very rare. If it occurs, the efficacy of second-generation tyrosine kinase inhibitors seems to be poor. Eligible pts should therefore be offered an allogeneic SCT.

S450

OUTCOMES OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION (HCT) IN PATIENTS WITH MYELOFIBROSIS (MF) EXPOSED TO JAK1/2 INHIBITORS

M. Shanavas[1,*] U. Popat[2], L.C. Michaelis[3], V. Fauble[4], D. Mclornan[5], R. Klisovic[6], J. Mascarenhas[7], R. Tamari[8], M. Arcasoy[9], J. Davies[10], U. Gergis[11], O. Ukaegbu[12], R. Kamble[13], J. Storring[14], N.S. Majhail[15], R. Romee[16], J. Lew[7], A. Pagliuca[5], S. Vasu[6], B. Ernst[4], E. Atenafu[1], A. Hanif[3], R. Champlin[2], P. Hari[2], V. Gupta[1]
[1]Princess Margaret Cancer Centre, Toronto, Canada, [2]MD Anderson Cancer Centre, Texas, [3]Medical College Wisconsin, Milwaukee, [4]Mayo Clinic Arizona, Rochester, United States, [5]Kings College, London, United Kingdom, [6]The Ohio State University, Columbus, [7]Mount Sinai Medical Center, [8]Memorial Sloan Kettering Cancer Center, New York, [9]Duke University School of Medicine, Durham, United States, [10]Churchill Hospital, Oxford University Hospitals NHS Trust, Oxford, United Kingdom, [11]Weill Cornell Medical College, New York, [12]Vanderbilt University Medical Center, Nashville, [13]Baylor College of Medicine and Houston Methodist Hospital, Houston, United States, [14]McGill University Health Centre, Montreal, Canada, [15]Taussig Cancer Institute, The Cleveland Clinic Foundation, Cleveland, [16]Washington University School of Medicine, St Louis, United States

Background: JAK1/2 inhibitors (JAK#) have the potential to effectively control MF-related symptoms, and improve the clinical status prior to HCT. However, the clinical experience is limited, and data are conflicting. (Robin *et al.*, Blood, 2013, ASH abstract 306; Stübig *et al.*, Leukemia, 2014). Additionally, the relationship between the response to JAK #, and outcomes of HCT is not clear.
Aims: To report outcomes of HCT in MF patients exposed to JAK#
Methods: In this multi-institutional retrospective study, we evaluated the outcomes of 93 MF patients (pts.) who had exposure to JAK# prior to HCT. A working definition of response to JAK# was established inspired by International Working Group-Myeloproliferative Neoplasms Research and Treatment (IWG-MRT) criteria. (Table1). The primary end point was overall survival (OS) from the date of HCT.

Table 1.

1. Gp-A: Clinical improvement: ≥50% reduction in palpable spleen length for spleen palpable by ≥10 cm, or complete resolution of splenomegaly for spleen <10 cm).
2. Gp-B: Stable disease: spleen response not meeting the criteria of clinical improvement.
3. Gp-C: New onset anemia requiring transfusions, or increase in blast to 10-19%.
4. Gp-D: Progressive disease: Loss of spleen response or progression of splenomegaly.
5. Gp-E: Progressive disease: Leukemic transformation (blast ≥20%).

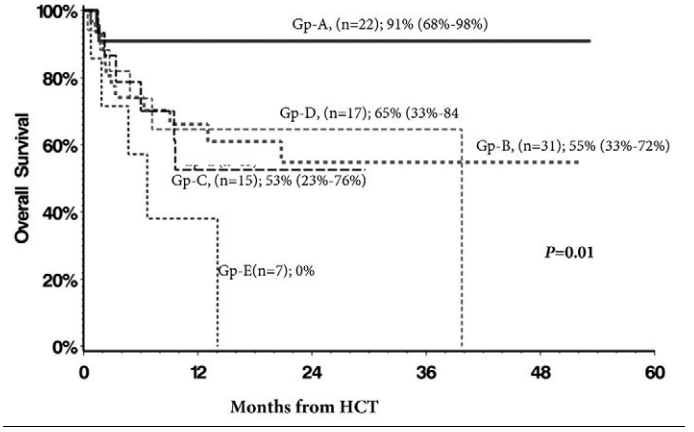

Figure 1. Probabilities of survival at 2 years and (95% CI).

Results: Median age at HCT was 59 years (range 32-72 years). Diagnosis was primary-MF (n=53), post polycythemia-MF (n=20), or post essential thrombocythemia-MF (n=20). DIPSS-plus score at the time of HCT was low in 2 (2%), INT-1 in 19 (22%), INT-2 in 47 (52%), high-risk in 22 (24%), and not available in 3 pts. Conditioning was full intensity in 42 (45%), and reduced intensity in 51 (55%). Donors were matched sibling in 36 (39%), matched unrelated in 47 (51%), and mismatched or haplo-identical in 10 (11%). JAK# used were ruxolitinib (n=84), momelitinib (n=6), or others (n=3). Sixty-five (70%) pts used JAK# leading to HCT, and stopped 0-16 days prior to conditioning regimen; 23 (25%) pts had discontinued the medication at least 4 weeks prior to HCT due to progression or intolerance, and in 5 pts this information was not available. Among pts who used JAK# leading to HCT, "withdrawal symptoms" were reported in 10 (15%), and were more common in pts who stopped JAK inhibitors ≥6 days prior to conditioning regimen compared to those who stopped

within 0-6 days (26% *vs* 11%, *p*=0.06). Withdrawal symptoms were non-severe in nature except in one pt. this resulted in rebound splenomegaly and pulmonary infiltrates necessitating splenectomy and delaying the HCT for 3 months. Primary graft failure was reported in 3 pts (3%). The cumulative incidence of grade ≥2, and ≥3 acute GVHD at 100 days were 44% and 16% respectively. Cumulative incidence of chronic GVHD at 2-years was 53%. Median follow-up of survivors were (2-53) months, and during this period, 12 (13%) pts had relapse/progression and 31 (33%) died. Probability of 2-year OS of whole cohort was 62% (95% CI, 50%>73%). Patient in group-A (n=22) had significantly superior survival *p*=0.01 (Figure 1) Other factors with significant effect on survival in univariate analysis were DIPSS-plus score, donor type, and performance status at HCT. In a limited multivariate analysis, response to JAK# was the strongest independent factor for survival (*p*=0.004). DIPSS-plus high-risk category (p=0.04), and mismatched/haplo donor groups (p=0.04) were other independent factors for survival.

Summary and Conclusions: Our data suggest that use of JAK# prior to HCT does not have adverse effects on early transplant outcomes. Continuation of JAK# until HCT appears to reduce the risk of "withdrawal symptoms". The HCT outcomes in patients responding to JAK# are particularly encouraging.

Molecular markers in AML

Krankenhaus Essen-Werden gGmbH, Essen, [12]Medizinische Hochschule Hannover, Hannover, Germany

Background: *DNMT3A* is frequently mutated in AML and associated with a poor overall (OS) and relapse-free survival (RFS). The presence of *DNMT3A* mutations (*DNMT3A*^{mut}) in early preleukemic stem cells and in apparently healthy elderly highlight its pathogenic role as a founder mutation and as predisposing event in leukemia. Within our clinical AMLSG trials we addressed the question if MRD monitoring in *DNMT3A*^{mut} patients (pts) has clinical impact and delivers further information for risk-adapted therapy and clonal hematopoiesis.

Aims: To monitor MRD for the most common *DNMT3A*^{mut} (*DNMT3A*^{mut}-R882H, n=111 and -R882C, n=48) in a large cohort of AML pts entered on three AMLSG treatment trials [AML HD98A (n=14; NCT00146120), AMLSG 07-04 (n=87; NCT00151242), AMLSG 09-09 (n=58; NCT00893399)].

Methods: *DNMT3A*^{mut} MRD monitoring was performed using a cDNA-based RQ-PCR-assay by TaqMan technology with a sensitivity between 10^{-3} and 10^{-4}. MRD levels have been reported as normalized values of *DNMT3A*^{mut} transcripts per 10^4 *ABL1* transcripts (*DNMT3A*^{mut}/10^4 *ABL1*).

Results: In total, 1,168 samples [bone marrow (BM), n=615; peripheral blood (PB), n=553] from 159 *DNMT3A*^{mut} pts were analysed [diagnosis, n=256; during therapy, n=719; follow-up, n=193]. Median BM *DNMT3A*^{mut} transcript level (TL) at the time of diagnosis was 12690 (range, 0-54280); TL were not associated with known clinical characteristics or mutations in *NPM1* or *FLT3;* there was no impact on OS and RFS. *DNMT3A*^{mut} TL during therapy were significantly higher in BM after induction I, consolidation I and II (p=0.01; p=0.0003; p=0.01) than in PB. After double induction therapy (DI) there was no difference in the median of TL between 102 pts in complete remission (CR) and 12 pts not in CR (12694 and 11309, respectively). There was no prognostic impact of BM *DNMT3A*^{mut} TL as log 10 transformed continuous variable during therapy with regard to death and relapse. Strikingly, the greatest TL reduction was seen after induction I (one log) whereas subsequent therapies did not significantly influence TL. Next, we evaluated the impact of *DNMT3A*^{mut} MRD monitoring for the clinical endpoints OS, cumulative incidence of relapse (CIR) and remission duration (RD) after DI and after end of therapy (ET). After DI and ET, only 7/75 and 4/63 BM samples became MRD negative. At these two time-points MRD positivity did not significantly impact OS (p=0.89; p=0.73), CIR (p=0.74; p=0.29) and RD (p=0.61; p=0.30). Then we investigated the MRD *DNMT3A*^{mut} log10-reduction (compared to level at diagnosis) using the median as a cut-off after DI and ET. Again, there was no significant correlation for pts with a higher TL reduction compared with a lower TL reduction for OS and RD after DI and ET (p=0.87; p=0.38; p=0.67; p=0.57, respectively). Finally, we evaluated the BM *DNMT3A*^{mut} TL as 4 increasing equally sized intervals according to the quartiles of the distribution. There was no prognostic impact after DI on OS and RD (p=0.24; p=0.85) and ET (p=0.38; p=0.44). To increase the number of samples, we also performed the analyses for BM and PB samples, but again, there was no significant impact on prognosis.

Summary and Conclusions: In our study neither the absolute BM *DNMT3A*^{mut} TL at the time of diagnosis nor the reduction of TL or the increasing quartiles after DI and ET showed prognostic impact. In contrast to AML with *NPM1* mutation or associated gene fusions, most pts had persistent *DNMT3A*^{mut} TL supporting the role of persistent clonal hematopoiesis. Serial investigation of *DNMT3A*^{mut} and its concurrent mutations will provide further insights into the clonal evolution of AML.

Trust Sanger Institute, Cambridge, United Kingdom, [3]Departmamento de Biologia Molecular, Instituto de Biomedicina y Biotecnologia de Cantabria (CSIC - UC-Sodercan), Universidad de Cantabria, Santander, Spain, [4]Department of Haematology, University of Cambridge, Cambridge, [5]Institute for Social and Economic Research, University of Essex, Colchester, [6]Department of Haematology, Cambridge University Hospitals NHS Trust, [7]Department of Haematology, Cambridge Blood and Stem Cell Biobank, University of Cambridge, Cambridge, United Kingdom, [8]German Cancer Consortium (DKTK), German Cancer Research Centre (DKFZ), Heidelberg, Germany, [9]Department of Medicine for the Elderly, Cambridge University Hospitals NHS Trust, [10]Human Genetics, Wellcome Trust Sanger Institute, [11]NHS Blood and Transplant, Cambridge Biomedical Campus, Cambridge, United Kingdom

Background: Clonal haemopoiesis driven by leukaemia-associated gene mutations can occur without evidence of a blood disorder.
Aims: To investigate the incidence, target genes and age distribution of age-related clonal haemopoiesis (ARCH).
Methods: We performed targeted ultra-deep re-sequencing for hotspot mutations at 15 gene loci recurrently mutated in myeloid malignancies in the blood DNA of 4219 individuals including a large number of elderly people.To do this we developed and validated a robust methodology, employing barcoded multiplex PCR of mutational hotspots followed by next-generation sequencing (MiSeq) and bioinformatic analysis. This reliably detected mutation-associated circulating blood cell clones with a variant allele fraction (VAF) ≥0.008 (0.8%).
Results: Using only the hotspots studied, we identified clonal haemopoiesis in 0.8% of individuals under 60, rising to 19.5% of those ≥90 years; predicting that clonal haemopoiesis is much more prevalent overall than was previously realized. Indeed, using our findings as a basis for projection, we estimate the overall prevalence of age related clonal haemopoiesis (ARCH) to be >70% in those older than 90 years. *DNMT3A*-R882 mutations were most common and, although their incidence increased with age, were found in individuals as young as 25 years. By contrast mutations affecting spliceosome genes *SF3B1* and *SRSF2*, closely associated with the myelodysplastic syndromes, were only identified in those aged >70 years, with several individuals harboring more than one such mutation.This indicates that spliceosome gene mutations drive clonal expansion under selection pressures operating in the ageing haemopoietic system and explains the high incidence of clonal disorders associated with these mutations in advanced old age. Finally, despite using a very sensitive method and a mutation-calling script written specifically for this purpose, no samples with NPM1 mutations of VAF ≥0.008 were identified.

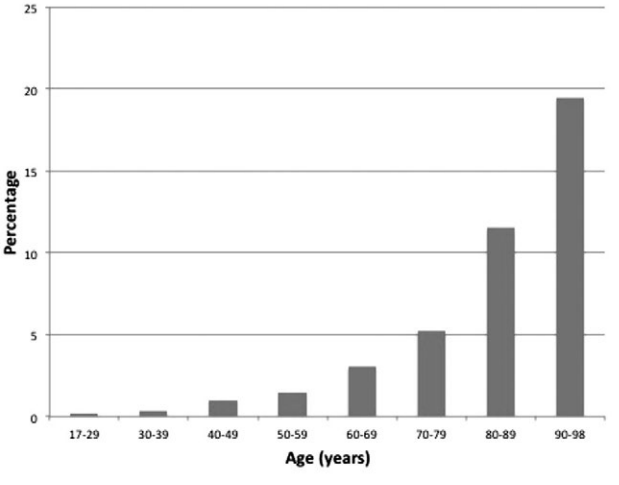

Figure 1. The prevalence of clonal haemopoiesis driven by only 9 hotspot mutations by age.

Summary and Conclusions: Our results demonstrate that the incidence of clonal haemopoiesis is much higher than suggested by exome sequencing studies, that splicesome gene mutations drive clonal outgrowth primarily in the context of an aging haematopoietic compartment, and that NPM1 mutations do not drive ARCH, indicating that their acquisition is closely associated with frank leukemia.

S453

JAM-C: A NEW LEUKEMIC STEM CELL BIOMARKER IN ACUTE MYELOID LEUKEMIA

M. De Grandis[1,*] A.-S. Chretien[2], L. Pouyet[3], F. Bardin[1], G. Bidaut[4], M.-J. Mozziconacci[5], S. Mancini[1], M. Balzano[1], R. Castellano[3], T. Prebet[5], D. Olive[2], C. Fauriat[2], Y. Colette[3], N. Vey[5], M. Aurrand-Lions[1]
[1]Team: Junctional Adhesion Molecules in Tumor/host Interaction, [2]Team: Immunity and Cancer, [3]Team: TrGET preclinical assay platform, [4]Team: Integrative Bioinformatics platform Cibi, CRCM; Inserm UMR1068; IPC; Aix-Marseille University UM105; CNRS UMR7258, [5]Onco-Hematology (EToH) Department, Institut Paoli-Calmettes, Marseille, France

Background: Acute myeloid leukemia (AML) is a clonal hematologic malignancy arising from a rare population of leukemic stem cells (LSCs) that initiate and propagate the disease. LSCs are enriched within the CD34+CD38low/- compartment expressing the IL-3 receptor α-chain, CD123. In contrast, normal hematopoietic stem cells do not express CD123. Several studies have recently shown that a fraction of LSCs, residing in particular niches of the bone marrow, resists to chemotherapy and is associated with poor clinical outcome.
Aims: We were interested to explore cell-adhesion and migratory properties of LSC aiming at identification of new cell-surface marker able to define a Leukemic Initiating Cell population within the LSC compartment.
Methods: AML patient samples were analyzed by flow cytometry to characterize protein expression profile in the LSC compartment and then engrafted in NOD scid gamma chain deficient (NSG) mice. Clonogenic and cobblestone-area forming cell (CAFC) assays *in vitro* and gene-expression profiling were performed to characterize *stemness* and regenerative *potential* of defined LSCs subsets.
Results: We confirmed in a large cohort of 34 AML *de novo* patients results showing correlation between mouse engraftment and poor AML disease prognosis. Engrafting patients had a significant poorer overall survival as compared to non-engrafting. Searching for molecular factors that could affect AML engraftment, we found that the junctional adhesion molecule-C (JAM-C) was expressed by a fraction of LSCs. JAM-C is an adhesion molecule that we have previously shown to be expressed by mouse and human hematopoietic stem cells. Functionally, JAM-C interaction with JAM-B expressed on stromal cells was involved in HSC retention in the bone marrow. Here, we showed that percentages of JAM-C expressing cells in CD34+CD38low/-CD123+ leukemic cells at diagnosis were significantly increased in engrafting AML patient samples as compared to non-engrafting samples. Since engraftment was correlated to survival, we then tested if the frequencies of circulating CD34+CD38low/-CD123+JAM-C+ cells could provide prognostic information. 60 AML *de novo* patient samples at diagnostic were analyzed. We found that high frequencies of JAM-C positive cells in the LSC compartment were correlated to poor overall survival and significant reduced leukemia-free survival. Along this line, the study of 10 paired AML samples at diagnosis and relapse revealed a significant increase of JAM-C positive cells in the LSC compartment in all patient samples at relapse as compared to diagnosis. Functional properties of these cells were then tested. Clonogenic and CAFC assays showed that JAM-C+ LSCs grow into colonies whereas JAM-C- cells do not. Moreover, JAM-C+ LSCs established leukemia *in vivo* whereas JAM-C- cells didn't engraft in mice. Finally we showed that JAM-C+ cells are predominantly in G0 phase and have a more immature gene expression profile compared to JAM-C- cells.
Summary and Conclusions: All together, these data indicate that JAM-C is a unique marker for primitive leukemic stem cells and strongly suggest that JAM-C expression defines a Leukemic Initiating Cell population within the LSC compartment. Given the increased expression of this adhesion molecule by LSCs during relapse, we propose that targeting JAM-C should be a promising adjuvant therapeutic strategy to inhibit retention of leukemic stem cells within bone marrow stromal niches.

UTILIZING EXOSOMES AS INNOVATIVE MICRORNA BIOMARKERS AND TARGETED DRUG-DELIVERY VEHICLES IN ACUTE MYELOID LEUKEMIA

R. McGlauflin[1,*] I. Prudovsky[1,2,3], C. Vary[1,2,3], P. Sathyanarayana[1,2,3]
[1]Center for Molecular Medicine, Maine Medical Center Research Institute, Scarborough, Maine, [2]The Graduate School of Biomedical Science and Engineering, University of Maine, Orono, Maine, [3]Department of Medicine, Tufts University School of Medicine, Boston, Massachusetts, United States

Background: Exosomes are microvesicles that play important roles in intercellular communications in both normal and tumor cells via their cargoes, which include microRNA (miRNA) and proteins. miRNAs play critical regulatory roles in hematopoiesis, and their abnormal expression is correlated with several hematological malignancies, including acute myeloid leukemia (AML). Exosome-derived miRNAs and proteins are increasingly recognized for their prognostic biomarker potential. Exosomes are being evaluated for their potential as novel drug-delivery vehicles due to their endogenous nature and ability to carry small molecule drugs.
Aims: We aim to characterize HSC-derived exosomes, investigate the biomarker potential of exosomes derived from AML patient samples (by examining their proteomic and miRNA profiles) and utilize exosomes as innovative drug delivery vehicles with the ability to eliminate leukemic stem cells in a targeted manner.
Methods: Secreted exosomes from murine bone marrow HSCs were isolated from conditioned medium and visualized using confocal microscopy. We isolated exosomes and performed miRNA profiling, using qPCR, and LC-MS/MS proteomic analysis to characterize the constituents. We also isolated exosomes from the CD34+ cells of three AML patient samples and profiled 372 of the

most abundantly expressed miRs in these cells compared to normal CD34+ cells. We analyzed the proteome of these exosomes as well. In order to assess the utility of exosomes as drug carriers, exosomes from bone marrow-derived OP9 stromal cells were transfected with Daunorubicin (1ug/ul). Normal CD34+ cells and patient-derived AML samples (from n=2 patients) were treated with varying doses of the drug-loaded exosomes. Drug-loaded exosomes uptake was tracked with a Texas Red siRNA. After 24 hours, cells were screened for apoptosis. To test the feasibility of targeted exosomes, OP9 cells were exposed to AML patient samples for 48 hours. The patient cells were then removed and, 24 hours later, "trained" stromal cell-derived exosomes were isolated from the media and transfected with Daunorubicin. These patient-specific, exosomes were plated with both the corresponding patient's CD34+ cells as well as normal CD34 cells (Figure 1A). After 24 hours, apoptosis was measured.

Results: miRNA profiling of murine bone marrow showed *miR-21a*, *miR-92a* and *miR-25* were most abundant in exosomes. Proteomic LC-MS/MS analysis revealed presence of exosome-associated novel proteins such as Syntenin-1. Syntenin-1, which is known to bind IL-5R and promote myelopoiesis, was present in significantly higher levels in HSCs compared to myeloid progenitors, implying a functional role for exosome derived Syntenin-1. miRNA profiling in AML samples revealed distinct signature profiles. Importantly, exosome derived miRs such as -1290, -375, -205 and -21—that are known prognostic markers in cancers such as prostate, ovarian and hepatocellular carcinoma—were significantly upregulated in all the three exosome-derived AML samples. The drug-loaded exosomes were successful in inducing significant apoptosis in two patient samples tested. These drug-loaded exosomes also induced cell death in CD34+ normal cells when compared to control exosomes. However, the patient-trained exosomes specifically eliminated 92% of CD34+ patient cells, while causing significantly less cell death (44%) of normal CD34+ cells exposed to drug-loaded, patient-trained exosomes (Figure 1B).

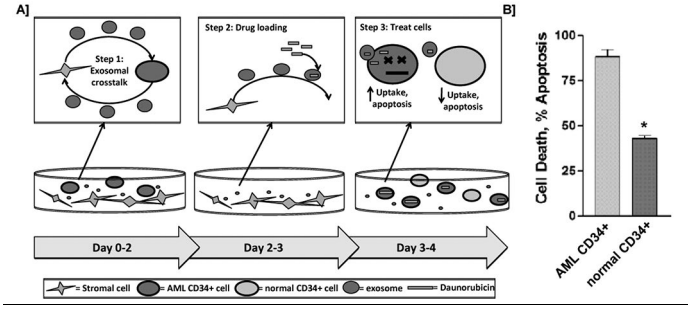

Figure 1. Trained loaded exosomes specifically target leukemic cells. A] Schematic diagram illustrating the experimental design for the generation of the trained loaded exosomes (TLE). B] Cell death analyses of the AML patient CD34+ cells compared to normal CD34+ cells upon exposure to TLE are graphen (mean +/- SEM, *p<0.05).

Summary and Conclusions: Taken together, our data predict important functional roles for exosome-derived Syntenin-1 in regulating lineage specific hematopoietic differentiations. Furthermore, for the first time, we have identified highly upregulated select exosome-derived miRs from AML patient samples whose prognostic value has been recently reported for other cancers, making these miRs promising candidates for AML biomarkers as well. Finally, stromal cell-derived, drug-loaded exosomes are not only able to induce apoptosis in AML patient samples, but they can effectively be trained by leukemic cells to favor uptake resulting in targeted elimination of leukemic over normal CD34+ cells.

S455

MICRORNA EXPRESSION BASED OUTCOME PREDICTION IN AML-CROSS-PLATFORM INTEGRATIVE ANALYSES LEAD THE WAY TO NOVEL INSIGHTS

V. Shivarov[1,*] K. Lang[2], A. Dolnik[2], J. Krönke[2], P. Paschka[2], V.I. Gaidzik[2], D. Hartmut[2], R.F. Schlenk[2], K. Döhner[2], L. Bullinger[2]
[1]Laboratory of Clinical Immunology, Sofiamed University Hospital, Sofia, Bulgaria, [2]Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: Recent advances in omics technologies allowed for affordable generation of large scale molecular data including microRNA expression profiling. These data are expected to serve as an invaluable source for molecular based classification and prognostication of genetically heterogeneous diseases such as acute myeloid leukemia (AML). Besides, the integration of various layers of omics data may serve for the generation of novel testable hypotheses regarding disease pathogenesis.

Aims: Here, we aimed to develop a novel microRNA expression based prognostic score using data from two different platforms-microarrays and RNA-Seq data from adult patients with de novo AML and to investigate the underlying biological pathways.

Methods: We used microRNA microarray expression data from 91 adult patients with de novo AML enrolled into the AMLSG treatment protocol AML HD98A (ClinicalTrials.gov Identifier: NCT00146120) (training dataset). Another group of 177 AML patients with microRNA expression profiling data (RNA-Seq) from the Cancer Genome Atlas (TCGA) served as a validation set. A scoring system was built using the Robust Likelihood-Based Survival Modeling with Microarray Data method. The selected model included 7 microRNAs (miR-100, miR-132, miR-185, miR-186, miR-302a, miR-330, and miR-422a). A total continuous score was calculated for each patient sample using the Cox regression coefficients obtained for the training dataset multiplied by the expression levels in each sample and summed afterwards. Discrete scores (low *vs* high) were defined using Receiver Operating Characteristics (ROC) curve analysis. In addition, bioinformatic analysis of the GEP, RNA-Seq and DNA methylation data from the TCGA was performed.

Results: For both the training and validation dataset the discrete scores were significant prognostic factors in univariate analysis (p=0.001 and p=0.002, respectively). The continuous score, which performed almost identically, was also a significant factor in multivariate analysis (p<0.001 and p=0.022, respectively). In an analysis restricted to cytogenetically normal (CN) AML the discrete score was a significant adverse prognostic factor in the training dataset based on the log-rank test (p=0.045), and it appeared as independent prognostic factor in the validation subset of younger CN-AML patients in a multivariate model including age, gender, *FLT3*-ITD and *NPM1* mutational status (p=0.001). Next, we performed a network analysis of the 7 microRNAs and their known and putative targets and found an enrichment with nucleic acids binding proteins. Using the TCGA GEP data we identified 850 probe sets that were differentially expressed between Low and High Score patients at the level of p<0.01. GO analysis showed that "General transcription regulation" was the most significantly overrepresented pathway. Similarly, when Gene Set Enrichment Analysis (GSEA) was used for the subset of CN-AML <61 years the 7 top scoring gene signatures were associated with RNA metabolism and processing. The top scoring gene set was the "RNA SPLICING" signature. The differential exon usage (DEU) analysis between Low and High Score patients showed a total of 7500 differentially expressed tags at a level of significance of 0.05. Finally, we obtained the TCGA DNA methylation data and found a total of 1218 CpG sites differentially methylated between the Low and High Score patients and hierarchical clustering showed a very good correlation with the miRNA score.

Summary and Conclusions: We demonstrated the feasibility to integrate microRNA expression data from different platforms (microarray and RNA-Seq data) for building prognostic scores in AML. Moreover, the integrated analysis of omics data from microRNA expression score-defined subgroups provided further evidence for the potential biological relevance of these subgroups and a role of the RNA splicing machinery deregulation in the pathogenesis of AML.

Oncogenic mechanisms and novel targets in non-Hodgkin's lymphoma

S456

THE LANDSCAPE OF SOMATIC ALTERATIONS IN ADULT T-CELL LEUKEMIA/LYMPHOMA

Background: Adult T-cell leukemia/lymphoma (ATL) is one of the most aggressive peripheral T-cell malignancies, which is etiologically associated with human T-cell leukemia virus type 1 (HTLV-1) infection. Although HTLV-1 can effectively immortalize infected T cells, there is a long latency period of 30~50 years before the onset of ATL, suggesting that HTLV-1 infection alone may be insufficient for the development of ATL, but additional genetic lesions that accumulate during the later life are essential. However, such somatic alterations underlying the pathogenesis of ATL remain elusive.
Aims: The aim of this study is to elucidate the landscape of genetic alterations in ATL.
Methods: We performed an integrated molecular study, in which whole-genome/exome and transcriptome sequencing were performed together with array-based methylation and genomic copy number analysis among a cohort of 81 paired ATL samples, followed by extensive validation using targeted capture sequencing of detected mutations in 370 follow-up samples.
Results: Compared with other hematologic malignancies, ATL cells harbored higher numbers of sequence mutations, copy number alterations, and structural variants, suggesting the presence of global genomic instability in ATL. In addition to previously reported mutational targets in ATL (*TP53, FAS,* and *CCR4)* and known targets frequently mutated in other lymphoid malignancies (*CARD11*, *GATA3*, *IRF4*, *POT1, CD58, STAT3* and *RHOA*), we identified a variety of recurrent mutations affecting previously unknown mutational targets, many of which are involved in development, activation and migration of T-cells, immune surveillance, transcriptional regulation, and histone modification. Molecular and functional analysis using human cell lines showed that some of these novel mutations actually enhance T-cell function, validating their biological significance in ATL. A comparison of mutations among disease subtypes revealed several subtype-specific mutations, including *TP53* and *IRF4* mutations in acute and lymphoma types, and *STAT3* mutation in chronic and smoldering types, suggesting that there is a difference in the underlying oncogenic mechanisms between indolent and aggressive forms. Moreover, several mutations, including those in *TP53*, *IRF4* and *CCR4*, independently predicted worse clinical outcomes. ATL cells showed a distinct pattern of copy number changes and genomic rearrangements. Interestingly, their gene targets showed a significant overlap to mutational targets. Intriguingly, somatic focal deletions involving the 14q31.1 locus were observed in all the cases examined by whole-genome sequencing and therefore are thought to characterize ATL genomes, although their gene targets remained to be identified. Conspicuously, pathway analysis demonstrated that multiple genes involved in the Tax interactome were systematically altered in ATL, although Tax itself underwent gene silencing in most cases. These data suggested that ATL cells can escape from immune surveillance by silencing immunogenic Tax expression, while developing alternative oncogenic mechanisms through acquiring somatic mutations or copy number alterations in the Tax-related pathway.
Summary and Conclusions: Our findings suggest that the deregulation of T-cell functionalities caused by genetic alterations, especially those related with HTLV-1 Tax oncoprotein, are pivotal to ATL pathogenesis, and provide a novel clue to contrive new diagnostics and therapeutics to combat this intractable disease.

S457

NPM-ALK MIMICS THYMIC PRE-T CELL RECEPTOR (TCR) EXPANSION BUT REQUIRES TRANSIENT TCR EXPRESSION FOR THYMIC EGRESS AND PERIPHERAL ANAPLASTIC LARGE CELL LYMPHOMA DEVELOPMENT

Background: Anaplastic Large Cell Lymphoma (ALCL) is a peripheral T cell lymphoma of children and adults which is characterized by aberrant ALK expression and signaling, usually driven by the *NPM* promoter resulting from the t(2;5)(p23;q35). Although ALK+ ALCL cells commonly express T cell activation (CD30) and cytotoxic (Granzyme, perforin, TIA1) markers and have clonal TCR gene rearrangements, the TCR/CD3 signaling complex is strikingly absent. It is also not clear at what stage of T lymphoid development lymphomagenesis initiates, but since NPM expression is ubiquitous it is possible that this may occur before thymic egress.
Aims: We undertook a combined human and murine approach to evaluate the place of TCR rearrangement in ALCL development and the timing of NPM-ALK driven lymphoma onset.
Methods: Human ALCL were analyzed by multiplex TCR PCR from DNA (d, g and b loci) or cDNA (a locus), with Sanger sequencing and TCRa/d Agilent CGHa analysis for cases with available material. We used the murine model of T cell lymphomagenesis in which NPM-ALK is expressed from the CD4 promoter and following back-crosses to the RAG deficient and/or OTI TCR transgenic lines assessed tumor development and phenotype.
Results: Of 57 human, ALK+ ALCL (48 pediatric, 9 adult) with at least 40% tumor involvement, cases with predominantly in-frame TCRa and TCRb rearrangements were the most common category (56%), followed by 19% with predominantly in-frame TCRg and TCRd rearrangements and 14% with no clonal TCR rearrangements. More surprisingly, 6 cases (11%) demonstrated clonal out-of-frame TCRg but in-frame TCRa rearrangements in the absence of apparent clonal TCRB rearrangement, suggesting that NPM-ALK may in some way replace TCRb mediated signaling. In keeping with this, CD4 driven NPM-ALK rag competent transgenic mice (CD4NA/rag2$^{+/+}$) demonstrated a block in thymic T lymphoid development at the Double Negative (DN)3 stage, which was not observed in the CD4NArag2$^{-/-}$ mice, which developed cortical thymic tumors composed of CD4/8 DP and CD4 SP cells, but no peripheral tumors. Crossing these mice with the ovalbumin (ova) TCR transgene allowed thymic egress (in the absence of ova) and the development of peripheral ALCL, pathologically similar to those observed in humans. Intriguingly, this only occurred in a RAG competent context and in the absence of ova and was associated with loss of the TCR transgene, since CD4NA/OTImice exposed to ova and CD4NA/rag2$^{-/-}$ mice only developed non-hematopoietic hepatic or gastro-intestinal sarcomas, although TCR transgene expressing T cells were seen in the peripheryin the former.
Summary and Conclusions: These data demonstrate that NPM-ALK (and ALK signaling) allows replacement of the thymic proliferative process of TCR beta-selection, mediated by the pre-TCR, and development of thymic tumors, but that TCR expression is required for thymic egress and development of peripheral lymphoma resembling human ALCL. However, the latter is dependenton loss of TCR signaling, suggesting that simultaneous NPM-ALK and TCR activities are not permissive of ALCL development and/or survival. In this context, TCR signaling (but not unstimulated TCR expression) appears to act as a tumor suppressor. These data also represent the first murine model resembling human ALCL and provide proof of concept of an explanation of the pathogenic role for the long recognized "missing TCR" in peripheral T cell lymphomas, which may have implications beyond ALCL.

S458

IDENTIFICATION OF DIFFERENTIALLY METHYLATED DISTANT ENHANCERS RELATED TO ABERRANT EXPRESSION OF SOX11 IN MANTLE CELL LYMPHOMA

R. Beekman[1,*] R. Vilarrasa-Blasi[1], A. Queirós[1], H. van de Werken[2], A. Enjuanes[1], N. Russiñol[1], G. Castellano[1], G. Clot[1], A. Navarro[1], S. Beà[1], A. Bergmann[3], J. Martens[4], H. Stunnenberg[4], R. Siebert[3], E. Campo[1], J.-I. Martín-Subero[1]

[1]IDIBAPS, Barcelona, Spain, [2]Erasmus MC, Rotterdam, Netherlands, [3]Christian-Albrechts-University and Kiel and University Hospital Schleswig-Holstein, Kiel, Germany, [4]Radboud University Nijmegen, Nijmegen, Netherlands

Background: SOX11 is an SRY-related HMG-box transcription factor (TF) family member aberrantly expressed in the majority of mantle cell lymphoma (MCL) cases. The transcriptional program regulated by SOX11 and its potential oncogenic mechanisms in MCL pathogenesis have recently started to be elucidated. However, the mechanisms underlying its aberrant expression in MCL remain unclear. No mutations, genetic aberrations or direct correlations with differential DNA methylation at the promoter region related to its expression have been found in MCL. As it is becoming increasingly clear that remote enhancers may regulate gene expression, we hypothesized that distant regulatory regions might be involved in regulating aberrant SOX11 expression in MCL.
Aims: In this study, we aimed to identify and characterize distal regulatory elements associated with aberrant SOX11 expression in MCL.
Methods: We analyzed the 3-dimensional structure of the *SOX11* genomic region and its chromatin architecture by combining 4C- and ChIP-sequencing in Z-138 and JVM-2, a SOX11-positive and a SOX11-negative MCL cell line, respectively. Additionally, we analyzed the DNA methylation status of distant enhancers that potentially regulate SOX11 expression by bisulfite pyrosequencing in normal naive B cells, SOX11-positive and SOX11-negative primary MCL cases. Finally, we performed TF motif enrichment analysis to identify TFs that potentially regulate aberrant SOX11 expression in MCL.
Results: By 4C-sequencing in the SOX11-positive cell line Z-138, we identified two genomic regions that show high contact frequencies with the *SOX11* locus in 3-dimensional space. These regions were located between 500KB and 1MB from the *SOX11* locus. In Z-138, these regions were enriched for histone marks H3K4me1 and H3K27ac, indicative of enhancer activity. In the SOX11-negative MCL cell line JVM-2, neither high contact frequencies with the *SOX11* locus, nor enrichment of H3K4me1 and H3K27ac were observed at these loci. Next, we investigated whether enhancer activity and DNA methylation levels are inversely associated at the identified distant regulatory regions, as described for other loci. We observed that DNA methylation levels in these regions were significantly lower in SOX11-positive (n=12, average methylation levels 13-21%) than in SOX11-negative primary MCL cases (n=10, average methylation levels 51-85%) (*P-value* <0.01). Furthermore, in normal naive B cells these regions were highly methylated (n=4, average methylation levels 76-92%). These data support our 4C-seq findings in MCL cell lines and suggest that these regions harbour active enhancers only in SOX11-positive primary MCL cases. Next, we investigated the binding of 161 TFs (as identified by the ENCODE project) at the *SOX11* locus and its potential distant enhancers. In total we identified binding sites of 13 TFs bound both to the *SOX11* locus and to one or both potential distant enhancers. None of these were significantly higher expressed in SOX11-positive compared to SOX11-negative primary MCL cases. Surprisingly, one of the distant enhancer regions is bound by many TFs involved in B-cell development. However, it remains to be elucidated how these B-cell related TFs play a role in SOX11 expression in MCL, as in normal B cells SOX11 is not expressed.
Summary and Conclusions: Altogether, our data suggest a model in which SOX11 expression in MCL is associated with looping of the *SOX11* locus to two newly-identified distant enhancer regions. Further experiments, however, are necessary to elucidate the mechanisms underlying their aberrant activation in SOX11-positive MCL cases.

S459

BCL6 AND EZH2 COOPERATE TO ASSEMBLE NON-CANONICAL PRC1-BCOR COMPLEX TO MEDIATE GERMINAL CENTER FORMATION AND PROMOTE LYMPHOMAGENESIS BY REPRESSING BIVALENT CHROMATIN DOMAINS

W. Béguelin[1,*] M. Teater[1,2], K. Hatzi[1], Y. Jiang[1,2], R. D. Gascoyne[3], O. Abdel-Wahab[4], R. Shaknovich[1], V.J. Bardwell[5], O. Elemento[2], A.M. Melnick[1]
[1]Medicine, Weill Cornell Medical College, [2]Institute for Computational Biomedicine, Weill Cornell Medical College, New York City, United States, [3]Centre for Lymphoid Cancer and Departments of Pathology and Experimental Therapeutics, British Columbia Cancer Research Centre, Vancouver, Canada, [4]Human Oncology and Pathogenesis Program, Memorial Sloan-Kettering Cancer Center, New York City, [5]Developmental Biology Center, Masonic Cancer Center, and Department of Genetics, Cell Biology, and Development, University of Minnesota, Minneapolis, United States

Background: The majority of B cell lymphomas arise from germinal center (GC) B cells, which form part of the humoral immune response to T cell-dependent antigen stimulation. Understanding how B cells impose and maintain the GC phenotype may thus provide important clues to explain the pathogenesis of GC B cell-derived lymphomas and inform the design of rational therapeutic strategies for patients with diffuse large B cell lymphomas (DLBCLs) and follicular lymphomas (FLs). Upon activation, GC B cells upregulate EZH2, a histone methyltransferase that forms part of Polycomb Repressive Complex 2 (PRC2). EZH2 is targeted by gain-of-function somatic mutations that enhance its ability to trimethylate histone 3 lysine 27 in DLBCLs and FLs. We previously found that EZH2 mediates the GC phenotype through *de novo* formation of bivalently marked chromatin domains (characterized by overlapping H3K27me3 repressive mark with the H3K4me3 activation mark) at the promoters of target genes involved in cell cycle regulation and in GC exit, to transiently suppress GC B cell differentiation. Mutant EZH2 reinforced these effects through enhanced silencing of these bivalent genes. EZH2 mutation induced GC hyperplasia in mice, and DLBCL patients with mutant EZH2 displayed more profound repression of the GC bivalent genes, suggesting that mutant EZH2 contributes to human lymphomagenesis through repression of bivalent chromatin domains.
This scenario is reminiscent of the role of the transcriptional repressor BCL6, which is also required for GC formation and survival of DLBCL cells. Notably BCL6 represses its targets by associating with BCoR, which forms a variant of Polycomb Repressive Complex 1 (PRC1).
Aims: We hypothesized that EZH2, BCL6, and PRC1-BCoR cooperate to mediate the GC B cell phenotype and when aberrantly active may cooperate to form GC-derived B cell lymphomas.
Methods and Results: Using transgenic animal models we found that EZH2, BCL6, and BCoR are mutually dependent to induce formation of GCs. ChIP-seq studies revealed that EZH2 bivalent promoter genes significantly overlap with BCL6 targets only when is associated with BCoR in primary human GC B cells and lymphoma cells (hypergeometric test, p=2.9e-20). Treatment of DLBCL cells with EZH2 or BCL6-BCoR inhibitors or siRNA partially derepressed these genes, indicating that these factors cooperate and are required to mediate full repression of these crucial bivalent loci. Accordingly, ChIP assays in DLBCL cells treated with EZH2 inhibitor showed impaired binding of PRC2 complex proteins (EZH2, EED and SUZ12) and PRC1-BCoR complex proteins (BCoR, RNF2 and KDM2B) to bivalent promoters. This was accompanied with corresponding loss of H3K27me3 and H2AK119ub1, the histone repressive marks catalyzed by PRC2 and PRC1, respectively. Similar results were obtained when cells were exposed to a small molecule that disrupts BCL6 recruitment of BCoR.
Conditional expression of mutant EZH2 in mice accelerated lymphomagenesis driven by BCL6. Accordingly, the combination of EZH2 inhibitor with BCL6-BCoR inhibitor, suppressed DLBCLs proliferation and tumor growth in xenografted mice more effectively than either agent alone. The combination also yielded further killing of primary human DLBCL cells growth.
Summary and Conclusions: We identified the first epigenetic mechanism of lymphomagenesis involving aberrant repression of GC-specific bivalent domains by PRC2 and BCL6 in cooperation with PRC1-BCoR complex, as well as a rational epigenetic-based and molecular targeted therapeutic approach with the potential to eradicate lymphomas without harming normal tissues.

A HYPOPHOSPHORYLATED AUTOANTIGEN IS THE FIRST MOLECULARLY DEFINED RISK FACTOR AND A DOMINANT ANTIGENIC TARGET/STIMULUS OF THE B-CELL RECEPTOR FROM ABC-TYPE DLBCL

M. Pfreundschuh[1,*] K.-D. Preuss[1], N. Fadle[1], E. Regitz[1], M. Kemele[1], R.-M. Bohle[2], S. Hartmann[3], M.-L. Hansmann[3], L. Thurner[1]
[1]Internal Medicine I, [2]Institute of Pathology, Saarland University Medical School, Homburg, [3]Senckenbergsches Institut für Pathologie, Universität Frankfurt, Frankfurt, Germany

Background: Chronic antigenic stimulation may has been hypothesized to play an important role in the pathogenesis of malignant lymphomas. We have previously shown that a hyperglycosylated version of neurabin/SAMD14, a protein strongly expressed in the CNS, is the antigenic target of the B-cell receptor (BCR) of 2/3 of all primary CNS lymphomas, but antigenic targets of peripheral DLBCL-BCRs have not been defined to date.
Aims: To identify the antigenic targets/stimuli of BCR derived from peripheral DLBCL.
Methods: BCRs were expressed as recombinant Fabs based on corresponding pairs of functional variable region heavy and light chain genes, which had been amplified from isolated genomic DNA of snap-frozen lymphoma specimens and DLBCL-derived cell lines. The purified BCR-Fabs were checked for binding to proteins expressed on macroarrays of human cDNA expression libraries.
Results: The BCR from 10 DLBCL cell lines (5 of the germinal center type and 5 of the activated B-cell type) were tested on the protein macroarray. None of the GC-type BCR reacted with any of the proteins expressed on the protein macroarrays, but the BCR from 3/5 (60%) of the ABC-derived cell lines reacted with ARS2 (arsenite resistance protein 2), a conserved mammalian protein which is important for microRNA biogenesis. Isoelectric focusing and phosphatase treatment of ARS2 derived from ABC cell lines with a BCR specific for ARS2 revealed that ARS2 was hypophosphorylated (hypo-ARS2) in the respective cell lines. Analysis of peripheral blood lymphocytes from patients with DLBCL of unknown cell of origin and healthy controls revealed that 5/100 patients (5%), but only 1/200 controls (0.5%) were carriers of hypo-ARS2, resulting in a 10x increased risk for healthy carriers of hypo-

ARS2 to develop DLBCL. All patients with BCRs targeting ARS2 had polyclonal antibodies against ARS2 in their serum.
Summary and Conclusions: Hypo-ARS2 is the first molecular defined risk factor for DLBCL identified to date. The increased risk for healthy carriers of this posttranslational modification to develop DLBCL supports the hypothesis of chronic antigenic stimulation as an important factor in the pathogenesis of DLBCL of the ABC subtype and indicates that posttranslationally modified autoantigens are a frequent target and stimulus for ABC-DLBCL-BCR. That antibodies against ARS2 are found in the respective patients suggests that the hypo-ASR reactive DLBCL evolves from a polyclonal B-cell response against this autoantigen. Investigations into the mechanism underlying the hypophosphorylation of ARS2 are underway and therapeutic options will be discussed. *Supported by Wilhelm-Sander-Stiftung.*

Novel actors in chronic myeloid leukemia biology

SECOND GENERATION TYROSINE KINASE INHIBITORS SUPPRESS THE CIP2A/C-MYC/E2F1 PATHWAY

C. Lucas[1], R. Harris[1], A. Holcroft[1], L. Scott[1], N. Carmell[1], E. McDonald[1], R. Clark[1,*]
[1]Haematology, University of Liverpool, Liverpool, United Kingdom

Background: Impairment of PP2A activity by its negative regulators SET and cancerous inhibitor of PP2A (CIP2A) plays an important role in the pathogenesis and progression of chronic myeloid leukaemia (CML). CIP2A is associated with increased proliferation in several human malignancies and its over-expression can cause cellular transformation. High levels are an adverse prognostic indicator in many malignancies. In CML a high CIP2A protein level at diagnosis in imatinib treated patients may be a biomarker for subsequent blast crisis. However, its role in CML patients receiving second generation tyrosine kinase inhibitors (2G TKIs) is not known.
Aims: Our aim was to investigate if the superior clinical outcome seen in patients treated with 2G TKIs could be explained by modulation of the CIP2A pathway.
Methods: CIP2A, PP2A, PP2A^{Y307}, c-Myc and E2F1 proteins were assessed by FACS. CIP2A, c-Myc and E2F1 were depleted in K562 and CD34+ cells using siRNA.
Results: In mononuclear cells taken at diagnosis from 20 chronic phase CML patients, those with high CIP2A levels significantly decreased following dasatinib or nilotinib treatment (p=0.007 and p=0.001 respectively) and this was accompanied by a significant decrease in c-Myc, (p=0.002). Y307 phosphorylated (inactive) PP2A also decreased in dasatinib (p=0.03) and nilotinib (p=0.04) treated cells, thus increasing PP2A activity, but imatinib had no significant effect. These differences in TKI effects are not mediated by differential suppression of BCR-ABL activity (as assessed using the pCrKL assay). E2F1 transcriptionally regulates both c-Myc and CIP2A and has previously been shown to be over-expressed in CML. E2F1 is high in patients with high diagnostic CIP2A protein levels compared to those with low CIP2A protein levels (p=0.04). Following 1 month of clinical 2G TKI treatment, E2F1 protein levels significantly decreased (p=0.01) and this was accompanied by a decrease in mRNA levels of its transcriptional target *CIP2A*. In sharp contrast, imatinib did not suppress E2F1, and thus *CIP2A* mRNA levels remain unchanged. Our data demonstrate that E2F1 is stabilised in CML as a result of PP2A inactivation. CIP2A acts to inhibit PP2A leading to stabilisation of E2F1, creating a positive feedback loop generating constant transcription and stabilisation of both CIP2A and c-Myc (Figure 1). The positive feedback loop was interrogated by sequentially depleting CIP2A, c-Myc and E2F1 in K562 and CD34+ CML cells. Depleting CIP2A in CD34+ CML cells reactivates PP2A, resulting in the dephosphorylation of E2F1, and thus a decrease in E2F1 and c-Myc. This may occur by two mechanisms; firstly the decrease in CIP2A level means that CIP2A can no longer stabilise c-Myc, and secondly the reduction in E2F1 removes its drive to transcribe c-Myc. In CD34+ cells, c-Myc knockdown resulted in a decrease in CIP2A (p=0.04) and E2F1 (p=0.04). This is consistent with our model, whereby decreased CIP2A will reactivate PP2A, leading to the dephosphorylation of E2F1 and therefore a decrease in E2F1. Finally E2F1 was depleted in CD34+ cells. This resulted in a decrease in CIP2A (p=0.002) and c-Myc.

A suggested model for the CIP2A/c-Myc/E2F1 pathway. Arrows denote activation, blunt ended arrows indicated inhibition. Phosphorylated E2F1 can transcribe both CIP2A and c-Myc, which stabilise each other and cause PP2A inhibition. Inactive PP2A cannot dephosphorylate E2F1 and thus E2F1 remains active, creating a positive feedback loop.

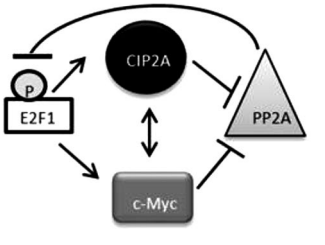

Figure 1. CIP2A/c-Myc/E2F1 pathway.

Summary and Conclusions: In summary, we have shown that a positive feedback loop occurs between CIP2A, E2F1 and c-Myc which inhibits PP2A activity and that only the 2G TKIs and not imatinib are able to supress it. Our study highlights a role for E2F1 in the CIP2A pathway, although it cannot be assumed that E2F1 is the only transcription factor regulating CIP2A and others may influence this dynamic process. Thus, CIP2A remains an attractive therapeutic target since high levels are only found in malignant cells.

S462

MYC-MAX HETERODYMER POSITIVELY REGULATES BCR AND BCR/ABL EXPRESSION

V. Magistroni[1,*] N. Sharma[1], R. Piazza[1,2], C. Mezzatesta[1], C. Gambacorti Passerini[1,2]
[1]Dept. Health Sciences, University of Milano Bicocca, [2]Clinical Research Unit, San Gerardo Hospital, Monza, Italy

Background: Chronic Myeloid Leukemia(CML) is caused by the BCR/ABL fusion gene. Both the presence and the levels of BCR/ABL expression seems critical for CML progression from Chronic phase(CP) to Blast crisis(BC). At the molecular level BC is a heterogeneous disease. Regardless of the additionally secondary changes, one common feature during the evolution from CP to BC is a marked increase in BCR/ABL expression. After the oncogenic translocation, the BCR/ABL gene is under the transcriptional control of BCR promoter but the molecular mechanisms involved in the regulation of oncogene expression are mostly unknown.
Aims: The aim of this study is the identification of molecular mechanisms responsible for BCR promoter regulation and BCR/ABL expression.
Methods: To identify the transcription factors directly acting on BCR promoter, we studied in-silico a region of 1443bp upstream of the human BCR gene coding sequence(Gene ID:613). Chromatin Immunoprecipitation was used to confirm in-silico data. The role of transcription factors on BCR and BCR/ABL expression have been determined through transfection of the K562 cell line with selected expression vectors and through specific silencing in K562, LAMA-84 and KCL-22 cells. mRNA and protein expression levels of BCR and BCR-ABL were detected by quantitative PCR(RT-qPCR) and western blot. BCR reporter activity was also analyzed by reporter luciferase assay in the 293T cell line. The role of the identified transcription factors in CML progression was investigated with in-vitro experiments.
Results: These data demonstrate that MYC-MAX heterocomplex binds to the BCR promoter at four different binding sites(PBS1-4), leading to up-regulation of BCR and BCR/ABL at both transcriptional and protein levels in the K562 cells. We found that both MYC and MYC-MAX overexpression significantly upregulate BCR/ABL compared to control cells, as assessed by RT-qPCR (MYC_BCR/ABL fold induction: 2.27±0.48,p=0.01; MYC-MAX_BCR/ABL fold induction: 2.55±0.34,p=0.002) and western blot. Accordingly, silencing of MYC(shMYC) expression in various BCR/ABL+ cell lines causes significant down-regulation of BCR and BCR/ABL compared to the negative controls(BCR fold change: KCL-22shMYC 0.49±0.07, p=0.013; LAMA-84shMYC 0.07±0.03, p=0.0003. BCR/ABL fold change: KCL-22shMYC 0.58±0.02, p=0.0007; LAMA-84shMYC 0.38±0.006, p<0.0001). In addition, MYC silencing in these cell lines leads to decreased proliferation and induction of cell death as assessed by cell cycle analysis and PARP-1 cleavage. In order to assess the effect of MYC-MAX on BCR promoter, we tested the activity of the luciferase reporter assay in presence of MYC expression and in a lentiviral MYC silencing model, showing that MYC silencing significantly decreases BCR promoter activity in all of the constructs analysed(p<0.0001). Notably, deletion of PBS1 and PBS2 and/or deletion of PBS3 and PBS4, dramatically decreases the promoter strength, therefore confirming the critical role of these region in controlling BCR promoter activity. Interestingly, the deletion of PBS3 and PBS4 induces a greater down-modulation of luciferase activity compared to PBS1 and PBS2 deletion (BCR-promoter: 6.11±0.11; PBS3-4deleted: 1.86±0.14; PBS1-2deleted: 3.92±0.07).
Summary and Conclusions: This is the first description of a new pathway which places BCR and BCR/ABL under the transcriptional control of the MYC-MAX heterodimer. Since MYC is frequently over-expressed in BC, this phenomenon could play a critical role in BCR/ABL up-regulation and blast aggressiveness acquired during CML evolution.

S463

CORRECTION OF MUTATIONS OF THE EPIGENETIC MODIFIER ASXL1 IN MYELOID LEUKEMIA CELLS BY CRISPR/CAS9 GENOME EDITING

S. Valletta[1,*] H. Dolatshad[1], E. Bello[1], B.H. Yip[1], M. Bartenstein[2], S. Gordon[2], J. Shaw[1], S. Roy[1], L. Scifo[1], A. Pellagatti[1], T. A. Fulga[3], A. Verm [2], J. Boultwood[1]
[1]LLR Molecular Haematology Unit, Nuffield Division of Clinical Laboratory Sciences, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom, [2]Albert Einstein College of Medicine, Bronx, NY, United States, [3]Weatherall Institute of Molecular Medicine, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom

Background: The CRISPR/Cas9 genome editing system has recently emerged as a powerful tool for genome engineering, and has been used for gene correction in cultured cells from patients with monogenic hereditary defects. We reasoned that this technology could be employed to correct acquired gene mutations in human cancer cells. Recurrent somatic mutations of the epigenetic modifier *ASXL1* are common in myeloid malignancies, including myelodysplastic syndromes and chronic myeloid leukemia (CML). Loss-of-function *ASXL1* mutations are strongly associated with a poor prognosis in these disorders. We studied the CML line KBM5 which lacks wild-type ASXL1 protein expression, due to a homozygous nonsense mutation (G710X) in the *ASXL1* gene.
Aims: We used CRISPR/Cas9-mediated homology directed repair (HDR) to correct the *ASXL1* mutation in KBM5 cells and performed functional studies to determine whether the wild-type function of ASXL1 was restored.
Methods: We used three synthetic guide RNAs (sgRNAs) targeting the genomic region overlapping the *ASXL1* mutation and a single-stranded oligonucleotide as a repair template. We sequenced 1,027 colonies expanded from single FACS-sorted KBM5 cells to determine successful HDR-mediated correction of *ASXL1* mutation. Each sgRNA generated heterozygous precise correction (yield 0.46-2%). Importantly, homozygous precise correction was observed for two sgRNAs (yield 1.13-1.63%). The frequency of correction obtained is consistent with previous studies using the CRISPR/Cas9 system for precise genome editing through HDR.
Results: Western blot analysis showed restoration of full-length ASXL1 protein expression in heterozygous and homozygous corrected KBM5 clones. ASXL1 plays an important role in Polycomb Repressive Complex 2 (PRC2) recruitment to specific target loci, including the HOXA cluster. Loss of ASXL1 is associated with increased expression of *HOXA* genes. We observed significant downregulation of *HOXA5, 6, 7, 9, 10* and *13* in *ASXL1* mutation-corrected KBM5 clones. The PRC2 plays a critical role in the deposition of H3K27me3 histone repressive marks, and *ASXL1* mutations are associated with H3K27me3 loss in myeloid cells. Western blots on purified histones showed a marked increase in global H3K27me3 levels in *ASXL1* mutation-corrected KBM5 clones. ASXL1 forms a protein complex *in vitro* with the chromatin deubiquitinase BAP1. This interaction is reduced in cell lines carrying *ASXL1* mutations. Immunoprecipitation studies showed that the interaction between ASXL1 and BAP1 was restored in *ASXL1* mutation-corrected KBM5 clones. Moreover, we observed growth suppression and a significant increase in the expression of the myeloid marker CD15 in *ASXL1* mutation-corrected cells. No sequence alterations were detected in any of the off-target sites examined in all *ASXL1* mutation-corrected clones identified, suggesting high specificity of CRISPR/Cas9 system in our experiments. Preliminary *in vivo* data show that mice xenografted with *ASXL1* mutation-corrected KBM5 clones have a longer survival compared to mice xenografted with uncorrected KBM5 cells (p=0.046) (Figure 1). A larger cohort is in progress.

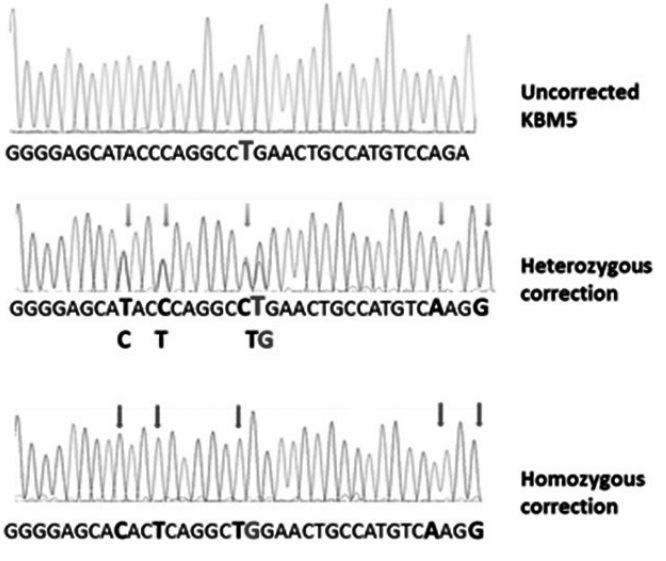

Figure 1. Evaluation of *ASX1* mutation correction in KBM5 cells using Sanger sequencing. The arrows in the middle and bottom panel indicate silent nucleotides changes that were introduced in the single-stranded oligonucleotide (repair template) sequence to avoid undesired Cas9 activity in mutation-corrected cells.

Summary and Conclusions: In summary, we have corrected a specific *ASXL1* point mutation in a leukemia cell line using CRISPR/Cas9 technology, resulting in restored protein function. This study presents a new strategy to illuminate the impact of oncogenic mutations on cellular function and may lay the foundations for a new approach to leukemia therapeutics (*e.g.* modified autoSCT). We provide proof-of-concept for gene correction via CRISPR/Cas9 technology in leukemic cells from patients with a myeloid malignancy.

MUTATION ANALYSIS OF EPIGENETIC MODIFIERS IN CHRONIC PHASE CML USING NEXT GENERATION SEQUENCING

G. Nteliopoulos[1,*] G. Gerrard[2], H.E. Foong[2], L. Foroni[2], J.F. Apperley[1], A. Bazeos[1]
[1]Centre for Haematology, Faculty of Medicine, [2]Imperial College Healthcare NHS Trust, Hammersmith Hospital, Imperial College London, London, United Kingdom

Background: Chronic myeloid leukaemia (CML) originates from a single genetic aberration (BCR-ABL1); however the clinical disease is remarkably heteroge-

neous and the genetic mechanisms of resistance to tyrosine kinase inhibitors (TKI) are still poorly understood. Recently, we have identified consistent differences in genome-wide DNA methylation patterns in patients with chronic phase CML (CML-CP) compared to healthy controls, indicating an involvement of epigenetic mechanism in CML pathogenesis. Several epigenetic modifying enzymes have been found frequently mutated in other haematopoietic neoplasms.
Aims: The aim of this study is to analyse a panel of mutations in epigenetic modifiers in chronic phase CML using Ion Torrent next-generation sequencing. The panel design was based on a combination of gene expression analysis we generated and literature search for frequently mutated enzymes in leukaemia. Potential mutations involved in epigenetic deregulation of CML may be used as novel prognostic biomarkers for TKI response.
Methods: 53 samples from untreated patients with newly diagnosed CML-CP ($CD34^+$) who started treatment with imatinib were included in the study. Patients were classified as responders (n=26) /non-responders (n=27) based on 10% BCR-ABL1/ABL ratio at 3 months. 6 samples from GCSF mobilised healthy donors ($CD34^+$) were used as negative controls, to exclude false positive variants and 2 samples from CML-BC (blast crisis) as positive controls. A custom panel of 71 epigenetic enzymes was designed, containing 2002 amplicons. We used the Ion AmpliSeq Library, the Ion PGM Template OT2 200 and the Ion PGM Sequencing 200 kits, running 8 samples on a 318 Chip. Data were analysed using Ion Reporter (Life Technologies), while the web-based application Mutation Taster was used for the evaluation of the disease-causing potential of a variant.
Results: A mean of 636,170 mapped reads per sample with mean depth of 273 and mean coverage (at x20) of 95.9% was obtained, detecting mutations with high sensitivity. The filtering steps included exclusion of UCSC common SNPs, use of healthy controls for excluding false positive variants, exclusion of intronic variants, exclusion of variants called as polymorphisms by Mutation Taster, quality control including all variants with frequency of the mutated allele>20% and some variants with lower frequency based on QC, and exclusion of synonymous variants. 59 disease causing variants were identified in 34 genes including missense, nonsense and frameshift insertions. No difference of overall number of variants between responders/non-responders, however nonsense variants in ASXL1, IKZF1 and EP300, similar to ones found in CML-BC samples, were found only in non-responders. No variant was present in frequency more than 2/53 samples and were mutually exclusive between R-NR except for a missense variant in HDAC2, RUNX1 and a TET2 found in 5, 4, 3 samples respectively. At least one variant was present in 85% of NR and in 67% of R. The findings were validated using Sanger sequencing. For some genes, there was correlation of gain or loss of function mutation with differences in gene expression.
Summary and Conclusions: We demonstrate the feasibility of using the Ion Torrent PGM platform for mutation analysis of epigenetic modifiers in CML. The findings may be the first report for the presence of these mutations in CML-CP, which will allow a better understanding of the abnormal epigenetic changes in CML. Some mutations found in high frequency can be considered characteristic for CML whereas some others (found only in responders or non-responders) can be considered as novel prognostic biomarkers for IM response.

S465

RUNX1 MUTATION AND/OR DISRUPTION OF THE C-TERMINAL DOMAIN MAY BE CRITICAL FOR CHRONIC MYELOID LEUKAEMIA (CML) BLAST CRISIS TRANSFORMATION

L. Wang[1,2,*] G. Austin[2], R. Clark[2]
[1]Department of Haematology, Royal Liverpool University Hospital, [2]Section of Haematology, Department of Molecular ans Clinical Cancer Medicine, University of Liverpool, Liverpool, United Kingdom

Background: Runt-related transcription factor 1 (Runx1)/ AML1 plays a crucial role in haematopoiesis and its dysfunction may contribute to leukaemogenesis. RUNX1 is frequently involved in chromosomal translocations including t(8;21), t(3;21), and t(16;21). Normal RUNX1 function is repressed by all truncated variants of RUNX1 that retain the entire Runt domain and lack the C-terminal domain. RUNX1 with various point mutations also has a dominant-negative effect on wild type and exhibits decreased transactivation activity; these have been found in AML, myelodysplastic syndromes and accelerated phase/blast crisis (AP/BC) of CML.
Aims: To explore the role of RUNX1 lesions in disease evolution of CML, we investigated RUNX1 splice variants and point mutations in CML chronic phase (CP) and BC.
Methods: The cases studied included 54 cases of Philadelphia chromosome positive (Ph^+) acute leukaemia (22 cases of myeloid, 21 lymphoid, 3 bi-phenotypic and 8 unknown lineage of leukaemia). Of these 54 cases, 35 evolved from previous CP CML and 19 were *de novo* Ph^+ acute leukaemia. Twenty cases of newly diagnosed CP CML were also studied. RNA was extracted and cDNA synthesised from whole blood white cells. First round PCR primers were designed to amplify the full length cDNA of the longest RUNX1 isoform 1c. Then two overlapping fragments were amplified by nested PCR primers. For several cases, it was found that there were PCR products of different size in addition to the PCR product of wild type RUNX1 1c. All PCR products of various sizes for each sample were gel-purified and subject to Sanger sequencing.
Results: A total of 18 types of transcript variant were found. Of these, 2 types (39 bp spliced out from exon3 and 99 bp spliced out from the end of exon10) were universally present and were excluded from this analysis. The 16 other types each had either all or the majority of the RUNT domain spliced out (named as Group 1 variants, 8 types) or had apparent aberrant C-terminal alteration (named as Group2 variants, 8 types). Group 2 variants were detected predominantly in Ph+ acute leukaemia cases, *i.e.* 8 of 54 Ph+ acute leukaemia cases. In contrast, Group 2 variants were only found in 1 of 20 CP cases and this one case was the only case that could not be controlled by imatinib treatment. The presence of Group1 variants was not significantly different between Ph+ acute leukaemia cases and CP cases. There were 35 types of nonsynonymous mutation and 14 types of synonymous mutation detected. All nonsynonymous mutations have been aligned to various single nucleotide polymorphism databases to exclude known polymorphisms. Nonsynonymous RUNX1 mutations were detected in of 20 of 54 cases of Ph+ acute leukaemia (37%). In contrast only 2/20 (10%) cases of CP CML had a nonsynonymous RUNX1 point mutation ($p=0.025$). Combining RUNX1 splicing variant Group 2 and point mutation together, 23/54 (43%) Ph+ acute leukaemia cases had either a Group 2 splice variant or point mutations, which were only present in 3/20 (15%) CML CP ($p=0.03$). 5/8 cases of CML who had transformed had point mutations at the BC stage. In 4 of these 5 cases new point mutations were only detected at the BC stage; 1 case had mutations that were present in the earlier CP sample. 6/8 cases of CML who had transformed had variants detected, and 3 of these had Group 2 splice variants that were not present in CP.
Summary and Conclusions: RUNX1 splicing variants with disrupted C-terminal domain and RUNX1 point mutations are predominantly found in Ph+ acute leukaemia and at the transformation of CML, but are uncommon in chronic phase; these lesions may therefore be crucial transformation events, and candidate biomarkers of transformation.

Gene therapy, cellular immunotherapy and vaccination

Background: In patients with hemoglobinopathies, hematopoietic stem cell (HSC) gene therapy has the potential to induce production of functional β-globin in the red blood cell lineage with the aim of reducing or eliminating the symptoms of disease. Results for 2 subjects with β^0/β^E-thalassemia major treated in clinical study HGB-205 that were previously presented (EHA 2014, ASH 2014) suggested that transplantation with autologous $CD34^+$ cells transduced with the self-inactivating LentiGlobin BB305 lentiviral vector containing an engineered $\beta^{A\text{-}T87Q}$-hemoglobin (Hb) and early transfusion independence.
Aims: Herein, we provide additional follow-up data on these two subjects as well as early safety and efficacy data on the first subject with sickle cell disease (SCD) treated with gene therapy.
Methods: After obtaining informed consent, subjects with β-thalassemia major undergo HSC collection via peripheral blood apheresis, while subjects with severe sickle cell disease undergo HSC collection via bone marrow harvest. $CD34^+$ cells were selected and transduced with LentiGlobin BB305 lentiviral vector. Estimation of the mean *ex- vivo* vector copy number (VCN) was obtained by quantitative PCR performed on pooled colony-forming progenitors. Subjects underwent myeloablation with intravenous busulfan, followed by infusion of transduced $CD34^+$ cells. Subjects were monitored for overall safety including hematological engraftment, $\beta^{A\text{-}T87Q}$-globin expression (by high performance liquid chromatography) and transfusion requirements. Integration site analysis (ISA, by linear amplification-mediated PCR and high-throughput sequencing on nucleated cells) and replication-competent lentivirus (RCL) assays were performed. Prophylactic pRBC transfusions are continued in sickle cell subjects who are transfusion dependent pre-treatment to maintain HbS <30%, followed by gradual tapering over time.

Table 1. Demographics and transplantation outcomes.

Subject	Age (years) /gender	Genotype	BB305 Drug Product VCN[a]	BB305 Drug Product $CD34^+$ cell dose ($x10^6$ per kg)	Day of Neutrophil Engraftment	Drug Product-related Adverse Events	Day of last pRBC transfusion	Last Study Visit	Hb amounts at last visit (g/dL)
Subjects with β-thalassemia major									**HbA^{T87Q}/ Total Hb**
1201	18 F	β^0/β^E	1.5	8.9	Day +13	None	Day +10	12M	7.7/11.0
1202	16 M	β^0/β^E	2.1	13.6	Day +15	None	Day +12	9M	9.4/13.2
Subject with severe sickle cell disease									**HbA^{T87Q}/ HbS/HbF/Total Hb**
1204	13 M	β^S/β^S	1.2 / 1.0	5.6	Day +37	None	Day +88	4.5M	2.9/4.0/0.9/12.0

As of February 2015
[a] VCN, vector copy number; F=female; M= Male for gender, and months for day of last follow-up
^these authors contributed equally

Results: As of February 2015, 2 subjects with β^0/β^E thalassemia major (Subjects 1201 and 1202) and 1 subject with β^S/β^S severe sickle cell disease (Subject 1204, who was on prophylactic transfusion therapy for multiple veno-occlusive crises and acute chest syndrome) have undergone treatment. The outcome of these subjects to date is shown in Table 1. No subject has experienced a drug product related adverse event, and ISA analyses demonstrate highly polyclonal reconstitution without clonal dominance. Both β-thalassemia major subjects remain transfusion-free for 14 and 11 months respectively, post-treatment. Subject 1204, at his most recent visit (Month 4.5 post-treatment), has a total hemoglobin of 12.0 g/dl, of which 24% is HbA^{T87Q} (from 9.6% at Month 3) and 33% is HbS (from 14.7% at Month 3), with increasing levels of transduced cells detected in peripheral blood (PBL VCN of 2.4 at Month 4.5). This subject has not had a post-treatment hospitalization for a SCD-related event and his transfusion support is being tapered.
Summary and Conclusions: The subjects with β-thalassemia major remain transfusion-free for 14 and 11 months. The subject with SCD demonstrates increasing production of HbA^{T87Q} over time. Gene therapy using autologous HSC transduced with LentiGlobin BB305 lentiviral vector *ex vivo* is a promising approach for the treatment of patients with both β-thalassemia major and severe SCD.

GENERATION OF EBV-SPECIFIC AND EBV-SPECIFIC, TCR-REPROGRAMMED HUMAN CD8+ CYTOTOXIC T LYMPHOCYTES WITH STEM CELL MEMORY AND CENTRAL MEMORY PROPERTIES BY MODULATING GLYCOLYTIC T CELL METABOLISM

I. Weber[1], S. Khan[1], M. Theobald[1], U.F. Hartwig[1,*]
[1]III. Dept. of Medicine-Hematology, Internal Oncology & Pneumology, University Medical Center Mainz, Mainz, Germany

Background: Adoptive transfer of virus-specific and TCR- or CAR-reprogrammed cytotoxic T lymphocyzes (CTL) has advanced as a valuable cellular therapy for opportunistic viral infections, Epstein-Barr Virus (EBV)-mediated lymphoma and leukemia relapse. However, durable clinical responses are often hampered by limited capability of terminally differentiated, high avidity effector T cells (T_{EFF}) to establish sustained antileukemic immunity whereas less differentiated stem cell memory (T_{SCM}) and central memory (T_{CM}) T cells could be shown to elicit potent antitumor responses, prolonged survival and memory. Moreover, T_{SCM} and T_{CM} depend less on glucose consumption to drive oxidative phosphorylation (OXPHOS) as their primary source of adenosine triphosphate (ATP) production whereas T_{EFF} require additional aerobic glycolysis to generate the ATP needed.
Aims: In the current study, we therefore investigated means of modulating T cell metabolism to generate EBV-specific T_{SCM} and T_{CM} as well as EBV-specific $T_{SCM/CM}$ TCR-reprogrammed T cells.
Methods: Naïve $CD8^+CD45RA^+$ T cells isolated from peripheral blood mononuclear cells (PBMC) of healthy $HLA\text{-}A2^+$ donors using the Naive T cell isolation kit® (Milenyi Biotec, Bergisch Gladbach, Germany) and unselected (total) $CD8^+$ T cells were primed by autologous dendritic cells loaded with EBV-peptides followed by restimulation with peptide loaded autologous PBMC in the presence of low (1 mM) glucose, glutamine, an optimized cytokine cocktail and 1 mM of the non-metabolizable glucose analogue 2-deoxy-glucose (2-DG). Moreover, either galactose or 9-oleic acid was added to glucose deprived cultures. In addition to phenotypic and functional *in vitro* analyses by FACS, IFN-g ELISPOT- and ^{51}Cr-release assays, glucose uptake and lactate production was determined. OXPHOS and aerobic glycolysis were assessed by measuring oxygen-consumption rate (OCR) and extracellular acidification rate (ECAR), respectively, using a Seahorse Analyzer. Finally, the biological activity of EBV-reactive $T_{SCM/CM}$ was tested *in vivo* in NSG mice.
Results: We obtained strong expansion of EBV-reactive CTL expressing a $CD8^+CD45RA^+CD45RO^-CD95^+$ $CD27^+CD28^+CD62L^+CCR7^+T_{SCM}$ and $CD8^+CD45RA^-CD45RO^+CD95^+CD27^+CD28^+CD62L^+CCR7^+$ T_{CM} phenotype upon repetitive stimulation of naïve T cells in the presence of low glucose, glutamine and 2-DG when compared to CTL stimulated without 2-DG. This effect was also seen in total $CD8^+$ T cells although less pronounced. In contrast, supply of galactose or oleic-acid to glucose free (but glutamine containing) medium did not result in reduced T_{EFF} differentiation, suggesting OXPHOS by galactose converted to glucose and fatty acid oxidation. Moreover, 2-DG treated T_{SCM} and T_{CM} as well as total $CD8^+$ CTL showed less lactate production and ECAR as compared to untreated controls, confirming that differentiation to T_{EFF} requires aerobic glycolytic ATP production. Functional assays *in vitro* did not only reveal cytolytic activity of 2-DG treated EBV-T_{SCM} and T_{CM} comparable to controls but elicited superior migration properties of these cells when tested to untreated naïve or total $CD8^+$ T cells in a transwell- migration assay. We further showed that EBV-$T_{SCM/CM}$ can be successfully TCR-reprogrammed to recognize primary acute myeloid leukaemia (AML) blasts.
Finally, first adoptive transfer studies into NSG mice indicated that EBV-$T_{SCM/CM}$ generated in low glucose can persist and mount an immune response to EBV-transformed B cells engrafted into NSG recipients.
Summary and Conclusions: These studies demonstrate that modulation of T cell metabolism may be a promising approach to generate stem cell memory and central memory T cells *in vitro* for virus-specific and redirected immunity in adoptive cellular therapy.

A THERAPEUTIC NKT CELL ADJUVANT-BASED VACCINE INDUCES AN EFFECTIVE ANTITUMORAL IMMUNE RESPONSE IN B-CELL LYMPHOMA

L. Escribà-Garcia[1,*] C. Alvarez-Fernández[1], J. Sierra[1], J. Briones[1]
[1]Hematology Service, Hospital de Sant Pau, Barcelona, Spain

Background: Type I natural killer T (NKT) cells are lymphocytes with unique

specificity for glycolipid antigens presented by nonpolymorphic CD1d receptor on dendritic cells (DCs). NKT cells play a central role in tumor immunology since they coordinate innate and adaptive immune responses. Activation of NKT cells with the prototypic lipid α-galactosylceramide (α-GalCer) stimulate INF-γ production and cytokine secretion (eg, IL-12, IL-17, IL-21) which contribute to the enhancement of T cell activation.
Aims: We evaluated the antitumor effect of a combination of DCs and irradiated tumor cells with the NKT cell agonist α-GalCer in a mouse model of B cell lymphoma.
Methods: The murine B cell lymphoma line 4TOO was used as tumor model. A therapeutic vaccine was generated by mixing DCs and irradiated 4TOO tumor cells (10^6 cells in a 1:1 ratio) in the presence of α-GalCer (2μg/mouse). A single dose of the therapeutic vaccine was injected iv. into Balb/c mice (n=10 per group) two days after tumor challenge ($4x10^5$ cells/mouse, iv), and mice were followed for survival. NKT cell expansion was analyzed by flow cytometry using a PE conjugated CD1d: α-GalCer analogue (PBS-57) loaded tetramer (NIH Tetramer Core Facility, Atlanta GA). Intracellular IFN-γ production on NKT cells and $CD4^+$ and $CD8^+$ T cells was detected by flow cytometry. One-way ANOVA was used for comparisons between different experimental groups. Differences in survival were analyzed using the log-rank test.
Results: Therapeutic vaccine eradicated B cell lymphoma in all treated mice, and was superior to any vaccine combination, including α-GalCer alone, irradiated tumor cells with DCs, and DCs with α-GalCer (100%, 10%, 0% and 50% of survival at day 100, respectively; p<0.001). Importantly, 90% of treated mice with the vaccine were resistant to a tumor rechallenge, suggesting the development of a memory immune response. In addition, the immune response was tumor-specific since all the mice were unable to reject a syngeneic A20 B cell lymphoma. A significant NKT cell expansion in the spleen and liver of vaccinated mice was observed compared with control groups (4.8 *vs* 1.2 fold expansion; p=0.02, and 3.8 *vs* 1.4 fold expansion; p=0.04, respectively). Moreover, this vaccination strategy induced an increase of IFN-γ secreting NKT cells (58.4% *vs* 39.5% (p=0.05) and of IFN-γ secreting T cells compared to control groups (25.7% *vs* 16.8% in $CD8^+$ cells (p=0,04), and 31.2% *vs* 14% in $CD4^+$ cells (p=0,04).
Summary and Conclusions: A therapeutic vaccine consisting of dendritic cells pulsed with tumor cells plus the NKT agonist α-GalCer efficiently eradicates B cell lymphoma in a therapeutic setting. This immune response is long-lasting, tumor-specific, and it is associated with an expansion of NKT cells in lymphoid organs and with an increase in IFN-γ secreting NKT and T cells. These data support the development of immunotherapy strategies in patients with B cell lymphoma using DCs and NKT cell agonists.

ALLOGENIC ADOPTIVE IMMUNOTHERAPY OF ACUTE MYELOID LEUKEMIA (AML) BY TARGETING CD123 WITH CAR T-CELLS

R. Galetto[1,*] C. Lebuhotel[1], P. Francon[1], A. Gouble[1], J. Smith[1]
[1]Cellectis, Paris, France

Background: Adoptive immunotherapy using autologous T-cells endowed with chimeric antigen receptors (CARs) has given rise to long-term durable remissions and remarkable objective response rates in patients with refractory leukemia, raising hopes that a wider application of CAR technology may lead to a new paradigm in cancer treatment. However, a limitation of the current autologous approach is that CAR T-cells must be manufactured on a "per patient basis".
Aims: To overcome this limitation we have developed a standardized platform for manufacturing T-cells from third-party healthy donors to generate allogeneic "off-the-shelf" engineered CAR+ T-cell-based frozen products.
Methods: This allogenic platform utilizes Transcription Activator-Like Effector Nuclease (TALEN) gene editing technology to inactivate the TCRa constant (TRAC) gene, eliminating the potential for T-cells bearing alloreactive TCR's to mediate Graft *versus* Host Disease (GvHD). We have previously demonstrated that editing of the TRAC gene can be achieved at high frequencies, yielding up to 80% of TCRab negative cells and allowing efficient production and purification of TCR-deficient T-cells that no longer mediate alloreactivity in a xeno-GvHD mouse model. As a safety feature, T-cells are engineered to co-express the RQR8 gene, with the aim of rendering them sensitive to the monoclonal antibody rituximab.
Results: Here, we have adapted this allogeneic platform to the production of T cells targeting CD123, the transmembrane alpha chain of the interleukin-3 receptor, which is expressed on tumor cells from the majority of patients with Acute Myeloid Leukemia (AML). In a first step, we have screened multiple antigen recognition domains in the context of different CAR architectures to identify effective CAR candidates displaying activity against cells expressing variable levels of the CD123 antigen. In addition, experiments in an orthotopic AML mouse model using UCART123 cells demonstrate important anti-tumor activity *in vivo*.
Summary and Conclusions: The ability to carry out large scale manufacturing of allogeneic, non alloreactive CD123 specific T-cells from a single healthy donor can offer the possibility of an off-the-shelf treatment that would be immediately available for administration to a large number of AML patients.

S470

UCART19, AN ALLOGENEIC "OFF-THE-SHELF" ADOPTIVE T-CELL IMMUNOTHERAPY AGAINST CD19+ B-CELL LEUKEMIAS

L. Poirot[1], B. Philip[2], C. Schiffer Mannioui[1], S. Derniame[1], H. Zhan[3], S. Stafford[3], S. Reynier[1], S. Arnould[1], A. Gouble[1], W. Qasim[3], K. Peggs[4], M. Pule[2], J. Smith[1,*]
[1]Cellectis, Paris, France, [2]Department of Hematology, [3]Institute of Child Health, University College London, London, United Kingdom, [4]Department of Hematology, University College London, Paris, France

Background: Autologous T-cells engineered to express chimeric antigen receptors (CARs) that target specific tumor antigens are known to be of high potential in treating different kinds of cancer. However, they must be generated on a "per patient" basis, thereby limiting the population of patients that could benefit from this approach. In particular, immune homeostasis may be affected in heavily pre-treated patients, such that autologous T-cells may be low in number, not fully functional, or unable to expand, thereby restricting the amount of cells that could be manufactured.
Aims: The use of allogeneic T-cells isolated from healthy third party donors could constitute an easy-to-scale-up alternative, producible in advance, with potential for standardized quality controls, better batch consistency, and immediate availability for administration to a larger number of patients.
Methods: We have developed a standardized platform for manufacturing T-cells from third-party healthy donors to generate allogeneic "off-the-shelf" engineered CD19-CAR+ T-cell-based frozen products. Our platform involves the use of transcription activator-like effector nucleases (TALEN), which mediate the simultaneous inactivation of two genes through genome editing. The knock-out of the TCR alpha gene eliminates TCR expression and is intended to abrogate the donor T-cell's potential for graft-*versus*-host disease (GvHD), while knocking out the CD52 gene makes donor T-cells resistant to the lymphodepleting agent alemtuzumab. In addition, our T-cells are engineered to co-express the RQR8 gene as a safety feature, with the aim of rendering them sensitive to the monoclonal antibody rituximab.
Results: We have obtained proof-of-concept for the application of this approach by manufacturing TCR/CD52-deficient RQR8+ and CD19-CAR+ T-cells (UCART19) using a good manufacturing practice-compatible process and have demonstrated that the resulting UCART19 cells were functional using *in vitro* assays. Furthermore we have demonstrated that the ability of UCART19 cells to engraft into an orthotopic human CD19+ lymphoma xenograft immunodeficient mouse model. UCART19 cells exhibited antitumor activity equivalent to that of standard CD19 CAR T-cells. We also demonstrated that UCART19 cells did not mediate alloreactivity in a xeno-GvHD mouse model. Finally, the effectiveness of the rituximab-induced depletion mechanism of $RQR8^+$ cells was shown in an immunocompetent mouse model.
Summary and Conclusions: This valuable dataset supports the development of allogeneic CAR T-cells, and UCART19 will be investigated in an exploratory, first-in-human, clinical trial where refractory/relapsed CD19+ B-cell leukemia patients are to be enrolled.

Background: Elotuzumab, an immunotherapeutic monoclonal antibody (mAb), recognizes Signaling Lymphocytic Activation Molecule F7 (SLAMF7), a protein highly expressed on myeloma cells and natural killer cells. Elotuzumab targets and kills SLAMF7-expressing myeloma cells by direct activation of natural killer cells with minimal effect on normal tissues. Elotuzumab showed encouraging activity with lenalidomide/dexamethasone (Ld) in a Phase 1b/2 study in patients with relapsed/refractory multiple myeloma (RRMM).
Aims: ELOQUENT-2, a Phase 3 study (NCT01239797) compared efficacy and safety of elotuzumab plus lenalidomide/dexamethasone (ELd) *vs* Ld.
Methods: Patients with RRMM and 1-3 prior therapies were randomized 1:1 to ELd or Ld in 28-day cycles until disease progression or unacceptable toxicity: elotuzumab (10 mg/kg IV) was given weekly during Cycles 1 and 2 and then biweekly; lenalidomide (25 mg) was given on Days 1-21; dexamethasone was given weekly (40 mg or 28 mg PO+8 mg IV on elotuzumab dosing weeks). Written informed consent was obtained for all patients. Response/progression was assessed by an independent review committee using European Group for Blood and Bone Marrow Transplant criteria. Primary endpoints were progression-free survival (PFS) and overall response rate (ORR). Results of a prespecified interim analysis are reported.

Figure. Progression-free survival (PFS)

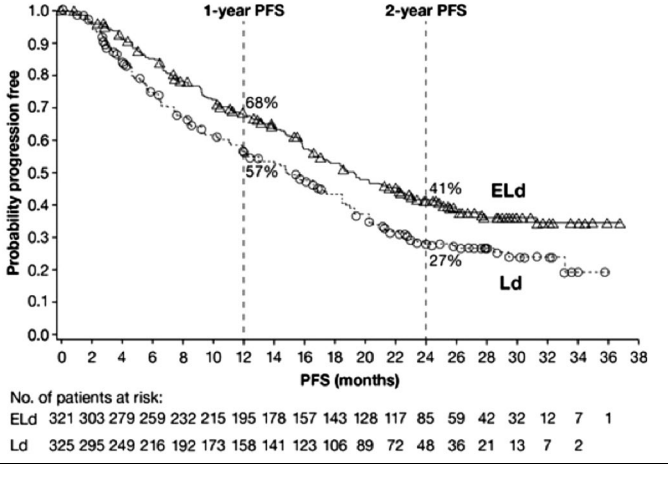

Figure 1. Progression-free survival (PFS).

Results: 646 RRMM patients were randomized (321 to ELd, 325 to Ld; median age 66 years [20% of patients ≥75 years old]; refractory to last therapy 35%). Median number of prior therapies was 2, including bortezomib 70%, thalidomide 48% and lenalidomide 6%. High-risk patients were included: del(17p) in 32%; t(4;14) in 9%. At the data cut-off (4 Nov 2014), 35% (ELd arm) and 21% (Ld arm) of patients remained on therapy; discontinuation was mainly due to disease progression (42% in the ELd arm, 47% in the Ld arm). Median number of cycles was 19 and 14 in the ELd and Ld arms, respectively. After a median follow-up of 24 months, PFS rate was superior in the ELd over the Ld arm: 68% *vs* 57% at 1 year and 41% *vs* 27% at 2 years. Hazard ratio for PFS was 0.70 (95% CI 0.57, 0.85; p=0.0004). Median (95% CI) PFS in the ELd arm was 19.4 (16.6, 22.2) months *vs* 14.9 (12.1, 17.2) months in the Ld arm (Figure 1). PFS benefit with ELd was consistent across key subgroups. ORR (95% CI) was 79% (74, 83) in the ELd arm *vs* 66% (60, 71) in the Ld arm (p=0.0002). Very good partial response or better was seen in 32.7% and 28.0% of patients in the ELd and Ld arms, respectively; partial response was seen in 45.8% and 37.5%, respectively. Grade 3-4 adverse events in ≥15% of patients include neutropenia (25% in the ELd arm, 33% in the Ld arm) and anemia (15% in the ELd arm, 16% in the Ld arm). Infections (any grade) occurred in 81% of patients in the ELd arm and 74% in the Ld arm. Exposure-adjusted infection rates were the same in both arms (incidence rate/100 person-years of exposure, 197). Infusion reactions occurred in 10% of patients with ELd (mostly Grade 1-2). There were 210 deaths (94 in the ELd arm, 116 in the Ld arm).
Summary and Conclusions: This is the first positive randomized Phase 3 trial with an immunotherapeutic mAb, assessing Ld with or without elotuzumab in RRMM. It showed a 30% reduction in risk of progression or death with ELd *vs* Ld. More patients remain on ELd *vs* Ld, and follow-up for long-term outcomes is ongoing. Infusion reactions were manageable. Elotuzumab, a mAb with a novel mechanism of action, showed improved PFS at 1 year and 2 years, with minimal added toxicity in combination with Ld *vs* Ld alone in patients with multiple myeloma.

Background: Follicular lymphoma (FL) is an incurable B-cell malignancy characterized by the t(14;18) and mutations in one or more components of the epigenome in virtually all cases. Whilst frequent gene mutations in signalling pathways, including JAK-STAT, NOTCH and NF-κB, have also been defined, the spectrum of these mutations typically overlaps with the closely-related diffuse large B cell lymphoma (DLBCL). Through a combination of discovery exome and extended targeted sequencing, we reveal recurrent somatic mutations in components of the mTOR pathway in FL patients.
Aims: We sought to identify novel gene mutations in FL that might serve as therapeutic targets.
Methods: Whole exome sequencing (WES) was conducted on 24 FL matched tumour/normal samples (mean coverage: 133x) from 5 patients that had multiple episodes of FL but have not transformed to a more aggressive disease. Prevalence screening and clonality assessment were performed by targeted deep sequencing of candidate and FL-associated genes, using Fluidigm-Miseq, in an extension cohort of 176 FL cases, with further Sanger sequencing in 329 related mature B-cell NHLs and 51 B-cell lymphoma cell lines. Functional analyses were carried out by expressing wild-type and mutant *RRAGC* in HEK-293T for signalling and co-immunoprecipitation experiments and purified wild-type and RagC mutant proteins were used in nucleotide-binding assays.
Results: Novel somatic mutations in *RRAGC* encoding a Rag GTPase protein (RagC) were identified in 4 out of the 5 untransformed FL patients analysed by WES. Clonal density plots demonstrated the *RRAGC* mutations resided within the dominant clone, with temporal analyses of multiple biopsies from the same individual showing stability of the *RRAGC* mutations during disease progression. Coding *RRAGC* mutations were identified in 28 of 176 cases (16%) from our FL extension cohort with mutations rare or absent in other mature B-NHL

entities. Mutations were heterozygous, predominantly missense (93%) and clustered within the nucleotide binding domain of RagC. The somatic origin of 10 of these mutations was confirmed by sequencing of matched constitutional DNA. A search for additional mutations in regulatory components upstream and downstream of the pathway uncovered co-occurring mutations in 2 subunits of the vacuolar H+-adenosine triphosphate ATPase (v-ATPase) complex, in more than half of *RRAGC* mutated cases. Together, Rag GTPases form a super-complex with the v-ATPase, Ragulator and SLC38A9 on the lysosomal surface and promote amino acid-mediated activation of the mechanistic target of rapamycin complex 1 (mTORC1). By transiently expressing RagC mutants ($RagC^{muts}$) in HEK-293T cells, we showed increased co-immunoprecipitation with a key regulatory component of mTORC1, raptor, compared to wild-type. Furthermore, stable overexpression of the $RagC^{muts}$ not only activated mTORC1 but rendered it resistant to leucine or arginine deprivation, as indicated by phosphorylation of a canonical mTORC1 substrate. Moreover, whilst all $RagC^{muts}$ were activating, mutations at amino acid residue Serine-75 led to mTOR activation by specifically disrupting nucleotide binding.
Summary and Conclusions: We report novel recurrent mutations in *RRAGC* and associated v-ATPase subunits, uniquely enriched in FL. The *RRAGC* mutations lead to activation of mTORC1 in the absence of amino acids. Overall, the emergence of frequent, gain-of-function *RRAGC* mutations that are clonally represented and maintained during progression provides an excellent candidate to be therapeutically exploited.

DNMT3A R882 MUTATION PROMOTE CHEMORESISTANCE AND THERAPEUTIC RELAPSE THROUGH IMPAIRED DNA-DAMAGE SENSING
O. Guryanova[1,*] K. Shank[1], F. Garrett-Bakelman[2], B. Spitzer[1], C. Ganzel[3], F. Rapaport[1], M. Keller[1], L. Evangelia[1], J. Glass[2], J. Rowe[3], F. Pastore[1], M. Tallman[1], M. Gonen[1], E. Paietta[4], O. Abdel-Wahab[1], A. Melnick[2], R. Levine[1]

Background: Although most patients with AML initially respond to anti-leukemic chemotherapy, the majority subsequently relapse and die of relapsed, refractory disease. Recent studies have suggested that therapeutic relapse is due to persistent, chemoresistant AML cells that survive initial therapy, and serve as a reservoir for genetic/epigenetic evolution and subsequent clinical relapse. Although many AML patients have evidence of residual leukemia at clinical remission, the mechanisms leading to chemoresistance and to the survival of AML cells in response to chemotherapy have not been delineated.
Aims: Investigate the link between specific mutations and minimal residual disease (MRD); deliniate molecular mechanism of therapeutic resistance in *DNMT3A*-mutant AML.
Methods: MRD was assessed by multi-parameter flow cytometry at day 28 in patients in clinical/pathologic complete remission. Novel genetic mouse model was used to study the role *DNMT3A* R882 mutation in AML pathogenesis and chemoresistance.
Results: Multivariate analysis revealed that *DNMT3A* R882 mutations were associated with an increased risk of MRD at the time of complete remission (p=0.007). By contrast, non-R882 mutations in *DNMT3A* did not predict for MRD, nor did other recurrent AML mutations. These data suggest an important role for *DNMT3A* R882 mutations in chemoresistance in AML, consistent with studies suggesting that *DNMT3A*-mutant, pre-leukemic stem cells persist after anti-leukemic chemotherapy. Next we generated a mouse model that conditionally expressed *Dnmt3a(mut)* from the endogenous locus. In agreement with clinical observations, *Dnmt3a(mut)* animals were characterized by expansion of the stem-cell-enriched $Lineage^{-}$ $Sca1^{+}$ $cKit^{+}$ (LSK) compartment. Consistent with enhanced clonal stem cell fitness in clonal hematopoiesis, we observed robust serial hematopoietic repopulation ability of *Dnmt3a(mut)* cells over 3-4 rounds of retransplantation *in vivo*. Notably, expression of *Dnmt3a*(mut) in hematopoietic cells from the endogenous locus did not induce AML *in vivo*. By contrast, we found that co-expression of mutant *Dnmt3a*, *Flt3-ITD* and *Npm1c* mutations, the most common "triad" of mutations observed in AML, resulted in a fully penetrant, short latency AML phenotype capable of propagating disease in secondary recipients. We next investigated the basis for *DNMT3A* R882 mutant-induced chemoresistance. Cells expressing *Dnmt3a(mut)* showed a survival advantage compared to wild-type controls and preserved clonogenic potential after *in vitro* and *in vivo* exposure to daunorubicin, but not in response to other DNA damaging agents. Of note, although *DNMT3A* mutant cells had attenuated pro-apoptotic signaling through the p53 pathway in response to anthracyclines, we observed increased single strand breaks and increased mutagenesis in *DNMT3A*-mutant cells consistent with impaired DNA-damage sensing in response to DNA strand torsion induced by daunorubicin. Most importantly, *Dnmt3a(mut)* cells fail to remodel their chromatin after anthracycline-induced DNA damage, with impaired nucleosome remodeling and reduced recruitment of the FACT chromatin remodeling complex subunit SPT-16 in response to anthacycline induced DNA torsion. This results in defective sensing of DNA breaks, attenuated pro-apoptotic signaling and reduced DNA repair, leading to increased mutagenesis in response to AML chemotherapy.
Summary and Conclusions: These data provide a novel mechanism by which mutant *DNMT3A* promotes chemoresistance in AML, and suggests the possibility of unique vulnerabilities in *DNMT3A*-mutant cells that can be exploited therapeutically to this common AML subset.

ANALYSIS OF NEW GFI1B VARIANTS IN PATIENTS WITH INHERITED BLEEDING AND PLATELET DISORDERS
A.E. Marneth[1,*] R. van Oorschot[1], S.M. Bergevoet[1], A. Wijgaerts[2], E. Turro[3,4], B.A. Laros-van Gorkom[5], W. van Heerde[1], G. Huls[5], J.H. Jansen[1], W.H. Ouwehand[3,4], K. Downes[3,4], K. Freson[2], B.A. van der Reijden[1]
[1]Laboratory Medicine, Laboratory of Hematology, Radboudumc, Nijmegen, Netherlands, [2]Center for Molecular and Vascular Biology, University of Leuven, Leuven, Belgium, [3]Department of Haematology, University of Cambridge, [4]NHS Blood and Transplant Centre, Cambridge Biomedical Campus, Cambridge, United Kingdom, [5]Department of Hematology, Radboudumc, Nijmegen, Netherlands

Background: Recently, we found that a heterozygous mutation in *Growth Factor Independence 1B* (*GFI1B*) causes an autosomal-dominant bleeding disorder characterized by gray platelets.[1] Affected individuals exhibited thrombocytopenia and suffered from mild to severe bleeding episodes. Their platelets appeared gray in blood films, as they contained reduced numbers of α-granules. GFI1B is an essential transcription factor for megakaryocyte differentiation. It contains six C terminal zinc fingers (Znfs), of which 3-5 are essential for DNA binding. The mutation that we reported caused a truncation of Znf 5. The mutant protein lost its repressive function and inhibited the repressive capacity of the wild type GFI1B protein (dominant-negative effect). Platelets from affected individuals expressed CD34, which had not been reported for bleeding and platelet disorders (BPD) caused by other genetic aberrations.
Aims: Here, we study eight new *GFI1B* variants that we identified in cases with inherited BPD. We assessed platelet α-granule numbers and CD34 expression of these patients and CD34 expression of BPD cases with proven pathogenic mutations in FLI1, GATA1, NBEAL2 and RUNX1. We also investigated the repressive capacity of the GFI1B variants.
Methods: Variants found in *GFI1B* in 529 whole exome-sequenced BPD cases, enrolled by the BRIDGE-BPD consortium, were compared to ~60,000 reference genomes (1000 genomes and ExAC databases).[2] Platelet α-granule numbers were assessed by electron microscopy. CD34 expression was measured on GPIbα/CD42B positive platelets by flow cytometry. Luciferase repression assays using GFI1B binding sequences were performed as described before.[1] Informed consent was obtained from all patients.
Results: Eight new *GFI1B* variants were found in patients with BPD.[2] Four variants were located upstream of the Znfs (D23N, Q89fs, G139S and C168F). The other four variants were located in or close to Znfs 1 and 2 (H181Y, R184P, R190W and G198S). All variants were heterozygous except for C168F being homozygous. Most variants were extremely rare (<2 hits/121,198 alleles) or absent in the reference samples. Approximately half of the patients had thrombocytopenia. Reduced platelet α-granule numbers were found for patients carrying Q89fs and H181Y, but normal α-granule numbers were found for patients carrying R184P and R190W. Platelets from all tested individuals with GFI1B variants (H181Y, R184P and R190W) exhibited CD34 expression. NBEAL2, GATA1, RUNX1 and FLI1 mutated platelets were CD34 negative. We tested the repressive capacity of Q89fs, G139S, C168F, H181Y, R184P and R190W. Q89fs lacked all Znfs and did not repress in a luciferase reporter assay, whereas all missense variants did repress.
Summary and Conclusions: We found eight new *GFI1B* variants in families with BPD. Platelet α-granule numbers were reduced for two out of four variants, while all tested variants had platelet CD34 expression. The latter seems unique to GFI1B variants. Only the frameshift variant lacking the DNA binding Znfs lost its repressive capacity. Therefore, distinct molecular mechanisms may cause platelet abnormalities. The frameshift variant might inhibit the function of wild type GFI1B by quenching co-factors, whereas the missense variants might do this by occupying DNA while lacking the ability to bind certain co-factors. The identification of these new variants opens new avenues to understand how GFI1B dictates megakaryopoiesis at the molecular level.

COMBINATION OF GENE TRANSFER AND FORCED CHROMATIN LOOPING CONCURRENTLY DECREASES SICKLE CELL HEMOGLOBIN AND REACTIVATES THE SYNTHESIS OF FETAL HEMOGLOBIN IN PATIENT CELLS

Background: The hemoglobinopathies, such as beta-thalassemia and sickle cell anemia (SCA), are characterized by mutations of the beta-globin gene resulting in either decreased or functionally abnormal hemoglobin (Hb) production. As bone marrow transplant is the only curative option for these patients, there is a strong need for new therapeutic approaches. Both beta-thalassemia and SCA represent ideal targets for gene therapy since introduction of a normal beta-globin gene can ameliorate the phenotype, as we and others have shown previously. In addition, overcoming the developmental silencing of the fetal gamma-globin gene represents an additional approach for the treatment of hemoglobinopathies. Here, we directly compare a recently established approach to activate the gamma-globin gene using forced chromatin looping with pharmacologic approaches to raise gamma-globin expression.

The beta-type globin genes are activated through dynamic interactions with the distal locus control region. This region physically contacts the developmental stage appropriate globin gene via chromatin looping, a process partially dependent on the protein Ldb1. We have shown that tethering Ldb1 to the human gamma-globin promoter with a custom designed zinc finger protein (ZF-Ldb1) can redirect loop formation from the beta- to gamma-promoter and potently reactivate gamma- globin gene expression in adult human erythroid cells (Deng *et al.*, Cell, 2012 and 2014).

Aims: Our objective is to compare this recently established approach to pharmacological induction of fetal hemoglobin (HbF) in cells with abnormal beta-globin function, as in Sickle Cell Anemia (SCA).

Methods: We isolated hematopoietic stem cells from blood of 11 SCA patients. These cells were expanded and differentiated into mature erythroid cells *in vitro*, and treated with a lentivirus expressing the ZF- Ldb1 transgene. 10 of these specimens were also treated with hydroxyurea, the only FDA-approved HbF inducer used in SCA patients, or with the experimental inducers decitabine, tranylcypromine, pomalidomide and butyrate.

Results: ZF-Ldb1 increased HbF synthesis in SCA erythroid cells up to 86% and, concurrently, reduced sickle Hb (HbS) below 15%, showing a balanced synthesis between alpha and beta like globins, and consistent with additional studies with healthy erythroid cells. In addition, the induction of HbF in cells treated with ZF-Ldb1 was roughly three times higher (+34%, at a dose of ~ one transgene copy per cell) than that observed using pomalidomide (+12%, 10μM). Decitabine and tranylcypromine had an intermediate effect (+9% for both drugs, 0.5 μM and 1.5 μM, respectively). Hydroxyurea and butyrate showed the lowest HbF increase (+2% and +3%, respectively, both 100μM). Importantly, pomalidomide treatment lowered to 46% cell viability, which remained unaltered in ZF-Ldb1 expressing cells. In related experiments, we compared the expression of a battery of genes known to regulate HbF levels (BCL11A, SOX6, KLF1 and C-Myb) in normal and SCA derived erythroid cells treated with ZF-Ldb1 or HbF inducers and compared to controls. Quantitative PCR analyses indicate reduced expression of KLF1 in and SOX6 in SCA specimens, in line with a higher HbF synthesis at steady state.

Summary and Conclusions: Given its efficacy and safety, lentiviral-mediated ZF-Ldb1 gene transfer has great therapeutic potential for SCA erythroid cells and appears superior to drug induction. Moreover, a reduced expression of HbF repressors in SCA cells might facilitate ZF-Ldb1-induced expression of HbF

Multiple myeloma - Biology

Background: Malignant transformation of normal to tumour cells is a multistep process followed by sequential aggregation of hits at different molecular levels. Genetic events including single nucleotide variants (SNVs), insertion-deletion changes (indels) as well as copy number alterations (CNAs) affect the phenotype of the tumour population and consequently patient prognosis. Transformation from a symptomless state, monoclonal gammopathy of undetermined significance (MGUS) to multiple myeloma (MM) can be used as a unique model for cancer development studies. To date, there is very little data regarding the mechanisms leading to disease progression at molecular level.

Aims: To perform exome sequencing together with SNP array analysis in MGUS patients to describe the premalignant phenotype and compared these to advanced tumour cells at the DNA level.

Methods: Overall, 33 and 69 MGUS patients were included in a WES and SNP array study, respectively. Plasma cells (PC) were isolated from bone marrow by FACSAria (BD Biosciences) system using CD138, CD19 and CD56 markers to obtain a pure abnormal PC population with a purity >90%. For WES, NEBNext kit and SureSelect Human All Exon V5 (Agilent) were used, samples were sequenced by HiSeq2000 (Illumina). Copy number alterations (CNAs) were tested by SurePrint G3 CGH+SNP, 4x180K (Agilent). Results were compared to 463 and 91 MM patients analysed by WES and SNP arrays, respectively.

Results: CNAs and acquired somatic gene mutations (SNVs) were detected in 68% (47/69) and 100% (33/33) of MGUS patients in comparison to 100% (91/91, $p<10^{-4}$) and 100% (463/463) of MM patients, respectively. However, the overall number of both CNAs and SN*Vs* per patient was significantly lower in MGUS (CNAs: median 2, range 0-15; SNVs: median 89, range 9-315) than in MM (CNAs: median 16, range 2-49, $p<10^{-18}$; SN*Vs* median 123, range 1-897, $p<10^{-4}$). Non-synonymous SN*Vs* (NS-SNVs) were present in 97% (32/33) cases with a median 19 (range 0-70) NS-SN*Vs* per patient. Overall, 42 genes were recurrently mutated in at least 2 patients and 2 non-large protein coding genes were mutated in at least 3 cases including *KLHL6* and *NPIPL2*. We identified 7 genes which were significantly mutated in MM in our previous study including *KRAS* (n=2), *HIST1H1E* (n=2) and *NRAS*, *DIS3*, *EGR1*, *LTB*, *PRKD2* (all n=1). *IGH* translocations were identified in 27% (9/33) of patients: t(11;14) in 12% (4/33), t(4;14) in 9% (3/33), t(14;16) in 3% (1/33) and t(14;20) in 3% (1/33). As previously described in MM, only one type of *IGH* translocation was found per patient and all 9 cases with *IGH* translocation did not have additional hyperdiploidy. We did not find any translocations involving *MYC* (8q24.21) or the light chain loci *IGK* (2p12) and *IGL* (22q11.2) and any mutations in *TP53*, *ATM*, *ATR* and *ZNFH4* genes involved in DNA repair pathway alterations which were identified as unfavourable factors to MM patients survival.

Summary and Conclusions: We have performed the first comprehensive analysis of MGUS patients using exome sequencing together with SNP arrays and described the main genetic events that are already present in this premalignant state. We proved that complex genetic instability is formed before clinical manifestation first at the gene level then at the chromosome level. Then, a number of random genetic hits increases to form a landscape for significant oncogenic hits driving the transition to a malignant state.

EXPRESSION LEVELS OF CD38 AND COMPLEMENT INHIBITORY PROTEINS CD55 AND CD59 PREDICT RESPONSE TO DARATUMUMAB IN MULTIPLE MYELOMA

I. Nijhof[1,*] A. Axel[2], T. Casneuf[3], T. Mutis[1], A. Bloem[4], J. Van Velzen[4], B. Van Kessel[1], M. Minnema[4], P. Doshi[2], H. Lokhorst[1], K. Sasser[2], N. Van De Donk[1]
[1]Hematology, VUMC, Amsterdam, Netherlands, [2]Johnson & Johnson Pharmaceutical Research & Development, Springhouse, United States, [3]Johnson & Johnson Pharmaceutical Research & Development, Beerse, Belgium, [4]Hematology, UMCU, Utrecht, Netherlands

Background: Daratumumab (DARA), an anti-CD38 monoclonal antibody, induces lysis of multiple myeloma (MM) cells through complement dependent cytotoxicity (CDC) and antibody-dependent cellular cytotoxicity (ADCC). Immunotherapy with DARA is clinically effective, but there is a significant variability in quality of response among patients.
Aims: We examined potential determinants of DARA sensitivity before start of treatment, and mechanisms of resistance during therapy, with special emphasis on the target protein CD38. Since several studies have stressed the importance of CDC for therapeutic efficacy of antibodies, we also focused on the complement inhibitory proteins (CIPs), including CD46, CD55, and CD59.
Methods: We investigated a panel of cell lines, as well as patient samples by flow cytometry for CD38, CD46, CD55, and CD59 and assessed their sensitivity to DARA-mediated CDC *in vitro*. We also evaluated samples from relapsed/refractory MM patients treated with DARA as a single agent (GEN501 study).
Results: MM and lymphoma cell lines (n=33), as well as primary MM cells (n=31) expressing high levels of CD38 and low levels of CD55 and CD59 were significantly more sensitive to DARA-mediated CDC, compared to cells with low CD38 expression and high levels of CD55 or CD59. However, CD46 expression was not associated with CDC sensitivity. We also analyzed the expression of CD38 and CIPs on MM cells from 21 relapsed/refractory MM patients directly before start and during DARA treatment. The CD38/CD59 and CD38/CD55 ratios prior to treatment were predictive of clinical response. Also the sensitivity of pretreatment MM cells towards DARA-mediated CDC *ex vivo*, correlated positively with clinical response to DARA, expressed as maximum reduction in tumor load (R=0.70, *P*=0.005). At the time of progression during DARA therapy, there was a significant reduction of CD38 expression and significant increase in CD59 and CD55 expression on both bone marrow-localized and circulating MM cells, whereas CD46 levels did not change. As expected, at the time of relapse, a significant decrease in DARA-mediated CDC was found when compared to baseline values. Interestingly, before start of DARA therapy, two out of 21 patients had two coexisting populations of MM cells based on differential expression of CD55 and/or CD59. In both cases, the dominant relapsing clone was strongly positive for both CD55 and CD59, whereas these clones were present as minor populations before initiation of DARA treatment. Altogether, these data suggest that elevated CIP expression results in reduced sensitivity to DARA-mediated CDC, and that upregulation of CD55 and CD59 during DARA treatment may contribute to the development of resistance. With the intention to improve CDC sensitivity, we evaluated phospholipase C, which enzymatically removes the GPI-anchored CD55 and CD59 molecules from the cell surface. Indeed, loss of CD55 and CD59 improved DARA-mediated CDC sensitivity *in vitro*. Similarly, all-*trans* retinoic acid (ATRA) enhanced CD38 expression levels and reduced CD55 and CD59 expression resulting in a significant enhancement of CDC in MM cell lines and primary MM cells. Also in a humanized mouse model, ATRA significantly enhanced the anti-MM effect of DARA.
Summary and Conclusions: These results show that baseline CD38/CD55/CD59 expression may be useful to predict response to DARA, and that targeting CIPs could be a potential adjuvant therapy for DARA or other monoclonal antibodies with CDC activity.

Background: Current prognosis in multiple myeloma (MM) is based on International Staging System (ISS) and the presence of chromosomal abnormalities detected by Fluorescent *in situ* Hybridization (FISH). However, their ability to stratify patients is still suboptimal and novel biomarkers are required to better predict survival. We identified circulating miRNAs as a non-invasive biomarker to stratify MM patients.
Aims: To evaluate the role of circulating miRNA in combination with usual prognostic factors in MM. In details: 1) to confirm the prognostic value of circulating miRNAs in MM; 2) to investigate their relationship with classical prognostic parameters; 3) to evaluate the addition of circulating miRNAs into a prognostic model together with ISS and FISH.
Methods: Circulating miRNA expression has been evaluated in newly diagnosed MM patients enrolled in the GIMEMA clinical trial NCT#01063179. Patients were randomized to receive VMP (Velcade-Melphalan-Prednisone) or VMPT-VT (Velcade-Melphalan-Prednisolone-Thalidomide with Velcade-Thalidomide maintenance). We used NanoString assay to screen more than 800 miRNAs in serum at baseline and qRT-PCR to validate significant miRNAs as reported elsewhere (Rocci A *et al.*, *Leukemia* 2014). High and low expression of miRNAs were defined using the 233 patients median value as a cut-off. We defined high risk FISH as the presence of del(17p) or t(4;14) or t(14;16) and standard risk as all other patients. Proportional hazard regression model was used, stratified by maintenance (to remove the effect of different chemotherapy regimens), with ISS treated as time-dependent covariate.
Results: We analyzed serum from 233 evaluable patients, with a median follow-up of 71 months. Patient's characteristics are reported in Table 1 and are balanced by age, treatment received and maintenance. Ten miRNAs were significantly expressed in serum (≥100 counts in at least 20% of patients) and confirmed by miRNA qRT-PCR. High expression of circulating miR-16 was confirmed as a strong predictor of better PFS (median PFS 32 *vs* 26 months, p=0.020) and OS (median OS unreached *vs* 58 months, p=0.006) when compared to low miR-16 in univariate analyses. High expression of miR-25 showed a trend for improved survival (PFS p=0.063; OS p=0.064). In multivariate analysis including age (>75 yrs *vs* ≤75 yrs), FISH (standard *vs* high risk), isolated Del17 by FISH, and ISS (I *vs* II and I *vs* III), miR-16 was a strong predictor of OS (p=0.014). Grouping miR-16, ISS and FISH identified those patients with a poor prognosis (miR-16 low, ISS 3, high risk FISH) *versus* good prognosis (miR-16 high, ISS 1, standard risk FISH) with a median OS of 18.4 months *vs* unreached respectively (p=0.0003). MiR-16 expression divides patients with standard FISH (n=127) into those with good outcome (high miR-16, 5 yrs OS: 68%) and those with poor outcome (low miR-16, 5 yrs OS: 47%, p=0.012). High miR-16 identifies patients with better outcome independently from treatment arm, however its effect was strongest in patients receiving VMPT-VT: patients with high miR-16 have a better 5-years PFS (38% *vs* 21%, p=0.07) and 5-year OS (76% *vs* 47%, p=0.0009).

Table 1.

VMP	116 (50%)
VMP-VT	117 (50%)

Abbreviations: B2M - β_2-microglobulin; ISS - International Staging System; LDH - lactate dehydrogenase; FISH - Fluorescent *in-situ* hybridization; VMP - Bortezomib-Melphalan-Prednisone; VMPT-VT - Bortezomib-Melphalan-Prednisone-Thalidomide followed by maintenance therapy with Bortezomib-Thalidomide

Summary and Conclusions: Circulating miR-16 is a strong prognostic factor in newly diagnosed MM patients. It independently predicts overall survival in a model that includes ISS and FISH abnormalities. MiR-16 is independent from ISS and FISH and these three covariates together dichotomize the population in terms of overall survival.

S479

TARGETING EPITHELIAL TO MESENCHYMAL TRANSITION (EMT) THROUGH CXCR4 BLOCKADE IN MULTIPLE MYELOMA

A. Roccaro[1,*] A. Sacco[1], M. Moschetta[1], J. Shi[1], M. Chiarini[2], C. Pan[3], P. Cardarelli[3], M. Kuhne[3], I. Ghobrial[1]
[1]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States, [2]Centro per la Ricerca Onco-ematologica AIL (CREA), Spedali Civili di Brescia, Brescia, Italy, [3]Bristol-Myers Squibb, Redwood City, CA, United States

Background: Multiple osteolytic lesions are one of the main clinical features of patients with multiple myeloma (MM), thus suggesting the ability of clonal plasma cells to disseminate from bone to bone. The bone marrow (BM) homing process of MM cells is supported by the CXCR4/CXCL12 axis activation. Nevertheless, the role of CXCR4 in mediating MM cell bone metastasis, and the role of CXCR4-targeted therapy in inhibiting MM cell dissemination has not been previously reported.
Aims: 1) To define the pro-metastatic role of CXCR4 *in vivo*; 2) to investigate the mechanisms of CXCR4-mediated EMT both *in vitro* and *in vivo*; 3) and to test the anti-CXCR4 monoclonal antibody (Ulocuplumab) in inhibiting CXCR4-mediated EMT phenotype *in vivo*.
Methods: Gene set enrichment analysis and Atlas of Cancer Signaling Networks were used to study publically available gene expression dataset of primary BM-derived MM plasma cells (GSE24080; n=577; FDR<0.25; P<0.05). The functional relevance of CXCR4 in mediating MM cell dissemination was studied by generating CXCR4-gain and -loss-of-function expressing cell lines, using an *in vivo* model of MM cell dissemination from bone to bone. Modulation of EMT-related genes and proteins was tested both *in vitro* and *ex vivo*, using qRT-PCR, western blot, confocal miscroscopy, IHC and flow cytometry. The anti-tumor effect of Ulocuplumab was tested both *in vitro* and in an *in vivo* model of MM cell bone metastasis, bioluminescence imaging (BLI) and intravital confocal miscroscopy.
Results: We categorized BM-MM-derived CD138+ cells (GSE24080; n=577) according to their CXCR4 mRNA expression; and identified an EMT-related pathway to be significantly activated in high-CXCR4- *versus* low-CXCR4-BM-MM CD138+ cells. We next performed CXCR4-gain-of-function studies and demonstrated that CXCR4+ cells presented with changes in actin cytoskeleton, with protrusion of cell pseudopodia, sustained by modulation of EMT-related markers (Slug/Snail/Twist up-regulation; E-cadherin down-regulation), compared to control cells. These findings were recapitulated using an *in vivo* model of MM cell bone-to-bone metastasis: $CXCR4^+$ MM cells showed higher levels of bone-to-bone metastasescompared to control cells, as confirmed on harvested host femurs. Lower expression of human (h)-E-cadherin, and higher expression of h-Twist/h-Snail/h-Slug was confirmed within the BM of the host femurs. The monoclonal antibody, anti-CXCR4 (Ulocuplumab) exerted an anti-MM activity *in situ*, within the s.q. implanted bones; and also reduced MM cell dissemination from the implanted bone to the host bone. Importantly, Ulocuplumab modulated EMT-related genes in the MM cells that metastasized to the host bones, with enhanced mRNA expression of human (h)-E-cadherin, and reduced expression of h-Twist/h-Snail/h-Slug and h-CXCR4 in the BM cells harvested from the host bones of Ulocuplumab-treated mice. Similar findings were confirmed in an *in vivo* breast cancer model (MDA-MB-231 intra-cardiac injected). CXCR4-loss of function in MM cells led to inhibited BM homing and tumor growth *in vivo*; with prolonged survival compared to control mice injected with scramble-transfected control cells. Moreover, Ulocuplumab led to inhibition of MM tumor growth *in vivo*, using MM.1S- and RPMI.8226- xenograft s.q.models; with a synergistic effect when used in combination with lenalidomide or bortezomib.
Summary and Conclusions: Our study supports the pro-metastatic role of CXCR4, due to its effect in mediating EMT in both MM and breast cancer *in vivo* models, thus suggesting the potential role for using CXCR4-neutralizing agents in order to delay or prevent tumor cell metastasis to bones.

S480

OVEREXPRESSION OF ARGINASE AND PROK-2 MAKES NEUTROPHILS OF MULTIPLE MYELOMA DYSFUNCTIONAL AND IMMUNOSUPPRESSIVE

A. Romano[1,*] V. Simeon[2], P. La Cava[1], N.L. Parrinello[1], A. La Fauci[1], C. Vetro[1], D. Tibullo[1], C. Giallongo[1], M. Cavalli[1], A. Chiarenza[1], C. Conticello[1], P. Musto[3], F. Di Raimondo[1]
[1]Division of Hematology, Azienda Policlinico-OVE, University of Catania, CATANIA, [2]Laboratory of Pre-clinical and Translational Research, IRCCS-CROB Referral Cancer Center of Basilicata, Rionero in Vulture, [3]Laboratory of Pre-clinical and Translational Research, IRCCS-CROB Referral Cancer Center of Basilicata, Rionero in Vulture, Italy

Background: Multiple Myeloma (MM) is a plasma cell malignancy with a well documented immune dysfunction. However, the function of neutrophils in MM and monoclonal gammopathy of undetermined significance (MGUS) has been poorly investigated.
Aims: The objective of this investigation was evaluating the activation status of peripheral neutrophils (N) isolated from MM and MGUS patients.
Methods: Using oligonucleotide microarrays we first evaluated the gene expression profile (GEP) of granulocytes at the steady state in 10 MM, 5 MGUS and 8 healthy subjects matched for sex and age, identifying Arg-1 and PROK-2 among the first 10 genes differentially expressed in MM *versus* healthy granulocytes. Thus, we validated Arg-1 and PROK-2 by RT-PCR in a series of 60 newly-diagnosed MM patients, 30 MGUS and 30 healthy subjects. Activation status on N was then investigated in the same series, evaluating phagocytic and burst activity by commercial kit, surface expression of CD64, CD16, CD62L and CD11b, markers of neutrophil activation and reactive oxygen species (ROS) by flow cytometer. Finally, we tested the immunosuppressive properties of N isolated from MGUS or MM patients, through functional assays, based on *in vitro* co-culture of N isolated from patients and T-lymphocytes from healthy subjects.
Results: MM-N exhibit an increased expression of ARG-1 compared to MGUS and healthy subjects (25.5 *vs* 6.2 *vs* 1 fold changes in gene expression, p=0.003), confirmed by functional assay of enzymatic activity of ARG-1, positively correlated with advanced disease. PROK-2 expression was two times higher in MGUS than healthy subjects (p=.02) and up to ten times higher in MM (p=.001). In MM patients, increased levels of PROK-2 were positively associated with advanced bone disease and unfavourable cytogenetics. The phagocytic activity was reduced in MM-N compared to HS-N and MGUS-N (46% *versus* 75% *versus* 72%, p<0.0001 and p<0.0001 respectively). Oxidative burst was 71% in MM-N, lower than HS-N (85%, p=0.01) and MGUS-N (86%, p=0.01). The MM-N exhibit higher levels of ROS (MFI 113±9) compared to HS-N (MFI 46±7) and MGUS-N (MFI 62±8, p<0.0001 and p=0.0001 respectively). Expression of CD64 was significantly elevated in MM-N compared to MGUS-N or healthy subjects-N (p=0.01 and p=0.007 respectively) and was inversely correlated with phagocytic activity (p=0,01). After 72 hours, MM-N were able to reduce T-cell proliferation at both tested 1:2 and 1:8 ratios, while MGUS-N could induce a similar effect only at the highest ratio 1:8. This effect was partially reverted with the treatment of 200 μM nor-NOHA, an Arg-1 inhibitor.
Summary and Conclusions: Compared to controls, neutrophils obtained from MM patients have a reduced phagocytic activity, a greater expression of Arg-1 and PROK-2 and exhibit an immunosuppressive function on T lymphocytes. These features are only minimally present in neuthophils from MGUS patients

Optimization and innovation in treating aggressive lymphomas

S481

THE B CELL RECEPTOR SIGNALING OUTPUT IN BURKITT'S LYMPHOMA IS GENOTYPE-SPECIFIC AND IMPACTS SENSITIVITY TOWARDS BCR SIGNALING INHIBITORS

T. Oellerich[1,*] J. Corso[2], J. Beck[3]K.-T. Pan[4], C. Doebele[1], A. Wachter[5], C. Lenz[4], T. Beissbarth[5], E. Schuetz[3], K. Tomska[6], L. Sellner[6], T. Zenz[7], H. Serve[1], H. Urlaub[4]
[1]Hematology/Oncology, Goethe University Frankfurt, Frankfurt, [2]Bioanalytical Mass Sepctrometry Group, Max Planck Institute for Biophysical Chemistry, [3]Chronix Biomedical, [4]Bioanaytical Mass Spectrometry Group, Max Planck Institute for Biophysical Chemistry, [5]Institute of Medical Statistics, University Medical Center Göttingen, Goettingen, [6]Department of Translational Oncology, National Center for Tumor Diseases and German Cancer Research Center, [7]Department of Medicine V, Heidelberg University Medical Center, Heidelberg, Germany

Background: B cell antigen receptors (BCR) control important cell fate decisions of the B-lineage such as differentiation, proliferation and B cell survival. Recently, it was demonstrated that major subgroups of Burkitt lymphomas (BL) critically depend on BCR expression. The current treatment regimens consist of intensive chemotherapy in combination with anti-CD20 antibodies and show significant toxicity. Pharmacological interference with critical BCR signaling pathways might open up the possibility for targeted therapies in BL that are needed in particular for elderly patients and patients with endemic BL in developing countries.
Aims: Our study aims (i) to identify drug targets in BL, (ii) to validate selected drug targets *in vitro* and *in vivo* and (iii) to elucidate BCR induced processes.
Methods: We performed mass-spectrometry-based phosphoproteomics, transcriptome sequencing and bioinformatic analyses to elucidate BCR signaling networks in BL cell lines and patient-derived BL cells. Moreover, we validated identified drug targets using a compound library and BL xenograft models. Detailed functional analyses were performed for identifying the role of HSP90 in BL.
Results: We identified and quantified about 10.000 phospho-sites in various BL cell-lines and patient-derived BL cells, of which more than 1000 phospho-sites in almost 600 proteins were regulated in a BCR-dependent manner leading to dynamic transcription of more than 100 genes. The identified BCR signaling effectors belong to various functional groups, of which kinases, transcription factors and cytoskeleton regulators are most represented and bioinformatic analyses revealed that 83% of the identified BCR effectors were not described in the context of B cells or lymphoma before. Our data-sets allowed to investigate the dynamic interplay between receptor-triggered kinase activation, phosphorylation events and mRNA-/protein expression changes. While BCR-proximal signaling networks were concordantly regulated among genetically distinct BL cell-types, BCR-distal signaling turned out to be genotype-specific. Based on the detailed signaling information we established genotype-specific kinase/substrate/transcriptome networks that provide functional insights and information about druggable BCR-signaling pathways in BL. Predicted drug targets were furthermore validated in more than twenty BL cell lines using a compound screen that allowed us to correlate BCR signaling profiles with responsiveness to compounds targeting BCR signaling. For instance, heat shock protein 90 (HSP90) inhibition by small molecule inhibitors such as AT13387 induced apoptosis in most analyzed BL cell models and BL xenografts. This was achieved by disruption of BCR signal initiation due to destabilzation of spleen tyrosine kinase expression that turned out to critically depend on HSP90 function in BL. In contrast, compounds like Bruton's tyrosine kinase and protein kinase B inhibitors targeting the more heterogenous BCR-distal signaling networks induced apoptosis only in certain BL cell-types.
Summary and Conclusions: Taken together our study is a considerable complement to recent genetic studies that elucidated the mutational landscape in BL as it reveals mechanisms of signaling addiction to non-mutated druggable BCR effector proteins. Their further (pre)clinical evaluation as drug targets seems warranted.

S482

THE PRESENCE OF GENOMIC IMBALANCES IS ASSOCIATED WITH WORSE OUTCOME IN PATIENTS WITH BURKITT LYMPHOMA TREATED WITH DOSE-INTENSIVE CHEMOTHERAPY INCLUDING RITUXIMAB

Background: The introduction of intensive cycles of high-dose immunotherapy with rituximab has improved the outcome and survival rates in patients with Burkitt lymphoma (BL). However, early relapse and refractoriness are current limitations of BL treatment and new biological factors affecting the outcome of the patients treated with dose-intensive chemotherapy including Rituximab have not been explored.
Aims: To characterize by array-based comparative genomic hybridization (aCGH) and next generation sequencing (NGS) the presence of genetic changes that could be predictive of the clinical response to Rituximab in a selected group of BL patients included in the Dose-Intensive Chemotherapy Including Rituximab (Burkimab trial) from the Spanish PETHEMA cooperative group.
Methods: Forty adolescent and adult BL patients were included. All of them were homogeneously treated according to Burkimab trial established by the PETHEMA group. The inclusion criteria were: a) diagnosis of BL or Burkitt-like lymphoma according to WHO criteria, b) *MYC*-rearrangement demonstrated by karyotype and/or fluorescence *in situ* hybridization c) age greater than 14 years. The segmentation analysis was performed using CGHweb tool. In addition, amplicon-based NGS was carried out to investigate the mutational status of *TP53* gene (4 to 11 exons). The 454 Life Sciences, a Roche company GS Junior system was used. The variant analysis was performed using Amplicon Variant Analyzer (AVA-Roche 454) and Sequence Pilot (JSI Medical Systems) software. The genomic alterations were associated with clinical, biological and survival parameters.
Results: CNAs were present in 97.5% of patients. The most common aberrations were gains on chromosomes 1q (33%), 7q (31%) and 8q (18%), whereas the losses predominantly involved chromosomes 9p (23%), 13q (23%), 15q (21%), 11q (15%) and 6q (10%). The losses on 11q, 13q, 15q or 17p (p=0.028) and poor performance status (ECOG≥2) (p=0.016) was associated with the poor response Burkimab. These losses were also associated with shorter four-year progression free survival (PSF) (50% *vs* 93%, p=0.012). Shorter DFS was observed in BL patients with losses on 11q (p=0.003), 15q (p=0.002) or 17p (p=0.03). The four-year DFS of patients with these losses was 56% *versus* 93% for patients without losses. Likewise, BL patients with losses on 11q (p=0.001) or 15q (p=0.02) had shorter OS than patients without these abnormalities; the four-year OS of patients with these losses was 60% *vs* 96% for patients without them. The ECOG≥2 was associated with a shorter PFS (p=0.02), DFS (p=0.036) and OS (p=0.012). The losses on 11q, 13q, 15q or 17p (HR, 5.506; 95%CI, 1.283-23.624; p=0.022) and ECOG≥2 (HR, 8.605; 95%CI: 1.044-70.900; p=0.045) were independent risk factors associated with shorter PFS. Losses in 11q, 15q or 17p were identified as risk factors independently associated with shorter DFS (HR, 4.921; 95%CI: 1.0-22.4; p=0.040) and OS (HR, 7.2; 95%CI: 1.2-41.5; p=0.026). In addition, the integrative analysis of aCGH and NGS showed that 26% (5/19) of patients carried at least one alteration in *TP53* gene, two cases had loss of 17p and three cases had missense mutations. *TP53*alt was associated with a poor response to Burkimab therapy (p=0.044) and a shorter four-year PFS: 84.6% *vs* 25% (p=0.022).
Summary and Conclusions: Losses of 11q, 13q, 15q, or 17p, as well as *TP53*alt are associated with a poor response to Dose-Intensive Chemotherapy Including Rituximab (Burkimab trial). These non-random losses could be used for the risk stratification of BL patients treated with Rituximab.

Hospital Costa del Sol, Marbella, Spain, [3]Division of Hematology, Tel Aviv Sourasky Medical Center, Tel Aviv, [4]Department of Hematology, Chaim Sheba Medical Center, Tel Hashomer, Israel, [5]Department of Clinical Hematology, University Hospital of Amiens, Amiens, France, [6]Hematology Unit, S. Maria Delle Croci Hospital, Ravenna, Italy, [7]Department of Internal Medicine, Albert Schweitzer Hospital, Dordrecht, Netherlands, [8]Biometrics, [9]Pharmaceuticals Division, F. Hoffmann-La Roche Ltd, Basel, Switzerland, [10]Department of Internal Medicine I, University Hospital of Saarland, Homburg, Germany

Background: Subcutaneous rituximab (R^{SC}) offers improved patient (pt) convenience and healthcare resource savings *versus* intravenous R (R^{IV}), with similar efficacy and safety outcomes in the SABRINA study in follicular lymphoma (FL). R^{SC} is approved in Europe and other countries for use in FL and diffuse large B-cell lymphoma (DLBCL).
Aims: To confirm the efficacy and safety of R^{SC} *versus* R^{IV} plus CHOP (cyclophosphamide, doxorubicin, vincristine and prednisone) for the treatment of DLBCL.
Methods: The open-label, randomised MABEASE study (NCT01649856) investigated the efficacy of R^{SC} *versus* R^{IV} plus CHOP in untreated DLBCL. Pts were randomised 2:1 to receive R^{SC} (R^{IV} 375 mg/m^2 cycle 1; R^{SC} 1400 mg fixed dose cycles 2-8) or R^{IV} (R^{IV} 375 mg/m^2 cycles 1-8), plus 6 or 8 cycles of CHOP every 14 or 21 days. Responses (complete response [CR], unconfirmed CR [CRu], partial response [PR], progressive disease [PD]) were determined by investigator assessment (Cheson 1999 criteria). Administration-related reactions (ARRs) were defined as R-related adverse events (AEs) that occurred ≤24 hours of administration. The primary endpoint was response rate at end of treatment (EOT). Safety was a secondary endpoint.
Results: In total, 576 pts were randomised (R^{SC} n=381; R^{IV} n=195; intent-to-treat [ITT] population); baseline characteristics were balanced between arms. A total of 572 pts (R^{SC} n=378; R^{IV} n=194) received ≥1 dose of R. Nine R^{SC} pts discontinued after cycle 1, due to AE (n=5), withdrawn consent (n=2), PD and protocol violation (both n=1); as both arms received R^{IV} during cycle 1, these pts were included in the R^{IV} arm for safety analyses (R^{SC} n=369; R^{IV} n=203). At EOT (R^{SC} n=342; R^{IV} n=177), response rates were similar between arms in the ITT population overall (R^{SC} 52%; R^{IV} 51%) and when pts were stratified by age (~50% for all groups; Table 1). AE rates were comparable between the R^{SC} and R^{IV} arms overall (92% *vs* 91%) and during cycle 1 (61% *vs* 64%); the most common AE overall was neutropaenia (R^{SC} 36%; R^{IV} 33%). During cycles 2-8, R^{SC} and R^{IV} pts had similar rates of grade ≥3 AEs (53% *vs* 50%) and serious AEs (SAEs; 34% *vs* 31%); the most frequent grade ≥3 AE was neutropaenia (R^{SC} 22%; R^{IV} 20%) and the most common SAE was febrile neutropaenia (R^{SC} 11%; R^{IV} 6%). ARR rates were similar between R^{SC} and R^{IV} pts overall (28%/arm), during cycle 1 (11% *vs* 14%) and cycles 2-8 (22% *vs* 20%). From cycle 2-8, the most common ARR by System Organ Class (SOC) was general disorders and administrative site conditions (R^{SC} 10%; R^{IV} 4%). Rates of grade ≥3 ARRs was similar between arms overall (2% *vs* 5%), during cycle 1 (0% *vs* 2%) and cycles 2-8 (2% *vs* 4%); from cycles 2-8, the most common grade ≥3 ARR by SOC was blood and lymphatic system disorders (R^{SC} 1%; R^{IV} 3%). In total, 52% (R^{SC}) and 54% (R^{IV}) of pts had R-related AEs; the most frequent R-related AE was neutropaenia (R^{SC} 14%; R^{IV} 16%). Overall, 8% (R^{SC}) and 9% (R^{IV}) of pts discontinued R due to AEs, most commonly infections (R^{SC} 2%; R^{IV} 3%). In total, 63 pts (11%) died (R^{SC} 10%; R^{IV} 13%). AEs led to death in 6% (R^{SC}) and 7% (R^{IV}) of pts, most commonly due to infections (2%/arm).

Table 1. Response rates at EOT.

Pts, n (%)		CR/CRu	PR	PD
ITT	R^{SC} (n=342)	178 (52)	103 (30)	13 (4)
	R^{IV} (n=177)	90 (51)	56 (32)	9 (5)
Age <60 years	R^{SC} (n=138)	64 (46)	48 (35)	7 (5)
	R^{IV} (n=74)	38 (51)	22 (30)	4 (5)
Age ≥60 years	R^{SC} (n=204)	114 (56)	55 (27)	6 (3)
	R^{IV} (n=103)	52 (50)	34 (33)	5 (5)

Summary and Conclusions: R^{SC} and R^{IV} plus CHOP had similar efficacy and safety outcomes in previously untreated DLBCL. R^{SC} offers convenience for pts and efficient utilisation of healthcare resources.

S484

MANAGEMENT AND OUTCOME OF PRIMARY CNS LYMPHOMA AT FIRST RELAPSE/PROGRESSION: ANALYSIS OF 256 PATIENTS FROM THE FRENCH LOC NETWORK

Background: A significant proportion of primary CNS lymphoma (PCNSL) patients is refractory or relapses after first line therapy. Clinical presentation and therapeutic management of patients with relapsed/refractory (R/R) PCNSL are heterogeneous.
Aims: The aim of this study was to analyze the characteristics, management, and outcome of R/R PCNSL patients after first-line therapy.
Methods: We analyzed patients with R/R PCNSL who had been prospectively registered in the database of the French LOC network between 2011 and 2014.
Results: Among 563 PCNSL patients registered in the LOC database, we identified 256 patients with relapsed (N=93, 16.5%) or refractory (N=163, 29.0%) disease after a median follow-up of 9 [0.3-43.0] months. Median age was 68 [26-93] years. Most patients (92.6%) had received a methotrexate-based chemotherapy as first line treatment. First relapse/progression occurred after a median progression-free survival from diagnosis (PFS1) of 5.1 [0.3-35.8] months. Relapse/progression was asymptomatic in 25.5% of the cases, mostly diagnosed on systematic neuroimaging. Overall survival after relapse/progression (OS2) was 3.5 [0-29.6] months for the entire cohort. At first relapse/progression, 28.2% of the patients received palliative care. All of them died within 5 months with a median OS2 of 0.6 months. The remaining patients (71.8%) received salvage chemotherapy (methotrexate, cytarabine or ifosfamide-based regimens) without (79.5%) or with (20.5%) consolidation therapy consisting in radiotherapy (14.7%) or intensive chemotherapy followed by autologous stem cell transplantation (ICT+ASCT) (85.3%). Survival was significantly longer in patients receiving consolidation therapy with a median PFS2 (PFS from first relapse/progression) of 13.5 *vs* 2.6 months and a median OS2 not reached *vs* 6.7 months (p<0.01). In patients receiving ICT+ASCT, 44.8% (13/29) experienced a PFS2 longer than their PFS1. Survival was significantly worse in refractory patients and in relapsed patients with a PFS1<1 year (median OS2=2.1 and 3.7 months, respectively) compared to relapsed patients with a PFS1>1 year (median OS2 not reached, p<0.01) (Figure 1). Other prognostic factors were age (<*vs* >60 years), Karnofsky index (KI, >*vs* <70%), administration of a salvage therapy, and administration of Rituximab. In multivariate analysis, three prognostic factors remained statistically independent: performance status (KI), duration of first remission (PFS1) and administration of a salvage therapy.

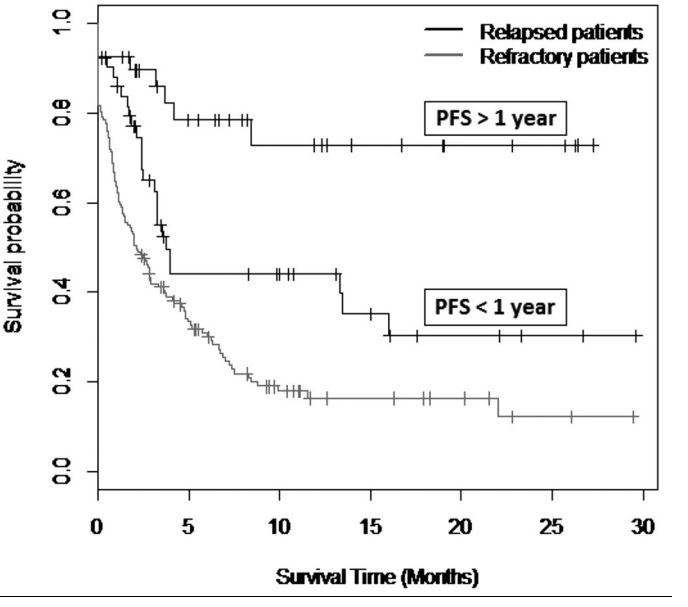

Figure 1.

Summary and Conclusions: One fourth of R/R PCNSL are asymptomatic underlining the need for systematic neuroimaging in surveillance. Duration of first remission (PFS1) is a strong prognostic factor. Salvage chemotherapy followed by consolidation with ICT+ASCT is associated with prolonged remission in a subset of patients.

Lee Moffitt Cancer Center & Research Institute, Tampa, [9]MD Anderson Cancer Center, Houston, [10]Weil Cornell Medical College, New York, [11]Gabrail Cancer Center, Canton, [12]Hackensack University Hospital, Hackensack, [13]Karyopharm Therapeutics, Newton, [14]Vanderbilt University School of Medicine, Nashville, United States, [15]Ozmosis Research, Toronto, Canada

Background: The nuclear export protein XPO1 (CRM1) is overexpressed in all types of malignant lymphoma including DLBCL. Selinexor is a selective inhibitor of nuclear export (SINE) that inhibits XPO1 to force nuclear retention & activation of >10 tumor suppressor proteins such as p53, IkBa, FOXO & p21. Selinexor also reduces levels of c-myc, BCL2 & other oncoproteins. Current therapy for DLBCL leads to cures in >50% of patients (pts) after 1-2 lines of therapy. Pts with relapsed/refractory DLBCL have a very poor prognosis with expected median survival <1 year.
Aims: We previously reported efficacy & safety of selinexor in pts with relapsed/refractory Non-Hodgkin's Lymphoma (NHL) (J. Kuruvilla *et al*. ASH 2014). Here we correlate response to selinexor with progression-free (PFS) & overall (OS) survival of pts with heavily pretreated DLBCL.
Methods: Selinexor was administered orally (3-80 mg/m^2) for 8 or 10 doses in a 28-day cycle in this phase 1 study (NCT01607892). Response evaluation was performed in cycle 1 and 2 & then every 2 cycles. Comparison of survival rates was done by Kaplan Meier analysis using 10-weeks timepoint as landmark. All pts had heavily pretreated DLBCL (prior R-CHOP & additional therapies) with documented progressive disease on study entry.
Results: In 31 (of 33) pts with heavily pretreated DLBCL, the median number of prior therapies was 3 (range 1-11). The most common adverse effects (Grade 1/2) occurring *after* cycle 1 are fatigue (43%), anorexia (38%), nausea (29%), & dysgeusia (24%). Grade 3/4 adverse events occurring in ≥2 pts are thrombocytopenia (62%), neutropenia (24%), anemia (24%), fatigue (10%), hyponatremia (10%), syncope (10%), & confusion (10%). These are managed with dose interruption, platelet stimulators and/or standard supportive care. Among 31 pts treated with at least 1 cycle of selinexor, the overall response rate was 39% (12/31) with a median duration of response of ~7 months. 8 pts (26%) achieved partial response (PR), & 4 pts (13%) complete response (CR) confirmed by PET scan. Selinexor showed similar activity in GCB & non-GCB subtypes of DLBCL. The overall median PFS & OS for pts on study ≥10 weeks were 104 days & 155 days, respectively. In order to determine if best response of CR or PR to selinexor was associated with improved clinical outcomes, the PFS & OS of responding pts were compared with those of pts with stable (SD) or progressive (PD) disease. Comparison of OS & PFS for pts with objective responses *vs* those with SD & PD revealed a strong correlation between response & survival (N=24): Median PFS of pts with CR/PR *vs* SD/PD were 329 & 49 days respectively (p<0.001). Median OS of pts with CR/PR *vs* SD/PD were 571 & 108 days, respectively (p<0.01). Furthermore, 4 pts with CR remained on study for 217, 505+, 525+, & 650+ days.
Summary and Conclusions: Selinexor monotherapy shows significant anticancer activity in pts with heavily pretreated relapsed/refractory DLBCL. Objective responses to selinexor are durable & correlate with improved OS & PFS compared with pts who achieve SD or PD, suggesting that these responses are associated with clinical benefit. Clinical & molecular predictors of objective response to selinexor are being evaluated. A study of selinexor monotherapy (pts randomized to high *versus* low dose) in pts with heavily pretreated DLBCL is ongoing & combination studies are being initiated.

CML: Clinical trials

Background: The Evaluating Nilotinib Efficacy and Safety in Clinical Trials as First-Line Treatment (ENEST1st) study evaluated the efficacy and safety of nilotinib in a large population of pts with newly diagnosed CML-CP using a network of 14 European Treatment and Outcome Study (EUTOS) standardized laboratories to monitor molecular response (MR).
Aims: Final results of ENEST1st, evaluated after all pts completed 24 mo of treatment or discontinued early, are reported.
Methods: ENEST1st was a phase 3b, open-label, multicenter study of nilotinib 300 mg twice daily in adults with newly diagnosed CML-CP. The primary endpoint was the rate of MR^4 (*BCR-ABL* ≤0.01% on the International Scale [*BCR-ABL*^{IS}] or undetectable *BCR-ABL* in cDNA with ≥10,000 *ABL* transcripts) at 18 mo. Results from 11 ancillary substudies, driven by national investigators and local study groups, will help shape the future management of CML. All pts provided written informed consent before entering the study.

Table 1.

Response	Nilotinib 300 mg Twice Daily 18 mo	24 mo
MR^4 at 18 or 24 mo, %		
All (n = 1052)[a]	38.4	40.4
Low EUTOS score (n = 876)[b]	38.9	41.4
High EUTOS score (n = 90)[b]	28.9	27.8
Low Sokal score (n = 367)[b]	44.4	44.7
Intermediate Sokal score (n = 395)[b]	35.7	39.7
High Sokal score (n = 191)[b]	29.3	31.4
Cumulative incidence by 18 mo or 24 mo, %		
MMR		
All (n = 1052)[a]	77.2	80.4
BCR-ABL^{IS} ≤1% at 3 mo (n = 615)[b]	91.4	93.0
BCR-ABL^{IS} >1% to ≤10% at 3 mo (n = 145)[b]	43.4	55.9
BCR-ABL^{IS} >10% at 3 mo (n = 23)[b]	21.7	34.8
MR^4		
All (n = 1052)[a]	48.7	55.2
BCR-ABL^{IS} ≤1% at 3 mo (n = 615)[b]	59.0	67.6
BCR-ABL^{IS} >1% to ≤10% at 3 mo (n = 145)[b]	20.0	24.1
BCR-ABL^{IS} >10% at 3 mo (n = 23)[b]	0	0
MR$^{4.5}$		
All (n = 1052)[a]	31.7	38.6
BCR-ABL^{IS} ≤1% at 3 mo (n = 615)[b]	39.5	47.0
BCR-ABL^{IS} >1% to ≤10% at 3 mo (n = 145)[b]	9.0	14.5
BCR-ABL^{IS} >10% at 3 mo (n = 23)[b]	0	0

MMR, major molecular response (*BCR-ABL*^{IS} ≤0.1%); MR$^{4.5}$, *BCR-ABL*^{IS} ≤0.0032% or undetectable *BCR-ABL* in cDNA with ≥32,000 *ABL* transcripts.
[a] Pts with typical b2a2 and/or b3a2 *BCR-ABL* transcripts and ≤3 mo of prior imatinib.
[b] n = number of pts in the indicated subgroup.

Results: In 26 European countries, 1089 pts were treated. Median age was 53 y, 59.0% of pts were male, 90.3% were Philadelphia chromosome positive, 97.0% had typical b2a2 and/or b3a2 *BCR-ABL* transcripts, and 16.9% were previously treated with imatinib for ≤3 mo. EUTOS scores were low in 82.6% and high in 8.6% of pts (8.7% missing). Sokal risk scores were low, intermediate, and high in 34.6%, 37.5%, and 18.1% of pts, respectively (9.8% missing). A total of 80.9% of pts completed 24 mo of treatment; 19.1% discontinued

early, most frequently due to adverse events (AEs; 11.7%). The MR[4] rate at 18 mo in all treated pts with typical transcripts and ≤3 mo of prior imatinib (n=1052) was 38.4% (95% CI, 35.5%-41.3%). Among pts with typical transcripts and without prior exposure to imatinib, 70.5%, 16.6%, and 2.6% of pts, respectively, achieved *BCR-ABL*^{IS} ≤1%, >1% to ≤10%, and >10% at 3 mo. MR rates are further detailed in the Table 1. Six pts (0.6%) progressed to accelerated phase/blast crisis (AP/BC) on study; 13 pts (1.2%) died by 24 mo, including one due to CML progression (16 mo after study drug discontinuation). The most common AEs of any cause were rash (21.4%), pruritus (16.5%), and headache (15.2%). Peripheral artery disease occurred in 1.9% of pts, ischemic heart disease in 3.4%, and ischemic cerebrovascular conditions in 0.8%; 0.6% of pts had pleural effusions. Grade 3/4 AEs related to hepatotoxicity and pancreatitis occurred in 0.4% and 0.6% of pts, respectively. Grade 3/4 thrombocytopenia and neutropenia occurred in 6.0% and 4.8% of pts, respectively. The most frequently observed grade 3/4 biochemical abnormalities were decreased phosphate (14.3%) and increased lipase (7.2%); glucose and lipid monitoring was not mandated in the study protocol.

Summary and Conclusions: In this large study, frontline nilotinib yielded rapid and high rates of response and a very low rate of progression to AP/BC; however, some pts discontinued treatment by 24 mo. As assessed with multicenter molecular monitoring, MR rates in this study provided prospective confirmation of the centrally reviewed MR rates in the pivotal ENESTnd study. This process contributed to the development of standardized definitions for deep MR. Despite the higher median age of pts in ENEST1st than in prior studies, safety results were consistent with the known safety profile of nilotinib. Relatively low rates of the most common AEs may reflect improvements in the management of nilotinib-treated pts. These results support the use of frontline nilotinib 300 mg twice daily in pts with CML-CP.

Background: Most of the knowledge about treatments and outcomes of patients with chronic myeloid leukemia (CML) originates from clinical trials. To get new and unbiased insights the European Treatment and Outcome Study (EUTOS) for CML collected population based data in 20 European countries.

Aims: The population-based registry was set up inside the infrastructure of the EUTOS to further explore the epidemiology, patient and disease characteristics, treatment and outcomes of CML in Europe. This work focuses on the treatment and early outcomes of CML in Europe.

Methods: The population-based registry aimed to identify and to document all newly diagnosed adult patients with Ph+ and/or BCR-ABL+ CML at any stage of disease in whole countries or specified regions in Europe. First-line treatment and treatment changes were documented. Cytogenetic responses are analyzed using cumulative incidences considering death and progression as competing risks.

Results: Overall 2904 Ph+ and/or BCR/ABL1+ adult CML-patients were registered. 94% of the patients were diagnosed in chronic phase (CP), 3.5% in accelerated phase (AP) and 2% in blastic phase (BP). 57% of patients were male. The median age was 56 years (18-99). Clonal chromosomal abnormalities (CCAs) in Ph+ cells were found in 11% of patients. 12% of the patients were at high risk of not achieving CCyR 18 months after start of therapy according to the EUTOS score. According to the Euro score 38% of patients were low risk, 51% intermediate risk and 11% high risk. The follow-up data of 2499 and the first-line therapy of 1986 patients were documented, for 1954 patients both, first-line therapy and follow-up is known. As first-line therapy 81% of patients received imatinib, 12% nilotinib, 3% dasatinib and 4% a treatment based on HU. Patients with high EUTOS or Euro risk and patients in AP and BP did not receive second generation tyrosine kinase inhibitors (TKIs) as a frontline therapy more often than patients with low EUTOS risk or Euro low and intermediate risk or in chronic phase (16% EUTOS low risk *vs* 13% EUTOS high risk, 16% euro low risk *vs* 14% Euro high or intermediate risk, 16% in CP *vs* 12% in AC or BP received second generation TKIs). Patients with CCAs in Ph+ cells, however, received more often second generation TKIs (22% *vs* 15%). Median time to first complete cytogenetic remission (CCyR) was 8 months for all patients. There were major differences observed between different EUTOS classes (high: 13 months *vs* low: 8 months), CCAs in Ph+ cells (with CCAs: 10 months *vs* without CCAs: 8 months) and treated with different medications first-line (Imatinib: 8 months *vs* second generation TKIs: 5 months). Survival probabilities 12 and 24 months after diagnosis were 95% and 92%, respectively. Stratified by Euro score the survival probability at 12 months was 97% for Euro low and intermediate risk patients and 96% for Euro high risk patients. At 24 months the survival probability was 96%, 93% and 91%, for Euro low, intermediate and high risk, respectively.

Summary and Conclusions: This is the first analysis of the treatment and outcome data from the EUTOS population-based registry, which provides an unselected sample of Ph+ and/or BCR/ABL1+ adult CML patients in Europe. Imatinib is the first choice in treatment of CML, while second generation TKIs as a first-line treatment are not very common. Median time to CCyR in the population is comparable to the one reported in patients enrolled in prospective randomized trials, while survival at 12 and 24 months are lower probably due to the selection of patients that are included in clinical trials.

S488

LONG-TERM OUTCOME OF ALTERNATING NILOTINIB 400 MG TWICE DAILY AND IMATINIB 400 MG ONCE DAILY AS FIRST-LINE TREATMENT OF CHRONIC MYELOID LEUKEMIA: A PHASE 2 STUDY OF THE GIMEMA CML WORKING PARTY

Background: Imatinib (IM) is the standard treatment for Ph+ Chronic Myeloid Leukemia (CML) in early Chronic Phase (ECP). Nilotinib (NIL) has demonstrated superior efficacy to IM (phase 3 ENESTnd trial). The treatment with more than one TKI, according to the principles of cancer poly-chemotherapy, may improve the response rates and may decrease the frequency of drug-resistance. The combination of different TKIs is potentially toxic, difficult to be explored in the ECP setting, while the alternating administration of IM and NIL could be better tolerated.

Aims: To evaluate the response (either cytogenetic and molecular) and the long-term outcome of ECP Ph+ CML pts treated with the alternating administration of NIL and IM.

Methods: Phase 2 study (ClinicalTrials.gov. NCT00769327). Schedule: NIL 400 mg twice daily for the first 3 months; IM 400 mg daily for the next 3 months; then, NIL and IM rotating every 3 months, for a total duration of 24 months (study core). The primary end-point was the Complete Cytogenetic Response (CCyR) rate at 12 months. The pts remained on study unless both drugs were discontinued. Definition of failure: according to 2013 ELN recommendations; event: failure, permanent discontinuation of both drug for any reason, patient refusal of alternating schedule during the study core. All the analysis was performed according to the ITT principle.

Results: 123 pts were enrolled in 38 Italian hematologic Centers; median age 56 years (range 18-84); 33% low, 45% intermediate and 22% high Sokal score; 94% low EUTOS score; median follow-up 60 months. The CCyR rates at early milestones were: 68% at 3 months, 73% at 6 months and 67% at 12 months (primary efficacy variable). The cumulative CCyR rate by 60 months was 93%. The cumulative MMR rates by 12 and 60 months were 82% and 84%, respectively. The cumulative MR4.0 rates by 12, 24 and 60 months were 43%, 61% and 62%, respectively. At the end of the 60 months, 69% of pts were on study, being the majority on monotherapy with NIL (35%) or IM (23%), and only 11%

still on alternating schedule. Events were observed in 52 (42%) pts: 22 failures, 13 adverse events; 14 patient refusal; 3 others. Failures included: 7 (5.6%) progressions to accelerated/blast phase (AP/BP); 5 primary resistances; 9 secondary resistances. The progressions to AP/BP occurred after a median time of 10 months (4-25 months); 4 pts had an ABL mutation (2 T315I, 1 Y253H, 1 F359V); all pts subsequently died. Athero-thrombotic adverse events (AAE) were observed in 6 (4.8%) pts: 3 acute myocardial infarctions, 1 unstable angina, 1 peripheral arterial occlusive disease and 1 aortic atherosclerosis. All pts discontinued permanently NIL and were treated with IM (4 pts) or dasatinib (2 pts). Overall, 12 pts died: 7 for progression to AP/BP, 2 for a second malignancy, 1 after ASCT, 1 for pulmonary embolism, and 1 for cerebral hemorrhage. The 5-year overall survival, progression-free survival, failure-free survival and event-free survival were 90%, 90%, 78% and 57%, respectively.

Summary and Conclusions: The early response rates achieved with the alternating administration of NIL and IM seem to be higher compared to historical data with IM alone; however, no difference seems evident in the long-term. Moreover, we observed a high number of progressions to AP/BP, which can be only partially justified by the relevant proportion of pts at intermediate or high Sokal risk. If compared to the results of NIL as monotherapy in ECP CML, this final analysis, despite the lower rate of AAE, does not support the alternating schedule of NIL and IM as first-line treatment of ECP CML.

Background: SPIRIT 2 is the largest trial comparing imatinib 400mg with dasatinib 100mg daily.

Aims: The primary end point of the study is event-free survival at 5 years. A key secondary endpoint is rate of a major molecular response (MMR, MR3, BCR-ABL1/ABL ratio <0.1% international scale).

Methods: 814 patients were recruited from 144 hospitals in the UK between August 2008 and March 2013. 812 patients were randomised, 406 in each arm.

Results: With a median follow up of 37.4 months, 236 imatinib and 276 dasatinib patients still received study treatment. 133 patients discontinued due to non-haematological toxicity. 53/406 (13.1%) on the imatinib arm (predominantly gastrointestinal toxicity) and 80/406 (19.7%) dasatinib patients (predominantly thrombocytopenia). 45/814 patients discontinued due to sub-optimal response as assessed by the treating physician (not defined by the protocol). These were predominantly patients on imatinib (42 of 406, 10.3%) as compared to dasatinib-3 of 406, 0.7%. Pleural effusions occurred in 90/406 (22.2%) patients on dasatinib and 13 required drainage. There was no significant difference in arterial cardiovascular events: imatinib 3/406 (0.7%); dasatinib 9/406 (2.2%). The MR3 rate at 12 months was significantly (p<0.001) higher with dasatinib 237/406 (58.4%) compared to imatinib 175/406 (43.1%) patients. In contrast to previous studies, pleural effusion was not associated with a significantly higher rate of MR3. Accelerated phase (imatinib 1/406; dasatinib 2/406) and blast crisis (imatinib 7/406; dasatinib 4/406) were observed in 14 patients. 38 patients died and there was no significant difference in deat rate in the two arms (Figure 1).

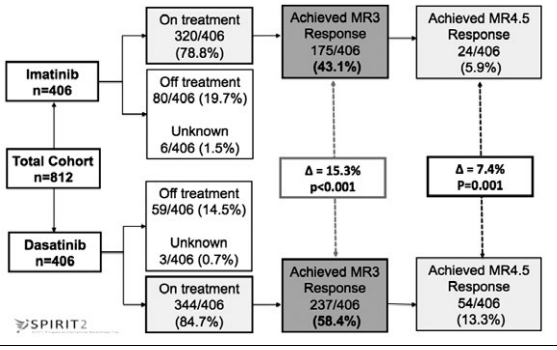

Figure 1.

Summary and Conclusions: In conclusion, dasatinib-treated patients have a significantly higher rate of molecular response at 1 year but so far there is no significant difference in rates of disease progression or overall survival. More patients abandoned imatinib than dasatinib due to investigator and/or patient concerns about sub-optimal responses. Further follow up will evaluate differences in the primary endpoint: event free survival at five years.

S490

BCR-ABL LEVELS AT LANDMARK TIMEPOINTS BETWEEN 1-3 YEARS OF IMATINIB ARE PREDICTIVE OF TIME TO A DEEP MOLECULAR RESPONSE AND CAN GUIDE THERAPY SWITCH DECISIONS WHERE TKI DISCONTINUATION IS THE GOAL

S. Branford[1,*] D. Yeung[1], H. Altamura[1], J.F. Seymour[2], D.M. Ross[1], T. Hughes[3]
[1]Centre for Cancer Biology, SA Pathology, Adelaide, [2]Peter MacCallum Cancer Centre, Melbourne, [3]South Australian Health and Medical Research Institute, Adelaide, Australia

Background: For patients (pts) with CML, achieving and maintaining a deep molecular response (MR^4 ≤0.01% or $MR^{4.5}$ ≤0.0032%) is necessary to minimize the risk of relapse after tyrosine kinase inhibitor (TKI) discontinuation, which is desirable for long term management of side effects, pregnancy and for economic reasons. For most pts, TKI therapy achieves an initial rapid BCR-ABL reduction, followed by a slow decline over many years. Thus, attaining a deep molecular response requires a long time. More potent TKIs administered as first line or after switch from imatinib (IM) yield higher rates of $MR^{4.5}$. IM treated pts who switched to nilotinib were indeed more likely to achieve $MR^{4.5}$ in the subsequent 2 years compared to continuing on IM (Hughes Blood 2014). However, decisions on treatment switch warrant careful consideration for a responding patient tolerating IM, who risks toxicity of second-line therapy. We analyzed BCR-ABL levels during IM therapy to determine the probability and timing of subsequent deep molecular response. This information could guide decisions on treatment switch if certain BCR-ABL response levels are associated with slow achievement of deep molecular response.

Aims: We 1) determined the probability of achieving MR^4 or $MR^{4.5}$ on IM, based on BCR-ABL levels attained; 2) assessed the time to reach these responses; and 3) identified subgroups where a switch to a more potent TKI may be warranted if timely TKI discontinuation is the goal.

Methods: 528 consecutive first line IM treated pts were examined. Pts were grouped by their BCR-ABL level at 12, 18, 24 and 36 months (mo) of IM and cumulative incidence of confirmed MR^4 and $MR^{4.5}$ by 8 years were calculated. The BCR-ABL groups were >0.01-0.1% and >0.1-1% for subsequent achievement of MR^4, and >0.0032-0.01%, >0.01-0.1% and >0.1-1% for $MR^{4.5}$.

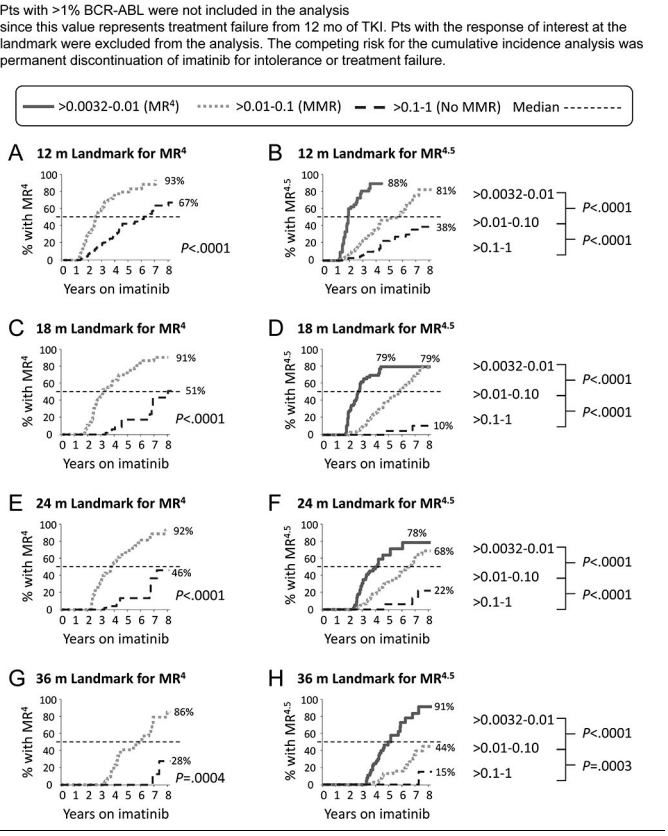

Figure 1. Cumulative incidence of MR^4 and $MR^{4.5}$ according to the molecular response level at landmark timepoints of imatinib therapy.

Results: By 8 years, the overall cumulative incidence of MR^4 and $MR^{4.5}$ were 66% and 53%. At landmark timepoints the subsequent rates of MR^4 or $MR^{4.5}$ were significantly associated with the BCR-ABL level, Figure 1. Rates at 8 years ranged from 91% $MR^{4.5}$ for pts with >0.0032-0.01% (MR^4) at 36 mo to 15% $MR^{4.5}$ for pts with >0.1-1% (no MMR) at 36 mo, *P*<.0001. The majority of pts with MR^4 at any of the landmarks achieved $MR^{4.5}$ within the subsequent 2 years with continued IM. The median time to achieve $MR^{4.5}$ for pts without an MMR at ≥12 mo was not reached with up to 7 additional years of IM. A substantial temporal lag in attaining the deep molecular responses was evident between the BCR-ABL groups for each landmark analysis. For example, for patients with MR^4 at 12 mo the median time to $MR^{4.5}$ was 23 mo after start of IM. However, for pts with BCR-ABL >0.01-0.1% at 12 mo (MMR) the median time to $MR^{4.5}$ was 69 mo after start of IM, a difference of >3.5 years (Figure 1B).
Summary and Conclusions: BCR-ABL levels are a powerful predictor of long term response. Whether switching therapy to achieve timely deep response will be associated with higher rates of treatment free remission compared with continuing on IM is currently unknown. Nevertheless, our data show that pts with <1% BCR-ABL without an MMR by 18-36 mo have a low chance of attaining $MR^{4.5}$, even with up to 6.5 additional years of IM, whereas most pts with MR^4 at any time achieved $MR^{4.5}$ with ~2 additional years of IM. These data provide timelines for the achievement of molecular response levels to clinicians and their IM-treated pts, and will guide decisions for potential therapy switch to optimise TKI discontinuation opportunities in pts where this is the goal of long term management.

Stem cell transplantation: Experimental

S491

LEUKEMIA RELAPSES AFTER ALLOGENENIC HSCT DISPLAY A DISTINCTIVE IMMUNE-RELATED SIGNATURE, WITH FUNCTIONALLY RELEVANT ALTERATIONS IN HLA CLASS II ANTIGEN PRESENTATION AND T CELL COSTIMULATION

C. Toffalori[1,*] M. Riba[2], L. Zito[1], G. Oliveira[1,3], G. Bucci[2], M. Barcella[4], O. Spinelli[5], L. Crucitti[6], N. Cieri[6], D. Cittaro[2], D. Lazarevic[2], J. Peccatori[6], M. Bernardi[6], C. Bonini[3], A. Rambaldi[5], C. Barlassina[4], E. Stupka[2], M. Bianchi[2], F. Ciceri[6], K. Fleischhauer[1,7], L. Vago[1,6]
[1]Unit of Molecular and Functional Immunogenetics, Division of Regenerative Medicine, Stem Cells and Gene Therapy, [2]Genome Function Unit, Center for Translational Genomics and Bioinformatics, [3]Experimental Hematology Unit, Division of Immunology, Transplantation and Infectious Disease, San Raffaele Scientific Institute, [4]Department of Health Science, University of Milano, Milano, [5]Hematology and Bone Marrow Transplant Unit, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, [6]Hematology and Bone Marrow Transplantation Unit, Division of Regenerative Medicine, Stem Cells and Gene Therapy, San Raffaele Scientific Institute, Milano, Italy, [7]Institute for Experimental Cellular Therapy, Universitatsklinikum Essen KMT, Essen, Germany

Background: Allogeneic Hematopoietic Stem Cell Transplantation (allo-HSCT) can cure Acute Myeloid Leukemia (AML) thanks to the synergistic combination of chemotherapy and antitumor immunity. Still, relapse after transplantation remains an unsolved issue for a large proportion of patients, warranting further investigation on the immunobiology of AML. Our group demonstrated that, after partially HLA-compatible HSCT, AML relapse is frequently due to the genomic loss of the HLA determinants targeted by alloreactive donor T cells (*Vago, N Engl J Med, 2009; Crucitti, Leukemia, 2014*), suggesting that relapse might represent an expression of immune veasion from the donor-derived immune system.
Aims: To identify and characterize novel mechanisms of post-transplantation leukemia relapse.
Methods: Serial AML samples purified from 9 patients at diagnosis, relapse after chemotherapy and relapse after allo-HSCT were employed for whole transcriptome profiling using Illumina microarrays. Deregulated genes were identified by pair-wise LIMMA analysis and used in an unsupervised gene ontology enrichment analysis. Results obtained by gene expression microarrays were confirmed in a validation cohort of 21 patients by *ad hoc* optimized molecular and cellular assays, including qPCR, immunophenotypic analysis, and functional *ex vivo* and *in vivo* experiments.
Results: A 110-gene signature (p<0.1) was able to discriminate between AML collected at disease diagnosis and at relapse after allo-HSCT. Most of the transcripts deregulated at post-transplantation relapse were involved in immune-related processes, and in particular in T cell costimulation and in the antigen presentation machinery. Conversely, no significant enrichment in immune-related processes was documented when comparing diagnosis with relapses after sole chemotherapy. We validated the significant upregulation of the PDL1 and B7H3 coinhibitory ligands on leukemic cells, accompanied by high levels of PD1 on the respective donor-derived T cells. Blocking this inhibitory axis by the usage of an anti-PDL1 monoclonal antibody, we rescued the ability of donor T cells to proliferate in response to the patient AML blasts. Even more evident were the *de novo* changes observed in the antigen presentation machinery at post-transplantation relapse: selective loss of surface expression of all HLA class II molecules and downregulation of their master regulator CIITA were detected in 4 out of 14 patients analyzed, occurring exclusively in patients transplanted from partially HLA-incompatible donors. SNP arrays documented no genomic rearrangement in HLA Class II genes or their regulators, suggesting an epigenetic origin of the alteration: accordingly, surface expression could be recovered upon culturing AML blasts in the presence of interferon-γ. Notably, loss of HLA-II expression on AML blasts abolished their recognition and killing by donor-derived T cells both *in vitro* and *in vivo*, which was recovered upon exposure of AML blasts to γ-interferon.
Summary and Conclusions: Our results demonstrate that the deregulation of immune-related processes, and in particular of the pathways involved in T cell-mediated allorecognition, is a distinctive feature of AML relapses after allo-HSCT. Identification of patient-specific mechanisms of immune evasion and relapse might be rapidly translated into personalized therapeutic approaches.

S492

AN INNOVATIVE HUMANIZED MOUSE MODEL TO INVESTIGATE THE INTERPLAY BETWEEN IMMUNE SYSTEM AND ACUTE MYELOID LEUKEMIA IN ALLOGENEIC HSCT

G. Oliveira[1,2,3,*] C. Casera[2,3], G. Bucci[2,4], C. Toffalori[2], J.M. Garcia-Manteiga[4], B. Camisa[1,5], D. Lazarevic[4], L. Crucitti[6], L. Zito[2], M. Carrabba[6], M. Bernardi[6], M. Bianchi[4], A. Bondanza[5,6], F. Ciceri[6], C. Bonini[1], L. Vago[2,6]

Immunotherapies Unit, [6]Unit of Hematology and Bone Marrow Transplantation, IRCCS San Raffaele Scientific Institute, Milan, Italy

Background: In spite of the efficacy of allogeneic Hematopoietic Stem Cell Transplantation (allo-HSCT) in curing Acute Myeloid Leukemia (AML), post-transplantation relapse remain a major issue. According to the "leukemia immunoediting" hypothesis relapse may be due to the outgrowth of immune-resistant leukemic variants upon the selective pressure of the transplanted immune system. Immunodeficient mouse models might represent a precious tool to provide insights into the immunobiology of this phenomenon.
Aims: In the present study, we set up a novel mouse-human chimeric model to characterize the biology of AML engraftment into mice and to model its interactions with adoptively transferred human T cells.
Methods: AML samples harvested at diagnosis from 26 patients were purified and infused into non-irradiated immunodeficient NOD/SCID γ-chain null (NSG) mice. Upon leukemia engraftment mice were sacrificed and purified leukemic cells were reinfused in serial recipients. To mimic immune pressure, mice received serial infusions of human T cells, either autologous or allogeneic (HLA-identical, HLA-matched, HLA-haploidentical or HLA-disparate) to the AML. At sacrifice, leukemic cells were FACS-purified and gene expression profile was analyzed using Illumina microarray. Deregulated genes were identified by pairwise LIMMA analysis. Gene Ontology and Gene Set Enrichment Analysis curated databases were interrogated to identify deregulated processes.
Results: Twelve out of 26 primary samples (46%) generated AML xenografts. Engraftment into mice significantly correlated with poor patient prognosis, and in particular with relapse after allo-HSCT (p=0.005). Infused leukemic cells reproducibly engrafted and exponentially expanded in mice, displaying a stable gene expression profile amongst littermates and upon serial transfer. Noticeably, serially transplanted AML exhibited an accelerated and more aggressive growth kinetic, with selective deregulation of genes involved in cell proliferation, myeloid differentiation and sister chromathide organization during mythosis.
Four selected AML xenografts were challenged *in vivo* with serial injection of T cells. We observed rapid and complete eradication of AML after treatment with HLA-disparate and HLA-haploidentical T cells from 20/20 treated mice. In all the cases, HLA matched cells harvested from unrelated donors were effective in controlling disease outgrowth. On the contrary HLA-identical T cells granted only temporary control in 6/10 mice, while autologous T cells were completely inefficacious in 14/14 mice. Leukemic blasts subjected to T cell-mediated immune pressure showed a specific and reproducible gene signature, with selective deregulation of genes involved in immune processes. Among the top-ranked upregulated genes we identified those related to response to interferons, comprising proteasome and immunoproteasome subunits, as well as molecules involved in antigen processing and presentation, comprising HLA Class I and II molecules. This data were further validated *in vivo*, observing in real-time the activation of this transcriptional program during the antileukemic immune response. Interestingly, in several experiments upon initial eradication we documented AML recurrence, with patterns which were highly reminiscent of post-transplantation relapses in human.
Summary and Conclusions: The model we set up represents a precious asset to mimic and decipher the complex dynamics of allo-HSCT, and thus to provide novel insights into the mechanisms of graft-*versus*-leukemia effect and relapse.

S493

MIR-153-3P, A NEW BIO-TARGET, IS INVOLVED IN THE PATHOGENESIS OF ACUTE GRAFT-*VERSUS*-HOST DISEASE THROUGH THE REGULATION OF INDOLEAMINE-2,3-DIOXYGENASE

X. Zhao[1,*] Y. Wang[2], M. Lv[1], H. Luo[2], H. Zhang[2], J. Wan[2], X. Huang[1]
[1]Peking University Institute of Hematology, Beijing, [2]Shenzhen Key Laboratory for Neuronal Structural Biology, Biomedical Research Institute, Shenzhen Peking University, Shenzhen, China

Background: To date, many studies investigating acute graft-*versus*-host disease (aGVHD) have focused on seeking potential biomarkers to initiate early intervention. MicroRNAs (miRNAs) have been reported to be promising diagnostic biomarkers for various types of diseases. A few studies have also demonstrated roles for miRNAs in the pathogenesis of aGVHD. However, data regarding the function of these miRNAs in human GVHD are limited. Using a miRNA polymerase chain reaction (PCR) chip, miR-153-3p was detected as a potential biomarker of aGVHD. Interestingly, indoleamine-2,3-dioxygenase (IDO) was found to be a potential target of miR-153-3p. Many previous studies have demonstrated that IDO plays important roles in the immunosuppression. Increased IDO expression may serve as a protective mechanism during aGVHD.
Aims: This study was aim to confirm the regulation of miRNA-153-3p on IDO both *in vitro* and mice model experiments, and to elucidate its role during GVHD development.
Methods: Plasma samples from 70 patients who underwent allogeneic hematopoietic stem cell transplantation (allo-HSCT) from Sep 2012 to Jun 2013 were prospectively collected at fixed time points from Peking University Institute of Hematology. RQ-PCR analysis was performed to examine the miRNA expression of plasma. BALB/c (H-2d) and C57BL/6 (H-2b) mice were used to establish the GVHD model. Antagomir and its control of miRNA-153-3p were administered via tail vein injection after allo-HSCT. Clinical and histological assessment of GVHD was performed. The expression levels of miRNA-153-3p and IDO in mice organs were also examined by Western Blot and RQ-PCR analysis.
Results: In this study, elevated plasma miR-153-3p levels at +7 d after transplant appeared to be a good predictor for subsequent aGVHD. IDO was found to be a potential target protein of miR-153-3p using bio-informative analysis. *In vitro* experiments confirmed that miRNA-153 could bind directly to the promoter region of IDO gene and affect its transcription and protein expression (above data have been reported on 2014 ASH meeting as a poster). In addition, the expression of plasma IDO was also lower in the aGVHD group at +7d compared to that of control group after allo-HSCT. To confirm the relationship between miR-153-3p and aGVHD, we established the MHC-mismatched murine GVHD model. Two groups received antagomir-control and antagomir-153-3p injection, respectively. The incidence and severity of the aGVHD were significantly decreased in the recipients of antagomir-153-3p infusion, as evidenced by the clinical GVHD scores (p<0.0001). Recipients of the antagomir-153-3p infusion survived longer compared to those of the antagomir-control infusion (log-rank test, p=0.0089). The pathological severity of aGVHD at day +21 in the liver and colon was also reduced in recipients who received antagomir-153-3p with positively stained granzyme B cell proportions as a marker. Besides, recipient mice of antagomir-153-3p displayed relatively higher IDO expression at the early stage after transplantation.
Summary and Conclusions: This is the first study to demonstrate, using *in vitro* and animal model experiments, that IDO can be directly regulated by miR-153-3p and that this miRNA might participate in aGVHD development by down-regulating IDO. Therefore, miR-153-3p may be a putative bio-target for a novel strategy for aGVHD intervention.

S494

IMMUNOSUPPRESSION BY MESENCHYMAL STROMAL CELLS DERIVED FROM HUMAN INDUCED PLURIPOTENT STEM CELLS: EVALUATION IN AN AGVHD MODEL

C. Roux[1,2,3,*] G. Saviane[2,3], G. Dhib[2,3], J. Pini[2,3], P.-S. Rohrlich[4], A. Wakkach[2,3], C. Blin[2,3], M. Rouleau[2,3]
[1]Centre Hospitalier Universitaire de Nice, Hôpital de l'Archet, Service d'Hématologie Clinique, Nice, France, Centre Hospitalier Universitaire de Nice, Hôpital de l'Archet, Service d'Hématologie Clinique, Nice, France, [2]CNRS, UMR 7370, LP2M, Faculté de Médecine, 28 Ave de Valombrose, [3]Université de Nice-Sophia Antipolis, Université de Nice-Sophia Antipolis, [4]Centre Hospitalier Universitaire de Nice, Hôpital de l'Archet, Service d'Hématologie Clinique, Centre Hospitalier Universitaire de Nice, Hôpital de l'Archet, Service d'Hématologie Clinique, Nice, France, Nice, France

Background: One major problem of allogeneic hematopoietic stem cell transplantation (HSCT) is acute Graft *versus* Host Disease (aGVHD). aGVHD has been managed until now with HLA matching and a constant evolving repertoire of immunosuppressive drugs. One alternative would be to generate in the host a permanent tolerance state toward the graft. Tolerant inducing cell therapy has been proposed with adult mesenchymal stromal cells (MSCs). *Ex vivo* isolated somatic MSCs have been implicated in immunoregulatory functions on cells from both the innate and adaptive immune system. They were proposed for cell therapies for treatment of aGVHD, Nevertheless, their use is restricted because of the few number that can be recovered from adult tissues, their limited *in vitro* expansion, and the absence of a full phenotypic characterization. Therefore other sources of well-defined and unlimited number of MSCs are needed, and MSCs derived *in vitro* from human Induced pluripotent stem cell (huIPS) would be a valuable tool for therapeutic approaches.
Aims: Because of our expertise in pluripotent stem cell differentiation, we generated huiPS-MSCs that present a strong immunosuppressive activity on allogeneic T cell responses. Our objectives are: 1) To evaluate and characterize *in vitro* this immunosuppression. 2) To validate *in vivo* these results using a xenoGVHD model.
Methods: To characterize the huIPS-MSCs i*n vitro,* FACS phenotyping and multipotency were tested. Their immunogenicity *in vitro* was monitored in co-cultures with allogenic peripheral blood mononuclear cells (PBMC). The *in vivo* immunosuppressive activity of huiPS-MSCs was evaluated using a xenoGVHD model in immunodeficient NSG (NOD/SCID/IL2rγKO) mice in which human PBMC were injected intra-peritonally. We established 3 groups: 1) huIPS-MSCs (control) 2) PBMC 3) PBMC+IPS-MSCs. We repeated huIPS-MSCs injection weekly with median number of injection n=3 (range 2-3). The activation state of human allogeneic T lymphocytes recovered from mice between 5 to 8 weeks after initial injection was evaluated and indicated the level of the xenoGVHD process and the efficiency of huiPS-MSCs to prevent it.
Results: a) *In vitro* characterization of huIPS-MSCs - As expected, the huiPS-MSCs were positive for CD73, CD90, CD105, HLA-I Ags and negative for CD45, CD34, HLA-II Ags and they were capable of differentiation into the classical mesenchymal-derived cells (osteoblast, chondrocytes and adipocytes). To test their immunosuppressive properties, we analyzed their action on the proliferation of human T lymphocytes stimulated in an allogeneic manner (Figure 1). The stimulation of PBMC in mixed lymphocyte reaction resulted in CD4 and CD8 T cell

proliferation (28±7% and 47±8%, respectively), which was significantly reduced in co-culture with huiPS-MSCs (4±2% and 10±2 respectively, n=3 p<0,05). We were able to demonstrate using blocking antibodies that part of the inhibition exerted by the iPS-MSCs is due to a) B7H1, a membrane receptor for the B7 family, known for its inhibitory action on the activation of T lymphocytes b) and B7H3 (from the same family) whose role remains controversial. b) *In vivo ch*aracterization of huIPS-MSCs - After sacrifice of mice, human circulating cells, those present in the peritoneal cavity and in the spleen were analysed by FACS. Mostly T lymphocytes were detected, and their number was significantly reduced in mice treated with huIPS-MSCs p<0,05. Intracytoplasmic labelling of recovered T cells showed that untreated mice displayed high percentages of human differentiated T cells producing IFN g and TNF a (typical of a inflammatory Th1 cytokine polarization profile), while little or none produced low inflammatory (IL-4) or anti-inflammatory (IL-10) cytokines. In contrast, in mice treated with the huiPS-MSCs, the proportion of T cells of the Th1 type was substantially reduced, while that of T cells producing IL-4 and/or IL-10 was slightly increased. In parallel, T cells expressing FoxP3 appeared (Figure 1).

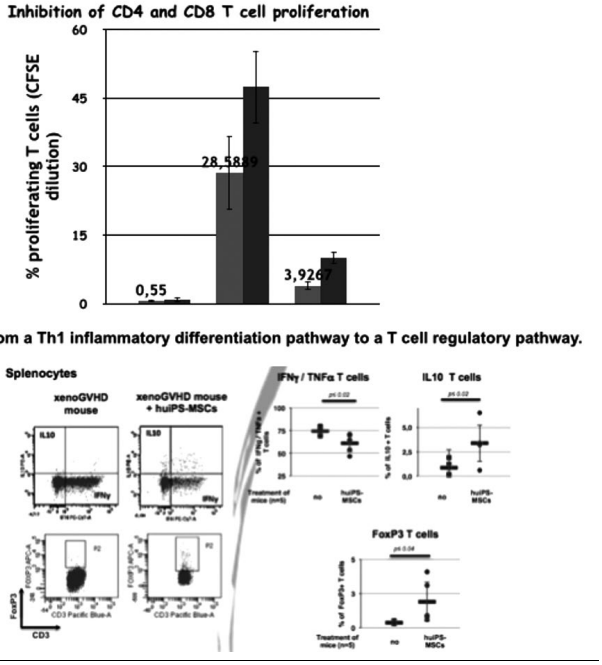

Figure 1.

Summary and Conclusions: We were able to generate immune-modulatory huiPS-MSCs that can be used to reduce activation of T cells in a xeno-aGVHD model through a switch from a Th1 inflammatory differentiation pathway to a T cell regulatory pathway. Our results may favor the development of new tools and strategies based on the use of pluripotent stem cells and their derivatives to prevent aGVHD but also for the induction of specific tolerance.

S495

IN VITRO-GENERATED MYELOID-DERIVED SUPPRESSOR CELLS (MDSC) PREVENT MURINE GRAFT-*VERSUS*-HOST DISEASE (GVHD) BY INDUCING TYPE 2 T CELLS WITHOUT DISABLING ANTI-TUMOR CYTOTOXICITY

J. Messmann[1], F. Leithäuser[2], M. Lutz[3], K.-M. Debatin[1], G. Strauss[1,*]
[1]Department of Pediatrics and Adolescent Medicine, University Medical Center Ulm, [2]Institute of Pathology, University of Ulm, Ulm, [3]Institute of Virology and Immunobiology, Julius-Maximilians University, Würzburg, Würzburg, Germany

Background: Allogeneic bone marrow transplantation (BMT) is a curative treatment modality for hematopoietic malignancies such as acute and chronic leukemias and lymphomas. Mature donor T cells in the allograft support engraftment, promote early T cell immunity of the recipient and mediate the graft-*versus*-tumor (GVT) effect. However, these donor T cells are also responsible for the induction of graft-*versus*-host disease (GVHD) by destroying recipient tissue such as liver, skin, and bowel. Myeloid-derived suppressor cells (MDSCs) are a population of immature myeloid cells preventing T cell activation, proliferation and functions.
Aims: Therefore, we tested whether and how *in vitro*-generated MDSCs suppress GVHD development without disabling the GVT effect in allogeneic BMT models.
Methods: MDSCs were generated *in vitro* by culturing BM cells in the presence of GM-CSF and G-CSF. After 4 days more than 90% of the cells exhibited the $CD11b^{+}Gr\text{-}1^{+}$ MDSC phenotype. To test, whether and how MDSCs prevent GVHD, we transplanted allogeneic BM and spleen cells in lethally irradiated recipient mice in combination with *in vitro*-generated MDSCs and analyzed survival and allogeneic T phenotype and functions. By co-injection of syngeneic tumor cells, the effect of MDSC-treatment on the anti-tumor capacity of allogeneic T cells was analyzed.
Results: In-vitro generated MDSCs efficiently suppressed alloantigen-specific T cell proliferation *in vitro*. Transplantation of $1x10^{7}$ MDSCs together with allogeneic BM and spleen cells efficiently prevented clinical GVHD and attenuated histological GVHD. MDSCs expanded *in vivo* and invaded lymphatic and GVHD target organs and were still detectable 30 days after BMT. MDSC-mediated GVHD suppression was antigen-independent since transplantation of MHC class I deficient MDSCs prevented GVHD development comparable to wild type MDSCs. Inhibition of GVHD required the presence of MDSCs during T cell priming because transplantation of MDSCs one week after BMT was ineffective in GVHD prevention. Interestingly, MDSC treatment did not significantly reduce allogeneic T cell numbers in lymphoid and GVHD target organs or change their homing behavior. However, MDSCs skewed allogeneic T cells towards type 2 T cells up-regulating Th2-specific transcription factors and cytokines. Polarization towards type 2 T cell immunity was indispensable for GVHD prevention since MDSC-treatment failed to prevent GVHD when allogeneic STAT6-deficient T cells, which are unable to differentiate into Th2 cells, were transplanted. However, MDSC-mediated type 2 T cell polarization did not abrogate anti-tumor cytotoxicity of alloantigen-specific T cells since syngeneic thymoma tumor cells were efficiently eradicated.
Summary and Conclusions: Therefore, MDSC-induced Th2 polarization might be exploited in clinical settings for GVHD prophylaxis while simultaneously maintaining anti-tumor cytotoxicity.

Platelet and bleeding disorders

S496

DOWN-REGULATED BETA2-GPI IS ASSOCIATED WITH A REDUCED ABILITY TO MITIGATE COMPLEMENT ACTIVATION BY INHIBITING JNK/BID-DEPENDENT PLATELET DESTRUCTION IN THE PATHOGENESIS OF IMMUNE THROMBOCYTOPAENIA

X.-H. Zhang[1,*] X.-L. Zhu[1], J.-M. Zhang[1], J.-Z. Zhao[2], Q.-M. Wang[1], F.-E. Feng[1], H.-X. Fu[1], M. Lv[1], L.-P. Xu[1], K.-Y. Liu[1], X.-J. Huang[1]
[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking University People's Hospital, Department of clinical laboratory, Beijing, China

Background: It is widely accepted that immune complex-mediated classical complement pathway activation represents an important mechanism of platelet destruction in immune thrombocytopaenia (ITP) (Peerschke at al. Br J Haematol. 2010). However, not all patients diagnosed with ITP have detectable antibodies, suggesting a potential mechanism of complement activation in the plasma of ITP patients. Moreover, the mechanisms involved in complement-mediated platelets lysis are elusive. β2-glycoprotein I (β2-GPI) is a plasma glycoprotein that functions as a complement regulator (Gropp *et al.* Blood. 2011); however, there is no information available on the role of β2-GPI in patients with ITP to date.
Aims: The aim of the present study was to assess the contribution of β□-GPI in complement activation and the details of its underlying mechanism.
Methods: Twenty-four consecutive patients with primary ITP and 24 healthy donors were enrolled in this prospective study. The levels of plasma β2-GPI and serum C1q, C4d, C3b and C5b-9 were determined by ELISA in ITP patients and healthy donors. The deposition of the fore-mentioned complement components on immobilized heterologous platelets was quantified. The levels of C3 convertases in plasma and the phosphorylation of MAPKs (phospho-ERK, phospho-JNK, phospho-p38^{MAPK}) and Bid in C5b-9 mediated platelet lysis were determined using Western blot. To study the effect of β2-GPI on complement activation, β2-GPI was added to ITP plasma, C3 convertase activity was assayed via the determination of C3a generation, and serum levels of C5b-9 and its deposition and signalling proteins were re-evaluated.
Results: We first explored the significantly lower concentrations of β2-GPI in plasma from patients with ITP (80±21 ng/ml) compared with healthy donors (180±22 ng/ml) ($p<0.05$). Increased deposition of C5b-9 was observed, indicating the complement activation in ITP plasma. Evidence for enhanced classical complement pathway activation (C1q and/or C4d deposition) was noted in 45.8% of patient plasma samples, and alternative pathway activation (C3b) was observed in 37.5% of plasma samples. Additional evidence for enhanced complement activation was noted with increased serum levels of C3 convertases (C4b2b and C3bBb). β2-GPI plasma levels and C5b-9 serum levels were negatively correlated. The intensity of phospho-MAPKs bands revealed the over-expression of phospho-JNK, and detection of Bid exhibited similar results. SP600125 (JNK) and BI-6C9 (Bid) inhibitors significantly reduced complement-mediated JNK/Bid-dependent platelet lysis. Treatment of ITP plasma with β2-GPI *in vitro* resulted in a dose-dependent reduction of serum C5b-9 generation and platelet deposition as well as reduced phospho-JNK and Bid. Moreover, β2-GPI inhibited C3a generation and formed complexes with C3 in plasma.
Summary and Conclusions: This original observation highlights the role of β2-GPI in ITP in harbouring complement activation at the level of the C3 convertase and inhibiting JNK/Bid-dependent platelet destruction. The first mention of decreased β2-GPI in ITP is suggestive of abnormal complement activation. Our data provide important insights into immune dys-regulation via decreased plasma β2-GPI, which may be exploited in the pathogenesis of ITP.

S497

BLEEDING RISK OF SURGERY IN PATIENTS WITH INHERITED PLATELET FUNCTION DISORDERS (IPFD): OUTCOME OF 389 SURGERIES IN 205 PATIENTS

Background: IPFD are a heterogeneous group of rare mucocutaneous bleeding diseases of variable clinical severity. Excessive bleeding at surgery is a feared complication for bleeding disorders. While studies on the bleeding risk of surgical procedures in other hemorrhagic disorders, like hemophilia or von Willebrand disease, have been conducted, very few and small studies have evaluated the bleeding risk associated with surgery in IPFD.
Aims: Our aim was to evaluate the bleeding complications of surgical procedures in patients with IPFD, the therapeutic approaches adopted for the prevention/treatment of hemorrhage and their efficacy.
Methods: Retrospective, multicentre worldwide study involving clinical centers managing IPFD. Participants were asked to examine retrospectively their patient records and to enroll all cases who had undergone surgery fulfilling strict inclusion criteria. Patients had to have a definite IPDF diagnosis, confirmed according to well-defined laboratory and/or molecular genetic criteria. All types of surgical procedures, including biopsies and dental extractions, were admitted. Bleeding tendency before surgery was scored by the WHO bleeding scale, while the extent of bleeding at surgery was assessed by the BARC classification, subjective evaluation from the surgeon, and/or duration of bleeding at surgery. Information about prophylactic antihemorrhagic preparation and emergency treatment of bleeding was requested.
Results: 205 patients (Age 5 to 86, 56.6% females) from 36 centers with 13 different forms of IPFD were enrolled: 43.4% had Glanzmann Thrombasthenia (GT), 22.4% Primary Secretion Defect (PSD), 6.8% combined α-δ granule deficiency (αδ-SPD), 5.4% Hermansky-Pudlak syndrome (HPS), 4.4% Gray platelet syndrome (GPS). Data from 389 surgeries were collected, the most frequent being dental extraction (26.7%), adenotonsillectomy (3.3%), appendectomy (2.8%), endoscopic polipectomy (2.8%). Major procedures, like cholecystectomy (2.6%), hernia repair (2.6%), gastrectomy (2.3%), hysterectomy (1.8%), were also reported. The frequency of excessive bleeding at surgery was 19.8% by subjective evaluation, 19.7% by the BARC classification and 23.1% by the combination of the two. High frequency of excessive bleeding was observed in GT (29.5% of 183 procedures), HPS (27.3% of 22) and α-δ SPD (12.5% of 32). Frequency of excessive bleeding in some forms remains uncertain due to the low number, but some of them (thromboxane A2 receptor defect, CalDAG, platelet-type von Willebrand Disease) appear to be at high risk. Excessive bleeding at surgery was significantly predicted by presurgical WHO bleeding score=3 (OR 8.1, 95% CI 1.1-61.8) and=4 (OR 28, 95% CI: 2.9-270.5). Prophylactic platelet transfusions were given in 38.5% of procedures and antifibrinolytic agents or DDAVP in 32.9%, and reduced significantly the risk of excessive bleeding (OR 0.3, 95% CI: 0.2-0.5). Emergency treatment was administered in 85.5% of the procedures with excessive bleeding (platelet transfusions in 50.6%, antifibrinolytic agents in 23.4%, FVIIa in 7.8%, DDAVP in 3.9%, other in 14.3%), and was successful in 81.8% of cases.
Summary and Conclusions: IPFD are associated with a significant surgical bleeding risk. The risk of excessive bleeding varies according to the diagnosis, with GT having the highest risk, and is predicted by the preoperative WHO bleeding score. Preoperative prohemostatic prophylactic treatments prevent excessive bleeding in most cases. Treatment of excessive bleeding with platelet transfusions and/or other measures stops excessive bleeding in most, but not all, treated cases.

tologia, Hospital Virgen del Puerto de Plasencia., Plasencia, Cáceres, [11]Servicio Hematologia, Hospital El Bierzo, Ponferrada, León, [12]Servicio Hematologia, Complejo Asistencial de León, León, [13]Servicio Pediatria, Hospital Universitario Virgen de la Arrixaca, Murcia, [14]Servicio Hematologia, Hospital Universitario de Burgos, Burgos, [15]Servicio Hematologia, Hospital de Mérida, Merida, Badajoz, [16]Servicio Pediatria, Hospital Universitario La Paz, Madrid, [17]Servicio Pediatria, Hospital Clínico Universitario Valladolid, Valladolid, [18]Unidad de Trombosis y Hemostasia, Hospital Universitario de Salamanca, Salamanca, Spain

Background: Inherited platelet disorders (IPDs) cause bleeding diathesis with varying severity. Due to their rarity and extreme heterogeneity, the diagnosis is complex, poorly standardized, time consuming and expensive. Based on clinical and laboratory findings, gene mutations may be assessed by means of conventional Sanger sequencing to diagnose the disease. However, in many cases a proper diagnosis and the genetic cause for the disease remain unknown. Next generation sequencing (NGS) enables the simultaneous analysis of large groups of candidate genes in IPDs and may be useful for rapid genetic diagnosis and allow optimal disease classification and understanding of the pathogenesis of the disease.
Aims: To improve the diagnosis of IPDs by using a next generation sequencing panel.
Methods: Forty patients with suspected IPDs were analysed by NGS panel to identify a pathogenic mutation causes them. Patients had abnormal bleeding symptoms, normal coagulation factors levels, platelet function testing pathological or thrombocytopenia without evidence of acquired causes. Two groups were established, first group, 19 patients with specific phenotype and 21 without a proper diagnosis or unknown phenotype. For the 70 genes associated with IPDs (figure1) baits were generated to tile 400 kb DNA, corresponding to the exons and splice sites of all known transcripts of the candidate genes. The bait library was tested by enriching candidate genes from 50 ng DNA using the Nextera Rapid Custom Enrichment system followed by massive parallel sequencing (Illumina).
Results: Genotype were determined in 16 of 19 patients with specific phenotype, therefore IPDs diagnosis were confirmed: 4 Von Willebrand Disease (VWD), 1 Glanzmann Thrombastenia (GT), 4 Bernard Soulier syndrome (BSS), 2 MYH9-related disease, 1 Hermansky Pudlack Syndrome, 1 Prekalicrein defiency, 2 Dysfibrinogenemia, 1 Signalling defect (GP6). Patients with unknown phenotype, were subdivided in patients with or without thrombocytopenia. In patients with thrombocytopenia diagnosis were indentified in 7/10: 2 BSS (*GP1BA*; c.463C>; c.1280_1291delCCTCAGAGCCCG); VWD-PT (*GP1BA*; c.733G>A); Bening Mediterranean macrothrombocytopenia (*GP1BB*; c.1A>T), Gray Platelet syndrome (*NBEAL2*; c.3422_3423insC), Wiskott-Aldrich Syndrome (*WAS*; c.802delC) and Thrombocytopenia FLNA-related (*FLNA*; c.3695C>T). In IPD patients without thrombocytopenia diagnosis were identified in 6/11: GT (*ITGA2B*; c.2063C>T); VWD 2N (*VWF*; c.2561G>A), mild Hemophilia A (*F8*, c.6623A>G), GATA-related disease (*GATA1*; C.865C>T), RUNX1-related disease (*RUNX1*; c.167T>T), and Defect ADP receptor (*P2YR12*, c.835G>A). No mutations were found in 3 patients with "Aspirin-like" syndrome. In fact, genotype were determined in 13 of 21; and 22 mutations have not previously been described in the literature. Types of mutations described were 33 missense and 8 frameshift (3 insertion, 5 deletion). All mutations identified by NGS were confirmed by Sanger sequencing. Once, diagnosis was determined, functional testing, flow cytometry and electron microscopy were done to establish a proper diagnosis of IPDs (Table 1).

Table 1.

IPDs	Genes = 70 / 1570 Exons
Transcription Factors	*HOXA11, MPL, RBM8A, RUNX1, GATA1, FLI1, STIM1, GFI1B*
Agonist platelet receptors	*P2RX1, P2RY1, P2RY12, TBXA2R, TBXAS1, ADRA2A, GP6, CD36 o GP4, DTNBP1, ITGA2*
Platelet granules	*NBEAL2, PLAU, HPS1, HPS3, HPS4, HPS5, HPS6, LYST, MLPH, USF1 BLOC1S3, BLOC1S6, AP3B1, VIPAS39, VPS33B, RAB27A, MYO5A,*
Cytoskeletal Assembly and Structural Proteins	*ACTN1, WAS, MYH9, FLNA, ANKRD26, GP1BA, GP1BB, GPV, A2M, GPIX, ITGA2B, ITGB3, ABCA1, ANO6, FERMT3, MASTL*
Signal transduction	*GNAI3, GNAQ, GNAS, PLA2G7, PLCB2PTS, GGCX, DPAGT1, DHCR24*
Others	*F8, VWF, KLKB1, C1QBP, CLEC3B*
Dysfibrinogenemia	*FGA, FGB, FGG, FIBCD1*

Summary and Conclusions: NGS by amplicon-based capture enables a fast diagnosis of IPDs. This tool cold be used ina clinical setting to facilitate the diagnosis of IPD displaying an unclear phenoptype.

S499

CLINICAL CHARACTERSTICS AND RISK FACTORS OF INTRACRANIAL HAEMORRHAGE IN PATIENTS FOLLOWING ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

X.-H. Zhang[1,*] Q.-M. Wang[1], F.-E. Feng[1], X.-L. Zhu[1], C.-C. Wang[1], J.-M. Zhang[1], J.-Z. Zhao[2], F.-R. Wang[1], H. Chen[1], Y.-Y. Zhang[1], X.-D. Mo[1], Y.-H. Chen[1], W. Han[1], L.-P. Xu[1], K.-Y. Liu[1], X.-J. Huang[1]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking University People's Hospital, department of clinical laboratory, Beijing, China

Background: Although cerebral complications and causes after allogeneic haematopoietic stem cell transplantation (allo-HSCT) are well documented, assessment of incidence rates and risk factors of intracranial haemorrhage (ICH) following allo-HSCT are less frequently reported (Najima *et al.*, Am J Hematol 2009).
Aims: The aim of this study is to determine the clinical characteristics, risk factors and prognosis of ICH following allo-HSCT.
Methods: A nested case-control study was conducted that included 175 subjects obtained from 2165 subjects who underwent HSCT in Peking University People's Hospital between Sept. 2004 and Jul. 2014. In total, 35 patients with ICH and 140 controls matched for age, sex, transplantation type and time after transplantation were identified (total n=175). The incidence of ICH was identified by searching hospital records of CT and MRI scans.
Results: Among the 2165 patients, 35 patients (1.6%) developed intracranial haemorrhage, including 29 cases (82.9%) of intraparenchymal haemorrhage (IPH), 2 cases (5.7%) of subdural haematoma (SDH), 1 case (2.9%) of subarachnoid haemorrhage (SAH), and 3 cases (8.6%) of multiple haemorrhage lesions in the brain parenchyma. The median time of appearance for cerebral haemorrhages was 129 days (range, 1-450 days). ICH patients exhibited unique characteristics compared with controls, including systemic infections, severe graft *versus* host disease (GvHD), and coagulation disorders. Multivariate analysis revealed that systemic infections, III-IV acute GvHD, lower platelet count and fibrinogen levels are independent risk factors for ICH among HSCT patients. The risk of ICH increases when platelet counts are below 13.2×10^9/L and fibrinogen is below 129.5 g/L. However, in addition to the causes indicated above, chronic GvHD, hypertension, central nervous system leukaemia, and INR were identified as risk factors by universal analysis. Transplantation-related mortality rates in the intracranial haemorrhage and control groups were 50% and 22.2%, respectively. The cumulative survival rates in the intracranial haemorrhage and control groups were 47.1% and 75.7% (P<0.001).
Summary and Conclusions: ICH is one of the most common cerebral complications after HSCT and is associated with a high mortality and reduced overall survival rate. Systemic infections, III-IV acute GvHD, lower platelet count, and lower fibrinogen levels are individual independent risk factors. To prevent ICH, it is useful to increase platelet counts and fibrinogen to safe levels.

S500

A LONGITUDINAL PROSPECTIVE STUDY EVALUATING THE EFFECTS OF ELTROMBOPAG (EPAG) TREATMENT ON BONE MARROW (BM) IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: FINAL ANALYSIS

R.K. Brynes[1,*] A. Orazi[2], R.S. Wong[3], M.M. Thein[1], P. Burgess[4], C.K. Bailey[5], D. Theodore[6], K.K. Bakshi[5]
[1]Keck School of Medicine, University of Southern California, Los Angeles, [2]Weill Medical College of Cornell University, New York, United States, [3]Prince of Wales Hospital, The Chinese University of Hong Kong, Shatin, Hong Kong, [4]GlaxoSmithKline, Stockley Park, United Kingdom, [5]GlaxoSmithKline, Collegeville, [6]GlaxoSmithKline, Research Triangle Park, United States

Background: EPAG, an oral thrombopoietin receptor agonist (TPO-RA), is approved for treating thrombocytopenia in adults with chronic immune thrombocytopenia (cITP) with insufficient response to prior therapy. TPO-RAs are associated with varying degrees of BM reticulin increases.[1] Due to lack of pretreatment evaluations, the incidence and clinical significance of these findings have not been established. Inconsistencies in specimen preparation, staining, and analysis across institutions further confound conclusions.
Aims: To assess the degree of BM fibrosis (reticulin and/or collagen) in cITP patients (pts) treated for up to 2 years with EPAG.
Methods: Informed consent was provided. BM biopsies were collected at baseline (prior to study treatment) and at 1 and 2 years on treatment. Specimens were centrally processed, stained for reticulin (silver) and collagen (trichrome), and reviewed by central independent hematopathologists for cellularity; megakaryocyte, erythroid, and myeloid quantity and appearance; trabecular bone quality; reticulin grade (European Consensus scale of marrow fibrosis [MF][2]); and presence of collagen.
Results: Of 162 pts analyzed, the median age was 42 years (range, 18-80), 104 pts (64%) were female, 50% were White, 20% East Asian, and 29% South Central Asian. A total of 77% were diagnosed with ITP ≥12 months before study entry. Prior ITP therapy was reported by 70%, and 8% received prior TPO-RA treatment. Of 162 pts, 44 withdrew from the study, 118 completed the study, and 93 had all 3 on-treatment biopsies. MF grades at each time point are shown in the Figure 1. Of the 3 pts with MF-2 at 1 year, 1 completed 2 years of treatment and had MF-2 at 22 days post-treatment and MF-1 at 288 days post-treatment. Another pt received 17 months EPAG and had MF-0 at 44 days post-treatment. The third pt did not have a follow-up biopsy. Of the 2 pts with MF-3, 1 had an on-treatment MF-0 biopsy 31 days after the MF-3 biopsy and at 2 years and 1 had MF-0 at 184 days post-treatment. At 2 years, no pt on

treatment had ≥MF-2. When comparing biopsies at 2 years *vs* baseline, 80 pts (86%) had no change in MF grade, 9 (10%) had a 1-grade increase from MF-0 to MF-1, and 2 (2%) had a 1-grade decrease from MF-1 to MF-0. All pts were negative for collagen at baseline. At 1 year, 5 pts (4%) were positive for collagen, 3 of whom had MF-2 or MF-3. At 2 years, 1 pt (1%) with MF-1 had collagen present. None of the on-treatment biopsies were prompted by an abnormal peripheral blood smear or done at the investigator's discretion for clinical symptoms suggestive of BM dysfunction. Cellularity was normal in 80%, 80%, and 76% of pts at baseline, 1 year, and 2 years, respectively. Trabecular bone thinning was found in 73 pts (50%) at baseline, 61 (50%) at 1 year, and 33 (38%) at 2 years, likely the result of prior steroid therapy.

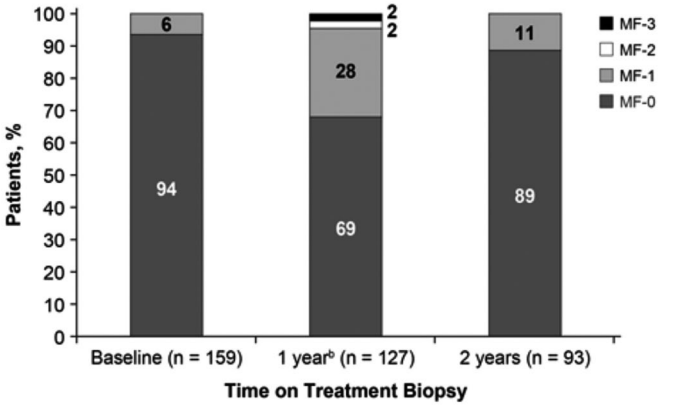

Figure 1. Maximum reticulin grade[a].

Summary and Conclusions: After 2 years of treatment, no increase in reticulin was observed in the majority of pts (86%) while few pts (10%) had a mild increase in reticulin. No pt had an on-treatment biopsy of ≥MF-2 at 2 years or clinical signs/symptoms indicative of BM dysfunction. Results were similar to those reported for EXTEND, an EPAG extension study (treatment duration up to 5.5 years[3]). These data suggest that treatment with EPAG is generally not associated with clinically relevant increases in BM reticulin or collagen. This study (NCT01098487) was funded by GlaxoSmithKline.

TP-0184 LOWERS HEPCIDIN LEVELS AND IS A POTENTIAL THERAPEUTIC FOR ANEMIA OF CHRONIC DISEASE

P. Peterson[1], B. Bahr[1], K. Soh[1], J. Bearss[1], W. Kim[1], C. Whatcott[1], A. Siddiqui-Jain[1], D. Bearss[1], S. Warner[1,*]
[1]Tolero Pharmaceuticals, Inc., Lehi, United States

Background: The liver peptide hormone, hepcidin, is known as a master regulator of bioavailable iron and red blood cell formation. Hepcidin expression is in part regulated by pro-inflammatory cytokines that ultimately signal through the activin-like kinase receptor 2 (ALK2) and SMAD transcription factors leading to the expression of hepcidin. In chronic inflammatory conditions, such as chronic kidney disease, rheumatoid arthritis, colitis, and in some forms of cancer, hepcidin levels remain high, lowering bioavailable iron leading to anemia. Hepcidin functions by binding to and inhibiting ferroportin, an iron pump that functions in macrophage-based iron recycling and intestinal iron uptake. Several studies demonstrated that lowering hepcidin could provide a novel approach for targeting this complicated clinical challenge. Current clinical strategies for these patients focus on red blood cell transfusions and the use of erythropoetin-based therapies. Neither of these approaches target the underlying mechanism behind the anemia associated with chronic inflammation and cancer.
Aims: The aim of this work is to develop a small molecule inhibitor of ALK2 for the treatment of hepcidin-driven anemia of chronic diseases.
Methods: Two animal models were primarily employed for these studies. First, turpentine oil (TO) was used to induce an acute inflammatory response in C57BL/6 mice with associated hepcidin-driven anemia. The animals were orally administered TP-0184 1 hour prior to TO treatment and then 8 hours later. Plasma and livers were collected 16 hours after TO treatment. Second, a TC-1 lung cancer syngeneic model was used in C57BL/6 mice. The TC-1 cells were injected intraperitoneally and allowed to establish for about 1 week. The mice were then administered TP-0184 repeatedly for 3-5 days, after which, plasma and livers were collected. Liver hepcidin levels were determined by RT-qPCR and plasma hepcidin levels by mass spectrometry. Iron levels were measured by ELISA.
Results: TP-0184 is a small molecule inhibitor of the kinase activity of ALK2 with an IC_{50} value of 5 nM. It has minimal activity against JAK2 (IC50=8540 nM), compared to other analogs within the same series. TP-0184 is effective at targeting hepcidin expression in a HepG2 cell culture model with an EC_{50} lower than 100 nM. It achieves this activity in HepG2 cells with no observable toxicities and in a pathway-specific manner. Furthermore, TP-0184 has been evaluated in multiple animal models of inflammation and anemia. TO was used to induce an acute inflammatory response in mice resulting in a 14-fold increase in liver hepcidin levels. Two oral doses of TP-0184 at 100 mg/kg, separated by 8 hours, was able to almost completely reverse the induction of hepcidin that was stimulated by the TO treatment. In this same TO model, TP-0184 was evaluated at doses as low as 25 mg/kg to further explore the lower limits of its efficacy and to establish a therapeutic window. Similarly, TP-0184 was tested in an anemia of cancer model utilizing TC-1 lung cancer cells. Tumor-bearing animals experienced a 3-fold increase in liver hepcidin expression, which was again completely reversed by dosing with TP-0184 at 25 mg/kg. In addition to the activity observed in these models, TP-0184 demonstrates favorable pharmacokinetic properties and good drug-like characteristics making it a viable candidate molecule to move into advanced preclinical testing, IND-enabling studies and formal clinical development.
Summary and Conclusions: TP-0184 is a potent and selective inhibitor of ALK2 with good activity in preclinical models of anemia associated with inflammation. We anticipate a clinical development strategy that focuses on anemia of chronic disease where an erythropoetin-sparing approach might offer significant clinical benefit both to patients and to health management institutions.

S502

HEME AND IRON CONTROL OF MACROPHAGE PLASTICITY IS PREVENTED BY THE HEME SCAVENGER HEMOPEXIN AND THE IRON CHELATOR DFO: LESSON FROM SICKLE CELL ANEMIA

F. Vinchi[1,*] M. Costa Da Silva[1], G. Ingoglia[2], S. Petrillo[2], E. Tolosano[2], M. Muckenthaler[1]
[1]Molecular Medicine Partnership Unit (MMPU), University of Heidelberg & EMBL, Heidelberg, Germany, [2]Department of Molecular Biotechnology and Health, Molecular Biotechnology Center, University of Torino, Torino, Italy

Background: Hemolytic disorders are associated with recurrent events of intra- and extra-vascular hemolysis. Under these conditions, circulating heme levels and erythrophagocytosis are increased resulting in heme and iron accumulation in macrophages of the reticuloendothelial system (RES). The heme scavenger Hemopexin limits heme accumulation in RES macrophages in heme-overloaded Hx-null mice, a model mimicking heme release in hemolytic

events. As a consequence cell activation as well as cytokine and ROS production is reduced.
Aims: Here we investigated, both *in vitro* and *in vivo*, whether heme and/or iron affect macrophage activation and polarization (*e.g.* M1 inflammatory *vs* M2 anti-inflammatory macrophages) and, whether this is prevented by heme/iron scavengers.
Methods: We characterized bone marrow-derived macrophages treated with aged RBCs (Red blood cells), heme or iron and analyzed the expression of iron-related genes and cytokines, ROS production and polarization markers. Additionally, we evaluated the effect of co-treatment with the heme scavenger Hemopexin or the iron chelator Desferrioxamine. Macrophage polarization was further assessed *in vivo*, in mice injected with heme or iron-dextran as well as in a mouse model of sickle cell disease, which is hallmarked by enhanced macrophage heme/iron retention. Finally the effect of Hemopexin administration on macrophage polarization was evaluated *in vivo*.
Results: Macrophages treated with RBC, heme or iron increase mRNA expression of HO-1, L-Ferritin and FPN and decrease TfR1 mRNA levels. This correlates with an increase of M1 markers (MHCII/CD86/TNFa) and a decrease of M2 markers (CD206/Arg1), indicating that heme and iron drive macrophage polarization towards a M1-like pro-inflammatory phenotype. Interestingly, heme/iron treatment further potentiates M1 polarization and shifts M2 macrophages to the M1 phenotype. Similarly, heme and iron affect macrophage plasticity *in vivo*, promoting macrophage polarization towards a M1 phenotype. These effects are reversible by the co-treatment with Hemopexin or Desferrioxamine both *in vitro* and *in vivo*. Additionally, the treatment with heme together with the anti-oxidant N-acetyl-cystein or the TLR4 inhibitor, TAK-242, rescued the up-regulation of some M1 markers and the down-regulation of some M2 markers, likely suggesting that both oxidative stress (induced by both heme and iron) and the activation of the TLR4 pathway (activated by heme) are responsible for heme-induced M1 polarization of macrophages. Interestingly, hepatic macrophages from sickle mice show an enhanced M1-like phenotype, correlating with increased iron accumulation in these cells and Hemopexin depletion. The administration of Hemopexin to sickle mice rescued the expression of M1 markers in liver macrophages to levels similar to control mice, indicating that heme scavenging reduces the pro-inflammatory state of macrophages, by reducing cell heme-iron loading.
Summary and Conclusions: Here we show that heme and iron induce the polarization of macrophages towards the M1 pro-inflammatory phenotype. This finding is of pathophysiological relevance in disorders associated with heme and iron loading in RES macrophages, such as sickle cell disease. We expect that the heme/iron-induced increase in cytokine production and ROS will significantly contribute to the enhanced inflammatory status of some hemolytic diseases. The administration of anti-oxidant and hemoglobin/heme scavenger could be beneficial to counteract the heme-induce pro-inflammatory status of macrophages in these disorders.

S503

FUNCTIONAL CHARACTERIZATION OF NOVEL ABCB6 MUTATIONS AND THEIR CLINICAL IMPLICATIONS IN FAMILIAL PSEUDOHYPERKALEMIA

I. Andolfo[1,*] C. Auriemma[1], R. Russo[1], F. Manna[1], M.L. Salve[1], F. Vallefuoco[1], A.K. Sharma[2], S. L. Alper[2], L. De Franceschi[3], A. Iolascon[1]
[1]Dept. of Molecular Medicine and Medical Biotechnologies, University Federico II of Naples, Ceinge, biotecnologie avanzate, Naples, Italy, [2]Division of Nephrology, Beth Israel Deaconess Medical Center, Department of Medicine, Harvard Medical School, Boston, MA, United States, [3]Department of Medicine, University of Verona, Piazzale Lo Scuro 10, Verona, Italy

Background: Isolated Familial Pseudohyperkalemia (FP) is a dominant red cell trait characterized by cold-induced slow 'passive leak' of red cell K+ into plasma, first described in a large Scottish family from Edinburgh (Stewart GW, *et al.*, 1979). Although in freshly obtained blood samples plasma [K+] was normal, it was increased when measured in blood stored at or below room temperature. This trait was unaccompanied by clinical symptoms or signs except for mild abnormalities of red cell shape. Functional gene mapping and sequencing analysis of the candidate genes within the 2q35-q36 critical interval in three multigenerational FP families with 20 affected individuals identified two novel heterozygous missense mutations in the ABCB6 gene that cosegregated with disease phenotype (Andolfo I. *et al.*, 2013). The two genomic substitutions altered two adjacent nucleotides within codon 375 of ABCB6, a porphyrin transporter that in erythrocyte membranes bears the Langereis blood group antigen system (Krishnamurthy PC, *et al.*, 2006; Helias V, *et al.*, 2012).
Aims: In this study we analyzed three additional families and report the first functional characterization of ABCB6 mutants towards understanding the pathogenic mechanism of FP.
Methods: DNA was obtained for genetic analysis from affected and unaffected family members, after signed informed consent, according to the Declaration of Helsinki. The search for mutations was performed by direct sequencing of the *ABCB6* gene. cDNAs encoding full-length wildtype ABCB6 were cloned in pcDNA3.1 vector. The novel point mutations found in our patients: c.1361T>C, p.V454A; c.826C>T, p. R276W; c.2168G>A, p.R723Q were introduced into pcDNA3.1-ABCB6 by site-directed mutagenesis. WT and mutants constructs were transfected into HEK-293 cells for 72h. The cells were maintained at 30°C to evaluate the effects of reduced temperature. After transfection, the cells were incubated in a medium containing ^{86}rubidium ($^{86}Rb^+$) as a tracer for K^+. ^{86}Rb was determined in cell lysate, and K was determined in the supernatant by atomic absorption spectrometry.
Results: In one Bolivian patient we found the homozygous mutation c.1361T>C, p.V454A. In one patient from Cardiff we found two heterozygous mutations in trans: c.826G>T, p. R276W and c.2168G>A, p.R723Q. In Ireland family we found the heterozygous mutation c.826G>T, p. R276W. All these mutations are annotated in public databases as single nucleotide variants (SNVs), suggesting that many patients with FP could be present in donor blood population and are predicted to be damaging by *in silico* analysis by PolyPhen2 and SIFT tools. V454A, R276W, and R723Q as well as the previously identified, R375Q and R375W, were expressed into HEK-293 cells. Expression analysis of all mutants showed no alterations in levels of expression of mutant RNA or polypeptide, and molecular modeling predicted minimal structural changes resulting from the novel missense mutations. However, measurement of ouabain- and bumetanide-resistant net cation flux demonstrated a greater loss of cell K from ABCB6 mutant-expressing cells compared to ABCB6 WT-expressing cells. The coexpressed R276W/R723Q mutations, in particular, elicited greater efflux of cellular K^+ into extracellular medium than did the other mutants studied.
Summary and Conclusions: Our findings demonstrate that missense mutations in *ABCB6* lead to increased cellular K^+ efflux as exhibited in RBCs of FP patients. Storage of FP blood can cause a significant increase in blood K^+ levels, with serious clinical implications mostly in neonates and infants receiving large-volume transfusions of whole blood. Furthermore, the prevalence of FP might be underestimated, since patients with FP can be asymptomatic and thus undetected in the donor population. In the future, genetic tests for FP could be added to blood donor prescreening.

S504

DISSECTING THE CONTRIBUTION OF UNREGULATED MACROPHAGE IRON RECYCLING AND DIETARY IRON UPTAKE IN GENERATING SYSTEMIC IRON OVERLOAD

M. Muckenthaler[1,2] S. Altamura[1,2,*]
[1]Pediatric Oncology, Hematology and Immunology, University of Heidelberg, [2]MMPU-Molecular Medicine Partnership Unit, Heidelberg, Germany

Background: Dysregulated iron homeostasis causes a wide spectrum of diseases including hepatic fibrosis and cirrhosis, endocrinopathy and cardiac failure. This is evident not only in hereditary hemochromatosis, a genetically inherited primary iron overload disorder, but also in many dyserythropoietic syndromes (*e.g.* beta-thalassemia or congenital *dyserythropoietic* anemias) in which the ineffective eyrhtropoiesis drives an abnormal request for iron causing secondary iron overload.
Systemic iron levels are balanced by the hepatic iron hormone hepcidin and its "receptor" ferroportin (FPN) to prevent the pathological consequences of iron overload or iron deficiency. Hepcidin binding to the iron export channel FPN reduces dietary iron uptake in duodenal enterocytes and iron recycling from aging erythrocytes in reticuloendothelial macrophages. Despite the importance of these two cell types as iron exporters, their single contribution in maintaining systemic iron content has not yet been elucidated.
Aims: The aim of this study is to quantify the individual contributions of macrophage iron recycling and dietary iron uptake to systemic iron levels. This knowledge is an important prerequisite to develop specific pharmacological strategies to limit iron export in iron-related disorders.
Methods: Central to this study is a novel mouse line that expresses a FPN mutant protein that is unable to bind to hepcidin FPN(C326S) (Altamura *et al.*, Cell Met. 2014). Constitutive disruption of the hepcidin/FPN regulatory loop causes increased serum and hepatic iron levels and a dramatic decrease in the splenic and duodenal iron content. By using the cre/lox technology, we generated mice expressing the FPN(C326S) mutation only in duodenal enterocytes (Villin-Cre/FpnC326S) or in macrophages (Lyz-Cre/FpnC326S) to dissect the contribution of the two iron-exporting cell types in generating systemic iron overload. 10-week old C57BL6/J congenic male mice have been analyzed. Hematological parameters have been measured using the Scil-Vet blood analyzer while serum iron levels have been assessed using the SFBC and UIBC iron kits (Biolabo). Gene expression analysis has been performed using SYBR-green qRT-PCR. All mouse breeding and animal experiments were approved by and conducted in compliance with the guidelines of the EMBL Institutional Animal Care and Use Committee.
Results: Mice carrying the FPN(C326S) mutation specifically in the duodenum have the same alterations in hematological parameters found both in hemochromatotic patients and in constitutive FPN(C326S) mice, showing increased hemoglobin (Hb), hematocrit (HCT) and mean corpuscular volume (MCV). Serum iron content and transferrin saturation are strongly increased mirroring a hemochromatotic phenotype. Interestingly, Lyz-Cre/FpnC326S mice of unregulated macrophage iron export failed to show both hematological and serum iron alterations, providing the first indication that dietary iron uptake could be the major responsible mechanism in causing systemic iron overload in hemochromatosis. Hepatic iron measurement revealed a strong iron accumu-

lation only in Villin-Cre/FpnC326S mice. This, together with the systemic iron overload, causes an increase in circulating hepcidin levels triggering the FPN degradation in reticuloendothelial macrophages and causing splenic iron overload. Lyz-Cre/FpnC326S mice, instead, have splenic iron deficiency due to the presence of the FPN(C326S) unregulated iron channel that continuously exports iron from reticuloendothelial macrophages.
Summary and Conclusions: Our results show for the first time that unregulated duodenal iron export is the major contributor in the generation of systemic iron overload. This finding opens new insights in developing pharmacological strategies aimed to specifically limit dietary iron import for the treatment of primary and secondary iron overload diseases.

S505

REGULATORY NETWORK GATA1-MEDIATED ON SEC23B GENE IN ERYTHROID CELLS

R. Russo[1,*] I. Andolfo[1], A. Gambale[1], F. Wandroo[2], M.G. Bisconte[3], A. Iolascon[1]
[1]Molecular Medicine and Medical Biotechnologies, University "Federico II", Naples, CEINGE-Biotecnologie Avanzate, Naples, Naples, Italy, [2]Department of Haematology, Sandwell and West Birmingham Hospital, Birmingham, United Kingdom, [3]Dipartimento Oncoematologico, Azienda Ospedaliera di Cosenza, Cosenza, Italy

Background: Mutations in *SEC23B* gene cause the congenital dyserythropoietic anemia II (CDA II), an autosomal recessive disorder with ineffective erythropoiesis. Most of patients show biallelic mutations, according to the pattern of autosomal recessive inheritance. However, the 14% of the cases exhibit an incomplete pattern of inheritance, with a monoallelic *SEC23B* mutation. Mutations in deep regulatory regions of the *SEC23B* gene as well as in CDA-related loci could be hypothesized as further pathogenetic mechanisms of CDA II.
In *SEC23B* monoallelic patients we postulated the occurrence of a second mutation in *GATA1* gene, assuming that it could be involved in the regulation of SEC23B expression. GATA1 transcription factor is a key regulator of the erythro- and thrombopoiesis. Indeed, mutations in this gene have been already associated to specific CDA variants, as X-linked dyserythropoietic anemia and thrombocytopenia (XLTDA).
Aims: Our aims are: (i) to perform a mutational screening of *GATA1* genomic sequence in *SEC23B* monoallelic patients, as well as in those without *SEC23B* mutations; (ii) to characterize the promoter region of *SEC23B* and (iii) to analyze GATA1-mediated regulation of SEC23B expression.
Methods: Genomic mutational screening, gene and protein expression analyses were performed as described (Russo *et al.*, 2014; Russo *et al.*, 2013). In order to characterize *SEC23B* promoter region, 10 overlapping fragments covering a 3500 bp upstream region of the gene were cloned upstream the luciferase gene into PGL3 vector. Putative binding sites for GATA1 (GATA1bs) in the promoter sequence of *SEC23B* were predicted by MatInspector and PROMO web server tools. GATA1 cDNA was cloned into the expression vector pcDNA3.1. All mutants were obtained by site-direct mutagenesis. Direct binding of GATA1 to the GATA1bs was assayed by chromatin immunoprecipitation (ChIP) in both K562 and HEL cells at 6 days of erythroid differentiation.
Results: In our cohort we found one XLTDA patient with the hemizygous mutation GATA1-Gly208Arg. Two *SEC23B* monoallelic patients showed the single nucleotide variant rs113966884 G/A in GATA 1 5'upstream region. Both GATA1 variants resulted in a reduced gene expression, which in turn correlates with a decrease of SEC23B expression. By luciferase assay of the deletion mutants we identified the promoter region of the *SEC23B* gene (HuSEC23B/3.44). Ten putative GATA1bs were predicted. However, direct GATA1 binding were confirmed for only two sites, GATA1bs/HuSEC23B-2475 and -463. The co-transfection of GATA1bs/HuSEC23B-2475 and -463 mutants and GATA1 WT showed a reduction of 30-40% luciferase activity respectively, compared to WT sequence. Finally, we analyzed the GATA1-mediated regulation of SEC23B expression by co-transfection of several GATA1 mutants (GATA1/G208R, GATA1/R216W, GATA1/D218G, and GATA1/V205M) and the HuSEC23B/3.44 in HEK-293 cell line. We demonstrated a marked reduction of HuSEC23B/3.44 luciferase activity induced by the mutants G208R and R216W, which are the causative variants related to XLTDA and congenital erythropoietic porphyria (CEP), respectively.
Summary and Conclusions: This study provided new insights into the molecular mechanisms of SEC23B regulation. We also suggested an explanation of the variability of phenotypes GATA1-related by means of the crosstalk of this gene with *SEC23B*. Moreover, the identification of transcriptional regulatory elements in *SEC23B* promoter could allow the definitive diagnosis of CDAII patients with peculiar clinical phenotypes or those with incomplete mutation pattern in *SEC23B*.

MDS - Clinical

S506

PROGRESSIVE ANEMIA CAN BE DETECTED MORE THAN 2 YEARS PRIOR TO THE DIAGNOSIS OF MYELODYSPLASTIC SYNDROME: RESULTS FROM THE PRIMARY CARE SETTING IN DENMARK

J.W. Hansen[1,*] H. Sandholdt[2], V.D. Siersma[2], A.D. Ørskov[1], H. Hasselbalch[3], O.W. Bjerrum[1], N.D.F. Olivarius[2], K. Grønbæk[1], C.L. Andersen[3]
[1]Department of Hematology, Rigshospitalet, University of Copenhagen, [2]The Research Unit for General Practice and Section of General Practice, Department of Public Health, University of Copenhagen, Copenhagen, [3]Department of Hematology, Roskilde Hospital, University of Copenhagen, Roskilde, Denmark

Background: Myelodysplastic syndrome (MDS) is a clonal hematopoietic disorder, characterized by inefficient hematopoiesis and peripheral blood cytopenias. Cytopenias are frequently observed in the primary care setting, where the clinical presentation of the patient determines further investigations instituted by the general practitioner (GP). Cytopenias have diverse origins such as inefficient hematopoiesis due to hematological malignancy, but also carcinomatosis, vitamin deficiency, immune dysfunction and viral infections. In primary care, MDS is a rare cause of cytopenias. However, if untreated they are persistent, and important predictors of survival in MDS according to the revised international prognostic scoring system (IPSS-R).
Aims: The aim was to investigate the association between pre-diagnostic cytopenias in primary care patients and the characteristics and prognosis of subsequently occurring MDS with focus on the hemoglobin concentration.
Methods: Between 2000 and 2010, GPs in the Copenhagen area were all served by one laboratory, The Elective Laboratory of the Capital Region (ELCR). The Copenhagen Primary Care Differential Count *(CopDiff)* database based on ELCR data contains information on all complete blood cell counts requested by GPs for 555,039 individuals during this period. Cancer occurrence within the *CopDiff* population has been obtained by linkage to the Danish Cancer Registry, which is known to have valid and almost complete registration of cancer cases in Denmark. For the present study, we included cases of MDS (ICD-10=D46) between 2000 and 2010Consecutive hemoglobin counts obtained prior to diagnosis were modeled using linear regression models. An estimate of the time point at which hemoglobin levels fell below the sex specific threshold, was derived from this regression. In this model patients with secondary MDS were excluded, n=3.
Results: We identified 284 patients with MDS of whom 221 had undergone primary care laboratory work-up in the preceding 10 years. The remaining patients (n=63) only had laboratory workup performed after diagnosis and were excluded from the present study. Hence, we included 221 patients with an average of four prediagnostic complete blood counts measured (SD=4,5). Anemia prior to MDS diagnosis was observed for 69% of men and 84% of women (p=0.01). Using the linear regression model, we estimated that male patients in average dropped below the hemoglobin reference range 780 days prior to diagnosis. The corresponding estimate for women was 250 days. At diagnosis women had estimated hemoglobin levels of 5.5 mmol/L (8.8 g/dL) and men of 5.1 mmol/L (8.3 g/dL). The proportion of patients presenting with prediagnostic thrombocytopenia and neutropenia were similar between men and women (Table 1).

Table 1.

Patients	Female (n=103)	Male (n=118)
Median age at diagnosis, years	74	73
Average number of complete blood cell counts prior to diagnosis of MDS per patient, (SD)	4.1 (3.4)	3.8 (3.8)
Anemia (hemoglobin ? <7 mmol/L ? < 8mmol/L) n (%)**	71 (69)	99 (84)
Thrombocytopenia (platelets < 150-10^9/L), n (%)	62 (60)	72 (61)
Neutropenia (neutrophils < 1.8 10^9/L) , n (%)	40 (39)	46 (39)
Mean interval to diagnosis of MDS in days*	250	780
Mean hemoglobin at diagnosis, predicted	5.46	5.14
Mean Charlson score	0.83	0.68

*Days are counted from the day the hemoglobin count was below sex specific reference interval
**P=0.01

Summary and Conclusions: Cytopenia is a cardinal finding in MDS. In this study we demonstrate that men on average are anemic two years prior to diagnosis. This is significantly longer than for women. According to the IPSS-R we know that the severity of anemia is a risk factor, and we speculate that this risk factor is an indirect marker of disease duration. If so, it would emphasize the need for earlier diagnosis to improve prognosis, especially in male patients. We are currently performing subgroup analysis according to bone marrow histology, cytogenetics and IPSS-score. This will elucidate if the duration of prediagnostic anemia *per se* has prognostic impact. Furthermore we will investigate these patterns in subgroups of low- and high-risk MDS and estimate prediagnostic neutro-and thrombocytopenia as well. These data will be presented at the meeting.

S507

CLINICAL AND MOLECULAR PREDICTORS OF RESPONSE TO ERYTHROPOIESIS STIMULATING AGENTS (ESA) IN LOWER RISK MDS PATIENTS

O. Kosmider[1], M. Passet[2], V. Santini[3], U. Platzbecker[4], V. Andrieu[5], G. Zini[6], O. Beyne-Rauzy[7], P. Fenaux[8], F. Dreyfus[9], M. Fontenay[9], S. Park[10,*]
[1]Hôpital COCHIN, [2]Hopital COCHIN, PARIS, France, [3]AOU Careggi, University of Florence, Firenze, Italy, [4]Dresden, Dresden, Germany, [5]Bichat, Paris, France, [6]Catholic University of Sacred Heart, Roma, Italy, [7]Toulouse, Toulouse, [8]Saint Louis, [9]Cochin, Paris, [10]Hematologie Clinique, CHU de Grenoble, 38043 GRENOBLE Cedex 09, France

Background: Up to 50% of lower risk MDS respond to ESA. While response can be predicted by serum(s) EPO level and transfusion dependence (TD), it is unknown if molecular findings are also prognostic.
Aims: We studied prognostic factors of erythroid response (HI-E, IWG 2006 criteria) to ESA in 90 lower risk MDS treated with ESA in France (GFM), Italy (FISM) and Germany (GMDS) with a focus on molecular mutations.
Methods: We studied prognostic factors of erythroid response (HI-E, IWG 2006 criteria) to ESA in 90 lower risk MDS treated with ESA in France (GFM), Italy (FISM) and Germany (GMDS) selected on the availability of all the following: sEPO, serum ferritin (SF), marrow slides for review (especially of dysplasia). In 79 of them, mutational analysis of 39 genes recurrently mutated in myeloid malignancies was performed on marrow cell DNA collected before ESA treatment, using an AmpliSeq approach (Life Technologies), and confirmed by Sanger method when the variant allele frequency was found upper than 20%.
Results: Median age was 74 years, with 56% males, 26% RBC TD patients, median Hb level 9.5 (range 6.2-11) in non RBC-TD patients, median sEPO level 59 U/l (range 9-402), median SF 411 µg/l (range 11-1856), WHO diagnosis: 21% RA; 24.4% RAEB-1; 24.6% RARS; 24.4% RCMD; 2% del(5q); 3.6% MDS-U. IPSS was low (45.3%) and int-1 (54.7%), IPSS R: very low (6.6%), low (59.7%) and int (33.7%). 85% pts had dyserythropoiesis, 62% dysgranulopoiesis, 67% dysmegakaryopoiesis. HI-E, was 64.5% and median response duration 19.8 months. Clonal and subclonal mutations were found in: SF3B1 (40.5% patients), TET 2 (35.4%), ASXL1 (31.4%), DNMT3A (20.2%), U2AF1 (10.1%), SRSF2 (8.8%), IDH1/IDH2 (7.4%), RUNX1 (2.5%), STAG2 (11.4%), NRas (3.7%), KRas (3.7%), BCOR (3.7%), Jak2, PHF6, and CBL in 1 pt each. 86.1% patients had at least one mutation (median number 2,range 0-6). As previously described by others, SF3B1, DNMT3A and TET2 co-occurred frequently. ASXL1 and DNMT3A seemed to be mutually exclusive and SRSF2 never co-occurred with SF3B1.The number of mutations was not correlated with the degree of dysplasia. By univariate analysis, male gender, sEPO level >100U/L, IPSS-R (int *vs* very low and low) were correlated with worse HI-E. Patients with ≤2 mutations had better HI-E (OR: 0.32, p=0.02), but none of the most frequent mutations (SF3B1, ASXL1, TET2, DNMT3A), age, karyotype and importance of dysplasia had any impact on HI-E. In an adjusted logistic regression model, male gender, sEPO level>100U/L and RBC- TD, but not number of mutations, were significantly correlated with poorer HI-E.
Summary and Conclusions: Presence of >2 mutations predicted worse HI-E to ESA in lower risk MDS. However, in multivariate analysis, mutational analysis lost its prognostic value compared to more conventional factors, especially RBC-TD and sEPO level.

S508

ANALYSIS OF PROGNOSTIC MARKERS IN 615 PATIENTS WITH THERAPY-RELATED MYELODYSPLASTIC SYNDROMES-ARE CURRENTLY AVAILABLE SCORING SYSTEMS SUITABLE IN THIS PATIENT GROUP?

Background: Prognostication in myelodysplastic syndromes (MDS) has recently been improved by the revised International Prognostic Scoring System (IPSS-R). However this score, as the original IPSS, was developed analyzing primary, untreated patients (pts) only. Data on its usefulness in pts with therapy-related MDS (tMDS) is limited.
Aims: We analyzed 615 pts from Spanish, German, Swiss, and Austrian centers diagnosed 1975-2015.
Methods: Complete data to calculate the IPSS/-R was available in 446 pts. Prognostic impact of features was analyzed by uni- and multivariable models and estimated by a measure of concordance for censored data (Dxy).
Results: Median age was 67 years. According to WHO classification 2% of pts had 5q-syndrome, 6% RA, 3% RARS, 27% RCMD, 9% RCMD-RS, 16% RAEB-1, 18% RAEB-2, 6% CMML-1, 2% CMML-2, 3% MDS-U, and 8% AML (RAEB-T). Cytogenetics were 47% good, 14% intermediate, and 39% poor according to IPSS, and 2% very good, 44% good, 17% intermediate, 16% poor, and 21% very poor according to IPSS-R. Regarding prognostic risk groups 19% exhibited IPSS-low, 33% int-1, 30% int-2, and 18% high, while the IPSS-R was very low in 8%, low in 26%, intermediate in 16%, high in 22%, and very high in 27%. Regarding the primary disease most frequent diagnoses were NHL 19%, breast cancer 16%, myeloma 10%, Hodgkin's disease, and AML 6% each. 75% of pts received chemotherapy and 47% received radiotherapy. Most pts received combination regimen containing alkylating agents in 59%, topoisomerase inhibitors in 35%, antitubulin agents in 28%, and antimetabolites in 38%. Latency periods varied broadly (≤3 yrs 22%, >3-≤6 yrs 26%, >6-≤12 yrs 31%, >12 yrs 21%). Median follow-up from MDS diagnosis was 56 months, median survival 17 months. After MDS diagnosis 30% of pts received disease altering treatment, including stem cell transplantation in 17%. Features with influence on survival and time to AML in univariable analysis included age, FAB, WHO, IPSS, IPSS-R, cytogenetic risk, platelets, marrow and peripheral blasts, ferritin, fibrosis, year of primary diagnosis. Predominantly influence on survival was seen for year of MDS diagnosis, hemoglobin, LDH, and use of alkylating agents. A latency period >12 years showed higher risk of AML. Neutrophil count, use of chemo or radiotherapy as well as other chemotherapeutic agents had no influence on both outcomes. Our results indicate that both the IPSS (Dxy 0.26 for survival, 0.35 for AML), and IPSS-R (Dxy 0.32 for both) perform moderately in tMDS, but not as well as in primary MDS. Adjusting prognostic models to tMDS seems therefore required. Score versions including peripheral blasts perform somewhat better. Separate score versions for survival and time to AML would give differing weights to most features. Hemoglobin and cytogenetics would get more weight for survival, while marrow blasts would be more important regarding AML. Another issue is the possible integration of data on primary disease/therapy (Figure 1).

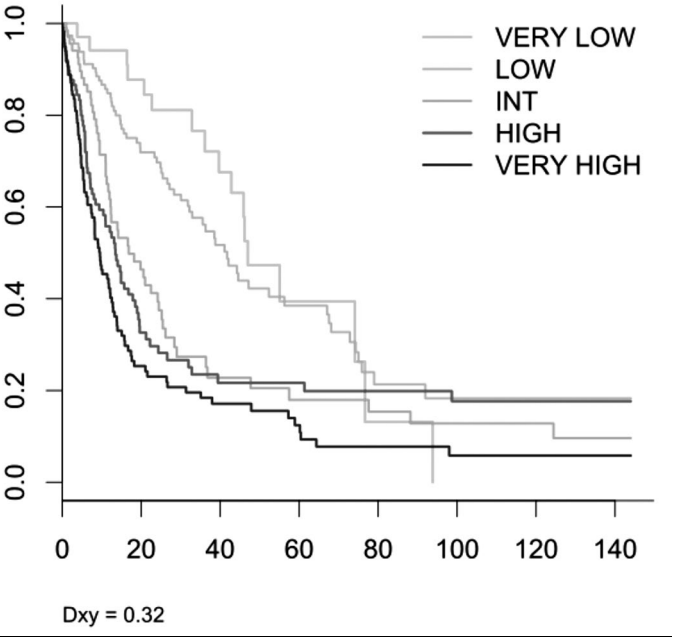

Figure 1. Survival by IPSS-R.

Summary and Conclusions: In contrast to early publications on tMDS, where aberrant cytogenetics were described in >90% of pts and prognosis was seen uniformly poor, surprisingly we find good risk karyotypes in a relatively large number. Although some cases might be unrelated to previous therapy and poor

risk cytogenetics are still overrepresented, this indicates, different types of tMDS exist. Our analysis shows that indeed many variables exhibit a prognostic influence in tMDS. About one third of our pts were treated for MDS. However, censoring/leaving them out would not show a representative cohort. Further analyses are performed to propose an optimized scoring system for tMDS.

S509

LUSPATERCEPT INCREASES HEMOGLOBIN AND REDUCES TRANSFUSION BURDEN IN PATIENTS WITH LOW OR INTERMEDIATE-1 RISK MYELODYSPLASTIC SYNDROMES (MDS): PRELIMINARY RESULTS FROM THE PHASE 2 PACE-MDS STUDY

U. Platzbecker[1,*] U. Germing[2], A. Giagounidis[3], K. Götze[4], P. Kiewe[5], K. Mayer[6], O. Ottmann[7], M. Radsak[8], T. Wolff[9], D. Haase[10], M. Hankin[11], D. Wilson[11], X. Zhang[11], A. Laadem[12], M. Sherman[11], K. Attie[11]
[1]Universitatsklinikum Carl Gustav Carus, Dresden, [2]Universitätsklinikum Düsseldorf, [3]Marien Hospital Düsseldorf, Düsseldorf, [4]Technical University of Munich, Munich, [5]Onkologischer Schwerpunkt am Oskar-Helene-Heim, Berlin, [6]Universitätsklinikum Bonn, Bonn, [7]Klinikum der J.W. Goethe-Universität Frankfurt, Frankfurt/Main, [8]University Medical Center-Johannes Gutenberg-Universität, Mainz, [9]OncoResearch Lerchenfeld UG, Hamburg, [10]Universitätsmedizin Göttingen, Göttingen, Germany, [11]Acceleron Pharma, Cambridge, MA, [12]Celgene Corporation, Summit, NJ, United States

Background: Luspatercept (ACE-536) is a fusion protein (modified activin receptor IIB-IgG Fc) being investigated for the treatment of anemias with ineffective erythropoiesis. MDS patients have increased GDF11 levels (Suragani, Nat Med 2014) and aberrant Smad2,3 signaling in the bone marrow. Luspatercept binds TGF-β superfamily ligands, including GDF11, inhibits Smad2,3 signaling, and promotes late-stage erythroid differentiation, distinct from ESAs. In a healthy volunteer study, luspatercept was well-tolerated and increased hemoglobin (Hb) levels (Attie, Am J Hematol 2014).
Aims: This is an ongoing, phase 2, multicenter, open-label, dose-finding study to evaluate the effects of luspatercept on anemia in patients (pts) with low/int-1 risk MDS (IPSS classification). Study outcomes include erythroid response of increased Hb in low transfusion burden (LTB) pts (<4 RBC units/8 weeks), reduced transfusions in high transfusion burden (HTB) patients (≥4 RBC units/8 weeks), safety, PK, and PD biomarkers.
Methods: Inclusion criteria include age ≥18 yr, anemia, defined as being HTB or LTB with Hb <10.0 g/dL, EPO >500 U/L or nonresponsive/refractory to ESAs, no prior azacitidine or decitabine, and no current treatment with ESA, G-CSF, GM-CSF, or lenalidomide. Luspatercept was administered by SC injection once every 3 weeks in sequential cohorts (n=3-6 each) at dose levels ranging from 0.125 to 1.75 mg/kg for up to 5 doses with a 3-month follow-up. Treatment of an expansion cohort is ongoing, with individual pt dose titration allowed. Patients completing this study may enroll into a 12-month extension study.
Results: Enrollment is complete for 27 pts in the dose escalation cohorts and 31 pts in the expansion cohort. Preliminary safety and efficacy data (as of 23Feb2015) were available for 44 pts (19F/25M, 15 LTB/29 HTB). Mean age was 68.1 yr, 61% had prior EPO therapy, and 21% had prior lenalidomide. 35 (80%) patients had ≥15% ring sideroblasts (RS) in bone marrow. The mean baseline Hb for LTB patients was 8.6 g/dL, ranging from 6.8 to 10.1 g/dL. LTB pts treated at 0.75-1.75 mg/kg (n=13) had a 77% response rate for the primary endpoint (Hb increase ≥1.5 g/dL for ≥2 weeks) and a 69% IWG HI-E response rate (Hb increase ≥1.5 g/dL over 8 weeks). The mean (SD) maximum change in hemoglobin was 2.7 (1.1) g/dL in the higher dose groups compared with 0.9 (0.1) g/dL in the lower dose groups. HTB patients treated at 0.75-1.75 mg/kg (n=22) had a 50% HI-E response rate (reduction of ≥4 RBC units over 8 weeks). Higher response rates were observed in pts with ring sideroblasts and/or mutations of SF3B1 (data to be presented). Of the patients with RBC transfusions during the 8 weeks prior to treatment, 10/28 (36%) patients were transfusion-free for ≥8 weeks during treatment. Luspatercept was generally well-tolerated. Adverse events were mostly mild-moderate. The most frequent related adverse events (>10% patients) were bone pain, headache, diarrhea, myalgia, and pain in extremity.
Summary and Conclusions: Based on preliminary data in Low/Int-1 MDS patients, luspatercept treatment at therapeutic dose levels for 3 months led to HI-E response for increased Hb levels and/or decreased transfusion requirement in the majority of patients, with a favorable safety profile. Higher response rates were observed in patients with ring sideroblasts and/or SF3B1 mutations. These data strongly support further evaluation of luspatercept in patients with low to intermediate risk MDS.

S510

A PHASE 2, DOSE-FINDING STUDY OF SOTATERCEPT (ACE-011) IN PATIENTS (PTS) WITH LOWER-RISK MYELODYSPLASTIC SYNDROMES (MDS) AND ANEMIA REQUIRING TRANSFUSION

R. Komrokji[1,*] G. Garcia-Manero[2], L. Ades[3], A. Laadem[4], B. Vo[4], T. Prebet[5], A. Stamatoullas[6], T. Boyd[7], J. Delaunay[8], D.P. Steensma[9], M.A. Sekeres[10], O. Beyne-Rauzy[11], J. Zou[4], K.M. Attie[12], M.L. Sherman[12], P. Fenaux[3], A.F. List[1]

Background: Anemia, a hallmark of MDS, is challenging to treat, particularly after failure of erythropoiesis-stimulating agents (ESAs). Sotatercept (ACE-011) is a novel and first-in-class activin type IIA receptor fusion protein that acts on late-stage erythropoiesis to increase release of mature erythrocytes into circulation (Carrancio S, *et al.* Br J Haematol 2014;165:870-82).
Aims: This phase 2, open-label, dose-finding study aims to determine a safe, tolerable, and effective dose of sotatercept in anemic pts with lower-risk MDS.
Methods: The primary endpoint was erythroid hematological improvement (HI-E; modified International Working Group 2006 criteria). Secondary endpoints included rate of RBC transfusion independence (TI) ≥8 weeks and safety. Eligible pts had International Prognostic Scoring System-defined Low or Intermediate-1-risk MDS (Greenberg P, *et al.* Blood 1997;89:2079-88) and anemia, with no response, loss of response, or low chance of response to ESAs. Pts received subcutaneous sotatercept at 0.1, 0.3, 0.5, 1.0, or 2.0 mg/kg every 3 weeks for up to 8 doses; pts with clinical benefit may receive treatment beyond 8 doses until meeting protocol discontinuation criteria. Informed consent was obtained from all pts. ClinicalTrials.gov identifier: NCT01736683.
Results: As of February 4, 2015, a total of 59 MDS pts were enrolled: 7, 6, 21, 20, and 5 in the 0.1, 0.3, 0.5, 1.0, and 2.0 mg/kg groups, respectively. Overall, 66% of pts were male, median age was 71 years, and median time from diagnosis 4 years. Pts received a median 6 RBC units (range 0-16) in the 8 weeks prior to treatment; 50 (85%) received ≥4 RBC units (high transfusion burden; HTB) and 9 (15%) received <4 RBC units (low transfusion burden; LTB). In this heavily pre-treated cohort, 56 (95%) pts were previously treated with ESAs, 31 (53%) with hypomethylating agents, 27 (46%) with lenalidomide, and 26 (44%) with other MDS treatments. Of 53 pts evaluable for efficacy, 23 (43%) achieved HI-E: 0 of 7 (0%), 4 of 6 (67%), 9 of 20 (45%), and 10 of 20 (50%) pts in the 0.1, 0.3, 0.5, and 1.0 mg/kg groups, respectively. Review of efficacy data for the 2.0 mg/kg dose group is ongoing. Of 45 evaluable HTB pts, 6 (13%) achieved RBC-TI ≥8 weeks; median duration of longest response was 67.5 days, 107 days, and 122.5 days in the 0.3, 0.5, and 1.0 mg/kg dose groups, respectively. Of 8 evaluable LTB pts, 5 (63%) achieved RBC-TI ≥8 weeks and a mean hemoglobin increase of ≥1.5 g/dL sustained for ≥8 weeks; duration of RBC-TI for responders ranged from 175-472+ days. Sotatercept was generally well tolerated. The most common adverse events (AEs), all grades, were asthenia/fatigue (n=24), peripheral edema (n=12), and diarrhea (n=12). Eighteen (31%) pts had ≥1 grade 3 or 4 AE; of these, 3 (5%) were reported as suspected to be study drug-related (1 each with grade 3 pain in extremity, grade 3 hypertension, and grade 4 acute myeloid leukemia, all in the 0.5 mg/kg dose group). Overall, 4 pts discontinued due to suspected treatment-related AEs: 1 each with grade 2 hemolytic anemia, grade 2 hypertension, grade 2 muscular weakness, and grade 2 increased blood pressure with grade 2 diarrhea in the 0.3, 0.5, 1.0, and 2.0 mg/kg groups, respectively.
Summary and Conclusions: Data from this ongoing study suggest sotatercept was well tolerated, with promising evidence of clinical activity in this cohort of heavily pre-treated, anemic, lower-risk MDS pts who had failed or were refractory to prior ESAs.

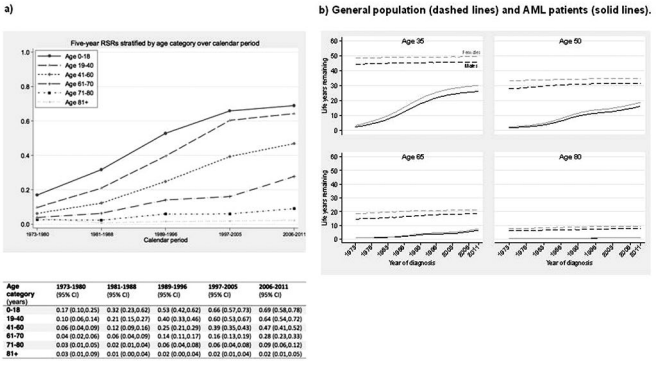
CONTINUED IMPROVEMENT IN SURVIVAL OF ACUTE MYELOID LEUKEMIA PATIENTS AND AN APPLICATION OF THE LOSS IN EXPECTATION OF LIFE

H. Bower[1], T.M.-L. Andersson[1], M. Björkholm[2], P. Dickman[1], P. Lambert[3], Å. Derolf[2,*]
[1]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, [2]Division of Hematology, Karolinska University Hospital, Stockholm, Sweden, [3]Department of Health Sciences, University of Leicester, Leicester, United Kingdom

Background: Survival in acute myeloid leukemia (AML) is increasing, but most survival data come from clinical trials. National registries provide population-based survival data. Relative survival ratios (RSRs) provide a measure of total excess mortality associated with AML irrespective of whether the excess mortality is directly or indirectly because of AML. A new statistical method, loss in expectation of life (LEL), has recently been developed and provides an alternative for presenting survival.
Aims: We previously evaluated RSRs in Swedish AML patients 1973 -2005 and found a large improvement in survival for younger patients, while less improvement was seen among those 71+ years.[1] We now extend the study to include patients diagnosed -2011 aiming to investigate whether there was a continuous improvement in survival and whether any improvement was seen among elderly. The aim was also to present trends in survival using LEL.
1 Derolf *et al.*, Blood 2009
Methods: AML patients in the Swedish Cancer Registry 1973-2011 were included. Date of death was obtained from the Register of Causes of Death. RSRs and LEL were used to quantify survival. RSR is defined as the all-cause survival of the patients under study divided by the expected survival of a comparable group from the general population. LEL is calculated by subtracting the life expectancy for a patient from the life expectancy of a matched subset of the general population. This is interpreted as the number of life years lost due to an AML diagnosis. 5-year conditional LEL measures the LEL for patients conditional on the fact that they have survived 5 years since diagnosis.
Results: 11598 AML patients (51% males; 2212 diagnosed 2006-2011) were included. Median age was 69 years. 10 and 69 allogeneic SCTs were perfomed in patients 61-70 years (EBMT register data) in the two last calendar periods, respectively. The increase in RSRs for 1973-2005 continued into the additional 6 years for all ages except patients 81+ years (Figure 1). The increase was most pronounced for patients 61-70 years; 0.16 (95% CI: 0.13-0.19) and 0.28 (95% CI: 0.23-0.33) in 1997-2005 and 2006-2011, respectively. Among patients 41-60 years RSRs increased from 0.39 (95% CI 0.35-0.43) to 0.47 (95% CI 0.41-0.52). The greatest improvement in survival 1973-2005 was seen among patients ≤40 years; now the increase in survival was modest. LEL decreased for all AML patients 1973-2011 but most for those aged 35 and 50 years (Figure 1). A 35-year old male diagnosed in 1973 lost, on average, 41.6 (95%CI: 40.7-42.5) life years whereas a 35-year old male diagnosed in 2011 is predicted to lose 19.5 (95%CI: 16.4-22.5) life years. 5-year conditional LEL decreased for younger patients during the study period suggesting less long-term complications of applied treatment and fewer relapses. However, young patients surviving 5 years still have their lives shortened by about two years.



Age category (years)	1973-1980 (95% CI)	1981-1988 (95% CI)	1989-1996 (95% CI)	1997-2005 (95% CI)	2006-2011 (95% CI)
0-18	0.17 (0.10,0.25)	0.32 (0.23,0.42)	0.53 (0.42,0.62)	0.66 (0.57,0.73)	0.69 (0.58,0.78)
19-40	0.10 (0.06,0.14)	0.21 (0.15,0.27)	0.40 (0.33,0.46)	0.60 (0.53,0.67)	0.64 (0.54,0.72)
41-60	0.06 (0.04,0.09)	0.12 (0.09,0.16)	0.25 (0.21,0.29)	0.39 (0.35,0.43)	0.47 (0.41,0.52)
61-70	0.04 (0.02,0.06)	0.06 (0.04,0.09)	0.14 (0.11,0.17)	0.16 (0.13,0.19)	0.28 (0.23,0.33)
71-80	0.03 (0.01,0.05)	0.02 (0.01,0.04)	0.06 (0.04,0.08)	0.06 (0.04,0.08)	0.09 (0.06,0.12)
81+	0.03 (0.01,0.09)	0.01 (0.00,0.04)	0.02 (0.00,0.04)	0.02 (0.01,0.04)	0.02 (0.01,0.05)

Figure 1. Temporal trends in survival of AML patients illustrated by a) relative survival rations stratified by age category over calendar period; and b) temporal trends in the life expectancy of the general population and AML patiens.

Summary and Conclusions: AML survival continued to improve except among patients 81+ years. Most improvement was seen among patients 61-70 years. In Sweden at least 85% of patients of this age are treated with induction chemotherapy. Our results suggest clear benefit from intensive treatment including allogenic SCT. Posakonazol profylaxis was introduced during the last calendar period and risk stratification has improved, both are factors that may also contribute to increased survival in all age groups.
RSR is useful for comparisons of survival but we believe that using the LEL and comparing survival in terms of years, rather than proportions, is more intuitive and useful for communicating survival statistics.

Background: Comparative population-based outcome data in AML of older patients not fit for intensive chemotherapy are rare. Currently available treatment options outside clinical trials are best supportive care (BSC), decitabine (DAC), azacitidine (AZA), and low-dose cytarabine (LDAC).
Aims: To assess clinical outcome in patients older than 60 years not fit for intensive chemotherapy within the registry/molecular-screening trial AMLSG BiO (NCT01252485).
Methods: Between 2011 and 2014 a total of 2651 patients (median age 72 years, range 60- 94) have been registered. Molecular screening was performed within 48hours for *NPM1* and *FLT3* mutations as well as for the fusion-genes *PML-RARA*, *RUNX1-RUNX1T1*, *MYH11-CBFβ*. Treatment and outcome data were documented based on medical records and case record forms.
Results: Of the 2651 patients, n=1104 (42%) received intensive chemotherapy, n=88 (3%) AZA, n=162 (6%) DAC, n=250 (9%) LDAC, n=229 (9%) BSC, n=818 (31%) unknown. Of the 729 patients treated non-intensively n=176 (LDAC, n=134; DAC, n=40; AZA, n=1) were treated in clinical trials. Of the remaining 553 patients, the distribution according to treatment was n=116 LDAC, n=122 DAC, n=87 AZA and n=228 BSC. There was no difference in the age distribution between the groups BSC, AZA, DAC, LDAC (p=0.22, median 76 years, range 60-92), cytogenetic risk group according to ELN recommendations (high, 26%; intermediate, 72%; low, 2%; p=0.35), HCT-CI score <3 (p=0.50), but significantly more patients with ECOG performance status >1 (p<0.001) were in the BSC group, however, without difference between the treatment-groups AZA, DAC, LDAC (p=0.76). Patients with a *NPM1* mutation were more frequently (p<0.001) found in the BSC (23%) and the LDAC (22%) group compared to AZA (5%) and DAC (10%). Overall, *FLT3*-ITD and *FLT3*-TKD were detected rarely and mutually exclusive (3% each) without a difference between the groups (p=0.87, p=0.89). Significantly (p<0.001) higher white blood counts (WBC) at diagnosis were present in the BSC (median, 27/nl) and LDAC (median, 29.6/nl) compared to AZA (median, 3.5/nl) and DAC (median, 5.0/nl), no differences between groups were present for platelets (p=0.97) and hemoglobin (p=0.60). Median, one-year and two-year survival according to the 4 groups (BSC, AZA, DAC, LDAC) are given in the Table 1.

Table 1.

	BSC	AZA	DAC	LDAC
Median survival (months)	0.9	9.7	10.1	3.5
One-year survival	12%	45%	46%	29%
Two-years survival	2%	13%	8%	14%

In a Cox regression model including all patients receiving therapy (AZA, DAC, LDAC), overall survival was significantly influenced by cytogenetic high-risk category (HR, 1.8; p=0.006), ECOG performance status <2 (HR, 0.5;

p=0.0008), treatment (reference LDAC) with AZA (HR, 0.37; p=0.00003), DAC (HR, 0.38; p=0.00008), but not by NPM1 (p=0.72) and FLT3 (p=0.40) mutational status. In univariable comparisons, treatment with AZA and DAC resulted in a significantly better survival of patients with high-risk cytogenetics (p=0.001), normal cytogenetics (p=0.03), ECOG performance status <2 (p=0.0007), HCT-CI score <3 (p=0.0006) and low WBC (<4.0/nl).
Summary and Conclusions: In older patients with AML treatment with AZA or DAC is in the short-term perspective of one to two years superior to LDAC. However, results beyond 2 years are still dismal for all treatment options.

S513

A COMPARISON OF LIMITED CONSOLIDATION CHEMOTHERAPY THERAPY OR NOT, AND DEMETHYLATION MAINTENANCE OR NOT IN OLDER PATIENTS WITH AML AND HIGH RISK MDS: LONG TERM RESULTS OF THE UK NCRI AML16 TRIAL

A. Burnett[1,*] N. Russell[2], S. Freeman[3], L. Kjeldsen[4], D. Milligan[5], C. Pocock[6], P. Cahalin[7], J. Kell[8], M. Dennis[9], R. Hills[10]
[1]Blackwaterfoot, Isle of Arran, [2]Department of Haematology, Nottingham University Hospitals, Nottingham, [3]University of Birmingham, Birmingham, United Kingdom, [4]Rigshospitalet, Copenhagen, Denmark, [5]Birmingham Heartlands Hospital, Birmingham, [6]Kent and Canterbury Hospital, Canterbury, [7]Blackpool Victoria Hospital, Blackpool, [8]Department of Haematology, University Hospital of Wales, Cardiff, [9]Department of Haematology, Christie Hospital, Manchester, [10]HCTU, Department of Haematology, Cardiff University School of Medicine, Cardiff, United Kingdom

Background: In older patients (>60yrs) with AML or high risk MDS (>10% marrow blasts), the UK NCRI AML16 trial compared two induction courses of DA *vs* DClo +/- gemtuzumab ozogamicin (GO). The benefit of GO has been reported (Burnett *et al.* J Clin. Oncol *30*(32); 3924-31, 2012). The trial also compared adding etoposide or ATRA to DA induction in a 2x2 design, and considered the optimal number of courses of treatment and the use of maintenance therapy.
Aims: Following 2 courses of induction patients with at least a partial remission (<15% marrow blasts) after course 1, and in CR after course 2 were eligible to be randomised to one course of consolidation (Dauno 50mg/m^2 d 1, 2$^+$ara-C 100mg/m^2 bid d 1-5) or not; patients in remission after course 2 could be randomised to maintenance (Azacitidine 75mg/m^2 for 5 d x9 every 6 wks) or not.
Methods: From 8/2006-5/2012, 1880 patients entered the intensive induction options: 573 patients were randomised between 3 *vs* 2 courses in total, and 530 between maintenance and not. Of those randomised for consolidation 474 entered CR after course 1 and 99 achieved PR after course 1 and were in CR after course 2. Of the 530 patients entering the maintenance randomisation, 421 were in CR post course 1. A total of 453 patients entered both questions. Randomisations were stratified by induction chemotherapy and other demographics to ensure balance. The demographics of those entering the post induction options were: median age 67y (53-84); 77% de novo, 14% secondary, 8% high risk MDS; 4%, 82%, 14% favourable, intermediate, poor risk cytogenetics: 18% *FLT3*-ITD and 30% *NPM1* mutant*:* 32%, 40%, 28% Wheatley good, standard, poor risk. Follow-up is complete to 1st January 2014 (median 50.4 months).
Results: For all trial entrants the overall response rate was 69% (CR 59%, CRi 10%) and 5-yr OS was 14%. There were no significant outcome differences between induction arms. There was no difference in 5-year survival by consolidation randomisation (consolidation 25% *vs* not 22% HR 0.92 (0.75-1.12) p=0.4). Similarly, there was no difference in 5-year OS in those who did (24%) or did not (20%) receive maintenance (HR 0.93 (0.76-1.14) p=0.5). In the 226 patients allocated consolidation there was no difference in 5 year survival whether they received maintenance (26%) or not (21%) (p=0.7). Of 227 patients allocated no consolidation there was a non-significant benefit of maintenance (5yr OS 27% *vs* 18%, p=0.15), but no significant interaction (p=0.5). During the study marrow samples were tested for MRD by immuno-flow analysis (Freeman S. *et al.* J Clin. Oncol. *31;* 4123-4131, 2013) with a sensitivity of 1 in 10^4. This showed that for patients in CR after course 1, MRD positivity was the most powerful predictor of survival in multivariable analysis. In the 74 MRD -ve patients who received consolidation or not, there was a trend for improved OS (36% *vs* 26%) for recipients of consolidation (p=0.09); however, in the 74 patients who were in CR but MRD +ve, survival was significantly inferior with consolidation (11% *vs* 27%; p=0.03). In the 73 MRD -ve patients in the maintenance randomisation, there was a significant survival benefit for maintenance (40% *vs* 13%, p=0.003), but no difference for MRD +ve patients (20% *vs* 23%, p=0.9). There was no additional benefit from both consolidation and maintenance irrespective of MRD status.
Summary and Conclusions: Overall, neither a 3rd course nor demethylation maintenance improved survival. However in the ~50% of patients who achieved CR with course 1 who were MRD -ve, OS was improved by consolidation or maintenance but not incrementally by both. MRD appears to identify chemosensitive patients who benefit from additional treatment whereas the chemoinsensitive do not.
Acknowledgements: This study received research support from Cancer Research UK. Celgene provided Azacitidine for the trial.

S514

A COMPARISON OF DAUNORUBICIN/ARA-C *VERSUS* DAUNORUBICIN/CLOFARABINE AS INDUCTION TREATMENT IN OLDER PATIENTS WITH AML AND HIGH RISK MDS: LONG TERM RESULTS OF THE UK NCRI AML16 TRIAL IN 806 PATIENTS.

N. Russell[1,*] A. Burnett[2], L. Kjeldsen[3], D. Milligan[4], P. Cahalin[5], J. Kell[6], M. Dennis[7], R. Hills[8]
[1]Department of Haematology, Nottingham University Hospitals, Nottingham, [2]Blackwaterfoot, Isle of Arran, United Kingdom, [3]Rigshospitalet, Copenhagen, Denmark, [4]Birmingham Heartlands Hospital, Birmingham, [5]Blackpool Victoria Hospital, Blackpool, [6]Deparment of Haematology, University Hospital of Wales, Cardiff, [7]Department of Haematology, Christie Hospital, Manchester, [8]HCTU, Department of Haematology, Cardiff University School of Medicine, Cardiff, United Kingdom

Background: In older patients (>60yrs) the UK NCRI AML16 trial compared two courses of DA *vs* DClo induction with or without gemtuzumab ozogamicin (GO). The benefit of the addition of GO has been reported (Burnett *et al.* J Clin. Oncol *30*(32);3924-3931, 2012).
Aims: Based on a feasibility study a schedule of Clofarabine 20mg/m^2 d 1-5 was combined with Daunorubicin (Dauno) 50mg/m^2 d 1-3 for two courses, and compared with Dauno 50mg/m^2 d 1,3,5+ara-C 100mg/m^2 bid d 1-10 (course 1) or d 1-8 (course 2). Subsequently, patients with at least a partial remission (<15% marrow blasts) after course 1, and CR after course 2 were eligible to be randomised to one course of consolidation (Dauno 50mg/m^2 days 1, 2$^+$ara-C 100mg/m^2 bid days 1-5); patients in CR could be randomised to azacytidine maintenance or not.
Methods: From 8/2006-12/2009, 806 patients were randomised between DA and DClo, of whom 683 entered the GO randomisation. The median age was 67y (56-84); 72% had de novo, 17% secondary, and 11% high risk MDS; 4%, 73% and 23% had favourable, intermediate, poor risk cytogenetics; 14% were *FLT3*-ITD and 20% *NPM1* mutant; 30%, 34%, 36% had good, standard, poor Wheatley risk. Following the two courses of induction, 263 patients were randomised to 2 *vs* 3 courses (138 from DA and 125 from DClo; 42% were Wheatley good risk, 37% standard risk, 21% poor risk). 274 were randomised to maintenance or not (137 from DA and 137 from DClo). The post induction interventions will be reported separately, but are taken into account in this assessment of induction treatments. Follow-up is complete to 1/1/2014 (median FU 66 months).
Results: In the DA *vs* DClo randomisation, the overall response rate (ORR) was 68% (CR 61%, CRi 7%) and 5-year OS 14%. The ORR was not different between DA: 71% (CR 64%, CRi 6%) and DClo 66% (CR 58%, CRi 8%), OR 1.26 (0.94-1.70) p=0.12, with 60 day all-cause mortality of 15% and 14% respectively. Remission rates after course 1 were higher with DA (54% *vs* 47%, OR 1.33 (1.01-1.76) p=0.04). There were no significant differences between DA and DClo at 5 years in RFS (14% *vs* 15%, HR 0.98 (0.82-1.18) p=0.9), CIR (78% *vs* 71%, HR 0.92 (0.76-1.12) p=0.4), death in CR (8% *vs* 14%, HR 1.50 (0.90-2.49) p=0.12), survival from CR (20% *vs* 22%, HR 0.96 (0.79-1.16) p=0.6), survival from relapse (4% *vs* 7%, HR 0.92 (0.75-1.13) p=0.4) or OS (15% *vs* 14%, HR 1.04 (0.89-1.21) p=0.6). The schedules were equi-toxic, and although neutrophil and platelet recovery was quicker in the DA arm in both courses DClo patients received significantly less transfusion support, days on antibiotics and hospitalisation. There was no evidence of interaction between the two induction randomisations, or between the DA *vs* DClo randomisation and any demographic feature. There was no evidence of interaction between the number of courses (3 *vs* 2) or receipt of maintenance or not. 135/410 patients in the clofarabine induction randomisation who achieved CR post course 1had information for MRD by immuno-flow analysis (Freeman S. *et al.* J Clin. Oncol. *31;* 4123-4131, 2013), Of patients in morphological CR after the first induction course 48% of DA and 47% of DClo patients were MRD -ve which resulted in a survival of 25% and 37% respectively. For those who were in CR but were MRD +ve the survival was 14% for DA and 19% for DClo patients.
Summary and Conclusions: DA and DClo in induction give similar outcomes in older patients, with equivalent toxicity, and slightly lower resource usage on the DClo arm. Of patients in CR after course 1, as defined by immunoflow MRD +ve.

DASATINIB (DAS) IN COMBINATION WITH CHEMOTHERAPY AND AS MAINTENANCE IN CORE-BINDING FACTOR (CBF) ACUTE MYELOID LEUKEMIA (AML): A PHASE IB/IIA STUDY OF THE GERMAN-AUSTRIAN AML STUDY GROUP (AMLSG)

P. Paschka[1,*] R.F. Schlenk[1], D. Weber[1], W. Fiedler[2], M. Lübbert[3], M. Theobald[4], R. Greil[5], H.-A. Horst[6], J. Krauter[7], H.R. Salih[8], G. Heil[9], U. Martens[10], A. Kündgen[11], P. Brossart[12], M. Heuser[13], V.I. Gaidzik[1], F. Thol[13], G. Göhring[13], A. Ganser[13], K. Döhner[1], H. Döhner[1]

Salzburg, Salzburg, Austria, [6]Universitätsklinikum Schleswig-Holstein, Kiel, [7]Klinikum Braunschweig, Braunschweig, [8]Universitätsklinikum Tübingen, Tübingen, [9]Klinikum Lüdenscheid, Lüdenscheid, [10]SLK-Kliniken Heilbronn GmbH, Heilbronn, [11]Universitätsklinikum Düsseldorf, Düsseldorf, [12]Universitätsklinikum Bonn, Bonn, [13]Medizinische Hochschule Hannover, Hannover, Germany

Background: The outcome in CBF-AML [AML with t(8;21)(q22;q22) or inv(16)(p13.1q22) or t(16;16)(p13.1;q22)] has been largely improved by using repetitive cycles of high-dose cytarabine (HiDAC) for postremission treatment. However, still only half of the CBF-AML patients (pts) have a favorable long term outcome, indicating the need for improved therapeutic approaches. Dasatinib (DAS) is a multikinase inhibitor with activity against the KIT kinase, which is highly expressed in CBF-AML and mutated in around one third of the cases. In preclinical studies DAS inhibited growth and survival of AML progenitor cells, enhanced the sensitivity to chemotherapy and induced *in vitro* differentiation of AML cells (Dos Santos *et al.*, Blood 2013; Fang *et al.*, PLoS One 2013). Anecdotally, DAS also induced differentiation of blasts in an AML patient with t(8;21) after single-drug treatment (Chevalier *et al.*, Leukemia 2010).
Aims: The primary endpoint in the open-label AMLSG 11-08 study (NCT00850382) was to assess the feasibility of DAS after intensive induction and postremission chemotherapy, and as single agent in 1-year maintenance therapy in pts with newly diagnosed CBF-AML.
Methods: Adults [≥18 years (yrs)] with CBF-AML received induction with daunorubicin (60 mg/m^2/d, d1-3) and cytarabine (200 mg/m^2/d, d1-7); DAS 100 mg/d was added on days 8-21; pts with partial remission could receive a second induction cycle. Pts achieving a complete remission (CR) or CR with incomplete hematologic recovery (CRi), were intended to receive four cycles of HiDAC [cytarabine 3 g/m^2 (in pts >60 yrs 1 g/m^2) q12h, d1,3,5); DAS 100 mg/d was added on days 6-28 of each cycle. Maintenance with DAS 100 mg/d was continued for 1 year after completion of chemotherapy or until relapse.
Results: Eighty-nine pts [median age 48.5 yrs; males, n=47; t(8;21), n=37; inv(16), n=52] were included in the study. The median baseline WBC in AML with t(8;21) and inv(16) was 9.2 Giga (G)/l and 34.1 G/l, respectively. The current median follow-up is 2.9 yrs. The overall CR/CRi rate was 93% (83/89); CR/CRi rate in AML with t(8;21) and inv(16) was 94% and 92%, respectively. Overall, there were 2 cases with refractory disease and 5 cases with early/hypoplastic death. The median time until recovery of neutrophils (>0.5 G/l) and platelets (>20 G/l) after induction cycles was 27d and 23d, respectively, and after the consolidation cycles 22d and 21d, respectively. To date, a total of 64 serious adverse events (SAEs) with suspected causal relationship to DAS have been reported. Among them the most frequent SAEs were infection-related (n=23); they only rarely occurred during maintenance phase (n=2). Pleural/pericardial effusion and liver toxicity CTC ≥3° was reported in 11% (10/89) and 10% (9/89) of the pts, respectively. There was no significant difference in event-free (EFS) and relapse-free survival between AML with t(8;21) and inv(16), but overall survival (OS) was superior (P=.04) in AML with inv(16) (OS at 3-yrs: 80.5% *vs* 63.4%). When compared with an AMLSG historical control group, there was an improvement in EFS (P=.04), but so far not for OS (P=.4).
Summary and Conclusions: There was no unexpected excess in toxicity by the addition of DAS to intensive induction and postremission therapy as well as of single-agent maintenance. The preliminary data indicate efficacy of the treatment when compared to historical controls. Based on the favorable toxicity profile and the encouraging efficacy data, a confirmatory phase III trial with DAS (AMLSG 21-13; NCT02013648) has been initiated.

Biological pathway deregulation in B Cell Precursor ALL

S516

ABERRANT EXPRESSION OF THE STEM CELL MICRORNA-126 INDUCES B CELL MALIGNANCY

S. Nucera[1,*] F. Boccalatte[1], A. Giustacchini[1], A. Calabria[1], T. Plati[1], C. Fanciullo[1], J. Garcia Manteiga[2], F. Benedicenti[1], F. Ciceri[3], M. Ponzoni[4], L. Naldini[1], B. Gentner[1]

Background: MicroRNAs are essential regulators of normal and malignant hematopoiesis. We previously described the function of miR-126 in HSC where it regulates the balance between quiescence and self-renewal (Lechman *et al.*, 2012).
Aims: We aimed at studying the role of miR-126 in induction and maintenance of high-grade B cell malignancies in mouse and humans.
Methods: We exploited the following techniques: Transduction of murine bone marrow (BM) cells and human primary ALL blasts with lentiviral vectors (LV); LV integration site (IS) analysis by linear amplification mediated PCR and mapping on the murine genome; RNA sequencing; Immunofluorescence staining
Results: We here report a novel role for miR-126 in the induction and maintenance of high-grade B cell malignancies. By ectopically expressing miR-126 in transplanted BM cells, we observed that up to 60% of mice (n=71) developed B cell tumors. LV IS analysis revealed that all tumors were monoclonal. We then tracked back the leukemic clone to different hematopoietic lineages prospectively purified from the mice 2-6 months before disease onset. IS sharing between normal lineages and the leukemic clone suggests a stem or multipotent progenitor cell origin for most tumors. Importantly, we show that miR-126 is the direct cause for the induction and maintenance of leukemia, since (i) leukemogenesis is abolished when miRNA expression is inhibited by doxycycline (doxy) using a tetracycline-repressible miR-126 cassette, and (ii) established symptomatic leukemia completely regresses when miR-126 is switched off by doxy. We then performed RNA sequencing on blasts purified *ex vivo* before and 24 to 72h after doxy administration. Gene sets that changed were significantly enriched in migratory functions, cancer pathways and cell cycle regulators. Strikingly, there was a near-complete overlap with pathways that resulted significantly regulated by miR-126 in a second RNAseq dataset obtained from human cord blood (huCB) CD34+ cells following lentiviral miR-126 overexpression or knockdown. Many genes converged on the p53 pathway in both murine B-ALL and huCB CD34+ cells. Indeed, overexpression of miR-126 in huCB CD34+ cells physically displaced p53 from the nucleus and caused a significant reduction of its transcriptional activity. We identified a dozen of genes involved in p53 regulation that were directly targeted by miR-126 or miR-126*, suggesting extensive cooperative regulation of this central tumor suppressor pathway by miR-126. We further studied the function of miR-126 in Philadelphia+ human primary B acute lymphoblastic leukemia (Ph+ B-ALL) where miR-126 expression ranges from low to high in individual patients. We stably knocked down miR-126 in primary blasts from five Ph+ B-ALL patients using a miR-126 sponge LV. Following xenotransplantation, we observed increased apoptosis and impaired engraftment after primary and secondary transplantation in 4 out of 5 diseases (miR-126/KD: n=32 mice; Ctrl: n=37 mice), demonstrating the relevance of miR-126 in human B-ALL.
Summary and Conclusions: Down-regulation of miR-126 could be exploited as therapeutic strategy in ALL, since it would deplete leukemic cells while expanding normal HSC, two ways to restore normal hematopoieis.

Background: Somatic genetic abnormalities are key initiators and drivers of disease in acute lymphoblastic leukaemia (ALL). Several chromosomal abnormalities have proven clinical utility as prognostic and predictive biomarkers at initial diagnosis. However, the role of genetic biomarkers in relapsed ALL is less well understood and has rarely been studied comprehensively within a clinical trial.
Aims: To evaluate the role of genetics in predicting outcome among children with relapsed B-cell precursor ALL treated on the international trial, ALLR3.
Methods: We analysed cytogenetic, copy number alteration (CNA) and sequence mutation data at relapse in representative cohorts of patients. Patients with a very early relapse (<18 months from first diagnosis) and those patients with an isolated marrow relapse who had an early relapse (<6 months from stopping frontline therapy) were treated as clinical high risk (HR) whereas all other patients were treated as clinical standard risk (SR).
Results: Clinical HR patients accounted for 25% of the cohort and had a significantly inferior overall survival (OS) compared to SR patients: 25% (95% CI 15-37) v 65% (57-72), p<0.0001. A total of 427 patients were assigned to predefined cytogenetic risk groups which were predictive of survival post-relapse in both univariate and multivariate analysis adjusting for clinical risk: good risk (GR) cytogenetics (*ETV6-RUNX1*, high hyperdiploidy) 5 years OS 68% (60-75); intermediate risk (IR) cytogenetics (*TCF3-PBX1*, *IGH* translocations, B-other ALL) 47% (38-55); and HR cytogenetics (*BCR-ABL1*, *MLL* translocations, near haploidy, low hypodiploidy, iAMP21, *TCF3-HLF*) 26% (14-40), p<0.001. However, the prognostic effect of cytogenetic risk group was strongest within the clinical SR group. A representative cohort of 240 patients with marrow involvement was screened for CNA and mutations affecting key genes in ALL. Over 75% patients harboured at least one CNA or mutation: *CDKN2A/B* (39%), *IKZF1* (22%), *PAX5* (20%), *TP53* (17%), *ETV6* (16%), *KRAS* (12%), *NRAS* (12%), *NR3C1* (9%), *PAR1* (8%), *PTPN11* (8%), *RB1* (4%), *EBF1* (4%), *BTG1* (4%), *FLT3* (4%), *CBL* (1%). Cox models adjusted for clinical risk revealed that only four genes were associated with outcome. Patients with a *TP53* alteration or a deletion of either *NR3C1 or BTG1* had an inferior progression free survival (PFS) with hazard ratios of 2.07 (95% CI 1.20-3.58), p=0.009 and 2.26 (1.38-3.70), p=0.001, respectively. In addition, cytogenetic GR patients with a *NRAS* mutation had an inferior PFS compared with other GR cytogenetic patients 2.54 (1.24-5.22), p=0.01. The integration of clinical and cytogenetic risk groups with *TP53*, *NR3C1*, *BTG1* and *NRAS* gene status revealed three groups: (1) Favourable-clinical SR patients with GR cytogenetics and without a *TP53, NR3C1, BTG1* or *NRAS* abnormality; (2) Intermediate-clinical SR patients with GR cytogenetics and a *TP53, NR3C1, BTG1 or NRAS* abnormality plus clinical SR patients with IR cytogenetics; and (3) Adverse-all clinical and cytogenetic HR patients. The three groups accounted for 35%, 35% and 30% patients, respectively, and had markedly distinct OS rates: 78% (61-89), 56% (46-65) and 27% (19-35), p<0.001, respectively. Multivariate Cox models including variables for treatment and minimal residual disease did not materially alter the results. Receiver operating characteristic (ROC) curve analysis revealed that the new index had significantly greater predictive power than clinical risk alone for both PFS and OS: area under the curve (AUC)=0.73 v 0.67, p=0.02 and 0.75 v 0.69, p=0.03, respectively.
Summary and Conclusions: In conclusion, we have integrated key genetic information with clinical risk to improve risk prediction in relapsed ALL and propose a three-tier index which could be used to develop risk-directed therapy in future trials.

S518

CENTRAL NERVOUS SYSTEM ACUTE LYMPHOBLASTIC LEUKEMIA IS MEDIATED BY VASCULAR ENDOTHELIAL GROWTH FACTOR PROVIDING A NOVEL TARGET FOR DIRECTED THERAPY

V. Muench[1,*] L. Trentin[1], J. Herzig[1], J.M. Kraus[2], H.A. Kestler[2,3], G. te Kronnie[4], K.-M. Debatin[1], L.H. Meyer[1]
[1]Department of Pediatrics and Adolescent Medicine, Ulm University Medical Center, [2]Research Group Bioinformatics and Systems Biology, Ulm University, Ulm, [3]Leibniz Institute for Age Research, Fritz Lipmann Institute, Jena, Germany, [4]Laboratory of Oncohematology, Department of Women's and Children's Health, University of Padua, Padua, Italy

Background: In acute lymphoblastic leukemia (ALL), involvement of the central nervous system (CNS) is associated with adverse prognosis. Despite non-detectable CNS involvement in many cases, CNS-directed therapy is indispensible for relapse free survival indicating subclinical CNS manifestation in many patients. However, CNS therapy coincides with increased risk for secondary neoplasms and impaired cognitive skills in ALL survivors.
Aims: In this study, we aimed to characterize mechanisms mediating CNS involvement in ALL and to identify targets for CNS leukemia directed treatment.
Methods: Primary B-cell precursor (BCP) ALL cells were transplanted onto NOD/SCID mice. At onset of disease related morbidity, human ALL engraftment was analyzed in bone marrow (BM), spleen (S), peripheral blood (PB), and meninges of the recipients by flowcytometry staining for huCD19. Transcriptome profiles of ALL cells isolated from meningeal and BM infiltrates (8 pairs of 8 CNS+ ALLs) were analyzed. Gene expression was validated by qPCR. Proliferation, survival and trans-endothelial migration was analyzed in genetically modified (down-regulation or overexpression) ALL cells and in response to recombinant protein or an antagonizing antibody. In an *in vivo* model of CNS+ ALL, inhibition of CNS manifestation was evaluated.
Results: At onset of leukemia manifestation in recipients transplanted with BCP ALL, meningeal infiltration was detected along with ALL engraftment in BM, S and PB in a subset of samples (CNS+) in contrast to absent CNS involvement despite full-blown leukemia in BM, S and PB in others (CNS-). In line, magnetic resonance imaging revealed meningeal enhancement in CNS+ recipients. By expression profiling, the gene coding for *vascular endothelial growth factor A (VEGF)* was identified to be highly expressed in leukemia cells isolated from CNS as compared to BM-derived cells. Interestingly, VEGF was reported to mediate cell survival, vascular permeability and trans-endothelial cell migration and increased levels of VEGF protein were described in cerebrospinal fluid collected from CNS+ ALL and AML patients. Differential *VEGF* expression was confirmed in independent cohorts. VEGF receptor 1 expression was detected on all ALL cells. However, ALL cell proliferation and survival was not affected by VEGF overexpression, down-regulation, or exposure to VEGF or the antagonizing antibody bevacizumab. Further, we addressed the paracrine effect of VEGF on endothelial cells mediating trans-endothelial leukemia migration. Upon VEGF incubation, brain endothelial cells (bEND.3) showed induction of downstream VEGF receptor 2 signaling activity mediating cellular permeability. In a transwell assay, we identified VEGF-dependent trans-endothelial migration of BCP ALL cells (Nalm-6) with significantly increased or decreased migration in the presence of VEGF or bevacizumab through bEND.3 monolayers. Moreover, we investigated the effect of VEGF inhibition by bevacizumab on CNS leukemia manifestation in 3 patient-derived primografts (4 experiments including 1 replicate) *in vivo*. Most interestingly, in all 4 experiments anti-VEGF treatment significantly reduced the leukemia load exclusively in the CNS but not in BM, S and PB organ compartments indicating that the CNS+ phenotype is mediated by VEGF and can be controlled by VEGF inhibition.
Summary and Conclusions: We identified VEGF as a mediator of trans-endothelial leukemia cell migration and CNS manifestation in ALL. Most importantly, *in vivo* inhibition of VEGF by bevacizumab significantly decreased involvement of CNS ALL indicating a novel therapeutic strategy to control CNS leukemia.

S519

DEREGULATION OF SNO-RNAS IN THE GENOMICALLY IMPRINTED PRADER-WILLI LOCUS IN ERG-RELATED PEDIATRIC B CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA

E. Vendramini[1], [*]M. Giordan[2], E. Giarin[2], B. Michielotto[2], G. Fazio[3], G. Cazzaniga[3], A. Biondi[3], D. Silvestri[4], M.G. Valsecchi[4], M. Muckenthaler[5], A. Kulozik[5], S. Izraeli[1], G. Basso[2], G. te Kronnie[2]
[1]Sheba Medical Center, Ramat Gan, Israel, [2]Department of Women's and Children's Health, University of Padova, Padova, [3]Centro Ricerca Tettamanti, Clinica Pediatrica, University of Milano-Bicocca, Monza, [4]Department of Clinical Medicine and Prevention, University of Milano-Bicocca, Milano, Italy, [5]Department of Pediatric Oncology Hematology, University of Heidelberg, Heidelberg, Germany

Background: "ERG-related" childhood B cell precursor acute lymphoblastic leukemias (BCP-ALL) are characterized by a specific gene expression signature and by recurrent *ERG* intragenic deletion. ERG-related patients have a favourable outcome, despite a high incidence of *IKFZ1* deletions. Nothing is known about non-coding (nc) RNA regulation in this leukemia subtype.
Aims: To investigate the main features of ERG-related patients by integrative genomic and gene expression analysis in an Italian cohort of B-others ALLs enrolled in the AIEOP ALL 2000 therapeutic protocol with emphasis on ncRNAs.
Methods: 143 BCP-ALL patients lacking known genomic aberrations or a hyperdiploid karyotype ("B others") were assigned to the ERG-related subtype according to their gene expression profile (GEP) and *ERG* and *IKFZ1* aberrations were assessed by genomic analyses. A representative sub-cohort of "B others" including 8 ERG-related and 16 non-ERG-related samples were profiled by ncRNA microarray (Mirna1.0, Affymetrix) and validated by qRT-PCR.
Results: Non supervised clustering of 143 B-others patients identified a cluster of 35 samples (24.5%) in which 15 (45.5%) carried the *ERG* intragenic deletion. None of patients outside this "ERG-related" GEP cluster had *ERG* deletions. Similar to previous reports from BFM and EORTC childhood ALL protocols for the *ERG* deleted subgroup, our GEP defined ERG-related patients were characterized by more common *IKZF1* deletions (35.3% compared with 26.2% in non-ERG related) and a favourable outcome, with a cumulative relapse incidence at 5 years of 6%±4.1 *vs* 25.7%±4.3, p-value 0.03; (3/35 *vs* 29/108 relapses). Analysis of ncRNAs revealed two interesting findings: Upregulation of the oncogenic miR-125b-2 cluster (hsa-miR-125b, -125b-2*, -99a, let-7c) and the related hsa-miR-100, hsa-miR-125a-3p, and a specific signature of snoRNAs tightly clustered within the ERG-related group. Strikingly the differentially expressed snoRNA probe sets (adjusted p-value <0.05) were located mainly in the Prader-Willi syndrome (PWS) locus at chromosome 15q11.2, a locus controlled by genomic imprinting. These snoRNAs are processed from a paternally expressed transcript that includes the PWS imprinting center upstream from *SNURF/SNRPN*. Specifically, there was up-regulation of SNORD109a,

SNORD64, SNORD107 and 11 snoRNAs of the SNORD116 cluster (SNORD116-11, 14, 15, 16, 17, 20, 21, 22, 23, 24, 25) and downregulation of a subset of SNORD116 snoRNAs (SNORD116-4, 6, 10, 12, 13, 26) in ERG-related patients. Validation by qRT-PCR confirmed microarray findings.

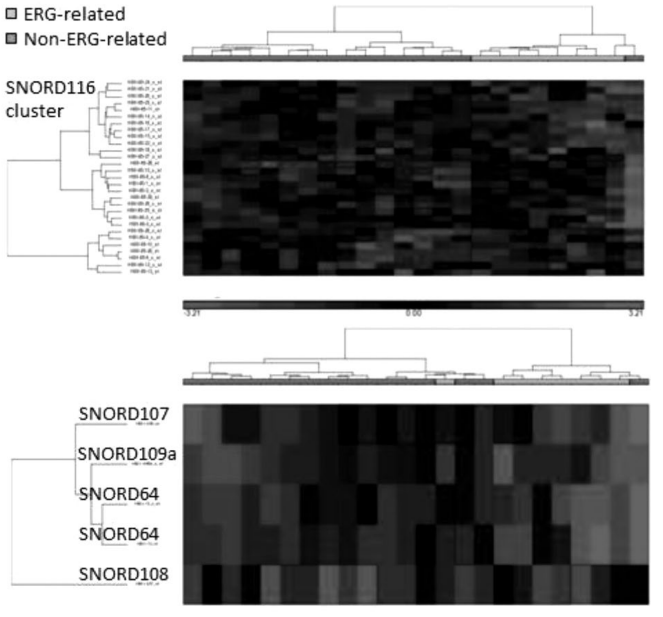

Figure 1.

Summary and Conclusions: ERG-related GEP defines a phenotypically unique subgroup in which only half carry *ERG* deletions, suggesting another underlying pathogenic mechanism beyond ERG intragenic deletion. We have identified a ncRNA signature specific of ERG-related BCP-ALL that can be used for differential diagnosis of these patients. While loss of imprinting associated with modified snoRNA expression was reported in acute promyelocytic leukemia, this is the first report of abnormal expression of snoRNAs in childhood BCP-ALL. The specific clustering of these snoRNAs within the imprinted PWS locus suggests a potential epigenetic mechanism underlying ERG-related ALLs.

Background: The translocation t(17;19)(q22;p13) results in the fusion of the transactivating domain of the B cell transcription factor TCF3 and the DNA binding domain of the hepatic leukemia factor HLF. TCF3-HLF defines a rare subtype of ALL that is currently incurable. In contrast, the fusion of the same portion of TCF3 to the PBX1 gene (t(1;19)) results in a leukemia subtype with a favorable prognosis. TCF3-HLF ALL constitutes a paradigm of treatment refractory leukemia in which the oncogenic fusion protein drives programs that are fundamental for the malignant process. However genetic engineering experiments in mice did not recapitulate disease, suggesting that the cellular context in which the translocation occurs is critical for transformation.
Aims: We explored the genetic landscape of ten TCF3-HLF positive ALL cases in comparison to TCF3-PBX1 positive ALL using primary diagnostic samples and corresponding patient derived leukemia xenografts in order to analyze whether TCF3-HLF is associated with characteristic patterns of genomic lesions and to establish a well characterized humanized mouse model for functional investigations.
Methods: We used an integrated multi-OMICs approach to identify mutation and gene expression patterns in TCF3-HLF- and TCF3-PBX1-positiveALL. To compare drug response profiles of treatment resistant TCF3-HLF-positive and responsive TCF3-PBX1-positive ALL we established a xenograft model of patient derived leukemia. At least two biological replicates per case were xenografted in NOD/SCID/IL2rγ^{null} (NSG) mice. Drug response profiles to a customized library of >100 therapeutic compounds were obtained and *in vivo* validation studies were performed using this model.
Results: In TCF3-HLF-positive ALL, intragenic deletions in the lymphoid transcription factor PAX5 or somatic mutations in the non-translocated allele of TCF3 (acting upstream of PAX5), but not in any of the IFKZ family members, were recurrent and frequently observed in conjunction with RAS pathway aberrations. The pattern of co-occurring mutations was not overlapping in TCF3-PBX1 ALL, supporting the notion that completely different genetic interactions may be required for disease pathogenesis. The profile of mutations was maintained in the corresponding xenografts. Sequence features at the translocation breakpoints suggested RAG mediated recombination and an already lymphoid-committed cell of origin, but the TCF3-HLF-positive ALL transcriptome was enriched for stem cell and myeloid features, consistent with reprogramming towards a hybrid, more drug-resistant hematopoietic state. This gene expression signature was maintained in matched patient-derived xenografts. TCF3-HLF-positive ALL revealed a distinct drug-response profile with resistance to some agents commonly used in ALL therapy, but sensitivity towards glucocorticoids and some therapeutic agents in clinical development. Striking on-target sensitivity was achieved with the BCL2-specific inhibitor ABT-199 indicating BCL2-dependency of TCF3-HLF-positive ALL. Our results show, that ABT-199 acts synergistically with conventional chemotherapeutic agents, including dexamethasone and vincristine, providing a rationale for experimental therapy.
Summary and Conclusions: The molecular portrait of TCF3-HLF-positive ALL indicates that the initiating event occurs in cells committed to the lymphoid lineage and that leukemogenesis requires a restricted pattern of additional genetic lesions. Maintenance of dominant genomic and transcriptomic patterns of both TCF3-translocated subtypes in the corresponding xenografts provides the basis for systematic functional investigations. Integration of drug response profiling revealed recurrent patterns of resistance and new options for the treatment of this deadly disease.

SPHINGOSINE KINASES ARE REQUIRED FOR IL-7-MEDIATED SIGNALING IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

A. Melão[1,*] J. Matos[1], H. Cadilha[1], J.T. Barata[1]
[1]Cancer Biology Unit, Instituto de Medicina Molecular, Lisboa, Portugal

Background: Acute lymphoblastic leukemia (ALL) is the most common pediatric malignancy. T-cell ALL is associated with high risk and poor prognosis. We have shown that IL-7, produced in the leukemia milieu by stromal cells, can accelerate leukemia progression *in vivo* and has a relevant contribution to the viability and proliferation of T-ALL cells (Silva *et al.*, Cancer Res 2011). Moreover, IL-7/IL-7R-mediated signaling may partake in leukemia development, as demonstrated by the identification of IL-7Rα gain-of-function mutations in around 9% of T-ALL patients (Zenatti *et al.*, Nat Genet 2011). Sphingosine Kinases (SPHKs), of which 2 isoforms have been described (SPHK1 and 2), are lipid kinases that promote cell viability by phosphorylating sphingosine and thereby regulating the ceramide/sphingosine 1-phosphate (S1P) rheostat. SPHKs play a fundamental role in many signaling pathways associated with cancer, although their involvement in leukemia development is not fully understood.
Aims: The aim of this study was to elucidate the crosstalk of SPHK isoenzymes and IL-7-mediated effects on pediatric T-ALL leukemogenesis.
Methods: SPHKs expression was determined by qRT-PCR, and activity measured by a luminescence-based assay. To test the involvement of SPHKs on IL-7-mediated signaling we incubated D1 (IL-7-dependent, thymocyte-like), TAIL7 (IL-7-dependent, T-ALL), HPB-ALL (IL-7-responsive, T-ALL) and DND-41 (IL-7Rα mutant, T-ALL) cell lines in the presence of IL-7 and/or SPHK1- or SPHK2-specific pharmacological inhibitors, SKi-II and K145 respectively. Cell viability was determined by flow cytometry analysis (FSCxSSC distribution and Annexin V/7AAD staining). Maintenance of mitochondrial membrane potential was measured by TMRE staining. Caspase 3 cleavage and activation of signaling pathways were measured by western blot. Proliferation was determined by evaluation of DNA synthesis upon ^{3}H-thymidine incorporation.
Results: We first observed that SPHK1, but not SPHK2, is increased in T-ALL patient samples as compared to normal controls. Analysis of SPHK activity revealed that IL-7 positively regulates SPHK activity without significantly affecting its expression. Furthermore, inhibition of SPHK1 or SPHK2 prevented the activation of both PI3K/AKT and JAK/STAT pathways in all cell lines studied, as determined by the phosphorylation status of key members of each pathway. These results suggest that SPHK activity is fundamental for the activation of pro-survival pathways derived from IL-7/IL-7R-dependent activation. In accordance, signaling downstream from IL-7 stimulation or IL-7Rα mutant activation was not able to improve leukemia cell viability upon SPHK inhibition. The antagonistic effect of SPHK inhibition on IL-7-mediated effects associated with increased apoptosis, decreased mitochondrial membrane potential and increased caspase-3 cleavage. Importantly, we found that both inhibitors completely prevented IL-7 viability effects not only in T-ALL cell lines but also in primary leukemia cells collected from patients at diagnosis. Moreover, T-ALL patient samples were significantly more sensitive to SPHK inhibition than their normal counterparts. Finally, we observed that T-ALL cell line proliferation upon IL-7 stimulation or IL-7Rα mutational activation was abrogated in the presence of SPHK inhibitors.
Summary and Conclusions: Our study identifies SPHK1 and 2 as essential modulators of IL-7-dependent activation of pro-survival and proliferative pathways in T-ALL, opening new possible therapeutic avenues in this pathology.

P522

MIR-146B IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: A POSSIBLE TUMOR SUPPRESSOR ROLE

N.C. Correia[1], R. Fragoso[1,*] V. Póvoa[1], F.J. Enguita[2], J.T. Barata[1]
[1]Cancer Biology Unit, [2]Instituto de Medicina Molecular, Lisboa, Portugal

Background: Regardless of improved therapy regimens, acute lymphoblastic leukemia from T-cell origin (T-ALL) is still not a curable disease. Therefore, the field currently faces the challenge of creating more efficacious therapies, rationally-designed and less toxic. A better understanding of the pathogenesis of the disease, namely molecular analysis of the common genetic alterations in leukemic cells, may be the solution to understand why some cases fail to respond to chemotherapy and to improve selective targeting of leukemic cells without long-term effects on the normal tissues. The transcription factor TAL1 is down-regulated early in T-cell development and over-expressed in more than 60% of pediatric T-ALL cases. TAL1 is able to either activate or repress the expression of downstream targets as part of a transcriptional complex.
Aims: This work aimed to contribute to a better comprehension of the biology of T-ALL, namely in relation to the means by which TAL1 exerts its oncogenic functions. Having shown previously that microRNA genes are regulated by TAL1 at the level of transcription (Correia *et al.*, *Leukemia* 2013), we hypothesized that some of these miRNAs may be part of the oncogenic network triggered by TAL1 ectopic expression in leukemia. We focused on miR-146b-5p and evaluated the functional and molecular effects of its deregulation by TAL1 in the context of T-ALL.
Methods: The expression of miR-146b-5p in T-ALL cell lines was determined by real time-PCR using LNA primers, whereas in T-ALL patients and normal counterparts it was analyzed from publicly available data (GSE51908 and Mets *et al.*, *Leukemia* 2014). To verify the functional effects of miR-146b aberrant expression in T-ALL we manipulated its levels in T-ALL cells using lentiviral transduction. *In vitro* functional assessment of the effects of miR-146b-5p modulation in T-ALL cell lines was performed by analysis of proliferation by cell counts, of viability by flow cytometry, and of migration and invasion by transwell assays. For the *in vivo* experiment ten NOD/SCID mice were either injected with CCRF-CEM cells over-expressing miR-146b or with mock transduced cells.
Results: The miR-146b-5p was found to be down-regulated by TAL1 in cell lines (Correia *et al.*, *Leukemia* 2013). We now further verified that pediatric T-ALL patients over-expressing TAL1 display significantly lower miR-146b-5p levels than other T-ALL patients (p=0.002). Moreover, T-ALL patients significantly express lower levels of miR-146b-5p compared to normal cells (p<0.0001). This led us to hypothesize that miR-146b-5p has a tumor suppressor role in this disease. Our results point to a direct down-regulation of miR-146b-5p by TAL1. Although no clear differences were found concerning cell viability or proliferation, miR-146-5p reduced expression improved the migration and invasion capacities of T-ALL cells. Moreover, we showed that over-expression of miR-146b in human T-ALL cells significantly increased the survival of recipient mice (p=0.039) in a xenotransplant model of human leukemia.
Summary and Conclusions: We have shown that miR-146b-5p is a functionally relevant TAL1 microRNA target gene, whose down-regulation may contribute to T-ALL by modulating leukemia cell motility and disease aggressiveness.

P523

IL-7 ACTIVATES THE JAK/STAT5/PIM1 KINASE AXIS THEREBY MEDIATING VIABILITY AND GROWTH OF T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

D. Ribeiro[1,*] A. Melão[1], R. van Boxtel[2], C.I. Santos[1], M.C. Silva[1], A. Silva[1], B.A. Cardoso[1], L.F. Moita[1], P.J. Coffer[2], J.T. Barata[1]
[1]Instituto de Medicina Molacular, Lisboa, Portugal, [2]UMC Utrecht, Utrecht, Netherlands

Background: T-cell acute lymphoblastic leukemia (T-ALL) constitutes, in general, an aggressive subset of ALL, the most frequent childhood malignancy. Although risk-adjusted chemotherapeutic regimens are currently extremely effective, their efficacy is associated with significant long-term side effects and those cases that relapse have dismal prognosis. New, more specific, therapies are therefore required. To achieve this goal it is essential to have a better understanding of T-ALL biology, including the contribution of tumor microenvironmental factors for leukemia progression. Interleukin 7 (IL-7) is produced in the bone marrow and thymus. While IL-7 is essential for normal T-cell development, there is also considerable evidence that it can partake in leukemia expansion. Previously, we have shown that IL-7 promotes T-ALL expansion *in vivo* (Silva *et al.*, Cancer Res. 2011) and leukemia cell survival and proliferation *in vitro* by activating PI3K/Akt/mTOR signaling pathway (Barata *et al.*, J Exp Med. 2004), consequently downregulating $p27^{kip1}$ and upregulating Bcl-2. However, it is also known that T-cell lymphomas arising spontaneously in IL-7 transgenic mice depend on STAT5 activity and IL7R gain-of-function mutations, found in around 10% of T-ALL patients (Zenatti *et al.*, Nat Genet. 2011), drive JAK/STAT5 pathway activation.
Aims: To investigate whether the JAK/STAT5 pathway may be involved in the IL-7/IL-7R pro-leukemia effects in human T-ALL.
Methods: We used an IL-7-dependent leukemia T-cell line (TAIL7), an IL-7-responsive T-ALL cell line (HPB-ALL) or primary T-ALL samples collected at diagnosis as cellular models. We used pharmacological inhibitors of JAK3 (WHI-P131), STATs in general (parthenolide), STAT5 in particular (N-((4-Oxo-4H-chromen-3-yl)methylene)nicotinohydrazide) and PIM1 (Smi-4a). Analysis of viability, cell size, cell cycle, surface CD71 and Bcl-2 expression was performed by flow cytometry. Signaling pathway activation, STAT5, PIM1 and cell cycle protein expression was performed by western blot analysis. Proliferation was assessed by ^{3}H-Thymidine incorporation. STAT5 ChIP-seq and RNA-seq were performed on TAIL7 cells.
Results: We show that IL-7 induces JAK1/3-STAT5 pathway activation, STAT5 DNA binding and transcriptional activity. To test the potential clinical applicability of these findings, we treated TAIL7 cells or primary T-ALL samples with inhibitors of JAK3, STATs in general or STAT5 in particular. All inhibitors abrogate IL-7-mediated T-ALL cell viability, growth and proliferation, with complete inhibition of IL-7-induced downmodulation of $p27^{kip1}$, upregulation of cyclin A and increased transferrin receptor (CD71) surface expression. Interestingly, IL-7-dependent Bcl-2 upregulation is not affected by STAT5 inhibition. To understand how STAT5 mediates the survival effects of IL-7 in T-ALL cells without affecting Bcl-2, we performed STAT5 ChIP-seq together with RNA-seq. Cross-analysis of the data revealed that IL-7 drives transcription of the serine/threo-

nine kinase PIM1 via STAT5. Notably, inhibition of PIM1 kinase activity abrogates IL-7-mediated T-ALL cell growth, viability and proliferation.
Summary and Conclusions: Overall, our results indicate that a JAK/STAT5/PIM1 axis is mandatory for IL-7/IL-7R-mediated T-ALL cell survival. Furthermore, these results indicate that JAK/STAT5 pathway inhibitors can eliminate T-ALL cells and that STAT5 plays a major role in mediating IL-7/IL-7R signaling effects in T-ALL cells, therefore constituting a promising target for therapeutic intervention in this malignancy.

P524

JAK2 MUTATIONS ARE HIGHLY ENRICHED IN CRLF2-REARRANGED B-ALL CASES WITH A PH-LIKE GENE SIGNATURE

T. Sadras[1,2,*] S. Heatley[1,2], E. Nievergall[1], C. Kok[1,2], P. Dang[1], D. Yeung[3,4], D. Watkins[1,2], S. Moore[5], T. Hughes[1,2,3,4], D. White[1,2,6]
[1]Cancer, South Australian Health and Medical Research Institute, [2]Discipline of Medicine, University of Adelaide, [3]Centre for Cancer Biology, [4]Department of Haematology, [5]Department of Genetic Pathology, SA Pathology, [6]Discipline of Paediatrics, University of Adelaide, Adelaide, Australia

Background: High expression of *CRLF2* occurs in 5-15% of adult and pediatric B-ALLs, and commonly results from a cryptic deletion that juxtaposes *CRLF2* to the promoter of *P2RY8* (*P2RY8-CRLF2*), or from the translocation of *CRLF2* to the immunoglobulin heavy chain locus (*IGH-CRLF2*), bringing *CLRF2* under the control of *IGH* enhancer elements. *CRLF2* overexpression alone is not sufficient for leukemic transformation, requiring additional oncogenic lesions, and a large proportion of *CRLF2*-rearranged cases harbor activating mutations in *JAK2*, and less commonly in *JAK1*. To date, the prognostic significance of *CRLF2* rearrangements (*CRLF2*-r) remains debatable, although recent reports demonstrate that *CRLF2*-r are enriched in Ph-like ALL, a high-risk sub-type. In this study we show that Ph-like B-ALL cases with *CRLF2*-r represent a distinct genetic sub-group that may reflect underlying differences in secondary cooperating lesions and disease progression.
Aims: The aims of this investigation are to characterize the genetic and biological differences between Ph-like and non-Ph-like *CRLF2*-r B-ALL cases, to better understand the prognostic significance and targetable pathways in these patients that have previously been grouped in one class.
Methods: Patients with high *CRLF2* expression detected by Taqman Low Density Arrays (TLDA), were screened for *P2RY8-CRLF2* and *IGH-CRLF2* rearrangements by RT-PCR and FISH, respectively. Ph-like ALL cases were identified by TLDA analysis using a customized 9-gene signature. gDNA from *CRLF2*-r samples was analyzed for *JAK1/2* mutations by Sanger sequencing, and where possible, phospho-flow cytometry detecting pathway activation of downstream kinase targets was used to assess sensitivity to JAK inhibitors *in vitro*.
Results: We have screened >300 B-ALL samples from our Australian cohort (age between 0.5 and 75 years) and identified 27 *CRLF2*-r cases (*P2RY8-CRLF2* n=14 and *IGH-CRLF2* n=13). Interestingly, the frequency of *IGH-CRLF2* rearrangements increased with age. Activating *JAK2* mutations were found in 10/27 cases (R683G/S n=4; F694L n=1; D873N n=1 and D875N n=4) and consistent with prior reports all cases harboring *JAK2* mutations that were tested, responded to JAK inhibitors *in vitro*. No *JAK1* mutations were identified in this cohort. Importantly, TLDA analysis showed that 20/27 cases classified as Ph-like, and these samples also expressed significantly higher levels of *MUC4* and *GPR110* than the non-Ph-like *CRLF2*-r cases, despite no significant difference in *CRLF2* levels. Most strikingly, the activating *JAK2* mutations were restricted to the Ph-like patients. Of note a rare non-synonymous polymporphism in *JAK2* (R1063H) was detected in one of the non-Ph-like patients. Importantly, these results suggest that *JAK2* mutations are highly enriched in Ph-like *CRLF2*-r cases, likely indicating differences in disease etiology, and highlighting the heterogeneity of ALL which can be observed within a subset of patients that harbor identical translocations, and which have previously been analyzed as one group. We are currently using NGS approaches to further elucidate the genetic landscape of *CRLF2*-r patients, with a particular focus on the Ph-like patients lacking *JAK2* mutations and the non-Ph-like subset of B-ALLs.
Summary and Conclusions: We propose that Ph-like and non-Ph-like *CRLF2*-r cases compose prognostically and biologically distinct groups of B-ALL patients that should be studied as independent entities, possibly addressing some of the discrepancies previously observed in large studies of *CRLF2* deregulation in ALL. Importantly, further study of these sub-groups may provide critical leads for the development of novel targeted therapies.

P525

CLONAL ORIGINS OF HIGH-HYPERDIPLOID ACUTE LYMPHOBLASTIC LEUKEMIA

D. Alpar[1,*] D. Wren[2], M.B. Mansur[1], N.E. Potter[1], C.M. Bateman[1], T. Szczepanski[3], D. Gonzalez de Castro[2], A.M. Ford[1], M. Greaves[1]
[1]Centre for Evolution and Cancer, Institute of Cancer Research, London, [2]Molecular Diagnostics, The Centre for Molecular Pathology, The Royal Marsden NHS FT, London, United Kingdom, [3]Department of Pediatric Hematology and Oncology, Zabrze, Medical University of Silesia, Katowice, Poland

Background: Monozygotic twins with concordant leukemia provide a unique model to analyze the timing and early genetic steps of leukemogenesis. Our previous studies on twins and cord blood samples revealed that pre-leukemic clones of high-hyperdiploid acute lymphoblastic leukemia (HHD ALL) are prenatal in origin.
Aims: Identification of the fetal cell type which is transformed in HHD ALL.
Methods: Diagnostic bone marrow samples from three monozygotic twin pairs concordant for HHD B-cell precursor ALL were screened for all varieties of immunoglobulin (*IG*) and T-cell receptor (*TCR*) gene rearrangements, which are hallmarks of lymphoid cell development, using a combination of targeted next-generation sequencing and conventional screening approaches. Identical rearrangements shared by twin siblings and indicative of the *IG/TCR* status of the cells giving rise to pre-leukemic clones were identified. Previous genome-wide SNP-array analysis indicated trisomy of chromosome 14 in all six patients. The study was conducted in accordance with the Declaration of Helsinki.
Results: In total, 23 rearrangements were identified in the three twin pairs. Clonal rearrangements were detected in *IGH*, *IGK*, *IGL*, *TCRD*, *TCRG* and *TCRB* genes in 6, 2, 1, 3, 1 and 2 patients, respectively. At least two different rearrangements were found in each child. Seven identical junctions shared by the siblings were observed with the following distribution: twins 1A/B *IGH* VDJx2 (non-functional); 2A/B *IGH* DJx2 and 3A/B *IGH* VDJx1 (non-functional), *IGK* VKdex1 and *TCRD* VD2-DD3x1. All these rearrangements must have occurred in the pre-leukemic cell population formed *in utero*. The majority of clonal markers proved to be patient-specific and is likely to have arisen post-natally in twin-specific sub-clones.
Summary and Conclusions: To date, only conventional screening of *IG/TCR* gene rearrangements was reported in a limited number of twins with concordant HHD ALL. We have carried out a comprehensive screen for these rearrangements in a cohort of twin pairs, also using advanced genomics. Our data suggest that the pre-leukemic clone spawned *in utero*, and shared by the twins, has the *IG* and *TCR* feature of precursor B-cells in all twin pairs tested. These results add to the accumulating evidence that the formation of the hyperdiploid karyotype can arise *in utero*, probably as an initiating mutation and it most likely occurs in early B-lineage progenitors at the stage of or after RAG-dependent *IGH* rearrangement. Therefore, the pre-leukemic clone expands preferentially in the pro- or pre-B lineage compartment, initially in one twin and spreads into the sibling via shared circulation. Clonally descendent cells with self-renewal stem cell activity are sustained in both twins after birth as independent targets for a number of secondary genetic hits - copy number changes and sequence mutations - essential for clinical development of ALL.

P526

INTEGRATED ANALYSIS OF JAK/STAT, RAS/AKT AND NOTCH1 PATHWAYS IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: PROGNOSTIC AND THERAPEUTIC IMPLICATIONS

V. Gianfelici[1,*] S. Chiaretti[1], N. Peragine[1], F. Di Giacomo[1,2], M. Messina[1], F. Paoloni[3], V. Apicella[1], A.M. Testi[1], A. Vitale[1], J. Cools[4,5], M. Vignetti[1,3], A. Guarini[1], R. Foà[1]
[1]Department of Cellular Biotechnologies and Hematology, "Sapienza" University of Rome, Rome, [2]Department of Molecular Biotechnology and Health Science, and Center for Experimental Research and Medical Studies (CeRMS), University of Turin, Turin, [3]Fondazione GIMEMA Onlus, Rome, Italy, [4]Center for Human Genetics, University of Leuven, [5]Center for the Biology of Disease, VIB, Leuven, Belgium

Background: We previously reported a high rate of mutations in the JAK/STAT and RAS/AKT pathways in refractory/early relapsed T-cell acute lymphoblastic leukemia (T-ALL) cases analyzed by RNAseq (Gianfelici *et al.*, ASH 2013). Conversely, the NOTCH1/FBXW7 pathway was less frequently affected.
Aims: Screening of JAK/STAT, RAS/AKT and NOTCH1/FBXW7 was performed to confirm their prognostic impact in T-ALL. *In vitro* assays were carried out to assess the sensitivity of primary cells to specific inhibitors.
Methods: The study included 49 adult T-ALL cases (median age 37 years, range 16-59) enrolled in 2 consecutive Italian GIMEMA ALL protocols, for which genomic material was available. Both refractory and responsive cases were included. Hotspot mutations of *JAK3*, *JAK1*, *IL7R* and *STAT5B* for JAK/STAT signaling, *N/K-RAS*, *PTEN* and *FLT3* for RAS/AKT and *NOTCH1/FBXW7* were analyzed by Sanger sequencing. Overall survival (OS) and disease-free survival (DFS) were estimated using the Kaplan-Meier method. The JAK1/2 inhibitor Ruxolitinib and the JAK3 selective inhibitor Tofacitinib were tested on primary diagnostic cells. Following 72 hours of incubation, proliferation and cytotoxicity were determined using the MTT assay.
Results: Eight T-ALL cases (16%) harbored JAK/STAT mutations, namely *JAK1* (n=3), *JAK3* (n=3), *STAT5B* (n=2) and *IL7R* (n=3). All *STAT5B* mutants carried concomitant mutations in *JAK3* (1 of them also had a *JAK1* mutation), whereas the *IL7R* positive patients had no additional mutations of the same pathway. RAS/AKT alterations were found in 10 cases (20%), namely *PTEN* (n=5), *N/K-RAS* (n=4) and *FLT3* (n=1). NOTCH1/FBXW7 mutations were found in 28 cases (57%), in 16 without additional alterations, while in 12 a concomitant mutation in JAK/STAT (n=8) or *N/K-RAS* (n=4) was documented. We observed an enrichment of JAK/STAT and RAS/AKT alterations within the group of patients developing

an early relapse or refractoriness: 6/8 and 7/10, respectively. A significantly shorter OS and DFS was observed in patients harboring JAK/STAT mutations compared to patients without alterations in the pathway: 15.7 *vs* 27.3 months (p=0.04) and 11 months *vs* median not reached (p=0.002), respectively. Similarly, a significantly shorter OS and worse DFS were observed in cases with RAS/AKT alterations compared to patients without alterations in the pathway: 7.9 *vs* 27.3 months (p=0.0108) and 4.3 *vs* 33.2 months (p=0.0005), respectively. Conversely, OS and DFS were significantly better for cases harboring NOTCH1/FBXW7 mutations alone compared to wild-type patients or cases with concomitant JAK/STAT or RAS/AKT mutations: median not reached *vs* 18.7 *vs* 15.7 months, respectively, (p=0.0325), and median not reached *vs* 14.5 *vs* 9.8 months, respectively (p=0.0015). Primary cells from *JAK1* mutated patients proved sensitive to Ruxolitinib, whereas viability was not affected by Tofacitinib, documenting a selective sensitivity to Ruxolitinib. Furthermore, primary cells carrying *JAK1* and *JAK3* mutations in association with a *STAT5B* alteration were poorly sensitive both to Ruxolitinib and to Tofacitinib.

Summary and Conclusions: This study documents the negative prognostic impact of JAK/STAT and RAS/AKT mutations in T-ALL, at least when standard chemotherapy regimens are used. Notably, the favorable impact of NOTCH1/FBXW7 was overcome by the presence of concomitant JAK/STAT or RAS/AKT mutations. Finally, *in vitro* experiments demonstrate that inhibitors directed specifically against the underlying lesions may be effective on primary T-ALL cells.

P527

DISTINCT ALL-ASSOCIATED JAK3 MUTANTS EXHIBIT DIFFERENT CYTOKINE-RECEPTOR REQUIREMENTS AND JAK-INHIBITOR SPECIFICITIES

E. Losdyck[1,2,*] L. Springuel[1,2], T. Hornakova[1,2], S. Degryse[3,4], J. Cools[3,4], S. Constantinescu[1,2], E. Flex[5], M. Tartaglia[5], J.-C. Renauld[1,2], L. Knoops[1,2,6]
[1]de Duve Institute, Université catholique de Louvain, [2]Ludwig Cancer Research, Brussels, [3]VIB Center for the Biology of the Disease, [4]KU Leuven Center for Human Genetics, Leuven, Belgium, [5]Istituto Superiore di Sanità, Rome, Italy, [6]Hematology unit, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Background: JAK1 and JAK3, which are intracellular tyrosine kinases associated to cytokine receptors, are recurrently mutated in acute lymphoblastic leukemia. These mutations are activating and scattered through the kinase and pseudokinase domains, which contrasts with the unique pseudokinase V617F mutation in JAK2 that is prevalent in myeloproliferative neoplasms. JAK1 and JAK3 associate with heterodimeric receptors such as IL-7R or IL-9R, in which JAK1 is appended to the specific chain and JAK3 to the common gamma chain.

Aims: To study the role of cytokine receptor complexes in mediating the oncogenic activity of JAK3 mutants.

Methods: STAT5 transcriptional activity downstream JAK3 mutants was assessed by measurements of luciferase expression in HEK293 cells or JAK1-deficient U4C cells upon transient co-transfection of appropriate cDNA constructs with a reporter construct harboring STAT5-responsive elements upstream a luciferase gene. Same experiments were conducted for JAK1 and JAK2 mutants. *In vivo* transforming characteristics of JAK3 mutants were studied by transplantation of mouse bone marrow progenitor cells transduced with retroviral vectors expressing JAK3 mutants in irradiated Balb/c mice. JAK3 mutants' sensitivity to JAK inhibitors was assesed by treating growth factor-independent Ba/F3 cells obtained after stable transduction with JAK3 mutants with increasing JAK inhibitors concentrations and measuring their proliferation using a tritiated thymidine incorporation assay. Phosphorylation of STATs and JAK proteins in these cells was also analyzed by western blotting.

Results: Our study demonstrated that $JAK3^{V674A}$ and the majority of other JAK3 mutants need to bind to a functional cytokine receptor complex in order to constitutively activate STAT5. However, one mutant, $JAK3^{L857P}$, was unexpectedly found to not depend on such receptor complexes for its activity, which was induced without receptor or JAK1 co-expression. Introducing a mutation in the FERM domain that abolished JAK-receptor interaction did not affect $JAK3^{L857P}$ activity, while it inhibited the other receptor-dependent mutants. The same cytokine receptor independence as for $JAK3^{L857P}$ was observed for homologous L^{857} mutations of JAK1 and JAK2 and for $JAK3^{L875H}$. This different cytokine receptor requirement correlated with different functional properties *in vivo* and with distinct sensitivity to JAK inhibitors. Transduction of murine hematopoietic cells with $JAK3^{V674A}$ led homogenously to lymphoblastic leukemias in mice. In contrast, transduction with $JAK3^{L857P}$ induced various types of lymphoid and myeloid leukemias, illustrating a broader oncogenic potential related to the absence of cytokine receptor restriction. Ruxolitinib, which preferentially blocks JAK1 and JAK2, abolished the proliferation of cells transformed by $JAK3^{V674A}$, which requires a functional JAK1-JAK3 associated receptor complex, yet proved much less potent on cells expressing $JAK3^{L857P}$. These particular cells were, in contrast, more sensitive to JAK3-specific inhibitors.

Summary and Conclusions: Altogether, our results have demonstrated that different JAK3 mutations can induce constitutive activation through distinct mechanisms, suggesting that an improved understanding of these mechanisms could offer new therapeutic perspectives.

P528

XIAP EXHIBITS AN ESSENTIAL ROLE FOR PATIENTS' ALL CELLS GROWING *IN VIVO* AS SHOWN BY A NOVEL TECHNIQUE FOR STABLE KNOCKDOWN IN PATIENT-DERIVED XENOGRAFT (PDX) ALL CELLS

M. Carlet[1,*] J. Vergalli[1], C. Finkenzeller[1], M. Grunert[1], I. Jeremias[1,2]
[1]Department of Gene Vectors, Helmholtz Zentrum Muenchen, [2]Oncology, Dr. von Haunersches Kinderspital, LMU, Muenchen, Germany

Background: Acute lymphoblastic leukemia (ALL) is a frequent disease in children and adults. XIAP, the X-linked inhibitor of apoptosis, is an anti-apoptotic protein which is frequently and highly overexpressed in hematological malignancies. Up-regulation of XIAP was shown to be associated with inferior prognosis of patients in various different types of tumors. No data exist so far on XIAP's role for growth and survival of hematological malignancies *in vivo*.

Aims: We aimed at characterizing the role of XIAP for survival and growth of patient-derived xenograft (PDX) acute lymphoblastic leukemia (ALL) cells *in vivo*. Towards this aim, we had to establish a novel technique allowing stable knockdown in PDX ALL cells.

Methods: Primary tumor cells from ALL patients were transplanted into severely immune-compromised NSG mice. PDX ALL cells were lentivirally transduced with a construct allowing stable knockdown in these cells. We decided to embed the shRNA in the context of a miRNA background using miR30 as it allowed expressing the shRNA under a Pol II promoter and coupling it to the expression of transgenes. We expressed different fluorochromes such that expression of blue indicated cells with control knockdown and expression of green cells with knockdown of XIAP. Additionally, we expressed either a codon optimized version of Firefly luciferase or a membrane bound form of Gaussia luciferase which require different substrates, Luciferine and Coelenterazine, respectively. Expression of luciferases enabled *in vivo* imaging for highly sensitive, reliable and continuous follow up of the growth of each subpopulation *in vivo.* Several established B-ALL and T-ALL cell lines were transduced in the same way. Taken together, we expressed the different luciferases and colors such that control cells and cells with knockdown of XIAP could be distinguished *in vivo* using dual luciferase imaging and post mortem using flow cytometry. We finally injected both populations into a single mouse and monitored the distribution of the two populations over time.

Results: Knockdown of XIAP in PDX ALL cells lead to the reduction of the XIAP protein by more than 90% as shown by Western Blot. Knockdown remained stable over three passages indicating a highly stable knockdown by our novel technical approach. In cell lines, down-regulation of XIAP expression did not affect proliferation of different T- and B-ALL cell lines *in vitro*, nor engraftment and development of preB-ALL NALM6 cells in NSG mice. In contrast, down-regulation of XIAP expression significantly reduced tumor load of PDX ALL samples *in vivo*, as measured both by dual luciferase imaging *in vivo* and by *ex vivo* quantification of the leukemic subpopulations using flow cytometric analysis of the different colors.

Summary and Conclusions: We established a technique allowing efficient silencing of target genes in PDX ALL cells growing in mice together with convenient readout systems. Our data show that the role of XIAP is highly different in cell lines and in PDX ALL cells. Targeting XIAP by knockdown significantly reduces leukemia burden in PDX ALL cells *in vivo.* Our novel technical approach for knockdown in PDX ALL cells *in vivo* enables the preclinical testing of the role of putative therapeutic targets in PDX cells. Cell lines represent unsuitable models for predicting the role of XIAP in PDX ALL cells *in vivo*. Upregulation of XIAP constitutes an essential oncogenic alteration in PDX ALL cells; XIAP represents a promising target for treatment of ALL.

P529

EXPRESSION OF GATA3 DEPENDS ON GENOTYPE VARIANT AT RS3824662 AND IS ASSOCIATED WITH CLINICAL COURSE OF B-CELL CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

J. Madzio[1,*] A. Pastorczak[1], M. Braun[1], J. Taha[1], M. Romiszewska[2], M. Matysiak[3], K. Derwich[4], M. Lejman[5], K. Jerzy[5], W. Badowska[6], B. Kazanowska[7], T. Szczepanski[8], J. Styczynski[9], J. Trelinska[1], B. Zalewska-Szewczyk[1], N. Irga-Jaworska[10], W. Mlynarski[1]

Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz, [10]Department of Pediatric Hematology, Oncology and Endocrinology, Medical University, Gdansk, Poland

Background: Polymorphic site at rs3824662 in *GATA3* gene is a susceptibility locus for newly identified subtype of BCP-ALL associated with poor outcome called *BCR-ABL1*-like.
Aims: The main purpose of the study was to investigate an association between the genotype variant at rs3824662 of *GATA3* gene and *GATA3* expression level in leukemic cells at diagnosis of childhood ALL as well as genetic and clinical features of pediatric ALL.
Methods: Between November 2010 and January 2015, 452 pediatric patients (median age 8.5 yrs; median follow-up 2.3±1.7 yrs), with newly diagnosed BCP-ALL treated according to ALL-IC BFM09 protocol in 15 centers of the Polish Pediatric Leukemia/Lymphoma Study Group were enrolled into the study. Patients with BCR/ABL gene fusion, MLL rearrangements, hypodiploidy, Down syndrome were excluded from analysis. MRD was measured at day 15 of induction therapy using FCM with EuroFlow 8-color antibody panels (n=358). Targeted copy number screening of selected 23 loci was performed on available DNA samples (n=448) by using the MLPA methods. Determination of genotype at polymorphic locus rs3824662 was performed in all the patients' samples using allelic discrimination assay. *GATA3* mRNA expression was quantified by Q-PCR using FAM-MGB probe.
Results: Genotype distribution in studied group: AA: n=26 (6%); CA: n=148 (33%); CC: n=278 (62%). Genotype variant AA at rs3824662 was associated with higher level of *GATA3* mRNA expression compared to CA and CC variant, with mean -0.11; -1.45 and -3.88 respectively (p=0.02).
We have not succeeded in defining microdeletion profile specific for polymorphic variant. Among AA homozygotes 27% are *IKZF1* deletion carriers, whereas among CA and CC genotypes 16% and 13% respectively. However, after exclusion of TEL/AML rearrangements and hyperdiploidy AA homozygous were more likely to be carriers of *IKZF1* deletion risk allele compared with patient without this defect (p=0.03). Homozygotes AA showed higher WBC level at diagnosis of childhood ALL compared to CA and CC variant, with median 13.8 [1000/μL] (quartiles: 7.3-50.0); 13.2 (q: 4.90-44.70); 9.7 (q: 4.40-25.00) respectively, p=0.05 and were older with median 7.6 (q: 4.20-12.11); 5.0 (q: 3.11-9.31); 4.3 (q: 2.75-7.68) and with p=0.05). There was no difference in terms of MRD level at day 15 between patients with specific genotype in *GATA3* gene.
Summary and Conclusions: The expression of *GATA3* gene in leukemic cells was associated with genotype variant at rs3824662 in the study cohort. Furthermore, carriers of AA variant at rs3824662 of *GATA3* showed clinical features at ALL diagnosis related with poor treatment outcome.

P530

PATIENT'S SINGLE STEM CELL CLONES OF ACUTE LYMPHOBLASTIC LEUKEMIA SHOW DRUG RESISTANCE AND SLOW PROLIFERATION IN MICE *IN VIVO*

C. Finkenzeller[1,*] M. Carlet[1], S. Vosberg[2,3,4,5], S. Wolf[2], P.A. Greif[2,3,4,5], I. Jeremias[1,2,3,6]
[1]Helmholtz Zentrum Munich, Munich, [2]German Cancer Research Center (DKFZ), [3]German Cancer Consortium (DKTK), Heidelberg, [4]Department of Internal Medicine III, University Hospital LMU Munich, [5]Clinical Cooperative Group Leukemia, Helmholtz Zentrum München, Germany, [6]Dr. von Hauner-sches Kinderspital, Oncology, Ludwig Maximilians University, Munich, Germany

Background: Acute lymphoblastic leukemia (ALL) consists of heterogeneous cell populations and the most aggressive subpopulation determines prognosis and outcome in each patient. Each subpopulation relies on a different ALL stem cell and a better understanding of challenging subclones is intensively required.
Aims: We aimed at functionally characterizing single stem cell clones *in vivo* regarding growth behavior and drug resistance and at correlating clone-specific functional characteristics with genetic features using a sample from a child with ALL growing in mice.
Methods: Primary tumor cells from a 5-year old girl with hyperdiploid ALL at first relapse were transplanted into severely immune-compromised mice and lentivirally modified to express the fluorochromes red, green and blue at different amounts and combinations (RGB marking, Weber *et al.*, 2011). Single cell clones were generated by limiting dilution transplantation and their uniqueness was verified by LM-PCR. Single cell clones were re-mixed for *in vivo* assays and analyzed one-by-one by flow cytometry where they could be distinguished from each other using their unique color expression. *In vivo* experiments were performed to evaluate spontaneous growth rate as well as drug resistance. Single cell clones and bulk cells were genetically analyzed for their exome, methylome and gene expression (RNA sequencing).
Results: 8 single stem cell subclones were generated and compared between each other and bulk cells. When several combinations of two clones were mixed within the same recipient mice, one clone overgrew the other in different amounts indicating that different clones grow at different rates. *In vitro*, chemosensitivity differed between several clones tested, especially regarding stimulation with glucocorticoids, including resistant clones. Two clones were mixed and transplanted into several mice and some mice were treated with glucocorticoids while others received buffer. One clone showed a significantly reduced sensitivity towards *in vivo* glucocorticoid treatment compared to the second clone indicating selective drug sensitivity in single cell clones. Exome sequencing and DNA methylation profiling revealed that passaging a bulk sample results in few changes only, while recurrent additional mutations in two clones suggest a common ancestor subclone. Individual clones showed divergent mutational and methylation signatures compared to the parental bulk sample. Glucocorticoid resistant clones show more alterations compared to sensitive clones.
Summary and Conclusions: Taken together, combining the individualized xenograft mouse model with genetic engineering allowed multicolor marking and generating viable single cell clones for functional characterization *in vivo*. Within the heterogeneous tumor bulk, aggressive subclones exist showing slow tumor growth or drug resistance which is associated with inferior genetic characteristics. Our studies allow the functional characterization of challenging subclones *in vivo* in order to develop efficient novel treatment approaches to eliminate aggressive stem cell clones in ALL.

P531

A RARE SUBPOPULATION OF QUIESCENT, DRUG RESISTANT STEM CELLS IN PATIENTS' ALL CELLS GROWING IN MICE

S. Tiedt[1], S. Ebinger[1], C. Castro Alves[1], E. Özdemir[1], O. Gires[2], I. Jeremias[1,*]
[1]Gene Vectors, Helmholtz Center Munich, [2]Otorhinolaryngology, Clinics of University Munich, Munich, Germany

Background: While ALL cells display major genetic heterogeneity upon clonal evolution, leukemia initiating potential is homogenously shared between many, if not all ALL cells. Nevertheless, drug resistant residual disease might persist after successful treatment cycles suggesting functional heterogeneity in ALL in response to therapy. We decided using quiescence as benchmark in searching for a clinically relevant subgroup of ALL cells.
Aims: We aimed at evaluating whether patients' ALL cells growing in mice exhibit differences in proliferation rate, drug sensitivity and stem cell behavior and whether a challenging subpopulation of stem cell might exist which is quiescent and drug resistant.
Methods: We engrafted patients' primary ALL cells in NSG mice. To monitor ALL growth patterns, we established a technique allowing for unbiased re-isolation of small numbers of human ALL cells from murine bone marrow. Towards this aim, we lentivirally transduced patient-derived ALL cells to express NGFR, a red fluorochrome and luciferase. A combined MACS/FACS procedure based on the expression of the transgenes enabled more than 10.000-fold enrichment of human ALL cells from murine bone marrow.
Results: CFSE labeling revealed a rare subpopulation of *in vivo* long-term quiescent cells which had not divided, even if tumor mass had increased by 3 orders of magnitude and 50% of the time from cell injection to animal's death by leukemia had passed. Re-transplantation into secondary recipients revealed that quiescent cells converted into cycling cells and vice-versa suggesting a major plasticity of patients' ALL cells *in vivo*. Limiting dilution transplantation assays revealed that both quiescent and cycling cells exhibited similar, high stem cell frequencies which were not further increased in quiescent cells. *In vitro*, quiescent and cycling cells displayed similar sensitivity towards cytotoxic drugs after 3 days of stimulation. In contrast and clinically most importantly, quiescent ALL cells displayed severe resistance against *in vivo* treatment of mice with cytotoxic drugs used in routine treatment of ALL patients; while the amount of cycling cells was decreased by more than 1 order of magnitude, the amount of quiescent cells remained completely unchanged.
Summary and Conclusions: Our data suggest that ALL consists of functionally heterogeneous cells. Non cell-autonomous factors and stimuli determine important functions of ALL cells. As the study was restricted to analysis of bone marrow, bone marrow niche factors determine both growth rate as well as drug sensitivity of patient-derived ALL cells *in vivo*. We conclude that uncoupling ALL cells from the bone marrow niche might represent an attractive approach for bringing these cells back into the cell cycle and sensitizing them towards chemotherapy. In summary, genetic engineering of ALL xenograft cells enabled the sensitive isolation and enrichment of ALL cells from murine bone marrow. We identified a small subpopulation of *in vivo* long-term quiescent and drug resistant cells in patient-derived ALL cells which obtain their phenotype from external stimuli exerted from the bone marrow niche. These cells might be important targets for therapy and should be considered when evaluating novel therapeutic approaches to treat ALL.

Acute lymphoblastic leukemia - Clinical 2

P532

PROGNOSIS IN OLDER/ELDERLY PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKAEMIA DIAGNOSED 2005-2012: RESULTS FROM A SWEDISH POPULATION-BASED STUDY

E. Bergfelt[1,*] P. Kozlowski[2], M. Åström[2], L. Ahlberg[3], P. Bernell[4], E. Hulegårdh[5], H. Karbach[6], K. Karlsson[7], B. Tomaszewska-Toporska[7], H. Hallböök[1]
[1]Haematology, Dept of Medical Sciences, Uppsala University, Uppsala, [2]Haematology Section, Dept of Medicine, Faculty of Medicine and Health, Örebro University, Örebro, [3]Dept of Haematology, University Hospital of Linköping, Linköping, [4]Div of Haematology, Dept of Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, [5]Dept of Haematology and Coagulation, Sahlgrenska University Hospital, Göteborg, [6]Dept of Haematology, Cancer Center, University Hospital of Umeå, Umeå, [7]Dept of Haematology, Skåne University Hospital, Lund, Sweden

Background: The knowledge of treatment results in older patients with acute lymphoblastic leukemia (ALL) is modest and derives mostly from clinical studies where selection mechanisms are present.
Aims: The aim of this study was to assess the outcome of treatment according to national guidelines in an unselected cohort of older/elderly ALL patients.
Methods: Data regarding all patients aged 55-85 years diagnosed with ALL from 2005 to 2012 in Sweden was obtained from the Swedish Acute Leukaemia Registry and the Swedish Acute Lymphoblastic Leukaemia Registry. Both are truly population-based registries with prospectively reported information including: date of diagnosis, phenotype, WHO performance status (WHO 0-4), treatment intention (induction therapy or palliative treatment), stem cell transplantation and dates of morphologic complete remission (CR)/relapse/death. Statistical analysis was carried out with SPSS v 22 (IBM). Overall survival (OS) was defined as time from diagnosis until last follow up or death. OS was calculated by the Kaplan-Meier method. Univariable and bivariable analyses regarding prognostic factors were performed using the Cox proportional hazards regression. Logistic regression was used to determine factors related to treatment decisions. Vital status was obtained until the 22nd of August 2014.
Results: In total, 182 patients (90 males and 92 females) with a median and mean age of 68 years were reported. Median follow up time of survivors was 61 (range: 20-115) months. Immunophenotype was reported for 172 patients; B-ALL 142 (82%), Burkitt-leukemia 17 (10%), and T-ALL 13 (8%). The median age in these groups was 67, 74 and 70 years, respectively. Induction therapy was given to 144 (79%), resulting in CR for 110/144 (76%) patients. Three year OS was 27 (95% CI, 20-33)% for all patients, 33 (95% CI, 25-41)% for patients receiving induction therapy, and 3 (95% CI, 0-8)% for patients reported as receiving palliative treatment (p<0.001, logrank test). The corresponding median OS was; 10 (95% CI, 6-14), 15 (95% CI, 11-19), and 1 (95% CI, 0-2) months respectively. Allogeneic stem cell transplantation was performed upfront in 19 patients (mean age 60; range: 55-66 years). CR frequency and OS for different age and WHO performance status groups are displayed in Table 1.
Treatment intention, age (as continuous variable), WHO performance status (0-1 *versus* 2-4), and gender were identified as significant prognostic factors for OS. The proportion of patients receiving induction treatment was negatively correlated to age and WHO performance status (p<0.001). Among 14 patients >80 years only three received induction therapy and none survived beyond one year. Although a significant difference in OS was found for the whole population regarding gender, sub-group analysis revealed that the difference was mainly located in the 55-64 year cohort (p<0.01, adjusted for WHO status) and was demonstrated also within the B-ALL cohort separately.

Table 1.

Age	N	OS 3y (95% CI) %	Induction therapy N (%)	CR %	OS 3y (95% CI) %
55-64 y:	69	41 (29-53)	67 (97)	79	42 (30-54)
Males	31	25 (9-40)	30 (97)	77	26 (10-42)
Females	38	55 (38-71)**	37 (97)	81	56 (40-72)**
65-74 y	68	24 (14-34)**	58 (85)	78	28 (16-40)
75-85 y	45	9 (1-17)**	19 (42)	63	16 (1-32)*
WHO 0-1	127	31 (23-40)	111 (87)	75	35 (26-44)
WHO 2-4	53	17 (7-27)**	32 (60)	84	28 (12-44)

* p< 0.05, **p≤ 0.01 log-rank test

Summary and Conclusions: We conclude that intensive ALL treatment could be given successfully to an older population up to at least 75 years of age. Age and performance status are important factors for decisions regarding treatment intensity and outcome. The difference in OS between males and females aged 55-64 years is striking and will need further evaluation. Elaborate studies regarding given treatments and risk factors are ongoing.

P533

GENOME-WIDE ANALYSIS OF WDR5 BINDING REVEALS ITS EFFECT ON TUMORIGENESIS IN ACUTE LEUKEMIA

Z. Ge[1,*] C. Song[2], R. Zhang[1], X. Guo[1], M. Li[1], J. Li[1]
[1]The First Affiliated Hospital of Nanjing Medical University, Nanjing, China, [2]Pennsylvania State University Medical College, Hershey, United States

Background: Mixed-lineage leukemia (MLL) fusion proteins are potent inducer of leukemia. It is reported that MLL fusion proteins lost their histone modification activity. WD repeat domain 5 (WDR5) is the conserved component in the multi-subunit complex of SET1 family enzymes with direct methyltransferase activity. WDR5 itself may also have histone H3 trimethyl Lysine 4 (H3K4me3) methyltransferase activity. We observed that WDR5 was significantly increased in the patients with acute leukemia.
Aims: To identify the global binding profiling of WDR5 and H3K4me3 in leukemia cells and to explore the role of WDR5-mediated H3K4 methylation in the leukemogenesis.
Methods: Bone marrow samples from 120 patients with newly diagnosed acute leukemia, including 60 cases of acute lymphoblastic leukemia (ALL) and 60 cases of acute myeloid leukemia (AML), were collected between June 2008 and July 2013 at the First Affiliated Hospital of Nanjing Medical University. All the patients provided their written informed consent in accordance with the Declaration of Helsinki before enrollment in the study. The study was approved by the Institutional Review Board of the Nanjing Medical University. Quantitative PCR was performed to detect the expression of WDR5 in the patients and 40 normal controls. ChIP-Seq analysis for WDR5 and H3K4me3 were done and ChIP-seq libraries were sequenced in two MLL-rearranged leukemia cell lines RS4:11(MLL-AF4) and THP-1(MLL-AF9). The peaks were called using Cisgenome 2.0 and SISSRS. The overlapping of WDR5 peaks and H3K4me3 peaks was analyzed.
Results: We found more than 10,000 H3K4me3 peaks in two detected MLL-rearranged leukemia cell lines RS4:11 and THP-1 which express MLL fusion proteins. This result indicated that H3K4me3 is highly genomic enriched in the cells and suggested that there is a mechanism responsible for the genomic recruitment of H3K4me3. Moreover, we examined the expression of the WDR5 in patients with acute leukemia and found WDR5 high expression in this cohort of patients. We also observed the interaction of WDR5 with the MLL protein in the MLL-rearranged cells by co-immunoprecipitation. We further identified the global genomic binding of WDR5 in RS4:11 and THP-1 cells by ChIP-seq and detected more than 2000 binding peaks in the two leukemia cells. Importantly, we found the genomic co-localization of WDR5 binding with H3K4me3 enrichment and WDR5 with H3K4me3 binds to the promoter regions of important genes involved in leukemogenesis and hematopoiesis. Our data suggested that WDR5-mediated H3K4 methylation plays an important role in the leukemogenesis.
Summary and Conclusions: WDR5 expression significantly increased in adult ALL and AML patients. We demonstrated global enrichment of H3K4me3 binding around WDR5 binding peaks and co-existence of WDR5 and H3K4me3 binding in promoter region of oncogenes in MLL-rearranged leukemia cells.

P534

IMPACT OF STEROID DOSE AT INDUCTION PHASE OF PEDIATRIC ALL ON MINIMAL RESIDUAL DISEASE AND SURVIVAL OF THE PATIENTS: A PROSPECTIVE RANDOMIZED STUDY

S. Unal[1,*] T. Bayhan[1], S. Aytac[1], B. Tavil[1], B. Kuskonmaz[1], M. Tuncer[1], F. Gumruk[1], M. Cetin[1]
[1]Hacettepe University, Division of Pediatric Hematology, Ankara, Turkey

Background: Previous studies have demonstrated apoptosis induction effect of high dose methylprednisolone (MPZ) on lymphoblasts. In a previous study, high dose MPZ (900 mg/m2) during induction therapy of children with acute lymphoblastic leukemia (ALL) was compared with standard dose prednisolone (60 mg/m2) and increased cure rates were shown with high dose MPZ therapy.
Aims: Aim of the study is to compare effectiveness of two different high doses of MPZ, both doses being higher than the standard doses, during induction phase of therapy.
Methods: Pediatric patients newly diagnosed with ALL between 2008 and 2014 were enrolled. Patients were randomized for high doses of MPZ treatment, which was given for 7 days before commencement of induction phase of St Jude Total XV protocol, at doses of 10 mg/kg/day or 20 mg/kg/day, po. The steroid dose was tapered to 5 mg/kg/day and 10 mg/kg/day, in each group respectively by the 2nd week and concomitant chemotherapy was initiated. By the 3rd week of diagnosis, steroid dose was tapered to 2 mg/kg/day in both groups and continued at this dose upto the end of induction phase. Minimal residual disease (MRD) levels were measured by flow cytometry at 15th, 22nd, and 42nd days of induction. Event-free (EFS) and overall survival (OS) rates were calculated with Kaplan-Meier analyses.
Results: A total of 154 pediatric patients with newly diagnosed ALL were enrolled in the study. When the patients who were initiated full dose chemotherapy earlier, without a 1 week steroid only course, were excluded, a total of 141 patients were randomized to each dose group (n=78 and n=63 patients in 10

and 20 mg/kg/day groups, respectively). Patient characteristics of the study group were summarized in Table 1. Median age of patients was 5 (1-19) years, male/female ratio was 1.4. Majority of the patients were CALLA+ B cell ALL (80.5%) and t(9;22) positivity was detected in 7 (4.5%). CNS involvement was present in 6 (3.9%) of the patients . The two dose groups were similar in terms of age at diagnosis, gender, flow type, CNS and t(9;22) positivity. The MRD levels on 15th, 22nd, and 42nd days between two groups were statistically indifferent (Table 1). To investigate the effect of MPZ dose on MRD of 42nd day, effects of age, initial white blood cell count, t(9;22) positivity and neutropenic fever were adjusted using ANCOVA test, and still there wasn't statistical difference between these groups (p=0.83). Median follow-up was 33 (1-85) months. Five year OS of patients treated with 10 and 20 mg/kg/day MPZ were 85±5% and 92±4%, respectively (p=0.29). Five year EFS of patients treated with 10 and 20 mg/kg/day MPZ were 83±6% and 86±7%, respectively (p=0.34).

Table 1. Comparison of MRD levels based on initial MPZ dose

	10 mg/kg MPZ*	20 mg/kg MPZ	p
MRD on 15th day	1 (0-814)	1 (0-896)	0.92
MRD on 22nd day	0 (0-323)	0.5 (0-378)	0.14
MRD on 42nd day	0.5 (0-959)	0.5 (0-1449)	0.80

** Median (range); MPZ, methylprednisolone; MRD, minimal residual disease.*

Summary and Conclusions: Related to our published institutional previous experience of the better outcomes of patients at higher doses of steroid at induction; we aimed to find out whether lesser doses MPZ were still effective, although still higher than the standard recommended doses. Our study indicates that the survival rates and MRD levels are similar among patients treated initially with 10 mg/kg/day MPZ compared to 20 mg/kg/day.

P535

IKZF1 DELETION AND PROGNOSIS OF ADULTS WITH COMMON B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Q.-M. Yao[1,*] K.-Y. Liu[1], R.P. Gale[2], B. Jiang[1], Y.-R. Liu[1], Q. Jiang[1], H. Jiang[1], X.-H. Zhang[1], S.-S. Chen[1], X.-J. Huang[1], L.-P. Xu[1], G.-R. Ruan[1]
[1]Peking University People's Hospital and Institute of Hematology, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China, [2]Haematology Research Center, Division of Experimental Medicine, Department of Medicine, Imperial College London, London, United Kingdom

Background: The role of IKZF1 deletions is extensively-evaluated in children with ALL and is the most common genetic maker associated with a poor prognosis. Few data are available on the role of IKZF1 deletions in adults with common B-cell ALL.
Aims: To Interrogate the impact of IKZF1 deletion on therapy-outcomes of adults with common B-cell acute lymphoblastic leukemia.
Methods: 144 adults with common B-cell ALL achieved complete remission were tested for IKZF1 deletion. Deletions in IKZF1 were detected using multiplex RQ-PCR, multiplex fluorescent PCR, sequence analysis and multiplex ligation-dependent probe amplification (MLPA). All subjects received chemotherapy and some also received an allotransplant and tyrosine kinase-inhibitors, especially those with BCR/ABL. Multivariate analyses were done to identify associations between IKZF1 deletion and other variables on cumulative incidence of relapse (CIR), leukemia-free survival (LFS) and survival.
Results: IKZF1 deletion was detected in 66/144 subjects (49%). Amongst subjects achieving complete remission those with IKZF1 deletion had a higher 5-year CIR (39% [38-40%] *vs* 19% [18-20%]; *P*=0.010) and worse 5-year LFS (34% [16-52%] *vs* 60% [42-74%]; *P*=0.009) and survival (48% [32-62%] *vs* 76% [58-87%]; *P*=0.001, Figure1). In multivariate analyses IKZF1 deletion was independently associated with an increased relapse (relative risk [RR]=2.8, [1.4-5.8]; *P*=0.005), a higher risk of treatment-failure (inverse of LFS; RR=2.3, [1.3-4.2]; *P*=0.007) and a higher risk of death (RR=3.0, [1.5-6.3]; *P*=0.003). The adverse impact of IKZF1 deletion on outcomes was stronger in subjects without *vs* with BCR/ABL and in subjects receiving chemotherapy-only *vs* an allotransplant.

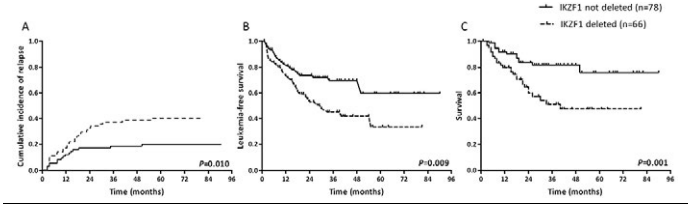

Figure 1. A) Cumulative incidence of relapse (CIR), B) leukemia-free survival (LFS) and C) survival of subjects with and without IKZF1 deletion.

Summary and Conclusions: IKZF1 deletion was independently-associated with a higher relapse risk and worse LFS and survival in adults with common B-cell ALL after adjusting for other prognostic variables and differences in therapies. These data suggest IKZF1 deletion may be a useful prognostic variable in adult common B-cell ALL, especially in persons without BCR/ABL and those receiving chemotherapy-only.

P536

EXTENSIVE PHENOTYPIC CHARACTERIZATION AND CYTOKINE PRODUCTION OF WHOLE BLOOD AT DAY 29 OF INDUCTION CHEMOTHERAPY FOR PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA

N. Rolf[1,*] A. Kariminia[1], K.K. Smolen[2], C. Strahlendorf[1], G.S. Reid[1]
[1]Pediatric Hem/Onc/BMT, [2]Experimental Medicine, University of British Columbia/Child & Family Research Institute, Vancouver, Canada

Background: Despite significant improvements in cure rates, recurrent acute lymphoblastic leukemia (ALL) causes 10% of childhood cancer deaths and the need for new treatment strategies has not diminished. Although ALL has long been viewed as a poor target for immune therapy, it has recently been reported that the peripheral blood absolute lymphocyte count (ALC) at completion of induction chemotherapy (Day 29) is prognostic for outcome. This finding suggests that the immune environment during therapy may play a role in protecting against disease progression. It is currently unknown, however, whether ALC is simply a marker of bone marrow recovery or whether particular immune cell subsets at this early time-point confer a beneficial effect.
Aims: To address this question, we have initiated a study to evaluate the lymphocyte composition as well as cytokine production after stimulation of whole blood with a panel of Toll-like receptor (TLR) ligands. Peripheral blood was obtained at Day 29 from children undergoing therapy for precursor B cell ALL at BC Children's Hospital. The goal of this study is to correlate the size and responsiveness of the immune cell subsets with ALC in order to identify potential immune-mediators of the high ALC-associated favorable outcome.
Methods: The study was approved by the University of British Columbia Ethics Board. Freshly collected whole blood was immediately processed for i) multicolour flow cytometry and ii) 24 hour stimulation with a panel of Toll-like receptor (TLR) ligands. We next performed an extensive phenotypic characterization of 20 immune cell subsets and also measured cytokine production in the supernatant of TLR ligand-stimulated whole blood.
Results: To date we have evaluated 11 patients for T cells (5 subsets), B cells (6 subsets), NK cells (3 subsets), NKT cells (2 subsets), dendritic cells (2 subsets), monocytes, and granulocytes. Although we have not yet identified a single lymphocyte population that significantly correlates with ALC, clear trends, most notably with myeloid dendritic cells, have emerged that suggest that ALC may be indicative of specific immune activity. TLR ligand-induced cytokine production is currently being quantified to determine whether higher ALC correlates with a specific pattern of response.
Summary and Conclusions: While a large-scale prospective study to validate prognostic significance of ALC in children with high-risk ALL is underway, to our knowledge our ongoing study is the first to investigate the specific immune cell composition of Day 29 peripheral whole blood for significant links with ALC. The identification of the mechanism(s) underlying ALC-associated outcomes may reveal novel strategies for enhanced immune-mediated control of ALL after chemotherapy.

P537

NONE OF THE COMMON RISK FACTORS IS SIGNIFICANT IN T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA TREATED ACCORDING TO NON-INTENSIVE BUT NON-INTERRUPTIVE PROTOCOL ALL-2009: RESULTS OF THE RUSSIAN ALL STUDY GROUP

Background: T-cell ALL is a distinct subgroup of ALL with better prognosis than B-cell ALL, especially with high-dose chemotherapy and allogeneic HSCT

in the majority of high risk patients (pts). RALL has initiated a prospective multicenter trial for adult Ph-negative ALL based on non-intensive but non-interruptive protocol "ALL-2009" (ClinicalTrials.gov public site; NCT01193933). The therapy was unified for all pts, but in T-cell ALL autologous hematopoietic stem cell transplantation (auto-HSCT) after non-myeloablative BEAM conditioning followed by prolonged maintenance was scheduled as late intensification. Allo-HSCT was planned to be an option for high risk pts with sibling donors.
Aims: Assess risk factors significance in T-cell acute lymphoblastic leukemia treated according ALL-2009 protocol.
Methods: From Jan 2009, till Dec 2014, 30 centers enrolled 263 ALL pts, including 90 (34,2%) T-cell ALL cases. Median age was 28 years (15-56 years), 33f/57 m; early T-cell (TI/II) phenotype was verified in 44 (49%), mature (T-IV) - in 11 (12%), thymic (TIII, CD1a+) ALL - in 35 pts (39%). T-lymphoblastic lymphoma (T-LBL) was diagnosed in 18,4%, CNS disease - 13,4%, mediastinal tumor - 57,3%. Cytogenetics was done in 61% of pts (n=55): 9% (n=5) had no mitosis, 45,5% (n=25) - normal karyotype, 45,5% (n=25) - different aberrations. 23% of pts (n=21) were in the standard risk, 77% (n=69) - in the high risk group (WBC >100; EGIL T-I-II-IV; LDH >2N; late CR). MRD levels by PCR analysis for clonal TCR rearrangements (10-3) before auto-HSCT were studied only in the minority of pts (n=7). The analysis was performed in Dec 2014. The median follow-up was 27,4 mo.
Results: CR rate in 86 available for analysis patients was 89,5% (n=77), induction death was registered in 5,8% (n=5), resistance - in 4,7% (n=4). CR was achieved after prephase in 16% (n=12) and after the 1st phase of induction - in 56% of pts (n=43). There was 28% of late responders (n=22). CR rate was higher -100% - in 34 thymic T-ALL pts in comparison with 85,7% in 42 early T-ALL and 70% in 10 mature T-ALL pts due to higher early death rate (7,1% and 10%, respectively) and more resistant forms (4,2% and 20%, respectively). Allo- HSCT was done in 6 pts (TI/II=4, T-IV=2) at a median of 7,2 mo from CR, all are alive without relapse. Only 28 of 77 (36%) CR pts underwent HSCT due to logistics problems and refusals. Auto-HSCT was done at a median time of 6 mo from CR and pts proceeded to further maintenance. We compared disease-free survival (DFS) and probability of relapse incidence (RI) in transplanted pts and those who survived in CR ≥6 months (land-mark) receiving only chemotherapy (n=27). Land-mark analysis demonstrated the essential benefit of auto-HSCT: DFS from time of transplantation was 100% and from land-mark for chemotherapy group - 66% (p=0,03). There were no relapses after auto-HSCT. RI at 5 years in the chemotherapy group constituted 21% (p=0,047). The MRD before HSCT was negative in 6 of 7 evaluated pts. At 5 years overall survival (OS) for the whole group constituted - 66%, DFS - 76% (Figure 1). In a multivariate analysis no relation was found between OS or DFS or RI and age, gender, initial risk group, T-LBL, leukocytosis, immunophenotype, late response, CNS disease, treating center.

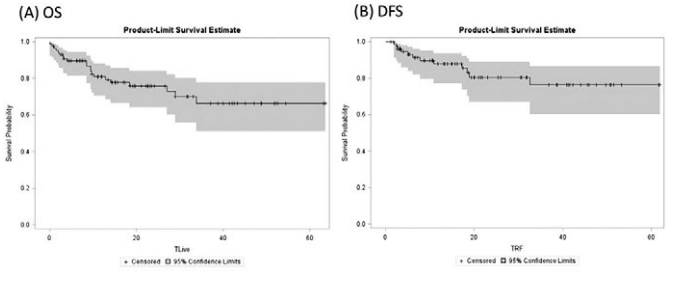

Figure 1.

Summary and Conclusions: Though small our data demonstrate that non-intensive, but non-interruptive treatment approach is effective. Auto-HSCT after BEAM conditioning followed by maintenance provides an adequate alternative to allo-HSCT. OS and DFS were not found to be depended on various common risk factors.

P538

OSTEONECROSIS IN AIEOP ALL 2000 AND 2006R TRIALS

R. Parasole[1,*] D. Silvestri[2], M.G. Valsecchi[2], E. Barisone[3], N. Santoro[4], C. Micalizzi[5], R. Mura[6], M. Zecca[7], A.M. Testi[8], L.D. Notarangelo[9], F. Petruzziello[1], C. Consarino[10], T. Casini[11], C. Rizzari[12], V. Conter[12]

Gerardo, Monza, Italy

Background: Osteonecrosis (ON) is a potentially disabling complication in children and adolescents treated for acute lymphoblastic leukaemia (ALL), that could negatively impact on the quality of life (QoL).
Aims: We retrospectively assessed the incidence of ON and sequelae on patients enrolled in 2 consecutive ALL trials (ALL 2000 and 2006R) of the Italian Association of Pediatric Hematology and Oncology (AIEOP), from September 2000 to December 2011.
Methods: Using ad hoc report forms, data on 3691 ALL patients were reviewed in AIEOP participating centers in order to identify ON occurrence, ON-related symptoms, radiological findings, treatment, risk factors and outcome. Patients with Ph+ ALL, infants or who underwent an hematopoietic stem cell transplant (HSCT), in first remission or after relapse, were excluded from the study. Descriptive statistics and chi-square test for association were used. Cumulative incidence of ON were estimated adjusting for competing risks and compared with the Gray test.
Results: Overall, 99 ON (2.7%) were identified of whom 82% were symptomatic. ON was diagnosed during induction/consolidation therapy in 12% of patients, during reinduction in 24% and during maintenance or after therapy discontinuation in 64% of cases. The 5-year cumulative incidence of ON was significantly different by age, being 9.9% (n=77) in 781 patients ≥10 years *vs* 0.8% (n=22) in those under this age (p <0.001). Within each of these two age groups, the incidence of ON did not differ by gender, white blood cell count at onset, immunophenotype B or T lineage, type of steroid induction (dexamethasone or prednisone) and was not greater in patients treated in the high risk arm or in patients who received cranial radiotherapy. Table 1 summarizes the characteristics of patients aged ≥10 years. ON incidence in our study does not seem related to other risk factors such as obesity or thyroid dysfunctions. Involved-site was single in one-third of cases; the most frequent sites were hip, knee, ankle and shoulder. ON (unilateral or bilateral) in these sites was diagnosed in 64%, 51%, 35% and 9% of patients, respectively. ON-related treatment was performed in 34 (41%) patients, including: arthroprothesis' intervention (n=21), therapy with bisphosphonates (n=9) or other non-invasive procedures, such as physiokinesitherapy (n=4). At the last follow-up visit, 81% of patients were asymptomatic, 12% had persistent pain without functional limitations and 7% had pain with limitations of daily activities.

Table 1. Characteristics of patients aged ≥10 years.

	ON		No ON		TOTAL

Pred	61	*10.2*	535	*89.8*	596
p-value=0.64					

Summary and Conclusions: This study confirms that ON is a challenging problem, with possible consequent morbidity that could compromise the QoL. ON occurrence was not related to the type of treatment but closely influenced by older age at diagnosis. An early detection of ON symptoms and the intro-

duction of innovative therapies to prevent sequelae for children or adolescents treated in ALL trials are needed.

P539

HDAC EXPRESSION PATTERNS ASSOCIATE WITH HIGH-RISK FEATURES IN PEDIATRIC LEUKEMIA

N. Vega-Garcia[1,*] R. Malatesta[1], S. Rives[2], A. Català[2], R. Berrueco[2], M. Torrebadell[1], C. Estella[1], B. Barneda-Zahonero[3], M. Mesegué[1], A. Alonso[2], M. Trabazo[2], A. Ruiz-Llobet[2], M. Parra[3], A. Bigas[4], M. Camós[1]
[1]Hematology Laboratory, [2]Pediatric Hematology. Department of Hematology and Oncology, Hospital Sant Joan de Deu, Fundació Sant Joan de Deu, University of Barcelona, [3]Cellular Differentiation Group, Cancer Epigenetics and Biology Program (PEBC), Bellvitge Biomedical Research institute (IDIBELL), [4]Cancer and Stem Cells Research Group, Institut Hospital del Mar d'Investigacions Mèdiques (IMIM), Barcelona, Spain

Background: Altered expression of histone deacetylases (HDACs) is a common feature in cancer, including hematological malignancies. Thus, HDAC inhibitors have rapidly emerged as promising targets in cancer therapeutics (Stubbs, 2015). However, expression patterns of HDACs in childhood leukemia have been scarcely studied.
Aims: To analyze the expression of HDAC isoforms in different subtypes of pediatric leukemia and correlate them with prognosis and clinic-biological features.
Methods: We evaluated the mRNA gene expression profile of class I, II and IV HDAC genes (HDAC 1-11) by quantitative PCR in 54 leukemic pediatric samples and a pool of non-neoplastic samples as control. Samples were obtained from the Biobank of our hospital after appropriate informed consent was signed by patients and/or legal tutors. Our series included 35 boys and 19 girls diagnosed with acute leukemia (median age 5.4 years, range 0-16.7), treated according to Spanish Pediatric Hemato-Oncology Cooperative Group protocols in a single center. Nineteen (35%) cases were B-cell precursor acute lymphoblastic leukemia (pre-B-ALL), 22 cases T-cell ALL and 13 patients had acute myeloblastic leukemia (AML). The HDAC expression levels in different groups of patients were compared by the Mann-Whitney test. The level of significance was set up at $p<0.05$. The analyses were performed with SPSS 22.0.
Results: We found high expression levels of class I HDAC isozymes (HDAC 1, 2, 3 & 8) in leukemic samples compared to non-neoplastic samples, as previously reported (Gruhn, 2013; Moreno, 2010). We also noted a trend towards a downregulation of HDAC10 in all leukemia subtypes. A higher expression of HDAC1, HDAC2, HDAC3, HDAC4 & HDAC11 and a lower expression of HDAC5 and HDAC9 was observed in T-ALL compared to pre-B-ALL. HDAC11 was significantly overexpressed in AML cases. The class I HDACs HDAC1 & HDAC3 expression correlated with age, with patients >10 years old expressing the highest levels. In contrast, infant patients (<1 year-old) had a significant lower expression of HDAC7 ($p=0.022$). Interestingly, 3/4 cases with a pro-B phenotype had low levels of HDAC7, in line with our recently published data (Barneda-Zahonero, 2015). Of note, patients with MLL rearrangement had significantly higher expression of HDAC9 ($p=0.001$). Male patients had higher expression of HDAC4 ($p=0.008$). We did not find a correlation between HDACs expression and WBC count levels at diagnosis. In general, overexpression of all HDACs isoforms was associated with worse outcome. Noticeably, in T-ALL patients HDAC5 and HDAC9 expression levels above Q3 upper quartile significantly correlated with worse overall survival (OS) ($p=0.03$ and $p=0.04$, respectively). T-ALL cases with high HDAC1 had inferior OS (91% *vs* 51%), but the low number of patients precluded the finding of statistical significance. In summary, high expression of HDACs isoforms in leukemic patients correlate with worse outcome and older age. In addition, some isozymes associated with specific features. Thus, T-cell phenotype cases overexpressed HDAC1-4 & HDAC11 and underexpressed HDAC5 & 9. However, those T-ALL cases with high HDAC5 & 9 levels did worse, with inferior OS. HDAC7 levels were lower in infant patients and in those pre-B-ALL cases with pro-B phenotype. Finally, MLL rearranged cases showed higher expression of HDAC9.
Summary and Conclusions: We have observed a different pattern of HDACs expression in different subtypes of pediatric leukemia. Some of these profiles identified high risk patients who could benefit from a targeted treatment with HDAC inhibitors.

P540

DEVELOPMENT OF AN NGS ASSAY FOR IGK THAT CAN BE COMBINED WITH IGH FOR IDENTIFYING CLONAL POPULATIONS IN LYMPHOID MALIGNANCIES

G. Pawlowsky[1], S. Englert[1], Y. Huang[2], K. Hutt[2], Z. Xie[2], J. Miller[1,2], M. Klass[2], N. Adams[1,*]
[1]LabPMM GmbH, Martinsried, Germany, [2]Invivoscribe Technologies, Inc., San Diego, United States

Background: Previously we developed next generation sequencing assays for the detection and characterization of clonality in B-cells, targeting the *IGH* locus with single step PCR approach followed by sequencing and analysis. These *IGH* assays were shown to be both sensitive and robust in a number of different laboratories and have demonstrated utility for tracking residual disease. *IGK* is also an important locus that can be used for the identification and tracking of clonality, as *IGK* rearrangements are stable markers that are retained even in lambda light chain expressing B-cells, as Kde rearranges to Vk elements as well as to the recombination signal sequence (RSS) in the Jk5-Ck intron (INTR) prior to rearrangements within *IGL*. Accordingly, IGK is an ideal marker for tracking residual disease in B-lineage ALL.
Aims: The development of an assay for *IGK* that can be combined with *IGH* that will increase the chance of identifying clonal populations in lymphoid malignancies such as non-Hodgkin's Lymphoma and tracking a variety of B-cell tumours.
Methods: Genomic DNA from peripheral blood, tonsil and bone marrow aspirates were tested for *IGK* gene rearrangements. Optimized V and J consensus primers targeted all *IGK* V and J region gene segments that are rearranged in lymphoid cells as well as the Kde rearrangements that precede lambda selection. Multiplex PCR master mixes simultaneously amplified *IGK* V-J gene rearrangements and incorporated sample identifying indices into amplicons, which facilitated combining and sequencing libraries generated testing up to 12 samples and controls in each run. Amplicon products were purified, quantified, the concentrations adjusted, pooled, and the harmonized libraries were loaded into the OneTouch 2. The enriched emulsion PCR libraries were sequenced using Ion 316 Chip Kit v2s and Ion PGM Sequencing 400 Kits. Data were analysed using Invivoscribe's proprietary bioinformatics software (included with the test kits) on a standard personal computer. The bioinformatics package allows for *IGH* and *IGK* libraries with the same barcodes to be analysed on the same run. The PGM platform allows a sustainable, rapid turn around time, less than 36 hours from primary sample to result.
Results: Data generated with the LymphoTrack® IGK assay and bioinformatics package reproducibly identified clonality and DNA sequences of *IGK* Vk-Jk, as well as Vk-Kde and INTR-Kde, gene rearrangements. Automated data outputs include frequency distributions and V-J gene usage. DNAs from cell lines serially diluted into polyclonal tonsil DNA, confirmed the linearity (R^2 >0.99) and low run-to-run variance of the assay. This assay may be used with genomic DNA from peripheral blood, bone marrow and FFPE. In addition to the assay development, the break point of the INTR element was also identified.
Summary and Conclusions: We have previously developed *IGH* and *TRG* assays for the IonTorrent PGM. We now add an NGS clonality assay for *IGK* that identifies clonal *IGK* Vk-Jk, as well as Vk-Kde and INTR-Kde, rearrangements and associated specific rearranged DNA sequences to the repertoire that can either be used in reflex testing to further characterise samples that are difficult to characterize by *IGH* alone. Alternatively, a more time and cost efficient approach would be to run both assays at the same time on samples to be run on the same sequencing run. These assays can be used to both detect and monitor lymphoproliferative disease. A further advantage is that the assays identify clonal lymphocyte populations by their unique DNA sequences that can subsequently be used to track clones in residual disease testing.

P541

SIGNIFICANCE OF RECURRENCE OF MINIMAL RESIDUAL DISEASE (MRD) DETECTED BY MULTI-PARAMETER FLOW CYTOMETRY (MFC) IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN MORPHOLOGICAL REMISSION

N. Pemmaraju[1,*] H. Kantarjian[1], J. Jorgensen[2], E. Jabbour[1], N. Jain[1], D. Thomas[1], S. O'Brien[1], S. Wang[2], M. Konopleva[1], S. Konoplev[2], T. Kadia[1], R. Garris[1], S. Pierce[1], J. Cortes[1], F. Ravandi[1]
[1]Leukemia, [2]Pathology, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Minimal residual disease (MRD) assessment is now established as an important predictor of outcome in both pediatric and adult patients (pts) with acute lymphoblastic leukemia (ALL). Availability of novel agents able to eradicate MRD is a further factor emphasizing the need for MRD monitoring in these pts.
Aims: To determine the significance of MRD relapse as detected by multi-parameter flow cytometry (MFC) in pts with ALL after achieving an MRD negative status following induction and consolidation therapy.
Methods: Between January 2003 and August 2013, 585 newly diagnosed pts with ALL (excluding Burkitt's leukemia/lymphoma) were treated with regimens including the hyperCVAD backbone or Augmented BFM. 540 (92%) achieved complete remission (CR), of whom, 490 (91%) became MRD negative as assessed by MFC. 47 pts (41 with B-ALL, 6 with T-ALL) developed recurrence of MFC detectable disease while still in morphological CR and are subjects of this study. MRD was assessed by 4-color (and since 2009, 6-color) flow cytometry at CR and multiple time points thereafter, as clinically indicated.
Results: Median age was 43 years (yrs)(range,18-72 yrs), 27 (57%) were male. Median laboratory values at initial presentation were: WBC 7.3 K/uL (range, 0.6-303.8) and bone marrow (BM) blasts 89% (range, 26-98). Cytogenetics at initial presentation were: 11 diploid, 14 Philadelphia positive (Ph+), 6 insufficient metaphases/not done, 15 miscellaneous, and 1 with 11q23 rearrangement. Chemotherapy regimens included: 42 HCVAD +/- other (10 HCVAD, 8 HCVAD+Dasatinib, 10 HCVAD+Rituximab, 6 HCVAD+Imatinib, 5

HCVAD+Nelarabine, 3 HCVAD+Ofatumumab) and 5 Augmented BFM. Median Event-free survival (EFS) of the whole group was 24 months (mos) (range, 3.7-138 mos); median OS, 30 mos (range, 3.7-138 mos). Thirty-nine (83%) pts subsequently developed morphological relapse (32 BM, 3 BM+ central nervous system (CNS), 3 CNS, and 1 non-CNS extramedullary), after a median of 110 days (range, 3-540 days) from detection of MRD recurrence. Median EFS for this group was 24 mos (range, 7.6-72 mos), and median OS was 30 mos (range, 9-82 mos). Eight pts did not have morphological relapse including 5 pts who died in complete morphological remission, with only 3 pts alive in continued CR. Of the 5 pts who died prior to relapse, 4 had undergone stem cell transplantation (SCT) (2 related, 1 cord, and 1 haplotype), and died of post-SCT complications. 3 pts (2 B-ALL, 1 T-ALL,) are still alive and in CR despite having had MRD recurrence, all with normal karyotype and all having undergone matched unrelated donor(MUD) SCT with a median OS of 3.8 yrs (range, 3 -11.5 yrs).

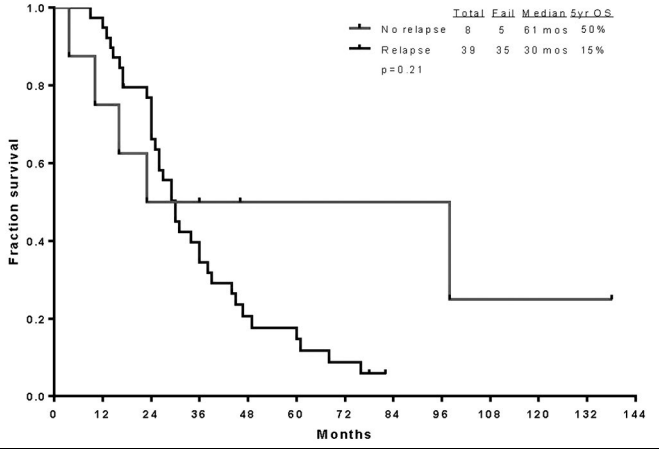

Figure 1. Overall survival for pts with MRD relapse with no morphological relapse (n=8) *versus* pts with MRD relapse followed by morphological relapse (n=39).

Summary and Conclusions: In this single institution retrospective analysis, the vast majority of pts with ALL who achieved MRD negative CR, followed by MRD relapse at any time point, subsequently experienced morphological relapse, suggesting that MRD relapse at any time point during a patient's follow-up is associated with a high risk for relapse. Although allogeneic SCT rescued some patients with ongoing long-term remission, it was associated with mortality in others. Prospective studies of long-term MRD assessments throughout a patient's treatment course, together with less toxic strategies to eradicate MRD, are warranted.

P542

IMPROVED SURVIVAL IN ADULT PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) IN THE NETHERLANDS: A POPULATION-BASED STUDY ON TREATMENT, TRIAL PARTICIPATION AND SURVIVAL, 1989-2012

A. Szabo[1,*] A.G. Dinmohamed[1], M. van der Mark[2], O. Visser[2], J.J. Cornelissen[1], P. Sonneveld[1], M. Jongen-Lavrencic[1], A.W. Rijneveld[1]
[1]Department of Hematology, Erasmus MC Cancer Institute, Erasmus University Medical Center, Rotterdam, [2]Department of Registration and Research, Comprehensive Cancer Centre the Netherlands, Utrecht, Netherlands

Background: Pediatric ALL has shown an impressive improvement in survival over the last decades. The outcome in adult patients is far less optimistic with current survival rates in several published trials reaching 60% only. Large, comprehensive population-based studies among unselected adult ALL patients are lacking.
Aims: We conducted a population-based study to assess trends in treatment, trial participation and survival among adult ALL patients diagnosed in the Netherlands from 1989-2012.
Methods: We identified 1833 over 18-year-old ALL patients (median age 49 years) from the nationwide Netherlands Cancer Registry (NCR) with follow-up until February, 2014. Patients were categorized into 4 calendar periods (1989-1994, 1995-2000, 2001-2006 and 2007-2012) and 5 age groups (18-24, 25-39, 40-59, 60-69 and ≥70 years). Data on treatment (ie, supportive care only, chemotherapy (CT) and stem cell transplantation (SCT)) were retrieved from the NCR. We obtained data on the type of SCT (ie, autologous (autoSCT) or allogeneic SCT (alloSCT)) from the HOVON SCT working party, and data on trial participation from the HOVON and EORTC cooperative groups. To correct for the life expectancy of the general population, relative survival rates (RSRs) were computed as a measure of patient survival. Overall survival (OS) according to treatment by calendar period was estimated by the Kaplan-Meier method.

Results: The annual age-standardized incidence remained stable over time at around 0.6/100,000 with a consistent male predominance (54% males). Overall, 38%, 41%, 49%, 72% and 43% of the patients in the 5 age groups received CT, 22%, 15%, 10%, 1% and 0% received autoSCT, 38%, 41%, 31%, 10% and 0% received alloSCT, while 2%, 3%, 9%, 17% and 57% received supportive care only, respectively. The application of alloSCTs increased over time among patients up to 70 years and was steadily introduced in the treatment of patients aged 60-69 years during the mid-1990s. Treatment remained essentially unchanged over time among patients aged ≥70 years.
When clinical trials were open for accrual, the inclusion rate was 67%, 66%, 55% and 58% in the first 4 age groups, respectively. No trials were available for patients aged ≥70 years.
Relative survival (RS) improved over time as 5-year RSRs (95% CI) were 19% (15%>23%) in 1989-1994 and 37% (32%>42%) in 2007-2012 (Figure 1A). This improvement was confined to patients up to 70 years, and was most pronounced among patients up to 40 years, especially in the most recent calendar period (Figure 1B). RS worsened sharply with age. 5-year RSRs (95% CI) for patients diagnosed in 2007-2012 were 75% (63%>84%), 57% (44%>68%), 37% (27%>47%), 22% (13%>31%) and 5% (1%>18%) for the 5 age groups, respectively. Among 18-39-year-olds, 5-year OS was 25% and 68% for those who received CT (Figure 1C) and 46% and 66% for recipients of an alloSCT (Figure 1D) in the first and last calendar periods, respectively.

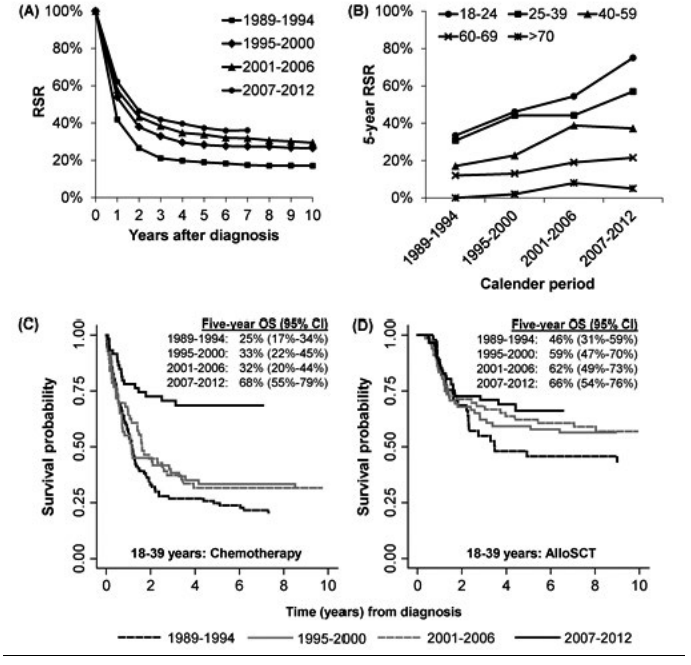

Figure 1.

Summary and Conclusions: We show that survival of unselected adult ALL patients up to 70 years of age improved over time in the Netherlands. The intensification of adult chemotherapeutic approaches based on more intensive, pediatric protocols implemented since 2007 and the increased application of alloSCT along with improved supportive care, are most likely important factors contributing to this improvement. The accrual into clinical trials slightly decreased with age, with no trials available for patients aged ≥70 years yet. Novel, and more targeted treatment options with a tolerable toxicity profile are needed to further improve outcome, particularly in the elderly.

Acute myeloid leukemia - Biology 2

P543

A DISTINCTIVE LONG-NON CODING RNA SIGNATURE CHARACTERIZES ACUTE MYELOID LEUKEMIA WITH TRANSLOCATION T(8;16)(P11;P13) AND MYST3-CREBBP REARRANGEMENT

M. Diaz-Beya[1,*]A. Navarro[2], A. Cordeiro[2], M. Pratcorona[1], J. Castellano[2], M. Nomdedeu[1], R. Risueño[3], M.A. Torrente[1], M. Camós[4], M. Monzo[2], J. Esteve[1]
[1]Hematology Department,, Hospital Clínic, IDIBAPS, Barcelona, Spain, [2]Molecular Oncology and Embryology Laboratory, Human Anatomy Unit, School of Medicine, University of Barcelona., [3]Josep Carreras Leukaemia Research Institute, [4]Hematology Laboratory, Hospital Sant Joan de Deu, Fundació Sant Joan de Deu, Barcelona, Spain

Background: Long Non-coding RNAs (lncRNAs) have recently emerged as important actors in the regulation of multiple cellular processes including cancer. Acute myeloid leukemia (AML) with translocation t(8;16)(p11;p13) (t(8;16) AML) is a subtype with specific clinical and biological characteristics including a specific gene (Camós *et al.*, 2008) and a microRNA (Díaz-Beyá *et al.*, 2013) expression profile. In this translocation, *MYST3* on chromosome 8p11 fuses with *CREBBP* on chromosome 16p13.3. The MYST3-CREBBP fusion protein is able to interact with multiple transcription factors producing a disturbed transcriptional program. However, the lncRNA expression pattern of t(8;16) AML has not been described yet.
Aims: The main objective of this study was to characterize the expression pattern of lncRNAs in t(8;16) AML in comparison to other AML subtypes.
Methods: Forty six AML patients, 4 normal bone marrow (NBM) and 3 CD34+ NBM samples were included in the study. Patient samples included a wide diversity of different AML subtypes: intermediate-risk cytogenetics AML (IR-AML, n=18), acute promyelocitic leukemia (APL, n=4), t(8;21) AML (n=4), inv(16) AML(n=2), t(6;9) AML (n=7), monosomal karyotype AML (n=4), t(3;3) AML (n=1), t(9;11) AML (n=1) and t(8;16) AML (n=5). Within IR-AML, 7 harbored an *FLT3*-ITD, 5 *NPM1,* 7 *CEBPA* and 6 *DNMT3A* mutations. The lncRNA expression was studied using Affymetrix® Human Gene 2.1 ST platform which includes 9698 lncRNAs transcripts. The filtering and normalization of the array data was performed using oligo package from Bioconductor. Statistical analyses were performed with TiGR MultiExperiment Viewer, BRB tools and R. The Transcription factor Affinity Prediction Web Tool was used to determine the putative transcription factors binding to the differentially expressed lncRNAs promoters.
Results: The hierarchical cluster analysis showed that all 4 NBM clustered together, as well as all 3 CD34+ NBM according to their lncRNA expression. Interestingly, all 5 t(8;16) AML samples clustered together, as well as the 3 APL, the 7 t(6;9) AML and 5 out of 7 cases with *CEBPA* mutations. Afterwards, we focused on t(8;16) AML and the supervised analysis identified an specific 113-lncRNA signature. Interestingly, when we analyzed which transcription factors (TF) had motifs overrepresented in the promoters regions of the t(8;16) AML lncRNA signature, we identified motifs for GATA2 (p<0.001) and Evi1 (p=0.04). These two TFs have been described to interact with *CREBBP,* one of the partners involved in t(8;16) AML. Of note, 4 overexpressed lncRNAs of the signature (*linc-HOXA11, HOXA11-AS, HOTTIP* and *NR_038120*) were located in the *HOXA* genomic region, previously found upregulated in t(8:16) AML. Since several studies suggest an active crosstalk between microRNAs and lncRNAs, we correlated the expression of these lncRNAs with the microRNA profile. We found significant correlations between *linc-HOXA11* and miR-222* (R^2=0.996, p=0.003), *HOXA11-AS* and miR-let-7c (R^2=0.994, p=0.006), *HOTTIP* and miR-196b*(R^2=0.958, p=0.041), *NR_038120* and miR-486-3p (R^2=0.999, p=0.0004), and miR-19a (R^2=0.953, p=0.04).
Summary and Conclusions: t(8;16) AML harbors a characteristic lncRNA signature. Some of the lncRNAs of this signature are located in the *HOXA* genomic region, and correlate with several of the distinctive microRNAs of this entity. Interestingly, we have identified *in silico* GATA2, which interacts with CREBBP, as the most significant TF that could regulate this lncRNAs signature. Further investigation is warranted to determine the importance of this lncRNA signature.

NEW JAK2 HETEROZYGOUS LOSS: A ROLE IN OVERALL SURVIVAL IN ACUTE MYELOID LEUKEMIA PATIENTS

V. Guadagnuolo[1,*] M.C. Fontana[1], C. Papayannidis[1], I. Iacobucci[1], M. Manfrini[1], A. Padella[1], G. Simonetti[1], A. Ferrari[1], G. Marconi[1], A. Ghelli Luserna di Rora[1], S. Paolini[1], M.C. Abbenante[1], S. Parisi[1], C. Sartor[1], E. Ottaviani[1], M. Cavo[1], G. Martinelli[1]
[1]Department of Hematology and Medical Sciences "L. and A. Seràgnoli",, Bologna, Italy

Background: Acute Myeloid Leukemia (AML) is a hematologic malignancy that originates in hematopoietic stem and myeloid progenitor cells. Age and karyotype have been recognized as the most prominent prognostic factors in AML patients. Novel array-based technique-single-nucleotide polymorphism (SNP) microarray can detect cytogenetic lesions involve mostly structural alterations with losses or gains of chromosomic material. Those chromosomic abnormalities are predictive of response and are very important to define therapeutic strategies. SNP microarray can detect copy-neutral loss of heterozygosity (CN-LOH), which plays a role in oncogenesis by duplicating oncogenes, inhibiting tumor suppressors, and stimulating improper epigenetic programming.
Aims: Our objective is to evaluate the prognostic impact of these genetic alterations on clinical outcome.
Methods: We analyzed 58 AML patients by high-density CytoScan HD Array (Affymetrix, Inc). The results obtained by SNP Array, were analyzed by Chromosome Analysis Suite (ChAS) v1.2 (Affymetrix Inc.) and Nexus Copy Number™ v7.5 (BioDiscovery).
Results: We treated 58 AML patients (pts) with a median age of 52 years, of which 9 were insensitive pts and 49 sensitive to therapies. The median age at diagnosis was 51,3 years (range: 19-89 years), and they have a female/male ratio of 53% and 47%, while the median follow up is of 28,5 and 34,4 months respectively. Copy Number Alterations (CNAs) were detected in all patients affecting all the chromosomes, in particular our cohort of pts present a percentage of CNA, divided as follow: 42% of LOH, 19% of Copy Number (CN) gain, 39% CN of loss. By SNP array analysis we found that several important genes were preferentially deleted: ADAM3A (62,2% pts; Chr 8), JAK2 (34,5% pts; Chr 9), HRAS (8,6% pts; Chr11), WT1 (20,7% pts; Chr 11), FLT3 (13,8% pts; Chr 13), SIRPB1 (41,4%; Chr 20) and CRLF2 (50% pts; Chr X). We observed a significant involvement of the Chromosome X, infact in several leukemia-related genes as ATRX (43,1% pts), BCOR (34,5% pts), GATA1 (39,7% pts), KDM6A (43,1% pts), PHF6 (29,3% pts), ZRSR2 (31% pts), STAG2 (29,3% pts) are concurrent events of loss and LOH: this double lesion may inactive their function as transcriptional regulators. While genes preferentially involved in amplifications are PRDM16 (12% pts), KIT (24,1% pts), IKZF1 (12% pts), MYC (8,6% pts), KRAS (8,6% pts). Moreover we focused on a particular heterozygosis loss of *JAK2*, detected in 5/58 (8,6%) pts, which goes from 5080280 bp to 5098786 bp, involving half of exon 17 and exons 18, 19, 20, 21 and 22. This region include the second tyrosine-kinase domain required for a correct function of the protein. We showed that a group of patients which present this deletion have an overall survival rate better than the group with an amplification of the gene (p-value <0,01) (Figure 1). None CNV in this region of JAK2 had been described in hematopoietic tissue before.

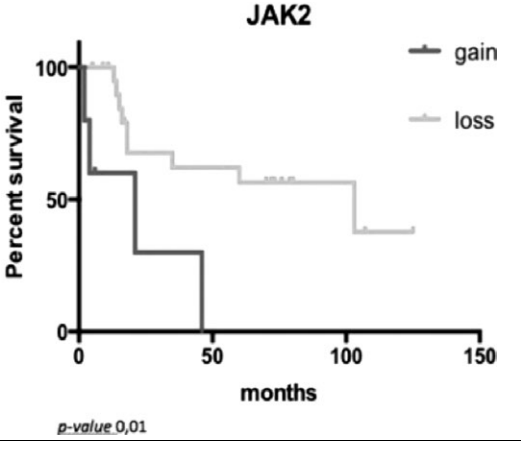

Figure 1.

Summary and Conclusions: By SNP arrays we have identified Copy Number Alterations involving important cancer genes in AML and we showed that a new deletion involving *JAK2* may have a role in overall survival. Future prospective will be to correlate other cancer genes alterations and mutations with the prognosis of AML, in order to identify new biomarkers relevant for the disease.

SELECTIVE DEATH OF LEUKEMIC STEM CELLS INDUCED BY DEFERASIROX

S. Shapira[1,*] P. Raanani[1,2], I. Lubin[1], A. Nagler[3], N. Arber[4], G. Granot[1]
[1]Felsenstein Medical Research Center, Beilinson Hospital, [2]Institute of Hematology, Beilinson Hospital, Sackler School of Medicine, Tel Aviv University, Petah Tikva, [3]Department of Hematology and Bone Marrow Transplantation, Chaim Sheba Medical Center, Tel-Hashomer, [4]Integrated Cancer Prevention Center and Department of Gastroenterology, Tel- Aviv Sourasky Medical Center, Sackler School of Medicine, Tel-Aviv University, Tel Aviv, Israel

Background: Despite high remission rate after therapy, only 30-40% of acute

myeloid leukemia (AML) patients survive 5 years after diagnosis. The main cause of treatment failure is thought to be insufficient eradication of leukemic stem cells (LSC). Identifying drugs that can efficiently eradicate LSCs is therefore imperative. HIF1α is essential for LSC maintenance and targeting HIF1α selectively eliminates LSC. Deferasirox is an iron chelator used to reduce chronic iron overload in patients receiving long-term blood transfusions.
Aims: To study the ability of deferasirox to induce apoptosis and to target HIF1α in AML LSCs.
Methods: We isolated $CD34^+CD38^-$ LSC-like cells from the leukemic progenitor CD34+ KG1a cell line using CD38 magnetic separation. We isolated the phenotypically primitive leukemic $CD34^+CD38^-CD123^+$ cells and the progenitor $CD34^+CD38^+CD123^+$ cells from bone marrow samples of newly diagnosed AML patients using a double CD34 & CD38 magnetic separation. Cell proliferation and apoptosis were analyzed by WST-1 and FACS assays, respectively. Synergism was calculated by Chou.T.C combination index. HIF1α expression was measured by real-time PCR and Western blot assays.
Results: $CD34^+CD38^-$ LSC-like cells, sorted from the KG1a cell line, exhibited increased sensitivity to deferasirox with an IC50 of 1.3μM compared to 8.9μM calculated for the more mature $CD34^+CD38^+$ cells. The LSC-like cells, which were more sensitive to deferasirox, were less sensitive to ARA-C compared to the $CD34^+/CD38^+$ cells. Deferasirox was >2-fold more efficient in inducing apoptosis in the CD34+CD38− cells, compared to the CD34+CD38+ cells (74±7.2% & 32±6.2% apoptosis, respectively). Deferasirox demonstrated a synergistic cytotoxic effect with ARA-C on both the CD34+CD38− and CD34+CD38+ KG1a cell fractions. Similar results were observed with $CD34^+CD38^-CD123^+$ LSCs and $CD34^+CD38^+$ $CD123^+$ progenitor cells isolated from AML patients. As shown with the cell line, AML patient LSCs were 2-fold more sensitive to deferasirox treatment showing a 62±15% induction of cell death compared to only a 34±9% induction in leukemic progenitor cell death. The increase in cell death was accompanied by an increment of reactive oxygen species (ROS) levels which was more prominent in the LSCs compared to the progenitor cells. Furthermore, deferasirox enhanced the cytotoxic effects of ARA-C on both the LSCs and the leukemic progenitor cells. These data indicate that deferasirox is highly cytotoxic to AML cells; however, it is significantly more specific to AML stem cells. Since deferasirox is an NFkB inhibitor which regulates HIF1α levels, and since HIF1α is selectively activated in AML stem cells and is essential for maintenance of these cells, we studied the effect of deferasirox on HIF1α expression. We found that HIF1α was downregulated transcriptionally (~40% reduction) and translationally (~55% reduction) in the LSC-like cells while it was upregulated in the $CD34^+CD38^+$ KG1a cells following deferasirox treatment. These data hint that AML-LSCs are selectively targeted by deferasirox.
Summary and Conclusions: We describe a novel and unique anti-LSC property of deferasirox, which was originally developed as an iron chelator. We found clinically relevant concentrations of deferasirox to be cytotoxic *in vitro* to AML cells but even more potent against LSCs. We believe that deferasirox exerts its cytotoxic effect, at least in part, by downregulating HIF1α levels in the LSC population. Pending further characterization, deferasirox can be considered as a potential therapeutic agent for eradicating LSCs.

Background: Familial platelet disorder with predisposition to acute myeloid leukemia (FPD/AML) is a rare autosomal dominant disorder characterized by quantitative and qualitative platelet abnormalities and considered as a model of genetic predisposition to hematological malignancies. FPD/AML syndrome is caused by inherited *RUNX1* mutations (21q22) reported so far in less than 40 pedigrees. However, evolution remained very heterogeneous since only 30-40% of such patients develop hematopoietic neoplasms, usually after a long period.
Aims: In this context, it is likely that the acquisition of secondary molecular events functions as a driver to promote malignant transformation, thus the FPD/AML syndrome constitutes a unique multi-step leukemogenesis model *in vivo*. Recently, acquired mutations of *CDC25C* and *GATA2* have been reported in 53% and 23% of FPD/AML patients respectively (Yoshimi *et al.*, Nat Commun, 2014), particularly during disease progression.
Methods: We studied 24 patients from 15 FPD/AML families identified from 2005 to 2014. Twelve of them progressed to leukemic stage: 9 patients developed AML and 3 patients developed T-ALL. Cytogenetics and next-generation sequencing (MiSeq, Illumina®) of 44 genes (including *CDC25C* and *GATA2*) were performed for all patients. For patients who progressed to leukemic stage, samples were collected at the time of diagnosis and during complete remission allowing to confirm the acquired status of mutations.
Results: Characteristics of the patients studied are presented in the following Table 1.

Table 1.

Pedigree/patient	Sex	Germline RUNX1 alteration	Leukemic transformation	Age at leukemia diagnosis	Acquired RUNX1 alteration (leukemic stage)	Other acquired mutations	Loss of acquired alterations in complete remission

†Acquired mutation at FPD stage without leukemic transformation.
§Not studied at T-ALL stage.

Summary and Conclusions: Acquisition of a secondary genetic or molecular event was identified in all patients of our cohort. Acquired mutations involved genes implicated in tyrosine kinase pathway, epigenetic, spliceosome and transcription regulation. In addition to germline *RUNX1* mutation, a second aberration of *RUNX1* was found in all patients who developed AML, in line with our previous report (Preudhomme *et al.*, Blood, 2009). Four patients acquired mutation in the second allele and 4 patients had duplication of the abnormal copy by uniparental disomy (n=2) or acquired trisomy 21 (n=2). On the other hand, patients who developed T-ALL were younger and did not acquire second aberration of *RUNX1*. Interestingly, *CDC25C* or *GATA2* mutations were not identified in our cohort, in contrast with Yoshimi *et al.*

P547

LEUKEMOGENIC MLL-ENL FUSIONS INDUCE ALTERNATIVE CHROMATIN STATES TO DRIVE A FUNCTIONALLY DICHOTOMIC GROUP OF TARGET GENES.

M.-P. Garcia-Cuellar[1], C. Büttner[2], E. Füller[1], K. Hetzner[1], J. Steger[1], R. Slany[1,*]
[1]Genetics, [2]Human Genetics, University Erlangen, Erlangen, Germany

Background: MLL fusion proteins provoke leukemogenic transformation by inappropriate activation of downstream target genes.
Aims: To identify MLL-ENL subordinate transcripts with importance for malignant development, primary hematopoietic precursor cells containing a conditional MLL-ENL knock-in were used in NGS experiments to monitor the molecular process driving the transition from a transformed, self-renewing to a normal, differentiating cell.
Methods: Nascent RNA-seq and ChIP-seq identified 165 high confidence MLL-ENL target genes.
Results: Correlation of individual transcription rates with cellular physiology suggested that about 40% of MLL-ENL targets play an important role in transformation thus assigning them a "driver" status with the remainder likely to act mainly as "bystanders". Next to well-known MLL-fusion targets like the *HoxA* cluster hitherto unknown MLL-ENL controlled regulatory units could be identified. Many of those supported pro-transformation traits like accelerated proliferation, reduced differentiation and inhibition of apoptosis. In addition mechanistic insight was gained from ChIP patterns that were linked to activation by MLL-ENL. MLL-ENL targets fell in two distinct clades characterized by unique MLL-ENL binding arrangements and chromatin configurations. In an "ME5" group the fusion protein bound at the transcription initiation site, RNA synthesis rates were directly proportional to H3K79 methylation and extensive transcriptional pausing was suggested by RNA-PolII Ser2-P distribution. In contrast, hallmarks of an "ME3" group were a location of MLL-ENL downstream of the transcription termination site, transcription rates that were inversely correlated to H3K79 methylation and an unusual RNA PolII accumulation associated with the occurrence of non-coding transcripts. This chromatin-based dichotomy was

mirrored by a functional separation into DNA and RNA related activities for ME5 and ME3 genes respectively.
Summary and Conclusions: As current small-molecule approaches aim to eliminate exclusively H3K79 methylation they may not be sufficient for complete leukemia eradication. Our results suggest that targeting both subsets of MLL-ENL subordinate genes may be potentially more efficient for treatment of MLL fusion induced leukemia.

P548

GENOMIC LANDSCAPE OF CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA

N. Duployez[1,2,*] A. Marceau-Renaut[1,2], N. Boissel[3], A. Petit[4], M. Bucci[1], S. Geffroy[1,2], C. Ragu[4], K. Celli-Lebras[3], C. Lacombe[5], N. Ifrah[6], H. Dombret[3], G. Leverger[4], E. Jourdan[7], H. Lapillonne[8], C. Preudhomme[1,2]
[1]Hematology Laboratory, Lille University Hospital, [2]U837, Team3, INSERM, Lille, [3]Department of Hematology, St Louis Hospital, APHP, [4]Department of Pediatric Hematology and Oncology, Trousseau Hospital, APHP, [5]Hematology Laboratory, Cochin Hospital, APHP, Paris, [6]Department of Hematology, Angers University Hospital, Angers, [7]Department of Hematology, Nîmes University Hospital, Nîmes, [8]Hematology Laboratory, Trousseau Hospital, APHP, Paris, France

Background: Core-binding factor (CBF) acute myeloid leukemia (AML) includes AML with t(8;21)/*RUNX1-RUNX1T1* chromosomal translocation and AML with inv(16)/t(16;16)/*CBFB-MYH11* chromosomal rearrangement. These recurrent genetic abnormalities are both associated with the disruption of the CBF, a heterodimeric transcription factor involved in hematopoiesis. Although the fusion proteins appear to be crucial for the leukemogenic process, considerable experimental evidences indicate that they are no sufficient to induce AML on their own. CBF-AML accounts for about 15% of de novo AML and is associated with a relatively favorable prognosis due to the high sensitivity to standard chemotherapy with high complete remission rates. Nonetheless, relapse incidence may reach 40% in such patients.
Aims: In this context, identification of additional molecular events is considered of great interest to improve our understanding of CBF-AML leukemogenesis, better predict clinical outcome and identify novel therapeutic approaches.
Methods: This study focused on 123 patients with CBF-AML including 68 AML with t(8;21) and 55 AML with inv(16)/t(16;16). Patients were enrolled in the 2 French therapeutic trials ELAM02 (n=68; median age: 10 years [4-17]) and CBF2006 (n=55; median age: 40 years [18-60]). All patients were studied at the time of diagnosis by next-generation sequencing (MiSeq, Illumina®) includnding 57 genes well-known in hematological malignancies.
Results: Identified mutations are indicated in the Figure 1 according to the CBF-AML subtype. Mutations involving genes from the tyrosine kinase pathways (i.e *KIT*, *NRAS*, *KRAS* or *FLT3*) were the most frequent aberration and were found in both subtypes as previously reported. Interestingly, mutations involving genes that control chromatin modifications (i.e *ASXL1*, *ASXL2*, *EZH2*, *KDM6A*) or implicated in the cohesin complex (*i.e. RAD21*, *SMC1A*, *SMC3*, *STAG2*, *NIPBL*) were frequent especially in the t(8;21)-AML subtype, whereas they were nearly absent in the inv(16)/t(16;16)-AML subtype. Finally, the two CBF-AML subtypes showed greatly distinct mutational profiles.

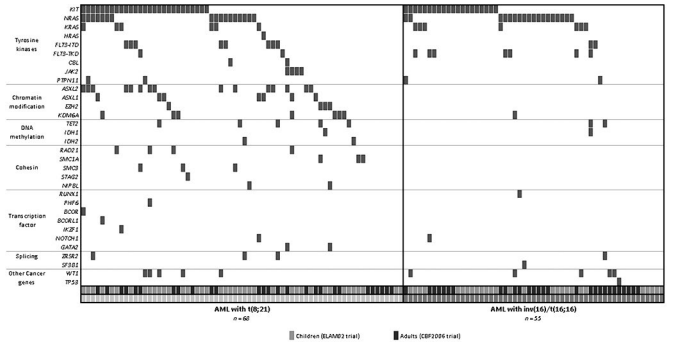

Figure 1.

Summary and Conclusions: Due to similarities between their molecular and prognostic features, t(8;21) and inv(16)/t(16;16)-AML are usually grouped and reported together in clinical studies. However, considerable experimental evidences have highlighted that they represent two distinct entities and should be considered separately for further studies. Particularly, t(8;21)-AML is characterized by the high frequency of mutations of genes involved in the epigenetic machinery and the cohesin complex. It is currently known that polycomb proteins functionally interact with cohesin to control transcription. Together, these results suggest an important pathway in t(8;21) leukemogenesis.
Note: Increase of our cohort size and correlations with clinical outcome are in progress to identify prognostic markers.

P549

PRO-METASTASIS PHOSPHATASE PRL-3 TRANSFORMS LEUKEMIA STEM CELLS AND PROMOTES LEUKEMOGENESIS IN AML VIA ACTIVATION OF SOX4/LIN28B/LET-7 SIGNALING

J. Zhou[1,*] Z.-L. Chan[1], C. Bi[1], X. Lu[1], S.Y.P. Chong[1], J.-Y. Chooi[1], L.-L. Cheong[1], S.-C. Liu[1], Y.Q. Ching[1], Y. Zhou[1], M. Osato[1], T.Z. Tan[1], Q. Zeng[2], W.-J. Chng[1]
[1]Cancer Science Institute of Singapore, National University of Singapore,, [2]Institute of Molecular and Cell Biology, Agency for Science, Technology and Research, Singapoore, Singapore

Background: The reversible phosphorylation and dephosphorylation of tyrosine residues on proteins is mediated by protein tyrosine kinases (PTKs) and protein tyrosine phosphatases (PTPs). This process regulates a wide range of signalling pathways and dysregulation of these signalling pathways are common biochemical phenomena in cancer cells. Protein-tyrosine phosphatase of regenerating liver 3 (PRL-3, encoded by *PTP4A3* gene) is a member of VH1-like PTP family with dual-specificity. Elevated expression of PRL-3 is associated with metastasis in solid tumors. Acute myeloid leukemia (AML) arises from abnormal clonal hematopoietic cells characteristic with uncontrolled proliferation and blocked differentiation of immature myeloid cells. A larger body of evidence supports the notion that leukemia stem cell (LSC), a distinct subpopulation of AML cells with self-renewal capacity, initiates and sustains the bulk leukemia. The molecular mechanisms underlying the transformation of LSC are not fully understood yet. We and others identified that PRL-3 is over expressed in patients with acute myeloid leukemia (AML) and serves a poor prognostic factor.
Aims: The aims of this study were to explore the role of PRL-3 in transformation of LSC in AML and to investigate the molecular mechanism by which PRL-3 was regulated.
Methods: Whole genome microarray was used to compare the transcriptome of a pair of iosgeneic cell line TF1-pEGFP *vs* TF1-hPRL-3. Colony formation assay and serial replating assay were employed to examine the *in vitro* self-renewal capacity of AML cells. To assess the *in vivo* function of PRL-3 in leukemogenesis, we performed limited serial dilution and bone marrow transplantation of TF1-hPRL-3 cells in nonobese diabetic/severe combined immunodeficiency (NOD/SCID) mice.
Results: We first show that ectopic expression of PRL-3 promotes proliferation, colony forming capacity of AML cells *in vitro* and leukemogenicity *in vivo*. Next, we conduct gene expression profiling of TF1-pEGFP and TF1-hPRL-3 cell lines and reveal upregulation of some stemness factors such as LIN28B, c-KIT, IGF2BP1 and downregulation of mature cell surface marker CD36 and CD38 by PRL-3. Importantly, gene-set enrichment analysis (GSEA) of this microarray result revealed a significant enrichment of genes identified in a previously defined gene expression signature of leukemia stem cell (LSC SIGNATURE_SAITO) and hematopoietic stem cell (HSC SIGNATURE_EPPERT). Notably, we unravel that LIN28B, a stem cell reprogramming factor, represses let-7 microRNA family in TF1-hPRL-3 cells. Furthermore, we identify IGF2BP1 as a novel target of let-7 miRNA. Through combination of shRNA targeting with serial replating assay and xenotransplantation mouse models, we validate that this regulatory axis is critical to PRL-3-medidated LSC phenotype. We also demonstrate SOX4 is a mediator to elevate LIN28B expression. LIN28B overexpression is associated with poor prognosis in a cohort of AML patients.
Summary and Conclusions: In conclusion, our investigation has identified a critical regulatory PRL-3/SOX4/LIN28B/let-7 networks, which play an important role in transformation of LSC and development of AML. Thus, we believe the novel regulatory uncovered in our study may represent the “Achilles’ heel” of LSC in AML and apprises the possibility of eliminating LSC in a molecular subset of AML in which PRL-3/LIN28B appears pivotal for the transformation.

P550

RATIONAL TARGETING OF NOTCH SIGNALLING IN ACUTE MYELOID LEUKAEMIA

P. Takam Kamga[1,*] G. Bassi[1], A. Cassaro[1], R. Stradoni[1], M. Midolo[1], M. Di Trapani[1], F. Canella[1], R. Carusone[1], A. Gatti[1], O. Perbellini[1], M. Gottardi[2], M. Krampera[1]
[1]Medicine, University of Verona, Verona, [2]Ematologia, Azienda Ospedaliera ULSS 9, Trevise, Italy

Background: Growing evidences from both preclinical and clinical investigations reveal Notch signalling as critical for the development of many cancers, and for their response to chemotherapy. Our lab has previously showed that Notch inhibition was efficient to abrogate stromal-induced chemoresistance in CLL and B-ALL. In contrast, the role of Notch in AML and its contribution to the crosstalk between AML cells and bone marrow stroma remains controversial: that makes unclear which could be the best therapeutic strategy (activation or inhibition) to target Notch in AML.
Aims: In this study, we sought to validate Notch signalling as potent successful therapeutic target in AML. We tested different modulators for their ability to influence Notch signalling at different levels, including the interaction ligand-receptor, the transactivation of the receptors and the transcriptional activation of the pathway. We then analysed the effects of Notch modulators, alone or in synergy with chemotherapeutic agents, on AML cells in culture or co-culture with bone marrow mesenchymal stromal cells (BM-MSCs).

Methods: AML blast cells were obtained from bone marrow samples (33) and peripheral blood (22) of AML patients. BM-MSCs were expanded from bone marrow of 20 healthy donors (BM-MSCs) and of 20 AML patients (BM-MSCs*). *In silico* analysis, RT-qPCR, FACS analysis and western immunoblotting were used to study the expression of Notch receptors and ligands, as well as Notch activation status, in AML cells and BM-MSCs. AML cells were cultured or co-cultured with BM-MSCs or BM-MSCs* at 10:1 (AML:BM-MSCs) ratio in presence or absence of Notch modulators including: recombinant human Jagged-1 and Jagged-2; anti-Notch-1, -2, -3, -4, anti-Jagged-1, -2 and anti-DLL-3 blocking antibodies; gamma secretase inhibitor-IX, -XII (GSI-IX, GSI-XII) and Notch transcription factor inhibitor (SAHM1). The chemotherapeutic agents used were: cytarabine, etoposide and idarubicin. Cell viability was evaluated by Annexin-V/Propidium Iodide (PI) and MTT assays; proliferation and cell cycle were assessed through CFSE dilution and PI method, respectively.
Results: *In vitro* and *in silico* analysis showed that disregarding FAB classification or molecular pattern, AML cells expressed Notch receptors and ligands. Notably, 50% of AML samples showed basal Notch signalling activation as demonstrated by the detection, at mRNA and protein level, of HES-1. The activation of Notch signalling using recombinant Jagged-1 or Jagged-2 did not lead to any changes neither in AML cell survival nor in cell proliferation. On the contrary, the pan blockade of Notch, at the membrane level by GSIs or by the combination of Notch blocking antibodies, or, at the transcriptional level using SAHM1, inhibited AML cell proliferation in culture. Notably, BM-MSCs* showed higher level of Notch1 and Jagged1 as compared to BM-MSCs. Interestingly, we observed that BM-MSCs*, but not BM-MSCs, stimulated AML proliferation and the pan Notch inhibition was sufficient to revert this phenomenon. In addition BM-MSCs* were more efficient to rescue AML cells from apoptosis induced by chemotherapeutic agents. Pan Notch signalling blockage by either GSI-XII or combination of Notch receptor-blocking antibodies in presence of chemotherapeutic agents, significant lowered the supportive role of BM-MSCs towards AML blasts; conversely SAHM1 has a slight effect. The specific blockade of Notch-1, -2, -3 or Jagged-1, -2 reduced partially the chemoresistance, while blockade of Notch-4 or DLL-3 rescued totally the chemosensitivity of primary AML cells in co-culture with BM-MSCs.
Summary and Conclusions: These results suggest that the inhibition of Notch signalling may represent a potential therapeutic strategy to improve AML treatment, overcoming bone marrow stromal-mediated anti-apoptotic and chemoresistance effects. Clinical application of GSIs is limited due their toxic and multiple off targets. In this study we showed that blocking antibodies were sufficient to recapitulate GSIs effects, making them a useful and less harmful strategy to target Notch signalling.

ARSENIC TRIOXIDE AND ALL-TRANS-RETINOIC ACID TARGET NPM1 MUTANT ONCOPROTEIN LEVELS AND INDUCE APOPTOSIS IN NPM1-MUTATED AML CELLS

Background: Acute myeloid leukemia (AML) is the most common acute leukemia in adults and a molecularly heterogeneous disease. Standard chemotherapy±hemopoietic-stem-cell transplantation can cure about 40-50% of younger adults and 10-15% of elderly patients (>60 years old). Thus, it is clearly needed to develop novel therapeutic approaches. At present, the only highly effective molecular targeted therapy for AML is based on all-*trans*-retinoic acid (ATRA) and/or arsenic trioxide (ATO) in acute promyelocytic leukemia (APL) with *promyelocytic leukemia* (*PML*)-*retinoic acid receptor a* (*RARa*) gene rearrangement. *Nucleophosmin* (*NPM1)* gene mutations represent the most frequent genetic lesion in AML accounting for about 30% of adult AML. NPM1 is an ubiquitously expressed nucleolar phosphoprotein with nuclear-cytoplasmic shuttling activity, involved in multiple cellular functions and essential for life. *NPM1* mutations in AML are heterozygous and lead to NPM1 wild-type haploinsufficiency and cytoplasmic accumulation of the leukemic NPM1 mutant protein. Because *NPM1* mutations are common, stable and represent a founder genetic lesion in AML, they are an appealing therapeutic target. However, whether and how the NPM1 mutant oncoprotein is druggable remain to be established.
Aims: Here we explored whether NPM1 mutant protein levels could be affected by treatment with drugs such all-*trans*-retinoic acid (ATRA) or arsenic trioxide (ATO) which have been shown to target specific oncoproteins (*i.e.* PML-RAR-alpha, Bcr-Abl) and display some anti-leukemic activity *in vitro* and in patients in AML cells carrying *NPM1* gene mutations.
Methods: For these purposes, we treated *in vitro* either AML cell lines (OCI/AML3 and IMS-M2, carrying *NPM1* gene mutation A, and OCI/AML2 and U937, with wild-type *NPM1*) or primary AML cells from patients (25 *NPM1*-mutated and 19 *NPM1*-wild type AML) with ATRA, ATO or combination of either drug and analyzed their effects on cell growth and apoptosis and on levels of NPM1 either mutant or wild-type protein. To explore the underlying mechanisms, we used pretreatment with the proteasome inhibitor MG132, to analyze the role of the proteasome machinery in protein degradation, and with *N*-Acetyl-*L*-Cysteine (NAC), to analyze the role of reactive oxygen species (ROS) which are known to be elicited by treatment with ATO.
Results: We found that whilst ATRA exerts a more general anti-leukemic effect in non-APL AML cells including *NPM1*-mutated AML, ATO displays a peculiar anti-leukemic activity in *NPM1*-mutated as compared to *NPM1*-wild type AML, and that this activity can be potentiated by ATRA. Interestingly, we found basally a partially altered PML nuclear bodies (NBs) organization in *NPM1*-mutated AML, which can be restored by treatment with ATO. Strikingly, ATO, as well ATRA, induced proteasome-dependent NPM1 mutant oncoprotein degradation in either cell lines or primary AML patients cells, relocalized NPM1 wild type protein in the nucleus with rearrangements of nucleoli, and increased daunorubicin-sensitivity. All these events resulted to be dependent on ROS, being prevented by pretreatment with the ROS-scavenger NAC. Collectively, these findings are reminiscent of the ATRA/ATO-induced PML/RARα degradation in APL.
Summary and Conclusions: Altogether, our data show that NPM1 mutant is targeted by ATO and, at least in some cases, also by ATRA and, although probably not the only mechanism, its downregulation might contribute to the pro-apoptotic and/or anti-proliferative effects of these drugs in *NPM1*-mutated AML. This suggests that ATO and ATRA are potential drugs for a molecular targeted-based therapy in *NPM1*-mutated AML leading to NPM1 mutant oncoprotein degradation. These findings provide experimental evidences for further exploring ATO/ATRA in preclinical *NPM1*-mutated AML *in vivo* models and a rationale for exploiting these compounds in chemotherapic regimens in clinics.

Background: Chromosomal translocations associated with RUNX family transcription factors, such as t(8;21) and inv(16), are frequently observed in human acute myeloid leukemia (AML). These chromosomal abnormalities produce fusion proteins which suppress function and/or expression of both RUNX1 and RUNX3. We previously reported that *Runx1$^{fl/fl}$;Runx3$^{fl/fl}$;Mx1-Cre^{+}* [double knockout (DKO)] mice exhibited two paradoxical lethal phenotypes: bone marrow failure and myeloproliferative disorder. These contradictory manifestations were shown to be caused by defect in DNA repair pathway. Accumulation of non-repaired DNA damage leads to massive cell death, while occasional acquisition of oncogenic mutations result in leukemia development.
Aims: In this study, we aim to identify cooperative genetic hits which cooperate with *Runx1* and *Runx3* deficiency in leukemogenesis.
Methods: To identify such cooperative genetic alterations, retroviral insertional mutagenesis (RIM) was performed on *Runx1;Runx3* DKO mice. DKO and their control mice were injected with Moloney murine leukemic virus (MoMuLV) and monitored for disease presentation. Bone marrow transplantation and colony forming assay were conducted to validate the cooperativity. To correlate findings in mice to human AML, publicly available gene expression datasets were also analyzed.
